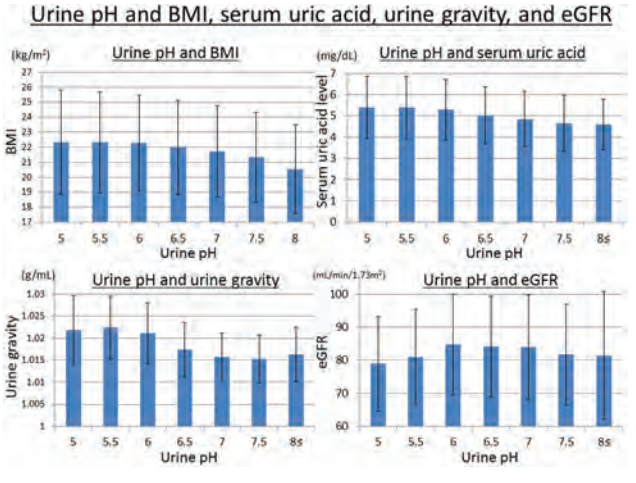
Background: Obesity and metabolic syndrome are increasing in decades. Obesity usually decreases urine pH, and low urine pH is a good marked for metabolic diseases. Serum uric acid is also a good marker for metabolic syndrome. Uric acid is crystallized in low pH, which induces renal dysfunctions. This study is to clarify the association between urine pH and body mass index, serum uric acid, and kidney function.

Methods: This study is a large-scale cross-sectional study. We retrospectively analyzed the database from 90,143 Japanese people (men, 49.1%; age, 46.3 ± 12.0 years) undergoing annual medical examination at the Center for Preventive Medicine, St. Luke's International Hospital, Tokyo between January 2004 and June 2010. The subjects with any current medication were excluded. We tested the association between body mass index and urine pH. Furthermore, we analyzed the association between urine pH and body mass index (BMI), serum uric acid, urine gravity, and estimated glomerulus filtration rate (eGFR) levels in a healthy population.

Results: Of 90,143 subjects, 21,574 subjects with current medication and 595 subjects without urine data were excluded, and finally 67,974 subjects were enrolled in the study. Urine pH had significantly inverse correlation with BMI ($r=-0.1$, $p<0.001$), serum uric acid ($r=-0.12$, $p<0.001$), and urine gravity ($r=-0.28$, $p<0.001$). Moreover, low urine pH (less than 6.0, eGFR=80.9±14.4) and high urine pH (more than 7, eGFR=81.7±15.9) showed significantly lower eGFR compared to normal urine pH (from 6 to 7, eGFR=84.5±15.3) ($p<0.001$). **Figure** showed the mean level of BMI, serum uric acid, urine gravity and eGFR in each urine pH.

Conclusions: Low urine pH (less than 6) becomes a good marker for high BMI, high serum uric acid, and dehydration status (high urine gravity), which is associated with low eGFR.



TH-PO1123

A Low Initial Serum Sodium Level Is Associated with an Increased Risk of Overcorrection in Patients with Chronic Profound Hyponatremia: A Retrospective Cohort Analysis Sae Aratani,[1,8] Masahiko Hara,[4] Masahiko Nagahama,[5] Fumika Taki,[6] Miyuki Futatsuyama,[7] Shuichi Tsuruoka,[3] Yasuhiro Komatsu.[2] *[1]Nephrology, Nippon Medical School Hospital, Tokyo, Japan; [2]St. Lukes International Hospital, Tokyo, Japan; [3]Nephrology, Nippon Medical School, Tokyo, Japan; [4]Osaka City University Graduate School of Medicine, Osaka, Japan; [5]St. Luke's international hospital, Tokyo, Japan; [6]Nephrology, St. Lukes' International Hospital, Tokyo, Japan; [7]Nephrology, st.luke's international hospial, Tokyo, Japan; [8]Nephrology, St. Luke's International Hospital, Tokyo, Japan.*

Background: Even with abundant evidence for osmotic demyelination in patients with hyponatremia, the risk factors for overcorrection have not been fully investigated. Therefore the purpose of this study is to clarify the risks for overcorrection during the treatment of chronic profound hyponatremia.

Methods: This is a single-center retrospective observational study. We enrolled 56 adult patients with a serum sodium (SNa) concentration of ≤125 mEq/L treated by nephrologists in an intensive care between February 2012 and April 2014. The impact of patient parameters on the incidence of overcorrection was estimated using univariable and multivariable logistic regression models. Overcorrection was defined as an increase of SNa by >10 mEq/L and >18 mEq/L during the first 24 and 48 hours, respectively.

Results: The median age was 78 years, 48.2% were male, and 94.6% of the patients presented with symptoms associated with hyponatremia. The initial median SNa was 115 mEq/L (quartile, 111–119 mEq/L). A total of 11 (19.6%) patients met the criteria for overcorrection with 9 (16.0%) occurring in 24 hours, 6 (10.7%) in 48 hours, and 4 (7.1%) in both 24 and 48 hours. Primary polydipsia, initial SNa, and early urine output were the significant risk factors for overcorrection on univariable analysis. Multivariable analysis revealed that the initial SNa had a statistically significant impact on the incidence of overcorrection with an adjusted odds ratio of 0.84 (95% confidence interval, 0.70–0.98; $p=0.037$) for every 1 mEq/L increase. Additionaly, the increase in SNa during the first 4 hours and early urine output were significantly higher in patients with overcorrection than in those without ($p=0.001$ and 0.005, respectively).

Conclusions: An initial low level of SNa was associated with an increased risk of overcorrection in patients with profound hyponatremia. In this regard, the rapid increase in SNa during the first 4 hours may play an important role.

TH-PO1124

New Sodium Equation with Built-In Rate of Correction to Simplify Therapeutic Orders for Hyponatremia or Hypernatremia Sheldon Chen. *MD Anderson, Houston, TX.*

Background: Both hyponatremia and hypernatremia occur frequently in hospitalized patients. To understand these disorders, investigators have mathematically modeled the serum sodium concentration in humans. Edelman published the seminal equation (*J Clin Invest* 37: 1236-56, 1958), and others have refined it for clinical use.

Methods: The model has been expanded to incorporate time, and then a term explicitly appears for a rate of sodium correction, a key consideration to avoid treatment complications like osmotic demyelination. The equation is solved for the fluid administration rate to assist the clinician with the hospital order in the management of dysnatremia. To handle the calculations, we programmed the equation into a spreadsheet that aggregates the relevant data, *e.g.*, urine [Na+K], and provides immediate results to facilitate patient care on rounds.

Results: Entering baseline data on the inputs and outputs of Na/K/water along with the patient's body weight, a clinician can use the new sodium equation to aim for a desired serum [sodium] over a safe timeframe. The formula returns the infusion rate for any treatment fluid such as normal saline, hypertonic saline, or 5% dextrose in water. The formula can also calculate treatment in terms of the dosage of salt tablets. With a slight modification, it can handle an abrupt water diuresis and appropriately decrease the IV fluid rate so that hyponatremia is not overcorrected. Demonstrating efficacy, the new sodium equation has performed well in real-life cases of hyponatremia and hypernatremia.

Conclusions: The proposed equation improves upon existing sodium equations by accounting for all inputs and outputs, if known, and incorporating a rate of correction. The quantitative approach provides a rational and effective basis for prescribing intravenous fluids and salt tablets in the hospital.

TH-PO1125

Diagnostic Accuracy of a Central Venous Blood Gas in the Diagnosis of Acid-Base Disorders in the Medical Intensive Care Unit Sarah J. Schrauben, Dan Negoianu, Raphael M. Cohen, Jeffrey S. Berns. *University of Pennsylvania, Philadelphia, PA.*

Background: Acid-base disturbances are frequently encountered in critically ill patients. Arterial blood gas (ABG) is the gold standard in the diagnosis but has potential hazards to the patient. For patients with a central venous catheter, venous blood gas (VBG) sampling may be an alternative, less-invasive diagnostic tool. However, little is known about the central VBG diagnostic accuracy. The primary objective of this study was to assess the accuracy of a central VBG for the diagnosis of acid-base disorders in critically ill adult patients.

Methods: This was a cross-sectional single blinded study at two university-based urban hospitals. Study participants were adults in a medical intensive care unit (MICU) that had simultaneously drawn ABG and central VBG samples. Expert acid-base diagnosticians, all nephrologists, were blinded to the clinical data and blood gas origin to interpret the acid-base disorder(s) from each sample. Blood gas samples were classified as: no disorder, metabolic acidosis, metabolic alkalosis, respiratory acidosis, respiratory acidosis, or as a mixed disorder. Diagnostic accuracy of central VBG-based diagnoses were compared to ABG-based diagnoses by assessing percent clinical agreement, sensitivity and specificity.

Results: The study involved 23 participants. The most common underlying primary diagnoses were respiratory-related (45.5%) and sepsis-related (40.9%). Overall, the central VBG had 100% sensitivity for metabolic acidosis, metabolic alkalosis, and respiratory acidosis, and 71% for respiratory alkalosis, and high percent clinical agreement, ranging from 75-94%, with a lower agreement of 57% for respiratory alkalosis. VBG-based diagnoses in vasopressor dependent patients (n=13, 56.5%) performed very similarly.

Conclusions: In critically ill adult patients, central VBG detects acid-base disturbances with good diagnostic accuracy, even in shock states. This study supports the use of central VBG for diagnosis of acid-base disturbances in MICU patients.

Funding: NIDDK Support

Diagnostic Accuracy of VBG-based Diagnosis compared to ABG-based Diagnosis.

Disorder	Sensitivity	Specificity	% Clinical Agreement
Metabolic Acidosis	100%	64%	87.5%
Metabolic Alkalosis	100%	100%	75%
Respiratory Acidosis	100%	60%	94%
Respiratory Alkalosis	71%	100%	57%

TH-PO1126

Primary Aldosteronism Associated with a Mutation of CACNA1H Kendra E. Wulczyn,[4] Robert L. Nussbaum,[1] Lowell J. Lo,[2] Edward Perez-Reyes,[5] Meyeon Park.[3] *[1]Invitae Corp, San Francisco, CA; [2]None, San Francisco, CA; [3]UCSF, San Francisco, CA; [4]University of California San Francisco, San Francisco, CA; [5]University of Virginia, Charlottesville, VA.*

Background: Several genetic mutations have been described in rare forms of primary aldosteronism (PA). We report a case of aldosteronism with hypokalemia and hypotension, found to have a mutation of CACNA1H, encoding a voltage-gated calcium channel ($Ca_v3.2$) expressed in adrenal glomerulosa.

Methods: A 31 year old female with type III Ehlers-Danlos syndrome and postural orthostatic tachycardia syndrome (POTS) presented for evaluation of chronic hypokalemia. The patient was receiving infusions of potassium every 2-4 weeks (baseline K 2.6-3.6 mmol/L) for profound weakness. Prior evaluation had revealed elevated plasma aldosterone level (38 ng/dL) and suppressed renin (0.17 pg/dl), and MRI demonstrated normal appearing adrenal glands. Low-dose spironolactone was initiated, which improved the hypokalemia, yet the patient still required monthly potassium infusions for symptoms. A laboratory assessment was made pre- and post-hydration with 2L IVF, supplemented with 25 mEq K and 2.5g Mg (shown in table below). Results demonstrated persistently elevated aldosterone level despite volume repletion (of note, patient was unable to stop spironolactone for the testing). During this course, results of whole exome sequencing (Personalis, Inc.) revealed a de novo loss-of-function missense mutation, R890H, in the voltage-sensing domain of the CACNA1H gene.

Results:

Conclusions: POTS has been associated with both increased and decreased activity of the RAAS system; however, in this patient, laboratory testing pre- and post-fluid resuscitation suggest aldosterone secretion was independent of volume status. Therefore, the mutation of CACNA1H, not previously described, is the likely cause of pathologic aldosterone secretion. $Ca_v3.2$ has been implicated in genetic forms of PA in which a mutation to CACNA1H results in increased intracellular Ca^{2+}, the signal for cholesterol transport into mitochondria and induction of steroidogenesis. Unique to our case is the absence of hypertension experienced by this patient, expanding our understanding of the different phenotypes associated with mutations of CACNA1H.

	Pre-Hydration	Post-Hydration
Aldosterone (ng/dl)	17	45
Plasma Renin Activity (pg/dl)	0.23	0.27
Potassium, serum (mmol/L)	3.8	4.1
Potassium, 24-hr urine (mmol/d)	38.5	61.4
Sodium, 24-hr urine (mmol/d)	94	99

Relationship between Central Venous, Peripheral Venous, and Arterial Potassium in the ICU Richard M. Treger,[1,2] Caleb Hsieh,[3,2] Tristan Grogan,[4,2] Nader Kamangar.[3,2] *[1]Nephrology, VA Greater Los Angeles Healthcare System, Los Angeles, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Critical Care, Olive View-UCLA Medical Center, Sylmar, CA; [4]Medicine and Biostatistics, UCLA, Los Angeles, CA.*

Background: As shown in small studies evaluating regional hypoperfusion, venous potassium concentration (K^+) may better reflect interstitial and tissue K^+ than arterial values, and thus better predict serious cardiac manifestations of hyperkalemia. Moreover, because central veins drain a much greater tissue mass (muscle and splanchnic) than peripheral veins, discrepancies between peripheral venous (PV), central venous (CV), and arterial (Art) K^+ may exist, especially in states of global hypoperfusion such as sepsis. No prior study has examined this relationship.

Methods: Art, CV, and PV samples were prospectively obtained within 10 minutes of each other from single-center adult medical ICU patients.

Results: 51 paired samples from 23 patients were included. The correlations between Art-PV K^+, Art-CV K^+ and CV lactate (Figure) were not statistically significant ($p = 0.60$ and 0.99, respectively). The correlations between PV and Art K^+, as well as CV and Art K^+ yielded an R^2 of 0.83 and 0.83, respectively. Bland-Altman plots of Art K^+ and PV K^+, as well as Art K^+ and CV K^+ showed 95% limits of agreement of -0.42 to 0.35 and -0.43 to 0.51, respectively.

Conclusions: In medical ICU patients with global hypoperfusion, CV K^+ was not different from that of Art and PV K^+ and did not correlate with serum lactate. This disproved our hypothesis that in global hypoperfusion CV blood would demonstrate higher K^+ and better reflect tissue K^+ compared with Art blood. In fact, CV and PV K^+ showed high correlation and strong agreement with Art K^+ and can be used interchangeably. This contrasts with prior studies of regional hypoperfusion that demonstrated a higher K^+ in venous blood relative to arterial blood, reflective of local interstitial and tissue K^+ levels. Our results likely did not demonstrate this because of augmented intracellular K^+ shifting and CV system dilution of K^+ in global hypoperfusion.

TH-PO1128

Rate of Cisplatin Salt Wasting (CSW) Sheron Latcha.[1,2] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell, New York, NY.*

Background: CSW likely results from cisplatin injury to the proximal renal tubules, the major site of sodium and water reabsorption. Up to 10% of patients developed CSW in early clinical studies with cisplatin. Subsequently, CSW has only been rarely reported. The rate of CSW may have declined due to agressive hydration with normal saline (NS), which is renoprotective, or it may be due to under recognition and therefore under reporting of CSW.

Methods: We obtained retrospective data on adult patients who received cisplatin from 1/1/2014-12/34-2015 who met the following criteria: sodium ≤135mEq/l, received IV normal saline (NS) ≥24H after cisplatin administration, and diagnosis codes for hypotension, polyuria, dehydration, hypovolemia or shock. A nephrologist randomly reviewed the medical record of 35% of episodes, and determined if the patient had SIADH, dehyration, CHF, CSW or other cause for to explain the criterion outlined above. The diagnosis of CSW was based on the findings of hypotension, nocturia, polyuria with the absence of other causes of dehydration (decreased oral intake, infection, diarrhea).

Results: 652 patients and 829 hyponatremic episodes were identified; 300 episodes in 230 patients were reviewed; 48 episodes were removed from analysis (record incomplete, duplicates)/ 252 episodes were analyzed. CSW was identified in 8 (3.2%) epispodes, dehydration in 111 (44%), SIADH in 86 (34.1%) and CHF 11 (4.4%). Urine sodium and osmolarity were checked in 41 (16%) and renal consults in 5 (2%) episodes. With the exception of episodes of CHF, hyponatremia was empirically treated with IV NS, even when patients were normotensive, and had no tachycardia or edema. Patients were not asked for symptoms of polyuria, nocturia or thirst.

Conclusions: CSW is likely underdiagnosed and underreported. Nausea is most often interpreted as a cause of dehydration as opposed to a symptom of hyponatremia itself and patients complaining of dizziness and lightheadness are assumed to have dehydration from decreased oral intake. Patients were not specifically questioned about symptoms of CSW, specifically polyuria, nocturia or thirst. Orthostatic blood pressure reading, and urine and serum sodium and osmolarity are rarely used to evaluate hyponatremia. Consequently, patients with CSW may remain hyponatremic because they are not receiving adequate hydration, and patients with SIADH are inappropriately receiving IVF.

TH-PO1129

Occurrence of Proton-Pump Inhibitor-Induced Severe Hypocalcemic Hypomagnesemia Only after Thiazide Withdrawal: A Case Report Yohei Kita, Atsuko Uehara, Tsutomu Sakurada, Yugo Shibagaki. *Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine., Kawasaki-shi, Kanagawa, Japan.*

Background: Although relatively common, hypomagnesemia is often undiagnosed because its clinical significance is underrated and therefore magnesium levels are not routinely checked. Symptomatic hypocalcemia is a key indicator for a diagnosis of hypomagnesemia; however, if patients are administered thiazide, hypocalcemia is masked, which may disguise hypomagnesemia. We describe a case of symptomatic hypocalcemic hypomagnesemia after thiazide withdrawal. The patient was a 79-year-old woman with a medical history of asthma, chronic heart failure, diabetes mellitus, and hypothyroidism. Five weeks prior to admission, she developed thiazide-induced hyponatremia and thiazide was discontinued. Two weeks before admission, she experienced hand tremors and found it difficult to hold chopsticks. Two days before admission, she vomited and was admitted to our hospital. A physical examination revealed Trousseau's sign and her albumin-corrected calcium and magnesium levels were 5.8 mg/dL and 0.4 mg/dL, respectively, revealing hypocalcemia and hypomagnesemia. Urine magnesium was low, which indicated increased gastrointestinal magnesium excretion. We reviewed the medical charts and discovered that 4 years earlier, her serum magnesium was 2.2 mg/dL; but 2 years earlier, it had already decreased to 0.4 mg/dL, which indicated that her hypomagnesemia had been present for at least 2 years. As the patient had started proton-pump inhibitor therapy approximately 2 years previously, proton-pump inhibitor-induced hypomagnesemia was strongly suspected. Hypocalcemia was thought to result from decreased parathyroid hormone secretion and increased parathyroid hormone resistance induced by hypomagnesemia. We hypothesized that symptomatic and profound hypocalcemia had not developed over the previous 2 years because the concomitant use of thiazide contributed to calcium reabsorption; thus, the thiazide withdrawal 5 weeks earlier had triggered progressive hypocalcemia. We withdrew the proton-pump inhibitor and prescribed a calcium and magnesium supplement, which normalized serum calcium and magnesium with symptomatic improvements. Our findings indicated that even severe hypomagnesemia may be overlooked in patients with concomitant use of a proton-pump inhibitor and thiazide.

Narrow Upper Airway Due to Fluid Overload Affects Severity of Asymptomatic Sleep Apnea Syndrome in ESRD Toshiki Kano, Hitoshi Suzuki, Ryotaro Shioda, Yusuke Suzuki. *Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Sleep apnea syndrome (SAS) has been reported in 50% of patients with end-stage renal disease (ESRD). It is hypothesized that SAS in ESRD patients is caused by narrow upper airway due to fluid overload. SAS is considered as an independent risk factor for hypertension, congestive heart failure, acute coronary syndrome, pulmonary hypertension, arrhythmia and cerebrovascular event. The aim of present study is to clarify involvement of SAS in ESRD patients and to evaluate the association between severity of SAS and body fluid condition in ESRD patients.

Methods: The apnea-hypopnea index (AHI) and its severity were measured in twenty-five patients with ESRD using a portable sleep monitoring device. Body weight (BW), cardio thoracic ratio (CTR), serum levels of BNP, AHI were measured during the therapeutic course of hemodialysis. The association of AHI with age, gender, body mass index (BMI), history of smoking and complication of ESRD were analyzed.

Results: In twenty-five patients with ESRD, 96.0 % patients were diagnosed as asymptomatic SAS. Those ESRD patients with SAS were divided according to AHI scores into mild (AHI 5-14.9, 20.8%), moderate (AHI 15-29.9, 29.2%) and severe SAS (AHI ≥30, 50.0%) groups. Patients with hypoalbuminemia showed severe SAS ($P<0.05$). Moreover, there was a trend that patients with diabetes showed severe SAS. Asymptomatic SAS was improved by treatment of fluid overload ($P<0.01$). Changes of AHI by intervention of fluid overload was associated with decrease of BNP ($P<0.05$) and CTR ($P<0.05$).

Conclusions: Asymptomatic SAS is a major complication in patients with ESRD. Present findings suggested that fluid overload induced edema of upper airway resulted in asymptomatic SAS. Diagnosis and appropriate management of SAS is important to improve the mortality of ESRD patients.

TH-PO1131

Prevalence and Predictors of Hypomagnesemia in CKD Monika Aggarwal (Gupta), George M. Feldman. *Medicine, Hunter Holmes McGuire VAMC, Richmond, VA.*

Background: Hypomagnesemia has been reported in patients with chronic kidney disease (CKD), and shown to be associated with progression of CKD and increased mortality. We studied the prevalence and predictors of hypomagnesemia in patients with CKD.

Methods: We reviewed charts of all patients (n=891) seen in our outpatient CKD clinic in the year 2014, at Hunter Holmes McGuire Veterans Affairs Medical Center. We collected five most recent serum values for magnesium, creatinine, estimated glomerular filtration rate (EGFR), calcium, phosphorus, parathyroid hormone intact (PTH) and 25(OH) Vitamin D, presence of diabetes, and use of diuretics, proton pump inhibitors (PPI), phosphate binders, and magnesium supplementation in past 5 years. Hypomagnesemia was defined as serum magnesium less than 1.8 mg/dl or a serum magnesium ≥1.8 mg/dl on magnesium supplement. We then determined possible associations of plasma magnesium with age, presence of diabetes, use of PPI, diuretics, and phosphate binders, and mean values of serum calcium, phosphorus, eGFR, PTH, and 25(OH)Vitamin D.

Results: Mean age was 70.01±10.87 years. All patients were male, with 60.36% (N=536) with diabetes. 53% (N=471) had stage 3 CKD. 57.9 % (N=514) were on a PPI. 32% (N=286) were on magnesium supplement. 33.67% (N=299) had a mean serum magnesium <1.8 mg/dl. While 66.33% (N=589) had a mean serum magnesium ≥ 1.8 mg/dl, 121 of those patients were on magnesium supplement. Hence, 47.29% (N=420) had hypomagnesemia. Presence of diabetes mellitus, use of potassium supplement, thiazide diuretics, and PPI increased odds of having hypomagnesemia (Table 1).

Conclusions: Hypomagnesemia is common in patients with CKD. Use of PPI and presence of diabetes have the highest odds of developing hypomagnesemia.

Case of Amphotericin Induced Refractory Hypokalemia Mark Kozicky,[2] Maya K. Rao,[1] Jacob Stevens.[3] *[1]Columbia University, New York, NY; [2]Nephrology, Columbia University, New York, NY; [3]NYP Columbia - Nephrology Fellowship, New York, NY.*

Background: Amphotericin (AmB) B is often used to treat severe fungal infections. It increases membrane permability of the renal tubular cell potentially leading to hypomagnesemia, hypokalemia and renal tubular acidosis. It also causes resistance to anti-diuretic hormone leading to polyuria that can potentiate hypokalemia by increasing distal urinary flow.

Methods: A 29 yr old male with sinonasal & intracranial aspergilloma infection was admitted to NICU in septic shock and respiratory failure requiring intubation. Despite anti-fungal treatment with micafungin, voriconazole, imaging showed growth of the fungal mass and treatment with AmB was initiated. Within 2 days of starting amphotericin the patient developed new onset hypokalemia ranging from 2.3 to 3.4mmol/L with U waves seen on EKG. Hypokalemia remained refractory to supplementation over a week despite intravenous potassium repletion of ~ 200meq/ day plus an additional 40-100meq of oral KCl. Pt had some polyuria during this time with urine output(UOP) ranging from 1.5 - 5L daily in part driven by high input of ~ 5-6L/day, though UOP remained elevated over 2L/day even once IV hydration was reduced. While polyuria continued urine osmolarity ranged from 380 to 472 mOsm/kg demonstrating some persistent tubular concentrating function. Pt had no diarrhea noted and magnesium was supplemented to maintain adequate levels. Diagnostic studies for hypokalemia including a cortisol level of 21.5ug/dL, renin & aldosterone levels of 0.38 ng/mL/h and 4.7ng/dL respectively were unremarkable upon evaluation of alternative causes of hypokalemia. 24 hour urinary potassium was elevated at 292 mmol/day while coincident serum potassium was 2.8mmol/L. Due to refractory hypokalemia despite aggressive repletion and evidence of urinary potassium wasting, the patient started amiloride with slight improvement of potassium to ~3- 3.5mmol/L though not until AmB was discontinued after nearly 1 month of therapy did potassium levels normalize consistently to > 3.5mmol/L without further need of repletion and amiloride.

Results:

Conclusions: This case demonstrated amphotericin induced urinary potassium wasting via increased excretion along with polyuria refractory to high dose supplementation showing the potential harm & limitations in using AmB. It also demonstrates benefit of early initiation of potassium sparing diuretics to achieve potassium stabilization in patients requiring this medication.

TH-PO1133

Recurrent SIADH: A Rare Complication of Intrathecal Interleukin-2 Treatment for Melanoma with Brain Metastases Ali Ziaolhagh,[2] Chinonye C. Ogbonnaya-Odor,[2] Jade M. Teakell,[2] Amit Lahoti.[1] *[1]M D Anderson Cancer Center, Houston, TX; [2]Univ of Texas Medical School at Houston, Houston, TX.*

Background: The 10- year survival rate for patients with metastatic melanoma is less than 10%. Systemic therapy is the mainstay of treatment for most patients, and immunotherapeutic agents have been associated with durable response in some patients. High dose Interleukin-2 (IL-2), which activates T-cells and NK cells, was approved by FDA in 1998 for treatment of metastatic melanoma. Common adverse effects include fever, chills, hypotension, cardiac arrhythmias, oliguria, volume overload, delirium, and rash. Hyponatremia has not been commonly reported. We present an unusual case of recurrent SIADH with each cycle of intrathecal IL-2.

Methods: A 65 year old man with Stage IV melanoma with left parietotemporal hemorrhagic metastases, underwent stereotactic radiosurgery of a left temporal lesion. He was subsequently treated with intrathecal IL-2 every 3 months for 4 years. After every infusion, he developed symptomatic hyponatremia (gait instability and confusion). Elevated urine osmolality and urine sodium were consistent with SIADH (Table). The patient did not complain of pain or nausea with treatment. During each cycle of IL-2, hyponatremia improved with a single dose of oral tolvaptan 15 mg (Figure).

Results:

Conclusions: To our knowledge, this is the first reported case of recurrent SIADH with long-term intrathecal IL-2 administration. While this does not appear to be a common side effect, physicians should be aware of this potential complication. Hyponatremia in this situation appears to respond well to single dose of tolvaptan 15 mg orally.

Pseudohypernatremia in Patients with Hemodialysis Catheters Locked with Trisodium Citrate Szymon Brzosko,[1,4] Maciej B. Drozdz,[2] Alicja Rydzewska-Rosolowska,[4] Stefan H. Jacobson.[3] *[1]DaVita, Bialystok, Poland; [2]DaVita, Krakow, Poland; [3]Danderyd Hospital, Stockholm, Sweden; [4]Medical University of Bialystok, BIALYSTOK, Poland.*

Background: International guidelines recommend arterio-venous fistula (AVF) as the preferred type of vascular access (VA) for hemodialysis (HD). Infections and patency-related complications of central venous catheters (CVC) pose a potential risk for patients. Trisodium citrate (TSC) locking solution is a promising alternative to unfractionated heparin (UFH) for prevention of CVC dysfunction. Pseudohypernatremia secondary to TSC contamination of blood specimens obtained from the CVC may potentially lead to profound but unnecessary diagnostic interventions. The aim of the study was to analyze pre-dialysis Na concentration and the prevalence of hypernatremia in relation to the type of locking solution (TSC vs UFH) and VA in a large cohort of HD patients (DaVita Poland).

Methods: The population studied consisted of 543 prevalent hemodialysis patients (45% female), mean age 67±14 years treated in a standard HD program (100% High Flux, 94% HD time>12h/week, 94% spKt/V>1.3, 18.5% CVC). We analyzed laboratory results from February & March 2017. Pre-dialysis Na concentration was compared between patients with CVC locked with 30%TSC, UFH (5000 IU/ml) and non-CVC types of VA (AVF, AVG). The proportion of patients with pre-dialysis Na ≥145 mEq/l (hypernatremia) was analyzed in both groups and from both months separately. Descriptive statistics was used together with ANOVA, t and X^2 tests as appropriate.

Results: The mean plasma concentration of Na was significantly higher in patients with TSC locking solution (141±3 mEq/l n=26, 142±3 mEq/l n=35) when compared to UFH (138±3 mEq/l n=76, 138±4 mEq/l n=75) and non-CVC VA (138±2 mEq/l n=430, 138±3 mEq/l n=440; ANOVA p<0.001 for February & March respectively). The proportion of patients with Na≥145 mEq/l was significantly higher in patients with CVCs with TSC (n=11/61) as a locking solution than in patients with UFH (n=4/152; 18.0% vs 2.6%; X^2 p<0.001). The highest plasma concentration of Na was 171 mEq/l, obtained from a patient with uneventful follow up. Repeated analysis from a peripheral vein showed a Na concentration of 138 mEq/l.

Conclusions: Pseudohypernatremia is may occur in HD patients when 30% TSC is used as a locking solution. Need for diagnostic laboratory investigations may be lowered by strictly following procedures for blood sample collection from CVC (including discarding proper volume of blood).

TH-PO1135

Sorafenib Induced Resistant Hypocalcemia in a Patient with Chronic Mild Hypocalcemia from Possible Lysozyme Induced Nephropathy: A Nightmare to Treat Sanjeev Gupta, Anastasios Papanagnou, Yorg Al Azzi, Maureen E. Brogan. *Westchester Medical Center, Valhalla, NY.*

Background: Sorafenib is a multikinase inhibitor; approved for treatment of multiple cancers. A lesser-known side effect of this drug is hypocalcemia (hypoCa). Diarrhea and Vit D malabsorption due to exocrine pancreatic dysfunction are proposed causes for hypoCa from Sorafenib. We present a case of Sorafenib induced severe hypoCa in a patient with chronic mild asymptomatic hypoCa.

Methods: A 67-year-old man with a history of CMML, MDS and hypoCa with c/o joint pain and weakness admitted for management of possible AML. Work-up showed anemia, thrombocytopenia, and leukocytosis. Bone marrow aspiration confirmed AML. A single dose of Cytarabine and Sorafenib was administered. His serum calcium (S.Ca) dropped to 6.2 from 7.9 (at admission). IV and oral calcium with Vit D were initiated. The patient, however, became symptomatic with oral numbness due to a further drop in S.Ca to 5.8. IV calcium drip was added to oral calcium and Vit D. His S.Ca was difficult to maintain above 7, even on an IV calcium drip with Vit D. High-dose IV calcitriol was added to the treatment plan. His PTH and 25-Vit D levels were 576 and 20 respectively. Given his history of CMML, lysozyme-induced proximal RTA was considered as an underlying etiology of chronic hypoCa supported by glycosuria, high fractional excretion of phosphate, elevated trans-tubular potassium gradient and increased urinary level of alpha-aminobutyric acid, alanine, arginine, and asparagine. His urinary Ca/Cr ratio was low (<7). The patient finally responded to treatment and was subsequently switched to oral calcium and calcitriol and discharged home with S.Ca of 7.9.

Results:

Conclusions: Lysozyme-induced nephropathy is an under-recognized complication of CMML. A persistently elevated level of lysozyme exceeds the reabsorption capacity of tubules leading to tubular injury. The exact mechanism of action of Sorafenib induced hypoCa is still unknown attributing to challenges in managing such patients. Our patient's S.Ca level did not respond well to Vit D as suggested by few case reports and required heavy doses of calcitriol along with IV calcium and Vit D analogues. This case highlights that it is essential to consider underlying history of hypoCa before starting a patient on Sorafenib, as it can lead to severe hypoCa, which can be difficult to manage.

TH-PO1136

Fluid Overload Is a Risk Factor for AKI and Mortality in Influenza Patients Luis I. Bonilla,[1,2] Raymundo Vera,[1] Raymundo A. Sánchez,[1] Israel A. Villegas-Gasson,[1] Sara Samoni,[2] Claudio Ronco,[2] Lilia M. Rizo Topete.[1,2] *[1]Nephrology, University Hospital "Dr. José Eleuterio González", Monterrey, Mexico; [2]International Renal Research Institute of Vicenza, Vicenza, Italy.*

Background: Influenza virus, especially A(H1N1) has been consistently associated with high mortality in the subset of critically ill patients who develop Acute Distress Respiratory Syndrome (ADRS). Risk factors for this association have not been well described. Fluid overload (FO) is now a recognized condition which increases the incidence of acute kidney injury (AKI) and its association with mortality in critically ill patients has been well documented. Nevertheless the impact of FO in mortality of ARDS influenza patients has not been yet described.

Methods: This is a retrospective analysis of 30 records of patients who were admitted to the ICU with the diagnosis of ARDS and suspicion of influenza infection during the Influenza season 2016-2017. Demographic, laboratory, and clinical data were obtained. We calculated FO as the algebraic sum of the inputs and outputs recorded every day during the whole ICU stay divided by the patient's weight at admission and expressed as a %. We divided patients into 2 groups: A) < 5% FO and B) > 10% FO and compared mortality among both groups.

Results: Mean age in our cohort was 46.4yrs, 66.6% were male and 46.6% were obese. Influenza was confirmed in 12 patients; 41.6% with A(H1N1). Mortality among A(H1N1) patients was 100%. AKI was diagnosed in 20 patients (66.6%) with 16.6%, 10% and 36.6% of KDIGO stages 1-3 respectively. RRT was initiated in 10 (50%) of AKI patients. Among groups A and B AKI was diagnosed in 50% and 75% of patients respectively p=0.23. ICU mortality was 60% among the whole cohort. Median fluid balance (FB) among survivors was +3,885.8ml (2,108.7-7,525.5) and among non-survivors +8,036.5ml (5,283-18,863) p=0.043. Mortality in group A was 35.7% and in group B 63.3% p=0.22. The OR for mortality and AKI in group A was 0.58 (CI95% 0.22-1.54) and in group B 3.0 (CI 95% 0.49-18.1) p=0.22.

Conclusions: In our cohort of ARDS patients, FO >10% was associated with increasing incidence of AKI and mortality. Also, the presence of a confirmatory diagnosis influenza A(H1N1) conferred a 100% mortality. With these findings, we can strongly recommend a conservative fluid strategy in the treatment of this kind of patients. More studies with bigger cohorts are needed to obtain statistical significance and clearly demonstrate these associations.

TH-PO1137

Prediction of Hyponatremia from Electronic Medical Records Using an Deep Learning Approach with an Artificial Neural Network Algorithm Young-Il Jo,[1] Sug kyun Shin.[2] *[1]Nephrology, Konkuk University Medical Center, Seoul, Republic of Korea; [2]Ilsan Hospital NHIS, , GOYANG-SI, GYEONGGI-DO, Republic of Korea.*

Background: Hyponatremia is associated with increased morbidity and mortality in both hospitalized and ambulatory patients. In the era of big data, analysis of electronic medical records (EMR) may have a significant impact on patient's outcomes by identifying high-risk patients or supporting clinical decision making. The aim of this study was to predict hyponatremia from EMR using an deep learning approach with artificial neural network (ANN) algorithm.

Methods: A total 182,181 patients who measured serum sodium concentrations from 2010 to 2016 in a tertiary referral hospital were enrolled. Clinical, biochemical and medication data were obtained from EMR data warehouse. A total of 853 columns were presented along with basic patient information. For training, 500 random number trees

were given to the random forest algorithm. The medication dataset was based on a neural network based on Dense Matrix. Learning and modeling have attempted to construct a combined dataset by using Ensemble model. The predictive value and diagnostic accuracy were calculated for the dataset based on serum sodium concentration less than 134 mEq/L.

Results: Using the confusion matrix and statistics for clinical and laboratory data set, the predicted value was 0.9104 (95% CI, 0.9040-0.9157). In the medication data set, he predicted value was 0.7515. Deep learning predictive approaches using the Ensemble model, the prediction probability for hyponatremia was 92.05% (Table).

Conclusions: Using an deep learning approach with the ensemble model, an artificial neural network can accurately predict hyponatremia from the laboratory dataset and the medication dataset of EMR.

Confusion matrix and statistics (Prediction/Real) for prediction of hyponatremia in the Ensemble model

The Association between Serum Sodium and Potassium Concentration and the Risk of Cardiovascular Disease: A Large Community-Based Cohort Study Nicholas I. Cole,[1] Pauline A. Swift,[1] Feng J. He,[2] William Hinton,[3] Filipa I. Ferreira,[3] Simon De lusignan,[3] Rebecca Suckling.[1] *[1]Epsom and St Helier NHS Trust, London, United Kingdom; [2]Queen Mary University of London, London, United Kingdom; [3]University of Surrey, Guildford, United Kingdom.*

Background: Observational and randomised studies have shown that reduced dietary sodium (Na) and higher potassium (K) are associated with lower blood pressure and cardiovascular (CV) disease. Changes in dietary intake may alter the serum concentration of these electrolytes, but few studies have investigated if there is a relationship between serum Na, K and CV risk.

Methods: This was a retrospective cohort study using data from the Royal College of General Practitioners Research and Surveillance Centre, a database of routinely-collected primary care data in the UK. Data were extracted using Read V2 and EMIS codes. Only individuals with both a serum Na and K value were included, with the most recent data prior to April 2010 used to define baseline levels. Exclusion criteria were: age less than 40 years; diabetes mellitus; prior CV event; end-stage renal disease; liver cirrhosis. The primary outcome was incident CV disease (acute coronary syndrome; coronary revascularisation; stroke; new diagnosis of heart failure) over 5 years.

Results: 235,676 individuals met the criteria for inclusion in the study. The median age was 59 years (IQR 49-68), 57% were female, and 5% were known to be of non-white ethnicity. The median serum Na was 140 mmol/L (IQR 139-142), and the median serum K was 4.4 mmol/L (IQR 4.1-4.6). 21% were prescribed at least one diuretic medication, and 23% were prescribed a renin angiotensin system (RAS) inhibitor. There were 9,464 (4.0%) incident CV events during the follow-up period. After multivariate adjustment for confounding factors, there were significant associations between the primary outcome and serum Na (≤ 140 and ≥ 144 mmol/L) and serum K (≥ 4.5 mmol/L) – see *Figure*. No relationship with blood pressure was demonstrated.

Conclusions: There is a significant association between serum Na, serum K and primary CV events. This relationship is unexplained but could be associated with activation of the RAS.

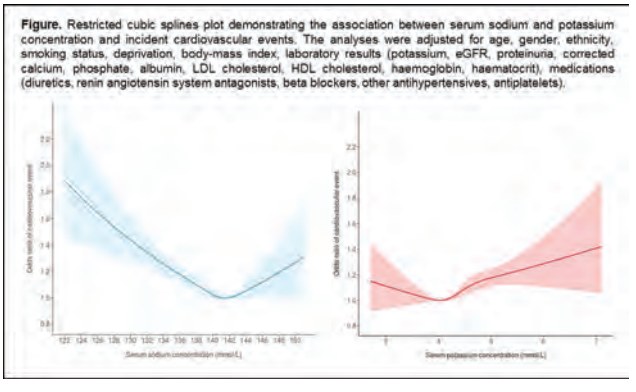

Figure. Restricted cubic splines plot demonstrating the association between serum sodium and potassium concentration and incident cardiovascular events. The analyses were adjusted for age, gender, ethnicity, smoking status, deprivation, body-mass index, laboratory results (potassium, eGFR, proteinuria, corrected calcium, phosphate, albumin, LDL cholesterol, HDL cholesterol, haemoglobin, haematocrit), medications (diuretics, renin angiotensin system antagonists, beta blockers, other antihypertensives, antiplatelets).

TH-PO1139

Quantitative Urine Proteomics by SWATH-MS Reflects Intricate Metabolic Processing in Cirrhosis Patients Bo Xu, Yoshitoshi Hirao, Keiko Yamamoto, Ichiei Narita, Tadashi Yamamoto. *Niigata University, Niigata, Japan.*

Background: Cirrhosis of the liver often has no signs or symptoms until damages is extensive, 3-4 million people are suffered from cirrhosis in the world. However, early diagnosis and treatment are difficult due to cirrhosis could be leaded by a wide range of disease. The aim of this study is to reveal sophisticated metabolic processing pathway in cirrhosis patients by comparison of quantitative analysis of urine proteins between health volunteers and cirrhosis patients.

Methods: Urine proteins were purified by precipitation method from patients and health volunteers individually. After digestion, purified urine peptides were analyzed by optimized Sequential window acquisition of all theoretical mass spectra (SWATH-MS). ProteinPilot™ and PeakView™ were used for protein identification and SWATH data analysis respectively. Differentially expressed molecules were further analyzed by Gene Ontology (GO) and KEGG pathway analysis using DAVID.

Results: In total 2047 proteins were identified. 1425 proteins were reliably quantified in both groups. 861 proteins were observed with more than 2 times fold change (FC),415 proteins with over 5 times FC between cirrhosis and health control (HV) groups. We focused on these 415 molecules that were regulated in cirrhosis, since they will be supposed as potential molecules involved in the onset of cirrhosis. GO analysis indicated 282 of these 415 genes were clustered in extracellular exosome, and enrichment analysis revealed serine-type endopeptidase activity was the most significant over-represented molecular function for the 282 molecules. KEGG pathway analysis showed 38 proteins related to metabolic pathway. Glycolysis / Gluconeogenesis pathway is most significantly enriched. Low abundance proteins revealed that protein expression of cell adhesion, immune response, and proteolysis in cirrhosis patients.

Conclusions: Quantitative proteomic results of urine proteins from cirrhosis patients show significant increase of proteins related to the complement and coagulation cascades, regulation of actin cytoskeleton pathway, and decrease of proteins in the cell adhesion molecules (CAMs), endocytosis, PI3K/Akt signaling and phagosome pathways. Our pilot studies of cirrhosis patient urinary proteomes may promote to discover urine biomarkers of cirrhosis in the early stage of liver dysfunction.

Dietary Acid Load Is Associated with Greater Urinary Nitrogen and Muscle Mass Loss in CKD Patients Larissa R. Angeloco,[1] Tanushree Banerjee,[3] Lynda A. Frassetto.[2] *[1]University Of São Paulo, Ribeirao Preto, Brazil; [2]University of California San Francisco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA.*

Background: In chronic kidney disease (CKD), high dietary acid loads may promote metabolic acidosis, which in turn may contribute to adverse clinical health outcomes. We hypothesize that high diet acid load plus higher acid body content in CKD leads to greater muscle breakdown and greater urine nitrogen loss. We examined associations between dietary acid load, serum bicarbonate, 24- hour urine urea nitrogen (UUN), arm muscle area (AMA), and diet protein/potassium (K) ratio in pre-dialysis CKD subjects.

Methods: 100 subjects with CKD stage 3 and 4 and 29 healthy control subjects were enrolled in this cross-sectional study. Potential renal acid load (PRAL) and net acid excretion (NAE) were determined by the average of 3-day food records using the equations by Remer, Frassetto, and Lemann. PRAL and NAE were divided into quintiles. Pearson correlation and multivariable regression analysis were used to evaluate the associations of dietary acid measurements (PRAL and NAE) with serum bicarbonate, UUN, AMA, and diet protein/K ratio. The regression models were adjusted for demographics, body mass index, diabetes, systolic and diastolic blood pressure, urine pH, and creatinine clearance.

Results: Mean age of the population was 57 yrs (range 28-69) with 53% females. Median eGFR was 30 ml/min for the CKD subjects, and 100 ml/min for the controls. The correlation coefficients (p value) in CKD subjects in the highest quintile of diet acid load are presented (see table). PRAL correlated significantly with UUN in the control subjects (r=0.9). In adjusted analysis, compared to the lowest quintile, no significant association was observed between the higher quintiles of PRAL with serum bicarbonate in CKD patients (β[95% CI]: -0.4[-2.5-1.7] in quintile 5, -0.4[-2.4-1.6] in quintile 4, -0.05[-1.9-1.8] in quintile 3, 1.3[-0.5-3.2] in quintile 2).

Conclusions: We found a significant association of higher body acid balance with urinary nitrogen loss, but not with serum bicarbonate. In patients with CKD, limiting diet acid load may improve metabolic acidosis and its long-term adverse health effects.

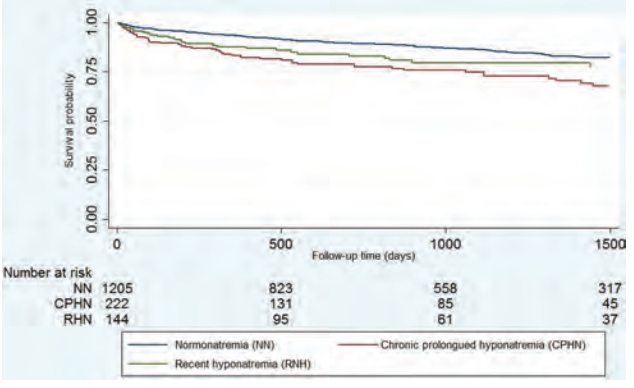
Mild Chronic Prolonged Hyponatremia at Admission Is Associated with Long Term Mortality in Patients with Hip Fracture Repair Juan Carlos Ayus,[4] Nora Fuentes,[5] Michael L. Moritz,[1] Alan S. Go,[2] Armando L. Negri.[3] *[1]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [2]Kaiser Permanente Northern California, Oakland, CA; [3]Instituto de Investigaciones Metabólicas, Buenos Aires, Argentina; [4]Renal Consultants of Houston, Houston, TX; [5]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.*

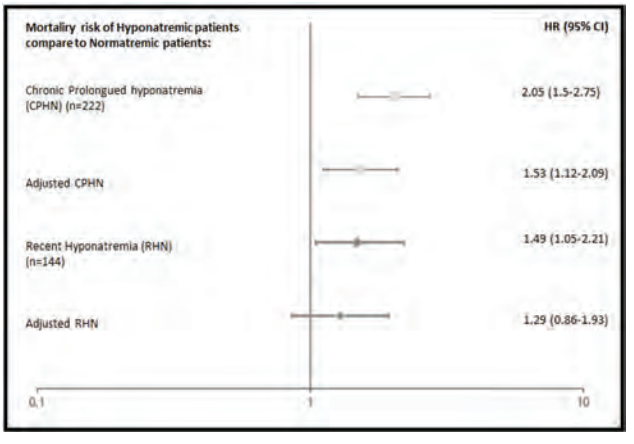
Background: A recent study indicates that chronic prolonged hyponatremia is a significant risk factor for hip fracture in the elderly (Ayus JC; NDT 2016; 31(10):1662-9). No information exists with respect the chronicity of the hyponatremia prior to admission and its effects on long term mortality.

Methods: We designed a cohort study in adults admitted for traumatic hip fracture who had at least one serum Na performed at admission. Hyponatremic patients (HN) were divided in those with chronic prolonged (hyponatremia for 90 days or more, CPHN), and those with recent hyponatremia (hyponatremia for 30 days or less, RHN) prior to admission.

Results: 1205 (76.7%) patients were normonatremic (NN) and 366 (23.3%) were HN at admission (138 ± 3 vs 132 ± 4 mmol/L Na; p <0,001). Of these, 222 (14%) had CPHN and 144 (9.1%) had RHN. Overall mortality rate was higher in CPHN 25% (56/222), followed by RHN 20% (29/144) and finally NN 14% (169/1205). Five year survival in patients with CPHN and RHN was lower than those with NN: 0.83 and 0.87 compared to 0.93 (p <0.001) **figure 1**. Unadjusted HR for long term mortality > in CPHN and RHN vs NN but adjusted HR was only significant for CPHN **figure 2**.

Conclusions: Mild chronic prolonged hyponatremia at admissionin in patients with hip fracture repair is associated with increased long term mortality.





TH-PO1142

Villous Adenoma: A Rare Cause of Hypokalemia and Metabolic Alkalosis

Daniel Bianchi,[2] James I. McMillan.[1] *[1]Loma Linda University, Loma Linda, CA; [2]Loma Linda University School of Medicine, Loma Linda, CA.*

Background: The differential diagnosis of hypokalemia and metabolic alkalosis is large and includes fluid loss without HCO3- wasting (vomiting/diuretics), mineralocorticoid excess, and hereditary conditions such as Bartter syndrome. We present an unusual case of hypokalemia and metabolic alkalosis.

Methods: A 58 year-old previously healthy male was admitted to the ICU after 15 days of weakness, muscle cramps, orthostatis and blood streaked stools. He had hyponatremia and acute kidney injury, and was fluid resuscitated. Two months later his physician saw him for rectal pain, diagnosing hemorrhoids, and noted a potassium of 2.4. He was given KCl without work up. He had two more ICU admissions for severe volume depletion in 4 weeks. Representative labs: serum Na 131, K 2.9, Cl 88, CO2 34, Cr 1.5, aldosterone 78 and plasma renin activity 39.5. He was believed to have Bartter's syndrome, given amiloride and ibuprofen, and referred to our facility for nephrology consultation. A history of rectal mucoid discharge prompted a suspicion of villous adenoma, confirmed by colonoscopy. The 11 cm distal rectal lesion was resected transrectally. All symptoms resolved.

Results:

Conclusions: The mistaken initial diagnosis of Bartter Syndrome was based on the elevated aldosterone, hypokalemia, metabolic alkalosis, and lack of hypertension. However inadequate resuscitation of his fluid and electrolyte loss from the villous adenoma explains the hormonal and electrolyte abnormalities. Villous adenoma depletion syndrome (McCrittrick Wheelock) is rare, resulting from a mucous secreting villous adenoma in the distal colon causing volume depletion, hypokalemia, and usually metabolic acidosis. Up to 3% of villous adenomas are secretory. Hypersecretion of bicarbonate and electrolytes from abnormal enterocytes is likely the cause. We describe a rare case of villous adenoma with metabolic alkalosis. Literature review identified 58 cases of villous adenoma depletion syndrome; 7 had metabolic alkalosis. The cause of the metabolic alkalosis variant may be over expression or activation of apical chloride channels in adenoma goblet cells. Increased cAMP or cGMP production in goblet cells could also lead to over activity of CFTR channels causing chloride secretion. Finally, decreased expression of the Downregulated in Adenoma (DRA) gene may decrease expression of Cl/Na exchangers reducing chloride absorption.

FR-PO001

Serious Breakdown: A Rare Case of Spontaneous Tumor Lysis Syndrome from Aggressive Diffuse Large B-Cell Lymphoma

Stephen P. Regina,[1] Michael M. Strauss,[2] Roberto L. Collazo-Maldonado.[2] *[1]Methodist Health System, Dallas, TX; [2]Nephrology Division, Methodist Dallas Medical Center, Dallas, TX.*

Background: Introduction: Tumor Lysis Syndrome (TLS) is a well-known cause of AKI classically seen in patients with high grade tumors treated with chemotherapy. However, spontaneous TLS is a rare presentation that has been described mostly in Diffuse High Grade B-cell Lymphomas.

Methods: Case Description: This is a 67 year old woman with PMH of hypertension, hypothyroidism, and marginal cell lymphoma in remission after receiving treatment with rituximab 6 months prior to admission. She was admitted with non-oliguric Stage 3 AKI after her routine outpatient labs revealed an elevated serum creatinine of 3.5 mg/dL from a baseline of 1.0 mg/dL. She was normotensive, euvolemic, and physical exam revealed some wasting, but otherwise unremarkable. Her renal ultrasound showed bilateral hydronephrosis, but renal scan showed no obstruction. Labs were significant for WBC 20,600, Hgb 10.3 g/dL, platelets 470,000 /mm3., K 4.4 mmol/L, phosphate 4.8 mg/dL, calcium 10.8 mg/dL, uric acid 14.9 mg/dL, LDH 1,458 U/L, CPK was normal. A PET scan showed multiple enhancing pelvic lymph nodes as well as supra- and infra-diaphragmatic tracer uptake. Biopsy of left axillary lymph nodes revealed diffuse large B cell lymphoma (DLBCL). Patient was started on IVFs, rasburicase, and allopurinol. After tissue diagnosis was obtained, she initiated chemotherapy with R-CHOP for her aggressive DLBCL. With therapy, her creatinine improved to her baseline 1.01 mg/dL, uric acid level decreased to 1.2 mg/dL, and calcium normalized to 9.8 mg/dL by discharge.

Results:

Conclusions: Discussion: While rare, spontaneous TLS occurring in the absence of current or prior chemotherapy have been reported mostly occurring in the context of B-cell lymphomas. Nephrologists should consider an occult malignancy in the differential diagnosis of a patient presenting with AKI and hyperuricemia. With high level of suspicion, early initiation of therapy may result in renal improvement and avoid potential complications which may increase morbidity and mortality.

FR-PO002

Spontaneous Tumor Lysis Syndrome Presenting as Acute Renal Failure from Numerous Bilateral Obstructing Uric Acid Stones

Laura Binari,[1] Anna M. Burgner.[2] *[1]Vanderbilt University Medical Cente, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Tumor lysis syndrome (TLS) causes a recognized collection of metabolic abnormalities including hyperkalemia, hypocalcemia, hyperuricemia, and hyperphosphatemia. TLS can result in acute renal failure (ARF) from multiple mechanisms including intra-renal precipitation of uric acid, xanthine, or calcium phosphate crystals resulting in obstruction and inflammation. It is an anticipated complication after initiation of chemotherapy for lymphoproliferative malignancies or in patients with high tumor burden; it can also occur spontaneously. We report an unusual case of a B-cell lymphoma presenting as ARF from extensive obstructing bilateral uric acid nephrolithiasis from spontaneous TLS.

Methods: A 36-year-old male with HIV was admitted to the hospital with oliguric ARF after presenting with 2 weeks of weight loss and dysphagia. He had started Bactrim and Atripla one month prior to presentation. Admission plasma lab values: creatinine 17.44 mg/dl, BUN 158 mg/dl, potassium 7.7 mEq/l, LDH 2097 u/l, phosphorous 11.7 mg/dl, and calcium 9.1 mg/dl. Urine studies were notable for 130 RBC/hpf and spot urine protein to creatinine ratio of 12. He underwent emergent hemodialysis for his hyperkalemia and work up of his ARF was initiated. A peripheral blood smear demonstrated the presence of lymphoma cells. Uric acid was found to be 24.5 mg/dL. Renal ultrasound demonstrated bilateral enlarged and echogenic kidneys with mild hydronephrosis of the left kidney and multiple bilateral renal calculi. A cystoscopy revealed heavy stone burden bilaterally with numerous calculi requiring placement of double J-stents for bilateral obstructive nephrolithiasis. Bone marrow biopsy and PET scan showed an aggressive B-cell lymphoma and he was started on rasburicase and chemotherapy while on renal replacement therapy. He ultimately regained kidney function and was able to stop dialysis 3 weeks after presentation.

Results:

Conclusions: To our knowledge, there is only one other case report of a patient with HIV and lymphoma who presented with spontaneous TLS. Despite multiple case reports discussing ARF due to spontaneous TLS, there are limited reports of nephrolithiasis as the etiology for renal failure. This case demonstrates the importance of including TLS in the differential when a patient presents in new ARF with significant bilateral nephrolithiasis despite no known malignancy.

FR-PO003

Tumor Lysis Syndrome in Multiple Myeloma Treated with Carfilzomib Nupur N. Uppal,[1] Rimda Wanchoo,[1] Jamil Ibrahim,[1] Anna T. Levy,[2] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra Northwell School of Medicine, Great Neck, NY; [2]Hematology/Oncology, Hofstra Northwell School of Medicine, Lake Success, NY.*

Background: Tumor lysis syndrome(TLS) is extremely uncommon in patients with multiple myeloma(MM) because of low rate of proliferation of the plasma cells. Carfilzomib is a proteasome inhibitor that has been recently used for treatment of relapsed/refractory MM. Only a few cases of MM associated TLS have been reported in the literature. These cases include spontaneous TLS, drug induced TLS, or TLS due to plasmablastic transformation of MM. While acute kidney injury(AKI) has been seen with carfilzomib treatment, TLS has been rarely reported. We describe a case of TLS in patient with MM on carfilzomib therapy.

Methods: A 58-year-old female with known IgG kappa MM, with poor and complex cytogenetics and a plasma cell pleural mass, who had failed treatment with standard MM therapy, followed by lenalidomide, presented with shortness of breath and hypotension, and was noted to have AKI [serum creatinine (Scr) of 1.7mg/dL) on admission. She was started on carfilzomib treatment 4 weeks prior to presentation. Lab work also revealed elevated levels of LDH (1700U/L), phosphorus (9.1mg/dl), potassium (5.1mmol/L) and uric acid (22mg/dl). A diagnosis of TLS was made. Besides usual therapy with hydration, and rasburicase, she also required continuous renal replacement therapy (CRRT), followed by hemodialysis (once hemodynamically stable) for management of TLS. After a week of RRT, renal function improved and TLS labs stabilized. However, her kappa/lambda free light chain ratio increased from 144 to 344. Patient opted for end of treatment and hospice care. Her Scr stabilized ~2mg/dl upon discharge.

Results:

Conclusions: TLS has been seen in 1% of patients treated with high-dose chemotherapy following autologous stem cell transplant, and ~1.4% in patients receiving bortezomib. Although rare in patients with MM, TLS can occur in this population, especially in patients with poor prognostic features including high tumor mass, immature morphology, high proliferative activity, and poor cytogenetics. To our knowledge, our case is the second reported case of TLS following carfilzomib treatment. While risk of TLS is small in patients with MM, physicians should be aware of this potential adverse effect in patients receiving carfilzomib therapy.

FR-PO004

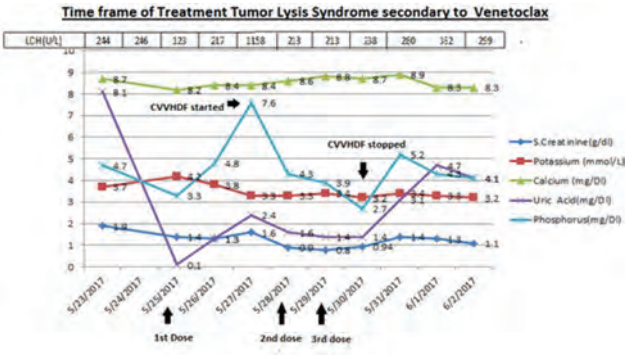
Tumor Lysis Syndrome with Venetoclax Nishita Parikh,[1] Jacqueline Barrientos,[2] Richard L. Barnett,[1] John F. Katsetos,[2] Massini Merzkani,[3] Anna Mathew,[1] Kenar D. Jhaveri.[1] *[1]Nephrology, Hofstra Northwell School of Medicine, Great neck, NY; [2]Hofstra Northwell School of Medicine, CLL Research and Treatment Center, Lake Success, NY; [3]Nephrology, Hofstra Northwell School of Medicine, Great Neck, NY.*

Background: Venetoclax is a BCL2 inhibitor approved for CLL treatment. A low dose of this drug has led to fatal cases of tumor lysis syndrome (TLS) in the initial trials.

Methods: A 64 year old female with CLL was admitted for worsening lymphadenopathy. After failing all therapy, she was planned to start on venetoclax (BCL2 inhibitor). Given her admission serum creatinine(Scr) of 1.9mg/dl, uric acid level of 8.1mg/dl, and serum phosphorus was 4.8mg/dl, she was started on crystalloid fluid resusitation and received one dose of rasburicase(0.2mg/kg). Pt. Scr improved to 1.3mg/dl. Given high tumor burden, nephrology was consulted early for TLS prevention. The patient was initiated at 20mg dose of venetoclax and TLS labs were monitored every four hours. Three hours after the initial dose, the patient had a sudden rise in the LDH to 1158u/dl, Scr was 1.6mg/dl and serum phosphorus was 7.6 g/dL, despite urine output of 100 cc of urine per hour. An early transfer to intensive care unit and initiation of continuous renal replacement therapy (CRRT) allowed for ongoing dosing of venetoclax with controlled clearance of phosphate, potassium and uric acid. She received a modified dosing of this drug and ultimately was given 50mg of the dose before CRRT was discontinued. LDH was followed serially as a marker for ongoing TLS. Following resolution of TLS lab markers, CRRT was stopped, the patient received 100mg of venetoclax, with stable renal function and no abnormal TLS markers. Figure below summarizes the lab data supporting early successful prevention of fatal TLS reported with this agent.

Results:

Conclusions: This case illustrates that early involvement of nephrology in high risk TLS associated with venetoclax can improve patient outcomes. Early initiation of CRRT even without significant renal injury along with modified dose escalation can prevent fatal TLS outcomes as described in the initial trials of this agent. Nephrologists need to be aware of this toxicity with this agent as it becomes commonly used.



FR-PO005

Hypothyroidism with Rhabdomyolysis Causing AKI Antonio M. Villegas, Macgivenny A. Goris felix, Alberto Flores, Freddy Mejia, Guillermo Alvarez. *CEDIMAT., Santo Domingo, Dominican Republic.*

Background: Muscle complaints is frequent in adult onset hypothyroidism, accompanied by mild elevation of serum creatine kinase, but few cases have reported extremely high elevations of serum creatine kinase and rhabdomyolysis and acute renal failure. We report a case of acute kidney injury (AKI) associated with rhabdomyolysis secondary to severe hypothyroidism in a 57 year old female. The patient had general weakness, without muscle tenderness, elevated muscle enzymes and thyroid stimulating hormone (TSH), which normalized with thyroid replacement therapy.

Methods: A 57 year old female admitted to the general ward with complaints of general weakness, fatigue and body swelling, prominently on both legs. She denied any neither physical activity nor trauma, all beginning 1 week prior admission. She was pale, afebrile, had leg pitting edema, no goiter with no muscle weakness or tenderness. Investigation revealed: hemoglobin 10.2 g/dL, white blood cells 3.9 x 10^9L, blood urea nitrogen 53 mg/dL, creatinin 7.24 mg/dL, aspartate aminotransferase 257 IU/L. Serum muscle enzymes were elevated; creatinin phosphokinase (CPK) >1600 U/L (upper normal limit (UNL) of 135), lactate dehydrogenase 1430 U/L (UNL of 618), and a negative antinuclear antibody. Urine analysis showed mild blood with dipstick with no erythrocytes, and a 24 hour urine collection with 0.36 g/day of protein. She reported fluctuation in mood, and weight gain in the last 6 months, TSH >100 μUI/mL, free T4 0.08 ng/dL, free T3 0.26 pg/mL and a extremely elevated anti-thyroid peroxidase (236.4 IU/mL). A thyroid scintigraphy revealed a low Tc-99m uptake. Hydration and replacement therapy with thyroxine was started at a dose of 50 μg/day for 1 week, increased to 100 μg/day for 3 more weeks, TSH in 10.7 μUI/mL in 2 weeks, with normalization at week 8, creatinin 4.1 mg/dL and CPK 610 U/L after 2 weeks of treatment, also patient reporting the disappearing of the legs edema and the weakness after 1 week of treatment. At 3 month follow up all clinical and laboratory findings were normalized, with a creatinin 0.8 mg/dL.

Results:

Conclusions: Hypothyroidism associated rhabdomyolysis is quite rare, depending on its severity, may be complicated with acute renal failure, hypothyroidism should be suspected in patients presenting with AKI in the absence of common causes of AKI, and in patients with vague muscular symptoms.

FR-PO006

AKI Secondary to Trabectedin Induced Rhabdomyolysis Deepa Amberker, Sreelatha Katari, Anitha Vijayan. *Washington University in St. Louis, St. Louis, MO.*

Background: Onconephrology is a growing field with nephrologists being consulted for various renal issues. Chemotherapy(chemotx) is associated with multiple renal complications including TMA, AIN, electrolyte abnormalities and CKD. Rhabdomyolysis (rhabdo) secondary to chemotx is extremely rare. We report a case of severe AKI secondary to rhabdo from trabectidin, an alkylating agent approved for soft tissue sarcomas in 2015.

Methods: A 46 year old Caucasian male with relapse of retroperitoneal liposarcoma was started on trabectedin 4wk prior to admission. He presented with 10d history of n/v, diarrhea, chest pain and sob, starting a week after his 2nd cycle of trabectedin given 1wk before admission. Initial labs showed pancytopenia, Trop-I of 0.15 and SCr of 1.4 (baseline 1.1). On day 9, SCr started increasing and peaked at 5.61. Creatinine kinase (CK) was obtained and noted to be elevated and peaked at 93300. He was treated with bicarbonate drip with subsequent improvement in renal function.(Table1)

Results:

Conclusions: Trabectedin has been associated with pancytopenia, myocarditis, transaminitis and GI side effects. In the company drug data base, rhabdo has only been reported in 0.7% of cases, but had a high mortality of 41%. CK elevation is typically reported after the 2nd cycle and rare after the 4th cycle. Median time to CK elevation was 2mo post chemotx. Trabectidin undergoes hepatic metabolism and inhibitors of CYP3A4 increase risk for adverse events. Our patient was not on any medications which is known to inhibit this pathway. With increasing use of trabectedin in soft tissue sarcomas, it is critical that physicians be aware of this devastating complication and monitor patients closely during chemotx. Early, adequate hydration, frequent lab checks including SCr and CK is crucial in preventing AKI and its complications.

Lab Trend

Labs	1 week before admission	Day 1 of admission	Day 9 of admission	Day 18 of admission (peak values	At Discharge (day 35)
SCr (mg/dl)	1.10	1.40	1.95	5.61	0.9
K (mmol/l)	3.5	4.1	3.7	3.5	3.5
Ca (mg/dl)	8.8	7.8	7.2	<5	8.2

FR-PO007

A Case of AKI due to Rhabdomyolysis in Association with Exposure to Daptomycin Eldrid Baez, Juan Carlos Q. Velez. *Ochsner Clinic Foundation, Kenner, LA.*

Background: Rhabdomyolysis has been reported in association with exposure to the cyclic lipopeptide daptomycin. However, reports of acute kidney injury (AKI) resulting from daptomycin-associated rhabdomyloysis are sparse in the medical litearature.

Methods: A 35 year-old Caucasian man presented to the hospital with a 3-day history of fever and worsening delirium after a recent reduction and fixation of a motor vehicle accident-related wrist fracture which had been performed 2 weeks prior to presentation. Past medical and family history were unremarkable. Vital signs were significant for temperature of 38ºC and blood pressure of 99/56 mmHg. Physical examination disclosed confusion and an erythematous, inflamed right wrist. Laboratrory data on admission revealed a serum creatinine (sCr) of 1.3 mg/dL. Blood cultures revealed growth of methicillin-resistant *Staphyloccous aureus.* He was initiated on empiric antibiotic therapy with vancomycin, tobramycin and aztreonam. The patient remained febrile and blood cultures failed to clear after 3 days of therapy. The wrist hardware was then surgically removed. Antibiotic coveraged was broadened with the addition of daptomycin. Three days after the addition of daptomycin, sCr began to increase progressively, reaching a peak level of 7.1 mg/dL 4 days later. Serum creatinine kinase (CK) was found to be 29,000 U/L. Urine microscopy revealed muddy brown granular casts, no red blood cells and 1+ blood by urine disptick. As a result, daptomycin was discontinued in light of suspected toxic acute tubular necrosis (ATN) due to rhabdomyolysis. He transiently required renal replacement therapy. One week later, sCr and CK began to normalize.

Results:

Conclusions: While rhabdomyolysis was reported in up to 3% of patients receiving daptomycin in pre-marketing clinical trials, AKI due to rhabdomyolysis was not reported until the post-marketing era. To date, only 3 probable cases are found in the literature. By the Naranjo criteria, our case is also classified as probable. This case demonstrates that awareness should be raised about the risk of severe AKI due to toxic ATN from daptomycin-associated rhabdomyolysis.

FR-PO008

Recurrent Exercise Associated AKI: An Unusual Presentation of Malignant Hyperthermia Megha R. Joshi,[2] Sarah M. Gordon.[1] *[1]WRNMMC, Rockville, MD; [2]Walter Reed, Bethesda, MD.*

Background: We present a healthy soldier with recurrent exercise associated acute kidney injury (AKI) and hematuria. After extensive testing, muscle biopsy was diagnostic of malignant hyperthermia (MH). This case suggests myopathic disorders should be discussed in exercise-associated AKI.

Methods: A thirty-five year old white male was referred for recurrent painless dark urine after running. He had no medical or surgical history, and no family history of renal disease. He denied new medications, substance or supplement use. There was no history of nephrolithiasis or urinary tract infection.

Results: He was normotensive with an unremarkable physical exam. Pre-exercise renal function, proteinuria quantification, urine dipstick and microscopy, sickle cell screen, drug screen, and creatinine kinase (CK) were normal. Serum creatinine was 0.9 mg/dL. Post exercise serum creatinine rose to 1.5mg/dL. Testing demonstrated elevated serum and urine myoglobin (111ng/mL and 29ng/mL respectively) and mildly elevated CK (309 U/L). Repeat urine sediment showed muddy brown casts consistent with acute tubular necrosis (ATN) and 20 isomorphic red cells per field. Labs normalized within one week of rest. He was evaluated by Hematology and Rheumatology for muscular and red blood cell abnormalities; no etiology was identified. Cystoscopy and contrasted tomography urogram were normal. Pre- and post-exercise renal artery dopplers were normal. He was referred to a neuromuscular specialist, and a muscle biopsy was diagnostic for malignant hyperthermia. We recommended avoidance of strenuous exercise and anesthetic agents. Renal function is normal without symptom recurrence following de-escalation of his exercise regimen.

Conclusions: The classic presentation of MH is characterized by acute hyperthermia, muscle rigidity, and rhabdomyolysis with AKI. There are also case reports of subclinical rhabdomyolysis in MH, however none document evidence of ATN. Exercise-induced AKI is a rare clinical presentation of MH, and should be considered in the differential. Avoidance of AKI precipitants is important, as the risk for CKD among individuals with recurrent AKI is well documented.

FR-PO009

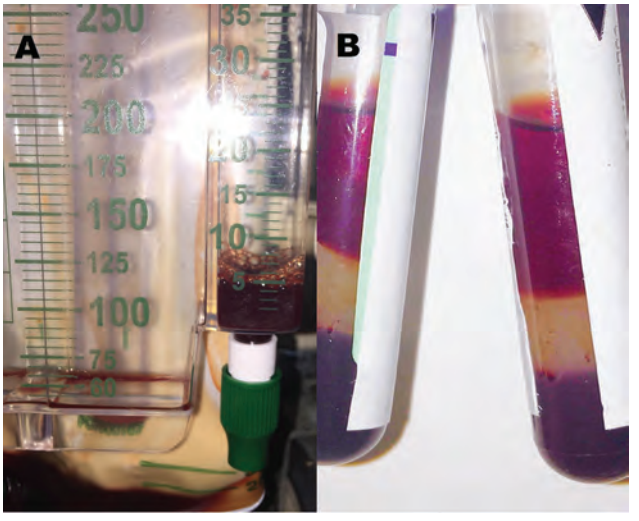
Acute Intravascular Hemolysis and Kidney Injury from an Amplatzer Device: Complication of an Innovative Cardiac Procedure and the Challenge of Dialysis Kevin D. Marquez, Andrew I. Chin. *University of California Davis Medical Center, Sacramento, CA.*

Background: The Amplatzer septal occluder is a transcatheter device used as a treatment option for ostium secundum atrial septal defects. It has also been used to treat residual mitral regurgitation (MR) in patients with a high open surgical risk. We describe a rare complication of rapid mechanical hemolysis leading to acute kidney injury, and describe the challenge of hemodialysis (HD) in this setting.

Methods: A 68 yo man with persistent MR despite 2 prior procedures had an elective 3rd MitraClip with placement of the Amplatzer septal occluder device in the lateral mitral commissure. The procedure went well. The following morning, his serum creatinine doubled from 1.33 to 2.62 mg/dL, his urine turned dark in color (Figure A), and he became oliguric. Labs at that time: potassium 5.9 mEq/L, lactate dehydrogenase 2200 U/L, haptoglobin 4 mg/dL, and peripheral smear with schistocytes. Notably, plasma was red in color (Figure B). Rapid mechanical hemolysis due to the Amplatzer device was suspected. The device was immediately removed. HD was initiated. However, within a minute, the dialysate blood leak detector alarm was triggered. No blood was visualized in the dialysate, which tested positive using hemoglobin test strips. Blood was not returned and a new circuit and machine were set up. Using low blood flow of 100 cc/min and high dialysate flow of 800 cc/min, HD was resumed with minimal alarms. Subsequent HD treatments did not activate the blood leak alarms.

Results:

Conclusions: While intravascular hemolysis with the Amplarzer device has been reported, this is the second reported case of hemolysis when this device is used to treat residual mitral regurgitation. This case demonstrates the sensitivity of the dialysate blood leak detector to being triggered by the diffusion of free hemoglobin into dialysate due to intravascular hemolysis.



FR-PO010

Renal Hemosiderosis as a Complication of Total Artificial Heart Therapy Mirza S. Baig,[2] Gaurav Gupta,[1] Dhiren Kumar.[1] *[1]Medical College of Virginia/Virginia Commonwealth University, Richmond, VA; [2]VCU Medical Centre, Richmond, VA.*

Background: Mechanical circulatory support with a total artificial heart (TAH) is approved as a bridge to heart transplantation. Hemolysis is a common complication after implantation of a TAH. The incidence of renal failure requiring dialysis after TAH has been estimated at 12-15%. Kidney biopsy findings in patients with TAH and chronic hemolysis with renal failure have not been described.

Methods: A 57-year-old male with a history of non-ischemic cardiomyopathy underwent implantation of TAH. Post-TAH he developed progressive renal dysfunction (GFR decline= 70ml/min to 40 ml/min) presumed secondary to cardio-renal syndrome. He was also noted to have chronic hemolysis confirmed by evidence of fragmented RBC's on smear, elevated LDH and undetectable haptoglobin concentration. Due to this, he required blood transfusions for the next seven months till the time he underwent an orthotopic heart transplant (OHT). Post-OHT he developed worsening acute kidney injury requiring hemodialysis (HD). After being maintained on HD for 8 weeks, a kidney biopsy was performed. In addition to moderate interstitial fibrosis, his biopsy was remarkable for extensive intracytoplasmic and luminal iron deposition in tubular epithelial cells. His renal function recovered partially over the next 4 weeks with a most recent recorded GFR of 20 and dialysis was withdrawn. He was listed pre-emptively for a kidney transplant.

Results:

Conclusions: We posit that the TAH-induced hemolysis and subsequent hemosiderosis contributed to the renal dysfunction seen in this patient. This pre-transplant injury could predispose OHT patients to further acute kidney injury in the setting of hemodynamic peri-operative insults and calcineurin inhibitor therapy. We propose that

assessment of renal histology might shed further light on the etiopathogenesis of renal failure and to assess the potential for renal recovery in patients with artificial heart devices and/or heart transplant.

FR-PO011

A Stitch in Time Saves Nine: Renal Infarction Secondary to Forgotten Prophylaxis Muhannad Leghrouz, Volodymyr Chornyy, Abhilash Koratala. *University of Florida, Gainesville, FL.*

Background: Antibiotic prophylaxis against bacterial endocarditis is indicated prior to invasive procedures in patients with certain high-risk cardiac conditions and thorough history needs to be elicited prior to performing such procedures. We present a case of spleno-renal infarction secondary to septic emboli in a patient with prosthetic aortic valve who underwent a dental procedure without endocarditis prophylaxis.

Methods: A 42-year-old white man with history of bioprosthetic aortic valve presented with intermittent fevers for a week and bilateral flank pain for 2 days. He saw a dentist 2 weeks ago for toothache and underwent a dental procedure involving manipulation of gingival tissue. Exam was significant for systolic murmur in the aortic area and tenderness in bilateral flanks. Serum LDH was elevated. A CT scan of the abdomen with contrast demonstrated areas of non-enhancement involving more than 50% of the right kidney predominantly involving the lower pole and also most of the spleen consistent with renal and splenic infarction [Figure 1a]. Interestingly, the patient was noted to have an accessory right renal artery providing flow to the upper part and probably accounts for relative sparing of this portion of the kidney [Figure 1b]. Subsequently, patient's blood cultures grew Streptococcus mitis and oralis; trans-esophageal echo revealed infective endocarditis, which supports the diagnosis of renal and splenic infarction from septic emboli. Patient improved with antibiotic therapy and renal function remained stable.

Results:

Conclusions: The learning point from our case is that thorough history taking before invasive procedures might prevent potentially life-threatening complications. Our patient had prosthetic valve, and appropriate antibiotic prophylaxis prior to the dental procedure could have evaded the complications he developed.

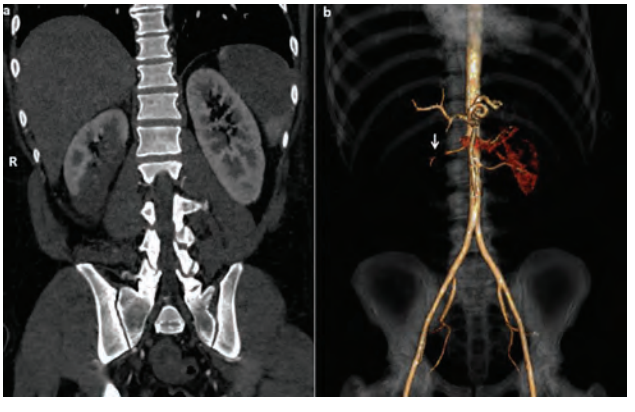

Figure 1a and 1b

FR-PO012

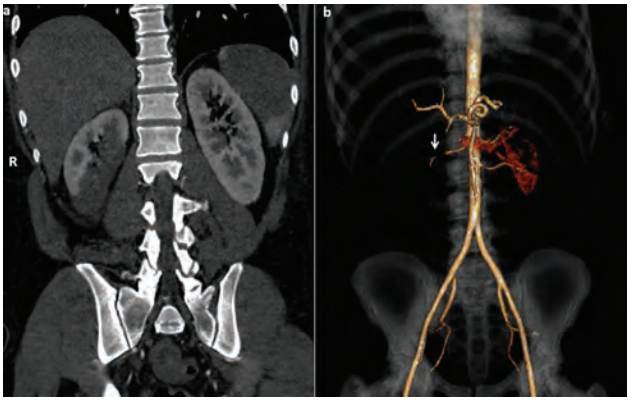
Idiopathic Renal Infarction Volodymyr Chornyy, Abhilash Koratala. *University of Florida, Gainesville, FL.*

Background: Renal infarction is a rare condition that typically presents with back pain, flank or abdominal pain, hematuria and laboratory abnormalities such as leukocytosis, high CRP and elevated LDH. Most common causes of renal infarction are cardiac conditions such as atrial fibrillation, ischemic or valvular heart disease followed by other etiologies including hypercoagulable states and renal artery dissection. Interestingly no cause can be found in about a third of patient. Herein, we present a case of idiopathic renal infarction, which presented without the classic laboratory abnormalities.

Methods: A 42-year-old man with a history of hypertension has presented with nausea and abdominal pain for 2 days. Approximately 6 months prior to presentation, he was diagnosed with deep venous thrombosis of the right leg and was treated with warfarin for 3 months. Notably, he had similar pain at that time but of lesser intensity and no abdominal imaging was done. He was afebrile and urinalysis was negative for blood or WBC. Serum creatinine was 0.7 mg/dL and LDH, CRP normal. CT scan of the abdomen without contrast showed possible bilateral renal infarcts. MRA of the abdomen was performed which showed subacute bilateral focal infarcts in both the kidneys with a new wedge-shaped infarct in the right kidney (Figure 1A). Aorta and branch vessels demonstrated normal vascular enhancement without evidence for wall thickness, aneurysm or stenosis (Figure 1B). EKG showed sinus rhythm and telemetry monitoring during his inpatient stay did not show any arrhythmia. ANA, ANCA, viral hepatitis panel, HIV test were negative. Hypercoagulability work up was essentially negative. He was discharged on oral anti-coagulation.

Results:

Conclusions: Our case emphasizes the fact that high index of suspicion is required to diagnose renal infarction in patients presenting with abdominal pain. Early recognition is important because it may have long-term implications on kidney health.



FR-PO013

Acute Spontaneous Bilateral Renal Vein Thrombosis in a Healthy Young Woman Yuzana K. Zaw, Mira T. Keddis. *Mayo Clinic, Chandler, AZ.*

Background: Introduction: Acute spontaneous bilateral renal vein thrombosis in native kidneys is extremely rare. We report the first case of acute spontaneous bilateral renal vein thrombosis in a healthy young woman.

Methods: Case Description: A 26 year old Caucasian female non-smoker presented to Mayo Clinic with a chief complaint of 24hr history of acute left flank pain. She has asthma, dyslipidemia and polycystic ovarian syndrome for which she was on oral contraceptives, Azurette for 9 years and then switched to Ashlyna 4 months ago. She experienced dyspnea two weeks before which was initially attributed to her underlying asthma. CT scan of abdomen and pelvis showed acute bilateral renal vein thrombosis with extension of thrombus to involve a long segment of IVC with associated segmental ischemia to lower pole of right kidney. CT chest showed bilateral acute pulmonary emboli. She had transient microscopic hematuria, low grade proteinuria (2grams) and acute kidney injury with serum creatinine of 1.3 mg/dL from baseline 1 mg/dL. She was initiated on intravenous Heparin drip and transitioned to Apixaban therapy. Hypercoagulable workup was negative. She had Minera intrauterine contraceptive device placed during admission and she was advised not to use estrogen containing contraception or supplements in the future due to her history of massive thrombosis while taking oral contraceptives.

Results:

Conclusions: Discussion: We report the first case of spontaneous bilateral renal vein thrombosis (RVT) and acute bilateral pulmonary emboli in an otherwise healthy young woman with long term contraceptive use. This case illustrates the importance of high clinical suspicion for RVT in the differential diagnosis of acute flank pain particularly, in patients with oral contraceptive use. Early recognition and prompt treatment is the corner stone of management.

FR-PO014

Managing Bilateral Renal Artery Stenosis (RAS) Franklin Lam,[2] Rafia I. Chaudhry,[2] Loay H. Salman,[1] Mauricio Monrroy.[2] *[1]Albany Medical College, Albany, NY; [2]None, Providence, RI.*

Background: Renal artery stenosis (RAS) accounts for 2-4% cases of HTN in the US. Etiology of RAS includes age related atherosclerosis, and fibromuscular dysplasia in young females.

Methods: 79-year-old Caucasian female, with PMHx of well controlled HTN, HLD, DM 2 and CKD (baseline Cr 1.7 mg/dL) presented with HTNsive urgency (BP 220/90 mm Hg), AKI (Cr 2 mg/dL), pulmonary edema and severe LE edema. Cr notably worsened over 6 months. Abdominal CTA revealed severe bilateral RAS. Renal artery stenting was held due to AKI with Cr rising to 3 mg/dL. After prolonged hospitalization, pt was discharged on medical therapy (Bumetanide, Doxazosin, Clonidine, Metoprolol, and Nifedipine). Cr remained elevated at 3.1 mg/dL on follow-up. Pt underwent left renal artery stenting at this time. Right renal artery was not amenable to stenting due to complete occlusion. Renal function improved, Cr stabilized at 1.4 mg/dL at five months later. BP and volume status well controlled.

Results:

Conclusions: RAS results in decreased renal perfusion and activation of renin-angiotensin-aldosterone system (RAAS), resulting in systemic vasoconstriction, Na retention and HTN. Significant reduction of renal blood flow occurs at greater than 70% narrowing of the artery. As the stenosis worsens global renal ischemia leads to shrinking of the affected kidney, and AKI or CKD. While medical therapy is initially indicated, failure of medical therapy i.e. worsening renal function, poorly-controlled BP, recurrent pulmonary edema and hypervolemia are indications for revascularization that is performed with percutaneous transluminal renal angioplasty (PRTA). Despite multiple studies showing the effectiveness of medical therapy, there is still a role for targeted endovascular therapy in cases of RAS resistant to conventional therapy.

FR-PO015

Pseudo-AKI Due to "Reverse Autodialysis": A Case of Spontaneous Rupture of the Urinary Bladder Connor Deal, Xixi Zhao, Casey N. Gashti, Stephen M. Korbet. *Rush University Medical Center, Chicago, IL.*

Background: Spontaneous rupture of the urinary bladder (SRUB) is rare and can appear to present as AKI. This "Pseudo" AKI results from reabsorption of Cr and urea across the peritoneal membrane, referred to as "reverse autodialysis". We describe a case of SRUB following an alcohol binge.

Methods: A 46 yo WM p/w abdominal distention, anuria and AKI following a 2-day alcohol binge. On exam his abdomen was distended with urgency upon suprapubic palpation. Labs: BUN- 63 mg/dl, SCr- 6.4 mg/dl and SAlb-4.4 g/dl, LFTs were nml. A non-con abd CT showed large "ascites" and no urinary obstruction. Paracentesis yielded 5L of clear fluid with a Cr level elevated at 27 mg/dl indicating the presence of urine in the peritoneal cavity. A Foley catheter was placed with 12L of UOP over 1-hour. CT cystography demonstrated extravasation of contrast into the peritoneal space(Fig 1). At laparoscopy a 1cm defect at the superior dome of the bladder was repaired. Renal function normalized within two days.

Results:

Conclusions: SRUB in the setting of alcohol intoxication is thought to be due to altered sensorium and decreased urge to urinate. The volume of ingested alcohol and its diuretic effect further increase bladder filling. The pt's elevation in BUN and Cr are the result of reabsorption of urine across the peritoneal membrane ("reverse autodialysis"). This gives the appearance of AKI when in fact GFR is normal. The rarity of SRUB as well as the nonspecific presenting symptoms of abdominal distention with ascites and AKI presents a diagnostic challenge. Analysis of the ascitic fluid for Cr to establish a urine leak is a critical diagnostic step. Treatment is immediate surgical repair of the bladder with good prognosis.

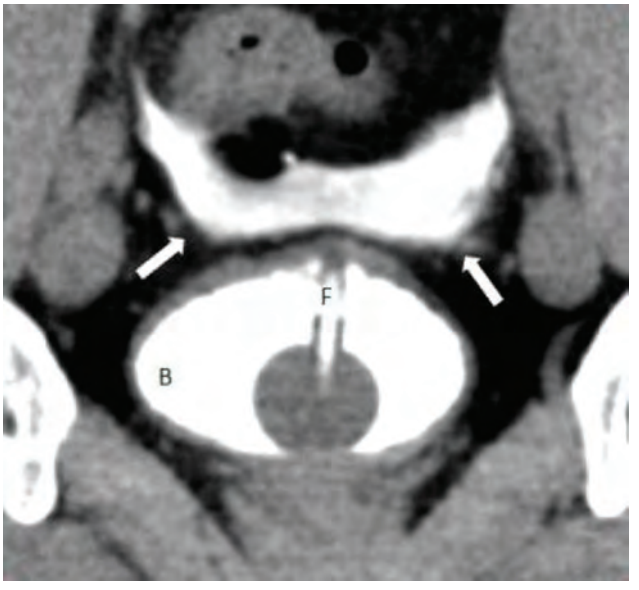


Fig 1. Foley catheter (F) penetration through the bladder (B) wall with contrast extravasation in the peritoneal cavity (white arrows).

FR-PO016

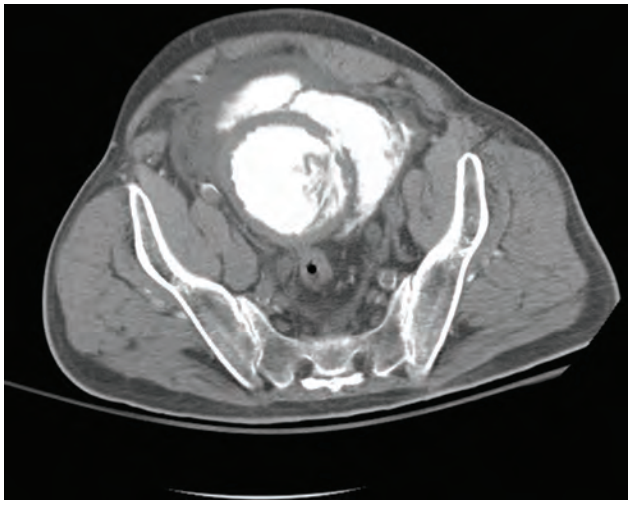
AKI Due to Bladder Rupture After a Fall Brad Long, Josephine Abraham. *University of Utah, Salt Lake City, UT.*

Background: Urinary bladder rupture is usually associated with high impact trauma and is rarely seen in milder trauma. We present a case in which a patient sustained a ground level fall leading to bladder rupture and acute kidney injury.

Methods: A 68 year old male with CKD stage III due to diabetic nephropathy with baseline creatinine of 2.5-2.9mg/dL presented to the emergency department after falling onto his walker after having cocktails with friends. The fall resulted in brief loss of consciousness and right wrist injury. On presentation he had exquisitely tender abdomen and nausea and emesis. Foley catheter was placed resulting in drainage of gross hematuria. Initial labs showed acute kidney injury with creatinine of 6.3mg/dL, serum potassium 7.2meq/L, and serum bicarbonate of 16mmol/L. He had no elevation in anion gap or serum lactate. The hyperkalemia and acidosis were not improved with boluses of IV sodium bicarbonate and furosemide. CT abdomen/pelvis revealed extraperitoneal bladder rupture that was further characterized on CT cystography.

Results: The patient was taken emergently to the operating room emergently by the consulting urology service for exploratory laparotomy and repair of the bladder. He did require a single treatment of hemodialysis for hyperkalemia. Following repair of the bladder, his renal function rapidly returned to baseline and the hyperkalemia and metabolic acidosis resolved.

Conclusions: Traumatic bladder injury resulting in obstructive uropathy is a cause of AKI that should be excluded in patients suffering even mild trauma. A full bladder is more susceptible to rupture than an empty bladder. In this setting, a low-impact event can produce dramatic internal injury. CT cystography provides accurate and rapid identification of bladder injuries. Prompt surgical management is crucial.



CT cystogram demonstrating extraperitoneal bladder rupture

FR-PO017

Wunderlich Syndrome Bilal Ahmed, Muhammad Afzal, Krishna M. Baradhi. *University of Oklahoma, Tulsa, OK.*

Background: Wunderlich syndrome is spontaneous, nontraumatic renal hematoma confined to perirenal and subcapsular space and is often due to underlying renal pathology. We herein present a rare case of wunderlich syndrome secondary to acute pyelonephritis.

Methods: 55-year-old woman presented with fever, acute abdominal pain, nausea, vomiting and dizziness. Examination was pertinent for orthostatic hypotension and mild right flank tenderness. Initial labs showed acute kidney injury with creatinine of 4.8 mg/dl and Bun of 50 mg /dl along with anemia and leukocytosis. Urine sediment showed muddy-brown granular casts as well as pyuria with bacteriuria. She was diagnosed with acute pyelonephritis and acute tubular necrosis, which gradually improved with antibiotics and fluid resuscitation. However CT scan revealed a large right subcapsular perinephric hematoma concerning for renal cancer. A follow up contrast enhanced MRI, a week after her renal function improved showed much smaller and a more organized evolving right subcapsular renal hematoma making a diagnosis of wunderlich syndrome, which is indeed a rare complication of pyelonephritis. Patient was managed conservatively with eventual resolution of hematoma.

Results:

Conclusions: Spontaneous perinephric hematoma (SPH) also called wunderlich syndrome, first described by wunderlich in 1856, is characterized by lenk's triad of abdominal pain, flank mass and hypovolemic shock. Most common etiologies are renal cell carcinoma, angiomyolipoma and vascular diseases. Amongst the rare causes include infectious and inflammatory renal diseases. Pyelonephritis complicating SPH is exceedingly rare and should be considered with intractable symptoms despite antibiotics or concurrent anemia without identified cause. Etiology and clinical severity dictates treatment, varying from close monitoring to nephrectomy. SPH requires high index of suspicion and careful investigation to rule out renal tumors and vascular disorders

FR-PO018

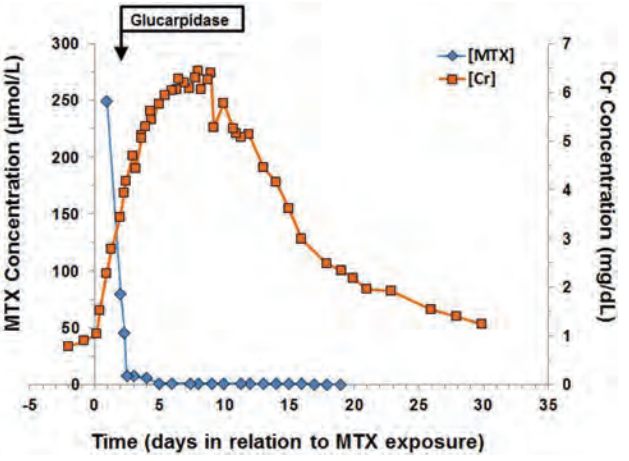
Use of Glucarpidase in AKI from Methotrexate Toxicity and Delayed Methotrexate Clearance from Levetiracetam Jacob Stevens, Andrew S. Bomback. *Columbia University, New York, NY.*

Background: Methotrexate (MTX) is the backbone of many chemotherapeutic regimens, and the management of subsequent toxicity from delayed elimination is challenging. We describe a case of MTX toxicity and delayed MTX elimination and demonstrate the successful use of glucarpidase, a recombinant bacterial enzyme carboxypeptidease G2 that rapidly metabolizes MTX into glutamate and the inactive 2,4-diamino-N-methylpteroic acid.

Methods: A 67-year-old woman with hypothyroidism and CKD-3 presented with a 2-week history of progressive right hemiparesis. A R-thalamic lesion with vasogenic edema was found on imaging and dexamethasone and levetiracetam were started. A brain biopsy showed diffuse large B-cell lymphoma and temozolomide 150mg/m2, rituximab 500mg/m2, and high dose MTX (4271mg/m2 adjusted as a ~50% reduction based on a 24h CrCl of 47mL/min) were initiated, with leucovorin (LV) rescue 50mg q6h initiated at 24h. She developed delayed early MTX elimination and acute kidney injury (AKI) attributed to MTX crystal nephropathy despite urinary alkalinization (urine pH 8.0-9.0). She was supported with LV and isotonic bicarbonate with furosemide; despite these measures her MTX level remained elevated at 80μmol/L at 48h and a single dose of glucarpidase (3600units, 50units/kg) was given 53h after MTX exposure (LV held for 2h before and after) resulting in a rapid and precipitous fall in her MTX levels. She developed a mild transaminitis but no mucositis or severe myelosuppression. Her Cr peaked 10 days after MTX exposure, and returned to baseline before discharge.

Results:

Conclusions: This case of delayed early MTX elimination and AKI illustrates the importance of dose adjustment in the setting of co-administration of MTX and levetiracetam, which has been reported to delay MTX clearance, and highlights the successful use of glucarpidase for rapid metabolism of MTX in challenging cases when levels remain toxic despite LV and IVF supportive management.



FR-PO019

Everolimus-Associated Acute Tubular Necrosis Nupur N. Uppal,[1] Rimda Wanchoo,[1] James M. Pullman,[3] Anna T. Levy,[1] Kenar D. Jhaveri.[2] *[1]Hofstra Northwell School of Medicine, Great Neck, NY; [2]Hofstra Northwell School of Medicine- Northwell health system, Great neck, NY; [3]Montefiore Medical Center, Bronx, NY.*

Background: Everolimus is a mTOR inhibitor used in treatment of renal cell cancer (RCC). Acute kidney injury (AKI) is a rarely seen adverse event of everolimus treatment. We report a case of biopsy-proven acute tubular necrosis(ATN) with everolimus treatment.

Methods: A 43 year old male with history of nephrectomy for RCC 7 months prior to admission presented with AKI and a serum creatinine(Scr) of 3.7mg/dl (baseline of 1.2mg/dl). He had begun everolimus treatment for metastatic RCC to the liver 4 weeks prior to admission and also received radiation. On admission his urinalysis revealed 150 mg/dl/day protein, granular casts, and moderate blood (10-15 RBCS and 20-25 WBCs). ANA was 1:360 but all other serologies were negative. A renal sonogram with Doppler ruled out hydronephrosis and renal vein thrombosis. When sCr rose to 7.5mg/dl, hemodialysis was initiated. A biopsy of the solitary kidney showed toxic ATN with vacuolization, minimal interstitial fibrosis and tubular atrophy, all likely related to everolimus treatment. There was no glomerular disease. He required dialysis for 6 weeks and his ATN recovered and his most recent Scr is 1.4mg/dl, supporting the pathology diagnosis of ATN. A pulmonary embolism requiring anticoagulation was the only complication. He is being considered for treatment with a tyrosine kinase inhibitor for his metastatic RCC.

Results:

Conclusions: We describe the second published case of ATN secondary to everolimus treatment. This toxic kidney injury from anti-neoplastic use of of an mTOR inhibitor is more severe than the more common form seen when used in transplants, proteinuria. A dose dependent effect might explain this difference since toxicity might be enhanced when there is a solitary kidney, as in this case. Although this risk of nephrotoxicity is still small, physicians should be aware of it and renal function should be closely monitored during everolimus therapy.

FR-PO020

Rapid Progression of CKD to ESRD after Tyrosine Kinase Inhibitor Use for Chronic Phase CML Sandhya L. Kommana,[2] Cynthia C. Nast,[1] Sharon G. Adler.[3] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]Harbor ULCA MEDICAL CENTER, Harbor City, CA; [3]Harbor-UCLA Medical Center, Torrance, CA.*

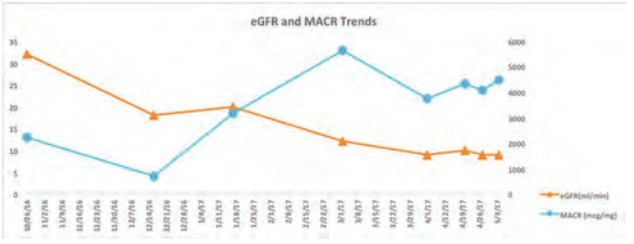
Background: Long-term tyrosine kinase inhibitor (TKI) use may cause AKI, CKD, proteinuria and/or hypertension, but case reports document that these are transient and reversibile with drug discontinuation. We report a case of rapid progression of CKD to ESRD with no improvement despite discontinuation of TKIs.

Methods: A 39-year-old woman with presumed diabetic kidney disease (DKD), eGFR 28 ml/min/1.73m^2 and UACR 700 mcg/ml, was diagnosed with chronic myelogenous leukemia (CML). She was started on Imatinib 100 mg QD with dose escalation to 400 mg QD. Her eGFR rapidly declined in 3 weeks and remained low despite dose reduction, and then discontinuation. She was changed to dasatinib but she developed shortness of breath, fatigue and pleural effusions, which prompted switching to nilotinib. During follow-up, her eGFR fell further, and nilotinib was discontinued. During this 4-month period, hypertension and proteinuria worsened. Her UACR increased to 5000 mcg/mg. A renal biopsy performed when her eGFR was 10 ml/min/1.73 m^2 showed focal moderate interstitial nephritis containing mononuclear leukocytes, neutrophils, and few eosinophils with ATN on underlying nodular diabetic glomerulosclerosis. Urine culture was negative. Arterioles showed arteriolosclerosis and thrombotic microangioapthy. Her

renal function continued to worsen despite discontinuation of TKIs and she was initiated on hemodialysis.

Results:

Conclusions: In this patient with underlying DKD, sequential impairment of eGFR, worsening proteinuria, and HTN exacerbation occurred with serial introduction of imatinib, dasatinib, and nilotinib, contributing to rapid progression to ESRD. To our knowledge, this is the first reported case in which progression of CKD to ESRD was associated with TKI use. Our case suggests that in patients with underlying advanced CKD, irreversible renal injury may occur and patients should be informed of this possibility. Further studies are warranted to understand the effects of TKIs on renal function.



FR-PO021

Tyrosine Kinase Inhibitors: Need Not Be TMA! Franklin Lam,[4] Apryl Jacobs,[5] Llewellyn A. Foulke,[5] Anum Bilal,[1] Swati Mehta,[3] Loay H. Salman,[2] Krishnakumar D. Hongalgi.[4] *[1]AMC, Albany, NY; [2]Albany Medical College, Albany, NY; [3]Icahn school of medicine at Mount Sinai, Rensselaer, NY; [4]None, Providence, RI; [5]Albany Medical Center, Albany, NY.*

Background: Multi-targeted receptor tyrosine kinase inhibitors (TKIs) are considered the standard of care for renal cell carcinoma (RCC). Few reports have raised concern for nephrotoxicity (NT) with TKIs. We report a case of biopsy-proven acute interstitial nephritis (AIN) after sunitinib use.

Methods: A 69-year-old male with stage IV left clear cell RCC began sunitinib 50 mg daily with baseline SCr of 1.0 mg/dL and BUN of 18 mg/dL. On day 18 of the sunitinib dosing cycle, the patient presented with a three-day history of hematuria, non-oliguric AKI with SCr of 2.7 mg/dL and BUN of 39 mg/dL, and other electrolytes within normal limits. Sunitinib was held upon admission but the patient subsequently required renal replacement therapy (RRT) for worsening acute renal failure (ARF). Thrombocytopenia developed, but hematuria occurred intermittently.

Results: Renal biopsy was performed on hospital day six, which confirmed AIN with extensive interstitial inflammation, frequent eosinophils and interstitial edema. No endothelial swelling, loss of endothelial fenestration, subendothelial widening, abnormal glomerular basement membrane thickness, or evidence of thrombotic microangiopathy (TMA) was seen. Renal function partially improved with prednisone and intermittent hemodialysis (HD) and he was discharged 32 days later on weekly HD.

Conclusions: AIN is a common cause of renal failure and is seen in as many as 15% of renal biopsies performed as part of the work up for ARF. Sunitinib is rarely associated with NT, although there are multiple reports of sunitinib-induced TMA. There are only few case reports of TKI-associated, biopsy-proven AIN to our knowledge to date. Our patient's AIN was consistent with sunitinib use and other causes were ruled out. This report highlights the importance of recognizing AIN as one of the differential diagnoses in a patient receiving sunitinib who develops AKI and thus vigilant renal monitoring is required during TKI use.

FR-PO022

Nephrotoxicity of Immune Checkpoint Inhibitors: MD Anderson Cancer Center's Experience Umut Selamet,[1] Ali Ziaolhagh,[2] Laila S. Lakhani,[2] Amit Lahoti,[1] Biruh Workeneh,[1] Amanda Tchakarov,[2] William F. Glass,[2] Ala Abudayyeh.[1] *[1]MD Anderson Cancer Center, Houston, TX; [2]UT Houston, Houston, TX.*

Background: Immune checkpoint (ICP) inhibitors, anti-CTLA-4 (Ipilimumab) and anti-PD-1 (Nivolumab and Pembrolizumab) have revolutionized treatment options for many types of cancers. Adverse events associated with ICP inhibitors are mainly due to uninhibited immune system causing autoimmune diseases. Literature on nephrotoxicity of these novel agents is limited. Acute tubulointerstitial nephritis (ATIN) is the most commonly described kidney injury secondary to ICP inhibitors. Few case reports also identified glomerulonephritis (GN) induced by ICP inhibitors.

Methods: We present 7 cases of biopsy proven nephrotoxicity during treatment with ICP inhibitors. Malignancies asscoiated with the cases were as following: Renal cell carcinoma (n=1), smoldering myeloma (n=2), melanoma (n=1), chondroma (n=1), bladder cancer (n=1) and lung cancer (n=1). Six out of 7 cases showed features of ATIN at kidney biopsy specimens. Several types of GNs were also observed: membranous GN, IgA nephropathy, and pauci immune GN. One patient had AA type amyloidosis. ICP inhibitors discontinued in all cases, and 5 cases were also treated with steroid. Steroid treatment resulted in either partial or full renal recovery in 4 out of 5 cases. Cases are summarized at Tables 1 and 2.

Results:

Conclusions: Early recognition of nephrotoxicity, utilization of kidney biopsy and steroid treatment for both ATIN and GN are the hallmarks of management of nephrotoxicities induced by ICP inhibitors.

Funding: Clinical Revenue Support

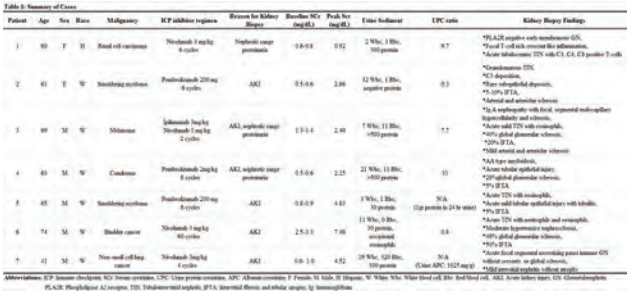


Table 2: Management of Nephrotoxicity and Renal Outcomes

Patient	Nephrotoxicity Management	Renal Outcome	Cancer/Patient Status
1	ICP inhibitor discontinued, Prednisone 80 mg/day tapered off in 6 months	Full recovery	Started on Axitinib, regression of metastasis
2	ICP inhibitor discontinued, Prednisone 80 mg/day tapered off in 5 months	Partial recovery	No progression on observation
3	ICP inhibitor discontinued, Prednisone 60 mg/day tapered off in 2 months	Full recovery followed by recurrence of AKI and nephrotic range proteinuria after prednisone tapered off. Restarted on Prednisone 60 mg/day with plans of slow taper	No evidence of disease on observation
4	ICP inhibitor discontinued	No recovery	Patient deceased due to bowel perforation and sepsis
5	ICP inhibitor discontinued	Full recovery	Progression to multiple myeloma, started on Cyclophosphamide/Bortezomib/Dexamethasone
6	ICP inhibitor discontinued, Prednisone 60 mg/day tapered off in 6 weeks due to infections	No recovery	Minimal residual disease
7	ICP inhibitor discontinued, Rituximab 1gr iv given for one dose, Prednisone 60 mg/day tapered off in 3 months	Full recovery	Patient deceased due to progression of cancer

FR-PO023

Using Steroids in Acute Interstitial Nephritis Secondary to Immune Checkpoint Inhibitors Sean Verma, Kayla Shirley, Claude Bassil. *University of South Florida, Tampa, FL.*

Background: Immune checkpoint inhibitors (ICI), both anti programmed death ligand 1 (PD-L1) and anti-cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) antibodies, are novel immunotherapies that have transformed the treatment of non-small cell lung cancer, renal cell cancer, and metastatic melanoma. Renal toxicities associated with ICI are a rare side effect that must be elucidated.

Methods: A 78 year old man with metastatic lung adenocarcinoma on PD-L1 antibody durvalumab and anti-CTLA-4 antibody tremelimumab had acute kidney injury (AKI) with creatinine of 3.2 mg/dL (baseline 1.4 mg/dL) on routine labs. He completed 4 cycles of therapy and his last cycle finished 1 month ago. Labs were notable for bicarbonate 12 meq/L and phosphorus 4.7 mg/dL. Urinalysis revealed pH 7, specific gravity 1.008, and hyaline casts. Urine eosinophils were positive and he was started on intravenous methylprednisolone at 1mg/kg BID (80 mg BID) for acute interstitial nephritis (AIN). With 4 days of methylprednisolone 80 mg BID, creatinine improved to 2.3 mg/dL. He was transitioned to 80 mg PO prednisone daily for 2 days with creatinine improving to 1.9 mg/dL. He was discharged on 60 mg prednisone daily with instructions to decrease prednisone by 10 mg every 5 days. One week later creatinine was 1.4 mg/dL and his creatinine continues to be at baseline 2 months later.

Results:

Conclusions: ICI upregulate the patient's innate anti-tumor T cell response to the tumor and have been shown to significantly decrease tumor progression in comparison to standard treatment options previously available. Renal injury has seldomly been described in cases of both CTLA-4 and PD-L1 antibodies alone or in combination, though combination increases the risk of AKI. A variety of renal injury may occur, though AIN appears most reported. Hematuria, eosinophilia, worsening or new hypertension, and nephrotic syndrome have occurred in a few cases. The pathogenesis of AIN with ICI is unclear but it is thought to be due to uncontrolled increased T regulatory cell activity in which auto-reactive T cells infiltrate the kidney and cause cytotoxic injury. PD-L1 knockout mice have shown to spontaneously develop granulomatous AIN. Treatment is based on case reports and anecdotal data with prednisone 1 mg/kg over a taper of 1-2 months. A renal biopsy can be considered in cases with unclear etiology of AKI or if steroids aren't effective.

FR-PO024

Acute Tubulointerstitial Nephritis Induced by Anti-PD-1 Antibody: An Analysis of Infiltrating Cells in the Kidney Akifumi Tabei,[1,2] Hidekazu Ikeuchi,[1] Masao Nakasatomi,[1] Toru Sakairi,[1] Yoriaki Kaneko,[1] Akito Maeshima,[1] Yoshihisa Nojima,[3] Keiju Hiromura.[1] *[1]Department of Nephrology and Rheumatology, Gunma University Graduate School of Medicine, Maebashi, Japan; [2]Department of Nephrology and Rheumatology, Gunma Prefecture Saiseikai-Maebashi Hospital, Maebashi, Japan; [3]Department of Rheumatology and Nephrology, Japan Red Cross Maebashi Hospital, Maebashi, Japan.*

Background: Nivolumab, an anti-PD-1 antibody, is one of the immune checkpoint inhibitors (ICIs), which are increasingly used as anti-cancer agents. It has been known to induce various autoimmune diseases in some patients, such as thyroiditis, pneumonitis and pancreatitis, via disruption of immune tolerance. As for kidneys, acute interstitial nephritis has recently been reported. However, the precise renal pathology has not been well understood yet.

Methods: A 57-year-old man was admitted to our department due to an acute increase of serum creatinine (SCr). He had been treated with nivolumab for stage IV lung cancer for 2 months with 2 weeks interval. On the 5th scheduled administration day, he was found to have an elevated SCr level from 0.80 mg/dL to 1.57 mg/dL. Nivolumab was stopped and he was referred to our department and admitted 8 days later. Renal biopsy was performed immediately. A marked infiltration of inflammatory and immune cells was observed in tubulointerstitial area. Immunohistochemical staining revealed that infiltrating cells were positive for CD3 (T cell), CD20 (B cell), CD68 (macrophage), CD163 (M2 macrophage), BDCA-1 (dendritic cell) and DC-SIGN (dendritic cell). Among these cells, CD68 and CD163 were predominant, followed by CD3. Proton pump inhibitor (PPI), rabeprazole, was discontinued, because previous reports showed a possible association between PPI and tubulointerstitial nephritis under the treatment of ICIs. By the treatment with 50 mg/day of prednisolone, the peaked SCr of 3.48 mg/dL retuned to baseline level within 2 months.

Results:

Conclusions: Just recently, several reports showed increased T cells accumulation in ICIs-induced acute tubulointerstitial nephritis. Our case highlights a potential role of macrophage, as well as T cells, in the pathogenesis of interstitial nephritis caused by anti-PD-1 antibody.

FR-PO025

Tubulitis in a Patient Treated with Nivolumab: Case Report and Literature Review Viral Vakil, Mark Birkenbach, Katti Woerner, Safwan Muhammad, Lihong Bu. *University of Minnesota, Minneapolis, MN.*

Background: Immune checkpoint inhibitors are monoclonal antibodies that are increasingly approved by FDA for treatment of solid organ and hematologic malignancies by enhancing anti-tumor T cell immune response. Nivolumab is a monoclonal antibody targeting programmed death-1 (PD1), an inhibitory molecule expressed on cell surface of activated effector T cells. PD1 has two ligands programmed death ligand-1 (PD-L1) and programmed death ligand-2 (PD-L2), located on antigen presenting cells and hematopoietic cells respectively. Nivolumab prevents interaction of PD1 and PD-L1, allowing T cells to continue to attack tumor cells expressing PD-L1. Immune related adverse events (IRAEs), the effect of activated cytotoxic T cells on non-neoplastic antigens, are commonly seen across various organ systems. Renal toxicities associated with PD1 inhibitors are thought to be very low (0.9%), however some reports are more frequent and as high as 29%. Kidney injury associated with PD1 inhibitors commonly manifests as acute tubulointerstitial nephritis on kidney biopsy, with a late onset ranging from 3 to 10 months. Steroids appear to be effective in treating such IRAEs. Here we describe a patient with metastatic urothelial carcinoma treated with Nivolumab who develops acute kidney injury at 6 months after initiation of treatment. A renal biopsy showed focal moderate to severe tubulitis without evident interstitial inflammation. PD-L1 immunopositivity was detected only in tubules with lymphocytic tubulitis. The patient's renal function improved to baseline after withholding Nivolumab followed by prednisone treatment.

Hemodialysis in the Management of Ifosfamide-Induced Fanconi Syndrome Priyamvada Singh,[1] Hanni Menn-Josephy,[1] Craig E. Gordon.[2] *[1]Renal, Boston University, Boston, MA; [2]None, Newton, MA.*

Background: Chemotherapy-induced nephrotoxicity is an emerging problem.

Methods: A 32-year-old man with CKD stage 4 secondary to biopsy-proven hypertension, and metastatic stage 3c mixed non-seminomatous germ-cell testicular cancer was admitted for the first of four planned chemotherapy cycles. Each cycle was comprised of five days of cisplatin/etoposide/ifosfamide and mesna. Based on case reports showing the benefit of HD in preventing ifosfamide-induced encephalopathy, HD was performed 10-12 hours following ifosfamide therapy. On day 2 of cycle #1, testing revealed urine pH of 8, 2+ glucosuria (with normal blood sugar), hypophosphatemia (1.0 mg/dL), and normal anion gap metabolic acidosis, consistent with Fanconi syndrome (FS). Baseline studies were normal the day prior to chemotherapy. FS resolved shortly after cessation of treatment but recurred during treatment for all 4 cycles. Upon completion of chemotherapy, there was no evidence of FS.

Results:

Conclusions: Ifosfamide-induced nephrotoxicity is characterized by proximal tubulopathy. Chloroacetaldehyde, a metabolite of ifosfamide, is toxic to renal tubules and depletes the antioxidant glutathione and adenosine triphosphate while inhibiting the activity of NA+/K+-ATPase. Risk factors for ifosfamide nephrotoxicity include cumulative dose, underlying CKD, and concomitant cisplatin therapy. This case highlights that FS can occur rapidly following a single dose of ifosfamide and in spite of HD performed to remove chloroacetaldehyde. Another noteworthy feature was the rapid reversibility of FS, which resolved within 3-5 days of the last dose of any chemotherapy cycle. Often, it takes few years for Ifosfamide-induced FS to resolve following completion of chemotherapy. The rapid resolution in our patient could be secondary to HD treatment and clearance of chloroacetaldehyde which is thought to be the cause of both neurotoxicity and proximal tubulopathy. This case highlights the role of HD to prevent tubular and neurotoxicity in ifosfamide-treated patients with advanced CKD.

FR-PO027

6-Mercaptopurine (6-MP)-Associated Acute Interstitial Nephritis (AIN) Brian C. Y'Barbo, John M. Childs, James D. Oliver. *Walter Reed Natl Mil Medical Center, Bethesda, MD.*

Background: AIN is an uncommon complication of Inflammatory Bowel Disease (IBD) which occurs from medications such as 5-aminosalicylate (5-ASA) or as an extra-intestinal manifestation of IBD (granulomatous interstital nephritis). We present the first reported implication of 6-MP as a cause of AIN.

Methods: A 38 yo M was admitted for cough, cytopenias, and acute kidney injury. Seven months prior to admission (PTA) he was diagnosed with ulcerative colitis and initially treated with prednisone+5-ASA. Ten weeks PTA therapy was switched to prednisone+6-MP for better symptom control. Two weeks PTA he developed cough which prompted evaluation and admission. IBD activity was mild. Labs were significant for leukopenia, anemia, and AKI (see Table). Urine sediment showed numerous WBCs

and WBC casts. Workup for infection was negative, and 6-MP metabolite levels were not supertherapeutic. Renal biopsy showed patchy interstitial inflammation with eosinophils, normal glomeruli, and no evidence of granulomas or viral cytopathic effect. 6-MP was held and sCr and cytopenias improved over a week. 15 weeks post-discharge sCr was near baseline and the patient was doing well on methotrexate+adalimumab.

Results:

Conclusions: A PUBMED search resulted in no previous reports of AIN from 6-MP. Azathioprine (AZA, the inactive prodrug of 6-MP) has known associations with AIN and delayed hypersensitivity reactions in the treatment of vasculitis. In such patients, it has been reported that 6-MP can safely be used in place of AZA. This case shows that AIN may result from 6-MP therapy as well, though it cannot be determined if this is a cross-sensitivity with AZA or a separate mechanism. In this patient, AIN did not occur with 5-ASA (a common culprit) and occurred despite concomitant treatment with steroids, which likely ameliorated the degree of injury. 6-MP should be included in the differential diagnosis of medications associated with AIN. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Departments of Army or Navy, Department of Defense, or U.S. Government.

Funding: Other U.S. Government Support

Day	11w PTA	Admit	Biopsy	Discharge	6d Post-d/c	15w Post-d/c

A Friend on Marijuana Is a Friend in Need: A Report of Acute Interstitial Nephritis (AIN) after Marijuana Use Mario J. Robles-Franceschini, Michael M. Strauss, Roberto L. Collazo-Maldonado. *Nephrology Division, Methodist Dallas Medical Center, Dallas, TX.*

Background: Acute kidney injury from synthetic Marijuana use has been reported, but until now no reports are available involving the non-synthetic variety. This is a rare case of Acute Interstitial Nephritis caused by non-synthetic Marijuana smoking.

Methods: A 20 y/o AA man with PMH of asthma, presents to the ER complaining of excruciating bilateral flank pain with associated nausea for 1 day prior to admission. His only medication was PRN albuterol inhaler. He denied OTC drugs or NSAIDS use. Three days prior to the symptoms, he smoked marijuana, but denied other illicit drugs. Physical examination was remarkable for obesity (BMI 37), hypertension 168/92mmhg and unilateral subconjunctival hemorrhage. On admission his creatinine was 1.75 mg/dL, urinalysis revealed protein 300mg/dl, RBCs 10-20/HPF, WBC's 0-5 /HPF, with no casts or eosinophils. Urine toxicology was positive for tetrahydrocannabinol. Serology studies were normal, including ANA panel, anti GBM, ANCA, ASO titers, HIV, Hepatitis B/C complements, ESR, IgG 4, SSA/B/ and ACE levels. His renal ultrasound with Doppler was normal. An abdominal CT scan showed perinephric stranding surrounding both kidneys with no stones. Initial management included blood pressure control, volume expansion and he was started empirically on IV steroids due to active sediment and worsening creatinine that peaked at 5mg/dL. Kidney biopsy was performed and showed AIN with marked interstitial lymphocytic infiltrate with eosinophils, interstitial and tubular edema, with normal glomeruli. His kidney function improved with steroids and he was discharged with a creatinine of 2.1 mg/dL.

Results:

Conclusions: Acute interstitial Nephritis from smoking non-synthetic marijuana has not been reported. The presentation of this young man with hypertension, active sediment, worsening renal function suggested possibility of Rapidly Progressive Glomerulonephritis and it prompted early treatment with steroids. The finding of AIN on the renal biopsy was crucial in establishing the association to the use of marijuana. It is important to consider AIN in the differential diagnosis of marijuana users that present with AKI, particularly in light of its increasing legalization.

FR-PO029

Azithromycin-Induced Severe Acute Interstitial Nephritis: Role of Corticosteroids Nupur N. Uppal, Nishita Parikh, Hitesh H. Shah. *Hofstra Northwell School of Medicine, Great Neck, NY.*

Background: Acute interstitial nephritis (AIN) is characterized by deterioration of renal function with inflammatory infiltration of the renal interstitium. B-lactam antibiotics, NSAIDs and proton pump inhibitors have been recognized as the leading causes of drug induced AIN, however any drug can potentially cause AIN. We present a very rare case of AIN following treatment with oral azithromycin that was successfully treated with use of corticosteroids.

Methods: 73-year-old Caucasian female with history of hyperlipidemia was sent to the hospital for evaluation of elevated serum creatinine (Scr) of 6.8 mg/dL. Patient had a normal Scr of 0.7 mg/dL, 6 months prior to this presentation. Patient was asymptomatic at the time of presentation. Patient however completed a course of oral azithromycin therapy (first time use) for upper respiratory tract infection, 5 weeks prior to her presentation. Her only home medication was rosuvastatin. Her BP was elevated at 160/75 and physical examination was unremarkable. Renal ultrasound ruled out obstructive uropathy, however showed bilateral enlarged kidneys. Urinalysis showed trace blood and 5-10 white blood cells. Spot urine total protein to creatinine ratio was elevated at 1.1. Serological work up for proteinuria was negative. Scr peaked to 7.6 mg/dL, however patient remained non-oliguric and did not require hemodialysis. A kidney biopsy was subsequently performed which revealed findings of AIN that was thought to be secondary to previous azithromycin use. Patient received intravenous pulse dose corticosteroid therapy for 3 days, followed by transition to oral prednisone taper over the following 8 weeks. AKI resolved and Scr decreased to 1.1 mg/dL, a week after completion of prednisone therapy.

Results:

Conclusions: Azithromycin is a readily available and widely used macrolide antibiotic all over the world. This drug is considered generally well tolerated. To our knowledge, only four cases of kidney biopsy proven AIN associated with azithromycin use have been reported in the literature. Although rare, physicians should be aware of this potential serious nephrotoxic effect of this agent. Our patient responded well to a prolonged course of oral corticosteroid therapy with significant improvement in renal function.

FR-PO030

Tubulointerstitial Nephritis with Uveitis Syndrome: A Case Report of a Rare Syndrome Adam W. Scott,[1,3] Matthew M. Hand,[2] Lisa Teot,[1] Deborah R. Stein.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Elliot Hospital, Manchester, NH; [3]Nephrology, Brigham & Women's/Harvard Medical School, Boston, MA.*

Background: Tubulointerstitial nephritis with uveitis (TINU) syndrome is a rare disorder characterized by acute interstitial nephritis (AIN) along with concurrent development of uveitis. First described in 1975, there have been few case reports in both the ophthalmology and nephrology literature since. The underlying pathogenesis and etiology remains poorly understood. We present a case of a young adolescent male with an antecedent Epstein-Barr virus (EBV) infection who presented with severe AIN who later developed uveitis. This case highlights the importance of considering TINU in the evaluation of patients with AIN, and provides a framework for the evaluation and follow-up of such patients.

Methods: A 13 year old previously healthy Caucasian male, diagnosed with EBV via positive heterophile antibody test 2 months prior, presented to the hospital with severe fatigue and unintentional weight loss. His examination revealed a non-toxic, pale-appearing young man with a normal blood pressure. Ophthalmologic examination was unremarkable on presentation. Initial evaluation revealed severe acute kidney injury, with a peak serum creatinine of 6.8 mg/dL. His urine sediment was significantly active, with abundant white blood cell casts. He had evidence of proximal tubular dysfunction with low-molecular weight proteinuria, renal glycosuria, and renal tubular acidosis. A renal biopsy demonstrated typical findings of AIN, with only minimal fibrosis, no vascular changes, and unremarkable immunofluorescence and electron microscopy. He was started on pulse-dose steroids, followed by oral steroids. After a prolonged steroid taper over about 3 months, his creatinine improved to a nadir of 1.0 mg/dL. Shortly after discontinuing steroids, he developed bilateral eye pain and conjunctivitis. Repeat ophthalmology evaluation revealed active uveitis. The patient was placed on topical steroid therapy, with little response, and then started back on oral steroids. His renal function remained acceptable, and his urinalysis quiescent.

Results:

Conclusions: This case highlights the importance of considering TINU in patients with AIN, and the need for ongoing monitoring for the development of uveitis following resolution of AIN, as uveitis may occur sequentially and remotely from the initial presentation. The case also implicates antecedent EBV infection as a possible etiology for TINU.

FR-PO031

Sarcoidosis Associated AKI: The Path Less Traveled Haris F. Murad, Valerie Jorge Cabrera, Mamta Shah. *Yale School of Medicine, New Haven, CT.*

Background: Mechanisms of kidney injury in sarcoidosis include interstitial nephritis with or without granuloma formation and/or abnormal calcium metabolism with nephrolithiasis and nephrocalcinosis. Calcium phosphate deposition on biopsy is uncommon and prior case reports have speculated its association with the more common calcium oxalate crystals, representing an underreported finding in sarcoid related kidney injury.

Methods: A 43 year-old Caucasian man presented with worsening wrist pain and swelling following a traumatic injury. He had noticed recent fatigue and weight loss. Further questioning revealed excessive milk and calcium carbonate intake. His examination was remarkable for a palpable tender mass on his right wrist. He was noted to have an elevated serum creatinine of 4.3mg/dL and serum calcium of 14mg/dL. Other investigations included parathyroid hormone of 9.3 pg/mL, ionized calcium of 6.02 mg/dL and 1,25-OH vitamin D (vit D) level of 112 pg/mL. Imaging of the wrist was suspicious for secondary tumoral calcinosis and computed tomography (CT) of the chest showed ground glass opacities and hilar lymphadenopathy. Ultrasound demonstrated bilateral non obstructing renal calculi. Kidney biopsy revealed non necrotizing granulomas and calcium phosphate crystals with surrounding giant cell formation. The diagnosis of sarcoidosis was established. In addition to management of hypercalcemia, he was started on oral prednisone. Serum creatinine improved to 2.2mg/dL along with normalization of 1,25-OH vitamin D and serum calcium in the following weeks.

Results:

Conclusions: Although the most common pathological lesion in renal sarcoidosis is non caseating granuloma formation, nephrocalcinosis with calcium oxalate deposition may be seen. Calcium phosphate deposition with surrounding giant cell formation is less common and has been pathologically associated with kidney injury in sarcoid. Although our patient had granulomas, the proximity of the giant cell formation to the calcium phosphate crystals suggests a localized reaction and may potentially be a significant

contributor to kidney injury. This case highlights the importance of renal biopsy in patients with sarcoidosis. Findings are important to help clarify the pathology, prognosis and guide treatment.

FR-PO032

Recurrent Acute Interstitial Nephritis Secondary to Crohn's Disease Dina Abdelwahab, Mira T. Keddis. *Mayo Clinic, Scottsdale, AZ.*

Background: Immune mediated tubulointerstitial nephritis secondary to Crohn's disease is uncommon. We report a case of recurrent episodes of acute kidney injury (AKI) due to acute interstitial nephritis (AIN) coinciding with Crohn's flare-up in an otherwise healthy man

Methods: A 37 year old male with 7 year history of Crohn's disease was found to have an increased creatinine to 1.7 mg/dL from a normal baseline of 1.3 mg/dL. He was treated with mesalamine for 18 months prior to the increase in creatinine. Kidney biopsy showed acute eosinophilic interstitial nephritis suspicious for mesalamine associated AIN. Mesalamine was discontinued and he was treated with a 6 months course of tapering dose of prednisone. His creatinine peaked as high as 2.2 mg/dl and ranged between 1.7-1.9 mg/dl during treatment. 4 months after discontinuation of prednisone, he developed a flare up of his Crohn's disease with diarrhea and hematochezia. Laboratory results showed an increase in creatinine to 2.4 mg/dl in absence of any medications. Urinalysis was performed and showed 1-3 white blood cells. Repeat kidney biopsy was performed and showed acute on chronic tubulointerstitial nephritis with eosinophils with moderate background fibrosis and tubular atrophy. The findings of acute on chronic interstitial nephritis in the context of active Crohn's flare and absence of nephrotoxic medications confirmed suspicion for Crohn's associated AIN. He was treated with prednisone for 8 weeks and started on adalimumab for treatment of his Crohn's disease.

Results:

Conclusions: This case highlights the uncommon presentation of AIN as a primary extra-intestinal complication of Crohn's disease. We hypothesize that treatment of Crohn's disease will improve renal outcome.

FR-PO033

Vancomycin: New Player in the World of Cast Nephropathy Srikanth Thiruvarudsothy,[3] Samantha Pettigrew,[4] Ryan Butzko,[3] Mary elizabeth Swift-Taylor,[7] Neeraj Sharma,[6] Aravindan V. Jeyarajasingam,[1] Sushma Munugoti,[5] Anuradha Konkesa,[2] Jennine Michaud,[1] Michelle Dallapiazza,[3] Alluru S. Reddi,[4] Surya V. Seshan.[8] *[1]None, Swedesboro, NJ; [2]Rutgers, Morrisplains, NJ; [3]Rutgers NJMS, Belleville, NJ; [4]Rutgers New Jersey Medical School, Kearny, NJ; [5]Rutgers UNIVERSITY, Montclair, NJ; [6]Rutgers University, Bloomfield, NJ; [7]Rutgers-NJMS, Newark, NJ; [8]Weill Cornell Medical Center, New York, NY.*

Background: Vancomycin associated cast nephropathy (VACN) is a rare entity that has only recently been described in literature, is an additional mechanism by which vancomycin can induce renal injury.

Methods: A 20-year-old African American man, presented with bilateral pneumonia complicated by a large loculated pleural effusion. He was treated with vancomycin, piperacillin-tazobactam, azithromycin and oseltamivir. Urinalysis showed an isolated proteinuria. His renal function worsened with an increase in creatinine from 0.9 mg/dL to 3.2 mg/dL with oliguria. Vancomycin trough at that time was 43.3 mg/L. Creatinine peaked at 10.6 mg/dL despite adequate hydration. Work-up for acute kidney injury was unrevealing. He was started on hemodialysis, and subsequently underwent a renal biopsy. The biopsy showed diffuse acute tubular injury with focal eosinophilic tubular casts containing tubular protein and nanospheric vancomycin, consistent with VACN. Patient required three sessions of hemodialysis with recovery of renal function. At a 4- month follow-up, his creatinine was 0.7 mg/dL.

Results:

Conclusions: Vancomycin is known to cause acute kidney injury due to acute tubular injury (ATI) and acute interstitial nephritis (AIN). VACN was first described by Luque et al. in Feb. 2017. They reported a patient with severe acute tubular necrosis on renal biopsy that also had proteinaceous casts with nano-to-microspherical formations that corresponded with vancomycin spectral signature. They also retrospectively reviewed biopsies on patients who had vancomycin toxicity and found similar casts. Vancomycin nanospheres are incorporated into Tamm–Horsfall protein and then cause tubular obstruction. Presence of vancomycin in the casts was confirmed by infrared spectroscopy and immunohistochemistry. Our report confirms the findings of Luque and associates, and suggests that VACN is another mechanism for vancomycin-induced nephrotoxicity.

FR-PO034

Acute Oxalate Nephropathy from Vegetable Juicing and Lower Dose Vitamin C Supplementation Youngjun Park, Daniil Shimonov, Shayan Shirazian, James Drakakis, Nobuyuki (Bill) Miyawaki. *NYU Winthrop Hospital, Mineola, NY.*

Background: High dose intravenous and oral ascorbic acid are associated with acute kidney injury (AKI) with oxalate nephropathy. We report a case of oxalate nephropathy at a lower than often described doses in combination with high oxalate juicing.

Methods: A 47-year-old male with newly diagnosed Diffuse Large B Cell Lymphoma with consistently normal creatinine of 0.8mg/dL had deferred chemotherapy and instead started kale, spinach and berry juicing with daily apricot kernels plus 2 grams/day of Vitamin C supplement. This continued for 2 months, at which point his creatinine was noted to be 5.3mg/dL on routine labs prompting an admission. Additional labs indicated calcium level of 13.3mg/dL, Vitamin D-25-OH of 75ng/mL, serum bicarbonate level of 32mEq/L and K of 3.9mEq/L. Phosphate and uric acid level from that admission is unfortunately not available. AKI with microscopic hematuria and 1-2+ proteinuria led to a kidney biopsy which revealed acute tubular injury with dilated lumina, cytoplasmic vacuolization and abundant intratubular calcium oxalate crystals. Scattered large calcium phosphate crystals were also seen. Additional workup did not reveal hydronephrosis. Without recovery, he was initiated on hemodialysis.

Results:

Conclusions: Even in the absence of known primary hyperoxaluria, AKI from oxalate nephropathy is associated with varying Vitamin C doses. Typical descriptions of oxalate nephropathy from IV ascorbic acid have referenced doses of 45 grams to as much as 224 grams per day. Oral ingestions of more than 4 grams/day consecutively over 30 days have been implicated in AKI yet high oral doses of 10 grams/day also have been documented to not induce AKI in others. This patient sustained AKI with far less Vitamin C intake than typically-described toxic doses, but the combined impact of high oxalate foods (spinach, kale, berries, kernels) along with 2 grams of daily oral Vitamin C and hypercalcemia possibly from lymphoma contributed to oxalate nephropathy. While the patient denies knowingly using significant calcium carbonate, high dose Vitamin D or other associated agents to induce milk-alkali syndrome, rather ample Vitamin D level, metabolic alkalosis and high calcium suggest its contribution to the calcium phosphate crystals noted on the biopsy as well. Extra caution may be needed on diet and modest dose supplements.

FR-PO035

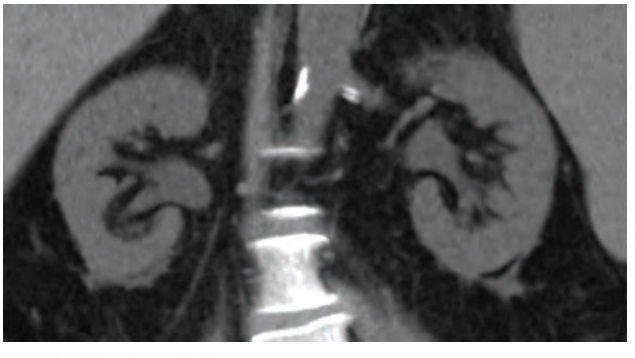
An Uncommon Presentation of Acute Uric Acid Nephropathy Anna J. Lee-Mulay,[1] Gauri Bhutani.[2] *[1]University of Wiconsin, Madison, WI; [2]University of Wisconsin, Madison, WI.*

Background: Secondary hyperuricemia from ineffective erythropoiesis can be seen in myeloproliferative disorders. Uric acid (UA) crystal precipitation may cause acute tubular injury and urinary obstruction in this rare disease group but is not commonly described in myelofibrosis (MF).

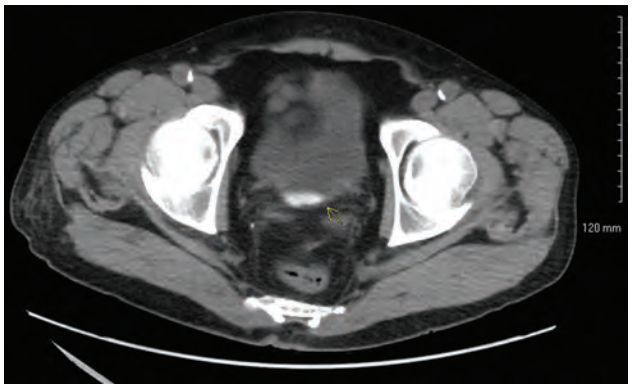
Methods: A 68-year-old male with essential thrombocythemia & secondary MF diagnosed 6 years ago, who has been on ruxolitinib for 2 years with a dose increase within the last 3 months, presented with a few hours of nausea and vomiting following a fall 1 day prior. Serum creatinine (S.Cr) was 2.71 mg/dL (baseline 1.1 mg/dL). A CT abdomen pelvis showed gravel layers within bladder & distal ureters with resultant bilateral hydroureter & pelviectesis. Serum UA was 19.4 mg/dL. Cystoscopy showed stone debris (100% UA) & bilateral ureteral stents were placed. S.Cr increased to 4.5 mg/dL over next 2 days with UA still >15 mg/dL despite intravenous hydration, urinary alkalinization & initiation of allopurinol. Rasburicase (2 doses of 3 mg IV) was started next with prompt renal recovery & normalization of UA levels. Now, 6 months later, S.Cr is 1.06 mg/dL, UA 7.1 mg/dL, on allopurinol 300 mg daily.

Results:

Conclusions: Acute UA nephropathy is only rarely described in MF, especially in secondary MF. Hyperuricemia has not been described with use of JAK2 inhibitor ruxolitinib, although it is not clear if & how much this medication contributed to the above presentation. Our case highlights that UA related renal diseases should be an important consideration in all myeloproliferative disorders. Timely intervention with rapid uric acid lowering is needed for renal recovery.



UA gravel within urinary bladder



bilateral hydronephrosis from UA debris in urinary collecting system

FR-PO036

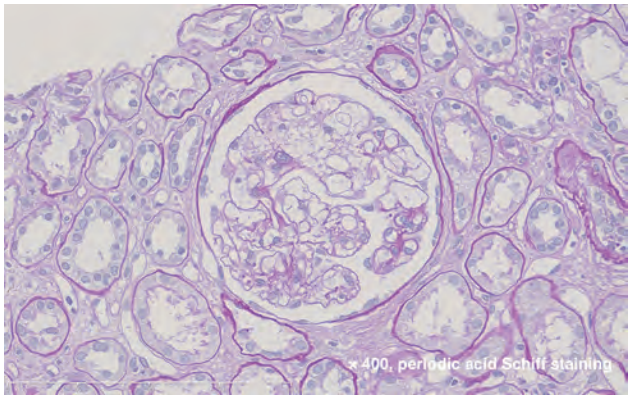
A Case of Radiation Nephropathy Presented with Delayed Massive Proteinuria and Renal Dysfunction Following Hematopoietic Stem Cell Transplantation Norisuke Shimamura,[1] Yosuke Nakagawa,[1] Chiaki Kawabata,[1] Naoto Hamano,[1] Masahiro Koizumi,[1] Go Ogura,[2] Takehiko Wada,[1] Masafumi Fukagawa.[1] *[1]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [2]Department of Pathology, Tokai University School of Medicine, Isehara, Japan.*

Background: Hematopoietic stem cell transplantation (HSCT)-associated nephropathy can progress to end stage renal disease and can also increase mortality risk. Its etiologies are often multifactorial, including medication such as calcineurin inhibitors and antineoplastic agents including molecular targeted drugs, transplantation-associated thrombotic microangiopathy, graft-versus-host disease (GVHD), and radiation. Because therapeutic approaches vary depending on the diagnoses, renal biopsy should be considered to determine the cause. Here, we report a case of radiation nephropathy with delayed massive proteinuria and renal dysfunction following HSCT.

Methods: A 33-year-old Japanese woman had been diagnosed with Philadelphia chromosome-positive acute lymphoblastic leukemia two years prior to this episode. Complete remission was achieved by cytarabine and daunorubicin followed by dasatinib, a tyrosine kinase inhibitor. She underwent allogeneic HSCT from matched unrelated donor. She had received total body irradiation and intravenous cyclophosphamide as myeloablative conditioning and methotrexate plus tacrolimus as acute GVHD prophylaxis. At one month after HSCT her serum creatinine level (sCr) was 0.9 mg/dL and her urinalysis was normal. However, her sCr elevated to 1.2 mg/dL and proteinuria developed at 4 months after HSCT. SCr did not decrease even after tacrolimus was discontinued, and proteinuria gradually got worse to 2-3 g/gCr. Renal biopsy at 15 months after HSCT demonstrated prominent mesangiolysis with formation of capillary mircroaneurysms. Under the diagnosis of radiation nephropathy, an angiotensin receptor blocker was started to mitigate proteinuria.

Results:

Conclusions: Radiation nephropathy often develops with a latent period of 6-12 months after radiation exposure. We should take radiation nephropathy into account if renal dysfunction and proteinuria exacerbate in a late phase.



FR-PO037

Focal and Segmental Glomerulosclerosis (FSGS) in Association with Carfilzomib Therapy Roshni Radhakrishna,[2] Volker Nickeleit,[1] Gerald A. Hladik.[3] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of North Carolina, Carrboro, NC; [3]University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC.*

Background: Carfilzomib is a proteasome inhibitor widely used for treatment of multiple myeloma and monoclonal gammopathies of renal significance (MGRS). Herein, we report a case of new onset FSGS in association with carfilzomib therapy.

Methods: A 63-year-old man with stage G3b chronic kidney disease secondary to biopsy proven monoclonal immunoglobulin deposition disease (MIDD) secondary to monoclonal kappa light chains developed nephrotic range proteinuria during therapy with carfilzomib and dexamethasone. He was initially diagnosed with biopsy-proven MIDD 10 years ago. He was treated with bortezomib and dexamethasone followed by melphalan/prednisone with achievement of a sustained remission over the next 10 years. Over that interval, his proteinuria ranged between 200 to 400 mg/d, decreased from 800 mg/d prior to therapy. His serum free light chain-kappa (SFLC-kappa) level was subsequently found to rise from 7 to 110 mg/dl, prompting therapy with 2 cycles of carfilzomib and dexamethasone. He had an excellent clinical response with a decline in the SFLC-kappa level to 29 mg/dl. Despite this response, he developed increased leg edema with a rise in proteinuria from 400 mg/d to 3700 mg/d (72% albumin). Urine immunoelectrophoresis showed no monoclonal spike. His serum creatinine level increased from 2 to 2.4 mg/dl. He did not have evidence of infection. A kidney biopsy showed focal and segmental glomerulosclerosis with collapsing features without evidence of light chain deposition disease. His proteinuria fell to 1.7 g/d over the next 5 months.

Results:

Conclusions: Proteasome inhibitors have had proven efficacy in relapsed/refractory multiple myeloma and MGRS. Carfilzomib is a second generation proteasome inhibitor that previously has been reported to cause thrombotic microangiopathy. The temporal onset of this lesion coincident with carfilzomib therapy raises the possibility of carfilzomib-induced FSGS. Worsening proteinuria despite improvement in SFLCs during carfilzomib therapy should raise suspicion for this lesion. This is the first reported case of carfilzomib-associated FSGS and highlights the importance of ongoing surveillance for renal toxicity of novel therapeutic agents

FR-PO038

Dysregulated Neutrophil Extracellular Traps in a Patient with Propylthiouracil-Induced Microscopic Polyangiitis Kanako Watanabe, Daigo Nakazawa, Saori Nishio, Tatsuya Atsumi. *Internal Medicine II, Hokkaido University Hospital, Sapporo, Japan.*

Background: Neutrophil extracellular traps (NETs) are one of the immune defense system, which spread out DNA fibers with histons and myeloperoxidase (MPO) after phagocytosis in order to trap and kill microbes effectively. However, when NETs are not properly regulated, they could possibly become autoantigens, which result in the production of myeloperoxidase-anti-neutrophil cytoplasmic antibodies (MPO-ANCA), developing Microscopic polyangiitis (MPA). Propylthiouracil (PTU) is an antithyroid drug, clinically known to produce MPO-ANCA and develop MPA. A recent study showed that in vitro experiment neutrophils with PTU were induced to morphologically-abnormal NETs, which were hardly degraded by DNaseI. In Rat model, dysregulated NETs led to the production of MPO-ANCA, causing pulmonary capillaritis and glomerulonephritis. In this report, we examined whether neutrophils of a patient with PTU-induced MPA show the similar characterization during NETs formation.

Methods: A 19-year-old woman who had been treated with PTU for Graves' disease showed the presence of high fever and arthritis. Increased levels of proteinuria, hematuria, and C-reactive protein were found. In immunological examination, MPO-ANCAs were detected. Computed tomography revealed pulmonary infiltrates. Based on these findings, the patient was diagnosed with PTU-induced MPA. For evaluating NETs formation, we analyzed neutrophils of this patient. The fluorescence microscopy revealed NETs formation in unstimulated neutrophils of the patient, which was more massive in phorbol myristate acetate-stimulated neutrophils. Furthermore, they were not degraded by DNaseI, which can degrade the NET-DNA. On the other hand, the healthy NETs were degraded by DNaseI.

Results:

Conclusions: This is the first case report showing that abnormal and dysregulated NETs persisted in a PTU-induced MPA patient. These results indicate that dysregulated NETs can lead to the breakdown of immunological tolerance for NETs components and result in the production of autoantibody for NETs, developing autoimmune vasculitis.

FR-PO039

A Case of Life-Threatening Pulmonary-Renal Syndrome from Hydralazine Ranadheer Dande,[1] Pravir V. Baxi,[1] Sejal K. Kalawadia,[2] Casey N. Gashti.[1] *[1]Rush University Medical Center, Chicago, IL; [2]NANI (Nephrology Associates of Northern Illinois), Blue Island, IL.*

Background: Drug-induced lupus (DIL) from hydralazine is well described but renal involvement is uncommon. Hydralazine induced vasculitis presenting with pulmonary-renal syndrome is exceedingly rare, despite the widespread use of the drug. We describe an unusual case of hydralazine-induced, ANCA+, immune complex (IC) mediated GN with pulmonary involvement that exhibits features of both DIL and vasculitis.

Methods: A 60 yo male p/w dyspnea and fatigue. He was noted to have a HgB of 5.7 g/dl, b/l pulmonary opacities on CXR, AKI and microhematuria. His meds included hydralazine. Exam was significant for respiratory distress. His SCr was 4.06 mg/dL from a nl prior bsl. UA showed 2+ protein and 3+ blood. His ANA was 1:160, p-ANCA was 1:640, anti-MPO Ab of 647 AI (>1 pos), neg anti-PR3, and nl C3+C4. Renal biopsy showed crescentic GN on LM. There was a full house pattern of IC deposition in the subendothelial and mesangial space on IF. Bronchoscopy was c/w diffuse alveolar hemorrhage (DAH). His hydralazine was discontinued. He was started on IV steroids, IV cyclophosphamide (CYC) and daily membrane based therapeutic plasma exchange (TPE). After 3 days, his respiratory status improved. On 2 month follow up, anti-MPO was 6.7 AI and SCr was 2.4 mg/dL (Graph 1). CXR showed resolution of opacities.

Results:

Conclusions: Drug induced syndromes can often be overlooked as features mimic idiopathic disease. A positive p-ANCA with exceedingly high anti-MPO titers are highly suggestive of a drug-induced vasculitis. We postulate that our pt's severe clinical manifestations are a result of hydralazine-induced ANCA vasculitis. The presence of subendothelial IC desposits on the renal biopsy also suggest coexisting DIL from hydralazine, leading to an unusual overlap syndrome. Prompt cessation of the drug is the initial step in management. In cases with severe clinical symptoms, treatment is identical to idiopathic disease with immunosuppressive therapy. Pts who present with DAH require immediate initiation of TPE due to their high risk of mortality.

FR-PO040

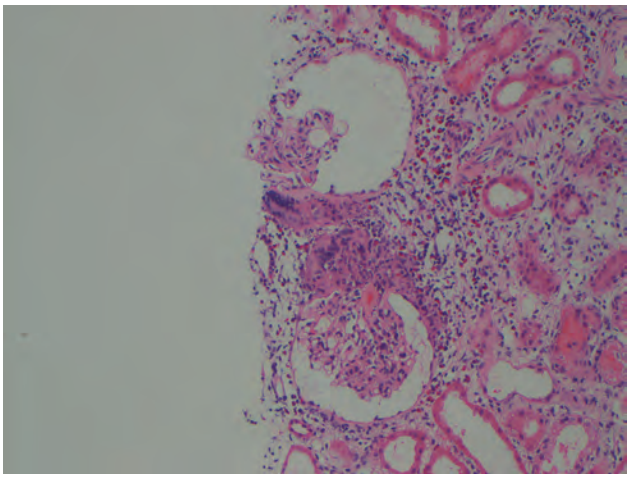
Alemtuzumab Induced Anti-Glomerular Basement Membrane Disease with Histological Evidence of Perihilar Giant Cell Vasculitis Ryan P. Gately,[4] Aye San,[2] Tegan Stevenson,[1] Sonu Nigam,[3] Jagadeesh Kurtkoti,[2] Dakshinamurthy Divi.[2] *[1]Gold Coast Hospital, Ashmore, NSW, Australia; [2]Gold Coast University Hospital, Southport, QLD, Australia; [3]Pathology Queensland, Gold Coast, QLD, NSW, Australia; [4]Nephrology, Gold Coast University Hospital, City of Gold Coast, QLD, Australia.*

Background: To our knowledge there have been three published cases of alemtuzumab induced anti-glomerular basement membrane(GBM) disease to date. Here we report a case of fulminant anti-GBM disease that was exceptional given its unusual histological features

Methods: A 34 year-old Caucasian female presented with a one-week history of malaise and painless, frank hematuria. She had a background of relapsing-remitting multiple sclerosis(RRMS) previously treated with two courses of alemtuzumab(anti-CD52 monoclonal antibody) the most recent course completed six months prior. On admission creatinine was 2.26mg/dL and imaging did not reveal any nephrolithiasis or masses. Renal biopsy showed granulomatous vasculitis in a perihilar distribution with evidence of arteriolitis and glomerulitis with giant cells(figure 1). Immunofluorescence confirmed linear IGG staining along the GBM.ANCA titers were negative however anti-GBM antibodies were markedly elevated at 855 CU(<20). Plasma exchange, methylprednisolone and cyclophosphamide failed to prevent worsening of the patient's renal function and six days after admission haemodialysis was initiated. Cyclophosphamide was ceased due to intolerable side effects however two days subsequent to this the patient developed severe hemoptysis. Chest X-ray was suggestive of pulmonary hemorrhage. Daily plasma exchange and pulse methylprednisone were reinitiated resulting in attenuation of haemoptysis without improvement in renal function. The patient remains dialysis dependent with slowly falling antibody titers and it is hoped that she will ultimately be eligible for renal transplantation

Results:

Conclusions: Anti-GBM disease is an extremely rare but catastrophic complication of alemtuzumab therapy. With increasing use of alemtuzumab in RRMS we believe it is imperative to consider this condition in those exposed to this medication with worsening renal function or hematuria



FR-PO041

Nintedanib-Induced Nephrotic Syndrome: First Case Report Reio Sekine,[6] Masataka Hasegawa,[5] Tomo Suzuki,[5] Masahiko Yazawa,[1] Daisuke Ichikawa,[3] Junki Koike,[4] Yugo Shibagaki.[2] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, St.Marianna University School of Medicine, Kawasaki, Japan; [2]Division of Nephrology and Hypertension, St Marianna University Hospital, Kawasaki, Japan; [3]St Marianna University of Medical School, Yokohama City, Japan; [4]St.Marianna University, Kawasaki, Kanagawa, Japan; [5]St.Marianna university school of medicine, Tokyo, Japan; [6]St.Marianna university school of medicine, Kawasaki, Kanagawa, Japan.*

Background: Nintedanib, a triple kinase inhibitor of platelet derived growth factor receptor, fibroblast growth factor receptor and vascular endothelial growth factor receptor (VEGF), has been used in non-small cell lung cancer and idiopathic pulmonary fibrosis offering substantial benefit. We report a very rare case of nephrotic syndrome caused by nintedanib.

Methods: A 68-year old man after partial lung resection for cancer was treated with nintedanib as the adjuvant therapy. At the initiation of nintedanib, his serum creatinine was 0.78 mg/dl and neither hematuria nor proteinuria was evident before. One week after the initiation of nintedanib, his dipstick urine showed 2+ proteinuria. Since proteinuria had persisted afterwards, he was referred to us for evaluation of heavy proteinuria in January 2017 (8 months after nintedanib initiation). On physical examination, he had developed lower extremity edema. Urinalysis showed proteinuria of 4 g/day with mild glomerular hematuria with cast. Though his serum creatinine was normal, he was diagnosed nephrotic syndrome for concomitant hypoalbuminemia. Renal biopsy at 10 months after the onset of proteinuria showed mild mesangial proliferation and widely expanded subendothelial area occupied by hyaline-like materials with some huge subendothelial deposition. Mesangiolysis and double contour were also observed focally in some glomeruli. Immunofluorescence (IF) staining showed only moderate IgM deposition in huge subendothelial depositions without any other positive staining. Electron microscopy showed electron dense deposits in subendothelial areas and mesangial areas. Foot process effacement was not noticeable. Histologic diagnosis was intracapillary deposition disease with severe endothelial injury. After renal biopsy, nintedanib was withdrawn and the patient underwent follow-up with unremarkable therapy. Proteinuria and hematuria very gradually but substantially decreased to 1.0 gram/gram creatinine.

Results:

Conclusions: To our knowledge, this is the first case report of nephrotic syndrome highly suspected to be due to nintedanib. Recently Anti-VEGF antibody therapy was often used for the various kinds of cancer. Paramesangial and subendothelial deposits caused by Anti-VEGF antibody therapy was reported and histology of our case was very similar.

FR-PO042

Can a Patient with Membranoproliferative Glomerulonephritis (MPGN) Following Anabolic Testosterone and Supplement Abuse Benefit from Glucocorticoid Treatment? Olumide O. Rowaiye,[1] Piotr Donizy,[2] Mariusz Kusztal,[1] Jozef Penar,[1] Agnieszka Halon,[2] Magdalena Krajewska,[1] Marian Klinger.[1] *[1]Nephrology and Transplantation Medicine, Wroclaw Medical University, Wroclaw, Poland; [2]Pathomorphology, Wroclaw Medical University, Wroclaw, Poland.*

Background: The use of anabolic androgenic steroids (AAS) have been associated with a number of adverse effects; however, the occurrence of MPGN is uncommon. We describe a rare case of MPGN following anabolic testosterone and supplement abuse.

Methods: a 22-yr-old man with no significant past medical history presents with high serum creatinine (3.62 mg/dl), edema and gross hematuria. He admits that 8 months prior to presentation, he started a regimen of regular intensive physical workouts and OTC supplements (7 kg/month of a product containing 60.7 g of protein and 177.8 g of complex carbs). He used i.m. injections of testosterone enanthate (250 mg every 5 days

for 3 months). Last testosterone dose was 3 months prior to presentation. On examination, he was found to have BP 150/80 mmHg and lower extremity edema. Urinalysis revealed 2+ blood, active urinary sediments. Urine protein excretion was 4.6 g/day while serum albumin was 2.8 g/dl. Serological studies were negative for ANA, anti-dsDNA, ANCA, anti-GBM, HBV, HCV and HIV. CRP was normal. Serum C3 factor was low (0.17 g/l) while C4 was normal. Ultrasound showed enlarged kidneys: right -12.9 cm, left - 13.1 cm. Renal biopsy was performed which revealed active MPGN with segmental fibrinoid necrosis in 5 glomeruli but no crescents (fig 1). Also moderate tubulo-interstitial nephritis (TIN I/II°) (fig 2) was seen. Immunohistochemistry showed moderately intense mesangial IgG deposits in most glomeruli with a few mesangial IgM deposits; C3 was negative. Patient was treated with i.v. pulse methylprednisolone and i.v. diuretics which resulted in serum creatinine level of 1.77 mg/dl and disappearance of the edema. On follow-up visit 4 weeks later, serum creatinine was 1.38 mg/dl and patient continued to further improve.

Results:

Conclusions: Patients with MPGN following AAS and supplement abuse, with features of rapidly progressive glomerulonephritis may benefit from glucocorticoid treatment.

Nephrotic Syndrome in Dasatinib-Treated Patients with Chronic Myeloid Leukemia Takeo Koshida, Hitoshi Suzuki, Masao Kihara, Chieko Nogi, Yusuke Suzuki. *Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Chronic myeloid leukemia (CML) is now a manageable disease with the tyrosine kinase inhibitors (TKI). Dasatinib, a second-generation of TKI, has proven to be effective for the long-term treatment of CML, both as initial and subsequent lines of therapy. Off-target effects of these medications can have beneficial or adverse effects on the kidney. We present a case of CML who developed nephrotic-range proteinuria after initiation on Dasatinib therapy that resolved after changing therapy to Imatinib.

Methods: A 70-year-old woman was detected leukocytosis at a medical check-up, and diagnosed with CML by bone marrow examination. Treatment with Dasatinib was initiated and was effective for CML resulted in clinical remission. After one year from the initiation of medication with Dasatinib, proteinuria was detected. Finally, she was consulted to the nephrologist and had a thorough examination. Nephrotic-range proteinuria (5.2 g/gCr) and hypoalbuminemia (2.6 g/dL) was detected and then kidney biopsy was performed. Pathological findings of kidney biopsy specimen showed edematous thickening of basement membrane, duplicated glomerular capillary wall and reticuloendothelial cells. Those pathological findings are compatible as the kidney injuries induced by Dasatinib. After switchover from Dasatinib to Imatinib, levels of proteinuria significantly decreased.

Results:

Conclusions: We present a case of nephrotic syndrome during the course of medication with Dasatinib for CML. Pathological findings indicated thrombotic microangiopathy with endothelial cell injuries and the proteinuria resolved after changing therapy from Dasatinib to Imatinib. Therefore, it is suggested that those kidney injuries was caused by Dasatinib. We should concern that off-target effects of Dasatinib can have adverse effects on the kidney.

FR-PO044

Successful Treatment of Hashimoto Encephalopathy with Therapeutic Plasma Exchange Hassan B. Attique, Arundati Rao, Lalarukh Haider, Ruchir D. Trivedi. *University of CT Health Center, West Hartford, CT.*

Background: Hashimoto's encephalopathy (HE) is a rare neuropsychiatric syndrome characterized by encephalopathy of unknown etiology associated with the high titers of antithyroid antibodies in the absence of alternative diagnoses. HE with robust clinical response to therapeutic plasma exchange (TPE) in the setting of end stage renal disease (ESRD) has not been published. We present steroid-resistant HE with reliable reduction in antithyroid peroxidase antibodies (anti-TPO), after 5 sessions of TPE along with linear improvement in clinical status.

Methods: 72 year old lady with ESRD on maintenance hemodialysis (HD) presented with altered mental status. Investigations including CT scan did not suggest central nervous system (CNS) infection, tumor or stroke. There were no signs of uremia or underdialysis as well. Further investigations revealed status epilepticus controlled with propofol infusion apart from maximal dose of three anti-epileptic agents. As part of resistant status epilepticus work up, free thyroxine was 0.52 ng/dl, thyroglobulin antibody level of 2299 IU/ml and anti-TPO antibody level was 4886 IU/ml. Her cerebrospinal fluid (CSF) anti-TPO antibody was 36.4 IU/ml and CSF protein of 50 mg/dl. This led to diagnosis of HE and treatment with pulse dose IV Methylprednisone 500mg every day was initiated for five days. She remained clinically refractory for which 1.5 plasma volume TPE was initiated using 5% albumin as replacement fluid on alternate days in an attempt to remove detectable antibodies and provide immunomodulation. She continued to receive daily HD to optimize fluid electrolyte status during entire course. Clinical condition improved with reduction in anti-TPO antibody. She was continued on maintenance steroids and rituximab.

Results:

Conclusions: HE is presumably autoimmune in origin. Proposed etiology includes autoimmune reaction between antibodies and cerebral vascular and brain cells and perivascular lymphocytic inflammation. Available literature is unclear about pathogenic role of antithyroid antibodies. Our case did not improve with steroid but showed remarkable clinical improvement with TPE. This suggests possible immunomodulatory role of TPE in select case of acute HE. Our case is in line with considerable variance that exists in ESRD and non-ESRD population. ESRD may represent a distinct subgroup in which HE may respond favourably to TPE.

FR-PO045

Denosumab: Is It Safe to Use in CKD? Eimear Mckenna,[1] Girish H. Shivashankar,[3,1] Francis Mccarroll.[2] *[1]Altnagelvin Area Hospital, Coleraine, United Kingdom; [2]Western Health and Social Care Trust, Derry, United Kingdom; [3]Western Health and social care Trust, Londonderry, United Kingdom.*

Background: Denosumab is a monoclonal antibody directed against receptor activator of RANK ligand used to treat osteoporosis. It has been promoted as safe to use in Chronic Kidney Disease (CKD) as it does not appear to accumulate in kidney failure and because of the experience in a small number of patients with CKD stages 3 and 4 in RCTs. There is no evidence for use in CKD stage 5. Published case reports suggest patients with severe CKD are at higher risk of developing hypocalcemia following Denosumab which may be due to hyperparathyroidism and vitamin D deficiency. In this case series we have examined the incidence of hypocalcemia following Denosumab to identify risk factors for hypocalcemia.

Methods: Retrospective data was collected using an electronic patient database on patients with CKD stages 3-5 attending our service who received Denosumab in the last 5 years. We examined Corrected calcium levels prior to and after each dose, Vitamin D and Parathormone (PTH) levels prior to each dose.

Results: 14 patients were identified; 9 had a functioning renal transplant and 1 patient was on hemodialysis. 4 patients were male and 10 female. Mean duration of treatment was 2.2 years. Average eGFR was 27 ml/min/1.73m2. Mean patient age was 60 years. Mean BMI was 25. 11 patients were on oral steroids. The average calcium prior to dosing was 2.35 mmol/l, falling to 1.98mmol/l after dosing. 9 patients achieved their lowest calcium at 1 week, 2 at 4 weeks and 3 at 8 weeks. Average PTH level prior to dosing was 153ng/l and after was 888ng/l. 5 patients developed severe hypocalcemia (corrected calcium less than1.9mmol/l), the average prior calcium in this group was 2.39mmol/l, falling to 1.77mmol/l. The average prior PTH was 206ng/l, rising to 1171ng/l. Four patients did not have Vitamin D status checked before dosing.

Conclusions: Denosumab will cause a small but not clinically significant reduction in serum Calcium in most patients with CKD. Severe hypocalcaemia can result if Vitamin D levels are unknown or in higher PTH levels. eGFR does not seem to correlate with the risk of hypocalcaemia. Biochemical abnormalities associated with CKD should be corrected, specifically, calcium, phosphate, PTH and vitamin D. Densoumab is the preferred treatment in CKD 4/5 however its use should be avoided in severe hyperparathyroidism and vitamin D deficiency.

FR-PO046

Native BK Nephropathy: A Case Series Ankur Shah,[1] Matthew Palmer,[2] Jonathan J. Hogan,[1] Deirdre L. Sawinski.[1] *[1]Division of Nephrology, University of Pennsylvania, Philadelphia, PA; [2]Pathology, University of Pennsylvania, Philadelphia, PA.*

Background: BK Polyoma Virus is highly seroprevalent but rarely pathologic in humans. Genitourinary BK disease is most commonly seen after kidney transplantation. Here we present two cases of native kidney BK nephropathy.

Methods: The first patient was a 70 yo man with ischemic cardiomyopathy s/p OHT in 2011 and was on tacrolimus, mycophenolate mofetil, and prednisone maintenance immunosuppression. His pre-transplant SCr was 1.5-1.7 mg/dL which remained stable after OHT. In 2013 he experienced a rapid rise in SCr over 5 months to 3.8 mg/dL. His urinalysis was negative for blood and albumin, microscopy showed no cells, and UProt:Cr ratio was 200 mg/g. A kidney biopsy showed tubular epithelial cells with focal glassy nuclear inclusions, and positive nuclear staining for SV40 and Pab597. Serum BK PCR was positive (296075 copies/ml). MMF was stopped. His serum BK viral load decreased and SCr stabilized at 3.5 for approximately 3 years before beginning to rise again and his progressing to ESRD. The second patient was a 34 yo man who was treated for non-Hodgkin's lymphoma at age 18 with chemotherapy (CHOP regimen). He was hospitalized for weakness, diarrhea and volume depletion and found to have AKI (Cr 4.0 mg/dL, baseline 1.2 mg/dL) and transaminitis (AST 134, ALT 61 IU/L) Urinalysis showed 500+ mg/dl protein and small blood with 1-2 rbc/hpf on microscopy and UProt:Cr was 13 g/g. A kidney biopsy revealed tubular epithelial cells with widespread degenerative and regenerative epithelial changes, frequent epithelial mitoses and intranuclear inclusions. IHC staining for polyoma virus showed positive nuclear staining in tubular epithelial cells. He was subsequently diagnosed with hemophagocytic syndrome and died of multi-organ system failure.

Results:

Conclusions: BK Virus infection has long been described as a cause of renal disease after renal transplantation but has been described in 41 cases to date in non-kidney transplant patients. These patients included HIV, bone marrow transplant, heart transplant, and other solid organ transplant recipients. BK nephropathy in the native kidney should be considered as a cause of renal injury in immunocompromised patients.

FR-PO047

Hello, Goodbye Proteinuria Jeremy J. Sorkin,[4] Patrick H. Nachman,[5] Vimal K. Derebail,[2] Roshni Radhakrishna,[4] Volker Nickeleit,[1] Alexei V. Mikhailov.[3] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University North Carolina at Chapel Hill, Chapel Hill, NC; [3]University of North Carolina, Chapel Hill, NC; [4]University of North Carolina, Chapel Hill, NC; [5]University of North Carolina School of Medicine, Chapel Hill, NC.*

Background: Tyrosine kinase inhibitors (TKIs) have been associated with proteinuria and even overt nephrotic syndrome with variable renal histopathology (thrombotic microangiopathy (TMA), FSGS, or minimal change disease (MCD)). These agents have been thought to indirectly inhibit vascular endothelial growth factor (VEGF) receptors on glomerular endothelial cells. Sorafenib has been reported to cause proteinuria in several cases and discontinuation may result in resolution of proteinuria, although typically over several months. We present a case of severe nephrotic syndrome after starting sorafenib in a patient with a history of graft-versus-host disease (GVHD) whose history suggested several potential etiologies.

Methods: A 61-year-old man was evaluated for acute onset severe edema. He had acute myeloid leukemia (AML) and had received allogeneic-stem cell transplantation from his sister, complicated by steroid-induced diabetes and prior GVHD. Immunosuppression included tacrolimus and daily prednisone. He was started on sorafenib 400mg daily three months prior to admission. He was found to have a serum albumin to 2.1 mg/dl and new nephrotic range proteinuria with urine albumin/creatinine ratio (UACR) 9.0g/g. Baseline serum creatinine was <1mg/dl. Hgb and platelets were at baseline. Tacrolimus troughs were <2ng/ml. Bone marrow biopsy was negative for active GVHD. Renal biopsy was pursued to differentiate between GVHD-associated immune complex-mediated disease versus proteinuria related to VEGF inhibition by sorafenib. Pathology revealed a podocytopathy consistent with MCD and arteriolopathy indicative of early calcineurin inhibitor toxicity. Sorafenib was discontinued and no additional corticosteroids were administered. After two weeks, the patient had complete resolution of proteinuria, and increase in serum albumin to 2.9 mg/dl.

Results:

Conclusions: TKIs can lead to proteinuria, overt nephrotic syndrome, and TMA. In this case, no clinical signs suggestive of TMA were present and pathology showed only MCD. Discontinuation of sorafenib led to surprisingly fast resolution of nephrotic syndrome, more rapid than typically reported. This case highlights the variable etiologies and timing to proteinuria resolution related to nephrotic syndrome and TKIs.

FR-PO048

Idiopathic Diffuse Global Hypertrophic Podocytopathy without Proteinuria with AKI in a Patient with a Solitary Kidney Jaime A. Baynes-Fields,[1] Sandeep Aggarwal,[2] Myriam C. Vela-Ortiz.[1] *[1]Drexel University, Philadelphia, PA; [2]Drexel University College of Medicine, Philadelphia, PA.*

Background: Podocytopathies in adults usually present as significant proteinuria but can be associated with AKI, especially in elderly patients. We present a case with AKI without proteinuria with predominant finding of diffuse podocytopathy on renal biopsy.

Methods: A 35 year old black male with history of Wilms tumor and left nephrectomy (age 2 years) presented with 2 day history of progressive anasarca, and muscle soreness. Patient denied arthralgia, upper respiratory infections, rashes, joint pain, or new prescription medications. **Pertinent initial physical examination:** blood pressure 140/78 mmHg, HR 106 per minute and generalized anasarca, no lymphadenopathy appreciated, and otherwise normal examination. **Laboratory workup:** serum creatinine (cr) 6.28mg/dl, with baseline cr 1.4 mg/dL. CPK 350 IU/L. Albumin 2.6g/dL. Paraproteinemia workup, rheumatological serologies, HIV, and Hepatitis panel were negative. Urine drug screen was positive for opiates and THC. Urinalysis specific gravity 1.019, negative for protein and blood. Urine protein/cr ratio 0.12mg/g of cr. **Imaging:** renal ultrasound, with enlarged right solitary kidney (17.9cm), otherwise normal. Chest xray was normal. Renal biopsy was performed with; **light microscopy:** diffuse global glomerulomegaly with severe glomeruli hyper cellularity without inflammatory cells, capillary lumens and glomerular space were globally obliterated without crescents. There was no glomerular sclerosis seen. No evidence of tubulitis, interstitial nephritis or vasculitis/capillaritis. Proximal tubular cells showed luminal obliteration with occasional mitotic bodies. **Electron microscopy**: diffuse global podocyte hypertrophy with >80% foot process effacement and microvillus changes, proximal tubular showed protein reabsorption bodies, no immune complexes were identified. **Immunofluorescence:** no immune deposits and negative parvovirus. Given predominant podocytopathy with otherwise preserved renal histology, patient was treated with total 3g IV methylprednisolone and transitioned to oral prednisone taper with improvement in serum creatinine.

Results:

Conclusions: In the emerging field of biomarkers, our case emphasizes the role of renal biopsy in diagnosing the otherwise unidentifiable causes of AKI. An atypical presentation of podocytopathy with non-proteinuric AKI was revealed by biopsy in this case.

FR-PO049

Blast from the Past: Methysergide Induced Retroperitoneal Fibrosis Ayushi Chauhan,[2] Shehryar H. Ashraf,[2] Sankar N. Niranjan.[1] *[1]Greater Hartford Nephrology, Bloomfield, CT; [2]University of Connecticut, Hartford, CT.*

Background: Methysergide induced retroperitoneal fibrosis (RPF) lapsed into relative obscurity at culmination of the ergot era in migraine prophylaxis. Consequently, our collective vigilance has diminished regarding this entity. We describe an uncommon case of methysergide induced RPF causing acute kidney injury (AKI).

Methods: 34-year-old woman with history of intractable migraines requiring multiple hospitalizations for parenteral pain management, bipolar disorder on chronic lithium therapy, and hypertension presented with a 3-week history of abdominal pain, associated with nausea, and daily episodes of non-bloody emesis. She also reported decreased urine output, difficulty voiding and new bilateral lower extremity edema. Review of systems was positive for constipation due to increased use of previously prescribed opiates for analgesia. She used Ketorolac for pain and also was treated with trimethoprim/sulfamethoxazole for a presumed UTI. Laboratory data revealed mild leukocytosis (14.4), acute on chronic anemia (hemoglobin and hematocrit 9.0/26.9) and AKI with BUN/ serum creatinine (SCr) at 22/2.7 mg/dl. BUN/SCr was 13/0.7 mg/dl a year prior. Urinalysis as well as an abdominal X-ray did not exhibit any abnormalities. Lithium levels were normal. CT abdomen/pelvis showed bilateral hydronephrosis with prominence of the left ureter and associated perinephric stranding. Urology performed cystoscopy, bilateral retrograde pyelography and left ureteroscopy. During the procedure, bilateral symmetric narrowing of mid to distal ureters was noted with medial deviation suggestive of RPF. On specifically questioning the patient, she disclosed surreptitious use of Methysergide which was deemed the culprit agent. She was treated with bilateral ureteric stenting with improvement in SCr levels.

Results:

Conclusions: RPF is a chronic, predominantly idiopathic, fibroinflammatory disorder. Only one-third of cases are secondary with Methysergide being an established etiologic agent. Pathogenesis is thought to involve drug-related pro-fibrotic haptenic role or a feedback rebound serotonin release resulting in TGF-β/Smads cascade-mediated myoblast proliferation. This case highlights the importance of careful history-taking especially in cases of AKI where multiple intersecting nephrotoxins might play a role and brings to the forefront a now rare disease.

FR-PO050

Timing of AKI after Urgent Percutaneous Coronary Intervention and Adverse Outcomes: The PATTERN Study Thida C. Tan,[2] Thomas Leong,[2] Robert J. Lundstrom,[2] Jamal S. Rana,[2] Douglas J. Watson,[1] Alan S. Go.[2] *[1]CSL Behring, King of Prussia, PA; [2]Kaiser Permanente Northern California, Oakland, CA.*

Background: Conflicting evidence exists about the frequency and outcomes associated with acute kidney injury (AKI) after percutaneous coronary interventions (PCI). Limited insights also exist about whether the timing of AKI influences outcomes after PCI in contemporary populations. We examined the association between AKI at 12 and 24 hours post-PCI with subsequent renal and mortality outcomes.

Methods: We identified all adult members within Kaiser Permanente Northern California undergoing urgent PCI from 2008-2013 who had both pre- and post-PCI serum creatinine data. Patients with prior dialysis, renal transplant or estimated glomerular filtration rate (eGFR) <15 mL/min/1.73 m^2 were excluded. AKI was defined as a ≥50% relative increase or ≥0.3 mg/dL increase in post- vs. pre-PCI serum creatinine measures at 12 (±6) and 24 (±6) hours post-PCI. We ascertained post-discharge significant loss of renal function (defined as a 50% decrease from baseline eGFR or development of ESRD) and all-cause death up to 1 year post-PCI based on data from electronic health records. We used Cox regression to evaluate the independent association between timing of AKI and outcomes after adjustment for a high-dimensional propensity score for developing AKI and pre-PCI eGFR and proteinuria.

Results: Among 8522 urgent PCI patients, mean age was 67 years, with 29% were women, and 21% minorities. AKI was documented in 1.8% of patients at 12 hours and 1.6% at 24 hours post-PCI. In multivariable Cox models, the risk of all-cause death up to 1 year was similarly high for AKI at 12 hours (adjusted hazard ratio [HR] 3.35, 95%CI:2.08-5.40) and 24 hours (HR 3.68, 2.18-6.21) post-PCI. In contrast, AKI at 24 hours post-PCI (HR 4.56, 2.37-8.79) was more strongly associated with significant loss of kidney function at 1-year than was AKI at 12 hours (HR 2.27, 1.19-4.32) post-PCI.

Conclusions: In a large, community-based population undergoing urgent PCI, AKI at 12 and 24 hours post-PCI were independently associated with high excess mortality at 1-year to a similar degree, while AKI at 24 hours was more strongly associated with subsequent significant loss of kidney function at 1 year compared with AKI at 12 hours. Studies are needed to determine whether prevention or treatment of AKI after PCI can mitigate the excess risks of death and renal function loss.

FR-PO051

Slope-Based Staging Outperforms KDIGO Staging for Assessing Inpatient Mortality Risk with AKI David G. Warnock,[3] Mirela Bojan,[2] Christoph Wanner,[5] Anupam Agarwal,[4] Marc Froissart.[1] *[1]CHUV / UNIL, Lausanne, Switzerland; [2]Necker-Enfants Malades University Hospital, Paris, France; [3]UAB, Birmingham, AL; [4]University of Alabama at Birmingham, Birmingham, AL; [5]University Hospital, Wuerzburg, Germany.*

Background: The association between AKI severity and mortality is well described, but current staging criteria have not be optimized for risk assessment or developing prognostic models for specific outcomes

Methods: Confidence limits (CI) for individual patient serum creatinine (sCr) trajectories were developed using an adaptive Bayesian approach. AKI episodes were defined by sCr excursions above the CI, with a) ≥3 sCr values between baseline and peak; b) ≥6 hours between peak and baseline; and c) sCr increase ≥0.3 mg/dL. Specific baseline sCr values were defined for each as the minimal sCr value immediately preceding each AKI episode. Survivor functions, and relative Integrated Discrimination Improvement (rIDI) were done with Stata version 14.1.

Results: All adult 1st admissions were reviewed for FY2010-2013 at UAB Hospital, for patients with ≥3 sCr determinations, length of stay ≥1 & <31 days, excluding patients with ESRD before admission; 35, 079 patients with 1,544 inpatient deaths. AKI staging was done with KDIGO criteria, and slope-based staging for patients with AKI episodes. Survivor functions (Figure) show better discrimination between AKI stages with slope-based criteria compared to KDIGO criteria: rIDI=15.5% (95% CI: 13.5%–17.6%, P<0.001); C-statistics of 0.7694 vs. 0.7226, and AUC/ROC 0.8616 vs. 0.8551 (P=0.012).

Conclusions: Slope-based AKI staging outperforms KDIGO staging criteria for describing the association of AKI severity with inpatient mortality at UAB Hospital. Sloped-based staging is compatible with real-time, dynamic risk assessment than KDIGO staging, and also recognizes multiple AKI episodes during a single admission, with baseline sCr defined for each AKI episode. KDIGO staging is based on the absolute inclrease in sCr with reference to a prior baseline sCr, and does not recognize multiple AKI episodes.

Survivor Functions for AKI Staging by a) KDIGO criteria and b) Slope-Based criteria

FR-PO052

Thrombocytopenia Predicts Mortality in Patients with AKI Requiring Renal Replacement Therapy (RRT) Benjamin Griffin,[2] Zhiying You,[1] Paul M. Palevsky,[5] Sarah Faubel,[3] Diana I. Jalal.[4] *[1]UC Denver, Aurora, CO; [2]University of Colorado, Aurora, CO; [3]University of Colorado Denver, Denver, CO; [4]University of Colorado Denver Health Science Center, Aurora, CO; [5]University of Pittsburgh, Pittsburgh, PA.*

Background: Thrombocytopenia is common in critically ill patients and is associated with increased mortality. The impact of thrombocytopenia in patients requiring RRT for AKI is unknown. In this study we assessed the prognostic value of thrombocytopenia at RRT initiation in a large database of critically patients with AKI requiring RRT.

Methods: We conducted a secondary analysis of the Acute Renal Failure Trial Network (ATN) database. The ATN study compared intensive to less-intensive RRT dosing strategies in patients with AKI. In this analysis, patients were categorized based on pre-RRT platelet levels, which were classified as normal (> 100 x 10^3/μL), moderate (50-100 x 10^3/μL) and severe (<50 x 10^3/μL) thrombocytopenia. 60-day mortality was compared using chi-squared test. Logistic regression was used to adjust for age, race, and gender in the initial model, and body mass index (BMI) and SOFA score in the final model.

Results: 62% of patients had at least moderate thrombocytopenia prior to initiation, and 14% had severe thrombocytopenia. Thrombocytopenia was highly associated with 60-day mortality even after adjustments for demographics and illness severity (Table 1). In patients who survived >72 hours, the platelet decrease at day 3 as a continuous variable did not have a clinically relevant association with 60-day mortality, with an OR of 0.996 (0.993 - 0 .999, p = 0.02).

Conclusions: Thrombocytopenia is present > 60% of patients with at the initiation of RRT and is independently and significantly associated with increased mortality even after adjusting for illness severity. The role of thrombocytopenia in outcomes of patients with AKI requiring RRT merits future study.

Table 1. Final multivariate model for 60-day ICU mortality. Platelet levels are compared to <50 x10^3/μL

Variable	OR (95% CI)	P value
Platelet Level 50-100 x10^3/μL	0.46 (0.27 -0 .79)	.0047
Platelet Level >100 x10^3/μL	0.34 (0.20 – 0.55)	<0.0001
SOFA Score	1.30 (1.18 – 1.42)	<0.0001
Female Gender	0.91 (0.64 – 1.28)	0.57
African-American Race	1.21 (0.78 – 1.86)	0.38
Age (years)	1.03 (1.02 – 1.04)	<0.0001
BMI (kg/m^2)	0.98 (.095 – 1.00)	0.06

FR-PO053

Renal Recovery and Progression of CKD Following Postoperative AKI Thorir E. Long,[3,2] Sólveig Helgadóttir,[1] Dadi Helgason,[3,2] Runolfur Palsson,[2,3] Tomas Gudbjartsson,[2,3] Gisli H. Sigurdsson,[2,3] Martin I. Sigurdsson,[4] Olafur S. Indridason.[2] *[1]Akademiska Hospital Uppsala University, Uppsala, Sweden; [2]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [3]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [4]Duke University Medical Center, Durham, NC.*

Background: Acute kidney injury (AKI) is a known risk factor for chronic kidney disease (CKD). The aim of this study was to examine how renal recovery associates with the development or progression of CKD among individuals with AKI following surgical procedures.

Methods: This was a retrospective study of all adult patients undergoing abdominal, cardiothoracic, vascular or orthopedic surgery at the University Hospital in Reykjavik in 1998-2015. AKI was defined according to the KDIGO serum creatinine (SCr) criteria. CKD was defined as eGFR <60 ml/min/1.73m^2 persistent for ≥90 days, and development and progression of CKD as increase to a higher stage, present for ≥90 days. Association between incident CKD or CKD progression and renal recovery of varying degree (SCr reduction to <1.5, <1.25 and <1.1 x baseline SCr) at 30 days following AKI was compared with a non-AKI control group using propensity score matching (1:1).

Results: Following a total of 43,876 surgeries, 2,497 (5.7%) patients developed AKI. In the AKI group, 1,071 (42.9%) had baseline eGFR <60 ml/min/1.73 m^2, compared with 8,562 (20.7%) among those who did not develop AKI. Median follow-up time was 4.4 (range 0.1-18.1) years and 36,563 (83%) patients had two or more SCr measurements available at least 90 days apart. Development or progression of CKD was observed during follow-up in 585 (23.4%) patients with AKI compared with 3.181 (7.7%) of those without AKI (<0.001). Progression of CKD was observed in 19.8%, 25.1%, 36.2% and 27.8% of individuals with renal recovery to <1.10, <1.10-1.25, <1.25-1.5 x baseline SCr and no recovery (SCr >1.5 x baseline SCr) at 30-days, respectively. In comparison, 11% of a propensity score-matched control group without AKI experienced CKD progression during follow-up (p<0.001).

Conclusions: Postoperative AKI increases the risk of development of incident CKD and/or progression of existing CKD, even in patients who experience apparent good renal recovery.

FR-PO054

Early Renal Replacement Therapy Improves Outcome of Burned Patients with AKI Zhong hong Liew,[1] Manish Kaushik,[1] Han K. Tan,[1] Andrew Cheah,[2] Si jack Chong,[1] Bien keem Tan.[1] *[1]Singapore General Hospital, Singapore, Singapore; [2]Singhealth, Singapore, Singapore.*

Background: Burned patients with acute kidney injury (AKI) require renal replacement therapy (RRT) have exceedingly high mortality rates of 73-100%. Since January 2011, we have been adopting early RRT approach in managing burned patients with AKI. Our hypothesis was that early initiation of RRT leads to improved outcome and survival among burned patients with AKI by allowing better management of fluid, electrolytes and acid-base balance

Methods: We conducted a retrospective analysis of Burns Database from January 2011 to February 2016. Indications for dialysis included serum creatinine > 1.5 times baseline or urine output < 0.5 ml/kg/h for at least 2 consecutive hours. Patients with similar parameters from January 2006 to December 2010 were recruited for comparison.

Results: A total of 27 patients with burns and AKI were recruited from January 2011 to February 2016. Mean age was 45.4 years and 88.9% were male. Mean TBSA was 54.8%. Total volume of fluid resuscitation was 2.7 ml/kg/TBSA. Time from onset of burn to RRT was 6.4 days. Majority of patients presented with stage 1 AKI (51.9%); while 22.2% and 25.9% had stage 2 and stage 3 AKI respectively. Most patients (74.1%) received CRRT and 18.5% received SLED. The mortality rate was 37.0% with majority (70%) were due to sepsis/multiorgan failure. Only 1 patient required long-term RRT after discharge and there was no occurrence of abdominal compartment syndrome. Mean age of 15 patients from 2006 to 2010 was 47.8 years. Mean TBSA was 49.5%. Only 26.7% of patients were started on RRT. The mortality rate was 66.7%, which was higher than that of subjects from 2011 to 2016 (37.0%).

Conclusions: We compared our findings with 5 studies published in recent 10 years on burned patients with AKI started on RRT and found that early RRT approach reduced mortality of burned patients with AKI. Optimal timing of RRT for burned patients with AKI has not been established and further large clinical trials are required.

AKI and Remission of Proteinuria in Adult-Onset Minimal Change Disease: A Multicenter Retrospective Cohort Study Maki Shinzawa,[4] Yasuyuki Nagasawa,[4] Ryohei Yamamoto,[4] Atsushi Yamauchi,[3] Megumu Fukunaga,[5] Terumasa Hayashi,[2] Masaaki Izumi,[1] Yoshitaka Isaka.[4] *[1]Kansai Rosai Hospital, Amagasaki, Hyogo, Japan; [2]Osaka General Medical Center, Osaka, Japan; [3]Osaka Rosai Hospital, Sakai-city, Japan; [4]Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [5]Toyonaka Municipal Hospital, Toyonaka, Japan. Group/Team: STOP-MCD.*

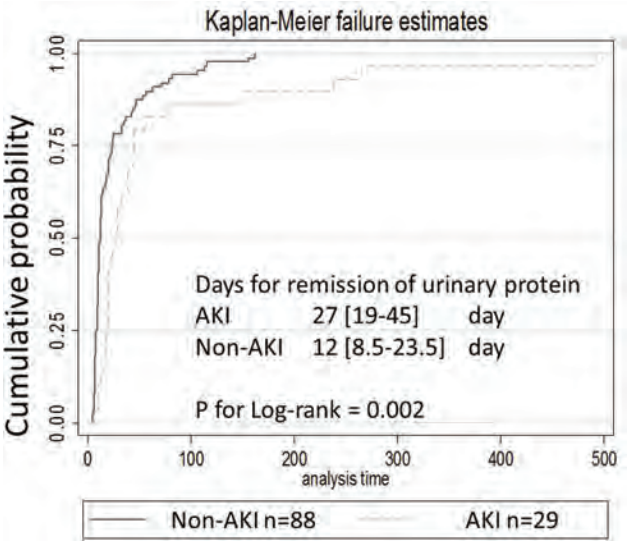
Background: Acute kidney injury (AKI) is common (20% to 50%) in adult-onset minimal change disease (MCD). However, its effect on remission of proteinuria is unknown.

Methods: Design: a multicenter retrospective cohort study, the STudy of Outcomes and Practice patterns of Minimal-Change Disease (STOP-MCD). Patients: 117 nephrotic patients aged ≥15 years with histological diagnosis of primary MCD between 2000 and 2009 in 5 hospitals in Japan. Outcome: First remission of proteinuria defined as urinary protein < 0.3 g/day, urinary protein / creatinine ratio < 0.3, and/or negative/trace result of dipstick test. Exposure: AKI defined as ≥0.3mg/dL of an increase of creatinine (Cre) at initiating immunosuppressive therapy. Statistics: Multivariable Cox proportional hazards (CPH) model.

Results: Baseline characteristics at initiating of immunosuppressive therapy.of AKI group (n=29) and non-AKI group (n=88) were as follows; age, median 53 [interquantile range 28, 63] vs. 37 [22, 58] yr (P=0.135); male, 66 vs. 61 % (P=0.689); Cre, 1.6 [1.3, 2.0] vs. 0.8 [0.7, 0.9] mg/dL (P<0.001); serum albumin, mean 1.8 ± SD 0.6 vs. 1.8 ± 0.6 g/L (P=0.950); urinary protein, 11.6 [7.9, 14.7] vs. 7.2 [3.3, 14.4]) g/day (P=0.021); initial dose of prednisolone, 0.7 ± 0.1vs. 0.7 ± 0.2 mg/Kg (P=0.449). During 4.2 [2.2-7.2] year of the observational period, all patient achieved remission. Maximum Cre after initial treatment was 2.5 [2.0-3.6] mg./dL in AKI group and 0.9 [0.8-1.2] mg/dL in non-AKI group. Remission was delayed in AKI group (27 [19, 45] vs. 12 [9, 24] day, P=0.002) (Figure). AKI was identified as a significant predictor of remission in the multivariable CPH model (AKI vs. non-AKI, hazard ratio 0.48 [95% confidence interval 0.29–0.79, P=0.004]).

Conclusions: AKI before immunosuppressive therapy delayed remission of proteinuria in adult-onset MCD.

Funding: NIDDK Support



FR-PO056

Subclinical AKI Is Associated with Poor Patient Outcomes in Critically Ill Children Natalja Stanski,[1] Shina Menon,[2] Stuart Goldstein,[1] Rajit K. Basu.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Seattle Children's Hospital, University of Washington, Seattle, WA.*

Background: The diagnosis of acute kidney injury (AKI) depends on the detection of increases in serum creatinine (SCr), which can result in delayed recognition. Neutrophil gelatinase-associated lipocalin (NGAL) is a biomarker of renal tubular injury that rises early and can be used to detect AKI sooner. Subclinical AKI, a state defined by biomarker positivity in the absence of SCr elevation, has not been well studied in children thus far.

Methods: We conducted a single center, prospective study of children admitted to the ICU with urinary NGAL and SCr samples collected in the first day of admission. NGAL elevation (NGAL+) was defined as >500 ng/ml and SCr elevation (SCr+) was defined as KDIGO stage 1 AKI or greater. Patients were separated into 4 groups: NGAL+/SCr+, NGAL+/SCr-, NGAL-/SCr+ and NGAL-/SCr-. Groups were compared across a variety of outcomes: in-hospital mortality, need for renal replacement therapy (RRT) (primary outcomes), incidence and duration of mechanical ventilation, ICU and hospital length of stay (LOS), organ failure days and incidence of late onset-AKI (day 3-7). Particular attention was paid to the comparison of the NGAL-/SCr- and NGAL+/SCr- groups.

Results: 178 patients (51.6% male, median age 6.7 years) were included. 115 (64.6%) were NGAL-/SCr-, 12 (6.7%) were NGAL+/SCr-, 26 (14.6%) were NGAL-/SCr+ and 25 (14.1%) were NGAL+/SCr+. Compared to NGAL-/SCr- patients, NGAL+/SCr- patients had higher odds of in-hospital mortality [OR 1.64 (95% CI: 0.18,14.8) p=0.66], need for mechanical ventilation [OR 2.92 (95% CI: 0.61,13.9) p=0.18], and late-onset AKI [OR 2.5 (95% CI: 0.68,9.1) p=0.16]. This group also had longer mean duration of mechanical ventilation, more organ failure days, and longer LOS (both ICU and hospital). There was no difference in need for RRT initiation as no patients in either group required RRT use.

Conclusions: Elevated urine NGAL on ICU admission is associated with increased morbidity and mortality in pediatric patients, even in the absence of elevated SCr, and may represent a state of subclinical AKI.

FR-PO057

Analysis of Morbidity and Mortality in Patients with Biliary Obstruction and AKI Di Pan,[1,3] Yumeng Wen,[1,3] David Mariuma,[1,3] Michael Gramuglia,[4] Ira S. Meisels.[2,3] *[1]Mount Sinai St. Luke's and Mount Sinai West Hospitals, New York, NY; [2]Division of Nephrology, Mount Sinai St. Lukes and Mount Sinai West Hospitals, New York, NY; [3]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [4]Montefiore Health System, New York, NY.*

Background: Acute kidney injury has been shown to be a negative prognostic factor for a variety of diseases. Patients with biliary obstruction are unique in the fact that they may develop acute kidney injury through the nephrotoxic effects of hyperbilirubinemia in addition to the conventional mechanisms of renal failure. The goal of this study is to analyze the impact and burden of acute kidney injury on patients with biliary obstruction.

Methods: This is a retrospective cohort study using the 2014 National Inpatient Sample (NIS), which is the largest inpatient database in the United States. A total cohort of 59,500 patients over the age of 18 admitted with either a primary or secondary diagnosis of biliary obstruction were identified using ICD-9 codes. 8,760 (17%) individuals had a concurrent diagnosis of acute kidney injury. The primary outcome was overall in-hospital mortality. Secondary outcomes included length of stay (LOS), total hospital charge, and incidence of receiving renal replacement therapy. Multivariate regression analyses were performed to test for independent associations between AKI and outcomes of interest adjusting for age, gender, race and comorbidities. Independent t-tests were performed

for continuous variables, and chi-squared and fisher's exact tests were performed for categorical variables. Analysis was performed using Stata 14.2.

Results: The presence of acute kidney injury was independently associated with increased overall in-hospital mortality in patients with biliary obstruction (adjusted OR 2.93 p<0.0001, 95% CI 2.34-3.65). LOS was 2.08 days longer (P<0.0001, 95% CI 1.43 -2.73) in patients with acute kidney injury, and total hospital charges were $24832.04 more than in patients without acute kidney injury (p<0.0001 95% CI 14673.35 - 34990.74). 3.2% of patients received renal-replacement therapy.

Conclusions: The presence of acute kidney injury poses significant burden on patients with biliary obstruction. It is associated with increased mortality, with increased length of stay and hospital charge. We should pay close attention and be aggressive in the monitoring and treatment of AKI in this population.

FR-PO058

Definition of Baseline Serum Creatinine Levels Which Are the Best to Predict Clinical Prognosis in Acute Kidney Injury Patients Jeonghwan Lee,[2] Dong Ho Shin,[1] Ho Jun Chin,[3] Ki Young Na,[3] Sejoong Kim.[3] *[1]College of Medicine, Hallym University, Seoul, Republic of Korea; [2]Hallym University Hangang Sacred Heart Hospital, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seong nam, Republic of Korea.*

Background: The classification of acute kidney injury (AKI) may be different depending on how the baseline serum creatinine is defined. The authors aimed to determine the best way to define the baseline serum creatinine according to the patients' kidney function.

Methods: A total of 19656 adult patients were enrolled at one university hospital during the year 2013. The baseline serum creatinine levels were defined by 4 different methods (the lowest value of serum creatinine levels during 14 days, 92 days, or 184 days before admission; and the serum creatinine levels inversely calculated from the MDRD GFR 75 ml/min/1.73m^2 values). Using the Receiver Operating Characteristic curve analysis, the area under the curve (AUC) was measured to compare the diagnostic performance of AKI for clinical outcomes according to the definition of baseline serum creatinine levels.

Results: In patients with a baseline GFR above 60 ml/min/1.73m^2, the AUCs for in-hospital mortality were similar for the four definitions of baseline creatinine levels. The AUC for ESRD was significantly superior when the baseline serum creatinine values were calculated from the GFR 75 value. In patients with a baseline GFR below 60 ml/min/1.73m^2, when the baseline serum creatinine values calculated from the GFR 75 value, the AUC for in-hospital mortality was poor and the AUC for ESRD was significantly lower.

Conclusions: In patients with normal GFR, serum creatinine levels, which were back-calculated from the GFR 75 values, can be used as the baseline creatinine levels to define AKI. However, in patients with impaired kidney function, baseline serum creatinine levels obtained directly from the 6-month serum creatinine levels before admission can predict the prognosis of AKI more accurately.

C-statistics for ROC curve for in-hospital mortality and end-stage renal disease according to the AKI with 4 different baseline creatinine definitions

		In-hospital mortality		ESRD	
Basal GFR	Baseline Creatinine (Cr) Definition	AUC	95% confidence interval	AUC	95% confidence interval
GFR ≥ 60 ml/min/1.73m^2	Cr from GFR 75	0.569	0.556-0.582	0.920	0.877-0.962
	Lowest Cr 14 days before admission	0.558	0.545-0.571	0.775	0.702-0.848
	Lowest Cr 92 days before admission	0.570	0.557-0.583	0.778	0.707-0.849
	Lowest Cr 184 days before admission	0.574	0.561-0.587	0.775	0.704-0.846
GFR < 60 ml/min/1.73m^2	Cr from GFR 75	0.639	0.579-0.699	0.638	0.593-0.684
	Lowest Cr 14 days before admission	0.741	0.672-0.810	0.730	0.677-0.783
	Lowest Cr 92 days before admission	0.735	0.669-0.800	0.770	0.725-0.814
	Lowest Cr 184 days before admission	0.735	0.673-0.797	0.782	0.744-0.821

FR-PO059

A 10-Year National Trend in AKI among Hospitalized Adults Undergoing Invasive Cardiac Electrophysiology Studies Yumeng Wen,[1,2] Di Pan,[1,2] David Mariuma,[1,2] Fernando Vazquez de lara,[1,2] Yiming Luo,[1,2] Michael Gramuglia,[3] Ira S. Meisels.[1,2] *[1]Division of Nephrology, Department of Medicine, Mount Sinai St. Luke's and Mount Sinai West Hospitals, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Department of Medicine, Montefiore Medical Center, Scarsdale, NY.*

Background: Invasive cardiac electrophysiology (EP) study is a collection of clinical techniques for investigation and treatment of cardiac rhythm disorders. Limited literature has addressed the risk of acute kidney injury (AKI) following invasive EP procedures. The aim of this study is to analyze the temporal trend of AKI among patients undergoing invasive cardiac EP studies, as well as in-hospital mortality and other outcomes among those developed AKI between 2005 and 2014.

Methods: This is a retrospective study using the 2005-2014 National Inpatient Sample, which is the largest publically available inpatient database in the United States. A cohort of 962,394 patients over the age of 18 undergoing invasive cardiac EP studies based on ICD-9 CM codes was included in the study. There were no exclusion criteria. In the primary analysis, we examined the temporal trend in the incidence of AKI and dialysis-requiring AKI. In the secondary analysis, we examined temporal changes in in-hospital mortality, length of stay (LOS), and total charges in hospitalizations complicated by AKI over the study time period. Odds ratios (OR) were calculated based on multivariate logistic analyses, adjusted for demographics and comorbidities. Analysis was performed using Stata, version 14.2.

Results: Our results showed that from 2005 to 2014 there was a significant increase in the incidence of AKI (3.26% in 2005 vs. 13.03% in 2014, p<0.001), as well as in dialysis-requiring AKI (0.22% in 2005 vs. 0.61% in 2014, p<0.001). Among those who developed AKI, the in-hospital mortality rate remained stable over time (OR 0.96, p=0.071). The LOS decreased significantly (15.85 days in 2005 vs. 11.22 days in in 2014, p<0.001), along with an increase in total hospital charges over time ($151,369 in 2005 vs. $193,384 in 2014, p<0.001). Hospitalizations complicated by AKI compared to those that were not were associated with significant higher in-hospital mortality (OR 3.77, p<0.001).

Conclusions: Our study demonstrated a significant increase in the incidence of AKI and dialysis-requiring AKI among patients undergoing invasive cardiac EP studies, however in-hospital mortality remained the same over time. Development of AKI after invasive cardiac EP studies was associated with higher hospital mortality rate and financial burden.

FR-PO060

A 10-Year National Trend in Dialysis-Requiring AKI among Hospitalized Adults with HIV Infection Yumeng Wen,[1,2] Di Pan,[1,2] David Mariuma,[1,2] Marcelo X. Hernandez cuchillas,[1,2] Yiming Luo,[1,2] Michael Gramuglia,[3] Ira S. Meisels.[1,2] *[1]Division of Nephrology, Department of Medicine, Mount Sinai St. Luke's and Mount Sinai West Hospitals, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Department of Medicine, Montefiore Medical Center, Scarsdale, NY.*

Background: Patients with HIV are at risk for both acute kidney injury (AKI) and chronic kidney disease (CKD). Previous studies demonstrated an increasing incidence of AKI among HIV population. The aim of this study is to observe beyond the time frame of the previous studies and to explore the in-hospital mortality and other outcomes among hospitalized HIV patients who developed dialysis-requiring AKI between 2005 and 2014.

Methods: This is a retrospective study using the 2005-2014 National Inpatient Sample, the largest inpatient database in the US. A cohort of 2,133,610 patients over the age of 18 diagnosed with HIV based on ICD-9 CM codes was included in this study. Patients hospitalized for elective procedures were excluded. In the primary analysis, we examined the temporal trend in the incidence of dialysis-requiring AKI. In the secondary analysis, we examined temporal changes in in-hospital mortality, length of stay, and total charges in hospitalizations complicated by dialysis-requiring AKI. Odds ratios (OR) were calculated based on multivariate logistic analyses, adjusted for demographics, related comorbidities and procedures. Analysis was performed using Stata 14.2.

Results: There was an increasing incidence of dialysis-requiring AKI among the HIV population over time (1.03% in 2005 vs 1.49% in 2014). Among HIV patients developing dialysis-requiring AKI, the in-hospital mortality rates decreased over time (25.35% in 2005 vs 18.79% in 2014, OR 0.93, p<0.001). The length of hospital stay had a increasing trend after initial decline (18.62 days in 2005 vs 15.62 days in 2011 vs 17.03 days in 2014, p=0.016). There was also a increase in total hospital charges ($122,273 in 2005 vs. $188,613 in 2014, p<0.001). Hospitalizations complicated by dialysis-requiring AKI compared to those that were not were associated with higher in-hospital mortality (OR 1.64, p<0.001)

Conclusions: This study demonstrates that despite an increase in incidence of dialysis-requiring AKI among patients with HIV, the in-hospital mortality of these patients has improved over time. The development of dialysis-requiring AKI continues to have significant life-altering impact and financial burden on HIV patients within our health-care system.

FR-PO061

Prospective Cohort Study Assessing the Role of Urine Microscopy in Diagnosis and Management of AKI Arani D. Nanavati, James F. Simon. *Cleveland Clinic, Cleveland, OH.*

Background: Nephrologist-performed urine microscopy is a competency taught during training and encouraged in practice when working up acute kidney injury (AKI). Despite this its use in clinical practice has waned for multiple reasons. Available data showing that nephrologist-performed microscopy(NPM) positively impacts the diagnosis and management of AKI patients is limited to differentiating prerenal azotemia from ATN. We conducted a prospective cohort study at a tertiary care center to identify to what extent NPM aids in identifying the etiology and proposed management of AKI when all cases are considered.

Methods: Fresh urine samples were obtained from 113 patients with AKI on inpatient Nephrology consult service between September and December 2016. AKI was defined by at least stage 1 AKI as per the Kidney Disease Improving Global Outcomes definition [an increase of serum creatinine (SCr) by ≥0.3 mg/dl and/or increase ≥50%-100% from baseline]. Only cases reviewed by staff nephrologists were included. Nephrologists were provided with questionnaires before inspecting the urine sediment. They were asked to provide the proposed etiology of AKI and planned management prior to and after performing urine microscopy. A logistic regression model was created to investigate how often the etiology and proposed management changed based on urine sediment review and what variables may have increased the likelihood of either change.

Results: Presumptive etiology of AKI was changed with urine microscopy in 24%(n=27) of patients. Proposed management of AKI was changed in 12% of patients.

Management remained unchanged in 98% of patients in whom diagnosis was unchanged after microscopy. But of 27 patients in whom the etiology was changed after urine microscopy, management was changed in 44% of cases (n=12) (p<0.001) (Fischer's exact test). In a multivariable logistic regression model sepsis on presentation was found to be associated with higher odds of change in diagnosis of AKI after urine microscopy after adjusting for baseline and consult SCr (Odds ratio 4.19, 95% CI- 1.59-11.47, p= 0.004).

Conclusions: Nephrologist-performed urine microscopy plays a significant role in identifying the etiology and in management of patients with AKI in hospital. The likelihood was found to be higher in patients who were septic on presentation in our study.

FR-PO062

Use of a Serum Creatinine Point of Care Test in Low Resource Settings: Correlation and Agreement with Hospital Based Assessment Etienne Macedo,[5] Ulla Hemmila,[3] Sanjib K. Sharma,[2] Rolando Claure-Del Granado,[4] Emmanuel A. Burdmann,[6] Michael V. Rocco,[7] Jorge Cerda,[1] Ravindra L. Mehta.[5] *[1]Albany Medical College, Albany, NY; [2]B P Koirala Institute of Health Sciences, Dharan, Nepal; [3]College of Medicine, Malawi, Kokemäki, Finland; [4]Universidad Mayor de San Simon, School of Medicine, Cochabamba, Bolivia, Plurinational State of; [5]University of California San Diego Medical Center, San Diego, CA; [6]University of Sao Paulo Medical School, Sao Paulo, Brazil; [7]Wake Forest School of Medicine, Winston-Salem, NC.*

Background: The ISN0by25Pilot Project was designed to evaluate an education and training program coupled with a point of care (POC) serum creatinine (sCR) test and teleconsultation to improve detection and management of AKI in low resource settings. We evaluated in paired samples the correlation between the POC sCR test applied in the health center to the hospital lab sCR results.

Methods: Paired results of sCR POC test and hospital lab values were compared in adults and childre with and without CKD in the 3 clusters (Bolivia, Nepal and Malawi) participating in the project. sCR was measured by Jaffe reaction and the sCR POC test was performed using the StatSensor® Cr Xpress™ Meter. Correlation between lab and POC test was evaluated by Spearman's test and Bland Altman tests.

Results: We assessed 58 samples collected during clinical care obtained at the same time as the POC test. None of the pts were receiving renal support. Lab sCR values ranged from 0.5-25.9 mg/dl in adults and 0.4-13 mg/dl in children. Overall, correlation between hospital lab assessment and POC test was 0.872, (adults 0.879 and children 0.962) and similar for pts with and without CKD (no CKD 0.817, CKD 0.857); p<0.001. Bland Altman plot (Figure 1) showed a good agreement between the two measurements through the middle range of CR values.

Conclusions: The sCR POC test performed well in adult and children and can be utilized to assess kidney function in health care centers in low resource settings. The good correlation and agreement between the two measurements, suggests that POC test values are probably valuable for pt follow up through their course of illness and to assess kidney function recovery.

Funding: Private Foundation Support

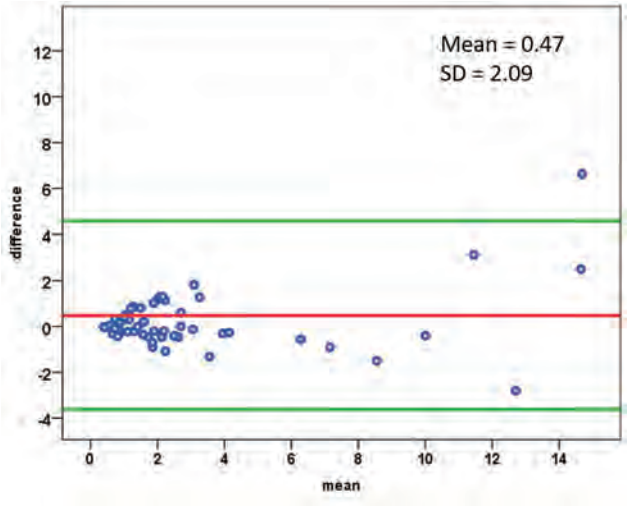


Figure 1 – Bland Altman plot showing the differences between laboratory and Xpress values and *vs*. the mean of the two measurements.

FR-PO063

Prevention of AKI in a Tertiary Pediatric Hospital by Real Time Risk Surveillance and Curated Alerts Abhay N. Vats, Sheena Sharma, Franca M. Iorember, Martin A. Turman, Brittany Wold, Melinda Loya, Nina Farhoudi, David F. Carpentieri, Jamie Librizzi, Vinay Vaidya, Kanwal K. Kher. *Phoenix Children's Hospital, Phoenix, AZ.*

Background: Hospital acquired acute kidney injury (HA-AKI) can significantly increase morbidity, mortality and health care costs in children. We developed a novel electronic health record (EHR) based real-time surveillance system for AKI detection & generation of curated alerts.

Methods: A software designed to provide enterprise-wide data analysis based on algorithms utilizing AKIN criteria for staging was developed. It queries EHR every 6 hours for AKI risks including: baseline serum creatinine (SC), % change, rate of rise in SC, nephrotoxic medications (NTM), therapeutic drug levels (TDM), and renal replacement therapy /nephrology intervention. Quick links to the patient charts are available. The analytic output is automated and made available on a self-updating dashboard which is utilized to generate curated alerts by the enterprise nephrologists.

Results: The dashboard (Fig) generates color coded signals for stage I to III AKI, plots weekly change in SC, NTM exposure, TDM listing, day(s) since last SC & documented nephrology intervention. It detects both NTM & non NTM associated AKI & risk factors. It is even programmed to detect AKI where the absolute SC is <0.5 mg/dl. An AKI surveillance team (pharmacist & nephrologist) reviews the dashboard daily to direct AKI prevention and treatment strategies through curated alerts to the responsible healthcare providers through "two way" integrated Vocera® secure messaging system. This avoids "alert fatigue" and has led to a proactive change in provider's approach to HA-AKI prevention. The dashboard access progressively increased from 45% to 87% over a short period of 6 weeks.

Conclusions: This novel EHR dashboard and AKI alert system serves as an early warning tool for enterprise wide application. The alerts are traceable, auditable & are HIPAA compliant. AKI biomarkers will be incorporated in the dashboard in near future. This tool allows the HA-AKI prevention team to track at risk patients, provide early detection & prevention of HA-AKI.

AKI Dashboard Screen Shot

FR-PO064

Initial Application of Electronic Alert for AKI among High-Risk Wards Yanhua Wu, Yuanhan Chen, Wei Dong, Xinling Liang. *Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China. Group/Team: China collaborative study on AKI.*

Background: The effectiveness of acute kidney injury alert might differ in different care settings. We aimed to investigate the value of electronic alert for acute kidney injury among high-risk wards.

Methods: A prospective, randomized, controlled study was conducted. We developed an electronic alert for AKI and ran the system in intensive care units and cardiovascular departments. Eligible participants were adults aged 18 years or older who were in hospital with acute kidney injury as defined by Kidney Disease Improving Global Outcomes creatinine-based criteria. Exclusion criteria were initial hospital creatinine 353.6μmol/L or greater, end-stage renal disease, renal replacement therapy before randomization, kidney transplantation and amputation. The primary outcomes were AKI and expanded AKI diagnosis rates, nephrology consultation, dialysis, recovery of renal function and death. Patients were randomly assigned to alert group and non-alert group. Alert group could receive popup messages. This study is registered with ClinicalTrials.gov, number NCT02793167.

Results: Between Mar.1 2016 and Jul.31 2016, 5535 patients were screened.318 eligible participants were assigned to the alert group and 623 were assigned to the non-alert group. The diagnosis rate of AKI in alert group was higher than non-alert group(5.6% vs. 2.1%,P=0.004). The expanded AKI (AKI and multiple organ dysfunction syndrome) diagnosis rate was also higher in alert group (11.2% vs. 4.5%,P<0.001). Patients were stratified according to the severity of AKI and different wards. At AKI stage 1, the AKI and expanded AKI diagnosis rates in alert group were higher than non-alert group (AKI: 2.8% vs. 0.8%,P=0.037; expanded AKI: 4.7% and 1.3%, P=0.011). There was no difference at AKI stage 2 and stage 3. Among the different wards, the AKI alert had greater impact on AKI and expanded AKI diagnosis rates in cardiovascular surgery wards(AKI:3.9% vs. 1.2%,P=0.077; expanded AKI:9.0% vs. 2.9%, P=0.003). There was not significantly different in nephrology consultation, dialysis, recovery of renal function or death in the two groups.

Conclusions: Electronic warning system could reduce the misdiagnosis rates of AKI and expanded AKI in high-risk wards. Standard diagnosis rate of AKI was still very low. The electronic alert system for AKI did not improve clinical outcomes in these wards.

FR-PO065

Assessment of the Renal Angina Index for Prediction of Severe AKI Prediction in Critically Ill Children

Rajit K. Basu,[1] Ahmad Kaddourah,[2] Stuart Goldstein.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]None, Doha, Qatar.*

Background: Acute kidney injury (AKI) occurs in one in four children admitted to the intensive care unit (ICU) and escalating AKI severity is independently associated with increased risk of patient morbidity and mortality. Early prediction of AKI has the potential to improve outcomes.

Methods: We conducted a multi-national, multi-center, prospective study of children admitted to the intensive care unit (ICU) between January-December 2014 with an expected length of stay ≥ 48 hours (NCT01987921). Our primary aim was to assess the performance of fulfillment of renal angina (RA+), a context-driven risk stratification system, on the day of ICU admission (Day_0) for prediction of severe AKI occurrence 3 days after ICU admission (Day_3). The primary outcome was the performance of renal angina for prediction of severe AKI three days after ICU admission (Day_3-severe AKI) by Stage 2-3 AKI KDIGO AKI guidelines. Renal angina was determined at 12 hours into Day_0 using the renal angina index (RAI); RA+ was defined as a RAI ≥ 8. The predictive performance of the Day_0-RAI was compared to changes in serum creatinine (SCr) (measured in the first 12 hours of ICU admission) relative to baseline (Day_0-SCr/Base).

Results: 1590 patients studied were 55% male and median age of 54.5 months. 286 patients (17.9%) were Day_0-RA+, 121 (42.3%) of whom developed Day_3-severe AKI (versus 247 (18.9%) of Day_0-RA- patients, relative risk (RR) 2.23; 95% confidence interval (CI): 1.87-2.66, p<0.001). Patients with Day_3-severe AKI (368, 23.1%) had increased utilization of renal replacement therapy (10.9% vs. 1.5%, p<0.001), and higher rate of Day_{28} mortality (7.6% vs. 4.3%, p=0.01) versus patients without Day_3-severe AKI. Day_0-RA+ demonstrated superior prediction for Day_3-severe AKI than SCr>Base (RR: 1.61; (1.33-1.93), p<0.001) and maintained this superiority with Day3-severe AKI on multivariate regression (independent odds ratio (OR): RA+ 3.21; 95% CI (2.20-4.67) vs. SCr>Base 0.68; 95% CI (0.49-4.94)).

Conclusions: Compared to isolated context-free changes in SCr, the RAI demonstrates improved accuracy for prediction of severe AKI in critically ill children and young adults. Earlier, more accurate prediction of severe AKI has the potential to improve AKI associated patient outcomes.

FR-PO066

Spectrum of AKI in Patients from Low Income Countries Participating in the ISN0by25 Initiative

Etienne Macedo,[4] Sanjib K. Sharma,[3] Ulla Hemmila,[2] Rolando Claure-Del Granado,[5] Jorge Cerda,[1] Emmanuel A. Burdmann,[7] Michael V. Rocco,[8] Ravindra L. Mehta.[6] *[1]Albany Medical College, Albany, NY; [2]College of Medicine, Malawi, Kokemäki, Finland; [3]B P Koirala Institute of Health Sciences, Dharan, Nepal; [4]UCSD, San Diego, CA; [5]Universidad Mayor de San Simon, School of Medicine, Cochabamba, Bolivia, Plurinational State of; [6]University of California San Diego Medical Center, San Diego, CA; [7]University of Sao Paulo Medical School, Sao Paulo, Brazil; [8]Wake Forest School of Medicine, Winston-Salem, NC.*

Background: The ISN0by25 Pilot Project is designed to evaluate the effects of an education and training program, point of care (POC) test and teleconsultation on the detection and management of AKI in low resource settings with the goal of reduce preventable deaths from AKI.

Methods: Study consist of 3 phases: observation, education, training and intervention over 1year. In the observation phase, patients presenting at a health care center (HCC) or hospital ER with signs and symptoms associated with moderate/high AKI risk underwent a serum creatinine (sCR) POC test and a urine dipstick. We assessed progression of AKI, need for RRT, hospitalization, mortality and kidney recovery at 7days, 1, 3 and 6 mo, and compared patient characteristics, management and outcomes.

Results: Of 851 adults enrolled, pt characteristics were different within the 3 countries (Table 1). Dehydration as an AKI risk factor was present in>85% of pts enrolled in Bolivia and Nepal, but only in 38% in Malawi. AKI was diagnosed at enrollment in 48%: 42% KDIGO AKI stage1, 20% stage2 and 38% stage3. Of 778 pts with discharge information, 35% were admitted to the hospital and 55% were observed in a HCC for a maximum of 24 hrs. 58% of patients received PO fluids, 62% IV fluids, 10% diuretics, and 2.7% were dialyzed. Mortality at discharge was 4.3% and increased to 10% at 3 mo. AKI pts had higher mortality rate at discharge (AKI 6% vs. non-AKI 2.5%, p=0.02) and at 3 mo (AKI 13% vs non-AKI 6%, p<0.001).

Conclusions: Risk factors for AKI varied according to the region and local health care delivery. Frequency of AKI and hospitalization were high in patients with high AKI risk across these low resource settings. sCR POC test helped to identify patients with higher risk for worse outcomes. This ongoing study will help to understand the profile of preventable deaths from AKI around the globe.

AKI in Patients Treated for Cancer: A Population-Based Cohort Study

Abhijat Kitchlu,[1] Eric McArthur,[2] Eitan Amir,[3] Christopher Booth,[4,2] Rinku Sutradhar,[2] Habeeb Majeed,[3] Danielle M. Nash,[2] Samuel A. Silver,[6] Amit X. Garg,[5,2] Christopher T. Chan,[1] Joseph Kim,[1,2] Ron Wald.[1] *[1]Nephrology, University of Toronto, Toronto, ON, Canada; [2]Institute for Clinical Evaluative Sciences, London, ON, Canada; [3]Princess Margaret Cancer Centre, Toronto, ON, Canada; [4]Medical Oncology, Queen's University, Kingston, ON, Canada; [5]Nephrology, Western University, London, ON, Canada; [6]Nephrology, Queen's University, Kingston, ON, Canada.*

Background: Patients undergoing treatment for cancer are at increased risk of acute kidney injury (AKI). There are few data on AKI incidence and risk factors in the current era of treatment.

Methods: Using linked administrative datasets, we conducted a population-level cohort study of all patients initiating systemic therapy (inclusive of chemotherapy and targeted agents) for a new cancer diagnosis in Ontario, Canada from 2007 to 2014. The primary outcome was hospitalization with AKI or acute dialysis. We estimated the cumulative incidence of AKI and fitted Cox proportional hazards models (accounting for the competing risk of death), adjusting for demographics, cancer characteristics, comorbidities and co-prescriptions. We modeled exposure to systemic therapy (the 90-day period following each treatment) as a time-varying covariate. We also assessed secular trends in annual AKI incidence according to year of systemic therapy initiation.

Results: We identified 163,071 patients initiating systemic therapy, of whom 10,880 were hospitalized with AKI. The rate of AKI was 27 per 1000 person-years (PY), with 1-, 5-year and overall cumulative incidences of 3.9, 7.8 and 9.3%, respectively. Cancers with the highest 5-year AKI incidence were myeloma (26%), bladder (19%), and leukemia (15%). Advanced stage, pre-existing chronic kidney disease (CKD), and diabetes mellitus (DM) were associated with increased risk of AKI [adjusted hazard ratios (aHR) 1.41 (95%CI 1.28, 1.45), 1.80 (95%CI 1.67, 1.93) and 1.43 (95%CI 1.37, 1.50), respectively]. In patients age ≥66 years, use of diuretics and angiotensin-converting enzyme inhibitors/ angiotensin receptor blockers (ACEi/ARBs) were associated with increased risk [aHR 1.20 (95%CI 1.14, 1.28) and 1.30 (95%CI 1.23, 1.38)]. AKI risk was significantly elevated in the 90 day period following systemic therapy exposure [aHR 2.34 (95%CI 2.24, 2.45)]. The annual incidence of AKI increased over time (from 18 to 52 per 1000-PY between 2007 and 2014).

Conclusions: Cancer-related AKI is common and associated with more advanced stage, CKD, DM and the concomitant receipt of diuretics or ACEi/ARBs. Risk is heightened in the 90 days after systemic therapy. Preventive strategies are needed to address the increasing burden of AKI in this population.

FR-PO068

Assessment of the Pathophysiology of AKI Using Magnetic Resonance Imaging

Huda Mahmoud,[1] Charlotte E. Buchanan,[2] Eleanor Cox,[2] Benjamin L. Prestwich,[2] Maarten W. Taal,[1] Susan Francis,[2] Nicholas M. Selby.[1] *[1]Center for Kidney Research and Innovation, Derby, United Kingdom; [2]Sir Peter Mansfield Imaging Centre, Nottingham, United Kingdom.*

Background: The pathophysiology of Acute Kidney Injury(AKI) in humans is not well delineated, in part due to limitations in current methods of renal imaging. Recent advances in Magnetic Resonance Imaging(MR) allow assessment of structural and functional changes relevant to kidney disease. We performed a multiparametric MR study to assess its utility and reproducibility in patients with AKI.

Methods: We studied 9 patients with AKI stage2/3(with no pre-existing CKD) and 13 healthy volunteers(HV). Patients underwent multiparametric renal MR scans at the time of AKI and 90d later. MR scans were performed on a 3T Philips Ingenia scanner. Structural assessments included renal volume, longitudinal-relaxation time(T_1) and Diffusion-Weighted Imaging(DWI) as markers of fibrosis and/or inflammation. Functional assessments included Arterial Spin Labelling(ASL) to measure renal perfusion and Blood Oxygenation Level Dependant Imaging(BOLD) as an indicator of renal oxygenation.

Results: AKI patients: mean 47±19yrs, baseline creatinine 78±14μmol/L, peak creatinine 467±254μmol/L. All achieved complete biochemical recovery(creatinine 88±17μmol/L) and 5 have had repeat scans at 90d. Renal volumes were significantly increased at time of AKI as compared to HVs(270±92ml vs 189±25ml respectively p=0.001). BOLD T_2*, cortical and medullary T_1 values were significantly increased in AKI patients at the time of injury compared to HVs. 90d post AKI renal volumes had reduced(210±75ml p=0.04), as had T_2*, cortical and medullary T_1 values. T_1 values at 90d remained significantly higher than the HVs(p<0.001).

Conclusions: This is the first study to use multiparametric MR in patients with AKI, assessing kidney function and structure at time of AKI and during recovery. The

increase in renal volumes and T_1 values at time of AKI may be indicate inflammation or oedema. The persistent increase in T_1 at 90d may represent persistent inflammation or fibrosis development. Importantly, persistent MR abnormalities at 90d despite complete biochemical normalisation show the potential of MR to better characterise recovery. Further studies are required to build on this initial pilot work, and determine how best multiparametric MR can be used to characterise the nature of renal injury in AKI and its recovery.

FR-PO069

Does the Ultrasound Intrarenal Resistive Index Have a Diagnostic and Prognostic Value in Acute Graft Dysfunction? Juan Carlos Ramirez-Sandoval,[2] Monica Chapa,[2] Tábata Cano-Gámez,[3] Elena López-Sosa,[5] Mariana Oria-y-Anaya,[4] E G. Ramírez-Gutiérrez,[3] Luis E. Morales-Buenrostro,[2] Ricardo Correa-Rotter.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, México city, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, MEXICO, Mexico; [3]Escuela de Medicina, Universidad Panamericana., Mexico, Mexico; [4]Escuela de Medicina, Universidad Panamericana, Mexico, Mexico; [5]Escuela de Medicina, Universidad Panamericana, México City, Mexico.*

Background: The intrarenal resistive index is commonly employed in kidney transplant recipients (KTR) with acute kidney injury (AKI) yet its clinical usefulness remains controversial. Our objective was to evaluate the prognostic performance of the resistive index in KTR with AKI after 1 year of follow-up. We also analyzed the relation between the index and graft histologic features.

Methods: Retrospective analysis of the resistive index measured at the time of renal graft biopsies performed due to AKI (rise in serum creatinine [SCr] ≥0.3mg/dL from baseline). We excluded KTR with shock, significant renal-artery stenosis, hydronephrosis, and perigraft-fluid collections with marked compression. All KTR were followed for at least 1 year after the AKI event.

Results: 91 KTR with AKI were included: 46 (51%) females, median age 36 yr (IQR 27-48), median time post kidney transplant 5.1 yr (IQR 2.1-9.2), median SCr at AKI 2.5 mg/dl (IQR 2.0-4.3), and 22 (24%) with a severe AKI (AKIN 3). The resistive index of arcuate arteries was higher in 13 (14%) KTR with graft loss caused by AKI as compared to 78 (76%) of KTR without graft loss (0.69± 0.11 Vs. 0.63±0.09 respectively, p=0.047) yet no differences were observed in the resistive index of interlobar or segmental arteries. SCr at AKI diagnosis and age of KTR were associated with a higher resistive index in segmental and arcuate arteries (p=0.002). The resistive index of all measured arteries was not useful to differentiate causes of AKI (Table) and was also not useful to predict graft outcomes (graft survival, requirement of dialysis during AKI episode or eGFR after AKI episode).

Conclusions: The resistive index is time consuming and not useful to define etiology or graft outcomes in KTR with AKI. Our results support that it should not be employed to evaluate acute kidney-graft dysfunction.

Area under the curve in ROC curve for resistive index and AKI etiology

Resistive index	Immunological rejection (n=41)	Acute tubular necrosis (n=8)	Calcineurin toxicity (n=8)
Interlobar	0.57	0.58	0.50
Arcuate	0.50	0.60	0.62
Segmental	0.49	0.53	0.51

*Other causes of aki were mixed [immunological+calcineurin toxicity or BK virus] (n=29), parvovirus (n=1), and prerenal with normal biopsy (n=4).

FR-PO070

AKI Following CABG versus PCI in Advanced CKD Patients Abduzhappar Gaipov,[4] Miklos Z. Molnar,[4] Praveen Kumar Potukuchi,[4] Keiichi Sumida,[2] Oguz Akbilgic,[4] Elani Streja,[1] Connie Rhee,[3] Robert B. Canada,[4] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[4] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]University of California Irvine, School of Medicine, Orange, CA; [4]University of Tennessee Health Science Center, Memphis, TN.*

Background: Previous studies reported that GABG is associated with reduced risk of mortality and repeat revascularization in mild-to-moderate CKD, ESRD, and in diabetics. However, the relative risk of acute kidney injury (AKI) associated with CABG vs. PCI in patients with advanced CKD is not clear.

Methods: We examined 655 US veterans with incident ESRD who underwent a first CABG or PCI up to 5 years prior to dialysis initiation. Stages of AKI following the procedures were classified according to the Acute Kidney Injury Network classification. The association of CABG vs. PCI with AKI was examined in multivariable adjusted logistic regression analyses.

Results: 472 patients underwent CABG and 183 patients underwent PCI. Mean age was 63.7 (SD=8.1) years, 99% were male, 76.5% were white, and 21.8% were African Americans. The pre-procedure eGFR and the incidence of AKI in the CABG vs PCI group were 36.4 (IQR=23.5–58.2) vs. 33.2 (IQR=20.6–48.6) ml/min/1.73m^2 and 75.2% vs 30.6%, respectively. The incidence of all stages of AKI were higher after CABG compared to PCI (Figure). CABG was associated with a 5.1-fold higher crude risk of AKI (odds ratio and 95%CI: 5.1, 2.9–8.8; p<0.001), which remained significant after multivariable adjustments (5.2, 2.9–9.2; p<0.001).

Conclusions: CABG was associated with a 5-fold higher risk of AKI compared to PCI in patients with advanced CKD. Despite other benefits of CABG over the PCI, the extremely high risk of AKI associated with GABG should be considered in this vulnerable population when deciding on the optimal revascularization strategy.

IgG4-Related Disease as a Cause of Urinary Tract Obstruction and AKI: A Case Report Suhaib A. Andrabi,[2] Beenish Noor,[2] Melissa C. Fajardo,[2] Olurntobi Rahaman,[1] Sudhanshu Jain,[2] Jeffrey D. Wallach.[2] *[1]Harlem Hospital Center, New York, NY; [2]Nephrology, Harlem hospital Center, New York, NY.*

Background: IgG4-related disease (IgG4-RD) is a fibroinflammatory condition with multisystem involvement. We report the case of a male admitted for with chronic abdominal pain who was found to have acute kidney injury, retroperitoneal fibrosis and hydroureteronephrosis.

Methods: A 61 year old male presented with a 4-month history of persistent lower abdominal pain, unintentional weight loss of ~15 kg over last year but no urinary complaints. Medical history significant for Hypertension, cerebrovascular accident and chronic kidney disease. Examination findings included a BP 163/101, lower abdomen tenderness and hyper pigmented skin macules on both shins. Initial investigations revealed BUN/Creatinine of 51 /7.9 (previous Creatinine 1.6 one year ago), leukocytosis, severe anemia, and thrombocytosis. Urinalysis was bland. Initial non-contrast Abdominal CT showed bilateral hydroureteronephrosis, perinephric stranding and mid-ureter compression by a soft tissue mass. Also noted was a tissue mass, suspicious for an acute hemorrhage from a aneurysmal infrarenal aorta and retroperitoneal fibrosis. A contrast CT scan ruled out a ruptured aneurysm. The patient underwent IR-guided nephrostomy tubes/stents with subsequent internalization. There was rapid improvement in renal function and Cr stabilized at ~2. The focus then shifted to evaluation of retroperitoneal fibrosis(RPF). Serum IgG4 levels were elevated [258, normal <121]. Flow cytometry showed no evidence oflymphoproliferative disorder or presence of blasts. Steroid therapy was initated. Biopsy of the retroperitoneal mass revealed extensively hyalinized and fibrotic soft tissue without evidence of fibromatosis or malignancy. Immunohistochemical analyses revealed plasma cells including IgG4 positive plasma cells. A renal biopsy was not performed due to hydronephrosis. Given patient's prompt response to treatment, he was discharged to follow up as outpatient.

Results:

Conclusions: IgG4-RD is now recognized as a link between many clinical entities that were previously regarded as organ-specific disorders. Obstructive uropathy occurs in about 45%-65% of reported patients with IgG4-related RPF. Management involves relieving the obstruction, halting progression of the fibrotic process and preventing recurrence. Obstructive uropathy with RPF should prompt a work up for IgG4-RD.

FR-PO072

Biomarkers for the Prediction of AKI Progression after Pediatric Cardiac Surgery Jason H. Greenberg,[4] Michael Zappitelli,[3] Yaqi Jia,[4] Heather Thiessen Philbrook,[4] Christina A. de Fontnouvelle,[4] Francis P. Wilson,[4] Steven G. Coca,[2] Prasad Devarajan,[1] Chirag R. Parikh.[5] *[1]Cincinnati Children's Hospital, Cincinnati, OH; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]McGill University Health Centre, Montreal Children's Hospital, Montreal, QC, Canada; [4]Yale University, New Haven, CT; [5]Yale University and VAMC, New Haven, CT.*

Background: The risk for adverse outcomes dramatically increase as children progress to higher stages of AKI. No reliable methods currently exist to predict AKI progression in hospitalized children.

Methods: The TRIBE-AKI pediatric study is a three-center prospective cohort of children, 1 month to 18 years old, undergoing cardiopulmonary bypass. Urine biomarkers of injury (neutrophil gelatinase–associated lipocalin (NGAL), interleukin (IL) 18 (IL-18), kidney injury molecule 1 (KIM-1), liver fatty acid binding protein (LFABP), albumin) and plasma biomarkers of inflammation (interferon (INF), IL-1, IL-2, IL-4, IL-6, IL-8, IL-10, IL-13, tumor necrosis factor alpha (TNF)) were measured on the first day of serum

creatinine defined AKI. AKI progression was defined as a worsening of AKIN stage; from stage I to stage II or III, from stage II to III, or stage III at any time.

Results: 408 children were enrolled, of which 176 (43%) were diagnosed with AKI. On the first day of AKI, Stage I, Stage II, and Stage III AKI was diagnosed in 145 (36%), 25 (6%), and 6 (1.4%) children, respectively. 28 (7%) children had AKI progression. On the first day of serum creatinine diagnosed AKI, 11/17 biomarkers were significantly higher in patients with AKI progression *vs* without (Table). Urine LFABP among injury biomarkers and plasma IL-8 among inflammatory biomarkers had the highest discrimination for AKI progression [optimism adjusted AUC 0.70 (95% CI:0.58-0.81) and 0.80 (95% CI:0.67-0.90), respectively].

Conclusions: Urine and plasma biomarkers predict AKI progression in children after cardiac surgery. If validated, these biomarkers could be used to improve clinical care and guide enrollment in therapeutic trials of AKI.

Funding: NIDDK Support, Veterans Affairs Support

Table: Biomarkers of AKI Progression

Biomarker	AKI Without Progression (N=148)	AKI With Progression (N=28)	P-value♦	Optimism Adjusted AUC (95% CI)*
Traditional Biomarkers				
Serum Cr Rise (%)	0.67 (0.5, 1)	0.8 (0.58, 1.33)	0.05	0.62 (0.49, 0.74)

♦ p-values obtained by the Kruskal-Wallace test. AUC, area under the curve. SE, standard error. * The optimism corrected AUC was estimated using a bootstrap procedure with 1000 replicates. The model fitted using the bootstrap dataset was applied to the original dataset as well as the bootstrap dataset. The average difference in predictive abilities is the optimism. The average optimism in AUCs was subtracted from the apparent AUC to get the optimism adjusted AUC.

FR-PO073

Evaluation of the Clinical Utility of Urinary Sediment in Predicting Prognosis of AKI Mingfeng Lee,[2] Masahiko Nagahama,[3] Yasuhiro Komatsu.[1]
[1]St. Lukes International Hospital, Tokyo, Japan; [2]Internal medicine, St. Luke's international hospital, Tokyo, Japan; [3]St. Luke's international hospital, Tokyo, Japan.

Background: Urinary sediment is helpful for differential diagnosis of acute kidney injury (AKI), but evidence is lacking whether urinary sediment findings are related to prognosis of AKI. In this study, we evaluate the relationship between urinary cast and prognosis of AKI.

Methods: We retrospectively collected the data from the patients who developed AKI during hospitalization at our hospital between April 2011 and March 2016. AKI was defined by KDIGO definition (either increase in S-Cr of ≥0.3 mg/dl within 48 hours or ≥50% within 7 days). Known risk factors for AKI, such as baseline CKD stage and comorbidities as well as urinalysis at the time of AKI were obtained. Patients with CKD stage 5, including on maintenance dialysis, received kidney transplantation, or age<18yr were excluded. We set our primary endpoint as "long term prognosis of AKI: recovery of renal function 3 months after AKI", and secondary endpoint as "short term prognosis of AKI: the receipt of renal replacement therapy (RRT) during the hospitalization". Baseline S-Cr level was defined as the lowest outpatient value within 6 months before admission. Risk factors for AKI were sought using univariate and multivariate logistic regression.

Results: We identified 833 patients for the study. The mean age of the patients was 68.4±16 (mean+/-S.D.) yr, the male ratio was 60.6%. Among them, 292 patients (35.1%) showed granular cast at the time of AKI, 51 patients (6.1%) needed RRT during hospitalization and 146 patients (17.5%) showed worsened renal function 3 months after AKI. On multivariate logistic regression analysis, baseline CKD stage was associated with both "long term prognosis of AKI" (OR=2.01, P=0.04) and "short term prognosis of AKI" (OR=8.95, P<0.001). In contrast, the presence of granular cast was associated with "short term prognosis of AKI" (OR=2.9, P=0.001), but was not with "long term prognosis of AKI" (P=0.26).

Conclusions: The presence of granular cast at the time of AKI can predict the need for RRT during hospitalization, but cannot predict recovery of renal function 3 months after AKI. Our study underscores the importance of urinalysis not only for diagnosis but also for "short term prognosis". Baseline renal function affects renal function recovery.

FR-PO074

Urine Injury Biomarker Level before and after AKI: Results from the CRIC Study and CKD Biomarker Consortium Chi-yuan Hsu,[8] Dawei Xie,[15] Xiaoming Zhang,[14] Joseph V. Bonventre,[1] Jing Chen,[7] Paul E. Drawz,[12] Harold I. Feldman,[13] Alan S. Go,[4] Edward J. Horwitz,[6] Paul L. Kimmel,[5] Mitchell R. Lunn,[10] Theodore E. Mifflin,[13] Ana C. Ricardo,[11] Sushrut S. Waikar,[2] Jingrong Yang,[3] Kathleen D. Liu.[9]
[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Kaiser Permanente, Oakland, CA; [4]Kaiser Permanente Northern California, Oakland, CA; [5]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [6]None, Solon, OH; [7]Tulane School of Medicine, New Orleans, LA; [8]University of California San Francisco, San Francisco, CA; [9]University of California at San Francisco School of Medicine, San Francisco, CA; [10]University of California, San Francisco, San Francisco, CA; [11]University of Illinois at Chicago, Chicago, IL; [12]University of Minnesota, Minneapolis, MN; [13]University of Pennsylvania, Wilmington, DE; [14]University of Pennsylvania School of Medicine, Philadelphia, PA; [15]University of Pennsylvania School of Medicine Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA.

Background: Change in serum creatinine (SCr) estimated glomerular filtration rate (GFR) may underestimate the renal sequelae of AKI since SCr rise after AKI may be blunted due to loss of muscle mass, decreased creatinine production, compensatory increase in single nephron GFR and other factors. Changes in levels of sensitive tubular injury biomarkers may capture more subtle persistent damage to the kidneys following an episode of mild-moderate AKI.

