Results: Exposure of HK2 cells to HG (50 mM) resulted in an increase of the expression of α-SMA and vimentin, and was associated with a decrease in the expression of E-cadherin. Treatment of HK2 cells with Nrf2 activator, Sulforaphan, showed a dosage-dependent amelioration of HG induced changes in markers of EMT with an increase of HO-1 expression. We found that SFN ameliorated experimental diabetic nephropathy, at least in part, via GSK3β /Nrf2 signaling pathway. We observed NRF2 activator inhibited high glucose-induced generation of reactive oxygen species (ROS), phosphorylation of PI3K/Akt at serine 473, and phosphoratory inhibition of serine/therionine kinase gycogen synthase kinase-3β (GSK-3β) at serine 9. These signaling resulted in the down-regulation of Snail transcriptional factor and recovery of E-cadherin. The Nrf2 activation attenuates high glucose-induced epithelial-to-mesenchymal transition via modulation of GSK-3β activity in human renal tubular cells.

Conclusions: Taken together, our results suggest that Nrf2-HO-1 has a critical role in the regulation of EMT through modulation of GSK-3β activity, highlighting Nrf2-HO-1 and GSK-3β as a potential therapeutic target in diabetic nephropathy.

TH-PO360

Constitutive Akt1 Activation in Renal Tubule Cells Ameliorates TGF-β Induced Oxidative Stress and Pro-Fibrotic Signaling by Preserving NF-E2 Expression

Shunying Jin,[2] Arushi Gupta,[3] Sanjana Rane,[3] Erik Korte,[1] Michelle T. Barati,[3] Lu Cai,[3] Michael Merchant,[4] Madhavi J. Rane.[3] *[1]None, Louisville, KY; [2]UNIVERSITY OF LOUISVILLE, LOUISVILLE, KY; [3]University of Louisville, Louisville, KY; [4]University of Louisville Medicine, Louisville, KY.*

Background: TGF-β-induced renal fibrosis is mediated by p38 and JNK MAPK activation. Preliminary laboratory studies found TGF-β (10 ng/ml; 24 h) treatment of human renal proximal tubule (HK-11) cells decreased Akt1 activation and Nuclear Factor-Erythroid derived 2 (NF-E2) protein expression and increased CTGF and PAI-1 expression. Current studies identified signaling mechanisms by which TGF-β regulates NF-E2 and renal fibrosis which may lead to generation of new therapies.

Methods: *In vitro* Akt kinase assay was performed using active Akt, recombinant NF-E2 and γ-^{32}P-ATP. Real-time NF-E2 PCR was performed on total RNA from control and TGF-β treated HK-11 cells. HK-11 cells were transfected with pUse vector or pUse-NF-E2 or pUse-AktCA (c-myc tagged), or scrambled or NF-E2 siRNA and treated with TGF-β for 24 h. Cell lysates were subjected to immunoblotting for pp38 MAPK, cleaved caspase-3, pJNK, NF-E2, CTGF, PAI-1, c-myc, and GAPDH antisera. Additionally, HK-11 cells were pre-treated (1 h) with DMSO or p38 MAPK inhibitor, 3 μM SB203580, or transfected with pUse or pUse-NF-E2 or pUse-AktCA followed by treatment with/without TGF-β for 24 h. Following day cell were stained with dihydroethidium (DHE) (10 μg/ml) for 30 m. Cells were washed and viewed by confocal microscopy for superoxide generation.

Results: RT-PCR and immunoblotting demonstrated that NF-E2 transcript was significantly induced after TGF-β treatment for 24 h but protein expression was down-regulated. NF-E2 was identified as an Akt substrate *in vitro* and over-expression of AktCA preserved NF-E2 expression in presence of TGF-β (24 h). NF-E2 overexpression, AktCA overexpression, or SB203580 inhibited TGF-β-induced superoxide in HK-11 cells. AktCA over-expression inhibited TGF-β-induced pp38 activation, pJNK activation, caspase-3 cleavage, CTGF and PAI-1 expression. NF-E2 over-expression inhibited CTGF and PAI-1 expression while silencing NF-E2 expression significantly increased CTGF expression in presence of TGF-β.

Conclusions: Akt1 substrate NF-E2, serves as a putative negative regulator of oxidative stress and pro-fibrotic signaling and its expression is regulated by post-translational modification in TGF-β treated HK-11 cells.

Differential Effects of Two Nrf2 Inducers on Renal Tubule Cells Austin King,[1] Shruti Wadhwa,[1] Kayvon Ghayoumi,[1] Susan M. Isaacs,[1] Michael Merchant,[2] Madhavi J. Rane,[1] Michelle T. Barati.[1] *[1]University of Louisville, Louisville, KY; [2]University of Louisville Medicine, Louisville, KY.*

Background: A variety of compounds inducing the cytoprotective transcription factor Nrf2 have shown promise to reduce renal injury in experimental murine models. However, comparison of mechanisms of action of these agents on renal cell biology is limited. This study examined effects two Nrf2 inducing compounds on renal tubule cells: Dimethyl fumarate (DMF), an FDA approved and clinically used drug, and Protandim, a dietary supplement with no previously reported findings in renal cells.

Methods: Human proximal tubule cells (HK11 cells) were treated with DMF (10-80μM) or Protandim (5-80μg/ml; comprised of Milk Thistle, Bacopa, Ashwagandha, turmeric, and green tea extracts) for various time points. Cell viability was analyzed by reduction of MTT and cell counting. Immunoblotting used to analyze Nrf2 expression/localization, phosphorylation of kinases known to regulate Nrf2 activation (Akt, GSK3β, ERK and p38 MAPK), and expression of Nrf2 transcriptional targets (NQO1 and SOD-1). Apoptosis was analyzed by immunostaining for cleaved caspase 3.

Results: MTT reduction and number of adherent cells was decreased with ≧40μM DMF and ≧40μg/ml Protandim, and DMF caused cells to round up while Protandim caused cell shrinkage, at these concentrations. The lowest concentration of Protandim (5μg/ml) and DMF (10μM)) increased nuclear localization of Nrf2, indicative of Nrf2 activation. Both inducers increased expression of NQO1 at multiple concentrations whereas expression of SOD1 was induced more by DMF. Protandim caused a concentration-dependent increase in p38 phosphorylation. Neither compound altered Akt phosphorylation whereas phospho-ERK and GSK3β-Ser9 phosphorylation (inactive GSK3β) were increased by Protandim. High concentrations of Protandim (80μg/ml) increased caspase3 cleavage and nuclear condensation, indicating apoptosis, while 80μM DMF caused nuclear swelling.

Conclusions: Activation of p38 by Protandim may activate Nrf2 through direct phosphorylation and inhibition of GSK3β, a cellular Nrf2 inhibitor. Alternatively, p38 may play a role in high concentration Protandim-induced cell death. The results suggest that differential effects on tubule cell morphology, kinase signaling, and induction of Nrf2 transcriptional targets by DMF and Protandim may result in different tubule cell responses during stress stimuli or kidney injury.

NF-E2 Is Induced in the Lungs of ABIN1-(D485N) Mice David W. Powell,[3] Sanjana Rane,[3] Shunying Jin,[2] Erik Korte,[1] Michelle T. Barati,[3] Madhavi J. Rane.[3] *[1]None, Louisville, KY; [2]UNIVERSITY OF LOUISVILLE, LOUISVILLE, KY; [3]University of Louisville, Louisville, KY.*

Background: Inflammation caused by systemic lupus erythematosus (SLE) can affect the kidneys and lungs. Variants for the ABIN1 gene (*TNIP1*) are risk factors for glomerulonephritis (GN) in SLE and a knock-in mouse expressing an inactive form of ABIN1-(D485N) spontaneously developed systemic autoimmunity and progressive GN. IL-8 increases in plasma of ABIN1 (D485N) mice, a target of Nuclear Factor-Erythroid derived 2 (NF-E2). Inflammatory mediators in the lungs, bronchoalveolar lavage fluid (BALf), and plasma of WT and ABIN1-(D485N) mice were examined in the current study.

Methods: Three and six month old wild-type (WT) and ABIN1-(D485N) mouse lung homogenates, BALF, and plasma samples were immunoblotted for Myeloperoxidase (MPO), Thrombospondin 1 (TSP1), Nuclear Factor-Erythroid derived 2 (NF-E2) and CRP. Six-month old WT and ABIN1-(D485N) mouse kidneys were also subjected to H&E staining and MPO immunohistochemistry.

Results: Increased pulmonary MPO, TSP1 and NF-E2 expression was detected in 3 m old ABIN1-(D485N) mice. Concurrently, increased TSP-1, NF-E2 and CRP were detected in the plasma of 3 m old ABIN1-(D485N) mice. Cleaved caspase-3 was detected in lungs of ABIN1-(D485N) mice suggesting increased pulmonary apoptosis. In 6 m old ABIN1-(D485N) mice, H&E and MPO staining demonstrated immune cell recruitment in lung tissue sections. CRP and NF-E2 expression persisted in ABIN1-(D485N) mice at 6 m of age. NF-E2 and CRP was detected in the BALf of 6 m old ABIN1-(D485N) mice. To examine the role of NF-E2 in BALf, recombinant purified NF-E2 protein or control vector protein was intratracheally administered to long evans rats and 2 h after administration the rats were sacrificed and BALf, lung homogenates and lung tissue sections were obtained. Neutrophils were recruited into the BALf of rats treated with recombinant NF-E2 but not control protein and H&E staining of tissue demonstrated lung damage. Moreover, recombinant NF-E2 was shown to promote human neutrophil actin polymerization, chemotaxis, and survival.

Conclusions: Thus, an inactive form of ABIN1-(D485N) leads to induction of NF-E2 in the lungs. Neutrophil recruitment in the lungs and *ex-vivo* activation of neutrophils by recombinant NF-E2 suggests that NF-E2 may serve as a novel immune modulator and a potential therapeutic target.

Manganese Promotes Intracellular Accumulation of AQP2 via Modulating F-Actin Polymerization and Reduces Urinary Concentration in Mice Ming Huang,[1] Lei Lei,[1,2] Teodor G. Paunescu,[1] Baoxue Yang,[2] Hua A. Lu.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Department of Pharmacology, School of Basic Medical Sciences, Peking University, Beijing, China.*

Background: Aquaporin-2 (AQP2) is a water channel protein expressed in principal cells (PCs) of the kidney collecting ducts (CDs) and plays a critical role in urine concentration. F-actin polymerization through Rho phosphorylation is one of the key determinants for the cytoskeletal dynamics controlling AQP2 trafficking. Preliminary studies have shown that manganese stabilizes F-actin nuclei and decreases the concentration of its monomers at the steady state. We report in this study that manganese chloride ($MnCl_2$) is a novel and potent regulator of AQP2 trafficking in cells and in the kidney. We observed aperinuclear accumulation of AQP2 in both cultured cells and kidney CDs in response to $MnCl_2$ treatment. This effect of $MnCl_2$ on AQP2 distribution was associated with an increase in the rate of AQP2 endocytosis without alteration of the overall exocytosis. This perinuclear accumulation of AQP2 induced by $MnCl_2$ was resistant to vasopressin (VP) simulation. Although the level of total and phosphorylated AQP2 did not change, $MnCl_2$ treatment impeded VP-induced phosphorylation of AQP2 at its serine residues 256, 264, 269 and dephosphorylation at serine 261. In addition, $MnCl_2$ significantly promoted F-actin polymerization along with downregulation of RhoA activity, and prevented VP-induced AQP2 membrane accumulation. Finally, $MnCl_2$ treatment caused significant polyuria and reduced urinary concentration in mice, likely by promoting intracellular accumulation of AQP2. More importantly, this reduced urinary concentration induced by $MnCl_2$ was resistant to VP treatment. In summary, our study identified a novel effect of $MnCl_2$ on AQP2 trafficking, and proved its potent impact on regulating urinary concentration in animals.

Oxidative Stress-Induced Intracellular Fatty Acids Imbalance Contributes to Renal Tubular Cell Damage Tadashi Imafuku,[1] Hiroshi Watanabe,[1] Masafumi Fukagawa,[2] Toru Maruyama.[1] *[1]Department of Biopharmaceutics, School of Pharmacy, Kumamoto University, Kumamoto, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: Although chronic kidney disease (CKD) is one of the oxidative stress related diseases, the mechanism by which oxidative stress contributes to pathophysiology of CKD still remains unclear. Previous reports indicated that the addition of exogenous saturated fatty acid induced lipotoxicity in renal tubular cell, whereas co-incubation with unsaturated fatty acid attenuated saturated fatty acid-mediated tubular damage. However, the relationship between oxidative stress and fatty acid composition in proximal tubular cells has not been investigated.

Methods: Intracellular fatty acids composition in immortalized proximal tubule epithelial cells (HK-2 cells) was measured by GC-MS.

Results: In HK-2 cells, hydrogen peroxide treatment decreased the expression of both elongation of long chain fatty acid member 6 (Elovl6), which elongates saturated and unsaturated fatty acid with 12, 14, and 16 carbons, and stearoyl-CoA desaturase-1 (SCD1), which catalyzes the formation of monounsaturated fatty acids. At that time, intracellular unsaturated fatty acids content was significantly decreased, while cellular ER stress/apoptosis was increased. Co-treatment of anti-oxidant, N-acetylcystein recovered the reduction of Elovl6 and SCD1 expression and consequently, enhanced cellular ER stress/apoptosis were reduced. This was further confirmed by the inhibition of these enzymes using siRNA and inhibitor in which these treatments caused to the increases of cellular ER stress/apoptosis via the reduction of intracellular contents of unsaturated fatty acids. Interestingly, co-incubation with exogenous unsaturated fatty acids with siRNA for Elovl6 and inhibitor of SCD1 attenuated tubular toxicity.

Conclusions: Oxidative stress-induced intracellular fatty acids imbalance contributes to renal tubular cell damage.

TGFβ Signals to Chromatin via Direct Interaction of Smad3 with the Polycomb Repressive Complex during the Determination of Renal Epithelial Cell Fate Darrell C. Andrews,[2] Thomas K. Dodd,[2] Jessica Davis,[2] Ciarán F. Kennedy,[2] Eoin P. Brennan,[2] Caitriona M. McEvoy,[2] Peter J. Conlon,[1] Catherine Godson,[2] John Crean.[2] *[1]Beaumont Hospital, Dublin 9, Co Dublin, Ireland; [2]Diabetes Complications Research Centre, UCD Conway Institute of Biomolecular and Biomedical Science, Belfield, Dublin 4, Ireland.*

Background: TGFβ resides at the centre of therapeutic approaches for the treatment of renal fibrosis, however despite significant efforts in this area, few intervention studies have demonstrated clinical efficacy. At the core of this issue remains a fundamental gap in our knowledge of how TGFβ signalling converges and interacts with transcriptional machinery to regulate gene expression. We recently demonstrated that silencing of the TGFβ type II receptor and repression of Smad2/3 signalling by miR302 promotes the acquisition of plasticity, suggesting that TGFβ signalling to chromatin plays a critical role in determining renal cell fate decisions.

Methods:

Results: Here, we have identified and characterized a novel direct interaction between Smad3 and EZH2, the enzymatic component of the PRC2 complex, during fate specification and TGFβ mediated epithelial dedifferentiation. Using iPSC derived renal organoids we established that targeting the interaction between Smad3 and EZH2 protected against TGFβ mediated tubular epithelial differentiation and loss of apical basolateral polarity. We interrogated the ChIP-Seq data (GSE75297) in which embryonic stem cells were differentiated by exposure to activin, identifying 2882 Smad3 peaks after 48h treatment with Activin of which 1618 mapped to Gene IDs. Smad3 peaks were significantly enriched for Oct/Sox motifs in ESCs whereas in ESCs treated with Activin, Smad3 peaks were prominently enriched for Nanog; 816/2112 peaks contained Nanog motifs, 243 of which mapped to known superenhancers, suggesting cooperativity between Smad3/PRC2 and superenhancer repression in the determination of cell fate. A number of these genes were also identified by RNA-seq as significantly differentially regulated in patients with chronic kidney disease (CKD).

Conclusions: We propose that this complex forms a molecular switch that regulates promoter access through epigenetic mechanisms and controls gene silencing, informing the fundamental mechanisms through which subsets of genes are switched on and off during fate specification and the pathogenesis of CKD.

RNA Sequencing of Enriched Collecting Duct Specific Cells Reveals Novel Immune Cell Signature in Intercalated and Principal Cells

Vijay Saxena,[2] Andrew L. Schwaderer,[4] John Ketz,[1] David S. Hains.[3] *[1]Nationwide Children's Hospital, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH; [3]Riley Children's Hospital, Indianapolis, IN; [4]The Ohio State University, Westerville, OH.*

Background: The collecting duct is well known to be involved with acid-base and water balance, but other functions are relatively unexplored. Recently we generated two reporter mice models to enrich collecting duct specific principal cell (PC) and intercalated cell (IC) and reported targeted gene expression of anti-microbial peptide genes because these cells are the "1st responders" to ascending pathogens. In this study, we performed global unbiased gene expression profiling on enriched ICs and PCs using RNA sequencing.

Methods: In this study, we performed global unbiased gene expression profiling on enriched ICs and PCs using RNA sequencing and performed pathway analysis with Ingenuity software.

Results: Lineage marker expression analysis indicated enrichment of ICs and PCs. IC lineage marker (*Atp6v1b1, Slc4a1 and Slc26a4*) normalized read counts were 11-27 fold higher in ICs compared to non-ICs, while PC lineage marker (*Aqp2, Elf2, Scnn1a, Scnn1b* and *Scnn1g*) normalized read counts were 24-198 fold higher in PCs compared to non-PCs. In direct comparison between ICs and PCs, IC marker expression was 2-3 fold higher in ICs while PC marker expression was 2-fold higher in PCs. The genes upregulated in ICs included innate immune receptor *Il1r1,* tight junction protein such as *Cldn4* and electrolyte exchanges such as *Slc8a1*. Ingenuity analysis of upstream regulators revealed ICs involvement in proliferation, inflammation and anti-bacterial response. PC's top predicted upstream regulators with a Z-score > 2 were TGFβ1, TP53, and cisplatin (a drug which is reported to cause polyuria). The top PC functions are cellular assembly and organization, and organismal survival. In direct comparison, both IC and PCs revealed overlapping innate immune function with expression of nod like receptors such as *Nlrp6, Nod1, Nod2*, toll like receptor such ad *Tlr1, Tlr3 and Tlr12,* interleukin receptor such as *Il13ra1, Il17r, Il1r1, Il15r*, and chemokine receptor such as *Cxcl10, Cxcl12, Cxcr4* - which are shown to be involved in response to pathogen challenge. Both cells had expression of beta defensin 1, 11, 29, and 42, as well as secretogranin V (*Scg V*), while lipocalin 2 (*Lcn2*) was also highly enriched in principal cells.

Conclusions: This study identifies collecting duct cells as innate immune effector cells with overlapping function.

Identification of Circular RNAs Underlying Circadian Cycling in Mouse Kidney Samples

Fabian Braun,[2] Marc Johnsen,[2] Bernhard Schermer,[2,3] Thomas Benzing,[2,3] Pål O. Westermark,[1] Roman-Ulrich Mueller.[2,3] *[1]Leibniz Institute for Farm Animal Biology, Dummerstorf, Germany; [2]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University Hospital Cologne, Cologne, Germany; [3]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, Cologne, Germany.*

Background: Over the past years circular RNAs have emerged as a new species of noncoding RNAs and a subject of intense research efforts. They are more stable than linear stranded RNA species and seem to be involved in post transcriptional gene regulation. Only last year, the first dataset of circular RNAs expressed in the murine kidney was published, yet we are far from understanding the precise involvement and bio molecular functions of these nucleic acids. Furthermore the question whether their expression is partially regulated in a timely or circadian manner has not been addressed so far.

Methods: 10 week old wild type mice were sacrificed for their organs every three hours starting at 12pm for an overall period of 48 hours. We isolated RNA from the extracted kidneys, pooled samples of three mice per time point and performed RNA Sequencing. Using bioinformatics analyses of backsplicing events we identified circular RNA sequences. Furthermore, we analyzed quantitative changes of these backsplicing events during the circadian cycle. qPCR was used to further validate the rhythmicity of the cycling circular RNAs as well as their host genes.

Results: We identified more than 4000 distinct backsplicing events in our data set. A subset of these circles showed a distinct circadian rhythmicity. Of the 35 top cycling circular RNAs, we validated the circadian expression pattern for two circular RNAs derived from the *Strn3* and *Smad4* gene locus. Interestingly both host genes did not display a circadian expression pattern.

Conclusions: Our data set yields further insight into the expression pattern of circular RNAs in the murine kidney. Especially we present the first evidence for a circadian expression of certain circular RNA species. Ongoing experiments will focus on the analysis of potential miRNA binding sites on the two circadian circular RNAs and the rhythmicity of the potentially bound miRNAs.

TH-PO368

MicroRNA-200c Is Involved in Klotho Reduction by Oxidative Stress in Human Tubular Cells

Kenichi Morii,[1] Satoshi Yamasaki,[2] Shigehiro Doi,[1] Kensuke Sasaki,[1] Toshinori Ueno,[1] Ayumu Nakashima,[1] Takao Masaki.[1] *[1]Hiroshima University Hospital, Hiroshima, Japan; [2]Kurume University Medical Center, Kurume, Japan.*

Background: Klotho deficiency is reportedly associated with the progression of kidney dysfunction, whereas its overexpression exerts renoprotective effects. Previous studies report that oxidative stress suppressed Klotho expression in renal epithelial cells, and that microRNA-200c (miR-200c) is upregulated by oxidative stress in human umbilical vein endothelial cells. In this study, we investigated whether oxidative stress-induced miR-200c is implicated in Klotho reduction in human tubular cells (HK-2).

Methods: HK-2 were stimulated with hydrogen peroxide before Klotho expression was evaluated using western blotting (WB) and quantitative PCR (qRT-PCR). MiR-200c expression was determined by qRT-PCR and the miR-200c binding site at the *klotho* mRNA 3′-untranslated region (3′-UTR) was characterized using an online prediction tool (microRNA.org). After miR-200c mimic or inhibitor was transfected into HK-2, Klotho expression was examined using WB and qRT-PCR. Luciferase reporter plasmid containing *klotho* 3′-UTR was transfected into HK-2 to investigate the inhibitory effect of miR-200c on Klotho expression. Histological analysis was performed to examine the correlation between Klotho and oxidative stress markers (8-OHdG, 4-HHE). *In situ* hybridization was performed to reveal the localization of miR-200c in human kidney biopsy specimens.

Results: Hydrogen peroxide suppressed Klotho expression without any reduction in *klotho* mRNA levels but upregulated miR-200c expression. Similarly, transfection of miR-200c mimic reduced Klotho expression as well as luciferase activity without any reduction in *klotho* mRNA levels. In contrast, transfection of miR-200c inhibitor maintained Klotho expression. In human kidney biopsy specimens, Klotho expression inversely correlated with oxidative stress markers (8-OHdG: $\rho=-0.44$, $P=0.010$; 4-HHE: $\rho=-0.39$, $P=0.021$). MiR-200c was expressed in distal tubular cells whose renal function was lowered.

Conclusions: Oxidative stress-induced miR-200c binds to *klotho* mRNA 3′-UTR, resulting in a reduction in Klotho expression.

TH-PO369

Palmitate Aggravates Proteinuria-Induced Cell Apoptosis and Inflammation via CD36-NLRP3-Caspase-1 Axis in the Proximal Tubular Cells of Obese Mice

Lung-Chih Li,[1,2] Jenq-Lin Yang,[1] Wen-Chin Lee,[1] Chien-Te Lee,[1] J. B. Chen,[1] Xiong Z. Ruan,[2] Wei-Yu Chen.[1] *[1]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung city, Taiwan; [2]University College London (UCL) Medical School, London, United Kingdom.*

Background: Dyslipidemia is common in obesity and elevated free fatty acid (FFA) is prominent in these patients. Palmitate, a long-chain saturated FA, accounts for the majority of FFA and causes renal injury in obesity. CD36 is a class B scavenger with widespread tissue distribution, including renal proximal tubular cells. The NOD-like receptor family, pyrin domain containing 3 (NLRP3) inflammasome is a multi-protein complex, which contains NLRP3, apoptosis-associated speck-like protein containing a CARD (caspase recruitment domain)(ASC), and caspase-1, that forms upon exposure to pathogens or danger signals to activate IL-1β and IL-18 secretion and lead to cell death. Our aims are to investigate whether CD36 and NLRP3 inflammasome contribute to FFA-induced inflammation and cell death in obesity-related tubulopathy.

Methods: High fat diet (HFD)-fed C57BL/6 mice and palmitate-treated renal tubular cells were used as *in vivo* and *in vitro* models in the current study. Sulfo-N-succinimidyl oleate (SSO) was used to treat mice and cells as a CD36 inhibitor. Stable knockdown of caspase-1 using shRNA were developed in HK2 cells (a proximal tubular cell line). The protein expressions of IL-1β, IL-18, and NLRP3 were assessed by immunohistochemistry in the renal tissues and western blotting in the cells. The expression and colocalization of NLRP3 and ASC were examined by immunofluorescent staining. The cell death and apoptosis of HK2 cells were checked by cell viability assay and TUNEL staining, respectively.

Results: The expressions of CD36, IL-1β, and IL-18 were increased progressively in the kidney of HFD-fed mice. SSO attenuated HFD-induced upregulation of IL-1β, IL-18 and NLRP3 and also decreased the colocalization of NLRP3 and ASC in the proximal tubular cells of mouse kidney. In HK2 cells, palmitate induced the maturation of IL-1β, IL-18 and caspase-1 in a dose-dependent manner, while SSO ameliorated it. SSO also abolished palmitate-induced cell death and apoptosis in a dose-dependent manner. Furthermore, knockdown of caspase-1 abrogated palmitate-induced cell death and apoptosis in HK2 cells.

Conclusions: FFA causes renal tubular cells inflammation and cell death/apoptosis via CD36-NLRP3-caspase-1 axis, which may explain, at least partly, the mechanism of obesity-related nephropathy.

Funding: Government Support - Non-U.S.

TH-PO370

K-Cadherin Protein Transfer from Proximal to Distal Tubule Cells Is Associated with the Release of BMP-7 Kameljit K. Kalsi,[2] Seema Jain,[2] Mysore K. Phanish,[1] Mark E. Dockrell.[2] *[1]SW Thames renal and transplantation unit, London, United Kingdom; [2]South West Thames Institute for Renal Research, London, United Kingdom.*

Background: Cadherins are structural trans-membrane proteins that maintain the epithelial integrity by homodimerization. In the human kidney K-Cadherin (CDH6) is exclusively expressed in proximal tubular epithelial cells (PTEC) as opposed to the mouse, where K-Cadherin is only expressed in embryonic tubular cells. K-Cadherin exhibits low homology to N-(38%) & E-cadherin (35%) and the loss of K-Cadherin is associated with progression of kidney disease. Loss of K-Cadherin could suggest that it is a signal of proximal tubular damage and is involved in intercellular signalling between proximal and distal cells within the kidney which may prevent progression of epithelial remodelling.

Methods: Tissue from 3 months post-transplant human biopsies was probed for K-Cadherin by immunohistochemistry. Epithelial cells from mice kidneys were separated into predominantly distal and proximal fractions and cultured to confluence. Conditioned human PTEC media taken from confluent PTEC cells was added to mice cells, allowed to incubate for 24h; cells treated with conditioned media were compared to cells treated with control media. Media was collected and cells were lysed for western blot analysis.

Results: Analysis of human biopsy tissue identified vesicular K-Cadherin in distal tubules (in addition to membrane staining identified in proximal tubules). We identified the presence of full length K-Cadherin in the medium of primary human (PTEC) cultures and investigated the effects of conditioned media from human PTEC on mice distal or proximal tubular epithelial cells. *De novo* K-Cadherin expression was detected ($p<0.05$, n=3) in distal mice cells treated with PTEC media compared to treatment with control media, K-cadherin in mice proximal cells (megalin positive) treated with PTEC media was not as pronounced. Expression of the kidney specific cadherin (ksp-cadherin, CDH16) followed the same pattern. Media was analysed for the distal anti-fibrotic factor Bone Morphogenetic Protein 7 (BMP7) release from distal and proximal tubular cells treated with PTEC media, both were positive for BMP7 compared to treatment with control media.

Conclusions: Release of K-cadherin from PTECs is incorporated into distal cells is associated with BMP-7 secretion, possibly enhancing epithelial integrity and may represent a previously unrecognised trans-nephron communication.

Angiotensin II Selectively Activates SGK1, but Not Akt, via PKC-Dependent Modulation of mTORC2 in Renal Tubule Epithelial Cells Catherine Gleason, David Pearce. *University of California San Francisco, San Francisco, CA.*

Background: Angiotensin II (AngII) is a potent regulator of fluid balance and blood pressure homeostasis. In volume depletion, AngII stimulates production of the sodium retaining hormone, aldosterone, but also directly effects salt reabsorption through regulation of ion transporters located in various segments of the kidney tubules. Elevated circulating and local tissue AngII levels are a significant factor in the development of sodium and fluid retention and hypertension. Serum- and glucocorticoid-regulated kinase 1(SGK1) is implicated as a mediator of Ang II action, however, the molecular mechanisms underlying activation of SGK1 by AngII are not completely understood. SGK1 plays an important role in regulation of sodium and potassium transport in renal tubules of the kidney through activation of ENaC and NCC (in the cortical collecting duct (CCD) and distal connecting tubule (DCT), respectively), and NHE3 (in the proximal tubule (PT)).

Methods:

Results: SGK1 and the highly related kinase, Akt, are activated by mTOR through phosphorylation of a critical, homologous residue within their hydrophobic motif (HM). mTOR, an atypical serine/threonine kinase, is the catalytic core of two functionally distinct multi-protein complexes, mTORC1 and mTORC2. mTORC1 consists of mLST8, DEPTOR, PRAS40, and RAPTOR. mTORC2, also contains mLST8 and DEPTOR, but is defined by the presence of RICTOR, SIN1 and PROTOR. We find that AngII triggers selective mTORC2-dependent activation of SGK1 but not Akt. PKC activity is required for the AngII-stimulated SGK1 S422 phosphorylation and is mediated in part by PKC-induced SIN1 phosphorylation at three serine residues: S128, S315 and S356.

Conclusions: Our findings provide a mechanism for selective regulation of the mTORC2 substrate, SGK1, which is dependent on cPKC. Considering the well-described roles of SGK1 and Akt in regulation of ion and glucose homeostasis, respectively, these findings have important implications for defining molecular mechanisms that specify selective control of ion balance and glucose metabolism. Our results are particularly compelling in the context of metabolic diseases such as diabetes and obesity, which are frequently associated with impaired ion balance and hypertension.

TH-PO372

Resveratrol Attenuates Epithelial to Mesenchymal Transition of Human Renal Proximal Tubular Epithelial Cells by Induction of M2 Macrophages Polarization with High Expression of HO-1 Jun Li,[1,3] Ya-Fen Yu,[3] Ting Zhang.[2] *[1]Jiangnan University, Wuxi, China; [2]Department of tumor research, Affiliated hospital of Jiang nan university, Wu xi, China; [3]Department of nephrology, Affiliated hospital of Jiangnan University, Wuxi, China.*

Background: The aim of this study was to investigate the effect and mechanism of M2 macrophages with high expression of HO-1, which were induced with resveratrol, on TGF-β1 induced chronic tubular injury.

Methods: THP-1 cells (human leukemic monocyte) were treated with resveratrol concentration. HK-2 cells (human renal tubular epithelial cells) were treated with TGF-β1 to induce the chronic tubular damage. Co-culture technique was used to clarify the role of HO-1 positive M2 macrophages, which were induced by resveratrol, in the amelioration of chronic tubular injury.

Results: 1. THP-1 cells were treated with resveratrol, ICC showed the positive staining of HO-1 and the markers of M2 macrophage(CD206 and Macrophage mannose receptor 2, Mrc-2), and the supernatant showed increased IL-10 levels and decreased IL-12 levels. The western blot of the THP-1 cells protein showed the increased expression of p-STAT3 and IL-10. 2. After co-cultured of injured HK-2 cells with THP-1 cells intervened by resveratrol, the ratio of G2/M phase was lower than that treated with TGF-β1 alone. The ICC of HK-2 cells showed the increased expression of E-cadherin and the decreased expression of α-smooth muscle actin(α-SMA). The western blot of the HK-2 cells protein also showed the decreased p-STAT3 expression.

Conclusions: Small doses of resveratrol can induce the expression of HO-1 and M2 macrophages polarization, which might help to attenuate the progression of fibrosis in HK-2 cells by STAT3 signaling pathway.

Aldosterone-Induced Epithelial-to-Mesenchymal Transition (EMT) in Peritoneal Mesothelial Cells: Differential Role of NADPH Oxidase and Mitochondrial Dysfunction Duk-Hee Kang,[1] Eun sun Ryu,[3] Dal-ah Kim,[2] Hyun-Jung Kang.[4] *[1]Ewha University College of Medicine, Seoul, Republic of Korea; [2]Ewha Womans University Medical Center, Seoul, SEOUL, Republic of Korea; [3]Ewha Womans University School of Medicine, Seoul, Republic of Korea; [4]Ewha Womans University, Seoul, Republic of Korea.*

Background: Peritoneal fibrosis is one of the major causes of technical failure in patients on peritoneal dialysis. Epithelial-to-mesenchymal transition (EMT) of peritoneum has been known as an early and reversible mechanism of peritoneal fibrosis. Human peritoneal mesothelial cell (HPMC) is known to have its own renin-angiotensin-aldosterone system (RAAS), however it has not been investigated whether aldosterone, an end product of RAAS induces EMT in HPMC and which mechanisms are responsible for aldosterone-induced EMT

Methods: EMT of HPMCs was evaluated by comparing the expression of epithelial cell marker, E-cadherin and mesenchymal cell marker, α-smooth muscle actin (α-SMA) after the stimulation with aldosterone (1-100 nM) or spironolactone. Activation of Src, epidermal growth factor receptor (EGFR), phosphoinositide 3-kinase (PI3K), Akt and generation of reactive oxygen species (ROS) were assessed by Western blotting, DCF-DA and Mito-SOX staining. Effect of kinase inhibitors or anti-oxidants (N-acetyl cysteine, DPI, and MitoQ) on aldosterone-induced EMT was evaluated.

Results: Aldosterone induced EMT in cultured HPMC, which was blocked by spironolactone. Aldosterone induced an activation of both Src and EGFR from 15 and 30 minutes, followed by an activation of PI3K and Akt from 1 and 3 hours, respectively. The inhibitors of Src (PP2, 5 uM) and EGFR (Erlotinib, 10 uM) alleviated aldosterone-induced EMT. Aldosterone induced ROS in HPMCs from 5 minutes with an increase in NOX

activity and NOX-1, -2, -4 mRNA expression. Aldosterone also increased mitochondrial ROS production. Anti-oxidant treatment ameliorated the aldosterone-induced EMT. NAC an DPI alleviated an activation of Src/EGFR and PI3K/Akt pathways whereas mitoQ did not alter the phosphorylation of EGFR and PI3K in HPMCs

Conclusions: Aldosterone induced EMT in HPMC by acting through mineralocorticoid receptor. Aldosterone-induced generation of ROS followed by an activation of Src/EGFR and PI3K/Akt pathways served as the mechanism of aldosterone-induced EMT of HPMC via differential regulation of NOX and mitochondrial ubiquitone

TH-PO374

Uromodulin Is Essential for Correct Insertion of Uric Acid Transporter GLUT9 in the Plasma Membrane Eva Koenigshausen, Clara Porwoll, Paul Probst, Lars C. Rump, Lorenz Sellin. *Medical Faculty Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany.*

Background: Uromodulin (UMOD) mutations cause autosomal dominant tubulointerstitial kidney disease (ADTKD). Patients with ADTKD-UMOD usually show hyperuricemia in childhood and progressive renal failure in the course of the disease. The pathogenesis of hyperuricemia by mutation in UMOD is scarcely understood so far. In microdissection analyses of tubular structures, UMOD has been localized also to the proximal tubulus and uric acid transporters have been localized to the distal proximal tubulus.

Methods: HEK293T cells expressing UMOD WT and uric acid transporters ABCG2, Urat1, OAT4, GLUT9, NPT1, NPT4 and UAT were lysed and UMOD was precipitated. On western blot, uric acid transporters were visualized. Subcellular fractionation experiments with UMOD WT or its mutant P236L and GLUT9 were performed. Cos7 cells were transfected with UMOD WT and P236L. Immunofluorescent labeling with markers for the endoplasmic reticulum (calnexin), Golgi (giantin), endosomes (EEA1) and the plasma membrane (WGA) were performed. In addition, a triple staining for UMOD WT or P236L, GLUT9 and organelle markers were done.

Results: UMOD WT interacts with the uric acid transporters ABCG2, URAT1, OAT4 and GLUT9. In the subcellular fractionation experiment GLUT9 is localized to the membrane fraction if UMOD WT is expressed. However, if UMOD P236L is expressed, GLUT9 localizes to the vesicular fraction. UMOD WT colocalizes with WGA (plasma membrane), while UMOD P236L colocalizes in the ER (calnexin). UMOD WT and GLUT9 colocalize at the plasma membrane and UMOD P236L localizes with GLUT9 in the ER.

Conclusions: UMOD WT interacts with several uric acid transporters and is essential for the proper insertion of uric acid transporters in the plasma membrane. With UMOD mutation P236L, mutated UMOD and uric acid transporters are trapped in the ER. This retention of uric acid transporters could explain the reduced fractional uric acid excretion with resulting hyperuricemia in patients with ADTKD-UMOD.

TH-PO375

ANCA Stimulation of Monocytes Changes Their Cellular Metabolism Eóin O'Brien, Carla A. White, Safa H. Mohamed, Mark A. Little, Fionnuala B. Hickey. *Trinity College Dublin, Dublin, Ireland.*

Background: Anti-neutrophil cytoplasmic antibody (ANCA) vasculitis causes rapidly progressive glomerulonephritis and is characterised by autoantibodies against myeloperoxidase (MPO) or proteinase-3 (PR3). We have previously shown that stimulation of monocytes with anti-MPO, but not anti-PR3, antibodies results in increased pro-inflammatory cytokine release, suggesting a pathogenic role for this cell type. Cellular metabolism (particularly a switch to aerobic glycolysis), has recently been shown to be important in the immune response, and targeting metabolic pathways postulated as a potential treatment in autoimmunity. We investigated the effect of ANCA on the metabolism of monocytes.

Methods: Monocytes were isolated from healthy donors. Following stimulation with anti-MPO/PR3 antibodies, with or without a range of metabolic pathway inhibitors, changes in metabolism were measured using Seahorse extracellular flux analysis. Changes in cytokine production were assessed by ELISA.

Results: In accordance with prior data indicating that pro-inflammatory leukocytes preferentially use glycolysis for metabolism, we found increased glycolysis in ANCA-stimulated monocytes. However, we also observed upregulated oxidative respiration. These changes occur within minutes of exposure to ANCA. Cells treated with anti-PR3 antibodies displayed different oxygen consumption kinetics compared to those treated with anti-MPO; changes in these metabolic pathways were linked to the previously observed differences in cytokine production. To further investigate the mechanism by which metabolic pathways are involved in the response to ANCA, we used pharmacological inhibitors to block elements of glucose metabolism. Blocking oxidative phosphorylation, as measured by reduced oxygen consumption, resulted in no change in IL-1β production, but blocking glycolysis resulted in complete inhibition. Pyruvate dehydrogenase, a major point-of-no-return in the metabolism of glucose, was required for IL-1β production. In addition, using a specific scavenger of mitochondrial reactive oxygen species (mROS) we showed an inhibition of the IL-1β induced by anti-MPO treatment indicating that mROS has a role in activation of this inflammatory pathway.

Conclusions: These data indicate an important role for the upregulation of cellular metabolism in the pro-inflammatory activation of monocytes in response to ANCA.

TH-PO376

The Role of Chaperones and ROS in Trafficking of the mitoBK Channel in Response to Renal Cold Storage and Transplantation Stephen A. Shrum, Lee Ann MacMillan-Crow, Nirmala Parajuli, Julia Tobacyk. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Patients with renal failure require a kidney transplant in order to avoid dialysis with high mortality. Deceased donor kidneys regularly undergo cold storage (CS) preservation while a recipient is matched. However, the process of CS damages kidneys and greatly increases the chance of transplant failure. Our lab and others have previously reported that renal CS induces oxidative stress, mitochondrial dysfunction, and renal dysfunction. The mitochondrial isoform of the large-conductance Ca^{2+}-activated K^+ channel (mitoBK) is dynamically involved with ROS and is a promising therapeutic target in ischemia-reperfusion injury. Mitochondrial chaperone proteins, such as mortalin, are involved in protein trafficking, thus our goal was to investigate how CS+Tx alters the mitoBK channel and if ROS and chaperones are involved.

Methods: Rat kidneys or rat renal proximal tubular (NRK) cells were exposed to CS for 18h, followed by transplantation into syngeneic recipient rats (*in vivo;* CS+Tx) or rewarming (*in vitro; CS+RW*). Protein expression of mitoBK and chaperones was evaluated by western blot. Immunocytochemistry and confocal microscopy were used to assess intracellular localization of mitoBK with co-labeled organelle-specific dyes. The mechanistic relationships between mitoBK, chaperone proteins, and ROS during CS were examined using knockdown (siRNA), overexpression (plasmid), and relevant pharmacological agents (activators, inhibitors).

Results: Results show that the mitoBK channel is expressed in rat kidney *in vivo* and in NRK cells *in vitro* and that CS reduces its expression. Interestingly, CS substantially alters the intracellular localization of mitoBK. In addition, mortalin expression was decreased after CS+RW or CS+Tx. Molecular studies suggest that mortalin and ROS are involved with trafficking of mitoBK due to CS. Ongoing experiments are further examining these relationships in the context of CS+Tx.

Conclusions: Our results suggest that CS-/+Tx alters expression and trafficking of mitoBK and that ROS and mortalin are involved. Future studies will address whether mitochondrial targeted antioxidants restore mitoBK channel expression which may be informative for investigating therapeutic interventions for renal CS+Tx.

C-C Chemokine Receptor 2 (CCR2) Genetic Deletion Protects Against Gadolinium-Induced Skin Lesions by Preventing Recruitment of Bone Marrow-Derived Fibrocytes in a Novel Mouse Model Brent Wagner,[4,3] Chunyan Tan,[2] Catherine Do,[4,3] Viktor Drel,[2] Doug Y. Lee,[3] Yves C. Gorin.[1] *[1]University of Texas Health Science Center, San Antonio, TX; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX; [3]UTHSCSA, San Antonio, TX; [4]Medicine, South Texas Veterans Health Care System, San Antonio, TX.*

Background: Gadolinium-based contrast is now associated with a number of conditions, including 'nephrogenic' systemic fibrosis/gadolinium-associated systemic fibrosis (NSF) and gadolinium deposition disease. Bone marrow-derived fibrocytes and the monocyte chemoattractant protein 1 (MCP1) inflammatory pathway have been implicated as mediators in rats but mechanistic studies in this model have been limited. In the present work, we establish a mouse models of NSF.

Methods: Lethally-irradiated mice with 5/6 nephrectomies were salvaged with bone marrow from green fluorescent protein- (GFP-) expressing donors. Next, GFP-positive marrow was transplanted into wild-type and mice deficient of the C-C chemokine receptor 2 (CCR2), the prime effector of MCP-1. After an engraftment period, recipients were randomized to control or gadolinium-based contrast treatment.

Results: Dermal cellularity was increased in contrast-treated mice. Compared to control, skin GFP, fibronectin, and type I collagen were all increased in the contrast-treated animals as assessed by Western blot and immunofluorescence. Importantly, CD45RO, a marker for myeloid fibrocytes, was abundant in the dermis of contrast-treated animals, frequently expressed by the myeloid cells. Many of these cells expressed cytoplasmic α-smooth muscle cell actin, a marker of myofibroblast activation. Importantly, the markers of myofibroblast activation and fibrosis colocalized with GFP-positive cells in contrast-treated animals. MCP-1 and CCR-2 were increased in the tissues from contrast-treated mice. Recipients devoid of CCR2 had an abrogation of gadolinium-induced pathology and displayed fewer GFP-positive cells in the skin.

Conclusions: Systemic fibrosis can be induced by gadolinium contrast in mice. That GFP levels and expression increase in an involved organ, the skin, in tandem with a fibrocyte marker—CD45RO—supports the blood-borne circulating fibrocyte hypothesis of the disease. *This is the first demonstration of fibrocyte trafficking ever demonstrated in mice.* Importantly, similar to what is observed in a rat model, our data demonstrate that the monocyte chemoattractant protein 1/C-C chemokine receptor 2 axis plays a critical role in the pathogenesis of gadolinium-induced systemic fibrosis.

Sexual Dimorphic Response of Murine Kidneys to Dietary Cadmium and Fat Mitchell A. Jacobs,[1] Michelle T. Barati,[1] Madhavi J. Rane,[1] Adam E. Gaweda,[1] Alfred A. Jacobs,[1] Jon B. Klein,[1,2] Gavin E. Arteel,[1] Jonathan H. Freedman,[1] Lu Cai,[1] Michael Merchant.[1] *[1]University of Louisville, School of Medicine, Louisville, KY; [2]Robley Rex VA Medical Center, Louisville, KY.*

Background: Obesity and cadmium (Cd) are associated with CKD. This study examined the longer-term effects of heavy metal exposure and high dietary fat on kidneys of male and female mice.

Methods: C57B/6J mice were maintained/bred on normal or 5ppm Cd drinking water and normal chow. Offspring were maintained on identical drinking water as parents but split into male and female groups fed low fat or high fat (42% saturated fat) diets. Upon sacrifice (10wks) tissue was collected for histochemical and biochemical analysis. Tissue Cd levels were measured by ICP-MS. Cortical tissue phosphoproteome was studied using LCMS-based proteomics. Phosphopeptide data were compared using GO annotation, kinase motif enrichment (Motif-x, Phosphosite), fuzzy-c means clustering, protein-protein interaction (PPI) networks (StringDB) and Ingenuity Pathways Analysis (IPA).

Results: At 10wks, no gross effects of diet or Cd were observed in female kidneys. In contrast, Cd exposed male kidneys demonstrated cortical tubular vacuolization. Kidney wet weight was higher in males by diet or Cd. Cd levels (ngCd/g kidney) were significantly higher in females and high fat increased female Cd levels almost two fold. By LCMS 1,787 unique phosphopeptides were detected, including 14 unique kinase phosphorylation motifs. Clustering and GO analysis suggested high-fat and Cd effected FGF- & EGF-signaling in both sexes. PPI analyses identified effected molecular signaling pathways for gene transcription, protein translation, and cytoskeletal/cell junction maintenance. IPA identified the insulin signaling pathway as the most significantly affected pathway.

Conclusions: Cd and/or HFD affects the insulin signaling suggesting that these environmental factors may be contributors to diabetic CKD. The renal response to 5ppm Cd and/or a high fat diet suggests strong sexual dimorphism at the tissue and molecular signaling levels.

TH-PO379

Modulation of Oxidative Stress by Inhibition of Angiotensin II Type 1 Receptors in Cardiorenal Syndrome Firoozeh Farahmand. *Richmond Heights, MO.*

Background: Cardiorenal syndrome (CRS) has a complex pathophysiology that is still not completely understood. Oxidative stress is one of the key mediators of CRS. The aims of this study were to examine if an experimental model of CRS type 1 is associated with oxidative stress and whether blocking of the renin-angiotensin system (RAS) at the angiotensin II type 1 (AT1) receptor site is accompanied by changes in the oxidative stress parameters and attenuates CRS.

Methods: Rats were randomized into 4 groups: control, myocardial infarction (MI), MI group treated with losartan and control group treated with losartan. MI was induced by the ligation of the left coronary artery. At 4 weeks post-MI, animals were examined for hemodynamic function including left ventricle (LV) systolic pressure (LVSP), aortic systolic (AS)pressure, LV diastolic pressure, LV hypertrophy (LVH), and LV function. Hearts and the kidneys were analyzed for antioxidant enzyme activities including superoxide dismutase, glutathione peroxidase, catalase and oxidative stress. After sacrificing the animals, the renal cortex and the heart were removed for histology.

Results: At 4 weeks post MI there was a significant drop in LVSP and ASP associated with increased renal and myocardial lipid peroxidation to 63%, and 57% respectively. In MI group there was a decerase in in antioxidants enzymes activities in the kidney including catalase (34%), glutathione peroxidase (43%) and superoxide dismutase (51%). In the MI+ Losartan group losartan improved hemodynamic function and decerase oxidative stress in the kidney to 59% compared with MI group.(p-value less than 0.05).

Conclusions: In CRS type 1 congestive heart failure and acute kidney injury (AKI) in rats after MI correlates with a decrease in antioxidant and increase in oxidative stress in the heart and the kidney. Inhibition of the RAS with losartan improves cardiac function and survival in MI rats as well as oxidative stress parameter in the kidney. This study suggest the beneficial effects of angiotensin II type 1 (AT1) receptor blocker in the treatent of CRS.

TH-PO380

Multiple Roles for NHERF1 in Forward Trafficking and Apical Membrane Anchoring of NPT2a Kenneth Gagnon,[1] Michelle T. Barati,[1] Michael Merchant,[2] Barbara Clark,[1] Eleanor D. Lederer.[3] *[1]University of Louisville, Louisville, KY; [2]University of Louisville Medicine, Louisville, KY; [3]University of Louisville; Robley Rex VA Medical Center, Louisville, KY.*

Background: Loss of NHERF1 (Na-H Exchanger Regulatory Factor Isoform 1), a PDZ domain scaffolding protein, results in phosphate wasting and stone formation in animals and humans. NHERF1 knockout mice show diminished proximal tubule apical membrane expression of the sodium-phosphate cotransporter IIa (NPT2a). We have previously demonstrated in cell culture that NHERF1 and NPT2a exhibit a dynamic association between the Golgi and apical membrane, leading to the hypothesis that NHERF1 regulates trafficking and apical membrane anchoring of NPT2a through assembly of accessory protein partners.

Methods: To test this hypothesis, we immunoprecipitated (IP) NPT2a from kidney cortex lysate of wild-type (Wt) and NHERF1 KO (KO) littermates, compared the expression of associated proteins by mass spectrometry (MS), and performed western blot (WB) of proteins in cortex lysates. We compared mouse NPT2a localization and glycosylation status in HEK293 cells transfected with either a GFP-tagged full-length mouse NPT2a construct (NPT2a-FL) or a GFP-tagged mouse NPT2a construct lacking the PDZ binding motif required for interaction with NHERF1 (NPT2a-TRL).

Results: We identified 164 proteins having greater and 8 proteins having lower expression levels in Wt vs KO IPs. Expression of the F-actin binding protein ezrin decreased 75% in KO vs Wt, while total ezrin expression was similar in both pre-IP cortex lysates. WB's revealed a 2-fold increase in PDZK1 (a.k.a. NHERF3) and a 4-fold decrease in the SNARE accessory protein Munc18-2 in KO versus Wt. WB's for NPT2a in Wt revealed multiple bands at 35, 75-100, and 150-200 kDa and a 3-fold decrease in expression of the largest band in KO. WB from the NPT2a-TRL transfected cells showed a 41% decrease in expression of the larger band compared to the NPT2a-FL. F-glycosidase treatment of the NPT2a-FL and NPT2a-TRL lysates reduced the expression of the larger protein band by 68% and 44%, respectively. Confocal microscopy of transfected HEK293 cells showed NPT2a-FL localized at the plasma membrane, while NPT2a-TRL expression was cytosolic.

Conclusions: We conclude that NHERF1 is essential for the forward trafficking of NPT2a through direct PDZ domain interaction and through coordinated assembly of accessory proteins responsible for glycosylation, vesicle fusion, and membrane anchoring.

Characterizations of HSP90-Interacting Complex in Renal Cells Using Tandem Affinity Purification and Its Potential Role in Kidney Stone Formation Visith Thongboonkerd, Juthatip Manissorn. *Siriraj Hospital, Mahidol University, Bangkok, Thailand.*

Background: Heat shock protein 90 (HSP90) is a highly abundant molecular chaperone that interacts with many other intracellular proteins to regulate various cellular processes. However, compositions of the HSP90-interacting complex remain largely unknown. This study thus aimed to characterize such complex in renal cells by tandem affinity purification (TAP) followed by ultrahigh-resolution tandem mass spectrometry (Qq-TOF MS/MS).

Methods: The full-length *HSP90AB1* gene was constructed and subcloned into pGLUE vector, which was designed to express streptavidin- and calmodulin-binding affinity tags at the N-terminus of HSP90, whereas TAP-tag without HSP90 fusion served as the control for TAP purification system. Expression of TAP-tag fusion with HSP90 (TAP-HSP90) in the transfected HEK293T cells was confirmed by immunoblotting. The HSP90-interacting complex was purified by TAP-tag method and subjected to in-solution tryptic digestion and identification by Qq-TOF MS/MS. Functional significance of this complex was then addressed by using small-interfering RNA (siRNA) targeting to HSP90 (siHSP90).

Results: A total of 40 proteins, including four forms of HSP90 and 19 novel HSP90-interacting partners, were successfully identified from this complex using TAP control to subtract non-specific binders. Co-immunoprecipitation followed by immunoblotting and immunofluorescence co-staining confirmed the association of HSP90 with known (HSP70, α-tubulin, and β-actin) and novel (vimentin, calpain-1, and importin-β1) partners. Knockdown of HSP90 by siRNA (siHSP90) caused significant changes in levels of HSP70, α-tubulin, β-actin, vimentin, and calpain-1, all of which are calcium oxalate (CaOx) crystal-binding proteins that play significant roles in kidney stone formation. CaOx crystal-cell adhesion assay revealed that crystal-cell adhesion was significantly decreased in siHSP90-transfected cells as compared to non-transfected control and siControl-transfected cells.

Conclusions: We report herein a number of novel HSP90-interacting proteins in renal cells and demonstrate the potential role of HSP90-interacting complex in kidney stone formation.

Increased Expression of Soluble Fas in Patients with CKD Miguel A Goes,[2] Maria Eugenia F. Canziani,[1] Silvia R. Manfredi,[3] Maria Dalboni.[3] *[1]Federal University of Sao Paulo, Sao Paulo, Brazil; [2]Hospital Israelita Albert Einstein, Sao Paulo, Brazil; [3]Universidade Federal de São Paulo, São Paulo, Brazil.*

Background: Fas (CD95) is a cellular receptor for apoptosis in leukocytes and other cells. A soluble form of Fas (sFas) is an anti-apoptotic molecule devoid of the transmembrane domain from alternative splicing of CD95. Serum sFas levels are higher in CKD patients and associated with inflammation, anemia, and cardiovascular disease.

Objective: To investigate whether the expression of CD95mRNA and sFasmRNA is increase in leukocytes of CKD patients and their respective correlation with serum soluble Fas levels.

Methods: We performed the dosage of Hb concentration, serum creatinine and urea by conventional methods and serum sFas levels measured using an enzyme-linked immunosorbent assay from 51 CKD patients (eGFR 15 to 59 ml/min; CKD group) and 18 healthy volunteers (control group). We extracted leukocytes to measure the mRNA expression of CD95 and sFas. Total RNA was isolated from 5 x 10^6 leukocytes from each subject using TRIzol reagent, and cDNA was synthesized from 1 μg RNA using reverse transcriptase synthesis system. Relative levels of mRNA transcripts of sFas were

quantified by real-time PCR. We used the Epi-CKD formula. We perform correlations and comparisons between groups.

Results: When analyzed both groups together we observed negative correlation between eGFR serum sFas levels (r=-0.30, p=0.01), between eGFR and sFasmRNA expression (r= - 0.28, p= 0.02). Serum sFas levels correlated positively with sFasmRNA copies (r = 0.32, p = 0.007). The CD95mRNA did not correlate with eGFR (r= - 0.04, p= 0.9). The main etiologies of CKD were diabetes and hypertension. We observed lower concentration of Hb in the CKD group (10.8 ± 2.1, 14.2 ±1.7, p <0.001). There was a higher serum sFas levels in CKD group (3161± 1000, 1686± 996, p <0.001) and higher copies of sFasmRNA in the CKD group (32.3 + 2.3 x 10^6, 23.3 + 5.9 x 10^6, p <0.001). There was a negative correlation between CD95mRNA and sFasmRNA copies in CKD patients (r= - 0.49, p <0.001).

Conclusions: Serum sFas levels and sFasmRNA expression are elevated in patients with CKD. We observed correlation between sFasmRNA expression and serum levels of sFas

TH-PO383

Protein Bound Uremic Toxins p-Cresyl Sulfate and Indoxyl Sulfate Modulate the Human Endothelial Cells' Transcriptome Regiane S. Cunha,[1] Giane Favretto,[1] Paulo C. Gregório,[1] Rayana A. Maciel,[1] Valentina Busato,[1] Roberto Pecoits-Filho,[2] Fellype C. Barreto,[3] Wesley M. Souza,[4] Andréa M. Stinghen.[1] *[1]Basic Pathology Department, Universidade Federal do Paraná, Curitiba, Brazil; [2]School of Medicine, Pontifícia Universidade Católica do Paraná, Curitiba, Brazil; [3]Internal Medicine Department, Universidade Federal do Paraná, Curitiba, Brazil; [4]Clinical Analysis Department, Universidade Federal do Paraná, Curitiba, Brazil.*

Background: *p*-Cresyl sulfate (PCS) and indoxyl sulfate (IS) are protein bound uremic toxins associated with endothelial dysfunction in chronic kidney disease (CKD). Thus, PCS and IS could activate signaling pathways leading to changes in the cellular transcriptome. This study evaluated the effect of PCS and IS on the expression of Organic Anion Transporter (OAT) 1 and 3 and their transcription factors cAMP responsive element binding protein-1 (CREB1), activating transcription factor-1 (ATF1) and hepatocyte nuclear factor-4α (HNF4α).

Methods: Human endothelial cells were treated for 24 h at normal, uremic and maximal uremic concentration of PCS (0.08, 1.75 and 2.6 mg/L) and IS (0.6, 53 and 236 mg/L). Probenecid (Pb) and benzilpenicilin (Bp) were used as OATs inhibitors, vitamin C (Vit C) as antioxidant and the N-nitro-Larginine methyl ester (L-NAME) as the inhibitor of nitric oxide (NO) synthase in order to evaluate the NO pathway production. Cell viability was assessed by MTT. The protein levels of OAT1 and OAT3 was evaluated by Western blotting. CREB1, ATF-1 and HNF4α expression were evaluated by RT-qPCR.

Results: The cell viability was reduced (P<0.001) after PCS and IS treatments in dose-dependent manner, being restored with Pb or Bp (P<0.001). An increased OAT1 and OAT3 protein expression was observed after PCS treatment at maximal uremic concentration (P<0.05). The RT-qPCR analysis showed an increase (P<0.01) in the CREB1 and ATF1 expression in cells treated with PCS and IS, which was restored with Pb, Bp, Vit C and L-NAME (P<0.05). The HNF4α expression was increased (P<0.05) only after PCS treatments at maximal uremic concentration.

Conclusions: PCS and IS are able to modulate differentially the gene expression of transcription factors which could affect the OATs expression. These changes in the cellular transcriptome could lead to the pathological phenotype found in CKD.

TH-PO384

Multispectral Fluorescence Unmixing for Large-Scale Three-Dimensional Imaging and Quantitative Tissue Cytometry of Human Kidney Tissue Seth Winfree,[4] Katherine J. Kelly,[2] Carrie L. Phillips,[4] Michael T. Eadon,[3] Timothy A. Sutton,[4] Ken Dunn,[1] Pierre C. Dagher,[1] Tarek M. El-Achkar.[1] *[1]Indiana University, Indianapolis, IN; [2]Indiana University, Indianapolis, IN; [3]Indiana University Division of Nephrology, Indianapolis, IN; [4]Indiana University School of Medicine, Indianapolis, IN.*

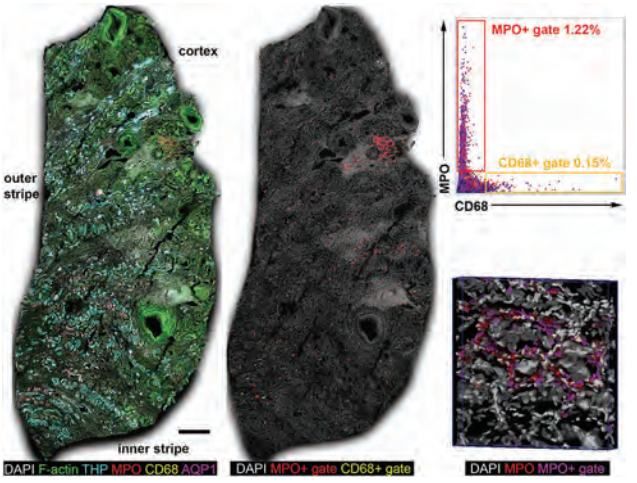
Background: Large-scale confocal fluorescence microscopy combined with three-dimensional tissue cytometry (3DTC) has the potential to provide quantitative data like flow cytometry, while preserving the localization and distribution of cells in intact kidney tissue. Confocal imaging is typically limited to 4 markers, dictated by available lasers and spectral bleed-through, limiting cell identification to 2 or 3 types.

Methods: To extend the palette of simultaneously distinguishable fluorophores (up to 8 colors), we implemented fluorescence spectral unmixing. Using this approach, we labeled proximal and distal tubular cells along with 4 basic types of immune cells in single human kidney tissue sections.

Results: Large-scale 3D imaging of these sections generated data suitable for 3DTC with our recently developed Volumetric Tissue Exploration and Analysis (VTEA) software tool. Using VTEA, we determined the abundance and localization of each labeled cell type. Furthermore, we explored the distribution of leukocytes in relation to nephron sub-segments and showed clustering of neutrophils around proximal tubules.

Conclusions: Multi-fluorescence labeling with spectral unmixing enhances our ability to simultaneously visualize and detect various cell types withn the kidney in 3D, and quantify the association of immune cells with nephron sub-segments *in situ*.

Funding: NIDDK Support, Veterans Affairs Support



Large-scale 3D multi-fluorescence imaging of a human nephrectomy section (≈ 7 x 3 x 0.05 mm^3, left), and tissue cytometry analysis (middle and right) using VTEA. Gates on the scatter plot identify CD68+ (macrophages) and MPO+ cells (neutrophils). The gated cells were mapped to the original volume to identify their spatial distribution (middle). A 3D rendered sub-volume demonstrates the resolution and precision of gating (lower right, gated cells identified by nuclear overlays). Scale bar = 500μm.

TH-PO385

FRMD3/Protein 4.1O Is a Novel Nephrin Adaptor to F-Actin Regulated by MAPK- and Src-Kinases and Linked to Diabetes Eva Koenigshausen,[1] Aida Bajraktarevic,[1] Sinja Ohlsson,[1] Klaus Stahl,[3] Marie Schönberger,[1] Thorsten Wiech,[2] Hermann G. Haller,[3] Lars C. Rump,[1] Mario Schiffer,[3] Lorenz Sellin.[1] *[1]Medical Faculty Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany; [2]Department of Pathology, University Hospital Hamburg Eppendorf, Hamburg, Germany; [3]Hannover Medical School, Hannover, Germany.*

Background: FRMD3 has been proposed as a candidate gene for diabetic nephropathy (DN). FRMD3 encodes for protein 4.1O, a member of the 4.1 protein family. In erythrocytes, protein 4.1R links membrane proteins to the actin cytoskeleton. The molecular function of protein 4.1O is unknown so far.

Methods: Expression and interaction of protein 4.1O were investigated by qPCR, IF and western blot in podocytes. Zebrafish larvae were treated with morpholinos against *moe* the orthologue of FRMD3. The loss of 78 kD-GFP tagged protein using the Tg(l-fab:DBP-eGFP) fish line was measured. Human 4.1O truncations were reexpressed in *moe* knockdown zebrafish larvae. Electronmicroscopy was performed. Cells expressing protein 4.1O, its truncations, its point mutations and nephrin or nck were subjected to co-immunoprecipitation. Cells were incubated with kinase inhibitors PP2 (10 μM) and SB202190 (50 μM). Kidney samples from patients with T1DN or T2DN and from streptozotocin treated mice were stained for protein 4.1O.

Results: Protein 4.1O is expressed in human podocytes and interacts with nephrin, GLEPP1, IQGAP1, Neph1 and actin in vitro and in vivo. Injection of *moe* morpholinos leads to zebrafish edema, complete loss of slit diaphragm, complete foot process effacement and increase in glomerular permeability. The phenotype can be rescued by expression of human protein 4.1O AA 506-553, the nephrin binding domain. AA 506-553 contain a MAPK and DEF (SFK phosphorylation) site. Inhibition of SFK and p38 attenuate significantly nephrin protein 4.1O interaction. 4.1O and nck compete for the binding to nephrin. Mutations of protein 4.1O at the DEF site reduces significantly nephrin protein 4.1O interaction. Protein 4.1O expression is increased in human DN, interestingly is reduced in streptozotocin treated mice.

Conclusions: Protein 4.1O is a novel podocyte protein that interacts with nephrin, GLEPP1, IQGAP1, Neph1 and the actin cytoskeleton. Protein 4.1O is essential for the intact glomerular filtration barrier. Knockdown of *moe* in zebrafish leads to nephrotic phenotype that is rescued by expression of human protein 4.1O AA 506-553. Nephrin protein 4.1O binding is regulated by SFKs and MAPK. The expression of protein 4.1O is increased in human DN and reduced in a mouse model.

Regulation of Actin Cytoskeletal Remodeling in Glomerular Podocytes by Testis Specific Protein Kinase 1 (TESK1) Liming Wang,[2] Anne Buckley,[1,3] Robert F. Spurney.[2,3] *[1]Duke University, Durham, NC; [2]Duke University Medical Center, Durham, NC; [3]Durham VA Medical Center, Durham, NC.*

Background: In published studies, we found that expression of a constitutively active Rho A construct (V14Rho) in glomerular podocytes *in vivo* induced albuminuria and foot process (FP) effacement (Kidney Int 81:1075, 2012). We postulated that these effects might be mediated by the Rho A effector Rho kinase (ROK).

Methods: V14Rho mice were treated with the ROK inhibitor Y27632. We then examined the effects of ROK inhibition on albuminuria and FP effacement. These *in vivo*

studies were supplemented with cell culture experiments using an immortalized mouse podocyte cell line.

Results: Treatment with the ROK inhibitor Y27632 failed to attenuate albuminuria or FP effacement in V14Rho mice. An important target phosphorylated and inhibited by ROK is the actin depolymerizing factor cofilin 1 (CFL1). Sustained phosphorylation of CFL1 is implicated in human nephrotic diseases. In V14Rho mice, Y27632 did not inhibit phosphorylation of CFL1 despite effective ROK inhibition in vivo. CFL1 is also phosphorylated by testis-specific kinase 1 (TESK1) on the same serine residue. While the cell type specific expression of TESK1 is restricted, TESK1 was expressed in podocytes. Integrins activate TESK1, and plating podocytes on fibronectin to activate integrins increased CFL1 phosphorylation. Fibronectin induced CFL1 phosphorylation was not blocked by Y27632 but was inhibited by the β1-integrin agonist pyrintegrin. To examine the role of TESK1 in podocytes, we created TESK1 knockout (KO) cells. In contrast to podocytes expressing TESK1, Y27632 inhibited phosphorylation of CFL1 in KO cells. TESK1 KO did not affect actin polymerization under basal conditions, but reduced actin polymerization in the presence of Y27632. ROK inhibition also promoted podocyte motility, which was blocked by either TESK1 KO or pyrintegrin.

Conclusions: TESK1 plays a key role in regulating podocyte cytoskeletal dynamics. Because glomerular filtration barrier integrity requires an intact podocyte cytoskeleton, TESK1 may be a novel target for the treatment of glomerular diseases.

Endocytosis and Intracellular Trafficking of AQP2 Is Regulated by the Notch Signaling Pathway

Huihui Huang,[1] Limin Su,[1] Teodor G. Paunescu,[1] Baoxue Yang,[2] Hua A. Lu.[1] *[1]Massachusetts General Hospital, Wayland, MA; [2]Peking University, Beijing, China.*

Background: The Notch signaling pathway plays important roles in development and pathological processes in multiple tissues, including the kidney. A role of Notch signaling in regulating trafficking of nephrin in podocytes and of monocarboxylic acid transporter 1 in brain endothelial cells has recently been reported, implicating an emerging function for Notch in protein trafficking. Aquaporin-2 (AQP2) is a water channel that mediates water reabsorption in the collecting ducts (CDs) of the kidney. It plays a predominant role in regulating water balance in mammals. In this study, we investigate the function of Notch signaling in AQP2 trafficking and urinary concentration. Our data show that inhibiting Notch signaling either by Notch inhibitors DAPT and LY-411575, or by siRNA knock down in cultured cells increases AQP2 membrane accumulation. A similar increase in AQP2 membrane accumulation is observed in CD principal cells (PCs) in cultured mouse kidney slices treated with DAPT or LY-411575. Notch inhibition causes AQP2 accumulation on the apical membrane in CDs from both cortex and medulla. Membrane accumulation of AQP2 induced by Notch inhibition does not affect AQP2 expression, and is independent of AQP2 phosphorylation. Further analysis reveals that Notch inhibition reduces the endocytosis of AQP2 without affecting the overall exocytosis, and Notch inhibition negatively impacts F-actin polymerization. The role of Notch signaling in water transport was next investigated in vivo. DAPT treatment of mice attenuates the polyuria and increases urinary concentration in lithium treated mice by promoting apical membrane accumulation of AQP2 in CD PCs. Further supporting this idea, increased membrane accumulation of AQP2 was observed in the hemizygous PC-specific rbpj $^{flox/+}$/aqp2 cre mice (recombination signal binding protein for immunoglobulin kappa J (RBPJ)-deficient mice). We further challenged the hemizygous rbpj $^{flox/+}$/aqp2 cre mice with lithium. We found that the hemizygous rbpj $^{flox/+}$/aqp2 cre mice are resistant to lithium induced nephrogenic diabetes insipidus. Our studies collectively show that AQP2 trafficking is regulated by the Notch signaling pathway both in vitro and in vivo, therefore uncovering a novel role of Notch signaling in modulating water homeostasis through regulating AQP2 trafficking.

Activated Renal Tubular Wnt/β-Catenin Signaling Triggers Renal Inflammation during Proteinuria

Dickson W. Wong,[1] Wai Han Yiu,[1] Kam wa Chan,[1] Ye Li,[1] Bin Li,[1] Makoto M. Taketo,[2] Peter Igarashi,[3] Loretta Y.Y. Chan,[1] Joseph C K Leung,[1] Kar Neng Lai,[1] Sydney C. Tang.[1] *[1]University of Hong Kong/Queen Mary Hospital, Hong Kong, Hong Kong; [2]Kyoto University Grad Sch Med, Kyoto, Japan; [3]University of Minnesota, Minneapolis, MN.*

Background: Imbalance of Wnt/β-catenin signaling in renal cells is associated with renal dysfunction, yet the precise mechanism is poorly understood. Previously we observed activated Wnt/β-catenin signaling in renal tubules during proteinuric nephropathy with an unknown net effect (rescue vs. damage?) (*Cell Death Dis* 2016; 24;7:e2155).

Methods: To identify the definitive role of tubular Wnt/β-catenin, we generated a novel transgenic "Tubcat" mouse, which conditionally expresses stabilized β-catenin specifically in renal tubules after tamoxifen administration.

Results: Four weeks after tamoxifen induction, Tubcat mice displayed proteinuria and elevated BUN levels, implying a detrimental effect of the activated signaling. This was associated with tubulointerstitial infiltration predominantly by M1 macrophages and overexpression of the inflammatory chemocytokines CCL-2 and RANTES. Induction of overload proteinuria by low-endotoxin BSA injection for 4 weeks aggravated proteinuria and increased BUN levels to a significantly greater extent in Tubcat mice. Renal dysfunction correlated with the degree of M1 macrophage infiltration in the tubulointerstitium and renal cortical up-regulation of CCL-2, IL-17A, IL-1β, CXCL1 and ICAM-1. Finally, there was overexpression of cortical TLR-4 and NLRP-3 in Tubcat mice, irrespective of BSA injection.

Conclusions: Conditional activation of renal tubular Wnt/β-catenin signaling enhances intrarenal inflammation via the TLR-4/NLRP-3 inflammasome axis in overload proteinuria. **Funding support:** National Natural Science Fund (NSFC) of China (grant no. 81570647)

Local Inflammatory Mechanism Aggravated by Intraglomerular Crosstalk in Diabetic Kidney

Shuro Umemoto,[1] Takashige Kuwabara,[1] Daisuke Fujimoto,[1] Tomoko Kanki,[1] Teruhiko Mizumoto,[1] Yutaka Kakizoe,[1] Yuichiro Izumi,[1] Kiyoshi Mori,[2] Masashi Mukoyama.[1] *[1]Department of Nephrology, Kumamoto university graduate school of medical sciences, Kumamoto, Japan; [2]School of Pharmaceut Sci, University of Shizuoka, Shizuoka, Japan.*

Background: We previously reported that the myeloid-related protein 8 (MRP8, S100A8)/toll-like receptor 4 (TLR4) signaling activated by glucolipotoxicity-associated ER stress plays an important role in the progression of diabetic nephropathy. Although local activation of the renin-angiotensin system (RAS) in the kidney has been observed in concurrence with the MRP8/TLR4 activation in the diabetic-hyperlipidemic model mice, the relationship between these signals remains obscure.

Methods: In vivo studies were performed using diabetic-hyperlipidemic mice (by streptozotocin plus high-fat diet, STZ-HFD) and db/db mice, treated with olmesartan (Olm) and angiotensin II (AngII), respectively. In vitro experiments were done with mouse macrophages (MΦ) that were co-cultured with rat mesangial cells (MC), or stimulated by MC-conditioned media (MC-sup). Expressions of the pro-inflammatory and profibrotic genes were analyzed by qPCR. Inflammation and ER stress were evaluated using a THP1-dual reporter cell line monitoring NF-κB and IRF pathways. Effects of a TLR4 antagonist on this crosstalk were also examined.

Results: Angiotensinogen (Agt) mRNA was upregulated in the glomeruli of STZ-HFD mice. Olm effectively suppressed upregulation of glomerular MRP8/TLR4 and Agt in STZ-HFD mice, which was associated with the reduction of albuminuria. In contrast, a subpressor dose of AngII markedly worsened albuminuria and increased glomerular infiltrated MRP8-positive cells in db/db mice. Glomerular MΦ showed obviously high MRP8 positivity compared to tubulointerstitial ones, suggesting intraglomerular crosstalk. MRP8 and TNFα in MΦ were dramatically induced by co-culture with MC, which was reproduced by stimulation with MC-sup. Dual reporter assay revealed that MC-sup stimulation activated IRF, which could cause ER stress, as well as NF-κB in a concentration-dependent manner. Such induction was partially abrogated by the TLR4 antagonist.

Conclusions: RAS activation should contribute to progression of diabetic nephropathy through promoting intraglomerular crosstalk, which may trigger MRP8 production in glomerular MΦ. Humoral factors secreted from MC could contribute to the crosstalk partly in a TLR4-dependent manner, thus facilitating local inflammation and ER stress.

Engineered Immune Complexes with Galactose-Deficient IgA1: A New Model for IgA Nephropathy

Colin Reily,[7] Zhi qiang Huang,[5] Nuo Xu,[8] Zina Moldoveanu,[4] Lea Novak,[6] Stacy D. Hall,[3] Rhubell T. Brown,[6] Terry L. Lewis,[6] Casey T. Weaver,[6] Bruce A. Julian,[6] Hitoshi Suzuki,[1] Christopher D. Willey,[2] Jan Novak.[6] *[1]Juntendo University Faculty of Medicine, Tokyo, Japan; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]UAB, Birmingham, AL; [4]Univ of Alabama at Birmingham, Birmingham, AL; [5]University of Alabama at Birmingham, Birmingham, AL; [6]University of Alabama at Birmingham, Birmingham, AL; [7]Medicine, University of Alabama at Birmingham, Birmingham, AL; [8]university of alabama at birmingham, Birmingham, AL.*

Background: IgA nephropathy (IgAN) is an autoimmune disease characterized by circulating immune complexes (CIC) that deposit in the kidney and incite kidney injury. These CICs contain galactose-deficient IgA1 (Gd-IgA1) bound by Gd-IgA1-specific autoantibodies. Development of models of IgAN has been hindered because only humans and hominoid primates have IgA1 with its *O*-glycans. To address these issues, we developed an animal model by using *in vitro*-formed, engineered immune complexes (EIC) from human Gd-IgA1 and recombinant Gd-IgA1-specific IgG. In this study, we profiled kidney transcriptomes from mice injected with these EIC, controls, and human IgAN kidney biopsies.

Methods: EICs were formed from Gd-IgA1 and recombinant Gd-IgA1-specific antibody. EIC or Gd-IgA1 only were injected intravenously 3 times every other day in 8-week old immunodeficient mice. Kidneys were harvested 1d after last injection, and either snap frozen in liquid nitrogen for RNAseq analysis or fixed for pathologic analysis. RNAseq data sets were compared against published data from IgAN patient kidney biopsy samples, and pathway analysis was performed using the Broad Institute GSEA tool.

Results: Mice injected with EIC exhibited glomerular matrix expansion and hypercellularity, with no morphological changes observed in the control group. Using 0.5 log2 fold-change parameter, gene expression analysis found 118 genes up-regulated and 165 down-regulated in the EIC-injected vs. control mice. Pathway analysis between the EIC model and IgAN biopsies identified multiple pathways in common, including estrogen early and late response, matrisome, interferon gamma response, and epithelial

to mesenchymal transition. In addition, similar genes between the EIC animal model and biopsies were found to be modified in a similar pattern and SDS/Western blotting of kidney tissue for selected targets showed protein expression followed mRNA changes for some genes.

Conclusions: Using EICs, we generated an IgAN passive mouse model that replicates some of the pathologic changes observed in renal biopsies of IgAN patients. This model thus provides a unique platform for testing disease-specific drugs for efficacy in reducing kidney damage from CICs.

TWEAK Increases CD74 Expression and Sensitizes to DDT Proinflammatory Actions in Tubular Cells Lara Valiño rivas,[3] Richard Bucala,[6] Lin Leng,[5] Ana B. Sanz,[4] Laura Gonzalez-Lafuente,[2] Alberto Ortiz,[1] Maria Dolores Sanchez-Nino.[1] *[1]Nephrology, Fundacion Jimenez Diaz, Madrid, Spain; [2]IIS-Fundacion Jimenez Diaz, Madrid, Spain; [3]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain; [4]Instituto de Investigacion Sanitaria Fundacion Jimenez Diaz, Madrid, Spain; [5]Yale School of Medicine, New Haven, CT; [6]Yale University School of Medicine, New Haven, CT.*

Background: TWEAK is a proinflammatory cytokine that promotes kidney injury. CD74 is a multifunctional protein upregulated in diabetic kidney disease another chronic nephropathies. One function of CD74 is being a receptor for Macrophage Migration Inhibitory Factor (MIF) and for the recently described MIF-2 / D-dopachrome tautomerase (DDT) cytokine. However, the molecular mechanisms of TWEAK-induced kidney injury, the drivers of CD74 expression and the function of DDT function in kidney cells are poorly characterized.

Methods: Wild type (WT) mice received a single i.p. injection of TWEAK. Cell culture studies were performed in murine proximal tubular MCT cells. TWEAK, DDT and MIF expression was determined by immunohistochemistry in kidney tissue from mice. The effects of TWEAK in mice and in cultured tubular cells was assessed by qRT-PCR, Western blot and flow cytometry.

Results: We have now identified CD74 gene expression as upregulated in the kidneys in response to systemic TWEAK administration in mice in a transcriptomics analysis, and have characterized the in vivo CD74 expression and the functional consequences in cultured cells. TWEAK administration to mice resulted in a progressive time-dependent (up to 24h) upregulation of kidney CD74 mRNA (RT-PCR) and protein (Western blot). Furthermore, the CD74 ligands MIF and DDT were also upregulated at the protein level 24h after TWEAK administration. Immunohistochemistry localized the increased CD74, MIF and DDT expression to tubular cells. In cultured tubular cells, TWEAK increased CD74 mRNA and protein expression dose-dependently, with the temporal pattern similar to the in vivo experiments. TWEAK-induced CD74 localized to the cell membrane, where it can function as a cytokine receptor. For the first time, we explored the actions of DDT in tubular cells and found that DDT amplified the increase in MCP-1 and RANTES expression in response to TWEAK. By contrast, DDT did not significantly modify TWEAK-induced Klotho downregulation.

Conclusions: In conclusion, TWEAK upregulates CD74 and its ligands MIF and DDT in renal tubular cells. This may have functional consequences for kidney injury since DDT amplified the inflammatory response to TWEAK.

TH-PO392

TGF-Beta Exposure Represses Fibroblast Transcription of the Anti-Fibrotic Molecule Slit2: A Novel Fibrogenic Mechanism? Monica F. Tolosa,[1,2] Darren A. Yuen.[1,2] *[1]Keenan Research Centre for Biomedical Science, St. Michael's Hospital, Toronto, ON, Canada; [2]Department of Laboratory Medicine & Pathobiology, Faculty of Medicine, University of Toronto, Toronto, ON, Canada.*

Background: Recent work has demonstrated that the molecular guidance ligand Slit2 may also serve as an important anti-fibrotic signal in the kidney. Specifically, we have previously shown that Slit2 is reduced following renal injury, and bioactive N-terminal Slit2 attenuates fibrosis following both ischemia-reperfusion injury and unilateral ureteral obstruction (UUO). While this provides early evidence that Slit2 could be a possible adjunct therapy for chronic kidney disease, the regulation of endogenous Slit2 during fibrosis—as well as its role in downstream injury—remains largely uncharacterized. **Objective:** To study the endogenous regulation of Slit2 expression by fibroblasts in fibrotic disease, and further characterize the role of Slit2 on fibroblast activation and renal injury.

Methods: Using real-time PCR and immunofluorescence, we measured Slit2 expression in primary human dermal fibroblasts in response to TGF-beta. *In vitro* tools, including siRNA-mediated knockdown and pharmacological inhibition, were used to further identify and characterize novel regulators of Slit2 expression.

Results: Here, we demonstrate that fibroblast exposure to TGF-beta, a master regulator of fibrosis, causes a downregulation of the anti-fibrotic factor, Slit2. Furthermore, we determined that TGF-beta mediated repression of Slit2 occurred at the level of transcription, by observing a corresponding downregulation of Slit2 pre-mRNA transcript levels. *In silico* analysis showed putative binding sites for TGF-beta-regulated transcription factors in the Slit2 promoter region, suggesting that repression may occur through proximal *cis*-acting elements. Finally, we determined that Slit2 repression occurs through a Smad- and YAP-dependent mechanism, as loss of each of these transcriptional regulators by siRNA reversed the repressive effect of TGF-beta.

Conclusions: While many forms of chronic kidney disease are characterized by fibrosis, few strategies exist to effectively suspend fibrotic progression. Here, we determined that fibroblast exposure to TGF-beta leads to a marked decrease in Slit2 expression, suggesting that loss of Slit2 may facilitate fibroblast activation in a disease context. Further studies will help to clarify the mechanism of Slit2 repression and how this may be targeted to potentially reduce fibrotic injury.

Calcium Dobesilate Reduces VEGF Signaling in Endothelial Cells, Preserves Cell Function, and Improves Vascular Complications in Diabetic Mice Florence Njau,[1] Nelli Shushakova,[3] Joon-Keun Park,[1] Jan Menne,[2] Hermann G. Haller.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Medical School Hannover, Hannover, Germany; [3]Nephrology and Hypertensiology, 30625 Hannover, Germany.*

Background: Calcium dobesilate is a small molecule with vasoprotective properties. Preliminary evidence suggests that calcium dobesilate interferes with heparan-sulfate binding sites of growth factors such as FGF and VEGF. We therefore tested the hypothesis that calcium dobesilate (1) ameliorates diabetic nephropathy and (2) directly and/or indirectly inhibits VEGF signaling in the microcirculation.

Methods: In vitro HUVECs were used for analysis of VEGF signaling as well as migration and proliferation. Streptozotocin-treated mice (STZ) were treated with calcium dobesilate and analyzed after 4 and 8 weeks of hyperglycemia. Diabetic neuropathy was assessed by thermal sensitivity Urinary albumin was measured by. ELISA and immunohistochemistry performed on cryostat or on paraffin sections.

Results: Dobesilate (100 and 200 μM) decreased VEGF (20 ng/ml)-induced migration by 50% and inhibited assembly of F-actin in lamellipodia-like structures and phosphorylation of focal adhesion kinase (FAK). Dobesilate reduced HUVECs proliferation by 30% and enhanced apoptosis of HUVECs induced by serum deprivation in a dose-dependent manner as evidenced by a decrease in Bcl-2/Bax ratio, and phosphorylation of Bad. It inhibited VEGF-induced phosphorylation of VEGFR2 kinase by 50% in concentration dependent manner and suppressed the phosphorylation of pERK1/2, pMEK1/2 and Pp38 MAPK. Diabetic mice treated with calcium dobesilate showed a decrease in albuminuria, less phosphorylation of VEGF-R2 and an increased thermal sensitivity as compared to sham-treated diabetic animals.

Conclusions: Calcium dobesilate ameliorates both hyperglycemia-induced nephropathy and neuropathy in mice. *In vitro* the signaling of VEGF in endothelial cells is reduced. Our findings suggest that calcium dobesilate is a VEGF inhibitor at high concentrations. The specific inhibition of FGF and VEGF signaling by blockading heparin sulfate binding sites may be a novel therapeutic strategy for diabetic vascular complications.

Funding: Government Support - Non-U.S.

TH-PO394

Urinary Activin A Is a Novel Biomarker Reflecting Renal Inflammation and Tubular Damage in ANCA-Associated Vasculitis Yoshinori Takei,[4] Shunsuke Takahashi,[2] Masao Nakasatomi,[1] Toru Sakairi,[3] Hidekazu Ikeuchi,[5] Yoriaki Kaneko,[2] Keiju Hiromura,[2] Yoshihisa Nojima,[1] Akito Maeshima.[2] *[1]Gunma University, Maebashi, Japan; [2]Gunma University Graduate School of Medicine, Maebashi, Japan; [3]Gunma University Graduate School of Medicine, Japan, Maebashi, Japan; [4]Gunma University School of Medicine, Maebashi, Japan; [5]Gunma university graduate school of medicine, Maebashi, Japan.*

Background: Activin A, a member of TGF-beta superfamily, is known to regulate cell growth and differentiation in various tissues. It has been reported that activin A is involved in kidney development, tubular regeneration, and renal fibrosis in rodents. However, the role of activin A in kidney diseases remains unknown in human. To address this issue, we analyzed renal biopsy specimens and urine from patients with ANCA-associated vasculitis (AAV).

Methods: Thirty-seven patients with biopsy-proven AAV who were treated in our department from 2011 and 2015 were included in this study. Serum activin A, urinary activin A, urinary follistatin (an activin antagonist), and urinary KIM-1 were measured by ELISA. Urine from healthy volunteers and rheumatic disease patients with normal urinalysis (control patients) were also used. The localization of activin A in renal biopsy specimens from AAV patients was examined by immunostaining. Normal kidney specimens from patients who underwent nephrectomy were used as a control.

Results: Urinary activin A was almost undetectable in healthy volunteers, but was significantly increased in AAV patients (7.2 ± 2.6 vs. 122.0 ± 38.6 ng/gCr, $p<0.001$). Urinary activin A levels of these patients was rapidly decreased after treatment. There was a significant correlation of urinary activin A level with urinary KIM-1 and urinary protein. On the other hand, compared with control patients, urinary follistatin levels were decreased in AAV patients (673.1 ± 135.3 vs. 291.7 ± 38.8 ng/gCr, $p<0.05$). Activin A was localized in the cytoplasm of distal tubules of normal kidneys. In contrast, activin A was present not only in distal tubules, but also in the apical lumen of proximal tubules, and infiltration macrophages in patients with AAV.

Conclusions: These data suggest that urinary activin A reflects renal inflammation and tubular damage in ANCA-associated vasculitis.

Osmotic Pressure Increases TGFβ1-Mediated Loss of SGLT2 Expression in Human Proximal Tubule Cells Xinlu Pan,[4,3] Deborah L. Baines,[3] Mysore K. Phanish,[2] Mark E. Dockrell.[1] [1]*South West Thames Institute for Renal Research, London, United Kingdom;* [2]*SW Thames renal and transplantation unit, London, United Kingdom;* [3]*St George's, University of London, London, United Kingdom;* [4]*St Helier Hospital, London, United Kingdom*.

Background: Approximately 90% of glucose is reabsorbed by the low affinity Na+/glucose co-transporter SGLT2, predominantly expressed in the early proximal tubule. This transporter has received renewed interest in the light of anti-diabetic drugs targeting its activity. Although reports suggest an increase in SGLT2 expression in diabetic nephropathy (DN), we hypothesised that the loss of phenotype of proximal tubule epithelial cells (PTEC) observed in DN may result in a decrease in SGLT2 expression.

Methods: Primary human PTEC were cultured on plain or collagen IV coated plastic-ware in supplemented medium. Cells at 80% confluence were treated with: 5mM D-Glucose (normoglycaemia), 25mM D-Glucose (hyperglycaemia), or 5 mM D-Glucose + 20mM L-Glucose (osmotic control) +/-TGFβ1(0.75ng/ml). After 24h, medium was collected and cells lysed. Western blot was used to detect protein expression; membranes were probed with antibodies against: SGLT2, SGLT1, K-Cadherin and tubulin.

Results: Primary PTEC expressed mature SGLT2, molecular weight of ~ 73KDa, indicating appropriate post-translational processing and membrane localisation. Probing with the SGLT1 antibody only identified bands of 60 KDa or lower, indicating an immature protein not expressed at the membrane. TGFβ1 treatment (24h) resulted in a decrease in SGLT2 expression in all treatments; this effect was more pronounced in cells grown on collagen and in osmotic control containing non-transported/non-metabolised L-glucose. K-Cadherin protein expression was not reduced by TGFβ1 at this time point; in fact there was a tendency to increased expression in cells treated with D-Glucose + TGFβ1.

Conclusions: Our data demonstrates that TGFβ1 reduced the expression of mature SGLT2 protein in human primary PTEC. This is not consistent with recent reports of a TGFβ1-induced increase in SGLT2 expression using transformed cells grown on plastic, less representative of the in vivo situation. SGLT2 was decreased prior to any measurable loss of K-Cadherin, suggesting that SGLT2 could be a more sensitive phenotypic marker than cadherin in PTEC. An increase in K-Cadherin expression in response to D-Glucose + TGFβ1 may be secondary to cellular hypertrophy observed in DN. In the other presentation from our group on this topic we investigate whether there is a metabolic interaction between TGFβ1 and SGLT2 activity.

Inhibition of Erythropoiesis by Soluble Fas in Cell Culture Miguel A Goes.[1,2] [1]*Wake Forest Institute for Regenerative Medicine, Wake Forest University, Winston Salem, NC;* [2]*Division of Nephrology, Federal University of São Paulo (UNIFESP), São Paulo, Brazil*.

Background: Serum soluble Fas (sFas) levels are associated with anemia in CKD patients. Cord blood cells (CBc) can generate hematopoietic stem cells ($CD34^+$). **Objective:** To investigate whether sFas interferes with erythropoiesis in cell culture

Methods: We studied $CD34^+$-cell culture after sorting from CBc. Analyzed on flow cytometry for glycophorin A, CD 34^+, CD 38^+ and CD 171^+. The $CD34^+$ cells were incubated for 14 days in methylcellulose medium containing growth factors added with sFas or without sFas. They were divided in 18 wells from 6 plates. We divided in 2 groups. Each group consisted in 9 wells with different concentrations of sFas (H group- [2, 4 and 8 ng/mL]; L group-[0, 0.5, and 1 ng/mL]). We performed counting of colony-forming unit (CFU) numbers in all wells for red series (B/CFU-E), white series (CFU-GM) and mixed series (CFU-GEMM) under inverted light microscopy. We performed correlations and comparisons.

Results: We found that CD34+ was the major marker after sorting. We observed a negative correlation between sFas concentration and B/CFU-E ($r=-0.74$; $p<0.001$) when analyzed all 18 wells together. We observed lower amount of B/CFU-E in plate with sFas-8ng/ml than in the plates with sFas-1ng/ml, 0.5 ng/ml and non-sFas, 3.7±1.1, 4.3±2.0, 5±1.7, respectively; $p=0.02$). There was a negative correlation between B/CFU-E and CFU-GM ($r=-0.69$; $p=0.03$) in the H-$CD34^+$ group. We observed lower number of B/CFU-E in H-$CD34^+$ group than in the L-$CD34^+$ group (1.5±0.9, 4.3±1.6; $p=0.008$).

Conclusions: We observed that higher concentrations of sFas interfere with erythropoiesis in $CD34^+$ cell culture.

TH-PO397

Differential Expression of Myogenic Regulators Following Aerobic or Combined Exercise in Non-Dialysis CKD Douglas W. Gould,[1] Emma L. Watson,[1] Matthew P. Graham-Brown,[1] Soteris Xenophontos,[1] Thomas J. Wilkinson,[1] Joao L. Viana,[2] Alice C. Smith.[1] [1]*University of Leicester, Leicester, United Kingdom;* [2]*University Institute of Maia, Porto, Portugal*.

Background: CKD is associated with satellite cell (SC) dysfunction and reduced expression of myogenic regulatory factors (MRFs), which contribute to muscle wasting. SCs are skeletal muscle stem cells responsible for muscle repair and regeneration following 'injury'. Such 'injury' occurs following exercise; this leads to SC activation, a process controlled by the MRFs MyoD and Myogenin. The effect of exercise on the expression of MRFs in CKD is currently unknown.

Methods: 19 CKD patients (62±14 years; 12 female; eGFR: 27±7ml/min/kg/1.73m^2) completed supervised aerobic exercise (AE) (n=10), or combined aerobic plus resistance exercise (CE) (n=9) 3x/week for 12 weeks. Muscle biopsies were obtained from the vastus lateralis at baseline (B1) and 24h (B2) post the first and final exercise sessions (B3). Gene expression of MyoD and Myogenin were analysed by RT-PCR and data reported as percentage change from B1. Data was analysed using repeated measures ANOVA with post-hoc paired t-tests.

Results: Analysis revealed effects between biopsy time-points ($F=5.795$, $p=.016$) and groups ($F=4.630$, $p=.031$) for MyoD expression. Post-hoc analysis revealed AE had a negligible effect on MyoD expression with a change of +0.5% ($p=.988$) at B2 and +14% ($p=.511$) at B3. Following CE, MyoD was downregulated by -70% ($p=.050$) at B2, but up regulated by +54% ($p=.123$) from baseline at B3, which was +429% ($p=.012$) from B2. No interactions were observed for Myogenin expression ($F=.492$, $p=.615$).

Conclusions: We report differential effects of AE and CE on MyoD gene expression in non-dialysis CKD. In the general population, exercise acts as a potent stimulus for SC activation, which is mediated by MRFs. We observed a small increases at both biopsy time points following AE. In contrast, CE suppressed MyoD gene expression following the initial bout of exercise, indicating a possible abnormal response. However, this appeared to be reversed following 12-weeks, where expression was increased above baseline. This demonstrates that regular exercise incorporating resistance training has the potential to overcome CKD induced abnormalities in SC activation.

TH-PO398

A New Deleterious Role for AMPD1 in the Pathogenesis of CKD-Dependent Muscle Waste Ana Andres-hernando, Richard J. Johnson, Miguel A. Lanaspa. *University of Colorado Denver, Aurora, CO*.

Background: Chronic Kidney Disease (CKD) reflects an overall catabolic state with significant loss of muscle mass. Mortality in CKD closely relates to muscle atrophy and no reliable methods to prevent CKD-induced muscle wasting currently exist. Proper glucose and phosphate uptake is essential for maintaining muscle mass which is controlled by the regulation of the Akt/As160/glut4 axis. AMP Deaminase 1 (AMPD1) is a muscle-specific protein inhibited by intracellular phosphate that negatively regulates the activation of the energy sensor protein AMPK and thus, AKt-signaling and glucose uptake. Based on this, we hypothesize that AMPD1-deficient mice by having an over-activation of AMPK and glucose uptake in the skeletal muscle will demonstrate a significant amelioration in CKD-dependent loss of muscle mass.

Methods: CKD-dependent muscle waste was induced in wild type and AMPD1 knockout mice by subtotal nephrectomy followed by a 5-week high protein diet. Body weight loss –a marker of muscle mass loss- in sham and nephrectomized mice was monitored weekly and renal function, muscle mass, intramuscular activation of AMPD1 and its signaling –AMPK and Akt activities, phosphate and uric acid levels- determined at sacrifice.

Results: AMPD1 activation in muscle of wild type mice undergoing CKD/High protein feeding is denoted by reduced intramuscular phosphate, increased AMP-dependent ammonia production and accumulation of AMPD-dependent products –uric acid and inosine-. Wild type but not AMPD1 deficient mice on CKD/high protein demonstrated significant weight and muscle –tibialis anterior, gastrocnemius and soleus- loss with elevation of serum creatinine kinase and glutamate –markers of muscle protein loss-. AMPD1 deficiency in mice results in AMPK activation leading to increased energy levels (ATP) and improved glucose uptake as reflected by the activation of the Akt/AS160/glut4 axis thus preventing protein loss and intramuscular catabolic processes. As a result, AMPD1 knockout mice on CKD demonstrated significant improved renal function with lower serum creatinine levels than wild type counterparts. .

Conclusions: AMPD1 activation in the skeletal muscle is a key step in the pathogenesis of CKD-dependent muscle wasting. Thus, AMPD1 blockade represents a new therapeutic approach for the prevention of this condition and to accelerate the recovery of muscle loss in subjects with CKD.

Abnormal Lipid Metabolism in Skeletal Muscle Mediates CKD-Induced Sarcopenia Yuki Niida,[1] Masashi Masuda,[1] Aika Yoshizawa,[1] Yuichiro Adachi,[1] Yilimulati Yimamu,[1] Serina Kabutoya,[1] Risa Yoshida,[1] Hisami Okumura,[1] Yoshichika Kawai,[2] Makoto Miyazaki,[4] Hironori Yamamoto,[1,3] Yutaka Taketani.[1] [1]*Department of Clinical Nutrition and Food management, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, Japan;* [2]*Department of Food Science, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima, Japan;* [3]*Dept. of Health and Nutrition, Jin-ai University, Echizen city, Fukui, Japan;* [4]*Division of Renal Diseases and Hypertension, Department of Medicine, University of Colorado Denver, Aurora, CO*.

Background: Sarcopenia is defined by decreased skeletal muscle mass and strength. Chronic kidney disease (CKD)-induced sarcopenia is associated with degraded quality of life and poor prognosis of the patient. However, there is currently no effective therapy available because the mechanisms of its pathogenesis are largely unknown. Recent evidence indicates that CKD increases circulating levels of the major saturated fatty acid stearic acid through repression of stearoyl-CoA desaturase (SCD), which induces lipotoxicities such as ER stress in tissues, including cardiovascular tissues. Several reports have also indicated that ER stress plays a causative role in sarcopenia and cahexia.

In this study, we examined the role of ER stress via abnormal lipid metabolism in the skeletal muscles of CKD rats with muscle atrophy.

Methods: Eight-week-old male Wistar rats were treated with either adenine diet (0.4%) (CKD rats) or vehicle (normal rats) for 6 weeks. Gastrocnemius muscles(GM), soleus muscles, tibialis anterior muscles, and extensor digitorum longus muscles were weighed and atrophy was evaluated by hematoxylin and eosin (H&E) staining. Gene expression of gastrocnemius muscles was evaluated by real-time qPCR. Fatty acid composition of gastrocnemius muscles was determined by the gas-liquid chromatography method.

Results: GM tissue weight was significantly decreased in CKD rats compared with normal rats. We confirmed infiltration of inflammatory cells and increased connective tissue in the GM of CKD rats by H&E staining. mRNA expression of muscle atrophy-related genes and ER stress responsive genes were increased in the GM of CKD rats compared with normal rats. Inversely, CKD rats presented a decrease in SCD1 mRNA expression of the GM compared with normal rats. In addition, the unsaturated fatty acid ratio (UFA/SFA) was significantly lower in the GM of CKD rats compared with normal rats. In mouse myoblasts, administration of SCD inhibitor increased mRNA expression of muscle atrophy-relating genes and ER stress response genes.

Conclusions: We suggest that the unbalanced SFA/UFA ratio in skeletal muscles due to a decrease in SCD activity induced by CKD causes lipotoxicity and sarcopenia via activation of various muscle atrophy systems.

TH-PO400

Plant versus Animal Protein Improves Anti-Inflammatory Effects of HDL and Lessens CKD-Induced Atherosclerosis Ryohei Kaseda,[1] Michihiro Hosojima,[1] Shoji Kuwahara,[1] Hideyuki Kabasawa,[1] Hiroyuki Aoki,[1] Yuki Higuchi,[1,3] Valentina Kon,[2] Kentaro Maruyama,[3] Ichiei Narita,[1] Akihiko Saito.[1] *[1]Niigata University, Niigata, Japan; [2]Vanderbilt University, Nashville, TN; [3]Rice Research Center, Kameda Seika Co., Ltd, Niigata, Japan.*

Background: Although CKD is known to cause endothelial injury that contributes to the many adverse consequences of CKD, few interventions specifically target endothelial cell injury. Little is known about the potential of nutritional effects on endothelial cell health, especially the impact of different dietary proteins. We and others have shown that in the CKD setting, HDL loses its anti-inflammatory effects, and even potentiates inflammation. Our aim was to determine whether differences in dietary protein source, namely animal protein versus plant protein can modulate renal injury-acceleration of atherosclerosis and anti-inflammatory properties of HDL.

Methods: 12-week-old ApoE-deficient hyperlipidemic mice underwent uninephrectomy. The mice were pair-fed the usual casein-based diet (animal protein) or rice protein-based diet (plant protein extracted from rice endosperm by alkaline extraction method) for 6 weeks. We compared atherosclerotic lesions by en-face Sudan IV staining. HDL fraction was obtained by eliminating Apo B by polyethylene glycol precipitation. Human umbilical vein endothelial cells (HUVEC) were exposed to TNF-α together with HDL for 6 hours. Cellular expression of inflammatory markers (MCP-1, IL-6, and IL-1β) was assessed by real time RT-PCR.

Results: Atherosclerotic lesions were significantly reduced in rice protein-fed group compared to casein-fed mice (en-face atherosclerotic lesions 0.28±0.06 vs. 0.67±0.15mm^2, p=0.038, N=5 and 5, respectively). HDL of rice protein-fed mice suppressed HUVEC's inflammatory response compered to casein-fed mice (MCP-1, 3.83±0.73 vs. 7.42±0.39, p=0.003; IL-1β, 1.54±0.19 vs. 5.70±1.32 p=0.02; and IL-6, 0.52±0.07 vs. 0.98±0.06, p<0.001, N=5 and 5, respectively)

Conclusions: Plant protein-based diet significantly reduced kidney-injury driven atherosclerosis compared to animal protein-based diet. This anti-atherogenic effect is associated with anti-inflammatory effects of HDL. The results underscore the potential utility of nutritionally-based intervention in affecting atherosclerosis for CKD.

TH-PO401

HDL from CKD Rabbits and Hemodialysis Patients Exhibit Impaired Anti-Aggregative Activity on Human Platelets through CD36 Pathway Nans Florens,[2,1] Catherine Calzada,[1] Dan Yi,[1] Sandrine Lemoine,[2,1] Laurent Juillard,[2,1] Christophe O. Soulage.[1] *[1]CarMeN, INSERM, U1060, INSA Lyon, Villeurbanne, France; [2]Hospices Civils de Lyon, Lyon, France.*

Background: Recent studies have shown altered biological properties of HDL in chronic kidney disease (CKD). As cardiovascular mortality remains the major cause of death in CKD and as oxidative stress is raised in CKD, we aimed to explore the specific role of oxidative modifications of HDL in CKD and their impact on anti-aggregant phenotype of HDL.

Methods: Rabbits were surgically 5/6-nephrectomized. Blood from healthy volunters (control) were sampled during their live-donor evaluation visit. Hemodialysis (HD) patients were sampled before the HD session. HDL were separated from plasma by potassium bromide stepwise density gradient ultracentrifugation. In rabbits, Malondialdehyde (MDA), 4-hydroxy-nonenal (HNE) and 4-hydroxy-2-hexenal (HHE) protein adducts levels were assayed. Platelet aggregation was measured after 5 min of incubation with HDL from each group in an aggregometer with or without anti-CD36 blocking antibody (Ab-CD36). HDL from control rabbits were modified by an incubation overnight at 37°C with 100mM of HNE.

Results: 8 CKD were compared with 9 Sham operated rabbits. CKD rabbits exhibited a higher creatinine level than the control group (93 ± 12 vs 214 ± 25 μM, p<0.001). MDA contents were significantly higher in the HDL from CKD group (0.89 ± 0.18 vs 2.64 ± 0.67 nmol/mg, p<0.05). HNE-adducts were also increased in HDL from CKD animals while HHE-adducts levels were not different. Percentage of platelet aggregation (PA) compared to collagen alone was 65% when were incubated with HDL from CKD group while it was 30% with HDL from the control group (p<0.05) evidencing a blunted anti-aggregative effect. PA in presence of HNE-modified HDL was 85% (p<0.05 compared to Control group). Incubation with Ab-CD36 decreased the PA with CKD and HNE-modified HDL to 27 and 23%, respectively (p<0.05). 5 control patients were compared with 6 HD patients. Percentage of PA compared to collagen alone with HDL from HD patients was higher than in the control group (63 vs 24%, p<0.01).

Conclusions: CKD is associated with oxidative modifications of HDL among which HNE-adducts. HDL from CKD rabbits and HD patients exhibited an impaired ability to inhibit platelet aggregation suggesting that altered HDL properties could contribute to the increased cardiovascular risk in this population.

TH-PO402

IL-1 Inhibition Improves HDL Functionality in CKD Adriana Hung,[4,6] Yohei Tsuchida,[4] Kristen L. Nowak,[3] Sudipa Sarkar,[4] Thomas G. Stewart,[5] Michel Chonchol,[1] Jiansheng Huang,[4] Macrae F. Linton,[2] Talat Alp Ikizler,[5,6] Valentina Kon.[4] *[1]University of Colorado, Aurora, CO; [2]Vanderbilt University School of Medicine, Nashville, TN; [3]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [4]Vanderbilt University, Nashville, TN; [5]Vanderbilt University Medical Center, Nashville, TN; [6]VA TVHS, Nashville, TN.*

Background: Cardiovascular disease (CVD) is the most prominent cause of morbidity and mortality among patients with chronic kidney disease (CKD). Inflammation and oxidative stress are considered to contribute to CVD in CKD. Both of these factors are also known promote HDL malfunction in CKD. Whether interventions that modulate systemic inflammation can improve anti-inflammatory aspects of HDL in the setting of advanced CKD or ESRD is unknown.

Methods: We conducted a post-hoc analysis to evaluate if IL-1 blockade could improve the anti-inflammatory and anti-oxidant functions of HDL in patients with CKD. We used serum samples from two pilot randomized clinical trials; one in CKD stages 3 & 4 patients (CKD3/4) and one in maintenance hemodialysis (MHD) patients. HDL was isolated from each participant's serum at baseline and at the end of the study. The anti-inflammatory and anti-oxidant function of HDL was measured as the response of LPS-activated THP-1 macrophages exposed to the participant's HDL (IL-6, TNF-α, NLRP3 response were measured by RT-PCR and cellular oxidant production by HPLC). Biomarkers were log transformed and repeated measures ANCOVA was used to estimate the percent change in biomarker expression with the intervention (btween group comparison).

Results: The mean age of the participants was 60±13, 72% (n=33) were male, 38% (n=17) were black. There were 32 CKD patients (16 intervention and 16 placebo) and 14 MHD (7 intervention and 7 CKD). IL-1 blockade down-regulated hsCRP and IL-6 in both studies (*Nowak et al 2017 and Hung et al 2011*). IL-1 blockade effectively improved HDL functionality: compared to baseline, IL-1 blockade reduced TNF expression by 30% (p=0.006) [18% in CKD (p=0.03) and 61% in MHD (p=0.06)], IL-6 by 40% (p=0.02) [36% in CKD (p=0.006) and 50% in MHD (p=0.3)], and NLRP3 by 17% (p=0.02) [15% in CKD (p=0.02) and 25% in MHD (p=0.02)]. Cellular superoxide production fell by 15% (p<0.001) [17% in CKD (p< 0.001) and 12% in MHD (p=0.004)].

Conclusions: IL-1 blockade improved the anti-inflammatory and anti-oxidative properties of HDL in patients with CKD stage 3 or stage 4 and MHD. Larger scale and longer term prospective studies are needed to confirm the utility of this intervention in clinical settings. (Hung and Tsuchida are first co-authors)

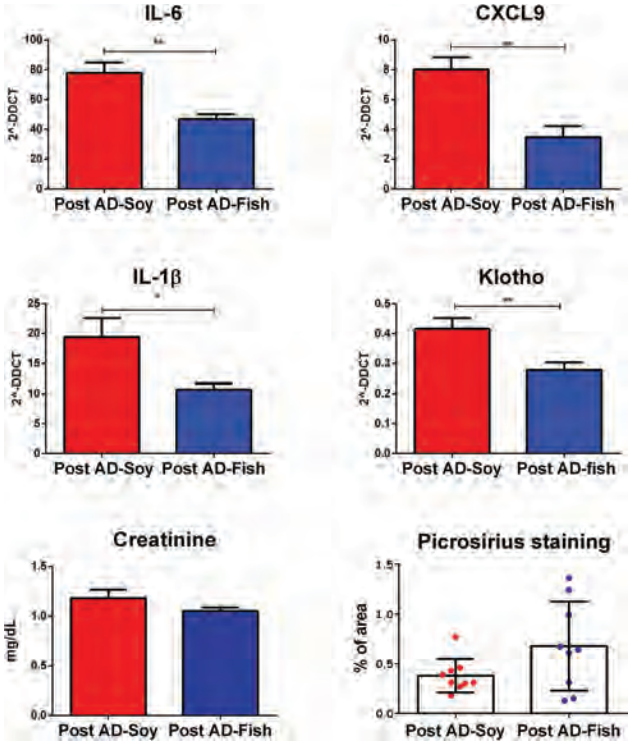
Fish Oil Supplementation Reduces Inflammation but Does Not Restore Renal Function and Klotho Expression in an Adenine-Induced CKD Model Juan S. Agudelo,[2] Leandro C. Baia,[1] Milene S. Ormanji,[2] Amandda rakell Peixoto dos santos,[2] Niels O. Camara,[2] Gerjan Navis,[1] Martin H. De Borst,[1] Ita P. Heilberg.[2] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Nephrology Division, Universidade Federal de São Paulo, São Paulo, Brazil.*

Background: CKD and inflammation promote loss of klotho expression. Given the well-established anti-inflammatory effects of n-3 fatty acids, we aimed to investigate the effect of fish oil supplementation in an experimental model of inflammatory renal damage.

Methods: Male C57BL/6 mice were fed an adenine-enriched diet (**AD-10days**) to induce inflammatory renal damage or standard chow (**CTL**) for 10 days, and in the subsequent 7 days received either fish oil (**Post AD-Fish**) or soybean oil (**Post AD-Soy**). Renal function, pro-inflammatory and profibrotic markers (picrosirius staining) were assessed and the expression of Klotho was evaluated by qPCR and Western-blot.

Results: When compared to **CTL,** the **AD-10days** group exhibited significantly higher mean serum creatinine (1.3±0.4 vs 0.8±0.1mg/dL), IL-6, CXCL10 and IL-1β (68.0±17.7 vs 1.0±0.2, 6.6±0.3 vs 1.0±0.2 & 3.5±1.5 vs 1.2±0.7, respectively), reduced renal klotho expression (0.2±0.0 vs 1.0±0.1), confirmed by Western-blot and a non-significant trend for increased fibrosis. As shown in the Figure, IL-6, CXCL9 and IL-1β were significantly decreased in **Post-AD-Fish** group but klotho expression was unaltered (also demonstrated by Western-blot). Serum creatinine and fibrosis did not differ statistically between **Post-AD-Fish** and **Post-AD-Soy** groups.

Conclusions: Fish oil supplementation reduced pro-inflammatory markers, but was not able to restore renal function or klotho expression in a model of inflammatory renal damage.



TH-PO404

Erythropoietin Pathway Dysregulation in Anemia of CKD Daniel Landau,[1] Lital London,[2] Inbar Bandach,[1] Yael Segev.[1] *[1]Microbiology and Immunology, Ben Gurion University of the Negev, Beer Sheva, Israel; [2]Ben Gurion University of the Negev, Beer-Sheva, Israel.*

Background: Anemia is a known driver for hypoxia inducible factor (HIF) which leads to increased renal erythropoietin (EPO) synthesis. Bone marrow (BM) EPO receptor (EPOR) signals are transduced through a JAK2-STAT5 pathway. Anemia of CKD is considered to be of multifactorial origin, including impaired renal EPO synthesis and intestinal iron absorption. EPO resistance in CKD may be an additional factor but its mechanisms are poorly understood. We investigated the HIF- EPO- EPOR axis in kidney, BM and proximal tibia in anemic juvenile CKD rats.

Methods: CKD was induced by 5/6 nephrectomy in young (20 days old) Sprague-Dawley rats while C group was sham operated. An additional control anemic (C-A) group was daily bled for 7 days. Rats were sacrificed 4 weeks after CKD induction and 5 minutes after a single bolus of IV rhEPO (25 U/kg).

Results: Hemoglobin levels were similarly reduced in CKD and C-A (11.7 ± 0.4 and 10.8±0.2 Vs 14.3±0.2 g/dL in C, p<0.0001). Liver hepcidin mRNA was decreased in CA but increased in CKD. Serum iron and transferrin levels were unchanged in CKD. Kidney HIF2α was elevated in C-A but unchanged in CKD. Remnant kidney EPO protein and mRNA levels were unchanged between groups. However, BM EPO protein (which reflects circulating EPO) was increased in C-A but remained unchanged in CKD. BM and proximal tibia EPOR were unchanged in C-A but decreased in CKD. Proximal tibial phsopho-STAT5 increased in C but not in CKD.

Conclusions: Compared to chronic blood loss, anemia in young CKD rats is associated with inappropriate responses: kidney HIF2α and BM EPO are not increased, BM and bone EPOR levels, as well as bone pSTAT5 response to EPO are reduced. This may allow the introduction of additional therapeutic avenues for CKD related anemia beyond iron and EPO supplementation.

TH-PO405

Hepcidin Response to IV Iron Is Different in CKD Compared with Pregnancy and Healthy Controls Lawrence P. McMahon,[1] Louis L. Huang,[1] Darren H. Lee,[1] Iain C. Macdougall.[2] *[1]Department of Renal Medicine, Eastern Health, Box Hill, VIC, Australia; [2]Department of Renal Medicine, King's College Hospital, London, United Kingdom.*

Background: The IDENTIFY Study investigated the effects of IV ferric carboxymaltose (FCM) on markers of bone metabolism in chronic kidney disease (CKD), pregnancy, and healthy controls, but data on iron status were also collected. When the results of the latter were analysed, it became clear that there were differences among the three groups of patients, and the aim of this analysis was to examine this in more detail.

Methods: IDENTIFY was a prospective observational study comprising 1g of IV FCM administered to 3 patient populations: CKD (n=25); healthy Controls (n=20); and Pregnancy (n=20). The following markers of iron status were collected on days 0, 2, 7 and 21: serum iron, ferritin, transferrin saturation (TSAT) and hepcidin (by mass spectrometry).

Results: Following IV FCM, there was a similar increase in serum iron and TSAT in all groups, which peaked at day-2, and returned to baseline at day-7. Ferritin increased to the same extent in all groups, reaching a maximum at day-7, and remaining significantly above baseline at day-21. Serum hepcidin peaked at day-2 in all groups, but the zenith varied (127±61 vs. 106±62 vs. 61±44 ng/mL, p=0.001) and the AUCs differed (1503±1173 vs. 953±718 vs. 629±360, p=0.004) in the CKD, Controls and Pregnancy groups, respectively.

Conclusions: Despite receiving the same dose of FCM, and with comparable levels of haematinics, the rise in hepcidin was significantly greater in CKD patients compared to healthy controls and pregnant women. The reason for this novel finding is unclear, and requires further study. Finally, the ferritin response observed in this study supports a recommendation that following administration of 1g FCM, serum ferritin should not be rechecked for at least 1-month.

Oxidative Stress after Intravenous Iron in Dialysis Patients – A Real Phenomenon or an In Vitro Artifact? Jaromir Eiselt,[1] Daniel Rajdl,[2] Lukas Kielberger,[1] Ladislav Trefil.[2] *[1]Dept. of Internal Medicine I, Charles University, Faculty of Medicine in Pilsen, Pilsen, Czech Republic; [2]Inst. of Clinical Biochemistry and Hematology, Charles Univversity, Faculty of Medicine in Pilsen, Pilsen, Czech Republic.*

Background: Intravenous iron can aggravate oxidative stress. However, the presence of the iron preparation in the serum sample may interfere with the determination of oxidative stress markers. The aim of the study was to measure markers of oxidative stress and serum iron after administration of i.v. iron.

Methods: A total of 10 patients on chronic hemodiafiltration (HDF) received in a random order physiological solution (CONTR), 200 mg of ferric carboxymaltose (FC) and 200 mg of iron succrose (IS). Infusions were given from min. 60 to min. 90 of 4 h HDF. In minutes 60, 90, 150 and 240 were measured thiobarbituric acid reacting substances (TBARS), 8-isoprostane (8-iso) and iron in serum. Iron was determined by a routine photometric method (Fe-PHOT) and by an atomic absorption spectrometry (Fe-AAS).

Results: We detected increase of TBARS after both FC and IS, while 8-iso rose only after administration of IS. Levels of serum iron were dramatically higher when using Fe-AAS, than Fe-PHOT. The Fe-AAS method, unlike Fe-PHOT, detects all plasmatic iron, including the one bound in iron-sugar complexes. Results are summarized in table. Changes in TBARS strongly correlated with serum iron measured by Fe-AAS after infusion of both IS (r=0.92, p<0.001) and FC (r=0.79, p<0.0001), but not after CONTR (r=0.23, p=0.133). On the other hand, 8-isoprostane did not correlate with Fe-AAS in any of the three tested treatments.

Conclusions: Immediate effect of i.v. administration of ferric carboxymaltose and iron succrose on oxidative stress of dialysis patients is probably small and difficult to prove with the respect to artifacts in analyses. Measurement of 8-isoprostane does not seem to be affected, compared to TBARS, by a false *in vitro* interference with intravenously administered iron-sugar complexes.

Funding: Government Support - Non-U.S.

	Ferric carboxymaltose	Iron sucrose	Physiol. sol.	P (AUC by ANOVA)
8-iso [ng.h/L]	62 (57-68) [a]	87 (79-93) [b]	69 (52-86)	<0.001
TBARS [µmol.h/L]	4.0 (3.5-4.5) [a,b]	3.1 (2.8-3.5) [b]	2.2 (1.7-2.5)	<0.001
Fe(PHOT) [µmol.h/L]	73 (56-93) [a,b]	139 (107-165) [b]	27 (19-42)	<0.001
Fe(AAS) [µmol.h/L]	1984 (1704-2141) [a,b]	1610 (1214-1729) [b]	59 (44-70)	<0.001

Values are medians (95 % CI) of serial measurements in serum; groups were compared using area under the curve (AUC) by ANOVA; Student-Newman-Keuls test was used for post-hoc pairwise comparisons; a P<0.05 vs. iron suc., b P<0.05 vs. physiol. sol.

TH-PO407

Erythropoietin (Epo) Inhibits Sodium-Driven Pro-Inflammatory Effects Andrea Angeletti,[2,4] Chiara Donadei,[3,4] Vivette D. D'Agati,[1] Miguel L. Fribourg,[2] Gaetano La Manna,[4] Paolo Cravedi.[2] *[1]Columbia University College of Physicians and Surgeons, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Icahn School of Medicine at Mt. Sinai, New York, NY; [4]Nephrology, DIMES, Bologna, Italy*.

Background: High sodium concentrations promote T cell IL-17 production and injury by increasing intracellular pSGK1. We tested whether EPO, which we previously showed has immune-modulating effects, can counteract sodium-induced human Th17 production in vitro, and in a murine kidney disease model, in which sodium and EPO concentrations are elevated.

Methods: We added EPO or vehicle to human PBMC (n=3-8 donors per experiment) cultured in vitro +/- high [NaCl] or [urea] (osmotic control) and measured T cell proliferation, IL-17/IFNg production, pSGK1 (flow cytometry) and Foxp3 expression. To assess in vivo effects we fed WT B6 mice with normal or high NaCl diet, treated them aristolochic acid (ArA) to induce T cell-mediated interstitial nephritis ± EPO and measured proteinuria and immune responses 6 weeks later.

Results: EPO (but not urea) inhibited human NaCl-driven SGK1 phosphorylation, T cell proliferation (Fig. 1A), and IFNg production (6.7±1.2% vs. 1.8±0.4%, vehicle vs. EPO in the presence of NaCl; P<0.05), without affecting apoptosis/necrosis. EPO prevented Na-driven Th17 induction (1.6±0.3% vs. 0.7±0.3%, vehicle vs. EPO; P<0.05) and increased $CD4^+CD25^+Foxp3^+$ Treg induction/function (Fig. 1B), while maintaining Treg stability. In mice fed a normal or a high NaCl diet, EPO reduced ArA-induced splenic Th1 and Th17 cells, increased Treg and reduced proteinuria (Fig. 1C).

Conclusions: EPO inhibits NaCl-induced proinflammatory T cell immunity in vitro and in vivo, in humans and mice. Our data support the concept of EPO is an immune-modulatory hormone that could physiologically counteract the proinflammatory effects of high intrarenal [NaCl].

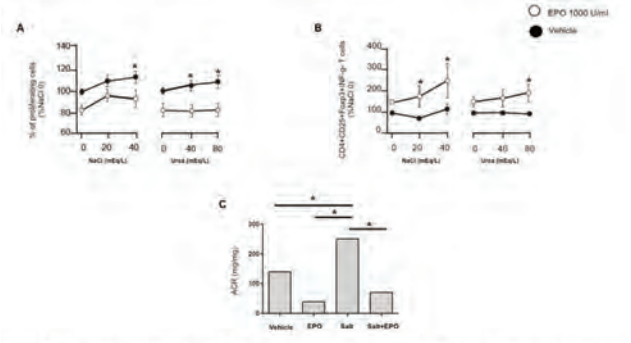

Figure 1. A) Number of human CD4+ T cells at 5 days after activation with aCD3/aCD28 and cultured in the presence of increasing concentrations of NaCl or Urea +/- EPO (data are mean +/- SD of 5 donors, normalized to untreated samples). B) Human naïve CD4+ T cells were cultured in the presence of monocytes, IL-2, and eCD3 in the presence of increasing concentrations of NaCl or Urea +/- EPO. At 5 days, we quantified the percentages of $CD4+CD25+Fxp3+IFNg-$ Treg (data are mean +/- SD of 8 donors, normalized to untreated samples). C) Albumin/creatinine ratio in WT B6 mice fed with regular diet or diet supplemented with NaCl at 3 weeks after aristolochic acid +/- EPO (median values of 3 animals per group).

TH-PO408

The Role of Nrf2/HO-1 Signaling Pathway in Mild Hyperuricemia Promoting the Progress of CKD Zhihong Zhao,[1] Qin Zhou,[1] Hequn Zou.[2] *[1]The Third Affiliated Hospital of Southern Medical University, Guangzhou, China; [2]The 3rd Affiliated Hospital of Southern Medical University, Guangzhou, China*.

Background: Previously it was believed that mild hyperuricemia had no pathogenic effect. However recently it is recognized that mild hyperuricemia can accelerate the progression of chronic kidney disease. The aim of this study was to investigate the role of Nrf2/HO-1 signaling pathway in mild hyperuricemia promoting the progress of chronic kidney disease in a rat model of 5/6 nephrectomy.

Methods: Rats were randomely dividided into five groups (n=8 in each group): Control Group, RK Group (5/6 nephrectomy), OA Group (750mg/kg/d oxonic acid treatment for 6 weeks), RK+OA Group and RK+OA+SFN Group (5mg/kg/d sulforaphane treatment for 6 weeks). Renal function, malondialdehyde (MDA) level, and SOD activity were determinated. Renal pathology was observed by light microscope. Western blot and immunohistochemical assays were used to test the expression of Nrf2, HO-1, P38/p-P38, ERK/p-ERK protein.

Results: Compared with the controls, the level of serum uric acid was increased in the OA Group and RK+OA Group respectively (P<0.05), but not significantly changed in the RK Group (P>0.05). Compared with RK Group, either the level of blood urea nitrogen (BUN), serum creatinine (Scr), 24-h urinary protein output or MDA was increased, the SOD activity was decreased in the RK+OA group(P<0.05). Compared with the RK+OA group, those blood and urine biochemical indices were decreased, MDA level was decreased, the SOD activity was increased, and the renal histological damage was ameliorated in the RK+OA+SFN group (P<0.05). The expression of Nrf2 nuclear protein and HO-1 protein were decreased in RK+OA group compared with either control or RK group, SFN increased the expression of Nrf2 and HO-1 in RK+OA+SFN group, the expression of P-p38 protein and p-ERK protein were decreased (P<0.05).

Conclusions: It is indicated by the results of our present study that mild hyperuricemia accelerated the progression of chronic kidney disease. Furthermore it is suggested by our results that the mechanism of mild hyperuricemia in inducing renal damage might be promoting oxidative stress by inactivating Nrf2/HO-1 signal pathway. It is also suggested that SFN could attenuate the renal injury induced by mild hyperuricemia and its mechanism might be allivateing the oxidative stress injury through activating Nrf2/HO-1 signal pathway. SFN may also affect the activity of ERK signaltransduction pathway.

pNaKtide Attenuates Kidney Dysfunction and Systemic Inflammation by Blocking Na/K-ATPase/Reactive Oxygen Species Amplification in ApoE -/- Mice Athar Nawab,[1] Brian J. Snoad,[2] Hari Vishal Lakhani,[2] Komal Sodhi,[2] Joseph I. Shapiro.[3] *[1]Marshall Health, Morgantown, WV; [2]Marshall University, Huntington, WV; [3]Marshall University School of Medicine, Huntington, WV*.

Background: We have previously reported that the alpha-1 subunit of the sodium potassium adenosine triphosphatase (Na/K-ATPase) acts as an amplifier for reactive oxygen species (ROS) in addition to its ion pumping function. We have also shown that blockade of this amplification with a novel peptide, pNaKtide, ameliorates oxidative stress and obesity in mice subjected to a high-fat diet.

Methods: pNaKtide was administered in ApoE knockout mouse fed western diet. 25 mg/Kg pNaKtide was administered intraperitoneally once every 7 days for 2 months. Lipid profile, ROS levels and plasma creatinine were measured Also, kidney fibrosis was quantified.

Results: pNaKtide administered to these mice significantly decreased plasma triglycerides, FFA, and LDL levels (p<0.05). Further, our results show that ApoE -/- mice fed a western diet had decreased plasma HDL levels and this decrease was reversed by pNaKtide. Plasma ROS levels were also significantly attenuated by pNaKtide treatment. Our results show that pNaKtide improved plasma creatinine and kidney fibrosis in in ApoE-/- mice fed a western diet (p<0.05

Conclusions: This study suggests that the Na/K-ATPase/ROS signaling cascade is a possible mechanism for the development of kidney dysfunction and systemic inflammation associated with the metabolic syndrome phenotype and pNaKtide presents a potential novel treatment for these pathologies.

TH-PO410

Factors Affecting Plasma Linoleic Acid in CKD Malgorzata Sikorska-Wisniewska,[1] Adriana Mika,[2] Tomasz Sledzinski,[1] Alicja Debska-Slizien,[1] Michal Chmielewski.[1] *[1]Medical University of Gdansk, Gdansk, Poland; [2]University of Gdansk, Gdansk, Poland.*

Background: Previous studies have shown that plasma linoleic acid (LA, 18:2n-6) is inversely associated with inflammatory markers and all-cause mortality in dialysis patients. The purpose of the present evaluation was to assess plasma LA percentage content in chronic kidney disease (CKD) subjects, and to evaluate factors that could affect it.

Methods: The study included a cohort of 224 participants, comprised of a group of controls free from any kidney disease (n=54), CKD stage 3-5 patients (n=86), dialysis subjects (n=60), and transplanted patients (n=24). LA amount was analyzed by gas

chromatography with a mass spectrometer detector, and expressed as percentage of total fatty acids of serum lipids. Intake of products rich in LA (nuts, seeds) was evaluated with a validated FFA-6 questionnaire.

Results: LA content decreased with CKD, as it equalled 26.2 ± 0.5% in controls, 24.2 ± 0.4% in CKD stage 3-5 patients, 22.6 ± 0.5% in dialysis subjects, and 24.2 ± 0.8 in kidney transplant recipients (ANOVA F = 7.75; p<0.001). As in previous studies, chronic inflammation, defined here as a persistently elevated hsCRP > 5 mg/L, was associated with decreased plasma LA, as compared to the group with hsCRP within the normal range (22.7 ± 3.6% vs. 25.1 ± 4.1%; p < 0.001). LA content was also inversely correlated with age and BMI. Ingestion of nuts and seeds showed a considerable linear relationship with the plasma LA content (Sperman rho = 0.22; p<0.05). Nevertheless, CKD turned out as an independent predictor of serum LA content, following adjustment for the abovementioned confounders (adjusted R^2 = 0.19; p<0.01).

Conclusions: Serum LA content is decreased in the course of CKD. Taking into account the potential impact of low LA on mortality, increased intake of products reach in this essential fatty acid could be of benefit for CKD patients.

AT2R Deficiency Accelerates Renal Dysfunction in Diabetic Progeny in a Sex-Dependent Manner Min-Chun Liao,[1] Shiao-Ying Chang,[1] Xin-Ping Zhao,[1] Chao-Sheng Lo,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[2] Shao-Ling Zhang.[1] *[1]CRCHUM, University of Montreal, Montreal, QC, Canada; [2]The New England Journal of Medicine, Boston, MA.*

Background: Angiotensin type 2 receptor (AT_2R) deficient mice (AT_2RKO) exhibit a spectrum of congenital abnormalities of the kidney and urinary tract. We aimed to study whether AT_2R deficiency in dams that also had diabetes mellitus would result in offspring with even more abnormalities in the urinary tract.

Methods: The offspring (male/female) of non-diabetic and diabetic dams of wild-type (WT) and AT_2RKO mice were followed until 20 weeks of age. Systolic blood pressure, insulin sensitivity test (IST), albumin/creatinine ratio (ACR), glomerular filtration rate (GFR), renal morphology and gene expression including angiotensin converting enzyme (ACE), angiotensin converting enzyme 2 (ACE2), synaptopodin (Synpo) and tyrosine phosphatase SHP-1 (qPCR and immunohistochemistry) were assessed.

Results: Compared to the age- and sex-matched offspring of non-diabetic dams, diabetic progeny of both WT and AT_2RKO mice developed more evidence of nephropathy (higher GFR and apparent glomerulosclerosis with podocyte loss) at 20 weeks of age, which were further aggravated in the offspring of AT_2RKO diabetic dams, particularly female mice. Female offspring from diabetic AT_2RKO dams developed insulin resistance, while male diabetic progeny of AT_2RKO dams had normal IST. Renal ACE2, Synpo and SHP-1 gene expression were downregulated in both sex's progenies of diabetic WT dams as well as male offspring of diabetic AT_2RKO dams. In contrast, female offspring of AT_2RKO dams had significant lower basal expression of ACE2, Synpo and SHP-1 genes in their kidneys, and those genes were completely blunted in female progeny of diabetic AT_2RKO dams.

Conclusions: AT_2R deficiency accelerated features of nephropathy in female progeny of diabetic dams, which might be due to loss of the protective effects of ACE2 and SHP1 expression in the kidney.

Therapeutic Targeting of Melanocortin 5 Receptor: A Novel Approach for Protection against AKI Rong Zhou,[1] Yahong Xu,[1,2] Rujun Gong.[2] *[1]Yangpu Hospital of Tongji University, Shanghai, China; [2]Brown Medical School, Providence, RI.*

Background: Melanocortin peptides belong to a neuroimmunoendocrine hormone system that sustains the homeostasis of diverse organ systems. Burgeoning evidence suggests that activation of melanocortin 5 receptor (MC5R) by melanocortin neuropeptides plays a pivotal role in immunoregulation and confers a protective effect in various disease models. Nevertheless, how therapeutic targeting of MC5R affects kidney injury was unknown and explored here.

Methods: Mice were treated with MC5A, a highly selective agonist of MC5R, or with PG20N, a highly selective antagonist, prior to folic acid injury. *In vitro*, primary renal proximal tubular cells (PTC) were injured with tumor necrosis factor (TNF) after MC5A or PG20N treatment. Kidney or cellular injuries were assessed.

Results: Selective activation of MC5R by MC5A strikingly improved the folic acid-elicited acute kidney injury (AKI), as evidenced by a mitigated elevation of serum creatinine, reduced urinary excretion and renal expression of lipocalin-2, diminished tubular damages and tubular cell death, and attenuated renal inflammation. Conversely, selective blockade of MC5R by PG20N exacerbated the folic acid induced AKI. In normal kidney tubulointerstitium, MC5R was sporadically expressed by some renal interstitial cells but absent from renal tubules, as demonstrated by immunohistochemistry, thus underscoring a possible non-tubular cell autonomous effect of MC5R on regulating kidney injury. In support of this, in primary renal PTC, the TNF-instigated apoptosis and production of proinflammatory cytokines, like CCL2, were barely altered by MC5A or PG20N. Rather, inflammatory infiltrations in the folic acid-injured kidney, as probed by CD45 staining, was mitigated by MC5A but amplified following PG20N treatment. In parallel, CD11b+Gr-1+ myeloid-derived suppressor cells (MDSC), which have been shown to mediate a renoprotective tolerogenic response in various types of AKI, were prominently expanded after MC5A treatment but remarkably diminished by PG20N in the injured kidney. Moreover, the kidney protective effect of adoptive transfer of MDSC in folic acid-injured mice was reinforced by MC5A pretreatment of MDSC, but blunted by PG20N, thus denoting a direct modifying effect of MC5R on MDSC.

Conclusions: Altogether, therapeutic targeting of MC5R protects against folic acid AKI likely *via* modulating the tolerogenic MDSC response.

TH-PO413

RhoA Effector mDia1 Contributes to Kidney Injury in the Early Stage of High-Fat Diet Induced Obesity Makiko Naitoh,[4] Hirobumi Tokuyama,[1] Shu Wakino,[2] Hiroshi Itoh.[3] *[1]Internal Medicine, Keio University, Tokyo, Japan; [2]Keio University, Tokyo, Japan; [3]Keio University School of Medicine, Tokyo, Japan; [4]Keio university, Tokyo, Japan.*

Background: Obesity is a critical contributor to kidney damages that are reported to be structurally characterized by glomerulomegaly, tubular hypertrophy and renal hypertrophy. We have previously demonstrated that proximal tubular (PT) hypertrophy occurred in obese mice fed with high-fat diet (HFD) for twelve weeks, which activated RhoA/ROCK signaling leading to inflammatory reaction. However, the early changes which precede this renal tubular cell change and RhoA activation was unclear.

Methods: We used male C57Bl/6J mice with overexpressed dominant negative RhoA genes selectively expressed in the PT ($dnRhoA^{Tg/Tg}$) to suppress RhoA activation. Morphological and biochemical changes were compared between $dnRhoA^{Tg/Tg}$ mice and their wild-type littermates (WT) fed with HFD or low-fat diet (LFD) for 2 weeks. To investigate the molecular mechanism, we utilized tissue culture system with human kidney-2 (HK-2) cells.

Results: Although the body weight, serum insulin and lipid levels were increased in HFD-fed WT mice, fasting glucose levels were not altered as compared with LFD-fed WT mice. HFD-fed WT mice showed no significant renal morphological changes except increased tubular proliferation even two weeks after the initiation of HFD as assessed by Ki67 staining. Although urinary albumin excretion was not altered, the excretion of NGAL was increased in HFD-fed WT mice. Immunoblot analysis revealed increased expression level of one of the RhoA effectors, Diaphanous-related formin-1 (mDia1) and decreased expression level of negative cell cycle regulator p27 in HFD-fed WT mice, while the activity of another RhoA downstream target ROCK was unaltered. Compared with WT on HFD, $RhoA^{Tg/Tg}$ on HFD exhibited less tubular cell proliferation and NGAL excretion. The upregulation of mDia1 and the downregulation of p27 in HFD-fed mice was restored in HFD-fed $RhoA^{Tg/Tg}$ mice. In cultured HK-2 cells, treatment with insulin upregulated mDia1 and downregulated p27, which were ameliorated by siRNA-mediated knockdown of mDia1.

Conclusions: The activation of RhoA/mDia1 pathway in PT promotes PT proliferation in early stage of obesity probably through insulin stimulation. The early activation of RhoA/mDia1 pathway may precede the activation of RhoA/ROCK pathway and may play a critical roles in the initiation process of obesity-induced renal damages.

TH-PO414

Activation of Browning in White Adipose Tissue during CKD Mathilde Luce,[2,1] Nyam Elsa,[3] Christophe O. Soulage,[1] Denis Fouque,[2] Laetitia Koppe.[2,1] *[1]CarMeN, INSERM u1060, INSA LYON, VILLEURBANNE, France; [2]Nephrology, Hospices Civils of Lyon, Lyon, France; [3]Montreal Diabetes Research Center, CRCHUM and Department of Medicine, University of Montréal, Montréal, QC, Canada.*

Background: In patients with chronic kidney disease (CKD), protein energy wasting (PEW) is characterized by an increased resting energy expenditure (REE) although the underlying mechanisms remain poorly understood. Browning corresponds to the activation of inducible brown adipocytes in white adipose tissue (WAT) and participates in cachexia associated with hypermetabolic diseases such as cancers. **The objective of this study is to highlight a phenomenon of browning associated with CKD and to study the potential role of uremic toxins in the activation of this phenomenon.**

Methods: 3T3L1 mouse adipocytes were incubated for 24h with plasma (20% v/v) from healthy volunteers or chronic haemodialysis patients; or with two major uremic toxins (p-Cresyl sulfate and Indoxyl-sulfate). We quantitated the content of uncoupling protein 1 (UCP-1) recognized as a hallmark of browning and studied the adipocytes differentiation. *In vivo*, study was carried out on 5/6 nephrectomy mice with measurement of indirect REE, WAT UCP-1 expression and content after 3 weeks of uremia.

Results: The incubation of 3T3L1 adipocytes with plasmas of uremic patients led to an increase of UCP-1 (+ 153%, p<0.001) compared to the control plasma and inhibited by cycloheximide, a protein synthesis inhibitor. Incubation of adipose cells with uremic toxins at concentrations found in CKD patients failed to alter UCP-1 synthesis or adipocytes differentiation. CKD mice exhibited an increase in REE compared to sham mice consistent with a possible transformation of WAT into brown adipose tissue (BAT) and activation of thermogenesis. Moreover, UCP-1 content is significantly higher in CKD WAT compared to sham mice (p = 0.02) with an increase in the expression of several thermogenesis genes in the WAT of CKD mice (e.g. UCP-1, PGC1α and PRMD16).

Conclusions: Taken together, these data, suggest the activation of a browning phenomenon during CKD. Uremic toxins do not appear to participate in this phenomenon although p-Cresyl sulfate was previously shown to induce adipocyte dysfunction *in vitro*. **The activation of browning in WAT could contribute to malnutrition associated with CKD through an increase in thermogenesis and REE. Further works are needed to decipher the molecular determinants of the browning associated with CKD.**

TH-PO415

Oral NaHCO3 Activates the Splenic Anti-Inflammatory Pathway Promoting M2-Macrophage Polarization Paul O'Connor, Babak Baban, Sarah C. Ray, Matthew Tucker, Ryan A. Harris. *Augusta University, Augusta, GA.*

Background: Oral sodium bicarbonate ($NaHCO_3$) may slow decline in kidney function in CKD, yet the mechanisms mediating this beneficial effect remain unclear. In the current study we tested the hypothesis that oral $NaHCO_3$ intake promotes anti-inflammatory-M2 macrophage polarization by activating the splenic anti-inflammatory pathway in both rats and humans.

Methods: 8-10 week old male Sprague Dawley rats maintained on a standard pellet diet with water *ad libitum* were utilized. To determine the effect of oral $NaHCO_3$ on macrophage polarization, drinking water was replaced with solutions of $NaHCO_3$ in tap water containing (0, 0.01, 0.05 or 0.1M $NaHCO_3$; n=3 per treatment group) with all solutions made equimolar (0.1M) with the addition of NaCl. Following 4 days of drinking $NaHCO_3$, rats were anesthetized, the left kidney and spleen harvested and prepared for flow cytometry analysis. In a separate study, 7 healthy volunteers were given a single dose of $NaHCO_3$ following an overnight fast. Venous blood was drawn for flow cytometry analysis, at baseline and 1 and 2 hours following ingestion of 2g of $NaHCO_3$ in 250 ml of bottled water.

Results: We found that addition of $NaHCO_3$ to the drinking water of rats resulted in a dose dependent increase in renal macrophage polarization away from an M1 (inflammatory) and toward an M2 (anti-inflammatory) phenotype with as little as 3 days of drinking 0.01M $NaHCO_3$ solution (P_{DOSE}=0.02). Most of the polarization effect could be attributed to an increase in renal M2 macrophages, with the % of renal cells identified as M2's increasing from 2% to 8% at the highest dose of $NaHCO_3$ (0.1M; P_{DOSE}=0.006). The effect of 0.1M $NaHCO_3$ on renal macrophage polarization was confirmed in a separate group of rats (n=5/5; P=0.007) and was abolished with prior splenectomy. In human blood, T-cells were reduced from 15.6±0.8 at baseline to 13.0±0.8% of all leukocytes at 2 hours post $NaHCO_3$ ingestion; (P=0.01). Inflammatory cells, M1 macrophages (P=0.054) and Th17+ cells (P=0.06), tended to decrease, whereas, M2 macrophages tended to increase from 48.4±1.2 at baseline to 50.9±0.4% of all macrophages 2 hours post $NaHCO_3$ (p=0.054).

Conclusions: Our data indicate that oral $NaHCO_3$ may activate the splenic anti-inflammatory pathway in rats and humans. Activation of these pathways may underlie part of the beneficial effects of $NaHCO_3$ observed in CKD patients.

TH-PO416

Expression of T Regulatory Cells in the Kidneys of Guanylyl Cyclase/Natriuretic Peptide Receptor-A Gene-Knockout Mice Venkateswara R. Gogulamudi, Umadevi Subramanian, Kailash N. Pandey. *Department of Physiology, Tulane University Health Sciences Center, School of Medicie, New Orleans, LA.*

Background: Background: Guanylyl cyclase/natriuretic peptide receptor-A (GC-A/NPRA) gene (*Npr1*) disruption activates the pro-inflammatory responses in null mutant mice. There is increasing evidence that imbalanced immune responses play important role in physiological changes and complications of hypertension leading to organ damage. T Regulatory cells are defined as vital immune cellular population and they are likely to aid in immune tolerance by dampening the harmful effects of the other immune cellular population. The objective of our study was to elucidate the role of T regulatory cell markers and their expression levels in *Npr1* gene-disrupted mice.

Methods: Methods: In the present study, 0-copy (*Npr1*$^{-/-}$), 1-copy (*Npr1*$^{+/-}$), and 2-copy (*Npr1*$^{+/+}$) mice were pre-treated with rapamycin (2mg/kg/day) for 14 days. Spleen was collected, T cells were pre-enriched from spleen by using magnetic separation columns, and phenotypic expression of T regulatory subsets ($Foxp3^+$, $CD25^+$ and $CD4^+$) were determined by flow cytometry.

Results: Results: The *Npr1* gene-disrupted mice displayed the significant reduction of $Foxp3^+$ expression in 0-copy (77.5%) and 1-copy (71.5%) mice compared with 2-copy wild-type mice. Similarly, $CD25^+$ expression was reduced in 0-copy (75%) and in 1-copy (60%) mice compared with wild-type controls. In contrast, the total $CD4^+$ count was potentially up-regulated by 40% in 0-copy and 31% in 1-copy mice compared with 2-copy control mice. Treatment with rapamycin showed a substantial increase of $Foxp3^+$ cells by 17.38% (P<0.001) in 0-copy and 8.23 % (P<0.001) in 1-copy mice and $CD25^+$ T cells by 62.2% (P<0.001) in 0-copy and 38.1 % (P<0.001) in 1-copy mice.

Conclusions: Conclusions: The present results demonstrate that plummeting levels of T regulatory cells in *Npr1* gene-disrupted 0-copy and 1-copy mice provoke inflammatory responses in the kidney compared with wild-type mice. The treatment of 0-copy and 1-copy mice with rapamycin renders elevation of Tregs, suggesting the potential roles of *Npr1* in down-regulation of pro- inflammatory renal immune conditions.

TH-PO417

Tissue-Type Plasminogen Activator Modulates Macrophage M2 to M1 Phenotypic Change through Annexin A2-Mediated NF-κB Pathway Ling Lin, Kebin Hu. *Penn State University College of Medicine, Hershey, PA.*

Background: Macrophage accumulation is one of the hallmarks of progressive kidney disease. In response to injury, macrophages undergo a phenotypic polarization to become two functionally distinct subsets: M1 and M2 macrophages. Macrophage polarization is a dynamic process, and recent work indicates that macrophages, in response to kidney injury, can shift their polarity. However, the underlying mechanisms remain largely unknown. Tissue-type plasminogen activator (tPA), a protease up-regulated in the chronically injured kidneys, has been shown to preferably promote M1 macrophage accumulation and renal inflammation. We hypothesized that tPA may be an endogenous factor that modulates macrophage M2 to M1 phenotypic change contributing to the accumulation of M1 macrophages in the injured kidneys.

Methods: We used integral *in vivo* and *in vitro* approaches to investigate the role of tPA in macrophage polarity shift, and clarified the underlying signaling mechanim.

Results: It was found that obstruction-induced renal M1 chemokine expression was alleviated in tPA knockout mice, and these knockout mice displayed increased M2 markers. *In vitro*, resting J774 macrophages were treated with IL-4 to induce M2 phenotype as indicated by de novo expression of arginase 1, Ym1, and IL-10, as well as suppression of iNOS, TNF-α, and IL-1β. Intriguingly, these IL-4-induced M2 macrophages, after tPA treatment, not only lost their M2 markers such as arginase 1, Ym1, and IL-10, but also displayed increased M1 chemokines including iNOS, TNF-α, and IL-1β. Possible endotoxin contamination was also excluded as heat-inactivated tPA lost its effect. Additionally, tPA-mediated macrophage M2 to M1 phenotypic change required its receptor annexin A2, and SN50, a specific NF-κB inhibitor, abolished tPA's effect.

Conclusions: It's clear that tPA promotes macrophage M2 to M1 phenotypic change through annexin A2-mediated NF-κB pathway.

Rubicon Deficiency Leads to Obesity by Promoting Excessive Lipid Efflux in Proximal Tubular Epithelial Cells Jun Matsuda,[4] Atsushi Takahashi,[5] Yoshitsugu Takabatake,[4] Takeshi Yamamoto,[4] Tomonori Kimura,[2] Tomoko Namba,[4] Satoshi Minami,[3] Shinsuke Sakai,[2] Ryuta Fujimura,[1] Jun-Ya Kaimori,[4] Isao Matsui,[4] Fumio Niimura,[6] Taiji Matsusaka,[6] Yoshitaka Isaka.[4] *[1]Osaka University Graduate School of Medicine, Suita, Japan; [2]Osaka University Graduate School of Medicine, Suita, Japan; [3]Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [4]Osaka University Graduate School of Medicine, Suita, Japan; [5]Osaka University Graduate School of Medicine, Suita, Japan; [6]Tokai University School of Medicine, Isehara, Japan.*

Background: Autophagy is a lysosomal degradation system which contributes to maintain nutritional status. It has been known that Rubicon (Run domain Beclin-1 interacting and cysteine-rich containing protein) negatively regulates autophagic activity by inhibiting the fusion of autophagosomes and lysosomes. However, its physiological role in proximal tubular epithelial cells (PTECs) remains poorly understood.

Methods: We analyzed the phenotype of newly generated PTEC-specific Rubicon-deficient mice (KO mice). We crossed KO mice with GFP-MAP1LC3 transgenic mice, in which GFP-positive puncta reflect autophagosomes, and evaluated autophagic flux by comparing the number of GFP-positive dots with or without chloroquine administration. We finally investigated the role of Rubicon in lipid metabolism using isolated Rubicon-deficient PTECs.

Results: The number of autophagosomes was increased after chloroquine administration even during the fed state in the PTECs of 3-month-old KO mice, indicating sustained high autophagic flux. When fed standard mouse chow, KO mice began to exhibit a significant increase in body weight compared with controls after the age of 4 months (12-month-old KO mice: 45.9 ± 5.2 kg vs controls: 38.5 ± 6.8 kg, P<0.01). At 12 months of age, we observed a gain of weight in liver and adipose tissue, fatty liver, impaired glucose tolerance, and hypercholesterolemia. Immunohistochemical and electron microscopic analysis revealed expanded lysosomes containing multi-layered phospholipids in the PTECs of 12-month-old KO mice. Isolated Rubicon-deficient (KO) and wildtype (WT) PTECs were loaded oleic acid (OA)-bound albumin to induce the formation of lipid droplets (LDs). Rubicon KO PTECs showed more rapid degradation of LDs compared with WT PTECs. Furthermore, cultured hepatocytes (BNL-CL2 cells) exhibited a significant increase in LD formation when co-cultured with OA-loaded KO PTECs compared with OA-loaded WT PTECs. These results suggest an accelerated lipid efflux from KO PTECs to blood circulation.

Conclusions: Rubicon deficiency in PTECs leads to systemic lipid accumulation and obesity by promoting excessive lipid efflux. Rubicon in PTECs can be a therapeutic target for metabolic syndrome.

TH-PO419

Knockdown of Ugcg Induces Kidney Autoimmune Disease Tess Dupre,[6] Cierra Sharp,[6] Mark A. Doll,[6] Ying Sun,[2] Judit Megyesi,[5] Levi J. Beverly,[4] Tamara Nowling,[3] Deanna L. Davis,[7] Leah J. Siskind,[6] Richard R. Drake,[3] Wujuan Zhang.[1] *[1]CCHMC, Cincinnati, OH; [2]Cincinnati Children's Hospital, Cincinnati, OH; [3]Medical University of South Carolina, Charleston, SC; [4]University Of Louisville, Louisville, KY; [5]University of Arkansas for Medical Science, Little Rock, AR; [6]University of Louisville, Louisville, KY; [7]Virginia Commonwealth University, Richmond, VA.*

Background: Glycosphingolipids (GSLs) play a role in autoimmune kidney diseases, including lupus nephritis. Autoimmune kidney diseases are associated with chronic inflammation and recruitment of immune cells into the kidney. N-glycans play a role in regulating inflammatory pathways in autoimmune diseases. Importantly, data in the literature suggest interplay between GSL and N-glycan biosynthetic pathways that may be important in regulating inflammatory responses.

Methods: We generated transgenic mice containing an inducible shRNA that targets expression of Ugcg (Tet-O-shUgcg). Ugcg is the gene that encodes for glucosylceramide synthase, the enzyme that catalyzes synthesis of glucosylceramide from ceramide. Tet-O-shUgcg mice were bred with $CAG^{+/-}$rtTA3 mice (CAG-rtTA3-Tet-O-shUgcg) for universal expression of the shRNA in the presence of doxycyline.

Results: Following Ugcg knockdown (KD), organized accumulations of $CD19^+$ B cells and $CD3^+$ T cells formed in the kidneys, which are defining features of tertiary lymphoid organs (TLOs). TLOs are ectopic accumulations of lymphoid cells that can arise in areas of chronic inflammation via lymphoid neogenesis. Data indicate that knockdown of Ugcg in kidney results in significant increases in levels of biantennary N-glycans relative to control, and decreases in branched multi-fucosylated glycans normally present in control kidneys. KD of Ugcg increases serum levels of total IgG and IgA.

Conclusions: KD of Ugcg alters N-glycan signatures in the kidney, induces TLO formation, and autoimmunity. This transgenic mouse model is novel tool for studying the role of GSLs and N-glycans in kidney inflammation and autoimmunity and may represent a new mouse model of autoimmune kidney disease.

ACF-TEI, a Novel Oral Adsorbent, Shows Potent Adsorption Effect on Uremic Toxin in the Rat Model and the System Mimicked Human Gastrointestinal Tract

Hiroshi Shimoyama,[1] Yasumi Nishiwaki,[1] Takashi Murakami,[2] Yoshimasa Takahashi,[1] Tsunefumi Kobayashi.[1] *[1]Pharmacology Research Department, Teijin Institute for Bio-Medical Research, Teijin Pharma Limited, Tokyo, Japan; [2]Pharmaceutical Discovery Research Laboratories, Teijin Institute for Bio-Medical Research, Teijin Pharma Limited, Tokyo, Japan.*

Background: Uremic toxins (UTs), such as indoxyl sulfate (IS) and *p*-cresyl sulfate (PCS), accumulate in the blood of patients with impaired renal function. Since several studies have demonstrated a link between serum UTs levels and clinical outcomes, they draw much attention as key factors in the progression of chronic kidney diseases (CKDs) and cardiovascular diseases. Thus, adsorbing UTs in the intestinal tract and excreting with feces is effective for inhibiting the progression of CKDs and delaying the introduction of dialysis treatment. We have identified a novel oral UTs adsorbent, ACF-TEI, which has more potent adsorption profiles to UTs than existing adsorbents. In this study, we examined *in vitro* adsorption capacities of ACF-TEI to several UTs and the reducing effect of ACF-TEI on serum UTs in CKD model rats. In addition, to estimate the effectiveness of ACF-TEI in human, we evaluated the effect of ACF-TEI on UT adsorption in a system that mimicked human gastrointestinal (GI) tract.

Methods: ACF-TEI was mixed with solutions of indole, the precursor of IS produced by enterobacteria, or other UTs and reacted, then the adsorption capacity was calculated. ACF-TEI was administered orally to bilateral nephrectomized rats, and then concentrations of serum IS and PCS were measured. Adsorption of indole in the human GI tract was estimated using dynamic multi-compartmental GI tract model.

Results: ACF-TEI showed higher adsorption capacity to indole and other UTs than existing adsorbent. In the bilateral nephrectomized rats, ACF-TEI dose-dependently reduced serum IS and PCS levels and the effects were more potent than the existing adsorbents. In the dynamic multi-compartmental GI tract model, ACF-TEI reduced colonic indole concentration at lower doses than the existing adsorbents.

Conclusions: ACF-TEI adsorbed various UTs and showed the potent effects not only in the rodent model but also in the human GI tract mimicked system. Therefore, in clinical, ACF-TEI is expected to show potent UTs reducing effect and to be beneficial for patients with CKDs.