Methods: We studied a subset of Chronic Renal Insufficiency (CRIC) participants enrolled from Kaiser Permanente Northern California (KPNC) who had urine specimen banked as part of annual research study visits. We used data gathered as part of clinical care and captured in the KPNC electronic medical record to define episodes of AKI (peak/nadir inpatient SCr ≥1.5). We measured level of kidney injury molecule-1 (KIM-1) in urine samples collected at the annual CRIC study visit before the AKI episode and urine samples collected at the annual CRIC study visit after the AKI episode. We compared 29 participants with documented AKI (69% with KDIGO severity stage 1; 10% stage 2; 21% stage 3) with 157 participants who did not (matched for calendar year and time gap between first and second measurement [overall mean 419 days]).

Results: Overall, 70% of participants were female; 48% were white/39% black and 70% had diabetes mellitus; mean age was 63 yrs, eGFR 49 ml/min/1.73m^2 and urine albumin/Cr ratio (ACR) 21 mg/mg. Although there were no change in eGFR or ACR from pre-AKI to post-AKI (Table), rise in urine KIM-1/Cr was greater for patients who had AKI vs. those who did not (median delta 381 vs. 46 ng/g; p<0.002)(Table).

Conclusions: These data suggests there is persistent tubular injury months after an episode of mild to moderate AKI.

Persistent Elevation of Biomarkers of Dysregulated Mineral Metabolism and Inflammation after AKI: The ASSESS-AKI Study Kathleen D. Liu,[6] Chi-yuan Hsu,[6] Thida C. Tan,[2] Valerie Arends,[8] Amy Saenger,[8] Chirag R. Parikh,[11] Talat Alp Ikizler,[10] Jonathan Himmelfarb,[3] Mark M. Wurfel,[12] Vernon M. Chinchilli,[5] Paul L. Kimmel,[4] James S. Kaufman,[9] Alan S. Go.[2]
[2]Kaiser Permanente Northern California, Oakland, CA; [3]Kidney Research Institute, Seattle, WA; [4]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [5]Penn State College of Medicine, Hershey, PA; [6]University of California San Francisco, San Francisco, CA; [8]University of Minnesota, Minneapolis, MN; [9]VA New York Harbor Healthcare System, New York, NY; [10]Vanderbilt University Medical Center, Nashville, TN; [11]Yale University and VAMC, New Haven, CT; [12]University of Washington, Seattle, WA. Group/Team: For ASSESS-AKI Study Investigators.

Background: AKI is associated with dysregulated mineral metabolism and inflammation. However, it is unknown if these abnormalities persist after AKI.

Methods: ASSESS-AKI is a parallel cohort study of hospitalized patients with and without AKI enrolled in 2009-2015, with matching based on center, age, baseline chronic kidney disease status, diabetes mellitus, prior cardiovascular disease, baseline eGFR, and ICU/non-ICU status during the index admission. Plasma biospecimens were collected at the index hospitalization (V0) and at the first outpatient 3-month study visit (V3).

Results: Mean age of the 1,484 participants analyzed was 55 yr and 48% were women. Baseline eGFR (from prior to the index hospitalization) was 69 mL/min/1.73m^2. Compared to non-AKI patients, levels of parathyroid hormone (PTH), phosphorus, fibroblast growth factor-23 (FGF-23) and C-reactive protein (CRP) and were higher in AKI patients at both V0 and V3 (and higher among those with more severe AKI) (p< 0.001 for all comparisons). At V3, FGF-23 and phosphorus levels increased in both AKI and non-AKI participants, whereas CRP fell markedly (Table). In those with AKI,

PTH levels fell modestly from V0 to V3, whereas there was no difference in non-AKI participants.

Conclusions: Markers of dysregulated mineral metabolism and inflammation are elevated during an episode of AKI; among these biomarkers, FGF-23 remains elevated months later. These raise the possibility that persistently dysregulated mineral metabolism may link AKI to adverse outcomes after hospital discharge.

Funding: NIDDK Support

	V0 : AKI	V3: AKI	P value	V0: No AKI	V3: No AKI	P value
PTH	65 (41-103)	54 (38.5-81)	< 0.0001	48 (35-68.5)	47 (36-62)	0.17

FR-PO076

A Novel Biomarker for Detecting Both AKI and CKD Andrea Sanchez-Navarro,[3] Rosalba Pérez-villalva,[2] Juan M. Mejia-Vilet,[1] Nadyeli Linares,[2] Norma Bobadilla.[3] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico; [2]Molecular Physiology Unit, México, Mexico; [3]Molecular Physology Unit, MEXICO, DF, Mexico.*

Background: The early diagnosis of AKI and CKD undoubtedly will have a potential impact on the treatment of these pathologies and on the kidney health. This study was designed to provide a suitable method for overcoming the limitations of the procedures or methods previously used for the AKI and CKD diagnosis.

Methods: Abnormal presence of serpinA3K in urine samples from animals with CKD was identified by mass spectrometry. We evaluated the urinary serpinA3K in rats and in patients with AKI, as well as, the temporal course of serpinA3K presence during the AKI to CKD transition and in urines from patients previously diagnosed with CKD by renal biopsy and without renal dysfunction. For AKI model, 44 Wistar rats were divided in different periods of reperfusion: 3, 6, 9, 12, 18, 24, 48, 72, 96, or 120 h after renal bilateral ischemia (45 min) and compared to sham-operated rats; in addition, 20 rats were studied to evaluate different renal injury severity induced by 15, 30, 45 or 60 min of ischemia. For CKD model, 36 rats were divided in: sham operated (S) or nephrectomy plus left renal ischemia of 45 min (UNx+IR) groups; these rats were studied 1, 2, 3, or 4 months. Mean arterial pressure, creatinine clearance, and renal blood flow were determined. Urinary serpinA3K was evaluated in all these rats and in the urines from patients diagnosed with AKI or CKD.

Results: SerpinA3K was not detected in the urines from sham rats or healthy volunteers. In contrast, serpinA3K appeared in the rat urines and it increased proportionally to the AKI severity. This protein was detected since 3 h post-ischemia. Accordingly, abnormal urinary serpinA3K was found in patients with AKI. After 4 months, the UNx+IR rats developed CKD characterized by a progressive proteinuria, renal dysfunction and tubulointerstitial fibrosis. Interestingly, urinary serpinA3K, was detected since the 1st-month and progressively increased in the follow-up and correlated with the tubulointerstitial fibrosis. In CKD patients, urinary serpinA3K was significantly elevated without changes in serum creatinine.

Conclusions: We demonstrated that urinary serpinA3K is a promising and early biomarker to detect AKI, AKI to CKD transition and CKD from different etiologies. In addition, this biomarker could detect renal injury before renal dysfunction.

A Mechanism for Interstitial Nephritis Associated with "Checkpoint" Blockade: Unleashing Renal Microvascular Endothelial Cell (RMEC) Secondary Signals for T Cell Activation Kimberly A. Muczynski, Bairbre A. McNicholas, Susan K. Anderson, Maria E. Danoviz. *Medicine-Nephrology, University of Washington, Seattle, WA.*

Background: T cell activation is a two-step process: 1) T cell receptor recognition of an antigenic peptide presented by a HLA molecule; and 2) engagement of activating secondary signal molecules. The second step is actually more complex because antigen presenting cells may have both stimulatory and inhibitory molecules for T cell activation. A new approach for treating metastatic cancer is to block inhibitory second signals such as the programmed death-1 (PD-1) pathway, allowing T cells greater activation and killing of a tumor. We and others have identified cases of interstitial nephritis in patients treated with the new "checkpoint" blockers (eg nivolumab, pembrolizumab). Other work in the lab identified high levels of HLA class II molecules on RMEC of normal kidneys without inflammation. We have been puzzled by this due to the potential exposure of RMEC to circulating peptides; and we found that isolated RMEC activate T cells in a class II-peptide dependent manner. We hypothesize that RMEC express inhibitory second signals which limit their ability to activate T cells.

Methods: Ex-vivo renal T cells and RMEC from normal human kidneys were evaluated by flow cytometry for expression of inhibitory and stimulatory second signal molecules. An assay was developed using CD3-activated T cells with isolated RMEC to assess the role of second signal molecules.

Results: RMEC express activating secondary signal molecules CD58 and CD275; and inhibitory molecules CD274 (PDL1), CD273 (PDL2), CD276 (B7-H3) and B7-H4. Intrarenal T cells in normal human kidney express CD28, CD2, CD274 (PDL1) and CD279 (PD1). Blockade of PD-1 or its ligands, or B7-H4 enhance T cell activation measured as cytokine release and expression of CD69. Blockade of CD58 or CD2 decreases T cell activation.

Conclusions: A unifying interpretation of results is that RMEC, while capable of activating T cells when the appropriate peptide is presented, limit the strength of the response by the PD-1 pathway. Blocking the PD-1 pathway with checkpoint agents unleashes RMEC's stimulatory second signal molecules creating the potential for inflammation when there is an appropriate signal 1. We suggest interstitial nephritis develops when a RMEC-T cell signal 1 is engaged in the presence of checkpoint blockade.

Knockout of Interleukin-36 Receptor Protects Against Renal Ischemia-Reperfusion Injury through Reduction of Proinflammatory Cytokines Hirofumi Nishikawa, Tomohiro Eguchi, Masami Ogasawara, Tatsuki Matsumoto, Kazu H. Ode, Yoshiko Shimamura, Kosuke Inoue, Yoshinori Taniguchi, Taro Horino, Yoshio Terada. *Kochi University, Nankoku, Japan.*

Background: IL-36, a newly named member of the IL-1 cytokine family, includes 3 isoforms, IL-36α, IL-36β, and IL-36γ, all of which bind to a heterodimer containing IL-36 receptor (IL-36R). Little is known about the role of the IL-36 axis in acute kidney injury (AKI) pathogenesis. We examined IL-36 function using mice AKI model and clinical samples.

Methods: We evaluated IL-36 function in the bilateral renal ischemia-reperfusion injury (IRI) AKI model by using IL-36R knockout (KO) and wild-type (WT) mice. We at first evaluate the localization of IL-36R in WT mice kidney by confocal microscopy. The effects of IL-36α on NF-kB and Erk activities were examined in primary cultured renal tubular cells. In clinical study, we measured urine IL-36α in AKI patients, and immunohistological examination of IL-36α in AKI and minimal change renal biopsy sample.

Results: IL-36R was found to be expressed in the kidney mainly in proximal tubules. IL-36R KO mice had significantly lower PCr (0.41+0.12 versus 1.08 + 0.21 mg/dl), BUN (65.3+14.8 versus 158+31.5 mg/dl) and IL-6 (24.3 + 5.7 versus 39.6+7.9 pg/ml) at 24h after IRI compared to WT mice. Immunohistological examination showed mild tubular injury in IL-36R KO mice. IL-36α/β/γ levels were increased after IRI, and IL-36α was expressed in lymphocytes and renal tubular cells, but post-IRI mRNA levels of IL-6 and TNF-α were low in IL-36R KO mice. We found that IL-36R expression in radioresistant renal tubule-resident cells, but not hematopoietic bone marrow-derived cells, was essential for IRI pathology by bone marrow chimeras experiments. In primary cultures of renal tubular epithelial cells, IL-36α treatment upregulated NF-κB activity and Erk phosphorylation. Notably, in AKI patients, urine IL-36α levels were increased, and IL-36α staining in renal-biopsy samples was enhanced.

Conclusions: Our results demonstrate that IL-36α is upregulated in renal tissues in both mouse and human AKI, and that IL-36α stimulates NF-κB and Erk pathways and might induce cytokines such as IL-6 and TNF-α in AKI. Thus, IL-36α/IL-36R blockage could serve as a potential therapeutic target in AKI.

FR-PO079

Treatment with PD-1 Inhibitor Associated with AKI and Hypocalcemia: A Meta-Analysis of Clinical Trials Sandhya Manohar,[2] Panagiotis Kompotiatis,[2] Charat Thongprayoon,[1] Wisit Cheungpasitporn,[2] Sandra Herrmann.[2] *[1]Bassett Medical Center, Cooperstown, NY; [2]Mayo Clinic, Rochester, MN.*

Background: Programmed cell death protein 1 (PD-1) inhibitors, Nivolumab and Pembrolizumab, are novel agents approved for use in many cancers. However, their renal safety profiles have not yet been systematically studied. The objective of this meta-analysis was to assess the risks of electrolyte abnormalities and nephrotoxicity in patients treated with PD-1 inhibitors.

Methods: A literature search was performed using MEDLINE, EMBASE and Cochrane Database from inception through April 2017. We included clinical trials that monitored electrolyte levels and kidney functions during treatment with PD-1 inhibitors. Pooled risk ratio (RR) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method. The protocol for this study is registered with PROSPERO (CRD42017060579).

Results: 48 clinical trials (with a total of 11,482 patients), which had electrolytes and/or serum creatinine monitored, were enrolled. The overall pooled RRs of acute kidney injury (AKI) and electrolyte abnormalities in patients treated with PD-1 inhibitors were 1.86 (95% CI, 0.95-3.64) and 1.67 (95% CI, 0.89-3.12), respectively. Compared with non-nephrotoxic controls, the pooled RR of AKI in patients treated with PD-1 inhibitors was 4.19 (95% CI, 1.57-11.18). Pre-specified subgroup analysis demonstrated a significant association between PD-1 inhibitors and hypocalcemia with pooled RR of 10.87 (1.40-84.16). The pooled estimated incidence rates of AKI and hypocalcemia in patients treated with PD-1 inhibitors were 2.2% (95%CI: 1.5%-3.0%) and 1.0% (95%CI: 0.6%-1.8%). Among patients who developed AKI with PD-1 inhibitors, the pooled estimated rate of interstitial nephritis was 16.6% (95%CI: 10.2%-26.0%). When hypocalcemia occurred after treatment with PD-1 inhibitors, the pooled estimated rate of severe hypocalcemia was 13.0% (95%CI: 3.3%-39.4%).

Conclusions: Based on the findings of our meta-analysis, treatment with PD-1 inhibitors is associated with higher risk of AKI compared with non-nephrotoxic agents. Interstitial nephritis can occur 16.6% in patients with AKI following treatment with PD-1 inhibitors. In addition, treatment with PD-1 inhibitors is also associated with hypocalcemia.

FR-PO080

Vancomycin-Associated AKI Geeta G. Gyamlani,[3] Praveen Kumar Potukuchi,[3] Oguz Akbilgic,[3] Melissa Soohoo,[2] Elani Streja,[2] Keiichi Sumida,[1] Kamyar Kalantar-Zadeh,[2] Miklos Z. Molnar,[3] Csaba P. Kovesdy.[3] *[1]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [2]University of California Irvine, School of Medicine, Orange, CA; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Vancomycin is a tricyclic glycopeptide antibiotic that is currently the mainstay of therapy for serious infections due to methicillin-resistant staph aureus. Data on the nephrotoxic potential of this agent is still highly controversial and based on small studies and meta-analyses.

Methods: From a nationally representative cohort of >3.5 million US veterans with baseline eGFR ≥60 ml/min/1.73m², we identified 40,059 patients who received either intravenous vancomycin (N=24,461) or nonglycopeptide antibiotics (linezolid/daptomycin, N=15,598). We matched patients in the two groups by propensity scores calculated from patient demographics, comorbidities, baseline eGFR and mean arterial pressure, and nephrotoxic medication exposure. Associations of vancomycin vs. nonglycopeptides with the risk of incident AKI by AKIN stages was assessed in logistic regressions.

Results: Among 27,964 propensity-matched patients (13,982 in both groups), the mean age was 66±11 years and the mean baseline eGFR was 72 ml/min/1.73m², 97% were male, 20% African-American, 51% diabetic, 27% had CHF and 8% received vasopressors. Baseline characteristics were identical in patients receiving vancomycin and nonglycopeptides. There were a total of 2,656 (19%) AKI events in the vancomycin group and 2,814 (20%) in the nonglycopeptide group. AKI stage 1 was less common, but stage 3 was more common among patients on vancomycin (Figure). The odds ratios of AKI stages 1, 2 and 3 in patients on vancomycin vs. nonglycopeptides were 0.83 (0.78-0.89), 1.02 (0.90-1.15) and 1.71 (1.44-2.03), respectively.

Conclusions: Vancomycin use is associated with a higher risk of severe AKI.

FR-PO081

Preoperative Renin-Angiotensin System Inhibitors Increased AKI after Noncardiac Major Surgery Hyunjeong Cho,[3] Seokwoo Park,[3] Sejoong Kim,[1] Dong Ki Kim,[3] Kook-Hwan Oh,[3] Kwon Wook Joo,[3] Yon Su Kim,[2] Hajeong Lee.[2] *[1]Seoul National University Bundang Hospital, Seongnam, GYEONGGI-DO, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Hospital, Jongno- gu, SEOUL, Republic of Korea.*

Background: Many conflicting results have been reported on the association between preoperative renin-angiotensin system (RAS) inhibitors and postoperative acute kidney injury (AKI). In this study, we evaluated the impact of RAS inhibitors on postoperative AKI and mortality after noncardiac major surgery.

Methods: We analyzed a retrospective cohort of 50,897 adult patients (age≥18) underwent noncardiac major surgery from 2004 to 2013. Major surgery was defined as surgery duration more than 1 hour. Patients with chronic kidney disease (CKD) 5, nephrectomy and kidney transplantation were excluded. The primary outcome was postoperative AKI defined by the KDIGO creatinine criteria and initiation of dialysis within 14 days of surgery. The secondary outcomes were all-cause mortality within 30 days of surgery and length of hospital stay. Propensity scores matching and multivariable logistic regression analyses were performed.

Results: The patient mean age was 54.3 years, 44.5% were males. In overall, 2,686 (5.3%) patients developed AKI events after operation. RAS inhibitors were used in 1,486 patients. After propensity score matching, 2,955 patients were divided into two groups: using (n=1,469) or not using (n=1,486) preoperative RAS inhibitors. There were no differences in baseline parameters, including age, sex, body mass index, CKD stage, history of diabetes and the American Society of Anesthesiologists physical status. Preoperative RAS inhibitor use was associated with 50% higher risk of postoperative AKI (adjusted relative risk (RR): 1.501; 95% confidence interval (CI): 1.103-2.044; P = 0.01) after adjusting for potential confounders. In addition, RAS inhibitor use was related to prolonged hospitalization (P = 0.000). The 30-day mortality rate was 0.6%, with no significant difference between RAS inhibitor use and non-use (P = 0.149).

Conclusions: This large cohort study demonstrates that preoperative RAS inhibitors were associated with a higher risk of AKI, but not mortality. Withholding preoperative RAS inhibitors should be considered in the perioperative setting.

FR-PO082

Factors Associated with the Development of AKI in Patients Treated with Tenofovir Disoproxil Fumarate – The AKIT Study Adrian Liew,[1,2] Ru S. Lim,[1] See Cheng Yeo.[1] *[1]Renal Medicine, Tan Tock Seng Hospital, Singapore, Singapore; [2]Lee Kong Chian School of Medicine, Nanyang Technological University-Imperial College London, Singapore, Singapore.*

Background: Acute kidney injury (AKI) from renal tubular mitochondrial toxicity had been reported with Tenofovir Disoproxil Fumarate (TDF) treatment. Whilst impaired baseline renal function had been consistently found to be associated with TDF-related AKI, studies looking at other predictors for renal dysfunction had demonstrated conflicting results. The current study aims to determine the risk factors for the development of AKI in the largest known cohort of Asian patients undergoing TDF treatment for HIV and/or Hepatitis B (HBV).

Methods: This is a retrospective cohort study of 1700 patients treated with TDF from 2006-2015. AKI was identified using KDIGO definition, and time to AKI was defined as time from TDF initiation to renal dysfunction or when censored. Risk factors for AKI were compared using Cox regression, between patients who developed AKI and in whom renal function remained stable.

Results: Of the 1700 patients in the study population (87% Males, 75% Chinese, Age 44.5±12.6 years), TDF was initiated for treatment of HBV (n=185; 10.8%), HIV (n=1412; 83.1%) or HBV-HIV co-infection (n=103; 6.1%). AKI occurred in 226 (13.3%) patients, with a median time to AKI of 23.5 months. Risk factors for AKI included older age (HR=1.028, 95%CI [1.016, 1.039], p<0.0001), lower weight (HR=0.984, 95%CI [0.974, 0.995], p=0.004), diabetes (HR=2.000, 95%CI [1.405, 2.849], p<0.0001), hypertension (HR=1.823, 95%CI [1.349, 2.464], p<0.0001), Charlson score (HR=1.217, 95%CI [1.104, 1.342], p<0.0001), use of ACE-inhibitors (HR=2.125, 95%CI [1.420, 3.180], p<0.0001) and diuretics (HR=2.894, 95%CI [1.484, 5.643], p=0.002), and lower CD4 counts (HR=0.997, 95%CI [0.996, 0.998], p<0.0001). A lower baseline serum creatinine below 75umol/L appears to be protective (HR=0.936, 95%CI [0.924, 0.949], p<0.0001) whilst creatinine levels above 75umol/L increases the risk of AKI (HR=1.012, 95%CI [1.006, 1.018], p<0.0001).

Conclusions: AKI is not uncommon with TDF use. The incidence and association with impaired baseline renal function are consistent with published literature, though the threshold creatinine level of 75umol/L is a new finding. Predictors of a frail health state and factors that may affect baseline renal function appears to increase the risk of AKI. The use of ACE inhibitors and diuretics with TDF-associated AKI requires further investigation.

FR-PO083

Utility of a Vascularized Microphysiological 3D Model of Human Kidney Proximal Tubule for Predictive Tenofovir Toxicity Testing Ranita S. Patel,[3] Jonathan Himmelfarb,[1] Edward J. Kelly.[2] *[1]Kidney Research Institute, Seattle, WA; [2]University of Washington, Seattle, WA; [3]Seattle Children's Hospital, Seattle, WA.*

Background: Tenofovir is a nucleotide reverse transcriptase inhibitor indicated for the treatment of HIV/AIDS and chronic hepatitis B and used worldwide. Despite its widespread use, nephrotoxic side effects of tenofovir remain a concern. Following exposure to tenofovir in animal and human subjects, clinical markers of kidney injury are increased and associated pathophysiological changes in the kidney proximal tubule are observed. Since tenofovir enters proximal tubule cells via organic anion transporters (OAT) localized to the basolateral membrane and because cells in 2-dimensional cultures often fail to polarize, *in vitro* cellular toxicity studies have been unsuccessful.

Methods: Primary human proximal tubule cells (PTECs) and human umbilical vein endothelial cells (HUVECs) were cultured in dual channel 3-dimensional microphysiological systems (MPS) to simulate a vascularized proximal tubule for evaluation of tenofovir-induced toxicity. Probenecid, an OAT competitive inhibitor, was added to the HUVEC (vascular) channel in select MPS to assess its role in attenuating tenofovir influx and toxicity. Renal injury biomarkers were used to determine the severity of cellular damage: heme oxygenase-1 (HO-1) signal intensity was quantified following immunocytochemistry and kidney injury molecule-1 (KIM-1) effluent concentrations were measured by ELISA.

Results: Exposure of MPS cultured PTECs from three different tissue donors to 10μM tenofovir for 48 hours induced a 0.9-fold, 4-fold, and 7-fold rise in KIM-1 expression. When 2mM probenecid is concurrently added to the MPS vascular channel, only a 0.5-fold and 2-fold rise in KIM-1 expression is observed. Exposure of MPS cultured PTECs to 100μM tenofovir for 5 days resulted in HO-1 signal intensity 1.8 times that of controls.

Conclusions: These results suggest that our dual channel MPS can function as an ideal *ex vivo* model to investigate transporter-dependent toxicity. Future efforts include directly inhibiting tenofovir toxicity with the OAT-1 inhibitor probenecid in both HUVEC and PTEC channels to affect both basolateral membrane OATs and apical membrane MRP transporters. Additionally, measurement of drug concentration differentials across HUVEC and PTEC channels can confirm active tubular transport since the HUVEC channel acts as a surrogate capillary for tenofovir infusion.

Supratherapeutic Vancomycin Levels: Risk Factors and Outcomes Reza Zonozi,[1] Aozhou Wu,[2] Jung-Im Shin,[2] Alex M. Secora,[2] Josef Coresh,[2] Alex R. Chang,[3] Morgan Grams.[1,2] *[1]Department of Medicine, The Johns Hopkins University, Baltimore, MD; [2]Department of Epidemiology, The Johns Hopkins University, Baltimore, MD; [3]Geisinger Medical Center, Danville, PA.*

Background: Vancomycin is a commonly administered intravenous (IV) antibiotic, and supratherapeutic levels of vancomycin may be an avoidable cause of nephrotoxicity. The objective of this study was to investigate the frequency of, risk factors for, and outcomes after elevated levels of vancomycin.

Methods: There were 31,316 hospitalizations in which IV vancomycin was given between 2008 and 2014 among 21,166 people in the Geisinger Health System, a large, integrated, tertiary, rural health care system.

Results: There were 12,713 hospitalizations with vancomycin monitoring, and 1.24% of these hospitalizations had a vancomycin level >50 mg/L. Among hospitalizations with >7 days duration of therapy, 2.65% had a vancomycin level >50 mg/L. The risk of vancomycin levels >50 mg/L was higher with younger age, female sex, black race, pre-hospitalization diuretic use, an ICU stay, sepsis, concurrent use of piperacillin-tazobactam, and higher doses of vancomycin (Table). Neither BMI nor eGFR was associated with vancomycin levels >50 mg/dL in adjusted analysis. Length of stay, acute kidney injury (AKI), and in-hospital mortality were all higher among persons with vancomycin levels >50 mg/L.

Conclusions: We identified modifiable risk factors for Vancomycin levels >50 mg/L, which were associated with greater in-hospital mortality, AKI, and length of stay.

Funding: NIDDK Support

Adjusted Incidence Rate Ratio (IRR) of High Vancomycin Levels (>50 mg/L)

Predictor	IRR (95% confidence interval)	P-value
Age, per 10 years	0.76 (0.68 to 0.84)	<0.001
Sex (female)	1.40 (1.00 to 1.94)	0.049
Race (Black)	2.04 (1.00 to 4.15)	0.049
eGFR		
Spline < 60	1.02 (0.86 to 1.21)	0.85
Spline ≥ 60	1.09 (0.94 to 1.27)	0.243
ICU	1.90 (1.33 to 2.71)	<0.001
Sepsis	1.75 (1.26 to 2.42)	0.001
Use of pre-hospitalization diuretics	1.48 (1.00 to 2.19)	0.048
Concurrent use of piperacillin-tazobactam	1.44 (1.04 to 2.00)	0.029
Vancomycin dose (mg)		
≤1000	1 (ref)	-
1000-1500	2.83 (1.74 to 4.59)	<0.001
1500-2000	3.02 (1.76 to 5.18)	<0.001
>2000	3.08 (1.75 to 5.44)	<0.001

FR-PO085

Proton Pump Inhibitor Use and Risk of AKI: A Meta-Analysis of Observational Studies Yi Yang,[3] Gang Xu,[2] Shuwang Ge.[1] *[1]Tongji Hospital, Huazhong University of Science and Technology, WUHAN, China; [2]Tongji Hospital, Tongji Medical College, Huazhong Univ of Science and Technology, WUHAN, China; [3]Tongji hospital affiliated to Tongji medical college, Huazhong University of Science and Technology, Wuhan, Hubei, China, Wuhan, China.*

Background: Recent studies have suggested a potential increased risk of acute kidney injury (AKI) among proton pump inhibitor (PPI) users. However, the present results are conflicting. Thus, we performed a meta-analysis to investigate the association between PPI therapy and the risk of AKI.

Methods: EMBASE, PubMed, Web of Science and Cochrane Library databases (up to September 23, 2016) were systematically searched for any studies assessing the relation between PPI use and risk of AKI. Studies that reported relevant relative risks (RRs), odds ratios or hazard ratios were included. We calculated the pooled relative risks with 95% confidence intervals (CI) using a random effects model of the meta- analysis. Subgroup analysis was conducted to explore the source of heterogeneity.

Results: Seven observational studies (five cohort studies, two case-control studies) were identified and included, and a total of 513,696 cases of PPI use among 2,404,236 participants were included in the meta-analysis. The pooled adjusted RR of AKI in patients with PPIs use was 1.61 (95% CI, 1.16–2.22; I^2=98.1%). Furthermore, higher risks of AKI were found in several subgroups of cohort studies, participant's average age < 60 years, participants with and without baseline PPI excluded, sample size < 300,000, and number of adjustments ≥ 11. Subgroup analyses revealed that participants with or without baseline PPI excluded might be a source of heterogeneity.

Conclusions: PPI use could be a risk factor for AKI and should be administered carefully. Nevertheless some confounding factors might impact the outcomes. More well-designed prospective studies are needed to clarify the association.

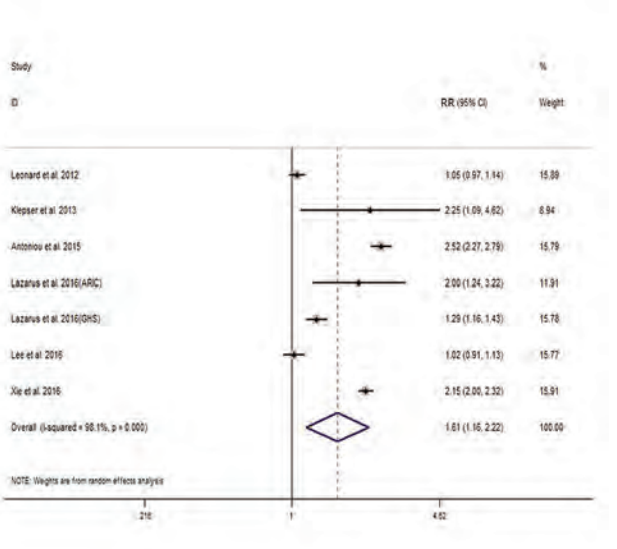

Figure 2 association between proton-pump inhibitors use and risk of acute kidney injury

FR-PO086

Renal Toxicities of Agents Used for CLL Rimda Wanchoo,[2] Vipulbhai Sakhiya,[2] John F. Katsetos,[3] Nishita Parikh,[2] Carolina Bernabe,[3] Jacqueline Barrientos,[1] Kenar D. Jhaveri.[2] *[1]CLL Research and Treatment Center, Lake Success, NY; [2]Nephrology, Hofstra Northwell School of Medicine, GREAT NECK, NY; [3]Heme/Onc, Hofstra Northwell School of Medicine, Lake Success, NY.*

Background: Drugs with novel mechanisms of action and targeted therapies are being explored in both the pre-clinical and clinical settings for chronic lymphocytic leukemia (CLL). A possible limiting complication for these agents could be their nephrotoxic potential.

Methods: We reviewed the FDA adverse event reporting system (FAERS) quarterly legacy data file 3rd quarter of 2014 to 2nd quarter of 2017 for all recently approved targeted agents for CLL. Well established chemotherapy agents used in CLL such as cyclophosphamide and fludarabine were excluded. The adverse event terms queried were: hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia, hypocalcemia, hypercalcemia, hyperkalemia, hypernatremia, hyperphosphatemia, proteinuria, renal failure acute, acute kidney injury, tumor lysis syndrome(TLS), hypertension, and nephritis. We reviewed the literature using pubmed, case series and the registrational studies of these agents for any reported nephrotoxicity. We compared renal toxicities of the newer agents such as ibrutinib, idelalisib, obinutuzumab, and venetoclax(to older targeted agents such as alemtuzumab and ofatumumab).

Results: The table here summarizes the drugs studied and results found. Ofatumumab, alemtuzumab and ibrutinib were the top three offenders with AKI as the most common finding reported followed by TLS and hyponatremia. The newer agents used to treat CLL had fewer renal toxicities than the older agents. The mechanism of AKI is likely related to TLS in most of these agents. The literature reviewed in the FAERS reported additional toxicities of the newer agents such as TLS with venetoclax that was fatal leading to early trial modifications.

Conclusions: Novel targeted agents are changing the CLL treatment paradigm with ensuing reports of nephrotoxic events such as AKI and TLS. As these drugs become more widely used, knowledge of novel agents used in CLL and their possible renal toxicities is important for the practicing nephrologists and the hematologists.

Table

Name	Renal injury	Hyponatremia	Hypokalemia	Hypophosphatemia	Hypomagnesemia	Hyperkalemia	Proteinuria	Tumor Lysis Syndrome	Grand Total
Alemtuzumab	25	4	0	0	0	0	3	1	33
Ofatumumab	29	7	6	0	0	3	0	16	61
Ibrutinib	9	9	5	4	1	3	0	6	37
Idelalisib	4	1	2	0	0	3	0	8	18
Obinutuzumab	10	0	0	1	0	1	0	8	20
Venetoclax	0	4	0	0	0	0	0	2	6

FR-PO087

AKI in Heart Failure Hospitalizations – National Trends and Outcomes Ankit Sakhuja, Kianoush Banaei-Kashani, Robert C. Albright. *Mayo Clinic, Rochester, MN.*

Background: Heart failure (HF) is an important cause of morbidity and mortality. Dialysis requiring acute kidney injury (AKI-D) is associated with worse outcomes in HF, however, longitudinal trends of AKI-D and its impact on mortality are unclear.

Methods: Using Nationwide/National Inpatient Sample from years 2000-2014, we identified patients with primary discharge diagnosis of HF and those with AKI-D by ICD-9-CM codes. We used linear regression to assess trends of AKI-D and multivariable regression models to estimate adjusted odds of AKI-D and mortality over time. Model for AKI-D was adjusted for patient age, sex, race, payer, admission day, history of peripheral vascular disease, coronary artery disease, hyperlipidemia, stroke, diabetes, chronic kidney disease, hypertension, presence of cardiogenic shock, use of balloon pump, mechanical ventilation, hospital location, teaching status, volume, bed-size and region. Model for mortality was also adjusted for AKI-D and interaction between year and AKI-D.

Results: Of 15,092,707 HF hospitalizations, 149,468 (0.99%) had AKI-D. Patients with AKI-D were <80 years old (77% vs 60.5%; p<0.001), males (55.6% vs 47.8%; p<0.001) and whites (70.5% vs 60.0%; p<0.001). Incidence of AKI-D increased from 0.5% in 2000 to 1.5% in 2014 (p<0.001 for trend). Odds of developing AKI-D steadily increased to nearly 4 times by year 2014 (Fig 1a). Though, odds of mortality due to AKI-D decreased steadily, AKI-D continued to be independently associated with 3.67 times higher mortality even by year 2014 (Fig 1b).

Conclusions: AKI-D is seen in about 1% HF hospitalizations, however, the risk of AKI-D in these admissions on the rise. Though the impact of AKI-D on mortality is decreasing, it is still a significant risk factor for mortality in HF admissions.

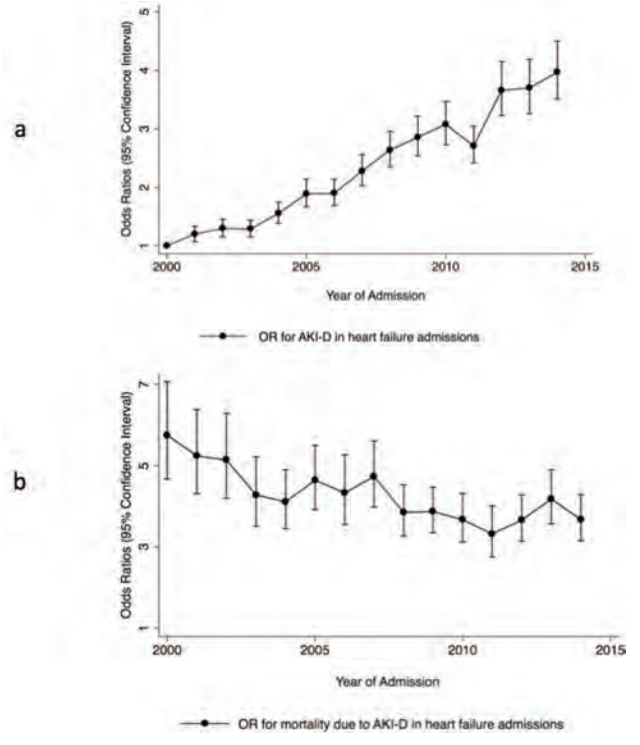

Fig1: OR for AKI-D(a) & its impact on mortality(b)

FR-PO088

Pre-Admission Proteinuria Increases Risk of Non-Recovery after Dialysis-Requiring AKI Benjamin J. Lee,[3] Alan S. Go,[4] Rishi V. Parikh,[4] Thomas Leong,[1] Thida C. Tan,[4] Sophia Walia,[2] Raymond K. Hsu,[3] Kathleen D. Liu,[6] Chi-yuan Hsu.[5] *[1]KPNC, Oakland, CA; [2]KPNC, Oakland, CA; [3]UCSF, San Francisco, CA; [4]KPNC, Oakland, CA; [5]UCSF, San Francisco, CA; [6]UCSF, San Francisco, CA.*

Background: Renal recovery after dialysis-requiring acute kidney injury (AKI-D) is an important clinical and patient-centered outcome. We examined whether pre-AKI-D proteinuria level is an independent risk factor for non-recovery within a diverse, community-based population.

Methods: We evaluated all adult members of Kaiser Permanente Northern California who experienced an episode of AKI-D between 1/1/2009 and 9/30/2015. Pre-admission dipstick proteinuria level was identified ≤4 years before hospitalization. Renal recovery was defined as alive and dialysis-independent ≥4 weeks at 90 days after starting renal replacement therapy. Baseline estimated glomerular filtration rate (eGFR), age, gender, race, short-term predicted risk of death, relevant comorbidities, and medication use were identified from electronic health records.

Results: Among 5,347 adults with AKI-D, mean age was 66 years, 59% were men, and 50% were white. In multivariable logistic regression, compared with negative/trace proteinuria, adjusted odds ratios for non-recovery were 1.47 (95%CI 1.19-1.82) for 1+ proteinuria and 1.92 (1.54-2.38) for ≥2+ proteinuria. Among survivors, crude probability of recovery ranged from 83% for negative/trace proteinuria with baseline eGFR >60 mL/min/1.73m^2 to 25% for ≥2+ proteinuria with eGFR 15-29 mL/min/1.73m^2 (Figure).

Conclusions: Dipstick proteinuria was a graded, independent risk factor for non-recovery after AKI-D and contributes to short-term risk stratification and prognostication in combination with baseline eGFR. Pre-AKI-D proteinuria information is important for appropriately counseling patients and planning follow-up care.

Funding: NIDDK Support

Figure. Crude probability of recovery conditional on survival, by baseline eGFR and proteinuria level. χ^2 tests compared the 3 proteinuria levels within each eGFR category.

Multicenter Evaluation of the Selective Cytopheretic Device (SCD) in Critically Ill Children Requiring CRRT: Report from the First 4 Patients Stuart Goldstein,[1] David T. Selewski,[1] David J. Askenazi,[1] Patrick D. Brophy,[1] Theresa A. Mottes,[1] Tara C. Terrell,[1] Matthew L. Paden,[1] H. David Humes.[2] *[1]Prospective Pediatric AKI Research Group, Cincinnati, OH; [2]University of Michigan Medical School, Ann Arbor, MI.*

Background: Critically ill children and adults who develop AKI requiring CRRT are at increased risk of death. In a randomized trial, adult pts on CRRT treated with the SCD, who maintained CRRT-SCD circuit ionized Ca (iCa) <0.4 mmol/L, had improved survival/dialysis independence. An CRRT-SCD circuit iCa< 0.4 mmol/L promotes an immunomodulatory effect in animal models of inflammation. We are conducting an FDA grant sponsored safety evaluation of the SCD in 16 critically ill children and report our experience with the first 4 treated patients.

Methods: 5 center US study of the SCD in children (>20 kg, ≤22 years) with AKI and multi-organ failure receiving CRRT as part of standard of care. The SCD is integrated into the CRRT circuit post CRRT membrane (Figure), changed daily, and CRRT-SCD circuit iCa is maintained <0.4 mmol/L. Pts receive SCD treatment for up to 7 days or CRRT discontinuation, whichever comes first.

Results: 4 pts (2F/2M) were enrolled since 12/2016 and completed SCD therapy. Age range = 12.5-17.5 years, PRISM-2 Score range = 2-14. Admission diagnoses were severe rhabdomyolysis(1), septic shock(1) STEC HUS(1) and pneumonia(1). Pts received 3 (1), 4 (1) and 7 (2) days of SCD therapy. Circuit iCa has been maintained at <0.4 mmol/L in 95% of assessments. All pts survived and were off RRT at hospital discharge. No SCD-related serious adverse events occurred. Evidence of hemolysis (increased LDH, thrombocytopenia) reversed within 24 hours of SCD therapy in the 2 pts with hemolysis at SCD initiation.

Conclusions: Our initial data suggest the SCD is safe in children. While we cannot make any efficacy claims, the unepxected early reversal of hemolysis in 2 pts may suggest a role for the SCD in mitigating leukocyte related endothelial damage.

Low-Density Lipoprotein Receptor-Related 2 (Megalin) as Target Antigen in Human Kidney Anti-Brush Border Antibody Disease Claire Trivin-Avillach,[1] Christopher P. Larsen,[2] Paige A. Coles,[1] A. Bernard Collins,[3] Michael Merchant,[4] Hong Ma,[1] Daniel W. Wilkey,[4] Josephine M. Ambruzs,[2] Nidia C. Messias,[6] Nicholas Cossey,[2] Ivy A. Rosales,[3] Thomas D. Wooldridge,[5] Patrick D. Walker,[2] Robert B. Colvin,[3] Jon B. Klein,[4] David J. Salant,[1] Laurence H. Beck.[1] *[1]Boston University Medical Center, Boston, MA; [2]Arkana Laboratories, Little Rock, AR; [3]Massachusetts General Hospital, Boston, MA; [4]University of Louisville Medicine, Louisville, KY; [5]Nephrology & Hypertension Associates, LTD, Tupelo, MS; [6]Nephrology Associates, PLC, Little Rock, AR.*

Background: Acute kidney injury (AKI) has a broad differential diagnosis. Autoimmune diseases against glomerular antigens are well recognized but tubular injury as a result of direct immunologic insult is not part of the routine evaluation. We report a cohort of patients with a distinct, underappreciated kidney disease characterized by kidney anti-brush border antibodies and renal failure (ABBA disease).

Methods: Ten cases of ABBA disease were identified that had a combination of proximal tubule damage, IgG-positive immune deposits in the tubular basement membrane, and circulating antibodies reactive with normal human kidney proximal tubular brush border. Immunoblotting of a protein extract from human tubular cells was performed with serum from cases and controls, and immunoprecipitation followed by mass spectrometry was used to identify the protein targeted by the anti-brush border antibodies. Cell expression of recombinant protein followed by immunoblotting and immunoprecipitation was used to confirm the identity of the antigen.

Results: Patients with ABBA disease were elderly (mean age 72.9 years), presented with acute kidney injury (median serum creatinine 4.0 mg/dl) and moderate proteinuria. The kidney biopsy showed acute tubular injury with apical cytoplasmic blebbing, loss of brush border, regenerative changes and granular IgG and C3 deposits along tubular basement membranes. All patient sera were reactive to the proximal tubular brush border on sections of normal human kidney. Serum from all patients but not controls recognized a high molecular weight protein in renal tubular protein extracts that was identified as low-density lipoprotein receptor-related 2 (LRP2) by immunoprecipitation and mass spectrometry. Recombinant expression of an N-terminal recombinant fragment of LRP2 was used to confirm this finding by Western blot and immunoprecipitation. LRP2 specifically co-localized with IgG in the tubular immune deposits.

Conclusions: We present the first case series detailing the clinicopathologic findings of patients with ABBA disease and show that the antigenic target of these autoantibodies is LRP2.

AKI in Pregnancy and the Puerperium Catherine Brumby, Graeme Duke, Elizabeth Low, Lawrence P. McMahon. *Eastern Health Clinical School, Monash University, Melbourne, VIC, Australia.*

Background: Acute kidney injury (AKI) either during pregnancy or postpartum is associated with significant maternal and neonatal morbidity. Past population-based studies (1999-2011) in US and Canada suggest the incidence may be increasing, with contributing factors including increasing rates of hypertensive disorders of pregnancy (HDP) and CKD. We aim to determine recent developments in this apparent trend.

Methods: All public hospital admissions with pregnancy >20 weeks gestation in Victoria, Australia (2006-2016) were identified by ICD-10 diagnostic codes from a validated administrative database. Analysis included 560,778 antenatal and postpartum admissions, of which 533,876 included delivery. Trends in AKI incidence and associated risk factors were examined, and multivariate logistic regression determined whether changes in risk factors explained observed temporal changes.

Results: The incidence of AKI per 10,000 deliveries rose from 2.37 in 2006 to 11.59 in 2016, p<0.001. Of the 499 AKI cases, 228(45.6%) also had CKD, 22(4.4%) required renal replacement therapy, and 3(0.6%) died. The strongest risks factors associated with AKI were CKD, HDP, diabetes, and critical care admission. After adjustment, the temporal relationship for AKI risk was maintained, with risk factors being CKD, HDP, and sepsis.

Conclusions: The incidence of obstetric-related AKI continues to rise. This trend persists after adjusting for factors such as HDP, CKD and maternal age. Other, as yet unidentified or unmeasured factors may be implicated, such as greater awareness and reporting of AKI and increasing complexity of maternal comorbidities. Longterm risks of obstetric-related AKI remain to be determined.

Risk Factors Assocated with Obstetric AKI: Logistic Regression Analysis

Risk Factor associated with AKI	Deliveries, number	AKI rate per 10,000 deliveries	Unadjusted OR (95% CI)	Adjusted OR* (95% CI)
Year of admission	560,778	n/a	1.16 (1.10-1.24)	1.11 (1.07-1.14)
Maternal age per 5yr	560,778	n/a	1.33 (1.18-1.50)	1.15 (1.04-1.28)
CKD	228	1842.1	473.9 (318.1-578.3)	37.5 (23.6-59.6)
Chronic HT	3,123	124.9	49.8 (28.17-88.03)	ns
Pre-existing diabetes	1,376	174.4	43.38 (29.23-64.41)	1.69 (1.21-2.36)
GH/Pre-eclampsia (HDP)	36,309	74.6	16.05 (4.69-12.27)	12.32 (9.63-15.76)
Sepsis	22,631	40.7	7.59 (4.69-12.27)	7.32 (5.32-10.08)
Postpartum haemorrhage	73,589	20.1	2.76 (2.01-3.8)	2.33 (1.86-2.92)
Caesarean delivery	155,734	18.2	3.22 (2.15-4.83)	2.02 (1.54-2.64)
Prematurity <33 weeks	13,491	54.84	7.27 (5.68-9.31)	not entered
Critical Care admission	1,412	687.0	153.4 (95.9-245.4)	not entered

MA-0204 Modulation of PPARδ Promotes Recovery after AKI in Normal and Aged Proteinuric Diabetic CKD Zsf1 Rats by Enhancing Fatty Acid Oxidation in Proximal Tubular Epithelial Cells Christina Bracken,[2] Katelyn Pulito,[2] Jeff H. Stanwix,[2] Hien G. Hoang,[2] Silvia B. Campos-bilderback,[1] Ruben M. Sandoval,[1] Bruce A. Molitoris,[1] Effie Tozzo.[2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Mitobridge, Cambridge, AL.*

Background: Ischemic acute kidney injury (AKI) is characterized by persistent proximal tubule mitochondrial dysfunction. Due to their highly oxidative metabolism, proximal tubule cells utilize fatty acids to generate the energy required for their specialized function. We hypothesized that enhancing fatty acid oxidation (FAO) with a PPARδ modulator will restore mitochondrial function and offer a potential therapeutic treatment for AKI.

Methods: Human hTERT RPTECs were treated with MA-0204 and analyzed for PPARδ target gene expression and their ability to utilize palmitate. Sprague-Dawley (SD) rats underwent ischemia-reperfusion (IR) AKI and were treated orally with 30 mg/kg of selective PPARδ modulator MA-0204 for 2 days. EPO served as positive control and was dosed IV at 1000 U/kg 30 minutes prior to ischemia. We also tested this hypothesis in aged (18 week old), diabetic and proteinuric CKD Zsf1 rats, a preclinical model that presents with similar comorbidities as diabetic-chronic kidney disease (CKD) patients.

Results: MA-0204 significantly increased expression of PPARδ-target genes associated with mitochondrial FAO (such as *Cpt1a)* and increased palmitate oxidation in RPTECs. In rats, MA-0204 treatment significantly reduced plasma creatinine (69%), BUN (62%), fractional excretion of Na^+ (82%) and restored creatinine clearance (800%) 24 and 48 hours post AKI. MA-0204 treated rats had significantly improved histopathology scores, normalized expression of kidney injury related genes (KIM-1, NGAL), and reduced urinary injury biomarker levels ([TIMP2]*[IGFBP7], FABP-1). Importantly MA-0204 attenuated AKI in diabetic proteinuric CKD Zsf1 rats, resulted in a decrease of plasma creatinine levels (33%), accelerated recovery of creatinine clearance and reduced urinary TNFR1, an indicator of CKD progression.

Conclusions: Our data demonstrates that enhancing fatty acid oxidation and improving mitochondrial function, through PPARδ modulation, following ischemic kidney injury is sufficient to recover renal function, reduce tubular injury and promote recovery in SD as well as in aged, diabetic, proteinuric CKD Zsf1 rats.

FR-PO093

AKI after Severe Burn Audra T. Clark,[4] Rohan Kulangara,[7] Xilong Li,[1] Tarik D. Madni,[6] Jonathan Imran,[5] Steven E. Wolf,[3] Javier A. Neyra.[2] *[1]UT Southwestern Medical Center, Dallas, TX; [2]University of Kentucky Medical Center, Lexington, KY; [3]University of Texas - Southwestern Medical Center, Dallas, TX; [4]University of Texas Southwestern, Dallas, TX; [5]University of Texas Southwestern Medical Center, Dallas, TX; [6]University of Texas Soutwestern, Dallas, TX; [7]Ut Southwestern medical center, Dallas, TX.*

Background: Acute kidney injury (AKI) is a common and morbid complication in patients with severe burn. We aim to examine the incidence, onset, severity, and mortality of AKI after thermal injury.

Methods: A retrospective cohort study of adults with thermal injury admitted to the Burn ICU from 2008-2015 was conducted. Patients with preexisting ESRD, kidney transplant, eGFR<15, or absent serum creatinine (SCr) data were excluded. AKI was defined by SCr-KDIGO criteria. The onset of AKI ≤7 days vs >7 days from ICU admission were used to define early vs late AKI, respectively. Patient- and burn-specific characteristics among those with or without AKI were compared. Multivariable logistic regression with AKI as the independent variable and hospital mortality as the dependent variable was utilized.

Results: 1040 patients with thermal injury were included in the study. Mean (SD) age was 48.9 (18.9), 70.5% were men and 16.4% black. The median total body surface area (TBSA) of burn was 16% (IQR: 6-29%). AKI was present in 617 (59%) patients, KDIGO stages: 1, 59.3%, 2, 20.3%, 3, 11.3%, 3D, 9.1%. Early AKI was present in 551/617 (89%) of patients. Patients with AKI had larger TBSA burn (median 20.5% vs 11.0%, p<0.001), received more mechanical ventilation days (median 2.0 vs 0.0, p<0.001), and stayed longer in the hospital (median 21.0 vs 10.0 days, p<0.001). Hospital mortality was higher in those with AKI vs those without AKI: 19.7% vs 4% (p<0.001) and increased by each KDIGO stage (p trend<0.001). AKI was independently associated with hospital mortality

(early AKI vs. no AKI adjusted OR 8.69, 95% CI 4.20–18.0; late AKI vs. no AKI adjusted 4.78, 1.61–14.15; early AKI vs. late AKI 1.82, 0.74–4.46). Other independent predictors of hospital mortality were age, TBSA, black race, mechanical ventilation, and inhalational injury.

Conclusions: AKI occurs frequently in patients after thermal injury and portends increased mortality. Further investigation is indicated to develop risk-stratification tools and examine AKI recovery patterns in this susceptible population.

FR-PO094

TissueFAXS Analysis as an Experimental Tool for Assessing the Degree of Intrarenal Lymphocytes Infiltration Minjung Kim,[1] Su Hyun Kim,[2] Junseok Jeon,[1] Jung eun Lee,[1] Wooseong Huh,[1] Yoon-Goo Kim,[1] Dae Joong Kim,[1] Ha Young Oh,[1] Hye Ryoun Jang.[1] *[1]Samsung medical center, Seoul, Republic of Korea; [2]samsung medical center, Seoul, Republic of Korea.*

Background: Intrarenal infiltration of immune cells is an established pathogenic mechanism in various inflammatory kidney diseases. Quantitative analyses of intrarenal immune cells, especially intrarenal lymphocytes, using flow cytometry analysis of kidney mononuclear cells (KMNCs) have been used as a precise and useful diagnostic method in a murine model of ischemic acute kidney injury (AKI). However, flow cytometry analysis of KMNCs is not feasible in patients because sufficient amount of renal tissue required for this method cannot be obtained with kidney biopsy. In this study, we investigated the diagnostic potential of tissueFAXS as a tool assessing the degree of intrarenal lymphocytes infiltration.

Methods: A total of 10 cynomolgus monkeys with various renal function were included. Kidney samples for flow cytometry analysis of KMNCs and immunohistochemistry were collected simultaneously. Flow cytometry analysis of KMNCs were performed using FACS verse. Immunohistochemistry of CD3, CD20, and CD45 on formalin-fixed kidney tissues were performed and followed by tissueFAXS analysis. The proportion of lymphocytes positive for each CD marker was acquired using different denominators as follows: kidney mononuclear cells isolated with percoll in flow cytometry vs. all nucleated cells stained with hematoxylin in tissueFAXS. Linear regression analysis was used to compare the association of CD3, CD20, and CD45 (+) lymphocytes evaluated with two different methods.

Results: Flow cytometry and tissueFAXS analyses showed positive correlation with CD45 (+) lymphocytes (R^2 =0.5378, P=0.0245). There was a positive correlation between the proportion of both CD3 (+) T cells (R^2 =0.8120, P=0.0002) and CD20 (+) B cells (R^2 =0.4587, P=0.0650). The ratio of CD3 (+) T cells and CD20 (+) B cells measured with both methods also showed positive correlation (R^2 =0.5144, P=0.0296).

Conclusions: Our study showed significant positive correlation of intrarenal CD3, CD20, and CD45 (+) lymphocytes measured with flow cytometry and tissueFAXS in cynomolgus monkeys. These results suggest that immunohistochemistry followed by tissueFAXS analysis may be used as a diagnostic tool performing semiquantitative evaluation of intrarenal lymphocytes in patients.

FR-PO095

AKI Detection Using a Novel 5-Plex Panel Candace M. Adamo,[1] Timothy H. Carlson,[1] Eibhlin M. Mccole,[2] Marie Mcgarvey,[2] Ciaran Richardson,[2] Peter Fitzgerald,[3] John Lamont,[3] Amar Sethi.[1] *[1]Pacific Biomarkers, Seattle, WA; [2]Randox Teoranta, Dungloe, Ireland; [3]Randox Laboratories Limited, Crumlin, United Kingdom.*

Background: Acute kidney injury (AKI) is classified using serum creatinine and urine output. However, since creatinine is a lagging index of impending AKI, studies are now underway to qualify a set of biomarkers for detecting drug-induced kidney injury (DIKI) in clinical trials. Since assessment of renal injury using multiple biomarkers is more clinically discriminating than single biomarker analysis, we report here the development and optimization of the first human multiplex for determining early and robust diagnosis of AKI.

Methods: Randox Biochip Array technology was used to develop a multiplex immunoassay panel for the below biomarkers. Performance goals for the multiplex were established by testing >1000 subjects using the predicate ELISA methods for KIM-1, NGAL, cystatin C, clusterin, and osteopontin (OPN). Functional sensitivity, cross reactivity, and interference were assessed, along with a sample correlation in 30 subjects.

Results: The 1000 patient samples provided dynamic ranges of 31.3-4000pg/mL; 1-100ng/mL; 1.5-150ng/mL; 10-1000ng/mL; 80-8000ng/mL for KIM-1, NGAL, cystatin C, clusterin, and OPN, respectively. The functional sensitivity was confirmed for all analytes at the low end of the dynamic range as the precision of the lowest non-zero standard was <20%CV for all five biomarkers (n=6). The effective upper limits of measurement, determined by calculating precision of the highest standard were <10%CV. There was no significant cross reactivity (<1% cross reactivity or <10% interference) for any of the analytes when spiked with x10 concentration of the highest standard of the other panel antigens. Cross reactivity from non-panel proteins were tested for cystatin C, clusterin and KIM-1 showing no significant cross-reactivity. Method comparison between the two methods provided correlations (r^2) of 0.927; 0.962; 0.872; 0.812; 0.899 for KIM-1, NGAL, cystatin C, clusterin and OPN, respectively. Slopes were 0.994, 0.544, 0.636, 1.67, and 0.685, respectively.

Conclusions: The AKI multiplex panel simultaneously detects KIM-1, NGAL, cystatin C, clusterin, and OPN with a solid performance and improved dynamic ranges compared to the predicate ELISA methods. This multiplex panel provides a robust and cost-effective solution for detecting DIKI in, not only, clinical trials, but potentially also in kidney patients for future diagnostic use.

FR-PO096

Clinical Factors Associated with Progression from Acute Mesoamerican Nephropathy to CKD Rebecca S. Fischer. *Baylor College of Medicine, Houston, TX.*

Background: Greater than 20,000 deaths in Central America have been attributed to the epidemic of Mesoamerican nephropathy (MeN). Men is a mysterious kidney disease of unknown etiology that disproportionately affects young agricultural workers without traditional risk factors for kidney disease. MeN had been characterized as a chronic kidney disease (CKD) until we recently documented an acute clinical scenario, characterized by acute kidney injury (AKI) with interstitial nephritis and markers of systemic inflammation, namely neutrophilic leukocytosis and leukocyturia. We also observed that some patients, but not all, later progressed to CKD.

Methods: We conducted an analysis to identify clinical characteristics of acute MeN that predict progression to CKD. Using univariate analysis, we compared patients with acute MeN who developed CKD to those who did not to identify clinical risk factors for CKD. Physicians at a private hospital in Nicaragua completed case reports detailing acute clinical encounters on cases of MeN and provided follow-up data on subsequent CKD diagnoses.

Results: From Feb 2015-Jan 2017, 468 cases of acute MeN were reported, mostly male (91%) and young (median age 27 yrs). Most (92%) had acute kidney injury (AKI). Frequent acute symptoms were fever (62%), nausea/vomiting (72%), back pain (61%), and headache (52%). Leukocytosis (80%), neutrophilia (84%), lymphopenia (53%), elevated C-reactive protein (76%), and anemia (59%) were common, along with leukocytes (99%) and leukocyte casts (30.2%) in urine. 30 patients (6%) progressed rapidly (median 90 days) to CKD, with half (51%) progressing to ≥Stage 3 CKD. We found that age >25 years (Prevalence Ratio [PR] 2.90 [1.03, 8.19], p=0.045), hyperuricemia (2.56 [1.26, 5.21], p=0.010), anemia (3.37 [1.31, 8.67], p=0.012) and hyponatremia (PR 3.20 [1.46, 7.02], p=0.004) were associated with CKD. Leukocytosis (PR 0.39 [95%CI 0.19, 0.81], p=0.012) and leukocyturia (PR 0.36 [0.17, 0.75], p=0.006) during the acute phase of MeN were negatively associated with CKD.

Conclusions: Our data suggest that acute systemic inflammation during acute MeN may mediate progression to CKD. Our ongoing longitudinal analysis will enhance our understanding of clinical events during disease progression and shed light on the mechanism of injury. This is the first of clinical factors associated with CKD and with recovery in MeN.

Impact of AKI on Urine Protein Excretion Chi-yuan Hsu,[12] Raymond K. Hsu,[14] Kathleen D. Liu,[13] Amanda H. Anderson,[16] Jing Chen,[9] Vernon M. Chinchilli,[8] Harold I. Feldman,[16] Amit X. Garg,[4] L. Lee Hamm,[10] James S. Kaufman,[17] Paul L. Kimmel,[7] John W. Kusek,[6] Chirag R. Parikh,[19] Ana C. Ricardo,[15] Sylvia E. Rosas,[2] Georges Saab,[5] Daohang Sha,[11] James H. Sondheimer,[18] Jonathan J. Taliercio,[1] Wei Yang,[16] Alan S. Go.[3] *[1]Glickman Urological and Kidney Institute, Cleveland, OH; [2]Joslin Diabetes Center, Boston, MA; [3]Kaiser Permanente Northern California, Oakland, CA; [4]London Health Sciences Centre, London, ON, Canada; [5]MetroHealth Medical Center, Rocky River, OH; [6]NIDDK, Bethesda, MD; [7]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [8]Penn State College of Medicine, Hershey, PA; [9]Tulane School of Medicine, New Orleans, LA; [10]Tulane University School of Medicine, New Orleans, LA; [11]Uiversity of Pennsylvania, Philadelphia, PA; [12]University of California San Francisco, San Francisco, CA; [13]University of California at San Francisco School of Medicine, San Francisco, CA; [14]University of California, San Francisco, San Francisco, CA; [15]University of Illinois at Chicago, Chicago, IL; [16]University of Pennsylvania, Philadelphia, PA; [17]VA New York Harbor Healthcare System, New York, NY; [18]Wayne State University School of Medicine, Detroit, MI; [19]Yale University and VAMC, New Haven, CT.*

Background: Little is known about the impact of AKI on proteinuria as existing studies of the adverse long-term renal consequences of AKI have almost exclusively focused on estimated glomerular filtration rate (eGFR). Some recent interventional studies suggest that mild-moderate severity AKI actually only lead to small loss of eGFR. However, examining changes in eGFR alone may underestimate the renal sequelae of AKI.

Methods: To increase sample size and generalizability, we combined data from participants of two prospective NIH cohort studies: all enrollees from ASsessment, Serial Evaluation, and Subsequent Sequelae of Acute Kidney Injury (ASSESS-AKI)(2003-16)(N=1599) and the subset of Chronic Renal Insufficiency Cohort (CRIC) study enrollees recruited from Kaiser Permanente Northern California (KPNC), a large integrated healthcare delivery system (2003-15)(N=455). Urine protein-creatinine ratio (PCR) was measured centrally once a year per ASSESS-AKI and CRIC research protocols. For study participants who were hospitalized, inpatient serum creatinine (SCr) measurements obtained as part of clinical care were abstracted from medical records and AKI defined as peak/nadir inpatient SCr≥1.5. Mixed effects regression was used to examine the impact of AKI on PCR, adjusting for demographics, co-morbidities and time-updated estimated GFR, sysotlic blood pressure (BP), number of BP medications and use of renin-angiotensin-system (RAS) blockers.

Results: Baseline eGFR was 66 (±25) ml/min/1.73m^2 and median PCR 0.12 [IQR 0.07-0.25] (g/g), There were 275 episodes of AKI during follow-up, of which 58% were KDIGO stage 1 in severity, 23% stage 2 and 18% stage 3 (including 22 cases requiring

dialyais). We found that an episode of AKI was independently associated with an increase in PCR of 0.17 g/g (P<0.0001). This increase in proteinuria is independent of changes in eGFR and does not appear to explained by higher BP or withdraw of BP medications (including RAS blockers) after AKI.

Conclusions: AKI is an independent risk factor for worsening of proteinuria among CKD patients.

Funding: NIDDK Support

FR-PO098

Impact of AKI and Source of Serum Creatinine Measurements on Subsequent Kidney Function Decline

Raymond K. Hsu,[5] Chi-yuan Hsu,[5] Charles E. McCulloch,[5] Jingrong Yang,[3] Amanda H. Anderson,[6] Jing Chen,[4] Harold I. Feldman,[6] Jiang He,[4] Kathleen D. Liu,[5] Sankar D. Navaneethan,[1] Anna C. Porter,[8] Mahboob Rahman,[2] Thida C. Tan,[3] Francis P. Wilson,[7] Dawei Xie,[6] Xiaoming Zhang,[6] Alan S. Go.[3] *[1]Baylor College of Medicine, Houston, TX; [2]Case Western Reserve University, Cleveland, OH; [3]Kaiser Permanente Northern California, Oakland, CA; [4]Tulane School of Medicine, New Orleans, LA; [5]University of California San Francisco, San Francisco, CA; [6]University of Pennsylvania, Philadelphia, PA; [7]Yale School of Medicine, New Haven, CT; [8]University of Illinois, Chicago, Chicago, IL.*

Background: Acute kidney injury (AKI) is linked to chronic kidney disease (CKD) progression, but this epidemiological association may be susceptible to ascertainment bias in studies using clinical data, as patients may be more likely to undergo kidney function testing post-AKI.

Methods: We evaluated whether impact of AKI on kidney function trajectory varied using clinical vs. research protocol-driven data in 444 adult CKD participants of the Chronic Renal Insufficiency Cohort (CRIC) Study who were also members of a large integrated healthcare system. We estimated separate eGFR trajectories using (1) serum creatinine (SCr) measurements performed annually through CRIC research protocol, or (2) SCr measurements performed in clinical care. We used linear mixed models to test the associations of AKI with absolute change in eGFR and post-AKI eGFR slope and whether these associations varied by source of serum creatinine (clinical vs. research), adjusting for demographics, baseline albuminuria and diabetes.

Results: During mean follow-up of 7.5 years, mean rate of eGFR loss was 0.31 ml/min/1.73m^2 per year overall (in the referent group with mean age of 60, male, non-black, and without albuminuria or diabetes); 74 individuals experienced AKI (54% Stage 1). An AKI episode was not significantly associated with an acute change in absolute eGFR level after discharge, but was significantly associated with a faster rate of eGFR decline (mean additional loss of 0.67 ml/min/1.73m^2 per year, P<0.0001). However, the latter association was attenuated and no longer significant when using only research measurements (Table1).

Conclusions: The impact of AKI on subsequent rate of kidney function loss is influenced by source of SCr, and may be modest after accounting for other risk factors.

Funding: NIDDK Support

Table1: Multivariable mixed effects model showing association of AKI and kidney function trajectory

Predictors	Coefficient	P
Impact of AKI episode on acute change in level of eGFR (overall)	2.01	0.59
Impact of AKI episode on acute change in level of eGFR (using research SCr only)	-0.35	0.69
Impact of AKI episode on subsequent rate of eGFR decline (overall)	-0.67	<0.0001
Impact of AKI episode on subsequent rate of eGFR decline (using research SCr only)	-0.029	0.9

FR-PO099

Late Onset Glutaric Acidemia Type 2 Caused by a Novel ETFDH Gene Mutation Presenting with Fulminant Hepatic and Acute Renal Failure

Xiangling Wang, Bekir Tanriover, Christopher Y. Lu, Mythili Ghanta. *University Texas Southwestern Medical Center, Dallas, TX.*

Background: Glutaric acidemia type 2 (GA 2) is an autosomal recessive disorder caused by deficiency of electron transfer flavoprotein. A vast majority of cases were diagnosed in early childhood and late onset cases were thought to present with mild clinical symptoms. Here we report one late onset case with novel ETFDH missense mutation presenting with metabolic decompensation requiring liver transplant and hemodialysis.

Methods: A 30-year-old African American female presented with fatigue, nausea, vomitings and abdominal pain. Hospital course was complicated by severe hypoglycemia, acute cardiopulmonary failure requiring mechanical ventilation, acute liver failure with biopsy findings of diffuse micro steatosis, rhabdomyolysis and acute renal failure requiring continuous renal replacement therapy. She emergently received a liver transplant (LT). Pretransplant plasma, concentrations of fatty acids C6-C16 were elevated suggestive of GA 2. Sanger sequencing disclosed homozygous missense mutation in ETFDH gene (c.1019 T>A; p.Phe340Tyr). This mutation has never been reported as pathogenic or benign variant in population database. Silico analysis revealed this novel mutation as likely pathogenic. One month after LT she was transferred to rehab facility with good allograft function tolerating 1-2 hours of moderate physical activity and recovered renal function to remain off dialysis.

Results:

Conclusions: Elevated fatty acids along with identification of this novel mutation support the diagnosis of late onset GA 2. In addition, inborn errors of metabolism should be suspected even in adults who present with unexplained rhabdomyolysis and acute renal failure.

Therapeutic Plasma Exchange as Rescue Therapy in Refractory Septic Shock

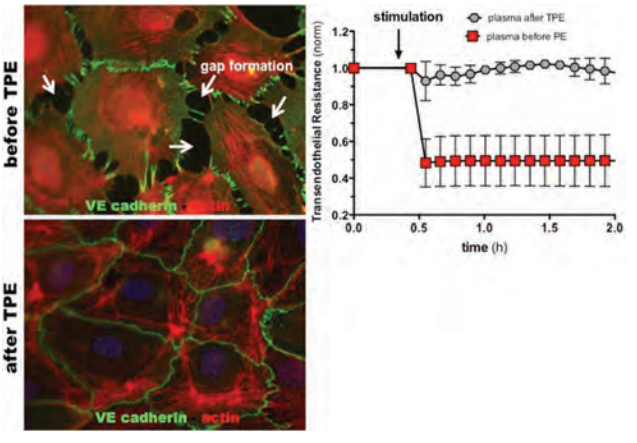
Sascha David,[3] Hermann G. Haller,[2] Bernhard M. Schmidt,[2] Jan T. Kielstein.[1] *[1]Academic Teaching Hospital Braunschweig, Braunschweig, Germany; [2]Hannover Medical School, Hannover, Germany; [3]Nephrology, Medizinische Hoschschule Hannover, Hannover, Germany.*

Background: Sepsis is a life-threatening dysregulated host response to infection. Given the injurious role of 1) the overwhelming immune response and 2) the consumption of protective plasmatic factors (vWF cleaving proteases etc.) we hypothesize that early therapeutic plasma exchange (TPE) in severely ill individuals might be beneficial. TPE combines 2 aspects in 1 procedure: Removal of harmful circulating molecules and replacement of protective plasma proteins.

Methods: We have included 14 septic shock patients (onset < 12 h) requiring high doses of noradrenaline (> 0.4 ug/kg/min). TPE (against FFP) was performed within 4 hrs. Clinical and chemical data were obtained longitudinally besides the evaluation of 28-day mortality. Plasma samples before and after TPE were obtained for stimulation of human umbilical vein endothelial cells (HUVECs) to analyze their phenotype with regard to permeability *in vitro* (fluorescent immunocytochemistry & transendothelial electrical resistance (TER)).

Results: The 28-day mortality in this study was found 20% lower (69.2%) as the predicted mortality (88.95%) by APACHE II score (37.6±4). TPE resulted in hemodynamic stabilization as indicated by mean arterial pressure (63±11 vs. 70±9 mmHg, p=0.002) and lower vasopressor requirement (NA 0.93±0.5 vs. 0.6±0.3 ug/kg/min, p<0.001). Fluid balance was also positively affected probably by reduced capillary leakage. This is supported by *ex vivo* stimulation of HUVECs with septic plasma where plasma before TPE induced severe alteration of cellular architecture including a disassembly of adherens junction (VE-cadherin IF) and a dramatic increase in permeability (TER, **Figure**). The same patients' plasma after TPE did not induce this typical septic phenotype.

Conclusions: This pilot study supports our hypothesis that early TPE in highly unstable patients might be beneficial with regard to hemodynamic stability, microcirculatory perfusion and overall outcome. A multicenter randomized trial powered for mortality is highly desirable.



FR-PO101

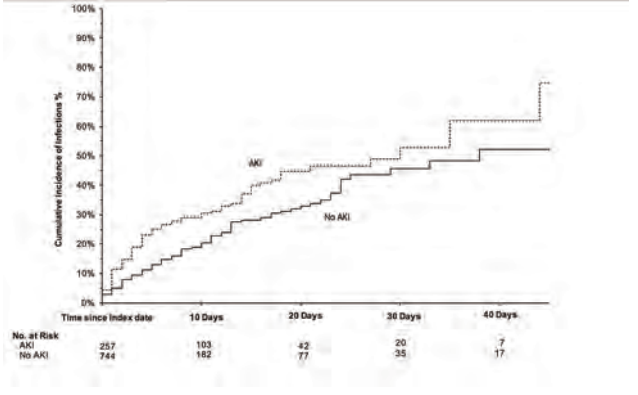
Risk of Infections Following AKI Amelie Bernier-Jean, William Beaubien-Souligny, Josee Bouchard. *Université de Montreal, Montreal, QC, Canada.*

Background: Recent studies suggest that AKI can affect distant organ function and increase non-renal complications. We aimed to determine whether AKI is independently associated with an increased risk of infectious complications in ICU patients.

Methods: We conducted a single-center retrospective cohort study of ICU patients over a year. We excluded readmission, patients on chronic dialysis, with a kidney transplant or an ICU stay less than 24 hours. The primary outcome was the development of de novo infections, analyzed with a time-dependent multivariate Cox regression model.

Results: We enrolled 1001 patients. Mean age was 64±15 years, 61% were male, 26% suffered from diabetes, 12% from CKD, 17% from COPD, and 6% were immunosuppressed. The SOFA score at ICU admission was 5 (2-8). During their stay, 51% of patients received vasopressors, 56% received mechanical ventilation (MV), and 68% underwent surgery. Twenty-six percent developed AKI and 44% had at least one infection. Patients with vs. without AKI were more likely to suffer from infections (62% vs 37%, p<0.001) (Figure 1). Pneumonia, intra-abdominal infections, and lower urinary tract infections were most common. In a time-dependent Cox-regression model, AKI (HR 1.57 95%CI 1.20-2.06) and MV (HR 1.88 95%CI 1.43-2.47) were predictors of incident infections. Patients who remained AKI and infection-free had the lowest mortality rate (2.6%), followed by those with infection alone (16.2%), infection after AKI (16.7%), AKI alone (20.4%) and infection before AKI (34.2%) (p<0.001 between groups;p=0.03 for infection after vs before AKI;p=0.03 for infection before AKI vs AKI alone;p=0.60 for infection after AKI vs AKI alone).

Conclusions: In a multivariate model, AKI was significantly associated with the development of incident infections. However, the occurrence of infection after AKI was not associated with increased mortality rate compared to infection-free AKI in our study. Patients with AKI should still be considered at higher risk for infections and targeted for infection prevention and rapid management of infections.



FR-PO102

Distinct Morphological Features of Acute Tubular Injury in Renal Allografts Correlate with Clinical Outcome Andrea Schumann-Bischoff,[1] Jessica Schmitz,[1] Irina Scheffner,[2] Roland Schmitt,[3] Verena Broecker,[4] Hermann G. Haller,[1] Jan H. Braesen,[3] Wilfried Gwinner.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Medical School Hannover, Nephrology, Hannover, Germany; [3]Medizinische Hochschule Hannover, Hannover, Germany; [4]Sahlgrenska University Hospital, Gothenburg, Sweden.*

Background: Acute tubular injury (ATI) is common in renal allografts and is related to inferior long-term allograft function. However, it is unknown which of the morphological features of ATI can predict outcome and how they should be graded. Here, we examine features of ATI systematically in protocol biopsies and biopsies for cause to define the most predictive features for allograft outcome.

Methods: Analyses included 521 protocol biopsies taken at 6 weeks, 3 and 6 months after transplantation and 141 biopsies for cause from 204 patients. Features of ATI included brush border loss, tubular epithelial lucency, flattening, pyknosis, nuclei loss and luminal debris, each graded semi-quantitatively. Additional immunohistochemical stainings were performed for markers of cell injury (NGAL), cell death (cleaved caspase-3, FACL4) and proliferation (Ki-67).

Results: Inter-observer reproducibility was good for pyknosis, flattening, brush border loss, fair for lucency and poor for nuclei loss and luminal debris. In protocol biopsies between 6 weeks and 6 months, the degree of ATI remained virtually unchanged. Biopsies for cause had generally higher injury scores. Deceased donor source, delayed graft function, ganciclovir/valganciclovir treatment and urinary tract infection correlated with ATI. The degree of brush border loss, lucency, pyknosis, and FACL4 expression correlated best with impaired allograft function. Only in patients with tubular Ki-67 expression long-term allograft function improved.

Conclusions: Reliable assessment of ATI is possible by semi-quantitative grading of tubular epithelial cell brush border loss, lucency and pyknosis, and the novel ferroptosis marker FACL4. Examination of Ki-67 expression can help determine the potential for recovery from this damage.

FR-PO103

AKI in the Tertiary Care Setting in Rwanda: Three Month and One Year Outcomes after Hospital Discharge Marla D. McKnight,[1,3] Fredric O. Finkelstein,[2] Grace Igiraneza.[4] *[1]Brigham and Women's Hospital, Renal Division and Division of Global Health Equity, Harvard Medical School, Boston, MA; [2]Yale University, New Haven, CT; [3]Human Resources for Health Program, Ministry of Health, Kigali, Rwanda; [4]Department of Medicine, University of Rwanda, Kigali, Rwanda.*

Background: Despite a burgeoning body of literature regarding the epidemiology and outcomes of acute kidney injury (AKI) in low-income settings, there remains limited data regarding the medium to long-term outcomes of patients presenting with or sustaining AKI in hospital.

Methods: In this observational, multicenter study in Rwanda, all patients > age 15 who met KDIGO definition of AKI, based on changes in serum creatinine, while admitted at one of the four national tertiary care hospitals between September 1, 2014 and January 31, 2015 had demographic and clinical information collected and were followed up post hospital discharge at 3 months (+/- 30 days) and at one year (+/- 3 months) for decline in estimated glomerular filtration rate (GFR) by 30% from baseline and mortality. Logistic regression models were performed to determine predictors of progression and mortality at 3 months.

Results: Of the 427 patients having met criteria for AKI in hospital, 291 survived to discharge. At 3 months post hospitalization, 241 were accounted for and 199 had creatinine measured. 63 (31.7%) demonstrated a GFR decline of >30%. Patients with exposure to traditional medicines prior to hospitalization were at higher risk of progression to CKD at 3 months (OR 3.02, p=0.08), whereas those who recovered baseline kidney function in hospital were significantly less likely to experience a drop in GFR at 3 months (OR 0.31, p=0.001). Patients that underwent dialysis uniformly experienced a >30% decline in GFR at 3 months. All-cause mortality at 3 months was 14.9% and having TB (OR 3.52, p=0.05), cancer (OR 3.82, p=0.03) and receiving dialysis (OR 9.01, p=0.003) were significantly associated with death. At one year, 120 patients were followed up and 102 had creatinine measured. 33 (32.3%) had a decline of GFR >30% at 12 months--10 additional patients had a decline of GFR >30% who had not at 3 months and 7 recovered renal function to within 30% of baseline. At one year there were 13 additional deaths, 9 of which had a decline of GFR>30 at 3 months.

Conclusions: Patients who experience AKI in hospital are at high risk for progression to CKD at three months and at one year. The study underscores the importance of careful follow-up of patients with AKI after hospital discharge and reflects the difficulty of capturing longterm outcome data in low-resource settings.

Effectiveness of AKI E-Alerts in Primary Care James Tollitt,[1] Lauren Emmett,[1] Samantha C. Glynn-Atkins,[2] Denise Darby,[1] Brandon Bennett,[3] Sheila Mccorkindale,[2] Smeeta Sinha,[1] Dimitrios J. Poulikakos.[1] *[1]Salford Royal NHS Foundation Trust, Salford, United Kingdom; [2]NHS Salford Clinical Commissioning Group, Salford, United Kingdom; [3]Improvement Science Consulting Inc., Washington, DC.*

Background: AKI e-alerts in secondary care are well researched but the impact of e-alerts in primary care is unknown. The NHS AKI alert algorithm, based on KDIGO AKI classification, was implemented across primary care in UK in 2016. This project analyzed the impact of the e-alert and AKI educational outreach sessions on primary care AKI 2&3.

Methods: GP practices were randomised into 4 groups. A 2x2 factorial design exposed each group to different combinations of the 2 interventions. The study population was 258,729. Time to repeat test or hospitalisation was measured. Age <18years and dialysis patients were excluded. Repeat tests within 48hrs were considered to be the same AKI event. When analysing time to response, AKI events were excluded if no repeat test had occurred within 14 days to avoid infinite time bias. Baseline data were collected between Jan 2015-Oct 2015. The study was undertaken from Oct 2015 to Aug 2016. The follow up period was Aug 2016-Apr 2017. All groups had e-alerts after August 2016. Yates algorithm analyzed the impact of each intervention during the study period. Time to response and mortality pre and post the intervention period was analyzed using Mann U Whitney and Chi Square respectively.

Results: 1807 (0.8%) primary care blood tests demonstrated AKI1-3 (78.4% AKI1, 14.8% AKI2, 6.9% AKI3). There were 391 AKI 2 & 3 from 251 patients. A total of 234 AKI events met all inclusion criteria. E-alerts demonstrated a marked reduction in mean response time (-29.2hrs) and educational outreach had a modest impact (-3.5hrs). Median response to AKI 2 & 3 pre and post interventions was 27 hours v 16 hours respectively (p=0.037). AKI event related 30-day mortality was significantly less (18.4% v 4.1% p=0.036).

Conclusions: AKI e-alerts in primary care hastens response to AKI and may reduce mortality. Educational outreach sessions further improve response time.

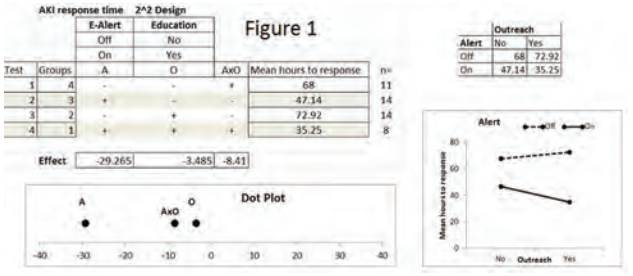

Figure 1: Yates algoirthm (left), response plot (right)

FR-PO105

AKI and CKD after Allogeneic Hematopoietic Stem Cell Transplantation (HSCT) – A Retrospective Analysis Elena K. Kirilova,[1] Jan Kowald,[3] Friedrich Stölzel,[1] Martin Bornhauser,[2] Christian Hugo.[4] *[1]Uniklinik Dresden, Dresden, Germany; [2]University Hospital, Dresden, Germany; [3]University Hospital of Dresden, Dresden, Germany; [4]University of Dresden, Dresden, Germany, Dresden, Germany.*

Background: Acute kidney injury is a common complication after HSCT and the procedure-related mortality rate increases with the stage of acute kidney injury. In the present study we assessed incidence and risk factors for acute kidney injury, chronic kidney disease and delta eGFR after HSCT.

Methods: In this retrospective study we included 312 patients which received allogeneic HSCT at our center between Jan. 2012 and Dec. 2014. The patients have been followed up until December 2016. We assessed Kidney function through documentated serum creatinine values. We evaluated the following risk factors before transplantation: age, co-morbidity index, previous CKD, diabetes mellitus, arterial hypertension, previous chemotherapy, conditioning regimens, stem cell source, HLA compatibility and relationship between donor and patient. Among the evaluated risk factors after transplantation were the complications: acute and chronic graft versus host disease, sepsis, cytomegalovirus reactivation, sinusoidal occlusive disease, immunosuppressive therapy, nephrotoxic medications and contrast medium.

Results: The incidence of acute kidney injury (AKI) amounts to 63.5 % (AKI stage 1: 27.8 %, AKI stage 2: 39.9 % and AKI stage 3: 32.3 %). Chronic kidney disease was found in 203 patients (65.1 %). 109 Patients (34.9%) did not show any signs of CKD. 127 patients (40.7%) from 203 patients with CKD after HSCT have developed CKD for the first time after HSCT. Multivariate analysis showed that CKD before HSCT and sepsis, contrast media and duration of the stay in an intensive care unit after HSCT were risk factors for AKI. Age, duration of the therapy with CsA and the count of acute kidney injuries were risk factors for chronic kidney disease in the multivariate analysis. Risk factors in the multivariate analysis for eGFR ≥ 15 ml/min/ 1.73 m^2 one year after HSCT were acute graft versus host disease and sepsis. Sepsis was the only risk factor in the multivariate analysis associated with mortality after HSCT.

Conclusions: AKI and CKD are common complications after HSCT. Sepsis was a universal risk factor in the multivariate analysis which was associated not only with kidney injury but also with excess mortality. The mortality rate after HSCT is high mostly in the first 6 months.

FR-PO106

The Epidemiology and Impact of Fluid Balance on Outcomes in Critically Ill Near-Term/Term Neonates: A Report from the AWAKEN Study David T. Selewski,[14] Ayse Akcan Arikan,[1] Elizabeth Bonachea,[8] Katja M. Gist,[12] Stuart Goldstein,[5] Mina Hanna,[13] Catherine Joseph,[15] John D. Mahan,[9] Arwa Nada,[6] Amy Nathan,[4] Kimberly J. Reidy,[3] Amy Staples,[15] Pia Wintermark,[7] Louis J. Boohaker,[2] Russell Griffin,[10] David J. Askenazi,[11] Ronnie Guillet.[16] *[1]Baylor College of Medicine, Houston, TX; [2]Children's of Alabama, Hoover, AL; [3]Children's Hospital at Monte iore/ Albert Einstein College of Medicine, Bronxville, NY; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [6]LeBonheur Children's Hospital, Memphis, TN; [7]McGill University, Montreal, QC, Canada; [8]Nationwide Children's hospital, Columbus, OH; [9]Nationwide Children's Hospital, Columbus, OH; [10]University of Alabama at Birmingham, Birmingham, AL; [11]University of Alabama at Birmingham, Birmingham, AL; [12]University of Colorado, Children's Hospital Colorado, Aurora, CO; [13]University of Kentucky, Lexington, KY; [14]University of Michigan, Ann Arbor, MI; [15]University of New Mexico, Albuquerque, NM; [16]University of Rochester, Rochester, NY. Group/Team: On behalf of Neonatal Kidney Collaborative.*

Background: Neonates in the neonatal intensive care unit(NICU) are at increased risk of AKI and disorders of fluid balance(FB). Although normal term neonates are expected to lose weight (5-10%) over the first week of life, a paucity of data exists on FB in critically ill neonates. We aim to evaluate FB in the first week of life in a multi-center cohort of critically ill near-term/term neonates and the impact of FB on outcomes.

Methods: The Assessment of Worldwide Acute Kidney injury Epidemiology in Neonates (AWAKEN) study included NICU admissions at 24 institutions (4 countries) from 01/14-03/14. Inclusion criteria: intravenous fluids for ≥48 hrs. Exclusion criteria: congenital heart disease repair at ≤7 days of life(DOL), lethal anomaly or death at ≤48 hrs. This analysis includes infants ≥36 wks gestational age admitted by DOL 7. FB was defined by percentage change in weight from birthweight(BW). Outcomes: Mechanical ventilation(MV) at DOL 7, NICU mortality

Results: 749 neonates were included, median peak FB was 0.6%(-0.8, 4.3) and occurred at a median DOL 2(IQR 1,5). Peak FB over the first week was: <0%(<BW) in 231(30.5%), 0-5% in 345(45.4%), 5-10% in 90(11.9%), 10-15% in 39(5.1%), and >15% in 44(5.9%). 67(9%) were on MV on DOL 7 and 17(2.3%) died. Table 1 describes the association of variables, including FB, with MV at DOL 7. FB was not associated with mortality.

Conclusions: The AWAKEN study describes for the first time, the epidemiology and impact of FB in critically ill near-term/term neonates. Over half of the cohort had a positive peak FB in the first week of life. Peak FB during the first week of life was associated with the need for MV at DOL 7.

Epidemiology of AKI among Hospitalized Children in China Sheng Nie,[2] Fan Fan Hou,[1] Xin Xu.[3] *[1]Nanfang Hospital, Guangzhou, China; [2]National Clinical Research Center for Kidney Disease of China, State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Guangzhou, China; [3]Renal Division, Nanfang Hospital, Southern Medical University; National Clinical Research Center for Kidney Disease, Guangzhou, China.*

Background: High quality epidemiological data on acute kidney injury (AKI) in children are particularly lacking in Asian countries.

Methods: We performed a nationwide, multicenter study in a cohort of hospitalized children aged 1 month to 18 years from 25 general and children's hospitals in China during 2013-2015. We obtained patient-level data from the electronic hospitalization information system and laboratory databases of all inpatients who had at least two serum creatinine tests within any 7-day window during their first 30 days of hospitalization. We identified AKI events according to the creatinine criteria of Kidney Disease Improving Global Outcomes.

Results: A total of 20 006 (19.6%) AKI cases were identified among 102 107 pediatric inpatients analyzed, of which 7283 (7.1%) were community acquired and 12 723 (12.5%) hospital acquired. Up to 96% of these AKI events were not diagnosed on the discharge records. The cumulative incidence of AKI in infants (27.6%) doubled that in adolescents (11.9%). The profiles of risk factors differed between CA- and HA-AKI and varied with age. Diarrhea and sepsis were the top risk factors for CA-AKI, contributing to 5.7% and 5.5% of the risk, respectively. Congenital heart disease/cardiac surgery was the major risk factor for HA-AKI, contributing to 18.7% of the risk. Exposure to nephrotoxic drugs, mostly non-steroidal anti-inflammatory drugs and proton pump inhibitors, was common in hospitalized children and associated with an increased risk of AKI. Death occurred in 845 of 20 006 patients (4.2%) with AKI *versus* 451 of 82 101 children (0.5%) without AKI. The risk of in-hospital death was higher among children with severe AKI, shock and respiratory failure. Pediatric AKI was associated with longer hospital stay and higher daily cost, even after adjustment for covariates.

Conclusions: Pediatric AKI is common with substantial under-diagnosis in China.

Variation in Community-Based AKI Trends Using Administrative Codes versus Serum Creatinine Values Among >5 Million Adults Between 2004-2014 Alan S. Go,[1] Chi-yuan Hsu,[2] Thida C. Tan,[1] Kathleen D. Liu,[2] Sijie Zheng,[1] Jingrong Yang.[1] *[1]Kaiser Permanente Northern California, Oakland, CA; [2]University of California San Francisco, San Francisco, CA.*

Background: We evaluated potential variation in community-based temporal trends in acute kidney injury (AKI) incidence using administrative codes vs. serum creatinine (SCr)-based changes.

Methods: In Kaiser Permanente Northern California, a large integrated healthcare delivery system, we identified all hospitalized AKI episodes between 2004-2014 using revised KDIGO criteria (≥50% relative rise in SCr from baseline, ≥0.3 mg/dL SCr increase within 48 hours or receipt of acute dialysis) (KDIGO-AKI) vs. primary or secondary discharge ICD-9 diagnostic codes (DIAG-AKI). We examined age-sex-adjusted incidence and multivariable-adjusted incidence of AKI per year using each AKI definition.

Results: Among 5,253,185 adults, mean age was 48 years, 53% were women and 45% were minorities. Age-sex-adjusted incidence (per 100,000 person-years) of KDIGO-AKI rose from 587 in 2004 to 645 in 2006 but then decreased progressively to 471 by 2014. In contrast, age-sex-adjusted incidence of primary DIAG-AKI remained stable over time, while secondary DIAG-AKI consistently increased from 297 in 2004 to 484 in 2014. After adjustment for potential confounders using Poisson regression, compared with 2004, the relative incidences of KDIGO-AKI and primary DIAG-AKI peaked in 2006 but decreased through 2014; however, the relative incidence of secondary DIAG-AKI steadily increased throughout the study period (Figure).

Conclusions: These data extend prior studies which have reported suboptimal operating characteristics of administrative AKI codes, with increased sensitivity for detecting AKI in later calendar years. Importantly, however, estimates of population-based temporal trends in AKI that rely solely on administrative codes to define AKI are likely to be biased compared with using SCr-based definitions.

FR-PO109

Hyperpolarized Carbon-13 MRI to Assess AKI David D. Aufhauser,[1] Mehrdad Pourfathi,[1] Douglas R. Murken,[1] Zhonglin Wang,[1] Guanghui Ge,[1] Seth Concors,[1] Wayne W. Hancock,[1,2] Matthew H. Levine.[1,2] *[1]University of Pennsylvania, Philadelphia, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Assessing the severity of renal disease often requires extended periods of observation and data collection. Hyperpolarized MRI (HP-MRI) offers a novel, noninvasive tool to probe metabolic pathways regionally with exceptional signal to noise, both in research and preclinical settings. Here we demonstrate its feasibility to assess changes in renal metabolism early after ischemia-reperfusion injury (IRI).

Methods: C57BL/6 mice were subjected to standardized unilateral warm renal IRI. 1 hour post-operatively, mice with placed in a 9.4T micro-imaging MRI system. Images were acquired using 30-mm H/^{13}C dual-tuned coils. Anatomical scans were obtained using a respiratory-gate multi-slice fast spin-echo pulse sequence. Proton T_2-weighted images were acquired using a multi-slice RARE sequence. [1-^{13}C]-pyruvate was polarized using a HyperSense DNP polarizer and injected via internal jugular venous cannula. A single-slice axial ^{13}C chemical shift image was acquired using FID-CSI sequence.

Results: Raw spectroscopic imaging data (Fig 1A) show tall peaks in each voxel indicating pyruvate signals and small peaks indicating lactate. Injured kidneys (IRI) had loss of structure on T2-weighted imaging (Fig 1B). Pyruvate intensity was higher in the control (CL) kidney (Fig 1C), and lactate-to-pyruvate ratio was elevated in the IRI kidney compared to CL (Fig 1D-E).

Conclusions: These data show that hyperpolarized [1-^{13}C]-pyruvate MRI is a promising technique to assess rapidly regional metabolic derangements associated with kidney disease, including renal IRI.

Using the Kinetic eGFR (KeGFR) Formula for Estimating GFR and Detecting AKI: A Pilot Study Manohar Bairy,[1] Faith H. See,[2] Ru S. Lim.[1] *[1]TTSH Singapore, Singapore, Singapore; [2]Yong Loo Lin School of Medicine, Singapore, Singapore.*

Background: Estimating GFR when the Creatinine(Cr) is rapidly changing as in AKI has been a challenge. The KeGFR formula by S.Chen estimates GFR by factoring in the time interval between rising Cr values and the Volume of distribution(Vd). It has the added advantage of providing the clinician with a eGFR value for each non steady state Cr value. We employed the KeGFR formula to detect AKI in an adult non ICU inpatient setting. We then compared KeGFR with the current standard (AKIN and RIFLE) and newer criteria (Waikar-Bonventre, Delta Check) for AKI detection.

Methods: 250 consecutive adult patients admitted to the Medical wards were screened. Patients with a change in Cr of >4.3 % (Biological Variation) were included in the study(n=80). The KeGFR formula was applied to this cohort after calculating the Vd individually after estimating the initial GFR by MDRD. A fall in eGFR of 25% or more was considered as AKI. The AKIN, Waikar-Bonventre, RIFLE and Delta Check criterion were also applied to this cohort and compared with the KeGFR criterion.

Results: Forty nine patients had AKI by AKIN classification. All but one patient (30) found to have AKI by KeGFR criterion fulfilled the AKI definition by AKIN(Table 1). AKIN diagnosed an additional 19 patients to have AKI. However, all of these had an elevated creatinine level on admission hence requiring the incorporation of baseline creatinine(BCr) by AKIN which is not part of the KeGFR formula. Moreover, the latest Cr value in the preceeding 3 months was assumed to be the BCr. 5 of these 19 patients were deemed not to have AKI by clinical adjudication. All patients with in-hospital AKI and progressive AKIwere detected by both the criteria.

Conclusions: The KeGFR formula can be readily applied to estimate GFR in the non-steady state. A KeGFR based criterion successfully detected progressive and in hospital AKI in this study.

Table 1Comparison of KeGFR against other AKI Criteria

Criteria	Kinetic eGFR No AKI	Kinetic eGFR With AKI	Total
AKIN			
No AKI	30	1	31
With AKI	19	30	49
Total	49	31	80
RIFLE

FR-PO111

Low Serum Bicarbonate Levels at Admission Predict the Development of Hospital Acquired AKI: A Retrospective Cohort Study Soojin Lee,[4] Sung Yoon Lim,[1] Anna Lee,[2] Ho Jun Chin,[3] Ki Young Na,[3] Sejoong Kim.[3] *[1]Korea University Medical Center, Sungbuk-Gu, SEoul, Republic of Korea; [2]SNUBH, Gyeonggi-do, Democratic People's Republic of Korea; [3]Seoul National University Bundang Hospital, Seong nam, Republic of Korea; [4]Seoul national university hospital, Seoul, Republic of Korea.*

Background: Acute kidney injury(AKI) is a common complication and is strongly related to increase in mortality. Low serum bicarbonate levels are associated with adverse renal outcomes and increased mortality in patients with chronic kidney injury. Nevertheless, it is unknown whether lower than normal serum bicarbonate levels can predict the development of AKI in hospitalized patients. The purpose of the study was to determine whether serum bicarbonate levels at admission could be a predictor for the AKI development and mortality in hospitalized patients.

Methods: 17706 adult patients who were admitted to Seoul National University, Bundang Hospital from January 2013 to December 2013 were enrolled, retrospectively. The patients were divided into 3 groups based on serum bicarbonate levels on the first measurement of their admission. The group 1 presented below normal levels, (<23 mEq/L); group 2 presented normal levels, (23 to 27 mEq/L); and group 3 presented elevated levels, (>27 mEq/L). AKI was defined as an increase in the serum creatinine level by ≥ 0.3 mg/dL or ≥ 1.5 times of the baseline value during the hospital stay.

Results: During the median 6.0 days of hospital stay, the incidence rates of AKI and in-hospital mortality were 5.1% and 0.9%, respectively. The incidence of AKI was higher in group 1 (8.1%) than in group 2 (4.1%) and group 3 (3.6%) ($P < 0.001$). Low serum bicarbonate levels at admission were significantly associated with AKI even after the adjustment for age, sex, hypertension, diabetes mellitus, and estimated glomerular filtration rate (adjusted odds ratio [OR] 2.181, $P < 0.001$). In addition, low serum bicarbonate levels also independently predicted in-hospital mortality (adjusted hazard ratio [HR] 1.864, $P < 0.001$). Pre-existing low bicarbonate levels and subsequent development of AKI increased in-hospital mortality by 15 times, compared to the in-hospital mortality of the patients with normal bicarbonate levels and absence of AKI.

Conclusions: Low serum bicarbonate levels may be associated with the development of AKI and increase in in-hospital-mortality. Clinical trials are needed to clarify the protective role of bicarbonate replacement therapy in preventing further AKI development.

FR-PO112

Incidence and Risk Factors of AKI in the General Population Arnar J. Jonsson,[1,2] Olafur S. Indridason,[1] Sigrun H. Lund,[2] Runolfur Palsson.[1,2] *[1]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [2]University of Iceland, Reykjavík, Iceland.*

Background: Acute kidney injury (AKI) in the setting of acute illness or major surgery is well described. Little is known about the burden of AKI in the general population. The purpose of this study was to estimate the incidence and risk factors for AKI in the Icelandic general population.

Methods: In this retrospective study, we obtained all serum creatinine (SCr) values from all clinical laboratories in Iceland for the years, 2008-2013. Data on age, gender, diagnoses of comorbid conditions and HbA1c values were retrieved from electronic medical records. Using computerized algorithms, we identified episodes of AKI defined according to the KDIGO criteria as a rise in SCr of ≥0.3 mg/dL over 48 hours and/or ≥50% from baseline over 7 days. CKD was defined and staged according to the KDIGO classification system. Chi-squared test and Students T-test were used to compare groups. Age-adjusted incidence was calculated for men and women and stratified by age groups and standardized to the EU27 population.

Results: We obtained 1,230,563 SCr values for 183,931 individuals aged ≥18 years. The median age was 62 years and 47.5% were men. For individuals with AKI, 19.1% had hypertension, 14.8% had diabetes, 19.5% had coronary artery disease and 10.5% had CKD compared with 6.7%, 5.3%, 5.8% and 1.2% for individuals without AKI, respectively ($p<0.001$ all variables). For men, the annual age-adjusted incidence of AKI was 1124/100,000 for stage 1, 57.7/100,000 for stage 2 and 18.1/100,000 for stage 3 AKI. In women, the annual age-adjusted incidence was 1349/100,000 for AKI stage 1, 62/100,000 for stage 2 and 21/100,000 for stage 3 AKI with significant difference between sexes ($p<0.05$). The incidence of AKI stages 1-3 rose with advancing age; it was 111/100.000, 329/100.000, 1076/100.000, 1984/100.000 and 3470/100.000 for the age groups 20-44 years, 45-64 years, 65-74 years, 74-85 years, and ≥85 years, respectively. Age-adjusted incidence of AKI stages 1-3 increased during the study period with RR of 1.026 (95%CI, 1.017-1.035) for each year.

Conclusions: This nationwide study shows a steep rise in the incidence of AKI with advancing age. Individuals who developed AKI had an increased prevalence of comorbid conditions, suggesting the need for caution in these groups of patients.

FR-PO113

Pre-Operative Plasma TNFR1, TNFR2, and KIM-1 Are Associated with AKI and One Year Mortality in Cardiac Surgery Patients Steven G. Coca,[1] Dennis G. Moledina,[5] Yaqi Jia,[5] Sherry Mansour,[5] Heather Thiessen Philbrook,[5] Michael Shlipak,[3] Jay L. Koyner,[4] Amit X. Garg,[2] Chirag R. Parikh.[6] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]London Health Sciences Centre, London, ON, Canada; [3]San Francisco VA Medical Center, San Francisco, CA; [4]University of Chicago, Chicago, IL; [5]Yale School of Medicine, New Haven, CT; [6]Yale University and VAMC, New Haven, CT. Group/Team: TRIBE-AKI Consortium.*

Background: Plasma tumor necrosis factor receptor (TNFR)1, TNFR2, and kidney injury molecule (KIM)1 provide prognostic information in ambulatory patients with diabetes for incident or progressive kidney disease. However, their utility is not well described in settings of acute kidney injury (AKI) post cardiac surgery.

Methods: In a prospective cohort study of 1444 high-risk adults undergoing cardiac surgery (CABG, valve, or both), we sought to assess the association of pre- and post-operative (peak days 1-3) concentrations of TNFR1, TNFR2, and KIM-1 with post-operative AKI (AKIN stage 1) and 1-year all-cause mortality after cardiac surgery. Plasma TNFR1, TNFR2 and KIM-1 were measured *via* MesoScale Discovery multiplex assay.

Results: Pre-operative concentrations of TNFR1, TNFR2, and KIM-1 were higher in those who developed post-operative AKI (n=492, 34%) and those who died (n= 68, 6.2%) by one-year. Each log-increase of pre-operative biomarker was independently associated with a 2-3 fold higher odds of both AKI and one-year mortality [Table]. TNFR1, TNFR2, and KIM-1 concentrations increased by 136, 65, and 36%, respectively, after surgery, and differed minimally by AKI status. After adjustment for pre-operative biomarker value, peak change in serum creatinine and 13 other covariates, peak post-operative levels of TNFR1 and TNFR2, but not KIM-1, were associated with one-year mortality [Table].

Conclusions: The panel of three pre-operative biomarkers, TNFR1, TNFR2, and KIM1, provided strong prognostic information about AKI and mortality in patients undergoing cardiac surgery. Post-operative concentrations of TNFR1 and TNFR2 also provided additional prognostic information for death.

Serum and Urine FGF23 and IGFBP-7 for the Prediction of AKI in Critically Ill Children Yanhong Li. *children hospital of Soochow University, SuZhou, China.*

Background: Fibroblast growth factor 23 (FGF23) and insulin-like growth factor binding protein 7 (IGFBP-7) are novel biomarkers of acute kidney injury (AKI). We compared them with proposed AKI biomarker of cystatin C (CysC), and aimed (1) to examine whether concentrations of these biomarkers vary with age, body weight, illness severity assessed by pediatric risk of mortality III score, and kidney function assessed by estimated glomerular filtration rate (eGFR), (2) to determine the association between these biomarkers and AKI, and (3) to evaluate whether these biomarkers could serve as early independent predictors of AKI in critically ill children.

Methods: Serum and spot urine samples were collected from 144 patients during the first 24 hours after pediatric intensive care unit admission. The diagnosis of AKI developed within 120 hours of sample collection was based on the AKI network (AKIN) criteria. AKIN stage 1 was defined as mild AKI, and AKIN stages 2 and 3 were defined as severe AKI.

Results: Of the 144 patients, 21 developed AKI within 120 hours of sample collection, including 11 with severe AKI defined as AKI Network stages 2 and 3. All the serum levels of FGF23, IGFBP-7, and CysC and urinary level of FGF23 were highest among children with lowest eGFR. However, only serum FGF23 levels were independently associated with eGFR after adjustment in a multivariate linear analysis (B =-0.557, $P <0.001$). Urinary IGFBP-7 (AOR =2.94 per 1,000 ng/mg increase, $P =0.035$), serum CysC (AOR =5.28, $P=0.005$), and urinary CysC (AOR =1.13 per 1,000 ng/mg increase, $P =0.022$) remained significantly associated with severe AKI after adjustment for body weight and illness severity. Urinary IGFBP-7 level was predictive of severe AKI and achieved the AUC of 0.79 ($P =0.001$), but was not better than serum CysC(AUC =0.89, $P <0.001$) or

urinary (AUC =088, P <0.001) CysC in predicting severe AKI. However, the difference between the two AUCs of either urinary IGFBP-7 (AUC =0.79) and serum CysC (AUC =0.89) (P =0.103) or urinary IGFBP-7 and urinary CysC (AUC =0.88) (P =0.225) did not reach statistically significant.

Conclusions: Serum FGF23 levels were inversely related to measures of eGFR, and an increased urinary IGFBP-7 level was independently associated with the increased risk of severe AKI, but not superior to serum or urinary CysC in predicting severe AKI in critically ill children.

FR-PO115

Early Increase in Renal Injury Urinary Biomarkers Is Associated with AKI Development in Major Elective Non-Vascular Abdominal Surgeries Lia J. Marçal,[1] Graziela R. Souza,[1] Veronica T. Costa e Silva,[1] Dirce M. Zanetta,[2] Luis Yu,[1] Leila Antonangelo,[1] Emmanuel A. Burdmann.[1] *[1]University of Sao Paulo Medical School, Sao Paulo, Brazil; [2]University of São Paulo, S Paulo, Brazil.*

Background: There are few data on the incidence of acute kidney injury (AKI) diagnosed by KDIGO criteria and the role of renal injury urinary biomarkers (BMs) for predicting AKI in patients (pts) submitted to major elective non-vascular abdominal surgeries (MENVAS).

Methods: A total of 171 pts submitted to MENVAS were prospectively assessed peri-operatively and from the ICU admission up to 7 d. Analyzed outcomes were AKI development, ICU and hospital length of stay (LoS) and mortality. AKI was diagnosed by serum creatinine increase or urinary output decrease (KDIGO criteria). Urine was collected 1 day before surgery (baseline), 30 min, 12 and 24 h after ICU admission. Five urinary BMs were assessed: NGAL, KIM-1, monocyte chemotactic protein 1 (MCP1), microalbuminuria (μalb) and interleukin-18 (IL-18) by Luminex x-MAP method. Data are mean (± SD), frequency or median (first and third quartiles). Statistical significance was set at p<0.05.

Results: Overall, age was 54±16 y, 59% were female, hospital LoS was 17.0±16.6 d, ICU LoS was 3.0±1.7 d and mortality was 7%. A total of 102 pts (59.6%) developed AKI and most were KDIGO I (81.4%). AKI pts were older (57±13 vs. 50±17 y, p=0.006), had longer hospital (20±20 vs. 12±8 d, p=0.001) and ICU LoS (3.3±2.0 vs. 2.5±0.8 d, p=0.02) and higher mortality (9.8 vs. 2.3%, NS), compared to non-AKI. Those developing AKI KDIGO II and III had significantly higher BMs values compared to pts KDIGO I or non-AKI in all studied times (Table).

Conclusions: We found a strikingly high incidence of MENVAS-associated AKI diagnosed by KDIGO criteria in patients admitted to the ICU. AKI was associated with significantly higher ICU and hospital LoS. Those who developed more severe AKI showed significantly higher BMs in all times studied, including the preoperative period.

The iTRAQ Technology Identifies Biomarkers for the Early Diagnosis of Contrast-Induced AKI Lina Han,[2,3] Qun Luo,[2,3] Fangfang Zhou,[2,3] Gen Shen,[4,3] Honghua Ye,[4,3] Zemin Wang,[1] Yumei Li.[1] *[1]Ningbo NO.2 Hospital, Ningbo, China; [2]Department of Nephrology, Ningbo NO.2 Hospital, Ningbo City, China; [3]School of Medicine, Ningbo University, Ningbo, China; [4]Department of Cardiology, Ningbo NO.2 Hospital, Ningbo, China.*

Background: This study was to detect differentially expressed urine proteins in contrast-induced acute kidney injury (CI-AKI) patients after percutaneous coronary intervention(PCI) by Isobaric Tags for Relative and Absolute Quantitation (iTRAQ) technology, and to find new biomarkers for early diagnosis of CI-AKI.

Methods: We collected urine samples of older patients(>60yrs) before PCI and at 6hrs after PCI. And the samples were collected between July 1st 2015 and Jan 31st 2016 in Ningbo No.2 Hospital. Blood collected for biochemical analyses. iTRAQ technique was used to screen differentially expressed proteins, and to identify potential biomarkers by analysis of the biological process, cellular components, molecular functions, Kyoto Encyclopedia of Genes and Genomes(KEGG) pathways and protein-protein interactions(PPI).

Results: 48 older patients admitted for elective PCI were included in the study. Among these patients, 6 (4 male cases and 2 female cases) developed CI-AKI. In our study, the mean Scr levels were measured at 24h (121.80 ±54.31umol/L vs 94.43±33.56umol/L, P=0.059) and 48h (133.1±41.21umol/L vs 94.43 ±33.56umol/L, P=0.009) after PCI in the CI-AKI patients. Comparing to patients before PCI, a total of 151 proteins were identified in the CI-AKI group (6hrs after PCI). 74 proteins were up-regulated and 77 proteins were down-regulated. We identified 20 biological process, 20 cellular components, 20 molecular functions and 10 significant KEGG pathways. Combined with the PPI results, mannan-binding lectin (MBL)-associated serine protease 2 (MASP2), angiotensinogen (AGT) and apolipoproteins A-I(apoA-I) might play a role in the pathogenesis of CI-AKI.

Conclusions: 1. The quantitative iTRAQ technology provided an accurate and effective assessment of identifying and profiling potential urine biomarkers for early diagnosis of CI-AKI in this study.2. Our research showed that MASP2, AGT, and apoA-I were significantly up-regulated at 6hr after PCI. And they were earlier than Scr for diagnosis of CI-AKI. They were potential urine biomarkers and played key roles in the pathogenesis of CI-AKI.

Relationship of Cardiac Biomarkers and AKI: The ASSESS-AKI Study Kathleen D. Liu,[6] Chi-yuan Hsu,[6] Thida C. Tan,[2] Valerie Arends,[8] Amy Saenger,[8] Chirag R. Parikh,[11] Talat Alp Ikizler,[10] Jonathan Himmelfarb,[3] Mark M. Wurfel,[12] Vernon M. Chinchilli,[5] Paul L. Kimmel,[4] James S. Kaufman,[9] Alan S. Go.[2] *[2]Kaiser Permanente Northern California, Oakland, CA; [3]Kidney Research Institute, Seattle, WA; [4]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [5]Penn State College of Medicine, Hershey, PA; [6]University of California San Francisco, San Francisco, CA; [8]University of Minnesota, Minneapolis, MN; [9]VA New York Harbor Healthcare System, New York, NY; [10]Vanderbilt University Medical Center, Nashville, TN; [11]Yale University and VAMC, New Haven, CT; [12]University of Washington, Seattle, WA. Group/Team: For ASSESS-AKI Study Investigators.*

Background: Several studies have reported AKI is associated with an increased risk of cardiovascular events after hospital discharge, especially heart failure. However, little is known about whether AKI impacts heart failure biomarker levels.

Methods: ASSESS-AKI study is a parallel cohort study of hospitalized AKI and matched non-AKI patients enrolled in 2009-2015. Plasma biospecimens were collected during the index hospitalization (V0) and at the first outpatient study visit 3 months later (V3) and tested for levels of Suppression of tumorigenicity 2 (ST-2) and galectin-3 (GAL-3) using clinical grade ELISA assays (Critical Diagnostics and BG Medicine, respectively).

Results: Mean age of the 1,484 participants analyzed was 55 yr, 48% were women, and baseline (pre-index admission) eGFR was 69 mL/min/1.73m^2. Compared to non-AKI patients, ST-2 and GAL-3 levels were higher in AKI patients during the index hospitalization and at V3 (Table), and both duration and severity of AKI were associated with biomarker levels (p< 0.001 for all comparisons). Of note, ST-2 levels fell markedly from V0 to V3 in both groups, to median ST-2 levels that are typically associated with a lower risk of heart failure (< 35 ng/mL).

Conclusions: ST-2 and GAL-3 are elevated during an episode of AKI, with GAL-3 remaining elevated but ST-2 declining at 3 months post-discharge. Future studies should determine whether patients with persistently elevated biomarker levels after AKI are at increased cardiovascular risk.

Funding: NIDDK Support

Measurements of Volatile Organic Compounds by Proton-Transfer-Reaction Mass Spectrometry for the Diagnosis of AKI in the Intensive Care Unit Michael G. Janech,[1] Mohammed Z. Mohialdeen,[1] Anand Achanti,[1] Milos N. Budisavljevic,[1] Juan Carlos Q. Velez,[2] Nithin Karakala,[3] John M. Arthur,[3] Peter A. Lee.[4] *[1]Department of Medicine, Division of Nephrology, Medical University of South Carolina, Charleston, SC; [2]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [3]Division of Nephrology, Department of Medicine, University of Arkansas for Medical Sciences, Little Rock, AR; [4]Department of Biology, College of Charleston, Charleston, SC.*

Background: Current biomarkers for acute kidney injury (AKI) in the intensive care unit (ICU) do not offer real-time detection capability, are based on serum creatinine or urine proteins, and diagnostic levels significantly lag behind the injury. A lesser explored area of AKI biomarker research is the volatile organic compound (VOC) space. The goal of this pilot study was to assess whether detection of VOCs using a mass spectrometer conducive to near real-time detection capability could detect urine VOCs and classify or characterize patients with AKI in the ICU.

Methods: Urine specimens (40 mL) from 32 ICU subjects with or without AKI (AKIN criteria) were collected at bedside and transferred to an adjacent laboratory for Proton-Transfer-Reaction Mass Spectrometry (PTR-MS)-based analysis. VOCs were detected in positive hydronium ion mode and spectra were background subtracted and aligned. Individual VOCs were assessed for ability to classify AKI or no AKI using

area under ROC (AUC) curves. Parametric statistics were utilized for individual VOC comparisons between AKI and non-AKI groups.

Results: 105 VOC masses were detected in urine from 32 ICU patients. Mean serum creatinine values were 3.3 ± 3.0 mg/dL for the AKI group (n=14) and 0.9 ± 0.3 mg/dL for the non-AKI (n=18) group. Ten masses comprised 98% of the signal intensity and were less than 63 m/z suggesting that more volatile components were better detected. Eighteen masses were significantly lower in AKI subjects (1.2 to 13 fold lower, P<0.05). A single VOC, putatively identified by molecular weight as formic acid or ethanol (47.2 m/z), was elevated 2-fold in AKI patients compared to non-AKI patients (AUC = 0.70; p=0.03). When the ratio of 47.2 and 70.9 m/z was calculated, this resulted in a better classifier (AUC = 0.78) than 47.2 m/z alone.

Conclusions: PTR-MS has the capability to detect urine VOCs. Elevated urinary formic acid/ethanol combined with a reduction in several VOCs may provide value for early real-time detection of AKI in the ICU. This platform may provide diagnostic and prognostic information during AKI.

Pre-Operative Level of Fibroblast Growth Factor 23 Is Associated with the Risk of Developing Severe AKI after Heart Surgery Stuart Goldstein,[2] Oded Volovelsky.[1] *[1]Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Fibroblast growth factor 23 (FGF23) has been assessed as an early AKI biomarker after renal ischemia in animals and humans. FGF23 is an early marker of chronic kidney disease in humans. We assessed the ability of pre-operative FGF23 to predict severe AKI after cardiac surgery in children.

Methods: Blood and urine samples were collected in a prospective observational study from 83 children with congenital heart disease. Serum creatinine, cystatin C, FGF23 and urine levels of NGAL, IL18, KIM-1, L-FABP were assessed pre-operatively. Severe AKI (sAKI; KDIGO stages II-III) was the primary outcome. Non-parametric multivariable linear regression and ROC analyses were used to evaluate the association between pre-operative FGF23, urine markers and the development of sAKI in the first week after CS.

Results: Median age [IQR] was 7 (2.2, 61) months and median bypass time was 135 [89,205] minutes. Surgical severity level, Cystatin C and urinary biomarkers did not differ between pts with vs. without sAKI. Pre-operative FGF23 was higher in pts who developed sAKI (Table) The AUC-ROC for preoperative FGF23 level to predict sAKI was 0.75 (0.56-0.95). Logistic regression of FGF23 had superior odd ratio for severe AKI (4.96).

Conclusions: Pre-operative FGF23 levels were associated with developing sAKI after CS. Current biomarker strategies focus on early postoperative diagnosis and treatment of AKI. Preoperative identification of children with higher risk of AKI after CS may help in developing AKI prevention strategies and risk stratification scores.

Glyco-iELISA: A Novel Assay to Detect STEC-HUS Kioa L. Wijnsma,[1] Susan Veissi,[1] Juan E. Ugalde,[3] Diego J. Comerci,[3] Nicole Van De Kar,[1] Bert Van den heuvel.[2,4] *[1]Pediatrics, Radboud medical center, Nijmegen, Netherlands; [2]Radboudumc, Nijmegen, Netherlands; [3]Universidad Nacional de San Martin, San Martin, Argentina; [4]Pediatrics, University Hospital Leuven, Leuven, Belgium.*

Background: Differentiation between hemolytic uremic syndrome (HUS) caused by Shiga toxin-producing *E. coli* (STEC-HUS) or a dysregulated complement system (atypical HUS; aHUS) is a clinical conundrum. As aHUS, whose treatment requires the highly expensive orphan drug eculizumab, is a diagnoses *per exclusionem*, a method to reliably detect STEC infection is warranted. Since the current golden standard (fecal diagnostics; FD) for the detection of STEC infection has important drawbacks, serological detection of antibodies against STEC-associated lipopolysaccharides by ELISA (LPS-ELISA) has proven its value. However, LPS-ELISA have important limitations. Therefore, we have developed and evaluated the diagnostic value of ELISA employing recombinant glycoproteins of STEC-associated LPS (glyco-iELISA).

Methods: In this retrospective study, patients (n=61) who presented with clinical STEC-HUS in the Radboudumc, Nijmegen, Netherlands, between 1990-2014 were included. Clinical, diagnostic and follow up data were gathered. Both LPS-ELISA and glyco-iELISA were employed to detect IgM antibodies against the most common serotype of STEC (*O157*).

Results: FD, LPS-ELISA, and glyco-iELISA identified STEC infection in respectively, 53%, 64%, and 75% of patients. Glyco-iELISA provided evidence of STEC infection in 7 (11%) and 20 (33%) additional patients when compared to LPS-ELISA or FD, respectively. Combining the glyco-iELISA with FD identified STEC infection in 89% of patients. The glyco-iELISA appeared highly reproducible and reliable, as the intra- and inter-assay variability was low.

Conclusions: The glyco-iELISA is a highly sensitive and accurate serological method to detect STEC in HUS patients. Combined with FD, the glyco-iELISA improves STEC detection by 36%. Thus, the glyco-iELISA may drastically limit the unnecessary use of eculizumab in STEC-HUS.

FR-PO121

Raised Serum Creatinine and Decrease in Renal Cyp2c11 Gene Expression in Bile Duct Ligated Rats Is Attenuated by the Adsorbent of Gut Bio-Toxins: YAQ001 Amin Oomatia,[1] Francesco Chiara,[2] Jane Macnaughtan,[2] Rajiv Jalan.[2] *[1]Centre for Nephrology, University College London, London, United Kingdom; [2]Institute for Liver and Digestive Health, University College London, London, United Kingdom.*

Background: Renal dysfunction confers a poor prognosis in patients suffering from acute-on-chronic liver failure. Bile duct ligation (BDL), an established model for cholestatic liver injury, potentiates LPS mediated acute kidney injury (AKI) in rats. Gut decontamination using antibiotics attenuates this, suggesting translocation of gut flora products in cirrhosis may prime the kidney for exaggerated inflammatory responses. Yaq001 (YQ) is a non-absorbable, ingested carbon polymer, which adsorbs and reduces translocation of biotoxins. We investigated the effect it has on BDL rats.

Methods: Sprague-Dawley rats underwent either BDL or sham laparotomy and were then randomised to normal or YQ supplemented chow for 2-weeks. At four weeks, LPS or saline was injected intraperitoneally. Rats were sacrificed two hours later. Serum and tissue were collected. Next generation sequencing of RNA expression in rat kidney (sham vs BDL vs BDL+YQ, n=2 vs 3 vs 3) was performed for 17,327 and then analysed using DESeq2 workflow.

Results: Serum creatinine (SC) of groups of interest are shown in table 1. A difference in SC in BDL+LPS+YQ vs BDL+LPS rats was seen (32vs41 μmol/L), and tended towards statistical significance (p=0.086). Differential gene expression was significant (q<0.05) for a 107 genes in the BDL vs Sham groups, and 886 in the BDL vs BDL+YQ groups. Shrunken log2 fold change of expression for Cyp2c11, a CYP450 enzyme, was decreased in Sham vs BDL (8.66 vs 6.64, q=0), only to return to normal levels with treatment Yaq001 (5.87 vs 8.11, q=0.001).

Conclusions: BDL predisposes rats to AKI when faced with a septic insult, which is attenuated by Yaq001. Decrease in Cyp2c11 expression in BDL animals, which is normalised by Yaq001, suggests that disruption of cellular responses to oxidative stress may account for why kidneys in BDL rats and possibly cirrhotic patients are more susceptible to septic injury. Further research is needed to determine the effects of Cyp2C11 dysregulation and its effects on kidneys in cirrhosis.

Plasma Cytokines Are Associated with Increased AKI and 1-Year Mortality after Cardiac Surgery Dennis G. Moledina,[6] Sherry Mansour,[6] Yaqi Jia,[6] Heather Thiessen Philbrook,[6] Jay L. Koyner,[5] Eric McArthur,[2] Amit X. Garg,[3] Francis P. Wilson,[6] Michael Shlipak,[4] Steven G. Coca,[1] Chirag R. Parikh.[7] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Institute for Clinical Evaluative Sciences, London, ON, Canada; [3]London Health Sciences Centre, London, ON, Canada; [4]San Francisco VA Medical Center, San Francisco, CA; [5]University of Chicago, Chicago, IL; [6]Yale School of Medicine, New Haven, CT; [7]Yale University and VAMC, New Haven, CT. Group/Team: TRIBE-AKI.*

Background: Inflammatory pathways are activated in ischemia reperfusion injury (IRI) and their decreases IRI-related acute kidney injury (AKI) and improves survival in animal models. However, the significance of these pathways in humans is unknown

Methods: In the TRIBE-AKI cohort of high-risk adults who underwent cardiac surgery (n=1444), we measured 10 inflammatory cytokines [interferon (IFN)-γ, tumor necrosis factor(TNF)-α, interleukin (IL)-1β, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12p70, and IL-13] from plasma samples collected after cardiac surgery using Mesoscale multiplex assay. We tested the association of peak postoperative cytokine values with postoperative AKI Network stage 1 AKI and 1-year mortality

Results: AKI occurred in 492 and 1-year mortality in 81 participants. Higher cytokine levels were independently associated with increased odds of AKI and 1-year mortality for 10 cytokines in the model adjusted for 14 key variables (**Figure**). After further adjustment for IL-6, only IL-2, IL-8 and IL-10 remained significantly associated with 1-year mortality, and IL-10 with AKI. Given that cytokines in the multiplex were highly collinear, we performed principal component analysis to combine these cytokines. Adding the principal components to the clinical model consisting of the above 14

variables improved the AUC by 0.01 (P<0.001) for AKI and 0.04 (P<0.001) for 1-year mortality resulting in final AUCs of 0.77 (0.75, 0.80) and 0.76 (0.70, 0.82), respectively

Conclusions: Combination of inflammatory cytokines measured using a multiplex assay after cardiac surgery provided higher discrimination for AKI and 1-year mortality as compared with the clinical model

Funding: NIDDK Support, Private Foundation Support

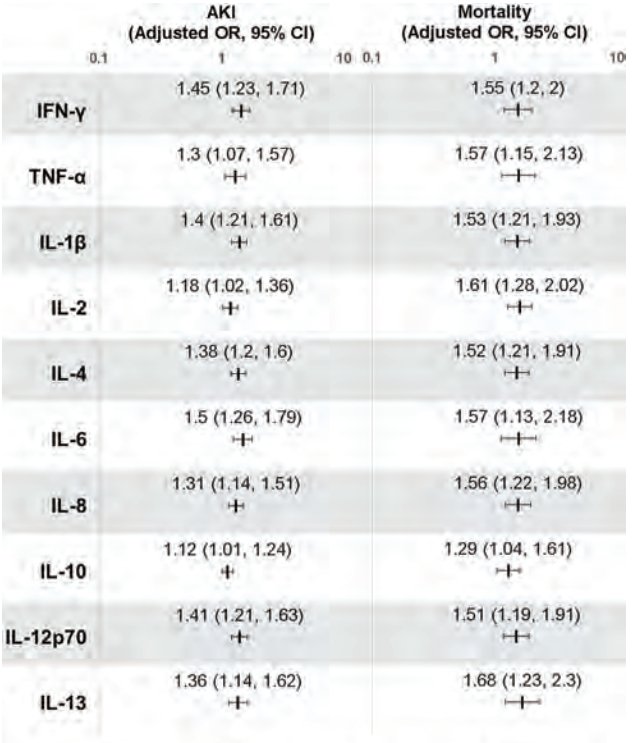

Figure. Association of plasma cytokine levels with 1-year mortality. Odds ratio (OR) per log increase in cytokine. Adjusted for age, sex, race, CPB time, non-elective surgery, surgery type, pre-op eGFR, diabetes, hypertension, congestive heart failure, myocardial infarction, pre-op urine albumin to creatinine ratio, site, corresponding pre-operation biomarker, and change in serum creatinine from pre-op

FR-PO123

Low-Dose Atrial Natriuretic Peptide for Preventing and Treating AKI: Systematic Review and Meta-Analysis Hiroyuki Yamada,[1] Kent Doi,[2] Tatsuo Tsukamoto,[3] Kazuto Yamashita,[4] Hideyasu Kiyomoto,[5] Motoko Yanagita,[1] Yoshio Terada,[6] Kiyoshi Mori.[7] *[1]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Department of Acute medicine, University of Tokyo, Tokyo, Japan; [3]Department of Nephrology & Dialysis, Kitano Hospital, Tazuke Kofukai Medical Research Institute, Osaka, Japan; [4]Department of Healthcare Economics and Quality Management, Kyoto University Graduate School of Medicine, Kyoto, Japan; [5]Division of Integrated Nephrology and Telemedicine, Department of Community Support, Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan; [6]Department of Endocrinology, Metabolism and Nephrology, Kochi Medical University, Kochi, Japan; [7]Department of Nephrology and Kidney Research, Shizuoka General Hospital, Shizuoka, Japan.*

Background: Low-dose atrial natriuretic peptide (ANP) could theoretically bring about beneficial effect for acute kidney injury (AKI) as a pharmacological intervention. We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) comparing low-dose ANP with placebo or conventional therapy for the prevention or treatment of AKI.

Methods: Low dose of ANP was defined as 50 ng/kg/min or smaller according to KDIGO AKI Guideline 2012. EMBASE, PubMed and Cochrane CENTRAL databases were searched for RCTs comparing low-dose ANP with placebo or conventional therapy for patients with high risk of AKI or with AKI. Two reviewers independently collected data assessed outcomes. The primary outcome was hospital mortality. Secondary outcomes were requirement of renal replacement therapy (RRT), length of intensive care unit (ICU) stay and incidence of hypotension. The risk of bias was evaluated using Cochrane risk of bias tool. Trial sequential analysis was used for the main outcome of interest. The publication bias of the included studies was assessed by funnel plot. All the statistical analyses were performed using Review Manager Version 5.3 and TSA version 0.9 version software.

Results: A total of 18 RCTs (16 prevention, 2 treatment) fulfilled our inclusion criteria. Most of them had a high or unclear risk of bias in more than two domains. Low-dose ANP showed a significantly beneficial effect to reduce RRT both in the prevention trials (RR 0.20; 95%CI 0.07–0.59; p=0.003) and treatment trials (RR 0.43; 95%CI 0.20–0.93; p=0.03). Regarding RRT, however, TSA indicated that the number of patients included was below the information size required for a definitive conclusion. On the other hand, no significant difference was observed on hospital mortality, length of ICU stay and induction of hypotension. The shape of the funnel plots in each outcome did not show an obvious asymmetry.

Conclusions: These results indicated that low-dose ANP could be potentially effective for the prevention and treatment of AKI. However, the quality and sample sizes of these RCTs were not sufficient to demonstrate the effects of low-dose ANP. It showed the necessity for RCTs with high-quality and large sample size.

FR-PO124

AKI after Cytoreductive Surgery and Intraoperative Cisplatin Exposure for Malignant Pleural Mesothelioma Tamar Hod, Katherine J. Freedberg, Margaret E. Chen, Joseph V. Bonventre, Sushrut S. Waikar. *Brigham and Women's Hospital, Boston, MA.*

Background: Cytoreductive surgery with or without intraoperative administration of intrathoracic cisplatin is a treatment for certain cases of malignant pleural mesothelioma. The combinations of surgery-induced inflammation, ischemia, and nephrotoxin administration increase the risk of acute kidney injury (AKI), but has not been thoroughly investigated in this unique patient population exposed to multiple kidney insults.

Methods: We assembled a retrospective cohort of patients undergoing cytoreductive surgery with or without intraoperative cisplatin for malignant pleural mesothelioma at Brigham and Women's Hospital between 2006-2015. We defined AKI according to the KDIGO criteria. Pre-operative characteristics, intra-operative blood loss, and post-operative outcomes of mortality and length of stay were compared in those who did versus did not develop post-operative AKI.

Results: Post-operative AKI occurred in over three quarters of the 504 patients studied (379 of 504, 75.2%); 261 (51.8%) had stage 1 AKI; 85 (16.9%) had stage 2 AKI, and 33 (6.5%) had stage 3 AKI. 16 patients required dialysis. 391 patients (77.6%) received intraoperative cisplatin. The following variables were found to be associated with an increased odds for postoperative AKI: baseline estimated glomerular filtration rate (odds ratio (OR) 0.97; 95% CI 0.96-0.99), male sex (OR 3.44; 95% CI 1.95-6.09), estimated blood loss during surgery (OR 1.47; 95% CI 1.07-2.02) and exposure to intraoperative cisplatin (OR 3.51; 95% CI 1.47-8.39). Higher stages of AKI were associated with longer length of stay (14.8 vs. 16.3 vs. 18.4 vs 30.2 days) and with increased risk of death at 1 year (30.4% vs. 26.4% vs. 41.2% vs 60.6%) for no AKI, stage 1 AKI, stage 2 AKI, and stage 3 AKI, respectively; P < 0.001).

Conclusions: Cytoreductive surgery with intraoperative cisplatin for the treatment of malignant pleural mesothelioma is associated with a substantially higher risk of post-operative AKI than other surgical procedures such as cardiac surgery. The high rate of AKI in this unique patient population makes it a suitable setting for investigation into ischemic and nephrotoxic AKI in humans.

FR-PO125

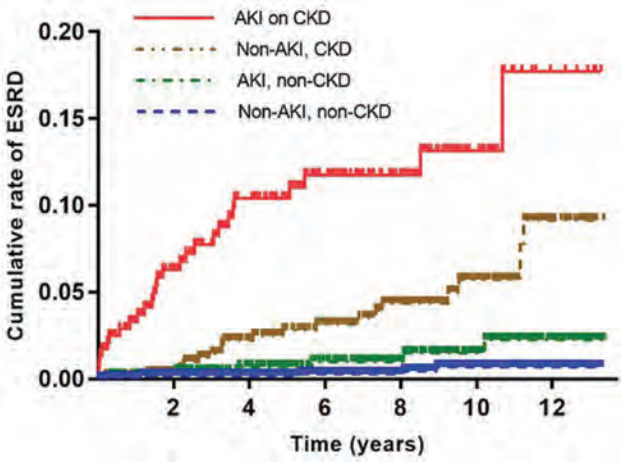
Synergistic Effects of AKI and CKD on the Development of ESRD after Coronary Artery Bypass Grafting Yeonhee Lee,[3] Hongran Moon,[3] Jung Pyo Lee,[1] Sejoong Kim,[2] Dong Ki Kim,[3] Yun Kyu Oh,[1] Ho Jun Chin,[2] Chun Soo Lim,[1] Yon Su Kim,[3] Ki Young Na,[2] Seung Seok Han.[3] *[1]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, GYEONGGI-DO, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Because end-stage renal disease (ESRD) affects patient outcomes in several diseases, exploring risk factors for ESRD is a critical issue in clinical practice. This study firstly addressed to evaluate the synergistic effects of acute kidney injury (AKI) and chronic kidney disease (CKD) on the development of ESRD in patients with coronary artery bypass grafting (CABG).

Methods: This study included 1,899 patients (aged ≥18 years) underwent CABG between 2004 and 2015 in two tertiary referral centers. Patients were classified as groups with postoperative AKI, preoperative CKD, or both according to the KDIGO guidelines. We performed the Kaplan-Meier method and the multivariable Cox regression model to calculate the cumulative incidence of ESRD and to estimate the hazard ratio of ESRD. Patients were followed for 74±44 months (maximum 13 years).

Results: Postoperative AKI occurred in 799 patients (26.5%), including 23.8% in stage 1 and 2.7% in stages 2 and 3. CKD was identified in 890 patients (29.5%). ESRD occurred in 60 patients (1.4%) as following subject numbers and proportions: the group without AKI and CKD, 6 (0.4%); the AKI group, 6 (1.2%); the CKD group, 20 (3.4%); and the group with both AKI and CKD, 28 (9.2%). The cumulative rate of ESRD increased in the following order, the group without AKI and CKD, the AKI group, the CKD group, and the group with both AKI and CKD (Figure). In multivariate analyses, both AKI [HR, 3.2 (1.01-10.13)] and CKD [HR, 9.2 (3.46-24.43)] were independently associated with the risk of ESRD (all Ps<0.05). Particularly, in the CKD patients, the presence of AKI significantly increased the risk of ESRD compared with the counterpart group without AKI, as follows: HR, 3.4 (1.91-6.04); P<0.05.

Conclusions: The presences of AKI and CKD synergistically increase the risk of ESRD in CABG patients.



FR-PO126

Dialysis-Requiring AKI in CKD Patients Receiving Radiocontrast Di Pan,[1,3] David Mariuma,[1,3] Yumeng Wen,[1,3] Michael Gramuglia,[4] Ira S. Meisels.[2,3] *[1]Mount Sinai St. Lukes and Mount Sinai West Hospitals, New York, NY; [2]Division of Nephrology, Mount Sinai St. Luke's and West Hospitals, New York, NY; [3]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [4]Montefiore Health System, New York, NY.*

Background: Contrast-induced nephropathy has been a widely recognized and long-accepted complication of radiocontrast administration. However, there have been recent studies that call into question whether a link between acute kidney injury (AKI) and radiocontrast truly exists in the setting of iso-osmolar or low-osmolar contrast use in imaging and vascular procedures. The goal of this study is to evaluate the relationship between dialysis-requiring AKI and contrast administration in patients with different stages of chronic kidney disease (CKD).

Methods: This is a retrospective analysis utilizing the 2014 Nationwide Inpatient Sample, the largest publically available inpatient database in the United States. A total of 3,367,411 patients over age 18 with CKD were included. End-stage renal disease patients on chronic dialysis were excluded. Multivariate logistic regression was performed to test for indepedent associations between dialysis-requiring AKI and exposure to either intravenous contrast (IV; n=8170), arteriography/angiogram (AG; n=160,110), or arterial catheterization with intervention (ACI; n=86,715), specifically coronary, peripheral vascular, or neurovascular interventions. Further subgroup analysis was performed for CKD stages 3 to 5. Procedures and diagnoses were identified using ICD-9-CM codes. Analysis was performed using Stata 14.2.

Results: All CKD patients regardless of stage, who received either IV (OR 2.4, p<0.0001), AG (OR 1.28, p<0.0001), or ACI (OR 1.24, p=0.005), had increased associations with dialysis-requiring AKI. Similar results were observed in the subgroup analyses. CKD 5 subgroup: IV (OR 3.15, p=0.007), AG (OR 2.34, p<0.0001), ACI (OR 1.24, p=0.005). CKD 4 subgroup: IV (OR 5.0, p<0.0001), AG (OR 2.13, p<0.0001), ACI (OR 1.66, p=0.022). CKD 3 subgroup: IV (OR 1.98, p=0.045), AG (OR 1.28, p=0.013), ACI (OR 1.81, p<0.0001).

Conclusions: Our results demonstrate that there are strong associations between dialysis-requiring AKI and radiocontrast exposure among patients with CKD. Despite conflicting data that challenge this relationship, clinicians should continue to exercise caution when administering radiocontrast in this patient population. Further prospective cohort and randomized controlled studies should be performed before definitive conclusions can be made.

FR-PO127

Factors Associated with Dialysis-Requiring AKI in Patients with Septic Shock Di Pan,[1,3] David Mariuma,[1,3] Yumeng Wen,[1,3] Fernando Vazquez de lara,[1,3] Marcelo X. Hernandez cuchillas,[1,3] Michael Gramuglia,[4] Ira S. Meisels.[2,3] *[1]Mount Sinai St. Lukes and Mount Sinai West Hospitals, New York, NY; [2]Division of Nephrology, Mount Sinai St. Luke's and Mount Sinai West Hospitals, New York, NY; [3]Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [4]Montefiore Health System, New York, NY.*

Background: Acute kidney injury (AKI) poses significant burden on patients with septic shock, especially for those who ultimately require renal replacement therapy (RRT). The aim of this study is to identify potential risk factors and patient characteristics associated with receiving RRT in patients with septic shock.

Methods: This is a retrospective analysis based on the 2014 Nationwide Inpatient Sample. A total of 435,835 patients over age 18 with either a primary or secondary diagnosis of septic shock were included. Patients on chronic RRT were excluded. The outcome of interest was dialysis-requiring AKI. Multivariate logistic regression adjusting for age, gender, hospital characteristics, insurance, and comorbidities was performed to test for independent associations between variables of interest (which included 29 AHRQ comorbidity measures), and dialysis-requiring AKI. Diagnoses and procedures were identified using ICD-9-CM codes. Analysis was performed using STATA 14.2.

Results: Our study revealed that male gender (OR 1.24, p<0.0001), African-American (OR 1.34, p<0.0001), and Hispanic (OR 1.14, p=0.03) race have increased odds of having AKI-requiring dialysis in septic shock. Pre-existing comorbidities and other factors found to have increased association with AKI-requiring dialysis were: chronic alcohol abuse (OR 1.20, P=0.005), chronic anemia (OR 1.16, p<0.0001), congestive heart failure (OR 1.13, p=0.001), coagulopathy (OR 2.07, p<0.0001), diabetes with complications (1.27, p<0.0001), history of hypertension (OR 1.14, P<0.0001), chronic liver disease (OR 1.45, p<0.0001), obesity (OR 1.67, p<0.0001), pulmonary circulation disorders (OR 1.21, p=0.001), and the presence of bacteremia (OR 1.97, p=0.005).

Conclusions: Clinical and microbiological characteristics, as well as pre-existing comorbidities should be considered in the prognostication and risk stratification of patients with septic shock, and the development of dialysis-requiring AKI. Future prospective studies can be considered for further evaluation.

FR-PO128

Non-Recovery After Dialysis-Requiring AKI Is Associated with Increased Short-Term Mortality and Cardiovascular Events in Incident ESRD Patients Benjamin J. Lee,[1] Chi-yuan Hsu,[1] Rishi V. Parikh,[2] Thomas Leong,[2] Thida C. Tan,[2] Sophia Walia,[2] Raymond K. Hsu,[1] Kathleen D. Liu,[1] Alan S. Go.[2,1] *[1]University of California, San Francisco, San Francisco, CA; [2]Kaiser Permanente Northern California, Oakland, CA.*

Background: There is a high burden of early mortality and cardiovascular disease (CVD) in ESRD patients. We hypothesized that patients with ESRD precipitated by non-recovery after dialysis-requiring acute kidney injury (AKI-D) are at higher risk for short-term death and CVD events compared to incident ESRD patients who did not experience AKI-D.

Methods: We evaluated adult members of Kaiser Permanente Northern California who initiated renal replacement therapy between January 2009 and September 2015. Outcomes were all-cause death, heart failure hospitalization, acute coronary syndrome (ACS), and acute ischemic stroke or transient ischemic attack (TIA) within 1 year of dialysis initiation. Baseline demographics, eGFR, dipstick proteinuria, other labs, comorbidities, and medication use were identified from electronic health records and used for multivariable adjustment.

Results: Patients with ESRD due to AKI-D (n=1,865) were older, more likely to be white, and had more baseline CVD than incident ESRD patients without AKI-D (n=3,772). Preceding AKI-D was associated with higher crude risks of death and CVD events (**Table**). In multivariable Cox regression, patients with ESRD due to AKI-D were at statistically significantly higher risk for death (adjusted hazard ratio [aHR] 1.79, 95% CI 1.49-2.13) and heart failure hospitalization (aHR 2.22, 1.43-3.33). Trends for ACS (aHR 1.25, 0.88-1.75) and acute ischemic stroke/TIA (aHR 1.27, 0.85-1.89) were not statistically significant.

Conclusions: Patients who transition to ESRD via AKI-D are a high-risk subgroup that may benefit from aggressive monitoring and medical management, particularly for heart failure.

Funding: NIDDK Support

Crude rates of death and CVD outcomes at 1 year after dialysis initiation, stratified by whether ESRD was precipitated by AKI-D.

Outcome	Subgroup	Rate per 100 person-years (95% Confidence Interval)	P-value
All-Cause Death	ESRD not due to AKI-D	9.51 (8.50-10.65)	**<0.0001**
	ESRD due to AKI-D	23.58 (18.06-30.78)	
Heart Failure Hospitalization	ESRD not due to AKI-D	3.00 (2.45-3.67)	**<0.0001**
	ESRD due to AKI-D	8.17 (5.09-13.11)	
Acute Coronary Syndrome	ESRD not due to AKI-D	3.45 (2.86-4.17)	**0.0081**
	ESRD due to AKI-D	5.14 (3.17-8.33)	
Acute Ischemic Stroke or TIA	ESRD not due to AKI-D	2.68 (2.16-3.32)	0.1168
	ESRD due to AKI-D	3.53 (2.02-6.18)	

FR-PO129

High Incidence of Transition to ESRD in Patients Discharged with Dialysis Dependent AKI: The Cleveland Clinic Experience Samir A. Brahmbhatt,[3] Sherif Armanyous,[2] Michael Lioudis,[1] Robert J. Heyka,[3] Leslie P. Wong,[1] Sevag Demirjian.[1] *[1]Cleveland Clinic, Solon, OH; [2]Cleveland Clinic Foundation, Cleveland Heights, OH; [3]Cleveland Clinic Foundation, Cleveland, Ohio, Beachwood, OH.*

Background: Acute kidney injury in hospitalized patients has been reported in 20-67% of patients and is a known cause of significant morbidity and mortality. Many of them continue to require dialysis support after discharge as an out-patient, while being monitored for renal recovery. Recent approval of financial reimbursement by the Centers for Medicare & Medicaid Services (CMS) for this group of patients, labelled as Acute Kidney Injury-requiring dialysis (AKI-D) in an out-patient dialysis center, even if not declared end-stage renal disease (ESRD), will change practice patterns and shift dialysis care to chronic units. Our goal is to describe the incidence of non-recovering AKI-D and associated risk factors.

Methods: A retrospective observational cohort study of patients with AKI-D discharged from Cleveland Clinic and received outpatient dialysis at Cleveland Clinic, Cleveland, OHIO from 2010 to 2016. Data were extracted from Cleveland Clinic Acute Renal Registry.

Results: The study included 390 patients discharged from index hospitalization with AKI-D. The median age was 62 years (52, 70); 62% were male and 65% white. Two thirds of patients were critically ill requiring intensive care and most had multifactorial etiology for kidney injury with acute tubular necrosis being the clinical diagnosis in 2/3. Comorbidities included baseline chronic kidney disease (CKD) in 38%, hypertension 62%, diabetes 42%, heart failure 23%, and liver disease 20%. Baseline serum creatinine was 1.4 mg/dL (1,2); serum creatinine and urine output at dialysis initiation were 5.8 mg/dL (4.2,8), and 290 mL/day (100,660). 221 patients (56%) were transitioned to ESRD, the primary endpoint of the study. Univariate analysis showed male gender, CKD, hypertension, diabetes mellitus and heart failure to be associated with transition to ESRD.

Conclusions: In a single center study of large cohort of patients with AKI-D, the presence of baseline kidney disease, diabetes mellitus, hypertension and heart failure were associated with higher incidence of transition to ESRD.

FR-PO130

Serum Troponin-T Levels and Intensity of Pulmonary Liquid Removal Can Indicate Myocardial Injury during Intermittent Hemodialysis Session in Patients with AKI Lygia Lussim, Fernanda D. Martins, Carolina Brianez, Isabella C. Ribeiro, Marco antonio D. Carvalho filho, Thiago Santos, Rodrigo B. de Oliveira. *School of Medical Sciences of the University of Campinas, Campinas, Brazil*.

Background: Intermittent hemodialysis (IHD) is a modality of renal replacement therapy used in critical patients with acute kidney injury (AKI), in which one of the most common complications is hemodynamic instability, assessed either by clinical, laboratory and point of care ultrasound parameters (POCUS). In this clinical study we evaluated the relationship between serum high sensitivity cardiac troponin-T levels (hs-cTnT) and clinical, POCUS and laboratorial parameters in critical ill patients with AKI over IHD session.

Methods: Clinical and observational study where critical ill patients with AKI were submitted to IHD sessions. Every hour over IHD session we evaluated POCUS parameters [inferior vena cava diameter (IVC) and distensibility (dIVC), extravascular lung water (SLESS score)], mean arterial blood pressure (ABP), heart rate, vasopressors dose, hs-cTnT (reference range: < 14 ng/L), lactate, bicarbonate levels and venous and arterial oxygen saturation.

Results: Six patients (mean SOFA and APACHE II scores of 13±4 and 25±4, respectively), four men (66%), aged 45±15 years, with AKIN III [3 (50%) due to sepsis] were enrolled during 11 IHD sessions. Urea reduction ratio (URR) and ultrafiltration rate (UF) were 43±12 % and 5.1±2.3 mL/kg/h, respectively. At the end of IHD sessions a significant increase of hs-cTnT was detected (186±157 *vs.* 229±195 ng/L; p=0.02). The magnitude of this variation was not correlated with hemodynamic instability, ABP variation, heart rate, vasopressors dose, UF, POCUS parameters or serum lactate levels. In contrast, a positive correlation was detected between the increase of hs-cTnT and the decrease of SLESS score variation (R=0.74; p=0.02), suggesting impairment of fluid removal from lungs.

Conclusions: Serum hs-cTnT levels as well as the range of variation of pulmonary fluid removal may signal worsening of myocardial injury in critically ill patients with severe AKI and under IHD.

FR-PO131

Vitamin D Deficiency Prevalent in Pediatric Patients with Severe AKI on Prolonged Continuous Renal Replacement Therapy Ayse Akcan Arikan,[1] Naile Tufan Pekkucuksen,[5] Molly R. Vega,[3] Peace D. Imani,[4] Eileen D. Brewer,[2] Poyyapakkam Srivaths.[4,1] *[1]Baylor College of Medicine, Houston, TX; [2]Baylor College of Medicine and Texas Children's Hospital, Houston, TX; [3]Texas Children's Hospital/Baylor College of Medicine, Houston, TX; [4]Texas Children's Hospital, Houston, TX; [5]texas childrens hospial, Houston, TX*.

Background: Vitamin D deficiency is reported in critically ill children and pediatric chronic kidney disease (CKD) patients (pts) with associated with adverse outcomes. Children on continuous renal replacement therapy(CRRT) are at risk of micronutrient deficiencies; however, serum vitamin D profiles in children with severe acute kidney injury on CRRT are unreported. We aimed to describe vitamin D levels and frequency of vitamin D deficiency in pediatric pts requiring prolonged CRRT(>28days).

Methods: Our center utilizes continuous venovenous hemodiafiltration with regional citrate anticoagulation per institutional protocol for CRRT. Calcium is infused postfilter to keep serum ionized calcium levels in the normal range. All prolonged CRRT pts are assumed to be at risk of CKD and undergo monthly monitoring for CKD labs, including vitD(25;1,25) and parathyroid hormone(PTH) levels. All pts receiving prolonged CRRT during 2015-2017 were included in this study.

Results: 16 patients, 56% male received prolonged CRRT for acute kidney injury; CRRT duration was 60±34 days. First vitD levels were obtained after 28 days on CRRT; 4 pts (25%) were vitD deficient (<20), 7(44%) were insufficient (<30). Mean vitD25 level was 25.4 ± 7.5 ng/ml, mean vitD1,25 level was 47 ± 55 pg/ml; total calcium was10 ±1.5 mg/dl, ionized calcium was 1.23(1.16-1.28) mmol/L, phosphorus was 4.2 ±1.3 mg/dl. Despite routine vitD supplementation in total parenteral nutrition and additional oral supplementation when needed, all 4 patients with normal vitD25 levels became insufficient over time, 6 deficient or insufficient pts never had vitD25 levels>30. There was a negative correlation between vitD25 and PTH levels which did not reach statistical significance (Spearman r=-0.28, p=0.08). Despite strict control of serum ionized calcium and phosphorus levels in the normal range, 4/6 patients who became vitD deficient/ insufficient developed rising PTH levels(from 52 (45-176) to 434 (348-656) pg/ml, p=0.06).

Conclusions: Vit D deficiency/insufficiency is prevalent in pediatric prolonged CRRT, and might worsen despite usual pharmacological supplementation. Our preliminary data suggesting vitamin D abnormalities might be related to developing bone mineral disease in prolonged CRRT require confirmation through further studies.

FR-PO132

Successful Treatment of Severe AKI Caused by Catastrophic Anti-Phospholipid Syndrome (CAPS) Associated Thrombotic Microangiopathy (TMA) by Anti-C5 Monoclonal Antibody Sanjeev Gupta,[1] Praveen N. Chander,[2] Anastasios Papanagnou,[1] Tasleem Katchi,[1] Savneek S. Chugh.[2] *[1]Westchester Medical Center, Valhalla, NY; [2]New York Medical College, Valhalla, NY*.

Background: CAPS is a severe form of the anti-phospholipid syndrome, characterized by arterial and/or venous thrombosis leading to multi-organ failure, occurring over a short period of time. Steroids, IVIG, and plasmapheresis have long been the standard of care. Recently, the role of complement inhibition in CAPS has been explored. We present a very rare case of refractory CAPS successfully treated with Eculizumab (Ecu) which is a monoclonal antibody against complement protein C5.

Methods: A 65 years old male with a history of positive antiphospholipid antibodies (APA) presented with intermittent abdominal pain for 5 months and altered mentation. Physical examination highlighted a malar rash and bluish discoloration of the left 5th toe. Laboratory workup revealed anemia (Hgb-7.5g/DL), thrombocytopenia (platelet-106,000) and AKI (SCr 7.53), positive ANA, anti-dsDNA Ab, elevated lupus anticoagulant (LA- 1.69:1), anti-cardiolipin IgM (33), anti-β2-glycoprotein (22), low C3 & C4 (52, <5) and schistocytes on peripheral blood smear. Renal biopsy showed typical findings of TMA. ADAMTS13 activity was 25 which ruled out thrombotic thrombocytopenic purpura. Given multiple organ involvements within a week, TMA on renal biopsy and positive APA, a diagnosis of CAPS was made and the patient was started on steroids, plasmapheresis, IVIG and hemodialysis (HD). Despite adequate immunosuppression, LA titers remained elevated, and Rituximab was started. The patient subsequently failed treatment and remained on HD for 3 months. Because of ongoing TMA, Ecu was started which resulted in improvement of thrombocytopenia and urine output. The patient subsequently recovered his renal function and HD was discontinued 2 months after Ecu initiation.

Results:

Conclusions: Therapeutic options for refractory cases are limited. Rituximab is the next line treatment but, our patient failed that as well. Based on few case reports patient was started on Ecu and responded well. Ecu is a potent terminal complement blockade, which appears to be equally effective in CAPS induced TMA as in aHUS. In conclusion, complement blockade can be a useful mode of therapy in CAPS even in cases that have failed standard treatment and after months of organ failure.

Multisystem Manifestations of Haemolytic Uremic Syndrome: A Pictorial Case Series Louise J. Hartley, Sandra Butler, Emily J. Stenhouse, Ben C. Reynolds. *NHS Greater Glasgow and Clyde, Glasgow, United Kingdom*.

Background: We present a comprehensive pictorial case series illustrating the diverse multisystem radiological manifestations of Shiga toxin-producing Escherichia coli Haemolytic Uremic Syndrome (STEC-HUS). STEC-HUS is characterised by haemolytic anaemia, thrombocytopenia and acute renal dysfunction with significant morbidity and mortality.

Methods: We retrospectively reviewed the imaging findings of 148 cases of STEC-HUS in a national paediatric nephrology centre over a 13 year period. The average presenting age was 5.5 years (52% female; 48% male).

Results: Renal: Renal ultrasound was performed in 18.2% of cases, of which a hyperechoic renal cortex was the most common finding (19/27). Three cases of renal cortical necrosis and one case of acquired cystic kidney disease were diagnosed on serial ultrasound and MRI imaging. **Gastrointestinal:** Abdominal radiography (AXR) was performed in 14.2% of cases, of which colonic wall thickening was the most common finding (14/21). On abdominal ultrasound colonic thickening (12/27) and free fluid (10/27) were the most common findings. One case of bowel ischaemia was diagnosed on MRI. **Neurological:** Neuroimaging was performed in 8.1% of cases, of which bilateral lentiform nuclei and/or thalamic infarctions were the most common abnormality (5/12). Two patients had multi-territorial infarcts including the first reported case of large vessel arterial thrombosis in HUS on imaging. **Hepatobiliary:** Two cases of hepatomegaly were seen on abdominal ultrasound. On AXR biliary excretion of contrast media due to renal failure was reported in one case. Haemodialysis-related secondary haemochromatosis was diagnosed on follow-up MRI in two cases. **Respiratory:** Chest radiography was performed in 21.6% of cases, of which pulmonary oedema was the most common abnormality (7/32). **Ocular:** Eye ultrasound demonstrated severe vitreous haemorrhages in one case.

Conclusions: This pictorial case series illustrates the imaging findings of common, rare and previously unreported multisystem manifestations of STEC-HUS. Awareness of the role of radiology will aid early diagnosis and subsequent management in this complex disease.

FR-PO134

Clinical Presentation and Outcome in a Series of 258 Japanese Pediatric Patients with Thrombotic Microangiopathy: A Nationwide Survey during 2012-2015 Akira Ashida,[1] Hideki Matsumura,[1] Toshihiro Sawai,[2] Rika Fujimaru,[3] Yuko Fujii,[1] Akihiko Shirasu,[1] Hyogo Nakakura,[1] Kazumoto Iijima.[4] *[1]Pediatrics, Osaka Medical College, Takatsuki, Japan; [2]Pediatrics, Shiga university of medical science, Shiga, Japan; [3]Pediatrics, Osaka City General Hospital, Osaka, Japan; [4]Dept. of Pediatrics, Kobe Univ. Graduate School of Medicine, Kobe, Japan.*

Background: Thrombotic microangiopathy (TMA) includes hemolytic uremic syndrome (HUS) and thrombotic thrombocytopenic purpura (TTP). As recent studies have shown that HUS has various pathogenesis, we conducted the present study to clarify in detail the epidemiological characteristics of pediatric patients with TMA classified according to etiology.

Methods: This survey evaluated 258 Japanese pediatric patients who were diagnosed as having TMA and followed up between 2012 and 2015.

Results: The primary diseases responsible for TMA were categorized as TTP, Shiga toxin-producing *Escherichia coli* associated HUS (STEC-HUS), atypical HUS, and secondary TMA. In these four categories, the most frequent primary disease was STEC-HUS which was present in 64.3% of the patients, followed in order by atypical HUS (15.5%), secondary TMA (10.1%), and TTP (5.8%). About 40% of patients with TMA required renal replacement therapy during the acute phase. The final outcomes in terms of renal functions were normal renal function with normal urinalysis parameters in 95 patients, and CKD stage I in 62. However, in 31 patients chronic renal insufficiency (CKD stage II to V) persisted, including 4 patients with end-stage kidney disease (CKD stage V). Seventeen patients suffered recurrence of TMA, and 8 patients died. Among extrarenal complications at the final outcome point, hypertension and neuro-psychological complications were most frequent.

Conclusions: This study of epidemiological and demographic information for Japanese pediatric patients with TMA over the period 2012-2015 has confirmed the relative proportions of the primary underlying diseases reported previously. Pediatric patients with TMA should be followed up with monitoring of laboratory data including urinalysis, as in this series various symptoms remained at the end of the observation period.

FR-PO135

Acquired Thrombotic Thrombocytopenic Purpura Secondary to Hereditary Autoimmunity: A Model for a New Pathogenic Mechanism? Sofia H. Marques,[2] Rute Carmo,[2] Ana R. Freitas,[1] Pedro S. Rodrigues,[2] Patricia Martinho,[3] Teresa Fidalgo,[3] Manuel Pestana.[2] *[1]Centro Hospitalar de Entre o Douro e Vouga, Vale de Cambra, Portugal; [2]Centro Hospitalar de São João, Porto, Portugal; [3]Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal.*

Background: Thrombotic thrombocytopenic purpura (TTP) may result from mutations of the ADAMTS13 gene (congenital TTP) or inactivating autoantibodies against the enzyme (acquired TTP).

Methods: We present the case of a 21-year-old male admitted for TTP with a suppressed ADAMTS13 enzyme activity (0%) and high titers of anti-ADAMTS13 antibody (99AU/mL) who was treated with plasmapheresis and rituximab. The patient's mother had an episode of thrombotic microangiopathy in 1998 without major health issues since then. After her son's disease, her blood tests were performed and revealed absent ADAMTS13 enzyme activity (0%) and positive anti-ADAMTS13 antibody (46AU/mL). Molecular studies were performed by a next generation sequencing - based gene panel (ADAMTS13, CFH, CFHR1, CFHR3, CFHR4, CFHR5, CFI, CFB, C3, THBD and DGKE), and no molecular abnormalities were detected. Results of HLA genotyping for both patients are displayed on Table 1.

Results:

Conclusions: As far as we know, this is the second report of an acquired TTP due to autoantibodies inactivating ADAMTS13 in two relatives. Our patients did not have any of the alleles which were associated by other authors with increased disease susceptibility. We discuss possible mechanisms behind hereditary antibody-mediated autoimmune diseases such as post-translational protein changes or epigenetic inherited processes. We also reflect on the fact that severe enzyme deficiency does not seem sufficient to express clinically as TTP and an environmental trigger may be required to precipitate an acute episode.

Table 1: HLA genotyping for patients 1 and 2

Ongoing Eculizumab (ECU) Prevents Thrombotic Microangiopathy (TMA) in Patients (Pts) with Atypical Hemolytic Uremic Syndrome (aHUS): Final Long-Term Observational Study Data Jan Menne,[1] Yahsou Delmas,[2] John F. Kincaid,[3] Christoph Licht,[4] Enrico E. Minetti,[5] Chris Mix,[3] Francois Provot,[6] Eric Rondeau,[7] Neil S. Sheerin,[8] Bradley Dain,[3] Laurent E. Weekers,[9] Larry A. Greenbaum.[10] *[1]Medical School Hannover, Hannover, Germany; [2]CHU Bordeaux, Bordeaux, France; [3]Alexion Pharmaceuticals, Inc., New Haven, CT; [4]The Hospital for Sick Children, Toronto, ON, Canada; [5]Careggi University Hospital - Florence, Firenze, Italy; [6]CHU de Lille, Lille, France; [7]APHP; University Paris 6, PARIS, France; [8]Newcastle University, Newcastle upon Tyne, United Kingdom; [9]CHU ULg, Esneux, Belgium; [10]Emory University, Atlanta, GA.*

Background: Pts from previous ECU trials in aHUS could enroll in this observational long-term follow-up study (NCT01522170; enrollment/follow-up concluded), regardless of ongoing ECU use. The objective was to evaluate TMA rates and safety off and on ECU.

Methods: Endpoints included TMA event rate (primary) and targeted serious adverse events (TSAEs).

Results: In 93 pts (42 with off-, 82 with on-treatment periods), the TMA event rate was 3-fold higher off vs on ECU. Rates were stratified by baseline characteristics (**Table**). TSAE rates were higher off vs on ECU. Four pts had meningococcal infections on ECU in the current study; all recovered with treatment and remained on ECU without dosing changes.

Conclusions: Final data from the largest prospective cohort with aHUS, with some pts receiving ECU for >5 yrs, demonstrate clinical benefits with ongoing ECU.
Acknowledgment: Medical writing support provided by Peloton Advantage with funding from Alexion.

Funding: Commercial Support - Alexion Pharmaceuticals, Inc.

Table. Outcomes Off and On ECU (N=93)[a]

TMA Events[b]	Off Treatment[c] (n=42)	On Treatment[c] (n=82)
TMA event rate overall, per 100 PY (number of events)	18.3 (19)	6.8 (20)
TMA event rate by ECU regimen,[d] per 100 PY (number of events)		
Labeled	—	6.1 (13) [n=73][f]
Non-labeled	—	9.0 (7) [n=34][f]
TMA event rate by complement abnormality, per 100 PY (number of events)		
Identified abnormality	26.0 (13) [n=24]	8.5 (16) [n=51]
No identified abnormality	11.2 (6) [n=18]	3.8 (4) [n=31]
TMA event rate by TMA manifestation[e] history, per 100 PY (number of events)		
Single	15.6 (11) [n=29]	8.3 (16) [n=51]
Multiple	24.0 (8) [n=13]	4.0 (4) [n=31]
TMA event rate by age at first ECU infusion, per 100 PY (number of events)		
Adult (≥18 years of age)	14.2 (10) [n=25]	5.1 (8) [n=47]
Pediatric (<18 years of age)	27.1 (9) [n=17]	8.8 (12) [n=35]
Safety Endpoints	**Off Treatment (n=42)**	**On Treatment (n=82)**
TSAEs[f] per 100 PY (number of events)	27.9 (29)	21.5 (63)
Renal impairment	11.6 (12)	6.8 (20)
Infection, other	10.6 (11)	11.3 (33)
TMA	4.8 (5)	1.4 (4)
Malignant neoplasm	1.0 (1)	0 (0)
Infection, meningitis/meningococcal	0 (0)	1.4 (4)
Infection, aspergillus	0 (0)	0.3 (1)
Leukopenia	0 (0)	0.3 (1)

Three pts died during the current study. An adult pt discontinued non-labeled dosing of ECU and died due to severe intensive care complications and multi-organ dysfunction secondary to a gastrointestinal hemorrhage, lithiasic cholecystitis, and severe sepsis. A 2-year-old pt with history of infection, fatigue, hypotension, pulmonary hemorrhage, dialysis, and blood transfusion, suffered a seizure and died after ~10 months of labeled-dose ECU. Another pt <1 year of age was on long-term dialysis and received ECU for 2 months but discontinued due to lack of efficacy; subsequently, the pt had a TMA manifestation with multi-organ failure and died of sepsis after being off treatment for 7 months. [b]Median (range) total exposure to ECU was 61.0 (1.3–94.1) months. Pts had a median (range) follow-up of 31.2 (0.7–95.1) months off treatment. [c]TMA was defined as ≥1 of the following: changes in ≥1 laboratory parameter (decreases in platelet counts or increases in lactate dehydrogenase or serum creatinine levels), clinical signs and symptoms of TMA, or required intervention due to TMA. [d]Pt groups were not mutually exclusive; individual pts could be represented in both groups. [e]After completion of the parent study and entry into the current study, the labeled dosing regimen of ECU was defined as that specified in the prescribing information approved by regulatory authorities and other dosing schedules were permitted and classified as non-labeled regimens. [f]All unique TMA manifestations occurring in all on- or off-treatment periods in the current study were included. [g]Defined as serious infections, meningococcal infection, sepsis, renal impairment, and malignancy occurring during the current observational study. ECU, eculizumab; pts, patients; PY, patient-years; TMA, thrombotic microangiopathy; TSAEs, targeted serious adverse events.

FR-PO137

Atypical Hemolytic Uremic Syndrome (aHUS) Presenting as Acute Heart Failure: A Rare Presentation Diagnosed on Skin Biopsy Sanjeev Gupta,[1] Savneek S. Chugh,[2] Anastasios Papanagnou,[1] Tasleem Katchi,[1] Praveen N. Chander.[2] *[1]Westchester Medical Center, Valhalla, NY; [2]New York Medical College, Valhalla, NY.*

Background: aHUS is associated with Complement over-activation secondary to regulatory gene mutations. Kidney is the most commonly involved organ due to unique characteristics of glomerular endothelium. Cardiac involvement occurs in about 3-10% cases with aHUS, can be severe with the acute presentation but, a diagnosis of aHUS remains unrecognized in many such cases. Cardiac manifestations include myocardial infarction, cardiomyopathy and heart failure (HF). Treatment of aHUS includes blockade of the terminal Complement pathway (C5b-9) however, spontaneous recovery can occur. We present a unique case of aHUS with primary cardiac involvement that affected kidney as well but, was diagnosed with specific manifestations on the skin biopsy.

Methods: A 24-year-old man presented with acute onset of shortness of breath. Initial workup revealed cardiogenic shock, acute kidney injury (serum creatinine 2.54 mg/dl) and thrombocytopenia (platelet count 69,000). Right heart catheterization showed an ejection fraction (EF) of 10% requiring intra-aortic balloon pump. Laboratory

investigations revealed new onset hematuria with RBC casts, proteinuria (0.7gm), low hemoglobin (11.5 g/dl) and Haptoglobin (< 8), low C3, C4 and CH-50 and ADAMTS13 activity- 84%. ANA, p and c-ANCA, hepatitis panel and antiphospholipid Ab tested negative. The patient also developed a skin rash on the arm, which on biopsy showed features consistent with thrombotic microangiopathy (TMA) with positive staining for C3 and C4d. He underwent spontaneous clinical remission before initiation of complement blockade therapy. The patient was discharged following significant improvement of renal function, cardiac output (EF 35%) and normalization of platelet count.

Results:

Conclusions: aHUS is a rare disease with diagnosis resting on clinical, laboratory and pathological features. In a clinical setting of aHUS, performing kidney biopsy at times may not be feasible in the presence of thrombocytopenia and hence, a skin biopsy may provide diagnostic findings of TMA associated with microvascular staining of Complement and its metabolic products (C4d). HF is a grave complication of aHUS requiring a prompt diagnosis for initiation of treatment and resultant good long-term prognosis. A skin biopsy can show specific changes of TMA and be of diagnostic value.

FR-PO138

The Burden of Kidney Dysfunction in Hospitalized Patients with Hepatorenal Syndrome in the United States (US): 2009-2015 An T. Pham,[1,2] Khurram Jamil,[3] Kunal Lodaya,[5] David K. Hayashida,[4] Belinda Lovelace,[3] Xingyue Huang.[3] *[1]Health Economics and Outcomes Research, Mallinckrodt Pharmaceuticals, Hampton, NJ; [2]University of California San Francisco, San Francisco, CA; [3]Mallinckrodt Pharmaceuticals, Hampton, NJ; [4]Boston Strategic Partners, Inc., BOSTON, MA; [5]Boston Strategic Partners, Boston, MA.*

Background: Hepatorenal Syndrome (HRS), the development of functional renal failure in patients with advanced chronic liver disease, is associated with high morbidity and mortality. The objective of this study was to assess the clinical sequelae, cost burden, and cost drivers of HRS from US hospital perspective.

Methods: A retrospective, longitudinal analysis of the CERNER Health Facts® electronic health record (EHR) database from a large network of US hospitals was performed. Adult patients diagnosed with HRS based on ICD-9 code (572.4) between 2009 and 2015 were included in the analysis. Clinical staging and laboratory data were used to assess the health impact of these patients.

Results: We identified 1,571 male (61.8%) and 971 female (38.2%) patients (mean age: 57.9). Overall, the average length of stay was 34.6 days and hospitalized cost was $91,504. Using Kidney Diseases Improving Global Outcomes Acute Kidney Injury (KDIGO®-AKI) staging classification, the average hospitalization cost for patients without AKI was $62,563, in comparison to $143,620 for patients with stage 2 AKI. In addition, when changes in serum creatinine were examined over the duration of the HRS hospitalization, 44.1% had either no change or <20% improvements in serum creatinine from the time of hospital admissions. During the first HRS hospitalization, 36.8% of patients died and average cost of hospitalization was $108,497 for deceased versus $82,048 for a surviving patient. The HRS hospital readmission rate was 33.1%, which was comprised of 13.5% unplanned readmissions and 19.6% planned readmissions. Patients with unplanned readmissions had an average total cost of care of $97,590 in comparison to $76,803 for patients with planned readmissions.

Conclusions: From a hospital perspective, results from this analysis of a large network of US hospital database indicate that HRS is associated with high cost burden along with high rate of readmission and mortality. More importantly, many patients had either limited or no serum creatinine improvement during their hospital stays. Higher disease severity and unplanned re-admissions may be associated with higher cost of care. Together, these results point to a significant unmet medical need in this patient population and the need for additional treatment options to improve patient outcomes.

FR-PO139

Vitamin C Therapy Attenuates the Severity of AKI in Mice Model of Hepatorenal Syndrome Nadia Yousef,[2] Siddhartha S. Ghosh,[3] Daniel E. Carl.[1] *[1]None, Richmond, VA; [2]VCU Medical Center, GLEN ALLEN, VA; [3]VCU Medical Ctr, Richmond, VA.*

Background: Hepatorenal syndrome (HRS) type 1 is a life threatening complication of cirrhosis with limited therapeutic options and it manifests when an acute insult leads to renal vasoconstriction and secondary impairment of glomerular filtration in the setting of liver disease. There are unfortunately few therapeutic options to offer. A significant limitation in HRS research is the lack of animal models investigating the pathophysiology of HRS as well as potential beneficial therapies. We hypothesized that Vit C has a protective effect in HRS. We tested this hypothesis in murine model of HRS.

Methods: C57BL6 mice received 1ml/kg of carbon tetrachloride (CCl4) biweekly for 12 weeks to induce cirrhosis. A 6 mg/Kg of Lipopolysaccharide (LPS) was given intraperitoneally to induce acute kidney injury by simulating the inflammatory stressor caused by acute infection. Vit C 200 mg/kg was given 15 min prior to LPS. Four mice populations were studied: 1. Control mice (received Vit C only) 2. CCl4 treated mice 3. CCl4 + LPS mice 4. CCl4+LPS+Vit C mice (N=4-6 per group). Serum BUN, creatinine, urine output and urinary Na+ were measured in all 4 groups. MCP-1 and NFkB proteins expression were determined by western blot. Plasma IL-6 was measured by ELISA

Results: Control group 1 received Vit C only and showed the ideal BUN, SrCr and urine output. CCl4+LPS treated mice had renal phenotype suggestive of HRS, including a higher SCr, lower UNa and UOP compared to CCl4 mice ($p<0.05$). Vit C treated mice in group 4 showed significant improvement in renal function, as CCl4+LPS+Vit C mice had a significant improvement SCr and UNa+ ($p<0.05$) compared with CCl4+LPS mice, and there was a trend towards an improvement in UOP (p 0.07). MCP-1 protein expression was significantly higher ($p<0.05$) in CCl4+ LPS group compared with control and with the CCl4+LPS+Vit C group. Moreover, NFkB protein expression was significantly higher ($p<0.05$) in CCl4+LPS compared to the control group and CCl4+LPS+Vit C

Conclusions: Vit C administration has a protective role in severity of HRS, manifested by improved SCr, UOP, and UNa+ in this model of HRS. One potential etiology is via inflammation, as pre-treatment with Vit C down-regulates both inflammatory markers.

FR-PO140

Achieved Mean Arterial Pressure Target and Renal Recovery during Treatment of Hepatorenal AKI Juan Carlos Q. Velez, Ana Belen Rivera de Rosales, Edgar Hernandez- Montalvo, Bronwyn Leblanc, Jason R. Ledoux, Ivo Lukitsch. *Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.*

Background: We previously reported that a rise in mean arterial pressure (MAP) during treatment of hepatorenal (HR) acute kidney injury (AKI) with vasoconstrictors is associated with improvement in kidney function. However, it remains unclear whether the treatment target should be a specific absolute MAP value or a defined increment in MAP respect to baseline.

Methods: Records from hospitalized adult patients with HR-AKI treated with vasoconstrictors without shock were reviewed. We selected those who achieved ≥ 5-mmHg rise in MAP within 48 hours. The relationship between the mean MAP achieved during the first 72 hours of therapy and the change in kidney function at the end of therapy as determined by serum creatinine (sCr) was examined by analyses of variance for trend and multiple comparisons.

Results: Ninety-two patients with HR-AKI treated for up to 3-7 days with either midodrine/octreotide (M/O, n=73) or norepinephrine (NE, n=19) were identified. Forty-three (47%) of the patients (mean age 52 years, 44% women, mean sCr 3.7 ± 1.3 mg/dL and MELD 33.5) achieved ≥ 5 mmHg rise in MAP by 48 hours [24 (33%) with M/O, 18 (95%) with NE]. When analyzed based on tertiles of absolute value of achieved MAP (65-74, 75-84, ≥ 85 mmHg), there was a significant trend for greater reduction in sCr with higher achieved MAP (p=0.002). Furthermore, those who achieved a MAP of ≥ 85 mmHg had a greater reduction in sCr [-1.76 ± 0.6 mg/dL] compared to those who reached a MAP of 65-74 or 75-84 mmHg [-0.03 ± 0.5 mg/dL (p=0.019) and -0.25 ± 0.6 mg/dL (p=0.02), respectively]. When analyzed based on tertiles of magnitude of MAP increment from baseline (5-9, 10-14, ≥ 15 mmHg), there was a significant trend for greater reduction in sCr with greater rise in MAP (p=0.005). Moreover, those who achieved a MAP increase ≥ 15 mmHg had a greater reduction in sCr [-1.95 ± 0.5 mg/dL] compared to those with either a 5-9 or 10-14 mmHg increment in MAP from baseline [+0.17 ± 0.4 mg/dL (p=0.0004) and -0.58 ± 0.5 mg/dL (p=0.04), respectively].

Conclusions: Achievement of either a target MAP ≥ 85 mmHg or an increment in MAP ≥ 15 mmHg from baseline within the first 3 days of vasoconstrictor therapy is associated with greater reduction in sCr in HR-AKI. These data support the notion of a shift in the renal autoregulatory curve in HR-AKI.

FR-PO141

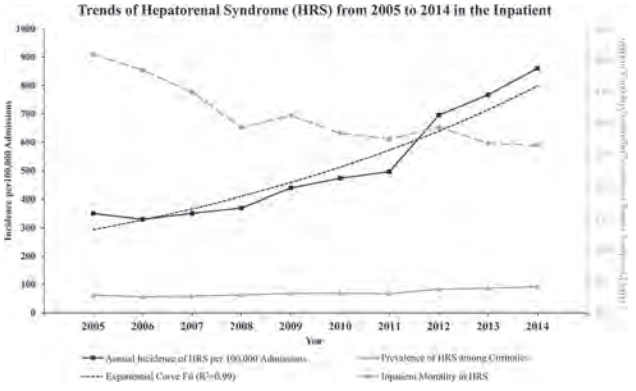
National Trends in Hospitalization and Resource Utilization in the Hepatorenal Syndrome Population: 2005-2014 Paris Charilaou,[3] Kalpit Devani,[1] Ayan De,[2] Alvaro Cornejo cobo,[6] Romela Petrosyan,[5] Pablo Garcia.[4] *[1]Division of Gastroenterology, East Tennessee State University, Johnson City, TN; [2]Internal Medicine, Saint Peter's University Hospital, New Brunswick, NJ; [3]Internal Medicine, Saint Peter's University Hospital, New Brunswick, NJ; [4]Internal Medicine, Saint Peter's University Hospital, New Brunswick, NJ; [5]Internal Medicine, Greenville Memorial Hospital, Greenville, SC; [6]Internal Medicine, Saint Peter's University Hospital, New Brunswick, NJ.*

Background: Recent changes in guidelines for diagnosis and treatment of Hepatorenal Syndrome (HRS) could have potentially affected hospital outcomes in these patients. We analyzed hospitalization and outcome trends of HRS cases, as well as outcome predictors, in the US inpatient population from 2005 to 2014.

Methods: We included all adults from the National Inpatient Sample (2005-2014), excluding cases with missing data on age/gender/inpatient mortality, who had documented liver cirrhosis (571.2, 571.5, 571.6) and HRS (572.4) as any discharge diagnosis, using the International Classification of Diseases Revision 9 – Clinical Modification (ICD-9-CM) codes. Multivariable mixed-effects regression was used to assess hospitalization trends as well as predictors of mortality, length of stay (LOS), and hospitalization costs. National estimates were calculated.

Results: We identified 158,306 HRS discharges, with males (65.4%) and white race (66.4%) being the majority. HRS annual prevalence increased exponentially (adjusted-R^2=0.99). Mean age was 57.6±0.08 years (increasing;p-trend<0.001). Mean mortality rate was 30.2% with decreasing trend (41% to 26.5%, $p<0.001$). Mean costs were unchanged at $31,061, as well as LOS (10.3 days), while aggregated costs increased by 2.5 times ($310.8 million in 2005 to $762.8 million in 2014). Significant (all $p<0.001$) mortality predictors included variceal bleed (aOR=1.90), hepatic encephalopathy (aOR=1.37), spontaneous bacterial peritonitis (aOR=1.42) and hepatocellular carcinoma (aOR=1.20). Urban and Midwest hospitals carried lower mortality risk ($p<0.001$). Urban and teaching hospitals exhibited longer LOS and higher costs. Midwest hospitals had 27% shorter LOS and 21% lower costs than the Northeast.

Conclusions: HRS hospitalizations are exponentially increasing, with an ever-growing financial burden to healthcare. While overall mortality is decreasing, there are disparities in hospitalization outcomes among regions.



FR-PO142

Renal Hypertrophy in End-Stage Liver Disease Marc M. Saad, Carla L. Ellis, W. Charles O'Neill. *Emory University, Atlanta, GA.*

Background: Renal failure has been extensively studied in liver disease but the normal physiologic responses to liver dysfunction remain unknown. We hypothesized that decreased clearance of metabolic products by the liver increases metabolic demand on the kidneys, leading to hypertrophy.

Methods: Renal parenchymal volume (RPV) was measured on outpatient CT scans performed in 29 patients with end-stage liver disease (ESLD) and 30 controls without liver disease. Cross-sectional kidney areas (excluding the renal sinus, vessels, collecting system, and cysts) from sequential transverse images were summed and muliplied by the slice thickness to derive RPV, which was normalized to body height. Renal histology was evaluated in 5 autopsies that were suitable for analysis and compared to 8 autopsies in patients without liver disease. Glomerular size was estimated from the area of Bowman's capsule measured at maximal cross-section (7-29 glomeruli/patient, mean 22). Subjects with diabetes, kidney stones, serum creatinine > 1.2 mg/dl, or proteinuria > 100 mg/dl by dipstick were excluded.

Results: The characteristics of the patients in whom RPV was measured are shown in the table. There were no significant differences between the groups. RPV/height was 21% greater in ESLD than in controls: 230 ± 7 ml/m vs 190 ± 7 ml/m (mean ± SE; p= 0.0002). This difference remained significant (p<0.001) in a multivariate analysis that included age, gender, serum creatinine, and degree of ascites. Glomerular volume was 24% greater in ESLD than in controls (3.68 ± 0.46 vs. 2.96 ± 0.41 $\mu m^3 x 10^6$) but significance was limited by the small sample size. No edema or vascular congestion was noted in any ESLD kidney.

Conclusions: Renal parenchymal volume is increased in patients with ESLD without evidence of renal disease. This cannot be explained by interstitial edema, vascular congestion, or ascites. There appears to be a similar increase in glomerular volume consistent with renal hypertrophy. This enlargement needs to be considered when evaluating kidney size in ESLD, and the hypertrophy could contribute to the increased risk of acute renal failure in ESLD.

Outcome of Decompensated Liver Cirrhosis Patients with AKI Treated with Renal Replacement Therapy Jian Li,[1] Lenar T. Yessayan,[2] Sandeep S. Soman.[1] *[1]Henry Ford Hospital, Detroit, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: Acute kindey injury(AKI) is a common complication in patients with cirrhosis and is associated with high mortality, renal repalcement therapy(RRT) is considered futile in hepatorenal syndrome if patient is not liver transplant candidate. The over survival and predictive factors has not been well established in those patients.

Methods: We retrospectively identified 123 patients with decompensated Liver cirrhosis receiving RRT for AKI between Nov. 1, 2013 and Dec. 31, 20015 in our hospital. Diagnosis of decompensated liver cirrhosis was based on previous histology findings or on various associations of clinical, biological, endoscopic, and/or imaging findings; AKI and HRS diagnosis were based on KDIGO and International Ascites Club 2007 criteria. The initiation of RRT was determined by nephrologist based on routine practice indications with assent of intensivist or hepatologist involved the care. RRT modality includes SLED-RCA, CVVH or IHD. Death served as outcome. 1, 3 and 6 month's mortality and selected clinical characteristics were examined. Chi-square two-sided tests were used to compare categorical variables, t test used for numerical data, P<0.05 is statistical significant.

Results: In this cohort, 52.8% was male; age 53.3 ±11.6; AKI causes: HRS 65; ATN 54, others 4. in 123 patients, Cirrhosis causes: alcohol 79, NSAH 18, hepatitis C and B: 10 and 1, others 15. 121 patients had outcome data, 2 patients lost follow up. In the death group, 1, 3 and 6 month's mortality rate was: 84.9%; 97.2% and 100%, average time on RRT were 20 ±30 days. In the 15 patients who survived till the time of transplanted, remained or off RRT, their average time on dialysis was 114 ± 106 days; 7 had simultaneous liver and kidney, 2 had liver transplant and off RRT, other 5 patients recovered or with CKD3, one was HD dependent. ICU admission, sepsis, infection and ventilator support were much higher in non-survival patients vs survival patients (P<0.0007-0.03). MELD score no difference in two groups, but all patients had higher score at time of RRT than at admission (P<0.01).

Conclusions: Patients with RRT dependent AKI in decompensated liver cirrhosis had very high short and long term mortality if they were not a liver transplant candidate. ICU admission, sepsis, infection and ventilator support rates were much higher in non-survival group than survived group.

FR-PO144

Hepatorenal Syndrome in Teaching versus Non Teaching Hospitals: A Nationwide Analysis Yumeng Wen,[1,2] Di Pan,[1,2] David Mariuma,[1,2] Marcelo X. Hernandez cuchillas,[1,2] Fernando Vazquez de lara,[1,2] Michael Gramuglia,[3] Ira S. Meisels.[1,2] *[1]Division of Nephrology, Department of Medicine, Mount Sinai St. Luke's and Mount Sinai West Hospitals, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Department of Medicine, Montefiore Medical Center, Scarsdale, NY.*

Background: Decompensated cirrhosis is a major cause of mortality and morbidity in the United States. Hepatorenal syndrome (HRS) is one of the potential causes of acute kidney injury (AKI) in patients with cirrhosis. The aim of our study is to determine the differences in outcomes and resource utilization in patients with HRS admitted to teaching hospitals as compared to nonteaching hospitals.

Methods: This is a retrospective cohort study using the 2014 National Inpatient Sample, the largest inpatient database in the United States. A corhort of 32,980 patients over the age of 18 diagnosed with HRS based on ICD-9 CM code was included in the study. Patients admitted for elective procedures were excluded. Hospitals were identified as teaching or nonteaching hospitals based on the American Hospital Association annual survey of hospitals. The primary outcome was in-hospital mortality. The secondary outcomes were morbidity, as measured by the development of shock, acute respiratory failure, variceal bleed, requirement for dialysis and resource utilization, as measured by the length of hospital stay (LOS) and total hospital charges. Odds ratios (OR) were estimated based on multivariate regression model adjusted for demographics, hepatitis C status, hospital region, primary insurance and household income. Analysis was performed using Stata, Version 14.2. Group 1: HRS admission to teaching hospital. Group 2: HRS admission to nonteaching hospital.

Results: Among patients with HRS, the in-hospital mortality rates were not significantly different between the two groups (OR 1.06, p=0.38). However patients in teaching hospital had significantly higher rates of shock (OR 2.33, p<0.001), acute respiratory failure (OR 1.44, p<0.001), variceal bleeding (OR 1.54, p<0.05) and requirement for dialysis (OR 1.34, p<0.001). In teaching hospitals the total charges were $57711.91 more (p<0.001), and the length of stay was also greater (12.02 days vs. 8.07 days, p<0.001).

Conclusions: Patients with HRS admitted to teaching hospitals had significant increase in morbidities as compared to those admitted to non-teaching hospitals. The development of shock, acute respiratory failure, variceal bleed, the requirements for dialysis and resource utilizations were greater in teaching hospitals despite similar rates of mortality.

FR-PO145

Different Effects of Aerobic and Combined Exercise on Mitochondrial OXPHOS Proteins in Skeletal Muscle of CKD Patients Douglas W. Gould,[2] Emma L. Watson,[2] Scott Mcguire,[1] Soteris Xenophontos,[2] Thomas J. Wilkinson,[2] Matthew P. Graham-Brown,[2] Joao L. Viana,[3] Alice C. Smith.[2] *[1]Coventry university, Coventry, United Kingdom; [2]University of Leicester, Leicester, United Kingdom; [3]University Institute of Maia, Porto, Portugal.*

Background: Patients with CKD exhibit skeletal muscle wasting and dysfunction. Mitochondrial dysfunction is observed in non-dialysis (ND) CKD, resulting in abnormal oxidative phosphorylation (OXPHOS) and reduced exercise capacity. Exercise is a potent stimulus for mitochondrial adaptations, however the effects in CKD are under investigated.

Methods: 17 ND-CKD patients (63±14 years; 11 female; eGFR: 28±8ml/min/kg/1.73m^2) completed 12-weeks aerobic exercise (AE) (n=9), or combined aerobic and resistance exercise (CE) (n=8) 3x/wk. Muscle biopsies were obtained from the vastus lateralis at baseline (B1) and 24h (B2) post the first and final exercise sessions (B3). Mitochondrial OXPHOS proteins were analysed by Western blotting and reported as %change (90% CI) from baseline. Data was analysed using Cohens effect size (*d*) and magnitude-based inferences (MBI) that calculates quantitative and qualitative probabilities of a true effect based on effect and 90%CI.

Results: CE showed moderate effects on total OXPHOS protein expression with mean increases of 27% (-11 – 80) *d*=0.39 and 34% (-3 – 80) *d*=0.47 at B2 and B3 respectively. In comparison, the effects of AE were negligible with mean changes of +2% (-28 – 50) *d*=0.03 at B2 and -3% (-70 – 150) *d*=0.04 at B3. Figure 1 shows the results

for the individual complexes along with MBI, where probability is the likelihood of a meaningful difference between time points in direction of change.

Conclusions: We report preliminary evidence of differential effects of AE and CE on OXPHOS complex protein expression in the muscle of ND-CKD. Mean % changes tended to be higher following CE, supported by larger effect sizes and MBI indicating beneficial effects for a number of respiratory chain complexes. This may suggest CE is more effective at modulating oxidative capacity of skeletal muscle in ND-CKD.

ABCA1 Mediated Mitochondrial Remodeling in Podocyte Injury and Diabetic Kidney Disease Gloria Michelle Ducasa,[1] Alexis J. Sloan,[1] Christopher E. Pedigo,[1] Mayrin Correa,[1] Matthias Kretzler,[2] Armando Mendez,[3] Robert G. Nelson,[4] Flavia Fontanesi,[5] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]Katz Family Center/ Div of Nephrology, Univ of Miami, Miami, FL; [2]U. Michigan, Ann Arbor, MI; [3]Diabetes Research Inst, Univ of Miami, Miami, FL; [4]NIDDK, Phoenix, AZ; [5]Biochem. and Molec. Bio., Univ of Miami, Miami, FL.*

Background: Diabetic kidney disease (DKD) is the most common cause of ESKD. Decreased podocyte number and glomerular lipid accumulation occurs in clinical and experimental DKD. It has been suggested that podocyte injury in DKD may result from impaired ATP Binding Cassette A1 (ABCA1) mediated cholesterol efflux, mitochondrial dysfunction or increased reactive oxygen species (ROS). However, if impaired ABCA1 function confers susceptibility to DKD by contributing to mitochondrial dysfunction or ROS remains to be established.

Methods: Patients enrolled in the *"Renoprotection in Early Diabetic Nephropathy in Pima Indians trial"* were separated into progressors and non-progressors (dGFR -97.39±8.2, n=15 and +40.62±8.6, n=16, respectively) based on the change in glomerular filtration rate (dGFR) between enrollment and last examination (10±1.7 years). Human podocytes were treated with patient sera. ABCA1 expression and cholesterol efflux were measured. SiRNA *ABCA1* (siABCA1p) and scrambled control (siCO) podocytes were treated with progressor sera and analyzed for caspase 3 activity. Mitochondrial respiratory chain complexes and ROS production were measured in siABCA1p. Podocyte specific Abca1 fl/fl mice were injected with streptozotocin (STZ) or bred to BTBR ob/ob (DKO) mice. Proteinuria was measured.

Results: Podocytes treated with progressor sera showed reduced ABCA1 mRNA expression ($p<0.05$) and cholesterol efflux ($p<0.01$) compared to non-progressors. siABCA1p treated with progressor sera have increased caspase 3 activity ($p<0.05$) compared to siCO. siABCA1p have increased mitochondrial respirasome formation ($p<0.01$), complex I activity ($p<0.05$) and ROS production ($p<0.001$). STZ injected Abca1 fl/fl ($p<0.05$) and DKO mice ($p<0.01$) have increased albuminuria compared to diabetic controls.

Conclusions: Our in vitro and in vivo studies show that reduced *ABCA1* expression confers susceptibility to DKD progression possibly by contributing to mitochondrial remodeling. Treatment strategies aimed at restoring ABCA1 function or mitochondrial dysfunction may be beneficial to prevent podocyte injury in DKD.

Kidney Injury Molecule-1 (KIM-1) Mediates the Proximal Tubule Uptake of Free Fatty Acids (FFA) Resulting in Mitochondrial Injury and the DNA Damage Response (DDR) Yutaro Mori, Pierre Galichon, Craig R. Brooks, Takaharu Ichimura, Joseph V. Bonventre. *Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: KIM-1 is the most upregulated proximal tubule protein in kidney injury. KIM-1 mediates the uptake of apoptotic cells and oxidized low-density lipoproteins (oxLDL). Deregulation of lipid metabolism during diabetes causes disturbed FFA metabolism which is implicated in injurious effects on the kidney in diabetic nephropathy (DN).

Methods: Renal epithelial cells expressing KIM-1 (KIM-1-PK1) were exposed to the FFA palmitic acid, and FFA uptake, necrotic cell death, accumulation of lipids and the DDR were assessed *in vitro*. Mitochondrial status and lysosomal activation were measured using the MitoTracker and LysoSenser dyes, respectively. Pro-fibrotic factor(s) production by FFA-treated KIM-1-PK1 cells were determined with a fibrosis bioassay using mouse primary baby kidney fibroblasts. Functional knockout of KIM-1 (KIM-$1^{\Delta mucin}$) and control mice were used for electron micrographic assessment of the effects of KIM-1 on mitochondrial fragmentation in diabetic nephropathy.

Results: FFA were taken up in the KIM-1-PK1 cells but not in control pcDNA-PK1 cells. Necrosis was increased after FFA treatment with FFA in KIM-1-PK1 cells when compared to controls. Lipid droplets were formed in the KIM-1 cells. FFA-treated KIM-1-PK1 cells had an increased number of fragmented mitochondria at 48 hr. These mitochondria co-localized with activated lysosomes suggesting mitophagy. Nuclear p-ATM and p-H2AX were increased in FFA-treated KIM-1-PK1 cells but not in the control cells. Conditioned media, harvested from KIM-1-PK1 cells treated with FFA, increased α-smooth muscle actin expression of mouse fibroblasts. oxLDL uptake also induced mitochondrial fragmentation and nuclear p-ATM and p-H2AX in a KIM-1 dependent way. Mitochondrial fragmentation occurred in a streptozotocin model of diabetic nephropathy in wild-type mice but not in KIM-$1^{\Delta mucin}$ mice.

Conclusions: KIM-1 mediates the epithelial uptake of FFA, which leads to cell death, lipid accumulation, activation of mitochondrial fragmentation and mitophagy, DDR and fibrosis. Our findings suggest that KIM-1-mediated FFA uptake may play an important role in pathophysiology of the DN.

The Iron Chelator Deferasirox Causes Kidney Disease via Mitochondrial Dysfunction Esther M. Gottwald, Claus D. Schuh, Dominik Haenni, Susan Ghazi, Milica Bugarski, Michael Duss, Ehud M. Landau, Andrew Hall. *University of Zurich, Zurich, Switzerland.*

Background: Deferasirox (DFX) is an oral iron chelator widely used in individuals at high risk of iron overload. It frequently causes kidney disease, by previously unknown mechanisms. Toxicity is localized to the proximal tubule (PT) and manifests clinically as the renal Fanconi syndrome (FS). PT cells are densely packed with mitochondria, which require iron for normal metabolism. We hypothesized that DFX causes kidney disease via mitochondrial toxicity.

Methods: Experimental models: PT-derived cell line, ex vivo mouse kidney cortex, in vivo mouse kidney. Techniques: confocal/multiphoton live imaging, electron microscopy, oxygen consumption measurements.

Results: In PT-derived cells and fresh slices of mouse kidney cortex we discovered that DFX induces rapid swelling of mitochondria, leading ultimately to rupture of the inner mitochondrial membrane (IMM). Other iron chelators did not have the same effect. Mitochondria remained polarized during the swelling process, which was not prevented by inhibition of the permeability transition pore, but was rapidly reversed by the addition of iron. Of note, DFX did not inhibit oxygen consumption or cause oxidative stress, and targeted anti-oxidants did not prevent the phenotype. Interestingly, DFX-induced mitochondrial swelling and rupture was accelerated by stimulation of respiratory chain (RC) activity, whilst RC inhibition had the opposite effect, suggesting that swelling is an active process. Moreover, DFX did not induce rupture in an artificial lipid vesicle model of the IMM, implying that toxicity requires proteins normally expressed within mitochondria. Using EM and intravital multiphoton microscopy, we observed that mice given DFX for 10 days showed evidence of mitochondrial swelling and dysfunction in vivo, exclusively in the PT, as well as impaired solute transport (consistent with FS). DFX is mainly albumin bound in blood, and we found that albumin binding reduced its toxicity in vitro, which might explain why the drug is tolerated by patients. Furthermore, since albumin is actively taken up by the PT, this could also explain the localization of DFX toxicity to this nephron segment.

Conclusions: In summary, we have found that DFX induces swelling and rupture of mitochondria in the PT, which most likely explains why it causes kidney disease in humans

FR-PO149

Bisphenol A Is an exogenous Toxin That Promotes Mitochondrial Injury and Death in Tubular Cells Enrique Bosch,[1] Alberto Ruiz,[1] Esther Civantos,[1] Alberto Ortiz,[2] Emilio E. Gonzalez-parra,[2] Sebastian Mas.[1] *[1]IIS- FJD, Madrid, Spain; [2]Fundacion Jimenez Diaz, Madrid, Spain.*

Background: Protein-bound uremix toxins, such a p-Cresol (pC) and metabolites, are harmful chemicals difficult to remove by hemodialysis. Bisphenol A is a ubiquitous environmental toxin, structurally related with pC, that accumulates in CKD, but is not currently considered a uremic toxin. Our aim was to characterize the nephrotoxic potential of BPA. Specifically, we addressed whether it disrupts mitochondrial function and causes cell death in energy demanding cells as tubular cells.

Methods: Experiments were performed on HK-2 human proximal tubular epithelial cells. Cell death and oxidative stress were evaluated by flow cytometry and confocal microscopy in HK-2 human proximal tubular epithelial cells. Functional assays tested ATP, intracellular Ca2+, mitochondrial function (TMRM), oxygen consumption, Nrf2-binding and NAPDH oxidase activity. Gene expression was assessed by qRT-PCR.

Results: Following acute exposure (24h), proximal tubulo-epithelial cell viability is only affected by BPA or pC at concentrations higher than 100 μM. The observed mechanisms are similar for both toxins, since they both promote mitochondrial dysfunction leading to energy depletion, mitochondrial and cytoplasmic oxidative stress (MitoSOX and NAPDH oxidase) and apoptosis in a concentration-dependent manner. An antioxidant response was observed consisting of Nrf2 translocation and increased expression of the Nrf2 target genes Heme oxygenase 1 (HO-1) and NAD(P)H dehydrogenase [quinone] 1 (NQO-1).

Conclusions: This study demonstrates for the first time that BPA causes mitochondrial injury, oxidative stress and apoptotic death in tubular cells. These results characterize BPA as an exogenous toxin that, similar to uremic toxins, may contribute to CKD progression.

FR-PO150

Elastica Masson's Trichrome (EMT) Staining Is Useful for the Visualization of Podocyte Foot Process and Tubular Mitochondria in the Kidney Ayumi Matsumoto, Isao Matsui, Karin Shimada, Nobuhiro Hashimoto, Daisuke Mori, Satoshi Yamaguchi, Keiichi Kubota, Tatsufumi Oka, Sayoko Yonemoto, Yusuke Sakaguchi, Tomoko Namba, Masayuki Mizui, Takayuki Hamano, Yoshitaka Isaka. *Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Changes in microstructures of renal cells, such as foot process effacement in podocytes and mitochondrial fission in tubular cells, are tightly correlated with the development and the progression of kidney disease. Because the sizes of these structures are less than the diffraction limit of visible light, electron microscopy is usually required for their observation. Super-resolution microscopy (SRM) is also available, but the common technique for SRM requires time-consuming immunofluorescent staining for specific molecules.

Methods: To visualize the microstructures more easily, we analyzed paraffin-embedded human renal biopsy sections stained with EMT, Hematoxylin Eosin (HE), Periodic Acid-Schiff (PAS), or Periodic Acid Methenamine Silver (PAM) using structured illumination microscopy. Sections of animal kidney disease models were also analyzed.

Results: EMT-stained paraffin-embedded sections excited by 457 or 561 nm laser were useful for the visualization of podocyte foot process. We could observe foot process in the sections from minor glomerular abnormalities but not from minimal change disease. Foot process was also observable in EMT-stained normal rat kidney but not in puromycin aminonucleoside injected kidney. The other staining methods — HE, PAS, and PAM — were not applicable to the evaluation of foot process. In the tubulointerstitial area of the human kidney, EMT-stained sections excited by 561 nm laser were useful for the evaluation of mitochondria. In some patients with kidney disease, we observed short mitochondria, which suggested the progression of mitochondrial fission. We confirmed the usefulness of EMT staining for the evaluation of mitochondria by observing mitochondrial fission in endotoxin-induced kidney injury and mitochondrial swelling in ischemia reperfusion kidney injury in mice. Tubular mitochondria were also observable in HE or PAS-stained sections, but the images obtained by these staining were less clear.

Conclusions: Paraffin-embedded kidney sections stained with EMT were useful for the visualization of foot process and mitochondria in the kidney.

Advanced Oxidation Protein Products Aggravate Tubulointerstitial Fibrosis through PKC-Dependent Mitochondrial Injury in Early Diabetic Nephropathy Xiaoyan Bai,[2] Xiao Li,[1] Jianwei Tian,[2] Wan Jiao.[3] *[1]Emergency, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China; [3]Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: The accumulation of advanced oxidation protein products (AOPPs) has been regarded as an initiating factor in podocyte injuries via the protein kinase C (PKC) signaling in diabetes. Yet, mechanisms of PKC signaling activation in renal tubular cell injuries and tubulointerstitial fibrosis (TIF) remain unclear. It has been established that PKC signaling plays a critical role in triggering oxidative stress and mitochondrial injuries in multiple diseases. Herein, we hypothesized that the accumulation of AOPPs in diabetes incurs mitochondrial dysfunction and oxidative stress causing renal TIF through the PKC signaling pathway.

Methods: The functional relevance of AOPP and PKC signaling in relation to mitochondrial injury, oxidative stress and fibrosis were investigated in high glucose (HG) cultured HK-2 cells and renal tubules from diabetic rats and patients using *in vitro* and *in vivo* approaches. Biological parameters were analyzed using enzyme linked immunosorbent assay (ELISA).

Results: *In vitro*, HG stimulated AOPP expression and augmented PKC-mediated oxidative stress and fibrosis in proximal tubular epithelial cells (PTECs). Further, we provide mechanistic evidences that inhibition of PKCη isoform alleviated mitochondrial injuries and function, attenuated apoptosis and renal fibrosis in HG cultured AOPPs-induced PTECs. *In vivo*, AOPPs-induced mitochondrial injuries, apoptosis and TIF were significantly decreased by PKCη inhibition in diabetic rats. Intrarenal AOPPs accumulation correlated with oxidative stress and fibrosis in renal biopsy samples from DN patients. AOPP and PKCη expression correlate with elevated proteinuria and declined renal function in diabetic rats and DN patients.

Conclusions: We propose a novel mechanism that AOPPs trigger mitochondrial dysfunction and oxidative stress causing TIF in diabetic nephropathy through activation of the PKCη isoform of the PKC signaling.

FR-PO152

Urinary Mitochondrial DNA Level as a Biomarker of Diabetic Nephropathy Zhongping Wei. *Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Hong Kong, China.*

Background: Diabetic nephropathy (DN) is the most common cause of end stage renal disease (ESRD). However, there is no reliable non-invasive biomarker for the diagnose or risk stratification of DN. Since mitochondrial dysfunction is involved in the progression of many kidney disease, we study the relation between urinary supernatant cell-free mitochondrial DNA (mtDNA) level and renal dysfunction in DN.

Methods: We recruited 92 patients with biopsy-proven DN. Urinary supernatant mtDNA level was measured by digital polymerase chain reaction, and compared to clinical, biochemical, histological data, as well as renal function decline in the subsequent 24 months.

Results: Mitochondrial DNA could be detected in all urine supernatant and renal biopsy specimens, with average levels 1421.0 ± 1827.5, and 286114.4 ± 193481.0 copies/μL, respectively. There was a modest but statistically significant inverse correlation between urinary supernatant and intra-renal mtDNA levels ($r = -0.453$, $p = 0.012$). Urinary supernatant mtDNA level had modest but statistically significant correlations, inversely with estimated glomerular filtration rate (GFR) ($r = -0.214$, $p = 0.04$), and positively with the severity of interstitial fibrosis ($r = 0.300$, $p = 0.005$). However, there was also no significant correlation between the rate of GFR decline in 2 years and urinary supernatant mtDNA level ($r = -0.070$, $p = 0.5$).

Conclusions: Urinary supernatant mtDNA level may reflect the severity of kidney damage and intra-renal mitochondrial depletion in DN. Further studies are needed to confirm its role as biomarker of diabetic nephropathy.

Funding: Government Support - Non-U.S.

Metabolic Reprogramming in Diabetic Kidney Disease Can Be Restored via SGLT2 Inhibition Manjula Darshi,[1,2] Akira Onishi,[2] Jiwan J. Kim,[1] Jessica Pham,[1] Benjamin F. Van espen,[1] Anne Murphy,[3] Hiddo J. Lambers Heerspink,[4] Volker Vallon,[2] Kumar Sharma.[1,2] *[1]Department of Medicine, University of California, San Diego, Irvine, CA; [2]Division of Nephrology-Hypertension, Veterans Affairs, San Diego, La Jolla, CA; [3]Department of Pharmacology, UCSD, La Jolla, CA; [4]Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center, Groningen, Netherlands.*

Background: Recent studies indicate mitochondrial dysfunction as a dominant pathway in diabetic kidney disease (DKD), however underlying mechanisms are unclear. In this study we used metabolomic and biochemical assays in the type 1 Akita DKD mouse model and in patients with DKD to decipher the consequences of high glucose on metabolic reprogramming leading to proximal tubule damage. Furthermore, we analyzed a therapeutic potential of the proximal tubule glucose transporter, SGLT2, responsible for reabsorption of the majority of the filtered glucose.

Methods: Metabolomic analysis was performed by GC-MS/MS from control and type 1 diabetic mice (Akita, n=6 each) in the presence and absence of SGLT2 inhibitor empagliflozin (~45mg kg^{-1} day^{-1}). Urinary lactate and pyruvate concentrations were measured using biochemical assays in patients with type 2 diabetes and albumin:creatinine ratio>100mg/g, enrolled in a cross-over study with the SGLT2 inhibitor dapagliflozin or placebo (6 weeks, 10mg/day, n=33 total). Mitochondrial functional changes in human kidney proximal tubule (HK2) cells were analyzed using Seahorse XF technology.

Results: Metabolomic analysis in Akita mice indicated a marked increase in glycolysis with an increase in the lactate/pyruvate ratio in urine ($p=0.0002$, 95% CI), plasma ($p=0.02$) and kidney tissue ($p=0.06$) as compared with non-diabetic controls. The urinary lactate/pyruvate levels in Akita mice were reduced upon treatment with empagliflozin ($p=0.002$) and in the urine of SGLT2 knockout mice vs wild type controls despite similar blood glucose levels ($p=0.03$). Furthermore, in T2D patients, dapagliflozin decreased the urine lactate /pyruvate ratio by 34% ($p=0.03$) compared to placebo and this decrease correlated with the decline in eGFR ($r-0.042$, $p=0.04$). Studies in HK2 cells further identified that acute glucose treatment can significantly inhibit rate of oxygen consumption and enhance lactate production suggesting a 'Crabtree' effect indicative of glucose suppression of mitochondrial respiration.

Conclusions: High glucose suppresses mitochondrial function with a shift to glycolysis and may be linked to proximal tubule injury. Our studies suggest ta protective role of SGLT2 inhibition, may be via reduction of the lactate/pyruvate ratio resulting in improved mitochondrial function.

Mitochondria-Targeted Antioxidant Peptide SS-31 Attenuates Renal Tubulointerstitial Injury via Regulating Mitochondrial Dynamics in DN Hao Zhang,[1] Shi-kun Yang,[3] Jianwen Wang.[2] *[1]The Third Xiangya Hospital of Central South University, Changsha, China; [2]The third Xiangya Hospital of Central South University, Changsha, China; [3]The third Xiangya Hospital, Central South University, Changsha, China.*

Background: Accumulating studies indicate that mitochondrial dysfunction is central to the pathogenesis of DN. We investigate the effects and mechanisms of mitochondria-targeted peptide SS-31 therapy on tubulointerstitial injury in DN.

Methods: 40 C57BL/6 mices were randomly divided into control, DN group, STZ+SS-31 group, STZ+ normal saline group. The DN model was induced by injection intraperitoneally with 40mg/kg body weight STZ for four times. SS-31 was intraperitoneally injected to the mice every other day for 24 weeks. Renal lesions and the expression of Drp1, P66Shc, Bcl-2, Bax, Caspase-1, IL-1, FN were detected by HE, Masson staining, TUNEL, DHE, immunohistochemistry and western-blot. In vitro, HK-2 cells were incubated with different concentrations of D-glucose (5, 30mM) or high glucose (30mM) combimed with SS-31(100nM) or Drp1 inhibitor Midivi1 for indicated time (0-

72h). The expression of Drp1, P66Shc, Bcl-2, Bax, Caspase-1, IL-1, FN were detected by Western-blot and immunoflurescence. Mitochondrial functional and morphology analysis were carried out by measuring ROS, TMRE, mitochondrial morphology.

Results: Extracellular matrix deposition and apoptosis of tubular cells were found in DN mices, The expressions of Drp1, P66Shc, Bax, Caspase-1, IL-1, FN were increased in the kidney of DN mices, while treatment with SS-31 could partially reverse such abnormalities, in addition, SS-31 treatment could attenuate renal pathological changes, serum creatinine, microalbuminuria, renal ROS and apoptosis levels. On the other side, the tubular mitochondrion of DN mice exhibiting deformations, such as swelling and fragmentation, while SS-31 treatment could reduce mitochondria fragmentation. In vitro, HG induced mitochondrial dysfunction, including altered membrane potential and increased overproduction of mitochondrial superoxide. Furthermore, HG increased the expression of Drp1 and P66Shc, Bax, Caspase-1, IL-1, FN. However, pretreatment with SS-31could partially reverse such abnormalities. Pretreatment with Drp1 inhibitor Midivi1 could also ameliorate HG-induced mitochondrial dysfunction, while SS-31 used in combination with Midivi1 could enhance the effects of antioxidant and anti-apoptosis.

Conclusions: These data indicate that SS-31 ameliorates tubulointerstitial injury via inhibiting mitochondrial fragmentation in DN.

FR-PO155

Re-Routing of Mutant Protein from Mitochondria to Peroxisome: A Therapeutic Approach for Primary Hyperoxaluria Type I Ruth Belostotsky,[2] Roman Lyakhovetsky,[3] Bodo B. Beck,[5] Björn Reusch,[4] Fanny Shkedy,[1] Yaacov Frishberg.[1] *[1]Shaare Zedek Medical Center, Jerusalem, Israel; [2]Shaarey Zedek Medical Center, Jerusalem, Israel; [3]Teva Pharmaceuticals, Maale Adumim, Israel; [4]University of Cologne, Cologne, Germany; [5]University of Cologne Medical Center, Cologne, Germany.*

Background: Primary hyperoxaluria type I (PH1) is caused by deficiency of the liver specific peroxisomal (Px) alanine-glyoxylate aminotransferase (AGT). Due to low solubility of calcium oxalate, PH1 results in progressive nephrocalcinosis and decline in kidney function to ESRD. The most frequent AGT mutation G170R results in aberrant mitochondrial localization with preserved catalytic activity. Thus, molecules that stimulate Px localization of the mutated protein may prevent oxalate production. To identify such molecules we developed the split GFP system in which only peroxisomal AGT sub-population produces a fluorescent signal. This sensitive and specific tool allows precise monitoring of Px sub-population of AGT: confocal microscopy confirms that GFP signal of both WT and G170R AGT is localized exclusively in Px and is substantially stronger in the WT-AGT. Using split GFP, we demonstrated that localization of G170R-AGT can be corrected by mild translation inhibition using the inhibitors emetine (a known antiprotozoal agent) and GC7. 7 days incubation of G170R-AGT-GFP transfected CHO cells with 40 nM emetine resulted in 70-80% increase in the number of GFP positive cells as quantified by FACS analysis. Under these conditions, total protein synthesis decreased by less than 25%. We also measured the effect of mitochondrial transport inhibitors: DECA and monensin, recently indicated to correct G170R-AGT localization. Both compounds, but not GC7, presented synergistic effect with emetine. We assume that DECA and monensin assist AGT relocation by mitochondrial transport interference while emetine and GC7 interfere with protein synthesis. The functional competence of peroxisomal retargeted AGT-LRM was confirmed in cultured human hepatocytes bearing G170R mutation. Augmented oxalate level in culture media was substantially reduced. In summary, we demonstrate that mild translation inhibition can re-route nascent AGT molecules into the Px. We suggest that this approach may be applicable not only for treating PH1 but also for other diseases caused by protein misfolding. The split-AGT system can be a useful tool in developing new treatments for PH1.

FR-PO156

Clearance of Damaged Mitochondria via Mitophagy Plays an Important Role in the Protective Effect of Renal Ischemic Preconditioning Man J. Livingston, Zheng Dong. *Augusta University Medical College of Georgia, Augusta, GA.*

Background: Ischemic preconditioning (IPC) affords tissue protective effects in organs including the kidney; however, the underlying mechanism remains unclear. Autophagy is induced in renal tubular cells during acute kidney injury (AKI) and plays a protective role, but whether autophagy contributes to the protective effect of IPC is unknown.

Methods: This study has examined the role of autophagy in the renoprotection of IPC using both in vivo and in vitro ischemic AKI models. IPC was induced in mice by mild (15 minutes) renal ischemia followed by 1-hour reperfusion. The mice were then subjected to more severe (27 minutes) renal ischemia to examine kidney injury. In in vitro, IPC was induced in proximal tubular cells (RPTC) by 30 minutes of "chemical ischemia" with CCCP followed by 40-minute recovery. The cells were then incubated with CCCP for 3 hours followed by 2-hour recovery (CCCP3h/R2h) to examine injury.

Results: IPC suppressed subsequent ischemic AKI. Autophagy was induced in kidneys by IPC. Notably, the renoprotective effect of IPC was abolished by autophagy inhibitors and also in kidney proximal tubule-specific Atg7 knockout mice, suggesting the dependence of IPC renoprotection on autophagy. Along with autophagy induction, the mitophagy regulator Pink1 was activated and there was a remarkable loss of mitochondrial proteins following ischemic AKI, suggesting that autophagy may protect kidneys by activating mitophagy. Consistent with in vivo observations, IPC in RPTC cells showed protective effects, which were abrogated by autophagy inhibition. Interestingly, IPC in RPTC cells induced a significant increase in the colocalization of autophagosomes with mitochondria, suggesting mitophagy induction. Moreover, IPC increased the delivery of mitochondria to lysosomes as shown by Cox8-EGFP-mCherry mitophagy reporter assay. Consistently, IPC induced higher levels of mitochondrial loss or clearance during subsequent CCCP treatment that was suppressed by autophagy inhibitors. IPC-induced clearance of mitochondria was associated with the reduction of ROS generation during subsequent CCCP treatment.

Conclusions: Together, these results suggest that autophagy, especially mitophagy, plays an important role in the protective effect of IPC.

PKC-a Inhibition Normalizes Nephrotoxic Serum Induced Disruption of Mitochondrial Membrane Potential and Morphology in Glomerular Endothelial Cells Nino Kvirkvelia,[1] Malgorzata McMenamin,[1] Marie Warren,[1] Raghavan Raju,[1] Rudolf Lucas,[2] Michael P. Madaio.[1] *[1]Augusta University, Augusta, GA; [2]Medical College of Georgia, Augusta University, Augusta, GA.*

Background: Nephrotoxic serum nephritis (NTN), an inflammatory model of antibody mediated nephritis caused by single injection of nephrotoxic serum (NTS), proceeds to end stage kidney disease. Earlier studies have shown that NTS treatment damages cultured glomerular endothelial cells by disrupting mitochondrial respiration, and that PKC-a Inhibition normalized these perturbations. The goal of this study was to determine the mitochronical pathways involved in this process.

Methods: Murine glomerular endothelial cell (GEC) viability was evaluated by LDH release following NTS exposure. PKC-α was pharmacologically inhibited with Ro-320432 (EMD Millipore, Billerica, MA). Changes in mitochondrial membrane potential ($\Delta\psi_m$) were measured using cationic carbocyanine dye, which changes fluorescence spectrum depending on mitochondrial potential status. Mitochondrial morphology and distribution were examined using Mitotracker–mitochondrion selective probes.

Results: Following NTS exposure, LDH release, measured as per cent of LDH cytotoxicity, was dramatically increased in GEC up to 50%, whereas PKC-α inhibition (50 nM Ro-320432) reduced cytotoxicity significantly (12%), indicating that PKC-α is involved in NTS-induced endothelial cell cytotoxicity. NTS treatment of GEC resulted in reduction of $\Delta\psi$ and in an increase of cells with depolarized mitochondria by 73%, PKC-α inhibition of NTS-treated cells reduced the number of cells with depolarized mitochondria to 15%. Furthermore, NTS reduced the fraction of cells with healthy mitochondria by 34%, whereas PKC-α inhibition increased that fraction to 79%. Severe mitochondrial swelling, documented by the appearance or large and round shaped mitochondria, was observed in endothelial cells after NTS treatment using Mitotracker–mitochondrion selective probes, which coincided with a loss of $\Delta\psi_m$. PKC-α inhibition in NTS-treated GEC restored the rod-type appearance in the majority of mitochondria.

Conclusions: PKC-α participates in NTS induced mitochondrial dysfunction in GEC cells and inhibition of PKC-α significantly improves endothelial cell viability by normalizing mitochondrial membrane potential and morphology. These results may foster the design of novel therapeutic approaches that preserve mitochondrial function during kidney injury.

Mitochondrial Protection Regulates Expression of Senescent Cell Regulators p16 and p21 in Parietal Epithelial Cells (PECs) of Aged Kidneys Mariya T. Sweetwyne, Peter S. Rabinovitch, Stuart J. Shankland. *University of Washington, Seattle, WA.*

Background: Mitochondrial dysfunction increases with age and can induce cellular senescence. Kidneys are a mitochondrial rich tissue and show predictable pathological changes with age. We have previously demonstrated that systemic late-age treatment with the mitochondrial protective peptide SS-31 reduced age-induced glomerulosclerosis in mice of 24-28 months of age (~70-85 yr old human). Additionally, mitochondria-protected aged kidneys showed reduced podocyte injury, preservation of endothelial cell number and increased parietal epithelial cell density. Concomitant to these changes was a significant reduction in senescence-associated-β-galactosidase (SA-β-gal) expression across all compartments of the renal cortex. Staining for cell-cycle senescence regulator, p16 increased with age, but with SS-31 treatment was reduced in both PECs and the glomerular tuft of aged mice relative to aged baseline.

Methods:

Results: In our current studies we further characterized PEC senescence by staining for expression of p21. Expression of p21 in PECs demonstrated an inverse relationship to that of p16 (p21 young =57.48% vs. aged vehicle =20.08% vs. aged SS-31 =31.46%; p16 young =11.9% vs. aged vehicle =55.0% vs. aged SS-31 =29.6%). Furthermore, expression of p21 in tuft cells did not change with either age or treatment. Close examination of glomeruli in serial sections showed a differential expression of p16 and p21 in PECs along Bowman's capsule, with individual PECs expressing either p16 or p21, but not both. To determine if senescence in PECs could be directly regulated by mitochondrial damage, we exposed immortalized mouse PECs (mPEC) to mitochondrial insult via low doses (5,15, 20 nM) of Rotenone, Oligomycin A and Antimycin A. After 3d exposure, mitochondrial injury and oxidative stress increased in cells with mid and high doses of all treatments, as detected by MitoTrackerFR and CellRox green respectively. At 2 weeks of culture, 20 nM

Rotenone increased expression of SA-β-gal in mPECs. In the treated cells, p16 but not p21 nuclear expression increased by immunocytochemistry.

Conclusions: Late-age SS-31 intervention amelorates renal mitochondrial damage and senecence. In the glomeruli of aged mice and in cell culture, mitochondrial dysfunction corresponds to PEC senescence with increased expression of p16 but not p21.

Alterations of Mitochondrial Oxidative Metabolism in an Aging Model of Cisplatin Induced AKI Kranti A. Mapuskar,[1] Hsiang M. Wen,[2] Michael L. Mccormick,[1] Gilbert V. Schaeffer,[3] Amy L. Sindler,[3] Danniele G. Holanda,[4] Prerna Rastogi,[4] Douglas R. Spitz,[1] Bryan Allen,[1] Diana Zepeda-Orozco.[2] *[1]Free Radical and Radiation Biology Program, Department of Radiation Oncology, University of Iowa, Iowa City, IA; [2]Stead Family Department of Pediatrics, Universiy of Iowa, Iowa City, IA; [3]College of Liberal Arts and Sciences, Department of Health and Human Physiology, University of Iowa, Iowa City, IA; [4]Department of Pathology, University of Iowa Health Care, Iowa City, IA.*

Background: Elderly patients have increased susceptibility to acute kidney injury (AKI). Increased oxidative stress and decreased antioxidant response may play a role in age associated AKI. The electron transport chain (ETC) complexes are a major metabolic site of reactive oxygen species (ROS) production in mammalian cells. In this study we hypothesized that aging is accompanied by abnormal mitochondrial oxidative metabolism that increases susceptibility to cisplatin induced AKI.

Methods: Young (4 months) and old (18 months) C57BL/6J mice received 10mg/kg intraperitoneal cisplatin injection *vs.* vehicle control. Blood urea nitrogen (BUN) and creatinine (Cr) measurements were obtained at baseline, 3, and 6 days post injection. Kidneys were harvested at 6 days to assess histological changes, mitochondrial oxidative metabolism, and antioxidant response

Results: Baseline renal function was not significantly different in young *vs.* old mice. Cisplatin caused significant renal function decline at 3 days in both groups. However, old cisplatin mice had less than 50% survival rate at 6 days compared to 100% survival in young mice. Control old mice demonstrated significant increased steady state levels of O_2^- and %GSH/GSSG, downregulation of mitochondrial ETC complex I, II, citrate synthase, and aconitase activities compared to young control mice. In both cisplatin groups, there was significant upregulation of complex I activity, with no significant change in complexes II-IV activity or citrate synthase activity compared to their respective vehicle controls suggesting that reverse electron transport (RET) may be a source of ROS production in cisplatin induced AKI. In cisplatin treated groups young mice had a significant upregulation of aconitase activity, which was not observed in old mice. Finally, in cisplatin treated old mice increased steady state levels of O_2^- were observed which was not seen in young mice

Conclusions: Our results support the hypothesis that aging is accompanied by alterations in oxidative mitochondrial metabolism that can be exacerbated by cisplatin injury. We hypothesize that RET through complex I may contribute to increased ROS production and enhanced kidney injury seen in older mice treated with cisplatin

Sulfotransferase 1C2 (SULT1C2) Post-Translationally Increases Mitochondria Respiration Alexander L. Kolb,[2] Zechariah Pfaffenberger,[4] Seth Winfree,[3] Simon J. Atkinson,[1] David P. Basile,[3] Robert L. Bacallao.[3] *[1]Indiana University - Purdue University Indianapolis, Indianapolis, IN; [2]Biology, Indiana University Purdue University Indianapolis, Indianapolis, IN; [3]Indiana University School of Medicine, Indianapolis, IN; [4]Indiana Wesleyan University, Mishawaka, IN.*

Background: Sulfotransferases are enzymes responsible for xenobiotic detoxification. Mechanistically, these enzymes add a sulfate group to xenobiotics which increases their water solubility and urinary excretion. We identified SULT1C2 in a proteomic screen of mitochondria isolated from ischemic preconditioned kidneys. Using hydrodynamic gene delivery, we show that SULT1C2 protects against subsequent ischemia one week after gene delivery.

Methods: To determine SULT1C2's mechanism of action, we assayed mitochondria function with and without human recombinant SULT1C2 and its substrate, 3' Phosophoadenosine-5'-phosophosulfate (PAPS). Mitochondria respiration was assayed using an Oroboros Oxygraph O2K.

Results: We found that that PAPS and SULT1C2 incubated with mitochondria increase mitochondria state 3 respiration (from 139.4 ±36 to 370.7 ±32 pmol/min/mg), following succinate and rotenone addition, 2.7-fold compared to mitochondria ($P<0.05$). The increase in SULT1C2/PAPS dependent respiration was inhibitable with antimycin A but not rotenone.

Conclusions: In conclusion SULT1C2 and PAPS increase the efficiency of complex II respiration indicating a potential change in the movement if electrons through the complex culminating in increased oxidative phosphorylation. This is a novel new function for an enzyme that heretofore was considered to be solely involved in detoxifying xenobiotics.

Megalin-Mediated Shuttling of Angiotensin II, TGF-ß, and Stanniocalcin-1 to the Mitochondria Qingtian Li,[1] Fan Lei,[3] Yi Tang,[2] Jenny S. Pan,[1] Qiang Tong,[1] David Sheikh-Hamad.[1] *[1]Baylor College of Medicine, Houston, TX; [2]West China Hospital of Sichuan University, Chengdu, China; [3]Baylor College of Medcine, Houston, TX.*

Background: Some extracellular signaling molecules are detected in the mitochondria, including angiotensin II, insulin, stanniocalcin-1 (STC1), TGF-ß and erythropoietin; these are known as mitochondrial intracrines. The mechanism of mitochondrial targeting of these proteins is unknown. Megalin/LRP2 is highly expressed on the apical surface of kidney proximal tubule cells, where it is involved in the uptake/reclamation of filtered vitamins, uptake and lysosomal degradation of filtered proteins, uptake of hormones including angiotensin II and angiotensin 1-7. Megalin mutations are linked to the pathogenesis of Donnai-Barrow and Lowe syndromes, characterized by developmental brain abnormalities and kidney dysfunction. Megalin has not been shown to reside in the mitochondria.

Methods:

Results: Mass spectroscopy analysis of mitochondrial acetyl proteome from kidneys of stanniocalcin-1 transgenic mice identified megalin as a resident mitochondrial protein. Megalin is also present in the mitochondria of a number of cell lines, including 293T, C2C12 and Raw267.4 cells, and associates stanniocalcin-1 and the mitochondrial longevity protein SIRT3. These observations were validated using immunoprecipitation, confocal immunofluorescence, electron microscopy and co-expression experiments. Because megalin, stanniocalcin-1, angiotensin II and TGF-ß are found at the plasma membrane and mitochondria, we hypothesized that megalin serves as a shuttle for mitochondrial intracrines from the cell surface to the mitochondria. CRISPR-Cas9-mediated knockdown of megalin in C2C12 cells diminishes whole-cell and mitochondrial content of megalin. Upon the addition of recombinant hSTC1-FLAG, hSTC1-FITC, angiotensin II-FITC or TGF-ß-FITC to the medium of WT C2C12 cells, we detect the corresponding FLAG or FITC within the mitochondria; however, we observe diminished presence of STC1-FLAG, STC1-FITC, angiotensin II-FITC or TGF-ß-FITC in the mitochondria of megalin knockdown cells.

Conclusions: The data suggest that megalin is present in the mitochondria and exists in complex with proteins involved in anti-oxidant defenses. Megalin serves as a shuttle for signaling molecules from the cell surface to the mitochondria, including angiotensin II, TGF-ß and stanniocalcin-1.

Muscle Mitochondrial Energetics, Objective Muscle Fatigability, and Symptoms of Fatigue in CKD Baback Roshanravan,[1] Sophia Liu,[2] Amir S. Ali,[2] Jorge Gamboa,[3] Ian H. de Boer,[1] Jonathan Himmelfarb,[1] Bryan R. Kestenbaum,[1] Kevin Conley.[2] *[1]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; [2]University of Washington, Seattle, WA; [3]Vanderbilt University, Nashville, TN.*

Background: People with chronic kidney disease (CKD) often report symptoms of fatigue. Impaired skeletal muscle mitochondrial function due to the abnormal uremic milieu of CKD may contribute to muscle fatigability and symptoms of fatigue.

Methods: We performed a cross-sectional analysis of 30 participants from the Muscle Mitochondrial ENergetics and Dysfunction (MEND) study. Persons were excluded from MEND if they used medications effecting mitochondrial metabolism, had mobility disability, or weighed >300 pounds. We measured mitochondrial capacity of the tibialis anterior muscle as ATPmax using ^{31}P magnetic resonance spectroscopy. We determined the force time integral (an objective measure of muscle fatigability) and assessed fatigue symptoms using the FACIT-F questionnaire.

Results: Mean GFR was 35 ±15 ml/min; mean age was 61 ±14yr; 53% were female, and 23% had diabetes. Lower muscle ATPmax was associated with lower force time integral (indicating greater fatigability) (figure 1; $P=0.007$) and greater symptoms of fatigue after adjustment (figure 2; $P=0.013$).

Conclusions: Muscle mitochondrial capacity measured by ATPmax is associated with objective fatigability and subjective symptoms of fatigue in CKD patients. These findings are the first connecting impaired human skeletal muscle mitochondrial energetics in CKD with functional and clinical measures.

Funding: NIDDK Support

Protease Inhibition Improves Renal Mitochondrial Function during Cold Storage and Transplantation Lee Ann MacMillan-Crow, Nirmala Parajuli, Julia Tobacyk, Stephen A. Shrum. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Kidneys were the first successfully transplanted organs and are the most common organ transplant today. Cold storage (CS) of deceased donors is required for successful renal transplantation, but it also leads to renal and mitochondrial damage. During stressful conditions such as CS, mitochondrial fusion allows compensatory mixing of functional mitochondrial content with damaged mitochondria. Thus, impaired fusion can limit acute damage control and ultimately lead to loss of respiratory capacity and cell death. OPA1 is a key mitochondrial fusion protein and is regulated by the mitochondrial protease OMA1. The goal of this study was to evaluate how CS alters mitochondrial fusion machinery and to evaluate the therapeutic benefit of OMA1 inhibition.

Methods: Male rodent (Lewis) kidneys were isolated and cold stored for 0 or 18 hr and then transplanted (CS/Tx) in a naïve Lewis rat followed by right nephrectomy. Mitochondrial function was assessed via high resolution respirometry and ATP measurement. Mitochondrial fusion and fission pathways were monitored using western blot. A novel method was developed to measure OMA1 activity. Renal injury was assessed by serum creatinine and PAS staining.

Results: Data clearly revealed that CS worsens mitochondrial function when compared to transplantation without CS. Combined CS/Tx lead to OPA1 inhibition and increased OMA1 activity along with an altered protein expression of OMA1. Inhibition of OMA1 using phenanthroline during CS lead to increased OPA1 expression and improved mitochondrial function. Further studies will characterize the benefit of mitochondrial targeted phenanthroline as a novel therapy to improve mitochondrial and renal function during CS/Tx.

Conclusions: Our results suggest that CS/Tx alters the mitochondrial protease, OMA1, and that OMA1 inhibition improves mitochondrial function. These findings raise the possibility that impaired mitochondrial dynamics may be an unrecognized contributor to cold storage induced injury and compromised renal graft function after transplantation. Supported in part by and AHA 16SDG276000026 (NP) and AHA 16PRE30830010 (SS); as well as NIH T32GM106999 (SS), T32GM106999 (JT).

Transfer of Exogenous Mitochondria Protects the Kidneys from Ischemia-Reperfusion Injury Amandeep Bajwa, Kailo H. Schlegel, Kyle J. Alexander, Elvira Kurmaeva. *University of Virginia, Charlottesville, VA.*

Background: Mitochondria, a critical player in acute kidney injury, have dual roles as primary source of energy (ATP) and as key regulators of cell death. Ischemia induces altered bioenergetics with increased mitochondrial swelling and reactive oxygen species and ultimately cell death. Ischemia followed by reperfusion (IRI) induces mitochondrial fragmentation in 30-40% of proximal tubule (PT) cells. Therapeutic interventions that target to improve mitochondrial health to repair, reprogram or replace mitochondria to restore respiratory functions are beneficial for prevention and/or treatment of disease.

Methods: Renal injury was assessed by plasma creatinine (PCr; mg/dl). 8-wk old C57BL/6 [WT or Rag1ko] mice were i.v. injected with exogenous mitochondria (Exo-Mito; 0-500mcg protein equivalent) 1d prior to 26 mins IRI. Exo-Mito was isolated from healthy non-ischemic mouse liver. Splnx was done 7d prior to IRI. Structure (sonicated) or function (Rot/Ant A) of Exo-Mito altered prior to injection. For *in vitro* studies, PT cells (TKPTS) were treated with 200 mcg of Exo-Mito 1d prior to analysis that included measurement of ATP levels, mitochondrial functions (Seahorse flux analyzer), cytokines (pcr), immunofluorescence microscopy (uptake efficiency) and flow cytometry (dyes [mitotracker or JC-1]).

Results: *In vivo* studies demonstrated mitochondria (200mcg, mouse or human) treated mice are significantly protected compared to vehicle treated mice after IRI [PCr (2.2±0.05 vs 0.62±0.2), $p<0.01$]. The protection by transferred Exo-Mito in IRI studies was partially abrogated in absence of a spleen but maintained in Rag1ko mice. Furthermore, structurally or functionally altered Exo-Mito no longer protected kidneys from IRI. Transfer of labeled Exo-Mito signal was found in spleen (in macrophages), kidney (in PT, identified with anti-CD13 antibody [labels brush border]), liver and lungs. *In vitro* studies demonstrate that Exo-Mitochondria are taken up by TKPTS in a dose dependent manner. TKPTS with Exo-Mito had significantly higher levels of extra- and intracellular ATP, higher basal oxygen consumption rate and spare respiratory capacity measured by Seahorse analyzer and lower cytokines after LPS stimulation.

Conclusions: Our current study demonstrates that up take of Exo-Mito by PT cells (*in vivo* and *in vitro*) helps maintain bioenergetics [ATP] to prevent injury.

Megalin Shuttles Extracellular Angiotensin II and Stanniocalcin-1 to the Mitochondria via Retrograde Early Endosomes to the Golgi Pathway and Regulates Glycolytic and Respiratory Capacities Qingtian Li,[1] Fan Lei,[3] Yi Tang,[2] Jenny S. Pan,[1] Qiang Tong,[1] David Sheikh-Hamad.[1] *[1]Baylor College of Medicine, Houston, TX; [2]West China Hospital of Sichuan University, Chengdu, China; [3]Baylor College of Medcine, Houston, TX.*

Background: Some extracellular signaling molecules are detected in the mitochondria, including angiotensin II, insulin, stanniocalcin-1 (STC1), TGF-ß and erythropoietin; these are known as mitochondrial intracrines. The mechanism of mitochondrial intracrine targeting is unknown. Megalin/LRP2 is highly expressed on the apical surface of kidney proximal tubule cells, and is involved in the uptake of filtered vitamins and proteins. Megalin mutations are linked to the pathogenesis of Donnai-Barrow and Lowe syndromes, characterized by brain defects and kidney dysfunction. Megalin has not been shown to reside in the mitochondria.

Methods:

Results: Our data suggest that megalin is present in kidney mitochondria in vivo, and mitochondria of cultured 293T, C2C12 and Raw267.4 cells, and associates with stanniocalcin-1 and SIRT3. Megalin shuttles extracellular angiotensin II, TGF-ß and STC1 to the mitochondria (detailed in separate abstract). We sought to characterize the shuttling pathway for megalin and its cargo (angiotensin II and STC1) from the cell surface to the mitochondria. Using chemical inhibitors of vesicular trafficking, we identified the microtubules and Golgi as key mediators, consistent with involvement of the retrograde early endosome-to-Golgi pathway. This was confirmed using an inhibitor of PIKfyve phosphoinositide kinase, a critical kinase involved in early endosome fusion with the Golgi. These findings were validated using CellLight® Reagent BacMan 2 technology, to trace the intracellular movement of extracellularly-applied rSTC1-FITC or angiotensin II-FITC. CRISPR-Cas9 knockdown of megalin in C2C12 cells prevents the entry of rSTC1-FITC and angiotensin II-FITC to the early endosome compartment (identified by early endosome RFP), while PIKfyve inhibition prevents their entry to the Golgi (identified by Golgi-RFP). Moreover, seahorse analysis reveals diminished glycolytic and respiratory capacities in megalin knockout C2C12 cells.

Conclusions: Megalin shuttles extracellularly applied angiotensin II and STC1 to the mitochondria through retrograde early endosome-to-Golgi pathway. Megalin is critical for glycolysis and respiration. The data also suggest that Donnai-Barrow and Lowe syndromes may represent mitochondrial intracrine signaling defects.

PKA/CREB Signaling Prevents Adriamycin-Induced Podocyte Apoptosis via Upregulation of Mitochondrial Respiratory Chain Complexes Production Kewei Xie, Zhaohui Ni, Leyi Gu. *Renji Hospital, Shanghai, China*.

Background: The present study was designed to explore the role of cAMP response element binding protein (CREB) in the PKA-induced protection in podocytes.

Methods: Conditionally immortalized differentiated murine podocytes were used in the present experiments. Cell toxicity was examined by using a cell count kit-8. Annexin V/PI staining and flow cytometry were uesd to detect cell apoptosis. MitoSOX™ Red mitochondrial superoxide indicator was used for detecting mitochondrial ROS. We also used Agilent expression profile chip to screen the mRNA expression in differential podocytes treated with or without PKA agonist in the presence or absence ADR. The message RNAs of respiratory chain complexes subunits encoded by mitochondrial genes were detected by using real-time PCR. Luciferase chemiluminescence was used to detect the production of ATP. Western blot was used to detect protein expression.

Results: We found that pretreatment with pCPT-cAMP prevented podocytes against Adriamycin (ADR)-induced increase of cleaved caspase-3 and the loss of podocytes. ADR treatment strikingly enhanced both mitochondrial superoxide and index of ROS in podocyte, this increase was prevented by pCPT-cAMP pre-treatment. Pretreatment with pCPT-cAMP was unable to prevent ADR-induced increase of cleaved caspase 3 expression in CREB RNAi treated podocytes. Data of Agilent expression profile chip studies showed that ADR predominantly decreased the mRNA expression of respiratory chain complex I subunits encoded by mitochondrial genes in podocytes, which was prevented by pretreatment with pCPT-cAMP. Immunoblot experiments showed that activation of PKA prevented ADR-induced decrease of mitochondrial respiratory chain complexes I subunits ND1/3/4 protein expression. Inhibiting of CREB expression prevented pCPT-cAMP-induced ND3, but not ND1/4 protein overproduction in podocytes. CREB RNAi can also block pCPT-cAMP-induced increase of ATP and the expression of Peroxisome proliferator-activated receptor gamma coactivator-1 alpha (PGC-1 a).

Conclusions: PKA signaling may upregulate expression of mitochondrial respiratory chain complexes, which reduced ROS production and increased ATP generation, thus prevented ADR-induced podocyte apoptosis. This was at least partially dependent on CREB activation.

Thioredoxin-Interacting Protein (TXNIP) Regulates Mitochondrial Function and Prognosis of Ischemia/Reperfusion Induced AKI Satoshi Inogtani,[3] Daisuke Hashimoto,[3] Masami Ogasawara,[3] Tomohiro Eguchi,[3] Hirofumi Nishikawa,[3] Tatsuki Matsumoto,[3] Kazu H. Ode,[3] Yoshiko Shimamura,[2] Kosuke Inoue,[4] Yoshinori Taniguchi,[3] Taro Horino,[1] Yoshio Terada.[5] *[1]Kochi Medical School, Kochi University, Kochi, Japan; [2]Kochi Medical School, Kochi University, Nankoku, Japan; [3]Kochi university, Nankokushi, Japan; [4]kochi medical school, Nankoku, Japan; [5]None, Nankoku-city, Japan*.

Background: Thioredoxin-interacting protein (TXNIP) has been found to regulate the cellular reduction-oxidation (redox) state by binding to and inhibiting thioredoxin in a redox-dependent fashion. However, little is known about the role of TXNIP in mitochondrial function and acute kidney injury (AKI) pathogenesis.

Methods: We evaluated the role of TXNIP in renal function in bilateral renal ischemia (27 min)/reperfusion injury (IRI) model using TXNIP knock-out (KO) and wild type (WT) mice. To elucidate the functional roles of TXNIP, we evaluated mitochondrial enzymes, morphology, and NLRP3 inflammasome in primary cultured renal tubular epithelial cells (TECs).

Results: TXNIP KO mice had significantly higher SCr (0.78±0.28 versus 0.45 ± 0.20 mg/dl) and significantly higher BUN (152.5±32.5 versus 75.3±18.2 mg/dl) at 24h post ischemia compared to WT mice. Immunohistological examination showed severer tubular injury in cortex and outer medulla in TXNIP KO mice. The number of TUNEL positive tubular cells and KIM-1 positive cells were increased in in TXNIP KO mice. Dysmorphic mitochondria were observed in proximal tubules of TXNIP KO mice compared to WT mice. The protein expressions of mitochondrial enzymes (ATP5a, UCP2 and complex IV) and ATP production were decreased in TXNIP KO mice at 24h post ischemia. In vitro experiments, protein and mRNA levels of ATP5a, complex IV, PGC-1a were significantly decreased by H2O2, and these reductions were more prominent in TECs of TXNIP KO mice. Moreover, NLRP3, IL-1β, and caspase 1 (p10) protein expressions were significantly increased by LPS in TECs of WT mice, but this effect was reduced in TECs of TXNIP KO mice.

Conclusions: These data demonstrate that TXNIP protects from IRI induced AKI. TXNIP regulates mitochondrial function and inflammasome in cytotoxic conditions. These results indicate that TXNIP plays a key role in the pathophysiology of AKI.

Collecting Duct Cell Specific Mitochondrial Dysfunction Influence to Inflammation and Fibrosis in UUO Mice Jin young Jeong,[1] Chang hun Song,[2] Hong jin Bae,[2] Jiwon M. Lee,[3] Youngrok Ham,[2] Kiryang Na,[2] Kang Wook Lee,[2] Dae Eun Choi.[2] *[1]Department of Medical Science, Chungnam National University, Daejeon, Republic of Korea; [2]Nephrology, School of Medicine, Chungnam National University, Daejeon, Republic of Korea; [3]Pediatrics, School of Medicine, Chungnam National University, Deajeon, Republic of Korea*.

Background: Unilateral ureteral obstruction (UUO) induced mitochondrial dysfunction resulting in increase of oxidative stress and infammation in obstructed kidney. Although mitochondria play a role in UUO injury including tubulo-interstitial apoptosis, infammation and fbrosis, the role of collecting duct cells was not evaluated. We evaluated whether collecting duct specifc mitochondrial dysfunction affect the renal injury induced by UUO.

Methods: For generation collecting duct specifc mitochondrial injury mice, CRIF flox/flox mice were bred with Hoxb7-Cre mice. For evaluation of the phenotype of mice, we observed mitochondria using electron microscopy in mice. For evaluation of influence of CRIF1 deletion on mitochondrial function, we measured O2 consumption and membrane potential in control and silencing RNA treated mIMCD cells. For evaluation of effect on UUO induced renal injury, we divided mice into the following 4 groups: CRIF1flox/flox(WT) group; CRIF1 flox/flox-Hob7 Cre (CRIF1-KO) group; WT UUO group; and CRIF1-KO UUO group. I evaluated oxidative stress, inflammatory, and fibrosis marker in urine and kidney tissue.

Results: There are no significant difrenence in phenotype between CRIF1-KO and WT mice. Renal expression of MCP-1, osteopontin (OPN), Numbers of F4/80 positive cells, TGF-b, a-SMA, and Masson Trichrome stained area were significantly increased in CRIF1-KO-UUO kidneys compared with WT UUO kidneys., Urinary 8-OHDG was increased in CRIF1-KO-mice compared with WT mice. Also, Crif1-KO mice had significantly increase of 8-OHDG-positive cell recruitment compared to WT mice. CRIF1-KO-UUO-kidneys were shown more increase recruitment of 8-OHDG-positive cells compared to WT-UUO-kindneys

Conclusions: Collecting duct specific mitochondrial injury induced increase of oxidative stress, renal inflammation, and renal fibrosis in UUO mice

Metabolic Syndrome Induces Transit Peptide Protein Import into the Mitochondria of Porcine Mesenchymal Stem Cells Arash Aghajani nargesi, LaTonya J. Hickson, Kyra L. Jordan, Lilach O. Lerman, Alfonso Eirin. *Mayo Clinic, Rochester, MN*.

Background: Autologous transplantation of mesenchymal stem cells (MSC) is currently being tested in clinical trials for patients with renal disease. Mitochondrial aerobic respiration is essential for successful differentiation of MSC, but whether coexisting cardiovascular risk factors modulate MSC mitochondrial function remains unknown. We hypothesized that metabolic syndrome (MetS) alters expression of genes regulating mitochondrial biogenesis and metabolism.

Methods: MSC were isolated from swine abdominal adipose tissue after 16 weeks of Lean or Obese diet (n=5 each). Next-generation sequencing was performed to detect differentially expressed mRNA in MetS-MSC, and mitochondrial genes were identified (MitoCarta). Expression of the mitochondrial biogenesis regulator peroxisome proliferator-activated receptor gamma coactivator (PGC)-1α was measured by western blot. Finally, we assessed protein expression of transporters of mitochondrial transit peptides (MTP), including translocase of outer membrane (TOMM)-34, heat shock protein (HSP)-70, and HSP90.

Results: Out of 1,088 unique mitochondrial mRNA, 45 were upregulated in MetS- vs. Lean-MSC (fold change >1.4, $p<0.05$), of which MTP, primarily involved in oxidative phosphorylation and electron transport, comprised the top category. Protein expression of PGC-1α, TOMM34, HSP70, and HSP90 was upregulated in MetS-MSC.

Conclusions: MetS upregulates MSC mRNA expression of MTP, and protein expression of mitochondrial membrane transporters that import them into mitochondria. These might be linked to altered mitochondrial biogenesis and may impact aerobic metabolism. These observations provide a molecular framework for optimization of cell-based strategies as we move towards clinical applications of MSC for renal repair.

Funding: NIDDK Support

FR-PO170

Downregulation of Akt Induces Mitochondrial Injury in Proteinuric States Elif Erkan,[1] Lu Lu.[2] *[1]Children's Hospital of Cincinnati, CIncinnati, OH; [2]Cincinnati Children's Hospital, Cincinnati, OH.*

Background: Nephrotic range proteinuria contributes to progression of glomerular diseases by causing tubulointerstitial injury. High concentrations of albumin in the glomerular filtrate triggers proximal tubular cell apoptosis, a precursor for tubular atrophy. We propose that downregulation of prosurvival serine/thereonine kinase, protein kinase B (Akt) induces apoptosis in proximal tubule epithelial cells by causing mitochondrial injury.

Methods: *In-vitro* albumin overload is induced by incubating human kidney proximal tubule epithelial (HKC-8) cells with 10mg/ml of human albumin for 24 hours. C57BL/6 B6 mouse with targeted deletion of Akt1/2 in proximal tubule epithelial cells(Akt1/2 $^{lox/lox}$ Sglt2 cre) is generated and subjected to intraperitoneal albumin injections (10 mg/g body weight) for 6 weeks. Intraperitoneal albumin and saline injected Sglt2 cre negative mice are utilized as negative controls. Apoptosis is evaluated by fluorogenic caspase-3 assay, caspase 9 staining and TUNEL assays. Mitochondrial and cytosolic translocation of cytochrome-c and Bax is assessed by Western Blotting.

Results: Albumin overload caused caspase-3 activation in association with downregulation in expression of pSer473 Akt and pThr 308 Akt and Akt substrate phospho Fork head box O1(FOXO 1) and fork head box O3 (FOXO 3) proteins in HKC-8 cells. Expression of FOXO target BIM is upregulated in association with albumin induced apoptosis. Furthermore overexpression of Akt by constitutively active Akt construct mitigates albumin induced-apoptosis where as treatment with pan Akt inhibitor MK-2206 potentiates the apoptotic response in HKSC-8 cells. In-vivo albumin overload results in cytochrome-c release in the cytoplasm of Akt1/2 $^{lox/lox}$ Sglt2 cre mice in association with tubular apoptosis. This response was associated with translocation of proapoptotic Bax to the mitochondria and increase in BIM expression.

Conclusions: We concluded that Akt plays an important role in protection of proximal tubule epithelial cells from apoptosis. We propose that in proteinuric states, inhibition of Akt phosphorylation causes nuclear translocation of FOXO 1 and FOXO 3 and an increase in transcription of BIM leading to cytochrome-c release to cytoplasm and apoptosis in proximal tubule epithelial cells. We postulate that therapeutic interventions that are targeted to increase tubular Akt expression can attenuate tubulointerstitial injury in proteinuric states.

FR-PO171

The Role of a Novel Mitochondrial Protease, OMA1, During Renal Cold Storage and Rewarming Julia Tobacyk, Lee Ann MacMillan-Crow, Nirmala Parajuli, Stephen A. Shrum. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Most kidney transplants come from deceased donors. These kidneys must undergo cold preservation before transplantation to maintain function of the organ during storage so that the graft will function at reperfusion. However, cold storage (CS) can result in renal and mitochondrial damage impairing overall graft outcome. OMA1 is a novel metallopeptidase in the mitochondria that plays a key role in mitochondrial dynamics. The goal of this study is to determine the role of OMA1 during renal CS in an *in vitro* model. Specifically, we will investigate the interaction of key proteins that regulate the fission and fusion machinery in the mitochondria such as OMA1, YME1L and OPA1.

Methods: Both rat and human normal proximal tubular kidney cells were exposed to 18 hr of CS followed by rewarming (CS/RW) for 6 hr. Expression of OMA1, YME1L, and OPA1 were assessed using western blot analysis. The interaction between these proteins was determined via OMA1 siRNA silencing techniques and OMA1 co-immunoprecipitation.

Results: In our studies we show that OMA1 expression is altered during CS both in rat and human normal proximal tubular kidney cells. Furthermore, expression of the long form of OPA1 is decreased in CS/RW suggesting compromised mitochondrial fusion. Our initial studies with OMA1 siRNA studies show successful knockdown, and further experiments will assess how OMA1 knockdown affects YME1L and OPA1.

Conclusions: Overall, CS initiates impairment of proteins related to mitochondrial fission and fusion. Our preliminary data suggest that OMA1 may be a promising therapeutic target for improving the function of kidneys transplanted after CS.

FR-PO172

Mitochondrial Protection Restores Renal Function and Partly Mitigates Cellular Senescence in Swine Atherosclerotic Renal Artery Stenotic Kidney Seo Rin Kim, Xin Zhang, Alfonso Eirin, James Krier, Amir Lerman, Lilach O. Lerman. *Mayo Clinic, Rochester, MN.*

Background: Atherosclerotic renal artery stenosis (ARAS) may cause kidney injury and mitochondrial dysfunction, which might be linked to cellular senescence. Elamipretide (ELAM), a mitochondrial cardiolipin-targeting peptide, improves renal function and tissue damage in ARAS. We hypothesized that ELAM would also reduce senescence in the ARAS stenotic kidney (STK).

Methods: Domestic pigs were randomized to a 4-week treatment with ELAM (0.1 mg/kg sc q.d.) or vehicle starting after 6 weeks of unilateral ARAS or sham (n=6 each). Then, single kidney renal blood flow (RBF) and glomerular filtration rate (GFR) were measured in-vivo using CT. Renal senescence markers (activity of senescence-associated β-galactosidase (SA-β-Gal), *p*16, *p*21, and telomerase reverse transcriptase (TERT)), mitochondrial markers (total cardiolipin content and complex IV (COX-IV) activity), and tissue fibrosis were studied ex-vivo.

Results: Blood pressure and tissue scarring was elevated whereas RBF and GFR were decreased in ARAS STK compared to sham. Renal SA-β-Gal and TERT activity increased in ARAS, suggesting cellular senescence, and total cardiolipin content decreased (Fig. A, B), suggesting mitochondrial impairment. Renal cardiolipin content was restored and COX IV activity was elevated in ELAM-treated ARAS pigs. ELAM also normalized STK-RBF and GFR and improved renal fibrosis in ARAS. ELAM normalized TERT activity, and improved but not normalized SA-β-Gal activity, whereas *p*16 and *p*21 gene expression remained unchanged in all groups.

Conclusions: Mitochondrial protection with ELAM improved renal function, fibrosis and mitochondrial dysfunction in the ARAS STK, and partly alleviated cellular senescence. These observations support development of senolytic strategies in ARAS.

The 5-HT1F Receptor as an In Vivo Regulator of Renal Mitochondrial Homeostasis Whitney S. Gibbs,[2,1] Justin B. Collier,[2,1] Rick G. Schnellmann.[1] *[1]Pharmacology and Toxicology, University of Arizona, Tucson, AZ; [2]Drug Discovery and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Background: Mitochondrial dysfunction limits repair mechanisms and restoration pathways required for the recovery of cellular functions following acute kidney injury. Stimulation of the 5-hydroxytryptamine 1F (5-HT_{1F}) receptor induces new, functional mitochondria through mitochondrial biogenesis (MB), resulting in accelerated renal recovery following ischemia/reperfusion (IR) induced acute kidney injury in mice. The goal of this study was to determine the contribution of the 5-HT_{1F} receptor in the regulation of renal mitochondrial homeostasis and renal function in healthy and injured mice.

Methods: Male 5-HT_{1F} receptor knockout (KO) mice and age-matched controls (WT) were euthanized at 10 and 26 weeks of age. In a second experiment, 10 week old male 5-HT_{1F} receptor WT and KO mice underwent renal IR injury and were euthanized at 24 hr. Renal mitochondrial homeostasis was assessed by RT- qPCR. Kidney function were assessed using serum creatinine and renal cortical KIM-1 and NGAL.

Results: In 5-HT_{1F} receptor KO mice, components of the electron transport chain, including ATP synthase β (ATSβ) and COX1 mRNA were elevated 1.3- and 1.6-fold at 10 weeks of age and these increases corresponded with elevated mitochondrial DNA (mtDNA) copy number. At 26 weeks of age, the master regulator of MB, peroxisome proliferator- activated receptor g coactivator- 1α, PGC-1α, ATPSβ, and mtDNA copy number were elevated 1.7-, 1.8- and 1.7-fold compared to WT mice. In addition, the mitochondrial fission protein Drp1 increased 1.7-fold at 10 weeks of age and remained elevated at 26 weeks of age in KO mice. The 5-HT_{1F} receptor KO mice did not exhibit basal renal injury. At 24 hr following renal IR, KO mice exhibited greater renal cortical levels KIM-1 and NGAL than WT mice. Serum creatinine was greater in KO mice compared to WT mice after IR. Finally, PGC-1α was decreased in IR KO mice but not in WT mice.

Conclusions: These findings reveal that mitochondrial homeostasis is disrupted in 5-HT_{1F} receptor KO mice, resulting in compensatory MB and mitochondrial fission. Moreover, the absence of the 5-HT_{1F} receptor potentiates tubular injury and suppresses MB in IR injury mice. These results demonstrate the 5-HT_{1F} receptor is a key mediator of MB and renal injury

Skeletal Muscle Mitochondrial Function and Dynamics in Patients on Maintenance Hemodialysis Jorge Gamboa,[1] Aaron M. Falck,[1] Chad A. Keller,[1] Baback Roshanravan,[2] Talat Alp Ikizler.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Kidnery Research Institute, University of Washington, Seattle, WA.*

Background: Patients on maintenance hemodialysis (MHD) commonly suffer of frailty and sarcopenia, which increase the risk of morbidity and mortality. The loss of muscle power is one of the components of the frailty phenotype, and poor muscle function is recognized as a major cause of frailty. Mitochondria are the main source of energy in skeletal muscle and are important for muscle function. Proper mitochondrial function depends on the balance between fission and fusion (mitochondrial dynamics). Thus, we evaluated changes in mitochondrial function and dynamics in skeletal muscle in patients on MHD.

Methods: We evaluated 20 patients on MHD and 19 controls with no history of CKD that were matched by age, gender, history of diabetes, BMI, and race. We measured *in vivo* mitochondrial function by 31-phosphorus magnetic resonance spectroscopy (^{31}P-MRS) in the quadriceps muscle. We used the half time recovery of phosphocreatine (P-Cr) after a brief exercise as the measure of mitochondrial function. A faster recovery correlates with better mitochondrial function. We also measured markers of mitochondrial fusion and fission by western blot in skeletal muscle biopsies from the vastus lateralis.

Results: Controls and patients on MHD were similar in terms of age (47.0±9.5 *vs.* 47.7±12.3) and BMI (30.0±6.0 vs. 30.4±7.8). We found that the half time recovery of P-Cr was faster in controls compared to patients on MHD (**Figure 1A**). We found an increase in the abundance of dynamin related protein 1 (DRP-1), a marker of mitochondrial fission, in patients on MHD (**Figure 1B**). We did not find changes in other marker of mitochondrial dynamics.

Conclusions: Our data suggest that *in vivo* mitochondrial function is impaired in patients on MHD. The increase in mitochondrial fission marker DRP-1 in MHD patients could be a mechanism for segregation and elimination of damaged mitochondria.

Osteopontin Deficiency Ameliorates Alport Pathology by Preventing DNM3-Mediated Cholesterol Influx and Mitochondrial Energetic Deficit Wen Ding,[3] Keyvan Yousefi,[4] Stefania Goncalves,[3] Bradley J. Goldstein,[5] Alfonso L. Sabater,[1] Armando Mendez,[2] Lina Shehadeh.[5] *[1]Bascom Palmer Eye Institute, Miami, FL; [2]UM, Miami, FL; [3]University of Miami Miller School of Medicine, Miami, FL; [4]University of Miami-Miller School of Medicine, Miami, FL; [5]University of Miami, Miami, FL.*

Background: Clinical implications of Alport Syndrome consist of proteinuria, hypertension, progressive renal failure, high frequency sensorineural hearing loss and ocular anomalies. Osteopontin (OPN) has not been studied in Alport Syndrome. We elected to investigate the role of OPN in Alport pathology.

Methods: At 8-9 weeks of age, WT, OPN-/-, COL4A3-/-, COL4A3-/-OPN+/-, COL4A3-/-OPN-/-, and COL4A3-/-LDLR+/- mice (n=7-25/group) were studied. Renal OPN protein expression was studied by immunofluoresce. KIM-1 protein expression and EdU and TUNEL staining were analyzed by immunofluorescence. Blood pressure was recorded by a tail cuff. Basement membrane morphology in kidneys, cochleas, and retinas was analyzed by electron microscopy. Optical coherence tomography was used to study corneal dimensions. 100ug DiI-LDL was injected via tail vein in Alport and wild type mice and kidneys were studied after 2 hours. Bioenergetics assays were performed on DNM3-over-expressing human tubular epithelial HK2 cells (or their isolated mitochondria) using a flux analyzer.

Results: We found that OPN is highly expressed in the renal tubules (not glomeruli) of the Alport mouse and plays a causative pathological role. OPN genetic deletion ameliorated albuminuria, hypertension, tubulointerstitial proliferation, renal apoptosis, lenticonus, and cochlear and retinal structural deficits in the Alport mouse. We found extensive cholesterol accumulation and increased protein expression of DNM3 and LDLR in Alport renal tubules. Increased pathological cholesterol influx was confirmed by a remarkably increased 50 fold uptake of injected DiI-LDL cholesterol by Alport renal tubules, and by the extended lifespan of the Alport mice when crossed with the *LDLR*$^{-/-}$ mice with defective cholesterol influx. Over-expressing DNM3 in HK2 cells resulted in elevated LDLR protein expression and defective fatty acid based- mitochondrial respiration, and impaired phosphorylating respiration, resting respiration, and maximal uncoupling respiration relative to the scrambled groups. All results reported here were statistically significant (at least $p<0.05$).

Conclusions: Our results suggest a new pathway in Alport pathology where renal tubular OPN causes DNM3-mediated enhanced cholesterol influx and reduced mitochondrial respiration.

FR-PO176

Inhibition of Mitochondrial Carnitine Palmitoyl Transferase 1 Prevents Renal Ischemia/Reperfusion Injury in Rats Mads V. Damgaard,[2] Rikke Norregaard,[2] Jorgen Frokiaer,[2] Søren Nielsen.[1] [1]*Aalborg University, Aalborg, Denmark;* [2]*Aarhus University, Aarhus C, Denmark.*

Background: Acute kidney injury is associated with high mortality and a lack of effective therapeutic treatment of the most common cause i.e., ischemia/reperfusion-injury (IR-I). Hypoxia leads to ATP depletion, apoptosis and necrosis, resulting in a marked inflammatory cascade causing further tissue damage. Inhibition of the inflammatory responses after IR-I is crucial for renal protection. Fatty acid β-oxidation is controlled by carnitine palmitoyl transferase 1 (CPT1). Etomoxir (ETO) inhibits CPT1 and block lipid metabolism. We hypothesize that CPT1 blockade can decrease the inflammatory response, induce an immune modulation, reduce mitochondrial dysfunction and hence alleviate renal IR-I.

Methods: Male Wistar rats (n = 10 animals per group) were subjected to either sham operation or renal ischemia/reperfusion (IR) by bilateral artery clamping for 40 min followed by ETO (5 mg/kg/day) or vehicle administrated at reperfusion. Clearance experiments were performed and renal tissue was removed and prepared for qPCR, immunohistochemistry and western blot analysis at sacrifice 48 hrs after reperfusion.

Results: IR-I resulted in polyuria *(ml/kg/day ± SEM, Sham: 36 ± 3, IR: 125 ± 5, IR+ETO: 62 ± 4),* increased fractional sodium excretion *(%, Sham: 0.3 ± 0.04, IR: 2 ± 0.3, IR+ETO: 0.3 ± 0.09),* plasma creatinine *(μmol/L/kg, Sham: 77 ± 3, IR: 649 ± 183, IR+ETO: 141 ± 19)* as well as BUN *(mmol/L/kg, Sham: 18 ± 1, IR: 102 ± 20, IR+ETO: 41 ± 8).* ETO treatment prevented these increases, improved creatinine clearance *(ml/min, Sham: 7.4 ± 0.6, IR: 1.9 ± 0.2, IR+ETO: 3.8 ± 0.4)* as well as attenuated downregulation of AQP1, Na/K-ATPase and AQP2 expression. All changes were significantly different between IR and IR+ETO. In addition, expression of (pro)inflammatory cytokines (IL-6, IL-1β, TNFα, MCP-1, IL-10) and key markers (ICAM-1) were significantly reduced including NGAL *(Sham: 1, IR: 49 ± 16, IR+ETO: 1 ± 0.1)* and KIM-1 *(Sham: 1, IR: 725 ± 101, IR+ETO: 218 ± 65)* in response to ETO administration. Expression of CPT1A increased following the ETO treatment *(Sham: 1, IR: 1.2 ± 0,1, IR+ETO: 1.6 ± 0.1*).

Conclusions: ETO treatment impaired development of renal dysfunction and attenuated tissue injury after renal IR-I. Decreasing the lipid metabolism attenuate the inflammatory response and may provide a novel potent pathway for treatment of renal IR-I.

FR-PO177

The Role of Gβγ-Dependent Signaling in Formoterol-Induced Mitochondrial Biogenesis and Recovery of Renal Function in Mice Robert B. Cameron,[1,2] Justin B. Collier,[1,2] Rick G. Schnellmann.[2] [1]*Medical University of South Carolina, Charleston, SC;* [2]*University of Arizona, Tucson, AZ.*

Background: Acute kidney injury (AKI) is prevalent and has substantial morbidity and mortality with few effective therapies. AKI is associated with the activation of kinases, such as ERK1/2, that prolong injury and prevent recovery. Our laboratory has recently shown that ERK1/2 activation suppresses mitochondrial function and induces KIM-1 expression following AKI in mice. Formoterol, a β_2 adrenoceptor agonist, accelerates recovery of renal function in mouse models of AKI. However, the effects of formoterol on signaling in healthy and injured kidney are unknown.

Methods: Male C57BL/6 mice received DMSO or 0.3 mg/kg formoterol i.p. and were euthanized at 30 min or 24 h. For inhibitor studies, mice received gallein (an inhibitor of the G protein heterodimer Gβγ) 1 h prior to formoterol or diluent control. To model the effects of formoterol on AKI, mice were subjected to bilateral ischemia-reperfusion (IR) injury and received formoterol 24 h following surgery. Injured and sham mice were euthanized 30 min and 24 h following formoterol administration.

Results: Formoterol increased Akt phosphorylation and cGMP in the renal cortex at 30 min following treatment. At 24 h, formoterol increased expression of the mitochondrial protein ATP synthase beta (ATPSβ), a marker of mitochondrial biogenesis (MB). The increases in Akt phosphorylation and ATPSβ were blocked by pretreatment with gallein. Following IR injury, formoterol accelerated recovery of renal function as measured by blood urea nitrogen (BUN) and serum creatinine (SCr) at 24 h following formoterol administration. This was accompanied by a decrease in renal injury as measured by KIM-1 expression in the renal cortex. At 30 minutes following formoterol administration after I/R, the phosphorylation of ERK1/2 was reduced compared to mice treated with vehicle.

Conclusions: In the healthy kidney, formoterol activates Gβγ-Akt dependent signaling to upregulate mitochondrial proteins and biogenesis. Following injury, formoterol has rapid effects on renal recovery, in part through modulation of ERK1/2. Modulation of Gβγ-dependent signaling and MB by formoterol may provide novel therapeutics for AKI.

Gender Differences in Renal Mitochondrial Injury during Sepsis Lee Ann MacMillan-Crow, Philip R. Mayeux. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Acute kidney injury (AKI) is a frequently encountered complication of sepsis. Sepsis accounts for about 50% of AKI cases in intensive care units and patients with sepsis complicated by AKI have markedly worse prognosis and have a higher mortality rate. Numerous studies, including our own, have reported the involvement of mitochondrial damage and oxidant production during sepsis. The goal of this study was to evaluate whether gender differences exist in the extent of mitochondrial damage using a murine model of sepsis.

Methods: Cecal ligation and puncture (CLP) was performed in male and female CD1 mice to induce sepsis. Briefly, the cecum was punctured twice with a 21-gauge needle, followed by a right nephrectomy. Animals received antibiotics and fluid resuscitation at 6 h and every 12 h thereafter. Mitochondrial function was assessed via high resolution respirometry (HRR) and ATP measurement. Mitochondrial fusion and fission pathways were monitored using western blot.

Results: Male mice exposed to CLP (18 hr) showed a significant decline in complex I, II, and III activities compared to sham animals. However, only complex I was inactivated in female mice exposed to CLP (18 hr). Interestingly, baseline (sham) complex II and IV activities were significantly higher in female mice, compared to male mice. In addition, studies show that sepsis in our male model leads to loss of the long form of Optic Atrophy Protein (OPA1), which normally fuses the inner mitochondrial membrane between mitochondria, as an essential part of the overall fusion process. OPA1 is cleaved to the short form by two zinc metalloproteinases, OMA1 and YME1L. OMA1 is considered a stress-induced protease and appears to be activated in our male sepsis model, but not in female mice. Interestingly, sepsis in female mice induced protein expression of the mitofusions (MFN1/2) proteins which regulate outer mitochondrial membrane fusion, which was not observed in male mice. Survival studies showed that female mice exposed to CLP were more likely to die compared to male mice.

Conclusions: Our results suggest that sepsis induces gender dependent differences in mitochondrial damage and remodeling via fusion/fission processes. These findings raise the possibility that altered mitochondrial dynamics may be an unrecognized contributor to gender specific responses to sepsis induced AKI.

SIRT1/P53/Drp1-Dependent Mitochondrial Fission Mediates Aldosterone-Induced Podocyte Injury and Mitochondrial Dysfunction Yanggang Yuan,[1] Aihua Zhang,[1] Changying Xing.[2] [1]*Nanjing Medical University, Nanjing, China;* [2]*The First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Mitochondrial dysfunction is increasingly recognized as an important factor in glomerular diseases. Previous study showed that mitochondrial fission contributed mitochondrial dysfunction. However, the mechanism of mitochondrial fission on mitochondrial dysfunction in aldosterone-induced podocyte injury remains ambiguous. This study aimed to investigate the pathogenic effect of mitochondrial fission both in vivo and in vitro.

Methods: Aldosterone-infused mice were implanted subcutaneously with 14-day-release pellets containing aldosterone. Mitochondrial fission inhibitor mdivi-1 was given by peritoneal injection. The expression of mitochondrial fission protein Drp1 (dynamin-related protein 1) was determined by western blotting and immunofluorescence. Podocyte injury was measured by nephrin expression and labelled by TUNEL assay. In vitro, podocytes were treated with aldosterone at the concentration of 0, 25, 50, 100 nmol/L. The expressions of Drp1, p53 and SIRT1 were examined by real-time PCR and western blot. Then podocytes were transfected with Drp1 siRNA, p53 siRNA and SIRT1 plasmid, respectively. After aldosterone treatment, podocyte injury, mitochondrial morphology and mitochondrial function were detected.

Results: In an animal model of aldosterone-induced nephropathy, inhibition of Drp1 suppressed aldosterone-induced podocyte injury. In cultured podocytes, aldosterone dose-dependently induced Drp1 expression. Knockdown of Drp1 inhibited aldosterone-induced mitochondrial fission, mitochondrial dysfunction and podocyte apoptosis. In addition, aldosterone dose-dependently induced p53 expression. Knockdown of p53 inhibited aldosterone-induced Drp1 expression, mitochondrial dysfunction and podocyte apoptosis. Furthermore, aldosterone dose-dependently decreased SIRT1 expression. SIRT1 overexpression blocked aldosterone-induced p53 and Drp1 expression, mitochondrial dysfunction and podocyte injury.

Conclusions: These findings implicated that aldosterone-induced mitochondrial dysfunction and podocyte injury mediated by SIRT1/p53/Drp1-dependent mitochondrial fission, which may provide opportunities for therapeutic intervention for podocyte injury.

Super Resolution Imaging of Kidney Tissue Is a Novel Technique to Study Three Dimensional Mitochondrial Networks and Functional Correlates In Vivo Craig R. Brooks,[2] Kensei Taguchi.[1] [1]*Department of Nephrology and Hypertension, Nashville, TN;* [2]*Vanderbilt University Medical Center, Nashville, TN.*

Background: Mitochondria are essential for all eukaryotic life. Kidney proximal tubule cells (PTCs) have the highest content of mitochondria, by surface area, of any cell type in mammals. The large complement of mitochondria is necessary to support the tremendous amount of transport that occurs in the PTC during the reabsorption of sodium and other solutes from urine. Previous studies have demonstrated that mitochondrial morphology is important to maintain both the health and functionality of mitochondria.

Methods: Sham or ischemically injured kidneys from wild-type C57BL/6 mice were fixed and embedded in paraffin following standard protocols. Sections of the kidneys were mounted on (3-Aminopropyl)trimethoxysilane treated coverslips and stained for

mitochondrial and PTC markers, and then imaged by Structured Illumination Microscopy (SIM) or Zeiss Airyscan.

Results: Super resolution imaging enabled the resolution of not only individual mitochondria but also distinguished inner membrane space vs. outer membrane. SIM revealed that PTC mitochondria form a 3D network *in vivo*. Mitochondrial networks extend throughout the cell body and into the interdigitations of the PTCs. Co-staining of mitochondrial makers with Na^+-K^+-ATPase revealed a tight association of the mitochondria with interdigitations of the basolateral membrane in PTCs, in which mitochondria from one PTC often run parallel to the mitochondria of neighboring cells within Na^+-K^+-ATPase positive inholdings of the plasma membrane. Injury to the kidney led to reduced mitochondrial interconnectivity and rearrangement of the inner membrane space. Injury also resulted in retraction of the basolateral interdigitations of the plasma membrane.

Conclusions: Super resolution imaging provides a novel approach to analyze individual mitochondria and inner vs. outer membrane structure *in vivo* and provides a 3D morphological analysis of the cell and mitochondrial network. Individual mitochondria that extend through interdigitations of the PTCs are part of a larger network that extends through the cell body. Injury to the kidney leads to a breakdown of this network and disassociation of mitochondria from the basolateral membrane.

Honokiol Decreases UUO-Induced Tubulointerstitial Inflammation and Fibrosis by Regulation of Mitochondrial Sirt3 and Its Dynamics Kyung Pyo Kang,[2] Woong Park,[2] Yi Quan,[2] Jin won Jang,[1] Sung K. Park,[2] Won Kim.[2] *[1]Chonbuk National University Hospital, Jeonju, Republic of Korea; [2]Chonbuk National University Medical School, Jeonju, Jeollabuk-Do, Republic of Korea.*

Background: Sirt3 is a NAD^+-dependent deacetylase in mitochondria, which has a role of maintain the mitochondrial function by deacetylation. Sirt3 might protect the cells from reactive oxygen species, apoptosis, and mitochondrial dynamics. In progressive renal disease, tubulointerstitial fibrosis is a final common feature, which is characterized by inflammation, excessive extracellular matrix deposition and organ dysfunction. Honokiol is a natural biphenolic compound derived from the bark of magnolia trees and known as an activator of sirt3 in murine cardiomyopathy model. In this study, we investigate the protective effect of honokiol on unilateral ureteral obstruction (UUO)-induced tubulointerstitial inflammation and fibrosis by regulation of mitochondrial Sirt3.

Methods: Renal fibrosis was induced by UUO in the six-week-old C57BL/6 mice for 10 days. Honokiol (5 mg/kg) was treated by intraperitoneal injection for 7 days before induction of renal fibrosis and continued for 10 days. Histologic examination and Western blot analysis for α-SMA, type I collagen were performed. We also evaluated cell adhesion molecule expression, mitochondrial dynamics and TGF-β1/Smad signaling pathway after ureteral obstruction.

Results: Renal tubular injury and fibrosis were increased after ureteral obstruction. After treatment of honokiol, renal tubular injury and fibrosis were significantly decreased. The number of α-SMA positive fibroblasts and F4/80 positive macrophages were significantly decreased after honokiol treatment in UUO kidney. In Western blot analysis, type I collagen and intercellular adhesion molecule (ICAM)-1 expression was decreased after honokiol treatment in UUO kidney. Sirt3 expression was significantly decreased after UUO surgery, however, honokiol treatment recovered Sirt3 expression in UUO kidney. Mitochondrial fission, as shown Drp1 expression, was increased afer ureteral obstruction, however, honokiol treatment decreased UUO-induced increases of Drp1 expression. In contrast, mitochondrial fusion, as shown OPA1 expression, was decreased after ureteral obstruction and honokiol treatment was recovered.

Conclusions: These results suggest that honokiol has a beneficial effect on UUO-induced tubulointersitial inflammation and fibrosis by regulation of mitochondrial sirt3 and its dynamics.

Impaired Cutaneous Wound Healing in a Rodent Model of Uremia Sai Krishna Duraisingham,[2,1] Julius E. Kieswich,[2] Steven M. Harwood,[2] Muhammad M. Yaqoob.[2,1] *[1]The Royal London Hospital, Barts Health NHS Trust, London, United Kingdom; [2]William Harvey Research Institute, Queen Mary University, London, United Kingdom.*

Background: Patients with CKD develop a multitude of skin changes associated with the duration and severity of renal failure. Additionally, causative comorbidities such as peripheral vascular disease and diabetes directly impact on wound healing. In clinical practice, poor healing contributes to prolonged hospital stays, a susceptibility to infective complications and significant morbidity, including a considerable negative psychological impact. For these reasons finding methods to assess wound healing in uremia will be valuable.

Methods: We developed a rodent model of excisional wound healing. Animals were maintained in a temperature controlled facility with a 12h light/dark cycle. After 2 weeks acclimatization, 6 week old male Wistar rats were fed a diet of standard rat chow supplemented with 0.75% adenine and given water *ad libitum* for 4 weeks to establish uremia. Healthy controls were fed standard chow. Survival, growth rate and well-being were monitored during the experimental period. Under inhaled 1.5% Isoflurane anesthesia a 30µl subcutaneous injection of Buprenorphine 0.3mg/ml was administered before creating bilateral 5mm full thickness dorsal punch biopsies with a Stiefel Biopsy Punch. Recovery from anesthesia was observed before returning animals to cages. Measurements of the wounds were taken on subsequent days. At day 3 and 7, half the animals were sacrificed under Ketamine and Xylazine anesthesia. Blood samples obtained by cardiac puncture were centrifuged for plasma and organs were harvested for histology or for protein and RNA analysis. Wounds were excised and bisected, one semicircle section was stored in formalin, the other snap frozen under liquid nitrogen. Experiments were conducted under our UK Home Office license after institutional approval.

Results: This model successfully established a uremic state with no premature deaths, excess bleeding or infected wounds observed. Serum urea was significantly higher in the uremic group at both day 3 and 7 ($p<0.01$) as was serum creatinine ($p<0.02$). Percentage of the wound area healed compared to day 0, was significantly greater in the control group at day 3 and day 7 ($p<0.02$ and $p<0.001$).

Conclusions: We have developed a novel rodent model with low complication rates to study factors contributing to delayed wound healing in uremia. Moreover, we have demonstrated a delay in healing in the uremic state.

FR-PO183

CD4 Lymphopenia Is Associated with Cardiovascular Disease in Patients with Non-Dialysis Dependent CKD Kenichiro Iio, Yutaka Ando. *National Hospital Organization, Osaka Minami Medical Center, Kawachinagano, Japan.*

Background: The role of T cells in the pathogenesis of atherosclerosis is complex. T-cell infiltration is thought to occur at atherosclerotic sites; CD4 lymphopenia in HIV patients is associated with atherosclerosis. Patients with chronic kidney disease (CKD) not only have a high prevalence of cardiovascular disease (CVD), but their circulating CD4 lymphocyte count is also decreased. The aim of this study was to assess the relationship between CVD and circulating T cell phenotype in patients with CKD.

Methods: We enrolled 97 patients with CKD stages 3-5 (mean age 68.4 ± 12.1 years; 65 males [67%]; CKD stage 3/4/5, 32/14/51) who were hospitalized between June 2013 and May 2017. We determined the numbers of immune cell phenotypes ($CD4^+$, $CD8^+$, $CD28^+CD8^+$) and the ratio of CD4/CD8 cells in peripheral blood or peripheral blood mononuclear cells using flow cytometry, to define their relationships with CVD, prospectively.

Results: Among 28 (29%) CVD patients, $CD4^+$ (678 vs. 473, $p = 0.004$) and $CD28^+CD8^+$ (147 vs. 97, $p = 0.012$) cell counts were significantly lower and this group was significantly older (age 67 vs. 72 y, $p = 0.09$) than non-CVD patients. Multivariate logistic analysis indicated a significant negative association between CVD and the number of $CD4^+$ T cells (odds ratio, 0.997; 95% confidence interval, 0.995 - 1.000, p=0.023).

Conclusions: Peripheral blood CD4 lymphopenia is associated with CVD in patients with non-dialysis CKD. CD4 lymphopenia may reflect atherosclerosis in CKD patients.

FR-PO184

CKD and Arterial Thrombosis: Role of the Receptor for Advanced Glycation End-Products (RAGE) Jeremy Ortillon,[8] Nathalie Hézard,[1] Karim Belmokhtar,[9] Kawecki Charlotte,[2] Christine Terryn,[5] Ann Marie Schmidt,[3] Pascal Maurice,[4] Philippe V. Nguyen,[6] Philippe Rieu,[7] Fatouma Toure.[7] *[1]EA 3801 HERVI, REIMS, France; [2]INSERM U1176, le Kremlin-Bicêtre, France; [3]NYU Medical Center, New York, NY; [4]UMR CNRS/URCA 7369, Reims, France; [5]Universite de Reims Champagne Ardenne, REIMS, France; [6]University of Reims, REIMS, France; [7]CHU and UMR CNRS URCA 7369, Reims, France; [8]CNRS UMR URCA 7369, Reims, France; [9]CNRS UMR URCA 7369, Reims, France.*

Background: Chronic kidney disease (CKD) is associated with extensive vascular wall remodelling and vasculopathy as well as accumulation of uremic toxins. Among these toxins, advanced glycation end-products (AGEs) interact with the receptor for advanced glycation end-products (RAGE). *In this study, we aimed to analyze the impact of CKD on* arterial thrombosis and the potential role of RAGE in this process.

Methods: *We used a mouse model of uremic vasculopathy consisting in a 2-step 5/6 nephrectomy. Four groups of animals were studied: $Apoe^{-/-}$ mice sham operated (n=12) or uremic (n=10) and $Apoe^{-/-}/Ager^{-/-}$ (= $Apoe^{-/-}RAGE^{-/-}$) mice sham operated (n=11) or uremic (n=15). Twelve weeks after surgery: 1) arterial thrombosis was induced by* ferric chloride application on the carotid artery and complete carotid occlusion time was measured, 2) platelet function was analysed in whole blood and in platelet rich plasma (PRP).

Results: *In-vivo*, uremia significantly accelerates the occlusion time in *$Apoe^{-/-}$ mice* (9.2 ±1,1min *vs* 11.1 ±0,6 min, $p<0.01$) compared to sham animals. IIn contrast, uremia had no effect on *$Apoe^{-/-}/Ager^{-/-}$ mice* carotid occlusion time (14,5 ±2,3 min, *vs* 13 ±1,5 min in sham, NS). Moreover occlusion time of the uremic *$Apoe^{-/-}$ mice was significantly accelerated compared to uremic $Apoe^{-/-}$ /$Ager^{-/-}$ mice ($p<0,0001$).* **Ex-vivo**, *agonist-induced platelet aggregation in whole blood was significantly increased in uremic condition in both $Apoe^{-/-}$ and $Apoe^{-/-}$ /$Ager^{-/-}$ mice. In PRP,* aggregation of uremic *$Apoe^{-/-}$ mice platelets was significantly increased compared to that of uremic $Apoe^{-/-}/Ager^{-/-}$ mice. In agreement, agonist induced expression of activated integrin* αIIbβ3 and P-selectin were both significantly increased at the surface of *$Apoe^{-/-}$ uremic platelets compared to 1) $Apoe^{-/-}$ sham platelets and to 2) $Apoe^{-/-}/Ager^{-/-}$ platelets (uremic & sham).*

Conclusions: In this murine model of thrombosis we report that uremia accelerates arterial thrombus formation and induces platelets hyperreactivity. We found that *Ager* deletion had a protective role on uremia-induced arterial thrombosis, and in uremia-induced platelet hyperreactivity. We suggest that RAGE signaling may be involved in CKD-induced atherothrombosis.

Renal Hemodynamic Effects of sGC Activation versus ACE Inhibition in Conscious Rats Karen A. Griffin,[6] Geoffrey A. Williamson,[3] Aaron J. Polichnowski,[2] Perriannan Sethupathi,[5] Agnes M. Benardeau,[1] Frank Eitner,[1] Anil K. Bidani.[4] *[1]Kidney Diseases Research, Bayer AG, Wuppertal, Germany; [2]East Tennessee State University, Johnson City, TN; [3]Illinois Institute of Technology, Chicago, AL; [4]Loyola University Med Ctr and Hines VA Hospital, Maywood, IL; [5]Loyola University Medical Center, Maywood, IL; [6]Loyola University Medical Center Hines VA Hospital, Maywood, IL.*

Background: Substantial evidence indicates that endothelial dysfunction and/or NO loss accelerates the progression of diabetic and non-diabetic chronic kidney disease (CKD). Therefore, soluble guanylate cyclase (sGC) modulators are being developed as potential novel therapeutic interventions in CKD, but only limited data are available as to their renal hemodynamic effects, particularly in the unanesthetized state.

Methods: Conscious chronically instrumented normal Sprague-Dawley rats (Charles River & Envigo) underwent repeated simultaneous 1-2 hr BP (radiotelemetry) and RBF (Transonic) recordings over 3 wks (2-4 x wk) while they were sequentially receiving: vehicle only by gavage (5 ml/kg), a low and a high dose of either the sGC activator (Bay-543) or enalapril (4 d/wk with a 3d washout). Effects on mean arterial pressure (MAP), RBF and the autoregulatory AR ability to buffer spontaneous BP fluctuations were assessed using a methodology recently developed in our lab (AR indices are calculated for ~500 adjacent pairs of short segments of 2.5 sec length/rat, which exhibit a difference in MAP of at least 5mmHg, SSARI). GFR was additionally measured during each wk using chronic FITC inulin infusion by osmotic pumps, and 24 hr urine collections. The data for both colonies of SD rats are combined as the results were similar.

Results: Table (mean ± SEM) GFR was not significantly or consistently altered by either agent. Thus, while both agents reduced BP comparably, significantly greater dose dependent renal vasodilation was observed with the sGC activator, while a more modest RBF increase was only seen with the higher dose of enalapril. Surprisingly, AR buffering of spontaneous BP fluctuations was moderately improved by the sGC activator but not enalapril.

Conclusions: Collectively, the BP and renal hemodynamic effects of sGC activation suggest that sGC modulators may have significant therapeutic utility in CKD states, meriting additional and more direct investigations in CKD models.

Endothelial Dysfunction in ESRD Results from Advanced Glycation End-Products (AGE)-Mediated Suppression of Krüppel-Like Factor 2 Keith L. Saum,[3] Begoña Campos,[3] Diego Celdran-Bonafonte,[2] Albert P. Owens,[3] Prabir Roy-Chaudhury.[1] *[1]University of Arizona, Tucson, AZ; [2]University of Arizona / BIO 5 Institute, Tucson, AZ; [3]University of Cincinnati, Cincinnati, OH.*

Background: Cardiovascular disease is the leading cause of morbidity and mortality in patients with end-stage renal disease. The accumulation of uremic toxins in this patient population is associated with endothelial dysfunction and accelerated arteriosclerosis. We investigated the impact of protein-bound uremic toxins such as advanced glycation end products (AGEs) on the expression of Krüppel-like Factor 2 (KLF2), the key regulator of endothelial function and activation.

Methods: We used serum from a porcine model of chronic renal failure to assess the impact of uremia on endothelial KLF2 expression in vitro. Human umbilical vein endothelial cells (HUVEC) were treated with increasing concentrations of uremic or non-uremic porcine serum and analyzed for cell viability, apoptosis, and KLF2 expression. Similarly, cells were treated with individual protein-bound toxins at average uremic concentrations. Reactive oxygen species (ROS) production and monocyte adhesion were then assessed in treated cells with and without KLF2 overexpression. Finally, we investigated nuclear factor kappa-B (NF-KB) signaling as a mechanism underlying the AGE-mediated suppression of KLF2 and the potential of a RAGE antagonist, TTP488, to increase endothelial KLF2 expression and function.

Results: Treatment with uremic serum decreased HUVEC viability and increased apoptosis in a dose-dependent manner compared to non-uremic serum. Furthermore, uremic serum suppressed HUVEC KLF2 expression > 50%, which was reversed by dialysis and shear stress. Of the uremic toxins tested, carboxymethyl-lysine (CML) modified albumin, an AGE, resulted in the greatest suppression of KLF2 similar to uremic serum. Overexpression of KLF2 inhibited the production of ROS and leukocyte adhesion by uremic serum and CML. Inhibition of RAGE-mediated NF-KB signaling blocked the translocation of p65 to the nucleus and suppression of KLF2 by CML.

Conclusions: Suppression of KLF2 by uremic toxins such as AGEs is associated with increased endothelial dysfunction. This study, therefore, identifies suppression of KLF2 as a potential mechanism by which uremic toxins impair endothelial function in regions prone to arteriosclerosis. Future studies targeting this pathway could lead to novel therapies to decrease cardiovascular mortality in ESRD.

Carotid Intima–Media Thickness Predicts Dialysis Vascular Access Failure in Hemodialysis Patients: A Prospective Study Hong joo Lee. *Seoul Red Cross Hospital, Seoul, Republic of Korea.*

Background: A well-functioning dialysis vascular access is a mainstay to perform an efficient hemodialysis. Dialysis vascular access dysfunction is a common cause of morbidity and mortality for the hemodialysis patients. Carotid intima–media thickness (cIMT) and carotid plaque are ultrasound imaging that measures carotid atherosclerosis and predicts potential stroke, myocardial infarction, and vascular death. Hence, we conducted our study to elucidate the predictive value of cIMT on dialysis vascular access failure from the patients with end-stage renal disease (ESRD) on hemodialysis.

Methods: All hemodialysis patients in Red Cross Hospital within a period of one year were included in the study. cIMT of the participants were measured at 6 points of the carotid artery including right and left common carotid artery, right and left bulb, and right and left internal carotid artery by using the carotid ultrasonography. Moreover, they were classified in 2 degrees of severity: more than 1.0 mm of maximal cIMT and less than 1.0mm of maximal cIMT. Dialysis vascular access dysfunction served as outcome variables over a median follow-up period of 12 months. Statistical analysis was carried out by using SPSS.

Results: Among the 58 cases, 19 of the patients and 29 events were having dialysis vascular access dysfunction for the 12 months follow-up period. The maximal cIMTs were 2.34±1.10. The patients with more than 1.0mm of maximal cIMT were older (66.08±11.92 versus 50.90±13.26) with lower protein and albumin and higher hemoglobin A1C than the patients with less than 1.0mm of maximal cIMT. However, maximal cIMT was not associated significantly with the level of lipid profiles, including total cholesterol, high and low density lipoprotein cholesterol, triglyceride, and phospholipid. We observed a positive correlation between weight, body mass index, triglyceride, and dialysis vascular access dysfunction. Dialysis vascular access dysfunction was significantly often occurred in the patients with more than 1mm of maximal cIMTs than the patients with less than 1mm of maximal cIMT.

Conclusions: Our results show that dialysis vascular access dysfunction may be associated with the maximal cIMT. Therefore, the measurement of cIMT may have an advantage for prediction of dialysis vascular access dysfunction in hemodialysis patients.

FR-PO188

Masked Uncontrolled Hypertension and Target Organ Damage in Patients with CKD Markus P. Schneider,[5] Ulrike Raff,[5] Rolf Janka,[5] Christoph Wanner,[2] Thorsten Klink,[2] Christian O. Ritter,[3] Turgay Saritas,[4] Georg Schlieper,[1] Jürgen Floege,[4] Roland E. Schmieder,[5] Kai-Uwe Eckardt,[5] Johannes B. Scheppach.[5] *[1]MVZ DaVita Karlstraße, Duesseldorf, Germany; [2]University Hospital Würzburg, Wuerzburg, Germany; [3]University Medicine of Goettingen, Goettingen, Germany; [4]RWTH University of Aachen, Aachen, Germany; [5]University of Erlangen-Nuremberg, Erlangen, Germany.*

Background: Masked uncontrolled hypertension (MUCH), i.e. normal blood pressure (BP) in the office but elevated ambulatory BP, has been associated with target organ damage and increased cardiovascular (CV) events in the general population. However, in patients with chronic kidney disease (CKD), who are exposed to a variety of additional CV risk factors, the role of MUCH for target organ damage is less clear.

Methods: In 305 CKD patients under treatment for arterial hypertension, we compared left ventricular mass (LVM, by magnetic resonance imaging), intima-media thickness (IMT), central augmentation index and pulse wave velocity (cAIx and PWV, Mobil-O-Graph®) between the four BP phenotypes: controlled hypertension (CH, normal office BP and normal ambulatory BP), white coat hypertension (WCH, elevated office BP but normal ambulatory BP), MUCH (normal office BP but elevated ambulatory BP) and sustained uncontrolled hypertension (SUCH, elevated office BP and elevated ambulatory BP).

Results: MUCH was present in 18% of patients (table). LVM, IMT, cAIx and PWV differed between BP phenotypes. LVM was greater in MUCH and SUCH versus CH (*P<0.05 for post-hoc comparisons). IMT was increased only in MUCH versus CH. Similarly, cAIx was increased only in MUCH versus CH. Finally, PWV was increased in WCH, MUCH and SUCH versus CH.

Conclusions: MUCH was found in 1 of 5 patients with mild to moderate CKD, and associated with several features of target organ damage. To identify CKD patients at high risk of subclinical target organ damage and future CV events, ambulatory BP monitoring should be used more frequently.

Funding: Commercial Support - Fresenius Medical Care

Biomarkers of Endothelial, Renal, and Platelet Dysfunction in Stage 5 CKD Hemodialysis (CKD5-HD) Patients with Heart Failure (HF) Vinod K. Bansal, Ryan Mcmillan, Debra Hoppensteadt, Jawed Fareed. *Loyola University Medical Center, Maywood, IL.*

Background: The aim of this study was to determine the role of endothelial, renal and inflammatory biomarkers in the pathogenesis of heart failure (HF) in patients with stage 5 chronic kidney disease (CKD5-HD) undergoing maintenance hemodialysis (HD).

Methods: Plasma levels of biomarkers: kidney injury molecule-1 (KIM-1), N terminal-pro brain natriuretic peptide (NT-proBNP), glycated hemoglobin (HgA1C), neutrophil gelatinase associated lipocalin (NGAL), interleukin-18 (IL-18), platelet derived growth factor (PDGF), platelet factor 4 (PF4), 25-OH vitamin D, parathyroid hormone (PTH), endothelin and endocan were measured in CKD5-HD patients at the Loyola University Ambulatory Dialysis facility. Normal plasma samples (n=50) were used as control.

Results: The HF (+) CKD5-HD patients, as compared to HF (-) CKD5-HD patients, exhibited significantly elevated NT-proBNP (P = 0.0194) and KIM-1 (P = 0.0485). The NT-proBNP in HF (+) CKD5-HD patients was found to correlate with the levels of serum potassium (P = 0.023 | R = -0.39), calcium (P = 0.029| R = -0.38) and PF4 (P = 0.045 | R = -0.35). The KIM-1 in HF (+) CKD5-HD patients was found to correlate with PTH (P = 0.043 | R = -0.36) and 25-OH vitamin D (P = 0.037 | R = 0.36). In comparison to the normal plasma samples the CKD5-HD patient plasma exhibited varying degrees of elevation in all of the parameters studied.

Conclusions: Elevated plasma NT-proBNP and KIM-1 in CKD5-HD and HF (+) CKD5-HD patients suggest that natriuretic peptides and KIM-1 may contribute to the pathogenesis of HF in CKD5-HD patients. Thus profiling of the biomarkers in CKD5-HD may be helpful in the risk stratification and identifying patients with heart failure.

FR-PO190

Renal Hemodynamic Effects of Sgc Activation Versus ACE Inhibition in Conscious Obese Diabetic ZSF1 Rats Anil K. Bidani,[4] Geoffrey A. Williamson,[3] Aaron J. Polichnowski,[2] Perriannan Sethupathi,[5] Agnes M. Benardeau,[1] Frank Eitner,[1] Karen A. Griffin.[4] *[1]Kidney Diseases Research, Bayer AG, Wuppertal, Germany; [2]East Tennessee State University, Johnson City, TN; [3]Illinois Institute of Technology, Chicago, AL; [4]Loyola University Med Ctr and Hines VA Hospital, Maywood, IL; [5]Loyola University Medical Center, Maywood, IL.*

Background: Substantial evidence indicates that endothelial dysfunction and/or NO loss accelerates the progression of diabetic and non-diabetic chronic kidney disease (CKD). Therefore, soluble guanylate cyclase (sGC) modulators are being developed as potential novel therapeutic interventions in CKD, but only limited data are available as to their renal hemodynamic effects and none in the unanesthetized rodent disease models.

Methods: Conscious chronically instrumented 12-14 wk old obese diabetic ZSF1 rats (body wt ~500g) underwent repeated simultaneous 1-2 hr BP (radiotelemetry) and RBF (Transonic) recordings over 3 wks (2-4 x wk) while they were sequentially receiving: vehicle only by gavage (5 ml/kg), a low and a high dose of either the sGC activator (Bay-543) or enalapril (3-4 days/wk with a ~3 day washout period). Effects on mean arterial pressure (MAP), RBF, renal vascular resistance (RVR) and the autoregulatory (AR) ability to buffer spontaneous BP fluctuations were assessed using a methodology recently developed in our lab (AR indices [fractional change in RBF / fractional change in MAP] are calculated for ~500 adjacent pairs of short segments of 2.5 sec length/rat, which exhibit a difference in MAP of at least 5mmHg, SSARI).

Results: Table (mean ± SEM) Similar to what we have observed in normal rats, at the dosages used, both agents reduced BP comparably. However, significantly greater dose-dependent renal vasodilation was observed with the sGC activator, but not enalapril. Although enalapril did reduce RVR at the higher dose, the increase in RBF did not reach statistical significance. AR buffering of spontaneous BP fluctuations was well preserved and not altered by either agent.

Conclusions: Collectively, the BP and renal hemodynamic effects of sGC activation in the conscious ZSF1 rat suggest that sGC modulators may have significant therapeutic utility in CKD states meriting additional investigations directly addressing CKD progression.

Lipoprotein-Apheresis (LA) Slows Down Artery Disease Progression by Modulating the Cytokine Network Involved in the Atherosclerosis Signaling Simona Simone,[1] Matteo Accetturo,[1] Paola Pontrelli,[1] Gianluigi Zaza,[2] F. Rascio,[1] Loreto Gesualdo,[1] Giuseppe Grandaliano,[3] Giovanni B. Pertosa.[1] *[1]University of Bari, BARI, Italy; [2]University of Verona, Verona, Italy; [3]UNIVERSITY OF FOGGIA, FOGGIA, Italy.*

Background: LA is a potentially valuable treatment applied to conventional therapy-resistant patients with familial hypercholesterolemia (FH). Several clinical studies report that LA is associated with a significantly greater reduction of cardiovascular events, but the molecular mechanisms underlying this effect are still unknown.

Methods: Aim of the study was to evaluate the progression of atherosclerosis lesions (by measuring intima-media thickness, IMT, and the brachial artery Flow-Mediated Dilation, FMD) in 8 pts treated with LA (HELP system, BBraun, Italy). Moreover, by using a high-throughput approach, was also evaluated the transcriptomic profile in PBMCs isolated before and after LA (Agilent Technologies). The results were evaluated by statistical (Genespring software) and functional pathway analysis (Ingenuity Pathway Analysis, IPA). The data were validated by real-time PCR and ELISA test in an independent testing-group (n=10).

Results: A significant reduction of IMT (p<.001) was observed after 36 months of LA along with an increase of FMD (p<.02). Using a fold-change (FC) ≥2, we demonstrated that LA modulates the expression of 84 genes. The top canonical pathways was atherosclerosis signaling (p=.0003). Many pro-inflammatory cytokines involved in the development and progression of the atherosclerotic process were significantly down-regulated: Interleukin 1 (IL-1b FC=-2.97), IL-6 (FC=-2.07), IL-8 (FC=-3.56) and MCP-1 (FC=-2.13). Real Time PCR showed a different gene expression before and after LA (IL-1 p<.0004; IL-6: .01; IL-8 p<.005; MCP1 p<.0002). Similarly, circulating protein level (ELISA) confirmed that IL-1β (Pre 2.77±0.4pg/ml, After 0.93±0.2, p=0.003), IL-6 (Pre 2.09±0.6, After: 1.02 ±0.5 pg/ml, p=0.01), IL-8 (Pre 141.53±45.0, After: 27.9±5.2 pg/ml, p=0.008) and MCP1 (Pre 485.5±38.0, After 330.2±51.0 pg/ml, p=.0001) were down-regulated after LA.

Conclusions: Our data suggest that LA may contribute to cardiovascular risk reduction through the modulation of different pathways involved in the progression of atherosclerotic disease and improvement of microcirculation. This observation might open new perspectives in the prevention of cardiovascular risk in patients with FH

Aerobic Exercise Improves Vascular Function in Non-Dialysis CKD Danielle L. Kirkman,[1] Meghan G. Ramick,[1] Bryce J. Muth,[1] Joseph M. Stock,[1] Raymond R. Townsend,[2] David G. Edwards.[1] *[1]University of Delaware, Newark, DE; [2]University of Pennsylvania School of Medicine, Villanova, PA.*

Background: Endothelial dysfunction is a cardiovascular disease risk factor (CVD) characteristic of chronic kidney disease (CKD). This study investigated the effect of aerobic exercise on vascular function in Stage 3-5 CKD.

Methods: In this randomized controlled trial, 36 patients (eGFR 44±2ml/min/1.73m^2) were randomized to an Exercise Training (EXT) or Control (CON) arm. EXT consisted of 3x45min of supervised exercise per week at 60-85%HRR for 12 weeks whereas CON received routine care. Outcomes were assessed at 0 and 12 weeks. VO_{2peak} was assessed by cardiopulmonary exercise testing. Conduit artery function was assessed via brachial artery flow mediated dilation (FMD). Microvascular function was assessed via cutaneous vasodilation during local heating coupled with intradermal microdialysis measured by laser Doppler flowmetry. Participants were instrumented with 3 microdialysis fibers for the delivery of 1) Ringer's solution; 2) superoxide scavenger Tempol; 3) NADPH oxidase inhibitor Apocynin. Cutanoues vascular conductance was calculated as a percent of maximum achieved with sodium nitroprusside infusion.

Results: A training response was indicated by an increase in VO_{2peak} following EXT (Week 0 *vs.* 12; EXT:17.9±1.2 *vs.* 19.9±1.60ml/kg/min, p=0.05; CON:18.2±1.7 *vs.* 17.4±1.6ml/kg/min, p=0.1). Brachial artery FMD was maintained and cutaneous microvascular function was improved following EXT compared to CON (Figure 1). At baseline, pharmacological delivery of Apocynin and Tempol improved microvascular function (Ringer's *vs.* Apocynin *vs.* Tempol:85±1% *vs.* 90±1% *vs.* 90±1%, p=0.02) but was no longer effective following EXT (91±2% *vs.* 87±2% *vs.* 87±2%, p=0.03), suggesting that reduced oxidative stress plays a role in vascular improvements following EXT.

Conclusions: Aerobic exercise improves vascular function and could be implemented as an adjunct therapy to reduce CVD risk in non-dialysis CKD patients.

Disruption of Angiopoietin-TIE2 Signaling Causes Loss of Ascending Vasa Recta and Cystic Kidney Disease Yael Kenig-Kozlovsky, Rizaldy P. Scott, Tuncer Onay, Isabel A. Carota, Benjamin R. Thomson, Susan E. Quaggin, Hyea Jin Gil. *Northwestern University, Feinberg School of Medicine, Chicago, IL.*

Background: The renal vasculature is a complex and highly specialized vascular network. Heterogeneous segments of the renal vasculature differ in their anatomical structure, expression of endothelial markers and their role in renal function. The specialized capillaries of the ascending and descending vasa recta form the vascular bundles of the outer medulla, which play a key role in countercurrent exchange and urine concentration. In this study we sought to determine how the angiopoietin-Tie2 signaling pathway, which is known to be important in development and remodeling of blood and lymphatic vessels, affects the complex renal vasculature.

Methods: Using a Cre-based inducible gene targeting strategy we deleted *Angpt1*, *Angpt2*, and *Tie2* at late gestational age in the mouse in order to overcome null mutant embryonic lethality.

Results: Compound deletion of Angpt1 and Angpt2 or Tie2 at late gestation age, leads to marked reduction in density of the vascular bundles and medullary capillary plexus, due largely to loss of the ascending vasa recta. Interestingly, we discovered that the ascending vasa recta (AVR) are "hybrid" vessels, which co-express blood (CD34, endomucin) and lymphatic markers (Prox1, VEGFR3). Loss of AVR in mutant animals leads to urine concentration defects with high urine output and low urine osmolality. As early as postnatal day P2 mutant animals develop renal cysts in the outer medulla. Cells lining the cysts do not express epithelial or vascular (blood and lymphatic) markers but do express several molecular markers of myofibroblasts including vimentin, calponin, SM-22α, and α –SMA.

Conclusions: Our results show for the first time the presence of "hybrid" vessels in the kidney that rely on Angpt-Tie2 signaling to develop. Furthermore, our data show that loss of AVR leads to dramatic cysts and renal insufficiency, underscoring the key functional role vasa recta play in draining interstitial fluid from the medulla that lacks classic lymphatic circulation.

FR-PO194

Central Blood Pressure, Statins, and LDL-Cholesterol: A Mediation Analysis Florence Lamarche,[1] Francois Madore,[1] Mohsen Agharazii,[2] Remi Goupil.[1] *[1]Hopital du Sacre-Coeur, Montreal, QC, Canada; [2]CHUQ-HDQ, Quebec City, AB, Canada.*

Background: Central blood pressure (CBP) is a better predictor of cardiovascular burden than peripheral blood pressure (BP). While studies have suggested a reduction in peripheral BP with statins, it remains uncertain to what extent statins reduce CBP and whether this reduction is mediated through a decrease in LDL-cholesterol (LDL).

Methods: Of the 20,004 CARTaGENE participants, 17,011 had CBP and LDL measurements (n=3,133 with statins; n=13,439 without). Multivariate regression analyses were used to evaluate the association between CBP, LDL and statin use (after stratification for treatment indication for the latter). The impact of LDL on the association between statin use and CBP was determined by mediation analyses. All analyses were adjusted for age, sex, diabetes, cardiovascular disease, smoking, eGFR, BMI, uric acid, heart rate, anti-hypertensive agents and aspirin.

Results: Lower levels of LDL were associated with lower systolic and diastolic CBP in participants treated with (b=0.098 and 0.125; p<0.001) and without statins (b=0.089 and 0.105; p<0.001). Statin use as primary prevention (per ACC/AHA guidelines; n=8,865) was also associated with lower systolic CBP, diastolic CBP and central pulse pressure (b=-0.091, -0.073 and -0.055; p<0,001). Mediation analyses demonstrated that 15%, 46% and -22% of these effects were achieved through the concomitant changes in LDL (Table 1). In secondary prevention (n=995), statins use was not associated with lower CBP, although the small sample size may lack power.

Conclusions: In this populational cohort, statin use is associated with lower CBP when used as primary prevention. These changes are mediated directly by statin use but also indirectly through the effects on LDL.

Table 1: Mediation analyses

	Path A (total effect)	Path A (direct effect)	Path BC (indirect effect)	Percent mediation
Systolic CBP	-3.0 (-3.8, -2.3)	-2.6 (-3.4, -1.7)	-0.5 (-0.2, -0.0)	15%
Diastolic CBP	-1.7 (-2.2, -1.2)	-1.0 (-1.5, -0.4)	-0.8 (-1.0, -0.5)	44%
Central pulse pressure	-1.3 (-1.8, -0.9)	-1.6 (-2.2, -1.1)	0.3 (0.0, 0.6)	-22%

Effect represent change of CBP parameter per 1 standard deviation of LDL (95% CI).

FR-PO195

The Rapid Membrane Insertion of the Endothelial Sodium Channel Is Induced by Shear Stress and Stiffens the Cell Cortex Kristina Kusche-Vihrog. *University of Muenster, Muenster, Germany.*

Background: The endothelial Na^+ channel (EnNaC) determines endothelial nanomechanics in that an increased membrane abundance of EnNaC stiffens the endothelial cell cortex. Surface EnNaC expression is mainly regulated by aldosterone via the mineralocorticoid receptor (MR). Endothelial cells are constantly exposed to wall shear stress by blood flow, whereas disturbed blood flow causes and maintains atherosclerotic processes. Here, it is hypothesized that EnNaC serves as a flow sensor. Thus, we tested whether laminar shear stress (LSS) and non-laminar shear stress (NLSS) influence EnNaC membrane abundance and endothelial stiffness.

Methods: LSS (8 dyne/cm^2) was applied by a shear stress pump on HUVECs seeded on slides with and without branching regions in the presence of 1nM aldosterone to simulate blood flow. After applying shear stress (chronic 48h and acute 15min) HUVECs were fixed. EnNaC membrane abundance was quantified by a Quantum Dot-based immunofluorescence approach. Cortical stiffness was monitored using nanoindentation measurements via atomic force microscopy (AFM) in LSS and NLSS regions of the slides.

Results: Under chronic shear stress (48h) a significant increase of membrane EnNaC was found. Importantly, already after 15 min. LSS αEnNaC membrane abundance was increased by 58.5±4.5%. Both (i) inhibition of exocytosis with Brefeldin A and (ii) (ii) MR antagonism with Canrenone, could prevent the acute shear stress-induced EnNaC membrane insertion indicating a rapid MR-mediated effect of shear stress. EnNaC membrane abundance under NLSS in branching regions was also significantly increased compared to static controls (+24.9±4.3%). AFM measurements revealed that the shear stress-induced increase in EnNaC lead to stiffening of the cell cortex by 18.9±5.5% compared to static controls.

Conclusions: Our results suggest that EnNaC, besides being a mechano-sensor, is regulated by shear stress. Since both chronic and acute shear stress increase the membrane abundance we postulate genomic and non-genomic mechanisms leading to the MR-dependent membrane insertion of EnNaC and subsequent endothelial stiffening. These changes in nanomechanics and thus endothelial function might be a physiological response to changes in hemodynamics and further explain the atherogenic potential of disturbed blood flow.

Decreased Blood Pressure in Vascular Smooth Muscle Specific ATP2B1 Overexpressing Mice Yosuke Ehara,[1] Nobuhito Hirawa,[2] Akira Fujiwara,[2] Kouichi Tamura.[1] *[1]Yokohama City University Graduate School of Medicine, Yokohama-shi, Kanagawa, Japan; [2]Yokohama City University Medical Center, Yokohama, Japan.*

Background: We reported the association between high blood pressure and ATP2B1 gene polymorphisms in Japanese population through Millennium Genome Project. ATP2B1 is a gene encoding plasma membrane calcium ATPase 1 (PMCA1), which is known to be expressed throughout the body. PMCA1 plays a role of discharging Ca^{2+} from the inside of the cell to the outside of the cell, and strictly adjusts the intracellular Ca^{2+} concentration. In subsequent studies we reported that ATP2B1 vascular smooth muscle-specific knockout mice exhibit hypertension and are associated with elevated Ca^{2+} concentrations in vascular smooth muscle cells(VSMC). However, there were no data concerning the effects of ATP2B1 overexpressions. Thus, we generate the vascular smooth muscle-specific ATP2B1 overexpressing mice, and investigate the effects of ATP2B1 on blood pressure.

Methods: ATP2B1 vascular smooth muscle-specific overexpressing mice (Tg^{ATP2B1}) was prepared by microinjection method using transgelin (sm22) as a promoter. The expression level of ATP2B1 was confirmed in the aorta. Birth rate, body weight, organ weight, biochemical findings of Tg^{ATP2B1} were compared with the wild type mice. We

compared the blood pressure and heart rate by the tail cuff method and telemetry method in the two groups.

Results: There was no significant change in birth rate, body weight (Tg^{ATP2B1} versus WT : 27.1 ± 0.6 versus 28.1 ± 1.1 ; P:0.46), organ weight. Serum calcium concentrations (8.83 ± 0.13 versus 8.78 ± 0.12 ; P:0.78) of Tg^{ATP2B1} were also the same with those of wild mice. Although there was no difference in heart rate, a significant decrease in blood pressure was observed in Tg^{ATP2B1} mice using tail-cuff methods (99.4 ± 2.73 versus 108.4 ± 2.72 ; P:0.03). By radio-telemetry methods, the blood pressure of Tg^{ATP2B1} were decreased throughout 24hrs. The blood pressure variabilities were not altered by the over-expression of ATP2B1 in vascular smooth muscle cells.

Conclusions: Vascular smooth muscle-specific ATP2B1 overexpressing mice exhibited lower blood pressure compared to those of wild mice by the tail cuff method and the telemetry method. ATP2B1 over-expression in VSMC might decrease the intra-celular Ca^{2+} concentrations and decrease the contractilities in Tg^{ATP2B1} mice.

Atherosclerosis Is Associated with a Reduction in the Density of Renal Microcirculation Miguel Hueso,[1] Angela I. Casas Parra,[1] Estanislao Navarro,[3] Nuria Bolanos,[3] Cristian Varela,[3] Elia Ripoll,[2] J. Grinyo,[1] Josep M. Cruzado,[1] Juan Torras.[1] *[1]Hospital Universitari de Bellvitge, Barcelona, Spain; [2]Laboratory of Experimental Nephrology, IDIBELL. Hospital Universitari de Bellvitge, Barcelona, Spain; [3]IDIBELL, L'Hospitalet, Spain.*

Background: Cardiovascular disease is increased in renal diseases but the role of renal microcirculation in the development of atherosclerosis is unknown. CD40/CD40L signaling has a critical role in atherosclerosis and CD40 silencing reduces their progression. In addition, CD40/CD40L signaling may lead to blood vessel dysfunction and occlusion. Thus, we used the CD40-silenced $ApoE^{-/-}$ model of atherosclerosis to study the interplay between atherosclerosis and renal microcirculation.

Methods: CD40 was silenced with a specific siRNA in the $ApoE^{-/-}$ mouse model during 16 weeks. We administrated scrambled siRNA (SC) or PBS (vehicle) as controls. Endothelium was identified by immunohistochemistry using PECAM-1 antibody (platelet endothelial cell adhesion molecule-1). Kidneys were isolated from 24 weeks-old mice. The density of peritubular capillaries was quantified using ImageJ v1.48 and expressed as a proportion. The extension of atherosclerotic lesions was quantified in HE staining from ascending aortas.

Results: SiRNA-CD40 treated $ApoE^{-/-}$ mice reduced the extension of atherosclerotic lesions in $ApoE^{-/-}$ mice. Furthermore, a decrease of renal microcirculation density was observed in this experimental model of atherosclerosis (siRNA-CD40, n=9, 4.5±2.2%; SC, n=4, 2.1±0.8 %; Vehicle, n=9, 2.0±1.4%, p<0.0001). No differences in serum creatinine was detected (siRNA-CD40: 0.6±0.18 mg/dL; SC: 0.54±0.2 mg/dL; Vehicle: 0.51±0.3 mg/dL, p=ns).

Conclusions: A reduction in peritubular capillaries was associated with severe atherosclerosis lesions. This data provide structural basis of renal disease in patients with atherosclerosis.

FR-PO198

Activin Receptor Activation in the Skeleton, Vasculature, Heart, and Kidney During CKD Toshifumi Sugatani,[2] Matthew J. Williams,[1] Olga A. Agapova,[3] Hartmut H. Malluche,[5] Keith A. Hruska.[4] *[1]None, Saint Louis, MO; [2]WASHINGTON UNIVERSITY IN ST. LOUIS SCHOOL OF MEDIC, St.Louis, MO; [3]Washington University School of Medicine, St. Louis, MO; [4]Washington University St. Louis, St. Louis, MO; [5]University of Kentucky, Lexington, KY.*

Background: To study whether factors stimulating renal fibrosis produce systemic disease, we examined activin receptor type IIA (ActRIIA) activation in CKD by signal analysis and inhibition in Alport syndrome mice, using a ActRIIA ligand trap (RAP-011) from 75 to 200 days of life.

Methods: We measured ActRIIA signaling and inhibited its activity with RAP-011.

Results: By 200 days, Alport mice had severe CKD and the CKD-MBD, consisting of osteodystrophy, vascular calcification, cardiac hypertrophy, hyperphosphatemia, hyperparathyroidism, and elevated FGF23 and reduced klotho levels. ActRIIA inhibition by RAP-011 reversed CKD-stimulated bone resorption and osteoblast dysfunction by inhibition of osteoclast function, while osteoblast function and bone formation were increased. ActRIIA inhibition prevented formation of calcium apatite deposits in aortic adventitia and tunica media and decreased aortic Ca levels from 0.59 mg/g in Alport mice to 0.36 in RAP-011 treated mice (p<.05). Aortic ActRIIA stimulation increased p-Smad2 levels and the transcriptional targets, sm22α and αSMA, in Alport mice. ActRIIA inhibition reversed aortic expression of Runx2 and osterix, markers of osteoblastic transition. Heart weight was 26% increased in Alport mice, but remained normal during RAP-011 treatment (p<.01). In 150 do Alport mice, GFR was reduced by 55%, p<0.05, but GFR was only 30% reduced in the RAP-011 treated group. At 200 do, the BUN was 100mg/dl in Alport mice compared to 60 in the treated group. In kidneys of 200 day old Alport mice, ActRIIA and p-Smad2 were induced and MCP-1, fibronectin and interstitial fibrosis were stimulated, but inhibited by RAP-011 treatment.

Conclusions: The results demonstrate CKD activation of ActRIIA signaling contributing to CKD-MBD components, osteodystrophy and cardiovascular disease, and to renal fibrosis. Inhibition of ActRIIA signaling may be efficacious in Alport syndrome.

FR-PO199

Endothelial Glucocorticoid Receptor (GR) Modulates Wnt Signaling in a Mouse Model of Atherosclerosis Han Zhou, Julie Goodwin. *Yale University School of Medicine, New Haven, CT.*

Background: Apo E KO/endothelial GR double knock-out (DKO) mice develop more severe atherosclerotic lesions compared to Apo E KO mice alone. Genomic data from ChIP-seq and RNA-seq experiments in endothelial cells indicate that endothelial GR binding to genes in the Wnt signaling pathway is enriched. The Wnt signaling pathway is a potentially important, yet understudied, mediator of vascular inflammation.

Methods: Male Apo E KO mice and Apo E KO/endothelial GR double knock-out mice (DKO) were bred to mice carrying the BAT GAL reporter to enable visualization of the activation of the canonical Wnt signaling pathway. Mice were fed a high-fat diet for 4-5 weeks and then sacrified for blood and tissue processing. Whole aortas and cross sections of brachiocephalics arteries were stained with X-gal. Brachiocephalics were also subjected to double immunofluorescent staining with antibodies to BAT GAL and CD31. Luciferase assay was used to invesigate modulation of canonical Wnt signaling by GR in vitro using mouse lung endothelial cells subjected to GR siRNA knockdown and treatment with Wnt3a, a canonical Wnt ligand.

Results: BAT GAL+ Cre+ mice had significantly more aortic area stained after X-gal than did BAT GAL+ Cre- mice (32% vs. 6%, p=.0061, n=5/group). Staining of BAT GAL- Cre- mice was used as a control. X gal staining in brachiocephalic arteries was also signficantly increased in BAT GAL+ Cre+ mice compared to BAT GAL+ Cre- littermate controls. TCF/LEF luciferase assay demonstrated a 3-fold higher induction in Wnt3a-treated GR knockdown cells compared to similarly treated GR replete cells.

Conclusions: We conclude from these results that: 1. Loss of endothelial GR augments canonical Wnt signaling both in vivo and in vitro 2. Modulation of the Wnt pathway may represent a novel therapeutic strategy for treatment of vascular disease

Funding: Other NIH Support - NHLBI

Representative images of whole aortas stained with X gal after 4-5 weeks of high fat diet feeding.

Mineralocorticoid Antagonism and Vascular Oxidative Stress and Inflammation in Early Autosomal Dominant Polycystic Kidney Disease: A Randomized-Controlled Trial Kristen L. Nowak,[1] Wei Wang,[1] Berenice Y. Gitomer,[1] Anna J. Jovanovich,[1,2] Heather Farmer-Bailey,[1] Michel Chonchol.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Denver VA Medical Center, Denver, CO.*

Background: Oxidative stress and inflammation are present in early autosomal dominant polycystic kidney disease (ADPKD) and contribute to reduced nitric oxide bioavailability and arterial dysfunction. Aldosterone may further exacerbate oxidative stress and inflammation. We hypothesized that aldosterone antagonism would reduce vascular oxidative stress and inflammation in patients with early-stage ADPKD.

Methods: In a randomized, controlled, double-blind trial, n=60 adults 30-55 years of age with ADPKD, normal kidney function (estimated glomerular filtration rate [eGFR] ≥60 mL/min/1.73 m^2), and receiving the maximum tolerable dose of an angiotensin converting enzyme inhibitor were randomized to receive either spironolactone (titrated to maximum dose of 50 mg/day) or placebo for 6 months. As secondary endpoints in this trial, we measured protein expression of NADPH oxidase, interleukin-6 (IL-6), nuclear factor k B (NFκB), and phosphorylated endothelial nitric oxide synthase (PeNOS) in vascular endothelial cells (ECs) collected from a peripheral vein of study participants, and change in brachial artery flow-mediated dilation (FMD_{BA}) in response to an acute infusion of ascorbic acid as an index of vascular endothelial oxidative stress.

Results: Participants were 34±10 (mean±s.d.) years of age, 53% female and 80% White, with an eGFR of 94+21ml/min/1.73m^2. Acute infusion of ascorbic acid improved FMD_{BA} at baseline (8.4±5.9 vs. 9.5±5.7%, p<0.05). After 6 months, ascorbic acid continued to improve FMD_{BA} in both the spironolactone and placebo group, indicating no reduction in vascular endothelial oxidative stress. Similarly, there was no change in EC protein expression of the oxidant enzyme NADPH oxidase. IL-6 and PeNOS EC expression were also unchanged. However, EC expression of the pro-inflammatory transcription factor NFκB was reduced in the spironolactone group (0.51±0.13 vs. 0.43±0.08 [immunofluorescence intensity relative to HUVEC control]; p<0.05) with no change in the placebo group (0.48±0.10 vs. 0.48±0.09).

Conclusions: Six months of aldosterone antagonism with spironolactone does not reduce ADPKD-associated vascular oxidative stress, but may attenuate vascular inflammation.

FR-PO201

Arteriolar Hyalinosis in Klotho Deficiency Rik Mencke,[1] Jakob Voelkl,[2] Geert Harms,[1] Marian L. Bulthuis - van der horst,[1] Anja Umbach,[3] Harry Van Goor,[1] Florian C. Lang,[3] Jan-luuk Hillebrands.[1] *[1]University Medical Center Gronigen, Groningen, Netherlands; [2]Charité University Medicine, Berlin, Germany; [3]University of Tübingen, Tübingen, Germany.*

Background: Hyalinosis is a vascular lesion affecting the renal vasculature in ageing, hypertension, and after transplantation. It is thought to contribute to renal function decline. We wanted to assess whether arteriolar hyalinosis is caused by Klotho deficiency – a state known to induce both renal and vascular ageing-related pathologies.

Methods: The presence of hyalinosis was assessed in kidneys from 7-week-old Klotho$^{-/-}$, Klotho$^{+/-}$, and WT mice. We used (immuno)histochemistry to investigate the composition of the lesions and the different layers of the vascular wall. Finally, using *kl/kl* mice (with a promoter disruption rather than the exon deletion of Klotho$^{-/-}$ mice and with more severe vascular calcification) we assessed the effect of spironolactone treatment (80 mg/L of drinking water, between 3 and 8 weeks of age) on the vascular lesions in the kidney as spironolactone inhibits vascular calcification.

Results: We detected marked arteriolar hyalinosis in Klotho$^{-/-}$ mice, present up to the afferent arterioles. Hyalinosis was accompanied by local loss of α-smooth muscle actin expression, while the endothelial lining was mostly intact. Hyalinous lesions were positive for IgM and iC3b/c/d, indicating subendothelial leakage of plasma proteins. The increased presence of extracellular matrix proteins suggests increased production by smooth muscle cells and the gain of S100A4 expression indicates smooth muscle cell de-differentiation towards a synthetic phenotype. In *kl/kl* mice, spironolactone treatment inhibited the development of calcification and resulted in the development of hyalinosis.

Conclusions: Klotho deficiency induces the development of hyalinosis: spontaneously in Klotho$^{-/-}$ mice and after inhibition of calcification in *kl/kl* mice, also attesting to the phenotypic variability of Klotho deficiency. Klotho deficiency potentiates both endothelial hyperpermeability and smooth muscle cell de-differentiation to a synthetic phenotype, likely in response to subendothelial leakage of plasma proteins. Klotho may play a role in preventing ageing-related or calcineurin inhibitor-induced arteriolar hyalinosis.

FR-PO202

Nephrotic Syndrome Modulates Flow and Composition of Mesenteric Lymph Jianyong Zhong, Babak Banan, Vance L. Albaugh, Yohei Tsuchida, Patricia G. Yancey, Carrie B. Wiese, Kasey C. Vickers, Haichun Yang, Valentina Kon. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Although hyperlipidemia and altered lipid/lipoprotein metabolism that characterize nephrotic syndrome (NS) are usually ascribed to functional changes in the liver, little is understood about how NS impacts another relevant organ system, i.e., gut. Small intestine functions not only to reabsorb dietary lipids but also contributes to lipoprotein synthesis, particularly apolipoprotein AI, the main protein in high density lipoprotein (HDL) that provides beneficial effects to many different tissues. All reabsorbed lipids and synthesized lipoproteins are taken-up and transported through the lymphatics. Since integral to NS is development of edema that reflects lymphatic inadequacy, we examined the lymphatic network in a model of NS.

Methods: NS was induced by puromycin aminonucleoside (PAN) in 12 Sprague Dawley rats, while 12 non-injected rats served as control (C). Eight days later, plasma, urine, mesenteric lymph, kidney and ileum were collected for further analysis.

Results: Along with massive proteinuria, PAN significantly increased plasma cholesterol and triglyceride that was accompanied by increased renal lymphatic vessel density (assessed by staining for podoplanin). Proteinuric injury caused a 6-fold increase in mesenteric lymph flow (PAN:10.7±1.3ml vs C:1.5±0.3 x 3h, p<0.001). Despite apparent dilution, the mass of cholesterol and triglycerides transported by mesenteric lymph over time was 3- and 5-fold higher in PAN than C (both p<0.05). PAN dramatically increased lymphatic transport of apoAI (PAN:108.3±13.0μg vs C:13.7±2.6 x 3 hours p<0.001). While plasma cytokines (IL-6, IL-10, IL-1, IL-17a) were not different, PAN significantly increased lymphatic concentration of IL-6 (>200%, p<0.05), IL-10 (>150%, p<0.05) and IL-17a (>200%, p<0.05). In addition, PAN raised the number of Th17 cells (>50%, p<0.05) and increased the level of VEGFA (>100%, p<0.05) compared to C.

Conclusions: Proteinuric kidney injury expands the renal lymphatic network and enhances mesenteric lymph flow which carries more fluid, lipids, lipoproteins, inflammatory cytokines and growth factors. These data suggest a potentially critical role for the intestinal lymphatic network in edema, inflammation and cardiovascular complications of NS and present a new target to lessen these complications.

FR-PO203

Chronic Kidney Dysfunction Impairs Experimental Arteriovenous Fistula Healing Makoto Orii,[1] Jie Cui,[2] Harkamal S. Jhajj,[2] Jason McCarthy,[2] Farouc A. Jaffer.[2] *[1]Massachusetts Genaral Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Thrombosis and neointimal hyperplasia are major causes of arteriovenous fistula (AVF) failure in chronic kidney disease (CKD) patients. Here, we utilize in vivo molecular imaging characterize fibrin deposition after AVF creation in CKD mice.

Methods: CKD was induced in C57BL/6 mice using daily adenine gavage(50mg/kg). Serial blood sampling was performed to measure the creatinine (Cr) and BUN. Fourteen days after adenine (n=3) or PBS gavage (n=6), AVF were created using an end-to-side internal jugular vein and carotid artery anastomosis. AVF blood flow was measured 15 minutes post-surgery (Transonic). Molecular imaging of fibrin deposition on AVF was enabled using fluorophore-labeled peptide (FTP11-Cym7). On day 7 after AVF creation, a 150 nmol/kg IV bolus of FTP11-Cym7 was administered. Forty-five minutes after FTP11 injection, fibrin deposition was imaged in vivo using epifluorescence microscopy. Mice were then sacrificed at day 14. AVF vein wall thickness area (WTA), vein outflow area (OA), and patent area (PA) were measured using picrosirius red staining. The fibrin target-to-background ratio (TBR) was calculated as mean signal intensity (MSI) of the fistula divided by the MSI of the control vein. Regions-of-interest were defined as areas between the anastomosis and 960μm away from the anastomosis.

Results: The BUN/Cr values on day 14 and 28 after adenine administration were 93±24/1.3±0.4 mg/dl and 94±6/0.6±0.1 mg/dl, respectively (p<0.001 vs. PBS). AVF blood flow immediately after AVF surgery were similar between CKD and PBS groups (1.44±0.25ml/min vs 1.22±0.19 ml/min, p=0.5). The in vivo day 7 fibrin deposition after AVF creation (FTP11-Cym7 TBR) was significantly higher in CKD mice (p<0.0001 vs. PBS mice). The vein WTA, OA, and PA was also significantly lower in CKD group (p<0.0001 vs. PBS).

Conclusions: Compared to non-CKD subjects, CKD impairs AVF healing, as indicated by greater fibrin deposition and reduced outward remodeling.

An Impairment of the Coagulation-Fibrinolysis System Implicates Vascular Access Patency in Patients on Hemodialysis after Vascular Access Intervention Yukiko Hasuike, Naoto Kakita, Aritoshi Kida, Masayoshi Nanami, Takeshi Nakanishi. *Internal Medicine, Division of Kidney and Dialysis, Nishinomiya, Japan.*

Background: Vascular access (VA) is essential for the HD patients. However, VA is often occluded even after the VA intervention therapy (VAIVT). There is increasing evidence indicating the importance of the coagulation-fibrinolysis system in the progression of vascular disease. We intended to clarify whether the imbalance of coagulation-fibrinolysis might be associated with VA failure after VAIVT.

Methods: Blood samples were taken from 462 HD patients at the VAIVT. Among them, 352 patients (76.2%) had native arteriovenous fistula (AVF). Thrombin/anti-thrombin (TAT) as a marker of coagulation, plasmin-α_2-plasmin inhibitor complex (PIC) as markers of fibrinolysis, and factors related to inflammation (CRP, interleukin-6, tumor necrosis factor-α, pentraxin-3), mineral-bone metabolism (calcium, phosphate, parathyroid hormone), and uremia were measured. Blood flow volume (FV) of VA was evaluated by Doppler ultrasonography before VAIVT. The end point was the re-vascularization or re-operation of VA during the observational period after VAIVT (mean follow-up periods 278.7±182.8 days). The results were analyzed using receiver operating characteristic curve, Kaplan-Meier methods, and Cox regression analyses.

Results: Age of patients was 69.9±10.6 years, and 225 female patients (48.7%). During follow-up period, re-VAIVT was performed in 82 patients and re-operation in 80

patients. The Kaplan-Meier analysis showed that the patients with lower FV (<344 ml/min), graft AVF, and higher TAT/PIC ratio (≥4.17) were associated with poor patency rates [figure A, B, C]. Cox regression analysis revealed that higher TAT/PIC ratio (adjusted HR 1.67, 95%CI 1.14 to 2.43, p=0.008) was linked to VA failure event.

Conclusions: The impaired coagulation-fibrinolysis system as well as lower FV and graft VA can affect VA failure after VAIVT.

Transcriptomic Profiling of Tight Junction Dysfunction in CKD Jen Xu,[1,2] Kenneth Lim,[3] Li-lun Ho,[1] Thomas F. Hiemstra,[4] Tzongshi Lu.[1] *[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Harvard College, Cambridge, MA; [3]Massachusetts General Hospital, Boston, MA; [4]University of Cambridge, Cambridge, United Kingdom.*

Background: Tight junctions (TJ) are specialized membrane domains that play multiple functions in endothelium and epithelium to maintain cellular homeostasis. TJ dysfunction is an important pathogenic process in the development of uremic-related cardiovascular disease (CVD), cerebral small-vessel diseases (CSVD) and cystogenesis in polycystic kidney disease. The goal of the present study was to elucidate the transcriptomic profile of TJ dysfunction in CKD.

Methods: We performed transcriptome analysis by RNA sequencing in: 1) primary human aortic endothelial cells (HAECs) and human brain microvascular endothelial cells (HBMECs) that were treated in calcification medium (CM: 5mM β-glycerolphosphate+5mM $CaCl_2$) in time-course experiments (0-48 hours), *in vitro*; 2) human kidney proximal tubule epithelial cells (HK-2) treated with H_2O_2, *in vitro* and 3) human arteries, *ex vivo* from healthy and CKD patients; Gene selections were performed by the combinations of fold-changes on log 2 ratio, and p value < 0.05.

Results: In primary cells treated with CM: we found that heat-shock protein 70 (HSP70) co-chaperone, BAG1 (Bcl2 Associated Athanogene 1) was significantly increased at 6 hours prior to upregulation of antiapoptotic gene, Bcl2 at 12 hours in HAECs but not in HBMECs. DNAJB6 (HSP40) and HSPA5 (HSP70 member5) was significantly increased at 24 and 12 hours respectively in HAECs. The major transmembrane TJ protein-Occludin was upregulated at 6 hours and peaked at 24 hours (HAECs) and 48 hours (HBMECs) under CM treatment respectively, but cytoplasma TJ-ZO1 displayed similar patterns in HAECs only. Inflammation sensitive TJ, Claudin-5 increased at 1 hour followed by upregulation of downstream ZO-1 at 6 hours. In addition, ZO1, occludin and Claudin-5 were downregulated after H_2O_2 treated but preserved by HSP70 induction in HK2 cells. In human CKD arteries, we found that claudin-5 was down-regulated (Fold changes, FC, 2.16) while ZO-1 was upregulated (FC=2.17). Bcl2 (FC=4.52) and HSPA5 (FC=3.85) was preserved in healthy arteries alone with activated BAG1 (FC=7.44).

Conclusions: Complex differential gene regulation involving apoptosis, TJ dysfunction and upregulation of the HSP stress response occur in endothelial and epithelial cells in renal failure. Our findings may serve to inform the rational development of therapeutic strategies for arterial and epithelial cells dysfunction in CKD.

Effect of Spironolactone on a Transgenic Rat Model of Hypertension and Myocardial Infarction Catherine Leader, Ivan A. Sammut, Gerard T. Wilkins, Robert J. Walker. *University of Otago, Dunedin, New Zealand.*

Background: Hypertension contributes to heart disease and renal injury. However the impact of MI plus hypertension on renal injury is not clearly described. Spironolactone (SP) can reduce cardiac fibrosis and improve cardiac re-modelling post MI; its effects on the kidney are unknown. We examined the effects of SP on renal fibrosis in hypertensive rats post MI.

Methods: Ffive groups of adult male Cyp1a1Ren2 rats: normotensive (N), hypertensive (H), hypertensive fed SP daily (50 mg day^{-1}) (H-SP), hypertensive with MI (left anterior coronary ligation) (H-MI) and hypertensive with MI plus daily SP (H-MI-SP). Hypertension (>160 mmHg systolic) was induced by 0.167 % (w/w) indole-3-carbinol added to the rat chow. Systolic blood pressure (SBP) and echocardiograms were recorded at termination, 28 days after MI. Cardiac and renal tissue was harvested for analysis.

Results: SBP was only reduced in the H-MI group (p=0.05) compared with all the other H groups (155±24 and 173±11mmHg respectively). SBP was not significantly reduced by SP in either of the treated groups. Ejection fraction (EF) was significantly reduced in all animals with MI (42±10%), addition of SP had no effect (43±10%). The Glomerulosclerosis Index (GSI) in normals was 0.2±0.1 and was significantly higher in all hypertensive groups (p>0.001). The H-SP group (0.9±0.04) showed a significant decrease in GSI from H controls (1.2±0.07) (p=0.002). The GSI in H-MI-SP (1±0.1) was significantly decreased from the H-MI group (1.3±0.1) (p=0.04). The degree of cortical interstitial fibrosis in all hypertensive groups was not modified by SP. Figure 1: PAS cortex pictures of representatives from each experimental groups. Scale bar is 200μm.

Conclusions: Conclusion: Severe hypertension caused extensive renal glomerulosclerosis and interstitial fibrosis. SP showed no effect on SBP or EF, but significantly improved GSI scores in hypertensive animals and post MI. SP did not reduce renal interstitial fibrosisl. Further work will aim to define the relation between cardiac injury and renal damage.

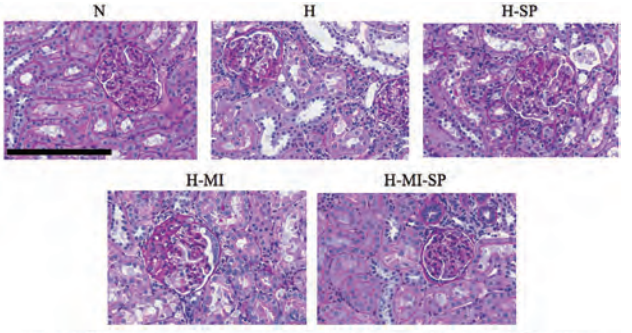

Figure 1: PAS cortex pictures of representatives from each experimental groups. Scale bar is 200μm.

Patients with CKD Have Heightened Vascular α1-Adrenergic Receptor Sensitivity Doree G. Morison,[1,2] Ryan M. Downey,[1,2] Dana Dacosta,[1,2] Jeanie Park.[1,2] *[1]Renal Division, Department of Medicine, Emory University School of Medicine, Atlanta, GA; [2]Research Service Line, Atlanta VA Medical Center, Decatur, GA.*

Background: Patients with chronic kidney disease (CKD) have sympathetic overactivity and difficult-to-control hypertension. Our previous studies showed that CKD patients have augmented increases in blood pressure in response to the same degree of sympathetic nerve activation, suggesting heightened neurovascular transduction. We hypothesized that augmented vascular α_1-adrenergic receptor (α_1-AR) sensitivity contributes to the exaggerated vasoconstriction and blood pressure responses to sympathetic activation in CKD.

Methods: In 13 CKD (Stage IIIB and IV) patients and 5 Controls, we measured the degree of vasoconstriction of a dorsal hand vein in response to serial infusions of 10 doses (ranging 15-12,000 ng/min) of the selective α_1-AR agonist phenylephrine (PE) using a linear variable differential transformer with a movable central core to detect changes in vascular diameter. Vascular diameters were expressed as a % reduction from baseline maximum dilation, and plotted against PE dose rates in individual semilogarithmic dose-response graphs, and analyzed using a 4-variable sigmoid dose-response model. The natural log (ln) PE dose that produced a 50% maximal constriction (ED_{50}) reflects sensitivity to PE (i.e. α_1-AR sensitivity).

Results: CKD patients had a significantly lower PE ED_{50} compared to Controls (ln PE dose 5.1±0.5 vs 8.3±0.9 ng/min, p=0.0045), demonstrating that CKD patients have heightened vasoconstriction in response to PE.

Conclusions: Augmented vascular α_1-AR sensitivity could contribute to increased neurovascular transduction and hypertension in CKD patients.

Funding: Other NIH Support - NHLBI, Veterans Affairs Support

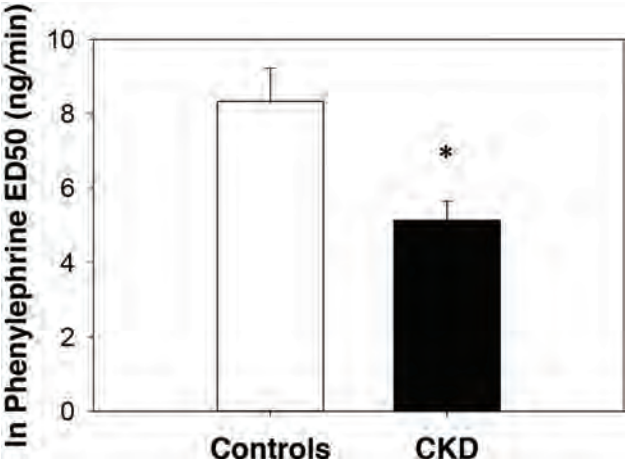

Figure. Vascular α_1-adrenergic receptor sensitivity is heightened in chronic kidney disease.

FR-PO208

Induction of Unique Scavenger Receptor Dysregulation Pattern in Advanced CKD Nobuyuki (Bill) Miyawaki, Nicolle M. Siegart, Farah Daccueil, Joshua De leon, Joseph Mattana, Lora Kasselman, Allison B. Reiss. *Medicine, NYU Winthrop Hospital, Mineola, NY.*

Background: In chronic kidney disease (CKD), scavenger receptors (SR) are the main cholesterol entry paths into macrophages, bypassing the regulated LDL receptors, to accelerate foam cell production in synergy with defective cholesterol efflux. Yet alteration patterns of SR in CKD remain poorly defined.

Methods: Following THP-1 human macrophage (10^6/ml) incubation for 24h with 10% plasma from 10 CKD Stage 4+5 patients (without diabetes, rheumatological illnesses or active infections) or plasma from 10 healthy control subjects, mRNA was isolated and reverse transcribed. The resulting cDNA was subjected to quantitative real-time PCR using specific primers for major cholesterol scavenger receptors CD36, LOX-1, SR-A1 as well as efflux proteins, ATP binding cassette transporter (ABC)A1 and G1.

Results: Exposure to CKD plasma decreased the expression of scavenger receptor CD36 with a 32% reduction (Fold change with CKD plasma exposure: 0.68, 95% CI [0.54, 0.87], p<0.01). SR-A1 expression with CKD plasma exposure was unaffected with a fold change of 0.80, 95% CI [0.52, 1.24], p<0.01). LOX-1 expression was not reduced; rather a very strong trend to LOX-1 enhancement with 1.54-fold increase with CKD plasma exposure (95% CI [1.01, 2.35], p=0.053). Downregulation of ABCA1 and ABCG1 were demonstrated, respectively, by 33% (0.67, 95% CI [0.04, 0.92], p=0.01) and by 30% (0.70, 95% CI [0.50, 0.98], p=0.03).

Conclusions: Prior studies of CKD populations have evaluated isolated SR and often without exclusion of other known inflammatory conditions which impact SR dysregulation patterns. Our demonstration of decreased CD36, unaffected SR-A1 and a very strong suggestion of increased LOX-1 in CKD differs from those previously described in rheumatoid arthritis or lupus and may provide future avenues for viable therapeutic targets. Additional studies on LOX-1 as well as impact of its inhibition may be helpful in further elucidation of SR mediated uptake mechanisms in CKD. Reduced ABC gene expression likely lowers defense against lipid overload and may be a target for therapeutic intervention.

CPAP Therapy Improves Central Arterial Stiffness and Decreases Arterial Renin Angiotensin System Activity in Humans with Obstructive Sleep Apnea David D. Nicholl,[2] Patrick Hanly,[2] Ann A. Zalucky,[2] Michelle C. Mann,[2] Jennifer M. MacRae,[2] Marc Poulin,[2] George Handley,[1] Darlene Y. Sola,[2] Sofia B. Ahmed.[2] *[1]Healthy Heart Sleep Company, Calgary, AB, Canada; [2]University of Calgary, Calgary, AB, Canada.*

Background: Chronic kidney disease (CKD) is associated with increased arterial stiffness, a marker of cardiovascular risk. Treatment of obstructive sleep apnea (OSA), common in CKD, reduces arterial stiffness, though the mechanism is not clear. Limited studies suggest a prominent role for the renin angiotensin system (RAS), activation of which is deleterious to kidney and cardiovascular function. We sought to determine the effect of CPAP therapy on arterial stiffness at baseline and in response to the physiological stressor, Angiotensin II (AngII), in humans with OSA.

Methods: Newly diagnosed OSA subjects (respiratory disturbance index [RDI]>15hr^{-1}) with nocturnal hypoxia (oxyhemoglobin saturation [SaO_2] <90% for >12% of night) who were otherwise healthy were studied in high-salt balance, at state of maximal RAS suppression, pre-CPAP and then after 4 weeks of effective CPAP therapy (>4h/night) in a second identical study day. Central (aortic augmentation index [AIx]) and peripheral (carotid-femoral pulse-wave velocity [PWV_{cf}]) arterial stiffness were measured by applanation tonometry. Arterial stiffness was measured at baseline and in response to a graded AngII infusion (3ng/kg/min x 30min, 6ng/kg/min x 30min, Recovery x 30min). The primary outcome was the effect of CPAP on the arterial stiffness responses to AngII.

Results: Twenty-six subjects (18 men, 8 women; 49±2y) completed the study. CPAP corrected OSA (RDI: 44.2±4.1 vs 3.5±0.5hr^{-1}, p<0.001; duration SaO_2<90%: 45.4±5.6 vs 6.7±2.1%, p<0.001; all values pre- vs post-CPAP). Treatment with CPAP was associated with increased sensitivity in central arterial stiffness (ΔAIx: AngII, 8.7±1.4 vs 11.6±1.6%, p=0.038; Recovery, 1.7±1.4 vs 1.0±2.0%, p=0.8), while no change in peripheral arterial stiffness (ΔPWV_{cf}: AngII, 1.0±0.3 vs 0.9±0.2 m/s, p=0.8; Recovery, 1.0±0.3 vs 0.2±0.4 m/s, p=0.13) was observed.

Conclusions: CPAP therapy was associated with increased central, but not peripheral, arterial stiffness sensitivity to AngII, consistent with downregulation of the vascular RAS. These findings may have important implications in mitigating cardiovascular risk in CKD patients with OSA.

FR-PO210

Mineralocorticoid Receptor Antagonists Augment Arginine Transport and Nitric Oxide Generation through Modulation of Cationic Amino Acid Transporter-1 in Human Umbilical Vein Endothelial Cell Doron Schwartz,[1] Moshe Shashar,[1] Idit F. Schwartz.[2] *[1]Sourasky Medican Center, Tel Aviv, Israel; [2]Tel Aviv Medical Sourasky Center, Tel Aviv, Israel.*

Background: Blockade of the mineralocorticoid receptor (MCR) has been shown to improve endothelial function far beyond blood pressure control. In the current studies we looked at the effect of MCR antagonists on the activity of cationic amino acid transporter-1 (CAT-1), a major modulator of endothelial nitric oxide (NO) generation.

Methods: Using radio-labeled arginine, {[3H] L-arginine} uptake was determined in Human umbilical vein endothelial cells (HUVEC) following incubation with either spironolactone or epleronone with or without silencing of the MCR. Western blotting for CAT-1, PKCα and their phosphorylated forms were performed. NO generation was measured by the Griess reaction.

Results: Both Spironolactone and epleronone significantly increased endothelial arginine transport, an effect which was augmented by co-incubation with aldosterone and blunted by either silencing of the MCR or Co-administration of amyloride. Following MCR blockade but not amyloride, we identified two bands for CAT-1. The addition of tunicamycin (a de-glycosylation agent) or silencing of the MCR resulted in disappearance of the extra band and prevented the increase in arginine transport. Spironolactone but not epleronone decreased CAT-1 phosphorylation through inhibition of PKCα (CAT-1 inhibitor). Subsequently, the concentration of NO2/NO3 (stable NO metabolites) following incubation with both MCR antagonists significantly increased. This was attenuated by silencing of MCR or tunicamycin. GO 6076 (PKCα inhibitor) augmented the increase of NO metabolites only in the epleronone treated cells.

Conclusions: Spironolactone and epleronone augment arginine transport and NO generation through modulation of CAT-1 in endothelial cells. Both MCR antagonists activate CAT-1 by facilitating its glycosylation while only spironolactone inhibits PKCα.

FR-PO211

Diabetes Mellitus Modulates Interaction of Inflammation with Asymmetric Dimethyl Arginine in Hemodialysis Marcelo C. Batista,[2,5] Mauro sergio M. Marrocos,[2,6] Beata M. Quinto,[2] Andrei A. Teixeira,[3] Maria Eugenia F. Canziani,[1] Silvia R. Manfredi,[4] Cassio J. Rodrigues.[1] *[1]Federal University of Sao Paulo, Sao Paulo, Brazil; [2]UNIFESP, São Paulo, Brazil; [3]UNIFESP / EPM, Pouso Alegre, Brazil; [4]Universidade Federal de São Paulo, Sao Paulo, Brazil; [5]Nephrology, Einstein Jewish Hospital, Nephrology, São Paulo, Brazil; [6]Nephrology, State Public Server Hospital of São Paulo, São Paulo, Brazil.*

Background: inflammation and Dimethyl Arginine Asymmetric (ADMA) are related to mortality in hemodialysis (HD). Study aims to analyze interaction between ADMA and CRP among DM- and + patients in HD.

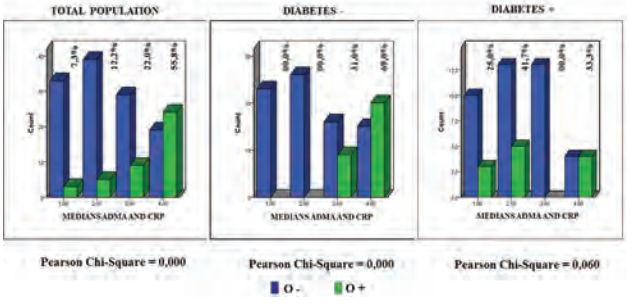
Methods: Pre-HD ADMA measured by HPLC in 202 adults prevalent in HD. CRP measured by ultra-sensitive immunoturbidimetry. Association with mortality in 4 years through SPSS 23.0.

Results: Forty individuals censored by transplantation. DM+ were older (57.1 ± 13.3 x 50.2 ± 15.1 years, P = .002), with higher BMI (25.9 ± 2.9 x 24.9 ± 2.4, P =, 017), and higher prevalence of coronary disease (36.9% x 15.0%, P = .001). ADMA and CRP were similar between DM+ and DM-. ADMA and CRP were similar between DM + and DM-. Only ADMA - median IQR μM - (0.88 0.60 - 1.37 and 1.71 1.34 - 2.17 P =, 000) and median CRP IQR mg / dL - (0.38-0.15 - 1.18 and 0.77 0.23 - 2.25 P = .034) differed between individuals with no evolution to death (O-) or with (O +). Only ADMA - median IQR μM - (1.03 0.81 - 1.55 and 1.95 1.75 - 2.54 P =, 000) differed between DM-, O- or O+. In binary logistic regression, ADMA remained as a variable related to mortality in DM- (OR 2,379 CI 1.36 - 3.68 P =, 000). DM + showed no differences between O- or O+. In 4 groups according to ADMA and CRP medians: I = lower ADMA and CRP, II = higher CRP and lower ADMA, III = lower CRP and higher ADMA and IV = higher ADMA and CRP - respective mortalities of 0.0%, 0, 0%, 31.0%, 69.0% among DM- (P =, 000). No differences in mortality between DM + (GRAPHIC).

Conclusions: ADMA has a significant relationship with mortality in prevalent DM- in HD and can improve evaluation of mortality risk in these patients. Other risk factors may overlap ADMA in DM +. Synergistic effect of ADMA and CRP; Mortality in group IV in DM- in HD higher than simple addition of mortality in group III with II or I. Previous work reported no differences between DM + and DM-, but DM + totaled 15% of the cohort (CJASN 6 1714 -21.2011).

Funding: Government Support - Non-U.S.

RELATION BETWEEN GROUPS MEDIANS ADMA AND CRP IN RELATION TO EVOLUTION



FR-PO212

Characterization of a Novel β-Common Receptor Inhibitory Peptide Cody Kilar,[3] Yanpeng Diao,[2] Shahar Keinan,[1] Yong Shen,[2] Jorg Bungert,[2] Rajesh Mohandas,[3,4] Mark S. Segal.[3,4] *[1]Cloud Pharmaceuticals, RTP, NC; [2]University of Florida, Gainesville, FL; [3]University of Florida, GAINESVILLE, FL; [4]North Florida/South Georgia Veterans Health System, Gainesville, FL.*

Background: In short term animal models of ischemia, erythropoietin (EPO) signaling through the heterodimeric EPO receptor/β-common receptor (βCR) is believed to elicit tissue protective effects. However, large randomized controlled trials demonstrate that administering high doses of EPO, which can activate the βCR, is associated with an increase in adverse cardiovascular events. Thus, inhibition of the βCR may have therapeutic implications. This study aimed to design and evaluate the efficacy of a novel computationally designed βCR inhibitory peptide (βIP).

Methods: The novel βIP was designed from the crystal structure of EPO consisting of 16-amino acids (VLERYLLEAKEAEKIT) from residues 11 to 26. Ultimately, the 16-amino acid peptide model comprising of *VLERYL**H**EAK**H**AEKIT,* was selected as a novel βIP. The efficacy of βIP to inhibit βCR-induced nitric oxide (NO) production and angiogenesis in human umbilical vein endothelial cells (HUVECs) was evaluated.

Results: We found that βIP completely abolished EPO-induced NO production, however could be overcome with super physiological doses of EPO. βCR-induced angiogenesis in HUVEC's was also abolished with treatment of βIP, but βIP did not inhibit vascular endothelial growth factor (VEGF)-induced angiogenesis. In addition, we show that the novel βIP does not increase erythropoiesis or inhibit EPO-induced erythropoiesis with use of peripheral blood mononuclear cells (PBMCs).

Conclusions: These results introduce, for the first time, a novel, potent βCR inhibitor that inhibit the actions of the βCR without affecting erythropoiesis. Experiments addressing the therapeutic use of this peptide will be discussed.

FR-PO213

Pathophysiological Analysis of Renal Congestion Using a Novel Rat Model Satoshi Shimada,[1] Takefumi Mori,[2] Yusuke Ohsaki,[1] Chika Takahashi,[1] Sadayoshi Ito.[1] *[1]Graduate School of Medicine, Tohoku University, Sendai, Japan; [2]TOHOKU MEDICAL AND PHARMACEUTICAL UNIVERSITY HOSPITAL, Sendai, Japan.*

Background: A physiological association between kidney and heart has been well known, however the mechanisms involved is remain unknown. Renal congestion (RC) has been shown to play a role in heart failure (HF), precise mechanism involved in the pathogenesis of cardio-renal injury and Na retention has not been well investigated. The present study designed to investigate the role of renal congestion on glomerular filtration rate (GFR), renal histology, volume and blood pressure (BP).

Methods: RC was made by occluding left renal vein in Sprague Dawley rats. First, RC was made in left kidney while right kidney remained intact in anesthetized rats. GFR, renal interstitial hydrostatic pressure (RIHP) and urinary Na excretion was monitored in each kidney. Next, renal histology was compared between RC left kidney and intact right kidney after 9 days of RC. Finally, BP was monitored in rats with left RC with the other kidney removed. Rats were fed either normal salt or high salt for 2 weeks in either RC rats or sham operated rats.

Results: GFR and renal medullary blood flow significantly decreased in RC kidney while those of contralateral intact kidney remained unchanged. RIHP was increased during RC. Tubulo-glomerular injury was observed in the RC left kidney compared to the contralateral intact right kidney. These renal injuries were improved by reducing RIHP with removing renal capsule. In one-kidney RC model, plasma renin activity (renal congestion group 5.6±0.7 ng/ml/h, n=13 vs sham group 10.1±0.8 ng/ml/h, n=9, p=0.011) and hematocrit (operation group 43.5±1.4 ng/ml/h, n=13 vs sham group 47.8±0.9 ng/ml/h, n=9, p=0.001) is significantly lower in RC group compared to those of sham group, which suggests the increase in volume of body fluid. High salt induced increase in systolic BP the one-kidney renal congestion rats (normal salt period 95.8±5.9mmHg vs high salt period 116.1±6.1 mmHg, n=7, p=0.013), while no significant changes in BP was observed in sham operated rats.

Conclusions: RC increases body fluid volume by Na retention and reduced GFR and renal circulation by increase in RIHP, thereby induce salt induced increase in BP and renal injury. These results indicate that renal congestion play a pathophysiological role in the pathogenesis of HF.

FR-PO214

Diffusion-Weighted Magnetic Resonance Imaging (DWI) Correlates with the Response to Renal Revascularization in Patients with Atherosclerotic Renovascular Disease (ARVD) Ahmad F. Hedayat, Alfonso Eirin, Christopher M. Ferguson, James Glockner, Stephen C. Textor, Lilach O. Lerman. *Mayo Clinic, Rochester, MN.*

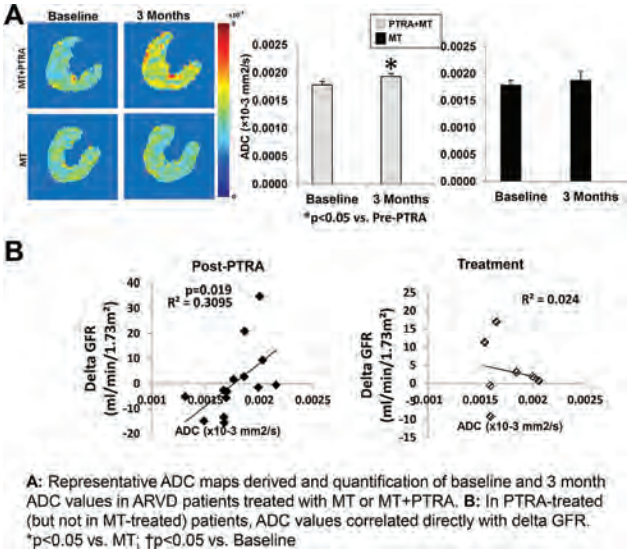
Background: Selecting patients with ARVD likely to improve glomerular filtration rate (GFR) after percutaneous transluminal renal angioplasty (PTRA) is challenging. DWI is an experimental tool to assess tissue morphology based on water molecule motion, and its index apparent diffusion coefficient (ADC) falls in damaged kidneys. We hypothesized that low basal ADC values would identify stenotic kidneys with subsequent diminished functional recovery after PTRA.

Methods: ADC was measured on 3T MRI in 20 patients with hemodynamically significant ARVD before and 3 months after standardized medical therapy (renin-angiotensin system inhibition) with or without PTRA. During protocol studies patients consumed a constant sodium intake, and eGFR was measured by CKD-EPI. Baseline ADC values were correlated with the change in eGFR after PTRA (delta eGFR).

Results: Baseline eGFR and ADC values were similar between groups (p>0.05). ADC values increased In patients 3 months after PTRA, and correlated directly with delta GFR, but remained unchanged in patients treated with medical therapy (MT) alone.

Conclusions: Low basal ADC value may serve as biomarker of kidney injury and predict benefit from revascularization in ARVD. This noninvasive imaging technique may be useful for identification of patients likely to improve renal function after revascularization.

Funding: NIDDK Support



A: Representative ADC maps derived and quantification of baseline and 3 month ADC values in ARVD patients treated with MT or MT+PTRA. **B:** In PTRA-treated (but not in MT-treated) patients, ADC values correlated directly with delta GFR. *p<0.05 vs. MT; †p<0.05 vs. Baseline

Gene Expression Analysis of Active and Chronic Renal Lesions in IgA Nephropathy Diagnosed Using the MEST-C Classification: A Multicenter Study Sharon N. Cox,[2,1] Claudia Curci,[2,1] Grazia Serino,[3,2] M. Rossini,[4] Mario Bonomini,[5] Vittorio Sirolli,[7] Paolo Felaco,[6] Gianluigi Zaza,[8] Isabella Squarzoni,[9] Concetta Gangemi,[10] Francesco P. Schena.[2,1] *[1]Schena Foundation, Valenzano, Bari, Italy; [2]University of Bari, Bari, Italy; [3]IRCCS "S de Bellis", Castellana Grotte, Bari, Italy; [4]University of Bari, Department of Emergency and Organ Transplantation, Nephrology Unit, Bari, Italy; [5]University of Chieti, Chieti, Italy; [6]Clinical of Nephrology, University G.d'Annunzio Chieti, Francavilla al Mare, Italy; [7]clinical nephrology university of chieti, Chieti, Italy; [8]University of Verona, Verona, Italy; [9]Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy; [10]AOUI verona, Verona, Italy.*

Background: The diagnosis of idiopathic IgA Nephopathy (IgAN) is based on the "split system" where 4 types of renal lesions are scored: Mesangial hypercellularity (M 0-1), Endocapillary hypercellularity (E 0-1), Segmental glomerulosclerosis (S 0-1) and Tubular atrophy/interstitial fi brosis (T 0-2). Recently an extension of the MEST score has been suggested introducing crescents (C 0-2) in the split system because this lesion, together with E, are predictive of outcome (Trimarchi H et al KI, 2017). Aim of our study was to identify specific gene expression changes that characterize active renal lesions (E and C) that may be more responsive to immunosuppressive therapy and chronic lesions (S and T).

Methods: Total RNA was extracted from archival FFPE renal tissue samples of 52 IgAN patients, 24 non-IgAN patients (Minimal change 12, membranous nephropathy 12) and 7 kidney living donors (controls). Genome-wide gene expression profiles were generated and Oneway ANOVA with tukeyHSD post hoc testing was used to identify specific transcripts associated with active and chronic lesions in IgAN. Real Time PCR was used for validation of the identified transcripts.

Results: We identified 391 genes exclusively modulated in IgAN biopsies with active lesions, 35 were down regulated and 355 were up-regulated. Some genes were specifically involved in glomerular injury. These genes belonged to renal cellular damage and immune system regulatory pathways. Moreover, we identified 194 genes that were differentially modulated in IgAN characterized by chronic lesions, 78 were down regulated and 116 were up-regulated. Candidate transcripts were validated by qRT-PCR in an extended cohort of IgAN biopsies.

Conclusions: Transcriptomics on FFPE renal biopsies integrates histomorphologic renal lesions. Our study identifies specific gene expression changes involved in active and chronic lesions at the time of renal biopsy. We are using system pharmacology on these genes to identify targeted molecules able to revert aberrant expression networks characterizing active and chronic lesions.

Inhibiting Na/K-ATPase Oxidant Amplification Loop Regulates Aging in C57B16 Old Mice Rebecca L. Klug,[4] Alexandra Nichols,[1] Brian J. Snoad,[3] Hari Vishal Lakhani,[3] Joseph I. Shapiro,[2] Komal Sodhi.[4] *[1]MUSOM, Huntington, WV; [2]Marshall University School of Medicine, Huntington, WV; [3]Marshall University, Huntington, WV; [4]Marshall University, Joan C. Edwards School of Medicine, Huntington, WV.*

Background: Aging, the inevitable and progressive decline of physiological integrity, manifests as: loss of cell division, oxidative stress, DNA damage, and senescence gene overexpression. Oxidant stress plays a role in the aging process, presumably in cellular and DNA damage. This contributes to impaired physiological function, disease development, and life span reduction. As we identified, the Na/K-ATPase amplifies oxidant signaling; we speculate a peptide inhibiting this pathway, pNaKtide, may be effective to regulate cellular senescence, thus delaying and/or reversing aging by attenuating oxidative stress.

Methods: C57Bl6 mice, young (6-8 weeks old, male) and old (17 weeks old, male) were fed normal chow diet or Western Diet (WD). They were randomly divided into 6 groups: (1) Young Control, (2) Young+pNaKtide (3) Old+Control, (4) Old+pNaKtide (5) Old+WD, (6) Old+WD+pNaKtide. After 8 weeks of control or WD diet respectively, groups 2, 4 and 6 were injected with pNaKtide for 8 weeks, (intraperitoneal dose of 25-mg/kg-body weight every 7 days).

Results: Histological analysis of liver shows increased steatosis and fibrosis with age and more so with WD, this decreased with pNaKtide treatment. Histological analysis of kidney shows increased fat infiltration and sclerosis with age and WD, which decreased with pNaKtide treatment. TUNEL assay of liver and kidney indicated more DNA damage with age and WD, this significantly decreased with pNaKtide treatment ($p \leq 0.05$). Indicative of oxidative stress, carbonylation of the Na/K-ATPase α1-subunit, activation of p-Src and TBARS were significantly elevated in old and WD liver and kidney compared to those given pNaKtide treatment ($p \leq 0.05$). RT-PCR of senescence genes: p21, Apo lipoprotein J, Collagenase 1, fibronectin, and MMP-9 were significantly increased in hepatic and renal tissue with age and WD compared to those given pNaKtide treatment ($p \leq 0.05$).

Conclusions: Our study demonstrates that Na/K-ATPase regulates aging and pNaKtide significantly alleviates genetic and phenotypic attributes of aging. pNaKtide holds potential as a novel drug for treating cellular damage that contributes to manifestations of aging and WD.

D-Serine, a Novel Uremic Toxin, Induces Senescence in Human Renal Tubular Cells via GCN2 Activation Akira Okada,[1] Tzu-Ming Jao,[2] Hiroshi Maekawa,[1] Yu Ishimoto,[1] Takahisa Kawakami,[1] Masaomi Nangaku,[1] Reiko Inagi.[2] *[1]Division of Nephrology and Endocrinology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Division of CKD Pathophysiology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan.*

Background: A recent metabolomic analysis revealed the change in profile of metabolites, including uremic toxins, in plasma or urine from CKD patients. Accumulation of D-serine, an enantiomer of L-serine, in plasma is associated with faster progression of renal dysfunction in CKD patients. We investigated whether chirality of the amino acid plays a crucial role in the pathogenesis of CKD.

Methods: To address the effect of D-serine on tubules, human proximal tubular cell line, HK-2, and primary culture of human renal tubular cells, NHREC, were treated with D- or L-serine for 48 hr and the cell damages were evaluated by cell proliferation (MTS assay and cell count), cell cycle status (PI and Phospho-Histone H3 staining), senescence (p21, p16, γH2AX, and SA-βG), senescence-associated secretory phenotype [SASP: pro-inflammatory cytokines (IL-6 and IL-8)] and apoptosis (Annexin V staining and caspase 3/7 activity). To find out the molecular mechanism of the cell damages by D-serine, we assessed the status of amino acid-mediated signaling (integrated stress response: GCN2, ATF4, and CHOP) and L-serine synthesis pathway (PHGDH and PSAT1), To confirm signal transduction, siRNAs of integrated stress response molecules were used.

Results: D-serine, but not L-serine, markedly induced cellular senescence and apoptosis both in HK-2 and NHREC. Such tubular damage by D-serine was accompanied by G2/M cell cycle arrest and induction of SASP, including pro-inflammatory factors, contributing to tubulointerstitial fibrosis. Importantly, we found that integrated stress response mediated by GCN2-ATF4-CHOP pathway played a central role in D-serine-induced cell toxicity: knockdown of GCN2 ameliorated D-serine-induced tubular cell senescence, suggesting CKD progression and kidney aging by D-serine. Furthermore, D-serine upregulated the L-serine synthesis pathway, possibly as a counteracting mechanism, and D-serine-induced tubular toxicity is counteracted by L-serine, suggest that the proportion of D-/L-serine is critical for D-serine toxicity to tubular cells.

Conclusions: This study unveils a pathogenic role of the chiral amino acid and molecular mechanisms underlying D-serine-induced tubular damage, such as senescence with SASP, in CKD pathogenesis.

TAM Receptor TYRO3 Plays a Role in Pococyte Injury liwen ?. zhang, Zhao-hong Chen, Qing Hou, Ling Wang, Zhi Li, Wei-song Qin, Zhi-Hong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing China, Nanjing, China.*

Background: Podocyte injury plays a critical role in the development and progress of diabetic nephropathy (DN). Analyzing transcriptional profile of renal biopsy from diabetic nephropathy patients and control donors identified TYRO3, a member transmembrane receptor kinase receptor (TAM), as one of the main hub genes that are strongly associated with proteinuria in type 2 DN patients. TAM receptors have been shown to play roles in immune homeostasis, neuronal differentiation and survival.

Methods: Colocalization studies detected TYRO3 protein along with the podocyte marker synaptopodin in glomeruli.

Results: No colocalization was observed between TYRO3 and endothelial marker (CD31). IHC demonstrated TYRO3 and phosphorylated TYRO3 were downregulated in the glomeruli from DN patients and db/db mice. Knockdown of tyro3 by ATG or splicing morpholino-oligos (MO) in zebrafish larvae exhibited edema (36.23%) and foot-process effacement. Permeability studies in these zebrafish morphants demonstrated disruption of the selective glomerular permeability filter. Rescue experiment showed that zebrafish co-injected with synthetic zebrafish tyro3 mRNA and MO were morphologically normal in terms of edema and foot process. While, zebrafish injected with MO of mertk, another TAM member, didn't exhibit abnormal morphology. *in* vitro studies showed that podocyte express TYRO3 and its ligand GAS6. High-glucose downregulated TYRO3 mRNA and protein expression in podocytes. Moreover, depletion of TYRO3 expression with siRNAs induced and augmented high glucose induced podocytes apoptosis via PI3K/AKT /Bax/ Bcl-2 pathway.

Conclusions: Taken together, our findings demonstrated that TYRO3 is a novel protein that might play a crucial role in podocyte homeostasis via stabilizing PI3K-AKT signal pathway.

FR-PO219

Recognition of Apoptotic Cells by Viable Proximal Tubular Epithelial Cells (PTEC) Induces Death Receptor (DR)-Dependent PTEC Death: Dual Modes of PTEC Death Following Injury Michael E. Dietrich,[1,2] Lanfei Feng,[1,2] Joyce Rauch,[3] Jerrold S. Levine.[1,2] *[1]University of Illinois at Chicago, Chicago, IL; [2]Jesse Brown VAMC, Chicago, IL; [3]McGill University, Montreal, QC, Canada.*

Background: We have shown that mouse kidney PTEC have distinct non-competing receptors for apoptotic and necrotic targets. Recognition of apoptotic, but not necrotic, targets induces apoptotic death of PTEC responders. Here we study the role of DRs and their ligands (DR-L) in this process.

Methods: Responder cells were BU.MPT cells, a conditionally immortalized PTEC line. Target cells, induced to undergo apoptosis or necrosis, were homologous (BU.MPT) or heterologous (DO11.10 lymphocytes).

Results: Apoptotic target-induced death of PTEC responders is profound (~100% by 48-72 h) and, at least in part, DR-dependent, as shown by caspase-8 activation and augmented survival upon caspase-8 inhibition. To evaluate the role of DRs, we compared expression of DR3, DR5, and Fas in PTEC responders, exposed to dead targets. Expression fell into one of two patterns: (1) DR3: Responders at rest (i.e., not exposed to targets) lacked DR expression. 18 h after exposure to apoptotic (but not necrotic) targets, ~50% of responders newly expressed DR3. (2) Fas and DR5: Responders at rest expressed Fas and DR5 constitutively. 18 h after exposure to apoptotic (but not necrotic) targets, ~50% of responders had undetectable Fas and DR5. We next examined DR-shifted responders (i.e, with new DR3 expression, or lost Fas and DR5 expression). Consistent with apoptosis induction following exposure to apoptotic (but not necrotic) targets, DR-shifted PTEC responders of both patterns were smaller in size and positive for caspase-3 activation. Notably, quiescent PTEC do not express DR-L. However, after exposure to apoptotic (but not necrotic) targets, PTEC produced and secreted FasL and TRAIL. Pharmacologic inhibition of FasL and TRAIL augmented survival of apoptotic target-exposed PTEC.

Conclusions: Exposure of viable PTEC to apoptotic (but not necrotic) targets induces PTEC apoptosis via DR-dependent mechanisms. Expression of Fas and DR5 is constitutive, while expression of their ligands, FasL and TRAIL, is induced by apoptotic target recognition. We hypothesize that PTEC injury is characterized by two distinct waves of cell death. In the 1st wave, PTEC death is the direct result of injury. In the 2nd wave, PTEC death is independent of injury, and the result of receptor-mediated recognition of dead or dying PTEC.

FR-PO220

Activation of PPAR-γ Suppresses AngII Induced Proliferation of HBZY-1 Cell via the GPCR/Gαq/PLCβ4/TRPC Signaling Pathway Linting Wei,[2] Rongguo Fu,[1] Jiamei Lu.[3] *[1]Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [3]Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: Mesangial cell proliferation and ECM is the main pathological change commonly can be seen in CKD. TRPC and PPAR-γ can regulate cell proliferation and apoptosis. AngII can induce mesangial cell proliferation and affect TRPC expressions. However, the mechanism has not been well elucidated. This study was aimed to investigate the role of TRPC and effect of rosiglitazone (RSG) in the proliferation of HBZY-1 cell and its underlying mechanisms.

Methods: Immuofluoresence staining and qRT-PCR were performed to examine the expressions of TRPCs in HBZY-1. Gene expressions of TRPC, PPAR-γ, RGS4, GPCR/Gαq/PLCβ4/TRPC signaling pathway and downstream main proliferative molecules (PCNA, SKP2, P21 and P27) were detected by qRT-PCR and Western blotting. Additionally, changes in intracellular Ca^{2+} concentration were determined through Fluo-4 Ca^{2+} imaging and cell cycle conditions were examined by flow cytometry.

Results: Our results found that TRPC1and TRPC6 were at higher expression levels in HBZY-1. Following AngII stimulation, there were increasing expressions of TRPC1 and TRPC6, Ca^{2+} influx, elevated gene expressions of PCNA and SKP2, decresing expressions of P21 and P27 and declined G_0/G_1 percentage (NC vs AngII, $p<0.05$). While silencing the TRPC1and TRPC6 by RNA interference led to decreasing in Ca^{2+} influx, G_0/G_1 cell cycle arrest and attenuated cell proliferations ($p<0.05$). Notably, activated PPAR-γ by RSG up-regulated RGS4 (regulators of G protein signaling) expressions, which can interact with the Gαq family to inhibit Gαq-mediated signaling pathways. The results were similar to silencing the TRPC1and TRPC6 by RNA interference techniques ($p<0.05$). All these results indicate that RSG could inhibite HBZY-1 cell proliferation via AT1R/Gαq/PLCβ4/TRPC signaling pathways.

Conclusions: This study suggests that activation of PPAR-γ and down-regulation of TRPC might be promising therapeutic targets for the treatment of mesangial cell prolifrative glomerulonephritis.

FR-PO221

Cytoprotective Role of Autophagy in Angiotensin II-Induced Podocyte Apoptosis Tae-Sun Ha. *Chungbuk National University College of Medicine, Cheongju-si, Republic of Korea.*

Background: Autophagy and apoptosis are two cellular processes through which injured and aging cells or organelles are eliminated. Angiotensin II (Ang II) induces podocyte injury resulting in apoptosis in vitro and in vivo. However, the relationship between autophagy and apoptosis in Ang II-induced podocyte injury is unknown and the role of Ang II-induced autophagy in podocyte survival or death remains unclear. We investigated the sequential relationship between autophagy and apoptosis in Ang II-induced podocytes as well as the role of PI3-kinase.

Methods: Mouse podocytes were incubated in media containing various concentrations of Ang II and at different incubation times. Cell survival/death-modifying reagents and Atg5 siRNA were applied. The changes of podocyte autophagy and apoptosis were observed by electron microscopy, confocal imaging, western blotting, TUNEL, and FACS assay according to the presence of Ang II.

Results: Ang II enhanced the podocyte expression of the autophagic proteins, LC3A/B-II and beclin-1, and also increased the number of autophagosomes compared with control cells at early phase of 12 hours in a dose-dependent manner. This pro-autophagic effect of Ang II was inhibited by pretreatment with 3-methyladenine (3-MA), a PI3-kinase class III inhibitor. Atg5 siRNA reduced LC3 puncta levels and increased the number of apoptotic podocytes over that observed with Ang II treatment at 12 hours. Thereafter, the Ang II-induced enhancement in autophagy decreased, whereas, podocyte apoptosis appeared later at 24 hours in concentration- and time-dependent manners in FACS and TUNEL assays. 3-MA and LY294002 further increased Ang II-induced podocyte apoptosis. Suppression of autophagy by Atg5 siRNA could induce podocyte apoptosis and further augment high-dose Ang II-induced podocyte apoptosis.

Conclusions: We suggest that Ang II induced autophagy in mouse podocytes prior to apoptosis as an early adaptive cytoprotective mechanism for podocyte survival after Ang II treatment and the imbalance between autophagy and apoptosis causes podocyte injury.

FR-PO222

Forkhead Box O3 (FoxO3) Regulates Kidney Tubular Autophagy Following Urinary Tract Obstruction Ling Li, Ronald Zviti, Catherine Ha, Fangming Lin. *Department of Pediatrics, Columbia University College of Physicians & Surgeons, New York, NY.*

Background: Autophagy has been shown to be important for normal homeostasis and adaptation to stress in the kidney. Yet, molecular mechanisms regulating renal epithelial autophagy are not fully understood.

Methods: We explore the role of the stress-responsive transcription factor forkhead box O3 (FoxO3) in mediating injury-induced proximal tubular autophagy in mice with unilateral ureteral obstruction (UUO), which is a reproducible model of persistent tubular autophagy.

Results: We show that following UUO, FoxO3 is activated over basal level and displays nuclear expression in 34.0 ± 3.4% of proximal tubules at 3 days ($n=3$, $p<0.01$) and 45.5 ± 2.8% at 7 days ($n=3$, $p<0.05$) when the hypoxic tubules exhibit high levels of autophagy. Activation of FoxO3 by mutating its phosphorylation sites to enhance its nuclear expression induces profound autophagy in primary cultures of renal epithelial cells. Conversely, deleting FoxO3 in mice results in fewer numbers of autophagic cells in the proximal tubules and reduces the conversion of the key autophagy-associated protein LC3-I to LC3-II post-UUO. Interestingly, autophagic cells deficient in FoxO3 contain lower numbers of autophagic vesicles per cell upon stimulation with nutrient deprivation. Analysis of individual cells treated with various autophagic inhibitors to sequentially block the autophagic flux suggests that FoxO3 stimulates the formation of autophagosomes to increase autophagic capacity without significant effects on autophagosome-lysosome fusion or autolysosomal clearance. Furthermore, in kidneys with persistent UUO for 7 days, FoxO3 activation increases the expression of core autophagy-associated (Atg) proteins, including Ulk1, Beclin-1, Atg9A, Atg4B, and Bnip3, suggesting that FoxO3 may also function to replenish components of the autophagic machinery that would otherwise be consumed during sustained autophagy.

Conclusions: In summary, our findings indicate that FoxO3 activation can both induce and maintain autophagic activities in renal epithelial cells in mouse models of prolong tubular stress and injury.

The NRF2-Heme Oxygenase-1 System Modulates Autophagy and Inhibits High Glucose Induced Apoptosis in Renal Tubular Epithelial Cells Kyeong Min Kim, Young woong Song. *Eulji medical center, Daejeon, Republic of Korea.*

Background: Autophagy is a tightly regulated process in which endogenous cellular proteins aggregate is degraded by the lysosomal pathway. It's renoprotective role including those used for aging and acute kidney injury, has also been demonstrated. However, The role of autophagy in diabetic nephropathy remains a largely undetermined.

Methods: In present study, we evaluated the effects of high glucose concentrations on the induction of autophagy in the human renal tubular epithelial cell line, HK-2 cells. We also investigated the ability of Sulforaphane(SFN, nuclear factor E2-related factor 2 (Nrf2) inhibitor) to protect HK-2 cells against apoptosis induced by high glucose levels by targeting autophagy.

Results: The HK-2 cells stimulated with a high concentration of glucose for 72h exhibited an increased expression of the autophagic markers, LC3-II and Beclin 1. The level of LC3-II and Beclin 1 in cells treated with SFN was decreased compared to control cells. The level of Caspase-3 activated in tubule cells cultured in high glucose medium was also decreased. One important NRF2 target gene, Heme oxygenase-1(HO-1) is known as a key molecule of NRF2 protective function. To examine whether HO-1 can modulate autophagy and apoptosis in tubule cells like SFN, HK-2 cells cultured in 250 mM glucose medium for 1-2 days were treated with Adneovirus-HO-1 gene for 1 day. HO-1 transfection decreased the expression of Beclin1 and LC3-II associated with a decrease in the expression Caspase-3 with HG for 1-2days compared with mock-treated cells. Reactive Oxygen Species(ROS) are important inducers of autophagy and apoptosis. As expected, an increase of ROS was observed in HK-2 cells cultured in 250 mM glucose medium for 1-3 days. A decrease of ROS was observed in cells treated with SFN.

Conclusions: HO-1 and autophagy are induced after high glucose injury to overcome to oxidative stress and serve as adaptive responses to prevent cell death. NRF2-HO-1 overexpression is able to limit ROS generation and oxidative stress during high glucose injury and thereby significantly inhibiting autophagy and apoptosis. This study is the first study to show the effect of NRF2-HO-1 system on high glucose induced autophagy and apoptosis of tubule cells. Targeting NRF2-HO-1 as a modulator of autophagy may result in novel therapeutic intervention in diabetic nephropathy.

FR-PO224

Unfolded Protein Responses Potentiated Uremic Sarcopenia through Perturbation of Myoblast Differentiation Jia-Rong Jheng,[1,3] Yuan-Siao Chen,[1] Chih-Kang Chiang,[1,2] Shing-Hwa Liu.[1] *[1]Graduate Institute of Toxicology, National Taiwan University, College of Medicine, Taipei, Taiwan; [2]Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan; [3]Department of Internal Medicine, National Taiwan University, College of Medicine, Taipei, Taiwan.*

Background: Sarcopenia is the age-related degeneration characterized with the decline of skeletal muscle mass, strength, and mobility. The imbalance of protein synthesis and degradation which jeopardizes immune, hormone regulation, and muscle-motor neuron connection is the main cause of sarcopenia. There are limited knowledge regarding molecular mechanism of sarcopeia. As the endoplasmic reticulum (ER) is the control center of the protein syntheses and degradation, we hypothesized that ER stress and unfolded protein response (UPR) are important causes of sarcopenia. Understanding the sarcopenia molecular mechanisms may benefit the therapeutic diagnosis and treatment in the future.

Methods: Mouse myoblast C2C12 cells are exposed to designated time and concentration of indoxyl sulfate (IS). The proliferation, differentiation, and myotube atrophy are examined. The protein and mRNA expression of IS treated C2C12 cells are inspected to distinguish the role of ER stress and oxidative stress underlying the sarcopenia.

Results: IS inhibits myoblast differentiation. We demonstrate that number of multi-nuclei myotube decreased, the differentiation markers including myoD, myoG, and myosin heavy chain are also suppressed. IS inhibits myoblast proliferation and induces the myotubular atrophy marker atrogin 1 protein expression. IS stimulates eIF2α phosphorylation and XBP1 mRNA splicing in UPR. Interestingly, the oxidative stress is related to eIF2α phosphorylation but not XBP1 mRNA splicing. The eIF2α phosphorylation triggered by IS reduces myoD, myoG and myosin heavy chain protein expression, which is the antimyogenic modulation on the early differentiation event. The XBP1 mRNA splicing induced by IS, however, is considered the late differentiation event which is a promyogenic modulation— an adaptive response.

Conclusions: Our studies indicated that the ER stress and UPR modulation are critical both in sarcopenia and the CKD uremic toxin accumulation model. We believe that UPR-related molecules showed great potential in clinical application.

FR-PO225

Darunavir Protects HIV-Transgenic Mice against Kidney Injury via HIV-Independent Mechanisms Xiaobo Gao, Alan Rosales, Heidi Karttunen, Michael J. Ross. *Albert Einstein College of Medicine/ Montefiore Medical Center, Hastings-on-Hudson, NY.*

Background: HIV-associated nephrology (HIVAN) is characterized by severe proteinuria and progressive CKD and is caused by infection of renal epithelial cells, though active viral replication is not necessary to induce disease in animal and in vitro models. Antiretroviral therapy (ART) markedly reduces the risk of progression to ESRD without eradicating HIV in the kidney and the mechanism(s) by which ART protects kidneys from HIVAN is poorly understood.

Methods: We studied HIV-transgenic mice, which develop a HIVAN phenotype. Since the transgene in these mice does not encode HIV Reverse Transcriptase (RT) or Protease we used these mice to determine if the HIV protease inhibitor darunavir (DRV) and/or RT inhibitor zidovidine (AZT) protect against HIVAN independent of effects on RT or HIV protease. Mice were treated for 4 weeks by daily oral gavage in 4 groups: DRV (100mg/kg), AZT (50mg/kg), DRV+AZT, or control.

Results: DRV and DRV+AZT, but not AZT alone reduced urinary albumin:creatinine ratio and histologic glomerular and tubulointerstitial injury. DRV and DRV+AZT, but not AZT also markedly reduced expression of the proliferation marker Ki67 in tubular cells, prevented loss of synaptopodin expression in podocytes, and reduced phosphorylation of ERK1,2, and Stat3, which are important mediators of HIV-induced kidney injury. To further examine the mechanism of DRV-induced protection, we studied the effects of DRV renal tubular epithelial cells (RTEC) transduced with gag/pol-deleted HIV lentivirus (lacking HIV protease and RT), HIV Vpr-expressing lentivirus, or control lentivirus. DRV significantly attenuated HIV and Vpr-induced activation of Stat3, ERK, and Src and decreased HIV and Vpr-induced expression of IL-6 and IL-8, which are key inflammatory mediators in HIVAN.

Conclusions: These data demonstrate that DRV but not AZT protects against HIV-induced renal injury via mechanisms that are at least partly independent of suppression of HIV replication and HIV Protease. Additional studies are needed to identify the non-HIV molecular targets of DRV which mediate these effects and to determine the efficacy in non-HIV related kidney diseases.

GLCCI1 as a Novel Therapeutic Target of Glucocorticoid-Resistant T-Cells Yukino Nishibori, Zentaro Kiuchi, Ichiro Hada, Kunimasa Yan. *Kyorin University School of Medicine, Tokyo, Japan.*

Background: Activation and dysfunction of T-cells underlie the pathogenesis of glomerular diseases including idiopathic nephrotic syndrome. Glucocorticoid (GC) is one of the major classes of drugs that target such T-cells; however, GC-dependence and resistance during the treatment are big issues to be solved. We previously reported that GC-induced transcript 1 (GLCCI1) of thymic T-cells is up-regulated through a GC-GC receptor cascade, bound to dynein-LC8, and phosphorylated by protein kinase-1, and its up-regulation is observed with the activation of a GC-induced apoptotic pathway (ASN meeting 2013). The aim of the present study is to determine the effect of GLCCI1 on T-cell apoptosis induced by GC.

Methods: Using a mouse thymocyte cell line, the GLCCI1 gene was knocked down by lentiviral sh-RNA delivery. Transgenic mice conditionally expressing human GLCCI1 were established using G57BL/6J mice and the tamoxifen-inducible CreER-LoxP system (*glcci1*-TG/Cre mice). Protein samples from thymocyte cell lines and thymi from mice were subjected to immunoblotting for caspases and Bim to compare the activation of apoptotic signaling. Thymi were analyzed to compare cell number, cell population and organ size between transgenic and non-transgenic mice (*glcci1*-TG mice).

Results: Immunoblotting for caspases and Bim in the samples from thymocyte cell lines revealed that knock-down of GLCCI1 activated the apoptotic pathway. The size of thymi was significantly larger in *glcci1*-TG/Cre mice compared to *glcci1*-TG mice. Cell number of thymi was increased in *glcci1*-TG/Cre mice compared to that in *glcci1*-TG mice, whereas there was no significant change in the ratio of T-cell subpopulations between these mice. Finally, immunoblotting for caspases and Bim revealed an apparent reduction of apoptotic signaling in thymi of *glcci1*-TG/Cre mice compared to *glcci1*-TG mice.

Conclusions: Although GC is known to cause T-cell death, the results of the present study indicate that GC-induced up-regulation of GLCCI1 limits apoptosis. Therefore, GLCCI1 may be a novel therapeutic target to overcome GC dependence and resistance.

FR-PO227

MicroRNA-21 Participates in IgA Nephropathy by Driving T Helper Cell Polarization Meng Sijun,[1] Hong Zhang,[2] Li Zhu.[3] *[1]Peking university first hospital, Beijing, China; [2]Peking University First Hospital, Beijing, China; [3]Renal Division, Peking University First Hospital, Beijing, China.*

Background: Previous studies revealed abnormal lymphocytes subsets in IgA nephropathy (IgAN). Recently, emerging studies indicate that miR-21 alters the balance of T helper cells differentiation and function. Here we explored the participation of miR-21 in IgAN, especially focused on T helper cell polarization.

Methods: Totally, 38 IgAN patients and 35 healthy controls (HC) were enrolled. Firstly, miRNAs and mRNA profiles in PBMC were determined by next-generation sequencing and gene expression array. Then, above identified miRNA were tested in both CD19+ B cells and CD3+ T cells. After the confirmation of differently expressed miRNA, expression of the miRNA target genes were further verified using real-time PCR. Meanwhile, T helper cells subgroups (Th1, Th2 and Th17), as well as plasma IgA1 and galactose deficient IgA1 (Gd-IgA1) levels were detected by FC and ELISA.

Results: MiR-21 showed highest level among 22 differently expressed miRNAs between IgANs and HCs. Through combined analysis of miRNA and mRNA profile data, SPRY1, SPRY2, FASLG were chosen as target genes for miR-21, for their negative correlation with miR-21 and bearing target sequence of miR-21. Next, we found that miR-21 levels in IgAN were only higher in CD3+ T cells (9.3±7.3 vs 4.0±3.4, p=0.02), but not CD19+ B cells. Accordingly, the mRNA levels of SPRY1, SPRY2, FASLG from CD3+ T cells were lower in IgAN than in HC (1.5±1. 3 vs 2.9±1.6, p<0.01; 1.2±1.2 vs 2.5±2.2, p<0.01; 0.9±0.6 vs 1.6±1.1, p<0.01). And miR-21 showed negative correlation with SPRY1 (r=-0.37, p<0. 01), while similar trend of correlation were observed to SPRY2 (r=-0.33, p=0.05) and FASLG (r=-0.31, p=0.07). FC analysis revealed elevated Th17 cells in IgAN than in HC (15.0±4.5 vs 12.6±1.8, p=0.04). Moreover, negative correlations were found between Th17 cells and SPRY1 (r=-0.33, p=0.04), SPRY2 (r=-0.36, p=0.03), FASLG;(r=-0.47, p<0.01). And in our recruited IgAN, the proportion of Th17 cells only showed a trend of positive correlation with plasma IgA1 (r=0.3, p=0.06), but not Gd-IgA1.

Conclusions: Our results showed higher miR-21 levels in IgAN, which inhibited the expression of *SPRY1, SPRY2, FASLG*, and thereby accelerated Th17 polarization.

FR-PO228

Effect of Huaier on the Proliferation of Mesangial Cells in Anti-Thy-1 Nephritis Xiangmei Chen. *Department of Nephrology, Chinese PLA General Hospital, Beijing, China.*

Background: Mesangial proliferative glomerulonephritis (MsPGN) is one of the common kidney diseases. In this study, we investigated whether aqueous extract of Trametes robiniophila murr (Huaier) could suppress mesangial cell proliferation in rat cells treated with platelet-derived growth factor (PDGF)-BB and in rat model of anti-Thy-1 mesangial proliferative glomerulonephritis, and further explored the possible mechanisms of its antiproliferation effects.

Methods: In Vivo: Thirty Wistar rats were randomly divided into five groups: (1) Sham surgery (Sham); (2) anti-Thy-1 nephritis model (Thy-1); (3) anti-Thy-1 nephritis model + low-dose of Huaier (HRL); (4) anti-Thy-1 nephritis model + medium-dose of Huaier (HRM); (5) anti-Thy-1 nephritis model + high-dose of Huaier (HRH). Two weeks after drug treatment, urinary proteins were quantified and renal pathological changes were thoroughly examined. Meanwhile, the expression levels of Mxi-1 and PCNA in isolated glomeruli were also tested. In Vitro: Rat mesangial cell viability was measured by CCK8. DNA synthesis and cell proliferation evaluated by with 5-ethynyl-2'-deoxyuridine(Edu) Assay. The distribution of cell cycle, PI-Annexin-V staining was analyzed by flow cytometry, and western blot were used to test the cell cycle pathways.

Results: Huaier diminished the proliferative damages and urinary protein secretion in Thy-1 rats. PCNA was downregulated, whereas Mxi-1 was upregulated in the isolated glomeruli of Huaier-treated groups compared with the Thy-1 group. Huaier inhibited PDGF-BB–stimulated proliferation of rat mesangial cells in a time- and dose-dependent manner (50% inhibitory concentration = 6.19 mg/mL) and induced G2 cell-cycle arrest. Cell-cycle pathway proteins were downregulated, whereas Mxi-1 was upregulated in Huaier-treated mesangial cells compared with PDGF-BB–stimulated cells.

Conclusions: Huaier reduces urinary protein excretion and relieves hyperplasia in mesangial cells in anti-Thy-1 MsPGN as well as inhibits PDGF-BB–stimulated proliferation and DNA synthesis of rat mesangial cells *in vitro*, suggesting its novel therapeutic potential in MsPGN.

Kidney Organoids Generated from Bone Marrow-Derived Mesenchymal Stem Cells Xiangmei Chen. *Chinese PLA General Hospital, Beijing, China.*

Background: Via the directed differentiation of stem cells, progenitors can be induced to both collecting duct and nephrons. The human kidney originates from intermediate mesoderm. Cells cephalad migrate from the primitive streak (presomitic mesoderm) to form the intermediated mesoderm. The intermediate mesoderm increases the number of key renal progenitor cells, as well as the ureteral epithelium and the metanephric mesenchyme, which respectively form the collecting ducts and nephrons. According to this theory, we have used bone marrow-derived mesenchymal stem cells (BM-MSCs) to differentiate into the kidney organoids by each other.

Methods: 1) By simulating the regulation of CHIR99021-FGF9 cytokines, and controlling the ratio of the formation of the ureteral epithelium and the metanephric mesenchyme, the kidney organoids were constructed by MSCs. 2) The kidney specific markers in the kidney organoids were detected by immunofluorescence staining. 3)The electron microscope was used to observe the structure of the organoids.

Results: 1) Using MSCs to differentiate into the kidney organoids through the regulation of cytokines. 2) Within these organoids, a single renal unit is divided into distal tubules, proximal tubules and glomeruli, which contains podocytes and blood vessels.

Conclusions: Such kidney organoids generated from MSCs represent powerful models of the human organ for future applications, including nephrotoxicity screening, disease modelling and as a source of cells for therapy.

CRISPR-Cas9-Induced Expression of Endogenous APOL1-G0 Reduced Cytotoxicity of Renal Risk Variant APOL1-G1 Opeyemi A. Olabisi,[3,4] Savannah Moore,[2,4] Martin R. Pollak.[1,4] *[1]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Brookline, MA; [3]Medicine, Massachusetts General Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA.*

Background: Two protein coding mutations in the APOL1 gene account for much of the excess risk of non-diabetic end stage kidney disease (ESRD) among individuals of recent African Ancestry. These 2 common mutations (named G1- missense mutation, and G2- 2 amino acid deletion), collectively referred to as renal risk variant (RRV) APOL1 increase the risk of FSGS, HIVAN and hypertension-associated ESRD. The pattern of inheritance of APOL1-nephropathy is recessive--the disease is most consistently seen in African Americans with 2 copies of RRV APOL1 relative to those with zero or 1 copy of the risk allele. Yet, strong evidence suggests that cytoxicity of RRV APOL1 is due to gain of function. Expression of both G1 or G2 APOL1 result in toxicity in HEK-293 cells, human and mouse podocytes. We predict that induced cellular expression of wildtype APOL1 (G0) would compete with and reduce cytotoxicity of RRV APOL1 in HEK-293 cells.

Methods: We generated HEK-293 cell line that stably express APOL1-G1 in the presence of exogenous tetracycline. Transient transfection of these stable HEK-293 cells with CRISPR-transcription activator complex(dCas9-Vp64, p65-HSF1, and guide RNA specific for APOL1 promoter) induced robust expression of endogenous APOL1-G0. We then measured cytotoxicity of APOL1-G1 in the presence or abscence of these induced APOL1-G0.

Results: In the presence of APOL1-G0, the cytotoxicity of APOL1-G1 is significantly reduced up to 50%.

Conclusions: This result suggests that the cytoxicity of renal risk variants APOL1-G1 could be competitively be reduced by wild type APOL1-G0. This may explain in part why the risk of APOL1-nephropathy is negligible among individuals who carry at least one copy of wild type APOL1-G0, but high among individuals with 2 copies of RRV. Also, this finding suggests that differential upregulation of APOL1-G0 or downregulation of RRV APOL1 in podocytes may be a useful have therapeutic intervention.

Apolipoprotein L-1 and the Wound Healing Pathway: A Fight for Survival Joseph A. Giovinazzo,[1,2] Russell P. Thomson,[1,2] Anibelky Almanzar,[1,2] Simranjit Singh,[3] Ji Won Kang,[1,2] Jayne Raper.[1,2] *[1]City University of New york, New York, NY; [2]Hunter College, New York, NY; [3]NYU Medical Center, New York, NY.*

Background: APOL1 is an innate immunity protein that forms pores in trypanosomes. Variants of APOL1 have been linked to kidney disease, yet the mechanism responsible remains controversial. We tested the hypothesis that APOL1 toxicity is cell intrinsic and dependent upon secretion via the Golgi. Along the secretory pathway, APOL1 is acidified and then neutralized upon delivery to the plasma membrane, wherein the cation selective pore initiates wound repair via the influx of Ca^{2+}.

Methods: HEK293 cells were transfected with APOL1 and its variants, including deletion of the signal peptide. 24-48h later cell toxicity and viability were measured. Treatment with ammonium chloride was performed 2h prior to transfection. Recombinant APOL1 was purified from *E. coli* and reconstituted in planar lipid bilayers to measure ion channel conductivity and selectivity. HEK293 cells that stably express APOL1 were generated using the FlpIn recombinase system. The cells were transfected with the fluorescent calcium reporter gCAMP6f. Expression of APOL1 was induced at several timepoints and then read in a fluorescent plate reader. Activity of β-hexosaminidase (β-hex) was assayed in the supernatant of transfected cells at various timepoints after APOL1 expression.

Results: Deletion of the signal peptide led to a significant reduction of toxicity across all variants. Pre-treatment of cells with ammonium chloride reduced the toxicity of APOL1 by 50%. In planar lipid bilayers, rAPOL1 of all three major variants allowed for the passage of Ca^{2+}. In stably transfected cells, induction of APOL1 expression lead to an increase in cytoplasmic Ca^{2+}. In a cell, this would cause lysosomes to fuse with the plasma membrane to initiate removal of the wound and repair the membrane. Indeed, release of the lysosomal enzyme β-hexosaminidase, a marker of wound-healing, was detected prior to cell death.

Conclusions: These data support a model of APOL1 mediated cell death that requires acidic activation along the secretory pathway prior to forming pores at the plasma membrane. Increases in Ca^{2+} flux and the release of lysosomal enzymes prior to cell death indicate activation of the wound healing pathway by APOL1 pore-formation. Maintaining the balance between secretion and excessive pore-formation of APOL1 and the ability to remove and repair the wounds are key to cell survival.

APOL1 Preserves Podocyte Differentiation in High Glucose Milieu through Down-Regulation of MicroRNA193a Abheepsa Mishra,[4] Kamesh R. Ayasolla,[1] Xiqian Lan,[1] Vinod Kumar,[7] Rukhsana Aslam,[2] Ali Hussain,[3] Seyedeh Shadafarin Marashi Shoshtari,[6] Manali Bhooplapur,[2] Sheetal Chowdhary,[3] Ashwani Malhotra,[8] Pravin C. Singhal.[5] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute for medical research, Glenoaks, NY; [3]Feinstein Institute of Medical Research, New York, NY; [4]Feinstein Institute of Medical Research, Northwell Health, MANHASSET, NY; [5]North Shore LIJ Health System, Great Neck, NY; [6]The Feinstein Institute for Medical Research, Manhasset, NY; [7]Immunolgy and Inflammation, Fienstine Institute for Medical Research, New York, NY; [8]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Dibetic podocytopathy is characterized by significant proteinuria an indication of loss of integrity of glomerular filatration barrier. High glucose milieu has been demonstrated to promote dedifferentiation of podocytes (PDs) contributing to the loss of integrity of glomerular filtration barrier; however, the involved mechanism is far from clear. APOL1 is expressed in kidneys of certain primates including humans. APOL1 risk alleles (G1 and G2) have been reported to be podocytotoxic, however, the role of APOL1G0 (wild-type) is far from clear. We hypothesize that APOL1 facilitates preservation of the molecular integrity of podocytes in adverse milieus such as high glucose through down-regulation of microRNA (miR) 193a.

Methods: To evaluate the effect of high glucose milieu, differentiated human podocytes (DIF-PDs, after incubation for 10 days at 37°C) were incubated in media containing different concentrations of glucose (5, 15, 25, 30, and 35 mM) for 48 hours. To evaluate the role of miR193a, DIF-PDs were incubated in media containing normal glucose (5mM, NGM), high glucose (30 mM) with/without miR193a inhibitor (25 nm) for 48 hours. To establish a causal relationship, DIF-PDs were transfected with either control or APOL1/miR193a siRNA followed by incubation in either normal (5 mM, NGM) or high glucose (HGM) media for 48 hours. To confirm a relationship, DIF-PDs were transfected with either vector or APOL1 lentivirus and then incubated in media containing either normal or high glucose for 48 hours. Proteins and RNA were extracted.

Protein blots were probed for APOL1, WT1, podocalyxin, nephrin and reprobed for actin. RNAs were assayed for miR193a.

Results: HGM down regulated WT1 and nephrin (2.5 fold) expressions but increased (3-fold) miR193a levels in PDs. HGM down regulated PD expression of APOL1 in a dose-dependent manner. PDs knocked down for APOL1 displayed enhanced (2.2 fold) levels of miR193a, whereas, PDs knocked down for miR193a displayed increased (2.5 fold) expression of APOL1. Over expression of APOL1 in PDs preserved podocyte molecular phenotype in HGM.

Conclusions: High glucose dedifferentiates PDs through down-regulation of APOL1; however, overexpression of APOL1 preserves PDs molecular integrity.

HIV and Interferon (IFN)-y Facilitate Parietal Epithelial Cell Transition through Induction of APOL1 Vinod Kumar,[4] Xiqian Lan,[1] Rukhsana Aslam,[2] Ali Hussain,[3] Seyedeh Shadafarin Marashi Shoshtari,[7] Manali Bhooplapur,[2] Sheetal Chowdhary,[3] Catherine Meyer-Schwesinger,[8] Ashwani Malhotra,[9] Karl Skorecki,[6] Pravin C. Singhal.[5] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute for medical research, Glenoaks, NY; [3]Feinstein Institute of Medical Research, New York, NY; [4]Immunolgy and Inflammation, Fienstine Institute for Medical Research, New York, NY; [5]North Shore LIJ Health System, Great Neck, NY; [6]Rambam Health Care Campus, Haifa, Israel; [7]The Feinstein Institute for Medical Research, Manhasset, NY; [8]University of Hamburg, Hamburg, Germany; [9]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Genetic epidemiology indicated that HIV-infected patients carrying APOL1 risk alleles with African ancestry carry a risk of developing HIV-associated neprhopathy at 10 times higher rates when compared to patients carrying APOL1 (wild-type). Podocytes (PDs) express APOL1 constitutively and this expression is enhanced by HIV and IFN-y. However, parietal epithelial cells (PECs) do not express APOL1. Both PDs and PECs are evolved from the same mesenchymal cells during embryogenesis. Since APOL1 expression seems to be a differentiating phenotypic molecule between PECs and PDs, we wished to consider its potential role in distinct cellular phenotype determination. We hypothesize that HIV could be facilitating PECs transition to PDs through the induction of APOL1.

Methods: Immortalized PECs proliferate at 33°C and differentiate (transit) to podocytes at 37°C. PECs were transduced with either vector (PECV) or HIV (NL4-3, PECHIV) and incubated for 48 hours at 33°C (n=4). In another set of experiments, PECs were incubated in media containing different concentrations of IFN-Y (0, 5, 10, 15, 20 nM) for 48 hours at 33° (n=4). To establish a causal relationship, PECV and PECHIV were transfected with either control or APOL1 siRNA (n=4). To confirm the role in PECs transition, mouse (M) PDs, which do not express APOL1, were transduced with either vector or APOL1 lentivirus (n=4). Proteins and RNAs were extracted. Protein blots were probed for APOL1, markers of PECs (PAX2, and Claudin 1) and PDs (WT1, nephrin, podocalyxin, and podocin) and reprobed for GAPDH. cDNAs were amplified for APOL1, WT1, podocalyxin, nephrin, and podocin.

Results: HIV induced APOL1 expression in PECs. IFN-γ also induced APOL1 expression in PECs in a dose dependent manner. PECHIV/IFN-γ-treated PECs displayed induction of nephrin, enhanced expression of WT1 (2.5-fold) and podocalyxin (3-fold) but down regulation of PAX2 (2-fold). PECHIVs with knockout APOL1 displayed down regulation of WT1, podocalyxin, and podocin; on the other hand, mouse podocytes (MPDs) expressing APOL1 displayed enhanced expression of WT1, podocalyxin, and podocin when compared to MPDVector.

Conclusions: HIV and IFN-y stimulate PECs transition through induction of APOL1.

FR-PO234

APOL1 Provides Podocyte Protection against Apoptosis through Down Regulation of MicroRNA (miR)193a in Adverse Milieus Vinod Kumar,[1] Xiqian Lan,[1] Rukhsana Aslam,[3] Ali Hussain,[4] Seyedeh Shadafarin Marashi Shoshtari,[5] Catherine Meyer-Schwesinger,[6] Ashwani Malhotra,[1] Karl Skorecki,[2] Pravin C. Singhal.[1] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Rambam Health Care Campus, Haifa, Israel; [3]Feinstein Institute for medical research, Glenoaks, NY; [4]Feinstein Institute of Medical Research, New York, NY; [5]The Feinstein Institute for Medical Research, Manhasset, NY; [6]University of Hamburg, Hamburg, Germany.*

Background: Adverse milieus such as high glucose and puromycin aminonucleoside (PAN) have been reported to induce podocyte (PD) injury both *in vitro* and *in vivo* studies. APOL1, expressed intracellularly is a minor component of circulating lipid-rich trypanolytic multiprotein complexes in certain primate species including humans. Genetic epidemiologic studies suggest that humans carrying APOL1 wild-type (G0) are less likely to develop chronic kidney disease when compared to humans carrying APOL1 risk alleles (APOL1G1 and G2). We hypothesize that PD expression of APOL1G0 provides protection against apoptosis in adverse milieus.

Methods: Human podocytes (PDs) were transduced with either vector (PDV) or APOL1G0 (wild- type, PDG0). PDVs and PDG0 were treated with different concentrations of glucose (5, 15, 30, and 35 mM) or PAN (0, 5, 10, 25, 50, and 100 nM) for 48 hours (n=4); in other set of experiments, PDs were incubated in media containing either buffer, high glucose (30 mM), PAN (50 nM) with or without interferon-γ (IFN-γ; 20 nM, an APOL1 inducer) for 48 hours (n=4); PDV were incubated in media containing, high glucose (30 mM), PAN (50 nM), with or without miR193a inhibitor (25 nM) for 48 hours (n=4). At the end of incubation periods, cells were evaluated for reactive oxygen species (ROS) generation and apoptosis. Proteins and RNAs were extracted from cells treated under similar conditions. Protein blots were probed for APOL1, and caspase-3; RNAs were assayed for miR193a.

Results: PDVs displayed higher generation of ROS and a greater number of apoptotic cells when compared to PDG0, both in high glucose and PAN milieus. PDG0 displayed enhanced expression of APOL1 but decreased miR193a levels when compared to PDVs. Both high glucose and PAN treated PDs displayed enhanced expression of caspase-3. IFN-γ increased APOL1 expression in PDs and attenuated induction of apoptosis as well as caspase-3 expression, both in high glucose and PAN milieus. MicroRNA193a inhibitor decreased miR193a levels, increased APOL1 expression and attenuated apoptosis, both in high glucose and PAN milieus.

Conclusions: APOL1G0 provides protection against apoptosis in adverse milieus through down regulation of miR193.

APOL1-microRNA193a Feedback Loop Facilitates Monocyte Macrophage Transition Vinod Kumar,[6] Xiqian Lan,[1] Seyedeh Shadafarin Marashi Shoshtari,[6] Sheetal Chowdhary,[3] Manali Bhooplapur,[2] Ashwani Malhotra,[7] Karl Skorecki,[5] Pravin C. Singhal.[4] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute for medical research, Dix Hills, NY; [3]Feinstein Institute of Medical Research, New Hyde Park, NY; [4]North Shore LIJ Health System, Great Neck, NY; [5]Rambam Health Care Campus, Haifa, Israel; [6]The Feinstein Institute for Medical Research, Manhasset, NY; [7]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Macrophage influx in the mesangium has been considered to be a precursor of mesangial expansion, a feature of focal segmental glomerulosclerosis. APOL1 is expressed by macrophages but not by monocytes. Therefore, APOL1 expression is associated with monocyte transition. However, the role of APOL1 in the conversion of monocytes to macrophages (transition) has not been investigated to date. We have studied feedback loop relationship between APOL1 and microRNA193a in parietal epithelial cells (abstract submitted to ASN). We now hypothesize that APOL1-microRNA (miR)-193a feedback loop facilitates monocyte macrophage transition.

Methods: Peripheral blood mononuclear cells (PBMCs) were harvested and incubated in media containing either buffer or experimental agents including, PMA (100 ng/ml), vitamin D receptor (VDR) agonist (EB1089, 50 nM), IFN-y (10 nM), HIV (NL4-3, 100 GEU units X1000), and LPS (10 ng/ml) for adherence for 48 hours followed by assays for adherence and expression of APOL1 mRNA and protein. To examine a causal relationship APOL1 and miR193a, control human monocytes (THPs) were transfected with control and APOL1 siRNAs and incubated in media containing either buffer or PMA, VDR agonist, IFN-y, HIV, and LPS for 48 hours, followed by assays for adherence and miR193a. To confirm the role of feedback loop relationship, THPs were transfected with either control or miR193a plasmids followed treatment with PMA or VDA for 48 hours and assay for APOL1 expression.

Results: Experimental agents enhanced (PMA, 50 fold, VDA, 10 fold, IFN-y 15 fold, HIV 10 fold, and LPS 15 fold) adherence when compared to control PBMCs. All experimental agents induced protein expression of APOL1 in THPs and PBMCs. However, knockout of APOL1 in THPs partially inhibited (<0.01) adherence of PBMCs and THPs treated with PMA (90%), VDA (80%), IFN-y (90%), and LPS (80%). Experimental agents down regulated (P<0.01) THPs expression of miR193a whereas knockout APOL1 reversed this effect of experimental agents on THPs expression of miR193a. However, overexpression of miR193a inhibited PMA/VDA –induced expression of APOL1 in THPs.

Conclusions: These findings suggest that APOL1 through mi193a feedback loop facilitates monocyte macrophage transition

APOL1 Facilitates Transition of Parietal Epithelial Cells (PECs) via Down-Regulation of miR193a Vinod Kumar,[2] Xiqian Lan,[1] Seyedeh Shadafarin Marashi Shoshtari,[4] Catherine Meyer-Schwesinger,[5] Ashwani Malhotra,[6] Karl Skorecki,[3] Pravin C. Singhal.[2] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Immunolgy and Inflammation, Fienstine Institute for Medical Research, New York, NY; [3]Rambam Health Care Campus, Haifa, Israel; [4]The Feinstein Institute for Medical Research, Manhasset, NY; [5]University of Hamburg, Hamburg, Germany; [6]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Progenitor cells play an important role to maintain podocyte (PD) homeostasis during podocyte cytotoxic environment. A subset of pareital epithelial cells (PEC) has been reported to act as progenitor cells for the maintenance of podocyte homeostasis. Down- regulation of microRNA (miR) 193a has been demonstrated to facilitate transition (acquirement of podocyte differentiatin markers) of cultured PECs. APOL1 is expressed intracellularly in podocytes, however, PECs do not express APOL1. APOL1 risk alleles (G1 and G2) have been reported to PD cytotoxic, however, the role of PD expression of APOL1G0 is far from clear. We hypothesize that APOL1 expression emerges in PECs to facilitate PECs transition through down-regulation of miR193a.

Methods: Human immortalized cultured PECs proliferate at 33°C and differentiate at 37°C. PECs were differentiated for variable time periods (4, 8, 12 days; n=4). To examine a causal relationship, PECs were transfected with either control or APOL1 siRNA and followed by differentiation at 37◦C (n=4). To study the feedback relationship between APOL1 and miR193a, PECs and Hep G2 cells (+ve control) were treated with different concentrations of an inhibitor of miR193a (25, 50, and 100 nM) followed by differentiation at 37◦C. To confirm the relationship between APOL1 and miR193a, HEK (human embryonic kidney) cells /mouse (M) PDs (-ve control for APOL1) were transfected with either control or APOL1 plasmids. Protein blots were probed for APOL1, WT1, podocalyxin, podocin, and reprobed for actin. RNAs were assayed for miR193a levels. To confirm binding of miR193a to the *APOL1* gene, RIP-ChIP assay was carried out.

Results: PECs started displaying APOL1 on day 4 during their transition at 37°C. APOL1 expression was associated with down- regulation of miR193a and enhanced expression of WT1, podocalyxin, and podocin. Knockdown of APOL1 up regulated (2 fold) miR193a levels in PECs and Hep G2, whereas, expression of APOL1 in HEKs and mouse podocytes down-regulated (2.5 fold) miR193a expression. Since miR193a also inversely up-regulated APOL1 expression, this suggests a feedback loop relationship in PECs. RIP-ChIP assay confirmed binding of miR193a to APOL1 gene promoter.

Conclusions: APOL1 facilitates PEC transition through down-regulation of miR193a.

Modulation of Epigenetics Preserves Podocyte Phenotype in HIV Milieu Vinod Kumar,[2] Kamesh R. Ayasolla,[1] Xiqian Lan,[1] Seyedeh Shadafarin Marashi Shoshtari,[4] Ashwani Malhotra,[5] Pravin C. Singhal.[3] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Immunolgy and Inflammation, Fienstine Institute for Medical Research, New York, NY; [3]North Shore LIJ Health System, Great Neck, NY; [4]The Feinstein Institute for Medical Research, Manhasset, NY; [5]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Epgenetics have been reported to play an important role in the development of HIV-Associated Nephropathy (HIVAN). Recent report demonstrated that epigenetic alterations upregulated podocyte expression of SNAIL in HIVAN. We hypothesize that HIV-induced podocyte SNAIL expression compromises podocyte integrity (loss of podocyte markers such as nephrin and p-cadherin), however, vitamin D receptor agonist (VDA) has the potential to reverse this effect of SNAIL in HIV milieu. In this scenario, VDA would not only down regulate podocyte expression of SNAIL but would also preserve podocyte phenotype in HIV milieu.

Methods: Renal tissues of 6- week old control, HIVAN (Tg26), and VDR agonist (VDA)- treated Tg26 (2 weeks) mice (4 mice in each group) and vector/human podocytes (V/HP) or HIV (NL4-3)-transduced human podocytes (HIV/HPs) (n=4) were evaluated for expression SNAIL, VDR, nephrin, and p-cadherin. ChIP assays was carried to confirm binding of SNAIL to nephrin promoter. Immunoprecipitation (IP) studies were carried out to analyze composition of SNAIL repressor complexes. Genomic DNA was isolated and CpG island methylation was measured in V/HPs and HIV/HPs

Results: Protein blots of renal tissues from HIVAN mice and HIV/HPs displayed enhanced expression of SNAIL but down regulation of nephrin, p-cadherin, and VDR. VDA partially preserved expression of nephrin in renal tissues of Tg26 mice as well as in HIV/HPs. Genomic DNA methylation studies confirmed hypermethylated CpG islands at Nephrin promoter in HIV/HPs. ChIP assay suggested that enhanced SNAIL expression by HIV/HPs was the consequence of histone 3 methylation at lysine (K) 4 residues (H3K4me3) on SNAIL promoter, whereas, down regulation of nephrin could be due to consequence of histone 3 methylation at lysine 27 residues (H3K27me3). Co-immunoprecipitation studies in lysates of HIV/HPs revealed the association of histone deacetylase (HDAC) 4, DNMT3b and DNMT1, mSin3A and EZH2 with SNAIL; conversely, VDA treatment of HIV/HPs decreased the expression of HDAC4, DNMT3B, DNMT1, mSin3A, and EZH2 (disruption of SNAIL complex).

Conclusions: VDA preserves podocyte nephrin expression through down regulation of SNAIL transcription, disruption of SNAIL repressor complex, and attenuation of methylation at H3K27 residues at nephrin promoter.

FR-PO238

Exogenous ApoL1 Alters Acidification and Trafficking of Endocytic Compartments in Human Podocytes John C. Edwards. *St. Louis University, Saint Louis, MO.*

Background: Variants in ApoL1 confer increased risk of certain types of chronic kidney disease in people of African ancestry. We assessed effects of exogenous wild type ApoL1 on immortalized human podocytes.

Methods: 6 His/T7-tagged recombinant ApoL1 was prepared by Ni affinity and gel filtration. Immortalized human podocytes were differentiated by growth at restrictive temperature for 2 weeks. Purified protein was added to serum-free culture medium at 5 μg/ml. Localization of exogenous ApoL1 was determined with confocal microscopy. Rates of endocytosis were determined by uptake of fluorescently labeled dextran or transferrin as assessed by flow cytometry. Endosomal acidification was assayed using confocal ratiometric fluorescence microscopy of living podocytes that had been loaded with dual labeled FITC/TRITC dextran.

Results: UPTAKE: Endocytic compartments of podocytes exposed to ApoL1 were labeled with fluorescently-tagged dextran or transferrin, then stained for ApoL1. ApoL1 infrequently colocalized with both dextran and transferrin in small endosomes. Transferrin also accumulated in large peripheral structures that stained for ApoL1 and were not present in cells not exposed to ApoL1. **ENDOCYTIC KINETICS:** Differentiated podocytes were exposed to FITC-labeled dextran or transferrin in the presence or absence of ApoL1 and uptake/cell determined. Dextran uptake was not significantly altered by ApoL1, but uptake of transferrin was significantly increased (P<0.00001 at 80 minutes of uptake). **ENDOSOMAL ACIDIFICATION: C**ells were exposed to ApoL1 for 1 hour prior to pulse loading with dual-labeled dextran. 24 minutes after endocytic loading, the fraction of endosomes with pH above 7 was 11% in the control cells and 56% in the ApoL1-treated cells (P<0.0001).

Conclusions: Exogenous ApoL1 is endocytosed by podocytes and accumulates in structures that colocalize with a recycling pathway marker. ApoL1 has little effect on endocytic kinetics of the fluid phase pathway, but increases accumulation of a marker of the recycling pathway. Exogenous ApoL1 induces accumulation of endosomes which fail to acidify. Taken together, the data are consistent with the hypothesis that endocytosed ApoL1 alters endosomal trafficking and acidification with selective effects on kinetics of the recycling pathway. Whether these properties vary among the disease associated variants remains to be determined.

Deubiquitinating Enzyme UCH-L1 Controls Dendritic Cell Cross Priming of the CD8+ T Cell Response Anna Reinicke,[4] Malte Mühlig,[6] Timo Lischke,[1] Christian Kurts,[3] Hans-willi Mittrücker,[2] Catherine Meyer-Schwesinger.[5] *[1]DRFZ, Berlin, Germany; [2]Institute for Immunology, Hamburg, Germany; [3]Institute of Experimental Immunology, Bonn, Germany; [4]University Clinic Eppendorf Hamburg, Hamburg, Germany; [5]University of Hamburg, Hamburg, Germany; [6]Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: The deubiquitinating enzyme Ubiquitin C-terminal Hydrolase-L1 (UCH-L1) is thought to regulate the intracellular pool of ubiquitin and is strictly required for the maintenance of axonal integrity in neurons. Within the kidney, UCH-L1 is *de novo* expressed in glomerular podocytes in human and rodent glomerulonephritis. Preliminary data demonstrate the expression of UCH-L1 in tubulo-interstitial cells of the kidney. Mice with constitutive UCH-L1-deficiency exhibit an exacerbated course of immune-complex nephritis suggesting that UCH-L1 affects the ability to mount an effective immune response in the kidney. Aims of this study were 1. To identify the origin of tubulo-interstitial UCH-L1-expressing cells in the kidney, 2. To analyze the immunologic phenotype of UCH-L1-deficient mice in response to a bacterial infection, 3. To analyze the role of UCH-L1 in dendritic cells for the degradation and cross-presentation of antigens by the ubiquitin proteasome system.

Methods: Mice with constitutive UCH-L1-deficiency were generated by Cre-Lox technology and back-crossed into the C57BL/6 background. The immunologic phenotype was investigated by challenging UCH-L1-deficient mice and dendritic cell-specific UCH-L1-deficient mice with *Listeria monocytogenes*. Cross presentation and cross priming assays were performed *in vitro* and *in vivo*. The dendritic cell (DC) phenotype and UCH-L1 expression was assessed in naïve and stimulated DCs by FACS, Western, proteasomal and deubiquitinase-based activity assays, and real-time PCR.

Results: In this study we show that UCH-L1 has an immunological function in DC antigen cross presentation. UCH-L1 is expressed in kidney, spleen, and bone-marrow derived DCs and its expression is regulated by the immune stimuli LPS and IFN-gamma. DCs from UCH-L1 knockout mice have reduced ability to cross present cell-associated antigens and mediate deficient CD8 T cell priming following Listeria infection while CD4 T cell priming is unaffected. Intriguingly, UCH-L1 colocalises with an ubiquitin selective segregase, VCP/p97 and in UCH-L1 knockout DCs, is strongly reduced suggesting a role for UCH-L1 in VCP/p97 dependent phagocytosis and sorting of ubiquitinated cargo in the endocytic pathway.

Conclusions: These results demonstrate a hitherto unrecognized role of UCH-L1 in DC-mediated immune responses.

Loss of Methylthioadenosine Phosphorylase Confers Malignant Potential in Renal Cell Carcinoma Ching-Hsien Chen,[1] Matthew Kyoshi,[1] David Yang,[1] Burl R. Don,[1] Robert H. Weiss.[2] *[1]UC Davis, Davis, CA; [2]UC Davis, Nephrology, Davis, CA.*

Background: Renal cell carcinoma (RCC) has emerged as a metabolic disease characterized by dysregulated expression of metabolic enzymes. Given that patients with metastatic RCC have an unusually poor prognosis, there is an urgent need to discover metabolic molecules useful for predicting malignant changes which will lead to RCC.

Methods: The Cancer Genome Atlas (TCGA) datasets were first analyzed to discover the potential metabolic molecules associated with RCC progression. We confirmed gene expression by immunohistochemistry, qRT-PCR and Western blots. Genetic manipulations were achieved by siRNA silencing, CRISPR and ectopic expression approaches. RCC cell invasion, migration and proliferation were determined by Boyden chamber, scratch and MTT assays. In addition, signaling pathway activity in RCC cells was assessed and compared through utilizing phospho-receptor tyrosine kinase arrays.

Results: Through an integrated two-step analysis of RCC metabolic pathways, we identified that methylthioadenosine phosphorylase (MTAP) and its substrate methylthioadenosine (MTA) are dysregulated in aggressive RCC. A decrease of MTAP expression was observed in RCC tissues and was correlated with tumor grade. We found that MTAP gene deletion was significantly associated with worse overall survival in

RCC patients (n=538). Genetic manipulation of MTAP studies demonstrated that MTAP expression inhibits epithelial-mesenchymal transition, invasion and migration of RCC cells. Surprisingly, an increase of sphere-forming ability was noted in MTAP-knockout RCC cells. Loss of MTAP resulted in an activation of the IGF1R-Src-STAT3 axis in RCC cells.

Conclusions: Our results suggest a novel role of MTAP in kidney disease and contribute to a better understanding of metabolic enzymes involved in RCC oncogenesis.

Cardiotrophin-Like Cytokine Factor 1 (CLCF1), Proposed Permeability Factor in FSGS, Attenuates Autophagy and Maintains p-STAT3 (Ser727) via Upregulation of Mammalian Target of Rapamycin (mTOR) Mukut Sharma,[3] Jianping Zhou,[3] Maohui Chen,[3] Alok De,[5] Ram Sharma,[4] Tarak Srivastava,[1] Ellen T. McCarthy,[6] Jean-francois Gauchat,[7] Virginia J. Savin.[2] *[1]Childrens's Mercy Hospital, Kansas City, MO; [2]KC VA Medical Center, Kansas City, AL; [3]KCVA Medical Center, Kansas City, MO; [4]Kansas City VA Medical Center, Kansas City, MO; [5]MBRF, Kansas City VAMC, Kansas City, MO; [6]University of Kansas Medical Center, Kansas City, KS; [7]University of Montreal, Montreal, AB, Canada*.

Background: Autophagy, a critical mechanism for survival of podocytes, is downregulated in FSGS. We showed that an affinity purified fraction (Gal-FS) of plasma of patients with recurrent FSGS (recFSGS) or CLCF1, a cytokine of the IL-6 family that we identified in Gal-FS, increases glomerular albumin permeability (P_{alb}) and upregulates JAK/STAT signaling. These effects are blocked by the heterodimer cytokine receptor-like factor1 (CRLF1)-CLCF1 (Trans Res 2015;166:384-398). Mechanism of CLCF1-induced damage to podocytes is not known. We hypothesized that monomeric CLCF1 and FSGS plasma/serum attenuate autophagy through upregulation of mTOR.

Methods: Galactose affinity chromatography was used to obtain Gal-FS containing CLCF1 detected by proteomic analysis using LC-MS/MS. Immortalized mouse podocytes were incubated (to 48h) with Gal-FS (<5μg protein), monomeric recombinant human CLCF1 (CLCF1,100 ng/mL), heterodimer CRLF1-CLCF1 (100-400ng/mL), Rapamycin (RAPA, ≥0.1μM) and activators/inhibitors at indicated concentrations. Cell morphology and expression of mTOR, STAT3 and autophagy molecules LC3s and other ATGs were determined using light/fluorescence microscopy and Western blot analysis.

Results: Gal-FS or CLCF1 increased phospho-mTOR (15min+) and total mTOR in a dose and time-dependent manner that was blocked by CRLF-CLCF1. CLCF1 blocked the RAPA-induced decrease in total mTOR (P<.05) and phospho-mTOR levels (P<.001). Replenishing CLCF1 at 24h further increased mTOR levels at 48h (P<.005). CLCF1 w/wo RAPA, downregulated MAP1 LC3B (ATG8), a marker of autophagy-related processes (P<.005). ATGs 3, 5, 6 (beclin) and 7 were also modulated by CLCF1. Further work showed that CLCF1 blocked (P<.002) the RAPA-induced downregulation (P<.001) of p-STAT3(Ser727 but not Tyr705) suggesting specific regulation of STAT3 by mTOR kinase activity. Ongoing work indicates that CLCF1 also alters the phosphorylation of ERK and AKT- key cellular regulators that interact with mTOR.

Conclusions: Monomeric CLCF1 changes cellular homeostasis through attenuation of autophagy process via upregulation of mTOR which, in turn, also modulates STAT3 function. This may contribute to long-term podocyte loss and glomerular damage in recFSGS.

FR-PO242

Podocyte-Specific Loss of Huwe1 Causes Vacuolization and Glomerular Damage Linus A. Volker,[2] Sabine Bertsch,[2] Sebastian Dittrich,[2] Markus M. Rinschen,[2,1] Bernhard Schermer,[2,1] Thomas Benzing,[2,1] Martin Höhne.[2,1] *[1]CECAD, Cologne, Germany; [2]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Cologne, Germany*.

Background: As terminally differentiated cells, podocytes rely on precise regulation of homeostasis and specific responses to cellular stress to forego cell damage and loss, which would ultimately lead to glomerular scarring and kidney disease. In an attempt to characterize the networks that regulate cell stress responses, we identified the E3-ubiquitin ligase Huwe1 via interaction screening. In other cell types, Huwe1 has been shown to be a regulator of a wide spectrum of intracellular signaling cascasdes such as MAPK/ERK, Wnt, DNA-damage and cell cycle controll.

Methods: We generated a podocyte-specific Huwe1-knockout mouse and a Huwe1-knockdown podocyte cell line to characterize the role of Huwe1 in podocyte stress response and homeostasis *in vivo* and *in vitro*.

Results: Huwe1-knockout mice were born at expected ratios. They showed signs of kidney disease beginning at 4 weeks of age. Affected mice weighed less than littermates, developed heavy proteinuria, and died prematurely of uremic complications. At ultrastructural level, we saw significant foot process effacement, podocyte vacuolization, and cell loss. We employed biochemistry and mass spectrometry to elucidate the effect of Huwe1-knockdown on podocyte signaling. No direct interactors of Huwe1 could be identified, most likely due to the transient nature of interaction of E3-ubiquitin ligases. Mass spectrometry revealed a significant differential regulation of protein networks associated with lysosome function and DNA-damage signaling. Fittingly, podocyte vesicles stained positive for Lamp1 indicating a lysosomal origin. Biochemical analyses showed a marked downregulation of mTOR signaling as a putative effector of vesicle formation. Experiments to elucidate the role of Huwe1 in DNA-damage response in podocytes are in progress.

Conclusions: We identified the E3-ubiquitin ligase Huwe1 at the center of crucial signaling cascades as an indispensable regulator of podocyte homeostasis. Future research will be directed at identifying direct Huwe1-targets in podocytes and potential therapeutic exploitability

FR-PO243

Inhibition of YAP Exacerbates Podocytes Apoptosis and Disease Progression in Adriamycin-Induced Focal Segmental Glomerulosclerosis Qiyuan Zhuang,[3] Fang Li,[1] Jianchun Chen,[4] Huijuan Wu.[2] *[1]AUGUSTA UNIVERSITY, AUGUSTA, GA; [2]Department of Pathology, School of Basic Medical Sciences, Fudan University, Shanghai, China; [3]Shanghai Medical College, Fudan University, Shanghai, China; [4]Vanderbilt University, Nashville, TN*.

Background: Focal Segmental Glomerulosclerosis (FSGS) is a common chronic glomerular disease with poor clinical outcomes, of which the main manifestation is nephrotic syndrome. Podocyte lost via apoptosis is one important mechanism underlying the pathogenesis of FSGS. Recently, Yes-associated-protein (YAP), one key downstream effector of Hippo pathway, was recognized as an activator for multiple gene transcriptional factors in nucleus to control cell proliferation, differentiation and apoptosis. However, the potential role of YAP activation in development and progression of FSGS remains unclear.

Methods: The localization, expression and phosphorylation of YAP were examined in kidney samples from patients with FSGS, adriamycin-induced FSGS mT/mG transgenic mouse model and the primary cultured podocytes treated with adriamycin.

Results: We first found that increases of podocyte apoptosis is closely correlated with the expression level of phospho-YAP at serine 397 which is associated with YAP degradation during the progression of FSGS. And then, we found that YAP distributed uniformly in the nucleus and cytoplasm in the podocytes of vehicle treated mouse kidney or in the primary cultured podocytes. Administration of adriamycin to the mice or exposure the primary cultures to adriamycin acutely induced YAP nuclear translocation, an indicator of YAP activation, followed by continuously exporting from the nucleus to the cytoplasm. Accordingly, our data also revealed that the expression of phospho-YAP at serine 127 in the podocytes was acutely decreased and then increased in response to Adriamycin treatment. In addition, administration of verteporfin, a YAP inhibitor, accelerated podocytes apoptosis and segmental glomerulosclerosis and deteriorated renal function in early phase after adriamycin treatment.

Conclusions: Our findings suggest that YAP activation in podocytes is an important endogenous anti-apoptotic mechanism during the progression of FSGS, and targeting YAP could be a potential therapeutic choice for treatment of FSGS.

FR-PO244

The Role of TLR4 in Hepatitis B Virus X Protein Induced Immunity Disorder in Renal Tubular Epithelial Cells Xuan Wang. *Shanghai Jiaotong University Affiliated First People's Hospital, Shanghai, China*.

Background: Hepatitis B virus X protein could activate inflammatory immune response, which may contribute to the pathogenesis of HBV-GN. How HBx change the function of renal tubular epithelial cells(RTECs) was unknown. We want to explore the role of TLR4 in immunity disorder of RTECs mediated by HBx.

Methods: C57BL/6J-TgN mice(6 week old) were randomly divided into the experimental group and the intervention group. C57BL/6J mice were used as normal control group. Mice of the intervention group were injected TLR4 shRNA lenti virus from 8-week old, and injected every four weeks. Serum and urine were collected at 8, 12, 16, 20, 24-week old. Mice were sacrificed at 24 week old to observe the mice renal function and pathological changes. HBx and TLR4 expression in renal tissue were observed by immunohistochemistry, and macrophages and T cells were also detected by immunohistochemistry. We constructed a HBx-overexpression plasmid and a TLR4 shRNA plasmid and transfected them into human proximal tubular epithelial cell line(HK-2). Flow cytometry was used to investigate the expression of MHC-II, CD40 on HK-2 cells. Mixed lymphocyte reaction was used to ddetect the ability of stimulating T cells proliferation. IFN-gamma and IL-4 in supernatant were determined by ELISA.

Results: Proteinuria of C57BL/6J-TgN mice increased from 16-week old, and renal function deteriorated up to 24 week-old. HBx and TLR4 expression was observed in tubular epithelial cells of C57BL/6J-TgN mice, and they had significant interstitial CD4+ T cells and macrophages accumulation. Mice with TLR4 shRNA lenti virus intervention appeared reduced proteinuria and remission of renal function and fewer CD4+ T cells and macrophages infiltration. After transfection of HBx gene, the expressions of MHC-II and CD40 in HK-2 cells were up-regulated, and IFN-gamma/IL-4 ratio increased. TLR4 shRNA transfection down-reagulated expression of MHC-II and CD40 on renal tubular epithelial cells, decreased ability of stimulating T cell proliferation and lowered ratio of IFN-gamma/IL-4.

Conclusions: HBx could stimulate HK-2 cells MHC-II and CD40 expression, functioning as nonprofessional antigen-presenting cells, and activate inflammatory immune response, which may contribute to the pathogenesis of HBV-GN. Inhibiton of TLR4 can depress immune function of tubular epithelial cells and have prevention and treatment effect.

Nrip2 Is Required for Endocytosis of Lrp6 and Wnt/β-Catenin Signaling Transduction in Zebrafish Pronephric Tubule Qing Hou,[1] Ling Wang,[2] Wei-bo Le,[5] Cai-hong Zeng,[5] Wei-song Qin,[4] Zhao-hong Chen,[5] Zhi-Hong Liu.[3] *[1]Jinling Hospital, Nanjing, China; [2]National Clinical Research Center of Kidney Disease, Jinling Hospital, Nanjing, China; [3]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing China, Nanjing, China; [4]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; [5]Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: Low-Density Lipoprotein Receptor-Related Protein 6 (LRP6) functions as a co-receptor for Wnt/β-catenin signaling and as a ligand receptor for endocytosis, which is implicated in pathogenesis of renal damage and transduction of Wnt/β-catenin signaling.

Methods: Here, we identified a nuclear receptor interacting protein 2 (nrip2) as being required for endocytosis of lrp6 in zebrafish. In zebrafish, nrip2 is dynamically and specifically localized in pronephric tubule.

Results: From 24 to 72hpf, nrip2 is dynamically expressed in distal tubule, proximal straight tubule and proximal convoluted tubule, which is examined by in situ hybridization. Global knockout of nrip2 in zebrafish by CRISPR/Cas9 genome editing approach leads to impaired low-molecular fluorescent dextran uptake in proximal tubule comparing with normal control, which is also companied by reduced amount of endocytic apparatus and cilia by Transmission Electron Microscope imaging, and decreased expression of EEA1, an early endosome antigen 1, by Immunoelectron Microscorpe. Interestingly, loss of nrip2 resulted in reduction of lrp6 expression, not lrp2a (megalin). Nrip2 knockdown in Tg(Tcf/Lef-mimiP:dGFP), expressing GFP under the control of β-catenin/TCF responsive elements, resulted in decreased GFP expression. Meanwhile, overexression of nrip2 in HK-2 cells activated total β-catenin and active β-catenin, which means nrip2 is required for activation of Wnt/β-catenin signaling.

Conclusions: Above all, we found that nrip2 is required for endocytosis of lrp6 and transduction of Wnt/β-catenin signaling. Next, we will investigate and demonstrate that Wnt/β-catenin signaling is activated by nrip2 through lrp6.

FR-PO246

Quantitative Proteomic Analysis of Induced Renal Tubular Epithelial Cells (iRECs) Sebastian Dittrich,[1] Thomas Benzing,[1] Soeren S. Lienkamp,[2] Michael Kaminski,[2] Markus M. Rinschen.[1] *[1]University Hospital Cologne, Cologne, Germany; [2]University Hospital Freiburg, Freiburg, Germany.*

Background: Reprogramming of differentiated cells into other cell types by forced expression of tissue specific transcription factors has been shown to be an effective tool to generate new cell models. iRECs are a renal epithelial cell line that has been reprogrammed from mouse embryonic fibroblasts (MEFs). While the cell line has been characterized at a genomic and transcriptomic level, proteomic studies still need to be performed to evaluate possible usage as an in vitro model.

Methods: We performed a proteomic mapping of proteins generated from iRECs and original MEFs. The method consists of protein solubilization, tryptic digestion and analysis of peptides by nLC-MS/MS on a quadrupole-orbitrap mass spectrometer.

Results: We mapped the iREC proteome and MEFs and quantified 5315 proteins using label-free quantification. The generated dataset was correlated with mRNA expression ("RNA-seq") data of microdissected rat kidney tubule segments. Consistent with previous transcriptome analysis, we found that iRECs expressed proteins from different segments of the tubule system, Henle loop and collecting ducts rather than resembling the expression profile of one specific segment. The iRECs had high abundance of mitochondrial proteins. In addition, the most strongly iREC-enriched proteins were the ligand- binding receptors Cubilin (Cubn) and Megalin (Lrp2) and its associated adaptor protein Disabled homolog 2 (Dab2), which mediate reuptake of albumin and other ligands. We furthermore found that iRECs expressed several soluble channels such as sodium bicarbonate transporter-like protein 11 (Slc4a11) which is highly expressed in the thin descending limb of Henle loop. Several subunits of V-type proton ATPase were highly expressed in iRECs as well as the transcription factors JunB and JunD.

Conclusions: Consistent with transcriptomic data, the iREC proteome does not resemble the protein expression profile of one single nephron segment. However, iRECs express several specialized segment specific proteins with high importance in physiological processes as well as for disease models. Especially the surprisingly high protein abundance of ligand-binding receptors Cubilin and Megalin could make this cell type a valuable new in vitro model for elucidating the yet unknown molecular signaling mechanisms of albumin reuptake in the proximal tubule of the nephron.

FR-PO247

Inhibition of Vasopressin Type 2 Receptor Signaling Suppresses Tumor Growth in Renal-Cell Carcinoma Sonali Sinha,[2] Nidhi Dwivedi,[1] Reena Rao.[1] *[1]University of Kansas Medical Center, Kansas City, KS; [2]university of kansas medical center, Kansas City, KS.*

Background: Renal cell carcinoma (RCC) accounts for 90% of all kidney cancers and is among the 10 most common cancers worldwide. Clear-cell and papillary-cell RCC represent 70-75% cases of all RCC. Clear cell RCC tumors originate from the renal proximal tubules that express vasopressin type 1 receptors (V_1R). However, in human clear cell RCC tumors we detected V_2R expression and V_2R mediated cell signaling. Since V_2R activity promotes cell proliferation in polycystic kidney disease, we hypothesized that V_2R activity is pathogenic in RCC, and V_2R inhibition can suppress tumor growth

Methods: In Caki-1 and 786-0 cells, we determined the effect of V_2R antagonist OPC31260 on cell viability, cell cycle, colonogenecity and cell migration. The effect of OPC31260 on tumor development was tested in female athymic nude mice. Mice were subcutaneously inoculated with a 100-µl suspension of Caki-1 cells. When tumor volume reached 80-100 mm^3 mice were randomized into groups (n=8) to receive vehicle or OPC31260, injected intraperitoneally daily for 28 days. Tumors volumes were measured and mice were weighed on alternate days. Tumors were harvested and weighed at the end of the study and portions were fixed in 10% formalin or snap frozen for protein and mRNA estimation.

Results: OPC31260 treatment dose dependently and significantly reduced cell viability, colony formation and cell migration. At higher doses of OPC31260, G2M cell cycle arrest was observed. In the mouse xenograft model, within 28 days of start of treatment, tumor volume increased by 9-folds in vehicle treated mice, while in the OPC31260 treated mice, less than 2-folds increase in tumor volume was observed. Tumor weights at sacrifice were 10- folds lesser in OPC31260 treated mice compared to vehicle treated mice. OPC31260 treatment significantly reduced pERK1/2 and pCREB levels compared to vehicle treated mice, suggesting suppression of V_2R signaling. Cell proliferation, detected by BRDU incorporation in the tumors was significantly reduced in OPC31260 treated mice and apoptosis detected by TUNEL assay was significantly high.

Conclusions: Vasopressin-V_2R signaling plays a pathogenic role in tumor progression in RCC and suppression of V_2R signaling by OPC31260 can suppress tumor growth in RCC. Hence V_2R is a novel target for therapy in RCC.

FR-PO248

Kidney Organoids Replicate Drug-Induced AKI in a Segment-Specific Manner Koichiro Susa,[1] Navin R. Gupta,[1,2] Joseph V. Bonventre,[1,2] Ryuji Morizane.[1,2] *[1]Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Harvard Stem Cell Inst, Cambridge, MA.*

Background: Drug-induced kidney injury is a serious problem in clinical settings and a major barrier to development of new drug candidates. Many nephrotoxicants are taken up into the cytoplasm through renal drug transporters such as organic cation/anion transporters (OCTs and OATs). These transporters, however, are generally not expressed in cell lines of immortalized human kidney tubules, a fact that markedly limits clinical translatability of drug screening systems *in vitro*. Recently, kidney organoids containing multi-segmented nephron epithelial cells have been generated from human pluripotent stem cells. These can to be used for drug screening as a novel technology using human cells.

Methods: Kidney organoids were differentiated from human ES and iPS cells by a previously established protocol. Organoids were exposed to various nephrotoxicants which induces segment specific injury: cisplatin, aristolochic acid (AA), tenofovir, puromycin aminonucleoside (PAN), adriamycin, and lithium. Drug transporter expression and kidney injury in organoids were evaluated by qRT-PCR and immunostaining and compared to a human kidney tubular cell line (HKC-8).

Results: qRT-PCR demonstrated marked expression of OCT2, OAT1 and 3, which are major renal drug transporters, in kidney organoids while HKC-8 cells showed much lower expression of these transporters. The organoids showed upregulated tubular injury markers such as KIM-1 and L-FABP after treatment with cisplatin, tenofovir, or AA, but not by PAN or lithium. Cimetidine and probenecid, which are inhibitors of OCT2 or OATs respectively, ameliorated the injury caused by cisplatin or tenofovir. Lithium caused significantly decreased expression of aquaporin 2 in kidney organoids. PAN and adriamycin induced severe morphological injury and decreased expression of nephrin in glomerulus-like structures of organoids, whereas cisplatin did not. On the other hand, HKC-8 treated with those nephrotoxicants did not exhibit significant change of tubular injury markers.

Conclusions: Kidney organoids faithfully mimic drug-induced tubular and glomerular injury, suggesting they will be useful for evaluation of nephrotoxicity of drugs and substantially superior to conventional nephrotoxicity screening method using cultured cells.

FR-PO249

An ATP/ADP Biosensor as a Real-Time Toxicity Assay in Kidney Organoids Pierre Galichon,[1] Koichiro Susa,[1] Navin R. Gupta,[1,2] Joseph V. Bonventre,[1,2] Ryuji Morizane.[1,2] *[1]Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Harvard Stem Cell Institute, Cambridge, MA.*

Background: Renal toxicity is frequent and a major limitation to drug development. Renal organoids have been generated from human pluripotent stem cells (hPSCs), overcoming limitations related to the expense and translatability of cell culture and animal experiments. Here, we present a novel system to evaluate the toxicity of drugs with a real-time biosensor of ATP/ADP ratio in kidney organoids.

Methods: Stable hPSC lines, expressing the ATP/ADP ratio PercevalHR, were established with lentiviral transduction and differentiated in kidney organoids as previously described. Organoids were used fresh or after freeze/thaw. ATP and ADP signal were acquired via live fluorescence microscopy, and a ratio was quantified with

the ImageJ RatioPlus plugin. Organoids were exposed to various toxicants (10 or 50 μM cisplatin, 10 mg/ml aristolochic acid (AA), 5 mM sodium azide (NaN3) or vehicle.

Results: The ATP and ADP signals were greater in nephron epithelial structures than in the stromal compartment and NaN3 induced a rapid decrease in ATP/ADP ratio within one minute. Cisplatin and AA significantly reduced the ATP/ADP ratio as compared to control organoids after 15 hours. Reduction in ATP/ADP ratios preceded contraction of the organoids.

Conclusions: Reduction in ATP/ADP ratio in kidney organoids is a sensitive indicator of drug toxicity, offering a direct live readout in human tissues *in vitro*. The unlimited availability of hPSC-derived organoids and the ability to freeze them at the pre-analytical stage is well-suited to high-throughput screening and might facilitate the identification of lead candidates during drug discovery.

FR-PO250

Laminar Flow Enhances Endothelial Differentiation from iPS Cells and Stabilizes Endothelial Cell Function Robin Bollin,[3] Yulia Kiyan,[1] Roman Kiyan,[2] Ulrich Martin,[3] Boris Chichkov,[2] Hermann G. Haller.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Laser Zentrum Hannover e.V., Hannover, Germany; [3]Medical School Hannover, Hannover, Germany.*

Background: Endothelial cells (ECs) have essential roles in organ development and regeneration, and therefore they could be used for regenerative therapies. However, generation of abundant functional endothelium from pluripotent stem cells has been difficult because ECs have limited proliferative potential and display vascular instability. Since stimulation of functional properties may enhance EC differentiation we have tested the hypothesis that laminar flow enhances EC differentiation and analyzed the underlying molecular mechanisms.

Methods: iPSC have been cultured under feeder free conditions for 3 passages, and then seeded in the Geltrex-coated microfluidic chips. Chips contained 4 parallel channels allowing simultaneous analysis of several experimental conditions. Mesoderm differentiation was induced by Bone morphogenetic protein 4 (BMP4) 30 ng ml^{-1}; Activin A 25 ng ml^{-1}; small-molecule inhibitor of glycogen synthase kinase-3β (CHIR) 1.5 μM; Vascular endothelial growth factor (VEGF) 50 ng ml^{-1} for 4 days. At day 4 of mesoderm differentiation microfluidic chips have been attached to the medium flow and stimulated with VEGF 50 ng ml^{-1}; TGF-β pathway small-molecule inhibitor SB431542 10 μM to induce EC differentiation. Static control chips have been stimulated with the same medium. After 3 days cells were fixed by perfusion with 2% PFA solution, and stained for Sox17, VE-Cadherin, CD31, and heparin sulfate. Confocal microscopy of the cells was performed directly in the microfluidic chips.

Results: Characteristic flow-oriented morphological changes have been observed in the cells incubated under flow but not under static conditions. Control iPSC without flow displayed a low rate of <1% EC differentiation after 3 days of stimulation. In contrast, iPSC cultivated under medium flow conditions showed a more rapid (50.8 ± 4.1% after 3 days) and sustained differentiation to EC. Cells demonstrated expression of EC-markers CD31 and VE-Cadherin, and expressed heparin sulfates on the apical side of the cells indicating terminal differentiation.

Conclusions: Laminar shear stress may directly activate growth factor receptors on stem/progenitor cells, initiating signaling pathways leading toward endothelial cell differentiation. Our results suggest that laminar flow is an important factor in endothelial cell differentiation protocols.

FR-PO251

RAD51 Inhibition Exacerbates Injury in a Human Pluripotent Stem Cell-Derived Nephron Organoid Model in Which Repetitive DNA Damage Models Acute Injury and Transition to Fibrosis Navin R. Gupta,[1,2] Edgar Garcia,[1] Tomoya Miyoshi,[1] Koichiro Susa,[1] Ryuji Morizane,[1,2] Joseph V. Bonventre.[1,2] *[1]Brigham and Women's Hospital, Cambridge, MA; [2]Harvard Stem Cell Institute, Cambridge, MA.*

Background: Tubular DNA damage has been demonstrated to play a central role in tubulointerstitial crosstalk, implicated in the pathogenesis of kidney injury and fibrosis. Unlike traditional cell culture techniques, human pluripotent stem cell (hPSC)-derived nephron organoids contain multiple compartments representing glomeruli, proximal and distal tubules, and an interstitium. Following interstitial characterization, the organoid's response to cisplatin, a known nephrotoxicant that induces proximal tubular (PT) DNA damage, may enable the study of DNA damage response (DDR) and interactions between the tubular and interstitial compartments *in vitro.*

Methods: Nephron organoids were treated with twice weekly, 24 hour periods of cisplatin (5μM) for 5 treatments. Following each treatment, samples and controls were gathered for immunostaining and qRT-PCR. Flow cytometric gating on LTL-fluorescein determined the preponderance of PTs in nephron organoids. B02 was used at 5μM for continuous inhibition of RAD51, a DDR element for double strand break (DSB) repair.

Results: PDGFR-β^+ $desmin^+$ cells (pericytes) and PDGFR- β^+ $desmin^-$ cells (fibroblasts) comprise the interstitium of nephron organoids, in a similar distribution and ratio as in our human nephrectomy samples. Following acute injury with cisplatin, LTL^+ PT cells manifested preferential DSBs, entered the cell cycle, expressed luminal KIM-1, underwent mesenchymal dedifferentiation, and were associated with $PTEN^+NCAM^+$ peritubular interstitial cells. Following repeated cisplatin injury, LTL^+ cells had a reduced brush border, arrested at the G2/M DNA damage checkpoint, and pro-inflammatory cytokines were upregulated on organoid lysates. With further injury, peritubular interstitial cells transdifferentiated into myofibroblasts and fibronectin and collagen I accumulated in the interstitial space. B02, a RAD51 inhibitor, exacerbated proximal tubular G2/M arrest and interstitial fibrosis.

Conclusions: Inhibition of RAD51 augmented injury in nephron organoids treated with repetitive cisplatin, implicating DDR in the pathogenesis of kidney fibrosis. As an effective human model system *in vitro*, nephron organoids can be exploited to understand mechanisms of injury and repair and screen anti-fibrotic therapeutics.

FGFs Are Required for Stem Cell Recruitment to Nephrogenic Aggregates during Adult Zebrafish Kidney Regeneration Thomas F. Gallegos, Caramai N. Kamei, Iain A. Drummond. *Massachusetts General Hospital, Boston, MA.*

Background: In zebrafish, adult kidney injury (AKI) results in stem cell-mediated regeneration by the *de novo* production of new nephrons. This process occurs by progenitor cell aggregation and differentiation on kidney collecting ducts, leading to the insertion of new nephrons. Expression of *dusp6*, a transcriptional readout of FGF signaling, was induced upon AKI, suggesting a role for FGF signaling in new nephron formation. Early broad *dusp6* expression became restricted to single cells and ultimately to nephrogenic aggregates abutting mature collecting ducts. In addition to *dusp6*, nascent nephrons are marked by expression of *lhx1a*. After gentamicin-induced AKI, pharmacological or dominant-negative based genetic inhibition of FGFR signaling completely prevented recruitment of progenitor cells to *dusp6* and *lhx1a*-expressing nephrogenic aggregates. In juvenile *Tg(lhx1a:egfp)* zebrafish treated with FGFR inhibitor during developmental nephrogenesis, progenitor cells survive but fail to condense into organized aggregates. Upon kidney injury, expression of *fgf4*, *fgf8a*, *fgf10a*, and the receptors *fgfr1* and *fgfr4* were induced, suggesting multiple roles for FGF signaling in the formation of nephrogenic aggregates from single cell progenitors. By qPCR of fractionated kidneys, *fgf4* and *fgf10a* were found to be specifically expressed in the tubular fraction of the injured kidney, suggesting that these ligands may play a role in recruiting nephrogenic cells to injured tubules. *fgf8a* expression was restricted to the most distal end of the nephrogenic aggregate, suggesting a role in patterning the new nephron aggregate. Our results demonstrate essential roles for FGF in recruitment of progenitor cells and patterning of nephrogenic aggregates during kidney regeneration in the adult zebrafish.

Effect of Integrin Signaling Blockade on Self-Renewal and Differentiation of Human Nephrogenic Progenitors In Vitro Astgik Petrosyan,[1] Sinem Karg?n,[1] Matthew E. Thornton,[2] Brendan Grubbs,[2] Roger E. De Filippo,[1] Laura Perin,[1] Stefano Da Sacco.[1] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Background: Mammalian kidney development is controlled through the proliferation and differentiation of a specific population of nephron progenitors (NP) characterized by the expression of CITED1 and SIX2. The mechanisms regulating the balance between self-renewal and renal differentiation in NP are still elusive, impairing our ability to effectively expand NP in vitro for long term. In particular, the effects of extracellular matrix (ECM) composition and ECM-NP interaction are poorly understood.

Methods: We have investigated the relationship between ECM and self-renewal traits in NP isolated from human fetal kidneys (hFK). NP were isolated using our established RNA Smartflare protocol. Nephrogenic characteristics were confirmed by RNA-seq and nephrogenic potential by in vitro differentiation and dissociation/reaggregation assays. By immunofluorescence we have characterized the ECM present within the nephrogenic niche of hFK. Subsequently we have tested NP expansion on these ECM substrates and assessed effects on signaling cascade by PCR array.

Results: Among others, laminin alpha 5, collagen 16 and collagen 18 where found to be highly expressed within the cap mesenchyme of developing hFK. In vitro, laminin was confirmed to better preserve self-renewal properties in NP, as confirmed by maintenance of higher co-expression of SIX2 and CITED1 in cultured NP, both in short and long term experiments. Interestingly, blocking integrin mediated ECM-NP interaction with specific antibodies lead to an increase in SIX2 and CITED1 co-expression, suggesting an important role of integrin mediated signaling pathway on balance between renal specification vs self-renewal. Effect of integrin blocking in NP on downstream WNT signaling was further confirmed by PCR array, suggesting a direct role of ECM-NP interaction on self-renewal.

Conclusions: Our data indicate a strong link between ECM-NP during human renal development. NP-laminin interaction appears to play an essential role on nephron endowment by directly controlling self-renewal/differentiation balance. These results could provide not only a tool for the optimization of in vitro NP expansion but also a platform to advance our understanding of human renal development and nephron cell commitment.

FR-PO254

A New Inducible Aqp2ECE System Reveals the Self-Renewal and Multipotentiality of Aqp2+ Progenitor Cells in Adult Mouse Kidneys Lihe Chen,[1] Ye Zhang,[2] Chao Gao,[2] Long Zhang,[2] Enuo Chen,[2] Wenzheng Zhang.[2] *[1]NIH, Bethesda, MD; [2]Albany Medical College, Albany, NY.*

Background: Stem cells are defined by unlimited self-renewal capacity and pluripotentiality. Progenitor cells have pluripotentiality, but no or limited self-renewal potential. Using *Aqp2Cre* driver, we previously showed that embryonic Aqp2$^+$ progenitor cells generate all known cell types in the connecting tubule/collecting duct. However, the constitutive *Aqp2Cre* driver cannot be used to assess adult Aqp2$^+$ progenitor cells.

Methods: Here, we report a new inducible *Aqp2ECE* knock-in mouse model, which allows us to demonstrate the self-renewal and multipotentiality of Aqp2$^+$ progenitor cells in adult kidneys. *Aqp2ECE* was created by inserting a cassette expressing a specific Cre fusion at the ATG of the endogenous *Aqp2* locus and used to generate *Aqp2ECE Rainbow* mice.

Results: Without Tamoxifen induction, no fluorescence proteins were detectable at P1, P23, and P42. In kidneys induced with Tamoxifen (4 mg/20g BW) at P42 and examined at P63, seldom and isolated individual cells expressing one of 4 fluorescence proteins (XFP$^+$, where X=G, R, C, or Y) were observed. Double and triple immunofluorescence (IF) staining revealed that all RFP$^+$ and GFP$^+$ cells were also Aqp2$^+$, with none of them having detectable expression of V-ATPase B1B2. In mice induced with Tamoxifen at P23 and P69, treated with dietary LiCl (40 mmol lithium/kg food) at P95 for 18 days, and examined at P113, there were clones of 2-5 cells expressing the same fluorescence protein without interruption by any single cell of another color. While the majority of the GFP$^+$ and RFP$^+$ cells remained Aqp2$^+$, some of them lost Aqp2 expression and gained expression of V-ATPase B1B2, AE1 or Pendrin, indicating conversion of "principal" cells to intercalated cells. Some GFP$^+$ and RFP$^+$ cells displayed an intermediate state and characterized by being positive for both a principal (Aqp2$^+$) and an intercalated cell marker (V-ATPase B1B2, AE1, or Pendrin).

Conclusions: We conclude that 1) *Aqp2ECE* has 0% leakiness (100% dependence of Cre recombinase activity on Tamoxifen), noticeable inducibility, and 100% fidelity in recapitulating the endogenous *Aqp2* expression; 2) Rare Aqp2$^+$ progenitor cells exist in adult mouse kidney, possess self-renewal and multipotentiality, and function in kidney maintenance and lithium-induced remodeling. Long-term chasing is underway to confirm and extend these findings.

Adipose Tissue-Derived Stem Cells (ASC) Reverses Kidney Disease Progression in SHR Rats Induced to Metabolic Syndrome Marcelo C. Batista,[1] Renata Nakamichi,[2] Camila N. Oliveira,[1] Mario luis R. Cesaretti,[2] Maria Dalboni,[2,3] Beata M. Quinto.[1] *[1]UNIFESP, São Paulo, Brazil; [2]Universidade Federal de São Paulo, Santo André, Brazil; [3]Uninove, Sao Paulo, Brazil.*

Background: Visceral obesity, the physiopathological basis of Metabolic Syndrome (MS), determines a set of metabolic abnormalities linked to increased risk of kidney disease in the overall population. The excessive expansion of visceral adipose tissue, resulting in hypertrophied adipocytes is implicated in the development of hypoxic environment and increases inflammatory proteins. The adipose tissue is also considered an important source of stem cells which are able to proliferate and differentiate into multiple cell lines reducing the expression of inflammatory proteins. The aim of the study is to evaluate the treatment of the kidney disease progression in SHR rats induced to MS with ASCs.

Methods: SHR rats were induced to MS by hyperlipid/hypercaloric diet for 12 weeks, and then treated with injection of 2x10^5 ASC for 1 and 2 weeks, respectively. After this period, rats were sacrificed for analysis of albuminuria, as well as kidney function (serum concentration of creatinine and Cystatin C, and urinary NGAL) for comparison with baseline parameters. The characterization of ASC extracted from subcutaneous tissue of SHR control rats was performed through flow cytometry method.

Results: Previous analysis has shown that ASC expressed the cell surfaces markers: CD34, CD35, CD90 and CD105, confirming its characterization in adipocyte. Our results demonstrated a statistically significant deterioration of lipid profile, as shown by decrease in HDL-c and increase in triglycerides and total cholesterol, on those animals induced to MS when compared with the control group (CT). This adverse lipid profile was reversed on those MS-induced animals treated with stem cells. Parallel with the induction of MS, we observed the development of kidney disease as shown by the enhancement in albuminuria as well as an increase in creatinine, Cystatin C and Ngal concentrations among those rats induced to MS. Similarly with lipid profile, we could also evidence a reversion of kidney disease progression through the improvement in the above mentioned kidney disease parameters, among the MS-Induced rats treated with adipose tissue-derived stem cells.

Conclusions: Adipose tissue-derived stem cells reversed Metabolic Syndrome related kidney disease progression in SHR rats.

FR-PO256

Mesenchymal Stem Cells Cultured in Serum-Free Medium Ameliorate Experimental Renal Fibrosis by Their Strong Immunosuppressive Effects Ken Yoshida,[1] Ayumu Nakashima,[1,2] Shigehiro Doi,[1] Toshinori Ueno,[1] Yukio Kato,[2,3] Yukihito Higashi,[4] Takao Masaki.[1] *[1]Nephrology, Hiroshima University Hospital, Hiroshima, Japan; [2]Stem Cell Biology and Medicine, Graduate School of Biomedical & Sciences, Hiroshima University, Hiroshima, Japan; [3]TWOCELLS Company, Limited, Hiroshima, Japan; [4]Cardiovascular Regeneration and Medicine, Research Institute for Radiation Biology and Medicine, Hiroshima University, Hiroshima, Japan.*

Background: The mechanism underlying the anti-inflammatory effect of mesenchymal stem cells (MSCs) has been elucidated. However, the anti-inflammatory effect of MSCs cultured in serum-free medium has not been clarified. Here we examined the effects of MSCs cultured in serum-free medium on infiltration of inflammatory cells and interstitial fibrosis induced by unilateral ureteral obstruction (UUO) operation in rats.

Methods:

Results: At 4 days post-UUO operation, we injected rat MSCs cultured in 10% fetal bovine serum containing DMEM (10%MSCs) or serum-free medium (SF-MSCs) or PBS only (control) through the tail vein. Although retention of MSCs collected from green fluorescent protein-positive rats was only observed for 3 days with no difference between 10%MSCs and SF-MSCs, immunohistochemistry revealed that SF-MSCs strongly ameliorated infiltration of macrophages and interstitial fibrosis. Next we examined whether serum-free culture conditions enhanced the anti-fibrotic and immunosuppressive effects by paracrine manners. Incubation of cultured human kidney-2 cells in human MSC-conditioned medium suppressed transforming growth factor-β1-induced phosphorylation of Smad2 and α-smooth muscle actin, but there was no significant difference in culture from 10%MSCs and SF-MSCs. Co-cultures of human MSCs and human monocytic THP-1 cell-derived pro-inflammatory phenotype (M1) macrophages using a transwell system showed significant increases in cells positive for CD163 and CD206, immunomodulatory phenotype (M2) macrophage markers, in SF-MSCs compared with 10%MSCs.

Conclusions: These results show that transplantation of MSCs cultured in serum-free medium ameliorated infiltration of inflammatory cells and renal fibrosis in UUO rats compared with MSCs cultured in serum containing medium, in part by enhancement of M2 macrophage polarization from MSCs cultured in serum-free medium. The replacement of serum containing medium of MSCs to serum-free medium is thought to reduce the risk of infections, and transplantation of MSCs cultured in serum-free medium may help alleviate renal diseases in which inflammation plays a critical role.

FR-PO257

Amniotic Fluid-Derived Mesenchymal Stem Cells (AFSCs) Are Renoprotective in Established Experimental CKD Rita de Cassia Cavaglieri,[1,2] Thalita Prado,[1] Luísa Albuquerque,[1] Marcelo Zugaib,[3] Sergio P. Bydlowski,[2] Irene L. Noronha.[1] *[1]Cellular and Molecular Nephrology Lab, University of São Paulo, São Paulo, Brazil; [2]Genetics and Molecular Hematology Lab, University of São Paulo, São Paulo, Brazil; [3]Obstetrics and Gynecology, University of São Paulo, São Paulo, Brazil.*

Background: AFSCs are a class of stem cells that present characteristics intermediate between embryonic stem cells (ESC) and adult mesenchymal stem cells (MSC). Given that the amniotic fluid consists of fetal urine, stem cell populations present in the amniotic fluid are likely derived from the fetal kidney. These characteristics have aroused great interest in the potential protective effects of AFSCs in renal diseases. The aim of this study was to analyze the effects of AFSCs in an experimental model of CKD, the 5/6 nephrectomy (Nx) model, after the disease has been established, in order to more closely resemble the clinical settings in humans.

Methods: Human AFSCs were isolated from second trimester amniocentesis samples by plastic adhesion and characterized as MSC. Male Wistar rats (n= 38) underwent 5/6 Nx or were Sham-operated. After 15 days, 14 rats were euthanized and renal disease was confirmed (**Nx-15d**). In subsequent experiments, the remaining 31 rats received $5x10^5$ AFSCs or saline, injected under the kidney capsule, and were followed for an additional 15 days. These rats were divided into 4 groups: **Sham 30d**, **Sham+AFSC 30d**, sham rats receiving AFSCs; **Nx,** 5/6 nephrectomy; and **Nx+AFSC**, Nx rats receiving AFSCs. The table shows the parameters analyzed.

Results: Nx rats with established CKD and treated with AFSCs displayed significant reductions in blood pressure, albuminuria and glomerulosclerosis. In addition, they showed lower expression of α-SMA and ED-1, as well as higher expression of WT-1, in comparison with untreated Nx rats.

Conclusions: These results demonstrate that inoculation of AFSCs ameliorate renal disease in established chronic kidney disease.

Lithocholic Acid Increases Plasma Levels of FGF23 Nobuhiro Hashimoto, Isao Matsui, Daisuke Mori, Ayumi Matsumoto, Karin Shimada, Satoshi Yamaguchi, Keiichi Kubota, Tatsufumi Oka, Sayoko Yonemoto, Yusuke Sakaguchi, Takayuki Hamano, Yoshitaka Isaka. *Osaka University Graduate School of Medicine, Suita, Japan.*

Background: The phosphate sensing mechanisms remain unresolved. Oral phosphate load can increase fibroblast growth factor 23 (FGF23) without affecting serum levels of phosphate. Vitamin D receptor (VDR) plays important roles in the regulation of FGF23. In addition to active vitamin D, lithocholic acid (LCA), a secondary bile acid, can activate VDR. Therefore, we examined effects of LCA on FGF23.

Methods: Vitamin D receptor knockout (VDR-KO) mice and their wild type (WT) littermates were maintained on rescue diet (20% lactose, 2% Ca, 1.25% P). Mice fed with diet containing 0.2% cholic acid (CA), chenodeoxycholic acid (CDCA), deoxycholic acid (DCA), or lithocholic acid (LCA) were analyzed. Effects of bile acids *in vitro* were analyzed by using UMR106 cells. Gut flora of phosphate loaded mice were analyzed by PCR.

Results: Orally administered LCA elevated plasma intact FGF23 (WT-control 97 ± 35 vs. WT-LCA 204 ± 62 pg/mL, *P* <0.001). The other bile acids did not affect plasma iFGF23. LCA increased urinary phosphate, whereas serum phosphate was not changed. In VDR-KO mice, whose serum calcium levels were corrected to normal range by the rescue diet, the effects of LCA were completely abrogated. Real time PCR analyses of the WT mice demonstrated that LCA upregulated mRNA of FGF23 in the bone. We also found that LCA upregulates mRNA levels of FGF23 in cultured UMR 106 cells. Because serum 1,25-dihydroxyvitamin D was suppressed by LCA in the WT mice, it was indicated that LCA *per se* elevated FGF23 in a VDR-dependent manner. We examined serum creatinine and urinary N-acetyl-β-D-glucosaminidase levels because kidney function is a critical determinant of plasma FGF23. LCA did not worsen kidney function. Dietary phosphate load increased fecal Firmicutes XIVa, an intestinal bacteria that produces secondary bile acid.

Conclusions: Oral administration of LCA elevates FGF23 in a VDR-dependent manner. The change in gut microbiota may contribute to the phosphate sensing mechanism.

FR-PO259

Erythropoietin Is a Major Determinant of C-Terminal Fibroblast Growth Factor 23 Michele F. Eisenga, Martin H. De Borst, Maarten A. de Jong, Stephan J. Bakker, Carlo A. Gaillard. *University Medical Center Groningen, Groningen, Netherlands.*

Background: An increased plasma level of the phosphaturic hormone fibroblast growth factor 23 (FGF23) is an independent risk factor for mortality and allograft loss in renal transplant recipients (RTR). Similarly, high erythropoietin (EPO) levels increase the risk of adverse outcomes in RTR. Here, we investigated whether EPO modulates C-terminal FGF23 (cFGF23) and intact FGF23 (iFGF23) in RTR and chronic kidney disease (CKD) patients.

Methods: Plasma cFGF23 and iFGF23 were measured with ELISA in two single-center RTR cohorts. Serum EPO levels were measured on Immulite 2000 assay. Statistical analyses were performed using univariable linear regression followed by stepwise backward linear regression. Additionally, we assessed the effect of exogenous EPO on FGF23 in a post-hoc analysis of a randomized trial in CKD patients who received exogenous EPO (50 IU/kg/wk) for 52 weeks (EPOCARES, Eur J Heart Fail 2010;12:943-50) using linear mixed models.

Results: We included 680 stable RTR (age 53±13 years; 56% males at 5.4 (1.9-12.1 years after Tx). Median [IQR] cFGF23 was 140 (95-234) RU/ml, median iFGF23 was 61 (43-100) pg/mL, EPO was 6.9 (4.2-11.2) IU/L, and mean eGFR was 47±16 ml/min/1.73m2. In univariable analysis, EPO was a major determinant of cFGF23 (ß=0.24, *P*<0.001), but not of iFGF23 (ß=0.04, *P*=0.35). Upon multivariable analysis, EPO remained a major determinant of cFGF23 (ß=0.20, *P*<0.001), independent of known determinants including phosphate (ß=0.19, P<0.001), hemoglobin (ß=-0.13, P<0.001), and eGFR (ß =-0.35, P<0.001). In an independent replication cohort of 598 RTR, EPO was also a major determinant of cFGF23, independent of potential confounders (ß=0.22, *P*<0.001). Finally, in 56 CKD patients, exogenous EPO was significantly associated with an increase in cFGF23 (*P*=0.04), but not iFGF23 (*P*=0.21).

Conclusions: Serum EPO levels are a major, potentially modifiable independent determinant of serum cFGF23 in RTR, independently of known correlates including eGFR and phosphate. In CKD patients, exogenous EPO increased cFGF23 levels. We found no relationship between EPO and iFGF23 in either analysis. Our data suggest that EPO resistance, or an underlying mechanism, is related to FGF23 processing in CKD and after kidney transplantation.

FR-PO260

Acute Blood Loss Stimulates Fibroblast Growth Factor 23 Production Seham M. Rabadi,[2] Ikemesit Udo,[2] David E. Leaf,[1] Sushrut S. Waikar,[1] Marta Christov.[2] *[1]Harvard Medical School, Boston, MA; [2]New York Medical College, Valhalla, NY.*

Background: Fibroblast growth factor 23 (FGF23) production is upregulated by iron deficiency and hypoxia. The influence of acute blood loss and erythropoietin on FGF23 production is unknown.

Methods: Using wild-type C57BL/6 mice we determined the effect of acute loss of 10% total blood volume on Fgf23 mRNA expression in bone and circulating total FGF23 protein levels (measured by the c-terminal assay, cFGF23) and other markers of mineral metabolism. We also measured plasma cFGF23 levels in 131 critically ill patients admitted to the intensive care unit to assess the association with number of blood transfusions as an indicator of acute blood loss.

Results: We found that acute blood loss leads to an increase in plasma cFGF23 levels 3-5 fold within six hours, while plasma levels of intact FGF23, phosphate, calcium, parathyroid hormone, iron, and ferritin remain similar to control mice without acute blood loss. Volume resuscitation with PBS did not significantly alter these findings. The increase in plasma cFGF23 levels in bled animals was accompanied by increased plasma erythropoietin levels at 6 hours. Administration of erythropoietin led to an acute increase in plasma cFGF23 levels similar to that observed in acute blood loss. Fgf23 mRNA expression was increased 20-fold in bone marrow, but not in bone, of bled versus control mice, suggesting bone marrow as a key source of elevated plasma FGF23 levels following acute blood loss. To extend these findings to humans, we measured plasma cFGF23 levels in 131 critically ill patients. In univariate and multivariate models, we found a positive association between number of red blood cell transfusions, an indirect indicator of acute blood loss, and plasma cFGF23 levels.

Conclusions: We conclude that FGF23 production is rapidly increased after acute blood loss, and that erythropoietin may be the mediator of this increase. Thus, erythropoietin may represent a novel physiologic regulator of FGF23 production.

FR-PO261

Ratios of Parathyroid Hormone, Fibroblast Growth Factor 23, and 1,25-Dihydroxylvitamin D and CKD Progression Adeera Levin,[2] Ognjenka Djurdjev,[1] Mila Tang,[5] Claudia Zierold,[3] Frank A. Blocki,[3] Fabrizio Bonelli,[3] Myles S. Wolf.[4] *[1]BC Renal Agency, Vancouver, AB, Canada; [2]UBC, Vancouver, BC, Canada; [3]DiaSorin, Stillwater, MN; [4]Duke University, Durham, NC; [5]St. Paul's Hospital, Vancouver, BC, Canada.*

Background: Patients with CKD experience variable rates of progression. Ratios of parathyroid hormone (PTH(1-84)), fibroblast growth factor 23 (FGF23) and 1,25-dihydroxylvitamin D ($1,25(OH)_2D$) describing relative values of important hormonal systems and renal tubular function that provide insight into risk of CKD progression.

Methods: We examined data from CanPREDDICT, a prospective CKD pan-Canadian cohort from 2008-2013, followed biannually for 5yrs, with adjudicated outcomes. PTH(1-84), intact FGF23 and $1,25(OH)_2D$ were evaluated at baseline using precise new assays (Diasorin Inc), on the LIAISON XL analyzer. We used Cox proportional hazards to examine composite renal events (CRE) defined by need for renal replacement therapy or 50% decline of baseline eGFR, adjusted for age, sex, BP, weight, eGFR, ACR, Alb, PO_4, HCO_3, Ca, Hgb and K+ (base). Univariate and multivariate adjusted HRs were calculated per one standard deviation increments using natural log-transformed variables where appropriate.

Results: The study cohort included 1784 pts with a median follow-up of 41 months; mean age of 68yrs; 62% males; and mean eGFR of 28 ml/min/1.73m² (19% <20ml/min, 42% 20-29ml/min and 39% 30-45mil/min). There were 429 (24%) CRE. Higher PTH(1-84) and FGF23 levels, and lower $1,25(OH)_2D$ and ratios of $1,25(OH)_2D$/PTH(1-84) and $1,25(OH)_2D$/FGF23 precited significantly higher risk of CRE in unadjusted and adjusted analyses [p<0.01; Figure 1a]. The corresponding category-free net reclassification indices [95%CI] were 13.5%[-0.2 to 32.3%], 6.2%[-8.1 to 22.9%], 6.2%[-11.4 to 26.9%], 17.6%[-1.7 to 34.4%], and 2.8%[-13.6 to 20.0%] respectively.

Conclusions: High levels of PTH(1-84) and FGF23 predict higher risk of CRE; higher levels of $1,25(OH)_2D$ may be protective against CRE. The ratio of these may offer better insights than any one value alone. Further study of individual and combinations of biomarker levels is needed.

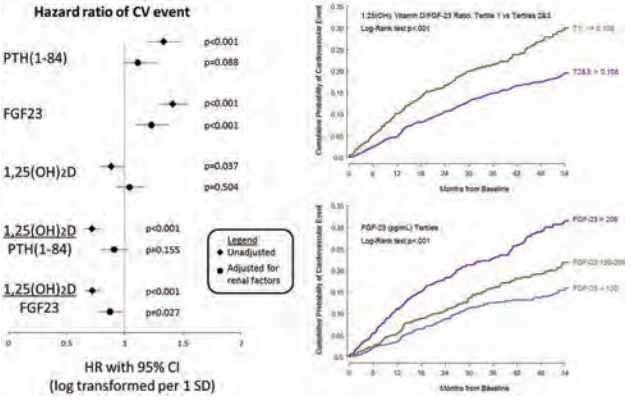
Ratios of Parathyroid Hormone, Fibroblast Growth Factor 23, and 1,25-Dihydroxylvitamin D and Cardiovascular Events Adeera Levin,[5] Ognjenka Djurdjev,[1] Mila Tang,[5] Claudia Zierold,[2] Frank A. Blocki,[3] Fabrizio Bonelli,[6] Myles S. Wolf.[4] *[1]BC Renal Agency, Vancouver, AB, Canada; [2]DiaSorin, Stillwater, MN; [3]DiaSorin INC, Stillwater, MN; [4]Duke University, Durham, NC; [5]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [6]diasorin spa, Stillwater, MN.*

Background: Abnormal calcium homeostasis in patients with CKD may impact vascular health. Ratios of parathyroid hormone (PTH(1-84)), fibroblast growth factor 23 (FGF23) and 1,25-dihydroxylvitamin D ($1,25(OH)_2D$) may provide insight into imbalances in the system and its relation to cardiovascular events (CVE).