Gut Microbiota-Dependent Trimethylamine-N-Oxide and Inflammatory Biomarkers in Patients with Diabetic Nephropathy

Mohammed A. Al-Obaide, Ruchi Singh, Palika Datta, Maria V. Salguero, Tetyana L. Vasylyeva. *Texas Tech University Health Sciences Center, Amarillo, TX.*

Background: Trimethylamine N-oxide (TMAO) is a product of diet, gut microbiome, and tissues metabolism. Elevated TMAO levels associated with heart attack, stroke and chronic kidney disease (CKD). We investigated the gut microbiome composition and TMAO levels in the serum of patients with type 2 diabetes mellitus (T2DM) and advanced stages of diabetic nephropathy (DN); and TMAO association with serum IL-6, TNFα, CRP, ET-1, LPS, and zonulin.

Methods: Twenty adult patients with T2DN and CKD 3-4 secondary to DN and 20 healthy subjects (HS) participated in the study. The analysis included: nutrition, metabolic parameters, trimethylamine (TMA) producing gut microbiota, and TMAO, LPS, zonulin and serum biomarkers of inflammation and endothelial dysfunction. The gut microbiota diversity identified by amplified V5-V6 region of the 16S ribosomal RNA (rRNA) genes and DNA sequencing by the MiSeq (Illumina Inc., San Diego, CA) using a 600 cycle v3 sequencing kit. The TMAO quantified by LC/MS method and serum biomarkers by ELISA.

Results: Dietary analysis showed that patients with T2DM and DN consumed less protein and more fat compared to HS and had more than two-fold elevated levels of triglycerides. The gut microbiome in DN patients exhibited a higher abundance of TMA-producing bacteria, $p < 0.05$. The serum level of TMAO in patients with DN was significantly higher (2.7 ± 0.52 μg/ml) compared to HS (0.43 ± 0.1 μg/ml), $p < 0.05$. The IL-6 and ET-1 also showed higher levels in the DN patients and positive correlation with TMAO. A positive correlation also observed between zonulin and LPS in both DN and HS groups.

Conclusions: Gut microbiota in patients' with T2DM-CKD has increased abundance of TMA-producing bacteria, which together with excessive dietary TMAO and increased gut permeability possess substantial risk for cardiovascular health through increased level of chronic inflammation and endothelial dysfunction. The pilot study findings are worth perusing further evaluation.

Homocysteine Aggravates Intestinal Permeability Increase and Tight Junction Destruction In Vivo and In Vitro

Shanshan Liang, Hongli Jiang. *Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi?an, China.*

Background: Intestinal injury is a common complication of uremia. Homocysteine (Hcy), as an important intestinal derived uremic toxin and pro-inflammatory molecule, whether it is involved in the increased intestinal permeability and epithelial barrier dysfunction in uremia remains unclear. This study aimed to investigate the effect of Hcy on intestinal epithelial in vitro and in vivo.

Methods: In vitro experiment, Caco2 cells were seeded on transwell plates and utilized when transepithelial electrical resistance (TEER) exceeded 500Ω*cm^2 to ensure full polarization and TJ formation. Cells were then incubated with Hcy (0.5 to 5.0mmol/L) for 24h. Paracellular permeability was determined by TEER and the fluorescent Lucifer yellow dye (FLY) flux across cell monolayers. In vivo experiment, SD rats were divided into control, uremia (induced by adenine) and uremia + vitamin B compounds (folate, vitamin B6 and B12) group. Serum Hcy levels, colon homogenate of Hcy, inflammatory factors (CRP, IL-6 and TNF-α), SOD, MDA, endotoxin and intestinal permeability were assessed. H&E and transmission electron microscopy were used for pathological analysis. TJ proteins of claudin-1, occludin, and ZO-1 were assessed by western blot.

Results: Fig.1 showed the TEER changes of Caco-2 cells during 21 days and the decreased TEER as well as the gradually increased FLY flux rates after Hcy incubation. Hcy down regulates TJ protein abundance in a concentration-dependent manner (Fig 4A), which was accompanied with the increased epithelial permeability. In animal experiments, uremia group showed elevated Hcy levels, oxidized inflammatory factors and intestinal permeability (Fig 2). The pathological changes of colon were obviously observed (Fig 3) with TJ protein levels decreased (Fig 4B). Fortunately, these parameters were improved in varying degrees after vitamin B compounds treatment.

Conclusions: Hcy aggravates intestinal permeability increase and epithelial barrier destruction by stimulating oxidative inflammatory damage. Supplementation of folate, vitamin B6 and B12 can improve the damage to some extent by reducing Hcy.

Inhibition of Glycolysis Attenuates Ischemia-Reperfusion Injury via Metabolic and Redox Changes in Proximal Tubular Cells

Akinari Shinohara, Takahisa Kawakami, Masaomi Nangaku. *Division of Nephrology and Endocrinology, The University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Proximal tubular cells utilize fatty acid oxidation (FAO) more than glycolysis for ATP production in the physiological state. However, it remains largely unknown whether their metabolism affects pathophysiology of renal diseases. In this study, we investigated effects of glycolysis inhibition with 2DG, a representative glycolysis inhibitor, on murine renal ischemia-reperfusion injury (IRI), to which proximal tubular cell (PTC) injury by oxidative stress is central.

Methods: Eight-week-old male C57BL/6J mice were treated with 500 mg/kg 2DG or vehicle by i.p. 24 hours before bilateral IR, and renal injury was evaluated on day 1. We also examined effects of 2DG on PTCs, using HK-2 in vitro. HK-2 cells were treated with 5 mM 2DG for 6 hours and exposed to oxidative stress with 4 mM hydrogen peroxide. Cytotoxicity was measured with generation of reactive oxygen species (ROS) assessed by flow cytometry using dihydroethidium and LDH assay.

Results: Glycolysis inhibition by 2DG ameliorated renal dysfunction on day 1: serum creatinine was 1.4 ± 0.4 mg/dL in the vehicle group and 0.9 ± 0.1 mg/dL in the 2DG group. The reduced IRI was also demonstrated by a decrease in histological tubular injury score and mRNA expression of Kim-1 in the 2DG group. 2DG-preconditioned kidney cortex showed far less phospho-AMPK in immunoblot, indicating increased ATP in PTCs, which can suppress cell injury and death in IRI. We investigated its mechanism and found that

2DG increased free fatty acid in serum and PPARα expression in the kidney, suggesting that activated FAO promoted ATP production in PTCs. In vitro, treatment with 2DG suppressed generation of ROS and cell death. We focused on pentose phosphorylation pathway (PPP), because glycolysis inhibition can promote PPP as a bypass of glucose metabolism, and its key function is generation of reducing equivalents of NADPH. Indeed, PPP enzymes, including glucose-6-phosphate dehydrogenase and transketolase, were up-regulated, and NADPH/NADP ratio was increased by 2DG. We also found that glutathione peroxidases, key antioxidative enzymes, were induced by 2DG.

Conclusions: In conclusion, glycolysis inhibition ameliorated renal IRI via an ATP increase by enhanced FAO and a favorable redox state by promoted PPP in PTCs, implicating the importance of PTC metabolism in renal diseases.

Combined Treatment with Cholecalciferol and Omega-3 Fatty Acid Modulates Molecules Associated with Sarcopenia and Cardiac Hypertrophy in 5/6 Nephrectomy Rats

Hyuck jae Choi,[4] Su mi Lee,[5] Sung Hyun Son,[1] Kitae Kim,[4] Young ki Son,[2] Seong Eun Kim,[3] Won Suk An.[2]
[1]BHS Han Seo Hospital, Suyeong-gu, Busan, Republic of Korea; [2]Dong-A University, Busan, Republic of Korea; [3]Dong-A University Hospital, Busan, Republic of Korea; [4]Dong-A university hospital, Pusan, Republic of Korea; [5]Seoul National University Hospital, Seoul, SEOUL, Republic of Korea.

Background: Cardiac hypertrophy and sarcopenia are common in dialysis patients and result in high probability for morbidity and mortality. Akt-mTOR axis is related with cardiac hypertrophy and muscle atrophy. The present study aimed to investigate whether omega-3 fatty acid (O-3FA) and cholecalciferol (Vit. D) affect on molecules associated with cardiac hypertrophy and sarcopenia in 5/6 Nx. rats.

Methods: Male Sprague Dawley rats were divided into 5 groups and treated for 6 weeks: sham control, 5/6 subtotal Nx control, 5/6 Nx treated with Vit.D, 5/6 Nx treated with O-3 FA, 5/6 Nx treated with Vit. D and O-3 FA. The expression of myostatin, myogenin, MyoD, Akt, phosphrylated(p) Akt and mTOR were examined by western blot analysis.

Results: Serum BUN and creatinine were the lowest in 5/6 Nx group treated with O-3 FA and Vit. D among other 5/6 Nx groups. Compared with sham control, 5/6 Nx control significantly up-regulated myostatin and down-regulated myogenin and MyoD in both cardiac and skeletal muscle. Increased expression of myostatin and decreased expression of myogenin and MyoD of cardiac and skeletal muscle were recovered by combined treatment with O-3 FA and Vit. D. Phosphorylated Akt and mTOR were up-regulated in the cardiac muscle but down-regulated in the skeletal muscle of 5/6 Nx control compared to sham control. Combined therapy of O-3 FA and Vit. D decreased p-Akt and mTOR expression in cardiac muscle and increased p-Akt and mTOR expression in skeletal muscle of 5/6 Nx rats.

Conclusions: Combined therapy of O-3 FA and Vit. D may be helpful for decreasing cardiac hypertrophy and sarcopenia by increasing myogenin and MyoD, decreasing myostatin and modulating Akt-mTOR axis in both cardiac and skeletal muscle of 5/6 Nx rats.

Funding: Private Foundation Support

TH-PO425

Combination of Cholecalciferol and Omega-3 Fatty Acid Increases 1, 25 Dihydroxy Vitamin D Level by Inhibiting 24-Hydroxylase of Kidney and Liver in 5/6 Nephrectomized Rats

Su mi Lee,[2] Hyuck jae Choi,[2] Kitae Kim,[1] Sung Hyun Son,[1] Young ki Son,[2] Seong Eun Kim,[2] Won Suk An.[2] *[1]BHS Han Seo Hospital, Busan, Republic of Korea; [2]Department of Internal Medicine, Dong-A University, Busan, Not Applicable, Republic of Korea.*

Background: The 1α-hydroxylase (CYP27b1) and 24-hydroxylase (CYP24) in renal proximal tubules primarily involve vitamin D metabolsim. Increased activity of CYP24 contributes vitamin D metabolism in chronic kidney disease (CKD). Recent reports showed that CYP27b1 was strongly expressed in monocytes developing into hepatic macrophages and omega-3 fatty acid (FA) elevated 1, 25-dihydroxy vitamin D level in dialysis patients with scanty renal function. In this study, we evaluated whether the effect of omega-3 FA and cholecalciferol on vitamin D metabolism are related with the activity of CYP27b1 and CYP24 in liver and kidney of 5/6 nephrectomy (Nx) rat model.

Methods: Male Sprague Dawley rats were divided into five groups and treated for 6 weeks: sham control (0.9% saline), 5/6 Nx control (0.9% saline), 5/6 Nx treated with vitamin D (cholecalciferol 3000 IU/kg/week by gastric gavage), 5/6 Nx treated with omega-3 FA (300 mg/kg/day by gastric gavage), 5/6 Nx treated with vitamin D and omega-3 FA. CYP27b1 and CYP24 in remnant kidney and liver were measured by western blot analysis.

Results: Serum BUN and creatinine were the lowest in 5/6 Nx group treated with omega-3 FA and vitamin D among other 5/6 Nx groups. The levels of serum 1, 25-dihydroxy vitamin D and 25-hydroxy vitamin D were the highest in 5/6 Nx group treated with omega-3 FA and vitamin D among other 5/6 Nx groups. The expression of CYP24 was significantly increased in remnant kidney and liver of 5/6 Nx control compared to sham control. Increased expression of CYP24 in remnant kidney and liver of 5/6 Nx control was significantly decreased by combined treatment with omega-3 FA and cholecalciferol. The expression of CYP27b1 was significantly increased in remnant kidney and significantly decreased in liver of 5/6 Nx control compared to sham control. The increased expression of CYP27b1 in remnant kidney and decreased expression of CYP27b1 in liver of 5/6 Nx control was nearly normalized by combined treatment with omega-3 FA and vitamin D.

Conclusions: Combined treatment with omega-3 FA and cholecalciferol definitely increases 1, 25-dihydroxy vitamin D level by inhibiting expression of 24-hydroxylase in remnant kidney and liver and activating expression of 1 α-hydroxylase in liver of 5/6 Nx rats.

TH-PO426

Correlation between Vitamin D Deficiency and Hematuria: Korean National Health and Nutrition Examination Survey

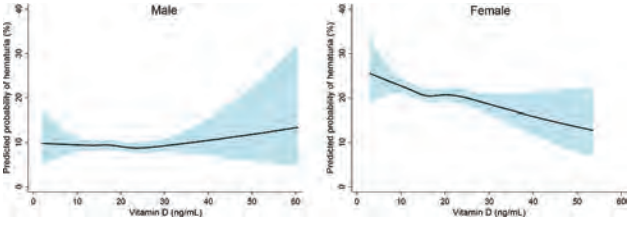
Hyunjin Ryu,[1] Young Lee Jung,[1] Yaerim Kim,[1] Cheolgu Hwang,[1] Jae shin Choi,[1] Dong Ki Kim,[1] Yun Kyu Oh,[2] Kwon Wook Joo,[1] Yon Su Kim,[1] Seung Seok Han.[1] *[1]Seoul National University Hospital, JongNo-Gu, Seoul, Republic of Korea; [2]Department of Internal Medicine, Boramae Medical Center, Seoul, Republic of Korea.*

Background: Vitamin D deficiency is an important health concern because it is related with several comorbidities and mortality. However, its relationship with the risk of hematuria remains undetermined in the general population.

Methods: Cross-sectional analysis was applied to the subjects (n=20,240, aged ≥18 years old) using Korean National Health and Nutrition Examination Survey (KNHANES) 2010–2014. Serum 25-hydroxyvitamin D [25(OH)] levels were measured in a central laboratory and hematuria was defined as ≥1+ on a dipstick test. Multivariate logistic regression was conducted to calculate the odds ratio (OR) of hematuria risk according to the 25(OH)D quartiles, after adjusting 10 covariates, such as comorbidities and laboratory findings.

Results: Of study subjects, 10,847 (53.6%) were female and 5,388 (26.6%) were identified as menopause. The mean age and estimated glomerular filtration rates were 49±16.3 year old and 88±17.4 mL/min/1.73m^2, respectively. The number of subjects with hematuria was 3,144 (15.5%). The mean 25(OH)D level was 17.4±6.2 ng/ml [median, 16.6 ng/ml (interquartile range, 13.1–20.8 ng/ml)]. The 3rd and 4th quartiles had a higher risk of hematuria than the 1st quartile, as following adjusted ORs; 1.1 (1.02-1.29) and 1.3 (1.12-1.42) in the 3rd and 4th quartiles, respectively. However, this relationship was only significant in the female subjects, not in the male subjects [Figure]. Subsequent analyses were stratified according to the menopausal status. For the premenopausal females, there was no significant increase of hematuria risk according to the quartiles. However, for the postmenopausal females, the increased risk of hematuria was shown in all the higher quartiles, compared with the 1st quartile.

Conclusions: Vitamin D deficiency was correlated with hematuria in female subjects, particularly after menopause. Further interventional studies are warranted to address whether the correction of vitamin D deficiency lowers the hematuria risk.



TH-PO427

Restriction of Both P and Caloric Intake Decrease Renal Damage Induced by Cafeteria-Style Diet

Ignacio Lopez,[1] Paula Esquinas,[3] Rafael Rios-Varo,[1] Carmen Pineda,[1] Ana isabel Raya bermudez,[1] Mariano Rodriguez,[2] Escolastico Aguilera-tejero.[1] *[1]Animal Medicine and Surgery, University of Cordoba, Cordoba, Spain; [2]Hospital Universitario Reina Sofia, Cordoba, Spain; [3]Universidad Nacional de Colombia, Bogota, Colombia.*

Background: Energy dense diets, which also tend to be rich in P (cafeteria-style diets), are associated to metabolic syndrome, diabetes and kidney disease. In this study, renal damage after feeding a diet rich in P and calories was investigated. In addition, the influence of P and caloric intake restriction on renal pathology was assessed.

Methods: Wistar rats (n=32) were divided in 4 groups (n=8) and fed either: normocaloric (3518 kcal/kg) with normal P (0.6%) diet (NC-NP), hypercaloric (5241 kcal/kg) with high P (1.2%) diet (HC-HP), HC with low P (0.2%) diet (HC-LP), and hypocaloric (1314 kcal/kg) with HP diet (hC-HP). After 210 days, renal tissue was obtained and processed for optical (OM) and electronic microscopy (TEM). Lesions were

graduated with a semi-quantitative scale of 0-3: 0 (absent), 1 (mild), 2 (moderate) and 3 (severe) or in percentage.

Results: The table 1 shows OM scores. Feeding HC-HP diet resulted in significant renal lesions. Both P and caloric restriction attenuated renal damage. P restriction was more effective at preventing nephrocalcinosis while caloric restriction was more effective at preventing glomerular damage. Ultrastructurally, TEM lesions correlated to OM lesions. The main alterations observed in the HC-HP group by TEM were: hyperactivity of the epithelial and mesangial cells, capillary remodeling, tubular atrophic changes and increased fibroblast and cell inflammatory activity. These lesions were attenuated in the HC-LP and hC-HP groups.

Conclusions: In conclusion, the results suggest a synergistic deleterious effect of high caloric and high phosphorus intake on the kidney. Both P and caloric restriction can attenuate renal damage although their influence on renal pathology show differential characteristics.

Values are mean ±SE; a,b,c For each parameter, data with different superscripts are significantly ($P < 0.05$) different between diets.

TH-PO428

Calciprotein Particle Contributes to the Synthesis and Secretion of Fibroblast Growth Factor 23 Induced by Dietary Phosphate Intake Kenichi Akiyama.[1,2] *[1]Tokyo Women's Medical University, Tokyo, Japan; [2]Center for Molecular Medicine, Jichi Medical University, Shimotsuke, Japan.*

Background: It has been reported that the synthesis and secretion of fibroblast growth factor 23 (FGF23) induced by phosphate also require calcium. However this mechanism is still unclear. Highly concentrated phosphate and calcium are crystallized and formed calciprotein particle (CPP) with some proteins including fetuin-A in extracellular fluid. CPP is considered the pathogenesis of some complications such as an inflammatory response in chronic kidney disease. The role of CPP on the synthesis and secretion of FGF23 was investigated.

Methods: Rat osteoblastic cell line (UMR-106 cell) was treated by various dose of phosphate or artificially made CPP for 4 and 24 hours. Protein level of FGF23 in the medium and mRNA expression level of FGF23 were analyzed. Serum phosphate, FGF23 and CPP levels and FGF23 mRNA expression level in cranial bone were also evaluated in C57BL/6J mice 2 and 6 hours after phosphate administration using a feeding tube and 10 days after switching to the high phosphate diet.

Results: Both phosphate and artificial CPP treatments for 4 and 24 hours significantly increased FGF23 protein level in the medium of UMR-106 cell at dose-dependent manner. The upregulation of FGF23 mRNA expression level was observed only 24 hours after both treatments. The supplementation of citrate as an inhibitor of CPP formation canceled all of these findings. The significant increases of serum CPP and serum FGF23 levels compared with control treatment were observed 2 and 6 hours, respectively after the gavage of phosphate. However FGF23 mRNA expression level in cranial bone did not change in these mice. Significant increases of serum phosphate, CPP and FGF23 levels and upregulation of FGF23 mRNA expression level in cranial bone were confirmed in mice fed high phosphate diet for 10 days.

Conclusions: These findings suggest CPP but not phosphate itself might be contributing to the dietary phosphate-induced both postprandial secretion and sustained high level of serum FGF23 level.

TH-PO429

In Vivo Responses of Phosphorus-Based Food Additives with Different Forms Toru Fujii, Yuka Kawabata, Hiroko Segawa, Ai Hanazaki, Kayo Ikuta, Aoi Kushi, Ichiro Kaneko, Sawako Tatsumi, Ken-ichi Miyamoto. *Tokushima University, Tokushima, Japan.*

Background: Hyperphosphatemia causes hyperparathyroidism and ectopic calcification in patients with chronic kidney disease, and dietary management for blood phosphate levels in patients with kidney disease is considered to be important. Both organic and inorganic phosphorus (Pi) are present in regularly consumed foods, such as eggs, and daily products. Pi is included in foods as an additive. Phosphorus-containing food additives were included with several forms (mono/polyphosphate-salt e.t.c.). In the small intestine, the luminal mono-phosphate can be available for absorption following ingestion of a food. Previous report suggested that polyphosphate salt have more harmful effects than those of monophosphate salt on bone physiology and renal function. The mechanism, however, has not been clarified. Recent studies suggested the presence of an gastro-renal signaling axis for dietary Pi as well as the existence of a mechanisms of intestinal Pi sensing, however, unknown. We focused that different forms of phosphorus-containing food additives have different effects in the body. In the present study, to clarify the mechanism, we investigated several responses of diet containing mono or polyphosphate on whole body.

Methods: C57B6 male mice were fed a test diet (low Pi diet, control Pi diet, high Pi diet 1 and 2) for short, middle and long periods. KH2PO4 (CP and HP1), and K5P3O10 (HP2) were used for phosphate additives.

Results: There were remarkable differences on blood, fecal, and urine biochemical analysis data between HP1 and HP2 diet group. Though HP1 and HP2 diet significantly increased inflammatory markers mRNA levels in several tissues, only HP2 diet increased fibrosis marker mRNA level in the kidney, urinary volume, and renal calcification. To identify the different response between HP1 and HP2 diet, renal and intestinal Pi regulating factors expression and activity were examined. There were no significantly differences on renal Pi regulating molecules between HP1 and HP2. However, we found differences on several intestinal molecules expression and activity levels between HP1 and HP2.

Conclusions: Intestine might detects difference luminal monophosphate and triphosphate form. It is necessary to consider about not only the phosphorus content but also the form of the phosphorus-containing food additives.

TH-PO430

Narrowing the Phosphate Divide: A Comparison between UK and Chinese Haemodialysis Patients Yan Song,[1] Patrick J. Highton,[2] Barbara P. Vogt,[3] Annabel Biruete,[4] Ken Wilund,[4] Alice C. Smith,[1] James Burton.[1] *[1]University of Leicester, Leicester, United Kingdom; [2]Loughborough University, Leicester, United Kingdom; [3]Universidade Estadual Paulista UNESP, Botucatu, Brazil; [4]University of Illinois, Urbana, IL.*

Background: Management of hyperphosphataemia requires a multi directional approach. Dietary restriction of phosphate (Ph) is often inadequate by itself; other strategies such as extended dialysis and Ph binders are often necessary. Designing an effective intervention to manage hyperphosphataemia, whilst balancing Ph restriction and maintaining adequate protein intake, requires a thorough understanding of dietary Ph. In addition, perception and habits related to dietary behaviour may be influenced by ethnicity and culture. The aim of the study was to contrast data about Ph intake on dialysis and non-dialysis days with haemodialysis (HD) patients from UK and China.

Methods: In this cross-sectional study, 24-hour diet recall interviews were undertaken with patients in UK and China during four normal dialysis sessions distributed evenly in two consecutive weeks. Patients were asked to recall food intake for the previous 24 hours on dialysis and non-dialysis days. Demographic and clinical data were collected from patients' medical records. Nutritics and China Food Composition were used as nutrition database for UK and Chinese dietary data respectively.

Results: A total of 83 patients were recruited (UK, n=40; China, n=43). The UK patients were older (56.8±16.1 vs. 42.4±9.1 years; P=0.001) with a higher body mass index (BMI) than the Chinese cohort (26.6±5.9 vs. 21.3±2.7 kg/m^2; P<0.001). Although energy intake was comparable between populations (UK, 25.3±1.5Kcal/kg/d; China, 23.0 ±1.3 kcal/kg/d, P=0.12), UK patients reported higher Ph intake on both dialysis (0.91g/d vs 0.72g/d, P=0.039) and non-dialysis days (0.90g/d vs. 0.73g/d, P=0.004) than their Chinese counterparts. Despite higher dietary intake, serum Ph levels in UK patients were lower compared to those in China (1.59±0.44 mmol/L vs 2.11±0.53 mmol/L, P<0.001). There was no difference in the number of patients prescribed Ph binders between two groups (UK, n=8; China, n=9, P=0.567).

Conclusions: Despite higher BMI and dietary intake, and with no difference in prescribed Ph binding medications, UK patients had lower serum Ph concentrations than their Chinese counterparts. Strategies to improve compliance with medications and increasing dialysis phosphate removal would have a greater impact on hyperphosphataemia than increased nutritional support in Chinese HD patients.

TH-PO431

Use of Urinary Metabolomics to Identify Potential Pathways Associated with Hyperuricemia in Hispanic Children: The Viva La Familia Study V. Saroja Voruganti,[7] Itzel Vazquez-Vidal,[4] Baba B. Mass,[6] Robert P. Mohney,[3] Nitesh R. Mehta,[2] Anthony G. Comuzzie,[5] Shelley A. Cole,[5] Nancy F. Butte.[1] *[1]Baylor Coll Medicine, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]Metabolon, Inc., Durham, NC; [4]Nutrition Research Institute, University of North Carolina at Chapel Hill, Kannapolis, NC; [5]Texas Biomedical Research Institute, San Antonio, TX; [6]UNIVERSITY OF NORTH CAROLINA AT CHAPEL HILL, CHARLOTTE, NC; [7]University of North Carolina at Chapel Hill, Kannapolis, NC.*

Background: Hyperuricemia (elevated serum uric acid) is associated with increased risk for gout, cardiovascular and kidney disease. Studies have shown hyperuricemia in children to be predictive of hypertension in adulthood. Our aim in this study was to identify urinary metabolites and pathways associated with hyperuricemia in a cross-sectional study of 260 Hispanic children from the Viva La Familia Study.

Methods: Urinary metabolomics profiling was conducted in 130 hyperuricemic and 130 normouricemic children using ultrahigh performance liquid chromatography mass spectroscopy. Hyperuricemia was characterized using upper most quartile of serum uric acid.

Results: A total of 703 urinary metabolites were identified, of which 377 metabolites were significantly different between the two groups. Key differences were found in amino acid, steroids and xenobiotics metabolic pathways, with 262 metabolites being higher in hyperuricemic than normouricemic group. Metabolites that were significantly higher in hyperuricemia group belonged to histidine (formimimoglutamate and methylhistidine), methionine (S-adenosylhomocysteine (SAH)), nicotinate and nicotinamide (nicotinamide

N-oxide and 1-metylnicotinamide), steroid (epiandrosterone glucuronide and cortisol glucuronide) and purine (1,3 dimethylurate and xanthosine) metabolic pathways. The metabolites that were significantly lower in hyperuricemia group were derivatives of glycine, serine, threonine, N-acetylglycine, N-acetylserine, glutamate and gamma-aminobutyrate, and xenobiotics (ferulate, caffeine acid sulfate, vanillate, saccharin, etc). Interestingly, xanthine oxidase, a key enzyme that catalyzes the conversion of xanthine to uric acid and nicotinamide N-oxide to nicotinamide, is also a major enzyme in xenobiotics metabolism. Elevated levels of formimimoglutamate indicate folate deficiency whereas folate is thought to inhibit xanthine oxidase.

Conclusions: Our global urinary metabolomics profiling not only revealed different pathways in hyperuricemic and normouricemic children, but also demonstrated a link between xanthine oxidase, xenobiotics and folate in hyperuricemia

TH-PO432

Targeted Metabolomics of Adolescent CKD Ellen Brooks,[1,5] Shannon Haymond,[2] Craig B. Langman,[1,5] Bradley A. Warady,[4] Susan L. Furth.[3] *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]The Children's Mercy Hospital, Kansas City, MO; [5]Kidney Disease, Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: Dysregulation of amino acids, biogenic amines, and phosphatidylcholines (PCs) have been described in advanced chronic kidney disease (CKD) in adults. Metabolic alterations related to oxidative stress and inflammation in children with mild to moderate CKD may have greater significance for risk of secondary morbidities since growth and development are not complete.

Methods: In this cross-sectional study, 2 CKD groups were matched for age and gender but had differing measured (*m*)GFR by iohexol clearance and CKD stage [n=20 per CKD group with 10 glomerular (G) and 10 non-glomerular (NG) disorder per group]. Targeted plasma metabolomics were completed at the Proteomics and Metabolomics Shared Resource, Duke University (Durham, NC) using the Biocrates Absolute*IDQ*® p180 panel-ultra-HPLC-tandem mass spectrometry and integrated software (Biocrates Life Sciences AG, Austria).

Results: The median (Md) and interquartile range (IQR) *m*GFR of the groups differed as planned: 74.3 (67.4, 82.9) CKD 2 vs. 32.8 (24.3, 35.5) ml/min/1.73m^2 CKD 3b ($p<0.001$) but age was similar 14.7 (11.7, 16.0) vs. 15.0 (12.7, 15.7) yrs. Plasma symmetric dimethylarginine (SDMA), creatinine, kynurenine (Kyn), sarcosine, trans-4-OH-proline, aspartic acid, alanine, and glycine were higher in CKD 3b (biogenic amines and amino acids p range=5.5E^{-7} to 0.04) but long chain PCs were lower (p=0.01-0.035). In CKD 3b, SDMA/asymmetric DMA, Kyn/tryptophan (tryp), and phenylalanine/tryp were higher (p=6.79E-7 to 4.4E-4), Kyn was greater in NG vs. G (p=0.009) and alanine was higher in G vs. NG (p=0.045).

Conclusions: The aberrant metabolic patterns in adolescents with CKD 3b infer augmented amino acid catabolism, including alanine via pyruvate and tryp via indoleamine 2,3-dioxygenase 1 (IDO-1). The Kyn pathway is upregulated by IDO-1 and -2 in acute/chronic infection to inhibit bacterial growth and amplify immunosuppression, which may occur in CKD 3b NG. The higher SDMA and SDMA/ADMA ratio are likely related to decreased GFR while PC derangement may be due to phospholipase A_2 increased mass and activity. Low plasma PCs can result from PC accumulation in LDLs and may signify increased cardiovascular risk, while CKD-MBD may be related to enhanced collagen turnover. Correlations with clinical and biochemical parameters will provide further evidence of altered metabolomic contributions to the excess morbidity of pediatric CKD.

TH-PO433

Systemic Oxalosis with Retinopathy Secondary to Vitamin C in a Patient on Peritoneal Dialysis Matthew R. D'Costa, Nelson S. Winkler, Dawn S. Milliner, Suzanne M. Norby, LaTonya J. Hickson, John C. Lieske. *Mayo Clinic, Rochester, MN.*

Background: We report a case of systemic oxalosis involving the eyes and joints due to long-term use of high-dose vitamin C in a peritoneal dialysis (PD) patient.

Methods: A 76-year-old female presented to the hospital with a 1-month history of decreasing vision and polyarthralgias. She had developed ESRD secondary to autosomal dominant polycystic kidney disease and underwent living unrelated kidney transplant 10 years earlier. Due to declining allograft function, biopsy was performed 1 year prior to admission revealing severe arteriosclerosis, focal segmental glomerulosclerosis, and early transplant glomerulopathy but no calcium oxalate (CaOx) crystals. She initiated hemodialysis (HD) 6 months later and transitioned to PD 2 months prior to admission. At presentation, ophthalmologic exam revealed crystalline retinopathy consistent with CaOx deposition. Fluorescein angiography demonstrated significant retinal non-perfusion, and optical coherence tomography showed hyperreflective deposits throughout the inner and outer retina. Plasma oxalate (POx) was markedly elevated at 187 μmol/L (normal < 1.7 μmol/L). Urine oxalate/creatinine ratio was high (0.18 mg/mg) while urine glycolate, glycerate and 4-hydroxy-2-oxoglutarate were normal. Genetic testing confirmed absence of pathogenic changes in *AGXT, GR/HPR* and *HOGA1*. Stool analysis did not suggest significant fat malabsorption and she had no previous gastrointestinal surgery, diarrhea, or other gastrointestinal symptoms. While excessive intake of high oxalate foods was not identified, she reported chronic use of high-dose vitamin C of up to 4 grams per day for many years. With discontinuation of vitamin C and nearly daily HD for 2 weeks, predialysis POx fell markedly to 30-50 μmol/L. Serial funduscopic examinations remained stable in the setting of mild improvement in visual acuity and marked improvement in joint pain. She was discharged on standard thrice weekly HD. Three months later, her most recent predialysis POx was 35.2 μmol/L.

Results:

Conclusions: This case demonstrates that *in vitro* conversion of vitamin C to oxalate can occur in patients with significant renal impairment producing significant hyperoxalemia. Therefore, high-dose vitamin C should be avoided in later stage CKD patients, especially those on PD which does not clear oxalate effectively.

TH-PO434

Lipidogenic Actions of Insulin in Patients with CKD Aseel Alsouqi,[5] Serpil muge Deger,[2] Feng Sha,[1] Aihua Bian,[4] Thomas G. Stewart,[5] Charles D. Ellis,[3] Adriana Hung,[4] Talat Alp Ikizler.[5] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Vanderbilt University Medical Center, Nashville, TN; [5]Vanderbilt University Medical Center, Nashville, TN.*

Background: Resistance to the metabolic actions of insulin is common in patients with CKD. We examined the acute effects of hyperinsulinemia on free fatty acid (FFA) levels during hyperinsulinemic euglycemic clamp (HEGC) study in patients with CKD and controls without kidney disease.

Methods: All participants underwent HEGC, where a fixed insulin infusion was started to achieve hyperinsulinemia with subsequent IV dextrose administration to maintain euglycemia (steady state). Peripheral resistance to insulin actions on glucose was assessed by Glucose Disposal Rate (GDR). Free fatty acid levels were measured at baseline and during steady state.

Results: We studied 165 individuals; 73 controls (59% females, 51% AA, median age 50 [IQR 38,65]) and 92 patients with CKD (31.5% females, 51% AA, median age 60, IQR[46,67]). FFA levels decreased similarly in response to insulin in all four groups: 88% in the control group, 89% in CKD Stages 3-4, 90% in HD and 86% in PD patients ($p < 0.05$ only for PD vs controls). Higher body mass index, fat mass, lean mass and Leptin Adiponectin Ratio were associated with lower rates of decrease in FFA levels. Increased age, higher baseline FFA levels, higher baseline adiponectin, higher GDR were significantly associated with higher rate of decrease in FFA levels. Leptin, C- reactive protein and interleukin-6 were not significantly associated with the change in FFA.

Conclusions: Body composition and adipocytokines are the primary determinants of actions of insulin on FFA metabolism in CKD patients. Patients on PD might have an underlying abnormality related to FFA metabolism, potentially related to excessive glucose exposure.

An Epigenetic Mechanism Controls Muscle Protein Synthesis in Mice with CKD Liping Zhang,[2] William E. Mitch.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Nephrology, Baylor College of Medicine, Houston, TX.*

Background: For patients with chronic kidney disease (CKD), loss of muscle mass is frequent leading to morbidity. Unfortunately, there are no approved, regularly effective treatments that overcome muscle wasting in part because mechanisms causing muscle protein losses are still being uncovered. Previously, we showed that CKD induces loss of muscle via increased protein degradation with decreased protein synthesis. The former is due to activation of caspase-3 and the ubiquitin-proteasome system (UPS) but mechanisms impairing muscle protein synthesis are unknown. Now, we show that CKD stimulates a chromatin modifying protein, NO66, in muscle resulting in reduced protein synthesis.

Methods: Mice with whole body deletion of NO66 (NO66$^{-/-}$) were created by crossing transgenic, Sox2-cre mice with NO66$^{flox/flox}$ mice. Mice with muscle-specific NO66 knockout (NO66^{mko}) were created by crossing tamoxifen-inducible, Pax7-cre mice with NO66$^{flox/flox}$ mice. CKD (subtotal nephrectomy) was created in mice and those with BUN >80 mg/dL were studied

Results: Our hypothesis is that expression of NO66 in muscles suppresses protein synthesis. During testing of this hypothesis, we found that NO66$^{-/-}$ mice exhibited a 20-30% increase in muscle mass *vs.* responses in NO66$^{flox/flox}$ control mice. Secondly, in NO66$^{-/-}$ mice the muscle wasting from CKD was blocked. To test the role of NO66 in muscle, we studied mice with muscle-specific NO66 KO (NO66^{mko}) and found there was an increase in muscle mass. To determine the mechanism underlying NO66-induced regulation of muscle mass in mice with CKD, we performed mass spectrometry assays and found that NO66 forms a repressive complex with two histone-modifying proteins, retinoblastoma binding protein 4 (RBBP4) and histone deacetylase 2 (HDAC2). This

complex represses expression of muscle genes and the transcription of ribosomal DNA via a demethylase mechanism. Lastly, we performed a RNA-seq analysis using soleus muscles and identified that absence of NO66 stimulates a ribosomal biogenesis signaling pathway

Conclusions: We have uncovered a new CKD-initiated pathway that proceeds *via* a novel epigenetic mechanism that regulates muscle protein synthesis

Eliminating SIRPα Replicates Exercise Induced Remodeling and Prevents Cardiac Dysfunction in CKD Jiao Wu,[1] Giovanni Davogustto,[2] Zhaoyong Hu,[1] Yanlin Wang,[1] Heinrich Taegtmeyer,[2] William E. Mitch,[1] Sandhya S. Thomas.[3,1] *[1]Baylor College of Medicine, Houston, TX; [2]The University of Texas Health Science Center at Houston, Houston, TX; [3]Michael E. Debakey Veteran Affairs Medical Center, Houston, TX.*

Background: A major consequence of chronic kidney disease (CKD) is uremic cardiomyopathy characterized by left ventricular hypertrophy (LVH), systolic and diastolic dysfunction. Even at early stages of CKD with near normal GFR, and normal blood pressure, LVH is present, which suggests an unidentified trigger unrelated to pressure overload. We now find that elevations of a novel protein, signal regulatory protein alpha (SIRPα) in CKD cardiac muscle not only adversely influences insulin signaling cardiac fibrosis, but also cardiac dysfunction classically associated with CKD. Suppression of SIRPα reverses CKD-induced cardiac dysfunction and promotes exercise induced cardiac remodeling.

Methods: SIRPα whole body mutant (Mt) mice and wild type mice (WT) were compared after 8 weeks of subtotal nephrectomy. Cardiac function was analyzed *in vivo* with M-mode and doppler echocardiography. N=8-9 mice/group, results are presented as mean±SD.

Results: Hearts of SIRPα Mt sham mice exhibit eccentric LVH compared with WT sham (LV mass/height 1.532±0.167 vs 1.329±0.216, p=0.04; Relative wall thickness 0.519±0.052 vs 0.608±0.098, p=0.03), preserved systolic function (EF 70.649±6.826 vs 65.901±5.304) as well as diastolic function (E/A 1.812±0.521 vs. 1.499±0.254). However, in WT Sham vs. WT CKD mice there is evidence of cardiac dysfunction characterized by reduced ejection fraction (EF) % (65.901±5.304 vs. 53.112±11.302, p =0.016) and reduced cardiac output (CO) ml/min (19.4±3.942 vs. 15.493±2.474, p=0.03). Doppler analysis revealed diastolic dysfunction in WT CKD as well (E/A: 1.499± 0.254 vs. 1.146±0.102, p=0.008). In WT CKD mice systolic blood pressure was not different than WT sham, suggesting changes observed are not due to pressure overload. On the contrary, in SIRPα Mt mice, induction of CKD did not significantly affect cardiac function (EF 70.649± 6.826 vs. 65.816±2.568, CO: 24.702±3.247 vs. 23.6±5.765, E/A 1.812±0.521 vs. 1.483±0.3, p > 0.05 for all).

Conclusions: In conclusion, suppression of SIRPα replicates exercise induced cardiac remodeling, similar to marathon-runners, as evidenced by eccentric LVH, preserved EF and diastolic function. Furthermore, hearts of SIRPα Mt mice were protected against CKD-induced cardiac dysfunction. Therefore, SIRPα may prove to be a key mediator for prevention of CKD-associated cardiomyopathy.

Biased Mortality Risk Associated with Change in Normalized Protein Catabolic Rate Due to Residual Kidney Function among Hemodialysis Patients Yoshitsugu Obi,[1] Elani Streja,[1] Rieko Eriguchi,[2] Melissa Soohoo,[1] Connie Rhee,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine, Orange, CA; [2]Kaizuka Hospital, Fukuoka, Japan; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Dietary protein intake among hemodialysis (HD) patients is estimated by dialysis urea clearance-based normalized protein catabolic rate (nPCR) in clinical practice, without accounting for renal urea clearance (rCL_{urea}). Decreases in rCL_{urea} directly increase nPCR by imposing greater dialysis clearance, and hence, patients appear to maintain nPCR values with decreased rCL_{urea} and decreased protein intake, both of which are associated with mortality.

Methods: We identified 10,066 HD patients with data on rCL_{urea} at both the 1st and 3rd quarters after dialysis initiation in a large U.S. dialysis organization (2007-2011). We calculated their 6-month change in nPCR with and without accounting for rCL_{urea} (i.e., $\Delta nPCR_{total}$ and $\Delta nPCR_{dial}$), and created 15 groups of combined $\Delta nPCR_{total}$ and $\Delta nPCR_{dial}$. All-cause mortality risk was estimated using Cox models with adjustment for 25 clinically relevant factors.

Results: Median (IQR) $\Delta nPCR_{dial}$ and $\Delta nPCR_{total}$ were 0.12 (-0.01, 0.26) and 0.11 (-0.06, 0.28) g/kg/day, respectively. $\Delta nPCR_{dial}$ and ΔrCL_{urea} explained 61% and 10% of the variation in $\Delta nPCR_{total}$ respectively. Within the same category of $\Delta nPCR_{dial}$, adjusted mortality risk was incrementally higher across lower $\Delta nPCR_{total}$ (P_{trend} <0.001). Contrary, within the same category of $\Delta nPCR_{total}$, mortality risk was paradoxically higher across higher $\Delta nPCR_{dial}$ (P_{trend} <0.001).

Conclusions: In the absence of data on rCL_{urea}, $\Delta nPCR$ does not adequately capture true changes in protein intake, leading to a biased evaluation of associated mortality risk among HD patients with rCL_{urea}.

Relationship between Body Mass Index, Inflammation, and Mortality in Hemodialysis Patients Rakesh Malhotra,[4] Xiaoling Ye,[3] Jochen G. Raimann,[3] Len A. Usvyat,[1] Joachim H. Ix,[4] Frank van der Sande,[2] Peter Kotanko,[3] Jeroen Kooman.[2] *[1]Fresenius Medical Care North America, Melrose, MA; [2]Maastricht University Medical Centre, Maastricht, Netherlands; [3]Renal Research Institute, New York, NY; [4]UCSD, San Diego, CA.*

Background: High body mass index (BMI) is associated with improved survival in hemodialysis (HD) patients. Mechanisms responsible are unknown. Here, we evaluate whether neutrophil-lymphocyte ratio (NLR) and serum albumin - markers of inflammation - affect the relationship of BMI with mortality in dialysis subjects.

Methods: We evaluated HD patients enrolled in MONDO (MONitoring Dialysis Outcomes) among whom measurements of neutrophil and lymphocyte counts, albumin, body weight and height were available (n=6162). BMI was categorized by quintiles:<21.3 kg/m^2, 21.3 to 24.0 kg/m^2, >24.0 to 26.7 kg/m^2, >26.7 to 30.4 kg/m^2 and >30.4 kg/m^2. Patients were classified as inflamed if NLR ≥5.0 or albumin ≤3.1 mg/dL. The main outcome was all-cause mortality over 2 years.

Results: The median (IQR) age was 66 (55-76) years, 57% were male, 46% white and median vintage 4-6 months. During 2-year follow-up, there were 2641(42.9%) deaths(864 in inflamed;1777 in non-inflamed). The protective effect of high BMI was observed in inflamed patients(HR (95% CI) Q1:2.48 (2.10-2.94); Q2:1.73 (1.44-2.09); Q3:1.77 (1.44-2.17); Q4:1.44 (1.16-1.80); and Q5:1.46 (1.18-1.81)); however this effect was mitigated in non-inflamed HD patients(HR (95% CI) for Q1:1.27 (1.08-1.49); Q2:1.06 (0.91-1.24); Q3:0.99 (0.85-1.16); Q4:0.93 (0.80-1.09); and Q5:1.0 (ref)). Further analysis showed that these findings were restricted to Europeans but not in Asians and United states subjects (**Fig1**).

Conclusions: Our results showed that inflammation may impact the relationship between BMI and survival. Further studies are needed to better understand the interaction between inflammation and the BMI in HD patients.

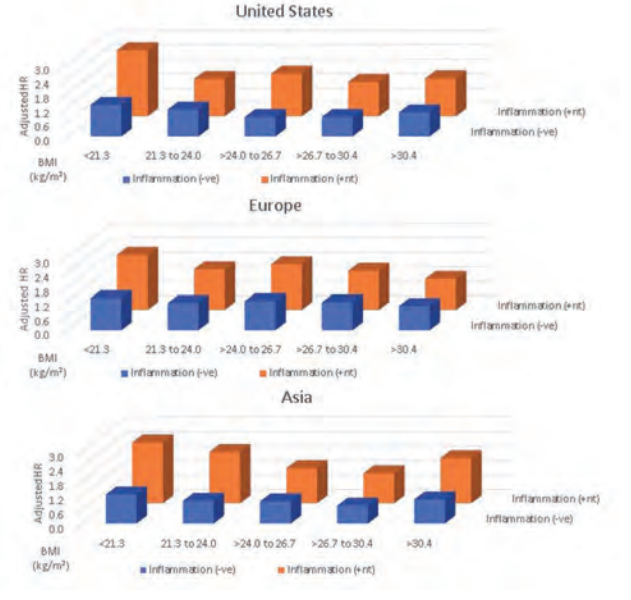

Figure 1. All-cause mortality by BMI and inflammation stratified by Region; adjusted Cox regression analysis

TH-PO439

Eculizumab and ECMO Rescue-Therapy of Most Severe ARDS in a Young Boy with Goodpasture's Syndrome Oliver Gross. *University Medicine Goettingen, Goettingen, Germany.*

Background: Goodpasture's syndrome is a life-threatening autoimmune disease characterized by the presence anti–glomerular basement membrane (GBM) antibodies, rapid progressive glomerulonephritis and/or pulmonary hemorrhage.

Methods: In a 17-year old boy, hydrocarbon exposure and additional severe bacterial infection triggered pulmonary hemorrhage due to Goodpasture's syndrome resulting in acute respiratory distress syndrome (ARDS). Within one day after hospital admission, the patient required extracorporeal membrane oxygenation (ECMO).

Results: Despite steroid-pulse and plasmapheresis, ARDS further deteriorated. Eleven days after admission, the boy was in a pre-final stage. At last, we decided to block the complement-driven lung damage by a single dose of Eculizumab. Three days after, lung-failure has stabilized in a way allowing us to initiate Cyclophosphamide-therapy. As mechanical ventilation further triggers Goodpasture-epitope exposure, the boy was taken from pressure support - breathing spontaneously by the help of maximal ECMO therapy. After a total of 24 days, ECMO could be stopped and pulmonary function further recovered within three weeks.

Conclusions: Our findings suggest that [1] Eculizumab can halt complement-driven organ-damage in life-threatening Goodpasture's syndrome and [2] lung-protective early withdrawal from pressure support by the help of ECMO can prevent further harm to the lung-tissue. Both therapeutic options take Goodpasture's pathogenesis into account and might serve as an important tool in otherwise hopeless situations to prevent further organ-damage and to gain time until the established immunosuppressive therapy works in otherwise fatal autoimmune-diseases.

Latent CMV reinforces Myeloid Inflammation in the Kidney and Other Organs Following a Septic Episode William Nash, Sundararaman Swaminathan, Michael G. Brown. *University of Virginia, Charlottesville, VA.*

Background: Although CMV reactivation is a well-known complication of renal transplant, the impact of CMV infection outside of the transplant field is relatively understudied. Reactivation of latent viral infections is a common occurrence in ICU patients diagnosed with sepsis and this coincides with high frequency of kidney dysfunction and failure. To date, such viral reactivation has been mostly viewed as a symptom of lympho-depression that can occur alongside or following the hyperinflammatory stage of sepsis. However, recent studies have indicated that CMV reactivation during sepsis is associated with longer hospital stays and increased risk of death.

Methods: We are designing a two-hit model to investigate the impact of latent CMV infection on sepsis. Mice are infected with MCMV for 60+ days to establish a latent infection. Naïve mice are used as comparators. A sepsis-like state is then induced by intraperitoneal injection of a cecal slurry prepared from naïve mice. Mice are monitored for 15 days post-septic insult and then serum and tissues are analyzed.

Results: All mice lost weight following cecal slurry injection, but we observed greater fluctations in body weight during recovery from sepsis in CMV(+) mice. In addition, of the 6 CMV(+) mice, one developed a massively cystic kidney and another exhibited aberrantly high numbers of monocytes in the lung and kidney. Mice that were previously infected with CMV displayed a greater proportion of Ly6C-hi inflammatory monocytes in the kidney as well as in the spleen, liver, and lung. Kidney and lung tissue from CMV+ mice also had a greater concentration of neutrophils per gram of tissue. At the time point investigated, we did not detect differences in histology, serum creatinine, or serum BUN between CMV(+) and CMV(-) mice, but the cecal slurrly dose used was generally well tolerated since all mice survived.

Conclusions: Our study shows that CMV may reinforce the myeloid inflammation occuring during sepsis. The tissues of mice previously infected with CMV maintain an inflammatory-skewed environment out to 15 days post-septic insult, even when mice are recovering body weight. It will be interesting to know if this skew predisposes mice to increased pathology in the kidney and lung upon additional infection and to determine the effects of CMV during more severe septic episodes.

Beverage Consumption and Kidney Disease Risk Casey Rebholz,[1] Bessie A. Young,[2] Ronit Katz,[6] Brandon J. Auerbach,[6] Katherine L. Tucker,[3] Teresa C. Carithers,[4] Arnita F. Norwood,[5] Victoria I. Okhomina,[5] Adolfo Correa.[5] *[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Uniiversity of Washington, Seattle, WA; [3]University of Massachusetts Lowell, Lowell, MA; [4]University of Mississippi, Oxford, MS; [5]University of Mississippi Medical Center, Jackson, MS; [6]University of Washington, Seattle, WA.*

Background: Sugar-sweetened beverages have been the target of health policies to reduce obesity and related cardiometabolic diseases. Identifying beverages that are associated with chronic kidney disease (CKD) risk could inform dietary guidelines.

Methods: We conducted a prospective analysis of participants in the Jackson Heart Study, a cohort of African-American men and women in Jackson, Mississippi. Beverage intake was assessed using a food frequency questionnaire administered at baseline (2000-04). Incident CKD was defined as eGFR <60 mL/min/1.73 m^2 and ≥30% eGFR decline at follow-up (2009-13) relative to baseline among those with baseline eGFR ≥60 mL/min/1.73 m^2. Logistic regression was used to estimate the association between the consumption of each individual beverage (energy-adjusted using the residual method), beverage patterns, and incident CKD. Beverage patterns were empirically-derived using principal components analysis (PCA) in which components were created based on the linear combinations of beverages consumed.

Results: Among 3,402 participants, 220 (6.5%) developed incident CKD over a median follow-up of 8 years. At baseline, median age was 54 years, 63% were female, and median eGFR was 98 mL/min/1.73 m^2. After adjusting for total energy intake, age, sex, income, body mass index, smoking, physical activity, hypertension, diabetes, high density lipoprotein cholesterol, history of cardiovascular disease, and baseline eGFR, higher intake of sweetened fruit drinks was significantly associated with increased risk of CKD (OR=1.12, 95% CI: 1.00, 1.27, p=0.05). A PCA-derived beverage pattern consisting of higher consumption of soda, sweetened fruit drinks, and water was more strongly associated with incident CKD (OR=1.23, 95% CI: 1.08, 1.41, p=0.002) than any beverage alone. No other individual types of beverages or beverage patterns were associated with CKD.

Conclusions: Higher consumption of sweetened fruit drinks was associated with elevated risk of subsequently developing CKD in this community-based population of African-Americans.

TH-PO442

Vitamin D Supplementation Increases Nephrocalcinosis but Not Bone Density in Preterm Infants Sabrina R. Malone jenkins,[2] Matthew M. Grinsell,[2] Kimberlee A. Weaver lewis,[1] Gary M. Chan.[2] *[1]Intermountain Medical Center, Murray, UT; [2]University of Utah, Salt Lake City, UT.*

Background: Vitamin D (VitD) supplementation is recommended for infants to maintain VitD status and improve bone density. One possible complication of VitD supplementation is nephrocalcinosis (NC), which is the calcification of renal tissue and is reported in 7-64% of infants with gestational age (GA)<32 wks or birth weight (BW)<1500g. Hypercalciuria and urine calcium crystal formation may also be complications of VitD supplementation. The relationship between VitD supplementation, NC, and the effect on bone density in preterm infants remains unknown. We hypothesize that VitD supplementation is associated with higher incidence of NC and hypercalciuria without improving bone density in preterm infants.

Methods: Prospective observational cohort study of 56 infants with GA≤32wks or BW≤1800g. We collected data on demographics, dietary intakes, and serum VitD levels until 40 wks corrected GA. Weekly urinalyses with microscopy were performed from 2 wks of age. NC was identified by renal ultrasound (US). Bone mineral density and content was assessed using DXA scan. Bone strength and elasticity was assessed by measuring speed of sound (SOS) through tibial US.

Results: 26/56 (46%) infants were diagnosed with NC. Infants with NC had a lower GA (28±2 vs 31±2wks, p<0.01) and BW (1102±305 vs 1449±428g, p<0.01) compared to Non-NC. There were no differences in VitD intake or urine calcium/creatinine ratios in NC vs NonNC infants. However, 69% of NC infants vs 40% NonNC had urinary calcium oxalate (CaOx) crystals on microscopy (p<0.03; PPV=60% & NPV=60%). Near discharge, 25-OH VitD levels were higher in the NC group compared to the NonNC group (46±24 vs 34±20ng/ml, p=0.03). DXA scan showed no difference in bone mass and density. However, tibial bone US demonstrated lower SOS (2774±159 vs 2910±158 m/s, p<0.01) and percentile (9±15 vs 28±27, p<0.01) in the NC group consistent with reduced bone strength and elasticity.

Conclusions: Infants born at an earlier GA and lower BW are at increased risk of NC. Our study shows that infants with NC had higher VitD levels and more frequent urine CaOx crystals. VitD supplementation did not increase bone density or mass on DXA but did have lower bone elasticity and strength on tibial US. We speculate that VitD supplementation may not improve bone density but may increase the risk for development of NC in preterm infants.

TH-PO443

Time-Updated Analysis of Potassium Intake, Serum Potassium, and Outcomes after Kidney Transplantation Lara C. Verschuur,[2] Antonio Gomes Neto,[2] Michele F. Eisenga,[1] Gerjan Navis,[1] Stephan J. Bakker,[2] Martin H. De Borst.[2] *[1]None, Groningen, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands.*

Background: Low potassium (K+) intake has been associated with an increased risk of hypertension, cardiovascular events, and mortality in patients with chronic kidney disease and in the general population. Kidney transplant recipients (KTRs) may nevertheless refrain from increasing K+ intake because of fear for hyperkalemia, which may be often unjustified.

Methods: We assessed the relationship between paired measurements of 24-hour urinary K+ excretion, as a proxy for K+ intake, and serum K+ in 1,108 with eGFR >15 mL/min/1.73 m^2. We subsequently analyzed associations of K+ intake with death-censored graft failure (DCGF) and all-cause mortality using time-updated Cox regression, adjusted for potential confounders, including age, sex, time-matched estimated GFR (eGFR, CKD-EPI), systolic blood pressure, and use of diuretics or RAAS-inhibitors.

Results: KTRs (55% men) were 44±13 yrs old at transplantation. Data from 8,904 paired urinary and serum K+ measurements were available. When considering intra-individual median K+ excretion, K+ excretion was 2.6 [2.0-3.1] g/d (median [IQR]). K+

intake was below the WHO-recommended intake (90-120 mmol/d, 3.5-4.7 g/d) in 87.4% of KTR. K+ intake decreased with advancing stages of CKD (P-trend<0.001). Overall, K+ intake explained 1.3% of the variation in serum K+; in stage 4 CKD it explained 1.0%. In multivariable linear regression, eGFR, diuretics use, sex, BMI, and ACE-inhibitor use (all P<0.05) were the main independent determinants of serum K+ (R^2=0.12), whereas K+ excretion was no significant independent determinant (P=0.16). During median follow-up for 14.3 [9.2-20.3] years, 291 patients developed DCGF and 676 patients died. In time-updated multivariable Cox regression analysis, K+ intake was inversely associated with the risk of DCGF (fully adjusted HR 0.60 [95% CI 0.49-0.74] per 1 g/d increase in K+ intake, P<0.0001) and mortality (0.76 [0.63-0.91], P<0.0001). Adjustment for serum K+ did not materially change the results.

Conclusions: K+ intake is low in the vast majority of KTR. The minimal impact of K+ intake on serum K+ and the association of low K+ intake with an increased risk of adverse outcomes suggest that dietary K+ intake should be stimulated in most KTRs.

TH-PO444

Effects of Diet and Exercise on Adipocytokine Levels in Patients with Moderate to Severe CKD Aseel Alsouqi,[1] Jacob M. Taylor,[1] Charles D. Ellis,[2] Aihua Bian,[3] Thomas G. Stewart,[1] Cassianne Robinson-Cohen,[6] Katherine R. Tuttle,[4] Michael J. Germain,[7] Elizabeth E. Evans,[5] Sam A. Headley,[5] Chutatip Limkunakul,[8] Jonathan Himmelfarb,[9] Talat Alp Ikizler.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University Medical Center, Nashville, TN; [4]University of Washington School of Medicine, Spokane, WA; [5]Springfield College, Wilbraham, MA; [6]University of Washington, Seattle, WA; [7]Renal and Transplant Assoc of New England, Hampden, MA; [8]Srinakharinwirot University, Nonthaburi, Thailand; [9]Kidney Research Institute, Seattle, WA.*

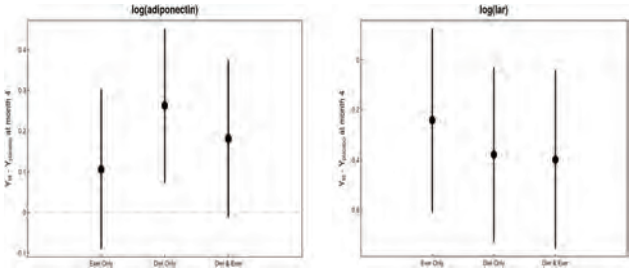
Background: Obesity is a pro-inflammatory risk factor for progression of CKD and cardiovascular disease. We hypothesized that implementation of caloric restriction and aerobic exercise improves adipocytokine profiles in patients with moderate to severe CKD.

Methods: We enrolled patients with moderate to severe CKD through a multi-center pilot randomized trial of diet and exercise in a 4-arm design (dietary restriction of 10%-15% reduction in caloric intake, exercise three times/week, combined diet and exercise and control) (NCT01150851). A total of 122 participants were consented, 111 were randomized (42% female, 25% diabetic, and 91% hypertensive), 104 started intervention and 92 completed the study. Adipocytokines (adiponectin, leptin and resistin) were measured at the beginning and end of the study period as secondary outcomes. Treatment effect was analyzed in a multivariable model adjusted for baseline outcome values, age, gender, site and diabetes.

Results: Adiponectin and resistin levels increased statistically significantly in response to diet whereas leptin levels did not change by either treatment (Figure-1). Leptin-Adiponectin Ratio (LAR) decreased statistically significantly in response to both interventions (Figure-2).

Conclusions: Our data suggest that dietary caloric restriction improves adiponectin and resistin levels in Stage 3-4 CKD patients with limited effect on leptin levels. LAR improved in response to both interventions indicating a potential beneficial effect of exercise intervention to the overall metabolic milieu.

Funding: Veterans Affairs Support



Effect of diet and exercise on Adiponectin and LAR levels in study groups compared to usual care.

TH-PO445

Cardiovascular Outcomes in CKD Patients with Sickle Cell Disorders Kabir O. Olaniran, Nwamaka D. Eneanya, Andrew S. Allegretti, Dihua Xu, Ravi I. Thadhani. *Massachusetts General Hospital, Boston, MA.*

Background: Sickle cell disease (SCD) patients are known to be at risk for ischemic stroke (CVA), heart failure (HF) and chronic kidney disease (CKD). However, cardiovascular (CV) outcomes in SCD CKD patients have not been described. Additionally, sickle cell trait (SCT) is independently associated with CKD. However, the effect of SCT with concurrent CKD on CV outcomes has not been explored.

Methods: We performed a multi-hospital retrospective cohort study in Boston using adult KDIGO criteria CKD patients between 2005-2017. Chart review was used to ascertain the following exposures: SCT with CKD, SCD with CKD and the reference group (RG; black race with CKD with normal hemoglobin electrophoresis). Outcomes were identified using diagnosis codes and defined as incident coronary heart disease (CHD), HF and CVA. Exposures and outcomes confirmed by diagnosis code only were then added for sensitivity analysis.

Results: 960 CKD subjects were initially included (241 SCT CKD, 45 SCD CKD, 674 RG). The mean baseline GFR in SCD CKD patients was higher vs the RG despite similar proportions per CKD stage (80±50 vs 70±36ml/min, p=0.17). SCD CKD patients were significantly younger (41±14 vs 52±17yrs, p<0.01), had lower mean systolic blood pressure (129±21 vs 137±23mmHg, p=0.03), fewer co-morbidities and less CV risk treatment vs the RG. No other significant differences in the baseline characteristics of the SCT CKD vs the RG were noted. Initial analysis showed an increasingly positive trend towards CHD risk from the RG to SCT CKD to SCD CKD which did not persist with HF and CVA. After adjustment for age, co-morbidities and medications, we found significantly increased odds for CHD in SCT CKD (OR 1.6, 95% CI 1.1-2.4) and SCD CKD (OR 3.2, 95% CI 1.2-8.3) compared to the RG. SCD CKD patients also had significantly increased odds for CVA (OR 3.8, 95% CI 1.2-12.3) and HF (OR 2.5, 95% CI 1.2-5.2) after multivariable analysis. Sensitivity analysis of 9,078 CKD subjects (360 SCT CKD, 498 SCD CKD, 8,220 RG) revealed similar findings.

Conclusions: Patients with CKD and either concurrent SCT or SCD have increased odds for adverse CV outcomes. Larger studies are needed to confirm these findings and to determine best practices for CV disease prevention in this patient population.

TH-PO446

The Association between Cardiac Troponin T and Coronary Artery Calcification in CKD: Result from the Korean Cohort Study for Outcomes in Patients with CKD Eunjeong Kang,[1] Hyo Jin Kim,[2] Hyunjin Ryu,[1] Miyeun Han,[3] Hyun suk Kim,[4] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Seoul National University Hospital, JongNo-Gu, SEOUL, Republic of Korea; [2]Internal medicine, Dongguk University Gyeongju Hospital, Gyeongju, Republic of Korea; [3]Internal medicine, Busan National University Hospital, Busan, Republic of Korea; [4]Internal Medicine, Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea.*

Background: Although cardiac troponin T (cTnT) is one of the biomarkers for the diagnosis of acute coronary syndromes, the association between cTnT and coronary artery calcification (CAC) in chronic kidney disease (CKD) patients are less well known, especially in Asian population.

Methods: We conducted a cross-sectional study and data were collected from the KNOW-CKD cohort. cTnT was measured by the highly sensitive assay and were categorized into 4 groups by quartiles (≤6.0, >6.0-10.0, >10.0-16.0, >16.0 pg/mL). CAC was evaluated through Agatston score calculated based on the extent of CAC detected by an electron-beam computed tomography scan. CAC scores were divided into 3 groups: 0-100, >100-400, and >400. We conducted multinomial logistic regression to evaluate the relationship between cTnT and CAC. Age, sex, CKD stage, diabetes, body mass index, hemoglobin, low density lipoprotein, and high density lipoprotein were included as covariates. We carried out subgroup analysis which divided into 2 groups based on estimated glomerular filtration rate (eGFR) 60mL/min/1.73m^2.

Results: Total 2,061 patients were included. The mean age was 53.5±12.3 years; 61.0% of patients were men, 5.3 % were diabetic and 1.4% were had history of myocardial infarction. CAC score was 183.2±523.1. After multivariable adjustments, compared to the lowest cTnT group, the highest cTnT group tended to have higher CACS in a fully adjusted multivariable model (CACS >100-400, odds ratio [OR] 2.460, 95% confidential interval [CI] 0.920-6.574, *P*=0.073; CACS >400, OR 10.175, 95% CI 2.076-49.878, *P*=0.004; reference group CACS 0-100). In a subgroup analysis according to eGFR, statistical significance was weakened in lower eGFR group with full adjustment. In receiver operating curve analysis, area under the curve was above 0.8, regardless of the eGFR subgroup.

Conclusions: Elevated concentration of cTnT was independently associated with the degree of severity of CAC in the CKD population of Korea. In subgroup analysis according to eGFR, the statistical significance regarding coronary artery calcification was weakened in lower eGFR group. Circulating cTnT levels is a fair screening test for the detection of coronary artery calcification in a subgroup with eGFR over 60 mL/min/1.73m^2.

Hypertension (HTN) Modifies the Association of Coronary Artery Calcification (CAC) with CV Events in CKD and Non-CKD Individuals Lucile Parker Gregg, Beverley Adams-Huet, Xilong Li, James Delemos, Susan Hedayati. *UT Southwestern, Dallas, TX.*

Background: Few studies examine whether HTN and CKD modify the association of CAC with CV events. We evaluated these associations at various CAC cutoffs with fatal or nonfatal CV events.

Methods: We studied 2,288 asymptomatic participants of the Dallas Heart Study followed for 12.5 years. Cox proportional hazards determined associations of CAC with CV events (CV death, myocardial infarction, stroke, CV revascularization, or hospitalization for heart failure or atrial fibrillation), adjusted for age, sex, race, smoking, HTN, diabetes, hyperlipidemia, HDL cholesterol, and CKD. Interactions for CKD (defined as eGFR<60 mL/min/1.73m^2 or albuminuria) and HTN (blood pressure >140/90 mmHg or on medication therapy for HTN) with CAC were tested at various CAC cutoffs, with *P*<0.1 considered significant.

Results: There were 170 (7.4%) participants with CKD and 811 (35.4%) with HTN. There were 232 CV events: 161 (19.9%) in those with HTN vs. 71 (4.8%) without HTN, and 60 (35.3%) in those with CKD vs. 172 (8.1%) without CKD, *P*<0.01 for each. CAC was associated with CV events in all non-CKD and non-HTN groups for each CAC cutoff point, but was not associated with CV events at any cutoff in individuals with both CKD and HTN. There was a CKDxCAC interaction for a CAC cutoff of 10 Agatston units, aHR 3.12 (2.20, 4.42) in non-CKD and 1.17 (0.68, 1.99) in CKD, *P*=0.001, but no CKDxCAC interaction for other CAC cutoffs. There was a significant HTNxCAC interaction at all tested cutoffs of CAC, such that CAC was less predictive of CV events in individuals with HTN (**Figure**).

Conclusions: CAC was more strongly predictive of CV events in individuals without HTN, but did not add to traditional risk factors for predicting CV events in hypertensive CKD participants.

TH-PO448

Differential Effects of Arterial Stiffness versus Fluid Overload on High Blood Pressure According to Renal Function in Patients at a Risk of Cardiovascular Disease Jaeyeol Kwon,[1] Seung Hyeok Han,[1] Meiyan Wu,[2] Boyoung Nam.[2] *[1]Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 21 PLUS, Yonsei University, Seoul, Republic of Korea.*

Background: Pathogenesis of hypertension is multifactorial in patients with chronic kidney disease (CKD). In this study, we explored the relative contribution of arterial stiffness and fluid overload to blood pressure (BP) in these patients. We evaluated 1531 patients of Cardiovascular and Metabolic Disease Etiology Research Center-High Risk (NCT02003781), a prospective observational cohort study of high risk patients with cardiovascular disease.

Methods: BP, arterial stiffness, and volume status expressed as an extracellular water/total body water ratio (ECW/TBW) were measured by 24-h BP monitoring, pulse wave velocity (PWV) and bioelectrical impedance analysis measurement, respectively.

Results: In patients with CKD, multiple linear regression analysis showed that both PWV and ECW/TBW were significantly associated with 24-h systolic BP (SBP). The area under the receiver operating characteristic curves (AUCs) for predicting 24-h SBP ≥130 mmHg significantly increased after PWV was added to conventional factors regardless of CKD status. However, the AUCs did not increase in ECW/TBW-based models. When a cut-off level of 24-h SBP was defined as 140 mmHg, predictability of ECW/TBW for elevated BP significantly improved in patients with CKD, but not in those without CKD. This association was further confirmed by the net reclassification and integrated discriminant improvements, RMSE with adjusted R^2, and interaction effects. In summary, as kidney function declines, fluid overload significantly contributes to high BP. The impact of fluid overload on BP is only observed in late stage of hypertension in patients with CKD.

Conclusions: Our findings suggest that a stepwise approach is required in the management of hypertension, depending on CKD stages.

TH-PO449

Determinants of Change in Arterial Stiffness over 5 Years in Early CKD Natasha J. Mcintyre,[2] Adam Shardlow,[2] Richard J. Fluck,[4] Christopher W. McIntyre,[1,3] Maarten W. Taal.[2,4] *[1]Division of Nephrology, Schulich School of Medicine and Dentistry, University of Western Ontario, London, ON, Canada; [2]Centre for Kidney Research and Innovation, Division of Medical Sciences and Graduate Entry Medicine, School of Medicine, The University of Nottingham, Derby, United Kingdom; [3]Department of Nephrology, London Health Sciences Centre, London, ON, Canada; [4]Department of Renal Medicine, The Royal Derby Hospital, Derby, United Kingdom.*

Background: Arterial stiffness (AS) is an established risk factor for cardiovascular disease (CVD) associated with CKD but there have been few studies to evaluate progression of AS over time or factors that contribute to this, particularly in early CKD, where most care is carried out in a primary care based setting. We therefore investigated AS in an elderly population with CKD stage 3 over 5 years.

Methods: 1741 persons with estimated GFR 59-30mL/min/1.73m^2 were recruited into the Renal Risk in Derby (RRID) study from Primary Care practices. Clinical assessments were completed at baseline, year 1 and 5. Carotid to femoral pulse wave velocity (PWV) was measured as a marker of AS, using a Vicorder™ device (Skidmore Medical Ltd, Bristol, UK). 978 participants had PWV assessments at baseline and 5 years and are included in this analysis.

Results: Changes in important variables over time are shown in the table. In our population, PWV increased significantly by 1.1m/sec over 5 years. Univariate analysis revealed significant correlations between ΔPWV at year 5 and previously identified risk factors for CVD. Multivariable linear regression analysis identified independent determinants of ΔPWV (R^2=0.37 for equation). These were Baseline Age (β=0.152, p<0.0001); Diabetes Mellitus (β=0.075, p=0.004); Baseline Systolic BP (β=0.112, p<0.0001); Baseline PWV (β= -0.342, p<0.0001); ΔPWV at year 1 (β=0.318, p<0.0001); ΔSerum Protein at year 5 (β=0.059, p=0.027); ΔSystolic BP at 5 years (β=0.214, p<0.0001).

Conclusions: We observed a clinically significant increase in PWV over 5 years in a primary care based cohort of elderly persons with early CKD. Systolic BP was identified as the most important modifiable determinant of change in PWV suggesting that interventions to prevent arterial disease should focus on control of blood pressure in this population.

Characteristics at 5 year follow up n=978

Elevated Pulse Amplification in Advanced Kidney Diseases Tsuneo Takenaka. *International University of Health and Welfare, Sanno Hospital, Tokyo, Japan.*

Background: The progression of chronic kidney disease (CKD) inverts arterial stiffness gradient. However, central haemodynamic pressure profiles in CKD have not been fully examined. A cross-sectional study was performed to assess the relationship between CKD stage and central haemodynamic processes.

Methods: The subjects were 2020 hypertensive patients who had undergone echocardiography and had their serum creatinine levels. Radial tonometry was applied in all patients to measure central blood pressure, and they were classified according to six CKD stages based on their estimated glomerular filtration rate (eGFR).

Results: Central (PP2) and brachial pulse pressure (PP) were elevated at stages 3a and 3b, respectively. Diastolic blood pressure (DBP) at stage 1 was higher than at the other stages. The left ventricular mass index (LVMI) was greater at CKD stages 3b-5 than that at stage 1. Either PP or PP2 is sensitive in detecting the presence of left ventricular hypertrophy (LVH), raising the possiblity that central hemodynamic changes in CKD progression participate in lowering the power of PP2 in predicting LVH in treated hypertensive patients. Age, weight, pulse rate, brachial blood pressures, and antihypertensive medication differed among the six stages. As shown in figure, pulse amplification adjusted with these confounders was the lowest in CKD stages 3a and 3b.

Conclusions: The present observations that LVMI was increased at CKD stages 3b-5 support that cardiovascular risk is higher in CKD stages 3b and later. Our findings indicate that pulse amplification is inverted in CKD stages 4 and 5, and suggest that aortic stiffening inadequately reduces PP in advanced CKD, which accounts for a high prevalence of micro- as well as macrovascular diseases of the brain and kidney. Taken together, these results implicate that CKD3b comes of age as an index for timely cardiovascular screening.

Body Composition Is Associated with Clinical Outcomes in Patients with Nondialysis-Dependent CKD Szu-Chun Hung,[1] Ting-yun Lin.[2] *[1]Taipei Tzu Chi Hospital, Taipei County, Taiwan; [2]Teipai Tzu Chi Hospital, Taipei City, Taiwan.*

Background: An inverse relationship between body mass index (BMI) and mortality (the"obesity paradox") has been demonstrated in patients with nondialysis-dependent chronic kidney disease (CKD). However, it is unclear whether increased muscle mass or body fat confers the survival advantage. We investigated the impact of body composition on the composite outcome of death or cardiovascular events in a prospective cohort of 326 patients with stage 3–5 CKD who were not yet on dialysis.

Methods: Lean mass and body fat were determined using the Body Composition Monitor (BCM), a multifrequency bioimpedance spectroscopy device, and were expressed as the lean tissue index (LTI) and fat tissue index (FTI), respectively. Patients were stratified as High (above median) or Low (below median) BMI, as High or Low LTI, or as High or Low FTI.

Results: During a median follow-up of 4.6 years, there were 40 deaths and 68 cardiovascular events. In Cox proportional hazards models, High LTI, but not High BMI or High FTI, predicted a lower risk of both the composite and its components (reference: below median). When patients were further stratified into 4 distinct body composition groups based on both LTI and FTI, only the High LTI/High FTI group had a significantly lower risk of the composite outcome (hazard ratio 0.38, 95% confidence interval 0.15–0.96; reference: Low LTI/Low FTI group).

Conclusions: LTI can provide better risk prediction than can BMI alone in nondialysis-dependent CKD patients. High LTI/High FTI appears to be associated with best outcomes. The optimal body composition for improving the prognosis of CKD needs to be determined.

Cox proportional hazards model for time to primary composite outcome

Body composition	Unadjusted		Model 1		Model 2	
	HR (95% CI)	P value	HR (95% CI)	P value	HR (95% CI)	P value
BMI (H vs L)	0.72 (0.47–1.11)	0.136	0.87 (0.57–1.33)	0.517	0.91 (0.58–1.43)	0.687
FTI (H vs L)	1.41 (0.92–2.17)	0.116	1.06 (0.67–1.68)	0.803	0.96 (0.59–1.55)	0.860
LTI (H vs L)	0.31 (0.19–0.49)	0.000	0.45 (0.26–0.78)	0.005	0.52 (0.30–0.91)	0.021

Serum Bicarbonate and Pulse Wave Velocity in CKD – A Report from the CRIC Study Mirela A. Dobre,[1] Raymond R. Townsend,[9] Wei Yang,[8] Amanda H. Anderson,[8] Vecihi Batuman,[6] Jing Chen,[5] Bernard G. Jaar,[4] Radhakrishna R. Kallem,[8] Hernan Rincon-Choles,[2] Stephen M. Sozio,[3] Susan P. Steigerwalt,[7] Harold I. Feldman,[8] Thomas H. Hostetter,[1] Mahboob Rahman.[1] *[1]Case Western Reserve University, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH; [3]Johns Hopkins University School of Medicine, Baltimore, MD; [4]Johns Hopkins University and Nephrology Center of Maryland, Baltimore, MD; [5]Tulane School of Medicine, New Orleans, LA; [6]Tulane University, New Orleans, LA; [7]University of Michigan, Ann Arbor, MI; [8]University of Pennsylvania, Philadelphia, PA; [9]University of Pennsylvania School of Medicine, Villanova, PA.*

Background: Vascular stiffness is an important phenotype of cardiovascular disease (CVD) in patients with CKD. Though common in CKD, acid base disturbances as risk factors for CVD are not well studied. We aimed to test the association between serum bicarbonate and vascular stiffness as expressed by carotid femoral pulse wave velocity (cfPWV).

Methods: Serum bicarbonate and cfPWV were simultaneously measured in 3206 participants enrolled in the Chronic Renal Insufficiency Cohort (CRIC) at study year 2. Serum bicarbonate was analyzed as a categorical variable using the following groups: <22 mEql/L, 22-26 mEq/L (reference group) and >26 mEq/L, and as a continuous variable using restricted cubic splines to accommodate potential nonlinear associations. The models were adjusted for age, sex, race, diabetes, smoking, CVD, hypertension, FGF 23, Calcium, eGFR and proteinuria.

Results: The mean eGFR was 43.3±17ml/min per 1.73m2 and mean serum bicarbonate was 23.9 mEq/L. Participants with serum bicarbonate < 22 and > 26 mEq/L had significantly higher cfPWV (10.04 and 9.84 m/s respectively) compared to reference group (9.47 m/s, p=0.004) ((Figure- Panel A). In non-linear models, we found a U-shaped association between serum bicarbonate and cfPWV (p<0.05), (Figure- Panel B).

Conclusions: In a large cohort of patients with CKD, serum bicarbonate below 22 or above 26 mEq/L was associated with higher cfPWV. Further studies are needed to determine if there is a direct causal link between acid base abnormalities and vascular stiffness and to define the optimal range of serum bicarbonate in CKD to prevent adverse clinical outcomes.

Funding: Private Foundation Support

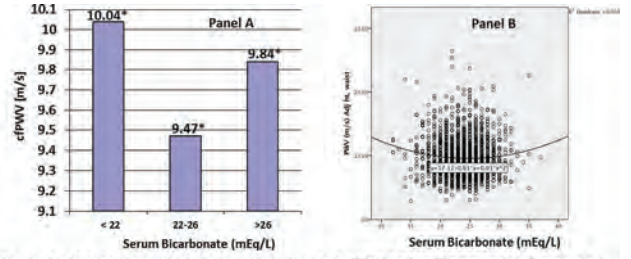

Figure - Panel A. Mean carotid femoral pulse wave velocity (cfPWV) (m/s) by serum bicarbonate strata (*p=0.004). Panel B. Association between serum bicarbonate and cfPWV: adjusted restricted cubic spline model. The solid line represents the effect (p <0.05).

TH-PO453

Renal Hyperfiltration and Central Blood Pressures: A Populational Cohort Study Marie-Eve Dupuis,[2] Francois Madore,[2] Mohsen Agharazii,[1] Remi Goupil.[2] *[1]CHUQ-HDQ, Quebec City, AB, Canada; [2]Hopital du Sacre-Coeur, Montreal, QC, Canada.*

Background: Renal hyperfiltration (RHF) in non-diabetic individuals is linked to mortality and cardiovascular events. Whether increased central blood pressure (BP) plays a role in this association is unknown.

Methods: Of the 20,004 CARTaGENE participants, 14,580 non-diabetics with central BP were identified. From these, a group with RHF (eGFR >95th percentilestratified for sex and age) was compared to a control group (eGFR 25th to 75th percentile). Central BP parameters adjusted for known confounding factors were compared using multivariate regression and propensity score matching analyses.

Results: Baseline characteristics between RHF [eGFR 108.4 (IQR 105.3, 113.3) ml/min/1.73m^2] and control [eGFR 89.9 (IQR 84.2, 95.9)] groups were similar apart from age, smoking status and BMI. All adjusted central BP parameters were higher with RHF on regression analyses. These results were replicated using propensity score matching (1:1 matching, n=721), apart from central systolic BP (113.2 ± 14.6 vs 112.3 ± 14.8, p=0.2).

Conclusions: In this populational cohort of non-diabetic individuals, RHF was associated with higher central BP parameters, independently of peripheral BP and other confounders. Whether this explain, at least in part, the increased cardiovascular morbidity and mortality associated with RHF remains to be determined.

Demographic characteristics	RHF (n=727)	Controls (n=7,292)	p
Age	52.1 ± 7.7	54.0 ± 7.7	<0.001
Sex	48%	48%	1.0
Cardiovascular disease	3.6%	3.2%	0.6
Hypertension	18%	18%	1.0
Smoking	27%	19%	<0.001
BMI	26.5 ± 5.4	27.1 ± 4.9	0.007
Brachial systolic BP	122.9 ± 15.3	123.5 ± 15.5	0.4
Brachial pulse pressure	49.7 ± 10.0	49.8 ± 10.6	0.8
Adjusted central BP parameters*			
Central systolic BP	114.9 (114.5, 115.3)	114.2 (113.9, 114.5)	<0.001
Central pulse pressure	40.7 (40.0, 41.4)	39.6 (39.2, 40.1)	<0.001
Augmentation index	28.7 (27.9, 29.5)	28.0 (27.4, 28.5)	0.03
Pulse pressure amplification	1.277 (1.268, 1.286)	1.287 (1.280, 1.293)	0.01
Augmented pressure	12.1 (11.7, 12.5)	11.6 (11.3, 11.9)	0.001

*Adjusted for age, sex, smoking, cardiovascular disease, mean BP, heart rate, total cholesterol, HDL, glucose, weight, height, bio-impedance lean body mass, aspirin, statins, beta-blockers, renin-angiotensin blockers, calcium channel blockers and diuretics.

TH-PO454

Obstructive Sleep Apnea and Cardiovascular Outcomes in CKD Patients Claudio P. Loivos, Julia F. Fernandes, Vagner S. Meira, Carla C. Lemos, Sergio E. Kaiser, Márcia R. Klein, Maria Ines Barreto-Silva, Rachel Bregman. *State University of Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: Chronic kidney disease (CKD) is a non-traditional risk factor for cardiovascular disease (CVD). The frequency of obstructive sleep apnea (OSA) in this population is not well established. CVD and hypertension are related to OSA. The aim was to investigate the presence of OSA in CKD patients, its relation with blood pressure (BP) and cardiovascular outcomes.

Methods: Longitudinal study including 74 CKD patients stages 3b-4 (eGFR: CKD-EPI) under regular treatment, for 21 months. Sleep study was performed with the equipment Watch-PAT200®. OSA diagnosis: apnea-hipopnea index (AHI) ≥ 5 events/h, mild: AHI ≥ 5 ≤ 15, moderate: AHI > 15 ≤ 30, severe: AHI > 30 events/h. Blood pressure (BP) evaluated in office and by 24-hour ambulatory BP monitoring (ABPM). Statistics: SPSS 20

Results: Mean age 63.2 ± 9.3 years, 55% men. Mean eGFR: 28.7 ± 8.3 ml/min/1.73m^2, 64% CKD stage 4. All patients were under regular treatment for at least 6 months. OSA was present in 70.3% (OSA group, n=52), of which mild form: 50%, moderate: 33%, severe: 17%. Office BP in OSA group, showed higher systolic (SBP) values (153 ± 23 vs 140 ± 17 mmHg, p=0.016) and pulse pressure (PP) (71 ± 21 vs 60 ± 15 mmHg, p=0.034). ABPM showed higher values for SBP and PP in all periods (p < 0.05). When comparing patients from stages 3b and 4, no differences were observed in office BP and ABPM. AHI showed a correlation with: 24-hour mean PP (R=0.274, p=0.033), daytime PP (R=0.281, p=0.028), SBP and diastolic BP in all periods (p<0.05) regardless eGFR values. Among nondippers 77.8% presented OSA. All cardiovascular events (n=7, acute myocardial infarction and/or cerebrovascular accident) occurred in patients with OSA

Conclusions: CKD patients 3b-4 presented high OSA frequency. OSA was associated with higher SBP and PP, both in office measurements and in ABPM, despite a higher usage of antihypertensive drugs in this group. We suggest that the presence of OSA as well as systolic hypertension might be modifiable risk factors for CVD in CKD (3b-4) patients.

TH-PO455

The Association of Body Mass Index (BMI) with Mortality and Institution of Renal Replacement Therapy (RRT) in CKD Patients in the CKD-QLD Registry: Queensland, Australia Samuel S. Chan,[1,2] Anne Cameron (Salisbury),[2,3] Zaimin Wang,[2,3] Helen G. Healy,[1,2] Wendy E. Hoy.[2,3] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Metro North Hospital and Health Service, Herston, Queensland, NSW, Australia; [2]CKD.QLD and the NHMRC CKD.CRE, The University of Queensland, Brisbane, QLD, Australia; [3]Faculty of Medicine, The University of Queensland, Brisbane, QLD, Australia.*

Background: Dialysis patients who are overweight and obese are reported to have better survival compared with those with lower BMI. We do not know if this is so in CKD patients.

Methods: A retrospective analysis of preterminal CKD patients from two major sites enrolled in the CKD. QLD registry was undertaken between May 2011 and July 2015. Associations of WHO BMI categories with subsequent death without RRT and with RRT were examined using Cox regression modelling, adjusting for hospital site, demographic variables, CKD stage, primary renal disease and co-morbidities.

Results: Of the 2,059 patients (median age 68, IQR 56–77 yr), median (IQR) BMI was 29.7 (25.9-35.0)kg/m^2. 216 died without RRT (10%) and 151 started RRT (7%). Median (IQR) ages at death and start of RRT were 78 (IQR 71-84) and 61 (IQR 49-69) yr, respectively. The incidence rates for death and start of RRT was 41.8 and 34.4 per 1000 person-years, respectively. With normal BMI (<25) persons as the referent group, the adjusted hazard ratios (HR) (95% CI) for death were 0.57 (0.40-0.81) p=0.002, for overweight subjects, 0.59 (0.41-0.85) p=0.004, for obese subjects, and 0.94 (0.56-1.60) p=0.83, for morbidly obese subjects. The adjusted HR for RRT were 1.08 (0.69-1.70) p=0.73, for overweight subjects, 1.09 (0.69-1.73) p=0.71, for obese subjects, and 1.04 (0.56-1.92) p=0.90, for morbidly obese subjects.

Conclusions: Demographic and clinical characteristics of CKD patients who die without RRT are different to patients who commence RRT. Overweight and obese, but not morbidly obese, subjects appear to be protective against death, compatible with the phenomenon observed in dialysis patients. In some patients, lower BMI may mark ill health and advanced age. However, with adjustments, there is no significant association of BMI with the likelihood of starting RRT.

Association between Body Mass Index and In-Hospital Mortality in Emergently Hospitalized Dialysis-Independent CKD Patients: A Nationwide Retrospective Cohort Study in Japan Hiroaki Kikuchi,[5] Eiichiro Kanda,[4] Fumiaki Ando,[5] Hidehiko Sato,[1] Kiyoshi Isobe,[1] Takayasu Mori,[5] Soichiro Iimori,[1] Naohiro Nomura,[5] Shotaro Naito,[5] Eisei Sohara,[5] Tomokazu Okado,[2] Shinichi Uchida,[5] Kiyohide Fushimi,[5] Tatemitsu Rai.[3] *[1]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan; [2]Department of Nephrology, Tokyo medical and dental university, Tokyo, Japan; [3]TOKYO MEDICAL & DENTAL UNIV, TOKYO, Japan; [4]Tokyo Kyosai Hospital, Meguro, Japan; [5]Tokyo Medical and Dental University, Tokyo, Japan.*

Background: The relationship between high body mass index (BMI) and in-hospital mortality in emergently hospitalized dialysis-independent chronic kidney disease (DI-CKD) patients is unknown.

Methods: The study cohort was comprised of 7936 emergently hospitalized DI-CKD patients (stages 3–5) age 20-70 years old who were treated in hospitals participating in the Diagnosis Procedure Combination (DPC) system. Data for patients hospitalized from April 2015 to March 2016 were collected. Patients were classified by presence (n=2427) or absence (n= 5509) of inflammation (coexistence with malignancy and/or infectious diseases). Patients were divided into tertiles by BMI: group 1, low BMI (< 20.5 kg/m^2); group 2, normal BMI (20.5-25.0 kg/m^2); group 3, high BMI (> 25.0 kg/m^2). Non-inflamed patients in BMI group 3 formed the reference group. The primary outcome was the occurrence of in-hospital death.

Results: Logistic regression analysis adjusted for baseline characteristics showed that among both inflamed and non-inflamed patients, group 1 was significantly associated with the highest risk of in-hospital mortality. For inflamed patients, the adjusted odds ratio (aOR) for group 1,2 and 3 were 3.62 [95% confidence interval (CI) (2.69, 4.86)], 2.88 (95% CI 2.13, 3.90), 2.34 (95% CI 1.68, 3.24), respectively. For non-inflamed patients, aOR for groups 1 and 2 were 2.00 (95% CI (1.51, 2.64), and 1.20 (95% CI 0.89, 1.62), respectively.

Conclusions: This study suggests that high BMI leads to better in-hospital mortality in emergently hospitalized dialysis-independent CKD patients irrespective of presence of inflammation.

Model	BMI tertile (kg/m^2)	Adjusted odds ratio (95% Confidence Interval)	
		Inflammation Present	Inflammation Absent
1[a]	1 (< 20.5 kg/m^2)	4.86 (3.65, 6.47)	2.28 (1.73, 2.99)
	2 (20.5-25.0 kg/m^2)	3.53 (2.63, 4.76)	1.26 (0.94, 1.70)
	3 (> 25.0 kg/m^2)	2.65 (1.92, 3.67)	1
2[a]	1 (< 20.5 kg/m^2)	3.55 (2.65, 4.77)	1.98 (1.50, 2.62)
	2 (20.5-25.0 kg/m^2)	2.84 (2.10, 3.84)	1.20 (0.89, 1.62)
	3 (> 25.0 kg/m^2)	2.31 (1.66, 3.20)	1
3[a]	1 (< 20.5 kg/m^2)	3.62 (2.69, 4.86)	2.00 (1.51, 2.64)
	2 (20.5-25.0 kg/m^2)	2.88 (2.13, 3.90)	1.20 (0.89, 1.62)
	3 (> 25.0 kg/m^2)	2.34 (1.68, 3.24)	1

[a] Model 1 adjusted for age and sex.
[b] Model 2 adjusted for all variables in model 1 plus history of DM and history of HTN.
[c] Model 3 adjusted for all variables in model 2 plus history of CAD and heavy smoking.

DM, diabetes mellitus; HTN, hypertension; CAD, coronary artery disease.

TH-PO457

Intensity of Statin Therapy and All-Cause Mortality in CKD Carl P. Walther, Peter Richardson, Jingbo Niu, Wolfgang C. Winkelmayer, Salim S. Virani, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

Background: KDIGO guidelines recommend statin therapy for primary or secondary prevention of vascular events in most persons with non-dialysis CKD, at doses which would be categorized as moderate-intensity by the 2013 AHA/ACC lipid guideline. It is unclear whether persons with CKD would benefit from higher intensity statin therapy given the potential higher risks of adverse events. We examined the association between incident statin therapy intensity and all-cause mortality in a non-dialysis CKD population.

Methods: Incident statin users were identified from a cohort of persons with sustained low eGFR (<60 for ≥90 days) receiving care through the Veterans Administration from 2005-08. The cohort was limited to those with filled prescriptions covering ≥67% of days in the first year of use. Exposure was categorized by preponderant dose intensity (high, moderate, low by AHA/ACC guideline) during the first year. The outcome was all-cause mortality following the exposure period. Patients were censored at last VA follow-up or 5 years. We used Cox proportional hazards regression adjusted for relevant covariates.

Results: Of 40,241 persons included, 33.9% received low-, 59.9% received moderate-, and 6.2% received high-intensity statin therapy. Median age [IQR] was 76 [66-82] years, 32.2% had diabetes, and 91.4% were CKD stage 3. High-intensity users were younger (median age 74) and more likely to have diabetes (34.6%). During 167,850 person-years of follow up 10,753 persons (26.7%) died. Unadjusted mortality was lower in the high-dose group. After multivariable regression adjustment, mortality risk did not differ across the high-, medium-, and low-intensity groups.

Conclusions: In an older, non-dialysis CKD population of US Veterans, statin therapy intensity over one year was not independently associated with all-cause mortality. This real-world analysis supports the KDIGO lipid guideline, which recommends doses of moderate intensity, although the question of whether lower intensity therapy might be equally effective is raised.

Statin intensity	Patients (N)	Events (N [%])	Event rate (per 100 person-years)	HR* (95% CI)
Low	13629	3756 (27.6)	6.44	1 (ref)
Moderate	24119	6461 (26.8)	6.41	1.03 (0.99-1.07)
High	2493	536 (21.5)	6.19	1.05 (0.96-1.15)

*Adjusted for age, CKD stage, BMI, SBP, DBP, ACEI/ARB, LDL, trig., DM, CHD, cerebrovasc. dis., PVD, COPD, CHF, malignancy

Pre-ESRD Systolic Blood Pressure Trajectory and Post-ESRD Mortality Keiichi Sumida,[2] Miklos Z. Molnar,[5] Praveen Kumar Potukuchi,[5] Fridtjof Thomas,[5] Elvira Gosmanova,[3] John J. Sim,[1] Kunihiro Yamagata,[6] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[5] *[1]Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]Stratton VA Medical Center, Albany, NY; [4]University of California Irvine, School of Medicine, Orange, CA; [5]University of Tennessee Health Science Center, Memphis, TN; [6]University of Tsukuba, Tsukuba, Japan.*

Background: Pre-ESRD systolic blood pressure (SBP) shows a reverse J-shaped association with post-ESRD mortality. However, the pre-ESRD association of SBP trajectories (decrease vs. increase vs. stable over time) with post-ESRD mortality is unknown.

Methods: We assessed SBP measurements in the last 3 years prior to dialysis in 39,383 US veterans with incident ESRD. SBP slopes and baseline levels were categorized (<-5, -5-<5, and ≥5 mmHg/year for slopes; and <130, 130-<150, and ≥150 mmHg for baseline) and combined into 9 mutually exclusive groups with slope of -5-<5 mmHg/year and baseline of 130-<150 mmHg as referent. Associations with all-cause post-ESRD mortality were examined in multivariable-adjusted Cox models.

Results: The median (interquartile interval) SBP slope and baseline SBP were -0.1 (-2.4-1.9) mmHg/year and 140 (133-149) mmHg. Decrease in SBP was associated with higher mortality, with the highest risk seen with SBP slope of <-5 mmHg/year combined with baseline SBP of <130 mmHg (adjusted hazard ratio [95% CI]: 2.02 [1.70-2.40], vs. referent; Figure). Increase in SBP was associated with lower mortality independent of baseline SBP, as was stable SBP in patients with baseline SBP ≥130 mmHg.

Conclusions: Decrease in SBP prior to dialysis start is associated with higher post-ESRD mortality, especially in patients with lower baseline SBP. Increasing SBP is associated with better outcomes independent of baseline SBP. Further studies are needed to test whether modification of pre-ESRD SBP trajectories can improve clinical outcomes in incident ESRD patients.

Clinical Characteristics and Outcomes Associated with Resistant Hypertension in the VA Million Veteran Program Csaba P. Kovesdy,[3] Todd L. Edwards,[4] Otis D. Wilson,[4] Philip S. Tsao,[5] Peter W. Wilson,[2] Christopher J. O'Donnell,[1] Adriana Hung.[4] *[1]Boston Veterans Administration, Boston, MA; [2]Emory University, Atlanta, GA; [3]University of Tennessee Health Science Center, Memphis, TN; [4]Vanderbilt University, Nashville, TN; [5]Stanford University, Nashville, TN. Group/Team: On behalf of VA Million Veteran Program.*

Background: The prevalence of resistant hypertension (RH), the characteristics of patients with RH and the association of RH with clinical outcomes is unclear.

Methods: Methods: From among 510,167 veterans enrolled in the Million Veteran Program (MVP), we identified 27,381 patients with the RH phenotype by using clinical data: failure to achieve outpatient BP <140/90 mmHg with three antihypertensive drugs (AHD), one being a thiazide, or success with 4 or more drugs, excluding BP measurements when pain score was >5, when interfering medications were prescribed and excluding patients with confounding medical conditions (CKD, secondary HTN, sleep apnea, urinary obstruction, adrenal, thyroid and parathyroid over-activity). Patients with RH were compared to 268,520 patients with non-resistant HTN (NRH). We examined associations with all-cause mortality, heart attacks (MI), strokes and ESRD in crude (Model 1) and multivariable Cox proportional hazards models adjusted for baseline demographics, comorbid conditions and estimated GFR (Model 2). The role of BP control was examined by additional adjustment for SBP, DBP and number of antihypertensive drugs (AHD) (Model 3).

Results: The SBP/DBP (mean/SD) and number of AHD (median/IQR) in RH vs. NRH patients were 143±18/81±13 vs. 134±12/79±11 mmHg and 4 (3-4) vs. 1 (1-2), respectively. In Model 2 RH (referent: NRH) was associated with similar mortality but significantly higher risk of MI, stroke and ESRD (Figure). The higher risks of MI and stroke were mediated by the higher BP seen in RH patients, and became non-significant after additional adjustment in Model 3. The higher risk of ESRD persisted in Model 3 (Figure). [figure1]

Conclusions: RH is associated with higher risk of incident MI, stroke and ESRD. Better BP control in patients with RH may alleviate the higher risk of MI and stroke. Further studies are needed to explain the mechanisms underlying the higher risk of ESRD in RH.

Apixaban versus Warfarin in Patients with Atrial Fibrillation (AF) and Stage 4 CKD John W. Stanifer,[3] Glenn M. Chertow,[6] Stefan H. Hohnloser,[4] Daniel Wojdyla,[2] Samira Garonzik,[1] Wonkyung Byon,[5] Renato D. Lopes,[2] John H. Alexander,[2] Lars Wallentin,[7] Christopher B. Granger.[2] *[1]BMS, Princeton, NJ; [2]Duke Clinical Research Institute, Durham, NC; [3]Duke University, Durham, NC; [4]J. W. Goethe University, Division of Clinical Electrophysiology, Frankfurt, Germany; [5]Pfizer, Groton, CT; [6]Stanford University School of Medicine, Palo Alto, CA; [7]Uppsala Clinical Research Center, Uppsala, Sweden.*

Background: Limited safety data exist for direct-acting oral anticoagulants in patients with advanced CKD. In Apixaban for Reduction of Stroke and Other Thromboembolic Events in Atrial Fibrillation (ARISTOTLE) trial, we evaluated the effects of apixaban vs. warfarin in stage 4 CKD.

Methods: ARISTOTLE included patients with AF with a serum creatinine ≤2.5 mg/dL and estimated CrCl ≥25 mL/min. Apixaban dose was 5 mg bid or 2.5 mg bid if 2 of 3 criteria were met: age ≥80, weight ≤60 kg or serum creatinine ≥1.5 mg/dL. We used Cox proportional hazard models to analyze treatment effect stratified by CrCl category (< 30 vs ≥ 30mL/min). We also evaluated drug exposure by apixaban dose for patients with CrCl <30mL/min.

Results: Overall 269 patients (median age 81; 61% women) had a CrCl <30 mL/min. The effect of apixaban vs warfarin on stroke or systemic embolism was similar across CrCl categories (p interaction=0.50). For those with CrCl <30 mL/min, major bleeding occurred in 7 patients with apixaban and 19 with warfarin (HR 0.34; 95% CI 0.14-0.79), and the median apixaban drug exposure was 5512 ng/mL*hr (n=12) for 5mg and 2792

ng/ml*hr (n=19) for 2.5mg. The relative safety of apixaban was similar across CrCl categories (**Table**).

Conclusions: Among patients with Stage 4 CKD in ARISTOTLE, those randomized to apixaban experienced lower bleeding rates compared with warfarin, consistent with the overall population. Studies evaluating the safety and efficacy of apixaban in patients with advanced CKD, including end-stage kidney disease, are needed.

Cause-Specific Mortality among Patients with CKD and Atrial Fibrillation Sankar D. Navaneethan,[1] Jesse D. Schold,[2] Stacey Jolly,[2] Susana Arrigain,[2] Medha Airy,[1] Nisha Bansal,[3] Wolfgang C. Winkelmayer,[1] Joseph V. Nally.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Cleveland Clinic, Cleveland, OH; [3]Kidney Research Institute, Seattle, WA.*

Background: Atrial fibrillation (AF) is associated with death in patients with chronic kidney disease (CKD). However, whether the increased mortality in patients with CKD is due to cardiovascular or other causes is unclear. We examined the associations between AF and cause-specific mortality in a large CKD population.

Methods: We included 62,459 patients with eGFR 15-59 ml/min/1.73 m² with AF (based on the presence of ≥2 ICD-9 codes for AF). Using the State mortality registry data, we classified deaths as follows: a) cardiovascular; b) malignancy-related; and c) non-cardiovascular/non-malignancy causes. We fitted Cox regression models for overall mortality and separate competing risk models for each cause of death category to evaluate their respective associations with AF. We conducted a separate analysis after excluding those with pre-existing malignancy.

Results: During a median follow-up of 4.1 years, 19,094 patients died; cause of death data was available for 18,854 patients. After adjusting for covariates, AF was associated with 23% increased risk of all-cause mortality, 45% increased risk of cardiovascular mortality and 13% lower risk of malignancy-related mortality in this CKD cohort (Table 1). Proportion of deaths due to ischemic heart disease (23.1% vs 16.5%) and heart failure (5.3% vs 2.4%) were higher in those with AF than among those without AF. Deaths due to cerebrovascular diseases were similar in those with and without AF. Exclusion of those with malignancy at baseline yielded similar results except that no association between AF and malignancy-related deaths was noted. Results were consistent across various stages of CKD.

Conclusions: In a non-dialysis dependent CKD population, presence of AF was associated with higher all-cause and cardiovascular mortality.

Funding: Commercial Support - Development of CCF CKD registry was suppoerted by an unrestricted educational fund to the Department of Nephrology and Hypertension from Amgen, Inc

Table 1. Associations of Atrial fibrillation with all-cause and cause-specific mortality

	Unadjusted HR (95% CI)	Adjusted* HR (95% CI)	Excluding those with malignancy Adjusted* HR (95% CI)
All-cause death	1.69 (1.62, 1.76)	1.23 (1.18, 1.29)	1.31 (1.25, 1.39)

White Matter Hyperintensities and Risk for Kidney Function Decline with Intensive Blood Pressure (BP) Lowering: The Secondary Prevention of Subcortical Strokes (SPS3) Trial Jesse C. Ikeme,[1] Michael Shlipak,[1] Oscar Benavente,[2] Carmen A. Peralta.[1] *[1]The Kidney Health Research Collaborative at SF VAMC and UCSF, San Francisco, CA; [2]University of British Columbia, Vancouver, BC, Canada.*

Background: Intensive BP lowering may help prevent stroke recurrence, but it can also cause rapid kidney function decline (RKFD). White matter hyperintensities (WMHs) on brain MRI are a marker of cerebral small vessel disease and may suggest small vessel disease in kidneys. We hypothesized that high WMH burden could identify stroke survivors susceptible to RKFD with intensive blood pressure (BP) lowering.

Methods: SPS3 randomized 3,020 participants with lacunar stroke to target systolic BPs 130-150 mmHg vs. <130 mmHg. We included 2,454 participants with baseline WMHs from brain MRI. We defined RKFD as ≥30% decline in eGFR from baseline to year 1. We tested for interaction between BP intervention and WMH severity on the incidence of RKFD in one year.

Results: At randomization, mean age was 63 years and eGFR 81 mL/min/1.73m². Two hundred thirty-four (9.5%) had RKFD at one year—100 (8.1%) in the usual BP and 134 (11.0%) in the intensive BP arm (p = 0.01). The proportion with RFKD increased with higher WMH tertile (8%, 10%, and 11% from lowest to highest tertile). The association of BP target with RKFD was qualitatively higher with increasing WMH tertile (Table), but the interaction was not significant (p = 0.65).

Conclusions: Higher WMH burden was not adequate to distinguish persons most susceptible to rapid kidney function decline in the setting of intensive BP lowering after stroke.

Funding: Other NIH Support - NIH-NIMHD grant R25MD006832 and NIH-NIA grant R01AG046206

Rapid kidney function decline (RKFD) among persons randomized to usual vs. intensive BP lowering in SPS3, stratified by WMH tertile.

BP intervention arm	Participants with RKFD at year 1	Odds ratio	(95% CI)	P
Lowest WMH tertile (n=1013)				
Usual BP arm (n=498)	7.2%	Referent		
Intensive BP arm (n=515)	9.0%	1.26	(0.80 - 1.98)	0.32
Medium WMH tertile (n=770)				
Usual BP arm (n=381)	8.7%	Referent		
Intensive BP arm (n=389)	11.3%	1.34	(0.84 - 2.16)	0.22
Highest WMH tertile (n=671)				
Usual BP arm (n=357)	8.7%	Referent		
Intensive BP arm (n=314)	14.0%	1.71	(1.05 - 2.80)	0.03

TH-PO463

Association of SNPs on FGFR4 and Klotho Genes with LVH and Cardiovascular Outcome in CKD Patients Alexander Sellier,[4] Sarah Seiler,[3] Insa E. Emrich,[1] Danilo Fliser,[5] Adam M. Zawada,[4] Gunnar H. Heine.[2] *[1]None, Haschbach, Germany; [2]Saarland University Faculty of Medicine, Homburg, Germany; [3]Saarland University Hospital, Homburg, Germany; [4]Saarland University Medical Center, Homburg (Saar), Germany; [5]Saarland University Medical Centre, Homburg/Saar, Germany.*

Background: High circulating levels of fibroblast growth factor 23 (FGF23) predict future cardiovascular events in CKD patients even after adjustment for baseline GFR. Recent rodent studies suggest that FGF23 may directly induce left ventricular hypertrophy by activating FGF-receptor 4 (FGFR4) independently from its co-receptor klotho. Opposing studies however reported a deficiency of soluble klotho, rather than high serum FGF23, to aggravate LVH. To compare the clinical relevance of these pathophysiological pathways, we examined whether SNPs within the FGFR4 and klotho gene affect the risk of prevalent LVH and incident cardiac events in our prospective CARE FOR HOMe study.

Methods: The ongoing CARE FOR HOMe study recruits chronic kidney disease G2-G4 patients, of whom 519 patients consented to DNA isolation and genotyping using qualitative real-time PCR (*Gly388Arg* for FGFR4 and *Phe352Val* for klotho). Echocardiography was conducted at baseline by one single physician following American Society of Echocardiography guidelines. All patients were followed for the occurrence of the primary endpoint cardiac decompensation for 4,2 ± 2,1 years.

Results: Carriers of the different alleles of *Gly388Arg* and *Phe352Val* did not differ significantly in their left ventricular mass index (*Gly388Arg*: Gly/Gly: 91.7 ± 28.5 g/m², Gly/Arg: 91.4 ± 24.4 g/m², Arg/Arg: 93.9 ± 28.7 g/m², p = 0.861; *Phe352Val*: Phe/Phe: 91.1 ± 25.4 g/m², Phe/Val: 92.8 ± 28.2 g/m², Val/Val: 100.9 ± 48.0 g/m², p = 0.379). During follow up, cardiovascular events occurred in 104 patients. Neither *Gly388Arg* nor *Phe352Val* was significantly associated with risk of cardiac decompensation in univariate analysis (log rank test: *Gly388Arg*: p = 0.241; *Phe352Val*: p = 0.817).

Conclusions: In CKD patients, SNPs of FGFR4 and Klotho are neither associated with LV mass, nor with the risk of future cardiac decompensation. We suggest to analyze the association between SNPs, LV hypertrophy and incident cardiac events in independent large CKD collectives before findings from rodent studies should be transferred to clinical nephrology.

TH-PO464

Renal Resistive Index in Cortical but Not in Segmental Arteries Reflects Renal Perfusion in Hypertensive CKD Patients Arkadiusz Lubas, Stanislaw Niemczyk. *Military Institute of Medicine, Warsaw, Poland.*

Background: Renal Resistive Index in segmental arteries (RI-S) is a well known marker of cardiovascular and renal organ damage. In many studies it is used as a marker of Renal Perfusion (RP). However this relation was not proved. Renal Resistive Index in cortical arteries (RI-C) is erroneously used as RI-S, because the difference between these indexes is unclear. The aim of the study was to investigate relations between segmental and cortical renal Resistive Indexes and Renal Perfusion.

Methods: Fifty patients (3F; 47M; age 56.6 ±13.3) with stable CKD (CKD-EPI 57.4 ±28.4 ml/min/1.73m^2) and a history of hypertension were enrolled in the study. Ultrasonic color and duplex Doppler examinations of intrarenal arteries in the right kidneys were performed. RI-S was calculated as a mean of 3 measurements. RI-C and RP (arterio-venous mean perfusion [mL/s]) were calculated with the use of Dynamic Tissue Perfusion Method (PixelFlux software). Echocardiographic Cardiac Index (CI), IMT, 24-h Pulse Pressure (PP) and renal function expressed as Creatinine and Cystatin based CKD-EPI formula were estimated.

Results: Renal Resistive Indexes were significantly correlated (r=0.63; R^2=0.40; p<0.001), but RI-S was lower than RI-C (0.684 ±0.075 vs 0.728 ±0.131; p=0.004). In the univariable analysis RI-S and RI-C both were significantly correlated with age, IMT, PP, CI, CKD-EPI, and RP. The multivariable regression analysis adjusted to age and BMI showed that CKD-EPI (p<0.001), CI (p=0.005) and PP (p=0.014) independently influenced RI-S (R^2=0.55, p<0.001). The same analysis for RI-C revealed an independent relation (R^2=0.41, p<0.001) with PR (p<0.001) and CI (p=0.024). When RI-S was added to the regression equation PR (p<0.001) and RI-S (p<0.001) independently modified RI-C (R^2=0.51, p<0.001).

Conclusions: Renal Resistive Index in segmental arteries is independently modified by cardiovascular and renal organ damage parameters with the exclusion of the Renal Perfusion. Although RI-S and RI-C correlate with each other, their values differ significantly. Renal cortical Resistive Index reflects both Renal Perfusion and segmental Resistive Index. Segmental and cortical renal Resistive Indexes cannot be used interchangeably.

Analysis of Genome-Wide Arterial Media-Specific DNA Methylation Demonstrates No Epigenetic Evidence of Aging but Reveals New Targets in CKD Associated Cardiovascular Pathology Athina Dritsoula,[1] Amin Oomatia,[1] Maria Kislikova,[1] Amy P. Webster,[2] Stephan Beck,[2] Jill T. Norman,[1] David C. Wheeler,[1] Thomas Oates,[1] Ben Caplin.[1] *[1]Centre for Nephrology, University College London, London, United Kingdom; [2]Cancer Institute, University College London, London, United Kingdom.*

Background: Cardiovascular disease (CVD) is the primary cause of morbidity and mortality among patients with chronic kidney disease (CKD). In CKD-related CVD, structural and morphological changes occur in the vascular bed leading to arterial stiffness, matrix deposition and calcification that have been described as accelerated arterial aging. These changes are mediated by the activation of vascular smooth muscle cells. Altered DNA methylation has been proposed to mediate the aging process and is also a manifestation of CKD. We aim to investigate tissue specific changes in DNA methylation that occur in CKD-related CVD.

Methods: DNA methylation analysis was performed (Illumina EPIC array) in bisulfite converted genomic DNA, isolated from the arterial media of 25 recipients (CKD patients; epigastric artery) and 7 donors (controls; renal artery) during kidney transplantation procedures, after the advintitia was removed and the endothelium was brushed away. Bioinformatics analysis was performed using Bioconductor packages in R (SNP and XY chromosome-related CpGs were excluded). BMIQ and Combat analysis were used for normalization and to correct technical variation respectively. DNA methylation age (DMAge) was estimated using the algorithm by Horvath *et al*. Methylation-specific PCR was used to validate the array data. P-values were adjusted for multiple comparisons.

Results: 3x10^5 differentially methylated CpGs encompassing 703 differentially methylated regions (DMR) were identified (adj p<0.05) spread across all autosomal chromosomes. Significant enrichment was found in promoters, exons, introns and 5' UTRs. DMRs were found in or in proximity to interfering RNAs (miR-196b) along with genes associated with vascular remodelling and ECM production (*COL6/7/9, ADAMTS8/9, MMP2, LOXL1*), and signalling mechanisms involved in fibrosis and vascular pathologies (*TGFβ1, FGF1/6, SMAD3, GATA3/4/5)*. DMAge and chronological age were highly correlated but there was no evidence of higher DMAge in CKD cases.

Conclusions: Overall, these data implicate altered arterial media-specific DNA methylation in CKD-related CVD, but this methylation profile does not reflect a process of accelerated aging.

TH-PO466

Methylarginines in CKD Insa E. Emrich,[7] Adam M. Zawada,[4] Jens Martens-lobenhoffer,[6] Stefan Wagenpfeil,[2] Danilo Fliser,[5] Gunnar H. Heine,[3] Stefanie M. Bode-Böger.[1] *[1]Institute of Clinical Phamacology, Medical Faculty, Otto-von Guericke University, Magdeburg, Germany; [2]Saarland University, Homburg, Germany; [3]Saarland University Faculty of Medicine, Homburg, Germany; [4]Saarland University Medical Center, Homburg, Germany; [5]Saarland University Medical Centre, Homburg/Saar, Germany; [6]University Magdeburg, Magdeburg, Germany; [7]Medical Center, Saarland University, Homburg, Germany.*

Background: Patients suffering from chronic kidney disease (CKD) have a substantial burden of cardiovascular disease, whose underlying pathophysiological mechanism cannot fully be explained by traditional risk factors. Therefore, non-traditional cardiovascular risk factors have to be taken into account. As such potential non-traditional risk factors, asymmetric dimethylarginine (ADMA) & symmetric dimethylarginine (SDMA) have been a focus of cardiorenal research for several years. It has recently been revealed that ADMA & SDMA become acetylated during their degradation. In murine models the acetylated ADMA (Ac-ADMA) & the acetylated SDMA (Ac-SDMA) were significantly associated with kidney function. We now hypothesize that (a) a similar accumulation of Ac-ADMA & Ac-SDMA occurs in humans & (b) Ac-ADMA & Ac-SDMA are more prominent predictors of incident cardiovascular events than ADMA & SDMA.

Methods: Blood samples of 528 CKD patients KDIGO stage G2 to G4 who participated in our CARE FOR HOMe study were analyzed. ADMA, SDMA & acetylated metabolites were measured by liquid chromatography – tandem mass spectrometry. All patients were followed annually with standardized interviews during a follow up period of 4.6 ± 2.0 years.

Results: Mean plasma ADMA concentration was 0.49 [0.44; 0.55] µmol/l, mean plasma SDMA concentration was 0.72 [0.59; 0.98] µmol/l, mean plasma Ac-ADMA concentration was 1.24 [0.74; 2.16] nmol/l & mean plasma Ac-SDMA concentration was 8.42 [3.60; 19.12] nmol/l. All four metabolites accumulated in patients with more advanced CKD. While Ac-ADMA was more strongly correlated with eGFR than ADMA, Ac-SDMA was less strongly correlated with eGFR than SDMA. During follow up, 144 patients suffered from a cardiovascular event. In univariate Cox-regression analyses, high plasma levels of all four metabolites were significantly associated with incident cardiovascular events. However, after adjustment for confounders including eGFR & traditional cardiovascular risk factors, only high plasma SDMA remained significantly associated with incident cardiovascular events.

Conclusions: In the future, we need further investigations to analyze the underlying acetylation's mechanism & we have to clarify the role of SDMA in cardiorenal pathophysiology.

TH-PO467

The Role of Neprilysin in CKD Insa E. Emrich,[2] Nicolas Vodovar,[1] Kathrin Untersteller,[2] Hélène Nougué,[1] Sarah Seiler,[4] Danilo Fliser,[5] Alexandre Mebazaa,[1] Jean-Marie Launay,[1] Gunnar H. Heine.[3] *[1]Inserm UMR-S 942, Paris, France; [2]None, Haschbach, Germany; [3]Saarland University Faculty of Medicine, Homburg, Germany; [4]Saarland University Hospital, Homburg, Germany; [5]Saarland University Medical Centre, Homburg/Saar, Germany.*

Background: Since the introduction of sacubitril in clinical cardiology, neprilysin has become a major treatment target for patients suffering from heart failure. Neprilysin inhibition with sacubitril prolongs survival of patients with systolic heart failure, and elevated plasma neprilysin concentrations predict adverse cardiac outcome in non-nephrological cohorts. However, natriuretic peptides were recently shown to inhibit plasma neprilysin. As natriuretic peptides accumulate in chronic kidney disease (CKD), we hypothesized that high plasma neprilysin loses its predictive role in patients with impaired renal function.

Methods: We measured plasma levels of neprilysin concentration, neprilysin activity and brain natriuretic peptide (BNP) in 542 CKD G2 - G4 patients within the CARE FOR HOMe study. Patients were followed annually for predefined endpoints (a) hospitalization for acute decompensated heart failure, and (b) atherosclerotic cardiovascular events.

Results: During 5.1 ± 2.1 years, 63 hospitalizations for acute decompensated heart failure and 125 incident atherosclerotic cardiovascular events occurred. Plasma BNP was inversely correlated with neprilysin activity (before adjustment for glomerular filtration rate: r = -0.118; p = 0.006; after adjustment: r = -0.193; p < 0.001), but not with neprilysin concentration (r = -0.022; p = 0.603 and r = 0.065; p = 0.132, respectively). Both in univariate Kaplan-Meier and in multivariate Cox regression analyses, high plasma BNP and low, rather than elevated, neprilysin activity predicted future hospitalization for acute decompensated heart failure, whereas neprilysin concentration was not predictive. Further, BNP was an independent predictor of incident atherosclerotic cardiovascular events, while neprilysin concentration and activity were not.

Conclusions: In line with experimental studies, high natriuretic peptides may inhibit neprilysin activity in CKD. In accordance, high neprilysin activity and concentrations are no predictors of adverse cardiovascular outcome in CKD patients. Thus, neprilysin inhibitors should be implemented with caution in patients with advanced CKD, and further studies are needed to better understand the benefits and risks of neprilysin inhibitors in these patients.

TH-PO468

Plasma Phospholipid Remodeling Associates with Stroke in CKD Adil Jadoon,[2] Thekkelnaycke Rajendiran,[1] Jaeman Byun,[2] Tanu Soni,[2] Subramaniam Pennathur,[2] Farsad Afshinnia.[2] *[1]Univeraity of MIchigan, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: Stroke is a prevalent co-morbidity in chronic kidney disease (CKD). Systematic identification and quantification of complex lipids in stroke are lacking. This study is aimed at comparison of 17 different lipid classes in patient with and without a history of stroke.

Methods: This is a cross-sectional study of CKD patients from Clinical Phenotyping Resource and Biobank Core. Inclusion criteria were age greater than 18 years from all stages of CKD, frequency matched by gender and race among the CKD stages. Baseline demographic and clinical characteristics at the time of enrolment were background variables. Predictors were plasma lipid features identified by an untargeted liquid chromatography/mass spectrometry-based lipidomics platform from plasma samples obtained at the time of enrolment. Outcome was history of stroke. Lipids were internal standard normalized, log2 transformed, underwent calculation of percentage contribution to the corresponding lipid class, logit transformed, and z-score standardized for the downstream analyses.

Results: Overall 214 patients were included consisting of 184 patients without and 30 patients with stroke. Mean age was 60 years (SD=16). There were 104 females (48.6%); 64 patients (29.9%) were African-American and 150 (70.1%) were Caucasians. Distribution of body mass index, blood pressure, serum albumin, total cholesterol, lipoprotein, total triglycerides, and urine albumin-creatinine ratio was not different in patients with and without stroke. Overall we identified 330 lipid features of which 106 (32.1%) consisted of phospholipids including Phosphatidylcholines (PC, n=50), Phosphatidylethanolamine (PEs, n=28), Plasmenyl-Phosphatidylcholine (pPCs, n=6), and Plasmenyl-phosphatidylethanolamine (pPEs, n=12). Using a t-test, 36 lipids passed the nominal threshold of $p<0.05$ comparing patients with and without stroke, of which 23 lipids belonged to one of the phospholipid classes (over representation enrichment p=0.00004). Accordingly, PC-38:4 was the top ranking lipid with 0.73 SD higher level (95% confidence interval: 0.35 to 1.10) in stroke as compared to no stroke.

Conclusions: These findings reveal sustained significant alterations and remodeling in major plasma phospholipid subclasses in stroke in CKD patients. Further research is required to elucidate causality or long term prognostication.

TH-PO469

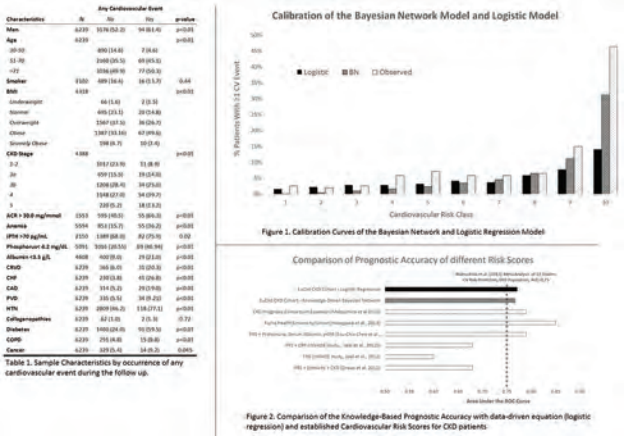
CALIBRA: A Cardiovascular, Literature-Based Risk Algorithm for CKD Patients Luca Neri, Francesco Bellocchio, Carlo Barbieri, Flavio Mari, Ulrich Tschulena, Stefano Stuard. *Fresenius Medical Care, Bad Homburg, Germany*.

Background: Current cardiovascular (CV) risk scores may have limited generizability; do not implement patient-specific prognostic reasoning; require large datasets for derivation and cannot be easily updated as new evidence emerge. CALIBRA is a Knowledge-Driven Bayesian Network risk algorithm overcoming such limitations. We compared CALIBRA predictions against established risk scores and a data-driven model.

Methods: CALIBRA is a Bayesian Network (BN) based on several meta-analyses of original cohort studies on CV risk among CKD patients. For each potential risk factor, all effect sizes were pooled with a fixed effect method and then converted to BN weights using epidemiologic data (incidence of CV events in the population; prevalence of risk factors). CALIBRA implements personalized prognostic reasoning by yielding a summary risk score, by ranking the most impacting risk factors for each patient, by suggesting further diagnostic testing maximizing prognostic accuracy. We evaluated CALIBRA accuracy (AUC) in the EuCliD CKD stage 3-5 cohort (2011-2015) and compared it to a data-driven model (logistic regression derived in the same data).

Results: We included 32 variables from high quality studies in the final model (e.g.: socio-demographic, life-style, antropometry, comorbidities, bipochemistry tests). We used the knowledge-driven model to predict CV occurrence in the validation cohort (n=6239). There were 153 CV hospitalizations in 12 months (0,025 events/100 person*year) in the validation sample, Due to incomplete clinical records, predictions were based on 16.9±2.0 variables per patient. CALIBRA accuracy was similar to the data-driven model (AUC=0.77 for both) (fig.1)

Conclusions: CALIBRA provides unique features of prognostic reasoning along with accurate risk prediction. It represents a valid tool for risk stratification and clinical evaluation. The tool is easily and promptly updatable with the most recent scientific knowledge.



TH-PO470

Design of a Clinical Risk Calculator for Atherosclerotic Renovascular Disease Diana Vassallo,[1] Robert N. Foley,[2] Philip A. Kalra.[1] *[1]Salford Royal Hospital NHS Foundation Trust, Salford, United Kingdom; [2]University of Minnesota, Minneapolis, MN.*

Background: Risk stratification in atherosclerotic renovascular disease (ARVD) can influence treatment decisions and facilitate patient selection for revascularization. In this study, we aim to use variables with the best predictive value to design a risk calculator that can assist clinicians with risk stratification and outcome prediction.

Methods: Patients with a radiological diagnosis of ARVD were recruited into a single-center prospective cohort study between 1986 and 2014. Primary clinical end-points included: death, end-stage kidney disease (ESKD) and cardiovascular events (CVE). A stepwise regression model was used to select variables with the most significant hazard ratio for each end-point. The risk calculator was designed using HyperText Markup language (HTML). Survival and CVE-free survival were estimated at 1, 5 and 10 years.

Results: In total 872 patients were recruited into this study with a median follow-up of 54.9 months (20.2-96.0). Only models predicting death and CVE showed good performance (c-index >0.80). The risk calculator (figure 1) showed that while all patients with ARVD had poor longterm survival, revascularization may improve outcomes in patients with better preserved eGFR and lower baseline proteinuria (table 1).

Conclusions: Although this risk calculator requires further independent validation in other ARVD cohorts, this study shows that a small number of easily obtained variables can help predict clinical outcomes and encourage a patient-specific therapeutic approach.

Table 1 Predicted survival probabilities for patients with different clinical phenotypes.

Overall Survival	Patient A-non-revascularized	Patient A-revascularized	Patient B-non-revascularized	Patient B-revascularized
1-year	0.75	0.89	0.75	0.75
5-year	0.36	0.48	0.36	0.36
10-year	0.08	0.17	0.08	0.08

Patient A – 70 years old, eGFR 30ml/min/1.73m2, proteinuria 0.5g/day, previous myocardial infarction, congestive heart failure and peripheral vascular disease.

Patient B – 70 years old, eGFR 20ml/min/1.73m2, proteinuria 1.0g/day, previous myocardial infarction, congestive heart failure and peripheral vascular disease.

Risk Calculator

Insulin Resistance Index from OGTT Predicts Outcomes of Ischemic Stroke in Non-Diabetic Patients with Renal Dysfunction Yi-Lun Zhou, Yin Zhang, Yuesong Pan, Yilong Wang, Yongjun Wang. *Beijing Tiantan hospital, Capital Medical University, Beijing, China. Group/Team: On behalf of ACROSS-China group*.

Background: Insulin resistance is associated with increased stroke risk and poor stroke outcomes. Renal dysfunction contributes substantially to both insulin resistance

and adverse outcomes of ischemic stroke. However, the impact of impaired renal function on the associations of insulin resistance with stroke outcomes is unknown. Therefore, we sought to investigate the associations of both fasting and post-glucose load insulin resistance indices with ischemic stroke prognosis in non-diabetic patients with impaired renal function.

Methods: Patients with ischemic stroke without a history of diabetes mellitus in the Abnormal Glucose Regulation in Patients with Acute Stroke across China (ACROSS-China) registry were included. Fasting and oral glucose tolerance test (OGTT) derived measures of insulin resistance,the homeostatic model assessment of insulin resistance (HOMA-IR) and the insulin sensitivity index (ISI) were calculated. The highest quartile of HOMA-IR (Q4) or the lowest quartile of ISI (Q1) in the overall population was defined as insulin resistance. The associations between insulin resistance and stroke outcomes were investigated according to estimated glomerular filtration rate (eGFR) strata.

Results: Among 1196 patients, HOMA-IR Q4 vs.Q1-3 was associated with increased 1-year mortality (adjusted hazard ratio [95% confidence interval], 1.75 [1.03-3.00]) and poor outcome (adjusted odds ratio 2.23 [1.43-3.46]) only in participants with eGFR≥90ml/min/1.73m^2. In comparison, ISI Q1 vs. Q2-4 was associated with higher risks of mortality (adjusted hazard ratios: 3.69 [0.95-14.40]; 2.21 [1.02-4.78]; and 1.81 [1.05-3.11]) and poor outcome (adjusted odds ratios: 3.96 [1.02-15.28]; 1.96 [1.00-3.82]; and 2.25 [1.42-3.57]) in all three subgroups with eGFR<60, 60-89, and ≥90 ml/min/1.73m^2, respectively.

Conclusions: OGTT derived estimate of insulin resistance with ISI was associated with increased risks of 1-year mortality and poor outcome in non-diabetic ischemic stroke patients with impaired renal function. While the predictive value of HOMA-IR was compromised in the context of renal dysfunction.

Left Ventricular Geometry in Type 2 Diabetic Patients with Kidney Disease: Predictive Factors Klotho and FGF23 Ana P. Silva,[3,2] Filipa B. Mendes,[1] Pedro L. Neves.[3,4] *[1]Centro Hospitalar do Algarve, Faro, Portugal; [2]Department of Biomedical Sciences and Medicine, University of Algarve, Faro, Portugal; [3]Nephrology, CHA, Faro, Portugal; [4]Department of Biomedical Sciences and Medicine, University of Algarve, Faro, Portugal.*

Background: Chronic Kidney Disease (CKD) is known to induce a cardiac overload that reconfigures the architecture and physiology of the myocardium, inducing hypertrophy and fibrosis. Those alterations begin in the early stages of the disease and aggravate as renal functions declines. The this work we evaluated a population of CKD patients to ascertain the potential use of plasmatic Klotho, FGF23 or both as markers for CKD-induced cardiac disease.

Methods: This prospective cohort study was conducted in our outpatient diabetic nephropathy (DN) clinic from 2012 to 2016. For this study we included one hundred and seven (107) patients with stage 2-3 CKD. The mean age was 57.2±7.1 years and the mean LVMI level was 99.31±23.45 g/m2. LVH and RWT were used to categorize LV geometry: normal (no LVH and normal RWT), eccentric hypertrophy (LVH and normal RWT), and concentric hypertrophy (LVH and increased RWT). Patients were classified as having LVH if they had LVMI 100 g/m2 in women and 131 g/m2 in men, and RWT was considered to be increased if .0.45.

Results: Multinomial regression analysis demonstrated that diminished eGFR (OR=0.959; 95% IC;0.921 – 0.999;p=0.043)and elevated P (OR=2.859;95%IC; 2.238 – 5.693; p=0.003) levels were associated with a greater risk of Eccentric Hypertrophy but not with Concentric Hypertrophy. On contrary, low Klotho (OR=0.737; 95% IC; 0.603 – 0.972;p=0.031) and higher FGF-23 (OR= 1.031; 95% IC 1.008 – 1.055; p=0.009) levels were associated with a greater risk of Concentric Hypertrophy. Using the Kaplan-Meier analysis, it was observed that patients' survival at 60 months was 90.2 % in patients without Hypertrophy, 76.3 % in patients with Eccentric Hypertrophy and 53.6 % in patients with Concentric Hypertrophy (log rank=9.422; p = 0.009).

Conclusions: In conclusion, both Klotho and FGF23 serum levels represent good biomarkers of CVD in CKD patients they might be used along with imaging techniques, as diagnostic parameters biomarkers of the CVD.

TH-PO473

Gut Microbiome Derived Short Chain Fatty Acids Alter with Advancing CKD and Improve Prediction of Associated Cardiovascular Disease Adil Jadoon, Anna V. Mathew, Jaeman Byun, Farsad Afshinnia, Subramaniam Pennathur. *University of Michigan, Ann Arbor, MI.*

Background: Short chain free fatty acids (SCFA) are products of dietary complex carbohydrate fermentation by the intestinal microbiota and exert multiple effects on mammalian energy metabolism. However, reports of alterations in SCFAs by CKD and association with CVD are lacking. In this study, utilizing targeted metabolomics by liquid-chromatography mass-spectrometry (LC/MS), we quantified SCFAs at different stages of CKD and analyzed their association with CVD.

Methods: This is a cross sectional observational study of the population in Clinical Phenotyping Resource and Biobank Core. Inclusion criteria are patients with CKD, aged older than 18. Clinical and demographic data at the time of enrolment were gathered. Secondary outcomes were history of CAD, CHF and peripheral artery disease (PAD). SCFAs were measured by LC/MS using the plasma at enrolment. We used analysis of variance to compare means by CKD stages, and applied Receiver Operating Characteristics Curve to compare c-statistic of different models.

Results: Overall we enrolled 214 patients, including 36, 99, 61, and 18 patients from stages 2 to 5 of CKD. Mean age was 60 years (SD=16), and 51.4% were males (n=110). We found a significant graded decrease in level of acetate from 14.3±2.8 ug/L in stage 2 to 12.2±1.9 ug/L in stage 5 (p=0.011), but a significant increase in mean level of butyrate, valerate, and caproate from stage 2 to stage 5 (p≤0.018). Specifically, level of valerate increased from 1.8±0.1 ug/L in CKD stage 2 to 1.9±0.3 ug/L in stage 5 (p=0.006), and caproate increased from 1.6±0.1 ug/L to 2.0±1.4 ug/L from CKD stage 2 to 5. Mean±SD of valerate in patients with and without CAD was 1.79±0.08 ug/L and 1.62±0.09 ug/L, respectively (P<0.0001). Similarly, this value was 1.80±0.08 ug/L and 1.84±0.09ug/L in patients with and without CHF, respectively (p=0.037). Compared to a model consisting of age, diabetes, and stages of CKD to predict CAD, addition of valerate significantly improved c-statistic from 0.74 to 0.78 (p=0.029).

Conclusions: This study provides evidence for alterations in gut-microbiome derived SCFAs with advancing CKD and links SCFAs to CVD, suggesting possible contribution of gut microbiome to CKD and its complications.

Urinary Biomarkers of Tubular Damage and Risk of Cardiovascular Disease and Mortality in Elders Vasantha Jotwani,[7] Ronit Katz,[5] Joachim H. Ix,[4] Orlando M. Gutierrez,[3] Chirag R. Parikh,[6] Mark J. Sarnak,[2] Michael Shlipak.[1] *[1]San Francisco VA Medical Center, San Francisco, CA; [2]Tufts Medical Center, Boston, MA; [3]UAB School of Medicine, Birmingham, AL; [4]UCSD, San Diego, CA; [5]University of Washington, Seattle, WA; [6]Yale University and VAMC, New Haven, CT; [7]UCSF, San Francisco, CA.*

Background: Novel urinary biomarkers have enabled earlier detection of kidney tubular damage, but their prognostic value for adverse cardiovascular outcomes is uncertain. We hypothesized that tubular damage, measured by urine α1-microglobulin (α1m), pro-collagen type III N-terminal pro-peptide (PIIINP), and neutrophil gelatinase-associated lipocalin (NGAL), would be associated with higher risks for cardiovascular events and mortality among elders.

Methods: In this case-cohort study of participants enrolled in the Health, Aging, and Body Composition Study, we measured urine concentrations of α1m, PIIINP, and NGAL among randomly selected CVD cases (n=245), heart failure cases (n=220), and a subcohort (n=502). We used Cox proportional hazards models to evaluate biomarker associations with incident CVD, heart failure, and all-cause mortality.

Results: At baseline, the mean age was 74 years and eGFR was 73 ml/min/1.73m^2. There were 248 deaths in the subcohort over a median follow-up of 12.4 years. After multivariable adjustment, urine α1m, PIIINP and NGAL were each associated with higher risks for CVD (**Table**). Urine α1m and NGAL were also associated with higher mortality risk. The biomarkers did not have statistically significant associations with heart failure.

Conclusions: Kidney tubular damage is an independent risk factor for CVD and death among elders. Future studies should investigate mechanisms by which renal tubular damage may adversely impact cardiovascular risk.

Funding: NIDDK Support, Other NIH Support - NIA funding of Health, Aging, and Body Composition Study (N01-AG-6-2101, N01-AG-6-2103, N01-AG-6-2106, R01-AG028050)

Associations of individual urine biomarkers with incident CVD, heart failure, and mortality

Biomarker	Incident CVD HR (95% CI)	Heart failure HR (95% CI)	All-cause mortality HR (95% CI)
α1-microglobulin	1.44 (1.11, 1.87)	1.18 (0.94, 1.48)	1.26 (1.07, 1.47)
PIIINP	1.20 (1.00, 1.44)	0.90 (0.77, 1.05)	1.06 (0.94, 1.18)
NGAL	1.12 (1.04, 1.20)	0.96 (0.88, 1.04)	1.07 (1.02, 1.12)

Hazard ratios per doubling in biomarker. Models adjust for demographics, cardiovascular risk factors, eGFR, urine albumin, and urine creatinine.

TH-PO475

Growth Differentiation Factor-15, Galectin-3, and Soluble ST-2 and Risk of Mortality and Cardiovascular Disease in CKD Courtney Tuegel,[2] Ronit Katz,[2] Zeenat Y. Bhat,[1] Keith A. Bellovich,[1] Ian H. de Boer,[2] Frank C. Brosius,[1] Crystal A. Gadegbeku,[1] Debbie S. Gipson,[1] Jennifer J. Hawkins,[1] Jonathan Himmelfarb,[2] Wenjun Ju,[1] Bryan R. Kestenbaum,[2] Matthias Kretzler,[1] Cassianne Robinson-Cohen,[2] Susan P. Steigerwalt,[1] Nisha Bansal.[2] *[1]University of Michigan, Ann Arbor, MI; [2]University of Washington, Seattle, WA.*

Background: Novel pathways may explain the excess risk of cardiovascular disease (CVD) in the chronic kidney disease (CKD) population. Growth differentiation factor-15 (GDF-15), galectin-3 (gal-3), and soluble ST-2 (sST-2) are biomarkers of inflammation, cardiac remodeling, and fibrosis that may reflect pathways promoting CVD in CKD.

Methods: We pooled CKD participants in the cohorts Seattle Kidney Study and Clinical Phenotyping and Resource Biobank Study. GDF-15, gal-3 and sST-2 were measured at baseline. Outcomes were physician-adjudicated heart failure (HF) events, atherosclerotic CVD events (myocardial infarction or cerebrovascular accident), and mortality. Cox proportional hazards were used to test associations of biomarker levels with each outcome, adjusting for demographics, CVD risk factors, and renal function.

Results: Among 883 participants, the mean eGFR was 49 mL/min per 1.73 m^2. Over median follow up of 3.10 years, there were 98 deaths (3.3%/year), 41 HF events (1.42%/year), and 29 atherosclerotic CVD events (1%/year). After adjusting for confounders, higher GDF-15, gal-3, and sST-2 levels were all independently associated with increased mortality (**Table**). Higher GDF-15 also associated with increased risk for HF and there was a trend for a similar association with sST-2. There were no statistically significant associations between GDF-15, gal-3, or sST-2 and risk of atherosclerotic CVD.

Conclusions: In adults with CKD, higher GDF-15, gal-3, and sST-2 are associated with increased risk of mortality. Elevated GDF-15 and sST-2 are also associated with increased risk of HF. The pathways of inflammation, cardiac remodeling, and fibrosis represented by these biomarkers may be important in the pathogenesis of CVD in those with CKD.

Funding: NIDDK Support

Table:

Associations of GDF-15, Gal-3 and sST2 with risks of all-cause mortality, heart failure, and atherosclerotic cardiovascular disease events

Biomarker	*Mortality* HR (95% CI)	*Heart Failure* HR (95% CI)	*Atherosclerotic CVD* HR (95% CI)
GDF-15	1.84 (1.49, 2.28)	1.74 (1.24, 2.44)	1.18 (0.77, 1.82)
Gal-3	1.57 (1.32, 1.86)	1.09 (0.76, 1.57)	1.18 (0.79, 1.59)
sST-2	1.36 (1.16, 1.58)	1.29 (0.99, 1.68)	0.77 (0.41, 1.45)

- Hazard ratios are reported per standard deviation increase in biomarker level. Standard deviation for GDF-15 (1607 pg/mL), Gal-3 (7.87 ng/mL), and sST-2 (17.49ng/mL).
- Data adjusted for demographics, CVD risk factors, and kidney function measures

Syndecan-4 Is Associated with eGFR and the Incidence of Myocardial Infarction in a General Population: The Tromsø Study Marit D. Solbu,[2,4] Trine M. Reine,[5] Svein O. Kolset,[3] Trond G. Jenssen.[1,4] *[1]Oslo University Hospital, Oslo, Norway; [2]University Hospital of North Norway, Tromsø, Norway; [3]University of Oslo, Oslo, Norway; [4]Metabolic and Renal Research Group, UiT The Arctic University of Norway, Tromsø, Norway; [5]Univrsity of Oslo, Oslo, Norway.*

Background: Cardiovascular disease (CVD) is a common cause of morbidity and mortality. A link between chronic kidney disease (CKD) and CVD exists, but mechanisms are poorly understood. The endothelial glycocalyx is essential in maintaining vascular integrity. Disruption and shedding of the glycocalyx may be a common pathway in CVD and CKD. Syndecans are components of the glycocalyx. Increased serum levels of syndecan-4 is a marker of glycocalyx change or damage. We studied the cross-sectional association between syndecan-4 and kidney function, and the longitudinal association of these markers with myocardial infarction.

Methods: We used a case-cohort design and included participants from the Tromsø 5 Study (2001-02). Syndecan-4 was measured in frozen serum specimens with ELISA-assays. Baseline variables also included age, sex, cardiovascular risk factors, estimated GFR (eGFR) and urinary albumin-creatinine ratio (ACR). We used Spearman correlation, linear regression, and in Cox regression models we applied Borgan II weights.

Results: Among the 1496 men and women included, 328 experienced a fatal or non-fatal myocardial infarction between inclusion and the end of 2007. In the subcohort (n=831), mean age was 63.8 (±10.0) years, and 60.3% were women. Mean syndecan-4 was 18.7 (±5.6) ng/mL, mean eGFR was 87.7 (±13.7) ml/min/1.73 m² and median ACR (IQR) was 0.43 (0.30, 0.77) mg/mmol. In the entire cohort, syndecan-4 was significantly correlated with eGFR (r=0.15; p<0.001), but only borderline significantly with ACR (r=0.05; p=0.045). In multiple linear regression analyses adjusted for age, sex, systolic blood pressure and waist circimference, syndecan-4 was positively associated with eGFR, but not significantly associated with ACR. Adjusted for the same variables plus smoking, glycosylated hemoglobin A1c, eGFR and ACR, syndecan-4 was an independent predictor of myocardial infarction (per 1 ng/mL: HR 1.24 (1.01, 1.52; P=0.04)), but eGFR and ACR were not.

Conclusions: In a general population serum syndecan-4 was positively associated with baseline eGFR and an independent predictor of myocardial infarction. Whether this association partly may be mediated through kidney function, remains to be studied.

Funding: Government Support - Non-U.S.

Decreased Serum Sulfatide Level and Hepatic Sulfatide Synthesis Ability in 5/6 Nephrectomy CKD Model Mice Yosuke Yamada,[1] Kosuke Yamaka,[1] Keita Inui,[1] Yuji Kamijo.[2] *[1]Shinshu University, Matsumoto, Japan; [2]Shinshu University School of Medicine, Matsumoto, Japan.*

Background: Chronic kidney disease (CKD) is increasing worldwide. As CKD is an independent risk factor of critical cardiovascular disease, its pathological clarification has become imperative. We earlier reported that the serum level of sulfatide, a glycosphingolipid, was decreased in CKD patients and that the risk of cardiovascular disease was higher in end-stage renal disease patients with diminished serum sulfatide. Accordingly, we have hypothesized that CKD impairs the ability to synthesize sulfatide and lowers serum sulfatide concentration to adversely affect peripheral circulation and contribute to cardiovascular disease onset. However, patients with CKD often possess comorbidities, such as hypertension and diabetes, which may act as confounders. It is therefore challenging to determine whether or not CKD influences sulfatide synthesis and serum level. To address this issue, CKD model mice whose renal function was impaired by 5/6 nephrectomy were produced for evaluation of serum sulfatide level and sulfatide synthesis ability in the liver, which is the major origin of sulfatide in the serum.

Methods: Of 14 C57B6J mice, 6 underwent 5/6 nephrectomy in which two thirds of the right kidney was removed at 11 weeks of age and the whole left kidney was removed at 12 weeks of age. The remaining 8 mice were used as controls and underwent sham operations of skin incisions only at 11 and 12 weeks of age, respectively. Both groups were maintained under identical circumstances post-operatively. The animals were sacrificed 12 weeks after the final operation and sulfatide concentrations in the serum and liver tissue were measured by Matrix-assisted laser desorption/ionization-time of flight mass spectrometry.

Results: The 5/6 nephrectomy mice developed CKD with elevated serum creatinine, urea nitrogen, and urine volume as compared with control mice. There were no significant differences in blood pressure or pulse rate between the groups. Serum sulfatide level and liver sulfatide concentration were significantly decreased in test mice versus controls (both P<0.01).

Conclusions: CKD is a cause of decreased serum sulfatide and diminished sulfatide-synthesizing ability in the liver. Further research is needed to investigate whether serum sulfatide level abnormalities contribute to the development of cardiovascular disease.

Uric Acid-Lowering and Markers of CKD-Associated Mineral and Bone Disorder, Vascular Calcification, and Atherosclerosis Emily Andrews,[4] Loni J. Perrenoud,[3] Kristen L. Nowak,[7] Zhiying You,[1] Andreas Pasch,[2] Michel Chonchol,[3] Jessica B. Kendrick,[6] Diana I. Jalal.[5] *[1]UC Denver, Aurora, CO; [2]University Hospital Bern, Bern, Switzerland; [3]University of Colorado, Aurora, CO; [4]University of Colorado Denver, Aurora, CO; [5]University of Colorado Denver Health Science Center, Aurora, CO; [6]University of Colorado Denver and Denver Health Medical Center, Denver, CO; [7]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO.*

Background: Chronic kidney disease (CKD)-associated mineral and bone disorder (MBD) is associated with vascular calcification and accelerated atherosclerosis. Higher uric acid reportedly suppresses 1,25-dihydroxyvitamin D (1,25(OH)2D). It is unknown if lowering serum uric acid improves markers of CKD-MBD, vascular calcification, or atherosclerosis in CKD.

Methods: Post-hoc analysis of a clinical trial randomizing 80 patients with stage 3 CKD and hyperuricemia to placebo vs allopurinol. Serum markers of CKD-MBD were measured. Protein expression of extra-renal 1α-hydroxylase was evaluated from participants' vascular endothelial cells. T_{50} and carotid intima-media thickness (CIMT) were measured as markers of serum calcification and vascular atherosclerosis, respectively. The Wilcoxon two-sample T-test was applied.

Results: Baseline characteristics between both study groups were similar except for significantly higher FGF-23 levels in the placebo group vs allopurinol. Allopurinol lowered serum uric acid levels significantly vs placebo (Table). We found no significant change in vitamin D metabolites or iPTH. Median FGF-23 levels increased slightly with allopurinol vs placebo (4.1(-10.2, 16.7) vs -1.83(-27.8, 19.1)), but this was not statistically significant. There was not a significant change in the expression of endothelial 1α-hydroxylase, serum T_{50}, or CIMT.

Conclusions: These data suggest that factors other than uric acid play a more important role in the regulation of CKD-MBD including vitamin D metabolism and the progression of vascular calcification and atherosclerosis in patients with CKD.

Impact of Renal Function on Association between Uric Acid and All-Cause Mortality in Patients with Chronic Heart Failure Viera Stubnva,[1,5] Ingrid Os,[3] Morten Grundtvig,[2] Bård Waldum-Grevbo.[4] *[1]Finnmark Hospital Trust, Kirkenes, Norway; [2]Innlandet Hospital Trust Lillehammer, Lillehammer, Norway; [3]Oslo University Hospital, Oslo, Norway; [4]Oslo University Hospital, Ullevål and University of Oslo, Oslo, Norway; [5]Institute of Clinical Medicine, University of Oslo, Oslo, Norway.*

Background: Serum uric acid (SUA) is associated with poor prognosis in patients with heart failure (HF). It is still unclear whether there is a causal inference between SUA and increased mortality. We investigated if SUA was an independent predictor of all-cause mortality in HF outpatients using a propensity score matching model to correct for

possible confounding variables. As SUA is closely related to renal function, we examined if renal function affected the relationship between SUA and all-cause mortality.

Methods: Patients from the Norwegian Heart Failure Registry with available baseline SUA were eligible for the study. Individuals in the highest SUA quartile were propensity score matched 1:1 with patients in the three lowest quartiles. The propensity score matching procedure was based on 16 measured baseline characteristics. Univariate Cox regression analyses were used to investigate the independent effect of SUA on all-cause mortality.

Results: A total of 4698 patients (70.4%) had valid registrations of SUA and were included in the study. Propensity score matching identified 886 pairs of patients (SUA quartile 4 compared to SUA quartiles 1 to 3). The groups were well matched, mean age was 71.1± 11.6 years, 74% were males, and mean eGFR was 50.0±20.8 ml/min/1.73 m^2. SUA was an independent predictor of all-cause mortality in HF outpatients (hazard ratio (HR) 1.21, 95% confidence interval (CI) 1.05-1.39). Renal function was found to interact the relationship between SUA and all-cause mortality (p=0.011). In patients with normal renal function (eGFR > 60 ml/min/1.73 m^2), SUA remained an independent predictor for all-cause mortality (HR1.67, 95% CI 1.25-2.24). In contrast, high SUA levels did not predict outcome in HF outpatients with renal dysfunction (HR 1.09, 95% CI 0.93-1.28).

Conclusions: Elevated SUA was an independent predictor of all-cause mortality in HF outpatients in this propensity matched study. However, SUA was associated with poor outcome only in patients with normal renal function, but not in patients with renal dysfunction.

TH-PO480

Identifying Sudden Cardiac Death using Electronic Health Records Melissa Makar,[2] Patrick H. Pun.[1] [1]*Duke University, Durham, NC;* [2]*Duke University, Durham, NC.*

Background: Sudden cardiac death (SCD) is a leading cause of mortality in the US, and disproportionally affects CKD patients. Ascertaining SCD events in electronic health records (EHRs) allows for a better understanding of modifiable risk factors and prevention; however, the complexity of the SCD phenotype makes accurate identification difficult using ICD-9 data alone. By comparing the identification of SCD using a non-machine algorithm versus physician adjudication, we aim to standardize the process of identifying cases of sudden cardiac death in large cohorts as the first step in ultimately reducing SCD incidence among CKD patients.

Methods: An automated search for ICD-9 code 427.5 (cardiac arrest) was applied to the Duke Databank for Cardiovascular Disease, a cohort of over 36,000 patients at a single institution that have undergone cardiac catheterization over the past twenty years. Non-physician, trained staff then applied an algorithm to review the EHRs of detected cases. This algorithm used questions about location, timing, and patient details to guide reviewers to pinpoint SCD cases. This was compared to the gold standard of adjudication by physicians using death certificate data, discharge summaries, and eye witness accounts.

Results: The ICD-9 search identified 1,334 potential events. Of these, 617 unique cases remained after excluding duplicate and missing records. Applying the algorithm then narrowed this to 209 cases of true sudden cardiac arrest events. A total of 88 of the 209 cardiac arrests (42%) resulted in death within 24 hours and qualified as SCD. In comparison, only 63 of the 88 cases (72%) were identified as SCD by the physician adjudication method. Additional information gathered identified the type of arrhythmia (43% VF/VT; 45% PEA or asystole; 12% other) and the type of death (75% witnessed/resuscitation attempted, 25% unobserved).

Conclusions: On its own, ICD-9 data mining to identify SCD is fraught with false positives. Adding an algorithm, based on a precise definition of sudden cardiac death, improves detection of SCD cases. This systematic approach compares favorably to the gold standard of physician adjudication. By following a standard approach to isolate cases of SCD in large cohorts, we hope to delineate a clear phenotype that can then be studied further to eventually lead to reduced SCD incidence among CKD patients.

TH-PO481

Utility of Screening for Albuminuria among US Hispanic Adults with Preserved eGFR Harini Sarathy,[7] Rebecca Scherzer,[2] Michael Shlipak,[1] James P. Lash,[5] Donglin Zeng,[3] Neil Schneiderman,[6] Carmen A. Peralta.[4] [1]*San Francisco VA Medical Center, San Francisco, CA;* [2]*UCSF, San Francisco, CA;* [3]*University of North Carolina, Chapel Hill, NC;* [4]*University of California San Francisco/SFVAMC, San Francisco, CA;* [5]*University of Illinois at Chicago, Chicago, IL;* [6]*University of Miami, Coral Gables, FL;* [7]*UC San Francisco, San Francisco, CA.*

Background: In the U.S., Hispanics have higher prevalence of albuminuria and faster rates of CKD progression, compared to non-Hispanic whites. The yield of screening for albuminuria among Hispanics without a current indication to screen i.e. without diabetes, cardiovascular disease (CVD), or CKD is unknown. Current rates of blood pressure control and use of angiotensin converting enzyme inhibitors/ angiotensin II receptor blockers (ACEI/ARB) in those with albuminuria are not known.

Methods: Among 9510 participants in the Hispanic Communities Health Study/ Study of Latinos (HCHS/SOL) with eGFR≥60ml/min/1.73m^2 and without diabetes or CVD, we determined prevalence of albuminuria (albumin to creatinine ratio ≥30mg/g) and calculated number needed to screen (NNS), overall, and within predefined subgroups. Among those identified with albuminuria, we determined rates of blood pressure (BP)≥140/90, and use of ACEI/ARB.

Results: The median age and eGFR were 34 years (IQR 25-45) and 113 ml/min/1.73m^2 (IQR 100- 123) respectively. Prevalence of albuminuria was 5.7% (95% CI 5.2%- 6.4%) resulting in NNS of 17.0 (95% CI 16.0-19.0), and NNS was lowest among those with BP≥140/90 mmHg, followed by those with BP≥130/80 mmHg. (Figure). Among Hispanics with albuminuria, rates of BP≥140/90mmHg was 23% and ranged from 8.5 to 53% with increasing age. Only 29.5% of persons with albuminuria and BP≥140/90 were on ACEI/ARB.

Conclusions: Among Hispanics without a current indication for albuminuria testing, screening for albuminuria identified opportunities to initiate and/or intensify CVD and CKD risk reduction therapies, especially persons with hypertension.

TH-PO482

Moderate Impairment in Kidney Function Is Correlated to Changes in Cardiac Function and Structure Anders Christensson. *Skåne University Hospital, Malmö, Sweden.*

Background: Patients with chronic kidney disease (CKD) have an increased risk of cardiovascular diseseas and in severe renal dysfunction changes in the structure and function of the heart is common. Previous reports show that also early renal dysfunction is a risk factor for cardiovascular death, but it is not fully known if the changes in cardiac structure and function already exist in early impairment of renal function. Cystatin C is a stronger predictor for the risk of cardiovascular morbidity compared with creatinine. This study aims to investigate if there is an early link between kidney disease and cardiac structural and/or functional changes

Methods: We used a population based cohort, Malmö Preventive Project Re-examination-study (MPP-RES). 1792 participants with mean age 67 ± 6 were examined in 2002-2006. Echocardiography with tissue doppler imaging (TDI) is a method that provides a precise measure of left ventricular (LV) wall motion. Cystatin C was measured in plasma and used in the CKD-EPI formula to estimate glomerular filtration rate (eGFR). General linear regression was used for statistical analyses. We included 1504 of the participants with no prior history of heart failure (HF), EF =>40% and eGFR based >15 mL/min/1,73m2. Patients were divided in 8 groups based on e-GFR levels =>90 mL/min/1.73m2; 80-89; 70-79; 60-69; 50-59; 40-49; 30-39 ;and <30. Number of participants in these groups were 167, 221, 376, 322, 238, 121, 51 and 8, respectivley. 29,9% of the participants were women and 70,1% were men. We studied associations between e-GFR groups and echocardiography parameters.