Methods: We examined data from CanPREDDICT, a prospective CKD pan-Canadian cohort from 2008-2013, followed biannually for 5yrs, with adjudicated outcomes. PTH(1-84), intact FGF23 and $1,25(OH)_2D$ were evaluated at baseline using precise new assays (Diasorin, Inc.). We used Cox proportional hazards to examine adjudicated CVE, adjusted for age, sex, diabetes and CVE history, BP, weight, eGFR, ACR, Alb, PO_4, HCO_3, Hgb, and ASA, ACEi, beta-blocker medications. Univariate and multivariate-adjusted HRs were calculated per 1 standard deviation increments using natural log-transformed variables where appropriate.

Results: The study cohort included 1789 pts with a median follow-up of 48 mo; mean age of 68yrs; 62% males; and mean eGFR of 28 ml/min/1.73m² (19% < 20ml/min, 42% 20-29ml/min and 39% 30-45ml/min). 44% of patients had history of CV disease and 46% had diabetes. 339 (19%) patients experienced CVE. Higher FGF23 levels, and lower $1,25(OH)_2D$ /FGF23 predicted significantly higher risk of CVE in unadjusted and adjusted analyses [p<0.01; Figure 1a]. The corresponding category-free net reclassification indices [95%CI] were 5%[-0.8 to 23.8%], and 7.7%[-6.4 to 20.2%] respectively.

Conclusions: High levels of FGF23 and lower $1,25(OH)_2D$/FGF23 predict higher risk of CVE. Further study of individual and combinations of biomarker levels is needed.



FR-PO263

Increased FGF23 Production in CKD Is Associated with Altered Osteocyte Development and Bone Mineralization Corey Dussold,[1] Samantha Neuburg,[1] Ying Liu,[2] Jian Feng,[2] Xueyan Wang,[1] Valentin David,[1] Myles S. Wolf,[3] Aline Martin.[1] *[1]Northwestern University, Chicago, IL; [2]Texas A&M-Baylor College of Dentistry, Dallas, TX; [3]Duke University, Durham, NC.*

Background: Fibroblast growth factor (FGF)-23 is a hormone produced by osteocytes that regulates phosphate (Pi) homeostasis. Chronic kidney disease mineral and bone disease (CKD-MBD) leads to alterations of mineral and bone metabolism, including elevation of circulating FGF23 levels that is associated with increased risk of cardiovascular mortality. The mechanism of increased FGF23 in CKD is poorly understood and the impact of CKD on osteocyte development and maturation has not been described. We tested the hypothesis that CKD induces changes in osteocyte morphology that result in altered osteocyte network, bone mineralization and mineral metabolism.

Methods: Using 3D-microtomography, acid-etched scanning electron microscopy, whole bone FITC staining and Imaris modelisation, we studied the bone and osteocyte phenotype of 9 week-old $Col4a3^{KO}$ mice with advanced CKD and wild-type (WT) littermates. We assessed in vitro matrix mineralization by alizarin red S (ARS) staining and osteoblast differentiation by alkaline phosphatase (ALP) staining of WT and $Col4a3^{KO}$ isolated primary osteoblasts (BMSCs). In parallel, we measured serum FGF23 and Pi levels, assessed renal function and measured FGF23 mRNA expression in vitro and in vivo.

Results: Renal function was dramatically impaired in $Col4a3^{KO}$ mice (BUN: 100±12 vs 18±1 mg/dL) and we observed a 15-fold increase in bone FGF23 mRNA expression, a 70-fold increase in serum FGF23 and a 50% increase in serum Pi levels (p<0.05 vs. WT for each). $Col4a3^{KO}$ mice displayed a 5% decrease in bone mineral density and a rounder, less polarized osteocyte morphology (osteocyte roundness index: 0.43±0.17 vs. 0.34±0.12) (p<0.05 vs. WT for each). The osteocyte network showed an 80% reduction in number and length of the dendritic processes (p<0.05 vs. WT). In vitro, $Col4a3^{KO}$ BMSCs maintained intrinsic abnormalities in activity and mineralization (-40% ALP activity and ARS; p<0.05 vs. WT).

Conclusions: Our data show that impaired osteocyte morphology and function is associated with defective bone mineralization and FGF23 overproduction in CKD. Whether altered osteocyte morphology is a cause of FGF23 overproduction and whether rescue of the bone mineralization and osteocyte morphology defects could prevent FGF23 elevation in CKD requires further investigation.

FR-PO264

Effects of Repeated Ferric Carboxymaltose on Phosphate and FGF23 Levels Rupal Mehta,[4] Alex Hodakowski,[3] Xuan Cai,[3] Myles S. Wolf,[1] Tamara Isakova.[2] *[1]Duke University, Durham, NC; [2]Feinberg School of Medicine, Northwestern University, Chicago, IL; [3]Northwestern University, Chicago, IL; [4]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL.*

Background: Treatment of iron deficiency anemia (IDA) with a single dose of ferric carboxymaltose (FCM) reduces c-terminal FGF23 (cFGF23) levels, but paradoxically increases levels of biologically intact FGF23 (iFGF23), which results in hypophosphatemia. Although clinical trials of single doses of FCM reported high rates of reversible hypophosphatemia of unknown clinical significance, numerous reports have emerged of prolonged hypophosphatemia with severe skeletal complications in those who received repeated doses of FCM. No studies reported on the effects of repeated FCM dosing on phosphate and FGF23 levels.

Methods: We are conducting a longitudinal observational study of individuals who are receiving two doses of FCM for treatment of their IDA. We aim to test the following hypotheses: 1) repeated FCM dosing will be associated with prolonged increases in

iFGF23 levels and hypophosphatemia; 2) repeated FCM dosing will be associated with increased levels of markers of inflammation.

Results: We present data from 7 enrolled participants. Laboratory measurements (Table 1) were taken prior to each dose of FCM, 1 week after completion of therapy, and monthly until hypophosphatemia resolved. After a single FCM dose, ferritin markedly increased, cFGF23 decreased, but iFGF23 increased resulting in hypophosphatemia. After a second dose of FCM, iFGF23 further increased and hypophosphatemia persisted (Figure 1). During FCM treatment, serum phosphate decreased to ≤ 1.9 mg/dl in all 7 participants and ≤ 1.4 mg/dl n 5 of 7 participants, and criticlly low < 1.0 mg/dl in 2 patients (Figure 2). Two patients had persistent hypophosphatemia < 2.5 mg/dl at 90 days. Analyses of inflammatory marker are pending.

Conclusions: Administration of repeated doses of FCM treats ID and can lower cFGF23, but results in elevation of iFGF23 and prolonged hypophosphatemia. Given the increased utilization of FCM, the mechanisms and consequences of prolonged hypophosphatemia and elevated iFGF23 on bone and mineral metabolism markers necessitate further study.

Effects of Iron Sucrose on Fibroblast Growth Factor 23 (FGF23) Levels in Iron-Deficient Patients with CKD and Heart Failure (HF) Rupal Mehta,[4] Alex Hodakowski,[3] Xuan Cai,[3] Myles S. Wolf,[1] Tamara Isakova.[2] *[1]Duke University, Durham, NC; [2]Feinberg School of Medicine, Northwestern University, Chicago, IL; [3]Northwestern University, Chicago, IL; [4]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL.*

Background: Iron deficiency (ID) is a potent stimulus for increased FGF23 production. In healthy individuals with ID, upregulated FGF23 production is matched by FGF23 cleavage resulting in elevated c-terminal FGF23 (cFGF23) but normal intact FGF23 (iFGF23) levels. We hypothesize that FGF23 cleavage is impaired in CKD and HF and that the resultant imbalance between production and relatively decreased FGF23 cleavage contributes to the known elevation of iFGF23 levels in CKD and HF. Furthermore, if FGF23 cleavage is impaired in CKD and HF, we hypothesize that correction of ID in CKD and HF will lower both c- and iFGF23 levels unlike healthy individuals with normal cleavage in whom iron treatment only lowers cFGF23.

Methods: We recruited 18 individuals with ID anemia with CKD and HF to investigate the effects of 5 weekly doses of iron sucrose on c- and iFGF23 levels. ID anemia was defined as hemoglobin <12 g/dl and transferrin saturation (TSAT) <20%, or a hemoglobin <12 g/dl with a ferritin <100 mg/dl and TSAT <30%. Measurements were taken at baseline, prior to each iron dose, after 5 weeks, and 3 months later.

Results: Baseline laboratory values were as follows: mean eGFR was 36 ± 18 ml/min/1.73m^2, median ferritin was 44.0 (interquartile range [IQR] 22, 44 mg/dl), median TSAT 8% (IQR 8-19), median cFGF23 335 (IQR 158-480) RU/ml, and median iFGF23 147 (IQR 81-267) pg/dl. Baseline c- and iFGF23 strongly correlated (Spearman Correlation Coefficient 0.71, p value < 0.001). After 5 weeks, median cFGF23 was 142 (IQR 90-433) RU/ml with a mean decrease of -118 Ru/ml (-135 Ru/ml). Median iFGF23 was 125 (IQR 97-224) pg/dl, with a mean a decrease of 13 (± 70) pg/dl. No significant changes in eGFR or phosphate were appreciated.

Conclusions: ID patients with CKD and HF have elevated levels of c- and iFGF23. Treatment with iron sucrose lowers cFGF23 and may lower iFGF23 in states where FGF23 cleavage is impaired such as CKD and HF.

Bone Content Is Related with Serum Fibroblast Growth Factor-23 (FGF23) in Patients on Maintenance Hemodialysis (MHD) Yukiko Hasuike, Wataru Fukao, Yuki Morikami, Tomoko Kimura, Yasuyuki Nagasawa, Takeshi Nakanishi. *Internal Medicine, Div Kidney and Dialysis, Nishinomiya, Japan.*

Background: FGF23 is a circulating factor that plays an critical role in the regulation of phosphate and vitamin D. In MHD patients, an increase in FGF23 can lead to the development of cardiovascular complications. FGF23 is produced by mature osteoblasts and osteocytes, however, the relationship between bone and FGF23 production remains poorly understood. We investigated whether bone content is related with FGF23 levels in MHD patients.

Methods: MHD patients with dialysis vintage at least 3 months (n=107) were enrolled in this study. Serum concentration of intact FGF23 (ELISA, Kainos) and the factors related to mineral bone disorders (calcium, phosphorus, bone-type ALP [BAP], 1,25(OH)$_2$vitamin D [calcitriol], 25(OH)vitamin D), inflammation (high-sensitivity CRP, interleukin-6, tumor necrosis factor-α), uremia (creatinine, p-crezol, indoxyl-sulfate, pentosidine) were measured. Walking speed, anthropometric parameters (body mass index, grip strength), bioelectrical impedance analysis (fat mass, body water volume) using inBody, and advanced body composition parameters (bone mineral content [BMC], bone mineral density [BMD], muscle mass) using Hologic QDR Discovery were assessed. The association between these factors and FGF23 were investigated.

Results: MHD patients recruited in this study showed mean age of 66.1±1.1 years, mean dialysis vintage 88.3±8.5 months, and median of serum FGF23 of 2100 (541 to 5825 pg/ml). Log-transformed FGF23 levels were associated with body weight, muscle mass, BMC, BMD, grip strength, serum calcium, phosphates, creatinine, and negatively linked with age, BAP, and walking speed. The stepwise regression analyses revealed that serum phosphorus, calcium, and BMC were the independent predictors of FGF23 (standardized regression coefficients were 0.620, 0.442, and 0.381, respectively, R^2=0.762, p<0.0001). There was no significant relationship between FGF23 and serum calcitriol.

Conclusions: FGF23 production can be independently associated with BMC as well as calcium and phosphate in MHD patients.

FR-PO267

Cardiac Fibroblast Growth Factor 23 Is Induced by Activated Renin-Angiotensin-Aldosterone System and Promotes the Pro-Fibrotic Crosstalk between Cardiac Myocytes and Fibroblasts Maren Leifheit-Nestler,[2] Felix Kirchhoff,[3] Julia Nespor,[1] Beatrice Richter,[4] Joerg Heineke,[1] Dieter Haffner.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Hannover Medical School, Hannover, Germany; [3]Hannover Medical School, Hannover, Germany; [4]University of Alabama at Birmingham, Birmingham, AL.*

Background: FGF23 is discussed as a new biomarker associated with cardiac hypertrophy and mortality in patients with CKD, heart failure, and cardiogenic shock. We previously demonstrated that FGF23 is expressed by cardiac myocytes, enhanced in CKD, and induces cardiac hypertrophy via FGFR4-dependent activation of PLCγ/calcineurin/NFAT signaling independent of its co-receptor klotho. However, the impact of FGF23 on cardiac fibrosis is largely elusive.

Methods: By conducting a retrospective case-control study including myocardial autopsy samples from 24 patients with end-stage CKD and *in vitro* studies in cardiac fibroblasts and myocytes, we investigated the pro-fibrotic properties of FGF23.

Results: The accumulation of fibrillar collagens I and III was increased in myocardial tissue of CKD patients, and correlated with duration of dialysis, PTH, klotho deficiency, and enhanced angiotensinogen (*AGT*) expression. Using human fibrosis profiler PCR array analyzes, TGF-β and its related TGF-β receptor/Smad complexes, extracellular matrix remodeling enzymes, as well as pro-fibrotic growth factors were significantly upregulated in myocardial tissue of dialysis patients. In cultured cardiac fibroblasts, FGF23 stimulated pro-fibrotic TGF-β receptor/Smad complexes and collagen synthesis, whereas treatment of isolated cardiac myocytes with FGF23 resulted in enhanced collagen remodeling, expression of pro-inflammatory genes, pro-survival pathways, and induction of pro-hypertrophic genes. FGF23 enhanced the expression of *Agt* in cardiac fibroblasts and myocytes, and angiotensin II and aldosterone, as components of the renin-

angiotensin-aldosterone system (RAAS), strongly induced FGF23 in cardiac myocytes to directly promote fibrotic and hypertrophic response.

Conclusions: In conclusion, stimulation with active RAAS components induces FGF23 expression in cardiac myocytes, which in turn stimulates the pro-fibrotic crosstalk between cardiac myocytes and fibroblasts.

FR-PO268

Change in Fibroblast Growth Factor 23 during the Progression of Left Ventricular Hypertrophy in Hypertensive Model Rats Hideki Fujii, Kentaro Watanabe, Keiji Kono, Shunsuke Goto, Shuhei Watanabe, Shinichi Nishi. *Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Many clinical studies have demonstrated that serum fibroblast growth factor-23 (FGF23) levels are significantly associated with left ventricular hypertrophy (LVH). Although LVH is frequently observed in hypertensive patients, no experimental and clinical data have proved that FGF23 induces LVH in these patients. A previous study showed that subjects with high serum FGF23 levels may lead to hypertension in the future. Thus, the association between FGF23, hypertension, and LVH is very complexed and remains unknown. The purpose of our study was to examine the change in serum and intracardiac FGF23 during the progression of hypertension using spontaneously hypertensive rats (SHR).

Methods: We used male SHRs (HT group) and Wistar Kyoto rats (WKY) as a control group in the present study. At 10 weeks, urinary and blood biochemical analyses and blood pressure measurements were performed for these rats. At 18 weeks, the rats were sacrificed and urinary and blood biochemical analyses and real time PCR were performed in the two groups.

Results: At baseline, serum calcium, phosphate and FGF23 levels were comparable between the two groups. Although serum creatinine levels were also comparable, blood pressure, urinary excretion of albumin and serum NT-pro BNP levels were significantly elevated in the HT group compared to the control group. At 18 weeks, relative heart weight and serum NT-proBNP levels were significantly greater in the HT group. In addition, serum calcium and phosphate levels were significantly lower and serum FGF23 levels were significantly higher in the HT group than in the control group. Further analysis showed that mRNA expression of FGF23 in the heart was significantly increased in the HT group than in the control group. Both serum FGF23 levels ($r=0.63$, $p<0.05$) and intracardiac mRNA expression of FGF23 ($r=0.79$, $p<0.05$) were significantly correlated with relative heart weight.

Conclusions: During the progression of hypertension, serum FGF23 levels were elevated and LVH progressed. Although it is not known whether change in FGF23 is a cause or result of LVH, we suggest that FGF23 is associated with the development of LVH in hypertension.

FR-PO269

Effect of Dietary Sodium and Phosphorus Intake on Fibroblast Growth Factor-23 in Patients with Diabetic Nephropathy Manoj Bhattarai,[3,1] Jeet Gandhi,[3,1] Chakradhar Velagapudi,[3,1] Shuko Lee,[1] Sue E. Cunningham,[3] Subrata Debnath,[3] Shirley L. Hu,[2] Shweta Bansal.[3,1] *[1]South Texas Veterans Health Care System, San Antonio, TX; [2]UTHealth Houston, McALlen, TX; [3]University of Texas Health Science Center at San Anotonio, San Antonio, TX.*

Background: High FGF23 levels independently associate with cardiovascular and all-cause mortality in CKD patients. Higher dietary phosphorus intake increases FGF23 levels in healthy individuals. However, this association in CKD patients in unclear. FGF23 levels have been positively associated with markers of volume status in renal transplant patients suggesting possible role of dietary sodium intake. The relationship between dietary sodium and phosphorus and plasma FGF-23 levels is not well-studied in advance diabetic nephropathy patients. We hypothesize that high dietary sodium and phosphorus associate with high plasma FGF23 levels in patients with diabetic nephropathy.

Methods: We conducted a sub-analysis of a randomized-controlled trial where subjects with type 2 DM with albumin-creatinine ratio of >150 mg/g and eGFR 15-60 ml/min were recruited to test the anti-proteinuric effect of Silybin and N-acetylcysteine. Dietary phosphorus intake was assessed from 3-day diet record. Daily sodium intake was estimated by measuring 12-hour urinary sodium excretion. Plasma FGF23 was measured using a second generation C-terminal ELISA kit.

Results: The study population was 62.9±7.5 years old, 89% male, 65% Hispanic, and 27% non-Hispanic white, had BMI of 35±8.54 kg/m2, and eGFR of 36.4±13.3 ml/min. Mean dietary phosphorus intake and urinary sodium was 1418±438 mg/d and 3882±2486 mg/d, respectively with median plasma FGF23 78 [44, 127] RU/ml at baseline. On univariate analysis, plasma FGF23 correlated negatively with eGFR ($r=-0.6$, $p<0.001$) and positively with serum phosphorus ($r=0.5$, $p<0.001$) and NGAL ($r=0.7$, $p<0.001$). There was no correlation between plasma FGF23 and daily phosphorus or sodium intake. In multivariable regression model including age, eGFR, daily sodium and phosphorus intake, serum phosphorus and NGAL, only eGFR predicted the plasma FGF23 significantly ($\beta=-0.47$, $p=0.02$).

Conclusions: Daily sodium and phosphorus intake do not correlate with plasma FGF23 in patients with advance diabetic nephropathy. This observation is in contrast with healthy individuals where high phosphorus intake increases plasma FGF23 levels.

FR-PO270

Effect of Treatment of Metabolic Acidosis on Fibroblast Growth Factor-23 in Patients with CKD Pratik B. Shah,[5] Emily Andrews,[3] Zhiying You,[1] Michel Chonchol,[2] Jessica B. Kendrick.[4] *[1]UC Denver, Aurora, CO; [2]University of Colorado, Aurora, CO; [3]University of Colorado Denver, Aurora, CO; [4]University of Colorado Denver and Denver Health Medical Center, Denver, CO; [5]University of Colorado at Denver and Health Sciences Center, Denver, CO.*

Background: The regulation of fibroblast growth factor-23 (FGF23) in patients with chronic kidney disease (CKD) is not understood. We conducted a study to test the hypothesis that treatment with oral sodium bicarbonate in patients with CKD and metabolic acidosis reduces intact FGF23 (iFGF23) levels.

Methods: We performed a prospective, randomized, open-label, 14 week crossover study of 20 subjects with stage 3B-4 CKD (eGFR 15-44 ml/min/1.73m^2) and metabolic acidosis (serum bicarbonate level of <22 and ≥16 mEq/L). Subjects were randomly assigned to start with treatment or control. Each period was 6 weeks in duration with a 2 week washout period in between. Patients were treated with oral sodium bicarbonate tablets for goal bicarbonate > 22 mEq/L. Outcome measures were repeated at the beginning and end of each period. Mixed effects models were employed in comparison of pre-post change in iFGF23 and phosphorus between treatment and control groups.

Results: The mean (SD) age and eGFR was 58.5 ± 12.8 years and 24.6 ± 8.1 ml/min/1.73m^2, respectively. iFGF23 increased significantly during the treatment period ($p=0.008$) and not during the control ($p=0.68$). When we compared iFGF23 between the treatment and the control periods, there was a trend towards significance ($p=0.065$). Serum phosphorus increased significantly during the treatment period but not in the control and the increase in phosphorus was significant between the groups ($p=0.038$). There was no significant change in serum parathyroid hormone or kidney function in either group.

Conclusions: Treatment of metabolic acidosis with sodium bicarbonate in CKD increases serum phosphorus and iFGF23. The mechanism of these observations is unexplained and further studies are needed to confirm these results.

Funding: NIDDK Support, Other NIH Support - NHLBI

FR-PO271

Changes in FGF23 and Soluble Klotho Levels after Initiation of Hemodialysis Chiaki Kawabata,[1] Hirotaka Komaba,[1,2] Yosuke Nakagawa,[1] Naoto Hamano,[1] Masahiro Koizumi,[1] Genta Kanai,[1] Takehiko Wada,[1] Masafumi Fukagawa.[1] *[1]Tokai University School of Medicine, Isehara, Japan; [2]The Institute of Medical Sciences, Tokai University, Isehara, Japan.*

Background: FGF23 is markedly elevated in end stage of renal disease and these levels have been associated with increased risk of mortality. It has been suggested but not proved that long-term management of hyperphosphatemia is required to achieve sufficient reductions in FGF23 levels. Initiation of hemodialysis leads to a marked removal of phosphate from the body and resultant reductions in PTH levels, but the effect of hemodialysis initiation on FGF23 levels has not been explored.

Methods: We conducted a prospective observational study of twenty patients initiating hemodialysis. We follow upped over five days with four hemodialysis sessions. We did not change the prescription of vitamin D receptor activators, phosphate binders, or cinacalcet during the study period. We measured biochemical parameters of mineral metabolism including FGF23 pre and post each hemodialysis session, a total of 8 times. Serum full-length FGF23 levels were measured using a chemiluminescent enzyme immunoassay (Kyowa Medex, Co., Ltd) and soluble Klotho levels were measured using an enzyme linked immunosorbent assay (Immuno-Biological Laboratories, Co., Ltd).

Results: At baseline, serum levels were as follows; phosphorus, 5.6 ± 1.9 mg/dl; intact PTH, 299 (182-356) pg/ml; FGF23, 517 (300-919) pg/ml; and soluble Klotho, 297 ± 107 pg/ml. Initiation of hemodialysis led to a progressive reduction in serum phosphorus, intact PTH, and FGF23 levels (median percent changes from baseline to the start of the 4th hemodialysis session were -32%, -8%, and -43%, respectively). Prescription of vitamin D receptor activators did not modify the effect of hemodialysis initiation on FGF23 levels. There was no meaningful change in soluble Klotho levels.

Conclusions: FGF23 levels decrease drastically after initiation of hemodialysis. A marked removal of phosphorus by hemodialysis initiation could suppress the production of FGF23 by osteocytes. Our findings suggest a critical role of phosphorus retention in markedly elevated FGF23 and support the importance of serum phosphorus management for suppressing FGF23 production, which may have diverse toxic effects.

FR-PO272

Oxygen Consumption Is the Major Determinant of Klotho Release by the Kidney Daniela Picciotto,[1,3] Giacomo Garibotto,[1,3] Samantha Milanesi,[4] Abitha Murugavel,[6,3] Francesca Viazzi,[5,3] Daniela Verzola.[2] *[1]DIMI, Genoa University, Genoa, Italy; [2]University of Genoa Di.M.I. Nephrology, Genoa, Italy; [3]Clinica nefrologica, Dialisi, Trapianto, Ospedale Policlinico San Martino, Genoa, Italy; [4]University of Genoa, Genoa, Italy; [5]University of Genoa, Genoa, Italy; [6]University of Genoa, Genoa, Italy*.

Background: Plasma levels of soluble αKlotho (sKlotho), an anti-aging protein which serves as the co-factor for FGF23, progressively decline along with CKD progression. However, our knowledge of the sites and mechanisms which regulate circulating sKlotho is still incomplete.

Methods: To explore the role of the kidney and of the extra-renal sites on the metabolic handling of sKlotho, we measured sKlotho levels in venous effluents from different organs, including the kidney, the splanchnic organs and lung, as well as in arterial blood, in a cohort of patients (n=20,10M/10F, age 56-82 yr, BMI 25±1 Kg/m^2, eGFR 63±4 ml/min-range 23-98 ml/min), undergoing a right-sided cardiac catheterization.

Results: Mean arterial sKlotho was 202 ± 26 pg/ml. Renal vein αKlotho concentrations were remarkably higher (by ~8 %, $p < 0.05$) than the corresponding arterial values, indicating that plasma αKlotho increases substantially after a single pass across the kidney. The fractional enrichment (FE) of sKlotho across the kidney was similar (8±6 vs. 9±4%, respectively) in patients with normal renal function (n=11) and in patients with GFR< 60 ml/min (n=9, eGFR 39±3 ml/min). sKlotho level in the liver vein was lower (by 23±6 %, $p<0.05$) than the arterial one in patients with GFR< 60 ml/min. Arterial sKlotho levels were almost identical to pulmonary artery levels. In all subjects, at univariate analysis, fractional enrichment (FE) of sKlotho across the kidney was directly related to the fractional extraction of oxygen ($r=0.412$, $p< 0.05$), and inversely, to plasma sodium ($r=0.434$, $p< 0.05$) and uric acid ($r=0.357$, $p < 0.06$) but not to eGFR, hemoglobin and phosphate levels. At multivariate analysis, the fractional extraction of oxygen across the kidney was the only determinant of sKlotho FE.

Conclusions: Our data show that the human kidney is the only site for sKlotho production in the body, while splanchnic organs may participate to sKlotho removal. Oxygen uptake by the kidney is the major determinant of sKlotho production by the human kidney, suggesting a role for hypoxemia on reducing the availability of sKlotho to the systemic circulation. Besides providing a better understanding of physiology of αKlotho metabolism, the data reported in this study could be useful to understand the alterations in αKlotho that are observed in CKD and many systemic and organ diseases.

The Effect and Possible Mechanism of Klotho on the Expression of Fibroblastic Growth Factor 23(FGF23) Secreted by Osteoblast-Like UMR-106 Cells Huijuan Mao, Lulu Ma. *First Affiliated Hospital of Nanjing Medical University, Nanjing, China*.

Background: To investigate the effect and possible mechanism of Klotho on the expression of FGF23 in UMR- 106 cells.

Methods: UMR-106 cells were divided into 5 groups and cultured for 72 h: (1) control group;(2)β-glycerophosphate(β-GP) group;(3)β-GP+Klotho group;(4)β-GP+LiCl group;(5)β-GP+Klotho+LiCl group, and then the expression of FGF23, P-GSK-3β and GSK-3β protein was measured by Western blotting. The levels of mRNA of FGF23 and c-myc were determined by RT-PCR.

Results: 1.β-GP induced the increase of expression of FGF23 mRNA and protein. Compared with β-GP group, FGF23 mRNA and protein expression was downregulated after treating with Klotho(Figure 1).2.β-GP induced the increase of expression of P-GSK-3β/GSK-3β and c-myc mRNA.Compared with β-GP group, P-GSK-3β/GSK -3β and c-myc mRNA were downregulated after treating with Klotho(Figure 2). 3. The expression of FGF23, P-GSK-3β/GSK-3β and c-myc mRNA were upregulated when treated with LiCl(Figure 1 and 2).

Conclusions: Klotho down-regulates the expression of FGF23 induced by hyperphosphate in osteoblast-like UMR-106 cells via Wnt/β-catenin pathway.

Funding: Government Support - Non-U.S.

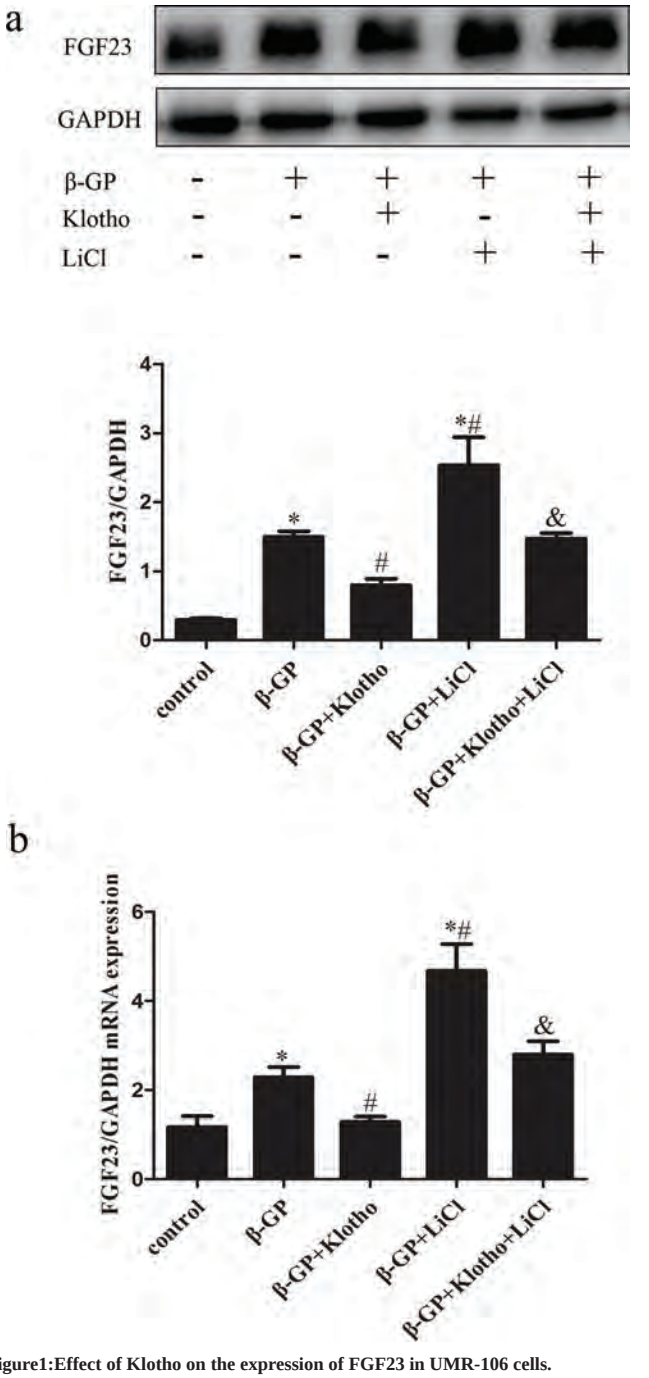

Figure1:Effect of Klotho on the expression of FGF23 in UMR-106 cells.

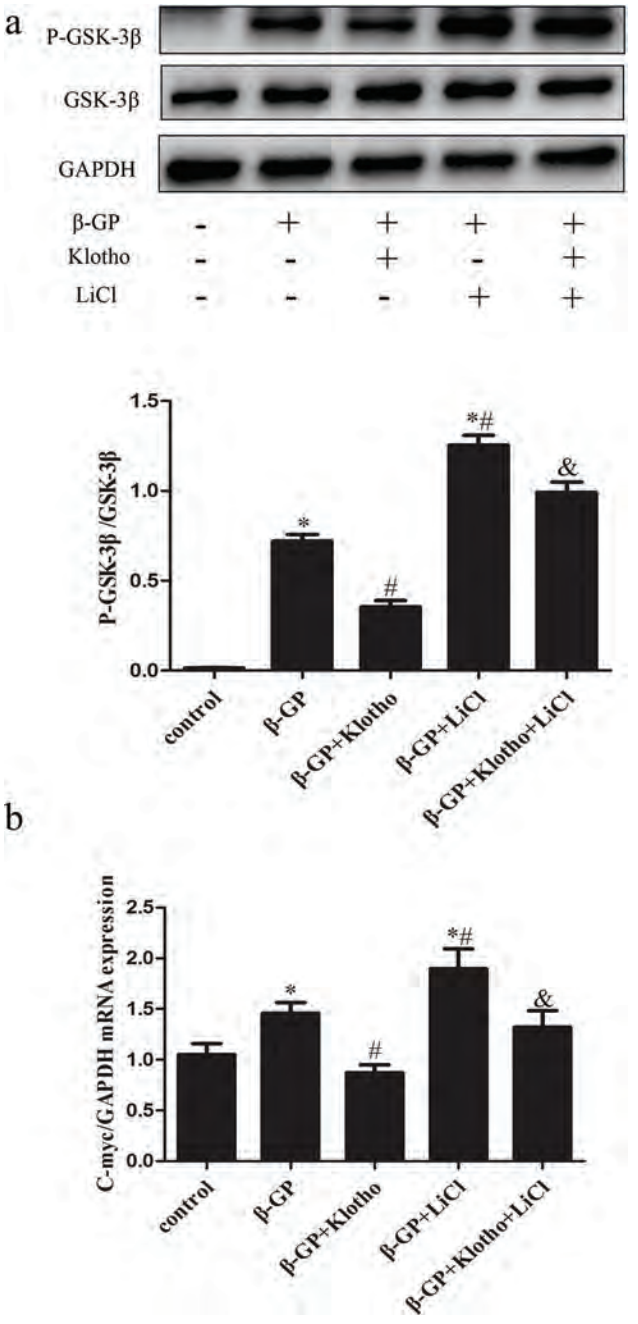

Figure2:Klotho regulated the expression of FGF23 through Wnt/β-catenin signaling pathway.

FR-PO274

Effects of Acute Administration of Ergocalciferol on Vitamin D Catabolism in Hemodialysis Patients Ornatcha Sirimongkolchaiyakul,[2] Anders H. Berg,[5] S. Ananth Karumanchi,[1] Katherine Wesseling-Perry,[2] Ravi I. Thadhani,[3] Isidro B. Salusky.[4] *[1]Beth Israel Deaconess Medical Ctr/ Harvard Medical School, Boston, MA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Massachusetts General Hospital, Boston, MA; [4]Mattel Children's Hospital, Los Angeles, CA; [5]None, Boston, MA.*

Background: Vitamin D deficiency is highly prevalent in dialysis patients and D supplementation has been recommended. However, there is limited data of vitamin D catabolism in advanced CKD. Stimulation of 24-hydroxylase mediated catabolism of vitamin D metabolites may reduce serum 25(OH)D and 1, 25$(OH)_2$D levels. To test this possibility, we assessed vitamin D catabolism after a single ergocalciferol administration (D2) in hemodialysis patients (HD) and healthy volunteers (HV).

Methods: All subjects ingested a single oral dose of 50,000 IU ergocalciferol, HD patients aged 65.8 (20.6, 71.0) years (n = 35) and HV aged 41.0 (29.0, 62.0) years (n = 7). Biochemical determinations of 25D, 1,25D, 24,25 D and DBP were measured at baseline and 2-5 days after D_2 ingestion. Biochemical markers at baseline and post-therapy were compared.

Results: Concentrations of $25D_2$ increased after D_2 in both HD and HV (average increases of +14.5 ng/mL [95%CI 9.5-29.4] and +21.2 [95%CI 14.6-29.8], respectively). Although average pre-treatment $25D_3$ concentrations were significantly higher in HD compared to HV (21.2 ng/mL [95% CI 14.6-29.8] vs. 14.5 ng/mL [95%CI 9.5-29.4], $p<0.05$), concentrations of 24,25D3 were lower in HD (5.5 ng/mL [95% CI 3.5-15.6] vs. 14.5 ng/mL [95%CI 9.5-29.4], $p<0.05$). Average concentrations of $1,25D_3$ was also lower in HD (4.7 pg/mL [95% CI 2.8-8.4] vs. 54.1 pg/mL [95%CI 47.7-69.2], $p<0.05$). Amongst HV, concentrations of $25D_3$ decreased on average by -0.6 ng/mL [95%CI -3.9 to -0.2] after Vitamin D_2 administration, and $1,25D_3$ decreased by -10.6 pg/mL(95%CI -20.2 to -0.5), whereas there was no significant decrease in $24,25D_3$. Amongst HD, no significant changes in $25D_3$, $24,25D_3$, or $1,25D_3$ were seen. Amongst HV, concentrations of both $1,25D_3$ and $24,25D_3$ correlated strongly with $25D_3$ ($R^2 = 0.4558$ and $R^2 = 0.6993$, respectively). In contrast, the correlations between $25D_3$ and $1,25D_3$ and between $25D_3$ and $24,25D_3$ in HD were weaker ($R^2 = 0.1285$ and $R^2 = 0.4654$, respectively).

Conclusions: CKD is associated with higher $25D_3$ but lower 24,25D and 1,25D concentrations, and 1,25 levels are more closely associated with 24,25D than with 25D in ESKD. Feedback regulation of both 1,25D and 24,25D by PTH and/or FGF23 in HD warrants further investigation.

Ix.[6] *[1]University of Anschutz Medical Center, Aurora, CO; [2]University of Washington, Seattle, WA; [3]San Francisco VA Medical Center, San Francisco, CA; [4]Tufts Medical Center, Boston, MA; [5]University of Washington, Seattle, WA; [6]University of California, San Diego, San Diego, CA; [7]University of California, San Francisco, San Francisco, CA.*

Background: Serum 25-hydroxyvitamin D [25(OH)D] concentrations may not optimally indicate vitamin D receptor (VDR) activity. Catabolism of 25(OH)D to 24,25-dihydroxyvitmin D [$24,25(OH)_2$D] is stimulated by active 1,25-dihydroxyvitamin D. Thus, higher concentrations of $24,25(OH)_2$D and a higher ratio of $24,25(OH)_2$D to 25(OH)D (the vitamin D metabolite ratio [VMR]) may provide additional information on receptor activity. We compared the strength of associations of these markers with serum PTH concentrations, hip bone mineral density (BMD), and incident hip fracture among community-living older participants in the Cardiovascular Health Study (CHS).

Methods: We conducted a case-cohort study of 1116 CHS participants with over sampling for fracture outcomes. We used multiple linear regression to assess associations of 25(OH)D, $24,25(OH)_2$D, and VMR with PTH and hip BMD in the random cohort. We used a Cox proportional hazards model to estimate the association of each marker with incident fracture in the complete case-cohort population.

Results: Mean age was 78, 60% were female, and mean eGFR was 64 +/-16 ml/min/1.73m2. Serum 25(OH)D, $24,25(OH)_2$D, and VMR were each associated with PTH; the sizes of these associations were statistically indistinguishable. Higher serum $24,25(OH)_2$D concentrations, but not 25(OH)D or VMR, were associated with greater hip BMD. There were 289 hip fractures during 8.4 years mean follow-up. Serum concentrations of $24,25(OH)_2$D and VMR but not 25(OH)D were associated with incident fracture (Table).

Conclusions: Lower 24,25(OH)2D concentrations and VMR but not 25(OH)D concentrations were associated with hip fracture risk in community-living older adults.

International Serum 25-OH-Vitamin D Measurement, Levels, and Treatment among Patients with CKD in Everyday Nephrology Practice: Results from CKDopps Sophie Liabeuf,[5] Keith McCullough,[4] Ronald L. Pisoni,[4] Yvonne Meier,[2] Jarcy Zee,[4] Helmut Reichel,[1] Roberto Pecoits-Filho,[6] Friedrich K. Port,[4] Bruce M. Robinson,[4] Ziad Massy.[3] *[1]Nephrological Center, Villingen-Schwenningen, Germany; [2]Vifor Pharma Ltd, Glattbrugg, Switzerland; [3]Ambroise Pare University Hospital, Boulogne Billancourt/ Paris cedex, France; [4]Arbor Research Collaborative for Health, Ann Arbor, AL; [5]CHU Amiens, Amiens, France; [6]Pontificia Universidade Catolica do Parana, Curitiba, Brazil.*

Background: CKD progression is linked to a decrease in 25 hydroxycholecalciferol (25[OH]D) with implications for secondary hyperparathyroidism. While the optimal

target for 25[OH]D has been defined in the general population as 30 ng/ml, the optimal target in CKD patients (pts) is under debate. We evaluate current international vitamin D (vit D) practices among CKD pts.

Methods: CKD pts with eGFR <60 ml/min/1.73m2 (N=3,360) from nephrology clinics in the prospective Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps) (2013-2016) from Brazil (BR), Germany (GER) and the US were included. Serum 25[OH]D and prescribed vit D were each based on the first value reported in health records. Nephrologist preferences are from survey responses.

Results: 25[OH]D level was reported for 54% of pts, but this varied across clinics by country, being measured for >90% of pts in 70% of GER clinics and 43-44% of US & BR clinics. Among pts with measured 25[OH]D, 46-66% had 25[OH]D<30 ng/mL across the countries and CKD stages. Figure 1 shows for the pts with 25[OH]D data: (a) vit D (nutritional and/or active) prescription was similar for pts with 25[OH]D D<30 vs ≥30 ng/ml; (b) fewer than half of pts prescribed vit D are prescribed active vit D. More pts had active vit D prescriptions in stages 4/5 (28%) vs stage 3 (12%). Most US and BR nephrologists indicated a lower serum 25[OH]D target limit of 30 ng/mL. A few US, BR, and most GER nephrologists indicated 15-25 ng/mL. There was no consensus on the upper target limit. Neither limit differed by CKD stage.

Conclusions: Measurement of 25[OH]D levels is infrequent in many nephrology CKD clinics but common in others. Vit D prescription was similar for pts with 25[OH]D <30 v. ≥30. These findings raise questions regarding optimal approaches to incorporating serum 25[OH]D levels into broader MBD management in CKD practice.

FR-PO277

The Impact of CKD on Analytical Performance of 25 Vitamin D Assays Hanna Karla A. Guapyass? Machado,[2] Carolina S. Martins,[2] Vanda Jorgetti,[2] Rosilene M. Elias,[2] Rosa M. Moyses.[2,1] [1]*Universidade Nove de Julho, São Paulo, Brazil;* [2]*Nephrology, Universidade de São Paulo, São Paulo, Brazil.*

Background: Current guidelines recommend evaluation of 25 vitamin D (25vitD) status and therapy when serum levels are below 30 ng/ml. Significant differences among some assays have been described. However, the impact of renal disease on these differences has never been assessed yet. In our service, the assay for 25vitD measurement was changed from Diasorin® to Beckman Coulter Unicel DXI 800®, which gave us the opportunity to evaluate the impact of the assay in the levels of 25vitD in CKD patients.

Methods: We obtained data from 540 patients [122 with eGFR > 90 ml/min (normal renal function); 138 with 30-60 ml/min (CKD3); 124 with 15-29 ml/min (CKD4) and 156 on dialysis (CKD5D)] in which serum 25vitD was measured with both assays with a time difference of 6 months.

Results: The median of serum 25vitD increased [23 (19-29) vs. 29 (22-37) ng/ml; p=0.0001], but could not be explained by seasonal differences, as the second measurement was done at wintertime. 25vitD increased in patients with CKD 3, 4 and 5D, but not in individuals with normal renal function. Indeed, the more advanced the CKD, the higher the median increase [-5 ng/ml (-9.3-4) in normal renal function; 3.5 ng/ml (-2.8-11) in CKD3; 3 ng/ml (-1.3-9) CKD4; and 8 ng/ml (1-15) in CKD5D; p<0.0001). The prevalence of 25vitD insufficiency increased from 49 to 62% in the entire population and from 44 to 57% only in CKD patients (p = 0.001 and 0.0001, respectively).

Conclusions: Our findings confirm the disagreement between 25vitD assays, showing higher levels with Beckman Coulter Unicel DXI 800®, which is more marked in CKD patients, suggesting that non-active fragments usually found in this population might be recognized as intact 25vitD. This technical problem will certainly affect hypovitaminosis D diagnosis and also therapy in CKD patients.

FR-PO278

Free 25-OH Vitamin D, but Not Total 25-OH Vitamin D, Is Correlated with Gestational Age and Calcium in Normal Human Pregnancy Berthold Hocher,[2] Oleg Tsuprykov,[1] Claudia Buse,[1] Roman Skoblo.[1] [1]*Institute for Laboratory Medicine, IFLB, Berlin, Germany, Berlin, Germany;* [2]*University of Potsdam, Potsdam, Germany.*

Background: Basic science as well as epidemiological studies showed that vitamin D is causally involved in the pathogenesis of pregnancy-related diseases such as gestational diabetes as well as pregnancy-related hypertensive disorders, short- and long-term outcomes of the offspring. To translate this knowledge to clinical practice, suitable tools to determine the vitamin D status during pregnancy are mandatory. Since 25-OH vitamin D (25-OHD) is mainly bound to vitamin D binding protein (VDBP) in the circulating blood and female sex steroids regulate hepatic VDBP synthesis, it is doubtful whether the determination of total vitamin D, as it is currently clinical practice, does adequately reflect the vitamin D status of an individual pregnant women.

Methods: We compared the correlations of total serum 25-OHD, free serum 25-OHD, and 1,25-$(OH)_2$D in 475 healthy pregnant women with gestational age, calcium, phosphorus, bone alkaline phosphatase and PTH. Free 25-OHD was either measured directly using a novel assay system for direct measurements of free 25-OHD as well as calculated free 25-OHD based on measurements of VDBP, albumin and total 25(OH)D.

Results: Correlation of serum vitamin D isoforms with gestational age and selected serum parameters is shown in the Table.

Conclusions: Calculated and measured free 25-OHD provide comparable data and correlate much better with components of the endocrine vitamin D system and targets of vitamin D induced gene expression. Free 25-OHD concentrations decrease slightly during healthy pregnancy, whereas 1,25-$(OH)_2$D concentrations increases substantially. Given the impact of vitamin D on maternal and offspring's health outcomes, an adequate monitoring of the vitamin D status during pregnancy might require measurements of both free 25-OHD and 1,25-$(OH)_2$D at different time points of gestation.

FR-PO279

Association between Urinary Full-Length Megalin and Serum Vitamin D Metabolites in CKD Norikazu Toi,[5] Shinsuke Yamada,[6] Eiji Ishimura,[4] Ayumi Nakatani,[5] Shinya Nakatani,[5] Yoshiaki Hirayama,[1] Naoko Tsugawa,[3] Akihiko Saito,[2] Masaaki Inaba.[5] [1]*Denka-seiken co., ltd., Gosen-shi, Japan;* [2]*Niigata University, Niigata, Japan;* [3]*Osaka Shoin Women's University, Higashi-osaka, Japan;* [4]*Meijibashi Hospital, Osaka, Japan;* [5]*Osaka City University Graduate School of Medicine, Osaka, Japan;* [6]*a. Department of Metabolism, Endocrinology, and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: 25-hydroxyvitamin D (25D) bound to vitamin D binding protein is reabsorbed by megalin, which is a membrane receptor highly expressed on proximal tubular epithelial cells. Increase in urinary megalin excretion due to tubular injury may affect vitamin D metabolism in chronic kidney disease (CKD) patients. The aim of the present study was to investigate whether increase in urinary excretion of megalin may have harmful effects on vitamin D metabolism in CKD patients.

Methods: One hundred fifty three CKD patients with eGFR less than 60 mL/min/1.73m^2 (101 males and 53 females, 64.7 ± 14.6 years) were recruited in this cross-sectional study. Urinary full-length megalin (C-megalin) and serum vitamin D metabolites (25D, 1α,25-dihydroxyvitamin D (1,25D), 24,25-dihydroxyvitamin D (24,25D) were measured.

Results: The mean levels of eGFR, serum levels of 25D, and urinary levels of C-megalin were 29.0 ± 15.8 mL/min/1.73m^2, 15.1 ± 6.2 ng/mL and 0.9 ± 1.1 pmol/gCr, respectively. In a simple regression analysis, 25D exhibited significant and negative correlation with urinary C-megalin (ρ = - 0.310, p = 0.0002), and urinary C-megalin had a significant and positive correlation with urinary protein (ρ = 0.603, p <0.0001), although both 25D and urinary C-megalin was not significantly correlated with eGFR. In a multiple regression analysis adjusted by age, gender, BMI, presence of diabetes, serum albumin, eGFR, serum PTH, serum FGF-23, and urinary C-megalin, urinary C-megalin was associated significantly with 25D in a negative manner (β = - 0.302, p = 0.0027). Furthermore, both 1,25D (β = 0.227, p = 0.0013) and 24,25D (β = 0.482, p <0.0001) were positively associated with 25D. The ratio of 1,25D/24,25D, which is a putative indicator of 1α-hydroxylase activity, was significantly, positively affected by urinary C-megalin independently to other clinical confounders.

Conclusions: This study demonstrated that serum 25D decreases with an increase in urinary C-megalin, and that serum 1,25D and 24,25D decrease with a decrease in 25D in CKD patients. Thus, decreased 25D induced by increased urinary C-megalin, which is a representative of tubular injury, affects decrease in 1,25D, suggesting the clinical importance of renal tubular dysfunction in vitamin D metabolism in CKD patients.

FR-PO280

VDR Deficiency Induces the Parathyroid Glands Lesions via NFκB Pathway Activation in Uremic Patients Jianping Mao, Minmin Zhang, Li Ni, Mengjing Wang, Jing Chen. *Huashan Hosopital, Fudan Univeristy, Shanghai, China.*

Background: Secondary hyperparathyroidism (SHPT) is one of the most common complications in CKD-MBD, but its pathogenesis remains unknown. Recent studies showed that 1,25D suppressed Nuclear Factor-κB (NFκB) activation to suppress tumor hyperplasia. Therefore, whether VDR deficiency induce the tumor-like hyperplasia of parathyroid gland(PTG) via the NFκB pathway activation in uremic patients.

Methods: PTG samples were collected from parathyroidectomy surgery of 10 uremic patients who failed to medical treatment with approval of the Ethics Committee on Human Research at Huashan Hospital. Immunohistochemistry and Western blot detected the expression of VDR, pp65 and PCNA in diffuse and nodular hyperplastic PTG. In vitro, freshly excised PTG tissues were minced into 1mm^3 fragments and incubated with 1,25D (0nM, 1nM, 10nM, 100nM, 1000nM) and PDTC (0uM, 2uM, 20uM, 200uM) for 24 hours. ELISA kit measured the levels of iPTH from supernatant. Real-time PCR measured the mRNA levels of preproPTH, PCNA, VDR and IκBα. Western blot measured the protein levels of VDR, p65, pp65 and PCNA.

Results: Compared with diffuse hyperplasia, immunohistochemistry results showed that VDR expression was down-regulated by 34.97% (P<0.01), while pp65 and PCNA were up-regulated by 86.51% (P<0.01) and 97.37% (P<0.01) in nodular hyperplastic glands. Western blot confirmed these above. In vitro, 1,25D up-regulated protein and mRNA levels of VDR by 150.62% (P<0.05) and 35.62% (P<0.05), down-regulated protein level of pp65 by 58.49% (P<0.01), up-regulated mRNA level of IκBα by 72.77% (P<0.01), and down-regulated protein and mRNA levels of PCNA by 42.48% (P<0.05) and 38.49% (P<0.01). These results suggested that 1,25D could activate VDR, inhibit cellular proliferation and inhibit NFκB activation. PDTC did not affect VDR expression, but down-regulated protein level of pp65 by 76.04% (P<0.01), down-regulated protein and mRNA levels of PCNA by 47.39% (P<0.05) and 26.95% (P<0.05). These results suggested that PDTC inhibit NFκB activation and inhibit cellular proliferation, while it had no effect on VDR expression. ELISA results showed that 1,25D and PDTC could both down-regulate iPTH levels by 61.16% (P<0.01) and 49.86% (P<0.05).

Conclusions: Deficiency of VDR and activation of NFκB pathway may be involved in the hyperplasia of PTG in uremic patients, the exact mechanism needs further study.

FR-PO281

Severe CKD Environment Affects CaSR Gene Expression and the Cascade of Genes in Parathyroid Glands Even without High Phosphorus Diets Taketo Uchiyama,[2] Ichiro Ohkido,[2] Sahoko Kamejima,[3] Akio Nakashima,[1] Takashi Yokoo.[4] *[1]Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan; [3]Jikei University School of Medicine, Tokyo, Japan; [4]The Jikei University School of Medicine, Tokyo, Japan.*

Background: Chronic kidney disease (CKD) disrupts mineral homeostasis and its representative pathosis is defined as secondary hyperparathyroidism (SHPT). SHPT occurs during the early course of progressive renal insufficiency, and is associated with mortality and cardiovascular events. Reduction of the calcium-sensing receptor (CaSR) occurs slowly and progressively throughout this process, although the underlying mechanism remains largely unknown.

Methods: CKD was induced by 0.75% adenine-containing diet. CKD rats and control rats were maintained for 2 weeks on diets containing 0.7% phosphorus or 1.3% phosphorus. In a gene expression analysis, TaqMan probes were used to do the quantitative real-time polymerase chain reactions. CaSR and glial cells missing-2 (Gcm2) protein expressions were analyzed using immunohistochemistry and western blotting. DNA methylation analysis was performed using a restriction digestion and quantitative PCR.

Results: CaSR mRNA was reduced in CKD rats fed the normal and high phosphorus diets (CKD NP and CKD HP, respetctively) (Figure 1), and the amount of CaSR protein was compatible with the gene expression assay. There is no significant difference in the DNA methylation status in the promoters of *CaSR* between the four groups. *Gcm2*, which has been shown to directly regulate *CaSR* and also to transactivate *CaSR* through *Gcm2* response elements in the *CaSR* promoter, was significantly decreased in CKD NP and CKD HP rats (Figure 2), and using western blotting the expression of Gcm2 was shown to be compatible.

Conclusions: A reduction of *CaSR* expression in parathyroid glands was observed in CKD NP and CKD HP rats; however, the DNA hypermethylaton was not demonstrated. We then analyzed the Gcm2 gene and its protein expression, as upstream transcription factor of *CaSR*, and we verified its depression in CKD NP and CKD HP rats. Consequently, our data suggest that *Gcm2* was responsible for the reduction in mRNA and protein levels of *CaSR* and *VDR* in PTGs of CKD HP rats.

FR-PO282

MicroRNA Analysis in Secondary Hyperparathyroidism Genta Kanai, Michio Nakamura, Masafumi Fukagawa. *Tokai University School of Medicine, Isehara, Japan.*

Background: Hyperparathyroidism is characterized by decreased calcium receptor expression and cell proliferation. However, the mechanism of progression is not clear. MicroRNA (miRNA) is a short RNA that is not translated into protein and has regulatory function of gene expression. To investigate the role of miRNA in cell proliferation of the parathyroid gland, we performed comprehensive miRNA analysis using the next generation sequence.

Methods: The parathyroid gland removed from patients with renal failure was used for the experiment. miRNAs extracted from the largest gland and the smallest gland in the same individual glands were examined. When analyzing the sequence of more than 1 million leads, about 25% of them corresponded to about 2,600 known miRNAs.

Results: There were 71 kinds of sequences detected in more than 10,000 leads in any glands, and 98 kinds of sequences with more than 1000 leads and less than 10,000 leads. The non-enlarged parathyroid gland was compared with the largest gland, and miRNAs that upregulated more than 2-fold were 11 and 10, respectively. Furthermore, miRNAs downregulated more than 2-fold were 14 and 24 kinds, respectively. Up to 31-fold expression difference was observed in these sequences.

Conclusions: The miRNA profile showed differential expression by parathyroid size. This suggests that miRNA may regulate parathyroid cell proliferation.

FR-PO283

A Mathematical Model of Parathyroid Gland Biology in Uremic Patients Gudrun Schappacher-Tilp,[3] Priscila Preciado,[2] Vaibhav Maheshwari,[1] Alhaji Cherif,[2] Doris H. Fuertinger,[2] Stephan Thijssen,[2] David A. Bushinsky,[4] Peter Kotanko.[2] *[1]Renal Research Insitute, New York, NY; [2]Renal Research Institute, New York, NY; [3]University of Graz, Graz, Austria; [4]University of Rochester Medical Center, Rochester, NY.*

Background: Chronic kidney disease-mineral bone disorder (CKD-MBD) affects the vast majority of CKD patients. A hallmark of CKD-MBD is an altered parathyroid gland biology with increased parathyroid hormone (PTH) secretion, reduced expression of calcium-sensing receptor (CaSR), and cell hyperplasia and hypertrophy. The aim of this study was to develop a mathematical model of the parathyroid gland enabling long-term simulations of parathyroid gland function in hemodialysis (HD) patients.

Methods: The mathematical model employs two PTH-producing cell populations, namely active secretory and quiescent cells that can proliferate or undergo apoptosis. PTH secretion can be modulated both on a cellular level and by increasing the number of secretory cells. The first mechanism involves the release of stored PTH, the decrease of intracellular degradation as well as increased biosynthesis. The second mechanism involves shorter secretory quiescence time as well as hyperplasia. All mechanisms are associated with different time constants implemented by positive or negative feedback loops on the CaSR and vitamin D receptor.

Results: We can successfully predict complex acute responses to changes in plasma calcium concentrations like different PTH values for the same serum calcium concentration during induction of and recovery from hypocalcemia. Moreover, we can predict a steady rising PTH release in hemodialysis patients due to high phosphate and low calcitriol levels. Long-term simulations allow the prediction of the effects of hyperplasia on PTH levels.

Conclusions: The *in silico* model of the parathyroid gland can be used to analyze pathophysiological alterations of the parathyroid gland in HD patients. It provides a useful tool to analyze long-term effects of dosing regimens of standard drugs like calcimimetics and vitamin D analogues on the parathyroid gland.

FR-PO284

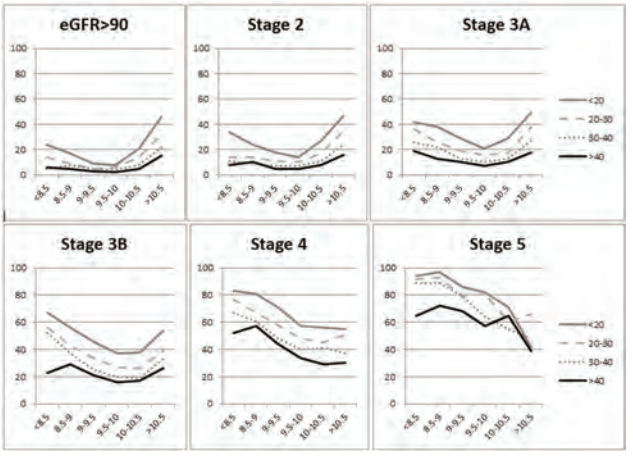
Interactions of Calcium, Vitamin D, and Kidney Function with Parathyroid Hormone Levels Rita L. McGill,[2] Elaine M. Worcester,[2] Jennifer L. Ennis,[1] Sangeet Dhillon-Jhattu,[2] Fredric L. Coe.[2] *[1]Litholink Corporation, Chicago, IL; [2]University of Chicago, Chicago, IL.*

Background: Parathyroid hormone (PTH) is a crucial factor in regulating calcium homeostasis and bone mineral deposition. Vitamin D and estimated glomerular filtration rate (eGFR) also interact with PTH, and we aimed to better characterize the interplay between these factors.

Methods: Laboratory results performed at LabCorp between April 2011 and February 2014 were assessed, if simultaneous PTH, calcium, vitamin D and eGFR were available. Calcium and vitamin D were categorized, and analyses were stratified for National Kidney Foundation stage of chronic kidney disease (CKD). Percentages of tests in which a PTH>65 was observed were calculated and plotted for each combination of calcium, vitamin D, and eGFR.

Results: Among 126,615 patients, 38% were male and mean age was 65.6 years. Compared to those withe GFR>90, PTH levels were more likely to be abnormal in CKD stages 2 and 3A. Higher vitamin D levels were associated with lower PTH in all patients, and this effect became more prominent with decreasing eGFR. The normal U-shaped relationships between calcium and PTH were distorted in CKD stages 4 and 5.

Conclusions: PTH levels become detectably abnormal even in very early CKD. Repletion of vitamin D to levels of 40 ng/mL or greater reduces PTH in patients with eGFR ≥ 15.



Percentage of Patients with PTH > 65, by Calcium, Vitamin D, and Chronic Kidney Disease Stage

FR-PO285

Kidney and Parathyroid Transplants for Hereditary Hypoparathyroidism Due to a Calcium Sensing Receptor (CaSR) Mutation Reduced Calciuria but Did Not Normalize Serum Calcium Kimberly A. Muczynski,[1] Michael O. Dorschner,[2] Nicolae Leca,[1] Ramasamy Bakthavatsalam,[3] Jorge D. Reyes,[3] David R. Byrd.[3] *[1]Medicine, University of Washington, Seattle, WA; [2]Pathology, University of Washington, Seattle, WA; [3]Surgery, University of Washington, Seattle, WA.*

Background: Parathyroid transplants have been reported for a couple cases of hereditary hypoparathyroidism using allografts from fetal and living donors. We now communicate success in transplantation of a living related kidney and deceased unrelated donor parathyroids into a patient with hereditary undetectable parathyroid hormone (PTH).

Methods: A father and daughter have had undetectable PTH levels since childhood. Calcium and vitamin D are essential to prevent symptomatic, life-threatening hypocalcemia. The father progressed to ESRD at age 52 due to nephrocalcinosis from his required calcium supplements. He received a kidney transplant pre-dialysis from an unaffected sister. The sister was felt not to be an appropriate parathyroid donor due to prior neck radiation for hyperthyroidism. Hence deceased donor parathyroids were transplanted into the father's forearm one week later, after institutional review board, hospital administration and organ procurement organization collaboration. Induction immunosuppression with ATG was used for the kidney and maintenance immunosuppression with tacrolimus, mycophenolate and prednisone were continued at the time of parathyroid transplant.

Results:

Conclusions: The father's kidney has functioned well, urine calcium excretion has been reduced by over 50%, and PTH levels are 13-15 pg/ml in the peripheral blood and 122 pg/ml from venous drainage of the parathyroid allograft seven months post-transplant. However, supplemental calcium and vitamin D are still required to prevent hypocalcemia. Perplexed by these findings, exome sequencing of genes that might account for hypoparathyroidism was performed by Precision Diagnostics at the University of Washington. PTH gene was normal but a mutation in the CaSR mapping to other gain of function mutations was identified. Having replaced the CaSR in the kidney and parathyroids with the combined allograft transplants we presume that renal calcium metabolism has been normalized and the new kidney will be protected from recurrent nephrocalcinosis. The need for supplemental calcium to prevent hypocalcemia suggests that CaSR in other organs (such as bone or gut), has a greater contribution in maintaining serum calcium levels than preventing calcium loss through the kidney.

FR-PO286

TRPC1 Gene Deletion Disturbs Homeostasis of Intracellular Free Ca ([Ca 2+]i), Produces Hyperparathyroidism, Hypercalcemia, Hyperphosphatemia, and Increased Bone Mass Due to Renal Ca and P Retention Bonnie Eby,[1] Marta Onopiuk,[2] Marybeth Humphrey,[3,4] Leonidas Tsiokas,[2] Kai Lau.[1,4] *[1]Nephrology, University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Cell Biology, University of Oklahoma Health Sciences Center, Oklahoma City, OK; [3]Rheumatology, University of Oklahoma Health Sciences Center, Oklahoma City, OK; [4]Medicine, VA Hospital, Oklahoma City, OK.*

Background: Mice deleted of the gene for transient receptor potential canonical channel 1 (TRPC1) have higher PTH (313 vs 218 pg/ml), hypercalcemia (11.3 vs.10.2 mg %) & hypocalciuria (1.2 vs 2.2 mg/d), indicating TRPC1 deficiency mimics familial hypocalciuric hypercalcemia phenotypes from CaSR inactivating mutations. Micro-CT shows increased tibia bone volume:tissue volume (11 vs 6 %). Their hind limbs were heavier (189 vs.151 mg). We now studied the potential mechanisms.

Methods: We measured Ca & P balance & clearance by standard methods, calciotropic hormones by ELISA, and $[Ca^{2+}]_i$ in cultured cells by fura 2.

Results: In rat parathyroid (PT) cells, $[Ca^{2+}]_i$ stimulation by CaSR allosteric agonists was markedly blunted by TRPC1 siRNA, showing CaSR signaling pathway depends on this store-operated Ca entry (SOCE). Without TRPC1, $[Ca^{2+}]_i$ is down & PTH secretion is up. In contrast, high medium [Ca] raises $[Ca^{2+}]_i$ & reduces PTH secretion. Transfection with plasmid overexpressing TRPC1 also inhibits PTH. The null mouse phenotypes cannot be attributed to the comparable serum calcitriol (301 vs.308 pg/ml) & calcitonin (21.9 vs.22.3 pg/ml). Renal cells transfected with TRPC1 siRNA & osteocytes from null mice also have blunted $[Ca^{2+}]_i$ response to CaSR agonists, indicating a generalized signaling defect in TRPC1-deficient cells. Since FGF23 synthesis &/or secretion are known to change directionally with $[Ca^{2+}]_i$, we tested the thesis that P excretion is reduced in null mice, due to putatively low FGF23 from reduced $[Ca^{2+}]_i$ in osteocytes. At similar diet intake, 24 h urine P was similar (3.5 vs. 4.1 mg/d). Fasting serum P was elevated (7.4 vs. 6.3 mg %) due to concurrently decreased P clearance (48 vs. 67 µl/min).

Conclusions: Conclusions: 1. Our data support the model that, activated by upstream CaSR signaling, TRPC1 functions as a SOCE channel to control PT $[Ca^{2+}]_i$ and regulate PTH secretion. 2. Increased bone mineral accretion in TRPC1 deletion is mediated by greater renal Ca & P retention, the latter likely due to low FGF23 from reduced osteocyte $[Ca^{2+}]_i$. 3. The apparent skeletal PTH resistance is explicable by the hypercalcemia, hyperphosphatemia, &/or the known impaired osteoclast proliferation, differentiation & function due to loss of TRPC1 functions.

FR-PO287

Accuracy, Precision, and Stability of the LIAISON 1-84 PTH 3rd Generation Assay: Comparison to Existing Intact PTH Assays Andre Valcour,[2] Kevin J. Martin,[4] Sudhaker D. Rao,[1] Douglas M. Hawkins,[1] Frank A. Blocki,[3] Claudia Zierold,[3] Fabrizio Bonelli.[5] *[1]Henry Ford Health System, Detroit, MI; [2]LabCorp, Burlington, NC; [3]DiaSorin Inc., Stillwater, MN; [4]Saint Louis University Med Ctr, St. Louis, MO; [5]DiaSorin spa, Stillwater, MN.*

Background: Over the past few decades, PTH immunoassays have progressed through successive generations resulting in increased specificity and accuracy for detecting circulating PTH. With the introduction of 3rd generation assays, in which the biologically active PTH (1-84) is specifically targeted, the PTH (7-84) and other fragments are not detected. The specific recognition of PTH (1-84) whole molecule allows standardization and calibration with existing standards.

Methods: Samples from patients on hemodialysis, with primary hyperparathyroidism, and apparently healthy subjects were examined in different collection tubes (plasma, unspun plasma, and SST) stored for 0, 24, or 72h at room temperature to reflect the prevailing sample collection methods, shipping, and processing conditions of centralized labs in the US. Samples were analyzed by the LIAISON 1-84 PTH and the N-TACT assays, and three additional commercially available intact PTH methods.

Results: PTH is stable for up to 72 hours in plasma, but less stable in serum (SST) beyond 24h (% change from 0h in Table). Both the LIAISON assays (1-84 and N-TACT) demonstrated good precision. Furthermore, defined samples, prepared using two different standards (WHO 95/646 international standard and the synthetically synthesized Bachem PTH(1-84)), read accurately with the LIAISON 1-84 PTH assay, but not with the intact PTH assays (5-9% vs. 54-142% bias).

Conclusions: The FDA-approved LIAISON 1-84 PTH assay is accurate and precise and reliably measures the biologically active PTH molecule in serum or plasma stored at room temperature for up 72h in plasma, and 24h in serum.

FR-PO288

Calcitriol at Therapeutic Doses for SHPT Promotes Vascular Calcification in Experimental CKD Bruno A. Svajger,[2] Cynthia M. Pruss,[2] Kimberly J. Laverty,[2] Jason Zelt,[1] Martin P. Petkovich,[1] Rachel M. Holden,[2] Michael A. Adams.[2] *[1]None, Kingston, ON, Canada; [2]Queen's University, Kingston, ON, Canada.*

Background: Vitamin D deficiency is common in CKD and leads to SHPT. Calcitriol (CAL) and active vitamin D analogs are often used to treat SHPT. CAL use has been associated with improved patient survival; however, it has also been linked with PTH over-suppression and increased risk of vascular calcification (VC). This study examined the effects of CAL dose frequency and magnitude on bone and mineral status (PTH, FGF23), endothelial function (von Willebrand Factor–VWF) and VC in experimental CKD.

Methods: CKD was induced by 0.25% dietary adenine in adult male Sprague-Dawley rats (n=42). At 4 weeks (W), CKD rats were divided into 4 groups and treated with CAL as follows: 0ng/kg (CKD control (Ctl), n=8), 5ng/kg QID (therapeutic dose divided, n=9), 20ng/kg SID (therapeutic dose, n=8), 20ng/kg QID (high dose divided, n=9), or 80ng/kg SID (high dose, n=8). After 3W treatment, rats were sacrificed, tissues and blood were collected and assessed for VC, PTH, FGF-23, and VWF.

Results: PTH therapeutic target levels (2-9x control) were achieved at some point during all CAL treatments. After 1W treatment, both 20 and 80ng/kg/day reduced PTH (-72%) relative to CKD Ctl ($p<0.05$). However, at 3W, CAL-induced PTH suppression was less effective (-41%). At 3W, PTH suppression (-55% vs -29%) and FGF-23 elevation (20x vs 10x) was greater in 80ng/kg/day compared to 20ng/kg/day ($p<0.05$). Increased serum calcium (+40%) and VC (94% vs 29%) was evident in all CAL treatments vs CKD Ctl ($p<0.05$), and VWF was significantly elevated in CAL treatment groups vs CKD Ctl at 1W (2x, $p<0.05$) and 3W(1.5x, $p<0.05$). Sub-analysis showed PTH suppression status (therapeutic, over-suppressed, no response) did not alter negative outcomes (FGF-23, VC).

Conclusions: CAL suppressed PTH as expected although the suppression effect was attenuated over time. All CAL treatment groups exhibited similar increases in FGF-23, VC, and endothelial dysfunction independent of dosing regimen. Importantly, mineral bone disorder occurrence was not corrected regardless of calcitriol treatment success (based on PTH response).

FR-PO289

Secondary Hyperparathyroidism in Hemodialysed Patients – Comparison of the Most Common Strategies of Treatment In a One-Year Observational Study Jacek P. Zawierucha,[1] Jolanta Malyszko,[3] Jacek S. Malyszko,[2] Wojciech Marcinkowski,[4] Grazyna Horowitz,[5] Tomasz R. Prystacki,[4] Teresa Dryl-Rydzynska.[1] *[1]Fresenius Medical Care Polska S.A., Poznan, Poland; [2]Medical University of Bialystok, Bialystok, Poland; [3]Medical University, Bialystok, Poland; [4]Fresenius Nephrocare Polska sp. z o.o., Poznan, Poland; [5]Gradatim, Tarnowo Podgorne, Poland.*

Background: Secondary hyperparathyroidism (sHPT) is one of the most common hormonal disorders in the course of chronic kidney disease (CKD). Associated with CKD hyperphosphatemia, hypocalcemia and active vitamin D deficiency are presumed the main causes of the sHPT. Two strategies of sHPT treatment are widely used – oral calcimimetics administration or intravenous paricalcitol administration during hemodialysis session. The third strategy is based on combination of both drugs – cinacalcet and paricalcitol administered in parallel. The aim of the study was to compare effectiveness of aforementioned therapeutic strategies.

Methods: 131 patients receiving hemodialysis and with inadequate parathyroid hormone level control were treated with iv paricalcitol – group of 60 patients (PAR) or cinalacet – group of 50 patients (CIN). Third group (21 patients) with unsatisfied results of the treatment with cinacalcet received also paricalcitol (PAR+CIN) and both drugs were administered simultaneously. Laboratory tests (iPTH, Ca, P, ALP) were performed on a monthly basis. The study duration was 12 months.

Results: In all groups significant decrease of iPTH level was observed. However, in group PAR iPTH level decrease was greater than in CIN and PAR+CIN groups. The highest change of iPTH level was noticed after three months of observation. After this period the iPTH level was stabilized and remained on similar level till the end of observation. The level of safety is similar for all the strategies. No severe hypercalcemia or hypocalcemia was observed during the whole period of observation.

Conclusions: The results of this study show significant advantage of intravenous treatment with paricalcitol. Adding paricalcitol to the therapy with cinacalcet does not improve outcomes of the treatment. In case of unsatisfactory results after 3-months treatment, a possible continuation should be considered carefully. Treatment with iv paricalcitol should be considered for all hemodialysed patients with inadequate serum PTH level control. sHPT treatment with cinacalcet should be considered for PD patients and when severe hypercalcemia occurs.

FR-PO290

The Novel Calcimimetic Agent Evocalcet (MT-4580/KHK7580) Has a Potential for the Treatment of Hyperparathyroidism with Less Effect on the Gastrointestinal Motility In Vivo Models Shin Tokunaga,[1] Hikaru Yoneda,[2] Masafumi Fukagawa,[3] Tadao Akizawa,[4] Kimihisa Ueno,[1] Ryutaro Shimazaki,[5] Takehisa Kawata.[1] *[1]Kyowa Hakko Kirin Co., Ltd., Shizuoka, Japan; [2]Mitsubishi Tanabe Pharma Corporation., Saitama, Japan; [3]Tokai University School of Medicine, Isehara, Japan; [4]Showa University School of Medicine, Tokyo, Japan; [5]Kyowa Hakko Kirin Co., Ltd., Tokyo, Japan.*

Background: Cinacalcet is widely used for the management of secondary hyperparathyroidism (SHPT). Nevertheless, cinacalcet has adverse effects on the gastrointestinal (GI) tract, which sometimes causes poor compliance or discontinuation of the treatment. Evocalcet (MT-4580/KHK7580) is a novel oral calcimimetic compound developed for dialysis patients with SHPT and is expected to improve upon several issues associated with cinacalcet. The objective of present preclinical study was to confirm the characteristics of evocalcet as a calcimimetic agent and to evaluate its effects on GI tract.

Methods: *In vitro* and *in vivo* pharmacological studies (using HEK293 cells expressing human calcium receptor and 5/6 nephrectomized rats) were conducted. To compare the effects of evocalcet and cinacalcet on GI tract, the emetic responses by each compound in common marmosets and gastric emptying in rats were evaluated. In addition, the binding affinity of some vomiting-associated receptors was assessed.

Results: The pharmacodynamic properties of evocalcet were similar to those of calcimimetics. In marmosets, evocalcet achieved wider safety margin between dosages which induced emesis or PTH reduction compared to cinacalcet. Although cinacalcet caused significant delay in gastric emptying in rats, evocalcet had no marked effect on gastric emptying at doses that showed similar pharmacological activity to cinacalcet (Table 1). Evocalcet had lower binding affinities to vomiting-associated receptors, such as dopamine, cannabinoid, opioid, serotonin, and other receptors compared with cinacalcet.

Conclusions: Evocalcet has a potential as the novel oral calcimimetic agent with better safety profile and medication adherence than cinacalcet for the treatment of SHPT.

FR-PO291

An Open-Label, Single-Arm Study to Assess the Safety, Tolerability, and Efficacy of Cinacalcet in Addition to Standard of Care in Pediatric Subjects Ages 28 Days to <6 Years William G. Goodman,[3] Jan Iles,[2] Jun Yang,[1] Bella Ertik,[1] Winnie Sohn,[1] Karel Vondrak,[6] Claus P. Schmitt,[4] Isidro B. Salusky.[5] *[1]Amgen, Thousand Oaks, CA; [2]Amgen Inc, Thousand Oaks, CO; [3]Amgen, Inc., CALABASAS, CA; [4]Center for Pediatric and Adolescent Medicine, Heidelberg, Germany; [5]Mattel Children's Hospital, Los Angeles, CA; [6]University Hospital Prague-Motol, Prague 5, Czech Republic.*

Background: Data are limited on the safety, tolerability, and efficacy of cinacalcet (CIN) in children with secondary hyperparathyroidism (SHPT) on dialysis. In this phase 2, multicenter, 26-week, single-arm, open-label study, we evaluated CIN+standard of care that includes vitamin D sterols in pediatric subjects with SHPT on dialysis.

Methods: Pediatric subjects ages 28d to <6yrs with SHPT on dialysis with parathyroid hormone (PTH) levels≥300pg/mL and serum corrected Ca≥9.4mg/dL (28d to <2yrs) or ≥8.8mg/dL (2 to <6yrs) were evaluated. The daily starting and maximum dose of CIN were changed during the study from 0.25mg/kg and 4.2mg/kg to 0.20mg/kg and 2.5mg/kg or 60mg maximum, whichever was lower. Primary endpoint: the proportion of subjects who developed cCa<9.0mg/dL (28d to <2yrs) and <8.4mg/dL (≥2 to <6yrs); secondary endpoints: percent change of plasma PTH from baseline, ≥30% reduction from baseline in PTH, PTH<300pg/mL, and cCa<8.8mg/dL. Nature, frequency, and severity of adverse events (AEs) were summarized.

Results: 17/18 enrolled subjects received ≥1dose of CIN; 66.7% were boys, 83.3% white, and mean age was 35.9mos. Mean CIN exposure time was 86.7days and the maximum daily dose of CIN was 30mg (2 subjects). Mean (SD) weight-adjusted daily starting dose and maximum dose during the study was 0.18(0.07)mg/kg and 0.73(0.66) mg/kg, respectively. No subject had cCa<9.0 or <8.4mg/dL for the 2 groups and 2 subjects (2 to <6yrs group) had cCa<8.8mg/dL. Overall, 70.6% of subjects showed

reductions in PTH≥30% and 52.9% subjects achieved PTH<300pg/mL during the study. All subjects received therapy with vitamin D sterols during the study. 94.1% of subjects had ≥1 treatment-emergent AE. The most common AEs were cough, hypertension, upper respiratory tract infection, and vomiting. There were no treatment-related serious AEs, fatal AEs nor AE leading to the discontinuation of CIN.

Conclusions: No subject had a Ca value below the threshold for the primary endpoint. Data show a downward trend in PTH from baseline after CIN administration. Safety data were consistent with the known safety profile.

FR-PO292

A Phase 3, Multicenter, Randomized, Open-Label, Controlled Study to Assess the Efficacy, Safety, and Tolerability of Cinacalcet in Addition to Standard of Care in Pediatric Subjects Ages 6 to 17 Years

Franz S. Schaefer,[7] Dorota Drozdz,[9] Bruno L. Fouqueray,[5] Jan Iles,[2] Xiaoye Ma,[3] Michelle N. Rheault,[8] Constantinos J. Stefanidis,[1] Nancy M. Rodig,[4] Bradley A. Warady.[6] *[1]A. and P. Kyriakou Childrens Hospital Athens, Greece, Athens, Greece; [2]Amgen Inc, Thousand Oaks, CO; [3]Amgen. Inc, San Bruno, CA; [4]Children's Hospital Boston, Boston, MA; [5]None, ZUG, Switzerland; [6]The Children's Mercy Hospital, Kansas City, MO; [7]University of Heidelberg, Heidelberg, Germany; [8]University of Minnesota, Minneapolis, MN; [9]Jagiellonian University Medical College, Krakow, Poland.*

Background: Standard of care (SoC) for secondary hyperparathyroidism for children on dialysis includes vitamin D sterols, calcium (Ca) supplementation, and phosphate (P) binders, while cinacalcet (CIN) has been shown to reduce parathyroid hormone (PTH), Ca, and P. Efficacy and safety data for CIN are limited in the pediatric chronic kidney disease population.

Methods: Pediatric subjects ages 6 to<18yrs were randomized 1:1 CIN+SoC:SoC stratified by age (6 to<12 & 12 to<18 yrs) to evaluate the efficacy of CIN+SoC for reducing mean plasma PTH by ≥30% from baseline during the efficacy assessment phase (EAP) wks 17-20. Eligible subjects had 2 consecutive PTH levels≥300pg/mL at entry and albumin corrected Ca (cCa) ≥8.8mg/dL. CIN was administered once daily starting at 0.20mg/kg/day and adjusted once monthly up to 2.5mg/kg/day or 180mg, whichever was lower, based on PTH, cCa, ionized Ca (iCa), and safety. CIN was held if cCa<8mg/dL or iCa<1mmol/L. Nature, frequency, and severity of adverse events (AEs) were assessed.

Results: 22/27 CIN+SoC (56% boys) and 25/28 SoC (46% boys) randomized subjects received ≥12wks of treatment. Mean age was 12.6yrs with more subjects in the 12 to<18yrs group. The proportion of subjects who achieved PTH reduction ≥30% was not significant: 22.2%(6/27) CIN; 32.1%(9/28) SoC (p=0.42 stratified by age). Mean(SD) duration of exposure to CIN was 112.8(41.0)days with average weight-adjusted daily dose of 0.398(0.467)mg/kg/day during EAP. 21(84.0%) CIN and 17(56.7%) SoC subjects had ≥1 AE during the study with most ≤grade 2 in severity. The most common CIN AEs were hypocalcemia(24.0%), muscle spasms(12.0%), nausea(12.0%) and headache(4.0%).

Conclusions: Efficacy of CIN was not demonstrated likely due to inadequate exposure. Safety data were consistent with the known safety profile.

FR-PO293

Demographic Predictors of Mineral and Bone Disorders in the Pediatric Dialysis Population

Marciana Laster,[1] Melissa Soohoo,[2] Elani Streja,[2] Keith C. Norris,[1] Isidro B. Salusky,[1] Kamyar Kalantar-Zadeh.[2] *[1]UCLA, Los Angeles, CA; [2]UCI, Orange, CA.*

Background: Secondary Hyperparathyroidism in pediatric patients on dialysis results in bone and cardiovascular abnormalities that have major implications on morbidity and mortality in both childhood and adulthood. Therefore, it is important to understand the factors which contribute to and predict perturbations in the markers of mineral and bone disorders (MBD).

Methods: In a sample of 661 children with ESRD we explored predictors of abnormalities in Calcium (Ca), Phosphorous (P04), Alkaline Phosphatase (ALP) and Parathyroid Hormone (PTH) levels within the first 3 months of dialysis using linear regression models adjusted for age, sex, race and ethnicity, disease type, Ca, P04, AP, and medication use.

Results: The cohort characteristics are displayed in Table 1. Using age-adjusted norms and KDIGO-defined goals of PTH values 2-9 times the upper limit of normal, we found that Ca, ALP and PTH were most frequently within goal ranges, while P04 was most frequently above goal (Figure 1). Significant predictors of these markers included age which predicted higher PTH, lower ALP and lower Ca; Female gender which predicted lower P04 and lower ALP; Black race which predicted higher PTH, lower P04 and lower ALP and Hispanic ethnicity which predicted higher PTH and lower Ca and P04 (Table 2).

Conclusions: Non-modifiable demographic factors associate with the markers of MBD. In particular, Black and Hispanic children have higher PTH levels and, in addition, Black children have lower AP levels. While optimization of CKD-MBD management requires consideration of these observed differences, further studies are needed to assess potential racial/ethnic differences in PTH targets in children on dialysis.

FR-PO294

Mineral and Bone Disorder (MBD) Markers and Management over the First 5 Years after Dialysis Start: Results from the DOPPS

Angelo Karaboyas,[1] Hal Morgenstern,[2] Bruce M. Robinson,[1] Friedrich K. Port,[1] Yvonne Meier,[3] Stefan H. Jacobson,[4] Masafumi Fukagawa,[5] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Vifor Pharma Ltd, St. Gallen, Switzerland; [4]Danderyd Hospital, Stockholm, Sweden; [5]Tokai University School of Medicine, Isehara, Japan.*

Background: Abnormalities in MBD markers - including parathyroid hormone (PTH), serum phosphorus (P), calcium, and 25-hydroxy (OH) vitamin D - in the period immediately following hemodialysis (HD) initiation may increase short- and long-term risk of morbidity and mortality. International and racial variations in MBD markers and treatments have been well-described, but not their trajectories after transition to HD.

Methods: Locally weighted regression (LOESS) was used to smooth trends in mean MBD markers and drug prevalence over the first 5 years of HD using 472,930 patient-months from 34,105 patients in phases 4-5 (2009-2015) of the Dialysis Outcomes and Practice Patterns Study (DOPPS).

Results: PTH levels were high at HD initiation, especially among black patients in the US. PTH then declined during the first year of HD before increasing in the US and Europe but not in Japan. P levels increased sharply after HD initiation before subsequently declining in Europe but not in the US or Japan. Active vitamin D and cinacalcet prescription increased over 5 years, and was greatest in US black patients. Oral nutritional vitamin D was not prescribed in Japan, but was in Europe (27%) and the US (12%) despite infrequent measurement of 25-OH vitamin D.

Conclusions: Variation in PTH at HD initiation by region and race may reflect differences in patient characteristics, pre-HD care, and/or timing of HD initiation. After an initial decline, we observed a rise in PTH with time on HD in US patients, particularly black patients, despite greater prescription of vitamin D and cinacalcet than in other regions. The rapid rise in P immediately following HD initiation may be partially attributable to loss of residual renal function. Future research is needed to study how MBD management before, during, and after the transition to HD can be optimized to improve clinical outcomes.

FR-PO295

Risk Factors for Hungry Bone Syndrome after Parathyroidectomy in CKD Patients on Dialysis Jorge I. Fonseca-Correa,[3] Juan Carlos Ramirez-Sandoval,[2] Luis Rojas-Concha,[6] Antonio Madrazo-Ibarra,[1] Pindaro S. Martínez-Delfín,[1] Paola Zinser-Peniche,[8] Juan Pablo Pantoja,[4] Mauricio Sierra-Salazar,[3] David VELAZQUEZ-FERNANDEZ,[5] Miguel Herrera-Hernández,[3] Ricardo Correa-Rotter.[7] *[1]Escuela de Medicina, Universidad Panamericana, Mexico City, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, México city, Mexico; [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, México City, Mexico; [4]Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubirán, Mexico, Mexico; [5]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [6]Instituto Nal Ciencias Med y Nutricion Salvador Zubiran, Puebla, Mexico; [7]Institutor Nacional de la Nutricion, Mexico City, Mexico; [8]Universidad Panamericana, CDMX, Mexico.*

Background: Hungry bone syndrome (HBS) is a frequent event after parathyroidectomy (PTx). While risk factors for HBS are well known in primary hyperparathyroidism (HPT), it is unclear whether these risk factors are similar in secondary or tertiary HPT.

Methods: We retrospectively analyzed the risk factors for HBS of a single-center cohort of 68 dialysis patients who underwent PTx. We defined HBS as persistent hypocalcemia (corrected calcium <7.5 mg/dL) lasting >3 days -with or without hypophosphatemia- requiring extended hospital stay for intravenous calcium supplementation. All patients were followed up for one year.

Results: HBS occurred in 36 (53%) patients. In the bivariate analysis, a higher preoperative intact parathyroid hormone (iPTH) (1984±777 vs. 940±581 pg/mL; p<0.001), a higher alkaline phosphatase (ALP) (706 [322-1155] vs. 132 [108-233] IU/L; p<0.001), and older dialysis vintage (4 [3-4] vs. 6 [4-11] years; p=0.049) independently predicted the development of HBS. Peritoneal dialysis (PD) treatment protected against HBS (68% Non-HBS vs. 47% HBS were on PD; p=0.02). Age, weight, preoperative phosphorus, and type of surgery did not predict HBS occurrence. Calcitriol prophylaxis for >2 days, prescribed in 91% of patients with HBS, was not effective to prevent HBS (median dose of 1.25 mcg/day [IQR 0.75-2.25]). When a multivariate analysis was performed only iPTH and ALP remained as predictors of HBS. During the year of follow-up, 4 (6%) patients died and 21 (31%) received a kidney transplant. At one year, patients who had HBS needed higher doses of calcium prescription (CaCO3 6.8 gr/day [IQR 4.5-14.8] vs. 1.5 gr/day [IQR 0-3.0]) and calcitriol (0.75 mcg/day [IQR 0.5-1.5] vs. 0.25 mcg/day [IQR 0-0.75].

Conclusions: HBS was a common complication after PTx and closely related to severity of HPT. At one year of follow up it was associated with continued prescription of higher doses of calcium and calcitriol. Consequences of this prolonged exposure to calcium and calcitriol could have deleterious systemic/vascular complications. Preoperative prophylactic calcitriol, prescribed in 91% of those who later developed HBS, was ineffective in preventing the appearance of this syndrome.

Correlates and Outcomes Related to Parathyroidectomy in Veterans Who Transition to Maintenance Dialysis: A Transition of Care in CKD Study Vanessa A. Ravel,[1] Elani Streja,[1] Melissa Soohoo,[1] Yoshitsugu Obi,[1] Wei Ling Lau,[1] Connie Rhee,[1] Rajiv Saran,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, Orange, CA; [2]University of Michigan, Ann Arbor, MI; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Parathyroidectomy in the form of an elective, surgical resection of the parathyroid glands occurs less frequently since approved use of calcimimetics in 2004. Among patients who transition to ESRD, the correlates and consequences of parathyroidectomy are not known. We hypothesized that parathyroidectomy would be associated with better outcomes in incident dialysis patients.

Methods: Data of almost 80,000 US veterans who transitioned to dialysis between 10/2007 and 3/2014 were examined to identify those with documented parathyroidectomy prior to transition. The likelihood of parathyroidectomy was estimated via adjusted logistic regression odds ratios and the outcome of 1-year mortality via adjusted Cox regression hazard ratio.

Results: Out of 79,331 veterans who transitioned to dialysis, we identified 179 who had undergone parathyroidectomy prior to transition. Patients were 71±12 years old and included 11% women, 25% blacks and 7% Hispanics. Odds ratios (and 95% confidence intervals) of parathyroidectomy are shown in **Table 1**. The death hazard ratios (95% confidence interval bars) are shown in **Figure 1**. Case-mix adjustment included gender, race/ethnicity, comorbid states, and Malnutrition-Inflammation-Cachexia Syndrome (MICS) which includes additional laboratory variables and BMI.

Conclusions: Parathyroidectomy is performed more frequently among older veterans, women, and those with COPD, cancer, or hyperlipidemia, and those with higher serum levels of phosphorus, calcium or PTH. A consistent trend of 15-20% better survival was observed among those who underwent parathyroidectomy prior to transition.

Funding: NIDDK Support

	Unadjusted	Case-mix adjusted	Case-mix & MICS
Age (each 10 years older)	1.23 (1.08, 1.41)	1.27 (1.10, 1.46)	1.27 (1.10, 1.47)
Female (vs. male)	2.09 (1.30, 3.36)	2.26 (1.40, 3.66)	2.28 (1.41, 3.68)
COPD (vs. none)	1.60 (1.19, 2.15)	1.45 (1.06, 1.96)	1.46 (1.07, 1.98)
Cancer (vs. none)	2.40 (1.77, 3.25)	2.24 (1.63, 3.07)	2.20 (1.60, 3.02)
Hyperlipidemia (vs. none)	2.38 (1.56, 3.63)	2.27 (1.44, 3.59)	2.18 (1.38, 3.46)
Phosphorus (mg/dL)	1.02 (0.84, 1.25)	1.06 (0.87, 1.29)	1.28 (0.99, 1.65)

Effects of Parathyroidectomy on Plasma Different Parathyroid Hormone Fragments Levels in CKD Patients Ningning Wang,[1] Huimin Chen,[1] Xiaoming Zha,[2] Chang Ying Xing.[2] *[1]Department of Nephrology, The First Affiliated Hospital with Nanjing Medical University, Nanjing, China; [2]First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Intact parathyroid hormone (iPTH) measured by the second generation assays include not only (1-84)PTH, but also (7-84)PTH. Now the third generation PTH assays have been shown specific test for (1-84)PTH. Here we investigated the levels of plasma iPTH, (1-84)PTH, (7-84)PTH in stage 5 chronic kidney disease (CKD) patients, and evaluate the effects of parathyroidectomy(PTX) on above parameters in severe secondary hyperparathyroidism(SHPT) subgroups.

Methods: We included 252 CKD patients divided by baseline plasma iPTH levels. Thirty-one PTX patients were followed up with median time of 7.1 months. Serum iPTH and (1-84)PTH were measured by electrochemiluminescence immunoassay. (7-84)PTH levels were calculated by subtracting the (1-84)PTH values from the iPTH values.

Results: Plasma iPTH, (1-84)PTH, (7-84)PTH levels were closely related with each other, while (1-84)PTH/iPTH gradually reduced with upregulated iPTH levels. For CKD subgroups with plasma iPTH level>800 pg/ml, (1-84)PTH/iPTH furtherly decreased to 0.5(Fig1). After PTX, plasma different PTH fragments levels were decreased obviously and (1-84)PTH/iPTH were increased in severe SHPT patients(Table 1).

Conclusions: PTX can diminish abnormal increased iPTH, (1-84)PTH,(7-84)PTH levels and upregulate (1-84)PTH/iPTH for severe SHPT patients. Blood iPTH value may overestimate the severity of SHPT. Measurement of (1-84)PTH is suggested for accurate diagnosis and treatment in chronic kidney disease-mineral and bone disorder(CKD-MBD) patients.

Funding: Government Support - Non-U.S.

PTX can diminish blood PTH fragments levels and upregulate (1-84)PTH/iPTH in severe SHPT patients

High Prevalence of Aluminum Deposition in Bone and Osteoporosis in CKD Patients: Data from the Brazilian Registry of Bone Biopsy (REBRABO) Cinthia E. Carbonara,[1] Luciene dos Reis,[2] Renata A. Franca,[1] Kelcia R. Quadros,[1] André B. Esteves,[1] Noemi A. Roza,[1] Vanda Jorgetti,[2] Rodrigo B. de Oliveira.[1] *[1]School of Medical Sciences, Department of Internal Medicine, University of Campinas, Campinas, Brazil; [2]Medical School, Department of Nephrology, University of São Paulo, São Paulo, Brazil.*

Background: Mineral and bone disorder (MBD) due CKD is related with significant morbidity and mortality. REBRABO is a database wich contains information about Brazilian CKD patients with MDB.

Methods: Clinical, demographics, laboratorial, imaging, and bone histology data were collected from CKD patients between Aug/15-Apr/17. Diagnose of aluminum (Al) intoxication was when Al covered ≥30% of bone surface by solochrome-azurine; diagnose of osteoporosis was considered either by T *score* ≤2.5 S.D. or decreased bone volume detected by bone biopsy (BB).

Results: Data from 175 patients who were submitted to BB were analyzed. Patients aged 51±13 years, 89 (51%) men and 81(46%) white; 34 (19%) patients had history of bone fracture; symptoms of bone pain, weakness or myalgia were observed in 87 (51%) patients. Serum intact parathormone, alkaline phosphatase, calcium, and phosphate levels were 450 (58-500) pg/mL, 165 (73-250) IU/L, 9.2±1 mg/dL and 4.9±1.6 mg/dL, respectively. The main indication for BB was clinical protocol in 78 (45%) and suspected Al intoxication in 41 (23%) patients. Fibrous osteitis (FO) was detected in 67 (38%), mixed bone disease in 26 (15%), adynamic bone disease in 21 (12%) and osteomalacia in 6 (3,4%). Dialysis modality had no correlation with the type of renal osteodistrophy (ROD). Al intoxication was prevalent in 38 (22%); osteoporosis was present in 27 (15%) by bone densitometry and 54 (31%) by BB. Patients with osteoporosis diagnosed by BB presented higher prevalence of fracture (p=0.001).

Conclusions: FO was the main type of ROD in Brazil. A high prevalence of Al intoxication was detected. Osteoporosis when diagnoses by BB, but not by bone densitometry, was related with fractures. BB remains the gold standard for the differential diagnosis of ROD, as well as osteoporosis in CKD patients. Future studies are needed to clarify the clinical impact of Al intoxication in these patients.

FR-PO299

Bone Metabolism Markers, Epidemiological Profile, and Renal Function of HIV-Infected Patients before Initiating Antiretroviral Therapy Mariana G. Paula,[5] Unai Tupinambas,[1] Milena Guimarães,[3] Nathalia S. De,[1] Maria Goretti M. Penido,[4,2] Joao M. Penido.[6] *[1]Federal University of MInas Gerais, Belo Horioznte, Brazil; [2]Pediatric Nephrology Unit, Federal University of Minas Geraisl, Belo Horizonte, Brazil; [3]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil; [4]Pediatric Nephrology Unit, Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [5]Nephrology Center, Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [6]Federal University of Ouro Preto, Ouro Preto, Brazil.*

Background: Data suggests that the HIV population is prone to changes in bone metabolism and renal function. The aim of this study was to describe the bone metabolism markers, epidemiological profile, and renal function of HIV-infected patients before initiating antiretroviral therapy (ART).

Methods: Transversal study with naive patients on ART, aged from 18 to 55 years of age, that underwent clinical evaluation, bone densitometry by DXA (lumbar spine L1-L4) and laboratory measurement: calcium, phosphorus, PTH, 25(OH)vitD, FGF23 and interleukin 1β (IL-1β) and 6 (IL-6) serum levels. The following statistic tests were used: Mann Whitney, Kruskal-Wallis, and the Spearman correlation test. The CKD-EPI formula was used to evaluate the glomerular filtration rate.

Results: We evaluated 70 patients (57M) with median age of 33.8 years. 93% had more than eight years of schooling, 84% were working, 77% were single, and sexual transmission was 93%. The time to diagnosis ranged from 0.13 to 300 months. 51 patients underwent DXA and 9 had reduced bone mineral density (BMD) at lumbar spine, 3 at femoral neck and 5 at total femur. 58% of the patients had altered 25(OH)vitD: 21% had deficient serum levels and 37% had insufficient levels. There was no change in serum calcium, phosphorus, and PTH. The FGF23 correlated positively with calcium (r=0.358; p=0.004) and with IL-1β (r=0.308; p=0.013). There was a significant difference in the FGF23 in relation to PTH, being higher in those who had normal PTH levels (p=0.025) and its relation to the femoral neck Z score, being higher in those with index ≤-2 (p=0.039). 9.4% had CKD II.

Conclusions: The majority of the patients were young, professionally active, singles, and had HIV sexual transmission. Although they were young and naive patients, 9.4% had compromised renal function and 8.5% of them had reduced BMD. There was a high prevalence of vitamin D deficiency/insufficiency, most likely because of early onset. The relationship between FGF23, PTH, BMD Z-score and the correlation between FGF23 and calcium and IL-1β suggests that this phosphatonin could be considered an early marker of bone metabolism. More studies are needed to improve the follow up of bone metabolism and renal function, which are crucial and important in HIV patients.

FR-PO300

Validating Whole Genome Sequencing (WGS) as a Diagnostic Technique for Autosomal Dominant Polycystic Kidney Disease (ADPKD) Amali Mallawaarachchi,[1] Yvonne Hort,[1] Sarah R. Senum,[2] Ben Lundie,[1] Jiang Tao,[1] Andre E. Minoche,[1] Mark J. Cowley,[1] John Shine,[1] Peter C. Harris,[2] Tim Furlong.[1] *[1]Garvan Institute of Medical Research, Sydney, NSW, Australia; [2]Mayo Clinic, Rochester, MN.*

Background: ADPKD is the most common monogenic renal disease. There are many benefits of genetic diagnosis (early diagnosis, family planning, cascade testing, living-donor selection and to predict disease severity). However genetic diagnostics is not routinely pursued. Diagnostic sequencing is challenged because 6 pseudogenes share 97% sequence homology with *PKD1* and confound standard sequencing techniques. WGS has the potential to overcome sequence homology, but has not been validated as a diagnostic test.

Methods: We studied 42 unrelated patients with an ADPKD phenotype. Thirty patients initially underwent long-range PCR/Sanger sequencing/MLPA (LR-PCR/SS/MLPA) of *PKD1* and *PKD2* in the Mayo Clinic (Grp1). Blinded WGS was then performed after PCR-free library preparation (Kappa Hyper kit, HiSeqX; 150bp paired-end sequencing) in the Garvan Institute. Concurrently, 12 patients were initially sequenced via WGS and then blinded LR-PCR/SS/MLPA of *PKD1* and *PKD2* (Grp2). Raw WGS data was analysed for single nucleotide and copy number variation via customized bioinformatics pipelines. WGS variant analysis was focussed on *PKD1* and *PKD2.*

Results: WGS provided uniform coverage (mean 36x; range 24-47), including in homologous and GC-rich regions. The same results as LR-PCR/SS/MLPA were obtained in 40/42 patients (37 disease-causing variants; 3 patients unknown with both methods). In 2/42 patients, using standard filters, WGS did not detect mosaic variants, however in 1 mosaic patient, reanalysis of WGS data showed the variant in 8% of reads. WGS defined the breakpoints of 2 multi-exon deletions, which was not possible with prior methods. On initial analysis of Grp1, the disease-causing variant was confirmed in 24/30 patients. After adjusting the variant filtering stringency, this was improved to 28/30. There were no false positive or false negative results with WGS.

Conclusions: WGS provides the basis of a new diagnostic test for ADPKD. It avoids laborious sample preparation and overcomes pseudogene homology. Unlike targeted sequencing, WGS allows scope for broadened genomic analysis if no *PKD1* or *PKD2* variants are identified. This study highlights the value of validating next generation sequencing against a gold-standard cohort prior to diagnostic application.

Evaluation of an Artificial Deep Neural Network for Fully Automated Segmentation of Individual Kidneys and Liver in Patients with Polycystic Kidney Disease Maatje D. van Gastel,[2,1] Marie E. Edwards,[1] Vicente E. Torres,[1] Ron T. Gansevoort,[2] Timothy L. Kline.[1] *[1]Mayo Clinic, Rochester, MN; [2]UMC Groningen, Groningen, Netherlands.*

Background: Polycystic kidney disease (PKD) leads to cyst formation in kidneys and often liver, with marked increase in total kidney volume (TKV) and total liver volume (TLV). TKV is recognized by the FDA and EMA as a biomarker that plays an important role in risk prediction in PKD. Thus far, there is no optimal alternative for the laborious and expensive measurement of manually tracing kidneys and liver in radiological imaging examinations. Therefore, we developed and validated a fully automated segmentation method for TKV and TLV measurement. This is the first study to propose a solution for measuring individual kidney volumes, and liver automatically in radiological examinations of patients with PKD.

Methods: The automated approach that was developed was a deep learning network optimized to perform voxel-based classification. The network was first trained (80%) and

validated (20%) on a set of 100 abdominal MRIs (T2 weighted HASTE or TRUFI coronal sequences) of patients with PKD which had both kidneys and liver segmented manually. A test set of 60 patients was used to evaluate the performance of the developed automated method.

Results: TKV as well as TLV measured using the deep neural network correlated highly with manually traced TKV and TLV (ICC 0.996 and 0.994, resp.), with a bias and precision of -0.3%±4.6% for TKV and 2.5%±4.9% for TLV with maximal percentage differences observed being 8.5% and 11.2%, respectively. No proportional bias was observed, meaning that percentage differences between both methods are regardless of kidney or liver size.

Conclusions: This is the first fully automated segmentation method that measures individual kidney volumes, TKV and TLV almost as accurate as manual tracing, that has an inter-reader variability of 2.3%. The developed technique will facilitate future studies where automated and reproducible measurement of individual kidney volumes, TKV, and TLV are needed to assess (i) disease severity, (ii) progression of the disease, and (iii) treatment response.

FR-PO302

Congenital Heart Disease (CHD) in Adult Patients with Autosomal Dominant Polycystic Kidney (ADPKD) Fouad T. Chebib, Maria V. Irazabal, Heidi M. Connolly, Emilie Cornec-Le Gall, Marie C. Hogan, Sarah R. Senum, Christina M. Heyer, Charles D. Madsen, Ziad El-Zoghby, Peter C. Harris, Vicente E. Torres. *Mayo Clinic, Rochester, MN.*

Background: Primary cilia and the polycystins have an important role in cardiac development. *Pkd1*$^{-/-}$ and *Pkd2*$^{-/-}$ mice have structural defects in cardiac septation including atrial and venticular septal defects (ASD,VSD). It is uncertain whether an association between ADPKD and CHD exists.

Methods: Clinical data was retrieved from medical records for patients with ADPKD and CHD evaluated at Mayo Clinic (1984-2015). Patent foramen ovale and isolated bicuspid aortic valve (BAV) were excluded from the prevalence analysis.

Results: Thirty of 667 patients with available echocardiograms had evidence of CHD:8 (1.2%) had a left-to-right shunt (4 ASD, 3 VSD, and 1 isolated PDA); 6 (0.9%) outflow obstruction (4 aortic coarctation, 1 aortic hypoplasia, and 1 pulmonic stenosis); 5 (0.75%) with cyanotic CHD (2 tetralogy of Fallot, 1 Ebstein's anomaly, 1 tricuspid atresia and 1 transposition of great arteries associated with double inlet left ventricle, pulmonic stenosis and ASD); and 14 (2.1%) BAV. Two additional patients had left coronary artery to pulmonary artery fistula and isolated persistent left superior vena cava. Genetic studies have revealed 18 patients with *PKD1* mutations (11 truncating and 4 non-truncating); none with *PKD2* mutations and no mutation was detected in 3 patients (Table 1).

Conclusions: Coexistence of ADPKD and CHD in our tertiary referral center cohort appears to be higher than expected by chance. The observed prevalence of CHD (excluding isolated BAV) in ADPKD patients seems higher than the general population (3.1 vs. 0.8%). We suggest that ADPKD mutations predispose to congenital heart malformations.

Funding: NIDDK Support

FR-PO303

Association of Serum FGF23 and Klotho with Long-Term Renal Outcomes of Polycystic Kidney Disease (PKD) in the Consortium for Radiologic Imaging Studies of PKD (CRISP) Cohort Mireille El Ters,[1] Jason R. Stubbs,[3] Jonathan D. Mahnken,[2] Darren P. Wallace,[3] Alan S. Yu.[3] *[1]Mayo Clinic, Rochester, MN; [2]The University of Kansas Medical Center, Kansas City, AL; [3]University of Kansas Medical Center, Kansas City, KS.*

Background: PKD is a slowly progressive disease leading to end-stage renal disease (ESRD). Levels of FGF23 are elevated in PKD out of proportion to kidney function, and circulating levels of its receptor, Klotho, decreased. Whether these are associated with long term renal outcomes is unknown.

Methods: CRISP is an observational cohort study of 241 PKD patients. Kidney function was serially measured with iothomalate clearance(iGFR) and height-adjusted total kidney volume(htTKV) measured by MRI. Intact FGF23 and soluble Klotho were measured on 191 available baseline serum samples and dichotomized into high/low FGF23 groups (cutoff 50 pg/ml) and high/low Klotho groups (cutoff 1000 pg/ml). The association of baseline FGF23 and Klotho level with follow-up log-htTKV and iGFR was tested using linear mixed models with random intercepts and adjusted for age, gender and Irazabal class. The risk of combined endpoint of ESRD and death was evaluated using a multivariable adjusted Cox proportional hazards model.

Results: Baseline serum FGF23 was 58±29 pg/ml and Klotho 918±925 pg/ml (mean ± SD). High FGF23 and low Klotho were both associated with higher baseline htTKV and lower baseline iGFR. Median follow-up was 13 years, during which 37 patients died or reached ESRD. High FGF23 was associated with faster growth of htTKV over the follow-up period and faster decline in iGFR (adjusted mean slope -3.04 vs -2.21 ml/min/y, p= 0.0013). Low Klotho also was associated with faster increase in htTKV and faster decline in iGFR (adjusted mean slope -2.97 vs -1.70 ml/min/y, p<0.01). High serum FGF23 was associated with increased risk of ESRD/death (adjusted HR=2.4, p=0.04). Low Klotho was also associated with increased risk however not when adjusted for baseline iGFR (Adjusted HR=0.4, p = 0.14 for Klotho).

Conclusions: Higher serum FGF23 and lower serum Klotho are associated with faster kidney growth and decline in renal function. Higher FGF23 was associated with increased risk of ESRD or death after adjustments for age, gender, Irazabal class and baseline iGFR.

FR-PO304

Mineralocorticoid Antagonism and Vascular Function in Early Autosomal Dominant Polycystic Kidney Disease: A Randomized-Controlled Trial Kristen L. Nowak, Berenice Y. Gitomer, Heather Farmer-Bailey, Wei Wang, Diana George, Michel Chonchol, Mikaela R. Malaczewski. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Arterial dysfunction, featuring impaired vascular endothelial function and increased large-elastic artery stiffness, is evident early autosomal dominant polycystic kidney disease (ADPKD), and is an important predictor of cardiovascular events and mortality. Aldosterone excess has been implicated in the development of endothelial dysfunction are arterial stiffness. We hypothesized that aldosterone antagonism would reduce arterial dysfunction in patients with early-stage ADPKD.

Methods: In a randomized, controlled, double-blind trial, n=60 adults 30-55 years of age with ADPKD, normal kidney function (estimated glomerular filtration rate [eGFR] ≥60 mL/min/1.73 m^2), and receiving the maximum tolerable dose of an angiotensin converting enzyme inhibitor were randomized to receive either spironolactone (titrated to maximum dose of 50 mg/day) or placebo for 6 months. The primary endpoints were change in vascular endothelial function, measured as brachial artery flow-mediated dilation (FMD_{BA}) and arterial stiffness, measured as carotid-femoral pulse-wave velocity (CFPWV).

Results: Participants were 34±10 (mean±s.d.) years of age, 53% female and 80% White, with an eGFR of 94+21ml/min/1.73m^2. Spironolactone did not change FMD_{BA} (baseline: 8.0±5.5%, 6 months: 7.7±4.1%; placebo: baseline: 8.4±6.2%, 6 months: 7.9±4.3%; p≥0.63), but reduced CFPWV (baseline: 640±127 cm/sec, 6 months: 4: 603±101 cm/sec; p<0.05) with no change in the placebo group (baseline: 659+138 cm/sec, 6 months: 661±132 cm/sec; p=0.90). Brachial systolic blood pressure (SBP) was also reduced in the spironolactone group (baseline: 124±13 mmHg, 6 months: 117±11 mmHg; p<0.05) with no change in the placebo group (p=0.50). Spironolactone also reduced brachial and carotid pulse pressure, carotid SBP, and carotid augmentation index (p<0.05), with no changes in the placebo group.

Conclusions: Six months of aldosterone antagonism with spironolactone reduced arterial stiffness and SBP without changing vascular endothelial function in patients with early-stage ADPKD.

FR-PO305

Transplant Outcomes in Patients with Autosomal Dominant Tubulointerstitial Kidney Disease (AD-TKD) Sarah Cormican,[1] Dervla M. Connaughton,[3] Claire Kennedy,[1] Katherine A. Benson,[4] Gianpiero Cavalleri,[5] Brendan Doyle,[1] Anthony M. Dorman,[1] Mark A. Little,[6] Peter J. Lavin,[6] Kendrah O. Kidd,[7] Anthony J. Bleyer,[7] Peter J. Conlon.[2] *[1]Beaumont Hospital, Dublin 9, Ireland; [2]Beaumont Hospital, Dublin 9, Co Dublin, Ireland; [3]Boston Children's Hospital, Boston, MA; [4]Queen's University, Belfast, Belfast, United Kingdom; [5]RCSI, Dublin, Italy; [6]Trinity College Dublin, Dublin, Ireland; [7]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: ADTKD is a rare genetic cause of chronic kidney disease which causes progressive tubular atrophy and interstitial fibrosis with loss of renal function. Patients with ADTKD frequently progress to end stage renal disease (ESRD). Little is known about transplant outcomes in this group.

Methods: Patients with clinical characteristics consistent with ADTKD by the criteria outlined in the 2015 KDIGO consensus report were identified through the Irish Kidney Gene Project. Clinical and histology records were reviewed for patients who received a renal transplant during follow-up. We compared ADTKD transplant outcomes with those of 4004 non-ADTKD transplant recipients.

Results: 29 patients were identified; fifteen of whom had a known mutation (ADTKD-*MUC1* n=9, ADTKD-*UMOD* n=6). Fourteen patients met KDIGO criteria for diagnosis based on histology and family history without an identified mutation (ADTKD-NOS). Four patients received a second transplant during follow-up. In total 33 grafts (28 deceased donor, 5 living related donor) were included. 1-year, 5-year and 10-year graft survival for patients with ADTKD vs. non-ADTKD patients were: 100% vs. 90%, 96% vs. 77% and 72% vs. 60%. On log-rank test for equality of survival functions these differences were not statistically significant. Fifteen patients had at least one transplant biopsy performed during follow-up (26 transplant biopsies were performed in total). The most common findings were chronic allograft nephropathy (n=11) and acute rejection (n=10). Cyclosporin toxicity (n=2), polyoma virus nephropathy (n=1), acute tubular necrosis (n=1) and donor-related fibrosis (n=1) were also seen. Features sugestive of recurrent disease were not described Fourteen grafts were lost during follow-up due to patient death (n=7), chronic allograft nephropathy (n=6) and polyoma-virus nephropathy combined with acute rejection (n=1).

Conclusions: In patients with ESRD due to ADTKD we demonstrate that transplant outcomes are comparable with the general transplant population. Increasing our ability to identify the responsible genetic mutation in each patient will allow screening of relatives who wish to donate but are potentially affected.

Efficacy and Safety of Tolvaptan in Autosomal Dominant Polycystic Kidney Disease with Renal Insufficiency Masahiko Oguro,[3] Junichi Hoshino,[3] Masayuki Yamanouchi,[2] Yoshifumi Ubara.[1] *[1]None, Setagaya, Japan; [2]Okinaka Memorial Institute for Medical Research, Tokyo, Japan; [3]Toranomon Hospital, Kawasaki, Japan.*

Background: A recent study demonstrated that tolvaptan slowed kidney volume growth and kidney function decline in autosomal dominant polycystic kidney disease (ADPKD) patients with creatinine clearance ≧60 ml per minute. However, tolvaptan's efficacy in advanced chronic kidney disease (CKD) patients—especially those whose eGFR is <30ml per minute—has remained unknown.

Methods: In this prospective cohort study, 54 patients with ADPKD who had eGFR≧15 per minute and total kidney volume (TKV) ≧750 ml were treated with tolvaptan. The primary endpoint was a change in TKV and eGFR over 1 year treatment with tolvaptan across CKD stages G2-G4. The secondary endpoint was the final dose of tolvaptan and proportion of tolerance at each CKD stage.

Results: The rate of kidney growth during the 1-year treatment didn't differ significantly across CKD stages G2-G4. The median [IQR] of relative change in TKV in CKD stages G2, G3a, G3b, and G4 was, respectively, 5.70 [-0.67, 8.75], 6.66 [2.02, 17.66], 8.22 [5.97, 31.39], and 8.80 [4.12, 25.88] %/year (P=0.34). Nor did the rate of eGFR decline during the 1-year treatment differ significantly across CKD stages G2-G4. The relative annual change in eGFR—compared with the baseline eGFR—was, respectively, -4.15 [-11.78, 0.08], -7.28 [-11.17, -0.49], -7.02 [-16.74, -2.68], and -10.76 [-13.93, -18.6] %/year (P=0.59). Tolerance didn't differ significantly across CKD stages G2-G4.

Conclusions: This analysis suggests that patients with advanced CKD stages—including G4—might benefit from treatment with tolvaptan as do patients with preserved kidney function.

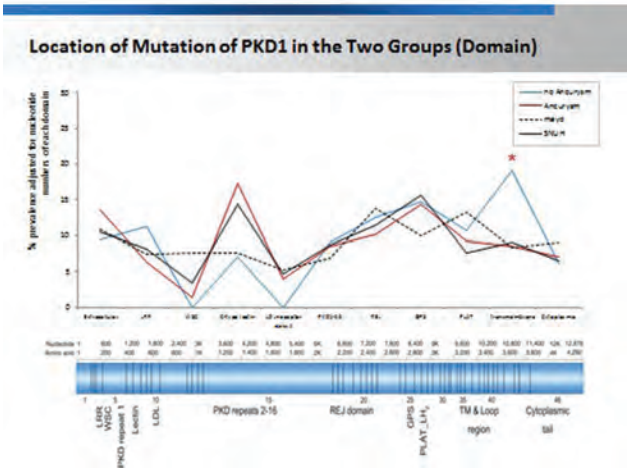
Cerebrovascular Phenotype and Genotype Correlation in ADPKD: A Study in HOPE-PKD Hyun suk Kim,[2] Hyunjin Ryu,[2] Chung Lee,[3] Jongho Heo,[4] Curie Ahn,[2] Yun Kyu Oh.[1] *[1]Department of Internal Medicine, Boramae Medical Center, Seoul, Republic of Korea; [2]Seoul National University Hospital, JongNo-Gu, SEOUL, Republic of Korea; [3]Samsung Genome Institute, Seoul, Republic of Korea; [4]JW LEE Center for Global Medicine, Seoul, Republic of Korea.*

Background: Cerebral aneurysm occurs in ADPKD (autosomal dominant polycystic kidney disease) by about 20% in the subjects older that 60years. The current study aimed to define phenotype characteristics of aneurysm, confirm the familial clustering effect and analyze the genetic differences in aneurysm vs. no aneurysm subjects in ADPKD.

Methods: Patients registered at the HOPE PKD cohort from October, 2009 to October, 2016 were included. Presence or absence of cerebral aneurysm and renal progression was reviewed, and PKD1/2 gene screening by targeted exome sequencing was performed. According to the presence or absence of cerebral aneurysm, the familial clustering effect was investigated and the proportions of PKD1 protein truncating (PT) mutations, PKD1 non-truncating (NT) mutations, PKD2, and no candidates (NC) were analyzed.

Results: A total of 398 families (n=538) were divided into aneurysm (n=131) or no-aneurysm group (n=407). In the aneurysm group, males were less prevalent (36.6 % vs. 49.9%, P=.010) and the mean age was significantly older (56.4 years vs. 50.2 years, P<.001). Similarly, females were prone to SAH events or intervention (n=21(72.4%)). The proportion of high risk group (Mayo classification 1C, 1D, and 1E) or ESRD, the median [IQR] of height adjusted kidney or liver were not different in age, and sex adjusted model. The family clustering effect adjusted for age and sex was significant in multilevel logistic regression model (P=0.012), However, the prevalence of genes (PT, NT, PKD2, NC) was not correlated with aneurysm. Four years later, aneurysm occurred in 16.1% (31/192, median follow up, 5.3 year) of the people who had not had it. The transmembrane domain was less related to occurrence of aneurysm.

Conclusions: Brain MRA is recommended at least every 4 years; every 3 years preferred for subjects with no aneurysm. The effect of PKD 1/2 gene type was not observed.



FR-PO308

Identifying ARPKD Patients at Risk for Dialysis in the First Year of Life – Data from the International Registry Study ARegPKD Kathrin Burgmaier,[3] Ismail Dursun,[7] Kevin Kunzmann,[4] Bruno Ranchin,[5] Rukshana Shroff,[1] Dorota Wicher,[2] Elke Wuehl,[4] Franz S. Schaefer,[4] Max Liebau.[3,6] *[1]Department of Nephrology, London, United Kingdom; [2]The Children's Memorial Health Institute, Department of Medical Genetics, Warsaw, Poland; [3]University Hospital Cologne, Cologne, Germany; [4]University of Heidelberg, Heidelberg, Germany; [5]Université de Lyon, Lyon, France; [6]Center for Molecular Medicine, University of Cologne, Cologne, Germany; [7]Erciyes University, Kayseri, Turkey. Group/Team: For ARegPKD consortium.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is a severe disease of early childhood and an important reason for renal replacement therapy in the first year of life. Yet, ARPKD shows pronounced phenotypic variability, making pre- and perinatal counseling challenging. Risk markers for the need of dialysis in the first year have not been established for ARPKD patients.

Methods: We studied the clinical courses of 385 patients from 18 countries included in the international ARPKD registry study ARegPKD using the time-to-event endpoint 'start of renal replacement therapy' and multivariate Cox regression.

Results: 36 patients started dialysis in the first year of life (median age at start of dialysis 0.14 years (0.00-0.91 years)). 30 children started peritoneal dialysis (PD), no patient underwent transplantation. Four patients deceased postnatally due to respiratory failure without onset of dialysis. Oligo/anhydramnios, enlarged prenatal kidney volume, high standardized birth weight and low 10-min APGAR score were associated with

an increased risk of dialysis need. Perinatal assisted breathing was associated with a markedly increased hazard ratio in the first 6 months of life but not thereafter.

Conclusions: The identification of indicators for the need of dialysis within the first year of life in ARPKD patients may allow predictive scoring to inform prenatal counseling.

FR-PO309

Relationship between Caffeine and Autosomal Dominant Polycystic Kidney Disease Progression Katelyn Mckenzie,[2] Mireille El Ters,[1] Alan S. Yu,[2] Jonathan D. Mahnken.[2] *[1]Mayo Clinic, Rochester, MN; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: Caffeine has been proposed, based on animal studies, to further progression of autosomal dominant polycystic kidney disease (ADPKD) by increasing cyst and kidney size. ADPKD patients are advised to minimize caffeine intake. We therefore investigated the effect of caffeine on kidney function in ADPKD.

Methods: Data from the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease study included 239 patients (96 males, mean age = 32.3 ± 8.9 years, 188 caffeine consumers) from 2001-2015. Caffeine intake was dichotomized (any vs. none). Linear mixed models, unadjusted and adjusted for age, sex, race, hypertension, genetics and time, were used to model the outcomes of height adjusted total kidney volume (htTKV) and iothalamate clearance (mGFR). Cox Proportional Hazard Models and Kaplan-Meier plots examined the effect of caffeine on time until ESRD/death, along with corresponding log-rank tests. Sensitivity analyses were conducted.

Results: Known risk factors (age, hypertension and genetics) were statistically significant in all adjusted models. While caffeine-by-time was statistically significant in unadjusted and adjusted models ($p < 0.01$) indicating faster growth in kidney volume using ln(htTKV) as an outcome, total kidney volume remained smaller from baseline (0 years) through 14 years (e.g., $p = 0.60$ for caffeine vs. none at 14 years). No differences in time to ESRD/death by caffeine were detected ($p > 0.12$).

Conclusions: We found that caffeine consumption in ADPKD was associated with statistically faster kidney growth. However, our models indicated kidney volume was smaller among caffeine consumers despite the increased rate of growth. This phenomenon persisted over all years modeled. No association with GFR over time was detected. Caffeine does not appear to be associated with larger kidney volumes.

Circulating Interleukin-6 Level Predicts Decline in Kidney Function in Autosomal Dominant Polycystic Kidney Disease Berenice Y. Gitomer,[2] Wei Wang,[9] Kristen L. Nowak,[11] Katharina Hopp,[10] Zhiying You,[6] Godela M. Brosnahan,[4] Peter C. Harris,[3] Vicente E. Torres,[3] Arlene B. Chapman,[7] Ronald D. Perrone,[5] Theodore I. Steinman,[1] Alan S. Yu,[12] Kaleab Z. Abebe,[13] Kyongtae T. Bae,[13] Michel Chonchol.[8] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Div. Renal Diseases and Hypertension, Aurora, CO; [3]Mayo Clinic, Rochester, MN; [4]None, Aurora, CO; [5]Tufts Medical Center, Boston, MA; [6]UC Denver, Aurora, CO; [7]University of Chicago, Chicago, IL; [8]University of Colorado, Aurora, CO; [9]University of Colorado Anschutz Medical Campus, Aurora, CO; [10]University of Colorado Denver, AMC, Aurora, CO; [11]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [12]University of Kansas Medical Center, Kansas City, KS; [13]University of Pittsburgh, Pittsburgh, PA.*

Background: There is significant variability in the rate of kidney function decline among patients with autosomal dominant polycystic kidney disease (ADPKD). Resultant from the growth of cysts, several processes contribute to kidney injury including inflammation and consequent fibrosis. We hypothesized that the level of the circulating pro-inflammatory cytokine interleukin-6 (IL-6) may indicate kidney inflammation and predict the rate of kidney function decline.

Methods: Serum from 407 subjects who participated in the HALT clinical trial and had a *PKD1* mutation were utilized in the study. IL-6 level was measured by a high sensitivity ELISA assay in the 24 month samples which were treated as baseline. Kidney function was assessed by eGFR using the CKD-EPI equation. Due to skewed distribution IL-6 was log transformed for analysis. Linear regression and mixed effects models were used to assess the association between circulating IL-6 and subsequent kidney function decline. Analyses were adjusted for age, sex, race, randomization group, systolic blood pressure and urinary albumin excretion.

Results: The mean age of included subjects was 40 ± 10 years and eGFR was 62 ± 27 ml/min/1.73m^2. In cross-sectional analysis when stratified by the median level, higher Ln IL-6 was significantly negatively associated with lower eGFR in the fully adjusted model (β -6.315, 95%CI -10.517,-2.109; $p = 0.003$). In longitudinal analysis, higher circulating IL-6 measured at baseline was independently associated with a greater decrease in eGFR in the fully adjusted model (β -10.207, 95% CI -11.315,-9.10; $p = < 0.0001$).

Conclusions: Inflammation indicated by higher IL-6 level at baseline predicts kidney function decline. This suggests that measurement of serum IL-6 or other inflammatory mediators at baseline may represent a predictive biomarker of kidney disease progression in ADPKD. Future validation of IL-6 as a biomarker of ADPKD progression in additional cohorts will be necessary to confirm these results.

Clinical Diagnosis of Senior Loken Syndrome in a Patient with SDCCAG8 Mutation Genetically Diagnosed as Having Bardet-Biedle Syndrome Yuko Fujii,[1] Akira Ashida,[1] Hideki Matsumura,[1] Akihiko Shirasu,[1] Satoshi Yamazaki,[1] Hyogo Nakakura,[1] Naoya Morisada,[3] Kazumoto Iijima,[3] Motoshi Hattori,[2] Hiroshi Tamai.[1] *[1]Pediatrics, Osaka Medical College, Takatsuki, Japan; [2]Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan; [3]Pediatrics, Kobe Univ. Graduate School of Medicine, Kobe, Japan.*

Background: Both Senior Loken Syndrome (SLS) and Bardet-Biedle Syndrome (BBS) are ciliopathies. SLS is characterized by retinitis pigmentosa (RP) and familial nephronophthisis, leading to end-stage kidney disease. BBS is characterized by six major symptoms: RP, polydactyly, obesity, genital abnormalities, learning difficulties, and renal defects. So far, ciliopathy has been diagnosed according to phenotypes, but now it is often diagnosed by genetic testing using techniques such as next-generation sequencing. Here we describe a patient who was clinically diagnosed as having SLS but in whom genetic testing indicated BBS.

Methods: The patient was diagnosed as having RP at the age of six years. She had learning disability, preobesity and dyslipidemia, but no polydactyly. When she was eight years old, she was diagnosed as having chronic kidney disease, anemia, and liver dysfunction. Kidney and liver biopsy revealed renal tubule cysts, tubule membrane disruption, and liver fibrosis. Therefore, SLS was diagnosed but no mutation in *NPHP1* was detected. Peritoneal dialysis was started at the age of nine years, and the patient underwent kidney transplantation with a graft from her father at the age of fourteen years. At the age of twenty years, she again underwent genetic testing for most of the mutations associated with ciliopathy. This revealed that she had a homozygous mutation in intron 11 of the *SDCCAG8* gene which had caused a frameshift mutation.

Results:

Conclusions: *SDCCAG8* is known to be one of the causative genes related to SLS and BBS without polydactyly. The fact that the patient had learning disability, preobesity and dyslipidemia suggested a high probably of BBS. Although these symptoms are not specific, she did not have the typical symptom of BBS including polydactyly. Therefore, a definitive diagnosis of BBS was difficult without any information concerning genetic mutation. As only a few cases of *SDCCAG8* mutation have been reported previously, accumulation of further cases will help to clarify the characteristics of the phenotype of *SDCCAG8* mutation, thus contributing to the better management of patients with ciliopathy.

FR-PO312

Reversibility of Serum Creatinine Elevation Observed in ADPKD Subjects Receiving the Tyrosine Kinase Inhibitor Tesevatinib David A. Eiznhamer,[1] Anjay Rastogi,[2] Michel Chonchol,[3] Ashraf El-Meanawy,[4] Theodore I. Steinman,[5] Karin Herrera,[1] Olivier Schueller,[1] John L. Ryan,[1] Pablo E. Pergola.[6] *[1]Kadmon Corporation, LLC, Cambridge, MA; [2]UCLA Medical Center, Los Angeles, CA; [3]University of Colorado, Aurora, CO; [4]Medical College of Wisconsin, Milwaukee, WI; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]Renal Associates PA, San Antonio, TX.*

Background: The KD019-101 trial has evaluated the safety and preliminary efficacy of tesevatinib in patients with ADPKD. Preliminary data suggested that subjects with ADPKD receiving tesevatinib experienced elevations of serum creatinine without concomitant elevations of cystatin C. Pre-clinical laboratory investigations determined that tesevatinib inhibited the human multidrug and toxin extrusion transporters MATE1 and MATE2-K (IC_{50} = 80nM and 68nM, respectively). This inhibition could result in increased serum creatinine in the absence of decrease in kidney function, due to the reduced tubular secretion of creatinine.

Methods: An additional cohort in Study KD019-101 enrolled subjects with eGFR ≥ 35 but ≤ 80 mL/min/1.73m^2 and htTKV ≥ 1000mL. These subjects had a mandatory 4-week drug holiday after the first 4 weeks of 50 mg QD tesevatinib treatment. During, and for 4 weeks after the drug holiday, subjects returned to the clinic weekly for serum creatinine and cystatin C measurement.

Results: 13 patients (6 males/7 females) were enrolled. Consistent with previous data, after an initial increase, serum creatinine stabilized. Creatinine levels begin to

decrease after 14 days of drug holiday and continued to decrease to baseline levels after 4 weeks of drug holiday. Resumption of drug resulted in similar increases as seen initially. Serum cystatin C levels were variable and did not show a pattern of increase before, during, or after the drug holiday period.

Conclusions: Serum creatinine elevations following tesevatinib dosing in patients with ADPKD are reversible upon cessation of dosing, and do not appear to result in a meaningful alteration in kidney function. This provides support for the hypothesis that serum creatinine elevation is a consequence of drug transporter inhibition resulting in the reduced tubular secretion of creatinine.

FR-PO313

First Year Follow-Up Data from the German ADPKD Tolvaptan Treatment Registry – AD(H)PKD Roman-Ulrich Mueller,[1] Franziska Grundmann,[1] Polina Todorova,[1] Katharina Burkert,[1] Claudia Witte,[2] Volker R. Burst,[1] Thorsten Persigehl,[3] Bernhard Schermer,[1] Thomas Benzing.[1] *[1]Department 2 of Internal Medicine, Renal Division; University of Cologne, Cologne, Germany; [2]University of Cologne, Cologne, Germany; [3]Department of Radiology, University Hospital Cologne, Cologne, Germany.*

Background: Admission of Tolvaptan in Europe by the EMA as the first targeted therapy of autosomal-dominant polycystic kidney disease (ADPKD) based on the findings of the TEMPO 3:4 trial is a milestone in the treatment of this disease. After the significant benefit on eGFR in TEMPO 3:4 and 4:4 more data on this therapy regarding crucial questions in the real-life setting would be highly valuable. How do patients accept the treatment taking into account polyuria? Is the target dose reached? What side effects occur? How is the effect regarding kidney function and volume? Which patients are selected for treatment? How does Tolvaptan affect quality of life? How good is the adherence to the therapy?

Methods: In order to answer these questions we established the multicentric German AD(H)PKD registry. Patients that are generally eligible for Tolvaptan, independent of whether actually taking the drug or not, can be included in this observational study. Blood values, kidney volume from imaging data, indicators of quality of life, adherence to therapy, the actual dose administered, genotype and data regarding extrarenal manifestations, comorbidity, side effects and complications are documented. After enrolment patients are followed-up in yearly visits for ten years.

Results: We have been able to recruit more than 270 ADPKD patients so far and have started the first-year follow-up visits at the end of 2016. Consequently, analysis of this cohort allows for the first characterization of patients presented for evaluation regarding initiation of Tolvaptan on the one hand. On the other hand the first-year data provide an interesting insight into which patients were selected for treatment and sheds light on dosing strategies. Furthermore, adherence to therapy and the impact on quality of life are analyzed.

Conclusions: The AD(H)PKD-registry provides the first comprising dataset on the German cohort of ADPKD patients eligible for treatment with Tolvaptan and analyzes the selection criteria applied by German nephrologists as well as tolerability, side effects and impact on other kidney-related outcomes. Follow-up of this cohort will provide valuable data that can help in counseling patients and informing physicians dealing with this novel treatment opportunity.

FR-PO314

Diagnosis of Renal Cyst Infection in Adult Polycystic Kidney Disease (ADPKD) Using 67-Gallium Citrate SPECT/CT: A Case Series Ester Casillas,[2] Victor Burguera,[2] Haridian Sosa Barrios,[2] Maria Delgado yagüe,[2] María eugenia Rioja garcia,[1] Laura V. Blanco,[2] Maite Rivera.[2] *[1]Hospital Universitario Ramon y cajal, Madrid, Spain; [2]Nephrology, Hospital Universitario Ramón y Cajal, Madrid, Spain.*

Background: Renal cyst infection in ADPKD patients is challenging, as it can be the source of life-threatening sepsis and frequently lack localizing symptoms. Recent guidelines establish that intracystic material compatible with infection should be obtained for definite diagnosis. Gold standard imaging to do so is PET/CT, which is expensive and restrained to certain centers. We sought to determine whether 67-Gallium-citrate scintigraphy is a valuable and inexpensive alternative to orientate renal cyst infection in these patients.

Methods: Between January 2015 and January 2016 (both included), five patients with ADPKD diagnosis presented in our center with kidney cyst infection. 3 were female and 2 male with a mean age of 50.4 ±17 years (range 32-72 years). Two patients were on renal replacement therapy (one HD and one PD), one had a functioning renal transplant and the remaining two had CKD. The most frequent presenting symptoms of cyst infection were fever (n=5) and abdominal pain (n=4) (Table).

Results: Ultrasound (US) scanning of both kidneys was done in 4 patients (80%) and computed tomography (CT) in all of them. US was compatible with infected cyst in one patient (sensitivity of 33%) and CT in two patients. 67-Ga-citrate SPECT/CT was positive in 4 patients (80%) and true negative in 1, proving better sensitivity (100%) and specificity than US and CT. During follow-up, we used 67-Ga-citrate scintigraphy in those patients with initial positive results treated to assess resolution and decide whether antibiotics should be discontinued. Two patients (50%) showed persistent tracer uptake despite a complete course of appropriate antibiotics for 6 weeks.

Conclusions: 67-Ga-citrate SPECT/CT is a non invasive and inexpensive study available in most centers. It can be used in all ADPKD patients with suspected renal cyst infection regardless of kidney function, being more cost-effective than PET/CT. Due to demonstrated potential as a diagnostic tool in this setting, we think it could be considered as an alternative to the PET/CT.

FR-PO315

Urinary L-Type Fatty Acid-Binding Protein (L-FABP) Reflects the Progression of Autosomal Dominant Polycystic Kidney Disease Shiika Watanabe,[4] Atsuko Ikemori,[4] Takeshi Sugaya,[3] Daisuke Ichikawa,[2] Mikako Hisamichi,[5] Kenjiro Kimura,[6] Yugo Shibagaki.[1] *[1]Division of Nephrology and Hypertension, St Marianna University Hospital, Kawasaki, Japan; [2]St Marianna University of Medical School, Yokohama City, Japan; [3]St. Marianna Univ, Tokyo, Japan; [4]St. Marianna University School, Kawasaki, Kanagawa, Japan; [5]St.Marianna university school of medicine, Kawasaki, Japan; [6]Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common inherited progressive kidney disease. Although some imaging modalities, such as ultrasonography, CT or MRI, are useful for diagnosing and staging ADPKD, these modalities are not adequate for monitoring the severity of ADPKD because the modalities detect cyst formation, but not tubulointerstitial inflammation and fibrosis. The aim of this study is to elucidate that urinary L-type fatty acid binding protein (L-FABP) is associated with the severity of ADPKD.

Methods: Male PCK/CrljCrl-Pkhd1pck/Crl (PCK) rats (n=21), of which features are similar to human ADPKD, were used as the ADPKD model. Age and gender-matched Sprague-Dawley rats (n=21) were used as control. Serum, urine, kidneys were obtained at 8, 12 and 16 weeks of age. Serum creatinine, serum L-FABP, urinary L-FABP, urinary KIM-1, urinary NGAL and urinary creatinine were measured.

Results: Serum creatinine and serum L-FABP levels in PCK rats were similar to those in the control rats. Cystic enlargement and progression of both tubulointerstitial inflammation and fibrosis along with age were observed in the PCK rats. Urinary L-FABP levels increased along with the severity of renal pathology, and the levels at 12 and 16 weeks in the PCK rats were significantly higher than in the control rats. Although urinary KIM-1 and urinary NGAL levels at 8, 12 and 16 weeks in the PCK rats were significantly higher than in the control rats, these markers did not increase along with the progression of renal pathology including the degree of cystic enlargement in the PCK rats.

Conclusions: Urinary L-FABP reflects not only the degree of cystic enlargement, but also the progression of tubulointerstitial damage and, therefore, may be useful for monitoring the progression of ADPKD.

FR-PO316

Pharmacogenomics of Tolvaptan's Inhibitory Effect on Kidney Volume Increase in Patients with Autosomal Dominant Polycystic Kidney Disease Shigeo Horie,[1] Masatoshi Masuda,[2] Steffen Neuber,[3] Satoru Muto,[1] Tadashi Okada,[2] Carsten Bergmann.[3] *[1]Advanced Informatics for Genetic Disease, Juntendo University, Tokyo, Japan; [2]Otsuka Pharmaceutical Co., Ltd., Osaka, Japan; [3]Center for Human Genetics, Bioscientia, Ingelheim, Germany.*

Background: We investigated the influence of genetic factors on tolvaptan treatment efficacy in patients with approved autosomal dominant polycystic kidney disease (ADPKD).

Methods: In the extension study of TEMPO 3:4 in Japan, DNA was collected from 100 patients. Germline variants of 116 genes (including all genes known for cystic/polycystic kidney disease) were sequenced by targeted next generation sequencing and called with a custom variant analysis pipeline sensitive for variants in sequence homology regions. Genetic architecture of samples was modeled as binary factor, discriminating those samples carrying solely *PKD1* or *PKD2* pathogenic variants from samples that harbored additional likely pathogenic variants in any of the other 114 targeted genes. Kidney volume growth rate was used as a marker for tolvaptan efficacy. A two-way factorial ANOVA was applied to test for a correlation between genetic architecture, treatment / placebo group and treatment efficacy as outcome.

Results: Sixty percent of our samples demonstrated multiple likely pathogenic variants in non-*PKD* genes. Statistical analysis revealed a significant main effect of

treatment vs placebo group as expected (p<0.009), and a non-significant main effect when considering modifier variants only (p<0.29). The interaction term combining modifier cases with treatment group was non-significant as well (p<0.14). We carried out subgroup analysis assuming that low power is the cause for not reaching significance in the interaction model, and observed that the kidney growth rate in patients with modifier pathogenic variants was significantly lower in the tolvaptan group. This difference was not clear in patients with singleton *PKD1* or *PKD2* pathogenic variants. Therefore, we hypothesize that tolvaptan may be more effective in patients with modifier pathogenic variants.

Conclusions: Additional pathogenic variants in modifier genes other than *PKD1* or *PKD2* may potentially affect the efficacy of tolvaptan in patients with ADPKD.

FR-PO317

Assessing Rapid ADPKD Progression in Clinical Practice in the Era of Tolvaptan Monica Furlano,[4] Teresa Marti,[2] Irene Loscos giménez,[4] Gemma Bullich vilanova,[1] Jose Ballarin,[4,3] Elisabet Ars,[1] Roser Torra.[4,3] *[1]Molecular Biology, Fundacio Puigvert, Barcelona, Spain; [2]Radiology, Fundació Puigvert, Barcelona, Spain; [3]Universitat Autónoma de Barcelona, Barcelona, Spain; [4]Nephrology, Fundacio Puigvert, Barcelona, Spain.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most frequent inherited kidney disease. The progressive cyst growth, together with interstitial damage causes progressive kidney failure but the severity of the diseases varies a lot among affected individuals. The EMA has approved tolvaptan for adults with CKD stage 1-3 at baseline who are rapid progressors (RP). Being the mean age in Europe of onset of ESRD for ADPKD patients 58 years, the ERA-EDTA WGKID/EBPG recommended to consider RP those patients predicted to reach ESRD before 58 years of age.

Methods: 297 ADPKD patients followed up in an outpatient clinic for inherited kidney diseases were assessed for rapid progression according to the EDTA-ERA WGIKD/EBPG recommendations. Only patients between 18-50 years of age were considered. Assessment was only indicated when eGFR was over 45ml/min and eGFR for patients 30-40 years old was below 90ml/min and for those 40-50 years old was below 60 ml/min. If the patients met these eGFR according to age, retrospective eGFR decline was assessed; if it was > 5 ml/year or >2.5 ml/year for 3 consecutive years patients were considered RP. For those who didn't met the retrospective eGFR criteria ultrasound (US) diameter was assessed. Patients younger than 45 with a renal diameter >16.5 cm were considered RP. For those not fulfilling any of the above criteria total kidney volume (TKV) by MRI was measured and the Mayo ADPKD calculator was applied. Patients class 1C,D,E were considered RP. Finally for patients younger than 35 with hypertension or urinary symptoms than did not met the above criteria genetic testing was performed and the PROPKD score was applied.

Results: The step by step process of RP assessment based on the EDTA-ERA/EBPG recommendations proved to be cost-effective and sensitive to identify RP. RP was identified in 16.5% of patients with CKD stage 1, 29% in CKD2 and 34.3% in CKD3a. 53.8% of patients aged 18-30 were rapid progressors while this number decreased with age: 30.9% from 31-40 years and 13.5% from 41-50 years.

Conclusions: The multi step algorithm provided by the EDTA-ERA/EBPG is useful to identify RP that would benefit from tolvaptan treatment. The use of the algorithm is cost-effective and fairly easy to incorporate into clinical practice.

FR-PO318

Total Kidney Volume (TKV) by Ellipsoid (EL) versus Manual Segmentation (MS) for Risk Classification in Autosomal Dominant Polycystic Kidney Disease (ADPKD): A Comparative Study Beili Shi,[1] Marina Pourafkari,[1,2] Ioan-Andrei Iliuta,[1] Elsa Guiard,[1] Crystal F. Quist,[1] Xuewen Song,[1] Korosh Khalili,[2] York P. Pei.[1] *[1]Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Department of Medical Imaging, University Health Network and University of Toronto, Toronto, ON, Canada.*

Background: TKV derived by EL is technically simple, less laborous, and used in the Mayo Clinic Risk Classifcation (MCRC).[1] However, it is less accurate than MS ("gold standard") and can result in risk misclassification. Our study aims to define the disagreement in TKV measuremnt and its resultant risk misclassification by EL vs. MS. [1] JASN 26:160-72,2015

Methods: A single center study of 409 consecutive PKD patients who underwent standardized MRI and genetic testing between 4/2011 and 2/2017. TKV by EL and MS will be measured in all patients by a single radiologist. Bland-Atman plots are used to assess agreement.

Results: Of 203 patients who completed analyses, 33 (16%) with atypical imaging patterns were excluded. The clinical characteristics of the remaining patients are shown in Table. The MC risk classes significantly correlated with distinct mutation classes (X2=48, P<0.001, Figure 1). We found >20% disagreement in 11.2% of individual kidney volume and 5.3% of TKV, resulting in misclassification of 24 (14.1%) patients. None of the misclassified cases spanned more than one risk category.

Conclusions: Our preliminary results suggest that TKV measured by EL in a standardized setting did not result in a high rate of risk misclassification of serious clinical consequence.

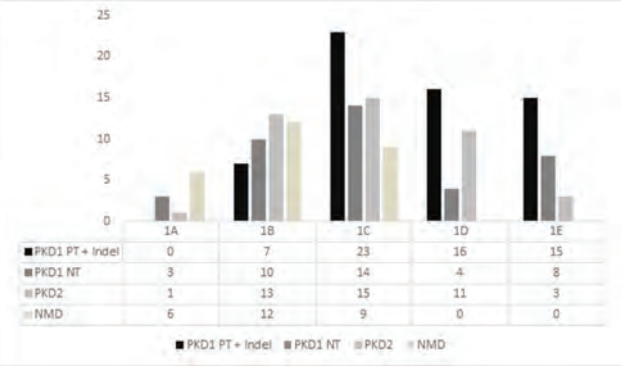
Patient Characteristics

Total Number	170
Gender (M/F)	1:1
Age at MRI (y, mean ± SD)	44.3 ± 1.1
Serum Creatinine (μmol/L, median with IQR)	91.0 (69.3 – 121.2)
Estimated GFR (ml/min.1.73m2, mean ± SD)	77.1 ± 2.5
Mutation Class N (%)	
PKD1 truncating + in-frame deletion	61 (35.9)
PKD1 non-truncating	39 (23.0)
PKD2	43 (25.3)
No Mutation Detected	27 (15.8)



Significant difference between NMD vs. other mutation classes (P<0.001) and PKD1 PT+Indel vs. PKD2 (P=0.043).

FR-PO319

Elevated Circulating Homocysteine Levels Precede Hemodynamic Changes and Correlate with Disease Severity in Young Autosomal Dominant Polycystic Kidney Disease (ADPKD) Patients Madhuri Chengappa, Ali Kahveci, Marie E. Edwards, Fouad T. Chebib, Sandra Herrmann, Bernard F. King, Amir Lerman, Lilach O. Lerman, Vicente E. Torres, Maria V. Irazabal. *Mayo Clinic, Rochester, MN.*

Background: Vascular manifestations are the most important non-cystic complications and the main cause of death in patients with ADPKD. Endothelial dysfunction and vascular remodeling are detectable early in ADPKD, and a decrease in magnetic resonance imaging (MRI)-derive renal blood flow (RBF) has been proposed as a marker of disease severity. Homocysteine (Hcy), a precursor of hydrogen sulfide, is an established biomarker for endothelial dysfunction and vascular disease and linked to increased oxidative stress. However, whether increased circulating Hcy levels correlate with disease severity and precede hemodynamic changes in early ADPKD has not been reported.

Methods: We prospectively measured circulating levels of Hcy (LC/MS/MS) and 8-isoprostane (ELISA) in early (18-30 years, eGFR>90 mL/min/1.73 m2) normotensive (<140/90 mmHg without BP medication) ADPKD patients, and in age-matched healthy volunteers (HV) (n=10, 6F/4M each). Total kidney volume (TKV) and RBF were evaluated with MRI.

Results: Mean age was 23 years old, but TKV twofold higher in ADPKD vs. HV (Table). BP tended to be elevated in ADPKD, but eGFR, RBF, and height adjusted RBF (HtRBF) were similar between the groups (Table). Circulating levels of Hcy and 8-isoprostanes were elevated in ADPKD vs. HV (Table, Fig, p<0.05). Furthermore, Hcy and isoprostane (but not RBF) levels directly correlated with TKV and HtTKV (Fig).

Conclusions: Early ADPKD is associated with elevation in circulating Hcy and isoprostane levels, which correlate with disease severity. These findings imply that oxidative stress and endothelial dysfunction might be present before overt hemodynamic changes, and possibly contribute to disease progression. Further experiments are needed to investigate the sources of oxidative stress in patients with ADPKD.

Baseline Parameter	ADPKD Patients	Healthy Volunteers	p value
Gender (M/F)	4/6	4/6	
Age	23 ± 3	23 ± 3	0.804
MAP (mmHg)	93 ± 9	85 ± 8	0.058
eGFR (mL/min/1.73m²)	110.6 ± 12.4	104.9 ± 19.3	0.436
TKV (mL)	641 (389 – 966)	304 (231 – 364)	<0.001
HtTKV (mL/m)	366 (239 – 529)	176 (144 – 198)	<0.001
RBF (cc/min)	1080 ± 147	1072 ± 137	0.903
HtRBF (cc/min/m)	621 ± 100	622 ± 78	0.993

Decreased Urinary Citrate Excretion Associates with Disease Severity in Autosomal Dominant Polycystic Kidney Disease Arlene B. Chapman,[6] Bharathi V. Reddy,[6] Matthew Lanktree,[4] Chengli Shen,[8] Vicente E. Torres,[3] Michal Mrug,[5] Frederic F. Rahbari-Oskoui,[1] Alan S. Yu,[7] William M. Bennett,[2] Peter C. Harris,[3] Kyongtae T. Bae,[8] Doug Landsittel.[8] *[1]Emory University School of Medicine, Atlanta, GA; [2]Legacy Good Samaritan Medical Center, Portland, OR; [3]Mayo Clinic, Rochester, MN; [4]None, Dundas, ON, Canada; [5]University of Alabama at Birmingham, Birmingham, AL; [6]University of Chicago, Chicago, IL; [7]University of Kansas Medical Center, Kansas City, KS; [8]University of Pittsburgh, Pittsburgh, PA.*

Background: Autosomal dominant polycystic kidney disease (PKD) is characterized by increased cyst burden measured by total kidney volume (TKV) and loss of kidney function. Urinary citrate excretion (UCE), known to be decreased in PKD associates with complications of disease including nephrolithiasis and urinary acidification defects. In the observational longitudinal Consortium for Radiologic Studies in Polycystic Kidney Disease (CRISP), 24 hour UCE was measured annually during the first three years of study. We postulate that decreased UCE is an independent marker of disease severity in PKD and associates with genotype, increased TKV, decreased eGFR and decreases over time.

Methods: 224 of 241 participating CRISP subjects with baseline creatinine clearance >70 ml/min had 24 hr UCE as well as DNA, TKV and corrected iothalamate clearance (CIC) measurements completed in a Clinical Research Center setting.

Results: UCE correlated inversely with TKV (r=-0.26, P<0.001) and directly with CIC (r=0.16, P<0.02). Irazabal Class 1A subjects (n=14) had greater UCE (653±257 mg/day) than Class 1C (n=68, 449+241 mg/day, P<0.03), 1D (n=54, 452±295 mg/day, P<0.02) or 1E (n=35, 393±198 mg/day P<0.008). UCE was significantly lower in PKD1 vs. PKD2 patients (276 ±269 vs.682± 523 mg/day, P<0.01) No differences (P=NS) were seen in UCE between PKD1 truncating and non-truncating mutations (275±211 vs. 278±289 mg/day). UCE decreased 19.1 mg/day/year over 3 years (P<0.03), and significantly declined in PKD1 patients only. A forward linear regression selection method with an entry criteria of p=0.1 demonstrated that PKD1 genotype, urine volume, TKV and age, associated negatively with baseline UCE, while increasing sodium excretion, CIC and male gender associated with UCE. When baseline UCE was combined with TKV, area under the receiver operator characteristic curve for predicting CKD stage 3 in 8 years was 0.83.

Conclusions: TKV and CIC associate with decreased UCE early in PKD. Reductions in UCE in PKD1 patients showed no difference between truncating and non-truncating mutations. Decline in UCE occurred over three years and UCE may be a biomarker that associates with disease severity and progression in PKD.

FR-PO321

Patient-Reported Disease Burden in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Using the ADPKD Pain and Discomfort Scale (ADPKD-PDS) and ADPKD Impact Scale (ADPKD-IS) Dorothee Oberdhan,[1] Siddhesh Kamat,[1] Alexis Denny.[2] *[1]Otsuka Pharmaceutical Development & Commercialization, Inc., Princeton, NJ; [2]PKD Foundation, Kansas City, MO.*

Background: ADPKD is an inherited disease leading to kidney enlargement, worsening of kidney function, and quality of life impacts. The objective of this research is to describe patient-reported pain, discomfort, and disease impact using two new questionnaires.

Methods: 2,353 ADPKD patients (age ≥18 years) were invited to participate in a survey. Assessments included: ADPKD-PDS measuring severity and impact of dull pain (chronic ache), sharp pain (acute), and discomfort (chronic fullness/pressure) over the last 7 days via 20 items, and ADPKD-IS measuring physical, emotional, and fatigue impact over the last 2 weeks via 18 items. Age, gender, ethnicity, chronic kidney disease (CKD) stage, and time since ADPKD diagnosis were collected.

Results: For 289 qualified respondents mean age was 48.8 years (SD ±12.3), 80.2% were female, and CKD stage broadly distributed: CKD Stage 1 (27.3%), CKD Stage 2 (21.1%), CKD Stage 3 (30.4%), CKD Stage 4 (11.4%), CKD Stage 5 (9.6%). Mean Scores for ADPKD-PDS and -IS are reported in the table below.

Conclusions: Patient burden starts early in disease with differentiation between CKD stages. Results follow clinically expected patterns where events triggering sharp pain (eg, cyst burst/infection) are rare and intermittent but chronic pain is more constant due to growing kidneys. Clinical significance of these scores needs further evaluation.

FR-PO322

Peritoneal Dialysis in Pediatric ARPKD Patients Aziz Akarkach,[1] Kathrin Ebner,[1] Anja C. Sander,[2] Franz S. Schaefer,[2] Max Liebau.[1,3] *[1]University Hospital Cologne, Cologne, Germany; [2]University of Heidelberg, Heidelberg, Germany; [3]Center for Molecular Medicine, University of Cologne, Cologne, Germany. Group/Team: For IPPN consortium.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is associated with dialysis-requiring end stage renal disease in about 40-50% of patients during childhood and adolescence. Many ARPKD patients receive peritoneal dialysis (PD) but structured data on PD in pediatric ARPKD patients is missing.

Methods: We identified ARPKD patients in the international pediatric peritoneal dialysis network (IPPN) registry and compared their clinical courses and PD-specific parameters to two control groups suffering from other renal disorders (CAKUT, Congenital Nephrotic Syndrome). Cohorts were matched for age and time on dialysis.

Results: 79 ARPKD patients were identified and matched to CNS (n=79) and CAKUT (n=158) patients. Mean age at inclusion into the IPPN registry was 4.38 years in the ARPKD group vs 4.33 years (CNS) and 4.40 years (CAKUT), respectively. Mean time on dialysis at inclusion was 1.01 years (ARPKD) vs. 0.77 years (CNS) and 1.00 years (CAKUT). Mean observation time within the frame of the registry was 14.6 months (ARPKD) vs. 11.2 months (CNS) and 13.2 months (CAKUT). There were no major differences in basic anthropometric data (height, weight, BMI) or general PD parameters (e.g. PD modality, applied PD fluids, fluid turnover per day, average glucose concentration), but ARPKD patients had regimes with lower overall fill volumes and more cycles than CNS- or CAKUT-patients. First longitudinal observations suggest that overall technique survival as well as the peritonitis rate in ARPKD children on PD do not show major differences compared to patients with other underlying disease entities.

Conclusions: Overall, children with ARPKD in this cohort do not show major dialysis-associated differences when compared to two age-matched pediatric PD control groups suggesting that PD can be applied in the same way as for children with other underlying renal disorders.

FR-PO323

Frequent Genetic Variants in Autosomal Dominant Tubulointerstitial Kidney Disease Eric G. Olinger,[3] Celine Schaeffer,[1] Kendrah O. Kidd,[4] Daniel G. Fuster,[2] Andreas D. Kistler,[5] John Sayer,[6] Anthony J. Bleyer,[4] Luca Rampoldi,[1] Olivier Devuyst.[3] *[1]San Raffaele Scientific Institute, MILAN, Italy; [2]University Hospital of Bern, Bern, Switzerland; [3]University of Zurich, Zurich, Switzerland; [4]Wake Forest University School of Medicine, Winston-Salem, NC; [5]Cantonal Hospital Frauenfeld, Frauenfeld, Switzerland; [6]Institute of Genetic Medicine, Newcastle, United Kingdom.*

Background: An increasing number of purported pathogenic genetic variants are detected as relatively common in exome data from the general population, suggesting previous misclassification. Mutations in *UMOD* cause autosomal dominant tubulointerstitial kidney disease (ADTKD) that is rare (1-10/1'000'000), well indexed and has genetic features (private mutations, complete penetrance) making it paradigmatically suited to address the evolving distinction between normal genetic variation and pathogenic variants.

Methods: Reported *UMOD* mutations from our ADTKD registry were retrospectively compared to sequencing data from gnomAD (http://gnomad.broadinstitute.org). Matching variants were tested by cellular studies and segregation analysis.

Results: Based on then-available filtering strategies, 107 *UMOD* variants were reported as pathogenic in 181 families from our ADTKD registry. Two of them are reported in gnomAD: p.T62P (AF 0.00034) and p.T469M (0.00070). An allele frequency of ~$5x10^{-8}$ would be expected based on the disease prevalence and the number of reported mutations. The p.T62P and p.T469M variants have been previously linked to ADTKD and they were detected respectively in 9 and 2 unrelated patients with CKD, gout and positive family history in our registry. T62 lacks any evolutionary constraint and trained classifiers (eg. PolyPhen-2) predict a benign to possibly damaging phenotype for p.T62P. T469 is a conserved residue and p.T469M is predicted to be damaging. Expression studies in kidney cell lines reveal an extremely mild or no trafficking defect for p.T62P and p.T469M, as opposed to the well-established mutation p.C150S. Furthermore, the p.T62P variant does not segregate with disease, including several aged carriers with absent kidney disease.

Conclusions: The high frequency of 2 imputed variants in *UMOD* led us to reevaluate the genetic diagnosis of several ADTKD families in our registry and to definitively infirm the pathogenicity of *UMOD* p.T62P. With evolving sequencing data, careful curation of implausibly common variants in Mendelian diseases other than ADTKD is warranted.

FR-PO324

Clinical Assessment and Prediction of Efficacy of Tolvaptan in Autosomal Dominant Polycystic Kidney (ADPKD) Kaori Takayanagi, Yuta Kogure, Minoru Hatano, Hiroaki Hara, Kento Hirose, Koki Ogawa, Yuichiro Kawai, Ryo Yamamoto, Tomonari Ogawa, Koichi Kanozawa, Hajime Hasegawa. *Nephrol, Hypertens, and Blood Purification, Saitama Med Center, Saitama Med Univ, Kawagoe, Japan.*

Background: In Japan, more than 3000 patients with autosomal dominant polycystic kidney disease (ADPKD) have received Tolvaptan therapy at present, and its averaged clinical efficacy is suggested to be approximately 50%. Here, we report the clinical efficacy of Tolvaptan in our facility, and refer to the clinical features shown in the highly effective patients.

Methods: ADPKD patients with Tolvaptan therapy who have received follow up-CT scanning one year after beginning the therapy (n=23) were retrospectively analyzed.

Results: Mean age, number of male, median value of total kidney volume (TKV), median value of kidney growth rate (KGR) and mean eGFR at the start of the therapy were 45.4±14.7 years-old, 18 cases (78.8%), 1478.3 mL, 5.4%/year, and 50.9±20 mL/min, respectively. After one year Tolvaptan therapy, TKV and KGR were reduced to 1306.5 mL and -3.7%/year, and 17 of 23 cases (73.9%) showed reduced TKV (KGR<0%) by one year Tolvaptan therapy. When all cases were divided into four groups by the quartile value of KGR, and the 1st quartile group (1-QG, most effective, median KGR=-16.3%/year) was compared to 4-QG (worst effective, median KGR=8.1%/year) by the clinical parameters at the start of the therapy, mean age, mean BMI, mean systolic blood pressure, median TKV, median KGR, mean eGFR, mean serum Na and Mg, median urine osmolality were 49.6 vs 46.4 years-old, 20.0 vs 22.0, 125.0 vs 127.0 mmHg, 1514.4 vs 2511.5 mL, 6.4 vs 9.5%/year, 54.5 vs 48.5 mL/min, 139.7 vs 141.2 mmol/L, 1.87 vs 2.08 mg/dL, 247.2 vs 415.0 mOsm/kg, respectively. In comparison of two groups, significant difference was observed in urine osmolality and serum Mg.

Conclusions: In our facility, reduction of kidney volume was observed in 73.9% of cases, and 87.6% of cases showed KGR less than 5%/year, indicating that Tolvaptan therapy is significantly effective for the inhibition of cyst growth. It is also suggested that patients showing diluted urine by accelerated water intake and low serum Mg would be particularly expectable regarding the clinical efficacy of Tolvaptan.

FR-PO325

An Atypical Case of Fungal Cyst Infection in ADPKD Laura Onuchic,[1] Antonio A. Portela Neto,[1] Fernanda T. Ferreira,[1] Leonardo A. Testagrossa,[2] Elieser H. Watanabe,[1] Bruno E. Balbo,[1] Luiz F. Onuchic.[1] *[1]Nephrology and Molecular Medicine, University of Sao Paulo, Sao Paulo, Brazil; [2]Pathology, University of Sao Paulo, Sao Paulo, Brazil.*

Background: Cyst infection is a significant cause of mortality in autosomal dominant polycystic kidney disease (ADPKD). It is typically associated with gram-negative bacteria and is most often related to the ascending urinary tract route. Fungal etiology is rare, with very few reports. Positron emission tomography/computed tomography (PET-CT) has become the most sensitive imaging technique to diagnose cyst infection.

Methods: A 34-year-old female with ADPKD was referred for persistent fever and malaise. She reported vaginal candidiasis 2 months prior to admission. Following right kidney obstruction secondary to ureteral calculus, she was submitted to double-J stent placement. After 2 days she developed fever and abdominal pain. Urine and blood cultures were negative; WBC count and C-reactive protein, however, were elevated. Initial CT scan was inconclusive for cyst infection. At this point she received broad-spectrum antibiotics, including ciprofloxacin. Despite treatment, the patient presented no clinical improvement and developed acute kidney injury, with a rise in serum creatinine from 0.38 to 2.3 mg/dL. She was then transferred to our referral center. In this scenario, PET-CT revealed high 18F-glucose uptake in multiple right kidney cysts. Ultrasound-guided percutaneous drainage of the dominant suspected cyst and culture of its material led to the diagnosis of *Candida albicans* infection. Histopathology analysis confirmed this finding, showing cystic and pericystic hypha and pseudohypha invasion. She was then started on fluconazole, but this therapy was not effective. Given the refractoriness to this treatment, she was submitted to right nephrectomy, which led to initiation of hemodialysis. Prolonged hospitalization led to urinary infection by carbapenemase-resistant *Klebsiella pneumoniae* followed by sepsis. In this setting, the patient was submitted to left nephectomy, which resulted in clinical improvement and hospital discharge.

Results:

Conclusions: We report a case of ascendant fungal cyst infection, a very unusual form of this complication in ADPKD. Antibiotic treatment algorithms targeting cyst infection do not contemplate antifungal therapy as an initial approach. This case underscores, however, the importance of considering such an etiology and the need of culturing cyst material in refractory cyst infections.

FR-PO326

Lixivaptan, a Novel Vasopressin V2 Receptor Antagonist in Development for the Treatment of Autosomal Dominant Polycystic Kidney Disease Lorenzo Pellegrini,[5] Jeffrey L. Woodhead,[3] Lisl Shoda,[1] Scott Q. Siler,[1] Brett A. Howell,[2] Cesare Orlandi.[4,6] *[1]DILIsym Services, Research Triangle Park, NC; [2]DILIsym Services Inc., Research Triangle Park, NC; [3]DILIsym Services, Inc., Research Triangle Park, NC; [4]Lantheus Medical Imaging, Boston, MA; [5]Palladio Biosciences, Newtown, PA; [6]Cardiokine, Inc., Philadelphia, PA.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is one of the most prevalent inherited genetic diseases in humans. Recent advances established vasopressin V2 receptor inhibition as a clinically validated mechanism of action for ADPKD, however safe and effective disease-modifying therapies for ADPKD are still lacking. Here we evaluated whether lixivaptan, a potent, selective vasopressin V2 antagonist, has characteristics that suggest a favorable benefit-risk profile for ADPKD.

Methods: Using the large body of existing preclinical and clinical data on lixivaptan encompassing 36 clinical studies and 1,673 independent patient exposures, we evaluated the projected efficacy and safety profile of lixivaptan for ADPKD. To explore efficacy, we compared the effect of lixivaptan with the related vasopressin V2 antagonist tolvaptan on accepted pharmacodynamic markers of efficacy in ADPKD. To explore safety, we conducted a multiscale computational model of drug-induced liver injury, a DILIsym evaluation, to determine lixivaptan's propensity to cause hepatocellular injury compared with the known hepatotoxin tolvaptan.

Results: Potent suppression of urine osmolality (U_{osm}) was seen with lixivaptan in healthy individuals and patients with hyponatremia of various etiologies, suggesting the potential for disease-modifying efficacy in ADPKD. In particular, 200mg BID doses of lixivaptan for 7 days resulted in uninterrupted U_{osm} below 300 mOsm/kg over 24 hours in 78% of healthy volunteers in study CK-0407. In contrast to tolvaptan, lixivaptan exposure was lower in patients with impaired renal function than in healthy individuals (32% and 31% lower for $AUC_{0-\infty}$ and C_{max}, respectively), without affecting lixivaptan's ability to attain target U_{osm} levels. Importantly, unlike tolvaptan, lixivaptan was not associated with hepatocellular toxicity at doses intended for ADPKD in the DILIsym evaluation.

Conclusions: Our analysis suggests that lixivaptan has the potential to become a safe and effective therapy for the treatment of ADPKD in a broad patient population, paving the way for upcoming clinical trials with lixivaptan for ADPKD.

The Burden of Autosomal Dominant Tubulo-Interstitial Kidney Disease (ADTKD) in Ireland Sarah Cormican,[1] Dervla M. Connaughton,[3] Claire Kennedy,[4,1] Katherine A. Benson,[5] Gianpiero Cavalleri,[6] Brendan Doyle,[1] Anthony M. Dorman,[1] Mark A. Little,[7] Peter J. Lavin,[7] Kendrah O. Kidd,[8] Anthony J. Bleyer,[8] Peter J. Conlon.[2] *[1]Beaumont Hospital, Dublin 9, Ireland; [2]Beaumont Hospital, Dublin 9, Co Dublin, Ireland; [3]Boston Children's Hospital, Boston, MA; [4]None, Dublin 9, Ireland; [5]Queen's University, Belfast, Belfast, United Kingdom; [6]RCSI, Dublin, Italy; [7]Trinity College Dublin, Dublin, Ireland; [8]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Hereditary mutations in the *MUC-1, UMOD, HNF* and *REN-1* genes cause renal tubular atrophy, interstitial inflammation and fibrosis with progressive renal impairment. A recent KDIGO consensus report advocated the unified term ADTKD (sub-classified by causative gene) for these conditions, replacing older terminology such as medullary cystic kidney disease.

Methods: Individuals with possible ADTKD were identified by the Irish Kidney Gene Project and invited to attend for DNA collection with the Rare Kidney Disease Registry and Biobank. Genetic analysis was undertaken in RCSI Renal Genetics Unit and the Nephrology Department in the Wake Forest School of Medicine. Patients were sub-categorised as ADTKD-*MUC1,* ADTKD-*UMOD* or ADTKD-*NOS* (not otherwise specified) based on the identification of a mutation in the patient or an affected relative.

Results: 64 individuals from 28 families were included. Genotyping results are available on 36 individuals from 22 families. Native kidney biopsy results were available for 32 patients. 19 patients from 3 families were categorised as ADTKD-*MUC,* 14 from 3 families were categorised as ADTKD-*UMOD*. 31 patients with clinical features of ADTKD met criteria for inclusion based on family history and renal biopsy findings. 18 have been tested without identified mutation, 4 have passed away and genetic material is not available. Details of genetic testing and clinical features are shown in Table 1. 40% of patients were hypertensive at presentation. Significant proteinuria occurred in 3/30 individuals with available. 26 patients with confirmed or suspected ADTKD have reached ESRD.

Conclusions: ADTKD accounts for approx. 0.06% of Irish cases of ESRD. Significant progress has been made in identifying causative mutations. Clinical awareness of ADTKD enables screening of relatives and early diagnosis.

Table 1

	UMOD (n=14)	MUC-1 (n=19)	ADTKD-NOS (n=31)	p-value
Confirmed Mutation (n) / Tested (n)	7/7	10/11	0/18	NA
Number of Families	3	3	22	NA
Mean Age at Presentation (years)	43	36	41	0.66
Mean Creatinine at Presentation	267	135	271	0.012
Mean Age at ESRD (years)	53	44	44	0.34
Gout (%)	86%	0%	31%	<0.0001

FR-PO328

Identifying Genetic Modifiers in Severe Polycystic Liver Disease (PLD) by Whole Exome Sequencing Amirreza Haghighi,[1] Xuewen Song,[1] Marina Pourafkari,[2] Beili Shi,[1] Emilie Cornec-Le Gall,[4] Ning He,[1] Wybrich R. Cnossen,[3] Joost P. Drenth,[3] Peter C. Harris,[4] Vicente E. Torres,[4] York P. Pei.[1] *[1]Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Department of Medical Imaging, University Health Network, Toronto, ON, Canada; [3]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [4]Division of Nephrology, Mayo Clinic, Rochester, MN.*

Background: Severe PLD is a rare and poorly understood phenotype seen in both ADPKD and ADPLD. Mutations of *SEC61, SEC63, PRKCSH, GANAB,* and *ALG8* have been shown to cause PLD by imparing the maturation and transit of polycystin-1 (PC1) through the endoplasmic reticulum protein-processing (ER-PP) pathway. We hypothesize that rare mutations including ER-PP pathway genes that segregate in multiple families may modify PLD in patients with ADPKD and ADPLD.

Methods: We performed whole exome sequencing (WES) using Illumina HiSeq2000/2500 with SSV4/5 capture kit in 150 patients including 23 affected discordant sib-pairs and 10 affected concordant sib-pairs for sPLD from 33 families (matched by gender and age) and 83 sporadic cases. All patients with sPLD had a cystic liver of >4x normal volume. In addition to a focused analysis on 166 genes involved in ER-PP pathway, we also performed a genome-wide analysis. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare (MAF ≤1%) deleterious variants of high and moderate impact as predicted by PolyPhen-2, Sift, Mutation Assessor, Mammalian and Vertebrate nucleotide-level conservation, and Combined Annotation Dependent Depletion (CADD).

Results: Overall, we achieved a mean target coverage of 108X with 90% of the targeted exomes having ≥30X read depth. In our preliminary analysis, we identified a total of 4,696 rare deleterious variants that segregated with PLD disease severity in at least one family. We found 8 ER-PP genes (i.e. *WFS1, UGGT1, UGGT2, SEC24D, SEC23B, EIF2AK4, ATF6B* and *RPN1*) with rare deleterious variants that segregated in at least one family and 3-4 sporadic sPLD cases. We also identified 7 non ER-PP genes (i.e. *TTN, DNAH10, DNAH14, HMCN2, NEB, OBSCN* and *ADAMTS8*) with rare deleterious variants that segregated in 4 to 6 families each.

Conclusions: Our preliminary results suggest extensive genetic heterogeneity with no one single gene accounting for a large proportion of severe PLD cases. Future *in-vitro* and/or *in-vivo* functional studies will be needed to define the potential pathogenicity of the most promising candidate genes. Identification of genetic modifiers of severe PLD has the potential to improve risk prediction and treatment of this unusual complication.

Genomic Background of Adult Polycystic Kidney Disease Patients without a Family History Takuya Fujimaru,[1] Takayasu Mori,[1] Akinari Sekine,[2] Shintaro Mandai,[1] Motoko Chiga,[1] Hiroaki Kikuchi,[1] Fumiaki Ando,[1] Yutaro Mori,[1] Naohiro Nomura,[1] Shotaro Naito,[1] Tomokazu Okado,[1] Tatemitsu Rai,[1] Junichi Hoshino,[2] Yoshifumi Ubara,[2] Shinichi Uchida,[1] Eisei Sohara.[1] *[1]Nephrology, Tokyo Medical and Dental University, Tokyo, Japan; [2]Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary kidney disease. Mutations in *PKD1* and *PKD2* are responsible for 85% and 15% of ADPKD patients, respectively. Diagnosis of ADPKD is usually based on positive family history and imaging findings. However, in the absence of a family history, there are no definitive imaging findings that provide an unequivocal diagnosis of ADPKD. Therefore, in the patients without a family history, it is required to distinguish ADPKD from other polycystic kidney diseases (PKDs), though it is difficult without genetic diagnosis in most of the cases.

Methods: We developed a custom panel for 69 genes that cause nine types of hereditary PKDs (ADPKD, autosomal recessive polycystic kidney disease, nephronophthisis, Joubert syndrome, Meckel syndrome, Senior-Loken syndrome, Bardet-Biedl syndrome, etc.) using next-generation sequencing. Comprehensive genetic screening approach was performed for the adult PKD patients without a family history. PKD was defined as more than 10 cysts in a kidney.

Results: Through the analysis for 35 patients (age 55±16, 68.6% of male), 19 patients (54.3%) had *PKD1*/*PKD2* mutations. Two patients (5.7%) identified compound heterozygous mutations in other genes, *PKHD1* and *NPHP4*, confirmed by trio analysis. De novo heterozygous frameshift mutation of *OFD1* was identified in one patient, which was likely to be causal. No obvious responsible mutations were detected in remaining 13 patients (37.1%).

Conclusions: In the adult PKD patients without a family history, other cystic kidney diseases than ADPKD may be overlooked, although it is hard to distinguish only by clinical data. Our custom panel appears to be useful to make genetic diagnosis of these patients.

Novel Semi-Automated Kidney Volume Measurements in Autosomal Dominant Polycystic Kidney Disease Satoru Muto,[2] Haruna Kawano,[3] Shigeo Horie.[1] *[1]Juntendo University, Tokyo, Japan; [2]Advanced Informatics for Genetic Disease, Juntendo University, Tokyo, Japan; [3]Juntendo university, Tokyo, Japan.*

Background: We assessed the effectiveness and convenience of a novel semi-automatic kidney volume (KV) measuring high-speed 3D-image analysis system SYNAPSE VINCENT® (Fuji Medical Systems, Tokyo, Japan) for autosomal dominant polycystic kidney disease (ADPKD) patients.

Methods: We developed a novel semi-automated KV measurement software for patients with ADPKD to be included in the imaging analysis software SYNAPSE VINCENT®. The software extracts renal regions using image recognition software and measures KV (VINCENT KV). The algorithm was designed to work with the manual designation of a long axis of a kidney including cysts. After using the software to assess the predictive accuracy of the VINCENT method, we performed an external validation study and compared accurate KV and ellipsoid KV based on geometric modeling by linear regression analysis and Bland-Altman analysis.

Results: One hundred twenty four patients (male 62, female 62) participated in this study. The median eGFR was 46.9 ml/min/1.73m². Median accurate KV, Vincent KV and ellipsoid KV were 627.7 ml, 619.4 ml (IQR: 431.5–947.0) and 694.0 ml (IQR: 488.1–1107.4), respectively. Compared with ellipsoid KV (r = 0.9504), Vincent KV correlated strongly with accurate KV (r = 0.9968). Ellipsoid KV systematically under- or overestimate accurate KV, with a mean (± SD) percentage difference of 14.2% ± 22.0% (Figure 1a). Vincent KV did not systematically under- or overestimate accurate KV, with a mean (± SD) percentage difference of – 0.6% ± 6.0% (Figure 1b). There were no significant slice thickness-specific differences (p = 0.2980).

Conclusions: The VINCENT method is an accurate and convenient semi-automatic method to measure KV in patients with ADPKD compared with the conventional ellipsoid method.

FR-PO331

PRKCSH as a Genetic Modifier in Early-Onset Autosomal Dominant Polycystic Kidney Disease Ria Schönauer,[3] Anna Seidel,[3] Jana Hoepke,[3] Katalin Dittrich,[2] Steffen Neuber,[1] Carsten Bergmann,[1] Jan Halbritter.[3] *[1]BIOSCIENTIA, Ingelheim, Germany; [2]University Children Hospital, Leipzig, Leipzig, Germany; [3]University Clinic Leipzig, Leipzig, Germany.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common hereditary renal disorder accounting for up to 10% of end-stage renal disease (ESRD). Germline mutations within the polycystin (PC) encoding genes *PKD1* and *PKD2* and accumulating somatic mutations continuously reduce the level of functional polycystins, which is a major determinant for cyst formation. Although most of the patients develop ESRD in the second half of life, a high intrafamilial clinical variability suggests that additional factors influence PC-levels in a disease relevant manner. We investigate the role of *PRKCSH* as a potential modifier in the family of a patient (index) who already developed ADPKD *in utero*.

Methods: Genomic mutations of the index patient were identified with an NGS-panel containing polycystic kidney and liver disease genes (*PKD1, PKD2, SEC63, PRKCSH, GANAB, HNF1B, LRP5, PKHD1)*. Analysis of cDNA transcribed from blood-derived mRNA was performed by PCR and Sanger sequencing. Functional impact of mutated *PRKCSH* and its influence on polycystins were characterized in vitro using transiently transfected cell culture systems.

Results: By NGS of a 2-year old male (index patient) with congenital PKD, we identified transheterozygous mutations in *PKD1 (*c.1723-1G>C) and *PRKCSH* (c.205G>A) that encodes the β-subunit of the glucosidase II (GlucII) and is involved in the development of polycystic liver disease. The *PKD1* mutation was found to affect the splice site donor of intron 8 and thus, the corresponding PC1 protein ([$(575\text{-}703)_{mut}$] $PC1_{1\text{-}703}$) is assumed to lose its function due to the lack of its transmembrane domains.

Additionally, the *PRKCSH* variant results in an amino acid exchange at the highly conserved position 69 of GlucIIβ (p.Ala69Thr), which abolishes its interaction with GlucIIα. Since GlucII participates in the maturation of polycystins in the endoplasmatic reticulum, its defect further reduces the level of functional polycystins.

Conclusions: In summary, while heterozygous loss-of-function mutation of *PKD1* resulted in adult onset of ADPKD, the presence of an additional deleterious *in-trans* variant in *PRKCSH* severely accelerated cystogenesis. Thus, we demonstrate that by interfering with polycystin maturation, *PRKCSH* plays a role as genetic modifier in ADPKD and contributes to the observed clinical variability.

FR-PO332

A Novel PKD1 Variant Demonstrates a Disease-Modifying Role in Trans with a Truncating PKD1 Mutation in Patients with ADPKD

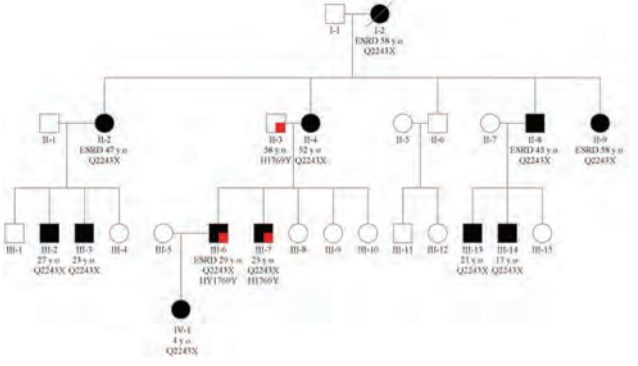
Medhat N. Ayoub. *Ministry of Health- Mubarak Hospital, KUWAIT, Kuwait.*

Background: Phenotypes associated with ADPKD in the terms of age of onset of end stage renal disease (ESRD), associated liver disease and other extrarenal manifestations showed high level of variability between patients. This phenotypic variability can be attributed to genic and allelic heterogeneity. Another element that adds to the complexity of phenotypic variability in ADPKD is the involvement of modifier genes which is suggested by the intrafamilial phenotypic variability observed in ADPKD families.

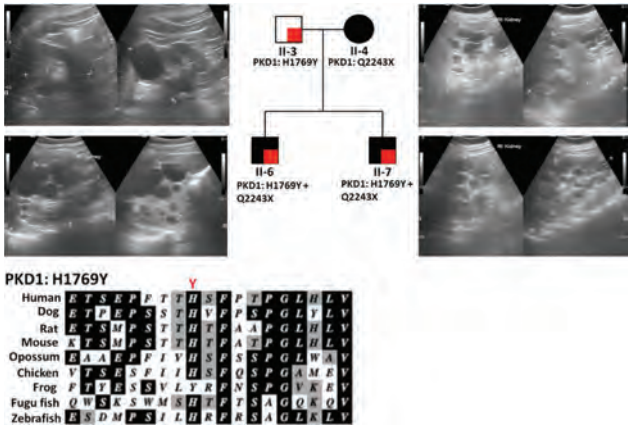
Methods: Patients were clinically evaluated using ultrasound and RFT. PKD1 was genotyped using next-generation sequencing by pooling long-range PCR amplicons and multiplexing bar-coded libraries. The significance of missense variants was assessed using the ADPKD Mutation Database, multisequence alignments and substitution assessment tools.

Results: In our case, we propose that the novel variant (p.H1769Y) aggravated the disease phenotype in patients resulting in early onset of ESRD and renal enlargement.

Conclusions: In summary, clinical evaluation of patients along with genetic prediction tools suggest that the novel PKD1 variant has a disease-modifying role, rather than disease causing role, in trans with the truncating PKD1 mutation in the studied family.



Pedigree of the ADPKD family showing the *PKD1* genotype of each member along with age and onset of ESRD.



Ultra soound of patients with the PKD1 novel variant and mutation.

GPR124 Regulates Development of Kidney Medulla and Adult Kidney Fibrosis via Wnt7a/b Dependent and Independent Signaling

Yoichiro Ikeda,[4] Jing Liu,[2] Andrew P. McMahon,[1] Benjamin D. Humphreys.[3] *[1]Keck School of Medicine of the University of Southern California, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA; [3]Washington University School of Medicine, Clayton, MO; [4]Washington University, School of Medicine, St. Louis, MO.*

Background: GPR124 is an orphan GPCR expressed in endothelial cells where it is a coreceptor for Wnt7a/b to activate canonical Wnt signaling. Wnt7b is required for the development of kidney medulla and cortico-medullary axis, and Wnt7a is associated with renal function and fibrosis. Pericyte-specific translational profiling revealed strong upregulation of GPR124 mRNA during kidney fibrosis. We investigated the role of GPR124 in pericytes and myofibroblasts during kidney development and fibrosis.

Methods: Models were developed for overexpression of GPR124 in fibroblasts (NRK-49F) and Crispr/Cas9-mediated knockout in myofibroblasts (10T1/2). Kidney stroma-specific deletion was accomplished with FoxD1-Cre;GPR124 floxed mice and conditional deletion with Gli1-CreER; GPR124 floxed; R26(tdTomato) mice.

Results: GPR124 mRNA was strongly upregulated in whole kidney during mouse UUO by qPCR, and specifically in the interstitium by in situ hybridization. GPR124 expression directly correlated with degree of fibrosis in human kidney. Lentiviral overexpression of GPR124 in NRK49f fibroblasts drove spontaneous myofibroblast differentiation even in the absence of Wnt ligand. By contrast, Crispr/Cas9 knockout of GPR124 in 10T1/2 mesenchymal cells, caused a strong reduction in fibrotic marker expression including aSMA and collagens. These knockout cells also failed to respond to Wnt7a and 7b ligand, confirming that GPR124 is a Wnt coreceptor in pericytes. Stromal specific GPR124 knockout mice resulted in a hypomorphic medulla phenotype and the loss of cortico-medullary axis, phenocopying the HoxB7-Cre; Wnt7b(f/f) phenotype. In addition, knockout mice showed microvascular hemorrhage in medulla. Conditional deletion of GPR124 in adult mouse kidney using Gli1-CreER; GPR124(f/f) ;tdTomato mice with tamoxifne administration resulted in reduced fibrosis in two fibrotic models also associated with reduced canonical Wnt-b-catenin signaling.

Conclusions: GPR124 is unexpectedly expressed in kidney pericytes and perivascular fibroblasts where it regulates Wnt7a/b signaling and drives myofibroblast differentiation. During development, stromal GPR124 is required for medullary development and in fibrosis GPR124 plays a critical role in regulating pericyte and fibroblast to myofibroblast transition.

Tubular-Specific Krüppel-Like Factor 15 Mediates the Progression from Tubular Injury to Interstitial Fibrosis

Ahmed A. Attallah,[1] Xiangchen Gu,[2,1] Yiqing Guo,[1] Sandeep K. Mallipattu.[1] *[1]Stony Brook Medicine, Stony Brook, NY; [2]Yueyang hospital of integrated Traditional Chinese and Western Medicine, Shanghai, China.*

Background: Mechanisms by which tubular injury results in fibroblast to myofibroblast differentiation in the transition from AKI to CKD remains poorly understood. Renal stromal-specific Krüppel-Like Factor 15 (KLF15), a zinc-finger transcription factor, was recently shown as a potential mediator of kidney fibrosis. Here, we sought to determine the mechanism by which the tubular KLF15 serves a key mediator of AKI to CKD in the setting of proximal tubular (PT) injury.

Methods: PT-specific *Klf15* knockout mice ($Klf15^{\Delta Pepck}$) were generated by crossing $Klf15^{fl/fl}$ mice with *Pepck-Cre* mice. We utilized low-dose Aristolochic Acid I (AAI) to model PT injury and AKI to CKD, 3 mg/kg every three days for 3 weeks, followed by 3 weeks for remodeling (DMSO served as control). Full-length ORF cDNA of human KLF15 (*hKLF15*) was cloned into a TRE plasmid. Mice with *TRE-hKLF15* and *Pax8-rtTA* transgenes (Pax8-*hKLF15*) were generated for doxycycline (DOX) inducible tubule-specific *hKLF15* induction. Finally, mice with *TRE-hKLF15* and *CAG-rtTA* transgenes (*CAG-hKLF15*) were also generated for DOX-inducible global *hKLF15* induction.

Results: KLF15 mRNA and protein expression were reduced at 3 weeks post AAI treatment (AKI phase) and at 6 weeks (remodeling phase). $Klf15^{\Delta Pepck}$ mice exhibited an increase in pro-fibrotic markers (αSMA, Col1α1, fibronectin, vimentin) and myofibroblast proliferation (Ki67) as compared to AAI-treated wildtype mice. $Klf15^{\Delta Pepck}$ mice also demonstrated an increase in PT injury (AQP1 & lotus lectin redistribution and reduced expression) with activation of tubular Wnt/β-catenin signaling (nuclear phosho-β-catenin) and worsened renal function (elevated serum urea nitrogen and creatinine) compared to AAI-treated wildtype mice. Conversely, AAI-treated *Pax8-hKLF15* mice exhibited a reduction in these pro-fibrotic markers, myofibroblast proliferation, and Wnt/β-catenin signaling with an improvement in PT markers as compared to AAI-treated wildtype mice. Finally, AAI-treated *CAG-hKLF15* also validated this improvement in tubular injury, renal fibrosis, and renal function as compared to AAI-treated wildtype mice.

Conclusions: These data suggest that modulating the expression of tubular KLF15 is critical to the progression of AKI to CKD in the AAI-induced nephropathy, suggesting a potential target for therapy.

Disruption of Genome Maintenance Mechanisms in Renal Proximal Tubular Epithelial Cells Exacerbates Human Kidney Fibrosis Seiji Kishi,[2,1] Kenji Nishimura,[2] Ryuji Morizane,[1] Takaharu Ichimura,[1] Joseph V. Bonventre,[1] Toshio Doi.[2] *[1]Brigham & Women's Hospital/Harvard Medical School, Boston, MA; [2]Nephrlogy, Tokushima University Hospital, TOKUSHIMA, Japan.*

Background: Renal proximal tubular epithelial cells (RPTECs) comprise the bulk of the renal parenchyma and are the primary target of a variety of insults to the kidney. While DNA damage and activation of the DNA damage response (DDR) play an important role in human disease, the role of DDR in the progression of human kidney disease remains unresolved. To investigate this mechanism, we evaluated the role of ataxia telangiectasia and Rad3-related (ATR) which is the key upstream regulator of cellular response to DNA damage.

Methods: We analyzed human kidney tissue from native kidney biopsy performed at Tokushima University Hospital. Of the 20 cases, 11 cases were kidneys with interstitial fibrosis and elevated serum creatinine, as well as 9 cases were with a pathologic diagnosis of minor glomerular abnormalities with normal serum creatinine and good preservation of tubules. An Active form of ATR (pATR) and the marker of DNA damage (γH2AX) were stained with KIM-1 to evaluate whether DDR correlates with eGFR or fibrosis. In vitro study, to examine whether the inhibition of the ATR affects the survival of a proximal tubular epithelial cell line (HKC-8) after toxic insult, we assessed the degree of DNA damage and cell viability with or without the ATR inhibitor; VE-821.

Results: In kidney tissue from humans with CKD, ATR was activated in chronically injured RPTECs. The number of pATR and KIM-1 double positive tubules was inversely correlated with eGFR and positively correlated with the degree of kidney fibrosis. The number of γH2AX and KIM-1 double positive tubules in each kidney section was markedly increased, inversely correlated with eGFR and positively correlated with the degree of kidney fibrosis. We found an inverse correlation between γH2AX/KIM-1 positive and pATR/KIM-1 positive cells in CKD kidney. DNA damage and decline of cell viability of HKC-8 cells were further exacerbated when exposed to cisplatin, aristolochic acid or hypoxia in the presence of VE-821. Furthermore, ATR inhibition upregulated p21 and CTGF expression in HKC-8 cells after aristolochic acid treatment.

Conclusions: We demonstrate that DDR is seen in human kidney disease and ATR plays a protective role against tubular cell injury, death and fibrotic response. Regulation of ATR may be a therapeutic target against human kidney disease.

Lineage Tracing Study Defines Erythropoietin-Producing Cells as the Distinct Subpopulation of Resident Fibroblasts with Unique Behaviors Keiichi Kaneko, Shuichiro Endo, Motoko Yanagita. *Kyoto University Graduate School of Medicine, Sakyo-ku, Japan.*

Background: We previously demonstrated that renal fibroblasts including erythropoeitin (Epo)-producing cells transdifferentiate into myofibroblasts with concomitant loss of Epo production during renal fibrosis. It has not been elucidated, however, whether Epo-producing cells, which account for less than 10 % of resident fibroblasts, are the distinct specialized population of resident fibroblasts. Lack of tools to label Epo-producing cells at desired time points has hindered our further understanding of the behavior of Epo-producing cells in adult kidneys.

Methods: We generated a novel mouse strain in which inducible Cre, Cre^{ERT2} was knocked-in at the locus of Epo gene (Epo-Cre^{ERT2} mice). Epo-Cre^{ERT2} mice were crossed with indicator mice, and tamoxifen was administered to the offspring to activate Cre^{ERT2}.

Results: Epo-Cre^{ERT2} labeled cells were located in the interstitium of the cortex and corticomedullary region of the kidney, and expressed PDGFRβ and CD73, indicating that these cells were resident fibroblasts. The labeled cells increased in parallel with the magnitude of anemia. Double in situ hybridization confirmed that around 50 % of the labeled cells expressed Epo mRNA, indicating that Epo-Cre^{ERT2} mice faithfully labeled the Epo-producing cells. Around 50 % of the labeled cells maintained Epo-producing ability even 16 weeks after the recombination, supporting the hypothesis that the labeled cells are the distinct population with Epo-producing ability. After unilateral ureteral obstruction (UUO), the labeled cells transdifferentiated into myofibroblasts, lost Epo-producing ability, and proliferated. The percentage of the labeled cells in resident fibroblasts increased 4.5 folds during fibrosis (1.9 % in healthy kidney and 9.2 % in UUO kidney, $p<0.01$), and Ki67 expression was more prevalent in the labeled cells than in other fibroblasts (12.7 % vs 8.3 %, $p<0.05$).

Conclusions: Utilizing the new mouse strain, Epo-Cre^{ERT2} mice, we, for the first time, analyzed the behavior of the Epo-producing cells. The maintenance of Epo-producing ability and faster proliferation during fibrosis indicate the possibility that Epo-producing cells are the distinct populations of renal fibroblasts. Detailed analysis of the population will provide us new therapeutic approach to renal anemia.

FR-PO337

Pathologic Cross-Talk between Hippo-TAZ and CTGF Pathways during Renal Fibrosis Progression Rohan Samarakoon,[1] Alex Arnouk,[2] Jiaqi Tang,[2] Roel Goldschmeding,[3] Paul J. Higgins.[2] *[1]Albany Medical Center, Albany, NY; [2]Albany Medical College, Watervliet, NY; [3]None, Utrecht, Netherlands.*

Background: TAZ is a nuclear transducer of the Hippo pathway. We recently demonstrated that TAZ, upregulated in the tubulorinterstitium in multiple models of kidney injury, is a novel profibrotic effector of the TGF-beta1 pathway that promotes CKD. Ectopic expression of TAZ in HK-2 human renal epithelial cells induces expression of CTGF, a known fibrosis causative factor. It is unknown whether CTGF upregulation deregulates Hippo-TAZ signaling during kidney fibrosis and if TAZ promotes epithelial dysfunction via CTGF-dependent mechanisms.

Methods: A novel mouse model of global conditional CTGF knockout (created by crossing CTGF-flox and ROSA26-CreET2 mice and subsequent tamoxifen administration) was utilized to determine the role of CTGF silencing on TAZ activation and renal fibrosis driven by ureteral ligation (UUO). Various transgenic HK-2 cells with stable TAZ and CTGF expression or depletion were created to investigate the potential cross-talk between TAZ and CTGF in fibrogenesis.

Results: Fibrotic obstructed kidneys have elevated CTGF and TAZ expression relative to contralateral controls. CTGF knockout animals have attenuated renal fibrotic response and TAZ expression compared to control mice (receiving corn oil instead of tamoxifen) subjected to UUO. CTGF stable expression in HK-2 cells, furthermore, robustly induced TAZ expression and promoted fibrosis factor expression (i.e., fibronectin and collagen-1), epithelial dedifferentiation (marked by increased vimentin and decreased E-cadherin expression) and G_2M cell cycle arrest. TAZ gene silencing, indeed, attenuated CTGF-mediated fibronectin, collagen-1 and vimentin expression. Similarly, fibrotic gene upregulation (e.g., CTGF and fibronectin), dedifferentiation and growth inhibition induced by stable epithelial TAZ expression were abrogated by stable CTGF suppression (via shRNA approaches).

Conclusions: Conditional silencing of CTGF expression during obstructive nephropathy in mice leads to attenuated TAZ expression and kidney fibrosis. Epithelial fibrotic response induced by sustained CTGF signaling requires TAZ. Conversely, TAZ induced CTGF expression orchestrates epithelial maladaptive repair, demonstrating reciprocal regulation of TAZ and CTGF in promoting CKD progression.

FR-PO338

Perivascular Cell CD73 Modulates Macrophages in the Renal Microenvironment during Progressive Fibrosis Heather M. Perry,[2] Nicole Görldt,[2] Liping Huang,[2] Sun-sang J. Sung,[2] Diane L. Rosin,[1] Mark D. Okusa.[2] *[1]Pharmacology, University of Virginia, Charlottesville, VA; [2]Medicine, University of Virginia, Charlottesville, VA.*

Background: Progressive tubulointerstitial fibrosis can occur following an acute kidney insult such as ischemia-reperfusion injury (IRI). Mechanisms underlying these maladaptive repair processes are not well understood. Purinergic signaling by CD73, an enzyme that converts AMP to adenosine on the extracellular surface, via adenosine receptors can suppress inflammation and reduce IRI. As CD73 is expressed on renal perivascular cells (pericytes and/or fibroblasts of the Foxd1+ lineage), we hypothesized that perivascular cell expression of CD73 is necessary to suppress inflammation and prevent fibrosis.

Methods: *Foxd1CreCD73*$^{fl/fl}$ and littermate control *CD73* $^{fl/fl}$ mice were subjected to 20' unilateral IRI operation and after 14d, plasma was collected to quantify plasma creatinine (PCr). Also, kidneys were prepared for assessment of fibrosis by histology and inflammation and myofibroblast density by immunofluorescence. Kidney fibrosis and macrophage polarization markers were quantified by RT-qPCR. Soluble CD73 or macrophage depletion by liposome clodronate and controls were initiated 2d after IRI and kidney function and fibrosis were assessed at 14d.

Results: PCr levels were elevated in *Foxd1CreCD73*$^{fl/fl}$ ($n = 10$) compared to control mice ($n = 9$) (0.29 ± 0.07 vs. 1.1 ± 0.20 mg/dl respectively, $p < 0.001$). Fibrosis and myofibroblast marker expression was increased in kidneys of *Foxd1CreCD73*$^{fl/fl}$ mice compared to controls. Kidney macrophages and expression of pro-inflammatory, pro-fibrotic phenotypic markers were also increased in *Foxd1CreCD73*$^{fl/fl}$ mice compared to controls. Exogenous CD73 rescued the decline in kidney function and fibrotic phenotype in *Foxd1CreCD73*$^{fl/fl}$ mice. As macrophages switch from a pro-inflammatory to a wound healing phenotype on day 2, we sought to address this as a potential mechanism of increased fibrosis in *Foxd1CreCD73*$^{fl/fl}$ mice. Macrophage depletion in *Foxd1CreCD73*$^{fl/fl}$ mice resulted in protection against kidney dysfunction and fibrosis.

Conclusions: These results demonstrate that perivascular cell CD73 orchestrates the renal inflammatory microenvironment to promote a wound healing response after an acute event resulting in recovery of kidney function and prevention of progressive fibrosis.

FR-PO339

Endothelial Tie2 Deficiency Increases Tubulointerstitial Fibrosis Marie Jeansson. *Uppsala University, Uppsala, Sweden.*

Background: Renal tubulointerstitial fibrosis is predictive of progressive decline in kidney function, independent of underlying disease. It is characterized by an increase in aSMA+ fibroblasts, myofibroblasts, that produce collagen. We previously showed that loss of Angiopoietin-1 (Angpt1) in adult mice predisposes to fibrosis in wound healing, diabetic nephropathy, and the unilateral ureter obstruction (UUO) model. The tyrosine kinase receptor, Tie2, is expressed on endothelial cells and Angpt1 binding results in Tie2 signaling that is pro-survival and anti-inflammatory. Here, we test the hypothesis that loss of Tie2 signaling in endothelial cells results in capillary defects leading to an increased fibrotic response in kidney fibrosis.

Methods: Tie2 floxed mice were crossed with tamoxifen inducible endothelial specific Cadh5-Cre and a reporter line expressing TdTomato upon Cre-activation. This line enables both an endothelial specific KO of Tie2 and an endothelial lineage tracer.

To study the role of Tie2 signaling in renal fibrosis we utilized the unilateral ureter obstruction (UUO) model of kidney fibrosis.

Results: Endothelial specific KO of Tie2 resulted in an increase in fibrosis as seen by a 2-fold increased expression of SM22a and Col1a1 compared to controls 3 days after UUO. At the same time, there was a 4-fold increase in Kim1, suggesting more injury to tubular cells in Tie2 KO. Investigation of blood vessels before fibrotic onset 1 day after UUO, revealed less perfused capillary area and increased hypoxia in Tie2 KO mice. Ongoing work is designed to investigate blood vessel function in the early fibrotic process and to estimate the endothelial-mesenchymal contribution after UUO in controls and Tie2 knockout mice, utilizing the lineage tag of endothelial cells in the system.

Conclusions: Our results suggest that loss of Tie2 signaling destabilizes the endothelial cell and increases tubulointerstitial fibrosis. The mechanisms we are investigating are an early loss of endothelial cells due to endothelial-mesenchymal transition and/or apoptosis, resulting in less functional peritubular capillaries and more fibrosis.

FR-PO340

ErbB4 Deletion Accelerates Renal Fibrosis Following Renal Injury Fenghua Zeng, Lance A. Kloepfer, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Tubulointerstitial fibrosis (TIF) is a component of chronic kidney disease (CKD) of any etiology and is the best predictor of progression toward end stage kidney disease. Mechanisms underlying the development and progression of TIF are still incompletely understood. Increased ErbB4 expression were seen in the tubular epithelium of CKD kidneys. However, its role in the tubulointerstitial injuries remains to be determined.

Methods: ErbB4 expression was examined using immunohistochemistry in human biopsy fibrotic kidneys. Two mouse models of renal injury, unilateral ureteral obstruction (UUO) and ischemia reperfusion injury followed by uninephrectomy (IRI/UNx), were used to study the possible impact of ErbB4 deletion in renal fibrosis by comparing heart rescued ErbB4 deletion ($ErbB4^{del}ht^{+}$) and wild-type (WT) mice. Renal function and pathological changes were examined.

Results: In human fibrotic kidneys, ErbB4 expression levels were inversely correlated to renal fibrosis as indicated by double immunofluorescence staining of ErbB4 and colagen I. In both UUO and IRI/UNx mouse models, expression levels of ErbB4 were elevated in the early stage of renal injury in the wild-type mice. In mice with global ErbB4 deletion except for transgenic rescue in cardiac tissue (*ErbB4*$^{-/-}$*ht*$^{+}$), UUO induced similar injury in proximal tubules compared to wild-type mice but more severe injury in distal nephrons. TIF was apparent earlier and was more pronounced following both UUO and IRI-UNx injuries in *ErbB4*$^{-/-}$*ht*$^{+}$ mice. With ErbB4 deletion, UUO injury inhibited AKT phosphorylation and increased the percentage of cells in G2/M arrest. Meanwhile, increased levels of nuclear immunostaining of YAP and increased expression of p-Smad3, snail1 and vimentin were also detected in kidneys wiith ErbB4 deletion compared to the wild-type mice.

Conclusions: In conclusion, increased expression of ErbB4 was detected in the early stages of human renal injury, whereas its level decreased with severe renal fibrosis, which is consistent with the finding that ErbB4 deletion promoted renal fibrosis in mouse injury models. Therefore, the early increased ErbB4 expression may reflect a compensatory effect to lessen tubulointerstitial injury.

Ablation of Transcription Factor HNF-1β Induces Epithelial-Mesenchymal Transition through Twist2 Derepression Siu Chiu Chan, Ying Zhang, Annie Shao, Sophia M. Vrba, Svetlana Avdulov, Jeremy Herrera, Shayan A. Farahani, Karam S. Aboudehen, Peter Igarashi. *University of Minnesota, Minneapolis, MN.*

Background: Hepatocyte nuclear factor-1β (HNF-1β) is a transcription factor that is essential for normal kidney development and function. Mutations of HNF-1β produce autosomal dominant tubulointerstitial kidney disease (ADTKD) characterized by tubular cysts, renal fibrosis, and progressive decline in kidney function. We have previously shown that HNF-1β regulates a network of cystic disease genes that are down-regulated in HNF-1β mutant kidneys.

Methods: To understand the mechanism whereby mutation of the epithelial-specific transcription factor HNF-1β leads to interstitial fibrosis, we used gene editing with CRISPR/Cas9 to ablate HNF-1β in mIMCD3 renal epithelial cells.

Results: HNF-1β mutant mIMCD3 cells exhibited loss of contact inhibition and adopted a spindle-shaped morphology. Compared with control cells, HNF-1β-deficient cells exhibited EMT features with increased cell migration and higher motility and produced a multilayered epithelium. RNA-seq analysis of HNF-1β-deficient cells and Ingenuity Pathway Analysis (IPA) revealed that fibrosis and epithelial-mesenchymal transition (EMT) pathways were highly activated in HNF-1β-deficient cells. Transcription factors involved in EMT, including TWIST2, SNAIL1, SNAIL2, and ZEB2, were upregulated in HNF-1β mutant cells. Mechanistically, we found that expression of *Twist2* was directly repressed by HNF-1β. Concomitant ablation of *Twist2* partially rescued the fibroblastic phenotype of HNF-1β mutant cells. Chromatin immunoprecipitation and qRT-PCR analysis of *Twist2* mutant cells showed that TWIST2 is an upstream transcriptional activator of *Snail2*. Immunohistochemistry and RNA in situ hybridization showed that the expression of TWIST and SNAIL, as well as downstream targets TGFβ2 and TGFβ3, was increased in the cyst epithelium of HNF-1β mutant kidneys.

Conclusions: We conclude that ablation of HNF-1β in renal epithelial cells leads to the activation of a transcriptional network that induces EMT and aberrant TGFβ signaling. Targeting this network may inhibit fibrosis in ADTKD and other chronic kidney diseases.

Tubule-Derived Extracellular Vesicles Promotes Fibroblast Activation in Kidney Fibrosis Xi Liu,[1] Lili Zhou,[1] Youhua Liu.[2] *[1]Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Kidney fibrogenesis is a complex process involving frequent cell-cell communication. Extracellular vesicles (EVs), consisting of exosomes and microvesicles, are increasingly recognized as an essential vehicle mediating cell-cell communication in both physiologic and pathologic conditions. Because tubular epithelium is the major constitute of kidney parenchyma and the epicenter of kidney injury, we hypothesized that tubular cells, in response to injury, may increase their production and release of EVs containing proteins, mRNAs and microRNAs, which act on interstitial fibroblasts, leading to their activation. In this study, we tested this hypothesis by in vitro and in vivo approaches.

Methods:

Results: In human kidney proximal tubular cells (HKC-8), TGF-β1 induced marked increase in the release of EVs. Conditioned media collected after TGF-β1 treatment promoted rat kidney interstitial fibroblast (NRK-49F) activation, proliferation and matrix production, compared with controls. However, depletion of EVs from TGF-β1-treated HKC-8 cell conditioned media abolished its action on NRK-49F cells, suggesting a predominant role of the EVs in mediating tubule-fibroblast communication. Interestingly, we found that Shh signal components were markedly induced in the EVs released by TGF-β1-treated HKC-8 cells. Knockdown of Shh in HKC-8 cells by RNAi abolished the tubular EVs-mediated induction of Gli1, Snail1, α-SMA, fibronectin, and collagen I in NRK-49F cells. In mouse model of kidney fibrosis induced by UUO, the secretion of EVs was dramatically increased, and blockade of EVs secretion with small molecule inhibitor DMA suppressed myofibroblast activation, inhibited fibronectin and collagen I expression and ameliorated renal fibrotic lesions.

Conclusions: These results indicate that tubule-derived EVs play a critical role in initiating fibroblast activation and development of renal fibrotic lesions. Our data also suggest that Shh signal components in the EVs may be responsible, at least partially, for mediating the tubule-fibroblast communication in renal fibrogenesis.

Nrf2 Deletion Promotes the Progression from Acute Tubular Damage to Chronic Renal Fibrosis Induced by Unilateral Ureteral Obstruction Weiwei Kong,[3] Jingqi Fu,[4] Congcong Jiao,[3] Guangying Guo,[3] Huihui Wang,[1] Lining Wang,[2] Jingbo Pi,[4] Hua Zhou.[3] *[1]China Medical University, Shenyang, China; [2]Department of Nephrology, First Affiliated Hospital of China Medical University, Shenyang, P. R. China, Shenyang, China; [3]The first hospital of China Medical University, Shenyang, China; [4]rogram of Environmental Toxicology, School of Public Health, China Medical University, Shenyang, China.*

Background: The role of Nrf2 (nuclear factor erythroid 2–related factor 2) in the progression from acute kidney damage to chronic renal fibrosis in obstructive nephropathy remains unclear. We aimed to verify whether Nrf2 deletion aggregates the progress of renal injury induced by unilateral ureteral obstruction (UUO) and further to investigate its mechanism in Nrf2-knockout mice ($Nrf2^{-/-}$ mice).

Methods: Renal injury was induced by UUO in 54 male $Nrf2^{+/+}$ mice and 36 male $Nrf2^{-/-}$ mice. The kidneys were collected at day 2, 5, and 14 after UUO and histological damage was evaluated by PAS or Masson staining. We compared tubular damage (cleaved caspase3 and PARP) on day 2, transdifferentiation (vimentin and PCNA) on day5, fibrosis (fibronectin and α-SMA), and inflammatory factors on day 14 after UUO in $Nrf2^{-/-}$ mice with $Nrf2^{+/+}$ mice on protein and mRNA levels. The temporal renal Nrf2 expression was examined in the mice with immunohitochemistry staining and western blotting. In addition, Nrf2 was also evaluated in renal biopsies from the patients with acute, sub-acute, or chronic tubulointerstitial nephritis.

Results: Tubular damage significantly occurred on day 2; vimentin, fibronectin, and α-SMA increased on day 5 and 14 in $Nrf2^{+/+}$ mice. Nrf2 downstream genes (Gclc and Ho-1) significantly increased from day 2 to 5, while Nrf2 protein remarkably rose on day 5 and 14 in $Nrf2^{+/+}$ mice. Renal Nrf2 positive staining was upregulated in patients with acute, sub-acute, and chronic tubulointerstitial nephritis conmared with normal huamn kidneys. Nrf2 deficiency significantly enhanced tubular damage, apoptotic cells evaluated by TUNEL staining, and levels of cleaved caspase3 and PARP on day 2. Nrf2 deletion markedly increased the cells co-expressed with vimentin and PCNA on double immunofluorecent staining on day 5. $Nrf2^{-/-}$ mice showed overproduction of fibronectin, α-SMA, and profibrotic inflammatory response genes (Tgfβ1, Tnfα, and IL6) on day 14 after UUO.

Conclusions: Nrf2 deficiency aggregated acute tubular damage, transdifferentiation, inflammation, and fibrosis under sustained UUO condition. The renalprotective role of Nrf2 in the development of tubulointerstitial fibrosis in UUO may be mediated by anti-apotosis and anti-inflammation. Nrf2 might be a potential therapeutic target for renal fibrosis.

FR-PO344

Dickkopf-3 (Dkk-3) Overexpressed in Dysfunctional Endothelium Secretome Instructs Fibroblast-to-Myofibroblast Formation by Activating the Wnt Pathway Mark Lipphardt,[2,4] Sina Dadafarin,[2] Brian B. Ratliff,[2] Hassan Dihazi,[3] Gerhard A. Mueller,[1] Michael S. Goligorsky.[2] *[1]Georg-August University, Gottingen, Germany; [2]New York Medical College, Valhalla, NY; [3]University Medical Centre Goettingen, Goettingen, Germany; [4]Nephrology & Rheumatology, Universitätsmedizin Göttingen, Göttingen, Germany*.

Background: We have previously demonstrated that Sirt1^{endo}-/- mice with endothelial dysfunction show exaggerated renal fibrosis, whereas mice with silenced endothelial TGF-β signaling are resistant to fibrogenic signals. Collectively, this indicates that secreted substances regulate these contrasting responses. Thus, we sought to examine the differential secretome of those cells.

Methods: We performed unbiased proteomic analysis of the secretome of renal microvascular endothelial cells (RMVEC) isolated from these two mutants, discovered Dkk-3 (a putative ligand of Wnt/β-catenin pathway) expressed exclusively in fibrogenic secretome. Since Dkk-3 is an orphan member of the family of Wnt ligands, and its precise effects are poorly understood, we examined effects of Dkk-3 in renal fibroblasts (RF) isolated from α-SMA-GFP mouse kidneys using positive and negative selection with magnetic beads.

Results: Application of Dkk3 to RF showed that Dkk3 (10 ug/ml) alone induced myofibroblastic phenotype without altering responses to TGFβ. Dkk-1, a known antagonist of Wnt pathway, reduced activation of RF. When Dkk-3 was combined with Dkk-1, it antagonized its antimyofibroblastic effect. In RMVEC, Dkk-3 induced endothelial-mesenchymal transition (endo-MT) as judged by the appearance of α-SMA-GFP signal, and reduced capillary cords formation and their branching angiogenesis. In microfluidic RF-RMVEC co-cultures (kindly provided by NL Jeon, Seoul National University, Seoul, Korea) Dkk-3 was confirmed as an inducer of endo-MT and inhibitor of angiogenesis. Chronic administration of Sulindac, a potent Wnt pathway inhibitor, ameliorated UUO-induced renal fibrosis.

Conclusions: In conclusion, a prominent member of the secretome of dysfunctional RMVEC, Dkk-3, affords a Dkk-1 antagonistic paracrine effect on RF and induces myofibroblastic prenotype. Dkk-3 exerts a autocrine effect leading to endo-MT of RMVEC and reducing their angiogenic competence. These actions make Dkk-3 a potent pro-fibrogenic agonist.

FR-PO345

Lactic Acid Production from Glycolysis Activates TGF-b/Smad Signaling Pathway in Tubular Epithelial Cells Engaged in the Development of Renal Fibrosis Jing Xu,[2] Yan Shen,[1] Lei Jiang,[4] Junwei Yang.[3] *[1]Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China; [3]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China; [4]Second Affliliated Hospital, Nanjing Medical University, Nanjing, China*.

Background: Renal proximal tubule is susceptible to hypoxic injury, because of the reliance on aerobic oxidative metabolism. Dysfunctional mitochondria participate the progression of chronic renal disease. In this paper, we investigate the profile of the energy metabolism of the proximal epithelial cell in fibrotic kidney, and evaluate the role of anaerobic metabolism in renal fibrosis.

Methods: 2-deoxyglucose (2-DG) was administered at a dose of 20mg/kg or 100mg/kg and Shikonin was oral performed at a dose of 1 or 5 mg/kg before unilateral ureter obstruction (UUO) surgery and administered for successive7 days. Human Recombinant TGF-β1 (5 ng/ml) and lactic acid (10mmol/L) were added to the serum-free medium for indicated time periods and concentration. 2-DG (0.2 or 1mM), dichloroacetic acid (DCA,2mM), BroPA (5nM) and oxamate (100nM) were added to the serum-free medium 30 minutes for indicated time periods and concentration before TGF-β1 treatment.

Results: The protein expression of key enzymes of glycolysis were markedly increased in a time depended in UUO induced renal interstitial fibrosis mice model. There was a similar result in primary renal tubular epithelial cells after disposed with TGF-β1. In addition, the fibrotic matrix was reduced and marks of collagen fibrils such as α-smooth muscle actin (α-SMA), fibronectin (FN) were down-regulated after mice or primary renal tubular epithelial cells (PTC) dealed with inhibitors of glycolytic pathway. At the same time, we found the expression of TGF-β1 receptor and p-smad3 were decreased. In the meantime, lactic acid, the production of glycolysis pathway, was involve in the activation of TGF-β1-smad pathway and changed renal tubular cells phenotype and contributed to the development of renal interstitial fibrosis.

Conclusions: Altered glucose metabolism of tubular epithelial cells is a hallmarks of renal fibrosis. Inhibition of aerobic glycolysis is effective to suppress renal fibrosis. Lactic acid production from glycolysis could further active TGFβ1/smad signaling and aggravate renal fibrosis.

FR-PO346

ATF6 Knockout Mice Revealed That ER Stress Links Lipotoxicity and Kidney Fibrosis Tzu-Ming Jao,[1] Chia-Hsien Wu,[1] Mai Sugahara,[2] Hisako Saito,[2] Yu Ishimoto,[2] Akira Okada,[2] Hiroshi Maekawa,[2] Mari Aoe,[2] Tetsuhiro Tanaka,[2] Masaomi Nangaku,[2] Reiko Inagi.[1] *[1]The University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]the University of Tokyo School of Medicine, Tokyo, Japan*.

Background: Lipid accumulation in tubules is frequently observed in chronic kidney disease (CKD) patients. However, the molecular mechanism underlying lipotoxicity-induced tubulointerstitial fibrosis is still largely unknown. ATF6, a transcription factor of unfolded protein response (UPR), has been reported as an upstream regulator of lipid metabolism. In addition, fatty acid is the main energy source of proximal tubular cell because of its high energy demand. We thus hypothesized that ATF6 regulates tubular lipid metabolisms, and thereby contributes to lipotoxicity-induced renal fibrosis.

Methods: We employed ATF6+/+ and ATF6-/- mice or Sprague-Dawley rats with unilateral ureteral obstruction (UUO) or unilateral ischemia-reperfusion injury (uIRI) as tubulointerstitial fibrosis models. In *in vitro* study, human proximal tubular cell line, HK-2, expressing active ATF6 (nATF6) was used. Change in ATF6 activation, fatty acid synthetic factors (ACC and DGAT2), b-oxidation regulators (PPARα, CPT1, CPT2 and MCAD), pro-fibrogenic factor (CTGF) were assessed.

Results: ATF6 was significantly activated in associated with tubular lipid accumulation in rat fibrotic kidneys induced by UUO and uIRI. In contrast, ATF6 deficient mice exhibited amelioration of uIRI-induced tubulointerstitial fibrosis via reduction of collagen I and a-SMA expression. Intriguingly, tubular lipid accumulation was also attenuated by ATF6 deficiency, indicating the pivotal role of ATF6 in lipotoxicity-mediated tubulointerstitial fibrosis. To reveal the molecular mechanism underlying ATF6-mediated lipotoxicity and subsequent tubulointerstitial fibrosis, we overexpressed nATF6 in HK-2 and observed that nATF6 enhances fatty acid synthetic factors, as well as downregulates b-oxidation regulators, suggesting the exacerbation effect of nATF6 in lipid accumulation. Importantly, such nATF6-induced lipotoxicity causes depleted mitochondrial respiration and ATP production, and thereby decreased cell viability, inducing apoptotic signaling and elevating CTGF expression.

Conclusions: Collectively, we unveiled the role of ATF6 in the derangement of fatty acid metabolism in the tubular cells, leading to lipotoxicity-mediated tubular apoptosis and CTGF upregulation, both of which may accelerate tubulointerstitial fibrosis.

FR-PO347

Alteration of Fatty Acid Oxidation in Proximal Tubular Epithelial Cells during Renal Fibrosis Hao Ding,[1] Junwei Yang.[2] *[1]Nanjing Medical University, Nanjing, China; [2]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China*.

Background: Chronic kidney diseases (CKD) generally lead to renal fibrosis and so far no effective therapeutic anti-fibrosis strategy is available. At the tubular cell scale, proximal tubular epithelial cells (PTCs) which prefer fatty acid as their energy source are the most energy-demanding cells in the body and involved in the process of interstitial fibrosis.

Methods: In this study, we employed mice with unilateral ureter obstruction (UUO) and TGFβ1-treated primary PTCs as two model systems. The Cre/loxP system was used to generate renal PTCs–specific CPT1α deletion mice (CPT1α^{KO}).

Results: Here we first demonstrated that a switch of metabolism from oxidative phosphorylation to aerobic glycolysis in mouse kidney with UUO surgery. We found rate-limiting enzymes and key transcription factors involved in FAO were reduced in fibrotic kidney and TGFβ1-treated primary PTCs. We uncovered that altered of FAO was associated with higher lipid accumulation in diseased renal and TGFβ1-treated primary PTCs. We also found that the enzymes and regulators of FAO were reduced in renal biopsy specimens of patients with CKD and was associated with the severity of renal interstitial fibrosis. PTCs-specific ablation of CPT1α resulted in a phenotype that body weight was lower compare with their control littermates. Kidney injury molecule-1, NAG enzyme in urine and blood urea nitrogen were increased within 4 months and recovery at 8 months. We noticed the expression of rate-limiting enzymes and key transcription factors involved in peroxisomal compartments pathway were up-regulated in kidneys of knockouts. In line with this, CPT1α^{KO} mice showed higher heat production compared to the controls which is indicative of proportion of energy expenditure derived from lipid oxidation in peroxisomal. Finally, inhibiting mitochondrial FAO of PTCs lead to up-regulation of peroxisomal FAO pathway.

Conclusions: In conclusion, our findings demonstrate altered of both mitochondrial and peroxisomal β-oxidation enzyme systems during the process of interstitial fibrosis. Furthermore, we found peroxisomal FAO pathway was compensatory up-regulated when mitochondrial FAO is shut down. Our results indicate that drugs that specifically restoring FAO may attenuate renal fibrosis.

FR-PO348

Adiponectin Attenuates Kidney Injury and Fibrosis in Deoxycorticosterone Acetate-Salt and Angiotensin II Induced CKD Mice Mi Tian, Li Tang, Srini Beddhu, Yufeng Huang. *Division of Nephrology, University of Utah Health, Salt Lake City, UT*.

Background: Adiponectin (ApN) is a multifunctional adipokine with insulin-sensitizing, anti-inflammatory, and vasoprotective properties. However high, rather than

low, concentrations of ApN are unexpectedly found in patients with chronic kidney disease (CKD) via an as yet unknown mechanism and the role of ApN in CKD is unclear. We, herein, investigated the effect of ApN overexpression on the progression of renal injury resulted from deoxycorticosterone acetate-salt (DOCA) and angiotensin II (DOCA+AII) infusion using a transgenic, inducible, hepatic ApN-overexpressing mouse model.

Methods: Uninephrectomy was firstly performed on all experimental mice. Two weeks after uninephrectomy, three groups of male mice (wild type receiving no infusion and normal drinking water (WT), wild type and cyp1a1 ApN transgenic mice receiving DOCA+AII infusion (WT/DOCA+AII and ApN-Tg/DOCA+AII) and 1% NaCl in drinking water) (n=5/each group) were then assigned to receive a normal diet containing 0.15% of the transgene inducer indol-3-carbinol (I3C) for 3 weeks.

Results: The I3C-induced ApN-Tg/DOCA+AII mice, not the WT or WT/DOCA+AII mice, overexpressing ApN in liver resulted in 3.15-fold increases in circulating ApN levels than non-transgenic controls. Of note, these transgenic mice receiving DOCA+AII infusion were still hypertensive (SBP, 148±5.09 vs. 148.07±3.43 mmHg, P>0.05 vs. WT/DOCA+AII) but had much less albuminuria and glomerular and tubulointerstitial fibrosis (decreased by 67.3%, 76.6% and 67.3% respectively (P<0.001), when compared to WT/DOCA+AII), which were associated with reduced podocyte injury determined by ameliorated DOCA+AII-induced podocyte loss and foot process effacement; and alleviated tubular injury determined by ameliorated DOCA+AII-induced increases in renal KIM-1 and NGLA mRNA expression and decreases in renal cubilin and megalin mRNA expression. In addition, renal macrophage infiltration and productions of NF-kB-p65, Nox2 and p47phox, markers of inflammation and oxidative stress, which were induced by DOCA+AII infusion in WT mice, were markedly reduced in ApN-Tg mice.

Conclusions: These results indicate that elevated ApN in CKD mouse model is renal protective. Enhancing adiponectin production or signaling may have therapeutic potential for renal disease.

FR-PO349

Indoxyl Sulfate Disturbs Normal Iron Metabolism via Hepcidin Upregulation in CKD Hirofumi Hamano,[1] Yasumasa Ikeda,[1] Yuya Horinouchi,[1] Yuki Izawa-ishizawa,[1] Shoji Kagami,[2] Toshiaki Tamaki.[1] *[1]Department of Pharmacology, Tokushima University Graduate School, Tokushima City, Japan; [2]Department of Pediatrics, Tokushima University Hospital, Tokushima City, Japan.*

Background: Hepcidin, a secreted hormone derived from hepatocytes, is a key regulator of systemic iron metabolism to regulate iron efflux from intracellular iron by the internalization and degradation of ferroportin (FPN). Hepcidin concentration is increased in patients with chronic kidney disease (CKD), suggesting to the dysregulation of iron metabolism in CKD. Levels of indoxyl sulfate (IS), a uremic toxin, is elevated during the course of CKD progression, and its accumulation exacerbates the status of CKD. However, the role of IS accumulation on iron metabolism has remained unclear. In the present study, we investigated the involvement of IS on iron metabolism.

Methods: In *in vitro* experiments, HepG2 cells were used to examine the mechanism of IS on hepcidin regulation. We used a mouse model of adenine-induced CKD to analyze hepcidin action on body iron metabolism in *in vivo*. The CKD mice were divided into two groups: one was treated using AST-120 (uremic toxin adsorbent) and the other received no treatment. In addition, we tested mice with direct IS administration.

Results: In *in vitro* experiments using HepG2 cells, IS augmented hepcidin expression in a dose-dependent manner. IS-induced hepcidin upregulation was inhibited by silencing or pharmacological inhibition of aryl hydrocarbon receptor (AhR), a receptor of IS. IS also augmented oxidative stress and anti-oxidant drugs suppressed IS-induced hepcidin upregulation. Adenine-induced CKD mice showed the elevation of hepatic hepcidin mRNA expression and blood hepcidin concentration compared with control mice. In CKD mice, renal anemia, decreased blood iron concentration, increased blood ferritin levels, and increased splenic iron content were seen, and ferroportin was decreased in the duodenum and increased in the spleen. These changes were ameliorated by AST-120 treatment. CKD mice showed iron-deficient anemia, and this was slightly ameliorated by AST-120 treatment. Moreover, mice treated by direct IS administration showed hepatic hepcidin upregulation.

Conclusions: IS participates in the dysregulation of iron metabolism through hepcidin regulation via AhR and oxidative stress in CKD. Removal of IS might be a therapeutic strategy for abnormality of iron metabolism in CKD.

FR-PO350

Endothelial Sirtuin 1 Deficiency Is a Super-Inducer of Syndecan 4 (Synd4): Role of Its Ectodomain in Renal Fibrosis Mark Lipphardt,[2,5] Jong Wook Song,[4] Brian B. Ratliff,[2] Hassan Dihazi,[3] Gerhard A. Mueller,[1] Michael S. Goligorsky.[2] *[1]Georg-August University, Gottingen, Germany; [2]New York Medical College, Valhalla, NY; [3]University Medical Centre Goettingen, Goettingen, Germany; [4]Yonsei University College of Medicine, Millwood, NY; [5]Nephrology & Rheumatology, Universitätsmedizin Göttingen, Göttingen, Germany.*

Background: Syndecans comprise a family of membrane-spanning, glycocalyx-forming proteoglycans with glycosaminoglycans covalently bound to their ectodomain. There is evidence that Synd4 is required for integrin function and wound healing, but mice with the deletion of Synd4 appeared to be protected from renal fibrosis. Synd4 expression is regulated by NF-kB activity while degradation of the latter requires deacetylation by Sirtuin 1 (Sirt1).

Methods: To elucidate the role of Synd4 in fibrosis, we compared wild type and fibrosis-prone endothelial Sirt1-deleted Sirt1^{endo}-/- mice serving as a model of global endothelial dysfunction.

Results: Synd4 transcripts were dramatically increased in Sirt1^{endo}-/- kidneys. UUO further induced it in control but especially in Sirt1^{endo}-/- mouse kidneys. Synd4 ectodomain expression was significantly enhanced after UUO compared to contralateral kidneys, whereas there were no differences in expression of the intracellular domain. We next performed mass-spectrometry analysis of the secretome of renal microvascular endothelial cells (RMVEC) which revealed that Synd4 was highly enriched in TGFβ1-stimulated cells obtained from Sirt1^{endo}-/- mice; notably all detectable peptides were confined to the ectodomain of Synd4. Furthermore, hyperplasia of myofibroblasts accompanied by microvascular rarefaction and overexpression of Synd4 were detected in Sirt1^{endo}-/- mouse kidneys. The ectodomain of Synd4 acted as a chemoattractant for monocytes with higher levels of macrophages and higher expression level of Synd4 detected in the extracellular matrix of Sirt1^{endo}-/- mice. In vitro, ectodomain application resulted in generation of myofibroblasts from cultured renal fibroblasts, while in vivo, subcapsular injection of ectodomain induced interstitial fibrosis.

Conclusions: Based on our experimental results and the existing body of published work, we propose that it is the Synd4 ectodomain rather than Synd4 per se that is partially responsible for fibrosis in UUO and, especially, when it is combined with endothelial dysfunction.

FR-PO351

Class IIa Histone Deacetylase Inhibition Suppresses Renal Fibroblast Activation and Lessens Fibrosis Chongxiang Xiong,[1] Shougang Zhuang.[2,3] *[1]Rhode Island Hospital, Providence, RI; [2]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [3]Department of Nephrology, Shanghai East Hospital, Tongji University, Shanghai, China.*

Background: Histone deacetylases (HDACs) are a family of enzymes involved in regulation of cellular functions, including proliferation, migration and survival. Class I and III HDACs are associated with renal fibrosis. The role of class II HDAC in this process is poorly understood.

Methods: We examined the role of class IIa HDACs (HDAC- 4, -5, -7, -9) in renal fibroblast activation and fibrosis using MC1568, a highly selective class IIa HDAC inhibitor, and the siRNA specifically targeting individual class IIa HDACs.

Results: Exposing cultured renal interstitial fibroblasts to MC1568, or silencing class IIa HDAC-4 and-7, significantly reduced activation as indicated by decreased a-smooth muscle actin, collagen 1 and fibronectin expression. In a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO), HDAC-4 was highly expressed whereas expression levels of HDAC-5, -7, -9 were only slightly elevated. MC1568 suppressed deposition of extracellular matrix proteins and renal fibroblast activation. This coincided with reduced numbers of renal epithelial cells arrested at G2/M cell cycle phase and restored expression of Klotho and BMP7 after UUO injury. MC1568 also abrogated UUO-induced phosphorylation of receptor tyrosine kinases (epidermal growth factor and platelet growth factor receptors) and several signaling molecules associated with renal fibrosis, including Smad-3, STAT3, and NF-κB and ERK1/2. Moreover, class IIa inhibition suppressed renal expression of HIF-1α, Notch-1 and -3 and preserved expression of PPAR-alpha and PPAR-gama following UUO.

Conclusions: Class IIa HDACs inhibition may attenuate renal fibrosis by inhibiting profibrotic signaling pathways and preserving expression of renoprotective factors.

FR-PO352

Lysyl Oxidase Like-2 Contributes to Alport Renal Disease Progression Dominic E. Cosgrove,[5] Daniel T. Meehan,[2] Brianna M. Dufek,[4] Duane C. Delimont,[1] Michael Hartnett,[1] Deidre Mackenna,[3] Gretchen Bain.[6] *[1]Boys Town National Research Hospital, Omaha, NE; [2]Boys Town National Research Hospital, Omaha, NE; [3]PharmAkea, San Diego, CA; [4]Boys Town National Research Hospital, Omaha, NE; [5]Boystown National Resident Hospital, Omaha, NE; [6]PharmAkea, Inc, San Diego, CA.*

Background: Lysyl oxidase like-2 (LOXL2) is thought to have both intracellular and extracellular functions. Extracellularly, LOXL2 performs the first step in the formation of crosslinks in collagen and elastin networks, resulting in increased stiffness which promotes the transition of fibroblasts to myofibroblasts. Intracellularly, LOXL2 modifies histones, stabilizes SNAIL, and reduces cell polarity which increases metastatic potential of tumors. LOXL2 promotes liver and lung fibrosis, but nothing is known regarding a role in the kidney. This study explored whether LOXL2 influences kidney disease in Col4a3(-/-) Alport mice.

Methods: LOXL2 protein and mRNA expression in WT versus Alport mice was examined. Alport mice were treated with a small molecule inhibitor (LOXL2i) or vehicle from 2 to 7 weeks of age. Both cortex and glomeruli were analyzed by real time PCR for genes associated with glomerular and interstitial disease, by immunofluorescence (IF) for collagen 1 and CD45 to assess interstitial fibrosis, by IF for fibronectin to score glomerulosclerosis, for mesangial filopodial invasion by IF for laminin α5 and integrin α8, and for albuminuria and BUN. TEM analysis was performed for ultrastructural analysis of the GBM. Lifespan was also assessed.

Results: LOXL2 protein and mRNA (>15-fold) are induced in Col4A3(-/-) Alport kidneys. LOXL2i-treatment significantly reduced interstitial fibrosis (by >50%) and mRNA expression for the fibrosis markers MMP-2, MMP-9, TBF-β1, and TNF-α in the interstitium. Additionally, LOXL2i treatment also reduced glomerulosclerosis (by

>75%) and mRNA expression of MMP-10, MMP-12, and MCP-1 in the glomeruli. Both albuminuria and BUN were significantly reduced in treated mice. Mesangial filopodial invasion of the capillary tufts was blunted, and the GBM ultrastructure was normalized. There was no effect on lifespan.

Conclusions: LOXL2 plays an important role in promoting both glomerular and interstitial pathogenesis associated with Alport syndrome in mice. LOXL2i may provide beneficial effects for treating human Alport syndrome and may extend to other etiologies of CKD given strong association between renal fibrosis and outcomes in end stage renal disease.

Dysfunction of the Intestinal Carnitine/Organic Cation Transporter 1 in CKD Impairs an Antioxidant Effect of Ergothioneine Yasuyuki Shinozaki, Kengo Furuichi, Tadashi Toyama, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Kanazawa University, Ishikawa, Japan.*

Background: Carnitine/organic cation transporter 1 (OCTN1) is a specific transporter of the food-derived antioxidant, ergothioneine (ERGO). ERGO absorbed by intestinal OCTN1 is distributed systemically through the bloodstream and incorporated into each organ by OCTN1. The OCTN1–ERGO axis is an adaptive antioxidant system that protects against further damage caused by oxidative stress. However, the role of OCTN1–ERGO axis in chronic kidney disease (CKD) progression remains unclear.

Methods: The ability of the intestine to absorb ERGO and OCTN1 expression were evaluated in CKD mice using the everted sac method, RT-PCR, western blot and immunohistochemistry. To identify the role of the OCTN1–ERGO axis in CKD, we evaluated kidney damage and oxidative stress in OCTN1-knockout CKD mice. To assess the protective effects of ERGO in CKD, we checked the antioxidant effect of ERGO using mProx24 cells. Moreover, we measured ERGO levels in the blood of CKD patients.

Results: Although the mRNA and protein expression of OCTN1 did not change as CKD progressed, the localization of OCTN1 to the apical cellular membrane was reduced in the intestines of CKD mice. OCTN1-knockout CKD mice showed enhanced kidney damage, interstitial fibrosis, and oxidative stress. An *in vitro* study using mProx24 cells treated with indoxyl sulfate, which was pretreated with ERGO, revealed a dose-dependent attenuation of oxidative stress. In CKD patients, ERGO levels decreased as CKD progressed and that there was a positive correlation between ERGO and eGFR levels. ERGO levels were restored 10 months after kidney transplants in three patients.

Conclusions: CKD attenuated the function of the OCTN1–ERGO axis because of the dysfunction of intestinal OCTN1. These results suggested that a novel inter-organ interaction mediated by transporters is associated with CKD progression.

FR-PO354

Myeloid TGFβ Receptor Promotes Fibrosis after AKI Ming-Zhi Zhang, Jessica M. Overstreet, Yinqiu Wang, Aolei Niu, Suwan Wang, Leslie S. Gewin, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Transforming growth factor-β (TGF-β) is a central mediator of fibrosis. TGF-β signals through a receptor complex composed of two type I and two type II transmembrane subunits. Renal macrophages are major producers of TGF-β1 and play important roles in the development of fibrosis after acute kidney injury (AKI). However, a previous study found that deletion of myeloid TGF-β1 did not prevent fibrosis after severe renal ischemia/reperfusion (I/R) or obstructive injury. In the present study we examined whether deletion of myeloid type II TGF-ß receptors (Tgfbr2) affected development of fibrosis after AKI.

Methods: Wild type ($Tgfbr2^{f/f}$) or KO (CD11b-Cre;$Tgfbr2^{f/f}$ or LysM-Cre;$Tgfbr2^{f/f}$) mice (male, 3 months old, C57BL/6) were used. For a severe I/R AKI model, the animals were uninephrectomized, immediately followed by unilateral I/R with renal pedicle clamping for 29 min. Mice were sacrificed after 3 weeks. For an AKI-chronic kidney disease (CKD) model, unilateral I/R with renal pedicle clamping for 31 min was performed, with contralateral uninephrectomy on the 8th day, and animal sacrifice on day 28.

Results: Deletion of macrophage/dendritic cell Tgfbr2 did not affect functional recovery from AKI, as indicated by similar rates of BUN and creatinine recovery. However, deletion of Tgfbr2 in macrophages/dendritic cells led to dramatic decreases in development of fibrosis at 3 weeks in the severe AKI model, as indicated by quantitative picro-sirius red staining and Masson's trichrome staining. Deletion of Tgfbr2 in macrophages/dendritic cells was associated with decreased expression levels of profibrotic and fibrotic components, including CTGF, α-SMA and collagen I. In addition, macrophage/dendritic cell Tgfbr2 deletion led to marked decreases in macrophage and T cell infiltration and oxidative stress. Macrophage/dendritic cell Tgfbr2 deletion also markedly reduced development of fibrosis in the AKI-CKD model. In renal macrophages/dendritic cells isolated with CD11b microbeads, Tgfbr2 deletion led to decreased expression levels of M2 markers and increased M1 markers.

Conclusions: These studies indicate that myeloid Tgfbr2 promotes fibrosis after severe AKI at least in part by promotion of M2 polarization and suggest that activation of myeloid TGF-β receptors by TGF-β produced by non-myeloid cell types plays an important role in this process.

Protective Effect of Vascular Endothelial Growth Factor-C on Renal Interstitial Fibrosis through Lymphangiogenesis in Mouse Unilateral Ureteral Obstruction Shoko Hasegawa,[2] Toshiaki Nakano,[2] Kumiko Torisu,[3] Akihiro Tsuchimoto,[2] Masahiro Eriguchi,[2] Kosuke Masutani,[2] Kazuhiko Tsuruya,[4] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Fukuoka, Japan; [2]Kyushu University, Higashi-ku, Japan; [3]Kyushu University Hospital, Fukuoka, Japan; [4]None, Fukuoka, Japan.*

Background: Renal fibrosis is the final common pathway of chronic kidney diseases. Lymphatic vessel (LV) proliferation is found in human renal diseases and other fibrotic diseases, suggesting that lymphangiogenesis is associated with the progression or suppression of kidney diseases. However, the purpose of LV proliferation is not completely understood. We have previously reported the effect of vascular endothelial growth factor (VEGF)-C on lymphangiogenesis and fibrosis in the mouse kidney using the unilateral ureteral obstruction (UUO) model. At this time, we additionally investigated the effect of VEGF-C on inflammation and M1 and M2 macrophages. Furthermore, we investigated the effect of VEGF-C in vitro using lymphatic endothelial cells (LECs) by VEGF-C administration.

Methods: We continuously administered recombinant human VEGF-C to UUO model mice using an osmotic pump (UUO+VEGF-C group) for 14 days. We investigated the lymphangiogenesis (LYVE-1 staining, western blotting of VEGFR-3), inflammation (F4/80 staining, MCP-1 staining, ym-1 staining, western blotting of TGF-β1) and fibrosis (Sirius-red staining, western blotting of collagen 1). Additionally, we investigated the proliferation and adhesion molecules (ICAM-1, VCAM-1, E-selectin) of cultured LECs by administration of VEGF-C.

Results: Lymphangiogenesis was significantly induced in the UUO+VEGF-C group compared with the vehicle group, despite similar numbers of capillaries in both groups. The number of infiltrating macrophages (especially M1 macrophages) and levels of inflammatory cytokines and transforming growth factor-β1 were reduced in the UUO+VEGF-C group compared with the vehicle group. Renal fibrosis was consequently attenuated in the UUO+VEGF-C group. In cultured LECs, administration of VEGF-C increased the proliferation of LECs and expression of adhesion molecules.

Conclusions: These findings suggest that induction of lymphangiogenesis ameliorates inflammation and fibrosis in the renal interstitium. Enhancement of the VEGF-C signaling pathway in LECs may be a therapeutic strategy for renal fibrosis.

Xanthine Oxidoreductase Inhibitor, Topiroxostat, Had a Renoprotective Role under Decreased Angiotensin II Type 1a Receptor Expression Atsuko Ikemori,[3,1] Takeshi Sugaya,[2] Mikako Hisamichi,[4] Kenjiro Kimura,[5] Yugo Shibagaki.[1] *[1]Division of Nephrology and Hypertension, St Marianna University Hospital, Kawasaki, Japan; [2]St. Marianna Univ, Tokyo, Japan; [3]Anatomy, St. Marianna University School, Kawasaki, Kanagawa, Japan; [4]St.Marianna university school of medicine, Kawasaki, Japan; [5]Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: Xanthine oxidoreductase (XOR) inhibitors may function as renoprotective agents as well as antioxidants via decrease in oxidative stress produced by renal xanthine oxidase converted from XOR. The aim of this study was to confirm the renoprotective effect of the XOR inhibitor, topiroxostat (Top) under decreased angiotensin II type 1a (AT1a) receptor expression in the model of renal injury caused by adenine.

Methods: To evaluate the degree of tubular damage using urinary liver-type fatty acid-binding protein (L-FABP) under decreased AT1a expression, we used AT1a receptor knockdown hetero and human L-FABP chromosomal transgenic (Tg) mice ($AT1a^{+/-}$L-$FABP^{+/-}$). Male $AT1a^{+/-}$L-$FABP^{+/-}$ mice were divided into two groups: the adenine diet group (n=24) was given a diet containing only 0.2% w/w adenine, and the normal diet group (n=5) was given a normal diet. When renal dysfunction was confirmed in the adenine diet group 4 weeks after starting the diet, the adenine diet group was further divided into three groups. The adenine diet group (n=8) was continuously given only the adenine diet. Each group receiving high-dose (3mg/kg) or low-dose (1mg/kg) Top (Top-H, n=8, Top-L, n=8) was given the adenine diet including the drug for another 4 weeks.

Results: The levels of renal XOR, renal dysfunction, urinary L-FABP, tubulointerstitial damage, hypoxia, and oxidative stress were decreased or attenuated after treatment with Top compared with the adenine diet group.

Conclusions: In conclusion, Top attenuated renal damage under decreased AT1a expression in the adenine-induced renal injury model. Combination treatment with an XOR inhibitor and an RAS inhibitor might be a useful strategy for prevention of the progression of CKD.

Febuxostat Attenuates ER Stress Mediated Kidney Injury in a Rat Model of Hyperuricemic Nephropathy Ying Fan,[1] Li He,[1] Wenzhen Xiao,[2] Jiejun Wen,[1] Yang Dong,[1] John C. He,[2] Niansong Wang.[1] *[1]Nephrology, Shanghai 6th People's Hospital affiliated to Shanghai Jiaotong University, Shanghai, China; [2]Mount Sinai School of Medicine, New York, NY.*

Background: Hyperuricemia contributes to the renal tubular injury and kidney fibrosis. Febuxostat, a novel inhibitor of xanthine oxidase, has been widely used for

the treatment of hyperuricemia and prevention of gout. Recent studies suggested that Urate-lowering therapy (ULT) by Febuxostat might also have cardiovascular and renal benefits, yet the the mechanism of this protective effect is unknown. Endoplasmic reticulum (ER) stress has been well recognized as one of the important mechanisms in the onset and progression of many kidney diseases. In recent studies, we identified a novel ER-associated gene, reticulon-1A (RTN1A), which is associated with the progression of kidney diseases. However, the exact role of RTN1A and ER stress in hyperuricemia induced kidney disease hasn't been fully studied.

Methods: In the present study, we studied the expression of RTN1A and other ER Stress markers in kidney biopsies of patients with hyperuricemia-related kidney injury. We determined the role of RTN1A and ER stress in uric acid induced renal tubular cell injury *in vitro* as well as in a rat model of hyperuricemic nephropathy (HN). We also examined whether treatment of Febuxostat diminished ER stress and apoptosis of renal tubular cells and attenuated kidney injury in HN rat model.

Results: We found the expression of RTN1A and ER stress markers was significantly increased in kidney biopsies of patients with hyperuricemia-related kidney injury. In HN rat model established by oral administration of a mixture of adenine and potassium oxonate, increased expression of RTN1A and ER stress were shown in tubular and interstitial compartment of rat kidneys. Treatment of Febuxostat not only attenuated ER stress mediated renal tubular injury and tubulointerstitial fibrosis, but also reduced uric acid crystals deposition in HN rat kidneys. *In vitro*, Febuxostat also suppressed uric acid-induced ER stress and apoptosis in cultured tubular cells.

Conclusions: In conclusion, RTN1A and ER stress mediate tubular cell injury and kidney fibrosis in hyperuricemia induced nephropathy. ULT with Febuxostat attenuates uric-acid induced ER stress in renal tubular cells and the progression of HN. This study suggests a therapeutic role of Febuxostat in hyperuricemia-related CKD.

SOX9 Is a Critical Regulator of Extracellular Matrix Deposition during Kidney Fibrosis Sayyid M. Raza,[1] James P. Pritchett,[3] Neil Hanley,[1] Philip A. Kalra,[2] Karen Piper hanley.[1] *[1]University of Manchester, Manchester, United Kingdom; [2]Salford Royal Hospital NHS Trust, Salford, United Kingdom; [3]Manchester Metropolitan University, Manchester, United Kingdom.*

Background: Renal fibrosis is a major cause of morbidity and mortality and a common feature of most chronic kidney disease (CKD). It is characterised by extracellular matrix (ECM) secretion from effector cells (myofibroblasts) resulting in tissue dysfunction and scarring. Discovering how to block scar production represents a very attractive therapeutic avenue for much needed antifibrotic drug development.

Methods: Primary pericytes were extracted from wild type mice. Cells were analysed by immunohistochemistry, western blotting and qPCR. Kidney fibrosis was induced in vivo by 2 week unilateral ureteric obstruction (UUO). SOX9-loss was achieved through tamoxifen injections of Sox9fl/fl; RosaCreERT2 mice. Fibrosis was assessed histologically in mice and human kidney fibrotic tissue.

Results: In wild type fibrotic kidneys SOX9 was increased and detected in α-SMA positive cells, demarcating activated myofibroblasts, along with collagen type 1 (COL1) rich fibrotic tracts disrupting normal tissue. In vitro, primary mouse pericytes expressed nuclear SOX9 surrounded by α-SMA. SOX9 knockdown in activated pericytes using RNA interference caused a commensurate reduction in COL1 protein expression (~60%), whereas the pro-fibrotic cytokine transforming growth factor-beta (TGF-β) induced expression of SOX9 by 2.5 fold in pericytes and 2.3 fold in the rat fibroblast cell line, NRK-49F. To model the stiffening environment of fibrotic kidneys we cultured pericytes on 1, 4 and 12 KPa hydrogels where α-SMA, SOX9 and the mechanosensitive factor YAP1 became robustly expressed at 12KPa. Moreover, YAP1 was also increased in UUO kidneys. To support a role for SOX9 in kidney fibrosis, following UUO-fibrosis mice lacking SOX9 had significantly reduced fibrosis by picrosrius red quantification (35% reduction) and α-SMA positive myofibroblasts were reduced by 45%. Importantly, in various human kidney diseases (Membranous nephropathy, Diabetic nephropathy, IgA nephropathy) fibrotic areas were associated with SOX9 positivity histologically.

Conclusions: These data support a pro-fibrotic role for SOX9 (similar to other organs) in kidney fibrosis where it is regulated by TGF-β and the mechnosignalling factor YAP1. Moreover, this provides an interesting opportunity for inhibiting SOX9 or its dependent pathways for anti-fibrotic therapy.

FR-PO359

Lymphocytes and PD-1 in Aristolochic Acid Nephropathy Gilbert R. Kinsey, Brian K. Stevens, Mana Yang. *Division of Nephrology; Center for Immunity, Inflammation and Regenerative Medicine, Univerisity of Virginia, Charlottesville, VA.*

Background: Aristolochic acid is a nephrotoxic agent previously used in traditional Chinese medicine and found as an adulterant in some herbal supplements. Clinical studies have revealed extensive inflammation in kidneys of patients with aristolochic acid nephropathy (AAN). AAN involves an acute toxic injury to tubular epithelial cells that leads to immune cell infiltration and progressive fibrosis over time. Programmed death 1 (PD-1) is a co-stimulatory molecule that limits the activation of T cells and lymphocytes have important roles in other forms of kidney injury, but their mechanistic role in AAN has not been previously reported.

Methods: Male wild-type (WT), PD-1 KO and lymphocyte-deficient RAG-1 KO mice (all on C57Bl/6 background) were treated with AA 5 mg/kg by i.p. injection. Five and 14 days after initiating AA treatment renal function, injury and inflammation were assessed.

Results: Over time, a marked infiltration of CD45+ immune cells, especially T lymphocytes was observed in kidneys of WT mice after AA treatment (For example: CD4 T cells/g: Vehicle: 77,000 ± 11,000 vs. AA: 1,860,000 ± 250,000 at day 14). CD8 T cell, mononuclear phagocyte and PMN cell numbers were also elevated at day 14. Five days after AA treatment there were no differences in renal function between WT, PD-1 KO or RAG-1 KO mice as measured by creatinine or BUN levels. At day 14, RAG-1 KO mice had significantly higher BUN levels, while PD-1 KO mice had lower BUN levels compared to WT AA-treated mice (BUN in (mg/dl) in WT: 38 ± 7 vs. RAG-1 KO: 87 ± 11 vs. PD-1 KO: 16 ± 1). At day 14, RAG-1 KO kidneys exhibited higher innate leukocyte accumulation compared to WT mice. Conversely, PD-1 KO kidneys had lower innate leukocytes and dramatically reduced CD3+CD4+ T cell infiltration.

Conclusions: These results suggest that lymphocytes are protective in this intermediate-length exposure of mice to AA. Unexpectedly, PD-1 deficiency ameliorated renal dysfunction and inflammation, suggesting a pro-inflammatory role for this co-stimulatory molecule in AAN.

Sonic Hedgehog Promotes Kidney Injury by Activating Renin-Angiotensin System via a Non-Canonical Pathway Songzhao Wu,[1] Lili Zhou,[1] Chunhong Wang,[1] Youhua Liu.[2] *[1]Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Sonic hedgehog (Shh) is a lipid-modified glycoprotein that plays a crucial role in embryonic development. Earlier studies indicate that Shh is a tubule-derived growth factor that specifically targets interstitial fibroblasts via a paracrine mechanism after various kidney injuries. Using hedgehog-responding reporter mice, studies show that kidney tubular epithelial cells are not responsive to hedgehog ligands via Gli-dependent canonical pathway. Whether Shh can target tubular epithelium via other mechanisms, however, remains to be defined.

Methods:

Results: In this study, we investigated this issue using both in vitro and in vivo approaches. We found that in cultured kidney proximal tubule cells (HKC-8), recombinant Shh protein induced multiple components of renin-angiotensin stystem (RAS), including renin, angiotensin-converting enzyme, and angiotensin II type 1 receptor (AT1). Shh also activated MAPK by inducing ERK, JNK and p38 phosphorylation, as well as its upstream PLC phosphorylation and activation. This cascade of events was dependent on Smo receptor, as either cyclopamine (CPN), a small molecule Smo inhibitor, or MAPK inhibitors abolished the Shh-mediated activation of MAPK and induction of RAS components, suggesting that Shh activates RAS via Gli-independent, MAPK-dependent non-canonical pathway. In vivo, overexpression of Shh aggravated the glomerular injury, interstitial matrix proteins expression and deposition, and renal fibrosis at 6 weeks after 5/6 nephrectomy. Shh also promoted the activation of PLC and MAPK and induction of multiple RAS proteins, and elevated blood pressure. However, CPN therapy attenuated glomerular lesions, reduced renal fibrosis. CPN also inhibited renal MAPK activation, repressed RAS protein expression and normalized blood pressure.

Conclusions: Collectively, these studies demonstrate that tubule-derived Shh can target tubular epithelium by inducing RAS protein expression via PLC/MAPK-dependent non-canonical pathway. Our results indicate that blockade of Shh signaling can repress multiple RAS genes, thereby leading to amelioration of kidney injury.

STAT3 Regulates Fibrogenic Signaling in Pericytes and Activates Migration, Differentiation, and Secretion of Pro-Fibrotic Cytokines Amrendra K. Ajay,[1,3] Shruti Vig,[2] Akinwande A. Akinfolarin,[1,3] Venkata Sabbisetti,[1,3] Joseph V. Bonventre.[1,3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Brigham and women's hospital, Boston, MA; [3]Medicine, Harvard Medical School, Boston, MA.*

Background: STAT3 is a key transcription factor, which plays an important role in cell proliferation, cellular pluripotency, and differentiation. Here, we investigated the pathophysiological role of STAT3 signaling in kidney fibrosis.

Methods: Stromal cell-specific STAT3 deletion was performed by breeding STAT3 floxed mice with FoxD1 Cre mice. Kidney fibrosis was induced by injecting a single dose of 300 mg/kg body weight folic acid (FA) or 5 mg/kg body weight aristolochic acid (AA). Immunostaining for STAT3 phosphorylations (Ser727 and Tyr705) was performed on mice kidneys and 10T1/2 cells. We developed two activation mutants and one-inactivation mutant of STAT3 using CRISPR-Cas9 technology in pericytes-like (10T1/2) cells. Cell migration was evaluated with Boyden chambers and wound scratch assays. Cell proliferation was measured by MTT assay. RT-PCR and western blotting were used to measure STAT3 dependent genes and luminex-based assay of cytokines (CTGF, TGF-β and IL-6) were performed to quantitate pro-fibrotic cytokines.

Results: STAT3 phosphorylation was increased in tubular epithelial cells and pericytes of 5 human subjects with chronic kidney disease. Deletion of STAT3 in pericytes protects against FA or AA-induced kidney fibrosis at 7 and 14 days post-treatment. Fibrotic markers, including fibronectin, collagen1a1 and α-smooth muscle actin (α-SMA), were reduced in STAT3 knockout mice. *In vitro*, CRISPR-Cas9 mediated activation of STAT3 caused increased cell migration whereas the inhibition of STAT3 was associated with decreased migration of 10T1/2 cells. Treatment of cells with TGF-β increased the production of profibrotic cytokines and differentiation of 10T1/2 cells to

myofibroblasts. Pretreatment with stattic, a small molecule inhibitor of STAT3 inhibited both cytokines production and cell differentiation.

Conclusions: Inhibition of STAT3 in pericytes protects mice from kidney fibrosis and the specific inhibition of STAT3 signaling in pericytes prevents their differentiation into myofibroblasts.

FR-PO362

FHL2 Promotes Fibroblast Activation and Kidney Fibrosis Involving the Activation of β-Catenin Signaling Ying Duan,[3] Ting Cai,[1] Junwei Yang,[4] Weichun He.[2] *[1]Nanjing Medical University, NANJING, China; [2]Nanjing Medical University, 2nd Affiliated Hospital, Nanjing, China; [3]Nanjing medical university, Nanjing, China; [4]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Four-and-a-half LIM domains protein 2 (FHL2) is an adaptor protein and has been implicated in β-catenin signaling. Previously, we found that FHL2 may mediate TGF-β1-induced tubular epithelial-to-mesenchymal transition through activating β-catenin signaling. The FHL2-positive cells were observed both in renal tubule and interstitium in mice with obstructive nephropathy. However, the potential role and mechanisms for FHL2 in fibroblast activation and kidney fibrosis remains to be clarified.

Methods: The regulation and function of FHL2 in TGF-β1-stimulated fibroblast activation were examined in cultured NRK-49F cells. Mice with fibroblast-specific deletion of FHL2 were generated by mating FHL2-floxed mice with S100a4-Cre transgenic mice. Mouse model of kidney fibrosis was established by unilateral ureteral obstruction (UUO).

Results: TGF-β1 induced FHL2 mRNA and protein expression in a time- or dose-dependent manner in cultured cells. Ectopic expression of FHL2 increased α-smooth muscle actin (α-SMA), type I collagen and fibronectin expression, whereas knockdown of FHL2 *via* small interfering RNA partially suppressed TGF-β1-induced expression of α-SMA, type I collagen and fibronectin. Overexpression of FHL2 led to activation of β-catenin signaling, which is evidenced by an increase in β-catenin nuclear translocation, β-catenin-mediated gene transcription, and expression of β-catenin target genes such as Snail and c-Myc. Treatment with TGF-β1 induced a physical interaction between FHL2 and β-catenin. *In vivo*, FHL2 was induced and β-catenin was activated in renal interstitial myofibroblasts from mice with obstructive nephropathy. Compared with wild-type littermates, the kidneys with fibroblast-specific ablation of FHL2 exhibited less interstitial extracellular matrix deposition at 2 weeks after UUO.

Conclusions: Our results suggest that FHL2, through activating β-catenin signaling, plays a critical role in mediating TGF-β1-induced fibroblast activation and contributes to the development and progression of kidney fibrosis, and FHL2 could be a potential future therapeutic target for chronic kidney disease.

FR-PO363

Fibroblast-Specific p90RSK Promotes Kidney Fibrosis Ling Lin, Chaowen Shi, Kebin Hu. *Penn State University College of Medicine, Hershey, PA.*

Background: The 90 kDa ribosomal s6 kinases (RSKs) are a group of serine/threonine kinases that regulate diverse cellular process, such as cell growth, cell motility, and cell survival. There are 4 RSK isoforms (RSK1-4), of which RSK1 is also designated as p90RSK and predominantly expressed in the kidney. p90RSK is recently shown to promote diabetic endothelial dysfunction and atherosclerosis, however, the role of p90RSK in the development and progression of chronic kidney disease has never been investigated *in vivo*.

Methods: We generated a novel fibroblast-specific p90RSK trangenic mouse strain and investigated the role of p90RSK in kidney fibrosis.

Results: We examined the expression of phospho-specific and total p90RSK during the course of chronic kidney injury in the classic unilateral ureter obstruction (UUO) model. It's found that p90RSK is dramatically activated, as indicated by phosphorylation of p90RSK, in the obstructed kidneys as early as 3 days after UUO; and the activation continued increasing until 14 days after UUO when the mice were sacrificed. Whereas, there is little difference in the level of total p90RSK between the obstructed and control kidneys. Intriguingly, double immune staining analysis found that the activation of p90RSK in the interstitium is largely induced in the FSP-1-positive fibroblasts. We generated fibroblast-specific p90RSK transgenic mouse, p90RSK-Tg, and found that this mouse has normal phenotype as the littermate control. However, when UUO was induced in the p90RSK-Tg mice, it was found that p90RSK-Tg mice display significantly worse tubular damage, and dramatically increased deposition of extracellular matrix components such as collagen and fibronectin than that of their littermates. Western blot analysis also showed that p90RSK-Tg mice had decreased E-cadherin expression and *de novo* activation of alpha-SMA comparing to their littermates.

Conclusions: It is clear that fibroblast-specific p90RSK activation promotes kidney fibrosis, possibly, through the epithelial-to-mesenchymal transition mechanism.

FR-PO364

A Novel, Highly Specific TGFβ1 Inhibiting Antibody Demonstrates Antifibrotic Activity without Cardiotoxicity Stefan Wawersik, Thomas Schurpf, Abhishek Datta, Christopher Littlefield, Christopher Chapron, Kathy Y. Morgan, Constance Martin, Kimberly Long, Allan Capili, Kaleigh Pavlik, Justin W. Jackson, Gregory Carven, Alan Buckler. *Scholar Rock Inc, Cambridge, MA.*

Background: Transforming growth factor-β1 (TGFβ1) has diverse biological functions, including regulation of immune response and tissue homeostasis. TGFβ1 activation has been associated with diseases including kidney fibrosis, where chronic activation is a key driver. Because of high homology between the TGFβ1 growth factor and its close relatives TGFβ2 and TGFβ3, truly TGFβ1-specific inhibitors have remained elusive. Pan-TGFβ inhibition, on the other hand, can cause dose-limiting heart valvulopathies, leading to concerns with long-term dosing. TGFβs are expressed as pro-proteins that are proteolytically cleaved into a C-terminal growth factor and an N-terminal prodomain that remains noncovalently associated with the growth factor, preventing receptor binding. This latent TGFβ complex resides on cells or in the extracellular matrix until it is activated by integrins, freeing the growth factor and allowing receptor binding.

Methods: To identify TGFβ1-specific antibodies, we targeted the prodomain, which shares much lower homology to TGFβ2 and TGFβ3 than the growth factor.

Results: We identified SR-AB1, a monoclonal antibody that binds latent TGFβ1 with no detectable binding to latent TGFβ2 or TGFβ3. SR-AB1 blocks latent TGFβ1 activation by αVβ6 or αVβ8 integrins, providing specificity unachieved by biologics that target the TGFβ1 growth factor/receptor interaction. SR-AB1 further inhibits latent TGFβ1 complexed with all four known TGFβ-presenting molecules, allowing targeting of TGFβ1 in multiple tissues. SR-AB1 blocks activation of endogenous TGFβ1 in a number of primary cells, including dermal myofibroblasts and hepatic stellate cells. Critically, while pan-TGFβ inhibitors show evidence of valvulopathy or other cardiotoxicity, SR-AB1 is free of such toxicities in 1 and 4 week rat studies. Finally, we tested the *in vivo* efficacy of TGFβ1 inhibition via this novel mechanism in the UUO model of kidney fibrosis, showing that SR-AB1 suppresses fibrosis to levels similar to those achieved by pan-TGFβ inhibition.

Conclusions: Our data show that isoform-specific inhibition of latent TGFβ1 is efficacious in a preclinical fibrosis model and has a superior safety profile compared to pan-TGFβ inhibition.

FR-PO365

Transplantation of Amniotic Fluid-Derived Stem Cells Preconditioned with Glial Cell Line–Derived Neurotrophic Factor Alleviates Renal Interstitial Fibrosis Dong Sun,[1] Shulin Li,[1] yuan Zhao,[2] Zhuojun Wang,[1] Jia Wang,[1] Caixia Liu.[1] *[1]Affiliated Hospital of Xuzhou Medical University, Xuzhou, China; [2]Xuzhou Medical University, Xuzhou, China.*

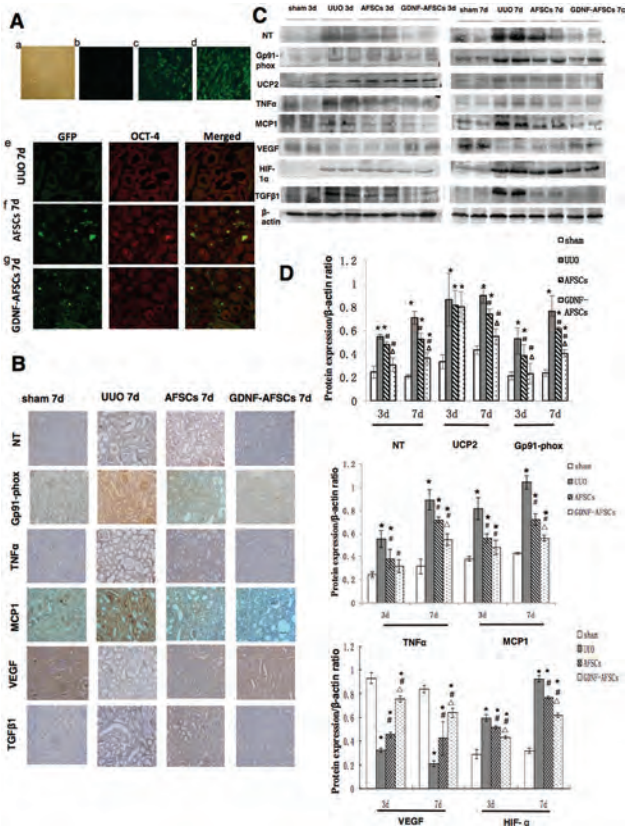
Background: The aim of the present study was to determine whether transplantation of glial cell line–derived neurotrophic factor (GDNF)–modified AFSCs is more useful than transplantation of unmodified AFSCs for the treatment of renal interstitial fibrosis.

Methods: A unilateral ureteral obstruction (UUO) model was established in mice. Either GDNF-AFSCs or AFSCs were transplanted into nu/nu mice via their caudal veins. The 48 mice (12 each group) were randomly assigned to sham-operation group (sham), UUO-saline solution group (UUO), AFSCs transplantation group (AFSCs) and GDNF-modified AFSCs transplantation group (GDNF-AFSCs). GFP fluorescent staining was used for the frozen sections in order to track the transplated AFSCs in the kidney under a fluorescence microscope. The oxidative, inflammatory, endothelial and mitochondrial makers were measured after 3 and 7 days transplantation.

Results: GDNF-AFSCs noticeably suppressed oxidative stress and inflammation; additionally, GDNF-AFSCs positively regulated peritubular capillaries (PTCs), vascular endothelial growth factor (VEGF), hypoxia inducible factor-1α (HIF-1α), transforming growth factor-β1 (TGF-β1) protein levels and mitochondrial factors.

Conclusions: GDNF promotes the abilities of AFSCs to inhibit inflammatory and oxidative stress effects, repair renal microvessels, relieve tissue hypoxia and mitochondrial damage and alleviate renal interstitial fibrosis.

Funding: Government Support - Non-U.S.



A. Culture of AFSCs, lentivirus vector transfection and immunofluorescent localization of frozen section in AFSC transplanted kidney.(B-D). Immunohistochemical staining (40×) and Western blot analysis of oxidative, inflammatory and endothelial markers.

The Role of β-Catenin/Foxo in Renal Fibrosis Padmashree Rao,[1] Min Pang,[3] Xi Qiao,[3] Hong Yu,[1] Hailong Wang,[3] Min Hu,[1] Qi Cao,[1] Yiping Wang,[1] Chow H. P'ng,[5] Brian J. Nankivell,[4] Vincent W. Lee,[4] Stephen I. Alexander,[2] Guoping Zheng,[1] David C. Harris.[1,4] *[1]Centre for Transplant and Renal Research, Westmead Institute for Medical Research, University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, Children's Hospital at Westmead., Sydney, NSW, Australia; [3]Shanxi Medical University, Taiyuan, China; [4]Westmead Hospital, Westmead, NSW, Australia; [5]Department of Tissue Pathology and Diagnostic Oncology, ICPMR, Westmead Hospital, Westmead, NSW, Australia.*

Background: TGF-β causes fibrosis by cross-talk with major profibrotic pathways. β-catenin is a common co-factor in different TGF-β signalling pathways. β-catenin binds to TCF to activate profibrotic genes, while β-catenin also binds to Foxo in competition with TCF. We propose that promoting β-catenin/Foxo will protect against β-catenin/TCF mediated profibrotic changes and kidney fibrosis.

Methods: Human kidney biopsies from kidney transplant and diabetic nephropathy patients were assessed for β-catenin/Foxo and β-catenin/TCF interactions in relation to kidney fibrosis. Mouse tubular epithelial C1.1 cells were treated with TGF-β1 with or without ICG-001 (5μM), an inhibitor of β-catenin/TCF. Foxo1 and TCF1 were knocked out by CRISPR/Cas9-mediated gene knockout. We evaluated kidney fibrosis in vivo in the unilateral ureteric obstruction (UUO) model. Profibrotic changes were examined by Western blot and immunofluorescence. Duolink - Proximity Ligation Assay (PLA) and co-immunoprecipitation assays (co-IP) were used to examine β-catenin/Foxo and β-catenin/TCF interactions.

Results: PLA of human kidney biopsies showed that β-catenin/Foxo correlated negatively (r=-0.785) whilst β-catenin/TCF correlated positively (r=0.679) with kidney fibrosis score (P<0.01). co-IP and PLA showed that ICG-001 promoted β-catenin/Foxo interaction by inhibiting β-catenin/TCF binding in TGF-β1-treated C1.1 cells. TGF-β1-induced β-catenin/TCF activity and expression of fibrotic genes (vimentin, N-cadherin, collagen I, III & IV) were reduced by ICG-001 and TCF1 knockout, while Foxo1 knockout prevented the reduction of the fibrotic gene expression. Kidney fibrosis was significantly reduced in UUO mice treated with TGF-β1 and ICG-001, which redirected TGF-β1 signalling from β-catenin/TCF to β-catenin/Foxo1 as shown by PLA.

Conclusions: These results indicate that β-catenin/Foxo plays a protective role against TGF-β's profibrotic activity by inhibiting β-catenin/TCF interaction and thereby preventing kidney fibrosis.

Inhibition of p300/CBP-Associated Factor Attenuates Renal Tubulointerstitial Fibrosis through Modulation of NF-kB and Nrf2 Sungjin Chung,[1,2] Zhilian Li,[1,3] Soojeong Kim,[4] Seok Joon Shin,[2] Cheol Whee Park,[2] Chul Woo Yang,[2] Yong-Soo Kim,[2] Eun Sil Koh.[2] *[1]Division of Nephrology, Department of Medicine, Vanderbilt University School of Medicine, Nashville, TN; [2]Department of Internal Medicine, The Catholic University of Korea College of Medicine, Seoul, Republic of Korea; [3]Department of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China; [4]Department of Biochemistry, The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: p300/CBP-associated factor (PCAF), a histone acetyltransferase, is involved in many cellular processes such as differentiation, proliferation, apoptosis and reaction to cell damage by modulating the activities of several genes and proteins through acetylation of either histones or transcription factors. Here, we examined a pathogenic role of PCAF and its potential as a novel therapeutic target in the progression of renal tubulointerstitial fibrosis induced by unilateral ureteral obstruction.

Methods: After UUO surgery, male C57BL/6 mice were administered either the PCAF inhibitor garcinol or a vehicle by intraperitoneal injection once a day for 3 or 7 days. Renal tubular epithelial cells (HK-2) were transfected with siRNA-PCAF and analyzed for expression of pro-fibrotic factors.

Results: Administration of garcinol reversed an increase in renal expression of total PCAF and histone 3 lysine 9 acetylation, and it reduced positive areas of trichrome and α-smooth muscle actin and collagen content in UUO kidneys. The increased mRNA levels of transforming growth factor-β1, matrix metalloproteinase (MMP) 2, MMP9 and fibronectin in obstructed kidneys was significantly reduced by garcinol treatment. Furthermore, garcinol suppressed nuclear factor-κB (NF-κB) and pro-inflammatory cytokines such as tumor necrosis factor (TNF)-α, interleukin (IL)-1β and IL-6 whereas it elevated nuclear expression of nuclear factor erythroid-derived 2-like factor 2 (Nrf2) and levels of Nrf2-dependent antioxidants including heme oxygense-1, catalase, superoxide dismutase 1 and NAD(P)H:quinone oxidoreductase-1. In addition, garcinol treatment resulted in reduction of TUNEL-positive cells and increased ratio of Bcl-2 to Bax in obstructed kidneys. PCAF siRNA in HK-2 cells inhibited the expression of type IV collagen and fibronectin when stimulated with TNF-α.

Conclusions: Our results suggest that inhibition of the inordinately enhanced PCAF could mitigate renal fibrosis by redressing the aberrant balance between inflammatory signaling and antioxidant response through modulation of NF-κB and Nrf2.

The Lysine Methyltransferase SETDB1 Inhibits Renal Myofibroblast Differentiation Victoria G. Shuttleworth,[2] Neil S. Sheerin,[1] Ian Logan.[3] *[1]Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Newcastle University, UK, Newcastle Upon Tyne, United Kingdom; [3]newcastle hospitals, Newcastle----, United Kingdom.*

Background: Renal fibrosis is characterised by accumulation of myofibroblasts expressing alpha-SMA. These cells deposit extracellular matrix that replaces normal kidney tissue, leading to chronic kidney disease and organ failure. TGF β-1 is critical to myofibroblast transdifferentiation, signalling through transmembrane receptors, resulting in SMAD3 phosphorylation. Phosphorylated SMAD3 undergoes nuclear translocation to regulate transcription of transdifferentiation genes, such as alpha-SMA. Regulatory mechanisms governing these events are unknown, but SMAD3 may utilise co-regulators from other pathways. For this reason, we screened for methyltransferases involved in TGF β-1 signaling. We identify SETDB1 as a new repressor of SMAD3 and TGF β-1 induced transdifferentiation.

Methods: siRNA Screen. siRNAs targeting 48 human methyltransferases were transfected into cells harboring a TGF β-1-responsive pCAGA12-luc reporter gene. These were treated with TGF β-1, prior to reporter gene assay. **Immunoprecipitation.** HKC-8 cells were starved in serum-free medium and treated with TGF β-1. SETDB1 immunoprecipitation was performed on nuclear fractions. **Immunofluorescence.** HKC-8 cells starved in serum-free medium were treated with TGF β-1 prior to immunofluorescence with SMAD3 and SETDB1 antibodies. Human primary renal fibroblasts were transfected with either control or SETDB1 siRNA then treated with TGF β-1 and subjected to immunofluorescence for alpha-SMA, or light microscopy to evaluate morphology.

Results: 1 siRNA screening identified SETDB1 as a strong corepressor of SMAD3, even in the presence of TGF β-1 2 Immunoprecipitation showed an interaction between SETDB1 and SMAD3 in nuclear fractions. No interaction was observed without TGF β-1 or control immunoglobulins 3 TGF β-1 promoted both SMAD3 and SETDB1 nuclear translocation, demonstrating co-localisation 4 Primary renal fibroblasts transfected with SETDB1 siRNA exhibited markedly more alpha-SMA expression and myofibroblastic changes in morphology, compared to control cells

Conclusions: 1 SETDB1 is a new SMAD3 co-repressor 2 TGF β-1 treatment promotes a specific interaction between with SMAD3 and SETDB1, in the nucleus 3 SETDB1 inhibits myofibroblast differentiation in human renal fibroblasts The conclusions are explained by SETDB1 acting as a brake on TGF β-1, preventing myofibroblast transdifferentiation, which may prevent progressive CKD.

FR-PO369

Calcineurin A-Alpha regulation of Nox2 via NFκB Is Involved in Cyclosporine-Induced Nephrotoxicity Aswathy Miriam Cheriyan,[1] Robert S. Hoover,[1,2] Clintoria R. Williams.[1,2] *[1]Emory University, Atlanta, GA; [2]Atlanta VA Medical Center, Atlanta, GA.*

Background: The calcineurin inhibitor cyclosporine (CsA) is an effective immunosuppressant and dramatically improved the outcomes of transplant patients. However, one long-term consequence of CsA and other calcineurin inhibitor treatments is nephrotoxicity attributed to oxidative damage. Calcineurin has two primary isoforms of the catalytic subunit - CnAα and CnAβ. The renal phenotype of $CnA\alpha^{-/-}$ mice substantially mirrors CsA nephrotoxicity whereas $CnA\beta^{-/-}$ mice do not. However, mechanisms downstream of CnAα that are involved in nephrotoxicity are poorly understood. Since NADPH oxidase-2 (Nox2) derived oxidative stress has been implicated in CsA nephrotoxicity, we hypothesized that inhibition of CnAα by CsA stimulates Nox2 upregulation and promotes oxidative stress.

Methods: To test this hypothesis, WT mice were administered CsA or vehicle alone daily for 6 weeks. Kidneys were then collected for analysis of CnAα isoform activity, Nox2 expression and ROS generation. In addition, Nox2 regulation was investigated in kidneys from $CnA\alpha^{-/-}$, $CnA\beta^{-/-}$ and WT mice. Since Nox2 may be transcriptionally regulated via the NFκB pathway, fibroblasts derived from $CnA\alpha^{-/-}$, $CnA\beta^{-/-}$ and WT mouse kidneys were treated with the NFκB inhibitor, caffeic acid phenethyl ester (CAPE).

Results: In WT mice, CnAα was the predominant isoform bound to calmodulin, consistent with previous in vitro findings showing that CnAα is the basally active isoform. CnAα-calmodulin association was disrupted with CsA treatment and was accompanied by enhanced Nox2 upregulation. Consistent with CsA inhibition of CnAα, Nox2 upregulation and ROS generation occurred only in $CnA\alpha^{-/-}$ mice. Interestingly, NFκB but not NFAT activation was observed. In $CnA\alpha^{-/-}$ renal fibroblasts, NFκB inhibition prevented Nox2 and ROS upregulation.

Conclusions: Our findings demonstrate that CnAα plays a key role in Nox2 regulation and ROS generation. Additionally, loss of CnAα activity, such as with CsA, promotes Nox2-mediated oxidative stress via an NFκB-dependent mechanism. These novel findings provide additional evidence of divergent CnA isoform signaling pathways. Therefore, selective targeting of CnAα and not CnAβ could improve the long-term outcomes of transplant patients.

Inhibition of NLRP3 Inflammasome Attenuates Renal Injury in Adriamycin Nephropathy Viviane D. Faustino, Leonardo L. Tavares, Sara C. Ribeiro, Victor F. Avila, Orestes Foresto-Neto, Fernanda F. Zambom, Simone C. Arias, Flavia G. Machado, Claudia R. Sena, Camilla Fanelli, Vivian L. Viana, Denise M. Malheiros, Niels O. Camara, Roberto Zatz, Clarice K. Fujihara. *University of Sao Paulo, Sao Paulo, Brazil.*

Background: Innate immunity is activated in proteinuric models, and may contribute to long term interstitial fibrosis. We investigated whether the NLRP3 inflammasome pathway is involved in the pathogenesis of CKD in the adriamycin (ADR) model.

Methods: Adult male Munich-Wistar rats were given ADR (5 mg/kg iv) and either no therapy or Allopurinol (Allo), used as a NLRP3 inhibitor, 36 mg/kg/day (ADR+Allo). Control rats (C) received saline only. After 4 weeks, we assessed body weight (BW, g), albuminuria (ALB, mg/day), serum creatinine concentration (SCr, mg/dL), glomerulosclerosis (GS, %) and interstitial collagen (COLL, %), as well as infiltration by macrophages (MΦ) and by NLRP3+ cells (/mm²). The renal content (x C) of CASP1 and superoxide dismutase (SOD2), as well as that of uric acid (rUA, mg/g) and IL1β (pg/mg), were also measured.

Results: As expected, ADR promoted massive ALB, intense MΦ, GS and COLL deposition, along with increased rUA, activation of CASP1 and NLRP3, as well as evidence of oxidative stress. Allo normalized rUA and attenuated renal inflammation/fibrosis, despite the persistence of massive ALB. Likewise, Allo prevented the upregulation of NLRP3, CASP1 and IL1β. These findings were associated with an increase of the renal abundance of SOD2, suggesting an antioxidant action of Allo.

Conclusions: NLRP3/CASP1/IL1β upregulation may be a mechanism by which massive protein filtration promotes interstitial fibrosis. Inhibition of this pathway with Allo prevented the activation of this innate immunity pathway and attenuated renal injury even in the face of unabated massive proteinuria. Amelioration of rUA and oxidative stress may contribute to this beneficial effect. Allo may help to prevent or limit the progression of CKD. FAPESP/CNPq

Oleanolic Acid Alleviates Renal Fibrosis through Regulating the Expression of miR-141 Minggang Wei, Jiaqi Yin. *The First Affiliated Hospital of Soochow University, Suzhou, China.*

Background: Renal fibrosis is characterized by the abnormal metabolism of extracellular matrix (ECM). However, ECM's abnormal metabolism mechanism has not been understood clearly. Recent studies suggested that metabolic regulation of ECM may be associated with some miRNA, such as miR-141, miR-21, miR-136 and so on. MiR-141 is the most important of them which control the ECM's metabolism. Both the cell signal pathway of TGF-β_1/Smads and the ECM's metabolism enzyme MMP-9 play important roles in renal fibrosis through effecting ECM's metabolism. So we hypothesize that miR-141 regulation the ECM's metabolism via both TGF-β_1/Smads and MMP-9. Oleanolic acid (OA) is the main extract of Achyranthes bidentate, which could reduce the symptoms of chronic kidney disease and improve the renal function. We have proved that OA can decrease the degree of renal fibrosis through regulating the metabolism of ECM. Therefore, we speculated that OA could lessen the excessive accumulation of ECM by enhancing the expression of miR-141.

Methods: Thirty-two healthy Balb/c male mice performed unilateral ureteral obstruction (UUO) surgery to induce ECM accumulation. Mice were randomly divided into 4 groups: sham-operated group (n=8), UUO group (n=8), OA (25mL/kg) group (n=8), Lotensin (25mL/kg) group (n=8). Daily OA and Lotensin was applied to mice by oral gavage for 10 days after surgery. Then all mice were killed and renal tissue were obtained for further analysis.

Results: We showed that OA group revealed obviously pathological injury including renal interstitial fibrosis compared with the model group by HE staining. And the expression of TGF-β1, Smad2/3, ColIV, FN were downregulated and the expression of MMP-9 was upregulated compared with the model group by immunohistochemistry ($P < 0.05$). Real-time quantitative PCR demonstrated that OA group increased significantly the expression of miR-141 and MMP-9, while obviously decreased the expression of TGF-β1, Smad2/3, ColIV and FN, compared with the model group ($P < 0.05$).

Conclusions: In summary, our study provides that OA could regulate the expression of miR-141 to release the abnormal accumulation of ECM through impacting TGF-β_1/Smads. On the other hand, OA could increase the expression of miR-141 to inhibit the excessive accumulation of ECM via upregulating the expression of MMP-9. OA may have beneficial effects on inhibiting the development of renal fibrosis.

RIPK3 Inhibition Alleviates Folic Acid-Induced Kidney Fibrosis of C57BL/6 Mouse Ying Shi,[2] Yongli Zhao,[1] Chunling Huang,[2] Xinming Chen,[2] Carol A. Pollock.[2] *[1]The Second Hospital of Dalian Medical University, Dalian, China; [2]kolling institute, the University of Sydney, Sydney, NSW, Australia.*

Background: Current therapies for renal fibrosis are largely ineffective. Therefore, identification of novel therapeutic targets is essential. RIPK3 is identified as a crucial regulator of necrosis, apoptosis and inflammation, which have been well recognised to be involved in renal fibrogenesis. To date, the role of RIPK3 in renal fibrosis has not been reported.

Methods: C57BL/6 wild-type and RIPK3 gene knock out (RIPK3-/-) mice and two interventional strategies were used in the study. 1. Folic acid was administrated i.p. to induce kidney injury in both WT and RIPK3-/- mice for 28 days; 2. C57BL/6 WT mice injected with folic acid were treated with Dabrafenib (RIPK3 inhibitor) or vehicle respectively for 28 days. Kidneys were harvested from above experiments and kidney function was assessed by measuring 24 hour of urinary albumin excretion and urinary albumin creatinine ratio (UACR) by ELISAs. Kidney histological change and ECM deposition was assessed by PAS, Masson's trichrome, picrosirius red staining and immunohistochemistry. MCP-1, TGF-β and a-SMA RNA expression level were detected by quantitative RT-PCR analysis.

Results: RIPK3 blockade reversed folic acid increased 24 hour urinary albumin excretion and decreased UACR compared to WT or vehicle control groups treated with folic acid. Histological analysis has shown that folic acid resulted in increased collagen accumulation and ECM deposition, whereas, RIPK3 inhibition attenuated ECM deposition and renal fibrosis. Similar results were also elucidated by immunohistochemistry on ECM components type I, III, IV Collagens and Fibronectin expression in renal interstitium. In addition, quantitative RT-PCR demonstrated Dabrafenib treated mice and RIPK3-/- mice inhibited RNA expression of MCP-1, TGF-β and a-SMA.

Conclusions: These results suggest that RIPK3 blockade may be a potential novel target in renal fibrosis.

Nuclear Localization of Phosphatase and Tensin Homolog (PTEN) Causes Cell Cycle Arrest and Is Associated with Kidney Fibrosis Amrendra K. Ajay, Akinwande A. Akinfolarin, Joseph V. Bonventre, Venkata Sabbisetti. *Brigham and Women's Hospital, Boston, MA.*

Background: PTEN is a lipid/tyrosine phosphatase that modulates various cellular processes including growth, survival and metabolism. Though the antagonistic effects of cytoplasmic PTEN on phosphatidylinositol-3-kinase (PI3K) is well defined, the function of nuclear PTEN is not known. Some studies have demonstrated that nuclear PTEN regulates DNA damage response followed by genotoxic stress and maintains genomic

stability. In this study, we investigated the function of nuclear PTEN in renal epithelial cells followed by DNA damage *in vitro* and *in vivo*.

Methods: HK2 cells were treated with aristolochic acid (AA) for 48 hrs and cell cycle and nuclear PTEN was assessed. HEK293 cells stably expressing wild-type-GFP-PTEN, NLS-GFP-PTEN, mutant (NLS-GFP-C124S-PTEN) were developed and treated with 5 mg/ml AA and 10 μM cisplatin for 48 hour and cell cycle analysis was performed. Bilateral ischemia/reperfusion (IR: 20 min) was performed in C57B6 mice and mice were sacrificed at 21 days post IR. Kidney fibrosis was evaluated by Masson's Trichrome and alpha-smooth muscle actin (α-SMA) staining. Immunostaining of PTEN was performed.

Results: HK2 cells displayed elevated nuclear PTEN localization following AA treatment. Cells stably expressing cytoplasmic PTEN exhibited G2/M arrest, while cells expressing nuclear PTEN rather displayed G1/S arrest. In mice, proximal tubular cells in fibrotic kidneys displayed elevated levels of nuclear PTEN staining.

Conclusions: Nuclear PTEN induces cell cycle arrest and is elevated after DNA damage in tubular epithelial cells *in vitro* and *in vivo*.

FR-PO374

Thymosin β4 Has Cell-Specific Effects on Renal Fibrosis Jianyong Zhong,[1] Jae Won Yang,[2] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Wonju Christian Hospital, Wonju, GangWon-Do, Republic of Korea*.

Background: Thymosin β4 (Tβ4) is a G-actin sequestering protein with effects on angiogenesis, cell migration and matrix. We previously showed that Tβ4 is increased in sclerotic glomeruli after 5/6 nephrectomy, but exogenous Tβ4 treatment ameliorated interstitial fibrosis after unilateral ureteral obstruction (UUO). In this study, we investigated the impact on renal fibrosis of Tβ4 knockdown in different cell types.

Methods: Endothelial cell Tβ4 knockdown mice (Tβ4 endo-KD) were generated by mating Tβ4 shRNA loxp mice with SCL Cre mice, with SCL Cre negative mice as control (endo-Cont). We also generated inducible macrophage Tβ4 knockdown mouse (Tβ4 mac-KD) by mating Tβ4 shRNA loxp mice with Lys Cre mice, inducing Tβ4 KD by tamoxifen, with Lys Cre negative mice as control (mac-Cont). Injury was induced by UUO and/or folic acid (FA), with in vitro study of primary macrophages.

Results: In UUO and FA models, Tβ4 endo-KD mice had significantly decreased peritubular capillary density vs control. After UUO at day 14, vascular permeability and interstitial fibrosis were significantly decreased in Tβ4 endo-KD. Endothelial-mesenchymal transition was also decreased in Tβ4 endo-KD vs control. In contrast, in the FA model, Tβ4 endo-KD mice had significantly increased collagen I mRNA, and slower recovery rate of tubular injury, measured by urinary KIM-1/Cr and NGAL/Cr, vs control. The hypoxia markers, HIF1 and HIF2 mRNA levels, were significantly higher in Tβ4 endo-KD mice vs control. Knockdown of Tβ4 in cultured macrophages reduced P-cJun and enhanced Ym-1, although in vivo in UUO, interstitial fibrosis and macrophage infiltration were not different in Tβ4 mac-KD vs control.

Conclusions: We conclude that endothelial cell Tβ4 affects peritubular capillary density and endothelial cell function, while the contribution of endothelial Tβ4 to renal outcome depends on disease model, whether a state of nonreversible interstitial fibrosis vs. toxic acute tubular injury, with beneficial effects of knockdown of Tβ4 in the former, contrasting impaired recovery in the latter. Tβ4 also affects M2 macrophage transition, but knockdown of Tβ4 only in macrophages did not change interstitial fibrosis. We conclude that thymosin b4 has cell and context-specific renal effects.

Pharmacological Induction of ARNT/HIF1β Attenuates Chronic Organ Failure Michael Zeisberg, Desiree Tampe, Gerhard A. Mueller, Bjoern Tampe. *University Medical Center Goettingen, Goettingen, Germany*.

Background: Injury in any organ triggers a complex signaling cascade, ultimately culminating in tissue fibrosis and organ failure. Prompted by various studies across multiple organs demonstrating that preconditioning regimens to pre-emptively induce endogenous regenerative mechanisms protect from later incurring injury, we here aimed to gain insights into the molecular mechanisms underlying successful preconditioning, and to explore whether such pathways could be utilized to inhibit progression of chronic organ injury.

Methods: The effect of picomolar versus nanomolar FK506 was assessed in multiple models of chronic injury in the kidney (UUO), heart (AT II infusion) and liver (CCl_4 injection). Using murine and human cell cultures, molecular mechanisms were analyzed by qRT-PCR, immunostaining and Western blotting.

Results: Based on existing transcriptional profiling data, enrichment analysis and array-based screening, we identified a novel protective mechanism that is controlled by the transcription factor ARNT (synonym HIF1β), which effectively inhibits progression of chronic kidney injury in both, preconditioning as well as interventional regimens. We further report that ARNT expression itself is controlled by the FKBP12/YY1 transcriptional repressor complex, and that disruption of such FKBP12/YY1 complexes by either depletion of FKBP12 or YY1, or by picomolar FK506 concentrations at sub-immunosuppressive doses increases ARNT expression, leading to transcriptional ARNT induction. On a molecular level, we provide evidence that supraphysiological ARNT levels induce formation of distinct ARNT homodimers independent of hypoxia or xenobiotic signaling. For the first time, we detect ARNT homodimer formation in mammalian cells, facilitating unique transcriptional properties of ARNT/ARNT by direct targeting of a palindromic E-box binding motifs (5'-*CACGTG* core sequence) within the proximal *ALK3* promoter. Subsequent activation of ALK3-dependent canonical BMP signaling responses attenuate chronic organ failure in models of chronic kidney, cardiac and liver injuries.

Conclusions: We report a novel organ protective mechanism that depends on ARNT/HIF1β homodimers, which can be pharmacologically modulated and targeted by immunophilin ligand FK506.

FR-PO376

Increased Sodium Chloride Cotransporter Expression in a Rat Remnant Kidney Model Ito Sakuya,[4] Yusuke Kaida,[4] Yosuke Nakayama,[1] Eisei Sohara,[3] Shinichi Uchida,[3] Kei Fukami.[2] *[1]Department of Medicine, Division of Nephrology, Department of Medicine, Kurume University, Kurume, Japan; [2]Kurume University School of Medicine, Kurume, Japan; [3]Tokyo Medical and Dental University, Tokyo, Japan; [4]Department of Medicine, Kurume University School of Medicine, Kurume, Japan*.

Background: Antihypertensive therapies such as renin-angiotensin system (RAS) inhibitor and diuretics are the promising therapeutic strategy for inhibiting the progression of chronic kidney disease (CKD). The salt-sensitive hypertension is associated with the progression of CKD through the activation of the sodium chloride cotransporter (NCC). However, changes in the expression of NCC in the distal tubule of the different CKD stages are unknown. Thus, we investigated the blood pressure and the expression of NCC in the distal tubule of rats with mild to severe renal failure induced by nephrectomy(Nx).

Methods: Sprague Dawley (SD) rats were randomly allocated into the control and CKD groups. We assigned the Nx rats to three groups by the several degrees of kidney resection: sham (n=4), mild CKD (n=3), moderate CKD (n=4), severe CKD (n=3). The Nx and sham-operated rats were sacrificed at 4 weeks after operation. We examined the blood pressure, renal function, and urinary albumin excretion in rats with remnant kidney. Further, we explored the expression of NCC in renal tubule of the remnant kidneys by western blotting and immunostaining.

Results: Systolic blood pressure was significantly higher in the moderate and severe CKD rats compared with those in the sham-operated rats at 4 weeks after operation (148.3±17.9, 149.3±19.7 vs 114.8±12.8 mmHg; $P<0.05$, respectively). However, there was no difference of blood pressure between the mild CKD and the sham-operated rats (119.2±29.2 vs 114.8±12.8 mmHg; $P=0.79$). Serum blood urea nitrogen (BUN) and creatinine (Cr) levels, and urinary albumin excretion were significantly increased in all stages of CKD rats at 4 weeks after operation. The expression of total NCC were gradually up-regulated with the progression of CKD in the remnant kidney model.

Conclusions: In this study, increased NCC protein expression was observed in the remnant kidney model, which might induce the salt-sensitive hypertension in CKD. Therefore, the thiazide diuretics might be useful for controlling blood pressure in CKD patients. Further studies are needed to clarify the precise mechanisms of the increased NCC and its therapeutic strategy in CKD patients with hypertension.

FR-PO377

Targeting mTORC2/PKCα Inhibits Fibroblast Activation and Kidney Fibrosis Involving Blockade of Autophagic Flux Jiafa Ren, Chunsun Dai. *Nanjing medical university, Nanjing, China*.

Background: Our published study reported that mTORC2 plays a critical role in fibroblast activation and kidney fibrosis. However, the role and mechanisms for PKCα, one of the major downstream targets of mTORC2, in regulating fibroblast activation and kidney fibrosis remain to be determined.

Methods: Rat kidney interstitial fibroblasts (NRK-49F) were stimulated with TGFβ1 and kidney fibrosis was induced by unilateral ureter obstruction (UUO) in CD1 mice. Go6976, a synthetic compound which selectively inhibits PKCα signaling, was employed.

Results: Here, we found that TGFβ1 could activate PKCα in cultured NRK-49F cells with a time-dependent manner. Blocking PKCα signaling with either Go6976 or PKCα small interfering RNA could markedly inhibit TGFβ1-induced fibroblast activation. Additionally, Go6976 treatment could impair autophagic flux exhibited as decreased autophagosome-lysosome fusion and autophagic degradation accompanied by increased SQSTM1/p62 and LC3-II in NRK-49F cells. Similarly, 3-Methyladenine (3-MA) and Chloroquine (CQ), two classical authophagy inhibitors, could markedly suppress TGFβ1-induced fibroblast activation. In UUO kidneys, PKCα signaling was activated in the interstitial myofibroblasts and blocking PKCα with Go6976 could significantly ameliorate kidney fibrosis as well as inflammatory infiltration in the UUO kidneys compared to those treated with vehicle. Administration of Go6976 in mice could induce the accumulation of SQSTM1/p62 and LC3-II in the UUO kidneys, suggesting the blockade of autophagic flux in the fibrotic kidneys.

Conclusions: Together, these results suggest that blockade of PKCα attenuates TGFβ1-induced fibroblast activation may be through inhibiting autophagic flux. Targeting PKCα may provide a novel therapeutic strategy for patients with kidney fibrosis.

FR-PO378

PBI-4050 Reduces Renal Injury and Anemia in a Mouse Model of Adenine-Induced CKD Jean-Francois Thibodeau,[1,3] Eldjonai Kamto,[1,2] Chet E. Holterman,[1] Rania Nasrallah,[1] Alex Gutsol,[1] Pierre Laurin,[3] Richard L. Hebert,[1,2] Chris R. Kennedy,[1,2] Lyne Gagnon.[3] *[1]Kidney Research Center, Ottawa Hospital, Ottawa, ON, Canada; [2]Department of Cellular and Molecular Medicine, University of Ottawa, Ottawa, ON, Canada; [3]Prometic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050, a novel first-in-class orally active compound currently in clinical phase Ib/II in CKD patients, exerts antifibrotic effects via a novel mechanism of action. Through targeting of specific receptors expressed in proximal tubule cells, fibroblasts and macrophages, PBI-4050 decreases inflammation and fibrosis. The aim of this study was to investigate the effects of PBI-4050 in a model of adenine-induced CKD.

Methods: Eight-week old male C57BL/6 mice were fed standard chow, or a diet supplemented with 0.25% adenine. Following one week of adenine diet, daily doses of PBI-4050 (200 mg/kg) or water (vehicle) were administered by oral-gavage for three weeks. Longitudinal renal function was assessed by plasma creatinine via HPLC. At endpoint, blood analysis, plasma electrolyte and erythropoietin levels were measured in blood obtained by cardiac puncture. Tubulointerstitial inflammation/fibrosis and overall renal injury score was assessed in Masson's trichrome and PAS-stained kidney sections. Pro-inflammatory and pro-fibrotic gene expression and fibronectin expression were measured in kidney cortex samples by qPCR and western immunoblotting respectively.

Results: PBI-4050 treatment reduced adenine-induced polyuria and maintained urine osmolality. Renal function assessed by plasma urea and creatinine were significantly increased four and two-fold respectively in vehicle treated mice, while PBI-4050 lowered these values. Hematocrit, hemoglobin and mean corpuscular volume were significantly decreased in CKD-mice, while PBI-4050 maintained these levels in addition to increasing plasma erythropoietin levels. Renal pro-inflammatory gene expression was equally upregulated in both adenine-groups, while. Masson's trichrome staining, α-SMA mRNA and fibronectin protein expression were significantly upregulated in vehicle treated mice, and were decreased with PBI-4050. PAS-staining revealed decreased tubular injury and cyst formation in the adenine+PBI-4050 group compared to adenine+vehicle.

Conclusions: PBI-4050 treatment for three weeks decreased the severity of several adenine-induced sequelae including tubular injury, tubulointerstitial fibrosis and anemia. Taken together, these data reinforce its use as a potential renoprotective therapy.

FR-PO379

A Role for IL-27 in Limiting Renal Fibrosis Gaia Muallem, Lillian R. Aronson, Christopher A. Hunter. *University of Pennsylvania, Philadelphia, PA.*

Background: Immune processes that contribute to chronic kidney disease (CKD) represent important targets for prevention of disease in the kidney. Clinical and preclinical studies have established an association between Th17 cells and alternatively activated (M2) macrophages and renal fibrosis; however, a knowledge gap exists regarding how these cells promote fibrosis and how they may be regulated. In other systems, endogenous regulators have been used to successfully skew the immune response towards protection and away from pathology. The endogenous regulatory cytokine IL-27 has been shown to limit M2 macrophages and Th17 cells in other models of inflammation, leading to the hypothesis that it would be protective against renal fibrosis.

Methods: A) Renal fibrosis was induced in wild type (WT) C57Bl/6 mice and IL-27Rα$^{-/-}$ mice by unilateral ureteral obstruction (UUO). Kidneys were evaluated at day 14 post obstruction for immune cell infiltration and cytokine production by flow cytometry as well as fibrosis by trichrome staining and qPCR. B) Renal biopsy samples were collected from the following patient groups: control, CKD, diabetic kidney disease (DKD), diabetes alone (DM), and hypertension alone (HTN). Tubules were microdissected and RNA sequencing was performed on the tubular epithelium.

Results: In mice, IL-27 deficiency was associated with increased renal fibrosis, indicated by trichrome staining and higher expression of the fibrotic marker MMP9. There were increased M2 macrophages and Th17 cells in the fibrotic kidneys of IL-27Rα$^{-/-}$ mice with one subset of the Th17 cells also producing TNFα. IL-17 blockade in the IL-27α$^{-/-}$ mice attenuated fibrosis after UUO. RNA sequencing of human tubular epithelium indicated increased expression of the IL-17R in patients with kidney disease compared to controls and also a positive association of IL-17R expression with fibrosis scoring.

Conclusions: These data identify a role for IL-27 in modulating clinically relevant immune pathways in the kidney. IL-27 deficiency led to reduced renal fibrosis in mice after UUO injury and to the emergence of inflammatory Th17 responses and enhanced M2 macrophage polarization. Higher IL-17R expression was associated with increased kidney fibrosis in human samples, and blocking IL-17 abrogated renal fibrosis in IL-27α$^{-/-}$ mice. Further work will focus on treating WT mice with exogenous IL-27 in an attempt to ameliorate disease in the kidney.

Relation of Uric Acid with Rapid Kidney Function Decline and Development of Kidney Disease: The Jackson Heart Study Stanford Mwasongwe,[2] Tibor Fulop,[1] Solomon K. Musani,[6] Mario Sims,[6] Adolfo Correa,[5] Bessie A. Young,[4] Michael F. Flessner.[3] *[1]FMC Organ Replacement Center, University of Debrecen, Debrecen, Hungary; [2]Jackson State University, Jackson, MS; [3]NIDDK, NIH, Bethesda, MD; [4]Uniiversity of Washington, Seattle, WA; [5]University of Mississippi Medical Center, Jackson, MS; [6]University of Mississippi Medical Center, JACKSON, MS.*

Background: Reports on whether elevated uric acid represents an independent risk factor for development and progression of chronic kidney disease (CKD) have been mixed. We evaluated the relationship of uric acid level with rapid kidney function decline (RKFD) and incident CKD among 3,702 Jackson Heart Study participants who had complete measures of uric acid at baseline (2000-2004) and estimated glomerular filtration rate (eGFR) available at both baseline and Exam 3 (2009-2013).

Methods: RKFD was defined as a decline in eGFR of ≥30% between Exams while incident CKD was defined as having eGFR < 60 mL/minute/1.73 m^2 at Exam 3 with ≥ 25% eGFR decline. Associations were evaluated using multiple logistic regression models. Odds ratios (OR, 95% confidence [CI]) were reported per 1 standard deviation (SD) increment.

Results: Mean baseline uric acid and eGFR were 5.4 ±1.6 mg/dL and 95.9 ±19.9 mL/min/1.73 m^2, respectively. During a median follow-up of 8.1 years, 422 (11.4%) and 268 (7.5%) participants experienced RKFD and developed incident CKD, respectively. In multivariable logistic regression, 1 SD increase in baseline uric acid concentration was associated with increased odds for RKFD (OR 1.8; 95% CI 1.25-2.49; p = 0.0013) and suggested a potential risk for incident CKD (OR, 1.39; 95% CI 0.89-2.16; p = 0.14). There was no interaction between sex and uric acid on both RKFD (p = 0.12) and incident CKD (p = 0.70).

Conclusions: In the community-based cohort of African Americans, elevated serum uric acid was significantly associated with RKFD and may represent a risk factor for development of CKD.

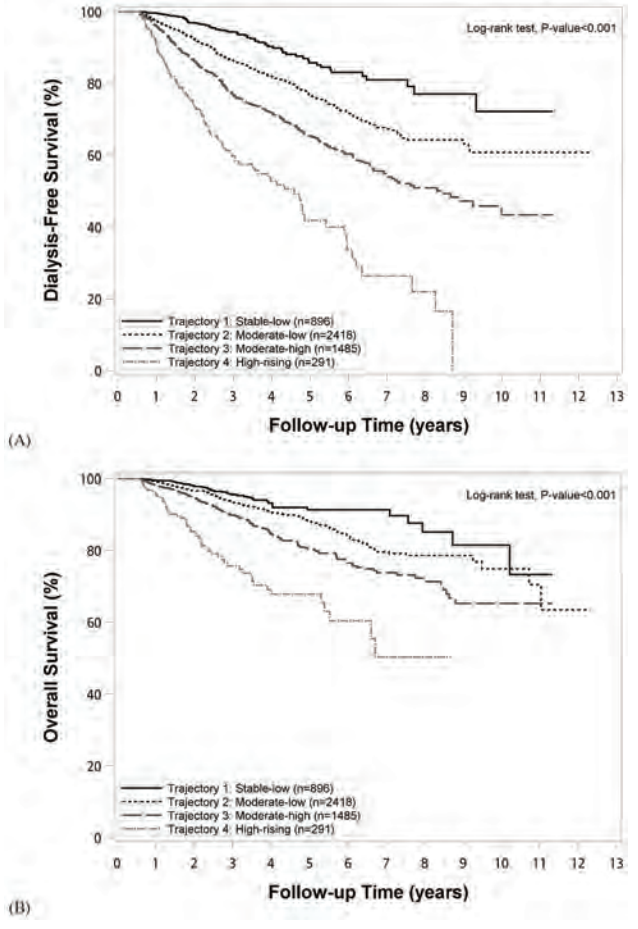
Uric Acid Predicts Adverse Outcomes in CKD: A Novel Insight from Trajectory Analyses Chin-Chi Kuo,[1] Ching-Wei Tsai.[2] *[1]Internal Medicine and Big Data Center, China Medical University Hospital, Taichung City, Taiwan; [2]Internal Medicine and Big Data Center, China Medical University Hospital, Taichung, Taiwan. Group/Team: CMUH Kidney Research Group.*

Background: Very little is known about longitudinal trajectories of serum uric acid (SUA) over the course of chronic kidney disease (CKD). We aimed to determine whether longitudinal SUA trajectories are associated with the risk of end-stage renal disease (ESRD) and all-cause mortality among CKD patients.

Methods: We conducted a prospective cohort study from a 13-year multidisciplinary pre-ESRD care registry. The final study population consisted of 5,090 CKD patients aged 20-90 years between 2003-2015. Individual's SUA trajectory was defined by group-based trajectory modeling in four distinct patterns: high-rising, moderate-high, moderate-low and stable-low. Time to ESRD and death was analyzed by multiple Cox regression.

Results: A total of 948 ESRD events and 472 deaths occurred with incidence rates of 57.9 and 28.7 per 1,000 person-years, respectively. Compared to those with a stable-low SUA trajectory, the adjusted hazard ratio (HR) of patients for incident ESRD was in a dose-response manner as follows: moderate-low: 1.89 (95% CI, 1.35-2.64); moderate-high: 2.74 (1.90-3.95), and high-rising: 3.24 (2.04-5.13), after considering the competing risk of death. For all-cause mortality, the corresponding risk estimate of the same SUA trajectory was 1.43 (95% CI, 0.93-2.21), 2.16 (1.35-3.44), and 5.18 (2.82-9.49), respectively.

Conclusions: Elevated SUA trajectories are associated with accelerated kidney failure and all-cause mortality in CKD patients. Adequate experimental evidence is urgently needed to inform when and how to optimize SUA in this population.



Kaplan-Meier curves of (A) dialysis-free survival and (B) overall survival by serum uric acid (SUA) trajectories based on group-based trajectory modelling (GBTM) (N = 5,090).

FR-PO382

Augmented Association between Blood Pressure and Proteinuria in Hyperuricemic Patients with Non-Nephrotic Chronic Kidney Disease Kentaro Kohagura, Tsuyoshi Miyagi, Ryo Zamami, Yusuke Ohya. *University of the Ryukyus, Nishihara-cho, Japan.*

Background: High serum uric acid levels (HU) may enhance susceptibility to hypertensive renal damage via disrupted autoregulation system of glomerular hemodynamics. However, effect of HU on the relationship between blood pressure (BP) levels and proteinuria is unknown in patients with chronic kidney disease (CKD).

Methods: A total of 109 patients with non-nephrotic CKD (55 men and 54 women) who underwent renal biopsy were recruited. Arteriolar hyalinosis was semiquantitatively assessed via arteriole grading. We examined the correlation between BP and urine protein levels (g/gCr) according to the presence of higher uric acid (HU) levels (mg/dl), defined as ≥7 in men and 5≥ in women, which were the levels from which risk of hyalinosis is increased in our previous study.

Results: The median for age, BP, estimated glomerular filtration rate (eGFR), and urine protein were as follows: 38 years, 124/74 mmHg, and 82 ml/min/1.73 m^2, and 0.8 g/gCr, respectively. In the patients with HU (n=58), log-transformed systolic BP was significantly correlated with log-transformed urine protein (r=0.49, p<0.0001). In contrast, there was no significant correlation between them in those without it (n=51). In the multiple regression model (R^2=0.18, p=0.0009), interaction of HU and log-transformed systolic BP for proteinuria was significantly correlated with logarithm-transformed urine protein (β=3.0, p=0.04) independent of age, sex and potential confounding factors. However, its statistical significance was completely disappeared after additional adjustment with arteriolar hyalinosis index.

Conclusions: These results suggested that HU might potentiate the susceptibility for hypertensive glomerular damage via disrupted autoregulation in non-nephrotic CKD patients.

FR-PO383

Uric Acid and Renal Pathological Features: A Cross-Sectional Study of 1070 Patients Receiving Renal Biopsy Li Wang, Daqing Hong. *Sichuan Provincial People's Hospital, Chengdu, China.*

Background: Hyperuricemia(HUA) is very common in Chronic kidney disease. Hyperuricemia increases the risk of cardiovascular events and accelerates the progression of chronic kidney disease. Our study attempt to determine the relationship between baseline uric acid levels and renal pathological features.

Methods: 1070 patients receiving renal biopsy in our center were involved in our study. The baseline characteristics at the time of kidney biopsy were collected from the medical records, including age, gender, serum uric acid(UA), glomerular filtration rate (eGFR), serum creatinine(Scr),Urea, 24 hours urine protein quantitation(24-u-pro),and serum albumin(Alb). Pathological morphological changes were evaluated with Oxford classification scoring system. Statistical analysis was done with SPSS 21.0.

Results: In the whole cohort, 429 of 1070 were IgA nephropathy(IgAN),641 of 1070 were non-IgAN. The prevalence of HUA was 61.2%(n=655), 56.2%(n=241), and 64.6%(n=414) in all patients, IgAN and non-IgAN patients, respectively. Serum uric acid levels were correlated to eGFR (r=-0.418, P<0.001), Scr(r=0.391,, P<0.001), Urea(r=0.410, P<0.001), and 24-u-pro(r=0.077, P=0.022). Univariate logistic regression analysis showed that HUA was associated with higher risk factor for segmental glomerulosclerosis (OR=1.918, 95%CI: 1.444-2.546) and tubular atrophy or interstitial fibrosis(OR=3.279, 95%CI:2.037-5.276). Multivariate logistic regression analysis showed that after adjustment of Scr,HUA was still a risk factor for segmental glomerulosclerosis (OR=1.783, 95%CI:1.327-2.397) and tubular atrophy or interstitial fibrosis(OR=1.715, 95%CI:1.000-2.942).

Conclusions: Hyperuricemia is prevalent in CKD patients receiving renal biopsy. Uric acid correlates not only to clinical renal injury indexes including serum creatinine, eGFR, urine protein, but also to renal pathology. Hyperuricemia is independently associated with segmental glomerulosclerosis and tubular atrophy or interstitial fibrosis. Reduce uric acid levels may delay the progression of worsening renal function.

FR-PO384

Developing a CKD Screening Algorithm for the Primary Care Setting Andy Y. Cheng, Manisha Jhamb, David Demoise, Amar R. Kohli. *University of Pittsburgh, Pittsburgh, PA.*

Background: CKD in the US not only has a significant prevalence, but also has an alarming projected incidence. Current guidelines for CKD screening are discordant, and few studies have been performed in evaluating various screening algorithms. This retrospective cohort study aims to propose a potential CKD screening algorithm for the primary care setting.

Methods: Adult patients aged 18-69 years seen for primary care visits at a tertiary hospital primary care clinic in Western PA were identified. Those with CKD, defined as two eGFR values of less than 60mL/min/1.73m^2 per MDRD calculation spaced at least 90 days apart in the EHR, were eligible for study inclusion. Characteristics including age ≥55, African American race, and comorbid DM or HTN were abstracted from the EHR. Statistical analyses, including percentage of CKD patients identified and number of patients needed to screen, were then performed using a reverse screening cohort of 650 patients to assess four potential screening algorithms.

Results: Known comorbid DM or HTN (81.8%) outperformed age ≥55 (69.7%) or African American race (49.5%) in identifying the largest percentage of CKD patients. Inclusion of age ≥55 to known comorbid DM or HTN yielded a greater percentage of CKD patients compared to addition of African American race to known comorbid DM or HTN (Table 1). A comprehensive screening algorithm including all four aforementioned variables mildly increased percentage of CKD patients identified, but at the expense of a moderate increase in number of patients needed to screen (Table 1).

Conclusions: A screening algorithm consisting of age ≥55 or known comorbid DM or HTN appeared to optimize percentage of CKD patients identified with number of patients needed to screen. Given that the proposed screening algorithm was derived via a reverse screening approach originating from a patient population with 100% CKD prevalance, further study applying the algorithm to a blanket primary care population is necessary to fully assess the algorithm's efficacy.

Funding: Private Foundation Support

Proposed Screening Algorithms & Associated Statistical Analyses

Screening Algorithm Components	% of CKD Cases Accounted (Number of Patients)	Number of Patients Needed to Screen (95% CI)
DM or HTN	81.8% (532)	5.5 (4.7-6.6)
DM or HTN or Age ≥55	92.0% (598)	12.5 (9.9-16.9)
DM or HTN or African American Race	87.2% (567)	7.8 (6.5-9.8)
DM or HTN or Age ≥55 or African American Race	94.6% (615)	18.6 (14.0-27.2)

FR-PO385

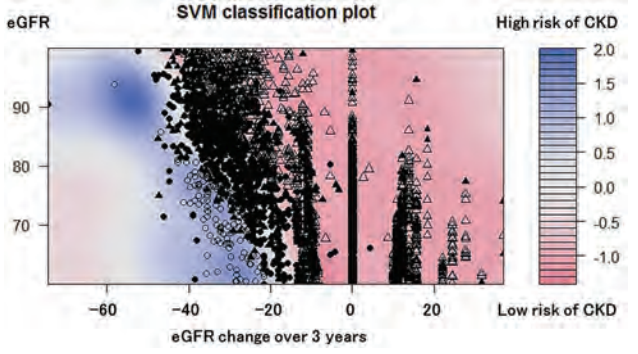
Evaluation of Glomerular Filtration Rate Change as an Indicator of Development of Incident CKD Using Support Vector Machine: Community-Based Prospective Cohort Study Eiichiro Kanda,[2] Bogdan I. Epureanu,[3] Kaname Suwa,[4] Kei Nakajima.[1] *[1]Kanagawa University of Human Services, Yokosuka, Japan; [2]Tokyo Kyosai Hospital, Meguro, Japan; [3]University of Michigan, Ann Arbor, MI; [4]Saitama Health Promotion, Saitama, Japan.*

Background: Chronic kidney disease (CKD) is a risk factor for cardiovascular disease and death. To decrease the number of CKD patients, it is important to identify people at high risk of developing CKD among healthy people from the public-health viewpoint. We investigated the role of estimated glomerular filtration rate (eGFR) change in the development of CKD in a community-based prospective cohort study using the support vector machine (SVM).

Methods: A total of 3295 healthy people (male, 72.7%) were enrolled in this prospective cohort study for 6 years (Saitama Cardiometabolic Disease and Organ Impairment Study) in Japan. The outcome event was incident CKD 6 years later. Subjects were categorized on the basis of eGFR change over 3 years by 10%.

Results: The mean±SD age was 38.8±10.1 years; eGFR, 81.8±17.3 ml/min/1.73m^2; and eGFR change over 3 years, -15.0±18.5%. Multivariate logistic regression models showed the relationship between eGFR change and incident CKD (reference 0 %): -10%, adjusted odds ratio 3.89 (95%CI, 2.0, 7.56); -20%, 40.3 (20.5, 79.0); -30%, 124.8 (59.9, 260.1); -40%, 297.9 (119.8, 741.1). Interaction between eGFR change and eGFR was also observed (p=0.0001). A receiver operating characteristic curve showed a cutoff value of -12.4% for CKD prediction. The use of SVM enabled the identification of high-risk patients and showed that cutoff values differ depending on eGFR: eGFR 90, eGFR change -40%; 80, -30%; 70, -20% (Figure 1).

Conclusions: eGFR change tends to be associated with the risk of CKD. The cutoff values for the prediction of CKD may differ depending on eGFR in the general population. The composite index of eGFR and eGFR change may have high potential use for detecting high-risk people for CKD.



FR-PO386

Lipodystrophy Increases the Risk of Developing CKD in HIV-Infected Patients in Switzerland: the LIPOKID Study Yassine R. Bouatou,[2] Angele Gayet-Ageron,[3] Alexandra Calmy,[1] Sophie M. De Seigneux.[2] *[1]HIV Unit, Geneva University Hospitals, Geneva, Switzerland; [2]Nephrology, Geneva University Hospitals, Geneva, Switzerland; [3]Clinical Epidemiology Unit, Geneva University Hospitals, Geneva, Switzerland. Group/Team: Swiss HIV Cohort Study.*

Background: Antiretroviral therapy (ART) improved HIV patient survival. However, metabolic complications such as dyslipidemia or lipodystrophy (LD) are the hallmark of first generation ART. Growing evidence points towards a role of lipid disturbances in chronic kidney disease (CKD). Also, as the HIV population is aging, identification of risk factors for (CKD) is crucial since both classical and HIV-related risk factors for CKD are highly prevalent among these patients. We studied the cumulative exposure to LD as an independent risk factor for CKD in HIV patients.

Methods: All patients from the Swiss HIV Cohort Study with an estimated glomerular filtration rate (eGFR) > 60 ml/min/1.73 m^2 at baseline (i.e. at entry in the cohort) and more than 3 months of follow-up from January 2002 to December 2015 were included. The primary endpoint was defined as a sustained eGFR < 60 ml/min/1.73 m^2. The secondary endpoint was sustained albuminuria (dipstick). Cox regression models were used to measure the risk to develop CKD associated with cumulative exposure to different patterns of LD.

Results: Among the 5'384 patients included, 4'246 did not have LD at entry in the cohort. 31.0% developed at least once LD during their follow-up after a median time of 17.1 months (IQR: 0-45.2 months) and 252 (4.7%) reached the primary endpoint after a median follow-up time of 43.7 months from baseline (IQR: 18.5-89.3 months). Overall exposure to LD increased significantly the risk of an eGFR < 60 ml/min/1.73 m^2 in univariate analysis with a hazard ratio (HR) 2.25 (95% confidence interval (CI): 1.68-3.00; p <0.001). After adjustment for main confounders, LD increased the risk of eGFR < 60 ml/min/1.73 m^2 by a HR 1.98 (95% CI: 1.31-2.99; p = 0.001). LD was not significantly associated with the development of albuminuria.

Conclusions: LD might be a risk factor for eGFR decline independently of previously reported risk factors for CKD.

FR-PO387

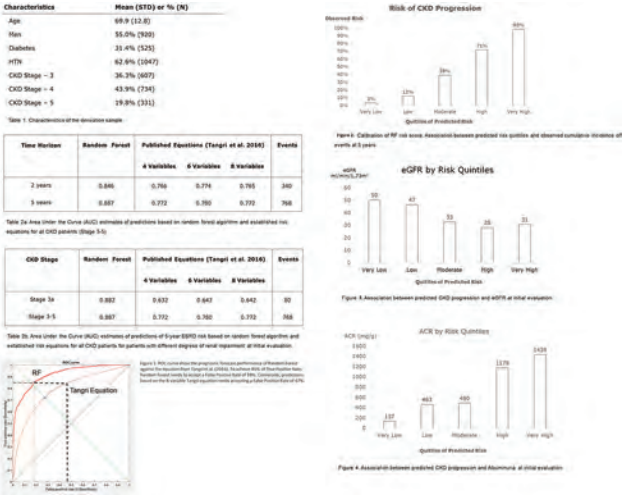
Artificial Intelligence Improves CKD Progression Forecasts Luca Neri, Francesco Bellocchio, Carlo Barbieri, Flavio Mari, Ulrich Tschulena, Stefano Stuard. *Fresenius Medical Care, Bad Homburg, Germany.*

Background: Accurate CKD progression forecasts are key to tailor interventions to real patients needs. Current prognostic tools rely on few dominant variables (e.g. eGFR, albuminuria) and do not incorporate potentially important patterns of association (e.g. interactions). Hence, their performance is suboptimal for high and low risk patients (i.e. early stages of CKD). We developed a risk score addressing such weaknesses with machine learning.

Methods: CKD patients (stages 3-5) registered in EuCliD® (2011-2015) entered the study cohort. Enpoints were Kidney Failure (KF) within 2 and 5 years. The algorithm was derived with random forest (RF) and tested in a partition of the original sample which was not used to develop the model. The RF algorithm exploited 82 variables. To reflect real-life clinical practice, in the validation study, the algorithm calculated a risk score for each patient based on non-missing variables abstracted from electronic clinical charts. We computed model AUC and calibration curves. We compared the predictive accuracy of RF against Tangri's Kidney Failure Risk Score (KFRS)

Results: Among 4064 patients, 2685 and 1672 patients had 2 and 5 years of follow up (fig. 1). Most influential variables for KF at 2 years were eGFR, its rate of change, proteinuria, body mass, haemoglobin, Charlson's index, phosphate. Most influential variables for KF at 5 years were blood pressure, CKD-BMD markers, eGFR, proteinuria, serum albumin, heart rate. FR outperformed KFRS both in the whole sample and among CKD3a patients (Fig 1).

Conclusions: Contrary to KFRS, the performance of RF was stable at different CKD stages and was less dependent on intial GFR and albuminuria. Differences in forecast accuracy between RF and KFRS equations may lead to very large reductions in health care cost and clinical risk due to unnecessary medical encounters.



FR-PO388

Time-Centered Approach to Understanding Progression of CKD Elaine Ku, Charles E. McCulloch, Kirsten L. Johansen. *University of California San Francisco, San Francisco, CA.*

Background: Traditional approaches to modeling risk of CKD progression do not provide estimates of the *time* it takes for disease progression to occur by stage of CKD, or the extent to which risk factors may differentially affect the time spent in various CKD stages.

Methods: We used mixed models to estimate person-specific trajectories of renal function among 3682 participants of Chronic Renal Insufficiency Cohort (CRIC), a longitudinal study of persons with CKD. We then used these trajectories to estimate time spent in each CKD stage and compared these times according to combinations of risk factors associated with disease progression.

Results: During 9.5 years of median follow-up, participants spent longer in earlier than later CKD stages, ranging from 9.5 yrs in stage 3 to 0.7 yrs in stage 5 [Figure 1]. Risk factors were associated with larger differences in duration in the earlier vs. later stages of CKD. For example, median duration of CKD was over 8 years shorter in stage 3a, 6 years shorter in stage 3b, but only 5.3 months shorter in stage 5 for those with proteinuria ≥1g/g (vs. <1g/g) [Figure 1]. Participants with controlled diabetes (A1C < 7.5%) and without significant proteinuria spent the longest time in CKD stage 3 [Figure 2a], but spent similar amount of time in stage 5 as participants with uncontrolled diabetes and proteinuria. We also found profound differences in the time spent in CKD stages by presence or absence of proteinuria and uncontrolled systolic BP (≥140 mm Hg) [Figure 2b].

Conclusions: We found marked variations in the time spent in the different stages of CKD based on different risk factors. Time-based metrics of CKD progression may help convey prognostic information to patients and guide clinical decisions, such as timing of access placement and RRT.

Long Term Effects of Intensive Low Salt Diet Education on Deterioration of Glomerular Filtration Rate among Non-Diabetic Hypertensive Patients with CKD Anna Lee,[1] Ho Jun Chin.[2] *[1]SNUBH, Gyeonggi-do, Democratic People's Republic of Korea; [2]Seoul National University Bundang Hospital, Seong nam, Republic of Korea.*

Background: We conducted a prospective cohort study to investigate whether lower dietary salt intake and the intensive low salt diet education are effective to reduce the rate of GFR decline among hypertensive CKD patients.

Methods: This study included 171 participants in the previous open-label, case-control, randomized clinical trial including 245 hypertensive CKD patients who took an olmesartan medoxomil until the end of the study and were assigned to receive an intensive low salt diet education or conventional education. We compared the eGFR change rate, the increase of serum creatinine ≥ 50%, the decrease of eGFR ≥ 30%, and the percent change of albuminuria during 36.3 ± 4.1 months after randomization between education groups.

Results: The mean differences of eGFR change rate between groups was 1.68 ml/min/1.73m^2/year and 1.64 ml/min/1.73m^2/year at 25.1 ± 4.0 months and at 36.3 ± 4.1 months after randomization, respectively. The percent of increment in serum creatinine ≥ 50% was 1.1 % in Intensive group and 8.2% in Control group (*p=0.025*), and the percent of decrease in eGFR ≥ 30% was 3.3 % in Intensive group and 11.1 % in Control group (*p=0.048*). Overall mean difference of 24-hour urine sodium excretion between groups were 10 mEq/day and did not show difference (*p=0.430*), however, in Control group, participants with higher urinary sodium excretion (≥200 mEq/day) showed rapid decline of eGFR (*p=0.012*) and participants with effective decrease of urinary sodium excretion during trial phase (decline≥ 25% of sodium excretion) showed more slow decline of eGFR (*p=0.035*).

Conclusions: This cohort study demonstrated intensive low salt diet education was independently related to slow eGFR decline during about 36 months follow-up period and higher salt intake resulted in more rapid decline of eGFR in participants with conventional low salt education.

Urinary Uromodulin Independently Predicts ESRD and Rapid Kidney Function Decline in CKD Patients Dominik Steubl. *Klinikum rechts der Isar, Munich, Germany. Group/Team: Munich Uromodulin Study Group.*

Background: Urinary uromodulin (uUMOD), exclusively secreted by the ascending limb of the loop of Henle and therefore a marker of tubular function has been shown to be a strong predictor of long term CKD progression and cardiovascular mortality. Data on risk factors predicting rapid progression to end-stage-renal-disease (ESRD) or rapid kidney function decline in chronic kidney disease (CKD) are rare but urgently needed to plan treatment. This article describes the predictive value of uUMOD for rapid progression of CKD.

Methods: We assessed uUMOD, demographic/treatment parameters, estimated glomerular filtration rate (eGFR) and proteinuria in 230 CKD patients stage I-V. ESRD or 25%-decline of eGFR was registered at the end of a follow-up of one year as the outcome variables. Association between logarithmic (log) uUMOD and (log) eGFR/proteinuria was calculated using linear regression analysis adjusted for demographic parameters. We performed multivariable Cox regression analysis to evaluate uUMOD as a predictor. Therefore, patients were categorized into quartiles. The predictive value was further assessed using receiver-operating-curve (ROC) analysis.

Results: Follow-up was 57.3±18.7 weeks. 47 (20.4%) patients reached the endpoint. (log) uUMOD concentrations were significantly associated with (log) eGFR and (log) proteinuria (r=0.554 and r=-0.429, p<0.001 resp.). In multivariable Cox-regression analysis, the two quartiles with the lowest uUMOD concentrations were at increased risk for ESRD/rapid eGFR loss with a hazard ratio (HR) of 3.589 (lowest quartile, uUMOD ≤ 2.6 µg/ml, 95%-confidence interval (CI) 1.002-12.992, p=0.049) and 5.409 (second lowest quartile, uUMOD 2.7-4.75 µg/ml, 95%-CI 1.444-20.269, p=0.011) in comparison to the highest quartile (≥ 11.45 µg/ml), respectively. In ROC-analysis, uUMOD predicted the endpoint with good sensitivity (74.6%) and specificity (76.6%) at an optimal-cut-off at 3.5 µg/ml and area-under-the-curve of 0.786 (95%-CI 0.712-0.860, p<0.001).

Conclusions: uUMOD was independently associated ESRD/rapid loss of eGFR. It might serve as a robust predictor of rapid kidney function decline and help to better schedule arrangements for future treatment.

FR-PO391

Anemia Is a Risk Factor for Incident ESRD Santosh Saraf,[6] Jesse Y. Hsu,[8] Jing Chen,[3] Teresa K. Chen,[1] Michael J. Fischer,[5] L. Lee Hamm,[4] Rupal Mehta,[2] James H. Sondheimer,[10] Matthew R. Weir,[7] Xiaoming Zhang,[9] Ana C. Ricardo,[6] James P. Lash.[6] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL; [3]Tulane School of Medicine, New Orleans, LA; [4]Tulane University School of Medicine, New Orleans, LA; [5]University of Illinois Hospital and Health Sciences Center, Chicago, IL; [6]University of Illinois at Chicago, Chicago, IL; [7]University of Maryland School of Medicine, Baltimore, MD; [8]University of Pennsylvania, Philadelphia, PA; [9]University of Pennsylvania School of Medicine, Philadelphia, PA; [10]Wayne State University School of Medicine, Detroit, MI.*

Background: Although anemia is a consequence of chronic kidney disease (CKD), anemia itself may accelerate CKD progression. However, the data regarding the impact of anemia on the progression of CKD are inconsistent.

Methods: We used Cox proportional hazards to examine the association of baseline anemia (defined using the World Health Organization criteria of hemoglobin [Hgb] <12 g/dL in women and <13 g/dL in men) with incident end-stage renal disease (ESRD) and all-cause death using data from the Chronic Renal Insufficiency Cohort Study.

Results: The study included 3,919 participants with CKD (mean age 58 years, 45% female, 42% white, 42% black, 13% Hispanic, mean estimated glomerular filtration rate (eGFR) 45 ml/min/1.73 m^2, and median proteinuria 0.19 g/24h). At study entry, 1,859 (47.4%) of participants had anemia. Compared to individuals without anemia, those with anemia were older, more likely to be black or Hispanic, have lower mean eGFR and more proteinuria (P<0.001 for each). Over a median follow-up of 7.8 years, we observed 1,010 ESRD events and 994 deaths. The table below summarizes the results of our multivariable analyses.

Conclusions: In a large cohort of adults with CKD, anemia was independently associated with increased risk for incident ESRD but not all-cause death. Future work is needed to evaluate the optimal Hgb level for CKD patients.

Funding: Other NIH Support - NHLBI

		Anemia vs. No Anemia	Per 1gm Hgb Decrease
		Hazard Ratio (95% CI)	
ESRD	Model 1 (a)	2.54 (2.22-2.90)	1.31 (1.26-1.36)
	Model 2 (b)	2.44 (2.13-2.80)	1.34 (1.29-1.39)
	Model 3 (c)	1.31 (1.13-1.52)	1.10 (1.05-1.14)
Death	Model 1 (a)	1.64 (1.44-1.86)	1.13 (1.09-1.18)
	Model 2 (b)	1.43 (1.25-1.63)	1.13 (1.09-1.18)

FR-PO392

The Association between Kidney Function and Genetic Polymorphisms among Japanese Male Employees Takahiro Imaizumi, Sawako Kato, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Previous studies have implicated several single nucleotide polymorphisms (SNPs) in predisposition to chronic kidney disease (CKD). Though atherosclerotic disease is deeply involved in the incidence of CKD, whether SNPs related to arteriosclerosis are involved in CKD remains unclear. The purpose of this study was to identify SNPs that confer susceptibility to CKD and to examine whether the risk allele accumulation is associated with CKD.

Methods: We conducted a cross-sectional study using data of 4814 male workers which contained 432 participants with CKD to examine the association between eGFR and 59 candidate polymorphisms (17 CKD and 42 atherosclerotic diseases). We defined the genetic risk score (GRS) as the total number of risk alleles that showed a significant association in this analysis, and examined the relationship with CKD (eGFR < 60 ml/min/1.73m2).

Results: We found eight candidate SNPs with *P* value < 0.05 (*CX3CR1* rs3732379, *SHROOM3* rs17319721, *MTP* rs1800591, *PIP5K1B* rs4744712, *APOA5* rs662799, *BRAP* rs3782886, *SPATA5L1* rs2467853, and *MCP1* rs1024611) in the multivariate linear regression adjusted for age, BMI, systolic blood pressure, and fasting blood glucose. Among these 8 SNPs, *BRAP* rs3782886 and *SPATA5L1* rs2467853 were significantly associated with eGFR (false discovery rate < 0.05). GRS was significantly associated with CKD [Odds ratio; 1.17, 95% confidence interval, 1.09-1.26]. C-statisics improved from 0.775 to 0.780 but showed no statistical significance ($P = 0.061$). However, adding GRS significantly improved IDI and cNRI (0.0057, $P = 0.0028$, and 0.212, $P < 0.001$, respectively).

Conclusions: After adjustment for clinical factors, kidney function was associated with *BRAP* rs3782886 and *SPATA5L1* rs2467853 and the GRS for CKD that we developed was associated with CKD.

Fibroblast Growth Factor 23 and Kidney Function Decline: The Health Aging and Body Composition Study David A. Drew,[3] Ronit Katz,[6] Stephen Kritchevsky,[8] Joachim H. Ix,[5] Michael Shlipak,[1] Anne B. Newman,[2] Linda F. Fried,[7] Mark J. Sarnak,[3] Orlando M. Gutierrez.[4] *[1]San Francisco VA Medical Center, San Francisco, CA; [2]University of Pittsburgh, Pittsburgh, PA; [3]Tufts Medical Center, Boston, MA; [4]UAB School of Medicine, Birmingham, AL; [5]UCSD, San Diego, CA; [6]University of Washington, Seattle, WA; [7]VA Pittsburgh Healthcare System, Pittsburgh, PA; [8]Wake Forest School of Medicine, Winston-Salem, NC.*

Background: Fibroblast growth factor 23 (FGF-23) is a potential biomarker for kidney disease. Previous studies have shown FGF-23 to be a risk factor for incident end-stage renal disease (ESRD); however, there are less data on the association of FGF-23 with earlier kidney related outcomes.

Methods: Serum FGF-23 was assayed using an intact ELISA assay in 2,496 participants of the Healthy Aging and Body Composition Study, a cohort of well-functioning older adults. Kidney function was estimated by assaying cystatin C at baseline and years 3 and 10. The associations between FGF-23 and decline in kidney function (defined by estimated glomerular filtration rate (eGFR) decline ≥30% or ≥3 ml/min/year) and incident CKD (incident eGFR <60 ml/min/1.73 m^2 and ≥1 ml/min/year decline) were evaluated. Models were adjusted for demographics, baseline eGFR, urine albumin/creatinine ratio, comorbidity, and serum calcium, phosphorus and parathyroid hormone.

Results: The mean (SD) age was 75 (3) years, with 52% female, and 38% black. There were 405 persons with 30% decline, 702 with > 3 ml/min/year decline, and 536 with incident CKD. In fully adjusted continuous models, FGF-23 concentrations were not associated with kidney function decline (OR [95%CI] = 0.99 [0.82, 1.19] for ≥30% decline and OR= 1.16 [0.99, 1.36] for ≥3 ml/min/year decline), or incident CKD (IRR= 1.05 [0.91, 1.22] per two fold higher FGF-23 level). In quartile analysis, the highest quartile of FGF-23 was significantly associated with incident CKD (IRR= 1.26 [1.02, 1.57] for highest vs lowest quartile).

Conclusions: Higher FGF-23 concentrations were not consistently associated with decline in kidney function or incident CKD in community-dwelling older adults.

Model 2 = Model 1 + adjustment for calcium, phosphorus, and PTH
^Incident rate ratio for incident CKD outcome
*Excludes those with eGFR < 60 ml/min/1.73 m2 at baseline

FR-PO394

Bilateral Oophorectomy and the Risk of CKD Andrea G. Kattah, Carin Y. Smith, Vesna D. Garovic, Walter A. Rocca. *Mayo Clinic, Rochester, MN.*

Background: Premenopausal women who undergo bilateral oophorectomy are at an increased risk for morbidity and mortality. Given the potential benefits of estrogen on renal structure and function, we hypothesized that women who undergo bilateral oophorectomy are at an increased risk of chronic kidney disease (CKD).

Methods: All premenopausal women who underwent bilateral oophorectomy for a noncancerous condition before age 50 years from 1/1/1988 to 12/31/2007 in Olmsted County, MN were identified and age-matched (± 1 year) to referent women who did not undergo oophorectomy. CKD was defined in 2 ways: (1) serum creatinine-based definition (Cr > 1.1 mg/dl on two occasions, greater than 90 days apart) and (2) medical record diagnosis of CKD (screening for diagnosis codes and confirmation by medical record review). The hazard ratio (HR) for CKD was estimated with Cox proportional hazards models using age as the time scale. Women with CKD before index were excluded from the analyses. Inverse probability weighting was used to balance the two cohorts with respect to 17 chronic diseases at the time of oophorectomy (or index date), age, education, race, BMI, smoking, and calendar year.

Results: There were 1,653 women with bilateral oophorectomy and 1,653 referent women, and the median length of follow-up was 14 years in both cohorts. Using the serum Cr-based definition, 69 referent women and 120 women with bilateral oophorectomy developed CKD, with an adjusted HR of 1.48 (95% CI 1.10-1.99). The adjusted HR was higher in women who underwent oophorectomy at age ≤ 45 years (HR 1.74 (95% CI 1.15-2.63). In a subgroup analysis of women without any chronic diseases at the index date, the risk of CKD remained significant (HR 1.85, 95% CI 1.12-3.05). Using the diagnosis of CKD confirmed at medical record review, 43 referent women and 61 women with bilateral oophorectomy developed CKD, with an adjusted HR of 1.17 (95% CI 0.79-1.74).

Conclusions: Premenopausal women who undergo bilateral oophorectomy are at an increased risk of developing CKD, even after adjusting for multiple chronic conditions. This risk may be due to the abrupt drop in systemic estrogen levels after surgery. Further research into the mechanism of renal injury and the correct dosage of hormone replacement after oophorectomy is needed.

Non-Alcoholic Fatty Liver Disease Does Not Accelerate Progressive Renal Progression in Non-Dialysis CKD Rajkumar Chinnadurai, Diana Vassallo, Philip A. Kalra. *SALFORD ROYAL NHS FOUNDATION TRUST, Manchester, United Kingdom.*

Background: Non-Alcoholic Fatty liver disease(NAFLD) is strongly associated with increased incidence and high prevalence of Chronic Kidney Disease(CKD). The association of NAFLD with renal disease progression in non-dialysis dependent CKD(NDD-CKD) has not been explored. Our aim is to access the impact of NAFLD on the rate of progression of CKD.

Methods: All patients recruited in the Salford Kidney Study(SKS)(Large prospective CKD database) who had an Ultrasound(US) of the liver performed between January 2000 to December 2014 were sampled in this retrospective observational study. Estimated Glomerular Filtration Rate(eGFR) as measured by CKD-EPI formula was collected for all patients from study start date (date of Ultrasound) until the study end which included commencement of renal replacement therapy or reaching eGFR <10 ml/min, death, loss to follow-up or censoring at 31 December 2015. The rate of decline in eGFR was calculated by the slope of linear regression in the total sample and a matched group obtained after propensity score matching of all baseline characteristics. All analysis was undertaken in SPSS.

Results: Of the 3061 patients registered in the SKS, 1419 patients had US imaging of the liver, either bespoke or as part of a general abdominal scan, during the study period. After excluding patients based on pre-set criteria, a sample of 852 (183 NAFLD and 669 normal US) patients with complete datasets remained. By Propensity Score matching 138 patients with and without NAFLD were matched. At baseline, the median age of the study group was 66 years, and median eGFR was 33.5 mL/min/1.73m^2. Patients with NAFLD had more hypertension, diabetes mellitus and hypercholesterolemia. Body Mass Index was significantly higher in the NAFLD group 31 vs 27 kg/m^2(p= <0.0001). Median Follow-up time was 73 months with no difference between groups(p=0.176). In terms of CKD progression, there was no difference in the rate of decline of eGFR between

the two groups in the total sample (NAFLD: -2.54 ml/min/yr; normal liver: -2.09 ml/min/yr; p=0.088). Similar results were observed in the propensity score matched sample (NAFLD: -2.62 ml/min/yr; normal liver: -3.07 ml/min/yr; p-0.583).

Conclusions: In our Cohort of NDD-CKD patients the presence of NAFLD did not accelerate the rate of CKD progression.

Particulate Matter Air Pollution and the Risk of Incident CKD and Progression to ESRD Benjamin C. Bowe,[1] Yan Xie,[1] Tingting Li,[1,3] Yan Yan,[1,4] Hong Xian,[1,2] Ziyad Al-Aly.[1,3] *[1]Clinical Epidemiology Center, Research and Development Service, Veterans Affairs St Louis Health Care System, St. Louis, MO; [2]Department of Biostatistics, Saint Louis University College for Public Health & Social Justice, St. Louis, MO; [3]Department of Medicine, Washington University School of Medicine, St. Louis, MO; [4]Department of Surgery, Washington University School of Medicine, St. Louis, MO.*

Background: Elevated levels of fine particulate matter of <2.5 μm in aerodynamic diameter ($PM_{2.5}$) are associated with increased risk of cardiovascular outcomes and death. However, whether higher concentrations of $PM_{2.5}$ are associated with increased risk of incident chronic kidney disease (CKD), CKD progression, and end stage renal disease (ESRD) is unknown.

Methods: We linked the Environmental Protection Agency and the Department of Veterans Affairs databases to build an observational cohort of 2,482,737 United States veterans, and used survival models to evaluate the association of $PM_{2.5}$ concentrations and risk of incident eGFR <60 ml/min/1.73m^2, incident CKD, eGFR decline ≥30%, and ESRD. County-level exposure was defined at baseline as the annual average $PM_{2.5}$ concentrations in 2004, and separately as time-varying where it was updated annually and as cohort participants moved.

Results: Over a median follow-up of 8.52 years (IQR:8.04-8.80); where exposure was defined at baseline (median 11.8 μg/m^3; IQR:10.1-13.7), a 10 μg/m^3 increase in $PM_{2.5}$ concentration was associated with increased risk of eGFR <60 ml/min/1.73m^2 (Hazard Ratio (HR)=1.21; 95% Confidence Interval (CI)=1.14-1.29); CKD (HR=1.27;CI=1.17-1.38); eGFR decline≥30% (HR=1.28;CI=1.18-1.39); and ESRD (HR=1.26;CI=1.17-1.35). In time-varying analyses, a 10 μg/m^3 increase in $PM_{2.5}$ concentration was associated with increased risk of eGFR <60 ml/min/1.73m^2 (HR=1.25;CI=1.17-1.34); CKD (HR=1.37;CI=1.26-1.48); eGFR decline≥30% (HR=1.36;CI=1.26-1.46); and ESRD (HR=1.31;CI=1.21-1.43). Spline analyses showed a linear relationship between $PM_{2.5}$ concentrations and risk of kidney outcomes. Exposure estimates derived from NASA's satellite data yielded consistent results.

Conclusions: Our findings demonstrate a significant association between exposure to ambient fine particulate matter and risk of incident CKD, eGFR decline, and ESRD.

Ambient Coarse Particulate Matter, Nitrogen Dioxide, Carbon Monoxide, and the Risk of Kidney Disease Benjamin C. Bowe,[1] Yan Xie,[1] Tingting Li,[1,3] Yan Yan,[1,4] Hong Xian,[1,2] Ziyad Al-Aly.[1,3] *[1]Clinical Epidemiology Center, Research and Development Service, Veterans Affairs St Louis Health Care System, St. Louis, MO; [2]Department of Biostatistics, Saint Louis University College for Public Health & Social Justice, St. Louis, MO; [3]Department of Medicine, Washington University School of Medicine, St. Louis, MO; [4]Department of Surgery, Washington University School of Medicine, St. Louis, MO.*

Background: Experimental and preliminary clinical evidence suggest that environmental air pollution adversely impacts kidney health. Prior work examined the association between fine particulate matter and risk of kidney disease. The relationship between ambient coarse particulate matter (PM_{10}), nitrogen dioxide (NO_2), and carbon monoxide (CO) and risk of incident chronic kidney disease (CKD), CKD progression, and end stage renal disease (ESRD) is not clear.

Methods: We merged multiple large databases including those of the Environmental Protection Agency and the Department of Veterans Affairs to build a longitudinal observational cohort of 2,201,969 United States veterans, and used survival models to evaluate the association of PM_{10}, NO_2, and CO concentrations and risk of incident eGFR <60 ml/min/1.73m^2, incident CKD, eGFR decline ≥30%, and ESRD. Exposure was treated as time-varying where it was updated annually and as cohort participants moved.

Results: Over a median follow-up of 8.52 years (IQR:8.05-8.80), an interquartile range (IQR) increase in concentrations of PM_{10}, NO_2, and CO was associated with increased risk of eGFR <60 ml/min/1.73m^2, HR=1.07 (CI=1.06-1.08), HR=1.09 (CI=1.08-1.10), and HR=1.09 (CI=1.08-1.10), respectively. An IQR increase in concentrations of PM_{10}, NO_2, and CO was associated with increased risk of incident CKD, HR= 1.07; (CI=1.05-1.08), HR=1.09; (CI=1.08-1.11), and HR=1.10; CI=1.08-1.11), respectively. An IQR increase in PM_{10}, NO_2, and CO concentrations was associated with increased risk of eGFR decline ≥30%; HR=1.08 (CI=1.07-1.09), HR=1.12 (CI=1.10-1.13), HR=1.09 (CI=1.08-1.10), respectively. An IQR increase in concentrations of PM_{10}, NO_2, and CO was associated with increased risk of ESRD; HR=1.09 (CI=1.06-1.12), HR=1.09 (CI=1.06-1.12), and HR=1.05 (CI=1.02-1.08), respectively. Spline analyses suggested a monotonic increasing relationship between PM_{10}, NO_2, and CO concentrations and risk of kidney outcomes.

Conclusions: Our results demonstrate that environmental exposure to higher levels of PM_{10}, NO_2, and CO is associated with increased risk of incident CKD, eGFR decline, and ESRD.

FR-PO398

Urinary Iron and Oxidative Stress: Association with Megalin in CKD Shinya Nakatani,[5] Ayumi Nakatani,[5] Eiji Ishimura,[3] Norikazu Toi,[5] Akihiro Tsuda,[2] Shinsuke Yamada,[6] Katsuhito Mori,[5] Yoshiaki Hirayama,[1] Akihiko Saito,[4] Masaaki Inaba.[5] *[1]Denka-seiken co., ltd., Gosen-shi, Japan; [2]Department of Nephrology, Endocrinology, Metabolism, and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan; [3]Meijibashi Hospital, Osaka, Japan; [4]Niigata University, Niigata, Japan; [5]Osaka City University Graduate School of Medicine, Osaka, Japan; [6]Department of Metabolism, Endocrinology, and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan.*

Background: Megalin mediates the uptake of glomerular-filtered iron in the proximal tubules. Sandwich enzyme-linked immunosorbent assays have been developed to measure urinary ectodomain (A-megalin) and full-length (C-megalin) forms of megalin using monoclonal antibodies against the amino- and carboxyl-terminal of megalin, respectively. Urinary C-megalin excretion is increased via exocytosis in association with megalin-mediated metabolic load to the endo-lysosomal systems in the proximal tubules of residual nephrons. Thus, the present study investigated the association between urinary iron and megalin in chronic kidney disease (CKD) patients, and the possible harmful effect of iron in renal tubules.

Methods: The urinary levels of iron, megalin, and other markers were measured in 63 CKD patients, and their associations were evaluated by Pearson's and Spearman's analyses followed by multiple regression analyses.

Results: Urinary iron was 109 [69.3–166] μg/g Cr. Urinary total protein correlated significantly ($r = 0.528$, $p < 0.001$) with urinary C-megalin, but not with A-megalin. Although both urinary C-megalin and urinary total protein correlated with urinary iron (C-megalin: $r = 0.574$, $p < 0.001$; total protein: $r = 0.500$, $p < 0.001$, respectively), urinary C-megalin alone emerged as an independent factor associated positively with urinary iron ($\beta = 0.520$, $p < 0.001$) ($R^2 = 0.75$, $p < 0.001$). Furthermore, urinary iron was associated significantly and positively with urinary 8-hydroxydeoxyguanosine, an oxidative stress marker, whereas none of the tubular markers, including urinary β_2-microglobulin and N-acetyl-β-D-glucosaminidase, were associated with urinary 8-hydroxydeoxyguanosine

Conclusions: In conclusion, renal iron handling may be associated with oxidative stress in renal tubules and megalin-mediated endo-lysosomal metabolic load in the proximal tubules of residual nephrons.

Magnesium and Progression of CKD in Children Enrolled in the CKiD Study Martin A. Turman,[1] Aisha Betoko,[4] George J. Schwartz,[3] Susan L. Furth,[5] Bradley A. Warady.[2] *[1]Phoenix Children's Hospital, Phoenix, AZ; [2]The Children's Mercy Hospital, Kansas City, MO; [3]University of Rochester, Rochester, NY; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [5]The Children's Hospital of Philadelphia, Philadelphia, PA. Group/Team: CKD in Children Study.*

Background: Studies in adults with CKD demonstrate that lower magnesium (Mg) levels correlate with more rapid progression of CKD. We hypothesized that hypomagnesemia is associated with more rapid disease progression in children with CKD.

Methods: We measured the initial serum Mg level in 418 children enrolled in the first cohort of the Chronic Kidney Disease in Children (CKiD) study. Participants were grouped into low Mg (< 1.7 mg/dL, n=84; 20%), intermediate Mg (1.7-1.9 mg/dL, n=217; 52%) or high Mg (2.0-2.7 mg/dL, n=117; 28%) categories. Using parametric failure-time models, we evaluated the association between Mg level and CKD progression, defined as time to the composite event of renal replacement therapy (dialysis or kidney transplant) or 50% decline in estimated glomerular filtration rate (eGFR) after adjustment for the following potential confounders: initial eGFR, proteinuria, age, sex, race, BMI, Tanner stage, anemia, hypertension, and CKD diagnosis.

Results: Median age was 11 years, 62% were male and 58% non-Hispanic white. Median eGFR and urine protein-to-creatinine (UP/C) ratio were 45.3 ml/min/1.73m^2 and 0.4 mg:mg, respectively; 21% of the children had a glomerular diagnosis. The baseline characteristics of the patients in the three groups were not significantly different with regard to all potential confounders except initial eGFR and proteinuria. Participants in the low Mg group had a significantly higher baseline eGFR, and lower UP/C ratio compared to those in the high Mg category (median [IQR]: 51 [41, 63] *vs.* 37 [29, 50] and 0.3 [0.1, 1.0] *vs.* 0.6 [0.2, 1.7] respectively). Mg levels were not significantly different for participants on diuretics (n=28), calcineurin inhibitors (n=14), or Mg supplements (n=7). After adjustment for potential confounders, the relative times to either 50% decline in eGFR or renal replacement therapy were not significantly different among Mg groups.

Conclusions: Hypomagnesemia (Mg <1.7 mg/dL) is surprisingly prevalent (20%) in pediatric patients with CKD. This high rate of hypomagnesemia does not correlate with diuretic or calcineurin inhibitor use. Unlike studies in adult populations, hypomagnesemia does not correlate with more rapid progression of pediatric CKD. Higher Mg levels (Mg>2.0 mg/dL) do not correlate with more rapid progression of pediatric CKD either.

CKD Self-Management: Identifying Phenotypes and Associations with Renal and Cardiovascular Outcomes Sarah J. Schrauben,[1] Jesse Y. Hsu,[1] Sylvia E. Rosas,[2] Rajat Deo,[2] Bernard G. Jaar,[2] Georges Saab,[2] Swati Lederer,[2] Jing Chen,[2] Ana C. Ricardo,[2] James P. Lash,[2] Harold I. Feldman,[1] Amanda H. Anderson.[1] *[1]U Penn, Philadelphia, PA; [2]CRIC, Bethesda, MD.*

Background: In the effort to slow chronic kidney disease (CKD) progression and its complications, patients need to engage in self-management behaviors. This study evaluated CKD self-management behaviors (CKD-SMB) by identifying patterns of engagement into groups (or phenotypes), and evaluating the association of these phenotypes with renal and cardiovascular outcomes, and death.

Methods: Data from the Chronic Renal Insufficiency Cohort (CRIC) Study were analyzed using a clustering technique, latent class analysis (LCA), to identify CKD-SMB phenotypes stratified by diabetes status. The original CRIC cohort (N=3939) was the derivation cohort, and 1,560 participants subsequently recruited served as the validation cohort. LCA was based on the following measures of CKD-SMB: BMI, diet, physical activity, blood pressure, smoking status, and hemoglobin A1c (if diabetic), which were dichotomized into "recommended" and "not recommended". Cox proportional hazards models calculated hazard ratios (HRs, 95% CI) of phenotypes for CKD progression, atherosclerotic and heart failure (HF) events, and death.

Results: Three CKD-SMB phenotypes were identified separately among diabetics (DM) and non-diabetics (ND) that varied by level of engagement in recommended CKD-SMB, with Phenotype I being the most engaged, Phenotype II moderately engaged, and Phenotype III, the least engaged. In multivariable-adjusted models, Phenotype III was strongly associated with CKD progression, atherosclerotic events, and death among both DM and ND, and Phenotype II was associated with atherosclerotic events in DM and with death in ND (Table).

Conclusions: This study demonstrates there are potentially three CKD-SMB phenotypes that distinguish risk for clinical outcomes. Given the rise of CKD and its complications, CKD-SMB phenotypes could identify high-risk groups and guide management.

Funding: NIDDK Support

Associations (HR, 95% CI) of Clinical Outcomes by CKD-SMB Phenotypes

	Phenotype II-DM	Phenotype II-ND	Phenotype III-DM	Phenotype III-ND
CKD Progression	1.11 (0.91-1.35)	1.01 (0.82-1.25)	1.82 (1.32-2.52)	1.49 (1.06-2.09)
Atherosclerotic Events	1.40 (1.04-1.89)	1.15 (0.83-1.60)	2.54 (1.61-3.99)	1.90 (1.18-3.06)
HF Events	1.08 (0.84-1.40)	1.35 (0.97-1.86)	0.90 (0.56-1.45)	1.12 (0.66-1.92)
Death	1.22 (0.97-1.55)	2.80 (1.60-4.89)	1.95 (1.35-2.81)	4.14 (2.06-8.33)

Factors Associated with Rapid CKD Progression in a Special Predialysis Population under Strict Volume Control Olimpia Ortega, Zsofia K. Baranyi, Melissa Vasquez, Diego Navazo, Rosa Camacho, Maria Sanchez, Cristina Di Gioia, Paloma Gallar, Aniana Oliet, Milagros Ortiz, Carmen Mon, Juan Carlos Herrero. *Nephrology, Hospital Severo Ochoa, Leganes, Spain.*

Background: Fluid overload has emerged recently as an independent predictor of chronic kidney disease (CKD) progression among patients with CKD. Fluid overload control has been our priority for many years in our predialysis outpatient unit using a strategy of strict volume control. The aim of this study was to analyse the hydration status achieved in our patient and to evaluate the independent factors associated with rapid CKD progression or the initiation of dialysis in this special population.

Methods: 99 patients with CKD stages 4 and 5 were enrolled and followed for 2.9 ± 1.4 years. All patients were under a strict volume control strategy based on clinical criteria. Body composition monitor was used to analyse the hydration status achieved in our patients. Patients were organized in tertiles of percentage annual GFR decline. Univariate and multivariate logistic regression analysis were used to evaluate the independent factors associated with rapid CKD progression (tertil 3, cutoff value>13%). Cox proportional hazard model was used to analyse the independent factors associated with the initiation of dialysis.

Results: Fluid overload in the whole population was 0.17 (-0.4 to 0.98) and median relative hydration status (fluid overload/ECW) was 1.4 % (-2.25 to 5.2%). During the study period 17 patients iniciate dialysis and 3 patients died. Multivariate logistic regression analysis shows that only NT-proBNP levels (OR 1.01; 95% CI 1.00-1.03; p=0.04) and proteinuria (OR 1.60; 95% CI 1.12-2.39; p=0.03) were associated with rapid CKD progression (tertil 3). The independent factors associated with the initiation of dialysis were NT-proBNP (HR 1.00; 95% CI 1.000-1.001; p=0.006), proteinuria (HR 4.4; 95% CI 1.23-16.1; p=0.02) and low plasma albumin (HR 0.002; 95% CI 0.000-0.69; p=0.04). Fluid overload was not associated with rapid CKD progression nor with the start of dialysis.

Conclusions: A practically normohydration status can be achived even in patients with advanced CKD using a strategy of strict volume control. In this setting, NT-proBNP levels, reflecting increased left ventricular filling pressure and not fluid overload by itself, are associated with rapid CKD progression and the initiation of dialysis.

FR-PO402

Biologic Use and Incident CKD in Rheumatoid Arthritis Keiichi Sumida,[1] Miklos Z. Molnar,[3] Praveen Kumar Potukuchi,[3] Fatima Hassan,[3] Fridtjof Thomas,[3] Kunihiro Yamagata,[4] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[3] *[1]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [2]University of California Irvine, School of Medicine, Orange, CA; [3]University of Tennessee Health Science Center, Memphis, TN; [4]University of Tsukuba, Tsukuba, Japan.*

Background: Rheumatoid arthritis (RA) is associated with reduced kidney function, possibly due to chronic inflammation or the use of nephrotoxic therapies. Little is known about the effects of RA therapy using novel non-nephrotoxic biologic agents on the risk of incident CKD.

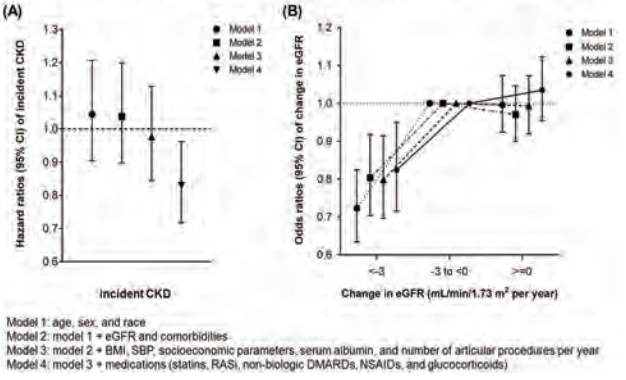
Methods: In a nationwide cohort of 20,757 U.S. veterans with an eGFR ≥60 mL/min/1.73 m^2 who were newly diagnosed with RA between 2004 and 2006, with follow-up through 2013, we examined the association of the use of biologic agents with incident CKD (>25% decrease in eGFR reaching <60 mL/min/1.73m^2) and change in eGFR (<-3, -3-<0 [reference], and ≥0 mL/min/1.73m^2/year), using time-dependent Cox models and multinomial logistic regression models, respectively, with adjustment for potential confounders.

Results: After multivariable adjustment, patients receiving (vs. not receiving) biologic treatment had a lower risk of incident CKD (adjusted HRs [95% CI], 0.83 [0.72-0.96]) and progressive eGFR decline (adjusted multinomial ORs [95% CI] for eGFR slopes <-3 and ≥0 [vs. -3-<0] mL/min/1.73m^2/year, 0.82 [0.72-0.95] and 1.03 [0.95-1.12], respectively) (Figure). A significant deceleration of eGFR decline was also observed after biologic administration in patients treated with biologics (-1.0±1.9 vs. -0.4±2.2 [mL/min/1.73m^2/year] before and after biologic use, respectively, *P* <0.001).

Conclusions: Biologic treatment was independently associated with lower risk of incident CKD and progressive eGFR decline. Clinical trials are warranted to test whether active interventions with biologic agents can prevent adverse renal outcomes associated with RA.

Funding: NIDDK Support

Association of biologic treatment with (A) incident CKD and (B) change in eGFR



Model 1: age, sex, and race
Model 2: model 1 + eGFR and comorbidities
Model 3: model 2 + BMI, SBP, socioeconomic parameters, serum albumin, and number of articular procedures per year
Model 4: model 3 + medications (statins, RASi, non-biologic DMARDs, NSAIDs, and glucocorticoids)

FR-PO403

Changes in Albuminuria and Subsequent Risk of Incident Kidney Disease Keiichi Sumida,[1] Miklos Z. Molnar,[4] Praveen Kumar Potukuchi,[4] Koshy K. George,[3] Fridtjof Thomas,[4] Jun Ling Lu,[4] Kunihiro Yamagata,[5] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[4] *[1]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [2]University of California Irvine, School of Medicine, Orange, CA; [3]University of Queensland, Memphis, TN; [4]University of Tennessee Health Science Center, Memphis, TN; [5]University of Tsukuba, Tsukuba, Japan.*

Background: Albuminuria is a robust predictor of CKD progression. However, little is known about the associations of changes in albuminuria with the risk of kidney events outside the settings of clinical trials.

Methods: In a nationwide cohort of 56,946 U.S. veterans with at least two albuminuria measurements and an eGFR ≥60 mL/min/1.73 m^2 between 2004 and 2006, we examined the associations of 1-year fold changes in albuminuria with incident CKD (>25% decrease of eGFR upon reaching <60 mL/min/1.73 m^2) and rapid eGFR decline (eGFR slope <-5 mL/min/1.73 m^2 per year), assessed using Cox models and logistic regression models, respectively, with adjustment for potential confounders.

Results: The mean (SD) age was 64.2 (10.4) years; 97% were male; and 91% were diabetic. There was a near linear association between 1-year fold changes in albuminuria and incident CKD (Figure). The multivariable-adjusted hazard ratios (95% CI) of incident CKD associated with 1-year albuminuria fold changes of <0.5, 0.5-<0.75, 1.25-<2, and ≥2 (vs. 0.75-<1.25) fold were 0.82 (0.76-0.88), 0.93 (0.86-1.00), 1.12 (1.05-1.20), and 1.29 (1.21-1.38), respectively. Qualitatively similar associations were present for rapid eGFR decline (adjusted odds ratios [95% CI] for albuminuria changes <0.5, 0.5-<0.75, 1.25-<2, and ≥2 [vs. 0.75-<1.25] fold, 0.86 [0.78-0.94], 0.98 [0.89-1.07], 1.18 [1.08-1.28], and 1.67 [1.54-1.81], respectively).

Conclusions: Changes in albuminuria were associated with subsequent risk of incident CKD and rapid eGFR decline. Further studies are warranted to test whether active interventions aimed at lowering elevated albuminuria can improve kidney outcomes.

Complications of RAAS Blockade in Patients with Advanced CKD Miklos Z. Molnar,[4] Adnan Naseer,[6] Keiichi Sumida,[2] Ariel R. Riezenman,[5] Barry M. Wall,[7] Praveen Kumar Potukuchi,[4] Abduzhappar Gaipov,[4] Elani Streja,[1] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[4] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]University of California Irvine, School of Medicine, Orange, CA; [4]University of Tennessee Health Science Center, Memphis, TN; [5]University of Tennessee Health Science Center - Memphis, Memphis, TN; [6]VAMC, Germantown, TN; [7]Veterans Affairs Medical Center, Memphis, TN.*

Background: Renin-Angiotensin-Aldosterone system inhibitors (RAASi) are associated with slower progression of chronic kidney disease (CKD) and lower mortality in patients with CKD, yet their discontinuation is frequent. The reasons for not using or for stopping RAASi in patients with advanced CKD are unclear.

Methods: We examined 15,966 US veterans initiating dialysis during 2007-2014, who displayed three RAASi use patterns in the last 3 years pre-dialysis: 1) never used (n=7,294), 2) discontinued in the last year before dialysis (n=6,833) and 3) uninterrupted use (n=1,839). We defined AKI as a >25% decrease in eGFR and hyperkalemia as a potassium >5.5 mmol/l during the 3 years prior to dialysis. Associations of RAASi use patterns with incidence of AKI and hyperkalemia were examined in logistic regression models adjusted for demographics, comorbidities, blood pressure and eGFR.

Results: Patients were 72±11 years old, 98% male, 23% African-American, and 65% diabetic. Compared to patients who never used RAASi, uninterrupted and interrupted RAASi use were associated with 16% and 32% higher multivariable adjusted risk of AKI [Figure Panel A], and with 11% and 81% higher multivariable adjusted risk of hyperkalemia [Figure Panel B], respectively.

Conclusions: RAASi before dialysis is associated with higher risk of AKI and hyperkalemia. These complications (especially hyperkalemia) may contribute to the discontinuation of RAASi in patients with advanced CKD. Additional studies are needed to determine if measures aimed at alleviating hyperkalemia and AKI could lead to higher RAASi use and improved outcomes.

Association between Serum Albumin Level and Incidence of ESRD in Patients with Immunoglobulin A Nephropathy: A Possible Role of Albumin as an Antioxidant Agent Yasuhiro Kawai,[2] Kosuke Masutani,[2] Kumiko Torisu,[2] Ritsuko Katafuchi,[3] Shigeru Tanaka,[1] Akihiro Tsuchimoto,[2] Koji Mitsuiki,[2] Kazuhiko Tsuruya,[2] Takanari Kitazono.[2] *[1]Fukuoka Dental College, Fukuoka, Japan; [2]Kyushu University, Graduate School of Medical Sciences, Fukuoka City, Japan; [3]National Fukuoka-Higashi Medical Center, Koga, Fukuoka, Japan.*

Background: Serum albumin is the most abundant intravascular protein and the major intravascular antioxidant. The association between serum albumin and the incidence of end-stage renal disease (ESRD) in patients with IgA nephropathy (IgAN) is not fully understood.

Methods: We retrospectively investigated 1,352 patients who were diagnosed with IgAN by kidney biopsy from seven institutions in Japan between October 1979 and December 2010. Patients were divided into three groups by tertile of serum albumin value: Low group, Middle group, and High group (≤3.9 g/dL, 4.0–4.3 g/dL, ≥4.4 g/dL, respectively). The association between serum albumin level and the incidence of ESRD was assessed using a Cox proportional hazards model. We also conducted an experiment of dihydroethidium staining for detection of decrease in intracellular superoxide anion induced by hydrogen peroxide in albumin-pretreated mouse mesangial cells.

Results: During the median 5.1-year follow-up period, 152 patients (11.2%) developed ESRD. Participants in Low group had a 1.88-fold (95% confidence intervals, 1.15–3.20) higher risk of the incidence of ESRD than those in High group after adjustment for age, sex, systolic blood pressure, urinary protein excretion, body mass index, estimated glomerular filtration rate, total cholesterol, triglycerides, and pathological parameters of the Oxford classification (M, E, S, T) and extracapillary proliferation (Ex). Furthermore, in *in vitro* experiments, generation of intracellular superoxide anion, a major form of reactive oxygen species, by hydrogen peroxide was significantly attenuated in albumin-pretreated mouse mesangial cells compared with γ-globulin-pretreated cells.

Conclusions: Low serum albumin level is an independent risk factor of ESRD in patients with IgAN. The mechanism could be explained by the antioxidant capacity of serum albumin.

FR-PO406

Association of Elevated Urinary miR-126, miR-155, and miR-29b with Diabetic Kidney Disease Cristina Beltrami,[3] Kate A. Simpson,[2] Mark D. Jesky,[1] Alexa Wonnacott,[2] Lucy J. Newbury,[2] Robert H. Jenkins,[2] Donald Fraser,[2] Timothy Bowen.[2] *[1]Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; [2]Cardiff University, Cardiff, United Kingdom; [3]Maastricht University, Eindhoven, Netherlands.*

Background: Around 9% of the adult global population has diabetes mellitus and approximately 40% of these individuals will develop diabetic kidney disease (DKD). Effective DKD biomarkers remain elusive, but urinary microRNAs (miRNAs) represent a potential source of novel non-invasive disease sentinels. The principal aim of this study was to analyse urinary miRNA biomarkers in DKD.

Methods: Unbiased RT-qPCR profiling of 754 miRNAs was compared in pooled urine samples from DKD patients (n = 20) and control subjects (n = 20). Candidate urinary miRNA biomarkers were then analysed by RT-qPCR in an independent cohort of 89 DKD patients, 62 diabetic patients without DKD and 41 controls. To locate the source of these miRNAs within the nephron, isolation of nephron regions from renal biopsy tissue by laser capture microdissection (LCM) was followed by RT-qPCR analysis of representative cell types.

Results: Significantly increased miR-126, miR-155 and miR-29b were detected in pooled DKD patient urine samples compared to control samples. These results were confirmed in our independent patient cohort: miR-126 (2.8-fold increase; $p<0.0001$), miR-155 (1.8-fold; $p<0.001$) and miR-29b (4.6-fold; $p = 0.024$). Combined receiver operating characteristic curve analysis for these miRNAs resulted in an area under the curve of 0.8. A relative quantification threshold equivalent to 80% sensitivity for each miRNA gave a positive signal for 48% of DKD patients compared to 3.6% of diabetic patients without DKD. LCM detected miR-155 in glomeruli, proximal and distal tubules, while miR-126 and miR-29b were most abundant in glomerular extracts. MiR-126 and miR-29b were enriched in glomerular endothelial cells (GEnCs) compared to podocytes, proximal tubular epithelial cells and fibroblasts. Significantly increased miR-126 and miR-29b were detected in GEnC conditioned medium in response to tumour necrosis factor-alpha and transforming growth factor-beta 1, respectively.

Conclusions: We have identified a urinary miRNA signature of increased miR-126, miR-155 and miR-29b detection that is associated with DKD, these miRNAs are therefore promising DKD biomarkers. MiR-126 and miR-29b were enriched in GEnCs and released from these cells in response to DKD-related cytokines, the pathological significance of this finding merits further evaluation.

Tracking of Microalbuminuria and A1c in a High-Risk Zuni Population Vallabh O. Shah,[2] V. Shane Pankratz,[2] Robert G. Nelson,[1] Donica M. Ghahate,[2] Jeanette Bobelu.[2] *[1]National Institutes of Health, Phoenix, AZ; [2]University of New Mexico Health Science Center, Albuquerque, NM.*

Background: The Zuni Indians are disproportionately affected by diabetes and chronic kidney disease, signaling a need for effective community-based prevention efforts. We previously reported on the epidemic of kidney disease and its intermediate phenotypes, and described the heritability of these conditions. Recently, through a Patient Center Outcomes Research Institute (PCORI)-funded study of home-based kidney care (HBKC), we rescreened 314 Zuni participants and examined changes in a constellation of markers of kidney disease and diabetes in a subset of these participants.

Methods: Summaries of the risk factors in the 155 participants (73 [47%] female; mean [SD] age at baseline 33.7 [11.5] years) at three key time points shown in the table 1.

Results: The development of ESRD in 7 individuals in this study set of 155 participants with longitudinal follow-up underscores the high incidence of renal disease in this population. These incident cases of renal disease occurred in 2081.7 person-years of follow-up, leading to an estimated incidence rate of CKD in this population of 3.8 (95% CI: 1.9 – 7.7) events per 1000 person years.

Conclusions: This analysis of a cohort of individuals from the PCORI studied at 3 time points over up to 14.3 years shows significantly increasing UACR and A1C levels, and a high incidence of kidney disease. These findings reinforce the need for interventions to modify risk factors for CKD progression, such as our PCORI-supported pilot HBKC intervention in this high-risk population, particularly amongst young adult Zuni.

Funding: Other U.S. Government Support

Table 1	Time 1 (Yr 2000)	Time 2 (Yr 2007)	Time 3 (Yr 2014)	
A1C	6.1 (1.4)	6.1 (1.4)	7.0 (2.0)	<0.001
UACR	58 (156)	106 (337)	976 (2679)	<0.001

*Mean (SD). Repeated measures analysis of variance models were performed to test for trends in risk factors over time (P<0.05 indicates statistical significance).

FR-PO408

Arsenic Exposure and Incident ESRD in the Southern Community Cohort Study (SCCS) Kerri L. Cavanaugh,[1] Edmond K. Kabagambe,[1] Jennifer Morse,[1] Thomas G. Stewart,[1] Aaron B. Bowman,[1] Yaofang Zhang,[2] William J. Blot,[1] Talat Alp Ikizler,[1] Loren Lipworth.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: Arsenic (As) is nephrotoxic at high doses. We hypothesized that long-term low to moderate exposure to As is associated with ESRD risk.

Methods: We conducted a nested case-control study within the SCCS, a prospective study of low income adults residing in underserved urban and rural communiities with potentially high toxicant burden in the southeastern US (2002-2009). Among 125 (63 black, 62 white) randomly selected incident ESRD cases and 250 controls, matched on age, race, sex and time of enrollment, baseline serum As was measured by inductively coupled plasma mass spectrometry. Data were modeled using conditional logistic regression, after log transformation of As. Generalized additive models examined the association of As exposure with ESRD probability adjusting for age, race, sex, diabetes, hypertension, and smoking.

Results: Mean age at SCCS enrollment of cases and controls was 55 years, and 55% were female. Median (25th, 75th percentile) levels of As (ng/ml) were significantly higher among ESRD cases (0.56; 0.32, 0.85) than among controls (0.39; 0.26, 0.73). An inter-quartile range increase in As log-transformed level was associated with significantly higher odds of ESRD (OR=1.58; 95% CI 1.21-2.06). The relative odds of ESRD as As varies from the median were computed from a multivariable logistic regression model controlling for hypertension, diabetes, enrollment age, race, sex, and smoking. The OR plotted against As (see Figure) shows the estimated association.

Conclusions: In summary, these results provide support for the hypothesis that chronic low to moderate exposure to As may be an important novel modifiable contributor to ESRD risk. Further work incorporating urinary As and geographic exposure modeling is ongoing.

Total Nephron Number Decreases with the Stage of CKD – A Study in Japanese Subjects Go Kanzaki,[3,4] Victor G. Puelles,[2] Luise A. Cullen-McEwen,[4] Yusuke Okabayashi,[3] Nobuo Tsuboi,[3] Akira Shimizu,[1] Takashi Yokoo,[3] John F. Bertram.[4] *[1]Department of Analytic Human Pathology, Nippon Medical School, Tokyo, Japan; [2]Department of Nephrology and Clinical Immunology, University Hospital RWTH Aachen, Aachen, Germany; [3]Division of Nephrology and Hypertension, The Jikei University School of Medicine, Tokyo, Japan; [4]Department of Anatomy and Developmental Biology, Monash University, Melbourne, VIC, Australia.*

Background: There is increasing evidence that low nephron number increases the risk for CKD. We have previously shown that nephron number predicts eGFR. However, changes in total nephron number across the stages of CKD have not previously been reported. In this study we assessed total nephron number and clinicopathological findings in Japanese subjects in order to determine the structural and functional changes associated with nephron loss in each CKD stage.

Methods: Kidneys from 58 Japanese subjects were collected at Nippon Medical School, Tokyo, Japan during autopsy and were divided into three groups; CKD stage 1 (n=13, eGFR>90 mL/min), CKD stage 2 (n=24, eGFR 89-60 mL/min), and CKD stage 3-4 (n=21, eGFR 59-15 mL/min). Total nephron number (Nglom) and mean glomerular volume (Vglom) were estimated by design-based stereology. Single nephron eGFR (SNeGFR) was calculated as eGFR divided by two times the number of non-sclerotic glomeruli.

Results: Total nephron number per kidney was significantly lower in CKD stage 3-4 (293,198±110,087; mean±SD; P<0.001) than in CKD stage 1 (591,377±238,149) and CKD stage 2 (505,303±132,917). Glomeruli were larger in CKD stage 3-4 (P<0.001) than in CKD stages 1 and 2. Kidney weights were similar in the three groups, even though subjects with CKD stage 3-4 had lower cortical volumes and total glomerular volume (combined volume of all non-sclerotic glomeruli) than with CKD stages 1 and 2. Although no differences in SNeGFR were observed between the three groups, SNeGFR/Vglom, which predicts glomerular capillary filtration, was reduced in CKD stages 2 and 3-4 (P<0.001).

Conclusions: Compared with subjects with eGFR>60 mL/min, CKD stage 3-4 patients had an apparent nephron deficit, with glomerular hypertrophy partially compensating for the nephron loss. Our findings also suggest that glomerular capillary filtration starts decreasing in CKD stage 2.

Demographic and renal functional and structural data with CKD stages

	CKD stage1 (N=13)	CKD stage2 (N=24)	CKD stage3-4 (N=21)	ANOVA (P value)

FR-PO410

Intrarenal Renin-Angiotensin System Activation in Nighttime Is Associated with Renal Arteriosclerosis in Normotensive IgA Nephropathy Patients Naro Ohashi,[1] Shinsuke Isobe,[1] Takashi Matsuyama,[1] Sayaka Ishigaki,[1] Naoko Tsuji,[2] Tomoyuki Fujikura,[3] Takayuki Tsuji,[3] Akihiko Kato,[4] Hideo Yasuda.[5] *[1]Hamamatsu University School of Medicine, Hamamatsu, Japan; [2]Hamamatsu University School of Medicine, Hamamatsu, Japan; [3]Hamamatsu University School of Medicine, Hamamatsu, Japan; [4]Hamamatsu University School of Medicine, Hamamatsu, Japan; [5]Hamamatsu University School of Medicine, Hamamatsu, Japan.*

Background: Intrarenal renin-angiotensin system (RAS) activation especially in nighttime plays an important role in the development of hypertension and renal damage. However, the association between intrarenal RAS activation in daytime and nighttime and renal structural damages has not been clearly investigated in IgA nephropathy patients without hypertension.

Methods: We investigated the urinary angiotensinogen (U-AGT) excretion in daytime and nighttime that reflects intrarenal RAS activity and renal structural damages in 27 normotensive IgA nephropathy patients (age 39.2 ± 13.6 years, 10 men and 17 women, blood pressure 112.0 ± 11.8 / 70.0 ± 9.5 mmHg, estimated glomerular filtration rate (eGFR) 74.0 ± 17.3 ml/min/1.73m^2, urinary protein excretion 0.58 ± 0.50 g/day). Renal structural damages of renal biopsy tissues were scored as follows: the levels of arteriolar hyalinosis; the proportion of arterioles affected (0: absent, 1: 1-25%, 2: 26-50%, 3: 51-100%), the levels of arteriosclerosis in arcuate and interlobular arteries (0: normal, 1: intima thickness and less than media thickness, 2: intima thickness and more than media thickness), and percentages of global sclerosis (GS) and tubulointerstitial fibrosis, as described previously.

Results: The levels of arteriosclerosis were significantly and positively associated with U-AGT excretion levels in daytime and nighttime. On the other hand, the levels of arteriolar hyalinosis and percentages of GS and tubulointerstitial fibrosis were not correlated with the U-AGT excretion levels in daytime and nighttime. Multiple liner regression analysis revealed that the levels of arteriosclerosis tended to be associated with U-AGT excretion levels in daytime, when age, sex, body mass index (BMI), and eGFR were adjusted (β=0.33, p=0.079). Moreover, the levels of arteriosclerosis were significantly and positively associated with U-AGT excretion levels in nighttime after adjustment of age, sex, BMI, and eGFR (β= 0.39, p= 0.043).

Conclusions: In normotensive IgA nephropathy patients, the activation of intrarenal RAS especially in nighttime is associated with renal arteriosclerosis.

FR-PO411

Performance Evaluation and Potential Utility of Urinary L-FABP as a Point of Care Device in CKD Nicos Mitsides,[1] Ananya Saha,[1] Ian Read,[1] Philip A. Kalra,[2] Sandip Mitra.[1] *[1]Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom; [2]Salford Royal Hospital NHS Trust, Salford, United Kingdom.*

Background: Liver-type fatty acid binding protein(L-FABP) is expressed by the proximal renal tubule during oxidative stress. Urinary L-FABP is released with tubular damage & is an established biomarker in acute kidney injury. However its value in Chronic Kidney Disease(CKD) & its progression has not been defined. We evaluate the clinical performance of a semi-quantitative point of care(POC) device for the detection of urinary L-FABP & assess the value of urinary L-FABP as a biomarker at different stages of CKD.

Methods: We report the baseline analysis of ELUDE, a multicentre study involving patients with CKD. Urine samples were tested for urinary protein creatinine ratio(PCR in mg/mmol) and urinary L-FABP using a semiquantitative POC & a quantitative ELISA(ug/gCr). A concomitant serum sample was analysed to calculate estimated glomerular filtration rate(MDRD eGFR in ml/min/1.73 m^2). CKD was staged as per KDOQI.

Results: In 624 CKD participants, 15% had CKD1-2(eGFR=77±11.0;uPCR=103±210.3), 13 % CKD3a(eGFR= 51±4.5;uPCR=46±89.9), 25% CKD3b (eGFR=36±4.5;uPCR=72±120.4), 33% CKD4(eGFR=22±4.5;uPCR= 139±191.5) & 15% CKD5 (eGFR=11±2.4;uPCR=265±282.2). The mean urinary L-FABP ELISA measurement was 21.0 ug/gCr. L-FABP levels increased with advancing stages of CKD(1-2: 4.3±19.1;3a: 7.2±30.4ug/L; 3b: 9.0±23.6ug/L; 4: 25.4±51.5ug/L; 5: 62.5±33.6ug/L). L-FABP correlated negatively with eGFR (r= -0.516, p<0.01) and positively with uPCR (r=0.567, p<0.01). The association of L-FABP with eGFR was more pronounced at advanced stages of CKD. In an adjusted linear regression model for prediction of eGFR, L-FABP was an independent predictor in CKD stages 4 (beta= -0.185, p=0.02) & 5 (beta= - 0.241, p=0.03) while PCR was only an independent predictor in CKD 5(CKD4:beta= -0.001, p=0.99;CKD5:beta= -0.243, p=0.03). POC derived L-FABP measurements correlated well with ELISA(r=0.656, p<0.01).

Conclusions: The study findings suggest that in advanced stages of CKD, L-FABP may be a more reliable predictor eGFR than proteinuria. High levels of L-FABP in advanced CKD 4 & 5 could reflect dominant tubular damage & atrophy & may act as a useful biomarker of progressive disease. Longitudinal follow-up data from this study will further inform these findings. POC device used in this study provides a reliable way of measuring urine L-FABP & may be of utility in the clinical setting

Soluble ST-2 and Galectin-3 and Risk of CKD Progression Mariam L. Alam,[8] Ronit Katz,[7] Keith A. Bellovich,[4] Zeenat Y. Bhat,[6] Frank C. Brosius,[2] Ian H. de Boer,[7] Crystal A. Gadegbeku,[5] Debbie S. Gipson,[3] Jennifer J. Hawkins,[3] Jonathan Himmelfarb,[7] Bryan R. Kestenbaum,[7] Matthias Kretzler,[1] Susan P. Steigerwalt,[3] Nisha Bansal.[7] *[1]U.Michigan, Ann Arbor, MI; [2]University of Arizona, Tucson, AZ; [3]University of Michigan, Ann Arbor, MI; [4]St. John Hospital Medical Center, Detroit, MI; [5]Temple University, Philadelphia, PA; [6]Wayne State University, Detroit, MI; [7]Kidney Research Institute, Seattle, WA; [8]University of Washington, Seattle, WA.*

Background: Cardiac biomarkers soluble ST-2 (sST-2) and galectin-3 may reflect inflammation and fibrosis. sST-2 and galectin-3 have been shown to be associated with cardiovascular events, but less is known about their associations with kidney disease. We examined associations of sST-2 and galectin-3 with kidney function decline in two chronic kidney disease (CKD) cohort studies.

Methods: The Clinical Phenotyping Phenotyping and Resource Biobank (CPROBE) and Seattle Kidney Study (SKS) are prospective studies of CKD patients. We measured serum concentrations of sST-2 and galectin-3 at baseline. Outcomes were 1) progression to end-stage renal disease (ESRD) (need for dialysis/transplant or eGFR <15 ml/min/1.73m^2) and 2) annualized relative change in eGFR. We used Cox regression and generalized estimating equation models to study the association of biomarker levels with kidney outcomes, adjusting for eGFR, urine ACR (UACR), demographics, cardiovascular disease, diabetes, body mass index, blood pressure and anti-hypertensive use.

Results: Among the 561 participants in CPROBE, the mean age was 55 ± 16 years, 42% were male and 35% had diabetes. Baseline eGFR was 55 ± 31 ml/min/1.73m^2 and median UACR was 217 (interquartile range [IQR] 16, 885) mg/g. Among the 280 SKS participants, the mean age was 62 ± 13 years, 82% were male and 56% had diabetes. Baseline eGFR was 42 ± 16 ml/min/1.73m^2 and median UACR was 118 (IQR 15, 626) mg/g. Incidence rates of ESRD were 5.41 (110 events) and 3.73 (30 events) per 100 person-years in CPROBE and SKS, respectively. Higher sST-2 was associated with a greater annual decline in eGFR in both CPROBE and SKS, but was not associated with progression to ESRD. Higher galectin-3 was associated with an increased risk of ESRD in CPROBE only (**Table**).

Conclusions: Higher levels of sST-2 and galectin-3 are associated with progression of CKD, highlighting possible shared cardiac and renal mechanisms that contribute to these diseases.

Funding: NIDDK Support

Table. sST-2 and galectin-3 and progression of CKD.

	Change in eGFR		ESRD	
	β (95% CI)*	p-value	HR (95% CI)**	p-value
sST-2 (per doubling)				
C-PROBE	**-3.25 (-5.63, 0.87)**	**0.009**	1.15 (0.81, 1.62)	0.439
SKS	**-3.35 (-6.18, -0.52)**	**0.023**	1.61 (0.59, 4.40)	0.354
Galectin-3 (per doubling)				
C-PROBE	0.46 (-1.14, 2.06)	0.572	**1.46 (1.07, 1.99)**	**0.016**
SKS	-2.42 (-4.91, 0.08)	0.061	0.67 (0.276, 1.64)	0.381

*β reflects mean difference in percent change in eGFR per year associated with a two-fold higher baseline biomarker concentration.
**HR reflects risk of ESRD associated with a two-fold higher baseline biomarker concentration.
***Models adjusted for age, race, gender, BMI, log(eGFR), log(UACR), education, smoking, cardiovascular disease, diabetes, systolic blood pressure and anti-hypertensive use.

CKD Progression in Patients with Sickle Cell Trait Kabir O. Olaniran, Nwamaka D. Eneanya, Andrew S. Allegretti, Dihua Xu, Ravi I. Thadhani. *Massachusetts General Hospital, Malden, MA.*

Background: Sickle cell trait (SCT) has been shown in recent studies to be independently associated with incident CKD and progression to end stage renal disease (ESRD). We sought to confirm the risk for ESRD and glomerular filtration rate (GFR) decline in a multi-hospital cohort.

Methods: This was a multi-hospital retrospective cohort study in Boston using adult KDIGO criteria CKD patients between 2005-2017. Chart review was used to ascertain the following exposures: SCT and the reference group (RG; black race with CKD and normal hemoglobin electrophoresis). Primary outcomes were ESRD on dialysis (identified by diagnosis codes) and GFR decline (defined as a decrease in GFR ≧1ml/min per follow up year). Exposures confirmed by diagnosis code only were then added for sensitivity analysis.

Results: 915 CKD subjects were initially included (241 SCT and 674 RG). Baseline age was 54±15 years in SCT CKD and 52±17 years in the RG, p=0.266. The mean baseline GFR in SCT CKD patients was similar vs the RG (69±33ml/min vs 70±36ml/min, p=0.57) with similar proportions per CKD stage. Treatment with renin-angiotensin system inhibitors was not significantly different (88% SCT CKD vs 85% RG, p=0.26). No other significant differences in the baseline characteristics of the SCT CKD vs the RG were noted including smoking status, co-morbidities and treatments. After adjustment for age, co-morbidities and medications, we found significantly increased odds for GFR decline in SCT CKD (OR 1.7, 95% CI 1.1-2.6) compared to the RG. SCT CKD patients also had significantly increased odds for dialysis (OR 1.8, 95% CI 1.04-2.98) after multivariable analysis. Sensitivity analysis of 8,580 subjects (360 SCT and 8,220 RG) found similar results for GFR decline (OR 1.6, 95% CI 1.2-2.2) and dialysis (OR 1.9, 95% CI 1.3-2.9).

Conclusions: SCT with concurrent CKD is associated with an increased risk for GFR decline and requirement for dialysis in our cohort. More detailed studies are needed to determine risk factors for progression in this patient population.

Factors Associated with Clinically Significant CKD and Their Clinical Utility in Primary Care Clinics in Singapore Quan Lan J. Lew,[3] Francis N. Nguyen,[4] John C. Allen,[1] Ngiap chuan Tan,[2] Tazeen H. Jafar.[1] *[1]Duke-NUS Graduate Medical School, Singapore, Singapore; [2]SingHealth Polyclinics, Singapore, Singapore; [3]Singhealth Polyclinic, Singapore, Singapore; [4]SingHealth, Singapore, Singapore.*

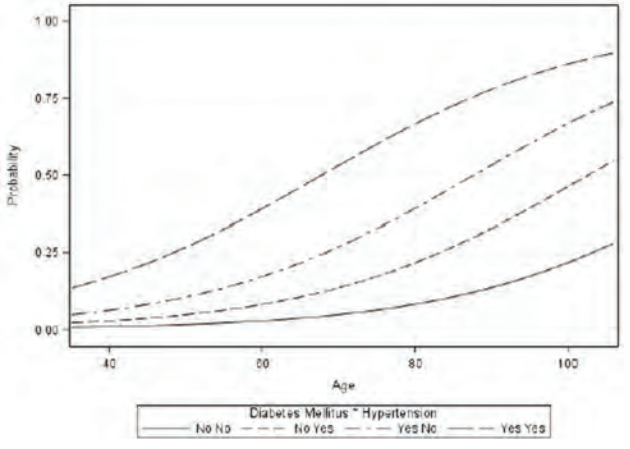
Background: Chronic kidney disease (CKD) is a major global public health challenge, including Southeast Asia. Factors associated with CKD in Singapore were determined by analyzing historical data on all individuals ≥ 40 years visiting 4 government polyclinics in Singapore from 1st Jan 2012 to 31st Dec 2015.

Methods: Clinically significant CKD patients had CKD-EPI serum creatinine-based estimated glomerular filtration rate < 60ml/min/1.73m^2 or 1+ dipstick proteinuria sustained ≥ 3 months. Multivariable and stepwise logistic regression analysis and receiver operator characteristic curve analysis were conducted for the outcome of clinically significant CKD.

Results: About 25.9% (95% CI: 25.6-26.2%) of the 88,765 individuals screened at Singapore Polyclinics (mean (SD) age of 65.9 (±11.1) years, and 53.3% women) had clinically significant CKD. Age [OR=1.06; 95% CI: (1.06-1.07) / year]; body mass index [1.02 (1.02-1.03) / kg/m^2]; male vs female [1.23 (1.17-1.27)]; Malay [1.31 (1.24-1.38)] and Indian [(0.80 (0.74-0.87)] vs Chinese; public vs private housing [1.25 (1.18-1.34)]; ever vs never smoker [1.08 (1.01-1.15)]; presence of hypertension [2.89 (2.69-3.11)], diabetes [7.23 (6.95-7.52)], or stroke [1.36 (1.27-1.45)] vs none were independently associated with clinically significant CKD. However, only age, presence of diabetes and hypertension incrementally added to the area under the curve of 0.808 (95% CI: 0.805-0.811) for clinically significant CKD.

Conclusions: Clinically significant CKD prevalence is high in primary care clinics in Singapore. Our results highlight the factors associated with clinically significant CKD and underscore the need for targeted screening of CKD in Southeast Asia.

Funding: Clinical Revenue Support



Probability of CKD increases with age, and presence of hypertension and diabetes.

FR-PO415

Long-term Prognosis and Predictive Factors of Non-Remission in IgA Nephropathy after Tonsillectomy and Steroid Pulse Therapy Kosuke Yamaka,[1] Keita Inui,[1] Yosuke Yamada,[1] Yuji Kamijo.[2] *[1]Shinshu University, Matsumoto CIty, Japan; [2]Shinshu University School of Medicine, Matsumoto, Japan.*

Background: Tonsillectomy and steroid pulse therapy (TSP) for IgA nephropathy (IgAN) is widely performed in Japan. However, the efficacy of TSP remains controversial, partly because even though IgAN is a chronic nephritis, most studies set the primary outcome as complete remission (CR) at 1 year after TSP and do not address long-term outcome. Therefore, we followed patients who had undergone TSP for a minimum of 3 years to clarify the long-term results and predictive factors of non-remission (NR) following TSP.

Methods: This retrospective, single-center, cohort study included 63 patients who were monitored for at least 3 years after TSP for IgAN at Shinshu University Hospital. The frequency of CR (urinary total protein <0.3 g/gCre and urinary red blood cells <5/high-power field) was assessed at 1 and 3 years following TSP. Using statistical methods, the predictive factors of NR at 3 years were investigated with relation to physical examination, serology, and urinalysis items.

Results: CR was observed in 29 (46%) patients at 1 year of follow-up. Of these, 6 (10%) experienced a recurrence and 23 (36%) maintained CR at 3 years. Among the 34 (54%) patients with NR at 1 year, 10 (16%) exhibited late remission and 24 (38%) remained unchanged at 3 years. Overall, tubulointerstitial fibrosis was significantly more severe in NR patients at 3 years than in CR patients (P<0.01). Among the 29 patients who showed CR at 1 year, tubulointerstitial fibrosis in patients with a recurrence at 3 years was significantly more severe as well (P<0.05). The most useful factor for predicting NR at 3 years was the well known tubulointerstitial injury marker urinary N-acetyl-β-D-glucosaminidase (U-NAG) according to receiver operator characteristic (ROC) analysis (cut-off: 4.35 U/gCre; sensitivity: 83%; selectivity: 75%; area under ROC curve: 0.817). Even in patients with CR at 1 year, those whose U-NAG was >4.35 U/gCre were more likely to relapse within 3 years (P<0.05).

Conclusions: At 3 years following TSP for IgAN, both recurrence and late remission are observed in relatively many patients. The severity of tubulointerstitial fibrosis is considered to be related to TSP resistance, and U-NAG represents a useful predictor of long-term prognosis.

FR-PO416

Epicardial Fat Is Associated with Traditional CV Risk Factors and Renal Function in Patients with Moderately Severe CKD Turgay Saritas,[5] Jonas Schmöe,[2] Jennifer Nadal,[1] Matthias Schmid,[10] Rolf Janka,[8] Christoph Wanner,[7] Kai-Uwe Eckardt,[6] Jürgen Floege,[4] Markus P. Schneider,[9] Georg Schlieper.[3,11] *[1]University of Bonn, Bonn, Germany; [2]University Hospital RWTH Aachen, Aachen, Germany; [3]University Hospital RWTH Aachen, Aachen, Germany; [4]University Hospital RWTH Aachen, Aachen, Germany; [5]University Hospital RWTH Aachen, Aachen, Germany; [6]University of Erlangen-Nuremberg, Erlangen, Germany; [7]University Hospital Wuerzberg, Wuerzburg, Germany; [8]University of Erlangen-Nuernberg, Erlangen, Germany; [9]Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [10]University of Bonn, Bonn, Germany; [11]MVZ DaVita Karlstraße, Düsseldorf, Germany.*

Background: Pathological increase of epicardial adipose tissue (EAT) has been proposed as a novel, imaging-based predictor of CV events. How traditional CV risk factors associate with EAT enlargement in patients with moderately severe chronic kidney disease (CKD) has not been examined yet.

Methods: We analyzed data from 257 patients from CARVIDA (CARdioVascular In Depth Assessment), which is a multi-center substudy of the German Chronic Kidney Disease (GCKD) study. Patients were enrolled on the basis of an eGFR of 30-60 ml/min/1.73m^2 or overt proteinuria, and EAT was measured by computed tomography. Multivariable association of EAT with CV risk factors (age, gender, BMI, smoking, diabetes mellitus, hypertensive nephropathy, cholesterol, HDL, eGFR (CKD-EPI equation) and urine albumin-to-creatinine (UACR)) was assessed using linear regression analysis. Framingham 10-year CV disease risk score and ACC-AHA 10-year atherosclerotic CV disease (ASCVD) risk score were calculated for each patient.

Results: EAT showed a median level of 121 cm^3 (IQR: 81-162 cm^3). Prevalence of traditional CV risk factors increased with quartiles of EAT (all p < 0.05). Using multivariable analysis, higher EAT was significantly associated with the majority of investigated risk factors (age, gender, BMI, smoking, HDL) (Table 1). Of note, lower eGFR was independently associated with increased EAT (OR 0.997 (95% CI: 0.994-0.999), p<0.05). Finally, EAT correlated with estimated 10-year risk for CV disease by Framingham (spearman rho = 0.257, p =0.002; median risk score: 18.5%) and ASCVD (spearman rho =0.192, p =0.020; median risk score: 13.7%).

Conclusions: Epicardial fat is associated with traditional CV risk factors in the presence of CKD. Moreover, we observed that lower eGFR is also associated with EAT. EAT may thus be an integrative risk marker and follow-up of our patients will determine whether assessment of EAT improves the prediction of CV events in CKD.

C-Reactive Protein Mediates the Association between Central Obesity and Microalbuminuria among Persons with the Metabolic Syndrome, Especially in African Americans Satyesh K. Sinha,[1,3] Magda Shaheen,[1,3] Deyu Pan,[1,2] Keith C. Norris,[2,3] Susanne B. Nicholas.[2,3] *[1]Charles R Drew University of Medicine and Science, Los Angeles, CA; [2]None, Westchester, CA; [3]University of California Los Angeles, Los Angeles, CA.*

Background: C-reactive protein (CRP), an inflammatory marker, is associated with the metabolic syndrome (MetS) and chronic kidney disease (CKD). However, little is known about the racial disparities of the effect of CRP on the association between individual components of the MetS and microalbuminuria (MA).

Methods: We analyzed National Health and Nutrition Examination Surveys (NHANES) data, (1999-2010) for adults (aged ≥20 years) with MetS (N=5700). We used multiple logistic regression to assess the independent relationship between MetS components and MA, adjusting for age, gender, race/ethnicity and estimated glomerular filtration rate (eGFR). We used the Sobel-Goodman mediation tests to examine the extent of how CRP influences the effect of MetS components on MA by race/ethnicity. We examined the association between CRP and MA and tested the ability of CRP to reclassify risk using the net reclassification index with and without CRP.

Results: In the multivariate model, CRP, as well as central obesity, blood pressure, fasting plasma glucose, and high-density lipoprotein (HDL), were independent predictors of MA, p<0.05. The mediation test showed that the proportion of total effect of the MetS components on MA, mediated by CRP, is: 0.11 for HDL and 0.40 for central obesity, p<0.05. These levels varied by race/ethnicity. The mediation effect of CRP for central obesity (highest prevalence in African Americans; AAs) was highest for AAs (0.94) compared to Whites (0.55) or Hispanics (0.18), p<0.05The addition of CRP to the adjusted model of MetS components, demographics and eGFR resulted in net reclassification improvement of 0.11 (standard error=0.03, p=0.002) but no significant change in the prediction of MA (receiver-operating characteristics–area under the curve; without CRP=0.66; with CRP=0.67).

Conclusions: We conclude that CRP mediates the association between MA and both HDL and central obesity. Importantly, for AAs, CRP mediates the relationship between MA and central obesity. **Grant Support:** Supported in part by NIH grants U54-MD-008149, UL1TR000124, P30AG021684, U54MD007598, and S21 MD000103.

FR-PO418

A New Way to Assess CKD Progression: Correlation of Renal Ultrasound Measurements to Co-Morbidities, CKD Stages, and Total Renal and Parenchymal Cortical Volume Harish R. Alappan,[1] Raj Alappan,[3] Raj Sehgal.[2] *[1]Emory University - Undergraduate, Atlanta, GA; [2]Radiology Institute, Atlanta, GA; [3]Renal Associates, LLC, Columbus, GA.*

Background: Correlating Renal Ultrasound (US) data to co-morbidity and Chronic Kidney Disease (CKD) stages is sparse. Kidney's volumetric US data and trends have not been reported previously in CKD stages.

Methods: Initial CKD evaluation was conducted at Renal Associates. Clinical data and renal US done at the center were analyzed. Using the *M7-Mindray US System,* the same radiographer did the imaging and the same radiologist read images. 612 renal US images from Aug. 2014 to Jan. 2016 were analyzed. The Renal and Medullary sagittal, transverse and AP axis and cortical thickness for the right (RK) and left (LK) kidneys were measured in cm. Using Total Renal (TRV), and the Medullary (MV) volume, the Cortical (CV) volume was calculated. Using a correction constant for each kidney (RK=0.4891, LK=0.4886) the true renal Cortical tissue Volume (RCV) was determined for each kidney.

Results: Overall study (n=612): mean age was 63.87 yrs., 339 (55.3%) females, BMI 31.23, Cr 1.49 mg/dL, CrCl 73.02 mL/min, PTH 62.14 and HCO_3 at 25.52. The RK and LK sagittal size was 10.72 cm and 10.71 cm (p-NS), cortical thickness was 1.51 cm and 1.59 cm (p<0.004), renal stone 54(8.8%), and 204 had renal cysts (34.6%). CKD stages correlated to both RK and LK for corrected TRV of 171.23 cm^3 and 178.32 cm^3, Cortical tissue volume 151.09 cm^3 and 154.44 cm^3 (p<0.001), and Combined total cortical tissue volume in male 356.89 cm^3 and female 263.99 cm^3 (p<0.001). For 1mL of the RCV(cm^3), Cr Cl per mL ratio linearly increased as CKD Stages advanced (3.125 cm^3 in Stage-1 to 9.62 cm^3 in Stage-4). All males and diabetics had a larger sagittal, cortex and renal Cortical volume. Af. Am had thicker cortex (see Table).

Conclusions: This study is the first of its kind that correlates renal measurements on Total Renal Volume and Renal Cortical Volume to CKD Stages and other co-morbidities. Cortical thickness and volumetric corrected Renal Cortical Volume in cm^3 were accurate and significant. We propose with this study a new way to use ultrasound to monitor CKD progression.

Change in Creatinine-Based Estimated GFR versus Cystatin-C-Based Estimated GFR and Renal Outcome in Patients with CKD Su Hyun Kim,[6] Junseok Jeon,[5] Minjung Kim,[4] Hye Ryoun Jang,[1] Yoon-Goo Kim,[2] Dae Joong Kim,[6] Ha Young Oh,[6] Wooseong Huh,[3] Jung eun Lee.[4] *[1]None, Seoul, Republic of Korea; [2]Samsung Medical Center, Seoul, Republic of Korea; [3]Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [4]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [5]Samsung medical center, Seoul, Republic of Korea; [6]Samsung medical center Sungkyunkwan University School of medicine, Seoul, Republic of Korea.*

Background: Many studies have demonstrated that an early change in estimated glomerular filtration rate (eGFR) predicts the risk of chronic kidney disease (CKD) progression. However, there are few studies comparing prognostic power between creatinine-based eGFR slope (eGFRcre slope) and cystatin-C-based eGFR slope (eGFRcys slope). This study examined which eGFR slope during first-year was superior in identification of high-risk group of progression to end-stage renal disease (ESRD) in patient with CKD.

Methods: From October 2010 to November 2016, patients who had simultaneous measurements of serum creatinine and cystatin-C more than 3 times for 1 year were identified. We calculated baseline eGFR values and first-year eGFR slopes using CKD-EPI equation and linear regression analyses. The patients with baseline eGFR ≥ 60 ml/min/1.73m² were excluded. We defined a rapid progression as eGFR slope < -5 mL/min/1.73m²/year. We assessed association between first-year eGFR slopes and progression to ESRD (defined as initiation of dialysis or kidney transplantation) by cox proportional hazard model.

Results: Total 857 patients were included. Forty% of subjects had diabetes. Baseline eGFRcre were 36.7 (25.8 – 47.2) ml/min/1.73m² and eGFRcys were 36.5 (25.3 – 49.1) ml/min/1.73m². During follow-up of 2.4 (1.3 – 3.3) years, 78 (9.1%) events occurred. Both eGFRcre slope and eGFRcys slope were associated with higher risk of ESRD independently of baseline eGFR (HR = 0.95 [0.93 – 0.97], HR = 0.96 [0.95 – 0.98], respectively). Both creatinine and cystatin-C based-rapid progression were associated with increased risk of ESRD (HR = 2.25 [1.44 – 3.52], HR = 1.77 [1.10 – 2.86], respectively). In subgroup analyses of rapid progression group by creatinine (N = 295), eGFRcys slope was not associated with risk of ESRD (HR = 0.99 [0.96 – 1.03], P = 0.68). Whereas, eGFRcre slopes contributed to further discrimination of higher risk of ESRD in subjects with rapid progression by cystatin-C (HR = 0.96 [0.93 – 0.98], P = 0.002).

Conclusions: These findings suggest that eGFRcre slope may be superior to eGFRcys in identification of high-risk group in patient with CKD.

FR-PO420

Laboratory Indices and Serum Biomarkers Associate with Prior Renal Functional Decline in CKD William P. Martin,[1] Serika D. Naicker,[1] Eibhlin M. Mccole,[2] Susan Logue,[1] Sarah Cormican,[1] Marie Mcgarvey,[2] Ciaran Richardson,[2] Ivan Mcconnell,[3] John Lamont,[3] John P. Ferguson,[4] Peter Fitzgerald,[3] Matthew D. Griffin.[1] *[1]Regenerative Medicine Institute, National University of Ireland, Galway, Ireland; [2]Randox Teoranta, Meenmore, Dungloe, Ireland; [3]Randox Laboratories Limited, 55 Diamond Road, Crumlin, United Kingdom; [4]HRB Clinical Research Facility, Galway, Ireland.*

Background: Prediction of renal functional decline in chronic kidney disease (CKD) is limited. We evaluated the relationship between laboratory indices and results from a novel serum biomarker chip assay with recent rate of decline of renal function.

Methods: Patients were recruited from Nephrology clinics at a tertiary referral center during 2014 and 2015, where they provided a serum sample for biomarker quantification with a novel multi-analyte chip assay. Relationships between laboratory indices and serum biomarkers at recruitment with slope of MDRD eGFR prior to recruitment were investigated using a custom weighted least squares algorithm adjusting for age, sex, and first eGFR during the study period.

Results: 170 subjects were identified (135 (79.4%) with native CKD, 35 (20.6%) with kidney transplants (KTs)). Mean age was 60.09 ± 17.38 years. 69 (40.6%) subjects were female. Native CKD stages were: 5 (3.7%) CKD1, 17 (12.6%) CKD2, 19 (14.1%) CKD3a, 40 (29.6%) CKD3b, 44 (32.6%) CKD4, and 10 (7.4%) CKD5. Median [IQR] number of eGFR measurements was 17.0 [10.8, 27.3] over 3.3 [2.4, 3.7] years prior to recruitment. Rate of eGFR decline was -2.59 ± 5.29 vs. -0.46 ± 5.27 mL/min/BSA/year in native CKD and KT subjects, respectively (p = .035). Analysis results for selected laboratory and biomarker indices are summarized in the Table.

Conclusions: Multiple serum biomarkers measured simultaneously with a novel chip assay and several laboratory indices were strongly associated with prior renal functional decline in CKD subjects. Retrospective eGFR trends may be of value for identifying biomarker signatures associated with rapid renal functional decline.

Non-Steroidal Anti-Inflammatory Drug (NSAID) Use and ESRD in the Southern Community Cohort Study (SCCS) Fabian Bock,[1] Edward D. Siew,[1] Jennifer Morse,[2] Thomas G. Stewart,[2] William J. Blot,[1] Talat Alp Ikizler,[1] Loren Lipworth.[1] *[1]Div of Nephrology&Hypertension, Dept of Medicine, Vanderbilt University Medical Center, Nashville, TN; [2]Dept of Biostatistics, Vanderbilt University Medical Center, Nashville, TN.*

Background: Evidence suggests increased ESRD risk among NSAID users, but data are inconsistent and limited, particularly among blacks at high ESRD risk. The SCCS is a prospective study of ~86,000 individuals, two thirds black, in the southeastern US, where ESRD rates are high.

Methods: We assembled a case-cohort study from the SCCS, comprising 292 incident ESRD cases, identified by linkage with the US Renal Data System through March 2015, and a probability sample of 1453 SCCS participants, who donated a blood sample and had serum creatinine measured. Data were collected at baseline on regular use (2 times/week for ≥one month) of prescription and OTC analgesics, including NSAIDs. The analysis was restricted to those who reported using any analgesic. The association of NSAID use with ESRD was estimated with a logistic regression model adjusted for age, sex, race, smoking, hypertension, diabetes, arthritis, baseline eGFR, aspirin, acetaminophen, and an estimated propensity score (PS). The PS is the covariate-adjusted probability of being an NSAID user and was calculated with predictors of NSAID use as covariates.

Results: At enrollment, mean (SD) age was 53 (8) and 55 (9) years among ESRD cases and subcohort controls, and 78% and 62%, respectively, were black. Median (25th, 75th percentile) baseline eGFR of cases and controls was 78 (39, 109) and 98 (83, 113) ml/min/1.73 m², respectively. Overall, NSAID, aspirin and acetaminophen use were reported by 38%, 53% and 33% of ESRD cases, respectively, compared to 53%, 40% and 33% of controls. Table 1 shows the distribution of analgesic use by baseline eGFR. In adjusted analyses, compared to non-NSAID analgesic users, the OR (95% CI) for the association between NSAID use and ESRD was 0.83 (0.54-1.27).

Conclusions: Among analgesics users, 25% of cases with baseline eGFR<60 used NSAIDs, but NSAID use was not significantly associated with risk of ESRD.

Indian Chronic Kidney Disease (ICKD) Study: A Prospective Cohort Study of CKD Patients in India Ashok K. Yadav,[3] Vivek Kumar,[9] Shobhit Bhansali,[3] Gopesh K. Modi,[2] Sishir D. Gang,[7] Jai Prakash,[1] Dipankar Sircar,[5] Sreejith Parameswaran,[6] Narayan Prasad,[10] MANISHA SAHAY,[8] Santosh Varughese,[11] Shivendra Singh,[1] Vivekanand Jha.[4] *[1]Banaras Hindu University, Varanasi, India; [2]Samarpan kidney Institute & Research Ctr., Bhopal, India; [3]Nephrology, PGIMER, Chandigarh, India; [4]George Institute for Global Health, New Delhi, India; [5]IPGMER, SSKM HOSPITAL, KOLKATA, India; [6]JIPMER, Ponidcherry, India; [7]MULJIBHAI PATEL UROLOGICAL HOSPITAL, Nadiad, India; [8]OSMANIA HOSPITAL, HYDERABAD, India; [9]Postgraduate Institute of Medical Education and Research, Chandigarh, India; [10]SGPGIMS CAMPUS, Lucknow, India; [11]Nephrology, CMC, Vellore, India.*

Background: The Indian Chronic Kidney Disease (ICKD) study (https://ickd.georgeinstitute.org.in/) is a multi-centric, prospective, observational cohort study of early stage CKD patients in India which will ascertain rate and factors influencing progression of CKD in India.

Methods: Adult subjects with mild to moderate CKD [estimated glomerular filtration rate (eGFR) 30-60 ml/min/1.73m² or eGFR >60 ml/min/1.73m² with proteinuria/albuminuria] are eligible for enrolment. Approximately 5000 subjects would be enrolled over 18 months. Time to 50% decline in eGFR, need of renal replacement therapy, CVD event or death are primary end points. A central bio-repository with serial biological samples is coupled with this cohort. Socio-economic aspects of treatment will also be studied.

Results: A total of 1567 subjects have been enrolled in the ICKD cohort till May 2017. The cause of CKD could not be ascertained in 25% of subjects. Chronic glomerulonephritis, diabetic kidney disease and chronic interstitial nephritis are causes for CKD in 16.5%, 18% and 17% of subjects, respectively. Tables 1 shows selective demographic characteristics of enrolled subjects. Majority are males belonging to rural areas with occupation exposure to sand, dust, chemicals or animals etc. 24% subjects had used alternative drugs and 10% had history suggestive of AKI in the past.

Conclusions: This is the first and most comprehensive description of an early stage CKD cohort from a developing country.

Funding: Government Support - Non-U.S.

Table 1: Selected demographic details of ICKD study subjects (n=1567)

Characteristics	Mean ± SD or No. of subjects (% of total)
Age (Years)	50.1±12.0
Male sex	1066 (68.0)
BMI (Kg/m²)	25.5±23.8
Waist/Hip ratio	1.90±0.2
Systolic blood pressure (mmHg)	133.3±19.9
Diastolic blood pressure (mmHg)	83.5±10.5
Disease duration (months)	43.6±171.8
Education: graduates and above	470 (30.0)
Residence: rural or semi-urban	938(59.8)
Occupational exposure to sand, dust, chemicals, animals etc.	528(33.7)
Strict vegetarians	536(34.4)
Family history of kidney disease present	148(9.5)
History of hypertension	1061(67.7)
History of diabetes	474(30.2)
History of use of alternative drugs or medicines	377(24.1)
History of AKI	154(9.8)
History of NSAIDS use after diagnosis of kidney disease	48(3.1)
Smoking history	491(31.3)
History of vaccination against hepatitis B	406(25.9)
Medical insurance available	431(27.5)
Monthly income (USD)	232.7(93.1-465.8)
Monthly medication cost (USD)	33.8 (13.8-61.5)

GDF-15 and FGF-23 Are Associated with Mortality in Type 2 Diabetic Patients with Microalbuminuria Marie Frimodt-møller,[1] Bernt Johan Von Scholten,[1] Henrik Reinhard,[1] Tine Hansen,[1] Frederik Persson,[1] Hans-Henrik Parving,[2] Peter Rossing.[1,3] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Rigshospitalet, Copenhagen, Denmark; [3]Copenhagen University, Copenhagen, Denmark.*

Background: We evaluated growth differentiation factor 15 (GDF-15) and fibroblast growth factor 23 (FGF23) reflecting different aspects of renal pathophysiology as determinants of decline in estimated glomerular filtration rate (eGFR), incident cardiovascular disease (CVD) and all-cause mortality in patients with type 2 diabetes (T2D) and microalbuminuria, but without clinical coronary artery disease

Methods: Prospective study including 200 patients. GDF-15 and FGF23 were measured at baseline. Adjusted Cox models included sex, age, LDL cholesterol, smoking, HbA_{1c}, creatinine, systolic blood pressure urine albumin excretion rate (UAER) and for FGF23 also 25(OH)vitamin D. *Main outcome measures:* A decline in eGFR of >30%, at any time point during follow-up was the predefined endpoint of CKD progression. Hazard ratios (HR) are provided per 1 SD increment of log-transformed values of the biomarkers.

Results: Patients were (± SD) 59 ± 9 years old, eGFR 91.1 ± 18.3 ml/min/1.73m² and UAER (IQR) 103 (39–230) mg/24-h. During a median 6.1 years follow-up, there were 40 incident CVD events, 26 deaths and a total of 42 patients reached the renal endpoint after 4.9 years (median). Higher GDF-15 was a determinant of decline in eGFR >30% in unadjusted (HR (95% CI) 1.7 (1.3-2.4); p=0.001) and adjusted (HR 1.7 (1.1-2.5); p=0.018) models, a predictor of CVD in the unadjusted model (HR 1.4 (1.0-1.9); p=0.034) and of all-cause mortality in unadjusted (HR 1.8 (1.3-2.6); p<0.001) and adjusted (HR 1.9 (1.2-2.9); p=0.003) models. Higher FGF-23 was associated with all-cause mortality in unadjusted (HR 1.5 (1.1-2.0); p=0.010) and adjusted (HR 1.6 (1.1-2.2); p=0.011) models.

Conclusions: In patients with T2D and microalbuminuria, GDF-15 was independently associated with decline in kidney function and all-cause mortality, and higher FGF23 was associated with all-cause mortality.

FR-PO424

Cigarette Smoking Exacerbated the Pathology of Diabetic Nephropathy with Severity of interstitial Inflammation Infiltration: A Multi-Center Study in Male Adults Qian Q. Han. *West China Hospital, ChengDu, SiChuan, China.*

Background: Cigarettes smoking have been identified as a progression factor in various kidney diseases, but no exact statement has been shown in DN at present. So we aim to investigate the association between cigarette smoking and renal injury of biopsy-proven diabetic nephropathy (DN) in male adults from Southwest China to provide more evidence for management.

Methods: A total number of 171 male adult patients with DN proven by renal biopsy from multicenter in Southwest China were recruited in our study. The patients are divided

into three groups according to smoking state: non-smoker, ex-smoker, and current smoker. Clinical data and pathological characteristics of all three groups were collected. Logistic regression analyses, with or without multivariable adjustments for other risk factors for DN, were used to evaluate the risk of pathology of DN based on the smoking status.

Results: Cigarette smoking is associated with the pathology of DN. Both the unadjusted regression analyses and the multivariable adjusted regression analyses suggested cigarette smoking was a risk factor for severity of glomerular lesions (p=0.030 & 0.030 respectively) and interstitial inflammation infiltration (p= 0.009 & 0.009 respectively) when compared with non-smoking group, and arterial hyaline (p=0.014 and 0.015 respectively) when compared with ex-smoking group. Especially, both unadjusted (p=0.01, OR=14.73) and multivariable adjusted (p=0.01, OR=17.50) regression analyses strongly significantly suggested that smoking was risk for interstitial inflammation. When analysing the subgroups divided by eGFR and urine protein, the results were still significant.

Conclusions: Smoking may be an independent risk factor for glomerular lesions, interstitial inflammation infiltration of DN, while persistent smoking is a risk factor for arterial hyaline, which suggesting no smoking or cessation of smoking is recommended for patients with diabetic nephropathy.

Self-Reported Tobacco, Alcohol, and Illicit Drug Use and Progression of CKD: The CRIC Study

Joshua D. Bundy,[1] Lydia Bazzano,[1] Dawei Xie,[2] Jacqueline Dolata,[3] Jeffrey C. Fink,[4] Chi-yuan Hsu,[5] Kenneth A. Jamerson,[6] James P. Lash,[7] Gail K. Makos,[8] Nancy Robinson,[2] Susan P. Steigerwalt,[6] Xue Wang,[2] Jiang He.[1] *[1]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [2]University of Pennsylvania School of Medicine, Philadelphia, PA; [3]MetroHealth Medical Center, Cleveland, OH; [4]University of Maryland, Baltimore, MD; [5]University of California San Francisco, San Francisco, CA; [6]University of Michigan, Ann Arbor, MI; [7]University of Illinois at Chicago, Chicago, IL; [8]St Clair Speciality Physicians, Detroit, MI.*

Background: The associations of tobacco, alcohol, and illicit drug use with risk of chronic kidney disease (CKD) progression and all-cause mortality have not been well studied among patients with CKD.

Methods: The Chronic Renal Insufficiency Cohort (CRIC) Study is a prospective cohort study of 3939 adults with CKD recruited from seven US clinical sites. Self-reported questionnaires annually assessed current smoking, weekly drinking (consumed alcohol ≥1 days per week), any marijuana use, and any hard illicit drug use (use of cocaine, heroin, or methamphetamine). CKD progression was defined as halving of estimated glomerular filtration rate (eGFR) or initiation of dialysis or kidney transplant. Deaths were confirmed by death certificate. Multiple time-dependent Cox regression was used to assess the associations of drug use with progression of CKD and all-cause mortality.

Results: Over an average 5.4-year follow-up, 1287 participants had CKD progression and 1001 died. Current smoking and hard illicit drug use were significantly associated with increased risk of CKD progression or all-cause mortality (Table).

Conclusions: Among patients with CKD, current smoking and hard illicit drug use may increase the risk of CKD progression and all-cause mortality.

Funding: NIDDK Support

Table. Hazard ratios (95% confidence intervals) of CKD progression and mortality associated with annually-updated drug use

	Age, sex, race, and clinical site-adjusted		Multivariable-adjusted*	
	HR (95% CI)	P Value	HR (95% CI)	P Value

Lower School Educational Level Is Associated with Lower eGFR in Patients with Moderately Severe CKD: The GCKD Study

Doris C. Al-Fartwsi,[1] Elke Schaeffner,[11] Seema Baid-Agrawal,[10] Matthias Schmid,[13] Jennifer Nadal,[2] Markus P. Schneider,[14] Martin Busch,[8] Gunter B. Wolf, MHBA,[7] Claudia Sommerer,[12] Heike Meiselbach,[6] Nadine Kaesler,[5] Sabine Ernst,[15] Kai-Uwe Eckardt,[6] Jürgen Floege,[4] Georg Schlieper,[4,3] Turgay Saritas.[9] *[1]University Hospital RWTH Aachen, Aachen, Germany; [2]University of Bonn, Bonn, Germany; [3]MVZ DaVita Karlstraße, Duesseldorf, Germany; [4]University Hospital RWTH Aachen, Aachen, Germany; [5]University Hospital RWTH Aachen, Aachen, Germany; [6]University of Erlangen-Nuremberg, Erlangen, Germany; [7]Jena University Hospital, Jena, Germany; [8]University Hospital Jena, Jena, Germany; [9]University Hospital RWTH Aachen, Aachen, Germany; [10]Sahlgrenska University Hospital, University of Gothenburg, Gothenburrg, Sweden; [11]Charité University Berlin, Berlin, Germany; [12]University Hospital of Heidelberg, Heidelberg, Germany; [13]University of Bonn, Bonn, Germany; [14]University of Erlangen-Nuremberg, Erlangen, Germany; [15]University Hospital RWTH Aachen, Aachen, Germany. Group/Team: For GCKD investigators.*

Background: Low socioeconomic status (SES) is associated with increased prevalence of chronic kidney disease (CKD) and mortality. However, previous studies were mainly conducted in the U.S. population. This study evaluated the association between SES and kidney function in a large German cohort of patients with moderately severe CKD.

Methods: We analyzed data from 5111 patients of the German CKD (GCKD) study, who were enrolled on the basis of an eGFR of 30-60 mL/min or overt proteinuria. Patients were divided into three categories according to their school educational level: "low" (completed ≤ 9th grade), "intermediate" (10th grade) and "high" (≥12th grade). In addition, patients were stratified in four groups according to their annual household income: ≤25.000 €; 25.000 to <50.000 €; 50.000 to <100.000 €; ≥100.000 €. An ordinal logistic regression was run to determine the association of education and income on eGFR (<30, 30-44, 45-59, >60 mL/min) and urine albumin-to-creatinine ratio (UACR) (<30, 30-300, >300mg/g), adjusted for multiple confounders.

Results: In comparison with those who had high school education, patients with low education had lower eGFR (median eGFR 43 vs. 51 ml/min, $p < 0.001$). However, autoimmune disease was more prevalent and UACR was higher (median 78 vs. 48 mg/g) in patients with high education ($p < 0.001$). An association was also found between low education and low annual household income, and the prevalence of diabetes mellitus, hypertension, coronary heart disease, stroke, and arrhythmia ($p < 0.001$). Similar significant differences were observed by comparing patients with low income vs. high income. In multivariate analysis, the odds ratio of being in a lower category of eGFR for low educated vs. high-educated patients was 1.254 (95% CI: 1.077 - 1.459); $p = 0.003$. No significant association was found between income and eGFR levels. Furthermore, no association was found between education/income and UACR categories.

Conclusions: Within the GCKD cohort, low education level but not income was independently associated with lower eGFR. Furthermore, low education and low income were associated with a greater burden of comorbidities.

FR-PO427

Hyperfiltration Predicts Rapid GFR Decline in a General Non-Diabetic Population and in Type 2 Diabetes

Toralf Melsom,[1,2] Viji Nair,[2] Jørgen Schei,[1] Laura H. Mariani,[2] Vidar T. Stefansson,[1] Jennifer L. Harder,[2] Trond G. Jenssen,[1] Marit D. Solbu,[1,3] Jon V. Norvik,[1,3] Helen C. Looker,[4] Matthias Kretzler,[2] Robert G. Nelson,[4] Bjorn O. Eriksen.[1,3] *[1]Metabolic and Renal Research Group, UiT The Arctic University of Norway, Tromso, Norway; [2]University of Michigan, Ann Arbor, MI; [3]University Hospital of North Norway, Tromso, Norway; [4]National Institutes of Health, Phoenix, AZ.*

Background: An abnormally high glomerular filtration rate (GFR), or renal hyperfiltration, may predispose individuals to subsequent rapid GFR decline in diabetes, prediabetes, obesity, and hypertension. This hypothesis remains controversial; however, in diabetes, it is supported by clinical trials showing that treatments that acutely reduce the GFR, such as ACE inhibitors and sodium-glucose cotransport inhibitors, may reduce medium-term GFR decline.

Methods: We investigated whether a higher GFR predicts a steeper long-term GFR decline in two diverse populations, Pima Indians with type 2 diabetes (N=319) and non-diabetic Caucasians in Norway (the Renal Iohexol Clearance Survey [RENIS], N=1594). Because spurious correlations between initial values (e.g., GFR level) and subsequent changes may bias ordinary regression methods, we assessed this relationship as the correlation between the random intercept and random slope in a linear mixed model. This method separately estimates the error term (e.g., the day-to-day variation in the GFR) and random effects, eliminating bias because of regression to the mean.

Results: The mean (SD) baseline GFRs were 149.4 (43.3) and 104.0 (20.1) ml/min, and the median (IQR) follow-up times were 9.1 (4.0-15.0) and 5.6 (5.2–6.0) years in the Pima and RENIS cohorts, respectively. Higher body weight and higher fasting plasma glucose concentration were associated with a higher baseline GFR (a higher intercept) in both cohorts in multivariable adjusted linear mixed regression models with a random intercept and slope ($p<0.001$). The adjusted correlation between the random intercept and random slope was -0.42 (95% confidence interval, -0.55 to -0.26) in the Pima cohort and

-0.32 (-0.40 to -0.23) in the RENIS cohort, demonstrating that higher baseline GFRs were associated with a steeper GFR decline.

Conclusions: Renal hyperfiltration predicts accelerated long-term GFR decline in type 2 diabetes and in the general non-diabetic population.

FR-PO428

Predictors of Net Acid Excretion in the Chronic Renal Insufficiency Cohort (CRIC) Study Landon C. Brown,[1] Alison Luciano,[1] Jane F. Pendergast,[1] Pascale Khairallah,[1] Cheryl A. Anderson,[2] James H. Sondheimer,[3] L. Lee Hamm,[4] Ana C. Ricardo,[5] Panduranga S. Rao,[6] Mahboob Rahman,[7] Edgar R. Miller,[8] Daohang Sha,[9] Dawei Xie,[9] John R. Asplin,[10] Harold I. Feldman,[9] Myles S. Wolf,[1] Julia J. Scialla.[1] *[1]Duke University School of Medicine, Durham, NC; [2]University of California San Diego, La Jolla, CA; [3]Wayne State University School of Medicine, Detroit, MI; [4]Tulane University School of Medicine, New Orleans, LA; [5]University of Illinois at Chicago, Chicago, IL; [6]University of Michigan Health System, Ann Arbor, MI; [7]Case Western Reserve University, Cleveland, OH; [8]Johns Hopkins University, Baltimore, MD; [9]University of Pennsylvania, Philadelphia, PA; [10]Litholink Corp, Chicago, IL.*

Background: In prior work, higher urine net acid excretion (NAE) was associated with lower risk of chronic kidney disease (CKD) progression in patients with diabetes. In order to (1) evaluate potential mechanisms underlying associations between NAE and outcomes, and (2) assess modifiable components for future intervention, we now evaluate independent predictors of NAE in the CRIC Study.

Methods: CRIC is a cohort of adults with entry estimated glomerular filtration rate (eGFR) of 20-70 ml/min/1.73 m^2. 24h NAE was measured as the sum of urine NH_4^+ and titratable acidity in a subset, excluding those with urine pH <4 or ≥7.4 (n=20) and 2 extreme outliers (final n=978). We identified individual variables and sets of variables associated with NAE across the domains of demographics, comorbidities, laboratory measurements, diet, body composition, and medications using linear regression and domain-specific model adjusted R^2.

Results: Mean ± SD of NAE was 33.2 ± 17.4 mEq/day and was higher among those with diabetes (n=496) vs. without diabetes (n=482, 34.4 ± 18.7 vs. 31.9 ± 15.9 mEq/day; p=0.02). Multiple variables associated with NAE in models adjusted for age, sex, eGFR, race/ethnicity, and body surface area (Table). By domains, most variance was explained by demographics, body composition, and laboratory values including kidney function and serum bicarbonate. Among medications, several metabolically active agents including biguanides and allopurinol associated with NAE.

Conclusions: NAE relates to body composition and metabolic factors in addition to diet. This result may help explain previously observed associations between NAE and kidney outcomes in diabetes.

Funding: NIDDK Support

Association of Low Bicarbonate with Increased Risk of Mortality, Dialysis, and Hospitalization in CKD Patients Jerry M. Buysse,[2] David A. Bushinsky,[4] Elizabeth Li,[1] Sarah McNulty,[3] Gerrit Klaerner.[3] *[1]PharmaStat, LLC, Newark, CA; [2]Tricida, Inc, South San Francisco, CA; [3]Tricida, Inc., South San Francisco, CA; [4]University of Rochester Medical Center, Rochester, NY.*

Background: Low bicarbonate has been associated with a higher risk of mortality, dialysis, and hospitalizations in CKD patients. Here we estimate these risks across different levels of low bicarbonate, compared to normal, in a database of 59,710 patients with stage 3-5 CKD (ICD9 585.4, 585.5) or eGFR <60 mL/min/1.73m^2 (Optum Electronic Health Record Dataset, 2007 – 2016).

Methods: Within this database, 43,777 patients were identified with a baseline bicarbonate of ≥12 to <29 mEq/L and baseline eGFR <60 mL/min/1.73m^2. Time-to-event analyses on this dataset evaluated death, progression to dialysis, and first hospitalization or emergency room (ER) visit by baseline bicarbonate groups: 12 – 20 (low), >20 – 22 (moderately low), and >22 – <29 (normal) mEq/L. Hazard ratios (HRs; 95% CIs) for these outcomes in the low and moderately low groups, compared with normal, were determined using a Cox regression model adjusted for time-independent covariates (age, gender, diabetes, hypertension, cerebrovascular disease, and baseline eGFR).

Results: Bicarbonate was low in 6,558 (15%), moderately low in 6,599 (15%) and normal in 30,620 (70%) of patients and the overall mean eGFR was 34.9 mL/min/1.73m^2. Compared with normal, the mortality HRs were 2.63 (95% CI, 2.46 to 2.80) in the low and 1.47 (95% CI, 1.36 to 1.59) in the moderately low bicarbonate groups (p<0.0001). The HRs for progression to dialysis and hospitalization/ER visits were 1.46 (95% CI, 1.32 to 1.62) and 1.46 (95% CI, 1.38 to 1.55), respectively, in the low bicarbonate group (p<0.0001); in contrast, the moderately low bicarbonate group had the same risk as normal for these outcomes [1.10 (95% CI 0.97, 1.24), p=0.13 and 1.08 (95% CI 1.01, 1.15), p=0.02, respectively, for dialysis and hospitalization/ER visits].

Conclusions: There is a strong correlation between low bicarbonate and risk of adverse outcomes (death, dialysis, hospitalizations or ER visits) in CKD, and the risk of these outcomes is significantly greater in patients with low bicarbonate levels (12 – 20 mEq/L) compared to those with normal bicarbonate levels (>22 – <29 mEq/L).

The Association of Metabolic Acidosis with Renal Progression in CKD: Results from the KNOW-CKD Study Hyo Jin Kim,[1] Hyunjin Ryu,[3] Eunjeong Kang,[3] Miyeun Han,[4] Curie Ahn,[3] Kook-Hwan Oh.[3] *[1]Department of Internal Medicine, Dongguk University College of Medicine, Gyeongju-si, Republic of Korea; [3]Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, GyeongGi-Do, Republic of Korea; [4]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Metabolic acidosis, usually manifested by low serum bicarbonate level, is prevalent in chronic kidney disease (CKD). However, its relationship to long-term outcomes is unclear in Korean CKD patients. The purpose of the present study is to evaluate serum bicarbonate as a risk factor for renal outcomes, cardiovascular events and mortality in large-scale Korean CKD cohort patients.

Methods: Among the subjects recruited in the KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease (KNOW-CKD) between 2011 and 2016, we analyzed 1,809 participants who measured for serum bicarbonate levels. Serum bicarbonate level was categorized as low, lower normal, higher normal, and high (< 22, 22-26, 26.1-29.1, ≥30 mmol/L, respectively) groups. Metabolic acidosis was defined as serum bicarbonate < 22 mmol/L. The primary outcome was renal events defined as doubling of serum creatinine, 50% reduction in eGFR from the baseline values, or end-stage renal disease. The secondary composite outcome consisted of cardiovascular events and death.

Results: Patients were 53.6±12.3 years old. The mean serum bicarbonate level was 25.7±3.7 mmol/L. A total 240 (13.3%) patients had metabolic acidosis. Patients were followed for 36.3±17.5 months. After adjustment, there was no significant association between serum bicarbonate and renal outcomes. There was significant interaction of serum bicarbonate with eGFR (interaction *P*=0.029). In an analysis with adjustment, in a subgroup with eGFR ≤45ml/min/1.73m^2, the risk of developing renal outcomes was significantly increased with decreasing (HR, 0.91; 95% CI, 0.87-0.94; *P*<0.001) and the low bicarbonate group was associated with a HR of 1.72 (95% CI, 1.28-2.32; *P*<0.001) compared with lower normal group. Serum bicarbonate was not independently associated with renal outcomes in those with eGFR >45ml/min/1.73m^2 (HR 0.92; 95% CI, 0.78-1.08; *P*=0.297). Serum bicarbonate was not independently associated with secondary outcomes neither in eGFR ≤45 (HR 0.96; 95% CI, 0.89-1.04; *P*=0.339) nor in eGFR >45ml/min/1.73m^2 (HR 0.90; 95% CI, 0.79-1.02; *P*=0.086).

Conclusions: In a cohort of participants with CKD, metabolic acidosis was an independent risk factor for renal progression, particularly for those with advanced decreasing kidney function.

Urinary Citrate Concentrations in a Multi-Ethnic Asian Population of Healthy Participants and CKD Patients Clara L. Ngoh,[2] Boon Wee Teo.[1,2] *[1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [2]Department of Medicine, University Medicine Cluster, National University Health System, Singapore, Singapore.*

Background: Hypocitraturia is a risk factor for nephrolithiasis. Urinary metabolomics from non-Asian centres have suggested that urinary citrate is important for chronic kidney disease (CKD) progression. We studied clinical associations between urinary citrate concentrations and CKD in a multi-ethnic Asian population.

Methods: Data of 187 CKD patients and 87 healthy participants from the Asian Kidney Disease Study and the Singapore Kidney Function Study were used. Four ethnic groups (Chinese, Malay, Indian and Others) were included. Glomerular filtration rate (eGFR) was estimated using the CKD Epidemiology Collaboration (CKD-EPI) equation. Urine citrate concentration was assayed using fluorescence mass-spectrometry. Hypocitraturia was defined as 24-hour urinary citrate excretion (UCE) <320 mmol.

Results: The mean 24-hour UCE in healthy controls and patients were 336 (209 - 443) mmol and 143 (63 - 208) mmol (CKD 1 and 2); 63 (17 - 93) mmol (CKD 3) and 21 (4 - 39) mmol (CKD 4 and 5) respectively (P <0.001). Hypocitraturia was first observed when eGFR <89 ± 12 ml/min/1.73 m^2. Hypocitraturia was also significantly associated with dietary protein intake (P =0.045), eGFR (P <0.001), metabolic acidosis (P <0.001)

and 24-hour proteinuria (P <0.001). In each CKD strata, Malay patients had the lowest 24-hour UCE (difference of 17 ± 24 mmol, P =0.025), after adjusting for age, eGFR, dietary protein intake and chronic medications. In the Malay population, 24-hour UCE was also associated with a history of coronary artery disease (P <0.001), but was not a risk factor for urolithiasis (P =0.590). In healthy controls, there were no ethnic disparities.

Conclusions: Hypocitraturia is observed in early CKD, with Asian ethnic disparities in terms of degree of UCE reduction. This has prognostic implications for renal and cardiac function. Further urinary metabolomics studies should focus on UCE to identify key signature differences between different Asian ethnic groups.

FR-PO432

Acid Retention Worsens as CKD Progresses to More Advanced Stages Nimrit Goraya,[4,5] Jan Simoni,[3] Lauren N. Sager,[2] Donald E. Wesson.[1,6] *[1]Diabetes Health and Wellness Institute, Dallas, TX; [2]Biostatistics, Baylor Scott & White, Temple, TX; [3]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX; [4]Internal Medicine, Texas A and M School of Medicine, Temple, TX; [5]Internal Medicine, Baylor Scott and White Health, Temple, TX; [6]Internal Medicine, Baylor Scott and White Health, Temple, TX.*

Background: Acid (H^+) retention, even without metabolic acidosis by plasma acid-base parameters, mediates eGFR decline in animal models of chronic kidney disease (CKD) and worsens with declining GFR. Patients with reduced eGFR but no metabolic acidosis also have H^+ retention (Wesson, et al. AJP 300:F830) and preliminary longitudinal studies showed that H^+ retention worsened as eGFR decreased over 10 years (Goraya, et al. JASN 26:58A, 2015). Because recent studies support that dietary H^+ reduction slows nephropathy progression, more advanced CKD patients might require more aggressive dietary H^+ reduction if their H^+ retention is indeed greater. Consequently, we further tested the hypothesis that H^+ retention worsens with declining eGFR by comparing cross-sectional measurements of H^+ retention across CKD stages 1 through 4.

Methods: Twenty-six CKD 1, 40 CKD 2, 36 CKD 3, and 36 CKD 4 macroalbuminuric, non-diabetic CKD subjects had H^+ retention measured by comparing the observed to the expected increase in plasma [HCO_3] in response to retained HCO_3 (dose-urine excretion) two hours after an oral $NaHCO_3$ bolus (0.5 meq/Kg bw), assuming 50% body weight HCO_3 space of distribution. Specifically, H^+ retention = [(retained HCO_3/0.5 x body weight) – observed increase in plasma [HCO_3]] x (0.5 x body weight). So, the greater the difference between the expected and observed increase in plasma [HCO_3], the greater the amount of "unaccounted HCO_3" which was assumed to have been HCO_3 that had been titrated by retained H^+.

Results: Cystatin C-calculated eGFR in ml/min/1.73m^2 was as follows: CKD 1=101±8, CKD2=76±6, CKD 3=40±7, and CKD 4=23±5. The Bonferroni correction required a p-value of < 0.0083 for significance among group comparisons for H^+ retention. Accordingly, H^+ retention was greater in CKD 2 vs. CKD 1 (17.4±8.9 vs. 3.0 ± 14.0 mmol, p<0.0001), in CKD 3 vs. CKD 2 (24.9±15.4 vs. 17.4±8.9 mmol, p=0.0079), but not for CKD 4 vs. CKD 3 (32.2±10.5 vs. 24.9±15.4 mmol, p=0.0108).

Conclusions: These cross-sectional data show that H^+ retention increased significantly and progressively from CKD stages 1 through 3 and, along with the previous longitudinal data, support that H^+ worsens as eGFR decreases. Greater H^+ retention in patients with lower eGFR might contribute to their faster eGFR decline and its resolution might require more aggressive dietary H^+ reduction to optimize eGFR preservation.

FR-PO433

Acid Retention Revealed by Urine Citrate Excretion Might Identify CKD Patients for Whom Dietary Alkali Is Kidney Protective Nimrit Goraya,[5,6] Jan Simoni,[4] Lauren N. Sager,[3] Nicolaos E. Madias,[2] Donald E. Wesson.[1,5] *[1]Diabetes Health and Wellness Institute, Dallas, TX; [2]Internal Medicine, Tufts University School of Medicine, Boston, MA; [3]Biostatistics, Baylor Scott & White, Temple, TX; [4]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX; [5]Internal Medicine, Baylor Scott & White Health, Temple, TX; [6]Internal Medicine, Texas A and M School of Medicine, Temple, TX.*

Background: Despite data showing that dietary alkali slows eGFR decline in chronic kidney disease (CKD) stage 3 (CKD 3) patients with mild metabolic acidosis (plasma total CO_2 [$PTCO_2$] >22 mM) (Goraya, et al. KI 86:1031, 2014) and in CKD stage 2 (CKD 2) patients with H^+ retention but no metabolic acidosis ($PTCO_2$ >24.5 mM) (Wesson, et al. AJP 300:F830, 2011; Mahajan, et al. KI 78:303, 2010), KDIGO recommends alkali for only CKD patients with $PTCO_2$ < 22 mM. We tested the hypothesis that urine excretion of the pH-sensitive metabolite citrate identifies H^+ retention, a form of acid stress which causes GFR decline in animal models of CKD, in CKD patients for whom dietary alkali provides kidney protection but for whom current guidelines do not recommend alkali therapy.

Methods: Macroalbuminuric, non-diabetic subjects with CKD stage 1 (CKD 1) and $PTCO_2$ > 24 mM (n=26), CKD 2 with $PTCO_2$ > 24 mM (n=40), and CKD 3 with $PTCO_2$ 22-24 mM (n=36), had H^+ retention measured by comparing observed to expected increase in $PTCO_2$ in response to retained HCO_3 (dose-urine excretion) two hours after oral $NaHCO_3$ bolus (0.5 meq/Kg bw), assuming 50% bw HCO_3 space of distribution. Specifically, H^+ retention = [(retained HCO_3/0.5 x body weight) – observed increase in plasma [HCO_3]] x (0.5 x body weight). Eight-hour urine citrate excretion (8h $U_{cit}V$) was measured after overnight fast.

Results: $PTCO_2$ was similar in CKD 2 (26.2±0.6 mM) and CKD 1 (26.8±0.7 mM) but was lower in CKD 3 (22.8±0.7 mM). Bonferroni correction required p-value significance < 0.0083 for within-group comparisons of H^+ retention and 8h $U_{cit}V$. H^+ retention was greater in CKD 2 than CKD 1 (17.4±8.9 vs. 3.0±14 mM, p<0.0001) despite similar $PTCO_2$ and that for CKD 3 (24.9±15.4 mM) was higher than both CKD 1 (p<0.0001) and CKD 2 (p=0.0079). Furthermore, 8h $U_{cit}V$ was less than CKD 1 (335±125 mg) for both CKD 2 (187±40 mg, p<0.0001) and CKD 3 (159±15 mg, p<0.0001).

Conclusions: Lower than CKD 1 8h $U_{cit}V$ identified H^+ retention in CKD 2 and CKD 3 patients for whom alkali therapy has been kidney protective but whose $PTCO_2$ was not low enough for alkali therapy by current guidelines. Urine citrate excretion is easily measurable in clinical settings and should be further explored as a strategy to identify CKD patients for whom alkali therapy might provide kidney protection.

FR-PO434

Association of Galectin-3 and MMP-2 with Risk of CKD Progression in the Chronic Renal Insufficiency Cohort (CRIC) Study Amanda H. Anderson,[2] Paula F. Orlandi,[2] Jason Roy,[2] Nisha Bansal,[3] Katalin Susztak,[2] John W. Kusek,[1] Harold I. Feldman.[2] *[1]NIDDK, Bethesda, MD; [2]University of Pennsylvania, Philadelphia, PA; [3]The CRIC Study, Philadelphia, PA. Group/ Team: CRIC Study.*

Background: Kidney fibrosis is a final common pathway of progressive chronic kidney disease (CKD). Markers of fibrosis may be independently associated with risk for CKD progression.

Methods: We measured galectin-3 and matrix metalloproteinase-2 (MMP-2) at baseline in a multi-center, prospective cohort study of men and women with CKD, the CRIC Study (N=3,828; mean estimated glomerular filtration rate (eGFR): 45 mL/min/1.73m^2; age range: 21-75 years; 48% diabetes). CKD progression was defined as either the onset of end-stage renal disease or a 50% reduction in eGFR. Cox proportional hazards models were fit to estimate the relationships between galectin-3 and MMP-2 with CKD progression.

Results: Higher baseline galectin-3 levels were significantly associated with patient characteristics; in particular, strong associations existed for females, non-Hispanic blacks, lower eGFR, higher FGF23, and higher inflammatory markers. MMP-2 levels were elevated most significantly among those with higher systolic blood pressure, diabetes, higher urine protein excretion, and higher cardiac biomarker levels. Over a median follow-up of 6 years, the highest quartiles of galectin-3 and MMP-2 were associated with a 2-fold and 1.5-fold increased risk for CKD progression, respectively (Table), after adjusting for traditional risk factors with the exception of eGFR (Model 2), which may be an intermediate factor in this relationship. Although further adjustment for baseline eGFR attenuated this risk, it remained statistically significant.

Conclusions: Galectin-3 and MMP-2 were found to be independent risk factors for CKD progression. Future studies should investigate if these measures improve identification of high-risk subgroups within the population of individuals with CKD.

Sleep Apnea and CKD Progression: A Prospective Observational Study Muna T. Canales,[1] Shahab Bozorgmehri,[2] Areef Ishani,[3] I. D. Weiner,[1] Richard Berry,[1] Rebecca Beyth.[1] *[1]Malcom Randall VAMC & Univ. of Florida, Gainesville, FL; [2]University of Florida, Gainesville, FL; [3]Dept of VA & Univ. of Minnesota, Minneapolis, MN.*

Background: Studies using retrospective data analysis or using diagnostic codes have suggested that sleep apnea (SA) accelerates kidney function decline. We report an interim analysis of the first large, prospective study in CKD assessing this interaction.

Methods: This is a planned 2-year interim analysis of the SNORE Study, an ongoing 3-year prospective study of 248 Veterans aged 18-89 years with eGFR 15-44 ml/min/1.73m^2 who were not on treatment for SA at time of enrollment. At baseline, Veterans underwent an overnight sleep study, and estimation of renal function (serum creatinine, SCr). Renal function was re-assessed annually and intercurrent SCr measures were obtained from the computerized medical record. We determined the association between baseline SA (defined by the apnea-hypopnea index, AHI) and 1) MDRD eGFR trajectory; and 2) risk of 30% decline in MDRD eGFR using linear mixed modeling and cox-proportional hazards regression, respectively.

Results: At entry into the study, mean ±SD age was 73±10 years; 95% were male; 78% were white; mean (±SD) body-mass-index(BMI) was 30±5 kg/m^2; 96% had HTN; and 55% had DM. Mean follow-up at time of this planned interim analysis was 2.2 ± 0.8 years. Median [IQR] number of SCr values was 10 [6-16]. Mean MDRD eGFR was 35±9 ml/min/1.73m^2. Median [IQR] AHI was 10 [4-22]. The proportion with no, mild, moderate or severe SA were 29%, 32%, 19%, and 20%, respectively. EGFR decline was faster among those with moderate to severe SA (-1.68 ± 0.61 ml/min/1.73m^2/year) vs none or mild SA (-0.68 ± 0.39 ml/min/1.73m^2/year) but this was not statistically significant (p = 0.10). Moderate to severe SA was associated with a 58% increased risk of 30% decline

in eGFR, despite adjustment for age and BMI (p=0.05) as compared to those with none or mild SA.

Conclusions: Among Veterans with CKD, the presence of moderate to severe SA is associated with a faster decline in eGFR and increased risk of 30% decline in eGFR over 2 years, but findings are of borderline statistical significance. Completion of 3-year follow-up as planned will provide additional power to make more definitive conclusions regarding the association between SA and CKD progression in this population.

FR-PO436

Urinary Epidermal Growth Factor (uEGF) and Monocyte Chemoattractant Protein-1 (uMCP1) as Biomarkers of Renal Involvement in ANCA-Associated Vasculitis (AAV) Wenjun Ju,[1] Catherine Najem,[2] Viji Nair,[1] David D. Cuthbertson,[3] Rennie L. Rhee,[2] Laura H. Mariani,[1] Jeffrey P. Krischer,[3] Matthias Kretzler,[1] Peter A. Merkel.[2] *[1]University of Michigan, Ann Arbor, MI; [2]University of Pennsylvania, Philadelphia, PA; [3]University of South Florida, Tampa, FL. Group/Team: Vasculitis Clinical Research Consortium and NEPTUNE Network.*

Background: EGF mediates distal tubular epithelial cell function and regeneration. MCP-1 recruits leukocytes to areas of inflammation. This study examined the utility of uEGF and uMCP-1 as biomarkers of renal disease in AAV.

Methods: uEGF and uMCP-1 (normalized to urine creatinine) were measured at enrollment, an active renal disease visit (index), 1-2 visits prior to and after the index, and at 1 year follow-up utilizing urine samples from a multicenter longitudinal cohort of patients with AAV. Chronic kidney disease (CKD) was defined as eGFR< 60 mL/min/1.73 m2 for >3 months. Index visit was defined as the first visit with a new/worse BVAS/WG renal item since prior visit. To assess the association of each biomarker with disease activity, a mixed effect model was used, adjusting for ANCA type (MPO or PR-3), urinary albumin/creatinine ratio (ACR), eGFR, visit type. To assess time to CKD, a Cox proportional hazard model was used, adjusting for demographics, ANCA type, ACR, and eGFR.

Results: At baseline, 165/544 patients had CKD. After adjusting for sex, age, race, ANCA type, eGFR, and albumin/Cr, for each unit increase in baseline uEGF/Cr there was a lower risk of CKD [HR=0.62, (0.43, 0.88), p=0.01)]. Higher baseline uMCP-1/Cr didn't predict risk of CKD [HR=1.14, (0.88, 1.48), p=0.33)]. 112 patients had active renal disease. uEGF/Cr levels did not significantly differ between pre-, post-, and index visits. Compared to index visit, uMCP-1/Cr was lower at pre- and post-index visits (p=0.04 and p<0.01).

Conclusions: In AAV, uEGF predicts progression to CKD independently of ACR and eGFR. uMCP-1, but not uEGF, correlates with renal disease activity. uEGF and uMCP-1 are useful biomarkers in AAV.

Neighborhood Socioeconomic Status and Incident ESRD Milda R. Saunders,[6] Esteban A. Cedillo-Couvert,[8] Lawrence J. Appel,[2] Jiang He,[4] Edward J. Horwitz,[3] Jesse Y. Hsu,[10] Martha L. Daviglus,[8] Michael J. Fischer,[7] Ana C. Ricardo,[8] Hernan Rincon-Choles,[1] Susan P. Steigerwalt,[9] Daohang Sha,[5] James H. Sondheimer,[11] James P. Lash.[8] *[1]Cleveland Clinic, Cleveland, OH; [2]Johns Hopkins Medical Institutions, Baltimore, MD; [3]Solon, OH; [4]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [5]Uiversity of Pennsylvania, Philadelphia, PA; [6]University of Chicago, Chicago, IL; [7]University of Illinois Hospital and Health Sciences Center, Chicago, IL; [8]University of Illinois at Chicago, Chicago, IL; [9]University of Michigan, Ann Arbor, MI; [10]University of Pennsylvania, Philadelphia, PA; [11]Wayne State University School of Medicine, Detroit, MI. Group/Team: On behalf of CRIC Investigators.*

Background: Although individuals with lower socioeconomic status (SES) are disproportionately affected by end-stage renal disease (ESRD), the association of neighborhood SES with incident ESRD has not been thoroughly evaluated. Using data from the Chronic Renal Insufficiency Cohort Study, we evaluated the relationship between neighborhood SES and ESRD.

Methods: Cox proportional hazards to examine the association between neighborhood SES quartiles and incident ESRD. We constructed a neighborhood-level SES summary measure using z scores for 6 census-derived variables using a validated approach.

Results: Among 3291 adults with CKD (mean eGFR 45 ml/min/1.73m^2, median proteinuria 0.19 g/24h), 41% were non-Hispanic white, 42% non-Hispanic black, 13% Hispanic. At study entry, compared to those in the highest quartile SES neighborhoods (Q4), individuals in lowest SES quartile neighborhoods (Q1) were more likely to be younger, female, non-Hispanic black or Hispanic, current smokers, have lower healthy eating scores and physical activity (p<0.001 for each). In addition, Q1 individuals had lower eGFR, higher proteinuria, and were more likely to have diabetes, hypertension, and cardiovascular disease; however, they were as likely as their Q4 counterparts to be on aspirin, statin, and ACE/ARB. During median follow-up of 6.8 years, there were 878 ESRD events. Multivariable analyses are summarized below.

Conclusions: While individuals in low SES neighborhoods had a greater burden of kidney disease risk factors and higher ESRD rates, likelihood of reaching ESRD was explained in part by individual SES.

Funding: NIDDK Support

Human Kidney Tubule Cytosine Methylation Changes Can Improve Models for CKD Progression Caroline A. Gluck,[5] Chengxiang Qiu,[6] Sang Youb Han,[2] Jing Huang,[6] Ae Seo Deok Park,[4] Yi-An Ko,[6] Ioannis Mantzaris,[3] Yong Chen,[6] Amit K. Verma,[1] Matthew Palmer,[6] Katalin Susztak.[6] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Inje University, GoYang, Republic of Korea; [3]Montefiore Medical Center, Bronx, NY; [4]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]University of Pennsylvania, Philadelphia, PA.*

Background: Chronic Kidney Disease (CKD) progresses at variable rates. Patients who progress rapidly are more likely to reach end stage renal disease (ESRD). Current models to predict CKD progression are centered on baseline GFR, age, and albuminuria. These clinical phenotypes do not explain the pathophysiology of progression and cannot account for environmental influence on progression. Cytosine methylation is a stable, cell type specific and environmentally responsive epigenetic signal that affects gene expression patterns. The aim of this project was to determine if genome wide cytosine methylation changes can improve baseline models for CKD progression and identify novel pathways underlying CKD progression.

Methods: Biobanked human kidney tissue was microdissected to isolate kidney tubules. The data set included 69 human kidney tubule samples with associated cross-sectional and longitudinal clinical data. Histopathology for samples were graded on 20 independent parameters. Genome wide cytosine methylation was analyzed using the Illumina Infinium 450K chip. Transcript level changes were determined using the Affymetrix RNA microarray. Subject-specific adjusted GFR slopes were determined using best linear unbiased prediction to account for random variation. Variables for CKD progression models were selected by a machine learning regression analysis method, "LASSO", to improve model accuracy and reduce model overfitting. Methylation and

transcript levels were added to baseline linear regression models and both R^2 and akaike information criterion (AIC) values were ranked to determine model fitness.

Results: The final model (M1) for CKD progression based on LASSO-selected variables included: baseline GFR, age, albuminuria (dipstick), CKD stage, diabetes, height, and vessel intimal fibrosis. Adding the top gene transcript level to M1 (M2) improved model fitness. Finally, addition of the methylation level at the top genome loci to M2 (M3) further improved model fitness.

Conclusions: Human kidney tubule cytosine methylation levels may improve CKD progression models even after gene expression levels are included. Methylation changes in kidney tissue may be useful biomarkers for CKD progression and may be functionally important in CKD progression.

Urinary Epidermal Growth Factor Predicts Rapid GFR Decline in the General Non-Diabetic Population Jon V. Norvik,[4,3] Wenjun Ju,[5] Viji Nair,[5] Vidar T. Stefansson,[3] Jørgen Schei,[4,3] Trond G. Jenssen,[1] Marit D. Solbu,[4] Matthias Kretzler,[2] Bjorn O. Eriksen,[6] Toralf Melsom.[4] *[1]Oslo University Hospital, Oslo, Norway; [2]U.Michigan, Ann Arbor, MI; [3]UiT The Arctic University of Norway, Tromso, Norway; [4]University Hospital of North Norway, Tromsø, Norway; [5]University of Michigan, Ann Arbor, MI; [6]University of Tromsø, Tromsø, Norway*.

Background: Biomarkers are needed to distinguish people at high risk to develop chronic kidney disease (CKD) for early and targeted clinical care. Lower levels of urinary epidermal growth factor (uEGF) have been associated with increased tubular atrophy, interstitial fibrosis and rapid progression in CKD of various etiologies. We investigated whether lower uEGF predicted risk for rapid glomerular filtration rate (GFR) decline in the general non-diabetic population.

Methods: In the Renal Iohexol Clearance Survey of Tromsø 6 (RENIS-T6), we measured GFR by iohexol-clearance in 1,594 middle-aged persons without diabetes or chronic kidney disease. Of these, 1,299 (81%) had a follow-up GFR measurement after a median of 5.6 years in the RENIS-Follow Up and a random sample of 87 persons had a third GFR measurement. uEGF levels at baseline were measured using an ELISA assay. We used a linear mixed model with random intercept and slope to assess the relationship between uEGF and change in GFR and a multiple logistic regression model to examine the association between uEGF and rapid GFR decline (defined as annual GFR decline > 3 mL/min/1.73m^2).

Results: The mean (SD) annual GFR decline rate was -0.86 (2.13) mL/min/1.73m^2. Lower baseline uEGF was independently associated with a steeper GFR decline rate (-0.16 (95% confidence interval (CI) -0.26 to -0.05) mL/min/1.73m^2 per 1 SD decrease in log-transformed uEGF after adjusting for CKD risk factors such as urinary albumin-to-creatinine ratio (ACR)). The annual GFR decline rate for participants with uEGF levels below the median was -1.00 (95% CI -1.14 to -0.86) mL/min/1.73m^2 compared to -0.71 (95% CI -0.86 to -0.56) mL/min/1.73m^2 for those above the median level (P=0.006), adjusted for sex, age and ACR. The multivariable adjusted odds ratio for rapid decline was 1.91 (95% CI 1.27 to 2.88) for those with uEGF below the median level.

Conclusions: Lower uEGF levels predicted rapid GFR decline in the general non-diabetic population.

FR-PO440

Rate of GFR Decline and Incident CKD among Primary Care Patients with Normal or Mildly Reduced Renal Function Farrukh M. Koraishy,[1,2] Joanne Salas,[1] Jeffrey F. Scherrer.[1] *[1]Saint Louis University, Saint Louis, MO; [2]Internal Medicine/Nephrology, John Cochran VA Medical Center, Saint Louis, MO*.

Background: Rapid GFR decline is associated with adverse outcomes. The risk factors associated with the rate of GFR decline in association with incident CKD among primary care patients with normal or mildly reduced GFR are not well defined.

Methods: From an academic primary care patient registry containing electronic health record data, we identified 2,219 adults with at least three eGFR values (calculated using the CKD-EPI equation) between July 1st 2008 – June 30th 2016. We required patients to have an initial (baseline) eGFR value between 60-119 ml/min/1.73 m^2. Rapid GFR decline was defined as a decline in eGFR of >5 ml/min/1.73 m^{2}per year and incident CKD was defined as an eGFR of <60 ml/min/1.73 m^2. The clinical and socio-demographic characteristics were compared using chi-square tests and independent samples t-tests. Adjusted logistic regression models were computed to measure the associations between covariates among rapid decliners stratified by baseline eGFR of 60-89 (mildly reduced) and 90-119 (normal) ml/min/1.73 m^2.

Results: Rapid GFR decline was significantly associated with incident CKD, older age, black race, unmarried status, lower neighborhood socioeconomic status (nSES), hypertension, type 2 diabetes, current smoking and initial eGFR (p<0.01). Incident CKD was significantly associated with unmarried status (p =0.028), and type 2 diabetes (p<0.0001) in rapid decliners and with anxiety (p = 0.005)and depression (p = 0.5) in slow decliners. Older age, hypertension and initial GFR were significantly (p< 0.0001) associated with incident CKD in both groups. Multivariate logistic regression analysis restricted to patients with rapid GFR decline and mildly reduced baseline eGFR, revealed only older age being significantly associated with incident CKD (OR = 1.04 [1.01-1.08]). A separate multivariate logistic regression model among rapid decliners with a normal baseline eGFR revealed only type 2 diabetes being significantly associated with incident CKD (OR = 3.83 [1.35-10.89]).

Conclusions: Among primary care patients with normal or mildly reduced GFR (who are typically not referred to nephrology), patient characteristics associated with incident CKD differ by the rate of GFR decline and by the baseline eGFR. Our findings identify high-risk patients in primary care and would inform development of risk prediction models for incident CKD.

The Effect of Statin Therapy on Clinical Outcomes in Patients with CKD: The Results from the KNOW-CKD Seong yeong An, Ki Heon Nam, Jong Hyun Jhee, Seohyun Park, Seung Hyeok Han, Dae-Suk Han. *Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea*.

Background: Statin therapy is a main part of the management of lipid disorders in patients with CKD. However, the effects of statin use against CKD progression and cardiovascular events are still under debate in these patients. Also, it is unknown whether clinical outcomes are affected by lipophilic or hydrophilic nature of statins.

Methods: We studied the effects of use and types of statins on clinical outcomes in 2,238 patients using the database from the Korean Cohort Study for Outcome in Patients with Chronic Kidney Disease (KNOW-CKD). Statin users were defined if they were treated with statins at baseline. And, statin users were further classified into lipophilic or hydrophilic statin users depending on types of statins. Primary outcome was a composite of a 50% decline in eGFR, ESRD, cardiovascular events, and death.

Results: During a mean follow-up duration of 38 months, the composite outcome occurred in 74 (9.3%) patients among statin users as compared to 55 (7.1%) among non-users (P=0.119). In a multivariable Cox model after adjustment of confounding factors, statin use was not associated with a decreased risk of primary outcome (HR, 0.85; 95% CI, 0.67-1.07; P=0.168). However, in a subgroup of patients with eGFR of ≥ 30 ml/min/1.73 m^2, statin users were significantly associated with a 39% reduction in primary outcome as compare to non-users (HR, 0.61; 95% CI, 0.39-0.95; P=0.030). In addition, hydrophilic statin users had a lower risk of developing the endpoint than non-users in this subgroup (HR, 0.57; 95% CI, 0.34-0.97; P=0.037), whereas lipophilic statin users did not have such benefit (HR, 0.65; 95% CI, 0.38-1.09; P=0.104). However, there was no difference in HRs for primary outcome between hydrophilic and lipophilic statin users.

Conclusions: Statin use was associated with improved outcomes in early stages of CKD and the effectiveness was similar between hydrophilic and lipophilic statin users.

FR-PO442

The Association between Alcohol Consumption and Renal Outcome Is Modified by CKD Stages: The Results from the KNOW-CKD Heebyung Koh, Jaeyeol Kwon, Ki Heon Nam, Seong yeong An, Seung Hyeok Han. *Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea*.

Background: Several studies have suggested that moderate alcohol drinking exhibits beneficial effects on the development of CKD. However, studies that examined the association between alcohol consumption and progression of CKD in patients with CKD are scarce.

Methods: We analyzed drinking pattern according to CKD stages and examined the association between alcohol consumption and CKD progression using the database from the prospective KoreaN cohort study for Outcome in patients With CKD (KNOW-CKD). After excluding 641 patients who have missing data, a total 1597 patients were included. Alcohol consumption within last 1 year was categorized into none, ≤ 1 drinks/month, 2-4 drinks/month, 2-3 drinks/week, and ≥ 4 drinks/week. Primary outcome was a composite of halving of eGFR or the onset of ESRD.

Results: The mean age was 53.5 years and 61.6% were male. Patients with decreased renal function were less likely to consume alcohol (P for trend < 0.001). There was a significant interaction between alcohol consumption and eGFR (p < 0.001). During a median follow-up of 38.1 months, primary outcome occurred in 263 (16.5%) patients. In a multivariate Cox regression after adjustment of age, sex, BMI, SBP, CRP, total cholesterol, smoking and CCI score, more alcohol consumption was significantly associated with a lower risk for adverse outcome. Compared to non-drinkers, hazard ratios (HRs) for developing primary renal outcome who consumed 2-4 drinks/month, 2-3 drinks/week, ≥ 4 drinks/week were 0.67 (95% confidence interval [CI], 0.47-0.97; p=0.034), 0.59 (95% CI, 0.37-0.95; p=0.031) and 0.29 (95% CI, 0.11-0.79; p=0.015), respectively. However, beneficial effect of alcohol was lost after eGFR, urine protein-creatinine ratio, and hemoglobin were added to the model.

Conclusions: We demonstrated no association between alcohol consumption and renal adverse outcomes after adjustment of CKD-related factors. Thus, beneficial effects of alcohol on CKD progression should be interpreted cautiously with CKD severity taken into account.

FR-PO443

Self-Reported Snoring Is Associated with Incident CKD Development: A Community-Based Prospective Cohort Study Jaeyeol Kwon, Heebyung Koh, Ki Heon Nam, Seong yeong An, Tae-Hyun Yoo. *Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea.*

Background: Reports have shown sleep disordered breathing symptoms including habitual snoringto be clearly associated with the development ofmetabolic derangements and vascular diseases. However, the relationship between habitual snoring and renal function is not well investigated. Therefore, this study aimed to evaluate the association between habitual snoring and the development of incident chronic kidney disease in a cohort of subjects with normal renal function.

Methods: Data were retrieved from the Korean Genome and Epidemiology Study, a prospective community-based cohort study. A total of 9304 subjects with normal renal function were included in the final analysis. Subjects were classified into three groups, based on self-reported snoring frequency at baseline: non-snorer, infrequent snorer, frequent snorer. The primary endpoint of study was development of CKD, defined as estimated glomerular filtration rate < 60 mL/min/1.73 m^2.

Results: The mean age was 52 years. The non-snorer, infrequent snorer, frequent snorer groups each included 3573(38.4%), 3856(41.4%) and 1875(20.2%)subjects. During a mean follow-up duration of 101±53 months, 272(7.6%), 332(8.6%) and 197(10.5%) subjects developed CKD in the non-snorer, infrequent snorer and frequent snorer group. Cox Proportional Hazard model analysis revealed that snoring was an independent risk factor for incident CKD development [HR, 1.21; 95% CI,1.007-1.468; P 0.0043]. This finding was significant even after adjustments were made for confounding factors including the presence of metabolic syndrome and eGFR at baseline.

Conclusions: Snoring may increase the risk of CKD development in subjects with normal renal function. Managing sleep quality could play a role in preserving renal function.

FR-PO444

The Effects of Coffee Intake on the Incident CKD in General Population Heebyung Koh,[1] Ki Heon Nam,[1] Meiyan Wu,[2] Boyoung Nam,[2] Seung Hyeok Han.[1] *[1]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 21 PLUS, Yonsei University, Seoul, Republic of Korea.*

Background: The effects of habitual coffee consumption on health have been a public concern. However, the association between coffee intake and kidney disease is unknown. This study aimed to investigate whether coffee intake can have an impact on the development of chronic kidney disease (CKD) in general population.

Methods: Using the database from the Korean Genome and Epidemiology Study (KoGES) from 2001 to 2014, we analyzed 9644 subjects with normal renal function. Coffee consumption was categorized into 5 groups; 0/wk (n=2232), < 1 cup/wk (n=618), 1-6 cups/wk (n=1690), 1 cup/day (n=2645), and ≥ 2 cups/day (n=2459). All measurements such as blood pressure, body mass index, estimated glomerular filtration rate (eGFR), fasting glucose, hemoglobin, and lipid profiles during follow-up period were treated as time-varying covariates. The primary outcome was incident CKD defined as an eGFR < 60 mL/min/1.73m^2.

Results: The mean age was 52.0 years and 4594 (47.6%) were male. At baseline, higher coffee consumers were younger, had lower blood pressure, and had lower prevalence of hypertension and diabetes as compared to non-drinkers or lower consumers. Time-averaged blood pressure was also lower as coffee consumption was increased. A multivariate linear regression model showed that high coffee consumption independently associated with low systolic blood pressure (ß = -0.52, P < 0.001). During a mean follow up of 124.8 months, 839 (8.6%) participants developed CKD. The incident CKD occurred in 224 (10.0%), 69 (11.2%), 148 (8.8%), 209 (7.9%), and 174 (7.1%) individuals in the coffee consumption groups of 0/wk, < 1 cup/wk, 1-6 cups/wk, 1 cup/day, and ≥ 2 cups/day, respectively (P for trend < 0.001). In a time-varying Cox model after adjustment of confounding factors, coffee consumption of ≥ 1 cup/day [hazard ratio (HR), 0.74; 95% confidence interval (CI), 0.59-0.92; P = 0.01] and ≥ 2 cups/day (HR, 0.77; 95% CI, 0.60-0.98; P = 0.03) were significantly associated with a lower risk of CKD development.

Conclusions: Our findings suggest beneficial effect of coffee intake of ≥ 1 cup/day on the incident CKD. This can be partly explained by coffee intake-associated decrease in blood pressure.

FR-PO445

Optimal Target for Blood Pressure Control in Patients with CKD: The Results from the KNOW-CKD Study Seong yeong An, Seung Hyeok Han, Heebyung Koh, Jaeyeol Kwon. *Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea.*

Background: There has been a long debate regarding what level blood pressure (BP) should be lowered to in patients with chronic kidney disease (CKD). This study aimed to investigate the optimal target BP levels to retard the progression of CKD in participants in the KoreaN cohort study for Outcome in patients With Chronic Kidney Disease (KNOW-CKD).

Methods: Between February 2011 and July 2016, a total of 2,238 patients were enrolled. After excluding 22 patients in whom systolic blood pressure (SBP) was not measured, 2,226 patients were included in the analysis. Patients were categorized into 7 groups according to baseline SBP levels; <110, 110-119, 120-129, 130-139, 140-149, 150-159, and ≥160 mmHg. Primary outcome was a composite of a 50% decline in estimated glomerular filtration rate, or end stage renal disease.

Results: The mean age of the patients were 53.6 years and 1,362 (61.2%) were male. At enrollment, 2,138 (96%) had hypertension and the mean SBP was 127.9±16.2 mmHg. During a mean follow up of 36.7 months, primary outcome occurred in 334 (15.0%) patients. There were increases in the number of the composite outcome as SBP increased (P for trend < 0.001). In a multivariate Cox analysis after full adjustment for confounding factors including age, sex, body mass index, smoking status, comorbidities, use of antihypertensive agents, eGFR, and overt proteinuria, SBP of < 110 mmHg [hazard ratio (HR), 0.52; (95% confidence interval (CI), 0.31-0.87, P=0.012] and SBP of 110-119 mmHg (HR, 0.62; 95% CI, 0.42-0.91; P=0.015) were significantly associated with a lower risk of the composite endpoint as compared to SBP of 130-139 mmHg. In contrast, HRs for the composite outcome were significantly higher in patients with SBP of 150 to 159 mmHg (HR, 1.47; 95% CI, 1.00-2.15; P=0.049) and those with SBP of ≥ 160mmHg (HR, 2.00; 95% CI, 1.30-3.09; P=0.002) than in patients with SBP of 130-139 mmHg. There was no difference in the risk of primary outcome between SBP categories of 120-129, 130-139, and 140-149 mmHg.

Conclusions: In this study, we found a significant linear relationship between SBP and adverse renal outcomes in patients with CKD. Thus, lowering the target BP below the levels proposed by the current guideline may be beneficial to attenuate deterioration of kidney function.

FR-PO446

Smoking Is a Risk Factor for the Progression of CKD: From the Korean Cohort Study for Outcome in Patients With CKD Arum Choi,[1] Meiyan Wu,[1] Seung Hyeok Han.[2] *[1]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 21 PLUS, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea.*

Background: Smoking is a risk factor of developing incident chronic kidney disease (CKD). However, most studies included relatively healthy participants without CKD and studies on the association between smoking and deterioration of kidney function in patients with CKD are scarce. Therefore, we aimed to evaluate the effect of smoking on kidney disease progression and dose-response relationship by pack-years in these patients.

Methods: The KoreaN cohort study for Outcome in patients With Chronic Kidney Disease (KNOW-CKD) is a nation-wide prospective observational cohort study from 9 centers in Korea. A total of 2218 patients were included in the final analysis. Patients were categorized into never-, former-, and current- smokers. Primary outcome was a composite of a reduction of eGFR of ≥ 50%, initiation of dialysis, or kidney transplantation.

Results: The mean age was 53.6±12.3 years and 1356 patients (61.1%) were male. Compared to never-smokers, former- or current- smokers had higher prevalence of diabetes (38.4% vs. 29.6%, P < 0.001) and cardiovascular disease (14.3% vs. 7.8%, P < 0.001) at baseline. In addition, these patients had higher blood pressure (128.9±16.7 vs. 127.0±15.8 mmHg, P = 0.007), lower eGFR (48.6±27.9 vs. 52.2±32.2 ml/min/1.73m^2, P = 0.004) and higher level of proteinuria [1.6 (0.2-1.8) vs. 1.2 (0.1-1.2) g/day, P < 0.001] than never-smokers. During a mean follow-up duration of 36.7±18.2 months, primary outcome occurred in 168 (16.5%) in former- or current-smokers as compared to 164 (13.6%) in never-smokers (P = 0.057). In a multivariable Cox regression analysis after adjustment of confounding factors, smokers were significantly associated with an increased risk of primary outcome (HR, 1.36; 95% CI, 1.05-1.77; P = 0.020). In addition, HRs for primary outcome were 0.94 (95% CI, 0.65-1.35; P = 0.723), 1.49 (95% CI, 1.04-2.14; P = 0.030), 1.83 (95% CI, 1.12-2.86; P = 0.008), and 2.21 (95% CI, 1.39-3.51; P = 0.001) for <14.9, 15-29.9, 30-44.4 and ≥45 pack-years, respectively, suggesting that there was a dose-response relationship between smoking consumption and CKD progression.

Conclusions: This study clearly showed that smoking is associated with deterioration of kidney disease. Thus, quitting smoking should be a part of preventative strategy in management of CKD.

FR-PO447

Secondhand Smoking Is a Risk Factor for Incident CKD Development Sukyung Kang,[1] Tae-Hyun Yoo,[2] Jaeyeol Kwon,[2] Heebyung Koh,[2] Youn kyung Kee.[2] *[1]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 21 PLUS, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea.*

Background: Smoking is a well-known risk factor for renal function decline. However, the risk of CKD development in nonsmokers exposed to secondhand smoke is not well elucidated yet. This study aimed to investigate the association between secondhand smoking and the risk of CKD development among never-smoking adults.

Methods: Subjects who participated in the Korean Genome and Epidemiology Study (KoGES) from 2001 to 2014 were enrolled. A total of 4856 subjects with normal renal function and without a history of smoking were included in the final analysis. The subjects were divided into two groups depending on secondhand smoke exposure (SSE).

The primary outcome was development of CKD defined as estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73m^2.

Results: In the SSE and non-SSE groups, the mean ages of the subjects were 49.5 ± 7.4 and 51.6 ± 7.9 years, the numbers of male subjects were 289 (14.0) and 466 (16.7), and the mean estimated glomerular filtration rates (eGFR) were 95.1 ± 12.7 and 93.9 ± 12.8 ml/min/1.73 m^2, respectively. Among the subjects in the SSE group, the duration of SSE showed a significant positive correlation with BMI and HbA1c. Cox analysis revealed that SSE was a significant risk of CKD development even after adjustments were made for confounding factors (Hazard ratio, 1.15; 95% confidence interval, 1.02-1.33; P = 0.049).

Conclusions: Secondhand smoking significantly increased the risk of CKD development. In addition, factors such as obesity and insulin resistance may be affected by SSE. Avoiding SSE may have an effect on preventing the development of CKD.

FR-PO448

Significance of Cardio-Ankle Vascular Index in the Long-Term Renal Prognosis for Patients with Non-Diabetic CKD Akihiro Shimizu, Hideo Okonogi, Tetsuya Kawamura, Shinya Yokote, Masahiro Suyama, Kei Matsumoto, Kentaro Koike, Nobuo Tsuboi, Yoichi Miyazaki, Masato Ikeda, Makoto Ogura, Takashi Yokoo. *Division of nephrology and hypertension, The Jikei university school of medicine, Tokyo, Japan.*

Background: Cardio-ankle vascular index (CAVI) is a non-invasive index of arterial stiffness and, theoretically, independent of blood pressure at the time of measurement. Although the role of CAVI as a predictor of cardiovascular events has been reported, few studies have considered the renal prognosis. The present retrospective cohort study was undertaken to investigate the association between CAVI and the long-term renal prognosis in patients with non-diabetic chronic kidney disease (NDCKD).

Methods: We included 44 NDCKD patients (CKD stages 1, 2, 3 and 4, and follow-up period ≥2 years), who were diagnosed by first time renal biopsy (RBx). Renal outcome was defined as reaching 30% decline in eGFR from baseline. We analyzed the association between CAVI and outcome, and risk factors affecting the incidence of outcome, by Cox proportional hazard model, receiver-operating characteristic (ROC) analysis, and Kaplan–Meier analysis.