Results: Significant correlations were found between eGFR groups and Mean é latsept and Mean E/é in the total cohort (p=0,001 and p=0.022, respectively). These correlations remain significant among men but not among women. We also dichotomized the cohort in those with eGFR <40 and >40 mL/min/1.73m2 and those with eGFR <50 and >50 mL/min/1.73m2. This demonstrated that the association was found in partcipants with eGFR <40 mL/min/1.73m2.

Conclusions: Moderate impairment of renal function correlated significantly with functional and structual echocardiographic markers of early diastolic dysfunction.

TH-PO483

CKD Increases Risk for HFpEF Admission Independent of Cardiac Function Thomas Mavrakanas,[3,4] Aisha Khattak,[2,3] Wei Wang,[1] Karandeep Singh,[3,5] David M. Charytan.[3] [1]*Department of Medicine, Brigham & Women's Hospital, Boston, MA;* [2]*University of Texas Health Science Center of Huston, Houston, TX;* [3]*Renal Division, Brigham and Women's Hospital, Boston, MA;* [4]*Division of General Internal Medicine, Geneva University Hospitals, Geneva, Switzerland;* [5]*Departments of Learning Health Sciences and Internal Medicine, University of Michigan Medical School, Ann Arbor, MI.*

Background: Chronic kidney disease (CKD) is common among patients with heart failure with preserved ejection fraction (HFpEF) and is associated with worse clinical outcomes. Whether the association of CKD with HFpEF is independent of underlying echocardiographic abnormalities is uncertain.

Methods: This retrospective cohort study included adult patients without prevalent heart failure referred for echocardiography. Patients with serial echocardiograms, left ventricular ejection fraction (LVEF) ≥50% on baseline echocardiogram and estimated glomerular filtration rate (eGFR) ≥90 ml/min/1.73m2 were matched 1:1 with patients with eGFR<60 for age (±5 years), sex, history of hypertension or diabetes, use of renin-angiotensin inhibitors, and LVEF (±5%). A secondary analysis included patients with preserved LVEF and normal left ventricular mass index matched for the same parameters except for use of renin-angiotensin inhibitors.

Results: Among 685 matched pairs, those with CKD had higher prevalence of coronary disease and higher left atrial diameter compared with controls, as well as biochemical abnormalities associated with CKD. 256 admissions for HFpEF were observed. Patients with CKD were at increased risk for HFpEF admission: crude hazard ratio (HR) 1.79 [95% CI (confidence interval) 1.38-2.33, p<0.001] and adjusted HR (for coronary disease and left atrial diameter) 1.66 (95% CI 1.23-2.24, p=0.001). LVEF and left ventricular diameter decreased over time in both groups (p<0.001 and p<0.001 respectively) but no difference was observed in rate of dropping (p=0.39 and p=0.83 respectively). Results were similar in the secondary analysis that included 289 pairs with preserved LVEF and normal left ventricular mass index (crude HR 1.99, 95% CI 1.07-3.71, p=0.03 and HR adjusted for left atrial diameter 1.98, 95% CI 1.05-3.75, p=0.04). Rate of change was similar for LVEF, pulmonary artery pressure, and left ventricular mass index in both groups (p=0.80, p=0.38, and p=0.63 respectively).

Conclusions: The increased risk of HFpEF admission in CKD is independent of baseline cardiac function and occurs despite a similar change in relevant echocardiographic parameters over time in patients with or without CKD.

TH-PO484

Renal and Overall Survival (OS) in Type 5 Cardiorenal Syndrome in Systemic AL Amyloidosis Is Dictated by Cardiac Response at 12 Months Tamer Rezk,[1,2] Helen J. Lachmann,[2] Carol Whelan,[3] Ashutosh Wechalekar,[2] Philip N. Hawkins,[2] Julian D. Gillmore.[2] *[1]Center for Nephrology, UCL Division of Medicine, London, United Kingdom; [2]National Amyloidosis Centre, London, United Kingdom; [3]National Amyloidosis centre, UCL, London, United Kingdom.*

Background: Systemic AL amyloidosis is a progressive, fatal disease that is a cause of Type 5 cardiorenal syndrome. Renal involvement leading to ESRD is the main determinant of morbidity and cardiac involvement the main determinant of mortality. Current consensus is that renal progression (reduction in eGFR>25%) is the main determinant of renal survival. We hypothesize that in patients with systemic AL amyloidosis and type 5 cardiorenal syndrome both OS and renal survival is primarily dictated by cardiac organ response as defined by current consensus criteria.

Methods: 1000 patients were prospectively enrolled into the UK ALCHEMY study from 2009-2016; 318 patients were diagnosed with cardiorenal syndrome. We report OS, renal survival and time to the composite endpoint of death and dialysis. Organ outcomes were defined according to consensus criteria, NTproBNP increase/decrease of >30% (cardiac progression/regression) and reduction in eGFR >25% (renal progression).

Results: Median age was 66yr, eGFR 55ml/min and NTproBNP 655ng/L. Median systolic BP was 112mmHg. 199 patients died and 50 required RRT with an overall survival of 18.5 months by Kaplan Meier analysis. Factors predictive at baseline of OS, renal survival and composite endpoint were NTproBNP (p<0.001, p<0.008, 0<0.001), systolic BP (p<0.001, p<0.03, p<0.007) and eGFR (p<0.001, p<0.001, p<0.001). Cardiac progression (NTproBNP increase >30%) compared to renal progression (eGFR reduction of >25%) at 12 months was more predictive of death (HR 5.0 vs 1.3, p<0.001), dialysis (HR 3.7 vs 2.7, p=0.017) and composite endpoint (HR 3.8 vs 1.7, p<0.001). Cardiac response (NT-proBNP reduction of >30%) compared to renal response (reduction in proteinuria by 30% without >25% reduction in eGFR) at 12 months was also more predictive of OS (HR 0.3 vs 0.8, p<0.001), renal survival (HR 0.3 vs 0.6, p=0.008) and composite endpoint (HR 0.3 vs 1.0, p<0.001).

Conclusions: OS, renal survival and the composite endpoint of death or dialysis in patients with type 5 cardiorenal syndrome in systemic AL amyloidosis are strongly associated with baseline eGFR, systolic BP and NTproBNP. Cardiac organ response at 12 months, as defined by consensus criteria, is more predictive of both patient and renal survival in this cohort of patients than renal organ response.

TH-PO485

Associations of Cardio-Renal Biomarkers in CKD Patients with Non-Alcoholic Fatty Liver Disease Rajkumar Chinnadurai,[1] Helen Alderson,[1] Philip A. Kalra.[2] *[1]SALFORD ROYAL NHS FOUNDATION TRUST, Manchester, United Kingdom; [2]Salford Royal Hospital NHS Trust, Salford, United Kingdom.*

Background: Non-Alcoholic Fatty Liver Disease (NAFLD) and Chronic Kidney Disease (CKD) are both associated with increased risk of cardiovascular disease(CVD). Novel biomarkers may aid early diagnosis and guide prognosis. We studied the associations of Cardio-Renal biomarkers in a cohort of non-dialysis dependent CKD (NDD-CKD) patients with NAFLD.

Methods: Patients with and without ultrasound characteristics of NAFLD were identified within the Salford Kidney Study(SKS), a large single-centre NDD-CKD cohort study. Associations of important biomarkers (KIM-1, NGAL, MPO, Anti ApoA1, NTproBNP and HsTNT) with NAFLD and major outcomes (MACE, mortality and ESKD) were studied using Cox-Regression analysis.

Results: Of the 3061 patients registered in SKS, 630 patients (NAFLD-137, Normal-493) had had liver US, complete datasets and analysis of baseline CRBM. Demographics and median values (with IQR) of biomarkers are expressed in the Table. In a Multivariable Cox-Regression Model adjusted for age, gender, NAFLD Status and baseline history of cardiovascular risk factors, TropT (HR:1.008, P=0.021), NGAL (HR:1.003, P<0.001) and KIM-1(HR-1.001, P=0.005) showed associations with MACE. All biomarkers except Anti Apo-A1 showed a positive association with mortality with Trop T showing a strong association HR 1.012, P<0.001. Higher KIM-1 and NGAL were associated with progression to ESKD.

Conclusions: The biomarker associations were very much reflective of the renal and cardiac status of the patient group. A strong independent association of biomarkers was observed with outcomes in this cohort, but NAFLD was not independently associated with any particular pattern.

VARIABLE	NAFLD(n=137)	NORMAL(n=493)	pValue (NAFLD vs Normal)

TH-PO486

Iron Therapy Modifies Oxidative Stress in Uraemic Cardiomyopathy Faisal Nuhu,[3] Roger G. Sturmey,[1] Anne-Marie L. Seymour,[3] Sunil Bhandari.[2] *[1]Hull York Medical School, Hull, United Kingdom; [2]Hull and East Yorkshire Hospitals NHS Trust and Hull York Medical School, East Yorkshire, United Kingdom; [3]University of Hull, HULL, United Kingdom.*

Background: Uraemic cardiomyopathy (UCM) is characterised by cardiac hypertrophy (LVH), metabolic remodelling and mitochondrial dysfunction, key factors in the development of heart failure (HF). Anaemia and oxidative stress are closely associated with LVH. Thus, the co-existence of both factors in chronic kidney disease (CKD) may aggravate progression to HF and increase the risk of sudden cardiac death. The aim of this study was to characterise oxidant status and iron deficiency (ID) anaemia in animal model of UCM; and determine the impact of intravenous (IV) iron therapy.

Methods: Experimental uraemia was induced in male Sprague-Dawley rats via a subtotal nephrectomy, parenteral iron injected intravenously at week 6 (10mg/Kg body weight) and studies conducted 12 weeks post-surgery. Oxidative stress was evaluated through pro-oxidant enzyme activities and anti-oxidant capacities and levels of thiobarbituric acid-reactive substances (TBARS) in UCM. The extent of uraemia, anaemia and iron status was determined by serum biochemistry. Cardiac, renal and skeletal iron content was measured by inductively coupled plasma atomic emission spectroscopy.

Results: The induction of uraemia resulted in LVH (HW/TL ratio (g/cm): 0.38 ± 0.01 vs 0.34 ± 0.01; p < 0.05); ID (serum iron (μM): 31.11 ± 1.80 vs 46.38 ± 1.44; p < 0.01), low total iron binding capacity (TIBC (μM): 26.43 ± 0.72 vs 29.46 ± 0.83; p < 0.05) and anaemia (haematocrit (%): 42.5 ± 3 vs 55.0 ± 3; p < 0.05); reduced systemic glutathione peroxidase (GPx) activity ((U/ml): 1.12 ± 0.11 vs 1.48 ± 0.12; p < 0.05). Oxidative stress in UCM was further evidenced by elevated cardiac GSSG/GSH ratio, TBARS and activities of pro-oxidant enzymes. IV iron therapy had little effect on LVH but caused repletion of hepatic iron stores, improved anaemia and systemic GPx activity. In turn, iron supplementation ameliorated oxidative stress in the heart by enhancing anti-oxidant defence system without any significant impact on the kidney. Therapy also improved oxidant status in both skeletal and hepatic tissues.

Conclusions: Iron therapy improved the anti-oxidant defence system and consequently oxidant status of cardiac and skeletal muscles. These data highlighted the benefits of managing ID anaemia in the early stages of CKD to reduce vulnerability to oxidative stress and may lessen associated adverse cardiovascular outcomes.

TH-PO487

Iron Status and the Risk for Heart Failure Hospitalization in Veterans with CKD Monique E. Cho,[1,2] Jared Hansen,[1] Celena B. Peters,[1] Brian C. Sauer.[1,2] *[1]Veterans Health Administration, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: The risk for heart failure (HF) hospitalization associated with abnormal iron balance has not been evaluated in a large pre-dialysis CKD population.

Methods: We performed a historical cohort study using the national data from the Veterans Affairs Informatics and Computing Infrastructure. We identified a pre-dialysis CKD cohort (MDRD eGFR <60 mL/min/1.73m^2) with at least one set of iron indices between 2006-2015. The clinical characteristics were determined from the ICD-9 codes and laboratory data during the *baseline period*, defined as the year preceding the first available iron indices (index date). Patients with ESRD, genetic and chronic disorders affecting iron metabolism were excluded. The cohort was divided into 4 iron groups based on the joint quartiles (Q) of transferrin saturation (Tsat) and ferritin: functional iron deficiency (FID), 1st Tsat Q + 3rd–4th ferritin Qs; Low Iron (LI), reflecting absolute iron deficiency, 1st Tsat+ferritin Qs; High Iron (HI), 4th Tsat+ferritin Qs; and Reference

(R), 2nd–3rd Tsat+ferritin Qs. First hospitalization for HF following the index date was determined by ICD-9 codes. Matching weights were used to determine the effect of FID, HI, and LI on HF hospitalization risk, using R as the reference. Diabetes was examined as a potential effect modifier.

Results: Of the 1,159,371 Veterans with CKD, 148,611 met the inclusion criteria. The mean±SD for age and eGFR were 72±11 years and 43±11 mL/min/1.73 m^2, respectively. The median (IQR) Tsat and ferritin values were 20 (14, 26)% and 119 (64, 196) ng/mL. Of the study cohort, 42% could not be categorized into any of the 4 iron groups. In the remaining 83,439 Veterans, the prevalence for FID, HI, LI, and R were 13%, 17%, 20%, and 50%, respectively. After matching weights were implemented, the clinical covariates were evenly distributed among the iron groups. During the mean±SD follow-up period of 4.0±2.7 years, FID and LI groups exhibited similarly increased risk for HF hospitalization [risk ratio (95% CI): 1.14 (1.08, 1.21) and 1.13 (1.08, 1.19), respectively]. HI was associated with lower risk for HF hospitalization, 0.86 (0.81, 0.92). The association between iron status and HF hospitalization risk was not modified by the diabetes status.

Conclusions: Iron deficiency, both functional and absolute, is associated with an increased risk for HF in CKD, regardless of the diabetes status.

Extracellular Vesicles (EV) Plus Swimming Exercise Training (EXE) Improve Creatinine Clearance (CrCl), Proteinuria, and Glomerulosclerosis and Decrease Mortality in Rats with CKD Rafael Luiz,[1] Rodolfo R. Rampaso,[1] Edson A. Pessoa,[1] Maria A. Gloria,[1] Luciana Jorge,[1] Kleiton A. Silva,[2] Mario luis R. Cesaretti,[1] Nestor Schor.[1] *[1]Universidade Federal de São Paulo, São Paulo, Brazil; [2]University of Missouri, Columbia, AL.*

Background: The aim of this study was to evaluate the EV and EXE on renal function and glomerulosclerosis in rats with by 5/6 Nephrectomy (5/6Nx).

Methods: Adult Wistar rats were divided in groups (n=8): Control (C), Exercise (E), Sedentary 5/6Nx (NS), Exercise 5/6Nx (NE), NS + EV (VSD) and NE + EV (VEX). The protocol was employed in 5/6Nx rats after 7 days from the surgical procedures. EXE periods were 60min/day, 5 days a week during 8 weeks and EV (100 μg) was induced into the tail vein. It was evaluated creatinine *clearance* (CrCl), proteinuria (uProt), glomerulosclerosis (%), mortality rate as well mean arterial pressure (MAP) and maximal exercise test (MEtest).

Results: The EV and EXE improve the CrCl vs NS group 0.96±0.20 ml/min, ($p<0.05$). Proteinuria was significantly different in VSE and VEX vs NE and NS groups. Glomerulosclerosis was higher in NS vs VSE and VEX ($p<0.05$). A higher mortality rate was observed in NS and VSE, but not in NE and VEX groups. BUN was normalized in NE, VSE and VEX vs NS. There is an increment in MAP but prevent, at least in part, a lower decline in the MEtest caused by 5/6Nx.

Conclusions: Results suggested that EV plus 8 weeks of EXE minimize the impact of 5/6Nx by decreasing of proteinuria, glomerulosclerosis and reduce the impact on CrCl. Finally, the decreasing mortality rate in NE and VEX vs NS and VSE indicate that exercise, at least swimming in this protocol, induced protection on renal function. Thus, it is reasonable to suggest that EV plus EXE could be an additional strategy to be employed in Chronic Kidney Disease.

TH-PO489

The Association between Neutrophil to Lymphocyte Ratio and Severity of Coronary Artery Disease in Patients with CKD Il Young Kim,[2] In seong Park,[1] Min Jeong Kim,[2] Miyeun Han,[1] Harin Rhee,[1] Sang Heon Song,[1] Eun Young Seong,[1] Dong Won Lee,[2] Soo Bong Lee,[2] Ihm Soo Kwak.[1] *[1]Pusan National University Hospital, Busan, Busan, Republic of Korea; [2]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea.*

Background: Chronic inflammation is associated with increased cardiovascular mortality in patients with chronic kidney disease (CKD). Neutrophil to lymphocyte ratio (NLR) was introduced as a potential marker of inflammation in cardiac disorder. Emerging evidence have suggested that NLR might be a useful marker of cardiovascular disease. This study aimed to investigate the association between NLR and severity of coronary artery disease (CAD) in patients with CKD.

Methods: A total of 952 pre-dialysis CKD patients [estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2] who underwent elective coronary angiography (CAG) were studied. Depending on eGFR, study subjects were categorized into 3 groups (stage 3: n = 617, stage 4: n = 240, stage 5: n = 95). NLR values were calculated from complete blood count before CAG. The severity of CAD was evaluated by Gensini score according to the degree of luminal narrowing and location(s) of obstruction in the involved main coronary artery. A significant CAD was defined as lumen narrowing of one or more main coronary artery ≥ 50%.

Results: In univariate analysis, Gensini score correlated with NLR ($r = 0.542$, $P < 0.001$), age ($r = 0.123$, $P < 0.001$), diabetes mellitus (DM) ($r = 0.124$, $P < 0.001$), hypertension ($r = 0.133$, $P < 0.001$), smoking ($r = 0.088$, $P = 0.007$), eGFR ($r = -0.343$, $P < 0.001$), uric acid ($r = 0.390$, $P = 0.001$), calcium ($r = -0.097$, $P = 0.003$), phosphate ($r = 0.107$, $P = 0.001$), total cholesterol ($r = 0.115$, $P < 0.001$), CRP ($r = 0.292$, $P < 0.001$), and hemoglobin ($r = -0.225$, $P < 0.001$). In multiple regression analysis, NLR ($\beta = 0.468$, $P < 0.001$), age ($\beta = 0.064$, $P = 0.013$), DM ($\beta = 0.07$, $P = 0.007$), hypertension ($\beta = 0.068$, $P = 0.009$), eGFR ($\beta = -0.227$, $P < 0.001$), total cholesterol ($\beta = 0.063$, $P = 0.015$), and CRP ($\beta = 0.095$, $P = 0.001$) were independent predictors of Gensini score. In ROC analysis (AUC: 0.741, 95% CI: 0.710-0.772), the best cut-off value of NLR for identifying the significant CAD was 2.26 with associated sensitivity of 70.2% and specificity of 67.2%.

Conclusions: A higher NLR was an independent predictor of the severity of CAD in CKD patients. NLR could be a valuable measure for CAD risk stratification in CKD patients.

TH-PO490

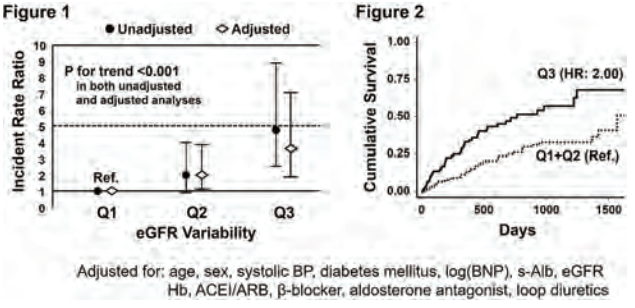
Estimated GFR Variability: A Novel Predictor of Cardiac Outcome in Outpatients with Congestive Heart Failure Tatsufumi Oka,[1] Takayuki Hamano,[2] Satoshi Yamaguchi,[1] Keiichi Kubota,[1] Masamitsu Senda,[1] Sayoko Yonemoto,[1] Yusuke Sakaguchi,[2] Isao Matsui,[1] Yoshitaka Isaka.[1] *[1]Nephrology, Osaka University Graduate School of Medicine, Suita, Japan; [2]Comprehensive Kidney Disease Research, Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Reportedly, variability in renal function is associated with mortality and CKD progression in predialysis patients with CKD. However, its clinical relevance in patients with congestive heart failure (CHF) is uncertain.

Methods: In this retrospective cohort study, we enrolled CHF patients who were discharged from an educational hospital. Using 6-month data just after discharge, we linearly regressed each patient's eGFR on time and calculated eGFR variability (EGV) as "mean sqrt(residuals of eGFR)^2 / mean eGFR ×100(%)". Exposure of this study was EGV, and outcome was death or hospitalization rates over the follow-up period starting 6 months after discharge. For main analyses, we employed negative binomial regression models. As sensitivity analyses, we used Cox proportional hazards models to estimate the hazard risk of mortality or readmission whichever occurred first. Additionally, we calculated the net reclassification index (NRI) and the integrated discrimination index (IDI) of EGV.

Results: Among the 351 outpatients, median left ventricular ejection fraction, eGFR, EGV, and follow-up period were 54%, 57.5 mL/min/1.73m^2, 4.4%, and 23.6 months, respectively. Multivariate negative binomial regression analyses showed that higher EGV was associated with an increased incidence rate ratio for the outcome (Figure 1). Excluding the patients with their eGFR measured only 3 times during 6 months after discharge didn't change the results substantially. Cox regression analyses also showed that EGV of Q3 had significantly higher hazard ratio (HR) than the combined group of Q1 and Q2 (HR, 2.00; 95%CI, 1.27 to 3.15) (Figure 2). The NRI and IDI were 0.283 (P=0.014) and 0.013 (P=0.038), respectively.

Conclusions: Higher eGFR variability predicts worse cardiac outcome in outpatients with CHF.



TH-PO491

Assessment of Comorbidities and Pre-Dialysis Adverse Outcomes among Incident Renal Replacement Therapy Patients MinJeong Lee,[1,2] Inwhee Park,[1] Heungsoo Kim,[1] Gyu Tae Shin,[1] Jong Cheol Jeong.[1] *[1]Nephrology, Ajou University School of Medicine, Suwon, Republic of Korea; [2]Emergency Medicine, Ajou University School of Medicine, Suwon, Republic of Korea.*

Background: Several observational studies have shown that initiation of RRT at high estimated glomerular filtration rate(eGFR) was associated with poorer post-RRT patient survival. But, most of previous studies have been based on registry data by patients who survived to initiate RRT. Therefore, we investigated pre-dialysis morbidity and adverse outcome preceding initiation of dialysis as clinical outcomes and the association of pre-dialysis clinical outcomes with eGFR at RRT initiation.

Methods: EMR of incident dialysis patients who started maintenance dialysis between Jan 2010 and Dec 2015 were reviewed. Patients with eGFR≤20ml/min were enrolled. Comorbidity indices were calculated for each patient based on the comorbidity at the enrolled time. Patients were classified as 'safe RRT' group vs 'urgent RRT' group, defined as the patients who started RRT from urgent indication such as uremic encephalopathy, uremic pericarditis, pulmonary edema, or serum potassium≥7.0mEq/L.

Results: Among total 1,044 patients, mean eGFR at RRT initiation was 6.7±4.3ml/min/1.73m^2. Mean eGFR at RRT initiation was higher in larger comorbidity burdens(Fig1). Urgent RRT group had higher modified Charlson score than safe RRT group(4.9±2.1 vs 3.5±2.3, p< 0.001). During pre-dialysis period from enroll time to RRT initiation, patients with higher comorbidities experienced more cardiovascular adverse outcome such as MI or angina, and more infection event requiring hospitalization(Fig2).

Conclusions: Patients with larger comorbidities experienced more adverse events during pre-RRT period. Timing of RRT initiation should be individualized considering burden of comorbidities.

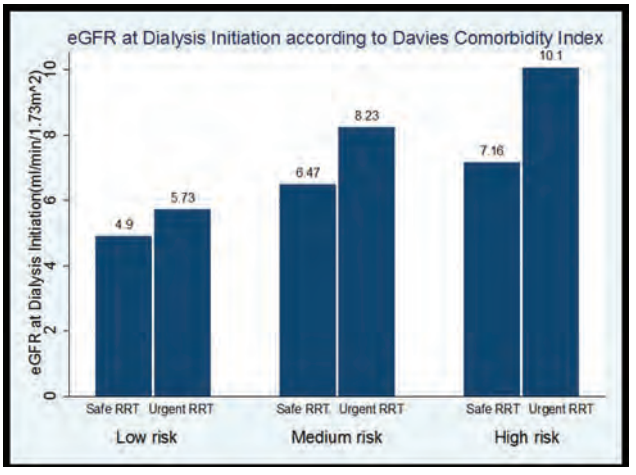


Fig1. eGFR at Dialysis Initiation

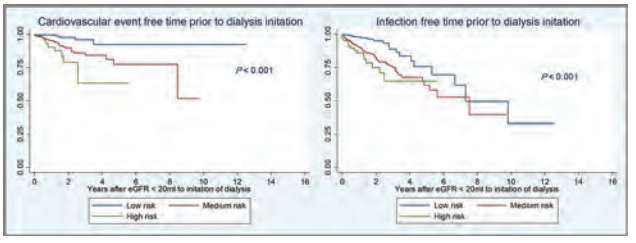

Figure 2. Pre-Dialysis Adverse Outcomes

TH-PO492

The Association between Cardiac Troponin T and Left Ventricular Structure in CKD: Result from the Korean Cohort Study for Outcomes in Patients with Chronic Kidney Disease (KNOW-CKD) Eunjeong Kang,[1] Hyo Jin Kim,[2] Hyunjin Ryu,[1] Miyeun Han,[3] Hyun suk Kim,[4] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Internal medicine, Dongguk University Gyeongju Hospital, Gyeongju, Republic of Korea; [3]Internal medicine, Busan National University Hospital, Busan, Republic of Korea; [4]Internal Medicine, Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea.*

Background: Serum cardiac troponin T (cTnT) is a useful marker for cardiovascular disease risk in several population settings. We investigated the association between cTnT and cardiac structure and function in chronic kidney disease (CKD) patients in Korea.

Methods: Data were collected from the KNOW-CKD cohort. cTnT was measured using the highly sensitive assay and was categorized into 4 groups by quartiles (≤6.0, >6.0-10.0, >10.0-16.0, >16.0 pg/mL). Left ventricular hypertrophy (LVH) was defined as LV mass/height$^{2.7}$ ≥47g/m$^{2.7}$ in female and ≥50g/ m$^{2.7}$ in male. LV geometry was categorized into 4groups using left ventricular (LV) mass index and relative wall thickness. Systolic dysfunction was defined as ejection fraction <50% and diastolic dysfunction as E/E' >15. Demographic and clinical characteristics including age, sex, CKD stage, history of myocardial infarction, body mass index, hemoglobin, and lipid profile were included as covariates. We carried out subgroup analysis dividing into 2 groups based on estimated glomerular filtration rate (eGFR) 60mL/min/1.73m^2.

Results: Total 2,061 patients were included and the mean age was 53.5±12.3 years old. The highest 2 quartiles of cTnT were related to more than 2-fold odds ratio(OR) of LVH in the fully adjusted model. The highest quartile of cTnT was significantly associated with concentric remodeling, eccentric and concentric LVH, although such associations were not evident with the 2nd or 3rd quartile groups. Systolic and diastolic dysfunction had independent association with increment of cTnT. After the analysis according to eGFR, LVH, diastolic dysfunction, concentric and eccentric LVH were associated with cTnT independently, but not with systolic dysfunction and concentric remodeling. In ROC analysis, area under the curve for both LVH and diastolic dysfunction are above 0.7, regardless of eGFR subgroups.

Conclusions: cTnT was associated strongly with alterations of LV structure and functional abnormalities including systolic and diastolic dysfunction. These tendencies were still observed in subgroup analysis according to the eGFR, except systolic dysfunction. In ROC analysis, cTnT concentration is a reliable screening test for LVH, diastolic dysfunction, regardless of renal function.

The Efficacy of Febuxostat in CKD Patients: A Systematic Review and Meta-Analysis of Randomized Controlled Trials Daqing Hong,[2] Ying Wang.[1] *[1]None, Epping, NSW, Australia; [2]Sichuan Provincial People's Hospital, CHENGDU, China.*

Background: Uric acid is considered as an independent risk factor for kidney disease. Hyperuricemia is associated with progression of renal dysfunction. Febuxostat, a xanthine oxidase (XO) inhibitor, is used to treat hyperuricemia in patients with gout. However, its effects on renal functions remain unclear. We aimed to systematically evaluate the efficacy and safety of febuxostat in patients with chronic kidney disease (CKD).

Methods: Cochrane library, MEDLINE, EMBASE and trial register system were searched for randomized controlled trials to May 18, 2017 with the terms of "febuxostat" and "chronic kidney disease". The primary outcomes were serum creatinine level, while secondary outcomes included serum uric acid level, eGFR, hsCRP, HDL-C, LDL-C, SBP and DBP. Fixed effects model analysis was used to explore the effect size of febuxostat versus control.

Results: Eight studies involving 981 participants were eventually included in this review. All studies were high quality studies. Compared with the control group, febuxostat significantly reduced the serum uric acid levels (WMD=-2.71, 95%CI: -3.68, -1.73, P<0.01, I^2=96%), with a nonsignificant effect on renal functions (a reduction in serum creatinine levels by 0.07mg/dl (WMD, 95%CI: -0.34, 0.20, P=0.60, I^2=90%), and an increase in the level of eGFR by 3.15ml/min/1.73 m^2 (WMD, 95%CI: -1.40, 7.71, P=0.17, I^2=83%)). Subgroup analysis show that febuxostat significantly increase in the level of eGFR by 6.58ml/min/1.73 m^2 compared with placebo (WMD, 95%CI: 5.04, 8.13, P<0.01, I^2=0%). Fixed effect model analysis showed that febuxostat can significantly reduce hsCRP levels by 0.24mg/L (WMD, 95%CI: -0.38, -0.09, P=0.001, I^2=31%), reduce HDL-C levels by 0.77mg/dl (WMD, 95%CI: -4.52, 2.98, P=0.69, I^2=0%) and reduce LDL-C levels by 5.95mg/dl (WMD, 95%CI: -11.89, -0.01, P=0.05, I^2=18%). There was no significant difference in the blood pressure between the febuxostat group and the control group.

Conclusions: Conclusions: Febuxostat can significantly reduce serum uric acid levels in patients with CKD with hyperuricemia with potential beneficial impact on renal function as compare to placebo. Further large RCTs are needed to assess the effect of febuxostat on renal outcomes as compared to other active uric acid lowering treatment.

TH-PO494

The Effect of Uric Acid Lowering on Albuminuria and Renal Function in Type 1 Diabetes: A Randomized Clinical Trial Sascha Pilemann-lyberg,[2,3] Frederik Persson,[1] Jan Frystyk,[3] Peter Rossing.[2] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [3]Aarhus University, Aarhus, Denmark.*

Background: Epidemiological studies indicate that uric acid (UA) is a risk factor for development and progression of CKD. Whether UA lowering with allopurinol changes urinary albumin excretion rate (UAER) or GFR in patients with type 1 diabetes (T1D) suffering from diabetic nephropathy is not known.

Methods: We conducted a randomized, placebo-controlled, double-blinded, cross-over trial enrolling patients with T1D and a plasma uric acid ≥ 4.4 mg/dL, persistent albuminuria (urinary albumin creatinine ration) ≥30 mg/g and an eGFR ≥ 40 ml/min/1.73m^2 on stable RAS blocking intervention. The participants were randomized to: (1) Allopurinol (400 mg daily) + standard therapy; or (2) placebo + standard therapy for 60 days. Participants underwent a 4 week washout period prior to cross-over. Primary end-point was change in UAER (3*24h collections), secondary endpoint was change in GFR (^{51}Cr-EDTA-plasma clearance) measured at the end of each treatment period. The effect of UA lowering was tested using a paired t-test, after testing for carryover effects.

Results: We enrolled 30 patients, blood pressure 133(3)/75(2) mmHg and HbA1c 67(3) mmol/mol. UA decreased to 3.6 (1.2) mg/dl with allopurinol compared to 5.8 (1.5) with placebo (p<0.001). The 24h UAER (geometric mean (IQR)) was 221 (131-367) mg/24h after treatment with allopurinol and 228 (151-344) mg/24h with placebo (p=0.83). Mean (SD) GFR (^{51}Cr-EDTA) was 74 (20) ml/min/1.73m^2 after allopurinol treatment compared with 73 (20) ml/min/1.73m^2 after placebo (p=0.51). Glycemic control 24h-blood pressure and RAS blockade was stable. We found no significant association (p=0.45) between uric acid and UAER. In an unadjusted linear model, UA was significantly associated with the level of GFR (^{51}Cr-EDTA) in the placebo treatment period (R^2=0.2, p=0.017).

Conclusions: Short term UA lowering by allopurinol did not improve UAER or GFR in patients with T1D and nephropathy. The clinical significance of long-term UA lowering is currently investigated in a large multicentre clinical trial (the PERL Study), investigating the effect of 3 years of allopurinol treatment on albuminuria and slopes of measured GFR.

TH-PO495

Effect of Losartan on Uric Acid in Patients with CKD Komal Patel,[2] Jordan L. Rosenstock.[1] *[1]None, New York, NY; [2]Northwell Health Lenox Hill Hospital, Paramus, NJ.*

Background: Increased serum uric acid (UA) is a risk factor for end-stage renal disease and agents that lower it such as allopurinol may decrease renal disease progression. Losartan inhibits URAT1 mediated renal tubule urate reabsorption by the proximal tubule, which results in an increase in urate excretion. This appears to be an effect that is unique to losartan of all the angiotensin receptor blockers. Losartan has previously been shown to increase UA excretion and decrease serum UA levels in patients without kidney disease. However, the effects of losartan on serum and urine UA in patients with kidney disease is unknown. The purpose of this study was to evaluate the change in serum and urine UA levels among individuals with stage 3 chronic kidney disease (CKD3).

Methods: The study enrolled 15 individual outpatients with CKD 3 that were to be started on losartan as part of standard clinical care indications such as proteinuria or hypertension. Baseline serum UA and 24 hour urine for fractional excretion of uric acid (FeUA) were collected prior to starting losartan and after 30 days. Patients were excluded if they had started other medications affecting UA levels within 30 days or during study period.

Results: Mean baseline GFR was 42.07 ± 6.05, and 60% were males. We found that serum UA 30 days post treatment was significantly lower than baseline (7.39 ± 1.47 to 6.85 ± 1.70) (p = 0.009). The median serum UA percent decrease from pre to post was 6% (p=0.008). However, the FE UA 30 days post treatment was not significantly different from baseline(p = 0.89).

Conclusions: This study did show a statistically significant change in serum UA levels in CKD 3 patients after the initiation of losartan. Though statistically sigfnicant, the small change in UA level may not be clinically meaningful. In patients without kidney disease levels may fall by as much as 20% and the difference suggests that renal disease may compromise the ability to respond to the uricosuric effect of losartan. Furthermore, we did not find a significant change in the FeUA. It has been suggested that the uricosuric effect with losartan is short lived as a new steady state is reached quickly, so 30 days may have been to long to recheck FeUA. This study involved a small cohort of patients, and a larger study is warranted to confirm our finding.

TH-PO496

The Effect of Uric Acid-Lowering via Allopurinol on Markers of Kidney Function and Damage in Stage III CKD Loni J. Perrenoud,[2] Emily Andrews,[3] Zhiying You,[1] Michel Chonchol,[2] Richard J. Johnson,[3] Diana I. Jalal.[4] *[1]UC Denver, Aurora, CO; [2]University of Colorado, Aurora, CO; [3]University of Colorado Denver, Aurora, CO; [4]University of Colorado Denver Health Science Center, Aurora, CO.*

Background: Hyperuricemia associates with kidney disease progression and pilot data suggest that lowering serum uric acid may slow kidney disease progression. It remains unknown if lowering serum uric acid levels improves markers of kidney damage in CKD.

Methods: Post-hoc analysis of a double-blind randomized placebo-controlled clinical study utilizing allopurinol to lower serum uric acid in 80 subjects with stage III CKD. The following markers of kidney damage were evaluated: urinary albumin/creatinine ratio (ACR), urinary neutrophil gelatinase-associated lipocalin (NGAL), urinary kidney injury molecule-1 (KIM-1), and urinary transforming growth factor (TGF)-β1. Urinary NGAL, KIM-1, and TGF-β1 were normalized to urinary creatinine. The Wilcoxon Two-Sample Test was applied.

Results: No significant differences existed between both groups at baseline. Specifically, serum uric acid levels, CKD-EPI estimated glomerular filtration rate (eGFR), and urinary ACR were similar in the placebo and allopruinol groups. After 12 weeks, allopurinol lowered serum uric acid significantly. CKD-EPI eGFR increased by 1.79 (8.08) mL/min/1.72m^2 with allopurinol group vs declined by 0.83 (5.2) mL/min/1.72m^2 in the placebo arm, but this did not achieve statistical significance (p=0.07). There was no significant difference between study groups regarding changes in serum cystatin C, cystatin C-eGFR, urinary ACR, or urinary NGAL, KIM-1, or TGF-β1 (Table).

Conclusions: Allopurinol significantly lowers serum uric acid levels in adults with stage III CKD and may increase CKD-EPI eGFR. The mechanism behind the increased eGFR is unclear as uric acid-lowering was not associated with significant change in markers of kidney damage.

Funding: NIDDK Support

Changes in markers of kidney function and kidney damage from baseline to the end of study visit (week 12)

Variable	Placebo (n=41)	Allopurinol (n=39)	P value

Reduction in Uric Acid Correlates with Better eGFR in Patients with Hyperuricemia and CKD Treated with XOIs – A Systematic Meta-Analysis Fredrik Erlandsson, Eva K. Johnsson, Anna Hellsten kronander, Magnus K. Bjursell, Magnus Andersson. *AstraZeneca R&D, Gothenburg, Sweden.*

Background: Hyperuricemia may contribute to worsening of renal function in patients with chronic kidney disease (CKD). Uric acid (UA) lowering xanthine oxidase inhibitors (XOIs) may therefore preserve GFR.

Methods: TrialTrove was queried for studies with results using the terms "+Uricosuric agent or xanthine oxidase inhibitor". Of 660 trials 8 were published randomized clinical trials in patients with hyperuricemia and CKD treated with XOI. The effect of XOI treatment relative to control on eGFR and the impact of reduction in serum uric acid on eGFR was assessed in a random effects meta-analysis model.

Results: Estimated GFR at end of treatment was significantly higher in the XOI arms (p<0.035) without significant heterogeneity in effect (p-value=0.075, I2- index: 45.7%). Greater reduction in UA correlated with better eGFR at the end of treatment (p<0.0062).

Conclusions: Renal function may benefit from intensive UA lowering therapy in CKD. Prospective studies of intensive UA lowering in CKD are warranted.

Prospective Comparative Pilot Study of the Short Term Efficacy and Oxidative Stress Effects of Various IV Iron Therapies in Iron Deficient CKD Patients Ahmed Zeidan.[1,2] *[1]Academic Renal Department, Hull & East Yorkshire Hospitals, NHS Trust, Hull, United Kingdom; [2]Research, Hull & York Medical School, Hul/York, United Kingdom.*

Background: Iron deficiency is common in chronic kidney disease (CKD) and usually leads to anaemia which is associated with fatigue, reduced quality of life and poorer clinical outcomes. Treatment with oral iron is often insufficient and guidelines recommend intravenous (i.v.) iron as an option for the treatment of iron deficiency anaemia in certain clinical situations. Reports have raised safety concerns regarding the potential increase in oxidative stress reactions and effects on cardiovascular events related to changes in endothelial function. In this study we hypothesized that CKD patients who receive intravenous iron, although efficacy may be similar, there may be differences in the

effects of iron preparation on the acute generation of oxidative stress markers and clinical effects on endothelial function.

Methods: Patients were randomised in a 1:1:1:1 ratio to intervention with one of 3 iron preparations (Cosmofer, Venofer at 200mg single dose or Monofer at 200mg or high single dose 1000mg). All patients underwent baseline assessments and following iron infusion, at 1 day, 1 week, 1 month and 3 monthly intervals. At each visit a SF-36, Pulse Wave Velocity (PWV) and blood samples for the assessment of renal function, changes in haemoglobin, iron markers, and markers of oxidative stress and endothelial function were collected.

Results: I.V. iron led to a rise in storage iron within the first 24 hours of administration and by one week a maximal rise with all iron preparations. Monofer 1000mg produced the most significant rise and reduced over the subsequent period. There was a rise in TS% within hours to levels within a toxic range (>80% for some irons). Venofer produced the greatest rise, while with Monofer this rise was more gradual in the first 24 hours. The most significant improvement in SF-36 score over the 3 month follow-up period was seen in patients who received Monofer. Acutely i.v. iron did not affect measures of endothelial function, but there was a trend in the reduction in PWV over the 3 month period.

Conclusions: All studied parenteral iron preparations led to a rise in storage and circulating iron. Those producing a saturation approaching 100% may cause an increase in catalytic iron which may lead to increased oxidative stress (under evaluation). Paradoxically there was a fall in PWV suggesting benefit in endothelial function.

TH-PO499

On Top of Standard Treatment Selective Endothelin-A Receptor Antagonism Improves Lipid Profile in CKD Neeraj Dhaun. *Cardiovascular Sciences, University of Edinburgh, Edinburgh, United Kingdom.*

Background: CKD patients have an increased risk of cardiovascular disease (CVD) that is partly explained by conventional CVD risk factors. Current guidelines recommend the use of HMG-CoA reductase inhibitors (statins) to improve lipid profile in patients with pre-dialysis CKD. Despite their use many patients continue to have elevated lipids and remain at increased CVD risk. Endothelin-A (ET_A) receptor antagonism is currently being investigated as a novel therapeutic approach to reduce proteinuria and blood pressure (BP), and to improve outcomes in pre-dialysis CKD. Here, we investigated the effects of ET_A antagonism on circulating lipids in these patients.

Methods: In a randomized double-blind, 3-way crossover study, 27 subjects with proteinuric, pre-dialysis CKD received 6 weeks treatment with placebo, sitaxentan 100mg, an ET_A antagonist, and nifedipine 30mg. Those with nephrotic syndrome were excluded. Serum total cholesterol, high-density lipoprotein (HDL), low-density lipoprotein (LDL) and triglycerides were measured at baseline and week 6 of each treatment period, alongside the primary endpoints of proteinuria, BP, and arterial stiffness.

Results: 18 of 27 subjects were prescribed statin therapy. Baseline lipid profile was similar in the 3 phases of the study (mean±SEM – total cholesterol: 4.9±0.1mmol/L; HDL: 0.9±0.1mmol/L; LDL: 2.8±0.2mmol/L; triglycerides: 1.7±0.3mmol/L). Whereas placebo and nifedipine did not affect total cholesterol, LDL or triglycerides, treatment with the ET_A antagonist reduced all three – baseline *vs.* week 6 – cholesterol: -11% (95% CI 8.7-13.2%, p <0.001); LDL: -21% (95% CI 17.8-27.3%, p <0.001); triglycerides: -26% (95% CI 15.1-36.5%, p <0.001). These effects were independent of the reductions seen in proteinuria, BP and arterial stiffness and were greatest in those receiving statin treatment. HDL was unaffected by all treatments.

Conclusions: In addition to currently recognized effects on proteinuria and BP, ET_A antagonism may modify lipid profile and so have broader cardioprotective effects in CKD. Larger and longer-term trials with this specific endpoint are now warranted.

TH-PO500

Phase I Evaluation of AZD9977, a First in Class Mineralocorticoid Receptor (MR) Modulator Fredrik Erlandsson,[1] Muna Albayaty,[2] Ligia E. Chialda,[2] Hans I. Ericsson,[1] Carl Amilon,[1] Karin Nelander,[1] Krister Bamberg,[1] Rasmus Jansson-Lofmark,[1] Linda C. Wernevik,[1] Magnus B. Kjaer,[1] Judith Hartleib-Geschwindner.[1] *[1]AstraZeneca R&D, Gothenburg, Sweden; [2]PAREXEL International, Berlin, Germany.*

Background: MR antagonists may improve outcomes in patients with chronic kidney disease, but are associated with hyperkalemia. Pre-clinical data indicate AZD9977 could be a first in class MR modulator with similar organ protection as eplerenone, but associated with minimal urinary electrolyte effects.

Methods: Phase I development began with a single dose escalation trial from 5mg to 1200mg, followed by a randomized placebo controlled cross-over four period clinical trial in 23 healthy volunteers. The treatments administered were fludrocortisone (A), 200mg AZD9977 + fludrocortisone (B), 100mg eplerenone + fludrocortisone (C), and 200mg AZD9977 + 100mg eplerenone + fludrocortisone (D). Treatment D was administered to assess if AZD9977 could attenuate the natriuresis induced by eplerenone as observed in rodent studies. A baseline session without treatment was performed. Food and fluid intake was controlled and urine collected in 2h intervals. The primary endpoint was log[Na]/[K] in urine collected from 2 to 8h.

Results: In the single dose escalation trial all doses were well tolerated. Pharmacokinetic and safety results were compatible with further development. In the cross-over trial 200mg AZD9977 (B) exhibited similar effects on diuresis and urinary electrolytes as 100mg eplerenone (C), and the combination (D) had an additive effect on urinary electrolytes. Fludrocortisone exposure was similar across treatments, and there was no significant pharmacokinetic interaction between eplerenone and AZD9977.

Conclusions: The results in man contradict the results in rodent models driven by aldosterone, in which AZD9977 had minimal electrolyte effects, but aligned with studies in rodent models driven by fludrocortisone. The effect of MR modulators on electrolyte excretion may depend on the MR agonist. Clinical studies of how AZD9977 or other MR modulators affect urinary electrolytes in the presence of aldosterone are needed.

A Phase 2a Trial of DMX-200: Synergistic Blockade of AT1R and CCR2 in Patients with CKD David A. Power,[1] Stephen G. Holt,[4] Paul J. Champion de Crespigny,[5] Matthew A. Roberts,[3] James H. Williams,[6] Kathryn M. Harrison,[2] David K. Packham.[7] *[1]Austin Health, Heidelberg, VIC, Australia; [2]Dimerix Bioscience Limited, Melbourne, NSW, Australia; [3]Eastern Health, Blackburn, VIC, Australia; [4]Royal Melbourne Hospital, Melbourne, NSW, Australia; [5]The Royal Melbourne Hospital, Parkville, NSW, Australia; [6]Dimerix Bioscience Pty Ltd, Nedlands, WA, Australia; [7]Melbourne Renal Research Group, Melbourne, VIC, Australia.*

Background: The angiotensin II receptor type 1 (AT1R) and chemokine receptor 2 (CCR2), both G protein-coupled receptors, form functional heteromers. Simultaneous antagonism of these receptors had a beneficial effect on proteinuria, podocyte viability and recruitment of inflammatory monocytes to the kidney in the sub-total nephrectomy rat model of nephrotic syndrome.

Methods: Patients (n=27) were enrolled in an open label, Phase 2a, dose escalation study at 4 sites in Australia. The primary objective was to determine the safety and tolerability of the CCR2 antagonist organic germanium added to stable treatment of the AT1R antagonist irbesartan in patients with proteinuria. The secondary objective was to evaluate the effects of organic germanium on various biomarkers including proteinuria. All patients were on a stable dose of irbesartan for ≥ 3-months prior to enrolment and throughout the study. Patients received escalating doses of organic germanium (10, 20, 30, 50, 80mg TID) at 4-week intervals unless proteinuria was within normal limits. Participants remained on their maximum dose for a further 2 intervals

Results: No serious safety concerns were observed in patients on irbesartan when treated with 10-80 mg TID organic germanium. The average age of patients was 61±13 (SD) years. Primary diagnoses were diabetic nephropathy (n=7), IgA nephropathy (n=5), and other proteinuric diseases (n=15). The baseline eGFR was 32±12 (range 15-59), PCR 255±174 mg/mmol (range 70-700), and irbesartan dose 75-300 mg (81% on 300 mg). Three patients withdrew from the study for reasons unlikely to be related to the study drug. There were no clinically relevant changes in blood pressure, eGFR and serum potassium. Of the 24 patients that completed dosing, 6 achieved ≥ 50% reduction in proteinuria during at least one dose level of organic germanium.

Conclusions: No safety concerns were observed in patients on irbesartan when treated with 10-80 mg TID organic germanium. The additive reduction in proteinuria over and above AT1R blockade in some patients warrants additional clinical investigation of DMX-200 for proteinuric CKD.

Stanniocalcin-1 Inhibits ER Stress and Renal Fibrosis via an AMP-Activated Protein Kinase-Dependent Pathway in HK2 Cells Eun mi Yang,[1,2] Eun Hui Bae,[1,2] Seong Kwon Ma,[1,2] Soo Wan Kim.[1,2] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea.*

Background: The role of endoplasmic reticulum (ER) stress in the development of renal disease is a relatively recently described, and has been suggested as a cause for the fibrotic remodeling. Therefore, modulation of ER stress could be one of the possible therapeutic approaches to renal fibrosis. Stanniocalcin-1 (STC-1) is a multifunctional glycoprotein with antioxidant and anti-inflammatory properties and regulates AMP-activated protein kinase (AMPK) activity in the kidney. Activation of AMPK may reduce ER stress. The present study aimed to investigate the effects of STC-1 in ER stress and renal fibrosis in human renal proximal tubular (HK-2) cells

Methods: HK2 cells pretreated with STC-1 (200 ng/ml) for 1 hours followed by treatment with TGF-β (10 ng/ml) for 16 hours. To determine whether effect of STC-1 mediated by AMPK activation, pharmacological inhibitor (compound C, 5 uM) pretreated with STC-1. The protein expression of ER stress markers and fibrosis markers was determined by semiquantitative immunoblotting. The level of reactive oxygen species (ROS) was determined by fluorescent microscopy immunofluorescence.

Results: TGF-β treatment induced upregulation of glucose-related protein (GRP)78 and C/EBP homologous protein (CHOP) and STC-1 pretreatment attenuated the rise in the GRP 79 and CHOP. TGF-β treatment also induced upregulation of fibronectin and alpha-smooth muscle actin (α-SMA) and STC-1 pretreatment attenuated the TGF-β induced upregulation of fibronectin and α-SMA. STC-1 pretreatment significantly blocked TGF-β induced downregulation of AMPK and decreased level of ROS via upregulate the uncoupling protein (UCP2). On the other hand, compound C pretreatment with STC-1

before TGF-β treatment abolished the activation of AMPK, diminished the upregulation of UCP2, and aggravated ER stress and fibrosis but did not affect STC-1 expression.

Conclusions: STC-1 Inhibits ER stress and renal fibrosis via an AMPK Pathway and STC-1 may be a therapeutic target through reducing ER stress and renal fibrosis.

Tubulointerstitial Nephritis with IgM-Positive Plasma Cells Naoki Takahashi,[1] Takako Saeki,[2] Atsushi Komatsuda,[3] Ken-ichi Samejima,[4] Yudai Nishikawa,[1] Kazuhisa Nishimori,[1] Sayu Morita,[1] Mamiko Kobayashi,[1] Yukie Morikawa,[1] Sachiko Fukushima,[1] Seiji Yokoi,[1] Daisuke Mikami,[1] Hideki Kimura,[1] Kenji Kasuno,[1] Ichiei Narita,[5] Masayuki Iwano.[1] *[1]Department of Nephrology, University of Fukui, Fukui, Japan; [2]Department of Internal Medicine, Nagaoka Red Cross Hospital, Nagaoka, Japan; [3]Department of Hematology, Nephrology and Rheumatology, Akita University School of Medicine, Akita, Japan; [4]First Department of Internal Medicine, Nara Medical University, Kashihara, Japan; [5]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Infiltration by IgG-positive plasma cells is a common finding in tubulointerstitial nephritis (TIN). Routine immunofluorescence of frozen sections is currently considered the gold standard for detection of immune deposits; however, the immunoenzyme method with formalin-fixed, paraffin-embedded sections is superior for detecting IgM- or IgG-positive cells within the renal interstitium. It was thought that CD138-positive mature plasma cells secrete IgG, and the occurrence of TIN with CD138-positive plasma cells secreting IgM has rarely been reported. We recently discovered a case of TIN showing IgM-positive plasma cell (IgMPC) accumulation within the interstitium (*Clin Nephrol* 74: 74-80, 2010).

Methods: To further explore the morphological and clinical features of such cases, we performed a nationwide search for patients with biopsy-proven TIN and high serum IgM levels.

Results: In 13 of those patients, the pathologic findings were interstitial nephritis with diffusely distributed CD3-positive T lymphocytes and co-localized IgMPCs as well as tubulitis in the proximal tubules and collecting ducts with CD3-positive T lymphocytes. The number of infiltrating IgMPCs per high-power field from 13 patients was significantly higher than from control patients with other forms of TIN chosen as controls for staining (n=44) ($p<0.001$). Receiver operating characteristic (ROC) curve analysis revealed that optimal predictive cutoff number for infiltrating IgMPCs was 13 per high-power field, with an area under the ROC curve of 0.99 ($p<0.0001$). The sensitivity and specificity were 100% and 93.2%, respectively. In addition, levels of H^+-ATPase, H^+, K^+-ATPase and HCO_3^--Cl^- anion exchanger in the collecting ducts were significantly lower in 13 patients than in control patients with TIN. The clinical findings with these patients were a high prevalence of distal RTA (100%), Fanconi syndrome (92%) and anti-mitochondrial antibodies (82%).

Conclusions: We propose to designate this group of cases, which have a common histological and clinical form, as "IgM-positive plasma cell-tubulointerstitial nephritis" (IgMPC-TIN).

TH-PO504

Clinicopathologic Characteristics, Treatment, and Outcome of Tubulointerstitial Nephritis and Uveitis Syndrome in Children Asako Hayashi, Takayuki Okamoto, Toshiyuki Takahashi, Yasuyuki Sato. *Hokkaido University Graduate School of Medicine, Hokkaido, Japan.*

Background: Tubulointerstitial nephritis and uveitis (TINU) syndrome is a rare disease, presenting as a combination of tubulointerstitial nephritis and uveitis. A few case-series previously reported good renal prognosis of this syndrome, but long-term prognosis is not known enough in children. To further investigate this syndrome, we report here the clinical features and outcome. All patients followed up at least 24 months (median, 47months; range 24-179).

Methods: Retrospective study of the case records of all patients diagnosed with the TINU syndrome in the Departments of Pediatrics and Medicine of the Hokkaido University Hospital (Sapporo, Japan) from February 1990 through April 2017.

Results: We report here the clinical features and outcome of 20 patients (female 12, F/M ratio: 3:2), aged 9 to 14 years at diagnosis (median, 13.0) with TINU syndrome. The initial symptoms were visual impairment in sixteen patients (80%) and deterioration of health status in six patients (30%). The median estimated glomerular filtration rate (eGFR) at diagnosis was 99.8 mL/min per 1.73m^2 (range 59.7-117.4) and deteriorated renal function (eGFR <90 mL/min per 1.73m^2) was observed in 9 patients (30%). An increase in urinary β_2-microglobulin levels was noticed at the initial checkup in all patients. Topical and oral corticosteroids were prescribed to 15patients (75%) and Mizoribine or Methotrexate therapy was required in 2 patients (10%). After 24 months follow-up, the median eGFR was 111.4mL/min per 1.73m^2 (range 80.1-127.9). In three patients (15%) decreased eGFR<90 mL/min per 1.73m^2 after 24 months but the renal function of all patients was normalized at the latest checkup. Urinary β_2-microglobulin excretion gradually declined but was slightly elevated in 11 patients (55%) at 24 months. Recurrent or exacerbating uveitis was seen in ten patients (50%). On the other hand, TIN is not recurrence.

Conclusions: The TINU syndrome should be considered in the differential diagnosis of patients presenting with visual and renal manifestations. The presence of increase in urinary β_2-microglobulin levels may be of some help for the early discovery of recognition of TINU syndrome. In children and adolescents with this syndrome, the long-term prognosis of TIN is good, but uveitis often relapse.

TH-PO505

Clinical Advantage of Renal Arterial Doppler Ultrasonography for the Assessment of Tubulo-Interstitial Nephropathy Minoru Hatano,[2] Kaori Takayanagi,[2] Hiroaki Hara,[2] Masaaki Terao,[2] Yuichiro Kawai,[2] Saeko Sato,[2] Takatsugu Iwashita,[2] Taisuke Shimizu,[2] Tomonari Ogawa,[3] Koichi Kanozawa,[1] Hajime Hasegawa.[4] *[1]Saitama Medical Center, Saitama Medical University, Kawagoe, Japan; [2]Nephrology, Hypertension, Blood Purification, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan; [3]Saitama Medical Center, Saitama Medical University, Kawagoe, Japan; [4]School of Medicine, Saitama Medical University, Kawagoe, Japan.*

Background: At present, potential clinical parameters for the assessment of tubulo-interstitial nephropathy (TIN) are poorly available. Here, we focused on the resistive index (RI) measured by renal arterial doppler ultrasonography (RAUS), and studied its efficacy for the assessment of TIN by comparative analysis with the conventional TIN parameter, urine N-acetylglusaminidase-to-creatinine ratio (NAG index) in patients with clinically suspected TIN.

Methods: Patients who have received RAUS under the clinical suspicion of renal artery disorders were retrospectively analyzed (n=33). Clinical diagnosis was renal artery stenosis, (n=13), diabetic nephropathy (n=4) and the others (n=16). We focused on RI measured at two different points independently, with the main trunk of the renal artery (RA) and intra-renal branch of the renal artery (IRA) corresponding to the inter-lobular artery.

Results: An analysis stratified by the median NAG index value for the estimation of TIN revealed a significant difference in the estimated glomerular filtration rate (eGFR), urine protein-to-creatinine ratio (uPCR) and RA/IRA-RI, although the correlation was not significant between the NAG index and the RI. Next, we focused the cases showing NAG index less than 20 U/mgCr because higher NAG index indicates advanced renal damage and the assessment of TIN is not required in those patients. When the patients showing higher NAG index are excluded, IRA-RI showed a significant correlation with NAG index ($R=0.59$, $p<0.01$), but RA-RI did not. A multivariate analysis for the NAG index as a response variable revealed that IRA-RI was a significant predictor variable ($\beta=0.59$, $P=0.02$), but RA-RI did not. A ROC analysis showed that the cut-off value of IRA-RI was 0.645 (AUC 0.80, sensitivity 72%, specificity 82%).

Conclusions: Resistive index by RA-US would be a useful clinical parameter for the assessment of TIN. For this purpose, RI should be measured at the intra-renal artery, not the main trunk of renal artery. In addition, threshold of NAG index value indicating the presence of TIN might be lower than the value corresponding the renal artery stenosis (0.8 U/mgCr).

TH-PO506

Blood Oxygen Level Dependent Imaging of CKD in Children Fenglan Luo, Yuhong Tao. *West China Second University hospital, Sichuan University, Chengdu, China.*

Background: Renal chronic hypoxia plays a vital role in the development of end-stage renal disease. Blood oxygen level dependent(BOLD) imaging can assess the oxygenation of kidney. Although BOLD-MRI is used for studying chronic kidney disease(CKD) in adults, BOLD has fewer applications in children with CKD. This study aims to investigate the values of BOLD-MRI in evaluating oxygenation of kidney and renal function of CKD in children.

Methods: All of these subjects underwent studies BOLD images on 1.5T MRI scanner as follows: scanning sequence FFE, FOV=200mm×282mm×70mm, slice thickness=5mm, slice number=12, TR=400ms, voxel size=3mm×3mm, flip angle =45°, echo train length=16. R2* value of cortex and medulla were obtained. The cortical and medullary R2* value were compared between the groups. The correlation of serum creatinine level(Scr) and eGFR with R2* value was also discussed. With the ROC curve, the diagnostic effectiveness of R2* value for severity of CKD was evaluated.

Results: The images of 6 healthy volunteers and 21 minor/moderate CKD children(CKD stage1-3), 16 severe CKD children(CKD stage4-5) were finally analyzed. Both in the CKD groups and control group, the R2* value in cortex was significantly lower than that in medulla. Cortical R2* value(11.61051±0.42012) of CKD stage1-3 was significantly higher than that of control group(10.74787±0.17737). Both cortical R2* value(12.99746±1.35398) and medullary R2* value(21.13990±1.90089) of CKD stage 4-5 were significantly higher than those of CKD stage1-3. In CKD patients, negative correlations were found between cortical R2* value with Scr level($r=0.800$,$P<0.001$), and also between medullary R2* value with Scr level($r=0.898$,$P<0.001$). Positive correlations were found between cortical R2* value($r=-0.586$,$P<0.001$) and medullary R2* value($r=-0.838$,$P<0.001$) with eGFR. The area under ROC curve for cortical R2* value in differentiating between minor/moderate CKD kidneys and normal kidneys, and between minor/moderate CKD kidneys and severe CKD kidneys were 1.00 and 0.89, respectively. With the threshold from ROC curve, the sensitivity and specificity of differentiating CKD stage1-3 and controls were all 100%.

Conclusions: BOLD-MRI is valuable in diagnosis and severity of CKD in children. Renal R2* value presents the level of oxygenation of kidney and reflects the change of

renal function. BOLD-MRI provides a novel technique to evaluate the severity of CKD in children.

TH-PO507

The Nephropathy Studied in the African American Study of Kidney Disease (AASK) May Be an Atypical Tubulopathy Salem Almaani,[2] Daniel J. Birmingham,[1] Brad H. Rovin,[1] Lee A. Hebert.[1] *[1]Ohio State University, Columbus, OH; [2]University Hospital Network - The University of Toronto, Toronto, ON, Canada.*

Background: It has been suggested that the nephropathy associated with patients enrolled in the AASK (AASK-N) may be a primary tubulopathy (and not a glomerulopathy or a vasculopathy related to hypertension) because it progresses at levels of proteinuria below that of progressive glomerulopathy. However, studying this in AASK-N urine samples has been hampered due to protein degradation because of the presence of acetic acid as a preservative. This report addresses this question by studying urine samples from patients enrolled in the Chronic Renal Insufficiency Cohort (CRIC) who met criteria for AASK enrollment.

Methods: Urine samples were obtained from 43 African American CRIC patients with urine protein-to-creatinine ratios (uPCRs) of 0.2 to 1.1 and eGFRs ranging from 65 to 20. Six kidney injury markers were measured in these samples by a multiplex platform (Meso Scale Discovery, MSD) that uses a capture and detection antibody pair for each analyte. For comparison, urine samples from 20 lupus nephritis (LN) patients with the same uPCR range were also tested.

Results: There were no differences in albumin-to-protein ratios (uAPR) between the CRIC cohort (mean 0.59) and the LN cohort (0.54). The results of the MSD analysis are shown in the table. Notably, levels of B2M, a classic marker of proximal tubule injury/dysfunction, were 8-fold higher in CRIC, while levels of cystatin C, another marker of proximal tubule dysfunction, were no different between the two cohorts. Decreased EGF levels in the CRIC cohort reflect their lower GFRs.

Conclusions: The 8-fold increase in urine B2M levels in the CRIC cohort compared to the LN cohort in the face of similar levels of uAPRs and other indicators of proximal tubular injury suggest that AASK-N is not a typical tubulopathy, but may involve unique proximal tubular damage.

TH-PO508

Successful Use of Renal Denervation (RDN) in Patients with Loin Pain Hematuria Syndrome (LPHS): The Prairie LPHS Study Bhanu Prasad,[3] Shelley Giebel,[2] Michelle C. McCarron.[1] *[1]Regina Qu'Appelle Health Region, Regina, SK, Canada; [2]Regina QuAppelle Health Region, Regina, SK, Canada; [3]Nephrology, Regina Qu'Appele Health Regiona, Regina, SK, Canada.*

Background: Loin Pain Hematuria Syndrome (LPHS) is a rare disease with a reported prevalence of 0.012%. Its characterized by painful unilateral or bilateral loin pain that suggests a renal origin but occurs in the absence of identifiable or relevant urinary tract disease. Hematuria can be either microscopic or macroscopic, and the renal abnormalities responsible for the hematuria are often unexplained. Debilitating pain refractory to conventional medications lead to multiple trips to the emergency rooms and is the main cause of morbidity. Treatment options include opiates, autotransplantation and autonephrectomy.

Methods: We conducted a single centre, single arm study. Twelve patients between the ages of 21-62 years (eleven females) with LPHS underwent RDN between July 2015 and November 2016 using the Vessix renal denervation system. Secondary causes were excluded by triphasic CT scan of the abdomen and pelvis and MAG3 split function renogram. The primary objective was a 30% reduction in self reported pain using the McGill pain questionnaire (MPQ). The secondary objectives were: changes in self reported diabilitity using Oswestry disability index (ODI), changes in quality of life using the EQ5D, Short Form Health Survey (SF-36), changes in mood using the Geriatric depression score (GDS) at 3 and 6 months as compared to the baseline.

Results: 11/12 patients had a >30% reduction in MPQ at 6 months. MPQ score median (IQR) at baseline was 38.5 (34.3-63.8), and 2.0 (0.018.5) at 6 months (p=0.001). ODI (%) mean (IQR) at baseline was 43.5% (20.8-59.3), and 4.4% (0.0-43.0) at 6 months (p=0.003). GDS was 3 (1.3-5) at baseline), and 1(1.0-4.5) at 6 months) (p=0.002). The visual analogus score (VAS) on EQ5D mean (IQR) improved from 50 (33.8-60.0) at baseline to 75.0 (55.2-88.3) at 6 months (p=0.022). There was consistent improvement across the spectrum of quality of life measures in both EQ5D and SF-36.

Conclusions: This is the first reported study that shows succesful pain relief post RDN in patients with LPHS. There was also considerable improvement in mood, functionality and quality of life post procedure. In a clinical condition, where autrotransplantation and autonephrectomy are considered to be reasonable therapeutic optons, this rapid, safe, minimlly invasive procedure should be considered in all patients with LPHS.

TH-PO509

Efficacy and Safety of Initial Pulse Methylprednisolone Treatment in Renal Sarcoidosis: A Randomized Trial Jean-Jacques Boffa,[7,11] Matthieu Mahevas,[8] Eric Daugas,[9] Dominique Guerrot,[5] Michel Delahousse,[2] Tabassome Simon,[6] Laurence Vrigneaud,[10] Evguenia Krastinova,[12,13] Evangeline Pillebout,[3] Vincent Audard,[14] David Verhelst,[4] Dominique Valeyre.[1] *[1]Avicenne Hospital AP-HP, Bobigny, France; [2]FOCH Hospital, Suresnes, France; [3]Hopital Saint-Louis, Paris, France; [4]None, PARIS, France; [5]Rouen University Hospital, Rouen, France; [6]Assistance Publique -Hôpitaux de Paris, Paris, France; [7]Tenon Hospital, AP-HP, Paris, France; [8]AP-HP, UPEC UNIVERSITY, Paris, France; [9]Bichat hospital, AP-HP, Paris, France; [10]hospital, Valenciennes, France; [11]INSERM U1155 / UPMC, Paris, France; [12]Creteil Hospital, Créteil, France; [13]URC-EST, AP-HP, Paris, France; [14]Mondor Hospital, AP-HP, Paris, France. Group/Team: Corticoïdose Group.*

Background: Sarcoidosis tubulo-interstitial nephritis (STIN) induces severe renal insufficiency with poor outcome. Despite treatment with steroids, most patients develop chronic kidney disease. Pulse methylprednisolone treatment has been used to improve renal function but this therapeutic strategy has never been evaluated. We assessed whether initial pulse methylprednisolone is effective and safe at improving renal function compared to oral steroids at 3 months of follow-up.

Methods: In a multicenter randomized open control trial, in patients with proven acute sarcoidosis tubulo-interstitial nephritis, we randomly assigned forty patients with STIN to receive pulse methylprednisolone 15 mg/kg/day for three days and per os steroids afterwards (group A) or per os 1 mg/kg/d steroids from the start (group B). The primary outcome was CKD-EPI estimated glomerular filtration rate (eGFR) during the follow-up. The primary efficacy end point was the percentage of patients having a positive response at 3 months of follow-up, defined by an improvement of more than 100% of eGFR compared to eGFR before treatment or eGFR ≥ 60 ml/min/1.73m². Secondary end points included side effects of steroids.

Results: The mean age of the trial participants was 59 (45-68) years and 70% were men. Among 40 participants, only one patient was excluded for a misdiagnosis of tuberculosis. Baseline eGFR before treatment were 25(22-37) ml/min/1.73m² for group A and 22(17-40) ml/min/1.73m² for group B, p=0.3. In the intent-to-treat population, the median eGFR was 45(39-64) ml/min/1.73m² for group A and 45(34-73) ml/min/1.73m² for group B at 3 months. Patients randomized to pulse methylprednisolone were significantly less likely to achieve the primary efficacy end point: 10 of 20 (50%) vs 16 of 20 (80%), p=0.047. eGFR were similar between groups after 1 month of treatment. No participants presented cardiac arrhythmia or conduction disorder during pulse methylprednisolone. Number of adverse effects was similar between groups: 15 in group A and 14 in group B.

Conclusions: Among patients with acute STIN, pulse methylprednisolone treatment was not significantly different from oral steroids in improving renal function at three months follow-up.

A Novel I-Body AD-114 Suppressed TGFβ1-Induced Fibronectin and Collagen 4 in Renal Proximal Tubular Cells via Smad and p38 Pathways Qinghua Cao,[1] Chunling Huang,[4] Hao Yi,[1] Stefanie Stangenberg,[3] Carol A. Pollock,[2] Xinming Chen.[4] *[1]Kolling Institute, Sydney, NSW, Australia; [2]The University of Sydney, Sydney, NSW, Australia; [3]None, Naremburn, NSW, Australia; [4]University of Sydney, Sydney, NSW, Australia.*

Background: Fibrosis is the final common pathway of chronic kidney disease (CKD). CXCR4 has been demonstrated to be a central player in the development of tissue fibrosis. However, the only approved CXCR4 antagonist was terminated due to its off-target cardiotoxicity. Our collaborator (Adalta Limited, Australia) has developed a fully human single-domain antibody-like scaffold termed i-body AD-114 with specific high binding affinity to CXCR4. AD-114 selectively blocks CXCR4 signaling and has shown anti-fibrotic effects in lung, liver and eye fibrosis. However, the role of AD-114 in renal fibrosis has not been studied.

Methods: To detect CXCR4 expression in the kidney, biopsies from patients with diabetic nephropathy (DN) and kidneys from three mouse models of CKD were collected and CXCR4 expression was detected using immunohistochemistry. To determine the role of TGFβ1 in AD-114 binding with CXCR4 in human renal proximal tubular cells (PTCs), PTCs were incubated with/without TGFβ1 (2ng/ml) in absence or presence of AD-114 for 48 hours, and then AD-114 binding with PTC was detected using immunocytochemistry. To examine whether AD-114 blocks TGFβ1-induced fibrotic responses in PTCs, PTCs were incubated with/without TGFβ1 (2ng/ml) in absence or presence of AD-114 (1mM or 3mM) for 48 hours and the supernatant and cell lysis protein were collected for Western blot analysis. Fibronectin (FN) and collagen 4 (Col 4) in the supernatant and phosphorylation of Smad2/3, p38 and NF-κB(p65) in cell lysis were measured by Western blot.

Results: CXCR4 expression was significantly upregulated in patients with DN and fibrotic kidneys of three mouse models of CKD compared to control groups (P<0.001, n=6). TGFβ1 significantly increased AD-114 binding to renal PTCs compared to negative control i-body and normal controls (P<0.001, n=4). AD-114 (3μM) suppressed TGFβ1-induced overexpression of FN and Col 4 via decreasing Smad2/3 and p38 phosphorylation compared to a lower concentration of AD-114 (1μM) and negative control i-body (P<0.001, n=4). However, AD-114 did not change the phosphorylation of NF-κB (p65).

Conclusions: Blocking CXCR4 using the i-body AD-114 is a promising therapeutic strategy to prevent the development of CKD.

Effect of Addition of Silybin and N-Acetylcysteine to Renin-Angiotensin System Inhibitors on Albuminuria in Type 2 Diabetic Patients with Overt Nephropathy: A Randomized Controlled Trial

Shweta Bansal,[4,5] Shirley L. Hu,[3] Shuko Lee,[1] Subrata Debnath,[2] Sue E. Cunningham,[4] Chakradhar Velagapudi.[4] *[1]South Texas Veterans Health Care System, San Antonio, TX; [2]University of Texas Health Science Center at San Anotonio, San Antonio, TX; [3]UTHealth Houston, McALlen, TX; [4]University of Texas Health Science Center at San Antonio, San Antonio, TX; [5]South Texas Veterans Health Care System, San Antonio, TX.*

Background: A large proportion of patients with type 2 diabetes mellitus have diabetic nephropathy. Despite current therapies including hypertension control and renin-angiotensin system inhibitors, diabetic nephropathy progresses to end-stage renal disease in many of these patients. The aim of this study was to evaluate the efficacy of silybin and N-acetylcysteine (NAC), natural supplements with antioxidant and anti-inflammatory properties, in preventing the progression of diabetic nephropathy.

Methods: After institutional IRB and VA R&D approval, we conducted a randomized, double-blind, placebo-controlled, 5-arm parallel trial where subjects with diabetic nephropathy with albumin-creatinine ratio (ACR) of =/>150 mg/g and eGFR of 15-60 ml/min on the background of angiotensin inhibition after 1 month run-in period received either A) double placebo BID (n=16); or B) silybin placebo + NAC 600 mg BID (n=12); or C) silybin 480 mg + NAC placebo BID (n=16); or D) silybin 480 mg + NAC 600 mg BID (n=16); or E) silybin 960 mg + NAC 600 mg BID (n=15) for 3 months. Primary outcome was absolute change in urinary ACR from baseline to the end of the treatment phase.

Results: Overall, the study population was 62.97±7.48 years old, 89% male, 65% Hispanic, 27% non-Hispanic white and 7% non-Hispanic blacks, had BMI of 35.02±8.54 kg/m^2, eGFR of 36.4±13.3 ml/min, and ACR of 702.8±608.5 mg/g at baseline. The baseline characteristics were similar across the treatment arms except for systolic and diastolic BP and fasting glucose. There was no difference in change in Urinary ACR in different arms (ΔUACR in B=-156±604.8, C=10.9±542.9, D=96.6±422.4 and E=353.7±732.7 mg/g) compared to placebo (ΔUACR in A=50.5±291.2, Anova p=ns). Moreover, the change in eGFR was not different in 4 treatment arms compared to placebo arm. Small sample size and short duration of the treatment phase were the major limitation of the study.

Conclusions: 3-month intervention with dietary supplements silybin and NAC did not reduce urinary excretion of albumin in diabetic nephropathy patients in our study cohort.

Multiple Determinants of Early Renal Decline in Type 2 Diabetes

Natalia Z. Nowak,[3] Jan Skupien,[3] Adam Smiles,[3] Masayuki Yamanouchi,[5] Monika A. Niewczas,[3] Kevin L. Duffin,[2] Matthew D. Breyer,[4] Nick Pullen,[6] Joseph V. Bonventre,[1] Andrzej S. Krolewski.[3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Eli Lilly and Company, Indianapolis, IN; [3]Joslin Diabetes Center, Boston, MA; [4]Lilly Research Laboratories, Indianapolis, IN; [5]Okinaka Memorial Institute for Medical Research, Tokyo, Japan; [6]Phizer Inc., Boston, MA.*

Background: There has been a significant effort to identify the mechanisms for progressive renal decline in diabetic patients with chronic kidney disease (late progressive renal decline). Much less is known about the mechanisms, determinants and markers of early progressive renal decline. We aimed to evaluate several markers as determinants of early renal decline in 1032 patients with Type 2 diabetes (T2D), enrolled into the 2nd Joslin Kidney Study. With these data, we aimed to develop a multi-marker index to improve the identification of patients with incipient renal decline.

Methods: At enrollment, all patients had preserved GFR (median of 98 mL/min (1st and 3rd quartile; 85 -110), 58% had normoalbuminuria (urinary ACR median of 4 μg/mg) and 42% had albuminuria (ACR median of 44 μg/mg). Early renal decline (defined as GFR loss from baseline of 30% per < 5 years) occurred in 38 (6%) normoalbuminurics and in 76 (18%) albuminurics. As predictors of the decline we examined: (1) baseline clinical characteristics, (2) several blood markers proposed by previous targeted studies, (2) new urinary biomarkers.

Results: When analyzed jointly with other markers/predictors, baseline systolic BP, plasma TNFR1, KIM-1 as well as urinary ACR predicted early renal decline; a strongest, negative association with the risk of early renal decline was found for the urinary EGF normalized to MCP1, expressed as EGF/MCP1 ratio (Nowak et al, submitted). Integration of the independent biomarkers into multi-marker index resulted in significant improvement of the accuracy of prediction, compared with a model with ACR and systolic BP alone (c-statistics=0.81 vs c-statistics=0.73; p<0.001).

Conclusions: Our study underscores the power of examining multiple pathways in plasma and urine for understanding the mechanisms of early renal decline in T2D. Two novel markers of tubular injury, KIM-1 and EGF/MCP ratio in urine, had independent effects on risk of early renal decline in T2D.

Effect of Baseline Serum Calcium on Responses to Extended-Release Calcifediol (ERC) in Stage 3-4 CKD

Nelson P. Kopyt,[1] Stephen A. Strugnell,[2] Akhtar Ashfaq,[2] Martin P. Petkovich,[3] Charles W. Bishop.[2] *[1]Lehigh Valley Hospital, Bethlehem, PA; [2]OPKO Health, Miami, FL; [3]Queen's University, Kingston, ON, Canada.*

Background: Calcitriol and its 1α-hydroxylated analogs frequently increase serum calcium (Ca) and the risk of vascular calcification in patients with stage 3-4 CKD. For this reason, the revised KDIGO guideline for CKD-Mineral and Bone Disorder suggests that these agents not be routinely used in this population. Randomized clinical trials (RCTs) with ERC, a new FDA-approved therapy for secondary hyperparathyroidism (SHPT), demonstrated effective control of iPTH with minimal changes in serum Ca in stage 3-4 CKD. Data from these RCTs were examined post-hoc to assess the potential impact of baseline serum Ca on end-of-treatment (EOT) serum Ca, phosphorus (P), total 25-hydroxyvitamin D (25D) and total 1,25-dihydroxyvitamin D (1,25D), and on plasma intact parathyroid hormone (iPTH) in ERC-treated and placebo (PL)-treated subjects.

Methods: Two identical, double-blind trials were conducted in 429 subjects with stage 3-4 CKD, SHPT (iPTH >85 pg/mL) and vitamin D insufficiency (25D of 10-29 ng/mL). Subjects were randomized 2:1 to receive ERC (30 or 60 mcg/day) or PL for 26 weeks. Per-protocol data were pooled and analyzed by baseline serum Ca tertile.

Results: The table below shows mean baseline values at left and EOT values at right for ERC tertiles (n= 78 each) and for PL tertiles (n=40-41 each). ERC and PL had similar effects on mean serum Ca and P irrespective of baseline serum Ca tertile. ERC increased mean serum 25D and 1,25D and decreased mean plasma iPTH to similar levels in all tertiles, with the greatest observed changes occurring in the lowest tertile (T1). PL treatment produced increases in iPTH and no changes in 25D and 1,25D.

Conclusions: Baseline serum Ca affected serum 1,25D and plasma iPTH responses to ERC treatment. ERC-induced increases in 1,25D and decreases in iPTH were greatest in subjects with the lowest baseline Ca.

Funding: Commercial Support - OPKO Health

Table 1

	Serum Ca (mg/dL)		Serum P (mg/dL)		25D (ng/mL)		1.25D (pg/mL)		iPTH (pg/mL)

Ferric Citrate Lowered Serum Phosphate Only When Elevated in Patients with Nondialysis-Dependent (NDD) CKD and Iron Deficiency Anemia (IDA)

Geoffrey A. Block,[1] Pablo E. Pergola,[3] Katrin Uhlig,[4] John F. Neylan,[4] Steven Fishbane,[5] Glenn M. Chertow.[2] *[1]Denver Nephrology, Denver, CO; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Renal Associates PA, San Antonio, TX; [4]Keryx Biopharmaceuticals, Boston, MA; [5]Hofstra Northwell Health, Great Neck, NY.*

Background: Ferric citrate (FC), an oral iron-based phosphate (P) binder approved for control of serum P in patients (pts) with CKD on dialysis, has also shown improvement in hemoglobin (Hb) and iron parameters in pts with NDD-CKD with IDA. Here, in a post-hoc analysis of a phase 3 study, we examine effects of FC on serum P in pts by different baseline (BL) P levels and stages of CKD.

Methods: 233 pts with NDD-CKD and IDA were randomized 1:1 to receive FC (n=117) or placebo (n=116) for 16 weeks. FC was initiated at 3 1-g tablets/day and titrated to achieve a Hb increase ≥1 g/dL from BL (max 12 g/day). FC effects on P were examined by BL strata of P, CKD stage (per eGFR), and FGF23 (grouped by BL quartile [Q]).

Results: Decreases in P with FC treatment were greater in pts with higher BL P levels. P remained stable in pts in the lowest BL P group even with increased FC dose. Likewise, P decrease was greatest in pts with lower BL eGFR (which correlated to higher BL P) [Figure]. Similar results were seen when pts were stratified by BL FGF23 [Table]. At 16 wks, the FC dose was similar across sub-groups, suggesting BL P did not affect dosing for treatment of IDA. Multivariate linear regression analysis confirmed BL P as a strong independent predictor of change in P (p<0.0001) after adjusting for treatment, BL eGFR and BL albumin.

Conclusions: In NDD-CKD pts with IDA, the effect of FC on P reduction is dependent on the BL P, with the greatest reduction in pts with the highest serum P. These results support the use of FC in NDD-CKD pts with IDA regardless of BL P.

Funding: Commercial Support - Keryx Pharmaceuticals

TH-PO515

PTH Suppression with Extended-Release Calcifediol (ERC) Is Directly Proportional to Severity of Secondary Hyperparathyroidism (SHPT) Stuart M. Sprague,[1] Stephen A. Strugnell,[2] Akhtar Ashfaq,[2] Martin P. Petkovich,[4] Charles W. Bishop.[3] *[1]NorthShore University HealthSystem University of Chicago Pritzker School of Medicine, Chicago, IL; [2]OPKO Health, Miami, FL; [3]Opko Health, Miami, FL; [4]Queen's University, Kingston, ON, Canada.*

Background: Oversuppression of parathyroid hormone (PTH) is a significant concern in patients with stage 3-4 CKD treated with calcitriol or its 1α-hydroxylated analogs since iatrogenic induction of a low PTH concentration is an independent strong risk factor for adynamic bone disease, fractures and cardiovascular death. Randomized controlled trials have shown that ERC gradually but effectively reduces PTH without oversuppression. These data have been further examined post-hoc to determine the impact of baseline PTH levels on end-of-treatment (EOT) levels.

Methods: Two identical, randomized, double-blind, placebo-controlled trials were conducted in 429 adult subjects with stage 3-4 CKD, SHPT (>85 pg/mL) and vitamin D insufficiency. Subjects were randomized 2:1 to receive ERC (30 or 60 mcg/day) or placebo (PL) for 26 weeks. Per-protocol data for plasma intact (i) PTH, serum calcium (Ca) and phosphorus (P), serum total 1,25-dihydroxyvitamin D (1,25D), and serum total 25-hydroxyvitamin D (25D) were pooled and analyzed by baseline plasma iPTH tertile. Mean baseline iPTH in each tertile was 98, 130 and 203 pg/mL for ERC and 102, 133, and 201 for PL.

Results: The table shows the mean changes from baseline to EOT in iPTH, Ca, P, 1,25D and 25D with ERC (n=78 in each tertile) and PL (n=40-41 in each tertile). Significant differences from the corresponding placebo groups are as marked. ERC and PL had similar, minor effects on mean serum Ca and P. ERC increased serum 25D and 1,25D significantly and to comparable levels irrespective of baseline iPTH tertile. However, decreases in mean iPTH with ERC differed between tertiles and were directly proportional to baseline levels, with EOT suppression increasing from 19 to 26% of baseline from T1 to T3. Oversuppression was not observed.

Conclusions: ERC produced mean absolute iPTH reductions that were proportional to baseline iPTH levels, consistent with a mechanism of action involving physiological regulation of iPTH modulated by SHPT severity.

Funding: Commercial Support - OPKO Health

Effect of Sodium Bicarbonate Treatment on a Novel Marker of Serum Calcification Propensity Jessica B. Kendrick,[5] Emily Andrews,[4] Andreas Pasch,[2] Zhiying You,[1] Michel Chonchol.[3] *[1]UC Denver, Aurora, CO; [2]University Hospital Bern, Bern, Switzerland; [3]University of Colorado, Aurora, CO; [4]University of Colorado Denver, Aurora, CO; [5]University of Colorado Denver and Denver Health Medical Center, Denver, CO.*

Background: Acid retention in patients with chronic kidney disease (CKD) results in increased production of inflammatory markers and activation of the renin-angiotensin-aldosterone system, all of which can induce vascular calcification. We examined the effect of treatment of metabolic acidosis with oral sodium bicarbonate therapy on a novel test that measures the overall calcification propensity of serum, T50, in patients with CKD stage 3-4.

Methods: We performed a prospective, randomized, open-label, 14-week crossover study of 20 patients with CKD stage 3-4 and metabolic acidosis (serum bicarbonate level of ≥ 16 and <22 mEq/L). Subjects were randomly assigned to start with either treatment or control. Each period was 6 weeks in duration with a 2-week washout period in between. Patients were treated with oral sodium bicarbonate tablets for goal bicarbonate of ≥ 22 mEq/L. Serum T50 was measured at the beginning and end of each treatment period. T_{50} measures the transformation time of amorphous calcium phosphate-containing primary calciprotein particles (CPP) to crystalline hydroxyapatite-containing secondary CPP. A higher T_{50} represents lower calcification propensity. Mixed effect models were used to examine changes in T50 during treatment and control conditions.

Results: The mean (SD) age and eGFR was 58.5 ± 12.8 years and 24.6 ± 8.1 ml/min/1.73m², respectively. The mean (SD) serum bicarbonate level and T50 level at baseline was 19.7 ± 2.3 mEq/L and 256.4 ± 56.2 minutes, respectively. Serum bicarbonate levels increased significantly with sodium bicarbonate therapy. There was no significant change in serum T50 during treatment or control conditions. Serum phosphate increased significantly with bicarbonate therapy.

Conclusions: In our study, treatment of metabolic acidosis with oral sodium bicarbonate therapy did not decrease serum calcification propensity in patients with CKD.

Dietary Acid Reduction with Fruits and Vegetables Better Prevents Transition of Stage 3 CKD to Stage 4 Than Oral NaHCO3 Nimrit Goraya,[4,5] Jan Simoni,[3] Yolanda Munoz Maldonado,[2] Donald E. Wesson.[1,6] *[1]Diabetes Health and Wellness Institute, Dallas, TX; [2]Biostatistics, Baylor Scott & White Health, Temple, TX; [3]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX; [4]Internal Medicine, Baylor Scott and White Health, Temple, TX; [5]Internal Medicine, Texas A and M School of Medicine, Temple, TX; [6]Internal Medicine, Baylor Scott and White Health, Temple, TX.*

Background: The USRDS most recently reported a net increased prevalence of individuals with chronic kidney disease (CKD) stage 3 (eGFR=30-59 ml/min/m²). The CKD 3 to CKD 4 transition yields the greatest net increase in morbidity and care cost in the CKD 1 to CKD 4 progression, supporting need for kidney-protective interventions. Because dietary acid reduction added to pharmacologic anti-angiotensin II therapy appears to provide adjunctive kidney protection, we tested the hypothesis that oral $NaHCO_3$ (HCO_3) or base-producing fruits and vegetables (F+V) reduce the proportion of CKD 3 subjects who transition to CKD 4.

Methods: One hundred eight macroalbuminuric, non-diabetic CKD 3 subjects with metabolic acidosis but with serum [HCO_3] between 22 -24 meq/L were randomized to receive F+V (n=36) in amounts to reduce dietary potential renal acid load by half, oral $NaHCO_3$ (HCO_3, n=36) 0.3 meq/Kg bw/day to approximate the base-producing potential of F+V, or to Usual Care (UC, n=36). All had a systolic blood pressure (SBP) goal < 130 mm Hg using drug regimens including ACE inhibition. Cystatin C-based eGFR and SBP were followed at baseline and annually for five years.

Results: Baseline eGFR among UC, HCO_3, and F+V (39.5 ± 6.9, 39.6 ± 6.6, and 39.4 ± 6.4 ml/min/m², respectively, p=0.99) was not different but baseline SBP for UC (159 ± 11 mm Hg) was lower (p=0.04) than HCO_3 and F+V (165 ± 10, and 163 ± 12 mm Hg, respectively). At five years, the % of patients (%, 95% confidence interval or CI) that maintained eGFR> 30 ml/min/m² was higher in F+V (40%, CI=24-58) than UC (6%, CI=0.7 - 20) but that for HCO_3 (34%, CI=19 – 52) was not higher than UC. Although the five-year increase in plasma [HCO_3] was not different between F+V (0.89 mM, CI=0.68-1.09) and HCO_3 (0.87 mM, CI=0.67-1.08) supporting similar dietary acid reduction, a greater % of F+V (89%, CI= 73-97) than HCO_3 (17%, CI=7-34) achieved SBP goal of < 130 mm Hg, possibly contributing to better eGFR preservation in F+V.

Conclusions: Adjunctive dietary acid reduction with F+V but not $NaHCO_3$ yielded a significantly greater proportion of CKD 3 patients who did not progress to CKD 4, possibly due to a greater proportion of F+V achieving blood pressure goal. The data support that dietary acid reduction with F+V better prevents the CKD 3 to CKD 4 transition than NaHCO3.

TH-PO518

Randomized, Placebo-Controlled Trial of Rifaximin Therapy for Lowering Gut-Derived Cardiovascular Toxins in CKD Cassandra A. Kimber,[1] Cassandra R. Johnson,[1] Alexander J. Prokopienko,[3] Kerri A. McGreal,[1] Thomas D. Nolin,[3] Jason R. Stubbs.[2] *[1]University of Kansas, Kansas City, KS; [2]University of Kansas Medical Center, FAIRWAY, KS; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: Accumulating evidence suggests that byproducts of gut bacteria contribute to cardiovascular morbidity in CKD patients. One example is trimethylamine-N-oxide (TMAO), a pro-atherosclerotic compound generated from metabolites produced by intestinal bacteria. Rifaximin is a minimally absorbed, oral antibiotic that targets intestinal pathogens and can chronically suppress circulating levels of gut-derived bacterial toxins that contribute to disease comorbidities in other patient populations.

Methods: We conducted a randomized, double-blinded, placebo-controlled trial to determine the impact of a 10-day course of oral rifaximin 550 mg BID vs. placebo on serum TMAO and fecal bacterial composition in patients with stage III-V CKD (*n*=38). Fasting serum, urine and stool samples were collected at baseline and immediately post-therapy. Our primary outcomes of interest were change in serum TMAO and relative abundance of fecal bacterial communities. Secondary analyses of interest included change in serum p-cresol, indoxyl sulfate, and pro-inflammatory cytokines.

Results: Rifaximin therapy decreased the relative abundance of bacterial families known to generate TMAO precursors; mean relative abundance of Clostridiaceae decreased from 0.6 to 0.1% (p<0.01) and Peptostreptococcaceae decreased from 2.2 to 1.4% (p=0.17) in the rifaximin group vs. a change from 0.5 to 0.6% (p=0.21) and 1.3

to 1.9% (p=0.57), respectively, in the placebo group. Despite an apparent reduction in these bacterial populations, we observed only a minor, non-significant reduction in serum TMAO with rifaximin; mean TMAO changed from 18.8 ± 18.7 μM at baseline to 14.8 ± 10.2 μM post-therapy (p=0.31) in the rifaximin group vs. a mean TMAO change from 15.6 ± 11.6 at baseline to 16.1 ± 13.4 μM post-therapy (p=0.84) in the placebo group. Analysis of the stated secondary outcomes is currently ongoing.

Conclusions: Short-term rifaximin therapy effectively suppresses bacteria that generate TMAO precursors; however, these changes in gut flora do not translate to significantly lower serum TMAO in CKD patients.

Acute and Chronic Effects of Different Exercise Modalities on Hepcidin Levels in Non-Dialysis CKD Soteris Xenophontos,[1] Douglas W. Gould,[1] Thomas J. Wilkinson,[1] Emma L. Watson,[1] Joao L. Viana,[2] Alice C. Smith.[1] *[1]University of Leicester, Leicester, United Kingdom; [2]University Institute of Maia, Maia, Portugal.*

Background: Functional iron deficiency (FID) is common in chronic kidney disease (CKD). Iron is essential for many cellular processes including energy generation. FID has negative effects on skeletal and cardiac muscle as well as haemoglobin (Hb) production, and contributes to anaemia, functional deficits, fatigue and cardiovascular (CV) risk. Hepcidin, which is upregulated by inflammatory cytokines and inhibits release of iron stores, is implicated in CKD FID due to chronic inflammation and reduced renal clearance. We have previously shown that regular exercise exerts anti-inflammatory effects in CKD. In this study, we investigated the effects of different exercise modalities on hepcidin levels in non-dialysis CKD.

Methods: 36 CKD patients (14 male, mean±SD age 61±12 years, eGFR 26±8 ml.min-1.1.73m-2, Hb 119±15 g/l) were randomised to 12 weeks thrice weekly aerobic exercise (AE, n=18) or combined aerobic and resistance exercise (CE, n=18). Plasma was collected to assess the chronic effects of exercise (resting samples at baseline and end of study) and the acute effects (collected 24h following the first and last exercise sessions). Hepcidin was measured by ELISA.

Results: Following 12 weeks training, resting hepcidin decreased by 21±35% (p=.037) in the CE group, but was unchanged in the AE group (1±50%, p=.976). Acutely, 24h after the first exercise session hepcidin decreased by 34±27% (p=.008) in the CE group and by 18±24% (p=.101) in the AE group. 24h after the final exercise session hepcidin decreased by 3±42% (p=.438) in the CE group and by 0±27% (p=.651) in the AE group, compared to resting levels.

Conclusions: CE training reduced resting plasma hepcidin, but there was no change with AE alone. An acute reduction in hepcidin was observed 24h after the first CE session, but not after the first AE session or in either group after the last session, indicating an adaptation effect of regular CE. Hepatic hepcidin release is stimulated by IL-6, which peaks after unaccustomed exertion but is reduced by regular exercise. Therefore, our results likely mirror the effects of exercise on circulating inflammatory cytokines. CE may ameliorate FID in CKD, thereby helping to reduce CV and anaemia risk, and improve muscle function and fatigue.

Supervised Exercise Intervention and Overall Physical Activity in Individuals with Moderate to Severe CKD Jacob M. Taylor,[1] Aseel Alsouqi,[1] Cassianne Robinson-Cohen,[2] Charles D. Ellis,[1] Sam A. Headley,[3] Katherine R. Tuttle,[2] Elizabeth E. Evans,[3] Michael J. Germain,[4] Chutatip Limkunakul,[5] Aihua Bian,[6] Thomas G. Stewart,[6] Jonathan Himmelfarb,[2] Talat Alp Ikizler.[1] *[1]Medicine, Vanderbilt University Medical Center, Nashville, TN; [2]University of Washington, Seattle, WA; [3]Springfield College, Wilbraham, MA; [4]Renal and Transplant Assoc of New England, Hampden, MA; [5]Srinakharinwirot University, Nonthaburi, Thailand; [6]Biostatistics, Vanderbilt University, Nashville, TN.*

Background: Patients are often instructed to engage in multiple weekly sessions of exercise to increase physical activity; however, whether this increases overall physical activity in individuals with chronic kidney disease (CKD) remains unknown.

Methods: We performed a post-hoc analysis of a pilot randomized 4-arm trial examining the effects of diet and exercise (dietary restriction of 10%-15% reduction in caloric intake, exercise three times/week, combined diet and exercise and control) (NCT01150851). A total of 122 participants were consented, 111 were randomized, 104 started intervention and 92 completed the study. Activity was measured as counts, which are proportional to the muscular force producing motion detected by the accelerometer (ie. higher counts = more activity). For the exercise arm, counts data were only collected on non-exercise days. The primary outcome was a change from baseline in counts/minute between individuals in the exercise arms and the control group. A t-test was used to assess differences with p<0.05 being considered statistically significant.

Results: We examined all individuals who had completed at least four days wearing an accelerometer device at baseline and at the four month follow-up (n=70, n=36 in exercise arms and n=34 controls). Most participants were male (57%), white (66%), hypertensive (89%) and small portion with diabetes (29%). Mean (SD) for age was 56 (11) years, for estimated glomerular filtration rate was 43 (17) mL/min/1.73m². Mean (SD) counts per min at baseline were 294 (257) and at month four were 288 (270). No differences were observed in change in counts/min between the exercise and control groups at month 4 (p=0.83). The results were similar in a sensitivity analysis including only those who were compliant with the exercise prescription in the exercise arm (n=11, >75% compliance at month four).

Conclusions: Our findings indicate that engaging in supervised exercise program does not necessarily increase overall physical activity in individuals with Stages 3 and 4 CKD.

Body Fat and Phase Angle, Rather Than Lean Mass, Show the Strongest Correlations with VO2 Peak in Stage 3 and 4 CKD Patients Jacob M. Taylor,[1] Aseel Alsouqi,[1] Cassianne Robinson-Cohen,[2] Charles D. Ellis,[1] Sam A. Headley,[3] Katherine R. Tuttle,[2] Elizabeth E. Evans,[3] Michael J. Germain,[4] Chutatip Limkunakul,[5] Aihua Bian,[6] Thomas G. Stewart,[6] Jonathan Himmelfarb,[2] Talat Alp Ikizler.[1] *[1]Medicine, Vanderbilt University Medical Center, Nashville, TN; [2]University of Washington, Seattle, WA; [3]Springfield College, Wilbraham, MA; [4]Renal and Transplant Assoc of New England, Hampden, MA; [5]Srinakharinwirot University, Nonthaburi, Thailand; [6]Biostatistics, Vanderbilt University Medical Center, Nashville, TN.*

Background: VO_2 peak is a measure of aerobic fitness and is a good indicator of cardiovascular health. Understanding how body composition measures are correlated with VO_2 peak is important for developing targeted interventions aimed at improving health.

Methods: We performed a post-hoc analysis of a pilot randomized 4-arm trial examining the effects of diet and exercise (dietary restriction of 10%-15% reduction in caloric intake, exercise three times/week, combined diet and exercise and control) (NCT01150851). A total of 122 participants were consented, 111 were randomized, and 108 completed baseline VO_2 peak testing. Body composition metrics were measured via dual energy x-ray absorptiometry, including total mass, fat mass, lean mass, and fat free mass, body fat percentage (including android and gynoid fat percentage), body mass index, weight, and waist to hip ratio. In addition, body cell mass and phase angle were measured by bioelectrical impedance analysis. The primary outcome was to determine whether body composition measurements were correlated with VO_2 peak at baseline. Correlations were adjusted for age, gender, diabetes status, and site of study visits in the model.

Results: Most participants were male (57%), white (68%), and had 24% diabetes. Median (IQR) for age was 57 (49-63) years, with baseline VO_2 peak 19.6 (16.2-22.6) mL/kg/min. At baseline, body fat percentage (rs=-0.38), android (rs=-0.336) and gynoid fat percentage (rs=-0.313), body mass index (rs=-0.372), weight (rs=-0.282), and phase angle (rs=0.278) were all significantly correlated with VO_2 peak after adjustment (p<0.03 for each individual variable). Holding other covariates at the mean, the difference in VO_2 peak between the 25th and 75th percentiles of lean mass was 1.9 (-0.5,4.2) mL/kg/min, whereas the same difference comparing the 25th and 75th percentiles of fat mass was -3.6 (-5.5,-1.3) mL/kg/min.

Conclusions: Our findings indicated that body fat composition and phase angle, rather than lean mass, show the strongest correlations to VO_2 peak. An intervention aimed at reducing body fat or improving phase angle may prove effective at improving VO_2 peak in future research.

Food Insecurity and Longitudinal Risk of Rapid Kidney Function Decline Deidra C. Crews,[2] Caroline Kwon,[5] Dingfen Han,[8] Yang Liu,[2] Tanushree Banerjee,[7] Michele K. Evans,[3] Alan B. Zonderman,[1] Neil R. Powe,[6] Marie Kuczmarski.[4] *[1]Intramural Research Program, NIA, NIH, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]National Institutes of Health/National Institute on Aging, Baltimore, MD; [4]University of Delaware, Newark, DE; [5]None, Washington, DC; [6]Priscilla Chan & Mark Zuckerberg San Francisco General Hospital & University of California SF, San Francisco, CA; [7]University of CA, San Francisco, San Francisco, CA; [8]Johns Hopkins University, Baltimore, MD.*

Background: Food insecurity, defined as limited or uncertain ability to acquire food, has been associated with prevalent CKD and CKD progression to ESRD. Whether food insecurity is associated with loss of kidney function among persons with preserved kidney function is not known.

Methods: We conducted a longitudinal analysis of the Healthy Aging in Neighborhoods of Diversity Across the Life Span (HANDLS) Study (Baltimore MD) to determine whether food insecurity was associated with rapid kidney function decline (KFD). Participants with eGFR≧60 ml/min per 1.73m² were included (n=1471). Food insecurity was defined as an affirmative response to, 'In the last 12 months, did you or your household ever cut the size of your meals or skip meals because there wasn't enough money for food?' KFD was defined over an average of 5-years' follow-up as: follow-up eGFR decreased by more than 3% per yr from baseline; or full follow-up eGFR decreased by more than 25%. Multivariable logistic regression models assessed the relation of food insecurity and KFD.

Results: At baseline, 24.8% of participants were food insecure. These persons were younger, more likely to be female, African American, living in poverty, with fewer yrs of education, uninsured and current smokers than were food secure persons (p<0.05 for all). Food insecure persons had lower Healthy Eating Index (HEI) 2010 scores and were more likely to be obese, but equally as likely to have diabetes and hypertension as food secure

persons. Overall, 13.3% had >3% per yr eGFR decline, while 4.2% had ≥25% eGFR decline over full follow-up. Food insecurity was not associated with >3% per yr eGFR decline, but was associated with ≥25% eGFR decline (**Table**). Clinical factors explained little of this association. Among 1,164 participants with HEI data, the magnitude of the association of food insecurity with ≥25% eGFR decline was similar, though not statistically significant (1.87, 95% CI 0.9, 3.9).

Conclusions: For persons free of CKD, food insecurity may be a risk factor for rapid loss of kidney function over time.

Funding: NIDDK Support, Other NIH Support - National Institute on Aging, Private Foundation Support

Association of Food Insecurity (vs. Security) and Rapid Kidney Function Decline

Model	>3% eGFR decline per year Odds Ratio (95% CI)	≥25% eGFR decline over full follow up Odds Ratio (95% CI)
1-Unadjusted	1.18 (0.78, 1.79)	1.84 (1.11, 3.06)
2-Adjusted for age, race, sex, poverty status and baseline eGFR	1.13 (0.72, 1.79)	1.86 (1.05, 3.29)
3-Adjusted for age, race, sex, poverty status, baseline eGFR, diabetes, hypertension and obesity	1.10 (0.66, 1.84)	1.83 (0.94, 3.58)

Mortality and Co-Morbidities in South Asian Individuals with CKD Compared to White Ethnicities Rupert Major,[1,2] Gang Xu,[1,3] Laura Gray,[2] Nigel J. Brunskill.[1,3] *[1]University Hospitals of Leicester, Leicester, United Kingdom; [2]Department of Health Sciences, University of Leicester, Leicester, United Kingdom; [3]Department of Infection, Immunity and Inflammation, University of Leicester, Leicester, United Kingdom. Group/Team: LCC-CKD Cohort.*

Background: The epidemiology of CKD in South Asian (SA) populations in high-income countries is poorly studied. The Leicester City and County Chronic Kidney Disease (LCC-CKD) cohort has been developed to study this population in comparison to other ethnic groups. To our knowledge no study has compared all-cause mortality in SA subpopulations with CKD compared to other ethnicities.

Methods: Data was collected for LCC-CKD from primary care electronic records. The cohort has 5 years of completed follow-up from 2011 to 2016. Comparison was made between individuals of SA and Whites ethnicities. The groups' baseline characteristics were compared using t-tests and Chi^2. Unadjusted and adjusted Cox proportional hazards models were used for comparison of all-cause mortality.

Results: 3,887 of 6,133 (63.4%) individuals in the LCC-CKD cohort have an ethnicity code of whom 268 are of SA ethnicity (6.9%). Gender proportions were similar, but mean age and EPI eGFR were lower and ACR higher for SA compared to White ethnicities. diabetes mellitus was more common in SA but clinical cardiovascular disease was less common (see table). Unadjusted all-cause survival analysis suggested all-causes mortality was 39% lower (HR 0.61, 95% CI 0.46-0.80, p<0.0001) in SA. However, in an adjusted model using the variables listed in the table, SA had similar risk to the White population (HR 0.97, 95% CI 0.71-1.33, p=0.85).

Conclusions: Compared to the White population, SA with CKD are younger with more advanced CKD and more likely to have diabetes. Adjusted all-cause mortality was similar between ethnicity groups. These factors may explain why SA individuals are more likely to progress to endstage renal disease.

Comparison of Cohort Characteristics in South Asian and White Ethncities

Variable	South Asian	White	p-value
n	268	3,552	
Female	60.8%	57.1%	0.23
Age	76.3 (12.0)	84.2 (9.1)	<0.001
EPI eGFR	46.8 (11.8)	48.8 (9.9)	0.001
ACR (mg/mmol)	19.9 (52.4)	10.0 (29.9)	<0.001
Hypertension	86.3%	90.3%	0.07
Diabetes Mellitus	55.2%	33.6%	<0.001
Cardiovascular Disease	36.2%	44.5%	0.008

p-values are for comparisons between South Asian and White ethnicities. For continuous variables, mean values are presented with standard deviations in parentheses.

Improving Implementation of Evidence-Based CKD Care for an Underserved Population: An IT-Enhanced Collaborative Care Model Miguel A. Vazquez,[7] George Oliver,[4] Adeola O. Jaiyeola,[3] Beverley Adams-Huet,[7] Nitin Budhwar,[7] Blake R. Barker,[7] Brett Moran,[3] Noel O. Santini,[6] Ying Ma,[2] Javier A. Velazquez,[5] Vibin Roy,[1] Xilong Li,[7] Robert D. Toto.[7] *[1]PCCI, Dallas, TX; [2]Parkland Center for Clinical Innovation, Dallas, TX; [3]Parkland Health & Hospital System, Dallas, TX; [4]Parkland Health and Hospital System, Dallas, TX; [5]Pieces Technologies, Dallas, TX; [6]UT Southwestern/PHHS, Dallas, TX; [7]University of Texas Southwestern Medical Center, Dallas, TX.*

Background: There is a gap between knowledge and implementation of evidence-based guidelines (EBG) for treating CKD. Developed at Parkland Health System (PHHS), a safety net hospital serving a predominantly minority population in Dallas County, PIECES is a novel health information technology (IT) that can be embedded in the electronic health record to detect patients with conditions of interest and monitor outcomes. We hypothesized that using PIECES in a collaborative model of primary and nephrology care for patients newly diagnosed with CKD or referred to a CKD clinic at PHHS would improve implementation of EBG.

Methods: PIECES was used to identify patients with previously undiagnosed CKD or newly referred to a CKD kidney clinic and to monitor clinical measures and improve adherence to EBG for CKD care. The main study outcomes were blood pressure (BP) control, use of renin-angiotensin-aldosterone system blockers (RAAS-ACE inhibitors or ARBs) and statins for patients receiving care enhanced by PIECES (implementation group) compared to control patients receiving usual care.

Results: Demographics and baseline (BL) characteristics were similar for patients in implementation (n=92) and control (n=127) groups. After a follow-up (FU) of 6-24 months the use of RAAS (88% vs 59.2%, p<0.0001) and statins (79.4 vs 51%, p<0.0001) was significantly higher in the implementation than in the control group (Figure). In the implementation group, BP of <140/90 at BL and FU was achieved by 50% and 59% (p=0.2) and BP of <130/80 was met by 22% and 28% (p=0.2) respectively; the BP responses were not statistically different from controls.

Conclusions: In this study of collaborative care in primary and nephrology practices use of an IT-embedded program improved implementation of CKD EBGs including use of RAAS and statins. This model can lead to better care, and has the potential to improve outcomes, in underserved populations with CKD.

TH-PO525

Primary Care Providers' Dietary Counseling of Their Low Income African American (AA) Patients with CKD Deidra C. Crews,[6] Debra L. Roter,[2] Raquel C. Greer,[4] Stella Park,[2] Patti Ephraim,[5] Jessica Ameling,[7] Lapricia L. Boyer,[5] Michael C. Albert,[3] Lisa A. Cooper,[6] L. Ebony Boulware.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]Johns Hopkins Health System, Baltimore, MD; [4]Johns Hopkins Medical Institutions, Baltimore, MD; [5]Johns Hopkins University, Baltimore, AL; [6]Johns Hopkins University School of Medicine, Baltimore, MD; [7]University of Michigan, Ann Arbor, MI.*

Background: Diet influences outcomes in CKD, but little is known about how patients with CKD are counseled about their diet. We examined primary care providers' (PCPs) use of the 5A's (*Assess, Advise, Agree, Assist, and Arrange*) counseling strategy in diet discussions with AA patients with CKD, and explored their use of a *6th* 'A' "*Awareness*", reflecting recognition and discussion of the home and community food environment within which the patient resides--especially relevant for patients living with food insecurity.

Methods: In a trial of urban AAs with uncontrolled hypertension, we audio-recorded patients' routine visits with their PCPs at the first visit after enrollment. Among 44 patients with CKD [eGFR<60 (33%) and/or ACR ≥30mg/g (88%)], we assessed presence of diet discussions and use of the 6A's in the discussions. Using linear regression, we examined predictors of number of A's used.

Results: Mean age was 59.5 years, 37% were male and 31% had annual income <$10K; 63% were obese, 70% had diabetes and mean systolic BP was 147 mmHg. A majority (67%) were either at risk for or with food insecurity (inability to afford nutritionally adequate foods). Most (88%) visits included dietary counseling, most commonly in the context of *Assess* (68%) and *Advise* (61%); *Agree* (14%), *Assist* (14%) and *Arrange* (9%) were infrequent. Only one visit included reference to *Awareness*. Median number of A's was 2 (IQR 1-2.5). No visit included all A's. Representative quotes are in the **Table**. Visits attended by patients earning <$10K included fewer A's than those of patients with higher incomes, though not statistically significant (-0.5, 95% CI -1.4, 0.4).

Conclusions: Among urban AAs with CKD, dietary counseling by their PCP primarily included assessing or advising on diet. PCPs may struggle to cover all A's in the context of visits with high risk patients. Multidisciplinary approaches to dietary counseling of high risk CKD patients warrants investigation.

Funding: NIDDK Support, Other NIH Support - NHLBI

6A's Framework and Representative Quotes

Assesses diet or weight	"How are you doing with the salt in your diet?"
Advises on topics of diet or weight	"Try to stay away from bananas. If you eat a banana, eat a half. Because of the diabetes."
Agrees on a specific plan	Physician: "Our plan for now is for you to continue all this dietary stuff you"
Assists in identifying barriers/supports for behavior change	Physician asks about eating out and the patient says they can seldom afford to, so doctor responds "But of course, that also makes it tough to afford the fresh stuff."
Arranges a specific plan for follow up	"I would like to see you back in a month. By then you should have seen the nutritionist."
Awareness, recognition and discussion of food environment	Physician suggests adding apricots to patient's diet, but patient does not know what they are. Physician recognizes that "Those aren't common. I wouldn't find them in a store around here."

TH-PO526

Sex Differences in Progression and Resource Utilization in CKD Pradeep Arora,[3] Edwin J. Anand,[3] Joseph A. Eberle,[1] Kabir Jalal,[2] Rocco C. Venuto.[3,1] *[1]Intelligent Care Management, East Amherst, NY; [2]University at Buffalo, Hamburg, NY; [3]Medicine, University at Buffalo, Buffalo, NY.*

Background: Prevalence of CKD in early stages is higher among females than males, in contrast more males develop ESRD. Resource utilization between sexes is not well studied. We hypothesized that resource utilization is greater among males when compared to females.

Methods: Data from a large third party payer, with an enrollment of 1.4 million, from 2007-14. CKD was defined as GFR less than 60 ml/min/1.73 BSA for more than three months. Data analyzed included demographics, comorbid conditions (CAD, CHF, PVD, COPD, depression, cancer, diabetes, and hypertension), hospitalization and cost of care. Univariate and multivariate analyses of the predictive variables were undertaken. Chi squared test was used to compare the proportions of clinical variables among the sexes.

Results: 33,328 CKD cases were identified. There were 18,146 females, 13, 257 males, 1,925 sex non specified. The proportion of CKD was higher in females compared to males (54 % vs 40 %, 6% unknown). CKD stages 3, 4 and 5 were found in respectively 51%, 54%, and 50% compared to 47%, 45%, and 48% in males. Female CKD patients had higher prevalence of comorbidities. Annual hospitalization rates were 2.26 for females and 2.35 for males. Cost/patient-year was higher in males $12,000 vs $10,426, which was statistically significant. Progression to renal replacement therapy revealed a shift to a male dominance (57% vs 43%). More males received renal transplantation (56% vs 42%)

Conclusions: The total per patient cost was higher for males in CKD 3-5. Males more often progressed to ESRD. The results of predictive modeling will be included.

Health Literacy and Blood Pressure Control in Individuals with CKD Rekha Kambhampati,[3] Marie Kuczmarski,[5] Mara McAdams-DeMarco,[2] Dingfen Han,[2] Alan B. Zonderman,[1] Michele K. Evans,[4] Deidra C. Crews.[6] *[1]Intramural Research Program, NIA, NIH, Baltimore, MD; [2]Johns Hopkins, Baltimore, MD; [3]Johns Hopkins University School of Medicine, Baltimore, MD; [4]National Institutes of Health/National Institute on Aging, Baltimore, MD; [5]University of Delaware, Newark, DE; [6]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Low health literacy is associated with poor clinical outcomes, including worse blood pressure (BP) control. The relation between health literacy and BP control among those with CKD is unknown. We examined this relation among participants in the Baltimore-based Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study.

Methods: Cross-sectional analyses were conducted of 276 HANDLS participants with CKD (eGFR <60 mL/min/1.73m^2 and/or urine albumin:creatinine ratio (ACR) of ≥30 mg/gm). Health literacy was defined by a Rapid Estimate of Adult Literacy in Medicine (REALM) score of ≤60 (lower) versus >60 (high). Multivariable logistic regression was used to assess the association of health literacy with BP control (systolic BP <140 mm Hg and diastolic BP <90 mm Hg) and linear regression was used to assess health literacy and systolic BP level among persons with self-reported hypertension.

Results: Participants' mean age was 56.4 years. At baseline, 134 (48.6%) had lower health literacy. Those with lower health literacy were more likely to be female (54.5%), African American (81.3%), and living in poverty (56.0%) than those with high health literacy (p <0.05 for all). Both literacy groups had similar levels of education, smoking status, eGFR, and self-reported hypertension and diabetes. A total of 105 (33.5%) had uncontrolled BP. Results of the multivariable regression models are found in the **table**.

Conclusions: Lower health literacy is associated with uncontrolled BP among persons with CKD. Addressing health literacy to improve risk factor control among CKD patients is worthy of further investigation.

Association of Lower Health Literacy (versus High Health Literacy) and BP Control

Model	Odds of BP control (OR (95% CI))	SBP continuous (B coefficient (95% CI))
1- Unadjusted	2.02 (1.26, 3.24)	9.70 mm Hg (1.97, 17.44)
2 – Adjustment for age, sex, race, poverty status, education	2.07 (1.26, 3.41)	9.48 mm Hg (1.23, 17.72)
3 – Model 2 + adjustment for diabetes and smoking status	2.15 (1.24, 3.73)	11.59 mm Hg (2.28, 20.91)
4 – Model 3 + adjustment for eGFR and ACR category*	2.19 (1.24, 3.87)	9.17 mm Hg (0.25-18.09)

*ACR categories (mg/gm): <30, ≥30-≤300, >300

TH-PO528

Sociodemographic Trends in CKD Prevalence in the US Priya Vart,[2] Neil R. Powe,[5] Charles E. McCulloch,[3] Rajiv Saran,[6] Brenda W. Gillespie,[6] Sharon Saydah,[1] Sundar Shrestha,[1] Deidra C. Crews.[4] *[1]Centers for Disease Control and Prevention, Hyattsville, AL; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]University of California San Francisco, San Francisco, CA; [4]Johns Hopkins University School of Medicine, Baltimore, MD; [5]Priscilla Chan and Mark Zuckerberg San Francisco General Hospital & University of California SF, San Francisco, CA; [6]University of Michigan, Ann Arbor, MI. Group/Team: CDC CKD Surveillance Team.*

Background: Overall prevalence of CKD in the U.S. has stabilized in recent years, however, whether this is true across sociodemographic groups is unknown. We examined trends in CKD prevalence by race/ethnicity, income (defined by poverty income ratio) and education using data from the population-based, cross-sectional National Health and Nutrition Examination Surveys (NHANES).

Methods: Participants >20 years with available creatinine were included. CKD prevalence was defined as eGFR 15 to <60 ml/min/1.73 m^2 (CKD-EPI). NHANES data included for every 2 years from 2009-2014 (n range 4,869 to 5,662 per period). Unadjusted CKD prevalence was calculated for each sociodemographic group in each period. Interactions were tested between each sociodemographic group and survey period to assess trends. Adjusted [for age, sex, race/ethnicity (when not being examined)] relative risks were obtained comparing most vs. least disadvantaged category in each sociodemographic group for all periods 2009-2014.

Results: Adjusted CKD prevalence was higher in the most recent time period (2013-2014) for non-Hispanic whites (8.0%), Mexican-Americans (5.8%), poor (10.1%), high income (7.5%), 9-11th grade (8.4%) and some college/equivalent -educated persons (8.6%), as compared to earlier time periods for each specific group. Adjusted CKD prevalence among persons with <9th grade education fell to 7.9% in 2013-2014 (from 9.2% in 2011-2012). A statistically significant trend was only present for income (P for 6 year time trend of CKD prevalence was 0.2 for race, 0.03 for income and 0.3 for education). Adjusted relative risks for CKD prevalence are presented in the **Table**.

Conclusions: In recent years, CKD prevalence has increased in some sociodemographic groups, while decreasing in others.

Funding: NIDDK Support, Other U.S. Government Support

Adjusted Relative Risk of CKD (95% CI) by Sociodemographic Group and Year

Group	2009-2010	2011-2012	2013-2014
Non-Hispanic black vs. Non-Hispanic white	1.3 (1.0-1.6)	1.2 (0.9-1.5)	0.9 (0.7-1.1)
Mexican American vs. Non-Hispanic white	0.7 (0.4-0.9)	0.7 (0.3-1.1)	0.7 (0.4-1.1)
Poor vs. high income	1.2 (0.7-1.6)	1.3 (0.9-1.7)	1.4 (0.7-2.0)
<9th grade vs. college education	1.7 (1.2-2.2)	1.4 (0.7-2.2)	1.2 (0.6-1.8)

TH-PO529

Racial/Ethnic Differences in CKD and Its Risk Factors in Hawaii Connie Rhee,[2] Victoria Page,[1] Glen Hayashida,[1] Merle R. Kataoka-Yahiro,[5] James Davis,[5] Linda L. Wong,[5] Krupa Gandhi,[5] Amy S. You,[2] Kamyar Kalantar-Zadeh.[2] *[1]National Kidney Foundation of Hawaii, Honolulu, AL; [2]University of California Irvine, Huntington Beach, CA; [5]University of Hawaii, Honolulu, HI.*

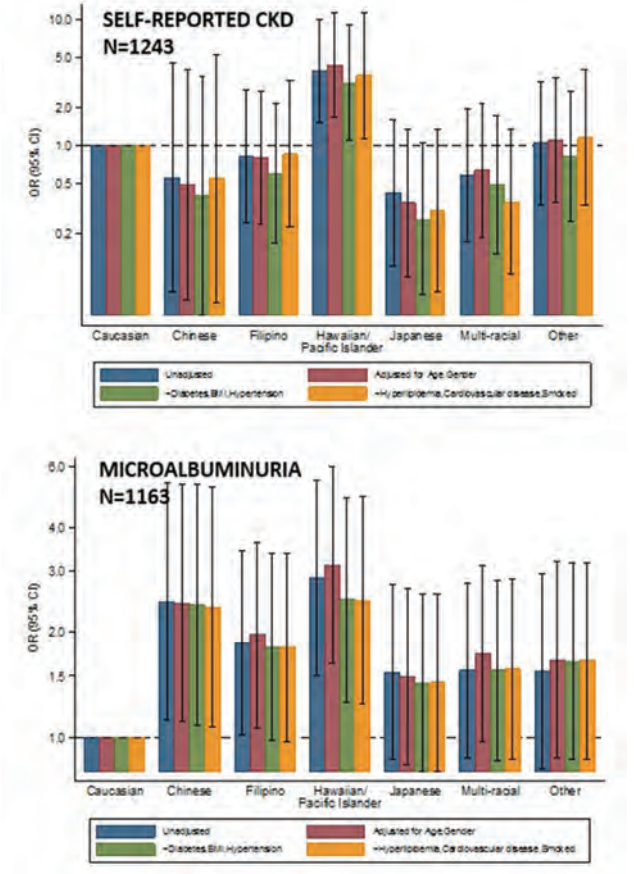
Background: While traditional risk factors for chronic kidney disease (CKD) are highly prevalent in Hawaii, there is limited data on the risk of early CKD among the racially/ethnically diverse population of this state. To address this knowledge gap, the National Kidney Foundation of Hawaii developed the Kidney Early Detection Screening (KEDS) Program to promote early CKD screening among its residents.

Methods: Among participants from the KEDS Waves 1 (2006-9) screening events, we examined the association between race/ethnicity and markers of early CKD, defined as 1) microalbuminuria (albumin-creatinine ratio ≥30mg/g) and 2) self-reported CKD using case-mix logistic regression models (adjusted for age, gender, diabetes, hypertension, body mass index, hyperlipidemia, cardiovascular disease, and smoking status).

Results: Among 1254 participants, the most predominant racial/ethnic groups were participants of Caucasian (22%), multi-race (19%), Japanese (19%), Filipino (16%), Hawaiian/Pacific Islander (8%), and Chinese (5%) background. Compared to Caucasian

participants, those of native Hawaiian/Pacific Islanders race/ethnicity had a higher likelihood of self-reported CKD: adjusted OR (aOR) 3.60 (1.14-11.40). Native Hawaiian/ Pacific Islander and Chinese participants also had a higher likelihood of microalbuminuria: aORs 2.37 (1.07-5.27) and 2.48 (1.25-4.91), respectively. Examination of CKD risk factors showed that Native Hawaiian/Pacific Islanders had higher risk of hypertension (aOR 1.86 [1.07-3.25]) and obesity (aOR 4.01 [2.42-6.67]).

Conclusions: These data suggest Hawaiian/Pacific Islanders have a higher risk of CKD markers compared to other racial/ethnic subgroups in the KEDS Program. Further studies are needed to determine the effectiveness of CKD interventions in this population.



TH-PO530

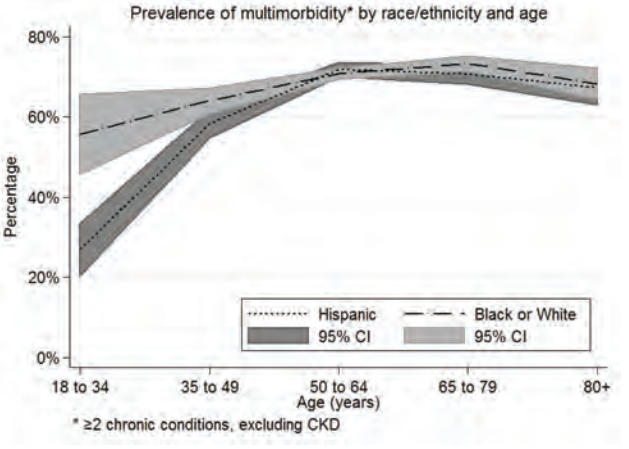
Multimorbidity and Race/Ethnicity in CKD Carl P. Walther, Jingbo Niu, Jingyin Yan, Wolfgang C. Winkelmayer, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

Background: Multimorbidity is common in CKD. It increases treatment burden and complexity, can result in conflicting therapies, and is associated with adverse outcomes. This may be especially important in socioeconomically disadvantaged populations. We examined the demographics of multimorbidity in a diverse, disadvantaged, non-dialysis CKD cohort.

Methods: We identified adults with eGFR <60 ml/min/1.73 m^2 for ≥90 days who received care through an urban safety-net health care system from 2006-16. ICD codes for chronic conditions (excluding CKD) prior to or within two weeks of cohort entry were identified and categorized into 21 groups. The relationships of comorbidity patterns with demographics and CKD stage (3A, 3B, 4, and 5) were studied. Multimorbidity was defined as 2 or more chronic conditions in addition to CKD. Race/ethnicity was recorded in 5 mutually-exclusive categories. We used proportions with binomial confidence intervals in stratified analyses, and multivariate logistic regression, to study relationships.

Results: We identified 13,678 patients, of whom 39.4% were Hispanic, 40.9% black, 11.5% white, 5.9% Asian/Pacific Islander, and 2.2% other/unknown. Comorbidity count (excluding CKD) ranged from 0 to 10, with median [interquartile range] of 2 [1,3]. Multimorbidity varied markedly by race/ethnicity and age (Figure). The logistic regression model (adjusted for gender, CKD stage, and year of cohort entry) corroborated this interaction (likelihood ratio test: $p < 0.001$). Among those aged 18-34, blacks or whites had slightly higher diabetes and HTN prevalences than Hispanics, compared with 10-fold higher HIV prevalence, and 4-fold higher depression and CHF.

Conclusions: Multimorbidity among young adults with non-dialysis CKD varies markedly by race/ethnicity, with lower prevalence among Hispanics than blacks or whites. This may be due to differences in CKD etiology, disparities in access to care, and other factors which warrant further investigation.



TH-PO531

Does Vitamin D Level Explain the Racial Disparity in Albuminuria? Marcelo B. Lopes,[4,5] Jennifer L. Bragg-Gresham,[5] Hal Morgenstern,[5] Nilka Rios Burrows,[1] Deidra C. Crews,[2] Neil R. Powe,[3] Rajiv Saran.[5] *[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Priscilla Chan and Mark Zuckerberg San Francisco General Hospital & University of California SF, San Francisco, CA; [4]Universidade Federal da Bahia, Salvador, BA, Brazil; [5]University of Michigan, Ann Arbor, MI.*

Background: Results from observational studies have shown that African Americans (AA) are more likely to have albuminuria than are whites and that 25-OH vitamin D3 (VitD) level is inversely associated with albuminuria. We hypothesized that VitD may partly explain the racial disparity in albuminuria risk by acting as a mediator in the causal pathway. Thus, the aim of this study was to estimate the direct and indirect (through VitD) effects of race on albuminuria in US adults.

Methods: Using cross-sectional data from 2007–2010 datasets from the National Health and Nutrition Examination Survey we applied the approach to mediation analysis of VanderWeele & Vansteelandt (2010) to estimate the direct and indirect effects of race on albuminuria prevalence, where VitD was treated as a continuous mediator. Estimated odds ratios (ORs with 95% CIs) were derived from: (1) a logistic model, where albuminuria prevalence was regressed on race, VitD, their product, and two potential confounders, age and sex; and (2) a linear model, where VitD was regressed on race, age, and sex. A secondary analysis adjusted for 6 additional risk factors for VitD or albuminuria. The total effect of race on albuminuria was estimated as the product of the direct and indirect effects.

Results: AA individuals had a higher prevalence of VitD<50nmol/L (72.4% vs. 20.5%. p<0.001) and albuminuria (11.2% vs. 8.6%. p=0.025) compared to Whites. The OR for the direct effect of race on albuminuria was 1.42 (95% CI: 1.10, 1.94), and the OR for the indirect effect was 1.29 (1.14, 1.46). The OR for the total race effect was 1.83, and the proportion of the race effect mediated by VitD was 42%. Additional adjustment for 6 other potential confounders yielded weaker direct and indirect effects but increased the proportion mediated to 51%.

Conclusions: The effect of VitD may explain nearly half the racial disparity in albuminuria prevalence in the United States; however, causal inference is limited by the cross-sectional design and possible residual confounding. Future research may address these limitations and consider other possible mediators of the race effect.

Disadvantaged Childhood Socioeconomic Position Represents a Critical Period for the Embedding of Kidney Disease Risk in Women Mark Canney,[1,2] Siobhan Leahy,[1] Siobhan Scarlett,[1] Rose Anne M. Kenny,[1] Mark A. Little,[2] Conall M. O'Seaghdha,[3] Cathal McCrory.[1] *[1]The Irish Longitudinal Study on Ageing, Trinity College Dublin, Dublin, Ireland; [2]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland; [3]Department of Nephrology and Transplantation, Beaumont Hospital, Dublin, Ireland.*

Background: Socioeconomic position (SEP) is an important determinant of health but is dynamic across the lifespan. This study examines the relationship between life course SEP and chronic kidney disease (CKD) using three conceptual life course models: critical period, pathway and accumulation. We test each model in a population of Irish adults who experienced dramatic social mobility during their lifetime, as Ireland transitioned rapidly from a primarily agricultural to post-industrial society.

Methods: Cross-sectional analysis of data from 4996 participants from The Irish Longitudinal Study on Ageing, a nationally representative sample of community-dwelling adults aged ≥50 years. We defined CKD as a glomerular filtration rate <60mL/min/1.73m^2 estimated from the combination of creatinine and cystatin C using the CKD-EPI formula. We defined childhood and adulthood SEP according to father's and respondent's

occupation respectively, and categorised SEP as high (reference), intermediate, low or never worked. We tested the critical period and pathway models by examining the age-adjusted relationship between SEP and CKD using logistic regression separately in men and women. We tested the accumulation model by fitting an interaction between childhood and adulthood SEP, and assessed social mobility trajectories arising from that interaction.

Results: Low childhood SEP was strongly associated with CKD in women, even after adjusting for adulthood SEP (odds ratio 1.90 [95% confidence interval 1.24, 2.92]), supporting the critical period over the pathway hypothesis. This association was not explained by traditional CKD risk factors including central obesity, diabetes, smoking or hypertension. Women who experienced low childhood SEP and whose circumstances improved in adulthood also had increased odds of CKD, further supporting a critical period effect in childhood. The interaction between childhood and adulthood SEP was not statistically significant in either sex. We did not observe any substantive association between SEP and CKD in men.

Conclusions: Our findings suggest that women exposed to disadvantaged SEP in childhood represent an at-risk group in whom there may be opportunities for identification of CKD and facilitation of health-promoting behaviours from an early age.

TH-PO533

Consideration of Living Donor Kidney Transplantation across the Continuum of Care in CKD Helene Vilme,[2] Clementina A. Davenport,[1] Jane F. Pendergast,[1] L. Ebony Boulware.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Duke University, School of Medicine, Durham, NC.*

Background: African Americans (AA) have had persistent disparities in achieving live donor kidney transplants (LDKT). It is unclear whether patients' interest and pursuit of LDKT varies based on their exposures to kidney disease treatments (pre-dialysis, dialysis, and transplant waitlist) and what knowledge or attitudinal factors might affect interest and pursuit among different groups.

Methods: We conducted separate secondary cross-sectional analyses of baseline data collected among AA with advanced kidney disease or kidney failure in three randomized clinical trials studying access to LDKT. Patients were either (1) not previously exposed to renal replacement therapies ('pre-dialysis'), (2) on hemodialysis, or (3) on the transplant waiting list. We measured participants' interest in LDKT on a 10-point scale ranging from 0-7 (not interested) to >7(highly interested). We measured patients' pursuit (present versus absent) of LDKT based on their self-reported discussion of LDKT with their families or physicians, or their completion of an LDKT evaluation. We quantified the association of knowledge, health literacy, and trust with medical care with interest and pursuit in separate multivariable logistic regression models adjusting for age, sex, marital status, and education.

Results: A majority of participants (total N=62 pre-dialysis, N=92 dialysis, N=156 transplant waitlist) in all three cohorts reported having high interest in LDKT (pre-dialysis, 62.9%; dialysis, 67.4%; transplant waitlist, 74.2%). Compared to pre-dialysis patients, those with exposure to dialysis and those on the waiting list more frequently pursued LDKT (pre-dialysis, 45.0%; dialysis, 72.7%; transplant waitlist, 92.2%). No significant association was observed between interest in LDKT, knowledge, health literacy, or the three trust factors for pre-dialysis, dialysis, and transplant waitlist, respectively ($p>.05$). Similarly, we found no significant association with LDKT pursuit in either of the study cohorts ($p>.05$).

Conclusions: Progress has been made in assisting African Americans to pursue LDKT. Our study showed that interest in LDKT is high at all stages of treatment, but pursuit is lower at early stages. Efforts are needed to assist individuals with interest in LDKT move towards LDKT pursuant behaviors.

TH-PO534

Cost of Potentially Preventable Hospitalizations among Patients with CKD: A Population-Based Analysis Paul E. Ronksley,[2] James Wick,[2] Scott Klarenbach,[1] Braden J. Manns.[2] *[1]University of Alberta, Edmonton, AB, Canada; [2]University of Calgary, Calgary, AB, Canada. Group/Team: Alberta Kidney Disease Network.*

Background: Prior studies have observed high rates of hospitalization among patients with chronic kidney disease (CKD). We conducted a population-based analysis to determine the proportion and cost of hospitalizations that are potentially preventable and whether this varies by CKD severity.

Methods: We identified all adults (≥18 years) with an outpatient serum creatinine measurement between January 1 and December 31, 2013 in Alberta, Canada. We used KDIGO guidelines to categorize CKD severity (including dialysis-dependent patients) based on measures of albuminuria and eGFR. Patients were then linked to administrative data to capture frequency and cost of hospital encounters, and followed until death or end of study (December 31, 2014). Within each CKD category we calculated the rate, proportion, and cost attributable to potentially preventable hospitalizations as defined by six CKD-related ambulatory care sensitive conditions (ACSCs); heart failure or volume overload, hyperkalemia, malignant hypertension, and diabetes with hyperosmolarity or ketoacidosis.

Results: Of the 1,007,051 adults with eGFR and albuminuria measurements, 157,465 had CKD of which 1.1% were dialysis-dependent. During a median follow-up of 1 year, there were 56,372 hospitalizations among CKD patients resulting in a total cost of $873 million CAD. Adjusted rates of all-cause hospitalization increased linearly with CKD severity with dialysis-dependent patients having 416 hospitalizations per 1,000 person-years and the highest average cost per inpatient encounter ($26,507 [95% CI: $23,504-$29,510]). Overall 3,769 (6.9%) of hospitalizations were for CKD-related ACSCs, with the majority being for heart failure. Adjusted rates of CKD-related ACSCs also increased with CKD severity and were highest among patients with non dialysis-dependent severe CKD (21 hospitalizations per 1,000 person-years). The total cost of potentially preventable hospitalizations was $54 million (6.1% of total cost), with an average cost per encounter of $13,734 (95% CI: $12,956-$14,511).

Conclusions: While only a small proportion of hospital costs among patients with CKD are for potentially preventable hospitalizations, these findings suggest that effective strategies that reduce preventable admissions among CKD patients may lead to significant cost savings.

TH-PO535

Clinical Profile and Outcomes of Young Adult Patients with CKD at Philippine General Hospital under the Pediatric to Adult Transition Program Lipat Kalinga Dianne V. Vieja. *Department of Medicine, UP-Philippine General Hospital, Manila, Philippines.*

Background: Advances in the care of patients with CKD resulted in substantial improvement in survival. More patients transfer from pediatric to adult medicine department, instigating the need for proper transition programs- a purposeful, planned movement from child-centered to adult-oriented health services. ISN-PNA in 2011 recommended development of locally appropriate practices for transferring patients. This study describes the transition experience of a pioneer transition program in a low-resources environment.

Methods: A retrospective chart review of 48 transitioned patients from 2011- 2016 was conducted. General data and laboratory parameters before transition and 2 years later were obtained. The no.of hospitalizations, ER consults, OPD followup and the rate of renal function decline after 2 years were also noted.

Results: One hundred thirteen patients were enrolled in the transition program from 2011- 2016. Sixtyfive (58%) patients were not transitioned, 31% were lost to follow-up before transfer. Fortyeight patients completed the transition process, but more than half disengaged from care. Nineteen patients (42%) were actively following up. Mean transition score was 81.18% and it was not associated with the no. of followup, hospital admissions and ER consults. Majority of patients missed their first scheduled adult followup. Mean no. of followup per year was 2 at an average of 1 consult in 6 months. Five patients were admitted post transition with 5 days mean hospital stay. Four patients had ER consults with a mean of 1 ER and 1 hospital admission per year. Fourteen of the patients had a higher BMI 2 years after with mean increase of 1.05 points. There was no significant difference between the baseline and the posttransfer laboratories (electrolytes, albumin, hemoglobin, proteinuria, creatinine and BUN). Mean decline in renal function was 1 ml/min/1.7 per year. There was no significant change in the eGFR of patients before and 2 years after transition.

Conclusions: To improve outcomes of young patients with CKD as they transfer to adult-focused services, transition preparation is critical. In this pioneer group, follow-up rate was only 42%. Obvious difficulties encountered suggest developing more standardized transition methods and strenghtening adult Nephrology participation in the pre-transfer period.

TH-PO536

A Business Case for New CKD Payment Models Harry Liu,[2] Sophia Zhao.[1] *[1]Massachusetts General Hospital, Brookline, MA; [2]RAND Corporation, Boston, MA.*

Background: Various interventions have been demonstrated to effectively slow down the progression of chronic kidney disease (CKD), smooth the transition to renal replacement therapy (RRT), and improve patient outcomes. Such interventions, however, are rarely adopted due to misaligned incentives in the current healthcare system. This study aims to quantify the savings from CKD interventions and design associated new payment models.

Methods: We constructed a simulation model that identifies and quantifies savings opportunities during the CKD progression and transition to RRT, and extracted the model's parameters from the published literature. Simulation model sensitivity analyses were conducted to account for the uncertainty in input parameters. Assumptions were made only when published data were lacking. New payment models were proposed to materialize such savings opportunities.

Results: The simulation includes the following interventions: increasing the use of pre-dialysis nephrology care to slow down disease progression; smoothing transition to dialysis initiation to decrease the use of inpatient services and increase the adoption of arteriovenous fistula and peritoneal dialysis; and decreasing the use of dialysis among patients with an eGFR of 15 or greater or among patients with advanced age and multiple conditions, for whom the benefits of dialysis is very limited or nonexistent. The simulation model results in an annual savings of $1.0 billion for Medicare [range: $0.5 - $1.8 billion] and $1.8 billion for all payers [range: $0.7 - $2.1 billion]. Increased use of pre-dialysis nephrology care and decreased use of inpatients services at dialysis initiation each contributes to about one third of savings, respectively. The simulation model also suggests that new payment models should focus on Stage 3 and 4 patients and the transition from CKD to RRT. Within Medicare, new payment models can be designed around ESRD Seamless Care Organizations, Special Needs Plans, or Medicare Advantage Plans to streamline incentives and optimize care efficiency. A joint program between Medicare and other payers should be set up so that Medicare and other payers can share savings from CKD interventions.

Conclusions: Tremendous savings opportunities exist in slowing CKD progression and smoothing the transition to RRT, and new payment models should be designed and implemented to reap the benefits.

TH-PO537

Limitations of ICD Codes in Detection, Staging, and Assessing Progression of CKD Kabir Jalal,[4] Edwin J. Anand,[3] Rocco C. Venuto,[1] Pradeep Arora,[5] Joseph A. Eberle.[2] *[1]Erie County Medical Center, Buffalo, NY; [2]Intelligent Care Management, East Amherst, NY; [3]None, Getzville, NY; [4]University at Buffalo, Hamburg, NY; [5]Nephrology, VAMC, Buffalo, NY.*

Background: The International Classification of Diseases (ICD) coding system is the industry standard tool for disease classification and epidemiology purposes. However, ICD codes in practice unreliably reflect the true diagnosis for a given disease/patient. This study seeks to quantify that inaccuracy among patients with Chronic Kidney disease (CKD).

Methods: Using insurance data consisting of 222,664 insured individuals with serum creatinine measurements over seven years, diagnoses based on a set of CKD-related ICD codes were compared against gold standard Kidney Disease Outcomes Quality Initiative (KDOQI) clinical guidelines to evaluate accuracy of ICD codes to detect CKD-positive patients. Patient serum creatinine levels were used to estimate progression of disease course using a longitudinal mixed model to identify advanced progressors, or those patients with loss of eGFR (estimated glomerular filtration rate) greater than 1 ml/year, and to assess accuracy of ICD codes in detecting advanced progressors.

Results: ICD codes correctly identified only 10,101 of 33,159 individuals as CKD, for a sensitivity of 30.46% with positive predictive value (PPV) of 65.05%; codes correctly identified 184,078 individuals as CKD-negative, for a specificity of 97.14% with negative predictive value (NPV) of 88.87%. In identifying rapid progressors, ICD codes achieved a sensitivity of 11.95% with PPV of 8.46%, and a specificity of 94.73% with NPV of 96.35%.

Conclusions: The use of ICD codes alone is insufficient in identifying patients with CKD. This study is the first to attempt the use of ICD codes in identifying rapidly progressing patients, revealing poor coding performance when compared to gold standard KDOQI guidelines. Use of ICD codes to identify CKD patients, assess disease severity, or to evaluate disease progression for either clinical or epidemiological purposes is not recommended.

Funding: Other U.S. Government Support

Progression Performance Measures

Measure	Mean	Lower 95%	Upper 95%
Sensitvity	11.95	8.020	16.90
Specificity	94.73	94.11	95.30
Positive Predictive Value	8.460	5.410	11.52
Negative Predictive Value	96.35	95.85	96.84

TH-PO538

Lab Vigilance in Patients with CKD on Renin Aldosterone Inhibitors and Diuretics: Are We Monitoring Appropriately? Katherine Garlo,[2] Diane Seger,[4] Julie Fiskio,[1] David W. Bates,[3] David M. Charytan.[2] *[1]Brigham & Womens Hospital, Boston, MA; [2]Renal Division, Brigham and Women's Hospital, Boston, MA; [3]Brigham and Women's Hospital/Harvard Medical School, Brookline, MA; [4]Partners Healthcare System, Somerville, MA.*

Background: Renin Aldosterone Inhibitors (RASi) are first line agents for hypertension. Their efficacy has been shown in reducing blood pressure, slowing progression of chronic kidney disease (CKD), and cardiovascular protection. Grade A level 1 evidence supports their use in CKD with or without proteinuria. However, ideal lab monitoring during initiation of RASi is uncertain and guidelines are opinion based if present at all. We assessed outpatient lab monitoring in a large cohort of patients with CKD prescribed a new RASi or diuretic.

Methods: We evaluated adults with pre-dialysis CKD stage 3-5 who received a new outpatient RASi or diuretic prescription during 2009-2011. Lab data was collected electronically and analyzed for baseline and follow-up labs creatinine and potassium.

Results: A total of 8,272 individuals (mean age 72±13.5 years, 44% male, 86% white) with CKD (90% stage 3) were included. The average interval following baseline labs to first prescription was 41±79 days. Fewer individuals in the RASi group received baseline labs within two weeks 61% compared to the diuretic group 59%, P =0.02. Mean time to follow up labs was 78 days and was longer in the RAS inhibitor group 86±103 days compared to the diuretic group 69 days ±90.4 days, P<0.01. Follow up labs were checked within 2 weeks in 28% (RASi: 24%, diuretic: 31%, P<0.01). Nearly half of individuals did not receive labs for >6 weeks (overall:45%, RASi: 48%, diuretic: 41%). Male sex, black race, CKD stage, cardiovascular disease, and diabetes were associated with lab monitoring within 14 days. Age >65 years and RASi were associated with a lower risk of having baseline labs within 14 days (OR 0.69, 95% CI 0.63-0.76, P <0.01, OR 0.91, 95% CI 0.83-0.98, P =0.02) and follow up (OR 0.74, 95% CI 0.66-0.82, P <0.01, OR 0.69, 95% CI 0.63-0.76, P <0.01).

Conclusions: Many patients with CKD do not receive lab monitoring with 2 weeks of initiating a RASi or diuretics. Elderly individuals and women may be at higher risk. The results suggest that advancements in electronic prescription ordering or automated reminders may improve safety of RASi and diuretic use in patients with CKD.

TH-PO539

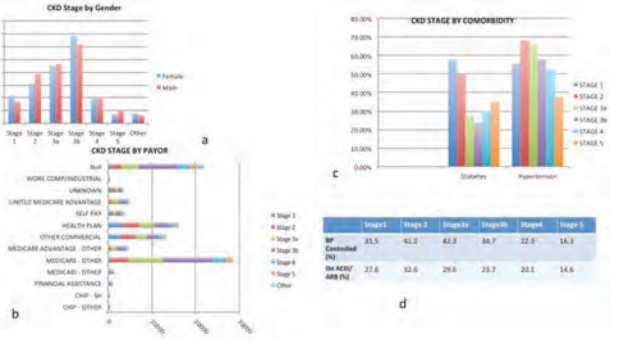
Electronic Health Record (EHR) Based Pre-ESRD Chronic Kidney (CKD) Registry in the Intermountain West as a Clinical Tool Titte Srinivas,[2] Denney Edgel,[2] Sharon Hamilton,[2] Mark R. Greenwood,[2] Steve Hadley,[2] Katie Larson,[2] Ray Morales.[1] *[1]Intermountain Healthcare, Murray, UT; [2]Intermountain Medical Center, Murray, UT.*

Background: The field of kidney disease is richly endowed with data sources. However, data are lacking on pre-End-Stage Renal Disease (ESRD) CKD especially at a granular level in the context of clinical care. Such data can be used to drive optimal care delivery in the clinic. We report on an EHR based CKD registry built at a large integrated health system in the Intermountain West that captures longitudinal patient level data as well as payer information from diverse sources. The scope of this registry encompasses 5 states, 179 clinics, 22 hospitals and 800,000 lives under a private payer and 2 million lives overall.

Methods: Patients were acccrued to this pre-ESRD CKD registry based on estimated GFR (eGFR), ICD 10 codes, CPT codes, EHR comorbidity data, prescription data, drug names and doses, laboratory data and claims data. Results were cross validated by eGFR and claims data. The registry was built off an Enterprise Data Warehouse that has been extant since 1990. A subset of patients recieved birth to death care within this Integrated Health System. Data from this registry are use to track quality and care delivery in real time with EHR advisories to drive care in the clinic as well as serving as vehicles to update care process modules based on accrued outcomes.

Results: Results are depicted in Figure 1. A total of 97877 patients with pre-ESRD CKD are included with a White predominance; 96.4 percent of patients in Stages 1 through 5 and CKD 2-4 comprising 81.6 %. Early stage CKD showed a male preponderance. The Registry was able to provide classification by demographics (a)and comorbidity (b), as well as by CKD Stage and Payer type (c) and BP control/ ACEI/ARB use (d) on a real time basis. Overall, BP was deemed controlled in 34.6 % and ACEI/ARBs were used in 25.5%.

Conclusions: We demonstrate the utility of an EHR based CKD Registry with Longitudinal Real Time Follow up as way to optimize pre-ESRD CKD care in a Large Integrated Health System.



TH-PO540

Use of Analgesics among Older Patients with CKD in the United States (2006-2015) Yun Han,[3] Rajesh Balkrishnan,[2] Kevin He,[1] David W. Hutton,[1] Diane Steffick,[3] Richard A. Hirth,[1] Rajiv Saran.[3] *[1]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI; [2]University of Virginia School of Medicine, Charlottesville, VA; [3]Internal Medicine - Nephrology, University of Michigan, Ann Arbor, MI.*

Background: Pain is common among patients with kidney disease yet few studies examine this, especially among older patients with non-dialysis CKD. We investigated US national trends in the use of nonsteroidal anti-inflammatory agents (NSAIDs) and opioid analgesics by older CKD patients over the past decade.

Methods: We identified eligible CKD patients enrolled in Medicare Part D through claims data (5% Medicare sample, 2006-2015). Demographics, CKD stages and comorbidities were assessed over a one-year entry period. Analgesic use by year was measured as the proportion of patients prescribed non-steroidal and opiate analgesics. The days-prescribed-per-user (DPPU) during a given calendar year were computed from medication claims. Logistic regression was used to explore factors associated with use of specific analgesics.

Results: There was a notable increase in use of NSAIDs among Medicare CKD patients in the past decade, from 10.5% in 2007 to a peak of 16.3% in 2011, with a decline to 14.3% in 2015 (Figure). DPPU were relatively stable, ranging from 104-109 days. NSAID use was consistently lower at higher stages of CKD. Opiates were prescribed to 39.4% of CKD patients in 2007, peaking at 48.3% in 2011 before declining to 44.6% in 2015 (Figure). Unlike NSAIDs, opioid use was highest in Stage 4-5 CKD. There was a significant increase in days prescribed in all CKD stages (30%-33%), from 89-104 to 116-138 per year. Younger age, female sex, not receiving the Part D subsidy, comorbid hypertension and diabetes were predictors of analgesic use in CKD patients. Opioids were more likely to be used by CKD patients who were white, or had higher stages of CKD, cancer or coronary artery disease.

Conclusions: Use of analgesics, particularly opioids, is very high in the Medicare CKD population, and rose substantially between 2007 and 2011. This study suggests both

a high burden of pain in this vulnerable population, and the potential for suboptimal pain management and dangerous adverse effects, including narcotic dependence.

CKD Patient Characteristics and Attitudes Towards Kidney Disease Education Devasmita Choudhury,[1,2] Urbi Dev,[1] Lesley Mcneil,[1] Suzanne T. West.[1] *[1]Salem Veterans Affair Medical Center, Salem, VA; [2]University of Virgnia, Salem, VA.*

Background: CKD education (CKD-Ed) is crucial to managing and improving CKD health outcomes. Patients (pts) often defer or miss CKD –Ed appointments. We compare characteristics and attitudes of pts who opt to receive education (R-Ed) to pts who decline (D-Ed).

Methods: A web-based CKD-Ed (VA-ekidneyclinic) education program designed at the 5th grade level was offered consecutively to 179 known CKD patients and their family members during CKD clinic appointments at Salem VAMC from 7/2016 to 5/2017 with continuing web-based home education as part of a study.

Results: R-Ed: 61/179 (34%); D-Ed: 118/179 (66%) patients. Reasons for declining education: 46% - no interest, 36% -no home web access, 12%- too busy, 5% live too far, 3% confused. See data table for age, ethnicity, CKD stage, number or medical problems, differences in education level between groups. 76% of "non-interested", 82% of "no computer", 100% "live too far" pts were from counties and cities with < 88% HS and higher education; 70% "too busy" pts came from >88% HS education counties and cities. 62% pts despite computer access declined both clinic and home CKD-Ed.

Conclusions: CKD patients who decline CKD education are more like to be older, male, from lower educated surroundings and interestingly fewer medical problems than those that opt to receive CKD education. Creative education tools and practices (eg: games, comics, jingles) need to be explored to motivate and educate a majority of CKD patient in order improve CKD health outcomes.

Funding: Private Foundation Support

Demographics Data: Opting to Receive (R-Ed) vs Decline (D-Ed) CKD Education

Cost-Effectiveness of a Multiple Intervention Model for Management of CKD in Primary Health-Care Rafael A. Ayala cortes,[2] Laura Cortes-Sanabria,[1] Alfonso M. Cueto-Manzano,[1] Enrique Rojas-Campos.[1] *[1]Unidad de Investigación Medica en Enfermedades Renales, IMSS, Guadalajara, Jalisco, Mexico; [2]Unidad de Investigación Médica en Enfermedades Renales, Guadalajara, Jalisco, Mexico.*

Background: Strategies to prevent and delay progression of early CKD are urgently needed; however, there is little information about costs and outcomes at the primary health-care. **Objective:** To evaluate cost-effectiveness of multiple intervention model (MIM) *vs* conventional health-care model (CHCM) for CKD diagnosis and treatment.

Methods: Prospective evaluation from the health-care provider perspective, performed in 2 Family Medicine Units of Guadalajara, Mexico: MIM and CHCM were evaluated in one unit each. Three phases evaluated: Educative intervention for health professionals, Screening of CKD, and Management/Follow-up of CKD patients. All resources were identified, quantified and recorded; official lists for drugs, medical materials and services, and laboratory/image tests were employed for costs calculation. Only direct medical costs (in USD) were considered. *Main outcome and measures:* Total cost, average cost per person, and incremental cost-effectiveness ratio (ICER) with bootstrap analysis were determined in each phase. Clinical competence of health professionals was measured with a validated questionnaire, and CKD progression was defined as decline in GFR category.

Results: Clinical competence was not different between models neither at baseline (MIM 63±21 *vs* CHCM 60±19, p=0.52) nor at final (MIM 94±14 *vs* CHCM 89±17, p=0.76) evaluations. Average cost per health professional receiving educative intervention in MIM was $833 (CI95% 762-899) *vs* $901 (819-976) in CHCM ($p$=0.26). ICER was $22.6 favoring MIM. CKD stages 1-3 were present in 30% of patients from MIM (N 336) and 32% from CHCM (N 454). Average cost per person of CKD screening was $45 (CI95% 41-47) in MIM and $42 (CI95% 37-45) in CHCM (p=0.60). ICER was $2.3 favoring CHCM. For Management/Follow-up phase, 57 patients with CKD stages 1-3 were studied during 12-month in MIM and 58 patients in CHCM. CKD progression was observed in 16% of patients in MIM *vs* 28% in CHCM (p=0.09). Average cost per patient was $826 (CI95% 760-900) in MIM *vs* $701 (CI95% 632-777) in CHCM. ICER was dominant in MIM.

Conclusions: MIM are more cost-effective than CHCM to delay kidney disease progression when strategies combining educative interventions for health professionals, screening and adequate management of early CKD are employed at the primary health care.

TH-PO543

Applying Lean Tools to Optimize Delivery of Patient CKD Education in Primary Care Julie A. Wright Nunes,[4] Emily P. Chen,[2] Eve Kerr,[3] Audrey Fan,[1] Tejpreet Nakai,[6] Gunjan Garg,[3] Angela Fagerlin.[5] *[1]Univ of Mich, Northville, MI; [2]University of Michgan, Ann Arbor, MI; [3]University of Michigan, Ann Arbor, MI; [4]University of Michigan Health System, Ann Arbor, MI; [5]University of Utah, Salt Lake City, UT; [6]Univeristy of Michigan, Ann Arbor, MI.*

Background: Eighty percent of patients with CKD do not have the knowledge necessary to be fully activated in CKD management. Efficient and sustainable programs are needed to address patient education needs early in the CKD care continuum.