Results: As a result, a median follow-up time was 86 months (range, 27–101 months), and 15 patients reached outcome. Baseline CAVI, eGFR, hypertension and uric acid were significantly associated with outcome by univariate Cox analysis (p<0.05). By ROC analysis, the areas under the curve for diagnosis of the future outcome by baseline CAVI was 0.838 (p=0.0007), and CAVI cut-off value was calculated as 7.50 (Sensitivity 93%, Specificity 62%). Then CAVI≥7.5 (HCAVI) and eGFR were independently associated with outcome by multivariate Cox analysis, (Hazard ratio (HR) 7.3, 95% confidence interval (CI) 1.2-141, p<0.05, and HR 0.97, 95%CI 0.94-0.99, p<0.05, respectively). Furthermore, Kaplan-Meier analysis showed that outcome-free survival was significantly lower in HCAVI group compared with CAVI<7.5 group (Log-rank test, p=0.0017).

Conclusions: These results indicated that CAVI at the time of RBx was independently associated with long-term renal prognosis in NDCKD patients.

FR-PO449

CKD Patients Are Exposed to More Proton Pump Inhibitors (PPIs) Compared to Non-CKD Patients in a Tertiary Single Center Heejeong Lee,[2] Songhee Oh,[3] Haekyung Lee,[4] Jin seok Jeon,[1] Dong-Cheol Han,[2] Soon hyo Kwon.[2] *[1]Soon Chun Hyang Univ. Hospital, Seoul, Republic of Korea; [2]Soon Chun Hyang University Hospital, SEOUL, Republic of Korea; [3]soon chun hyang university hospital, SEOUL, Republic of Korea; [4]Soonchunhyang University Hospital, SEOUL, Republic of Korea.*

Background: Proton pump inhibitor (PPI) is associated with incident chronic kidney disease (CKD), CKD progression and end-stage renal disease (ESRD). However, the extent of PPI in CKD patients comparing to non CKD patients is still unclear.

Methods: We conducted a retrospective study on patients (>18 years old) who received PPI in a single tertiary center out-patient clinic (750 beds, Seoul, South Korea) from Jan. 2014 to Dec. 2015. PPIs need doctor's prescription in South Korea. All data were collected from electronic medical record. The PPI prescription and their characteristics were analyzed according to CKD-EPI equation of the patients.

Results: Our sample consisted of 9,112 patients. Females were 50.3% were and CKD (eGFR<60mL/min) patients were 9.8%. Among CKD patients, 721 (7.9%) were categorized as stage 3 or 4, 176 (1.9%) were stage 5 or ESRD. Total 7 types of PPIs were prescribed. During the study period, median duration of PPI usage was 120days [interquartile range, 63-273] in CKD 3-4 group, 105 days [56-271] in CKD 5-ESRD group and 90 days [56-175] in non-CKD group. Patients with CKD stage 3 or 4 took longer duration of PPI than non-CKD paients (p<0.001). Main departments of medicine which prescribed PPIs in CKD group were gastroenterology (39.4%), cardiology (28.2%), nephrology (15.1%) and neurology (4.2%). Compared to the non-CKD group, the CKD stage 3 or 4 and CKD stage 5 orESRD group was taking more drugs simultaneously (6.9 ± 4.2 vs 4.5 ± 2.4; p<0.001, 5.6 ± 2.8 vs 4.5 ± 2.4 ; p<0.0001, respectively).

Conclusions: CKD patients are exposed to more PPIs compared to non-CKD patients. Physicians should pay careful attention when prescribing PPIs in patients with CKD.

FR-PO450

Augmented Effect of Blood Pressure on Renal Arteriolosclerosis via Increased Arterial Stiffness in CKD Ryo Zamami, Tsuyoshi Miyagi, Kentaro Kohagura, Masanobu Yamazato, Akio Ishida, Yusuke Ohya. *University of the Ryukyus, Nishihara-cho, Japan.*

Background: We reported arteriolar hyalinosis, a potential marker for disrupted autoregulation system may potentiate hypertensive glomerular damage. Arterial stiffness is suggested to relate hypertensive organ damage by interaction with arteriolar sclerosis. Therefore, we conducted a cross-sectional study to determine the effect of arterial stiffness on the relationship between blood pressure and renal arteriolar hyalinosis.

Methods: A total of 102 consecutive patients with chronic kidney disease (CKD) who underwent renal biopsy and had data of branchial-ankle pulse wave velocity (baPWV) were recruited. Arteriolar hyalinosis was semiquantitatively assessed via grading system (grade 0 –3).

Results: The mean value for age, blood pressure and estimated glomerular filtration rate (eGFR) were as follows: 46 years, 123/74 mmHg, and 72ml/min/1.73m^2. Patients were divided into four subgroup according to the median value of baPWV and systolic BP (SBP). Max hyalinosis grade was the highest in high baPWV / high SBP group. In multivariate logistic regression analysis, revealed that high baPWV / high SBP were significantly associated with the presence of highest max hyalinosis grade 3 (Odds ratio, 8.22; 95% confidence interval 1.79-37.7, P<0.01). Moreover, this group had the highest urine protein among four groups. Even in normal SBP, patients with high baPWV had higher max hyalinosis grade compared with low baPWV.

Conclusions: In CKD patients, arterial remodeling may cause progression of CKD via augmented effect of blood pressure on renal arteriolosclerosis.

FR-PO451

Even Overweight Relates to Proteinuria Accompanied with Glomerular Hypertrophy in Non-Nephrotic CKD Ryo Zamami, Tsuyoshi Miyagi, Kentaro Kohagura, Chisato Fukuhara, Masanobu Yamazato, Akio Ishida, Yusuke Ohya. *University of the Ryukyus, Nishihara-cho, Japan.*

Background: Glomerular hypertrophy (GH), a potential marker for glomerular hypertension is suggested to relate progression of chronic kidney disease (CKD). However, risk factors for GH are not clear. Thus, we conducted cross sectional study to elucidate clinical factors, which relate to the presence of GH among CKD patients.

Methods: A total of 107 patients with non-nephrotic CKD who underwent renal biopsy were recruited. The glomerular diameter of the biopsy specimen was measured. We compared clinical characteristics between the patients with GH and those without it, which defined as equal or larger than the 75th percentile value of glomerular diameter.

Results: The mean value for age, estimated glomerular filtration rate (eGFR), and body mass index (BMI) were as follows: 40 years, 86 ml/min/1.73m^2 and 24.0 kg/m^2. The median (quartile range) of maximal GD was 219 (202 – 245) mm, and the 75th percentile value was 245 mm. The group with GH had higher proportion of male and higher value of BMI, systolic blood pressure, uric acid and triglyceride. There was positive correlation between glomerular diameter and BMI. In the multivariate logistic regression analysis, overweight (BMI ≥ 25 kg/m^2) was significantly associated with GH (odds ratio 4.66, 95% confidence interval 1.33–16.3, P=0.02) independent of age, sex and some confounding factors such as diabetes mellitus. In the overweigh patients, glomerular diameter was significantly correlated with urine protein (r=0.52, P=0.0007).

Conclusions: Overweight is an independent determinant for glomerular hypertrophy. Even overweight may be a risk factor for progression of CKD in association with GH.

FR-PO452

The Impact of Prematurity on Postnatal Renal Medulla Development Joan Li,[5] Michael Guandalini,[2] Yoga Kandasamy,[4] Karen M. Moritz,[3] Peter Trnka.[1] *[1]Child and Adolescent Renal Service, South Brisbane, QLD, Australia; [2]Lady Cilento Children's Hospital, South Brisbane, NSW, Australia; [3]The University of Queensland, St Lucia, NSW, Australia; [4]Townsville Hospital, Douglas, NSW, Australia; [5]University of Queensland, Australia Institute for Bioengineering and Nanotechnology, Brisbane, QLD, Australia.*

Background: In humans, nephrogenesis ceases before birth but the renal medulla continues to develop postnatally and reaches full functional maturation at around 12-18 months of age. Premature birth is associated with reduced nephron number and increased risk of kidney and cardiovascular disease. However, the impact of prematurity on renal medulla remodelling and maturation and its contribution to the development of adult disease is unknown.

Methods: Preterm babies born at ~28 weeks of gestation and term babies without renal or urinary tract abnormalities were included in this study. Renal ultrasound was performed in 35 premature babies at 32 weeks and 37 weeks post menstrual age (PMA). In addition, 42 babies born at term were examined in the first week of life. Additional ultrasound images were taken at six months of age in all babies. Total kidney volume, renal cortical and pyramid thickness were measured.

Results: In premature babies the average kidney volume increased significantly from 32 weeks to 37 weeks PMA (post menstrual age) (6.89 ± 0.4 vs 10.38 ± 0.29, p ≤ 0.0001). However, at 37 weeks PMA the kidney volume and the pyramid/cortex ratio were still significantly smaller in premature babies compared to term babies (10.38 ± 0.29 vs 12.85 ± 0.48, p ≤ 0.0001; 2.22 ± 0.08 vs 2.79 ± 0.08, P = 0.0001 respectively). Premature infants

also had a significantly lower eGFR (73.6 vs. 79.3 mL/min/1.73 m^2; p = 0.03). By 6 months the average kidney volume was no longer different between premature and term babies due to significant catch-up growth of the premature kidney. The pyramid/cortex ratio remained significantly lower in the premature babies than term babies (2.01±0.05 vs 2.5±0.10, p = 0.0006). In term babies the medulla region continued to develop and mature; renal pyramid/parenchyma ratio increased from birth to 6 months (0.59±0.01 vs 0.62±0.05, p = 0.05). For premature babies the pyramid/parenchyma ratio didn't change significantly from birth to 6 month suggesting the medullary growth was significantly impaired.

Conclusions: Taken together, these results suggest that premature birth has sustained effects on postnatal renal medulla development and remodelling with potentially negative impact on renal function later in life.

FR-PO453

Urinary Epidermal Growth Factor as a Prognostic Marker for the Progression in Children with Alport Syndrome Baihong Li,[1] Fangrui Ding,[1] Fang Wang,[1] Viji Nair,[2] Matthias Kretzler,[2] Wenjun Ju,[2] Jie Ding.[1] *[1]Peking University First Hospital, Beijing, China; [2]University of Michigan, Ann Arbor, MI.*

Background: Alport syndrome (AS) is a rare hereditary kidney disease manifested with progressive renal failure, vast majority of the cases are caused by defects in type IV collagen genes. Considerable variation exists in terms of disease progression among patients with AS. Identification of patients at high risk of rapid progression remains an unmet need. Urinary epidermal growth factor has been shown to be independently associated with risk of progression to end stage kidney disease (ESKD) or 40% reduction of baseline eGFR in multiple independent adult CKD cohorts. In this study we aim to assess the prognostic value of uEGF in children with AS.

Methods: 117 pediatric patients with AS and 72 healthy children (3-18 year-old) were included in this study. uEGF was measured in duplicates in baseline urine samples using ELISA (R&D) and concentration was normalized by urine creatinine (uEGF/Cr). In patients with longitudinal follow up data (n=38), progression was defined as deteriorated kidney function (CKD stage increase) during follow-up period (average follow-up 29.92±16.18 months). The area under the receiver operating characteristic (ROC) curve was used to assess the discriminative power of the marker.

Results: uEGF/Cr decreases with age in both healthy children and pediatric patients with AS. The decrease rate of uEGF/Cr with age was faster in AS patients. uEGF/Cr is significantly correlated with GFR (r=0.75, p<0.001), after adjustment for age. In 38 patients with longitudinal follow-up, we observed a significant correlation between uEGF and eGFR slope (r=0.58, p<0.001). Patients with lower uEGF/Cr level were at increased risk of progression to a higher CKD stage. uEGF distinguished progressors from patients who do not show CKD stage advance with an AUC of 0.89, versus 0.80 by GFR and 0.79 by ACR.

Conclusions: Our work suggested that uEGF/Cr may be used as a biomarker for accelerated kidney function decline in pediatric patients with AS. It may help to identify patients at high risk of progression for targeted clinical care and improve the patients'stratification in interventional trials. Future validation with more patients and longer follow-up time will be required.

FR-PO454

Analysis of the Plasma Proteome Reveals Dysregulation of Molecular Pathways in Patients with Stage 4 CKD Ewelina Kulikowski,[2] Sylwia Wasiak,[2] Laura Tsujikawa,[2] Christopher Halliday,[2] Stephanie Stotz,[2] Dean Gilham,[2] Ravi Jahagirdar,[2] Kamyar Kalantar-Zadeh,[3] Richard A. Robson,[1] Michael Sweeney,[4] Jan O. Johansson,[4] Norman C. Wong.[2] *[1]CHristchurch Clinical Studies Trust, Christchurch, New Zealand; [2]Resverlogix Corp, Calgary, AB, Canada; [3]University of California Irvine, School of Medicine, Orange, CA; [4]Resverlogix Inc., San Francisco, CA.*

Background: Chronic kidney disease (CKD) is associated with progressive loss of renal function. To gain insight into molecular mechanisms and biological consequences of pathway dysregulation in CKD, plasma proteome profiling of stage 4 CKD patients was performed using a novel somamer-based approach coupled to bioinformatics.

Methods: Eight subjects with stage 4 CKD not on dialysis (mean eGFR=20 ml/min/1.73m^2) and eight matched control subjects (mean eGFR=78.5 ml/min/1.73m^2) participated in the study. Plasma samples were collected for analysis with the SOMAscan® 1.3K platform, which detects 1305 proteins in a multiplexed, sensitive and reproducible manner. Proteomics data were analysed with Ingenuity Pathway Analysis (IPA®).

Results: SOMAscan® proteomic analysis of plasma from CKD versus control subjects identified 289 differentially expressed proteins (difference>10%, p<0.05). 191 of those proteins were upregulated by more than 50% in CKD plasma relative to controls. Many of the enriched markers correlate with CKD progression, including cystatin C, B2M, LCN2, LFABP and FGF23. Other differentially expressed proteins include cytokines and their soluble receptors, adhesion molecules, metalloproteases, complement, coagulation and fibrinolytic factors. IPA® bioinformatics of the plasma proteome confirmed an upregulation of pathways known to be activated in CKD such as the inflammatory and immune response, endothelial dysfunction, thrombosis, renin-angiotensin system, calcification and oxidative stress.

Conclusions: This study provides an exhaustive list of plasma proteins that are dysregulated in stage 4 CKD. In combination with pathway analysis, this CKD plasma proteome contributes new knowledge of molecular processes that accompany CKD and potential new disease markers.

FR-PO455

Mineralocorticoid Receptor Blockers and Renal Outcomes in Patients with Heart Failure and CKD Thomas Mavrakanas,[2,3] Nadia Giannetti,[1] Ruth Sapir-Pichhadze,[2] Ahsan Alam.[2] *[1]Division of Cardiology, McGill University Health Centre, Montreal, QC, Canada; [2]Division of Nephrology, McGill University Health Centre, Montreal, QC, Canada; [3]Division of General Internal Medicine, Geneva University Hospitals, Geneva, Switzerland.*

Background: The protective effect of mineralocorticoid receptor blockers (MRBs) against cardiovascular death or heart failure hospitalization has been demonstrated in patients with chronic kidney disease (CKD). However, safety concerns limit their use in this population. Furthermore, the effect of MRBs on CKD progression is unknown.

Methods: We conducted a retrospective cohort study including consecutive adult patients from the heart failure clinic of a tertiary care center who were already treated with an angiotensin converting enzyme inhibitor or an angiotensin receptor blocker. The exposure of interest was treatment with MRBs by 6 months from registration to clinic. Persistent doubling of serum creatinine was the primary efficacy outcome. The composite of doubling of serum creatinine or potassium >6 mmol/l was the primary safety outcome. The composite of death from any cause, myocardial infarction, or admission for decompensated heart failure was the secondary outcome.

Results: A total of 314 patients who were prescribed MRBs were compared to 1116 patients who were never treated with MRBs. Among them, 121 and 408 patients, respectively, had CKD. MRBs had to be discontinued in 34/121 patients with CKD (28.1%) and 55/165 patients without CKD (33.3%) (p-value=0.35). While MRB treatment increased the risk of persistent creatinine doubling in patients without CKD, in CKD patients a protective trend was seen (p-value for interaction 0.02). Similarly, the primary safety outcome occurred more commonly with exposure versus non-exposure to MRBs in non-CKD but not in CKD patients (p-value for interaction 0.02). CKD status did not alter MRB effect on death from any cause, myocardial infarction, or admission for decompensated heart failure (p-value for interaction 0.27).

Conclusions: CKD status significantly alters MRB effect on renal outcomes. Treatment with MRBs may be nephroprotective in heart failure patients with CKD.

Markers of the Adaptive Immune Response Are Associated with Advancing CKD Status Dana C. Crawford, William S. Bush, Jessica N. Cooke Bailey, John F. O'Toole, John R. Sedor. *Case Western Reserve University, Cleveland Heights, OH.*

Background: Germline and somatic genomic variation represent the bulk of 'omics data in precision medicine research. These data, however, may fail to capture the dynamic biological processes that underlie disease development, particularly for diseases of aging such as chronic kidney disease (CKD).

Methods: To demonstrate the value of additional dynamic precision medicine data, we sequenced somatic T-cell receptor rearrangements from genomic DNA collected during a clinical encounter from 15 CKD participants. Participants were consented as part of a larger precision medicine research project at a large urban public hospital. Genomic DNA was extracted from whole blood, and T cell receptors were sequenced with six replicates per sample using Adaptive Biotechnologies' immunoSEQ assays coupled with the Illumina NextSeq PE. All sequences were assembled using Adaptive Biotechnologies' ANALYZER bioinformatics pipeline. Demographic and clinical data closest to the time of blood draw were extracted from the electronic health record.

Results: The average age of patients was 61.73 years, more than half (60%) were female, and the majority were African American (80%). T-cell receptor diversity was estimated using productive clonality, a measure ranging from 0 (polyclonal samples; more diversity) to 1 (oligoclonal samples; less diversity). Productive clonality in this sample ranged from 0.0151 to 0.2565 with a mean of 0.1030 (standard deviation or SD=0.0669). Average productive clonality did not statistically differ by sex: females = 0.0811 (SD=0.0533) and males = 0.1358 (SD=0.0764). We then tested for correlations between T-cell receptor diversity and biomarkers of CKD, including disease status calculated using the CKD-EPI equation. Reduced T-cell diversity was associated with increased creatinine (R^2=0.0995). BUN (R^2=0.0258), and eGFR (R^2=0.066) but not with white blood cell count (R^2=0.0004). Reduced T-cell diversity was also associated with worsening CKD status (R^2=0.2362), with a higher on average productive clonality (0.0488) among stage 4 patients (n=5) compared with stage 3 (0.0330; n=8) and stage 2 patients (0.0149; n=2).

Conclusions: These data suggest an association between advanced CKD and premature aging of the adaptive immune system and highlight the potential of dynamic 'omic data to generate novel hypotheses about disease mechanisms.

FR-PO457

Remote Candidate Prognostic Biomarkers of CKD among People with Type 1 Diabetes Mellitus (T1DM) Jian Cai,[1] Michael Merchant,[1] Adam E. Gaweda,[1] Michael E. Brier,[1] Brad H. Rovin,[2] Minghao Ye,[3] Jan Wysocki,[3] Mark E. Molitch,[3] Daniel Batlle,[3] Jon B. Klein.[1,4] *[1]University of Louisville School of Medicine, Louisville, KY; [2]Ohio State University Wexner Medical Center, Columbus, OH; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Robley Rex VAMC, Louisville, KY. Group/Team: For DCCT/EDIC study and CKD Biomarkers Consortium.*

Background: It has been difficult to identify biomarkers that antedate the development of CKD. We used a plasma proteomic approach to evaluate samples from participants in the Diabetes Control and Complications Trial/Epidemiology of Diabetes Intervention and Complications (DCCT/EDIC) with the goal to establish surrogate prognostic biomarkers of CKD in T1DM.

Methods: Samples from 23 cases (defined as participants who went on to develop CKD stage 3 (GFR<60ml/min/1.73m^2) were examined prior to developing CKD. Two samples from these cases were analyzed; an early sample during DCCT and a later sample from each same subject during EDIC. 23 controls were participants in whom GFR remained well above 60ml/min/1.73m^2 after collection of the two matching samples during DCCT and EDIC. Samples were immunodepleted, trypsinized, labeled with 10-plex tandem mass tag (TMT), and analyzed by high resolution 2D-LCMS. The data were processed prior to Wilcoxon Rank-Sum difference testing (p-value <0.05). Candidate biomarker selection was based on fold-changes (FC, <1.5 and >1.5) to identify case/control DCCT and EDIC differences.

Results: When the sample for proteomic analysis was obtained during DCCT, cases and controls had similar age, sex, GFR, HBA1C, blood pressure, albumin excretion rate (AER) and duration of DM. During EDIC, about 15 years later, there were differences (p<0.01) in GFR (83.9 vs 101.9 ml/min/1.73m^2), AER (810.5 vs 24.6mg/24h) and HbA1c (9.5 vs 8.3) between cases and controls. 1,667 identified protein groups were quantified. Cross sectional cases/control proteome differences were observed during DCCT (n=12) and EDIC (n=103) study time frames. Nine proteins were observed with >1.5FC (DCCT, n=2; EDIC, n=7), many involved in insulin signaling, inflammation, and coagulation/microvascular function. These differences in proteins were identified about 20 and 4yrs, respectively before the development of CKD.

Conclusions: In people with T1DM the plasma proteome, years prior CKD stage3, has unique proteins that are potential biomarkers of disease progression.

FR-PO458

Uromodulin Synthesis Is Reflected by Metabolic Profiles in the General Population Claire Boulange,[2,1] Eric G. Olinger,[4] Manuja Kaluarachchi,[2,1] John C. Lindon,[2,1] Natsuko Tokonami,[3] Tomoaki Takata,[3] Olivier Devuyst.[3] *[1]Imperial College london, London, United Kingdom; [2]Metabometrix Ltd, London, United Kingdom; [3]University of Zurich, Zurich, Switzerland; [4]University of Zürich, Zürich, Switzerland.*

Background: Uromodulin (UMOD) is the most abundant protein in mammalian urine, synthesized exclusively along the thick ascending limb (TAL) in the kidney and with highly variable urinary levels in the general population. GWAS associated common variants in the *UMOD* promoter region, driving higher UMOD production, with increased risk for chronic kidney disease (CKD). UMOD regulates TAL transport but the mechanisms linking UMOD and risk for CKD remain unknown. We hypothesize. We speculate that the production rate of this protein imposes a metabolic burden to the TAL that might be reflected by metabolic profiles.

Methods: Overnight urine was collected from male volunteers (eGFR>80mL/min) and overnight UMOD excretion was determined (14.71±0.60mg, n=279). gender Extreme low (2.79±0.26mg, n=25) and high (34.11±2.14mg, n=25) age-matched UMOD excretion groups were defined and urine was analyzed by ^{1}H NMR spectroscopy and UPLC-MS. Mitochondrial phenotyping was performed on isolated TAL's from *Umod*$^{-/-}$, *Umod*$^{+/+}$ and Tg$^{Umodwt/wt}$ mice on FVB background, mimicking variable UMOD production rates in humans.

Results: Unsupervised principal component analysis evidenced natural clustering of metabolic data for urine samples stratified according to UMOD excretion. Many significant metabolic features were associated with overnight UMOD excretion in both NMR and UPLC-MS datasets. Biological interpretation pinpoint to Metabolic pathways involving these metabolites are related to protein synthesis and degradation, energy metabolism (fatty acid metabolism, citric acid cycle) and oxidative stress. Mitochondrial phenotyping revealed lower oxygen consumption rates and mitochondrial ATP production at baseline in TAL samples from *Umod*$^{-/-}$ vs. *Umod*$^{+/+}$ mice; and an increased maximal respiratory capacity in those from Tg$^{Umodwt/wt}$ vs. *Umod*$^{+/+}$ mice.

Conclusions: These results indicate a particular specific urinary metabolic profile associated with divergent UMOD production in the general population, supported by specific changes in mitochondrial metabolism reflecting uromodulin production in mouse models. The metabolic burden of increased UMOD production may, over time, contribute to CKD susceptibility.

Risk of ESRD and Mortality in Stage 3 CKD Using a Risk Estimator Youngjun Park, Nawsheen Chowdhury, Candace D. Grant, Shayan Shirazian. *Department of Medicine, Division of Nephrology, NYU-Winthrop Hospital, Mineola, NY.*

Background: Accurate assessment of the risk of end stage renal disease (ESRD) is important in determining which patients with chronic kidney disease (CKD) to prepare for renal replacement therapy (RRT). This can be challenging in earlier CKD when the short term risk for ESRD can be low but the lifetime risk is high. We applied a short term (2-year) risk calculation method to a population of stage 3 CKD patients and carried out an observational study to assess outcomes.

Methods: This is a cross-sectional study of 409 patients with stage 3 CKD. The ESRD risk estimation was determined using the 2 year risk estimator developed and validated by Tangri et al. A 2-year risk of progression to ESRD of <2.5% was considered low risk (LR) and ≥ 2.5% was considered high risk (HR). Patients were then organized into groups by age (< 60, 60 to 79 and ≥80 years). Over the following 2 years development of ESRD and death were recorded.

Results: The average age for the entire group was 70±14 years, 68% were men, 78% were white, the mean GFR was 42 ml/min/1.73m2 and the mean 2 year ESRD risk was 2.2%. The 2 year calculator determined 76% (n=311) of our entire stage 3 cohort to be LR. None of the LR group reached ESRD versus 5% of the HR group and 5% of the LR group died versus 10% of the HR group. The 2 year risk of ESRD progressively diverged with younger age with a 4.2% risk for patients <60, versus a 1.9% and 1.1% risk for patients 60 to 79 and ≥ 80, respectively (p<0.001). For patients younger than 60, 46% of them were at high risk compared to 10% in the ≥ 80 year age group (p<0.001). We found none of the patients aged ≥ 80 versus 4% of the younger patients aged <60 years reached ESRD. In contrast, 11% of the older patients versus 4% of the younger patients died.

Conclusions: These results show that in our population age had a significant impact on 2 year estimated ESRD risk. Risk determinations and outcomes showed progressively higher ESRD risk with younger age and a higher risk of death with older age. A validated risk calculator to assign patients to LR and HR groups appears to help predict clinical outcomes and might be a useful tool in guiding proper selection of patients for preparation for RRT.

FR-PO460

Concomitant Acute Pyelonephritis and Obstruction Duration Affects Renal Outcome in Obstructive Uropathy by Urolithiasis Jung-ho Shin, So-hee Jeong, Jin Ho Hwang, Su Hyun Kim. *Chung-Ang University Hospital, Seoul, Republic of Korea.*

Background: Urolithiasis related obstructive uropathy is one of increasing causes of CKD, which commonly encountered in clinical field. Obstruction release from urolithiasis can be easily delayed with a lack of suggested golden time to prevent renal function deterioration. Here, we investigated the clinical significance and renal outcomes of urolithiasis related obstructive uropathy.

Methods: This is a pilot study of 414 from 2315 patients in urolithiasis related obstructive uropathy cohort which is recruited between Jan. 2005 and Dec. 2015. Clinical outcomes were evaluated with respect to obstruction duration, acute kidney injury (AKI), and acute pyelonephritis (APN) accompanied by obstructive uropathy.

Results: Median duration of obstruction (elapsed time to release obstruction) was 5 days and APN was accompanied in 17.1% of patients. In the patients whose obstruction was relieved within 2 days from the symptom onset, 14.5% showed spontaneous release of obstruction. In the patients with concomitant APN, mean age was older (57.67vs 52.5 years old, P=0.007), estimated GFR (eGFR) at the time of admission was lower (63.5 vs. 79.4 ml/min/1.73m2, P<0.001), and the use of NSAIDs were lower (49.3% vs. 74.9%, P<0.001). The eGFR decrease of >30% from baseline (P<0.001) and eGFR decrease of >50% (P<0.001) occurred significantly more in patients with concomitant APN. The AKI grades by KDIGO showed worse renal outcome in advanced stage (P=0.001). The patients whose obstruction was released within 2 days from the symptom onset, showed more favorable outcome in eGFR decrease of >30% (P=0.019). When we adjusted gender, age, HT, DM, use of NSAIDs, APN, AKI grades, and obstruction release over 2 days for a multivariate analysis, APN (HR 2.2, CI 1.01-4.65; P=0.047) and the obstruction release after 2 days (HR 3.55, CI 1.34-9.38; P=0.011) were independently associated with eGFR decrease of >30%. Concomitant APN was also associated with eGFR decrease of >50% (HR 8.006, CI 1.86-34.38, P=0.005). The use of NSAIDs was associated with favorable renal outcomes.

Conclusions: In urolithiasis related obstructive uropathy patients, concomitant APN was strongly associated with renal function deterioration after obstruction release. The elapsed time to release obstruction also affected to renal function.

FR-PO461

Prevalence and Severity of Dental Plaque and Dental Calculus in Patients with CKD Namita Kalra,[4] Ujjawal Roy,[1] Sunil Agarwal,[3] Ashok K. Tripathi,[5] Om P. Kalra.[2] *[1]Orchid Medical Centre, Ranchi, India; [2]Nephrology, Pt. B.D. Sharma University of Health Sciences, Rohtak, India; [3]Medicine, University College of Medical Sciences and GTB Hospital, Delhi, India; [4]Pedodontics, University College of Medical Sciences, Delhi, India; [5]Biochemistry, University College of Medical Sciences, Delhi, India*.

Background: Patients with CKD have impaired immune responses which may predispose them to various infections, such as dental plaque. Further, altered calcium phosphorus balance and high prevalence of mineral bone disease may result in poor dental health including dental calculus, decayed and missing teeth. The goal of this study was to assess the status of dental plaque, dental calculus and missing teeth in patients with CKD.

Methods: 150 age and sex matched subjects were recruited under 3 groups, 50 in each. These included : Group A - healthy controls; Group B - patients with CKD stage 3 to 5 not yet on maintenance hemodialysis (MHD) and Group C - patients of CKD stage 5 who were on MHD for >1 month. Detailed examination of the teeth for dental plaque and dental calculus was done. Severity of dental plaque and dental calculus was assessed by using dental plaque and calculus scores on a scale of 1 to 3. Dental plaque and dental calculus score was calculated after recording individual dental plaque and calculus score and dividing it by the number of teeth examined. Patients with history of recent tobacco use, diabetes mellitus, oral infection and drug intake such as calcium channel blockers, anticonvulsants, immuno-suppressants and allograft recipients were excluded.

Results: Mean dental plaque score and dental calculus score in patients with CKD were significantly higher as compared to healthy controls ($p<0.001$ for both). Mean dental plaque score was: healthy controls : 0.98±0.39, Group B : 1.56±0.52 and Group C : 1.81±0.53. Mean dental calculus score was: healthy controls : 0.91±0.65, Group B : 1.77±0.56 and Group C : 1.81±0.56. Further, it was found that the dental plaque score showed a progressive rise with increase in severity of kidney disease. Patients of CKD stage 5 who had been on MHD had significantly higher mean dental plaque score as compared to those with CKD stage 5 who had not yet been started on HD ($p=0.029$). Further, patients with CKD had higher number of missing teeth (Group B – 2.36±4.08, Group C – 2.64±3.60) as compared to healthy controls (1.10±2.28).

Conclusions: Patients with CKD have higher prevalence of dental plaque and dental calculus. The prevalence of dental plaque correlates with increase in severity of kidney disease. Higher prevalence of dental pathology may contribute to malnutrition in patients with CKD.

FR-PO462

Urinary Renin and Angiotensinogen for Predicting Antiproteinuric Effect of Angiotensin Receptor Blocker Do Hee Kim,[1,2] Junseok Jeon,[2] Hye Ryoun Jang,[2] Jung eun Lee,[2] Wooseong Huh,[2] Hye-Young Kim,[1,3] Dae Joong Kim,[2] Ha Young Oh,[2] Yoon-Goo Kim.[2] *[1]Division of nephrology, Department of Medicine, Chungbuk National University Hospital, Cheongju, Republic of Korea; [2]Division of nephrology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [3]Department of Medicine, Chungbuk National University College of Medicine, Cheongju, Republic of Korea*.

Background: Although urinary angiotensinogen (AGT) and renin were reported to reflect the activity of intrarenal renin-angiotensin system which is known to be activated in proteinuric chronic kidney disease patients, the clinical value of urinary AGT and renin during antiproteinuric treatment is yet to be determined. In this study, we investigated the clinical impact of baseline urinary AGT or renin on the antiproteinuric effect of angiotensin receptor blocker (ARB).

Methods: A multicenter, prospective observational cohort study was conducted in 205 patients with overt proteinuria (urinary protein/creatinine ratio [uPCR] ≥ 1 mg/mgCr) between April 2009 and December 2011. Low salt diet was thoroughly educated in all patients at the time of enrollment. Baseline urinary AGT/creatinine ratio (uAGT/Cr), renin/creatinine ratio (uR/Cr), and sodium/creatinine ratio (uNa/Cr) were measured before starting valsartan. The uPCR was followed up at 2 months and 6 months in all patients. A total of 60 patients were followed up for 5 years.

Results: The mean age of patients was 47.6 ± 12.5 years and 51.2% were male. The uPCR was 2.32 ± 1.43 mg/mgCr and the estimated glomerular filtration rate was 63.2 ±28.8 ml/min/1.73m^2. The uNa/Cr was 1.30 ± 1.25 mg/mgCr. Natural logarithms of uAGT/Cr (ln[uAGT/Cr]) and uR/Cr (ln[uR/Cr]) were significantly higher in 53 patients with uPCR decrement greater than 1mg/mgCr at 6 months. uNa/Cr was higher in patients with uPCR decrement greater than 1 mg/mgCr at 2 months. Multivariable regression analysis identified uNa/Cr as a significant factor associated with the degree of uPCR decrement at 6 months (β = -0.206, P = 0.047). Ln(uR/Cr) was identified as a predictive factor (OR 1.244, 95% CI 1.04-1.49, P = 0.018) for uPCR decrement higher than 1 mg/mgCr at 6 months in logistic regression analysis.

Conclusions: Our study showed that baseline ln(uR/Cr) and uNa/Cr have the potential to be used as prognostic markers predicting antiproteinuric effect of ARB. The clinical importance of low salt diet education was also shown.

FR-PO463

AKI after Radical Nephrectomy as Risk Factor for CKD: Retrospective Analysis from an Italian Cancer Center Laura Cosmai,[5] Camillo Porta,[2] Fabio Malberti,[1] Marina Foramitti,[3] Maurizio Gallieni.[4] *[1]Azienda Istituti Ospitalieri di Cremona, Cremona, Italy; [2]IRCCS San Matteo University Hospital Foundation, Pavia, Italy; [3]Istituti Spitalieri Cremona, Cremona, Italy; [4]Ospedale San Carlo Borromeo - ASST Santi Paolo e Carlo - University of Milano, Milano, Italy; [5]Nephrology and Dialysis, ASST Santi Paolo e Carlo, Milano, Italy*.

Background: Radical nephrectomy is a significant risk factor for chronic kidney disease (CKD), and there are few reports on the renal outcome after radical nephrectomy for cancer. The aim of this study was to determine the incidence of AKI and whether postoperative AKI is associated with new-onset CKD after radical nephrectomy for renal cell cancer (RCC).

Methods: We conducted a retrospective study of 650 adult patients (>40 years old), from an Italian Cancer Centers with normal renal function who underwent unilateral radical nephrectomy for a solitary renal cortical tumour and were pathologically diagnosed with RCC between January 2010 and February 2017. Post-operative AKI was classed using risk, injury, failure, loss and end-stage kidney disease (RIFLE) criteria. CKD was defined as a decrease in estimated glomerular filtration rate (GFR) to <60 mL/min/1.73 m2

Results: According to the RIFLE criteria, 195 of 216 patients fell into the AKI risk category 1, 16 patients fell into the AKI injury category and 5 patients fell into the AKI failure category. Multivariate analysis revealed as major result that higher preoperative GFR was an independent risk factor for postoperative AKI, although older age, male gender higher body mass index, smaller RCC size were independent risk factors too. New-onset CKD was more prevalent in the AKI risk group than in patients without AKI 1 year after surgery (56.1% versus 43.9%, respectively) and 3 years after surgery (52% versus 31%). Patients who experienced post-operative AKI had a 5.1-fold higher risk of new-onset CKD after multiple adjustments, that confirms other recent study.

Conclusions: AKI after radical nephrectomy in patients is a potent risk factor for new-onset CKD. Prevention of post-operative AKI, but also the assesment of kidney function pre-nephrectomy, is essential for reducing the incidence of CKD after nephrectomy.

FR-PO464

Elevated Time-Varying BP Is Associated with Greater Risk of Progression of CKD Than Elevated Baseline BP in Children with Non-Glomerular CKD Ben C. Reynolds,[3] Jennifer Roem,[1] Christopher B. Pierce,[2] Joseph T. Flynn,[4] Mina Matsuda-Abedini,[8] Susan L. Furth,[5] Bradley A. Warady,[6] Rulan S. Parekh.[7] *[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]Royal Hospital for Children, Glasgow, Glasgow, United Kingdom; [4]Seattle Children's Hospital, Seattle, WA; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]The Children's Mercy Hospital, Kansas City, MO; [7]The Hospital For Sick Children, Toronto, ON, Canada; [8]The Hospital for Sick Children, Toronto, Toronto, ON, Canada*.

Background: Effective treatment of hypertension in children with chronic kidney disease (CKD) slows the rate of progression to end stage renal disease (ESRD). Less clear is whether longitudinal (e.g. annual time varying) measures of blood pressure (BP) are associated with greater risk of progression. We quantified this risk with systolic or diastolic casual BP measurement > 90th centile at baseline or longitudinally in children with CKD.

Methods: Of 826 children (257 glomerular disease, 569 non-glomerular) enrolled in the CKiD cohort, we determined if BP <50th, 50th-90th, or >90th centile (for age, gender and height) was associated with a composite outcome of CKD progression: ESRD or GFR reduction of 50% from baseline. BP category was defined as time-fixed (baseline) and time-varying (last available). Pooled logistic models using inverse probability weighting were used to estimate the relative hazard odds of progression associated with each BP category and stratified by CKD diagnosis.

Results: Higher SBP percentile was associated with an elevated risk of progression, the time-varying metric estimating a higher magnitude of risk compared to time-fixed baseline measures (Table). Adjustment for potential confounders did not qualitatively change the risk in non-glomerular disease but nullified the estimate in glomerular disease.

Conclusions: Elevated time-varying systolic BP is associated with a greater risk of CKD progression than baseline BP in children with non-glomerular CKD. Clinicians can use updated BP to assess risk for progressive CKD and adjust management accordingly.

30% GFR Decline in 2 Years Was Observed among 62.5% of CKD Patients Initiated Hemodialysis: A Longitudinal GFR Trajectory Analysis Ahmad B. Kaihan,[4] Yoshinari Yasuda,[1] Takayuki Katsuno,[3] Sawako Kato,[3] Takahiro Imaizumi,[6] Takaya Ozeki,[5] Manabu Hishida,[2] Naotake Tsuboi,[3] Shoichi Maruyama.[3] *[1]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Aichi-ken, Japan, Nagoya, Japan; [2]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Nagoya University Graduate School of Medicine, Nagoya, Japan; [4]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [5]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, AICHI-KEN, Japan., Nagoya, Japan; [6]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: GFR decline rate has been highlighted as a new renal outcome for the clinical trial to reduce the sample size and shorten the observation period. We aimed to evaluate the eGFR trajectory among CKD patients initiated hemodialysis (HD).

Methods: A longitudinal GFR trajectory analysis was conducted among consecutive 112 CKD patients initiated HD between 2014 and 2016 at Nagoya University Hospital. All serum creatinine (SCr) values were collected from the electronic medical record from 2000 to the initiation of HD and eGFR annual decline rate (ADR) was calculated. eGFR ADR stratified into quartile classification and 30%, 40% eGFR decline and doubling of SCr in 2 years were analyzed in association with eGFR ADR.

Results: The causative kidney diseases were 41 (37%) diabetic nephropathy, 37 (33%) nephrosclerosis, 14 (13%) chronic glomerulonephritis, and 20 (18%) others. Median follow-up period was 5.6 years. The proportion of 30%, 40% eGFR decline, and the doubling of SCr in 2 years were shown in Table 1. Kaplan-Meier survival curve analysis for 30% eGFR decline revealed significant difference among quartiles (log-rank p< 0.0001). The associating factors for eGFR ADR were in SCr, eGFR, protein creatinine ratio (PCR), Hb, and SUA univariate, and eGFR (OR 1.14, 95% CI 1.04-1.26, p=0.0008) and PCR (OR 3.27, 95% CI 1.20-8.92, p= 0.02) in multivariate logistic regression analyses. 30% eGFR decline was observed significantly earlier in the greater amount of PCR quartiles (p<0.001). In GFR categories, G3a showed a tendency to meet 30% eGFR decline later than other GFR categories.

Conclusions: Although 30% GFR decline was the earlier renal outcome in 2 years, approximately 40% of patients initiated HD were negative in this study. The longer observation period should be considered among slowly progressive CKD patients with mild proteinuria and mild-moderately impaired renal function.

Funding: Other U.S. Government Support

Delayed Renal Recovery and Long-Term Renal Survival after Radical Nephrectomy for Renal Cell Carcinoma Hee jung Park,[3] Ha nee Jang,[5] Tae won Lee,[2] Hyun Seop Cho,[2] Hyun-Jung Kim,[4] Dong Jun Park,[2] Eunjin Bae,[1] Se-Ho Chang.[3] *[1]Gyeongsang National University Changwon Hospita, Changwon, SEOUL, Republic of Korea; [2]Gyeongsang National University Hospital, Jinju-si, Gyeongsangnam-do, Republic of Korea; [3]Gyeongsang national university hospital, Jinju, Jinju-si, Republic of Korea; [4]School of Medicine, Gyeongsang National University, Jinju, Republic of Korea; [5]Gyeongsang National Univ. Hospital, Jinju, Republic of Korea.*

Background: Radical nephrectomy has been associated with chronic kidney disease (CKD). It is unclear whether delayed renal recovery after surgery affects long-term renal outcome. We investigated the association between delayed renal recovery and long-term renal survival in patients undergoing radical nephrectomy for renal cell carcinoma. We assessed factors affecting the recovery of renal function.

Methods: We reviewed medical record database for all patients (>18 years old) who underwent radical nephrectomy for renal cell carcinoma between from January 2009 to December 2016. Among these, we included patients with a 3-month renal function test after surgery. Renal outcome was defined as a doubling in serum creatinine or End stage renal disease. Estimated GFR were evaluated at baseline, 3 months and the last follow-up. We excluded patients with estimated glomerular filtration rate (GFR) of less than 40 ml/min/1.73m2. Estimated GFR calculated using the Chronic Kidney Disease Epidemiology Collaboration equation. Delayed renal function was defined by creatinine did not decrease less than preoperative value.

Results: Among the 105 patients who met inclusion criteria, 70 (66.7%) were males. The median age at nephrectomy was 62 year (range 25-84 years). 60 (57.1%) were diagnosed with delayed renal recovery: The average serum creatinine was 0.85 ± 0.22 mg/dL, and average estimated GFR was 102.89 ± 29.46 ml/min/1.73m2. The average follow-up period was 39.55 ± 24.48 months. Multiple linear regression analysis shows delayed renal recovery, baseline estimated GFR to be significantly associated with long-term renal survival (p=0.05, p=0.040, respectively). Hypertension and increased baseline creatinine were the factors affecting early recovery of renal function.

Conclusions: Our results suggest that hypertension and renal impairment for renal cell carcinoma patients may delayed renal recovery after radical nephrectomy, and adversely affect kidney function over a long term period.

FR-PO467

Renal and Metabolic Complications of Long-Term Total Parental Nutrition (TPN) in Pediatric Patients Poornima Baddi,[4] Najeeb Zoubi,[2] Joseph L. Lelli,[1] Tej K. Mattoo.[3] *[1]Children's Hospital of Michigan, Detroit, MI; [2]Children's hospital of Michigan, Detroit, MI; [3]Children's Hospital of Michigan, Detroit, MI; [4]Pediatric Nephrology, Children's hospital of Michigan, Detroit, MI. Group/Team: Wayne state university.*

Background: The number of children requiring prolonged TPN is increasing and yet very little is known about its potential long term complications. The objective of this study was to evaluate renal and metabolic complications of prolonged TPN in patients at our institution.

Methods: We did a retrospective chart review with prospective follow-up of 26 patients who, with the exception of one patient, were followed at our Children's hospital Intestinal Rehabilitation Program (CHIRP) clinic. We included patients 1 to 15 (median of 4) years of age that had been on TPN for ≥ 6 months at the time of data collection. Patients who received <20% of nutrition as TPN and those with other co-morbidities were excluded. Variables that were studied included anthropometric data, indication and duration of TPN, TPN formulation and daily volume, intestinal anatomy, details on oral nutritional supplements, current medications, blood and urine chemistry results, renal imaging results, and number of acute kidney injury (AKI) episodes.

Results: Of the 26 patients, 8 (31%) received 100% nutrition as TPN; 10 (38%) patients received a mean of 80% and 8 received 20%-80% nutrition as TPN. The Median duration of TPN administration was 4 years (Range 1-15). Recurrent AKI was the commonest complication in 24 (92%) patients with a median of 8 (range 4 - 40) episodes per patient. Other complications were hypertension (38%), echogenic kidneys on ultrasound examination (27%), renal size asymmetry (15%), hydronephrosis (15%), renal calculi (11%), phosphaturia, hypophosphatemia and nephrocalcinosis (4%), and recurrent post-infectious Glomerulonephritis (4%). Glomerular hyper filtration, as defined by modified Schwartz eGFR of >135ml/min/m^2, was noted in 12 (46%) patients.

Conclusions: Children on long-term TPN are at risk of CKD due to recurrent AKI, hypertension, and glomerular hyperfiltration. Appropriate renal and metabolic monitoring is recommended.

FR-PO468

A Prediction Model for Progression to ESKD, Based on the Neural Network (ANN) Analysis, in IgA Nephropathy Patients Francesco P. Schena,[7] Vito walter Anelli,[5] Paolo Tomeo,[9] Tommaso Di noia,[6] Maria luisa Russo,[8] Graziella D'arrigo,[2] Giovanni Tripepi,[1] Vladimir Tesar,[4] Carmine Zoccali,[3] Rosanna Coppo.[4] *[1]CNR-IBIM, Reggio Calabria, Italy; [2]Clin. Epid. and Physiopath. of Renal Dis. and Hypertens., CNR-IBIM, Reggio Calabria, Italy; [3]Nephrology, Transplantation and Hypertension, Reggio Calabria, Italy; [4]Prague, Czech Republic; [5]Polytechnic University of Bari, Bari, Italy; [6]Polytechnic University of bari, Bari, Italy; [7]University of Bari, Bari, Italy; [8]University of Turin, Turin, Italy; [9]Polytechnic University of Bari, Italy, Bari, Italy. Group/Team: On behalf of VALIGA Study.*

Background: IgA nephropathy(IgAN) is the most common biopsy-proven glomerulonephritis in the world characterized by progressive deterioration of the renal function. Many statistical appoaches have been used to predict ESKD in IgN patients. The ANN is a non-linear statistical approach for pattern recognition in order to weight all the relationships between input and output variables. We have updated and used the clinical decision support system, previously published (NDT 2016), to estimate the ESKD risk.

Methods: A cohort of 680 adult patients from the European VALIGA study with complete dataset was used for this study. Of these 178 reached ESKD. Five indicators (age, sex, serum creatinine, daily proteinuria, hypertension) and MEST-C (mesangial and endocapillary hypercellularity, segmental glomerulosclerosis, tubular atrophy/interstitial fibrosis and presence of crescents) classification at time of kidney biopsy were used for

the training and validation process of the ANNs. Then, we included follow-up (years) and therapy. Two indipendent ANNs were used for predicting, first, ESKD and, then, the time occurring to ESKD. For every ANN, 80% of IgAN patients were included in the training set and 20% in the validation set. Four well-known classification metrics were used for the first ANN and two error-based metrics were used to evaluate the regression algorithm for the second ANN.

Results: The first model to predict ESKD by 15 years of clinical outcome had accuracy 98%, precision 93%, recall 87% and F1-measure 87%. The second ANN to predict the number of years to achieve ESKD showed a RMSE (root mean squared error) of 2.68 years and a MAE(mean absolute error) of 2.12 years.

Conclusions: We have developed a new clinical decision support system to estimate the risk of ESKD and its timing in IgAN patients. This tool showed an excellent performance. Interestingly, the VALIGA cohort included many patients who received or not ACEi or ARBs or immunosuppressive therapy that may influence the clinical course of the disease. Thus, the training and validation phase of our ANNs considered therapy exposure.

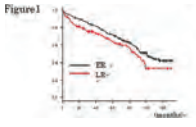
Can Early Referral to Nephrologists Reduce All-Cause and Cardiovascular Mortality and How Long Can the Effect of Pre-Dialysis Nephrology Care Last after Dialysis Initiation? Yukimasa Iwata, Taisuke Takatsuka, Daisuke Yoshimura, Hiroki Okushima, Rei Iio, Tatsuya Shoji, Terumasa Hayashi. *Osaka General Medical Center, Osaka-Shi, Japan*.

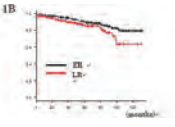
Background: Although early referral (ER) to nephrologists before dialysis initiation has been recognized to improve overall survival in patients on maintenance dialysis, we don't have any available data about how long the favorable effect of ER can last. Furthermore, its effect on cardiovascular (CV) mortality remains unclear. Thus, we conducted single center retrospective cohort study of incident dialysis patients to investigate the effect of ER on all-cause and CV mortality and how long ER could sustain its favorable effect on mortality after dialysis initiation.

Methods: A total of 875 patients with accurate clinical data and outcomes were extracted from 1131 patients who started chronic dialysis treatment from 2006 to 2015. Clinical status at dialysis initiation, all-cause and CV mortality were compared by referral timing (ER, referred to nephrologists more than 6 months before dialysis initiation; LR, other than ER). Cox and interval Cox proportional hazard model was used to evaluate the predictive factors for outcomes and how long favorable effect of ER on mortality could last after dialysis initiation.

Results: Median age and eGFR at dialysis were 70 years and 5.4 ml/min/1.73m^2, respectively. 654 patients were referred early (ER). 275 patients died and 82 of those from CV disease during the follow-up period (median, 40 months). Although, ER group showed fewer all-cause and CV mortality (Log-rank test; P=0.007, 0.019 respectively) than LR group (Figure1), multivariate Cox proportional analysis failed to show significant impact on all-cause and CV mortality. However, on the basis of the Kaplan-Meier curves, the excess overall survival among ER versus LR patients appeared limited to the several years of maintenance dialysis (Figure 1A). Thus, we built several interval Cox models: from onset of dialysis to 6, 12, 18, 24, 30 and 36 months of maintenance dialysis. The favorable effect of ER on overall survival was limited to the first 30 months on dialysis (Figure2).

Conclusions: ER was not associated with CV death, whereas ER may improve overall survival during early phase after dialysis initiation.





FR-PO470

Urinary Neutrophil Gelatinase-Associated Lipocalin Is a Possible Indicator of Tubulointerstitial Fibrosis and Glomerular Sclerosis in the Patients Undergoing Renal Biopsy Yoshifumi Hamasaki, Teruhiko Yoshida, Ryo Matsuura, Akihiro Tojo, Eisei Noiri, Masaomi Nangaku. *The University of Tokyo, Tokyo, Japan*.

Background: Renal tubulointerstitial fibrosis and glomerular sclerosis are common pathological changes occurring in association with chronic kidney disease (CKD). Non-invasive and reliable biomarkers which can predict the renal histopathological change will be helpful to decide the indication of renal biopsy. Neutrophil gelatinase-associated lipocalin (NGAL) is a promising marker of not only acute kidney injury but also CKD. We investigated whether urinary markers, including NGAL, can predict renal tubulointerstitial fibrosis (TF) and glomerular sclerosis (GS) in the patients undergoing percutaneous renal biopsy.

Methods: This study enrolled all consecutive adult patients undergone renal biopsy at The University of Tokyo Hospital from July 2014 to April 2017. We collected urine from these patients just before renal biopsy and measured N-Acetyl-β-D Glucosaminidase, L-type fatty acid binding protein, and NGAL. All markers were corrected by urinary creatinine (Cre) concentration. We also collected clinical parameters measured before renal biopsy. All biopsy specimens were evaluated by a pathologist for the medical purpose. We evaluated the relationships between urinary markers and the results of histopathological diagnoses.

Results: Ninety-six patients were enrolled in this study. Urinary NGAL/Cre (uNGAL/Cre) was significantly correlated with the severity of TF and the percentage of sclerotic glomeruli (Spearman's rank correlation coefficient ρ= 0.38 and 0.28, p <0.01 and <0.01, respectively) in the biopsy specimens. uNGAL/Cre was also significantly correlated with eGFR. When all patients were divided into two groups according to the severity of TF (less or more than 10% of interstitial area) or GS (less or more than 30% of total number of glomeruli), uNGAL/Cre in the severe group was significantly higher than in the mild group. When data from the patients with positive urine dipstick for both blood and protein (greater than 1+) were analyzed, uNGAL/Cre predicted severe TF and GS on ROC analysis (AUC [95%CI] = 0.72 [0.59-0.84] and 0.70 [0.56-0.83], respectively).

Conclusions: uNGAL/Cre may predict the severity of tubulointerstitial fibrosis and glomerular sclerosis in the patients undergoing renal biopsy.

FR-PO471

Incidence and Risk Factors of CKD in Thailand: Thai-SEEK Project Kraiwiporn Kiattisunthorn,[4] Pongsathorn Gojaseni,[1] Pornpen Sangthawan,[2] Atiporn Ingsathit.[3] *[1]Bhumibol Adulyadej hospital, Bangkok, Thailand; [2]Prince of Songkla University Hospital, Songkhla, Thailand; [3]Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [4]Siriraj Medical School, Mahidol University, Bangkok, Thailand. Group/Team: Thai-SEEK Steering Committee, Nephrology Society of Thailand* .

Background: Chronic kidney disease is one of the major public health problems which, in majority, can be preventable for progression to ESRD. Data from the first Thai-SEEK (Screening and Early Evaluation of Kidney Disease) survey completed in 2008, demonstrated prevalence of CKD for 17.5%. Data of incidence and etiologies of CKD in Thailand is scarce but is seriously concerned by policy makers of national health program for CKD prevention and slow progression. Therefore, we analyzed the data from the second survey to evaluate incidence and risk factors of CKD in Thailand.

Methods: A prospective cohort study was run from June 16, 2015 to December 15, 2016 by using subjects of the first survey. Data from history taking and physical examination, serum creatinine, urinalysis, and urine albumin creatinine ratio (UACR) were done in 2,396 subjects (70%) who gave responses for participating follow up program. One thousand, nine hundred and thirty-four subjects (71% of CKD-free in the first survey) were analyzed for CKD incidence and risk factors of new diagnosed CKD. Serum creatinine standardized with SRM967a (National Institute of Standards and Technology, MD, USA) was put in GFR calculation using CKD-EPI formula. Diagnosis and staging of CKD was based on KDIGO 2012 criteria, and rapid CKD progression was defined as a change in CKD staging plus a decline in GFR >25% or >5 ml/min/1.73m^2/year or renal replacement therapy was initiated.

Results: Mean age was 46.7±13.8 years old and 41% were male. Median follow-up time was 7.9 year (min-max 7.7, 9.1). The estimated incident CKD was 0.28 (95% CI: 0.26, 0.30) presented in 15.4%, 8.4%, 3.1%, 0.7% and 0.05%, for stage G1, G2, G3a, G3b and G4, respectively. The majority of CKD etiologies were hypertensive nephropathy (30.7%), diabetic nephropathy (19.2%), and tubulointerstitial nephritis (10.3%). Promoting factors of incident CKD were diabetes mellitus (RR 1.41; 95% CI: 1.15, 1.73), hypertension (RR 1.19; 95% CI: 1.01,1.41), and low socioeconomic status (<5,000 baht/month) (RR 1.54; 95% CI: 1.28,1.86).

Conclusions: Incidence of CKD was 28% in the 8-year cohort. Hypertension and diabetes mellitus were the most etiologies of CKD. Promoting primary prevention program for hypertension and diabetes mellitus, also effective screening in whom diagnosed hypertension and/or diabetes would be powerful in national CKD prevention policy.

FR-PO472

Post-Translational Modified Albumin in CKD Patients Joachim Jankowski,[1] Vera Jankowski.[2] *[1]RWTH Aachen, Aachen, Germany; [2]University hospital RWTH Aachen, Aachen, Germany*.

Background: Since post-translational modifications (PTM) of proteins may have an impact on the pathogenesis of diseases like atherosclerosis, diabetes mellitus and CKD, PTMs are currently gaining increasing interest. However, a comprehensive method for analysis of these PTMs is not established for the clinical diagnostic routine yet. Therefore, we have set up a MALDI-mass-spectrometric approach to detect post-translational modifications of plasma proteins for diagnostics.

Methods: In order to prove the significance of the approach, we analysed albumin – the most abundant plasma protein in human– isolated from CKD patients and healthy controls by mass-spectrometry. Post-translational modifications of albumin were identified after digestion by analysing mass-signal shifts of albumin peptides using pertinent mass-databases.

Results: Albumin isolated from plasma of CKD patients but not from healthy control subjects was specifically post-translationally modified by guanidylation of lysines. After identification of guanidylations as post-translational modifications of albumin isolated from CKD patients, these modifications were quantified by mass-spectrometry demonstrating a significant increase in the corresponding mass-signal intensities in CKD patients. The relative amount of guanidylation of lysine at position 468 in CKD patients was determined as 63% ± 32 (N=3). *In-vitro* guanidylation of albumin from healthy control subjects caused a decreased binding capacity of albumin in a time-dependent manner. Binding of indoxyl sulfate decreased from 82 ± 1 % of non post-translationally

modified albumin t o 5 6 ± 1 % after *in-vitro* g uanidylation w hereas t he b inding of tryptophan decreased from 20 to 4%. These results are in accordance with the binding of indoxyl sulfate to albumin from healthy control subjects and CKD patients. Thus, *in-vitro* post-translational guanidylation of albumin had a direct effect on the binding capacity of hydrophobic metabolites like indoxyl sulfate and tryptophan.

Conclusions: In conclusion, we established a mass spectrometry-based method for the characterisation of PTM and demonstrated the pathophysiological impact of a representative post-translational modification of plasma albumin. The approach described in this study may help to elucidate the pathophysiological role of protein modifications.

FR-PO473

Incidence and Outcomes of Syncope in Patients with CKD Manish M. Sood,[4] David Massicotte-Azarniouch,[3] John Paul Kuwornu,[6] Megan K. Mccallum,[6] Amit X. Garg,[1] Ngan Lam,[5] Amber O. Molnar.[2] *[1]London Health Sciences Centre, London, ON, Canada; [2]McMaster University, Hamilton, ON, Canada; [3]Ottawa, ON, Canada; [4]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [5]University of Alberta, Edmonton, AB, Canada; [6]Institute for Clinical Evaluative Sciences, Ottawa, ON, Canada.*

Background: Syncope is common condition, occurring in roughly 1 in 3 people during their lifetime, and may be a sign of life-threatening illness. CKD patients may be at an elevated risk of syncope due to concurrent medical conditions, medication usage or the etiology of CKD itself. We set out to examine the incidence of first episode and recurrent syncope and its outcomes in patients with CKD > 66 years of age.

Methods: A population-based, retrospective cohort study using administrative databases between 2006 and 2015. A total of 272,149 patients with no history of syncope, a urine albumin to creatinine ratio (ACR) and eGFR measure were included. First syncope by strata of eGFR and ACR was examined using Fine and Gray Models sub-distribution hazards ratio (sHR) and recurrent syncope by negative binomial models (RRR). Models were adjusted for demographics, resource utilization, demographics and medications. Among those with syncope, the incidence of adverse outcomes (ACS, arrhythmia, stroke, fracture and death) was determined by eGFR strata.

Results: A total of 15,074 (5.5%) first and 36,710 (13.5%) recurrent syncope events occurred during the study period. Lower eGFR was associated with a higher risk of first episode of syncope [eGFR 60-90: sHR 1.24(1.15-1.33), eGFR 45-60: sHR 1.45(1.34-1.57), eGFR 30-45: sHR 1.49 (1.36-1.62), eGFR < 30: sHR 1.40 (1.25-1.57), eGFR > 90 referent] whereas ACR was not. Recurrent syncope was associated with lower eGFR and higher ACR [eGFR 60-90: RRR 1.21(1.13-1.31), eGFR 45-60: RRR 1.46(1.34-1.58), eGFR 30-45: RRR 1.58 (1.44-1.73), eGFR < 30: RRR 1.73(1.53-1.94), eGFR > 90 referent; ACR 3-30: RRR 1.09 (1.04-1.13), ACR > 30: RRR 1.15(1.06-1.24), ACR < 3 referent]. Among those with a first syncope event, the event rate (per 100 pt-yrs) of all adverse outcomes was higher with lower eGFR strata compared to normal eGFR (ACS: eGFR < 30: 2.44, eGFR > 90: 0.98, Arrhythmia: GFR < 30: 21.63, eGFR > 90: 8.88, stroke: eGFR<30: 5.02, eGFR >90: 2.32, fracture: eGFR<30: 5.40, eGFR >90: 2.62, death: eGFR < 30: 23.23 eGFR>90: 5.31).

Conclusions: First episode and recurrent syncope events are associated with lower eGFR and only marginally with a higher ACR. The risk of all adverse events (cardiovascular, fracture and death) is higher post-syncope in patients with eGFR < 30.

FR-PO474

A First Assessment of Urinary Peptide Biomarkers Predictive of Cardiovascular Complications in Children with CKD Valerie Brunchault,[1] Benedicte Buffin-Meyer,[1] Benjamin Breuil,[1] Pedro Magalhães,[2] Petra Zürbig,[2] Kevin Kunzmann,[3] Franz S. Schaefer,[4] Joost Schanstra,[1] Julie Klein.[1] *[1]INSERM U1048, Toulouse, France; [2]Mosaiques Diagnostics GmbH, Hannover, Germany; [3]Institute of Medical Biometry and Informatics, Heidelberg University, Heidelberg, Germany; [4]University of Heidelberg, Heidelberg, Germany. Group/Team: 4C study consortium.*

Background: Cardiovascular disease (CVD) is the most important comorbidity affecting long-term survival in children and young adults with CKD. CVD is usually subclinical and early detection of pediatric CKD patients with high risk to develop CVD would be optimal. Our objective was to explore the urinary peptidome for biomarkers for early prognosis of CVD in children with CKD.

Methods: In this preliminary study, we used 86 pediatric patients from the Cardiovascular Comorbidity in Children with CKD (4C) cohort, which consists of children (6-17 years) with advanced CKD (eGFR=10–45 ml/min/1.73 m^2). During a 3-year follow-up, the carotid intima-media thickness (cIMT), pulse wave velocity (PWV) and left ventricular mass index (LVMI) were measured annually as surrogate markers of CVD complications. For each marker, the slope was calculated as a measure of CVD progression. Urine at baseline was analyzed by capillary-electrophoresis coupled to mass spectrometry for the identification of urinary peptides associated to progression of CVD.

Results: Among 7586 urinary peptides, 190, 22 and 14 urinary peptides were associated to progression of cIMT, PWV and LVMI, respectively ($p<0.05$). These peptides were combined in mathematical models to build the cIMT190P, PWV22P and LVMI14P classifiers. These classifiers were then validated using an independent validation cohort. The cIMT190P classifier predicted cIMT progression with 80% sensitivity [95% CI, 44.4 to 97.5], 100% specificity (95% CI, 66.4 to 100) and an area under the ROC curve (AUC) of 0.87 (95% CI, 0.68 to 1.00). The PWV22P classifier predicted PWV progression with 83% sensitivity (95% CI, 51.6 to 97.9), 70% specificity (95% CI, 34.8 to 93.3) and an AUC of 0.83 (95% CI, 0.64 to 1.00). However, the LVMI classifier was not validated.

Conclusions: These results indicate that urinary peptides could be used as a non-invasive tool for the early prediction of CVD complications associated to CKD in children. An additional 250 patients from the 4C study will now be used to refine and confirm these results. [Equal contribution JPS and JK]

Relationships between CKD and Progression of Left Ventricular Diastolic Dysfunction Yoshiyasu Miyajima, Tadashi Toyama, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Kanazawa University Hospital, Kanazawa, Japan.*

Background: CKD is known as a risk factor for heart failure, but its role on the left ventricular diastolic dysfunction as a preliminary stage of heart failure has not been adequately studied.

Methods: To investigate the relationship between CKD and progression of left ventricular diastolic dysfunction, we included patients who received echocardiography examination in Kanazawa University Hospital for more than twice with intervals of more than one year. We excluded clinically diagnosed coronary artery disease, moderate valvular heart disorder and structural heart disease. Patients were examined their left ventricular peak velocity of blood flow across the mitral valve (E) and their diastolic peak velocities of mitral annulus (e'); E/e' ratio was used as an index of left ventricular diastolic function, and E/e' ratio >14 was defined as left ventricular diastolic dysfunction. Baseline estimated glomerular filtration rate (eGFR) and dipstick proteinuria were used as a status of chronic kidney disease (CKD). Time to development of left ventricular diastolic dysfunction and baseline CKD status were assessed using Cox proportional hazard models adjusted for known risk factors.

Results: A total of 1,163 subjects were included and the average observation period was 3.2 years. Compared to the patients with the estimated GFR ≥90 mL/min/1.73 m2 as a reference, hazard ratios (95% confidence intervals) for the development of diastolic dysfunction were 1.25 (0.87–1.79), 1.51 (0.96–2.38), 2.06 (1.25–3.40), and 3.54 (2.13–5.88) for patients with eGFR 60–89 mL/min/1.73 m2, 45–59 mL/min/1.73 m2, 30–44 mL/min/1.73 m2, <30 mL/min/1.73 m2, respectively. Compared to patients with proteinuria – or trace, patients with proteinuria more than 2+ or more were also a significant risk factor (hazard ratio 2.15, 95% confidence interval 1.40–3.29).

Conclusions: Low GFR and proteinuria were risk factors for the development of left ventricular diastolic dysfunction.

FR-PO476

Impaired Delivery of Cholesterol to Hepatocytes by Serum from CKD Patients: Implications for the Associated CVD Risk Daniel E. Carl,[5] Graham T. Gipson,[3] Shobha Ghosh,[2] Salvatore Carbone,[3] Dave L. Dixon,[4] Ion S. Jovin.[1] *[1]McGuire VAMC/VCU, Richmond, VA; [2]VCU, Richmond, VA; [3]Virginia Commonwealth University, Richmond, VA; [4]Virginia Commonwealth University School of Pharmacy, Richmond, VA; [5]Internal Medicine, Virginia Commonwealth Univeristy, Richmond, VA.*

Background: Mortality in CKD patients is largely due to the development of CVD but the underlying mechanisms have not been elucidated. The flux of cholesterol through the body and final elimination by the liver rather than the plasma lipid profiles is now considered as a major contributor to development of CVD. Ability of the serum components to remove cholesterol from macrophage foam cells and deliver it to the liver for final elimination are the two critical steps in regulating cholesterol flux. Herein, we evaluated the ability of serum from CKD patients to facilitate these two processes.

Methods: Thirty-two consecutive patients with CKD (Stage 3, N=15 and Stage 4+5, N= 17) and 15 healthy subjects were enrolled in the study. Cholesterol efflux capacity (CEC) of the patient serum to remove cholesterol from human THP1 macrophage foam cells and the ability to deliver this effluxed cholesterol to primary hepatocytes was determined and compared between groups using the Mann-Whitney Test. Correlations between kidney function parameters, CEC and uptake by hepatocytes were performed using the Spearman's nonparametric rank test.

Results: CEC was significantly higher with serum from patients with CKD (Stages 3 and 4+5, $P<0.001$) compared to that from healthy subjects (Panel A). However, the ability of this effluxed FC to be delivered to hepatocytes was significantly lower in patients with CKD (Panel B, Stages 3 and 4+5, $P<0.001$). eGFR was inversely associated with CEC (Panel C) and positively associated with hepatocyte uptake (Panel D).

Conclusions: These data indicate that impaired delivery of cholesterol to the liver for final elimination from the body likely underlies the development of CVD in CKD patients. Studies are in progress to determine if this decrease in hepatocyte uptake in CKD is related to modifications of cholesterol carrying serum components (e.g., HDL or albumin) by reduced kidney function.

Blockade of the Chemokine Receptor CX3CR1 with a Single Chain Antibody Reduces the Progression of Atherosclerosis and Glomerulosclerosis in Mice Steven W. Kerr,[7] Valentina Berger,[2] Jorge L. Villalona,[6] Rajvee Dave,[6] Hong Wang,[6] Margaret M. O'Neill,[8] Joshuaine Toth,[5] Mary Mcfarland,[1] Lynn Pantages,[3] Xingtie Nie,[4] Hu Sheng Qian,[3] John Broadwater.[5] *[1]Beoheringer Ingelheim Pharmaceuticals, Ridgefield, CT; [2]Boehringe-Ingelheim Pharm, Ridgefield, CT; [3]Boehringer Ingelheim Pharmaceuticals, Inc, Ridgefield, CT; [4]Boehringer-ingelheim company, Danbury, CT; [5]Boehringer Ingelheim, Ridgefield, CT; [6]Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT; [7]Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT; [8]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, AL.*

Background: The fractalkine receptor CX3CR1 regulates leukocyte trafficking during inflammation and is associated with cardiovascular disease risk. We developed a high-affinity, selective, single chain antibody that targets human CX3CR1, designated BI655088. Since cardiovascular disease is the major cause of morbidity and mortality in patients with chronic kidney disease, we used a cardiorenal model to evaluate atherosclerosis and renal parameters.

Methods: Therefore, BI655088 was administered at 30mg/kg i.p. 2x/wk for 12 weeks to hyperlipidemic ApoE$^{-/-}$ mice expressing the human CX3CR1 gene and induced renal insufficiency by performing a uninephrectomy.

Results: BI655088 significantly reduced atherosclerotic plaque area by 28% compared to vehicle-treated mice with no change in total cholesterol or triglycerides. In addition, BI655088 significantly reduced glomerulosclerosis incidence by 43% and severity in the remnant kidney. This effect was accompanied by a significant decrease in macrophage infiltration consistent with the mechanism of action. Plasma levels of fractalkine, used as a biomarker for antibody blockade of CX3CR1, were significantly increased in treated animals. In order to evaluate the potential effect of BI655088 for treating diabetic nephropathy, BI655088 was tested in streptozotocin-treated C57BL/6 mice transgenic for the human CX3CR1 gene. BI655088 dosed at 30, 3, and 0.3mg/kg i.p. 2x/wk for 12 weeks showed dose dependent decreases in both glomerulosclerosis, (-46%, -27%, and -15%), and interstitial lesions (-56%, -33%, and -16%), respectively, compared to vehicle-treated mice with no effect on glucose levels.

Conclusions: These results demonstrate that treatment with the CX3CR1 antagonist BI655088 can mitigate both renal and vascular injury induced in diabetic and hyperlipidemic mouse models.

Urinary Orosomucoid Is Associated with Cardiovascular Risk Factors and Kidney Dysfunction: Cross-Sectional Data from the Tromsø Study Runa M. Andreassen,[1,2] Marit D. Solbu.[4,3] *[1]Department of Internal Medicine, Helgelandssykehuset, Sandnessjøen, Sandnessjøen, Norway; [2]Metabolic and Renal Research Group, UiT The Arctic University of Norway, Tromsø, Norway, Tromsø, Norway; [3]Metabolic and Renal Research Group, UiT The Arctic University of Norway, Tromsø, Norway, Tromsø, Norway; [4]Section of Nephrology, University Hospital of North Norway, Tromsø, Norway., Tromsø, Norway.*

Background: The acute phase protein orosomucoid is a component of the endothelial cell coat. It may be hypothesised that leakage of orosomucoid into the urine may be a more sensitive marker of a damaged filtration barrier than albuminuria. However, this has never been assessed in a general population. The aim of this cross-sectional study was to examine the univariate associations between urinary orosomucoid to creatinine ratio (UOCR), urinary albumin to creatinine ratio (UACR) and common cardiovascular (CV) risk factors, and to assess whether there is an independent association between eGFR and UOCR in a middle-aged cohort from the general population.

Methods: From the sixth wave of The Tromsø Study (2007/08) we included all participants who had measurements of urinary orosomucoid. Orosomucoid, albumin and creatinine were measured in three morning urinary specimens, and we used the median values from the three days for UACR and UOCR. The cohort was categorized according to some well known CV risk factors and the associations between UOCR, UACR, eGFR and risk factors were assessed by linear and logistic regressions analysis.

Results: A total of 3086 men and 4095 women were included; mean age was 63.5 (±9.2 SD) years. Mean eGFR was 88 (±14 SD) ml/min/1.73 m2. UOCR was significantly higher in men than in women and positively correlated with age. UOCR was also higher in subjects with BMI ≥25 kg/m2 than BMI <25 kg/m2 median 0.48 (IQR 0.24, 1.13) g/g vs. 0.37 (0.21, 0.85) g/g; P<0.001), as well as in hypertensive compared to normotensive subjects 0.56 (0.27, 1.31) g/g vs. 0.35 (0.20, 0.77); P<0.001) and smokers compared to non-smokers 0.50 (0.24, 1.18) g/g vs 0.43 (0.23, 0.99) g/g; P=0.002. UACR was positively associated with the same risk factors except BMI. In multivariable logistic regression analysis, both eGFR and UACR were independent risk factors for having UOCR above median (eGFR: odds ratio (OR) 0.83 (0.79-0,88) per 10 ml/min/1.73 m2, UACR: OR 2.05 (1.91-2.19)) per 0.5mg/mmol.

Conclusions: UOCR was positively associated with CV risk factors, and the association between eGFR and UOCR was independent of these factors and UACR. Our data indicate that increased UOCR may serve as a novel biomarker of atherosclerosis and kidney dysfunction, thereby supporting further research.

Increased Levels of Platelet Microparticles in CKD Patients with Acute Coronary Syndrome Josefin L. Mörtberg,[1,3] Kristina Lundwall,[1,3] Fariborz Mobarrez,[2] Hakan Wallen,[1,3] Stefan H. Jacobson,[1,3] Jonas Spaak.[1,3] *[1]Danderyd Hospital, Stockholm, Sweden; [2]Karolinska Institutet, Solna, Sweden; [3]Dept of Clinical Sciences, Karolinska Institutet, Danderyd hospital, Stockholm, Sweden.*

Background: Patients with CKD have worse outcome after an acute coronary syndrome (ACS). Traditional and nontraditional riskfactors, underutilization of coronary intervention, less active secondary prevention and lower adherence to medications all contribute to the poor prognosis. Microparticles MPs are circulating small sized vesicles shed from various cells upon activation, and they may induce biologically response and inter-cellular cross-talk. Platelet MPs(PMPs) are the most abundant MPs, and levels increase following myocardial infarction and in diabetes mellitus, hypertension, and CKD. We hypothesized that ACS patients with CKD had further elevated PMPs compared with non CKD patients.

Methods: 52 patients with ACS were included and fasting blood was acquired the day after admittance. Patients were divided in three groups according eGFR; average eGFR in group H (n=19) was 88 ml/min, in CKD 3 (n=16) 47 ml/min, and in CKD 4-5 (n=17) 19 ml/min. PMPs were measured by flow cytometry and phenotyped according to size (0.3 – 1.0 μm) and expression of CD41 (GPIIb; platelet specific marker) together with platelet activation markers, CD40ligand (CD154) and P-selectin (CD62P)

Results: Levels of PMPs were elevated in CKD 4-5 patients, and levels of PMPs expressing platelet activation markers CD40 ligand(CD 154)) and p-selectin (CD62p) were higher in both CKD groups, compared with non CKD patients

Conclusions: In ACS patients, levels of PMPs as well as levels of PMPs expressing CD40 ligand (CD154) and/or p-selectin (CD62p) are significantly higher in CKD patients compared with non CKD patients. These finding indicates a higher platelet activation in CKD patients, which might contribute to the poorer outcome for CKD patients following a myocardial infarction.

eGFR Trajectories and Risks of Death and Cardiovascular Events in Adults with Type 2 Diabetes Kenn B. Daratha,[1,2] Sterling McPherson,[1,2] Brad Dieter,[1] Radica Z. Alicic,[1] Katherine R. Tuttle.[1,3] *[1]Providence Health Services, Spokane, WA; [2]Washington State University, Spokane, WA; [3]University of Washington School of Medicine, Seattle, WA.*

Background: Diabetes is the most common cause of chronic kidney disease (CKD) worldwide. Most with diabetes and CKD will experience death or a cardiovascular disease (CVD) event before reaching end-stage kidney disease. Decline in estimated glomerular filtration rate (eGFR) may be an antecedent of such events. The aim of this study was to

determine the relationship of eGFR decline with death and CVD events among persons with type 2 diabetes.

Methods: The ACCORD trial tested intensive control of glycemia in adults with type 2 diabetes. In our study, group-based modeling classified eGFR trajectories of 10052/10251 (98%) ACCORD participants with at least 2 eGFR (CKD-EPI) measurements. Trajectory classification was based on greatest likelihood an individual trajectory fit within a hypothesized class structure (both in number and classes and order of each function). Cox proportional hazards models examined risk of the primary ACCORD outcome (CVD death, myocardial infarction, stroke) by eGFR trajectory assignment.

Results: Participants were followed up to 7 years. Baseline characteristics included: age 62.7±6.6 (mean±SD) years; women 38% (3857/10052); White race 62% (6281/10052); diabetes duration 10.7±7.6 years; HbA1c 8.3±1.1 %; eGFR 84.0±17.5 mL/min/1.73m^2; and urine albumin-to-creatinine ratio 13, 6-43 (median, IQR). Approximately 10% (1027/10052) of participants were classified in the lowest trajectory class with eGFR values persistently <60 mL/min/1.73m^2. In the next trajectory class, 21% (2101/10052) were classified with initial eGFR values above, but falling below, 60 mL/min/1.73m^2 over time. Three additional classes were defined with eGFR above 60 mL/min/1.73m^2 throughout the study. Fully-adjusted models controlled for baseline eGFR (isolating the independent effect of the trajectory slope), age, sex, race, diabetes duration, HbA1c, albuminuria, and treatment. Hazards for the primary outcome were greater for the two lowest compared to the highest eGFR trajectory class (HR_1=1.52; 95%CI=1.07-2.18; p=0.03 and HR_2=1.42; 95%CI=1.06-1.90; p=0.02).

Conclusions: More rapid eGFR decline in persons with type 2 diabetes independently predicted significantly greater risk of death and CVD events.

FR-PO481

Prevalence of Secondary Hyperparathyroidism among Patients with Diabetic Nephropathy Mahmoud H. Imam,[1] Ahmed W. Elshourbagy,[3] Amira Mohamady,[2] Rizk sayad rizk Sarhan.[2] *[1]Internal medicine, Benha University, Benha, Egypt; [2]Internal Medicine Department, Benha University, Benha, Egypt; [3]Internal Medicine Department, banha faculty of medicine, Benha, Egypt.*

Background: Both SHPT and diabetes mellitus have increased the risk for cardiovascular complication mainly through vascular calcification and endothelial dysfunction. The prevalence of SHPT among diabetic nephropathy patients is not previously studied. The aim of this study to evaluate the prevalence of SHPT among diabetic nephropathy patients attended to diabetes and nephrology outpatient clinic.

Methods: In this retrospective study, 437 diabetic patients were enrolled in this study from 864 diabetic patients who attended diabetes and nephrology outpatient clinics in our tertiary care hospital in Jeddah from Jan 2014 to Feb 2017. Inclusion criteria were: [1] Age ≥18 years, [2] Patient had diabetic nephropathy which was diagnosed based on the presence of urinary albumin/creatinine ratio (uACR) ≥ 30 mg/gm ± 24 hours' urinary protein measurement ≥ 300 mg/day. Exclusion criteria were|: [1] patients were already receiving cinacalcet and/or[2] patients had undergone neck surgery for parathyroidectomy. The intact parathyroid hormone, 25 vitamin D level, uACR and other kidney and biochemical investigation results were obtained from patients' medical records. Patients were divided into two groups: those with euparathyroidism (an iPTH level less than 65 pg/mL) and those with hyperparathyroidism with iPTH level above or equal to 66 pg/mL.

Results: Three hundred and seventy-four patients (85.5%) had an iPTH level above normal. When patients were divided according to their iPTH level into SHPT and euparathyroid groups, we found a significant mean difference between the two groups regarding uACR (2.38 ± 1.0 mg/g vs. 311 ± 180 mg/g; p <0.001), eGFR (49.15 ± 20.3 ml/min/1.73m^2 vs. 90.97 ± 3.93 ml/min/1.73m^2; p < 0.001), and serum urea (77.54 ± 26.19 mg/dL vs. 23.70 ± 5.66 mg/dL; p < 0.001). Our results showed that SHPT group had a statistically significant lower level of vitamin D and serum calcium. Furthermore, we found that there was a strong correlation between iPTH level and serum creatinine, eGFR, UACR, vitamin D.

Conclusions: Despite the absence of clinical manifestations, SHPT is common among diabetic nephropathy patients.

FR-PO482

The Effect of Digoxin on Renal Function in Patients with Heart Failure Parin M. Shah,[2] Sunil Bhandari.[1] *[1]Hull and East Yorkshire Hospitals NHS Trust and Hull York Medical School, East Yorkshire, United Kingdom; [2]Univerisity of Hull, Cottingham, United Kingdom.*

Background: We investigated the relation between digoxin use and change in renal function over time in patients with chronic heart failure (CHF).

Methods: 1241 patients with CHF (defined as symptoms/ signs of heart failure with either reduced left ventricular ejection fraction or raised amino terminal pro B type natriuretic peptide; NTproBNP >220 ng/l) were included. The patients were divided into four groups: never on digoxin (N=394); digoxin throughout (N= 449); started digoxin at some point after baseline (N=367); and stopped digoxin at some point after baseline (N= 31). The rate of change of estimated glomerular filtration rate (eGFR) was calculated using linear regression.

Results: The average age was 72 years (64% male), and median NTproBNP 1426 ng/L (IQR 632 - 2897). Patients on digoxin throughout had a significantly greater rate of decline in eGFR per year than patients not on digoxin throughout (mean (± standard deviation); -5 (13) ml/min/1.73m^2 per year *v* -2 (10) ml/min/1.73m^2 per year, P= 0.02). In those patients who started digoxin during follow-up, there was no significant difference in the rate of decline in eGFR before and after starting digoxin. There was no correlation between baseline eGFR (or rate of decline in eGFR) and age, body mass index, haemoglobin, or NTproBNP. Patients not taking angiotensin-converting enzyme inhibitors, angiotensin receptor blockers or beta blockers had a faster rate of decline in eGFR than those who were.

Conclusions: The rate of decline in renal function is greater in patients with CHF who are taking digoxin.

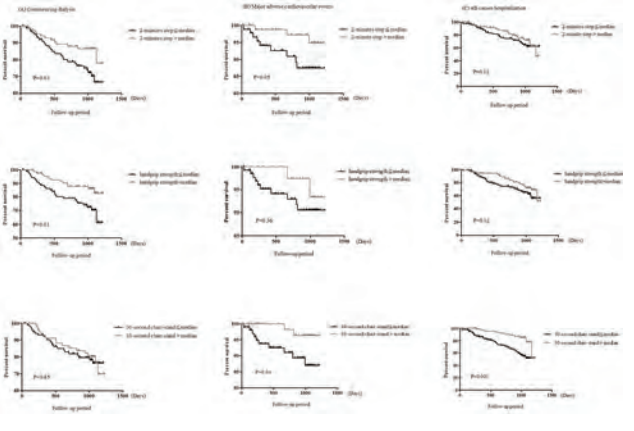
Association of Physical Activity with Cardiovascular and Renal Outcomes and Quality of Life in CKD Yi-chun Tsai,[2] Hung-Chun Chen,[2] Shang-Jyh Hwang.[1] *[1]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan.*

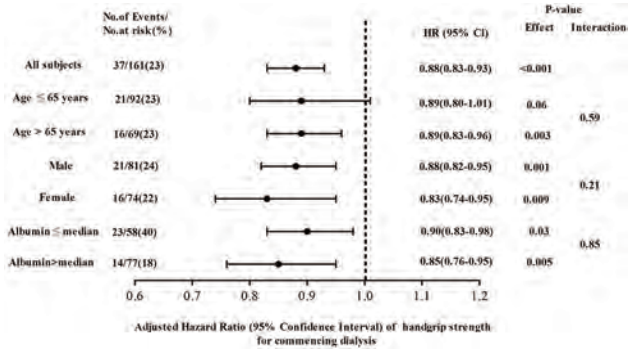
Background: Patients with chronic kidney disease (CKD) are more readily prone to have impaired physical activity than the general population. The aim of this study is to examine the relationship between physical activity and adverse clinical outcomes and quality of life (QOL) in CKD.

Methods: This cohort study enrolled 161 patients with CKD stages 1-5 from February 2013 to September 2013 and followed up until June 2016. Physical activity was measured using high handgrip strength, 30-second chair stand, and 2-minute step. The QOL was assessed using the Taiwan version of the WHOQOL-BREF. Clinical outcomes included commencing dialysis, major adverse cardiovascular events (MACEs), and first hospitalization.

Results: Of all participants, 1 kg/m^2 increase in handgrip strength was significantly associated with 0.13 score increase in total scores of QOL and 0.05 score increase in physical domain of QOL in adjusted analysis. One time increase in 30-second chair stand was significantly correlated with 0.14 score increase in psychological domain of QOL. Over a mean follow-up period of 29.1±11.2 months, 37 (23.0%) reached commencing dialysis, 11(6.8%) had MACEs, and 50(31.1%) had first hospitalization. High handgrip strength (hazard ratio (HR): 0.89, 95% CI: 0.84-0.96) and high 2-minute step (HR: 0.04, 95% CI: 0.01-0.95) were significantly associated with decreased risk for commencing dialysis in multivariate analysis. Thirty-second chair-stand was negatively associated with MACEs (HR: 0.65, 95%CI: 0.47-0.89) and first hospitalization (HR: 0.84, 95%CI: 0.74-0.95).

Conclusions: Physical activity is a potential predictor of QOL and clinical outcomes in CKD.





FR-PO484

Real Life Insights into the Use of Mineralocorticoid Receptor Antagonists in Patients with Diabetic and Non-Diabetic CKD with and without Heart Failure Michael Blankenburg,[2] Anne-Kathrin Fett,[4] Seline Eisenring,[4] Gabriele Haas,[3] Jonathan Korn,[4] Alain Gay.[1] *[1]Bayer AG, BERLIN, Germany; [2]Bayer AG, Berlin, Germany; [3]IMS Health, Frankfurt, Germany; [4]QuintilesIMS, Frankfurt, Germany.*

Background: Mineralocorticoid receptor antagonists (MRAs) are part of the treatment practice for patients with heart failure (HF) and/or hypertension. This study aimed to evaluate real-life MRA utilization in patients with chronic kidney disease (CKD) with or without diabetes mellitus (DM), HF and hypertension, respectively.

Methods: This retrospective cohort study used the US claims database PharMetricsPlus between 10/2009 and 09/2014. 229,143 patients ≥18 years with a first CKD diagnosis and 5,899 patients who initiated MRAs were included in two cohorts. Demographic characteristics, comorbidities, clinical events, medication use, and healthcare costs are reported for the overall cohorts and stratified by diagnosis: CKD (only), CKD+DM, CKD+HF and CKD+DM+HF, and MRA treatment (no MRA treatment, MRAs for < 6 and ≥ 6 months).

Results: We identified 114,129 CKD, 77,012 CKD+DM, 15,567 CKD+HF, and 22,435 CKD+DM+HF patients. The results showed low MRA usage in the population of interest. Overall, 2.3% of patients used MRAs. Use within the four diagnostic groups was 1.3%, 1.9%, 6.7%, and 6.7%, respectively. Hypertension was present in 78.5% of the overall population and in 94.1% of MRA users. HF was present in 16.6% of the overall population and in 46.6% of MRA users. 27.6% of patients who took MRAs had CKD stage 4, 5 or end-stage renal disease. MRA users generally presented with higher rates of comorbidities, medication use, and higher health-care costs. One-year persistence with MRA was less than 50%.

Conclusions: The use of MRAs in CKD patients is low and seems to be driven by the presence of hypertension and HF. Yet, MRAs are also given to CKD patients beyond stage 3, despite being contraindicated in the respective labels. Patients on MRAs tended to be more multi-morbid and to show higher healthcare resource use than patients without MRA.

FR-PO485

Impact of Transcatheter Aortic Valve Implantation on Renal Function Rita Calça, Rui C. Teles, Patricia Q. Branco, João Brito, Tiago Nolasco, Manuel D. Almeida, José P. Neves, Miguel Mendes, Domingos S. Machado, Andre L. Weigert. *Hospital Santa Cruz, Lisboa, Portugal.*

Background: Chronic kidney disease (CKD) is very prevalent in patients with aortic valve disease. Decreased renal perfusion as a consequence of diminished cardiac output may contribute to this patient's renal disfuncion. Given the potential reversibility of this mechanism after valve correction, the aim of this study was to verify the impact of percutaneous transcatether aortic implantation (TAVI) on kidney function.

Methods: We performed a retrospective analysis of 233 consecutive patients that underwent TAVI and were included in single center prospective registry between November 2008 and May 2017. Estimated Glomerular Filtration Rate (eGFR) was calculated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula and we considered 3 groups according their eGFR (mL/min/1.73 m^2); the categories sugested by Kidney Disease Improving Global Outcomes (KDIGO) 2012 guidelines were mentioned for each group. *Group 1* with eGFR≥60 included patients without CKD or CKD G1-2; *Group 2* with 30≤eGFR<60 (CKD G3a-b)*;* and *Group 3* with eGFR<30 (CKD G4). Patients on dialysis were excluded from the analysis. Previous to TAVI, 43,1% were in *Group 1*, 44,0% in *Group 2* and the remaining 12,9% in *Group 3*.

Results: 56.7% were female and the mean age was 81.8±7.5years (from 47 to 94years). No age or gender differences were found between groups. In patients from *Group 1*, a 15% fall in eGFR was verified after 1year follow-up (table1*).* Conversely, in patients from *Group 2* and *Group 3* we observed a significant increase in eGFR after TAVI (table1).

Conclusions: The association between worse outcomes in CKD patients undergoing TAVI is well established, but little is known about the potential reversibility of renal function after aortic valve replacement. We concluded that, for patients with moderate-to-severe CKD, there is a gain of function in the first month post-TAVI, which increased further 1 year after the procedure. This is probably due to improved renal perfusion post-procedure. We postulate that when evaluating patients that might need TAVI, this 'reversibility of CKD effect' should be considered.

Table 1

	eGFR pre-TAVI (mL/min/1.73m2)	eGFR 1month after TAVI (mL/min/1.73 m2)	eGFR 1 year after TAVI (mL/min/1.73 m2)	p value
Group 1	74,9±9,0	65,6±20,0	63,4 ±19,2	<0.001
Group 2	45.4±8,5	50,1±15,1	52,6±16,4	<0.01
Group 3	24,4±5,1	34,9±18,1	38,4±18,8	<0.01

FR-PO486

The Use of Renin-Angiotensin System Inhibitors and Aldosterone Receptor Antagonists in Heart Failure Patients with CKD Shreya Ghetiya, Sheila Kalathil, Aref Obagi, Kimberly J. Mccourt, Arif Asif, Dawn Calderon. *Jersey Shore University Medical Center, Neptune, NJ.*

Background: In order to reduce morbidity and mortality, ACCF/AHA guidelines for heart failure with reduced ejection fraction (HFrEF), (EF≤40%), recommend angiotensin converting enzyme inhibitors (ACE-I) unless contraindicated (c/i). Angiotensin Receptor Blockers (ARBs) should be used in those pts who are intolerant to ACEIs. In those pts who are tolerant to ACEIs/ARBs, ACC/AHA 2016 updated guideline recommends replacing it with Angiotensin-Receptor/Neprilysin inhibitor (ARNI) to further reduce mortality. Guideline also recommend to add Aldosterone receptor antagonists (ARA) in all pts with NYHA class II-IV and who have EF ≤35%, or EF ≤40% with MI/diabetes who develop symptom, unless c/i.

Methods: We conducted a retrospective chart review of 118 patients with EF≤40% discharged from our tertiary care hospital between 01/2016-12/2016 to ascertain if the guidelines were met. Prevalence of stage 3 chronic kidney disease (eGFR<60) and proteinuria were also measured.

Results: Demographics revealed that out of 118 pts evaluated, 68% were male and 80% were White, 16% Black, 2% Hispanic, 1% Asian, and 1% others. Only 69 (58%) were on ACEIs/ARBs/ARNI and 61 (52%) were on ARA upon discharge. Of these 69 pts, 41(59%) were on ACEIs, 12(17%) on ARBs and 16(23.18%) on ARNI. 5 pts (7.24%) were switched to ARNI from ACEIs/ARBs upon discharge. 35pts(30%) had c/i to ACEIs/ARBs/ARNIs and 29 pts (24%) had c/i to ARA. In this cohort, 67 pts (57%) had CKD 3. The average eGFR was 35.74ml/min/1.73m^2. Proteinuria was present in 35 pts (30%) of all 118 and 21(31%) out of 67 pts with CKD. Average serum sodium and potassium upon discharge were 136.7 and 4.14 mmol/l, respectively. Hyperkalemia (>=5.0mmol/l) was found in only 8(7%) pts. Average EF was 25%. Average SBP: 117mmHg and DBP: 671mmHg.

Conclusions: This analysis reveals opportunity for improvement in the utilization of ACEACEIs/ARBs/ARNI and ARA, both for cardiac and renal benefits.

FR-PO487

Change in Albuminuria and Risk of ESKD in a Global Consortium Josef Coresh. *CKD Prognosis Consortium, Baltimore, MD.*

Background: Albuminuria and proteinuria are used in chronic kidney disease (CKD) staging, but it is uncertain how change in these markers is associated with ESKD risk in clinical settings.

Methods: CKD-PC cohorts with multiple albumin or protein to creatinine ratio (ACR & PCR) measurements within a 2-year baseline period and subsequent ESKD risk were analyzed using Cox regression. Random effects meta-analysis results are presented and absolute risk was modeled.

Results: 76,234 participants (age 59 y, 47% female, 64% diabetic) had ≥2 ACR or PCR measurements during a 2-year baseline period, and were subsequently followed for over 5 years during which 3,181 ESKD events occurred in 14 cohorts. Adjusted for initial levels of ACR, eGFR and covariates, changes in both ACR (Figure, 10 cohorts) and PCR (9 cohorts) were linearly related to log hazard ratio (HR) of ESRD: 4-fold decrease and 4-fold increase had HRs (95% CI) of 0.53 (0.4-0.7) and 2.6 (1.8-3.8) for ACR and 0.48 (0.3-0.7) and 2.2 (1.7-2.9) for PCR. Results were consistent in most subgroups (DM, HTN, RAASI use, BP change and age) except baseline ACR where HRs for 4-fold decrease in ACR were stronger at higher baseline ACR. Absolute risk differences of ESKD associated with a 4-fold decrease were much larger at higher baseline ACR or PCR and follow-up time.

Conclusions: Change in ACR and PCR were consistently associated with risk of ESKD, beyond baseline eGFR, ACR and change in eGFR, informing their use as outcomes in clinical practice, observational and clinical trial research, and for regulatory purposes.

FR-PO488

Relationship of eGFR and ACR to Concurrent Abnormalities in a Global Consortium Lesley Inker. *CKD Prognosis Consortium, Baltimore, MD.*

Background: CKD is associated with many vascular and laboratory abnormalities. We describe the continuous relationship between abnormalities and CKD staged by eGFR and albuminuria (ACR; A1:<30, A2:30-299, A3:≥300 mg/g).

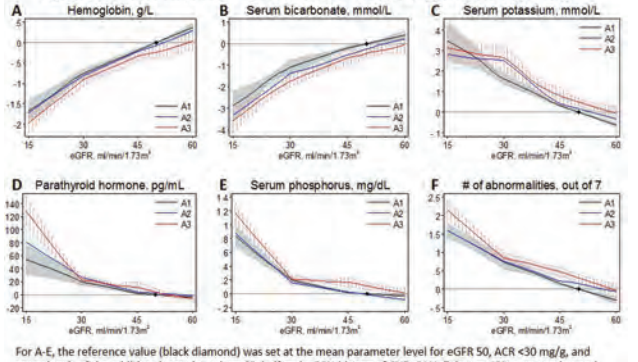
Methods: Using 12 CKD and 29 general population or high risk (GP/HR) cohorts, we performed random-effects meta-analyses for associations between eGFR (CKD-EPI creatinine equation, expressed as a linear spline with knots at 30, 45, 60, 75, 90 and 105) and the following parameters: systolic blood pressure (SBP, N=629,247), hemoglobin (N=405,633), bicarbonate (N=45,001, CKD cohorts only), phosphorous (N=128,769), parathyroid hormone (PTH, N=47,667), calcium (N=266,009), potassium (N=404,318), and total number of abnormalities (N=17,975, CKD cohorts only). Analyses were adjusted for demographics, comorbid conditions, and ACR stage. We assessed whether associations were modified by ACR stage and by diabetes by including interaction terms.

Results: The CKD cohorts were 52% female and 3% black, with mean age 67 (SD 14). The GP/HR cohorts were 53% female and 4% black, with mean age 53 (SD 18). In the CKD cohorts, lower eGFR was associated with lower hemoglobin and bicarbonate, and higher potassium, phosphorus, PTH and total number of abnormalities. (Figure) For phosphorus, there appeared to be a sharper increase in risk below eGFR <30. Associations with eGFR were relatively flat for SBP and calcium. There was no qualitative differences in associations by level of ACR or diabetes. In the GP/HR cohorts, there was a continuous association between eGFR and potassium; for hemoglobin, phosphorus and PTH, associations were present at eGFR <59, <51 and <70, respectively. Albuminuria was a weak risk factor for metabolic abnormalities.

Conclusions: There was a graded association between potentially reversible metabolic abnormalities and level of GFR with similar associations by ACR stage.

Funding: NIDDK Support, Private Foundation Support

Figure. Continuous associations between eGFR and laboratory parameters by A-stage



For A-E, the reference value (black diamond) was set at the mean parameter level for eGFR 50, ACR <30 mg/g, and mean levels of the additional covariates (age 60, half male, 20% history of CVD, 30% diabetes, 40% ever smoker and BMI 30). The y-axis reflects absolute difference in parameter value from the reference. For F, abnormalities were defined as hemoglobin <13 g/dL (12 g/dL for women), bicarbonate <22 mmol/L, potassium >5 mmol/L, PTH >65 pg/mL, phosphorus >5 mg/dL, calcium <8.5 mg/dL, SBP >140 mmHg or DBP >90 mmHg or taking antihypertensive medication, and the y-axis reflects the absolute difference in number of abnormalities compared to the mean number of abnormalities for an individual with eGFR 50, ACR <30 mg/g, and mean levels of additional covariates.

FR-PO489

Greater Variability in Kidney Function Is Associated with an Increased Risk of ESRD Yan Yan,[1,3] Benjamin C. Bowe,[1] Yan Xie,[1] Tingting Li,[1,2] Carlos E. Palant,[4,5] Ziyad Al-Aly.[1,2] *[1]Clinical Epidemiology Center, Research and Development Service, Veterans Affairs St Louis Health Care System, St. Louis, MO; [2]Department of Medicine, Washington University School of Medicine, St. Louis, MO; [3]Department of Surgery, Washington University School of Medicine, St. Louis, MO; [4]Research and Medical Service, Veterans Affairs Medical Center, Washington, DC; [5]George Washington University School of Medicine, Washington, DC.*

Background: Intra-individual variability in kidney function is an independent predictor of all-cause mortality, providing additional prognostic information beyond baseline kidney function and prior slope; however, its prognostic significance for ESRD is not known.

Methods: To examine this question we assembled a cohort of 1,004,741 United States veterans with an eGFR above 60 ml/min/1.73m^3 between October 2001-2002, where date of last measurement in this period was assigned T_0, and used adjusted Cox Proportional Hazard models to examine the association between eGFR variability and risk of ESRD. Variability in kidney function was defined for each participant as the coefficient of variation of the regression line modeled on all outpatient eGFR measures during the three years before T_0.

Results: After a median follow-up of 13.08 years, there were 2.76, 3.41, 4.01, and 5.57% cases of ESRD in the lowest to highest quartiles of eGFR variability, respectively. Compared with the referent category (lowest quartile), participants had a graded increase in risk of ESRD with a hazard ratio of 1.10 (95%CI: 1.06-1.13), 1.24 (1.20-1.28), and 1.73 (1.68-1.79) in quartiles 2, 3, and 4, respectively. Results were consistent across numerous sensitivity analyses.

Conclusions: Our results demonstrate that higher eGFR variability was associated with increased risk of ESRD.

FR-PO490

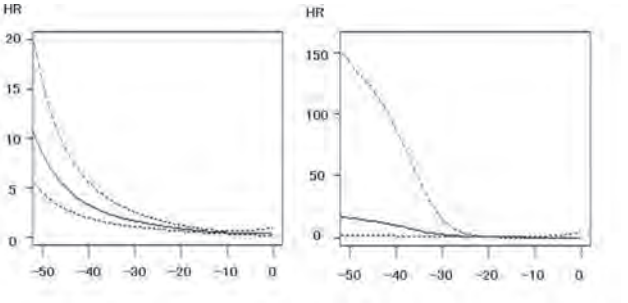
Importance of eGFR Change as a Surrogate End Point of ESRD in a Randomized Controlled Trial Eiichiro Kanda,[4] Enyu Imai,[3] Fumiaki Kobayashi,[1] Naoki Kashihara,[2] Masaomi Nangaku.[5] *[1]Daiichi Sankyo Inc, Somerset, NJ; [2]Kawasaki Medical School, Kurashiki City, Japan; [3]Nakayamadera Imai Clinic, Takarazuka, Japan; [4]Tokyo Kyosai Hospital, Meguro, Japan; [5]the University of Tokyo School of Medicine, Tokyo, Japan.*

Background: A use of a validated surrogate endpoint instead of a clinical endpoint could make a sample size small and shorten trial period. We evaluated a usefulness of an estimated glomerular filtration rate (eGFR) change as a surrogate endpoint using data from the randomized controlled clinical trial [Olmesartan Reducing Incidence of End-Stage Renal Disease (ESRD) in Diabetic Nephropathy Trial].

Methods: ESRD was defined as the true endpoint. eGFR changes over 1 to 3 years by 10% were defined as the surrogate endpoints. The relationship between eGFR changes and ESRD or the surrogate endpoints was evaluated using Cox proportional hazard models, which were adjusted for baseline characteristics. An effect of olmesartan on ESRD was compared with those on surrogate endpoints in terms of the ratio of the adjusted hazard ratio (aHR) of olmesartan to ESRD to those to surrogate endpoints by the bootstrap method.

Results: Diabetic kidney disease patients (n=566; male, 69.1%) were included in this analysis; average age±SD, 59.1±8.1 years; eGFR 37.1±9.8 ml/min. The Cox proportional hazard models with spline curves showed the relationships between eGFR changes over 1 and 2 years and ESRD (Figure 1). The ratios of aHR to ESRD to aHRs to surrogate endpoints near 1 were -30% or -40% over 2 years: -30%, 1.01 (95%CI 0.69-1.41); -40%, 1.0 (0.71-1.34). The events of eGFR changes of more than -30% showed good agreement with ESRD (0.6 < Cohen's kappas). The total sample sizes were 1004 for estimating eGFR change of -40% over 1 year; 800 for that of -40% over 2 years, which were smaller than that (1922) for one estimating ESRD.

Conclusions: eGFR change of more than -30% to -40% over 2 years would be a useful surrogate endpoint of ESRD in DKD patients.



FR-PO491

Identification and Prevalence of Pediatric CKD in a Large National Insurance Database Zubin J. Modi,[3] Ian T. Robinson,[3] Tanushree Banerjee,[2] Neil R. Powe,[2] Sharon Saydah,[1] Deborah Rolka,[1] Rajiv Saran,[3] Debbie S. Gipson.[3] *[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]University of California, San Francisco, San Francisco, CA; [3]University of Michigan, Ann Arbor, MI.*

Background: Population-level surveillance of chronic kidney disease (CKD) in pediatrics is undeveloped. Children and adolescents with CKD are currently poorly identified in large databases, as existing surveillance systems focus primarily on adults. We examined 3 different claims-based algorithms to identify children and adolescents with CKD in a large, national, single-payer insurance database.

Methods: Using the Clinformatics™ data from 2014, children and adolescents < 21 years with potential CKD were identified by 3 ICD-9 code algorithms: 585-CKD codes alone, adult CKD stage-specific algorithm and a novel pediatric-specific CKD algorithm derived from chart review (N=110) at a large academic center. Patients were included if code was used at least once during the study period. Demographics were compared between patients identified via each method and concordance between methods was evaluated.

Results: 860, 8637, and 4294 children were identified via the 585-CKD, adult, and pediatric algorithms, respectively. Of all patients identified by at least 1 of the 3 methods, 44.6% were identified by both the adult and pediatric algorithms. All 860 patients identified by the 585-CKD algorithm were also identified by both adult and pediatric algorithms. Some code differences included prostatic obstruction, abnormal creatinine testing and acute renal failure in adult algorithm and specific genetic, autoimmune, and urologic disorders in pediatric algorithm. 144 patients were uniquely identified by the pediatric algorithm and 5861 were unique to the adult algorithm. Of the uniquely identified patients, those in the pediatric group were older, compared to the adult group (11 y vs 8 y). A higher prevalence of anemia was observed among patients uniquely identified by the pediatric algorithm compared to adult algorithm (43% vs 23%).

Conclusions: Adult and pediatric code algorithms examined identified substantially more potential patients with CKD than the 585-CKD algorithm. Refinement and validation of code algorithms for pediatric CKD as well as expansion to use of ICD-10 codes may be necessary to allow for current and historic case identification and pediatric CKD surveillance efforts.

FR-PO492

Assessing Success in Transitioning of Young Adults from Pediatric to Adult Kidney Practice Cybele Ghossein,[1] Craig B. Langman,[1] Benjamin Joslin.[2] *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Transfer from a pediatric to an adult medical setting is associated with many barriers. There are little data on patients' assessment of the transition process itself. Three years ago at Lurie Children's Hospital, we established a kidney transition program with the help of an adult nephrologist, physician assistant and social worker. After 18 months, we evaluated the patients' perception of the program.

Methods: Patients who had transitioned from pediatric care and were seen at least once in the adult clinic were asked to take an established 5-point Likert scale survey. Survey questions addressed readiness to transition, the transition process itself, and the perception of adult care. Responses were categorized into Top 2 Box ("strongly agree" or "agree") and Bottom 2 Box ("strongly disagree" or "disagree"). Surveys were followed with semi-structured interviews. Three readers rated each response as either "negative," "neutral," or "positive." Average, standard deviation and reader reliability were calculated. The readers also selected a word that best depicted each response and those most-common words were counted by question and overall.

Results: 17 out of 42 patients completed the survey. Average age at transition (mean ± SD) was 20 ± 2 years; the majority of patients (82%) felt ready to transfer to adult care but only 59% felt they were consulted on the timing. 88% of patients felt having a transition appointment and meeting the adult care providers in the pediatric setting to be valuable. Although 94% of patients ultimately felt comfortable in the adult care environment, 18% experienced noticeable differences in treatment recommendations. 13 semi-structured interviews were conducted. Overall, the patients responded positively (3±0, 100% reader reliability) to the transition. But, when asked what could have improved the transition, the word the patients used most was, "earlier."

Conclusions: Young adults transitioning to adult care often feel ready to transition earlier than their transfer of care date. They subjectively benefit from a transition program that outlines the process of transferring their care. Communication regarding differences in treatment between pediatric and adult nephrology care is warranted.

FR-PO493

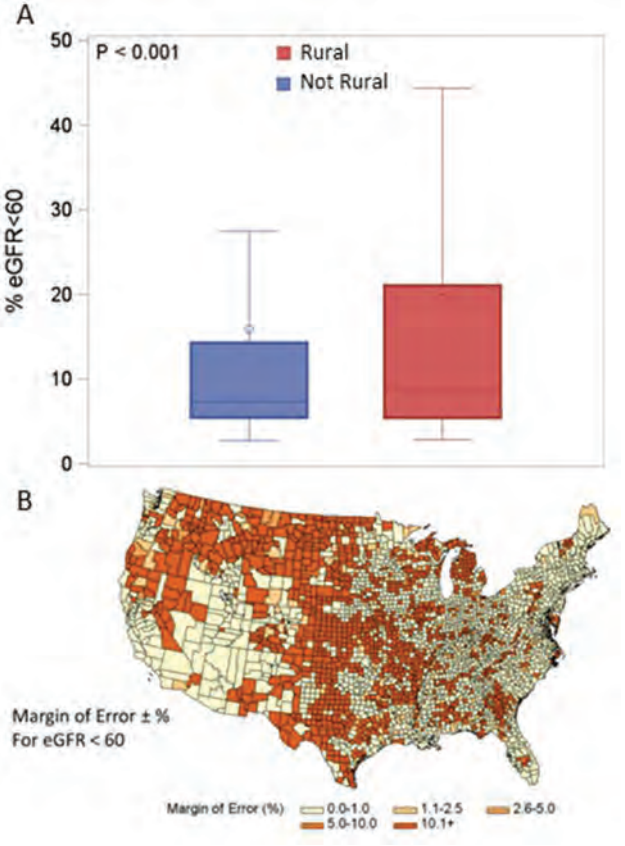
Spatial Analysis of CKD Prevalence in the US – A Joint Analysis of NHANES and KEEP Orrin Myers,[3] V. Shane Pankratz,[3] Keith C. Norris,[2] Joseph A. Vassalotti,[1] Mark L. Unruh,[3] Christos Argyropoulos.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]UCLA, Marina Del Rey, CA; [3]UNM Health Sciences Center, Albuquerque, NM.*

Background: Chronic Kidney Disease (CKD) is a public health concern in the US, but it lacks a nationwide surveillance system that can describe regional variation. We investigate the feasibility of estimating county-level CKD prevalence from the large-scale community disease detection Kidney Early Evaluation and Program (KEEP).

Methods: KEEP participants were recruited from two-thirds of the nation's counties but were self-selected after targeted recruitment. We combined KEEP (N=127,149) and NHANES samples (N=27,565) from 2001–2012 to estimate sampling weights. The weights reduce self-selection bias in KEEP when estimating county-level prevalence of CKD (eGFR<60 mL/min/1.73m^2).

Results: Nationwide prevalence of eGFR<60 was 8.9% (7.5-10.7) from KEEP and 6.8% (6.3-7.2) for NHANES. CKD prevalence was significantly higher in rural counties (Fig 1A), which also had higher uncertainty (Fig 1B).

Conclusions: A joint analysis of NHANES and KEEP produced estimates of eGFR<60 that are adjusted for selection bias. Our analysis found that CKD rates are higher in rural counties. This approach makes it possible to enhance spatial CKD surveillance systems.



FR-PO494

Reported Awareness of CKD in the United States According to KDIGO Risk Groups for Prognosis Joanne E. Rodrigue,[1] Tanushree Banerjee,[1] Delphine S. Tuot,[1] Meda E. Pavkov,[2] Vahakn B. Shahinian,[3] Nilka Rios Burrows,[2] Rajiv Saran,[3] Neil R. Powe.[1] *[1]University of California, San Francisco, San Francisco, CA; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]University of Michigan, Ann Arbor, MI.*

Background: Chronic kidney disease (CKD) awareness in high risk populations is a critical public health challenge. CKD is characterized by marked differences in prevalence across race/ethnicity. Trends in awareness among those at various risks of prognosis to CKD have not been well characterized in the general United States population overall, or by race/ethnicity.

Methods: Prevalence of reported CKD awareness was assessed among non-pregnant adults aged ≥20 years in the National Health and Nutrition Examination Survey 1999-2014 with affirmative response to the question "do you have a routine place to go for healthcare?" Participants with and without CKD were categorized into three KDIGO risk groups for prognosis to CKD of low, moderate, and high, based on eGFR and albuminuria. CKD awareness was defined by affirmative response to the question "have

you ever been told that you had weak or failing kidneys?" We determined the proportions of awareness overall, by risk groups, and by race/ethnicity over time periods 1999-2004, 2005-2010, and 2011-2014. A propensity score for KDIGO risk groups was used to adjust for differences over time in demographics, hypertension, diabetes, and frequency of healthcare use.

Results: Among 23,762 adults, the adjusted proportion of reported CKD awareness across all risk groups increased from 1999-2004 to 2011-2014 (p-trend=0.04). Awareness among Mexican Americans at high risk, increased from 13.4% in 1999-2004 to 36.6% in 2011-2014, and among those at moderate risk 2.3% to 11.1% (combined p-trend=0.003). Awareness among non-Hispanic (NH) whites and NH blacks at high and moderate risk showed moderate increases over time, but the trend was not significant.

Conclusions: Overall, increases in reported awareness of CKD, particularly in Mexican-Americans at moderate and high risk of progression may be due to improvements in detection of disease or due to increases in the number of persons with CKD knowing they have the disease.

Funding: Government Support - Non-U.S.

Adjusted Prevalence of Awareness by Risk Groups

Risk Groups	1999-2004	2005-2010	2011-2014
Low	1.1 (0.9-1.4)	1.1 (0.8-1.4)	1.5 (0.9-2.1)
Moderate	3.1 (2.0-4.2)	4.5 (2.7-6.2)	5.1 (2.9-7.3)
High	14.4 (7.0-21.8)	9.9 (5.9-14.0)	19.8 (11.6-28.0)

FR-PO495

Racial Disparities in Trajectory of eGFR Decline in Patients with or at Risk for CKD Susanne B. Nicholas,[5] Kenn B. Daratha,[4] Jenny I. Shen,[1] Douglas S. Bell,[5] Radica Z. Alicic,[2] Katherine R. Tuttle,[3] Keith C. Norris.[5] *[1]LaBiomed at Harbor-UCLA, Torrance, CA; [2]Providence Medical Research Center, Spokane, WA; [3]University of Washington School of Medicine, Spokane, WA; [4]Washington State University, Spokane, WA; [5]Medicine, UCLA, Los Angeles, CA. Group/Team: UCLA-PHS CKD Registry Study Team.*

Background: Blacks have a 3.5-fold greater prevalence of advanced chronic kidney disease (CKD) compared to non-Blacks. However, less is known about patterns of CKD progression in Blacks relative to non-Blacks in real world settings. UCLA and PHS have formed the largest combined electronic health record (EHR) based CKD and at-risk for CKD Registry. This study compares trajectories of estimated glomerular filtration rate (eGFR) between Blacks and non-Blacks in the UCLA dataset.

Methods: Data in the UCLA CKD and at-risk CKD Registry were analyzed from 176,406 patients who had at least two eGFR measurements from 2006-2016. Mean baseline eGFRs were compared using independent samples *t*-tests. Trajectories of eGFR of Blacks versus non-Blacks over the 11 years of the study were assessed using linear mixed models with random effects controlling for age and gender.

Results: Baseline characteristics of the overall cohort were: age 55±18 (mean±SD) years, CKD-EPI eGFR 90±24 mL/min/1.73m^2, 8% Black and 55% women. Among patients with baseline eGFR ≥60mL/min/1.73m^2, Blacks had higher mean baseline eGFR (103±23 versus 94±19 mL/min/1.73m^2, p<0.001), and higher mean difference in eGFR (6.8 mL/min/1.73m^2; 95% CI=6.6-6.9; p<0.001) than non-Blacks. Among patients with baseline eGFR 30-59 mL/min/1.73m^2, mean baseline eGFR was similar for Blacks and non-Blacks (49±8 versus 50±8 mL/min/1.73m^2, p=0.004). However, Blacks appear to have steeper trajectory of eGFR decline (mean difference in eGFR 1.8 mL/min/1.73m^2; 95% CI=1.4-2.3; p<0.001).

Conclusions: The trajectories of eGFR differed between Blacks and non-Blacks depending on baseline eGFR ≥60 or 30-59mL/min/1.73m^2, by a pattern shift from higher eGFR trajectories to lower, steeper eGFR trajectories. These data may signal critical windows for interventions to reduce disparities and improve kidney health in this high-risk group of Black patients.

Decreased Kidney Function Among a Rural Population in Veracruz, Mexico: A Cross-Sectional Study Magdalena Madero,[1] Diego J. Aguilar,[2] Alejandro Raña,[2] Alejandro Escobar,[1] Antonio Villa,[2] Gregorio T. Obrador.[2] *[1]National Heart Institute, Division of Nephrology, Mexico, Mexico; [2]Universidad Panamericana School of Medicine, Mexico, D.F., Mexico.*

Background: An epidemic of CKD of unknown origin (CKDu) has emerged in Central America, particularly in young male sugarcane workers. CKDu cases have been reported from Tierra Blanca, Veracruz, a region with similar environmental and socioeconomic characteristics to those described in Central America. To date, there are no epidemiologic reports of CKD hotspots in Mexico.

Methods: A cross-sectional study included adults with or without risk factors for CKD aged 20-60 from 3 communities in Tierra Blanca, Mexico. Sociodemographic, clinical, occupational and environmental data were collected from 613 participants. Standardized serum creatinine and albumin-creatinine ratio were measured; glomerular filtration rate (eGFR) was estimated using CKD-EPI equation. Patients were categorized with or without CKD according to KDIGO classification. Factors associated with lower eGFR were assessed using a multiple logistic regression model.

Results: Mean age was 41(±11), and 200(32.6%) were men. Prevalence of CKD (G1-G5) was 24.9%, mostly driven by albuminuria (Figure 1), and was similar between male and female participants. Presence of DM or HTN was more frequent in the group with CKD (33.9% and 33.9%); nevertheless, 68 (44.4%) of the participants identified with probable CKD did not have a traditional risk factor. Independent factors associated with an eGFR <90 mL/min/1.73 m^2 were older age(OR=1.07[1.04 - 1.10]), DM(OR=1.7[.99 - 3.19]), family history of CKD(OR=2.03[1.1 – 3.5]) and history of sugarcane work(OR=2.2 [1.1-4.3]).

Conclusions: This is the first epidemiologic report of a possible CKDu hotspot in Mexico. A high prevalence of CKD in these communities was found. Moreover, almost half of the cases could be classified as uCKD. Non-traditional risk factors, such as the history of sugarcane work, were associated with lower eGFR. The cross-sectional nature of the study prevents etiologic interpretations; a longitudinal assessment to further characterize this possible CKD hotspot is being planned.

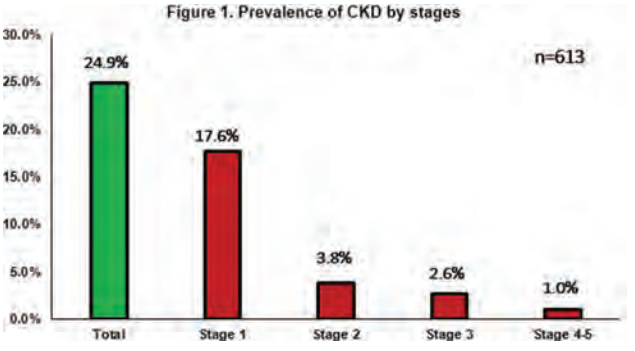
Figure 1. Prevalence of CKD by stages



FR-PO497

Prevalence and Risk Factors for CKD in Adults of El Salvador Carlos M. Orantes,[7] Raúl Herrera,[4] Miguel M. Almaguer,[2] Moises N. Diaz,[1] Xavier F. Parada,[3] Esmeralda G. Gavarrete Escobar,[6] Luis C. Silva.[5] *[1]ISSS, San Salvador, El Salvador; [2]Instituto de Nefrologia, La Habana, Cuba; [3]Massachusetts General Hospital, Boston, MA; [4]National Institute of Nephrology, La Habana, Cuba; [5]National School of Public Health, Cuba, La Habana, Cuba; [6]University of El Salvador, San Salvador, El Salvador; [7]Renal Research Unit, National Institute of Health, San Salvador, El Salvador.*

Background: An increase in deaths due to chronic kidney disease (CKD) has been observed in Central America. Mortality is 17 times higher in Nicaragua and El Salvador than in Cuba. Noted, CKD of unknown etiology (CKDu) is a major health problem in El Salvador

Methods: A cross-sectional analytical epidemiological study was conducted in a sample of 4,817 participants aged ≥20 years obtained from the national survey on non-communicable diseases to determine the prevalence and risk factors for CKD and CKDu. Stages of CKD (CKD-EPI equation) were estimated from serum creatinine and spot urine albumin. CKD-1 & 2 was confirmed at three months. Data analysis included descriptive, analytical, and bivariate measures

Results: Risk factors: diabetes mellitus (DM) 12.5%; hypertension (HTN) 37%; family history of CKD 8.7%; family history of DM 21.8%, family history of HTN 40.3%; obesity 27.3%, dyslipidemia 27%; current smoker 7.8%; alcoholism 9.4%; agricultural occupation 31.2%; NSAIDs 3.8%; nephrotoxic plants 3.8%, direct exposure to agrochemicals 12.6%. CKD prevalence was 12.6 (11.0-14.4) (Figure 1), of this one-third was CKDu 30.5% (25.9-35.5). Associations found were (OR; 95%CI): Age >64 (17.3; 11.7-25.6), DM (3.6; 2.9-4.7), obesity (3.5; 2.0-6.0), HTN (3.5; 2.8-4.5), male (2.3; 1.8-2.9), rural residency (1.3; 1.0-1.8), dyslipidemia (1.3; 1.0-1.6). At least 5 years of: use of agrochemicals (2.5; 1.9-3.4), exposure to agrochemicals in residency & work (2.4; 1.7-3.4), any agricultural activity (2.0; 1.5-2.5), direct exposure to agrochemicals (1.8; 1.4-2.4), drinking river water (1.8; 1.4-2.3), storage of products and hardware for fumigation (1.5; 1.2-2.0)

Conclusions: Adults in El Salvador have a double burden of risk factors (traditional and non-traditional) that can act synergistically to cause CKD

Funding: Government Support - Non-U.S.

	Male	Female	Total
CKD 1	2.2	1.6	1.8
CKD 2	1.7	1.6	1.6
CKD 3a	6.3	3.0	4.5
CKD3b	4.5	1.4	2.8
CKD 4	1.9	0.9	1.3
CKD5	1.3	0.2	0.7
CKD	17.8	8.5	12.6

FR-PO498

Survival of Patients with CKD Stage 3-5 in Iceland Arnar J. Jonsson,[1,2] Sigrun H. Lund,[2] Runolfur Palsson,[1,2] Olafur S. Indridason.[1] *[1]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [2]University of Iceland, Reykjavík, Iceland.*

Background: The purpose of this study was to estimate hazard ratio (HR) for death in patients with chronic kidney disease (CKD) stage 3-5 and to estimate the survival benefit of renal replacement therapy in CKD stage 5.

Methods: We obtained all SCr values from all clinical laboratories in Iceland for the years, 2008-2013. Data on age, gender, diagnoses of comorbid conditions (ICD-9 and ICD-10 codes) and HbA1c measurements were retrieved from electronic medical records. Information on initiation of renal replacement therapy was also obtained. The CKD-EPI equation was used to calculate eGFR. CKD was defined and staged according to the KDIGO classification system. Computerized algorithms were used to identify and exclude episodes of acute kidney injury. For CKD stage survival analysis, Cox regression model, using age as time scale was used to calculate hazard ratios adjusted for age, sex, hypertension, diabetes, coronary artery disease and acute kidney injury. For hazard ratio calculations for stage 5 with RRT compared to no RRT we used cox regression model with time on study, adjusted for age as continuous variable, sex, hypertension, diabetes and coronary artery disease.

Results: We retrieved 1,230,563 SCr values for 183,931 individuals aged 18 years and older. The median age was 62 years (range: 18 – 108) and 47.5% were men. A total of 13152 (7.2%) patients had CKD, 8951 (4.9%), 3252 (1.8%), 798 (0.4%) and 151 (0.08%) in stage 3A, 3B, 4 and 5, respectively and 234 patients received RRT. Compared to individuals without CKD, the adjusted hazard ratio for death for CKD stage 3a, 3b, 4 and 5 were 0.94 (95%CI: 0.88 – 1.00), 1.15 (95%CI: 1.05 - 1.26), 1.84(1.59 – 2.14) and 3.08(2.31 – 4.09) respectively in men and 0.85 (95%CI: 0.80 – 0.91), 0.98 (95%CI: 0.90 - 1.07), 1.60(1.38 – 1.85) and 4.48(3.18 – 6.30) in women, respectively. For individuals with stage 5 and receiving RRT the HR for death was: 0.43 (95%CI: 0.27 – 0.68) compared to those that did not receive RRT. For individuals aged 65-74 the HR was 0.80 (95%CI: 0.33 – 1.92) and for individuals aged 75 or older the HR was: 0.32 (95%CI: 0.17 – 0.57).

Conclusions: This nationwide study, comprising the majority of the Icelandic populations does not confirm increased risk of death with stage 3a and 3b as previously reported. Renal replacement therapy seems to improve survival for patients with CKD stage 5, particularly for the aged

Temporal Changes in the Pattern of Kidney Disease: Analysis Based on 40,759 Biopsy-Proven Cases in China From 2003 to 2014 Huixian Zhu, Jin-Hua Hou, Minlin Zhou, Dandan Liang, Si-Jia Shao, Ye Liu, Zhi-Hong Liu. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing China, Nanjing, China.*

Background: Global burden of disease showed that spectrum of disease in China has changed from infectious disease to non-infectious disease over the past 20 years and the latter has become one of the most leading public health problems. Epidemiologic studies reveal the temporal changes in the pattern of kidney disease, which might reliably inform future hypothesis driven studies and public health interventions. Thus, in this study we aimed to determine the temporal trends in kidney disease in 40,759 cases from 2003 to 2014.

Methods: We identified all patients with a native kidney biopsy specimen referred to the National Clinical Research Centre of Kidney Diseases in Jinling Hospital between 2003 and 2014. Temporal era was categorized into three consecutive 4-year time intervals (2003–2006, 2007–2010, and 2011–2014) and patients age was categorized into four intervals (14-24, 25-44, 45-59, and ≥60).

Results: In total, 40,759 cases with renal biopsy were analyzed. The mean age of the patients were 36.59±14.12 years old and 52.0% was male. Mean age of renal biopsy patients increased continuously and he proportion of patients over 60 years old mounted up from 5.6% to 9.9%. Primary glomerulonephritis (PGN), Secondary glomerulonephritis (SGN), Tubulointerstitial disease (TIN) and inherited kidney disease accounted for 67.1%, 26.4%, 2.9% and 2.5% respectively among cases of renal biopsy. IgA nephropathy (IgAN) (52.7%) was most common in PGN, immune-mediated disease accounted for 59.20% in SGN. The proportions of IgAN and focal segmental glomerulosclerosis (FSGS) had a downward tendency (P<0.001); while the proportion of membranous nephropathy (MN) increased significantly (P<0.001). Lupus nephritis and Henoch-Schonlein purpura nephritis this kind of immune-mediated diseases decreased significantly (P<0.001), diabetic nephropathy increased by nearly one time (P<0.001) from 2011 to 2014.

Conclusions: PGN remained the predominant kidney disease in China, of which, IgAN was the most common one. What was noteworthy was that the proportion of MN increased significantly, with a maximum increase in adolescent patients. The changing spectrum of kidney disease presented in this study provided a certain reference and basis for clinical diagnosis, prevention and epidemiological study.

FR-PO500

Consistency of the Obesity Paradox across Different Stages of CKD in Over 2 Million Veterans Melissa Soohoo,[1] Elani Streja,[1] Yoshitsugu Obi,[1] Connie Rhee,[1] Christina Park,[1] Hamid Moradi,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: The inverse relationship between body mass index (BMI) and mortality, also known as the "obesity paradox", has been described for both dialysis and non-dialysis dependent CKD patients. However, the relationship of BMI with mortality across all increasing CKD stages (including early CKD), is less well-known.

Methods: We investigated a cohort of 2.1 million US veterans with a BMI measurement between 2005-2006. CKD stages were created according to eGFR (estimated glomerular filtration rate) at the time of BMI measurement. Using Cox models adjusted for age, gender, race and diabetes status, we examined the relationship of BMI with all-cause mortality across strata of CKD stage.

Results: Patients were 64±14 years old, 5% female, 15% African-American, and 36% diabetic with a mean±SD baseline BMI 29±6 kg/m^2 and median[IQR] eGFR 75[61, 91] mL/min/1.73m^2. Patients were followed for a median[IQR] follow-up of 10.6[6.9, 11.1] years. We observed a reverse J-shaped association across all CKD stages compared to the referent BMI 25-<30 kg/m^2, where BMI≥40 kg/m^2 was associated with a higher risk of mortality across all CKD strata, except for CKD Stage 5 patients [HR(95%CI): 1.00[0.90, 1.12]. The relationship of BMI≥40 kg/m^2 with mortality incrementally declined towards the null across worsening kidney stages. However, across all stages of CKD, BMI<25 kg/m^2 was persistently associated with the highest risk of mortality. [Figure]

Conclusions: The relationship of morbid obesity with a higher risk of mortality in US veterans attenuates across worsening CKD stages, further supporting the notion of an "obesity paradox". Further studies are needed to understand the underlying mechanism of this relationship and whether weight management strategies are indicated in patients with worsening kidney disease.

FR-PO501

Weight Loss in Veterans with CKD after Enrollment in a Weight Management Program Niraj Desai,[3] Cameron D. Carter,[4] Mirela A. Dobre,[2] Khaldoon Shaheen,[2] Sankar D. Navaneethan,[1] Mahboob Rahman.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Case Western Reserve University, Cleveland, OH; [3]Cleveland VAMC, Case Western Reserve University, Cleveland, OH; [4]VHA, Cleveland, OH.*

Background: Though obesity is common in patients with CKD, interventions to reduce weight have not been well studied in this population. We examined the relationship between enrollment in a weight management program and weight loss across strata of eGFR.

Methods: We conducted a retrospective, observational analysis of patients enrolled in Managing Overweight/Obesity for Veterans Everywhere (MOVE!), a multidisciplinary weight management program within the Veteran's Affairs Medical Centers. Mean weight loss, and change in BMI for MOVE! participants was calculated comparing baseline weight measured upon enrollment to final weight measured at the last visit to the program. A control group not enrolled in MOVE! was evaluated for weight change over a similar time period. Paired t testing was used to assess statistical significance.

Results: 4935 veterans (age 59.5 +/- 9.4 yrs, weight 119.1 +/- 21.3 kg, BMI 37.4 +/- 6.5 kg/m2, 18% black, 67% diabetic) were enrolled in MOVE! between 2006 and 2011. Mean weight loss was 1.0 +/- 6.4 kg ($p<0.001$) and mean decrease in BMI was 0.33 +/- 2.1 kg/m^2 ($p<0.001$) after an average of 7.6 +/- 11.4 visits to the program. In an age, gender, BMI and weight matched cohort (n =4795), mean weight loss was 0.05 +/- 4.7 kg ($p=0.438$) and mean decrease in BMI was -0.05 +/- 1.7 kg/m^2 ($p=0.68$). Mean weight loss and decrease in BMI was similar for each stratum of eGFR in the intervention group (eGFR >90: 0.9 +/- 6.8 kg, 0.26 +/- 2.1 kg/m^2; eGFR 60-89: 1.1 +/- 6.6 kg, 0.36 +/- 2.2 kg/m^2; eGFR 45-59: 1.0 +/- 5.4 kg, 0.34 +/- 1.8; eGFR 30-44: 1.0 +/- 4.9 kg, 0.26 +/- 1.6 kg/m^2, all $p<0.001$). In the matched cohort, weight loss and decrease in BMI did not occur in any of the eGFR subgroups.

Conclusions: Enrollment in a multidisciplinary weight management program is associated with a modest weight loss across all strata of GFR.

FR-PO502

Weight Loss Has an Additive Effect on the Anti-Proteinuric Effects of Angiotensin II Receptor Blockers in Hypertensive Patients with CKD Shin-Young Ahn,[3] Dong Ki Kim,[7] Seung Seok Han,[6] Jung hwan Park,[2] Bumsoon Choi,[1] Chun Soo Lim,[4] Ho Jun Chin.[5] *[1]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea; [2]Konkuk University, Seoul, Republic of Korea; [3]Korea University Medical Center, Korea University Guro Hospital, Seoul, GYEONGGI-DO, Republic of Korea; [4]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [5]Seoul National University Bundang Hospital, Seong nam, Republic of Korea; [6]Seoul National University College of Medicine, Seoul, Republic of Korea; [7]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Because weight gain and obesity contribute to the development of chronic kidney disease (CKD) and end stage renal disease (ESRD), weight reduction is a lifestyle intervention that has been introduced for the prevention and management of CKD. However, CKD patients with obesity sometimes exhibit a slow progression of renal deterioration. We investigate the additive anti-proteinuric effect of weight reduction on the usage of an angiotensin II receptor blocker and the potential mechanisms of the beneficial effect in hypertensive CKD patients.

Methods: This study is a subanalysis of data from an open-label, randomized, controlled clinical trial (NCT01552954). Among the 235 participants, the body weight of 227 participants was measured and 24h urine samples were collected at baseline and after 16 weeks. The participants were assigned to subgroup according to changes in their body weight.

Results: Fifty-eight participants (25.7%) were assigned to group 1 (a ≥ 1.5% decrease in body weight after 16 weeks), 32 participants (14.1%) were group 2 (a 1.5% ~ 0.1% decrease in body weight), and 136 participants (60.2%) were group 3 (a ≥ 0.0% increase in body weight). Over the study period, unintentional weight loss independently increased the probability of reduced albuminuria (Group 1, RR 6.234, 95% CI 1.913 – 20.315, $p=0.002$). The relationship between weight loss and a decrease in albuminuria was even more significant in several subgroups, including participants who were female, younger (< 65 years), non-obese and obese (BMI ≥ 18.5 kg/m^2), as well as those who had a CKD stage ≥ 3a (≥ 45 ml/min/1.73m^2), consumed a low salt diet (urinary sodium excretion < 200 mEq/day) and a low protein diet (< 1.2 g/kg/day), and had a low baseline level of albuminuria (< 2000 mg/day). Among the urinary cytokines, only podocalyxin levels decreased significantly in participants who lost weight ($p=0.013$).

Conclusions: We observed that unintentional weight loss has additive effect on the anti-proteinuric effects of treatment with ARBs in hypertensive CKD patients, which is possibly related to the reduced damage of podocytes. Therefore, physicians could consider suggestion of weight reduction to hypertensive CKD patients even if they are not obese.

FR-PO503

Daily Sedentary Time and Physical Activity Are Independently Associated with ESRD Risk Jacob M. Taylor,[2] Edmond K. Kabagambe,[2] Thomas G. Stewart,[1] Jennifer Morse,[1] Edward D. Siew,[2] William J. Blot,[2] Loren Lipworth,[2] Talat Alp Ikizler.[2] *[1]Biostatistics, Vanderbilt University Medical Center, Nashville, TN; [2]Medicine, Vanderbilt University Medical Center, Nashville, TN.*

Background: Lifestyle factors, such as sedentary time and physical activity, could independently contribute to the risk of end stage renal disease (ESRD).

Methods: We assembled a case-cohort study from the Southern Community Cohort Study (SCCS) which recruited ~86,000 low-income blacks and whites in the southeastern US (2002-2009). 546 incident ESRD cases, identified by linkage with the US Renal Data System through March 2015, and a probability sample of 4049 SCCS participants, who donated a blood sample and had serum creatinine measured, were included. Demographic, medical, and lifestyle information, including detailed sedentary time and physical activity data, were obtained via questionnaire at baseline. Sedentary time was calculated as hr/d from daily sitting activities, while physical activity was calculated as met-hrs and derived from engagement in light, moderate, and vigorous activities. Hazard ratios (HRs) and 95% confidence intervals (CIs) for the association of sedentary time and physical activity with ESRD were computed from multivariable Cox models that included the two variables and age, sex, race, education, income, body mass index, eGFR, smoking, history of diabetes, hypertension, and hypercholesterolemia.

Results: At baseline, the mean (SD) was 55.5 (8.8) years for age and 96 (24) mL/min/1.73m2 for eGFR. Median (25th, 75th percentile) for sedentary time and physical activity were 7.9 (5.5, 11.4) hrs/d and 15.7 (8.0, 29.1) met-hrs, respectively. Most participants were women (58%), black (67%), reached high school (65%), had low income (61%), were overweight or obese (77%), were current/former smokers (58%), and had hypertension (61%), while 25% had diabetes and 39% had hypercholesterolemia. After median follow-up of 9.7 years (range 0.08-12.8), risk of ESRD increased per IQR increase in sedentary time (HR=1.13, 95% CI 1.09-1.16), while risk decreased per IQR increase in physical activity (HR=0.93, 95% CI 0.90-0.97) in adjusted analysis.

Conclusions: In this population at high risk for ESRD, sedentary time appears to increase the risk of ESRD, whereas physical activity is inversely associated with ESRD risk. Sedentary time and physical activity appear to play independent roles in ESRD risk.

FR-PO504

Conventional Measures of Body Composition Underestimate Sarcopenia and Overestimate Obesity in CKD Susan Ziolkowski,[4] Jin Long,[2] Glenn M. Chertow,[3] Mary B. Leonard.[1] *[1]Stanford School of Medicine, Stanford, CA; [2]Stanford University, Palo Alto, CA; [3]Stanford University School of Medicine, Palo Alto, CA; [4]Nephrology, Stanford University, Stanford, CA.*

Background: Fat and lean mass are directly correlated. Therefore, conventional definitions of sarcopenia (S) based on lean mass fail to capture low lean relative to fat, i.e. relative sarcopenia (RS) in those with greater adiposity. Recent data suggest RS better predicts incident morbidity than does S. Percent body fat (%BF) overestimates the prevalence of obesity if lean mass is low, while body mass index (BMI, kg/m^2) can underestimate. Fat mass indexed to height (kg/m^2) helps to address this limitation.

Methods: DXA appendicular lean mass index (ALMI, kg/m^2) and FMI were assessed in 13,980 NHANES participants. ALMI, FMI, and ALMI relative to FMI were expressed as sex- and race/ethnicity-specific standard deviation scores compared with young adults (T-scores) and for age. S was defined as ALMI T-score < -2, and RS as ALMI relative to FMI T-score < -2. Excess adiposity was defined using sex- and race/ethnicity specific FMI cutpoints and conventional BMI and %BF cutpoints. GFR was estimated using creatinine (eGFRcr) and cystatin C (eGFRcys).

Results: The prevalence of RS was higher than the prevalence of S, especially in CKD stages 3b (17 vs 6%) and 4 (36 vs 6%) using eGFRcr; these stages were associated with the highest FMI, accounting for the higher prevalence of RS vs S. In multivariable logistic regression, CKD stage was independently associated with lower ALMI relative to FMI for age, adjusted for smoking, physical activity and cardiovascular disease (OR stage 3b=1.47, stage 4=1.99, stage 5=2.38, vs eGFRcys > 90; p trend=0.05). The prevalence of obesity increased with CKD stage through stage 4, and was lower in stage 5 using FMI, BMI and %BF definitions. BMI and %BF under- and overestimated obesity prevalence, e.g., in CKD Stage 4, the prevalence of obesity was: BMI 42%, FMI 55%, %BF = 72%. CKD was not associated with obesity by FMI, adjusted for race, age, diabetes, liver disease, physical activity and cardiovascular disease.

Conclusions: In CKD, S underestimates muscle deficits and %BF overestimates the prevalence of obesity. CKD is independently associated with low lean mass relative to fat mass (RS) but is not associated with excess adiposity. Future studies are needed to determine how RS and excess adiposity (as defined by FMI) relate to morbidity and mortality in CKD.

FR-PO505

Association between Circulating Fibroblast Growth Factor 21 and Body Composition in CKD Mari Okada,[1] Takahiro Masuda,[1] Marina Kohara,[1,2] Hiromichi Yoshizawa,[1] Atsushi Miki,[1] Saki Nakagawa,[1] Ken Ohara,[1] Takuya Murakami,[1] Erika Hishida,[1] Hiroaki Myoga,[1] Miwa Shuto,[1] Yuko Watanabe,[1] Osamu Saito,[1] Tetsu Akimoto,[1] Shigeaki Muto,[1] Makoto Kuro-o,[2] Daisuke Nagata.[1] *[1]Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Japan; [2]Division of Anti-aging Medicine, Center for Melecular Medicine, Jichi Medical University, Shimotsuke, Japan.*

Background: Fibroblast growth factor 21 (FGF21) is a liver-derived hormone that induces responses to stress including activation of the sympathetic nervous system and the hypothalamus-pituitary-adrenal axis. Circulating FGF21 levels increase in the progression of chronic kidney disease (CKD), but the mechanism has not yet been fully evaluated. In this study, we examined the association between circulating FGF21 and body composition in predialysis CKD patients.

Methods: Seventy-two predialysis CKD patients were enrolled in this study (age 51.3 ± 17.1 years, male 51.4%, estimated glomerular filtration rate [eGFR] 66.3 ± 28.3 ml/min/1.73m^2). Body composition was measured by bioelectrical impedance analysis (BIA). Patients were divided into low- and high-FGF21 groups by the median value. Multivariable logistic regression analysis was used to examine the association between serum FGF21 levels and body composition.

Results: The median value of serum FGF21 was 131 pg/mL. Age (56.7 ± 15.4* vs. 45.2 ± 17.0 years, *p <0.05), body mass index (BMI) (26.1 ± 5.7* vs. 23.7 ± 4.3 kg/m^2), systolic blood pressure 133 ± 16* vs. 122 ± 27 mmHg), extracellular water (ECW) (22.0 ± 5.2 vs. 21.2 ± 4.4 L, p=0.06), the ratio of ECW to total body water (ECW/TBW) (0.387 ± 0.021* vs. 0.376 ± 0.023) were high, eGFR (55.2 ± 27.0* vs. 79.2 ± 24.5 ml/min/1.73m^2) and serum albumin (3.2 ± 0.9* vs. 3.8 ± 0.7 g/dL) were low in the high-FGF21. On the other hand, percentage of fat mass (26.6 ± 10.6 vs. 25.1 ± 9.3 %, p=0.264) and skeletal muscle (26.7 ± 6.8 vs. 25.7 ± 5.8 kg, p=0.264) were similar among the groups. In logistic regression analysis, ECW/TBW was an independent risk factor for higher FGF21 level (odds ratio 1.38: 95% confidence interval 1.04-1.96, p=0.024) even after adjustment for gender, BMI, systolic blood pressure, and percentage of fat mass.

Conclusions: In predialysis CKD patients, higher circulating FGF21 level is associated with increase in ECW/TBW. This result indicates that fluid retention is a novel indicator for circulating FGF21 levels.

Funding: Government Support - Non-U.S.

FR-PO506

Association of Body Composition with Frailty Status among Patients with Moderate to Advanced CKD Cynthia Delgado,[3,2] Kirsten L. Johansen.[1] *[1]University of California, San Franicsco, San Francisco, CA; [2]Medicine, Division of Nephrology, University of California, San Francisco, San Francisco, CA; [3]Medicine, Nephrology Section, San Francisco Department of Veterans Affairs, San Francisco, CA.*

Background: Frailty disproportionately affects individuals with chronic kidney disease (CKD) and is associated with hospitalization and loss of independence. The Frailty In Chronic Kidney diSease Intervention pilot sTudy (FICKSIT) aimed to determine the feasibility of a multi-faceted intervention to address frailty. We compared body composition of frail and non-frail patients enrolled in FICKSIT.

Methods: We enrolled 68 patients with CKD stage III-IV over the age of 18 who were receiving nephrology care. Frailty was defined according to the Fried Frailty index, which includes 5 criteria (weak grip, exhaustion, weight loss, low physical activity, slow gait). Participants meeting three or more criteria were considered frail (F); those meeting 1-2 criteria were intermediate frail (IF); and those not meeting any frailty criteria were not frail (NF). We performed whole-body bioelectrical impedance spectroscopy (BIS) to estimate ICW/kg as a proxy for muscle mass (ICW)), fat mass (FM) and extracellular water (ECW) as a percentage of total body weight. We used ANOVA to compare frailty status (F, IF and NF) and logistic regression analysis with NF participants as the reference group to determine if body composition was associated with frailty status after adjusting for covariates.

Results: Participants' mean age was 67 ± 8, and 93% were male. The majority of participants met at least one frailty criterion; 49% were IF and 25% were F. ICW/kg was lower among IF (0.28 ± 0.3 L/kg) and F (0.26 ± 0.3 L/kg) than among NF participants (0.29 ± 0.03 L/kg, p=0.05). In regression analysis, higher percent muscle mass (ICW/kg) (OR 0.38 per 1%, 95%CI 0.17, 0.83) and percent FM (FM/kg) (OR 0.76 per 1%, 95%CI 0.58, 0.98) were associated with lower odds of frailty.

Conclusions: Among FICKSIT participants, higher muscle and fat mass were associated with lower odds of frailty

Frailty Affects Treatment Decisions and Outcomes for Patients with CKD Reid Whitlock,[2] Frederick Eng,[1] Ranveer S. Brar,[1] Claudio Rigatto,[2] Paul Komenda,[2] Clara Bohm,[2] Navdeep Tangri.[2] *[1]Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]University of Manitoba, Winnipeg, MB, Canada.*

Background: Frailty is common in patients with Chronic Kidney Disease (CKD) and leads to accelerated aging. While there have been several studies examining frailty in patients with earlier stages of CKD and those on dialysis, little is known about the prevalence and impact of frailty on outcomes in patients with advanced CKD. We sought to determine the agreement between 3 different frailty measures and the association of these measures with dialysis modality decisions and mortality.

Methods: We studied 508 patients with advanced CKD who were enrolled in CKD clinics at 4 centers. We collected demographics, comorbid conditions, and laboratory results in addition to objective [Modified Fried Frailty Criteria (Fried) and Short Physical Performance Battery (SPPB)], and subjective measures (physician and nurse impression) of frailty. Our primary outcomes were choice of dialysis modality and all-cause mortality.

Results: Our cohort had a median age of 68 (interquartile range: 58, 77) and was 42.9% female. Estimates of frailty prevalence varied as 49.9% of the cohort were considered frail according to SPPB, 29.9% according to Fried, 33.4% according to physician impression, and 28.7% according to nursing impression. Agreement between objective frailty assessments (κ = 0.48) and subjective frailty assessments (κ = 0.46) was moderate. The objective frailty measures were not associated with choice of dialysis modality. In contrast, the subjective physician impression of frailty was associated with choosing hemodialysis (OR 3.74 [95% CI: 1.02-13.66]). The subjective frailty measures were not associated with choice of dialysis modality. Frailty measured objectively using Fried trended toward an association with mortality (OR 1.94 [95% CI: 0.97-3.88]).

Conclusions: In summary, we have demonstrated that the definition of frailty is important, as there is limited agreement between frailty construct and important differences in the relationship of each construct with clinical outcomes. Patients diagnosed as frail by Fried were more likely to die, and patients considered frail by physicians were more likely to choose in-center hemodialysis. Further research to understand the longitudinal trajectory of frailty and its impact on therapeutic choices, morbidity, mortality, and quality of life after initiation of dialysis is needed.

Recalibration and Validation of the Charlson Comorbidity Index in an Asian Population: The National Health Insurance Service – National Sample Cohort Study Jae shin Choi,[1] Myoung-Hee Kim,[2] Yong Chul Kim,[1] Jung Nam An,[3] Jae Yoon Park,[4] Dong Ki Kim,[1] Yun Kyu Oh,[3] Yon Su Kim,[1] Chun Soo Lim,[3] Jung Pyo Lee.[3] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Eulji University, Seongnam-si, Gyeonggi-do, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [4]Dongguk University Ilsan Hospital, Gyeonggido, Republic of Korea.*

Background: Weights assigned to comorbidities to predict mortality may vary based on the type of index disease and advances in the management of comorbidities. We aimed to develop a modified Charlson comorbidity index (CCI) in an Asian nationwide database (mCCI-A), thereby predicting their mortality more precisely.

Methods: The main data source used in this study was the National Health Insurance Service-National Sample Cohort (NHIS-NSC) constructed from the National Health Insurance database, which includes health insurance claims between January 1, 2002 and December 31, 2013 in Korea. Of the 1,025,340 individuals included in the NHIS-NSC, 578,547 patients who were hospitalized at least once were analyzed for this study. mCCI-A score were calculated by summing up the weights which were assigned to individual comorbidities according to their relative prognostic significance determined by multivariate Cox proportional hazard model. The modified index was validated in the same cohort.

Results: The Cox proportional hazards model provided reassigned severity weights for 17 comorbidities that significantly predicted mortality. Both the CCI and the mCCI-A were correlated with mortality. However, the mCCI-A showed modest but significant increases in **c** statistics compared with the CCI. The analyses using continuous net reclassification improvement(cNRI) revealed that the mCCI-A improved net mortality risk reclassification by 23.1% (95% CI, 22.0-24.3; P<0.001).

Conclusions: The mCCI-A facilitates better risk stratification for mortality in Korean inpatients compared with the CCI, suggesting that it may be a preferred index for use in clinical practice and the statistical analysis of epidemiological studies.

FR-PO509

Self-Reported Sleep Problems and Mortality among US Adults with and without CKD: NHANES 2007-2010 Monica Shieu,[5] Jennifer L. Bragg-Gresham,[5] Hal Morgenstern,[5] Delphine S. Tuot,[4] Deborah Rolka,[1] Nilka Rios Burrows,[2] Neil R. Powe,[3] Rajiv Saran.[5] *[1]CDC, Atlanta, AL; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]Priscilla Chan and Mark Zuckerberg San Francisco General Hospital & University of California SF, San Francisco, CA; [4]University of California, San Francisco, San Francisco, CA; [5]University of Michigan, Ann Arbor, MI.*

Background: Sleep problems are associated with several medical conditions including kidney disease. However, little research has been done assessing associations of sleep problems with mortality. We estimated the effects of self-reported sleep problems on mortality, by CKD status, among nationally representative, US adults.

Methods: A sample of 11,338 adults, ages 20+, from the mortality-linked National Health and Nutrition Examination Survey (NHANES; 2007-2010) with complete data on estimated glomerular filtration rate (eGFR) and urine albumin-to-creatinine ratio (UACR) were included in the analysis. Data on self-reported sleep problems were obtained from questionnaires. CKD was defined as eGFR < 60 ml/min/1.73 m^2 or UACR > 30 mg/g. Cox regression, stratified by CKD status, was used to estimate hazard ratios (HR; 95% CIs) for mortality over a median of 34 months of follow-up, adjusting for survey year, age, sex, and race/ethnicity. A combined model including all the subjects was investigated (not shown) to test for differences in associations by CKD status.

Results: Self-reported sleep problems were common among participants with CKD. Among individuals with CKD, 4 of the 5 sleep problems were positively associated with mortality, adjusting for demographic factors (table). For diagnosed sleep disorders and <6 hours sleep per night, these associations in CKD patients were stronger than in persons without CKD (though both p-values for interaction were >0.15). Nocturia and >9 hours of sleep were associated with mortality in patients with and without CKD.

Conclusions: If these findings are replicated in other studies with more extensive control for confounders, especially among CKD patients, efforts should be made to understand if ameliorating sleep problems improves wellbeing and survival.

Sleep Outcome (With problems vs. no problems)	No CKD (n=9352)			CKD (n=2036)

FR-PO510

Association of Chronic Insomnia with Mortality and Adverse Renal Outcomes Jun Ling Lu,[3] Amado X. Freire,[1] Miklos Z. Molnar,[3] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[3] *[1]UTHSC at Memphis, Memphis, TN; [2]University of California Irvine, School of Medicine, Orange, CA; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Chronic insomnia is highly prevalent in the world. Its effects on the sympatho-adrenal system could potentially worsen hypertension and cause metabolic abnormalities. However, there is lack of evidence of the association between insomnia and adverse renal outcomes.

Methods: We examined associations of chronic insomnia (defined as the presence of ICD9 codes 307.42, 307.49 and 780.52 and long-term use of insomnia medications) with all-cause mortality and renal outcomes, (ESRD, incidence of eGFR <45 ml/min/1.73m^2, and eGFR slopes <-3.0 ml/min/1.73m^2) in a national cohort of 957,587 US veterans with baseline estimated eGFR >60 ml/min/1.73m^2. Associations were examined in Cox proportional hazards models and logistic regressions. Besides crude models (model 1), adjustments were made for demographics and baseline estimated GFR (model 2), BMI and blood pressure (Model 3), comorbidities, antihypertensive drugs, and social-economic status (Model 4).

Results: 41,928 patients (4.4%) had chronic insomnia. Over a 6.1-year median follow-up period, 23.1% of patients died [mortality rate: 39.4/1000 patient-years (PY)], 0.2% reached ESRD (event rate: 0.2/1000PY), 6.6% of them progressed to eGFR <45 (event rate: 11.6/1000PY), and 2.7% displayed rapid progression. Insomnia was associated with higher risk of all-cause mortality (hazard ratio (HR):1.43 [95%CI:1.37, 1.48], p<0.001), incidence of eGFR <45ml/min/1.73m^2 (HR: 2.51 [95%CI:2.39, 2.64], p<0.001), ESRD (HR: 2.41 [95%CI:1.66, 3.48], p<0.001), and rapid loss of kidney function (odds ratio: 1.46[95%CI: 1.33, 1.62], p<0.001) [Figure].

Conclusions: Chronic insomnia is associated with higher risk of all-cause mortality, incident CKD and progressive loss of kidney function. Further studies are needed to determine if interventions to alleviate insomnia could improve clinical outcomes.

FR-PO511

The Risk of Adverse Events in Polycystic Kidney Disease Patients with Advanced CKD Manish M. Sood,[1] Sonali N. De chickera,[4] Adeera Levin,[3] Mila Tang,[2] Ayub Akbari.[5] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]St. Paul's Hospital, Vancouver, AB, Canada; [3]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [4]The Ottawa Hospital - University of Ottawa, Ottawa, ON, Canada; [5]University of Ottawa, Ottawa, ON, Canada.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) leads to progressive chronic kidney disease (CKD) with a subsequent increasing risk of adverse events such as cardiovascular disease (CV), infections, end-stage kidney disease (ESKD) and mortality. To date limited information exists regarding the risks of adverse events in ADPKD patients with advanced CKD. The objective of this study was to determine the risks of CKD-related adverse outcomes in ADPKD patients compared to non-ADPKD patients.

Methods: We examined data from the Canadian Study of Prediction of Death, Dialysis and Interim Cardiovascular Events (CanPREDDICT) cohort. CanPREDDICT was a prospective pan-Canadian cohort study from 2008-2013 involving 28 facilities caring for patients with advanced CKD (eGFR=15-45 ml/min/1.73m^2) with adjudicated outcomes. We used Cox proportional hazards and Fine and Gray models to examine the risk of CV (defined as coronary artery disease or CHF), infection, ESKD, or all-cause mortality in a propensity-score matched (4:1) cohort of non-ADPKD and ADPKD patients.

Results: Among a total of 2,370 patients, 105 with ADPKD were matched with 416 non-ADPKD patients with a baseline mean age and eGFR of 62.6 (SD 14.0) years and 27.8 (SD 9.0) mls/min/1.73m^2, respectively. During a total of 1,680 person-years of follow time (median follow-up 3.8 years), there were a total of 43 CV, 83 ESKD, 117 infectious and 39 all-cause mortality events. ADPKD was associated with a higher risk of cardiovascular events (9.5% vs. 7.9%, HR 1.46 95%CI 1.04-2.04) and ESKD (25.7% vs 13.5%, HR 2.00 95%CI 1.33-3.01), and with similar risks for infection (21.9% vs 22.6%, HR 1.16 95%CI 0.75-1.82) or all-cause mortality (6.7% vs 7.7%, HR 0.87 95%CI 0.40-1.91) compared to non-ADPKD. There were no differences in the types of infections (urinary, respiratory, hematologic or other) between the two groups (p=0.585).

Conclusions: ADPKD patients with advanced CKD are at higher risk of ESKD and cardiovascular events compared to non-ADPKD patients. These findings suggest that judicious monitoring, screening and treatment for adverse outcomes in ADPKD patients, especially related to cardiovascular disease, may be beneficial.

FR-PO512

Renal Resistive Index and Systematic Arterial Stiffness in the General Population Xiaohong Fan, Xuemei Li. *Peking Union Medical College Hospital, Chinese Academy of Medicine Sciences & Peking Union Medical College, Peiking, China.*

Background: Recent studies show that increased renal resistive index (RRI) is associated with kidney disease progression and cardiovascular disease (CVD). Greater arterial stiffness is also considered to be an independent predictor for CVD onset and associated with steeper decline in kidney function. RRI is presumed to be dependent on systematic vascular changes; however, the data about arterial stiffness and RRI is limited.

Methods: This study consisted of 3589 subjects ages between 35 and 85, recruited for a cross-sectional health survey in Pinggu, a suburb of Beijing, China in 2014. All subjects underwent assessment of ultrasonographic RRI and measurement of brachial-ankle pulse wave velocity (baPWV). Multiple linear regression modeling was performed to explore the RRI risk factors and the relationship between RRI and baPWV.

Results: The mean age of the study population was 53.7±9.1 years, 48.7% were males. RRI was positively associated with age (r=0.43; *P*<0.001). RRI in women was significantly higher than that in men (0.62±0.05 vs. 0.60±0.06; *P*<0.001) at all age groups, the sex difference existed even when adjusting for other factors. In all participants, baPWV was independently associated with increased RRI in multivariable analyses after adjustment for potential confounders. The other determinants of RRI in the general

population were age, sex, systolic and diastolic blood pressure, body mass index, estimate glomerular filtration rate and hemoglobin A1c(Table 1).

Conclusions: There was significantly association between systematic arterial stiffness and interenal RRI. The sex difference affect needs to be investigated in the future.

Funding: Government Support - Non-U.S.

Table 1: BaPWV was significantly associated with increased renal resistive index.

FR-PO513

The Association between Plasma PCSK9 Concentrations and CKD Ha yeon Kim,[2] Eun Hui Bae,[1] Seong Kwon Ma,[2] Soo Wan Kim.[2] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea.*

Background: Dyslipidemia commonly appear in patients with chronic kidney disease (CKD) presenting with unique characteristics. The proprotein convertase subtilisin/kexin type 9 (PCSK9) is a regulator of the low-density lipoprotein receptor and plasma cholesterol concentrations. We studied the association of circulating PCSK9 concentrations with both estimated glomerular filtration rate (eGFR) and serum lipid parameters in patients at different stage of CKD.

Methods: We evaluated plasma PCSK9 concentrations measured by ELISA in 90 non-dialysis patients at different stage of CKD. We assessed their lipid profile including total cholesterol, triglycerides, high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), apolipoprotein A1 (ApoA1), apolipoprotein B (ApoB), urine albumin creatinine ratio (UACR), C-reactive protein (CRP), use of statins or fibrate, presence of hypertension, diabetes, chronic kidney disease, smoking, malignancy and coronary artery disease.

Results: The mean plasma level of PCSK9 was 309.7 ± 74.6 ng/ml in the 90 patients. Plasma PCSK9 concentration has a positive correlation with UACR (r=0.261, *P* =0.029) and triglyceride (r = 0.316, *P* = 0.007), but not with total cholesterol (*P* =0.142), eGFR (*P* =0.058), HDL-C (*P* =0.319), LDL-C (*P* =0.101), ApoA1 (*P* =0.380), ApoB (*P* =0.805), ApoA1/B (*P* =0.893) and CRP (*P* =0.457). In the patients with UACR ≥ 1g/gCr, plasma PCSK9 levels increase compared to patient with UACR <1g/gCr, (361.9 ± 60.3 ng/ml vs. 299.3 ± 73.2 ng/ml, *P* =0.008). Plasma PCSK9 level was independently associated with existence of diabetes and statin/fibrate medication. The concentrations of PCSK9 according to CKD stages were 273.0 ± 56.5 ng/ml in the CKD stage 1, 317.5 ± 98.4 ng/ml in the CKD stage 2, 306.6 ± 68.7 ng/ml in the CKD stage 3, 333.1 ± 85.6 ng/ml in the CKD stage 4, and 306.0 ± 64.3 ng/ml in the CKD stage 5 without dialysis, respectively. The levels of PCSK9 in patients with CKD stage 1 were lower than those of other stages (*P* = 0.032).

Conclusions: Plasma PCSK9 concentrations are related to proteinuria, but not associated to eGFR in patient with CKD.

FR-PO514

The Risk of Venous Thromboembolism in Patients with Albuminuria and Normal or Reduced Kidney Function David Massicotte-Azarniouch,[3] Anan Bader eddeen,[8] Alejandro Lazo-Langner,[7] Amber O. Molnar,[2] Ngan Lam,[6] Deborah Lynn Zimmerman,[4] Amit X. Garg,[1] Ziv Harel,[3] Jeffrey Perl,[5] Ron Wald,[5] Manish M. Sood.[4] *[1]London Health Sciences Centre, London, ON, Canada; [2]McMaster University, Hamilton, ON, Canada; [3]None, Ottawa, ON, Canada; [4]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [5]St. Michael's Hospital, Toronto, ON, Canada; [6]University of Alberta, Edmonton, AB, Canada; [7]Western University, London, ON, Canada; [8]Istitution for Clinical Evaluative Sciences, Ottawa, ON, Canada.*

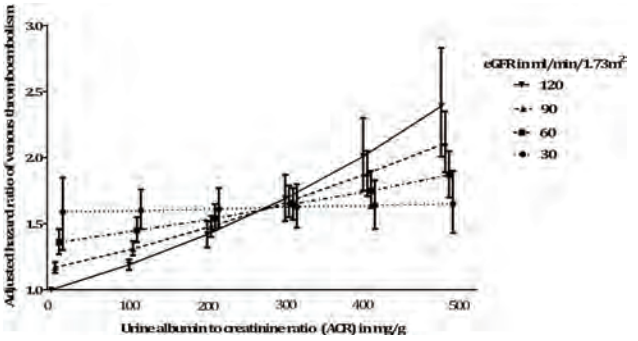
Background: Chronic kidney disease (CKD), defined by the presence of either albuminuria and/or reduced kidney function, is associated with a higher risk of venous thromboembolism (VTE). Whether the risk of VTE differs in CKD patients with albuminuria and normal or reduced kidney function remains unclear.

Methods: We conducted a retrospective population-based cohort study of 694, 956 patients in Ontario, Canada between 2002 and 2012. We included patients with a measurement of albuminuria (albumin-to-creatinine ratio, ACR) and serum creatinine (for estimated glomerular filtration rate, eGFR). The primary outcome was the time to a first VTE event examined across differing levels of albuminuria and kidney function using adjusted Cox proportional hazard models and accounting for the competing risk of death.

Results: A total of 15,180 (2.2%) VTE events occurred during the study period. Both albuminuria and kidney function were independently associated with VTE (p<0.0001). The association of albuminuria and VTE differed by the level of kidney function (ACR X eGFR interaction p=0.0001). The risk of VTE in patients with normal kidney function (eGFR 120 mL/min/1.73 m^2) and heavy albuminuria (ACR 500 mg/g) was HR 2.39 (95% CI 2.01-2.83) compared to those with normal kidney function and no albuminuria. Among those with reduced kidney function (eGFR 30 mL/min/1.73 m^2), the risk of VTE was increased, irrespective of albuminuria [ACR 0 vs. ACR 500 mg/g: HR 1.59 vs. 1.65).

Conclusions: Albuminuria increases the risk of VTE markedly in patient with normal kidney function but does not in those with reduced kidney function.

Funding: Government Support - Non-U.S.



Adjusted hazard ratio of venous thromboembolism by albuminuria at fixed levels of kidney function

FR-PO515

High Protein Intake Is Associated with Higher Mortality in Patients with Non-Dialysis Dependent CKD Jawed Akhtar,[2] Mahmoud A. Mahmoud,[2] Faisal M. Arif,[2] Angela M. Wallick,[1] Kamyar Kalantar-Zadeh,[3] Miklos Z. Molnar,[2] Barry M. Wall,[2] Csaba P. Kovesdy.[2] *[1]Department of Veterans Affairs, Memphis, TN; [2]University of Tennessee Health Science Center, Memphis, TN; [3]University of California Irvine, School of Medicine, Orange, CA.*

Background: High protein intake is associated with worse progression of CKD in patients with non-dialysis dependent CKD (NDD-CKD), but its effects on mortality are unclear.

Methods: We examined 854 NDD-CKD US veterans followed at a tertiary medical center. We estimated dietary protein intake (DPI) from urea nitrogen and creatinine measured from morning spot urine collections and using the Maroni formula. The associations of baseline DPI (analyzed as a continuous variable using splines, and divided into quartiles) with all-cause mortality was examined in Cox models adjusted for demographics, comorbidities, medication use, baseline estimated GFR and proteinuria.

Results: Patients were 66±11 years old, 96% were men, 59% were African American and 55% were diabetic. The baseline estimated GFR was 38±21 ml/min/1.73m^2. Higher DPI was associated with higher mortality (Figure). Compared to the second quartile, the hazard ratios (95%CI) of mortality associated with quartiles 1, 3 and 4 of DPI were 1.24 (0.76-2.01), 1.41 (0.88-2.26) and 2.17 (1.38-3.37), respectively.

Conclusions: In patients with moderate and advanced NDD-CKD, high DPI is associated with higher all-cause mortality. Further studies are needed to determine the amount of DPI providing optimal outcomes in this patient population.

FR-PO516

Caffeine Consumption and Mortality in CKD Miguel Bigotte Vieira,[1] Rita Magriço,[2] Catarina Viegas dias,[3] Lia Leitão,[4] João Sérgio Neves.[5] *[1]Nephrology and Renal Transplantation Department, Centro Hospitalar Lisboa Norte, Lisboa, Portugal; [2]Nephrology Department, Hospital Garcia de Orta, Almada, Portugal; [3]Dafundo Family Health Unit, Lisbon, Portugal; [4]Neurology Department, Hospital Prof. Doutor Fernando Fonseca, Amadora, Portugal; [5]Department of Endocrinology, Diabetes and Metabolism, São João Hospital, Faculty of Medicine, University of Porto, Portugal, Porto, Portugal.*

Background: An inverse relationship between coffee consumption and mortality has been reported in the general population. However, the association between caffeine consumption and mortality in patients with CKD remains unclear.

Methods: We examined the association of caffeine consumption with mortality among 2328 patients with CKD (defined by estimated GFR < 60 mL/min/1.73m^2, CKD-EPI) in a prospective nationwide cohort, using the continuous National Health and Nutrition Examination Survey (NHANES) 1999-2010. Caffeine consumption was assessed at baseline using 24-hour dietary recalls. Cox proportional hazard models were fitted to estimate hazard ratios (HR) for all-cause mortality according to quartiles of caffeine consumption, adjusting for potential confounders (age, gender, race, annual family income, education level, estimated GFR, albumin/creatinine ratio, hypertension, smoking status, dyslipidemia, body mass index, previous cardiovascular events and diet: consumption of alcohol, carbohydrates, polyunsaturated fatty acids and fibers). We assessed the extent to which CKD stage modified the effects of caffeine consumption on mortality with likelihood ratio tests for interaction.

Results: Quartiles of caffeine consumption were: 1st quartile (<29.5 mg of caffeine/day), 2nd (30.5 to 101.0 mg/day), 3rd (101.5 to 206.0 mg/day), and 4th quartile (206.5 to 1378.5 mg/day). A dose-dependent inverse association between caffeine and all-cause mortality was observed in patients with CKD. Comparing with 1st quartile of caffeine consumption, adjusted HR for death was 0.88 (95% CI, 0.68-1.44) for 2nd quartile, 0.78 (95% CI, 0.60-1.01) for 3rd quartile and 0.76 (95% CI, 0.59-0.97) for 4th quartile (p=0.027 for trend across quartiles). There were no significant interactions between caffeine consumption quartiles and CKD stages with respect to all-cause mortality.

Conclusions: Our study showed a dose-dependent protective effect of caffeine consumption on mortality among patients with CKD.

FR-PO517

The Effect of High Alcohol Consumption on Incidence of Proteinuria Was Different by Gender: A Retrospective Cohort Study Yoshiki Kimrua,[1] Ryohei Yamamoto,[2,1] Yoshitaka Isaka,[1] Kunitoshi Iseki,[3] Kunihiro Yamagata,[3] Kazuhiko Tsuruya,[3] Hideaki Yoshida,[3] Shouichi Fujimoto,[3] Koichi Asahi,[3] Toshiki Moriyama,[2,3] Tsuyoshi Watanabe.[3] *[1]Department of Nephrology, Osaka University Graduate School of Medicine, Suita, Japan; [2]Health and Counseling Center Osaka University, Toyonaka, Japan; [3]Steering Committee for the Research on the Positioning of Chronic Kidney Disease in Specific Health Check and Guidance in Japan, Fukushima, Japan.*

Background: Several studies reported that mild to moderate alcohol consumption reduced the risk of proteinuria, whereas a proteinuric effect of heavy alcohol consumption is controversial. The aim of this retrospective cohort study was to assess an association between high alcohol consumption and the incidence of proteinuria in males and females.

Methods: Participants who underwent annual health check examinations in Japan with dipstick urinary protein ≤± and/or eGFR <60 mL/min/1.73m^2 at their first examinations between 2008 and 2011 were included in this analysis. Main exposure was alcohol consumption categories defined as rare, occasional and daily drinkers with ≤19, 20-39, 40-59 and ≥60 g/day. The outcome was time to first incidence of proteinuria (dipstick urinary protein ≥1+). An association between alcohol consumption and incidence of proteinuria was assessed using Cox proportional hazards models.

Results: Background of participants in 78,327 males and 78,369 females; age 65 [57-69] (median [25%-75%]) and 64 [59-69] years; eGFR 75 [69-86] and 76 [68-90] ml/min/1.73m^2; respectively. Incidence of proteinuria was observed in 4,991 males and 3,040 females during 1.9 (1.0-2.1) years of the observational period. The association between alcohol consumption and incidence of proteinuria was U-shaped in males and J-shaped in females (Figure).

Conclusions: The effect of high alcohol consumption on incidence of proteinuria was different between males and females. The association was J-shaped in female and U-shape in males, respectively, suggesting that females were more vulnerable to alcohol than males.

Funding: Government Support - Non-U.S.

FR-PO518

Cannabis Use and Its Association with Clinical Characteristics and Post-ESRD Mortality Praveen Kumar Potukuchi,[4] Keiichi Sumida,[2] Miklos Z. Molnar,[4] Abduzhappar Gaipov,[4] Frank Park,[4] Hamid Moradi,[3] Fridtjof Thomas,[4] Elani Streja,[1] Melissa Soohoo,[3] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[4] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]University of California Irvine, School of Medicine, Orange, CA; [4]University of Tennessee Health Science Center, Memphis, TN.*

Background: The health effects of cannabis use in patients with advanced CKD are unknown.

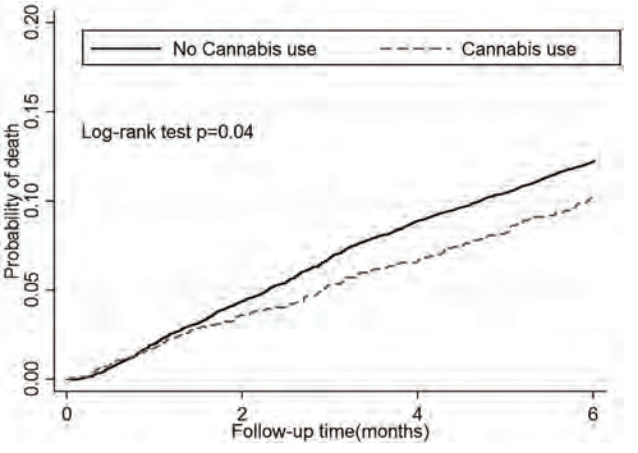
Methods: In 11,154 US veterans who transitioned to dialysis during 2007-2014 and had undergone urine toxicology tests (1,381 who tested positive for cannabis, and 9,773 who tested negative for cannabis), we examined the association of cannabis use with various clinical characteristics using logistic regressions and with 6-month all-cause mortality using multivariable adjusted Cox models.

Results: The mean (SD) age of the cohort was 61.9 (9.7) years; 97% were male, 45 % were African American and 69% were diabetic. Cannabis use was associated with younger age, higher mean pre-ESRD eGFR, unmarried status, smoking, cancer, liver disease, HIV and with the prescription of opioids and antidepressants (Table). Patients who tested positive for cannabis displayed lower mortality than patients who tested negative [Figure, unadjusted hazard ratio (95% CI): 0.83(0.7-0.99)], but the survival advantage was attenuated after multivariable adjustments [1.06 (0.86-1.31), p=0.6].

Conclusions: Among patients who underwent toxicology testing, cannabis use during the pre-ESRD period is associated with lower all-cause mortality in the immediate post-ESRD period. However, this association mitigates when adjusted for patient characteristics.

Funding: NIDDK Support

	Cannabis use yes vs no OR, (95% CI)
Age at dialysis	0.96 (0.95–0.97)
eGFR	1.01 (1.01–1.01)
Single vs married	1.29 (1.04–1.60)
Divorced vs married	1.47 (1.25–1.72)
Smoking	1.95 (1.62–2.35)
Cancer	1.51 (1.11–2.06)
Liver disease	2.03 (1.64–2.50)
HIV	3.00 (1.46–6.18)
Opioid use	1.45 (1.17–1.79)
Antidepressants use	1.51 (1.27–1.80)



FR-PO519

Iron Status and Mortality Risk in Diabetic and Non-Diabetic Veterans with CKD Monique E. Cho,[1,2] Jared Hansen,[1] Celena B. Peters,[1] Brian C. Sauer.[1,2] *[1]Veterans Health Administration, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: The mortality risk associated with abnormal iron balance has not been compared between diabetic and non-diabetic CKD populations.

Methods: We performed a historical cohort study using the Veterans Affairs Informatics and Computing Infrastructure. We identified a pre-dialysis CKD cohort (MDRD eGFR <60 mL/min/1.73m^2) with at least one set of iron indices between 2006-2015. The clinical characteristics were determined from the ICD-9 codes and laboratory data during the *baseline period*, defined as the year preceding the first available iron indices. Patients with ESRD, genetic and chronic disorders affecting iron metabolism were excluded. The cohort was divided into 4 iron groups based on the joint quartiles (Q) of transferrin saturation (Tsat) and ferritin: functional iron deficiency (FID), 1st Tsat Q + 3rd–4th ferritin Qs; Low Iron (LI), 1st Tsat+ferritin Qs; High Iron (HI), 4th Tsat+ferritin Qs; and Reference (R), 2nd–3rd Tsat+ferritin Qs. Matching weights were used to determine the effects of FID, HI, and LI on all-cause mortality, using R as the reference. Diabetes was examined as a potential effect modifier.

Results: Of the 1,159,371 Veterans with CKD, 148,611 met the inclusion criteria. The mean±SD for age and eGFR were 72±11 years and 43±11 mL/min/1.73 m^2, respectively. The median (IQR) Tsat and ferritin values were 20 (14, 26)% and 119 (64, 196) ng/mL. Of the study cohort, 42% could not be categorized into any of the 4 iron groups. In the remaining 83,439 Veterans, the prevalence for FID, HI, LI, and R were 13%, 17%, 20%, and 50%, respectively. After matching weights were implemented, the covariates were evenly distributed among the iron groups. During the mean±SD follow-up period of 4.0±2.7 years, FID exhibited the greatest risk for all-cause mortality [Risk Ratio, RR (95% CI): 1.21 (1.17, 1.25)], after being stratified by the diabetes status and matching for age, sex, race, BMI, dyslipidemia, eGFR, albumin, hemoglobin, eGFR, and CV history. The RRs for mortality with HI and LI were similarly increased, 1.09 (1.06, 1.13). The association between iron status and mortality risk was not modified by the diabetes status.

Conclusions: Abnormal iron status, particularly FID, is associated with increased all-cause mortality risk in pre-dialysis CKD, regardless of the diabetes status. Further studies are needed to investigate the underlying mechanism.

FR-PO520

Iron Status and the Risk of Incident ESRD in Veterans with CKD Monique E. Cho,[1,2] Jared Hansen,[1] Celena B. Peters,[1] Brian C. Sauer.[1,2] *[1]Veterans Health Administration, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: The risk for CKD progression associated with abnormal iron balance has not been evaluated in a large CKD population.

Methods: We performed a historical cohort study using the national data from the Veterans Affairs Informatics and Computing Infrastructure. We identified a pre-dialysis CKD cohort (MDRD eGFR <60 mL/min/1.73m^2) with at least one set of iron indices between 2006-2015. The clinical characteristics were determined from the ICD-9 codes and laboratory data during the *baseline period*, defined as the year preceding the first available iron indices. Patients with ESRD, genetic, and chronic disorders affecting iron metabolism were excluded. The cohort was divided into 4 iron groups based on the joint quartiles (Q) of transferrin saturation (Tsat) and ferritin: functional iron deficiency (FID), 1st Tsat Q + 3rd–4th ferritin Qs; Low Iron (LI), 1st Tsat+ferritin Qs; High Iron (HI), 4th Tsat+ferritin Qs; and Reference (R), 2nd–3rd Tsat+ferritin Qs. Incident ESRD was determined by the diagnosis and procedure codes reflecting renal transplantation or dialysis. Matching weights were used to determine the effects of FID, HI, and LI on incident ESRD, using R as the reference. Diabetes was examined as a potential effect modifier.

Results: Of the 1,159,371 Veterans with CKD, 148,611 met the inclusion criteria. The mean±SD for age and eGFR were 72±11 years and 43±11 mL/min/1.73 m^2, respectively. The median (IQR) Tsat and ferritin values were 20 (14, 26)% and 119 (64, 196) ng/mL. Of the study cohort, 42% could not be categorized into any of the 4 iron groups. In the remaining 83,439 Veterans, the prevalence for FID, HI, LI, and R were 13%, 17%, 20%, and 50%, respectively. After matching weights were implemented, the clinical covariates were evenly distributed among the iron groups. During the mean±SD follow-up period of 4.0±2.7 years, only HI exhibited increased risk for ESRD, [risk ratio, RR (95% CI): 1.16 (1.10, 1.23)]. The RRs for FID and LI were 0.97 (0.91, 1.03) and 0.78 (0.73, 0.83), respectively. The association between iron status and ESRD risk was not altered by the diabetes status.

Conclusions: High iron status is associated with increased risk for incident ESRD in CKD, while iron deficiency is associated with reduced risk for ESRD. Diabetes was not found to be an effect modifier. Further studies are required to confirm the finding and to investigate the underlying mechanisms.

FR-PO521

Functional Iron Deficiency and Incident Diabetes Risk in US Veterans with Pre-Dialysis CKD Monique E. Cho,[1,2] Jared Hansen,[1] Celena B. Peters,[1] Brian C. Sauer.[1,2] *[1]Veterans Health Administration, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: While the association between iron overload and diabetes is well established, the possible adverse metabolic effect of iron deficiency, both functional and absolute, has not been investigated in any population, including those with CKD.

Methods: We performed a historical cohort study using the national data from the Veterans Affairs Informatics and Computing Infrastructure. We identified a non-diabetic, pre-dialysis CKD cohort (MDRD eGFR <60 mL/min/1.73m^2) with at least one set of iron indices between 2006-2015. The clinical characteristics were determined from the ICD-9 codes and laboratory data during the *baseline period*, defined as the year preceding the first available iron indices. Patients with diabetes, ESRD, genetic and chronic disorders affecting iron metabolism were excluded. The cohort was divided into 4 iron groups based on the joint quartiles (Q) of transferrin saturation (Tsat) and ferritin: FID, 1st Tsat Q + 3rd–4th ferritin Qs; Low Iron (LI) reflecting absolute iron deficiency, 1st Tsat+ferritin Qs; High Iron (HI), 4th Tsat+ferritin Qs; and Reference (R), 2nd–3rd Tsat+ferritin Qs. Incident diabetes was determined by the ICD-9 codes. Matching weights were used to determine the effect of iron status on incident diabetes, using R as the comparison group.

Results: Of the 1,159,371 Veterans with CKD, 68,728 met the inclusion criteria. The mean±SD for age and eGFR were 74±12 years and 43±11 mL/min/1.73 m^2, respectively. The median (IQR) Tsat and ferritin values were 18 (13, 23)% and 98 (53, 150) ng/mL. Of the study cohort, 44% could not be categorized into any of the 4 iron groups. In the remaining 38,428 Veterans, the prevalence for FID, HI, LI, and R were 12%, 21%, 20%, and 47%, respectively. After matching weights were implemented, the covariates were evenly distributed among the iron groups. During the mean±SD follow-up period of 4.0±2.7 years, only FID was associated with increased risk for incident diabetes [Risk Ratio, RR (95% CI), 1.20 (1.09, 1.33)], after successful matching for age, sex, race, BMI, hyperlipidemia, CV history, albumin, hemoglobin, and eGFR. The RRs for HI and LI were 0.98 (0.90, 1.07)] and 1.04 (0.95, 1.13), respectively.

Conclusions: FID, but not absolute iron deficiency, is associated with increased risk for incident diabetes in CKD. Further studies are needed to investigate the underlying mechanisms.

Review of Safety of IV Iron Therapy in Patients with Non-Dialysis CKD (CKD-ND) Vikki M. Meyer,[1] Richard P. Cooper,[3] Sunil Bhandari.[2] *[1]HEY Hospitals, HULL, United Kingdom; [2]Hull and East Yorkshire Hospitals NHS Trust and Hull York Medical School, East Yorkshire, United Kingdom; [3]Hull and East Yorkshire NHS Trust, Hull, United Kingdom.*

Background: Anaemia in patients with Chronic Kidney Disease not on dialysis therapy (CKD-ND) is common, and often necessitates the use of intravenous iron products to correct both functional and absolute iron deficiency and iron deficiency anaemia. There has been a large increase in use but concerns on safety have been correctly raised. JAMA highlighted a high rate of '*anaphylaxis*' in parenteral iron administration and mortality related to anaphylaxis. Short term reactions are known to occur including acute anaphylactic and labile iron reactions (*Fishbane effect*) while longer term effects include elevated oxidative stress, possible increased risk of infections, and risk of iron overload.

Methods: This retrospective observational single-centre study, examined our experience of short term adverse effects with parenteral iron administration in CKD-ND using two preparations, MonoFer and CosmoFer. Our database recorded patients' demographics, iron administered, baseline haemoglobin, iron parameters, clinical observations and side effects. A total of 909 doses of MonoFer (1g-1.5g) and 870 doses of CosmoFer (1g-1.5g) were administered to 1271 patients with a mean age of 68.67y for CosmoFer and 65.56y for MonoFer, with no known allergies.

Results: CosmoFer: a total of 1 anaphylactic event in 870 doses (0.11%) occurred and infusion discontinued due to hypotension and respiratory distress. Other reactions consisted of headache (2), diarrhoea (1), vomiting (1), flushing (2) and numbness (1). MonoFer: a total of 5 reactions, vomiting (1), lethargy (1), constipation (1), flare up eczema (1) and one collapse requiring discontinuation of infusion, hydrocortisone, oxygen support, but no other intervention. Reactions requiring drug discontinuation were CosmoFer, 1 in 870 doses; and MonoFer, 1 in 909 doses, which incidentally was the same patient in both cases.

Conclusions: Hyper-sensitivity reactions can occur in anyone receiving intravenous iron and at any time. Vigilance during administration is important and in the immediate 30 minutes following the infusion as per EMA guidelines. At present the balance between the benefits and the risks remains in favour of iron administration and patients should be reassured until new data is available but care should be taken. More studies are required to delineate the short and longer term safety of iron therapy.

FR-PO523

Serum Fibroblast Growth Factor-23 Levels Are Associated with an Increased Risk of Developing Anemia in Patients with Non-Dialysis CKD Ki Heon Nam, Seong yeong An, Jong Hyun Jhee, Seohyun Park, Seung Hyeok Han, Dae-Suk Han. *Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea*.

Background: Fibroblast growth factor-23 (FGF23) is an established biomarker of adverse outcomes in patients with chronic kidney disease (CKD). Several cross-sectional studies have suggested possible association between FGF23 and anemia in these patients. Thus, we further explored this relationship and examined whether FGF23 level can predict the future development of anemia in a large-scale prospective cohort study.

Methods: Among 2,238 patients with non-dialysis CKD enrolled in the KoreaN cohort study for Outcome in patients With Chronic Kidney Disease (KNOW-CKD), 2,089 patients who measured hemoglobin, hepcidin, iron profiles and intact FGF23 (iFGF23) level were included in the analysis. Anemia was defined as a hemoglobin level of < 13.0 g/dL and 12.0 g/dL for male and female, respectively.

Results: The mean age was 53.6 ± 12.2 years and 1,275 (61.0%) patients were males. At baseline, anemia was found in 925 (44.3%) patients. Log iFGF23 significantly correlated with hepcidin, but inversely with iron profiles and hemoglobin. A multivariate logistic regression model showed that log iFGF23 was independently associated with anemia (odds ratio [OR], 1.12; 95% confidence interval [CI], 1.03-1.23, P=0.01). Among 1164 patients without baseline anemia, 295 (25.3%) patients developed anemia during a median follow-up duration of 21 (interquartile range, 7-38) months. In the fully adjusted multivariable Cox models, risk of developing anemia was significantly higher in the 3rd (hazard ratio [HR], 1.74; 95% CI, 1.17-2.59; P =0.007) and 4th (HR, 1.73; 95% CI, 1.15-2.59; P= 0.02) quartile of iFGF23 as compared to the 1st quartile. Similar association was observed in a model when iFGF23 was treated as a continuous variable.

Conclusions: We showed that high serum iFGF23 levels are associated with an increased risk of developing anemia in patients with non-dialysis CKD. Our findings suggest that serum iFGF23 levels can emerge as an independent predictor of anemia.

FR-PO524

Serum 1,25 Dihydroxyvitamin D Is Independently Associated with Erythropoietin Deficiency and Endogenous Erythropoietin Resistance in Patients with CKD Il Young Kim,[2] In seong Park,[1] Min Jeong Kim,[2] Miyeun Han,[1] Harin Rhee,[1] Sang Heon Song,[1] Eun Young Seong,[1] Dong Won Lee,[2] Soo Bong Lee,[2] Ihm Soo Kwak.[1] *[1]Pusan National University Hospital, Busan, Republic of Korea; [2]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea*.

Background: Erythropoietin (EPO) deficiency and resistance to endogenous EPO is an important pathophysiological feature in anemia of chronic kidney disease (CKD). 1,25 dihydroxyvitamin D [1,25$(OH)_2$D] deficiency is known to contribute to anemia of CKD. We aimed to investigate the associations between serum 1,25$(OH)_2$D, EPO deficiency and endogenous EPO resistance in patients with CKD.

Methods: This study included 409 patients with CKD [glomerular filtration rate (GFR) < 60 ml/min/1.73m^2] who were not on dialysis therapy. Patients on exogenous EPO therapy and patients with iron deficiencies were excluded. Endogenous EPO resistance was assessed by calculating the ratio of endogenous EPO to hemoglobin (Hb) (endogenous EPO/Hb ratio). The associations of Hb level, endogenous EPO level and the endogenous EPO/Hb ratio with clinical and laboratory variables were investigated by univariate and multivariate analyses.

Results: In univariate analysis, serum 1,25$(OH)_2$D level was correlated with the Hb level ($r = 0.705$, $P < 0.001$), endogenous EPO level ($r = 0.254$, $P < 0.001$) and the endogenous EPO/Hb ratio ($r = -0.132$, $P = 0.007$). Multiple regression analysis revealed that the serum 1,25$(OH)_2$D level remained significantly associated with the Hb level ($\beta = 0.530$, $P < 0.001$), endogenous EPO level ($\beta = 0.127$, $P = 0.025$) and the endogenous EPO/Hb ratio ($\beta = -0.106$, $P = 0.035$), even after adjusting for other confounding factors, including the levels of parathyroid hormone and the inflammatory marker C-reactive protein.

Conclusions: The serum 1,25$(OH)_2$D level exhibited significant associations with anemia, EPO deficiency and endogenous EPO resistance in CKD patients. These associations were independent of secondary hyperparathyroidism and inflammation status.

FR-PO525

CKD-MBD and the Use of Immunosuppressant in KNOW-pedCKD Joo Hoon Lee,[1] Hee Gyung Kang,[6] Eujin Park,[6] Yo Han Ahn,[2] Seong heon Kim,[5] Kyoung Hee Han,[3] Hyun Jin Choi,[6] Min Hyun Cho,[4] Young seo Park,[1] IL-Soo Ha.[6] *[1]Asan Medical Center, Seoul, Republic of Korea; [2]Hallym University Kangnam Sacred Heart Hospital, Seoul, SEOUL, Republic of Korea; [3]Jeju National University School of Medicine, Jeju, Republic of Korea; [4]Kyungpook National University Hospital, Daegu, Republic of Korea; [5]Pusan National University Children's Hospital, Yangsan, Republic of Korea; [6]Seoul National University Children's Hospital, Seoul, Republic of Korea*.

Background: CKD-MBD is abnormalities in mineral metabolism and bone structure in patients with chronic kidney disease (CKD). Many children with glomerulonephritis progress to CKD. In many patients with primary or secondary glomerulonephritis, the use of immunosuppresant may cause osteroporosis and growth retardation. We evaluated the effect of immunosuppresant on CKD-MBD in children.

Methods: KNOW-pedCKD is a Korean cohort study for outcomes in patients with pediatric CKD for 10 years which started from April 2011. 458 patients with CKD stage I to V below 20 years old were included. We divided the patients into 3 groups according to CKD stage: CKD stage I-II, III, IV-V. We compared calcium, phosphorus, alkaline phosphatase (ALP), intact parathyroid horome (PTH), vitamin D, FGF-23 and transtubular reabsorption of phosphorus (TRP) between patients who had immunosuppresants (IS group) and those without drug treatment (non-IS group) in each CKD group.

Results: In IS gruop, serum calcium level was lower in CKD stage I-II (10.18 vs 10.92 mg/dL, p=0.048), III (9.99 vs 10.87, p=0.001), IV-V group (9.45 vs 10.97, p=0.001), serum phosphorus level was higher in CKD stage I-II (4.93 vs 4.57, p=0.017), serum ALP was lower in CKD stage III (135 vs 262, p<0.001), IV-V (173 vs 265, p=0.017), serum calcidiol level was lower in CKD stage I-II (17.84 vs 22.43 mg/dL, p=0.003), III (15.68 vs 24.23, p=0.002), IV-V group (11.15 vs 23.02, p<0.001), serum calcitriol level and TRP was lower in CKD stage IV-V than non-IS group. Serum intact PTH and FGF-23 level did not show difference between IS and non-IS group.

Conclusions: The use of immunosuppressant in pediatric CKD patients may worsen CKD-MBD which was associated with hypocalcemia, hyperphosphatemia and vitamin D deficiency.

Funding: Government Support - Non-U.S.

FR-PO526

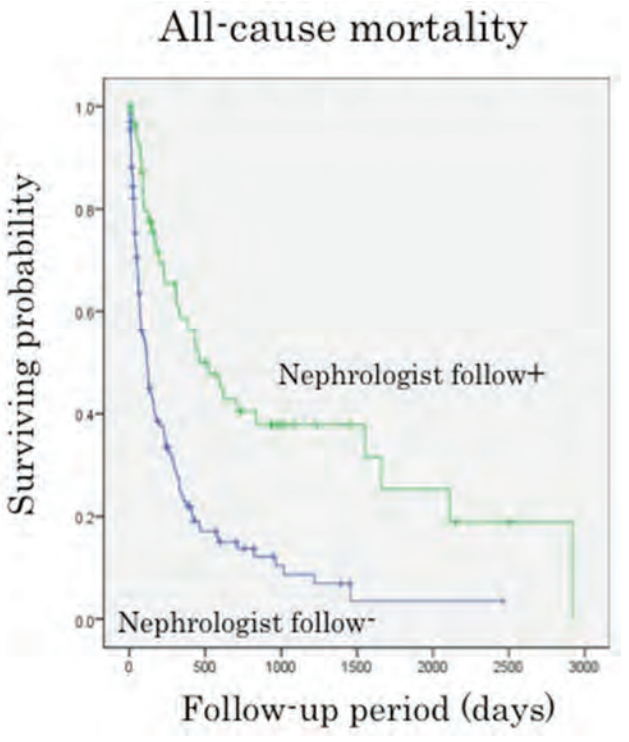
Survival Benefit of Nephrologist Follow-Up in Stage IV Cancer Patients with CKD Taisuke Ishii,[1] Takuya Fujimaru,[3] Eriko Nakano,[2] Yasuhiro Komatsu.[1] *[1]Nephrology, St.Luke's international hospital, Tokyo, Japan; [2]Medical oncology, St.Luke's international hospital, Tokyo, Japan; [3]Tokyo Medical and Dental University, Tokyo, Japan*.

Background: The prevalence of chronic kidney disease (CKD) is increasing among cancer patients. And CKD affects mortality of the patients with stage IV solid cancer. Several studies have shown that nephrologist follow-up resulted in improving survival of CKD patients. However, it is not clear whether nephrologist co-management could improve mortality.

Methods: In this single-center, retrospective cohort study, we collected data from all patients who were newly diagnosed as stage IV solid cancer with CKD from January 2007 to December 2016. The follow-up period lasted until April 2017. CKD was defined as eGFR ≤ 60 ml/min/1.73m^2 both at the time of cancer diagnosis and 90 days before the diagnosis. Nephrologist follow-up was defined as visit to nephrologist after diagnosed with the cancer. The primary endpoint was all-cause mortality. The secondary endpoint was cancer-specific mortality. Log-rank test and Cox proportional hazard analysis were used for analysis.

Results: 192 patients met inclusion criteria (age 78±9, 61.5% of males). CKD stage G3, G4, and G5 were 82.3%, 14.1%, and 3.6% respectively. In these patients, nephrologist follow-up were 24.7%, 48.1%, and 57.1%, respectively. During follow-up (median 134 days, IQR 46-415 days), 145 patients (75.5%) died. On Kaplan-Meier survival analysis, patients who visited nephrologist showed significantly better survival compared to those who did not visit at all (log-rank test, $p < 0.001$). After adjusting for age, gender, type of cancer, anticancer therapy, history of cardiovascular disease, baseline eGFR, serum WBC, CRP, proteinuria and ECOG Performance Status, nephrologist follow-up remained significant association with lower all-cause mortality and cancer specific mortality (HR 0.51, 95% CI 0.32-0.81 and HR 0.52, 95% CI 0.32-0.83, respectively).

Conclusions: Nephrologist follow-up was associated with lower risk of deaths in stage IV cancer patients with CKD.



FR-PO527

Lack of Nephrologist Follow-Up after Nephrectomy for Kidney Cancer Michael G. McCusker,[2,3] Naima Carter-Monroe,[1,4] Eric P. Cohen.[1,3] *[1]University of Maryland, Baltimore, MD; [2]University of Maryland Medical Center, Baltimore, MD; [3]Medicine, Baltimore VAMC, Baltimore, MD; [4]Pathology, Baltimore VAMC, Baltimore, MD.*

Background: Medical renal disease often accompanies kidney cancer. The American College of Pathology recommends that the tissue surrounding a resected kidney cancer be examined to identify significant medical renal disease, much as is done for a kidney biopsy done for non-cancerous disease. This can inform regarding pathogenesis of kidney cancer and is immediately important for nephrologic management of patients who have had nephrectomy, partial or complete.

Methods: We tested a prospectively maintained database at the Baltimore Veterans Affairs Medical Center to determine the adequacy of follow-up in such cases. Sixty six patients were identified from 2010 through 2016, who had at least six months of follow-up after surgery.

Results: All but one were men and 46 were black. The average age was 64 +/- 7 (sd). Forty-one had total and twenty-seven had partial nephrectomies. Two patients had partial followed by contralateral total nephrectomy. Twenty seven of the sixty eight had clear cell cancer, the rest were papillary. Thirteen patients with oncocytomas were not included. In the pathology reports, six had no comment regarding the non-cancerous renal tissue. Eight more reported no abnormality, but twenty four showed moderate or worse medical renal disease of the non-cancerous renal tissue. As reported by others, micro and macrovascular disease were present in the non-cancerous tissue of the majority of cases. The average preoperative serum creatinine (s creat) of the patients was 1.3 mg/dl +/- 0.6 (sd). The average discharge s creat was 1.7 mg/dl +/- 0.9 (sd). ($p<0.001$ vs preoperative s creat). The average s creat at one year was 1.8 mg/dl +/- 1.2 (sd). Only 23 of these 66 patients had any nephrology follow-up after their surgery, and only 13 had measurement of proteinuria.

Conclusions: We conclude that although Pathologists usually provide some report of the non-cancerous renal tissue, this is still not always done. The majority of cases show significant medical renal disease in the surrounding non-cancerous kidney. Importantly, nephrologic follow-up of these patients with chronic kidney disease is deficient. Because of the known risks of CKD, it is prudent to ensure Nephrologist follow-up for patients who have had a nephrectomy for kidney cancer.

FR-PO528

Independent Associations of eGFR and Albuminuria with Cancer Incidence Yejin Mok, Shoshana Ballew, Yingying Sang, Josef Coresh, Corinne Joshu, Elizabeth A. Platz, Kunihiro Matsushita. *Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Cancer is a potential complication of chronic kidney disease (CKD) recently attracting attention. However, no previous studies have simultaneously investigated two key CKD measures, estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (ACR), for the risk of cancer incidence.

Methods: In 9,191 participants without prevalent cancer from the Atherosclerosis Risk in Communities (ARIC) study in 1996 to 1998, the associations of eGFR (based on creatinine and cystatin C) and ACR with overall and site-specific cancer incidence were evaluated with Cox proportional hazards model adjusted for conventional lifestyle and clinical risk factors for CKD and/or cancer.

Results: During a median follow-up of 14.7 years, 2,063 incident cancer cases occurred in 117,420 person years. eGFR was not associated with total cancer incidence after adjusting for risk factors. ACR was possibly positively associated after adjustment for age, sex, and race, but further adjustment for other potential confounders attenuated the association. By cancer site, a higher ACR was significantly associated with increased risk of lung and hematopoietic cancers (hazard ratio per 8-fold higher ACR was 1.29 [1.08-1.53] and 1.27 [1.02-1.59], respectively). The results were consistent for lung cancer even after excluding cancer in the first three years. These results were largely consistent in subgroups of sex, race, and current smoking status.

Conclusions: Kidney measures, particularly higher albuminuria, were modestly associated with cancer incidence. The association of ACR was especially robust for lung cancer and this finding is consistent with previous studies. Mechanisms underlying this association are not clear, and further studies exploring potential mechanism are needed.

Funding: Other NIH Support - The ARIC Study is carried out as a collaborative study supported by National Heart, Lung and Blood Institute contracts (HHSN268201100005C, HHSN268201100006C, HHSN268201100007C, HHSN268201100008C, HHSN268201100009C, HHSN268201100010C, HHSN268201100011C, and HHSN268201100012C). Studies on cancer in ARIC are also supported by the National Cancer Institute (U01 CA164975).

Table. Hazard ratios (95% CI) of incident cancer for categories of creatinine and cystatin C based eGFR and ACR

	eGFR, mL/min/1.73m^2					
	≥90 (N=2,155)	60-89 (N=6,071)	45-69 (N=671)	<45 (N=294)	Per 30 ml/min/1.73m^2 lower eGFR	P for trend
Case	459	1,375	162	67

Model 1: adjusted for age, sex, and race

Model 2: Model 1 + adjusted for BMI, hypertension, diabetes, total cholesterol, statin use, hs-CRP, history of CVD, family history of cancer, current smoker, current drinker and kidney measures (ACR was accounted for in the analyses for eGFR and vice versa)

FR-PO529

Prevalence and Mortality of CKD in Lymphoma: A Large Retrospective Cohort Study Masamitsu Ubukata, Masaki Hara, Teruhiro Fujii, Akihito Ohta. *Division of Nephrology, Department of Medicine, Tokyo Metropolitan Komagome Hospital, Bunkyo-ku, Japan.*

Background: The prevalence, incidence, and mortality of chronic kidney disease (CKD) in lymphoma patients have not been fully understood. The objective of this study was to evaluate the prevalence of CKD and its contribution to mortality in patients with lymphoma.

Methods: This was a retrospective cohort study on 429 consecutive lymphoma patients who were admitted or regularly visited our hospital from January 2013 to October 2016. The prevalence of CKD at enrollment was evaluated according to the modified CKD classification by the KDIGO (eGFR and proteinuria category). Dipstick proteinuria was classified into three grades: A1, for – and +/–; A2 for 1+ or 2+; and A3 for ≥3+. eGFR (mL/min/1.73 m^2) was classified into six stages: G1 for ≥90, G2 for 60–89, G3a for 45–59, G3b for 30–44, G4 for 15–29, and G5 for <15. CKD was defined as eGFR <60 mL/min/1.73 m^2 and/ or proteinuria ≥1+ that was sustained at least for 3 months. The severity of CKD was classified into the following four categories: no risk for G1A1 and G2A1; moderate risk for G1A2, G2A2, and G3aA1; high risk for G1A3, G2A3, G3aA2, and G3bA1; and very high risk for G3aA3, G3bA2, G3bA3, G4, and G5. The cumulative mortality rate was estimated using the Kaplan–Meier method, with stratification into two groups based on the presence or absence of CKD. Further, a multivariate Cox proportional hazards regression model was used to calculate the hazard ratio (HR) and its 95% confidence interval (CI) for all-cause mortality, after adjustments for age, gender, pathologic type, clinical stage of lymphoma, presence or absence of diabetes mellitus, hypertension, and cardiovascular disease.

Results: The mean follow-up period was 3.1 ± 1.0 years and the prevalence of CKD at study enrollment was 34.5%. The cumulative mortality rate was 20.7% and was significantly higher in the CKD group than in the group without CKD (36.4% vs. 18.0%, p = 0.02). In the multivariate analysis, mortality was significantly associated with CKD (HR 1.61; 95% CI 1.03–2.50), and this association was the most robust with very high risk CKD (HR 6.32; 95% CI 2.41–14.54).

Conclusions: CKD should be considered a risk factor for mortality among patients with lymphoma.

FR-PO530

Nephrologists' Perspectives on Cancer Screening in Patients with CKD Laura J. James,[3,5] Germaine Wong,[1] Jonathan C. Craig,[4] Allison Tong.[2] *[1]None, Auambie, NSW, Australia; [2]The University of Sydney, Sydney, NSW, Australia; [3]Sydney School of Public Health, The University of Sydney, Westmead, NSW, Australia; [4]University of Sydney/Children's Hospital, Sydney, NSW, Australia; [5]Centre for Kidney Research, Westmead, NSW, Australia.*

Background: Cancer is a leading cause of morbidity and mortality in patients with chronic kidney disease (CKD). However, cancer screening practices are highly variable among nephrologists, which may reflect uncertainties around the benefits and harms of screening in this setting, and the competing risk of death from other causes. Therefore we aimed to describe nephrologists' perspectives on cancer screening and understand the factors impacting their practice.

Methods: Semi-structured interviews were conducted with 21 nephrologists from 11 centres across Australia and New Zealand. Transcripts were analysed thematically

Results: Five themes were identified: empowering patients to make informed decisions (respecting patient preferences, communicating evidence-based recommendations, creating awareness of consequences, preparing patients for transplantation); justifiable risk taking (avoiding undue consequences in vulnerable populations, ensuring cost effectiveness, warranted by long term immunosuppression, assurance of reasonable survival gains); prioritising current or imminent complications; ambiguity of evidence in supporting decisions (absence of standardised recommendations, limited transferability of population-based data); and depending on a shared multidisciplinary approach (collaboration with primary health care, wary of inadequate dermatological services, generating targeted cancer preventative services).

Conclusions: Nephrologists approach decisions about cancer screening in patients with CKD based on patient preferences, assessment of risk, justifiable survival gains, and current health priorities. Evidence-based guidelines and specialist clinics that address cancer screening may support shared decision making about cancer screening in CKD.

FR-PO531

Effectiveness of 12 Week Elbasvir/Grazoprevir (EBR/GZR) in Patients with Genotype 1 (GT1) Chronic Hepatitis C (HCV) and CKD Chizoba Nwankwo,[2] Bruce R. Bacon,[4] Michael P. Curry,[1] Steven Flamm,[3] Kris V. Kowdley,[5] Scott Milligan,[6] Naoky Tsai.[7] *[1]Beth Israel Deaconess Medical Center, Boston, AL; [2]Merck & Co, Lebanon, NJ; [3]Northwestern Feinberg School of Medicine, Chicago, IL; [4]Saint Louis University School of Medicine, Saint Louis, MO; [5]Swedish Medical Center, Seattle, WA; [6]Trio Health Analytics, La Jolla, CA; [7]University of Hawaii, Kailua, HI.*

Background: Elbasvir/grazoprevir (EBR/GZR) is recommended for use in the treatment of chronic HCV genotype (GT) 1 and 4 patients including those with renal impairment. The puprose of this study is to describe the real-world effectiveness of 12 week EBR/GZR in patients with GT1 chronic HCV and CKD.

Methods: Data were collected from US providers and specialty pharmacies through Trio Health's disease management platform. Patients with CKD and GT1 HCV who initiated 12 week EBR/GZR therapy between Jan 28, 2016 (FDA approval) to Dec 31, 2016 were included in the analyses. CKD was defined as renal impairment of baseline eGFR <90 ml/min. Effectiveness was defined as attainment of per protocol sustained virological response at week 12 post-treatment (PP SVR12).

Results: 228 patients with GT1 HCV and CKD were treated for 12 weeks with EBR/GZR and ribavirin (RBV) was added for 6 patients. 25% (56/228) of patients had mild stage 2 CKD, 21% (48/228) had moderate stage 3 CKD and 54% (124/228) had severe renal impairment (CKD stages 4-5). Other characteristics provided in (TABLE). At time of abstract submission, 144 of 228 were evaluable for PP SVR12; 98% (135/138) of patients treated with EBR/GZR and 100% (6/6) of patients treated with EBR/GZR+RBV achieved PP SVR12.

Conclusions: In the treatment of patients with GT1 chronic HCV and CKD, 12 week EBR/GZR was highly effective with an overall SVR12 (PP) of 98% (141/144).

FR-PO532

Real-World Cost-Effectiveness of Elbasvir/Grazoprevir (EBR/GZR) for the Treatment of Chronic Hepatitis C (CHC) in Treatment-Naïve (TN) Genotype (GT) 1 Patients with CKD Chizoba Nwankwo,[2] Bruce R. Bacon,[6] Shelby L. Corman,[5] Michael P. Curry,[1] Steven Flamm,[4] Yiling Jiang,[3] Kris V. Kowdley,[7] Scott Milligan,[8] Naoky Tsai.[9] *[1]Beth Israel Deaconess Medical Center, Boston, AL; [2]Merck & Co, Lebanon, NJ; [3]Merck Sharp & Dohme Ltd., Hoddesdon, United Kingdom; [4]Northwestern Feinberg School of Medicine, Chicago, IL; [5]Pharmerit International, Bethesda, MD; [6]Saint Louis University School of Medicine, Saint Louis, MO; [7]Swedish Medical Center, Seattle, WA; [8]Trio Health Analytics, La Jolla, CA; [9]University of Hawaii, Kailua, HI.*

Background: EBR/GZR, a once-daily fixed-dose combination direct-acting antiviral (DAA) was shown in the C-SURFER trial to be safe and effective for the treatment of CHC patients with CKD. The objective of this analysis was to evaluate real-world cost-effectiveness of EBR/GZR compared to no treatment using data from the TRIO Network.

Methods: A state-transition model of CHC, liver disease, and CKD was developed using Microsoft Excel. The model consists of 10 health states reflecting degree of liver fibrosis (F0-4), decompensated cirrhosis (DC), hepatocellular carcinoma (HCC), and liver transplant (LT); and 8 health states reflecting degree of CKD (Stages 1-5), hemodialysis, and kidney transplant. Baseline patient characteristics and the proportion of TN GT1 patients achieving sustained virologic response (SVR) were collected from a real-world study of 124 TN GT1 patients with CKD who were treated with EBR/GZR between January and October 2016, using data from the TRIO Network. Data on the rate of progression of hepatic and renal disease, annual costs for each health state, utilities, and risk of cardiovascular events were obtained from published literature. The primary outcome was the incremental cost-utility ratio (ICUR); secondary outcomes included the lifetime incidence of DC, HCC, LT, ESLD mortality, and life expectancy.

Results: TN GT1 patients who received EBR/GZR were less likely to develop DC or HCC, receive a liver transplant, or die of liver-related causes compared to untreated patients, with a 2.4-year increase in life expectancy. Discounted costs and QALYs were both greater in patients receiving EBR/GZR compared to no treatment, with an ICUR of $53,897 QALY.

Conclusions: The model projected that EBR/GZR significantly reduces the incidence of liver disease complications compared to no treatment, using real-world patient characteristics and treatment outcomes. In addition, EBR/GZR was cost-effective for the treatment of CHC in patients with CKD.

Lifetime incidence of liver disease complications, life expectancy, and ICUR for EBR/GZR vs. no treatment		
Outcome	**EBR/GZR**	**No treatment**
Decompensated cirrhosis (%)	2.35	9.79
Hepatocellular carcinoma (%)	0.77	11.41
Liver transplant (%)	0.01	0.64
End-stage liver disease mortality (%)	0.27	13.45
Life expectancy (years)	10.3	7.9
Discounted QALYs	5.52	4.31
Discounted costs, US$	312,682	247,335
ICUR, EBR/GZR vs. no treatment	$53,897/QALY	

FR-PO533

Uromodulin and Risk of Infection Related Hospitalizations Pranav S. Garimella,[8] Petra Buzkova,[3] Joachim H. Ix,[7] Tarek M. El-Achkar,[4] Prasad Devarajan,[1] Michael R. Bennett,[2] Michael Shlipak,[5] Mark J. Sarnak.[6] *[1]Cincinnati Children's Hospital, Cincinnati, OH; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]UW, Seattle, WA; [4]Indiana University, Indianapolis, IN; [5]San Francisco VA Medical Center, San Francisco, CA; [6]Tufts Medical Center, Boston, MA; [7]UCSD, San Diego, CA; [8]University of california san diego, San Diego, CA.*

Background: Higher uromodulin levels are associated with lower rates of urinary tract infections in humans, and laboratory studies indicate that uromodulin may also be beneficial in sepsis and bacteremia. Studies have not confirmed the association between uromodulin and risk of all-cause infections in humans.

Methods: Using data from a random, sub-cohort of 958 older adults enrolled in the Cardiovascular Health Study, we evaluated whether spot urine uromodulin levels are associated with risk of infectious hospitalizations using Poisson and Cox regression analysis with several nested models.

Results: The mean age of participants was 78.1 years, mean eGFR was 70.9 ml/min/1.73m2 and 39.5% were men. The median (IQR) urinary uromodulin level was 25.88 (17.25, 38.83) units. There were 592 infections hospitalizations among 362 participants during a median follow up of 9.2 years. Rates of hospitalizations (per100 person-years) decreased across higher quartiles of uromodulin: 7.4, 6.0, 5.8, and 5.6. Each doubling of uromodulin was associated with 20% lower number of infectious hospitalizations (Rate Ratio 0.80, 95% CI 0.66, 0.97) when adjusted for demographics, comorbidities and laboratory variables. Uromodulin levels were not associated with the hazard of first infectious hospitalization. When Cox regression was used to model multiple events per person, each doubling of uromodulin was associated with 23% lower risk of infectious hospitalization (HR 0.77, 95% CI 0.64, 0.94) in adjusted analyses.

Conclusions: Higher levels of uromodulin are associated with lower rates and hazard of total infectious hospitalizations. Uromodulin levels may provide information about global immune defense that may not be limited to urinary tract infections alone.

Funding: NIDDK Support, Other NIH Support - NHLBI

Table: Rates of total infectious hospitalization by uromodulin quartiles

	Total	Q1	Q2	Q3	Q4
Sample/Infections	958/592	240/154	239/147	239/136	240/155
Rate per 100 PY (95%CI)	6.1(5.4,7.0)	7.4 (5.6,9.7)	6.0 (4.6,7.8)	5.8 (4.6,7.4)	5.6 (4.5,6.9)

Association of uromodulin (continuous scale) with total infectious hospitalizations

	All Rate Ratio	p-val
Log2umod*	0.88 (0.76,1.00)	0.06
log2umod1**	0.88 (0.755,1.00)	0.05
log2umod2†	0.89 (0.76,1.051)	0.17
log2umod3††	0.80 (0.66,0.97)	0.02

Adjustment in sequential models as follows

Hospital Acquired Infections after Major Surgery among Patients with Clinical Comorbidities: The Stockholm Creatinine Measurements (SCREAM) Project Junichi Ishigami,[2] Marco Trevisan,[3] Hong Xu,[3] Josef Coresh,[4] Kunihiro Matsushita,[1] Juan J. Carrero.[3] *[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, AL; [2]Johns Hopkins School of Public Health, Baltimore, MD; [3]Karolinska Institutet, Stockholm, Sweden; [4]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD.*

Background: Whether incidence of hospital acquired infections (HAIs) after major surgery differs by types of clinical comorbidity has not been well characterized.

Methods: We evaluated 66,820 patients (mean age, 64 years; 58% female) undergoing four major types of surgery (neuro [n=1,922], cardiothoracic and vascular [n=6,403], abdominal [n=26,542], and orthopedic surgery [n=31,953]) with available serum creatinine measurement for estimating GFR up to 365 days prior to the hospitalization between 2007 and 2011 in Stockholm, Sweden, for the in-hospital incidence of four HAIs (pneumonia, urinary tract infections, surgical site infections, and bloodstream infections) across clinical comorbidities including low eGFR <60 ml/min/1.73m^2, diabetes, coronary heart disease (CHD), congestive heart failure (CHF), stroke, chronic obstructive pulmonary disease (COPD), liver disease, and cancer.

Results: Among clinical comorbidities, cancer and low eGFR were most frequently identified (**Table1**). During hospital stay, 5.7% (n=3,784) had at least one type of HAIs. For each clinical comorbidity, the prevalence was disproportionally higher in patients with HAIs, and risk of HAIs was significantly higher in multivariable Poisson models (**Table1**). When population attributable fraction (PAF) was estimated, the PAF was highest for low eGFR (PAF, 0.13), followed by cancer, CHF, stroke and COPD (PAF, 0.11, 0.08, 0.06, and 0.05, respectively) (**Table1**). These findings were mostly consistent across the four types of infection.

Conclusions: For HAIs after major surgery, low eGFR posed the highest PAF among major clinical comorbidities, underscoring the importance of HAIs prevention measures for persons with low eGFR.

Funding: Other NIH Support - NHLBI Cardiovascular Disease Epidemiology Training Program grant (T32HL007024).

Table1: Prevalence of clinical comorbidity and relative risk of HAIs

	% in the overall population (n=66,820)	% among patients with HAIs (n=3,784)	Adjusted relative risk* (95%CI)	Population attributable fraction (PAF)
eGFR <60 ml/min/1.73m^2	18%	35%	1.62 (1.50-1.75)	0.13
Cancer	21%	34%	1.45 (1.35-1.56)	0.11
CHF	12%	24%	1.49 (1.36-1.62)	0.08
Stroke	11%	20%	1.41 (1.29-1.53)	0.06
COPD	12%	18%	1.33 (1.22-1.44)	0.05
Diabetes	12%	17%	1.11 (1.02-1.21)	0.02
CHD	8.8%	14%	1.12 (1.02-1.25)	0.02
Liver disease	2.6%	3.2%	1.28 (1.07-1.53)	0.01

Lactobacillus Plantarum 299v Prevents Clostridium difficile Infection in Patients Hospitalized in Nephrological and Transplantation Department Marcin Adamczak, Sylwia M. Dudzicz, Agata Kujawa-Szewieczek, Katarzyna Kwiecien, Andrzej Wiecek. *Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia, Katowice, Poland.*

Background: *Lactobacillus plantarum 299v* (LP299v) has been introduced into the clinical practice in order to reduce gastrointestinal symptoms during antibiotic exposure. However, it remains controversial whether or not probiotics are also effective in the prevention of *Clostridium difficile* infections (CDI) among patients receiving antibiotics. The aim of this clinical, retrospective, single-centre study was to analyze the CDI among patients receiving antibiotics and hospitalized in the period before, during and after cessation of LP299v use, as a prevention of CDI, in the nephrological and transplantation department.

Methods: Among 5341 patients hospitalized in the nephrological and transplantation department during three years 40 patients with CDI were diagnosed and enrolled in this study. From November 2013 to December 2014 prevention of CDI with the oral use of LP299v was performed in all patients treated with antibiotics and after organ transplantation or receiving immunosuppressive drugs for any other reasons. For the further analysis the observation period was divided into three twelve-months periods: before, during LP299v use as the prophylactic manoeuvre against CDI and after cessation of such a prophylaxis

Results: A significant (p=0.0001) reduction of the number of cases with CDI was found during LP299v use (period 2) (n=2; 0.11% of 1791 hospitalized patients) compared two others periods i.e. before and after cessation of such a prophylaxis (n=21; 1.21% of 1742 hospitalized patients and period and n=17; 0.94% of 1808 hospitalized patients, respectively).

Conclusions: Routine use of *Lactobacillus plantarum 299v* during treatment with antibiotics may prevent *Clostridium difficile* infection in the nephrological and transplantation department.

Plasma Biomarkers and Response to Intensive Blood Pressure Control: The ACCORD Trial Girish N. Nadkarni,[1] Martine Pollack-Zollman,[1] Kinsuk Chauhan,[1] Veena Rao,[2] Priti Poojary,[1] Aparna Saha,[1] Chirag R. Parikh,[3] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Yale University, New Haven, CT; [3]Yale University and VAMC, New Haven, CT.*

Background: Plasma biomarkers of inflammation [tumour necrosis factor 1 (TNFR1); monocyte chemoattractant protein (MCP1) and interleukin 18 (IL18)], renal injury [Kidney Injury Molecule 1 (KIM1)] and fibrosis [YKL40] are associated with estimated glomerular filtration rate (eGFR) decline. There are limited data on association between these markers and response to intensive sytolic blood pressure (SBP) control. We examined the relationship between baseline plasma biomarker levels and longitudinal SBP change in the ACCORD trial.

Methods: We used a multiplex platform to measure plasma biomarkers in baseline plasma specimens from randomly selected ACCORD trial participants with type 2 diabetes in intensive SBP arm (goal <120; n=260) vs. standard SBP arm (goal <140; n=269). We estimated the association between longitudinal SBP change and baseline biomarker tertiles after stratifying by intensive vs. standard SBP arm using linear mixed models.

Results: Mean age was 61.7 years, 46.6% were female and baseline eGFR was 88 ml/min. There were no significant differences between the intensive and standard SBP arm. Participants in the third tertile of KIM-1 had a higher SBP at baseline after adjusting for eGFR, UACR and demographics [+3.7 mmHg, SE 1.6]. After randomization, participants in the third tertile of KIM-1 in intensive SBP group had a smaller change in sBP compared to the first tertile [-5.1 mmHg; SE 1.5; p<0.001]. There were no associations with other biomarkers and SBP change in either arm. (Figure 1)

Conclusions: Higher levels of plasma KIM-1 at baseline are associated with attenuated SBP changes with intensive control. These findings indicate that subclinical renal tubular injury is associated with poorer response to intensive SBP control, even in persons with normal eGFR.

FR-PO537

Did Non-Standard Withdrawal of Antihypertensive Agents Exaggerate Treatment Effect in SPRINT? Conor S. Judge, Alberto Alvarez-Iglesias, John P. Ferguson, Maria Costello, Andrew Smyth, Martin O'donnell. *HRB Clinical Research Facility, Galway, Ireland.*

Background: The control group in SPRINT targeted a blood pressure range of 130-140mmHg, which required down-titration of antihypertensive therapy when blood pressure was below 130mmHg on a single visit, or below 135mmHg on two consecutive visits. Such an approach would not be considered routine clinical care. We hypothesised that non-standard discontinuations of antihypertensive therapy in the control group, may have inflated the events rates and exaggerated the reported treatment effect.

Methods: Standard withdrawal of antihypertensive agents was defined as a withdrawal for systolic blood pressure less than 100mmHg at the current visit, or a reported, related adverse event occurring between the previous and current visit. We evaluated the association of antihypertensive withdrawal with CV events on follow-up using the Cox proportional-hazards regression. We repeated the primary analysis comparing the time to first occurrence of a primary outcome between treatment groups, adjusting for non-standard withdrawal in blood pressure medication, treated as time dependant covariates, to estimate the effect of intensive versus standard blood pressure control.

Results: Non-standard withdrawal of antihypertensive agents occurred in 9.3% of patient visits in the control group, compared with 5.1% in the treatment group ($p < 0.001$), and was associated with an increased risk of the composite outcome, which was significant for 2 follow-up periods (HR 1.65; 95% CI, 1.26-2.16 for initial 3 months, HR 1.47; 95% CI, 1.12-1.95 for 3 to 6-month period), which was independent of blood pressure effect. After adjusting for non-standard withdrawal/reduction of antihypertensive agents, the intensive-treatment group was associated with a lower risk of the composite outcome measure, compared to standard care (HR 0.81; 95% CI, 0.67 to 0.97).

Conclusions: Targeting a systolic BP range (130-140mmHg) in the control group of SPRINT, rather than a conventional blood pressure threshold (<140mmHg), resulted in withdrawals of antihypertensive medications that would not be considered routine care. An analysis that adjusted for non-standard withdrawal of blood pressure medications during the trial resulted in a significant, but diminished, treatment effect of intensive blood pressure control (HR 0.81 versus 0.75), and the effect on heart failure became non-significant.

FR-PO538

Influence of Baseline Diastolic Blood Pressure (DBP) Level on the Effects of Intensive Blood Pressure Lowering on Cardiovascular (CV) Outcome in SPRINT Srini Beddhu,[1] Glenn M. Chertow,[2] Alfred K. Cheung,[1] Mahboob Rahman,[3] Tom Greene,[1] Guo Wei,[1] William E. Haley,[5] William C. Cushman,[4] Paul K. Whelton.[6] *[1]Univ Utah, SLC, UT; [2]Stanford Univ, Palo Alto, CA; [3]Case Western Reserve University, Cleveland, OH; [4]VAMC, Memphis, TN; [5]Mayo Clinic, Jacksonville, FL; [6]Tulane Univ, New Orleans, LA. Group/Team: For SPRINT Research Group.*

Background: Lowering systolic blood pressure (SBP) in persons with low DBP might affect tissue perfusion and thereby, ↑ risk for CV events.

Methods: SPRINT tested the effects of SBP goal < 120 vs. < 140 mm Hg on CV outcomes in 9361 participants. We tested for effect modification by baseline DBP of the intervention on primary CV outcome (a composite of non-fatal MI, ACS not resulting in MI, stroke, CHF, or CV death).

Results: Mean age was 67.9 ± 9.4 years, with 35.6 % being women and 31.5 % Black. Means (± SD) baseline SBP and DBP were 139.7 ± 15.6 and 78.1 ± 11.9 mm Hg, respectively. There were 562 primary outcome events over 29,277 person-years of follow-up. Adjusted for age, gender, race and the intervention arm, baseline DBP had a U-shaped association with the primary outcome (figure, panel A). Intensive SBP treatment reduced the risk of the primary outcome vs. standard treatment (hazard ratio [HR] 0.76, 95% CI 0.64 to 0.89). P-value for the linear treatment by baseline DBP interaction did not approach statistical significance for the primary outcome ($p = 0.85$). HR for primary outcome across DBP quintiles are summarized in figure, panel B. HR for the primary outcome was 0.78 (95% CI 0.57 to 1.07) within the lowest DBP quintile and 0.74 (95% CI 0.61 to 0.90) within the upper four DBP quintiles (interaction p-value = 0.78).

Conclusions: While baseline low DBP was associated with increased risk of CV events, there is no evidence that the beneficial effects of the SPRINT intervention were modified by the level of baseline DBP.

Funding: NIDDK Support, Other NIH Support - NHLBI

PTH, FGF23, and Effects of Intensive Blood Pressure Lowering in SPRINT Participants with CKD Charles Ginsberg,[12] Timothy Craven,[8] Michel Chonchol,[14] Alfred K. Cheung,[13] Mark J. Sarnak,[11] Anthony A. Killeen,[3] Kalani L. Raphael,[4] Udayan Y. Bhatt,[2] Jing Chen,[9] Glenn M. Chertow,[10] Barry I. Freedman,[8] Suzanne Oparil,[7] Barry M. Wall,[6] Clinton B. Wright,[1] Michael Shlipak,[5] Joachim H. Ix.[12] *[1]NINDS, Rockville, MD; [2]The Ohio State University, Dublin, OH; [3]University of Minnesota, Minneapolis, MN; [4]VA Salt Lake City Health Care System, Salt Lake City, UT; [5]San Francisco VA Medical Center, San Francisco, CA; [6]VA Medical Center, Memphis, TN; [7]University of Alabama at Birmingham, Birmingham, AL; [8]Wake Forest University School of Medicine, Winston-Salem, NC; [9]Tulane School of Medicine, New Orleans, LA; [10]Stanford University School of Medicine, Palo Alto, CA; [11]Tufts Medical Center, Boston, MA; [12]UCSD, San Diego, CA; [13]University of Utah, Salt Lake City, UT; [14]University of Anschutz Medical Center, Aurora, CO.*

Background: Serum FGF23 and PTH levels are elevated in CKD patients, and are associated with CVD events. Prior work has demonstrated that the association with CVD events may be modified by tubular resistance to FGF-23, thereby giving insight into kidney tubule function above and beyond eGFR. We hypothesized that the therapeutic benefits of intensive blood pressure (BP) control may also be modified by tubular resistance to PTH and FGF-23.

Methods: Among 2486 SPRINT participants with baseline eGFR < 60 ml/min/1.73m^2, we measured intact FGF23 and intact PTH. We evaluated whether the effect of randomization to intensive vs. standard BP arms on CVD, HF events, and all-cause mortality was modified by serum PTH or FGF-23 levels.

Results: Mean age was 73 yrs, 60% were female, mean eGFR was 46±9 ml/min/1.73m^2. Median [IQR] iFGF23 was 66 [52, 88] pg/ml, and median iPTH was 48 [35, 67] pg/ml. PTH modified the effect of intensive BP lowering for CVD events (p_{int}=0.01) and HF (p_{int}=0.003). In stratified analyses, intensive BP lowering was associated with lower risk of CVD (HR 0.68, 95% CI 0.45-1.00) and HF (HR 0.41, 95% CI 0.20-0.85) among participants with PTH <48 pg/ml; but not those with PTH >48 pg/ml. FGF23 did not modify the association of intensive BP control with any of the 3 outcomes.

Conclusions: Lower serum PTH levels may identify a subset of CKD patients who receive the greatest benefit from intense BP lowering. Further work is necessary to elucidate if tubular resistance to PTH is the mechanism responsible for these findings.

Effect of Renal Function and Obstructive Sleep Apnoea on Nocturnal Blood Pressure in Patients with CKD Stage 3-4 Bodil G. Hornstrup,[3,1] Pia H. Gjørup,[2] Jost Wessels,[2] Thomas G. Lauridsen,[2,3] Erling B. Pedersen,[1] Jesper N. Bech.[3,1] *[1]Aarhus University, Aarhus, Denmark; [2]Department of Medicin, Holstebro, Denmark; [3]University Clinic of Nephrology and Hypertension, Holstebro, Denmark.*

Background: Many patients with chronic kidney disease (CKD) suffer from high nocturnal blood pressure (BP) and lack of nocturnal BP decrease. These are known to be associated with poorer outcome related to cardiovascular morbidity and mortality. Reasons for high nocturnal BP in patients with CKD are not known. In this case control study, we studied the effect of obstructive sleep apnoea (OSA) and renal function on nocturnal BP in CKD 3-4 subjects.

Methods: Seventy patients with CKD 3-4 (eGFR 15-59 mL/min) from the Renal Outpatients Clinic, Holstebro Hospital were compared with 56 healthy age-matched controls. 24 h ambulatory BP monitoring, blood samples (creatinine) and cardio respiratory monitoring (Apnoea Hypopnea Index, AHI) were performed in all participants.

Results: Non-dipping was seen in 44% (n=31) of CKD3-4 cases and 18% (n=10) of healthy controls (p=0.002). Moderate to severe OSA (AHI>15) was diagnosed in 26% (n=18) of CKD 3-4 cases and 2% (n=2) of controls (p<0.001). Regression analysis showed an association between BMI and nocturnal BP decrease in CKD (p = 0.001), but not in controls; eGFR or OSA were not associated with nocturnal BP. Compared to dipping CKD3-4 cases, non-dipping CKD3-4 cases had higher BMI (32 vs. 29 kg/m^2, p= 0.024) and HbA1c (52 vs. 43 mmol/mol, p=0.03), longer duration of antihypertensive treatment (10 vs. 6 years, p= 0.02), received more antihypertensive drugs (3 vs. 2, p<0.007), and more had history of AMI (29 vs. 5%, p=0.009).

Conclusions: Non-dipping and moderate to severe OSA were more frequently seen in CKD 3-4 than in healthy controls. In contrast to BMI, neither eGFR nor OSA were associated to nocturnal BP decrease in either group. Non-dipping CKD 3-4 had more obesity, diabetes and ischemic heart disease than dipping CKD. In addition, non-dipping in this CKD 3-4 population was associated with a longer duration and more complex hypertension treatment.

The Effect of Night-Time versus Sleep-Time on Blood Pressure Dipping Ali Mirza Onder,[1] Songul Onder,[2] Tamekia Jones.[2] *[1]Pediatrics, Le Bonheur Children's Hospital, Memphis, TN; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: There is limited information on the sleep blood pressure profiles and sleep related blood pressure dipping (BPD) for subjects who work at night-time and sleep at daytime.

Methods: 84 medical professionals are evaluated with 24 hour ambulatory blood pressure monitoring (ABPM) during three work- sleep schedules; work daytime and sleep at night-time, work night-time and sleep at daytime, and awake at daytime and sleep at night-time during an off-work day. Subjects were divided into four distinct groups: subjects who only work at daytime and always sleep at night-time (Group A), subjects who switch from working day to night-time in frequent intervals such as every 3-4 days(Group B) or prolonged intervals such as every 3-4 months(Group C) and subjects who only work at night-time and always sleep during daytime(Group D). Sleep score is defined as the product of the sleep BPD percentage and duration of sleep in hours. The Kruskal Wallis test was used to compare differences among groups, and the Signed rank test was used to evaluate paired differences.

Results: Average reported sleep duration was indifferent between the four groups for both periods of work schedule. Although the median BPD profile (15.5 vs 12) and sleep score (112 vs 90) were higher for Group A than Group D, the differences were not statistically significant (p=0.31 and p=0.24). Groups B&C were compared for daytime and night-time work BPD; there was no difference for sleep BPD between two different work times (p=0.47). However, the median sleep score was significantly better when subjects were sleeping at night-time (127.5 vs 103, P=0.02). When the four groups were compared for their BPD during an off-work day, there was no difference for sleep BPD (p=0.43) and for sleep score (p=0.36).

Conclusions: In this preliminary study, the blood pressure dipping was predominantly associated with sleep time rather than night-time. Subjects who work at night had similar sleep BPD compared to subjects who work at daytime. However, subjects who switch shifts achieved a significantly higher sleep score when they slept at night-time, due to longer duration of sleep. The history of night-time work did not affect the sleep BPD on an off-work day, sleeping at night for any of the groups.

FR-PO542

Nocturnal Hypertension Is Common and Is Associated with CKD Progression in the Chronic Kidney Disease in Children Study (CKiD) Cohort Monica L. Guzman- Limon,[1] Shuai Jiang,[2] Derek Ng,[2] Bradley A. Warady,[3] Susan L. Furth,[4] Joseph T. Flynn,[5] Joshua A. Samuels.[1] *[1]Pediatric Nephrology & Hypertension, McGovern Medical School at UTHealth, Houston, TX; [2]Johns Hopkins University, Baltimore, MD; [3]The Children's Mercy Hospital, Kansas City, MO; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]Seattle Children's Hospital, Seattle, WA.*

Background: Hypertension (HT) affects nearly half of all of children with chronic kidney disease (CKD) and is a major modifiable cause of end organ disease. 24 hour ambulatory blood pressure monitoring (ABPM) has demonstrated the significance of nocturnal HT on CKD progression among adults. In children with CKD, the effect of nocturnal HT on CKD progression is unknown.

Methods: Stratified by CKD etiology, we investigated the relationships between daytime or nocturnal HT (or both), and a composite outcome (defined as RRT or a 50% decline in GFR) amonng CkiD participants using Cox proportional hazards models. Daytime and nocturnal HT were defined as: mean BP > 95th percentile and/or load > 25% for either systolic or diastolic BP within wake or sleep periods, respectively.

Results: 1195 ABPM studies from 693 CKiD participants were reviewed. In 501 children with non-glomerular (NG) CKD, 40% were normotensive, 7% had daytime only HT, 19% had nocturnal only HT, and 34% had diurnal HT. In 192 children with glomerular (G) CKD, 44% were normotensive, 6% had daytime only HT, 20% had nocturnal only HT and 30% had diurnal HT. In models adjusting for age, gender and race, among NG children, presence of nocturnal only HT was significantly associated with outcome when compared to normotensive children (HR: 1.80, p=0.02). The presence of dirunal HT in this group had a more pronounced association (HR: 2.37, p<0.001). Among children with G CKD, the presence of nocturnal only HT or daytime only HT was not significantly associated with outcome (HR: 1.60, p=0.30 and HR: 1.31, p=0.67, respectively), while the presence of diurnal HT was strongly associated with outcome (HR: 4.38, p<0.001).

Conclusions: Nocturnal hypertension is associated with a significantly faster decline in kidney function (GFR decline or RRT) when compared to normotensive patients with CKD. This outcome is even more pronounced in patients with diurnal HT. This confirms the utility of ABPM in patients with CKD. Identifying and controlling both daytime and nocturnal HT using ABPM may improve outcomes and delay CKD progression in this population.

FR-PO543

Ambulatory Blood Pressure and CKD Progression in the CKiD Cohort Janis M. Dionne,[1] Shuai Jiang,[3] Derek Ng,[2] Joseph T. Flynn,[4] Susan L. Furth,[5] Bradley A. Warady,[6] Joshua A. Samuels.[7] *[1]BC Children's Hospital/ University of British Columbia, Vancouver, BC, Canada; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]Seattle Children's Hospital, Seattle, WA; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]The Children's Mercy Hospital, Kansas City, MO; [7]University of Texas, Houston, TX.*

Background: We evaluated mean arterial pressure (MAP) by ambulatory blood pressure monitoring (ABPM) in the CKiD cohort to investigate if low-normal MAP (<50th %ile) was associated with a decreased rate of CKD progression compared to conventional (50th-90th %ile) or high (>90th %ile) MAP.

Methods: The primary outcome was time to renal replacement therapy (RRT) or 50% decline in eGFR. The primary exposure was time-varying MAP. Analyses were stratified by glomerular and non-glomerular diagnosis. 3 Cox models were fit with conventional MAP as the reference: unadjusted; age, gender and race adjusted; + proteinuria adjusted.

Results: 190 children with glomerular and 489 with non-glomerular CKD contributed at least one ABPM study. Those with high MAP were more likely to be African American, had more proteinuria and were less likely to take ACEi/ARB. Among children with glomerular CKD, those with high MAP had a 2.49 higher hazard ratio (HR) for the outcome compared to conventional MAP (95%CI: 1.35, 4.57); the HR for low-normal MAP was protective (0.42, 95%CI: 0.15, 1.15) (Figure 1). The HR with non-glomerular CKD with high MAP was 1.76 (95%CI: 1.25, 2.47) and 0.71 (95%CI: 0.42, 1.21) for low-normal MAP. After adjusting for age, race, and gender results were similar. Adjustment for proteinuria reduced the effect size but not the direction of association or glomerular significance.

Conclusions: Ambulatory MAP >90th %ile was associated with a more rapid progression of CKD in children. The benefit of MAP <50th %ile was slightly reduced after adjustment for proteinuria. The prevalence of ACEi/ARB use was lower among those with high MAP indicating potential for benefit with therapy.

Reduction of Nocturnal Hypertension in Pediatric Renal Transplant Recipients Christine B. Sethna,[3] Shari Gurusinghe,[1] Rachel Frank,[2] Lulette Infante,[4] Kevin E. Meyers.[5] *[1]Cohen Children's Medical Center, New Hyde Park, NY; [2]Cohen Children's Medical Center, New Hyde Park, NY; [3]Cohen Children's Medical Center of NY, New Hyde Park, NY; [4]Cohen Children's Medical Center of New York, New Hyde Park, NY; [5]The Children Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA.*

Background: Nocturnal hypertension (nHTN) and non-dipper (ND) status are commonly found during ambulatory blood pressure monitoring (ABPM) in pediatric renal transplant recipients (Txp). These entities are associated with cardiovascular risk in adults. The aim was to investigate chronotherapeutic alteration of anti-hypertensive medication on nHTN and end-organ injury in ND Txp.

Methods: 33 ND Txp aged 5-21 with normal overall ABPM and eGFR >30 ml/min/1.73m^2 were randomized to intervention (enalapril, isradipine or propranolol added in the evening) or control (no medication change) in this open label, blinded endpoint clinical trial. ABPM, echocardiography for left ventricular mass index (LVMI) and pulse wave velocity (PWV) were performed at baseline, 3 and 6 months. ND was defined as a decline of <10% in average blood pressure (BP) from day to night. Differences were compared using Fisher's, t-test and paired t-test by intention-to-treat analysis.

Results: Txp included 17 intervention and 16 controls, age 13 (IQR 8,16) yr, 64% male. Baseline demographics, ABPM, LVMI and PWV were similar between groups. Conversion to dipper status occurred in 43% vs 10% at 3 months (p=0.08) and 53% vs 8% (p=0.02) at 6 months for intervention and controls, respectively. Although all ABPM parameters at 3 and 6 months were lower in intervention compared with controls, only systolic night BP at 6 months showed a significant difference (114.9±9.5 vs 106±8.3 mmHg, p=0.01). Changes over time in the intervention group are shown in the table. There were no significant changes over time in controls for ABPM, LVMI or PWV.

Conclusions: Reduction of nHTN and restoration of nocturnal dip in Txp is possible with chronotherapy. Future studies are needed with larger sample sizes to delineate the effect of improved nHTN on end-organ damage.

Ambulatory (ABP) Hypertension (HT) Over Time Is Associated with Subsequent GFR Decline in Children with CKD Joshua A. Samuels,[3] Derek Ng,[4] Shuai Jiang,[2] Joseph T. Flynn,[5] Susan L. Furth,[6] Bradley A. Warady,[7] Janis M. Dionne.[1] *[1]BC Children's Hospital/ University of British Columbia, Vancouver, BC, Canada; [2]Johns Hopkins University, Baltimore, MD; [3]McGovern Medical School at UTHealth, Houston, TX; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [5]Seattle Children's Hospital, Seattle, WA; [6]The Children's Hospital of Philadelphia, Philadelphia, PA; [7]The Children's Mercy Hospital, Kansas City, MO.*

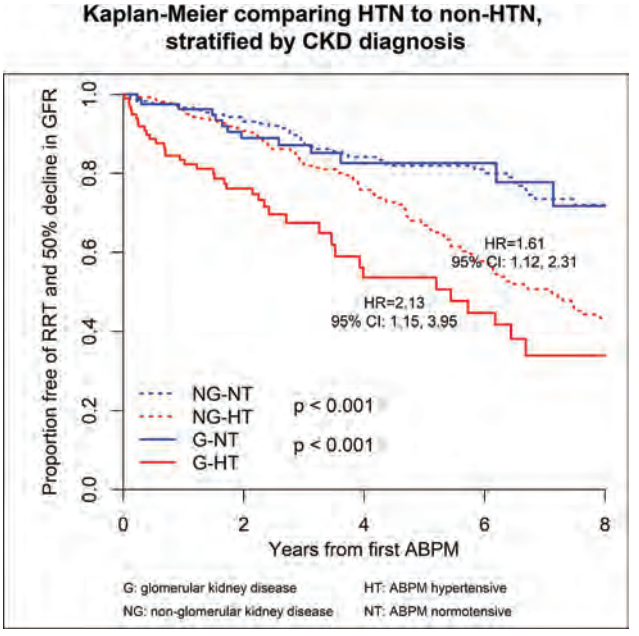
Background: Ambulatory HT is associated with CKD stage. Longitudinal changes in ambulatory blood pressure (ABP) and their relationship to subsequent pediatric CKD progression is poorly described. We characterize changes in ABP and GFR over time in children in the CKiD cohort.

Methods: BP based on ABP and HT defined by CKiD ABP criteria. HT status could change following repeat ABPM (every other year) and thus exposure varied over time. We quantified transitions from normotensive (NT) to HT, as well as the risk of progression to composite endpoint (RRT or 50% drop in GFR) by relative hazards (HR) using Cox proportional hazards models. Analyses adjusted for age, gender, and race and stratified by CKD diagnosis (i.e., glomerular (G=501) or non-glomerular (NG=192) etiology).

Results: A change in BP category was common. For G, 56% had HT at entry; 16% transitioned to a NT during ~6 years follow up. Of those with NT at entry, 20% transitioned to HT. For NG, 60% had HT at entry and 24% transitioned to NT. Among the 40% with NT at entry, 38% transitioned to HT. CKD progression was significantly greater during periods of HT compared to NT. Figure 1 displays the incidence of composite endpoint (GFR decline or RRT) by ABP status (HT= red; NT=blue) for G and NG CKD. Differences were significant by ABP (log rank p< 0.001 for both groups): HT was associated with 2.81 times higher hazard of endpoint among children with G (95%CI: 1.51, 5.24) and a 2.09 times higher hazard among those with NG CKD (95%CI: 1.46, 2.99) in adjusted models. HRs remained significant when adjusted for proteinuria.

Conclusions: Ambulatory HT is common (~58%) in children with CKD. NT transitioned to HT more than vice versa in both G and NG children. Ambulatory HT was strongly associated with CKD progression.

Funding: NIDDK Support



FR-PO546

Comparison of Blood Pressure (BP) Methods and Setting in Children with CKD Tammy M. Brady,[3] Shang-En Chung,[3] Michelle N. Eakin,[3] Andrea C. Goodman,[3] Cozumel S. Pruette,[3] Barbara A. Fivush,[3] Shamir Tuchman,[1] Susan R. Mendley,[4] Kristin Riekert.[2] *[1]Children's National Medical Center, Washington, DC; [2]Johns Hopkins School of Medicine, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]University of Maryland, Baltimore, MD.*

Background: Children with CKD are at greater risk for hypertension and high BP is a risk factor for CKD progression. Multiple methods exist to measure BP in clinical practice. We aimed to determine how differing methods of BP measurement:1) correlate with each other and 2) correctly identify hypertensive status.

Methods: Cross-sectional analysis of 116 children in the CKD: Hypertension Adherence in Teens (CHAT) study at baseline. Enrolled children were 11-19 years of age, had CKD, and were prescribed ≥1 BP medication. Children had a clinic BP, 3 consecutive

standardized home oscillometric BPs, and gold-standard 24-hour ambulatory BP (ABPM). BP index (BPi; measured BP/95th %ile BP; BP≥1 indicates hypertension) was calculated to standardize comparisons between BP measurements. Spearman correlation and Cohen's Kappa coefficient (k) were used to compare measurement methods.

Results: Mean age 15.6 +/-2.6 yrs, 53% African American, and 55% male. CKD Stage: I 23%; II 38%; III 26%; IV 6.3%; V 7.3%. 32% of children were classified as hypertensive via day ABPM measurements compared with 20% via home BP (mean or 1st value) and 26% via clinic BP. The prevalence of normotension was 37% using ABPM measurements. Compared to this gold standard, average home BP classified 70% as normotensive (k 0.23), 1st home BP classified 62% as normotensive (k 0.18), and clinic BP classified 53% as normotensive (k 0.2). Clinic BP did not correlate well with other methods of BP measurement [Table].

Conclusions: BP measured in clinic correlates poorly with other standardized measurements of BP and resulted in underdiagnosis of hypertension when compared to BPs obtained by gold-standard ABPM. Home BP measurements, used frequently in place of ABPM, also underdiagnosed hypertension. This underscores the importance of ABPM as part of routine care of children with CKD.

Funding: NIDDK Support

FR-PO547

Prevalence of Elevated Blood Pressure in Multiethnic School-Aged Children in New York City Bernarda Viteri Baquerizo,[3] Jeffrey M. Saland,[2] Clare Ceballos.[1] *[1]Mount Sinai School of Medicine, New York, NY; [2]Mount Sinai School of Medicine, New York, NY; [3]Mount Sinai School of Medicine, New York, NY.*

Background: Pediatric hypertension (HTN) is a public health problem defined by blood pressure (BP) ≥ 95th percentile relative to age, gender, and height on ≥ 3 occasions. Overweight increases the likelihood of elevated BP and HTN and is more common among minority, poor, and male children. These findings (28% overweight with 12% pre-hypertensive / 15% hypertensive range BP) were noted in School Based Health (SBH) centers by a team from this medical center 15 years ago. Our goal was to revisit these centers and a tertiary care hospital-based clinic to assess the quality of BP screening and follow-up and if needed to begin iterative quality improvement (QI) toward reducing consequences of HTN on childhood development and early-onset end organ damage.

Methods: Retrospective cross-section cohort, age 4-21 years, with at least one outpatient visit (SBH or hospital-based) between July 2015-June 2016.

Results: 5739 patients had 8225 encounters. 215 (3.74%) patients had at least one visit with elevated BP, out of which only 16 (7%) had follow-up within the period described. About 3/4 of the visits were at the hospital-based clinics and 2.65% of patients with elevated BP were seen in this setting vs. 4.39% seen at SBH clinics (p-value = 0.003). Appropriate follow-up in patients with elevated BP was noted in 14/126 seen at hospital-based clinics vs. 2/44 seen at SBH clinics. The children with or without elevated BP did not differ with respect to sex (female 52% and 48%, respectively), or AA race (40%), while Latinos were found in 46% patients with normal BP vs. 40% with elevated BP. Median age was 10 for the entire cohort. Obesity was noted in 63% of patients with elevated BP (median BMI 99th percentile.), vs. 34% in patients with normal BP (median BMI 82nd percentile (p-value 0.001;CI -13.65 to -13.56), despite a slightly higher prevalence of patients classified overweight (BMI ≥ 85th percentile) in the latter group.

Conclusions: Although the rate of elevated BP in this population was somewhat lower than other reports of general screening programs, there is nonetheless a significant population of children with elevated BP and overweight as a risk factor for elevated BP. The lack of follow-up among this group of patients with elevated BP highlights the need of quality improvement in the systematic screening and treatment of children in the East Harlem area of New York.

FR-PO548

Association of Creatinine Levels and Hypertension in an International Cross-Sectional Database of Pediatric Patients on Chronic Hemodialysis: The PICCOLO MONDO Initiative Alice Topping,[3] Ricardo Guerrero kanan,[2] Ana C. Alvarez-Elias,[5] Mara Medeiros,[1] Jochen G. Raimann,[3] Peter Kotanko,[3] Maria E. Ferris.[4] *[1]Hospital Infantil de México Federico Gómez, MEXICO, D.F., Mexico; [2]Instituto Nacional de Perinatologia, Mexico, Mexico; [3]Renal Research Institute, New York, NY; [4]University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]MEXICO CHILDRENS HOSPITAL. FEDERICO GOMEZ, Tlalnepantla de Baz, Mexico.*

Background: Hypertension is a concern when treating pediatric chronic hemodialysis (cHD) patients due its association with cardiovascular morbidity and mortality. We aim to describe the association of laboratory markers and demographic information with hypertension in pediatric cHD patients from the PICCOLO MONDO Initiative.

Methods: Routine treatment and laboratory information was compiled in the PICCOLO MONDO database from the years 2000 to 2010. Hypertension was classified as ≥ 95th percentile of pre-treatment systolic sitting blood pressure (SBP) based on age-, sex-, and height-specific percentiles. For subgroup analysis, patients were divided into 4 regions: Asia Pacific (AP), Europe (EU), Latin American (LA) and North America (NA) and 4 age groups: 0-5, 6-12, 13-15, 16-18 y.o.a. The study was approved by the University of North Carolina IRB.

Results: Data from 439 cHD patients < 18 y.o.a in 21 countries were analyzed. The median age was 16 y.o.a. (IQR 13 to 17) and 52.9% were male. Overall, 16.4% of patients were classified as hypertensive. This proportion varied by region: 31.9% of patients in NA, 26.5% in EU, 15.9% in AP and 12.4% of patients in LA were hypertensive (p=0.002). Creatinine was significantly higher in hypertensive patients (8.9±3.3 v. 7.7±3 p=0.02). Creatinine levels varied by age group and region (p=0.04 for regional and p=0.002 for age group comparisons). Logistic regression analysis shows that when controlling for region and age group, each one mg/dL increase in creatinine was associated with a 1.18 times increase in risk of having hypertension (95% CI 1.05 to 1.22).

Conclusions: We found differences in hypertension prevalence by region. Elevated creatinine was found to be a risk factor for hypertension, which may indicate that residual renal function protects against hypertension in pediatric cHD patients.

FR-PO549

Evolution of Systolic Blood Pressure in the First Year of Hemodialysis: A Comparison between Tassin, France, and Renal Research Institute, USA Alice Topping,[3] Hanjie Zhang,[2] Jochen G. Raimann,[3] Charles Chazot,[1] Peter Kotanko.[3] *[1]NephroCare Tassin Charcot, Sainte Foy-Les-Lyon, France; [2]Renal Research Institute, New York, NY; [3]Renal Research Institute, New York, NY.*

Background: Hypertension is common in hemodialysis (HD) patients. In HD patients blood pressure may be related to treatment practices. Currently the conventional HD in the US is prescribed as 3-4 hours, thrice per week. Tassin dialysis center in France performs long, 8-hour HD thrice per week and previously reported exemplary results regarding blood pressure control, fluid management, and phosphate clearance.

Methods: Patients from the Renal Research Institute (RRI) who started dialysis between 2000 and 2012 were propensity score matched to incident patients beginning HD between 2000 and 2013 from Tassin. RRI patients were matched on baseline (first week on HD) demographic, treatment and laboratory characteristics including age, sex, vascular access, dialysate and serum sodium levels and other relevant parameters. Weekly average SBP and weekly total Epogen doses (EPO) were plotted using generalized additive model over the first year of dialysis.

Results: 487 RRI patients were matched from a pool of 1,914 eligible patients to an equal number of Tassin patients. Patient groups were well balanced on age, sex, diabetes and other parameters. SBP declined steadily in the Tassin group until 18 weeks on HD then continued to decrease gradually until 40 weeks on HD. RRI patients had slightly higher SBP at baseline which increased in the first 12 weeks on dialysis, then declined gradually until week 42 (**Figure 1a**). EPO dose increased for RRI patients in the beginning of HD until 8 weeks, then decreased steadily during the first year of HD. Patients in Tassin showed a steady decrease in EPO use over the first year of HD (**Figure 1b**).

Conclusions: Patients in Tassin, France who receive longer HD times showed marked decreases in SBP compared to RRI patients. Weekly EPO dose decreased in both groups, but remained much higher in RRI patients throughout the first year of HD, particularly in the first weeks of HD. Sustained higher SBP in RRI patients may be related to the higher doses of EPO.

Radiological Imaging in Pediatric Renovascular Fibromuscular Dysplasia (FMD) Robert J. Louis, Anne marie Cahill, Kevin E. Meyers. *The Children Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA.*

Background: FMD is a non-inflammatory vascular disease that in children unlike adults has no sex-predilection. FMD is under-recognized, underdiagnosed, with unclear pathogenesis. Doppler Ultrasounds (US), Magnetic Resonance Angiography (MRA), Computed Tomography Angiography (CTA), and Catheter Based Angiography (Ang) are used to make a presumptive diagnosis of FMD.

Methods: We did a retrospective analysis of the clinical features and radiological findings in 26 children diagnosed with FMD at the Children's Hospital of Philadelphia (CHOP), all are entered into the national FMDSA database and have institutional IRB consent

Results: Mean age at diagnosis was 7.4 ± 4.7 yr (4m – 17yr). Family history HTN (54.2%) of FMD (8.3%), Caucasian (61.5%). Headache (46%) and HTN (89.7%) were the most prevalent symptoms and signs at presentation. FMD was unifocal single site 17/25 (68%) or unifocal multiple sites 7/25 (28%) and involved the main or first order renal branch in 17/25 (68%). Isolated deep vessel lesions beyond the 2nd order branches were found in 7/25 (28%) children (Table). Only Ang showed deep vessel disease. US imaging was significantly less sensitive (28% US vs 100% Ang, p = 0.003) and was the least sensitive imaging technique. The NPV of US (41.9%) was also less than that of Ang (100%). US had an equivalent specificity and PPV to that of Ang. This was true for the specificity and PPV of MRA imaging as well, but MRA imaging showed a lower NPV (40%) when compared with Ang. This was the lowest NPV of the imaging modalities. MRA had a better sensitivity (62.5%) than US. Overall, 3D CTA had the best sensitivity (84.2%) and NPV (70%) compared with Ang; but still had much lower specificity (70%) and PPV (84.2%) when compared with Ang.

Conclusions: Only Ang showed deep renal vascular disease. Ang should be done as part of the initial work-up of any child suspected of having renovascular FMD, no matter what the findings are on US, MRA, or 3D CTA.

Racial Disparities in Pediatric Hypertension Management Christopher Cates,[2] Bethany Crawford,[2] John Lin,[4] Nichaela A. Hoffman,[1] Thomas K. Davis,[3] Vikas R. Dharnidharka,[3] Laura Hesemann.[2] *[1]Barnes Jewish Hospital, St. Louis, MO; [2]University of Missouri School of Medicine, Columbia, MO; [3]Washington University School of Medicine, St Louis, MO; [4]Washington University in St. Louis, St. Louis, MO.*

Background: African American (AA) adults have a higher prevalence of HTN and lower rates of control when compared to non-Hispanic whites (non-AA). Evidence for a similar disparity in pediatric populations is mixed though there are differences in hypertension-related morbidity. Studies assessing differences in HTN control between ethnic groups are lacking for pediatric patients. The goal of this study was to evaluate rates of HTN control among pediatric patients of different ethnicity.

Methods: All patients with a diagnosis of HTN seen between May 2012 and April 2013 at a pediatric nephrology clinic in an academic center were evaluated. Patients with resolved HTN, ESRD, or history of kidney transplant were excluded. Blood pressure control was recorded as documented by the treating physician. Data were collected to evaluate risk factors for uncontrolled HTN, including race, age, gender, stage of HTN, number of medications, BMI, and presence of CKD.

Results: 126 subjects were included. 41 (33%) identified as African American, 85 (67%) identified as Caucasian, Asian, or Other. Median age was 14 (range 5 months-20 years). Among all subjects, 83% were documented as having adequate BP control. However, the rate of control among AA subjects was 68% compared to 87% among non-AA subjects (p=0.012). When comparing racial groups, there was no difference in BMI group, CKD, family history, use of multiple anti-hypertensive medications, or stage of HTN.

Conclusions: In this pediatric cohort, AA subjects were less likely to have adequately-controlled blood pressure when compared to non-AA despite no difference in commonly-assessed risk factors for HTN or the number of medications prescribed. This parallels results obtained through population-based studies showing lower rates of blood pressure control among AA adults compared to non-AA and highlights the need to further address racial disparities in pediatric health care.

Blood Pressure Control and Risk Factors by Ethnicity

	African American (N=41)	Non-African American (N=85)	p-value
Controlled	68%	87%	0.012
Overweight or obese	62%	60%	0.877
CKD	23%	28%	0.587
Family History of HTN	82%	76%	0.472
>1 medication	20%	29%	0.236

Ventricular Dysfunction in Children with Controlled Hypertension and CKD Wacharee Seeherunvong,[1] Aura J. Arenas Morales,[1] Arpit K. Agarwal,[2] Marissa J. Defreitas,[1] Chryso P. Katsoufis,[1] Gaston E. Zilleruelo,[1] Carolyn L. Abitbol,[1] Sethuraman Swaminathan,[2] Michael Freundlich.[1] *[1]University of Miami/ Pediatric Nephrology, Miami, FL; [2]University of Miami/ Pediatric Cardiology, Miami, FL.*

Background: Hypertension (HTN) contributes to left ventricular hypertrophy (LVH) and dysfunction, and accelerates cardiovascular (CV) disease in chronic kidney disease (CKD), but the thresholds linking blood pressure (BP) with eventual CV events in children are unknown. Suggested targets for optimal therapy are <95th %ile BP reference values, but whether sustaining BP within these targets averts LVH and ventricular dysfunction in children is uncertain.

Methods: From 70 patients (14.6±0.2 years) with an initial diagnosis of HTN and available echocardiographic evaluation, 33 (14 on renin-angiotensin system blockers) with controlled BP <95th %ile and eGFR-based CKD stages 1 (n=16), 2-4 (n=10) and 5D (n=7) were analyzed.

Results: BP Z-scores (Zs) were similar in all groups. Echocardiogram revealed LVH in 19%, 20% and 43% in stages 1, 2-4 and 5D, and abnormal relative wall thickness (RWT >0.37cm) in 44%, 60% and 71% respectively. While systolic function remained normal, diastolic function E/A ratio was reduced in 13%,20% and 71% of stages 1,2-4 and 5D and declined across stages (p<0.05) (Figure 1). E/Em and E/Es abnormal Zs were uncommon. At least 1 abnormal diastolic function was present in 25%, 50% and 86% in above stages (p<0.05). LVMI Zs correlated positively with BMI Zs, E/Em and E/Es Zs, and negatively with serum Ca (all p<0.05), but did not correlate with BP Zs. BP Zs did not correlate with any marker of diastolic function.

Conclusions: Despite controlled HTN, abnormal ventricular geometry and altered diastolic function were observed even in the earliest stages CKD. Other factors operative with declining kidney function may be responsible for the described changes. Longitudinal studies are needed to evaluate the effects of more stringent BP control on LVH and abnormal diastolic function in young CKD patients with HTN.

Epigenetic Clock and Biological Aging during Preeclampsia Natasa Milic,[2,3] Vesna D. Garovic.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Department for Medical Statistics and Informatics, School of Medicine University of Belgrade, Belgrade, Serbia; [3]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Preeclampsia is a pregnancy-specific disorder clinically characterized by hypertension (blood pressure ≥140/90 mmHg) and proteinuria (≥300 mg per day).

Aberrant placental aging and increased placental senescence have been demonstrated in preeclampsia, as well as the role of epigenetic mechanisms, such as DNA methylation, in control of maternal gene expression in normal pregnancies, which can be disrupted in preeclampsia. The aim of this study was to test the hypothesis that biological aging is accelerated in women with preeclampsia vs. those with normotensive pregnancies.

Methods: Biological age was measured by "epigenetic clock," an estimate of DNA methylation age using the elastic net regression model, consisting of methylation values across 353 specific CpGs that were found to vary with age. Data from the 450k methylation of 44 blood samples from preeclamptic (n=11, mean age 30±7 years) and normotensive (n=34, mean age 31±4 years) patients during the first and second trimesters and at the time of delivery were used to compare longitudinally the estimated DNA methylation (epigenetic) ages during preeclamptic and normotensive pregnancies.

Results: Biological age for women with normotensive pregnancies have not changed over the course of pregnancy (32±6 years for all time points). In contrast, biological age significantly increased over the course of preeclamptic pregnancies: first trimester, 30±8 years; second trimester, 31±9 years; and delivery, 32±9 years ($p<0.05$).

Conclusions: Our data suggest that preeclampsia may behave as a premature-aging-like state. These findings set the stage for future studies that may identify novel mechanistic pathways in preeclampsia.

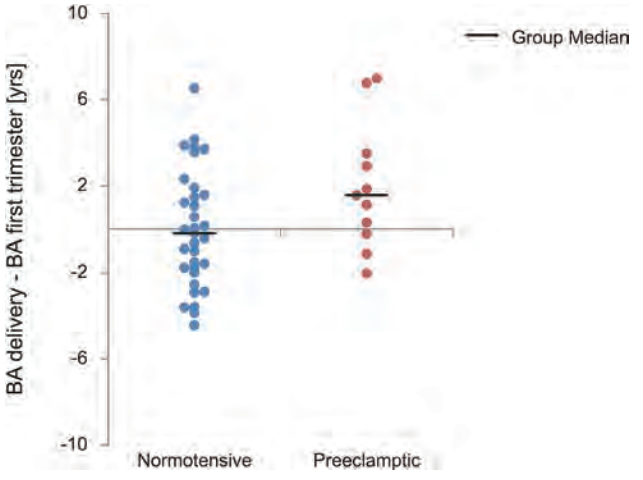

Figure 1. Difference in biological aging (BA) during course of pregnancy in normotensive and preeclamptic pregnacies

Fetal but Not Maternal APOL1 Genotype Is Associated with Increased Risk for Preeclampsia among African-Americans Rebecca C. Hjorten,[3,11] Kimberly J. Reidy,[3] Claire L. Simpson,[8] A Z. Rosenberg,[12] Stacy Rosenblum,[4] Csaba P. Kovesdy,[10] Frances A. Tylavsky,[10] Joseph Myrie,[1] Bianca L. Ruiz,[1] Khyobeni Mozhui,[10] Soulin Haque,[1] Masako Suzuki,[1] Sandra E. Reznik,[5] Frederick J. Kaskel,[2] Jeffrey B. Kopp,[7] Cheryl A. Winkler,[6] Robert L. Davis.[9] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Albert Einstein College of Medicine, Children's Hospital at Montefiore, Bronx, NY; [3]Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronxville, NY; [4]Montefiore Medical Center, Suffern, NY; [5]Montefiore Medical Center and Albert Einstein College of Medicine/St. John's University, Queens, NY; [6]NCI, NIH, Frederick National Laboratory, Frederick, MD; [7]NIDDK, NIH, Bethesda, MD; [8]UNIVERSITY OF TENNESSEE HEALTH SCI CTR, Memphis, TN; [9]University of Tennessee, Memphis, TN; [10]University of Tennessee Health Science Center, Memphis, TN; [11]Nephrology and Hypertension, Cincinnati Children's Hospital, Cincinnati, OH; [12]Pathology, Johns Hopkins University, Baltimore, MD.*

Background: African Americans are at increased risk for preeclampsia. Genetic variants in apolipoprotein L1 (*APOL1*) account for a substantial fraction of increased risk of kidney disease among African Americans. *APOL1* is expressed in human placenta, and transgenic mice expressing *APOL1* develop preeclampsia. The role of *APOL1* variants in human preeclampsia has not been studied.

Methods: Two studies were performed evaluating maternal and fetal *APOL1* genotypes in African American women with preeclampsia. At Albert Einstein College of Medicine (AECOM) Affiliated Hospitals, we studied 122 pregnancies in African American women with preeclampsia. At University of Tennessee Health Science Center (UTHSC), we studied 93 pregnancies in African American women with preeclampsia compared to 793 control birth mothers and infants.

Results: In both studies fetal *APOL1* high risk (HR) genotype was associated with preeclampsia in their mothers, relative risk at AECOM 1.65 (95% CI 1.11, 2.44) and odds ratio at UTHSC 1.92 (1.05,3.49). In both studies, maternal *APOL1* HR genotypes were not associated with preeclampsia. Gestational age, birth weight and Cesarean section did not vary by *APOL1* genotype. Fetal *APOL1* HR genotype births with preeclampsia were no more likely to have severe preeclampsia, but those mothers were more likely to have cerebral or visual disturbances (63% versus 37%, $p = 0.04$) and infants had lower APGAR scores at 5 minutes (8.0 versus 9.0, $p = 0.01$).

Conclusions: Fetal *APOL1* high-risk genotype confers an increased risk for preeclampsia, likely by adversely affecting placental function. *APOL1* genetic testing may have a clinical role to predict and perhaps improve pregnancy outcomes.

FR-PO555

Determinants of Preeclampsia and Low Birth Weight in Pregnant Women with CKD Bogdan M. Sorohan,[1] Bogdan Obrisca,[1] Vlad T. Berbecar,[2,1] Andreea Andronesi,[1,2] Gener Ismail.[1,2] *[1]Fundeni Clinical Institute, Bucharest, Romania; [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania, Bucharest, Romania.*

Background: Pregnant women with CKD are at high risk for adverse maternal and fetal outcomes, such as preeclampsia, low birth weight (LBW) and mortality, even those with mild CKD. Moreover, pregnancy itself is a risk factor for CKD progression. CKD and preeclampsia share common features, like proteinuria and hypertension, that make the differential diagnosis difficult during pregnancy. The aim of this study was to evaluate the clinico-biological determinants associated with preeclampsia and LBW in pregnant women with CKD.

Methods: We performed a prospective, observational cohort study on 32 pregnant patients with CKD. Exclusion criteria were eGFR <15ml/min and loss to follow-up. Definitions of preeclampsia in CKD and LBW were defined according to American College of Obstetricians and Gynecologists. To identify the predictors, we performed multivariate Cox and binary logistic regression.

Results: The median age was 23 years (IQR: 21.2-25) and 84.4% were nulliparous. Mean eGFR at referral was 46.5±16.1 mL/min//1.73m^2, 78.1% had CKD stage 3-4 and mean 24h proteinuria at referral was 1.01±0.6 g/24h, 50% of patients had >1.5g/24h. The most frequent primary disease for CKD was glomerulonephritis (78.1%), especially lupus nephritis (18.8%). The incidence of preeclampsia and LBW were 56.3% and 53.1%, respectively. Fetal death was present in one pregnancy (3.1%). Patients with preeclampsia were more hypertensive (61.3% vs 35.7%, p=0.15), proteinuric (1.23 vs 0.73 g/24h, p=0.02) and with a more decreased renal function (41.9 vs 52.4 ml/min/1.73m^2, p=0.004) at referral. By Cox multivariate analysis proteinuria >1.5g/24h at referral was independently associated with preeclampsia (HR=4.20, CI: 1.47-12.04, p=0.07) and preexisting hypertension presented a suggestive trend of association (HR=2.34, CI: 0.68-6.14, p=0.08). In multivariate logistic regression, proteinuria >1.5g/24h presented a close to significant association with LBW (OR=3.66, CI: 0.84-15.84, p=0.08).

Conclusions: In conclusion, proteinuria >1.5g/24h at referral is an independent determinant of preeclampsia, also presenting a trend of association with LBW and preexisting hypertension has a marginally significant tendency as a determinant for preeclampsia in pregnant women with CKD.

FR-PO556

Pregnancy Is Associated with Higher Central Systolic and Pulse Pressures in Later Life Karyne Pelletier,[2] Anne-Marie Cote,[1] Francois Madore,[2] Remi Goupil.[2] *[1]CHUS - Hopital Fleurimont, Sherbrooke, QC, Canada; [2]Hopital du Sacre-Coeur de Montreal, Montreal, AB, Canada.*

Background: Healthy pregnancy has been associated with increased arterial stiffness and central hemodynamics which normalises after delivery. Whether these changes portend to long-term changes in central blood pressures (BP) remains unknown.

Methods: Using the CARTaGENE populational database, central hemodynamic parameters were adjusted and compared between 1) women without previous pregnancies, 2) women with previous pregnancies of less than 20 weeks only and 3) women with previous pregnancies of longer term.

Results: Of 10,266 female CARTaGENE participants, 8,662 had previous pregnancies (666 with previous pregnancies ≤ 20 weeks only). Baseline characteristics are presented in the below table. After adjustment for important covariables, central systolic BP, central pulse pressure and augmentation index were higher in women with previous pregnancies ≤ 20 weeks than in women without pregnancies and with > 20 weeks pregnancies (p-values for trend <0.001, 0.001 and 0.04 respectively).

Conclusions: In this cohort, pregnancy was associated with increased central BP and indices of arterial stiffness in later life, the importance of which was greater when pregnancies longer than 20 weeks occurred. To what extent these differences could be explained by complications during pregnancy requires further investigations.

Characteristics	No pregnancy (n=1,604)	Pregnancy ≤ 20 weeks or less only (n=666)	Pregnancy > 20 weeks (n=7,996)
Age	54 ± 8	53 ± 7 [a]	54 ± 8 [b]
Age of first pregnancy	-	27 ± 7	25 ± 5 [b]
Diabetes	7%	7%	7%
Cardiovascular disease	4%	4%	4%
Treated hypertension	19%	15% [a]	22% [ab]
Brachial systolic BP	119 ± 15	118 ± 17	120 ± 16 [ab]
Brachial pulse pressure	47 ± 11	47 ± 11	48 ± 11 [ab]
Heart rate	70 ± 10	69 ± 11	69 ± 11 [a]
Adjusted central hemodynamic parameters			
Central systolic BP	113.2 (112.7, 113.7)	113.5 (112.9, 114.1)	114.1 (113.7, 114.6) [ab]
Central pulse pressure	41.1 (40.3, 41.8)	41.4 (40.6, 42.3)	42.4 (41.8, 43.1) [ab]
Augmentation index	31.2 (30.3, 32.0)	31.7 (30.6, 32.7)	31.8 (31.1, 32.6) [a]

[a] p<0.05 vs no pregnancy; [b] p<0.05 vs pregnancy 20 weeks or less.

Values are reported as mean ± standard deviation or as estimated marginal means (95%CI) adjusted for age, BMI, diabetes, cardiovascular disease, active smoking, total cholesterol, HDL-cholesterol, eGFR, uric acid, TSH, heart rate, mean BP and use of renin-angiotensin blockers, calcium channel blockers, diuretics, beta-blockers, statins and aspirin.

FR-PO557

Characterizing the Burden of Hypertension in High Alpine Himalayan Villages of Nepal

Katherine Garlo,[1] David M. Charytan.[1,2] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Hospital/Harvard Medical School, Brookline, MA.*

Background: Villages in the Ganesh Himal mountains are located in a remote high altitude regions of the Himalayans where there is limited access to basic resources and medical care. The burden of hypertension (HTN) has never been assessed in these communities. The primary objectives of this evaluation were to determine the prevalence of HTN while providing clinical care at medical camps with Himalayan Healthcare (HHC).

Methods: We conducted a retrospective observational evaluation of adults ≥18 years living in Himalayan villages at ≥15,000 feet elevation who attended HHC clinics during the spring medical trek of 2017. HTN was defined as systolic (SBP) and diastolic blood pressure (DBP) ≥150/80 mmHg on two measurements by manual cuff. This cut off was selected given the limited medical resources available for treatment. Urine samples were sought for albumin and glucose in individuals with HTN.

Results: A total of 650 individuals (mean 50±19.9 years, 75%F) received care at the medical camps. BP was ≥150/80 mmHg in 43 patients (6.6%, mean age 65±13.8 years, 60%F) mean SBP among hypertensive patients was 172±18.3 mm Hg, and mean DBP was 96 ±11.6 mm Hg. There were 607 individuals (93.4%) without HTN (mean age 49 yrs ±19.8, 76%F, **Table 1**). Urine analysis was available in 48.8% of the HTN group of which 23.8% had trace albumin and 0.0% had glucosuria.

Conclusions: In high elevation Himalayan villages of Nepal the prevalence of HTN with BP ≥150/80mmHg was low but the severity of hypertension was high. Nearly one quarter of hypertensive individuals had albuminuria suggesting that end organ damage to the kidney is common. Our findings may under estimate the true prevalence of HTN given the predominance of females in the sample population and the high BP cut off. These results support a need for targeted interventions to diagnosis and manage HTN in high-altitude communities. They also have implications for public health policy in developing countries with limited resources.

Table 1: Blood Pressure in Ganesh Himal Villages of the Himalayan Mountains

	Overall	Sertung Village	Lapa Village
All Individuals, N	650	346	304
Age years, (mean ±SD)	50 ±19.9	51 ±20.2	48 ±19.4

FR-PO558

Incidental Risk of Hypertension According to the Change of Body Weight (BW) in Korean Men

Sung keun Park,[1] Dong-Young Lee.[2] *[1]Kangbuk Samsung Hospital, Sungkyunkwan University, School of medicine, Seoul, Kore, Seoul, Republic of Korea; [2]None, Seoul, Republic of Korea.*

Background: Despite accumulated evidence of strong relationship between obesity and hypertension, risk for hypertension according to the change of BW is not clearly identified. Therefore, this study was to evaluate the incidental risk of hypertension according to the change of BW.

Methods: 26,483 normotensive Korean men had been followed up from 2005 to 2010. Based on baseline BW in 2005, the changes of BW [(BW at censoring time – BW at baseline)/follow-up period (person-years)] were categorized into 5 groups according to their change levels from the lowest to the highest quintile (Q) (1st – 5thQ). On the base of 3rd Q, 1st and 2nd Q had negative changes of BW, and 4th and 5th Q had positive changes of BW. Cox proportional hazard models was used to evaluate the effect of BW change on the incidental risk of hypertension.

Results: During follow-up, 4,445 (16.8 %) cases of hypertension newly developed (Q 1-5: 19.0, 12.9, 12.4, 14.8, and 24.8% respectively). When quintile 3 was set as a reference in adjusted model, the hazard ratios (HRs) for incidental hypertension exhibited a J-shaped relationship with the BW changes (Q1: 1.66 [95% confidence interval (CI): 1.41–1.95], Q2: 0.96 [95% CI: 0.80–1.14], Q3: 1.00 [reference], Q4: 1.30 [95% CI: 1.10–1.54], and Q5: 3.39 [95% CI: 2.91–3.96], respectively).

Conclusions: The incidental risk of hypertension increased in weight loss as well as weight gain, which demonstrated J-shaped relationship. This finding warrants further studies to investigate the incidental relationship between BW changes and hypertension.

Table 1. Baseline characteristics of participants according to the BW changes per person-year in quintile groups

Characteristic	Overall	BW changes per person-year				
		Quintile 1	Quintile 2	Quintile 3	Quintile 4	Quintile 5
Number (n)	26,483	5,296	5,297	5,296	5,298	5,296

Family history of HTN (%)	31.3	31.0	30.6	30.1	32.5	32.3
Diabetes (%)	3.2	3.2	2.9	2.2	2.9	2.8
Development of HTN (%)	16.8	19.0	12.9	12.4	14.8	24.8

Data are shown as means ± (standard deviations), medians (interquartile ranges), or percentages. BW, body weight; BMI, body mass index; BP, blood pressure; SCr, serum creatinine; HTN, hypertension.

Table 2. Hazard ratios (HRs) and 95% confidence intervals (CI) for hypertension incidence according to the BW change per person-year in quintile groups

	Person-year	Range of body weight changes	Incidence cases	Incidence density	HR (95% CI)		
					Unadjusted	Model 1	Model 2
Body weight changes per person-year							
Quintile 1	16,898.2	<-1.9	1,069	59.6	1.59 (1.31–2.20)	1.46 (1.30–1.63)	1.49 (1.27–1.75)
Quintile 2	21,590.3	-1.9 – -0.2	661	31.5	1.08 (0.97–1.20)	0.95 (0.85–1.07)	0.90 (0.76–1.07)
Quintile 3	21,903.2	-0.2–1.0	657	30.0	1.00 (reference)	1.00 (reference)	1.00 (reference)
Quintile 4	21,218.3	1.0–2.7	766	36.9	1.30 (1.17–1.44)	1.30 (1.20–1.45)	1.30 (1.10–1.45)
Quintile 5	16,103.3	≥2.7	1,313	81.7	2.92 (2.66–3.20)	3.33 (2.83–3.50)	3.34 (2.79–3.76)
P for quadratic trend					<0.001	<0.001	<0.001

Model 1 was adjusted for age, baseline body weight, baseline blood pressure, total cholesterol, GGT, ALT, log(hsCRP), log(HOMA-IR), and eGFR.

Model 2 was adjusted for all factors in model 1 plus alcohol intake, family history of HTN, current smoking status, regular exercise, and diabetes.

FR-PO559

Global Variation in Blood Pressure Control and Anti-Hypertensive Therapy in CKD Patients with Hypertension

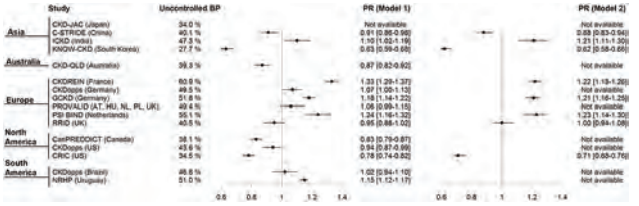
Natalia Alencar de Pinho,[3] Adeera Levin,[10] Masafumi Fukagawa,[12] Wendy E. Hoy,[11] Bruce M. Robinson,[1] Harold I. Feldman,[15] Luxia Zhang,[8] Kai-Uwe Eckardt,[14] Vivekanand Jha,[4] Kook-Hwan Oh,[9] Laura Sola,[2] Gert J. Mayer,[6] Martin H. De Borst,[13] Maarten W. Taal,[7] Benedicte Stengel.[5] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]CASMU-IAMPP, Montevideo, Uruguay; [3]CESP INSERM, VILLEJUIF, France; [4]George Institute for Global Health, New Delhi, India; [5]Inserm ? CESP, Villejuif, France; [6]Medical University Innsbruck, Innsbruck, Austria; [7]Derby, United Kingdom; [8]Peking University Institute of Nephrology, Beijing, China; [9]Seoul National University Hospital, Seoul, Republic of Korea; [10]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [11]The University of Queensland, Brisbane, QLD, Australia; [12]Tokai University School of Medicine, Isehara, Japan; [13]University Medical Center Groningen, Groningen, Netherlands; [14]University of Erlangen-Nuremberg, Erlangen, Germany; [15]University of Pennsylvania, Philadelphia, PA. Group/Team: ISN iNET-CKD .*

Background: Rates of blood pressure (BP) control in patients with CKD vary considerably worldwide. How differences in patient characteristics and antiHT treatment regimens relate to patterns of BP control is uncertain.

Methods: We used data from 14 studies participating in iNET-CKD, including 34,901 patients with eGFR <60 ml/min/1.73m2 and HT (defined as either BP ≥140/90 mmHg or antiHT drug use) to compare the prevalence of uncontrolled BP (≥140/90) across 16 countries using adjusted observed to expected prevalence ratios (PR).

Results: Rates of uncontrolled BP varied from 28% to 61% (Figure 1). After adjusting for age, gender, DM, and GFR, prevalence ratios remained higher in cohorts from continental Europe, India, and Uruguay. AntiHT use varied from 54% to 87% for RAAS inhibitors, 11% to 76% for diuretics, 26% to 75% for Ca channel blockers, and 22% to 68% for beta-blockers. In 8 out of 15 studies, >50% of patients with uncontrolled BP received <3 antiHT drugs. The number of prescribed antiHT classes was higher in cohorts from North America and Germany.

Conclusions: Global variation in BP control is only partly explained by patient characteristics. Heterogeneity of antiHT treatment practices may also play a role and would be potentially modifiable.



FR-PO560

Hypertension in High School Students: Genetic and Environmental Factors (HYGEF Study) Roberto Bigazzi,[1] Chiara Lanzani,[2] Laura Zagato,[2] Salvatore Lenti,[3] Simone Fontana,[2] Elisabetta Messaggio,[2] Nunzia Casamassima,[2] Valentina Batini,[1] Francesca Nistri,[1] Giada G. Santini,[1] Elena Brioni,[2] Simona Delli carpini,[2] Lorena Citterio,[2] Marco Simonini,[2] Stefano Tentori,[2] Filippo Cellai,[1] Cristiano Magnaghi,[2] Stefano Bianchi,[1] Vito M. Campese,[4] Paolo Manunta.[2] *[1]USL NO, Livorno, Italy; [2]Osp San Raffaele, Milan, Italy; [3]USL SE, Arezzo, Italy; [4]USC, Los Angeles, CA.*

Background: To evaluate the impact of gene pathways (Adducin (ADDs), Endogenous Ouabain (EO) genetic polymorphisms) in the transition from normotension to hypertension(HT) we performed an epidemiological study in 3 regions of northern(MI), central(Li), southern(Gr) Italy among young (age<18) high school students (St).

Methods: During a morning medical visit, we measured systolic (SBP) and diastolic (DBP) blood pressure, body weight, height, body mass index(BMI). A spot urine sample was collected to measure sodium (UNa), potassium (UK), creatinine, albumin. Finally, a saliva sample was obtained for DNA analyses. The 24 hour UNa was extimated according to Kawasaki's formula. Statistical analyzes were adjusted for age, sex, BMI and origin.

Results: Preliminary results on 2635 St (F1501, M1134, age 16,8±1,8 yrs) showed regional differences both for estimated UNa (Gt 196.4±2.5 mEq/24h; Mi 178.7±2.8; Li 171.5±2.1; p <0.001), and SBP (Li 121.1±0.4 vs Mi 118.9±0.4, Gt 118.4±0.4 mmHg). SBP was significantly correlated with BMI (r = 0.324, p <0.0001), and with UNa(r = 0.138 p <0.0001). Offspring with hypertensive parents (34%) showed higher SBP values than peers with negative familiarity (122±0.6 vs120±0.4 mmHg, p=0.04). In the analysis of the genotypes the Lanosterol Synthasi (LSS) polymorphism, the enzyme involved in the synthesis of EO, was associated with increased DBP (LSS AA 69.2±0.6; LSS AC 68.3±0.3; LSS CC 66.7±0.3 mmHg, p <0.0001). Carriers of both mutated variants of ADD1 and ADD2 (ADD1GT/ADD2 CT, n=167) showed greater (p = 0.015) UNa(192.9±4.3 mEq/24h) than St with genetic variants ADD1 GG/ADD2 CC (n = 826, 185.2±1.9 mEq/24h). The urine albumin/creatinine ratio was higher (12.3±2.3) in St with ADD3 GG / ADD2 CT(n=54) than in St with ADD3 AA / ADD2 CC (n=442, 8.1±0.8 mg/dl; p=0.05). The UNa/UK was greater in St carrying LSS AA/CYP1A1 CC (4 ± 0.4) vs. LSS GG/CYP1A1 AA (3.2±0.3; P=0.05).

Conclusions: These results confirm the role of the Adducin-EO genetic network in HT and identify interactions among environmental factors (Na and K intake) and genetic polymorphisms linked to HT.

FR-PO561

Genetic Factors Predicting BP Response to Thiazides Differ in Hypertensive African Americans with and without APOL1 Genotypes Patrick Cunningham,[1] Zhiying Wang,[3] Rhonda M. Cooper-DeHoff,[2] Arlene B. Chapman.[1] *[1]University of Chicago, Chicago, IL; [2]University of Florida, Gainesville, FL; [3]University of Houston, Houston, TX.*

Background: Essential hypertension (HBP) is common, and disproportionately affects African Americans (AAs) with higher rates of cardiovascular and renal disease. Recently, variants of the APOL1 gene have been associated with a higher rate of kidney disease, with studies suggesting a complex role in cardiovascular disease. We investigated whether genetic background in APOL1 affected individuals predicted sensitivity to thiazide diuretics in in AA with HBP.

Methods: We combined AA patients from three HBP trials (PEAR1: NCT002465519, n=298, PEAR2: NCT01203852, n=190, and GERA1, n=280) to assess whether APOL1 genotype predicted BP response to thiazide diuretics. Subjects with elevated serum creatinine or significant proteinuria were excluded from these studies. Patient genetic data (*n*=570) was analyzed by Affymetrix or Illumina Human Omni1-Quad Beadchip with correction for age, gender, baseline BP, and racial admixture. G1 and G2 variant alleles were detected by imputation using the g1000 data set (PEAR1, PEAR2), or by direct sequencing (GERA1). GWAS was performed on this data set to detect SNPs associated with differential response to thiazides.

Results: 14.9% of this combined HBP cohort (n=85) was positive for two APOL1 risk alleles. SBP or DBP at baseline and SBP or DBP response to thiazides, as measured by office or home cuff were similar between APOL1 negative and positive individuals. GWAS performed after adjusting for APOL1 genotype found that an intronic SNP rs111955547, located in *ROBO2*, was associated with a significantly decreased response to thiazides for office DBP (p=4.8 x 10^{-8}). Similarly, rs12943080, located in an intronic SNP in *SNF8*, was associated with a significantly decreased response to thiazides for night time SBP (p=5.0 x 10^{-7}).

Conclusions: Although HBP APOL1 AA individuals demonstrated similar BP responses to thiazides, genetic variants of *ROBO2*, which has a known role in podocyte development, as well as *SNF8*, which interacts with TRPC6, responsible for autosomal dominant FSGS, may identify individuals with poor response to thiazide diuretics.

APOL1 Hypertensive African Americans Show Greater BP Response and Urinary Albumin Reduction to Angiotensin Receptor Blockade with Different Genetic Predictors of Response versus Non-APOL1 Individuals Patrick Cunningham,[1] Zhiying Wang,[3] Rhonda M. Cooper-DeHoff,[2] Arlene B. Chapman.[1] *[1]University of Chicago, Chicago, IL; [2]University of Florida, Gainesville, FL; [3]University of Houston, Houston, TX.*

Background: Hypertension (HBP) is common and disproportionately affects African Americans (AAs). HBP AAs typically are salt sensitive and respond more to thiazide diuretics, with a relatively suppressed renin-angiotensin-aldosterone axis. Variants of the APOL1 gene specific to AAs are associated with a higher rate of kidney disease and a complex role in cardiovascular disease. We sought to characterize HBP *APOL1* AA individuals and their response to antihypertensive therapy.

Methods: HBP AA subjects from 4 trials (n=961) (PEAR1: NCT002465519 n=298, PEAR2: NCT01203852 n=190, GERA1 n=280, and GERA2 n=193: NCT 00005520) were evaluated at baseline after washout of BP meds. Genetic data was analyzed using Affymetrix or Illumina Human Omni1-Quad Beadchips. *APOL1* G1 and G2 variants were imputed using g1000 (PEAR1, PEAR2), or direct sequencing (GERA1, GERA2). Genome wide association analyses included age, gender, baseline BP, and racial admixture as covariates.

Results: 14.0% (n=135) were positive for two *APOL1* risk alleles. *APOL1* AAs had similar baseline office, home, ambulatory day and night SBP and DBP measures vs. others (n=827). *APOL1* AAs had significantly higher serum creatinine concentrations (0.93±0.24 vs 0.87±0.21 mg/dl, p=0.006) and lower eGFR (98.7±19.6 v. 104.4±18.7 ml/min, p=0.0008). AAs with an *APOL1* risk allele had a longer duration of HBP vs others (8.0±7.4 vs 6.7±7.5 yr, p=0.02). Subjects with an *APOL1* risk allele had a greater SBP response to candesartan (12.2±1.2 vs 7.5±1.8 mmHg, p=0.03; GERA2), a trend toward greater DBP response (8.9±0.9 vs 6.3±1.2 mmHg, p=0.08), and a greater decline in albuminuria (-8.3±3.1 vs -3.7±4.3 mg/day, p=0.03). An intronic SNP rs17825860, within *SDK1*, predicted greater office SBP response (p=6.9 x 10^{-7}) in *APOL1* AAs, and rs286856, an intronic SNP within *DPP6*, predicted greater office SBP response (p=3.2 x 10^{-7}) in *APOL1* negative individuals.

Conclusions: HBP APOL1 AAs demonstrate early differences in eGFR and serum creatinine with a greater SBP response to angiotensin receptor blockade (ARB) before clinical evidence of cardiac or renal disease. Genetic variants of the podocyte protein *SDK1*, and *DPP6*, which binds voltage gated potassium channels, may influence BP response to ARBs depending on *APOL1* status.

FR-PO563

Derivation and Validation of an Uplift Model to Personalize Blood Pressure Treatment Strategy Francis P. Wilson,[1] Aditya Biswas,[2] Chirag R. Parikh.[3] *[1]Yale School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT; [3]Yale University and VAMC, New Haven, CT.*

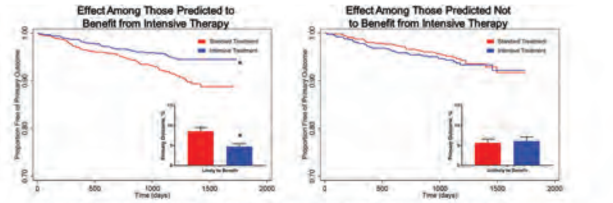
Background: The Systolic Blood Pressure Intervention Trial (SPRINT) demonstrated that, for non-diabetic patients with cardiovascular risk factors, a more intensive systolic blood pressure lowering strategy (<120 mm) was superior to a standard blood pressure lowering strategy to prevent cardiovascular outcomes. However, absolute risk reduction was low suggesting that the vast majority of patients exposed to lower systolic BP will not directly benefit. Uplift modeling is a novel strategy to predict the marginal benefit of an intervention at the level of an individual allowing for personalized targeting of interventions.

Methods: We divided the SPRINT cohort into a 70% training and 30% validation set. Using deep-phenotyping via auto-encoders and a random forest uplift model, we predicted the marginal benefit of the intensive blood pressure compared to standard strategy. We then dichotomized this metric into two groups - "likely to benefit" and "unlikely to benefit". We compared baseline factors in these two groups to examine factors strongly predictive of benefitting from intensive blood pressure control.

Results: In the test set, we identified 1,696 participants who would be likely to benefit from intensive blood pressure control and 1,112 who would be unlikely to benefit. The most common phenotypes of those likely to benefit included older white males with risk factors associated with the metabolic syndrome (such as higher serum glucose and microalbuminuria) but preserved eGFR. The hazard ratio (HR) of the intervention on the primary outcome in the "likely to benefit" group was 0.56 (95% CI 0.38 – 0.83, p=0.004) compared to 1.18 (0.71 – 1.98, p=0.53) among those unlikely to benefit (p-for-interaction 0.04).[Figure]

Conclusions: Use of an uplift-targeting approach in clinical practice would increase the efficacy of intensive blood pressure treatment, improve absolute risk reduction while simultaneously increasing the total number of cardiovascular events avoided at a population level.

Funding: NIDDK Support



Effect of intensive vs. standard treatment in the test set, stratified by predicted likelihood of benefit. Time-to Event analyses are presented with survival curves. Percent of patients experiencing the primary outcome appears in the inset bar charts. *p<0.005

	All Patient Strategy (n=2,808)	Uplift-Targeted Strategy (n=1,696)
HR (Intensive Vs. Control)	0.73 (0.54 - 0.99)	0.56 (0.38 - 0.83)
Absolute Risk Reduction (%)	0.64	1.68
Number Needed to Treat	156	60
Primary Outcome Events Avoided	18	28

Table: Treatment effects under a "treat all eligible patients" strategy vs. an uplift-targeted strategy in the test set. Uplift-targeting results in fewer individuals exposed to treatment while avoiding more primary outcome events. HR = Hazard Ratio

FR-PO564

Individualizing Hypertensive Treatment in Dialysis Population: Thinking beyond Intradialytic Blood Pressure Readings Rachana H. Jasani, Paras Dedhia, Viswanath Billa, SHRIRANG BICHU, Rajesh B. Kumar. *Apex Kidney Foundation, Mumbai, India.*

Background: Majority of hypertension treatment decisions are made based on dialysis unit BP readings. Out of dialysis unit blood pressure readings are shown to be associated with left ventricular hypertrophy and mortality.

Methods: Ambulatory BP monitoring (ABPM) performed for 44 hours in between 2 dialysis sessions. ABPM BP recorded every 20 min during the day (7am to 11pm) and every 30 min during the night (11pm to 7am) in non-fistula arm. Hourly means were averaged to obtain interdialytic systolic and diastolic blood pressure readings over 44 hours. Less than 70% readings were excluded from the study. Along with BP means, Percent Time Elevation (PTE-duration of day spent in high blood pressure state), dipping status at night, morning surge (the difference in systolic blood pressure during the first two hours after awakening and the lowest level recorded during night) and Pulse Pressure (PP) were assessed from ABPM data.

Results: Of 40 subjects, 68% were males. Average age was 54.5± 12.3 years. 45% had diabetes, 98% had hypertension and 20% had IHD. 80% subjects had >40% PTE. In terms of dipping status, 7.5% had normal dipping (10-20% drop in SBP at night), 67.5% were non-dippers (<10% drop in SBP at night) and 25% had reverse dipping status (nocturnal BP higher than diurnal BP). In our study, 10% had > 20% morning surge. We observed 27.5% had PP between 40 – 60 mm Hg, 45% had PP between 60 -80 mm Hg, 22.5% had PP between 80 – 100 mm Hg.

Conclusions: Blood pressure readings obtained from ABPM helps to individualize hypertension management in relation to timing and selection of anti-hypertensive agent. Also, it helps to provide a targeted approach in treating dialysis patients with diurnal variations in BP on dialysis and non-dialysis days.

FR-PO565

Cardiovascular Risk in Healthy Subjects Evaluated with Clinical-Genetic Test and Carotid Echography Francisco javier Lavilla, Pedro Errasti, Christian I. Alfaro Sanchez, Nuria Garcia-Fernandez, Pelayo M. Fdez-Felechosa, Jose maria Mora gutierrez. *Clinica Universidad de Navarra, Pamplona, Spain.*

Background: Evaluate cardiovascular risk (CVR) in healthy patients with clinical genetic test (Cardio inCode® test), and carotid echography.

Methods: cohort of 94 subjects (médium age 53 years 0.911, and male 73.5) We evaluate CVR with genetic test (Cardio inCode® that evaluated cardiovascular age -CVAGE- and global cardiovascular risk -GCVR-, using validated clinical and genetic score) and with carotid echography (intima.media thickness in left –IMTLC- and right -IMTRC- carotid). We evaluate levels of Glucose, Triglycerides, Total, HDL and LDL cholesterol, uric acid, creatinine (mg/dL) and creatinine clearance (ml/min) (MDRD-4 and CKD-EPI). We calculated the difference between cardiovascular (CVAGE) and biological age SPSS 20.0.

Results: Markers of CVR measure with Cardio inCode are associated with carotid and analytical parameters: **Carotid:** IMTLC is associated with AGE (r: 0.499, p: 0.001), CVAGE (r: 0.588, p= 0.001) and GCVR (r: 0.492, p: 0.001). IMTRC with AGE (r: 0.493, p: 0.001), CVAGE (r: 0.511, p= 0.001) and GCVR (r: 0.398, p: 0.001). **Renal function**:CKD-EPI is associated with AGE (r: -0.364, p: 0.001) and CVAGE (r: -0.361, p= 0.001) but MDRD not. **Metabolic parameters**: GLUCOSE is associated with CVAGE (r: 0.272, p= 0.008), GCVR (r: 0.224, p: 0.031), IMTLC (r: 0.254, p= 0.020), IMTRC (r: 0.214, p: 0.051) TG with CVAGE (r: 0.360, p= 0.001), GCVR (r: 0.453, p: 0.001), IMTLC (r: 0.400, p= 0.001), IMTRC (r: 0.241, p: 0.027) URIC ACID with CVAGE (r: 0.376, p= 0.001), GCVR (r: 0.353, p: 0.001) and IMTLC (r: 0.242, p= 0.001). **Differences between CVAGE and biological age** is associated with IMTLC (r:0.294, p: 0.007) and GCVR (r:0.363, p: 0.001). In 31.3% this difference is more than 10 years. No differences in biological age in this group.

Conclusions: Intima media thickness in left carotid is a good marker and better than in right carotid to evaluate CVR. CKD-EPI are better associated with CVR and Cardio inCode® than MDRD. Metabolic parameters (except cholesterol) are associated with Cardio inCode and intima media thickness. Difference between CVAGE and biological age are associated with cardiovascular risk. This difference depends on CVR, not biological age. In healthy subjects we can evaluated CVR with Cardio inCode® and carotid echography.

FR-PO566

Short-Term Blood Pressure Variability Predicts Cardiovascular Events and All-Cause Mortality Better Than Office and Ambulatory Blood Pressure in Hemodialysis Patients Pantelis Sarafidis,[1] Charalampos Loutradis,[1] Antonios Karpetas,[2] George Tzanis,[1] Georgios Koutroumpas,[3] Athanasios Bikos,[4] Vasilios Raptis,[4] Christos Syrganis,[3] Vassilios Liakopoulos,[5] Aikaterini A. Papagianni.[1] [1]*Department of Nephrology, Hippokration Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece;* [2]*Therapeutiki, Hemodialysis Unit, Thessaloniki, Greece;* [3]*Hemodialysis Unit, Achillopouleion General Hospital, Volos, Greece;* [4]*Hemodialysis Unit, Pieria, Katerini, Greece;* [5]*Section of Nephrology and Hypertension, 1st Department of Medicine, AHEPA Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece.*

Background: Hemodialysis patients are subjected to severe blood pressure (BP) fluctuations during intra- and interdialytic periods. Long-term predialytic BP variability (BPV) is associated with increased cardiovascular risk. This is the first study to examine the prognostic significance of short-term BPV using ambulatory blood pressure monitoring (ABPM) in hemodialysis.

Methods: 170 patients underwent 48h ABPM during dialysis and a standard interdialytic interval and were followed for 28±11 months. BPV parameters calculated were: standard deviation(SD), weighted SD(wSD), coefficient of variation(CV), average real variability(ARV). The primary end-point was: combination of all-cause death, non-fatal MI or stroke. Secondary end-points were: (i) all-cause death (ii) cardiovascular death (iii) combination of cardiovascular death, MI, stroke, resuscitation after cardiac arrest, coronary revascularization or hospitalization for HF.

Results: In total, 37(21.8%) patients died and 46(27.1%) had cardiovascular events. Freedom from primary end-point was similar for quartiles of predialysis SBP, 48h SBP, and SBP-SD, but was progressively shorter for SBP-wSD (p=0.03), SBP-CV (p=0.047), and SBP-ARV (81.4%, 81.0%, 73.8%, 51.2% p=0.001; Figure 1). Hazard Ratios for all outcomes were similar for quartiles of pre-dialysis SBP and 48h SBP but were progressively increasing with higher quartiles of 48h SBP-ARV (for primary outcome: Q1:reference; Q2:1.11, 95%CI:0.42-2.95; Q3:1.64, 95%CI:0.66-4.09; Q4:3.45, 95%CI:1.53-7.81).

Conclusions: Short-term BPV is associated with future cardiovascular events and mortality in hemodialysis patients, but office and ambulatory BP are not. These results add to evidence suggesting that BPV is independent cardiovascular risk factor in hemodialysis.

FR-PO567

Renal Functional Reserve Is Related to Exercise Heart Rate in Essential Hypertensive Patients: A Novel Link between the Kidneys and the Heart Aikaterini Damianaki,[2] Kyriakos Dimitriadis,[1] Aglaia Chalkia,[2] Konstantinos Tsioufis,[1] Dimitrios Petras.[2] [1]*First Cardiology Clinic, University of Athens, Hippokration Hospital, Athens, Greece;* [2]*Nephrology Department, Hippokration Hospital, ATHENS, Greece.*

Background: Renal functional reserve (RFR) refers to the capacity of the kidney to augment its level of function under the influence of certain stimuli and it constitutes a valuable diagnostic tool for recognizing high risk patients for acute kidney injury (AKI) and chronic kidney disease (CKD). The aim of our study was to assess the relation of RFR with diverse clinical parameters in patients with essential hypertension and GFR>60ml/min/1.73m^2.

Methods: 15 hypertensive subjects (mean age=57 years, BMI= 28.5 kg/m², office systolic/diastolic BP =148/90 mmHg) were included. All subjects underwent the exercise treadmill stress test, 24hour ABPM and cardiac ultrasound. Subjects who were on antihypertensive medication, stopped the agents for two weeks. All subjects were fasted for 8 hours and then baseline hydration status was recorded using bioimpedance analysis. Basal GFR was measured after hydration and stress GFR was achieved after ingestion of oral protein 1g/kg as cooked meal. Basal and Stress GFR were determined by Creatinine Clearance = Urine Creatinine/Serum CreatininexUrine Volume/time× 1.73/BSA). RFR was calculated as Stress GFR – Basal GFR.

Results: Patients with greater than 10years of HTN, had lower RFR values ($p<0.1$) (-14.59 ±43.26 ml/min/1.73m² vs 21.35±28.19 ml/min/1.73m²). There was no correlation of RFR values with respect to family history, smoking, BMI, age, dipping and office BP. In contrast, a statistically significant positive correlation was found between RFR and maximum heart rate (HR) during treadmill test ($r=0.880$, $p=0.009$). Hypertensives with high RFR were characterized by higher maximum HR during treadmill test.

Conclusions: RFR is related to treadmill exercise heart rate in essential hypertension, suggesting a link between the dynamic regulation of renal function and sympathetic overdrive influence on the heart. These findings suggest that treadmill test could be used to identify hypertensive patients with unfavorable RFR. Additionally, patients with greater than 10 years of HTN and/or on antihypertensive agents tend to have lower RFR values, indicating a possible susceptibility to renal injury.

FR-PO568

Thirty Day Readmissions in Patients Admitted for Hypertensive Emergency Aparna Saha, Lili Chan, Priti Poojary, Kinsuk Chauhan, Steven G. Coca, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Hypertensive (HTN) emergency accounted for 111/100,000 hospital readmissions in 2007 with increasing incidence. Few studies have examined 30-day readmission rates, reasons and outcomes in this growing population

Methods: Utilizing the Nationwide Readmission Database from year 2013, admissions for HTN emergency were queried by combining ICD-9 codes for malignant HTN and acute target organ damage. We excluded patients on dialysis, those<18 years old and admission occurring in December due to lack of 30 day follow up for readmissions. Index admissions were any admission without a preceding 30 day admission, while readmissions were any admission that followed a prior admission by less than 30 days

Results: In 2013, 30,936 index admissions were identified.15.4% of all index admissions had at least one 30-day readmission. When stratified by chronic kidney disease stage 3 or higher(CKD3) status, patients with CKD3 had higher readmission rate, 17% vs 14%, P<0.001. Of all index admissions, 44.8% were complicated by acute kidney injury(AKI) and AKI had higher rates of readmissions, 17% vs 14%, P<0.001. The top 10 causes for readmission are in Figure 1. While only 14% of readmissions were for repeat HTN emergency, 50% of all readmissions were likely related to complications from HTN emergency(congestive heart failure, HTN with complications, AKI, acute cerebrovascular disease and acute myocardial infarction). In-hospital mortality during index admission was 3%, while on readmission it was 4%

Conclusions: Over 1 out of 10 index admission for HTN emergency is followed by 30-day readmission. A high percentage of readmissions were for repeat HTN emergency. Both AKI and CKD are associated with higher readmission rates. Efforts should be directed towards identifying effective measures to improve blood pressure control and better follow-up post hospitalization, particularly in those with kidney disease

Urinary Plasmin(ogen), Blood Pressure, and Progression of Diabetic Kidney Disease Evan C. Ray,[3] Rachel G. Miller,[4] John E. Demko,[5] Tina Costacou,[1] Carol L. Kinlough,[3] Casey Allen,[3] Mark L. Unruh,[2] Trevor J. Orchard,[1] Thomas R. Kleyman.[3,6] *[1]School of Public Health, University of Pittsburgh, Pittsburgh, PA; [2]Internal Medicine, University of New Mexico, Los Ranchos, NM; [3]Renal-Electrolyte Division, University of Pittsburgh, Pittsburgh, PA; [4]School of Public Health, University of Pittsburgh, Pittsburgh, PA; [5]Internal Medicine, University of California San Francisco, San Francisco, CA; [6]Cell Biology, University of Pittsburgh, Pittsburgh, PA.*

Background: Urinary plasmin and its precursor, plasminogen, are detectable in the urine of patients with diabetic or other proteinuric kidney diseases. Urinary plasmin(ogen) levels correlate with increased extracellular fluid volume and blood pressure and have been hypothesized to contribute to renal Na retention by activating the epithelial Na channel (ENaC) and to progression of chronic kidney disease through podocyte and tubular toxicity. We assessed whether urinary plasmin(ogen) levels predict subsequent increases in blood pressure or decline in kidney function in type 1 diabetes.

Methods: Individuals with childhood-onset type 1 diabetes were enrolled as part of the Pittsburgh Epidemiology of Diabetes Complications Study in 1986-1988 and followed prospectively for 25 years. The present nested-cohort study included 70 subjects chosen to represent a spectrum of baseline urinary protein levels. Clinical outcomes included 1) increased blood pressure over a two-year period, defined as any increase in systolic or diastolic blood pressure or addition of a new anti-hypertensive agent; 2) incident hypertension over the full 25 year study period, defined as new-onset blood pressure of 140/90 mmHg or hypertensive medication use; and 3) 50% decline in eGFR over the 25-year study period, calculated from baseline using the CKD-EPI formula. The predictive values of urinary plasmin(ogen) and albumin were compared.

Results: In those who experienced increased blood pressure, baseline plasmin(ogen) levels where higher, with a difference approaching significance ($p = 0.08$). Albumin did not differ ($p = 0.43$). Plasmin(ogen) predicted both incident hypertension (HR=2.05, $p=0.001$) and 50% decline in eGFR (HR=2.26, $p<0.001$), however adjusting for urinary albumin attenuated plasmin(ogen)'s 25-year predictive abilities ($p= 0.95$ and 0.45, respectively).

Conclusions: Over 2 years of follow-up, baseline urinary plasmin(ogen) was associated with an increase in blood pressure approaching significance, suggestive of a role in stimulating urinary Na retention. Over 25-years of follow-up, plasmin(ogen) predicted incident hypertension and 50% decline in eGFR, though not independently of albumin, suggesting that over the long-term, mechanisms non-specific to plasmin(ogen) contribute to hypertension and diabetic kidney disease progression.

Inflammation and Apparent Treatment Resistant Hypertension in Patients with CKD – The Results from the CRIC Study Jing Chen,[7] Joshua D. Bundy,[10] L. Lee Hamm,[9] Chi-yuan Hsu,[11] James P. Lash,[12] Edgar R. Miller,[5] George Thomas,[3] Debbie L. Cohen,[15] Dominic S. Raj,[4] Hsiang-Yu Chen,[6] Dawei Xie,[16] Panduranga S. Rao,[14] Matthew R. Weir,[13] Jackson T. Wright,[1] Mahboob Rahman,[2] Jiang He.[8] *[1]Case Western Research University, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH; [3]Cleveland Clinic, CLEVELAND, OH; [4]GWU Medical Faculty Associates, Washington, DC; [5]Johns Hopkins University, Baltimore, MD; [6]The Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [7]Tulane School of Medicine, New Orleans, LA; [8]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [9]Tulane University School of Medicine, New Orleans, LA; [10]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [11]University of California San Francisco, San Francisco, CA; [12]University of Illinois at Chicago, Chicago, IL; [13]University of Maryland School of Medicine, Baltimore, MD; [14]University of Michigan Health System, Ann Arbor, MI; [15]University of Pennsylvania School of Medicine, Philadelphia, PA; [16]University of Pennsylvania School of Medicine Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA.*

Background: Apparent treatment resistant hypertension (ATRH) is highly prevalent and associated with increased risk of cardiovascular disease (CVD) in patients with chronic kidney disease (CKD). Inflammation may be associated with blood pressure and is increased in CKD patients. It is unknown if inflammation is associated with increased likelihood of ATRH in CKD.

Methods: ATRH is defined as systolic blood pressure (SBP) ≥140 mmHg or diastolic BP (DBP) ≥90 mmHg while taking ≥ 3 antihypertensive medications or taking ≥ 4 antihypertensive medications with SBP <140 mmHg and DBP <90 mmHg. 1359 Chronic Renal Insufficiency Cohort (CRIC) Study participants with ATRH and 2008 participants without ATRH, but with hypertension at the baseline visit, were included in this analysis. Multiple logistic regression models were adjusted for age, sex, race, clinical sites, diabetes, alcohol consumption, body mass index, physical activity, estimated glomerular filtration rate, 24-hour urinary protein, and 24-hour urinary sodium.

Results: Multiple-adjusted odds ratios (95% confidence intervals) of ATRH for the highest tertile comparing to the lowest tertile of the inflammatory biomarker levels were 1.31 (1.06-1.62, $p=0.026$) for tumor necrosis factor-α (TNF-α) and 0.75 (0.61-0.92, $p= 0.008$) for transforming growth factor beta (TGF-β). In addition, multiple-adjusted odds

ratios (95% confidence intervals) associated with one standard deviation difference in log-transformed TGF-β was 0.90 (0.83-0.98, p= 0.013). The levels of interleukin-6, interleukin-1 beta, and C-reactive protein were not significantly associated with odds of ATRH.

Conclusions: Higher levels of TNF-α and lower levels of TGF-β (as anti-inflammatory biomarker) were independently associated with odds of ATRH. Further study is warranted to investigate if targeting specific inflammatory pathways may improve blood pressure control among patients with CKD.

Diabetes Mellitus versus Vascular Calcification: Impact on Predialytic Blood Pressure and Incidence of Intradialytic Hypotension

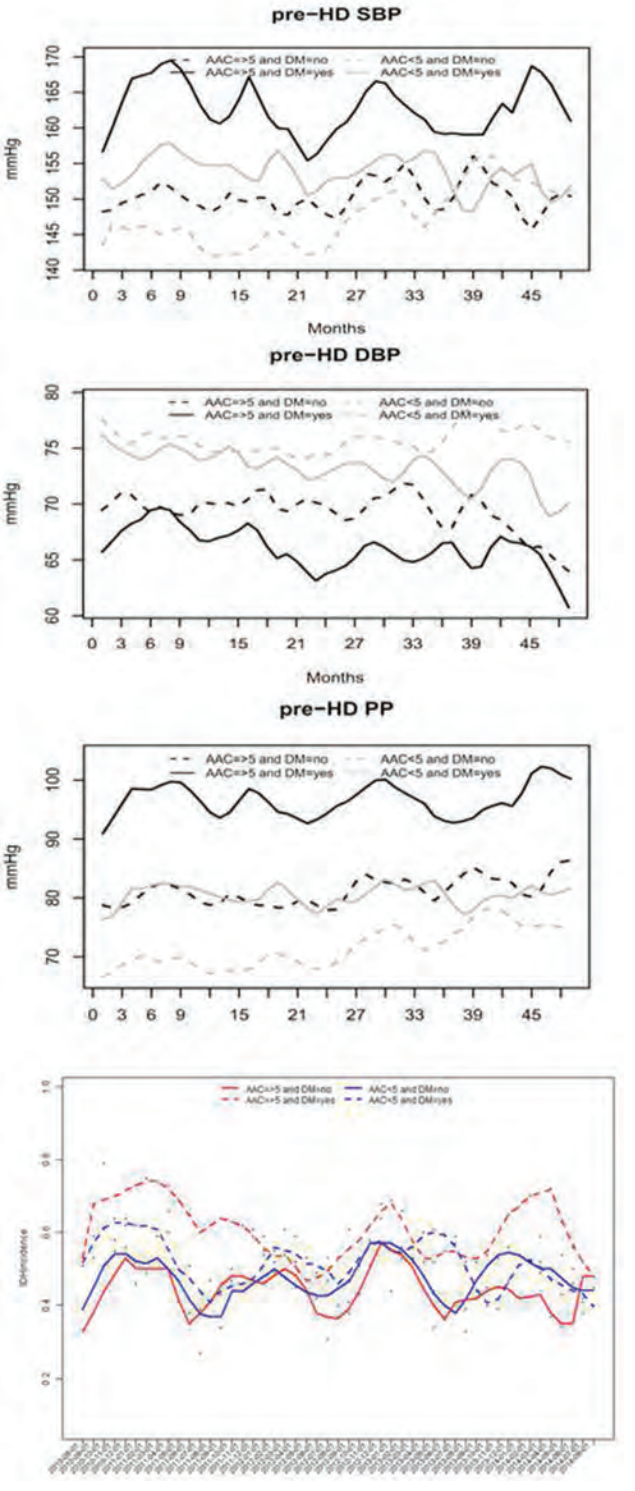
Sinae Lee,[1] Seoung Woo Lee.[2] *[1]none, Anyang-si, Republic of Korea; [2]Nephrology and Hypertension, Inha University Hospital, Incheon, Republic of Korea.*

Background: Diabetes mellitus (DM) and vascular calcification are highly prevalent in maintenance hemodialysis (HD) patients, but it has not known how they influence on pre-HD blood pressure (BP) and the incidence of intradialytic hypotension.

Methods: This study was performed from August 2010 to July 2014 in 66 patients who met the following criteria: HD duration for >6 months and HD 3 times weekly during the study. Four years of pre- and intradialytic BPs and laboratory data were collected. Abdominal aortic calcification (AAC) was assessed using the Kauppila score. Patients were classified as high (≥5) or low (<5) AAC. The KDOQI guideline was used to define IDH. IDH incidence was the number of sessions in which IDH occurred divided by the total number of monthly HD sessions. Subjects were classified into group 1 (high AAC, DM) (n=16), group 2 (high AAC, non-DM) (n=15), group 3 (low AAC, DM)(n=14), and group 4 (low AAC, non-DM) (n=21). Time series analysis (TSA) was performed to assess changes in pre-HD BP and the IDH incidence.

Results: Mean age was 61±11 years; 30 had DM; 50% were male; HD duration was 6.1±3.8 years; AAC score was 5.5±4.5; and HD sessions were 481±81. In TSA, pre-HD SBP, DBP, PP, and the IDH incidence were elevated by group in the order of 1>3>2>4, 4>2>3>1, 1>2=3>4, and 1>3>2=4, respectively (Fig. 1). Multiple regression showed that non-DM and low AAC was independently associated with pre-dialytic SBP (non-DM; β=-0.58, p<0.001; low AAC; β=-0.49, p=0.015), DBP (non-DM; β=0.34, p<0.001; low AAC; β=0.75, p<0.001), PP (non-DM; β=-0.57, p<0.001; low AAC; β= -0.69, p<0.001) and IDH incidence (non-DM; β=-0.31, p < 0.001; low AAC; β=-0.2, p=0.469).

Conclusions: Both DM and vascular calcification may influence pre-HD BPs and the IDH incidence; however, the effect of DM is more prominent.



FR-PO572

The Change of Glucose Metabolism in Primary Aldosteronism after Target Treatment

Yu-Fang Lin, Vincent Wu, Kwan-dun Wu. *Internal Medicine and College of Medicine, National Taiwan University Hospital, Taipei city, Taiwan.*

Background: Discrepant data have been published on the effects of aldosterone excess on abnormal glucose metabolism. There is no consistent result of follow-up glucose metabolism after adrenalectomy or spironolactone in patients with primary aldosteronism (PA).

Methods: Patients were enrolled during the screening test after adequate substitutive drug periods. Aldosterone, ARR(aldosterone renin ratio), glucose metabolism parameters

including HOMA-IR and HOMA-β were checked and calculated before and 1 year after on-target treatment.

Results: One hundred and thirty-eight PA patients were enrolled (mean age 50.6±11.5, 49% female), among them 72 patients with aldosterone producing adenoma (APA) received adrenalectomy (Group 1), 33 idiopathic hyperaldosteronism (IHA) treated with spironolactone (Group 2) and 33 APA treated with spironolactone (Group 3). There was no change of fasting glucose before and after treatment (P=0.056, 0.497, 0.575). Fasting insulin increased in group 1 and group 2 (P=0.019, 0007). Aldosterone decreased after adrenalectomy but increased after IHA treated with spironolactone. HOMA-β improved in patients in the former two groups (P=0.000, 0.015). HOMA-IR deteriorated significantly in group 2 (P=0.019) but not in group 1(P=0.109). The fasting glucose, fasting insulin, HOMA-IR and HOMA-β remained unchanged in group 3. At enrollment, APA had higher HOMA-IR (P=0.000) and fasting plasma glucose(P=0.019) than IHA. There was a negative correlation between aldosterone and HOMA-β or HOMA-IR after adjustment with serum potassium level, SBP, BMI, age, and sex.

Conclusions: At enrollment, APA had higher HOMA-IR and fasting plasma glucose than IHA. HOMA-β could improve in APA treated with adrenalectomy and IHA received spironolactone. HOMA-IR deteriorated in IHA patients but remained unchanged in other two groups. Thus, adrenalectomy of APA could improve glucose homeostasis other than spironolactone in APA.

Hyperuricemia Is Associated with Worse Renal Outcomes in Patients Undergoing Percutaneous Transluminal Renal Angioplasty (PTRA) Xiaojun Chen,[1,3] Alfonso Eirin,[1] Ahmed Saad,[1] Amir Lerman,[2] Stephen C. Textor,[1] Lilach O. Lerman.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Department of Cardiovascular Diseases, Mayo Clinic, Rochester, MN; [3]Department of Nephrology, The Second Xiangya Hospital of Central South University, Changsha, China.*

Background: Hyperuricemia is associated with elevated risk for hypertension and chronic renal disease. PTRA improves blood pressure (BP) and renal function only in selected patients with atherosclerotic renovascular disease (ARVD), likely due to post-stenotic kidney injury. We hypothesized that hyperuricemia contributes to poor BP and renal functional outcomes in ARVD after PTRA.

Methods: Outcomes were compared among ARVD patients stratified by elevated serum uric acid (SUA) levels (>6.0mg/dl in women; >7.0mg/dl in men) undergoing PTRA. Multivariate analysis was used to determine significant predictors for renal and BP outcomes after PTRA.

Results: In 94 patients with ARVD studied retrospectively, pre-PTRA eGFR was lower in hyperuricemic compared with normouricemic patients, and remained lower after PTRA (Table), after adjustment for body-mass index, number of antihypertensive drugs, baseline eGFR, diuretic use, and left ventricular (LV) mass (p<0.05). PTRA did not affect eGFR in either group, while diastolic BP decreased in both. In univariate analysis, lower SUA was associated with improved BP after PTRA (Hazard ratio 0.84, p<0.05), but multivariate analysis revealed that only age, coexisting cerebrovascular disease, and number of antihypertensive drugs remained independent predictors. Contrarily, in multivariate linear analysis SUA independently predicted post-PTRA proteinuria (odds ratio 68.5, p<0.05, Figure A) after adjustment for pre-PTRA proteinuria, LV ejection fraction, and eGFR, and for cerebrovascular, peripheral, and cardiovascular disease. In 11 additional ARVD patients studied prospectively under controlled sodium intake and antihypertensive regimens, PTRA improved renal function (Figure B) only in patients with normal SUA (n=6, p<0.05).

Conclusions: Hyperuricemia does not aggravate BP outcomes in ARVD patients, but may be associated with greater renal dysfunction and proteinuria after PTRA. Thus, SUA in patients with ARVD might be a predictor of worse outcomes after PTRA.

Funding: Other NIH Support - DK100081

Pre-PTRA eGFR is lower in hyperuricemic (n=44) compared with normouricemic (n=50) patients, and remains lower after PTRA

FR-PO574

The Benefit of Combined Calcium Channel Blockers with Angiotensin Converting Enzyme Inhibitors or Angiotensin II Receptor Blockers on Renal Outcomes in Hypertensive Patients: A Meta-Analysis Paweena Susantitaphong,[1] Punnaka Pongpanich,[2] Pasvich Pitakpaiboonkul,[3] Kearkiat Praditpornsilpa,[1] Somchai Eiam-Ong.[1] *[1]Chulalongkorn University, Bangkok, Thailand; [2]Chulalongkorn university, Bangkok, Thailand; [3]Chulalongkron university, Bangkok, Thailand.*

Background: The prevalence of hypertension and its associated complications are likely to grow as the population ages. In addition, control of the disease is far from adequate, only fifty percent of persons with hypertension have their blood pressure under control, which was defined as a level below 140/90 mmHg. Most people need more than one drug to achieve blood pressure target. However, several guidelines only focus on the first line treatment. We conducted a meta-analysis to explore the benefits of combined calcium channel blockers (CCBs) with angiotensin converting enzyme inhibitors (ACEIs) or angiotensin II receptor blockers (ARBs) on renal outcomes in hypertensive patients.

Methods: A systematic literature search was conducted in MEDLINE, Scopus, Cochrane Central Register of Controlled Trials, and Clinical Trials.gov (until April 7, 2016) to identify randomized controlled trials comparing the benefits of combined CCBs with ACEIs or ARBs vs. other combinations on renal outcomes in hypertensive patients. Random-effect models were used to compute the weighted mean difference (WMD) for continuous variables.

Results: Sixty randomized controlled trials (48,913 patients) were identified. Although, the combined CCBs with ACEIs or ARBs did not have statistically significant difference on the WMD of systolic blood pressure and diastolic blood pressure (73 study arms) when compared with other combinations (0.25 mmHg; 95%CI -0.33, 0.84 mmHg, P=0.40 and 0.05 mmHg, 95%CI -0.36, 0.47 mmHg, P=0.80, respectively), the benefits on renal outcomes including the decreasing of serum creatinine (22 study arms, 1,791 patients, -4.08 mmol/L, 95%CI -5.71, -2.45 mmol/L, P< 0.001) and improving of estimated glomerular filtration rate (15 study arms, 1,853 patients, 4.13 mL/min/1.73m^2,95% CI 2.26, 6.00 mL/min/1.73m^2, P< 0.001) were observed when compared with other combinations. The significant increase of serum potassium was also observed. (25 study arms, 2,505 patients, 0.13 mEq/L;95% CI 0.07, 0.19 mEq/L, P<0.001)

Conclusions: The combination of CCBs with ACEIs or ARBs have a benefit on renal function in hypertensive patients. Therefore, this combination should be considered whenever monotherapy does not achieve guideline target.

FR-PO575

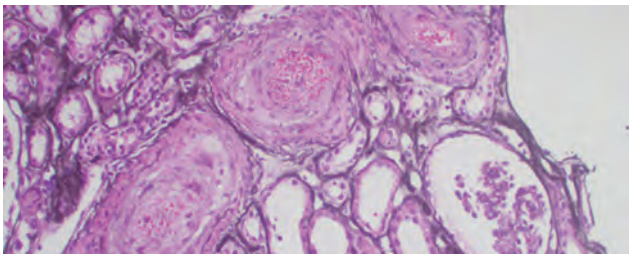
Scleroderma Renal Crisis Mimicking Rapidly Progressive Glomerulonephritis Ahmed Al-Sheyyab, Diego A. Beltran Melgarejo, Rachel B. Fissell, Jamie P. Dwyer. *Vanderbilt University Medical Center, Franklin, TN.*

Background: Thrombotic microangiopathies are a group of disorders which overlap in their clinical features. We describe a case with ambivalent presentation, as it highlights some of the differentiating clinical features and the impact of treatment choices on the patient's outcome.

Methods: A 78 year-old man presented with edema of the lower extremities and hands. Clinic evaluation revealed serum creatinine 2.2 mg/dL(baseline 0.7mg/dL), new hypertension(BP 200/103), anemia (hemoglobin 9.1mg/dL) and thrombocytopenia (platelets 69 x10^3/mcL). Additional testing showed microscopic hematuria with proteinuria (protein:creatinine ratio 0.65), LDH 512U/L, haptoglobin <8 mg/dL, ADAMTS13 of moderate activity, and peripheral smear negative for schistocytes. A complete serologic work up was unrevealing except for a positive Antinuclear Antibody (1:2560). Despite pulse steroids therapy, renal failure worsened and ultimately required hemodialysis. Examination of the hands showed skin thickening. Captopril was started. Anti-RNA polymerase III antibodies were positive. Kidney biopsy was consistent with the clinical diagnosis of scleroderma renal crisis(SRC).

Results:

Conclusions: SRC can present similarly to Rapidly Progressive Glomerulonephritis(RPGN). The renal biopsy is able to differentiate between RPGN and SRC. However, thrombocytopenia can delay the performance of kidney biopsy. Clinical suspicion followed by careful hand examination and obtaining extractable nuclear antigen antibodies were key steps in revealing the diagnosis. Early diagnosis of scleroderma is critical to initiate timely therapy. Previous studies showed dramatic improvement of mortality with angiotensin-converting-enzyme inhibitors. In SRC, careful clinical examination for signs of scleroderma and appropriate serologic testing can guide early therapy. The astute clinician requires a high index of suspicion to make the diagnosis of SRC.



FR-PO576

Clinical and Histopathologic Features of Atherosclerotic Renal Artery Stenosis (ARAS): An Autopsy Study Madhuri Chengappa,[3] Ahmed Saad,[1] Sandra Herrmann,[1] Joseph P. Grande.[2] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Foundation for Medical Research, Rochester, MN; [3]Mayo clinic, Rochester, MN.*

Background: ARAS is frequently seen in ageing population and contributes to morbidity in this group. Although a number of cohort studies have compared medical versus surgical therapies for ARAS, there are no previous autopsy-based studies correlating histopathologic and clinical features in patients with ARAS.

Methods: We queried Mayo Clinic database for autopsy cases with known diagnosis of ARAS between 1994 and 2013. We obtained 19 cases for which renal and cardiac histopathology slides were available. 6 patients had unilateral(UL) ARAS (4 medically managed, 2 stented) and 13 patients had bilateral(BL) ARAS (10 medically managed, 2 stented and 1 endarterectomy). All patients were treated for hypertension. Average systolic blood pressure (SBP) was 142mmHg. There was no significant difference SBP in BL or UL ARAS patients.

Results: Histopathology findings: Smaller kidney size correlated with increased SBP (p=0.02). There was a strong correlation with stenotic kidney(STK) size and corresponding STK weight(p=0.03). Glomerular filtration rate correlated with contralateral kidney(CLK) weight(p=0.01). STK/CLK weight ratio was significantly different between patients with UL(0.4) versus BL ARAS (0.7, p=0.002). Glomerular size strongly correlated with atrophy and kidney weight(p=0.0006). Intrarenal vascular disease correlated with glomerulosclerosis(GS) in both STK and CLK (p=0.004 and p=0.02 respectively). All patients with UL ARAS had medullary necrosis, only 1 patient with BL ARAS had medullary necrosis. Although 1 patient had atheroembolic disease documented, we identified 5 cases of intrarenal atheroemboli. Atheroemboli were not associated with presence of abdominal aortic aneurysms, but all 19 patients had severe aortic atherosclerosis. **Outcome:** Intrarenal vascular disease correlated with cardiovascular outcome making cardiovascular the most common cause of death in these patients. 57% of patients died either due to cardiovascular cause or stroke. All 19 patients had history of severe ischemic heart disease. 10.5% of patients developed end stage renal disease(ESRD) and died due to complications of ESRD.

Conclusions: Intrarenal vascular disease is a marker of severe atrophy and GS. Small glomerular size in STK was a robust marker of compensatory hypertrophy of CLK. Atheroembolic renal disease is an under-recognized complication of ARAS in this population.

FR-PO577

Percutaneous Intervention for Renal Artery Stenosis through the Years 2008 to 2014 Madhuri Ramakrishnan,[1] Siva sagar Taduru,[1] Reem Mustafa.[2] *[1]University of Missouri Kansas City, Kansas CIty, MO; [2]Nephrology, Kansas University Medical Center, Kansas City, KS.*

Background: Medical therapy remains the cornerstone of management of renal artery stenosis (RAS) with secondary hypertension. The indications of intervention by renal artery angioplasty with (PTRAS) or without (PTRA) stenting however, remains debated. Several trials in recent years have shown no difference in blood pressure control between medical management and percutaneous intervention. We aim to study the trends of utilization, outcomes, and complication rates of percutaneous intervention for RAS between 2008 to 2014.

Methods: We searched the National Inpatient Sample from 2008 – 2014 using International Classification of Diseases Clinical Modification (ICD-9-CM) codes to identify patients admitted with primary diagnosis of renal atherosclerosis, fibromuscular dysplasia (FMD), or reno-vascular hypertension. We excluded patients with vascular trauma, carotid stenosis, and mesenteric ischemia, to exclude patients who may have undergone endovascular procedures identified for these indications. We then identified patients who underwent PTRA and PTRAS. We identified complications of post-operative hematoma or bleeding, acute kidney injury (AKI), and atheroembolism. We described categorical variables as proportions and continuous variables as means. We analyzed the trend of utilization of the procedure using the Mantel-Haenzsel trend test.

Results: We identified 30,617 patients admitted with primary diagnosis of RAS. The mean age was 68.63 ± 15.5 years, 62.5% of patients were females, 79.5% were Caucasians, and the mean comorbidity score was 6.37 ± 7.33. Of these, 22,716 (74.2%) patients underwent percutaneous intervention. The mean age of these patients was 70.42 ± 12.6 years, 61.4% were females, 81.7% were Caucasians and the mean comorbidity score was 6.0 ± 7.1. We identified a trend towards lower rates of use of percutaneous interventions through our study period (84.1% in 2008 vs 50.7% in 2014, $P_{trend} < 0.0001$). Mortality rates were 0.2%, and the mean length of stay was 2.7 ± 3.3 days. Post-operative bleeding or hematoma was identified in 4%, AKI in 11.4% and atheroembolism in 0.3% of cases.

Conclusions: We found a significant downward trend of inpatient PTRA and PTRAS for RAS between 2008 and 2014. This is consistent with the lack of evidence to support the use of interventions. Patients who received intervention tended to be older, with lower comorbidity scores.

FR-PO578

Impedance Cardiography Informs Hypertensive Management Yossi Chait,[3] Barbara A. Greco,[2] Michael J. Germain.[1] *[1]Renal and Transplant Assoc of New England, Hampden, MA; [2]Renal and Transplant Associates of New England, Springfield, MA; [3]University of Massachusetts, Amherst, MA.*

Background: High blood pressure (BP) is a leading cause of death and disability in the US and worldwide. Approximately 1 of 3 U.S. adults (75 million) have high blood pressure, and only about half treated with antihypertensive protocol have their high blood pressure in recommended blood pressure target. Titration of medications involves a trial and error process, especially in resistant hypertension, and is typically guided by office blood pressure, an imprecise, indirect piece of overall hemodynamic status. It has been reported that cardiac power index (CPI) is the best hemodynamic correlate of mortality. Our aim was to follow standard hypertensive management using hemodynamic parameters as hypothesis generating. We measured hemodynamics (NICaS, NI Medical Israel) using a non-invasive, whole-body impedance cardiography technology. NICas reports stroke volume and pulse rate and therefore cardiac index (CI), and together with the measurement of BP it calculates total peripheral resistance index (TPRI).

Methods: We repeated NICaS measurements in 40 hypertensive patients with CKD, kidney transplant, and resistance hypertension over a follow up period up to 6 months (Treatment), andtitration was done after the first measurement (Baseline).

Results: We report results in 2 representative cases. BP was significantly reduced in both patients following medication changes. Hemodynamic changes from Baseline (Table, Figure) reveal that the reduction in TPRI in Patient A was associated with normalization of CI and CPI improving into their normal range after treatment. In Patient B an increase in TPRI was associated with decrease in CI and CPI out of normal range after treatment.

Conclusions: If BP alone was the single most important parameter, then the treatment could be considered a success. However, BP changes do not correlate well with direction of changes in other hemodynamic parameters, and can mask worsening CI and CPI. These results suggest that hemodynamics parameters should be guided using measurements of hemodynamics parameters beyond BP alone. Our hypothesis, to be tested in a large study in the near future, is that using impedance cardiography to guide hypertensive management will result in better BP control and patient experience (symptoms and compliance).

	SDP/DBP (mmHg)		Cardiac Index (L/min/m^2)		Total Peripheral Resistance Index (Dyn*sec/cm^5/m^2)		Cardiac Power Index (W/m^2)

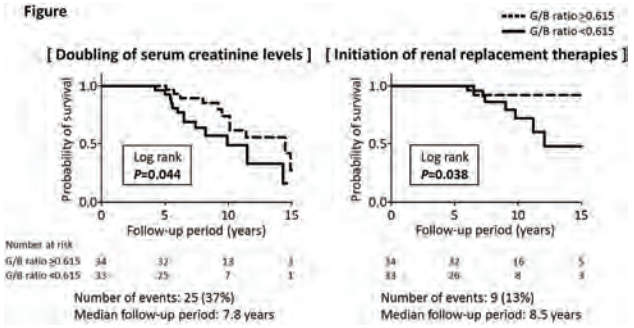
The Quantitative Evaluation of Glomerular Collapse Predicts the Long-Term Renal Outcome in Patients with Benign Nephrosclerosis Kotaro Haruhara, Nobuo Tsuboi, Hoichi Amano, Kentaro Koike, Go Kanzaki, Yusuke Okabayashi, Takaya Sasaki, Makoto Ogura, Takashi Yokoo. *Division of nephrology and hypertension, The Jikei university school of medicine, Tokyo, Japan.*

Background: Although the concomitant appearance of glomerular collapse and enlargement is a typical renal histological feature in benign nephrosclerosis (BNS), the definition of glomerular collapse has not been established. The aim of this study was to quantify the severity of glomerular collapse and to examine the predictive significance of this parameter regarding the renal outcome in patients with biopsy-proven BNS.

Methods: The clinical data and renal biopsy specimens from BNS patients with an eGFR of ≥30 mL/min/1.73m^2 were retrospectively reviewed. Based on the measurements of all cross-sectional areas of Bowman's capsules and glomerular capillaries in the specimens, the mean volume of the Bowman's capsules (BV) and the mean volume of the glomerular capillaries (GV) were separately calculated for each subject using Weibel's equation. The G/B ratio was defined as the ratio of GV to BV.

Results: This study included a total of 67 BNS patients, with a median G/B ratio of 0.615. The clinicopathological characteristics at the biopsy of the patients with a G/B ratio of ≥0.615 and those with a value of <0.615 were comparable, whereas the GV values of the patients with a G/B ratio of ≥0.615 were larger in comparison to the patients with a G/B ratio of <0.615. The survival analyses showed that a G/B ratio of <0.615 was associated with a worse renal outcome (**Figure**). In the Cox hazard analysis to determine the factors associated with the doubling of serum creatinine levels, a G/B ratio of <0.615 was found to be a significant predictor after adjustment by age, sex, and GV <median.

Conclusions: These results suggest that the G/B ratio of diagnostic biopsy specimens is a useful predictor of the long-term renal outcome in patients with BNS, the pathogenesis of which may involve glomerular collapse.



FR-PO580

Prevalence and Predictors of Orthostatic Hypotension at a Tertiary Care Hypertension Clinic with New Diagnostic Thresholds Mohammad A. Faraz,[1] Marcel Ruzicka,[2] Swapnil Hiremath.[1] *[1]University of Ottawa, Ottawa, ON, Canada; [2]None, Ottawa, ON, Canada.*

Background: Formal testing of orthostatic hypotension (OH), defined as a decrease of blood pressure (BP) of 20/10 mm Hg (systolic/diastolic) on change in posture from supine to standing, is seldom carried out in routine practice because of logistical constraints. A recent study reported a sit-to-stand decrease of 15/7 mm Hg as having high sensitivity and specificity. We measured the prevalence and risk factors associated with OH with the new threshold of sit-to- stand of either ≥15 mm Hg in systolic (SBP) or ≥ 7 mm Hg in diastolic BP (DBP).

Methods: We reviewed medical charts of patients being followed at Renal Hypertension Center, a referral centre for difficult to control hypertension. Sitting BP is measured after 5 minutes of resting, as an average of 5 measurements with an automated device. Standing BP is measured three times at one minute intervals and averaged. OH was determined on the basis of the difference in either average SBP or DBP. Demographic characteristics, comorbidities, medication details, laboratory values and BP measurements were extracted.

Results: Data from 219 patients was extracted. The overall difference in SBP (sitting - standing) was 0.94 and DBP was 2.1 mm Hg. 190 patients (87%) did not have OH, whereas 29 (13%) had OH using either SBP or DBP thresholds. The difference in SBP and DBP was 17 mm and 6 mm Hg in those with OH, versus 1.6 and 3 mm Hg amongst those without OH respectively. Higher sitting systolic BP was significantly associated with OH; age, gender, diabetes, number and hypertension medication class were not associated with OH.

Conclusions: Amongst referred patients to a specialist hypertension clinic, the prevalence of OH using a threshold of 15/7 mm Hg was 13%. The new diagnostic threshold allows for easy assessment of OH.

Categories	Overall	OH	No OH
Number (n/%)	219	29 (13%)	190 (87%)
Age (mean ± sd, years)	61.2 ± 17.7	63.8 ± 17.6	60.8 ± 17.8
Gender, male (N, %)	103 (47%)	15 (52%)	88 (46.3%)
BMI (mean ± sd, kg/m²)	31.2 ± 15.7	36.7 ± 39.3	30.3 ± 6.5
Ever Smoker (%)	55 (25.7%)	7 (24%)	48 (26.0%)
Comorbidities (N, %)			
Diabetes	73 (34.3%)	11 (37.9%)	62 (33.7%)
Cardiovascular disease	40 (18.9%)	4 (13.8%)	36 (19.7%)
Peripheral vascular disease	22 (10.4%)	4 (13.8%)	18 (9.8%)
Cerebrovascular disease	18 (8.5%)	2 (6.9%)	16 (8.7%)
Resistant hypertension	77 (35.2%)	10 (34.6%)	67 (35.3%)
Blood Pressure Measurements (mean ± standard deviation)			
Sitting SBP (mm Hg)	137.1 ± 22.2	151.3 ± 33.1	134.9 ± 19.2
Standing SBP (mm Hg)	136.2 ± 21.6	133.8 ± 32	136.5 ± 19.6
Sitting DBP (mm Hg)	76.6 ± 15.2	80.3 ± 23.1	76.0 ± 13.6
Standing DBP (mm Hg)	78.7 ± 14.9	74.5 ± 18.6	79.3 ± 14.2
Medications (N, %)			
ACEi or ARBs	157 (71.7%)	24 (82.8%)	133 (70%)
Beta blockers	103 (47%)	14 (48.3%)	89 (46.8%)

K-sparing diuretics	29 (13.2%)	2 (6.9%)	27 (14.2%)
Thiazide/ thiazide-like diuretic	96 (43.8%)	16 (55.2%)	80 (42.1%)

FR-PO581

Difference between Central and Peripheral Blood Pressure during Hemodialysis Jafar Al-Said, Corazon Suyao. *Bahrain Specialist Hospital, Manama, Bahrain.*

Background: Difference between the peripheral and central pressure had been confirmed in multiple studies. During hemodialysis, the blood pressure is measured regularly. Whether the difference between the peripheral and central pressure measurements is significant enough to favor checking the central rather than the peripheral pressure during the session is not known?

Methods: During regular hemodialysis treatments for 10 of our ESRD patients, we measured the central and the peripheral BP through one full session. The average systolic and diastolic pressures were estimated. The pulse pressure was calculated for the peripheral as well as the central pressure. The paired T test was used to determine the statistical significance.

Results: Among the 10 patients 70% were females. Mean age was 57.7 years (SE3.8). All of them were having hypertension and 80% were diabetic. The mean peripheral systolic pressure was 149mmHg. (SE 6.9). The mean central systolic pressure was 129mmHg (SE 5.8). The mean peripheral diastolic pressure was 77mmHg. (SE 4.8). The mean central diastolic pressure was 80mmHg (SE 4.6). The mean peripheral pulse pressure was 72mmHg (SE 6). The mean central pulse pressure was 49mmHg (SE 4.6). The difference between peripheral and central measurements for the systolic, diastolic and pulse pressure were statistically significant. The systolic pressure was 20mmHg higher in the peripheral measurement with P 0.012. The diastolic pressure was 3 mmHg lower in the peripheral measurement P 0.009. The pulse pressure was 22 mmHg higher in the peripheral measurement P 0.006.

Conclusions: There was a significant difference between the peripheral and central pressure measurements during dialysis. It suggests that monitoring of the central pressure would be more accurate than the peripheral pressure during the hemodialysis sessions. The difference was noticed more among patients with high CV risks.

FR-PO582

Pegloticase, a Mammalian Uricase, Significantly Decreases Mean Arterial Blood Pressure in Patients with Chronic Gout Peter E. Lipsky,[1] Richard J. Johnson,[3] Hyon Choi,[2] Anthony Yeo.[1] *[1]AMPEL BioSolutions, Charlottesville, VA; [2]Massachusetts General Hospital, Boston, MA; [3]University of Colorado Denver, Aurora, CO.*

Background: Hypertension is a recognized co-morbidity of hyperuricemia and gout,[1] and there are significant correlations between serum uric acid (sUA) and blood pressure (BP) in individuals with and without gout.[1] While some studies suggest lowering sUA may decrease BP,[2] a meta-analysis indicated no consistent effect of oral urate lowering

therapy.[3] Pegloticase persistently decreases sUA to <1 mg/dL in responders.[4] Results from the pegloticase randomized clinical trials (RCTs) permitted determination of the impact of persistent, very low sUA levels on BP in subjects with chronic refractory gout.

Methods: This analysis used results from two 6-month RCTs in which subjects received 8 mg pegloticase every 2 weeks or placebo.[4] sUA responders maintained sUA <6 mg/dL and usually <1mg/dL.[4] Sitting BP was measured at each visit and estimated glomerular filtration rate (eGFR) was determined at baseline and after 3 and 6 months.

Results: 29 sUA responders were assessed and their mean arterial pressure (MAP) at baseline was 94.9 ± 9.6 mm Hg. At baseline, 36%, 18%, 18%, 25%, and 4% of patients were in CKD eGFR categories G1, G2, G3a, G3b, and G4, respectively. There were significant reductions in MAP in responders throughout the 6-month trial (P=0.0029), with significant changes noted within 2 weeks of the first pegloticase dose. No consistent pattern of MAP decrease was noted in non-responders or subjects receiving placebo. Of the 29 sUA responders, 18 (62.1%) had persistent decreases in MAP. There were no significant differences in baseline age, gender, race, BMI, documented history of hypertension, duration of gout, MAP, sUA, cholesterol, eGFR or urinary uric acid /creatinine ratio in those who decreased MAP vs those who did not. There were no significant changes in eGFR in sUA responders to pegloticase and no significant correlation between changes from baseline MAP and eGFR in these subjects (r= -0.16, P=0.43).

Conclusions: sUA responders to pegloticase experienced significant reductions in MAP that were independent of changes in renal function. 1. Essex MN, *J Clin Rheumatol*. 2017;23:160. 2. FR-PO583

The Impact on Central Blood Pressure and Arterial Stiffness Post-Renal Denervation (RDN) in Patients with Stage 3 and 4 CKD: The Prairie RDN Study Bhanu Prasad,[1] Shelley Giebel,[3] Michelle C. McCarron.[2] *[1]None, Regina, SK, Canada; [2]Regina Qu'Appelle Health Region, Regina, SK, Canada; [3]Regina QuAppelle Health Region, Regina, SK, Canada*.

Background: It is now recognized that central blood pressures (CBP) and arterial stiffness are better indicators of cardiovascular outcomes than brachial blood pressures (BBP's). Renal denervation (RDN) procedure has been shown to improve blood pressures by interrupting the afferent and efferent sympathetic nerves that traverse through the adventitia of the renal arteries. While there is evidence of improvement in BBP's in patients with stages 3 and 4 CKD, the impact of RDN on CBP's has not yet been examined.

Methods: We conducted a single-center, prospective study with pre and post-RDN follow-up. 26 patients with Stage 3 or Stage 4 CKD and resistant hypertension, with no radiological or laboratory evidence of secondary causes of hypertension underwent RDN between Jan 2014 to July 2015 at the Regina General Hospital, Canada. CBP's were measured by radial tonometry (Sphygmocor), ambulatory 24-hour blood pressure (Welch Allyn), office blood pressures (BP Tru) and pulse wave velocity (PWV) by Sphygmocor. Our primary outcome was to identify an improvement in CBP at 6 months post procedure. Secondary outcomes were to identify improvement in peripheral pressures, central pressures, pulse wave velocity at baseline, 6 and 24 months.

Results: 'There was a significant improvement in brachial blood pressures (median, mm Hg) (147.5/77) at baseline, (135/75) at 6 months and (133/74.5) at 24 months (**p=<0.001**). Mean central blood pressures (mm Hg) were (126/77) at baseline, (118/75) at 6 months and (118/67) at 24 months (p=0.18). Mean ambulatory 12-hour day (mm Hg) was (147/67) at baseline, (144/67) at 6 months and (150/69) at 24 months (p=0.27). Mean ambulatory 12-hour night BP (mm Hg) was (142/65) at baseline, (141/63) at 6 months and (143/65) at 24 months (p=0.93). Mean PWV (in m/s) was (13.8) at baseline, (13.3) at 6 months and (15.6) at 24 months time.

Conclusions: Our study demonstrates that there was a significant improvement in peripheral blood pressures from baseline to 6 months and was maintained at 24 months. There was a downward trend in central blood pressures although it did not reach statistical significance. There was no change in ambulatory blood pressures and PWV. It's the first study that looks at central blood pressures post RDN in CKD patients to our knowledge.

FR-PO584

Functional Sympatholysis Is Impaired in Chronic Renal Disease Ryan M. Downey,[2,3] Peizhou Liao,[1] Dana Dacosta,[2,3] Jeanie Park.[2,3] *[1]Department of Biostatistics and Bioinformatics, Emory University Rollins School of Public Health, Atlanta, GA; [2]Division of Renal Medicine, Emory University School of Medicine, Atlanta, GA; [3]Research Service Line, Atlanta VA Medical Center, Decatur, GA*.

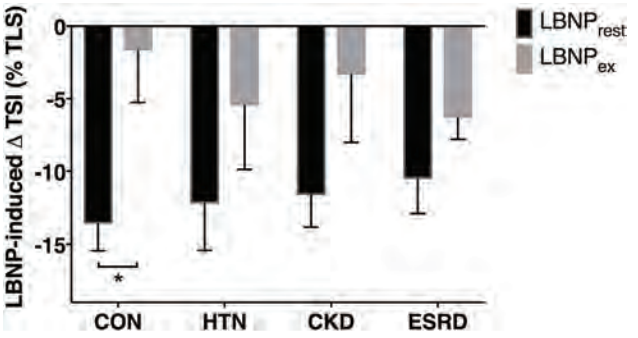
Background: Chronic renal failure is characterized by exercise intolerance. Although exercise induces reflex activation of sympathetic nerve activity (SNA), local metabolites within exercising skeletal muscle oppose SNA-mediated vasoconstriction, preserving blood flow and oxygenation to the working muscle, termed functional sympatholysis. We hypothesized that compared to healthy controls (CON), hypertensives without kidney disease (HTN), chronic kidney disease (CKD) and end-stage renal disease (ESRD) patients have impaired functional sympatholysis.

Methods: Muscle oxygen tissue saturation index (TSI) was measured using near-infrared spectroscopy (NIRS) of the forearm in 46 subjects (10 CON, 8 HTN, 12 CKD, 12 ESRD). Sympathetic activation was induced using lower-body negative pressure (LBNP). Continuous muscle TSI was measured at rest, during LBNP, and during LBNP with concomitant rhythmic handgrip exercise at 30% of maximum voluntary contraction.

Results: Baseline muscle TSI was significantly lower in HTN, CKD, and ESRD compared to CON (CON, 69.30±1.86%; HTN, 65.74±1.94%; CKD, 66.88±1.08%; ESRD, 62.79±1.60%; p=0.042). Muscle TSI decreased in all groups during SNS activation induced by LBNP at rest. When compared to muscle TSI changes during LBNP at rest, the reduction in muscle TSI was significantly ameliorated during LBNP with handgrip exercise in CON (-11.94±2.04% vs. -6.25±1.82%, p=0.011), demonstrating intact functional sympatholysis.

Conclusions: There was no significant improvement in muscle TSI during LBNP with concomitant exercise in HTN, CKD or ESRD suggesting impaired functional sympatholysis that could contribute to exercise intolerance.

Funding: Other NIH Support - R01HL135183, DK-00756, GM-000680, Veterans Affairs Support, Private Foundation Support



Exercise significantly attenuated the LBNP-induced decrease in TSI in healthy controls, indicating functional sympatholysis (p=0.011). Exercise did not significantly attenuate LBNP-induced decreases in TSI in hypertensive, CKD, nor ESRD groups, indicating impaired sympatholysis.

FR-PO585

The Effect of Renal Denervation on Kidney Function – Does Estimating Equation Matter? The ReShape CV-Risk Study Marit D. Solbu,[1,3] Atena Miroslawska,[4,2] Jon V. Norvik,[1,3] Terje K. Steigen.[2,1] *[1]University Hospital of North Norway, Tromsø, Norway; [2]UiT The Arctic University of Norway, Tromsø, Norway; [3]Metabolic and Renal Research Group, UiT The Arctic University of Norway, Tromsø, Norway; [4]Department of Cardiology, University Hospital of North Norway, Tromsø, Norway*.

Background: Renal denervation (RDN) is considered as a treatment option for patients with treatment resistant hypertension (TRHT). However, the short and long term effect of RDN on kidney function has not been evaluated. Moreover, whether the various commonly used equations to estimate GFR perform equally in RDN patients has never been assessed. The aim of our study was to track changes of measured and estimated GFR (mGFR and eGFR) in patients treated with RDN for TRHT, and to compare the methods to assess GFR in this patient group.

Methods: In the ReShape CV-Risk Study, non-diabetic patients with TRHT and eGFR >45 ml/min/1.73 m^2 were recruited from out-patient clinics. TRHT was defined as ambulatory daytime systolic blood pressure (SBP) >135 mm Hg while treated with ≥4 antihypertensive drugs including a diuretic. Investigations, which included fasting blood tests and iohexol clearance (mGFR), were done before RDN and after 6 and 24 months. eGFR was calculated using the CKD-EPI equations for creatinine, cystatin C and the combination ($eGFR_{cre}$, $eGFR_{cys}$, $eGFR_{crecys}$).

Results: Among the 23 patients who underwent bilateral RDN in the study, 20 completed the follow-ups at 6 and 24 months and were included in this sub-study. At baseline, mean age was 54 (±9) years, mean body mass index was 32 (±5) kg/m^2, and 2 patients were women. Mean ambulatory SBP was 155 (±21) mm Hg at baseline, fell significantly by 9.9 (±24) mm Hg at 6 months and remained stable at 24 months. Before RDN, mGFR was 83 (±20) ml/min/1.73 m^2. The value was 76 (±22) ml/min/1.73 m^2 at 6 months (P for change from baseline =0.07), but 78 (±28) ml/min/1.73 m^2 at 24 months. Whereas $eGFR_{cre}$ was stable from baseline to the first 6 months' follow-up, $eGFR_{cys}$ and $eGFR_{crecys}$ increased significantly during the same period. However, at 24 months, mean GFR was 3.1 – 4.4 ml/min/1.73 m^2 lower than the baseline value regardless of method.

Conclusions: During the first months after RDN for TRHT, estimates of GFR varied with the method used, whereas measured GFR fell slightly. In this setting, eGFR may not reflect kidney function only. After longer follow-up, all estimates of GFR showed similar GFR decline as measured GFR. These findings may be considered when evaluating kidney function after RDN.

FR-PO586

Activation of PI 3 Kinase (PI 3 K) by PDGF Receptor-Beta (PDGFRb) Regulates Akt-Dependent Hif1a to Express Glut1 for Mesangial Cell (MC) Hypertrophy in Response to High Glucose (HG) Falguni Das,[1] Nandini Ghosh-choudhury,[1] Balakuntalam S. Kasinath,[2] Goutam Ghosh-Choudhury.[2] *[1]UTHSCSA, SAN ANTONIO, TX; [2]University of Texas Health Science Center, San Antonio, TX.*

Background: Hyperglycemia increases PI 3 K/Akt to induce glomerular MC hypertrophy in diabetic nephropathy (DN). In DN, increased glomerular expression of PDGFRb is reported. As a mechanism of PI 3 K/Akt activation in DN, we hypothesized involvement of this receptor tyrosine kinase.

Methods: Human MCs, siRNA transfection, immunoblotting, protein synthesis and hypertrophy assays and rat model of streptozotocin-induced DN were used.

Results: HG significantly increased tyrosine phosphorylation-dependent activation of PI 3 K in MC, concomitant with increased tyrosine phosphorylation of PDGFRb at the catalytic loop and the PI 3 K binding sites. A specific PDGFRb inhibitor, JNJ-10198409 (JNJ), blocked these phosphorylations, which resulted in inhibition of association of PI 3 K with the PDGFRb. Similarly, siRNAs against PDGFRb and the PDGFRb mutant deficient in PI 3 K binding (PDGFRbM) inhibited HG-induced phosphorylation of PI 3 K and hence Akt. PI 3 K/Akt regulates Glut1 expression via Hif1alpha (Hif1a) transcription factor. siRNAs against Glut1 significantly inhibited HG-induced protein synthesis and hypertrophy of MCs. JNJ, siPDGFRb and PDGFRbM markedly suppressed the expression of Hif1a and Glut1 in response to HG. Interestingly, siRNAs against Hif1a inhibited HG-mediated protein synthesis and hypertrophy of MCs. Furthermore, JNJ, siPDGFRb and PDGFRbM inhibited MC hypertrophy induced by HG. This inhibition was reversed by the expression of constitutively active Akt kinase or Hif1a. Moreover, expression of Glut1 prevented the inhibition of hypertrophy induced by siPDGFRb or PDGFRbM. Finally, we observed increased phosphorylation of PDGFRb and PI 3 K in the glomerular fraction of STZ-induced diabetic rat. This increased phosphorylation was associated with Hif1a and Glut1 expression in the diabetic glomeruli.

Conclusions: Together our results provide the first evidence for a role of PDGFRb-mediated PI 3 K/Akt activation to control Hif1a/Glut1 axis in HG-induced MC hypertrophy.

Gastric Bypass versus "Medical Bypass" – Impact on Experimental Diabetic Kidney Disease Meera Nair,[3] Aoife L. Canney,[3] Jessie A. Elliott,[1] naomi m. fearon,[3] Anna Casselbrant,[2] Lars Fandriks,[2] Carel W. Le roux,[3,2] Neil G. Docherty.[3,2] *[1]St. James's Hospital, Dublin, Dublin 8, Ireland; [2]University of Gothenburg, Gothenburg, Sweden; [3]University College Dublin, Dublin, Ireland.*

Background: Reductions in albuminuria are reported after Roux-en-Y gastric bypass (RYGB). Herein, we assess the impact of RYGB on podocyte injury in the Zucker Diabetic Fatty (ZDF) rat model of diabetic kidney disease (DKD) and compare glomerular injury and global renal transcriptomic responses of RYGB and matched "Medical Bypass"(MB).

Methods: Study 1: Adult male ZDF rats underwent sham surgery (n=8) or RYGB (n=7). Study 2: Adult ZDF rats underwent sham surgery (n=15) or RYGB (n=9). Nine sham-operated rats were calorie restricted and received insulin, liraglutide, metformin, ramipril, rosuvastatin and fenofibrate for 2 months (MB). Zucker Fa/+ rats acted as healthy controls throughout. Bodyweight, glycaemia, albuminuria and glomerular injury specifically podocyte number, density and ultrastructure were assessed at follow up. Renal transcriptomes were compared by RNA-seq.

Results: RYGB resulted in 20-30% weight loss, normalized glycaemia and albuminuria and reduced indices of glomerular injury, specifically podocyte injury (foot process effacement). RYGB equivalent outcomes were obtained on all parameters following MB. A number of RYGB-discrete changes appear to relate to procedure rather than correction of disease. MB recapitulates many of the gene expression alterations observed after RYGB, but modifies expression of a much larger number of genes. A discrete and potentially beneficial response to RYGB was the induction of ALOX15 expression, a potential source of anti-inflammatory lipids.

Conclusions: Equivalent improvements in DKD are obtained following RYGB and matched MB. Shared transcriptional change may underpin comparable ultrastructural improvements, but similarities therein understate the degree of diversity at the molecular level. ALOX15 upregulation may be a useful component of RYGB amenable to targeting in non-surgical bariatric mimetic approaches.

Funding: Government Support - Non-U.S.

The Protective Effect of GSTK1 on Renal Injury in Diabetic Nephropathy by Anti-Inflammatory Chun Hu, Ming Yang, Peng Gao, Xianghui Chen, Yachun Han, Li Li, Xiaofen Xiong, Li Zhao, Li Xiao, Jun Li, Fuyou Liu, Lin Sun. *Departments of nephrology, Second Xiangya Hospital Central South University, ChangSha,Hunan, China.*

Background: Diabetic neprhropathy (DN) is one of the most serious microvascular complication in patients with diabetes mellitus. GSTK1 is a key protein which participate in adiponectin secretion and polymerization, it can also promote the expression of adiponectin. Our previous research has demonstrated that down-regulation of GSTK1 expression in the kidney of patients with DN, which consistent with decreased adiponectin levels in the serum. However, the role of GSTK1 in the development of DN is unclear.

Methods: C57BL/6 mouse were divided into four groups: normal group (control), STZ induced diabetic mouse group(STZ), overexpression GSTK1 group (GSTK1 transgenec mouse, fGSTK1) and fGSTK1 mouse with STZ iduced diabetc group (STZ fGSTK1)(n=8). In group of STZ and fGSTK1+STZ, mouse was feeding with high fat diet(HFD) for 4 weeks, and then single intraperitoneal injection of STZ 100mg/kg, continue with HFD feeding for 12 weeks. At the end of the experiment, blood and urine was collected for biochemical determination. The renal tissue was isolated and used for pathological examination,electron microscopy,DHE,IF,IHC,PCR and western blot analysis.

Results: Compared with the control group, the weight, blood sugar, blood lipid, urine protein levels, ROS were increased significantly in STZ mouse group. The pathological change were increased notable in the kidney in STZ mouse. In STZ mouse, the epithelial cell foot process effacement in kidney was seen as detected by electron microscope, in addition, both expression of GSTK1 and adiponectin were reduced compared to control($p<0.05$). Furthermore, the mRNA and protein expression of NLRP3, casepase1, IL1β, IL18 and NF-kB were increased significantly in the kidney of STZ mouse compared to control($p<0.01$), which accompany with the increased expression of FN, Collagen 1 and IV. All of this change were reversed partialy in fGSTK1+STZ group($p<0.01$). There was no significant difference between fGSTK1 and control groups

Conclusions: GSTK1 decreased the weight, blood glucose, blood lipid, urine protein, ROS level, increased adiponectinthe expression and reduced pathological changes in the kidney of STZ induced mouse. GSTK1 protected renal injury and reduce fibrosis in the kideny of diabetic mouse may through up-regulated expression of adiponectin and then inhibiting NLRP3 inflammation activity pathway

FR-PO589

Triptolide Alleviates Podocyte Injury in Hyperglycemia via Abrogating Activation of NALP3 Inflammasome and PI3K/Akt/mTOR Signaling Wenbei Han,[2] Yigang Wan.[1] *[1]Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China; [2]Nanjing University of Chinese Medicine, Nanjing, China.*

Background: *Triptolide* (TP), an extracted phytomedicine is frequently used for protecting against podocyte injury in early diabetic kidney disease (DKD) in China. However, the therapeutic mechanism remains unclear. In the process of DKD, the activation of NALP3 inflammasome and PI3K/Akt/mTOR signaling in kidneys is the important mechanisms by which renal inflammation contributes to podocyte damage. This study thereby aimed to examine the ameliorative effects of TP on podocyte lesion in hyperglycemia (HG), then to clarify its anti-inflammatory mechanisms in vitro by inhibiting the activation of NALP3 inflammasome and PI3K/Akt/mTOR signaling.

Methods: HG was used to induce murine podocyte to be in the state of damage. After the intervention of HG for 0, 3, 6, 12, 24 and 48 hours, firstly, the protein expressions of NALP3, active caspase-1 and active IL-1β were detected. Secondly, the protein expressions of desmin and synaptopodin were examined. Thirdly, the protein expressions of p-PI3K, p-Akt and p-mTOR were observed. And then, after the co-treatment of TP and HG without or with mTOR inhibitor (rapamycin), the protein expressions of the

key factors in NALP3 inflammasome activation, podocyte lesion and PI3K/Akt/mTOR signaling pathway were tested, respectively.

Results: The result showed that HG induced up-regulation of NALP3, active caspase-1, active IL-1β, p-PI3K, p-Akt and p-mTOR, and down-regulation of desmin and synaptopodin at protein expression level in podocyte. The co-treatment of TP and HG reversely regulated the protein expressions of NALP3, active IL-1β, desmin, synaptopodin, p-Akt and p-mTOR in HG-intervened podocyte significantly. The co-treatment of rapamycin, TP and HG recovered the level of NALP3 and p-mTOR protein expressions in HG-intervened podocyte obviously.

Conclusions: In conclusion, TP, as a natural regulator, attenuates podocyte injury in HG by abrogating the activation of NALP3 inflammasome and PI3K/Akt/mTOR signaling. This study may provide the first evidence that TP directly protects podocyte in HG via anti-inflammation.

FR-PO590

Long-Term Empagliflozin Administration Downregulates Aquaporin 2 despite the Increased Expression of V2 Vasopressin Receptor in Diabetic Rat Kidneys Sungjin Chung,[1,2] Zhilian Li,[1,3] Soojeong Kim,[4] Seok Joon Shin,[2] Cheol Whee Park,[2] Chul Woo Yang,[2] Yong-Soo Kim,[2] Eun Sil Koh.[2] *[1]Division of Nephrology and Hypertension, Department of Medicine, Vanderbilt University School of Medicine, Nashville, TN; [2]Department of Internal Medicine, The Catholic University of Korea College of Medicine, Seoul, Republic of Korea; [3]Department of Nephrology, Guangdong General Hospital, Guangzhou, China; [4]Department of Biochemistry, The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Beyond glucose lowering effect, it has been suggested that one of the possible mechanisms by which empagliflozin, a selective sodium-glucose cotransporter-2 (SGLT2) inhibitor, provides the remarkable cardiovascular and renal protection observed in a recent trial may relate to its effects on diuresis and natriuresis. However, the natriuretic effect of SGLT2 inhibitors is transient, and long-term data related to diuretic change are sparse.

Methods: This experiment assessed the effects of 12-week treatment with empagliflozin (3 mg/kg) on renal tubular function, related sodium transporters and water channels in diabetic OLETF rats by comparing it with other antihyperglycemic agents such as lixisenatide (10 μg/kg), a glucagon-like peptide receptor-1 agonist, and voglibose (0.6 mg/kg), an α-glucosidase inhibitor.

Results: At 12 weeks of treatment, serum sodium and potassium and fractional excretion of sodium did not significantly differ between empagliflozin-treated and control diabetic rats. Empagliflozin-treated diabetic rats produced slightly decreased but still high urine volume and glycosuria, and they showed significantly higher electrolyte-free water clearance than lixisenatide- or voglibose-treated diabetic rats. In empagliflozin-treated rats, renal protein expression of Na^+-K^+-$2Cl^-$ cotransporter (NKCC2), Na^+/H^+ exchanger isoform 3 (NHE3) and γ-epithelial Na^+ channel (ENaC) were decreased, and Na^+-Cl^- cotransporter (NCC) and α-ENaC expressions were unaltered compared with control diabetic rats. Empagliflozin increased the expressions of aquaporin (AQP)-3 and AQP7 but did not affect AQP1 protein expression in diabetic kidneys. Despite the increased expression in vasopressin V2 receptor (V2R), protein and mRNA levels of AQP2 in kidneys of empagliflozin-treated diabetic rats were significantly decreased than those of control diabetic rats. These were not observed in lixisenatide or voglibose-treated diabetic rats.

Conclusions: Taken together, longer use of empagliflozin may downregulate AQP2 expression regardless of the V2R activation by as-yet unidentified signaling pathways, contributing, in part, to polyuria in diabetic rats.

SGLT2 Inhibitor Dapagliflozin Is Renoprotective in Streptozotocin-Induced Diabetes Dora B. Balogh,[2,3] Lilla Lenart,[2] Judit Hodrea,[2] Adam Hosszu,[2,1] Ádám Vannay,[3,4] Laszlo J. Wagner,[1] Attila J. Szabo,[5] Andrea Fekete.[6,3] *[1]Department of Transplantation and Surgery, Semmelweis University, Budapest, Hungary; [2]MTA-SE Lendület Diabetes Research Group, Budapest, Hungary; [3]1st Department of Pediatrics, Semmelweis University, Budapest, Hungary; [4]MTA-SE Pediatrics and Nephrology Research Group, Budapest, Hungary; [5]1st Department of Pediatrics, Semmelweis University, Budapest, Hungary; [6]MTA-SE Lendület Diabetes Research Group, Budapest, Hungary.*

Background: Inhibitors of sodium-glucose co-transporter 2 (SGLT2) are a new class of antihyperglycemic drugs that act by inhibiting SGLT2 mediated glucose reabsorption in the proximal tubules. They have recently been approved type 2 diabetes, however their use is limited in renal impairment. They have not been registered yet in type 1 diabetes (T1DM) either. Previously we showed that in diabetic kidney injury activity of the hexosamine biosynthesis pathway is increased, resulting in protein *O*-linked N-acetylglucosamine modification (*O*-GlcNAcylation), which induces cellular processes leading to the progression of renal failure. The dynamic addition (by OGT) and removal (by OGA) of *O*-GlcNAc modulates signaling molecules which results in kidney fibrosis. Since there is still an unmet need for oral therapies in T1DM here we investigated the antidiabetic and possibly renoprotective effect of the highly selective SGLT2 inhibitor dapagliflozin (DAPA) in streptozotocin-induced model of DM.

Methods: T1DM was induced by streptozotocin (65 mg/bwkg, *ip.*) in male Wistar rats. Immediately following onset of DM the animals were treated *per os* for six weeks with DAPA (D+DAPA, 1 mg/bwkg/day). Metabolic, renal parameters and kidney histology was evaluated. Specific markers of tubular damage (NGAL, KIM-1), profibrotic factors (CTGF, PDGF, TGF-β), proinflammatory cytokines (IL-6, IL-1β, TNF-α) and α-SMA, *O*-GlcNAc, OGT and OGA protein levels were measured.

Results: Development of diabetic kidney injury was confirmed by impairment of renal function, massive proteinuria and structural damage of kidneys. DAPA reduced weight loss and decreased blood glucose level. DAPA Treatment improved GFR, ameliorated tubular damage and decreased of proinflammatory cytokines IL-6, IL-1β, TNF-α and profibrotic growth factors CTGF, PDGF, TGF-β. SGLT2 inhibition ameliorated DM-induced mesangial matrix expansion and tubulo-interstitial fibrosis. DM-induced elevated proteins *O*-GlcNAcylation, OGT, OGA and α-SMA levels were reduced by DAPA.

Conclusions: DAPA improved metabolic and renal parameters and decreased the histological lesions in the kidney. Decrease of *O*-GlcNAcylation by DAPA has a beneficial effect on profibrotic processes. These results support the effective and safe clinical application of DAPA in the prevention/treatment of T1DM and associated nephropathy.

Dapagliflozin Alone or Combined with Ramipril Improves Hyperglycemia and Hypertension and Prevents Kidney Complications and GFR Decline in the Nephrectomized SDT Fatty Rat Model of Diabetic Nephropathy Francois Briand,[3] Masami Shinohara,[1] Emmanuel Brousseau,[3] Takeshi Ohta,[2] Yasushi Kageyama,[1] Thierry Sulpice.[3] *[1]CLEA Japan, Inc., Meguro, Japan; [2]Japan Tobacco Inc., Osaka, Japan; [3]PHYSIOGENEX, LABEGE, France.*

Background: Combination of sodium glucose cotransporter 2 inhibitor (SGLT2i) and angiotensin converting enzyme inhibitor (ACEi) represents a potential therapeutic strategy to prevent diabetic nephropathy progression to end stage renal disease (ESRD). Here we evaluated SGLT2i dapagliflozin (DAPA) alone or combined with ACEi ramipril (RAMI) in the uni-nephrectomized Spontaneously Diabetic Torii (SDT) fatty rat. This hypertensive/obese/type 2 diabetic model develops advanced renal complications and >50% glomerular filtration rate (GFR) decline within 10 weeks.

Methods: One week after unilateral nephrectomy, SDT fatty rats were put on a chow diet with 0.3% salt in drinking water for 10 weeks. Rats were treated without (CTRL) or with DAPA 1mg/kg/day alone or with DAPA + RAMI both at 1mg/kg/day in the diet upon diet start (10-week treatment).

Results: Compared to CTRL, DAPA reduced hyperglycemia by 70%, and % HbA1c by 4.7% (both $p<0.001$). DAPA reduced systolic and diastolic blood pressure by 17 and 14% (both $p<0.05$). While CTRL rats showed a 64% GFR decline (as measured by FITC-inulin injection) at 5 weeks of treatment, DAPA markedly prevented this decline with a 71% higher GFR vs. CTRL ($p<0.01$). At the end of the 10-week treatment, DAPA significantly reduced glomerulosclerosis, inflammation and fibrosis histopathology scores. However, GFR values were not different between CTRL and DAPA, even after a wash-out period, excluding a tubuloglomerular feedback effect. As DAPA alone, DAPA + RAMI reduced hyperglycemia by 74%, and % HbA1c by 4.7% (both $p<0.001$ vs. CTRL). DAPA + RAMI further reduced systolic and diastolic blood pressure by 29 and 24% (both $p<0.01$ vs. CTRL). As well, DAPA + RAMI prevented GFR decline at 5 weeks of treatment (39% higher, $p<0.05$), but also at 10 weeks of treatment (63% higher, $p<0.05$ vs. CTRL).

Conclusions: In the 10-week Unx SDT fatty rat, DAPA alone prevents kidney complications, while the combination with RAMI adds benefits by better delaying GFR decline. Our data suggest that SGLT2i/ACEi combination prevents progression to ESRD.

PBI-4547 Prevents Renal Destruction and Fibrosis in Severely Obese db/db Mouse Model of Diabetes-Induced Kidney Disease Francois A. Leblond, Sylvie Létourneau, Jugurtha Ouboudinar, Liette Gervais, Pierre Laurin, Brigitte Grouix, Lyne Gagnon. *Prometic BioSciences Inc., Laval, QC, Canada.*

Background: Type 2 diabetes (T2D) is a major health problem worldwide. Comorbidities, such as kidney disease, associated to T2D are numerous and cause severe reduction of life expectancy. The uninephrectomized (NX) diabetic (*db/db*) mouse is a widely used model for the study of comorbidities associated to T2D. It also allows to study effects of obesity on diabetes-induced kidney disease. PBI-4547 is an orally active compound that displays anti-fibrotic and metabolic activities via a novel mechanism of action. The aim of this study was to investigate the protective effect of PBI-4547 on kidney health and function in NX *db/db* mice.

Methods: Total nephrectomy of the right kidney was performed on day 0 on 6-weeks old *db/db* (B6.BKS(D) and control C57BL/6 mice. Animals were treated with vehicle or PBI-4547 (25 mg/kg) from day 1 through 105 by daily oral gavage.

Results: PBI-4547 significantly improved diabetic condition of *db/db* mice, and lowered weight gain to that of control C57BL/6 mice. A significant reduction of fasting blood glucose, plasma insulin, and area under the curve in oral glucose tolerance test were observed in PBI-4547-treated *db/db* mice. PBI-4547 dosing also resulted in a reduction of plasma triglycerides and an increase in adiponectin. Moreover, PBI-4547 eventuated a significant reduction in the renal damage observed on *db/db* mice as shown by histopathological analysis of kidneys. When compared to control C57BL/6 mice, kidney glomeruli, tubules and capillaries of non-treated *db/db* mice were found significantly damaged. These modifications were almost absent on *db/db* mice treated with PBI-4547. Evaluation of numerous markers of fibrosis also confirmed that PBI-4547 significantly

reduced the fibrosis process in the kidney. Reduction of the mRNA expression of collagen type 1 (-40%), MCP-1 (-63%), TIMP-1 (-71%), MMP-2 (-47%) and GLEPP-1 (-13%) were shown in kidneys of PBI-4547-treated compared to untreated *db/db* mice. Neither BUN nor GFR were found significantly modified in the *db/db* non-treated mice (compared to NX C57BL/6 mice) and PBI-4547 had no impact on these parameters.

Conclusions: These studies suggest that, in addition to the improvement of T2D, PBI-4547 treatment precludes renal structure destruction and prevents fibrosis in the kidneys of severely obese *db/db* mice.

PBI-4547, a Novel Anti-Diabetic Agent, Prevents Diabetic Nephropathy and Protects β-Cells in NOD Mice, a Model of Type 1 Diabetes Lyne Gagnon, Kathy Hince, François Sarra-Bournet, Mikaël Tremblay, Marie-Pier Cloutier, Sylvie Létourneau, Pierre Laurin, Brigitte Grouix, Francois A. Leblond. *Prometic BioSciences Inc., Laval, QC, Canada.*

Background: Kidney disease is a cause of substantial morbidity and mortality in type 1 diabetes (T1D). Up to 40% of patients with T1D develop macroalbuminuria, and up to 75% of these patients progress to end-stage renal disease (ESRD) within 10 years. PBI-4547 is a novel first-in-class orally active antidiabetic compound which displays pleiotropic activities and has been shown to reduce NASH, diabetes and fibrosis of kidney in different animal models. In the present study, we examined whether PBI-4547 may prevent diabetic nephropathy in NOD mice, a model of type 1 diabetes.

Methods: NOD/ShiLtJ female mice (8 weeks of age) received vehicle (water) or PBI-4547 (10 and 25 mg/kg/day) by daily gastric gavage for 23 weeks.

Results: In kidney, PBI-4547 protects against lesions by reducing glomerular volume and mesangial cross sectional area. Furthermore, tubular lesions were absent in PBI-4547-treated mice. Tubular dystrophy as PAS granular accumulation was constantly present in proximal tubules of NOD control mice and was completely abrogated by treatment with PBI-4547. Mice treated with PBI-4547 did not develop diabetes. OGTT was also normalized in PBI-4547-treated mice. PBI-4547 partially prevented islets destruction, which contributed to maintain normoglycemia.

Conclusions: This data suggests that PBI-4547 prevents diabetic nephropathy and complete destruction of β-cells and islets in type 1 diabetes model.

Imbalance of Intestinal Microflora Disrupts LDL Receptor Pathway to Induce Lipid Accumulation at Renal Interstitium in Early Diabetic Nephropathy Zebo Hu, Kun ling Ma, Yang Zhang, Gui hua Wang, Peipei Chen, Jian Lu, Chenchen Lu. *Zhongda Hospital, Southeast University Medical School, Nanjing City, China.*

Background: Our previous studies demonstrated that lipid accumulation in kidneys contributes to the progression of diabetic nephropathy (DN). However, the exact mechanism of which caused lipid accumulation in kidney has not been completely elucidated. This study aimed to investigate the effect of imbalance of intestinal microflora on lipid deposition in the renal interstitium of DN.

Methods: Type 1 diabetic rats model were induced by streptozotocin injection. Broad-spectrum antibiotics were used to eliminate intestinal microflora. Intestinal microflora distribution was evaluated by 16S rDNA sequencing using samples from feces. Periodic acid-schiff (PAS) staining was used to observe basic structure and pathological changes of kidney. Lipid accumulation was detected by oil red O staining, Filipin staining, and intracellular free cholesterol quantitative assay. Immunohistochemical staining and Western blot were used to assess the protein expressions of low-density lipoprotein receptor (LDLr) pathway.

Results: Blautia, Roseburia, and Paraprevotella abundance were significantly increased in diabetic rats while Bacteroid abundance decreased when compared with the controls. Broad-spectrum antibiotics effectively cleared away intestinal microflora. PAS staining showed that tubular epithelium in diabetic mellitus group (DM group) exhibited obvious expansion, ballooning degeneration, cell detachment as well as increased glycogen deposition while antibiotics treatment alleviated those lesions. Lipid accumulation in tubular interstitium of diabetic rats was increased compared with the controls. After the application of antibiotics, the lipid accumulation in tubular interstitium of diabetic rats was significantly reduced. Moreover, immunohistochemical staining and Western blot suggested that LDLr expression in tubular interstitium was increased in DM group, while antibiotics treatment decreased LDLr expression.

Conclusions: Imbalance of intestinal microflora might disrupt LDLr pathway to induce lipid accumulation at renal interstitium in early diabetic nephropathy.

FR-PO596

Expression of Hepatic Cytochrome P450 Drug-Metabolizing Enzymes in a Mouse Model of Diabetic Nephropathy Cheng J. Fang,[4] Dylan Burger,[1] Chet E. Holterman,[2] Chris R. Kennedy,[1] Jean-Francois Thibodeau,[3] Brad Urquhart.[4] *[1]Kidney Research Centre, Ottawa, ON, Canada; [2]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [3]ProMetic BioSciences Inc., Laval, QC, Canada; [4]Western University, London, ON, Canada.*

Background: Out of 420 million diabetics, over a third will develop diabetic nephropathy. Studies in chronic kidney disease have demonstrated decreased expression of hepatic cytochrome P450 (CYP) drug-metabolizing enzymes. With polypharmacy in diabetic patients, diabetic kidney disease may lead to adverse drug reactions as a result of altered drug pharmacokinetics due to unexpected changes in CYP expression. This study evaluates the expression and metabolic activity of CYP3A11 and CYP2C29, mouse orthologues of human CYP3A4 and CYP2C9 in a mouse model of drug-induced diabetic nephropathy, as well as in a CYP3A4/PXR-humanized (TgCYP3A4/hPXR) mouse model.

Methods: Male C57BL/6 mice were treated with 50 mg/kg of streptozotocin (STZ; $n = 7$) intraperitoneally for 5 consecutive days. Control mice ($n = 8$) were injected with sodium acetate. After 16 weeks, blood glucose and kidney function (eGFR, urinary albumin-to-creatinine ratio (UACR)) were measured. Mouse livers were isolated for real-time PCR analysis and Western blot to determine CYP mRNA and protein expression. Activity of microsomes was assessed by metabolism of probe drugs (midazolam, testosterone) using liquid chromatography coupled to mass spectrometry (LC-MS).

Results: The UACR for STZ-treated mice was 667.3 μg/g compared to 145.5 μg/g in controls ($P < 0.001$). Similarly, eGFR was increased in STZ mice (20.2 mL/min/g body weight) compared to controls (10.2 mL/min/g body weight; $P < 0.001$). STZ-treated mice had higher plasma glucose (30.9 mM) compared to controls (6.4 mM; $P < 0.001$). Cyp3a11 mRNA expression showed a decreasing trend in diabetic nephropathy mice (-44%, $P = 0.10$) compared to control mice. Cyp2c29 mRNA expression was not significantly different in STZ mice compared to control.

Conclusions: Increased UACR, eGFR, and glucose are strong indicators of diabetic nephropathy, indicating reliability of the drug-induced diabetic mouse model. The same treatment is currently being used in studies investigating the impact of diabetic nephropathy on TgCYP3A4/hPXR mice. A decreasing trend in Cyp3a11 expression indicates possible down-regulation in diabetic nephropathy. Future directions will increase the sample size and evaluate hepatic differences caused by diabetic nephropathy by metabolomics in an effort to elucidate potential regulators of CYP expression.

FR-PO597

TMX-049, a Novel Xanthine Oxidase Inhibitor, Attenuates Renal Injury in an Experimental Model of Diabetic Kidney Disease Yoshiki Tsubosaka,[1] Takashi Shirakura,[1] Shunsuke Tsujimoto,[1] Reiko Aizawa,[1] Chieko Matsui,[1] Yohei Sakamoto,[2] Naoki Hase,[1] Tsunefumi Kobayashi.[1] *[1]Pharmacology Research Department, Teijin Institute for Bio-medical Research, Teijin Pharma Limited, Tokyo, Japan; [2]Toxicology Research Department, Teijin Institute for Bio-medical Research, Teijin Pharma Limited, Tokyo, Japan.*

Background: Diabetic kidney disease (DKD) is a major chronic renal complication of diabetes. Since several non-clinical and clinical studies imply the contribution of xanthine oxidase (XO) to the DKD progression, inhibiting XO activity may be one of the attractive therapeutic approaches. TMX-049 is a newly developed XO inhibitor with non-purine structure. In this study, we evaluate the effect of TMX-049 on renal damage in rat model of type 2 diabetes.

Methods: 1. To examine the pharmacological profile of TMX-049, in vitro and in vivo inhibition of XO activity with TMX-049 treatment was measured in human primary hepatocyte and SD rat kidney, respectively. 2. To evaluate in vivo efficacy of TMX-049 on renal injury, 8 week-old male ZDF rats were orally administrated vehicle or TMX-049 once daily for 13 weeks. Normoglycemic ZDF-lean (ZL) rats were used as non-DKD control. The amount of urinary albumin and KIM-1, a biomarker for proximal tubular cell injury, were quantified on weeks 0, 2, 4, 6, 8, 10 and 12. Measurement of XO activity in renal cortex and histological analysis were determined at 13 weeks.

Results: 1. TMX-049 inhibited cellular XO activity ($IC_{50} = 2.43 \pm 0.54$ nM) in human hepatocyte and did not change other enzymatic activities related to purine metabolism. TMX-049 also showed sustained inhibition of XO activity in normal rat kidney 24 hours after oral administration, and its effect was more potent than that of launched XO inhibitor. 2. Compared with ZL rats, ZDF rats exhibited the renal structural changes, elevation of urinary parameters such as albumin and KIM-1 and increased XO activity in renal cortex. Immunohistological analysis revealed that XO/xanthine dehydrogenase expression was detected in the proximal tubules. Administration of TMX-049 reduced the urinary excretion of albumin and KIM-1, and ameliorated histological renal damage seen in ZDF rats without affecting any metabolic parameters.

Conclusions: TMX-049 attenuated renal injury in an experimental model of DKD. These results suggest the therapeutic potential of TMX-049 in DKD.

FR-PO598

Endoglin Mediates Endothelial Activation and Monocyte Adhesion and Is Correlated with Glomerular VCAM-1 in Patients with Diabetic Nephropathy Pascal Bus,[2] Tessa Gerrits,[1] Sharon Heemskerk,[1] Malu Zandbergen,[1] Jan A. Bruijn,[3] Hans J. Baelde,[2] Marion Scharpfenecker.[2] *[1]LUMC, Leiden, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands; [3]Leiden University Medical Center, Dept.Pathology, Leiden, Netherlands.*

Background: Diabetic nephropathy is characterized by microvascular injury driven by hyperglycemia and enhanced growth factor production. Altered growth factor expression causes an angiogenic imbalance resulting in endothelial activation and dysfunction. Endothelial activation promotes the adhesion and subsequent infiltration of inflammatory cells, which promote renal damage in diabetic animal models. Endoglin is crucial for angiogenesis and vascular development, and is associated with endothelial activation and inflammation in animal models of renal disease. Here, we investigated whether reducing

endothelial endoglin expression affects endothelial activation and monocyte adhesion under diabetic conditions *in vitro*, and we investigated which glomerular cells express endoglin and VCAM-1, and whether glomerular endoglin expression is associated with endothelial activation in patients with diabetic nephropathy.

Methods: Immortalized endothelial cells with either wild type or reduced endoglin expression were used to study endothelial activation and monocyte adhesion after stimulation with either glucose or VEGF-A. Glomerular endoglin and VCAM-1 expression was studied by immunohistochemistry in biopsies of patients with diabetic nephropathy. Data were analyzed using a Student's t-test or a Mixed Model Regression Analysis. Double-labeled immunofluorescence was performed for endoglin and CD31 or VCAM-1. Differences were considered significant at $p<0.05$.

Results: Lowering endoglin expression in endothelial cells *in vitro* significantly impaired VEGF-A- and glucose-mediated induction of activation markers *VCAM1* and *SELE*, and significantly reduced monocyte adhesion ($p<0.05$). In diabetic patients, endoglin was primarily expressed in endothelial cells. Glomerular VCAM-1 expression co-localized with endoglin. Furthermore, glomerular VCAM-1 was significantly increased in patients with diabetic nephropathy ($p<0.05$) and correlated with glomerular endoglin levels ($p<0.001$).

Conclusions: Targeting endoglin function is a promising future strategy to interfere with endothelial activation in order to prevent or stop inflammation and thereby the progression of diabetic nephropathy.

FR-PO599

FK506 Attenuates Proteinuria by Inhibiting Endothelial-to-Mesenchymal Transition in Rats with Diabetic Nephropathy

Kaiyun Song. *Southeast University School of Medicine, Nanjing, China.*

Background: Many studies have shown that endothelial cell damage is present in the early stage of diabetic nephropathy(DN) and endothelium-podocytes crosstalk plays an important role in DN. FK506 was found to be beneficial for attenuating proteinuria in DN recently. However, the underlying mechanism is still unknown. In this study, we investigated whether endothelial-to-mesenchymal transition(EndMT) of DN could be attenuated by FK506.

Methods: Thirty-six **SD rats were randomly divided into three groups(n=12/ group)**: **control group,** DN **group,** FK506 **treatment group**. The DN model was established using strephozotocin(58mg/kg). The **diabetic** r**ats** were administered with FK506 **by** gavage **(0.15mg/kg/d) for 3**4 weeks. Some biochemical parameters, urinary albumin (UAL), and kidney weight/body weight (KW/BW) were measured. Nephrin and podocin were detected by Western blotting(WB) and Endothelial marker (CD31), FSP1 and α-SMA were detected by Double immunofluorescence staining, immunohistochemistry, real time-PCR and WB.

Results: There were significant increases in the levels of SCr, BUN, KW/BW, UAL, the glomerular volume, proliferative mesangial cells, width of the mesangial area in DN. However, these were reduced by FK506 treatment, compared with DN ($P<0.05$). Disorder, widening and fusion of podocyte processes were observed under the electron microscope in DN and they were reduced by FK506 treatment ($P<0.05$). The results of the WB showed that the expression of nephrin and podocin decreased in DN compared with the control and was significantly improved by FK506 treatment ($P<0.05$). Double immunofluorescence staining, Immunohistochemistry, real time-PCR and WB showed that the expression level of CD31 was downregulated in DN, whereas the expressions of FSP1, α-SMA were markedly upregulated. These changes were inhibited by FK506 treatment ($P<0.05$).

Conclusions: The results might provide a novel insight FK506 could attenuate the proteinuria by inhibiting endothelium-podocytes crosstalk in rats with DN. These results still need further study.

Funding: Government Support - Non-U.S.

FR-PO600

FK506 Attenuates Bone Loss by Inhibiting Endothelial-to-Adipocyte Transition in Diabetic Rats

Li-Hua Ni,[1] rining tang,[4] Kaiyun Song,[3] Bi-Cheng Liu.[2] *[1]Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, China, Nanjing, China; [2]Zhong Da Hospital, Southeast University Medical School, Nanjing, China; [3]Southeast University School of Medicine, Nanjing, China; [4]Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, China.*

Background: FK506, a well known immunosuppressant drugs, was found to be beneficial for bone health recently. However, the underlying mechanism is still under study. Our previous research has shown that high glucose induced phenotypic changes of endothelial cells (EndMT) in vivo and in vitro. Therefore, we asked the question of whether high glucose induced EndMT could be transformed to MSCs and differentiated into adipocytes (endothelial-to-adipocyte transition), and subsequently be involved in the bone loss in diabetes.

Methods: Diabetic rats were divided into two groups: the diabetic group (DM) and the FK506-treated group (DM+FK506). Diabetic models were established by intraperitoneal injection with streptozocin. Healthy rats served as control (CTL). Skeletal changes were determined by dual energy x-ray absorption (DEXA), micro-computed tomography (micro-CT), and bone mechanics tests. Immunofluorescence staining was performed to detect the co-expression of endothelial marker (CD31) and fibroblast marker (FSP1), CD31 and adipocyte marker (LPL). The expression of CD31, FSP1, mesenchymal stem cell markers (CD10, CD44, STRO-1), and LPL were detected by immunohistochemistry, real time-PCR and western blots. Adipocytes were detected by oil red O staining.

Results: Increased bone loss was detected in the DM group, which could be attenuated by FK506 treatment: the bone mineral density (BMD) of femur and lumbar assessed by DEXA were decreased in the DM group, which attenuated by FK506 treatment ($P<0.05$); the trabecular BV/TV, trabecular number, cortical area, cortical thickness measured by micro-CT were decreased in the DM group, which were alleviated in the DM+FK506 group ($P<0.05$). The adipocytes infiltration in the DM group detected by oil red O staining was significantly increased compared with the CTL group, which was improved by FK506 treatment ($P<0.05$). The expression of CD31 was notable down-regulated in DM group, whereas the expressions of FSP1, CD10, CD44, STRO-1, LPL were markedly up-regulated. These changes were inhibited by FK506 treatment ($P<0.05$).

Conclusions: This study provides a novel insight that bone marrow endothelial-to-adipocyte transition might contribute to the bone loss in diabetes, and FK506 treatment could attenuate the skeletal changes by inhibiting this phenotypic transition.

Experimental Diabetic Nephropathy and Effect of Atrasentan Administration on Renin Angiotensin System

Marta Riera,[1] Lidia Anguiano,[1] Vanesa Palau,[1] Julio Pascual,[2] Maria Jose Soler.[2] *[1]Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain; [2]Hospital del Mar, Parc de Salut Mar, Barcelona, Spain.*

Background: The endothelin A receptor specific blocker, atrasentan, has been shown to reduce residual albuminuria in diabetic nephropathy. However, edema has been described in some patients. We studied the effect of atrasentan in obese diabetic mice on renal pathology, renin angiotensin system and edema formation.

Methods: Male obese diabetic mice db/db(DB) and their controls(CONT) were used to study the effect of three doses of atrasentan(AS) administered for 16 weeks(10, 25 and 50mg/kgBW/day). Furthermore, a group receiving insulin(INS) was also included (10AS+INS). Body weight, glycemia, blood arterial pressure and bioimpedance were recorded throughout the follow-up and at the end of the study. WT1, ACE2 and AT1R were detected by IHC in kidney. ACE2 enzyme activity was detected in serum and renal cortex.

Results: DB animals showed higher blood glucose levels. Only the groups AS10+INS and AS50 showed significantly reduction of glycemia. Body weight in DB animals was higher than in control animals. Atrasentan significantly increased body weight in AS10+INS group reflected in the increase of extracellular fluid composition measured by bioimpedance. In kidney, DB animals showed lower number of podocytes than in controls. Only AS10 group recovered this number. Circulating and renal ACE2 activity were increased in DB and treatments with AS reduced these values to control level. IHC for ACE2 followed the same profile described for enzymatic activity. AT1R changed its expression in a dose-dependent fashion. AS10 group showed the same profile of expression as non-diabetic group.

Conclusions: In obese diabetic mouse, atrasentan treatment induced changes in body fluid composition when combined with insulin. Protective effects on kidney are observed at low doses of atrasentan by maintaining podocyte number in the glomeruli. Furthermore, atrasentan modulates ACE2 and AT1R, suggesting protective modifications in renin angiotensin system.

Renoprotective Effects of Aliskiren in a Non-Obese Type 2 Diabetic Model Rat

Kentaro Watanabe,[2] Hideki Fujii,[2] Kentaro Nakai,[2] Shuhei Watanabe,[2] Keiji Kono,[2] Shunsuke Goto,[2] Masami Shinohara,[1] Shinichi Nishi.[2] *[1]CLEA Japan, Inc., Meguro, Japan; [2]Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Previous experimental and clinical studies showed that various factors such as oxidative stress and renin-angiotensin system (RAS) were involved in pathogenesis of diabetic nephropathy (DN), and Aliskiren (ALS), which is a direct renin inhibitor, was useful for prevention of DN progression. However, there are no studies using non-obese type 2 diabetic animal models. The aim of our study was to elucidate the effects of ALS on DN in a non-obese type 2 diabetic rat model.

Methods: We used male Sprague-Dawley (SD) rats and Spontaneously Diabetic Torii (SDT) rats, which are known as non-obese type 2 diabetic animal models, in the present study. At 20 weeks of age, SD rats were assigned to the control group (SD group) and SDT rats were randomly divided into two groups: placebo-treated group (DM group) and ALS-treated group (ALS group). ALS was administered to the rats in the ALS group for 10 weeks. At 30 weeks of age, these rats were killed and then urinary and blood biochemical analyses and renal mRNA expression analysis were performed in all the groups.

Results: Despite similar blood pressure and renal function, urinary excretion of albumin was significantly lower in the ALS than in the DM group. Urinary excretion of angiotensinogen and 8-hydroxydeoxyguanosine (8-OHdG) were also significantly lower in the ALS compared to the DM group. Serum transforming growth factor-β (TGF-β) levels tended to be lower in the ALS than in the DM group. Renal mRNA expressions of angiotensin II type 1 receptor, nicotinamide adenine dinucleotide phosphate oxidase, and

TGF-β were significantly suppressed in the ALS compared to the DM group. Furthermore, renal nephrin mRNA expression was ameliorated by ALS treatment. Urinary excretion of albumin was positively and significantly correlated with urinary excretion of 8-OHdG as well as serum levels and renal mRNA expression of TGF-β.

Conclusions: The results of present study suggested that ALS provided renoprotective effects through RAS inhibition and reduction of oxidative stress and TGF-β even in a non-obese type 2 diabetic model rat.

FR-PO603

Protective Effect of an Oral Adsorbent AST-120 on Podocyte Injury Rieko Aoki, Ayako Fujieda, Atsuko Ezawa, Hiroko Iijima, Yusuke Yamashita, Kaori Kikuchi, Mariko Kato, Yoshiharu Itoh. *KUREHA CORPORATION, Tokyo, Japan.*

Background: Diabetic nephropathy is a major complication of diabetes and the leading cause of end-stage renal disease. An oral adsorbent AST-120 has been used clinically in Japan as a medicine for patients with chronic kidney disease (CKD) to slow down the progression of CKD. However, there is little evidence to support therapeutic efficacy of AST-120 for early stage overt diabetic nephropathy. Previously, we showed that the administration of AST-120 reduced the proteinuria and suppressed podocyte foot process effacement on SHR/NDmcr-cp (SHR/ND) rats, rodent model of metabolic syndrome/ type 2 diabetes. We also showed that AST-120 prevented the decrease of renal function and suppressed the levels of serum uremic toxins in unilateral nephrectomized (UNX) SHR/ND rats. In this study, we investigated whether the renal tissues of UNX SHR/ND rats were ameliorated by the administration of AST-120 and whether uremic toxins induced deleterious effects on the cultured podocyte cells *in vitro*.

Methods: Male SHR/ND rats, aged 8 weeks, underwent either UNX (n=20) or sham (n=6) surgery under anesthesia. Half of UNX rats were administered 8% AST-120 for 30 weeks in their diet, and serum and 24-hour urine samples were collected for biomedical studies. The gene expression of podocyte markers and fibrosis makers by real-time PCR in renal tissues from UNX-SHR/ND rats treated with or without AST-120. *In vitro* study, we evaluated effects of uremic toxins on the cytotoxicity and reactive oxygen species (ROS) production of mouse podocyte cells.

Results: AST-120-administered UNX-SHR/ND rats showed significantly lower levels of urinary protein excretion, serum creatinine, serum uremic toxins such as indole acetic acid (IAA) and kidney weight than UNX-SHR/ND rats. Nephrin, as a podocyte marker, in renal tissues was higher expressed in AST-120-administered UNX-SHR/ND rats than in UNX-SHR/ND rats. Plasminogen activator inhibitor-1 was lower expressed in AST-120-administered UNX SHR/ND rats. *In vitro* study, indoxy sulfate (IS) and IAA induced ROS production and the cytotoxicity of mouse podocyte cells, and N-acetyl-L-cysteine inhibited this effect.

Conclusions: These results indicate that the administration of AST-120 from the early stage of diabetic nephropathy has renoprotective effects. One of the mechanisms of the effect may be the reduction of uremic toxin by AST-120.

FR-PO604

P53 Mediates the Protective Effect of SRT2104 on Diabetic Kidney Disease Hao Wu, Junduo Wu, Shengzhu Zhou. *The Second Hospital of Jilin University, Changchun, China.*

Background: Silent mating type information regulation 2 homolog 1 (Sirt1) plays an important role in protection against diabetic kidney disease (DKD). Activation of Sirt1 by small molecules showed beneficial effects on experimental DKD. SRT2104 is a potent selective activator of Sirt1, and has been used in clinical trials, demonstrating both safety and tolerability. However, to date, the effect and mechanism of SRT2104 on DKD have remained unknown. P53 is an essential factor that induces the pathogenesis of DKD. Sirt1 deacetylates P53, leading to the inactivation of P53. Therefore, we hypothesize that SRT2104 inhibits P53 by activation of Sirt1, the effect of which ameliorates DKD.

Methods: Eight-week-old male C57BL/6 mice were induced to diabetes by streptozotocin, and were treated in the presence or absence of SRT2104, for a period of 24 weeks. To test whether or not P53 is required for SRT2104's action, mouse mesangial cells (MMCs) were treated with high glucose in combination with SRT2104, in the presence or absence of P53 siRNA.

Results: The diabetic mice exhibited remarkable renal inflammation, oxidative damage, fibrosis, pathological remodeling and albuminuria. These effects were significantly ameliorated by SRT2104. SRT2014 restored Sirt1 protein level and activity, and inactivated P53 in the kidneys of the diabetic mice. Interestingly, despite the activation of Sirt1, SRT2104 completely lost the protective effects in the presence of P53 siRNA in high glucose-treated MMCs.

Conclusions: The present study demonstrates, for the first time, that SRT2104 prevents DKD, the effect of which may be mediated by P53.

FR-PO605

Pioglitazone Stabilizes Nephrin Expression via SUMOylation Irini Schaefer, Mario Schiffer, Hermann G. Haller. *Hannover Medical School, Nephrology, Hannover, Germany.*

Background: Pioglitazone belongs to a group of thiazoldinediones, antihypergycaemic drugs that increase peripheral insuline sensitivity. As peroxisome proliferator-activated receptor (PPAR) agonists they have been demonstrated to significantly decrease urinary albumin excretion in patients with type-2 diabetes. Furthermore, treatment with pioglitazone exerts anti-apoptotic effects on podocytes. However, the nephroprotective effects on a cellular and molecular level of these drugs remain elusive. We have investigated the effects of pioglitazone-treatment on nephrin expression "in vitro".

Methods: Differentiated podocytes were treated with 20 μm pioglitazone over 72 hours and western blot was performed. Subcellular fractionation shows expression of nephrin in the compartments. To show if pioglitazone also stabilize nephrin in "aged" podocytes we differentiated them over 8 weeks. Immunoprecipitation were performed for analyzing SUMOylation of neprin after treatment with pioglitazone.

Results: We found that nephrin expression was strongly enhanced in human and murine podocytes after pioglitazone exposure. Subcellular fractionation shows that the enhanced neprin expression was restricted to the plasma membrane. When we "aged" podocytes in vitro by keeping them under differentiating conditions for more than 8 weeks we detected a significant decrease of nephrin expression under normal culture conditions. However, nephrin expression remained stable over 8 weeks in the presence of pioglitazone. Interestingly, we found that SUMOylation of nephrin was significantly enhanced in the presence of pioglitazone.

Conclusions: Our data strongly suggest that membrane expression of nephrin in podocytes is modulated by pioglitazone treatment. The strong expression of nephrin in cultivated podocytes after treatment with pioglitazone indicates a direct molecular mechanism which is most likely responsible for the renoprotective and anti-proteinuric effects of pioglitazone treatments in vivo.

The Classic and Trans-Signaling of Interleukin-6 Are Both Injurious in Podocyte under High Glucose Exposure Chun-Tao Lei,[1] Hua Su,[1] Chun Zhang.[2] *[1]Huazhong Science and Technology University, Wuhan, China; [2]Union Hospital, Huazhong University of Science and Technology, Wuhan Hubei Provicne, China.*

Background: Interleukin-6 (IL-6) is a multifunctional cytokine that employs IL-6 classic and trans-signaling pathways, and these two signal channels execute different or even opposite effects in certain diseases. As a cardinal event of diabetic kidney disease (DKD), whether the podocyte abnormalities are associated with IL-6 signaling, especially the individual role of IL-6 classic or trans-signaling, remains unclear.

Methods: The circulatory IL-6, soluble IL-6R (sIL-6R) and soluble glycoprotein 130 (sgp130) levels in subjects with or without DKD were measured. Human podocyte cell line was employed in vitro study. RNA interfere targeting gp130 and gp130 or IL-6 neutralizing antibodies were utilized to block the entire IL-6 signaling. RNA interfere targeting IL-6R and recombinant sgp130 were used to inhibit IL-6 classic and trans-signaling respectively.

Results: Our findings elucidated that the circulatory IL-6, sIL-6R and sgp130 levels are elevated in patients with DKD. The expressions of membrane bound IL-6R (mIL-6R), sIL-6R, and gp130 are enhanced in kidney cortex of diabetic mice accompanying with activated STAT3 by tyrosine 705 residue phosphorylation, while not serine 727. Above data infer both classic and trans-signaling of IL-6 are activated during DKD. In cultured podocyte, high glucose (HG) upregulates the expression of mIL-6R and gp130, as well as STAT3 tyrosine 705 phosphorylation, in a time-dependent manner. Entirely blocking IL-6 signaling attenuates HG-induced podocyte injury. Interestingly, either inhibiting IL-6 classic signaling or suppressing its trans-signaling individually also dramatically alleviates HG-induced podocyte injury, suggesting both IL-6 classic and trans-signaling play a detrimental role in HG-induced podocyte injury. Consistently, activation of IL-6 classic or trans-signaling aggravates podocyte damage in vitro.

Conclusions: In summary, our observations demonstrate that either IL-6 classic or trans-signaling aggravates hyperglycemia mediated podocyte impairment. Accordingly, suppressing IL-6 classic and trans-signaling, especially simultaneously, is a promising therapeutic strategy for podocyte injury during DKD.

FR-PO607

Attenuating Lymphatic Proliferation by Fenofibrate Ameliorates Diabetic Nephropathy and High-Fat Diet-Induced Renal Lipotoxicity Yaeni Kim,[1] Ji Hee Lim,[1] Min Young Kim,[1] Bumsoon Choi,[1] Yong-Soo Kim,[1] Seon Deok Hwang,[2] Cheol Whee Park.[1] *[1]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea; [2]Inha University College of Medicine, Incheon, Republic of Korea.*

Background: In diabetic nephropathy, the proliferation of lymphatic vessels correlates with the extent of intrarenal inflammatory cell infiltration and tubulointerstitial fibrosis. Peroxisome proliferative-activated receptor (PPAR)α plays an important role against lipotoxicity under the control of AMP-activated protein kinase (AMPK).

Methods: We evaluated whether fenofibrate, a PPARα agonist, has a renoprotective effect by ameliorating lipotoxicityassociated with lymphangiogenesis.

Results: In male C57BLKS/J *db/db* mice, fenofibrate ameliorated albuminuria and mesangialand tubular fibrosis and inflammation. Fenofibrate inhibited the accumulation of intra-renal free fatty acid and triglycerides, which was associated with increase in the expression of PPARα, phosphorylation of AMPK, activation of PPARγ co-activator 1α-phosphorylated acetyl-CoA carboxylase, and suppression of sterol regulatory element-binding protein 1 (SREBP-1) and carbohydrate regulatory element-binding protein 1 (ChREBP). Fenofibrate significantly decreased lymphatic growth, as represented by decreases in the expression of lymphatic endothelial hyaluronan receptor-1 (LYVE-1) and podoplanin, along with decreases in vascular endothelial growth factor-C (VEGF-C)

and vascular endothelial growth factor receptor-3 (VEGFR-3). Consequently, fenofibrate reversed renal apoptosis and oxidative stress. In high-fat diet-fed spontaneously hypertensive rats (SHRs), fenofibrate also attenuated renal lymphatic proliferation and lipotoxicity-induced oxidative stress and apoptosis. In cultured HK2 cells, fenofibrate prevented palmitate- and high glucose-induced expression of VEGF-C, VEGFR-3, and LYVE-1 via activation of PPARα-AMPK-pACC signaling and suppression of SREBP-1 and ChREBP.

Conclusions: These results suggested that fenofibrate prevents diabetic nephropathy in *db/db* mice and high-fat diet-induced renal injury in SHRs by attenuating lymphatic proliferation, inflammation, andoxidative stress through activation of PPARα-AMPK pathway, especially in renal proximal tubule cells.

FR-PO608

Inhibition of High Glucose Induced Senescence of Human Glomerular Mesangial Cells by Metformin Up-Regulating Autophagy Level Xiuying Wang,[2] Lining Wang,[1] Shuang Yang,[2] Dan Sun.[2] *[1]Department of Nephrology, First Affiliated Hospital of China Medical University, Shenyang, P. R. China, Shenyang, China; [2]The First Hospital of China Medical University, Shenyang, China.*

Background: Autophagy has been found to be closely related to aging and human disease. However, the role of autophagy in the process of human mesangial cell senescence and its mechanism is unclear. In recent years the study found that metformin can activate the AMPK signaling pathway, inhibition of mTOR pathway and affect autophagy. Here we try to investigate the effects of metformin on autophagy and human glomerular mesangial cells senescence induced by high glucose.

Methods: Human glomerular mesangial cells (HGMCs) were cultured in vitro, and exposed to high glucose (30.0 mmol / L glucose) for 12,24,48 and 72 h and stimulated by high glucose with 10mmol/L metformin for 72 h. Normal control group(5.5mmol/L glucose)and hypertonic group(5.5 mmol/L glucose+24.5 mmol/L mannitol) were set up. The best stimulating concentration of metformin was filtered by Cell Counting Kit(CCK-8/WST-8). The cell senescence was evaluated byβ-galactosidase(SA-β-gal) staining. The activation of AMPK/mTOR pathway, aging related proteins p53,p21 and autophagy marker proteins LC3,p62 / SQSTMI were determined by Western blotting. Autophagic flux was detected by (mRFP-GFP-LC3)adenovirus observed using confocal microscopy.

Results: Compared with the normal control group, the cells exposed to high glucose for 12,24 and 48h showed up-regulated p53 and mTOR expression(P<0.05),the cells exposed to high glucose for 24 and 48h showed up-regulated p21 and p-mTOR expression(P<0.05),the cells exposed to high glucose for 24,48 and 72h showed down-regulated p-AMPK expression(P<0.05), up-regulated p62/SQSTM1 expression and increased percentage of SA-β-gal positive cells(P<0.05). The cells exposed to high glucose for 72h showed down-regulated LC3 expression and decreased autophagic flux level(P<0.05). Compared with those in high glucose group, The autophagic flux level and the expression of p-AMPK, LC3were increased dramatically in high glucose with metformin group (P<0. 05),while the protein expressions of p62,p53, p21, mTOR and p-mTOR decreased (P<0. 05),and SA -β-gal positive cells decreased(P<0. 05).

Conclusions: The senescence of human glomerular mesangial cells is associated with defective autophagy level under high glucose condition. Metformin could postpone high glucose - induced senescence of human glomerular mesangial cells by increasing aotophagy level via modulating AMPK/mTOR pathway.

miRNA-27b and miRNA-1228 Urinary Levels Discriminate Specific Classes of Histological Damage in Diabetic Patients Paola Pontrelli,[5] Francesca Conserva,[2] Mariagrazia Barozzino,[2] Francesco Pesce,[2] Rossella Menghini,[6] Annarita Oranger,[7] Antonella Di Franco,[2] Massimo Papale,[2] Francesco Giorgino,[2] Luigi Laviola,[3] Simona Simone,[1] M. Rossini,[4] Massimo Federici,[6] Loreto Gesualdo.[2] *[1]None, BARI, Italy; [2]University of Bari, Bari, Italy; [3]University of Bari Aldo Moro, Bari, Italy; [4]University of Bari, Department of Emergency and Organ Transplantation, Nephrology Unit, Bari, Italy; [5]University of Bari-Dept. of Emergency and Organ Transplantation, Bari, Italy; [6]University of Rome Tor Vergata, Rome, Italy; [7]University of Bari, Bari, Italy.*

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease. Aim of our study was to identify novel urinary biomarkers which correlate with the histological damage. We focused on those miRNAs that modulate lysin63 ubiquitination, responsible of tubular damage in diabetic patients (PMID: 27881486).

Methods: Urinary samples were collected from 16 patients with type-2 diabetes (T2D) and DN, 7 with T2D and other nephrities (T2D-GN), including membranous nephropathy (MN) and Focal and Segmental Glomerulosclerosis (FSGS), 32 with other nephrities without T2D (GN), all with a biopsy proven diagnosis, 7 with T2D and normal renal function, 9 healthy subjects (HS). miRNAs expression was evaluated by qPCR in urines and in situ hybridization on tissues. Data were validated in a mouse model of DN (DBA2J mice treated with streptozotocin-STZ).

Results: miRNA-27b was down-regulated in urines of DN patients when compared to HS (p=0.03), to T2D (p=0.04) to T2D-GN (p=0.04), and to GN (p=0.05), such as miRNA-1228 (p=0.01 vs HS, p=0.01 vs T2D, p=0.04 vs T2D-GN, p=0.05 vs GN). Tissue expression of both miRNAs was also reduced at tubular level in DN vs T2D-GN (p<0.05) and was directly correlated with tubular-interstitial fibrosis (p<0.05). ROC curve from a predictive model (based on logistic regression) combining both miRNAs relative expression, was able to predict DN in the comparison with HS (AUC=0.93; p=5.9E-19), with T2D-GN (AUC=0.81; p=0.001), with T2D (AUC 0.90; p=2.7E-10) and with GN (AUC=0.69; p=0.002). miRNA-27b (conserved among species) was also down-regulated in urines of DBA2J/STZ mice vs DBA2J untreated controls (FC: -3.79; p<0.05) and was correlated with lysin63 protein accumulation and tubular-interstitial fibrosis (p<0.05).

Conclusions: miRNA-27b and -1228 expression correlate with increased fibrosis and discriminate DN patients vs other histological lesion in diabetic and non- diabetic patients.

Funding: Government Support - Non-U.S.

MicroRNA-148b Influences High Glucose-Induced Endoplasmic Reticulum Stress in Rat Mesangial Cells by Targeting AMPKα1 Qiuling Fan. *Department of Nephrology, The First Hospital, China Medical University, Shenyang, China.*

Background: To verify the expression of microRNA-148b (miRNA-148b) induced by high glucose in rat mesangial cells, and to explore its effect on its target gene AMP-activated protein kinaseα1 (AMPKα1) and extracellular matrix excretion.

Methods: Rat mesangial cells were divided into 3 groups: normal glucose (NG, 5.5 mmol/L glucose) group, hypertonic (MA, 5.5 mmol/L glucose+ 19.5 mmol/L mannitol) group and high glucose (HG, 25.0 mmol/L glucose) group. miR-148b expression was detected by real time PCR. Then miR-148b inhibitor was transfected to rat mesangial cells. Their expressions of AMPKα1, glucose regulated protein78 (GRP78), C/EBP homologous protein (CHOP), fibronectin (FN)and collagen 4 proteins were detected by Western blotting; the expression of AMPKα1 mRNA was detected by real time PCR; the expression of COl 4 was also detected by immunofluorescence.

Results: Compared with NG group, HG group showed upregulated miR-148b expression, downregulated AMPKα1 mRNA and protein expression, and upregulated CHOP, GRP78, collagen 44 and FN expression (all P<0.05). HG-induced mesangial cells with miR-148b inhibitor had up-regulated AMPKα1 mRNA and protein expression, and downregulated CHOP, GRP78, collagen 4, FN expression as compared with HG-induced cells without miR-148b inhibitor (all P<0.05).

Conclusions: HG can upregulate miR-148b expression and downregulate AMPKα1 expression in rat mesangial cells, then activate endoplasmic reticulum stress to induce extracellular matrix excretion. miR-148b inhibitor upregulates AMPKα1 expression, inhibits endoplasmic reticulum stress and reduces extracellular matrix excretion.

FR-PO611

Transcriptional Regulation of Long Non-Coding RNA Tug1 in Diabetic Nephropathy Jianyin Long, Farhad R. Danesh. *The University of Texas MD Anderson Cancer Center, Houston, TX.*

Background: Long non-coding RNAs (lncRNAs) have been implicated in the pathogenesis of a myriad of diseases, including cancer, heart diseases and kidney diseases. We recently reported that lncRNA Tug1 (Taurine-upregulated gene-1) is a differentially repressed lncRNA in a mouse model of diabetic nephropathy (DN), and podocyte-specific Tug1 overexpression exerts a renoprotective phenotype. However, how the expression of Tug1 is regulated in the diabetic milieu is unknown.

Methods: Transcription factor binding prediction algorithms (rVista 2.0 and PROMO) were used to analyze Tug1 proximal promoter region. Standard PCR, site-directed mutagenesis techniques were used to generate mouse Tug1 promoter constructs. ChIP-qPCR, eletromobility shift assays (EMSA) and luciferase reporter assays were used to identify the elements responsible for glucose and/or TGF-β1-mediated transcriptional repression of Tug1.

Results: We have generated a series of Tug1 promoter reporter constructs which were used to study the transcriptional regulation of Tug1 by high glucose and TGF-β1 signaling. Bioinformatics analysis revealed several glucose responsive elements in the highly evolutionarily conserved 1kb Tug1 promoter fragment immediately upstream of the Tug1 TSS (transcription start site). Specifically, a consensus ChoRE (carbohydrate response element) motif (CAYGYGnnnnnCRCRTG), was identified in the proximal promoter region (CACGTGACCGGATCTTG, -324 to -307) of Tug1. This motif was reported as a specific peak in our recent publication about genome-wide ChIP-Seq of the glucose-responsive transcription factor ChREBP (carbohydrate response element–binding protein, also known as MLXIPL, MLX Interacting Protein Like) in mouse liver and fat. Binding of ChREBP to this motif in podocytes was further validated by ChIP-qPCR and EMSA. We are currently identifying the cofactors/corepressors for this ChREBP-mediated repression of Tug1 in podocytes.

Conclusions: We identified glucose-responsive transcription factor ChREBP binding to the evolutional conserved ChoRE in the proximal promoter, as the mechanism of Tug1 down-regulaton in diabetic milieu.

Aerobic Exercise Training Reduces Renal Inflammatory Factors, Fibrosis, and Proteinuria in Diabetic Rats Rodolfo R. Rampaso,[2] Rafael Luiz,[2] Natalia Reinecke,[2] Edson A. Pessoa,[2] Kleiton A. Silva,[3] Luciana Jorge,[1] Maria A. Gloria,[2] Nestor Schor.[2] *[1]None, São Paulo, Brazil; [2]Universidade Federal de Sao Paulo/Escola Paulista de Medicina, Sao Paulo, Brazil; [3]University of Missouri, Columbia, AL.*

Background: The aim of this study was to evaluate the role of aerobic exercise in controlling the progression of diabetic nephropathy as proteinuria, fibrosis, inflammatory factors, and thus, its possible renoprotective effects

Methods: Adult male Wistar rats divided into 4 groups: Sedentary controls, (SED, n=8), Diabetes+Sedentary (DM-SED, n=8), Diabetes+Exercise (DM-EXE, n=8) and Exercise+Controls (EXE, n=8). DM was induced with streptozotocin (STZ), 50mg/kg i.v. The physical training was done on treadmill 60 min/day, 5 days a week for 8 weeks. Weekly it was determined the Maximal Exercise Test (set at 65-70% of MEtest). Fibrosis (m2), Glycemia 24h post training (glycemiapt), MEtest, creatinine clearance/BW (CrCl/BW), mean arterial pressure (MAP), proteinuria (uProt), renal inflammatory factors (IL-6, IL-10 and TNF-alpha) were measured

Results:

Conclusions: Reductions in glycemia, fibrosis and MAP comparing DM-EXE vs DM-SED. The DM-EXE controlled weight loss compared to DM-SED, but did not prevent alteration in the CrCl/BW. However, the effect of the EXE was strikingly observed in the reduction in both, mean uProt excretion (60% and 25%) and in inflammatory factors comparing DM-SED vs. DM-EXE. Therefore, preliminary data suggest that aerobic exercise can reduce proteinuria, renal fibrosis and inflammatory factors in diabetic animals and consequently diminish potential effects caused by diabetic and potentially could reduce the progression to renal failure

Quercetin Ameliorates Podocyte Injury by Inhibiting the ERK Signaling Pathway in Rats with Diabetic Nephropathy Fanfan Gao, Hongli Jiang. *Dialysis Centure of First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: An increasing number of investigations revealed that podocytes play a crucial role in the development and progression of diabetic nephropathy (DN). Quercetin, an antioxidant, may be a potential alternative to ameliorate podocyte injury in DN rats. The aim of this study was to investigate the protective effect and underlying mechanism of quercetin on podocyte injury in rats with diabetic nephropathy.

Methods: SD rats (180-200g) were randomly divided into four groups: normal control (NC, n=10), diabetic nephropathy (DN, n=10), DN treated with low-dose quercetin (DN+LQ, n=10) and DN treated with high-dose quercetin (DN+HQ, n=10). Diabetic nephropathy was induced by intraperitoneal injections of streptozotocin(STZ) (60mg/kg). DN+LQ rats were treated with 50mg/kg/d quercetin by gavage, DN+HQ rats were treated with 100mg/kg/d quercetin by gavage, NC and DN rats were treated with 100mg/kg/d DMSO by gavage. Blood glucose and body weight were obtained every two weeks, microalbuminuria and urine creatinine were obtained every four weeks. All animals were sacrificed after 12 weeks of treatments.

Results: In the present study, the levels of blood glucose, kidney hypertrophy index, microalbuminuria, SCr, BUN, TG were markedly increased in rats with STZ injection compared with NC rats, expectedly, these alterations were less intense in animals treated with quercetin. The picture of electron microscope showed foot process fusion in DN rats, while quercetin markedly inhibited foot process infusion. Immunohistochemical and western blotting results showed that the expression of nephrin and podocin in DN rats was significantly decreased, the expression of desmin, ERK, p-ERK in DN rats was significantly increased, whereas quercetin reversed these above changes. Additionally, the contents of nephrin and podocin in urine of DN rats were markedly higher than that of NC rats, while the contents of GSH and SOD in serum and kidney tissue of DN rats were significantly lower than that of NC rats. However, quercetin decreased the contents of nephrin and podocin in urine and increased the contents of SOD and GSH in blood and kidney tissue.

Conclusions: Quercetin treatment effectively ameliorated podocyte injury in rats with DN by inhibiting ERK signaling pathway. The manipulation of quercetin might act as a promising therapeutic intervention for diabetic nephropathy.

FR-PO614

TGF-Beta 1 Signaling May Be Mediated by Lysyl Oxidase-Like 2 in Human Podocytes in Diabetic Condition Beom Jin Lim,[2] Nara Jeon,[3] Hoon Young Choi.[1] *[1]Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seoul, Republic of Korea; [3]Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Lysyl oxidase-like 2 (LOXL2) is a molecule known to be related with invasive growth and metastasis of malignant neoplasm. Recently, LOXL2 has been also reported to play an important role in target organ fibrosis including heart, liver and lung. In this study, we investigated the expression of LOXL2 in human kidney and podocyte, and its contribution to the transforming growth factor beta 1 (TGF-beta1) and collagen expression in podocyte with high-glucose condition.

Methods: We evaluated the expression of LOXL2 in human kidney using immunofluorescence staining. Real-time PCR and western blotting analysis for LOXL2 mRNA and protein expression were performed using cultured human immortalized podocytes. After fully differentiated, cultured human podocytes were exposed to high glucose (HG) for 48 hours. Lenti-virus mediated gene silencing of LOXL2 was done in human podocyte.

Results: By immunofluorescence staining, LOXL2 expression was identified in human glomerulus and was significantly increased in that with diabetic kidney disease compared with normal control. LOXL2 mRNA (2.40±0.15 vs. 1.17±0.11, P<0.05) and protein expression were significantly higher in human podocyte with HG condition than those with normal glucose condition. TGF-beta 1 mRNA expression was also increased in podocyte with HG condition (9.79±0.63 vs. 1.70±0.36, P<0.05). Gene silencing of LOXL2 significantly reduced TGF-beta mRNA and protein expression in human podocytes. Western blot analysis showed that collagen I and phosphorylated Smad2 protein expression were significantly decreased in LOXL2 knock-down podocytes.

Conclusions: Our results showed that TGF-beta 1 signaling may mediated by LOXL2 in podocytes in diabetic condition.

FR-PO615

TGFbeta (TGFb)-Stimulated PI 3 Kinase (PI 3 K)/Akt Downregulates DEPTOR to Increase Podocyte Hypertrophy and Matrix Protein Expression Falguni Das,[1] Nandini Ghosh-choudhury,[1] Balakuntalam S. Kasinath,[2] Goutam Ghosh-Choudhury.[2] *[1]UTHSCSA, SAN ANTONIO, TX; [2]University of Texas Health Science Center, San Antonio, TX.*

Background: TGFb contributes to kidney injury in diabetic nephropathy (DN). mTOR controls renal cell hypertrophy and matrix protein expression. We have recently shown that TGFb regulates the expression of deptor, a negative regulatory component of both mTORC1 and mTORC2. We hypothesized that PI 3 K/Akt signaling may contribute to deptor regulation.

Methods: Recombinant TGFb (2 ng/ml), rat podocytes, pharmacological inhibitors, dominant negative (dn) expression vectors and siRNAs transfection, immunoblotting, immunoprecipitation, protein synthesis and hypertrophy assays, glomeruli from rats with streptozotocin (STZ)-induced DN were employed.

Results: TGFb decreased the expression of deptor in a time-dependent manner, leading to increase in the mTORC1 and mTORC2 activity, as judged by the increase in phosphorylation of their substrates S6 kinase/4EBP-1 (mTORC1) and Akt (Ser-473)/NDRG1 (mTORC2). To explore the mechanism of deptor suppression, we used the PI 3 kinase and Akt inhibitors, Ly 294002 and MK 2206, and PTEN or dominant negative (dn) PI 3 K or dn Akt kinase, which reversed the TGFb-induced deptor downregulation, resulting in inhibition of mTORC1 and mTORC2 activation. TGFb inhibited the deptor-mTOR complex formation in co-immunoprecipitation experiments. Expression of PTEN or dn Akt kinase restored the complex formation in the presence of TGFb. Furthermore, dn PI 3 K or dn Akt kinase significantly inhibited the TGFb-induced hypertrophy. Interestingly, siRNAs against deptor alone induced hypertrophy of podocytes similar to TGFb; additionally they reversed the inhibition of hypertrophy induced by dn PI 3 K or Akt kinase. Moreover, expression of dn PI 3 K or dn Akt kinase significantly inhibited the TGFb-stimulated expression of fibronectin, which was reversed by siDeptor. Finally, we found significantly reduced expression of deptor, concomitant with increased activation of mTORC1 and mTORC2 in the glomeruli of STZ-induced diabetic rats.

Conclusions: Our data for the first time demonstrate the involvement of PI 3 K/Akt signaling in the suppression of deptor by TGFb to maintain high mTOR activity necessary for renal cell hypertrophy and matrix protein expression.

The Impact of Glucagon-Like-Peptide-1on JAK-STAT Pathway in Diabetic Kidney Disease in db/db Mice and in Endothelial Cells Exposed to a Diabetic Environment Yael Einbinder,[2] Sydney Benchetrit.[1] *[1]Meir Medical Center, Kfar Saba, Israel; [2]Meir Medical Center, Kfar Saba, Kfar Saba, Israel.*

Background: The Janus kinase/signal transducer and transcription activator (JAK/STAT) proteins mediate the actions of many cytokines, chemokines, hormones, and growth factors critical to cell proliferation, differentiation, migration, and apoptosis. This study used db/db mice and endothelial cells (EC) to determine the effect of a diabetic

environment on the JAK-STAT pathway, and to assess the potential effect of GLP-1 analogue in both models.

Methods: C57BL/6 (WT) and BKS.Cg-*Dock7*^{m} +/+ *Lepr*$^{db/db}$ (db/db) mice were randomized to WT group, db/db mice (diabetic control group) and db/db mice treated with GLP-1 analog (Liraglutide) for 14 weeks. The kidneys were then perfused and removed for mRNA, protein analysis and Immunohistochemistry. EC obtained from Human umbilical vein were stimulated with AGE-HSA, glucose and GLP-1 for 24 hours.

Results: p-STAT3 (Ser 727) and p-STAT3 (Tyr 705) were significantly up-regulated in control db/db mice compared to WT mice. GLP-1 analog significantly down-regulated p-STAT3 (Ser 727, Tyr 705) protein expression compared to control db/db mice. P-STAT3 was mainly expressed in the glomeruli, while p-JAK2 was expressed in the tubules also. In EC stimulated with diabetic environment p-STAT3 (Tyr 705) and JAK2 were up regulated while GLP-1 analog significantly down-regulated there expression. The GLP-1 analog inhibited the target gene SIRT1 in db/db mice and in EC culture.

Conclusions: JAK-STAT pathway is activated in experimental models of diabetes mellitus. The GLP-1 analogue (liraglutide) inhibited STAT3 and JAK2 expression in db/db mice and in EC culture possibly through inhibition of SIRT1.

FR-PO617

Uromodulin Proteolytic Processing Is Altered in Youth with Type 1 Diabetes Julie Anh Dung Van,[4] Anne-Christin Hauschild,[3] Ihor Batruch,[1] Eleftherios P. Diamandis,[2] James W. Scholey,[4] Ana Konvalinka.[4] *[1]Mount Sinai Hospital, Toronto, ON, Canada; [2]Mount Sinai Hospital and University Health Network, Toronto, AB, Canada; [3]Princes Margaret Cancer Center, Toronto, Ontario, ON, Canada; [4]University of Toronto, Toronto, ON, Canada.*

Background: Dysregulated proteolytic activity in the kidney may induce early functional and structural changes in type 1 diabetes, and this activity may be specific to some proteases and their protein substrates. Thus, peptides generated within kidney may be excreted into the urine and provide a footprint of intrarenal proteolysis. We aim to compare urinary peptidomes of youth with type 1 diabetes in relation to healthy peers and to infer protease activity in the kidney from differentially excreted peptides.

Methods: We obtained second-morning, midstream urines from 15 cases with type 1 diabetes and 15 age- and sex-matched healthy controls. Urine volumes normalized to creatinine were subjected to 10kDa ultrafiltration to isolate naturally occurring peptides. Peptides were then fractionated and analyzed on Q-Exactive mass spectrometer. MaxQuant software was used for peptide identification and label-free quantification. Proteasix, an online tool, was used to predict proteases responsible for generating differentially excreted peptides.

Results: A total of 6323 naturally occurring peptides were quantified. Of these, 163 peptides were consistently detected across all thirty urine samples. Five peptides from this subset were differentially excreted between the groups (FDR, $q < 0.05$), and they derived from regions near the C-terminus of uromodulin and clusterin. Peptide intensities strongly correlated with glycated hemoglobin and blood glucose, and only weakly so with albumin/creatinine ratio. Interestingly, urinary excretion of the uromodulin protein was not different between groups, suggesting an increase in proteolysis of uromodulin in the kidney. The top predicted proteases included hepsin, neutrophil elastase, and plasmin.

Conclusions: Our analysis of the urinary peptidome revealed early differences in the excretion rates of uromodulin peptides in adolescents with diabetes in the absence of microvascular complications, compared to healthy age-matched subjects. We conclude that sustained hyperglycemia is associated with early activation of proteolytic enzymes in the kidney before the onset of microalbuminuria.

FR-PO618

Puerarin Attenuates Diabetic Kidney Injury through Suppression of NOX4 Expression in Podocytes Yifei Zhong,[1] Ruijie Liu,[2] Kyung Lee,[2] John C. He.[2] *[1]Longhua Hospital, Shanghai University of Traditional Chinese Medicine, China, Shanghai, China; [2]Mount Sinai School of Medicine, New York, NY.*

Background: *Radix puerariae*, a traditional Chinese herbal medication, has been used to treat patients with diabetic nephropathy (DN). Several studies demonstrated that puerarin, the active compound of *radix puerariae*, improves DN in streptozotocin (STZ)-induced rat and mouse models. However, as STZ injection alone results in mild kidney injury, the mechanisms of renoprotection afforded by puerarin remained inconclusive. Therefore in this study, we sought to clarify the role of puerarin by employing a STZ-induced diabetes in the mice lacking the endothelial nitric oxide synthase, which develop more advanced DN, and explored the mechanism of puerarin in cultured podocytes.

Methods: Diabetes was induced in the male eNOS homozygous knockout mice of 8 weeks old on a C57BL/6 background by injecting streptozotocin for 5 consecutive days. 2 weeks after diabetes was confirmed in mice, mice were given puerarin (Sigma-Aldrich) by oral gavage at a dose of 20mg/kg body weight/day, or vehicle as control, for 8 weeks. Urine albuminuria, kidney histology, IHC, and qPCR of isolated glomeruli were analyzed as desscribed. Conditionally immortalized murine podocytes were obtained from Dr. Peter Mundel. Podocytes were transfected using Viafect reagent and ROS and NAPDH oxidase activity were measured accordingly.

Results: Puerarin treatment of diabetic eNOS$^{-/-}$ mice significantly improved albuminuria and diabetic kidney injury. Puerarin also significantly reduced oxidative stress and inhibited the expression of NAPDH oxidase 4 (NOX4) in glomeruli of diabetic mice. In cultured conditionally immortalized murine podocytes, puerarin reduced superoxide production, as well as NOX4 expression at both mRNA and protein levels. Interestingly, we found that puerarin increased both mRNA and protein levels of Sirt1 in podocytes. Indeed, puerarin suppressed NOX4 expression through Sirt1-mediated deacetylation of NF-κB.

Conclusions: Our findings confirm the renal protective effects of puerarin in an animal model with more advanced DN and demonstrate a new mechanism that underlies the anti-oxidative effects of puerarin in kidney podocytes.

Deficient of Endothelial Function Exacerbates NLRP3-Inflammasome Activation in Podocyte of Diabetic Nephropathy Hajime Nagasu,[2] Yuji Sogawa,[1] Kengo Kidokoro,[2] Minoru Satoh,[2] Tamaki Sasaki,[2] Naoki Kashihara.[2] *[1]Kawasaki Medical School, Kurashiki, Japan; [2]Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Japan.*

Background: Previous studies have indicated that 30–40% of patients with type 1 DM develop overt nephropathy, but the detailed mechanism is not clear. Reactive oxygen species (ROS) are excessively produced in DM, and ROS production exacerbates nephropathy. We reported that the uncoupling of endothelial nitric oxide (NO) synthase (eNOS) is the source of glomerular ROS production. While NLRP3 inflammasome activation in podocytes plays an important role in the progression of DKD, whereas NO regulates inflammasome activation. However, it is unclear how the NLRP3 inflammasome is regulated in the kidney. In this study, we determined if eNOS/NO signaling suppresses inflammasome activation in DKD.

Methods: We used wild-type (WT) and eNOS-deficient mice (eNOSKO) to determine the role of the eNOS-NO pathway. Diabetes was induced by a single intraperitoneal injection of streptozocin (STZ; 65 mg/kg body weight). Subsequently, we divided mice into four groups: WT, WT-STZ, eNOSKO, and eNOS-STZ. Four weeks after the induction of DM, the mice were sacrificed, and their kidney tissues were harvested. Urinary albumin excretion was checked before the sacrifice, and glomerular damage was assessed by PAS staining. Next, the localization of inflammasome activation in glomeruli was evaluated with immunohistochemical analyses. To investigate inflammasome activation in glomeruli, glomeruli were isolated from the kidney tissue by using Dynabeads. The mRNA expression of inflammasome components NLRP3, IL-1β, and IL-18 were checked with real-time quantitative PCR.

Results: Urinary albumin excretion was increased in WT-STZ compared with WT. These urinary albumin excretions were increased much more in eNOS-STZ than in WT-STZ. The glomeruli were more damaged in eNOS-STZ compared with WT-STZ. In immunohistochemical analyses, the expression of ASC coexisted with podocytes detected by podocalyxin staining in eNOS-STZ. These data suggested that the NLRP3 inflammasome activation was located in podocytes. In isolated glomeruli, the mRNA of the inflammasome components were higher in eNOS-STZ than in WT-STZ.

Conclusions: eNOS/NO signaling attenuates glomerular injury in diabetic mice via suppression of inflammasome activation.

An N-Terminal Truncated Intracellular Isoform of Matrix Metalloproteinase-2 Is Induced by Hyperglycemia and Activates a Primary Innate Immune Response In Vitro Sang Heon Song,[2] In seong Park,[2] Miyeun Han,[2] Harin Rhee,[2] Eun Young Seong,[2] Dong Won Lee,[3] Soo Bong Lee,[3] Ihm Soo Kwak,[2] David H. Lovett.[1] *[1]Internal Medicine, University of California San Francisco, San Francisco, CA; [2]Internal Medicine, Pusan National University Hospital, Busan, Republic of Korea; [3]Pusan National University School of Medicine, Yangsan, Republic of Korea.*

Background: We have reported that matrix metalloproteinase-2 (MMP-2) exists in two discrete isoforms. The first consists of the classical full length isoform (FL-MMP-2) which is secreted as a latent proenzyme. A second novel isoform is generated by oxidative stress-mediated activation of an alternate promoter in the distal first intron of the MMP-2 gene. This results in synthesis of an N-terminal truncated isoform (NTT-MMP-2) that is intracellular, enzymatically active and concentrated within mitochondria. NTT-MMP-2 triggers mitochondrial-nuclear stress signaling via *NF-kB* transcriptional cascades. Renal proximal tubule-specific transgenic expression of the NTT-MMP-2 isoform results in regulated necrosis, activation of innate immunity and enhanced sensitivity to ischemia/reperfusion injury. In this study we examined the relationship between hyperglycemia and the induction of NTT-MMP-2 and innate immunity genes using the human HK2 proximal tubule cell line.

Methods: We manufactured the specific siRNA for NTT-MMP-2 and tested the inhibitory efficacy of NTT-MMP-2 for innate immunity-related genes using quantitative PCR in HK2 cells with high glucose stimulation.

Results: High glucose medium (30 mM) induced a 1.65±0.06 and a 3.20±0.18 fold increase in FL-MMP-2 and NTT-MMP-2 synthesis as determined by qPCR, respectively ($p<0.05$ for each). High glucose medium also resulted in statistically significant increases in the expression of the innate immunity genes *IFIT1, IRF7, IL6 and CXCL1* including *NF-kB.* To determine the relationship between high glucose medium enhanced NTT-MMP-2 and innate immune gene expression we developed an NTT-MMP-2 specific siRNA that targets the unique 5'UTR of this gene. Selective siRNA targeting inhibited high glucose mediated NTT-MMP-2 expression to 0.81±0.75 fold ($p<0.01$), with no effect on FL-MMP-2 expression (1.33±0.28 fold, $p>0.05$) compared with negative control. The selective NTT-MMP-2 siRNA suppressed high glucose mediated *NF-kB* expression, as well as *IFIT1, IRF7, IL6 and CXCL1.*

Conclusions: We conclude that selectively targeting NTT-MMP-2 with a siRNA approach offers a therapeutic approach for reduction of tubular epithelial cell necrosis and activation of innate immunity in the setting of diabetes mellitus.

TRAP Analysis of Podocyte Gene Expression in Diabetic Nephropathy

Yinqiu Wang, Ming-Zhi Zhang, Kasey C. Vickers, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease, and podocyte injury plays a critical role in its development. To better understand the role of podocytes in DN, we have utilized Translating Ribosome Affinity Purification (TRAP) to analyze mRNA translation in podocytes isolated from kidneys of mice with early onset of diabetes.

Methods: TRAP allows for the isolation and quantification of cell-specific active mRNA translation. We utilized a podocin-Cre transgene for podocyte-specific activation of a TRAP allele ($Rosa26^{fsTRAP}$). Translated mRNAs were quantified by high-throughput rRNA-depleted total RNA sequencing. To determine responses to early diabetes, mice were made diabetic with streptozotocin and mRNA was isolated 3 weeks after onset of hyperglycemia. To date, 9 diabetics (5 female, 4 male) and 9 controls (3 female, 6 male) have been studied.

Results: With TRAP isolation, mRNA of podocin and nephrin, two podocyte markers, were enriched 50 to 70 -fold. Overall, 1255 genes were upregulated >1.5 fold and 406 genes were downregulated >1.5 fold. However, there were marked sex differences in male vs. female: Up: 1292 vs. 413; Down: 580 vs. 350; 100 genes were up and 40 genes were down in both sexes. Unlike females, in males, predominant clusters of upregulated genes were related to cell cycle, cell division and apoptosis. In both sexes, there were gene clusters related to inflammation and alterations in cell metabolism. Of interest, both sexes had increased gene clusters related to cell responses to interferons.

Conclusions: Analysis of translated mRNA from podocytes after early onset of a model of type I diabetes indicates significant differences between sexes, with evidence of more dedifferentiation and injury in males. Our ongoing studies in mice with more established DN and in models of type II diabetes should provide further insight into podocyte injury and gender responses.

FR-PO622

High Intensity Interval Training (HIIT) Attenuates Proteinuria and Improves Physical Capacity in STZ Diabetic Rats

Natalia Reinecke,[3] Rafael Luiz,[2] Alexandre Saud,[3] Rodolfo R. Rampaso,[2] Wesley Silva,[5] Samuel T. Filho,[5] Waldemar S. Almeida,[1] Nestor Schor.[4] *[1]EPM/UNIFESP, São Paulo, Brazil; [2]None, São Paulo, Brazil; [3]UNIFESP, Sao Paulo, Brazil; [4]Universidade Federal de Sao Paulo/Escola Paulista de Medicina, Sao Paulo, Brazil; [5]Universidade Federal de São Paulo, Sao Paulo [SP], Brazil.*

Background: The insertion of Diabetic patients on a physical training program is a challenge, given that 'lack of time' is one of the most cited barriers. HIIT has demonstrated to have several benefits to these subjects, even requiring a lower commitment time than current recommendation of exercise for this population. The purpose of this investigation was to examine the effects of HIIT on renal function and physical capacity in STZ Diabetic rats and compare these results with the effects of endurance moderated exercise.

Methods: Wistar rats were divided into four groups 6-8 animals: Sedentary Control(SC), Sedentary Diabetic(SD), Diabetic Endurance(DE) and Diabetic HIIT(DH). DH group were submitted to following protocol: 10bursts of 1min(90% of maximal test) intersected with 10 periods of low intensity walking(40% of maximal test) 3days/wk, 8weeks total. Endurance training consisted of 60min of moderated exercise(60% of maximal test) 5days/wk, 8weeks total. Diabetes was induced by a single STZ injection(50mg/kg i.v.). At the end of protocol animals underwent to an Ergospirometry test to detect the peak of oxygen consumption(VO_{2peak}).

Results: HIIT improved Exercise Capacity(VO_{2peak}:48±16 vs 32.8±7ml/kg/min, DH vs SD,p<0.05) as well as Endurance training(VO_{2peak}:53.1±11 vs 32.8±7ml/kg/min, DE vs SD,p<0.05). HIIT, but not Endurance training, attenuated the increase in proteinuria caused by Diabetes in comparison to SD(9.9±6 vs 19.6±1.9mg/dL/24h, p<0.05, respectively). Both training attenuated the increase in urinary volume, water ingestion, Serum Urea and partially prevent low Creatinine Clearance(CrCl) when compared to SD.

Conclusions: Results of this study show that HIIT can improve exercise capacity, partially prevent low CrCl and attenuate the increase in proteinuria and in other diabetic symptoms as polyuria and polydipsia. These data suggests that HIIT can be a time-efficient adjunct treatment to minimize Diabetes complications.

Investigation of Protein Tyrosine Phosphatase, Non-Receptor Type 2 (PTPN2) and Its Interaction with Vitamin D Receptor (VDR) in Inflammation of Type 2 Diabetes Mellitus

Li Zheng, Wei Zhang, Hao Zhang. *Nephrology, The Third Xiangya Hospital of Central South University, Changsha, China.*

Background: To investigate the role of protein tyrosine phosphatase nonreceptor type 2 (PTPN2) in the inflammation of type 2 diabetes mellitus (T2DM) and its interaction with vitamin D receptor(VDR).

Methods: 101 T2DM patients were divided into three groups based on urinary albumin-to-creatinine ratio (uACR):normal albuminuria(30mg/g>uACR,n=29), microalbuminuria(30mg/g≤uACR<300mg/g,n=34), and macroalbuminuria(uACR≥300mg/g,n=38), with healthy individuals(n=18) as controls. Serum from these objects were analyzed for PTPN2 protein. Peripheral blood mononuclear cells (PBMCs) were cultured ex vivo to analyzed for PTPN2 and VDR in both protein and mRNA level. HK2 and THP1 cell were stimulated with tumor necrosis factor (TNF) or high glucose and treatment with paricalcitol. The expression of PTPN2 and VDR was analyzed by real-time PCR and Western blotting. The release of IL-6 and MCP-1 were analyzed by real-time PCR and ELISA after PTPN2 silencing or overexpression.

Results: PTPN2 expression was down-regulated in serum and PBMCs from T2DM patients with albuminuria and same with VDR expression in PBMCs. PTPN2 levels were negatively correlated with uACR. Logistic regression analysis revealed that PTPN2 down-regulation was an independent risk factor for the increase in uACR; PTPN2 expression was positively correlated with VDR expression in the PBMCs from T2DM patients. Stimulation of TNF-α or high glucose could both decrease the expression of PTPN2 and VDR in both protein and mRNA level in cultured HK2 and THP-1 cell, while treatment with paricalcitol can reverse the down-regulation of PTPN2 as well as VDR. After PTPN2 silencing in HK2 and THP-1 cell can significantly increased the production of the inflammatory cytokine IL-6 and chemokines MCP-1. Moreover, high PTPN2 levels contributed to decline the elevated IL-6and MCP-1. But treatment with paricalcitol after PTPN2 silencing could not reverse the up-regulation of IL-6 and MCP-1.

Conclusions: Down-regulation of serum PTPN2 is independently with the severity of albuminuria in T2DM.PTPN2 has anti-inflammatory activities in T2DM and the inflammation regulatory role may be associated with the Vitamin D/VDR pathway.

Advanced Glycation End Products (AGEs) Interrupted Podocyte Autophagy Flux through mTOR Activation

Xingchen Zhao, Yuanhan Chen, Xinling Liang, Wei Shi. *Guangdong General Hosiptial, Guangzhou, China.*

Background: Insufficient podocyte autophagy exacerbates podocyte injury and renal dysfunction under diabetic conditions. AGEs are a classic pathogenic factors under diabetic conditions. In present study, we studied the role of AGEs on podocyte autophagy and its underlying mechanism.

Methods: Db/db mice were gavaged by Pyridoxamine(inhibitor of AGE formation) to mimic diabetic conditions with low- AGEs serum levels. Autophagy were examed by Western blotting, immunofluorescent staining, transmission electron microscopy.

Results: 1. AGE inhibited podocyte autophagy and led to podocyte injury in vivo and in vitro (FIG 1A-D). 2. We further found that AGE blocked autophagy flux via interfering the formation of autophagosme, fusion of autophasome and lysosome in cultured podocyte(FIG1 E-F). 3. mTOR is an important autophagy negative regulator. Next, we found AGE activated mTOR activity in vivo and in vitro. mTOR activation mediated AGE-induced podocyte autophagy inhibition in vivo and in vitro(FIG2).

Conclusions: AGE interrupted podocyte autophagy flux through mTOR activation.

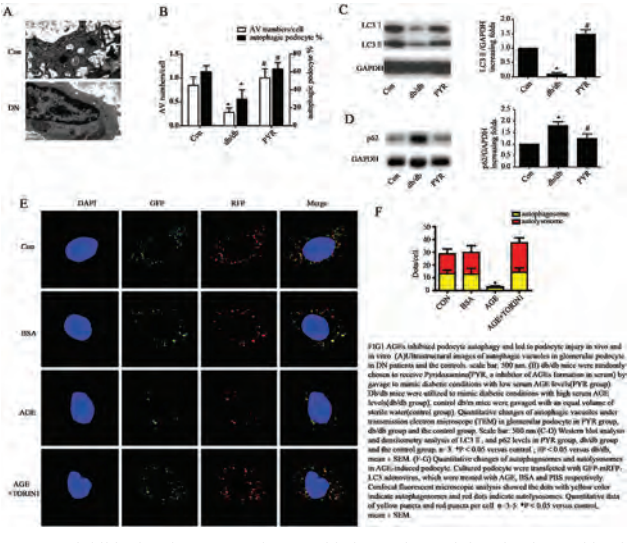

FIG1 AGEs inhibited podocyte autophagy and led to podocyte injury in vivo and in vitro

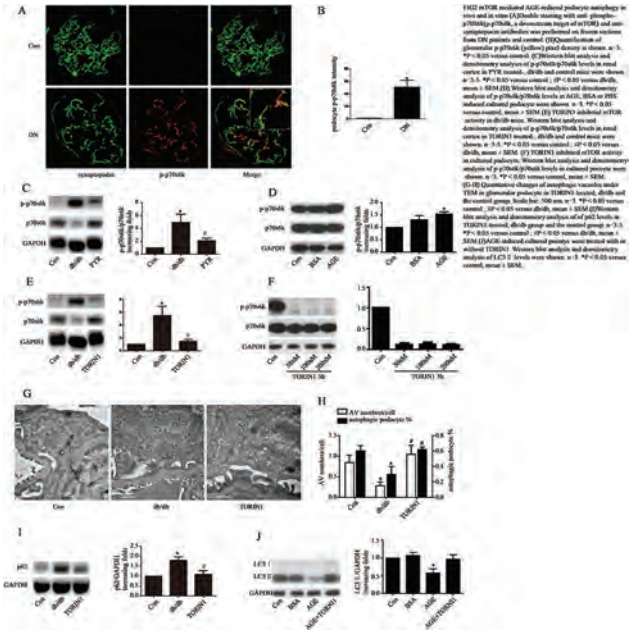

FIG2 mTOR mediated AGE-reduced podocyte autophagy in vivo and in vitro

FR-PO625

Endogenous Klotho May Play Direct Roles in the Pathogenesis of Diabetic Vascular Disease Langjing Zhu,[2,3] Qinghua Liu,[3,2] Yan Ding,[3] Yu-Chun Chang,[3] Li-Li Hsiao.[1] *[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Shenzhen, China; [3]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Diabetes is a known risk factor for cardiovascular disease (CVD) and chronic kidney disease. Dysfunction of vascular smooth muscle cells (VSMCs) plays a key role in the pathogenesis of diabetic vascular disease, which requires the migration and proliferation of VSMCs as well as the production of biological mediators such as TGF-β1, Fractalkine, and matrix metalloproteinases (MMPs). We previously showed that endogenous Klotho is a master regulator of CVD by reducing vascular calcification in the VSMC layer. This study aims to explore the functional roles of endogenous Klotho in the pathogenesis of diabetic vascular disease.

Methods: Diabetic model is created using Human Aortic-SMCs (HA-SMCs) with D-glucose under dose-response (5.5mM, 25mM, 35mM, and 50mM) and time-dependent fashion (0 day to 10 days); mannitol (35mM and 50mM) is used to assess the osmotic effects. Expression of endogenous Klotho, TGF-β1, Fractalkine, MMP2, and MMP9 are assessed by Western blot. The direct effects of endogenous Klotho are achieved by Klotho-siRNA and Klotho-plasmid transfection. MTS assay is used to assess the cell proliferation, flow cytometry with propidium iodide staining is used to study cell cycle, and the wound-healing migration assay is for the migratory activity.

Results: The Klotho expression in HA-SMCs is upregulated by high glucose (HG) in a dose-dependent manner; and the expression peaks at day 3 with 35mM D-glucose treatment. However, the Klotho expression is not affected by mannitol, indicating that differential expression of klotho is not caused by hyperosmolarity. HG (35mM D-glucose) also upregulates the expression of TGF-β1, Fractalkine, MMP2, and MMP9, which are further enhanced under the Klotho deficiency state using Klotho-siRNA transfection, and mitigated by Klotho over-expression using Klotho-plasmid transfection. Neither HG nor Klotho has effects on the migration or proliferation of HA-SMCs.

Conclusions: HG regulates the expression of endogenous Klotho and in an unique diphase pattern. Endogenous Klotho may play direct roles in the pathogenesis of diabetic vascular disease using the knock-down and knock-in Klotho system, which suggest that Klotho may serve as a potential treatment target in diabetic vascular disease.

FR-PO626

Renal and Cardiovascular Dysfunction in db/db Diabetic Mice Is Associated with Increased Cardiac Angiotensin Converting Enzyme 2 (ACE2) and Neprilysin (NEP) Rucha Fadnavis, Meenasri Kumbaji, Salim El-Amouri, Nadja Grobe, Khalid M. Elased. *Wright State University, Dayton, OH.*

Background: The prevalence of diabetic kidney disease (DKD) has increased in the recent decades and is considered one of the main causes of ESRD. DKD is also a major risk factor for cardiovascular diseases. Proteinuria is now widely accepted as an independent risk factor for cardiovascular morbidity and mortality. The renin angiotensin system (RAS) plays an important role in regulating both the renal and cardiovascular systems. The deleterious actions of Ang II are antagonized by Ang (1-7), which is generated by ACE2 and NEP. ACE2 and NEP are multifunctional enzymes and their shedding in the urine have emerged as early biomarkers for DKD. ACE2 has been shown to have renoprotective and cardioprotective role in diabetic mice. In addition, a combination of AT1 receptor blockade and NEP inhibition, Sacubitril-Valsartan is used for management of heart failure. The aim of this study was to investigate whether shedding of urinary ACE2 and NEP could be a predictor of cardiovascular disease and index of intra cardiac ACE2 and NEP status in *db*/*db* diabetic mice.

Methods: Radio-telemetry was used to measure blood pressure. Control and diabetic *db/db* mice (8 weeks) were treated with pioglitazone (20mg/Kg/day) for 10 weeks. Western blot, immunostaining and RAS enzyme assays were used to study renal, urinary and cardiac protein expression and activities.

Results: *db*/*db* mice are normotensive at the ages of 8-12 weeks. There were no significant differences in cardiac ACE2 and NEP between *db*/*db* and control mice. However, at 18 weeks, *db*/*db* mice developed albuminuria and hypertension. In addition, at this age there was a significant increase in urinary and cardiac ACE2, NEP expression and activity. Pioglitazone treatment of *db*/*db* diabetic mice normalized hyperglycemia and attenuated albuminuria. In addition, pioglitazone increased expression and activity of cardiac ACE2 whereas it decreased expression and activity of cardiac NEP compared to untreated *db*/*db* mice.

Conclusions: Pioglitazone treatment could be used as a renoprotective and cardioprotective since it attenuated albuminuria, increased cardiac ACE2 and decreased cardiac NEP. Increased urinary ACE2 and NEP could be used to predict alteration of cardiac RAS status and possible risk of cardiovascular diseases.

FR-PO627

Increased Phosphorylation of the Ubiquitin Ligase Kelch-Like 3 in the Kidney of Db/Db Mice Shigeru Shibata,[2] Kenichi Ishizawa,[2,1] Yoshikazu Nemoto,[2] Chikayuki Morimoto,[2] Shunya Uchida.[2] *[1]Shinsen-Ikebukuro Clinic, TOKYO, Japan; [2]Teikyo University School of Medicine, Tokyo, Japan.*

Background: Although clinical studies have shown that diabetic patients display salt-sensitive hypertension, its pathogenesis remains unclear. Kelch-like 3 (KLHL3) is a component of an E3 ubiquitin ligase complex that regulates blood pressure by targeting With-No-Lyisne (WNK) kinases for degradation. Mutations and inactivation of KLHL3 cause hypertension resulting from increased Na-Cl cotransporter (NCC) activity in the kidney. Previously, we have reported that angiotensin II (Shibata et al. PNAS 2014) and potassium depletion (Ishizawa et al. BBRC 2016) inactivate KLHL3 by protein kinase C (PKC)-mediated phosphorylation at S433 in the Kelch-domain, thereby contributing to blood pressure elevation. In this study, we examined the possible involvement of KLHL3 in the diabetic kidney using a model of type 2 diabetes.

Methods: We examined the expression levels of total KLHL3 and KLHL3 phosphorylated at S433 ($KLHL3^{S433\text{-}P}$) in the kidney of Db/+ and Db/Db mice. We also determined the levels of Cl transporters including NCC, Na-K-2Cl cotransporter NKCC2, and Cl/HCO_3 exchanger pendrin in the membrane fraction of the kidney in this model.

Results: Western blotting revealed that $KLHL3^{S433\text{-}P}$ levels were significantly increased in the kidneys of Db/Db mice (2.2-fold increase versus Db/+ mice; $P < 0.01$), which was associated with the increased levels of WNK1/4. Moreover, NCC levels in the membrane fraction were significantly higher in Db/Db mice than Db/+ mice **(**2.3-fold increase, $P < 0.01$**)**. Interestingly, NKCC2 was also increased, whereas pendrin was decreased in Db/Db mice. The decreased pendrin in this model was associated with the increased levels of inactive, phosphorylated form of mineralocorticoid receptor in the kidney. To determine the mechanism for the increased $KLHL3^{S433\text{-}P}$ levels, we evaluated PKC activity in the kidney. Of note, active, phosphorylated PKC was increased in Db/Db mice, explaining the $KLHL3^{S433\text{-}P}$ induction in this model.

Conclusions: These data indicate that the inactivation of KLHL3 is involved in the increased NCC activity in Db/Db mice, and suggest that KLHL3 is involved in the pathogenesis of salt-sensitive hypertension in type 2 diabetes.

Insulin Stimulates Urate Transporter 1 (URAT1) and Uric Acid Reabsorption Shigeru Shibata,[2] Daigo Toyoki,[2] Emiko Kuribayashi-Okuma,[2] Yoshikazu Nemoto,[2] Chikayuki Morimoto,[2] Yoshifuru Tamura,[2] Makoto Hosoyamada,[1] Shunya Uchida.[2] *[1]Teikyo University Faculty of Pharma-Sciences, Tokyo, Japan; [2]Teikyo University School of Medicine, Tokyo, Japan.*

Background: Accumulating data indicate that renal uric acid (UA) handling is altered in diabetes. In addition, hyperinsulinemia is associated with hyperuricemia and hypouricosuria. However, the underlying mechanisms remain unclear. In this study, we aimed to investigate how diabetes and insulin alter the levels of renal UA transporters.

Methods: Sprague-Dawley (SD) rats received intraperitoneal injection of streptozotocin. The rats were confirmed to be diabetic by measuring blood glucose after 72 hours (glucose levels > 250 mg/dl). Some rats received subcutaneous infusion of insulin *via* an osmotic minipump (3 U/day). In a separate experiment, non-diabetic SD rats received a low dose of insulin (0.75 U/day). We also performed in vitro experiments using NRK-52E cells, the rat kidney epithelial cell line.

Results: In insulin-depleted diabetic rats with streptozotocin treatment, both UA excretion and fractional excretion of UA (FEUA) were increased, suggesting that tubular handling of UA is altered in this model. In the membrane fraction of the kidney, the expression of urate transporter 1 (URAT1) was significantly decreased, whereas that of ATP-binding cassette sub-family G member 2 (ABCG2) was increased, consistent with the increased renal UA clearance. Importantly, administration of insulin (3 U/

day) to the diabetic rats decreased UA excretion and alleviated UA transporter level changes. To confirm the contribution of insulin in the regulation of urate transporters, normal rats received a low dose of insulin (0.75 U/day). Of note, insulin significantly increased URAT1 and decreased ABCG2 levels, resulting in increased UA reabsorption. Furthermore, URAT1 was present in NRK-52E cells, and the addition of insulin to the medium significantly increased the endogenous URAT1 levels in the membrane fraction of NRK-52E cells.

Conclusions: These results suggest a previously unrecognized mechanism for the anti-uricosuric effects of insulin, and provide novel insights into the renal UA handling in the diabetic state.

FR-PO629

Diabetes Aggravate Post-Ischemic Renal Fibrosis through Persistent Activation of Sonic Hedgehog Signaling Sang-Ho Lee,[3] Dong-Jin Kim,[4] Jun mo Kang,[5] Seon hwa Park,[3] Seok jong Song,[3] Su-Mi Kim,[2] Seo Jung-Woo,[2] Yu ho Lee,[3] Yang gyun Kim,[1] Ju young Moon,[3] So-young Lee.[5] *[1]Division of Nephrology Department of internal medicine Kyung Hee University College of Medicine, Seoul, Republic of Korea; [2]Kyung Hee University, Seoul, Republic of Korea; [3]Kyung Hee University Hospital at Gangdong, Seoul, Korea, Seoul, Republic of Korea; [4]KyungHee University, Seoul, Republic of Korea; [5]Bundang CHA Medical Center, CHA Univ., Bundang, Republic of Korea.*

Background: Diabetes has a high risk for chronic kidney disease (CKD) and increases the severity of acute kidney injury (AKI). AKI induces renal fibrosis, known as a key feature of CKD, and renal fibrosis is associated with transforming growth factor-β1 (TGF-β1) and sonic hedgehog (Shh) signaling pathway. However, it is not known whether diabetes accelerates CKD progression via Shh signaling after AKI. Here, we investigated the influence of diabetes on CKD progression after AKI.

Methods: We established unilateral renal ischemia–reperfusion injury (IRI) model in streptozotocin induced diabetic mice. Histological changes in the kidney were evaluated at 3 and 5 weeks after IRI. The expression levels of mRNAs and proteins related to fibrosis and inflammation were determined by qRT-PCR and western blot. The effect of hyperglycemia on the epithelial-mesenchymal transition (EMT) induced by TGF-β1 and Shh signaling pathway was demonstrated in HKC-8.

Results: When comparing between 3 and 5 weeks after IRI, there was no improvement of tubulointerstitial injury in diabetes. Renal fibrosis was significantly higher in diabetes than in non-diabetes at 5 weeks after IRI. The pattern of infiltrated T and B cell was also consistent with that of renal fibrosis. The mRNA and protein expression levels of related TGF-β1 and Shh signaling pathway were significantly higher in the diabetic IRI kidneys than in the non-diabetic IRI kidneys. In vitro, Hyperglycemia led to the expression levels of TGF-β1 and Shh, and then interacted with each other for the progression of fibrosis.

Conclusions: Taken together, we demonstrated that diabetes on IRI induced the persistent activation of TGF-β1 and Shh signaling pathway and aggravate the interstitial renal fibrosis. In addition, the susceptibility to TGF-β_1 and Shh was increased by hyperglycemia in renal tubular cells.

FR-PO630

Clusterin Is Increased in Glomeruli of Patients with Diabetic Nephropathy and after Induction of Damage in Podocytes In Vitro Junling He, Pascal Bus, Kimberley Veraar, Marion Scharpfenecker, Jan A. Bruijn, Hans J. Baelde. *Department of Pathology, Leiden University Medical Center, Leiden, Netherlands.*

Background: Clusterin is a glycoprotein which is ubiquitously expressed in many tissues, including the kidney. It is demonstrated that clusterin plays a role in apoptotic processes, and it is suggested to have protective properties on cells. The expression of clusterin has been reported to be up-regulated in diverse kidney injuries. In this study, we investigated whether clusterin is upregulated in glomeruli of diabetic nephropathy (DN), where clusterin is expressed in the glomeruli, and how clusterin is regulated under diabetic conditions.

Methods: Clusterin mRNA analysis was performed on kidney cortex and micro-dissected glomeruli from patients with DN (n=24), non-diabetic subjects were used as control (n=11). Clusterin protein expression was assessed by immunohistochemistry on renal tissue from patients with DN and non-diabetic subjects. Kidneys of streptozotocin-induced diabetic mice(n=10) and non-diabetic control mice (n=10) were sequentially stained for clusterin and WT1 (a podocyte marker). Furthermore, human podocytes (Moin Saleem, Bristol, UK) were cultured and incubated with glucose, VEGF-A, angiotensin II and puromycin aminonucleoside (PAN). qPCR was performed to investigate the regulation of clusterin under these diabetic conditions.

Results: Compared to non-diabetic subjects, clusterin mRNA expression was significantly increased in both glomeruli (2.3 times) and whole kidney lysates (3.6 times) of patients with DN ($p<0.05$). Clusterin protein levels were also increased in glomeruli of patients with DN compared to non-diabetic subjects($p<0.05$). Similar results were found in glomeruli of diabetic mice compared to non-diabetic control mice ($p<0.05$). Interestingly, clusterin partly co-localised with WT-1 in glomeruli of mice. Glucose, VEGF-A, and angiotensin II stimulation did not increase the clusterin mRNA expression in podocytes, whereas PAN-stimulation significantly increased the clusterin mRNA expression ($p<0.05$) *in vitro*.

Conclusions: Our data show that clusterin is increased in glomeruli of patients with DN and in podocytes after PAN-induced damage *in vitro*. Further studies have to elucidate whether clusterin has protective effects on podocytes upon damage during the development of DN.

FR-PO631

Renal-Selective Snx5 Gene Silencing Increases Insulin Resistance and Blood Pressure in Mice Xiaoyan Wang, Laureano D. Asico, Xiaobo Ma, Pedro A. Jose, Van Anthony M. Villar. *George Washington University School of Medicine, Washington, DC.*

Background: We have reported that sorting nexin 5 (SNX5) plays an important role in the positive regulation of insulin receptor expression and function in cultured renal proximal tubule cells and that renal-selective *SNX5* gene silencing increased blood pressure (BP) in WKY rats, via the D_1 dopamine receptor (D_1R).

Methods: In order to test the hypothesis that renal *Snx5* gene silencing increases insulin resistance and BP, we measured BP, blood glucose, serum insulin, urinary insulin excretion, and insulin sensitivity in C57Bl/6J mice treated with a 7-day renal subcapsular infusion of *Snx5*-siRNA; mock-siRNA was used as control (3 μg/kg/day, n=4/group).

Results: *Snx5* siRNA-treated mice had elevated BP (SBP: 119±5.2 *vs*. 101.5±0.5; DBP: 91.8±7.3 *vs*. 72±2.3, mm Hg, under pentobarbital anesthesia), non-fasting blood glucose (214±3 *vs*. 179±8, mg/dl) and fasting serum insulin (1.16±0.17 *vs*. 0.62±0.04, ng/ml) was increased while urinary excretion of insulin (0.15±0.03 vs 0.55±0.13, ng / mg of creatinine) was decreased. In another set of mice (n=4/group) that urine water/sodium excretion, and creatinine clearance between the two groups. Histologically, SNX5 was mainly located in the apical membrane of proximal tubules, thick ascending limbs of loop of Henle, and distal convoluted tubules. SNX5 colocalized with the insulin receptor β (IR-β), insulin-degrading enzyme (IDE), NHE3, NKCC2 and NCC. Renal protein expression (via immunoblotting) of SNX5 (29±10, % of control), IR-β (50±7) and IDE (57±6) were lesser while renal protein expression of NHE3 (172±29), NaPi2 (223±12), NKCC2 (440±12) and NCC (177±23) were greater in SNX5-depleted mice compared to control mice. Renal protein expressions of α/β/γ-ENaC, Na^+K^+ATPase, actin, and renal morphology(via H&E staining and brightfield microscopy) were similar in both groups.

Conclusions: Silencing of renal SNX5 expression with siRNA decreased renal IR-β/IDE and increased sodium transporters in proximal and distal nephron segments. These may impair the regulation of renal D_1R in insulin metabolism and sodium transport and cause increased BP and insulin resistance in SNX5 depleted mice.

Human Mesenchymal Stem Cells Suppress Glucose-Induced Inflammatory Responses of Stable Renal Proximal Tubular Epithelial Cell Monolayers Md nahidul Islam,[1] Tomas P. Griffin,[1,2] Stephanie Rocks,[1] Joana Cabral,[1] Thomas Ritter,[1] Tara McMorrow,[3] Timothy O'Brien,[1,2] Matthew D. Griffin.[1,4] *[1]Regenerative Medicine Institute, School of Medicine, National University of Ireland Galway, Galway, Ireland, Galway, Ireland; [2]Centre for Endocrinology, Diabetes and Metabolism, Galway University Hospitals, Galway, Ireland; [3]School of Biomolecular and Biomedical Science, Conway Institute, University College Dublin, Dublin, Ireland; [4]Department of Nephrology, Galway University Hospitals, Galway, Ireland.*

Background: Renal proximal tubular epithelial cells (RPTEC) are dysfunctional in diabetic kidney disease (DKD). Mesenchymal stem cells (MSCs) may modulate DKD pathogenesis. We aimed to investigate the pro-inflammatory effects of prolonged exposure to high-glucose concentration on RPTECs and to determine whether MSC-derived factors modulate this response.

Methods: Human RPTEC/TERT1 cells were cultured for 12 days to generate stable confluent monolayers. Media containing "Normal" (5mM) and "High" (25mM) D-Glucose or D-Mannitol (25mM) were added for a further 5 days. Supernatants/cells were collected for ELISA (IL-6, IL-8, MCP-1, NGAL) and flow-cytometry (cell death by Annexin-V/PI staining). 10X-concentrated "full" and "extracellular vesicle (EV) depleted" conditioned media (CM) from human bone marrow-derived MSCs were added for the final 2 days at 20:80v/v. Additionally, MSCs were co-cultured 1:10 with RPTEC for 2 days in a trans-well system. Results were statistically analysed with Graphpad Prism 6.0®.

Results: Five day exposure to high-glucose caused significant increases in RPTEC/TERT1 secretion of IL-6, IL-8, MCP-1 and NGAL compared to normal-glucose and mannitol without increasing cell death. The increases in cytokine secretion were only evident after 80-hours (IL-6, MCP-1, NGAL) or 96-hours (IL-8) of culture. Addition of either full- or EV-depleted-CM was associated with significantly reduced high glucose-induced RPTEC/TERT1 secretion of IL-6, IL-8 and MCP-1 (40%-125%), but not NGAL. Indirect contact of MSCs with RPTEC/TERT1 cells in trans-well cultures resulted in even more potent reduction in the secretion of IL-8, IL-6 and MCP-1 (90%-250%).

Conclusions: Prolonged high-glucose exposure induced secretion of pro-inflammatory mediators by RPTEC stable monolayers. Soluble factors released by MSC suppressed high-glucose-induced RPTEC secretion of inflammatory cytokines. EV depletion did not prevent this suppressive effect. Indirect contact of MSCs with RPTEC/TERT1 cells resulted in more potent anti-inflammatory effects.

FR-PO633

The Effects of Açai (Euterpe oleracea) Extract in the Oxidative Stress and Inflammation in Mouse Mesangial Cells Stimulated with High Glucose Elisa M. Higa,[1] Deyse Lima,[2] Giovana Punaro,[2] Adelson Rodrigues,[2] Margaret G. Mouro.[2] *[1]Medicine Department/Unifesp, Sao Paulo, Brazil; [2]UNIFESP, Sao Paulo, Brazil. Group/Team: Laboratory of Nitric Oxide and Oxidative Stress.*

Background: *Diabetes mellitus* is a chronic disease characterized by hyperglycemia, which generates oxidative stress, with injuries to several organs. 20 to 30% of diabetic patients develop nephropathy, characterized by excessive production of extracellular mesangial matrix, marked initially by albuminuria, with gradual reduction of renal function. Açai is a native fruit from Amazon, which could provide beneficial effects on human health due to its antioxidant properties. The aim of this study was to evaluate the effects of açai extract (EA) in the oxidative stress and inflammation induced by high glucose in immortalized mouse mesangial cells (MiMC).

Methods: MiMC were cultured in DMEM with 5% fetal bovine serum. At 60-70% of confluence, they were cultured in media with normal glucose (NG – 6.7mmol/L), mannitol (osmolar control – 30mmol/L) or high glucose (30mmol/L) for 24, 48 or 72h. After the treatment, cell viability was assessed through an automated counter (Coutess™, Invitrogen, USA). The supernatant was collected for measuring NO by Nitric Oxide Analyzer (NOA™, Sievers, CO, USA). NO was also measured in the cells by DAF-FM staining; reactive oxygen species (ROS) were measured using DCFH-DA. Catalase, Nrf2, iNOS and NF-κB p65 were analyzed by Western blot.

Results: The cell viability after treatment with EA remained greater than 90% in all groups, showing no cytotoxicity of the extract. There was a significant increase of the cellular proliferation in the HG when compared to the NG group, while EA managed to decrease it in all times studied. NO, ROS and inflammatory mediators were increased in the HG vs NG group, being also decreased after treatment with EA, $p < 0.05$. HG showed a decrease in the protein content of the antioxidants catalase and Nrf2 vs NG group, which were partially recovered by EA, with $p < 0.05$.

Conclusions: In this study, EA was able to decrease the proliferation and oxidative stress induced by high glucose, in MiMC, by suppressing inflammatory mediators signalling (NF-κB p65 and iNOS), and at the same time activating Nrf2/ antioxidant response pathways. The use of extract of açai could be an additional protective strategy for increase the antioxidant defense system in diabetes, and delay the progression of this disease and its complications, such as the nephropathy.

FR-PO634

Impact of P2X7 Receptor on the Progression of Diabetic Nephropathy in Rats Elisa M. Higa,[1] Robson S. Serralha,[2] Adelson Rodrigues,[3] Giovana Punaro,[3] Margaret G. Mouro,[3] Deyse Lima,[3] Camila Farias,[3] Daniela B. Rodrigues.[3] *[1]Medicine Department/Unifesp, Sao Paulo, Brazil; [2]Universidade Federal de São Paulo, Maua, Brazil; [3]UNIFESP, Sao Paulo, Brazil. Group/Team: Laboratory of Nitric Oxide and Oxidative Stress.*

Background: *Diabetes mellitus* (DM) is a chronic disease which occurs when there is a failure in insulin production or when the cells become resistant to this hormone, leading to hyperglycemia. This situation results in increase of extracellular ATP concentration, which is responsible for several biological functions, among them the activation of $P2X_7$ receptor. When rapidly activated, $P2X_7$ allows the cations influx to the cells, mainly calcium. Constant activation of $P2X_7$ results in opening of many non-selective pores and these in turn allow the passage of hydrophilic molecules with approximately 900 Da. In both processes, $P2X_7$ induces cell death by necrosis via cell swelling or apoptosis, through high concentrations of calcium. Studies from our Laboratory showed that $P2X_7$ expression and activation is associated with oxidative stress in DM. Our aim is to evaluate the effects of $P2X_7$ on the diabetic nephropathy progression in rats.

Methods: Male Wistar rats, 7 weeks old, were unilaterally nephrectomized and DM was induced using streptozotocin (STZ, 60mg/kg, i.v.). Control rats (CTL) received citrate buffer, STZ vehicle. The animals were placed in metabolic cages in different weeks for 24-hour urine collection and a small aliquot of 3-hour blood fasting, for biochemical analysis. The renal tissue was collected after euthanasia, under anesthesia, and prepared for Western blot (WB) test against $P2X_7$, from the 1st to 8th week of diabetes; the results were described as mean ± SEM, with significance at $p<0.05$.

Results: Plasma urea was significantly increased and urinary urea was significantly decreased in diabetic animals in all weeks of protocol when compared to the respective CTL. Proteinuria was increased in diabetic animals at 2nd to 8th week of protocol, when compared to the respective CTL. Analysis of $P2X_7$ expression by qPCR and protein analysis by WB presented a significant increase of this receptor at 6th week when compared to 1st week of DM. We observed a moderate positive correlation between $P2X_7$ protein and plasmatic urea, and a negative correlation between $P2X_7$ and urinary urea. We found a strong positive correlation between $P2X_7$ protein and proteinuria at 6th week ($p< 0.05$).

Conclusions: Our data, mainly proteinuria, suggest that $P2X_7$ plays a role on the progression of nephropathy in this model of DM.

FR-PO635

Vitamin D Receptor Agonist (VDA) Prevents Dedifferentiation of Podocytes through Down Regulation of MicroRNA193a in High Glucose Milieu Abheepsa Mishra,[4] Kamesh R. Ayasolla,[1] Vinod Kumar,[7] Xiqian Lan,[1] Rukhsana Aslam,[2] Ali Hussain,[3] Seyedeh Shadafarin Marashi Shoshtari,[6] Ashwani Malhotra,[8] Pravin C. Singhal.[5] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute for medical research, Glenoaks, NY; [3]Feinstein Institute of Medical Research, New York, NY; [4]Feinstein Institute of Medical Research, Northwell Health, MANHASSET, NY; [5]North Shore LIJ Health System, Great Neck, NY; [6]The Feinstein Institute for Medical Research, Manhasset, NY; [7]Immunolgy and Inflammation, Fienstine Institute for Medical Research, New York, NY; [8]Immunolgy and Inflammation, Feinstein Inst. Med research and NSLIJ, Manhasset, NY.*

Background: Both podocytes (PDs) and parietal epithelial cells (PECs) are derived from the same mesenchymal cells during embryogenesis. Expression of miR193a, which inversely regulates Wilms tumor (WT) 1 gene (the transcriptor of nephrin and podocalyxin) determines the net phenotype. Vitamin D receptor agonist (VDA) has been shown to down regulate miR193a in differentiating PECs. We hypothesize that if high glucose dedifferentiate PDs through up regulation of miR193a then VDA could prevent PDs dedifferentiation via down regulation of miR193a.

Methods: Differentiated (DIF)-PDs were incubated in media containing either buffer or high glucose (30 mM) for 48 hours (n=4). To evaluate the effect of VDR agonist, DIF-PDs were incubated in media containing a buffer, high glucose with/without VDA (EB1089, 1 nM) for 48 hours. To determine the effect of WT1 repressor complex on the PAX2 promoter in high glucose milieu, cellular lysates of control and high glucose treated PDs were immunoprecipitated with WT1 antibody and IP fraction was probed for DNMT1, EZH2, and menin. *In vivo* studies, four- months old wild-type and $BTBR^{ob/ob}$ mice were administered either normal saline or normal saline + VDA (0.1 µg/Kg), intraperitoneally, every other day for 4 weeks. Renal cortical sections were labeled for WT1, synaptopodin, and PAX2. Renal cortical sections were labeled for miR193a by fluorescent *in situ* hybridization technique.