Methods: Applying Lean Tools (cause/effect analysis, process mapping / re-engineering), we created an efficient and sustainable way to integrate CKD patient education seamlessly into primary care practice. Utilizing a multi-disciplinary team (including primary care and nephrology physicians, patients, medical assistants, nursing, check-out staff, Health IT, and Lean coaches) a current-state process map of patient care and education was created for a large primary care practice. Lean coaches facilitated the multi-disciplinary team to create an improved future-state process that incorporated a CKD education module (a patient education worksheet) into current practice, using existing staff and resources. Content of the worksheet was optimized using quality improvement techniques. Health IT staff created an electronic version to use in the electronic medical record (EMR). This electronic patient education worksheet auto-populates with each patient's eGFR, blood pressure, and urine protein values. Medical assistants enter the worksheet into the EMR for patients with CKD stages 3-5 during patient check-in for routine visits. Providers review this worksheet in the EMR with patients during clinic encounters. Providers may enter 1-2 tailored messages about shared care goals. The worksheet prints automatically upon check-out and is given to the patient.

Results: Pilot testing shows the process is efficient and feasible to integrate into busy clinical settings. It takes seconds (two key-strokes) to enter into the EMR and approximately ~2 minutes for providers to review. Next steps will examine the impact of the electronic education worksheet and future state process on patient, clinic and provider related outcomes.

Conclusions: We provide a model of a future state process that incorporates patient CKD education seamlessly into practice, leveraging IT resources and existing clinic staff. The ultimate aim of this project is to improve patient CKD knowledge by addressing the unmet need of providing disease-specific education to patients early in the care continuum.

TH-PO544

Primary Care-Nephrology Multidisciplinary Partnership Improves CKD Care Paula Haberman,[1] Denney Edgel,[3] Sharon Hamilton,[3] Arasu Gopinath,[4] Ray Morales,[2] Mark R. Greenwood,[3] Titte Srinivas.[3] *[1]Family Practice, Park City, UT; [2]Intermountain Healthcare, Murray, UT; [3]Intermountain Medical Center, Murray, UT; [4]Nephrology Associates, Salt Lake City, UT.*

Background: Resources for CKD care are often clustered around late stage CKD with poor medical care in early stages leading to increased costs of care. Patients with realy stage stage CKD may overburden alaredy stretched nephrology resources and are cared for by primary care providers (PCPs) who may not be fully empowered to render appropriate CKD Care. Structured partnerships between PCPs, health systems, payers and nephrologist could be used to improve early stage CKD care. We report on a process improvement and care delivery redesign in a large integrated health system serving 5 states in the Intermountain West that demonstrates initial success of a PCP centered multidisciplinary approach to CKD care.

Methods: As a first step, we aimed to increase the numbers of urine albumin creatinine ratios (ACR) obtained on patients in CKD stage 3a/ 3b from 15% to 25% over a year. Engagement of frontline staff in primary care practices was identified as a key driver to ensure success. EMR advisories werefollowed by academic detailing through care process modules to Drive change. Key Process Drivers and Change Implementation methods are shown in Figure 1, a, b.

Results: A robust and sustained increase in rates of ordering albumin creatinine ratios is shown in Figure 1, c. Marked improvement in adherence to ACR ordering followed academic detailing.

Conclusions: A multidisciplinary primary care-nephrology-health system partnership in care redesign can produce robust sustained improvements in Early Stage CKD evaluation. This approach will be extended to CKD treatment

CKD Phenotype Validation Using Electronic Health Records (EHR): A Pilot Study John W. Stanifer,[1] C. Blake Cameron,[2] Cherry M. Beasley,[4] Daphne W. Wang,[1] Nrupen A. Bhavsar,[3] L. Ebony Boulware,[3] Clarissa J. Diamantidis.[3] *[1]Duke University, Durham, NC; [2]Duke University Medical Center, Durham, NC; [3]Duke University School of Medicine, Durham, NC; [4]The University of North Carolina at Pembroke, Pembroke, NC.*

Background: Few studies have assessed the accuracy of EHR-based methods for detecting CKD, and phenotypes validated from EHR data abstraction alone are inadequate.

Methods: In a rural healthcare system we piloted a novel EHR-based CKD detection phenotype. Individuals were assigned to one of six mutually exclusive groups according to expected likelihood of CKD from available EHR data. Group 1 had individuals with persistently (≥90 days) reduced eGFR (<60ml/min/1.73m^2) or albuminuria (≥30mg/g) or an ICD diagnosis of ESRD or kidney replaced by transplant; (2) individuals with 1 reduced eGFR or albuminuria and a comorbidity index ≥4, adopted from the Screening for Occult Renal Disease prediction tool; (3) individuals with 1 reduced eGFR value or albuminuria and comorbidity index <4; (4) individuals with no kidney function measurements and comorbidity index ≥4; (5) individuals with no kidney function measurements and comorbidity index <4; (6) individuals with normal eGFR and no albuminuria. As a reference standard for validation, we randomly sampled individuals from each group and assessed for CKD through measured assessments, with CKD defined by KDIGO 2012 criteria or self-reported transplant or dialysis. We calculated sensitivity and specificity and used ROC curves to assess performance of the CKD phenotype.

Results: Of 59,848 adults in the EHR, 4036 (7%) were classified group 1; 1690 (3%) group 2; 3007 (5%) group 3; 4726 (8%) group 4; 39,349 group 5 (66%); and 7040 (12%) group 6. For validation, we enrolled 110 individuals, of whom 75 (68%) had CKD based on the reference standard. The CKD phenotype showed a range of sensitivity and specificity corresponding with the CKD phenotype groups (**table**). The ROC curve area was 0.82 (95% CI 0.74-0.90).

Conclusions: Our CKD phenotype showed ability to detect CKD in a small sample identified from the EHR. Additional studies are needed to validate the CKD detection phenotype in other settings and larger samples.

Funding: Private Foundation Support

CKD phenotype performance

Group	Sensitivity	Specificity	Likelihood Ratio
≤6	100%	0%	1.0
≤5	100%	9%	1.1
≤4	99%	17%	1.2

1	79%	83%	4.6

TH-PO546

Using Kidney Failure Risk Scores to Identify Veterans Needing CKD Care C. Blake Cameron,[1,2] Joel Boggan,[2,1] Susan B. Gurley,[1,2] Richard M. Atkins.[2,1] *[1]Duke University Medical Center, Durham, NC; [2]Durham VA Health Care System, Durham, NC.*

Background: Both over- and under-referral to nephrology threaten the quality and efficiency of CKD care. Optimizing veterans' nephrology referrals may improve their outcomes. Few studies have evaluated patterns of nephrology referral among veterans as a function of CKD progression risk.

Methods: Using the Veterans Health Administration Clinical Data Warehouse, we identified all non-ESRD individuals who received primary care at the Durham VA Health Care System between Dec 2014 and Jun 2017 and had ≥1 outpatient serum creatinine measurement during that time. For each individual, we identified the assigned primary care provider (PCP); tabulated nephrology/CKD clinic visits; and calculated the Kidney Failure Risk Equation (KFRE), an internationally validated predictor of 5-year ESRD risk utilizing age, sex, CKD-EPI eGFR, and optionally, urine albumin-to-creatinine ratio. We stratified the population by KFRE risk (low <5%, intermediate 5-15%, and high >15%), by nephrology referral status and by assigned PCP. We performed descriptive analyses.

Results: Overall, 48,700 unique, non-ESRD individuals with at least one creatinine measurement received care from 139 PCPs. Only 32% (n=359/1,116) and 58% (n=503/865) of individuals at intermediate and high risk for CKD progression respectively had been seen in nephrology clinic. Conversely, among the 1,816 individuals seen in nephrology clinic, 53% (n=957) were at low risk [Figure 1A]. Nephrology referral rates for high-risk patients varied widely across PCPs (mean 58% [s.d. 20%]) [Figure 1B].

Conclusions: Within a single integrated medical center, nephrology referral rates were not aligned with clinical risk. More than 40% of individuals with high-risk CKD had not received nephrology care. Conversely, approximately half of individuals seen in nephrology/CKD clinic were at low risk of progression to ESRD and potentially could have avoided referral. Substantial provider-to-provider variation in nephrology referral rates exists. Identifying the sources of variation will be critical to developing decision support tools and models of care that better align the provision of CKD care with clinical risk.

Cause-Specific Hospitalization among Older Adults with CKD in the US (2006-2015) Yun Han,[3] Kevin He,[1] Diane Steffick,[3] Rajesh Balkrishnan,[4] Brahmajee K. Nallamothu,[2] Rajiv Saran.[3] *[1]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Internal Medicine - Nephrology, University of Michigan, Ann Arbor, MI; [4]University of Virginia School of Medicine, Charlottesville, VA.*

Background: Patients with CKD are at high risk of hospitalization, but there are few long-term studies of cause-specific hospitalizations in this vulnerable patient population. We examined these and long-term trends in hospitalization rates among older adults with CKD in the US.

Methods: We identified eligible CKD patients through claims (5% Medicare sample, 2006-2015). Patients were censored at the earliest of death, start of ESRD, disenrollment from Medicare Parts A&B or the last day of each calendar year. The cause of hospitalization was determined by principal ICD-9-CM diagnosis code. Adjusted hospitalization rates were calculated using a GLM with adjustment for age, gender and race.

Results: There was a notable decrease in the adjusted all-cause hospitalization rates among older CKD patients over the past decade, from 926.9/1000 patient years in 2006 to 739.0/1000 in 2011, with a steeper slope thereafter to 602.9/1000 in 2015 (Fig.1.a). Cardiovascular diseases (CVDs) and infections were the leading causes of hospitalization in CKD, accounting for 26% and 22% of all-cause admissions in 2015 (156.3/1,000 and 131.4/1,000). Congestive heart failure-related admissions were the most common CVD cause in CKD (Fig.1.b). Although overall infection-related hospitalization decreased over time, admissions resulting from bacteremia, septicemia and viremia increased by 51% and admissions due to nervous system infections increased by 42% (Fig.1.c).

Conclusions: While all-cause hospitalization rates among CKD patients gradually decreased in the past decade, CVD (especially heart failure related) and certain specific infections remained the leading causes. Future research will focus on preventable hospitalizations (e.g., septicemia, heart failure), disparities, geographic variation, costs, and care coordination.

TH-PO548

Effect of Exercise Intensity on Renal Blood Flow in Patients with CKD Stage 2 Kazuko Koutoku,[2,6] Tetsuhiko Yasuno,[7] Syotaro Kawakami,[4] Takao Saito,[3] Takuro Matsuda,[8] Kanta Fujimi,[8] Yoshinari Uehara,[5,1] Yasuki Higaki,[5,1] Hiroaki Tanaka.[1,5] *[1]Fukuoka University Institute for Physical Activity, Fukuoka, Japan; [2]Graduate School of Sports and Health Science, Fukuoka University, Fukuoka, Japan; [3]Sanko Clinic, Fukuoka, Japan; [4]Rehabilitation, Fukuoka University Chikusa Hospital, Fukuoka, Japan; [5]Laboratory of Exercise Physiology, Faculty of Health and Sports Science, Fukuoka University, Fukuoka, Japan; [6]Nursing, Ube Frontier University, Yamaguchi, Japan; [7]Division of Nephrology and Rheumatology, Department of Internal Medicine, Fukuoka University School of Medicine, Fukuoka, Japan; [8]Rehabilitation, Fukuoka University Hospital, Fukuoka, Japan.*

Background: The 2014 American College of Sports Medicine (ACSM) guidelines recommend that patients with chronic kidney disease (CKD) perform moderate intensity aerobic exercise for 20-60 min per day, 3-5 days per week. Several studies have shown that aerobic and resistance exercise improve exercise capacity, muscular strength, left ventricular function, blood pressure, and cardiovascular function in patients with CKD. However, few studies have specifically assesed the risks of exercise specific to CKD patients. In particular, exercise causes a decrease in renal blood flow (RBF), as well as a less marked and more variable decrease in glomerular filtration rate (GFR). The purpose of this study was to determine the association of RBF with intensity of exercise in patients with CKD stage 2.

Methods: Eight males with CKD stage 2 (eGFRcys : 60-89/min/1.73m^2) participated in the study, consisting of three separate experiments using a cycle ergometer. In the first experiment, participants performed a maximal graded exercise test. In the second, they performed a multi-stage exercise test to determine their lactate threshold (LT). In the third, they performed a multi-stage exercise test (4 minutes/stage) at intensities of 60%, 80%, 100%, 120%, and 140% of LT. RBF was assessed by Duplex ultrasound (Aplio 300, TOSHIBA, Japan).

Results: The maximal graded exercise test resulted in a 53% reduction in RBF and a significant increase in the filtration fraction (FF) after strenuous exercise (100% of VO_{2peak}). RBF did not significantly decrease until 100%LT was attained, and showed significant decreases of 64% at 120%LT and 62% at 140%LT relative to its resting value ($p<0.01$). FF also did not change until the LT was reached. In addition, LT corresponded with anaerobic threshold, 40% heart rate reserve, and 55%VO_{2peak}.

Conclusions: Our results demonstrate that RBF and FF do not change during exercise until the LT is attained. These findings may assist in making appropriate exercise intensity recommendations to patients with CKD stage 2.

TH-PO549

Impacts of Pre-Dialysis Options Education on Albumin Levels and Catheter Use in Patients Starting Dialysis John W. Larkin, Yue Jiao, Marta Reviriego-Mendoza, Rob Lynch, Len A. Usvyat, Jeffrey L. Hymes, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Options education before progression to end stage renal disease (ESRD) teaches patients about optimal ways to prepare for dialysis (e.g. early access placement, nutritional requirements, renal replacement therapy options). We aimed to understand whether patients receiving options education prior to initiating dialysis exhibited improvements in their albumin (Alb) levels and rates of catheter use.

Methods: We analyzed data from incident Fresenius Kidney Care (FKC) patients who initiated dialysis between 2009 and 2016. Patients were grouped by enrollment in FKC options education prior to initiating dialysis or not, as well as whether patients started dialysis as an outpatient or inpatient. In these groups, we calculated the annual mean Alb levels in all dialysis patients and percent catheter use during the first 120 days of dialysis in hemodialysis patients.

Results: We studied data from a total of 300,818 patients, of which 68,721 patients received options education prior to initiating dialysis. Throughout 2009-2016, patients who received options education generally exhibited higher mean Alb levels and there was a lower proportion of patients with a catheter, as compared to those who did not receive education. These observations were similar, yet less pronounced for catheter use in patients starting dialysis as an inpatient versus outpatient. In 2016 specifically, we observed that patients who started as an outpatient and received options education had higher Alb levels (3.5 mg/dL options education versus 3.4 mg/dL no education); for those starting dialysis as inpatients, Alb levels were 3.3 mg/dL and did not differ with options education or not. Concurrently, we observed that catheter use in patients starting dialysis as an outpatient was 13.8 percentage points lower in those with options education versus patients without education; in those starting dialysis as inpatients, the catheter use was 4.9 percentage points lower in with options education, compared to patients without education.

Conclusions: These findings indicate that options education before progression to ESRD is associated with dialysis patients achieving higher Alb levels and hemodialysis patients having lower catheter use in the incident dialysis period. Further analyses are warranted to confirm these results.

Abstract Withdrawn

TH-PO551

Factors Associated with Non-Conservative Treatment of Stage 5 CKD Robert N. Foley, Scott Reule. *University of Minnesota, Minneapolis, MN.*

Background: Quality of death and patient autonomy are prominent public health issues. In this regard, the decision to institute dialysis in patients with non-dialysis Stage 5 chronic kidney disease (CKD_5, GFR ≤ 15) is often difficult, because comorbid illnesses are the rule, and survival and quality of life with maintenance dialysis are often poor. Hence, we set out to examine factors associated with choosing to institute maintenance dialysis, as opposed to conservative management, in older adults.

Methods: We used the (US) Medicare 5% CKD random sample to identify 15,884 patients with diagnostic claims for CKD_5 between 2006 and 2011, with at least 6 months of prior Parts A and B Medicare insurance. Hospital admission codes in the prior 6 months were used to characterize comorbidity. Time to renal replacement therapy (RRT) was the primary outcome.

Results: The mean age of the study population at diagnosis of CKD_5 was 76 years. Mean follow-up was 2.8 years and 51.3% opted to begin RRT. In models that adjusted for age, demography and comorbid illnesses, adjusted hazards ratios (AHR) for RRT were > 1 ($P < 0.05$) for African American race (AHR 1.25 Vs. white), Native American race (AHR 1.38) and cardiac failure (AHR 1.38). RRT was less likely with older age (AHR 0.73 for 70-79, 0.63 for 80-89 and 0.44 for ≥ 90 [Vs. < 70 years]), female sex (AHR 0.89) and malignancy (AHR 0.92).

Conclusions: These findings suggest that a substantial proportion of Medicare patients with GFR ≤ 15 decline the option of RRT. Age, sex, race and comorbidity profiles influence this choice.

TH-PO552

Effect of N-Acetyl Cysteine in Patients with CKD: The Longer, the Better? A Nationwide Population-Based Retrospective Cohort Study Chen-Yi Liao, Chia-chao Wu. *Division of Nephrology, Department of Internal Medicine, Tri-Service General Hospital, Taipei, Taiwan.*

Background: This study aimed to evaluate the potential benefits of N-acetylcysteine (NAC) on the risk for chronic kidney disease (CKD) progression to dialysis-requiring end-stage renal disease (ESRD)

Methods: In a population-based cohort study of 145,062 individuals, a total of 123,608 CKD patients who were followed up for 10 years were compared with patients who were prescribed NAC after been diagnosed as CKD (ICD-9-CM). Using propensity score matching, we analyzed the predictors of CKD progression to ESRDd by Cox proportional hazards regression with adjustment for sex, age, and comorbidities and evaluated the effect of NAC using cumulative defined daily dose (cDDD).

Results: NAC use was associated with reduced risk for progression to ESRDd (HR 0.819, 95% CI 0.781-0.965, p = 0.017). Risk reduction was accentuated by an increase in cDDD in patients on NAC compared with non-NAC users (HR was 0.8350, 0.811, and 0.799 for cDDDs 91-180, 180-360, and ≥360, respectively; P for trend =0.018). Risk reduction was apparent in women (P = 0.001); younger age at 18-29 years (P = 0.021) and 30–39 years (P = 0.033); the presence of hypertension (P = 0.003); the absence of diabetes mellitus (P = 0.042); and the absence of congestive heart failure (P = 0.036).

Conclusions: NAC administration was associated with a lower risk of subsequent ESRD. Further studies are warranted to confirm these findings.

TH-PO553

Metformin Prescription in a Contemporary Cohort of Patients with Stage 3a CKD Rocco Ferrandino, Tielman T. Van Vleck, Jeremy S. Leventhal, Bart Ferket, Jaime Uribarri, Steven G. Coca, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Eligibility criteria for metformin have shifted from serum creatinine (SCr) to estimated glomerular filtration rate (eGFR) based guidelines. In 2009, the American Diabetes Association endorsed metformin use in type 2 diabetes (T2D) patients with stage 3a chronic kidney disease (CKD3a). We evaluated contemporary prescribing patterns in patients with CKD3a with as well as patient/process of care factors associated with non-prescription of metformin in a large multiethnic cohort.

Methods: We identified T2D patients with CKD3a from Mount Sinai CKD registry and calculated proportion of eligible patients actually receiving metformin. We then used nearest neighbor propensity matching to compare adjusted odds ratios (aOR) for non-prescription in user: non-user pairs. We also used natural language processing (NLP) tools to query clinical documentation for process of care factors.

Results: We identified 5213 metformin-eligible patients in 2015-16 based on eGFR criteria. Of these, only 1992 (38.2%) received metformin. We identified 1820 user: non-user matched pairs. Patient-specific factors associated with non-prescription included male sex (aOR 1.67, 95% CI 1.12-2.47) and black race (aOR 1.79, 95% CI 1.09-2.91). Interestingly, 21.7% of male and 20.3% of black patients eligible by eGFR guidelines were ineligible by SCr guidelines. Patients in whom other preventative T2D guidelines were adhered to (identified by NLP) had lower non-prescription odds. (Figure)

Conclusions: Despite a shift to eGFR-based guidelines and eGFR threshold lowering, a substantial proportion of eligible patients do not receive metformin. Factors responsible may be continued adherence to outdated guidelines, and patient/process of care specific factors, which should be explored in greater detail.

Funding: Other NIH Support - RF was supported by 1TL1TR001434

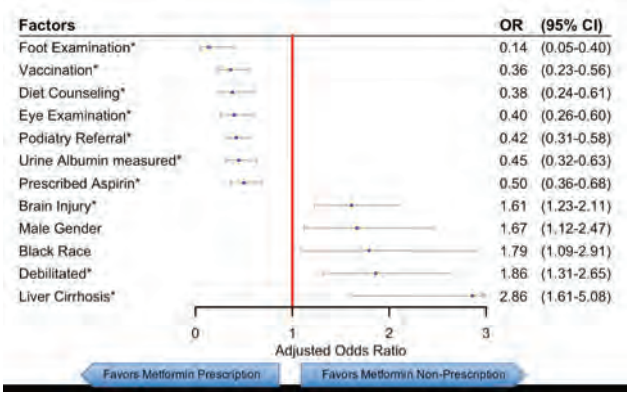

Figure. Factors associated with metformin non-prescription identified by analysis of structured and unstructured data. Asterisks(*) denote factors identified by NLP.

TH-PO554

Low Utilization of Statins in US Veterans with Non-Dialysis Dependent CKD David J. Leehey,[1,3] Talar Markossian,[2] Nicholas Burge,[1] Kevin Stroupe,[1] Ivan Pacold,[1] Julia Schneider,[1,3] Benjamin Ling,[1,3] Holly J. Kramer.[3,1] *[1]Hines VA Medical Center, Hines, IL; [2]Loyola University Chicago, Maywood, IL; [3]Loyola University Medical Center, Maywood, IL.*

Background: Cardiovascular disease is the major cause of morbidity and mortality among adults with non-dialysis dependent chronic kidney disease (CKD). Statin medications, especially when combined with ezetimibe, significantly reduce atherosclerotic cardiovascular disease (ASCVD) risk in this population. Renal guidelines therefore recommend statin use for all patients with non-dialysis dependent CKD age 50 years or older regardless of lipid profile. However, the recent AHA/ACC recommendations for statin use for adults (including those with CKD) in the absence of ASCVD or diabetes is based on the predicted 10-year ASCVD risk derived from the pooled risk cohort equation. The objective of this study was to examine statin utilization in a national sample of U.S. Veterans with non-dialysis dependent CKD, defined as an eGFR < 60 ml/min/1.73 m2, and to calculate the predicted ASCVD risk by diabetes status using the pooled risk cohort equation.

Methods: The design was a retrospective review of statin use and clinical and demographic factors associated with statin use. Statin use was ascertained from pharmacy dispensing records during fiscal years 2012 and 2013. The study included 581,344 Veterans age ≥ 50 years with non-dialysis dependent CKD stages 3-5 with no history of kidney transplantation or dialysis receiving care at VA healthcare facilities.

Results: 97% of patients were male and 58% were older than 70 years. Statin use ranged from as high as 76% in those with ASCVD or diabetes to as low as 22% in those without these conditions (p<0.001). Overall, 94% of Veterans without diabetes and 97% of Veterans with diabetes had a ASCVD risk score >7.5%, of whom 42% were not using statins. Strikingly, even in patients in whom the ASCVD risk score was very high (>= 20%), only 52% of non-diabetic CKD patients and 75% of diabetic patients were using statins.

Conclusions: Utilization of statins is low in Veterans with non-dialysis dependent CKD in the absence of well-known indications for statin use (i.e., ASCVD or diabetes) despite high-predicted ASCVD risk. We conclude that whether one follows renal or cardiovascular guidelines, statin utlization is suboptimal in CKD patients. National education efforts will be needed to increase statin use in CKD, especially in patients without established ASCVD or diabetes.

TH-PO555

Nephrology Practices and Patient Perspectives in regards to Conservative Care for ESKD: The Chronic Kidney Disease-Renal Epidemiology and Information Network Study (CKD-REIN) Elodie Speyer,[1] Luc Frimat,[2] Carole Ayav,[2] Christian Combe,[3] Denis Fouque,[4] Christian Jacquelinet,[5] Maurice Laville,[6] Ziad Massy,[7] Bruce M. Robinson,[8] Benedicte Stengel.[1] *[1]INSERM-CESP, UPSud, UVSQ, Villejuif, France; [2]CHU de Nancy, Vandoeuvre les Nancy, France; [3]CHU de Bordeaux, Bordeaux, France; [4]Université Claude Bernard, Pierre Benite, France; [5]Agence de la biomedecine, Saint-Denis La Plaine, France; [6]Université de Lyon, Pierre-Bénite, France; [7]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France; [8]Arbor Research Collaborative for Health, Ann Arbor, MI. Group/ Team: CKD-REIN Investigators.*

Background: Current KDIGO guidelines indicate that patients with advanced CKD should receive information on all renal replacement therapy (RRT) options, including conservative care (CC), but little is known about nephrologist practices and patient perspectives in regards to CC.

Methods: CKD-REIN is a prospective cohort study that enrolled 3,033 adult patient with CKD stage 3-5 (45% in stage 4-5) from a national representative sample of 40 nephrology clinics in France. Nephrologists were surveyed about practices regarding information, whether they offer, and clinic organization about CC. Patients completed a self-administered questionnaire (PQ) including their understanding of, education on, and preferences for RRT options, including CC.

Results: Among 31 clinics with data, 33% had a guideline (implemented or in preparation) for managing ESRD by CC. Eighty-two percent of the 131 respondent-nephrologists (mean age=44±10; 53% men) reported to be fairly or extremely comfortable with discussing CC with patients, but only 29% reported discussing it with all patients aged 75+. Patient's quality of life and preference for CC were more likely to influence nephrologists when contemplating the suitability of CC than medical or social conditions (figure 1). Among the 1,363 patients with CKD stage 4-5 (88% PQ respondents; 70% men; 35% aged ≥75), 5% of 75+ year-old patients reported to have been informed by their doctor about the "no treatment" option; and 2.3% stated they would choose the "no treatment" option if their kidneys failed.

Conclusions: Despite guidelines and that nephrologists declare that patients with advanced CKD receive information about all RRT options, patients report limited knowledge about CC, especially in elderly. In-depth studies about discrepancies between current practices and the CKD patient perception as they approach kidney failure are requested.

Does Longer Duration of Predialysis Care Improve Survival in People Treated with Dialysis? Ping Liu,[1] Robert R. Quinn,[1] Matthew J. Oliver,[2] Paul E. Ronksley,[1] Brenda Hemmelgarn,[1] Hude Quan,[1] Swapnil Hiremath,[3] Aminu K. Bello,[4] Peter G. Blake,[5] Amit X. Garg,[5] John F. Johnson,[5] Mauro Verrelli,[6] James M. Zacharias,[6] Samar Abd elhafeez,[7] Marcello Tonelli,[1] Pietro Ravani.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]Sunnybrook Health Sciences Center, Toronto, ON, Canada; [3]University of Ottawa, Ottawa, ON, Canada; [4]UNIVERSITY OF ALBERTA, Edmonton, AB, Canada; [5]London Health Sciences Centre, London, ON, Canada; [6]University of Manitoba, Winnipeg, MB, Canada; [7]High Institute of Public Health, Alexandria, Egypt.*

Background: Guidelines recommend early referral to nephrology care for people with chronic kidney disease, based on observational studies showing that longer nephrology care before dialysis start (predialysis care, PDC) is associated with lower mortality after dialysis start. This association may be observed because PDC truly improves patient outcomes, or because healthier people with an uncomplicated course of disease will have both longer PDC and better outcomes. We designed this study to assess whether the survival benefit of longer PDC exists after accounting for the potential confounding effect of acute events (markers of disease course) that may also be affected by prior PDC.

Methods: We did a retrospective cohort study in adults with kidney failure who initiated dialysis not following a failed kidney transplant between 2004 and 2014 in five Canadian programs. Data were collected from medical records and double-reviewed by two investigators.

Results: Of the 3152 participants: 23% had no PDC; 8%, 10%, and 59% received 1-119, 120-364, and ≥365 days of PDC, respectively. When we ignored markers of acute events (including unplanned dialysis start and higher residual kidney function around dialysis start) as in prior studies, longer PDC was associated with lower mortality (Hazard Ratio$_{120\text{-}364 \text{ vs. } 0\text{-}119 \text{ d}}$ 0.60, 95% CI 0.46-0.78; HR$_{\geq 365 \text{ vs. } 0\text{-}119 \text{ d}}$ 0.60 (0.51-0.71), standard Cox model adjusted for demographics, laboratory and clinical characteristics). When we accounted for markers of acute events, this association was weaker and no longer significant (HR$_{120\text{-}364 \text{ vs. } 0\text{-}119 \text{ d}}$ 0.84 (0.60-1.18); HR$_{\geq 365 \text{ vs. } 0\text{-}119 \text{ d}}$ 0.88 (0.69-1.13), marginal structural Cox model).

Conclusions: Current guidelines on early nephrology referral are based on studies that may have overestimated the survival benefit of longer PDC, because they may have inadequately addressed confounding by occurrence of acute events.

TH-PO557

Perspectives of Healthcare Professionals on Access to Emergency-Only Hemodialysis for Undocumented Immigrants with ESKD Lilia Cervantes,[1] Sara Richardson,[2] Rajeev Raghavan,[6] Nova Hou,[5] Allison Tong,[3] Romana Hasnain,[1] Michel Chonchol.[4] *[1]Denver Health, Denver, CO; [2]Denver Health Hospital, Denver, CO; [3]The University of Sydney, Sydney, NSW, Australia; [4]University of Colorado, Aurora, CO; [5]University of Texas at Houston Medical School, Houston, TX; [6]Baylor College of Medicine, Houston, TX.*

Background: Providing emergency-only hemodialysis for undocumented immigrants with end-stage kidney disease (ESKD) is challenging for healthcare providers as access is variable across the United States, can be legally and ethically complex, and is highly distressing for patients. We aimed to describe the perspectives of healthcare professionals on providing healthcare (emergency-only hemodialysis) to undocumented immigrants with ESKD.

Methods: We conducted face-to-face, semi-structured interviews with 50 healthcare professionals (nurses [N=16], physicians [N=27], physician assistants [N=3], social workers [1], and dieticians [1], certified nurse assistants [2]) at Denver Health (Denver, CO) and Harris Health (Houston, Texas). Interviews were transcribed and analyzed using thematic analysis.

Results: We identified five themes: Frustrated with hospital operations and care delivery (impersonal rationing of healthcare, struggle to provide primary care in the inpatient setting, inefficiencies lead to unnecessary labs and imaging, and lower priority for undocumented patients); overwhelmed by intense patient and family burden (advocating for a palliative care focus, anger seeing patients suffer when their friends die and receive cardiopulmonary resuscitation, disheartened when patients appear depressed and tired from the weekly accumulation of symptoms leading up to admission, and empathy for their families who struggle when patients require higher level of care); distressed by severity of patient condition (conflicted when patients take desperate measures to meet critically ill criteria, higher acuity care is commonplace, and frustrated by limited care options); and sense of uncertainty from the complex political and financial influence (lacking clarity about cost-benefit, sense that immigration status should not limit access to hemodialysis because other states provide routine dialysis, and desire to change current model of care because this care is more expensive and cruel).

Conclusions: Healthcare professionals are burdened by their patient's suffering and advocate for routine hemodialysis care.

Racial Disparities in Mortality in CKD versus ESRD: Results from the CRIC Study Elaine Ku,[1] Wei Yang,[2] Alan S. Go,[2] Nisha Bansal,[2] Harold I. Feldman,[2] Jiang He,[2] Edward J. Horwitz,[2] James P. Lash,[2] Ana C. Ricardo,[2] Tariq Shafi,[2] James H. Sondheimer,[2] Raymond R. Townsend,[2] Sushrut S. Waikar,[2] Chi-yuan Hsu.[1] *[1]University of California San Francisco, San Francisco, CA; [2]CRIC Study, Philadelphia, PA. Group/Team: CRIC Study.*

Background: Black individuals on maintenance dialysis have lower mortality rates than their white counterparts, but the reasons for this observation remain unexplained.

Methods: We examined risk of death among 3288 (non-Hispanic) white and black participants of a national CKD cohort, the Chronic Renal Insufficiency Cohort (CRIC) Study. We included deaths occurring *before and after dialysis* using Cox models. We also examined the evolution of comorbidities at baseline CRIC enrollment (prior to dialysis) vs. at dialysis initiation by race.

Results: Consistent with prior studies, risk of death was lower among blacks (Cox model HR 0.67 [95% CI 0.51- 0.88]) vs. whites when analysis began at incident dialysis. However, starting analysis at CKD/CRIC enrollment (mean eGFR 45±15 mL/min/1.73m^2), risk of death was higher (HR 1.41 [95% CI 1.22-1.64]) for blacks vs. whites counting deaths both before and after ESRD [Figure]. Longitudinal analyses of the evolution of comorbidities suggest that the relative prevalence of co-morbidities at baseline vs. at incident dialysis worsens for whites vs. blacks [Table].

Conclusions: Overall, risk of death was higher for blacks vs. whites when accounting for events occurring before and after ESRD. The apparent survival advantage among blacks on dialysis may be because the subset of whites who transition from CKD to dialysis are persons with a heavier burden of co-morbidities.

Funding: Other NIH Support - NHLBI

Figure 1. Distribution of deaths by race starting from baseline enrollment during 7.7 years median follow-up.*

	White		Black	
Death rate (per 100 P-Y)	CKD	Dialysis	CKD	Dialysis
	2.0	14.6	2.6	9.9

RR death (blacks vs whites) after dialysis =(155/475$_{blacks}$)/(81/200$_{whites}$) =0.83 → (survival paradox)
RR death (blacks vs whites) from CKD through dialysis= ((155+262)/1650$_{blacks}$)/((81+220)/1638$_{whites}$) =1.38 (no survival paradox)
*Preemptive transplants not shown.
P-Y = person-years

Table. Evolution of co-morbidities by race over time in Chronic Renal Insufficiency Cohort (CRIC) Study.

Characteristic N (%)	At time of CRIC enrollment			At time of dialysis initiation

Racial Differences in Nephron Number, Role of Body Size, Kidney Weight, and Cortical Volume in Adult Subjects among Five Populations Go Kanzaki,[1,5] Victor G. Puelles,[3] Luise A. Cullen-McEwen,[1] Wendy E. Hoy,[4] Yusuke Okabayashi,[5] Nobuo Tsuboi,[5] Akira Shimizu,[2] Takashi Yokoo,[5] John F. Bertram.[1] *[1]Department of Anatomy and Developmental Biology, Monash University, Melbourne, VIC, Australia; [2]Department of Analytic Human Pathology, Nippion Medical School, Tokyo, Japan; [3]Department of Nephrology and Clinical Immunology, University Hospital RWTH Aachen, Aachen, Germany; [4]Centre for Chronic Disease, The University of Queensland, Brisbane, QLD, Australia; [5]Division of Nephrology and Hypertension, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Nephron number in normal adult kidneys varies widely and is influenced by birth weight, age and race. Our recent studies have shown that Aboriginal and Japanese subjects have fewer nephrons than most populations studied to date and they are at high-risk for CKD. However, the cause of these racial differences in nephron number is not fully elucidated. In this study, we examined the effects of body size, kidney weight, and cortical volume on nephron number among races.

Methods: We analysed kidneys at autopsy from subjects aged 20-65 years without overt kidney disease in Aboriginal Australians (n=16), Japanese (n=12), Caucasian Americans (n=79), African Americans (n=65), and Senegalese (n=36). Total nephron number (Nglom) was estimated by design-based stereology. Cortical volume was calculated by Cavalieri Principle.

Results: Nglom per kidney in Aboriginal Australians (730,523±224,460; mean±SD) and Japanese subjects (716,236±185,767) was significantly lower than in Caucasian Americans (974,940±304,731), African Americans (943,446±276,017) and Senegalese (982,450±276,210). Although this difference was still present after adjustment for height or kidney weight, Nglom after adjustment for BMI, BSA, or cortical volume was similar in the five populations.

Conclusions: This study shows there is no difference in nephron number among the five races after adjustment for body size or cortical volume. It indicates that while Aboriginal and Japanese subjects with smaller body size have fewer nephrons than the other races, further nephron loss and/or increased body size would likely increase the risk of CKD.

TH-PO560

Angiomotin Is a Novel Interaction Partner of the Polycystin-1 C-Terminal Tail Kavita Mistry, Nikolay P. Gresko, Michael J. Caplan. *Yale University School of Medicine, New Haven, CT.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the fourth leading cause of adult end-stage renal disease. The majority of ADPKD cases are caused by mutations in the PKD1 gene, which codes for the membrane protein polycystin-1 (pc1). Pc1 is thought to play both direct and indirect roles in modulating gene expression; specifically, portions of the C- terminal tail of pc1, including a ~200 residue fragment ("p200"), are cleaved and may translocate to the nucleus, where they are hypothesized to regulate gene transcription. Previous work in our lab has focused on the transcriptional co-activator TAZ, and demonstrated that p200 stimulates the transcription of TAZ-target genes.

Methods: Using a mass spectrometry-based approach in HEK cells, we have identified angiomotin (AMOT) and Merlin (NF2) as novel interaction partners of the polycystin-1 C-terminal tail. AMOT and NF2 are critical upstream regulators of the Hippo pathway, and they exert their effects via direct binding to the downstream transcriptional co-activators YAP and TAZ, as well as to the inhibitory upstream Hippo kinases.

Results: We have shown using co-immunoprecipitation that AMOT and p200 interact with each other in the nucleus, and that deletion of the p200 nuclear localization sequence, which prevents nuclear trafficking of p200, abrogates the p200-AMOT interaction. In addition, we have shown using CRISPR/Cas9 knockout that AMOT is involved in the biochemical interaction between p200 and TAZ. Furthermore, the expression of several putative transcriptional targets of p200 is altered in AMOT knockout HEK cells. We have shown using co-immunoprecipitation that NF2 and p200 interact, and that NF2 phosphorylation status is altered in the setting of p200 overexpression.

Conclusions: In summary, our data show that the C-terminal tail of pc1 binds to AMOT and NF2, forming a nuclear protein complex that may facilitate target gene transcription.

Discovery of Novel Treatments for Ciliopathies and Cystic Kidney Disease Elisa Molinari,[2] Jacquelyn Bond,[1] Julie Higgins,[1] Shalabh Srivastava,[2] Simon Ramsbottom,[2] Colin A. Johnson,[1] John Sayer.[2] *[1]University of Leeds, Leeds, United Kingdom; [2]University of Newcastle, Newcastle upon Tyne, United Kingdom.*

Background: Nephronophthisis (NPHP) is an autosomal recessive cystic kidney disease that represents one of the most frequent genetic causes of end-stage kidney disease during childhood and adolescence. NPHP is a genetically heterogeneous disorder with 20 identified causative genes all encoding for proteins with a function in the primary cilium. NPHP is part of a spectrum of disease phenotypes associated with ciliopathies. We have previously generated a *Cep290*$^{LacZ/LacZ}$ viable mouse model for NPHP. These animals exhibit renal cysts that originate from collecting duct epithelium from which we derived an immortalised cell culture. In recent work, we have shown that the Hedgehog (Hh) agonist Purmorphamine can rescue the cellular and ciliary phenotype in these cells, indicating that ciliopathies are both reversible and treatable. However, the carcinogenic effects of Hh agonism make it unsuitable as a means of treatment, especially of paediatric patients. We set forth to identify existing compounds which can be repurposed for the treatment of NPHP.

Methods: A PerkinElmer "Operetta" High Content Imager, with an "Harmony' and "Columbus" analysis and data storage system, was used to test 1120 biologically active compounds from the Tocriscreen Mini drug library on ciliated monolayers of immortalised murine *Cep290*$^{LacZ/LacZ}$ collecting duct epithelial cells. Measured parameters were cell number, cilia incidence and cell junction integrity.

Results: Through a high-throughput screening approach, we have tested 1120 existing drugs for their efficacy in ameliorating the cellular and ciliary defect of NPHP cells and we identified 33 hits in a primary screen. A secondary screen validated the efficacy of 5 compounds.

Conclusions: Our high-throughput screening revealed that the ciliary phenotype of NPHP cells can be rescued by treatment with selected drugs. Positive hits from our high-throughput screening will be further validated on murine and human NPHP 2D and 3D cell models.

TH-PO562

Suppressive Effect of RXR Ligand and MEK Inhibitor on RXR Expression and Cellular Proliferation in Immortalized Polycystic Kidney Cells Masanori Kugita,[5] Tamio Yamaguchi,[2] Kazuhiro Nishii,[3] Mai Sasaki,[5] Noboru Ogiso,[1] Harold M. Aukema,[4] Shizuko Nagao.[5] *[1]Laboratory of Experimental animals, National Center for Geriatrics and Gerontology, Obu-city, Aichi, Japan; [2]Department of Clinical Nutrition, Suzuka University of Medical Science, Suzuka, Mie, Japan; [3]Faculty of Rehabilitation, Fujita Health University, Toyoake, Aichi, Japan; [4]Department of Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada; [5]Education and Research Facility of Animal Models for Human Diseases, Fujita Health University, Toyoake, Aichi, Japan.*

Background: We previously reported that expression of renal retinoid X receptor (RXR) was increased in three animal models of cystic kidney disease (Kugita et al AJP Renal 2011), and presented that treatment with bexaroten, a RXR agonist, significantly decreased renal RXR expression and kidney weight to body weight ratios in Han:SPRD-Cy/+ rats (Kugita et al ASN 2015). In hepatocellular carcinoma, phosphorylated RXR is related to aberrant cell proliferation accompanied by MEK-ERK phosphorylation to inhibit its degradation. RXR ligands may have suppressive effects on cell proliferation by dephosphorylation and degradation of RXR (Adachi et al Hepatology 2002). In the current study, we determined the phosphorylation sites of RXR, and elucidated the effects of a RXR ligand and a MEK inhibitor on expression of RXR and ERK, and proliferation of immortalized PKD cells.

Methods: An immortalized PKD cell line, WT9-12 was obtained from ATCC and was maintained in DMEM with 10% FBS. Phosphorylation of RXR was analyzed by Phos-tag SDS-PAGE. To elucidate the effect of RXR ligand and MEK inhibitor, starved WT9-12 cells were treated with 10mM 9-*cis* retinoic acid (9cRA) and/or 100mM U0126. The expression levels of RXR and phospho-ERK (pERK) were analyzed by western blotting. Cell proliferation activity was measured by the MTT assay.

Results: In WT9-12 cells, RXR was phosphorylated on Ser and Thr residues. Treatment with 9cAR alone, U0126 alone and the combination of these two reduced the expression of RXR by 20%, 8% and 23%, of pERK by 40%, 22% and 42%, and cell proliferation by 9%, 14% and 26%, respectively, when compared with vehicle treated cells.

Conclusions: The RXR ligand had a suppressive effect on proliferation of immortalized PKD cells, possibly by reducing expression of RXR and pERK. RXR ligands may have therapeutic potential either alone or in combination with MEK inhibitors to ameliorate PKD progression.

TH-PO563

TRPP2-Dependent Cellular Metabolism and Transcription Alexis Hofherr, Hannah Müller, Sebastian Keller, Michael Kottgen. *Medical Center - University of Freiburg, Freiburg im Breisgau, Germany*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenetic cause of chronic kidney disease, accounting for 7–10 % of patients with end-stage renal disease. ADPKD is caused by loss of function mutations in *PKD1* or *PKD2*. The gene products of *PKD1* and *PKD2*, Polycystin-1 (PC1) and Transient Receptor Potential ion channel Polycystin-2 (TRPP2), form a receptor-ion channel complex of unknown molecular function. In an unbiased forward genetic screen we have previously identified a Short Ca^{2+}-binding Mitochondrial metabolite Carrier (SCaMC) as a downstream effector of TRPP2. Here we investigate, whether TRPP2-SCaMC-associated metabolite fluctuations regulate cellular gene expression – translating transient TRPP2 ion channel activity into lasting cellular responses.

Methods: To correlate changes in metabolite levels with cellular gene expression, we performed broad-coverage discovery metabolomics and whole transcriptome shotgun sequencing in differentiated wild-type, *PKD2*$^{-/-}$, and *SCaMC*$^{-/-}$ renal epithelial cell lines.

Results: The quantitative measurement of the dynamic multiparametric metabolic response to the pathophysiological loss of TRPP2 and SCaMC identified significantly changed metabolites in both systems. We found that these metabolites are associated with amino acid metabolism including branched chain amino acids (BCAA) in mitochondria. Similarly, the expression of a large number of genes is affected by loss of TRPP2 and SCaMC. We are now correlating concordant changes in cellular metabolism and gene expression to identify novel molecular entities in the polycystin signaling cascade.

Conclusions: We have shown previously that loss of the metabolite carrier SCaMC phenocopies loss of TRPP2 in invertebrate and vertebrate model systems. Emerging evidence suggests that metabolite fluctuations regulate cellular signal transduction. We have tested this hypothesis and discovered a significant number of metabolites and genes indeed regulated by TRPP2 and SCaMC. It is tempting to speculate that concordantly changed molecular entities may provide mechanistic links between the polycystin receptor-ion channel complex and the diverse morphological changes observed in ADPKD.

Truncating PKHD1 Mutations Alter Energy Metabolism Phillip H. Chumley,[1] Sylvie Mrug,[1] Juling Zhou,[1] Bradley K. Yoder,[1] Michal Mrug.[1,2] [1]*University of Alabama at Birmingham, Birmingham, AL;* [2]*Department of Veterans Affairs Medical Center, Birmingham, AL*.

Background: Polycystin 1 deficiency triggers specific changes in energy metabolism. However, it remained uncertain whether similar changes are caused by relevant defects in other human cystoproteins. As our initial step addressing this question, we studied *in vitro* metabolism effects of engineered *PKHD1* gene disruption along sites of truncating mutations found in patients with autosomal recessive polycystic kidney disease (ARPKD).

Methods: We prioritized *PKHD1* mutations for targeting based on their reported frequency in the Aachen University Mutational Database for ARPKD. We used CRISPR/Cas9 technology to generate multiple clones of HEK293 cell lines with *PKHD1* truncating mutations. Clones without mutation in this gene (WT) served as controls.

Results: *PKHD1* gene mutations had no overall effect on proliferation rate estimated by MTT proliferation assay in this model, and neither did the position of the truncation. However, these mutations resulted in progressively increased extracellular media acidification. For example, when the acidity data for each of the six consecutive days (day in culture 3-8; D3-D8) were used for trajectory analyses, the trajectories of clones with *PKHD1* gene mutations did not differ from WT initially on D3 (b=-0.017, p=0.2436) but had greater increase in cell culture media acidity over time (i.e., steeper increase in acidity between D3 and D8; per day: b=-0.02, p<0.0001). Likewise, specific truncating *PKHD1* mutations did not differ from WT at D3 (b=-0.011 to -0.036, all p>0.2189) but each showed greater increase in acidity over time (per day: b=-0.018 to -0.029, all p<0.0001). These studies were done in aliquots of 10^4 cells plated in six replicates from each clone; replication with 2 x 10^4 cells yielded similar results. Our follow up analyses of the multiple clones point to several phenotypes that distinguish *PKHD1* mutant from WT effects; they include changes in non-glycolytic acidification rate (1.19 vs 1.03; p=0.002), basal oxygen consumption rate (7.59 vs 5.42; p=0.015) and ATP-linked oxygen consumption rate (4.55 vs 2.98, p=0.004).

Conclusions: Together, these data suggest that defects in the major ARPKD gene are associated with abnormal energy metabolism. Future validation of these initial observations in more relevant *in vivo* models would point to a potential benefit of energy metabolism targeting in ARPKD.

Preferential Utilization of Histidine as a Glucogenic Amino Acid for PKD Cyst Growth Peili Chen,[2] Chunyu Ma,[1] Arlene B. Chapman.[2] [1]*Emory University, Atlanta, GA;* [2]*University of Chicago, Chicago, IL*.

Background: Autosomal dominant polycystic kidney disease (PKD) is a proliferative disorder characterized by progressive development of renal cysts and renal failure. Alterations in metabolism in patients with PKD have been identified with increased representation of the histidine pathway with increasing disease severity. Histidine has multiple roles, regulating intracellular pH, entry into the Krebs cycle via glutamate/α-ketoglutarate, shared pathways with purine metabolism and generation of histamine for host defense purposes. To understand the role of histidine in PKD epithelial cell proliferation, non-targeted metabolomic analysis of cystic and non-cystic tubular epithelial cells were evaluated.

Methods: Primary human PKD cyst epithelial and human proximal and distal tubular cell lines were established. Conditioned media (8 replicates/sample) were harvested after 24h-incubation and subjected to high-resolution liquid chromatography mass spectrometry (LC-MS). Histidine decarboxylase inhibitor, α-fluromethylhistidine (α -FMH) in increasing doses (0-10uM) was administered and cell proliferation rates measured over 48 hrs with XTT assays. Data were analyzed using xMSanalyzer to identify metabolic features after normalization for protein content. Significant features were subjected to metabolic pathway analysis and enrichment with Mummichog.

Results: Metabolites were differentially expressed between PKD cells and controls. Histidine, histamine and methylimidazole acetaldehyde were decreased (P<0.05) in cystic cells vs. control media. Terminal histamine pathways not leading to further energy metabolism were decreased in cystic vs non-cystic cells (p<0.05). Aspartate and glutamate (entry points to the Krebs cycle) were increased in cystic vs. non-cystic cells (P<0.05). Cystic cells demonstrated an up to 21% increase in proliferation with α-FMH compared to baseline (P<0.05), and greater than non-cystic cells (P<0.001).

Conclusions: Histidine metabolism is abnormal PKD cystic epithelia demonstrating increased generation of aspartate and glutamate, precursors for energy generation. Inhibition of histidine decarboxylase reduced histamine generation, and thereby increased cell proliferation, consistent with increased energy substrate availability.

Prostaglandin E2 Stimulates Cyst Expansion and Induces Cyst Formation in ADPKD Morgane Lannoy,[1] Lijun Chang,[1] Fatma Abdela-Ali,[1] Dorien J. Peters,[2] Andrew J. Streets,[1] Albert C. Ong.[1] [1]*University of Sheffield, Sheffield, United Kingdom;* [2]*Leiden University Medical Center, Leiden, Netherlands*.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a major cause of kidney failure in man. Although multiple signalling pathways have been implicated in ADPKD pathogenesis, there is a general consensus that cyclic AMP (cAMP) signalling plays a central role in disease progression. Clinical trials lowering renal cAMP levels with a vasopressin 2 receptor antagonist, or a somatostatin agonist, have shown positive effects in slowing disease progression. Here, we report that selective blockade of prostaglandin E_2 (PGE_2) action, could be an alternative or adjunctive therapeutic strategy in ADPKD, through reducing cAMP.

Methods: cAMP, PGE_2 and its receptors (EP1-4) were analysed by qPCR, ELISA, immunoblotting and immunohistochemistry (IHC) on human cystic cell lines, human ADPKD kidney tissue and two mouse models of ADPKD. The functional effects of selective PGE_2 receptor agonists and antagonists on cyst growth were studied using 3D cyst assays in three cellular models.

Results: EP2 and EP4 mRNA were significantly elevated in cystic kidneys from two murine models of ADPKD (*Pkd1*$^{nl/nl}$, *Pkd1*-iKspCre). PGE_2 and cAMP were also found upregulated in *Pkd1*$^{nl/nl}$ at the peak of the disease. The overexpression of EP2 and EP4 were confirmed in human ADPKD kidney tissue by IHC. There was differential upregulation of EP2 in a panel of human cystic lines. PGE_2 stimulated a significant increase in cyst growth in dog (MDCKII), human (OX161) and mouse (F1/CRE) cells in a dose-dependent manner. This effect was mediated by EP2 and EP4 since its action was blocked by selective antagonists and reproduced by selective agonists in the absence of PGE_2. The effects of PGE_2, EP2 and EP4 agonists on cyst growth were closely correlated with increased proliferation and decreased apoptosis. Strikingly, PGE_2 was able to transform tubular structures formed by a non-cystic human kidney cell line (UCL93) in 3D culture to a predominant cystic phenotype. Current work is investigating the effect of EP2 and EP4 antagonists on cyst initiation and disease progression *in vivo*.

Diminished TRPV4 Activity and Glycosylation Contributes to Compromised [Ca2+]i Homeostasis in Human ADPKD Cells Viktor N. Tomilin,[2] Oleg L. Zaika,[2] Gail Reif,[1] Darren P. Wallace,[1] Oleh Pochynyuk.[2] [1]*University of Kansas Medical Center, Kansas City, KS;* [2]*University of Texas Health Science Center-Houston, Houston, TX*.

Background: PKD is a devastating clinical pathology leading to a decline in kidney function due to development of fluid-filled cysts. No effective pharmacological treatments exist for PKD patients. Defective flow-mediated $[Ca^{2+}]_i$ responses and disrupted $[Ca^{2+}]_i$ homeostasis have been repeatedly associated with the development of PKD. Our previous work in rodents demonstrated that the activity of the Ca2+-permeable TRPV4 channel is imperative for flow-mediated [Ca2+]i responses in the distal renal tubule. TRPV4 function is dramatically decreased in isolated cystic cell monolayers and systemic stimulation of TRPV4 interferes with PKD progression in PCK 453 rats, an ARPKD model.

Methods:

Results: Here, we determined the role of TRPV4 in Ca2+ signaling in human ADPKD and normal human kidney (NHK) cells. ADPKD cells failed to respond to flow and had significantly lower basal [Ca2+]i levels compared to NHK cells, consistent with our previous work (*Yamaguchi et al. J. Am. Soc. Nephrol. 17, 2006*). Application of TRPV4 antagonist, HC-067047 significantly reduced basal [Ca2+]i levels in NHK cells but had no measurable effect in ADPKD cells. TRPV4 activator, GSK1016790A elicited more than two times higher [Ca2+]i response in NHK than in ADPKD cells. GSK1016790A-

mediated responses were precluded by HC-067047 or a Ca2+-free media. Patch clamp analysis revealed significantly lower basal TRPV4 single channel activity and diminished responses to GSK101670A in ADPKD cells. Consistent with our previous results in an ARPKD rat model, we detected a marked decrease in TRPV4 glycosylation in human ADPKD cells pointing to the common mechanism of compromised mechanosensitive [Ca2+]i responses for both PKD forms. TRPV4 glycosylation and activity were dramatically reduced in cultured distal tubule cells upon silencing of polycystin 1 expression. Moreover, blockade of glycosylation with tunicamycin significantly inhibited TRPV4 activity pointing to a mechanism of reduced TRPV4 function in ADPKD cells.

Conclusions: Taken together, TRPV4 glycosylation and function are greatly diminished in human ADPKD cells, contributing importantly to aberrant [Ca2+]i signaling and deficient responses to flow. We speculate that TRPV4 stimulation might be beneficial in restoring [Ca2+]i homeostasis in cyst cells thereby counteracting ADPKD progression in humans.

Overexpression of Activated TGFβ1 in Collecting Ducts Induces Cyst-Like Tubule Dilations and Renal Fibrosis in Wildtype Mice and Accelerates the Decline in Renal Function in ADPKD Mice

Yuqiao Dai,[2] Yan Zhang,[2] Archana Raman,[2] Emily A. Daniel,[2] Aditi Khanna,[2] Gail Reif,[2] Fernando Pierucci-Alves,[1] Darren P. Wallace.[2] *[1]Kansas State University, Manhattan, KS; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: Transforming growth factor β1 (TGFβ1), a master regulator of extracellular matrix production, is elevated in autosomal dominant polycystic kidney disease (ADPKD). TGFβ1 is also elevated in Marfan Syndrome (MFS), a genetic disorder leading to abnormal connective tissue development, defects in multiple organs, and formation of renal cysts in approximately 60% of patients. Currently, the role of activated TGFβ1 in renal cyst formation in MFS and the effect of TGFβ1 on cyst growth and disease progression in ADPKD remain unclear.

Methods: To determine if activated TGFβ1 is sufficient to induce renal cyst formation and fibrosis, we crossed $\beta 1^{glo}$ (TGFβ1) mice, which conditionally express TGFβ1, with *Pkhd1-Cre* mice to express activated TGFβ1 selectively in collecting ducts (CD; $TGF\beta 1^{CD}$). We also overexpressed activated TGFβ1 in CDs of $Pkd1^{RC/RC}$ mice, a slowly progressive model of ADPKD.

Results: CD overexpression of TGFβ1 caused cyst-like tubule dilations and increased kidney weight (% body weight; KW%BW) by 5 wk of age. However, by 10 wk, the kidneys developed focal area of fibrosis and pitting of the surface that was indicative of scarring, and there was a significant reduction in KW%BW of $TGF\beta 1^{CD}$ mice compared to wildtype (WT) mice. There were increased renal levels of periostin, a marker for PKD progression, phosphorylated SMAD3, α-smooth muscle actin (α-SMA) and vimentin, markers for myofibroblasts. Blood urea nitrogen (BUN) was slightly increased in $TGF\beta 1^{CD}$ mice compared to WT mice at 20 wk, but this difference was not statistically significant. Similar results were obtained in $Pkd1^{RC/+}$ mice, which have one hypomorphic *Pkd1* allele. Overexpression of TGFβ1 in $Pkd1^{RC/RC}$ mice did not increase cystic index, but rather caused extensive fibrosis and contraction of the kidneys, leading to decreased KW%BW. This was accompanied by increased levels of periostin, α-SMA and vimentin, and a decline in renal function, evidenced by an elevation of BUN compared to $Pkd1^{RC/RC}$ mice.

Conclusions: Our results demonstrate that expression of activated TGFβ1 is sufficient to induce cyst-like tubule dilations and renal fibrosis in normal mice, and accelerate the decline in kidney function in ADPKD mice. .

Increased Wnt/β-Catenin Signaling in Postnatal Mouse Model of ADPKD

Yun Joon Jung,[1,2] Jordan A. Kreidberg.[1,2] *[1]Urology, Boston Children's Hospital, Boston, MA; [2]Surgery, Harvard Medical School, Boston, MA.*

Background: The Wnt signaling pathway has an important role for nephron development and elevated expression of β-Catenin, master regulator of the Wnt pathway, is shown to correlate with cystogenesis in autosomal dominant polycystic kidney disease (ADPKD). We previously demonstrated increased expression of *Wnt7a* and *7b* in an embryonic mouse model of ADPKD. Here we provide further evidence that β-catenin is elevated in a postnatal model of ADPKD using *Hoxb7-Cre-IRES-eGFP;*$Pkd1^{flox/flox}$ mice.

Methods: To understand the contribution of Wnt signaling in ADPKD, we measured β-Catenin expression, *in vivo* and *in vitro*, using cystic kidneys of *Hoxb7-Cre-IRES-eGFP;*$Pkd1^{flox/flox}$ mice and *Hoxb7-Cre-IRES-eGFP;*$Pkd1^{flox/+}$ controls and then used immunofluorescence and nuclear/cytoplasmic fractionation to quantify levels of β-Catenin with Western blotting at relevant subcellular locations. The use of two small molecules targeted the interaction of β-Catenin with p300 and CBP (Creb binding protein) and allowed us to measure, *in vitro*, the effect on the expression of Fibronectin and alpha smooth muscle actin (αSMA).

Results: Kidneys from *Hoxb7-Cre-IRES-eGFP;*$Pkd1^{flox/flox}$ develop cysts beginning at postnatal day 3 and have overwhelming cystogenesis by postnatal day 21. Nuclear b-catenin was evident in cyst lining cells of cystic kidneys at postnatal day 7. The expression of *Tcf-1*, a b-catenin target gene, was elevated in postnatal kidneys as further evidence of hyperactivation of the canonical Wnt pathway. Fibronectin and αSMA expression were also increased in cystic kidneys. Inhibition of the β-catenin-CBP with ICG-001 decreased expression of fibronectin and αSMA, suggesting that they are expressed downstream of the Wnt/b-catenin pathway.

Conclusions: The canonical Wnt pathway appears to be hyperactivated in mouse models of ADPKD and may serve as a therapeutic target to decrease cyst formation.

The Role of ATMIN in Autosomal Recessive Polycystic Kidney Disease (ARPKD)

Paraskevi Goggolidou,[1,2] Jill T. Norman,[2] Patricia D. Wilson.[2] *[1]University of Wolverhampton, Wolverhampton, United Kingdom; [2]Centre for Nephrology, UCL Medical Campus, Royal Free Hospital, London, United Kingdom.*

Background: ARPKD is a genetic disorder with an incidence of ~1:20,000 that can lead to perinatal mortality. In the ~60% of ARPKD patients who survive the neonatal period, there is a range of disease severity, however, little is known about the genetic mechanisms that regulate ARPKD. ARPKD is caused by mutations in *PKHD1* which encodes the large membrane protein, fibrocystin, required for normal branching morphogenesis of the ureteric bud during embryonic renal development. The range of disease severity observed in ARPKD suggests that besides *PKHD1* that when mutated causes ARPKD, other genes might also play a role in ARPKD, acting as modifiers of disease severity. Our previous work on ATMIN has shown that it plays a role in kidney morphogenesis by modulating Planar Cell Polarity (PCP) signalling.

Methods: Quantitative Real-time PCR and immunohistochemistry was employed in age-matched normal and ARPKD human kidneys, to investigate causal (fibrocystin) and PCP (Daam2, ATMIN, NPHP2/Inversin) effects. *Atmin* and *Pkhd1* siRNA-mediated knockdowns and Atmin-Green Fluorescent Protein (GFP) overexpression studies were conducted in mouse inner medullary collecting duct (IMCD3) cells, to study the mechanistic relationship between Atmin and Fibrocystin.

Results: A 2-fold increase in *ATMIN* was observed in human ARPKD vs normal kidneys; no significant differences were seen in *DAAM2* or *NPHP2*. In normal human kidneys ATMIN, Inversin and Fibrocystin were expressed in ureteric bud-derived collecting tubules, whereas in age-matched ARPKD tissue, strong ATMIN and Inversin expression was observed in cyst-lining epithelia. An association was observed between Atmin and Fibrocystin in IMCD3 cells, as siRNA-mediated knockdown of *Atmin* dramatically reduced *Pkhd1* expression; siRNA-mediated knockdown of *Pkhd1* almost completely depleted *Atmin* expression. Atmin-GFP overexpression in IMCD3 cells caused a 6-fold increase in *Pkhd1* expression. No significant change in other Wnt signalling (*Dvl1, Nphp2*) or polycystin (*Pkd1, Pkd2*) levels was observed. We are currently investigating whether ATMIN and Fibrocystin are in the same protein complex, with preliminary data in normal mouse kidney suggesting that this is the case.

Conclusions: This work suggests that ATMIN interacts with Fibrocystin, proposing *ATMIN* as a modifier of ARPKD that could in the long term be used as a biomarker of ARPKD severity and progression.

TH-PO571

Activation of CD8+ T-Cells Inhibits Cyst Growth in a Murine Model of ADPKD

Emily K. Kleczko, Kenneth H. Marsh, Eric T. Clambey, Seth B. Furgeson, Berenice Y. Gitomer, Michel Chonchol, Raphael A. Nemenoff, Katharina Hopp. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Phenotypic heterogeneity observed in Autosomal Dominant Polycystic Kidney Disease (ADPKD) cannot be explained solely by genic effects. As in other disorders, changes in the microenvironment likely contribute to disease variability. In ADPKD, the role of the adaptive immune system, a critical microenvironmental component, is largely unknown. The goal of this study was to determine the function of T-cells in ADPKD progression.

Methods: Using flow cytometry, immunofluorescence, qPCR, histopathology, and antibody depletion, we evaluated the role of T-cells in the ADPKD *Pkd1* p.R3277C (RC) model. In the C57BL/6 strain this model progresses slowly, while in the BALB/c strain disease advances rapidly.

Results: By flow cytometry, $Pkd1^{RC/RC}$ mice showed an increase in both $CD4^+$ and $CD8^+$ T-cells, correlating with disease severity (fold change RC vs wildtype (WT) (3mo, 9mo), C57BL/6: 1.9, 8.8; BALB/c: 6.0, 12.3). Importantly, by immunofluorescence, even at mild/moderate disease and modest overall increases in T-cell number, the majority of T-cells localized to cysts ($Pkd1^{RC/RC}$ 3mo; C57BL/6: 87.5%; BALB/c: 85.7%). This was associated with increased *Cxcl9* and *Cxcl10* expression, both implicated in T-cell recruitment ($Pkd1^{RC/RC}$ 3mo (fold change RC vs WT *Cxcl9*, *Cxcl10*); C57BL/6: 2.7, 2.8; BALB/c: 6.6, 17.6). We further observed increases in $CD44^+/CD69^+$ $CD8^+$ T-cells but not $CD4^+$ T-cells, and noted that WT animals of the more severe strain (BALB/c) have a lower $CD8^+$ to $CD4^+$ T-cell ratio (1:4 vs C57BL/6 1:1), suggesting selective activation of $CD8^+$ T-cells in our model and a potential correlation of $CD8^+$ T-cell numbers to disease severity. In concordance, antibody depletion of $CD8^+$ T-cells from 1-3 months in C57BL/6 $Pkd1^{RC/RC}$ mice versus IgG control significantly increased %kidney weight/body weight (2.3 vs 2.1), average cyst size (18.6 vs 14.2 $x10^3 \mu m^2$), and %fibrotic area (2.6 vs 1.7). However, cyst number did not change (8.4 vs 8.6 per mm^2), indicating that $CD8^+$ T-cells slow cyst progression/fibrosis, but not initiation.

Conclusions: These data indicate that T-cells are upregulated in ADPKD and are specifically recruited to cystic lesions. Further, $CD8^+$ T-cells play a crucial role in attenuating cyst growth, suggesting that therapeutic compounds designed to activate $CD8^+$ T-cells may be promising ADPKD treatment options.

Effectiveness of MTT in Liver Phenotype in a Model of Autosomal Recessive Polycystic Kidney Disease (ARPKD) Adrian Cordido,[3] Olaya Lamas-Gonzalez,[2] Ana Barcia de la Iglesia,[3] Jesus Bañales,[1] Candido Diaz-Rodriguez,[4] Miguel A. Garcia-Gonzalez.[2] *[1]Biodonostia Health Research Institute, San Sebastián, Spain; [2]Health Research Institute of Santiago de Compostela (IDIS)., Santiago de Compostela, Spain; [3]Instituto de Investigacion Sanitaria (IDIS) de Santiago de Compostela, Santiago de Compostela, Spain; [4]University Clinical Hospital of Santiago de Compostela (CHUS), Santiago de Compostela, Spain.*

Background: Polycystic liver disease (PLD) are genetic disorders characterized by progressive bile duct dilatation and cyst development in hepatic parenchyma. PLD are inherited in a dominant or recessive form and can develop alone or in association with polycystic kidney disease (PKD). A number of different mechanisms have been related to the pathogenesis of Polycystic Disease, which we focused on alteration in the extracellular matrix (ECM). MTT is a Metalloproteinases inhibitor. In previous work (ASN2016), we have shown the effectiveness of MTT in models of Autosomal Dominant PKD (ADPKD), both in renal and hepatic phenotype.

Methods: Here, we focused our work testing MTT as a potential therapy for PLD associated to Autosomal Recessive PKD (ARPKD). In this regard, we use a model of ARPKD, Pkhd1$^{del3-4/del3-4}$ (Pkhd1-KO), to test the effectiveness of MTT in hepatic cystogenesis.

Results: In our previous work, we showed the benefit effect of MTT in Autosomal Dominant Polycystic Kidney Disease (ADPKD) inhibiting the hepatic cystogeneis and collecting duct cyst (DBA+ cyst). Now, we have deeply characterized the liver phenotype in our ARPKD model, identifying a time depending gender effect of disease progression. We have also tested MTT, alone and in combination with Tolvaptan, in different points resulting in a significant inhibition of hepatic cystic progression in ARPKD.

Conclusions: In ASN 2016, our group showed the effect of MTT in Autosomal Dominant Polycystic Kidney Disease (ADPKD) inhibiting the hepatic cystogeneis and collecting duct cyst (DBA+ cyst). With this work, we have demonstrated the effectiveness of MTT in the inhibition of hepatic phenotype of ARPKD.

TH-PO573

Cytokine TWEAK Promotes Cystogenesis in Autosomal Dominant Polycystic Kidney Disease (ADPKD) in a Time Dependent Manner Adrian Cordido,[2] Ana B. Sanz,[3] Ana Barcia de la Iglesia,[2] Candido Diaz-Rodriguez,[4] Alberto Ortiz,[1] Miguel A. Garcia-Gonzalez.[2] *[1]Fundacion Jimenez Diaz, Madrid, Spain; [2]Instituto de Investigacion Sanitaria (IDIS) de Santiago de Compostela, Santiago de Compostela, Spain; [3]Instituto de Investigacion Sanitaria Fundacion Jimenez Diaz, Madrid, Spain; [4]University Clinical Hospital of Santiago de Compostela (CHUS), Santiago de Compostela, Spain.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common monogenic disorder in which kidneys develop fluid-filled cyst derived from the tubule epithelial cells. Several mechanisms are associated with cyst initiation and cyst progression, recent findings aim inflammation as one the most important molecular mechanism in the progression of ADPKD. TWEAK (tumor necrosis factor TNF-like weak inducer of apoptosis) is a TNF-like cytokine and member of the TNF superfamily. TWEAK promotes inflammation, proliferation, cell death and angiogenesis. However, the role of TWEAK in ADPKD is unknown.

Methods: We have studied the effect of TWEAK in our ADPKD animal model, *Pkd1*$^{cko/cko}$Tam-Cre. This model presents a cystogenesis developmental switch, because the inactivation of Pkd1 gene in different points of life determines cystic phenotype.

Results: We tested TWEAK in different developmental windows of our animal model (*Pkd1*$^{cko/cko}$Tam-Cre) we show that proinflammatory cytokines can be accelerates the progression of ADPKD. The mice that received TWEAK presented higher levels of BUN and worst survival rate than the group of control mice. In addition, TWEAK promotes the progression of hepatic cystic phenotype (PLD associated to ADPKD). These results suggest that TWEAK not online acts at the kidney level.

Conclusions: Doing use of *Pkd1*$^{cko/cko}$Tam-Cre animal model, we demonstrated that TWEAK promotes the progression of ADPKD in a time dependent manner. We results show how inflammation may modulate the severity of ADPKD and the possibility of a treatment with anti-inflammatory therapy.

TH-PO574

Effects of a Novel Vasopressin V2 Receptor Antagonist on Cystic Disease Progression in the PCK Rat Lorenzo Pellegrini,[2] Megan M. Constans,[1] Peter C. Harris,[1] Vicente E. Torres.[1] *[1]Mayo Clinic, Rochester, MN; [2]Palladio Biosciences, Newtown, PA.*

Background: Vasopressin V2 receptor inhibition is a clinically validated mechanism of action for Autosomal Dominant Polycystic Kidney Disease (ADPKD), a progressive genetic disease characterized by the formation and enlargement of fluid-filled cysts in the kidneys. However, safe and effective disease-modifying therapies for ADPKD are still lacking. Here we report the first evidence that lixivaptan, a promising, selective vasopressin V2 antagonist, could have utility for the treatment of ADPKD.

Methods: We examined the effects of lixivaptan in PCK rats, an orthologous animal model of Autosomal Recessive PKD that develops a phenotype reminiscent of ADPKD. 4-week old PCK rats were randomly assigned to vehicle control, standard dose of lixivaptan or two alternative lixivaptan dosing protocols and subsequently treated for 8 weeks. At the end of treatment, a comprehensive panel of biochemical and histomorphometric endpoints was evaluated to assess the effect of lixivaptan on disease progression.

Results: PCK rats in the control group showed enlarged kidneys and extensive cyst formation, consistent with the development of a polycystic kidney phenotype. Compared to control animals, PCK rats treated with the standard dose of lixivaptan showed a 27% reduction in kidney weight as a percentage of body weight (p=0.006), a 23% reduction in kidney cAMP levels (p=0.014), a small but statistically significant reduction in liver weight as a percentage of body weight (6%; p=0.03) and a reduction in cyst burden. As expected, these reductions were associated with statistically significant increases in 24h urine output (179%; p<0.0001) and serum sodium (1.7%; p=0.02). Pharmacological efficacy on disease manifestations was also observed in animals treated with the two alternative dosing regimens of lixivaptan, however the difference with the control group did not reach statistical significance.

Conclusions: The beneficial effect of lixivaptan in the PCK rat model of PKD adds to the body of evidence implicating vasopressin V2 receptors in the pathology of ADPKD. These results pave the way to the potential demonstration of a disease-modifying effect of lixivaptan in upcoming clinical trials in ADPKD patients.

TH-PO575

Targeting Epithelial Innate Immunity Improves Inflammation and Fibrosis in a Mouse Model of Nephronophthisis Heng Jin,[2] Shanshan Wang,[1] Qiong Ding,[2] Dongmei Lu,[1] Massimo Attanasio.[2] *[1]UT Southwestern Medical Center, Dallas, TX; [2]University of Iowa, Iowa City, IA.*

Background: Inactivation of the gene *GLIS2* causes nephronophthisis type 7 (NPHP7), a kidney disease characterized by progressive interstitial inflammatory infiltration and fibrosis. Recently, we have shown that cell senescence of kidney epithelial cells is a central pathogenic event in this disease. Senescent cells are known to secrete an array of molecules, referred to as senescence associated secretory phenotype (SASP), that is controlled by the NF-κB pathway and sustain organ inflammation and fibrosis. Toll-like receptors (TLRs) are 'surveillance' receptors that recognize microbial particles and endogenous molecules. TLR2 and TLR4 are abundantly expressed on the surface of kidney epithelial cell and, when stimulated, induce activation of the NF-κB pathway through the shared adaptor myeloid differenziation protein 88 (MyD88).

Methods: We found that multiple NF-κB genes are overexpressed in *Glis2* defective kidney tubular cells, including *Tlr2*, which is at the same time a target and an activator of NF-κB, and hypothesized that activation of epithelial innate immunity may affect inflammation and fibrosis in *Glis2* knockout kidneys. We tested this hypothesis by generating *Glis2*$^{mut/mut}$;*Tlr2*$^{-/-}$ and kidney epithelial specific *Glis2*$^{mut/mut}$;$^{Ksp\text{-}cre}$*Myd88*$^{f/f}$ double knockouts. We measured cystic area, tubular cells proliferation, apoptosis, DNA damage and senescence, interstitial inflammatory cells, fibrosis and kidney function in single and double knockout mice.

Results: No differences were detected in these parameters between *Glis2*$^{mut/mut}$;*Tlr2*$^{-/-}$ and *Glis2*$^{mut/mut}$ mice at 3, 6 and 9 months of age. On the other hand, proliferation, DNA damage, cystic index, interstitial inflammation and fibrosis was decreased in kidneys of *Glis2*$^{mut/mut}$;$^{Ksp\text{-}cre}$*Myd88*$^{f/f}$, comapred to *Glis2*$^{mut/mut}$ mice at 3 months of age. No differences of kidney function and tubular cell senescence were detected.

Conclusions: Our results indicate that epithelial innate immunity signaling concurs in maintaining inflammation and fibrosis in the mouse model of NPHP7.

TH-PO576

Tissue Mass Spectrometry Analysis of Glycosphingolipid Distribution in Murine Polycystic Kidney Disease Cristina I. Silvescu,[1] Lilu Guo,[2] Laurie A. Smith,[5] Mandy Cromwell,[1] Dinesh Bangari,[5] Susan Ryan,[4] Petra Oliva,[5] Alla Kloss,[1] Thomas J. O'Shea,[1] Walter Korfmacher,[1] Oxana Beskrovnaya,[5] Thomas A. Natoli.[3] *[1]Sanofi, Waltham, MA; [2]Sanofi, Waltham, MA; [3]Rare Disease Research, Sanofi, Framingham, MA; [4]Sanofi Corporation, Framingham, AL; [5]Sanofi Genzyme, Framingham, MA.*

Background: Elevated glucosylceramide synthase (GCS) activity is a hallmark of polycystic kidney disease (PKD), and pharmacologic or genetic reduction of glycosphingolipid (GSL) accumulation slows cyst growth and preserves kidney function in multiple models of murine PKD. To better understand the role of GSL accumulation in PKD progression, we sought to characterize spatial tissue distribution of GSLs in cystic kidneys of juvenile cystic kidney (jck) mice.

Methods: Liquid chromatography coupled to tandem mass spectrometry (LC/MS/MS) and tissue MALDI/TOF mass spectrometry imaging (MSI) were used to quantify GSL species in kidney tissue isolated from wild-type mice, jck mice, or jck mice treated with a GCS inhibitor.

Results: LC/MS/MS analysis demonstrates roughly 3- to 6-fold accumulation of Gb3, globoside, GM2, and GD3 in jck mouse kidneys compared to wild-type kidneys; these levels are all reduced following GCS inhibition. GM3 was detectable by tissue MSI in a diffuse pattern consistent with epithelial accumulation throughout the jck mouse kidney. A hydroxylated form of GM3 accumulates in blood vessels of the jck mouse kidneys. Elevated levels of GM1 species were detected in jck mouse kidneys in a patchy pattern that was distinguishable from that seen with GM3. Several sulfatide species could be detected in discrete patterns localizing to the cortex, medulla, and papilla; the C20

isoform was excluded from the papilla, while the C24 isoform was highly enriched in the papilla, and clear epithelial localization could be observed.

Conclusions: Accumulation of complex glycosphingolipids downstream of glucosylceramide is evident in cystic kidneys compared to normal kidneys, and tissue distribution of multiple GSL species can be assessed using mass spectrometry imaging. Differences in either the carbohydrate composition of the GSL or the chain length of the lipid moiety can result in localization to distinct cell types. Tissue MSI therefore provides a unique approach to better understand the role of glycosphingolipids in kidney disease.

TH-PO577

Phosphorylation Insensitive 4E-BP1 Reduces Hyperproliferative Phenotype In Vitro Sara Holditch,[1] Carolyn N. Brown,[1] Kameswaran Ravichandran,[1,3] Charles L. Edelstein.[2] *[1]UC Denver Anschutz Medical Campus, Aurora, CO; [2]University of Colorado Denver, Aurora, CO; [3]Hera BioLabs, Lexington, KY.*

Background: Unchecked proliferation of cystic epithelial cells is a major contributor to cyst growth in PKD. The 4E-BP1 pathway is a crucial checkpoint in protein translation initiation and cellular proliferation. Evidence from oncology supports the malignant potential of 4E-BP1. A recognized oncotarget, 4E-BP1 is associated with worsening progression, metastasis, and morbidity in oncology. The aim of this study was to determine 1) whether PKD patient and animal model kidney tissues have dysregulated phospho 4E-BP1 species and 2) the effect of a phosphorylation insensitive 4E-BP1 (F113A) on phospho 4E-BP1 species distribution, cap dependent protein translation, and proliferation in renal epithelial cells.

Methods: Immunofluorescence staining of phospho 4E-BP1 species (T70, T37/47, S65) was performed on human ADPKD and Han:SPRD rat (Cy) kidneys. Western blot analysis, Cyquant cellular proliferation, and Firefly-renilla assays were performed on human primary epithelial cells from normal renal cortical tubular epithelium ($PKD1^{+/+}$) and ADPKD cyst-lining epithelium ($PKD1^{-/-}$) transfected with control or pCAG-F113A or transduced with control or F113A lentivectors.

Results: Phospho 4E-BP1 species were present in cyst lining cells of human ADPKD and Cy renal tissues. F113A resulted in substantially reduced phospho 4E-BP1 T37/46(0.89±0.08 vs 0.012±0.004DU, $p<0.01$) and S65 (0.63±0.04 vs 0.003±0.001DU, $p<0.01$), reduced cap-dependent protein translation (37%, $p<0.01$), and reduced 72hr proliferation (250±4 vs 180±5 480/528nm O.D, $p<0.0001$) in $PKD1^{-/-}$ cells. Surprisingly, in $PKD1^{+/+}$ cells, F113A resulted in no phospho 4E-BP1 reduction, reduced cap-dependent protein translation (32%, $p<0.01$), and marginally reduced proliferation (375±5 vs 314±4 480/528nm O.D, $p<0.0001$). Acute stimulation with insulin resulted in maintained S65 suppression with F113A transfection in $PKD1^{-/-}$ (2.1±0.3 vs 0.2±0.1AU, $^*p<0.0001$).

Conclusions: F113A results in a shift towards hypophosphorylated 4E-BP1 species, reduced cap dependent protein translation, and reduced proliferation, with more aggressive effects in $PKD1^{-/-}$ vs $PKD1^{+/+}$. Utilizing F113A gene therapy to counter the loss of the translationally repressive 4E-BP1 pathway in a murine model of PKD, is the next step in addressing a pathway seemingly integral to the pathobiology of PKD.

TH-PO578

Altered Liver Bioactive Lipid (Oxylipin) Profiles in PCK Rats with Polycystic Kidney and Liver Disease Tamio Yamaguchi,[1] Jessay G. Devassy,[2] Aruni Jha,[3] Andrew J. Halayko,[3] Masanori Kugita,[4] Shizuko Nagao,[4] Amir Ravandi,[5] Harold M. Aukema.[2] *[1]Department of Clinical Nutrition, Suzuka University of Medical Science, Suzuka, Mie, Japan; [2]Department of Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada; [3]Children's Hospital Research Institute of Manitoba, University of Manitoba, Winnipeg, MB, Canada; [4]Education and Research Facility of Animal Models for Human Diseases, Fujita Health University, Toyoake, Aichi, Japan; [5]Institute of Cardiovascular Sciences, St. Boniface Hospital Research Centre, Winnipeg, MB, Canada.*

Background: Oxylipins are bioactive lipids derived from polyunsaturated fatty acids formed via cyclooxygenase (COX), cytochrome P450 (CYP) and lipoxygenase activities. Previously, we reported that renal COX oxylipins were elevated in diverse animal models of renal cystic kidney disease, suggesting that COX inhibition may be a viable approach to treating these types of renal disorders. Since liver cystic disease also commonly occurs in several types of renal cystic disease, we determined kidney and liver oxylipin profiles in the PCK rat, an orthologous model of autosomal recessive polycystic kidney disease (ARPKD) with cystic kidney and liver disease.

Methods: Liver oxylipin profiles of 16-week PCK and normal rats were determined by targeted lipidomic analyses using HPLC-tandem mass spectrometry. Correlations of oxylipins with disease were analyzed using supervised and unsupervised multivariate models.

Results: Both kidney and liver weight/body weight and lumen or cyst area/tissue section, as well as liver fibrosis were higher in PCK compared to normal rats. Based on the profile of the 61 oxylipins detected in liver, diseased rats clustered distinctly from normals. Consistent with previous findings in which higher levels of renal oxylipins derived via the COX pathway were associated with disease, the strongest predictor of diseased liver was elevated COX derived 6-keto-prostaglandin $F_{1\alpha}$, the main metabolite of prostacyclin. In addition, all 7 of the dihydroxy fatty acid oxylipins formed via CYP and soluble epoxide hydrolase (sEH) that were detected were reduced in diseased livers, also consistent with kidney findings. The unsupervised multivariate model also indicated the correlation of diseased livers with at least 9 lipoxygenase derived oxylipins.

Conclusions: Oxylipins from all three biosynthetic pathways are associated with diseased livers in the PCK rat model of ARPKD. The COX derived oxylipin 6-keto-prostaglandin $F_{1\alpha}$ is higher and CYP/sEH derived oxylipins are lower in PCK livers compared to normals. The potential effects of prostacyclin synthase inhibitors and the role of the novel CYP/sEH derived oxylipins in the development of cystic kidneys and livers remains to be elucidated.

Palmitoylation of Polycystin 1 Occurs in the Carboxylterminus and May Regulate Polycystin 1 Localization and Expression Levels Kasturi Roy, Lindsey K. Stavola, Michael J. Caplan, Ethan P. Marin. *Yale School of Medicine, New Haven, CT.*

Background: Polycystin 1 (PC1) is a polytopic membrane protein that localizes to primary cilia. Genetic mutations that lead to reduced PC1 expression levels and/or trafficking to cilia cause cystic disease of the kidney and/or liver. Such mutations may occur in the PC1 gene (*Pkd1*), or in genes encoding endoplasmic reticuluum proteins involved in the maturation and trafficking of PC1. Cysteine palmitoylation is the post-translational attachment of the 16-carbon lipid palmitic acid to a cysteine sidechain, and is known the affect trafficking and stability of numerous proteins.

Methods: Palmitoylation of PC1 was assessed using a variety of biochemical approaches including incorporation of a clickable palmitate analog as well as acyl exchange methods. Effects of palmitoylation were gauged using chemical inhibitors of palmitoylation and depalmitoylation, coupled with immunofluorescence to assess PC1 localization and semi-quantitative Western blotting to assess PC1 expression levels.

Results: PC1 is palmitoylated on at least one cysteine in the ~140kDa carboxylterminal domain. Experiments using inhibitors of enzymatic palmitoylation and de-palmitoylation suggest that the modification facilitates trafficking of PC1 from the plasma membrane into the cilia membrane. Pharmacological inhibition of palmitoylation or depalmitoylation also alters PC1 expression levels in reciprocal directions

Conclusions: Collectively, these data identify palmitoylation as a novel post-translational modification on PC1 which may affect its trafficking and stability. Both factors are relevant to the development of cystic kidney and liver disease. Consequently, a more detailed understanding of the palmitoylation of PC1 may identify targets to pharmacologically manipulate its expression level and localization, and potentially reverse the effects of disease-causing mutations.

Pkd1-Deficient Mice Show Increased Susceptibility to Induction of Endoplasmic Reticulum Stress Following Mild Renal Ischemia/Reperfusion Andressa G. Amaral,[1] Andre F. Pires,[2] Elieser H. Watanabe,[1] Luiz F. Onuchic.[1] *[1]Nephrology and Molecular Medicine, University of São Paulo, Sao Paulo, Brazil; [2]Sirio Libanes Hospital, Sao Paulo, Brazil.*

Background: *Pkd1* haploinsufficiency has been shown to increase susceptibility to renal ischemia-reperfusion (IR) in mice. IR is a classical cause of endoplasmic reticulum stress (RS) and RS can aggravate renal injury induced by IR. Inactivation of *Xbp1*, in turn, has been proposed to amplify the cystic phenotype of $Sec63^{flox/flox}$:Ksp-Cre mice by decreasing polycystin-1 activity. To investigate the effect of mild renal IR on RS in *Pkd1* deficiency, we analyzed RS and inflammation markers in $Pkd1^{+/-}$ (HT) and $Pkd1^{+/+}$ (WT) mice submitted to mild renal IR.

Methods: HT and WT male mice were submitted to 32-min bilateral renal IR or sham intervention (SI). Serum urea nitrogen (SUN) was measured 24h prior to and 48h after these procedures. Kidneys were harvested 48h post-IR or SI to evaluate IL1β, IL6, IL10, MCP1, TNFα and RANTES by multiplex assay; GRP78 and XBP1s by western blot; *Hif1α*, *Hspa5* and *Ddit3* by real time RT-PCR; and *Xbp1*s/*Xbp1*u transcript ratio by end-point RT-PCR.

Results: SUN did not differ between WT and HT mice after IR and SI. *Hif1α* expression did not significantly increase following renal IR in mice with either genotype, indicating that the induced insult was mild. The levels of IL1β, IL6, IL10, MCP1, TNFα and RANTES did not differ between HT and WT kidneys in response to IR and SI. Renal expression of XBP1s protein was higher in HT than WT animals after IR [0.67 (0.55-0.72) *vs* 0.48 (0.34-0.53), $p<0.01$)] while HT kidneys presented lower *Xbp1s/Xbp1*u than WT following this insult [6.59 (5.85-7.05) *vs* 10.29 (9.48-12.18); $p<0.001$). Notably, renal IR decreased this ratio in HT mice [*vs* 9.00 (8.24-9.14), $p<0.01$] whereas slightly increased it in WT animals [*vs* 8.22 (6.48-9.54), $p<0.05$]. No differences in *Hspa5* gene and GRP78 protein expression were detected between kidneys of both genotypes in response to IR and SI. *Ddit3* gene expression, in addition, did not differ between HT and WT kidneys after IR and SI.

Conclusions: Our findings support that *Pkd1* haploinsufficiency increases the level of RS following mild renal IR in mice, by favoring the activation of the IRE1α-XBP1 branch of UPR. Our data suggest that this effect may possibly modulate polycystin-1 functional activity and attenuate renal injury in mild IR, potentially limiting the increased susceptibility associated with *Pkd1* haploinsufficiency.

TH-PO581

Induced Inactivation of Pkd2 Results in Progressive Tubule Reduction and Loss in New, 3D Model of ADPKD Cystogenesis Eryn E. Dixon, Owen M. Woodward. *University of Maryland School of Medicine, Baltimore, MD.*

Background: The role of *PKD1/PKD2* loss in renal cytogenesis remains both unequivocal and undefined. Many disparate pathways are known to be altered in ADPKD without a definitive mechanistic pathway connecting back to the loss of either polycystin protein. A long standing roadblock has been the inability to model cystogenesis resulting from the spontaneous loss of *PKD1/PKD2* as postulated by the two-hit ADPKD hypothesis.

Methods: To better understand the local effects of *Pkd2* inactivation on cystogenesis, signaling, and organization of differentiated, E-cadherin positive, structures, a new, three-dimensional (3D) *in vitro* model has been developed that employs primary renal cells from an inducible Cre (*Pkd2 Pax8 rtTA TetOCre+mTmG*) mouse line. This 3D culture system combines a unique "sandwich" plating technique with a glial-derived neurotrophic factor (GDNF) growth factor cocktail to increase the yield of differentiated and complex epithelial structures, including spheroids and tubules. In addition, this new model system allows tracking of gross morphological changes of 3D structures and cellular components before and after the inactivation of *Pkd2*.

Results: Characterization of the differentiated tubule structures reveals that the cells of the organoids demonstrate typical apicobasolateral polarization and primary cilium as defined by basolateral Na+/K+-ATPase and lumenal acetylated tubulin, respectively. Interestingly, the differentiated organoids are positive for collecting duct markers, *Dolichos biflorous agluttinin* (DBA), and the apical water channel, aquaporin-2 (AQP2), while negative for proximal tubule markers, *Lotus tetrogonobulus lectin* (LTL) and ATP-binding cassette sub-family G member 2 (ABCG2). Addition of doxycycline induces Cre and mosaic inactivation of *Pkd2* with an approximately 50% decrease in the abundance of total polycystin-2 (PC2). The loss of PC2 protein results in a progressive reduction and eventual loss of tracked tubule structures when compared to control organoids.

Conclusions: Changes in morphology of differentiated structures following inactivation of *Pkd2* in this novel cystogenesis culture system suggest a defect in the 3D organization of epithelial structures that is dependent on PC2 and the study of cystogenesis in 3D organoid culture systems may provide novel insights into the pathogenesis of ADPKD.

Anks3 and Anks6 Expression Pattern and Co-Localization in the Kidney Is Tightly Regulated during Development and Disturbed by the Anks6pR823W Mutation in Rats with ADPKD Euan Clark,[2] Stamatia Matina Papagiannarou,[4] James Bowie,[3] Sigrid C. Hoffmann.[1] *[1]Medical Research Centre, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; [2]Medical Research Centre, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; [3]University of California, Los Angeles, Los Angeles, CA; [4]Medical Research Centre, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) in rats is caused by a missense mutation in Anks6 (Anks6^{pR823W}). The Anks6^{pR823W} mutation disrupts the interaction between the SAM domains of Anks6 and Anks3, a novel protein. The function of this interaction is unknown. Co-localization of Anks6 and Anks3 is a precondition that interaction can occur. Thus, this study aimed to analyze the spatial and developmental renal expression pattern of Anks6 and Anks3 in WT and Anks6^{pR823W} cy/cy rats.

Methods: Anks3 and Anks6 expression were studied during renal development (0- and 10-days of life) and in the mature kidney at the age of 4 weeks in normal wild type (WT) and homozygous Anks6^{pR823W} cy/cy rats by in situ hybridization, immunohistochemistry and confocal microscopy.

Results: In kidneys of 0d -10d old WT rats both, Anks6 and Anks3, were expressed only in the cortex, not in the medulla and do not co-localize. In contrast, in the mature WT kidney both, Anks3 and Anks6, are strikingly expressed in the medullary collecting ducts and co-localizes with aquaporin 2 (Aqp2). In the renal cortex they co-localizes in distal tubules, however, only Anks6 but not Anks3 expression was noted in the S3 segment of the proximal tubule; the tubular segment in which cysts originate in Anks6^{pR823W} cy/cy rats. Unlike WT kidneys, Anks6^{pR823W} cy/cy rats already show during kidney development a strong expression and co-localization of Anks6 and Anks3 in the medullary collecting ducts and the cortical tubules. The Aqp2 expression is significantly less in both, 0d -10d old and mature kidneys, of cy/cy rats when compared with WT rats indicating a reduced water retention.

Conclusions: A developmental regulated spatial expression pattern of Anks6 and Anks3 exist in the WT kidney, which is disturbed in Anks6^{pR823W} cy/cy rats. Since we have previously shown that Anks3 knockout in rats decreases urine production and increases Aqp2 expression, data suggests that Anks3 is overactive in Anks6^{pR823W} and suppresses Aqp2 expression. In WT kidneys, Anks6 and Anks3 interaction via their SAM domain might block this Anks3 effect. Further studies are required to relate these findings to the cystogenesis. *This study was supported by the grant of the NIH (5RO1DK100482) to JB and SH*

Kidney Glycosphingolipidomics and Metabolomics Reveal Metabolic Crosstalk between Elevated Glycosphingolipids and Glucose Metabolisms in PKD Progression Kazuki Nakajima,[1] Kazuo Takahashi,[3] Masanori Kugita,[2] Shizuko Nagao,[2] Yukio Yuzawa.[4] *[1]Fujita Academy, Fujita health university, Toyoake, Aichi, Japan; [2]Fujita Health University, Toyoake, Aichi, Japan; [3]Fujita Health University School of Medicine, Toyoake, Japan; [4]Fujita Health University School of Medicine, Toyoake, Japan.*

Background: Polycystic kidney diseases (PKDs) are characterized by abnormal proliferation and cyst formation in renal epithelial cells. Particularly, abnormal glucose and lipid metabolism are known therapeutic targets of PKD. We previously reported that a crucial cellular energy sensor, AMP-activated protein kinase, tightly regulates glycosphingolipid (GSL) biosynthesis by reducing nucleotide sugars, suggesting a metabolic crosstalk between GSLs and glucose metabolism (Ishibashi. Y et al. *J.Biol. Chem.* 2015). Herein, we investigated whether this crosstalk leads to cooperative effects in PKD progression by using lipidomics and metabolomics.

Methods: Glycosphingolipidomics and metabolomics in 10-week-old male juvenile cystic kidney (*JCK*) mice and control mice were performed by four newly developed methods using liquid chromatography electrospray ionization tandem mass spectrometry (LC-ESI-MS/MS). This study included the (1) global analysis of abundant sphingolipids, (2) quantification of glucosylceramides using an isometric separation system, and (3) acidic GSLs-focused analysis. Moreover, (4) metabolomics included the quantification of nucleotide sugars, the substrate of GSLs. The involvement of the crosstalk in PKD progression was demonstrated by analyzing changes in cell lines treated with several inhibitors.

Results: Global analysis of sphingolipids revealed no significant changes in more than 100 species of abundant ceramides and sphingomyelins. However, the second method showed higher levels of major GlcCer species in the PKD mouse kidney. Further, acidic GSL-focused analysis showed a remarkable increase in GM3 gangliosides, but not sulfatides. Metabolomics revealed that the UDP-glucose level was up-regulated in PKD. The elevated GSL levels were abrogated by treatment with 2-deoxy-glucose, an inhibitor of glucose metabolism. Conversely, treatment with Genz-123346, an inhibitor of GSL synthesis, suppressed UDP-glucose levels in a PKD model cell line.

Conclusions: The metabolic crosstalk between GSL and glucose metabolism may play a role in PKD progression. Our workflow provides valuable information regarding the molecular mechanisms studied during the search of novel therapeutic targets of PKD.

ADAM10-MMP14 Complex Regulates Renal Cystogenesis in Autosomal Dominant Polycystic Kidney Disease Frank Xu,[1] Li-lun Ho,[1] Bradley M. Denker,[2] Tianqing Kong,[1] Joseph V. Bonventre,[1] Tzongshi Lu.[1] *[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is associated with mutations in polycystins, alterations in cell-cell junctions and focal adhesions in renal epithelial cells. Polycystin 1 (PC1) forms a large protein complex that includes E-cadherin and Gα12 binding proteins that play key roles to maintain cell-cell junctions and cell polarity. We previously reported that deletion of PC1-regulated protein, Gα12, protected kidneys from kidney cystogenesis induced by Pkd1 inactivation, and activation of Gα12 increased the shedding of E-cadherin. However, signaling pathways of PC1 induced ADPKD are not fully understood.

Methods: We used Madin-Darby canine kidney (MDCK) cells, Pkd1 deletion renal cells and Pkd1 knockout mice kidney tissue. Inducible Pkd1 knockout mice were generated by flanking exons 2 through 6 with two LoxP sites (Mx1Cre+; Pkd1flox/flox). Double knockout of Pkd1 and Gα12 mice were obtained by crossing Mx1Cre^{+}Pkd1$^{flox/flox}$ mice with Gα12$^{-/-}$ mice (Pkd1-/-Gα12-/-). MDCK Tet-off inducible Gα12 and Gα12QL cell lines were used in 3D cell culture.

Results: The conditional deletion of Pkd1 (Pkd1$^{-/-}$) resulted in multiple kidney cysts forming within 9 weeks, but Pkd1-/-Gα12-/- mice had no structural and functional abnormalities in the kidneys. Pkd1 deletion promoted increased E-cadherin fragments in renal cystic fluid. No change in cyst E-cadherin fragments in Gα12$^{-/-}$ mice. Gα12 increased the active form of ADAM10, and knockdown of ADAM10 blocked the Gα12 mediated E-cadherin shedding. Our data indicate that ADAM10 is the major sheddase for cleavage of E-cadherin caused by Gα12 activation. Increased ADAM10/MMP14 complex promotes cystogenesis in renal epithelial cells. ADAM10 activity is dependent on the catalytic and hemopexin domains of MMP14. Inhibition of ADAM10 and MMP14 activity blocks cystogenesis induced by Gα12 activation. The deletion of Pkd1 increases the activation of Gα12, which subsequently decreases cell-matrix and cell-cell adhesion by affecting focal adhesion and E-cadherin cleavage.

Conclusions: Gα12 is an essential downstream signaling molecule for PC1, and Gα12 activation increases ADAM10 activity promoting the ectodomain shedding of E-cadherin that plays a key role in renal cystogenesis in Pkd1 deletion induced ADPKD. The ADAM10-MMP14-Ecadherin axis is a potential therapeutic target for ADPKD.

Recessive Mutations of MAP7D3 Cause a Renal Ciliopathy Tilman Jobst-Schwan,[1] Joao Goncalves,[2] Einat Lahav,[3] Deborah R. Stein,[1] Benjamin Dekel,[3] Laurence Pelletier,[2] Friedhelm Hildebrandt.[1] *[1]Division of Nephrology, Boston Children's Hospital, Boston, MA; [2]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada; [3]Sheba Medical Center, Safra Children's Hospital, Division of Pediatric Nephrology, Pediatric Stem Cell Research Institute, Ramat Gan, Israel.*

Background: Renal ciliopathies are characterized by dysfunction of the primary cilium and centrosomes. Mutations in one of 95 genes have been discovered to cause these single gene-disorders in ~65% of patients with renal ciliopathies.

Methods: To identify novel ciliopathy genes, we analyzed whole exome sequencing (WES) data in individuals with ciliopathies, who had no mutations in any known ciliopathy genes. We examined the subcellular localization of *MAP7D3* using confocal immunofluorescence (IF) analysis in and performed co-immunoprecipitation (co-IP) to test the interactions with other known ciliopathy genes.

Results: The male index patient from a non-consanguineous family presented with polyuria, enuresis, tubular proteinuria, impaired kidney function (GFR 30ml/min) and acidosis. Renal ultrasound (US) showed small, echogenic kidneys. By WES trio analysis, we identified the hemizygous truncating mutation c.1284_1285insC (p.Ser429Glnfs) in the X-chromosomal *MAP7D3* gene in this patient. In a second unrelated non-consanguineous family, the male patient presented with severe hyperkalemia, small echogenic kidneys upon US and end stage renal disease. Renal biopsy of this patient showed nephronophthisis-like features with additional glomerulosclerosis. By WES, we identified the hemizygous missense mutation c.65G>C, p.Arg22Pro in *MAP7D3* introducing a proline residue in a coiled-coil domain that is known to interact with microtubules. By IF, we show that wild type Flag-BirA-MAP7D3 localizes to the mitotic spindle. By co-IP, we show that wild type MAP7D3 interacts with CEP120, mutated in the ciliopathy Jeune asphyxiating thoracic dystrophy, and with SPICE1 as well as CP110, which are all centrosomal proteins.

Conclusions: We here identify mutations of *MAP7D3* as a novel monogenic cause of a renal ciliopathy in humans and demonstrate that the protein interacts with other ciliopathy associated or centrosomal proteins. Further studies will elucidate allele specific expression and pathogenic pathways involved.

TH-PO586

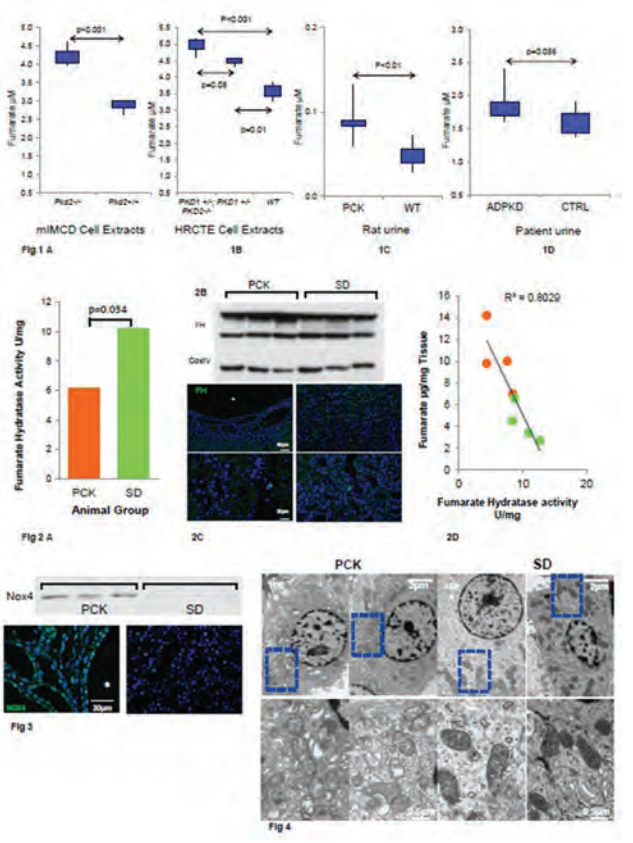
Possible Role of Nox4 in Cystogenesis through Its Effects on Fumarate Hydratase in Experimental PKD Ivan Vuckovic, Jennifer Arroyo, Fouad T. Chebib, Peter C. Harris, Slobodan Macura, Vicente E. Torres, Maria V. Irazabal. *Mayo Clinic, Rochester, MN.*

Background: Autosomal Dominant Polycystic Kidney Disease (PKD) is the most frequent hereditary renal disease, but the exact mechanisms of cystogenesis remain to be elucidated. Deficiency in fumarate hydratase (FH) is accompanied by increases in fumarate and is associated with the development of kidney cysts. Studies in diabetic nephropathy showed that NADPH oxidase (NOX)-4 (Nox4) can inhibit FH leading to accumulation of fumarate. No studies have explored the role of Nox4 in PKD.

Methods: Metabolomics analysis of cell extracts, urine, plasma & kidney of PCK (n=32) and wildtype (WT; n=24) rats, and human samples (ADPKD n=10; ctrl n=10) was performed by HNMR & confirmed by MS. Immunoreactivity and protein expression of FH & Nox4 were assessed by staining & western blotting, FH activity by a colorimetric method and mitochondria by electron microscopy.

Results: Fumarate was consistently increased in PKD-deficient cells, PCK rats & human samples (Fig1A-D). Mitochondrial FH activity was significantly lower in PCK rats (2A), but protein expression and immunoreactivity did not differ (fig2B-C). Furthermore, FH activity highly correlated with tissue fumarate (fig2D). Decreased FH activity was associated with significantly increased protein expression and immunoreactivity of Nox4 in PCK compared to WT rats (fig3). These findings were associated with disruption of mitochondria cristae, swelling, and decreased matrix density exclusively in tubular cells from CD lining microcysts in PCK rats (fig4).

Conclusions: Metabolomic analysis identified fumarate as a potential mediator of cystogenesis in PKD. Accumulation of fumarate in PKD may be due to FH inhibition through upregulation of Nox4. Further experiments are needed to investigate the role of Nox4, FH and fumarate in PKD.



TH-PO587

Suppressing Interferon Regulatory Factor-5 Synthesis Attenuates Kidney Macrophages and Cytokines in Polycystic Kidney Disease Kurt Zimmerman,[3] Lan He,[1] Bradley K. Yoder,[3] Alexey Revenko,[2] Adam E. Mullick,[2] P. Darwin Bell,[1] Takamitsu Saigusa.[1] *[1]Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL; [2]Ionis Pharmaceuticals, Carlsbad, CA; [3]Cell Developmental and Integrative Biology, University of Alabama at Birmingham, Birmingham, AL.*

Background: Inflammatory cells are increased in both human and mouse models of polycystic kidney diseases (PKD). Interestingly, macrophages in the kidney may appear before significant cystic development and deleting phagocytic macrophages with liposomal clodronate has been reported to slow cyst formation. Interferon regulatory factor-5 (IRF5) is a transcription factor involved in activation of macrophage and cytokine release and maybe an effective target for therapeutic intervention. To determine the significance of IRF5 and macrophages in PKD, we tested an antisense oligonucleotide (ASO) that inhibits IRF5 in adult *Pkd1* mice.

Methods: Four week old adult *Pkd1* conditional floxed allele mice with or without cre were administered tamoxifen to induce cre. Two weeks after tamoxifen injection, mice underwent unilateral nephrectomy to accelerate cyst formation. After nephrectomy, mice were treated with weekly injection of either IRF5 ASO (40mg/kg/wk) or scrambled ASO for a total of 3 weeks. Kidneys were harvested for analysis at the end of the treatment.

Results: Three weeks following nephrectomy, *Pkd1*$^{-/-}$ mice showed early focal cyst formation/dilated tubules in the kidney. *Pkd1*$^{-/-}$mice treated with IRF5 ASO demonstrated significant reduction in level of kidney IRF5 mRNA compared to scrambled ASO treatment. Flow cytometry analysis of kidneys suggest that treatment with IRF5 ASO specifically reduces the number of infiltrating and resident macrophages but the level of neutrophils and T cells was unaffected by IRF5 ASO. IRF5 ASO compared to control ASO reduced kidney mRNA levels of pro-inflammatory cytokines.

Conclusions: These results suggest that suppressing IRF5 reduced both resident and infiltrating macrophages in early stage of PKD and may potentially become a novel therapeutic target in PKD.

TH-PO588

Cardiac Valvulogenesis Is Cilia Dependent and Exocyst-Mediated Ciliogenic Programs Are Conserved across Species and Organs Diana B. Fulmer,[1] Ben Fogelgren,[2] Katelynn A. Toomer,[1] Russell A. Norris,[1] Joshua H. Lipschutz.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]University of Hawaii, Honolulu, HI.*

Background: Polycystic kidney diseases such as ADPKD, Joubert, and Meckel's syndromes are associated with cardiac valve abnormalities. Our recent data show that primary cilia are expressed on developing, but not adult, cardiac valves and are required for normal valvulogenesis. Mutations in the highly-conserved, octameric exocyst complex disrupt ciliogenesis, and result in Joubert and Meckel's syndromes. Exoc5 is a central component of the exocyst, and shRNA-induced knockdown in Madin Darby canine kidney cells inhibits ciliogenesis, increases cell proliferation, and results in low intracellular calcium levels that do not increase in response to fluid flow, all without grossly affecting cell polarity. Conversely, Exoc5 overexpression, results in longer cilia with normal intracellular calcium levels and enhanced response to fluid flow. The exocyst participates in cilogenesis by trafficking vesicles carrying ciliogenic cargo proteins, such as polycystin-2, from the Trans-Golgi network to the membrane. The exocyst and its cargo are localized to the nascent cilium by interactions with Cdc42 and other docking proteins. We have shown altered cilogenesis and nephrogenesis, in both exoc5 zebrafish morphants and *Exoc5*$^{fl/fl}$ mice bred with a kidney-specific Cre. *Cdc42*$^{fl/fl}$ kidney-specific Cre mice also displayed a cystic phenotype.

Methods: Exoc5 zebrafish mutants, along with cardiac-valve specific knockout in mice were used.

Results: Zebrafish morphants and two distinct lines of *exoc5*$^{-/-}$ mutant zebrafish have cardiac edema and severe outflow tract stenosis, and we demonstrate rescue of these phenotypes with human *EXOC5* mRNA. We also found significant activation of the Hippo pathway in the *exoc5* mutant zebrafish, which has been previously linked by us and others to PKD. Furthermore, *Exoc5*$^{fl/fl}$ mice bred with cardiac valve-specific *NfatC1* Cre, have highly penetrant bicuspid aortic valve disease.

Conclusions: These data show that ciliogenic programs are conserved across species and organs, which helps to explain the association of cardiac valve abnormalities and PKD, and offer new animal models for future testing of therapeutic compounds.

TH-PO589

Neutralization of Programmed Death Ligand 1 Delays Cyst Growth in ADPKD Jacqueline D. Peda, Ekaterina Marilovtseva, Xiaoyan Li, James P. Calvet, Xiaogang Li. *Kidney Institute at the University of Kansas Medical Center, Kansas City, KS.*

Background: Interstitial inflammation plays a significant role in polycystic kidney disease (PKD). This inflammation features macrophages and other inflammatory cells, and cytokines released by these cells can be found in cyst fluid and urine. The Programmed Death 1 (PD1)/PD Ligand 1 (PDL1) pathway is a recent target for the treatment of multiple cancers. The upregulation of PDL1 on the surface of tumor cells due to immune infiltrates acts as a natural 'balance' to limit tissue-specific responses to inflammation, limiting T-cell mediated destruction. However, the roles and mechanisms of T-cells and PDL1 in underlying inflammation of ADPKD remain unknown

Methods: To evaluate a potential role of T-cells and PDL1 in cyst immunopathology, we investigated the presence of T-cells in cystic kidneys from *Pkd1*$^{flox/flox}$*:Pkhd1-Cre* knockout mice using FACS sorting and immunostaining. The expression of PDL1 in cystic renal epithelial cells and tissues was evaluated via immunostaining, protein and RNA expression. A PDL1 neutralizing antibody was used to evaluate its effects on cyst growth *in vivo*.

Results: We found that T-cells were present in higher levels in cystic kidneys and that they were localized to the interstitium surrounding cystic tissue. We also found that the expression of PDL1 mRNA and protein was increased in *Pkd1* mutant renal epithelial cells compared to control cells. Additionally, we detected PDL1 in kidneys of *Pkd1* conditional knockout mice, where it was primarily expressed in the cyst-lining epithelia derived from collecting ducts. The expression of PDL1 could be epigenetically regulated and enhanced in response to inflammatory cytokines in cystic renal epithelial cells. We further found that neutralizing PDL1 with a monoclonal antibody, which is well tolerated and currently being studied in late phase cancer trials, delayed cyst growth. This was reflected by decreased cystic index and kidney weight (KW)/body weight (BW) ratios in *Pkd1* conditional knockout mice compared to untreated mice. Effects on disease progression is likely due to blocking the PDL1 interaction with PD1 on T-cells.

Conclusions: This is the first report that T-cells are present in higher numbers in cystic kidneys when compared to controls, and that PDL1 is uniquely expressed in non-cancerous renal epithelial cells. Blockade of PDL1 interaction with T-cells may prove therapeutic in ADPKD.

Macrophage Depletion Leads to Temporal and Spatial Changes in miRNA Profiles That Drive Fibrosis in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Ameya P. Patil,[1,2] William E. Sweeney,[1] Cynthia G. Pan,[1,2] Ellis D. Avner.[1] *[1]Medical College of Wisconsin, Wauwatosa, WI; [2]Childrens Hospital of Wisconsin, Wauwatosa, WI.*

Background: In ADPKD, the decline in kidney function correlates with onset of fibrosis. Such fibrosis begins in peri-cystic areas (PA) between multiple cysts. Key factors involved in process of fibrosis include macrophages (Ø) at a cellular level and miRNAs at a molecular level. We hypothesize that localized changes in miRNA's and Ø phenotypes drive fibrosis in ADPKD, and provide potential targets for future therapeutic intervention.

Methods: Cystic kidneys from mcwPkd1$^{(nl/nl)}$ mice and age matched controls at postnatal days (PN) 21, 28, 42 and 56 were evaluated. These stages encompasses the disease process from maximum cyst growth and total kidney volume (TKV) at PN28 to dramatically reduced TKV due to fibrosis at PN56. Clodronate, which eliminates Ø, was administered from PN14 to PN56. FFPE fixed cystic kidneys at PN 56 following clodronate treatment were analyzed with serial sections for miRNA, mRNA analysis and trichrome (TriC) and compared to age-matched untreated cystic kidneys. Øs and Ø phenotypes were analyzed by flow cytometry, IHC and IF in serial sections and following clodronate treatment.

Results: Flow cytometry reveals significant increase in Øs from PN21 to PN28. At PN21, Øs located in PAs express predominantly INOS, a marker for M1 Øs. Between PN28 and PN56, Øs predominantly express arginase, a marker of M2 Øs. These findings correlate directly with increasing TriC staining in PAs and the decline in renal function. As expected, clodronate treatment :1) depleted Øs in both spleen and kidney; 2) resulted in significantly less TriC positivity; and 3) inhibited the decrease in TKV. miRNA analysis of serial sections in both treated and untreated cystic kidney showed a total of 158 miRNA's that were differentially expressed with 85 upregulated in treated kidneys. mRNA analysis on the same section was significant for differentially expressed AKT1 and EGF, 11 and 6.4-fold respectively.

Conclusions: (1) In this unique model of ADPKD; changes in Ø number and phenotype play a key role in fibrosis; (2) Changes in miRNA profiles after macrophage elimination with clodronate provide unique miRNA targets that may guide future therapeutic intervention; (3) This profile correlates with change in EGF and AKT which play critical roles in ADPKD.

TH-PO591

Gli1 Rescues the Angiogenic Potential of Polycystic Kidney Disease-Derived Endothelial Cells Federico Franchi, Karen M. Peterson, Ezequiel J. Tolosa, Peter C. Harris, Martin E. Fernandez-Zapico, Martin G. Rodriguez- Porcel. *Mayo Clinic, Rochester, MN.*

Background: We showed that Polycystic Kidney Disease (PKD)-derived Endothelial Cells (ECs) have a diminished response to the ligand-dependent activation of the Hedgehog (Hh) pathway, leading to an impaired angiogenic potential of these cells. We then hypothesized that restoring the activity of the Hh signaling by overexpressing GLI1, a central effector of this pathway, will ameliorate the vascular defects in PKD-ECs.

Methods: To assess the role of Gli1 in ECs, we knocked-down the expression of Gli1 (using siRNA) in WT-ECs and study their angiogenic profile. To restore function, we overexpressed Gli1 in PKD-ECs and measured the expression levels of pro-angiogenic markers (phenotype) and the capacity to form vascular structures (function).

Results: A 50% decrease in Gli1 mRNA expression was associated with a decrease in vascular endothelial growth factor A (VEGFA) expression, similar to that seen in PKD-ECs (Fig. 1A). Chromatin immunoprecipitation shows that the pro-angiogenic factors VEGFA and fibroblast growth factor 2 (FGF2) are direct targets of GLI1 in ECs. The overexpression of Gli1 in PKD-ECs led to a 740-fold increase in Gli1 mRNA expression. Importantly, exogenous Gli1 substantially restored the expression levels of the pro-angiogenic molecules VEGFA, VEGF receptor 1 (FLK1) and FGF2 (Fig. 1B), as well as the ability of PKD-ECs to form angiogenic tubes (Fig. 1C).

Conclusions: Our data suggest that a dysregulation in Hh signaling, and particularly of GLI1, may be responsible for the abnormal angiogenic profile seen in PKD-ECs. Furthermore, we provide evidence that Gli1 overexpression rescues the vascular deficiencies in PKD. These studies can be useful for the development of novel therapeutic strategies that focus on the vascular aspects of PKD.

Autophagy Induction in Mouse Kidneys Carolyn N. Brown, Sara Holditch, Charles L. Edelstein. *UC Denver Anschutz Medical Campus, Aurora, CO.*

Background: Autophagy occurs in all eukaryotic cells in order to adapt under stressful conditions. Damaged organelles and proteins are sequestered into autophagosomes, which subsequently fuse with lysosomes where cargo is degraded and recycled. The aim of the current study was to determine the effects of autophagy inducers metformin (MET), 2-deoxyglusoce (DOG), and trehalose (TRE) on autophagy in wild type (WT) and RC/RC (PKD) mouse kidneys *in vivo*.

Methods: WT and PKD mice were treated with MET (250mg/kg IP), DOG (100mg/kg IP), or TRE (2% P.O.) for 6-12 days. At the end of the study, mice received wither vehicle (VEH) or bafilomycin (BAF) (1.75mg/kg IP) to block autophagic flux. P62, an autophagy-specific tag for degradation and a marker of autophagy inhibition, and LC3-II, a marker of autophagome formation, were measured by immunoblot.

Results: WT Kidneys: Significantly reduced LC3-II was detected in the kidneys of MET and DOG mice compared to VEH, suggesting an increase in autophagosome turnover by the lysosome. This was supported by increased LC3-II in MET+BAF vs MET, and DOG+BAF vs DOG, which were notably larger than VEH+BAF vs VEH. TRE had modest effects on LC3-II. PKD Kidneys: LC3-II was increased after BAF treatment in both TRE and MET, but not DOG. Most importantly, in PKD kidneys, MET, DOG, and TRE cleared most p62 protein aggregates, which are characteristic of defective autophagy. Further studies will be performed in PKD kidneys to achieve statistical significance. ImageJ software was used for densitometry (Table 1).

Conclusions: In summary, MET and DOG were both able to successfully induce autophagy in WT and PKD kidneys. Autophagy plays an important role in maintaining kidney homeostasis, and PKD has been described as a case of suppressed autophagy. The effect of autophagy inducers on PKD progression merits further study.

TH-PO593

Lack of Alpha-Intercalated Cells Links Autosomal Dominant Polycystic Kidney Disease to Urinary Tract Infection in Mice and Humans Chao Gao,[3] Long Zhang,[3] Lihe Chen,[4] Ye Zhang,[1] Enuo Chen,[2] Darren P. Wallace,[5] Qiaoling Zhou,[6] Paul J. Higgins,[2] Wenzheng Zhang.[2] *[1]AMC, Albany, NY; [2]Albany Medical College, Albany, NY; [3]Albany medical college, Albany, NY; [4]NIH, Bethesda, MD; [5]University of Kansas Medical Center, Kansas City, KS; [6]Xiangya Hospital, Changsha, China.*

Background: Urinary tract infection (UTI) is a common feature of autosomal dominant polycystic kidney disease (ADPKD) with ~30-50% of ADPKD patients having at least one UTI during their lifetime. However, the underlying cellular and molecular mechanisms linking ADPKD to UTI remain unaddressed.

Methods: Hence, *Pkd2$^{f/f}$ Aqp2Cre* mice were generated to disrupt *Pkd2* in Aqp2$^+$ progenitor cells, which give rise to all known cell types of the connecting tubule/collecting duct (CNT/CD).

Results: *Pkd2$^{f/f}$ Aqp2Cre* mice developed severe PKD and died by P17. Double and triple immunofluorescence (IF) staining for various segment- and/or cell-specific markers were conducted. At least 1000 CNT/CD cells from 3 *Pkd2$^{f/f}$ Aqp2Cre* and 3 WT mice for each IF combination were categorized and counted based on the marker expression. Using Aqp2, V-ATPase B1B2 and AE1 as markers for principal cells (PC), intercalated cells (IC) and a-IC, respectively, we found that *Pkd2$^{f/f}$ Aqp2Cre* mice had a reduced IC/PC ratio from 37.61±1.23% in WT to 7.45±1.08% and completely lost a-IC at P17. Neutralized urine from *Pkd2$^{f/f}$ Aqp2Cre* mice is significantly less inhibitory for bacterial growth than that from WT mice. In P6 *Pkd2$^{f/f}$ Aqp2Cre* mice, cysts began to be detectable with occasional presence of a-IC. TUNEL assay showed that IC, particular a-IC, were more apoptotic than PC. We conducted the same IF with kidneys from ADPKD patients (n=27) and minimal change disease patients (MCD) as normal control (n=5). While all PC and IC markers were readily detectable in each of MCD samples, cysts containing AQP2$^+$ cells were found only in 13 ADPKD samples. Among these 13 ADPKD samples, we counted >4000 CNT/CD cells and found that ADPKD diminished the IC/PC ratio from 26.07±6.19% in MCD to 10.12±6.53%. None of the ADPKD kidneys had AE1$^+$ cells in Aqp2$^+$ labeled cystic structure. Seldom AE1$^+$ cells were observed in apparently normal CNT/CD of some ADPKD kidneys.

Conclusions: Our data suggest that *Pkd2* deletion in Aqp2$^+$ progenitor cells is sufficient for PKD development, and a-IC are selectively depleted with the disease development in both mice and human. The lack of a-IC to acidify urine and secret neutrophil gelatinase-associated lipocalin (NGAL) that chelates siderophore-containing iron may link ADPKD to UTI.

A Mouse Model of Tsc Renal Cystic Disease John J. Bissler,[2] Kamyar A. Zahedi,[1] Sharon L. Barone,[1] Manoocher Soleimani.[1] *[1]University of Cincinnati, Cincinnati, OH; [2]University of Tennessee, Le Bonheur Children's Hospital and St. Jude Children's Research Hospital, Memphis, TN.*

Background: Tuberous sclerosis complex (TSC) renal cystic disease affects over 500,000 patients world-wide. There are five patterns of TSC-associated renal cystic disease, and they are the macrocystic diseases including polycystic, cortical cystic, multicystic, focal cystic diseases, and microcystic disease. The cysts can have a simple single cellular layer, have a multiply layer or even papillary histology. Although the basic histology has been described, the cystogenic mechanism in TSC is poorly understood.

Methods: To begin to better understand this cystic disease process, we created a mouse model of TSC renal cystic disease by targeting principle cells by using aquaporin 2-driven Cre recombinase expression to delete the floxed *Tsc2* gene. Double immunofluorescence labeling was performed to determine the identity of cyst epithelium.

Results: In this cell specific model, we identify the similar histological characteristics of the renal cystic epithelium as occurs in the human. Interestingly, the cyst epithelium was predominantly comprised of intercalated cells as determined by intense and uniform apical expression of H+-ATPase in both mouse and human. There was no expression of AQP-2, NHE-3, NBC-e1, NCC or Na-K-ATPase, indicating the absence of principal, proximal tubule, distal convoluted and thick ascending limb epithelial cells in the cyst wall. The cysts in human and mouse also exhibited a significant decrease in cilia expression.

Conclusions: We have developed a mouse model that resembles human TSC-associated renal cystic disease. This TSC renal cystic disease in both the mouse model and human exhibits significant histolopathological differences compared to other renal cystic

diseases. These differences raise the possibility that therapies like V_2 receptor antagonism may not have similar efficacy.

Lessons from Pkd1 Therapeutic Targeting Strategies in a Loss-of-Function Mouse Model Camila Parrot, Almira Kurbegovic, Jennifer Lake, Guanhan Yao, Marie Trudel. *Institut de Recherches Cliniques de Montréal, Montréal, QC, Canada.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) causes renal and extrarenal phenotypes. The PKD1 gene responsible for most cases of ADPKD has a developmentally and temporally regulated expression pattern. While CRISPR-Cas as a therapeutic strategy for PKD is attractive, the high frequency of off-targets preclude clinical application. Because microscopic cysts below clinical detection are likely formed *in utero* in ADPKD kidneys (Grantham et al CJASN 2010,2012), we targeted *Pkd1* at early stage in mouse model to assess for long-term treatment. *Pkd1* null mouse model that display severe renal cysts and die by birth, were used to assess whether wild type Pc1 from 2 series of transgenic lines prevent cyst formation.

Methods: One mating overexpressing Pc1 was generated with 2 systemic $Pkd1_{TAG}$ mouse lines and the second with 2 renal-specific $SBPkd1_{TAG}$ mice. RNA and proteins in kidneys and pancreas were assessed along with histomorphologic and cellular longitudinal analysis.

Results: $Pkd1^{-/-}$ mice crossed into each of the $Pkd1_{TAG}$ transgenic lines escaped perinatal lethality. These mice exhibit no renal or pancreatic phenotypes in the first few months of age. Thus, the $Pkd1_{TAG}$ transgene produced a functional protein with proper transgene regulation. $Pkd1_{TAG}$;$Pkd1^{-/-}$ mice at >8mo developed however renal cysts but milder than the parental transgenic line consistent with their Pkd1 overexpression and a gene-dosage pathogenic mechanism. $Pkd1^{-/-}$ mice mated to $SBPkd1_{TAG}$ renal specific expressors avoided neonatal death but consistently, developed renal (kidney/body weight 2.3 fold that of normal mice) and pancreatic cysts. Despite Pc1 ~7 and 15-fold overexpression, deaths occur at P10-P15 with the mild Pc1 expressor and ~3 mo in the high expressor, indicating that renal cysts likely result from differential tubular response: insufficient expression and/or overexpression of Pc1. Collectively, these results demonstrate that early Pc1 expression can delay cystogenesis and extend mouse lifespan, and revealed that Pc1 re-expression requires highly controlled spatiotemporal regulation.

Conclusions: Maintenance of tightly regulated PKD1/PC1 expression will be a major clinical challenge as PC1 expression varies between renal cell types and age. Presently, targeting PC1 in ADPKD is a double-edge sword and cannot practically serve as a useful therapeutic target.

Compound-Homozygous Pkd1 and Pkd2 Inactivation Has No Additive Effect on Cyst Formation Xin Tian, Yiqiang Cai, Ming Ma, Chao Zhang, Whitney E. Besse, Ashima Gulati, Stefan Somlo. *Yale University School of Medicine, New Haven, CT.*

Background: Autosomal dominant polycystic kidney disease results from mutations in PKD1 or PKD2. The two genes work together in a common signaling pathway in which PKD1 is the rate limiting step. We previously showed an extra-additive increase in cystogenic events in Pkd1+/-;Pkd2+/- mice that may result from a modified threshold effect. In the current study, we examined whether there is a similar effect with conditional homozygous inactivation of both genes in mouse kidney collecting ducts.

Methods: We generated Pkd1fl/fl;Pkd2fl/fl;Pkhd1Cre mice which inactivate both genes in collecting ducts by postnatal day 7 (P7). Pkd1fl/fl;Pkd2fl/fl;Pkhd1Cre mice (n=7), Pkd1fl/fl;Pkhd1Cre mice (n=8) and Pkd2fl/fl;Pkhd1Cre mice (n=7) were examined at P14, P24 and P48.

Results: Histological and functional examination of kidneys from Pkd1fl/fl;Pkd2fl/fl;Pkhd1Cre mice at P14 and P24 showed no significant difference in kidney-body weight ratio (KW/BW), cystic index (CI) and BUN when compared with Pkd1fl/fl;Pkhd1Cre mice. When compared with Pkd2fl/fl;Pkhd1Cre mice, both groups had statistically significant increase in KW/BW ($P<0.05$), CI ($P<0.05$) and BUN ($P<0.05$) at both time points. At P48, multiple comparison showed no significant differences in any parameter among the three groups. We also documented normal appearance of cilia by immunofluorescence microscopy in the cyst lining cells of Pkd1fl/fl;Pkd2fl/fl;Pkhd1Cre mice. There was no significant difference in cyst cell proliferation by BrdU incorporation and apoptotic activity by TUNEL between Pkd1fl/fl;Pkd2fl/fl;Pkhd1Cre mice and Pkd1fl/fl;Pkhd1Cre mice at P14, P24 and P48. However, both these groups had significantly higher cell proliferation rates when compare to Pkd2fl/fl;Pkhd1Cre mice at P14 ($P<0.05$). Notably, all three groups has significantly increased apoptosis at P48 when compared to P24 and P14.

Conclusions: Dual inactivation of Pkd1 and Pkd2 shows no additive effect on cyst formation but early stage inactivation of Pkd1 results in more rapid cyst growth than inactivation of Pkd2, likely due to longer persistence of the Pkd2 protein. Late stage models show genotype-independent increase in apoptosis.

TH-PO597

Disruption of Ca2+-Binding in the EF-Hand Domain of Polycystin-2 Does Not Result in a Cystic Phenotype Matteus Krappitz, Ke Dong, Sorin V. Fedeles, Rachel Gallagher, Yiqiang Cai, Stefan Somlo. *Yale University School of Medicine, New Haven, CT.*

Background: Polycystin-2 (PC2/TRPP2), the product of one of the genes mutated in ADPKD, is expressed in the endoplasmic reticulum (ER) and ciliary membranes. The COOH-terminal tail of PC2 contains 2 potential Ca^{2+} binding EF hand motifs, an ER retention domain and a coiled-coiled domain. Only the second EF hand motif can bind Ca^{2+}. It has been proposed that a mutation in this EF hand abrogates Ca^{2+} binding which leads to a substantial reduction of channel function resulting in decreased inward Ca^{2+} currents conducted by PC2. This study investigates the relevance of abolishing the Ca^{2+} binding properties of the EF-hand domain in PC2 by generating a mouse model mutated at critical residues.

Methods: CRISPR/Cas9 methodology was used to generate a mouse model termed $Pkd2^{TEAA}$, in which critical residues at the EF hand *–z, –x* coordination vertices were substituted with alanine (T769A, E772A) to eliminate Ca^{2+} binding. Mutant alleles were further modified by insertion of a V5 epitope tag in-frame at the C-terminus.

Results: The animals were aged up to 18 months. All organs were extracted and analyzed. The kidney and livers were examined by measuring kidney weight (KW) and liver weight (LW) as a fraction of body weight (BW) and by detailed histological examination. Expression of the mutated protein in the kidney was confirmed by immunoblot analysis with anti-V5. Homozygous $Pkd2^{TEAA/TEAA}$ animals survive up to and past 18 months of age with no histological signs of cystic disease in either kidney or liver. There was no significant difference in BW, KW or LW between wild type, $Pkd2^{TEAA/TEAA}$ or $Pkd2^{+/-}$ animals at the same age. The $Pkd2^{TEAA/+}$ mice were crossed with $Pkd2^{+/-}$ animals to generate $Pkd2^{TEAA/-}$ mice. These mice also did not display a kidney or liver cystic phenotype at 9 months of age.

Conclusions: Inactivation of the Ca^{2+}-binding properties of PC2-EF hand does not result in a significant loss of PC2 function as evidenced by the lack of cystic disease phenotype in the kidney and livers of the $Pkd2^{TEAA/TEAA}$ and $Pkd2^{TEAA/-}$ animals. This suggests that the PC2 channel does not require EF-hand Ca^{2+} binding in order to function in vivo.

TH-PO598

mTORC2 (Rictor) Knockout Decreases the Cystic Phenotype in Pkd1-/- Mice Sara Holditch,[1] Carolyn N. Brown,[1] Kameswaran Ravichandran,[2,1] Charles L. Edelstein.[1] *[1]UC Denver Anschutz Medical Campus, Aurora, CO; [2]Hera BioLabs, Lexington, KY.*

Background: mTOR exists in two distinct structural and functional complexes mTORC1 (Raptor) and mTORC2 (Rictor-Rapamycin-independent companion of mTOR). We have shown that mTOR kinase inhibition, capable of inhibiting both Raptor and Rictor, reduces cyst growth. However, the effect of mTORC2 (Rictor) inhibition alone on PKD is not known. The aim of our study was to determine the effect of $Rictor^{-/-}$ on the cystic phenotype of $Pkd1^{-/-}$ mice.

Methods: Expression of kidney specific Cre recombinase, with Tamoxifen administration on days 19-21, in Pkd1 fl/fl mice results in $Pkd1^{-/-}$ mice that have a slow onset of cystic disease with severe PKD and renal failure at 130 days post tamoxifen injection. To determine if the effect of $Rictor^{-/-}$ on the cystic phenotype of $Pkd1^{-/-}$mice, Rictor fl/fl mice were bred with the Pkd1 fl/fl; KspCad-CreERT2 mice to develop Rictor fl/fl, Pkd1 fl/fl; KspCad-CreERT2 mice treated with tamoxifen to develop kidney-specific $Rictor^{-/-}Pkd1^{-/-}$ mice and aged to 150 days post Tamoxifen. Non-invasive quantitative assessment of cyst development per kidney at 90 days, a time when nascent cysts are forming, was performed by T2-weighted and FISP-MRI at 4.7 Tesla.

Results: Genetic deletion of mTORC2 (Rictor) in $Pkd1^{-/-}$mice results in significantly lower kidney weight, cyst volume, number of cysts and SCr. (See Table)

Conclusions: Study of signaling pathways downstream of mTORC2 (pAkt, SGK1, PKCα) and a head to head study of sirolimus (Raptor inhibitor) VS. new generation mTOR kinase inhibitors (inhibit both Raptor and Rictor) is warranted to better understand the pathways responsible for PKD cyst expansion.

Anks6-/- Mice Have Laterality Defects and Develop Renal Cystic Disease Rannar Airik,[2,3] Merlin Airik,[1] Nathan A. Herdman.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Pediatrics, University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]Developmental Biology, University of Pittsburg, Pittsburgh, PA.*

Background: Nephronophthisis-related ciliopathies (NPHP-RC) are a group of heterogeneous recessive kidney diseases, that are frequently associated with extra-renal organ malformations. Recently mutations in the ankyrin repeat and sterile alpha motif domain containing 6 (ANKS6) gene were identified, as causing nephronophthisis with extrarenal manifestations in humans (1). Anks6 localizes to the inversin compartment (INVS, NEK8, NPHP3) in the primary cilium, where it regulates the activity of NEK8 kinase (2). In order to study the function of Anks6 in mouse we generated an Anks6 transgenic mouse model.

Methods: Targeted Anks6 ES cells were obtained from KOMP and injected into blastocysts to generate the *Anks6*$^{-/-}$ mice. Loss of Anks6 expression in the mutant animals was confirmed by immunoblotting. Anks6 tissue expression in the kidneys was studied using X-gal staining and in situ hybridization. Gross morphological characterization and tissue histological analysis of the mutant mice was performed at E15.5, E18.5 and P0.

Results: Inactivation of Anks6 causes perinatal lethality in mice due to multiorgan abnormalities. Homozygous Anks6 mutant mice displayed situs inversus, with morphogenesis defects of the heart, lungs, liver and kidneys. Histological and molecular analysis of the kidneys revealed a defect in nephrogenesis that we localized to the glomerulus and proximal tubles in the mutant animals. In kidneys the mutant mice developed glomerular cystic disease.

Conclusions: Our data demonstrate that abrogation of Anks6 in mice leads to laterality and developmental defects in multiple organs, which resemble the phenotypes of mouse models for other inversin compartment components. Homozygous mutant mice recapitulate the major features of loss of ANKS6 function in humans, including liver fibrosis, cystic kidney disease and situs inversus. Together, Anks6$^{-/-}$ mouse represents a novel genetic model of NPHP-RC.

TH-PO600

A Systems Biology Approach Identifies Reciprocal Changes in mir-193b-3p and PIK3R1 as Drivers of Cyst Growth in ADPKD Laura Vergoz,[2] Andrew J. Streets,[2] Tareq B. Malas,[1] Morgane Lannoy,[2] Peter A. 't Hoen,[1] Dorien J. Peters,[1] Albert C. Ong.[2] *[1]Leiden University Medical Center, Leiden, Netherlands; [2]University of Sheffield, Sheffield, United Kingdom.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited cause of end-stage renal disease worldwide. *PKD1* and *PKD2* mutations are present in most patients with clear genotype-phenotype correlations. However, the intra-familial phenotypic variability in some pedigrees suggests the influence of non-allelic factors. Non-coding RNAs e.g. microRNAs are known to play a major role in health and disease (including PKD) via control of mRNA stability or translation. We recently conducted a parallel mRNA/miRNA array study which found mir-193b-3p, among others, downregulated in human ADPKD cells (Streets et al, 2017), associated with dysregulation of the ErbB4/EGF pathway.

Methods: To select other relevant genes regulated by mir-193b-3p, we compared our human mRNA dataset with mRNA expression data from *Pkd1* mutant mice (Malas et al, 2017). Dual-reporter luciferase assays with native and mutant seed sequences and immunoblotting were used to demonstrate functional binding of mir-193b-3p to the 3'UTR of *PIK3R1* mRNA. IGF-1 stimulation of human ADPKD cystic cells in 2D and 3D cultures characterized the role of *PIK3R1* in Akt or ERK signaling and on cyst growth.

Results: *PIK3R1* was selected as a strong candidate gene and shown to be upregulated ~3-fold in human cells and mouse *Pkd1* kidney tissue. In parallel, the catalytic subunit *PIK3CA* was also overexpressed suggesting the most common PI3K enzyme combination is upregulated in ADPKD cells. A functional interaction between *PIK3R1* and mir-193b-3p was confirmed by luciferase assays and immunoblotting. Knockdown of *PIK3R1* or PI3K chemical inhibitors significantly reduced cyst growth in ADPKD cells and influenced Akt and ERK activation by IGF-1.

Conclusions: We report that *PIK3R1* and one of its catalytic subunits are upregulated in ADPKD and confirm that it is a target for mir-193b-3p. The role of *PIK3R1*/*PIK3CA* in driving cyst growth in ADPKD was functionally linked to hyperactivation of Akt and ERK. Co-regulation of *PIK3R1* and *ErbB4* by mir-193b-3p supports the development of PI3K and ErbB4 inhibitors or mir-193b-3p activators for the treatment of ADPKD.

Anks3 Knockout in Rats Causes Prenatal Lethality Due to Major Disturbances in Organ Patterning Euan Clark,[3] Stamatia Matina Papagiannarou,[1] Christian Gosmann,[8] Hermann-Josef Groene,[4] Gergana D. Dobreva,[7] Brigitte Lelongt,[5] Dominique Gauguier,[6] James Bowie,[2] Sigrid C. Hoffmann.[3] *[1]Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; [2]University of California, Los Angeles, Los Angeles, CA; [3]Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; [4]German Cancer Research Center, Heidelberg, Germany; [5]UMR_S1155, PARIS, France; [6]INSERM, Paris, France; [7]Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; [8]Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany.*

Background: Anks3 was first discovered as a novel interacting partner of Anks6. The Anks6^{R823W} mutation disrupts binding to Anks3 and causes dominant polycystic kidney disease (ADPKD) in rats. Though its function remains obscure, Anks3 involvement in nephronophthisis was suggested. The present study aimed to study the consequences of a total Anks3 knockout (Anks3KO) in rats.

Methods: Anks3KO rats were generated by injection of a gRNA targeting the second exon of Anks3 (aa5-12) and Cas9 mRNA into fertilized Sprague Dawley rat zygotes. Rats were genotyped by sequencing the amplified targeted region. RT-PCR and Western blotting were used to prove loss of Anks3. We determines clinical parameters in 24-hr urine and blood plasma to evaluate renal function Histological analysis was performed by standard techniques.

Results: Founders were obtained carrying either a 5bp or an 8bp deletion at the targeted position, which resulted in a premature translational stop at positions aa46 and aa45 respectively, and were used for breeding. Among 82 progenies, 39% were genotyped as wildtype and 61% as heterozygotes. Homozygous Anks3KO rats frequently died in mid-gestation and never survived birth. They exhibited a complex pattern of disturbances in organ patterning including defects in cortex and midbrain development, craniofacial defects, focal hemorrhages and complex structural heart defects. Kidney size was often recduced and associated with abnormal glomerulogenesis and tubulogenesis. Heterozygous Anks3 +/- rats survived and developed mild kidney abnormalities when aged, including small medullary cysts and fibrosis in the cortico-medullary renal border. Urine production was significantly less in Anks3 +/- rats compared to WT littermates. However, Anks3KO rats never developed an ADPKD-like phenotype, as seen in Anks6^{R823W} rats.

Conclusions: Conclusion: Here we provide the first evidence that Anks3KO in mammals causes major, lethal developmental disturbances in organ patterning, similarly to heterotaxy mutants with cilia defects, and a nephronophthisis like phenotype in heterozygous adults. We conclude that Anks3 might be a major factor in regulating ciliary function and controls urine concentration. *This study was supported by the grant of the NIH (5RO1DK100482) to JB and SH*

TH-PO602

Effects of Moderate and High Intensity Chronic Exercise on Renal Function in PCK Rats of Polycystic Kidney Disease Jiahe Qiu,[1] Takahiro Miura,[1] Sato Yoichi,[1] Masahiro Kohzuki,[1] Osamu Ito.[2] *[1]Department of Internal Medicine and Rehabilitation Science, Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Division of General Medicine and Rehabilitation Faculty of Medicine, Tohoku Medical and Pharmaceutical University, Sendai, Japan.*

Background: Polycystic Kidney Disease (PKD) is a genetic disorder characterized by progressive enlargement of epithelial cysts, leading to destruction of renal function and which is a major cause of chronic kidney disease. We have previously shown that chronic exercise exerts beneficial effects including renal protection in hypertensive, diabetic and 5/6-nephrectomized rats. Therefore, we assessed the effects of moderate and high intensity chronic exercise on renal function in the PCK rat model of PKD.

Methods: Six-week-old, male PCK rats were divided into three groups: sedentary group (Sed, n=10), moderate exercise group (Exm, n=9) and high intensity exercise group (Exi, n=10). Exm and Exi underwent forced treadmill exercise for 12 weeks with the following protocols: 20m/min and 28m/min respectively for 60 min/day, 5 days/week. At the end of experiment, the blood and urine was collected and the kidney were removed. Cyst Area/Total Kidney Area ratio and podocyte injury index were examined.

Results: The present research showed the body weight (504.1±8.4 vs.431.8±7.9 and 433.6±4.3g) and total kidney weight (5.34±0.27 vs.4.22±0.41 and 4.20±0.06g) was significantly lower in both Exm and Exi compared with Sed after 12-week protocol of exercise. The kidney/body weight ratio had a declining tendency but not significant different between the groups. The urine volume(18.0±1.2 vs.13.1±0.9 and 13.0±0.8ml/day), urinary protein excretion (1426±120 vs.537±50 and 452±77mg/day) and blood urea nitrogen (18.2±0.9 vs.15.4±0.4 and 15.9±0.3mg/dL) also had remarkable decrease in both Exm and Exi compared with Sed. The result of serum creatinine had a declining tendency in both exercise groups. As demonstrated by the data, exercise alleviated cyst formation in PCK rats. The Cyst Area/Total Kidney Area ratio had significant decrease in the both exercise groups (30.2±3.4% vs.14.5±1.0% and 17.3±1.3%). The staining of desmin positive staining area in glomeruli as a marker of podocyte injury also had a descending tendency after the chronic exercise.

Conclusions: Both moderate and high intensity chronic exercise significantly decreased cystic area in PCK rats, which also have beneficial effects on attenuating the urinary protein excretion and preventing podocyte injury in this model of PKD.

TH-PO603

Inhibition of PLK1 Delays Cyst Growth in Autosomal Dominant Polycystic Kidney Disease Xia Zhou, Guangqiang Ma, Xiaoyan Li, James P. Calvet, Xiaogang Li. *University of Kansas Medical Center, Kansas City, KS.*

Background: The G2/M DNA damage checkpoint serves to prevent the cell from entering mitosis with genomic DNA damage. G2-phase transition is dependent on the activity of the Cyclin B-cdc2 complex which is regulated by CDC25 phosphatases, CDC25B and CDC25C. Polo-Like Kinase 1 (PLK1) is a major kinase with pivotal roles in multiple aspects of cell division (mitosis) by activating CDC25. However, the roles of PLK1 and CDC25B/C in cystogenesis in ADPKD remain elusive.

Methods: To understand dysregulated signaling pathways in cystic kidneys, we performed RNA-seq and Ingenuity Pathway Analysis (IPA). To explore the roles of PLK1 and CDC25B in regulating cyst growth, we targeted PLK1 in *Pkd1* mutant cells and mice with a PLK1 inhibitor volasertib.

Results: We found that DNA damage response was increased in *Pkd1* mutant PN24 cells and kidneys of *Pkd1*$^{flox/flox}$*:Tamoxifen-Cre* mice by phospho-H2AX staining. Our RNA-seq and IPA analysis indicated that the genes related to the cell cycle G2/M DNA damage checkpoint regulation pathway, including PLK1, CDC25B and CDC25C, were upregulated and activated in cystic kidneys compared to those in wild type kidneys. The upregulation of PLK1, CDC25B and CDC25C was confirmed by qRT-PCR, western blot and immunohistochemistry (IHC) staining in cystic kidneys versus controls. Treatment with the PLK1 inhibitor volasertib and the CDC25 inhibitor NSC663284 decreased cystic renal epithelial cell proliferation as examined by MTT assay. We also found that volasertib treatment increased the expression of p21, phospho-CDK2, active caspase 3, and cleaved PARP expression, and decreased the phosphorylation of ERK, S6 and Rb in PN24 cells. Furthermore, treatment with volasertib delayed cyst growth in *Pkd1* conditional knockout mice. Volasertib treatment decreased cyst lining epithelial cell proliferation as examined by PCNA and Ki67 staining, decreased the phosphorylation of ERK, S6, STAT3 and Rb, but increased cyst lining epithelial cell apoptosis as examined by TUNEL assay in cystic kidneys.

Conclusions: The cell cycle G2/M DNA damage signaling pathway is dysregulated in ADPKD. Inhibition of PLK1 produces a potent anti-proliferative and pro-apoptotic effect, regulates the known PKD associated pathways in cystic renal epithelia, and delays cyst growth *in vivo*, which suggests that targeting PLK1 may be a potential therapeutic strategy for ADPKD treatment.

Effects of Smoking on Pkd1-Deficient Cystic Mice: An Extended Study on the Renal and Cardiac Phenotypes Marciana V. Sousa,[1] Andressa G. Amaral,[1] Bruno E. Balbo,[1] Fernanda S. Messias,[1] Marcelo D. Melo,[2] Renato A. Hortegal,[2] Isac D. Castro,[1] Vera M. Salemi,[2] Luiz F. Onuchic.[1] *[1]Nephrology and Molecular Medicine, University of Sao Paulo, Sao Paulo, Brazil; [2]Cardiopneumology, University of Sao Paulo, Sao Paulo, Brazil.*

Background: Previous studies have shown that heavy smoking increases the risk of advanced chronic kidney disease and that smoking raises the risk of progression to ESKD in men with ADPKD.

Methods: Cystic *Pkd1*$^{flox/flox}$*:Nestin*^{cre} and noncystic *Pkd1*$^{flox/flox}$ mice were exposed to cigarette smoking (CYS and NCS, respectively) from conception to 18 weeks of life, twice a day, 30-min periods. Control groups also included cystic and noncystic mice not submitted to smoking (CY and NC, respectively). Renal function, cystic index and cell proliferation; cardiac function, including deformation (strain); body weight (BW); and kidney and heart apoptosis, fibrosis and weight were analyzed at 16-18 weeks.

Results: We showed in a 2016 ASN abstract that BUN was higher in CYS mice than CY and NC, and in NCS than NC, while no difference was detected between CYS and NCS. CYS kidneys developed increased cystic index, cell proliferation in cyst epithelium and fibrosis compared to CY. Higher tubular cell proliferation and fibrosis were found in NCS kidneys than NC. CYS animals had lower BW than CY and NC. In the present work we show increased apoptosis in CYS kidneys compared to NCS and NC, and in CY and NCS compared to NC. Renal weight/BW was higher in CYS mice than NCS and NC but not than CY. Cardiac apoptosis and heart weight/BW did not differ among the groups. Increased fibrosis was found in CYS hearts compared to NCS [1.10% (0.79-2.95) *vs* 0.26% (0.15-0.45), $p<0.05$] and NC ($p<0.01$), and in CY hearts compared to NC [0.82% (0.64-1.60) *vs* 0.21% (0.09-0.38), $p<0.05$]. Left ventricle ejection fraction was lower in CYS mice than NCS (35.6±15.1% *vs* 49.5±11.1%, $p<0.05$) and NC (*vs* 52.3±9.5%, $p<0.01$). CYS animals showed decreased circumferential strain and strain rate compared to CY, NCS and NC; lower values were also found in CY compared to NC. CYS and CY mice presented lower radial strain on the short axis than NC. Radial strain rate on the short axis and longitudinal strain were decreased in CYS and NCS animals in comparison to NC.

Conclusions: Our findings show that smoking worsened the renal and cardiac phenotypes of *Pkd1*-deficient cystic mice. Detrimental effects also affected noncystic animals. Our results suggest that smoking aggravates the kidney and heart phenotypes associated with ADPKD.

TH-PO605

CMV Infection as a Trigger for APOL1-Associated Collapsing FSGS in Renal Allograft Leigh-Anne Dale,[3] Syed A. Husain,[3] Jae Hyung Chang,[3] Russell J. Crew,[1] David J. Cohen,[2] Mariana C. Chiles,[3] Yifu Li,[2] Ali G. Gharavi,[2] Sumit Mohan.[2] *[1]Columbia University, New York, NY; [2]Columbia University, New York, NY; [3]Columbia University Medical Center, New York, NY.*

Background: Apolipoprotein L1 gene (APOL1) risk alleles are associated with increased risk of focal segmental glomerulosclerosis (FSGS) in patients with 2 risk alleles (G1 or G2) compared to those with at least 1 wild type allele (G0). The mechanisms of APOL1-mediated renal disease remain unclear. While 13% of African Americans (AA) carry two APOL1 risk alleles and only a minority of these individuals develop kidney disease, this appears to contribute to inferior allograft outcomes with kidneys transplanted from AA donors. We present 2 cases of FSGS in transplanted kidneys from a donor with 2 APOL1 risk alleles.

Methods: The donor was a 57-year-old AA man with a history of hypertension who died from a stroke. Recipient 1 was a 47-year-old AA woman with diabetes-associated end stage renal disease (ESRD). Post-reperfusion biopsy was notable for mild focal global glomerulosclerosis. Post-operative course was notable for delayed graft function (DGF), and a nadir creatinine (SCr) of 1.6mg/dL. She subsequently developed proteinuria (6.7g/g) and elevated SCr (3.7) 7 months post-transplant in the setting of a diarrheal illness secondary to cytomegalovirus (CMV) infection. Viremia cleared with reduced immunosuppression. Repeat biopsy for persistent proteinuria showed tubular injury, and collapsing FSGS that led to allograft failure 18 months post-transplant. Recipient 2 was a 64-year-old Caucasian woman with ESRD from polycystic kidney disease. Post-operative course was notable for DGF, with a nadir SCr of 1.3mg/dL. She developed CMV viremia and colitis 12 months post-transplant that was followed by SCr rising to 2.9mg/dl with 7.6g/g proteinuria. Renal biopsy showed acute tubular injury and collapsing FSGS. Viremia cleared after mycophenolic acid was discontinued and ganciclovir was initiated. Allograft failed 14 months after transplant. While both the donor (G1/G1) and recipient 1 (G1/G1) had 2 APOL1 risk variants, recipient 2 (G0/G0) did not have any risk alleles.

Results:

Conclusions: This suggests that the genetic susceptibility for APOL1-related lesions is linked to the presence of donor risk alleles. Additionally, CMV infection appears to be a second hit resulting in the development of collapsing FSGS after transplant in kidneys with 2 risk alleles.

TH-PO606

A Girl with a Mutation of the Ciliary Gene CC2D2A Presenting with FSGS and Nephronophthisis Kazuya Matsumura,[1] Nariaki Asada,[1] Akinori Hashiguchi,[2] Kenjiro Kosaki,[3] Midori Awazu.[1] *[1]Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan; [2]Department of Pathology, Keio University School of Medicine, Tokyo, Japan; [3]Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan.*

Background: It has been reported that mutations in the ciliary gene *TTC21B* and *NPHP4* cause familial FSGS. We report a girl with a mutation of the ciliary gene *CC2D2A* presenting with FSGS and nephronophthisis.

Methods: The patient is a 6-year-old girl with mental retardation, postaxial polydactyly, and ataxic breathing. She was diagnosed as having compound heterozygous *CC2D2A* missense mutation at age 5. In retrospect, azotemia at 1 year and proteinuria at 5 years were recorded but unnoticed at local hospitals. At age 6, she was referred to pediatric nephrology service. Height was 106 cm (-1.5 SD), weight 12.6 kg (-2.3 SD), and BP 116/53 mmHg (>95th percentile). She had pretibial pitting edema. Urinalysis showed protein 3+, blood 2+, granular cast +, protein to creatinine ratio (pro/Cr) 6.6 g/gCr, ß2 microglobulin 112 μg/l, NAG/Cr 33 U/gCr, and selectivity index 0.09. Blood test revealed Hb 13.2 g/dl, UN 23.2 mg/dl, Cr 0.56 mg/dl (eGFR 66 ml/min/1.73 m^2), cystatin C 1.34 mg/l, total protein 5.3 g/dl, albumin 2.4 g/dl, cholesterol 317 mg/dl, and uric acid 7.5 mg/dl. Serologic tests for glomerulonephritis were negative. Ultrasonography showed normal-sized kidneys with a cyst in the right. Losartan was started for hypertension and proteinuria. Open renal biopsy was performed. On light microscopy, 8 out of 24 glomeruli were globally sclerosed, and 3 showed segmental sclerosis or hyalinosis. Mild tubular dilatation, tubular atrophy, and interstitial fibrosis were observed. No immune deposits were seen. On electron microscopy, glomeruli showed foot process effacement with no electron dense deposits. Since losartan did not exert an obvious effect, treatment with prednisolone was tried. Urine pro/Cr decreased to 3.7 g/gCr, but prednisolone was discontinued after 10 days because she developed duodenal ulcer perforation that necessitated omentoplasty. CT scan performed then showed bilateral multiple cysts in the kidney. Since then she had been treated with losartan and dipyridamole. Her renal function rapidly deteriorated. Current serum creatinine is 2.6 mg/dl with urine pro/Cr 13 g/gCr.

Results:

Conclusions: Based on the clinically overt nephrotic syndrome and foot process effacement, FSGS in this patient was thought to be due to podocytopathy associated with *CC2D2A* mutation, rather than subsequent to chronic injuries secondary to nephronophthisis.

TH-PO607

Not Just Sickle Nephropathy: Hematuria and Proteinuria in a Child with Hemoglobin SS Disease and Alport Syndrome Stephanie Lynch,[1] Elizabeth Yang,[3] Haresh Mani,[2] Patricia Seo-Mayer.[4,1] *[1]Inova Children's Hospital, Alexandria, VA; [2]Inova Fairfax Hospital, Falls Church, VA; [3]Pediatric Specialists of Virginia, Falls Church, VA; [4]Pediatric Specialists of Virginia (Inova-CNMC) and Georgetown University School of Medicine, Fairfax, VA.*

Background: Nephropathy is known complication of sickle cell disease but is seldom observed in young children. We report the case of a 9-year-old boy with Hemoglobin SS Disease, hematuria and proteinuria, who had concurrent Alport Syndrome. This case illustrates the value of targeted investigation in patients with primary conditions with known renal sequelae who demonstrate atypical presentation or progression. For our patient, this approach uncovered a second unrelated diagnosis.