Results: High glucose down regulated ($P<0.05$ vs. control) PD expression of WT1, nephrin, podocalyxin but enhanced ($P<0.01$ vs. control) expression of PAX2 and miR193a. VDA not only down regulated PD expression of mIR193a and PAX2 but also upregulated ($P<0.05$ vs. control) expression of WT1. High glucose upregulated PD expression of PAX2 through disruption of WT1 repressor complex binding on PAX2 promoter. VDA treatment not only increased PD expression of WT1 but also displayed binding of WT1 repressor complex on the PAX2 promoter. Renal cortical sections of $BTBR^{ob/ob}$ mice displayed enhanced PD expression of miR193a, decreased PD expression of WT1 and enhanced expression of PAX2.

Conclusions: High glucose dedifferentiates PD via up regulation of miR193a and VDA preserves PD phenotype in high glucose milieu by down regulating miR193a.

TRAM34, an Inhibitor of KCa3.1: A Novel Therapy for Treatment of Established Diabetic Nephropathy Chunling Huang, Ling Zhang, Hao Yi, Ying Shi, Xinming Chen, Carol A. Pollock. *kolling institute, the University of Sydney, Sydney, NSW, Australia.*

Background: Existing treatments of established diabetic nephropathy have not been proven to have long term efficacy. Hence it is essential and indeed urgent to discover novel therapeutic targets to stabilize or reverse diabetic nephropathy. KCa3.1 is an intermediate/small-conductance calcium activated potassium channel. The most well defined role of KCa3.1 channels is to regulate calcium entry into cells and thereby modulate calcium-signaling processes. We have previously demonstrated in murine models of diabetes mellitus that gene silencing or pharmacological blockade of KCa3.1, when introduced at the induction of diabetes mellitus, confers significant protection against the subsequent development of diabetic induced interstitial fibrosis through inhibition of TGF-β1 signalling pathways. Therefore, this study aimed to investigate the therapeutic effect of the KCa3.1 inhibitor TRAM34 in a mouse model of established diabetic nephropathy.

Methods: Diabetic eNOS-/- mice with established nephropathy (24 weeks after induction of type 1 diabetes induced by streptozotocin) were treated with TRAM34 or DMSO (vehicle control) for a further 14 weeks. Preterminal kidney function and subsequent renal structure were assessed as well as inflammatory, fibrotic markers and the TGF-β1 signalling pathway.

Results: 24h urinary albumin was significantly increased in the diabetic animals compared to the non-diabetic controls ($P< 0.01$). Albuminuria was significantly reduced in TRAM 34 treated diabetic animals compared to the diabetic group ($P<0.05$). Immunohistochemistry demonstrated increased CD68 and F4/80 expression, indicating increased macrophage infiltration in the diabetic animals ($P< 0.05$), which was reversed by treatment with TRAM34 ($P< 0.05$). Similarly, TRAM34 reversed the increased mRNA and protein expression of type I and type III collagen and fibronectin observed in the diabetic animals ($P< 0.05$). Furthermore, blocking the KCa3.1 channel by TRAM34 led to the reduction of TGF-β1 signaling through inhibiting phosphorylation of Smad2/3 ($P< 0.05$).

Conclusions: Blockade of KCa3.1 by TRAM34 is a promising therapeutic intervention in established diabetic nephropathy.

GFR Correlates with the Homogeneity of Glomerular Capillary Blood Velocity in Diabetic Rats Jacob S. Engbjerg,[4] Donato Sardella,[5,4] Luca Bordoni,[4] Francesco Trepiccione,[3] George Rhodes,[2] Ruben M. Sandoval,[1] Leif Østergaard,[4] Giovambattista Capasso,[6] Bruce A. Molitoris,[1] Sebastian Frische.[4] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University School of Medicine Division of Nephrology, Indianapolis, IN; [3]Second University of Naples, Naples, Italy; [4]University of Aarhus, Aarhus, Denmark; [5]University of Camerino, Corridonia, Italy; [6]University of Campania Luigi Vanvitelli, Napoli, Italy.*

Background: Hyperfiltration is common in early diabetes, but the mechanisms behind the rise in GFR are not well understood. Theory predicts that glomerular capillary blood flow dynamics can influence GFR. We therefore aim to investigate if the heterogeneity of glomerular capilary blood velocity influence GFR in experimental diabetic rats.

Methods: 3 groups of male Munich Wistar Frömter rats were studied: Control (C) (n=8), Diabetic (D) (7 days after STZ-injection (40 mg/kg)) (n=10) and acutely hyperglycemic (H) (i.v glucose injections to reach blood glucose (BG) > 20 mM) (n=7). Rats were anesthetized with Inactin and prepared for 2-photon in vivo microscopy (2PM) by externalization of the left kidney. BP and HR were monitored. Blood plasma was labelled by injection of Setau-647-coupled 500kD dextran. Blood flow velocity was measured in ≧6 glomerular capillaries in each glomerulus using longitudinal linescans at >1.3 kHz in the capillary lumen. GFR was measured by fitting a double-exponential decay function to the FITC signal in the plasma recorded by 2PM during 30 min after a bolus of FITC-3kD-dextran. Blood samples were obtained before and after microscopy.

Results: A significant correlation between the homogeneity of glomerular capillary blood flow velocity and GFR was found in the D-rats (p = 0.028), but not in C- or H-rats. In C-rats GFR correlated significantly with BP (p=0.0047), age (p=0.026) and plasma osmolality (p=0.011). GFR did not correlate with these parameters in D-rats (p =0.08, p=0.84 and p=0.45) or H-rats (p=0.15, p=0.22, and p=0.68).

Conclusions: Homogenization of blood flow velocities in the glomerular capillaries seems a new powerful mechanism, which may underlie hyperfiltration in diabetic rats. Mechanistically, it may result from mesangial cell dysfunctionality and it appears to override the influence of parameters influencing GFR in control rats.

A New Model of Diabetic Nephropathy with Advanced CKD Progression in C57BL/6 Mice Xiaoyan Bai,[1] Xiao Li,[2] Jianwei Tian,[1] Wan Jiao,[1] Youhua Liu.[3] *[1]Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Emergency, Nanfang Hospital, Southern Medical University, Guangzhou, China; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage kidney disease in industrialized nations. However, there is a lack of robust mouse models with key features of advanced human DN. Very few options of murine models for studying DN include Akita and OVE26 type 1 diabetic mice, and C57BL/6J db/db, C57BL/KsJ ob/ob, eNOS(-/-) db/db and BT/BR ob/ob type 2 diabetic mice. The limitation of these mice is the requirement for mutation to be superimposed to obtain desired phenotypic characteristics. Most genetically modified mice are on the C57BL/6 background; however, they are notorious for resistance to develop DN. To overcome these conundrums, this study reports a novel DN model by challenging with advanced oxidation protein products (AOPPs) in streptozotocin-induced diabetic C57BL/6 mice.

Methods: Uninephrectomized male C57BL/6 mice were divided as follows: 1) non-diabetic; 2) AOPPs-challenged NC; 3) losartan-treated AOPPs-challenged NC; 4) diabetic; 5) AOPPs-challenged diabetic and 6) losartan-treated AOPPs-challenged diabetic mice. After 8, 12 and 24 weeks, biological parameters were evaluated and kidneys harvested for morphology and morphometry.

Results: Glomerular hypertrophy and accumulation of mesangial matrix were present by 8 weeks. By 24 weeks, glomerular lesions similar to those of advanced human DN were present, as demonstrated morphologically by significant mesangial expansion ($p<0.001$) and sclerosis resembling Kimmelstiel-Wilson nodules, diffuse podocyte foot process effacement ($p<0.05$), increased glomerular basement membrane width ($p<0.001$), and worsened tubulointerstitial fibrosis. Immunofluorescence microscopy excluded immune complex diseases for IgG, IgM, and IgA. These morphological changes recapitulate the renal pathology of advanced human DN. AOPPs-challenged diabetic C57BL/6 mice were more sensitive to develop progressive proteinuria beginning at 8 weeks. By 24 weeks, increased albumin excretion rate ($p<0.001$) was found and losartan treatment alleviated these changes.

Conclusions: AOPPs can accelerate the progression of DN in resistant C57BL/6 mice. This mouse model offers a homogeneous genetic background for studying the pathogenesis of advanced DN that resembles human diabetic kidney disease. It also makes it possible to interrogate the role of specific genetic modifications and to evaluate novel therapeutics in the preclinical setting.

Distinct Patterns of Dysregulated Autophagy in Type 1 and 2 Diabetic Nephropathy Shinsuke Sakai,[1] Takeshi Yamamoto,[1] Yoshitsugu Takabatake,[1] Atsushi Takahashi,[1] Tomoko Namba,[1] Satoshi Minami,[1] Ryuta Fujimura,[1] Jun Matsuda,[1] Tomonori Kimura,[1] Taiji Matsusaka,[2] Fumio Niimura,[2] Yoshitaka Isaka.[1] *[1]Osaka University Graduate School of Medicine, Suita, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: Autophagy maintains cellular homeostasis and has protective roles against several stresses. Although it has been reported that high blood glucose can impair some nutrient signalings, suppress autophagy induction during type 2 diabetic nephropathy, how autophagy is dysregulated is still largely unknown.

Methods: 1) We accessed the autophagic flux *in vivo* by investigating the difference in the numbers of GFP-LC3-positive dots by chloroquine administration under fed or starved condition in streptozotocin (STZ)-treated GFP-LC3 transgenic mice (type 1 diabetes) or in obese db/db mice crossed with GFP-LC3 transgenic mice (type 2 diabetes). 2) We compared the inhibitory effects of glucose, insulin, and amino acids on autophagic activity in proximal tubules of 24 h-starved GFP-LC3 transgenic mice. 3) We examined the consequences of long-term autophagy deficiency using STZ-treated proximal tubular cell (PTC)-specific *Atg5*-deficient mice (*Atg5*$^{F/F}$;KAP) or *Atg5*$^{F/F}$;KAP crossed with db/db mice. Then, we examined the effects of rapamycin (an inhibitor of the mechanistic target of rapamycin; mTOR) on vulnerability to ischemia-reperfusion (I/R) injury in these mice.

Results: 1) Autophagy induction was suppressed even under starvation in the PTCs of db/db mice. In contrast, autophagic activity was enhanced in STZ-treated mice even under fed condition. 2) Insulin and amino acids, but not glucose, suppressed starvation-induced autophagy by activating mTOR pathway. 3) Urinary albumin excretion, mitochondrial damage (assessed by COX and SDH staining) and fibrosis (type I collagen immunostaining) were significantly increased in STZ-treated *Atg5*$^{F/F}$;KAP mice compared with control STZ-treated mice. In contrast, these were increased in db/db mice regardless of autophagy deficiency. I/R lead to more severe injury in both diabetic mice compared with nondiabetic mice. Rapamycin exaggerated I/R injury in STZ-induced mice, while it attenuated in db/db mice.

Conclusions: Distinct patterns of dysregulated autophagy in type 1 and 2 diabetic nephropathy should be considered in prevention and treatment.

FR-PO640

Inhibition of Prolyl Hydroxylase Domain (PHD) Reduces Glomerular Macrophage Infiltration and Improves Albuminuria in Mice with a High Fat Diet Hisako Saito,[2] Tetsuhiro Tanaka,[2] Mai Sugahara,[2] Kenji Fukui,[2,1] Takeshi Wakashima,[2,1] Masaomi Nangaku.[3] *[1]JT CPRI, Osaka, Japan; [2]The University of Tokyo graduate School of Medicine, Tokyo, Japan; [3]the University of Tokyo School of Medicine, Tokyo, Japan.*

Background: The epidemic of obesity and its complications is rapidly growing all over the world. Chronic hypoxia in the tubulointerstitium is a major pathogenic factor mediating progression of CKD, and kidneys of metabolic disorders suffer from significant degrees of tubulointerstitial hypoxia. Recent drug discovery established utility of prolyl hydroxylase domain (PHD) inhibitors as stabilizers of hypoxia-inducible factors (HIFs) in vivo, which are currently in human clinical studies for the treatment of anemia in CKD. Notably some clinical studies suggest a role of PHD inhibitors in ameliorating obesity and hyperlipidemia. In this study, we hypothesized that HIF activation using a PHD inhibitor, JTZ-951, protects from obesity-related glomerulopathy (ORG) in mice fed with high fat diet (HFD).

Methods: Eight-week-old, C57BL/6J mice were fed with HFD for 12 or 20 weeks with or without JTZ-951 (0.005%; mixed in chow). Renal consequences of PHD inhibition was investigated at 20 or 28 weeks of age.

Results: JTZ-951 caused a transient rise in hematocrit levels (at 12 weeks of age). Successful activation of HIF in the kidney was confirmed by immunostaining for HIF-1α. Body weight was significantly lower in the JTZ-951 group as compared with the vehicle group. Plasma cholesterol levels were also significantly lower in the JTZ-951 group. PHD inhibition reduced albuminuria (120.8 vs 89.3 μg/mgCr, $P<0.03$). Histologically, glomerular tuft area, mesangial expansion and podocyte density were comparable between groups, but the number of F4/80- positive infiltrating macrophages was lower in the JTZ-951 group. Arginase 1 mRNA expression was higher in the JTZ-951 group, suggesting a possible role of PHD inhibition in altering macrophage polarity, which may have contributed to reducing albuminuria.

Conclusions: Activation HIF by PHD inhibitors mediated multiple renal and non-renal consequences in mice with HFD. JTZ-951 significantly improved obesity and lowered total cholesterol levels. In the kidney, a decrease in albuminuria was associated with decreases in infiltrating macrophages and their possible skewing toward the M2 phenotype. Results of the present study offer a promising view that pharmacological PHD inhibition may be beneficial for the treatment of CKD associated with obesity.

FR-PO641

Does SGLT2 Inhibition with Dapagliflozin Overcome Therapy Resistance to RAAS Inhibition? Hiddo J. Lambers Heerspink,[2] Sergei Petrykiv,[1] Gozewijn D. Laverman,[3] Dick de Zeeuw.[2] *[1]None, Groningen, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands; [3]ZGT Almelo, Almelo, Netherlands.*

Background: Renin-Angiotensin-Aldosterone-System inhibitors (RAASi) is a mainstay for renal and cardiovascular protective treatment in patients with chronic kidney disease. However, individual patients show a large variation in their response to RAASi both in surrogates like albuminuria and the hard renal outcomes. Sodium-glucose co-transporter 2 inhibitors (SGLT2) lower albuminuria and confer cardiovascular and possibly renal protection. To establish whether individual therapy resistance to RAASi can be overcome by adding an SGLT2 inhibitor we assessed individual albuminuria responses in patients exposed both to RAASi and the SGLT2 inhibitor dapagliflozin.

Methods: We used data from a randomized controlled cross-over trial designed to assess the albuminuria lowering effect of 6-weeks treatment with dapagliflozin. The trial enrolled 33 patients with type 2 diabetes, albumin:creatinine ratio (U_{ACR}) between 100 and 3500 mg/g who were all using an ACEI or ARB at the time of enrollment. We extracted from the electronic medical records data on the U_{ACR} response upon start of RAASi before the trial period, and analyzed the individual albuminuria response to RAASi and to dapagliflozin.

Results: We retrieved data on RAASi from 26 patients (age 62 (SD 8); male gender 20 (77%); U_{ACR} 355 [150 – 533] mg/g. Thirteen patients started an ACEi, and 13 an ARB before entry into the study. The mean U_{ACR} lowering response to RAASi was 26.5% with a large between individual variability (range -76.1 to +135.1%). The addition of dapaglifozin resulted in a mean U_{ACR} lowering response of 34.9%, again with a large between individual variability (range -83.9 to +94.2). Interestingly, there was a significant positive correlation between the response to RAASi and dapagliflozin (Pearson correlation coefficient 0.635; p<0.001) indicating that patients who did not respond to RAASi also did not respond to dapagliflozin. Therapy adherence during the study was excellent with 97.5% of all medications being taken.

Conclusions: Individual therapy resistance to RAASi cannot be overcome with the addition of a completely different class of drugs, SGLT-2 inhibitors. These data suggest that the individual drug response is an intrinsic individual characteristic possibly unrelated to the type of intervention, unless the mode of action of dapaglifozin on albuminuria is through the RAAS.

Funding: Commercial Support - AstraZeneca provided dapagliflozin study medication

FR-PO642

The Study of Mechanisms of SGLT2 Inhibitors for Renoprotection in Human Diabetic Kidney Disease Saeko Sato. *Saitama Medical center, Saitama Medical University, Kawagoe, Japan.*

Background: SGLT2 inhibitor (SGLT2i) has been reported to suppress not only glomerular hyperfiltration, but also have direct action on renal proximal tubule cells in vitro. There have been no reports on detailed investigations of its mechanism in humans, and there are many discussions about that. Therefore, we explore the effect of verious SGLT2i on kidney function and kidney injury in patients with diabetic kidney disease (DKD).

Methods: In patients with type 2 diabetes (T2DM) with DKD, the usual dose of SGLT2 inhibitor (Iplagliflozin 50mg or Canagliflozin 100mg or Dapagliflozin 5mg or Luceogliflozin 2.5mg or Tofogliflozin 20mg or Empagliflozin 10 mg) (when the effect was insufficient, it could be increased to the maximum dose), we compared and examined the several items before administration and one month after, 12 months after.

Results: 73 cases was subjected. Administration of SGLT2i significantly reduced HbA1c and mean blood pressure in the examination room also decreased significantly after one month and 12 month (data not shown). In renal function, estimate glomerular filtration rate (eGFRcreat) decreased significantly after one month, but improved after 12 months (61.3 ± 21.8 → 59.7 ± 22.5 (p = 0.0201) → 61.4 ± 23.7 mg/gCr). The urine albumin-to-creatinine ratio (u-ACR) decreased significantly both after one month and 12 months (560.2 ± 882.7 → 323.4 ± 553.4 (p = 0.0082) → 281.5 ± 430.2 mg/gCr (p = 0.0054)). In inflammation or oxidative stress biomarkers, malondialdehyde modified LDL (MDA-LDL) was significantly decreased after one month and 12 months (133.4 ± 39.5 → 109 ± 28.2 U / L (p = 0.0141) after 12 months). Urinary monocyte chemoattractant protein 1 (MCP-1) did not change after one month, but it decreased significantly after 12 months (2.49 ± 1.75 → 1.27 ± 1.39 pg/gCr (p = 0.0169)). Urinary liver-type fatty-acid-binding protein (L-FABP) also did not change after one month, but it decreased significantly in 12 months (11.4 ± 21.7 → 8.0 ± 16.8 μg/gCr (p = 0.0004)). There was no correlation between the rate of change in HbA1c or the rate of change in blood pressure and the rates of change in eGFR, u-ACR, MDA-LDL, u-MCP-1 and u-L-FABP.

Conclusions: Renoprotection of SGLT2i for DKD in T2DM is considered to be the main mechanism of improvement of glomerular hypertension at early stage, but direct suppression of inflammation and oxidative stress acts in the long term.

FR-PO643

Insulin Use Is a Surrogate Marker of Insulin Resistance (IR) Christine K. Raj,[1] R. E. Boucher,[2] Guo Wei,[2] Terrence S. Bjordahl,[2] A. N. Habib,[2] Srini Beddhu.[2] *[1]UC Berkeley, Saratoga, CA; [2]Univ. of Utah, SLC, UT.*

Background: We previously noted that diabetics needing insulin therapy are at ↑ risk of reaching ESRD than those that do not need insulin adjusted for duration of diabetes mellitus (DM), concurrent use of other hypoglycemic agents and HbA1C levels. We hypothesized that need for insulin is a reflection of underlying IR.

Methods: We examined whether insulin use is reflective of IR in 1756 participants with DM and non-missing data for insulin use and IR in the Chronic Renal Insufficiency Cohort. Insulin use was related to IR estimated by homeostatic model of assessment of insulin resistance (HOMA-IR) in logistic regression models.

Results: Mean age was 59 ±10 years, 55.4% were men and 44.0% were black. Baseline characteristics of diabetics on insulin and not on insulin are summarized in the table. Compared to the lowest quartile of HOMA-IR, there was a graded ↑ in odds of insulin use in the upper three quartiles in a multivariate logistic regression model (Figure).

Conclusions: We conclude that need for insulin use is a surrogate marker of insulin resistance and interventions that target insulin resistance might ↓ the need for insulin use in DKD.

The Role of the Renal Biopsy in 6003 Patients with Diabetic Nephropathy Dao-Fu Dai, Shree G. Sharma, Christopher P. Larsen, Patrick D. Walker. *Arkana Laboratories, Little Rock, AR.*

Background: Diabetic nephropathy (DN) is a leading cause of end stage renal disease (ESRD). Proteinuria and progressive decline in renal function in patients with diabetes mellitus (DM) are usually thought to be secondary to DN. However, recognition of superimposed non-diabetic renal disease (NDRD) is critical and, with appropriate diagnosis and treatment, may prevent accelerated progression to ESRD.

Methods: This was a retrospective clinical pathological study of 6003 patients with DM and a biopsy diagnosis of DN, to determine the spectrum of superimposed NDRD and to evaluate the relationship between the presence or absence of NDRD with various clinical manifestations, including rapid worsening of proteinuria and renal function, hematuria with or without an active urine sediment, or the acute nephritic syndrome.

Results: The renal biopsy identified superimposed NDRD in 36.6% of patients with DN. Importantly, the biopsy excluded NDRD in 16.7% of patients with systemic diseases and clinical/laboratory findings suspicious for a superimposed disease. Multivariate analysis identified that a rapid rise in serum creatinine is the strongest predictor for superimposed NDRD (OR: 2.19, p<0.001). Other independent predictors include the acute nephritic syndrome and clinical features suspicious for NDRD. The spectrum of

superimposed NDRD varied according to indications leading to renal biopsy. Acute tubular injury (21%) was most common in patients with rapid decline of renal function; focal segmental glomerulosclerosis was most common (7.1%) in patients with an unexpected swift rise in proteinuria; pauci-immune crescentic glomerulonephritis (15.7%) was most common in patients with rapidly progressive renal failure; infection-associated glomerulonephritis (16.5%) was most common in patients with the acute nephritic syndrome and IgA nephropathy was the most common in patients with hematuria (7.6%).

Conclusions: The renal biopsy is critical to identify the presence or absence of a superimposed NDRD in patients with DN. This study documents the relationship between various clinical manifestations of renal disease and specific NDRD. Finally, it demonstrates the importance of the biopsy in ruling in or out suspected non-diabetic renal disease in clinical settings that would support such a concern.

FR-PO645

Renal Biopsies in Diabetic Patients: Hematuria or Absence of Retinopathy Do Not Indicate Non Diabetic Renal Disease: A 10-Year Single-Center Experience

Jonathan M. Chemouny,[1,2] Christophe Barba,[1] Eric Daugas,[1,2] Aurelie Sannier,[1] Francois Vrtovsnik.[1,2] *[1]AP-HP, Hopital Bichat, Paris, France; [2]U1149, INSERM, Paris, France.*

Background: Diabetic nephropathy (DN) is usually a presomptive diagnosis based on clinical and biological evidences. However, renal biopsies (RB) may be performed in diabetic patients with glomerular proteinuria lacking classical features of DN and/or in patients with diabetes and another disease with potential renal involvement who could benefit from specific therapy. We compared the frequencies of Non Diabetic Renal Disease (NDRD) according to the RB indications to assess if RB performed for atypical findings are justified.

Methods: 144 RB were performed in diabetic patients with glomerular proteinuria in our center in ten years and divided into two groups: Group 1 (G1): atypical findings (absence of diabetic retinopathy (DR), hematuria (HU), rapid eGFR decline, rapid increase of proteinuria or sudden nephrotic syndrome); Group 2 (G2): clinical and/or biological features of suggesting NDRD. We compared frequencies of NDRD and RB related adverse events in each group.

Results: 68 patients were identified in G1 and 76 in G2. Gender, age, high blood pressure, serum creatinine, urinary protein-to-creatinine ratio, HU, DR, renin-angiotensin system blockade and diabetes duration were not different between both groups. Glycated hemoglobin was higher in G1 (7.8±2.2 vs 7.1±1.4, p=0.04). NDRD was diagnosed in 7 % of patients in G1 and 50% in G2 (p<0.001). None of the 37 patients who underwent RB for HU, and/or absence of DR had NDRD. Adverse events were more frequent in G1 than in G2 (10% vs 1%, p=0.027) (Table).

Conclusions: Absence of DR or presence of HU should not be the only motivation to indicate RB in diabetic patients as they convey an increased risk of adverse event without any benefit.

Funding: Clinical Revenue Support, Government Support - Non-U.S.

FR-PO646

Metformin Is Renoprotective Only in Patients with Progressive Renal Function Decline

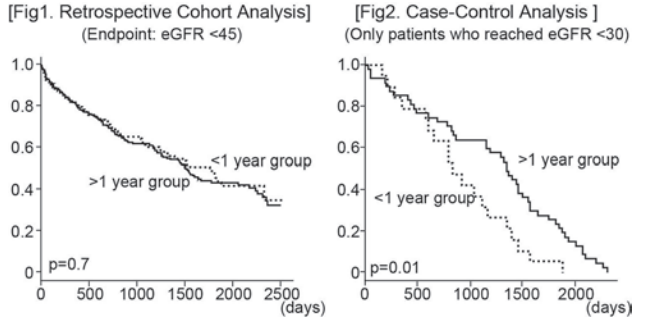
Makoto Araki. *Suwa Central Hospital, Nagano-ken, Japan.*

Background: SGLT2 inhibitors have renoprotective properties. Metformin is a first-line drug for treating diabetes mellitus, but it is unknown if it is renoprotective.

Methods: This was a retrospective observational study. From January 2009 to December 2015, we obtained medical records of patients prescribed metformin at our facility. The medical record sampling began on the day the patient demonstrated eGFR <60 ml/min/1.73m² (hereinafter, omit "ml/min/1.73m²") and ended on the day when eGFR <45 or <30. Exclusion criteria are as follows: (1) Short-term period between date reached eGFR <60 and the last creatinine (Cr) measurement date, (2) The same day reached eGFR <60 and <45. All patients were divided into two groups depending on whether metformin was prescribed for less than or more than 1 year ("<1 year group" and ">1 year group"). The survival curve for the outcome was illustrated using the Kaplan–Meier method.

Results: Of the 1,334 subjects who received metformin, 691 (51.8%) had recorded eGFR <60 more than once. Overall, 469 subjects meet the criteria (average age 68.5 years, 299 males, eGFR 55.5 ± 3.84, "<1 year group" was 162 people). 222 subjects with eGFR <45 and 66 subjects with eGFR <30 reached the study endpoint. First, we conducted a retrospective cohort study. No between-group differences were found for reaching the study endpoint(Fig1). Next, we conducted a case-control analysis in the people who reached the study endpoint. We found no differences at the endpoint of eGFR <45. But at the endpoint of eGFR <30, ">1 year group" demonstrated slower renal function decline than the "<1 year group" (Fig2. 47 vs 19 subjects; median 1354 vs 830 days, log-rank test p = 0.01). No subjects developed lactic acidosis over the course of the study.

Conclusions: Metformin exhibited a renoprotective effect in patients. However, it was limited to the progressive renal function decline group



FR-PO647

Effects of Hydrochlorothiazide and Amiloride on the Antialbuminuric Efficacy of Losartan in Patients with Diabetic Kidney Disease

Tanun Ngamvichchukorn, Oraphan Lertsakornprasert. *Renal Unit, Department of Medicine, Faculty of Medicine, Vajira Hospital, Navamindradhiraj University, Bangkok, Thailand.*

Background: The best strategy to slow progression of diabetic kidney disease (DKD) and reduce cardiovascular risk of DKD patients is controlling blood pressure (BP) and reducing albuminuria. The first line treatment for patients with DKD and hypertension is using renin-angiotensin-aldosterone system (RAAS) blockers. However, some DKD patients have persisted albuminuria after reaching the maximum tolerated dosage of RAAS blockers and proper BP control. Therefore, this study aims to prove an efficacy of alternative medicine which is a combination of HCTZ and amiloride (HCT+A) to reduce albuminuria apart from RAAS blockade therapy.

Methods: This prospective randomized, single blinded study assigned 75 patients with DKD, CKD stage 1-3 and urine albumin-to-creatinine ratio (UACR) > 300 mg/g received stable dosage of losartan during the last 3 months in Vajira hospital from 1 June 2016 to 31 January 2017. There were 39 cases received HCT+A group compared with 36 cases in placebo group. All patients were eligible to receive conventional therapy. The patients were followed for 4 weeks. The primary composite end point was the percent change in the median of UACR between the baseline and final value of each treatment period. The primary analysis was performed on the independent t test or Mann-whitney U test.

Results: The UACR showed a significant reduction with HCT+A 42.84% compared with placebo group – 7.95% (p < 0.001). There were a > 30% reduction in UACR in 24 patients (64.1%) treated with HCT+A and in 6 patients (16.7%) in placebo. The percentage of patients with >50% UACR reduction in the HCT+A group 16 patients (41%) compared with the placebo group (2 patients (5.6%)). Glomerular filtration rate (GFR), body weight decreased with HCT+A regimen. Blood pressure had no significant change after treatment. There was one patient developed severe hyperkalemia until stopped treatment.

Conclusions: The addition of HCTZ and amiloride to patients with DKD (CKD stage 1-3) with UACR > 300 mg/day on top Losartan induces a significant antialbuminuric effect and associated with the degree of GFR reduction.

Incremental Value of Renal Pathological Score to Kidney Failure Risk Equation in Advanced Diabetic Nephropathy

Masayuki Yamanouchi,[6,5] Junichi Hoshino,[5] Yoshifumi Ubara,[5] Tadashi Toyama,[4] Shinji Kitajima,[1] Akinori Hara,[3] Miho Shimizu,[2] Kengo Furuichi,[3] Takashi Wada.[3] *[1]Department of Nephrology, Kanazawa University Hospital, Kanazawa, Japan; [2]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Japan; [3]Kanazawa University, Kanazawa, Japan; [4]Kanazawa University Hospital, Kanazawa, Japan; [5]Toranomon Hospital, Tokyo, Japan; [6]Graduate School of Medical Sciences, Kanazawa University, Kanazawa, Japan.*

Background: The Kidney Failure Risk Equation (KFRE) that enables to accurately predict end-stage renal disease (ESRD) in patients with chronic kidney disease (CKD) in stages 3 to 5 was developed and validated worldwide. We aimed to first assess the

performance of KFRE on individuals with biopsy proven diabetic nephropathy in advanced CKD stages at the time of biopsy and then evaluate the incremental value of pathologic information of renal biopsy to KFRE on them.

Methods: 296 individuals with biopsy proven diabetic nephropathy in CKD stages 3 to 5 at the time of biopsy was identified at four nephrology centers in Japan. Pathological classification was performed by three pathologists based on the Pathologic Classification of Diabetic Nephropathy. Individuals were randomly assigned to two cohorts (2:1 cohorts). The development cohort of 198 was used to validate the KFRE and to assess the incremental value of pathological score on diabetic nephropathy (D-score). Model performance was assessed by chi-squared test, Akaike information criterion, and Harrell's c-statistics. Incremental value of D-score to KFRE was evaluated with net reclassification improvement (NRI), integrated discrimination improvement (IDI), Integrated sensitivity (IS) and integrated specificity (IP). Validation of the models was performed in the validation cohort of 98.

Results: Median follow-up durations (25th, 75th percentiles) were 1.8 (1.0, 5.0) years and 2.0 (1.0, 3.8) years, respectively (p=0.89). Both KFRE and KFRE+D-score were significant predictors of ESRD in both the development cohort and validation cohort (Hazard Ratios of KFRE and KFRE+D-score in the development cohort were 2.44 (1.89-3.15) and 1.08 (1.04-1.13), and those in the validation cohort were 2.30 (1.57-3.38) and 1.08 (1.01-1.16), respectively). Incremental value of D-score using free cut-points showed positive overall NRI (0.5%; CI, 0.1-0.5%) but the IDI showed no significant change (0.0002; CI, -0.00007-0.0005). The KFRE+D-score model improved the both IS and IP but showed little differences.

Conclusions: KFRE worked well to identify individuals at high risk of ESRD in both the development and validation cohort. Adding pathological information to the KFRE improved the risk prediction of ESRD but did not statistically outperform the KFRE.

FR-PO649

The Effect of Ursodiol on Kidney Function: A Retrospective Case Series of Patients with Diabetic Kidney Disease Fabian Bock,[1] Moh'd Mohanad A. Al-Dabet,[2] Khurrum Shahzad,[2] Berend H. Isermann,[2] Talat Alp Ikizler.[1] *[1]Div of Nephrology&Hypertension, Dept. of Medicine, Vanderbilt University Medical Center, Nashvile, TN; [2]Dept of Clinical Chemistry and Pathobiochemistry, Otto-von-Guericke University, Magdeburg, Germany.*

Background: Experimental evidence suggests that bile acids are protective in diabetic nephropathy. *Ursodeoxycholic acid* (*UDCA, Ursodiol*) has been shown to attenuate renal damage in mouse models of diabetic nephropathy in part through reducing oxidative or ER stress. Ursodiol is in clinical use for the prevention of gall stone disease and in primary biliary cirrhosis (PBC) but clinical data on the effect on kidney function in patients with diabetic kidney disease (DKD) are lacking

Methods: We retrospectively screened Synthetic Derivative, a de-identified copy of over 2 million patient records at Vanderbilt University Medical Center for the following inclusion criteria: ICD9/10 code of diabetes with diabetic nephropathy, diabetic kidney disease or renal manifestation (diagnosed between 2000 and 2008), Ursodiol started for any indication (between 2010 and 2014) and serial eGFR assessments thereafter. Repeated measures ANOVA was used to examine the effect of Ursodiol on kidney function overtime.

Results: A total of 13 patients met the inclusion criteria. At inclusion, median age was 55 (30-72) years. The majority of cases was white (10/13) had hypertension (12/13) and were on ACEi or ARB (12/13) therapy. Gender distribution was equal. Five, one, five, two and zero patients had CKD Stage 1, 2, 3, 4, and 5, respectively. Median diabetes duration was 12 years, the median Ursodiol treatment duration was 1.25 (0.5-10) years and indications for Ursodiol included: gallstone prevention post bariatric surgery, cryptogenic cirrhosis or primary biliary cirrhosis. At 12 months after initiation of Ursodiol, 92% (12/13) patients had increased eGFR (p=0.02, compared to baseline). The mean eGFR (±SD) increase from baseline was 13.5 ± 18.4 ml/min/m^2 (median: 8.5 and 25-75 percentiles: 4.7-13.5).

Conclusions: This retrospective analysis showed a significant improvement in kidney function at 12 months after starting the bile acid Ursodiol in patients with diabetic kidney disease. While the results are limited by a small case number, the heterogeneity of clinical indications for Ursodiol and the number of potential confounding factors, there is precedent for prospective studies examining the use of Ursodiol as a potential treatment for amelioration of CKD progression in patients with DKD.

The Effects of Dapagliflozin on Urinary Metabolites in Patients with Type 2 Diabetes Michelle Pena,[1] Skander Mulder,[1] Manjula Darshi,[2] Benjamin F. Van espen,[2] Jiwan J. Kim,[2] Kumar Sharma,[2] Hiddo J. Lambers Heerspink.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]University of California San Diego, La Jolla, CA.*

Background: The cardiovascular and possibly kidney protective effects of SGLT2 inhibition are hypothesized in part due to improved mitochondrial function in the heart and kidney. To test this, we assessed the effects of dapagliflozin, an SGLT2 inhibitor, on a pre-specified panel of 13 urinary metabolites known to reflect mitochondrial function in patients with diabetes and elevated albuminuria.

Methods: Urine samples were used from a double-blind, randomized, placebo controlled crossover trial in 28 patients with type 2 diabetes, albumin/creatinine ratio >100 mg/g, and on a stable dose of an Angiotensin Converting Enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB). Dapagliflozin and placebo treatment periods each lasted for 6 weeks. Urinary metabolites were quantified by gas-chromatography mass spectrometry, corrected for urinary creatinine, and combined into a single-valued index.

Results: Twelve of the 13 metabolites were detectable. At baseline, higher values of the metabolite index positively correlated with eGFR (pearson's r = 0.36, p = 0.05). Preliminary findings showed that after 6 weeks of dapagliflozin treatment, eight of the 12 metabolites were significantly increased from baseline. The metabolite index increased by 17% (95%CI: -3 – 49, p = 0.14) with placebo compared to 60% (26 – 102, p <0.001) with dapaglifozin. Accordingly, the placebo-adjusted effect was 45% (2 – 76, p = 0.03). Changes in the metabolite index during dapagliflozin treatment did not correlate with changes in HbA1c (r = 0.21, p = 0.28), eGFR (r = -0.16, p = 0.42), or albuminuria (r = 0.18, p = 0.37).

Conclusions: Dapagliflozin significantly increased a panel of mitochondrial metabolites previously associated with progressive diabetic kidney disease. These data suggest that SGLT2 inhibitors may improve mitochondrial function leading to kidney protection. Future studies of longer treatment duration and clinical outcomes are needed to confirm the clinical impact of these findings.

FR-PO651

Comparison between Liraglutide and Sitagliptin Effects on Cardiac Function in Diabetic Patients with Renal Failure Takeyuki Hiramatsu. *Konan Kosei Hospital, Konan Aichi, Japan.*

Background: Diabetes mellitus with renal failure (DM-CRF) is a progressive multifactorial disease associated with cardiovascular complications. To prevent progression of cardiovascular complications in DM-CRF, glycemic control is important. But in DM-CRF, using of anti-diabetic agents(ADAs) were limited. In this study, we examined the efficacy of liraglutide or sitagliptin to treat type 2 diabetes patients with renal failure.

Methods: Seventy two type 2 diabetes patients with renal failure (eGFR< 60mL/min/1.73m^2) were divided into two groups. Twenty four were used liraglutide 0.9 mg once a day (Group A), fourty eight were used sitagliptin 50mg once a day (Group B). ADAs were switched to these agents because of bad glycemic control. Moreover after that, all drugs were not changed during the study period. During 48 months of study period, we examined the blood pressure and renal function every three months. Echocardiography was examined at baseline and every 12 months after starting drugs to detect systolic and diastolic cardiac function.

Results: Hemoglobin A$_1$c, and systolic/diastolic blood pressure levels were gradually decreased in group A, but in group B was not. The eGFR value was not changed in both groups, however albuminuria was decreased significantly in both groups. Left ventricular ejection fraction(EF) was not changed during 48 months in both groups. But left atrial dimension(LAD) and tissue Doppler index(E/e') in group A were improved significantly. In group B, at 48 months after using agents, E/e' was worsened. No remarkable adverse events were seen in both groups.

Conclusions: These findings suggest that liraglutide and sitagliptin have similar effects on renal function, but according to cardiac diastolic function, liraglutide therapy is more beneficial for type 2 diabetes patients than sitagliptin therapy. Further studies with larger samples were needed to detect these effects.

Clinical Data

	Group A (n = 24)			Group B (n = 48)		
	at baseline	24 months	48 months	at baseline	24 months	48 months
eGFR (mL/min/1.73m^2)	35.9 ± 16.1	39.1 ± 20.8	35.6 ± 20.6	40.9 ± 15.6	40.8 ± 17.6	38.5 ± 18.5
Albuminuria(mg/day)	410.0 ± 270.9	330.9 ± 209.7	287.8 ± 187.0 *	349.8 ± 271.2	331.2 ± 265.3	296.3 ± 153.4 *
EF (%)	62.2 ± 12.1	67.1 ± 12.2	62.0 ± 9.7	67.2 ± 14.2	66.3 ± 16.2	65.1 ± 14.3
LAD (mm)	38.6 ± 6.3	35.6 ± 5.1 *	35.9 ± 3.6	35.4 ± 5.9	36.9 ± 5.7	37.6 ± 4.7 *
E/e'	15.1 ± 2.4	11.9 ± 2.0 **	13.1 ± 2.3 *	10.9 ± 2.0	11.9 ± 3.6	13.6 ± 4.4 **

*: P < 0.05, **: P < 0.01 vs. at baseline

In group A, diastolic funftion was improved, but in group B, was not.

Metformin Use Does Not Increase Risk of Clinical Acidosis in Diverse Population of CKD Patients Rocco Ferrandino,[1] Tielman T. Van Vleck,[2] Jeremy S. Leventhal,[1] Bart Ferket,[1] Jaime Uribarri,[1] Girish N. Nadkarni,[1] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mount Sinai School of Medicine, New York, NY.*

Background: Metformin use in type 2 diabetes (T2D) patients with Stage 3a chronic kidney disease (CKD3a) has been cautioned because of concerns for associated metabolic acidosis. We used a large multiethnic urban cohort to assess both rates of acidosis and absolute difference in serum bicarbonate in new users of metformin compared to non-users.

Methods: We identified T2D with CKD3a from the Mount Sinai CKD Registry and propensity-matched metformin new-user: non-user pairs 1:1 on baseline data. We calculated incidence rate ratios (IRR) of acidosis (bicarbonate level ≤22 MEQ/L and serum anion gap (SAG)≥12) using negative binomial regression. We examined the longitudinal effect of metformin use on patient bicarbonate levels using linear mixed effect modeling.

Results: We had data on 1494 patients (747 matched pairs). Median age was 74, 45.2% was male, baseline eGFR was 49.6. Baseline bicarbonate was similar in both metformin user (25.7 MEQ/L) and non-users (25.0 MEQ/L). Acidosis events in new metformin users and non-users were 13.8 and 23.0 events/100 patient years over follow up. Adjusted IRR over follow up were 0.73 (95% CI 0.61 – 0.88), respectively. The serum

bicarbonate over follow up was statistically higher but not clinically different in the user vs. non-user group (Difference= 0.18, SE=0.08, P=0.02).

Conclusions: In a large healthcare cohort of T2D patients with CKD3a, new prescription of metformin was not associated with either acidosis events or lower bicarbonate levels compared to non-users, suggesting that concerns for metformin associated lactic acidosis in this population may not be warranted.

Presence of Kimmelstiel-Wilson Nodules in Diabetic Nephropathy Correlates with Duration of Diabetes and Poor Glycemic Control Monica Sircar, Ivy A. Rosales, Dihua Xu, Sahir Kalim, Ravi I. Thadhani. *MGH, Boston, MA.*

Background: Mesangial nodules are regarded as a major histologic correlate of diabetic nephropathy. However, whether there is an association between the presence of nodules with various stages of diabetic chronic kidney disease (CKD) is not known. Here we report clinicopathologic association between the presence of nodules in diabetic patients with varying stages of CKD.

Methods: All seventy-five available autopsy records and charts from 2013 to 2016 of type 1 and 2 diabetics were examined. Twenty-six patients had all necessary demographic data in their records, including age, sex, race, hemoglobin A1c level, duration of diabetes, hypertension status, at least 2 creatinine levels within the last six months prior to death, and treatment information. Archived autopsy kidney sections were reviewed by a pathologist blind to clinical data. Nineteen kidneys free of autolysis were systematically assessed for (i) percent global glomerulosclerosis, (ii) mesangial hypercellularity, (iii) percent glomeruli with nodules, and (iv) percent interstitial fibrosis.

Results: Mesangial nodules were present in diabetic patients with CKD II (50%, n=4), III (86%, n=7), IV (86%, n=7), and V (100%, n=1). Poor glycemic control, defined as HgbA1c ≥7.5% (Welch's t test p = 0.035), and duration of diabetes >10 years (p=0.036) showed strong associations with higher percent of nodules. Although a linear trend was evident, the correlation between percent of nodules and CKD stage was not statistically significant. The extent of glomerulosclerosis did not correlate with clinical factors such as age, sex, hypertension, treatment with RAAS blockade or longstanding diabetes.

Conclusions: The presence of nodules in diabetic kidneys showed significant associations with duration of diabetes >10 years and poor glycemic control. Mesangial nodules were present in kidneys of diabetic patients at all stages of CKD, with apparently more nodule formation in the later stages of the disease. These preliminary findings suggest a trend towards increased nodule formation as chronic kidney disease progresses. Together, our study suggests that diabetic nephropathy is associated with significant nodule formation, and the percentage of glomeruli with nodules may be a more definitive readout of CKD progression than determining just the presence or absence of nodules in glomeruli.

Lack of Diabetic Glomerulosclerosis in Patients with Longstanding Diabetic Complications Amy K. Mottl,[2] John M. Basgen,[5] Susan L. Hogan,[2] Susanne B. Nicholas,[4] J. Charles Jennette,[2] Ronald Klein,[3] Michael Mauer.[1] *[1]University of Minnesota, Minneapolis, MN; [2]University of North Carolina, Chapel Hill, Chapel Hill, NC; [3]University of Wisconsin-Madison, Madison, WI; [4]Department of Medicine, University of California, Los Angeles, CA; [5]Charles Drew University, Los Angeles, CA.*

Background: There is heterogeneity of renal complications in diabetes. We sought to determine the nephropathologic light microscopic characteristics and ultrastructural measurements in adults with type 2 diabetes undergoing research protocol kidney biopsy.

Methods: Inclusion criteria included type 2 diabetes ≥5 years duration, retinopathy and/or microalbuminuria or decreased estimated glomerular filtration rate (GFR) <60ml/min/1.73m^2. Nineteen participants (mean age 54y) underwent kidney biopsy, measured GFR using iohexol clearance, first morning void (FMV) urine albumin:creatinine ratio (UACR) and retinal photography. Nephropathologic characteristics were scored by a nephropathologist using usual methods. Stereologic ultrastructural parameters included glomerular basement membrane (GBM) thickness (measured using orthogonal methods) and fractional volume of mesangium (V/v(mes/glom). Typical diabetic glomerulosclerosis was diagnosed if V/v(mes/glom) exceeded 0.20 with GBM thickening (>470nm for women; >520nm for men). Predominant diabetic vasculopathy was diagnosed if V/v(mes/glom) was less than 0.20 in the presence of arterial hyalinosis and/or arteriosclerosis and GBM thickening. Arteriosclerosis without GBM thickening was attributed to nondiabetic arterionephrosclerosis.

Results: Results (see table) showed that 5 of 19 participants had nondiabetic arterionephrosclerosis, and while there were trends in the degree of albuminuria and retinopathy severity, this alone did not distinguish between diabetic and nondiabetic vasculopathy, nor the severity of vasculopathy.

Conclusions: Molecular studies aimed at deciphering between diabetic and nondiabetic complications will require research protocol kidney biopsies from patients with a wide spectrum of clinical disease characteristics.

Association between Severity of Diabetic Retinopathy and Renal Pathology or Renal Prognosis in Patients with Biopsy-Proven Diabetic Nephropathy in Type 2 Diabetes Mellitus Katsuhiko Morimoto,[1,2] Ken-ichi Samejima,[1] Masaru Matsui,[1] Tomoko Kanki,[1] Masatoshi Nishimoto,[1] Miho Tagawa,[1] Yasuhiro Akai,[1] Yoshihiko Saito.[1] *[1]First Department of Internal Medicine, Nara Medical University, Kashihara, Japan; [2]Department of Cardiology and Nephrology, Nara Prefecture General Medical Center, Nara, Japan.*

Background: Diabetic nephropathy and retinopathy are generally believed to develop concomitantly. However, much remains unclear about the association between renal pathology andretinopathy as renal biopsy is rarely indicated.

Methods: This is a retrospective observational study. Inclusion criteria were patients with type 2 diabetes, biopsy-proven diabetic nephropathy, and evaluation for retinopathy by ophthalmologists from 1984 to 2014. Exposure of interest was severity of retinopathy by the modified Davis and the Scheie Classification. Outcome variable was development of end-stage renal disease (ESRD). Statistical analyses were performed using Cox regression model. Correlation between severity of retinopathy and renal pathology were examined using Spearman's rank correlation.

Results: Data for 376 patients were available, Mean age was 57.5 years. Retinopathy was found in 168 (44.7%). During mean follow-up of 9.4 years, ESRD developed in 67. Renal prognosis was significantly poorer in the group with retinopathy. In terms of modified Davis classification, more severe retinopathy indicated poorer renal prognosis (log-rank p<0.001). In Cox regression analysis, severity of retinopathy was an independent risk factor for the development of ESRD (Table). Positive correlations with retinopathy were observed for diffuse glomerular lesions (ρ=0.48, p<0.001), nodular lesions (ρ=0.50, p<0.001), interstitial fibrosis and tubular atrophy (ρ=0.36, p<0.001), and arteriolar hyalinosis (ρ=0.34, p<0.001).

Conclusions: Only about half of patients with biopsy-proven diabetic nephropathy had retinopathy. The severity of retinopathy was an independent predictor of progression of nephropathy.

Relationship between diabetic retinopathy and ESRD (Cox regression)

	Adjusted HR	95% CI	P value
Non-proliferative retinopathy	3.51	1.68 to 7.64	<0.001
Preproliferative retinopathy	3.76	1.35 to 10.1	0.01
Proliferative retinopathy	15.5	6.33 to 38.9	<0.001

Covariates included age, sex, eGFR, systolic blood pressure, proteinuria (g/gCr), HbA1c.

FR-PO656

Collagen Type III Degradation Is Associated with Deterioration of Kidney Function in Patients with Type 2 Diabetes with Microalbuminuria Federica Genovese,[1] Tine Hansen,[3] Daniel Guldager Kring Rasmussen,[1,5] Signe Holm Nielsen,[1,4] Henrik Reinhard,[3] Hans-Henrik Parving,[2] Morten A. Karsdal,[1] Peter Rossing.[3,6] *[1]Nordic Bioscience, Herlev, Denmark; [2]Rigshospitalet, Copenhagen, Denmark; [3]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [4]Department of Biomedicine and Biotechnology, Technical University of Denmark, Kgs. Lyngby, Denmark; [5]Institute of Molecular Medicine, Cardiovascular and Renal Research, University of Southern Denmark, Odense, Denmark; [6]University of Copenhagen, Copenhagen, Denmark.*

Background: In diabetes one of the main features of the progression to diabetic kidney disease is a pathological deposition of extracellular matrix components triggering renal fibrosis. The main structural component of the fibrotic core is collagen. One of the most prominent collagens is collagen type III (COL III), which is excessively synthesized and incorporated into the fibrotic extracellular matrix. Multiple studies in both humans and mice have suggested that MMP-9 activity is increased in diabetic kidney disease. We investigated whether a neo-epitope fragment of COL III generated by MMP-9 (C3M) was associated with deterioration of kidney function in a well-characterised type 2 diabetic population with microalbuminuria and without symptoms of coronary artery disease.

Methods: The cohort included 200 participants, followed for 6.1 years. We measured C3M levels in serum (S-C3M) and urine (U-C3M) at baseline. To adjust for urine output levels of U-C3M were normalized for urinary creatinine. The investigated endpoint was a decline in eGFR of >30% (n=42). Cox proportional hazards regression analysis was performed for S-C3M and U-C3M both unadjusted and adjusted for traditional risk factors (sex, age, systolic blood pressure, LDL-cholesterol, smoking, HbA1c, creatinine and urinary albumin excretion rate). To assess whether S-C3M or U-C3M improved risk prediction beyond traditional risk factors we calculated the relative integrated discrimination improvement (rIDI).

Results: The hazard ratio per doubling of S-C3M was 3.00 (95% CI 1.52-5.90, p=0.002). When adjusted for traditional risk factors the hazard ratio per doubling of S-C3M was 2.84 (95% CI 1.35-5.97, p=0.006). Addition of S-C3M to a model containing traditional risk factors improved the relative discrimination by 19.8 percentage points (p=0.007). U-C3M was not associated with declining eGFR.

Conclusions: In conclusion, S-C3M was independently associated with decline in renal function, and added significant improved discriminatory power to a model containing traditional risk factors.

FR-PO657

Serum and Urine Markers of Collagen Type VI Formation (Pro-C6) and Type III Degradation (C3M) Reflect Renal Function in Type 1 Diabetes Tine Hansen,[6] Daniel Guldager Kring Rasmussen,[5] Sascha Pilemann-lyberg,[4] Signe Holm Nielsen,[3] Morten A. Karsdal,[5] Frederik Persson,[2] Simone Theilade,[1] Federica Genovese,[5] Peter Rossing.[2,7] *[1]Steno Diabetes Center Copenhagen, Hellerup, Denmark; [2]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [3]Nordic Bioscience A/S, Herlev, Denmark; [4]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [5]Nordic Bioscience, Herlev, Denmark; [6]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [7]University of Copenhagen, Copenhagen, Denmark.*

Background: Progression of diabetic kidney disease is associated with renal fibrogenesis and associated with increased extracellular matrix remodeling and release of collagen fragments in urine in progressive renal disease. We evaluated associations between kidney function and a marker of collagen type VI formation (Pro-C6) and a marker of collagen type III degradation (C3M) in type 1 diabetes.

Methods: Serum and urinary levels of Pro-C6 and C3M were measured with ELISA in 668 patients with type 1 diabetes. Kidney function was evaluated as eGFR (CKD-EPI) and urinary albumin excretion rate (UAER). We applied unadjusted and adjusted linear regression analyses. Adjustment included age, sex, LDL cholesterol, smoking, HbA_{1c}, systolic blood pressure, UAER (in analyses of eGFR) and eGFR (in analyses of UAER). To adjust for urine output levels, the urinary markers were normalized for urinary creatinine.

Results: Of the 668 patients, 368 (55%) were male, mean±SD age was 54.6±12.6 years and eGFR 81.6±25.5 ml/min/1.73m^2. Median (IQR) UAER was 17 (8-65) mg/g. Both higher serum and urinary levels of Pro-C6 were associated with lower eGFR (unadjusted: p<0.001; adjusted: p<0.001) and higher UAER (unadjusted: p<0.001; adjusted: p<0.001). Lower urinary levels of C3M were associated with lower eGFR (unadjusted: p<0.001; adjusted: p<0.001) and higher UAER in the unadjusted model (p<0.001), but significance was lost after adjustment (p=0.43). Higher serum levels of C3M were associated with lower eGFR (unadjusted: p<0.001; adjusted: p=0.001) and higher UAER (unadjusted: p<0.001; adjusted: p=0.007).

Conclusions: In type 1 diabetes, higher serum and urine levels of the collagen type VI formation marker Pro-C6 were associated with poorer kidney function. Moreover, higher serum levels and lower urine levels of the collagen type III degradation marker C3M were related to poorer kidney function. Longitudinal data are needed to clarify the predictive role of these markers.

A Novel Marker of Collagen Type VI Formation Is Prognostic for Cardiovascular Disease, All-Cause Mortality, and Deterioration of Kidney Function in Patients with Type 2 Diabetes with Microalbuminuria Daniel Guldager Kring Rasmussen,[1,4] Tine Hansen,[3] Signe Holm Nielsen,[1,5] Henrik Reinhard,[3] Hans-Henrik Parving,[2] Morten A. Karsdal,[1] Federica Genovese,[1] Peter Rossing.[3,6] *[1]Nordic Bioscience, Herlev, Denmark; [2]Rigshospitalet, Copenhagen, Denmark; [3]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [4]Institute of Molecular Medicine, Cardiovascular and Renal Research, University of Southern Denmark, Odense, Denmark; [5]Department of Biomedicine and Biotechnology, Technical University of Denmark, Kgs Lyngby, Denmark; [6]University of Copenhagen, Copenhagen, Denmark.*

Background: Type 2 diabetes is a common risk factor for the development of renal fibrosis and chronic kidney disease (CKD). Recent findings have shown that type VI collagen (COL VI) is markedly upregulated during fibrosis. The role of COL VI has been sparsely investigated in fibrosis onset and progression. We evaluated a novel biomarker of COL VI formation as a prognostic marker for cardiovascular events, all-cause mortality, and decline in eGFR in patients with type 2 diabetes with microalbuminuria and without symptoms of coronary artery disease.

Methods: The cohort included 200 participants followed for 6.1 years. COL VI formation was assessed with the Pro-C6 assay, detecting a specific fragment of COL VI released upon deposition in the extracellular matrix. Pro-C6 levels were measured in serum at baseline. Endpoints included: 1) a composite of cardiovascular events (n=40); 2) all-cause mortality (n=26); and 3) decline in eGFR of >30% (n=42). Cox models were unadjusted and adjusted for traditional risk factors (sex, age, systolic blood pressure, LDL-cholesterol, smoking, HbA_{1c}, creatinine and urinary albumin excretion rate). Pro-C6 was assessed per doubling in the analysis. To assess if Pro-C6 improved risk prediction beyond traditional risk factors we calculated relative integrated discrimination improvement (rIDI).

Results: Levels of Pro-C6 were associated with an increased risk of cardiovascular events (unadjusted HR 2.65, 95% CI 1.47-4.79, p=0.0013; adjusted HR 2.32, 95% CI 1.08-5.01, p=0.032), all-cause mortality (unadjusted HR 3.95, 95% CI 1.98-7.86, p=0.0001; adjusted HR 6.98, 95% CI 3.06-15.9, p<0.0001), and decline in eGFR (unadjusted HR 3.00, 95% CI 1.72-5.21, p=0.0001; adjusted HR 2.67, 95% CI 1.21-5.89, p=0.015). Addition of Pro-C6 to a model containing traditional risk factors improved the rIDI by 14.5% (p=0.04) for cardiovascular events, 64.3% (p<0.001) for all-cause mortality, and 19.8% (p=0.007) for decline in eGFR.

Conclusions: In conclusion, Pro-C6 was associated with cardiovascular events, all-cause mortality, and decline in eGFR in patients with type 2 diabetes and microalbuminuria.

FR-PO659

A Novel Oxidative Stress Biomarker, APX-501 Protein as a Promising New Biomarker for Progression of Diabetic Nephropathy in Type 2 Diabetic Patients Ho jun Lee, Jin Joo Cha, Dae R. Cha, Young Sun Kang. *Korea University Medical College Ansan Hospital, Ansan city, Republic of Korea.*

Background: A large body of evidence indicates that oxidative stress is one of the most important mechanism link for the major pathways involved in the development and progression of diabetic vascular complications. Recently, we've identified that APX-501 protein was synthesized from renal cells, and found that APX-501 was involved in oxidative stress in the kidney. Therefore, we investigated the role of APX-501 as a new biomarker for diabetic nephropathy in type 2 diabetic patients.

Methods: Total 166 patients were enrolled and prospectively followed up for 6 months. Study patients were divided into four groups; 1) non-diabetic patients with nephrotic range of proteinuria (n=35), 2) type 2 diabetic patients with normoalbuminuria (n=34), 3) type 2 diabetic patients with microalbuminuria (n=26), 4) type 2 diabetic patients with overt proteinuria (n=71). Plasma level of APX-501 were measured at baseline and 6 months using ELISA. Addiitionally, we performed in vitro and in vivo experiment to further confirm the presence of APX-501 in diabetic nephropathy.

Results: Plasma APX-501 level was significantly higher in diabetic patients with microalbuminuria and overt proteinuria compared to non-diabetic patients with nephrotic range proteinuria and diabetic patients with normoalbuminuria. APX-501 level was positively correlated with systolic blood pressure, serum creatinine level and urinary albumin excretion. The level of APX-501 was significantly different after 6 months compared to the baseline in all diabetic patients, whereas there were no significant difference between the two time point in the level of microalbuminuria and proteinuria. The degree of increment of APX-501 were greater in patients with microalbuminuria and overt proteinuria. In cultured renal cells, high glucose and angiotensin II increased synthesis of APX-501 level. Gene silencing of APX-501 ameliorated high glucose-induced ECM synthesis and oxidative stress markers. in type 2 diabetic db/db mice, plasma level and renal expression of APX-501 was significantly increased in diabetic mice according to its age.

Conclusions: These findings suggest that APX-501 synthesis may be activated in early stage of diabetic environment, and may be increased according to the progression of diabetic nephropathy.

FR-PO660

What Is the Potential for RAAS Blockade Optimisation for Patients with Diabetic Kidney Disease in the Era of Potassium Binders? Stephanie Chong,[3,2] Katharine Pates,[3,1] Kieran Mccafferty.[3,2] *[1]Barts Health NHS Trust, London, United Kingdom; [2]NHS, LONDON, United Kingdom; [3]Royal London Hospital, London, United Kingdom.*

Background: Diabetes is the leading cause of renal failure in both worldwide and in the UK. For 2 decades RAAS blockade has been the cornerstone of management of diabetic kidney disease. Recent registry data suggest that RAAS dose maximisation is key to reduce population health care costs and improve outcomes. However, the use of RAAS blockade is often limited by hypotension or hyperkalaemia. Potassium binders may provide a novel strategy to safely enable dose maximisation of RAAS therapy, but it is unknown how many patients are not treated or sub-maximally treated due to fears of hyperkalaemia.

Methods: We performed a retrospective study, analysing our electronic patient record to establish how many patients were sub-maximally treated with RAAS therapy and the reasons for failure of dose maximisation. We included all adult patients with type 2 diabetes, in our tertiary renal unit which covers a population of 2.5 million ethnically diverse patients across North and East London. We excluded any patients due to commence dialysis imminently or already on renal replacement therapy and patients with secondary glomerular lesion or other clear cause of CKD.

Results: We identified 415 diabetic patients meeting the inclusion/exclusion criteria. We found that only 72% were on ACE or ARB therapy. Of these, only 50.3% were on maximum dose therapy. This means that only 37% of patients of the total cohort were on maximal RAAS therapy. The main limiting factors were hyperkalaemia (Potassium > 5.0mmol/L) in 30.8%, hypotension (BP < 120/70 and not on other blood pressure lowering agents) in 15.4%, both in 2.3% and dose was not maximised for no specified reason despite inadequate BP control and acceptable potassium levels in 51.3% of patients. Additional reasons found to explain the lack of dose maximisation in this group of patients, were historical hyperkalaemia, fear of new hyperkalaemia, progressive CKD or AKI.

Conclusions: Our study demonstrated the huge unmet potential for safe dose maximisation of RAAS therapy using potassium binders in a cohort of patients with diabetic kidney disease. We estimate that if these findings were extrapolated across the 3 million patients with diabetic kidney disease across the UK then almost 1 million patients may benefit from potassium binder enabled dose maximisation.

FR-PO661

Effect of Angiotensin Converting Enzyme (ACE) and Angiotensinogen (AGT) Gene Polymorphisms on the Anti-Proteinuric Efficacy of ACE Inhibitor Therapy in Patients with Type 2 Diabetes with Nephropathy Om P. Kalra,[6] Neerja Aggarwal,[7] Pawan K. Kare,[5] Parul Varshney,[9] Anil K. Yadav,[4] Alpana Raizada,[3] Ashok K. Tripathi,[8] Basu D. Banerjee,[2] Madhu V. S.[1] *[1]Medicine, University College of Medical Sciences, Delhi, India; [2]Biochemistry, University College of Medical Sciences and GTB Hospital, Delhi, India; [3]Medicine, University College of Medical Sciences, Delhi, India; [4]Medicine, GTB Hospital and University College of Medical Sciences, Delhi, India; [5]Biochemistry, University College of Medical Sciences, Delhi, India; [6]Nephrology, Pt. B.D. Sharma University of Health Sciences, Rohtak, India; [7]Biochemistry, University College of Medical Sciences, Delhi, India; [8]Biochemistry, University College of Medical Sciences, Delhi, India; [9]Biochemistry, University College of Medical Sciences, Delhi, India.*

Background: Diabetic nephropathy (DN) is the leading cause of chronic kidney disease worldwide and affects approximately 20-30% of diabetic patients. ACE inhibitor drugs are commonly prescribed for reno-protection; however, anti-proteinuric response is not uniformly observed in all patients. The aim of this study was to evaluate the role of genetic variants of ACE and AGT genes on the anti-proteinuric efficacy of ACE inhibitor therapy in patients with DN.

Methods: In the present study, 270 patients with Type 2 diabetes mellitus with nephropathy aged between 30 to 65 years and a duration of diabetes ≥5 years were enrolled and treated with ACE inhibitor (ramipril) and followed at regular intervals for 6 months for assessment of urinary albumin/creatinine ratio (ACR) and eGFR (MDRD). Patients were classified as responders when they had a decrease in urinary ACR ≥30% at the end of 6 month follow up. Genotyping of *ACE I/D* and *AGT M235T* polymorphisms were performed by using primer specific polymerase chain reaction and PCR-RFLP technique, respectively.

Results: An overall significant reduction in ACR 36.2% was observed in the whole group at the end of 6 months; however, macro-albuminuric patients (55%) showed better response to therapy as compared to micro-albuminuric patients (45%). Overall, 130 (48%) of patients with DN were found to be responders to ACEI. The frequency of ACE genotype II, ID and DD was found to be 31%, 53% and 16% respectively. The frequency of AGT genotype MM, MT and TT was found to be 25%, 53% and 22% respecively. A reduction in urinary ACR was found to be independent of genotypes of *ACE I/D* and *AGT M235T* polymorphisms although macro-albuminuric patients having TT genotype showed higher response (72%) although it was statistically not significant. eGFR decreased from the base line value of 73.65±24.71 ml per minute per 1.73 m^2 to 68.90±24.44 ml per minute per 1.73 m^2 at the end of 6 months (p<0.081).

Conclusions: ACE inhibitor therapy reduced urinary ACR by ≥ 30% in 48% of patients with diabetic nephropathy and macroalbuminuric patients exhibited better response. The anti-proteinuric response was found to be independent of *ACE I/D* and *AGT M235T* polymorphisms.

Relationship between Transition in CKD Category and Renal Outcome in Japanese Type 2 Diabetic Patients with Biopsy-Proven Diabetic Nephropathy Tomoaki Funamoto, Miho Shimizu, Tadashi Toyama, Shinji Kitajima, Kengo Furuichi, Takashi Wada. *Division of Nephrology, Kanazawa University Hospital, Kanazawa, Japan.*

Background: We examined the association between transition in chronic kidney disease (CKD) category over 5 years and 10 years after renal biopsy and renal outcome in Japanese type 2 diabetic patients with biopsy-proven diabetic nephropathy.

Methods: Based on up to 5 years and 10 years observation after renal biopsy, we determined transition in CKD category. We first evaluated the association of renal composite events (requirement of dialysis, or a 50% decline in estimated glomerular filtration rate (eGFR) from baseline (at the time of renal biopsy)) with progression of CKD categories over 5-years (n=54) and 10-years (n=54) after renal biopsy in patients with normo-/microalbuminuria with eGFR ≥ 15 mL/min per 1.73m^2. We subsequently evaluated the association of renal composite events with remission of macroalbuminuria to normo-/microalbuminuria over 5-years (n=58) and 10-years (n=42) after renal biopsy in patients with macroalbuminuria.

Results: (1) In the 5-year analysis in patients with normo-/microalbuminuria with eGFR ≥ 15 mL/min per 1.73m^2, 8 patients showed progression of albuminuria stage, whereas 9 patients showed progression of eGFR stage. The corresponding numbers in the 10-year analysis were 12 patients and 16 patients, respectively. Cumulative incidences of renal composite events in patients with progression of albuminuria stage and eGFR stage were higher than no progression. The risk for renal composite events was associated with progression of albuminuria stage rather than eGFR stage. The progression of albuminuria was associated with nodular lesions, whereas the progression of eGFR stage was associated with diffuse lesions. (2) In the 5-year analysis, 10 patients showed remission of macroalbuminuria. The corresponding number in the 10-year analysis was 16 patients. Cumulative incidences of renal composite events in patients with remission were lower than no remission. In the 10-year analysis, remission was a determinant for renal composite events. Low urinary protein excretion at renal biopsy and female were the determinants for remission.

Conclusions: Our study suggests that transition in CKD category over 5-years and 10-years as well as diabetic kidney lesions add significant prognostic information about risk for renal outcome in type 2 diabetes.

FR-PO663

Is Urinary KIM-1 a Predictor of EGFR Decline, Incident Cardiovascular Disease, and All Cause Mortality? Mie K. Eickhoff,[3] Bernt Johan Von Scholten,[1] Henrik Reinhard,[4] Tine Hansen,[3] Frederik Persson,[3] Hans-Henrik Parving,[2] Peter Rossing.[5] *[1]Novo Nordisk A/S, Soborg, Denmark; [2]Rigshospitalet, Copenhagen, Denmark; [3]Steno Diabetes Center, Gentofte, Denmark; [4]Steno Diabetes Center A/S, Gentofte, Denmark; [5]Steno Diabetes Center Copenhagen, Gentofte, Denmark.*

Background: Urinary levels of kidney injury molecule 1 (KIM-1) has shown to reflect tubular pathophysiology. We evaluated KIM-1 as a predictor of decline in estimated glomerular filtration rate (eGFR), incident cardiovascular disease (CVD) and all-cause mortality in patients with type 2 diabetes (T2D) and microalbuminuria without clinical coronary artery disease.

Methods: We performed a prospective study including 200 patients, all receiving multifactorial treatment. Urinary KIM-1 was measured at baseline and was available in 191 patients. Adjusted Cox models included sex, age, LDL cholesterol, smoking, HbA_{1c}, creatinine, systolic blood pressure and urine albumin excretion rate (UAER). A decline in eGFR of >30%, which has recently been suggested as a valid renal outcome, at any time point during follow-up was the predefined endpoint of CKD progression. Hazard ratios (HR) are provided per 1 SD increment of log-transformed values of the urinary biomarker.

Results: Patients were (± SD) 59 ± 9 years old, eGFR 91.1 ± 18.3 ml/min/1.73m^2 and UAER (IQR) 103 (39–230) mg/24-h. During a median 6.1 years follow-up, there were 40 incident CVD events and 26 deaths and a total of 42 patients reached the predefined CKD progression endpoint after 4.9 years (median). Higher urinary KIM-1 was a predictor of eGFR decline, unadjusted HR (95% CI): 1.9 (1.2-2.8); p=0.003, and in the adjusted model HR 1.7 (1.0-2.7); p=0.034. For CVD events urinary KIM-1 was a determinant in the unadjusted model (HR 1.4 (1.0-2.1); p=0.04) but not in the adjusted model (HR 1.4 (1.0-2.1); p=0.08), and of all-cause mortality in unadjusted (HR 2.0 (1.2-3.2); p=0.008) and adjusted (HR 2.3 (1.2-4.1); p=0.008) models.

Conclusions: In patients with T2D and microalbuminuria receiving multifactorial treatment, urinary KIM-1 was independently associated with deterioration in renal function and all-cause mortality.

FR-PO664

IL-6 Assessment as a Non-Traditional Risk Factor for Cardiovascular Risk and Hospital Admission in Type 2 Diabetes Patients with Diabetic Nephropathy Ana P. Pimentel,[1] Filipa B. Mendes,[1] Luisa H. Pereira,[1] Ana P. Silva,[2] Pedro L. Neves.[3] *[1]Centro Hospitalar do Algarve, Faro, Portugal; [2]Hospital de Faro E.P.E, Faro, Portugal; [3]Nephrology, CHA, Faro, Portugal.*

Background: Oxidative stress and inflammatory cytokines in diabetic nephropathy are major triggers regarding the development of microvascular complications of type 2 diabetes. Interleukin-6 (IL-6) is one proinflammatory cytokine, implicated in the pathogenesis of diabetic nephropathy where vascular inflammation and fibrosis are the rule with influence on the development of cardiovascular disease. The aim of this study is to verify the relationship between plasmatic IL-6 and non-traditional cardiovascular risk factors, inherent comorbidities, mineral metabolism parameters, insulin resistance score of type 2 diabetic (DM) patients with nephropathy and hospital admissions due to ischemic heart disease (IHD).

Methods: Retrospectively data from a cohort of 175 type 2 DM patients followed in an outpatient clinic from January 2008 to August 2011 were obtained, including Homeostatic Model Assessment (HOMA) for insulin resistance, homocysteine, fibrinogen and brain natriuretic peptide (BNP) levels and Charlson Comorbidity Index (CCI) was calculated. The patients were divided into groups using serum IL-6. Group 1 (N=113) was defined as having IL-6 <4.9pg/mL and group 2 (N=62) had IL-6 ≥4.9pg/mL.

Results: Statistically significant differences were found between the groups (p<0,003) with higher values of IL-6 being associated with greater CCI, higher phosphorus and PTH level, but also HOMA, BNP, diastolic pressure and albumin-creatinine ratio. CCI (OR 3.714 95% CI (1.6-8.2) p=0.001) and IL-6 (OR 1.5 95% CI (1.104-2.486) p=0.015) were predictive factors in terms of hospital admission for IHD, and using a generalized linear model, higher values of IL-6 were predictive for acute coronary syndrome (ACS) (Wald=0.1219; CI 95% (0.14-0.59) p=0.01) with an AUC=0.79, p=0.0001.

Conclusions: In type 2 diabetic patients, elevated serum levels of IL-6 are associated with the presence of non-traditional cardiovascular risk factors, as well as higher insulin resistance, worst mineral metabolism parameters and more comorbidity. In our cohort study, IL-6 levels were predictive of ACS and hospital admission for IHD.

FR-PO665

The Expression of Serum lncRNA GAS5 and miR-21 ceRNA Associated with Clinical and Pathological Changes in Patients with Diabetes and Diabetic Nephropathy Qiuling Fan. *Department of Nephrology, The First Hospital, China Medical University, Shenyang, China.*

Background: To analyze the expression of serum lncRNA GAS5 and miR-21 in patients with diabetes mellitus and diabetic nephropathy, and to analyze the correlation between the expression of them and the clinical and pathlogical parameters, and to testify the function of them in the pathogenesis of diabetes mellitus and diabetic nephropathy, in order to find novel therapeutic targets and biomarkers.

Methods: The patients were divided into three groups, diabetic nephropathy group: patients proven by renal biopsy, diabetes group: patients with diabetes of normal Urine albumin creatinine ratio, normal control group. The expression of lncRNA GAS5 and miR-21 in serum samples were detected by real-time quantitative PCR. The correlation of serum lncRNA GAS5 and miR-21 expression with the clinical parameters were analyzed.

Results: The expression of serum lncRNA GAS5 was significantly down-regulated and the expression of serum miR-21 was significantly up-regulatedin in diabetes mellitus and diabetic nephropathy patients comparing with the normal control group. The expression of serum miR-21 was gradually up-regulated (P=0.038) along with the progression of renal biopsy stage IIb-IV of DN. FBG and HbA1cwere significantly negatively correlated with serum lncRNA GAS5, and FBG was independently correlated with serum lncRNA GAS5. urine microalbumin, TC, Cr, Urea(r=0.516,P<0.001) and SBP were significantly positively correlated with serum miR-21. ALB and eGFRwere significantly negativly correlated with serum miR-21, and ALB was independently correlated with serum miR-21. The diagnostic efficiency of serum lncRNA GAS5, miR-21 and lncRNA GAS5/miR-21 as "diagnostic signature" for DM were good, for lncRNA GAS5, AUC=0.7302, p=0.03, cutoff point was 0.0056, sensitivity was 62.86%, specificity was 77.78%; for miR-21, AUC=0.8397, p=0.002, cutoff point was 0.6600, sensitivity was 77.14%, specificity was 77.78%. The diagnostic efficiency of serum miR-21 and lncRNA GAS5/miR-21 as "diagnostic signature" for DN were good, for miR-21, AUC=0.9179, p<0.0001, cutoff point was 0.9900, sensitivity was 76.00%, specificity was 94.74%.

Conclusions: Serum lncRNA GAS5 and miR-21 expression can be used as noninvasive diagnostic marker for diabetes and diabetic nephropathy.

FR-PO666

Reduced Sublingual Endothelial Glycocalyx in Type 1 Diabetic Patients with Diabetic Nephropathy Signe Abitz Winther,[1,2] Marie Frimodt-møller,[1] Emilie Hein Zobel,[1] Tine Hansen,[1] Peter Rossing.[1,3] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Novo Nordisk A/S, Maaløv, Denmark; [3]University of Copenhagen, Copenhagen, Denmark.*

Background: Glycocalyx is a glycoprotein layer that lines and protects the capillary endothelium. Damage to the glycocalyx may be an early stage in development of microvascular complications in diabetes. Insight into the function and thickness of glycocalyx in vivo, has been limited by the lack of easy and non-invasive quantification tools. With capillaroscopy it is possible to visualize the sublingual capillaries by sidestream dark field imaging and estimates the dimensions of the glycocalyx by measuring the perfused boundary region (PBR). We evaluated the glycocalyx thickness non-invasively in type 1 diabetic patients with different levels of historical and current albuminuria.

Methods: Cross-sectional study including 77 type 1 diabetic patients stratified by history of normoalbuminuria (<30 mg/g;n=26), microalbuminuria (30-299 mg/g;n=27) and macroalbuminuria (>300 mg/g;n=24). Glycocalyx thickness was assessed by 5 measurements with the GlucoCheck device (GlucoCheck BV, The Netherlands), a non-invasive hand-held microscope generating video recordings of the sublingual capillaries. Endothelial glycocalyx thickness was estimated from the PBR in capillaries with a diameter range of 5-25 μm. Higher PBR indicates smaller glycocalyx width. Urinary albumin-to-creatinine ratio (UACR) was measured in 3 morning samples.

Results: In normo-, micro-, and macroalbuminuric patients PBR was (mean±SD) 2.30±0.22 μm, 2.32±0.25 μm, and 2.49±0.35 μm, respectively. Differences between normo- and macroalbuminuric patients (p=0.020) and micro- and macroalbuminuric patients (p=0.042) were significant, but the difference between normo- and microalbuminuric patients was not (p=0.74). After adjustment for age, sex, HbA_{1c}, diabetes duration and systolic blood pressure, differences between normo- and macroalbuminuric patients (p=0.018) and micro- and macroalbuminuric patients (p=0.004) remained significant. In pooled (n=77) multivariate linear regression, higher level of current UACR was associated with a higher PBR (p=0.0007).

Conclusions: In type 1 diabetic patients with a history of macroalbuminuria, measurements with the non-invasive GlucoCheck device revealed significantly higher PBR, suggesting an impaired glycocalyx, compared to patients with normo- or microalbuminuria. Moreover, higher current level of albuminuria was associated with higher PBR.

FR-PO667

Automatic Data Analysis for Standardization of Renal Diffusion Tensor MRI Keren Doenyas-Barak, Shai Efrati. *Asaf-Harofhe MC, Zerifin, Israel.*

Background: Diffusion tensor MRI (DTI) noninvasively evaluates renal microstructure, especially fibrosis. DTI parameters and creatinine clearance have shown good correlation. However, neither a uniform technique for data analysis nor standard values exists. DTI is analyzed using manual selection of regions of interest (ROIs). Subjectivity of operator's interpretation and poor reproducibility limit the clinical value of this technique. We evaluated standard protocols for renal DTI quantification.

Methods: Twelve adults with diabetic kidney disease, defined as eGFR<60 ml/min/1.73m2 or proteinuria, and 5 healthy volunteers were scanned in a 3T Siemens scanner. Data were analyzed using 3 definitions of ROI: Manual selection of ROI based on intensity: Four circle ROIs are placed on high and low signal intensity regions of the 4 anatomical slices to define the medulla and cortex, respectively. Automatic ROI selection: The cortex was defined as 5-10 mm from the external margin of the kidney and the medulla as the region from the internal margin of the cortex to the inner margin of the kidney of 4 slices. Fiber tracking: DTI fiber-tracking was performed on 4 coronal slices of the kidney medulla, reconstruction kidney fibrils. Fiber volume, calculated as a percent of the whole kidney volume, was extracted in 5 fractional anisotropy (FA) thresholds: 0.1-0.2.

Results: Mean age was 65.9 years (60.5-70.7) and mean eGFR 62.9 ml/min/1.73m2 (37.1-83.5). The mean cortical apparent diffusion coefficient (ADC) and FA were 0.0029(0.0026-0.0032) and 0.165(0.152-0.184) using manual ROI selection, and 0.0024 (0.0026-0.0029) and 0.175(0.172-0.196) using automatic selection. Respective values for medullary ADC and FA were 0.0028 (0.0026-0.0029) and 0.175(0.160-0.196); and 0.0022(0.0021-0.0034) and 0.023(0.126-0.182). A strong correlation with eGFR was demonstrated for medullary ADC and FA (r=0.748 and r=0.657 p<0.05) and for cortical ADC (r=0.617 p<0.05) using automatic ROI selection, but only for medullary FA using manual ROI selection (r=0.678 p<0.05). Fiber tracking at FA thresholds of 0.12, 0.15 and 0.17 showed a strong correlation with eGFR (r=0.783, 0.787, 0.712 p<0.05 for all).

Conclusions: Objective data analysis using anatomic ROIs or fiber tracking strongly correlate to renal function and may be used for standard analysis of renal DTI.

FR-PO668

Safety of Liraglutide versus Placebo in Patients with T2D and CKD in the LEADER Trial Johannes F. Mann,[6] Vivian A. Fonseca,[5] Ofri Mosenzon,[1] Itamar Raz,[2] Helle Frimer-Larsen,[4] Bernt Johan Von Scholten,[4] Thomas Idorn,[4] Neil Poulter.[3] *[1]Hadassah Hebrew University Hospital, Jerusalem, Israel; [2]Hadassah Hebrew University Hospital, Jerusalem, Israel; [3]Imperial College, London, United Kingdom; [4]Novo Nordisk A/S, Soborg, Denmark; [5]Tulane University Medical Center, New Orleans, LA; [6]KfH Kidney Center, Munich, Germany. Group/Team: On behalf of LEADER Trial Steering Committee and Investigators .*

Background: We assessed the safety of liraglutide vs placebo (PBO) in patients with chronic kidney disease (CKD) in the LEADER trial.

Methods: LEADER was a randomized, double-blind, multicenter, placebo-controlled cardiovascular (CV) outcome trial assessing CV and long-term safety of liraglutide up to 1.8mg/day vs PBO plus standard of care for 3.5-5 years in 9340 type 2 diabetes (T2D) patients at high risk for CV disease. We stratified participants according to baseline estimated glomerular filtration rate (eGFR) <60 (with CKD) or ≥60ml/min/1.73m^2 (without CKD) and analyzed: serious adverse events (SAEs), SAEs leading to discontinuation, acute renal failure, nausea leading to discontinuation, acute gallstone disease, severe hypoglycemia and foot ulcers.

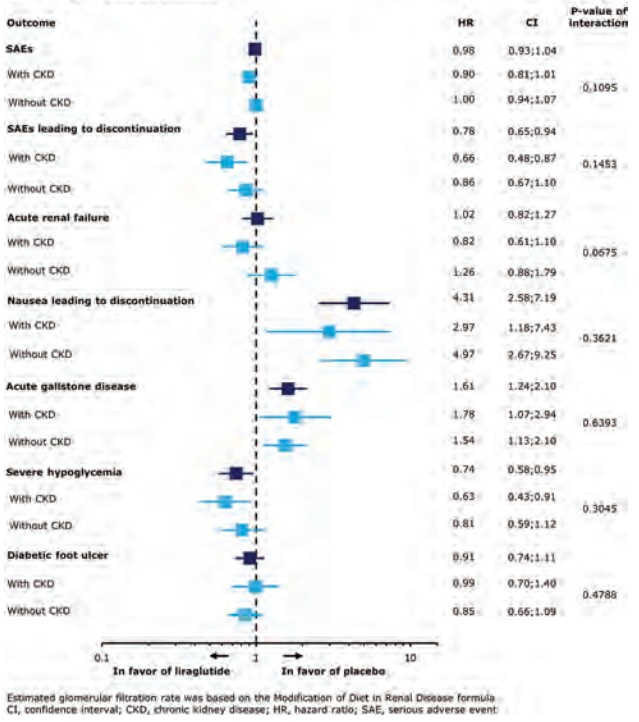
Results: Mean eGFR in patients with (n=2158) or without CKD (n=7158) was 45.7 ±10.9 and 90.8±21.6mL/min/1.73m^2, respectively. There was no increased risk of SAEs or SAEs leading to discontinuation with liraglutide vs PBO in those with and

without CKD (Fig); and no conclusive risk of acute renal failure in those with CKD (hazard ratio [HR] 0.82, confidence interval [CI] 0.61;1.10) or without CKD (HR 1.26, CI 0.88;1.79) with liraglutide vs PBO. There was no difference in the risk of nausea leading to discontinuation or acute gallstone disease in patients with and without CKD. Severe hypoglycemia risk was significantly reduced with liraglutide by 37% (with CKD, HR 0.63, CI 0.43;0.91) and non-significantly reduced by 19% (without CKD, HR 0.81, CI 0.59;1.12). Diabetic foot ulcer risk was not increased with liraglutide in those with and without CKD (Fig).

Conclusions: In LEADER, liraglutide was as well tolerated in patients with CKD as in those without CKD.

Funding: Commercial Support - Novo Nordisk A/S

Figure: Risk of selected adverse events with liraglutide vs placebo according to CKD at baseline



Estimated glomerular filtration rate was based on the Modification of Diet in Renal Disease formula

FR-PO669

Renal Histology Does Not Predict Progression of Diabetic Nephropathy Paraish S. Misra,[2] Adriana Krizova,[3] Richard E. Gilbert,[1,4] Darren A. Yuen.[1,4] *[1]Keenan Research Centre for Biomedical Sciences, St. Michael's Hospital, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]St Michael's Hospital, Toronto, ON, Canada; [4]Faculty of Medicine, University of Toronto, Toronto, ON, Canada.*

Background: The ability to predict renal disease progression in diabetes remains limited, despite the identification of well-established risk factors including glycemic control, blood pressure, and albuminuria. The consensus pathologic classification system developed by the Renal Pathology Society (RPS) was designed to assist clinical and research assessment of diabetic nephropathy. While some reports have suggested that the RPS classification correlates with disease progression, its predictive potential has not yet been completely evaluated. Our aim was to determine the relationship between the RPS score and progression of diabetic renal disease.

Methods: Slope of estimated glomerular filtration rate (eGFR) decline was calculated for patients with biopsy-proven diabetic kidney disease, and correlated with RPS histologic classification scores. Results were adjusted for baseline eGFR and urine albumin-to-creatinine ratios (ACR) at the time of biopsy. Additionally, the correlation between slope of eGFR decline and histologic and clinic parameters was assessed, and renal survival curves (time off dialysis) were generated for subgroups of ACR, eGFR, and histology scores.

Results: 26 patients with biopsy-proven diabetic kidney disease and at least 6 months of eGFR follow-up data were identified among 394 biopsies performed at St. Michael's Hospital between 2011 and 2016. While renal survival was significantly worse with increasing glomerular and interstitial fibrosis/tubular atrophy scores ($p < 0.0001$ and $p = 0.0124$, respectively), patients with higher fibrosis scores had lower eGFR at the time of biopsy ($r = -0.6623$, $p = 0.0002$). Slope of eGFR decline did not correlate with either histologic classification or baseline clinical parameters on univariate or multivariate analyses.

Conclusions: Beyond establishing the diagnosis of diabetic nephropathy, our results suggest that renal biopsy does not provide any additional information regarding the rate of disease progression. While patients with higher fibrosis scores on biopsy tended to have poorer renal survival, such individuals also had lower baseline eGFR. Importantly, histologic scores did not correlate with future changes in eGFR. Larger studies are needed to confirm these observations.

FR-PO670

Low Estimated Glomerular Filtration Rate (eGFR < 60 ml/min/1.73 m2) with Albumin-to-Creatinine Ratio [ACR)] <30 mg/g Is Associated with Increased Mortality Risk in Diabetics Holly J. Kramer,[1] R. E. Boucher,[3] Guo Wei,[2] Alfred K. Cheung,[3] William C. Cushman,[4] Srini Beddhu.[3] *[1]Loyola University Medical Center, Maywood, IL; [2]University of Utah, Salt Lake City, UT; [3]University of Utah School of Medicine, Salt Lake City, UT; [4]Memphis VA Medical Center, Memphis, TN.*

Background: Prevalence of low eGFR (< 60 ml/min/1.73 m^2) with an ACR < 30 mg/g is increasing, especially among adults with diabetes, likely due to better management of chronic kidney disease (CKD) risk factors. Determining the association between CKD phenotypes including low eGFR with ACR < 30 mg/g in adults with and without diabetes may help guide prevention efforts to reduce CKD associated morbidity and mortality.

Methods: We examined unadjusted mortality rates by CKD phenotype (based on eGFR and ACR grouops) using data from the Action to Control Cardiovascular Disease (ACCORD), which included 9777 adults with diabetes, and the Systolic Blood Pressure Intervention trial (SPRINT), which included 8900 adults without diabetes. Cox proprortional hazards models were used to calculate the hazard ratio of mortality by CKD phenotype in these two study populations with simultaneous adjustment for demographics, blood pressure and prevalent cardiovascular disease with the eGFR ≥90 ml/min/1.73 m^2 and ACR < 30 mg/g as referent group.

Results: The mean age was 62.8 (6.7) and 67.9 (9.4) years in ACCORD and SPRINT, respectively. In the ACCORD and SPRINT trials, mortality rates in the group with eGFR < 60 ml/min/1.73 m^2 and ACR < 30 mg/g were 1.99 and 1.36 deaths per 100 person-years, respectively. After adjustment for covariates, presence of eGFR < 60 ml/min/1.73 m^2 with ACR < 30 mg/g was associated with a 1.58-fold higher hazard rate for mortality (95% CI 1.19, 2.10) relative to eGFR ≥ 90 ml/min/1.73 m^2 with ACR < 30 mg/g in ACCORD. No significant association was noted with this CKD phenotype and mortality in SPRINT (hazard ratio 1.17; 95% CI 0.76, 1.80) (see Figure).

Conclusions: Low eGFR with ACR < 30 mg/g is associated with increased mortality risk in adults with diabetes. These data demonstrate the need to identify and implement interventions that reduce mortality in adults with diabetes and CKD, including those without albuminuria.

Urine sCD163 Is a Biomarker of Active Nephrotic Syndrome Sarah M. Moran,[2] Dearbhaile Dooley,[2] Matthias Kretzler,[1] Mark A. Little.[2] *[1]U.Michigan, Ann Arbor, MI; [2]Trinity Health Kidney Centre, Trinity College, Dublin, Ireland. Group/Team: Neptune Nephrotic Syndrome Study Network.*

Background: Prior work has demonstrated that urinary soluble CD163 (usCD163) displays excellent biomarker characteristics for detection of active renal vasculitis in patients with ANCA-associated vasculitis and Lupus. We sought to assess the levels of usCD163 in active and remission nephrotic syndrome.

Methods: Patients with biopsy proven nephrotic syndrome (Minimal change (MCD), focal and segmental glomerulosclerosis (FSGS) and membranous glomerulonephritis (MN) were included. Paired urine samples from time of remission (urine protein creatinine ratio (uPCR) <0.5mg/mmol) and of active nephrotic syndrome (uPCR >3.5mg/mmol) were selected from NEPTUNE a multicentre longitudinal cohort. Creatinine-normalised usCD163 levels were measured in urine by ELISA.

Results: 53 patients were included (MN n=22, MCD n=20, FSGS n=11). Median age at onset of NS was 34.5 years (IQR 13.5-59.8 yrs), median eGFR was 77.3mls/min/1.73m^2 (SD ±30.3mls/min/1.73m^2). Median usCD163 levels were higher in active nephrotic syndrome (536.3ng/mmol (IQR 222.7-1061 ng/mmol))) compared to remission (0.9ng/mmol (IQR 0-19.6 ng/mmol), $p<0.0001$) with median values in active FSGS of 372.9ng/mmol (IQR 151.4-639mg/mmol), active MCD of 539.2ng/mmol (IQR 114.3-1511/mmol), and active MN of 604.2ng/mmol (IQR 305.8-1423/mmol), $p=0.417$. (figure 1A). uProtein:Creatinine Ratio and usCD163 levels were significantly correlated with a low correlation coefficient – in active NS $r^2=0.14$, $p=0.006$ (figure 1B).

Conclusions: usCD163 levels are markedly elevated in active nephrotic syndrome. 14% of the observed variance in usCD163 was explained by total urine protein excretion. This suggests that, although some of the measurable usCD163 in urine of patients with

nephrotic syndrome is due to leak across the GBM, most appears to be derived directly from the glomerular immune process.

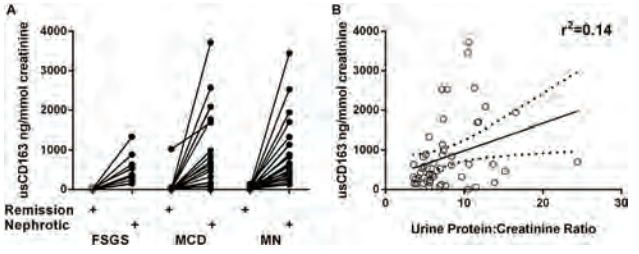

Figure 1A: usCD163 levels in remission and active nephrotic syndrome. FSGS=focal and segmental glomerulosclerosis, MCD=minimal change disease, MN= membranous glomerulonephritis. Figure 1B: Correlation between urine protein creatinine ratio and usCD163 in active nephrotic syndrome.

Urinary CD80 as a Biomarker for Nephrotic Syndrome Marie C. Hogan,[2] Anatilde M. Gonzalez guerrico,[1] Adam M. Wright,[1] Jonathan P. Troost,[3] Fernando C. Fervenza,[1] John C. Lieske,[1] George G. Klee.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN; [3]University of Michigan, Ann Arbor, MI.*

Background: The immune system appears to play a significant role in the pathogenesis of certain nephrotic syndrome (NS) patients with minimal change disease (MCD) and focal segmental glomerular sclerosis (FSGS). CD80/B7-1, a co-stimulatory receptor expressed on activated antigen presenting cells, has been implicated in certain cases. However, CD80 assays have suffered from lack of sensitivity and specificity.

Methods: Use a newly-validated ELISA to determine association of urinary CD80 with renal histology and disease status in biopsy proven MCD, FSGS, or other renal diseases (lupus nephritis, diabetic nephropathy, IgA, membranous nephropathy (MN), or polycystic kidney disease. We modified commercial CD80 ELISAs assays to increase sensitivity (biotinyl tyramide amplification) and analytically validated the assay for urine (uCD80). Cases were recruited from the Mayo and NEPTUNE cohorts(Table). Data is expressed as (mean, median (IQR)) and analyzed by t-test or GEE.

Results: uCD80 levels associated with MCD and FSGS compared to other pathologies, and also was higher in disease relapse (table). Using a GEE model of CD80 levels in all diagnsoses versus MCD we observed strong separation by disease type (MN β= -269; CI -469 to-69; p<0.01; FSGS β=-228, CI -429 to-27, p=0.03; IgA β=-289; CI-489 to-89, p<0.01).

Conclusions: Our results confirm that uCD80 excretion correlates with MCD and FSGS disease status. Further study (ongoing) is warranted to determine whether uCD80 is a useful biomarker for diagnosis, prognosis, and predictor of response to immunosuppression. These results also suggest that uCD80 may reflect immune pathways involved in the pathogenesis of certain MCD and FSGS cases, and further research is needed to understand its cellular source.

Beneficial Effects of Proteasome Inhibitors (PIs) Administered after Onset of Proteinuria in a Model of Minimal Change Disease (MCD) Himanshu Vashistha,[3] Allyson E. Bradley,[3] Frank C. Abbruscato,[3] Patrick D. Walker,[1] Sudhir V. Shah,[2] Radhakrishna Baliga.[3] *[1]Arkana Laboratories, Little Rock, AR; [2]University of Arkansas, Little Rock, AR; [3]Ochsner Health System, New Orleans, LA.*

Background: Proteasomes play a major role in the pathophysiology of several disease processes in part through its action on a crucial transcription factor, nuclear factor-kappa B (NF-κB). NF-κB regulates the expression of a variety of inflammatory genes including cytochrome P450 (CYP) which plays a major role in MCD. We have shown previously that administration of PIs prior to the onset of proteinuria resulted in marked protection against puromycin aminonucleoside (PAN) -induced proteinuria. However, the role of PIs in ongoing glomerular injury and their potential beneficial effects following the establishment of significant proteinuria have not been previously examined. The current study was designed to determine the effect of PIs administration following the onset of proteinuria in a model of MCD and to study the potential mechanism involved utilizing in vitro cultured human podocytes (HP)

Methods: MCD was induced in SD rats by injecting a single dose of PAN intravenously (IV). Proteinuria was measured as albumin to creatinine ratio (ACR) (μg/mg) until day 10. MG-132 was administered by osmotic pumps and Carfilzomib (CAR) was administered IV following onset of proteinuria. Proteins were analyzed by western blot and immunocytochemistry. Immunohistochemical analysis was also performed on the kidney cortical sections.

Results: Administration of MG-132 and CAR after the onset of PAN induced proteinuria (PAN 75±14, PAN+MG132 84±6, PAN+CAR 52±7; NS differences between groups; values are mean ±se) prevented the further increase until sacrifice (PAN 147±13, PAN+MG132 104±17*, PAN+CAR 98+13*; P<0.05* compared to PAN alone). This was accompanied by marked decrease in lipid peroxidation in PIs treated rats. MG-132 significantly decreased the nuclear translocation of NF-KB, activation of IL-6, up regulation of CYP, marked reduction in H_2O_2 release and 8-Oxo-dG expression in cultured HPs. MG-132 and CAR blunted the nuclear translocation of Nrf-2, preserved Keap-1 expression, upregulated PAN induced HO-1 and SOD with significant decrease in apoptosis.

Conclusions: These in vitro and in vivo data imply the crucial role of proteasome in progressive glomerular injury. CAR, which is currently used in humans should be considered as a potential therapeutic alternative in MCD.

Study of a Breakthrough Therapy Utilizing Alternative Actions of Vitamins A and D in a Murine Model of Minimal Change Nephrotic Syndrome Shoji Tsuji, Jiro Kino, Chikushi Suruda, Takahisa Kimata, Sohsaku Yamanouchi, Kazunari Kaneko. *Department of Pediatrics, Kansai Medical University, Osaka, Japan.*

Background: The etiology of minimal change nephrotic syndrome (MCNS) remains unclear, although recent research suggests that regulatory T cell (Treg) malfunction and associated functional and structural podocyte abnormalities play a role. Steroids are shown to have high efficacy against MCNS, and are utilized to correct the above-stated podocyte abnormalities. However, long-term steroid treatment may induce various adverse effects. In addition to their intrinsic vitamin functionality, vitamins A and D have recently demonstrated immunoregulatory functions, including effects on Treg differentiation and induction. Furthermore, they have been shown to restore damaged podocytes, directly [Okamura M, et al. *Nephrol Dial Transplant* 2009;24:3006]. The objective of this study was to investigate if vitamins A and D, which have fewer adverse effects, can correct the causes of MCNS in an animal model, and to search for a non-steroidal therapy for this syndrome.

Methods: Six-week-old MCNS model Wistar rats with puromycin aminonucleoside (PAN)-induced nephrosis were categorized into 4 treatment groups (n=3 per regimen): 1) VA Group received subcutaneous vitamin A 2.5 mg/kg dissolved in 1 mL dimethyl sulfoxide [DMSO]), 2) VD Group received intraperitoneal vitamin D 0.4 μg/kg dissolved in 0.2 mL phosphate-buffered saline [PBS]), 3) VAD Group received both the subcutaneous VA and intraperitoneal VD, 4) C (Control) Group received 0.2 mL subcutaneous DMSO and 0.2 mL intraperitoneal PBS. Starting two days pre-PAN administration, each regimen involved daily treatment for 12 days. Urinary protein excretion was measured and compared among the four groups. The Kruskal-Wallis Test was used for statistical analyses.

Results: Peak urinary protein excretion occurred at Day 9 post-PAN administration, when the median value was significantly lower in the VAD group than the C group (16.4 vs. 731.8 mg/kg/day; p=0.0144) and tended to be lower, although not significantly different, in the VAD group than the single-vitamin-treated rats (16.4 vs. 44.8 [VA] or 264.9 [VD] mg/kg/day.

Conclusions: Vitamins A and D exhibit an antiproteinuric effect with an additive action in MCNS model rats, and are potential therapeutic agents.

FR-PO675

APOL1-B3 Isoform Is Involved in the Processing of the IL-1β Production Hidefumi Wakashin,[1] Jeffrey B. Kopp.[2] *[1]Dokkyo Medical University, Shimotsuga, Japan; [2]NIDDK, NIH, Bethesda, MD.*

Background: *APOL1* genetic variants G1 and G2 increase risk for glomerular disease. Previously, we identified an intracellular splice isoform, APOL1-B3, that is expressed in glomerular cells and tubular cells *in vivo* (ms submitted). In transgenic mice, APOL1-B3-G2 expression enhanced podocyte injury, increased pro-IL-1β mRNA from isolated glomeruli, and increased renal IL-1β protein production. APOL1-B3 interacted with NLRP12, a negative regulator of Toll-like receptor signaling, potentially explaining elevation of pro-IL-1β mRNA in glomeruli. Here we examined the role of APOL1-B3 in inflammasome activation and production of mature IL-1β.

Methods: We generated stable THP-1 monocytic cell lines expressing APOL1 under the control of the chicken actin promoter, CAG-APOL1-B3-FLAG-G0 (common variant) or -G2 (renal risk variant); G1 variant cells were not viable. THP-1 cells were treated with phorbol myristate acetate to induce differentiation into macrophages, which were stimulated with lipopolysaccharide (LPS) and nigericin to activate inflammasomes. We generated CAG-APOL1-B3 transgenic mice, using linear DNA encoding CAG promoter-APOL1-B3 (G0 or G2), with FLAG-SV40 polyA signal sequence. Mice were studied at 6-8 w of age. Random urine was obtained prior to and 3 days after uninephrectomy.

Results: In THP-1 derived macrophages, over expression of APOL1-B3-G0 and –G2 significantly enhanced both LPS-stimulated IL-1β production (mean±SD:

control =193±3.8, G0=585±33, G2=669±79) (P<0.05) and release of caspase-1 into supernatant (control =3393±520, G0=9828±1541, G2= 6783±608) (P<0.05). Following uninephrectomy, increased urinary caspase-1 was seen in both APOL-B3 mice (G0, G2) and wild type mice, with no difference among groups. The ratio of IL-1β to pro-IL-1β in the kidney, assessed by Western blot, increased following uninephrectomy, and was numerically greater in APOL1-B3-G2 mice. These findings suggest enhanced processing of pro-IL-1β by the APOL1 risk variant. By Western blot, both APOL1-B3-G0- and -G2 interacted with NLRP3.

Conclusions: These findings suggest that under the conditions studied, the APOL1-B3 isoform affects processing of IL-1b and add a further dimension to the role of APOL1-B3 in modulating NLRP3 pathway signaling.

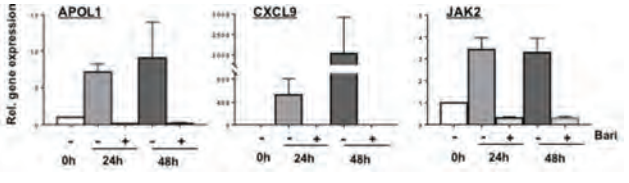
JAK1/2 Regulate APOL1, CXCL9 and JAK2 Expression in Human Kidney Cells Hongyu Zhang,[2] Gordon S. Wu,[3] V Vega-Warner,[2] Matt G. Sampson,[2] Frank C. Brosius.[1,2] *[1]University of Arizona, Tucson, AZ; [2]University of Michigan, Ann Arbor, MI; [3]Wayne State University School of Medicine, Ann Arbor, MI.*

Background: Chronic inflammation contributes to progression of all glomerular diseases. Recent data suggest that both APOL1 and JAK1/2 signaling contribute to the pro-inflammatory milieu in a variety of kidney diseases including FSGS, diabetic kidney disease, and other causes of nephrotic syndrome. Based on systems genetic and transcriptomic analyses of humans and of murine models of glomerular diseases, the expression of CXCL9, a T-cell chemoattractant belonging to the CXC chemokine family, is increased by APOL1 high risk genotype expression and by JAK2 overexpression in podocytes.

Methods: Human kidney 2 (HK-2) cell monolayers were grown to confluence and treated with interferon-gamma (IFN) (30ng/ml), interleukin-6 (IL-6) (10ng/ml), or tumor necrosis factor-alpha (TNF) (10ng/ml) from 30 min to 48 hr. mRNA levels of JAK2, APOL1 and CXCL-9 were determined at multiple timepoints in response to these agonists. A commercially available inhibitor of JAK1 and JAK2, baricitinib (Bari; 500nM), was then applied 30 min prior to agonist incubation.

Results: HK-2 cells were found to express APOL1, JAK2 and CXCL9. Stimulation of HK-2 cell monolayers of with IFN, but not IL-6 or TNF, resulted in a large, rapid and sustained (maximal at 48 hr) increases in mRNA expression of JAK2, APOL1 and CXCL9 (Figure). All of these increases were abrogated by 30 minutes of pretreatment with the JAK1/2 inhibitor as was the IFN induced increase in STAT3 phosphorylation.

Conclusions: In cultured human kidney cells, IFN stimulation triggers a cascade of events resulting in large increases in expression of pro-inflammatory mediators and APOL1. This cascade is completely abrogated by specific inhibition of JAK1/2 signaling. These findings suggest that JAK1/2-STAT3 signaling regulates APOL1, CXCL9 chemokine and JAK2 expression by parenchymal cells in the kidney. Future studies will examine effects of APOL1 modulation and genotype on this process.



IFN-induced increases in APOL1, CXCL9 and JAK2 (-) were completely inhibited by preincubation with Bari (+). N = 3 separate experiments for each timepoint.

FR-PO677

Flt3 Inhibitor Attenuates Renal Injury in Adriamycin Nephropathy by Suppressing CD103+ DC-Mediated T Cell Activation Qi Cao, Titi Chen, Vincent W. Lee, Guoping Zheng, Yiping Wang, David C. Harris. *The Westmead Institute for Medical Research, Westmead, NSW, Australia.*

Background: In our previous study, CD103+ DCs were shown to play a pathogenic role via activation of CD8 T cells in Adriamycin nephropathy (AN), a model of focal segmental glomerulosclerosis. FMS-like tyrosine kinase 3 (Flt3) is a receptor which is highly and specifically expressed on tissue resident CD103+ DCs. To test the effect on renal injury of inhibition of Flt3 on CD103+ DCs, we used a selective Flt3 inhibitor (AC220) to treat mice with AN.

Methods: AN was induced in BALB/c mice, who were treated daily for 14 days with 10mg/kg AC220 or Vehicle (n=8/group) from day 7 after adriamycin, when AN was established. Renal functional and structural injury, as well as inflammatory cytokine expression and cell infiltration were assessed.

Results: The number of kidney CD103+ DCs, but not CD103- DCs or plasmacytoid DCs, was significantly decreased in AN mice after AC220 administration. Treatment with AC220 significantly improved renal function (creatinine clearance: 22.8±4.9 vs. 50.2±13.3 μl/min) and reduced structural renal injury and fibrosis in AN mice. AC220-treated AN mice had decreased levels of inflammatory cytokines IL-1beta, IL-6 and TNF-a in kidney. AC220 treatment decreased infiltration of CD4 T cells, CD8 T cells and macrophages in kidney, and reduced inflammatory cytokine and cytotoxic molecule expression of kidney CD8 T cells in AN mice.

Conclusions: Flt3 inhibitor AC220 effectively reduced renal injury in AN mice, suggesting that this inhibitor might be a useful pharmaceutical agent to treat chronic kidney disease.

MBL2 Gene Polymorphism and IgG4 in Membranous Nephropathy Denise M. Costa,[2,1] Gisele Vajgel,[2] Maria Alina G. Cavalcante,[2] Camila B. Oliveira,[2,1] Carolina A. Vasconcelos,[1] Lucila Maria Valente.[2] *[1]Nephrology, Instituto de Medicina Integral Prof. Fernando Figueira, Recife, Brazil; [2]Nephrology, Hospital das Clinicas - UFPE, Recife, Brazil.*

Background: Although there is evidence regarding the involvement of the lectin pathway and IgG4 in idiopathic membranous nephropathy (IMN), the trigger responsible for the immune complexes formation is uncertain. It is known that IMN occurs in genetically susceptible individuals, however, very few studies have investigated the possible relationship between this glomerulopathy and polymorphisms of the *MBL2* gene, which is responsible for producing mannose-binding lectin (MBL) protein, a major component of the lectin pathway of the complement. We investigated the frequency of *MBL2* gene polymorphisms and the serum ratio of IgG4 in patients with membranous nephropathy (MN).

Methods: Polymorphisms in the exon 1 of the *MBL2* gene (codons 52, 54 and 57) and SNPs at positions -550 (HL) and -221 (XY) in the promoter region were evaluated in 60 patients compared to a control group of 101 blood donors. It established the frequency of polymorphisms and the serum ratio of IgG4 comparing the two main etiologies of membranous nephropathy: idiopathic (35 patients) and secondary to systemic lupus erythematosus (LMN) in 25 patients.

Results: The O allele, variant of exon 1, was more frequent in the group with MN compared to CG (42% × 22%; p <0.001). The heterozygous A/O was predominant among patients with MN compared to genotype A/A (OR = 11.16; 95% CI = 4.77 - 28.41). There was no difference for genotypes or alleles frequencies among patients and CG in H/L and X/Y promoter variants. When comparing the IMN and LMN groups there was no difference in the frequency of alleles or genotypes with a specific etiology. It was possible to reconstruct combined *MBL2* genotypes from 29 patients, and split in groups as high producers (HYA/HYA, HYA/ LYA, HYA/LXA, LYA/LYA and LYA/LXA), low producers (LXA/LXA, HYA/O and LYA/O) and deficient producers (LXA/O and O/O). A low-producer combined genotype was associated with a greater chance of developing MN (OR = 6.31, 95% CI = 2.26 - 19.7, p = 0.0001) when compared to CG. Serum levels of IgG4 and IgG were measured in 32 patients with IMN and 24 with LMN. The median of serum ratio IgG4 was 5% for IMN and 3% for LMN (p = 0.016).

Conclusions: Our data indicates that *MBL2* polymorphisms may be associated with the activation of lectin pathway by IgG4 subclass antibodies in MN.

FR-PO679

Immunodominant Epitope Regions and Clinical Outcome in THSD7A-Associated Membranous Nephropathy Larissa Seifert, Elion Hoxha, Anna M. Eichhoff, Gunther Zahner, Friedrich Koch-nolte, Rolf A. Stahl, Nicola M. Tomas. *University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: THSD7A has been identified as an autoantigen in patients with membranous nephropathy (MN). The epitopes targeted by patient autoantibodies are unknown.

Methods: In order to define the domain topology of THSD7A, we performed structure-based alignments with thrombospondin type 1 (TSP_1) domains in the protein data bank (pdb). We then cloned THSD7A fragments and tested for reactivity with serum from 31 patients with THSD7A-associated MN in a two-step approach using Western blotting. Clinical and serological follow-up was available from 16 of the 31 patients. We evaluated epitope profiles for associations with disease activity, incidence of malignancy, and clinical outcome.

Results: Protein structural analysis revealed a tandem string of 21 TSP_1 domains (d1 to d21). In a first unbiased approach, three consecutive fragments of the antigen (d1_d4, d5_d10 and d11_d21) were cloned, expressed in HEK293 cells, and tested for reactivity with patient autoantibodies. We found that 84% of patients recognized at least two of the constructs. Therefore, we cloned soluble fragments of 2-3 adjacent TSP_1 domains (d1_d2, d2_d3, d3_d4, d5_d6, d7_d8, d9_d10, d11_d12, d13_d14, d15_d16, d17_d18, d19_d21) in a second approach and tested again for serum reactivity. The d1_d2 fragment was recognized by 84% of the patients and therefore considered the immunodominant epitope region. However, epitope profiles among our patients varied greatly with 9 out of 11 TSP_1 domain fragments being recognized by at least three different sera. There was no association of epitope profiles with proteinuria, renal function or malignancy at the time of diagnosis. However, patients who recognized only one or two epitopes had lower anti-THSD7A antibody levels and less proteinuria. Among the patients with clinical and serological follow-up, 5 patients showed stable epitope profiles and persistent active disease, 8 patients lost reactivity with one or more constructs over time, and 3 patients showed a change in epitope profile during follow-up.

Conclusions: Our study demonstrates that autoantibodies in THSD7A-associated MN target a great variety of epitopes within the antigen. We could not identify epitope risk profiles regarding disease activity, clinical outcome during follow-up or incidence of malignancy.

Visualization of Myeloma Light Chain Filtration and Proximal Tubule Trafficking: Implication for MGUS Dawson Dean,[1] Ruben M. Sandoval,[1,2] Mark C. Wagner,[1,2] Silvia B. Campos-bilderback,[1,2] Bruce A. Molitoris.[1,2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Roudabush VAMC, Indianapolis, IN.*

Background: Myeloma light chains are thought to cause acute and chronic kidney injury by several mechanisms including tubular obstruction and direct proximal tubule (PT) injury. Earlier forms of this disease, including Monoclonal Gammopathy of Undetermined Significance (MGUS), are detected by serum markers but their impact on the nephron is not fully understood.

Methods: To study directly the fate of serum myeloma light chains we isolated myeloma light chains from patient urines using gel sizing techniques, conjugated them to Texas Red, and injected either in a pulse chase or pulse with a continuous infusion.

Results: Using 2-photon microscopy of surface glomeruli of Munich Wistar Fromter rats, the glomerular sieving coefficients of these conjugated Myeloma proteins were determined to be 0.14 ± 0.02. Additionally, light chains attached to PT apical membranes within 20 seconds following IV injection, accumulated rapidly in a linear fashion within the apical aspect of the cell and subsequently trafficked to lysosomes. No transcytosis was visualized. Both S1 and S2 segments of PT participated equally in a saturable process with non-reabsorbed light chains being concentrated in distal tubule lumens. These data indicate myeloma light chains are readily filtered across the glomerulus, reabsorbed effectively by PT cells and do not appear in the urine until saturation of PT reabsorption has occurred.

Conclusions: This has important implications in MGUS where PT protein overload and subclinical injury could be occurring without serum or urine evidence of paraproteinemia.

FR-PO681

Estrogen-Related Receptor α (ERRα) Plays Proapoptotic and Proinflammatory Roles in Mesangial Cells Wei Gong, Yue Zhang, Songming Huang, Zhanjun Jia, Aihua Zhang. *Nephrology Department, Children's Hospital of Nanjing Medical University, Nanjing, China.*

Background: Mesangial Cell **(**MC) apoptosis has been proposed as an important cell clearance mechanism during the uncontrolled MC proliferation. The present study is undertaken to investigate the role of ERRα in MC apoptosis under the normal and pathological conditions.

Methods: The mouse MC line was treated with vehicle or puromycin aminonucleoside (PAN). Then the regulation of ERRα and the role of ERRα in MC apoptosis and inflammation was examined.

Results: PAN induced MC apoptosis by 2.3 folds accompanied by the declined cell viability and enhanced inflammatory response. The apoptosis was further evidenced by the increments of BAX/Bcl-2 ratio and caspase-3 expression. In line with the apoptotic response, we also found a remarkable induction of ERRα, an orphan nuclear receptor, at both mRNA (>5-fold) and protein levels (>2-fold). Interestingly, ERRα silencing by a siRNA approach resulted in an attenuation of MC apoptosis by 45% caused by PAN. Meantime, the inflammatory response was also markedly ameliorated. More importantly, overexpression of ERRα in MCs significantly triggered MC apoptosis in line with increased BAX/Bcl-2 ratio and caspase-3 expression. In PAN-treated MCs, ERRα overexpression further aggravated PAN-induced apoptosis by 2.3-fold.

Conclusions: These data suggested a detrimental effect of ERRα on PAN-induced MC apoptosis and inflammatory response, which could help us to better understand the pathogenic mechanism of MC injury in PAN nephropathy and other glomerular diseases.

Prescribed Chinese Herbal Medicine, Shen Ping Decoction, Blocks Activation of Human Mesangial Cells Induced by Different Pathogenic Mechanisms Xianwen Zhang,[1,3] Zhi qiang Huang,[3] Lin Wang,[1] Stacy D. Hall,[2] Bruce A. Julian,[3] Yiping Chen,[4] Jan Novak.[3] *[1]Longhua Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China; [2]UAB, Birmingham, AL; [3]University of Alabama at Birmingham, Birmingham, AL; [4]longhua hospital, SHANGHAI, China.*

Background: Mesangioproliferative glomerular diseases are characterized by increased proliferation of mesangial cells (MC), often due to the activation by PDGF and/or angiotensin II (AII). Shen Ping decoction (SP), an herbal medicine, has been prescribed to treat IgA nephropathy (IgAN) in China for decades; SP treatment effectively reduces proteinuria and stabilizes renal function. To investigate the pharmaceutical mechanisms of SP, we assessed the effects of SP in our model of primary human MC using MC activators PDGF-BB or AII.

Methods: MCs were treated using PDGF-BB for 15 min with or without SP. Phosphorylation of PDGF receptor-β (PGDFR-β), its down-stream signaling, and a TAM-family kinase Axl were assessed by Western blotting using MC lysates. Binding of biotylated PDGF-BB to its receptor was measured with or without SP. Cellular proliferation was determined using BrdU uptake. MCs were also treated with AII for 15 min with or without SP and transactivation of EGFR by AII was assessed.

Results: SP inhibited proliferation of MCs induced by PDGF-BB in a dose-dependent manner. SP blocked binding of PDGF to its receptor, thus inhibiting phosphorylation of PDGFR-β. Activation of down-stream signaling, including phosphorylation of ERK1/2 and AKT, was also blocked by SP. Moreover, SP inhibited PDGF-induced transactivation of TAM-family kinase Axl. Phosphorylation of EGFR in MCs was activated by AII treatment and was inhibited by SP in a dose-dependent manner. Activation of EGFR down-stream signaling, including ERK1/2 and AKT, was also inhibited.

Conclusions: Chinese herbal medicine SP blocked MC activation induced by PDGF-BB or AII through inhibition of multiple signaling pathways. These findings thus explain some of the mechanisms of SP treatment to benefit patients with IgAN.

Heparanase II Inhibits Heparanase I-Mediated Cleavage of Endothelial Glycocalyx, Preserves Glomerular Integrity, and Prevents Microvascular Injury Yulia Kiyan,[1] Klaus Stahl,[4] Sergey Tkachuk,[5] Patricia A. Schroder,[6] Laura L. Beverly-Staggs,[3] Mario Schiffer,[1] Roman Kiyan,[2] Boris Chichkov,[2] Hermann G. Haller.[1,6] *[1]Hannover Medical School, Hannover, Germany; [2]Laser Zentrum Hannover e.V., Hannover, Germany; [3]Mount Desert Island Biological Lab, Salisbury Harbor, ME; [4]MHH, Hannover, Germany; [5]Medizinische Hochschule Hannover, Hannover, Germany; [6]Mount Desert Island Biological Laboratory, Salisbury Cove, ME.*

Background: Regulation of heparan sulfate (HS) chains of the glycocalyx is an important pathomechanism of vascular and renal diseases. Heparanase 1 (HPSE1) is the only known glucuronidase capable of degrading HS chains. Recently cloned heparanase 2 (HPSE2) is catalytically inactive and its functions are yet unclear. We have tested the hypothesis that HPSE2 antagonizes HPSE1, prevents HS chain cleavage and protects endothelial cell function.

Methods: In vitro study of endothelial cells (EC) were carried out (1) in cell culture and (2) in a microfluidic chip under flow conditions. We developed a lentiviral construct and upregulated HPSE2 expression in EC. To assess HSPE2 function in vivo we used a transgenic zebrafish model (Tg(I-fabp:GFP-DBP) and measured loss of fluorescent protein form the circulation.

Results: Addition of active HPSE1 led to the shedding of HS layer from endothelial cell surface. Overexpressing HPSE2 protected against HPSE1-induced glycocalyx shedding and damage of VE-cadherin junctions, cytoskeletal rearrangements and from glucose-induced ICAM expression and adhesion of AM-labelled monocytes. LPS stimulation with increased expression of IL-6, IL-1β, and RANTES, as well as phosphorylation of p65 subunit of NFκB, p38, and MEK kinases was diminished by HPSE2 overexpression. HPSE2 knockdown in zebrafish showed a phenotype characterized by general body edema and albuminuria. Diffuse leakage of from the intravascular compartment into the interstitial tissue of the fish tail was visualized. Simultaneous injection of human HPSE2 full length mRNA we partially rescued the proteinuric phenotype of HPSE2-KD fish.

Conclusions: HPSE2 is important for endothelial development and function in zebrafish model and in vitro under flow conditions. Our results suggest that HPSE2, expressed locally by EC or delivered with blood, fulfills protective role in microvasculature via several distinct mechanisms. First, it binds to and protects the HS glycocalyx from enzymatic shedding by HPSE1. In addition, HPSE2 binding to HS diminishes HS involvement in receptor-ligand interaction and is anti-inflammatory. We suggest that the C-terminal part of the HPSE2 protein containing HS-binding motif might be critical for endothelial function.

Podocyte Cross Talk with Parietal Epithelial Cells (PECs) Stimulates PECs Proliferation in HIV Milieu Vinod Kumar,[4] Xiqian Lan,[1] Rukhsana Aslam,[2] Ali Hussain,[3] Seyedeh Shadafarin Marashi Shoshtari,[6] Catherine Meyer-Schwesinger,[7] Ashwani Malhotra,[8] Pravin C. Singhal.[5] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute for medical research, Glenoaks, NY; [3]Feinstein Institute of Medical Research, New York, NY; [4]Immunolgy and Inflammation, Fienstine Institute for Medical Research, New York, NY; [5]North Shore LIJ Health System, Great Neck, NY; [6]The Feinstein Institute for Medical Research, Manhasset, NY; [7]University of Hamburg, Hamburg, Germany; [8]Immunolgy and Inflammation, Feinstein Inst. Med research and NSLIJ, Manhasset, NY.*

Background: HIV-associated nephropathy is characterized by an abundance of proliferating PECs in Bowman's space. The involved mechanism of PECs proliferation in HIV milieu is not clear. Recently, we demonstrated that HIV stimulates IL-1β generation by PDs. We now hypothesize that cross talk between PDs to PECs and PECs to PECs promotes PECs proliferation.

Methods: Immortalized PECs and differentiated PDs were transduced with either vector (PECV/PDV) or HIV (PECHIV/PDHIV, NL4-3) and assayed for pyroptosis (morphologic assay). Control PECs/PDs, PECV/PDV, and PECHIV/PDHIV were incubated in serum-free media for 24 hours. Incubation (conditioned, C) media was collected and stored at -80°C. PECs were incubated in serum-free media containing 10% of control (PECV/PDV) and experimental (PECHIV/PDHIV) conditioned media for 48 hours. In another set of experiments, PECs were incubated in serum free media containing 10% control and experimental media with or without IL-1β (neutralizing) antibodies for 48 hours. Cells were evaluated for proliferation by MTT cellular viability

assay. To confirm the role of cross talk, PECs were grown in outer wells and PECHIVs/PDHIVs were seeded into inner wells (Trans-well plates). After 48 hours, cells in outer wells were assayed for proliferation. Cellular lysates/incubation media of PECs/PDs and PECHIV/PDHIV were assayed for IL-1β by ELISA. Additionally, PECs grown on coverslips were treated with 10% control and experimental media for 48 hours followed by immunolabeling for either PCNA or Ki67.

Results: Both PDHIV and PECHIV displayed a higher percentage of pyroptosed cells (P<0.01 vs respective controls). Cellular lysates and incubation media of PDHIV and PECHIV displayed enhanced (P<0.05 vs. PDHIV and PECHIV) generation of IL-1β. Conditioned media of PDHIV and PECHIV promoted PECs proliferation; however, anti-IL-1β antibody partially inhibited PDHIV/PECHIV-conditioned media-mediated proliferation. PECs growing in outer wells of trans-well plates containing PDHIV/PECHIV also displayed enhanced proliferation. PECs treated with PECHIV/PDHIV conditioned media higher percentage (P<0.01 vs. PECV/PDV) of PCNA/Ki67 +ve cells.

Conclusions: Cross talks between PDs to PECs and PECs to PECs promote PECs proliferation in HIV milieu.

FR-PO685

Vitamin D Receptor (VDR) Agonist Slows Down Progression of HIVAN via Down Regulation of HIV Gene Expression Seyedeh Shadafarin Marashi Shoshtari,[3] Rukhsana Aslam,[1] Vinod Kumar,[3] Ashwani Malhotra,[1] Pravin C. Singhal.[2] *[1]Feinstein Institute for medical research, Glenoaks, NY; [2]North Shore LIJ Health System, Great Neck, NY; [3]The Feinstein Institute for Medical Research, Manhasset, NY.*

Background: Activation of renin angiotensin system (RAS) has been demonstrated to play an important role for the progression of HIVAN. This effect of RAS has been attributed to modulation of hemodynamic factors as well as direct cytotoxicity to kidney cells. We have previously demonstrated that HIV enhances kidney cell renin expression. We now hypothesize that renin enhances HIV gene expression and this effect of renin could be prevented by VDR agonist, resulting in slowing down the progression of HIVAN.

Methods: Human podocytes (HPs) were transdudced with either vector (V/HP) or HIV (NL4-3, HIV/HP). To increase endogenous renin production, V/HPs and HIV/HPs were transfected with siRNA vitamin D receptor (siRNA-VDR/HIV/HPs) or scrambled (Scr-siRNA/HIV/HP) siRNA; protein blots were probed for renin and actin expressions. To evaluate the effect of renin in vivo, mRNA expressions of HIV genes from renal tissues of HIVAN (Tg26) mice with higher endogenous renin (Tg26 mice expressing 2, 3 and 4 copies of angiotensinogen [Agt] or lacking VDR) were quantified by qPCR. To down regulate renal tissue renin expression, Tg26 mice were treated with either vehicle or a VDR agonist (VDA) for 2 weeks and renal tissues were evaluated for HIV gene expression. In addition, gene expression and progression of renal lesions in Tg26 mice, Tg26 mice lacking renin, and Tg26 mice treated with VDA. were compared.

Results: HIV enhanced renin expression in HPs. Silencing of VDR in HIV/HPs further enhanced expression of Nef, Tat, and Vif. However, VDA down regulated HIV gene expression in HIV/HPs. Renal tissues of Tg26 with 4 Agt copies displayed 2-4 fold increase in mRNA expression of gp120, Vpr, Tat, Nef and Vpu vs. Tg26 (Agt 2 copies). Similarly, Tg26 mice lacking VDR displayed greater HIV gene expression when compared to Tg26 mice with intact VDR. VDA-treated of Tg26 mice not only down regulated renal tissue expressions of renin but also attenuated expression of HIV genes. Tg26 mice lacking renin or treated with VDA, displayed attenuated renal tissue HIV gene expression and slowed down the rate of progression of renal lesions.

Conclusions: Renin enhances renal tissue and podocyte HIV gene expression and induces accelerated progression of renal lesions; however, this effect of renin could be prevented by VDA treatment.

IRAK4 Inactivation Eliminates Disease Phenotype in a Murine Model of Lupus/Lupus Nephritis Barry K. Horne, Ian R. Rifkin, Ramon G. Bonegio. *Boston University School of Medicine, South Weymouth, MA.*

Background: Toll-like Receptor (TLR) signaling has been shown to play a major role in the progression of lupus and lupus nephritis (LN). Interleukin-1 Receptor-Associated Kinase 4 (IRAK4) is a protein kinase that is critical to mammalian TLR signaling. Humans with homozygous loss-of-function (LOF) mutations in IRAK4 lead relatively normal lives upon reaching adulthood. Attempts at specific *in vivo* inactivation of kinases in other human diseases have met with great success, and they are currently considered attractive targets for the development of new therapeutics. Thus, we hypothesized that inactivation of IRAK4 would ameliorate disease in our murine model of lupus / LN, and validate it as a potential therapeutic.

Methods: We crossed lupus prone Yaa, FcγRIIb$^{-/-}$ mice to mice with inactive IRAK4 kinase to allow the comparison of lupus prone mice with (IRAK4$^{+/+}$) or without (IRAK4$^{KD/KD}$) functional IRAK4. We conducted a survival study, and analyzed the groups for markers of the lupus phenotype: body weight, spleen weight, cervical lymph node weight, perigonadal fat weight, and proteinuria.

Results: IRAK4$^{+/+}$ mice developed severe lupus and lupus nephritis, and died at a median age of 27 weeks (range: 22 to 28 weeks). In contrast, IRAK4$^{KD/KD}$ mice had a dramatic survival advantage (p<0.001), and mice analyzed at 1 year of age had no evidence of lupus. They exhibited no signs of nephritis, lacked proteinuria, and had normal spleen, cervical lymph node, and fat weights.

Conclusions: IRAK4 kinase activity is indispensable for the development of lupus and lupus nephritis in the Yaa, FcγRIIb$^{-/-}$ mice, indicating that the IRAK4 signaling pathway is an attractive therapeutic target.

Increased MERTK Glomerular mRNA Expression in LN Multiethnic Populations: A Modulator of Innate Inflammation Iris J. Lee,[1] Paris Barkan,[1] Kalyani Perumal,[2] Sudha Visvanathan,[3] Matthias Kretzler,[4] Crystal A. Gadegbeku,[1] Brad A. Godfrey,[4] Celine C. Berthier.[4] *[1]Temple University School of Medicine, Philadelphia, PA; [2]Stroger Hospital, Chicago, IL; [3]Boehringer-Ingelheim, Ridgefield, CT; [4]University of Michigan, Ann Arbor, MI.*

Background: Inflammation and cytokine dysregulation contribute to disease pathogenesis in Systemic Lupus Erythematous (SLE) and lupus nephritis (LN). MERTK, a receptor protein tyrosine kinase, limits toll like receptor (TLR)-induced production of pro-inflammatory cytokines (IL-6, IL-1β and TNF-α) through the induction of suppressor of cytokine signaling proteins (SOCS). MERTK also mediates phagocytosis and clearance of apoptotic cells, a function known to be defective in SLE. Furthermore, mice deficient in MERTK develop glomerulonephritis. Therefore, we investigated MERTK mRNA expression in human LN renal biopsies.

Methods: Gene expression profiles of microdissected renal biopsies from LN patient (European and Multiethnic cohorts, including WHO class II, III, IV, V) were analyzed.

Results: In the European cohort, glomerular MERTK transcript was 2.6 fold up-regulated in LN compared to controls (q-value<0.0001), and was the most highly altered compared to kidney biopsies from other proteinuric diseases (FSGS, Hypertensive nephropathy, IgAN, Minimal change, Membranous). For diabetic nephropathy and rapidly progressive GN, fold-change was 1.2 and 1.7 respectively (q-value<0.005). Like the European cohort, glomerular MERTK was also 2.3 fold up-regulated in the Multiethnic cohort (q-value <0.0001). MERTK mRNA was not significantly regulated in the tubular compartment of any kidney disease. Finally, MERTK mRNA expression was not significantly different among CKD stages I-V, and did not correlate with GFR or level of proteinuria.

Conclusions: Our data show preferential expression of MERTK in the glomerular compartment of LN tissue compared to controls. In addition, expression was unrelated to level of GFR or proteinuria. MERTK is known to regulate innate inflammation, and its expression in LN likely represents an adaptive response to an upregulated immune system. Further research is necessary to understand how alterations in MERTK gene expression pattern contributes to pathogenesis of glomerular injury and inflammation in LN, or would be useful as a biomarker for LN outcomes.

Robust Improvement in Lupus Nephritis after Hyaluronidase Treatment Due to the Removal of Accumulated Hyaluronic Acid in Glomerular Endothelial Glycocalyx Hiroyuki Kadoya, Chaim O. Jacob, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: Lupus Nephritis (LN) is a major cause of morbidity and mortality in patients with systemic lupus. The exact pathomechanism of LN has been elusive, and therefore current non-specific therapies are limited to general immunosuppression. Recently, we developed an intravital multiphoton microscopy (MPM) imaging approach to visualize the interplay between cellular components of the immune system and local kidney tissue factors. We observed the glomerular homing of IL-17-producing activated memory T cells, which were the vast majority of all immune cells found in LN kidney. The present study tested the hypothesis that T cell homing is due to the accumulation of the CD44 ligand hyaluronic acid (HA) in the glomerular endothelial glycocalyx, and its removal by hyaluronidase improves LN.

Methods: Serial MPM was used to track the fate of endogenous T cells labeled with anti-CD3 and anti-CD44 antibodies in vivo in a model of rapid LN (BAFF transgenic New Zealand mixed (NZM) mice). FITC-labeled wheat germ agglutinin (WGA) lectin and Alexa594-labeled HA-binding protein (HABP) were used to evaluate glomerular endothelial glycocalyx and HA content, respectively.

Results: Glomerular size, microthrombi, albumin leakage, T cell homing were significantly increased at 4-6 weeks old LN mice compared with control healthy mice. Robust accumulation of endothelial glycocalyx and HA content (thickness and intensity of WGA and HABP fluorescence, respectively) were observed in LN mice, but not in control. Hyaluronidase injection significantly and dose-dependently (EC50=20U) reduced WGA and HABP fluorescence, T cell homing, and albumin leakage within 1 hour. Hyaluronidase treatment caused a 5-fold reduction in albuminuria and 4-fold increase in survival rate of LN mice.

Conclusions: Our results support the major importance of HA in the endothelial glycocalyx in the glomerular homing of memory T cells in the development and pathobiology of LN. Hyaluronidase treatment is a promising new therapeutic approach for LN.

FR-PO689

Neuraminidase Activity Mediates IL-6 Production by Lupus Prone Mesangial Cells Tamara Nowling, Kamala Sundararaj, Jessalyn I. Rodgers. *Medical University of South Carolina, Charleston, SC.*

Background: Glycosphingolipid (GSL) levels and neuraminidase (NEU) (an enzyme that mediates GSL catabolism) activity/expression are altered in the kidneys and/or urine of lupus mice and human patients with proliferative nephritis compared to their non-nephritic counterparts and healthy controls. Specifically, elevated GSL levels were observed in the mesangial region of glomeruli. We hypothesize that activation of mesangial cells (MCs) in the progression of lupus nephritis is mediated in part by NEU activity, contributing to renal inflammation in lupus nephritis. Here we investigated the role and possible mechanisms by which NEU activity contributes to MC activation.

Methods: For these studies, we used the MES13 mouse MC line and primary MCs grown out from glomeruli isolated from MRL/lpr lupus prone mice. MCs were analyzed in the absence or presence of heat aggregated IgG (mimic of immune complex deposition), inhibitors for NEU activity or MAP kinase pathways inhibitors include real-time RTPCR, NEU activity assays, IL-6 and MCP-1 ELISAs, immunohistochemistry of renal sections, and confocal immunofluorescence of MCs.

Results: While HA-IgG alone fails to activate MES13 cells to produce IL-6, over-expressing NEU1 or NEU3 alone results in significant production of IL-6. HA-IgG added to MES13 cells over-expressing NEU1 or NEU3 further increased IL-6 production over NEU1 or NEU3 alone. In primary MCs, Neu1 message levels, NEU activity, and IL-6 and MCP-1 production are dose-dependently and significantly increased following addition of HA-IgG. Addition of an FDA-approved inhibitor of NEU activity significantly and dose-dependently inhibited HA-IgG-induced IL-6 while higher concentrations were required to inhibit MCP-1 production. NEU1 and NEU3 appear to co-localize with HA-IgG at the surface of the MES13 and primary MCs. JNK and p38 MAP kinase inhibitors prevented IL-6 production in response to NEU1 or NEU3 over-expression in MES13 cells.

Conclusions: Together these results suggest that immune complex activated IL-6 production of MCs is mediated by NEU activity. This may occur at the cell surface in a complex of HA-IgG and surface receptor that recognizes HA-IgG. Furthermore, the NEU1/NEU3 mediated IL-6 production appears to involve the p38/JNK stress-activated MAPK pathways. Targeting NEU activity may reduce MC cytokine production and thus renal inflammation in lupus nephritis.

Effects of High Titers of Anti-Chimeric Antibodies Following Rituximab Dario Roccatello,[1] Savino Sciascia,[2] Roberta Fenoglio.[1] *[1]Ospedale San GIovanni Bosco, Torino, Italy; [2]Center of Research of Immunopathology and Rare Diseases (CMID), Division of Clinical Immunology, Giovanni Bosco Hospital and University of Turin, Ita, Torino, Italy.*

Background: Monoclonal antibodies (MoAbs) are highly successful in treating various immunological disorders. The development of anti-drug antibodies (ADA) against the therapeutic MoAb is relatively common. In recent years, knowledge of how to assess immunogenicity of biological drugs has improved. ADA are thought to form immune complexes with the MoAb, leading to accelerated MoAB clearance and low decrease levels in the blood stream. Several reports showed an inverse relationship between MoAb levels and anti MoAb antibody formation. Further, patients who develop ADA are more likely to present with infusion-related adverse effects. Acute infusion reactions, including anaphylaxis, develop in a close temporal relationship to MoAb infusion. Among the others MoAbs, Rituximab (RTX), an anti-CD20 monoclonal antibody, often results in the production of human anti-chimeric antibodies (HACA). In this study, we aimed to to evaluate the presence of HACA in patients with poor response to treatment with RTX

Methods: We assessed the incidence of HACA in patients with autoimmune diseases treated with the RTX and determine the potential relationship with trough drug concentration, efficacy, and patient-reported outcomes.

Results: When investigating 37 patients treated with RTX, we found very high-titer of HACA (> 1,000 AU) in 5 patients (13.5%): 2 with Systemic Lupus Erythematosus (SLE), 2 with Membranous Nephropathy (MN) and 1 patient with Mixed Cryoglobulinemia (MC). Details are given in table 1. In 4 of them, high titers of HACA were clearly related to unresponsiveness to RTX treatment. In the other case the appearance of high HACA titers was consonant with a severe hypersensitivity reaction during RTX re-treatment.

Conclusions: HACA detection and monitoring, especially in the cases of RTX re-treatment, could not only assure a safer administration, but also support a more rational strategy of treatment.

Table 1

Case	Disease	# of cycles of RTX	Steroids Therapy	HACA titers (AU)	RTX-level
1	SLE	1	Yes	15,720	ND
2	SLE	1	Yes	3,719	ND
3	MC	3	No	14,670	0
4	MN	1	No	1,007	0
5*	MN	2	No	10,363	0

Abbreviations are: NP: not determined. * Patient with severe hypersensitivity reaction

FR-PO691

CD11b Activation Reduces Inflammation in Lupus Nephritis by Downregulating TLR Pathways Samia Khan, Mohd Hafeez Faridi, Ha Won Lee, Mehmet M. Altintas, Shehryar J. Khaliqdina, David J. Cimbaluk, Vineet Gupta. *Rush University Medical Center, Chicago, IL.*

Background: Single nucleotide polymorphisms (SNPs) in the *ITGAM* gene, coding for CD11b subunit of the integrin CD11b/CD18, produce defective protein and confers a strong predisposition to systemic lupus erythematosus (SLE, lupus) and lupus nephritis. Elevated levels of IFN I in circulation is a heritable risk factor for SLE and play a pathogenic role and are likely driven by a combination of genetic variations and environmental stress. Here we investigate if variations in ITGAM are linked to high IFN I and whether pharmacological CD11b activation could be a therapeutic strategy.

Methods: To test for a direct link between ITGAM SNPs and the TLR induced IFN-I pathways, we measured serum IFN I activity in 171 SLE patients and determined their *ITGAM* genotype. Since ITGAM SNPs result in functionally deficient CD11b, we tested whether partial CD11b activation with small molecule agonist, leukadherin-1 (LA1) can suppress IFN-I pathways and determined TLR signaling components that are regulated by CD11b activation. To test the efficacy of LA1 in a lupus model, we used the MRL/*lpr* mice that develop IFN I-dependent multi-organ lupus similar to human lupus with renal inflammation.

Results: We report that SLE subjects carrying ITGAM SNPs have significantly elevated serum IFN-I activity indicating a direct link between reduced CD11b activity and elevated inflammation in patients. LA1 treatment reduced IFN I responses and protected lupus-prone MRL/*lpr* mice from kidney injury. LA1-treated mice had reduced glomerular damage, proteinuria, and IgG renal immune complex deposition as compared to vehicle-treated controls. CD11b agonist LA1 suppressed proinflammatory cytokine secretion by TLR-activated leukocytes and suppressed IFN I signaling, via an AKT-FOXO3-IRF7 pathway. TLR-stimulated macrophages from CD11b SNP carriers showed increased expression of IRF7 and IFNB, as well as increased nuclear exclusion of FOXO3, which was reversed by LA1.

Conclusions: LA1 suppresses TLR-induced cytokine production that has been directly linked to exacerbation of lupus nephritis. Hence pharmacological CD11b activation is a promising potential novel therapeutic target, particularly in patients identified as carriers of ITGAM variants.

FR-PO692

Exogenous Hepcidin Mitigates and Delays Onset of Lupus Nephritis Yogesh M. Scindia,[2] Ewa U. Mandziak,[3] Valentina Loi,[1] Saleh Mohammad,[3] Sundararaman Swaminathan.[3] *[1]AO Brotzu Cagliari, Cagliari, Italy; [2]Univerisity of Virginia, Charlottesville, VA; [3]University of Virginia, Charlottesville, VA.*

Background: Lupus nephritis (LN) is an end-organ manifestation of systemic lupus erythematosus (SLE) with a strong gender bias and affects mostly pre-menopausal women. Current interventions are imprecise and broadly immunosuppressive and hence there is a constant need for identifying new therapeutic targets. Recent human studies have identified Hepcidin (*Hamp*), the master regulator of iron metabolism as a biomarker of LN, and renal flares are associated with low *Hamp* levels. So far there are no mechanistic studies examining the role of hepcidin in the pathogenesis of SLE. We therefore hypothesized that *Hamp* treatment would mitigate SLE-induced kidney disease.

Methods: 7-week-old female MRL/*lpr* mice (a spontaneous model of SLE, n = 4-5) were treated bi-weekly with saline or 50 µg of hepcidin (i.p) for 10 weeks, following which outcomes like microalbuminuria, histopathology, circulating autoantibody levels and other markers of inflammation were examined.

Results: Saline treated mice developed severe LN by 17 weeks of age as indicated by high microalbuminuria, collagen deposition, renal IL-6, CXCL-1 and M-CSF transcripts, and an infiltration of CD45 cells, F4/80+ve macrophages and T cells. There was a concomitant increase in circulating autoantibodies and serum MCP-1, IL-6, GM-CSF and TNFa. *Hamp* treatment significantly reduced all theses manifestations of LN (Microalbuminuria; PBS, 914.6 ± 64.6 mg/gm vs *Hamp* 314.2 ± 111.2 mg/gm). *Hamp* treatment was associated with a systemic decrease in Cox-2, a mediator of inflammation. There was an increase in renal H-ferritin and a concomitant decrease in iron dependent enzymes, Rrm-1 and Rrm-2, both of which are required for DNA synthesis.

Conclusions: This is the first study to demonstrate therapeutic benefit of *Hamp* in LN. Our results indicate that *Hamp* protects against LN by decreasing Cox-2 and reducing inflammation as well as by reducing cell proliferation through the induction of cytoprotective H-ferritin. Further studies are required to investigate whether *Hamp* mediated protection leads to end-organ resistance to LN or through to modulation of immune responses.

FR-PO693

Antirenal CD4+ T Cells Arise in Lupus Nephritis, Are Mainly of the Th1 Phenotype, Are Only Partially Controlled by Their Regulatory Counterparts, and Invade the Inflamed Kidneys Philipp Enghard,[1] Sebastian Tesch,[2] Dimas Abdirama,[2] Gabriela Riemekasten.[3] *[1]Charité, Berlin, Germany; [2]Charité Universitätsmedizin Berlin, Berlin, Germany; [3]University Lübeck, Lübeck, Germany*.

Background: Lupus nephritis (LN) is associated with local MHC II upregulation and a T cell rich infiltration, suggesting an antigen-specific immune response. However, up to date no renal target antigens are known in LN. Here we report the identification of a set of target autoantigens and characterize the respective CD4+ T cell response.

Methods: Peripheral blood T cells from 57 SLE patients and 11 healthy controls (HC) were analyzed. In an initial cohort T cells were stimulated with kidney lysates from healthy kidneys. Subsequently five candidate autoantigens were identified based on the assumption that a corresponding autoantibody is present and that the respective antigen is upregulated in the inflamed kidney in LN. Enrichment via CD40L expression was performed and intracellular cytokine production was measured with flowcytometry (ARTE method). Regulatory T cells were assessed via CD137 enrichment. Urinary T cells from six patients with active LN were isolated and probed for the presence of autoreactive T cells.

Results: Only marginal T cell reactivity was detectable when stimulating peripheral blood T cells with kidney lysates. In subsequent experiments, a pool of renal candidate autoantigens was used and autoreactive CD4+ T cells were detected in patients with SLE and healthy controls. These cells were mainly IFN-y producing Th1 T cells and were significantly expanded in patients with active LN, compared to inactive SLE patients and HC. IL-4, IL-10 and IL-17 producing antirenal CD4+ T cells were present in lower frequencies, albeit also expanded in patients with active LN. Upon stimulation with renal autoantigens, CD137 expressing Tregs were also detected, and the ratio of IFN-y+ T cells to CD137+ Treg cells was significantly higher in active LN patients and correlated with disease activity. Using T cell libraries we identified Vimentin and Annexin A2 as the main, but not exclusive targets of the antirenal T cell response. Finally, we were able to also detect antirenal T cells in the urine of patients with active LN, indicating renal invasion of these cells.

Conclusions: An antirenal CD4+ T cell response arises in LN. These cells are mainly of the Th1 phenotype, invade the inflamed renal tissue and are only partly controlled by their regulatory counterparts.

Update about PEARL: Pathway Exploration and Analysis in Renal Disease in the Accelerating Medicine Partnership (AMP) Lupus Network Celine C. Berthier,[1] Arnon Arazi,[2] Deepak Rao,[3] Thomas Eisenhaure,[2] Nir Hacohen,[2] David J. Lieb,[2] Betty Diamond,[4] Matthias Kretzler.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Broad Institute, Cambridge, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]The Feinstein Institute for Medical Research, Manhasset, NY. Group/Team: PEARL team members*.

Background: Despite treatments, a substantial proportion of lupus nephritis (LN) patients progress to end stage renal disease and death. Detailed transcriptomic analyses of LN kidneys may identify new therapeutic targets. The AMP-PEARL Phase 1 project is to identify renal and urine LN single cell signatures.

Methods: Cells from urine and renal biopsies performed for clinical diagnosis from inform-consented patients (26 LN, 10 healthy controls) were isolated, frozen into Cryostor solution, sorted and profiled by RNAseq.

Results: A total of 15 immune cell populations active in the inflamed kidney were identified and revealed significant differences in subset frequencies across LN patients (e.g. B-cells, dendritic cells). Genes expression in cells from LN patients compared to those in healthy controls highlighted unique LN dysregulated genes/pathways (such as the expected IFN). The renal and urine signatures significantly correlated, suggesting that urine cells could be used as potential markers for longitudinal monitoring and assessment of kidney inflammation. Two chemokine receptors (CXCR4 and CX3CR1) were expressed on the surface of almost all infiltrating immune cells which may be new therapeutic targets.

Conclusions: Preliminary results from the AMP-PEARL-Phase 1 study identified LN active cells and pathways, that can be used to guide the development of novel therapies. Analyses at a bigger scale in the phase 2 of the project will accelerate discovery of new therapeutic targets and identification of biomarkers to guide therapeutic decisions in LN and integrate the treatment effect.

Funding: Other NIH Support - Accelerating Medicines Partnership (AMP)

Synergetic B-Cell Immunomodulation with Rituximab and Belimumab Combination Treatment in Severe, Refractory SLE: The SynBiose Proof-of-Concept Study Tineke Kraaij,[1] Sylvia Kamerling,[1] Esther de Rooij,[1] Paul L. Van daele,[2] Edwin Bredewold,[1] Jaap A. Bakker,[3] Ingeborg M. Bajema,[4] Hans Ulrich Scherer,[5] Rene Toes,[5] Tom Huizinga,[5] Ton J. Rabelink,[1] Cees van Kooten,[1] Yoe Kie Onno Teng.[1] *[1]Nephrology, Leiden University Medical Center, Leiden, Netherlands; [2]Clinical Immunology, Erasmus MC, Rotterdam, Netherlands; [3]Clinical Chemistry, Leiden University Medical Center, Leiden, Netherlands; [4]Pathology, Leiden University Medical Center, Leiden, Netherlands; [5]Rheumatology, Leiden University Medical Center, Leiden, Netherlands*.

Background: Neutrophil extracellular traps (NETs) are auto-antigenic DNA strands and could give rise to SLE-specific autoantibodies that can deposit in glomeruli. It has been shown that autoantibodies can induce NETs, contributing to a vicious circle of immune activation in SLE. We hypothesized that eliminating autoantibodies can lead to decreased NET induction and thereby ameliorating disease in SLE. We designed a proof-of-concept study to eliminate autoantibodies and NET formation through synergetic B-cell immunomodulation with rituximab and belimumab (RTX+BLM) in severe refractory SLE.

Methods: We treated patients with severe, refractory SLE in a phase 2 study with RTX+BLM. The primary endpoint assessed reduction of pathogenic autoantibodies and NET induction at week 24. Anti-dsDNA autoantibodies were measured and high sensitivity FACS was performed to assess B-cell subsets. NET induction was measured with 3D confocal microscopy.

Results: We included 14 patients with severe, refractory SLE of whom 11 had a renal flare. At 24 weeks we observed significant reductions in anti-dsDNA autoantibodies ($p=0.0015$). CD19+ B-cells were depleted throughout the study ($p=0.0005$) while plasma cells (PCs) temporarily decreased but returned at week 24 despite persistent depletion of transitional B-cells. Taken together with reductions of autoantibodies and stable total IgG, there is no reconstitution of autoreactive PCs. We observed significant decrease in NET reduction ($p=0.0017$). In vitro studies elucidated this resulted in reduction of immune complexes by RTX+BLM. Importantly, beneficial immunological effects translated to amelioration of clinical disease activity: SLEDAI decreased from a median of 18 to 2 ($p=0.0002$). Ten out of 11 LN patients showed a response (4 complete renal responders). The response was achieved while tapering immunosuppressive drugs. Treatment was well-tolerated.

Conclusions: The SynBiose study is the first to demonstrate that RTX+BLM ameliorated disease in severe SLE in association with the reduction of pathogenic autoantibodies and immune complex-mediated NET induction. Therefore, RTX+BLM represents a novel treatment concept in SLE. ClinicalTrials.gov NCT02284984

Erythropoietin (EPO) Ameliorates Lupus Nephritis by Inhibiting TFH and Increasing Treg Andrea Angeletti,[2,4] Chiara Donadei,[2,4] Vivette D. D'Agati,[1] Arun Cumpelik,[2] Joaquin Manrique,[3] Miguel L. Fribourg,[2] Gaetano La Manna,[4] Peter S. Heeger,[2] Paolo Cravedi.[2] *[1]Columbia University College of Physicians and Surgeons, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Complejo Hospital de Navarra, Pamplona, Spain; [4]Nephrology, DIMES, Bologna, Italy*.

Background: Systemic lupus erythematosus (SLE) is characterized by impaired immune regulation and enhanced follicular helper T cell (Tfh)-dependent B cell activation, autoantibody production and tissue deposition/injury. Building upon evidence that EPO inhibits effector T cells (Teff) while promoting regulatory T cells (Treg) (JASN 2017), we tested the effects of EPO in murine lupus.

Methods: We treated MRL/lpr mice with rEPO (5,000IU/ml, 3/week mo 4-6) or vehicle, serially measured proteinuria and at 6 mo quantified anti-dsDNA, glomerular Ig deposition and splenic Treg/Teff/Tfh. We also administered EPO or vehicle to (bxd) F1 mice given B6 spleen cells and quantified splenic Tfh, Treg and germinal center (GC) B cells 2 weeks later.

Results: In MRL/lpr mice, rEPO increased Treg (20.1±3.3 vs. 11.5±4.2%; $P<0.05$) and reduced proteinuria, autoantibodies, glomerular IgG deposition, and histological score (is that right?) (**Fig 1A**). In the parent to F1 model, EPO inhibited T_{FH} and GC B cells formation (**Fig 1B-C**), while it increased Treg cells vs. vehicle (1.4±0.3 vs. 0.4±0.2%; $P<0.05$).

Conclusions: EPO administration inhibits T_{FH} and GC B cell formation while promoting Treg, together reducing the clinical and histological expression of murine lupus nephritis. Together with our published evidence that EPO promotes human Treg, the data support safety/efficacy testing of rEPO as an immunemodulating agent in lupus patients.

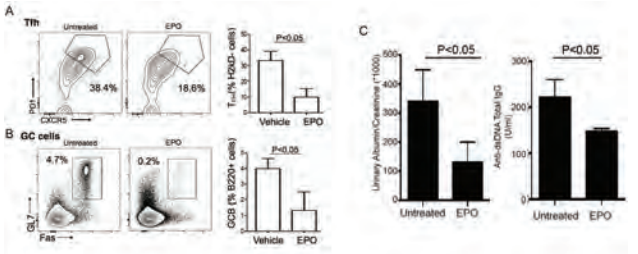

Figure. EPO reduces T_{FH} and germinal center (GC) B cells in GVHD lupus model and ameliorates MRL/lpr model. Donor ($H2kd^a$) $CD4^+PD1^+CXCR5^+$ Tfh cells (A, representative plots, left, and data quantification, right) and host ($H2kd^-$) $B200^+IgM^-IgD^-GL7^+Fas^+$ GC B cells (B) in B6 x BALB/c mice treated with or without EPO (5,000IU x 3/week) at 7 days after adoptive transfer of CD8-depleted splenocytes. C) Proteinuria and serum anti-dsDNA autoantibodies in MRL/lpr mice treated with or without EPO. Data are representative of 3-5 mice per group.

FR-PO697

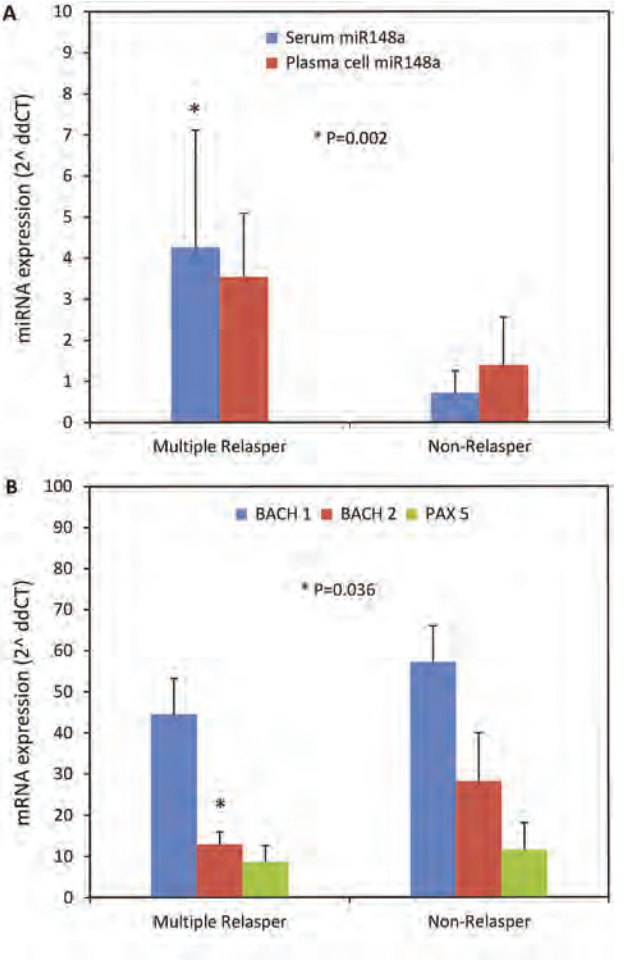
Relationship between B Cell Signatures and Disease Flare in Lupus Nephritis Patients Desmond Y. Yap,[1] Susan Yung,[2] Irene Yam,[2] Paul Lee,[2] Cheryl Tam,[2] Daniel Tak Mao Chan.[1] *[1]Queen Mary Hospital, Hong Kong, China; [2]The University of Hong Kong, Hong Kong, China.*

Background: Nephritic flares in patients with lupus nephritis (LN) reduce renal survival but factors contributing to flares remain elusive. Perturbations of B cell subsets have been implicated in the pathogenesis of LN, but the relationship between B cell signatures and relapse has not been investigated.

Methods: We compared circulating B cell subsets and signatures (miRNA148a, BACH1, BACH2 and PAX5) in the serum and plasma cells during disease quiescence between Class III/IV±V LN patients who are multiple relapsers (MR, defined as ≥3 relapses within 36 months unrelated to non-compliance) or non-relapsers (NR, defined as no relapse after the presenting episode).

Results: 33 patients were included (MR n=20; NR n=13). MR showed lower percentage of circulating naïve and memory B cells (0.48%, IQR 0.24%-3.15% vs. 4.52%, IQR 3.18%-8.25%; and 0.51%, IQR 0.26%-0.67% vs. 0.96%, IQR 0.86%-1.91%; p=0.014 and 0.014 respectively) and higher plasma cell-to-naïve B cell ratio (1.52±2.19 vs. 0.21±0.33, p=0.011) compared with NR. MR had higher miRNA148a in serum and plasma cells compared with NR [relative expression (RQ) 4.25±2.86 vs. 0.71±0.55 and 3.53±1.56 vs. 1.38±1.17, p=0.002 and 0.128] (Figure 1A). MR also showed lower BACH2 expression in circulating plasma cells [RQ 12.86±3.10 vs. 28.10±11.87, p=0.036)], but no difference in BACH1 and PAX5 (p>0.05 for both) (Figure 1B).

Conclusions: Elevated serum and plasma cell miRNA148a might be related to BACH2 downregulation in plasma cells and altered circulating B cell subsets, thereby increasing risk of LN relapse.



FR-PO698

Serum VCAM-1 Level in Patients with Lupus Nephritis and Its Clinical Associations Daniel Tak Mao Chan, Kelvin Yu, Mel Chau, Kwok Fan Cheung, Susan Yung. *Department of Medicine, The University of Hong Kong, Hong Kong SAR, Hong Kong.*

Background: Cardiovascular disease is more common in patients with lupus nephritis. Endothelial cell activation or injury is associated with shedding of adhesion molecules into the circulation. We investigated circulating VCAM-1 level in lupus nephritis patients and its clinical associations.

Methods: Archived paired serum samples, one during flare and the other during clinical remission, from 29 patients with biopsy-proven Class III/IV lupus nephritis were included. Serial samples obtained at intervals of 3-4 months over two years in 27 stable patients were included for longitudinal studies. Smokers and patients with serum creatinine above 450μmol/l or eGFR below 15ml/min were excluded. Age- and sex-matched patients with non-lupus glomerular diseases and healthy subjects (n=25 for each group) were included as controls. Serum VCAM-1 level was measured by ELISA.

Results: 482 serum samples from lupus nephritis patients (20 females and 9 males; age 39.0±10.2 years; disease duration 7.6±8.6 years) were studied. Only one patient had clinically evident vascular disease. Serum VCAM-1 level was significantly higher during active lupus nephritis, compared to remission samples, patients with non-lupus renal diseases or healthy subjects (P<0.001, for all). VCAM-1 level correlated with SLEDAI and the level of anti-dsDNA antibody, serum creatinine, urine albumin-to-creatinine ratio, and prevailing prednisolone daily dose, and inversely correlated with serum C3 and albumin levels. VCAM-1 level was not associated with lipid parameters. Longitudinal studies showed that increased circulating VCAM-1 level preceded clinically evident renal flare by 4.6±3.4 months, and persisted for 11.7±8.8 months after clinical disease quiescence. Analysis with ROC curve showed that serum VCAM-1 level distinguished patients with active lupus nephritis from healthy subjects with sensitivity and specificity rates of 96.5% and 96.0% respectively (P<0.0001), and from patients with non-lupus renal diseases with sensitivity and specificity rates of 89.6% and 82.6% respectively (P<0.0001).

Conclusions: Active lupus nephritis was associated with elevated VCAM-1 level in serum, which persisted for many months despite renal response after treatment. The findings suggest prolonged subclinical vascular endothelial injury and could have implications on the pathogenesis of cardiovascular complications.

Pathologic Findings in Monoclonal Glomerulopathy with Features of Cryoglobulinemic Nephropathy in the Kidneys of a Vk*MYC Transgenic Model of Multiple Myeloma Ping L. Zhang,[1] Guillermo A. Herrera,[3] Karen L. Lewinski,[1] Bei Liu.[2] *[1]Anatomic Pathology, Beaumont Health System, Royal Oak, MI; [2]Immunology, Medical University of South Carolina, Charleston, SC; [3]Pathology, Louisiana State University Health Sciences Center, Shreveport, LA.*

Background: There are only a few animal models of monoclonal light chain-associated renal diseases and no animal models of monoclonal cryoglobulinemic nephropathy (CN) that can be used to evaluate treatment modalities. The Vk*MYC transgenic model in 50-70 weeks old mice with renal involvement has been reported before (Chesi *et al*., 2008) but detailed renal pathologic changes have not been well documented. This study fully investigates pathologic changes in these kidneys.

Methods: The kidneys of 6 wild type and 12 Vk*MYC transgenic mice were investigated using routine light microscopy (LM), immunofluorescence stains for light chains (IF), and electron microscopy (EM). The EM score system developed to evaluate findings is as follows: 0 – no deposits, +/- minimal electron dense deposits, 1+ - mild deposits, 2+ - moderate deposits and 3+ - moderate to prominent deposits with subendothelial deposits.

Results: By LM, wild-type kidneys were unremarkable. However, the kidneys from transgenic mice showed either mesangial segmental expansion, some with associated hypercellularity and /or thrombotic obstruction of glomerular capillaries. By IF, the glomeruli of wild-type mice showed minimal or no staining for both kappa and lambda. In the transgenic mice, lambda was 2+, stronger than kappa 1+ staining in glomeruli as a reversed pattern in 3 mice. In the aging wild-type mice, minimal electron dense deposits can be seen in the mesangial areas by EM. Notably, in transgenic mice, 6 out of 12 kidneys showed mild mesangial deposits (1+). The other 6 kidneys from the transgenic mice showed 2-3+ electron dense deposits. The deposits were located in glomerular capillary lumina in 3 cases. Large luminal and subendothelial deposits were characterized by randomly disposed microtubular structures measuring up to 16 nm in diameter**,** with overall features consistent with findings CN. Segmental fusion of foot processes were seen, but no mesangial interposition was noted.

Conclusions: Our pathology evaluation suggests that 50% (6/12) of kidneys from the Vk*MYC model of MM had significant EM deposits with features of CN in 3 of them (most likely lambda dominant). This transgenic model of monoclonal-associated glomerulopathy may be useful to evaluate treatment of neoplastic B cell clones with renal manifestations.

C4d Deposits in FSGS before the Development of Sclerosis Nina A. van de Lest,[1] Malu Zandbergen,[1] Reinhold Kreutz,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema,[1] Marion Scharpfenecker,[1] Jamie S. Chua.[1] *[1]Leiden University Medical Center, Dept.Pathology, Leiden, Netherlands; [2]Charite-University Medicine Berlin, Berlin, Germany.*

Background: Immune deposits of complement components are occasionally seen in patients with FSGS. These deposits are non-diagnostic and are often considered as nonspecific entrapment in sclerotic lesions. However, deposits of IgM and C3 have also been observed in non-sclerotic glomeruli. Moreover, recent animal studies demonstrated a role for the complement system in the pathogenesis of FSGS. Here, we investigated the pattern of complement deposition in glomeruli of experimental and human FSGS, using the complement activation biomarker C4d.

Methods: Kidney sections of Munich Wistar Frömter (MWF) rats of 4 (no proteinuria), 8 (only proteinuria) and 24 (proteinuria with glomerulosclerosis) weeks of age were stained for C4d. Age-matched spontaneously hypertensive rats (SHR) with no proteinuria were used as controls. Also, we performed a C4d staining on 40 kidney biopsies of patients with FSGS and 46 control biopsies of patients with minimal change disease (MCD) who have proteinuria without segmental glomerulosclerosis. Prevalence and localisation of C4d deposition in glomeruli were investigated.

Results: The percentage of C4d positive glomeruli was significantly higher in MWF rats at 8 and 24 weeks of age compared to controls ($p<0.001$ and $p<0.01$ respectively). C4d deposits were also more frequently observed in rats of 4 weeks of age, yet not significant. At 24 weeks, 94% of sclerotic glomeruli were C4d positive, whereas 50% of C4d positive glomeruli showed segmental glomerulosclerosis. In human biopsies, glomerular C4d deposits were observed in 75% of FSGS and 35% of MCD cases ($p<0.001$). Of positive cases, 40% of glomeruli were positive in FSGS compared to 33% in MCD. In FSGS, C4d was co-localized with segmental sclerosis in 57% and was present in non-sclerotic glomeruli or non-sclerotic parts of sclerotic glomeruli in 45%.

Conclusions: Here, we show that in the MWF rat model for FSGS, C4d deposits are present before the development of glomerulosclerosis. Similarly, C4d deposits were present in non-sclerotic glomeruli of patients with FSGS and in patients with MCD who have proteinuria without segmental glomerulosclerosis. These results indicate that C4d deposition could be involved in the development of FSGS.

Blockade of TNF Alpha Signaling Reverses Toxic Effects of Focal Segmental Glomerulosclerosis Sera on Podocyte Adhesion Independently of Serum TNFa Level Elena Torban,[1] Nadezda Kachurina,[1] Chen-Fang Chung,[1] Katarina S. Pessina,[1] Thomas Kitzler,[1] Nada Alachkar,[2] Paul R. Goodyer,[1] Andrey V. Cybulsky.[1] *[1]McGill University Health Center, Montreal, QC, Canada; [2]The Johns Hopkins University, Baltimore, MD.*

Background: Patients with primary FSGS often progress to end stage renal disease and require renal transplantation. In about half, the disease recurs in the allograft, suggesting a circulating podocyte-toxic factor in the host. We and others have reported clinical improvement following TNFα blockade in a subset of recurrent FSGS patients. Likewise, blockade of TNFα signaling in cultured human podocytes reverses the toxicity of some FSGS sera. In this study, we tested 100 FSGS serum/plasma samples for in vitro podocyte toxicity and responsiveness to TNFα blockade, and measured serum TNFα levels or serum effects on expression of podocyte TNFα pathway genes.

Methods: Plasma/serum samples from steroid-resistant nephrotic syndrome patients with biopsy-confirmed FSGS were tested for toxicity to human podocytes, as judged by disassembly of focal adhesion complexes (FACs) (Kachurina, AJP-R, 2016). Pre-treatment with blocking anti-TNFα Receptor I&II antibodies was used in some experiments. Expression of 8 TNFα pathway genes, whose expression differs significantly between FSGS and control samples in the Nephroseq database, was assessed by RT-qPCR.

Results: A significant loss of FACs (less than 60% of control) was induced by 47% of FSGS samples. Among these, TNFα blockade reversed podocyte toxicity in 24%. Neither serum toxicity nor responsiveness to TNFα blockade in podocytes correlated with circulating TNFα levels. Significant changes in expression of TNFα signaling pathway genes were induced by exposure to FSGS sera that disrupted podocyte FACs and that could be reversed by TNFα blockade, but not by sera from healthy controls or rheumatoid arthritis patients.

Conclusions: Sera from a subset of primary FSGS patients cause striking dispersion of podocyte FACs. This activity is unrelated to serum TNFα level but may be due to the effect of FSGS serum on activation of endogenous podocyte TNFα pathway signaling. Our assay may be useful in identifying patients at high risk for recurrence of FSGS in the renal allograft and who may potentially benefit from TNFα blockade to attenuate podocyte injury.

FR-PO702

Proteomic Analysis of Glomerular Extracellular Matrix Demonstrates Differences between FSGS Variants Michael Merchant,[1] Dawn J. Caster,[1,2] Daniel W. Wilkey,[1] Michelle T. Barati,[1] Kenneth R. McLeish.[1] *[1]Department of Medicine, Division of Nephrology & Hypertension, University of Louisville, Louisville, KY; [2]Robley Rex VA Medical Center, Louisville, KY.*

Background: Abnormal remodeling of glomerular extracellular matrix (ECM) is a prominent feature of focal segmental glomerular sclerosis (FSGS). Changes in ECM that accompany FSGS have not been defined in humans. We postulated that FSGS is characterized by specific changes in ECM composition. The current study used laser capture microdissection (LCMD) of glomeruli from human biopsy specimens and mass spectrometry (MS) and immunohistochemical (IHC) methods to compare -ECM composition among patients with FSGS-NOS, collapsing FSGS (CFSGS), and normal subjects.

Methods: Glomerular sections were obtained by LCMD from de-identified FFPE tissue from FSGS-NOS (n=6), CFSGS (n=7), and from 2 kidneys retrieved, but not used, for transplantation. Samples were analyzed as recently published (Hobeika L, et al. Characterization of glomerular extracellular matrix by proteomic analysis of laser-captured microdissected glomeruli. Kidney Int. 2017 91:501-511). Abundance data were filtered by GO annotation and matrixome designation for confirmatory IHC studies using Human Proteome Atlas validated antibodies and an expanded disease/normal- control renal biopsy panel.

Results: IHC was performed on 7 of 25 ECM proteins unique to CFSGS, 3 of 6 unique to FSGS-NOS, and 2 of 20 present in both subtypes of FSGS but not normal. All ECM proteins identified from normal were present in FSGS glomeruli. Annexin 3, marker of parietal epithelial cells (PEC), and cathepsin C, an inflammatory protease, showed intraglomerular staining in 10% to 20% of glomeruli in biopsies from CFSGS patients, while only staining Bowman's capsule in biopsies of FSGS-NOS, minimal change disease, IgAN, primary membranous nephropathy, and congenital nephrotic syndrome. Annexin 3 and cathepsin C co-localized within CFSGS glomeruli, while staining with a marker of activated PEC (CD44), was negative.

Conclusions: PEC infiltration of glomerular tufts was characteristic of CFSGS, not FSGS-NOS. Although PEC did not express activation markers, they produced a protease unique to glomerular ECM. Cathepsin C may represent a novel mediator of PEC-mediated glomerulosclerosis leading to collapse.

FR-PO703

Role of Monocyte Interleukin (IL)-27 in Minimal Change Nephrotic Syndrome (MCNS) Chang-Yien Chan,[2,4] Wee Song Yeo,[2,4] Jinmiao Chen,[3] Henry H. Yang,[1] Hui Kim Yap.[2,4] *[1]Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore; [2]Paediatrics, National University of Singapore, Singapore, Singapore; [3]Singapore Immunology Network (SIgN), (BMSI, A*STAR), Singapore, Singapore; [4]KTP-National University Children's Medical Institute, National University Hospital, Singapore, Singapore.*

Background: We have previously shown upregulation of lymphocyte IL-13 gene expression during nephrotic relapses in MCNS patients, associated with downregulation of pro-inflammatory cytokines, IL-8 and tumor necrosis factor (TNF)-α in lipopolysaccharide (LPS)-stimulated monocytes, and decreased monocyte CD14 expression, suggestive of an IL-13-induced anti-inflammatory effect. This study aimed to identify the monocyte 'gene signature' in MCNS patients and subsequently to validate the findings in human podocytes.

Methods: Monocyte RNA from 5 patients in relapse and remission were analysed using Illumina Human Ref8 chips. Subsequently plasma IL-27 levels were measured in 14 MCNS patients in relapse and remission and 20 healthy controls. The role of IL-27 in human podocytes was studied using cell migration assay (cultrex). Podocyte RhoA/Rac1 activity were measured using ELISA and STAT1/3 levels were studied using Western blot. Statistical analysis was done using Mann-Whitney test and Wilcoxon signed rank test for paired data.

Results: Metacore™ analysis on the monocyte transcriptome of MCNS patients in relapse compared to remission revealed involvement of genes in IL-1 signaling, regulation of actin cytoskeleton by RhoGTPases, toll-interleukin receptor (TIR)-domain-containing adapter-inducing interferon-β (TRIF) and IFN-induction (IRF4, IRF7, IFI6, IFI27, IFI35, IFI44, SERPING1, OAS1, OAS2, OAS3, OASL, CXCL9, CXCL10, DDX58) pathways. Of note gene expression of *IL27* was 2.7 times upregulated in MCNS patients in relapse. Consistent with the microarray results, plasma IL-27 levels were significantly higher in MCNS patients in relapse (1.56±0.19 pg/ml) compared to remission (0.95±0.13 pg/ml) ($p<0.05$) and controls (0.89±0.14 pg/ml) ($p\leq0.01$). IL-27 stimulation in human podocytes resulted in phosphorylation of both STAT1 and STAT3. RhoA activity in IL-27 stimulated podocytes remained largely unchanged whereas activated Rac1 levels in podocytes were 1.56-fold higher compared with unstimulated podocytes at 20 minutes. Moreover, IL-27 induced 6.35% podocytes migration, comparable to the 6.96% podocytes migration observed in LPS-stimulated podocytes.

Conclusions: Monocytes may play a role in the pathogenesis of MCNS relapses via production of IL-27 and subsequent activation of STAT1, STAT3 and Rac1 as well as induction of cell migration in human podocytes.

FR-PO704

Loss of Mitf Aggravates PAN Induced Proteinuria in Zebrafish Philipp Niggemann,[1] Patricia A. Schroder,[2] Patricia Bolanos-Palmieri,[1] Janina Müller-Deile,[1] Heiko J. Schenk,[1] Laura L. Beverly-Staggs,[2] Beina Teng,[1] Hermann G. Haller,[1] Mario Schiffer.[1] *[1]Hanover Medical School, Freiburg, Germany; [2]Mount Desert Island Biological Laboratory, Salisbury Cove, ME.*

Background: We developed a standardized proteinuria model in zebrafish using puromycin aminonucleoside (PAN) through treatment via the water. We noticed, that fish with the *nacre* mutation show a significantly higher susceptibility to PAN than AB fish upon exposure to the same dosage of PAN. (AB is a standard wild-type line) *Nacre* is the name of a mutation yielding a truncated version of Microphthalmia-associated transcription factor (Mitf) in zebrafish. Mitf is an evolutionary conserved transcription factor that controls pigment cell fate in vertebrates. It is well known that a mutation in *mitf* leads to missing neural-crest-derived melanophores and results in a pigment-less phenotype, making this mutation a commonly used fish line to study organ development.

Methods: Tg(l-fabp:eGFP-DBP) zebrafish were backcrossed onto AB or *nacre* background and were exposed to PAN in the water at varying timepoints from 44 hours post fertilization (hpf) to 50 hpf. Loss of high molecular weight proteins from the circulation was measured at 96 hpf as a surrogate marker for proteinuria. In addition, we performed *mitf* knockdown experiments in AB zebrafish using morpholinos. Moreover, cultured human podocytes were examined after silencing of *MITF in vitro*.

Results: Zebrafish homozygous for the *nacre* mutation and AB zebrafish after knockdown of *mitf* exhibited stronger proteinuria after PAN treatment compared to control animals. Moreover, a treatment with PAN at 46 hpf yielded the strongest proteinuria. Treatments at later timepoints were less effective in proteinuria induction. Silencing of *MITF* in human podocytes led to a disrupted cytoskeletal organization after PAN treatment. At the same time the expression of MITF downstream partners like INF2 was changed, indicating that MITF plays an important role for cytoskeleton recovery in podocytes.

Conclusions: We present the first reproducible PAN-nephrosis model in zebrafish, which could serve as a suitable setting for drug testing in zebrafish. Furthermore, we can demonstrate that a mutation in *mitf* leads to a higher susceptibility for disruption of the glomerular filtration barrier upon PAN treatment, which results in stronger proteinuria.

FR-PO705

Heterogeneous Nuclear Ribonucleoprotein F Deficiency Aggravates Podocyte Loss via Down-Regulation of Sirtuin-1 Expression in Adriamycin-Induced Nephropathy in Mice Chao-Sheng Lo,[2] Isabelle Chenier,[1] Janos G. Filep,[4] Julie R. Ingelfinger,[6] Shao-Ling Zhang,[5] John S. Chan.[3] *[1]CHUM-Hotel Dieu Hosp, Montreal, QC, Canada; [2]CRCHUM, Universite de Montreal, Montreal, QC, Canada; [3]CRCHUM, University of Montreal, Montreal, QC, Canada; [4]Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [5]Research Center of Centre Hospitalier de l Universite de Montreal (CRCHUM), Montreal, QC, Canada; [6]The New England Journal of Medicine, Boston, MA.*

Background: We reported that overexpression of heterogeneous nuclear ribonucleoprotein F (hnRNP F) enhances sirtuin-1 expression and attenuates apoptosis in renal proximal tubular cells in db/db hnRNP F-transgenic mice (Diabetes 2017). In the present study, we investigated whether hnRNP F deficiency in podocytes would aggravate podocyte injury in adriamycin (ADR)-induced nephropathy in mice.

Methods: Podocyte-specific hnRNP F knockout (KO) mice were generated by crossbreeding podocin (Pod)-Cre mice with floxed hnRNP F mice on a C57BL/6 background. Male adult non-KO littermates (controls) and Pod-hnRNP F KO mice were studied at age 10 to 20 weeks. Body weight (BW) and urinary albumin/creatinine ratio (ACR) were monitored bi-weekly. To induce nephropathy, male controls and Pod-hnRNP F KO mice were administered ADR (doxorubicin) (18 mg/kg BW) via tail vein at the age of 10 weeks. Urinary ACR were assessed 7 and 11 days post-ADR. Mice were euthanized on day 12. Kidneys were processed for histology. Freshly isolated glomeruli were assessed for mRNA and protein expression by real time-qPCR and Western blotting, respectively. In addition, primary podocytes isolated from controls and Pod-hnRNP F KO mice ± ADR were studied in vitro.

Results: Pod-hnRNP F KO mice were phenotypically normal with a slight increase in ACR at week 20. Glomeruli isolated from POD-hnRNP F KO mice exhibited significantly lower mRNA and protein levels of sirtuin-1 and podocyte markers including nephrin, WT1 and synaptopodin than controls. Administration of ADR significantly increased urinary ACR and apoptotic podocytes in both groups. However, these changes were more pronounced in Pod-hnRNP F KO mice, parallel with significant decreases in sirtuin-1, nephrin, WT1 and synaptopodin expression. Finally, in vitro studies confirmed that primary podocytes from hnRNP F KO mice exhibited lower sirtuin-1 expression and higher acetylated p53 expression and apoptotic podocytes after ADR treatment.

Conclusions: HnRNP F deficiency aggravates podocyte apoptosis in ADR-induced nephropathy in mice, indicating a protective role for hnRNP F against podocyte injury.

Recombinant Mutated Human Angiopoietin-Like 4 Reduces the Progression of CKD Due to Diabetes and FSGS Maria Del Nogal Avila,[1] Hector Donoro blazquez,[1] Joubert B. Kharlyngdoh,[1] Ranjan Das,[1] Eduardo Molina-Jijon,[1] Szymon Filip,[1] Carmen Avila-Casado,[2] Camille E. Mace,[1] Lionel C. Clement,[1] Sumant S. Chugh.[1] *[1]Rush University Medical Center, Chicago, IL; [2]University Health Network, University of Toronto, Toronto, ON, Canada.*

Background: Angptl4 is a major molecular mediator of nephrotic syndrome secreted in two forms: a hyposialylated form secreted from podocytes that causes proteinuria in minimal change disease (MCD), and a sialylated circulating form secreted from skeletal muscle, heart and adipose tissue that reduces proteinuria and causes hypertriglyceridemia in nephrotic syndrome. Short-term studies with FSGS and diabetic nephropathy (DN) rats using recombinant mutant Angptl4 reduces proteinuria without causing hypertriglyceridemia.

Methods: We injected recombinant human mutated Angptl4 (protein 8520) or control albumin weekly subcutaneously into rats with FSGS (B. Mna; n=6/group) and DN (ZSF1; n=5/group) according to different dosing regimens. Recombinant sialylated Angptl4 mutant 8520 was produced in HEK923 cells growing in hollow fiber bioreactors. To study the effect of higher native circulating sialylated Angptl4 expression in FSGS, adipose tissue-specific Angptl4 TG (372) were backcrossed for 8 generations into B. Mna rats.

Results: ZSF1 rats treated with 500μg of 8520 had less proteinuria (38.95±6.6 mg per 18h) than controls (64.8±3.3 mg per 18h) after 3 weeks of weekly treatment ($p<0.05$). When the dose was reduced, proteinuria was not significantly different between the two groups. Differences were restored after increasing the amount of protein at week 13 (8520: 172.4±14.5 mg per 18h and control 210.6±13.5 mg per 18 h; $p<0.05$). BUN and creatinine levels were significantly lower in rats treated with 8520 at different time-points, with better histology morphology than controls after 28 weeks of treatment. After 15 weeks of Angptl4 mutant therapy, B. Mna rats had less prominent visceral epithelial cells, less VEP hypertrophy, less tubular-interstitial inflammation and less periglomerular fibrosis compare with control group. 8 month old male 372-B. Mna has less creatinine and BUN than non-TG B. Mna rats and remarkable improved histology. Female 372-B. Mna showed less proteinuria (238.5±39.4 mg per 18h) than non-TG B. Mna rats (307.8±15.7 mg per 18h) ($p=0.048$).

Conclusions: These findings suggest a protective effect of recombinant mutated human Angptl4, as well as increased circulating native rat Angptl4 in the progression of CKD.

Albumin Modification Leads to Altered Glomerular and Podocyte Injury Shipra Agrawal,[1,2] Amanda P. Waller,[1] Jiro Kino,[1] Melinda A. Chanley,[1] Bryce A. Kerlin,[1,2] William E. Smoyer.[1,2] *[1]CCTR, The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Pediatrics, The Ohio State University, Columbus, OH.*

Background: Albuminuria is associated with an increased risk of progressive glomerular disease. However, the molecular basis for potential causative roles for albuminuria and/or its modification [free fatty acid (FFA) binding and ionic forms] in progressive glomerular disease remains poorly understood. We hypothesized that albumin modification by altering its levels, FFA binding ratio, and charge can regulate glomerular and podocyte injury.

Methods: A model of chronic glomerular disease was studied in wild type (WT), Nagase Analbuminemic Rat (NAR), and NAR-Het on a Fischer344 background female rats (~160 g, N=4-5/group) by multiple puromycin-aminonucleoside (PAN) injections (100 mg/kg i.p., every 4 weeks) over a course of 3 months, with serial measurements of proteinuria, serum creatinine, urinary podocalyxin, and N-acetyl-b-D-glucosaminidase (NAG) activity. Moreover, direct podocyte injury was compared following exposure to albumin and FFA at varying molar ratios, as well as exposure to cationic vs. regular albumin.

Results: Consistent proteinuria was induced at week 11 in WT rats, which was significantly higher vs. NAR or NAR-Het rats. Moreover, comparable plasma protein levels were observed in NAR vs. WT rats, despite complete absence of albumin in NAR. Serum creatinine levels were similarly increased in both NAR and WT rats at week 12, while podocalyxin levels were slightly increased only in WT rats, and NAG activity was not altered in either group. Since the FFA:albumin ratio is massively altered in NAR, the ability of FFA to cause direct podocyte injury in vitro was measured in the absence/presence of albumin at different molar ratios. Both the absence of albumin and exceeding the FFA binding capacity of albumin (>10:1 FFA:albumin) resulted in increased podocyte toxicity, especially for oleic acid and arachidonic acid. Additionally, cationic albumin induced dramatically greater podocyte toxicity vs. regular negatively charged albumin, even at 400 times lower concentration (0.1 g/dL, 20 hr exposure vs. 4g/dL, 4-7 days exposure).

Conclusions: Modification of albumin by altering its levels, FFA:albumin ratio, or ionic charge dramatically alters its glomerular and direct podocyte toxicity.

FR-PO708

Inhibition of p53 Desumoylation by SENP1 Exacerbates Puromycin Aminonucleoside-Induced Apoptosis in Podocytes Lingyu Wang. *the First Affiliated Hospital of Dalian Medical University, Dalian, China.*

Background: Apoptosis is a major cause of reduced podocyte numbers, which leads to proteinuria and/or glomerulosclerosis. Emerging evidence has indicated that deSUMOylation, a dynamic post-translational modification that reverses SUMOylation, is involved in the apoptosis of Burkitt'slymphoma cells and cardiomyocytes; however, the impact of deSUMOylation on podocyte apoptosis remains unexplored. The p53 protein plays a major role in the pathogenesis of podocyte apoptosis, and p53 can be SUMOylated.

Methods: Therefore, in the present study, we evaluated the effect of p53 deSUMOylation, which is regulated by sentrin/SUMO-specific protease 1 (SENP1), on podocyte apoptosis.

Results: Our results showed that SENP1 deficiency significantly increases PAN-induced podocyte apoptosis. Moreover, SENP1 knockdown results in the accumulation of SUMOylated p53 protein and the increased expression of the p53 target pro-apoptotic genes, *BAX*, *Noxa* and *PUMA*, in podocytes during PAN stimulation.

Conclusions: Thus, SENP1 may be essential for preventing podocyte apoptosis, at least partly through regulating the functions of p53 protein via deSUMOylation. The regulation of deSUMOylationmay provide a novel strategy for the treatment of glomerular disorders that involve podocyte apoptosis.

FR-PO709

Antibody-Based Targeting of APRIL as a Therapeutic Strategy in the Treatment of IgA Nephropathy—A Case Study in a Grouped ddY Mouse Model James R. Myette,[2] Toshiki Kano,[1] Hitoshi Suzuki,[1] Hedy Adari,[2] Ketan Deotale,[2] Brian J. Pereira,[2] Yusuke Suzuki.[1] *[1]Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Visterra, Inc., Cambridge, MA.*

Background: IgA nephropathy (IgAN) is a chronic, "autoimmune" glomerular disease of high unmet medical need. The cytokine APRIL (TNFSF13) is emerging as a key player in disease onset and progression, based on a recent convergence of biological and translational data. The pathogenic role of APRIL in IgAN has been previously established in grouped ddY (gddY) mice, an early-onset disease model which recapitulates many of the clinical hallmarks of IgAN pathophysiology and progression. VIS649, a humanized IgG2 specifically targeting human APRIL, is being developed as a therapy for IgA nephropathy. Based on its overlapping epitope and functional attributes, surrogate antibody mAb 4540, which neutralizes mouse APRIL, was used to evaluate anti-APRIL intervention in controlling disease in gddY mice.

Methods: 6-7 week old female mice were administered mAb 4540 (10-20 mg/kg) once weekly for up to eight weeks by i.p. injection. Relevant endpoints included serum immunoglobulin profiling by ELISA; IgA, IgG, and C3 deposition in kidney by IFC; proteinuria based on albumin:creatinine ratios (uACR) from spot urine; and glomerular histopathology by PAS staining. Cellular B-cell profiling in bone marrow was completed by flow cytometry.

Results: Treatment of gddY mice with mAb 4540, relative to the control groups, resulted in the suppression of serum IgA profiles and a markedly lower deposition of IgA, IgG, and C3 in the kidney mesangium. These observations correlated with a better glomerular histopathology profile and a lower uACR profile, indicative of reduced kidney injury. Treatment efficacy was observed as early as 4 weeks after the start of intervention and was sustained during the recovery phase of this study. Targeting APRIL with mAb 4540 demonstrated no overt differences in serum IgG levels or plasma cell profiles.

Conclusions: This study both confirms and extends the rationale for targeting the cytokine APRIL for treatment of IgAN. The demonstrated efficacy of mAb4540 in this model also highlights the potential therapeutic benefit of VIS649, a first-in-class human monoclonal antibody being developed for the treatment of IgAN.

Mesenchymal Stem Cells Acquire Phagocytotic Functions and Contractibility When They Repair Light Chain-Induced Mesangial Damage Chun Zeng, Guillermo A. Herrera, Man Liang, Hongzhi Xu, Elba Turbat-herrera, Jiamin Teng. *Pathology, LSUHSC-Shreveport, Shreveport, LA.*

Background: Using mesenchymal stem cells (MSCs) to repair the injured mesangium has been shown experimentally to be a promising approach. However, the precise role MSCs play in the repair process is still unclear. In this study, we investigated phagocytotic and contractibility capabilities of MSCs in the process of mesangial repair.

Methods: Mesangial cells (MCs) were incubated with AL-amyloidosis and light chain deposition disease G-LCs for 4 days to establish an in vitro mesangial cell injury model. Green fluorescent protein (GFP)-labeled MSCs were added together with florescent-labeled latex beads to assess phagocytotic activity of MSCs. A 6 dimensional (6D) live cell imaging system was used to record the process for 7 days after the introduction of the MSCs. Immunofluorescence, immunohistochemistry and electron microscopy were used to evaluate samples obtained at different time frames. Stains for smoothelin, CD68, CD29 and CD54 were used to monitor phenotypic expressions of MSCs. Collagen assay was used to evaluate contractibility.

Results: MSCs migrated to the damaged mesangial areas and morphologically transformed from an undifferentiated to a macrophage phenotype. MSCs lost CD29/54 stem cell makers after G-LCs treatment, acquiring CD68, and later expressed smoothelin / muscle specific actin. Significant amount of the florescent-labeled latex beads were engulfed by transformed MSCs indicating active phagocytosis during the initial cleaning phase of the repair. MCs revealed decreased contractibility after G-LCs treatment while MSCs exhibited contractability during the late phase of the process, but not at the beginning of the repair. The plasticity of MSCs was confirmed ultrastructurally with findings of macrophage and smooth muscle differentiation at different stages of the repair process.

Conclusions: MSCs undergo both morphological and functional transformations as they proceed to repair the damaged mesangium. In contrast to previous belief that MSCs only enhance repair via a paracrine mechanism, this study provides evidence that MSCs differentiate sequentially from uncommitted to macrophage and finally smooth muscle (mesangial cell) phenotypes during the process of mesangial repair. This permits the repair process to replace the damaged mesangium with fully differentiated mesangial cells.

FR-PO711

MicroRNA-181a (miR-181a) Drives Deptor Downregulation by TGFbeta (TGFb) to Induce Mesangial Cell (MC) Hypertrophy and Fibronectin Expression Soumya Maity,[3] Falguni Das,[1] Nandini Ghosh-choudhury,[1] Balakuntalam S. Kasinath,[2] Goutam Ghosh-Choudhury.[2] *[1]UTHSCSA, SAN ANTONIO, TX; [2]University of Texas Health Science Center, San Antonio, TX; [3]University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: TGFb-stimulated noncanonical mTOR signaling contributes to MC hypertrophy and matrix protein expansion. The molecular mechanism of mTOR activation is not known. Deptor is a common inhibitory subunit for both mTORC1 and mTORC2.

Methods: MCs, qRT-PCR, reporter transfection, immunoblotting, anti-miR-181a and miR-181 mimic transfection, protein synthesis and hypertrophy assays were used.

Results: In MCs, TGFb reduced the expression of deptor in a time-dependent and prolonged manner. This deptor downregulation was associated with increased activation of both mTORC1 and mTORC2 as determined by the phosphorylation of S6 kinase and Akt (Ser-473), respectively. To study the mechanism of repression of deptor, we considered microRNA-mediated post-transcriptional regulation. Bioinformatic analysis revealed the presence of miR-181a recognition element in the 3'UTR (untranslated region) of deptor mRNA. In MCs, TGFb significantly increased the expression of miR-181a in time-dependent manner. Overexpression of miR-181a mimic inhibited the expression of deptor. To determine the responsiveness of the miR-181a recognition element, we used a reporter construct in which deptor 3' UTR was fused to the luciferase gene (3'UTR-Luc). Co-transfection of miR-181a mimic with this reporter plasmid showed significant reduction in luciferase activity, indicating the responsiveness of the recognition element. Incubation of 3'UTR-Luc-transfected MCs with TGFb significantly decreased the luciferase activity. Importantly, transfection of anti-miR-181a inhibited TGFb-induced phosphorylation of S6 kinase and Akt (Ser-473), two substrates of mTORC1 and mTORC2, respectively. In contrast transfection of miR-181a mimic increased the activity of mTORC1 and mTORC2. Furthermore, anti-miR-181a significantly inhibited TGFb-induced protein

synthesis and hypertrophy of mesangial cells. Similarly, anti-miR-181a attenuated TGFb-stimulated fibronectin expression.

Conclusions: Our results provide the first evidence for the mechanism of deptor downregulation by TGFb, involving miR-181a. Furthermore, we demonstrate for the first time that miR-181a contributes to TGFb-induced mesangial cell hypertrophy and matrix protein expression. Use of anti-miR-181a may be beneficial in TGFb-mediated fibrotic kidney disease.

FR-PO712

Exosomes from High Glucose-Treated Human Mesangial Cells Activate Renin Angiotensin System in Healthy Mesangial Cells Antonio S. Novaes,[1] Fernanda T. Borges,[2] Mirian A. Boim.[2] *[1]Federal University of São Paulo, São Paulo, Brazil; [2]UNIFESP, São Paulo, Brazil.*

Background: High glucose (HG) induced-intracellular angiotensin II (Ang II) accumulation is correlated with upregulation of Ang II target genes, such as pro-fibrotic cytokines. This effect can be propagated via microRNAs and peptides transferred to other cells via exosomes (Ex), which play a key role in cellular communication under physiological and pathological conditions.

Methods: To verify whether exosomal signaling initiated in HG stimulated human mesangial cells (HCM) would affect control cells function, HMC were cultured under standard (5 mM) or HG (30 mM) concentrations for 24 hr. Ex secreted to culture medium were purified by ultracentrifugation and analyzed by electron microscopy. The vesicles size/concentration ratio was determined by the particle tracking using a nanoparticles analyzer and the Ex were characterized by the presence of CD63 and CD81 by western blot. Ex from control (C-Ex) or HG stimulated-HMC (Ex-HG) were labeled with PKH26 and added in normal HMC. The Ex internalization was evaluated by confocal microscopy (CM). The presence angiotensinogen (AGT), renin and ACE in the Ex was analyzed by western blot. The bioactivity of the Ex was evaluated in Chinese Hamster Ovary cells (CHO-K1), which do not express components of RAS, and in CHO-K1 transfected ECA (ECA-CHO) in the presence of C-Ex or HG-Ex. The synthesis of Ang II in ECA-CHO was analyzed by CM. Expressions of fibronectin, AGT, renin, AT1, AT2 receptors and proliferation were used to assess the cellular response to signal transferred through the Ex in control HMC exposed to C-Ex or HG-Ex.

Results: HG stimulus induced a change in the amount, but not in the size of Ex. HG-Ex are internalized by normal HMC. C-Ex contained AGT and renin proteins, whose expressions were increased in cells exposed to HG-Ex. ACE was not detected in C-Ex and HG-Ex. The exposure of HG-Ex to ECA-CHO resulted in Ang II formation in these cells. The expression levels of fibronectin, AGT, renin, AT1 and AT2 were higher in control HMC treated with HG-Ex compared with those treated with C-Ex, indicating that HG-Ex can modify the function of target control HMC.

Conclusions: These results suggest that the intercellular communication through the exosomes may have pathophysiological implications in the diabetic kidney.

Connective Tissue Growth Factor (CTGF, CCN2) Is Sufficient to Drive Expression of Collagen IV, Fibronectin and Mesangial Expansion Yongxin Gao,[1,2] Charles W. Heilig,[1,2] Leighton R. James.[1,2] *[1]Medicine, University of Florida, Jacksonville, FL; [2]Diabetes Institute, University of Florida, Gainesville, FL.*

Background: CTGF has been linked to organ fibrosis. Using an animal model and cultured mouse embryonic fibroblast, we previously demonstrated that CTGF expression modulates response to hyperglycemia and diabetes mellitus. Accordingly, we hypothesized that CTGF directly influences expression of extracellular matrix protein to drive glomerulosclerosis. To test our hypothesis, we used animals that express 1 to 4 copies of mice CTGF gene to assess a) levels of ECM proteins (Fibronectin [Fn] and Collagen IV [Coll IV]), vascular endothelial growth factor (VEGF), mechano growth factor (MGF), as well as, b) mesangial expansion and.fibrosis.

Methods: CTGF knockout and gene-duplicated mice were generated using standard gene-targeting methodologies. Mice harboring 1 to 4 copies of CTGF were generated through breeding and have been previously described. Lysates were obtained from Kidney cortices retrieved from 6-month old mice and used for immunoblotting analysis of CTGF, Collagen IV, Fn, VEGF and MGF. Histologic examination was performed on fixed kidney sections using Hematoxylin and eosin (H&E), Periodic-schiff and Mason-trichrome staining. Immunohistochemistry utilized CTGF antibody and flourescent labelled secondary antibody.

Results: There was a graded increase in CTGF (3.5-fold), Coll IV (4-fold), Fn (7-fold), VEGF (8-fold) and MGF (7-fold) in 4-copy mice when compared with heterozygous (1-copy) animals. In addition, we observed mesangial matrix expansion and increased mesangial and perivascular fibrosis in kidney from 4-copy animals as compared with heterozygous and wild-type mice.

Conclusions: Graded CTGF expression directly increases expression of collagen, fibronectin, VEGF and MGF in mice kidney. Increased peri-vascular and glomerular sclerosis links CTGF expression with fibrosis, blood pressure and urine protein excretion previously observed in these models.

Down Regulation of Gamma-Adducin Diminishes Glomerular Function and Promotes Hypertension Related CKD Xiaochen He, Fan Fan, Bibek Poudel, Shaoxun Wang, Paige N. Mims, Richard J. Roman. *University of Mississippi Medical Center, Jackson, MS.*

Background: Fawn Hooded Hypertensive (FHH) rat is a genetic model of hypertension-induced chronic kidney disease (CKD). Using overlapping Chr 1 congenic strains, we identified a K572Q mutation in Add3 as a positional candidate gene for proteinuria in FHH rats. The present study examined whether knockin of wild type Add3 alters the development of proteinuria and hypertension induced renal injury in FHH rats.

Methods: Blood pressure and proteinuria were evaluated weekly in FHH and FHH.Add3 transgenic rats as they aged from 12 to 24 weeks of age or during the development of DOCA/salt induced hypertension. Renal injury was assessed by histology analysis. *In vitro*, Add3 was knocked down in normal rat kidney epithelial cells, a model system of podocyte, by using 27-mer Dicer-substrate RNAi, followed by MTS assay, F-actin immunostaining, or mitochondrial function assay.

Results: Blood pressure was similar in FHH and FHH.Add3 transgenic rats. Proteinuria increased from 37±2 to 260±32 mg/day as they aged in FHH rats (n=30), but this increase was attenuated in FHH.Add3 transgenic rats (24±3 to 170±16 mg/day, n=12). Moreover, DOCA hypertensive FHH rats (484±78 mg/day, n=21) exhibited more severe proteinuria than that seen in FHH.Add3 transgenic rats (259±5 mg/day, n=12). DOCA hypertensive FHH rats developed more severe renal injury than hypertensive FHH.1^{BN} and FHH.Add3 transgenic rats that express wt-Add3. The glomerular injury score averaged 3.31±0.01 in FHH versus 2.54±0.01 and 2.50±0.03, in FHH.1^{BN} and FHH.Add3 rats. The percentage of fibrosis in the renal cortex and vascular remodeling were significantly higher in DOCA treated hypertensive FHH rats than in FHH.1^{BN} and FHH.Add3 transgenic rats. In normal rat kidney epithelial cells, down-regulation of Add3 decreased cell proliferation by 50%, disrupted the actin cytoskeleton, and impaired mitochondrial function.

Conclusions: These results suggest that down regulation of Add3 may decrease glomerular function in FHH rats by disrupting the actin cytoskeleton and impairing mitochondrial function of podocytes, which may contribute to the development of renal end organ damage with aging and after the onset of hypertension.

FR-PO715

Mice Deficient in Aminopeptidase A Have Augmented Albuminuria Following Renal Mass Reduction Wayne R. Fitzgibbon,[1] Ehtesham Arif,[1] Peifeng Deng,[1] Fengxia Xiao,[2] Dylan Burger,[3] Michael G. Janech,[1] Deepak Nihalani,[1] Juan Carlos Q. Velez.[4] *[1]Medical University of South Carolina, Charleston, SC; [2]Ottawa Hospital Research Institute, Ottawa, AB, Canada; [3]Kidney Research Centre, Ottawa, ON, Canada; [4]Ochsner Clinic Foundation, New Orleans, LA.*

Background: Aminopeptidase A (APA) is a membrane-bound metalloproteinase expressed in podocytes and tubular epithelia. We have previously shown that global deficiency in APA increases susceptibility to acute immune- or Ang-dependent glomerular injury. We hypothesized that APA acts to minimize podocyte damage during progressive chronic kidney disease.

Methods: To test this hypothesis we measured urine flow rate, urine albumin (Alb), creatinine (Cr), and microparticle (MP) levels in 129Sv/C57Bl6 wild type (WT, n=6) and APA KO (n=6) mice subjected to remnant nephropathy. Twenty-four hour (24h) urine collections were obtained prior to, and 2 and 4 weeks following 5/6 reduction in renal mass.

Results: Baseline values were not different between the two strains. Renal mass reduction induced albuminuria in both groups at 2 weeks; however, 24h albumin excretion (UAlbV) was markedly higher for the KO compared to the WT mice at both 2 weeks ($p<0.001$) and 4 weeks ($p<0.001$). UAlbV was 11 (6–21), 161 (57–497) and 169 (42–1230) μg/24h, and 17 (6–43), 1554 (712–2217) and 1400 (629–2882) μg/24h for baseline, 2 and 4 week periods for the WT and the APAKO mice, respectively. Similar findings were observed when albumin levels were expressed as albumin/creatinine ratio (UACR). UACRs were 277 (113–743) vs 1856 (842–2539) at 2 weeks ($p<0.001$) and 242 (116–1781) vs 1837 (618–3845) at 4 weeks ($p<0.001$) for the WT and APAKO respectively. Concomitant with the reduction in renal mass was a decrease in the generation of total urinary MP (uMP/Cr) that was similar in both groups. Further, the formation of podocyte-derived podoplanin-stained (ps) MP also decreased in both groups. For WT, the generation of psMP at baseline and 2 weeks was $2.2x10^6 \pm 1.0x10^6$ vs $4.8x10^5 \pm 9.2x10^5$ psMP/mg ($p=0.03$) and at 4 weeks $2.6x10^5 \pm 1.4x10^5$ psMP/mg ($p<0.01$). For the APAKO mice psMP at baseline and 2 weeks was $2.2x10^6 \pm 1.2x10^6$ vs $4.3x10^4 \pm 4.1x10^4$ psMP/mg ($p<0.01$) and at 4 weeks $1.7x10^5 \pm 2.4x10^5$ psMP/mg ($p<0.01$).

Conclusions: Our findings support a role for APA in ameliorating glomerular injury following 5/6 renal ablation. The finding that the formation of (ps)MP was not different between the 2 groups 2 weeks after renal injury, suggests that the chronic renoprotective role of APA may not be associated with attenuation of podocyte MP formation.

FR-PO716

3D Analysis of Optically Cleared Kidney Slices Reveals Focal Podocyte Loss in Crescentic Nephritis Victor G. Puelles,[1,2] David Fleck,[3] Michael Vogt,[4] Stella Papadouri,[1] Thiago Strieder,[1] Turgay Saritas,[1] David J. Nikolic-Paterson,[2] Marc Spehr,[3] Marcus J. Moeller.[1] *[1]Nephrology and Clinical Immunology, University Hospital RWTH Aachen, Aachen, Germany; [2]Nephrology, Monash Medical Centre, Clayton, VIC, Australia; [3]Chemosensation, RWTH Aachen University, Aachen, Germany; [4]Core Facility "Two-Photon Imaging" IZKF, RWTH Aachen University, Aachen, Germany.*

Background: Podocyte depletion is a common feature of glomerulosclerosis (FSGS), but its role in crescentic nephritis remains unclear. This study combined genetic tagging of podocytes with three different optical clearing techniques to determine podocyte depletion in whole glomeruli from mice with crescentic nephritis.

Methods: Podocyte nuclei were labeled by eGFP-histone in of adult male Pod-rtTA/H2B-eGFP mice by oral doxycycline, followed by a 7-day wash out period, and a single intra-peritoneal injection of nephrotoxic serum (NTS; 5mg/g). Experimental mice were killed 10 days after NTS injection, and compared to age-matched controls. Kidney slices were optically cleared with SCALE-A4, CLARITY and Ethyl Cinnamate (ECi). High-resolution serial optical images were obtained by confocal and two-photon microscopy.

Results: Mean podocyte number per mouse showed very low variability within controls (1-5% variability, P>0.05) and within NTS-injected mice (1-9% variability, P>0.05) independent of the clearing technique. In NTS-injected mice, a similar degree of average podocyte depletion per mouse was identified with all clearing methods (60-63%, P<0.001). The technical (dis-)advantages of each clearing protocol were also analysed, including optimal penetration depth and resolution, compatibility with immunofluorescence, microscopy set-ups, and cost-efficiency. Importantly, total podocyte number per glomerulus showed great variability: controls (mean: 78,81; ranging from 49 to 128 podocytes per glomerulus) and in NTS-injected mice (mean: 29,99; ranging from 1 to 95 podocytes per glomerulus). Using the lowest value for podocyte number in controls as a cut-off reference, only 78% of analysed glomeruli (141 of 180) from NTS-injected mice had a certain degree of podocyte depletion. While deposition of the NTS within glomeruli occurred in a global and homogeneous fashion, podocyte loss was focal.

Conclusions: This study has identified early focal podocyte depletion in mice with crescentic nephritis suggesting a so far unrecognized role of podocyte depletion in the development of the focal crescentic lesions. The combination of lineage tracing and optical clearing provides a powerful new tool for analysis of podocyte depletion in large tissue samples.

FR-PO717

Metformin Ameliorates the Progressive Nephritis of an Experimental Alport Syndrome Mouse Model Kohei Omachi, Shota Kaseda, Tsubasa Yokota, Mary Ann Suico, Tsuyoshi Shuto, Hirofumi Kai. *Kumamoto University, Kumamoto, Japan.*

Background: Alport syndrome (AS) is a hereditary glomerular disease for which renin-angiotensin-aldosterone (RAAS) inhibitor is primarily prescribed. Although RAAS inhibitor is effective for proteinuria, it is not a cure for AS and most patients develop end-stage renal disease. Thus, there is a need to explore other therapeutic avenues. Here, we show the occurrence of metabolic disorder in the glomeruli of Alport mouse model, and that metformin, an anti-diabetic agent, ameliorated the progressive nephritis in AS mice.

Methods: To clarify the molecular underpinning of AS, glomerular samples were collected from 12-week-old wild type and Alport mice (*B6, Col4a5 G5X*), and global protein expression analysis was performed by LC-MS/MS. To improve the metabolic dysregulation, Alport mice were treated with metformin (6-11w: 5 mg/mL,12-20w: 2.5mg/mL, *po*) or vehicle from 6 to 20 weeks old. RAS inhibitor losartan (6-11w: 250μg/mL,12-20w: 125μg/mL, *po*) was used as positive control. Urine samples were collected once every two weeks. Plasma and kidney tissue samples were collected from 20-week-old mice and histological analysis (PAM and Masson trichrome staining) was performed. Expression of genes associated with kidney injury (*Lysozyme, Kim1*), pro-inflammatory cytokines (*Il-6, Il-1b, KC*) and pro-fibrotic factors (*Tgfb, Mmp9/12*) were assessed by qRT-PCR.

Results: Proteomics analysis revealed dysregulation of mitochondrial energy pathway (COX I biogenesis, respiratory electron transport, and ATP synthesis) in addition to already known glomerular damage-associated pathway (nephrin interaction and laminin interaction). Metformin suppressed proteinuria. Although the reduction of proteinuria was lower than losartan, metformin reduced the expression of pro-inflammatory cytokines and pro-fibrotic genes better than losartan. Correlated with these results, metformin suppressed fibrotic area and macrophage invasion histologically.

Conclusions: This study revealed that metabolic disorder occurs in Alport glomerulus and that metformin suppressed progressive nephritis. Metformin is an inexpensive drug that is applicable to pediatric patients. With these findings, metformin could be considered as a novel option for AS therapy.

ENU-Induced Point Mutation in the Laminin Alpha 5 L4a Domain Results in Nephrotic Syndrome Sara Falcone,[2] Thomas Nicol,[2] Jeffrey H. Miner,[3] Frederick W. Tam,[1] Paul K. Potter.[2] *[1]Imperial College Kidney and Transplant Institute, London, United Kingdom; [2]Medical Research Council, Didcot, United Kingdom; [3]Washington University School of Medicine, St. Louis, MO.*

Background: Nephrotic syndrome (NS) is a heterogeneous group of disorders characterised by renal and extrarenal manifestations. Classic symptoms of NS include severe proteinuria and hypoalbuminemia, oedema and hyperlipidemia. Genetic studies of hereditary forms of NS have led to the identification of proteins playing a crucial role in slit diaphragm signalling, regulation of actin cytoskeleton dynamics and cell-matrix interactions. As part of the MRC Harwell ageing screen a missense mutation was identified in the gene *Lama5* coding for the laminin alpha 5 chain, a major component of the renal extracellular matrix. Homozygous mice showed symptoms of NS including a severe proteinuria that preceded histological lesions and alteration of renal markers in plasma.

Methods: The *Lama5*^{E884G} mouse line was derived from a G3 pedigree produced in the MRC Harwell N-ethyl-N-nitrosourea (ENU) mutagenesis screen. The mutation was identified by combining the use of a dense SNP panel and whole genome sequencing. *Lama5*$^{E884G/-}$ mice were then backcrossed for a total of 10 generations to C57BL/6J mice. Urine and plasma were collected at different time points and markers of kidney function were measured. Kidneys were also collected for pathological assessment and study of the molecular mechanism. Concurrently, an *in vitro* study is ongoing to look at the expression and secretion of LAMA5 and its interaction with other laminin chains.

Results: Time course studies of *Lama5*^{E884G} homozygotes showed high levels of proteinuria from 25 weeks of age but no other signs of kidney impairment. Affected mice also have significantly elevated cholesterol levels. The *Lama5*$^{E884G/-}$ compound heterozygote exhibited severe proteinuria, thus confirming the *Lama5*^{E884G} mutation as the causative allele. Alterations in the expression of genes and proteins associated with integrin signal-mediation show an abnormal response of the glomeruli that could possibly have an effect on the podocytes' F-actin bundles. Preliminary *in vitro* results show an impaired secretion of the LAMA5 short arm.

Conclusions: We have identified a novel mutant mouse line exhibiting NS resulting from a point mutation in *Lama5*. This gene has recently been associated with renal disease in patients. We are currently dissecting the molecular pathogenesis of disease in these animals to provide insight into human disease.

Proteomic Analysis of Renal Tissue in Lupus Nephritis Asmaa Abu Maziad,[1] Ram R. Singh.[2] *[1]Mattel Children's Hospital, UCLA, Los Angeles, CA; [2]UCLA School of Medicine, Los Angeles, CA.*

Background: Lupus nephritis (LN) occurs in 40-80% of children with systemic lupus erythematosus (SLE) and is a major cause of morbidity and mortality in childhood SLE. Pathogenesis of LN progression is unclear. Identification of molecules that are differentially expressed between early to late stages of LN may help in detecting the progression of kidney damage and to identify potential new targets of treatment.

Methods: This is a case-controlled study involving children and adolescents of 1-21 years of age who have biopsy-proven LN by the 2003 International Society of Nephrology/Renal Pathology Society classification. A total of 54 archived formalin-fixed and paraffin embedded kidney biopsy specimens obtained from UCLA Translational Pathology Core. These included 13 control specimens from transplanted kidneys with normal histology and 6-8 specimens for each of the six classes of LN. These tissues were subjected to proteomics analysis using nano-scale liquid chromatography tandem mass spectroscopy (nLCMSMS) by Tandom Mass Tag method for protein labeling. Quantitative relative expression data is extracted using Proteome Discoverer 2.0 Software. DAVID software was used for data analysis. Clinical /kidney biopsy data and outcomes were collected for both cohorts and entered in UCLA RedCap software.

Results: We have thus far completed the mass spectroscopy analysis of 22 kidney biopsies (2 class II, 2 class III, 5 class IV, 7 class V, 3 class VI, and 3 control), and identified a total of 2,000 proteins in the global analysis. Among these, 86 proteins were significantly different between control and LN specimens. Among the differentially expressed proteins, the following were upregulated: MHC Class I, LIM domain and actin binding 1, WD repeat domain 7, Rho GDP dissociation inhibitor beta, and cadherin 13. The significantly downregulated proteins included G protein subunit alpha i3, catenin beta 1, ubiquinol-cytochrome c reductase core protein I, heterogeneous nuclear ribonucleoprotein U-like 2, histone deacetylase 6, NFS1 cysteine desulfurase, and Thy-1 cell surface antigen. In-depth analyses of the data are in progress.

Conclusions: This preliminary work delineates proteins that are differentially expressed between control and LN kidneys. Ongoing work will complete the proteomic analyses of the remaining specimens, and perform pathway analyses of the controls and different classes of LN

Validation of the Prognostic Value of the Histopathological Classification of ANCA-Associated Glomerulonephritis: A Meta-Analysis Maria Wester Trejo,[1] Emma Van Daalen,[1] Jan W. Schoones,[2] Olaf Dekkers,[3] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden University Medical Center, Leiden, Netherlands; [2]Walaeus Library, Leiden University Medical Center, Leiden, Netherlands; [3]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands.*

Background: In 2010, a histopathological classification of antineutrophil cytoplasmic autoantibody (ANCA)-associated glomerulonephritis (AAGN) was proposed by an international consortium of renal pathologists and nephrologists. It comprises four biopsy classes: focal, crescentic, mixed and sclerotic, the order of which was shown, in the initial publication, to correspond to increasing severity of renal impairment during follow-up. The aim of this meta-analysis was to evaluate the prognostic value of these phenotypical classes by means of validation studies that have been published since.

Methods: A literature search was performed using Web of Science, Google Scholar, PubMed and Embase in March 2017, selecting studies that associated histopathological class to renal outcome in adult patients with AAGN. The risk of developing end-stage renal disease (ESRD) during follow-up was compared between classes using a meta-analysis with random effects model. Weighted relative risks (RR) with 95% confidence intervals (95% CI) were reported.

Results: Nineteen studies were included with a total of 2,408 patients. Using sclerotic class as a reference category, ESDR risk was lower in the crescentic class (RR 0.53, 95% CI 0.43-0.64); RR in focal was lower than in crescentic class (RR 0.27 95% CI 0.20-0.37). RR in crescentic compared to mixed class was 1.18 (95% CI 0.95-1.45); RR in focal compared to mixed class was 0.34 (95% CI 0.25-0.47).

Conclusions: Our meta-analysis shows that the risk for developing ESRD increased with more severe histopathological lesions. We found no difference between the crescentic and mixed classes, pointing towards a comparable risk profile with regard to ESRD. We are currently performing an individual patient data meta-analysis, as this technique is better equipped to deal with study heterogeneity. For the moment, this meta-analysis confirms the use of the histopathological classification system as a predictor of renal outcome in the prognostication of patients with AAGN.

FR-PO721

Clinical Impact of Peritubular Capillaritis on Renal Prognosis in ANCA-Associated Glomerulonephritis Satoshi Hara,[3] Fae Suzuki,[4] Ichiro Mizushima,[4] Kiyoaki Ito,[5] Hiroshi Fujii,[1] Kazunori Yamada,[4] Mitsuhiro Kawano.[2] *[1]Division of Rheumatology, Department of Internal Medicine, Kanazawa University Graduate School of Medicine, Kanazawa, Kanazawa, Japan; [2]Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan; [3]Kanazawa Graduate School of Medicine, Kanazawa, Japan; [4]Kanazawa University Graduate School of Medicine, Kanazawa, Japan; [5]Kanazawa universtiy, Kanazawa, Japan.*

Background: A predictive histopathologic classification of anti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis has been widely used; however, the classification is based on only glomerular lesions, and tubulointerstitial lesions including peritubular capillaritis (PTCitis) are excluded. The present study was aimed to clarify the clinical impact of PTCitis on renal prognosis in ANCA-associated glomerulonephritis.

Methods: Sixty-one patients of ANCA-associated glomerulonephritis, diagnosed by kidney biopsy at our center between January 2003 and May 2016, were included in the study. PTCitis is defined as infiltration of inflammatory cells at least one leukocyte in ≧10% of cortical PTCs with ≧3 leukocytes in most severely involved PTC. According to the presence/absence of PTCitis, patients were retrospectively divided into 2 groups [PTCitis (+) or PTCitis (-)], and clinical and histological findings correlated with PTCitis were estimated. The primary predictor was the presence of PTCitis. The primary endpoint was the cumulative percentage of patients who developed end-stage renal disease.

Results: PTCitis was detected in 39 of 61 (63.9%) cases. Clinically, age, gender, serum C-reactive protein, kidney function, urinary protein were all insignificant between PTCitis (+) and PTCitis (-) groups. Histologically, arteritis of small artery and interstitial fibrosis were evident in PTCitis (+) group (p=0.005, p=0.033, respectively), although histological subclass type and tubular atrophy were not different. Renal survival at 6 months was 87.2% in PTCitis (+) group compared with 86.4% in PTCitis (-) group (p=0.96). When adjusted by renal function and other histologic parameters, PTCitis was not an independent predictor for renal survival (hazard ratio, 1.3; 95%confidence interval 0.3-6.1; p=0.71).

Conclusions: PTCitis may not affect renal prognosis in ANCA-associated glomerulonephritis, while PTCitis is correlated with interstitial fibrosis. The further studies of larger population would be required.

FR-PO722

Chemokine Receptor 8 in Peripheral Blood Mononuclear Cells Can Distinguish Active ANCA-Associated Vasculitis from Infectious Complications Satoru Sanada,[1] Yukako Akiyama,[2] Mitsuhiro Sato,[1] Toshinobu Sato,[1] Yoshio Taguma.[1] *[1]Japan Community Health Care Organization Sendai Hospital, Sendai, Japan; [2]Tohoku university, Sendai Miyagi, Japan.*

Background: Infectious complications are major causes of death in ANCA-associated vasculitis (AAV). Similar clinical symptoms between AAV and infection may cause diagnostic difficulty despite totally opposite treatment in two situations. Aim of this study is to identify a new biomarker for AAV, which enables to distinguish vasculitis and infections.

Methods: Peripheral blood mononuclear cells (PBMC) were collected from 222 patients with AAV, including patients in active, remission and infectious complications and patients with other rapidly progressive glomerulonephritis. Chemokine receptor 8 (CCR8) was assessed using quantitative PCR and flow cytometry. Quality of mRNA was measured by bioanalyzer before reverse transcription to provide reproducible results.

Results: CCR8 mRNA level in PBMC was significantly higher in patients with MPO-ANCA vasculitis compared to that in healthy control, which was confirmed by upregulated CCR8 protein expression in FACS. The area under ROC curve was 0.923 (95%CI: 0.842-1.000) with a sensitivity of 87.5% and a specificity of 100%. Lupus nephritis nor purpura nephritis did not show high CCR8 mRNA levels. Among MPO-ANCA vasculitis, CCR8 mRNA levels in patients with remission and patients with infectious complications during remission were lower compared to that in patients with active. The area under ROC curve was 0.924 (95%CI: 0.846-1.000) compared with active AAV and infectious complication.

Conclusions: CCR8 mRNA level in PBMC was associated with AAV activity, however, infectious complications did not affect CCR8 expression, suggesting that CCR8 could be a useful diagnosis biomarker for AAV.

Thrombotic Microangiopathy in Pauci-Immune Glomerulonephritis Jianling Tao,[3] Megan L. Troxell,[2] Jessica B. Lapasia,[1] Neeraja Kambham.[2] *[1]Medicine, Kaiser Permanente, San Francisco, CA; [2]Pathology, Stanford University School of Medicine, Stanford, CA; [3]Medicine, Stanford University, Stanford, CA.*

Background: Renal thrombotic microangiopathy (TMA) is occasionally seen in biopsies with pauci-immune necrotizing crescentic glomerulonephritis (NCGN). Recent studies indicate that NCGN patients with TMA have more severe renal injury and higher mortality rate.

Methods: Biopsies from 2 centers with diagnosis of NCGN and TMA changes were identified (5/2003- 4/2017) from Pathology records. Patients with connective tissue disorders, HBV, HCV, HIV, and monoclonal gammopathy were excluded. Biopsies were re-reviewed and detailed clinical and follow up data was documented.

Results: Ten patients met our inclusion criteria. Patients were predominantly female (9:1) and average age at biopsy was 48 years (range 10-72). Clinical presentation was nephritic syndrome +/- acute renal failure and 3 patients had nephrotic range proteinuria. ANCA was positive in 8 patients and schistocytes were noted on peripheral smear in 2 patients. Of 7 patients with available complement data, only 1 had low C3 at presentation; one patient with previously normal C3 developed hypocomplementemia and clinical TMA 3 years later. In addition to glomerular crescents and necrosis, prominent TMA changes (unrelated to GBM rupture or crescents) were seen in glomeruli/blood vessels on light microscopy in 6 patients and on EM in 4 patients. Glomerular mesangial C3 (+/- IgG) staining was documented in 3 patients, with ultrastructural confirmation of deposits in 2. The mean follow up was 40 months (range 0.5-156). At last follow up, 5 patients reached ESRD or died; 1 has mild chronic kidney disease and 2 have normal renal function. Treatment in most cases included steroids and Cytoxan, with a few receiving rituximab and plasmapheresis. One patient received anti-complement treatment after biopsy and another received it 3 years later; both were dialysis dependent at last follow-up.

Conclusions: NCGN patients rarely have clinical or biopsy-proven TMA. Based on this limited sample, the clinical outcome appears to be poor. The underlying mechanism has been postulated to be alternative complement pathway abnormality. The nephrologist should be alerted to the presence of TMA for potential therapeutic implications and further complement investigations.

FR-PO724

Unravelling the Pathophysiology of C3G/IC-MPGN and How to Predict Disease Progression and Orient Therapies Paraskevas Iatropoulos,[1] Erica Daina,[1] Manuela Curreri,[1] Rossella Piras,[1] Elisabetta Valoti,[1] Caterina Mele,[1] Elena Bresin,[1] Sara Gamba,[1] Marta Alberti,[1] Matteo Breno,[1] Ettore Sabadini,[2] Marina Noris,[1] Giuseppe Remuzzi.[1,2] *[1]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; [2]Unit of Nephrology and Dialysis, Ospedale Papa Giovanni XXIII, Bergamo, Italy. Group/Team: Registry of Membranoproliferative Glomerulonephritis/C3 Glomerulopathy*.

Background: Membranoproliferative glomerulonephritis (MPGN) was recently reclassified into alternative pathway (AP) complement-mediated C3 glomerulopathy (C3G) and immune-complex-mediated MPGN (IC-MPGN). However, genetic and acquired AP abnormalities are also observed in IC-MPGN. Here, in patients with C3G/IC-MPGN, we explored the presence of distinct disease entities characterized by specific pathophysiologic mechanisms.

Methods: We performed unsupervised hierarchical clustering, a data-driven statistical approach not biased by operator hypotheses, on 163 C3G/IC-MPGN patients using histology, genetic, serum complement and clinical features.

Results: This approach divided C3G/IC-MPGN patients into four clusters, characterized by specific histology, clinical and complements features indicating the existence of four different pathogenetic patterns. Specifically, patients with fluid-phase complement activation, showing low serum C3 and a high prevalence of AP gene mutations and/or C3NeF (clusters 1-3), were separated from patients with solid-phase complement activation (cluster 4), showing likely normal serum C3, late onset and poor renal survival. In patients with fluid-phase complement activation, clusters 1 and 2 were characterized by massive AP activation as far as the terminal pathway and the highest prevalence of subendothelial deposits, but cluster 2 was characterized by the additional activation of the classical pathway and the highest prevalence of nephrotic syndrome at onset. Patients in cluster 3 were characterized by prevalent activation of the C3 convertase and highly electron-dense deposits.

Conclusions: These clusters of C3G/IC-MPGN patients may be useful for better clarifying disease etiology, defining the risk of ESRD and paving the way for personalized treatment.

	Cluster 1	Cluster 2	Cluster 3	Cluster 4	*p*-value

FR-PO725

More Than C3 Deposition: The Unique Characteristics of One Family with C3 Glomerulopathy Alexandria I. Leonhardt,[1] Nicole Meyer,[1] Nicolò Borsa,[2] Yuzhou Zhang,[1] Richard J. Smith,[1] Carla M. Nester.[1] *[1]University of Iowa, Iowa City, IA; [2]The University of Iowa, Iowa City, IA.*

Background: As a disease, C3 Glomerulopathy is currently defined by the single diagnostic criteria of a predominant immune fluorescent staining of C3 on renal biopsy. Additonal diagnositic requirements have not been defined. After cases are ascertained, infrequently, it may be discovered that those affected have a genetic abnormality in a complement gene – supporting the underlying complement abnormality as the disease causing agent. We present a familial case of C3G identified after a proband with predominant C3 staining was discovered to have a homozygous *C3* gene mutation.

Methods: After obtaining informed consent, a medical record review was completed on all available family members. The disease phenotype was confirmed by renal biopsies in persons with >1gm/24hr of urine protein. Comprehensive genetic screening was completed on all complement genes using standard procedures. An extensive complement analysis was performed that included serum levels of complement proteins and their cleavage products, assays of complement function, and screens for autoantibodies.

Results: A pathogenic variant in *C3* segregated with each patient with a renal phenotype: c.443G>A, p.R148Q. Both the matriarch and patriarch of the family were heterozygous for this variant, consistent with their relationship as first cousins. The spectrum of clinical renal disease ranged from asymptomatic hematuria (N=2) or proteinuria (N=1) to end stage renal disease (N=3). One family member had multiple cysts by ultrasound. Renal biopsies confirmed C3GN in 3 family members and FSGS in a fourth person. Serum C3 levels were normal in all asymptomatic individuals (both with and without the variant). C3 levels were low in individuals with symptomatic C3GN pathology. All persons carrying the p.R148Q mutation had elevated serum levels of C3c. Surface plasmon resonance assays, as well as an expanded functional and cofactor assessment of the mutation is ongoing.

Conclusions: We present a rare case of familial C3 Glomerulpathy. Unique to this case is an underlying gene abnormality that segregates not only with the diagnostic C3G requirement, but also with FSGS and cystic renal disease. This pedigree highlights not only the narrow nature of the C3G definition, but also calls into question whether the C3 protein may play a functional role in other renal abnormalities.

FR-PO726

C3G-Associated with Monoclonal Gammopathy Aishwarya Ravindran, Fernando C. Fervenza, Sanjeev Sethi. *Mayo Clinic, Rochester, MN*.

Background: Monoclonal immunoglobulins (MIg) may act a functional inhibitor of the alternate complement pathway thereby playing a causal role in the pathogenesis of C3 glomerulopathy (C3G). In this study, we describe the clinicopathological features, hematological evaluation, treatment and outcomes of C3G associated with MIg.

Methods: We identified 95 patients seen at the Mayo Clinic from 2007-2016 with a diagnosis of C3 glomerulopathy (C3GN or DDD) who were tested for a monoclonal protein.

Results: 36 (37.9%) patients were positive for MIg; 65.1% of patient ≥50 years were positive (17 times higher than the expected rate). The median age at diagnosis was 60 years (range: 20-85), 25 males and 11 females. The median serum creatinine and proteinuria was 1.9 mg/dL and 3000 mg/24 hours. Hematuria was present in 28 (93.3%) patients. Twelve (34.3%) patients had low C3 and 4 (11.4%) had low C4. Twenty-six (72.2%) patients were classified as MGUS/MGRS, 5 (13.9%) multiple myeloma, 2 (5.6%) smoldering myeloma, 1 (2.8%) CLL, 2 with cryoglobulins (5.6%) 1 of which was type I cryoglobulin and the other was associated with lymphoma of the stomach. The most common abnormality was the presence of C3 nephritic factor in 10 (43.5%) patients and autoantibodies to complement factor H or B in 3 patients (13%). Six (30%) patients had mutations in complement regulating proteins. Of the 36 patients, 33 (91.7%) received steroids and/or other immunosuppressive drugs. At a median follow-up of 43.5 months, the median serum creatinine and proteinuria was 1.4 mg/dL and 749 mg/24 hours. Nine (25%) patients progressed to end stage renal disease. Sixteen (44.4%) received targeted therapy for MIg. Of these 11 (68.8%) patients achieved stable renal function, while the remaining 5 (31.2%) progressed to ESRD, of which 3 (18.7%) had multiple myeloma and only 2 (12.5%) had MGUS/MGRS. With regards to non-targeted treatment for the MGUS/MGRS group, 4 (20%) patients progressed to ESRD.

Conclusions: Our study shows a high prevalence of MIg in C3G patients. C3 nephritic and autoantibodies were more common compared to mutations suggesting that the MIg likely acts as an autoantibody to complement regulating proteins. Targeted treatment of MIg, in particular with MGUS/MGRS, resulted in stabilization of renal function in a majority of the patients.

FR-PO727

Autoimmune and Genetic Workup in Post-Transplant C3 Glomerulopathy Ashwani Kumar,[1] Ritambhra Nada,[1] Raja Ramachandran,[2] Charan S. Rayat,[1] Krishan Lal L. Gupta.[2] *[1]Postgraduate Institute of Medical Education & Research, Chandigarh, India; [2]Nehru Hospital, Chandigarh, India*.

Background: Post-transplant C3 glomerulopathy (Tx-C3GP) is associated with alternate complement pathway (ACP) dysregulation and the literature is scanty. Hence, serological and genetic workup for Tx-C3GP was performed.

Methods: We performed Tx-C3GP workup in all patients reported during 2010-16. Tests included ACP functional assay (APFA), C3, C4 levels, complement factors H (CFH) and B (CFB) estimation. Paraproteins and autoantibodies to CFH (ab-CFH), CFB (ab-CFB), C3 convertase (C3Nef), PCR for CFH and complement factor H-related 5 (CFHR5) genes were done followed by Sanger sequencing. Clinical outcome of the patients was also recorded.

Results: Twenty-six cases of Tx-C3GP included 11 cases of dense deposit disease (DDD), 10 C3 glomerulonephritis (C3GN) and 5 C3GP (EM not available). Mean age was 31.88 years. Two-thirds presented with graft dysfunction (Mean time; <1 week-C3GN, 8 Months-DDD). Nephrotic syndrome and asymptomatic urine abnormality were present in 17%. Basic disease was known in 50% (DDD-4, C3GN-3, C3GP-5, & Diabetic nephropathy-2) cases. Native kidney histology ranged from normal to membranoproliferative (MP) morphology, whereas in early post-transplant recurrences, it was focal segmental proliferative and MP in late recurrences. We observed low APFA and C3 in all cases. Positive findings in DDD included, low CFH levels, ab-CFH, low CFB levels in 56, 25 and 11%, respectively. Low CFH levels (22%) and ab-CFH were present in 15% of C3GN. In contrast to DDD, 22% patients of C3GN had low CFB levels and ab-CFB (22%). C3NeF was positive in 44% DDD and 33% of C3GN. We found CFH SNP rs800292 (Val62Ile) in 44% and -18TT insertion in 22% cases of DDD and both SNPs were seen in 11% cases of tx-C3GN. SNP rs1061147 (p.Ala243Ala) and rs1061170 (p.His402Tyr) of CFH were more frequent in tx-C3GN (56% & 45%) and seen lesser in tx-DDD (33% and 11%). SNP rs2274700 (p.Ala473Ala) was equally present (22%) in both the groups. No variant of CFHR5 was present in any tx-C3GP case. 43% of the patients experienced graft loss.

Conclusions: Both DDD and C3GN reccur post-transplant. C3GN has an early recurrence compared to DDD. Low CFH and ab-CFH were evident in DDD, whereas low

CFB and ab-CFB are seen in C3GN. Genetic findings for CFH gene revealed difference among variants for these two entities.

FR-PO728

Dense Deposit Disease: Is There a Racial Difference in the Prevalence? Anila Abraham,[2] Patrick D. Walker.[1] *[1]Arkana Laboratories, Little Rock, AR; [2]Renopath, Center for Renal and Urological Pathology, Chennai, India.*

Background: Dense deposit disease(DDD) is a rare glomerulonephritis that commonly affects children. It is defined at the ultrastructural level by the presence of extremely electron dense material in the lamina densa of the glomerular basement membrane. This results in various patterns of glomerular injury with mesangioproliferative and membranoproliferative patterns being the most common

Methods: Native kidney biopsies reported from August 2013 to November 2016 at Renopath, Chennai, Tamil Nadu, India were reviewed. Cases of DDD were identified and clinicopathologic features compared. We then compared our findings with data published in literature. The databases at Renopath and Arkana Laboratories were utilized to compare the rates of DDD diagnosis

Results: During the study period, there were 25 patients with DDD among the 7335 native kidney biopsies (0.34%) at Renopath. Arkana Laboratories in Little Rock, AR, USA, had 21 cases of DDD among their 26,319 native kidney biopsies (0.08%) during the same time period. The mean age of patients was 20.7 years, with only 9 (36%) patients < 16 years of age. Male to female ratio was 1.3:1. Serum C3 was decreased in all patients. At the time of biopsy, proteinuria was present in all patients, five were hypertensive, 2 had partial lipodystrophy and one had drusen. Membranoproliferative, mesangioproliferative, exudative and crescentic patterns were observed. Only 52% of the biopsies showed membranoproliferative pattern. Interstitial inflammation was significantly higher in the biopsies with this pattern. All the patients with crescentic pattern (16%) were below 16 years of age. Mesangioproliferative pattern was seen only in adults. Arteriosclerosis, interstitial fibrosis and tubular atrophy were significantly more frequent in adults

Conclusions: The mean age of patients in our study was 20.7 years, unlike many studies which considered DDD as a childhood disease. Only half of our patients had the membranoproliferative pattern of glomerular injury. Crescentic pattern was seen exclusively in children and mesangioproliferative pattern was seen only in adults. Although DDD is rare, it is much more common (>400%) in this Indian population when compared with the American population. In addition to genetic differences, environmental factors and chronic infections may possibly contribute to the high incidence in this South Indian population

FR-PO729

Urine Micro-RNAs as Histology Biomarkers in Lupus Nephritis Xiaolan Zhang,[1] Juan M. Mejia-Vilet,[2] Huijuan Song,[1] Samir V. Parikh,[1] Anjali A. Satoskar,[1] Tibor Nadasdy,[1] Brad H. Rovin.[1] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico. Group/ Team: CKD Biomarker Consortium.*

Background: Urine micro-RNAs (miRNA) have emerged as potential biomarkers for lupus nephritis (LN). The relationship of urine miRNAs with renal histology in LN was investigated.

Methods: This study examined 98 biopsy-proven LN patients and 19 healthy controls. Total urine RNA was enriched using ExoQuick columns. miRNA was extracted and screened for differential expression of individual miRNAs between LN and controls using Nanostring miRNA profiling. The miRNAs showing the most significant differential expression on screening were validated by duplex real-time PCR after cDNA synthesis using a TaqMan Advanced miRNA cDNA Synthesis kit. miRNA levels were normalized to urine creatinine and the housekeeping miRNA, miR-191-5p. Urine miRNA expression and kidney histology were compared by t-test, ANOVA followed by Wilcoxon ranked-sum testing or multiple linear regression, as appropriate.

Results: Several miRNAs identified by Nanostring screening were confirmed by PCR. Of these, miR-29c-3p correlated with kidney biopsy chronicity index (R2=0.38, p=0.0022), and was significantly increased in the urine of patients with interstitial fibrosis (4.86-fold; p=0.006) and tubular atrophy (5.92-fold; p=0.0029). miR-1290 expression was 39-fold higher (p=0.007) in patients who did not have crescents compared to those with crescents. miR-200b-3p was also decreased in patients with crescents (7.78-fold; P=0.024), glomerular neutrophil accumulation (10-fold; P=0.006) and endocapillary proliferation (2.82-fold, P=0.01) compared to patients without these acute lesions.

Conclusions: A subset of miRNAs that are differentially-expressed in the urine of LN patients appear to correlate with acute or chronic changes on kidney biopsy and are candidate renal histology biomarkers that may be useful for non-invasively following changes in renal pathology during LN.

FR-PO730

Urine Epidermal Growth Factor, Monocyte Chemoattractant Protein-1, or Their Ratio in Lupus Nephritis: Relationship with Renal Histology and Response to Therapy Chagriya Kitiyakara, Pintip Ngamjanyaporn, Suchin Worawichawong, Khantong Khiewngam, Piyanuch Radinahamed. *Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.*

Background: The balance between pro-inflammatory cytokines such as monocyte chemoattractant protein- 1 (MCP-1) and protective cytokines such as epidermal growth factor (EGF) likely determines the disease activity and outcomes in glomerular diseases, but there is limited data in lupus nephritis (LN). In this study, we evaluated the relationship between urinary EGF, MCP-1 or their ratio at baseline with renal histology and the response to immunosuppressive therapy at 6 months follow-up.

Methods: This is a prospective study of biopsy-proven LN (n = 69). Urine samples were collected at biopsy. MCP-1 and EGF were analyzed by ELISA. Response to treatment was defined as 50% or greater reduction in proteinuria or proteinuria <0.5g/g Cr. Biomarker levels were compared between histological categories. Factors associated with treatment response at 6 months were analyzed by multivariate logistic regression in LN Classes III-IV.