Methods: A 4 month old African boy presented with fever, anemia, hematuria and proteinuria. He was diagnosed with urosepsis and Hemoglobin SS disease. Over time, hematuria and mild proteinuria persisted. He had normal blood pressure, albumin, creatinine, complements, and RBUS. Family history was negative for CKD. Sickle nephropathy was considered, and ACE-inhibitor was initiated for renoprotection. He later developed gross hematuria and worsened proteinuria in the context of fever and abdominal pain. Papillary necrosis and pyelonephritis were ruled out. Revised family history revealed a maternal male cousin with new hematuria, and a deaf maternal uncle who died in the Congo at an early age of kidney disease, raising suspicion for Alport Syndrome. Genetic testing revealed COL4A5 mutation (Exon 5, c.305_306dupGG), confirming X-linked Alports. Renal biopsy revealed abnormal GBMs with variable areas of thinning and thickening, and retained α1 but lack of staining for α3/α5 chains of type IV collagen.

Results:

Conclusions: This is an unusual case of a boy with two concurrent genetic diseases, both with known renal sequelae. Sickle nephropathy usually manifests in the 3rd decade of life, but our patient had early and persistent hematuria and proteinuria, resulting in diagnosis of Alports. Future management will be challenging. Alports will inevitably lead to ESRD, and ongoing vaso-occlusive crises and ischemia reperfusion injury will hasten progression. ACE-inhibitors are key, as they have shown benefit for both conditions, and hydroxyurea may reduce progression of sickle nephropathy. Stem cell transplantation may prove useful to mitigate CKD progression, but risks exist due to lack of a sibling-matched donor. In summary, this case describes a child with two indepedent and unrelated genetic causes of CKD, illustrating an exception to the rule of Occam's razor.

TH-PO608

Digenic Heterozygous Mutations in CEP164 and ALMS1 May Cause Nephronophthisis Haris F. Murad, Neera K. Dahl. *Yale School of Medicine, New Haven, CT.*

Background: Nephronophthisis is a cystic kidney disease that is the most common genetic cause of End Stage Renal Disease (ESRD) in the first three decades of life. It is a genetically heterogeneous disorder associated with extra renal manifestations (eyes, liver, bones, and central nervous system) in 15% of cases. Renal histology shows tubular basement membrane disruption and tubulointerstitial nephropathy. The cysts are usually in the corticomedullary junction and kidney size is normal or slightly reduced in contrast to polycystic kidney disease. Here we describe two cases with Nephronophthisis from novel genetic mutations.

Methods: A 51-year old lady presents with a gradually rising serum Creatinine up to 2.7mg/dL. Renal biopsy showed interstitial nephritis, and her ultrasound showed several scattered subcentimeter cysts and a 1.6 cm cyst. Whole exome sequencing showed heterozygous mutations in both the CEP164 and ALMS1 genes. Both mutations, CEP164, pL248fs, and ALMS1 pY1713X, resulted in the creation of a premature stop codon and are known to be pathogenic. MUC1 and UMOD were normal. The patient's sister has a history of cerebral palsy developed ESRD at the age of 30. Her CT abdomen shows innumerable bilateral renal cysts. Biopsy revealed interstitial nephritis as well. Whole exome sequencing is currently in process.

Results:

Conclusions: Nephronophthisis is a disorder in the normal functioning of primary cilia, which are sensory organelles detecting flow, osmotic, chemo and other stimuli and link them to cellular processes. A homozygous or compound heterozygous mutation in the CEP164 gene is known to cause NPHP15 which causes an alteration in DNA damage response signaling pathway. A mutation in ALMS1 gene causes abnormal ciliary structure in knockout mice. A homozygous or compound heterozygous mutation in this gene causes Alstrom syndrome which is a rare cause of renal failure associated with blindness, hearing loss, systemic fibrosis as well as hepatic, urologic and pulmonary dysfunction. To our knowledge, this is the first case of a clinical nephronophthisis phenotype caused by digenic pathogenic alleles rather than by a homozygous or compound heterozygous mutations in the above genes. It is possible that ALMS and CEP164 mutations have a complementary effect in exerting this phenotype.

TH-PO609

Functional Splicing Analysis in an Infantile Case of Atypical Hemolytic Uremic Syndrome Caused by Digenic Mutations in C3 and MCP Genes Tomohiko Yamamura,[2] Kandai Nozu,[2] Keita Nakanishi,[2] Junya Fujimura,[2] Shogo Minamikawa,[2] Hiroaki Ueda,[3] Rika Fujimaru,[3] Yuko Shima,[4] Koichi Nakanishi,[1] Hiroshi Kaito,[2] Kazumoto Iijima.[2] *[1]Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan; [2]Kobe University Graduate School of Medicine, Kobe, Japan; [3]Osaka City General Hospital, Osaka, Japan; [4]Wakayama Medical University, Wakayama City, Japan.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a heterogeneous disease that is caused by defective complement regulation as reported in over 50% of cases. Up to now, pathogenic variants have been identified in various compliment related genes. Some reports also indicated that patients of aHUS with digenic inheritance of these genes might present more severe phenotype than monogenic inheritance. In addition, generally, transcript analysis is necessary for variants located outside of the splicing consensus sequence to assess the biological effect. However, this technique is often difficult for the influence of nonsense-mediated mRNA decay (NMD) for the products of truncating variants and quantity of mRNA of sample.

Methods: Here we report an infantile case with aHUS from unrelated parents. Targeted resequencing detected a reported variant of *C3* gene and a novel intronic variant of *MCP* gene (c.97 + 5 G>A, IVS1 + 5 G>A), on maternal and paternal alleles respectively. These variants were thought to be working digenically since there was early onset in this patient although the parents were asymptomatic. However, the pathogenicity of a variant in *MCP* gene was unknown because this is a novel variant and located outside apparent splice consensus sequence. To assess the pathogenicity of a novel intronic variant of *MCP* gene, we tried to detect abnormal splicing variant by standard transcriptional analysis using mRNA extracted from peripheral blood. However, we obtained only normal splicing variant from maternal allele and transcript from paternal allele was missing. Then, we conducted functional splicing assay using minigene construction to detect abnormal splicing caused by c.97 + 5 G>A variant and quantitative mRNA PCR to confirm the result. As a result, it was revealed that the paternal allele of *MCP* gene with c.97 + 5 G>A variant did not produce any transcript as confirmed by qPCR and minigene splicing assay. These results lead us to conclude *MCP* gene c.97 + 5 G>A was pathogenic.

Results:

Conclusions: A combination of minigene assay and quantitative analysis is non-invasive and useful as methods for functional splicing assay of inherited diseases even if standard transcriptional analysis could not detect abnormal splicing.

TH-PO610

Upshaw–Schulman Syndrome Muhammad Afzal,[2] Krishna M. Baradhi.[1] *[1]None, TULSA, OK; [2]OU Tulsa, Tulsa, OK.*

Background: Hereditary Thrombotic Thrombocytopenic Purpura (TTP) is an extremely rare life threatening disorder characterized by thrombotic microangiopathy caused by severely reduced activity of the von-Willebrand factor-cleaving protease ADAMTS13. It is characterized by small-vessel platelet-rich thrombi that cause thrombocytopenia and microangiopathic hemolytic anemia.

Methods: A male infant who was cyanotic at birth was found to have thrombocytopenia of 18000/microliter presumed to be from sepsis as it improved with platelet transfusion and antibiotics. This was followed by recurrent hospitalizations every few years either for diarrhea or anemia or renal failure in the context of severe thrombocytopenia. However, each time, he was misdiagnosed as Evan's syndrome or Hemolytic uremic syndrome(HUS) until he succumbed to stroke at the age of 18 years. This time, as he had classical features of TTP in the form of stroke, anemia, renal failure and thrombocytopenia, an evaluation for TTP was initiated. His ADAMTS 13 activity came back as < 10% without the inhibitor. Genetic testing showed biallelic mutations in the *ADAMTS13* gene. Both parents were carriers. He was diagnosed with Hereditary TTP and was started on monthly plasma infusions. His renal function eventually deteriorated by the age of 31 years requiring dialysis. He continues to have monthly plasma infusion and is relatively doing well.

Results:

Conclusions: Hereditary TTP also known as Upshaw–Schulman Syndrome is an autosomal recessive condition caused by biallelic mutations in *ADAMTS13*. It represents <5 percent of all TTP cases. Clinical features are similar to acquired TTP or other thrombotic microangiopathies often leading to patients being misdiagnosed as having ITP, HUS, HELLP, or Evan's syndrome. Hereditary TTP should be considered in any one who presents with microangiopathic hemolytic anemia and thrombocytopenia in infancy, childhood or pregnancy. The diagnosis is made by demonstration of severe ADAMTS13 deficiency without an inhibitor and confirmed by demonstration of *ADAMTS13* gene mutation(s). Without appropriate diagnosis and treatment, it can be life threatening. Treatment of an acute episode with plasma infusion should not be delayed while confirming the diagnosis. Plasma infusion is the treatment of choice rather plasma exchange. Recombinant ADAMTS13 is under development. All siblings of an individual with hereditary TTP should be tested.

TH-PO611

A Case of Lesch-Nyhan Syndrome in an Adult Presenting with AKI

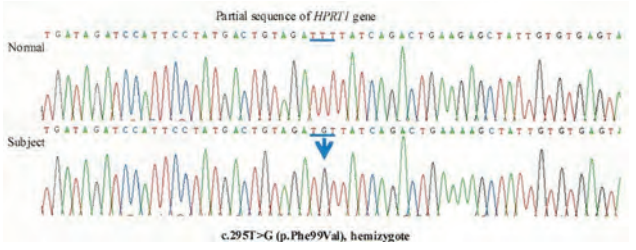
A young Cho. *Presbyterian Medical Center, Jeonju, Republic of Korea.*

Background: Lesch-Nyhan syndrome (LNS) is a rare X-linked disorder caused by a deficiency of the enzyme hypoxanthine-guanine phosphoribosyl transferase (HPRT) and underlying HPRT gene mutations. When the enzyme HPRT is nonfunctional, substrates accumulate and are converted to uric acid by the action of xanthine-oxidase. LNS diagnosis is based on clinical symptoms and hyperuricemia, together with neurological evaluation of mental function, molecular testing for pathogenic mutations, and enzymatic analysis for HPRT function.

Methods: We report a case of LNS in a 26-year-old man, who presented with acute kidney injury and excessive hyperuricemia. He had a 7-year history of gout. He had tophectomy for gouty arthritis on left ankle 3 months ago and was taking aceclofenac (NSAID) from then on. He had a 3-year history of dystonia. Mutation analysis and enzyme assay revealed a mutation of exon 3 of the HPRT gene (c.295T>G (p.Phe99Val)) and total deficient HPRT confirming the diagnosis of LNS. His renal function and serum uric acid level improved after hydration and allopurinol treatment.

Results:

Conclusions: The diagnosis of LNS in adults is extremely rare. We report a case of LNS in a 26-year old man, who presented with acute kidney injury and excessive hyperuricemia, with molecular diagnosis.



TH-PO612

Proteinuric Renal Injury in an Adolescent with a Distal Partial Trisomy Chromosome 1

Takeshi Tosaki,[1] Takaya Sasaki,[1,2] Masahiro Okabe,[1,2] Yu Honda,[1,2] Masahiro Ishikawa,[1,2] Nobuo Tsuboi,[2] Takashi Yokoo.[2] *[1]Kawaguchi Municipal Medical Center, Kawaguchi-shi, Saitama, Japan; [2]The Jikei University School of Medicine, Minato-ku Tokyo-to, Japan.*

Background: Distal partial trisomy 1q is a rare disease, with no previous case reports of renal insufficiency occurring in relation to this chromosomal disorder. We report a case of distal partial trisomy 1q that showed proteinuric renal injury.

Methods: We treated a 17-year-old adolescent with clinical features of low birth weight, mild mental retardation, and mild deafness. When he was 13 years old, he was diagnosed as having a partial trisomy of chromosome 1 from q32.1 to 41 using chromosomal and microarray tests. He showed persistent proteinuria since age 16 and underwent medical check-up at our hospital. Proteinuria was estimated to be approximately 1-2 g/day, although serological examination revealed no abnormal findings. Computed tomography detected no morphological abnormalities of the kidneys other than their slightly small size. Renal biopsy showed no evidence of immune-mediated glomerular diseases, but revealed a very low glomerular density and glomerulomegaly, as evidenced by a marked increase in the estimated mean glomerular volume (10.3×10^6 μm^3). Combination therapy with dietary sodium restriction, body weight reduction, and the administration of losartan potassium markedly reduced his proteinuria to 0.3 g/day.

Results:

Conclusions: The section of partial trisomy found in this case does not include podocyte-related genes that have been related to proteinuric renal injuries. Thus, in this case, the mismatch between congenital reduction in the number of nephrons due to low birth weight and catch-up growth of whole body size may have resulted in glomerular hyperfiltration and renal injury. Renal prognosis is poor in patients with a history of low birth weight, which is sometimes complicated in patients with genetic comorbidities. In such patients, where the renal prognosis has not been studied well, continuous follow-up is necessary to evaluate renal complications and inhibit progression of renal disease.

TH-PO613

Headache and Diplopia in a Patient with Nephropathic Cystinosis

Stephanie P. Kerkvliet, Sarah L. Elfering. *University of Minnesota, Minneapolis, MN.*

Background: Nephropathic cystinosis is a lysosomal storage disease resulting in the accumulation of cystine, development of Fanconi syndrome, and progression to end-stage renal disease. Extrarenal manifestations of cystinosis affecting the endocrine, muscular, and ophthalmologic systems have been well described. However, idiopathic intracranial hypertension (IIH) is a rare and poorly understood condition associated with cystinosis.

Methods: A 33 year old female with nephropathic cystinosis three years status post living donor kidney transplant on immunosuppressive therapy had been experiencing one month of headache, diplopia, and nausea. Approximately one and a half years prior to presentation, she had switched from cysteamine bitartrate (Cystagon) to extended release cysteamine bitartrate (Procysbi), both of which are cystine depleting agents. Four months prior to presentation, her WBC cystine level was subtherapeutic, and her Procysbi dose was increased. Dilated retinal exam revealed bilateral optic disc swelling and right optic disc hemorrhage. Additional workup revealed an elevated lumbar CSF opening pressure with unremarkable MRI and MRV consistent with IIH. Her symptoms and papilledema improved with acetazolamide, discontinuation of Procysbi, and resumption of Cystagon.

Results:

Conclusions: There is a known increased incidence of IIH in individuals with cystinosis; although, the underlying cause is unknown. Potential etiologies include decreased CSF reabsorption secondary to crystal deposition or increased thrombotic risk secondary to renal disease. Additional risk factors such as immunosuppressive therapy, growth hormone supplementation, and renal transplant have been associated with IIH, but no study has correlated a specific risk factor with development of IIH in patients with cystinosis. Procysbi is reported to have a more favorable side effect profile and less medication noncompliance compared to Cystagon due to twice rather than four times daily dosing. However, in the setting of subtherapeutic WBC cystine levels with Procysbi, the patient developed IIH. This case highlights the rare, but known, association between cystinosis and IIH, and encourages clinicians to consider this diagnosis in patients with cystinosis presenting with headache and vision changes.

TH-PO614

Moyamoya Disease – A Rare Association of Autosomal Dominant Polycystic Kidney Disease

Dearbhla Kelly,[4] Ayanfeoluwa Obilana,[2] Michael Marnane,[3] Aisling O'Riordan,[1] Sean Murphy.[5] *[1]Mater Hospital, Dublin, Ireland; [2]Mater Misericordiae University Hospital, Dublin, Ireland; [3]Mater Misericordiae University Hospital, Dublin, Ireland; [4]Nephrology, Mater Misericordiae University Hospital, Dublin, Ireland; [5]Mater Misericordiae University Hospital, Dublin, Ireland.*

Background: Moyamoya disease is an idiopathic progressive vaso-occlusive disorder of the intracranial arteries located at the base of the brain that can predispose to stroke. Although cerebral aneurysms and other vascular abnormalities are well described in autosomal dominant polycystic kidney disease (ADPKD), co-incident Moyamoya syndrome and ADPKD has only previously been reported on two occasions.

Methods: A 29-year old Romanian woman presented with a 3 days of headache and right hemiparesis. She was a smoker with a history of untreated hypertension. Her mother, sister and maternal uncle also had ADPKD. No family member had a history of intracranial aneurysms. MRI Brain with contrast revealed a left middle cerebral artery (MCA) territory subcortical infarct, with established infarcts in the right caudate nucleus, left internal capsule and left parietal lobe. Digital Subtraction Angiography confirmed no flow in the MCAs bilaterally with good flow in distal ICAs, ACAs and PCAs bilaterally, multiple collateral vessels consistent with Moyamoya disease. She had a renal ultrasound as part of her work up for hypertension and this revealed bilateral cystic changes consistent with polycystic kidney disease.

Results:

Conclusions: The coexistence of these malformations suggests a common genetic background predisposing to these structural abnormalities. Although the genetic contribution in Moyamoya is indisputable, its cause remains uncertain. In this case, alterations in the arterial wall may be linked to the PKD1 or PKD2 genes, expanding the phenotypic variability of ADPKD and providing insight into the pathogenesis of Moyamoya.

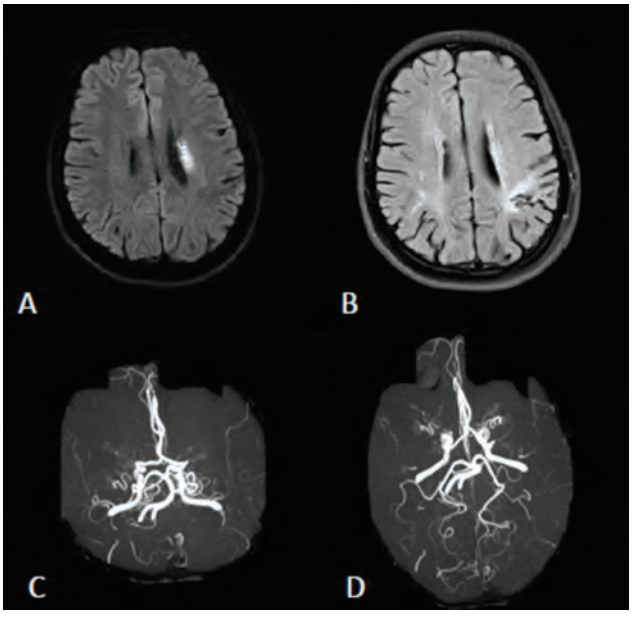


Figure 1: A: MRI DWI shows acute left MCA subcortical infarct. B: Flair sequences reveal MCA-PCA watershed infarcts C+D: Bilateral proximal M1 MCA occlusions with collateralization

TH-PO615

Painful Cyst Hemorrhage with Trivial Trauma in Tuberous Sclerosis Complex with Angiomyolipomas without Nephromegaly – A Case Report Jaime A. Baynes-Fields, Myriam C. Vela-Ortiz, Sandeep Aggarwal. *Drexel University College of Medicine, Philadelphia, PA.*

Background: Tuberous sclerosis complex (TSC) is characterized by renal angiomyolipomas and cysts which have the potential to be complicated by hemorrhagic and malignant conversion. Cyst hemorrhage in such cases may happen spontaneously or by trivial trauma due to their highly vascular nature.

Methods: We present a case of a 25 year old male with TSC with subependymal giant cell astrocytoma, seizure disorder, ash leaf spots, bicuspid aortic valve with cardiac rhabdomyoma, multiple renal angiomyolipomas and cysts, hypertension, and CKD stage 1. On a follow up visit, patient presented with right flank pain of one week duration. Patient's symptoms were preceded by a motor vehicle accident, characterized by sudden deceleration of his vehicle without bodily impact. Patient denied hematuria, lower urinary tract symptoms, or change in urine output. Pertinent physical examination –blood pressure 126/72 mmHg, pulse 85 per minute, right flank tenderness, remainder of physical exam at baseline. Work up – gadolinium enhanced MRI: hemorrhagic conversion of large cystic lesion (1.4cm) as well as increasing angiomyolipomas with stable renal size (right 11.33cm, left 11.2cm). Patient's renal function remained stable with baseline creatinine 0.66mg/dL, trace proteinuria, no hematuria on dipstick, and 5mcg/mg microalbumin to creatinine ratio. Conservative treatment was provided with pain control and oral hydration given hemodynamic and laboratory stability. Patient improved clinically in follow up.

Results:

Conclusions: Cystic nephropathies with nephromegaly present a high risk of hemorrhagic conversion due to fragility and lack of protection by our thoracic cage. TSC with angiomyolipomas present a higher risk due to pathological vascular aneurysms even without nephromegaly, which is emphasized in this case. Hemorrhagic risk of angiomyolipomas are approximately 25-50% and may lead to circulatory shock. Frequent assessment of patient's symptoms and history, especially related to physical trauma should be sought during each visit. Emphasis should be laid on seizure control, preventative measures and patient education of avoidable injury with immediate follow up after such an event which could be life threatening.

TH-PO616

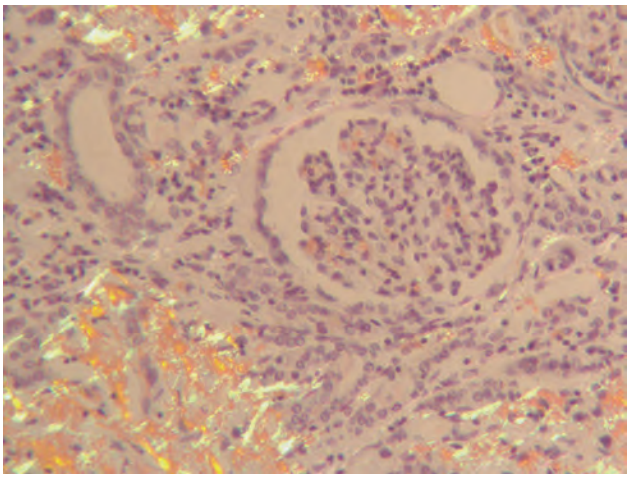
LECT2 Amyloidosis – An Entity in Elderly Hispanics with Distinct Pathologic Features Nilin Raj, William L. Whittier, David J. Cimbaluk. *Rush University Medical Center, Chicago, IL.*

Background: Leukocyte chemotactic factor 2 amyloidosis (ALECT2), discovered in 2008, is characterized by renal and liver involvement. It mainly affects elderly Hispanics and typically presents with a bland urine, subnephrotic proteinuria, and progressive CKD. Histologically, ALECT2 has a preferential interstitial involvment. Diagnosis is made by liquid chromotagraphy mass spectrometry (LC/MS) of affected tissue.

Methods: A 71 y/o Mexican man presented with a 2 month history of gross hematuria. PMHx includes recently diagnosed DM II. His vitals and exam were unremarkable. Creatinine (SCr) 3.8 mg/dl, K+ 5.4 mmol/L, Hgb 6.3 g/dl. UA grossly red, 1+ protein, large blood, and >300 RBCs. Renal U/S: left renal mass with adjacent lymphadenopathy and blood clots in the bladder. Left radical nephrectomy was consistent with sarcomatoid renal cell carcinoma but the renal cortex revealed tubulointerstitial amyloidosis. Amyloid A stain (-). Immunofluorescence without light chain restriction. EM with characteristic fibrils. Serum/urine immunofixation nl. Serum free κ 8.6, λ 4.5 mg/dl (ratio of 1.9), consistent with CKD. Echo and bone scan were nl. LC/MS confirmed LECT2 type amyloidosis. Following curative surgery, his hematuria resolved and his SCr stabilized at 1.8 mg/dl. Urine p/c ratio 593 mg/g. He was placed empirically on colchicine and at one year follow up his SCr is 1.8 mg/dl.

Results:

Conclusions: ALECT2 is an emerging disease that predominantly affects pts of Hispanic ethinicity. Its characteristic demographic predilection and tubulointerstitial involvement should raise suspicion of this disease and alert one to perform LC/MS. Our pt's diagnosis was discovered by examination of a nephrectomy specimen and confirmed by LC/MS. Althouth there are no known treatments, colchicine impairs chemotaxis of leukocytes and on this therapy his SCr remains stable at one year.



Congo red stain: apple green birefringence under polarized light in the interstitium, sparing the glomerulus.

TH-PO617

Predominantly Vascular AL Amyloidosis Mimicking Vascular Hyalinosis on Renal Biopsy – A Diagnostic Pitfall Anthony F. Iluyomade,[1] Niti Madan,[2] Kuang-Yu Jen.[2] *[1]University of California Davis Medical Center, Sacramento, CA; [2]University of California, Davis, Sacramento, CA.*

Background: Vascular-limited renal amyloidosis accounts for ~5% of AL amyloidosis cases. In this form, patients often present with minimal proteinuria, making the diagnosis clinically challenging. Histologically, vascular hyalinosis mimics vascular amyloidosis and may lead to errors in diagnosis, especially in elderly patients with a history of hypertension where chronic vascular disease is expected on biopsy.

Methods: An unusual case of predominantly vascular AL amyloidosis with nephrotic range proteinuria and histologic appearance indistinguishable from vascular hyalinosis is presented. A 75-year-old male was noted to have normal serum creatinine but nephrotic range proteinuria. Physical examination was significant for anasarca. Further work-up showed elevated serum free light chains with lambda predominance. A kidney biopsy was performed to characterize renal involvement. The biopsy contained 12 glomeruli, 2 of which were globally sclerotic. All the non-sclerotic glomeruli showed normal histology with no evidence of amyloid deposition. Severe chronic vascular disease was noted with prominent arteriosclerosis in larger caliber vessels. Smaller caliber vessels including small arteries and arterioles exhibited mural deposition of hyaline-like material that stained strongly for PAS but showed minimal silver staining. Congo red stain revealed that this material within the vessels was positive, confirming vascular amyloid deposition. No Congo red staining was seen in any of the glomeruli. Ultrastructural examination confirmed the widespread presence of amyloid within the vessels. Rare and minimal amyloid deposition was noted in the glomerular capillary loops and mesangium. He was started on CYBORD (Cyclophosphamide, Bortezomib and Dexamethasone), a repeat serum immunofixation showed undetectable overt evidence of monoclonal protein.

Results:

Conclusions: This case of predominantly vascular renal amyloidosis was indistinguishable from vascular hyalinosis based on routine light microscopic stains for renal biopsy, showing similar intense PAS positivity in the amyloid as normally seen in hyaline arterio- and arteriolosclerosis. However, Congo red stain and electron microscopy confirmed the presence of amyloid. Vascular-limited or predominantly vascular renal amyloidosis can be mistaken for vascular hyalinosis in such instances, resulting in a diagnostic pitfall.

TH-PO618

Gelsolin Amyloidosis (Familial Amyloidosis of Finnish Type) in a North American Kindred Hassan A. Salameh,[1] Aneel A. Ashrani,[2] Matthew Howard,[1] Lynn D. Cornell,[1] Marie C. Hogan.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN.*

Background: Gelsolin amyloidosis is a rare form of systemic amyloidosis characterized by lattice corneal dystrophy, cranial nerve neuropathies and elastolysis. Renal involvement with nephrotic syndrome is rare. Early onset severe kidney disease has been reported in homozygotes and late onset slowly progressive forms in heterozygotes. It is usually caused by a gelsolin gene defect, namely a G640A previously known as G654A or G654T mutation.

Methods: We report a 74-year-old man presenting with CKD3 and nephrotic syndrome (NS). Medical history was significant for hypertension and lattice corneal dystrophy type II (LCD II) and family history of LCD II (son, mother, two maternal uncles and maternal aunts, (all of Lithuanian-Finnish heritage)) and no family history of kidney disease. Exam showed periorbital and ankle edema. Serum creatinine was 2.1 mg/dL with eGFR 33 mL/min/1.73 m2 and 5.6 g proteinuria/24h. SPEP and UPEP were negative. Free light chains were mildly elevated. Kidney biopsy (KB) showed minimal Congo red positivity along

with immunofluorescence findings revealed amyloidosis of undetermined type. Electron microscopy showed 10.8 nm fibrils focally replacing the glomerular basement membrane. No additional KB material was available for laser microdissection (LMD) and mass spectroscopy (MS). MS proteomics of fat aspirate material (with equivocal Congo red stain) typed the most abundant peptides were from GELS_HUMAN with p.D214N AA change identified. A heterozygous pathogenic variant c.640G>A (g.124073097; p.D214N also known as p.D187N) in the GSN gene was confirmed by Sanger sequencing consistent with familial amyloidosis Finnish type.

Results:

Conclusions: Our patient had an unusual presentation with renal and ophthalmic involvement and no neurologic or dermatologic manifestations. This report highlights (1) importance of MS evaluation in atypical amyloidosis cases (2) implications for management (therapies are now in pre-clinical studies) (3) genetic counseling implications for families; heterozygous cases have late onset slowly progressive disease and (4) in cases where there is insufficient KB tissue for MS analysis, fat aspirate material (a relatively minimally invasive procedure) permitted confirmation.

TH-PO619

Renal-Limited Fabry Disease with Negative Genetic Screening

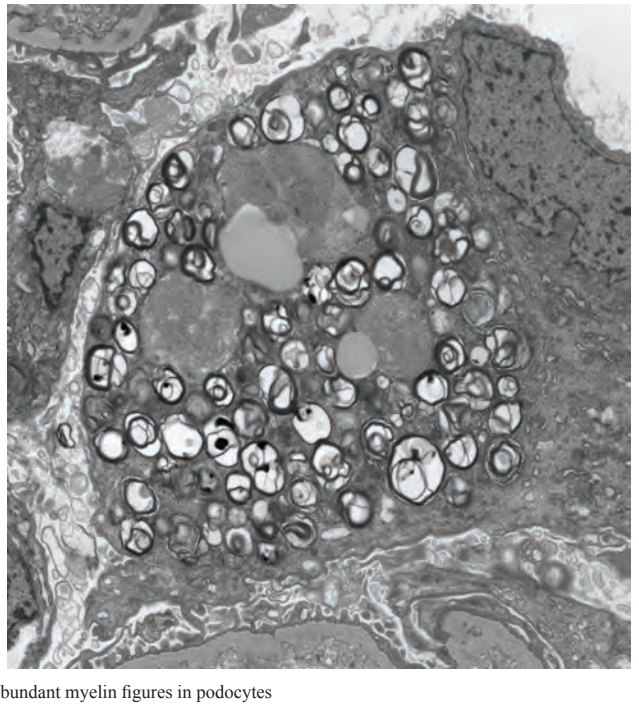
Madhuri Chengappa,[2] Michael Mauer,[3] Samih H. Nasr,[1] Fernando C. Fervenza,[1] Sandra Herrmann.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo clinic, Rochester, MN; [3]University of Minnesota, Minneapolis, MN.*

Background: Fabry disease(FD) is an X-linked lysosomal storage disorder caused by deficient α-galactosidase A(α-GLA) activity. Female carriers disease severity is substantially dependent on random inactivation of X chromosome.

Methods: A 65year old female with history of hypertension was evaluated for lower extremity edema, proteinuria and serum creatinine (SCr) of 1.2mg/dL. Kidney biopsy showed mild mesangial hypercellularity and myelin figures in few podocytes. Genetic testing for FD was negative. No history of supplement use, exposure to silica or amiodarone. Her mother was diagnosed with focal segmental glomerulosclerosis(FSGS) at age 69 and started dialysis 2 years later. Despite treatment with antihypertensive over 4 years her SCr increased to 1.7 mg/dL. She was referred to Mayo Clinic for further evaluation. On exam she had trace edema, no neuropathy or skin changes and normal ophthalmology evaluation. Proteinuria was 6.1g/24h. Second kidney biopsy showed FSGS pattern of injury, severe hypertensive arteriosclerosis and abundant myelin figures in podocytes(PC). Repeat FD genetic testing was negative. Magnetic resonance cardiac and brain imaging showed no FD features. Serum α-GLA was normal 35(>23.1nmol/h/mg). Urine Globotriaosylceramide(GL3) was 0.019 mg/mmol Creatinine(control <0.030). However urine globotriaosylsphingosine(Lyso-GL3) was elevated at 12.3 ng/mmol Creatinine(Fabry range 0.4-356.6).

Results:

Conclusions: This is a case of a renal-limited FD in a female patient apparently superimposed on familial FSGS. Myelin inclusions in some but not all PC is consistent with finding in females with FD. Genetic testing was negative as has been reported in, especially in females. It highlights the importance of measurement of Lyso-GL3/Gb3 in cases where genetic mutation can't be found.



Abundant myelin figures in podocytes

TH-PO620

An Unusual Case of Presumed Lecithin-Cholesterol Acyltransferase Inhibitor

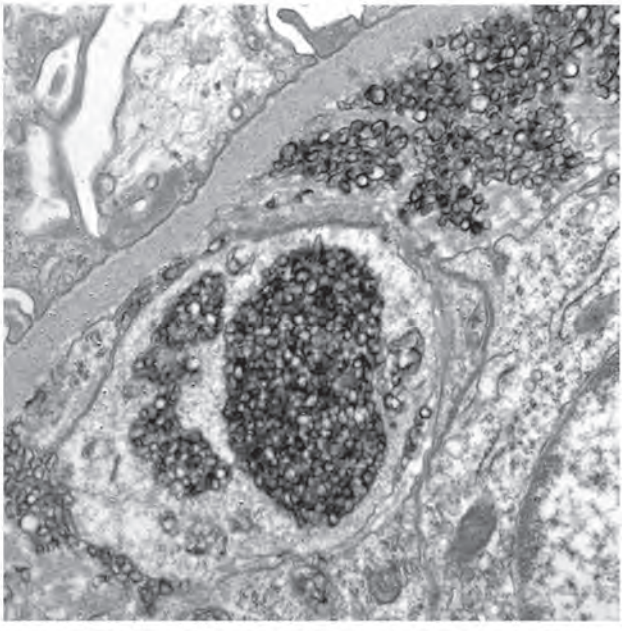
Mohammad Katout,[3] Lynn A. Fussner,[5] Sergey V. Brodsky,[2] Tibor Nadasdy,[4] Isabelle Ayoub.[1] *[1]None, Columbus, OH; [2]OSU, Columbus, OH; [3]OSU Nephrology, Columbus, OH; [4]Ohio State University, Columbus, OH; [5]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Lecithin-cholesterol acyltransferase (LCAT) is a glycoprotein produced predominantly by the liver. LCAT binds mainly to HDL particles and contributes to HDL maturation and cholesterol homeostasis. LCAT deficiency is a rare autosomal recessive disease, however an immune-mediated, acquired form has been reported. In both situations lipoprotein deposition in the glomeruli may lead to end stage kidney disease. This case illustrates the challenge of managing acquired LCAT deficiency when the underlying etiology is unclear.

Methods:

Results: A 27 *y* old woman transferred to our center for worsening shortness of breath over 2 months. She already received 1g of rituximab and was on prednisone for concerns of an underlying auto-immune disease. Diagnostic work up was significant for AKI, hemolytic anemia, thrombocytopenia, hyperbilirubinemia, high ferritin, low HDL (3mg/dl), + ANA,+ SSA and bilateral pulmonary infiltrates. Kidney biopsy showed lipoprotein deposits in the widened sub-endothelial space with some mesangial and intracellular deposits(see figure). Some features of TMA were noted. Lung biopsy showed NSIP and isolated intravascular foreign material. LCAT activity was checked, but after rituximab infusion and having been on prednisone for 2 weeks, and it was normal. LCAT genetic testing didn't show sequence variants. The patient was continued on high dose prednisone. Cytopenia and hyperbilirubinemia resolved. Her HDL level began normalizing (up to 20 mg/dl) and AKI resolved. She had a mild improvement in respiratory symptoms.

Conclusions: Immune-mediated acquired LCAT deficiency may be difficult to diagnose. In this case clues to the presence of an inhibitor of LCAT included response to steroids and negative genetic testing. Confirming an underlying auto-immune disease remains a challenge for future decisions regarding immunosuppressive therapy to prevent further organ damage.



Mesangial lipoprotein deposits

TH-PO621

An Unusual Cause of Nephrotic Syndrome: LCAT Deficiency

Melissa Makar,[2] Eugene C. Kovalik.[1] *[1]Duke University Medical Center, Durham, NC; [2]Duke University Medical Center, Durham, NC.*

Background: Lecithin-cholesterol acyltransferase (LCAT) deficiency is an autosomal recessive disorder in which cholesterol cannot be esterified on high-density lipoprotein (HDL). The subsequent accumulation of unesterified cholesterol leads to kidney failure. Although it mainly affects those of European decent, we present two cases in African-Americans.

Methods: In Case 1, a 30 year old African-American female was evaluated for proteinuria and hematuria seen on routine urinalysis during a pre-operative evaluation. She had lower extremity edema; an estimated glomerular filtration rate (eGFR) of 115 ml/min/1.73m^2; and 9 grams of proteinuria on 24 hour urine collection. Her serologies were negative; and on kidney biopsy, her light microscopy showed vacuolization of her capillary loop basement membranes while her electron microscopy showed subendothelial, intermembranous, and mesangial deposits of lamellated, myelin-figure lipid material along with mesangial and endocapillary foam cells. In support of LCAT deficiency, her HDL and serum cholesteryl levels were very low at 8 mg/dl and 13%, respectively.

Unfortunately, as expected with LCAT deficiency, she progressed to end-stage kidney disease at age 36 despite blood pressure control with an angiotensin-converting enzyme inhibitor (ACEI). Two years later, she underwent a deceased donor kidney transplant and was doing well at last check. In Case 2, a 69 year old African-American female with a longstanding history of dyslipidemia was seen for a HDL of less than 5 mg/dl. A low serum cholesteryl ester level of 15% confirmed her diagnosis. At the time, her eGFR was 102 ml/min/1.73m^2 and she had no proteinuria while on three anti-hypertensive agents including an ACEI. Over the past seven years, her eGFR has fallen to 52 ml/min/1.73m^2 and she has developed proteinuria of 4 grams on spot check. A subsequent full evaluation was otherwise negative, and she is followed closely as an outpatient.

Results:

Conclusions: Although rare, LCAT deficiency should be included in the differential for nephrotic syndrome in all persons with a low HDL. The diagnosis can be made by low serum cholesteryl ester levels; kidney biopsy shows diffuse foam cells and lipid deposits. Current treatment is supportive care.

TH-PO622

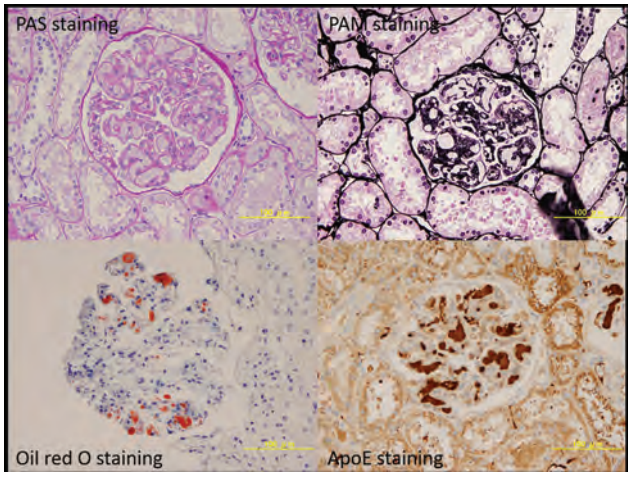
A Case of Lipoprotein Glomerulopathy Which Achieved Remission by Bezafibrate Monotherapy Manabu Kanda,[5] Mitsuhiro Sato,[1] Satoru Sanada,[4] Hiroshi Sato,[2] Toshinobu Sato,[1] Yoshio Taguma.[3] *[1]Japan Community Health care Organization Sendai Hospital, Sendai, Japan; [2]Clinical Pharamacology and Therapeutics, Graduate School of pharmaceutical Sciences, Tohoku University, Sendai, Japan; [3]Japan Community Health care Organization Sendai Hospital, Sendai, Miyagi, Japan; [4]Japan Community Health Care Organization Sendai Hospital, Sendai, Japan; [5]Japan Community Health care Organization Sendai Hospital, Sendai, Japan.*

Background: Lipoprotein glomerulopathy (LPG) is a rare hereditary renal disease with a relatively rapid progression to renal failure, accompany with proteinuria, hyperlipidemia, and lipoprotein thrombi in glomeruli. The first LPG case was reported in 1989, then our facility firstly reported efficacy of intensive therapy with combination of three lipid-lowering agents, which decreased proteinuria by removal of lipoprotein thrombi in 2000. In this report, we show that even fibrate monotherapy could ameliorate proteinuria in patients with LPG.

Methods: A 38-year-old Japanese man was admitted with a 10-year history of proteinuria. None of his family has renal disease or dyslipidemia. His body mass index was 17.8, and blood pressure was 140/90 mmHg. He has no corneal opacity, xanthoma nor leg edema. Laboratory tests showed urine protein 1.30 g/day, serum creatinine 0.80 mg/dL, total cholesterol 155 mg/dL, and the triglyceride 142mg/dL. Apolipoprotein profiles revealed B 66 mg/dL, normal range 73 to 109, and E 11.9 mg/dL, 2.7 to 4.3. Heterozygous ApoE-Sendai mutation was detected by DNA sequencing analysis. Renal Biopsy showed distinct dilatation of glomerular capillary lumina filled with lipoprotein thrombi which was positive for oil red O and apoE staining (figure). Bezafibrate monotherapy decreased proteinuria to less than 0.3 g/day in five months. Clinical remission has been lasted for 2 years, though the ApoE level was still high.

Results:

Conclusions: We experienced a LPG case without dyslipidemia and family history. The previous reports have shown the effectiveness of combination therapy multiple lipid-lowering agents, however, in our case even monotherapy with fibrate could decrease proteinuria and prevent disease progression.



TH-PO623

Hemihypertrophy versus Hemiatrophy: A Unique Presentation of Midaortic Syndrome Rachel Herdes, Nikita R. Patel, Cullen Clark, Isa Ashoor. *Pediatrics, Louisiana State University Health Sciences Center, New Orleans, LA.*

Background: Midaortic syndrome is the acquired or congenital narrowing of the abdominal aorta and associated branches. Patients often present prior to adolescence with severe hypertension (HTN), headaches, claudication, or abdominal angina. Treatment consists of multiple antihypertensive medications and often requires surgical intervention for adequate control. Left untreated, patients usually die in their 40s from malignant HTN.

Methods: Case report

Results: A previously healthy 10-year-old girl was referred to genetics for right-lower extremity (RLE) hemihypertrophy. She was incidentally noted to have severe HTN (180/100 mmHg) in clinic and was admitted to the ICU for BP control. She denied headaches, vision changes, or abdominal discomfort. Exam was notable for coarse facies, enlarged RLE compared to left lower extremity (LLE), and a paraumbilical bruit. ECHO demonstrated mild LVH. CRP, serum aldosterone, plasma renin activity, creatinine, and metanephrines were normal. Renal ultrasound showed elevated bilateral peak systolic velocities. Abdominal CT angiogram revealed significant vasculopathy with abdominal aorta narrowing and multiple stenotic areas along the main branches, including complete left common iliac artery occlusion with collateral flow (Figure 1). She was diagnosed with idiopathic midaortic syndrome and treated with amlodipine, atenolol and chlorthalidone. Genetics evaluation of vascular anomalies is pending.

Conclusions: We present an unusual case of unilateral anatomic asymmetry. While the patient had been given a diagnosis of RLE hemihypertrophy, it is more likely that she suffered from LLE hemiatrophy due to ischemia from midaortic syndrome. This case demonstrates the importance of pediatric HTN evaluation including thorough examination to identify abdominal bruits, extremity size discrepancy, or end-organ damage from severe HTN.

TH-PO624

Inconceivable! A Case of Hydralazine Induced ANCA Vasculitis and Alport's Syndrome Derian Lai, Natasha N. Dave, Rajeev Raghavan. *Baylor College of Medicine, Houston, TX.*

Background: Hydralazine induced ANCA associated vasculitis (AAV) is one of the earliest described drug induced vasculitides. The diagnosis is challenging due to the variety of clinical presentations. We present a patient who developed acute kidney injury due to Hydralazine induced AAV superimposed on Alport's syndrome.

Methods: A 53 year-old woman with atrial fibrillation, hypertension and a baseline creatinine of 2.3mg/dl (unknown etiology) presented to the hospital with 2 weeks of malaise, intractable vomiting and diarrhea. She was started on hydralazine 7 months ago. Her brother was on dialysis (unknown etiology). On admission she was afebrile with a blood pressure of 130/92. Her BUN was 189 mg/dl and creatinine was 16.6 mg/dl. Urinalysis had 600mg/dL of protein and >182 RBCs. Urine drug screen was negative. Immunologic serologies revealed: ANA titers of 1:2560 (homogenous pattern), complement levels (C3 71, C4 23), Anti –MPO antibody titers > 800AI (n<1), Anti-Proteinase 3 antibody titers 2.7 AI (n<1), and Anti-histone antibodies 7.1 U (n<1). On renal biopsy, the histology revealed characteristic findings of Alport's syndrome: loss of staining of alpha 3 and 5 chains of type 4 collagen; splitting of the lamina densa in the basement membrane. There was 60% interstitial fibrosis and tubular atrophy. No crescents or glomerular necrosis identified. ANCA serologies 1 week later showed persistently elevated titers (Anti PR3 1.2AI, Anti MPO >800AI). Despite lack of clear evidence of vasculitis on renal biopsy, we concluded patient had hydralazine induced AAV based on her clinical presentation and immunologic lab values. The patient's kidney function never recovered despite cessation of Hydralazine and immunosuppressive therapy.

Results:

Conclusions: We present a rare case of double glomerulonephropathy (DGN): Alport's and hydralazine induced AAV. DGNs are defined as pathologic confirmation of 2 coexisting glomerular diseases or superimposition of a second glomerulopathy onto an original glomerulopathy. One center reported Alport's as the original disease in 6 of 9 patients with DGN. There is no known association between Alport's and Hydralazine induced AAV.

Funding: Government Support - Non-U.S.

TH-PO625

Geller Syndrome: Two Cases of Hypertension and Hypokalemia in Pregnancy Vinay Mulkanoor, Sharon E. Maynard. *Lehigh Valley Health Network, Emmaus, PA.*

Background: In 2000, Geller et al described a familial syndrome of hypertension (HTN) and hypokalemia, exacerbated by pregnancy, caused by an activating mutation of the mineralocorticoid receptor (MR). Since this description, no further cases have been reported. Here we describe 2 patients with features consistent with Geller syndrome.

Methods: Case 1: A 38 yo woman was admitted at 32 weeks gestation for HTN and hypokalemia. She had a history of HTN prior to pregnancy but was on no medications. At 22 weeks, she developed weakness and hypokalemia (K 2.8 mg/dl). The BP was 130/99. She received IV and PO KCl replacement. At 30 weeks, the BP was 150/80 and she was prescribed methyldopa. One week later, the BP was 160/100 and labetalol was started. On the day of admission, 32 weeks gestation, the BP was 163/89 and the K was 3.0 mg/dl. She denied nausea, vomiting, or diarrhea. There was a family history of HTN in the patient's mother and father, but no family history of hypokalemia. Physical examination showed 1+ bilateral lower extremity edema. There was no proteinuria. Urine K was 23.2 mmol/L, urine Cr 44.5 mg/dl, plasma Aldosterone <3.0 ng/dL, and renin activity 2.1 ng/ml/h **Case 2:** A 36 yo woman was admitted at 26 weeks gestation for HTN and hypokalemia. She had a history of gestational HTN in two prior pregnancies, and chronic HTN diagnosed 2 years prior. Her BP was normal off medications for the first half of pregnancy. At 24 weeks, the BP was 151/91. At 26 weeks, she reported weakness and her K was 2.6 mg/dl; she was admitted. Physical exam showed BP 179/80 and peripheral edema. There was no proteinuria. Urine K was 20.3 mmol/L, urine Cr 43.7 mg/dl, plasma aldosterone 1 ng/dl, renin activity 1.9 ng/ml/h

Results:

Conclusions: Normally the MR is activated by aldosterone, but inhibited by progesterone. The novel MR S810L, described by Geller et al, is activated by both aldosterone and progesterone. In the initial description, two MR L810 carriers had a pregnancy-induced exacerbation of HTN and hypokalemia in 5 pregnancies, with low aldosterone levels. High progesterone in pregnancy was implicated. Our patients experienced worsening HTN and new hypokalemia in pregnancy, with renal potassium wasting and low renin and aldosterone levels, consistent with Geller syndrome. Both patients responded to amiloride. Geller syndrome should be considered in women with HTN and hypokalemia in pregnancy.

TH-PO626

HUStling for HELLP: A Case of Pregnancy Induced Atypical HUS (aHUS) and HELLP Syndrome Huda N. Khan,[2] Roberto L. Collazo-Maldonado,[2,1] Lisa M. Sebastian.[2,1] *[1]Dallas Nephrology Associates, Dallas, TX; [2]Methodist Dallas Medical Center, Dallas, TX.*

Background: Atypical or complement mediated Hemolytic uremic syndrome (aHUS) is a rare disorder mostly associated to gene mutations of complement factors and/or antibodies to complement factors. In rare cases it may be triggered by the stress of pregnancy. This is a case of a pregnant woman with aHUS that initially presented with HELLP Syndrome which made the diagnosis of aHUS challenging.

Methods: A 32 y/o AA woman G6P4A1 with no known past medical history presented to the ER at 25 weeks of gestation with acute onset of lower abdominal pain that started 48 hours prior to admission. On her physical exam, she was very hypertensive at 180/100 mmHg. Labs revealed new onset of proteinuria (urine prot/creat 9.5 g), elevated AST 226/ALT 48, thrombocytopenia 83,000, anemia Hgb 8.5/ Hct 24.9. She was admitted with initial diagnosis of pre-eclampsia with HELLP. She was taken to L&D due to abruptio placenta and intrauterine fetal demise. D&C was performed which was complicated with massive blood loss requiring multiple blood transfusions. She developed anuric AKI that required CRRT. Her condition stabilized, but remained anuric and was still dependent on intermittent dialysis. She continued to be hypertensive and developed anemia with schistocytes on the peripheral smear. Renal biopsy revealed thrombotic microangiopathy and classic findings of aHUS. ADAMTS13 level was normal. Patient was treated with plasmapheresis for 7 days followed by Eculizumab. Once treatment was initiated, the patient's condition improved with resolution of AKI and hemolysis, and normalization of platelet count. She was discharged to continue indefinite treatment with Eculizimab as outpatient.

Results:

Conclusions: Complement mediated HUS may present as a complication from pregnancy. The diagnosis of aHUS during pregnancy may be challenging because the clinical presentation may resemble that of HELLP syndrome as both conditions can coexist and may present with similar laboratory findings. Nephrologists should have high level of suspicion for aHUS in a pregnant woman who presents with HELLP Syndrome. Renal biopsy is valuable in making appropriate diagnosis.

TH-PO627

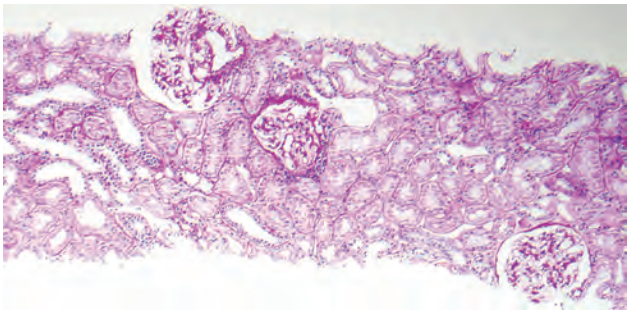
Successful Twin Pregnancy in a Patient with IgA Nephropathy and Nephrotic Range Proteinuria Robert S. Niznik, Andrea G. Kattah, Vesna D. Garovic. *Mayo Clinic, Rochester, MN.*

Background: There is literature for using tacrolimus in patients with IgA nephropathy for anti-proteinuric effect in those that cannot tolerate ACE inhibitors due to hypotension. We present a case of tacrolimus use in pregnancy primarily for anti-proteinuric effects.

Methods: This is a 29 year old female with a history of IgA nephropathy diagnosed in 2003. A renal biopsy at the time showed a small fibrocellular crescent. She was initially treated with steroids; however, she experienced significant side effects and this was discontinued after 3 days. Subsequently, she was treated with lisinopril, irbesartan and omega-3 fatty acid with improvement of her 24 hr urine protein, blood pressure and 24 hour creatinine clearance. She then had a recurrence of subnephrotic proteinuria in May of 2012 and was treated with Myfortic with improvement in proteinuria. In 2015, she desired pregnancy and so a repeat biopsy was done, showing focal glomerulosclerosis and minimal mesangial changes (M1 E0 S0 T0). She had 1.3g/24 hr of proteinuria and a creatinine of 1.0. Her Myfortic and lisinopril were stopped and nifedipine was initiated for hypertension. Unfortunately, she had rapid worsening of her proteinuria off of the ACE inhibitor up to 5.9g/24 hrs and refused steroids. She had decreased levels of TPMT and so was started on a low dose of azathioprine for immunosuppression. She continued to have worsening disease activity with 10g of proteinuria and dysmorphic hematuria and so low-dose tacrolimus (trough 2-4) was started with improvement in proteinuria to 4g/24 hrs. She then naturally conceived a twin pregnancy and had a full term delivery without complications.

Results:

Conclusions: Intolerance to steroids and contraindication to mycophenolate in addition to low TPMPT limited the therapeutic options in this case. Using tacrolimus for its antiproteinuric effects at low dose can be beneficial.



Light microscopy with PAS stain showing IgA nephropathy with mild mesangial proliferative changes and focal global glomerulosclerosis

TH-PO628

Normal GFR to ESRD after Pregnancy with Diabetic Nephropathy Hassan B. Attique, Anika Lucas, Ibrahim Elali. *University of Connecticut Health Center, Farmington, CT.*

Background: While pregnancy associated incidence of complications in Type 1 diabetic (T1D) patients with nephropathy is well established, the rate of progression of the nephropathy is yet to be adequately studied.

Methods: 36 year old female with history of uncontrolled HTN and T1D, complicated with diabetic nephropathy, presented at 12 weeks of gestation with nephrotic range proteinuria of 7.6 g, creatinine clearance (Ccr) of 104 ml/min on 24- hour urine collection and a serum creatinine (SCr) of 0.8mg/dl. Prior to her pregnancy, her baseline SCr was 0.61mg/dl with estimated glomerular filtration rate (eGFR) of 118 ml/min/1.73m^2, and reported urinalysis with 2$^+$- 3$^+$ proteinuria or sub-nephrotic range. During pregnancy, diabetes remained uncontrolled despite intensive insulin regimen. Blood pressure ranged from 116-167 mmHg systolic and 68-101 mmHg diastolic. Peak SCr was 1.2 mg/dl and protein-creatinine ratio (PCR) of 17 g/g. She developed preeclampsia at 35 weeks of gestation resulting in preterm delivery of 2095 g newborn via caesarean section. Post-delivery SCr at one month was 1.1 mg/dl with eGFR of 60 ml/min/1.73m^2, and albumin-creatinine ratio of 9 g/g. Over the course of eight months postpartum, renal function continued to decline, and progressed to ESRD, requiring chronic renal replacement therapy support. Peak SCr was 4.3 mg/dl, and 24-hour urine collection revealed Ccr of 12.4 ml/min with 20 grams proteinuria. Serological workup was negative. Renal biopsy was consistent with diabetic nephropathy and showed diffuse nodular global sclerosis.

Results:

Conclusions: Although preclampsia, caesarean section, and preterm delivery are known complications in diabetic nephropathy, nephrotic range proteinuria with preserved GFR progressing to ESRD post pregnancy is not well documented. Previous studies showed no increased risk of overt nephropathy or ESRD in women with preserved GFR at conception, and proteinuria generally returns to baseline postpartum. We observed an accelerated decline in renal function as well as worsening proteinuria leading to ESRD post partum, requiring chronic hemodialysis support. Pre-existing Proteinuria seems to be a stronger factor than preserved GFR pre-pregnancy in predicting future progression and disease outcome. Aggressive preconception counseling should be considered to avoid preventable fetal and maternal morbidity, including the possibility of disease progression to ESRD.

Thrombotic Thrombocytopenic Purpura in Early Second Trimester Pregnancy Successfully Treated with Membrane Therapeutic Plasma Exchange Charissa Marie R. Carag, Casey N. Gashti, William L. Whittier. *Rush University Medical Center, Chicago, IL.*

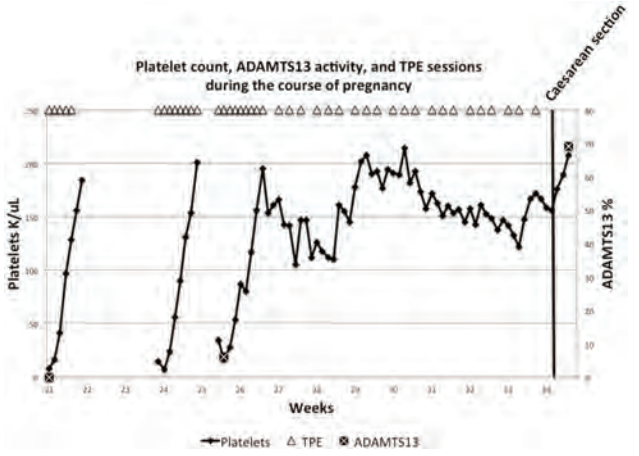
Background: Thrombotic thrombocytopenic purpura (TTP) is a life-threatening thrombotic microangiopathy which presents with hemolytic anemia, thrombocytopenia, and an ADAMTS13 activity <10%. Although rare, it can flare in pregnancy, and should be considered in the differential diagnosis of thrombocytopenia in pregnancy. In the general population, acquired TTP is more common, although recently, more studies have demonstrated that hereditary TTP makes up a greater number of pregnancy-associated TTP. We report a case of acquired TTP in pregnancy successfully managed by membrane-based therapeutic plasma exchange (mTPE) leading to delivery of a healthy child 13 weeks after diagnosis.

Methods: The patient was a 34-year-old G4P2012 woman with severe thrombocytopenia (platelets 8 K/uL) and anemia (Hgb 4.9 g/dl) in the 21st week of gestation. Her ADAMTS13 activity was <10% on two occasions with the presence of

an inhibitor. She was started on daily mTPE and high-dose steroids, followed by thrice-weekly mTPE to maintain a platelet count of at least 150 K/uL. The patient received 43 mTPE sessions during pregnancy without any complications. She delivered a healthy child at 34 weeks of gestation. After delivery, her platelets normalized without mTPE or steroids. An ADAMTS13 activity after delivery was 69%. (Fig 1)

Results:

Conclusions: TPE should be initiated immediately in cases of TTP, and can be performed safely in pregnancy. This case highlights the unique pathophysiology of TTP in pregnancy, as the mother did not require TPE once the placenta was delivered and her ADAMTS13 activity normalized. It has been theorized that certain proteins in the placental circulation induce antigen-triggering antibody production against ADAMTS13. Our case is the first report of using mTPE in pregnancy and demonstrates its efficacy and safety with 43 sessions over 13 weeks.



TH-PO630

Eculizumab, a Novel Treatment for Acute Kidney Failure Associated with Severe Preeclampsia Hatem Elabd, Rushi K. Nayak, Belinda Jim, Kisra Anis, Anjali Acharya. *Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY.*

Background: Preeclampsia is a leading cause of maternal and neonatal morbidity and mortality. It is the most common cause of AKI during pregnancy. Preeclampsia complicates approximately 5% of all pregnancies, making it perhaps the most common glomerular disease in the world. The complement system is a key mediator of systemic inflammation and is excessively activated in preeclampsia. As alloantibodies commonly develop against the semi-allogeneic fetal tissues, the placenta is potentially a target for complement-mediated immune attack.

Methods: A 29-year-old female multiparous at 40 weeks of gestation admitted to surgical ICU post emergent cesarean section for severe preeclampsia complicated with rupture membrane and fetal heart deceleration. Peri-operatively course complicated with bleeding, shock and acute kidney injury, for which patient needed resuscitation, and mechanical ventilation. She remained anuric with progressive kidney failure and continuous renal replacement therapy was started. We performed extensive workup to rule out acute fatty liver of pregnancy, TTP, atypical HUS, SLE, or antiphospholipid syndrome. Also complement gene mutation studies associated with atypical HUS were checked, which later turned out to be negative. Therefore, she was diagnosed with severe preeclampsia with multi-organ dysfunction. We decided to give Eculizumab 900mg/dose, a C5 inibitor, on day 4 post admission. One week later, patient had marked clinical improvement, and dialysis was discontinued. Furthermore, there was complete normalization of all laboratory abnormalities and complement activation markers.

Results:

Conclusions: To our knowledge this is the first case describing the use of Eculizumab in acute kidney injury (AKI) in setting of severe preeclampsia. The use of Eculizumab was previously described in a women with HELLP syndrome which led to improved liver function tests and pregnancy prolongation for 17 days. As opposed to our case, Eculizumab was given intrapartum and their patient had no evidence of kidney failure. The use of Eculizumab in this report supports a possible benefit of C5 inhibition for the treatment of severe preeclampsia and AKI. Its use may be particularly helpful among women with mutations in complement regulatory proteins. Further research is warranted to validate our findings.

TH-PO631

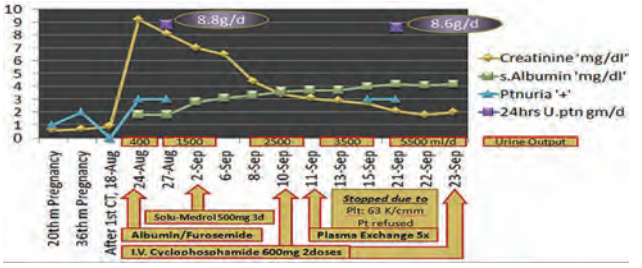
New-Onset Crescentic Glomerulonephritis Following Preeclampsia: A Diagnostic Dilemma Karim M. Soliman,[1,2] Mohammed Z. Mohialdeen,[1] David W. Ploth.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]Nephrology, Cairo University, Cairo, Egypt.*

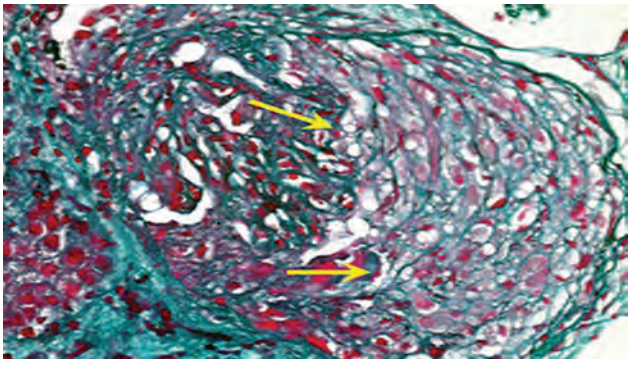
Background: New-onset crescentic Glomerulonephritis (GN) in the postpartum period following preeclampsia with normal GFR after delivery has not been reported. AKI 2 days post CT with contrast complicates making this diagnosis.

Methods: A 28 year old female G3P2 with no significant past medical history presented during her 36th week of pregnancy with preeclampsia and urine protein excretion of 4 gm/24hr. C-section delivered a viable fetus. She was discharged with serum creatinine (Cr) 0.8 mg/dl. She returned with fatigue and abdominal tenderness 2 weeks later. CT imaging with contrast revealed a supra-uterine hematoma prompting surgical evacuation. Two days later she developed progressive increase in lower extremity edema, puffiness of eyelids, oliguria and microscopic hematuria. Hemoglobin was 7.6 gm/dl, platelets 220 K/cmm, Cr 9.2 mg/dl, albumin 1.8 gm/dL and urine protein excretion 8.8 gm/24hr (clinical course in Fig.1). Viral markers (Hepatitis B, C and HIV), C3, C4 and immune profile, were all negative. Renal biopsy revealed twenty glomeruli, all showed cellular crescents (arrows in Fig.2) and collapsing of capillary loops with moderate endocapillary proliferation. Immunoperoxidase staining was negative for IgA, IgG with weak focal positive staining for IgM within the crescents.

Results:

Conclusions: The patient did not require dialysis and renal functions responded favourably to plasma exchange, steroids and cyclophosphamide. Three months later Cr was 2 mg/dl and urine protein 4 gm/24 hr. At this time, further therapy options are being discussed. Educational objectives include; always confirm the clinical suspicion of glomerular disease with biopsy whenever possible. Hidden triggering elements for crescentic GN merit consideration.





TH-PO632

Microscopic Polyangiitis with Pulmonary Renal Syndrome in a Pregnant Woman: Management Challenges Ramprasad Kandavar,[2] Sandhya L. Kommana,[1] Anuja P. Shah.[3] *[1]Harbor ULCA MEDICAL CENTER, Harbor City, CA; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]Los Angeles Biomedical Research Institute at Harbor-UCLA, Torrance, CA.*

Background: Introduction Microscopic Polyangiitis occurring either de novo or relapse during pregnancy has significant maternal and fetal morbidity and mortality. Here we report a case of pregnant woman developing de novo MPA manifesting as pulmonary renal syndrome posing considerable management challenges

Methods: Case Description A 21year-old pregnant woman (G1P0) presented to the Emergency department at 21 weeks gestation with uncontrolled blood pressure, pulmonary edema and acute renal failure. Laboratory data significant for Hemoglobin of 6.4, BUN 49 and Serum Creatinine 7.15 mg/dl. UA showed 3+protein, 3+ blood with numerous Acanthocytes. Further studies revealed P- ANCA 1:160 and Anti MPO: 24. Renal US was revealed normal sized kidneys. Early clinical course also complicated by hemoptysis suggestive of pulmonary hemorrhage. A diagnosis of RPGN secondary to Microscopic Polyangiitis was made. She was started on pulse steroids followed by oral Prednisone, IV cyclophosphamide, Hemodialysis 6 times/week and Plasmapheresis. Over the course of several days patient made significant clinical stabilization, hemoptysis resolved and ANCA and anti-MPO titers became negative. Patient was managed in close consultation with Obstetrics Service and underwent Cesarean section at 27.2 weeks. Patient received monthly infusion of Cyclophosphamide with no signs of renal recovery and currently is dependent on hemodialysis. Renal biopsy was done after delivery, showed immune complex mediated glomerulonephritis, chronic/inactive crescentic glomerulonephritis involving 85% of glomeruli with moderate to severe scarring.

Results:

Conclusions: Discussion: The data on MPA in pregnancy and its outcomes is very limited and is thought to have a more aggressive course. A systematic review of 48 pregnancies with small vessel vasculitis showed 33 % prematurity, 8% miscarriage, pre-eclampsia 17% and maternal death 4%. Many of the immunosuppression drugs including Cyclophosphamide are contraindicated in pregnancy because of teratogenicity, ovarian

failure, and fetal prematurity. However, there are anecdotal reports of Cyclophosphamide use in pregnant women with malignancies like leukemia, lymphoma and breast cancer confirming safety of the drug in pregnancy. In our case we faced similar treatment dilemmas though in the end we were able to deliver a viable fetus.

Funding: Other U.S. Government Support

TH-PO633

Transient Hypertension in a Preterm Infant after the Administration of Indomethacin for Patent Ductus Arteriosus Takahiro Tominaga,[2] Sayu Omori,[2] Midori Awazu.[1] *[1]Keio University School of Medicine, Tokyo, Japan; [2]Saitama Municipal Hospital, Saitama, Japan.*

Background: While hypertension is a known complication of non-steroidal anti-inflammatory drugs (NSAIDs) in adults, it has not been reported in children. We report a preterm infant who developed hypertension after the administration of indomethacin for patent ductus arteriosus (PDA).

Methods: A preterm boy was delivered at 31 weeks' gestation *via* caesarean section for placenta previa. Birth weight was 1676 g. PDA was detected on day 2. Indomethacin 0.2 mg/g/dose was given intravenously from day 2 to day 4. On day 5, the ductus arteriosus was still patent. Although serum creatinine increased from 0.62 mg/dL to 1.05 mg/dL, urine output was normal (2.4 ml/kg/hr) and indomethacin was readministered on day 5 and 6. On day 7, the ductus arteriosus was closed. On day 8, urine output decreased to 0.8 ml/kg/hr, and fluid was restricted to 60 ml/kg/day. FE_{Na} was 2.2% which could be normal for preterm infants. Urine output gradually increased. Blood pressure (BP) had been normal until day 12. On day 13, BP increased to 82/41 mmHg and became 90/58 mmHg (99th percentile for postconceptional age 34 weeks) on day 14. Body weight did not change from day 7 to day 14. Physical examination was unremarkable with heart rate of 140 beates/min with no edema. Blood urea nitrogen was 2.5 mg/dL, serum creatinine 0.41 mg/dL, calcium 9.2 mg/dL, phosphorus 3.8 mg/dL, sodium 130 mmol/L, potassium 4.3 mmol/L, chloride 101 mmol/L, bicarbonate 16.3 mmol/l, uric acid 1.0 mg/dL, TP 4.7 mg/dL, albumin 3.0 mg/dL, NT-pro BNP 18210 pg/dL, plasma renin activity 1.1 ng/mL/hr, and aldosterone 382 pg/mL. Cardiac ultrasonography showed mean velocity of circumferential fiber shortening (mVcfc) of 0.6 circ/s and end-systolic wall stress (ESWS) of 119.3 g/cm^2 suggesting afterload mismatch, which occurs in response to an acute increase in vascular resistance. Nitroglycerin infusion was started. On day 15, BP decreased to 78/44 mmHg. Cardiac ultrasonography showed improvement of after load mismatch.

Results:

Conclusions: NSAID-induced hypertension has been ascribed to sodium retention due to COX-2 inhibition in the kidney. The major mechanism of the increased blood pressure of this patient, however, is thought to be high afterload due to increased peripheral vascular resistance presumably by indomethacin.

TH-PO634

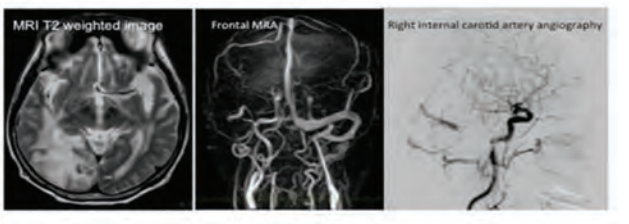
A Case of Dural Arteriovenous Fistula Caused by Dural Venous Sinus Thrombosis Complicated by Minimal Change Nephrotic Syndrome (MCNS) Risa Yamashita, Shoko Ochiai, Akihiro Minakawa, Takashi Iwakiri, Ryuzoh Nishizono, Masao Kikuchi, Hideto Nakagawa, Yuji Sato, Shouichi Fujimoto. *Division of Nephrology, Department of Internal Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan.*

Background: Venous thrombosis is an important complication of nephrotic syndrome (NS). Dural sinus venous thrombosis is uncommon, but it is a major risk of dural arteriovenous fistula (DAF). We present a case of DAF due to dural venous thrombosis that was successfully treated by an intravascular approach.

Methods: A 78-year-old man was admitted to our hospital with a 1-week history of edema, weight gain, exertional dyspnea, and new-onset of disorientation. On admission, a urinary examination showed microscopic hematuria and heavy proteinuria (protein/creatinine ratio of 9.5 g/g creatinine). A blood examination showed an elevated blood urea nitrogen level of 24.3 mg/dL, creatinine level of 1.38 mg/dL, fibrinogen level of 352 mg/dL, D-dimer level of 21.6 μg/mL, and antithrombin-III was 57%. Additionally, serum albumin was reduced to 1.49 g/dL. His renal biopsy findings showed minor glomerular abnormalities. These findings were compatible with MCNS. Deep vein thrombosis of the right leg was found by echogram. Prednisolone, cyclosporine, and oral anticoagulant were administered. Despite proteinuria being reduced, his disorientation became worse daily. Head computed tomography showed a low-density area in his occipital lobes. Magnetic resonance imaging showed DAF with sigmoid sinus thrombosis in addition to cerebral venous reflux, micro-hemorrhages, and venous blood stasis. Thereafter, transcatheter embolization was performed on the 29th hospital day, and then his disorientation improved. He was discharged on the 42nd hospital day. At an 8-month follow-up, MCNS and DAF had not relapsed.

Results:

Conclusions: Hypoalbuminemia and reduced anticoagulant activity are considered as major risk factors for thrombosis in NS. When thrombus in the cranial sinus occurs, increased venous pressure may cause DAF, dural hypertension, or arterial steal, followed by neurological deficits. We describe the first case of NS that was complicated by disorientation due to DAF in association with dural sinus thrombosis.



TH-PO635

Renovascular Hypertension: A Diagnostic and Therapeutic Conundrum Abhilash Koratala,[2] Freddy R. Malpartida,[2] Siddharth Wayangankar,[1] Rajesh Mohandas.[2] *[1]University of Florida, Gainesville, FL; [2]University of Florida, Gainesville, FL.*

Background: The commonest causes of renal artery stenosis (RAS) are atherosclerosis and fibromuscular dysplasia (FMD). Despite the availability of advanced imaging modalities, there are substantial challenges to accurately distinguishing between the two. Since treatment options and benefits of revascularization are different in FMD and atherosclerosis, it is essential to make an accurate diagnosis. Herein, we present the case of a young patient with hypertension (HTN) and RAS who was mistakenly labelled as FMD and later diagnosed with atherosclerotic RAS.

Methods: A 46-year-old woman with a diagnosis of FMD was referred to us for evaluation of resistant HTN. Uncontrolled HTN was confirmed by ambulatory blood pressure monitoring. 3 months prior to presentation, she had undergone angioplasty and stenting of the left renal artery for imaging suggestive of FMD. We optimized her anti-hypertensive regimen and recommended life-style modifications. At follow up, her clinic BP was 258/130 mmHg. She was on lisinopril 10mg, amlodipine 10mg, Chlorthalidone 25mg and spironolactone 25mg/ day. Renal angiography confirmed in-stent restenosis (90%) of the left renal artery and 80% diffuse stenosis of the ostial and proximal segments of the right renal artery. Intvascular ultrasound (IVUS) demonstrated atherosclerotic plaques. The proximal and ostial nature of the disease, absence of beading, and presence of plaques in a patient with diabetes and history of irradiation suggested atherosclerotic RAS. The restenosis was successfully treated with IVUS guided angioplasty [Figure]. Her blood pressures improved immediately after the procedure and she was weaned off all antihypertensive medications other than Lisinopril and chlorthalidone.

Results:

Conclusions: Accurately distinguishing between FMD and atherosclerotic RAS is critical. FMD is usually treated with angioplasty while most patients with atherosclerotic RAS do not benefit from revascularization. Patients who have stents placed should undergo periodic surveillance for restenosis with Doppler ultrasound.

TH-PO636

Labetalol or Amphetamine? : That Is the Question Shimontini Mitra,[2,3] Nikhil Agrawal.[1] *[1]Beth Israel Deaconess Medical Center, Brookline, MA; [2]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [3]Harvard Medical School, Boston, MA.*

Background: Uncontrolled hypertension is a frequent cause of hospitalizations. Evaluation for causes of accelerated hypertension includes urine analysis for ingested substances like amphetamine. Interpretation of urine amphetamine testing becomes difficult when patients are administered high doses of labetalol. Understanding the chemical structures of amphetamines and their breakdown products can help distinguish true amphetamine use from labetalol effect. In this case, mass spectroscopy proved helpful in interpreting a positive urine amphetamine test.

Methods: A forty-two year old male with ESRD and Type I Diabetes status post pancreas and kidney transplant in October 2015 and hypertension presented with elevated blood pressures and acute kidney injury. The patient was noted to have uncontrolled blood pressures for the past month. His blood pressure on admission was 211/113 and throughout most of his stay ranged 160-190/90-110mm Hg. His admission physical exam was notable for a chronic systolic murmur, no abdominal or carotid bruits, non-tenderness over kidney and pancreatic graft sites, no papilledema, and no edema. His admission creatinine was 1.8 mg/dL from a baseline of 1.4 mg/dL. Cardiac enzymes and EKG were unrevealing. His blood pressure regimen in-house consisted of labetalol 800mg TID, hydralazine 75mg QID and clonidine patch 0.3mg QD. A urine toxicology screen was also performed which returned positive for amphetamine. The patient denied the use of illicit substances prompting further analysis. Mass spectroscopy of the sample was negative for amphetamine but demonstrated a breakdown compound of labetalol, 3-amino-1-phenylbutane (APB). His blood pressures were eventually controlled with the addition

of isosorbide mononitrate 120mg QD and furosemide 40mg QD orally. His creatinine returned back to baseline and patient was discharged.

Results:

Conclusions: Labetalol breaks down into multiple compounds. One of these metabolites is APB. Urine amphetamine assays work by competitive inhibition between glucose-6-phosphate dehydrogenase (G6PDH)-labeled amphetamine and urinary amphetamine for a fixed number of reagent antibody binding sites. APB is structurally similar to amphetamine and can bind to reagent antibody in this assay resulting in false positivity. Therefore, for patients with uncontrolled hypertension who are also on high doses of labetalol, mass spectroscopy is a means of correctly interpreting a positive test.

TH-PO637

Systemic Sclerosis Sine Syndrome: Another Cardio Renal Collusion! Panpan Chen, Anum Bilal, Loay H. Salman, Mauricio Monrroy, Rafia I. Chaudhry. *Albany Medical College, Albany, NY.*

Background: SSc is a diffuse connective tissue disorder with cutaneous and visceral involvement, presenting with characteristic skin sclerosis. Systemic Sclerosis sine scleroderma (ssSSC) is a rare (<10%) subset of SSc with visceral and immunologic features of SSc without skin involvement. Additionally, hypocomplementemia can be found in 20% cases of SSc, and may represent an "Overlap Syndrome", i.e. second autoimmune condition. Scleroderma renal crisis occurs in 5-20% of SSc, and diagnosis can be missed without the characteristic sclerotic skin findings of SSc.

Methods: A 26 yr-old female with a PMHx of HTN and CKD III, presented with sub-sternal chest pain, palpitations, headaches and malignant hypertension. Exam was significant for BP 211/136 mm Hg, HR 84/m and trace LE edema. Laboratory data: Hb 10.6 g/dL, Sr Cr 2.5 mg/dL, and troponin, b-hCG and urine toxicology screen were negative. Urine microscopy did not reveal RBC casts; spot urine protein/Cr ratio was 1.14. TTE showed moderate pericardial effusion, and a pericardial window drained 100 mL of transudative fluid with benign mesothelial cells, and benign pericardial tissue on biopsy. An ANA titer of 160 and low C4 < 8.0 mg/dL (C3 normal 93.9 mg/dL) increased suspicion for lupus nephritis. However, renal pathology revealed thrombotic microangiopathy, moderate to severe chronic sclerosing nephropathy, severe arteriolar hyalinosis, myxoid intimal hyperplasia, fibrin thrombi, suggestive of chronic thrombotic microangiopathy. IF did not show "full house" staining. While the patient had no history of Raynaud's phenomenon, or hallmark sclerotic skin changes of Systemic sclerosis (SSc), diagnosis of SSc was confirmed with positive scleroderma Ab (6.0); antiphospholipid Ab, and serum cryoglobulin were also positive. Beta blockers were discontinued to prevent vasospasm; ACE inhibitor and calcium channel blocker were initiated.

Results:

Conclusions: Prompt diagnosis is needed for timely initiation of ACE inhibition, which has dramatically improved renal outcomes. Hence it is crucial to recognize atypical clinical features of SSc such as pericardial effusion due to primary cardiac involvement, or secondary to pulmonary hypertension. Pericardial effusion may also be a surrogate for active or severe disease, signifying poor prognosis in cases with primary cardiac involvement.

TH-PO638

Renovascular Hypertension Due to a Bcr-Abl Tyrosine Kinase Inhibitor and Response to Revascularization Syed O. Amin,[3] Marcel Ruzicka,[2] Swapnil Hiremath.[1] *[1]University of Ottawa, Ottawa, ON, Canada; [2]None, Ottawa, ON, Canada; [3]Windsor Regional Kidney Care and Hypertension Clinic, WINDSOR, ON, Canada.*

Background: Bcr-Abl tyrosine kinase inhibitors (TKI) are first line agents for management of chronic myelogenous leukemia (CML). Amongst the second generation TKIs, which have less resistance and improved side effect profile, nilotinib and ponatinib have also been reported to be associated with vascular adverse events (VAEs), including systemic and peripheral arterial stenosis.

Methods: We report on a patient with CML treated with ponatinib, who developed bilateral renal artery stenoses, difficult to control hypertension, and responded to revascularization.

Results: Case: A 55 year old man, with CML due to a Bcr-Abl truncating mutation diagnosed in 2007, was treated with ponatinib 45 mg daily starting in 2011, which induced a complete remission. He subsequently developed hypertension. Hypertension appeared angiotensin II-dependent as BP normalized on combination of candesartan 32 mg once daily and hydrochlorothiazide 25 mg once daily. This treatment was however associated with an increase in serum creatinine from 1.4 to 2.6 mg/dL. Consistent with our clinical suspicion, a computed tomography angiogram revealed bilateral renal artery stenosis. He eventually required bilateral renal artery angioplasty and stenting as the BP could not be controlled without renin-angiotensin system blockers despite using up 5 classes of BP lowering drugs. Furthermore, follow up imaging of renal arteries showed progressive renal artery stenosis bilaterally. He underwent angioplasty and stenting in the left renal artery and angioplasty of both the branches of the right main renal artery, which could not be stented because of the early branching. After 6 months, BP is within target with 8 mg candesartan, amlodipine 10 mg and bisoprolol 2.5 mg daily, and the renal function is stable (creatinine 1.1 mg/dL). Overall, in this case, renal artery angioplasty and stenting stabilized renal function and improved control of hypertension.

Conclusions: Second generation TKIs are associated with VAEs, including renal artery stenosis. Renal artery angioplasty and stenting stabilized renal function and improved control of hypertension in this case. Future research should clarify the mechanisms of VAEs with TKIs, natural history, and long term response to revascularization in this setting.

TH-PO639

Nephrotic Syndrome as First Presentation of Waldenstrom's Macroglobulinemia Ayushi Chauhan. *University of Connecticut, Hartford, CT.*

Background: Waldenstrom's macroglobulinemia (WM) is a disorder characterized by bone marrow (BM) infiltration by a lymphoplasmacytic lymphoma and a serum immunoglobulin M (IgM) paraprotein. In contrast to multiple myeloma, renal involvement is uncommon in WM with nephrotic syndrome (NS) being rare. Here we describe a case of NS as a first presentation of WM.

Methods: 83-year-old male with a history of hemorrhagic stroke and hypertension presented for evaluation of anasarca. He reported worsening bilateral lower extremity, scrotal and penile edema over 4 weeks. He also felt "slowed down" and noted vision changes and gait instability. Lab values yielded the following: Hemoglobin 9.5, hematocrit 28.2, WBC 6.9 and platelets 282. BUN/creatinine (Cr) was 29/0.8. ESR was markedly elevated at 101. Urinalysis showed a bland sediment and more than 300 mg/dL protein without casts. Urine protein excretion was 5188 mg/g Cr. Serum protein electrophoresis showed significant hypoalbuminemia with a gamma region spike consistent with the presence of a monoclonal protein: IgM >3150, IgA 32 and IgG <108. Serum and urine immunofixation showed monoclonal IgM lambda (λ) and Bence-Jones proteinuria, respectively. λ free light chains were elevated at 13.10 with the Kappa/ λ ratio 0.19. β-2 microglobulin was 4.1. Serum viscosity and complement (C3 and C4) levels were within normal limits and cryoglobulins were negative. A subsequent BM biopsy revealed near effacement of marrow by diffuse interstitial B-Cell infiltrate and a positive MYD88 mutation indicative of WM. A kidney biopsy was not performed and no cancer-targeted therapy was initiated as the patient elected comfort focused care.

Results:

Conclusions: Diagnosis of WM-associated nephropathy is of immense clinical import due to its prognostic impact. Biopsy-proven WM nephropathy is associated with shortened overall survival especially in those with renal function decline despite treatment. Pathology can be variable however light-chain amyloidosis usually causes NS in WM. Despite presence of Bence-Jones proteinuria, as in our case, cast nephropathy is less culpable due to low quantity of the light chains. Reports are also emerging on minimal change disease as a paraneoplastic manifestation of WM with resultant NS. Regardless of mechanism of nephropathy, treatment of the underlying WM with chemoimmunotherapy, especially Rituximab, has largely shown to result in NS resolution.

TH-PO640

Lambda Light Chain Tubulopathy in Waldenstrom's Macroglobulinemia Joseph De Leon,[2] Sandhya L. Kommana,[1] Ramanath B. Dukkipati.[2] *[1]Harbor ULCA MEDICAL CENTER, Harbor City, CA; [2]Harbor-UCLA Medical Center, Torrance, CA.*

Background: Light Chain Tubulopathy is typically seen in Plasma cell dyscrasias such as Multiple Myeloma, however it has been reported in Waldenstrom's Macroglobulinemia. The vast majority of cases involve the Kappa Light Chains, with Lambda Light Chains being exceedingly rare.

Methods: A 63 year old female with untreated Waldenstrom's Macroglobulinemia was admitted for decreased oral intake resulting into acute kidney injury(AKI). She has not had definitive treatment due to absence of absolute indications such as cytopenias, organomegaly, hyperviscosity symptoms and nephropathy until 2 months prior to admission, when she had a rising creatinine of 1.6 mg/dl (baseline 1.3) and opted not to get the treatment of Rituximab. She presented on admission with AKI with creatinine of 3.9 mg/dl, trace proteinuria, 2-3RBC/HPF and FeNa<1%. She was volume repleted to manage the pre renal state although the possibility of plasmacytoma related kidney injury remained high. Unexpectedly, her kidney function did not have robust improvement and she eventually underwent kidney biopsy, the strongest suspicion being immune mediated MPGN. Pathology revealed renal involvement by atypical lymphoplasmacytic infiltrate with λ-light chain restriction with inclusions within proximal tubular epithelial cells with crystalloid appearance consistent with λ-light chain tubulopathy.

Results:

Conclusions: Waldenstrom's Macroglobulinemia have circulating monoclonal IgM proteins in association with a B cell lymphoproliferative disorder. Renal involvement occurs in < 5% of patients with varied pathology including direct invasion of renal parenchyma by neoplastic lymphoplasmacytic cells, intraglomerular occlusive thrombi of the IgM paraprotein and in some, development of MPGN with associated type I or type II cryoglobulinemia. Light chain proximal tubulopathy (LCPT) is characterized by cytoplasmic inclusions of monoclonal light chains within proximal tubular cells. One study focused on pathologic features of 40 cases of crystalline LCPT from 2000-2014 all of which showed κ-restriction. The incidence of LCPT is typically seen in Multiple Myeloma and has been reported in Waldenstrom's Macroglobulinemia. The vast majority of reported cases of LCPT are κ-restricted. The finding of LCPT, from Waldenstrom's Macroglobulinemia, with λ-light chain restriction makes this case exceedingly rare and to our knowledge, never been reported.

TH-PO641

Renal Heavy/Light-Chain Amyloidosis Diagnosed by Immunostaining and Liquid Chromatography-Tandem Mass Spectrometry in a Patient with Non-Ischemic Cardiomyopathy Mami Sugimoto,[5] Hideki Inoue,[2] Mikiko Fukagawa,[5] Tomoko Yamasaki,[5] Yutaka Kakizoe,[2] Yuichiro Izumi,[3] Takashige Kuwabara,[4] Masataka Adachi,[1] Yushi Nakayama,[2] Masashi Mukoyama.[4] *[1]Department of Nephrology, Kumamoto University, Kumamoto, Japan; [2]Department of Nephrology, Kumamoto university graduate school of medical sciences, Kumamoto, Japan; [3]Kumamoto University, Kumamoto, Japan; [4]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [5]Kumamoto University Hospital, Kumamoto, Japan.*

Background: Heavy- and light-chain amyloidosis (AHL) is a rare type of amyloidosis caused by deposition of monoclonal immunoglobulin heavy and light chain. Compared with patients with renal light-chain amyloidosis (AL), those with renal AHL are reported to be rarely complicated with cardiac amyloidosis, resulting in relatively better survival. We here report a rare case of renal AHL diagnosed by immunofluorescent staining and liquid chromatography-tandem mass spectrometry (LC-MS/MS) in a patient with non-ischemic cardiomyopathy.

Methods: A 73-year-old woman was referred to our hospital due to proteinuria and hematuria. Non-ischemic cardiomyopathy had been diagnosed 6 years before. Cardiac amyloidosis was suspected, but only slightly delayed gadolinium enhancement by cardiac MRI, which was confined to the inferolateral wall, did not meet the criteria for cardiac amyloidosis. She had received implantable cardioverter defibrillator because of ventricular arrhythmia. Approximately 1 year before the referral, she had experienced hematuria with no proteinuria when her serum creatinine level was 0.7 mg/dL. Upon admission, she exhibited an increased serum creatinine level to 1.89 mg/dL and significant proteinuria of 2.83 g/g creatinine. Plasma electrophoresis showed the presence of IgG-κ monoclonal protein. The ratio of κ:λ free light chain levels in serum was increased. Renal AL was first suspected on the basis of diagnosis by kidney biopsy. However, monoclonal immunoglobulin heavy-chain deposition was revealed by immunofluorescent staining and LC-MS/MS. Therefore, we finally diagnosed her as having renal AHL. We started to treat her with low doses of dexamethasone and lenalidomide, but the treatment was abandoned due to acute exacerbation of chronic heart failure. Echocardiogram exhibited concentric left ventricular hypertrophy. Further scrutiny and close follow-up are crucial to demonstrate that she suffered from cardiac amyloidosis complicated with AHL.

Results:

Conclusions: We here report a rare case of renal AHL diagnosed with LC-MS/MS, who could be probably complicated with morbid cardiac amyloidosis. Accurate diagnosis is extremely important to give insight into prognostic implication in patients with AHL.

TH-PO642

Light Chain Cast Nephropathy and Vascular Limited Renal Amyloidosis Occurring Simultaneously in a Patient Krishna Sury,[1] Gilbert W. Moeckel,[2] Jeffrey M. Turner.[1] *[1]Section of Nephrology, Yale University School of Medicine, New Haven, CT; [2]Department of Renal Pathology, Yale University School of Medicine, New Haven, CT.*

Background: Bence Jones proteins can lead to renal injury by multiple mechanisms; the biochemical properties of the immunoglobulin light chain play a central role in determining which type of kidney insult occurs. We present a case in which a patient simultaneously had vascular limited AL amyloidosis and light chain cast nephropathy. This sparked our interest in the molecular characteristics that, when present, might allow an immunoglobulin light chain to concurrently cause two distinct types of injury in separate compartments of the kidney.

Methods: A 53-year-old man presented with acute kidney injury (AKI) in the setting of six months of dizziness and progressively worsening pain from lower extremity claudication. Imaging revealed lucent lesions in the vertebrae, prompting a bone marrow biopsy that was diagnostic for multiple myeloma. The Congo red stain was negative for amyloid. Treatment of myeloma was delayed by onset of severe, symptomatic orthostatic hypotension. Workup including echocardiogram and cosyntropin stimulation test was unrevealing, and administration of intravenous fluids, fludrocortisone and midodrine was ineffective. His AKI progressed and he required dialysis but could not tolerate treatment due to severe hypotension. We attributed his renal decline to untreated myeloma, but this did not explain the orthostasis. Kidney biopsy revealed both light chain cast nephropathy and vascular-limited AL amyloidosis. Sadly, shortly thereafter the patient developed bradyarrhythmias and died of bradycardic arrest.

Results:

Conclusions: Multiple myeloma can present with a variety of renal manifestations; the type of injury depends upon the biochemical properties of the causative immunoglobulin light chain. AL amyloidosis occurs when the specific amino acid sequences and charge properties present promote the conformational change of light chains into amyloid fibrils. Alternatively, cast nephropathy occurs when there is an amino acid segment that stimulates light chain binding to uromodulin within the tubules. Rarely, these two distinct lesions occur simultaneously, as seen in our patient. We speculate that this occurs when a single species of monoclonal light chain possesses biochemical properties encompassing characteristics of both AL amyloidosis and cast nephropathy.

TH-PO643

A Case of Rapidly Progressive Glomerulonephritis Secondary to Monoclonal Gammopathy Diego A. Beltran Melgarejo, Ahmed Al-Sheyyab, Neil S. Sanghani. *Division of Nephrology, Vanderbilt University Medical Center, Nashville, TN.*

Background: Proliferative glomerulonephritis with monoclonal IgG deposition (PGNMID) is characterized by monoclonal glomerular deposits staining for a single light-chain isotype and a single heavy-chain subclass. It is more common in white female adults and usually presents with hematuria, nephrotic range proteinuria, and renal failure. Evidence of dysproteinemia is seen in only ~30% of the cases.

Methods: A 74 y/o Caucasian man with history of hypertension presented with a rash and rapidly progressive glomerulonephritis (RPGN). Physical exam revealed severe hypertension, trace lower extremity edema, and a non-blanching purpuric rash in all 4 extremities. The rest of his exam was normal. Lab results showed a serum creatinine (SCr) of 4.5 mg/dl (baseline 1 mg/dl), hematuria, and nephrotic range proteinuria. C3 and C4 were normal. There was no hemolysis or thrombocytopenia. ANA, AntiDNA, ANCA, antiGBMAb, cryoglobulins, and HCV/HBV/HIV serologies, were negative. Immunofixation electrophoresis did not show a monoclonal protein in the serum or urine. Kappa (κ) and lambda (λ) serum light chains were mildly elevated but κ/λ ratio was normal. Skin biopsy demonstrated superficial perivascular dermatitis suggestive of a drug eruption or urticaria. Renal biopsy revealed endocapillary proliferation, cellular crescents, and fibrinoid necrosis. There was granular mesangial and pseudo-linear capillary loop staining by IF with monoclonal IgG λ (2-3+), C3 (3+) and C1q (1-2+), IgG3 (3+) and IgG4 (1-2+), with trace IgG1 and IgG2. Subendothelial and mesangial deposits without specific substructure were seen on EM. Pulse steroids resulted in stabilization of SCr and resolution of skin rash, but were discontinued due to delirium. Rituximab was started with further improvement in SCr to 3.7mg/dl.

Results:

Conclusions: PGNMID is a monoclonal gammopathy that resembles an immune-complex GN. This case highlights RPGN and possibly skin involvement as atypical presentations of this condition. Renal biopsy with particular attention to light chain and IgG subclass restriction is key to confirm the diagnosis. Though no treatment guidelines are available, the severity of renal involvement might guide immunosuppressive choice. Pulse steroids and rituximab could be a potential effective treatment for this pathology.

TH-PO644

Proliferative Glomerulonephritis with Monoclonal IgG Deposits in a Heart Transplant Patient with Hypogammaglobulinemia Jennifer Scott, Mira T. Keddis. *Mayo Clinic, Phoenix, AZ.*

Background: We report a case of proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) in a heart transplant recipient with hypogammaglobulinemia.

Methods: A 70 year-old man status post heart transplantation 4 years prior presented with peripheral edema, new onset hypertension, rising creatinine(creatinine 2.7 mg/dL), hypoalbuminemia (3.1 g/dL), hematuria and nephrotic proteinuria (7.7 g/24Hr). Baseline chronic kidney disease (creatinine 1.5-1.9 mg/dL) was attributed to immunosuppression with calcineurin inhibition. Kidney biopsy revealed membranoproliferative glomerulonephritis with monoclonal IgG3 kappa deposit. Despite persistent absolute hypogammaglobulinemia, serum IgG3 levels were normal. Bone marrow biopsies at diagnosis, and 4 years later were both negative. No monoclonal spike was detected on serum or urine protein electrophoresis with immunofixation and free light chain ratio was normal during follow-up. He was initially treated with 6 months course of cyclophosphamide and tapering prednisone and mycophenolate mofetil was held during that time. He achieved partial remission with resolution of hematuria, normalizaton of serum albumin and reduction in proteinuria by ≥50% (2.9 g/24Hr) and creatinine nadir was 1.6 mg/dL. Four months after cessation of treatment, he suffered renal relapse with creatinine peak at 3.8 mg/dL and 7g/24 Hr proteinuria. He was treated with two doses of rituximab and tapering dose of prednisone and IgG3 levels nadired to 28.6 mg/dL (normal reference 18.4-106 mg/dL). Creatinine plateaued at 3.0 mg/dL with mimal improvement to proteinuria. Progressive renal failure developed and he was commenced on dialysis 31 months after diagnosis.

Results:

Conclusions: We describe the first case of PGNMID post heart transplant, despite immunosuppression and chronic hypogammaglobulinemia. We hypothesize that treatment failure was due to persistently normal IgG3 serum levels and absence of an identified clone for targeted therapy.

TH-PO645

A Case Report of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin G Kappa Deposits in the Setting of Propionibacterium granulosum Infection Sara Syeda, Sairah Sharif. *Div of Kidney Diseases and Hypertension, Brown University, Providence, RI.*

Background: Proliferative glomerulonephritis with monoclonal immunoglobulin deposition disease (PGNMID) is a rare disease that is caused by monoclonal IgG deposition. On light and electron microscopy it mimics immune complex glomerulonephritis (GN). Here we report a patient with Propionibacterium granulosum (P. granulosum) joint infection who developed acute nephrotic-nephritic syndrome, without detectable paraprotein, eventually found to have PGNMID.

Methods: An 80-year-old Hispanic male with history of insulin dependent diabetes who was being treated with penicillin for left hip P. granulosum prosthetic infection,

presented with sudden onset anasarca and serum creatinine (SCr) of 2.8mg/dL (baseline SCr was 0.7mg/dL). Workup showed nephrotic syndrome with microscopic hematuria. Over the span of next two weeks he developed anuric failure requiring dialysis. He underwent a renal biopsy which showed PGNMID on a background of diabetic nephropathy. Immunofluorescence showed 3+ granular staining for IgG, C3 and kappa light chain. Electron microscopy showed diffuse sub-epithelial "humps" and diffuse podocyte foot process effacement. Few mesangial deposits were present, but no sub-endothelial deposits seen. Serology was non-revealing, hepatitis and HIV screens were negative, complement levels (C3, C4) were normal and no paraprotein could be detected in serum or urine. He was started on steroids and given rituximab therapy (4 doses) but he remains dialysis dependent to date.

Results:

Conclusions: We report a case of PGNMID in a patient with P. granulosum infection. PGNMID typically presents with nephrotic range proteinuria, hematuria, and renal failure. Approximately one fifth patients progress to end stage renal disease. The pathogenesis is elusive, but one hypothesis is that there is hyper secretion of IgG by plasma cells or a clonal B cell population leading to its glomerular deposition. Only about 30% cases have a monoclonal spike. We speculate that an immune reaction against bacterial antigen may have triggered the process in our case. This may explain widespread sub-epithelial deposits seen on his biopsy, contrary to the literature reports of the deposits being primarily sub-endothelial and mesangial. Overall, PGNMID remains a poorly understood disease and there is no validated optimum therapy for it.

Natural History of Proliferative Glomerulonephritis with Monoclonal IgG Deposits: A Unique Case with 3 Renal Biopsies Obtained over 46 Years of Follow-Up Omar A. Aleter, Marjan Afrouzian, John Badalamenti, Hania Kassem. *University of Texas Medical Branch, Galveston, TX.*

Background: Introduction: Proliferative Glomerulonephritis (GN) with Monoclonal IgG deposits (PGNMID) is a rare entity first described in 2004 by Nasr et al. Since then, only 49 cases have been reported. We present a case of PGNMID with recurrent hematuria and nephrotic range proteinuria with almost half a century of follow-up.

Methods: Case Description: 79 year old Caucasian female presents with a history of two separate episodes of biopsy-proven recurrent GN over a course of 46 years. Both biopsies from 1974, and 1987 were reported as Membranoproliferative GN. The patient presented in 2016 for the third time with symptoms of fluid overload, a slight worsening in renal function (creatinine increased from 1 to 1.3), 7grams of proteinuria along with glomerular hematuria. Serological work up including serum cryoglobulins, Hepatitis B and C, ANA, Anti DNA, Complement levels, and rheumatoid factor was negative. Serum and urine protein electrophoresis showed no M spike. The third kidney biopsy was performed.

Results: Pathology: Light microscopy revealed the following glomerular findings in 9 glomeruli: global sclerosis (1/9), segmental sclerosis (3/9), endocapillary proliferation (6/9) and double contours. Other findings included mild tubular atrophy, moderate interstitial inflammation and fibrosis, and mild arteriolar hyalinosis. By immunofluorescence microscopy (IF), 12 glomeruli showed severe (+++) staining with IgG (IgG3), C3 and Kappa, only. Electron microscopy (EM) showed intramembranous and mesangial electron dense deposits, spikes and massive subepithelial humps. None of the findings fit the diagnostic criteria for any glomerular disease caused by monoclonal deposits. The final diagnosis was PGNMID with monotypic IgG/Kappa deposits

Conclusions: Discussion: With 3 renal biopsies obtained over 46 years of follow-up, our case opens a unique window into the natural history, and most importantly the pathogenesis of PGNMID. The biopsies show the immunologic/morphologic evolution of PGNMID in the kidney, confirming the benign course of the entity and its slow progression as our patient did not develop any hematological malignancy and was treated only with ACE inhibitors.

TH-PO647

Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits in Adolescent Patient Successfully Treated with Daratumumab Maria E. Drosou, Hassan A. Salameh, Fernando C. Fervenza, Nelson Leung. *Mayo Clinic, Rochester, MN.*

Background: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is a renal complication of monoclonal gammopathy of renal significance (MGRS). Treatment with renin-angiotensin system blockade and immunosuppressive therapy with steroids, cyclosporine, cyclophosphamide, mycophenolate mofetil, and clone directed with rituximab and bortezomib have produced varying results. Daratumumab is a monoclonal antibody that targets the CD38 antigen on the surface of plasma cells. Since 50% of the clones in PGNMID are plasma cell in origin, this makes daratumumab a reasonable treatment option.

Methods: A 17 year old previously healthy female patient presented with nephrotic syndrome and hematuria without renal function impairment. Laboratory findings included serum albumin of 2.4 g/dl, serum creatinine (Scr) of 0.8mg/dl and proteinuria of 9 g/d. Renal biopsy revealed a PGNMID with IgG3 lambda deposits. Serum and urine monoclonal studies were negative and serum free light chains were normal.

Results: Initial treatment included steroids, mycophenolic acid and rituximab transiently reduced proteinuria to below the nephrotic range. In the next 7 months, multiple doses of intravenous steroids was administered for recurrent proteinuria and hematuria. Twelve months after initial presentation, proteinuria was back up to 5 g/d and bortezomib dexamethasone was started. Proteinuria initially improved to 2 g/d but was increasing to 3 g/d. The decision was made to add daratumumab to bortezomib dexamethasone. After 2 cycles, proteinuria was reduced by 80% to 0.7 g/d and the hematuria resolved. Scr was stable at 0.8 mg/dl.

Conclusions: To our knowledge, this is the first case of PGNMID treated with daratumumab. The young age of this patient made the treatment options more limited as preservation of her future fertility was a concern and little data exist on the long term effects of immunomodulatory drugs (IMiDs) on teratogenicity of future pregnancy. Daratumumab was chosen in order to avoid some of these complications. In combination with bortezomib and dexamethasone, it was very effective at reducing proteinuria and resolving her hematuria. With its high activity against plasma cells and its safety profile, daratumumab could be an excellent choice in the treatment of MGRS patients.

TH-PO648

De Novo Proliferative Glomerulonephritis with Monoclonal IgG in Renal Allograft Brad Long, Catreena Marji, Faris Ahmed, Mazdak A. Khalighi, Fuad S. Shihab, Laith Al-Rabadi. *University of Utah Hospital, Salt lake, UT.*

Background: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) has recently been recognized as a unique type of glomerular injury with a wide spectrum of pathologic and clinical manifestations. It is characterized by deposition of monotypic IgG in glomeruli and is often accompanied by C3 and C1q deposition. We have previously reported a series of three cases of recurrent PGNMID in renal allografts, all of which were associated with IgG3-Kappa deposition. De novo PGNMID in renal allografts has only been reported in three cases.

Methods:

Results: Herein, we present a fourth case of de novo disease that occurred in the renal allograft of a 32 year old man with primary disease of renal dysplasia since birth and prior allograft failure due to chonic antibody-mediated rejection. The patient presented to the hospital with 10 day history of dark urine. He was found to have acute kidney injury with Cr up to 2.5 mg/dl from 1.4 mg/dl. Urine microscopy showed many RBCs and several WBCs. Urine protein to Creatinine ratio was 1.5 g/g. Serum protein electrophoresis and immunofixation were normal. Serum kappa lambda ratio was 1.3. Cryoglobulins were negative. Biopsy showed mild mesangial hypercellularity without evidence of allograft rejection. Immunofluorescence microscopy revealed mesangial deposits staining for IgG, C3, C1q and kappa light chain without staining for lambda light chain. IgG subtype staining revealed IgG1-restriction. Electron microscopy showed mesangial electron dense deposits without substructural organisation.

Conclusions: Similar to native cases of PGNMID, recurrent disease in the allograft is most often related to deposition of IgG3-kappa. However, of the four reported cases of de novo PGNMID, three were IgG1-Kappa and only one was IgG3-kappa. IgG1-kappa in renal allografts has so far been described only in de novo cases, not in recurrent cases. Ours is the fourth de novo case but is the only one that occured in the second allograft. Patients with renal transplants are on immunosuppressive therapy that may alter the disease course. Deposition of IgG1-kappa in renal allografts may represent a distinict entity which is more resistant to IS therapy. More studies are needed to investigate the impact of different immunoglobulin subclasses on disease phenotype.

TH-PO649

Acute Interstitial Nephritis in the Setting of Fibrillary Glomerulonephritis: Case Report and Review of Literature Khetisuda Suvarnasuddhi, Sairah Sharif. *Brown University, Providence, RI.*

Background: Fibrillary glomerulonephritis (FGN) is a rare primary glomerular disease that presents with hypertension, proteinuria, microscopic hematuria and variable renal failure. It is often associated with hepatitis C virus (HCV). We report a case of FGN along with acute interstitial nephritis (AIN) in patient with HCV who had response to therapy.

Methods: A 61 year old Caucasian male with past history HCV (viral load PCR 979330IU/ml), HTN, chronic kidney disease (baseline creatinine (Cr) 1.2 mg/dL), and hemorrhagic stroke presented for evaluation of hypotension and fatigue. He was found to have urinary tract infection secondary to Proteus and Enterococcus started on piperacillin/tazobactam; later de-escalated to amoxicillin/clavulanate. Course complicated by acute kidney injury (AKI). Initial etiology of AKI thought to be pre-renal azotemia from poor oral intake and ischemia from hypotension. Urine sediment revealed few muddy brown casts, WBCs> 100/HPF, RBCs >100/HPF, and few dysmorphic RBCs. Serologies were negative for autoimmune diseases, and C3 and C4 were normal. Renal ultrasound showed increased echogenicity of renal cortex; and no hydronephrosis. AKI worsened and Cr peaked at 4.3mg/dL. Due to worsening AKI renal biopsy was performed that showed on light microscopy (LM) mesangial expansion, interstitial nephritis, mild interstitial fibrosis and tubular atrophy, electron microscopy (EM) demonstrated numerous random fibrils average 15nm identified as FGN. Patient was started on steroids for interstitial nephritis, and plan to start outpatient HCV therapy. His SCr improved to 1.7 in about 2 weeks from steroid initiation.

Results:

Conclusions: FGN is found in about 1% renal biopsies. It typically presents in the fifth to sixth decade. There maybe background of HCV, polyclonal gammopathy, and/ or lymphoproliferative disorders. The LM is heterogenous usually membranoproliferative, or mesangioproliferative, or diffuse proliferative GN. EM (EM) shows randomly oriented fibrils about 20nm in diameter. Optimal therapy is not known but corticosteroids and immunosuppressants have been tried with little success. About half of patients progress to dialysis. To the best of our knowledge this is the first case of FGN with AIN reported that showed response to corticosteroids.

TH-PO650

The Uroplakin Plaque Promotes Renal Structural Integrity During Congenital and Acquired Urinary Tract Obstruction Ashley R. Jackson,[1,2] Birong Li,[1] Sudipti Gupta,[1] Shira H. Cohen,[1] Rachel Millner,[1,2] Christina B. Ching,[1,3] Kirk M. McHugh,[1,4] Brian Becknell.[1,2] *[1]Center for Clinical and Translational Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Nephrology Section, Nationwide Children's Hospital, Columbus, OH; [3]Division of Pediatric Urology, Department of Surgery, Nationwide Children's Hospital, Columbus, OH; [4]Department of Anatomy, The Ohio State University College of Medicine, Columbus, OH.*

Background: Congenital urinary tract obstruction (UTO) is the leading cause of chronic kidney disease and end stage renal disease in children. Yet many children with congenital ureteropelvic junction obstruction (UPJO) can be managed nonoperatively, with spontaneous improvement or resolution of hydronephrosis on postnatal imaging. This implies the existence of renal adaptations during UTO that preserve parenchymal integrity and function. We hypothesized that uroplakin (Upk) expression by renal urothelial cells initiates a protective adaptation during congenital and acquired UTO, serving as a gatekeeper to progressive renal injury.

Methods: The Upk plaque was destabilized in a congenital model of functional lower UTO by generating *Mgb*$^{-/-}$;*Upk1b*$^{-/-}$ mice. Diphtheria toxin (DT)-mediated depletion of Upk(+) cells was induced following unilateral ureteral obstruction (UUO) in *Upk2*$^{CreERT2/+}$;*R26*$^{DTR/+}$ mice (acute UTO model). Urine UPK2 and UPK3A levels were measured by ELISA in children undergoing pyeloplasty for UPJO versus nonobstructed controls.

Results: In *Mgb*$^{-/-}$ mice with congenital hydronephrosis, the renal urothelium acquires a bladder-like cellular composition and ultrastructure. The extent of hydronephrosis positively correlates with *Upk* mRNA content in *Mgb*$^{-/-}$ kidneys. Likewise, urinary UPK3A and UPK2 levels increase in children with UPJO, when compared to nonobstructed controls. *Mgb*$^{-/-}$; *Upk1b*$^{-/-}$ mice display disrupted renal urothelial ultrastructure; rapid onset of bilateral hydronephrosis; and adolescent mortality due to renal failure, compared to single gene deficient or wild type control mice. DT-depletion of Upk(+) cells in *Upk2*$^{CreERT2/+}$;*R26*$^{DTR/+}$ mice accelerates the progression of hydronephrosis following UUO. Absence of the Upk plaque leads to increased interstitial fibrosis in both congenital and acute UTO models, respectively, compared to Upk intact controls.

Conclusions: These studies provide the first experimental evidence that the renal Upk plaque confers an essential, protective adaptation during congenital and acquired UTO. Conversely, loss of the Upk plaque leaves the kidney vulnerable to obstructive hydronephrosis and may identify patients in need of surveillance or more immediate surgical intervention for renal deterioration.

TH-PO651

The Renal Urothelial Plaque Protects the Kidney Following Obstructive Injury Birong Li,[1] Ashley R. Jackson,[1,4] Hanna H. Cortado,[1] Sudipti Gupta,[1] Christina B. Ching,[1,2] Kirk M. McHugh,[1,3] Brian Becknell.[1,4] *[1]Center for Clinical and Translational Research, The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Division of Pediatric Urology, Department of Surgery, Nationwide Children's Hospital, Columbus, OH; [3]Department of Anatomy, The Ohio State University College of Medicine, Columbus, OH; [4]Nephrology Section, Nationwide Children's Hospital, Columbus, OH.*

Background: The urothelial plaque, comprised of Uroplakin (Upk) proteins, establishes the urine permeability barrier and promotes structural integrity of the urinary tract. The role of the plaque in obstructive nephropathy remains incompletely understood. We tested the hypothesis that the plaque serves a critical role in limiting hydronephrosis and parenchymal injury following obstruction.

Methods: Unilateral ureteral obstruction (UUO) was induced in three week old *Upk1b*$^{-/-}$ and wild type (WT) mice. Hydronephrosis was measured by serial ultrasound. Kidneys were analyzed by standard histologic stains and immunohistochemistry (IHC). The plaque was visualized by transmission electron microscopy (TEM). Upk protein levels in total kidney extracts were evaluated by Western blotting. Urothelium from children undergoing pyeloplasty for ureteropelvic junction obstruction (UPJO) was subject to IHC, TEM, and FITC-Dextran permeability studies.

Results: UUO leads to increased Upk protein levels; urothelial stratification and uniform apical Upk expression; and ultrastructural evidence of mature, bladder-like plaque formation in WT mice. In contrast, *Upk1b*$^{-/-}$ UUO renal urothelium lacks Upk expression and urothelial plaque, and displays hyperplasia of Krt5/Krt14 cells. *Upk1b*$^{-/-}$ UUO kidneys displayed accelerated progression of hydronephrosis and increased parenchymal injury, compared to WT UUO. Urothelium from the renal pelvis and ureteropelvic junction of children with UPJO displayed Krt5/Krt14 hyperplasia, disrupted plaque and tight junctions, and increased permeability to FITC-Dextran, compared to distal urothelium.

Conclusions: Renal urothelium undergoes extensive remodeling following obstructive injury, acquiring the appearance of lower tract urothelium with increased stratification and a mature plaque. The rapid progression of hydronephrosis and parenchymal injury in *Upk1b*$^{-/-}$ mice with UUO supports the hypothesis that the plaque serves a key role in protecting the obstructed kidney. Chronic obstructive injury in children with UPJO leads to disruption of the plaque and compromised barrier function. Strategies to augment or stabilize the renal uroplakin plaque may offer a formidable therapeutic approach to preventing acute and chronic obstructive renal injury.

TH-PO652

Urothelial Injury Markers Are Elevated in Neurogenic Bladder Patients and Correlate with the Presence of Hydronephrosis Rachel Millner, Janae Preece, Sudipti Gupta, Brian Becknell, Christina B. Ching. *Nationwide Children's Hospital, Columbus, OH.*

Background: Neurogenic bladder (NGB) leads to varying bladder dysfunction and poses a high risk for chronic kidney disease. Urinary markers of urothelial injury are an intriguing approach to monitor NGB and associated urinary tract abnormalities. We hypothesize that urinary markers of urothelial integrity and injury are significantly altered in NGB vs non NGB patients and that these markers correlate with renal injury and degree of bladder dysfunction. We measured Uroplakin 3a (Upk3a), a structural urothelial protein, as a marker of urothelial integrity; and HIP/PAP, an antimicrobial peptide expressed solely by damaged urothelium, as a marker of urothelial injury.

Methods: We recruited 87 NGB patients for urine collection. Mean age was 8.7y (0.2-33y). Healthy controls consisted of 18 patients with a mean age of 13y (7-18y). Urine Upk3a and HIP/PAP were measured by ELISA. We estimated GFR using age appropriate equations and obtained urodynamics (UDS), VCUG, and renal ultrasound results by chart review. In NGB, we correlated UPK3a and HIP/PAP levels with GFR; presence of VUR, hydronephrosis, or scarring; and bladder dysfunction based on UDS classification. UDS classification was based on CDC protocol. Statistical analysis was performed by Mann Whitney U test, Spearman Correlation, and logistic regression; $p<0.05$ was considered statistically significant.

Results: Urinary HIP/PAP and UPK3a levels were significantly higher in NGB vs controls ($p<0.005$ and <0.0001, respectively) regardless of age, sex, or race. HIP/PAP was significantly associated with hydronephrosis ($p=0.02$) but not VUR, scarring, GFR, or UDS classification. Upk3a expression correlated only with presence of NGB. Type of bladder management (catheterization vs free voiding) did not impact UPk3a or HIP/PAP level. There was a negative correlation between presence of hydronephrosis and GFR ($p=0.03$).

Conclusions: NGB may be associated with urothelial exfoliation. HIP/PAP and UPK3a are potential, noninvasive biomarkers of NGB. Elevated levels of UPK3a and HIP/PAP in NGB are independent of renal function and may reflect alterations in urothelial remodeling or mechanical shedding of urothelium in response to bladder dysfunction. Furthermore, HIP/PAP may serve as an early, noninvasive marker of hydronephrosis in NGB, which is associated with reduced renal function.

TH-PO653

Identification of Novel Urinary Proteins to Distinguish Urinary Tract Infection from Colonization in Catheterization-Dependent Children Catherine Forster,[3] Stuart Goldstein,[3] Ken Greis,[2] Prasad Devarajan.[1] *[1]Cincinnati Children's Hospital, Cincinnati, OH; [2]University of Cincinnati, Cincinnati, OH; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Children with neurogenic bladders who require clean intermittent catheterization (CIC) often have bacteriuria. Distinguishing urinary tract infection (UTI) from urinary tract colonization (UTC) is difficult. Our objective was to identify urinary proteins to distinguish UTI from UTC in CIC-dependent children.

Methods: 10 CIC-dependent children were included (UTI=5, UTC=5). UTI was defined as: 1) ≥ 50,000 cfu/ mL of a uropathogen, 2) ≥ 10 urinary white blood cells, and 3) ≥2 of the following: fever, abdominal or back pain, worsened incontinence, pain with CIC, or cloudy or malodorous urine. UTC was defined as a bacteriuria in an asymptomatic patient. Medical records of patients who met UTI criteria were reviewed to select those with clear UTI symptomatology. 5 UTC patients were matched on age and uropathogen. Quantitative profiling of urine proteins with isobaric protein labeling was performed using tandem mass spectrometry. Candidate markers were normalized using a collective mixture of proteins from all samples. Relative quantitative abundance of proteins across all samples were compared. Proteins with a significant fold-change across either UTI or UTC, with ≥50% change in the average abundance across groups were identified as proteins of interest.

Results: Eight proteins were differentially expressed. These included: haptoglobin and liver fatty-acid binding protein (LFABP) overexpressed in UTI; and apolipoprotein D, α-amylase 2B, inter-α-trypsin inhibitor heavy chain H4, non-secretory ribonuclease, CD44 antigen, and prosaposin overexpressed in UTC. Protein functions include antimicrobial activity (haptoglobin), inflammation (LFABP, apolipoprotein D, inter-α-trypsin inhibitor heavy chain H4, non-secretory ribonuclease, prosaposin, and CD44 antigen), and metal binding (α-amylase 2B).

Conclusions: These urinary proteins have potential to distinguish UTI from UTC in CIC-dependent children.

Figure 1

Protein of Interest	Mean log UTC	p-value for UTC	Mean log UTI	p-value for UTI	Log ratio UTI/UTC
Haptoglobin	-0.06	0.60	0.17	0.02	0.23
Apolipoprotein D	0.20	0.01	-0.001	0.99	-0.20
a-amylase 2B	0.22	0.02	0.004	0.93	-0.22
Inter-a-trypsin inhibitor heavy chain H4	0.11	0.12	-0.11	0.04	-0.23
Non-secretory ribonuclease	0.22	0.08	-0.12	0.04	-0.34
CD44 antigen	0.22	<0.01	-0.09	0.35	-0.31
LFABP	-0.46	0.01	-0.12	0.60	0.34
Prosaposin	0.38	<0.01	0.13	0.21	-0.26

TH-PO654

Tubular Epithelial Cell Function in Polycystic Kidney Disease (PKD): Analysis of Cells from Children with ARPKD and NPH Wolfgang H. Ziegler, Birga Soetje, Kathrin Swolana, Arne Mertens, Amrit Khera, Dieter Haffner. *Hannover Medical School, Hannover, Germany.*

Background: PKD-related cellular defects are best understood genetically or in epithelial (cell) models analysing cell proliferation and signalling. Use of primary patient-derived renal epithelial cells provides a unique opportunity to study and quantify cell properties in epithelial function-related assays. Apart from the analysis of differences due to specific mutation, it appears interesting to correlate the severity of the renal disease i.e. GFR or organ size / morphology with alterations in epithelial cell function determined *ex vivo*.

Methods: We culture urine-derived renal epithelial cells (URECs) of patients with genetically confirmed causes of PKD, autosomal recessive polycystic kidney disease (ARPKD) and nephronophtisis (NPH), and of age-matched healthy controls. Populations of primary cells obtained within 14 days of culture are tested with respect to their proliferation rates, formation of cell-cell junctions in monolayer and barrier function (impedance) in 2D culture. In addition, their capacity to build spheroids and form cilia is addressed in 3D culture conditions using matrigel and micro-patterned adhesion chips.

Results: URECs from cohorts of patients (5-6 each) with ARPKD or NPH (mostly NPHP-1 mutation), and controls are compared in cell culture to measure quantitative characteristics that can be correlated to clinical parameters and progress of PKD. We observe a much higher success rate of epithelial cell cultivation from urine of PKD patients. Cells are mostly of collecting duct origin as determined by aquaporin 2- positive staining. MTS-based assessment of cell proliferation shows relatively stable rates between days 10 and 15 (20) of culture, which are moderately higher in patient cells. Analysis of spheroid formation in matrigel (6 days) reveals on average bigger clusters of patient cells and an individual tendency of defective lumen formation. Barrier function of UREC monolayers is increased in a patient-specific manner.

Conclusions: Determination of genotype and / or disease state specific renal epithelial cell properties in URECs is expected to provide a better understanding of the mechanism and progression of disease processes in renal epithelium and may provide options for testing of pharmaceutical intervention.

Early Proteinuria Lowering by ACE Inhibition Predicts Renal Survival in Children with CKD Sophie Van den Belt,[1] Hiddo J. Lambers Heerspink,[1] Valentina Gracchi,[1] Dick de Zeeuw,[1] Elke Wuehl,[2] Franz S. Schaefer.[2] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]University of Heidelberg, Heidelberg, Germany.*

Background: Proteinuria predicts renal disease progression in adults and children with chronic kidney disease (CKD). While lowering of proteinuria by various interventional strategies has been demonstrated to be nephroprotective in adults, pediatric data are scarce. Here, we present a post-hoc analysis of the ESCAPE Trial regarding the relationship between the initial antiproteinuric effect of standardized ACE inhibition and renal disease progression in children with CKD.

Methods: All children were started on a fixed dose of ramipril (6 mg/m^2/day) and subsequently randomized to aim for conventional (<95th percentile) or intensified (<50th percentile) blood pressure control. The initial log-transformed change in proteinuria was assessed from baseline to first measurement after starting ramipril (at 2.6 ± 1.4 months). Cox proportional hazard models were used to estimate the association between initial proteinuria change and risk of reaching the renal end point (composite of 50% decline in eGFR or progression to end-stage-renal disease), adjusted for age, gender, renal diagnosis, baseline proteinuria, blood pressure, eGFR and change in blood pressure.

Results: Of 285 eligible children (60% male, age 11.5±3.9 years), 81 reached the composite endpoint within 5 years of follow-up. Proteinuria was reduced following start of ramipril treatment by a median of 39% (interquartile range 7-64%). The initial proteinuria reduction was associated with a reduction in the renal composite endpoint: hazard ratio 0.71 (CI 0.41-1.23) and 0.44 (CI 0.23-0.82) for the 30-60% and >60% proteinuria reduction groups respectively compared to the <30% reduction group. This association was independent of all the above mentioned tested covariates.

Conclusions: The degree of early anti-proteinuric effect of ACE inhibition is independently predictive of long-term preservation of renal function in children with CKD. This finding lends support to the notion that proteinuria lowering should be considered an important target in the management of pediatric CKD.

Association between Routine Newborn Metabolic Profiles, CKD, and the Need for Dialysis in Infants and Children Manish M. Sood. *Ottawa Hospital Research Institute, Ottawa, ON, Canada. Group/Team: Ottawa Newborn Metabolomics Project.*

Background: Metabolomics offers considerable promise in early disease detection. We set out to test the hypothesis that routine newborn metabolic profiles at birth, obtained as screening for inborn errors of metabolism, would be associated with kidney disease and add incremental information to known clinical risk factors.

Methods: We conducted a population-level cohort study in Ontario, Canada including metabolic profiles from 1, 288, 905 newborns from 2006 to 2015. The primary outcome was CKD or dialysis. Individual metabolites and their ratio combinations were examined in logistic regression models after adjustment for established risk factors for kidney disease and incremental risk prediction measured.

Results: : CKD occurred in 2,086(0.16%, median time 612 days) and dialysis in 641(0.05%, median time 99 days) infants and children. Individual metabolites consisted of amino acids, acyl-carnitines, markers of fatty acid oxidation and others. Base models incorporating clinical risk factors only provided C-statistics of 0.61 for CKD and 0.70 for dialysis. The addition of identified metabolites to the models composed of clinical risk factors resulted in significant incremental improvement in the performance of both models (CKD model: c-statistic 0.66 NRI 0.36 IDI 0.04, dialysis model: c-statistic 0.77 NRI 0.57 IDI 0.09). This was consistent after internal validation using bootstrapping and a sensitivity analysis excluding outcomes within the first 30 days.

Conclusions: Routinely collected screening metabolites at birth are associated with chronic kidney disease and the need for dialytic therapies in infants and children and add incremental information to traditional clinical risk factors.

Proteomic Study Revealed the Elevation of Urinary Alpha-1-Microglobulin/Bikunin Excretion in Nephrolithiasis Familial Members Thasinas Dissayabutra, Trairak Pisitkun, Piyaratana Tosukhowong. *Chulalongkorn University, Pathumwan, Bangkok, Thailand. Group/Team: Biochemistry and Molecular Disease Research Unit.*

Background: Several literatures demonstrated higher incidence of urinary tract stone formation in familial members of nephrolithiasis (NL), although no responsible gene was established. Our previous studies revealed elevated urinary excretion rate of calcium, phosphate, albumin and protein as well as diminished urinary citrate and sulfated glycosaminoglycan excretion in non-stone-forming children of NL patients compare with normal children. These disorders were similarly observed in NL patients comparing with general population but in the greater severity pattern. Hence, to indicate which proteins were over-excreted in children with NL parents, we investigated proteomic profile in the susceptible children comparing with stone patients and general population.

Methods: Fourteen NL patients (N) and 29 of their children (NC), 26 healthy volunteers (V) and 28 of their children (VC) were enrolled. The 24-hour urine were collected. Except for NL, participants were screened for hematuria by urine strip test. Then, urine of NC and VC (children group) were used for proteomic study by mass spectrophotometry (LC-MS). Alpha-1-microglobulin/bikunin [AMBP] was subsequently measured in all participants using ELISA.

Results: According to proteomic profiles, the urinary excretion rate of 29 proteins were higher in non-stone-forming NC than VC. Among these, many proteins were previously reported to be associated with NL, such as AMBP, α_1-antitrypsin, serotransferrin, trefoil factor, prothrombin, vitronectin, etc. Our study observed the elevation of AMBP excretion in both NL patients (28.3±41.2 *vs* 10.2±20.1 mg/day, p=0.048) and their children (25.2±27.8 *vs* 10.2±10.6 mg/day, p=0.011.)

Conclusions: Urinary excretion rate of several stone-related proteins, including AMBP, appeared to be elevated in NL family even in members who yet to develop stone. Our results indicated that these abnormal urinary proteins may be the risks for high incidence of NL in familial members, and may be heritable. Further study aims to validate other susceptible urinary proteins, the pathogenesis and inherited pattern.

A Novel SLC12A1 Compound Heterozygous Mutation in Antenatal Bartter Syndrome Type 1 Showing Benign Clinical Course Zentaro Kiuchi,[2] Kandai Nozu,[1] Kunimasa Yan.[2] *[1]Kobe University, Kobe, Japan; [2]Kyorin University School of Medicine, Tokyo, Japan.*

Background: [Introduction]Antenatal Bartter syndrome (BS) type 1 is an autosomal recessive kidney disorder that shows severe renal dysfunction caused by loss-of-function mutations in the solute carrier family 12 member 1 (*SLC12A1*) gene.

Methods: [Case Description]This case is currently a 2 year-old girl. At 24 weeks of gestation, she had polyhydramnios in utero. She was born by vaginal delivery at 33 weeks 3 days. Polyuria (5-7ml/kg/hr) was observed from at the age of 1 day, accompanied by hyponatremia and hypokalemia and mild metabolic alkalosis. Urine osmotic pressure was always under 200mOsm/L. She had high reninemia and hyperaldosteronism. There was no morphological abnormality in kidney ultrasonography. Abdominal CT did not show kidney calcification. She had no hypertension or edema, but she suffered from failure to thrive (body length –2.1SD, body weight -2.7SD). Her psychomotor development is

currently normal and growth is becoming to be within normal range. Analysis of the *SLC12A1* gene demonstrated heterozygous mutation consisting of 2 novel mutations: c.2094delG in exon16 from father and c.1094T>C (p.I365T) in exon8 from mother, which led to the final diagnosis as BS type 1. Currently she receives treatment with oral medications including NaCl, KCl, Spironolactone and Alfacalcidol.

Results:

Conclusions: [Discussion]We here present an antenatal BS type 1 caused by novel heterozygous mutations of the *SLC12A1* gene. c.2094delG leads to the final formation of the protein mass of 75 kDa compared to the mature mass of 120 kDa. This immature mass is predicted to interfere homo-oligomer formation. On the other hand, the functional influence of p.I365T is not able to speculate so far. However, this report clearly indicates that a combination of heterozygous mutation found in our case would not severely impact on the renal tubular function after birth even in the cases with antenatal Bartter syndrome type1.

TH-PO659

Combination of Different Urinary Omics Traits Improves the Prediction of Postnatal Renal Outcome in Fetuses with Posterior Urethral Valves (PUV) Benedicte Buffin-Meyer, Julie Klein, Francoise Muller, Benjamin Breuil, Panagiotis Moulos, Lounis Nadia, Jean-loup Bascands, Stéphane Decramer, Joost Schanstra. *Inserm U1048, Toulouse, France.*

Background: Urinary omics-based strategies are promising tools in medicine as they have already led to the design of multimarker models for the assessment of complex diseases. Nevertheless, advances still need to be made since most models using single omics traits are unable to reach a 100% accuracy and display a so-called "gray zone" defined by the uncertainty of the prediction. Here we verified the hypothesis whether a combination of urinary fetal peptides and metabolites provides an improved prediction of postnatal renal function in fetuses with PUV compared to the individual omics traits.

Methods: Using capillary electrophoresis coupled to mass spectrometry, we explored the urinary metabolome from 13 PUV fetuses with early ESRD and 12 PUV fetuses without postnatal ESRD at 2 years.

Results: This allowed the identification of 24 differentially abundant fetal urinary metabolites which were modelled into a svm classifier, alone or in combination with 12 peptides predictive of disease progression (Klein et al, PMID:23946195). The predictive capacities of models composed of metabolites (24m model), peptides (12p model) or association of both (24m_12p model) were compared in a separate independent validation cohort of 35 fetuses with PUV. The gray zone was generated as the range of svm scores for which the negative likelihood ratio (LR) was >0.05 and the positive LR was <20. Sensitivity, specificity (excluding patients in gray zone) as well as area under the ROC curve (AUC) and net reclassification improvements (NRI) of PUV patients were evaluated (Table 1).

Conclusions: While the individual metabolome- and peptidome-based models already display high accuracy for identification of the disease classes, the discriminative power can be significantly improved by combination of omics traits. This supports the general concept that multi-omics approaches can improve the clinical assessment of disease.

Comparison of Different Urine Collection Techniques to Establish and Monitor Albuminuria in Healthy Toddlers Sophie Van den Belt, Valentina Gracchi, Dick de Zeeuw, Hiddo J. Lambers Heerspink. *UMC Groningen, Groningen, Netherlands.*

Background: For measurement of albuminuria, guidelines in adults recommend to measure urinary albumin creatinine ratio (U_{ACR}) in first morning void (FMV) urine samples collected over three consecutive days. Since such a guideline is absent in toddlers, we compared several urine collection strategies.

Methods: Both a FMV and a random daytime urine sample were collected on three consecutive days at week 0 (visit 1), week 4 (visit 2) and week 8 (visit 3) in toddlers aged 12 to 48 months. Urinary albumin (U_{AC}), urinary creatinine (U_{CR}) and U_{ACR} were assessed. Intra-individual coefficients of variation (CV) of U_{AC} and U_{ACR} were determined using only the first U_{AC} or U_{ACR} measurement of each visit and using all three U_{AC} or U_{ACR} measurements per visit, and were compared with published CV of adults (Witte et al. JASN 2009).

Results: 80 toddlers (mean age 26.6 months, 53% male) were included. Geometric Mean (GM) U_{AC} was 5.7 mg/L (SD 1.9) in FMV and 5.5 mg/L (SD 2.0) in random samples. GM U_{ACR} was 17.6 mg/g (SD 2.6) in FMV and 21.7 mg/g (SD 2.3) in random samples. The variation in GM U_{AC} or U_{ACR} between toddlers derived from three FMV or random samples at visit 1 was smaller compared to single samples. The lowest intra-individual CV was observed when U_{AC} was measured in FMV over three consecutive days (table). CV's of U_{AC} and U_{CR} were similar to adults. However, U_{ACR} CV was considerably higher in toddlers.

Conclusions: These data confirm that FMV samples are preferred over random samples to establish and monitor (micro)albuminuria in toddlers, just like in adults. Surprisingly, unlike adults, within-individual CV was smaller for U_{AC} compared to U_{ACR} in toddlers. This appears not to be explained by a higher U_{CR} variability in toddlers. Further studies, particularly into variations in other renal functions that cause the mismatch between albumin and creatinine variation, are needed to explain these differences between children and adults.

Intra-individual CV, median (25th-75th percentile)

	Toddlers				Adults (Witte et al. JASN 2009)	
	Single urine sample per visit		Three urine samples per visit		Three urine samples	
	FMV sample	Random sample	FMV sample	Random sample	FMV sample	Random sample
UAC	47.5% (20.4-99.8)*‡	44.7% (11.8-85.6)	38.3% (22.1-56.7)	41.7% (24.4-64.1)	30.9% (19.4-47.8)	40.9% (27.8-70.2)
UACR	54.3% (27.5-114.6)*†	81.6% (39.5-144.3)*†	44.5% (28.2-74.2)*	61.7% (34.1-90.4)*†	19.1% (11.6-28.4)*	35.8% (17.6-55.6)
UCR	42.3% (20.4-77.6)	58.4% (35.6-87.7)	27.8% (15.8-57.3)	46.4% (23.9-69.5)	23.5% (13.8-66.7)	31.3% (19.1-56.1)

Effect of Growth Hormone Therapy on Renal Function in Children Born Small for Gestational Age Kazuya Matsumura, Hironori Shibata, Tomohiro Ishii, Tomonobu Hasegawa, Midori Awazu. *Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan.*

Background: Low birth weight infants, especially those born small for gestational age (SGA), are known to have fewer nephrons. Growth hormone (GH) induces catch-up growth in short children born SGA, which is a risk factor for chronic kidney disease (CKD). GH also causes hyperfiltration, which may lead to glomerulosclerosis. We retrospectively examined the effect of GH therapy on renal function in children born SGA.

Methods: Nineteen subjects born SGA (age 3 to 25 years) were studied. Ten were treated with GH and 9 served as controls. Blood pressure, serum creatinine, uric acid, urine microalbumin to creatinine ratio (malb/Cr), and the trajectory of eGFR, calculated by quantic equation for Japanese children (2 to 18 years) or formulas for Japanese adults (≥19 years), were compared.

Results: GH was started at the median age of 4 years (range 3-5). The median dose and duration was 0.25 mg/kg/week (range 0.2-0.3) and 66 months (range 23-95). There were no significant differences in the background characteristics between GH group and controls including age (11 vs 10 years), birth weight (1109 vs 804 g), gestational age (32.3 vs 28.5 weeks), sex, and initial eGFR (107 vs 98 ml/min/1.73 m^2). Only one child in each group did not show catch-up growth. eGFR declined in 6 (60%) in GH group and in 1 (11%) in controls (P<0.05). Of 6 GH-treated children whose eGFR declined (107 to 89 ml/min/1.73 m^2, P=0.09), eGFR before GH was stable in 2, increasing in 2, and declining in 2. In the remaining children who received GH, eGFR trajectory before and after the start of GH was decline followed by increasing (2), decline followed by stable (1), and continuously increasing (1), suggesting GH-induced hyperfiltration. There was no change in eGFR trajectory in control children; 2 increasing, 6 stable, and 1 decline. Urine malb/Cr (9.7 vs 9.6 mg/g) and the number of children with elevated malb/Cr (6 vs 4) were not different between GH group and controls. One child, however, developed microalbuminuria after GH was started. Hypertension or hyperuricemia was not observed in either group throughout the observation period.

Conclusions: eGFR decline was more frequent in SGA children with GH therapy compared with those not on GH. Initially stable or increasing eGFR followed by decline after the initiation of GH suggests that GH may promote progression of CKD in SGA children.

TH-PO662

Identifying Important Outcomes for Children with CKD and Their Caregivers: Focus Groups with Nominal Group Technique Camilla S. Hanson,[2,3] Gayathri Raman,[3] Yifan Zhang,[3] Angelique F. Ralph,[2,3] Angela Ju,[2,3] Laura J. James,[2,3] Andrea K. Viecelli,[1] Jonathan C. Craig,[2,3] Allison Tong.[2,3] *[1]Sir Charles Gairdner Hospital, Perth, NSW, Australia; [2]University of Sydney, Sydney School of Public Health, Faculty of Medicine, Westmead, NSW, Australia; [3]Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, NSW, Australia. Group/Team: SONG Kids Investigators and Steering Committee.*

Background: Chronic kidney disease has a devastating impact on the lives of children and their families, due to delayed development, debilitating symptoms and life-threatening complications. Trials frequently report surrogate outcomes, rather than clinical and patient-centered outcomes, and children and caregivers are rarely involved in determining what outcomes should be reported. We aimed to identify outcomes that are important to children with CKD and their caregivers, and ultimately to inform clinical care and a patient-focussed research agenda.

Methods: Children and adolescents with CKD (stage 1-5, dialysis, transplant) and caregivers were purposively sampled from 4 centers across Australia, the United States and Canada. Participants identified and ranked outcomes, and discussed the reasons for their priorities. The mean rank score was determined, and qualitative data were analyzed thematically.

Results: Twenty-six patients (aged 10 – 21 years, mean 14 years) and 45 caregivers participated in 12 groups, and identified 32 outcomes. The five highest ranked outcomes for patients were: physical activity (7.6/10), kidney function (7.6), fatigue (6.9), infection (6.8) and survival (6.8). Caregiver's five highest ranked outcomes were: kidney function (8.5), weight gain (8.2), survival (7.5), infection/immunity (7.4), and graft survival (7.2). The themes underpinning their choices were gaining independence and realizing potential; upheaval and intrusion on daily living; preserving health and kidney function; seeking control; and certainty of future.

Conclusions: Children prioritized their kidney health and survival, appearance, and social, sport, and school participation. Caregivers were most concerned about their child's kidney function, graft survival, infection, survival, and gaining weight. Trials that include outcomes important to children with CKD and their caregivers can better inform shared decision-making.

TH-PO663

Renal Function and Blood Pressure in Adolescents Born Preterm with Very Low Birth Weight Andrew M. South,[5,6] Patricia A. Nixon,[4,5] Mark C. Chappell,[6,3] Debra I. Diz,[6,3] Gregory B. Russell,[2] Elizabeth T. Jensen,[1] Hossam A. Shaltout,[6] Lisa Washburn.[5,6] *[1]Wake Forest School of Medicine, Winston-Salem, NC; [2]Public Health Sciences, Wake Forest School of Medicine, Winston-Salem, NC; [3]Surgery-Hypertension and Vascular Research, Wake Forest School of Medicine, Winston-Salem, NC; [4]Health and Exercise Science, Wake Forest University, Winston Salem, NC; [5]Pediatrics, Wake Forest School of Medicine, Winston Salem, NC; [6]Cardiovascular Sciences Center, Wake Forest School of Medicine, Winston Salem, NC.*

Background: Survival of children born prematurely has improved, but preterm birth as well as low birth weight may increase the risk of developing kidney disease in adulthood. However, the timing of the development of renal dysfunction and its progression is unclear. We hypothesize that worse kidney function will be present in early adolescence in children born preterm with very low birth weight (VLBW) as compared to term controls.

Methods: We measured systolic and diastolic blood pressure (BP), serum creatinine, and urine albumin at age 14 years in 96 subjects born preterm with VLBW (mean birth weight 1048 g) and 43 term controls. We calculated the glomerular filtration rate (GFR) by the Schwartz equation and urine albumin-to-creatinine ratio (ACR). We used generalized linear models to estimate the association between preterm birth and renal function, adjusting for maternal hypertensive pregnancy and socioeconomic status.

Results: In addition to higher mean systolic and diastolic BP (p<0.01 and p=0.03, respectively), adolescents born preterm had significantly-decreased GFR (β: -8.17 mL/min/1.73 m^2, 95% CI -15.93 to -0.4) as compared to term controls. Adjustment for covariates attenuated this relationship (β: -6.34 mL/min/1.73 m^2, -15.04 to 2.36). While subjects born preterm had higher median ACR, adjustment for potential confounders attenuated this relationship (ln ACR β: 0.34, -0.04 to 0.72).

Conclusions: Higher BP and reduced renal function were present in adolescents born preterm with VLBW compared to term peers, though the association between preterm birth and GFR was weakened after adjusting for confounders. While other factors should be considered, our study provides evidence of an early divergence of renal function during adolescence as a consequence of prematurity.

TH-PO664

Assessing the Hydration Status of Children with CKD and On Dialysis: A Comparison of Techniques Caroline S. Eng,[1] Rukshana Shroff.[2] *[1]Hospital Tuanku Jaafar Seremban, SEREMBAN, Malaysia; [2]Department of Paediatric Nephrology, Great Ormond Street Hospital for Children, London, United Kingdom.*

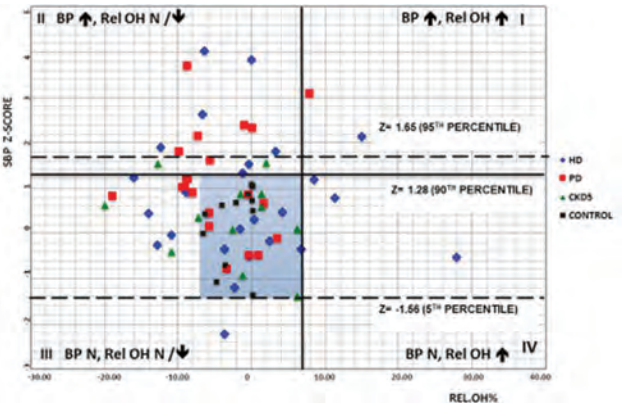
Background: Fluid balance is pivotal in the management of children with chronic kidney disease (CKD) and on dialysis. Although many techniques are available to assess fluid status, there are few studies in children, and none of the techniques have been compared against each other or against cardiovascular outcome measures.

Methods: We performed a longitudinal study in 30 CKD children and 13 age-matched healthy controls (71 measurements) to determine a correlation between optimal weight by bioimpedance spectroscopy (Wt-BIS) and clinical assessment (Wt-CA). The accuracy of Wt-BIS (relative overhydration [Rel-OH]) was compared against indicators of fluid status and cardiovascular measures.

Results: There was poor agreement between Wt-CA and Wt-BIS in children on dialysis when compared to CKD5 or control subjects (p=0.01). We developed a modified chart to plot Rel-OH against systolic BP z-score for the appropriate representation of volume status and BP in children. 25% of measurements showed systolic BP >90th percentile but not with concurrent overhydration. Rel-OH correlated with peripheral pulse pressure (p=0.03; R=0.3), higher NT-proBNP (p=0.02; R=0.33) and left ventricular end-diastolic diameter (p=0.05;R=0.38). Central aortic mean and pulse pressure significantly associated with the left ventricular end-diastolic diameter (p=0.03;R=0.47 and p=0.01;R=0.50 respectively), but not with Rel-OH. Systolic BP was positively associated with PWV z-score (p=0.04). 40% of children on HD and 30% on PD had increased LVMI.

Conclusions: BIS provides an objective method for the assessment of hydration status in children on dialysis. We noted a marked discrepancy between BP and hydration status in children on dialysis that warrants further investigation.

Funding: Clinical Revenue Support



Relative overhydration (Rel-OH) against systolic blood pressure (SBP) Z-score.

TH-PO665

Effect of Glomerulus Endocapillary Proliferation Lesion on the Heavy Proteinuria in Children with HSPN Yanjie Huang, Xia Liu. *The First Affiliated Hospital of Henan University of Traditional Chinese Medicine, Zhengzhou, China.*

Background: To analyse whether glomerulus endocapillary proliferation lesion is one of important pathologic factors in HSPN and its influence on high and medium molecular weight proteins in urine.

Methods: The pathological features of 148 children HSPN with heavy proteinuria were investigated retrospectively. The means of 24h proteinuria and urinary IgG, transferrin and albumin were detected using immunonephelometry method. The correlation between endocapillary proliferation lesion and 24h proteinuria, urinary IgG, transferrin and albumin were analyzed respectively.

Results: Of 581 cases of HSPN who underwent renal biopsy, 148 cases of HSPN accompanied by heavy proteinuria accounted for 25.47%. Pathological types of HSPN accompanied by heavy proteinuria included IIb, IIIb, IIIb and endocapillary proliferation, IVb, and pure endocapillary proliferation type. Among these types, pure endocapillary proliferation type accounted for 7.43%. The value of 24h proteinuria and urine albumin quantitation in endocapillary proliferation type HSPN were higher than other pathological types, and the percentage of endocapillary proliferation is correlated positively with 24h proteinuria and urine albumin quantitation.

Conclusions: The pathological type of HSPN with heavy proteinuria is diversity. Glomerulus endocapillary proliferation is one of the important pathological factor of HSPN heavy proteinuria, and albumin is major urine protein composition.

TH-PO666

Polycythemia in Subjects Born with a History of Preterm Birth and Extremely Low Birth Weight Nariaki Asada,[2] Kazuya Matsumura,[2] Yohei Matsuzaki,[1] Midori Awazu.[2] *[1]Keio University, Tokyo, Japan; [2]Keio University School of Medicine, Tokyo, Japan.*

Background: Low birth weight (LBW) infants have reduced number of nephrons and are at risk of chronic kidney disease (CKD). While capillary rarefaction has been reported in other organs, it had been unknown whether LBW affects peritubular capillary (PTC) development. We recently reported 2 subjects with a history of preterm birth and extremely LBW (ELBW) who showed PTC rarefaction and erythropoietin (EPO)-induced polycythemia in adolescence (Asada N. Pediatr Nephrol 2017). In the present study, we examined the frequency and risk factors of polycythemia in subjects born with preterm and ELBW.

Methods: Thirty-six patients with a history of ELBW whose hemoglobin, eGFR, and urinalysis had been measured were analyzed retrospectively (17 male, 19 female; age at analysis 4-19 years; birth weight 316-998 g; gestational age 22-32 weeks). Polycythemia was defined as hemoglobin levels more than 2 SD above the mean for age and gender for at least 2 consecutive years (>13.5 g/dL under 6 years, >15.5 g/dL from 6 to 12 years, and >16.0 g/dL above 12 years. Expected EPO levels were calculated from hemoglobin levels using an equation of "Log (EPO) = 3.436 – 0.1675 × Hb".

Results: Twelve patients (33.3%) showed polycythemia (7 male, 5 female; age at finding 2-16 years). Serum EPO, evaluated in 4 patients, were higher than expected levels. Birth weight was significantly smaller in polycythemia group (618 g vs 802 g). Gestational age, intrauterine growth restriction, and sex were not associated with polycythemia. In polycythemia group, eGFR was significantly smaller (72.7 vs 106.8 ml/min/1.73 m^2), and eGFR less than 90 ml/min/1.73 m^2 and proteinuria were found in 9 (75%) and 3 (25%), respectively. In non-polycythemia group, on the other hand, only 5 (21%, P=0.06) and 1 (4%, P<0.05) had reduced eGFR and proteinuria, respectively. Thus CKD was more prevalent in polycythemia group (75% vs 25%, P<0.05). Among perinatal complications, chronic lung disease was significantly associated with polycythemia, while retinopathy of prematurity and acute kidney injury were not.

Conclusions: Polycythemia was observed in one third of subjects born preterm with ELBW, and was associated with CKD.

TH-PO667

Role of Endothelial Leptin Receptor in the Development of Renal Injury Induced by a High Fat Diet Hidenori Urai, Takeshi Kanda, Arata Kurokochi, Rina Kitahama, Shu Wakino, Hiroshi Itoh. *Keio University School of Medicine, Tokyo, Japan.*

Background: Obesity and type 2 diabetes promotes endothelial dysfunction, which contributes to the progression of chronic kidney disease. Leptin is secreted from adipocyte and decreases body weight by controlling energy expenditure and food intake. Leptin-deficient ob/ob mice and leptin receptor (ObR)-deficient db/db mice are prone to glomerulosclerosis. However, the effect of leptin on renal injury is controversial and the site target of leptin action in the kidney has not been fully elucidated. In this study, we examined the role of ObR in the endothelium on glomerulosclerosis on high fat diet.

Methods: Using the Cre/loxP system, vascular endothelial (VE)-cadherin-Cre transgenic mice were crossed with $ObR^{flox/flox}$ mice to generate vascular endothelial ObR deficient mice (EC-KO mice). EC-KO mice and control $ObR^{flox/flox}$ without Cre (EC-WT) mice were fed on standard diet or 45% high-fat diet for 24 weeks. Urinary albumin, blood pressure and pathological findings were examined. The We evaluated gene expressions in isolated microvascular endothelial cells from EC-WT and EC-KO mice were also evaluated.

Results: The expression of ObR was detected in glomerulus and peritubular capillaries in EC-WT mice while its expression was not detected in EC-KO mice. When comparing EC-WT with EC-KO on high fat diet, Tthere was no significant difference in body weight, kidney weight, blood pressure and serum parameters between EC-WT and EC-KO on high fat diet,. However, high fat diet-induced increase in urinary albumin excretion was significantly lower in EC-KO mice (0.453 ± 0.064 g/gCr) compared with EC-WT mice (0.656 ± 0.052 g/gCr). High fat diet-induced glomerular hypertrophy was also ameliorated in EC-KO mice compared with EC-WT mice (2874 ± 110 μm^2 vs. 3269 ± 129 μm^2, n=6). Glomerular sclerosis, evaluated by masson's trichrome staining, was significantly reduced in EC-KO mice. The tissue fibrosis was also reduced in EC-KO mice. In addition, The expression of TGFβ1 and PAI-1, which are known for promoting fibrosis and downstream target of leptin, were significantly decreased in primary endothelial cells from EC-KO mice.

Conclusions: These data suggest that leptin exacerbates renal injury through the development of glomerular hyperfiltration and endothelial induction of TGFβ1 and PAI-1 genes.

TH-PO668

Evaluation of the Reno-Protective Effects of Empagliflozin in Diabetic Nephropathy Using In Vivo Imaging Kengo Kidokoro,[2] Atsushi Uchida,[1] Yuji Sogawa,[1] Hajime Nagasu,[1] Minoru Satoh,[1] Tamaki Sasaki,[3] Naoki Kashihara.[1] *[1]Kawasaki Medical School, Kurashiki, Japan; [2]Kawasaki Medical school, Kurashiki Okayama, Japan; [3]None, Kurashiki, Japan.*

Background: Diabetic nephropathy (DN) is one of the most common vascular complications associated with diabetes mellitus. In the EMPA-REG outcome trial, Empagliflozin (Empa), a sodium–glucose cotransporter 2 inhibitor, not only reduced the risk of cardiovascular events but also slowed the progression of DN in patients with type 2 diabetes. Improvement of glomerular hyperfiltraion via the tubulo-glomerular feedback (TGF) mechanism is considered one of the possible reasons for renal protection by Empa in DN. However, the theory remains a matter of speculation. In this study, the in vivo multiphoton microscope (MPM) imaging technique was used to investigate the glomerular protective effects of Empa and whether Empa regulated the vascular tonus of the glomerular afferent artery via the TGF mechanism.

Methods: We used C57BL/6 mice and spontaneously diabetic Ins2Akita mice (Akita). In the first experiment, mice were treated with Empa (20mg/kg/day; gavage) and insulin (0.1U/body; i.s.) for four weeks. Glomerular reactive oxygen species (ROS) and nitric oxide (NO) production were evaluated in an ex vivo study. Next, we measured a single nephron GFR (SNGFR) using MPM in each group. Furthermore, the change of the SNGFRs in the same glomeruli before and two hours after medication were also studied to evaluate the acute effect of Empa. Finally, an nNOS inhibitor and a COX2 inhibitor were administered to these groups to inhibit vasodilator factors delivered from the macula densa. The SNGFR was then evaluated.

Results: Increased ROS and decreased NO productions in the glomeruli were observed in the Akita, but they were improved with the Empa treatment. The SNGFR in the Akita was significantly higher than in the control, however, Empa improved that alteration. In the acute study using Akita, the SNGFR in the same glomeruli were significantly reduced by Empa with blood glucose level lowering. Moreover, the diameter of the afferent artery was significantly decreased after the Empa treatment. An nNOS inhibitor and a COX2 inhibitor reduced the SNGFR in the Akita, and no additional effect regarding Empa was observed. These data indicate that Empa can reduce glomerular hyperfiltration in DN via TGF.

Conclusions: Empagliflozin improved glomerular hyperfiltration in DN via the TGF mechanism and contributed to glomerular protection.

PBI-4050 Prevents Diabetic Nephropathy and Protects β-Cells in NOD Mice: A Model of Type 1 Diabetes Lyne Gagnon, Kathy Hince, François Sarra-Bournet, Mikaël Tremblay, Marie-Pier Cloutier, Sylvie Létourneau, Pierre Laurin, Brigitte Grouix, Francois A. Leblond. *Prometic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050, a novel first-in-class orally active antifibrotic compound, which is currently in a phase II clinical trial, significantly reduced glycated hemoglobin (HbA1c) after 12 and 24 weeks of treatment in patients with type 2 diabetes and metabolic syndrome with elevated HbA1c despite anti-hyperglycemic treatment. PBI-4050 also reduced biomarkers associated to kidney injury. In the present study, we examined whether PBI-4050 may prevent diabetic nephropathy in NOD mice, a model of type 1 diabetes.

Methods: NOD/ShiLtJ female mice (8 weeks of age) received vehicle (water) or PBI-4050 (200 mg/kg/day) by daily gastric gavage for 23 weeks.

Results: In kidney, PBI-4050 protects against lesions by reducing glomerular volume and mesangial cross sectional area. Furthermore, tubular lesions were absent in PBI-4050-treated mice. Tubular dystrophy as PAS granular accumulation was constantly present in proximal tubules of NOD control mice and was completely abrogated by treatment with PBI-4050. Mice treated with PBI-4050 did not develop diabetes. OGTT was also normalized in PBI-4050 treated mice. Despite a reduced number of islets compared to non-diabetic mice, NOD mice treated with PBI-4050 maintained normoglycemia and showed a 30% reduction in the number of islets with grade 4 lesions.

Conclusions: This data suggests that PBI-4050 prevents diabetic nephropathy and complete destruction of β-cells and islets in type 1 diabetes model.

Inhibiting Inflammasome Activation with Suramin Protects against Progression of Diabetic Kidney Disease in KK-Ay Mice Kaori Oda,[1] Satoshi Miyamoto,[2] Ryo Kodera,[2,3] Jun Wada,[1] Kenichi Shikata.[2] *[1]Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan; [2]Center for Innovative Clinical Medicine, Okayama University Hospital, Okayama, Japan; [3]Osafune Clinic, Setouchi, Japan.*

Background: Recent reports have suggested that innate inflammation via inflammasome activation is involved in the pathogenesis of diabetic kidney disease (DKD). Inflammasome, a protein complex, is activated in various diseases, leading to production of IL-1β and IL-18 through activation of caspase-1. In addition, danger-associated molecular patterns (DAMPs) are the crucial triggers for inflammasome activation via its receptors including P2X and P2Y receptors. We have demonstrated that both serum and urinary IL-18 levels are elevated in patients with DKD (Nakamura A et al. Diabetes Care, 2005), and that ATP, one of the important DAMPs, is increased in the glomeruli of diabetic mice by mass spectrometry imaging (Miyamoto S et al. EBioMedicine, 2016). The aim of this study was to determine if suramin, a non-selective P2X and P2Y antagonist, protects against DKD in KK-Ay mice.

Methods: Four weeks-aged male nondiabetic C57BL/6 mice and diabetic KK-Ay mice ($KK\text{-}A^y$/TaJcl) were randomly assigned to four groups: C57BL/6+vehicle (Control), C57BL/6+suramin, KK-Ay+vehicle (KK-Ay), KK-Ay+suramin, n=6-12/group. Vehicle or suramin (1 mg/kgBW) were injected intraperitoneally once every two weeks over an 8-week period. Glomerular size and mesangial matrix area were assessed by morphometric analysis. Expression of inflammasome-related genes in renal cortex were examined by quantitative real-time PCR.

Results: Urinary albumin/creatinine ratio, elevated in KK-Ay (280.0 ± 29.3 mg/gCr, p<0.001) vs. Control (1.7 ± 0.3 mg/gCr) mice, was significantly reduced with suramin (160.6 ± 27.3 mg/gCr, p<0.01), whereas there were no significant differences in body weight or HbA1c between both diabetic groups. The increases in both glomerular size and glomerular mesangial matrix area in KK-Ay group, were significantly reduced with suramin (p<0.001). In addition, the increase in inflammasome-related gene expressions including IL-18, P2X4 and P2X7 in KK-Ay group were significantly suppressed with suramin (p<0.001).

Conclusions: Our results suggest that inflammasome is activated in the diabetic kidney and the inhibition of inflammasome with suramin protects against progression of DKD. Suramin may be beneficial for the treatment of DKD.

The Effect of GSTK1 on the MAM Related Apoptosis in Diabetic Nephropathy Li Zhao, Chun Hu, Xianghui Chen, Yachun Han, Xiaofen Xiong, Li Li, Ming Yang, Peng Gao, Li Xiao, Jun Li, Fuyou Liu, Lin Sun. *Department of Nephrology, 2nd Xiangya Hospital, Central South University, Changsha, China.*

Background: Mitochondria-associated ER Membrane (MAM)is a platform between mitochondria and ER, which involved in mitochondrial dynamic, calcium signaling, autophagy, apoptosis and so on. GSTK1 has glutathione peroxidase activity, which as an important antioxidant enzyme can blocking ROS damage. We found by first time GSTK1 locates on MAM of the mouse kidney, but its function in MAM is nuclear. Here we

hypothesize that GSTK1 in MAM modulates cell apoptosis may paly an important role in the kidney damagy of DN.

Methods: Morphological change of MAM was measured by EM in db/db and db/m mice. The protein of mitochondria, MAM and ER were extracted from the kdieny of diabetic mouse. The expression of GSTK1, Mfn-2, cytochrome C, caspase-3 and Bax were measured by Western blot analyse. In vitro study: MAM morphology was detected by confocal scanning in HK-2 cells. The mitochondria and MAM were also isolated from HK-2 cells induced by high glucose transfection with or without GSTK1 plasmid. The expression and distribution of GSTK1,Mfn-2,cytochrome C and Bax in MAM were detected by Western blot. Further, the interaction between GSTK1 and cytochrome C was observed by physical conformation, Confocal scanning and co-immunoprecipitation.

Results: Compared with db/m mice, the morphology of MAM was abnormal with the distance widen in the kidney of db/db mice. The expression of GSTK1 and Mfn-2 in mitochondria and MAM subdomain were down-regulated in db/db mices kidney. Conversely, the expression of Bax, Caspase-3 and cytochrome C were up-regulated. In addition, mitochondria was less adjacent to ER in HK-2 cells treated with high glucose(HG), while the expression of Mfn-2 was increased in mitochondria and MAM. all of altered were reversed in that transfection of GSTK1. Furthermore, a increased GSTK1 binding to cytochrome C was obsvered in HK-2 cells treated by HG. Overexpression of GSTK1 in HK-2 cells inhibited the release of mito.cytochrome C into the cytosol and Bax translocation to mitochondria, and reduced mitochondria modulate cells apoptosis.

Conclusions: The integrity of MAM were damaged and the distance between mitochondria and ER was increased in diabetic kidney or HG induced HK-2 cells. Overexpression of GSTK1 up-regulated the expression of Mfn-2 and then enhanced the interaction of MAM, which could inhibits apoptosis in DN.

Amelioration of Kidney Injury by Inhibition of Sodium Glucose Cotransporter 2 with Canagliflozin in Mice with Type 2 Diabetes Mellitus L. Gabriel Navar,[1] Ryousuke Satou,[2] Kayoko Miyata,[2] Akemi Katsurada,[1] Courtney M. Dugas,[1] Daniel J. Lightell, jr.,[1] T C. Woods.[1] *[1]Tulane University, New Orleans, LA; [2]Tulane University Health Science Center, New Orleans, LA.*

Background: Type 2 diabetes mellitus (T2DM) is associated with progressively declining renal function resulting from hyperglycemia, oxidative stress and activated intrarenal renin-angiotensin system. The sodium glucose co-transporter 2 (SGLT2) is responsible for most of the glucose reabsorption by renal tubules. SGLT2 inhibitors increase glucose excretion and lower blood glucose levels, thus serving as a new therapy for T2DM. However, their effects on the developing renal injury in T2DM remain unclear.

Methods: Accordingly, we evaluated the ability of canagliflozin (CANA), an SGLT2 inhibitor, to ameliorate kidney injury in T2DM. Intrarenal angiotensinogen (AGT) and oxidative stress were also evaluated as contributing factors to diabetic nephropathy. Male New Zealand Obese mice were fed a regular fat diet (RFD, 4% fat) or a high fat diet (HFD, 40% fat) to induce diabetes. When the mice fed with the HFD exhibited >350 mg/dl blood glucose levels, both RFD and HFD fed mice were treated with 10 mg/kg/day CANA or vehicle for 6 weeks by daily oral gavage.

Results: CANA treatment decreased blood glucose levels and suppressed body weight gain in HFD mice, which remained suppressed for the duration of the study. Systolic blood pressure in HFD groups (134.7±3.6 mmHg) was also normalized by CANA (110.0±6.0 mmHg). The augmented cortical AGT mRNA and protein levels and elevated urinary 8-isoprostane levels caused by the HFD were ameliorated by CANA treatment. Histological analysis revealed the development of renal tubular fibrosis in HFD group (3.4±0.9-fold, fibrotic score, ratio to RFD) that was suppressed by CANA (0.9±0.3-fold). Furthermore, elevated macrophage infiltration into the interstitium caused by HFD was attenuated by CANA (RFD: 0.35±0.07, HFD: 0.99±0.09 and HFD+CANA: 0.49±0.07, positive area %). In contrast, CANA did not improve glomerular matrix expansion and albuminuria observed in the HFD group.

Conclusions: These results demonstrate that CANA mitigates renal tubular fibrosis and renal inflammation accompanied by suppression of renal oxidative stress and AGT expression in T2DM.

Contribution of Myo-Inositol Oxygenase in Age: Rage Mediated Renal Tubulo-Interstitial Injury Isha Sharma,[1] Rashmi S. Tupe,[2] Yashpal S. Kanwar.[3] *[1]NORTHWESTERN UNIVERSITY, CHICAGO, IL; [2]Northwestern University, Chicago, IL; [3]Northwestern University Medical School, Chicago, IL.*

Background: Advanced glycation end products (AGEs) have been postulated to play a critical role in pathogenesis of diabetic nephropathy (DN). Myo-inositol Oxygenase (MIOX), a proximal tubular enzyme, which has been implicated in tubulo-interstitial injury in the context of DN.

Methods: Aim of the present study was to investigate the effect of AGEs on MIOX expression and to delineate the mechanisms that lead to tubulo-interstitial injury. To test this we examined the status of MIOX, RAGE and relevant cellular signaling pathway activated following AGE:RAGE interaction in cultured tubular cells and kidneys of AGE-BSA treated mice.

Results: Using solid phase binding assay an enhanced binding of RAGE with AGE-BSA, -laminin and -collagen IV was observed compared to non-glycated proteins. AGE-BSA treatment led to an increased MIOX activity and its expression in a time- and dose-dependent manner. AGE-BSA also increased MIOX promoter activity. This was associated with activation of various signaling kinases of PI3K-AKT pathway and increased expression of NF-κB, TGF-β and fibronectin. Treatment with MIOX- and RAGE-siRNA negatively impacted the activation of PI3K-AKT signaling cascade and expression of fibronectin, NF-κB and TGF-β. Interestingly, concomitant with the up-regulation of MIOX there was an increased generation of reactive oxygen species (ROS), which could be abrogated with the MIOX- or RAGE-siRNA treatment. *In vivo* the kidneys of mice treated with AGE-BSA for 2 weeks had significantly high urinary AC ratio, up-regulation of MIOX, RAGE and NF-κB along with influx of monocytes in the tubulo-interstitium, increased expression of MCP-1, IL-6 and fibronectin, and generation of ROS. These molecular derangements were abrogated with the concomitant treatment of inhibitors MIOX or RAGE (D-glucarate & FPS-ZM1).

Conclusions: These *in vivo* and *in vitro* studies support a critical role of AGE:RAGE interaction in the activation of PI3K-AKT pathway and up-regulation of MIOX; as a result of which there is an excessive generation of ROS, increased expression of NF-κB, inflammatory cytokines, TGF-β and fibronectin. Collectively, these observations highlight the importance of MIOX in the contribution towards tubulo-interstitial injury in DN.

Dyslipidemia Worsens Diabetic Kidney Disease in a Novel Type 2 Diabetes Mouse Model of Combined Kidney Disease and Atherosclerosis – A Possible Role for ApoC-III Jenny E. Kanter,[3] Farah Kramer,[3] Anna Batorsky,[4] Baohai Shao,[4] Jinkuk Choi,[1] Kelly L. Hudkins,[2] Karin Bornfeldt,[3] Charles E. Alpers.[5] *[1]UCLA, Los Angeles, CA; [2]University of WA, Seattle, WA; [3]University of Washington, Seattle, WA; [4]University of Washington, Seattle, WA; [5]University of Washington Medical Center, Seattle, WA.*

Background: Diabetic kidney disease and atherosclerotic disease are major causes of morbidity and mortality associated with type 2 diabetes (T2D), and diabetic kidney disease is a major cardiovascular risk factor. The BTBR mouse strain with leptin-deficiency (*Lep*^{ob}) has emerged as one of the best mouse models of human diabetic kidney disease. However, no T2D mouse model of combined diabetic kidney disease and atherosclerosis exists. Our goal was to generate such a model.

Methods: To this end, the LDL receptor was targeted for degradation via IDOL (inducible degrader of the LDL receptor) overexpression, using a liver-targeted adeno-associated virus (AAV-DJ/8) in BTBR wildtype (WT) and BTBR *Lep*^{ob} (OB) mice.

Results: Liver-targeted IDOL-AAV-DJ/8 increased plasma LDL cholesterol, as compared with the control eGFP-AAV-DJ/8 (OB eGFP 194 ± 15 vs OB IDOL 250 ± 10 mg/dl LDL cholesterol). IDOL-induced dyslipidemia caused formation of atherosclerotic lesions of an intermediate stage, which contained both macrophages and smooth muscle cells. BTBR OB mice exhibited diabetic kidney disease. IDOL-induced dyslipidemia worsened albumin/creatinine ratio (885 ± 96 μg/mg in OB eGFP vs 1681 ± 391μg/mg in OB IDOL) and glomerular macrophage accumulation (1.9 ± 0.4 Mac-2 positive cells/glomerulus in OB eGFP vs 3.5 ± 0.7 in OB IDOL) and cortex inflammation (increased expression of *Ccl2, Il1b* and *Vcam1* comparing OB IDOL to OB eGFP), but had no effect on mesangial expansion or podocyte numbers. Furthermore, HDL-associated apolipoprotein C-III (apoC-III) was elevated in OB mice compared with WT mice and this was further increased by IDOL-induced dyslipidemia. ApoC-III in turn correlated positively with both atherosclerosis and albuminuria.

Conclusions: Thus, by inducing hepatic degradation of the LDL receptor, we generated a T2D model of combined kidney disease and atherosclerosis in which dyslipidemia may worsen the kidney disease, potentially through elevated apoC-III. This model provides a new tool to study mechanisms, interactions, and treatment strategies of diabetic kidney disease and atherosclerosis.

NADPH-Oxidase NOX5 Aggravates Renal Injury in Human Diabetic Nephropathy Jay C. Jha,[4] Melinda T. Coughlan,[3] David A. Power,[1] Chris R. Kennedy,[2] Mark E. Cooper,[3] Karin Jandeleit-Dahm.[3] *[1]Austin Health, Heidelberg, NSW, Australia; [2]Kidney Research Centre, Ottawa, ON, Canada; [3]Monash University, Melbourne, VIC, Australia; [4]Department of Diabetes, Monash University, Melbourne, VIC, Australia.*

Background: Renal oxidative stress plays an important role in mediating kidney injury in diabetes. There is increasing evidences that recently discovered pro-oxidant enzyme, Nox5 plays a significant role in human diabetic nephropathy (DN). Nox5 is present in humans and rabbits but not in mice or rats. Thus, there is a paucity of information about Nox5 in conventional animal models of DN. We examined the role of Nox5 in human diabetic nephropathy, in human renal cell populations as well as in a high fat fed rabbit model of kidney disease.

Methods: Protein expression of Nox5 and its localization in glomerular cells (podocytes and mesangial cells) and tubular cells were examined by immunostaining in human kidney biopsies obtained from non-diabetic and diabetic individuals. In vitro, human mesangial cells, podocytes and proximal tubules were exposed to high glucose, TGF-β and AngII and Nox5 was knockdown in these renal cells. Cell morphology, gene and protein expression of markers of fibrosis and inflammation as well as putative signalling pathways and the level of ROS were assessed in these human renal cells. We

also examined expression of pro-fibrotic gene in high fat fed rabbits by next generation sequencing (NGS) and RT-PCR and renal injury by histochemistry.

Results: Expression of Nox5 was increased in both glomerular and tubular compartments of kidney biopsies obtained from diabetic individuals when compared to non-diabetic individuals. In addition, silencing of Nox5 in human renal cells resulted in reduced ROS production and decreased expression of pro-fibrotic and pro-inflammatory markers as well as putative elements that are implicated in DN. Moreover, increased expression of Nox5 in high fat fed rabbits versus normal diet fed rabbits was associated with increased expression of fibronectin, CTGF, collagen IV and VCAM-1 as well as increased mesangial expansion in the kidney.

Conclusions: These findings suggest that Nox5 accelerates renal injury in diabetes and provide proof of principle for the development of a new renoprotective agent in diabetes.

TH-PO676

Function of NADPH Oxidase in Diabetic Nephropathy and Development of Its Inhibitor as a Therapeutic Candidate Sae rom Lee, Eunjung An, Yun soo Bae. *Ewha Womans University, Seoul, Republic of Korea.*

Background: Substantial evidence has indicated that transient reactive oxygen species (ROS) can be produced by receptor-mediated biochemical processes, although ROS including superoxide anion and hydrogen peroxide (H2O2) are thought to be by-products of aerobic respiration damaging effects on DNA, protein, and lipid. ROS generation in cell signaling has been extensively studied in terms of NADPH oxidase (gp91phox) in phagocytic cells. However, after identification of the homologs of gp91phox (Nox1, Nox3-5, Duox1-2) from non-phagocytic cells, the function of the generated ROS has been extended into an understanding of various cellular events, including cell growth, differentiation, apoptosis, and inflammation responses. We show the effect of a novel pan-NOX-inhibitor, EWHA-18278, on diabetic nephropathy in type 2 diabetic mice.

Methods: Six-week-old male diabetic db/db mice was treated with EWHA-18278(60mpk) per day and sacrificed after 12 weeks. The effect of EHWA-18278 on oxidative markers such as 8-isoprostane in plasma or urine was measured. Furthermore, EHWA-18278 effect on renal function was investigated by urinary albumin excretion and creatinine clearance and PAS-staining, alpha-SMA histologically.

Results: EWHA-18278 significantly improved insulin resistance in diabetic mice, similar to GKT137831. Oxidative stress as measured by plasma 8-isoprostane level was decreased in the EWHA-18278 group compared to diabetic controls. All lipid profiles, both in plasma and tissues improved with Nox inhibition. EWHA-18278 decreased urinary albumin excretion and preserved creatinine clearance. In diabetic kidneys, EWHA-18278 significantly improved mesangial expansion, but GKT137831 did not. Additionally, F4/80 infiltration in the adipose tissue and kidney decreased with EWHA-18278 treatment.

Conclusions: In conclusion, our findings provide evidence that pan-Nox inhibition by EWHA-18278 may have greater renoprotective potential than does GKT137831 in diabetic nephropathy. These findings suggest that EWHA-18278 may be a useful new therapeutic agent in treating type II diabetes and diabetic nephropathy.

Calorie Intake Reduction May Prevent Progression of Diabetic Nephropathy by Suppressing Podocyte Hypertrophic Injury via mTORC1 Pathway Activation Akihiro Minakawa,[1] Akihiro Fukuda,[2] Masao Kikuchi,[1] Yuji Sato,[1] Shouichi Fujimoto.[1] *[1]Division of Nephrology, Department of Internal Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan; [2]Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Faculty of Medicine, Oita University, Yufu, Japan.*

Background: Glomerular hypertrophy is a well-established component of diabetic nephropathy. We have previously shown that a mismatch between glomerular volume and podocyte mass (reduced podocyte density) was associated with development of albuminuria and accelerated podocyte hypertrophic stress in a rat model of type 2 diabetes. Here, we tested whether calorie intake reduction prevents progression of diabetic nephropathy by suppressing podocyte hypertrophic injury.

Methods: Using the leptin-deficient Zucker diabetic fatty rat model of type 2 diabetes with *ad libitum* feeding, we have found increased glomerular volume and decreased podocyte density at 15 weeks. At 15 weeks, we thus divided the rats into an *ad libitum* diet group (n=5) and a 40% calorie intake reduction group (n=6). Urine samples were collected every 4 weeks and the rats were sacrificed at 30 weeks. We measured the urinary excretion of podocyte mRNA, urine albumin/creatinine ratio, glomerular volume, podocyte number per glomerular tuft, podocyte density, and P-S6 expression of podocytes.

Results: In the calorie intake reduction group, urine volume and blood glucose were significantly decreased by 18 weeks, albuminuria was significantly decreased by 22 weeks and urinary excretion of podocyte mRNA was decreased by 26 weeks, compared with the *ad libitum* diet group. At 30 weeks, in the calorie intake reduction group, podocyte number per glomerular tuft was not decreased ($p=0.30$), while glomerular volume tended to be decreased (12% decrease, $p=0.052$), podocyte density was significantly preserved ($p=0.02$), and P-S6 expression of podocytes was significantly decreased ($p<0.01$), compared to the *ad libitum* diet group.

Conclusions: Our results suggest that calorie intake reduction prevented the progression of diabetic nephropathy in a rat model of type 2 diabetes by suppressing podocyte hypertrophic injury via mTORC1 pathway activation. Calorie intake reduction could thus be a useful tool for slowing the progression of diabetic nephropathy.

TH-PO678

Elevated Prorenin Accelerates the Development of Diabetic Nephropathy in STZ-Induced Cyp1a1-Prorenin Transgenic Rats Chunyan Gu,[1] Alfred K. Cheung,[1] Yufeng Huang.[1,2] *[1]Division of Nephrology, University of Utah, Salt Lake City, UT; [2]Dept. of Pathophysiology, University of Nantong School of Medicine, Nantong, China.*

Background: Elevated plasma prorenin levels are commonly found in diabetic patients and appear to predict the development of diabetic nephropathy (DN). However, the potential pathological role of prorenin in diabetes is unclear. In this study, a transgenic, inducible, hepatic prorenin-overexpressing rat model (cyp1a1-prorenin transgenic rat, TG) was generated and then a model of STZ-induced diabetic cyp1a1-prorenin transgenic rat was established to mimic diabetic patients with elevated plasma prorenin.

Methods: Four transgenic groups (5 rats per group): TG controls, STZ-induced diabetic TG rats, and STZ-induced diabetic TG rats treated with either amlodipine (AM, 10mg/kg/d by daily gavage) or enalapril (Ena, 200mg/L in drinking water), were assigned to receive a diet containing 0.15% of the gene activator indole-3-carbinonl (I3C) started at 2wks after diabetes was confirmed (BG>250 mg/dl). Four corresponding groups of 5 wild-type (WT) rats receiving same treatments served as WT controls. Treatments were given at the same as I3C was given for 6 wks. Animals in all groups were sacrificed at 8 wks after induction of diabetes.

Results: Diabetic WT rats had normal blood pressure but developed microalbuminuria and had kidney hypertrophy and mildly increased glomerular ECM accumulation. Diabetic TG rats with elevated plasma prorenin levels showed hypertension and much worsen features of DN when compared with the diabetic WT animals or non-diabetic transgenic rats, including worsen albuminuria, kidney hypertrophy, enhanced podocyte foot effacement and glomerulosclerosis. Furthermore, increased prorenin in diabetes further stimulated renal cellular signals of Nox2, p47phox and NF-kB-p65, which have been shown to contribute to the development of DN. Treatment with either amlodipine or enalapril had no effect on blood glucose levels, but prevented the development of hypertension and ameliorated, but did not prevented, the development of renal fibrosis, related pro-fibrotic signals and podocyte injury.

Conclusions: These results indicate that prorenin accelerates the development of DN, which is only partially dependent on prorenin-induced hypertension and angiotensin II's action. These results may suggest the involvement of additional angiotensin II-independent effects of prorenin in DN.

TH-PO679

Transcriptomic Profile in Early versus Late Stages of Murine Diabetic Nephropathy Haichun Yang,[4] Anette E. Ericsson,[3] Anna Reznichenko,[3] José Sanchez,[2] Lena William-Olsson,[3] Magnus Soderberg,[1] Anna Granqvist,[3] Raymond C. Harris,[4] Kasey C. Vickers,[4] Agnes B. Fogo.[4] *[1]Drug, Safety and Metabolism, AstraZeneca, Molndal, Sweden; [2]Discovery Sciences, AstraZeneca, Molndal, Sweden; [3]Innovative Medicines and Early Development, Cardiovascular and Metabolic Diseases, AstraZeneca R&D Molndal, Molndal, Sweden; [4]Vanderbilt University Medical Center, Nashville, TN.*

Background: Diabetic nephropathy (DN) has both glomerular and tubular injury. As a DN model, db/db/eNOS$^{-/-}$ mice develop albuminuria and glomerular hypertrophy by age 10 weeks, and progress to nodular glomerular injury and reduced GFR by week 18. By RNA sequencing of isolated glomeruli and kidney cortex at different time points, we aimed to determine the transcriptional profiles critical for glomeruli vs tubular injury in DN.

Methods: db/db/eNOS$^{-/-}$ (DN) and nondiabetic control db/eNOS$^{-/-}$ mice (C) were sacrificed at week 10 and 18. The left kidney was harvested for isolating glomerular RNA, while the right kidney was used for extracting cortex RNA.

Results: 86 genes from the glomerular extract showed different expression levels in DN vs C at week 10 (49 upregulated and 37 downregulated), and 5248 genes differed at week 18 (3599 up and 1649 down). 528 transcripts from cortical extracts were different in DN and C at week 10 (213 up and 315 down), and 684 transcripts differed) at week 18 (456 up and 228 down, but with overlap of only 116 genes in early vs late cortical samples. Metabolic processes, such as calcium, urea and P450 pathways, differed mostly in tubular vs glomerular analysis. Genes expressed at week 10 but not week 18 suggest a role in early but not progressive DN. We detected 118 upregulated and 188 downregulated genes at week 10, which did not differ at week 18 in DN. Among them, only 10 genes (7 up and 3 down) were present only in glomerular but not cortical samples, and include genes that modulate matrix, cell proliferation and tissue-specific differentiation.

Conclusions: In summary, by comparing db/db/eNOS$^{-/-}$ vs db/eNOS$^{-/-}$ mice, early vs late stage diabetics, and glomeruli vs cortex, we determined that there were marked increases in differentially modulated glomerular genes at later stages of disease, with different gene expression patterns in the tubulointerstitial compartment over time. These data indicate that glomerular and tubular mechanisms of DN injury are not identical, and also evolve over time.

Comparison of Glomerular Endothelial Cell Gene Expression Profiles in Diabetic Mice with or without eNOS Deficiency Jia Fu,[1,3] Chengguo Wei,[3] Weijia Zhang,[3] Detlef O. Schlondorff,[3] Peter Y. Chuang,[2,3] Zhihong Liu,[1] John C. He,[3] Kyung Lee.[3] *[1]National Clinical Research Center of Kidney Diseases, Nanjing, China; [2]Connecticut Kidney Center, LLC, Orange, CT; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Glomerular endothelial cell (GEC) injury is a key early event in DN, but the underlining mechanisms remain unclear. In order to assess the key molecular changes in GECs in early DN, we performed a transcriptomic analysis of GECs isolated from diabetic and nondiabetic mice. Two diabetic models were used: 1) streptozotocin (STZ)-induced diabetic mice and 2) STZ-induced diabetic eNOS$^{-/-}$ mice to take advantage of the accelerated DN development with eNOS-deficiency.

Methods: GECs were isolated from transgenic mice expressing histone H2B-fused enhanced yellow fluorescent protein (EYFP) under the Flk-1 promoter. Flk1-EYFP mice were crossed with wildypte or eNOS$^{-/-}$ mice, and diabetes was induced with STZ. Vehicle-injected mice served as controls. All mice were sacrificed at 10 weeks post-injection, and GECs were sorted for mRNA sequencing. Differentially expressed genes (DEGs) from GECs of diabetic mice were analyzed. Key altered pathways were validated by qPCR and immunostaining in second set of experimental mice, and kidney biopsies were performed over time in diabetic and control mice to determine GEC numbers.

Results: DEGs in both diabetic models showed significant alterations in genes related to apoptosis, oxidative stress, cell migration, and proliferation. GECs from diabetic eNOS$^{-/-}$ mice further exhibited altered expressions in genes related to vascular endothelial cell function and epigenetic regulation. We confirmed by immunostaining that GECs indeed exhibited increased oxidative stress and apoptosis in diabetic wildtype mice, which were further exacerbated in diabetic eNOS$^{-/-}$ mice. We also confirmed that epigenetic regulation was altered specifically in diabetic eNOS$^{-/-}$ GECs. Interestingly, we observed a biphasic change in GECs of diabetic eNOS$^{-/-}$ mice that was characterized by an increase at 6-weeks post-diabetes induction, followed by a significant loss by 10-weeks post-induction, suggesting that an early angiogenic process precedes increased apoptosis and failure of regeneration at the subsequent phase of DN injury.

Conclusions: Our results reveal several novel mechanisms of GEC injury in early DN, which can serve as a basis for further exploration into the mechanism of early diabetic GEC injury and for potential new therapeutic intervention to prevent GEC injury in early DN.

Gene Expression Profiles of Glomeruli from BTBR ob/ob Mice Treated with Prolyl Hydroxylase Inhibitor Suggest Involvement of Extracellular Matrix Modulators in Pathogenesis of Diabetic Kidney Disease Mai Sugahara,[1] Tetsuhiro Tanaka,[1] Shinji Tanaka,[1] Kenji Fukui,[1,2] Akira Shimizu,[3] Yu Ishimoto,[1] Reiko Inagi,[1] Masaomi Nangaku.[1] *[1]University of Tokyo, Tokyo, Japan; [2]JT CPRI, Osaka, Japan; [3]Nippion Medical School, Tokyo, Japan.*

Background: We have previously shown that administration of prolyl hydroxylase (PHD) inhibitor, JTZ-951 (Japan Tobacco Inc.), improved glucose/lipid metabolism and decreased albuminuria in BTBR ob/ob mice (TH-PO450, ASN Kidney Week 2016). In order to elucidate the mechanism, we performed microarray gene expression analysis using isolated glomeruli.

Methods: Four-week-old male BTBR ob/ob mice were divided into the vehicle and JTZ-951 groups. JTZ-951 (0.005%; in feed) was administered from 4 weeks of age until euthanasia at 22 weeks. cDNA samples from isolated glomeruli were hybridized using Agilent SurePrint G3 Mouse GE Microarray 8x60K ver. 2.0.

Results: During the study period, mice in the JTZ-951 group tended to exhibit lower blood glucose levels (HbA1c: 8.9±0.3 vs 8.2±0.2%) and significantly lower total cholesterol levels (260±26 vs 164±19 mg/dL) with comparable food intake. JTZ-951 significantly decreased urinary albumin at 16 and 22 weeks (4.8±0.7 vs 1.9±0.4 and 5.9±1.3 vs 2.3±0.5 mg/mgCr, respectively) without affecting GFR. Podocyte and endothelial damages were markedly ameliorated in the JTZ-951 group. In gene expression analysis, 315 transcripts were upregulated and 150 were downregulated more than 3-fold in BTBR ob/ob mice compared to the wild type (WT). Among the 315 diabetes-upregulated genes, 102 revealed smaller increases in the JTZ-951 group (JTZ-951/WT<3). Similarly, the expression of 103 of the 150 diabetes-downregulated genes were restored in the JTZ-951 group (JTZ-951/WT>1/3). Pathway analysis of these 205 genes using Reactome database indicated that 5 out of the 25 top-ranked enriched pathways were related to extracellular matrix (ECM) organization and cell-matrix interactions; the corresponding entities included lysyl oxidase-like 2, thrombospondin 1, collagen type VIII alpha 1, bone morphogenetic protein 2, and CD44.

Conclusions: Long-term administration of JTZ-951 decreased albuminuria and ameliorated podocyte and endothelial damage, along with improvement in glucose/lipid metabolism. Microarray analysis revealed changes in the expression of genes associated with ECM, suggesting that ECM modulation within the glomerulus may play a role in the pathogenesis of diabetic kidney disease.

TH-PO682

Reduced C/EBP-α Expression Aggravates the Podocyte Impairment and Renal Injury in Experimental Diabetes Liwen Zhang, Fangfang Zhou, Jian Liu, Ji Ying, Weiming Wang, Nan Chen. *Department of Nephrology, Ruijin Hospoital, Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: CCAAT/enhancer binding protein-α (C/EBP-α) is one of the critical transcription factors involved in inflammation, cell proliferation and lipid metabolism. We have previously showed that C/EBP-α expression was suppressed in glomerular cells in focal segmental glomerulosclerosis. However, its specific role in diabetic nephropathy (DN) is unclear. We developed a podocyte-specific C/EBP-α-null mouse model to study the function of C/EBP-α in DN progression.

Methods: By crossing floxed C/EBP-α mice with Pod-Cre mice, we generated podocyte specific C/EBP-α knockout mice. The transgenic mice and their wild-type littermates underwent either high-fat diet for 6 months with a single injection of streptozotocin as diabetic models or general diet as control.

Results: We confirmed that C/EBP-α expression was significantly reduced in the renal cortex in podocyte-specific knockout mice by western blotting. Genetic ablation of C/EBP-α in podocytes led to more serious deterioration of diabetic kidney injuries, characterized by increased urinary albumin-to-creatinine ratio, increased mesangial matrix expansion, glomerulosclerosis and tubulointerstitial fibrosis (determined by Mason's trichrome and Picrosirius Red stains). Diabetes induced down-regulation in the expression of podocyte and epithelial markers such as nephrin, podocin and E-cadherin, and these markers were further reduced in C/EBP-α knockout diabetic mice. In addition, a further increased expression of markers of fibrosis (vimentin, fibronectin) and inflammation (MCP-1, TNF-α) were found in diabetic C/EBP-α knockout mice when compared to diabetic WT mice. Mechanistically, we identified that conditional deletion of C/EBP-α in podocytes resulted in significantly decreased p-AMPK and PGC-1α expression in diabetic mice.

Conclusions: These findings suggest that knockdown of C/EBP-α expression in podocytes aggravates the podocyte impairment and the progressing of DN, and point to C/EBP-α as a potential therapeutic target in DN.

TH-PO683

Intestine Can Modulate Diabetes in Renal Failure (RF) in Animals Siddhartha S. Ghosh,[2] Austin J. Gonzalez,[3] Daniel E. Carl,[2] Richard Krieg,[1] Todd W. Gehr,[3] Shobha Ghosh.[1] *[1]VCU, Richmond, VA; [2]VCU Medical Ctr, Richmond, VA; [3]Virginia Commonwealth University, Fredericksburg, VA.*

Background: Intestine and gut microbiota play a major role in various diseases including diabetic nephropathy. Changes in gut microbiota influences glucagon like peptide (GLP-1) secretion. Drugs that modulate GLP-1 has been known to ameliorate not only diabetes but also improve renal function. Butyrate commonly secreted by commensal bacteria has be shown to stimulate GLP-1 release. We hypothesized that sodium butyrate (BU) might improve diabetes and renal function in animals with renal failure.

Methods: 5/6 nephrectomy was done in ten Sprague dawley rats to induce RF and divided into 2 groups, untreated (RF) and butyrate treated (RF+BU). Na Butyrate (250 mg/100ml) was given in drinking water for 6 weeks. Oral Glucose tolerance test GTT and insulin tolerance test (ITT) were done by oral 2 g/kg glucose and pyruvate tolerance test (PTT) were done by giving sodium pyruvate (1.5 g/Kg) ip. Tail blood glucose was measured by at baseline and at 15, 30, 60, and 120 mins after administration to measure area under the curve (AUC). Duodenal AMPK and colon calmodulin-dependent protein kinase II (CAMKII) were measured by western blots

Results: Results in the table show that both renal failure and diabetes were ameliorated by butyrate. AMPK and CAMKII play a major role in the secretion of GLP-1. Both proteins are downregulated in RF and were restored by butyrate.

Conclusions: In a recent study it has been shown that metformin activates duodenal AMPK dependent pathway to lower hepatic glucose production. PTT, a measure hepato-gluconeogenesis suggests that butyrate may act by similar mechanism. In addition recent clinical trials have shown GLP- 1 agonist improves GFR in renal failure. By improving GLP-1 secretion butyrate may improve diabetes and renal function in renal failure.

Insulin Resistance Suppresses Intercalated Cell Antibacterial Defenses Matthew J. Murtha,[2] Tad Eichler,[4] Birong Li,[1] Brian Becknell,[1] John D. Spencer.[3] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Research Institute at Nationwide Children's Hospital, Columbus Ohio, Pickerington, OH; [3]The Research Institute at Nationwide Children's, Columbus, OH; [4]The Research Institute at Nationwide Childrens Hospital, COLUMBUS, OH.*

Background: Urinary tract infection (UTI) is prevalent in people with diabetes mellitus. New evidence suggests antimicrobial peptides (AMP) play a role in maintaining urine sterility. Data from our lab shows that the kidney's intercalated cells (IC) secrete AMPs into the urine. Our data also show that insulin induces AMPs to shield the host from uropathogenic *E. coli* (UPEC). To investigate the impact of insulin resistance on renal antibacterial defense and AMP production, we selectively deleted the insulin receptor (IR) in murine ICs.

Methods: Using a Cre-loxP approach, mice homozygous for the floxed IR gene were crossed with mice expressing Cre recombinase under the ATP6V1B1 promoter (IC-specific isoform of VATPaseB1) to create IC-specific IR knockout mice (IRKO). A Cre-dependent tdTomato fluorescent reporter was incorporated to isolate ICs by fluorescent activated cell sorting (FACS). IRKO mice and Cre-negative littermates (IRflox) were subjected to experimental UTI with UPEC. 24 and 48 hrs post infection, UPEC burden was enumerated. The effects of IR deletion on host defense were confirmed *in vitro* using siRNA and *ex vivo* with urine neutralization assays.

Results: Compared to IRflox mice, IRKO mice exhibit a normal phenotype with normal serum insulin/glucose levels and serum/urine pH. qRT-PCR and Western blot confirmed IR mRNA and protein deletion in FACs-isolated ICs. qRT-PCR on FACS-isolated ICs shows that IRKO mice have decreased transcript expression of several AMPs, including RNase 4 and Lipocalin 2. ELISA confirmed lower urinary AMP peptide concentrations in IRKO mice compared to controls. Following experimental UTI, IRKO mice had 2-3 fold greater UPEC burden in urine, bladder, and kidneys. To confirm that suppressed AMP production increases UPEC susceptibility, RNase 4 was silenced in medullary cells *in vitro.* Cells were challenged with UPEC. With RNase 4 knock-down, UPEC invasion increased. When anti-RNase 4 blocking antibodies were added to mouse urine, UPEC survival increased.

Conclusions: This data suggest that intact IC insulin signaling is critical for UTI defense. Also, they indicate that the hyperglycemic environment alone does not explain diabetes-associated UTI risk. In part, increased UTI risk may be due to decreased expression of AMPs. Studies are needed to develop agents that target IC-specific insulin signaling or AMP production to reduce UTI risk.

Lysosomal Enzymes Dominate the Urinary Proteome of Adolescents with Early Type 1 Diabetes Julie Anh Dung Van,[5] Anne-Christin Hauschild,[3] Ihor Batruch,[1] Eleftherios P. Diamandis,[2] James W. Scholey,[5] Ana Konvalinka.[4] *[1]Mount Sinai Hospital, Toronto, ON, Canada; [2]Mount Sinai Hospital and University Health Network, Toronto, AB, Canada; [3]Princes Margaret Cancer Center, Toronto, Ontario, ON, Canada; [4]University Health Network, University of Toronto, Toronto, ON, Canada; [5]University of Toronto, Toronto, ON, Canada.*

Background: Diabetes is the leading cause of kidney disease worldwide. Microalbuminuria has been recognized as one of the earliest indicators of renal damage in diabetes. However, maladaptive changes have been described in the diabetic kidney long before the onset of microalbuminuria, in the form of renal hyperfiltration and hypertrophy. Our aim is to examine the urinary proteome of adolescents with early type 1 diabetes and to examine the biological processes and pathways underlying early changes in the diabetic kidney.

Methods: We collected second-morning, midstream urines from 15 cases with type 1 diabetes and 15 age- and sex-matched controls. Urine volumes normalized to creatinine were subjected to 10kDa ultrafiltration to isolate proteins. Proteins (200 ug) were digested with trypsin, fractionated, and analyzed on Q-Exactive mass spectrometer. MaxQuant software was used for peptide/protein identification and label-free quantification. Pathway Data Integration Portal (pathDIP), an annotated database of signaling cascades and core pathways, was used to examine the significantly altered pathways in early type 1 diabetes.

Results: A total of 576 proteins were consistently detected across all thirty urine samples, representing roughly 25% of our total urinary proteome (n = 2313). Of these, 34 were differentially excreted between groups (Benjamini-Hochberg FDR, $q < 0.05$): seven were decreased in diabetes (e.g., ACY1, TIMP1, FSTL1), and 27 were increased (e.g., LRG1, MAN2B1, NAGA). More than half of these differentially excreted proteins were lysosomal enzymes, and the dominant pathways and processes associated with these lysosomal enzymes include "hydrolase activity", "glycosaminoglycan degradation", and "spingolipid metabolism".

Conclusions: Differences in the urinary proteome can be detected prior to the onset of microalbuminuria in adolescents with type 1 diabetes, compared to healthy controls. Enzymes from lysosomal compartment were overrepresented in diabetes, suggesting that lysosomal protease activity is an early response of the kidney to hyperglycemia.

Diabetes-Induced Impairments in Robo Signalling Augment Glomerular Angiogenesis Johnny Y. Zhang,[1,2] Ahmad M. Sidiqi,[1,2] Xiaolin He,[1] Feng Gao,[1] Darren A. Yuen.[1,2] *[1]Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada; [2]Faculty of Medicine, University of Toronto, Toronto, ON, Canada.*

Background: Diabetic glomerular angiogenesis represents an early form of diabetic kidney injury, and is classically thought of as being driven by increased podocyte VEGF production. Robo1 and Robo4 are cell surface receptors that can regulate VEGF-mediated endothelial angiogenic activity. We have shown previously that glomerular endothelial Robo4 expression is downregulated by high glucose exposure, whereas Robo1 expression is unchanged, and that Robo1 is essential for VEGF-induced angiogenic activity. Our objective is to determine whether high glucose-induced alterations in Robo4 levels regulate VEGF-induced glomerular angiogenesis in diabetes.

Methods: Glomerular endothelial cell (GEC) responsiveness to VEGF in angiogenesis assays was examined in both normal glucose (NG) and high glucose (HG) conditions, and following Robo4 knockdown. Using Robo4 knockout (KO) mice, the effect of Robo4 deficiency on diabetic glomerular angiogenesis was also analyzed using fluorescence microangiography (FMA) and PECAM-1 immunohistochemistry, while kidney functional output was measured by creatinine clearance.

Results: As compared to GEC grown in NG medium, GEC grown in HG medium expressed lower levels of the anti-angiogenic Robo4 receptor, but not the pro-angiogenic Robo1 receptor, and exhibited greater VEGF responsiveness. Robo4 deficiency was associated with augmented migration in vitro and increased PECAM-1 density, glomerular capillary length, and creatinine clearance in Robo4 KO mice (compared to their WT littermates) after 5 weeks of STZ-induced diabetes.

Conclusions: Our observations suggest that diabetic glomerular angiogenesis is driven not only by enhanced VEGF production, but also by enhanced glomerular endothelial VEGF responsiveness. This increased responsiveness appears to be promoted by a shift in glomerular endothelial Robo signalling, favouring more pro-angiogenic Robo1, and less anti-angiogenic Robo4 activity.

TH-PO687

Deficiency of Ketohexokinase-A Exacerbates Renal Tubular Injury in Streptozotocin-Induced Diabetic Mice Tomohito Doke,[1] Takuji Ishimoto,[1] Takahiro Hayasaki,[1] Miguel A. Lanaspa,[2] Richard J. Johnson,[2] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]University of Colorado Denver, Aurora, CO.*

Background: Ketohexokinase (KHK), a primary enzyme for fructose, exists as two isoforms, KHK-C and KHK-A. Recently, we have reported that the metabolism of fructose endogenously produced by polyol pathway activation in diabetes may have a deleterious role in the pathogenesis of diabetic nephropathy using mice lacking both KHK-A and KHK-C (KHK-A/C KO). Although both isoforms express in proximal tubule, the role of KHK-A is not yet elucidated. The aim of this study is to determine the role of KHK-A in the development of diabetic nephropathy.

Methods: Male wild-type mice (WT), KHK-A knockout mice (KHK-A KO), and KHK-A/C KO were used. Diabetes was induced with i.p. injections of streptozotocin (5 days). At 18 weeks, urine, blood, and kidney tissues were collected from diabetic (D) and control mice. Renal injuries, inflammation, hypoxia, oxidative stress, and polyol pathway enzymes were analyzed. Metabolomic analysis including polyol pathway, fructose metabolism, nucleotides, glycolysis, and TCA cycle in kidney and urine was done.

Results: The levels of blood glucose were equally elevated, and polyol pathway in kidney was similarly activated among all mice induced diabetes. However, D-WT and D-KHK-A KO showed increases of urinary NGAL, glomerular hypertrophy, and tubular injuries with increased oxidative stress and renal XO activity compared to D- KHK-A/C KO. Urinary NGAL was significantly associated with renal AMP and urinary allantoin. Moreover, those renal injuries were more severe in D-KHK-A KO accompanied by significant renal dysfunction, increases of renal inflammatory cytokines and HIF1alpha expressions. Metabolomic analysis revealed elevations of renal fructose and fructose-1-phosphate contents in D-WT and D-KHK-A KO compared with respective controls. Furthermore, downstream metabolites of fructose, renal DHAP (Dihydroxyacetone phosphate) and TCA cycle were significantly increased in D-KHK-A KO compared with D-WT and D-KHK-A/C KO.

Conclusions: Kidney injury in streptozotocin-induced diabetes was exacerbated in mice lacking KHK-A with increased endogenous fructose metabolism than WT, while that was prevented in mice lacking both isoforms. These results suggest that KHK-C has a deleterious role, and KHK-A might has an opposite role in endogenous fructose-related kidney injury in diabetic mice.

TH-PO688

Proteomics and Systems Biology Analysis of Human Kidney Cells Reveals a Link between Androgen-Induced Alterations in Renal Metabolism and Circulating Metabolite Levels in CKD Sergi Clotet freixas,[1,3] Maria Jose Soler,[1] Marta Riera,[1] Julio Pascual,[1] Ihor Batruch,[2] Stella K. Vasiliou,[2] Apostolos Dimitromanolakis,[2] Eleftherios P. Diamandis,[2] James W. Scholey,[3] Ana Konvalinka.[2,3] *[1]Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain; [2]Mount Sinai Hospital, Toronto, Canada, Toronto, ON, Canada; [3]University Health Network, University of Toronto, Toronto, ON, Canada*.

Background: Male sex predisposes to chronic kidney disease (CKD) progression. We hypothesized that dihydrotestosterone (DHT) would affect renal cells by altering the proteome.

Methods: We used isotope labeling to quantify the proteome in human proximal tubular epithelial cells (PTEC) exposed to DHT or estradiol. Top proteins were verified in vitro and in vivo. Renal oxidative stress (OS) was assessed by N-Tyr staining. Systems biology of sex hormone-protein signatures was studied in Cytoscape.

Results: Of 5043 quantified proteins, 76 were regulated by sex hormones. Processes related to metabolism were significantly enriched in proteins regulated by DHT. Proteins representing glucose, glucosamine and fatty acid metabolism, namely glucose-P-isomerase (GPI), glucosamine-P-N-acetyltransferase (GNPNAT1), and mitochondrial trifunctional protein subunit alpha(HADHA), were validated in vitro and in vivo. Renal expression of GPI, GNPNAT1 and HADHA was significantly higher in males compared to females, in 2 models of diabetes. OS was enriched in our proteins and genes highly expressed in diabetic kidneys. We demonstrated increased OS in diabetic and control male mice kidneys. We asked whether dysregulated metabolic enzymes in male kidneys may be responsible for changes in circulating metabolites. Using data from the human KORA F4 study, we found that serum metabolites related to TCA cycle and aminoacid metabolism (e.g.malate, glutamine and proline) were increased in CKD men and also associated with our DHT-proteins.

Conclusions: Androgen-induced perturbations in renal metabolism may be responsible for the more rapid kidney disease progression ascribed to men. Metabolic alterations in the male kidney may be reflected in circulating levels of malate, glutamine, and proline metabolites in CKD.

MDM2 Contributes to High Glucose-Induced Glomerular Mesangial Cell Proliferation and Extracellular Matrix Accumulation via Notch1 Signaling Chun-Tao Lei, Hua Su, Chun Zhang. *Union Hospital, Huazhong University of Science and Technology, Wuhan Hubei Provicne, China*.

Background: Murine double minute 2 (MDM2), an E3-ubiquitin ligase, is critical for various biological functions and its dysregulation is involved in tumorigenesis. Previous data have documented an indispensable role of MDM2 in kidney homeostasis and disorders. However, its role in glomerular mesangial cell (GMC) proliferation and extracellular matrix (ECM) accumulation under hyperglycemia remains unclear.

Methods: In vitro study, rat mesangial cell line was employed, and subjected to different treatments. RNA interfere and Nutlin-3a treatment were utilized to knockdown MDM2 expression and block MDM2-p53 interaction respectively. Diabetic mice model was established by intraperitoneal injection of streptozotocin (STZ) and intraperitoneal administration of Nutlin-3a was adopted to disrupt the in vivo binding between MDM2 and p53.

Results: In the present study, we found MDM2 protein level is upregulated in high glucose-cultured GMCs. Knocking down MDM2 by siRNA attenuates high glucose-induced ECM accumulation and cell proliferation. However, MDM2-p53 interaction blocker Nutlin-3a, cannot protect diabetic mice from renal impairment not only in vivo but also has no benefit on high glucose-induced ECM accumulation in vitro. Intriguingly, we found Notch1 signaling is activated in GMCs with high glucose exposure which is obviously attenuated by MDM2 depletion. However, Numb, another substrate of MDM2 which suppresses Notch1 signaling, is not involved in the MDM2 mediated Notch1 regulation. Lastly, our findings revealed that MDM2 binds with and ubiquitinates Notch1 intracellular domain (NICD1), however the ubiquitination status of NICD1 does not lead it to degradation but activates its downstream gene expression.

Conclusions: Collectively, our data propose a pivotal role of MDM2 in high glucose-induced GMC proliferation and ECM accumulation, through modulating the activation of Notch1 signaling in an ubiquitination-dependent but p53-independent way.

FcgRIIb-Deficience and FcgRIII-Deficience Exacerbate Renal Injury Respectively in Diabetic Mice Rui Zhang. *Division of Nephrology, West China Hospital, Sichuan university, Chengdu, China*.

Background: Fcg receptors are key immune receptors responsible for both humoral and innate immunity. FcgRI, FcgRIIb and FcgRIII are the members of Fcg receptors superfamily. We aimed to investigate the involvement of Fcg receptors respectively in diabetic mice.

Methods: Eight week-old C57BL/6 mice, FcgRIIb knockout mice and FcgRIII knockout mice were subdivided into three groups: the normal diet group, high fat diet group, type 2 diabetes group induced by high fat diet combined with streptozotocin. The levels of blood glucose, serum creatinine, urineprotein were tested. The expressions of TGF-β, TNF-α, pNK-κB, oxLDL were detected by real-time PCR or westernblot in isolated glomeruli. In vitro studies were performed in mice renal glomerular mesangial cell (GMCs) tranfected with lentivirus vectors carrying siRNA targeting FcgRIII, FcgRII and FcgRI gene respectively. GMCs were cultured with normal glucose, high glucose, oxLDL, high glucose combined with oxLDL.

Results: FcgRIII-/- diabetic mice and FcgRIIb-/- diabetic mice had elevated levels of fasting blood glucose, creatinine, urine protein compared with WT diabetic mice. Renal histology showed mesangial expansion, westernblot and real-time PCR indicated higher expression of TGF-β, TNF-α and pNK-κB, immunofluorescence or immunohistochemistry showed expressing in glomeruli, in diabetic FcgRIII knockout and FcgRIIb knockout than wild type and HFD respectively. The HFD group exist more severely biochemical dates, renal injury factors than control group and appeared most oxLDL deposition. To further examine the mechanism that which fc gamma receptor exacerbated renal injury for the most part, in vitro we observed that high glucose, high glucose combined with oxLDL activated expression of TGF-β, TNF-α, pNF-κB in mice renal glomerular mesangial cells, the transfection of FcgRIIb or FcgRIII siRNA had upregulated TGF-β, TNF-α, pNF-κB expression, whereas the transfection of FcgRI siRNA had appeared to attenuate the level of TGF-β, TNF-α, pNF-κB expression.

Conclusions: FcgRI deficience downregulated inflammation, fibrosis. FcgRIIb deficience accelarated inflammation, fibrosis and anomalous deposition of oxLDL. FcgRIII deficience failed to delay renal injury. These observations suggest that FcgRs represent a novel target in the therapeutic interventions for diabetic nephropathy. MAD2B-Numb Interaction Is Involved in High Glucose Induced Podocyte Injury by Regulating Cell Polarity Hua Su,[1] Hui Tang,[2] Chun Zhang.[3] *[1]Huazhong Science and Technology University, Wuhan, China; [2]Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [3]Union Hospital, Huazhong University of Science and Technology, Wuhan Hubei Provicne, China*.

Background: The loss of podocyte is a critical event in the pathogenesis of diabetic nephropathy (DN). Recent studies have demonstrated the importance of cell polarity in the maintenance of podocyte architecture. Previously, our group found the mitotic arrest deficient protein MAD2B is implicated in high glucose (HG) induced podocyte injury. However, the exact mechanism of MAD2B in podocyte injury still remains to be established.

Methods: Patients diagnosed with DN were enrolled in this study, and DN model was constructed on C57BL/6 mice by a single intra-peritoneal injection of STZ. In vitro study, immortalized human podocyte cell line was employed, and exposed to different treatments after differentiation. The expression of MAD2B and Numb was suppressed by recombinant lentivirus infection.

Results: Previously we have demonstrated the enhancement of MAD2B in DN mice and HG treated podocytes. Using a yeast two-hybrid interaction trap we identified Numb as a novel MAD2B binding protein in human kidney. Through confocal laser scanning microscopy we confirmed the co-localization of MAD2B and Numb in podocyte in vivo and in vitro. Subsequent endogenous co-immunoprecipitation established the direct interaction between MAD2B and Numb. HG exposure upregulated MAD2B expression and Numb phosphorylation in podocyte. Interestingly, HG also induced Numb translocation from podocyte basolateral membrane to cytoplasm, which accompanied by podocyte cytoskeleton re-organization. MAD2B genetic deletion partly reversed Numb phosphorylation and cytoplasm translocation as well as cytoskeleton re-organization in podocyte. In addition, Numb bound to integrin-β1 and correlated with its basolateral membrane distribution. But this binding was greatly disrupted by HG or phosphatase inhibitor calyculin-A or Numb depletion.

Conclusions: Upregulated MAD2B expression accelerates Numb phosphorylation and its translocation from podocyte basolateral membrane to cytoplasm in HG condition. Phosphorylated Numb has a reduced binding affinity to integrin-β1 which diminishes integrin-β1 distribution on podocyte basolateral membrane and ultimately leads to the loss of cell polarity and podocyte injury.

Insulin Prevents Bcl2 Modifying Factor-Induced Renal Proximal Tubular Cell Apoptosis via Stimulation of Heterogeneous Nuclear Ribonucleoprotein F and Sirtuin-1 Expression in Diabetic Akita Mice Anindya Ghosh,[3] Chao-Sheng Lo,[2] Isabelle Chenier,[1] Shaaban Abdo,[3] Janos G. Filep,[5] Julie R. Ingelfinger,[7] Shao-Ling Zhang,[6] John S. Chan.[4] *[1]CHUM-Hotel Dieu Hosp, Montreal, QC, Canada; [2]CRCHUM, Universite de Montreal, Montreal, QC, Canada; [3]CRCHUM, University of Montreal, Montreal, QC, Canada; [4]CRCHUM, University of Montreal, Montreal, QC, Canada; [5]Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [6]Research Center of Centre Hospitalier de l Universite de Montreal (CRCHUM), Montreal, QC, Canada; [7]The New England Journal of Medicine, Boston, MA.*

Background: Tubular atrophy and tubulointerstitial fibrosis are closely associated with loss of renal function in diabetes. However, the underlying mechanisms are not fully understood. Here we investigated the role of the pro-apoptotic BH3-only protein, BCL2-modifying factor (Bmf), in renal proximal tubular cell (RPTC) apoptosis in mice and studied the effects of insulin on Bmf in rat immortalized RPTCs (IRPTCs) in vitro.

Methods: Non-transgenic (Tg) and Tg mice specifically overexpressing human Bmf in RPTCs were studied at 10 to 20 weeks of age. Non-Akita littermates and Akita mice (a type 1 diabetes model) +/- insulin implant from the age of 12 weeks were also studied until week 16. Blood glucose, systolic blood pressure (SBP), and urinary albumin creatinine ratio (ACR) were measured bi-weekly. Kidneys were processed for histology. RPTC apoptosis was evaluated by TUNEL assay. Freshly isolated RPTs were assessed for gene and protein expression by qPCR and Western blotting, respectively. Urinary cells were assessed by flow cytometry and then qunatified by qPCR for human Bmf transgene expression. Rat IRPTC stably transfected with a plasmid containing the full length Bmf promoter fused to luciferase reporter (pGL4.20 N-1370/+102) were cultured in normal glucose (5mM) or high glucose (HG, 25mM) medium +/- insulin.

Results: Bmf-Tg mice exhibited higher systolic blood pressure, ACR, RPTC apoptosis and more urinary RPTCs than non-Tg mice. Insulin treatment suppressed Bmf expression and tubular apoptosis and reduced urinary RPTCs in Akita mice. In vitro, insulin stimulated hnRNP F and sirtuin-1 expression and inhibited Bmf promoter activity in HG medium. Promoter DNA analysis identified putative responsive elements for hnRNP F, p53 and Foxo3 in rat Bmf promoter. Transfection of small interference RNA of hnRNP F or sirtuin-1 abrogated insulin inhibition of Bmf promoter activity.

Conclusions: Overexpression of Bmf in RPTCs induces RPTC apoptosis. Insulin prevents RPTC apoptosis via stimulation of hnRNP F and sirtuin-1 expression to inhibit Bmf gene expression in the diabetic kidney.

Nuclear Factor Erythroid 2-Related Factor 2 Deficiency Attenuates Hypertension and Nephropathy via Up-Regulation of Renal Angiotensin Converting Enzyme-2 and Mas Receptor Expression in Diabetic Mice Shuiling Zhao,[2] Anindya Ghosh,[4] Chao-Sheng Lo,[3] Isabelle Chenier,[1] Janos G. Filep,[6] Julie R. Ingelfinger,[8] Shao-Ling Zhang,[7] John S. Chan.[5] *[1]CHUM-Hotel Dieu Hosp, Montreal, QC, Canada; [2]CRCHUM, MONTREAL, QC, Canada; [3]CRCHUM, Universite de Montreal, Montreal, QC, Canada; [4]CRCHUM, University of Montreal, Montreal, QC, Canada; [5]CRCHUM, University of Montreal, Montreal, QC, Canada; [6]Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [7]Research Center of Centre Hospitalier de l Universite de Montreal (CRCHUM), Montreal, QC, Canada; [8]The New England Journal of Medicine, Boston, MA.*

Background: We investigated the impact of nuclear factor erythroid 2-related factor 2 (Nrf2) deficiency on *hypertension, kidney injury and* renin-angiotensin system (RAS) *gene expression* in renal proximal tubule cells (RPTCs) *in diabetic* Akita (type 1 diabetes model) Nrf2 knockout (KO) mice and Akita mice treated with trigonelline (a Nrf2 inhibitor).

Methods: Male wild type (WT), Akita and Akita Nrf2 KO mice at 12 to 20 weeks were studied. Akita mice receiving trigonelline from weeks 12-18 +/- oltipraz (a Nrf2 activator) from weeks 16-18 were also studied. Blood glucose and systolic blood pressure were monitored weekly. Urinary albumin/creatinine ratio (ACR), angiotensin II (Ang II) and angiotensin 1-7 (Ang 1-7) levels were measured by ELISA. Kidneys were processed for histology. RAS mRNA and protein expression in renal proximal tubules (RPTs) were evaluated by RT-qPCR and Western blotting, respectively. We also performed Nrf2 knockdown in rat immortalized RPTCs (IRPTCs) stably transfected with plasmid containing rat angiotensinogen (Agt), angiotensin converting enzyme (ACE), angiotensin converting enzyme-2 (Ace2) or angiotensin 1-7 receptor (MasR) gene promoter.

Results: Nrf2 deficiency attenuated hypertension, renal hypertrophy, tubulointerstitial fibrosis, urinary ACR and Ang II, down-regulated RPTC Agt, ACE and pro-fibrotic gene expression and up-regulated Ace2 and MasR expression and urinary Ang 1-7 levels in Akita Nrf2 KO mice, compared to Akita mice. Similar changes were observed in Akita mice treated with trigonelline +/- oltipraz. Transfection of siRNA of Nrf2 prevented high glucose (HG, 25 mM)-stimulation of Agt and ACE expression and enhanced Ace2 and MasR expression in IRPTCs in vitro. Trigonelline decreased Agt/ACE and up-regulated Ace2/MasR mRNA expression in HG and these actions were reversed by oltipraz.

Conclusions: Nrf2 deficiency attenuates hypertension and kidney injury, via decreasing renal Agt/ACE expression and increasing Ace2/MasR expression. These results identify Nrf2 as a novel target for the prevention of hypertension and kidney injury in diabetes.

High Fat Diet Increases Plasma Soluble Prorenin Receptor (sPRR), Ang II, Systolic Blood Pressure (SBP), and Arterial Stiffness in Type 2 Diabetic (T2D) Male but Not in Female Mice Bruna Visniauskas, Virginia Reverte, Carla B. Rosales, Michelle Galeas-Pena, Caleb M. Abshire, Sarah Lindsey, Minolfa C. Prieto. *Physiology and Pharmacology, Tulane University School of Medicine, New Orleans, LA.*

Background: Activation of the renin angiotensin system (RAS) leads to complications during T2D; however, whether these outcomes exhibit sex differences remains unknown. Plasma prorenin levels are high in T2D patients and associated to microvascular complications. The sPRR activates prorenin in the extracellular compartments. In this study, we determined if plasma sPRR contributes to sex differences in the RAS and complications in a murine model of high fat diet (HFD)-induced T2D.

Methods: Male and female C57BL/6 mice were subjected to normal diet (NFD; Protein: 25% Kcal/ Fat: 13%/ Carbohydrate: 62%) or HFD (Protein: 18% Kcal/ Fat: 45%/ Carbohydrate: 36%) for 28 weeks to assess temporal changes in plasma sPRR and Ang II quantified by ELISA, and SBP measured by telemetry. Phenotype of T2D was established based on changes in body weight, glucose tolerance test, and plasma insulin and lipid levels. Vascular stiffness was measured in carotid arteries by pressure myography.

Results: By Week 16, a T2D phenotype was evident in HFD mice with greater exacerbation in males than in females. After Week 20, plasma sPRR started to increase in HFD male mice (4±3 vs. 3±1 ng/day; $P<0.05$) and remained elevated until Week 28 (5±3 vs. 3±.1 ng/day; $P<0.05$). No significant changes were observed in females. These changes paralleled increases in Ang II and SBP only in males [Ang II (HFD: 131±20 vs. NFD: 59±12 pg/day; $P<0.05$), SBP (HFD: 135 ±7 vs. NFD: 115± 2mmHg; $P<0.001$)] but not in females. Males on HFD also showed significant decreases in carotid compliance and distensibility. After Week 20, urinary angiotensinogen excretion (uAGT) started to increase only in HFD males compared to NFD; and by the end of the study, it was 4X higher, even in the absence of overt microalbuminuria.

Conclusions: In conclusion, in mice with HFD-induced T2D, plasma sPRR contributes to marked sex differences in systemic Ang II, SBP, and vascular stiffness. Concomitant uAGT differences support the concept of sexual dimorphism of intrarenal RAS activation. Plasma sPRR may reflect the status of systemic RAS and anticipate vascular complications during T2D.

Prolonged Exposure of Podocytes to Insulin Induces Insulin Resistance through Lysosomal and Proteasomal Degradation of the Insulin Receptor Abigail C. Lay,[2] Jenny Hurcombe,[2] Mette V. Østergaard,[2] Fern Barrington,[2] Rachel Lennon,[3] Gavin I. Welsh,[2] Richard Coward.[2] *[2]University of Bristol, Bristol, United Kingdom; [3]University of Manchester, Manchester, United Kingdom.*

Background: Podocytes are insulin responsive cells of the glomerular filtration barrier and are key in preventing albuminuria, a hallmark feature of diabetic nephropathy. While there is evidence that a loss of insulin signalling to podocytes is detrimental, the molecular mechanisms underpinning the development of podocyte insulin resistance in diabetes remain unclear. Thus, we aimed to further investigate podocyte insulin responses early in the context of diabetic nephropathy.

Methods: Conditionally immortalised human and mouse podocyte cell lines and glomeruli isolated from db/db DBA2J mice were studied. Podocyte insulin responses were investigated with western blotting, cellular glucose uptake assays and automated fluorescent imaging of the actin cytoskeleton. Q-PCR was employed to investigate changes in mRNA. Human cell lines stably overexpressing the IR and nephrin were also generated, using lentiviral constructs.

Results: Podocytes exposed to a diabetic environment (high glucose, high insulin and the pro-inflammatory cytokines TNF-α and IL-6) become insulin resistant with respect to glucose uptake and activation of PI3K and MAPK signalling. These podocytes lose expression of the insulin receptor (IR) as a direct consequence of prolonged exposure to high insulin concentrations, which causes an increase in IR protein degradation via a proteasome-dependent and bafilomycin-sensitive pathway. Reintroducing the IR into insulin resistant human podocytes rescues upstream phosphorylation events, but not glucose uptake. Stable expression of nephrin is also required for the insulin-stimulated glucose uptake response in podocytes and for efficient insulin-stimulated remodelling of the actin cytoskeleton.

Conclusions: Together these results suggest that IR degradation, caused by high levels of insulin, drives early podocyte insulin resistance and that both the IR and nephrin are required for full insulin sensitivity of this cell. This could be highly relevant for the development of nephropathy in diabetic patients and patients with the metabolic syndrome who are commonly hyperinsulinaemic in the early phases of their disease.

Inactivation of the SPAK Kinase Generates an Obesity-Resistant Phenotype in Mice Braulio A. Marfil,[1] Ivan Torre-Villalvazo,[1] Luz G. Cervantes-perez,[1] Lilia G. Noriega,[1] Maria Chavez-Canales,[2] Jose V. Jimenez,[1] Norma O. Uribe-uribe,[1] Nimbe Torres,[1] Norma Bobadilla,[1,2] Armando R. Tovar,[1] Gerardo Gamba.[1,2] *[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [2]Instituto de Investigaciones Biomédicas, UNAM, Mexico City, Mexico.*

Background: The WNK (with-no-lysine)/SPAK (Ste20-related proline/alanine rich kinase) pathway has a well-known role in hypertension through its predominant effect on renal salt reabsorption. Recent evidence suggests this pathway could also be involved in the pathophysiology of obesity, which could link both diseases intrinsically. In humans the STK39 gene, which encodes SPAK, has been suggested as a susceptibility gene for arterial hypertension and for obesity. In this regard, the lack of SPAK activity in a knockin mice model (SPAK-T243A/T243A) leads to a reduction in blood pressure, but the effect of SPAK inactivation on body weight balance has not been evaluated.

Methods: To characterize the role of SPAK in energy balance, we fed wild-type and SPAK-knockin mice (SPAK-T243A/T243A) a high-fat diet (HFD) for 17 weeks and evaluated body composition, energy expenditure, thermogenesis, lipid metabolism, leptin levels, glucose metabolism and end-organ damage such as hepatic lipid content and pancreatic islet hypertrophy.

Results: Our results reveal that in contrast to wild type mice fed with HFD, the SPAK-T243A/T243A mice fed a HFD exhibit a significantly lower weight gain (15.1 ± 0.8 vs 10.2 ± 2.0 g; $p<0.001$) and decreased adiposity along the study, exhibiting at the end a better glucose tolerance, lower cholesterol, triglyceride and leptin levels, less hepatic steatosis and less pancreatic islet hypertrophy. The HFD intake was similar in both groups along the study. Calorimetric studies showed in the SPAK-T243A/T243A mice an increased thermogenic activity in brown adipose tissue, increased UCP1 expression, and white adipose tissue browning.

Conclusions: Our data suggest that SPAK-T243A/T243A mice are partially resistant to obesity induced with a HFD due to an increase in energy expenditure and thermogenesis, suggesting that the WNK/SPAK pathway could play a role in the pathophysiology of obesity and energy balance. Our results also suggest that inhibition of SPAK activity could have a therapeutic value in obesity. Supported by "Fronteras de la Ciencia" grant No. 23 from Conacyt, Mexico to GG.

TH-PO697

Effect of ACE2 Deletion on Glucose Homeostasis, Renin Angiotensin System, and Necrosis Vanesa Palau,[1] Marta Riera,[1] Heleia Roca Ho,[1] David Benito,[1] Julio Pascual,[2] Maria Jose Soler.[2] *[1]Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain; [2]Hospital del Mar, Parc de Salut Mar, Barcelona, Spain.*

Background: Angiotensin converting enzyme 2 (ACE2) acts as a negative regulator of renin angiotensin system (RAS). Downregulation of ACE2 either by gene deletion or by pharmacological inhibition worsens renal injury and hypertension. Indiabetes, ACE2 activity is increased in pancreas from non-obese diabetic (NOD) mice. ACE2 deletion on pancreas from NOD mice has not been previously studied. We propose to study the effect of ACE2 deletion in NOD mice in an early pre-diabetic stage on glucose homeostasis, insulin secretion, RAS, oxidative stress and necroptosis.

Methods: Female NOD-ACE2$^{-/-}$ mice were studied at 12 weeks of age and compared to NOD-ACE2$^{+/+}$ mice. Glucose tolerance tests were performed by intraperitoneal administration of D-glucose bolus. Circulating glucose levels were determined at 0, 15, 30 and 60 minutes after injection. Insulin secretion was determined by ELISA technique from serum samples collected at 0, 2 and 5 minutes after glucose bolus injection. Immunohistochemistry studies for insulin, ACE, angiotensin II receptor 1 (AT1R), nitrotyrosine and RIP-1 were performed in paraffin-embedded pancreas.

Results: NOD-ACE2$^{-/-}$ mice had less tolerance to glucose bolus, lower insulin secretion after glucose administration, less insulin production and smaller islet area. Regarding RAS, NOD-ACE2$^{-/-}$ mice presented higher levels of ACE and AT1R staining as compared to NOD-ACE2$^{+/+}$ mice. NOD-ACE2$^{-/-}$ mice had higher levels of nitrotyrosine and RIP-1 as markers of oxidative stress and necroptosis, respectively (Table).

Conclusions: NOD mice with ACE2 deletion present altered glucose tolerance, functional and morphological alterations at a pancreatic level due to insulin synthesis and secretion as well as decreased islet area. ACE2 deletion leads to a worsening glucose homeostasis in NOD mice accompanied to higher levels of oxidative stress and necroptosis and RAS stimulation by increasing ACE and AT1R expression.

	Glucose bolus tolerance (AUC) (mg/dl60min)	Insulin secretion (ng/mL5min)	Insulin/renin pancreatic islet (µm²)	Pancreatic islet area (µm²)	Pancreatic islet ACE staining (MGV)	Pancreatic islet AT1R staining (MGV)	Pancreatic islet Nitrotyrosine staining (Scale 0-4)	Pancreatic islet Rip-1 staining (MGV)

TH-PO698

Urinary Ubiquitinated Factor XII and Beta-2-Glycoprotein-1 May Identify Different Histological Patterns of Diabetic Kidney Disease Massimo Papale,[2] Chiara Divella,[2] Francesca Conserva,[2] Giuseppe Castellano,[2] Paola Pontrelli,[2] Antonella Di Franco,[2] Mariagrazia Barozzino,[2] Francesco Pesce,[2] Annarita Oranger,[2] Francesco Giorgino,[2] Luigi Laviola,[2] Simona Simone,[2] Vincenzo Trischitta,[1] Salvatore De Cosmo,[1] Giuseppe Grandaliano,[3] Loreto Gesualdo.[2] *[1]Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo (Fg), Italy; [2]University of Bari-Dept. of Emergency and Organ Transplantation, Bari, Italy; [3]University of Foggia, Foggia, Italy.*

Background: Diabetic Kidney Disease (DKD) is a heterogeneous disease with distinct histopathological phenotypes spanning from the typical nodular Kimmelstiel-Wilson lesions (DN) observed in ≈ 40% of the cases to the arteriolosclerotic changes and other primitive glomerulonephropathies (non DN-CKD) reported in the remaining cases. Recent studies (PMID: 20671095; 27881486) suggest a role of protein ubiquitination in DKD thus we tested the usefulness of urinary ubiquitinated proteins (ubi-prot) as novel biomarkers for DKD.

Methods: Sixty-four Type 2 Diabetes Mellitus patients (pts) with normoalbuminuria (NORMO), microalbuminuria (MICRO), and micro or macroalbuminuria with biopsy-proven DN or non DN-CKD were enrolled. Urinary ubi-prot were purified by Immunoprecipitation with specific anti-ubiquitin antibody and identified by LTQ Orbitrap XL™ Mass Spectrometry (MS) analysis. Protein Pattern Analysis (PPA) allowed the recognition of specific molecular patterns in each group and the most confident biomarkers were then validated by IF and ELISA or immunoblotting in tissue and urine samples, respectively.

Results: MS analysis identified 79 ubi-prot in NORMO, 111 in MICRO, 135 in non DN-CKD and 116 in DN, respectively. PPA analysis associated differentially excreted ubi-prot to the activation of the classical pathway of complement system in DKD. Urinary C5b9, measured in an independent set of pts, was significantly more excreted ($P < 0.01$) in DKD Vs. non proteinuric T2DM and pts with Lupus Nephritis and correlated, in the DN subset, with an increased deposition in proximal tubuli. Furthermore, 5 unique ubi-prot namely Factor XII, Ig K and Lambda chains, Beta-2-glycoprotein-1 (B2GP-1) and C6 were excreted in DN group only. Independent validation in 8 DN Vs 8 non DN-CKD pts confirmed that urinary ubiquitinated Factor XII and B2GP-1 were significantly more excreted in DN Vs. non DN-CKD ($P< 0.001$ and $P < 0.0001$, respectively).

Conclusions: Combined evaluation of urinary C5b9, ubiquitinated Factor XII and B2GP-1 may allow noninvasive stratification of pts with DKD

TH-PO699

Neuropeptide Y Is a Novel Modulator of Podocyte Function and Its Loss Is Protective in Several Models of Albuminuric Renal Disease Abigail C. Lay, Jenny Hurcombe, Eleanor W. Ross, Fern Barrington, Gavin I. Welsh, Richard Coward. *University of Bristol, Bristol, United Kingdom.*

Background: Neuropeptide Y (NPY) is one of the most abundant peptides of the central and peripheral nervous systems, with a key role in energy homeostasis. However its function in the glomerulus has not previously been reported. Using a non-biased transcriptomic approach we discovered that NPY was highly significantly down-regulated in both human and mouse conditionally immoralised podocytes when rendered insulin resistant mimicking a diabetic environment (25-fold down regulated $p=10^{-125}$). Data from the nephromine database, comparing diabetic nephropathy (DN) patient groups, suggests this also occurs in human glomeruli. We therefore went on to study the biological importance of NPY on podocyte and glomerular biology.

Methods: Conditionally immortalized human and mouse podocytes were studied *in vitro* to determine NPY receptor signalling. For our *in vivo* investigations we studied wild-type (WT) 129Sv and NPY-deficient (NPY-/-) 129Sv mice, comparing two models of albuminuric renal injury; adriamycin nephropathy and streptozotocin (STZ)-induced diabetic nephropathy (DN).

Results: NPY rapidly signals to human and mouse podocytes through the PI3K and MAPK pathways and this is blocked in the presence of the Y2 receptor antagonist BIIE0246, indicating these responses are NPY2R-dependent. NPY also causes a rapid increase in intracellular calcium, which in turn promotes the nuclear translocation of NFAT. Interestingly, in contrast to WT controls, NPY-/- mice are protected from albuminuria 6 months after the induction of STZ-DN (a 4-fold increase in albuminuria is observed in WT mice, $p=0.036$ WT citrate vs STZ. No significant increase in albuminuria is observed in NPY-/- mice, $p=0.6828$ NPY-/- citrate vs STZ). Similarly, 14 days after the induction of adriamycin nephropathy, NPY-/- mice had a significantly ($p=0.0172$) lower level of albuminuria than WT controls.

Conclusions: NPY has a novel role in regulating podocyte and glomerular biology. Our data suggests that in diabetic nephropathy and insulin resistant states its glomerular secretion is supressed to protect against disease progression.

Modulation of Epigenetics Led to a Decrease in Proteinuria in a Mouse Model of Diabetic Podocytopathy Himanshu Vashistha,[3] Abheepsa Mishra,[1] Ashwani Malhotra,[5] Leonard G. Meggs,[4] Pravin C. Singhal.[2] *[1]Feinstein Institute of Medical Research, Northwell Health, MANHASSET, NY; [2]North Shore LIJ Health System, Great Neck, NY; [3]Ochsner Health System, New Orleans, LA; [4]Ochsnher Health Foundation, New Orleans, LA; [5]Immunolgy and Inflammation, Feinstein Inst.Med research and NSLIJ, Manhasset, NY.*

Background: Modulation of renin angiotensin system has been reported to slow down the progression of diabetic podocytopathy by alterations of hemodynamic factors. Recent reports suggest that epigenetic factors also contribute to the development and progression of diabetic podocytopathy. We evaluated blockade effect of Angiotensin II (Ang II) on reversal of epigenetic alterations in diabetic podocytopathy. We hypothesize that demethylation by a low-dose hydralazine (HYDZ, non-hypertensive dose) would further augment the effect of Ang II blockade on reversal of epigenetic factors and decrease proteinuria in diabetic mice

Methods: Protein blots of renal tissues/cortical sections of 2, 4, and 6 months old control and Akita mice (diabetic, n=3) were probed for methylation at histone (H)3 lysine (K)4 residues, acetylation at H3 lysine (K)9 residues, SNAIL, vitamin D receptor (VDR), and nephrin. *In vitro* studies, protein blots of control (glucose, 5 mM) and high glucose (30 mM, HG)-treated human podocytes (HPs) were probed for SNAIL, VDR, nephrin, H3K4me3, H3K9ac and actin. Podocyte VDR and nephrin gene methylation status (Bisulphite pyrosequencing) and SNAIL binding to VDR and nephrin promoters (ChIP assay) were determined. Control and Akita mice (n=4) were treated with losartan (an Ang II receptor blocker, 10 mg/Kg/day) with/without HYDZ (10 mg/kg/day, 4 weeks) followed by evaluation of proteinuria and renal epigenetic alterations.

Results: Protein blots of renal tissues/cortical sections of Akita mice and HG/HPs displayed enhanced expression of SNAIL and H3K4me3 but down regulation of VDR, nephrin and H3K9ac. Losartan not only decreased proteinuria but also partially reversed epigenetic alterations and associated SNAIL, VDR and nephrin expressions; HYDZ alone has similar effects on proteinuria and epigenetic markers and further augmented these effects when combined with losartan. Both nephrin and VDR displayed more than 70% cytosine methylation (CpG islands). HG/HP displayed deacetylation of nephrin and degradation via ubiquitation. ChIP assays revealed binding of SNAIL at VDR and nephrin promoters.

Conclusions: Reversal of epigenetic alterations in renal tissues contributed to decrease in proteinuria in diabetic mice.

Absence of Inner Medullary Urea Transporters Attenuates Fibrosis in Diabetic Nephropathy Fitra Rianto,[3] Mitsi A. Blount,[3] Faten Hasounah,[1] Joseph A. Ruiz,[1] Jeff M. Sands,[2] Janet D. Klein.[1] *[1]Emory University, Atlanta, GA; [2]Emory University Renal Division, Atlanta, GA; [3]Emory University School of Medicine, Atlanta, GA.*

Background: Kidney fibrosis is commonly observed in diabetic nephropathy. Animal studies show that a low protein diet reduces the incidence of diabetic nephropathy and kidney fibrosis, suggesting that kidney urea levels may contribute to nephropathy. Benefits of low protein diets in patients are controversial. We investigated diabetes (DM)-related kidney fibrosis under conditions of minimal urea reabsorption and maximal urea load.

Methods: C57Bl6 mice +/- genetic ablation of UT-A1 and UT-A3 urea transporters (A1/A3 KO mice) were given daily doses of streptozotocin (55mg/kg/day) until blood glucose >200mg/dl. After 4 weeks mice were given low (14%) or high (40%) protein diets for 2 weeks (group 1) or 5 weeks (group 2). Kidneys were collected for protein and histochemical analysis.

Results: Mice required between 4 to 7 days injection of STZ to produce blood glucose levels >200 mg/dl. Body weights of non-DM mice remained stable while DM WT mice lost ~2% and A1/A3 KO mice lost ~14% body weight prior to termination. Urine values for 40%-fed DM mice: urine urea: 2.5±03 mmol/Uv WT vs 2.9±0.3 mmol/Uv KO; in mEq/L: Na: 147±6.8 WT /132±2.2 KO; Cl: 102±0.7 WT/97±0.7 KO; K: 6.3±0.5 WT/5.8±0.8 KO. Urine volume in both WT and UT-A1/A3 mice was increased by diabetes, but UT-A1/A3 KO mice still produced more urine than WT. Smooth muscle actin (SMA), vimentin were used as markers of fibrosis. In the 2 week high protein fed mice, diabetic WT mice showed 56% increased SMA vs diabetic WT mice fed a 14% protein diet whereas the A1/A3 KO mice showed a 26% increase with 40% protein feeding. Vimentin was 70% increased in high protein fed animals vs 12% increase in comparably fed A1/A3 KO mice. Trichrome staining of histological sections revealed higher collagen levels in 40%-fed WT mice vs A1/A3 KO mice.

Conclusions: These data show that fibrosis that characterizes diabetic nephropathy is attenuated by the absence of urea transporters. This suggests that urea reabsorption mediated by urea transporters in the inner medulla contributes to the development of diabetic renal fibrosis and is aggravated by high protein diet. If urea transport inhibitors replicate the effects of genetic knock out, they may represent a promising future therapy.

Nicotine Enhances Renal Mesangial Cell Proliferation and Fibronectin Production in High Glucose Milieu via Activation of Wnt/β-Catenin Pathway Xiqian Lan,[1] Rukhsana Aslam,[2] Seyedeh Shadafarin Marashi Shoshtari,[6] Abheepsa Mishra,[3] Ashwani Malhotra,[4] Pravin C. Singhal.[5] *[1]Feinstein Institute for Medical Research, Great Neck, NY; [2]Feinstein Institute for medical research, Glenoaks, NY; [3]Feinstein Institute of Medical Research, Northwell Health, MANHASSET, NY; [4]Feinstein Inst.Med research, Manhasset, NY; [5]North Shore LIJ Health System, Great Neck, NY; [6]The Feinstein Institute for Medical Research, Manhasset, NY.*

Background: Diabetic nephropathy (DN) is a major complication of diabetes mellitus, and the commonest cause of end-stage renal disease (ESRD) in developed countries, including USA. Clinical reports have demonstrated that cigarette smoking is an independent risk factor for chronic kidney disease including DN; however, the underlying molecular mechanisms are still not clear. Recent studies have demonstrated that nicotine, one of the highly active compounds in cigarette smoke, is required for cigarette smoking-accelerated chronic kidney disease. DN is characterized by mesangial expansion, a precursor of glomerulosclerosis. In this study, we examine the role of Wnt/β-catenin pathway in nicotine-mediated mesangial cell phenotype in high glucose milieu.

Methods: We treated human mesangial cells (HRMC) with both normal/high glucose (5 mM and 25 mM) and nicotine (0.1, 1, and 10 uM), and then examined their phenotype. To evaluatet proliferation, we counted the total cell numbers (in a hemocytometer), or calculated the Ki-67 positive cell ratio by using immunofluorescent staining. We also performed real-time PCR to detect the expression of Wnts, β -catenin, and fibronectin. In addition, we used β-catenin inhibitor FH535 to examine a causal relationship between nicotine and high glucose treatment-mediated mesangial cell proliferation and fibronectin production.

Results: In 5 mM glucose medium, nicotine increased the total cell count and Ki-67 positive cell ratio in a dose-dependent manner, indicating that nicotine enhanced mesangial cell proliferation in normal glucose milieu, only moderately; 25 mM glucose further exacerbated nicotine-mediated mesangial cell proliferation. Similarly, nicotine increased the expression of Wnts, β-catenin, and fibronectin in normal glucose milieu, however, high glucose further increased these expressions. Addition of FH535 significantly inhibited the cell proliferation and fibronectin production.

Conclusions: Nicotine enhansces renal mesangial cell proliferation and fibornectin production in high glucose milieu, and Wnt/ β-catenin pathway plays an important role to regulate these effects. The present study provides insight into molecular mechanisms involved in diabetic nephropathy.

Endothelial Dysfunction in High Fat Diet Fed Diabetic Mice Is Dependent on Ketohexokinase Tomohito Doke,[1] Takuji Ishimoto,[1] Takahiro Hayasaki,[1] Mayumi Kawabe,[3] Miguel A. Lanaspa,[2] Richard J. Johnson,[2] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]University of Colorado Denver, Aurora, CO; [3]Nagoya City University, Nagoya, Japan.*

Background: The metabolism of both dietary and endogenously produced fructose via activated polyol pathway by ketohexokinase (KHK) has been reported to induce metabolic syndrome, a cluster of hyperglycemia, hypertension, and obesity, and also hyperuricemia attributed to ATP depletion and activation of nucleotide degradation pathway in human and rodents. Metabolic syndrome is associated with vascular dysfunctions. KHK have two splicing variant, KHK-C and KHK-A. The aim of this study is to determine the role of KHK in the development of vascular dysfunction in diabetes.

Methods: Diabetes was induced by low-dose streptozotocin in male wild-type (WT), KHK-A knockout mice (KHK-A KO), and both KHK-C and KHK-A knockout mice (KHK-A/C KO). Then they were fed high fat diet (45% fat). At 24 weeks, blood, urine, and tissue samples including aorta were collected. Biochemical analysis, urinary nitrate/nitrite measurement, and metabolomic analysis of urine was done. The relaxing effects of acetylcholine (ACh) and effects of NO synthase inhibitors, N-nitro-L-arginine (LNA), on the contractions by phenylephrine (PE) were measured in endothelium-intact aortas.

Results: The level of blood glucose, body weight and blood pressure was similar among diabetic mice. However, urinary nitrate/nitrite concentration was significantly lower in diabetic WT and diabetic KHK-A KO compared with diabetic KHK-A/C KO. Whereas ACh-induced relaxation in the aortas did not show significant difference among diabetic mice, PE-induced contractions with pretreatment of LNA (LNA/PE ratio) was significantly decreased in both diabetic WT and diabetic KHK-A KO compared to A/C KO mice, indicating endothelial dysfunction was alleviated in diabetic KHK-A/C KO mice. Metabolomic analysis revealed the significant correlations between LNA/PE ratio and urinary metabolites. Especially, urinary uric acid was inversely correlated with LNA/PE ratio in diabetic mice.

Conclusions: Vascular dysfunction was attenuated in diabetic KHK-A/C KO compared with WT and KHK-A KO. These results suggest that endothelial dysfunction in high fat fed diabetic mice might be due to fructose metabolism dependent on KHK-C.

TH-PO704

Effects of Clinically Validated Renal Therapies in the Renin AAV db/db Uninephrectomized (uNx) Mouse Model Shannon M. Harlan, Josef G. Heuer, Matthew D. Breyer, Kevin L. Duffin, Tao Wei, Hana Baker. *Eli Lilly and Company, Indianapolis, IN.*

Background: The recently developed ReninAAV *db/db* uNx mouse model, exhibits key hallmarks of advanced human diabetic kidney disease (DKD), including progressive elevations in albuminuria, increased serum creatinine, loss of glomerular filtration rate and pathological changes similar to human DKD. The renal transcriptome changes in this model were demonstrated to be more similar to human DKD when compared to the *db/db* eNOS$^{-/-}$ model. Recent clinical studies have demonstrated inhibiting the JAK/STAT pathway or SGLT2 inhibition improves renal function on top of ACEi or ARB. To further explore similarities of this model to human DKD we tested the response of Renin AAV db/db uNx to clinically validated therapeutics.

Methods: Four weeks after ReninAAV, mice were randomized and treated with vehicle, lisinopril (ACEi), losartan (ARB), Canagliflozin (SGLT2i) or Ruxolotinib (JAK/STATi). At 48 hours or 2 weeks post treatment urine was collected for measurement of albumin to creatinine ratio (ACR) and serum collected for measurement of clinical parameters and kidney collected for gene expression.

Results: Vehicle treated ReninAAV mice exhibited significant ($p<0.02$) elevations in ACR compared to baseline at 48 hour (+53,776ug/mg) and 2 weeks (+12,842ug/mg). Lisinopril and losartan reduced ACR ($p<0.01$) as compared to baseline at both 48 hour (-15,973ug/mg and -17,655ug/mg respectively) and 2 week time points (-15,622ug/mg and -7,774ug/mg respectively. Treatment with Canagliflozin led to significant ($p<0.01$) reductions in ACR at 48 hours (-12,238ug/mg) as compared to baseline, with no reductions ($p=0.5$) in ACR at 2 weeks (+257ug/mg). Ruxolotinib treated mice did not exhibit a significant lowering of ACR at 48 hours, with only a trend ($p=0.07$) at 2 weeks post treatment (-6,569ug/mg). However, significant ($p<0.01$) reductions from vehicle treated mice were observed in both Canagliflozin and Ruxolotinib treated mice (-5,791ug/mg and -9,103ug/mg, respectively) indicating a halting of disease progression. Effects of the inhibitors on gene expression in the model were compared.

Conclusions: The results support further clinical validation of this mouse model of DKD and provide further insights into disease pathophysiology allowing for a better understanding of human disease progression and identification of potential new targets.

TH-PO705

Insulin Suppresses Gluconeogenesis in Renal Proximal Tubules via the IRS1/Akt2/mTORC Pathway Motonobu Nakamura,[1] Masashi Suzuki,[2] Nobuhiko Satoh,[1] Atsushi Suzuki,[1] Hiroyuki Tsukada,[1] George Seki,[3] Yusuke Sato,[4] Yukio Homma,[5] Shoko Horita,[1] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, The University of Tokyo, Graduate School of Medicine, Bunkyo, Tokyo, Japan; [2]Tokyo Gakugei University, Koganei, Tokyo, Japan; [3]Yaizu City Hospital, Yaizu, Shizuoka, Japan; [4]Department of Urology, The University of Tokyo, Graduate School of Medicine, Bunkyo, Tokyo, Japan; [5]Japanese Red Cross Medical Center, Shibuya, Tokyo, Japan.*

Background: Previously, we found that the stimulatory effect of insulin on sodium transport in proximal tubules (PTs) is dependent on insulin receptor substrate (IRS)2/Akt2/mammalian target of rapamycin complex (mTORC) 2 and preserved even in insulin resistance and diabetes mellitus (Kidney Int 87:535,2015, ASN Kidney Week 2016). In addition to liver, kidney also significantly contributes to whole body gluconeogenesis particularly after prolonged fasting. Insulin is known to suppress gluconeogenesis in PTs, the only nephron segment where gluconeogenesis takes place. However, little is known about the signaling mechanism underlying this insulin action.

Methods: PTs freshly isolated from rat kidneys were incubated overnight in DMEM with or without 0.2 mM cAMP, and 10^{-8}M insulin was subsequently added for 4-hr. Total RNA was extracted from the PTs, and quantitative PCR was performed to determine the relative mRNA expression levels of glucogenic enzymes phosphoenolpyruvate carboxykinase (PEPCK) and glucose-6-phosphatase (G6P). To uncover the signaling mechanism, PTs were incubated in the presence of Akt1/2 inhibitor VIII or an mTORC1 inhibitor rapamycin. PTs were also incubated with siRNAs against IRS1, IRS2, Akt1, Akt2, raptor (a component of mTORC1), or rictor (a component of mTORC2) in the presence of lipofectamine.

Results: cAMP increased the expression levels of PEPCK and G6P 19 and 7-fold, respectively. Insulin decreased both of the cAMP-stimulated expression levels of PEPCK and G6P by more than 80% (n = 12-13). Akt1/2 inhibitor VIII and rapamycin completely abolished this inhibitory effect of insulin on gluconeogenesis. siRNAs against IRS1, Akt2, raptor and rictor also completely abolished the inhibitory effect of insulin. By contrast, siRNAs against IRS2 or Akt1 failed to affect the insulin effect.

Conclusions: Our results, for the first time to our knowledge, revealed that insulin suppresses gluconeogenesis in PTs via IRS1/Akt2/mTORC pathway. In insulin resistance and diabetes mellitus, the reduced expression of IRS1 in PTs that we reported (Kidney Int 87:535,2015, BBRC 461:154,2015) is expected to selectively attenuate the IRS1-dependent insulin action. The resultant enhancement in renal gluconeogenesis may at least partially contribute to hyperglycemia in these conditions.

TH-PO706

Glomerulosclerosis Attenuated by Retinoic Acid through Bone Morphogenetic Protein 4 Suppression in Mice with Streptozotocin-Induced Diabetes Masanori Tamaki, Tatsuya Tominaga, Yui Fujita, Seiji Kishi, Taichi Murakami, Kojiro Nagai, Hideharu Abe, Toshio Doi. *Department of Nephrology, Graduate School of Biomedical Sciences, Tokushima University, Tokushima, Japan.*

Background: Mesangial matrix expansion, leading to glomerulosclerosis and renal dysfunction, is an important histologic change in diabetic nephropathy. A major component of mesangial matrix is collagen IV (COL4), which increases by bone morphogenetic protein 4 (BMP4)/mothers against decapentaplegic (Smad1) signaling. Retinoic acid (RA) attenuates glomerulosclerosis, although details are unclear. In general, RA receptor (RAR) combines directly with RA response element (RARE), although RARE is not determined around *BMP4* gene. In the present study, we investigated the effect of RA on diabetic nephropathy, focusing on the regulatory mechanism of BMP4.

Methods: Male CD-1 mice were given streptozotocin at 12 weeks of age, followed a month later by intraperitoneal all-*trans* RA (atRA, 15 μg/gBW) or corn oil, each given thrice weekly. Animals' kidneys were harvested after sacrifice at 24 weeks of age. atRA or specific agonists for each subtype of RAR were added to cultured CD-1 mice derived mesangial cells for 24 hours (from 1 nM to 10 μM). RAR binding capacity to RARE, suggested by genome analysis, was confirmed by ChIP analysis.

Results: Serum creatinine levels and urinary protein excretion increased in diabetic mice. Renal BMP4 and COL4 expression levels increased in diabetic mice. Glomerulosclerosis worsened in diabetic mice, and glomeruli phosphorylated Smad1 and COL4 levels increased. These findings were attenuated after atRA administration. In cultured mice mesangial cells, BMP4 and COL4 expression levels decreased after atRA addition or a low concentration addition of AM580, a specific agonist for RARα, but did not after a low concentration addition of either RARβ or RARγ agonist. ChIP analysis showed that a suggested RARE around mice *Bmp4* gene combined with RARα after atRA addition.

Conclusions: atRA administration attenuated glomerulosclerosis and decreased BMP4 and COL4 expression levels in diabetic mice. Our study suggests that RARα combined with a novel RARE around the *Bmp4* gene, plays an important role for regulating BMP4 expression, although further study is needed. These findings indicate that RA may provide a novel therapeutic mechanism for diabetic nephropathy.

Stem-Cell Derived Nano-Extracellular Vesicles Promote Recovery of Diabetic Nephropathy Damaged Kidneys in Mice Cristina Grange,[1] Benedetta Bussolati,[1] Marta Reviriego-Mendoza,[2] Ciro Tetta,[2] Franklin W. Maddux.[2] *[1]Molecular Biotechnology & Health Science, University of Turin, Turin, Italy; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Nano-Extracellular Vesicles (nEVs) released by stem cells carry transcriptional regulators and secreted RNAs that could be transferred to target cells and induce phenotypic changes. nEVs can reprogram injured cells by activating regenerative processes in acute tissue injury. The aim of this study was to evaluate whether nEVs inhibit chronic kidney injury in a mouse model of diabetic nephropathy (DN).

Methods: To develop ND, NSG mice were injected with 35 mg/Kg of streptozotocin for 4 consecutive days. All treated mice developed diabetes (glycaemia > 250 mg/ml) within 10 days, and DN within 1 month. Mice were intravenously treated with n-EVs derived from human bone marrow stromal cells (MSCs), adipose derived stem cells or liver stem cells (HLSCs) once a week for 5 weeks. Empty n-EVs were used as control[MMRM1]. Kidney function and morphology were evaluated a week later by histological analyses. A comparative bioinformatics analysis of n-EVs-associated miRNAs and proteins was used to identify common anti-fibrotic and pro-regenerative pathways from different kidney cells. The anti-fibrotic effect of n-EVs was analysed by treating mouse kidney fibroblasts *in-vitro* with TGF-β1 and collagen, and a-sma production.

Results: n-EV treatment resulted in reductions of albumin/creatinine excretion ratio and plasma creatinine, and restoration of urinary acidification when compared to control animals. Histological analyses showed a significant reduction of glomerular and interstitial fibrosis, vascular injury and of Bowman's space enlargement. Using specific markers, we found significant reduction of cell death and enhanced proliferation in the tubules. All MSC and HLSC stem cell derived n-EVs, but not n-EVs derived from fibroblasts, displayed similar positive effects on reducing DN development. Comparative analyses showed that HLSC and, to a lesser extent MSC n-EVs interfered with the expression of pro-fibrotic miRNAs and inhibited collagen/a-sma production.

Conclusions: We show that n-EVs prevent development of DN in mice by inhibiting fibrosis and promoting regeneration.

VEPTP Inhibition as a Vasculoprotective Strategy to Treat Diabetic Kidney Disease Isabel A. Carota,[3,7] Christina S. Bartlett,[8] Tuncer Onay,[2] Rizaldy P. Scott,[4] Yael Kenig-Kozlovsky,[1] Sunday S. Oladipupo,[6] Matthew D. Breyer,[5] Susan E. Quaggin.[2] *[1]Feinberg cardiovascular Research Inst, Northwestern University, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]FCVRI and Division of Nephrology, Northwestern University, Chicago, IL; [4]Northwestern University, Feinberg School of Medicine, Chicago, IL; [5]Lilly Research Laboratories, Indianapolis, IN; [6]Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN; [7]BioTDR, Eli Lilly & Company, Indianapolis, IN; [8]Boehringer Ingelheim, Ridgefield, CT.*

Background: With a growing number of patients suffering from diabetic kidney disease new treatments to halt progression of DKD are urgently needed. Silenced Tie2 signaling following dysregulated expression of its ligands Angpt1 and 2 found in diabetic patients has been linked to increased mesangial expansion and glomerular scarring. Here we show that the endothelial specific phosphatase VEPTP is upregulated in kidney tissue of diabetic, hypertensive rodents, suggesting VEPTP as effector of reduced Tie2 activity in diabetes. Following this finding we investigated VEPTP inhibition as target to prevent deterioration of renal function and glomerular endothelium under diabetic conditions.

Methods: To test the impact of VEPTP blockade on the progression of DKD we postnatally deleted VEPTP in a model of diabetic hypertension (Akita/ReninAAV+) and followed the mice until 24 weeks of age, before evaluating renal function, blood pressure, ACR and renal histology as measurement for the degree of DKD.

Results: Genetic deletion of VEPTP in non-diabetic mice promotes Tie2 phosphorylation and eNOS signaling resulting in elevated glomerular filtration rates and decreased systolic blood pressure. At 24 weeks of age GFRs of Ak/Ren mice declined significantly compared to their start values, whereas GFRs from diabetic VEPTP iKOs maintained their baseline GFR values (Ak/Ren=242.6, Ak/Ren VEPTP iKO=480.3 ul/min). The prevention of decline in GFR over time correlated with lower elevation of urine albumin/creatinine ratios in diabetic VEPTP iKO compared to diabetic controls (Ak/Ren=1549.4, Ak/Ren/VEPTP iKO=741.2 ul/min). Additional histological analysis revealed that diabetic/hypertensive VEPTP deficient mice presented less glomerular scarring, mesangial expansion as well as a lower number of aSMA positive glomeruli. Analysis of kidney lysates from Ak/Ren/VEPTP iKO mice showed rescue of Tie2 phosphorylation levels compared to Ak/Ren mice, demonstrating that blockade of VEPTP slows the progression of renal complications under diabetic and hypertensive conditions by stabilizing Tie2 signaling.

Conclusions: Genetic loss of VEPTP causes increased TIE2 activity in diabetic hypertension, slowing the development of DKD in mice. In sum, we identify VEPTP as a candidate therapeutic target to protect the kidney from diabetic injury.

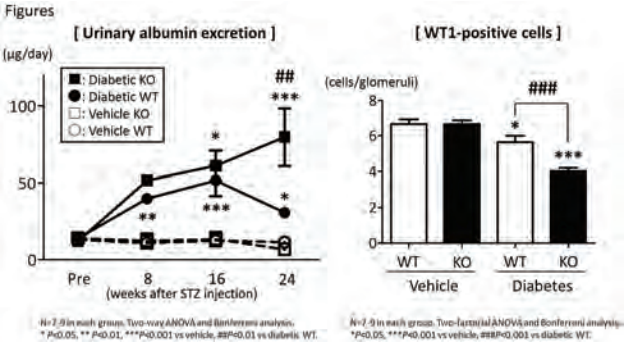
Angiotensin II Type 1 Receptor-Associated Protein Ameliorates Streptozotocin-Induced Diabetic Nephropathy in Mice Kotaro Haruhara,[1,4] Hiromichi Wakui,[1] Ryu Kobayashi,[1] Kenichi Ohashi,[2] Daisuke Kurotaki,[3] Nobuo Tsuboi,[4] Takashi Yokoo,[4] Kouichi Tamura.[1] *[1]Department of Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Medicine, Yokohama, Japan; [2]Department of Pathology, Yokohama City University Graduate School of Medicine, Yokohama, Japan; [3]Department of Immunology, Yokohama City University Graduate School of Medicine, Yokohama, Japan; [4]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Over-activation of renin-angiotensin system and enhanced infiltration of immune cells are critical factors in the development and progression of diabetic nephropathy (DN). AT1 receptor-associated protein (ATRAP) binds specifically to the AT1 receptor, and suppresses the over-activation of AT1 receptor signals. We have previously shown that ATRAP inhibits hypertension and cardiovascular disease in the animal models of renin-angiotensin system over-activation. Our aim was to determine the protective role of ATRAP in a mouse model of DN.

Methods: Diabetes was induced in wild-type mice (WT) and systemic ATRAP knock-out mice (KO) on a C57BL/6J background by the intraperitoneal injection of streptozotocin (55 mg/kg, daily for 5 consecutive days).

Results: The glycemic and blood pressure status of the diabetic WT and KO were comparable throughout the study period. The urinary albumin excretion was increased and the podocyte number, as estimated by immunohistochemical staining for WT-1, was decreased in the diabetic KO in comparison to the diabetic WT at 24 weeks after the streptozotocin injection (**Figure**). Furthermore, the renal expression of alternatively activated macrophage-related genes, including *Chil3*, *Arg1*, *Il4*, and *Il-13*, were suppressed in diabetic KO in comparison to diabetic WT; these macrophages are known to be factors associated with anti-inflammation and tissue repair.

Conclusions: These results suggested that ATRAP plays protective roles in the progression of DN via the maintenance of the renal expression of alternatively activated macrophages, indicating that ATRAP is therefore a novel therapeutic target of DN.



TH-PO711

Renal Inflammation, Insulin Resistance, and Enhanced Renal Gluconeogenesis in Type 2 Diabetic Nephropathy: The Missing Links Qianling Liu, Liangyan Zhang, Wei Qiu, Wei Zhang, Yubing Wen, Haiyun Wang, Xuemei Li. *Department of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medicine Sciences & Peking Union Medical College, Beijing, China.*

Background: Renal gluconeogenesis is substantially stimulated in patients with type 2 diabetes, but the mechanism remains unknown. Renal gluconeogenesis is negatively regulated by insulin. Since inflammation is activated in diabetic nephropathy (DN), however, inflammation is well known to induce insulin resistance, we wondered whether enhanced renal gluconeogenesis in DN was partially resulted from renal inflammation-mediated insulin resistance. If so, whether inflammation inhibitor could partially reverse this change.

Methods: Eight-week-old male diabetic db/db (C57BLKS/J-LepR^{db}/LepR^{db}) mice and their non-diabetic littermates db/m (C57BLKS/J-LepR$^{db/+}$) mice were used in this study. Diabetic db/db mice were treated with 1 mg/kg NF-κB inhibitor parthenolide (PTN) or saline as control intraperitoneal every other day. After 12 weeks of treatment, blood, urine and kidney samples were collected for measurement.

Results: Expression of inflammatory factors and the gluconeogenic rate-limiting enzyme phosphoenolpyruvate carboxykinase (PEPCK) were increased in the renal cortex of both type 2 DN human patients and db/db mice. Moreover, reduced insulin signaling as demonstrated by downregulated phosphorylation of AKT and increased expression of downstream gene FOXO1 were detected in db/db+saline mice compaired with db/m mice. Consistant with our hypothesis, NF-κB inhibitor PTN significantly reduced renal expression of NF-κB, TNF-a, ICAM-1, MIP-1α and macrophage infiltration in db/db+PTN mice compaired with db/db+saline mice. Moreover, it partially alleviated renal insulin resistance and reduced the expression of gluconeogenic enzyme PEPCK (1.62±0.47 VS 0.89 ±0.14, $p<0.05$), indicating that inflammation could be one of the triggers for insulin resistance and enhanced renal gluconeogenesis.

Conclusions: Our study demonstrated for the first time that renal gluconeogenesis is upregulated in db/db mice, and this was associated with renal inflammation-mediated insulin resistance. PTN partially reversed this change by promoting renal insulin sensitivity. This work shed light on the role of inflammation in enhanced renal gluconeogenesis and may yield a novel target for hyperglycemia.

TH-PO712

Agonistic Anti-CD148 Monoclonal Antibody Attenuates Diabetic Nephropathy in Mice Keiko Takahashi, Rachel H. Kim, Shinya Nagasaka, Daisuke Katagiri, Ray Mernaugh, Takamune Takahashi. *Vanderbilt University, Nashville, TN.*

Background: CD148 is a transmembrane protein tyrosine phosphatase (PTP) that is expressed in renal vasculature, including glomerular endothelial cells and podocytes. Previous studies have shown that CD148 suppresses multiple growth factor signaling pathways (e.g. VEGF, EGF) and prominently inhibits endothelial or epithelial cell proliferation. Here, we have generated an agonistic anti-CD148 monoclonal antibody (18E1) and evaluated its effects in murine diabetic nephropathy.

Methods: Monoclonal antibodies (mAbs) against mouse CD148 ectodomain (CD148ecto) were produced by immunizing CD148 -/- mice with CD148ecto-Fc fusion protein. The mAbs that specifically bind to CD148 and increase its catalytic activity and inhibit the proliferation of CD148 stably- transfected cells were selected by a series of biochemical (Western blot, PTP activity) and biological (proliferation) assays. The specificity of the effects was evaluated by CD148 knockdown or knockout. The mAb (18E1) that showed strong agonistic activity was injected (10 mg/kg, i.p., three times per week) into wild-type (WT) and CD148 -/- (KO) diabetic mice (DBA2 strain, 8 week-old, N=6 per group) for 6 weeks, then renal phenotype was assessed. Diabetes was induced by low-dose STZ injections and mouse IgG was used as a control. Furthermore, the effects of 18E1 mAb in glomerular endothelial cell and podocyte cell proliferation were also assessed in culture.

Results: As compared with control Ab, the 18E1 mAb significantly decreased albuminuria (~50%) and mesangial expansion (~30%) without altering hyperglycemia and blood pressure in WT diabetic mice. Immunohistochemical evaluation showed that the 18E1 mAb significantly prevents the reduction of podocyte number and nephrin

expression and decreases glomerular macrophage (F4/80) infiltration (~40%) and matrix expansion (fibronectin) (~30%). The 18E1 mAb showed no effects in CD148KO diabetic mice. In addition, the 18E1 mAb significantly (~50%) inhibited proliferation of glomerular endothelial cells and podocytes in culture concomitant with reduction of VEGFR2 or EGFR phosphorylation. These inhibitory effects were largely abolished by CD148 knockdown.

Conclusions: Agonistic anti-CD148 antibody attenuates diabetic nephropathy in mice. Anti-CD148 antibody may be used as a new therapeutic agent for the treatment of early phase diabetic nephropathy.

NO and SIRT1 Protect Glomerular Endothelial Cells with TERC Deletion from Hyperglycemia-Induced Senescence Huifang Cheng,[2] Raymond C. Harris.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Medicine/Nephrology, Vanderbilt University Medical Center, Nashville, TN.*

Background: Endothelial dysfunction plays an important role in the development of diabetic nephropathy (DN). We have previously reported that telomerase deficiency may predispose to diabetic renal injury.

Methods: To investigate the role of nitric oxide (NO) and SIRT1 in mediation of telomerase-dependent vulnerability to DN, we used streptozotocin (STZ) to induce diabetes in fourth generation (G4) TerC /T KO mice and compared their response with wild type (Wt) in response to treatment with NO precursor, L-arginine (L-arg). We also used primary cultured glomerular endothelial cells (GEnCs) for *in vitro* studies to explore the interaction of NO and SIRT1.

Results: STZ induced similar hyperglycemia, but TERC/T KO mice had increased renal involvement, which was alleviated by L-arg administration, with decreased albuminuria and less GBM thickening. Increased cell senescence and more severe oxidative stress was seen in diabetic mice with TERC/T deficiency, indicated by higher urinary F2-isoprostane and accumulation of renal nitrotyrosine. L-arg treatment partially ameliorated those alterations. In addition, L-arg limited the reduction in SIRT1 expression, associated with decreased senescence in the diabetic kidney, especially with telomerase deficiency. Ex vivo study with freshly isolated de-capsulated glomeruli demonstrated that high glucose (HG, 30 mM) incubation stimulated endothelial cell detachment from GBM in glomeruli with TERC deletion, which could be prevented by co-incubation with a SIRT activator, SRT1720. Primary cultured GEnCs exhibited reduced NO and cellular senescence after incubation for 96 hours in HG medium, with a marked increase in cells with TERC deletion. HG also decreased SIRT 1 expression and activity to a greater extent in the TERC deficient GEnCs. SRT1720 partially restored NO expression, and co-incubation with either SRT1720 or L-arg attenuated HG induced senescence in TERC deleted GEnCs.

Conclusions: These results suggested that both NO and the SIRT1 pathway are involved in the telomerase dependent susceptibility to DN progression and GEnCs senescence.

pNaKtide Targeted to Adipocytes Inhibits Na/K-ATPase Reactive Oxygen Species, Systemic Inflammation, and Obesity Development in Mice Fed a Western Diet Rebecca Martin,[4] Cameron Brickman,[3] Jiang Liu,[2] Komal Sodhi,[1] Joseph I. Shapiro.[4] *[1]Marsha, Huntington, WV; [2]Marshall University JCE School of Medicine, Huntington, WV; [3]Marshall University JCESOM, Huntington, WV; [4]Marshall University School of Medicine, Huntington, WV.*

Background: Obesity is a worldwide epidemic with many comorbidities. It has been demonstrated that oxidative stress can exacerbate obesity development. We have previously published that systemic administration of pNaKtide, a Na/K-ATPase signaling antagonist, decreased oxidative stress and adipogenesis by blocking Na/K-ATPase signaling mediated amplification of oxidative stress. Adipocyte dysfunction may be prevented by lentiviral mediated adipocyte-specific delivery of pNaKtide.

Methods: C57Bl6 mice were randomly divided into five groups: 1) normal chow 2) normal chow+lenti-adipo-pNaKtide 3) WD 4) WD+lenti-adipo-GFP and 5) WD+lenti-adipo-pNaKtide (n=6-8/group). Lentiviral constructs with pNaKtide driven by an adiponectin promoter were used to achieve pNaKtide expression specifically in adipose tissue. Groups 2 and 5 were given an intraperitoneal injection of lenti-adipo-pNaKtide and group 4 was given an intraperitoneal injection of lenti-adipo-GFP at beginning of the experiment and again at week 2; total time 12 weeks. Body weight was measured weekly. Glucose clearance was determined using an intraperitoneal glucose tolerance test before termination of the experiment. At sacrifice body weight, visceral and subcutaneous fat content of all mice were measured. Blood samples were collected for determination of inflammatory cytokines. Tissues were flash frozen and maintained at -80°C.

Results: Lenti-adipo-pNaKtide significantly reduced WD-induced weight gain, and visceral and subcutaneous fat content. Lenti-adipo-pNaKtide reduced WD-induced changes in glucose tolerance and inflammatory markers TNFα, IL-6 and MCP-1 ($p<0.05$). An increase in cardiac hypertrophy in WD animals was attenuated ($p<0.05$). Visceral fat of WD mice expressed higher levels of adipogenic markers PPARγ, FAS, and C/EBP. WD-induced Na/K-ATPase signaling was decreased. Renal function was not significantly impacted; slight decreases in function are evident, suggesting a potential decrease in renal function with chronic obesity.

Conclusions: Collectively this study introduces the novel idea that adipocytes may have a systemic effect. Specifically targeting pNaKtide to the adipocytes with lenti-adipo-pNaKtide ameliorates this systemic effect. This new information is important in the development of new therapeutic targets for obesity.

TH-PO715

Effect of Dietary Fat/Carbohydrate Ratio on Renal Lipid Deposition in Rats with Diabetic Nephropathy Miho Sugimoto,[1] Takuya Yoshida,[1] Naoki Ikegaya,[2] Hiromichi Kumagai.[1] *[1]Dept. of Clinical Nutrition, Univ. of Shizuoka, Shizuoka, Japan; [2]Dept. of Medicine, Yaizu City Hospital, Yaizu, Japan.*

Background: High-fat/low-carbohydrate diet (HFD) has been used to achieve glycemic control among diabetic patients. However, HFD may be harmful to those with diabetic nephropathy. This study aimed to examine the effect of HFD on diabetic nephropathy.

Methods: Twelve-week-old male Hos:ZFDM-*Lepr*$^{fa/fa}$ (a novel diabetic rat strain) rats were maintained under a calorie-restrictive (60%–70% *ad libitum*) and isoenergetic condition with either HFD (14% protein, 40% fat, and 46% carbohydrate) or pair-fed control diet (14% protein, 15% fat, and 71% carbohydrate) for 7 weeks. Oral glucose tolerance test (OGTT), urinary protein excretion, creatinine clearance (Ccr), and renal triglyceride (TG) content were assessed at the end of the experiment. The renal histology and lipid deposition were also evaluated.

Results: The HFD rats had lower plasma glucose levels at 60 and 120 min OGTT than the control rats (at 120 min OGTT: 524±24 and 648±38 mg/dl for HFD and control rats, respectively; $p<0.001$). However, although the HFD rats had better glycemic control than the control rats, the former showed significantly lower Ccr (HFD and control rats: 1.63±0.13 and 3.86±0.34 L/day, respectively: $p<0.001$) and higher proteinuria than the latter. Furthermore, the HFD rats displayed significantly higher plasma and renal TG concentrations than the control rats. Glomerular mesangial expansion and lipid deposition in the proximal tubular cells were observed in the HFD rats. The renal TG content was correlated with the urinary liver-type fatty acid-binding protein excretion.

Conclusions: These results indicated that HFD may accelerate the progression of diabetic nephropathy, even under caloric restriction.

Funding: Government Support - Non-U.S.

Study of mTORC2 Pathway on CD4+CD25+Treg in Diabetic Nephropathy Qiu yue Li,[1] Jing Zhou.[2] *[1]The First Affiliated Hospital of Nan Chang University, Nanchang, China; [2]The first affiliated hospital of Nanchang University, Nanchang, China.*

Background: To investigate the effect of mTORC2 pathway blocker on $CD4^+CD25^+$Treg in diabetic nephropathy (DN) rats, and to explore the possible mechanism of Treg in DN podocyte injury.

Methods: Thirty SD rats were randomly divided into DN group, DN + FK506 group and DN + ku0063794 group. Treantment groups were respectively given FK506 1mg/kg/d, ku0063794 1mg/kg/d orally every day. Blood glucose, Creatinine clearance (Ccr) and urinary protein were measured at 0, 4, 8 weeks. The expression of mTOR, Raptor, Rictor in renal tissue was detected at 4, 8 weeks. The levels of IL-17 and TGF-β1 in peripheral blood were detected by ELISA, and the percentage of $CD4^+CD25^+$Treg was detected by flow cytometry at 4, 8 weeks.

Results: Urinary protein of model group was higher than control group($P<0.05$), intervention groups were lower than model group ($P<0.05$); Ccr of model group compared with control group significantly decreased ($P<0.05$), intervention groups compared with model group significantly increased ($P<0.05$); mTOR, Raptor, Rictor increased significantly in the model group and decreased in the intervention groups ($P<0.05$); $CD4^+CD25^+$Treg of the model group was significantly lower than control group ($P<0.05$), and intervention groups were higher than model group ($P<0.05$); it of intervention groups at 8 week were higher than at 4 week ($P<0.05$); Pathological score of intervention groups compared with model group significantly decreased($P<0.05$); TGF-β1 and IL-17 of the model group were significantly higher than control group ($P<0.05$), and the intervention groups were lower than model group ($P<0.05$); TGF-β1 of FK506 intervention group was lower than that of ku0063794 intervention group ($P<0.05$); Correlation analysis: In model group at 8 weeks, Rictor was negative correlation with $CD4^+$ $CD25^-$Treg and Ccr ($P<0.05$), positive correlation with TGF-β1, IL-17, urinary protein, pathological score ($P<0.05$); Raptor was positively correlated with urinary protein and pathological score ($P<0.05$), negative correlation with Ccr ($P<0.05$), no correlation with $CD4^+CD25^+$ Treg, TGF-β1, IL-17.

Conclusions: $CD4^+CD25^+$Treg may be regulated by the mTORC2 pathway in DN rats, and involved in the pathogenesis of DN.

TH-PO717

ESRD and Mortality after VA NEPHRON-D Linda F. Fried,[6] Yuan Huang,[7] Jane H. Zhang,[8] Paul M. Palevsky,[4] Gary R. Johnson,[8] Stephen L. Seliger,[3] Peter A. McCullough,[1] Todd A. Conner,[8] Mary Brophy,[5] Nicholas Emanuele.[2] *[1]Baylor University Medical Center, Dallas, TX; [2]Hines VA, Hines, IL; [3]University of Maryland School of Medicine, Baltimore, MD; [4]University of Pittsburgh, Pittsburgh, PA; [5]VA Boston Healthcare System, Boston, MA; [6]VA Pittsburgh Healthcare System, Pittsburgh, PA; [7]Yale University, New Haven, CT; [8]VA CSP, Albuquerque, NM.*

Background: VA NEPHRON-D, a trial of ACEI+ARB vs. ARB alone in type 2 diabetes, eGFR 30-89.9 ml/min/1.73m^2 and ACR ≥ 300mg/g, was stopped for safety; questions of benefit remained.

Methods: At the end of the study, participants were asked to join passive follow-up with electronic data abstraction through 9/30/14. ESRD was defined during study as eGFR < 15 or chronic dialysis; and during follow-up by USRDS linkage of ICD9 and CPT coding. AKI was a study safety event; during follow-up it was defined by ICD9 code or 50% rise in creatinine. All-cause mortality was obtained from VHA Vital Status File.

Results: Of the 1448 randomized, 895 (61.8%, 445 in the ARB alone and 450 in the ARB+ACEI) consented to follow-up. Over the entire study, 75 (10.4%) in the monotherapy arm developed ESRD and 157 (21.7%) died vs. 63 (8.7%) and 146 (20.2%) respectively in the ACEI + ARB arm, which was not statistically significant. There was a significant decline in eGFR slope over time, but the slope was similar in both treatment groups (p= 0.13); eGFR at start of study and end of followup was 59.0 and 38.2 in ARB alone vs. 57.6 and 37.1 in ACEI + ARB. There was a significant AKI*treatment interaction for ESRD (p=0.013) (table). Combination therapy was associated with a decreased risk of ESRD in those without AKI (HR=0.61), but with a higher risk in those with AKI (HR=1.3). AKI predicted mortality, but there was no AKI*treatment interaction.

Conclusions: Overall, there was not an apparent long-term benefit or harm for combination therapy. Further research into the AKI * treatment interaction to determine whether it is unmasking a higher risk of ESRD or could be used to identify sub-populations that may benefit from combination therapy is needed

Funding: Veterans Affairs Support

Number of ESRD events by AKI and Treatment

	no AKI	AKI
ARB alone	10.0%	11.5%
ACEI + ARB	5.8%	19.1%

Baseline Characteristics in PRIORITY Study: Proteomics and Mineralocorticoid Receptor Antagonism for Prevention of Diabetic Nephropathy in Type 2 Diabetes Nete Tofte. *Steno Diabetes Center, Copenhagen, Denmark. Group/Team: On behalf of PRIORITY study group.*

Background: In PRIORITY (Proteomic prediction and Renin angiotensin aldosterone system Inhibition prevention Of early diabetic nephRopathy In TYpe 2 diabetic patients with normoalbuminuria) the aim is to test if the urinary proteomics based classifier CKD273 can predict microalbuminuria prospectively, and to test whether mineralocorticoid receptor antagonism (MRA) delays progression to microalbuminuria.

Methods: Prospective, randomized, double-blind, placebo-controlled multicentre clinical trial and observational study in normoalbuminuric type 2 diabetic patients. Patients are stratified into high- or low risk groups based on CKD273. Patients in the high risk group are assigned to spironolactone 25 mg once daily or placebo, the low-risk group is followed on standard care. Patients are followed for up to 4.5 years. Primary endpoint is development of microalbuminuria.

Results: From 15 sites we have included 1811 patients. The high- and low-risk populations differ in terms of gender, age, diabetes duration, UACR and eGFR (table). Univariate regression analyses of CKD273 vs each baseline variable demonstrated weak associations (R^2 of 0.03, p <0.0001) for the strongest correlations with UACR and eGFR. In a logistic regression model predicting CKD273 risk strata, including all baseline variables, eGFR and UACR remain statistically significant (p < 0.0003) with an AUC of 0.70 (95 % CI: 0.65, 0.74).

Conclusions: Classical risk factors for diabetic kidney disease differ only slightly, and overlap to a great extent, between high and low risk patients based on the urinary proteomics based risk classifier CKD273 in type 2 diabetes, suggesting it provides additional information to the measures already available in the clinic. The potential added value will be tested in this prospective study. Funding received from European Union Seventh Framework Programme (FP7/2007-2013) grant agreement no. 279277.

TH-PO719

Non Albuminuric Chronic Kidney Disease (NA-CKD) Phenotype in Patients (Pts) with Type 2 Diabetes (DM2): Results from a Population Based Study Stefano Bianchi, Elisa Poderelli, Chiara Bilanceri, Sara Samoni, Eva D'Aurizio, Andrea Grillo, Roberto Bigazzi. *ASL Toscana Nordovest, Livorno, Italy.*

Background: Albuminuria (A) is considered the first clinical sign of renal involvment and it is widely used as the most useful screening test for CKD in pts with DM2. However, in the last years increasing evidences have shown that a significant number of pts with DM2 has stage 3-5 CKD without significant A, a condition known as NA-CKD. The aim of this study was to determine the prevalence of NA-CKD in pts with DM2, living in the Province of Livorno, Italy.

Methods: Pts with DM2 living in the Province of Livorno, Italy are routinely screened for the presence of CKD, as a part of a three years project financed by the Italian Ministry of Health Care (Italian HC system RF-2011-02346990). We have screened 6,142 pts (2,898 F and 3,244 M, mean age 71.3±(SD)11.1 yrs), measuring the estimated glomerular filtration rate (eGFR, CKD-EPI) and A (Ualb,mg/Ucreat,g).

Results: 3,071 pts (50%) presented CKD in different stage (222 Stage 1,13.6%; 856 Stage 2,13.9%;1,227 Stage 3a, 20%; 579 Stage 3b, 9.4%; 147 Stage 4, 2.4% and 40 Stage 5, 0.6%). 1,573 pts with stage 3-5 CKD and measured A were classified as non albuminuric (748, 47.5%, 399 M and 409 F, mean age 77.1±(SD) 8.8 yrs) or albuminuric (825, 52.5%, 460 M and 365 F, mean age 76.9±(SD)9.4 yrs). 677 albuminuric pts had A >30<300 (82%) while148 (18%) had A >300. The albuminuric CKD phenotype was more prevalent in M than in F.

Conclusions: In our study half of pts with DM2 and stage 3-5 CKD shows NA-CKD and most of albuminuric pts have A in microalbuminuric range. Our population is under active investigation (blood pressure and lipis control, duration and metabolic control of diabetes etc) to evaluate which clinical pathways could be involved in the development of different CKD phenotypes in DM2. We are also following up these patients to investigate the renal and cardiovascular outcomes of the different phenotypes.

Body Fat Distribution Is More Predictive of All-Cause Mortality Than Overall Adiposity Sung Woo Lee,[1] Nam ju Heo.[2] *[1]Eulji General Hospital, Seoul, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: The relationship between directly measured body fat and all-cause mortality has been rarely studied. The aim of this study was to evaluate the predictive significance of computed tomography (CT)-measured body fat, including both visceral fat area (VFA) and subcutaneous fat area (SFA), for mortality.

Methods: The study included 36,656 participants who underwent abdominal CT as part of a health check-up at a single university-affiliated healthcare centre in 2007–2015. Of those, 32,593 participants with data regarding vital status as of May 2016 were included in the final analysis. The main factors evaluated were VFA, SFA and visceral-to-subcutaneous fat area ratio (VSR), and the primary outcome was all-cause mortality.

Results: There were 253 deaths during a mean follow-up of 5.7 years. Increased SFA was associated with decreased all-cause mortality, whereas an increased VFA and VSR were related to increased all-cause mortality. Compared with the predictive power of body mass index (BMI), SFA and VSR showed a larger area under the curve than did BMI. In Kaplan-Meier survival curve analysis, increased SFA and VSR were associated with decreased and increased hazard of all-cause death, respectively. However, in multivariate Cox proportional hazard regression analysis, only VSR was independently associated with all-cause mortality. Moreover, this relationship was paralleled by the harmful impact of increased VSR on metabolic profiles.

Conclusions: Increased VSR was an independent predictor of all-cause mortality. This suggests that the location of fat deposits may be more important than the actual amount of body fat.

	AUC	95% CI	Cut-off	Sp.	Se.	P*
SFA (cm²)	0.62	0.59-0.66	133.5	0.59	0.62	<0.001

TH-PO721

Glycemic Status and Mortality in CKD According to Transition versus Non-Transition to Dialysis Connie Rhee,[3] Csaba P. Kovesdy,[7] Vanessa A. Ravel,[2] Elani Streja,[1] Melissa Soohoo,[5] Gregory Brent,[8] Danh V. Nguyen,[6] Kamyar Kalantar-Zadeh.[4] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Harold Simmons Center, University of California at Irvine, Orange, CA; [3]University of California Irvine, Huntington Beach, CA; [4]University of California Irvine, School of Medicine, Orange, CA; [5]University of California at Irvine, Orange, CA; [6]University of California, Irvine, Irvine, CA; [7]University of Tennessee Health Science Center, Memphis, TN; [8]VA Greater Los Angeles Healthcare, Los Angeles, CA.*

Background: The optimal glycemic target in diabetic non-dialysis dependent chronic kidney disease (NDD-CKD) patients remains uncertain, as most trials of glycemic control excluded advanced kidney disease patients. We examined pre-ESRD glycemic status, defined by random blood glucose and hemoglobin A1c (HbA1c), with *early* post-ESRD mortality among diabetic NDD-CKD patients transitioning to dialysis. In parallel, we examined glycemic status and mortality in a matched cohort of NDD-CKD patients who did not transition to dialysis.

Methods: Among US veterans with diabetic NDD-CKD transitioning to dialysis from 2007-11 (Transition Cohort), we examined 1-year pre-ESRD averaged random glucose and HbA1c with 1-year all-cause mortality using expanded case-mix Cox models. Analogous analyses were conducted among CKD patients who did not transition to dialysis within 1-year (Non-Transition Cohort) matched on the basis of age, sex, race, ethnicity, and baseline CKD stage.

Results: Among 17,121 patients in the Transition Cohort, averaged random glucose ≥200mg/dl was associated with higher mortality (ref: 100-<120mg/dl), and HbA1c ≥8% was associated with higher mortality (reference: 6-<8%). Among 8711 patients in the Non-Transition Cohort, lower glucose <100mg/dl and higher glucose ≥160mg/dl were associated with higher mortality, whereas HbA1c was not associated with death.

Conclusions: In diabetic NDD-CKD patients transitioning to dialysis, higher averaged random glucose and HbA1c were associated with early dialysis mortality. In patients who did not transition, there was a U-shaped association between glucose and mortality. These data suggest liberal glycemic status is associated with long-term mortality risk, whereas intensive glycemic status is associated with short-term risk.

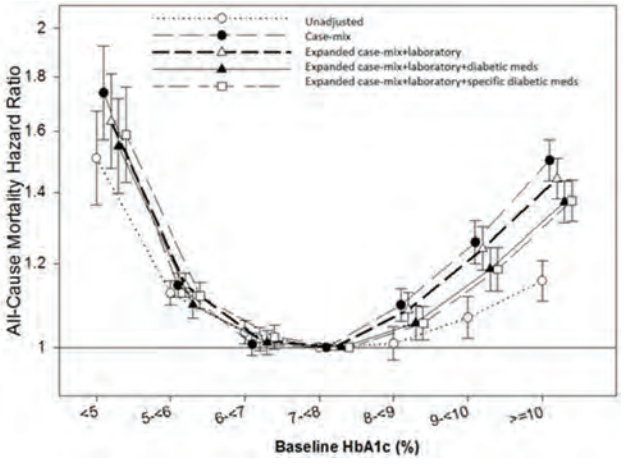
Glycemic Status and Mortality Among Patients with CKD Connie Rhee,[3] Kamyar Kalantar-Zadeh,[4] Vanessa A. Ravel,[2] Gregory Brent,[7] Danh V. Nguyen,[5] Elani Streja,[1] Csaba P. Kovesdy.[6] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]Harold Simmons Center, University of California at Irvine, Orange, CA; [3]University of California Irvine, Huntington Beach, CA; [4]University of California Irvine, School of Medicine, Orange, CA; [5]University of California, Irvine, Irvine, CA; [6]University of Tennessee Health Science Center, Memphis, TN; [7]VA Greater Los Angeles Healthcare, Los Angeles, CA.*

Background: There is uncertainty with regards to the optimal, precise glycemic level in diabetic non-dialysis dependent chronic kidney disease (NDD-CKD) patients. Whereas multiple studies show both lower and higher hemoglobin A1c (HbA1c) levels are associated with worse survival in diabetic dialysis patients, there are sparse data in NDD-CKD patients showing conflicting findings.

Methods: We examined the association of glycemic status, defined by baseline HbA1c, with all-cause mortality among US veterans with diabetes and Stage 3-5 NDD-CKD who underwent ≥1 HbA1c measure(s) over 2004-12 using expanded case-mix+laboratory Cox models. Sensitivity analyses incrementally adjusted for broad categories of anti-diabetic medications (insulin, oral medications) as well as specific categories (biguanides, thiazolidinediones, alpha-glucosidase inhibitors, insulin, insulin secretors, other oral medications).

Results: Among 213,123 patients who met eligibility criteria, both lower HbA1c <6% and higher HbA1c ≥8% were associated with higher mortality (ref: 7-<8%): adjusted HRs (95% CI) 1.63 (1.47-1.81), 1.15 (1.12-1.18), 1.02 (0.99-1.04), 1.09 (1.05-1.13), 1.24 (1.18-1.30), 1.44 (1.38-1.51) for HbA1c <5, 5-<6, 6-<7, 8-<9, 9-<10, and ≥10%, respectively. This pattern of association was robust across analyses incrementally adjusted for broad and specific categories of anti-diabetic medications.

Conclusions: Among diabetic US veterans with NDD-CKD, there was a U-shaped association between HbA1c levels and mortality. Further studies are needed to determine whether treatment to a HbA1c target of 6-<8% improves survival in this population.



TH-PO723

Hemoglobin A1c Levels and Infection Risk Among Dialysis Patients Connie Rhee,[3] Kamyar Kalantar-Zadeh,[4] Amy S. You,[5] Elani Streja,[2] Steven M. Brunelli,[1] Gregory Brent,[7] Csaba P. Kovesdy,[6] Danh V. Nguyen.[5] *[1]DaVita Clinical Research, Needham, MA; [2]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [3]University of California Irvine, Huntington Beach, CA; [4]University of California Irvine, School of Medicine, Orange, CA; [5]University of California, Irvine, Orange, CA; [6]University of Tennessee Health Science Center, Memphis, TN; [7]VA Greater Los Angeles Healthcare, Los Angeles, CA.*

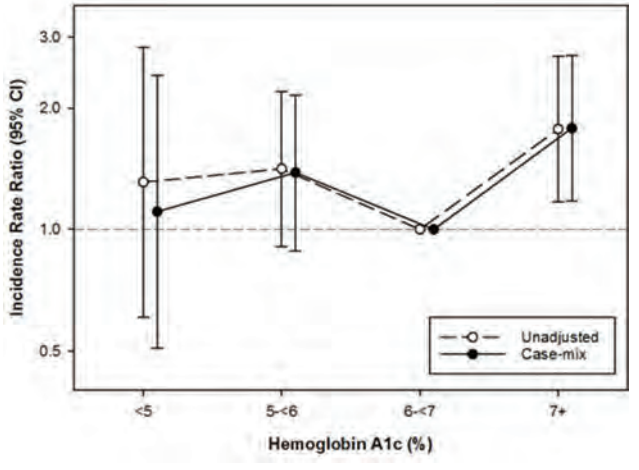
Background: Diabetic patients are at heightened risk of infection due to the immune dysfunction (i.e., impaired neutrophil function, antioxidant system, and humoral immunity) ensuing from hyperglycemia. While infections are the second leading cause of death in end-stage renal disease patients, little is known about the relationship between average glucose control defined by hemoglobin A1c (HbA1c) and infection risk in the dialysis population.

Methods: Among 642 dialysis patients from the national Biospecimen Registry Grant Program (BioReG) who underwent HbA1c testing over 1/2008-12/2014, we examined the relationship between average glucose control, as reflected in the HbA1c, and risk of bacteremia using case-mix adjusted Poisson regression models adjusted for age, sex, and race/ethnicity.

Results: In the overall cohort, the mean±SD and minimum-maximum HbA1c values were 6.7±1.5% and 3.8-16.0%, respectively; approximately 16% of patients experienced one or more bacteremia events during the follow-up period. Compared to a HbA1c level 6-<7%, patients with HbA1c levels ≥7% had a higher incident rate of bacteremia in case-

mix models: adjusted IRRs [aIRRs] 1.11 (0.51-2.41), 1.38 (0.89-2.16), and 1.79 (1.18-2.71) for HbA1c levels <5, 5-<6, and ≥7%, respectively.

Conclusions: Higher HbA1c levels were associated with higher incident rates of bacteremia in dialysis patients. While clinical practice guidelines advise against tight glycemic control in diabetic ESRD patients due to risk of hypoglycemia, liberal glycemic status may also contribute to adverse outcomes due to heightened infection risk. Further studies are needed to more granularly define the upper threshold for heightened infection risk within specific populations.



TH-PO724

Coronary Artery Calcification Scores and Intrarenal Hemodynamic Function in Adults with Type 1 Diabetes of ≥50 Years' Duration: Results from Canadian Study for Longevity in Type 1 Diabetes Julie A. Lovshin,[4] Petter Bjornstad,[2] Leif E. Lovblom,[1] Yuliya Lytvyn,[4] Genevieve Boulet,[1] Mohammed A. Farooqi,[1] Johnny-Wei Bai,[1] Vesta S. Lai,[4] Leslie Cham,[4] Josephine Tse,[4] Andrej Orszag,[1] Daniel Scarr,[1] Alanna Weisman,[1] Hillary A. Keenan,[3] Michael Brent,[4] Narinder Paul,[4] Vera Bril,[4] Bruce A. Perkins,[4] David Cherney.[4] *[1]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada; [2]Children's Hospital Colorado, Aurora, CO; [3]Joslin Diabetes Center, Boston, MA; [4]University of Toronto, Toronto, ON, Canada.*

Background: Diabetic nephropathy (DN) carries a significant risk for premature cardiovascular (CV) mortality. It is unclear whether atherosclerosis associates with intrarenal hemodynamic dysfunction in type 1 diabetes (T1D).

Methods: T1D (n=69) and age/sex-matched controls without diabetes (n=73) underwent CAC volume scoring by electron beam CT [mean age 65±8 years, 81(57%) female]. Gold standard measures of glomerular filtration rate [GFR_{INULIN}] and effective renal plasma flow [$ERPF_{PAH}$] were used, and renal blood flow [RBF], renal vascular resistance [RVR], and afferent (R_A) and efferent (R_E) arteriole resistances were derived from Gomez' equations. The cohort was dichotomized to high (≥300 AU) or low (<300 AU) CAC and stratified by T1D status. Additionally, linear regression was used to examine relationships between CAC (transformed) and intrarenal hemodynamic function, adjusting for age, sex, and HbA1c.

Results: Compared to controls, T1D subjects had higher prevalence of high CAC (68 vs. 14%, p<0.001) and median CAC volumes (1000[222,2373] AU vs. 1[0,75] AU, p<0.001). Mean baseline GFR_{INULIN} was 103±17 mL/min/1.73m^2 in T1D and 106±19 mL/min/1.73m^2 in controls (p=0.34). In T1D, high CAC was associated with higher HbA1c, presence of neuropathy, and a history of macrovascular disease. In T1D and in controls, no parameter of intrarenal hemodynamic function including GFR

Conclusions: Despite the strong epidemiologic relationships between DN and CV disease, the presence of atherosclerosis did not impact intrarenal hemodynamic function to RAAS activation in older adults with longstanding T1D.

TH-PO725

Kidney Disease and Risk of Incident Diabetes Mellitus Yan Xie,[1] Benjamin C. Bowe,[1] Tingting Li,[2] Hong Xian,[3] Yan Yan,[2] Ziyad Al-Aly.[1] *[1]Clinical Epidemiology Center, Research and Development Service, Veterans Affairs St Louis Health Care System, St. Louis, MO; [2]Washington University School of Medicine, Saint Louis, MO; [3]Saint Louis University College for Public Health & Social Justice, St. Louis, MO.*

Background: Kidney disease is associated with disturbances in glucose and insulin homeostasis. Experimental evidence suggests that urea causes a state of insulin resistance and may also suppress insulin secretion. However, whether higher levels of Blood Urea Nitrogen (BUN) are associated with increased risk of incident diabetes mellitus in humans is not known.

Methods: We built a national cohort of 1,337,452 United States Veterans without diabetes to characterize the association of BUN and risk of incident diabetes. Cause specific survival analyses with time-varying variables were conducted.

Results: Over a median follow-up of 4.93 years, in joint risk models of eGFR and BUN; there was no association between eGFR and the risk of incident diabetes in those with BUN ≤25 mg/dl, the risk was significantly increased in those with BUN>25 mg/dl at all eGFR levels even in those with eGFR≥60 ml/min/1.73m^2 (HR=1.27;CI=1.24-1.31). The risk of incident diabetes was highest in those with BUN >25 mg/dL and eGFR<15 ml/min/1.73m^2 (HR=1.68;CI=1.51-1.87). Spline analyses of the relationship between BUN and risk of incident diabetes showed that risk was progressively higher as BUN increased. In models where eGFR was included as a continuous covariate; compared to BUN≤25 mg/dl, BUN>25 mg/dl was associated with increased risk of incident diabetes (HR=1.23;CI=1.21-1.25); every 10 ml/min/1.73m^2 increase in eGFR was not associated with risk of incident diabetes (HR=1.00;CI=1.00-1.01). Two-stage residual inclusion analyses showed that independent of the impact of eGFR, every 10 mg/dL increase in BUN concentration was associated with increased risk of incident diabetes (HR=1.15;CI=1.14-1.16).

Conclusions: Our results suggest that higher levels of BUN are associated with increased risk of incident diabetes mellitus. A bidirectional nexus (between diabetes and kidney disease) likely exists, in that diabetes causes kidney disease, and elevated levels of urea-often present in the context of advanced kidney disease-are associated with increased risk of incident diabetes.

TH-PO726

Mortality in Diabetic Adults with Low eGFR in the Absence of Increased Urine Albumin Excretion Is Increasing Holly J. Kramer,[1] R. E. Boucher,[2] Guo Wei,[2] Tom Greene,[2] David J. Leehey,[1] Linda F. Fried,[4] Sylvia E. Rosas,[5] Srini Beddhu.[3] *[1]Loyola University Medical Center, Maywood, IL; [2]University of Utah, Salt Lake City, UT; [3]University of Utah School of Medicine, Salt Lake City, UT; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA; [5]Joslin Diabetes Center, Boston, MA.*

Background: Due to improvements in diabetes management, the prevalence of low estimated glomerular filtration rate (eGFR) has increased while prevalence of increased urine albumin excretion (albumin-to-creatinine ratio [ACR] ≥ 30 mg/g) has decreased. These trends may influence mortality due to the heterogeneity of risk across chronic kidney disease (CKD) phenotypes.

Methods: We used data from the National Health and Nutrition Examination Surveys 1988-2006 linked with the National Death Index through December 31, 2011 to examine temporal trends in mortality and total number of deaths by CKD phenotype in the U.S. diabetic population by CKD phenotype. Diabetes was defined as presence of a fasting glucose ≥ 126 mg/dl, hemoglobin A1c > 6.5% or use of glucose lowering medications. The analyses accounted for the complex survey design.

Results: From 1988 to 2006, diabetic adults with low eGFR and ACR < 30 mg/g increased from approximately 0.9 (95% CI 0.7, 1.1) million during years 1988-1994 to 2.0 (95% CI 1.5, 2.6) million during years 2007-2010. During years 1988-2006, mortality rates generally trended downward for all groups with ACR ≥ 30 mg/g but increased in adults with low eGFR and ACR < 30 mg/g from 35 deaths per 1000 person-years (95% CI 22,55) during years 1988-1994 to 51 deaths per 1000 person-years (95% CI 33, 83) during years 2003-2006 (Figure). The proportion of deaths in the total U.S. population with diabetes occurring in the setting of low eGFR and ACR < 30 mg/g increased from 8.7% during years 1988-1994 to 21.9% during years 2003-2006. Findings did not change substantially after standardizing for the age distribution of the populations.

Conclusions: These findings demonstrate an urgent need to determine optimal management strategies to reduce mortality in diabetics with low eGFR in the absence of increased urine albumin excretion.

TH-PO727

Greater Insulin Use with More Advanced Stages of DKD Christine K. Raj,[1] Vishwa Srinivasan,[2] Arianna N. Jensen,[2] R. E. Boucher,[2] Guo Wei,[2] Srini Beddhu.[2] *[1]UC Berkeley, Saratoga, CA; [2]Univ. of Utah, SLC, UT.*

Background: Those with more advanced CKD are assumed to require less insulin because of decreased renal metabolism of insulin. On the other hand, uremia might result in insulin resistance and/or pancreatic islet cell failure which can ↑ the need for insulin.

Methods: Veterans in the national VA data with a diagnosis of type 2 DM (defined by ICD-9 codes) from January 1, 2008 to December 31, 2010 and non-missing data for variables of interest were included (N = 943,995). CKD stages defined by CKD-EPI eGFR was related to insulin use in multivariate logistic regression models.

Results: Mean age was 66.0 ± 10.7, 96.8% were men, and 16.3% were black. Clinical characteristics by insulin usage are summarized in the table. Prevalence of insulin use was higher with more advanced CKD (Figure 1 panel A). In multivariate logistic regression model adjusted for demographics, comorbidity, duration of DM, BMI, HBA1C and medications use, the odds of insulin use was significantly higher with more advanced CKD (panel B).

Conclusions: Contrary to the commonly held belief that insulin use is lower in more advanced CKD, insulin use is indeed higher in this population.

Funding: NIDDK Support

	Not on Insulin (N = 735,446)	On Insulin (N = 208,549)
Age (years)	67 ± 11	65 ± 11

Higher Concentrations of Urea Are Associated with Increased Risk of Failure of Oral Hypoglycemic among Diabetic Patients with CKD Yan Xie,[1] Benjamin C. Bowe,[1] Tingting Li,[1,2] Hong Xian,[1,3] Yan Yan,[1,4] Ziyad Al-Aly.[1,5] *[1]Clinical Epidemiology Center, Research and Education Service, VA Saint Louis Health Care System, Saint Louis, MO; [2]Department of Medicine, Washington University School of Medicine, Saint Louis, MO; [3]Department of Biostatistics, College for Public Health and Social Justice, Saint Louis University, Saint Louis, MO; [4]Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, Saint Louis, MO; [5]Renal Section, Medicine Service, VA Saint Louis Health Care System, Saint Louis, MO.*

Background: Kidney disease is associated with disturbances in glucose and insulin homeostasis. Experimental evidence suggests that urea suppresses insulin secretion and increases insulin resistance. However, whether elevated concentrations of urea are associated with increased risk of failure of oral hypoglycemic agents, and increased risk of insulin requirement among diabetic patients with kidney disease is unknown.

Methods: We built a national cohort of 158,099 United States Veterans with incident diabetes and used time-varying survival model to estimate the cause-specific hazards of requiring treatment with insulin.

Results: Over a follow-up period of 4.93 years, compared to those with BUN <=25 mg/dl, the risk of requiring insulin was significantly increased among those with BUN>25 mg/dl (HR=2.55; CI=2.38-2.72). An analysis which considered BUN categorized in quintiles suggested a graded association in that risk of insulin treatment was gradually increased with increased BUN concentrations. An Analysis which only included those with incident diabetes who were on diabetes medications (N=56,702) yielded consistent results; compared to BUN<=25 mg/dl, risk of transitioning from oral hypoglycemic agents to insulin was increased in those with BUN>25 mg/dl (HR=2.52; CI=2.36-2.70). The results were consistent in analyses considering BUN in quintiles.

Conclusions: Our results suggest that higher levels of BUN are associated with increased risk of requiring insulin within patients with diabetes. Further studies are required to examine whether interventions to reduce urea will ameliorate glycemic control or reduce the need for insulin treatment among patients with diabetes.

Improvement of Glycaemic Control in Patients with Diabetes and CKD through a "One-Stop" Joint Diabetes Kidney Clinic Jayna Patel,[3] Niyati Sodani,[1] Mona Wahba.[2] *[1]St. George's, University of London, London, United Kingdom; [2]st Helier Hospital NHS Trust, London, United Kingdom; [3]St HELIER HOSPITAL, LONDON, United Kingdom.*

Background: Diabetic nephropathy is a significant complication of diabetes mellitus and is associated with increased cardiovascular morbidity and mortality. There is substantial evidence to show that optimal glycaemic control has a significant impact on the progression of diabetic nephropathy. There is no consensus regarding the best model for following up patients with diabetes and CKD in the outpatient setting.

Methods: We conducted a single centre, retrospective observational analysis of patients that attended a monthly 'one stop' joint diabetic and nephrology clinic between 2013 and 2016. This newly established service is run by a consultant nephrologist, endocrinologist and diabetic specialist nurse. Reasons for referral were suboptimal diabetic control, hypoglycaemic episodes in the context of CKD, or where renal function had deteriorated to a point necessitating a change in diabetic medications (e.g. a switch to insulin). They were also referred for further management of weight gain and new onset diabetes after transplantation (NODAT).

Results: A total of 93 patients were reviewed in the clinic. Mean age was 65 years [39-92years]. 57 patients were male and 36 were female. Mean HbA1c of patients at referral was 73 [35-151]. Mean eGFR at referral was 33.6 ml/min [9-90ml/min]. 69.9% of patients were type 2 diabetics and 45% of these patients were switched to an insulin based regimen. 16 patients were started on liraglutide and their mean eGFR at referral was 52.7mls/min [24-90 ml/min]; 13 of these patients were followed up at 1 year and 92% of these patients had lost weight and had a stable eGFR, mean 51.6mls/min [23-90ml/min]. At 1 year follow up, 71% saw an improvement in HbA1c ($p<0.05$, paired t test).

Conclusions: This study showed that this model of care for patients with diabetes and CKD may be used to help improve diabetic control. Liraglutide, a glucagon-like peptide-1 receptor agonist, seems to be an effective agent to promote weight reduction in patients without causing deterioration in renal function.

TH-PO730

Use of Fundus Photography in the Dialysis Facility to Screen for Diabetic Retinopathy Greg S. Garza,[2] Michael P. Martin,[1] Chris Richmond,[1] Andrew Aronson,[1] Maria Radonova,[1] Marta Reviriego-Mendoza,[2] John W. Larkin,[2] Len A. Usvyat,[2] Terry L. Ketchersid,[2] Franklin W. Maddux.[2] *[1]Fresenius Health Partners, Austin, TX; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Diabetic retinopathy is a leading cause of vision loss in the United States and 2 times more prevalent in kidney disease patients (Varma 2014; Ricardo 2014). Through the Comprehensive ESRD Care (CEC) Model, Fresenius Medical Care North America has partnered with CMS to identify, test, and evaluate new ways to improve care for Medicare beneficiaries with ESRD. We aimed to increase preventative retinal exams that diabetic end stage renal disease (ESRD) patients receive. We are obligated to disclose that the statements contained in this document are solely those of the authors and do not necessarily reflect the views or policies of CMS. The authors assume responsibility for the accuracy and completeness of the information contained in this document.

Methods: We implemented a preventative retinal exam initiative at one Fresenius Kidney Care (FKC) dialysis clinic. Claims data was utilized to identify patients diagnosed with diabetes (Type 1 or Type 2). Eligible patients were invited to have fundal eye examinations performed in the dialysis facility. The exam was ordered by the nephrologist and administered by nurses in the Care Navigation Unit. Photography results were transmitted in a HIPAA compliant fashion to be reviewed and interpreted by a board certified ophthalmologist. The interpretation of the retinal exam was uploaded into FKC's electronic medical records for nephrologist review.

Results: We identified 27 diabetic patients who were eligible for retinal screening. 22% had successful images captured without the need for pupil dilation. For those who did not obtain a successful eye exam, reasons were: Presence of cataracts (<30%), anxiety (<10%) or small pupils (<25%). Ophthalmologists reported the interpreted results within 90 minutes.

Conclusions: Introduction of this device may yield favorable retinal exam screenings in greater than 20% of the eligible diabetic population without pupil dilation. Counseling to reduce anxiety and the use of mydriatics may improve the proportion of successful retinal exam screenings.

TH-PO731

The Magnitude of Obesity and Metabolic Syndrome among the Diabetic CKD Population: A Nationwide Study Piyawan Kittiskulnam,[2] Nintita S. Thokanit,[4] Pisut Katavetin,[3] Paweena Susantitaphong,[1] Kearkiat Praditpornsilpa,[1] Somchai Eiam-Ong.[1] *[1]Chulalongkorn University, Bangkok, Thailand; [2]Chulalongkorn university, Bangkok, Thailand; [3]King Chulalongkorn Memorial Hospital, Thai Red Cross Society and Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [4]Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.*

Background: Although the prevalence of obesity among dialysis patients has been exceeding than that of in general population, little is known regarding obesity in non-

dialysis CKD. We aimed to find the magnitude of obesity and metabolic syndrome (MetS) and their associations with the development of CKD among diabetic patients.

Methods: A national survey of type 2 diabetes mellitus (T2DM) patients was collected in the Thai National Health Security Office database during 2014-5. The sampling frame was designated as distinct geographic regions throughout the country. A stratified two-stage cluster sampling was used to select study population. Anthropometry and 12-hour fasting blood samples were obtained by trained personnel. BMI of ≥25 kg/m^2 was classified as obesity. MetS was defined as having elevated waist circumference (>90 cm in men and >80 cm in women) plus any 2 of the followings: triglyceride>150 mg/dL, HDL<40 in men or <50 mg/dL in women, BP≥130/85 mmHg, and blood sugar ≥100 mg/dL. CKD was defined as eGFR <60 ml/min according to the CKD-EPI equation. Logistic regression analysis was performed to examine the relationship between obesity and MetS with the development of CKD.

Results: A total of 32,616 patients were finally recruited from 997 hospitals. The mean age was 61.5±10.9 years and eGFR 70.9±26.6 ml/min with 32% men. Of the participants, 35% were CKD patients (n=10,672). The prevalence of obesity was 46.5% in CKD and 54.1% in non-CKD patients with T2DM. In contrast, the prevalence of MetS in CKD was higher than non-CKD patients (58.5 vs 57.2, p=0.03). There was a trend association between the prevalence of MetS with CKD stage from 3 to 5 (58.1, 61.6, and 63.2%, respectively, p=0.01). When stratified by sex in diabetic CKD group, the presence of MetS was significantly higher among female compared to male (68.6% vs 38.0%, p<0.001). MetS, but not obesity, had a significant higher risk prediction for developing of CKD among T2DM patients after adjusting for age, sex, and comorbidities [OR 1.11; 95%CI 1.03-1.21, p=0.01].

Conclusions: The relatively high prevalence of both obesity and MetS were observed in diabetic CKD community. Identification of obesity-related metabolic phenotypes is necessary to determine risk for the development of CKD among T2DM patients.

Funding: Government Support - Non-U.S.

TH-PO732

Association of Anthropometric Obesity Measures with CKD in Chinese Individuals with Type 2 Diabetes Dongsheng Cheng, Niansong Wang. *Department of Nephrology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Obesity is associated with both type 2 diabetes and chronic kidney disease (CKD). It remains controversial whether anthropometric obesity measures are related to the risk of CKD in type 2 diabetic patients.

Methods: We investigated the association between anthropometric obesity measures including body mass index (BMI), waist circumference (WC), and waist-to-hip ratio (WHR) with chronic kidney disease in Chinese individuals with type 2 diabetes. CKD was defined as eGFR < 60ml/min/1.73m^2, the presence of albuminuria or both. Logistic regression was used to examine associations of obesity and CKD.

Results: A total of 4701 patients were included in the final analysis. The mean age was 55.7 years, and 59.7% was male. Of these patients, 1362 (29.0%) had CKD. Obesity (BMI≥28 kg/m^2) was found in 18.2%, and overweight (BMI 24–28kg/m^2) was 43.0%. The highest quartile of BMI (odds ratio [OR] 2.55 [95% CI 2.05-3.17]), WC (OR 1.86 [95% CI 1.50-2.30]) and WHR (OR 1.88 [95% CI 1.52-2.32]) was significantly associated with CKD compared with the lowest quartile after adjustment for multiple confounding factors. Interestingly, in the normal weight patients (BMI<24 kg/m^2), no associations were found between quartiles of WC and CKD, whereas increased WHR were associated with CKD.

Conclusions: This study has highlighted a strong association between obesity and CKD in type 2 diabetes. In selected population, such as normal weight patients with type 2 diabetes, larger waist-to-hip ratio but not waist circumference is associated with CKD.

TH-PO733

Effect of GSTK1 on Ectopic Fat Deposition in the Kidney of Patients with Diabetic Nephropathy Xianghui Chen, Chun Hu, Li Zhao, Yachun Han, Xiaofen Xiong, Li Li, Ming Yang, Peng Gao, Li Xiao, Fuyou Liu, Lin Sun. *Departments of nephrology, Second Xiangya Hospital Central South University, Changsha, China.*

Background: Ectopic fat deposition in kidney is closely related to the progression of diabetic nephropathy(DN). GSTK1 is a kind of protein involved in adiponectin secretion and multimerization. This study to observe by first time the relationship between the expression of GSTK1 and ectopic fat deposition(EFD) induced kidney injury in DN patients.

Methods: 36 DN patients diagnosed by renal biopsy were enrolled. 30 patients with mild glomerular lesions were selected as controls. ADRP expression was used as a marker of EFD in the kidney. The expression of GSTK1 and ADRP were detected by immunohistochemistry staining. RT-PCR was used to test the GSTK1mRNA expression in PBMCs. ROS was measured by DHE staining. Lipid accumulation in kidney and cells were observed by Oil Red O staining. HK-2 cells were treated with different concentrations of glucose for 24 hours. The expression of GSTK1 and ADRP was tested by Western blot or immunofluorescence in HK-2 cell transfected with or without GSTK1 plasmid, or treated with MitoQ respectively. Mitochondrial ROS production was detected by Mitosox staining.

Results: Compared with the control group, the levels of TG, CHOL, LDL-C, BUN, SCr, UA and 24h urine protein in DN patients were incresed (p <0.05), while the HDL-C, ALB were decreased (p <0.05). The expression of GSTK1 mRNA in PBMCs was down-regulated(p<0. 01). In addition, the protein expression of GSTK1 in kidneys were decreased, while ADRP, ROS level and the deposition of lipids were significantly increased (p<0.01), which assocaited with different stages of DN. Moreover,the expression of ADRP was positively correlated with UACR, URBP and tubulointerstitial injury score, while GSTK1 was negatively correlated with ROS level and EFD as detected by the ADRP expression and Oil red O staining in DN kidneys. In vitro study showed a notablely increased of ADRP expression, mitochondrial ROS level and intracellular lipid accumulation in HK-2 cells treated by HG or H_2O2 were seen, while downregulated expression of GSTK1 protein was found. All changes above could be bloacked partially by overexpression of GSTK1 or mito Q,a target mitochondrial antioxidants, but failure to co-treatment with H_2O_2.

Conclusions: This data suggested that the decreased expression of GSTK1 in the kidney was significantly correlated with EFD induced renal injury in DN patients.

TH-PO734

Differences in the Prevalence of Metabolic Syndrome and Its Components among Ethnic Minorities with CKD Robert Lorch, Jingbo Niu, Carl P. Walther, Rajeev Raghavan, Wolfgang C. Winkelmayer, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

Background: Metabolic syndrome (MetS) and chronic kidney disease (CKD) are common among ethnic minorities. Whether clustering of various metabolic risk factors occurs irrespective of race is unclear. Herein, we studied whether the prevalence of MetS and its components differed between African Americans (AAs) and Hispanics with CKD.

Methods: We identified patients with stage 3 and 4 CKD (based on 15≤ eGFR <60 ml/min/1.73 m^2) who were followed during 2006-2016 in the Harris Health System, a safety-net health system in Houston, TX. Demographics, comorbid conditions, and laboratory data were extracted from electronic medical records. MetS was defined as the presence of three or more of the following components: body mass index (BMI) ≥30 kg/m^2, serum triglyceride level≥150 mg/dl, HDL≤50 mg/dl in women and ≤40 mg/dl in men, hypertension (BP>130/85 mmHg or on antihypertensive medications), and impaired glucose metabolism (presence of diabetes, use of oral hypoglycemics, or blood glucose level≥200 mg/dl). Age- and sex-adjusted prevalence ratios were calculated using modified Poisson regression with robust variance.

Results: Of 8664 patients with CKD Stage 3 or 4, 6954 (80%) had MetS. The prevalence of MetS was highest among Hispanics (87%), followed by non-Hispanic whites (85%), AA (74%), and Asian Americans (71%). While comparing MetS and its components between AAs and Hispanics, we noted higher prevalence for high triglycerides, low HDL levels, and diabetes, but lower prevalence of obesity among Hispanics than AAs (Table 1).

Conclusions: MetS and its components were highly prevalent in patients with CKD receiving care in a Texan safety-net system, particularly among Hispanics and non-Hispanic Whites. Differences in the prevalences of MetS-defining components between AAs and Hispanics suggest that interventions targeting MetS might need to be tailored based on race.

Funding: NIDDK Support

Table 1. Prevalence of metabolic syndrome and its components among Hispanics and African American patients with CKD stage 3-4

Variable	Race/ ethnicity	Crude prevalence, N (%)	Age and sex-adjusted Prevalence (95% CI)	Prevalence ratio* (95% CI)
MetS	African American	2720 (74.4)	0.713 (0.696, 0.730)	1.0(referent)

Altered Functional Characteristics of Adipose-Derived Mesenchymal Stem/Stromal Cells (MSC) in Diabetic Kidney Disease (DKD) LaTonya J. Hickson, Ahmed Saad, Alfonso Eirin, James L. Kirkland, Tamara Tchkonia, Travis Mckenzie, Andrew D. Rule, Allyson Palmer, Stephen C. Textor, Lilach O. Lerman. *Mayo Clinic, Rochester, MN.*

Background: Novel interventions such as MSC to delay the progression of DKD are needed. However, the origin of MSC may affect the regenerative capacity of autologous cell-based therapy. We hypothesized that functional capacity and senescent cell burden of MSC from DKD subjects would be impaired compared to healthy volunteers (HV).

Methods: MSC were cultured from subcutaneous abdominal adipose tissue from 21 subjects with DKD and 5 HV (kidney donors). MSC proliferation, migration, senescence-associated β-galactosidase activity, Activin A, and Annexin V (apoptosis marker) were studied.

Results: DKD subjects were older (65±8 vs 35±16 years; p<0.001), with higher body mass index (37±5 vs 31±4 kg/m^2; p=0.03) and lower eGFR [median 40 (IQR: 31, 54) vs 87 (IQR: 76, 114); p<0.001] compared to HV. Race (76% vs 100% white) and sex (43% vs 60% female) were not different. MSC migration and proliferation were decreased in DKD-MSC compared to HV-MSC. Senescence was increased in DKD-MSC, but

apoptosis was similar between groups. Similarly, markers of senescence (Activin A) measured in the MSC-cultured media were higher in DKD. [Figure]

Conclusions: DKD-MSC exhibit altered functional characteristics and increased senescence, possibly due to aging and diabetic microenvironments. Diabetes and uremia may alter the function of MSC, potentially limiting the effectiveness of autologous-based therapy.

TH-PO736

Ectopic Lipid Accumulation and Its Clinic Relevance in Type 2 Diabetic Kidney Disease Patients Li Xiao,[1] Ying Luo,[1] Wenxia Yang,[1] Hang Liang,[1] Fan Zhang,[1] Yiming Zhou,[2] Mengru Zeng,[1] Lin Sun,[1] Fuyou Liu.[1] *[1]Department of Nephrology, The Second Xiangya Hospital, Central South University, Changsha, China; [2]Renal Division, Department of Medicine and Glom-NExT Center for Glomerular Kidney Disease and Novel Experimental Therapeutics, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Background: Growing evidence suggests that ectopic lipid accumulation may contribute to organ injury in the context of metabolic diseases, including diabetes. However, the ectopic lipid accumulation in the kidney and its clinic relevance in the patients with Diabetic kidney disease (DKD) remains unknown.

Methods: Twelve patients of type 2 DKD (stage II-III) were enrolled and kidney tissue biopsy were stained with Oil red and immunohistochemistry assay for key lipid droplet marker and regulator protein, including adipose differentiation-related protein (ADRP), sterol regulatory element binding protein-1 (SREBP-1) and PPAR-α, while 8 patients of MCD and 10 patients of primary FSGS served as the control. At the same time, the expression of serum and urine ADRP, β-NG and inflammation marker (IL-1, TNF-α) were also detected in 15 DM patients and 35 DKD patients (including 12 patients of stage III, 13 patients of stage IV and 10 patients of stage V) with ELISA. qPCR and western blot assay were used to detect the expression of SREBP-1 mRNA and protein from peripheral blood mononuclear cells (PBMC). The correlation of ADRP, SREBP-1 and the clinic parameter, inflammation and tubular damage were evaluated with Pearson (SPSS) analysis.

Results: We observed heavy lipid deposition and increased intracellular lipid droplets in the kidney, especially in proximal tubule of DKD patients, as compared to that of MCD and FSGS. In accordance with lipid accumulation, intensity of ADRP and SREBP expression in the kidney sections obviously increased, while PPAR-α expression decreased. Moreover, compared to DM patients, the expression of ADRP both in serum and urine were unregulated in DKD patients. Similarly, both mRNA and protein expression of SREBP1 from PBMC in DKD patients also increased. Notably, the urine ADRP level and the expression of SREBP showed a parallel change with that of serum creatinine, proteinuria, β-NG, IL-1and TNF-α expression and tubular-interstitial damage.

Conclusions: Aberrant lipid regulation and ecotopic kidney lipid accumulation were observed in the DKD patients, which correlated to the inflammation and disease progression. Suggesting that amelioration of ecotopic lipid deposit may provide a new approach for prevention of DKD.

TH-PO737

Proteinuria and Cholesterol Reduction Are Independently Associated with Less Renal Function Decline in Statin Treated Patients: A Post-Hoc Analysis of the PLANET Trials Nienke Idzerda,[2] Michelle Pena,[2] Hans-Henrik Parving,[1] Dick de Zeeuw,[2] Hiddo J. Lambers Heerspink.[2] *[1]Rigshospitalet, Copenhagen, Denmark; [2]University Medical Center Groningen, Groningen, Netherlands.*

Background: Statins have shown multiple effects on different renal risk factors such as lowering of cholesterol (TC) and lowering of proteinuria (U_{PCR}). These effects seem to vary between individuals. We questioned whether the changes in U_{PCR} and TC run in parallel within one individual, and secondly, how this contributes to renal outcome (eGFR decline).

Methods: The PLANET studies studied the effects of a 52-week treatment with atorvastatin and rosuvastatin on U_{PCR} and renal function (eGFR) in proteinuric patients. In this post-hoc analysis, we first assessed the individual variability in U_{PCR} and TC response (0-14 weeks). U_{PCR} response was defined as a decrease in U_{PCR} of >0% and TC response as decrease in TC of >100 mg/dl (2.59 mmol/l) from baseline. Second, we determined whether these responses were predictive of eGFR decline during subsequent 9 months follow-up.

Results: U_{PCR} and TC response varied between patients: mean U_{PCR} response was -1.3% (5^{th} – 95^{th} percentile -59.9, 141.8), mean TC response was -93.9 mg/dl (-169.1, -26.9). Out of 471 patients, 123 (26.1%) showed a response in U_{PCR} but not in TC, and 96 (20.4%) showed a response in TC but not in U_{PCR}. eGFR (ml/min/1.73m²) decreased non-significantly from baseline in both U_{PCR} responders (0.4; 95%CI [-1.6, 0.8]; p=0.54) and TC responders (0.4; [-1.8, 1.1]; p=0.62), whereas U_{PCR} and TC non-responders showed a significant decline in eGFR (1.8; [0.6, 3.0]; p=0.004 and 1.7; [0.5, 2.9]; p=0.006, respectively). A lack of response in both parameters resulted in the fastest rate of eGFR decline (2.1; [0.5, 3.7]; p=0.01). These findings were not different for rosuvastatin or atorvastatin.

Conclusions: TC and U_{PCR} response to statins vary between individuals and do not run in parallel within an individual. The initial fall in cholesterol and proteinuria are independently associated with a reduction in the long term eGFR decline. This highlights the importance of both monitoring TC and U_{PCR} after initiating statin therapy.

TH-PO738

Impact of Gender on the Pattern of Glucose-Lowering Treatment and Hypoglycaemia in Patients with Type 2 Diabetes and Advanced CKD: The French CKD-REIN Study Marie Metzger,[1] Beverley Balkau,[1] Luc Frimat,[2] Christian Combe,[3] Maurice Laville,[4,5] Christian Jacquelinet,[6,1] Ziad Massy,[1,7] Benedicte Stengel,[1] Denis Fouque.[4,5] *[1]CESP U1018, INSERM, UPS-UVSQ, Villejuif, France; [2]Nancy University Hospital, Vandoeuvre les Nancy, France; [3]CHU de Bordeaux, Bordeaux, France; [4]Claude Bernard University Lyon 1, Lyon, France; [5]Hospices Civils de Lyon - Centre Hospitalier Lyon-Sud, Pierre Bénite, France; [6]Agence de la biomedecine, Saint-Denis La Plaine, France; [7]Ambroise Pare University Hospital, Boulogne Billancourt/ Paris cedex, France. Group/Team: On behalf of CKD Rein and CKDopps investigators.*

Background: Recommendations for glucose lowering treatments differ according to CKD stage, but not by gender, despite possible differences in efficacy; in consequence, glucose control and hypoglycaemia may differ.

Methods: Of the 3033 patients recruited with CKD stages 3 to 5, 645 men and 288 women were treated by glucose lowering drugs. Uncontrolled glucose was defined by HbA1c ≥ 7%, hypoglycaemia by self-report.

Results: Treatment with insulin (55% men, 65% women) was more frequent in the later stages of CKD (see Figure) with fewer women than men treated with insulin at lower CKD stages, more at higher stages (P_{inter}=0.008); overall, 31% were treated only with insulin, 28% with combinations: insulin and another drug, 42% by non-insulin glucose lowering drugs. The prevalence of uncontrolled glucose was 57%; in a multivariable model, only insulin treatment, longer diabetes duration and higher BMI were associated with uncontrolled glucose, not gender, age, nor eGFR. Hypoglycaemia were reported by 40% of men and 59% of women; they were not related with eGFR, nor to HbA1c, but were more frequent in people treated with insulin, after adjustment for age, sex, BMI, diabetes duration.

Conclusions: In people with diabetes and CKD, HbA1c, CKD stage and reported hypoglycaemia were not associated. However, glucose–lowering treatment, hypoglycaemia but not glucose control were gender dependent; this seems to be related to insulin treatment which may need to be adapted to avoid hypoglycaemia, especially in women.

AdipoRon Ameliorates Diabetic Nephropathy through Activation of Intracellular Ca++-AMPK-PPARα in Type 2 Diabetes Yaeni Kim, Ji Hee Lim, Min Young Kim, Eun Nim Kim, Hye Eun Yoon, Seok Joon Shin, Bumsoon Choi, Yong-Soo Kim, Cheol Whee Park. *The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: In diabetic nephropathy (DN), adiponectin's renoprotective effects are related to the activation of AMP protein kinase (AMPK)-peroxisome proliferative-activated receptor (PPAR)α pathway by binding to adiponectin receptors, AdipoR1/R2, respectively

Methods: We investigated the expression of AdipoRs and their relevant intracellular pathway in twenty-seven type 2 diabetic patients and found the role of AdipoRon on DN in male C57BLKS/J *db/db mice* and glomerular endothelial cell (GEC) and podocyte.

Results: While the degree and extent of glomerulosclerosis and tubulointerstitial fibrosis correlated with renal functional deterioration, the expression of AdipoR1/R2 and Ca^{++}/calmodulin-dependent protein kinase kinase (CaMKK)b and number of phosphorylated liver-kinase B (LKB)-1and AMPK-positive cells in the glomerulus was significantly decreased even in earlier stages of human DN. Diabetes-induced alterations shown in human DN were relieved by AdipoRon in *db/db* mice. The protective role of AdipoRon occurred through a direct activation of intrarenal AdipoR1/R2, which in turn increased expression of CaMKKb-phospho-Ser^{431}LKB1-phospho-Thr^{172}AMPK-PPARα pathway independently of systemic effects of adiponectin. Subsequent their relevant intracellular pathways related to lipid accumulation and endothelial dysfunction were reduced by improving diabetes-induced oxidative stress and apoptosis in the kidney. In human GECs and murine podocytes exposed to high glucose, AdipoRon increased the expression of intracellular Ca^{++}, which subsequently activated CaMKKb-phospho-Ser^{431}LKB1-phospho-Thr^{172}AMPK-PPARα and their downstream signals and resulted in decreased high glucose-induced oxidative stress, apoptosis, and endothelial dysfunction.

Conclusions: Our study suggests AdipoRon may be an effective therapeutic strategy for type 2 DN via ameliorating GEC and podocyte injury by the activation of intracellular Ca^{++}-AMPK-PPARα pathway.

Development of a Differential Diagnostic Model of Diabetic Kidney Disease and Non-Diabetic Kidney Disease in Patients with Type 2 Diabetes Mellitus Hui Zhuan Tan,[2,1] Jia Liang Kwek,[2] Stephanie C. Fook,[2] Chan Choong Meng,[2] Jason Choo Chon Jun.[2] *[1]Ministry of Health Holdings, Singapore, Singapore, Singapore; [2]Singapore General Hospital, Singapore, Singapore.*

Background: Renal biopsy is the gold standard for distinguishing diabetic kidney disease (DKD) from non-diabetic kidney disease (NDKD) but is invasive. We aimed to identify predictive factors of DKD in diabetic patients with kidney disease in our population and develop a quantitative differential diagnostic model to guide decision for kidney biopsy.

Methods: Clinical and laboratory data from 102 patients with Type 2 Diabetes Mellitus (T2DM) who underwent kidney biopsy from 2007 to 2016 in our tertiary hospital were analyzed. Univariate analysis and multivariate logistic regression were performed to identify independent predictors of DKD and generate a differential diagnostic model. Model discrimination and calibration were evaluated using the area under the receiver operating characteristic curve (AUROC) and Hosmer-Lemeshow goodness-of-fit test respectively.

Results: The cohort included 64 males (62.7%), mean age 55.7 years (±11.0) and duration of T2DM 10.4 years (±7.2). Mean serum creatinine at time of biopsy was 121.7 μmol/L (±46.4) with mean estimated glomerular filtration rate (eGFR) (MDRD) of 61.7 ml/min/1.73m^2 (±30.8). Sixty-five patients (63.7%) were diagnosed with diabetic nephropathy (DN) on kidney biopsy. In multivariate analysis, presence of diabetic retinopathy (Dr), higher Hba1c (Gh), absence of hematuria defined as urinary red blood cells <10 per high power field (Hu), and absence of positive systemic markers were revealed to be independent predictors of DN. A differential diagnostic model was constructed as follows: exp (-4.857 + 0.623 Gh – 1.208 Hu + 2.742 Dr -1.402 SM) / [1 + exp ((-4.857 + 0.623 Gh – 1.208 Hu + 2.742 Dr -1.402 SM)]. The model showed excellent discrimination (AUC=0.886; 95% CI 0.815-0.956) and calibration (Hosmer-Lemeshow p=0.242, good calibration plot of observed vs predicted probability, close to equality line).

Conclusions: The differential diagnostic model may be useful in the clinical differentiation of DKD and NDKD in patients with T2DM. Further validation of the model is required to determine its clinical utility.

TH-PO741

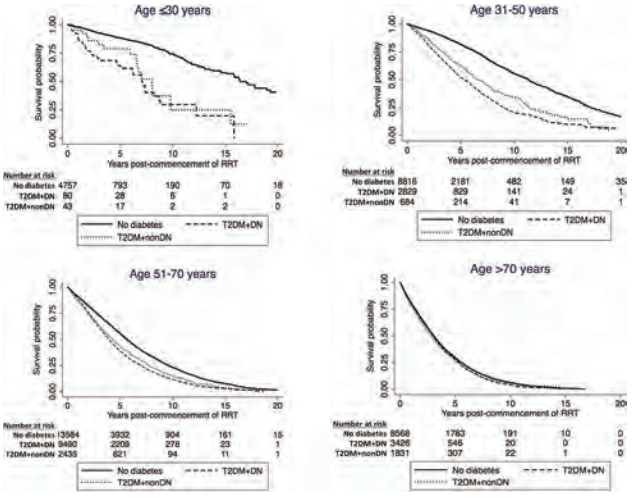
Impact of Type 2 Diabetes Mellitus (T2DM) with or without Diabetic Nephropathy (DN) on Long-Term Outcomes in ESKD Patients Initiated on Dialysis Wai H. Lim,[4] David W. Johnson,[3] Kevan Polkinghorne,[1] Carmel M. Hawley,[3] Charmaine E. Lok,[5] Germaine Wong.[2] *[1]Monash Medical Centre and Monash University, Melbourne, VIC, Australia; [2]None, Auambie, NSW, Australia; [3]Princess Alexandra Hospital, Brisbane, QLD, Australia; [4]Sir Charles Gairdner Hospital, Perth, NSW, Australia; [5]Toronto General Hospital, Toronto, ON, Canada.*

Background: DN is the most common cause of ESKD among patients with T2DM, however there is growing evidence that T2DM patients with non-DN as a cause of ESKD form a distinct clinical entity with differential prognostic significance

Methods: All incident ESKD patients initiated on hemodialysis/peritoneal dialysis in Australia and New Zealand between 1980-2014 were included, using data from the ANZDATA Registry. The association between diabetes status at dialysis initiation (i.e. no diabetes, T2DM+DN or T2DM+non-DN) and mortality were examined using Cox regression and competing risk analyses, with transplantation censored or considered as competing risk, respectively

Results: Of 56,552 incident dialysis patients followed for a median of 2.5 years, 15,829 (28%) and 4993 (9%) had T2DM+DN and T2DM+non-DN, respectively. Patients with T2DM were significantly older and a greater proportion had vascular comorbidities. Compared to patients with no diabetes, the adjusted HR (95%CI) for mortality in those with T2DM+DN and T2DM+non-DN were 1.39 (1.35-1.43) and 1.24 (1.29-1.29) in the Cox regression model, and the adjusted subdistribution HR were 1.52 (1.47-1.56) and 1.32 (1.27-1.38), respectively in the competing risk model. There was a significant interaction (p<0.001) between age and diabetes status, with the hazard for mortality greater in younger compared to older patients. Cardiovascular disease as a cause of mortality was more common in patients with T2DM compared to no diabetes (43% vs. 34%, p<0.001). Kaplan Meier survival curves for mortality stratified by age categories are shown below

Conclusions: Younger ESKD diabetic patients with or without DN experienced substantially poorer survival compared to non-diabetic patients. A vigilant approach to CVD prevention and monitoring is critical to improve clinical outcomes in diabetic patients with ESKD



TH-PO742

Risk Factors for Anemia in Diabetic Kidney Disease Andreea Andronesi, Bogdan M. Sorohan, Cristina Robe, Danut Andronesi, Bogdan Obrisca, Gener Ismail. *Fundeni Clinical Institute, Bucharest, Romania.*

Background: Anemia is a frequent complication of diabetic kidney disease (DKD). It is diagnosed at earlier stages and is associated with important morbidity and mortality. The aim of our study was to identify risk factors for the presence and severity of anemia in chronic kidney disease (CKD) due to DKD not under renal replacement therapy (RRT).

Methods: We performed a case-control study in which we included 156 patients with type 2 diabetes mellitus: study group with 72 patients with DKD-associated CKD and anemia, control group with 84 patients with DKD-associated CKD without anemia. We excluded patients in RRT, other causes of anemia, recent history of malignancy, blood transfusions and recent treatment with erythropoietin / immunosuppressive agents. Independent risk factors for anemia were identified by logistic regression using *IBM SPSS ver. 20.0.*

Results: Patients from study group had significantly lower body mass index (BMI) (27.4±3.5 *vs.* 30.4±4.9 kg/m^2, p=0.01) and albuminemia (3.4±0.5 g/dl *vs* 4.1±0.7 g/dl, p<0.001). We found strong positive correlations between Hb and albuminemia (R=0.515, p<0.001), Hb and eGFR (R=0.465, p<0.001) and weak negative correlation between Hb

and phosphatemia (R=-0.307, p=0.02). Time from CKD diagnosis (5.7±2.6 *vs* 3.5±1.5 years, p=0.003) and time from DM diagnosis (15.8±7.3 *vs* 13.1±6.3 years, p=0.04) were significantly longer in study group. Prevalence of anemia was higher with advancing CKD stage (p<0.001). Anemia was diagnosed even in patients with stage 2 CKD. Abnormal proteinuria was risk factor for anemia (OR 3.13, 95%CI 1.5-7.6, p=0.01). Calcemia was significantly lower (9.2±0.6 mg/dl *vs* 9.5±0.5 mg/dl, p=0.006) and phosphatemia significantly higher (4.7±0.9 mg/dl *vs* 3.8±0.7 mg/dl, p<0.001) in the study group. After adjustment for confounders, independent risk factors for anemia were abnormal proteinuria (adjusted OR 5.9, 95%CI 1.5-22.9) and treatment with renin-angiotensin-aldosteron system (RAAS) blockers (adjusted OR 6.2, 95%CI 1.3-30.1).

Conclusions: We found an increased prevalence of anemia in CKD due to DKD, even in patients with mild CKD. Anemia was associated with malnutrition (low BMI and albuminemia) and abnormal calcium-phosphate metabolism (low calcemia and high phosphatemia), mechanisms involved in the pathogenesis of anemia in these patients. Independent risk factors for anemia were proteinuria and RAAS blockers.

TH-PO743

Burnt-Out Diabetes Phenomenon and Association between Glycemic Control and Cardiovascular Comorbidity Rate in Hemodialysis Patients Masanori Abe,[3] Takayuki Hamano,[4] Junichi Hoshino,[5] Shigeru Nakai,[1] Ikuto Masakane.[2] *[1]Fujita Health University School of Health Scieneces, Toyoake, Aichi, Japan; [2]Honcho-Yabuki Clinic, Yamagata, Japan; [3]Nihon University School of Medicine, Tokyo, Japan; [4]Osaka University Graduate School of Medicine, Suita, Japan; [5]Toranomon Hospital, Tokyo, Japan. Group/Team: Committee of Japanese Renal Data Registry, Japanese Society for Dialysis Therapy.*

Background: In patients with diabetes on hemodialysis (HD), glycemic control improves spontaneously, leading to normal glycated hemoglobin (HbA1c) levels; this phenomenon is known as "burnt-out diabetes." However, glycated albumin (GA) might be a better indicator of glycemic control than HbA1c in HD patients. Therefore, the aim of this study was to identify how many patients experience "burnt-out diabetes" using HbA1c and GA levels and to examine the association between glycemic control and cardiovascular comorbidity risk in patients on HD.

Methods: The data were obtained from the annual nationwide surveys of dialysis patients conducted by the Japanese Society for Dialysis Therapy (JSDT) in 2013. Patients with diabetes on HD whose HbA1c and GA levels were measured and whose antidiabetic therapy was recorded were included. The "burnt-out diabetes" phenomenon was investigated in patients who were assessed for both HbA1c and GA levels. The association between cardiovascular comorbidity risk and HbA1c and GA levels were assessed using multivariable logistic regression models.

Results: In this cohort study, 23,668 patients were included. When "burnt-out diabetes" was defined as HbA1c <6.0% without treatment with antidiabetic medication, it was noted in 4,899 patients (20.7%). However, when "burnt-out diabetes" was defined as HbA1c <6.0% and GA <16.0% without treatment with antidiabetic medication, it was found in 1,286 patients (5.4%). Higher HbA1c levels were associated with the comorbidity rate of all cardiovascular diseases. However, higher GA levels were associated with comorbidities of all cardiovascular diseases except cerebral hemorrhage. The odds ratio (OR) of the cardiovascular comorbidity rate based on the GA category, with GA 16.0 to <18.0% treated as the reference group. The OR of cardiovascular comorbidity risk were significantly associated with GA >18%. After adjustment for confounders, the OR of the GA <16.0% group was significantly decreased as compared to the reference group.

Conclusions: Although the "burnt-out diabetes" phenomenon might be present in 20.7% of patients with diabetes on HD in terms of HbA1c, the rate was significantly decreased to 5.4% in terms of GA. The risk of cardiovascular comorbidity was higher in patients with GA > 18%.

Absolute versus Percentage Renal Functional Losses in Patients with Diabetes and CKD William P. Martin,[1,2] Tomas P. Griffin,[1,2] David W. Lappin,[2] Damian G. Griffin,[2] John P. Ferguson,[3] Timothy O'Brien,[1,2] Matthew D. Griffin.[1,2] *[1]Regenerative Medicine Institute, National University of Ireland, Galway, Ireland; [2]Endocrinology and Nephrology Services, Saolta University Health Care Group, Galway, Ireland; [3]HRB Clinical Research Facility, Galway, Ireland.*

Background: Chronic kidney disease (CKD) management focuses on minimizing the rate of renal functional loss, usually expressed in absolute terms of mL/min/BSA lost per annum. We evaluated the impact of expressing renal functional loss as a percentage of existing renal function on the interpretation of renal functional trends of patients with diabetes before and after attending a Diabetes Renal Clinic (DRC).

Methods: All patients attending a DRC at a tertiary referral center from 2008 to 2012 were reviewed. Serial laboratory indices were recorded from 2004 to 2014. Linear mixed effects models fitted using the R-package ImerTest were used to calculate absolute eGFR slopes. In a second analysis, similar mixed effects models were fitted with log-transformed eGFR as the response, to estimate annual percentage decline in eGFR. Renal function was estimated using both MDRD and CKD-EPI equations.

Results: 147 subjects with ≥3 available eGFR values for ≥1 year before and after first DRC attendance were categorized based on presumptive CKD etiology. Rates of renal functional loss were calculated with similar results being obtained using both MDRD and CKD-EPI estimating equations (Table).

Conclusions: Following DRC consultation, absolute rate of eGFR decline was similar for T1D but slower for T2D and additional CKD etiology groups. Expressed as a percentage of prior eGFR, renal function declined more rapidly in T1D, similarly in T2D, and more slowly in those with additional CKD etiologies. Thus, interpretation of the impact of a CKD intervention is influenced by the initial eGFR and by the approach used to calculate renal functional decline.

Funding: Government Support - Non-U.S.

Baseline characteristics at first DRC attendance and renal functional losses before and after first DRC attendance stratified by CKD etiology (n = 147).

	Type 1 Diabetes (T1D) (n = 32)			Type 2 Diabetes (T2D) (n = 91)			Diabetes with Additional CKD Etiology (n = 24)		
Age [mean ± SD; years]	43.8 ± 16.2			69.1 ± 10.0			69.5 ± 10.5		
Male [n (%)]	19 (59.4)			60 (65.9)			17 (70.8)		
Diabetes duration [median (IQR); years]	21.0 (16.7)			10.1 (11.7)			9.3 (4.8)

TH-PO745

Comparison of Clinicopathological Features of Biopsy-Proven Diabetic Nephropathy between CKD Heat Map Classification and the Japanese Classification of Diabetic Nephropathy Kengo Furuichi,[2] Miho Shimizu,[2] Tadashi Toyama,[2] Yasunori Iwata,[2] Norihiko Sakai,[2] Takashi Wada.[1] *[1]Dept of Nephrology and Labo Med, Kanazawa University, Kanazawa, Japan; [2]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Japan.*

Background: CKD heat map classification and the Japanese classification of diabetic nephropathy reflects the risks of mortality, cardiovascular events and kidney prognosis and is clinically useful. Furthermore, pathological findings of diabetic nephropathy are also known to be useful for predicting prognoses. In this study, we evaluated the characteristics of clinicopathological features between the two clinical classification of diabetic nephropathy.

Methods: The clinical data of 600 biopsy-confirmed diabetic nephropathy patients were collected retrospectively from 13 centres across Japan. Pthologica features and decreasing rate of estimated GFR (eGFR) were evaluated, and compared between CKD heat map classification and the Japanese classification of diabetic nephropathy.

Results: The median observation period was 70.4 (IQR; 20.9-101.0) months. Each stage had specific characteristic pathological features. Diffuse lesions, interstitial fibrosis and/or tubular atrophy (IFTA), interstitial cell infiltration, arteriolar hyalinosis and atherosclerosis were detected in more than half the cases, even in Green and Yellow in CKD heat map and Stage 1 in the Japanese classification of diabetic nephropathy. Median declining speed of eGFR in all cases was 5.61 mL/min/1.73m^2/year, and the median rate of declining kidney function within 2 years after kidney biopsy was 24.0%. Declining rate of eGFR within 2 years after kidney biopsy increased as CKD heat map classification and the stage of Japanese classification of diabetic nephropathy increased; and Green and Yellow, Orange, Red; 3.7, 17.9, 34.3 %, respectively, Stage 1, 2, 3, 4; -0.9, 10.7, 26.5, 38.8 %, respectively. Sensitivity of 30% reduction of the eGFR in two years as a surrogate end point of kidney death was 56.7% (Green and Yellow, Orange, Red; 0, 80.0, 56.5 %, and Stage 1, 2, 3, 4; 0, 0, 84.2, 11.1 %, respectively).

Conclusions: This study indicated that there were characteristic pathological features in each clinical classification. Moreover, decreasing rate of eGFR increased in advanced stages of diabetic nephropathy, and sensitivity of surrogate end point (30% reduction of the eGFR in two years) was relatively high in Stage 3 Japanese classification of diabetic nephropathy, and Orange in CKD heat map.

TH-PO746

Endothelial Cell Transfusion Inhibits Venous Neointima Formation in Arteriovenous Fistulae of Rats with CKD Dongqi Xing, Li Li, Yuanyuan Guo, Yiu-Fai Chen, Yasin Oduk, Suzanne Oparil, Fadi G. Hage. *University of Alabama at Birmingham, Birmingham, AL.*

Background: The arteriovenous fistula (AVF) is the preferred choice of vascular access for hemodialysis patients with chronic kidney disease (CKD). However, AVF fail to mature in ~ 40% of cases due to early neointimal hyperplasia (neointimal formation) in AVF vein and persistent inadequate outward remodeling (expansion) of the AVF vein. We have shown that intravenous (i.v.) transfusion of rat aortic endothelial cells (RAECs) ameliorates endothelial dysfunction in a rat model of CKD. In this study, we tested the hypothesis that i.v. transfusion of RAECs inhibits venous neointima formation in AVF of CKD rats.

Methods: Female ovariectomized Sprague-Dawley rats underwent 5/6th nephrectomy (Nx). After 4 wks, an AVF was created by anastomosing the right femoral vein to the right femoral artery in an end-to-side manner, and rats received i.v. transfusion of 3.0x10^6 RAECs in 2 ml saline or saline vehicle control. Rats were sacrificed and perfused with

formalin 4 wks later. Fistulae were fixed, sectioned and stained with hematoxylin and eosin (HE). The ligation site was identified and the vein was sectioned a 400, 600, 800, 1000 and 1200 μm proximal to the ligation site. To calculate the neointima area to vessel size (cross-sectional area) ratio, the circumferential profiles of the lumen and the external lamina of the vein were delineated, and the areas encompassed by these boundaries were determined by ImageJ software.

Results: Serum creatinine level increased from 4.6±0.5 μg/ml to 8.5±1.1 μg/ml after 5/6 Nx (n=11). EC transfusion significantly inhibited neointima formation in femoral vein at 4 wks after AVF (Figure).

Conclusions: EC transfusion inhibited venous neointima formation in AVF, suggesting that EC therapy after AVF may provide a novel strategy for the maintenance of vascular access in hemodialysis patients.

Funding: Other NIH Support - R56 HL128285-01A1,RO1HL116727, Veterans Affairs Support

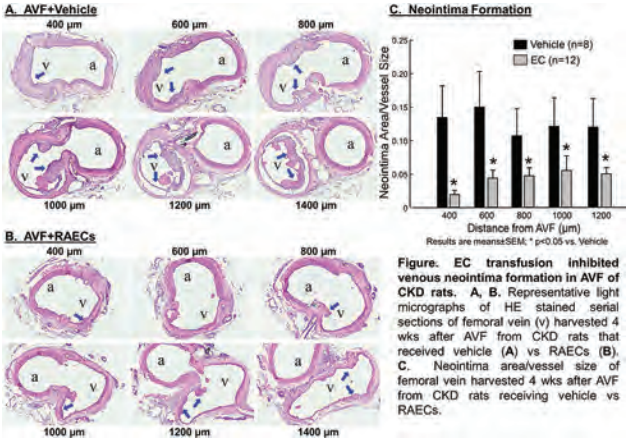

Figure. EC transfusion inhibited venous neointima formation in AVF of CKD rats. A, B. Reduced Endothelium-Dependent Vasodilation and Impaired Arteriovenous Fistula (AVF) Development in a Rat Model with CKD Yan-Ting Shiu,[3] Yuxia He,[3] Daniel R. Machin,[5] CS Jason Tey,[3] Jack Z. Fan,[3] Zhen Chen,[1] Miriam E. Leary,[2] Hirofumi Tanaka,[4] Tony J. Donato,[3] Alfred K. Cheung.[3] *[1]Beckman Research institute, City of Hope, Duarte, CA; [2]University of Texas at Austin, Austin, TX; [3]University of Utah, SALT LAKE CITY, UT; [4]University of Texas at Austin, Austin, TX; [5]University of Utah, SALT LAKE CITY, UT.*

Background: AVF maturation failure results from neointimal hyperplasia (NH) and insufficient dilation of lumen, but the latter remains largely unexplored. We investigated endothelium-dependent vasodilation (EDV) and AVF development in a clinically relevant CKD-AVF model.

Methods: CKD was induced in 10-week-old Wistar male rats fed a 0.25% adenine-containing diet (AD) for 10 wk. EDV of femoral arteries was non-invasively assessed at baseline, 10 wk on AD, and 4 wk after returning to normal diet (ND). Gene expression of key endothelial regulators, including transcription factors Krüppel-like factor 2 (KLF2) and KLF4 and their target endothelial nitric oxide synthase (eNOS), was assessed in the aorta of CKD and normal rats. Femoral AVFs were created in CKD and normal rats. AVF lumen diameter was measured by ultrasound, and animals were euthanized for histology.

Results: In CKD rats, plasma creatinine and BUN increased 3-fold after 10 wk on AD, and the elevated levels persisted after return to ND for 4 wk. EDV was lower after AD (5.6±2.2%) than baseline (16.3±1.7%)($p<0.05$; n=8) and remained impaired after CKD rats returned to ND (6.0±2.8%, n=4). Aortic eNOS expression was lower in CKD rats than in control rats (0.77±0.25 vs. 2.84±0.71; $p<0.05$; n=4 each), and the expression of KLF2/4 was also lower in CKD. At 4 wk after AVF creation, while NH was observed in both groups, AVF lumen was significantly smaller in CKD than in control rats **(Fig. 1)**.

Conclusions: CKD decreased the expression of KLF2/4 and eNOS, which may decrease the NO availability and NO-mediated dilation. CKD may impair AVF dilation via decreased EDV.

Funding: NIDDK Support

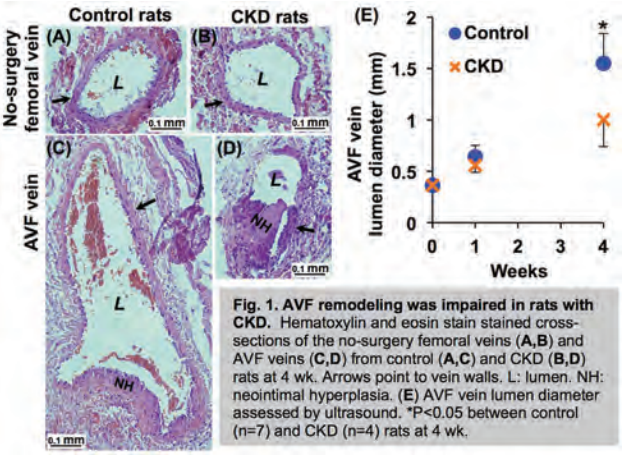

Fig. 1. AVF remodeling was impaired in rats with CKD. Hematoxylin and eosin stain stained cross-sections of the no-surgery femoral veins (**A,B**) and AVF veins (**C,D**) from control (**A,C**) and CKD (**B,D**) rats at 4 wk. Arrows point to vein walls. L: lumen. NH: neointimal hyperplasia. (**E**) AVF vein lumen diameter assessed by ultrasound. *P<0.05 between control (n=7) and CKD (n=4) rats at 4 wk.

Decreased Collagen Cross-Linking Improves the Biomechanical Performance of Experimental Arteriovenous Fistulas Diana R. Hernandez,[2] Yuntao Wei,[2] Fotios M. Andreopoulos,[3] Laisel Martinez,[2] Loay H. Salman,[1] Roberto I. Vazquez-Padron.[2] *[1]Albany Medical College, Albany, NY; [2]University of Miami Miller School of Medicine, Miami, FL; [3]University of Miami, Miami, FL.*

Background: The role of lysyl oxidase (LOX) in arteriovenous fistula (AVF) remodeling has never been studied. As the enzyme that catalyzes the cross-linking of collagen and elastin precursors in the vascular wall, a deficiency in LOX activity may impair wall integrity while excessive activity may lead to stiffness and favor occlusive stenosis. This study hypothesizes that local or systemic inhibition of LOX with β-aminopropionitrile (BAPN) prevents excessive cross-linking of collagen and other extracellular matrix (ECM) proteins and improves the biomechanical performance of experimental AVFs.

Methods: Surrogate indicators of vascular remodeling included fibrosis (% area of collagen) by Masson's trichrome staining, and gene expression of ECM proteins by RT-PCR. Biomechanical properties were evaluated by pressure myography.

Results: We first demonstrated that gene expression of LOX, but not of LOX-like enzymes (LOXL1-4), was significantly upregulated in a rat AVF model created by anastomosing the left epigastric vein to the nearby femoral artery. Systemic administration of BAPN (100 mg/kg, ip) decreased collagen deposition in treated versus control AVFs ($p=0.013$). In addition, BAPN treatment upregulated the elastin and fibronectin genes in the fistula wall. Next, we electro-spun a PLGA/BAPN (15:1.5) scaffold to locally deliver the drug around the juxta-anastomotic area of experimental AVFs for 21 days post-op. In vitro, BAPN release from the scaffold was almost complete within 7 days, while it took 60 days at 37°C for the scaffold to be fully degraded. Local delivery of BAPN to experimental AVFs improved vascular remodeling by decreasing fibrosis, compared to AVFs wrapped with scaffold alone (n=6 per group, $p=0.043$). Furthermore, local delivery of BAPN increased distensibility and decreased the incremental elastic modulus (E_{inc}) (4.93 ± 0.85 vs. 2.22 ± 0.39 x 10^6 dynes cm^{-2}, $p=0.019$) as determined by pressure myography.

Conclusions: In conclusion, we have demonstrated that inhibition of LOX mediated cross-linking with BAPN significantly improved vascular compliance and the biomechanical properties of experimental AVFs.

Altered Molecular Profiles in Hemodynamically Vulnerable Segments of Arteriovenous Fistulae (AVF) in a Uremic Pig Model Jaroslav Janda,[2] Begoña Campos,[4] Aous Jarrouj,[1] Frank C. Brosius,[2] Lindsay N. Kohler,[2] Prabir Roy-Chaudhury,[2] Diego Celdran-Bonafonte.[3,5] *[1]Banner-University of Arizona, Tucson, AZ; [2]University of Arizona, Tucson, AZ; [3]University of Arizona / BIO 5 Institute, Tucson, AZ; [4]University of Cincinnati, Cincinnati, OH; [5]Southern Arizona VA Healthcare System, Tucson, AZ.*

Background: Arteriovenous fistulae (AVF) are the preferred vascular access for hemodialysis patients but are subject to stenosis, disrupted flow and failure. The uremic pig serves as a useful model for studying the pathogenesis of AVF dysfunction in humans. Previously, we reported properties of vascular structure and flow in pig AVF that mimicked changes in human AVF. In the current project, we determine whether known differences in AVF hemodynamics between the inner and outer curves of the venous segment of an AVF and between the anastomotic and more proximal segments, were associated with altered gene expression for 8 candidate genes in adjacent AVF segments.

Methods: Renal insufficiency in 4 Yorkshire pigs was surgically induced by 5/6 nephrectomy, and 2 weeks later bilateral AVFs were created between femoral arteries and veins. The inner and outer curves of each AVF were harvested 6 wk later. Four sequential samples from the anastomosis to the more proximal venous segment were collected

for each AVF. cDNA was generated from total RNA from these individual segments. Quantitative real time-PCR reactions were performed for ICAM, VCAM, NOS3, NOX4, KLF2, CCL2, MMP2, and MMP9.

Results: MMP9 levels (average of all four venous segments) were consistently and significantly higher in the outer curve of the AVF than the inner curve ($p < 0.05$). ICAM and VCAM mRNA levels also showed similar trends. eNOS levels trended towards being lower at the anastomosis (both inner and outer curves) as compared to the most proximal venous segment.

Conclusions: Our findings suggest that differences in fluid hemodynamics especially wall shear stress (we have previously demonstrated differences in wall shear stress [WSS] between the inner and outer curves of an AVF, and also between the anastomosis and more proximal segment), could be important determinants of the molecular profile (and subsequent stenosis or lack thereof) in AVFs. Future studies will aim to assess whether manipulation of both upstream WSS and downstream molecular biology (as identified in this work) could reduce AVF stenosis in our uremic pig model.

MRI Modeling of Arteriovenous Fistula (AVF) Stenosis in a Pig Model: Creating a Test Bed for Mechanistic and Therapeutic Innovation

Diego Celdran-Bonafonte,[1] Begoña Campos,[2] Aous Jarrouj,[1] Keith L. Saum,[2] Jaroslav Janda,[1] Lindsay N. Kohler,[1] Frank C. Brosius,[1] Prabir Roy-Chaudhury.[1,3] *[1]University of Arizona, Tucson, AZ; [2]University of Cincinnati, Cincinnati, OH; [3]SAVAHCS, Tucson, AZ.*

Background: Arteriovenous fistula (AVF) stenosis (resulting in the use dialysis catheters) is an important cause of morbidity and mortality in hemodialysis patients. We have previously described a pig model of AVF stenosis. We now describe the use of MRI imaging in this model to enhance its capabilities for mechanistic and therapeutic innovation.

Methods: AVFs were created in the groin in 6 male Yorkshire Cross pigs. Black blood contrast-free MRIs were performed at days 28 and 56 (Figure A). MIMICS software was used for segmentation and 3D processing. 3-D reconstructions were analyzed along the first 35 mm of the venous segment. Centerline software was used to identify regions of maximal and minimal stenosis and to create a model for average stenosis, using cross sectional images at 5mm intervals (Figure B). Flow data was collected and is currently being analyzed.

Results: MRI imaging described a peri-anastomotic stenosis very similar to the human lesion (Figure B). The mean maximal stenosis area was 10.042 and 13.037mm^2 at 28 and 56 days respectively. Mean minimal stenosis (maximal dilation) was 34.175 and 69.290mm^2 at 28 and 56 days respectively. The average sectional area of the entire venous segment increased from 28.863 mm^2 at 28 days to 32.626 mm^2 at 56 days.

Conclusions: The use of sophisticated 3D MRI technology to obtain standardized end points for AVF stenosis (both anatomy and flow) significantly reduces the subjectivity associated with the evaluation of novel therapies in this test bed. We hope that the use of these sophisticated technologies in a reproducible and validated large animal model, will incentivize much needed innovation in this area, both at a mechanistic and therapeutic level.

Study of Vascular Intimal Thickness around Different Locations of Catheter Tips in Dog Model

Li H. Wang,[1] Lan Jia,[2] Hai B. Yu,[3] Fang Wei,[4] Ai L. Jiang.[5] *[1]Department of Kidney Disease and Blood Purification Centre, nstitute of Urology & Key Laboratory of Tianjin, Tianjin, China; [2]Department of Kidney Disease and Blood Purification Centre, 2nd Hospital of Tianjin Medical University, Tianjin, China; [3]Department of Kidney Disease and Blood Purification Centre, 2nd Hospital of Tianjin Medical University, Tianjin, China; [4]Department of Kidney Disease and Blood Purification Centre, 2nd Hospital of Tianjin Medical University, Tianjin, China; [5]Department of Kidney Disease and Blood Purification Centre, 2nd Hospital of Tianjin Medical University, Tianjin, China.*

Background: Many studies have found intimal thickness around catheter tip after catheterization. Meanwhile Caveolin-1 is a shear sensor that may transmit mechanical change into biochemical signals resulting in vascualr remodeling.

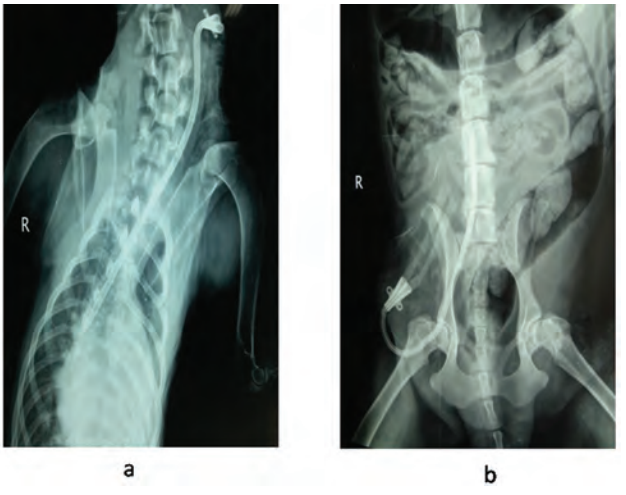
Methods: TDCs were inserted into the left jugular vein and right femoral vein in eight dogs for 28 days. Histological and immunohistochemistry were performed to confirm specific cell populations after extracorporeal circulation.

Results: There were higher catheter dysfunction rates and low blood flow rates in the femoral vein group compared to left jugular vein group. There was intimal hyperplasia around the catheter tip in both group with no significant difference. There were also caveolin-1 expression between the different groups.

Conclusions: After catheter placement, focal areas of intimal thickening were seen in the venous wall adjacent to the catheter tip with a high expression of caveolin-1. These findings indicate that different catheter tip locations may influence catheter function and targeting of specific caveonlin-1 could be possible future novel therapies for haemodialysis vascular access stenosis.

Comparison of catheter function of study groups

Parameter	Left internal jugular vein catheter group	Right Femoral vein catheter group	P value
Blood flow(ml/min)	236±21	197±13	0.001
Episode of catheter dysfunction	1(12.5%)	5(62.5%)	0.035
Episode of catheter infection	3(37.5%)	4(50%)	0.614



TH-PO752

AFE System Treatment Rapidly Dilates Ovine Cephalic Veins before AVF Surgery

F. Nicholas Franano,[1] Howard M. Loree,[1] J. S. Richardson,[1] Dale M. Groth,[2] Maneesh Taneja,[3] Lesley A. Szenay,[3] Barrett S. Hutto,[4] Bradley S. Dixon.[5] *[1]Flow Forward Medical, Inc., Olathe, KS; [2]Dale Groth Preclinical Consulting, LLC, Forest Lake, MN; [3]Surpass, Inc., Osceola, WI; [4]CIRTEC Medical Systems LLC, Los Gatos, CA; [5]University of Iowa Hospital and Clinics, Iowa City, IA.*

Background: Suboptimal wall shear stress (WSS) and cyclic stretching may slow AVF outflow vein dilation and lead to maturation failure. The AFE System™ is a medical device that delivers non-pulsatile blood flow to a peripheral vein, stimulating vein dilation prior to AVF surgery. During treatment, blood flow can be adjusted to maintain a mean WSS dose of 4 Pa in the vein. Use of larger veins to make AVFs may result in greater eligibility for AVF surgery, faster maturation, reduced maturation failure, and better primary and secondary patency rates.

Methods: AFE System prototypes were used to treat five sheep (54-68 kg). The devices comprised an extracorporeal centrifugal blood pump, heparin-coated and cuffed inflow and outflow conduits, and a benchtop controller. The inflow conduit was inserted into an external jugular vein and the tip was positioned in the superior vena cava. The outflow conduit was connected to a cephalic vein. Three sheep were treated using a duckbill tip inflow conduit and an outflow conduit with a distal ePTFE segment sutured to the vein. Two sheep were treated using an inflow conduit with a duckbill tip surrounded

by a nitinol cage to prevent vein wall suction and an outflow conduit with an intravascular connector inserted into the vein lumen.

Results: Mean vein diameter increased significantly from 4.5 to 8.4 mm with 6-11 days of treatment (n=5, *p*=0.005). Variation in conduit designs had no effect on final vein diameter. The average rate of vein dilation was 0.51 mm/day. The intravascular connector simplified placement of the outflow conduit and the inflow conduit tip-protecting nitinol cage prevented low flow events. AVFs were made with the dilated veins in all animals.

Conclusions: This pilot study shows the feasibility of dilating peripheral veins with the AFE System prior to AVF surgery.

Vonapanitase Increases Fistula Use for Hemodialysis Using a Robust and Clinically Relevant Definition Anthony J. Bleyer,[5] Bradley S. Dixon,[4] Timmy C. Lee,[3] Steven K. Burke,[2] Rick E. Mishler.[1] *[1]Arizona Kidney Disease and Hypertension Center, Ltd., Phoenix, AZ; [2]Proteon Therapeutics, Inc., Waltham, MA; [3]Univ of Alabama at Birmingham, Birmingham, AL; [4]University of Iowa Hospital and Clinics, Iowa City, IA; [5]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Vonapanitase is an investigational recombinant human elastase applied to the external surface of the fistula at the time of surgical creation. A recently reported randomized double-blind trial (NCT02110901) showed vonapanitase increased radiocephalic fistula survival and use for hemodialysis (HD) compared with placebo in 311 pre-HD (56%) and HD (44%) patients over 1 year. In other trials, varying definitions of use have been employed that required shorter durations of use but detailed information on individual HD session blood flow or urea clearance. The current trial employed a pragmatic definition based on continued 2-needle hemodialysis for ≧ 90 days.

Methods: Successful use was defined as (1) ≥90 days or (2) ≥30 days and in use at the final study visit for those pre-HD patients initiating HD late in the follow-up period. Non-use was defined as insufficient duration of use or fistula abandonment prior to use. Those not defined as having use or non-use were considered indeterminate (eg, a pre-HD patient who never initiated HD) and excluded from analysis. Of those with use, 82% had at least one Kt/V or URR recorded. Adequate HD was defined as Kt/V≥1.2 or URR≥65%.

Results: More vonapanitase than placebo patients successfully used the fistula for HD (n=230, 64% vs 44%, p=0.006). Use was established by the 90-day rule in 92% and the 30-day rule in 8%. Only 3 patients abandoned the fistula following successful use (2 placebo, 1 vonapanitase) the others continued use in a follow-on registry. Non-use was defined by fistula abandonment prior to use in 91% and by insufficient duration of use in 9%. Fistula abandonment was due to thrombosis (occlusion) in 64% of cases and a mix of intractable stenosis, non-maturation, inadequate HD, inability to cannulate, and steal syndrome in the remaining. The percentages of those with successful use who had adequate HD were vonapanitase 99% and placebo 97%. In those on HD at baseline, median duration from surgical creation to first use was 103 days for vonapanitase and 135 days for placebo patients.

Conclusions: Vonapanitase increased successful use of the fistula for HD employing a robust and pragmatic definition of use that is clinically relevant and associated with adequate hemodialysis. These results are being confirmed in a larger ongoing trial (NCT02414841).

Six Month AV Fistulae Outcomes Following Local Perianastomotic Delivery of Sirolimus – Preliminary Report from a US Phase 3 Clinical Trial (ACCESS Trial) Sriram Iyer,[1] Nelson P. Kopyt,[2] Joseph J. Lee,[3] Osman S. Khawar,[4] Thomas D. Wooldridge,[5] Nirav Gandhi,[6] Robert I. Lynn,[7] William D. Paulson,[8] Maria V. DeVita.[9] *[1]Vascular Therapies Inc;, Cresskill, NJ; [2]Lehigh Valley Hospital, Allentown, PA; [3]Nephrology Associates Medical Group, Riverside, CA; [4]Balboa Nephrology Medical Group, Escondido, CA; [5]Nephrology & Hypertension Associates, LTD, Tupelo, MS; [6]Nephrology Medical Group of Orange County, Anaheim, CA; [7]Kidney Medical Associates, Bronx, NY; [8]Augusta University, Augusta, GA; [9]Lenox Hill Hospital- Northwell Health System, New York, NY. Group/Team: On behalf of ACCESS Trial investigators.*

Background: AV Fistula (AVF) maturation delay impacts its functional patency and prolongs catheter dependence. USRDS (2015) reports median time to first cannulation of 112 days and only 45% of AVF are suitable for dialysis at 6 months [Range 38% (DAC) - 65% (HFM)]. A prior single arm Phase 2 study (Table) tested the value of perivascular Sirolimus delivered intraoperatively at and around the AVF anastomosis from a collagen membrane (drug product; Vascular Therapies, Cresskill, NJ), for improving AVF outcomes.

Methods: Incident ESRD patients undergoing hemodialysis via catheter at time of AVF creation (Radiocephalic RCF or Brachiocephalic BCF) are eligible for enrollment in this ongoing US Phase 3 multicenter, randomized controlled clinical trial (NCT02513303). The first subject enrolled at each site received the drug product ["Open-label" subject (OL)]. Baseline vascular mapping (Cephalic vein ≥ 2.5mm; Artery ≥ 2mm; vein depth ≤5mm) was performed to ensure suitability.

Results: There were no product related serious adverse events. Table lists key demographic and outcome metrics. Time to First Dialysis (TTFD): Time from AVF creation, to the time when the fistula can support three consecutive 2-needle dialysis sessions with a mean dialysis pump flow of ≥300 mL/min (2N/300). Fistula Suitability for Dialysis at 6 months (FSD6): Ability to use the fistula (2N/300) for two-thirds of the dialysis sessions during a 30 day suitability ascertainment period commencing on day150. Excluding the 2 AVF that thrombosed early, TTFD was <90 days for 11/16 (69%) subjects.

Conclusions: 1. Time to maturation and AVF suitability for dialysis at 6 months in the open label Phase 3 subjects are similar to Phase 2 results and signal an improvement in comparison to historical controls. 2. Results are promising and may suggest that prophylactic local treatment with Sirolimus at time of AVF creation could *predictably* reduce catheter dependence to less than 90 days with durable AV fistula functionality. Enrollment is ongoing in the ACCESS trial.

Vascular Histology of Upper Extremities in Patients with CKD and Normal Controls Yan-Ting Shiu,[2] Silvio H. Litovsky,[1] CS Jason Tey,[2] Chad A. Sundberg,[2] Y. Zhang,[2] Alfred K. Cheung,[2] Michael Allon.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Utah, SALT LAKE CITY, UT.*

Background: Several studies have documented histologic features in the peripheral arteries and veins of patients with chronic kidney disease (CKD), but few have compared them to the vascular histology observed in control subjects.

Methods: We obtained upper extremity arterial and venous specimens used to create arteriovenous fistulas from 125 CKD patients, and from 15 cadavers with no CKD. Intimal hyperplasia was quantified using elastic stains as well as hematoxylin and eosin stains, medial fibrosis using Masson's trichrome stains, and micro-calcification using von Kossa stains. Second-harmonic-generation microscopy was used to quantify the anisotropy index (measure of randomness of fiber orientation, ranging from 0 for completely random to 1 for completely aligned) and the dominant direction of the medial collagen fibers (measure of the angle of the fibers relative of the vascular lumen, ranging from 0° (parallel with lumen) to 90° (perpendicular to lumen)).

Results: The CKD patients were significantly younger (53±14 vs 76±11 yr; p<0.001). As compared to the control subjects, the CKD patients had greater arterial medial fibrosis (69±14 vs 51±10%, p<0.001), greater arterial micro-calcification (3.03±5.17 vs 0.01±0.03%, p<0.001), and greater venous intimal thickness 37±40 vs 14±6 um, p<0.001), but less arterial intimal thickness (30±25 vs 63±25 um, p<0.001). The anisotropy index of the collagen fibers was lower in both arteries (0.24±0.10 vs 0.44±0.04, p<0.001) and veins (0.28±0.09 vs 0.53±0.10, p<0.001) obtained from CKD patients. The dominant medial direction of the collagen fibers in CKD patients was greater in the arteries (49.3±23.6 vs 4.0±2.0, p<0.001) and the veins (30.0±19.6 vs 3.9±2.1, p<0.001).

Conclusions: CKD is associated with greater arterial medial fibrosis, arterial micro-calcification and venous intimal hyperplasia, but less arterial intimal hyperplasia than that present in control subjects. In addition, the collagen fibers in the arteries and veins of CKD patients are oriented more randomly and more perpendicular to the vascular

lumen. The vascular histology in CKD patients may affect the maturation outcomes of arteriovenous fistulas.

Differences in Vascular Fibrosis Explain Sex Disparities in AVF Maturation Outcomes Laisel Martinez,[2] Juan C. Duque Ballesteros,[2] Angela Paez,[2] Marwan Tabbara,[2] Diana R. Hernandez,[2] Guillermo Selman,[1] Loay H. Salman,[1] Omaida C. Velazquez,[2] Roberto I. Vazquez-Padron.[2] *[1]Albany Medical College, Albany, NY; [2]University of Miami, Miller School of Medicine, Miami, FL.*

Background: Women have a higher risk of arteriovenous fistula (AVF) maturation failure than men, and the reason for this propensity is still unknown. Several studies have excluded sex-related differences in the diameter of native vessels as the explanation for this disparity, which suggests that the remodeling process in women is inferior. The purpose of this study was to compare two surrogate indicators of venous remodeling in females and males undergoing surgeries for two-stage AVF creation.

Methods: We measured intimal hyperplasia (IH) and medial fibrosis in native veins and AVF venous samples obtained during AVF creation (first-stage) and transposition (second-stage) surgeries, respectively. The analysis of native veins allowed the assessment of pre-existing sex-related differences in IH and medial fibrosis, whereas evaluation of AVFs allowed the comparison of postoperative remodeling between both sexes.

Results: Anatomical maturation failure (an AVF that never achieved an internal luminal diameter ≥ 6mm) occurred in 22/64 (34.4%) females and 18/97 (18.6%) males (p=0.027). The internal luminal diameter of the native basilic vein was similar between females and males (median 4.0 mm, interquartile range 4.0-4.0 in both, p=0.7). There were no significant sex-related differences in pre-existing IH and medial fibrosis between AVFs with successful maturation and maturation failure. Postoperative IH was also similar in AVFs with distinct maturation outcomes in both sexes. Interestingly, there was a significant increase in postoperative medial fibrosis in AVFs with maturation failure vs. successful maturation in females (55.0±2.7% vs. 44.0±2.2 [mean ± SEM], p=0.003), but not in males (51.2±2.9% vs. 48.0±1.6, p=0.4). Accordingly, logistic regression analyses demonstrated that the degree of medial fibrosis was associated with maturation failure in women (odds ratio [OR] 1.80 per 10% increase in medial fibrosis, p=0.034) but not in men (OR 1.03, p=0.4).

Conclusions: This study demonstrates for the first time the existence of sex-related differences in vascular remodeling after AVF creation, and that medial fibrosis is a major contributing factor to the increased risk of maturation failure in females.

TH-PO757

Extracellular Vesicles as Novel Markers in Hemodialysis Access Complications Tushar Chopra,[1] Sabrina La salvia,[2] Luca Musante,[2] Kambiz Kalantari,[2] Nicolas Intagliata,[2] Thu H. Le,[1] Uta Erdbruegger.[3] *[1]None, Nashville, TN; [2]University of Virginia, Charlottesville, WV; [3]University of Virginia Health System, Charlottesville, VA.*

Background: Failure of hemodialysis vascular access (HVA) is the most common cause of hospitalization and morbidity among end stage renal disease (ESRD) patients. Circulating extracellular vesicles (EVs) are potential candidate biomarkers to identify patients at risk for these HVA complications and failure. We hypothesize that these circulating EVs reflect endothelial damage in patients with vascular access complications, are pro-coagulant and predict VA longterm outcome.

Methods: EVs were isolated from platelet free plasma from citrated blood of 19 patients with recurrent HVA complications (mean age 64, HD vintage 2.8 years) and 16 patients without (mean age 61, HD vintage 5.7 years). Enumeration and phenotyping of EVs was performed using imaging flow cytometry. CD42 positive, CD31, S-Endoglin (CD105), E-Selectin (CD62E) and Annexin V (AnV) positive EVs were used as surface markers for circulating EVs. The size and concentration of EVs was measured with tunable resistive pulse sensing by qNano (Izon). A thrombin generation assay (TGA) (Stago) was performed and compared between groups. All patients were followed prospectively up to 4 years and assessed for total failure of their HVA.

Results: Endothelial derived EVs (activated (CD62E+), and non-activated (CD105+)) were significantly higher in patients with vascular access stenosis and thrombosis (CD62E: median 141,596/µl plasma, CD105: 114,983/µl plasma) compared to patients without VA complications (CD62E: median 63411/µl plasma, CD105 86505/µl plasma, CD62E p=0.014, CD105 p=0.004). Out of the 35 patients 19 (80%) had a functioning graft at time of follow up. Higher CD31+/CD41- EV levels correlated with a functioning access up to 5 years (CD31+/CD41- EVs: functioning 406,514/µl plasma, failed 161,000/µl plasma, p=0.02). However, EV concentration, EV size profile and endogenous thrombin potential were not statistically different between patients with and without HVA complications.

Conclusions: Activated and non-activated endothelial derived EVs are elevated in HD patients with vascular access complications, independent of HD vintage. These EVs might reflect endothelial pathology in HVA and have the potential to guide surveillance and treatment. A larger cohort of patients needs to be examined to confirm this finding.

TH-PO758

Isolation of High-Quality RNA from Human Veins and Arteriovenous Fistulas Guillermo Selman,[1] Nieves Santos,[2] Laisel Martinez,[2] Juan C. Duque Ballesteros,[2] Marwan Tabbara,[2] Loay H. Salman,[1] Roberto I. Vazquez-Padron.[2] *[1]Albany Medical College, Albany, NY; [2]University of Miami, Miller School of Medicine, Miami, FL.*

Background: Functional genomics and transcriptome analysis of pre-access veins and arteriovenous fistulas (AVF) require RNA of high quality and integrity. However, the vast majority of intraoperative vascular biopsies have a small size, are low in cell density, and rich in collagen and other extracellular matrix components that hinder the complete disruption of the tissue by guanidine isothiocyanate-based RNA extraction buffers. The application of current extraction protocols to AVF samples typically results in low RNA yields with poor quality. In this work, we developed a standard operating procedure that combines a pulverizing method that keeps the tissue completely frozen for RNA extraction with commercial reagents for purification.

Methods: We optimized this method using RNA-later (Qiagen) preserved veins (n=63) and AVFs (n=30) that were obtained intraoperatively during the creation of two-stage brachiobasilic fistulas in consented patients at the University of Miami. Briefly, 50-60 mg of tissue was cut in small pieces and ground to a fine powder in a Spex/Mill 6770 (15 min pre-cooling; 30 sec run; 2 min cycle cooling; 15 cycles total, 10 Hz rate) in the presence of 100 uL of Trizol. The homogenate was collected with 700 uL Trizol, transferred to 2-mL RNase-free microcentrifuge tubes, and further homogenized using an Ultra-Turrax T8 instrument for 30-45 seconds. After removing cellular debris by centrifugation (12,000 x g, 5 min, RT), the clear homogenate was extracted with chloroform according to the standard Trizol protocol, and 0.55 volumes of ethanol were added prior to loading onto an Omega EZNA column for further purification (Omega Bio-tek). On-column DNase digestion was applied as desired. Total RNA was eluted with 40 uL of RNAse-free water.

Results: The total RNA yield had a median of 44.5 ng/ul (interquartile range [IQR] 32.1 – 68.0) in veins and 124.0 ng/ul (IQR 85.2 – 220.0) in AVFs. High-quality RNA (RIN > 5) was obtained in 79.4% of veins and 86.7% of AVFs as demonstrated using an Agilent 2100 Bioanalyzer.

Conclusions: In conclusion, we have developed a new protocol for isolation of high-quality RNA from small vascular biopsies. We have successfully used these RNAs for RT-PCR and highly sensitive techniques for transcriptome analysis (RNA-seq).

TH-PO759

Percutaneous AV Fistula Creation for Vascular Access Randy I. Cooper,[2] Rajeev Narayan,[1] Matthew E. Schaefer,[1] Umar Waheed.[2] *[1]San Antonio Kidney Disease Center, San Antonio, TX; [2]Southwest Kidney Institute, PLC, Phoenix, AZ.*

Background: In the era of Fistula First, nephrologists are well versed on the pitfalls of arterio-venous fistula (AVF) failure rates and surgical issues related to AVF creation. USRDS 2016 reports a primary fistula failure rate of 35.9%. Few innovations have evolved in AVF creation but recently several novel devices have been developed that can create AVF percutaneously.

Methods: Two nephrology groups with vascular centers were among 5 centers in a U.S. IDE pivotal study using a percutaneous device (Ellipsys; Avenu Medical, San Juan Capistrano, CA) to create AVF. Patients were selected based upon suitable anatomy as determined by ultrasound mapping. All procedures were performed in the physician's centers. The primary outcome is maturation rate, defined as percentage of fistula suitable to allow successful cannulation for dialysis within 90 days including vein size and flow. The device is a single catheter that engages the walls of a perforating vein and proximal radial artery in the forearm. The AVF is created using thermal energy to "heat weld" the vessels together and cut the anastomosis.

Results: The Interventional Nephrologists (INs) in the study reported an average procedure time of 23 minutes. In addition, available 12 month follow-up data indicate a high patency rate of 96% and no significant clinical sequelae such as mega-fistulas or steal syndrome have been reported. One year data will be provided at the meeting.

Conclusions: Despite the advances from Fistula First, 80% of incident patients still initiate HD without a functioning AV access and 30% are still dialyzing with a catheter at 1 year. Our study demonstrates that PAVF offers a minimally invasive option for AVF creation that can be safely performed in an office-based setting by INs. The 90 day and 1 year data demonstrate technical and clinical success as well as a reduction in the maturation period in comparison to surgically created AVF. It is estimated, with the process under the control of the nephrologist, that catheter contact time (CCT) can be reduced by 90 days or more.

Funding: Commercial Support - Avenu Medical

RESULTS

TH-PO760

Real-World Experience Utilizing Endovascular Arteriovenous Fistula (endoAVF) to Deliver Hemodialysis Treatment Frank Dellanna,[1] Christoph Radosa,[2] Ralf Hoffmann,[2] Linda Nuth,[3] Robert Shahverdyan,[3] Tobias Steinke.[3] *[1]MVZ DaVita Rhein-Ruhr GmbH, Duesseldorf, Germany; [2]Universitätsklinikum Carl Gustav Carus, Dresden, Dresden, Germany; [3]Schön Klinik Düsseldorf, Düsseldorf, Germany.*

Background: The arteriovenous fistula (AVF) is the primary option for end stage renal disease patients to receive hemodialysis treatment. However, the surgical trauma of dissecting, mobilizing and suturing the vein to the artery can lead to early AVF failure rates as high as 60% [1-4]. A novel endovascular approach to create AVFs has been developed to avoid this surgical trauma. This report describes the initial real-world experience with the endoAVF at two European vascular centers.

Methods: Consecutive dialysis and pre-dialysis patients who underwent the endoAVF procedure were followed to assess the ability to create a functional vascular access. Eligible patients were traditional surgical candidates for upper arm AVFs. Patients did not receive an endoAVF if they were ideally suited for a radiocephalic fistula (healthy arteries with a >2.5 mm forearm cephalic vein) or had a previously failed upper arm vascular access. Patients were followed to assess the technical success of the procedure, functional usability via two-needle cannulation, interventions necessary to mature and maintain the endoAVF and maturation time.

Results: An endoAVF was attempted in 23 patients between 07/2015 and 05/2017. The median age was 60 (25-84) with 65% male 61% pre-dialysis, 9% having a failed forearm fistula and typical comorbidities of the German dialysis patient population. Technical success was reported at 100%. Dialysis was successfully administered via 2-needle cannulation in 72% (13/18) of the patients; three patients were still pre-dialysis, one patient had less than 2 months follow-up and one was lost to follow-up. Three pre-planned vein elevations as well as three interventions to augment flow were performed. The median maturation time was 56 days (range: 10 – 86 days) at one center and 63 days (range: 26 – 137) at the other with the longest maturation times associated with elevation procedures.

Conclusions: The endoAVF procedure produced usable AVFs with high technical success. These real-world results are consistent with the results demonstrated in previous endoAVF clinical studies, FLEX [5] and NEAT [6]. 1. J Vasc Surg 2012;55:274-80. 2. Kidney International, 2003;64:1487–1494 3. J Nephrol 2007;20:150-163. 4. JAMA 2008; 299:2164–2171 5. J Vasc Interv Radiol. 2015;26(4):484-490. 6. J Am Soc Nephrol 2016; 27:31A.

TH-PO761

Long-Term Outcomes of Arteriovenous Fistulas and Grafts in a Large European Cohort Bram M. Voorzaat,[2] Koen E. van der Bogt,[1,2] Cynthia J. Janmaat,[2] Friedo W. Dekker,[2] Joris I. Rotmans.[2] *[1]Haaglanden Medisch Centrum, Den Haag, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands. Group/Team: Dutch Vascular Access Study Group.*

Background: For hemodialysis (HD), arteriovenous fistulas (AVF) are the preferred type of vascular access (VA). Most data on VA durability originate from North America. As practice patterns and patient characteristics differ between Europe and the US, we evaluated outcomes of radiocephalic (RCAVF) and upper arm AVFs and arteriovenous grafts (AVG) in a large retrospective cohort of Dutch HD patients.

Methods: This Dutch Vascular Access Study cohort consists of 1,656 VAs in 1,221 patients in 8 hospitals. To obtain independent observations, only the first matured VA per patient was included. Primary patency started at VA creation and ended at the first intervention or abandonment. Functional patency started at the first cannulation and ended at abandonment. Patency was censored at death or transplant. Patency is presented as median VA survival and analysed using Kaplan-Meier analysis. Hazard ratios for patency loss are calculated using Cox regression analysis using RCAVFs as the reference. Procedure rates are presented per year of functional patency.

Results: 863 VAs (420 RCAVF, 341 upper arm AVF, 102 AVG) were analysed. The median primary patency for RCAVFs was 13.8 ± 1.8 months, for upper arm AVFs 26.6 ± 4.5 months and for AVGs 11.4 ± 1.8 months. The hazard ratio for loss of primary patency was higher for AVGs than RCAVFs (HR 1.52, 95% confidence interval: 1.18 – 1.96), and lower for upper arm AVFs (HR 0.74, 0.60 – 0.90). The median of functional patency was not met during the follow-up (fig 1). At 48 months 82% of RCAVFs, 79% of upper arm AVFs and 73% of AVGs were still functionally patent (death-censored). The number of procedures was lowest for RCAVFs (0.8 ± 2.1/year) versus upper arm AVFs (1.4 ± 8.7/year) and AVGs (2.5 ± 5.8/year).

Conclusions: In the Dutch Vascular Access Study cohort, long-term functional patency was comparable between the 3 groups of arteriovenous access configurations. However, the number of procedures required to maintain AVG patency is 3-fold higher compared to RCAVFs.

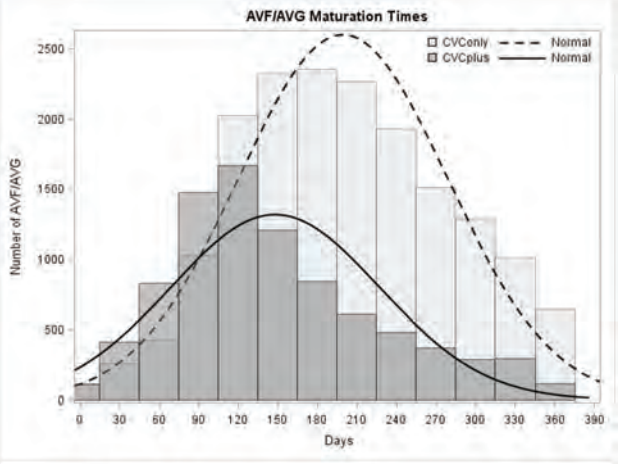
The Significance of a Maturing Fistula or Graft at HD Initiation Rita L. McGill,[2] Eduardo K. Lacson.[1] *[1]Tufts University School of Medicine, Boston, MA; [2]University of Chicago Medicine, Chicago, IL.*

Background: Increasing use of fistulas (AVF) and grafts (AVG) is a national priority, especially for incident hemodialysis (HD) patients. One-quarter of patients who initiated HD with catheters (CVC) have an accompanying 'maturing' AVF or AVG. We examined the characteristics and one-year outcomes of these patients.

Methods: All patients initiating HD from 7/2010 – 12/2011 were assessed. Medical Evidence forms were used to determine baseline characteristics and vascular access at 1st outpatient HD. HD claims were used to assess changes in vascular access, and treatment history files were used to identify deaths during the first year of HD.

Results: Among 52,573 patients initiating HD with CVCs, 12,201 (23.2%) had a maturing AVF/G. Compared to patients with CVC-only, patients with maturing AVF/G were more likely to be black (30.6 vs. 27.3%, P<0.01) and diabetic (61.7 vs 55.6%, P<0.01), but similar in age, sex, and body mass index. Patients with pre-HD nephrology care were twice as likely to have maturing AVF/G (31.1 vs. 15.6%, *P*<0.001). Over the first year, 10.9% of patients with maturing AVF/G died, 71.6% converted to AVF/G use, and 14.1% had CVC at one year. Among patients with CVC-alone, 23.0% died, 42.7% converted to AVF/G, and 23.8% had CVC at 1 year. Among patients who transitioned to AVF/G, median catheter-days were 131 (IQR=94-194) for patients with maturing access versus 195 (IQR=95-252) for those with CVC-only. The distributions of maturation times were unimodal for both groups.

Conclusions: HD initiation with a maturing AVF/AVG is associated with improved first-year outcomes relative to CVC as sole access, suggesting that vigorous efforts to secure access may be beneficial even in advanced CKD. Although a maturing AVF/AVG was associated with fewer catheter days, CVC use was prolonged in both groups. The reasons for prolonged CVC use merit further investigation.



TH-PO763

Comparison of FTM Risk Score versus Surgical Opinion for Primary and Secondary AV-Fistula Creations Eliot J. Winkler,[3] Sami Suleiman,[2] Prakash Gudsoorkar,[1] Charmaine E. Lok.[2] *[1]None, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada; [3]University Health Network, Toronto, ON, Canada.*

Background: Arteriovenous fistulas (AVF) continue to have high failure-to mature (FTM) rates. A validated FTM Risk Score may help stratify patients by FTM risk to improve VA decision making. It is unclear how well the FTM Risk Score correlates with surgical opinion. We aimed to describe the FTM risks of primary and secondary AVFs and elucidate the relationship between the FTM Risk Score and surigcial opinion for these two subgroups.

Methods: Data was propsectively collected between 2006-2014 during VA clinics where 5 surgeons assessed patients for potential VA creation at an academic hospital. The FTM Score was determined for each patient ("FTM Score") while surgeons independently evaluated the patient's likelhood of AVF maturation as: Excellent, Good, Marginal, or Poor ("Surgeon Score"), which corrleated to the FTM Risk Score e.g. FTM Risk of "low" corresponded to Surgeon Score "Excellent". Descriptive statistics categorized the surgeon and clinician risk scores as low, moderate, high, or very high risk;overall Fleiss Kappa statistics were calculated (SPSS, V. 23).

Results: There were 355 primary AVF, 42 secondary AVF with both Scores collected and verified. Overall, the Risk Scores were: low risk-26%; moderate risk-41.5%; high risk-30.3%; very high risk-2.2%. The Risk Score had a Kappa agreement of 0.78 with the Surgeon Score ($p<0.001$). The categories of risks were similar (Table 1). The FTM Score and Surgeon Score had Kappas of 0.72 (primary) and 0.75 (secondary). Mean FTM Risk Score was 3.11 (primary) and 3.45 (secondary); mean Surgeon Score was 3.22 (primary and 3.64 (secondary).

Conclusions: The distribution of AVF failure risk was similar between the FTM Risk Score and Surgeon's clinical evaluation. However, the agreeement improved with secondary AVFs, suggesting that more clinical information from prior AVF outcomes improve clinical predication. The AVF outcomes according to FTM Risk Score and Surgeon Score are the focus of ongoing research.

TH-PO764

Prediction for Maturation of Arteriovenous Fistula by Vascular Ultrasonography Jae seok Kim,[5] Jun young Lee,[3] Byoung Geun Han,[1] Seung-Ok Choi,[4] Jae Won Yang.[2] *[1]None, Wonju, Republic of Korea; [2]Wonju Christian Hospital, Wonju, GANGWON-DO, Republic of Korea; [3]Wonju christian severance hospital, Wonju, Kangwon do, Republic of Korea; [4]Yonsei University Wonju College of Medicine, Wonju, Kangwon, Republic of Korea; [5]Yonsei wonju college of medicine, Won-ju, Republic of Korea.*

Background: Vascular access formation is an important step in starting hemodialysis therapy. However, because most patients with end stage renal disease have poor vascular condition, the rate of success in maturation of arteriovenous fistula (AVF) is lower than expected. We aim to investigate the predictors for successful AVF maturation through the ultrasound examination which was performed at pre and post AVF surgery.

Methods: We collected the data of vascular sonography from the seventy patients undergoing AVF formation surgery at Wonju Severance Christian Hospital in South Korea. We performed ultrasound vascular mapping as a pre-evaluation searching appropriate vessels for AVF, and followed it at around one-month after the surgery to evaluate whether the AVF is maturated possible to use for hemodialysis. In the ultrasonography, we measured the diameter of artery (A1) and vein (V1) before surgery, and feeding artery (A2) and AVF (V2) after AVF formation. Additionally, we evaluated blood flow (Bf) of AVF and calculated the change of diameter in artery (A2-A1, delta A) and vein (V2-V1, delta V).

Results: Thirty-seven men and thirty-three women comprised of the subjects. The mean age was fifty-nine years old. We defined the cases with Bf<600 mL/min as a poor maturation group and the other cases with Bf>600 mL/min as a good maturation group. The independent T-test showed that there were significant differences in the parameters of A2 (poor vs. good; 4.0±1.1 vs. 5.1±1.2 mm, $p=0.003$), delta A (0.7±0.6 vs. 1.2±0.7 mm, $p=0.025$), V2 (4.5±0.9 vs. 5.7±1.3 mm, $p<0.001$) and delta V (1.3±0.7 vs. 2.1±1.2 mm, $p=0.001$) between the poor and good maturation groups. ROC analysis demonstrated that 4.0 mm of A2, 0.6 mm of delta A, 4.9 mm of V2 and 4.2 mm of delta V were suggested to predict good AVF maturation. In pearson's correlation analysis, Bf of AVF had the positive relationships with A1 ($p=0.005$), A2 ($p<0.001$), delta A ($p<0.001$), V1 (0.002) and V2 ($p<0.001$). In regression test, the results demonstrated that delta A best predict the success in the AVF maturation.

Conclusions: In conclusion, the change of the arterial diameter between before and after the AVF formation is the most important factor for AVF maturation.

TH-PO765

Influence of Arterial Dilatation on Fistula Maturation with Adequate Blood Flow: Supports Concept That Arterial Elasticity Has Key Role William D. Paulson,[1] Sulav Bastola,[3] Steven A. Jones.[2] *[1]Augusta University, Augusta, GA; [2]Louisiana Tech University, Ruston, LA; [3]Charu Polyclinic and Diagnostic Center, Kathmandu, Nepal.*

Background: Fistula maturation success is strongly dependent on adequate dilatation of the inflow artery and outflow vein. The Rule of 6s emphasizes an adequate vein luminal diameter is needed to allow successful cannulation. However, poor arterial elasticity is associated with maturation failure, probably because of failure of the inflow artery to dilate adequately. We further explored this issue by applying a mathematical model of the fistula in which the outflow vein dilates but the artery dilates minimally or not at all.

Methods: Mathematical model was a brachiocephalic fistula that included cephalic vein anastomosed end to side to the brachial artery; ulnar artery; palmar arch; and vein that drains the hand and connects to the cephalic vein. We set mean arterial pressure = 93 mmHg, central venous pressure = 5 mmHg. We predicted fistula blood flow at dilated vein luminal diameters ranging from 4 to 8 mm, and arterial diameters ranging from 2 to 6 mm. We also evaluated influence of stenosis at arteriovenous anastomosis on blood flow.

Results: A fistula with an arterial diameter of 2 mm is predicted to have a blood flow ranging from only 232 to 241 ml/min despite widely accepted adequate venous diameters ranging from 4 to 8 mm. Even arterial dilatation to 3 mm diameter will provide only marginal blood flows ranging from 581 to 665 ml/min. Flows in the range of 1,000 ml/min or more require an arterial diameter of at least approximately 4 mm. Development of stenosis at the arteriovenous anastomosis will significantly impair flow and thereby require even larger arterial diameters if blood flow is to be adequate.

Conclusions: These results support the concept that dilatation of the inflow artery is a key step in fistula maturation. Arterial properties are as important as venous in assessing suitability of vessels for fistula formation. Poor arterial elasticity may result in a high resistance fistula circuit despite adequate dilatation of the outflow vein. An arterial diameter of 2 mm is widely accepted as a minimally acceptable preoperative diameter, but such an artery cannot support adequate blood flow unless it is able to dilate.

Funding: Clinical Revenue Support

	Fistula blood flow (ml/min) at inflow artery luminal diameters ranging from 2 to 6 mm				
Vein diameter	2 mm	3 mm	4 mm	5 mm	6 mm
4 mm	232	581	971	1221	1352
6 mm	240	652	1344	2097	2715

TH-PO766

CKD-Mineral Bone Disorder and Risk of Maturation Failure in Hemodialysis Arteriovenous Fistula Chung-te Liu.[1,2] *[1]Division of Nephrology, Department of Internal Medicine, Wanfang Hospital, Taipei Medical University, Taipei, Taiwan; [2]Graduate Institute of Clinical Medicine, Collage of Medicine, Taipei Medical University, Taipei, Taiwan.*

Background: Arteriovenous fistula (AVF) is the preferred vascular access for hemodialysis. However, instant usability of this vascular access type is limited by high rates of maturation failure. Chronic kidney disease-mineral bone disorder (CKD-MBD) is associated systemic vascular calcification and increased mortality in dialysis patients. While CKD-MBD correlates with cardiovascular disease in dialysis patients, the association between CKD-MBD and maturation failure of AVF remains to be elucidated.

Methods: A retrospective cohort study was conducted to enroll patients receiving AVF creation and maintenance hemodialysis in Wanfang Hospital, Taipei Medical University from January, 2004 to February, 2017. The outcome of the study was maturation failure of AVF, which was defined as non-usage of the AVF for hemodialysis from its creation to the establishment of another hemodialysis vascular access. Predictors included baseline demographic profiles and laboratory data. Categorical and continuous variables were compared using chi square test and two-tailed t-test for unpaired samples, respectively. The association of predictors to outcome was tested using logistic regression.

Results: During the study period, 408 patients receiving AVF creation and maintenance hemodialysis were included. Among the included patients, the mean age was 56.6±13.7 years. In addition, 56.4% were male and 49.3% had diabetes. Fifty-nine (14.5%) patients had maturation failure. Compared with patients with mature AVF, the maturation failure patients had significantly more diabetes, higher serum glucose and parathyroid hormone (PTH) levels. Serum calcium, phosphorus and other laboratory tests were not significantly different between the two groups. Univariate logistic regression showed that diabetes and serum PTH were significantly associated with maturation failure. In multivariate logistic regression, only PTH remained significantly associated with maturation failure. The above findings showed that higher PTH level was associated higher risk of AVF maturation failure.

Conclusions: This study preliminarily showed the association between higher PTH level and AVF maturation failure. This finding indicate that secondary hyperparathyroidism may have detrimental effect on successful rate of AVF creation.

TH-PO767

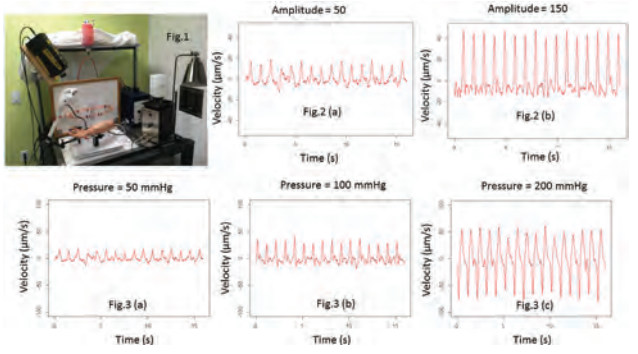
Feasibility of Laser Doppler Vibrometry to Quantitate Arterio-Venous Fistula Thrill Israel Campos,[1] Schantel Williams,[1] Laura Rosales,[1] Fansan Zhu,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Clinical examination is the corner stone of identifying arterio-venous fistula (AVF) pathologies and recognizing changes in AVF thrill carries important information. While currently subjective, quantitating AVF thrill objectively may improve the diagnosis of AVF pathologies. AVF thrill is vibrational in nature and depends on AVF pressure and flow rate. The aims of this study was to evaluate how pressure and flow rate affect the vibrational characteristics.

Methods: In this bench study we used a 3D printed AVF cannulation simulator (Phacon, Germany) with artificial "skin" above the AVF and a pumping system to provide flow. In this study, the pump rate was set to 60 per minute. Two series of experiments were conducted. In one series the pressures varied and the flow was set constant. In a second series of experiments the pressure was set constant and the pumping amplitude varied. The motion characteristics (amplitude, velocity) of the artificial "skin" above the AVF were measured by laser Doppler vibrometry (PDV100, Polytec, Germany). The set-up is shown in Fig. 1.

Results: The laser Doppler vibrometry provided excellent high-resolution measurements of the "skin" movements. The "skin" movements clearly depended on both AVF pressure and stroke volume (Fig.2a, b and Fig.3a-c).

Conclusions: Our in vitro study demonstrates that, first, laser Doppler vibrometry can determine regional "skin" vibrations above AVF with high accuracy and precision. Second, vibration characteristics ("thrill") of the "skin" above the AVF depend on both flow and pressure. Clinical studies are required to extend these findings to hemodialysis patients with AVF as vascular access.



TH-PO768

Postoperative Vascularization of the Arteriovenous Fistula Is Not Associated with Maturation: A Pilot Study Juan C. Duque Ballesteros,[2] Laisel Martinez,[2] Angela Paez,[2] Marwan Tabbara,[2] Guillermo Selman,[1] Loay H. Salman,[1] Roberto I. Vazquez-Padron.[2] *[1]Albany Medical College, Albany, NY; [2]University of Miami, Miller School of Medicine, Miami, FL.*

Background: The venous vasa vasorum provides oxygen and nutrients to the walls of native veins and arteriovenous fistulas (AVF). Nonetheless, whether expansion or growth of the AVF microvasculature has an effect on clinical outcomes remains undetermined. The purpose of this study was to evaluate the association of AVF vascularization with maturation and with the development of medial fibrosis and intimal hyperplasia (IH).

Methods: We assessed pre-existing and postoperative vascularization in both native veins and AVF venous samples (*i.e.*, tissue pairs) from 19 patients undergoing two-stage AVF creation. Patients with successful maturation (N=9) and maturation failure (N=10) were matched with respect to age, demographics, and comorbidities. Vasa vasorum density (VVD; microvessel count/wall area) and area (VVA; microvessel luminal area/wall area) were quantified in the vascular layers of CD31-stained cross-sections. Change in vascularization after AVF creation was calculated by subtracting pre-existing VVD and VVA from the postoperative values in tissue pairs.

Results: Total VVD in native veins was 6/mm^2 (interquartile range [IQR] 2-10), with no significant change in AVFs as determined by pairwise comparisons (p=0.3). Total VVA increased during remodeling, from 956 um^2/mm^2 (IQR 509-1466) in native veins to 1879 um^2/mm^2 in AVFs (IQR 766-2578; p=0.046), with the most significant increase observed in the adventitia (1751 vs. 4798, respectively; p=0.004). AVF vascularization was not associated with baseline factors (age, ethnicity, sex, diabetes), nor with the time interval between AVF creation (first-stage) and transposition (second-stage) surgeries. Interestingly, although IH increased significantly in AVFs compared to veins (p=0.0003), microvessels were detected in the intima of only four AVFs and not in veins, and neither VVD nor VVA was associated with the degree of IH. Similarly, none of the vascularization parameters measured were associated with medial fibrosis. Lastly, there were no significant differences in VVD or VVA between AVFs with distinct maturation outcomes.

Conclusions: This study indicates that AVF vascularization is not a major contributing factor in remodeling after access creation, and it does not determine maturation.

Funding: NIDDK Support

TH-PO769

Outcome of Endovascular Salvage of Immature Hemodialysis (HD) Arteriovenous Fistulae (AVF) Hye Eun Yoon, Yaeni Kim, Byung ha Chung, Bumsoon Choi, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim. *The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: To assess the anatomical causes of immature AVF and the outcome of endovascular salvage.

Methods: Anatomical causes, clinical characteristics, and the success rate of endovascular salvage of 110 immature AVF were analyzed.

Results: A total of 110 patients included 52 females and 64 diabetics. The mean age was 63±13 years old. The access types were radiocephalic (n=62), brachiocephalic (n=45), and transposed brachiobasilic (n=3) fistulae. At the time of angiography, 75 patients were maintained on HD using catheters. Mean interval between AVF creation and referral to angiography was 94±69 days. Angiography revealed stenoses (n=49; 26 inflow, 9 outflow, and 14 mixed), accessory veins (n=16), and inadequate selection of vessels (n=2) in 62 patients with radiocephalic fistulae. It revealed stenoses (n=41; 14 inflow, 17 outflow, and 10 mixed), accessory veins (n=11), deeply located cephalic veins (n=2), and inadequate selection of vessels (n=4) in 48 patients with upper arm fistulae. Endovascular procedures performed in 107 patients included percutaneous transluminal angioplasty (PTA) (n=95) and accessory vein obliteration (n=27; 1 percutaneous, 12 surgical ligations, 14 coil insertions). The number of procedures was once in 83, twice in 17, and three times in 7 patients. The overall technical and clinical success rates were 95.2% and 92.3%. Mean interval between endovascular procedure and the first successful cannulation of the fistula was 26±17 days in patients on maintenance HD At 3, 6, 12, and 24 months following the first successful cannulation, the primary patency rates were 84.7%, 71.0%, 57.4%, and 39.7%, respectively. Assisted patency rates of 97.7%, 95.2%, 91.0%, and 79.0% and secondary patency rates of 98.9%, 97.5%, 96.1% and 91.4% at 3, 6, 12, and 24 months, respectively. Multivatiate Cox regression analyses revealed mixed stenosis to be the only determinant that affects secondary patency rate of immature AVF. Consistently, immature AVF with mixed stenosis showed poorer access outcome in terms of secondary patency rate compared with that of no mixed stenosis. ($p < 0.001$)

Conclusions: Immature AVF can be salvaged by aggressive and timely intervention. Endovascular procedures can salvage the majority of cases with high success and patency rates. The presence of mixed stenosis is associated with poor access outcome.

TH-PO770

Tailored Selection of Elevation Transposition and Lipectomy for Superficialization of Cephalic Arteriovenous Fistula Veins Shouwen Wang. *Arizona Kidney Disease and Hypertension Center, Phoenix, AZ.*

Background: Cephalic vein arteriovenous fistulas are the most commonly used vascular accesses for hemodialysis. However, as high as 34% of these fistulas are situated too deep under the skin and require superficialization before use. Various superficialization techniques have been employed, such as tunnel transposition, elevation, elevation transposition, and lipectomy. Each of these techniques may have advantages and disadvantages, and there have been few reports comparing their outcomes. This report compares the clinical outcomes of cephalic elevation transposition (CET) vs lipectomy and discusses tailored selection of these techniques.

Methods: The clinical data of patients who underwent second-stage cephalic vein elevation transposition or lipectomy at an ambulatory surgery center were collected and analyzed. The patients who underwent basilic elevation transposition (BET) were included for comparison with CET.

Results: A total of 240 patients were included. Comparing the CET group (n=118) vs the lipectomy group (n=28) vs the BET group (n=94): males were 28% vs 32% vs 59%; the mean age was 58.0±14.1 vs 56.3±12.1 vs 60.0±15.0; the mean body mass index was 36.9±7.8 vs 38.1±7.2 vs 26.8±6.9; the percentages of upper arm fistulas were 84% vs 61% vs 100% and of the forearm fistulas were 16% vs 39% vs 0%; and the mean follow-up was 18.8±17.6 vs 37.1±24.4 vs 24.6±20.0 months. For the CET vs the lipectomy vs the BET groups, the primary patency rates of the whole fistula conduit were 40% vs 49% vs 44% at one year and 17% vs 37% vs 37% at three years; the assisted primary patency rates were 93% vs 96% vs 97% at one year and 78% vs 96% vs 88% at three years; the secondary patency rates were 99% vs 100% vs 100% at one year and 92% vs 100% vs 98% at three years; the primary patency rates of the superficialized fistula vein segments were 72% vs 67% vs 65% at one year and 57% vs 51% vs 53% at three years; and the mean numbers of percutaneous interventions required for the superficialized fistula vein segments were 0.55±1.10 vs 0.43±0.71 vs 0.60±1.02 per access-year.

Conclusions: CET and lipectomy are reliable approaches for superficialization of cephalic fistula veins that yield high cumulative fistula survival rates, which are comparable to that of BET for basilic fistula veins. The selection of CET or lipectomy is mainly based on the location and depth of a fistula vein.

TH-PO771

Changes in Blood Pressures, Adequacy, and Blood and Dialysate Flow Rates before and after Arteriovenous Access Angioplasty Hao Han,[1] Tommy C. Blanchard,[1] Hanjie Zhang,[3] Murat Sor,[2] Elsie Koh,[2] Yue Jiao,[1] Sheetal Chaudhuri,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Peter Kotanko,[3] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Vascular Care, Malvern, PA; [3]Renal Research Institute, New York, NY.*

Background: Stenosis is a common complication in arteriovenous fistulas and grafts (AVFs/AVGs), and is a major cause of hospitalizations and dialysis access failure. Clinical predictors for early detection of severe stenosis in AVFs/AVGs are sparse. To determine predictors of stenosis, we investigated trends in levels of predialysis systolic and diastolic blood pressures (preSBP/preDBP), dialysis adequacy, blood flow rate (Qb), and dialysate flow rate (Qd) before and after angioplasties in hemodialysis (HD) patients.

Methods: We analyzed data from 7,910 Fresenius Kidney Care HD patients who had an AVF/AVG angioplasty in 2015 and 2016. The preSBP, preDBP, Kt/V, Qb, and Qd were tracked in HD patients for 90 days before and after an angioplasty, and plotted using a penalized B-spline to fit the mean with 95% confidence limits.

Results: During the 90 days prior to an angioplasty, HD patients exhibited a slight decline of approximately 1.5 mmHg in both mean preSBP and preDBP. The most precipitous decline for both preSBP and preDBP was in the final 2 weeks prior to angioplasty. About a week after an angioplasty, mean preSBP and preDBP increased by approximately 1.0 mmHg and 0.5 mmHg, respectively. The preSBP blood pressures at 90 days after an angioplasty were found to decrease by about 0.5 mmHg below the levels seen 2 weeks before an angioplasty. We also observed similar findings for all parameters; specifically, the following changes occurred after angioplasty compared to before angioplasty: i) average Kt/V increased by about 1%; ii) average Qb increased by about 1%; and iii) average Qd increased by approximately 0.5%.

Conclusions: These findings indicate that blood pressures, Kt/V, Qb and Qd decline before and increase after an AVF/AVG stenosis requiring an angioplasty. While

individually these are small changes in patient parameters, they can be useful for creation of comprehensive AVF/AVG stenosis prediction models. Nonetheless, further analyses are needed to confirm these observations and assess their usefulness.

TH-PO772

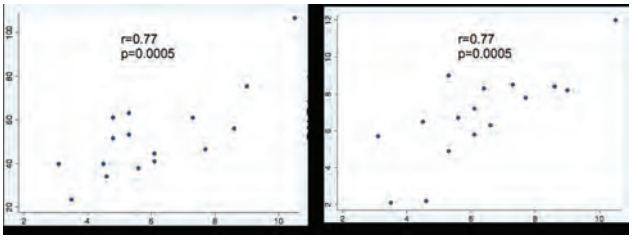
Arterial Diameter Following AVF Creation May Predict Aneurysmal Formation Alexis M. Cahalane, Vivek G. Sahani, Zubin Irani, Jie Cui. *Massachusetts General Hospital, Boston, MA.*

Background: Aneurysmal formation in arteriovenous fistulae (AVF), which is the preferred vascular access for hemodialysis in end-stage renal disease, can lead to insufficient hemodialysis, risk of rupture and access abandonment.

Methods: This retrospective chart review study looked at patients with AVF aneurysmal dilatation requiring surgical correction between 01/01/2014 and 07/30/2016. All fistulogram images were reviewed and the diameter of the feeding artery, venous outflow, maximum aneurysmal segment (AnS), and length of AnS were measured. Location of any stenotic lesions were also recorded.

Results: 10 female and 17 male patients were identified. 21 patients (77.78%) had brachiocephalic fistula and 6 had radiocephalic fistula (22.22%). Mean interval between surgical creation of the AVF and access revision was 1411± 955days. On the first fistulogram, there was a significant correlation between diameter of feeding artery and diameter of fistula (r=0.51, p=0.02), the maximum diameter of the aneurysm (r=0.67, p=0.03) and the length of the AnS (r=0.92, p=0.0001). The most common venous outflow lesion was cephalic arch stenosis (64.7%), while 7 patients had no outflow stenosis. Interval between first recorded fistulogram and surgical revision was 818 days. On the presurigical fistulagram the diameter of the artery was strongly correlated with the diameter of the artery in the first fistulogram (Figure 1A, p<0.05). Furthermore, the length of the AnS on the last fistulogram also correlated with the diameter of the artery in the first fistulogram (Figure 1B).

Conclusions: Aneurysm formation is a long-term complication of AVF. In AVF created using the cephalic vein, cephalic arch stenosis was the most common stenotic lesion. The diameter of the feeding artery at time of the first fistulogram can predict the likelihood of aneurysm formation and its calibre. AVF with relative larger arterial diameter should be closely monitored for aneurysm formation and early intervention may avoid loss of the access.



TH-PO773

Vein Grafting – A Novel Approach for Forearm Dialysis Arteriovenous Fistula Creation Jian Chen, Jie Tang. *University Medicine, Brown University, Providence, RI.*

Background: With the growing need for reliable and durable forearm hemodialysis access, here we describe a novel "autologous vein grafting" technique for the creation of forearm arteriovenous fistula (AVF).

Methods: All study participants failed to have native distal cephalic or basilic veins large enough for forearm AVF creation. Therefore, we harvested a segment of contralateral forearm mid-basilic vein or leg great saphenous vein from the same patient, and performed an end-to-side anastomosis to the radial artery and an end-to-end anastomosis to the mid-cephalic or basilic vein to create a forearm AVF. We identified patients who underwent this procedure between January 2014 and January 2016, and report measurements of fistula diameter (at 1 cm from the arterial anastomosis) and doppler flow at 6 weeks and 3 months after surgery, as well as 1-year primary unassisted patency, cumulative patency, and complications.

Results: We identified a total of 7 study participants. 6 underwent surgeries for radiobasilic AVF and 1 for radiocephalic AVF. Among the 6 who had radiobasilic AVF, 5 used contralateral forearm basilic vein segments, 1 used great saphenous vein segment. The one with the radiocephalic AVF used great saphenous vein. The diameters of their native forearm distal cephalic or basilic veins were <1.5mm, and the mean diameter of harvested vein graft segments was 2.4 mm (range 2.1-3.9 mm). 6 weeks after surgery, the mean diameter of AVF was 5.1 mm (range 4.6-5.3 mm), the mean fistula flow was 684 ml/min (range 521-772 ml/min). 3 months after surgery, the mean diameter of AVF was 5.2 mm (range 4.8-5.5 mm), the mean fistula flow was 756 ml/min (range 627-820 ml/min). The 1-year primary unassisted patency was 86%, and cumulative patency was 100%. There have been no complications reported.

Conclusions: Autologous vein grafting appeared to be an effective way to create a forearm AVF.

Racial and Gender Disparities in Initial Hemodialysis Access among Medicare Beneficiaries Silvi Shah, Anthony C. Leonard, Charuhas V. Thakar. *University of Cincinnati, Cincinnati, OH.*

Background: Arteriovenous (AV) access confers survival and economic benefits over catheters in incident hemodialysis (HD) patients. However, after considering the influence of pre-dialysis health status (defined as nephrology care and acute care hospitalizations), the effects of race and gender in the utilization of HD access is not known.

Methods: We evaluated 47,602 adult incident HD patients (1/1/2008 to 12/31/2008) from the United States Renal Data System (USRDS) with linked Medicare data for at least 2 years prior to HD initiation. Information on pre-dialysis health status was obtained from form 2728 and linked Medicare claims. Using case-mix adjusted logistic regression models; we examined the effects of race and gender on type of vascular access (arteriovenous [AV] access vs. catheter) at HD initiation.

Results: The majority of patients were male (55%) and White (62%). Catheter was the dominant access method used to initiate HD (82% vs. 18% AV access). A higher rate of Blacks (19%) and Asians (19%) initiated HD with AV access than did Whites (17%), Native Americans (16%) or Hispanics (15%) (unadjusted p<0.001). Pre-dialysis nephrology care was received by 58% of patients; and was associated with higher rate of AV access for initial HD than those without pre-dialysis nephrology care (27% vs. 4%, p<0.001). Acute hospitalization during the 2 years prior to HD initiation occurred in 89% of patients; and was associated with lower rate of AV access than those without pre-dialysis acute hospitalization (15% vs. 40%, p<0.001). In adjusted analyses, Blacks were more likely than Whites (odds ratio [OR], 1.10; 95% confidence interval [CI], 1.03-1.17) and Hispanics were less likely than Whites (OR, 0.82; CI, 0.74-0.90) to initiate HD with AV access. Similarly, females were less likely to initiate HD with AV access than were males (OR, 0.83; CI, 0.72-0.87).

Conclusions: Among Medicare beneficiaries', Blacks are more likely than Whites to use AV access for first outpatient HD; whereas Hispanics are less likely than Whites and females are less likely than males to initiate HD with AV access. These differences across race and gender are independent of pre-dialysis health status, among other factors. Further investigation of biological and process of care factors is warranted to reduce these disparities.

TH-PO775

Effects of Denosumab in Osteoporotic Hemodialysis (HD) Patients with Secondary Hyperparathyroidism (SHPT) Satoshi Funakoshi,[2] Naoto Taguchi,[2] Jyunichiro Hashiguchi,[2] Makiko Yamashita,[2] Tayo Kawazu,[2] Osamu Sasaki,[2] Hiroshi Ichinose,[2] Kenji Sawase,[2] Yoko Obata,[1] Tomoya Nishino,[1] Takashi Harada.[2] *[1]Nagasaki University School of Medicine, Nagasaki, Japan; [2]Nagasaki Kidney Center, Nagasaski, Japan.*

Background: Denosumab, a human monoclonal antibody which binds to RANKL, inhibits osteoclast differentiation/activation and exerts primarily anti-resorptive action. Denosumab also inhibits bone formation and hence may correct high bone turnover observed in HD patients. Meanwhile serum markers for bone metabolism are reported to correlate with PTH but not with circulating fibroblast growth factor 23 (FGF23), which decreases bone mineralization and is markedly increased in HD patients.

Methods: Among HD patients with secondary hyperparathyroidism (SHPT) who received intravenous pulse therapy with vitamin D (VD) analogues, those with bone mineral density < 70% YAM were enrolled in this study after their informed consent was obtained. Serum calcium, phosphate, PTH, bone metabolism markers and FGF23 were measured before and 4 weeks after subcutaneous administration of 60mg of denosumab.

Results: A steep decline in serum calcium levels was observed in all 16 subjects (5 males and 11 females; mean age, 66.7±7.4 years old; mean HD duration, 11.4±7.6 years), and calcium-based phosphate binders and VD analogues were started to adjust their calcium levels. After 4 weeks of denosumab administration, significant decreases were seen in the bone resorption markers TRCP-5B and NTX, and the bone formation markers BAP and P1NP as well as in PTH; furthermore, FGF23 was significantly decreased (table).

Conclusions: Study results suggest that denosumab may potentially correct bone turnover in osteoporotic HD patients with SHPT. A possible explanations for decreased FGF 23 could be that the addition of calcium-based phosphate binders lowered the phosphate burden in HD patients and that VD signaling resulted in a negative feedback loop within FGF family.

Hemodialysis (HD) Treatment Can Improve Taste Sensitivity to Salt – Assessment by the Filter Paper Disc (FPD) Method Satoshi Funakoshi,[1] Kenta Torigoe,[2] Miki Torigoe,[2] Asami Nakamura,[1] Makiko Yamashita,[1] Osamu Sasaki,[1] Hiroshi Ichinose,[1] Kenji Sawase,[1] Takashi Harada,[1] Yoko Obata,[2] Tomoya Nishino,[2] Jyunichiro Hashiguchi.[1] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki University Hospital, Nagasaki, Japan.*

Background: Several studies in chronic uremic and HD patients indicate decreased taste sensitivity. However, whether a single HD session can improve their sensitivity or not warrants investigation. The aim of this study was to determine if the taste sensitivity to salt is affected by HD treatment in maintenance HD patients by using FPD method, a reliable method to measure taste with a high degree of reproducibility.

Methods: All subjects were assessed for their taste sensitivity to salt by the FPD method before and after HD sessions. Filter paper discs prepared with different concentrations of sodium chloride from 0.6 mg/cm^2 (level 1) to1.6 mg/cm^2 (level 6) for scoring, and the lowest level at which taste was identified was defined as the taste threshold to salt. Relevant clinical parameters were determined in each patient, and the correlation to the taste sensitivity was analyzed.

Results: At our Facility, 122 HD patients (mean age, 66.5±28.2 years old; mean HD duration, 12.0±9.5 years) were assessed for taste sensitivity by FPD method. According to the taste threshold subjects were diagnosed as normal (score <2), moderately impaired (score 3-4) and severely impaired (score >5). As shown in table, a significant decrease in taste threshold to salt was observed in the moderately - severely impaired group, but not in the group with normal taste sensitivity to salt. There was no correlation between altered taste sensitivity and various parameters including age, gender, HD vintage, serum zinc and prescribed medications.

Conclusions: Our findings suggest that HD treatment favorably affects tasting function by improving uremia. It remains to be seen whether taste sensitivity is correlated with various clinical factors in HD patients.

Factors Associated with Gastrointestinal Bleeding in ESRD Patients Tommy C. Blanchard, Teresa A. Nash-Hampton, Ashish Goulatia, Jay Ray, Len A. Usvyat, Dugan Maddux, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Gastrointestinal (GI) bleeding is a serious problem among patients with End Stage Renal Disease (ESRD), affecting this population at rates almost two orders of magnitude higher than in the general population (Yang et al., 2012). We aimed to characterize the demographic, treatment, and laboratory parameters in dialysis patients with GI bleeds and build prediction models that could identify patients at a higher risk of experiencing a GI bleed.

Methods: We analyzed data on all dialysis patients treated at Fresenius Medical Care North America dialysis clinics as of December 2016. We used a logistic regression with 40 variables including demographics, comorbidities, treatment parameters and laboratories to identify factors highly associated with GI bleeds and measured the effect size. Variables on treatment and laboratory parameters were determined from mean values at 90 to 183 days prior to December 2016.

Results: We studied data from 141,973 dialysis patients, of which 0.7% were diagnosed with a GI bleed. We found that lower hemoglobin, calcium, and transferrin saturation (TSAT) values were associated with GI bleeds. Variability in calcium and hemoglobin (using standard deviation) was also associated with GI bleeds. Further, GI bleeds were more common among those diagnosed with ulcers and with older patients. When tested on a held-out set of 50% of the data, the model was able to accurately predict which patients have a GI bleed with a receiver operating characteristic area under the curve of 0.81.

Conclusions: Our analysis identifies several factors associated with GI bleeds in dialysis patients, which may be useful for predicting patients who are likely to experience a GI bleed. Further research validating the accuracy of the prediction of patients with GI bleed is needed to confirm these findings.

T Regulatory Cells in Uremia: Effect of the First Dialysis Session Carlotta Caprara,[2] Elisa Scalzotto,[2] Anna chiara Frigo,[3] Francesca Paderi,[2] Fiorenza Ferrari,[2] Valentina Corradi,[1,2] Claudio Ronco.[1,2] *[1]Hospital, San Bortolo Vicenza, Vicenza, Italy; [2]IRRIV, Vicenza----, Italy; [3]University of Padova, Padova, Italy.*

Background: In the literature, contrasting results have been reported about the influence of dialysis on Treg cells in chronic kidney disease stage G5 patients (CKD G5) that show activated but impaired immune system. Moreover the influence of dialysis on T cells needs further investigation.

Methods: A total of 22 CKD G5 patients that have to start dialysis (8 HD and 14 PD) were enrolled. Treg were studied by flow cytometry with: CD3(PerCP); CD4(FITC); CD25(PECy7); CD127(PE) and FOXP3(APC) antibodies. Time point: T0 (before the first dialysis treatment) for HD and PD; T1 (after the first dialysis); T2 (after 48 hours) and T3 (after 1 month) for HD; T1 (after 48 hours) and T2 (after 1 month) for PD.

Results: Medians for Treg/CD4+ ratio (%) in HD pts are: 7.405 (5.220; 18.940)(T0); 6.26 (3.55; 14.12)(T1), 8.140 (4.190; 17.210)(T2); 9.305 (3.840; 12.050)(T3); in PD are: 5.36 (2.96; 9.37)(T0); 4.98 (2.22; 8.69)(T1); 6.17 (1.65; 9.97)(T2). The ratio Treg/CD4 didn't change during time of the study (HD: p= 0.6310; PD: p= 0.4191). While, as showed in Fig.1, we observed a trend in increase Treg number, more evident in HD, between T0 and after 1 month of treatment. Medians for Treg absolute number (cells/μl) in HD are: 349.895 (42.910; 912.240)(T0); 194.595 (57.150; 1266.850)(T1); 199.905 (43.700; 961.160)(T2); 659.60 (160.04; 1039.86)(T3); in PD are: 194.970 (16.420; 250.880)(T0); 90.535 (34.530; 444.640)(T1); 281.63 (19.75; 575.51)(T2). This difference didn't reach significativity (HD: p= 0.16; PD: p=0.3995).

Conclusions: For the first time the same patient was analyzed during time before and after the first dialysis treatment. It seems that heamodialysis treatment improve T cells status, increasing Treg absolute number, while it does not interfere with Treg/CD4 ratio. Due to extreme variability of Treg values and poor number of patients we need further analysis.

Outcomes in ESRD Patients on Hemodialysis Taking Patiromer for Hyperkalemia Dinesh K. Chatoth,[1] Peter M. Wahl,[2] Viatcheslav Rakov,[3] Carly R. Van Zandt,[4] Kathryn P. Anastassopoulos,[2] Sam Colman,[2] Tyler Knight,[2] Nina Oestreicher,[5,6] Ann Mooney,[4] David M. Spiegel,[5] Matthew R. Weir.[7]
[1]Fresenius Medical Care North America, Waltham, MA; [2]Covance Market Access Inc., Gaithersburg, MD; [3]Vifor Pharma, Glattbrugg, Switzerland; [4]Frenova Renal Research, Waltham, MA; [5]Relypsa Inc., a Vifor Pharma Company, Redwood City, CA; [6]University of California, San Francisco, San Francisco, CA; [7]University of Maryland Medical Center, Baltimore, MD.

Background: Real-world data on hyperkalemia (HK) treatment with patiromer in dialysis patients in the United States (US) are limited. We sought to examine outcomes of end-stage renal disease (ESRD) patients on hemodialysis (HD) and treated with patiromer for HK at US Fresenius Kidney Care (FKC) centers.

Methods: We identified adult patients who initiated patiromer between 10/1/2015 and 7/31/2016; were prescribed permanent in-center HD ≥3 times per week; and had ≥1 serum potassium (sK) lab value in the 91 days prior to patiromer initiation (baseline). We examined changes from baseline in sK values and potassium (1K) baths over 6 months.

Results: Among 268 patients included in the analysis, mean age was 57.5 years, 55.2% male, and 77.2% white, with a mean of 4.9 years on dialysis. Median patiromer daily dose was 8.4 g/day. Overall, sK decreased by 0.5 mEq/L (decrease of 0.8 and 1.7 among those with baseline sK >5.5 and sK >6.5, respectively) (Table 1). Unobserved events may have prompted treatment in patients with baseline sK <5.5 mEq/L. The percentage of patients treated with 1K baths decreased by 2.2%.

Conclusions: These results demonstrate that treatment with patiromer lowers sK levels in real-world settings, with the greatest effect among patients with sK >6.5 mEq/L. The predominant use of the recommended starting dose (8.4 g/day) supports the feasibility of this dose for long-term (≥6 months) sK control.

Patient Characteristics and Correlates of Patiromer Initiation for Hyperkalemia in Hemodialysis Christopher G. Rowan,[1] Wolfgang C. Winkelmayer,[2] Nina Oestreicher,[3,4] Viatcheslav Rakov,[5] Jeffrey J. Connaire,[6] David M. Spiegel,[3] Csaba P. Kovesdy.[7]
[1]COHRDATA, Santa Monica, CA; [2]Baylor College of Medicine, Houston, TX; [3]Relypsa Inc., a Vifor Pharma Company, Redwood City, CA; [4]University of California, San Francisco, San Francisco, CA; [5]Vifor Pharma, St. Gallen, Switzerland; [6]DaVita Clinical Research, Minneapolis, MN; [7]University of Tennessee, Memphis, TN.

Background: Patiromer is a novel potassium-binding polymer for treatment of chronic hyperkalemia. We retrospectively compared U.S. hemodialysis (HD) patients (pts) who initiated patiromer *vs* sodium polystyrene sulfate (SPS) in typical practice.

Methods: We identified new users of patiromer or SPS between 12/2015-12/2016 from a large U.S. dialysis provider. Baseline characteristics were obtained in the year prior to the 1st patiromer or SPS order. We identified correlates of patiromer *vs* SPS using multivariable logistic regression.

Results: Pts initiating patiromer *vs* SPS were less likely to be black, more likely to use a dialysate K^+<2 mEq/L; had higher serum K^+, and more electrolyte-related hospitalizations (Table). Having ≥3 serum K^+ tests ≥5.0 was associated with 5x the odds of initiating patiromer *vs* SPS (Figure).

Conclusions: Multiple hyperkalemia episodes and a recent SPS order were associated with patiromer initiation. Patiromer may be used predominantly in HD pts with more severe hyperkalemia who failed SPS. Studies are needed to determine the clinical impact of patiromer.

Association of Continuation of Loop Diuretics at Hemodialysis Initiation with Clinical Outcomes Steven M. Brunelli,[1] Scott Sibbel,[1] Adam G. Walker,[1] Carey Colson,[1] Francesca Tentori,[1] Jennifer E. Flythe.[2]
[1]DaVita Clinical Research, Minneapolis, MN; [2]University of North Carolina Kidney Center, Chapel Hill, NC.

Background: Loop diuretics are commonly utilized in the management of non-dialysis dependent chronic kidney disease. Despite potential benefits of augmented urine output, loop diuretics are often discontinued after hemodialysis initiation. In the present study, we assessed the association of the early decision to continue vs discontinue loop diuretics at dialysis start with clinical outcomes during the first year of dialysis.

Methods: This analysis considered all patients who initiated in-center hemodialysis at a large dialysis organization (2007-2013) with Medicare part A & D benefits who had an active supply of loop diuretic at the time of dialysis initiation (N = 11,297). Exposure status was based on whether loop diuretic prescription was refilled after dialysis initiation and within 30 days of exhaustion of prior supply. Patients were followed under an intention-to-treat paradigm for up to 12 months for death, hospitalization, and intradialytic hypotension (IDH).

Results: We identified 5219 patients who refilled a loop diuretic prescription and 6078 eligible controls who did not. After adjustments for case mix and clinical differences, continuation of loop diuretics (vs not) was associated with lower hospitalization (P < 0.001) and IDH (P < 0.001) rates, and a lower death rate which did not achieve statistical significance (P =0.07).

Conclusions: Among incident hemodialysis patients, continuation of loop diuretics in the immediate post-transition period was associated with lower rates of hospitalization and IDH over the first year of dialysis. The practice of discontinuing loop diuretics should be re-evaluated.

The Influence of Frailty and Body Composition on Risk of Mortality in Incident Hemodialysis Patients Jessica Fitzpatrick,[1] Stephen M. Sozio,[2] Bernard G. Jaar,[2] Michelle M. Estrella,[3] Jose M. Monroy-Trujillo,[2] Dorry L. Segev,[2] Rulan S. Parekh,[1] Mara McAdams-DeMarco.[2] *[1]University of Toronto, Toronto, ON, Canada; [2]Johns Hopkins University, Baltimore, MD; [3]UCSF/San Francisco VA Medical Center, San Francisco, CA.*

Background: Increased body mass index (BMI) is associated with lower risk of mortality in end stage renal disease (ESRD). Frailty is a phenotype of decreased physiologic reserve common among hemodialysis (HD) patients and associated with sarcopenia in this population. We sought to understand the role of body composition on mortality among frail and non-frail incident HD patients.

Methods: This study included 370 incident HD patients enrolled in the Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) Study. Frailty was defined as presence of ≥ 3 of the following: shrinkage, weakness, reduced gait speed, exhaustion, and low physical activity. General and abdominal adiposity were assessed with BMI and waist-to-hip ratio (WHR), respectively. Proportional hazards regression was used to estimate the association of frailty and WHR with all-cause mortality.

Results: The mean age was 55 years, 42% were female, 73% were African American, 57% had diabetes, the mean comorbidity index was 5.2, and 52% were frail. BMI, but not WHR, was higher (P<0.05) among frail vs. non-frail participants. There were 81 deaths over a mean of 2.5 years of follow-up. Frailty, but not WHR, was associated with higher mortality risk. There was no evidence of an interaction between frailty and BMI (P=0.33) or WHR (P=0.88). There was, however, a trend for stronger association between frailty and mortality among those above the median WHR.[Figure]

Conclusions: Frailty was associated with higher risk of mortality independently of WHR and BMI. These results suggest that general and central adiposity do not mitigate the influence of frailty on mortality among HD patients.

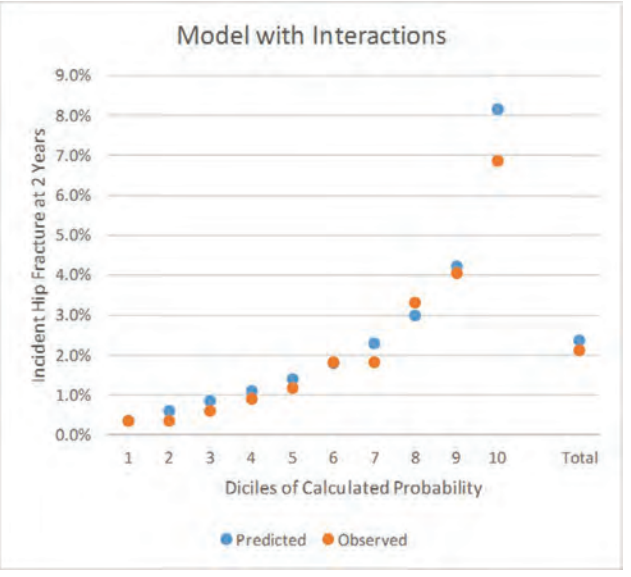
FRAX-HD: A Two-Year Incident Hip Fracture Risk Assessment Tool for Japanese Hemodialysis Patients Naohiko Fujii,[2] Takayuki Hamano,[3] Ikuto Masakane.[1] *[1]Honcho-Yabuki Clinic, Yamagata, Japan; [2]Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan; [3]Osaka University Graduate School of Medicine, Suita, Japan. Group/Team: Committee of Japanese Renal Data Registry, Japanese Society for Dialysis Therapy.*

Background: Dialysis patients are at 5-to-6-fold higher risk of hip fracture than general population. FRAX® is a useful tool for assessing future fracture risk; however, it is not optimized for hemodialysis (HD) patients. Our aim was to create a 2-year risk assessment tool for hip fracture among Japanese HD patients (FRAX_HD).

Methods: We extracted patients on facility-based HD, aged 20-100, with ≥1 yr of vintage at the end of 2007 using the Japanese nation-wide dialysis registry (JRDR-08102). Hip fractures were detected annually up to 2 years by questionnaire. We excluded patients who later received cinacalcet during the follow-up period, and randomly-selected 60%, 20%, and 20% of the eligible subjects to generate TRAIN, VALIDATE, and TEST sets, respectively. Multivariable Poisson regression analyses with interaction terms were performed to create prediction models, and validation was done later.

Results: TRAIN, VALIDATE, and TEST sets included 73999, 24667, and 24665 patients and 1574, 525, and 524 hip fractures, respectively. The subjects, aged 65.2 ± 12.3, included 39% of female and 34% of diabetes, with median vintage of 5.6 yrs. In TRAIN set, there were significant interactions between sex and age, sex and prior PTX/PEIT, and diabetes and vintage. Incidence rate ratio (IRR) elevated with age more prominently in female than in male (IRR 5.62 [95%CI: 3.32, 7.91]; females aged ≥80 vs. males aged <50). Prior history of PTX/PEIT was associated with lower risk only in female (IRR 0.58 [0.36, 0.81]). The model including these interactions demonstrated best performance and was selected as final model, which also achieved similar results in TEST set (AUC 0.739).

Conclusions: We successfully generated a 2-year risk assessment tool for hip fracture among HD patients. Further refinement and sensitivity analyses are required before its clinical application.



TH-PO784

Fracture Rates and Post-Discharge Outcomes Among Patients Undergoing Hemodialysis Across Etiologies of Kidney Diseases Berenice Y. Gitomer,[1] Lorien S. Dalrymple,[5] Zhiying You,[8] Norma J. Ofsthun,[6] Franklin W. Maddux,[4] Tamara Isakova,[3] Isidro B. Salusky,[7] Myles S. Wolf,[2] Michel Chonchol.[9] *[1]Div. Renal Diseases and Hypertension, Aurora, CO; [2]Duke University, Durham, NC; [3]Feinberg School of Medicine, Northwestern University, Chicago, IL; [4]Fresenius Medical Care, Waltham, MA; [5]Fresenius Medical Care NA, Waltham, MA; [6]Fresenius Medical Care North America, Waltham, MA; [7]Mattel Children's Hospital, Los Angeles, CA; [8]UC Denver, Aurora, CO; [9]University of Colorado, Aurora, CO.*

Background: We have previously identified a low bone turnover state in patients with autosomal dominant polycystic kidney disease (ADPKD) and normal kidney function based on histomorphometric measurements. This is indicated by both decreased indices of bone formation and resorption measured in trabecular bone. However, the rates and risk of fracture have not been characterized in ADPKD patients compared to other etiologies of kidney disease among hemodialysis patients.

Methods: The cohort included incident in-center hemodialysis patients aged 18–100 years with kidney disease secondary to diabetes, hypertension, glomerulonephritis (GN) or ADPKD starting hemodialysis at Fresenius Medical Care Norh America 2000-2013. Cohort was followed through 2014 for the first fracture-related hospitalization and up to one additional year for post-fracture mortality. Fractures were identified using ICD-9-CM diagnosis codes. Fracture rates were calculated within strata of etiology of kidney disease. Among patients with complete data, one year mortality following hospital discharge was examined using Cox regression models.

Results: A total of 10,131 fracture-related hospitalizations were observed during follow-up. Age, gender, and race adjusted fracture rates per 1,000 person-years (PYs) varied across etiology of kidney disease: patients with ADPKD had the lowest rate (8.1, 95% CI 6.6-10.0) and patients with diabetes had the highest rate (12.3, 95% CI 11.4-13.4). Patients with hypertension and GN had fracture rates of 8.8 (95% CI 8.1-9.6) and 8.9 (95% 7.9-9.9), respectively. Patients with ADPKD had a significantly lower adjusted incident rate ratio (aIRR) of fractures compared with patients with diabetes [aIRR: 0.66 (053, 0.82); p=0.0002]. After adjustment for demographics, vintage, comorbidities, albumin and measures of mineral metabolism, the mortality in the first year post-discharge for a

fracture-related hospitalization was lower in patients with ADPKD compared to patients with diabetes (HR 0.65 95% CI 0.46-0.92; p=0.01).

Conclusions: The decrease in bone formation rate observed in patients with early ADPKD does not appear to increase the risk of fracture or portend a worse prognosis among those who survive hospitalization when compared to other etiologies of kidney disease.

TH-PO785

Changes in Serum Phosphorus, Pill Burden, and Medication Possession Ratio among Chronic Hemodialysis Patients Who Converted to Sucroferric Oxyhydroxide as Part of Routine Care

Kathryn S. Gray,[1] Linda H. Ficociello,[2] Abigail Hunt,[1] Claudy Mullon,[2] Steven M. Brunelli.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Fresenius Medical Care - North America, Waltham, MA.*

Background: The large pill burden associated with many phosphate binders (PB) may decrease adherence to PB therapy. The current analysis examines the changes in serum phosphorus, PB pills/day, and medication possession ratio (MPR; estimate of adherence) among patients who converted from a baseline PB to sucroferric oxyhydroxide (SO) as part of routine care.

Methods: Patients eligible for analysis were ≥18 years, received chronic hemodialysis at a large dialysis organization (LDO), and received benefits through the LDO's pharmacy program. Patients converting to SO use were those who had supply of another PB, received a first prescription fill for SO as part of routine care, and subsequently did not refill a non-SO PB. Baseline (BL) was considered as the 6-month period leading up to first SO fill and SO follow-up (SO-F) the 6-month period following the first SO fill. Patients were censored from the analysis upon loss to follow-up, dialysis modality change, discontinuation of SO, or fill of a prescription for another PB after SO initiation. MPR is the proportion of time that a patient had enough medicine to take as prescribed and was assessed among patients not enrolled in the LDO pharmacy automated refill management service.

Results: There were 490 patients who converted to SO. The majority of patients (66%) were using sevelamer at time of SO initiation, followed by calcium acetate (19%). There was an improvement in serum phosphorus (sP): mean (95% CI) sP was 6.9 mg/dL (6.8, 7.1) at BL and 6.8 mg/dL (6.6, 6.9) at SO-F (P=0.02). The percent of patients achieving sP ≤5.5 mg/dL increased from 21.7% at BL to 28.8% at SO-F (P<0.001). The mean total PB pill burden at BL was 10.8 pills/day and this decreased by 49% to 5.5 pills/day at SO-F (P<0.001). Among patients who were not using the LDO refill management service (n=30), mean total PB MPR was 0.68 at BL and 0.80 at SO-F.

Conclusions: In a cohort of hemodialysis patients prescribed SO through a renal pharmacy service as part of routine care, improvements in sP were observed along with a 49% decrease in prescribed PB pills/day and, among the subset of patients not using the LDO pharmacy refill management service, an increase in MPR from 0.68 to 0.80.

TH-PO786

Phosphate Removal in Maintenance Hemodialysis with Different Dialysis Modality and Different Dialyzer

Jing Luo,[1] Li Fang,[1] Hong Ye,[2] Junwei Yang.[2] *[1]Nanjing Medical University, Nanjing, China; [2]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Hyperphosphatemia is one of the most common complications of maintenance hemodialysis (MHD) patients, and the association with an increased risk of mortality has been demonstrated. The normalization of phosphate plasma levels is therefore an important goal in the treatment of MHD patients. Accordingly, to assess phosphate removal by hemodialysis (HD) is important to improve phosphate control in patients on maintenance HD.

Methods: 48 MHD patients enrolled in this study underwent three period: one week HD with B3-1.6a (Toray, 1.6m^2, low-flux) (period 1), then one week HD with TS-1.6SL (Toray, 1.6m^2, high-flux) (period 2) and switched to another week hemodiafiltration (HDF) with TS-1.6SL (period 3). Each study period was separated by a washout of 2 weeks. Blood samples were collected at 0 min, 30 min, 60 min, 120 min, 180 min, 240 min after the start of dialysis and 60 min postdialysis. Effluent dialysate samples were collected every 15 min during the 4-hour HD treatment to measure the phosphate removal. Predialysis levels of serum phosphate, potassium, hematocrit, intact parathyroid hormone, alkaline phosphatase Echocardiogram, clinical and dialysis characteristics were obtained.

Results: The reduction of phosphate concentration of blood in dialysis process were 34.74%±6.01%, 48.10%±6.62%, 60.76%±6.98%, 63.81%±7.35%, 63.07%±7.93% at 30 min, 60 min, 120 min, 180 min, 240 min point respectively and returned to 52.41%±9.18% at 60 min postdialysis. There were statistical differences in the period 1, period 2 and period 3 at 30min point (29,79%±3.79%, 36.79%±6.82% and 36.64%±3.95%, P=0.000), 60min point (43.36%±4.94%, 49.86%±6.87% and 51.07%±5.44%, P=0.002), 120 min point (56.14%±6.36%, 62.86%±6.27% and 63.29%±6.28%, P=0.007). Total amount of phosphate removal within the 4-hour HD was mostly 25.54±5.77 mmol during per four-hour treatment. The first hour of treatment removed 39.85%±3.99% of the total mass, and 24.41%±1.67%, 18.34%±1.94%, 17.32%±3.00% at the second, the third and the forth hour respectively. However, no statistical differences were found in the three periods.

Conclusions: The maximum reduction of blood phosphate concentration was about 60% at 120 min point, and rised again postdialysis. The reduction of blood phosphate concentration was higher with HDF or with high-flux dialyzer.

FGF23 and Mortality in a Large Cohort of Prevalent Hemodialysis Patients: Results from the J-DOPPS

Hirotaka Komaba,[1] Douglas S. Fuller,[2] Masatomo Taniguchi,[3] Suguru Yamamoto,[4] Takanobu Nomura,[5] Brian Bieber,[2] Bruce M. Robinson,[2] Ronald L. Pisoni,[2] Masafumi Fukagawa.[1] *[1]Tokai University School of Medicine, Isehara, Japan; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Kyushu University, Fukukoka, Japan; [4]Niigata University, Niigata, Japan; [5]Kyowa Hakko Kirin Co Ltd, Tokyo, Japan.*

Background: Elevated levels of fibroblast growth factor 23 (FGF23) have been associated with mortality in the pre-dialysis and incident hemodialysis population, but few studies have examined this relationship in a large cohort of maintenance hemodialysis patients. We analyzed the Japan Dialysis Outcomes and Practice Patterns Study (J-DOPPS) data to explore the association between FGF23 levels and all-cause mortality among maintenance hemodialysis patients.

Methods: We included 1,122 maintenance hemodialysis patients from the J-DOPPS phase 5 (2012-2015) who had FGF23 measurements. We evaluated the association between FGF23 levels and all-cause mortality using Cox regression adjusted for potential confounders.

Results: At study enrollment, the median FGF23 level was 2,113 (IQR, 583-6,880) pg/ml. These levels remained essentially unchanged among patients with repeated measurements. During 3-year follow-up, 154 of the 1,122 participants died. FGF23 was associated with younger age and fewer comorbidities. After adjustment for these plus dialysis vintage, albumin, and creatinine, FGF23 was positively associated with death (HR per unit increase in log-transformed FGF23, 1.17; 95% CI, 1.04-1.32). Although median FGF23 was higher in patients with longer dialysis vintage, the adjusted association between FGF23 and mortality was less pronounced as the duration of dialysis increased.

Conclusions: FGF23 was positively associated with mortality in chronic hemodialysis patients. However, this association was less pronounced in patients with longer dialysis vintage. These results suggest that long-term hemodialysis patients may be less susceptible to the toxic effects of FGF23, or correlated biological processes.

Phase 2 Open Label Single Arm Repeat Dose Study to Assess the Effect of SNF472 on Wound Healing in Uraemic Calciphylaxis Patients

Vincent Brandenburg,[1] Smeeta Sinha,[2] Jose-Vicente Torregrosa,[3] Carolina Salcedo,[4] Preston Klassen,[4] Rekha Garg,[4] Pieter H. Joubert,[4,5] Joan Perelló.[4,6] *[1]University Hospital Aachen, Herzogenrath, Germany; [2]Salford Royal NHS Foundation Trust, Salford, United Kingdom; [3]D. Nefrologia, Hospital Clínic de Barcelona, Barcelona, Spain; [4]Sanifit, Palma, Spain; [5]King's College, London, United Kingdom; [6]Lab. Investigació en Litiasi Renal, UIB, Palma, Spain.*

Background: SNF472, an intravenous (i.v.) formulation of myo-inositol hexaphosphate, is being developed for treating calciphylaxis (CUA) in patients with end-stage renal disease on hemodialysis (HD). It selectively inhibits the final common pathway in the etiology of vascular calcification, the formation and growth of hydroxyapatite crystals.

Methods: An open label, single arm trial investigating the effect of SNF472 on top of standard of care in the treatment of CUA in HD patients. Inclusion criteria was a new diagnosis of CUA or a recurrence of CUA after a period of at least 90 days without evidence of active CUA-related skin lesions. Patients are treated for 12 weeks with i.v. 6-9 mg/kg of SNF472 three times per week during each dialysis session. The endpoints are lesion score based on the Bates-Jensen Wound Assessment tool (BWAT; primary endpoint), pain assessed by Visual Analog Pain Scale (VAS) and a validated wound-associated quality of life (QoL) questionnaire. The BWAT and VAS are assessed every 2 weeks; wound-QoL is assessed at baseline, week 6 and week 12.

Results: The study has enrolled 12 patients with 9 completing the 12-week treatment, and 2 discontinued early due to death (not related to study drug) and 1 withdrew consent. Data from 9 completers shows a statistically significant reduction in BWAT score by week 10 which continued to week 12. Similarly, there was a statistically significant reduction in mean pain VAS score by week 8 and week 12. An increase in pain is noted one week after ending SNF472 treatment, strengthening the likelihood of a causal impact on pain. SNF472 has a statistically significant improvement on global wound-QoL, by week 12. Similarly, the 3 subscales of the global wound QoL scale all show improvements by week 12. There were 14 serious adverse events and 2 deaths, and none were related to SNF472 as per investigator.

Conclusions: These results suggest that SNF472 has a consistent benefit across multiple parameters and is well tolerated in patients with CUA. Thus, SNF472 has the potential to treat CUA, a rare and serious disease with a high mortality rate and no approved treatment.

TH-PO789

Low Parathyroid Hormone Levels Predict Infection-Related Mortality in Incident Dialysis Patients Yu ah Hong,[2] Su Hyun Kim,[3] Yong-Lim Kim,[4] Yon Su Kim,[5] Shin-Wook Kang,[6] Seong il Jo,[1] Yoon-Kyung Chang,[1] Suk young Kim,[1] Yong Kyun Kim.[1] *[1]The Catholic University of Korea, Daejeon, Republic of Korea; [2]College of Medicine, The Catholic University of Korea, Daejeon, Republic of Korea; [3]Chung-Ang University Hospital, Seoul, Republic of Korea; [4]Kyungpook National University Hospital, Daegu, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea; [6]College of Medicine, BK21, Yonsei Univ., Seoul, Republic of Korea.*

Background: Background/Aims: Dialysis patients have increased susceptibility to infection, and infection related mortality is considerably high in dialysis patients. Parathyroid hormone (PTH) receptors were located in most immunologic cells, and has been known as an immunoregulatory factor. We evaluated the impact of intact PTH (iPTH) levels on infection related outcomes in incident dialysis patients.

Methods: Methods: Incident dialysis patients were selected from the Clinical Research Center registry a prospective Cohort study on dialysis patients in Korea. Serum iPTH levels were divided into three groups (iPTH <150 pg/mL, 150 ≤iPTH< 300 pg/mL, and iPTH ≥300 pg/mL). The primary outcome was all cause and infection-related mortality and the secondary outcome was infection-related hospitalization.

Results: Results: A total of 1,260 hemodialysis and 511 peritoneal dialysis patients were included. The median follow-up period was 24 months. During follow up period, 175/1,771 (9.9 %) was died and 35/1,771 (2.0 %) was died of infection related cause. Kaplan-Meier analysis showed that the all-cause mortality rates ($P < 0.001$, Log-rank) as well as infection-related mortality rates ($P = 0.003$, Log-rank) were significantly higher in patients with lower iPTH levels than in patients with higher iPTH levels. There were no significant differences among groups in rates of infection-related hospitalization. Serum iPTH levels were independently correlated with age, albumin, corrected calcium, alkaline phosphatase and phosphate by multiple logistic regression. The multivariate Cox regression analysis showed that patients with serum iPTH <150 pg/mL remained at higher risk for infection-related mortality than those with target range of iPTH levels by KDIGO guideline, 150 ≤iPTH< 300 pg/mL, after adjusting for confounding variables (Hazard Ratio = 2.439 [1.027-5.793], $P = 0.043$). However, there was no significant risk for all-cause mortality after adjusting for confounding variables.

Conclusions: Conclusion: Low iPTH levels was an independent predictor marker of infection related mortality after adjustment of multiple confounders in incident dialysis patients.

TH-PO790

HCV Viraemia in Anti-HCV-Negative Haemodialysis Patients: A Myth? Ioannis Griveas.[1,2] *[1]401 General Military Hospital of Athens, Athens, Greece; [2]PRIVATE DIALYSIS UNIT "NEFROIATRIKI", ATHENS, Greece.*

Background: Hepatitis C virus (HCV) infection is still common among dialysis patients. The Centers for Disease Control and Prevention (CDC) recommends that chronic hemodialysis (HD) patients should be screened for HCV antibody upon admission to the dialysis clinic and every six months thereafter if susceptible to HCV infection. However, previous studies have shown the presence of HCV viraemia in anti-HCV negative HD patients as up to 22%. **Aim:** To evaluate the presence of HCV viraemia using HCV-RNA detection among anti-HCV-negative HD patients from a tertiary dialysis unit in Athens.

Methods: We enrolled 41 anti-HCV negative HD patients [M/F: 31/10, median age: 55 years (range: 18-88), median hemodialysis duration: 29 months (range: 2-345)] diagnosed with third generation enzyme immunoassay. One patient was HBsAg positive. HCV viraemia was evaluated using a sensitive (cut-off 12IU/ml) reverse transcriptase polymerase chain reaction (COBAS AmpliPrep/TaqMan system) test for HCV-RNA.

Results: None of the 41 anti-HCV-negative HD patients were shown to be viraemic.

Conclusions: Routine HCV RNA testing appears not to be necessary in HCV antibody negative HD patients.

TH-PO791

Direct-Acting Antiviral Agents Therapy Reduce Beta2 Microglobulin Levels of Hemodialysis Patients with Hepatitis C Virus Infection Minoru Ito. *Yabuki Hospital, Yamagata City, Japan.*

Background: Hepatitis C virus (HCV) infection is still major comorbidity in patients receiving hemodialysis. Recently, the direct-acting antiviral agents (DAAs) against HCV has been allowed to use for end-stage renal disease patients in Japan. Moreover, a prior study reported that HCV infection was related to serum beta2 microglobulin (ß2MG) elevation. ß2MG is known as a causative substance of dialysis-related amyloidosis (DRA). In this study, we evaluated the ß2MG lowering effect of the DAAs therapy to hemodialysis patients with HCV infection.

Methods: We treated sixteen HCV (Serotype 1)-infected hemodialysis patients with DAAs between October 2015 and April 2017. We prescribed daclatasvir and asunaprevir combination for twelve patients, and elbasvir and grazoprevir combination for four patients. We evaluated the sustained virologic response (SVR) and the serum ß2MG level before and after DAAs therapy.

Results: 16 patients were enrolled in this study (age: 62.2 years old, dialysis vintage: 20.4 years, male 12, female 4). All the 16 patients completed the DAAs therapy without remarkable side effects. At the end of treatments, all patients had undetectable HCV RNA levels. However, one patient had a virological failure a month after. The serum ß2MG levels before the treatment were higher than the target level that several clinical guidelines recommend. Just after the treatments, the ß2MG levels decreased significantly (30.4 mg/L v.s. 24.8 mg/L, p=0.0016). ß2MG levels of 15 patients with satisfactory results remained lower after several weeks (observational periods) of treatment. A patient with virological failure showed ß2MG level increased again immediately.

Conclusions: ß2MG-removal therapies have developed dramatically. Online-hemodiafiltration, hemodialysis with high-flux membrane and ß2MG apheresis column show high ß2MG removal performance. However, these treatments were insufficient for the patients with HCV infection. In this study, we found the ß2MG lowering effect of DAAs therapy. DAAs therapy is highly likely to prevent DRA for dialysis patients with HCV infection.

TH-PO792

Association of Hepatitis B Vaccination Response and Sleep in Chronic Hemodialysis Patients Maggie Han,[1] Xiaoling Ye,[1] Sharon Rao,[1] Stephan Thijssen,[1] Marcee Bonner,[2] Candace Young,[2] Daniel Marsh,[2] Jeffrey L. Hymes,[3] Peter Kotanko.[1,4] *[1]Renal Research Institute, NYC, NY; [2]Renal Associates of Baton Rouge, Baton Rouge, LA; [3]Fresenius Medical Care North America, Franklin, TN; [4]Icahn School of Medicine, NYC, NY.*

Background: While hepatitis B vaccination (HBVacc) is standard of care in chronic hemodialysis (HD) patients, seroconversion (SC) rate is only 58%, and poor SC has been linked to age, dialysis vintage, albumin level, and diabetes [Lacson, HDI 2005]. In healthy subjects, poor sleep in the night after HBVacc results in a significantly lower SC rate [Lang, J Immnol 2011]. Recent work revealed that patients who start HD early in the day have disturbed sleep-wake patterns [Han, Blood Purif 2016]. We hypothesize that sleep duration in the night after HD (post-HD) impacts HBVacc SC.

Methods: We conducted two studies. First, HD patients in Fresenius Medical Care North America (FMCNA) clinics were followed between 01/2010-12/2015. HBVacc was administered concurrent to HD treatment. Patients who completed the prescribed HBVacc series were included. SC was recorded if a hepatitis B antibody titer of ≥10 IU/mL was detected up to a year after HBVacc. Patients were stratified into early and late groups if 90% of treatments started before or after 8:30am, respectively. In the 2nd study, nightly sleep duration of HD patients were collected over a 5-week period using the Fitbit Flex. Mean post-HD sleep was calculated for shift 1(HD start before 8:30am) and shifts 2, 3, and 4 combined(HD start after 8:30am).

Results: Descriptive statistics of the vaccination and sleep study cohort are listed in **Table 1**. HBVacc SC rates in early vs. late group were 74% vs 72% (Δ=2%;95% C.I. 0.7 to 3.3;p=0.003). Mean post-HD sleep of those patients scheduled for HD in shift 1 vs. shifts 2,3, and 4 combined were 417 minutes vs 380 minutes(Δ=38 minutes;95% CI -3.2 to 78.6;p=0.069).

Conclusions: Patients who started HD before 8:30am had a significantly higher SC rate than those who started later. A previously unrecognized, yet plausible, explanation is that patients in shift 1 slept more on the post-HD night. This finding may add to the many effects sleep, or lack thereof, exerts on HD patients' health. Further work looking at the sleep following HD in a bigger cohort is required to confirm or reject these initial findings. If confirmed, sleep hygiene intervention in non-seroconverting patients could be considered.

Funding: Commercial Support - Renal Research Institute

TH-PO793

Effects of Access to Vascular Surgeons on Catheter Rates in Hemodialysis Patients Hao Han,[1] Tommy C. Blanchard,[1] Sheetal Chaudhuri,[1] Sophia Rosen,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Walead Latif,[2] Elsie Koh,[2] Murat Sor,[2] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Vascular Care, Malvern, PA.*

Background: The rates of central venous catheter (CVC) use in hemodialysis (HD) patients have been relatively unaltered over the last decade. In 2016, the United States Renal Data System estimated that 68% of incident HD patients utilize a CVC 90 days after starting HD, and approximately 20% of patients never transition to a permanent vascular access (VA). We aimed to investigate if availability of surgeons at outpatient VA centers proximal to the patients' residence is associated with lower CVC rates in incident and prevalent HD patient populations.

Methods: We analyzed data from incident and prevalent patients treated by Fresenius Medical Care North America between January 1, 2016 and December 31, 2016. We selected patients who resided in a zip code that was within 5 miles of a Fresenius Vascular Care (FVC) VA center. Patients were stratified into groups based on whether they resided near a VA clinic with or without a vascular surgeon on site. We analyzed the percentage of catheters in incident patients and prevalent patients within these two groups.

Results: We observed that incident HD patients who lived proximal to a VA center without a surgeon were more likely to have a CVC (72% with a CVC) when compared to incident patients who resided near a VA center with a surgeon (66% with a CVC). Likewise, when analyzing all HD patients (incident and prevalent), 29% of patients who

were living near a VA center without a surgeon used a CVC, as compared to 27% who lived close to a VA facility with a surgeon.

Conclusions: Our findings suggest that incident and prevalent HD patients residing in the proximities of an outpatient VA center with a surgeon on site are more likely to have a permanent access, possibly due to better access to care. Additional studies are necessary to confirm this observation and assess longitudinal trends for VA utilization.

TH-PO794

Attitudes of Dialysis Patients to Information Technology: Disinterest or Overload? Anthony F. Iluyomade,[2] Andrew I. Chin.[1] *[1]University of California Davis, Sacramento, CA; [2]University of California Davis Medical Center, Sacramento, CA.*

Background: The utilization of information technology in enhancing the delivery of healthcare is becoming ubiquitous. Dialysis patients tend to have access to a number of technologies (smart phones, computers e.t.c) and utilize these as an essential part of their daily lives. The question is whether these patients would be interested in incorporating their devices in their overall dialysis and medical care.

Methods: This is an English-language, 1 page questionnaire-based study, of prevalent in-center adult HD patients from 5 clinics in an urban Northern California city. The questionnaires were answered by the patients or read to them and filled out by a nurse. All questionnaires were completed within a one-month period. The questionnaire consisted of 7 "yes or no" questions related to: 1) access to text messages; 2) access to "smart phone" and computer technologies; and 3) willingness to use or receive information on these devices.

Results: Out of a population of 355 in-center HD patients, 245 (69%) completed the questionnaire. In total, 194 patients (79%) could potentially receive text messages; 160 patients (65%) had a phone that could receive text messages. An additional 34 patients had a caregiver who could receive texts. When asked if they would like to receive text message about upcoming medical appointments or dietary reminders such as to take oral phosphate binders, only 90 patients who had access to texts (46%) would be willing to participate. When asked about access to a "smart device" or computer for viewing educational materials, 106 patients (43%) had a "smart phone", 38 patients (16%) had a caregiver with a smart phone, and 22 (9%) had access to only a computer. Therefore, 166 (68%) had potential to view educational materials related to diet and overall health on HD, if they brought their device into the clinic. However, when asked if willing to view such videos, only 80 (48% of those with access) indicated a desire to do so.

Conclusions: Most of our in-center HD patients (or through their caregivers) were able to receive text messages for appointment, medication or dietary reminders. However, more than half of the patients who had access to these technologies desire not to participate. This attenuates the main goal of integrating technology platform in dialysis patients care and more research is needed in this regard to fully understand their perceptions of such integration.

TH-PO795

Burden of ESKD in Latin America Maria C. Gonzalez-Bedat,[1] Guillermo Rosa Diez,[1,2] Alejandro Ferreiro,[1] Rosario Luxardo.[1,2] *[1]Latinoamerican Registry of Dialysis and Trasplantation, Montevideo, Uruguay; [2]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina. Group/Team: RLADTR Delegates.*

Background: End Stage Renal Disease (ESKD) represents a major challenge for Latin America (LA). The strategic plan from the Panamerican Health Association (PAHO) has proposed goal for ESKD in LA: Renal Replacement Therapy (RRT) prevalence of at least 700 patients pmp by 2019. Then, epidemiological information is needed to assist in the development of ESKD care in the region.

Methods: Participant countries completed an annual survey to provide data on incident and prevalent cases of patients undergoing RRT by means of all modalities: Hemodialysis (HD), Peritoneal Dialysis (PD), and trasplantation as well as other relevant parameters. Analyses of these variables were performed to determine correlations with GNI and life expectancy at birth as well as other socioeconomic indexes. For the statistical analysis, the Pearson (r) coefficient was applied, and a p-value < 0.05 was considered significant. The incidence and prevalence of LA RRT rate was compared with USA and Europe.

Results: 20 countries participated in the survey, more than 90% of the LA countries. The prevalence of RRT in LA increased from 119 patients pmp in 1991 to 709 pmp in 2014, but only 6 countries have a prevalence above of goal of PAHO. HD continues to be the choice of treatment (90%). The RRT prevalence correlated positively with GNI (r 0.81; $p < 0.001$) and life expectancy at birth (r 0.56; $p < 0.01$). A wide incidence rate variation was observed, from 420.9 pmp in Jalisco to 22.6 in Paraguay. When compared with the United States data from 2014, incidence in LA, was substantially lower (157.6 vs 370 respectively), but when compared to the European ERA/EDTA registry (133 pmp) the rate is higher in most LA countries. Diabetes remained the leading cause of ESRD in the region. The most frequent cause of death was cardiovascular. There is a wide rate variation of nephrologists by country.

Conclusions: The heterogeneity or even the absence of registries in some LA countries is congruent with the inequities in access to RRT in such countries, as well as the availability of qualified personnel. The SLANH in cooperation with PAHO, is currently running training programs as well as cooperation programs between LA countries to support less developed ESKD programs. In this spirit, RLADTR is training personnel to carry out dialysis and transplant registries in LA.

TH-PO796

Outcomes of Chronic Dialysis in Infants under Two Years Natasha Jawa,[1] Claire M. Gallibois,[1] Damien G. Noone.[1,2] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Paediatrics, University of Toronto, Toronto, ON, Canada.*

Background: Infants with end-stage renal disease require renal replacement therapy in the form of dialysis, until of sufficient weight to be transplanted; typically by age two. Infant dialysis is associated with significant morbidity and mortality. Peritoneal dialysis (PD) has historically been the preferred choice for infant dialysis, due to technical complexities and risk for complications associated with hemodialysis (HD). Management of very young patients on HD has improved in recent years, but outcomes have yet to be assessed. This study retrospectively reviewed long-term patient- and dialysis-specific outcomes of chronic PD and HD in a contemporary cohort of infants less than two years of age and weighing <10 kg at The Hospital for Sick Children, Toronto.

Methods: Infants <2 years of age and <10 kg undergoing chronic dialysis from 2005-2015 were included. Demographic, dialysis-related and outcome data were extracted from patient's electronic medical records. Summary statistics were analyzed using STATA v.14. Median with interquartile range is provided.

Results: A total of 28 infants (64.3% male) were included. 20 (71.4%) were diagnosed antenatally. Time from birth to dialysis initiation was 13.5 (10, 67) days. 14 (50%) were initiated on PD and 14 (50%) on HD. 8 infants switched modalities a median of 3 (2, 11) times. In patients on PD, the rate of peritonitis was 1 episode/22 patient months. In patients on HD, 11 (64.7%) required a central line change and the central line associated blood stream infection (CLABSI) rate was 1.48 per 1000 central line days. Median time in hospital from dialysis initiation until death/transplant was 8.5 (3.6, 16.7) months. 6 (21.4%) infants died, 17 (61%) were transplanted and 5 (17.9%) remain on dialysis at study end. In those receiving a transplant, median time to transplantation was 2.1 (1.8, 2.7) years.

Conclusions: There has been an increase in the use of HD in recent years. Survival and transplantation rates have improved over time as compared to previously reported rates; however this is associated with prolonged hospital stays and multiple switches between dialysis modalities.

TH-PO797

An International Multicenter Analysis of Incident Patients on Hemodialysis – Practice Patterns, Vascular Access, Demographics and Laboratory Profiles Stefan H. Jacobson,[6,4] Maciej B. Drozdz,[1,4] Andre L. Weigert,[2] Werner Kleophas,[5] Szymon Brzosko,[1] Abdulkareem Alsuwaida.[3,2] *[1]DaVita Poland, Bialystok, Poland; [2]Nephrology, Davita, Lisbon, Portugal; [3]King Saud University, Riyadh, Saudi Arabia; [4]DaVita, Washington, DC; [5]DaVita Deutschland, Dusseldorf, Germany; [6]Nephrology, Danderyd Hospital, Stockholm, Sweden.*

Background: Mortality rates are particularly high in the first few months following initiation of hemodialysis. The risk is associated with characteristics of predialysis care including delayed nephrology referral, type of vascular access and failure to attain guideline-based targets. In this study we analyzed the clinical characteristics in a large international cohort of incident hemodialysis patients.

Methods: We analyzed patient demographics, practice patterns, and laboratory data (February 2017) from 2592 patients (median age: 62 years; 46% female) receiving hemodialysis at 25 DaVita centers in Poland (8 centers, 529 patients), Portugal (5 centers, 529 patients), and Saudi Arabia (12 centers, 1306 patients) with the objective of comparing incident and prevalent patients. We considered the 10th percentile of time on hemodialysis (4.7 months) and compared practices and laboratory data between incident patients (<4.7 months on dialysis; mean 2 months) and prevalent patients (>4.7; mean 44 months).

Results: Incident patients (n=259) were younger ($p<0.001$) than prevalent patients (n=2333), and had lower Charlson comorbidity index ($p<0.001$) and BMI ($p<0.001$). There were significant differences in renal anemia, nutrition, and mineral bone disease variables (Table). Incident patients were more often treated using a central dialysis catheter (CDC, $p<0.001$). The proportion of patients within treatment targets for Kt/V (>1.3), Hb (10-12 g/dL), phosphate (<5.5 mg/dL), albumin (>35 g/L) and treated blood volume (>1 L/kg bw) were all lower in incident patients compared to prevalent patients (all comparisons $p<0.001$).

Conclusions: This large, international, multicenter analysis of incident hemodialysis patients indicates that there is opportunity to improve predialysis management, especially in terms of earlier placement of a permanent vascular access prior to start of hemodialysis. Since mortality is high after initiation of dialysis, such efforts may contribute to improved treatment results.

Comparison of 259 incident vs 2333 prevalent patients on hemodialysis (mean values)

	Age	CDC %	BMI	Charlson median	Albumin	Hb	TSAT	Ferritin	Ca	P	PTH
Incident	57	64	24.3	0	37	10.8	28.4	343	8.6	5.3	412
Prevalent	62	24	25.2	2	39	11.1	29.0	507	8.8	4.8	465
p	<0.001	<0.001	<0.05	<0.001	<0.001	<0.001	<0.001	<0.001	<0.05	<0.001	NS

TH-PO798

Chronic Pain Poses a Significant Burden on Lives of Dialysis Patients Nancy Culkin,[2] Kathryn M. Aebel-Groesch,[2] Duane V. Dunn,[2] Sean Mayes,[2] Deborah A. Benner,[2] Francesca Tentori.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita, Inc, Denver, CO.*

Background: Chronic pain is common in end-stage renal disease (ESRD) due both to multiple comorbidities as well as the dialysis treatment itself. Given differences in dialysis treatment and underlying health status, it is possible that pain perception and burden may differ for in-center hemodialysis (ICHD) and peritoneal dialysis (PD) patients. We characterized the impact of pain on the daily life among patients treated in a large dialysis organization (LDO).

Methods: Pain was assessed monthly by LDO nurses using the Wong-Baker 0-10 scale (May 2016-April 2017). For those patients indicating the presence of pain (rating ≥ 2), a follow-up survey was administered further assessing pain characteristics and burden.

Results: There were a total of 1,094,897 pain assessments performed for ICHD patients (6.5 screenings per patient on average) and 173,739 for PD patients (7.2 screenings per patient on average). Of these, 161,800 (14.8%) ICHD and 23,101 (13.3%) PD assessments had ratings ≥ 2. Back pain was the most common location for both modalities. ICHD patients were more likely to report dialysis-related pain (8.5% responses, 5.7% in PD) and pain of duration ≥ 3 weeks (73.8% vs. 67.0%). Chronic pain had a great impact on lives of both ICHD and PD patients. Use of pain medications was more common in ICHD (74.8%) vs PD (65.1%). For both modalities, acetaminophen was the most common pain medication (~ 30% responses) followed by hydrocodone/acetaminophen (ICHD 15.4%, PD 13.5%).

Conclusions: Our results indicate that pain poses a great burden on lives of dialysis patients, affecting many everyday activities and likely contributing to depressive symptoms. Interestingly, perception of pain and its impact were largely similar between ICHD and PD patients, suggesting that the dialysis treatment process may only play a marginal role. There is a need to integrate pain management in the care of dialysis patients in order to optimize quality of life.

Funding: Commercial Support - DaVita, Inc

Impact of Pain on Quality of Life in ICHD and PD Patients

	ICHD	PD
Affects activities of daily life	55.9%	53.7%
Affects ability to sleep	43.8%	42.8%
Affects appetite	18.8%	20.6%
Affects ability to concentrate	25.7%	26.4%
Has negative effects on relationships	12.8%	15.5%
Symptoms of depression [a]	4.0%	3.8%

[a] Defined as receiving a score ≥ 2 using the PHQ-2 scale (range 0-6).

Data presented as the percentage responding "yes" to the respective question in the follow-up survey administered to those with an overall Wong-Baker score ≥ 2.

Abbreviations: ICHD, in-center hemodialysis; PD, peritoneal dialysis.

TH-PO799

Internet-Based Positive Psychological Intervention for Hemodialysis Patients with Comorbid Depression: Design and Feasibility Brett Burrows,[1] Ken Wilund,[1] Michael A. Cohn,[2] Judith T. Moskowitz,[3] Shuo Xu,[1] Rosalba Hernandez.[1] *[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]University of California San Francisco, San Francisco, CA; [3]Northwestern University, Chicago, IL.*

Background: Depression is the most pervasive psychological issue facing hemodialysis (HD) patients and treatment strategies have mainly concentrated on the use of pharmacotherapy. Alternative treatment strategies that circumvent drug-related side effects and poor medication adherence (i.e., psychosocial interventions) have not been the focus for therapy and few published studies exist. The aim of the current trial was to determine the feasibility and acceptability of a 5-week Internet-based positive psychological intervention in HD patients with comorbid depression.

Methods: HD patients (n=14) with elevated symptoms of depression were enrolled in a single-arm pre-post pilot trial with clinical assessments at baseline and immediately post intervention. Chairside during regularly scheduled HD treatment, patients completed on-line modules promoting skills for increasing positive emotion over a 5-week period using an Apple IPad. Targeted skills included noting of daily positive events, cultivation of gratitude, practicing positive reappraisal, partaking in acts of kindness, and engagement in mindfulness/meditation.

Results: Mean age was 57.4 years; 50% female; 50% non-Hispanic White; mean duration on dialysis was 3.6 years. Twelve of 14 patients completed the program for an 85.7% retention rate. Participants felt satisfied overall with each session and offered consistently positive feedback. At the end of the intervention, significant improvements were evident for depressive symptoms (15.3 vs. 10.9; p=0.04) as measured by the Center for Epidemiological Studies Depression Scale. Statistical trends indicated clinically meaningful improvement in emotional well-being, kidney disease burden, and quality of social interactions as per the Kidney Disease Quality of Life Instrument.

Conclusions: Results indicate that an innovative and low-cost Internet-based positive psychological intervention represents a feasible and useful therapeutic option for HD patients with comorbid depression. This psychosocial strategy can be a valuable self-guided tool that reduces costly face-time with clinical staff.

TH-PO800

Hospitalization and Missed Dialysis Treatments Are More Common in Hemodialysis Patients with Depressive Symptoms Kathryn M. Aebel-Groesch,[2] Duane V. Dunn,[2] Angie Major,[2] Sean Mayes,[2] Deborah A. Benner,[2] Francesca Tentori.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita, Inc, Denver, CO.*

Background: Depression is common in end-stage renal disease and is likely to have a negative impact on patient engagement in self-care and clinical outcomes. Here we characterized incidence of hospitalization and missed dialysis treatments among in-center hemodialysis patients who screened positive for depressive symptoms.

Methods: We analyzed data from a large dialysis organization electronic health record database. Depression screenings were performed biannually (May 2016-April 2017) with the PHQ-2 scale (range 0-6). Patients with active diagnosis of depression, bipolar disorder, cognitive impairment, language barriers, or who were hospitalized were not screened. Rates of hospitalization and of missed dialysis treatments due to non-adherence in the 3 months after screening were compared in patients with depressive symptoms (PHQ-2 score ≥ 2) and those without.

Results: A total of 54,441 (17.3%) screenings were positive for depression. The hospitalization rate was higher among those with depressive symptoms compared to those without (2.2 vs 1.5 admissions per patient-year). Patients who screened positive for depression were also more likely to miss dialysis treatments (7.7 vs 5.1 missed HD session per patient-year). Overall, patients with higher PHQ-2 scores were more likely to have higher hospitalization and missed treatment rates.

Conclusions: These findings indicate that hemodialysis patients who screen positive for depression are more likely to be hospitalized and be non-adherent to dialysis treatment schedules. Since the PHQ-2 may underestimate actual depression rates, our results represent conservative estimates of the possible impact of depression on clinical outcomes. Clinical initiatives should be designed to specifically target high-risk patients who screen positive for depression.

TH-PO801

Impact of Baseline Scores on the Responsiveness of Quality of Life (QOL) Tools to Interventions: An ACTIVE Dialysis Trial Secondary Analysis Meg J. Jardine,[1,2] Brendan Smyth,[1,3] Oliver van den Broek-Best,[1,3] Li Zuo,[1] Nicholas A. Gray,[4] Christopher T. Chan,[5] Janak R. de Zoysa,[6] Kirsten Howard,[7] Kris Rogers,[1] Vlado Perkovic.[1] *[1]The George Institute for Global Health, UNSW, Sydney, NSW, Australia; [2]Nephrology, Concord Repatriation General Hospital, Sydney, NSW, Australia; [3]University of Sydney, Sydney, NSW, Australia; [4]Sunshine Coast University Hospital, Birtinya, NSW, Australia; [5]Toronto General Hospital, Toronto, ON, Canada; [6]Waitemata District Health Board, AUCKLAND, New Zealand; [7]School of Public Health, University of Sydney, Sydney, NSW, Australia. Group/Team: ACTIVE Dialysis Steering Committee.*

Background: There is little clarity on the relative validity, reproducibility and generalisability of available tools for measuring the patient experience in the trial context. The ACTIVE Dialysis trial found no benefit from extended hemodialysis (HD) hours for the utility-based QOL measure, EQ-5D, with small but significant benefits for generic health-related SF-36 QOL. Participants in extended hours trials have better average health than patients overall raising the possibility EQ-5D responsiveness may be limited by a 'ceiling' effect. **Aim:** To explore whether the impact of extended hours HD on QOL scores is dependent on baseline scores.

Methods: The ACTIVE Dialysis trial randomized 200 HD patients to standard (median 12) or extended (median 24) weekly HD hours for 12 months. Dialysis population-validated QOL assessments including the EQ-5D utility instrument and SF-36 Physical (PCS) and Mental (MCS) Composite Scores were administered by blinded interviewers during the trial. After confirming the absence of an interaction of the score with time, the average intervention effect was determined using mixed linear regression and analysed in subgroups defined by tertiles of the relevant baseline score.

Results: Overall extended weekly HD hours had no impact on EQ-5D (mean difference 0.03, CI -0.03, 0.09; p=0.30) with small but significant improvements in PCS and MCS (mean difference PCS 2.30, 95%CI 0.52-4.07; MCS 2.54, 95%CI 0.42-4.65). The lack of impact on EQ-5D results were consistent across all tertiles (lowest third 0.01 [CI -0.12-0.14, p=0.89], middle third 0.05 [CI -0.03-0.13, p=0.26], highest third 0.02 [CI -0.07-0.12, p=0.60], p-interaction 0.80). The benefits for PCS and MCS were similarly consistent across tertiles (p-interaction: PCS 0.96; MCS 0.34).

Conclusions: The impact of extended dialysis hours on EQ-5D, PCS and MCS QOL was not dependent on baseline scores. The scores appear to be at least internally robust to variation in baseline QOL. NCT00649298

TH-PO802

Identifying the Critical Dimensions of Fatigue for a Core Outcome Measure for Trials in Haemodialysis: An International Survey Angela Ju,[3] Mark L. Unruh,[2] Jonathan C. Craig,[4] Allison Tong.[1] *[1]The University of Sydney, Sydney, NSW, Australia; [2]University of New Mexico, Los Ranchos, NM; [3]University of Sydney, Sydney, NSW, Australia; [4]University of Sydney/ Children's Hospital, Sydney, NSW, Australia.*

Background: Measures of fatigue used for research in patients on haemodialysis have differing dimensions, length, and scales. The extent to which of the dimensions of fatigue are valued by patients and health professionals are unknown.

Methods: An online survey was conducted among patients/caregivers and health professionals in English and Spanish. The survey consisted of 11 content dimensions of fatigue such as 'life participation' and 'muscle weakness', and 4 modes of assessment such as 'severity' and 'frequency', identified in existing measures. A 9-point Likert scale was used to assess absolute importance and relative importance obtained from a best-worst scale (BWS) task. Multivariate regression analysis was used to examine the Likert scores and mixed-multinominal regression for the BWS scores.

Results: In total, 342 (60%) health professionals and 227 (40%) patients/caregivers from 60 countries participated in the two surveys. Among all participants, the top rated dimension was 'life participation' (impact of fatigue on life participation) with a mean Likert score of 7.55 (95%CI: 7.42-7.68) for the English survey and 5.50 (95% CI: 4.90-6.10) for the Spanish survey. Severity was more important than frequency, duration or change in fatigue in both the English (7.20: 7.06-7.34) and Spanish survey (5.13: 4.52-5.74). English-speaking patients placed highest relative importance on 'life participation' (BWS score 9.0:7.8-10.4), compared with Spanish-speaking patients for whom 'post-dialysis fatigue' was most important (9.0:7.0-11.0).

Conclusions: Impact of fatigue on life participation was identified as a critical dimension of fatigue, and severity the most important metric. Differences in relative importance of fatigue dimensions suggest cultural differences in priorities. The core outcome measure for fatigue should include severity of impact upon life participation with consideration of cultural validity.

TH-PO803

The Association of RAAS Blockade and the Progression of Residual Kidney Function Decline: A Nationwide Prospective Cohort Study Yunmi Kim,[4] Kyung Don Yoo,[4] Clara T. Kim,[6] Yun Kyu Oh,[3] Shin-Wook Kang,[1] Chul Woo Yang,[2] Yong-Lim Kim,[5] Yon Su Kim,[8] Chun Soo Lim,[7] Jung Pyo Lee.[7] *[1]College of Medicine, BK21, Yonsei Univ., Seoul, Republic of Korea; [2]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [3]Department of Internal Medicine, Boramae Medical Center, Seoul, Republic of Korea; [4]Dongguk University Gyeongju Hospital, Gyeongsangbuk-do, Republic of Korea; [5]Kyungpook National University Hospital, Daegu, Republic of Korea; [6]School of Public Health, Seoul National University, Seoul, Republic of Korea; [7]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [8]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Our aim was to evaluate the clinical effects of renin angiotensin aldosterone system (RAAS) blockade on residual renal function (RRF) in newly diagnosed patients with end-stage renal disease (ESRD) undergoing hemodialysis in Korea.

Methods: Total of 1,571 patients were enrolled in the Clinical Research Center for ESRD prospective observation cohort. RAAS treatment was defined as the use of angiotensin converting enzyme inhibitor or angiotensin receptor blocker for at least 3 months. RRF was defined using 24-hour urine volume and Creatinine Clearance measured at 0, 3 and 12 months after dialysis initiation.

Results: The 671 patients (43%) were in the RAAS group. The RAAS and control groups were comparable in terms of age, sex, primary renal disease, comorbidities, and dialysis dose including Kt/V, ultrafiltration volume per session. The development of total anuria at 12 months was similar in both groups (39.3% vs. 41.1%, RAAS group vs. control group). The RRF in both group decreased over a 12-month period. After adjustment for age, sex, diabetes history, blood pressure and ultrafiltration volume, use of RAAS did not provide a significant protective effect on RRF preservation (Odds ratio 0.57 95% CI 0.31-1.04, p=0.069). Mixed effect linear regression revealed no significant difference in the course of residual renal function between RAAS group and control group (p value=0.127). In subgroup analysis for patients with completely followed-up cases, patients using RAAS over 12 months did not significantly lower the RRF than other patients(p value=0.388).

Conclusions: In Korean patients with ESRD, RAAS blockade failed to clarify the protective effect for RRF. Further research is needed to provide optimal treatment for preservation of RRF, especially in Korean patients with incident dialysis.

TH-PO804

Validation of a New Physical Activity Instrument against Pedometers among Dialysis Patients Piyawan Kittiskulnam,[1] Anoop Sheshadri,[2] Kirsten L. Johansen.[3] *[1]Chulalongkorn university, Bangkok, Thailand; [2]None, San Francisco, CA; [3]University of California, San Franicsco, San Francisco, CA.*

Background: The newly developed Low Physical Activity Questionnaire (LoPAQ) was designed to capture the low activity level among physically inactive patients undergoing dialysis and correlated well with physical activity questionnaires used in general population. However, this instrument has not been validated against a more objective measure.

Methods: We performed a cross-sectional study and recruited 55 ambulatory patients receiving HD or PD for ≥3 months from 3 dialysis facilities in San Francisco during 2016-7. Spontaneous walking activity was measured by pedometers over 7 days including a dialysis-free weekend and used as the reference. Patients were instructed to record their activities and step count readings. Study coordinators administered the LoPAQ and recorded participants' responses during a dialysis session (HD) or clinic visit (PD). We used measures in the LoPAQ that can be compared with available metrics, including minutes of walking in the past week and time expended from light to vigorous, and total physical activity. We also asked about the average time spent in sitting activities over 1 week. Spearman correlation was used to determine whether the LoPAQ results correlate with step counts.

Results: Fifty-two dialysis patients (HD=45, PD=7) completed the LoPAQ. Mean age was 57±12 years with 80% men. Median dialysis vintage was 39 (IQR, 17-708) months. Total kilocalories per week (kcal/wk) of physical activity reported on the LoPAQ were 630 (420-2,222). Participants reported an average of 5.7±3.2 sedentary hours per day. Most patients (83%) reported walking activity around the neighborhood, for transportation, and/or for fitness or pleasure, with a median of 560 (52-1,225) kcal/wk. The patients had average step counts of 18,578 (9,701-37,029) steps/week (2,630 [1,360-5,176] steps/day). The activity reported on the LoPAQ correlated with that reported on weekly pedometer readings (r=0.37, p=0.006). In addition, energy expenditure in walking between the LoPAQ and weekly step counts was highly correlated (r=0.59, p<0.001), particularly among PD patients (r=0.82, p=0.01).

Conclusions: The LoPAQ was easier and less time-consuming than previously validated physical activity questionnaires. LoPAQ demonstrated a good correlation, similar to other widely used physical activity instruments, with objective pedometer step counts among dialysis patients.

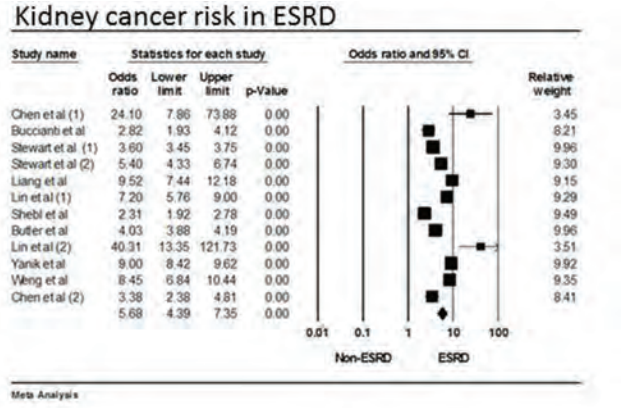
Incidence and Association of Urologic Malignancies with ESRD: A Meta-Analysis Panagiotis Kompotiatis,[3] Charat Thongprayoon,[1] Sandhya Manohar,[2] Wisit Cheungpasitporn,[2] Sandra Herrmann.[2] *[1]Bassett Medical Center, Cooperstown, NY; [2]Mayo Clinic, Rochester, MN; [3]Nephrology, Mayo Clinic, Rochester, MN.*

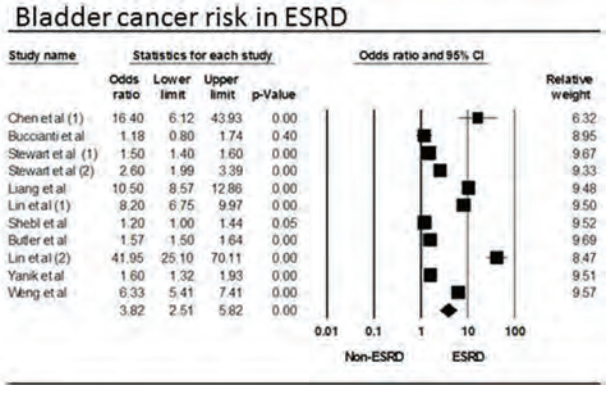
Background: Previous studies have suggested higher incidence of urologic malignancies in patients with end-stage renal disease (ESRD). However, incidence trends of urologic malignancies in ESRD patients remain unclear. The study's aims were 1) to investigate the pooled incidence/incidence trends 2) to assess the risks of urologic malignancies in ESRD patients.

Methods: A literature search was performed using MEDLINE, EMBASE and Cochrane Database from inception through April 2017. Studies that reported incidence or odd ratios (OR) of urologic malignancies among ESRD patients were included. Pooled OR and 95%CI were calculated using a random-effect model. The protocol for this study is registered with PROSPERO (International Prospective Register of Systematic Reviews; no. CRD42017067687).

Results: Eighteen observational studies with 1,872,952 ESRD patients were included. The pooled estimated incidence of kidney cancer and bladder cancer in ESRD patients were 0.4% (95%CI: 0.3%-0.6%) and 0.5% (95%CI: 0.3%-0.7%), respectively. Meta-regression showed significant positive correlation between incidence of urologic malignancies in ESRD patients and year of study (slopes=+0.06, p<0.001 for both kidney and bladder cancers). Compared to non-ESRD status, ESRD was significantly associated with both kidney cancer (pooled OR 5.68; 95% CI 4.39-7.35) and bladder cancer (pooled OR 3.82; 95% CI 2.51-5.82).

Conclusions: Our study demonstrates a significant association between ESRD and urologic malignancies. The overall estimated incidence rates of kidney cancer and bladder cancer are 0.4% and 0.5%, respectively. There is also a significant positive correlation between the incidence of urologic malignancies and year of study.





TH-PO806

Time between Predicted versus Actual Time to RRT Initiation: Just How Early Are We Starting? Elaine Ku, Charles E. McCulloch, Kirsten L. Johansen. *University of California San Francisco, San Francisco, CA.*

Background: Prior studies have defined "early" vs. "late" renal replacement therapy (RRT) initiation based on eGFR at the time of RRT. Few studies have described timing of RRT based on *time spent in CKD stage 5*. Our goal was to compare time that could be spent in CKD stage 5 if RRT were initiated after a fall in eGFR to below 5mL/min/1.73 m^2 (a conservative threshold for RRT) vs. actual observed time spent in CKD stage 5.

Methods: We used mixed models to estimate the person-specific trajectory of renal function decline (using all eGFRs prior to RRT) among 736 Chronic Renal Insufficiency Cohort (CRIC) participants followed longitudinally for 9.6 years who eventually began RRT. We used these trajectories to estimate the expected amount of time in CKD stage 5 (between eGFR of 15 and 5 mL/min/1.73 m^2), which we compared to the observed time spent in CKD stage 5 (until actual receipt of RRT). We then tested for differences between predicted and actual times in stage 5 according to known risk factors for CKD progression.

Results: Overall, the median difference between the predicted and actual time spent in CKD stage 5 was 9.6 months (i.e., patients started RRT 9.6 months before they were predicted to reach an eGFR of 5 mL/min/1.73 m^2). Variations in the predicted time in CKD stage 5 were observed by race and ethnicity, co-morbidities, and laboratory parameters, but not by age or sex [figure]. In general, patients at lower risk of progression were started earlier than those at higher risk [Figure], with the time difference being largest among white patients (10.1 months), those with SBP <140 mmHg (9.7 months) and proteinuria <1 g/g (9.1 months).

Conclusions: We found marked differences in the actual vs. predicted amount of time spent in CKD stage 5 based on various risk factors of interest. RRT initiation occurred 10 months earlier than would be expected based on projected time to eGFR of <5 mL/min/1.73 m^2. Given the lack of mortality benefit to early RRT initiation, we have identified subgroups that may especially benefit from more a concerted effort to delay RRT.

Association between Low-Molecular-Weight Heparin and Risk of Bleeding among Hemodialysis Patients: A Retrospective Cohort Study Hind H. Lazrak,[1] Emilie Rene,[1] Naoual Elftouh,[1] Annie-Claire Nadeau-Fredette,[1,2] Louis-Philippe Laurin,[1,2] Jean-Philippe Lafrance.[1,2] *[1]Research center, Maisonneuve-Rosemont hospital, Montreal, QC, Canada; [2]Division of nephrology, Maisonneuve-Rosemont hospital, Montreal, QC, Canada.*

Background: Low molecular weight heparins (LMWH) replaced unfractionated heparin (UFH) in multiple indications. While their efficacy in hemodialysis was proved through multiple studies, their safety remains controversial. The potential bioaccumulation in patients undergoing chronic hemodialysis raised the question of bleeding risk among this population. The aim of this study was to evaluate bleeding risk among patients with chronic hemodialysis receiving LMWH or UFH for the extracorporeal circuit anticoagulation.

Methods: We conducted a retrospective cohort study of patients undergoing chronic hemodialysis in 22 participating centers using data extracted from administrative databases in Quebec, Canada, from January 2007 to March 2013. Minor, major and total bleeding risk for a first event with LMWH compared to UFH was estimated using a proportional Cox model with time-dependent exposure using demographics, comorbidities and drug use as covariates.

Results: We identified 5322 prevalent and incident chronic hemodialysis patients. The incidence rate for minor, major and total bleeding was 9.5 events /1000 patient-year (95%CI: 7.6-11.0), 24.2 events /1000 patient-year (95%CI: 21.5-27.1) and 32.9 events /1000 patient-year (95%CI: 29.8-36.3) respectively. We found similar risks of minor (adjusted hazard ratio (HR)=1.04; 95%CI: 0.67-1.61), major (HR=0.84; 95%CI: 0.64-1.10) and total bleeding (HR=0.91; 95%CI: 0.72-1.15) when comparing LMWH to UFH.

Conclusions: LMWH was not associated with a higher minor, major or total bleeding risk compared to UFH in a large cohort of chronic hemodialysis patients. LMWH is a suitable alternative to UFH in hemodialysis.

TH-PO808

Survival in Patients on Hemodialysis: Effect of Sex According to Body Mass Index and Creatinine Jong-Hak Lee,[1] Jeong hoon Lim,[3] Man-hoon Han,[3] Hee-Yeon Jung,[3] Ji-Young Choi,[4] Sun-Hee Park,[3] Chan-Duck Kim,[2] Jang-Hee Cho,[3] Yong-Lim Kim.[3] *[1]Daegu Fatima Hospital, Daegu, Republic of Korea; [2]Kyungpook University Hospital, Daegu, Republic of Korea; [3]Kyungpook National University Hospital, Daegu, Republic of Korea; [4]Kyungpook National University School of Medicine, Daegu, Republic of Korea.*

Background: The association of a higher body mass index (BMI) with better survival is a well-known "obesity paradox" in patients on hemodialysis (HD). However, men and women have different body compositions, which could impact the effect of BMI on mortality. We investigated the effect of sex on the obesity-mortality relationship in Korean patients on HD.

Methods: This study included 2,833 maintenance patients on HD from a multicenter prospective cohort study in Korea (NCT00931970). The relationship between categorized BMI and sex-specific all-cause mortality was analyzed by an adjusted Cox proportional hazard model with restricted cubic spline analyses. We also investigated the effect of changes in BMI over 12 months and serum creatinine level on survival in male and female patients on HD.

Results: The mean BMI was 22.6 ± 3.3 kg/m2 and the mean follow up duration was 24.2 ± 3.4 months. The patients with the highest quintile of BMI (≥25.1 kg/m2) showed lower mortality (Hazard ratio [HR]=0.63, 95% confidence interval [CI]=0.42-0.95, P=0.026) compared with those with the reference BMI quintile. When analyzed by sex, male patients with a BMI over 25.1 kg/m2 had lower mortality risk (HR=0.43, 95% CI=0.25-0.75, P=0.003); however, no significant difference was found in female patients. Increased BMI after 12 months and high serum creatinine were associated with better survival only in male patients on HD.

Conclusions: BMI could be used as a risk factor for mortality in male patients on HD. However, the mortality of female patients on HD was not related with baseline

and follow-up BMI. This suggests that BMI is a good surrogate marker of lean body composition, especially in male patients on HD.

Pre- and Post-ESRD Trajectories of Serum Albumin among Incident ESRD Patients: A Transition of Care in CKD Study Patricia W. Lieu,[1] Melissa Soohoo,[2] Christina Park,[2] Connie Rhee,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh,[2] Elani Streja.[2] *[1]UCLA, Los Angeles, CA; [2]UC Irvine, Orange, CA; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Hypoalbuminemia is a strong predictor of mortality in chronic kidney disease patients, however the extent of change in serum albumin (Alb) in the year surrounding transition to end-stage renal disease (ESRD) is relatively unknown.

Methods: We examined serum Alb trajectories in the 1-year pre- and post-ESRD initiation among 31,053 patients who transitioned to ESRD from 2007-2014 using a mixed-effects regression model. Trajectories were stratified by baseline Alb levels in the 6-month pre-ESRD (prelude) period. Finally, we examined the association of 1-year pre-ESRD Alb slope with early mortality using Cox models adjusted for demographics and lab variables.

Results: The mean±SD age of the cohort was 68±11 years and included 2% females and 30% blacks. The median[IQR] of 1-year prelude Alb slope was -0.22[-0.48,0.23] g/dL/year. Among baseline Alb ≥2.8 g/dL, there was a sharp decline at initiation and a slow rise then plateau towards a normal range in the year after initiation. In patients with Alb <2.8 g/dL, there was a steep drop and a sudden increase in Alb in the few months surrounding transition. Moreover, a steep drop in pre-ESRD Alb of greater than -0.5 g/dL/year was associated with the highest risk of early 12-month post-ESRD mortality compared to no change in Alb slope [HR[95%CI]: 1.07[1.01, 1.13].

Conclusions: Across baseline albumin levels, pre-ESRD serum albumin tends to drop and then rise in the months around ESRD transition, while distinctions are observed for low baseline Alb. Also, a drop in Alb was associated with a higher risk of early mortality. Screening for rapid drops in Alb in the prelude period may identify those at greatest risk of early ESRD mortality. Further studies are required to determine if dietary and medication intervention to maintain elevated Alb impacts early ESRD outcomes.

TH-PO810

Employment among Patients Starting Dialysis in the United States Kevin F. Erickson,[2,1] Bo Zhao,[2] Vivian Ho,[1] Wolfgang C. Winkelmayer.[2] *[1]Baker Institute for Public Policy, Houston, TX; [2]Baylor College of Medicine, Bellaire, TX.*

Background: Patients with end-stage renal disease (ESRD) face significant challenges to remaining employed, and the rate of employment among the prevalent population of patients receiving dialysis is low. It is unknown when in the course of their kidney disease patients stop working. We examined employment trends among patients in the United States who are initiating dialysis and in the six months prior to ESRD.

Methods: We selected patients aged 18-54 who initiated dialysis between 1996 and 2013 from a U.S. registry of patients with ESRD. We compared unadjusted trends in employment at the start of dialysis and six months prior to ESRD, and used linear probability models to estimate changes in employment over time after adjusting for patient health, demographic and socioeconomic characteristics along with local unemployment rates in the general population. We also examined employment among selected vulnerable patient populations.

Results: Employment was low among patients starting dialysis throughout the study period at 22%-23%. However, after adjusting for observed characteristics, the probability of employment increased over time; patients starting dialysis between 2008 and 2013 had a 3.6% (95% CI 3.2%-4.0%) increase in the absolute probability of employment at the start of dialysis compared to patients starting dialysis between 1996 and 2001. More than 30% of patients who were employed six months prior to ESRD stopped working by dialysis initiation, but the adjusted probabilities of employment six months prior to ESRD and of remaining employed among those employed six months prior increased during the study period by 5.5% (95% CI 5.1%-5.9%) and 4.6% (95% CI 3.9%-5.3%), respectively. Black and Hispanic patients were less likely to be employed than other patients starting dialysis, but this gap narrowed during the study period.

Conclusions: Although working-aged patients starting dialysis between 1996 and 2013 experienced increases in the adjusted probability of employment over time, rates of employment remained low. Efforts to help patients with ESRD remain employed should target patients approaching ESRD as well as those already on dialysis.

TH-PO811

Impact of Employment Status or Insurance Type on Outcomes Among Patients with ESRD Jiacong Luo, Dena E. Cohen, Steven M. Brunelli. *DaVita Clinical Research, Minneapolis, MN.*

Background: It is widely thought that patients with end-stage renal disease who remain employed and/or commercially insured following dialysis initiation have better clinical outcomes and higher quality of life than those who do not. However, scientifically robust data are lacking.

Methods: This retrospective (2015-2016) study considered incident patients at a large US dialysis organization. Exposures of interest were insurance status (commercial, N=4858; Medicare/self-pay, N=13,329) and employment status (employed, N=1848; unemployed, N=10,001). Clinical outcomes and Kidney Disease Quality of Life (KDQoL) scores were determined from electronic health records. Comparisons were made using intention-to-treat principles and generalized linear models adjusted for imbalanced patient characteristics, including sociodemographic variables.

Results: Compared to commercial insurance, Medicare/self-pay was independently associated with higher rates of mortality and hospitalization, lower rates of transplant, and lower KDQoL scores in 4 of 5 domains. Similarly, unemployment (vs. employment) was independently associated with higher rates of mortality and hospitalization, lower rates of transplant, and lower KDQoL scores in 4 of 5 domains. Among patients who initiated dialysis while unemployed, those who resumed work by dialysis day 180 had lower rates of hospitalization (adjusted rate ratio 0.46, 95% confidence interval 0.25-0.84) than those who remained unemployed.

Conclusions: Commercial insurance, and separately, employment, were independently associated with better clinical and quality of life outcomes compared to other insurance and employment categories. These findings may inform patient and physician education, and guide advocacy efforts.

TH-PO812

Association of Hemodialysis Quality Measures with Patients Dialysis Facility Rating Ziad M. Ashkar. *Lafayette, LA.*

Background: The ICH-CAHPS In-Center Hemodialysis Survey is designed to measure the experiences of people receiving in-center hemodialysis care. Studies of Hospital HCAHPS have shown a significant positive associations between quality measures and patient satisfaction scores. Non profit hospitals and smaller hospitals also scored more favorably. The purpose of this study is to look into the association ICH-CAHPS global patient dialysis facility rating (GDR) with dialysis quality measures.

Methods: An observational retrospective, cross-sectional design. Data are obtained and matched from CMS Dialysis Facility Compare, release date April 2017. From ICH CAHPS, percent of patients who gave their dialysis facility a rating of 9 or 10 over 10 are divided into deciles and used as outcome variables. Ordinal logistic regression with cluster by state is then done with averages of % hemodialysis patients with hemoglobin < 10 g/dl, % KT/V>= 1.2, % with AV Fistula use, % with catheters more than 90 days, phosphorus < 3.5 mg/dl and > 7mg/dl, average mortality rate, readmission rate, hospitalization rate, standardized infection ratio, number of dialysis stations, for-profit status, and chain ownership.

Results: For each unit increase in number of dialysis stations, there was 3% decrease in odds of a decile improvement in global facility rating(GDR). For each unit increase in percent patients with KT/V>=1.2 there was 10% increase in odds of a decile improvement in GDR. % AV fistula in use was only associated with 2% increase. Each unit change in phosphorus of <3.5 and > 7.0 was associated with 11% and 7% decrease odds of a decile change in facility rating. Readmission rate was associated with 2% decrease and for-profit status was associated with 67% decrease odds of GDR. There were no significant relationship with other variables.

Conclusions: Using data from dialysis facility compare, there is significant positive association between higher KT/V, AV fistula use and GDR. Hospital readmission rate, low and high serum phosphorus were negatively related to GDR. Units with more stations, and for-profit units are negatively associated with GDR. More studies are needed to

understand deteminants for dialysis clearance and mineral bone disease with patients satisfaction. More is also needed to understand factors behind relationship of for-profit status and dialysis unit size with patients satisfaction.

TH-PO813

Trends in Insurance Coverage among ESRD Medicare Beneficiaries Claudia Dahlerus, John Wheeler, J. M. Messana, John Stephen, Tempie H. Shearon, Yi Li. *University of Michigan, Kidney Epidemiology and Cost Center, Ann Arbor, MI.*

Background: The 2010 Patient Protection Affordable Care Act (ACA) reduced the number of uninsured in the U.S. general population. Most ESRD patients are eligible for and covered by Medicare; however, it is unclear how implementation of the ACA impacted insurance status for ESRD Medicare beneficiaries. The ACA increased access to Medicaid for more people and made it possible for more people to purchase private health insurance. This potentially resulted in an increase in patients with Medicare/Medicaid Dual Eligibility (DE) coverage. Our objective is to examine whether there were changes in insurance status of ESRD dialysis patients in the initial period following ACA implementation.

Methods: Administrative data (Medicare claims files and Medicare Enrollment Data Base for 2012-2015) were used to classify ESRD dialysis patients by whether they were covered by both Medicare and Medicaid (Medicare/Medicaid DE). Trends were examined for coverage changes.

Results: From 2012-2015, there was an increase of 9.7% in the number of patients with ESRD eligible for Medicare. Over this period, the number of DE patients increased by 14.9%. Therefore, the percentage of Medicare ESRD patients with DE rose steadily from 39% to 41%.

Conclusions: The ACA extended Medicaid eligibility to more people in states choosing to participate in the Medicaid expansion. As a result, the trend in growth of persons with Medicare-Medicaid dual eligibility exceeded that of the overall Medicare ESRD population. This aspect of the ACA may therefore have improved access to dialysis care for more relatively low income people, by enabling them to afford the coinsurance and deductibles of the Medicare ESRD Program.

Funding: Other U.S. Government Support

Number of ESRD Beneficiaries by Insurance Coverage and Year

					% Change
Insurance Coverage	2012	2013	2014	2015	2012-2015
Medicare/Medicaid Dual Eligible	165,796	168,770	182,949	190,549	14.9%
All Medicare	422,609	436,358	449,611	463,568	9.7%

Utilization of Benchmarks to Reduce Transportation Costs for Dialysis Patients Terry L. Ketchersid,[2] Michael P. Martin,[1] Chris Richmond,[1] Greg S. Garza,[1] Daniel E. Geary,[1] John W. Larkin,[2] Marta Reviriego-Mendoza,[2] Len A. Usvyat,[2] Franklin W. Maddux.[2] *[1]Fresenius Health Partners, Austin, TX; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: End stage renal disease (ESRD) patients have high costs for transportation services. We examined if using benchmark data to identify outliers was associated with reductions in transportation costs. Through the Comprehensive ESRD Care (CEC) Model, Fresenius Medical Care, North America (FMCNA) has partnered with CMS to identify, test, and evaluate new ways to improve care for Medicare beneficiaries with ESRD. We are obligated to disclose that the statements contained in this document are solely those of the authors and do not necessarily reflect the views or policies of CMS. The authors assume responsibility for the accuracy and completeness of the information contained in this document.

Methods: We analyzed annual transportation costs and monthly treatment rates during 2015 to 2016 at 6 FMCNA ESRD Seamless Care Organizations (ESCOs). Two ESCOs with persistent historically high utilization of transportation costs (ESCO "A" & ESCO "B") were provided with benchmarking metrics and a root cause analysis. Quality improvement (QI) initiatives with enhanced education on medical necessity documentation were implemented.

Results: Mean transportation cost was $174 per member per month (PMPM) at the six ESCOs in 2015. ESCO "A" and "B" were identified as outliers with a transportation cost of $681 PMPM, and $263 PMPM, respectively. After implementation of the QI initiatives, ESCO "A" and "B" showed decreased transportation cost PMPM of 25% and 30%, respectively. As % of total PMPM, there was a decrease of 19% in transportation cost PMPM for ESCO "A", and a 30% decrease for ESCO "B". Associated with these QI initiatives, ESCO "A" and "B" recognized year-over-year reductions in transportation costs equal to $1,798,940 and $791,185, respectively. We found no differences in dialysis treatment rates before and after the implementation of the initiatives.

Conclusions: Our findings suggest that benchmarking transportation costs in ESCOs may help to identify outliers and lead providers to implement QI initiatives to reduce healthcare costs.

TH-PO815

Effects of the Affordable Care Act (ACA) and Medicaid Expansion on Incident ESRD Patients Richard A. Hirth,[3] Diane Steffick,[4] Jeffrey Pearson,[1] David W. Hutton,[3] William H. Herman,[2] Vahakn B. Shahinian,[4] John Z. Ayanian,[2] Rajiv Saran.[4] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Kidney Epidemiology and Cost Center, University of Michigan, Ann Arbor, MI; [4]Internal Medicine - Nephrology, University of Michigan, Ann Arbor, MI.*

Background: The expansion of insurance coverage under the ACA may have improved access to pre-ESRD care in the United States through the health insurance exchanges and the expansion of the Medicaid program. We assessed whether changes in insurance status at onset of ESRD were accompanied by changes in markers of pre-ESRD care.

Methods: Data were from the CMS Medical Evidence Form 2728. Patients whose first dialysis treatment occurred before the ACA's insurance expansions (10/1/11-12/31/13) were compared to patients incident after the ACA (1/1/14-3/31/16). A difference-in-difference approach was utilized to control for background trends in populations not likely to be affected by the ACA. The primary pre- vs. post-ACA comparisons were: 1) patients <65 years old with no Medicare coverage vs. patients 66+ with coverage, and 2) patients <65 in states expanding Medicaid on 1/1/14 vs. patients <65 in states that did not expand.

Results: Overall, the percent of patients <65 uninsured at incidence fell from 17.6% pre-ACA to 11.3% post-ACA [Figure]. Relative to trends for patients 66+, among patients <65, 6.2% saw gain in insurance coverage, 1.6% had gain in pre-ESRD nephrology care, 1.7% increased to use of home dialysis, and 1.4% showed a slower decline in use of EPO, but no improvement in vascular access type. Relative to trends for patients <65 in non-Medicaid expansion states, those in expansion states had a 3.4% gain in insurance, 1.1% gain in pre-ESRD nephrology care, 1.7% gain in fistula-in-use or maturing, but no change in EPO or home dialysis.

Conclusions: The ACA improved insurance coverage for patients initiating dialysis in the US, and increased many but not all markers of pre-ESRD care.

Data source: USRDS ESRD database, Medical Evidence form (CMS 2728). Exclusions: (1) patients not living in the 50 states or DC; (2) patients without a 2728 form; (3) patients missing residence at incidence. Patients aged 65 at incidence are excluded from Panel A as they would likely have received Medicare only a short time before incidence. Pre-Period: 10/1/2011 - 12/31/2013 (27m Post-period: 1/1/2014 to 3/31/2016 (27m). States expanding Medicaid immediately (N=25) are: AZ, AR, CA, CO, CT, DE, DC, HI, IL, IA, KY, MD, MA, MN, NV, NJ, NM, NY, ND, OH, OR, RI, VT, WA, WV. States that did not expand Medicaid (N=20 are: AL, FL, GA, ID, KS, LA, ME, MS, MO, NE, NC, OK, SC, SD, TN, TX, UT, VA, WI, WY.

Impact of the Affordable Care Act (ACA) on Incident ESRD Patients

TH-PO816

Socioeconomic Status and Dialysis Quality of Care Rathika Krishnasamy,[1] Dev K. Jegatheesan,[2] Paul D. Lawton,[3] Nicholas A. Gray.[1] *[1]Sunshine Coast University Hospital, Birtinya, QLD, Australia; [2]University of Queensland School of Medicine, Brisbane, QLD, Australia; [3]Menzies School of Health Research, Casuarina, NT, Australia.*

Background: Lower socioeconomic status (SES) has been associated with increased mortality in end stage kidney disease (ESKD) populations across USA, South America, Europe and Australasia. However, less is known about the association between SES and the quality of care (QOC) delivered to dialysis patients.

Methods: This study included all non-Indigenous adults commencing hemodialysis (HD) or peritoneal dialysis (PD) registered with Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry between 2002 and 2012 (n=16867). Each patient's location at dialysis start was classified into SES quartiles of advantaged through to disadvantaged using Australian Bureau of Statistics socio-economic indexes for areas. National and international guidelines were used to set limits for QOC attainment. The association between area-level SES and attainment of QOC indicators at 6-18 months and 18-24 months after dialysis start were assessed using logistic regression models. QOC measures included pre-dialysis phosphate, calcium, hemoglobin, transferrin saturation and ferritin. HD-related parameters included single pool Kt/V and percentage with functioning arteriovenous fistula/graft. PD-related parameters included weekly Kt/V and percentage lost to HD.

Results: The median age was 65 years (interquartile range 53-74), 62.2% were male and 85.1% were Caucasian. There were no significant differences in attainment of biochemical targets, PD or HD adequacy between the SES quartiles at 6-18 months after dialysis commencement. The least advantaged quartile were less likely to achieve hemoglobin target [Odds Ratio (OR) 0.89, 0.79-0.99, p=0.03] or to have a functioning fistula or graft (OR 0.75, 0.61-0.94, p=0.01] compared with the most advantaged group at 18-24 months.

Conclusions: Area-level SES has minimal impact on QOC attainment among non-Indigenous dialysis patients in Australia, where all residents have equal access to government funded healthcare. Increased mortality in lower SES groups is therefore likely due to pre-dialysis, other area-level and individual patient factors such as health-related behaviors, lifestyle and literacy, rather than disparities in QOC.

TH-PO817

CAHPS Domains as Predictors of Dialysis Facility Star Ratings and QIP Abhijit V. Kshirsagar,[1] Amir Alishahitabriz,[1] Heejung Bang,[2] Shoou-Yih D. Lee.[1] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]UC-Davis, Davis, CA.*

Background: Recent national initiatives have focused on differing aspects of dialysis care quality in the United States. The Dialysis Facilities Compare (DFC) star rating & the Quality Incentive Program (QIP) generate distinct scores from clinical measures to quantify care quality. The Consumer Assessment of Healthcare Providers and Systems (CAHPS) survey evaluates the patient experience to assess the perceived quality of care in separate domains related to dialysis facility & staff, nephrologists, and peer-to-peer counseling. Knowing how the patient experience relates to star ratings & QIP may help providers develop strategies to improve dialysis care delivery.

Methods: We linked the star ratings and QIP scores with CAHPS survey results for each dialysis clinic by its unique identifier (available at the DFC website) for calendar year 2016. With the CAHPS domains as independent variables, we calculated odds ratio from an ordered Logit model for star ratings, and calculated the linear strength of association for QIP. We adjusted for facility size, profit status, and home dialysis status. Peer-to-peer counseling was not analyzed due to a large proportion of non-reported data.

Results: From a total of 6750 dialysis facilities nationally, 6027 had star ratings (1 - low to 5 - high), 6229 facilities had QIP score and 3354 facilities had CAHPS survey results. CAHPS domains related to preceived facility delivery of care (staff and operations) were consistently stronger predictors of a 5-star rating or high QIP than domains related to perceived delivery of care by nephrologists, Table.

Conclusions: Patient's perception of care delivery, captured by CAHPS, is directly related to the known quality measures-- star ratings and QIP. Interestingly the facility staff and environment are stronger predictors of quality than nephrologists. Understanding patients' perception of care may help with their engagement to ultimately reach important quality goals.

Patient Reported Clinical Symptoms Are Associated with Patient Outcomes Dugan Maddux,[1] Hao Han,[1] John W. Larkin,[1] Len A. Usvyat,[1] Frank van der Sande,[2] Jeroen Kooman,[2] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Maastricht University Medical Centre, Maastricht, Netherlands.*

Background: Traditional outcomes-related research on dialysis patients typically focuses on biomarkers such as blood pressure, body size, albumin (alb) and hemoglobin. During dialysis treatment, however, nurse-documented "chairside" patient information is also collected, and majorly includes patients' symptoms that may have an effect on patients' clinical outcomes. The association of chairside data with patient outcomes has not been well described. We aim to understand the relationship of "shortness of breath" (SOB), a nurse-reported patient symptom, to patient outcomes.

Methods: We included all patients who initiated dialysis treatment in the network of Fresenius Medical Care North America clinics between Jan 1, 2013 and June 30, 2015. Only patients who survived the first 365 days on dialysis were included. Patient laboratory and treatment parameters including The Kidney Disease Quality of Life (KDQOL) survey were computed as averages of the first year on dialysis. Patient hospitalization outcomes were assessed in year 2 on dialysis. We computed percent of treatments where patients experienced SOB symptoms as determined by either nursing notes or checkbox-based assessment in the electronic health record. A Poisson model using hospital admissions as an outcome was utilized to calculate the association of SOB to hospital admissions.

Results: We analyzed data on 39,594 dialysis patients. In a univariate analysis, we noted that the strongest correlation with percent of treatments with SOB were hospital admission rate (r=0.14, p<0.001), alb level (r=-0.09, p<0.001), KDQOL physical composite score (r=-0.12, p<0.001), and KDQOL symptom problem score (r=-0.11, p<0.001). We also observed that the percent of treatments with SOB was clearly significantly associated with more hospital admissions.

Conclusions: Chairside observation and clinician documentation of patient-reported symptoms may be an important predictor of outcomes in dialysis patients. Additional analyses are needed to understand the association of SOB and other symptoms to patient outcomes.

Transplantation as a Competing Risk in Dialysis RCTs Christos Argyropoulos,[5] Maria-Eleni Roumelioti,[4] Mark L. Unruh,[5] V. Shane Pankratz,[3] Francesco Locatelli,[1] Adelheid Gauly.[2] *[1]Azienda Ospedaliera Della Provincia di Lecco-Ospedale Alessandro Manzoni, Lecco, Italy; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]UNM Health Sciences Center, Albuquerque, NM; [4]University of New Mexico, Albuquerque, NM; [5]University of New Mexico, Albuquerque, NM.*

Background: Transplantation is a competing risk and potential confounder in the analysis of outcomes in ESRD RCTs. We examined whether results of RCTs are affected by the method to account for these informative censoring events.

Methods: We analyzed patient level data from the NIDDK sponsored HEMO and the European MPO RCTs of high flux (HF) membranes. Together these two studies contribute 96% of the evidence for the use of HF in clinical practice. We compared conventional Cox proportional hazards (CPH) models and methods for competing risk events (cumulative incidence functions, CIF) and relevant regressions models.

Results: In HEMO there were 194 transplantation out of 1846 patients; 170 out of 647 participants were transplanted during MPO. In unadjusted analyses of CIF[figure], HF dialysis was not associated with improved survival (p=0.20). In adjusted CPH analyses, treatment effects differed in both studies (HR 0.82 in MPO, but 0.95 in HEMO). In analyses that accounted for the competing risks of transplant, treatment effects were similar in magnitude [table]. Furthermore, when the studies were analyzed together HF was associated with 16% reduction in the incidence of death (p=0.022).

Conclusions: Effect sizes, and perceived congruency of interventions in RCTs in ESRD, may depend on the methods for handling censoring due to transplantation. Our findings mirror recent reports in hemodiafiltration (HDF) RCTs [Nephrol Dial Transplant (2017) 32: ii31–ii39], raising the question whether many negative (e.g. statins) and/or discrepant results in nephrology (HF or HDF) are due to the statistical methods employed to analyze trials.

Early Mortality Comparison between Hemodialysis and Peritoneal Dialysis Patients Who Transition with an Optimal Outpatient Start John J. Sim,[1] Hui Zhou,[1] Jiaxiao Shi,[1] Sally F. Shaw,[1] Scott A. Rasgon,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh,[2] Steven J. Jacobsen.[1] *[1]Kaiser Permanente Southern California, Pasadena, CA; [2]University of California Irvine, School of Medicine, Orange, CA; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Lower early mortality observed in peritoneal dialysis (PD) compared to hemodialysis (HD) may be due to differential pre- end stage renal disease (ESRD) care and the stable setting of transition to dialysis. Specifically, PD starts occur more frequently in an outpatient setting rather than during a hospitalization. To account for these circumstances, we sought to compare early mortality among PD and HD patients who had optimal ESRD starts and first transitioned to dialysis on an outpatient basis.

Methods: A retrospective cohort study (1/1/2002-12/31/2013) within Kaiser Permanente Southern California (an integrated health system) was performed on chronic kideny disease patients who had optimal start transition to ESRD in an outpatient setting. Optimal start was defined as 1) initiation of HD with an arteriovenous fistula or graft or 2) initiation with PD. Propensity score modeling factoring sex, race, age, co morbidities, eGFR level, and change in eGFR prior to ESRD was used to create a matched cohort of HD and PD patients. All-cause mortality odds ratio (OR)'s were estimated for 6 months, 1 yr, and 2yr post transition to ESRD.

Results: A total of 2,094 (1398 HD and 696 PD) patients had an optimal outpatient transition to ESRD. The mean age was 62 yrs with 40% females, 39% Hispanics, 26% whites, and 21% blacks. In the 2 year observation window, 20% PD patients switched to HD while only 2% of HD patients switched to PD. 547 HD patients were matched to 547 PD patients on the propensity score with caliper distance <=0.001. All-cause mortality OR in HD compared to PD patients were 1.09 (0.47-2.57), 1.64 (0.92-2.93), and 0.90 (0.61-1.33) for 6 months, 1yr, and 2yrs, respectively. White race and age >/=60 yrs were associated with higher mortality.

Conclusions: There were no differences in early mortality between PD and HD patients who transitioned to ESRD with an optimal start in an outpatient setting. While prior observations have suggested an early survival advantage with PD, our finding suggest that the pre-ESRD care and the stable transition to dialysis likely account for lower early mortality among the ESRD population.

KDOQI Nutrition Guideline 21 Associates with Overfeeding in Critically Ill ESRD Patients Eli McKenna-Weiss, Daniel L. Landry, Patrick Mailloux, Young hee Kim, Gregory L. Braden. *Medicine, U Mass Medical School/ Baystate, Springfield, MA.*

Background: KDOQI nutrition guideline 21 states that critically ill ESRD patients(pts) less than 60 yr old receive at least 35 kcal/kg/day of total parenteral nutrition(TPN) & pts over 60 should receive 30-35 kcal/kg/day TPN. U.S. guidelines for ICU nutrition suggest 22-24 kcal/kg/d for critically ill non ESRD pts.

Methods: We studied 11 intubated ESRD pts (4W/7M) in the ICU with the Puritan Bennett indirect calorimeter on 3 different non dialysis days while NPO and during TPN with 28 or 38 kcal/kg/d. 4 pts were under age 60 & 7 pts were over age 60. Only 1 pt had diabetes mellitus. Causes for the ICU: sepsis 4, respiratory failure 5, cva 1 & chf 1. Mean time on hemodialysis was 1.5 years and mean serum albumin pre study was only 2.4+/- 0.2 gm/dl. Pts were studied from 5 am to 1 pm & the results of resting energy expenditure (REE), VO2 (ml/min), VCO2 (ml/min) and respiratory quotient(RQ) were calculated by the continuous machine averages for all parameters. Time averaged glucose levels q 4 hours were calculated. TPN intake ratios for both the 28 and 38 kcal studies were: 20% protein, 30% fat & 50% carbohydrates.

Results: Baseline REE for age under 60 was 26.0 +/- 4 kcal/kg/d and for over 60 was 22.0 +/- 2 kcal/kg/d despite sepsis in 2 pts in each group (p NS). REE for all NPO pts was only 23.5 +/- 4 kcal/kg/d & only 24.5 +/- 4 & 26.0 +/- 3 for TPN days with 28 or 38 kcal/kg/d (p NS). The mean +/- SE for indirect calorimetry are shown in the table:

Conclusions: We conclude: 1) The REE in critically ill ESRD pts is similar to non ESRD pts with a mean REE of 23.5 kcal/kg/d. 2) There are no differences in REE in ESRD pts less than or over age 60. 3) Early feeding TPN in ICU ESRD pts at 28 or 38 ckal/kg/d signicantly increaed VO2, VCO2, RQ and glucose levels which indicates excessive carbohydrate metabolism &/or increased lipogenesis which may be harmful to these pts. 4) KDOQI nutrition guideline 21 needs to be modified based on our study.

	VO2 (ml/min)	VCO2 (ml/min)	RQ	Glucose
NPO	208+/- 19	166 +/- 12	0.80	106 +/- 15
28 Kcal/kg	204 +/- 20	192 +/- 13#	0.95#	162 +/- 30#
38 Kcal/kg	239 +/- 32#	214 +/- 24#	0.95#	159 +/- 25#

# $p < 0.05$ compared to NPO. The increased VCO2, RQ & glucose levels suggest carbohydrate overfeeding and increased lipogenesis in the TPN groups. No differences found between 28 and 38 kcal groups in any parameter.

TH-PO822

Limitations of the KDQoL for Assessing Quality of Life Among Patients with ESRD Andrew Lee,[1] Dena E. Cohen,[1] Scott Sibbel,[1] Deborah A. Benner,[2] Steven M. Brunelli,[1] Francesca Tentori.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita, Inc, Denver, CO.*

Background: Achieving the best possible quality of life (QoL) is a key goal for patients with end-stage renal disease (ESRD). The Centers for Medicaid and Medicare Services mandate regular assessment using the Kidney Disease Quality of Life (KDQoL) survey. Given concerns that the KDQoL may not adequately capture QoL among contemporary ESRD patients, we examined its construct validity.

Methods: We considered 282,895 KDQoL surveys completed by 175,826 adult patients receiving in-center hemodialysis at a large US dialysis organization (2014-2016). Correlations between item responses, domain scores, and interdialytic weight gain (IDWG) were calculated using Pearson correlations computed with pairwise complete observations.

Results: Patient perceptions of general health were not correlated (R<0.05) with any other question in the physical composite score (PCS) or the symptoms and problems subscale (SPS). Mean SPS (77.9 ± 16.9) exceeded mean PCS (36.3 ± 12.2); correlation between the two was modest (R=0.42). Many items in the SPS showed ceiling effects: for all 12 items, <10% of patients were "extremely bothered," while >65% of patients reported being "not at all" or only "somewhat bothered;" for 3 items, >85% of patients gave these two responses. IDWG was not correlated with patient-reported shortness of breath, PCS, or SPS.

Conclusions: We identified possible limitations in the mandated tool that is used for assessment of QoL in ESRD patients. New measures of QoL that focus on factors that affect a considerable proportion of contemporary dialysis patients, particularly those that can be addressed by modifiable clinical practices, are needed.

TH-PO823

Adverse Drug Effects in Patients with ESRD Who Present to the Emergency Department Lili Chan,[1] Priti Poojary,[1] Aparna Saha,[1] Kinsuk Chauhan,[1] Steven G. Coca,[1] Pranav S. Garimella,[2] Girish N. Nadkarni.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]University of California San Diego, San Diego, CA.*

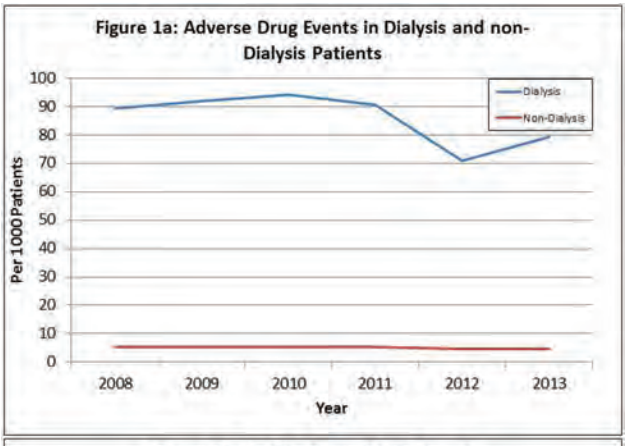
Background: Patients on dialysis are at high risk for adverse drug effects (ADEs) due to impaired renal clearance of medications and polypharmacy. We aimed to explore trends and outcomes of ADEs in dialysis patients.

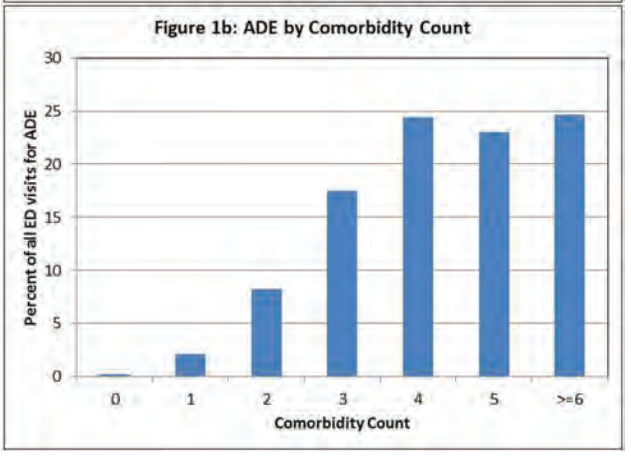
Methods: We utilized a nationally representative database, the Nationwide Emergency Department Sample, to identify dialysis patients who present to the emergency

department (ED) for an ADE. We excluded illicit drug toxicities, intentional poisoning, renal transplantation, pregnancy and age <18. Incidence was calculated using the United States Renal Data System and the United States Census Bureau data.

Results: From 2008 to 2013, there were 9,734,821 ED visits for ADEs. ED visits for ADEs were consistently higher in dialysis patients compared to non-dialysis patients, 70-94/1000 patients vs. 4-5/1000 patients (Figure 1a). In dialysis patients, ADEs were more common in females, age ≥ 65 years, and hemodialysis vs. peritoneal dialysis patients. Incidence of ED visits for ADEs increased with increasing number of co-morbidities (Figure 1b). In-patient admission was more common in dialysis patients, 88% vs. 58%, P <0.001. Mortality of ESRD patients who were admitted was 3 times that of non-dialysis patients.

Conclusions: ED visits for ADEs are common in dialysis patients, and substantially higher than in non-dialysis patients. Nearly 90% of all ER visits for ADEs in dialysis patients results in an inpatient hospital admission which contributes to great financial burden on the health care system.





TH-PO824

Impact of Pre-Dialysis Acute Hospitalizations on Post-Dialysis Outcomes in Incident Dialysis Patients Silvi Shah, Anthony C. Leonard, Charuhas V. Thakar. *University of Cincinnati, Cincinnati, OH.*

Background: Mortality in end stage renal disease (ESRD) patients is highest during the first year of dialysis. Although survival is similar in hemodialysis (HD) and peritoneal dialysis (PD), overall costs of care are lower in PD. In spite of the increasing burden of cardiovascular (CV) disease and infections with kidney disease progression, the impact of pre-dialysis acute hospitalizations on dialysis modality and on mortality in dialysis patients is not known.

Methods: We evaluated 49,645 adult incident dialysis patients (1/1/2008 to 12/31/2008) from the United States Renal Data System (USRDS) with linked Medicare data for at least 2 years prior to dialysis initiation. Using case-mix adjusted logistic regression models (16 variables), we examined the impact of pre-dialysis acute hospitalizations on type of dialysis modality (PD vs. HD) and one-year all-cause mortality. We evaluated 4 groups of patients by cause of hospitalizations: CV related, infection related [INF], both CV and INF [CV+INF]; and neither CV nor INF related.

Results: The sample was 55% male, 63% White with a mean age of 72±11 years. Only 4% of patients received PD as initial modality. Among the study cohort, 89% had at least one pre-dialysis hospitalization [CV-34%; INF-11%; CV + INF-12%; and 33%-neither CV nor INF]. In adjusted analyses, as compared with no pre-dialysis hospitalizations, patients with INF, CV, CV+INF and neither CV nor INF hospitalizations were more likely to be started on HD (odds ratio [OR] 2.7, 95% confidence interval [CI] 2.24-3.26; OR 2.7, CI 2.37-3.08; OR 3.3, CI 2.68-4.08; OR 2.6, CI 2.3-2.93 respectively). In adjusted analyses, one-year mortality was higher with pre-dialysis INF hospitalizations (OR, 1.41; CI 1.28-1.54), CV hospitalizations (OR, 1.47; CI 1.35-1.59) and INF+CV hospitalizations (OR, 1.87; CI 1.7-2.05), compared with no pre-dialysis hospitalizations.

Conclusions: Pre-dialysis hospitalizations are frequent; infection or cardiovascular related hospitalization independently increases the odds of HD vs. PD; and is an independent predictor of one-year mortality in incident dialysis patients. Effects of pre-ESRD hospitalization should be considered while comparing mortality as quality of dialysis care. Reducing pre-ESRD hospitalizations may improve survival and costs of care after initiating dialysis.

TH-PO825

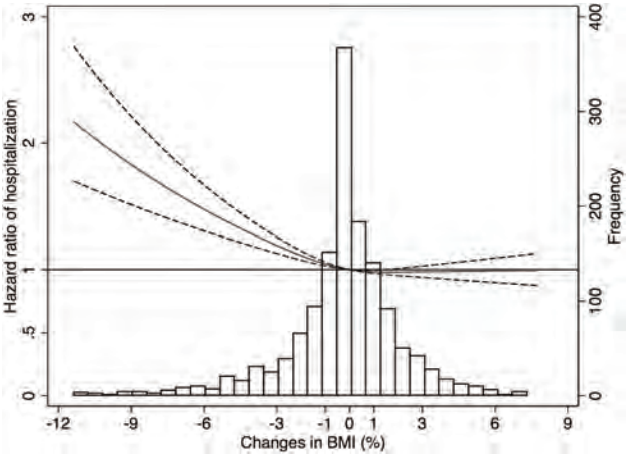
Change in Body Mass Index and Subsequent Risk of Hospitalization in Elderly Hemodialysis Patients: The Japanese Dialysis Outcome and Practice Patterns Study (J-DOPPS) Keiichi Sumida,[1] Shungo Yamamoto,[2] Tadao Akizawa,[3] Shunichi Fukuhara,[2] Shingo Fukuma.[2] *[1]Toranomon Hospital Kajigaya, Kawasaki, Japan; [2]Kyoto University, KYOTO, Japan; [3]Showa University School of Medicine, Tokyo, Japan.*

Background: Short-term weight gains and losses are associated with lower and higher mortality risk, respectively, in patients on hemodialysis (HD). However, little is known about their association with the risk of subsequent hospitalization.

Methods: In a prospective cohort of 1,804 HD patients aged ≥65 years enrolled in the J-DOPPS phases 3 (2005–2008) and 4 (2009–2011), we examined the associations of changes in body mass index (BMI) over a 4-month baseline period (<-3, -3-<-1, -1-<1 [reference], 1-<3, and ≥3%) with subsequent risk of all-cause, cardiovascular (CV), and non-CV hospitalizations, respectively, using Cox models with adjustment for potential confounders.

Results: During a median follow-up of 1.2 years, there were 1,027 incident hospitalizations for any cause. There was an L-shaped association between BMI change and all-cause hospitalization (Figure). The adjusted HRs (95% CI) of all-cause hospitalization associated with BMI changes of <-3, -3-<-1, 1-<3, and ≥3% (vs. -1-<1%) were 1.30 (1.04-1.63), 1.23 (0.99-1.52), 1.04 (0.84-1.30), and 1.13 (0.86-1.49), respectively. Qualitatively similar associations were present for non-CV hospitalization (corresponding HRs [95% CI] were 1.33 [1.04-1.69], 1.24 [0.98-1.56], 1.07 [0.85-1.35], and 1.14 [0.84-1.56], respectively), but not for CV hospitalization (corresponding HRs [95% CI] were 1.23 [0.65-2.33], 1.10 [0.69-1.75], 0.87 [0.51-1.49], and 1.03 [0.46-2.33], respectively).

Conclusions: Decreases in BMI over a relatively short-term period were independently associated with higher risk of subsequent hospitalization, particularly non-CV hospitalization, among elderly HD patients.



TH-PO826

Weekend versus Weekday Admission in Dialysis Dependent Patients Requiring Hospitalization – A Nationwide Analysis Yumeng Wen,[1,2] Di Pan,[1,2] David Mariuma,[1,2] Michael Gramuglia,[3] Ira S. Meisels.[1,2] *[1]Division of Nephrology, Department of Medicine, Mount Sinai St. Luke's and Mount Sinai West Hospitals, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Department of Medicine, Montefiore Medical Center, Scarsdale, NY.*

Background: End Stage Renal Disease (ESRD) is a major cause of worldwide mortality and morbidity. ESRD requiring chronic dialysis is associated with high mortality and morbidity, requiring frequent hospitalization for complications from dialysis and comorbidities. The aim of this study is to determine the differences in outcomes and resource utilization of dialysis dependent patients hospitalized on weekends compared to weekdays.

Methods: This is a retrospective cohort study using the 2014 National Inpatient Sample, the largest publically available inpatient database in the United States. The inclusion criteria were age above 18 and an ICD-9 CM code for diagnosis of ESRD on chronic dialysis. Patients hospitalized for elective procedures were excluded. The primary outcome was in-hospital mortality. The secondary outcomes were morbidities, as measured

by the development of shock and acute respiratory failure, as well as resource utilization including length of hospital stay (LOS) and total hospitalization charges. Analysis is performed by using Stata, version 14.2. Odds ratio (OR) and means were adjusted for the following confounders using multivariate regression models: demographics, Charlson Comorbidity Index, early dialysis in hospital (defined as receiving dialysis within 1 day of admission), primary insurance, hospital bedsize, hospital region and household income.

Results: 934,575 patients with ESRD on chronic dialysis were included in the study. Patients admitted on weekends were associated with significantly higher in-hospital mortality rates (5.45% versus 4.87%, p=0.02) and higher rate of acute respiratory failure (3.89% versus 3.32%, OR 1.11, p=0.001). The development of shock was not significantly different (OR 0.97, p=0.69). Weekend admission was associated with greater length of stay (6.90 versus 6.89, p<0.001), however the total hospital charges were not significantly different (p=0.07). Patients admitted on weekends had lower rate of receiving early dialysis (43.72% versus 52.72%, p<0.001).

Conclusions: Compared to weekday admission, weekend admission in patients with ESRD on chronic dialysis was associated with higher rates of mortality and acute respiratory failure, as well as greater length of stay even after controlling for early dialysis. Patients admitted on weekends were less likely to receive early dialysis.

TH-PO827

Urgent Start Dialysis: Peritoneal Dialysis versus Hemodialysis via a Central Venous Catheter Neelam M. Bhalla,[3] Neiha Arora,[2] Jeanne A. Darbinian,[1] Sijie Zheng.[2] *[1]Kaiser Permanente, Oakland, CA; [2]The Permanente Medical Group, Oakland, CA; [3]nephrology, kaiser permanente, Hayward, CA.*

Background: Though underutilised in the US, PD is a safe and effective home modality of renal replacement therapy. One reason for under use of PD is the practice of initiating patients on HD via a central venous catheter (CVC) if they do not have a functional AVF/AVG. When compared with AVF/AVG, CVC use is associated with increased mortality. Recently, use of urgent start PD has gained interest since it decreases use of CVCs, while affording a mechanism of increased PD utilization. In this retrospective cohort study, we compared complications and outcomes between the two urgent start dialysis modalities.

Methods: We identified a subpopulation of KPNC members who met clinical criteria for being in urgent need of beginning PD or HD between 1/1/2011 and 12/31/2014. Urgent start HD patients were matched 3:1 with PD urgent starts on selected characteristics. Medical records of all cohort members were reviewed by three nephrologists. Complications and outcomes occurring after initiation of dialysis were compared between the modalities using Chi-square or Fisher exact tests.

Results: We compared 335 HD starts with 84 PD starts. There were no modality switches in the PD cohort; in HD start cases one changed to home HD and four to PD. Transferring to hospice accounted for 92% of modality terminations in HD; reasons in PD were psychosocial (43%); medical (28.6%); peritonitis (14.3%) and others (14.3%). Major complications were low in both groups (<5%), though rate of catheter malfunction was higher in HD (12.8% vs. 6.0%, p=0.09). There was a statistically significant difference in overall infectious complications between PD (20%: peritonitis -13%; exit site - 7%) and HD (9%: bacteremia - 7.2%; exit site - 1.8%, p<0.01). There were more deaths in the HD group (19.7% vs 7%, p=0.015). Furthermore a higher proportion of deaths was observed in patients with bacteremia compared with those who had peritonitis (25 vs. 16.7%). Pericatheter leaks developed in 7% of PD cases and in no HD patients.

Conclusions: Urgent PD start is a viable alternative to urgent HD start via CVC. Although infectious complications were higher in PD, peritonitis was associated with less mortality than bacteremia. Notably there is a high patient retention rate, leading to increased utilization of PD.

Urgent-Start Peritoneal Dialysis by the Nephrologist Javier Soto-Vargas,[3] Heriberto R. López,[3] Martín D. Vargas ezquivel,[3] Carlos Daniel Jiménez Mejía,[3] Ana L. Garc?a-Vera,[3] Rodolfo A. Cortina,[2] Alfonso Ramos,[1] Renato Parra,[3] Mario A. Garc?a C?rdenas.[3] *[1]Baxter Mexico, San Jer?nimo Chicahualco, Mexico; [2]ISSSTE, MEXICO CITY, Mexico; [3]Regional General Hosptial 46, Mexican Institute of Social Security, Guadalajara, Mexico, Guadalajara, Mexico.*

Background: Urgent-start peritoneal dialysis is an alternative to initiation of renal support in patients with end-stage renal disease. The objective is to describe our experience with an urgent-start PD program.

Methods: In this prospective observational study, we report on our experience in a single academic center. All patients treated with urgent-start PD, defined as PD therapy initiated within 1 week after catheter insertion, and from September 2016 to April 2017 were included. Peritoneal dialysis catheters were inserted percutaneously by punction. Dialysis was initiated in an inpatient setting whit a fix dose of 60 liters in fast cycles.

Results: Seventy three patients were started on urgent PD during our study period. Follow-up of 30.5 days (IQR 25-55.5). Dialysis was initiated with a median of 1 day (IQR, 0.6-2.0). The major indications for treatment were acidosis and uremic syndrome. The median hemoglobin was 8 g/dL (IQR 6.9-8.9), urea 224.5 mg/dL (194-293), potassium 4.8 mEq/dL (IQR 4.1-5.4), pH 7.32 (IQR 7.2-7.38) and HCO3 12.8 mEq (IQR 9.5-16.1). Twenty-five patients (34%) developed a mechanical complication of which: nine (12.2%) were peri-catheter leak, flow dysfunction in 7 (9.5%) patients and 6 (8.1%) cases of peri-catheter bleed. Eight (10.8%) patients required catheter removal and reinsertion, and only one (1.4%) patient required modality switch. No demographic or biochemical characteristic was associated with the development of any complication.

Conclusions: Urgent-start PD is an acceptable and safe alternative compared to hemodialysis for initiation of renal support in patients with end-stage renal disease.

The Gastrointestinal Symptoms in Peritoneal Dialysis Patients I-kuan Wang,[2] Chin-Chi Kuo,[1] Chiu-Ching Huang.[2] *[1]None, Taichung, Taiwan; [2]China Medical University Hospital, Taichung, Taiwan.*

Background: Gastrointestinal (GI) symptoms such as gastrointestinal reflux, constipation, indigestion, abdominal pain and diarrhea are common in peritoneal dialysis (PD) patients. Constipation is a risk factor of PD-related peritonitis. The aim of this study is to evaluate the prevalence of GI symptoms in PD patients.

Methods: Patients undergoing PD more than one month in China Medical University hospital was enrolled from July 2011 to March 2013. To evaluate the presence of GI symptoms, PD patients were asked to complete the gastrointestinal symptom rating scale (GSRS). The GSRS, a questionnaire, include 15 items, which could be classified into abdominal pain, reflux, diarrhea, indigestion, and constipation. Each item was rated as 0, 1, 2, and 3 according to severity.

Results: A total of 40 patients completed the questionnaire. The mean age was 49.58 ± 11.49 years. The duration of PD was 43.26 ± 31.47 months. 21 (52.5%) patients were female. The etiology of ESRD includes chronic glomerulonephritis (19 patients, 46.3%), diabetes (8 patients, 20%), hypertension (6 patients, 15%), chronic tubulointerstitial nephritis (4 patients, 10%) and polycystic kidney disease (3 patients, 7.5%). Only 3 patients (7.5%) have no GI symptoms. The prevalence of abdominal pain, reflux, diarrhea, indigestion, and constipation was 40% (16 of 40), 35% (14 of 40), 37.5% (15 of 40), 77.5% (31 of 40), and 62.5% (25 of 40). The prevalence of 0, 1, 2, 3, 4, 5 GI symptoms was 7.5% (3 of 40), 15% (6 of 40), 30% (12 of 40), 20% (8 of 40), 20% (8 of 40), and 7.5% (3 of 40), respectively.

Conclusions: GI symptoms are highly prevalent in PD patients. Medical staffs have to pay attention to and take good care of these GI problems

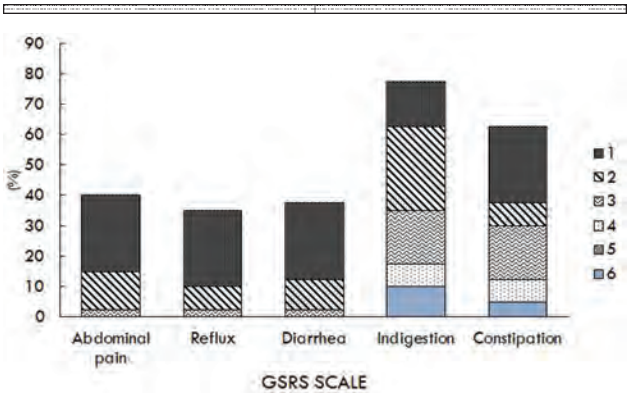

Figure 1. The prevalence and grading of gastrointestinal symptoms in peritoneal dialysis patients according to the gastrointestinal symptom rating scale.

TH-PO831

Allopurinol Does Not Protect Renal Function in Patients on Peritoneal Dialysis Antonio A. Portela Neto,[4] Rosilene M. Elias,[5] Rosa M. Moyses,[2] Hugo Abensur,[3] Benedito J. Pereira,[6] Lilian Cordeiro.[1] *[1]None, Sao Paulo, Brazil; [2]Universidade Nove de Julho, São Paulo, Brazil; [3]Universidade de Sao Paulo, Sao Paulo, Brazil; [4]University State of São Paulo, São Paulo, Brazil; [5]University of Sao Paulo, Sao Paulo, Brazil; [6]University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Preservation of renal function in peritoneal dialysis (PD) patients is essential, since it is directly associated with increased survival in this method. Although there is evidence that allopurinol protects residual renal function (RRF) in patients with chronic renal disease not yet on dialysis, whether there is still benefit after these patients started PD is unknown. We therefore examined a cross-section of incident patients on PD to test the association between uric acid (UA) and the use of allopurinol with preservation of RRF.

Methods: Patients starting PD between January 2009 and December 2016 in an academic center, with demographic, clinical and laboratorial data were included. The outcome of interest was renal Kt/V, obtained in two moments: within the first 6 months of PD and at the end of the follow-up period. The difference between final and initial Kt/V was defined as Kt/V delta.

Results: Sixty-nine patients (age 47±18 years, 47% male, 79% hypertensive and 25% diabetic) were included. The UA was 7.2±1.8, ranging from 3.2 to 12.8 mg/dl. More than half of the patients (53.6%) presented UA higher than 7.0 mg/dl, with no difference in Kt/V delta [-0.33 (-0.55, -0.05 vs. -0.19 (-0.44, -0.01) in patients with UA higher and lower than 7.0 mg/dl, respectively; p = 0.382]. Delta Kt/V correlated with UA delta (r=-0.390, p=0.001), but it was not different between patients with and without allopurinol [-0.17 (-0.45; -0.01) vs. -0.29 (-0.66, 0.93; -0.02, respectively; p = 0.443]. Multiple regression analysis showed that neither UA nor UA delta (adjusted for allopurinol use) were independently associated with Kt/V delta.

Conclusions: The use of allopurinol had no impact on the preservation of RRF in patients on PD. In view of possible harm associated with allopurinol, prospective and interventional studies are required prior to recommendation of a regular prescription of such a drug for the PD population, as an attempt for renal preservation.

TH-PO832

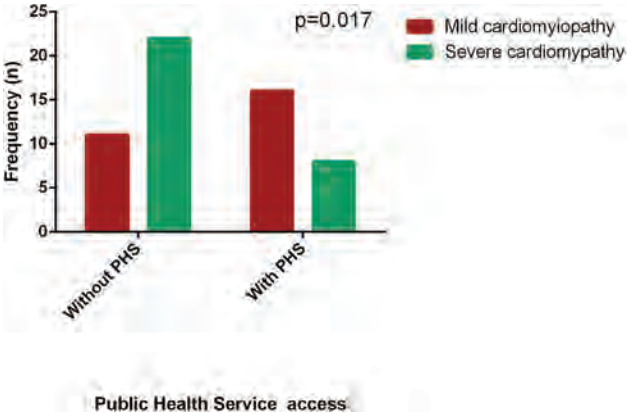
Uremic Cardiomyopathy in Young Incident Peritoneal Dialysis Patients According to the Access of Public Health Services Perla T. Figueroa-Gonzalez,[1] Javier Soto-Vargas,[1] Ana S. Espinoza,[1] Julio A. Gutierrez,[1] Osvaldo Rafael Medina Zepeda,[2] Leonardo Pazarin-Villaseñor.[1] *[1]Nephrology, Regional General Hospital 46, Mexican Institute of Social Security, Guadalajara, Mexico, Guadalajara, Mexico; [2]Cardiology, Regional General Hospital 46, Mexican Institute of Social Security, Guadalajara, Mexico.*

Background: Uremic cardiomyopathy is responsible for high morbidity and mortality rates among patients with end-stage renal disease. Our objective was to describe and compare the echocardiography characteristics of young incident peritoneal dialysis (PD) patients with and without access to Public Health Services (PHS).

Methods: Seventy-two incidents PD patients under 35 years old and with no history of cardiovascular disease underwent Doppler echocardiography evaluation. The results were reported according to the American Society of Echocardiography and the European Association of Cardiovascular Imaging.

Results: Thirty-six patients with universal medical care access and 36 without it were evaluated. Fifty-seven (79.2%) of the total cohort had at least one alteration on Doppler echocardiography evaluation. Thirteen (18.1%) had systolic dysfunction, and the median VEF was 60% (IQR, 51-63.7), in 9 (12.5%) patients diastolic dysfunction was present and 21 (11.1%) had a degree of pulmonary hypertension. The patients without access to PHS were younger (median 20 years, IQR 19-24, p=0.005), had higher left ventricular mass (median 238 grams, IQR 200-270, p <0.000), greater systolic dysfunction, VEF (median 55.5, IQR 42.25-60, p = 0.003), higher pulmonary arterial pressure (median 30 mmHg, IQR 28 -49, p <0.000), had more frequency of cardiomyopathy (91.7% vs 66.7%, p=0.018), and severity of the cardiomyopathy (66.7% vs 33.3% p=0.017).

Conclusions: The uremic cardiomyopathy is highly prevalent in young incident peritoneal dialysis patients. There is a difference according to the social security status, in the frequency of echocardiographic alterations and their severity.



PHS, Public Health Services. Fisher's Exact test.

TH-PO833

Functional Status among Patients Receiving Peritoneal Dialysis: Results from the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) Karthik K. Tennankore,[1] Junhui Zhao,[2] Angelo Karaboyas,[2] Hal Morgenstern,[3] Fredric O. Finkelstein,[4] Areewan Cheawchanwattana,[5] Ronald L. Pisoni,[2] Jenny I. Shen,[6] Jeffrey Perl.[7] *[1]Dalhousie/Nova Scotia Health, Halifax, NS, Canada; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]University of Michigan, Ann Arbor, MI; [4]Yale University, New Haven, CT; [5]Khon Kaen University, Khon Kaen, Thailand; [6]LaBiomed at Harbor-UCLA, Torrance, CA; [7]St. Michael's Hospital, Toronto, ON, Canada. Group/Team: On behalf of PDOPPS patient support working group.*

Background: We have shown that high functional dependence among hemodialysis (HD) patients is associated with mortality. Little is known about functional status in peritoneal dialysis (PD) patients and its variation by country.

Methods: In our cross-sectional study of PD patients (PDOPPS 2014-17), functional status (FS) was assessed by self-reported patient questionnaire. Numerical scores were assigned to 8 instrumental and 5 basic activities of daily living, based on one's ability to perform each activity with or without assistance. A summed FS score (range: 1.25-13) was calculated for each patient and categorized as <8 (functionally dependent), 8-<11, 11-<13, or 13 (independent).

Results: To date, 2405 enrolled patients have complete data on FS. The distribution of FS scores varied across countries; scores were lowest in Thailand and highest in Japan (Fig 1). Among patients with FS=13 (48%), mean age was 58 and 35% had diabetes. The 20% of patients with FS <11 were older and have more comorbidities; 68-97% were receiving some assistance with PD, compared to 11% with FS=13. Only 6% of PD patients but 14% of HD patients (Am J Kidney Dis. 2016;67(2):283-92) had FS scores <8; 48% of PD patients but only 36% of HD patients had scores of 13.

Conclusions: Differences in FS scores were observed across countries in the PDOPPS. These differences may have been influenced by regional differences in PD utilization (i.e. availability of PD assistance) or measurement error. FS scores are higher in PD patients than in previously studied HD patients, but future work will need to address the sources of these differences, how interventions for improving functional status might benefit PD patients and assess the outcomes of functionally dependent patients with the use of assisted PD.

The Effect of Combined Therapy with Peritoneal Dialysis and Hemodialysis on Patient Survival: A Prospective Multicenter Study in Japan Yukio Maruyama,[5,10] Keitaro Yokoyama,[5,10] Masaaki Nakayama,[5,4] Chieko Higuchi,[5,1] Tsutomu Sanaka,[5,7] Yoshihide Tanaka,[5,2] Ken Sakai,[5,2] Yoshihiko Kanno,[5,6] Munekazu Ryuzaki,[5,3] Tsutomu Sakurada,[5,8] Tatsuo Hosoya.[5,9] *[1]Division of Internal Medicine, Tokyo Women's Medical University Medical Center East, Tokyo, Japan; [2]Department of Nephrology, Toho University School of Medicine, Tokyo, Japan; [3]Division of Nephrology, Tokyo Saiseikai Central Hospital, Tokyo, Japan; [4]Center for Advanced Integrated Renal Science, Tohoku University Graduate School of Medicine, Sendai, Japan; [5]EARTH (Evaluation on the Adequacy of Renal Replacement Therapy) Study Group, Tokyo, Japan; [6]Department of Nephrology, Tokyo Medical University, Tokyo, Japan; [7]Center of CKD and Lifestyle Related Diseases, Edogwa Hospital, Medical Center, Tokyo, Japan; [8]Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; [9]Department of Pathophysiology and Therapy in Chronic Kidney Disease, The Jikei University School of Medicine, Tokyo, Japan; [10]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan. Group/Team: EARTH Study Group.*

Background: Combined therapy with peritoneal dialysis (PD) and hemodialysis (HD) was widely performed to correct underdialysis and/or overhydration in Japan. However, its clinical result was only reported in retrospective observational studies, and the effect on patient survival is unknown. Hence, we conducted a prospective study to investigate its clinical efficacy in Japan.

Methods: In this prospective multicenter study, we recruited 164 patients started PD from January 1, 2011 to December 31, 2016 (59±16 years, 118 males, and 61 diabetes), and collected clinical information on an annual basis until March 31, 2017.

Results: Median follow-up period was 35 months (range, 0-71 months). During follow-up, 21 patients were switched to the combined therapy with PD and HD, and 15 were switched to HD alone 30±16 and 23±13 months after PD initiation, respectively. The reasons for switching therapy were underdialysis in 8 (22%), overhydration in 12 (33%), both in 1 (3%), and others or unknown in 15 patients (42%). Nineteen patients (11.6%) died of all causes, including 6 (3.7%) died of CVD. Sixteen patients on PD alone, 1 patient on HD alone, and 2 patients on combined therapy were dead. Mortality after switching therapy was no significantly difference between patients on HD alone and those on combined therapy (Log-rank p=0.25, Figure 1).

Conclusions: The effect of switching combined therapy with PD and HD from PD alone on patient survival could not be inferior to switching HD directly. Long-term observation is needed to prove survival advantage of combined therapy.

TH-PO835

Patient-Reported Advantages and Disadvantages of Peritoneal Dialysis: Results from the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) Jeffrey Perl,[1] Junhui Zhao,[2] Douglas S. Fuller,[2] Brian Bieber,[2] James A. Sloand,[3] Lalita Subramanian,[2] David W. Johnson,[4] Matthew J. Oliver,[5] Kriang Tungsanga,[6] Tadashi Tomo,[7] Rachael L. Morton,[8] Bruce M. Robinson.[2] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Baxter Healthcare Corporation, Deer ield, IL; [4]Princess Alexandra Hospital, Brisbane, QLD, Australia; [5]Sunnybrook Health Sciences Center, Toronto, ON, Canada; [6]King Chulalong Memorial lHospital, Bangkok, Thailand; [7]Oita University Hospital, Yufu, Japan; [8]The University of Sydney, Sydney, NSW, Australia. Group/Team: On behalf of clinical application of PD therapy working group.*

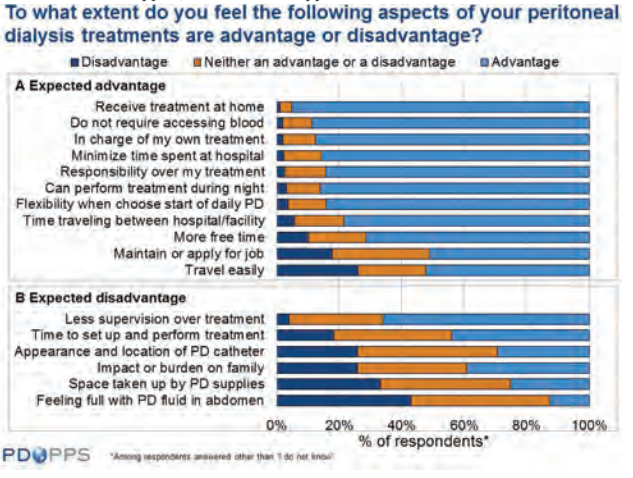
Background: Compared to facility-based hemodialysis, home-based peritoneal dialysis (PD) may offer patients advantages and disadvantages. We sought to better understand patient-reported perceptions of the advantages and disadvantages of PD treatment.

Methods: PDOPPS is a prospective cohort study of PD treatment and outcomes in Australia, Canada, Japan, New Zealand, Thailand, the United Kingdom (UK) and the United States (US). Opinions on how PD treatment impacts 17 aspects of daily life were assessed using the self-reported PDOPPS patient questionnaire (PQ).

Results: Between 2014 and 2017, 2641 patients returned a PQ; item-level response rates ranged from 88% to 96%. Among the 11 factors of expected advantages (Figure 1A), "receive treatment at home" was most commonly perceived as an advantage (95%), followed by "do not require accessing of blood" (89%). The most commonly cited disadvantages of PD treatments were "feeling full with PD fluid in abdomen" (43%) and "space taken up by PD supplies" (overall 33%, Figure 1B), which was particularly regarded as a disadvantage by patients in UK (53%), Canada (40%), US (36%), vs. 16-32% elsewhere. Fewer patients in Japan and Thailand (28% and 43%, respectively, compared to over 57-67% elsewhere) perceived "able to travel more easily" as an advantage of PD.

Conclusions: Abdominal fullness and space taken up by PD supplies appear to be concerns for a substantial minority of patients receiving PD, while treatment receipt at home obviating the need for accessing blood appear to be the predominant advantages. Better understanding of the patient, treatment and regional variation associated with these concerns may provide insights into improving the patient experience of PD and allow for more informed dialysis modality education.

Funding: Commercial Support - Amgen, AstraZeneca, Baxter Healthcare, Kyowa Hakko Kirin, Hexal AG, Janssen, Keryx, Proteon, Relypsa, Roche, Vifor Fresenius Medical Care Renal Pharma, ERA-EDTA, Japanese Society for PD, Association of German Nephrology Centres, Societies for Nephrology in Germany, Italy, & Spain., Private Foundation Support, Government Support - Non-U.S.



TH-PO836

Transitions from Peritoneal Dialysis (PD) to In-Center Hemodialysis or Death: Trends in the United States Renal Data System from 1996-2011 Nidhi Sukul,[2] Purna Mukhopadhyay,[1] Jeffrey Pearson,[1] Douglas E. Schaubel,[2] Marc Turenne,[1] Rajiv Saran,[2] Bruce M. Robinson,[1] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: Transitioning from PD to in-center hemodialysis (ICHD) is disruptive to care. To understand changes in rates of mortality and transition from PD to ICHD among incident PD patients, we examined trends in the US Renal Data System from 1996-2011.

Methods: Annual cohorts of incident PD patients were followed for up to 3 years (Fig.1) for the outcomes of death, transition to ICHD, or the combined outcome of the two. Time at risk (expressed per 100 patient years [PY]) was calculated as days from PD incidence until date of transplant, death, 30 days after switching to ICHD or home hemodialysis, recovery of renal function, loss to follow-up, discontinuation of dialysis, or

end of follow-up. Kaplan-Meier curves for 5-year survival on PD, adjusted for age, sex, race, ethnicity, and primary cause of ESRD, are shown for 5 annual cohorts (Figure 2).

Results: Trends in transition rates per 100 PY from 1996-2011 were: 20.2 to 10.7 for death, 24.7 to 20.7 for ICHD, 44.9 to 31.3 for death/ICHD (Fig.1). The Kaplan-Meier curves demonstrate that 50% of patients died or transitioned to ICHD by 1.63, 1.72, 1.83, 2.02, and 2.18 PY for 1996, 2002, 2005, and 2009 (Fig.2).

Conclusions: While rates of mortality and transition to ICHD have both declined, this was greater among mortality rates. Overall longer PD survival seen in recent years could potentially be due to better PD education, treatment, and/or patient selection. Further investigation is needed to better understand patient- and center-level predictors of these outcomes to further extend survival time on PD and the experiences of patients selecting this modality.

TH-PO837

The Superiority of Combination Therapy with Peritoneal Dialysis and Hemodialysis over Conventional Hemodialysis Hironori Nakamura, Anayama Mariko, Yasushi Makino, Masaki Nagasawa. *Nephrology, Shinonoi General Hospital, Nagano, Japan.*

Background: Combination therapy consisting of peritoneal dialysis (PD) and hemodialysis (HD) is a type of renal replacement therapy that possesses the advantages of both types of dialysis. In Japan, approximately 20% of all PD patients receive this unique combination of PD and HD (PD+HD) therapy, which consists of 6 days of PD and 1 session of HD a week. However, little is known about the differences in clinical characteristics or QOL between PD+HD and HD patients.

Methods: The aim of this study was to verify the superiority of PD+HD over HD in the clinical characteristics and Kidney Disease Quality of Life Short Form (KDQOL-SF36) score in dialysis patients. One single-center cross-sectional comparative study was conducted. Seven PD+HD patients and 11 control patients were included; age- (±3 years) and dialysis duration- (±5 months) matched controls were selected from HD patients who were undergoing HD thrice a week in our dialysis center.

Results: The mean age of the patients was 73.1 ± 5.7 years, and dialysis duration was 66.7 ± 42.3 months. Laboratory data showed that the values for blood urea nitrogen (44.0 ± 9.2 vs. 58.6 ± 13.4 mg/dL, p = 0.015), potassium (4.1 ± 0.70 vs. 5.0 ± 0.88 mEq/L, p = 0.028), iron (72.5 ± 17.0 vs. 42.3 ± 15.5 mg/dL, p = 0.005), transferrin saturation (27.0% ± 7.8% vs. 17.9% ± 6.4%, p = 0.039), pH (7.40 ± 0.02 vs. 7.34 ± 0.04, p = 0.005), and HCO_3 (23.6 ± 2.8 vs. 19.7 ± 1.7 mEq/L, p = 0.018) were significantly better in PD+HD than HD patients. Total protein (5.5 ± 0.48 vs. 6.2 ± 0.39 mg/dL, p = 0.01) and albumin (2.7 ± 0.48 vs. 3.3 ± 0.38, p = 0.019) levels were lower in PD+HD than HD patients. Regarding the KDQOL questionnaire results, the score for the item indicating patient satisfaction to dialysis care was significantly higher in PD+HD than HD (90.4 ± 8.9 vs. 66.6 ± 19.2 points, p = 0.004). No significant items were observed for the superiority of HD over PD+HD.

Conclusions: Our results suggested that PD+HD may have meaningful advantages in terms of iron metabolism, acid–base balance, and patient satisfaction compared with those in conventional HD in this study population.

TH-PO838

Evaluation of Healthcare Resource Consumption in Simulated Patients on Automated Peritoneal Dialysis (APD) Using a Remote Monitoring System Kiyotaka Uchiyama,[5] Naoki Washida,[7] Nobuyuki Yube,[1] Takahiro Kasai,[3] Kohkichi Morimoto,[6] Shu Wakino,[3] Souzana S. Deenitchina,[2] Hiroshi Itoh.[4] *[1]Baxter, Tokyo, Japan; [2]Baxter Limited Japan, Tokyo, Japan; [3]Keio University, Tokyo-to, Japan; [4]Keio University School of Medicine, Tokyo, Japan; [5]Keio University, School of Medicine, Tokyo, Japan; [6]School of Medicine, Keio University, Tokyo, Japan; [7]keio university, school of medicine, Tokyo, Japan.*

Background: Studies are in progress to evaluate the usefulness of remote monitoring (RM) in chronic disease patients. For patients undergoing peritoneal dialysis (PD), who also have chronic disease (e.g., end-stage renal failure) and are basically on home care, RM is highly likely to contribute to better prognosis and improved quality of life (QOL). However, evidence is scarce in this area. Automated peritoneal dialysis (APD) involves the use of a device to enable automated PD while the patient is asleep, and has greatly contributed to the improved QOL of PD patients. However, no APD device with RM function is available in Japan. In this preliminary study, we evaluated the usefulness of RM in APD patients employing a simulated patient approach.

Methods: We prepared two clinical scenarios with RM (RM+) and without RM (RM-), consisting of 12 simulated patients with PD-related problems commonly experienced in daily clinical practice, with modifications from the original US Baxter's scenarios to reflect the actual clinical situation in Japan. Each scenario was evaluated by two teams consisting of one nephrologist and one nurse each, or by two nephrologists for the frequency of healthcare resource consumption, such as "hospitalizations" and "emergency room visits", for comparison between the RM+ and RM- groups.

Results: The RM+ group showed a significantly reduced total healthcare resource consumption (36.8 vs. 107.5 times, $p = 0.002$), as compared to the RM- group. More specifically, the RM+ group showed significantly lower frequency of the following resource consumption: "unplanned hospital visits" ($p = 0.005$), "emergency room visits"gency room visits ($p = 0.003$), "home visits" ($p = 0.020$), "exchanges over the telephone" ($p = 0.002$)," change to hemodialysis" ($p = 0.003$) and "other" ($p = 0.004$).

Conclusions: The present results indirectly demonstrate the usefulness of RM in reducing the frequency of healthcare resource consumption in APD patients. This is the first time this evidence has been found in Japan.

Peritoneal Dialysis Annual Drop Out Monitoring Increases Patient and Technique Survival Belen Marron,[1] Delia Timofte,[2] Michael Roesch,[3] Janusz Ostrowski,[4] Marietta Török,[5] Dan Munteanu,[6] Pawel Kochman,[4] Attila Orosz,[7] Gustavo L. Moretta,[8] Paul Stroumza,[9] Elisabeth Fabricius,[10] Jorgen B. Hegbrant.[11] *[1]Medical Office, Diaverum, Madrid, Spain; [2]Sema Clinic, Diaverum, Bucharest, Romania; [3]Schlankreye Clinic, Diaverum, Hamburg, Germany; [4]Wloclawek Clinic, Diaverum, Wloclawek, Poland; [5]Rokus Clinic, Diaverum Hungary Ltd., Budapest, Hungary; [6]Fundeni Clinic, Diaverum, Bucharest, Romania; [7]Bajcsy Clinic, Diaverum, Budapest, Hungary; [8]LATAM Medical Office, Diaverum, Buenos Aires, Argentina; [9]Marseille Clinic, Diaverum, Marseille, France; [10]Visby Clinic, Diaverum, Visby, Sweden; [11]Medical Office, Diaverum, Lund, Sweden.*

Background: PD drop out (DO) is often not routinely measured and seldom reported in the literature.

Methods: Observational, prospective registry in 9 countries (FR, DE, HU, PL, RO, SE, AR, CL, UR) during 2 years. Only EU countries with ≥ 100 prevalent PD patients (pts) [RO, DE, PL, HU] are presented here. All PD pts were tracked on a monthly basis for DO due to: TX, RRF recovery, transfer to HD (due to peritonitis, exit site or catheter issues, UFF, low adequacy, burn out or others), transferred to other centers, death or others. Total DO, controllable DO (transfer to HD and to other centers) and underlying causes are provided as percentage of pts at risk.

Results: 565 pts (372 prevalent, 193 incident) in 47 clinics, 2015 and 813 (623 prevalent, 190 incident) in 61 clinics, 2016. DO results (2016 vs. 2015) was as follows: total annual DO (41 vs. 49%), controllable DO (18.3 vs. 19.1%), TX (5.9 vs. 9.3%), RRF recovery (0.3 vs. 0.5%), transfer to other centers (1.2 vs. 2.9%), death (14.9 vs. 18.3%) and HD (14.8 vs. 15.4%). Cardiac events deaths decreased from 50 to 47.6% (n=42 pts) and fatal peritonitis from 6 to 4.6% (n=4 pts). Causes of HD transfer in 2016 were: peritonitis 5%, low adequacy 2.4%, UF failure 2%, catheter issues 1.7%, burn out 0.3% and other reasons 3%. Results improved in all countries, in terms of total and controllable DO, death and transfer to HD. By contrast, RRF recovery and TX rate decreased in all countries. Country specific data not shown here.

Conclusions: Annual DO monitoring increased quality in PD, comparisons across countries and resulted in a decreased mortality and HD transfer DO rate.

TH-PO840

Amyloidosis Mimicking Calciphylaxis in a Peritoneal Dialysis Patient Mabel H. Aoun,[1,2] Christelle Riachi,[3] Dania Chelala.[2] *[1]Saint-Georges Hospital Ajaltoun, Beirut, Lebanon; [2]Saint-Joseph University, Beirut, Lebanon; [3]Holy Spirit University, Kaslik, Lebanon.*

Background: Skin lesions in ESRD patients on dialysis are frequent mostly benign related to itching. More severe necrotic lesions usually point out to calciphylaxis. However the diagnosis is not so easy to establish in some cases and appears to be a real challenge.

Methods: We report the case of a 60-year-old Caucasian male who presented to our clinic in October 2013 for advanced chronic kidney disease. He had hypertension and several episodes of malaria 10 years ago treated with chloroquine. He was known to have focal and segmental glomerulosclerosis confirmed by a kidney biopsy in 2008 and was put on ARB. He was started on peritoneal dialysis in July 2014. Six months later during the pre-transplant work-up he was diagnosed with triple coronary artery disease and he underwent coronary artery bypass graft. Following the surgery, he developed severe oral aphtosis and necrotic lesion of the sternotomy that took 6 months to heal. He was treated with colchicine for his presumed cutaneous Behçet disease. His ANA were negative. After the thoracic healing he presented with ulcerative lesions of the legs that raised the suspicion of calciphylaxis. The PTH level was 88 pg/ml, serum phosphorus 6 mg/dl and serum calcium 10.1 mg/dl. He was put on lanthanum instead of calcium carbonate. He developed later chronic hypotension and macroglossia. Serum protein electrophoresis was normal. A salivary gland and skin biopsies revealed amyloidosis AA (Congo-red positive staining, permanganate sensitive). His cutaneous lesions worsened dramatically and got infected. He died from septic shock.

Results:

Conclusions: This is the first report showing secondary amyloidosis presenting as necrotic skin lesions in a peritoneal dialysis patient. This case highlights the importance of an early skin biopsy to confirm the diagnosis and lead the treatment.

Epimorphin Expression in the Repair Process of Experimental Peritoneal Fibrosis in Mice Muneharu Yamada,[2] Shuuhei Komatsu,[2] Aki Kojima,[2] Taito Oshima,[2] Go Hirose,[2] Tadasu Kojima,[2] Kentaro Sugisaki,[1] Tomohiro Tomiyasu,[2] Noriko Yoshikawa,[2] Takashi Oda.[2] *[1]Hachioji Medical Center, Tokyo, Japan; [2]Tokyo Medical University Hachioji Medical Center, Tokyo, Japan.*

Background: Epimorphin is a mesenchymal cell surface-associated protein that is essential for epithelial morphogenesis in embryonic organs. However, recent studies indicate important roles of epimorphin in the repair process from pathologic organ damages, such as pulmonary fibrosis and liver injury. We previously reported that epimorphin was involved in the repair of fibrosis in UUO release mice (*Lab Invest 2010)*. In the previous Meeting, we presented the increased epimorphin expressions in the submethothelial area corresponding to the fibrotic area in mice model of peritoneal fibrosis. In the present study, we evaluated the expression of epimorphin in the repair of peritoneal fibrosis.

Methods: Peritoneal fibrosis was induced by the injection of 0.1% chlorhexidine gluconate in 15% ethanol and 85% normal saline (CG-injected mice) into peritoneal cavity of 10 week-old male C57/Bl6 mice every other day for three weeks. As the repair phase of peritoneal fibrosis mice model, we used peritoneal tissues of the CG-injected mice which were harvested at 1,2,3,7 and 14 days after the last CG injection. Morphologic peritoneal changes were assessed by Masson's Trichrome staining. Epimorphin expressions were assessed by immunohistochemically and real-time RT-PCR.

Results: In the repair of CG-injected mice, the thickening of the submesothelial compact zone was decreased over time in Masson's trichrome staining. However epimorphin expression was increased at 2 days rather than at 1 day after the last CG injection, and significantly decreased at 3, 7 and 14 days compared to 2days after the last CG injection by real-time RT-PCR.

Conclusions: These findings suggest that epimorphin may have important role in the repair of peritoneal fibrosis similar to that of UUO release model in mice as reported previously.

TH-PO842

A Way to Woman's Heart Is through Her Stomach: A Case of a Pericardial-Peritoneal Fistula Natasha N. Dave,[1] Jingyin Yan.[2] *[1]Baylor College of Medicine, Houston, TX; [2]None, Houston, TX.*

Background: An exceedingly rare and potentially life-threatening complication of peritoneal dialysis (PD) is the development of a pericardial-peritoneal fistula (PPF). Typically this communication can occur in cases of pericardiocentesis or an embryological defect in diaphragmatic closure. We report a case of a young female who developed PPF after history of multiple pericardial windows.

Methods: A 26 year-old female with a history of end stage renal disease (ESRD) on PD presented to cardiology clinic for kidney transplant clearance. She was diagnosed with ESRD secondary to focal segmental glomerulosclerosis (FSGS) 6 months ago. At that time, she had a large pericardial effusion deemed uremic pericarditis warranting a sub-xiphoid pericardial window. She was initiated on hemodialysis (HD) then transitioned to PD and has since been compliant with a Kt/V above 2.0. In clinic, an echocardiogram showed a large circumferential pericardial effusion and early right ventricular diastolic collapse. She was taken to surgery for drainage of pericardial effusion with pericardial biopsy and creation of pericardial window into the left pleural cavity. The biopsy showed fibrosis and mild chronic inflammation. Immediately after the surgery, she resumed PD. Two weeks later, she developed shortness of breath (SOB) with exertion and orthopnea during dialysis. A chest X-ray revealed an enlarged cardiomediastinal silhouette and large left sided pleural effusion; she was taken to surgery. Intra-operatively the previous upper midline incision was dissected down to the subxiphoid matter. The surgeon was able to identify the defect in the pericardium that communicated with the abdominal cavity above the caudate lobe of the liver. A second window was made through the left thoracotomy and the defective area was sutured closed. About 2L of serous pleural fluid was drained as well. Post-operatively, she tolerated low volumes of CCPD and was discharged with a prescription to advance dialysis as tolerated. One month later, she developed recurrent episode of SOB secondary to a left sided pleural effusion. A CT peritoneography was negative for peritoneal leakage. She transitioned to HD and her symptoms have since resolved.

Results:

Conclusions: This case of recurrent pericardial effusions in patient on PD emphasizes the need for the clinician to suspect a PPF especially with a history of multiple pericardial interventions.

TH-PO843

Inhibition of H3K4 Methyltransferase SET7/9 Ameliorates Peritoneal Fibrosis Ryo Tamura, Shigehiro Doi, Ayumu Nakashima, Kensuke Sasaki, Toshinori Ueno, Takao Masaki. *Hiroshima University Hospital, Hiroshima, Japan.*

Background: Transforming growth factor-β1 (TGF-β1) is widely recognized as a major mediator of peritoneal fibrosis. TGF-β1 is reportedly responsible for the expression of the H3K4 methyltransferase, SET7/9. SET7/9-induced H3K4 monomethylation (H3K4me1) has a critical function in transcriptional activation of fibrotic genes. In this study, we examined the inhibitory effects of SET7/9 on peritoneal fibrosis in mice and human peritoneal mesothelial cells (HPMCs). We also investigated SET7/9 expression in nonadherent cells isolated from peritoneal dialysis (PD) effluent from actual PD patients.

Methods: Peritoneal fibrosis was induced by intraperitoneal injection of methylglyoxal (MGO) in male C57/B6 mice for 21 days. Sinefungin, a SET7/9 inhibitor, was administered subcutaneously just before MGO injections at 10 mg/kg. In *in vitro* experiments, HPMCs were pre-incubated with 3 or 10 μL/mL sinefungin 1 hour before stimulation with 5 ng/ml of TGF-β1.

Results: SET7/9 expression increased in both MGO-injected mice and nonadherent cells isolated from effluent of PD patients, and was positively correlated with dialysate-to-plasma ratio of creatinine. Immunohistochemical staining showed that sinefungin suppressed expression of mesenchymal cells and collagen deposition, which was accompanied by decreased H3K4me1 expression. A peritoneal equilibration test showed that sinefungin attenuated the transport rate of blood urea nitrogen from plasma and the absorption rate of glucose from dialysate. In *in vitro* experiments, sinefungin suppressed TGF-β1-induced expression of fibrotic markers while inhibiting H3K4me1.

Conclusions: These findings suggest that inhibition of H3K4 methyltransferase SET7/9 ameliorates peritoneal fibrosis by inhibiting H3K4me1.

Mortality after Switching from Peritoneal Dialysis to In-Center Hemodialysis: Trends in the United States Renal Data System from 1996-2013 Nidhi Sukul,[2] Purna Mukhopadhyay,[1] Jeffrey Pearson,[1] Douglas E. Schaubel,[2] Marc Turenne,[1] Rajiv Saran,[2] Bruce M. Robinson,[1] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: Switching from peritoneal dialysis (PD) to in-center hemodialysis (ICHD) is disruptive to patients' care, and transitioning from PD to ICHD has been associated with higher mortality risk when transitions are unplanned. To understand how mortality rates after a switch from PD to ICHD have changed over time, we examined trends in the United States Renal Data System from 1996-2013.

Methods: Five annual cohorts of incident PD patients who initiated PD within 180 days of ESRD designation and switched from PD to ICHD for ≥1 day were followed for death events for up to 180 days after switch. This 180-day risk period was divided into six consecutive 30-day segments. Death and time at risk were determined in each time segment, censoring for transplantation, return to PD, recovery of renal function, or loss to follow-up. Death rates are expressed per 100 patient years (PY).

Results: In each cohort, mortality was highest in the first 30 days post-switch, thereafter gradually declining (Figure). Death rates during the first 30 day period following switch to ICHD were 42.4 and 31.2 deaths/100 PY for the 1996 and 2013 cohorts, and decreased to 27.1 and 23.2 deaths/100 PY for the 151-180 days post-switch period. The percentage of patients in the first 30-day risk set who died decreased from 3.4% to 2.2% from 1996 to 2013, and in the 151-180-day risk set decreased from 2.2% to 1.6%. The summary death rate (combining the six time periods) was 33.2 deaths/100 PY for 1996 and 22.6 deaths/100 PY for 2013.

Conclusions: The initial 30 days post-switch from PD to ICHD is a high risk period, though there is an extended period of elevated risk after transition. The lower mortality rate for more recent cohorts may reflect improved peri-transition care in more recent years. Next steps will include adjusted analyses, and defining patient and center-level predictors to help inform means to improve mortality rates during this high-risk period.

Apoptosis Inhibitor of Macrophage Ameliorates Fungus-Induced Peritoneal Injury Model in Mice Yasuhiko Ito,[1,2] Takako Tomita,[2] Masashi Mizuno,[2] Yasuhiro Suzuki,[2] Fumiko Sakata,[2] Yoshifumi Takei,[3] Shoichi Maruyama.[2] *[1]Aichi Medical University, Nagakute, Japan; [2]Nagoya Univeristy Graduate School of Medicine, Nagoya, Japan; [3]Aichi Gakuin University, Nagoya, Japan.*

Background: Fungal peritonitis is not common, but carries a most serious and poor prognosis due to severe inflammation. In addition, a single episode of fungal peritonitis can reportedly induce encapsulating peritoneal sclerosis. A decrease in the clearance of debris, such as that of apoptotic or necrotic cells, has been reported to prevent resolution of inflammation and tissue remodeling, leading to fibrosis and organ dysfunction. Recently, apoptosis inhibitor of macrophage (AIM/CD5L) was reported to enhance the phagocytic removal of debris by epithelial cells, contributing to kidney tissue repair. In this study, we investigated the roles of AIM in zymosan-induced fungal peritonitis models (zymosan models) that we previously reported (J Immunol 2009).

Methods: We studied zymosan models in wild and AIM deficient mice and evaluated the effects of recombinant AIM (rAIM) in AIM deficient zymosan models. We investigated whether rAIM enhances engulfment of cell debris by cultured macrophages and mesothelial cells.

Results: Inflammation with necrosis was much more severe in the AIM deficient mice at 4 weeks. M1 macrophages and neutrophils were predominant on days 7 and 14. M2 macrophages were higher in wild mice than in AIM deficient mice on days 21 and 28. IL-6, TNF-a, iNOS, and CD86 mRNA expression was significantly higher on day 28 in AIM deficient mice compared with wild mice. AIM levels in serum increased and peaked on day 14, and AIM was strongly detected in the necrotic area in zymosan models of wild mice on day 14. Inflammation with necrosis was suppressed by administration of rAIM in AIM deficient mice on day 28. In vitro, AIM enhanced the engulfment of necrotic debris by macrophages derived from zymosan-induced peritonitis, M1- and M2a-like bone marrow derived macrophages, as well as by mesothelial cells.

Conclusions: AIM was found to play a role in the reduction of inflammation by clearance of necrotic debris in zymosan-induced peritonitis models. Enhancement of engulfment could be a novel therapeutic strategy for improving fungal peritonitis-induced peritoneal membrane injury and prognosis.

TH-PO847

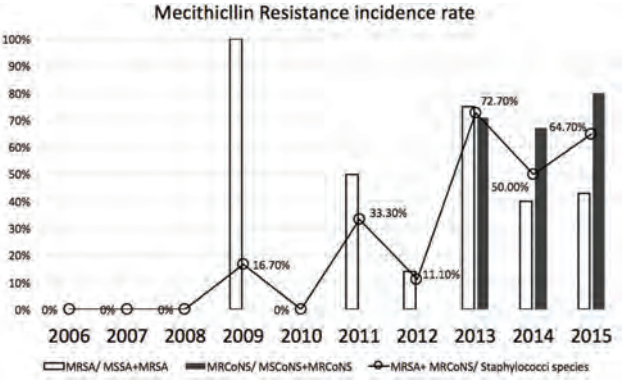
Increasing Staphylococcus Species Resistance in Peritoneal Dialysis-Related Peritonitis over 10 Years in Southern Taiwan Hoching Chen. *E-Da hospital, Kaohsiung City, Taiwan.*

Background: Peritonitis remains the major complication of peritoneal dialysis. Staphylococcus species are the most associated gram-positive peritoneal peritonitis. The increasing antimicrobial resistance rate has become a very important burden when considering the initial choice of antibiotics. The aim of this investigation was to exam the trends of Staphylococcus species, resistance rate and the clinical outcomes from 2006 to 2015 in southern Taiwan.

Methods: We retrospectively investigated all peritoneal dialysis-related peritonitis episodes in southern Taiwan between January 2006 and December 2015. We also evaluated the clinical characteristics, microbiology prevalence, resistance incidence of Staphylococcus species, and outcomes.

Results: Out of 244 episodes of peritonitis, Staphylococcus species accounted for around 30% gram positive bacteria. Methicillin resistance rate among staphylococcus species infection has greatly increased to 64% in 2015 both in Staphylococcus aureus and Coagulase-negative Staphylococci in southern Taiwan. Importantly, Methicillin resistance Staphylococcus species (59.1%) has significant higher hospitalization rate compare to Methicillin-sensitive Staphylococcus species(34.6%) ($p<0.01$). However, the catheter removal rate and transfer to hemodialysis didn't have a difference between two groups.

Conclusions: Peritonitis is the most serious complication in peritoneal dialysis patients and microbiological trends have changed during the past 10 years at a single center in southern Taiwan. Methicillin resistance Staphylococcus species has increased significantly. Empirical initial antibiotics therapy should take in consideration according to growing resistance of microbiology.



Methicillin resistance incidence rate in Staphylococcus aureus, CoNS and Staphylococci species

Astragalus Inhibits Epithelial-to-Mesenchymal Transition of Peritoneal Mesothelial Cells via Suppressing Wnt/β-Catenin Signaling and Promoting Smad7 Jun Shi,[1,2] Manshu Yu,[1,2] Kun Gao,[3] Lu Zhang,[3] Meixiao Sheng.[3] *[1]First Clinical Medical College, Nanjing University of Chinese Medicine, Nanjing, China; [2]Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, China; [3]Department of nephrology, the affiliated hospital of Nanjing University of Chinese Medicine, Nanjing, China.*

Background: Epithelial-to-mesenchymal transition (EMT) of peritoneal mesothelial cells (PMCs) is a crucial event inducing peritoneal fibrosis (PF), in which Wnt/β-catenin signaling participates. Smads signaling is reported to interact with β-catenin and synergistically regulates EMT. This study was aimed to reveal the effect of *Astragalus*(a famous Chinese herbal)on Wnt/β-catenin signaling in PMCs with EMT, as well as on the crosstalk between β-catenin and Smads.

Methods: Rats with peritoneal fibrosis and the human HMrSV5 peritoneal mesothelial cell line were used to explore the effects of *Astragalus* on EMT. EMT markers or signaling pathway-related indicators were detected by Western blotting, immunofluorescence, immunohistochemistry, immunoprecipitation and rt-PCR.

Results: β-Catenin knockdown inhibited EMT of PMCs. *Astragalus* not only relieved EMT and peritoneal fibrosis in rats but also inhibited β-catenin-mediated EMT in the HMrSV5 cell line, resulting from increased E-cadherin and decreased α-SMA.

The nuclear translocation of β-catenin was suppressed by *Astragalus* as a result of the stabilization of GSK-3β promoting dissociative β-catenin degradation. Smad7, which was associated with β-catenin, was enhanced by *Astragalus* during EMT. The knockdown of Smad7 induced an increase in β-catenin and EMT.

Conclusions: *Astragalus* promotes Smad7 expression and effectively inhibits the Wnt/β-catenin signaling pathway during EMT of PMCs, indicating its potential therapeutic effect for PF.

TH-PO849

Prediction of Peritoneal Membrane Function in Pre-Dialysis ESRD Patients

Hui Xu. *Nephrology Department, Xiangya Hospital, Central South University, Changsha, Hunan, China, Changsha, China.*

Background: Background: Peritoneal membrane function decides the efficiency of peritoneal dialysis (PD). However, an effective method is still lack to value the peritoneal membrane function discrimination for pre-dialysis patient is. As a valid classification and prediction tool, random forest using clmay serve efficiently for predicting pre-dialysis peritoneal membrane function in ESRD patients.

Methods: Firstly, random forest method was used to build discrimination model for predicting peritoneal membrane function. The clinical data of 247 patients was used as the training set and the other 50 was used as the validation set. Secondly, random forest-based algorithm was applied in training set for model development and validation set.

Results: The discrimination model performed well for the primary objective. 10-fold cross validation was considered to be internal validation, the evaluation for this model showed that its accuracy rate, sensitivity and specificity respectively reached 0.862, 0.877, and 0.795. The coefficient of martensite (MCC) was turned out to be 0.60 and AUC (area under the receiver operating characteristics curve) was 0.840 (Fig.1a). For external validation, test was conducted on validation set. And the results showed that the accuracy rate, sensitivity, and specificity were respectively 0.78, 0.765, and 0.812. MCC was 0.546, AUC was 0.731(Figure.1b). Of the 28 variables considered, 7 were selected by the model for peritoneal membrane function prediction, among which thrombin time and urine volume reveal evident significance(Figure1c).

Conclusions: Conclusion: Random forest based model provides a robust tool to predict the peritoneal membrane function in non-dialysis ESRD patients.

TH-PO850

Percutaneous Re-Positioning of PD Catheter Accidentally Placed in the Subcutaneous Space Leaving the Tunnel and Exit-Site Intact – A Novel Idea

Santosh Varughese. *Christian Medical College, Vellore, India.*

Background: Peritoneal dialysis (PD) catheter insertion by blind bedside percutaneous technique is a simple procedure. Rarely, the intra-abdominal portion of the catheter may accidentally be placed in the subcutaneous space if the introducer needle does not enter the peritoneal cavity during the initial part of the procedure. If this happens, the catheter insertion has to be redone either percutaneously or surgcially. The catheter often has to be replaced as part of it has been externalized and the external portion is unsterile.

Methods: A 70 year old man with end stage renal disease underwent PD catheter insertion by blind bedside percutaneous technique. Unfortunately, the cathteter was accidentally placed in the subcutaneous space. There was inflow and outflow of PD fluid as the subcutaneous space had expanded with the PD fluid infused during the procedure, but the outflow rate was slow. On CT scan, the intra-abdominal portion of catheter was seen to be lying in the subcutaneous space. A novel technique of repositioning was attempted in which the exit site and tunnel were untouched. The abdomen was scrubbed and cleaned. The skin sutures and subcutanous sutures at the original insertion site were removed. The deep cuff of the catheter was dissected free of the surrounding tissue. The intra-abdominal part of the cathteter was exteriorized. A Veress needle was advanced till it reached the peritoneal space. The track was dilated using a peel-away sheath-dilator assembly. The dilator was removed and the intra-abdominal portion of the catheter (that had just been exteriorized) was slid in and the peel-away sheath was removed. The wound was closed in layers after ensuring good inflow and outflow. Peritoneal dialysis exchanges were begun the same day and was the patient was continued on continuous ambulatory peritoneal dialysis successfully.

Results:

Conclusions: This novel technique allows for a simple bedside repositioning technique of a PD catheter accidentally placed in the subcutanous space without change of catheter or disruption of the tunnel or exit-site. Compared to a repeat PD catheter insertion, this procedure has the advantages of saving operating room time, reducing costs, reducing duration of hospital stay and possibly avoiding unnecessary hemodialysis.

TH-PO851

Fat Mass Monitoring in the Follow-Up of Peritoneal Dialysis Patients: Prognostic Value of Excessive Fat Gain

Jwa-kyung Kim,[2] Hyung jik Kim.[1] *[1]Hallym Univ. Sacred Heart Hospital, Anyang, Republic of Korea; [2]Hallym University, Seoul, Republic of Korea.*

Background: Visceral obesity caused by fat accumulation is an important change in body composition among patients undergoing peritoneal dialysis (PD). Although a significant portion of patients become obese, its long-term effect is not clear and associated changes in peritoneal characteristics are also unknown.

Methods: In this prospective observational study, the prognostic value of excessive fat accumulation on technical failure rate and death was tested. Body composition monitoring was performed twice, 18.0 ± 6.0 months apart, and increment of percentage of body fat (delta_PBF, %) were used to predict long-term outcomes during the following 28.1 ± 8.5 months. Also, accompanying changes of peritoneal characterises with fat accumulation were evaluated by modified peritoneal equilibration test. Technical failure was defined as a transfer from PD to haemodialysis (HD).

Results: Among the 205 patients, 66.8% (N=137) and 59.5% (N=122) experienced BMI increase and PBF gain during the 18 months. The mean PBF was 24.5% and 35.3% at first test, and 25.9% and 37.0% at second test in men and women respectively. Excessive fat gain was defined as a delta_PBF over the gender-specific highest quartile (4.8% for men and 5.7% for women). However, lean mass was not significantly changed. Patients with excessive fat gain was more diabetic and had higher systolic blood pressure. Interestingly, they exprienced significantly higher rate of technical failure than those without excessive fat accumulation (90.5 cases vs. 22.4 cases per 1000 patient-year, p=0.002), but mortality was not affected. Even after adjusting the volume status and other comorbidities, excessive fat gain increased the risk of technical failure by 4.86-fold. Furthermore, with excessive fat gain, the peritoneal characteristics showed a tendency to change to a low transporter (p=0.013). However, mortality was not affected by the excessive fat gain.

Conclusions: Excessive fat gain during PD have an independent prognostic value for technical failure. Concomitant peritoneal membrane changes, decreased solute clearance in low transporter, may affect the higher rate of technical failure.

Itraconazole Ameliorates Chlorhexidine Gluconate-Induced Peritoneal Fibrosis in Mice through Regulating Hedgehog Signaling Pathway

Jin sug Kim,[2] Yu ho Lee,[1] Eun ji Park,[2] Su Woong Jung,[2] Chun-Gyoo Ihm,[2] Tae won Lee,[2] Yang gyun Kim,[1] Ju young Moon,[1] Sang-Ho Lee,[1] Kyung-hwan Jeong.[2] *[1]Kyung Hee University Hospital at Gangdong, Seoul, Korea, Seoul, Republic of Korea; [2]Kyung Hee University Medical Center, Seoul, Republic of Korea.*

Background: Peritoneal fibrosis is a devastating complication of peritoneal dialysis (PD). However, the precise mechanism is unclear and specific treatment has not yet been established. Recent evidence suggests that Sonic hedgehog (Shh) signaling pathway is

involved in fibrogenesis, and drugs that inhibit this pathway are emerging in the treatment of fibrosis. Itraconazole, an anti-fungal agent, is recently also reported as an inhibitor of Shh signaling pathway. In this study, we investigated whether itraconazole suppressed chlorhexidine gluconate (CG)-induced peritoneal fibrosis in mice.

Methods: Peritoneal fibrosis was induced by intraperitoneal (IP) injection of 0.1% CG every other day for 4 weeks, with or without itraconazole treatment (20mg/kg, IP injection on a daily basis). Saline was administered intraperitoneally to the control groups. Male C57BL/6 mice were divided into four groups: saline injection (group 1), saline injection plus itraconazole (group 2), CG injection (group 3), CG injection plus itraconazole (group 4). The effects of itraconazole were evaluated based on peritoneal thickness, immunohistochemical staining, and real-time polymerase chain reaction. The peritoneal thickness was identified by Masson's trichrome staining.

Results: Peritoneal thickening was evident in group 3 (CG injection), and the thickening was markedly decreased in group 4 (CG injection plus itraconazole) (59.9±34.9 μm vs. 16.8±9.0 μm, $p<0.001$). The mRNA expression of markers for fibrosis, including transforming growth factor-β1 (TGF-β1), fibronectin, and α-smooth muscle actin (α-SMA), were increased in the group 3 and were downregulated in the group 4. Similar results were shown in the markers for Shh signaling pathway. Itraconazole suppressed mRNA expression of Shh, Patched 1 (PTCH1), Smoothened (SMO), and Gli in peritoneal tissues. Immunohistochemistry analysis revealed that the expression of Hedgehog pathway components were increased in group 3, and decreased by using Itraconaozle in peritoneal tissues.

Conclusions: Our results suggest that itraconazole ameliorates the peritoneal fibrosis by regulating Shh signaling pathway. Itraconazole can be a potential therapeutic strategy for peritoneal fibrosis.

TH-PO853

Hemophagocytic Lymphohistiocytosis Secondary to Tubercular CAPD Peritonitis Manisha Dassi,[1] Garima Aggarwal.[2] *[1]Max Super Speciality Hospital, Vaishali, Ghaziabad, India; [2]Amrita Insitiute Of Medical Sciences, New Delhi, India.*

Background: Tubercular CAPD peritontis, though infrequent, has been reported to have a higher incidence in developing countries. HLH, seen in both inherited and secondary forms, is a rare & lethal disorder of the immune system. We report a case of HLH secondary to tubercular CAPD peritonitis.

Methods: A 49 years old male ESRD, on CAPD since 01 year presented with CAPD peritonitis. He required CAPD catheter explantation & shift to HD in view of refractory peritonitis. Though fever resolved, he continued to have clear watery discharge from the poorly healed surgical wound. He was lost to follow up & presented again 03 months later with complaints of fever, weight loss, fatigability and copious amount of yellowish discharge from the surgical wound. Clinically, he was hemodynamically stable, febrile, had pallor, multiple cutaneous ecchymotic spots, hepatosplenomegaly, reduced air entry at right lung base and a 5 cm infra-umbilical midline horizontal poorly healed discharging surgical scar mark with surrounding skin inflammation. Relevant clinical & lab parameters are shown in Table 1. NCCT abdomen revealed hepatosplenomegaly, moderate ascites & loculated fluid collection in the right subphrenic space extending inferiorly into the abdominal & pelvic cavity. Subphrenic fluid aspirate revealed a yellow turbid fluid which was sterile on pyogenic and fungal culture, negative on gram's, fungal and ZN stains, positive for *M tuberculosis* on PCR & positive on tubercular culture. Bone marrow asp + biopsy revealed marked degree of histiocytic hemophagocytosis. Patient fulfilled 6/8 criteria for diagnosis of HLH. He was managed with Dexamethasone (6 wks) & ATT (HRZE → HR). He gradually became afebrile with resolution of the infra-umbilical wound discharge, improvement in pancytopenia (Inv at 6 mnths: Hb 11.3 gm%, TLC 4000, Plts 95000/uL) along with improvement in general condition.

Results:

Conclusions: HLH should be considered in ESRD patients with tubercular peritonitis in presence of pertinent clinical and lab findings. It has been reported in association with tuberculosis especially extrapulmonary forms. A high index of suspicion is necessary for timely diagnosis & management.

Clinical and Lab Parameters for diagnosis of HLH

HLH Diagnostic Criteria	Criteria fulfilled by Index Patient
1.Fever	
2.Splenomegaly	1.Fever
3.Cytopenias (affecting ≥ 2/3 on PBS)	2.Splenomegaly
4.Fasting TG ≥ 265 mg/dl and/or fibrinogen ≤ 150 mg/dl	3.Hb 5.0 gm/dl, TLC 1800/uL, Plts 45000/uL

Blunting Toll-Like Receptor Activity with Soluble TLR2 Inhibits PD Solution-Induced Fibrosis Anne-Catherine Raby,[2] Guadalupe T. Gonz?lez-Mateo,[4] Donald Fraser,[1] Manuel Lopez-Cabrera,[3] Mario O. Labéta.[1] *[1]Cardiff University, Cardiff, United Kingdom; [2]Welsh Kidney Research Unit, Cardiff University, Cardiff, United Kingdom; [3]Consejo Superior de Investigaciones Cientificas (CSIC). Spain, Madrid, Spain; [4]Molecular Biology Research Centre Severo Ochoa, Spanish Research Council, Madrid, Spain.*

Background: Membrane failure due to fibrosis limits the use of peritoneal dialysis (PD). Fibrosis results from peritoneal inflammation caused by infections or by ongoing cellular stress induced by PD (sterile inflammation). The immune mechanisms involved in sterile peritoneal inflammation leading to fibrosis are still poorly defined. Toll-like receptors (TLRs) mediate sterile inflammation by recognising endogenous components released by cellular stress (DAMPs). We hypothesise that TLRs play a crucial role in sterile inflammation and fibrosis by recognising DAMPs released during PD and, thus, are major therapeutic targets for fibrosis prevention.

Methods:

Results: A range of PD solutions (PDS) underwent comprehensive *in vivo* and *ex vivo* characterisation of TLR-mediated inflammatory and fibrotic mediator production (genes and proteins). All PDS elicited proinflammatory and fibrotic responses from primary human uremic peritoneal leukocytes and mesothelial cells. TLR2/4 blockade inhibited these effects. PDS did not induce rapid ERK phosphorylation, suggesting that they do not contain components capable of direct TLR activation. However, PDS increased the release of Hsp70 and HA from a panel of DAMPs tested, and their blockade repressed PDS-driven inflammation. The peritoneal response to Hsp70 and HA was mediated mainly by TLR4 and to a lesser extent TLR2. Soluble TLR2 (sTLR2), an inhibitor of DAMP-TLR interaction, was found to inhibit Hsp70-, HA- and PDS-induced peritoneal proinflammatory cytokine release. PDS exposure also increased peritoneal Hsp70 and HA in mice, and the use of TLRKO mice confirmed a major role of TLR2/4 in PD solution-induced fibrotic responses. The therapeutic potential of sTLR2 was examined in a mouse model of PDS-induced sterile peritoneal fibrosis. Daily catheter infusion of PDS led to robust peritoneal fibrosis by day 40. Co-administration of sTLR2 prevented peritoneal fibrosis development by suppressing profibrotic gene expression, proinflammatory cytokine production and reducing leukocyte recruitment.

Conclusions: The study reveals a major role of TLR2 and TLR4 in PD solution-associated peritoneal inflammation and fibrosis, identifies Hsp70 and HA as main DAMPs and demonstrates the therapeutic potential of blunting TLR activity to prevent PD solution-induced fibrosis by using a TLR modulator, sTLR2.

Peritoneal Inflammation Increases over Time, with an Associated Increase in Plasma IL-6 Predicting Worse Survival: Results From the Global Fluid Study Emma H. Elphick,[1] Vasileios Zavvos,[2] Simon J. Davies,[1] Nicholas Topley,[2] Donald Fraser,[2] Mark Lambie.[1] *[1]Keele University, Stoke on Trent, United Kingdom; [2]Cardiff University, Cardiff, United Kingdom.*

Background: Local peritoneal inflammation is a feature of peritoneal dialysis (PD) treatment and high concentrations of dialysate IL-6 (dIL6) are a strong determinant of solute transport. Solute transport increases during long term PD but it is unknown whether dialysate IL-6 rises. Plasma IL-6 (pIL6) is an independent predictor of patient survival but whether dialysate IL-6 contributes to plasma levels is unknown.

Methods: We conducted a longitudinal analysis of the Global Fluid study, a multinational cohort study from UK, Canada and Korea. All incident patients with 3 or more paired dialysate/plasma samples were assayed for IL-6 by electrochemiluminescence. A linear mixed model with random intercept/slopes was used, including time on PD, centre, dIL6, gender, baseline age, comorbidity score and urine volume with backwards selection, for log transformed pIL6. An unadjusted joint longitudinal survival model (JLSM) assessed pIL6 values and changes over time on survival.

Results: There were 217 patients with 1274 measurements, with a median follow up time of 2.2 years from 6 centres. Over time there is a significant increase in dIL6 (1.17 pg/ml/year 95% CI 1.11 to 1.24) and pIL6 (1.08 pg/ml/year per year 95% CI 1.02 to 2.24). In the multivariate model pIL6 was significantly positively associated with dIL6 (β =0.099 95% CI 0.063 to 0.135) and negatively associated with urine volume (coeff=-0.0058 95% CI 0.0020 to 0.010 p=0.005, time interaction coeff=-0.019 95% CI -0.032 to -0.005 p=0.006). In adjusted Cox models, time varying pIL6 was negatively associated with survival (HR 4.51 per $\log_{10}$ order, 95% CI 1.85 to 11.0). In a JLSM there was a significant negative effect on survival of pIL6 values (β=4.31 95% CI 2.73 to 5.90) and trajectories over time (β=-23398 95% CI -31313 to -15483). pIL6 trajectories were a better predictor of survival than raw values (AIC 1283 vs AIC 1333 respectively) or combined raw values with trajectories (AIC 1331).

Conclusions: There is a rise in pIL6 over time, associated with increasing dIL6 and decreasing urine volume. pIL6 is a strong predictor of mortality, and the rate of increase in pIL6 is a stronger predictor of mortality than the absolute value.

TH-PO856

Inhibition of NLRP3 Inflammasome Blocks Peritoneal Dialysis Solution-Induced Mesothelial-to-Mesenchymal Transition Lu Zhang,[2] Min Zheng,[2] Dong Zhou,[1] Kun Gao,[2] Weiming He,[2] Qing Li,[2] Zhenghong Li,[2] Meixiao Sheng,[2] Wei Sun.[2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]nephrology, the affiliated hospital of Nanjing University of Chinese Medicine, Nanjing, China.*

Background: To investigate the role of activated Nod-like Receptor Protein 3 (NLRP3) inflammasome in peritoneal dialysis (PD) solution-induced mesothelial-mesenchymal transition (MMT) in peritoneal mesothelial cells (PMC).

Methods: 1. Human peritoneal mesothelial cells (HMrSV5) were incubated with different concentrations of PD solution (1.5%,2.5%,4.25%) for 24h or 4.25% PD solution for various periods of time at 0, 6, 12, 24, 48 hours, respectively. The supernatant was collected for ELISA assay and cells were lysed using RIPA buffer for a western blot assay.2. After stable transfection of siRNA plasmid targeting NLRP3, HMrSV5 were incubated with 4.25% PD solution for 24h, cells were then harvested for western blot assay.3. HMrSV5 were treated with 4.25% PD solution for 24h in the absence or presence

of different doses of Astragaloside IV (As-IV), which is a cycloartane triterpene saponin with a clear formula($C_{41}H_{68}O_{14}$).

Results: 1. The PD solution promotes IL-18 secretion in the condition medium of cultured PMCs as dose- and time-dependent manner. Accordingly, it significantly induced NLRP3, pro-IL-1β, IL-1β, pro-casepase-1, and caspase-1 expression in vitro. 2. The PD solution induces MMT which is featured with decreased E-cadherin and increased vimentin, α-SMA. 3. Knockdown NLRP3 partially preserve PMCs from MMT by inhibited IL-18 secretion and NLRP3, caspase-1, pro-IL-1β, IL-1β expression in cultured PMC. 4. Therapeutic inhibition of NLRP3 inflammasome with a novel small molecule inhibitor, As-IV, preserves mesothelial phenotypes in the established model in vitro.

Conclusions: The activated NLRP3 inflammasome mediates PD solution-induced MMT in PMCs. Targeting NLRP3 inflammasome activity by small molecule inhibitor AS-IV abolishes inflammatory factors and blocks mesenchymal conversion of mesothelium.

The Effects of Peritoneal Dialysis and Intraperitoneal Amino Acids on Protein Carbamylation Sahir Kalim,[1] Jeffrey Perl,[2] Megan J. Freeman,[2] Caitlin A. Trottier,[1] Anders H. Berg.[3] *[1]Massachusetts General Hospital, Boston, MA; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Protein carbamylation is a urea-driven post translational protein modification associated with mortality in hemodialysis (HD) patients. Free amino acids (AA) competitively inhibit protein carbamylation and parenteral AA therapy reduces carbamylation in HD patients. Peritoneal dialysis (PD) yields differences in urea clearance and AA balance compared to HD, but its effects on carbamylation are unclear. We assessed carbamylation burden in PD patients and determined the effects of AA enriched PD solutions on carbamylation.

Methods: We measured carbamylated albumin levels (C-Alb; a marker of total body carbamylation load) in 100 diabetic HD subjects, matched by age, sex, and race to 98 PD subjects with available plasma samples from the IMPENDIA trial. The IMPENDIA randomized trial (n=180) examined whether low-glucose PD solutions (combination of dextrose, icodextrin, and amino acids) improved metabolic control in diabetic PD patients compared to a control group (dextrose only solutions; 48 treated and 50 control subjects had samples available). C-Alb was compared between HD and PD groups and within IMPENDIA by treatment allocation.

Results: PD patients had a higher baseline C-Alb level compared to HD patients (Table). There were no major differences in basic clinical parameters between the complete IMPENDIA group and the subset with available samples. Among the IMPENDIA participants analyzed, there was no significant difference in C-Alb change from baseline to 6 months in either arm, but treated subjects showed a trend to increased carbamylation (Table). The intervention arm demonstrated a greater change in blood urea nitrogen, possibly explaining the trend for increased carbamylation (Table).

Conclusions: For the first time, we show that carbamylation levels in PD patients run higher than matched HD patients. Incorporating intraperitoneal AA solutions was associated with an increase in urea levels and a marginal increase in C-Alb. PD outcomes may improve if carbamylation burden can be reduced. However, unlike HD where parenteral AA therapy reduces carbamylation, AA-based intraperitoneal solutions as part of the IMPENDIA treatment arm were not effective at reducing carbamylation.

Funding: NIDDK Support, Commercial Support - Baxter Healthcare funded the parent study

Peritoneal Membrane Morphology Following Peritonitis in Low GDP Peritoneal Dialysis Betti Schaefer,[1] Maria Bartosova,[1] Akos Ujszaszi,[1] Bruno Ranchin,[3] Karel Vondrak,[6] Gema Ariceta,[2] Ariane Zaloszyc,[4] Franz S. Schaefer,[7] Bradley A. Warady,[5] Claus P. Schmitt.[1] *[1]Center for Pediatric and Adolescent Medicine, Heidelberg, Germany; [2]Hospital Universitari Vall d' Hebron, Barcelona, Spain; [3]Pediatrics, Lyon, France; [4]Strasbourg's Hospital University, Strasbourg, France; [5]The Children's Mercy Hospital, Kansas City, MO; [6]University Hospital Prague-Motol, Prague 5, Czech Republic; [7]University of Heidelberg, Heidelberg, Germany. Group/Team: International Pediatric Peritoneal Biopsy Study Group.*

Background: Long term impact of peritonitis on peritoneal membrane integrity and function is incompletely understood. Whereas experimental studies suggest a major impact of peritonitis, respective human data is scant. Children are uniquely suited for analyses of specific PD related effects, since they are devoid of preexisting tissue changes.

Methods: Within the scope of the International Pediatric Peritoneal Biopsy Study we obtained 94 standardized peritoneal specimens from children on low GDP PD for automated quantitative morphometric and molecular tissue analyses. Ten patients who had acute peritonitis less than 4 weeks before biopsy sampling were excluded from the analysis.

Results: 37/84 children had a history of peritonitis and 16/37 had 2 or more episodes of peritonitis. Median age at biopsy was 6.2 (2.6, 13.2) years, 46% girls, and median PD vintage was 15.0 (8.5, 32.9) months. The 37 patients who previously suffered from peritonitis did not differ in anthropometrical parameters from those without peritonitis. Patients with peritonitis were on PD longer (21.0 (12.0, 36.0) v. 12.8 (7.3, 27.0) months; p=0.053). The mesothelial cell layer integrity and the submesothelial zone thickness were similar in both groups. There was no difference in median capillary density, lymphatic capillary density or in the endothelial surface area. Lymphatic vessel density remained low in both groups. Lumen / Vessel ratio as a marker of vasculopathy was also comparable in both groups. $ASMA^+$ activated fibroblasts (59% v. 47%; p=0.27), CD45+ lymphocytes (65% v. 66%; p=0.97) and CD68+ macrophages (60% v. 70%; p=0.18) had a similar prevalence. There were no alterations in fibrin deposits or the degree of Epithelial-Mesenchymal Transition (EMT). In a sensitivity analysis where 24 (total 48) patients were matched for age and PD duration, we did not find any significant differences.

Conclusions: Peritonitis is a common complication of PD. The impact on peritoneal membrane integrity, however, is low. Non-acute post peritonitis peritoneal membrane morphology does not differ with regard to inflammation, EMT, fibrosis and vessel density as compared to children without a history of peritonitis.

TH-PO859

Help of Remote Patient Monitoring in the Assessment of Changes in Ultrafiltration before, during, and after a Peritonitis Episode in Patients on Automated Peritoneal Dialysis Mario R. ---,[2] Alfonso Ramos.[1] *[1]Baxter Mexico, San Jer?nimo Chicahualco, Mexico; [2]Hospital Especialidades Dr Belisario Dominguez SEDESA, Mexico, Mexico.*

Background: Peritonitis is a common complication in patients on peritoneal dialysis and it has become the single most important cause of failure of the technique. The aim of this study is to assess if remote patient monitoring (RPM) allow to detect changes in ultrafiltration (UF) before, during and after a peritonitis episode.

Methods: This report is a retrospective review of a series of cases involving the use of RPM to evaluate UF in Automated Peritoneal Dialysis (APD) patients before, during and after a peritonitis episode. The day of clinical diagnosis of peritonitis was considered day zero. UF volumes from day 7 prior to diagnosis to day 10 after the diagnosis were collected from electronic records of RPM device. For analysis purpose, data were categorized in four groups: Group one: 7 days before the onset of peritonitis; Group 2: One day before the episode; Group 3: Two days after the diagnosis; and Group 4: Days 3-7 after the diagnosis. Group comparison was performed using the Wilcoxon test.

Results: Ten patients were studied, 5 female and 5 male, median age of 48 ± 6 years, with a median length of stay in the program of 18 months. The analysis showed a difference in UF between the values measured 1) 7 days before (194 ml) vs the day before the event (-302 ml) (P<0.04); 2) 7 days before (194 ml) vs during the event (-1,062 ml) (p<0.009); and 3) during the peritonitis (-1,062 ml) vs after the peritonitis episode (-319 ml) (p< 0.01)

Conclusions: This is the first report documenting the use of RMP for the detection of minor changes in UF in a group of APD patients, which will allow us to suspect the presence of peritonitis and monitor its progress over time before conventional clinical data are available.

TH-PO860

Relation between BCM and Echocardiographic Parameters to Reflect Volume Status in Peritoneal Dialysis Min ji Kim,[1] Sunwoo Kang,[2] Tae Hee Kim,[4] Yeong Hoon Kim.[3] *[1]Nephrology, Busan Paik Hospital, Busan, Republic of Korea; [2]Inje University, Busan, BUSAN, Republic of Korea; [3]Inje University Medical School, Busan, Republic of Korea; [4]None, Busan, Republic of Korea.*

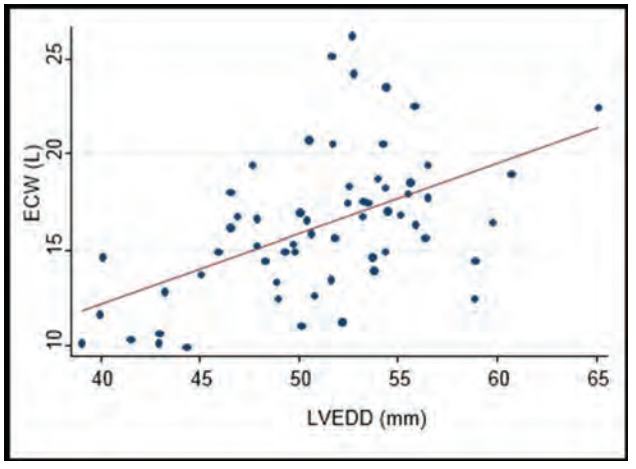
Background: Fluid imbalance is a frequent condition in peritoneal dialysis (PD) patients. Fluid overloading is one of causes to lead to cardiovascular instability. Even though there are no accurate methods to determine volume status in PD, body composition monitor (BCM) is used as an objective measurement. The aim of this study was to find echocardiographic parameters associated with volume status compared to BCM parameters in PD patients.

Methods: This study was conducted on 74 PD patients in Busan Paik Hospital during 2014 – 2015. We used BCM to assess volume status, echocardiography to evaluate heart function and structure, and collected epidemiologic data. To account for the relation between BCM and echocardiographic parameters, we conducted regression analysis.

Results: Patients were 46±12 years old, 55% female, and 39% diabetic. A total of 6 (8%) all-deaths were reported. 10 (13%) among 74 patients received kidney transplantation, 10 patients transferred from PD to hemodialysis. Median dialysis vintage was 25.3 months (IQR 1.6, 127.2 months). Relative overhydration had positive correlation with systolic blood pressure ((r^2=0.12, p=0.003), diastolic blood pressure (r^2=0.07, p=0.03), and extracellular water (ECW) (r^2=0.27, p<0.001). Conversely relative OH had negative correlation with intracellular water (r^2=0.08, p=0.02) and lean tissue index (r^2=0.17, p=0.003). ECW had positive correlation with left ventricular end diastolic dimension (LVEDD) (r^2=0.27, p<0.001) (Figure 1) and left ventricular diastolic posterior wall thickness (LVDPWT) (r^2*=0.14, p=0.003)*.

Conclusions: Fluid overload in PD patients was associated with rise in ECW, which increased according as LVEDD enlargement. Echocardiographic parameters of

Left ventricle were good markers of volume status in PD patients. Further studies to understand the change in volume status over time are needed.



TH-PO861

APD Could Alleviate Acute Left-Heart Failure via Increasing Peritoneal Dialysis Ultra-Filtration: A Single Center Observation Clinical Research Jun Ai. *Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Ultrafiltration failure (UFF) is a major reason which causing water retension, acute left-heart failure (LHF), and peritoneal dialysis (PD) failure for PD patients. Automated peritoneal dialysis (APD) might have better ultra-filtration than CAPD. We had observed whether short time APD could increase UF and alleviate LHF.

Methods: Patients had been collected since December 1, 2015 to Jan 1, 2017 in Renal Department, Nanfang Hosipital of Southern Medical University. All patients had been treated with CAPD (mean dialysate glucose concentration 2.0±0.3%, total dialysate volume 8.3±1.1L) before came to our center and were treated with APD in the hosipital (mean dialysate glucose concentration 2.0±0.2%, 4 cycles per night, total treatment volume 9.6±1.2L, total treatment time 12.0±2.0h). Fluid state, peritoneal ultra-filtration volume, 24h urine volume, body weight, blood pressure were collected and compared between the last three days before receiving short-time APD and in those when receiving short-time APD. Serum creatinine, BUN, albumin, potassium, hemoglobin and glucose were collected and compared before and after receiving APD, respectively. Manifestation and grades of left heart failure were collected and comparted before and 3 days after receiving APD.

Results: A total of 47 patients (31 men, mean age 46.8±16.2yr) were enrolled in this study. The mean duration of CAPD was 26 months (2-195months). Of the 47 patients, peritoneal dialysis UF was significantly increased when receiving short-time APD than that of CAPD (1261.9±329.6ml vs 706.2±222.3ml, p<0.001), and body wights had significantly decreased 3 days after treated with APD (57.73±10.5 Vs 59.81±10.8, p<0.001). The grades of LHF were significantly decreased 3 days after receiving APD (1.7±0.8 vs 2.4±1.0, p<0.001), also manifestation of LHF had been significant improved 3 days after receiving APD (40% vs 70%, p= 0.007). Blood pressre were well controled 3 days after treated with APD (146.6±14.4 vs 162.5±23.8 of SBP, p= 0.0007, and 85.6±11.1 vs 95.6±14.7 of DBP, p=0.001). There were no changed in serum creatinine, albumin, potassium, nor hemoglobin.

Conclusions: In conclusion, short-time APD could significantly increase ultrafiltration, alleviate edema and acute left heart failure, which might be an effective method to treat UFF and acute left heart failure in PD patients.

TH-PO862

Left Ventricular Mass Index at Peritoneal Dialysis Initiation Is Possible Risk of Cardiovascular Disease and Death in Peritoneal Dialysis Patients Using Biocompatible Solution Yoshifumi Hamasaki, Teruhiko Yoshida, Ryo Matsuura, Kent Doi, Eisei Noiri, Masaomi Nangaku. *The University of Tokyo, Tokyo, Japan.*

Background: Left ventricular hypertrophy (LVH) is recognized as a predictor of cardiovascular disease (CVD) and risk of mortality in patients undergoing maintenance peritoneal dialysis (PD). It is not well known whether LVH at PD initiation is associated with the mortality or CVD in patients even when they are treated using biocompatible PD solution (BPDS). We investigated the relationship between clinical parameters including left ventricular mass index (LVMI) at PD initiation and prognosis of patients using BPDS.

Methods: The data from patients who started PD from 2001 to 2015 at The University of Tokyo Hospital were collected retrospectively. To identify the predictors of death and major cardiovascular adverse event (MACE), we analyzed data including clinical parameters measured within 6 months after starting PD using BPDS. LVMI was also evaluated using the data of echocardiography performed at the same period. MACE is defined as cardiovascular death or CVD (cerebrovascular disease, ischemic heart disease or heart failure, and peripheral arterial disease), occurred until April 2017.

Results: 121 patients who started PD as their first dialysis modality were included. The mortality rate was 10.7% (13/121), and MACE were occurred in 31 patients. Logistic regression analysis found that LVMI and age were independent risk factors of mortality (odds ratio, 1.04 and 1.19; 95% confidence interval (CI), 1.01 to 1.07 and 1.08 to 1.32; p <0.01 and p <0.01; respectively). When patients were divided into two groups according to LVMI, Kaplan-Meier analysis revealed that higher LVMI group had significant higher mortality, higher incidence of MACE, and lower persistence rate of PD (Log rank: p = 0.003, 0.005 and 0.011, respectively). On ROC analysis, LVMI predicted mortality with statistical significance (AUC [95%CI] =0.87 [0.76-0.98]). The result of Cox proportional hazards model on mortality demonstrated that LVMI and age were independent predictor of mortality (hazard ration, 1.02 and 1.08; 95%CI, 1.00 to 1.05 and 1.02 to 1.15; p = 0.02 and <0.01; respectively).

Conclusions: LVMI at PD initiation may be a predictor of mortality and CVD in patients using BPDS.

TH-PO863

Therapeutic Experiences of Peritoneal Dialysis Therapy for Patients with Severe Heart Failure and/or Liver Cirrhosis Eiichi Sato,[1,2] Tsukasa Nakamura,[2] Takao Ono,[2] Manaka Degawa,[2] Hongmei Lu,[2] Daisuke Matsumura,[2] Mayumi Nomura,[2] Mayuko Amaha,[2] Akiko Fujii,[1] Yuko Ono,[1] Yoshihiko Ueda.[1] *[1]Dokkyo Medical University, Koshigaya Hospital, Koshigaya, Saitama prefecture, Japan; [2]Shinmatsudo Central General Hospital, Matsudo city, Japan.*

Background: Peritoneal Dialysis (PD) is one type of renal replacement therapy for end-stage renal failure, however, some reports have described the application of PD for severe heart failure and liver cirrhosis using the slight change in hemodynamics caused by the gradual dehydration effect. We describe our experience of introducing PD to patients with severe heart failure or refractory ascites with liver cirrhosis.

Methods: The study included 6 out of 11 patients for whom PD was introduced at our department over the past year. Three patients had severe heart failure and difficulty in weaning off extracorporeal circulation, one patient had refractory ascites caused by liver cirrhosis, and two patients had both conditions.

Results: The subject sample consisted of four male and two female patients, aged 78.3 ± 5.0 years (mean ± standard deviation), and the underlying disease was dilated cardiomyopathy concurrent with diabetes, with ischemic heart disease in four patients, non-alcoholic steatohepatitis in one patient, and hypoalbuminemia in one patient. The mean estimated glomerular filtration rate was 21.8 ± 2.8 ml/min/1.73m2. The mean survival period was 60.7 ± 14.5 days, with two fatal cases at 65 days and 45 days, respectively, both of which were caused by sepsis unrelated to PD. In five patients weaning off extracorporeal circulation was possible, and in one patient, who was unsuited to extracorporeal circulation, heart failure was managed by PD alone and the patient was successfully weaned off the mechanical ventilator. Brain natriuretic peptide was 516.0 ± 172.9 pg/mL prior to PD introduction, and 316.7 ± 82.3 pg/mL following PD introduction, with a significant decrease (p = 0.01).

Conclusions: In patients with chronic heart failure or renal failure concurrent with liver cirrhosis, dehydration management is often performed by extracorporeal circulation, however in many instances, hemodynamics become unstable, making dehydration difficult. At our department, in such cases, it is expected that PD will achieve gradual dehydration, and we experienced cases in which PD enabled CHDF weaning and the control of heart failure and refractory ascites. The effectiveness of PD was suggested as a means of fluid management in severe heart failure and refractory ascites.

TH-PO864

Bioimpedance Monitoring and Blood Pressure in Peritoneal Dialysis Patients Malik Touam,[2] Marielle L. Cottereau,[2] Didier Biroteau,[2] Dominique A. Joly.[1] *[1]Assistance Publique Hôpitaux de Paris, Paris, France; [2]Necker Hospital, Paris, France.*

Background: We used bioelectrical impedance analysis (BIA) to determine body composition parameters in peritoneal dialysis patients (PD), and we compared the relationships of hydratation status with home blood pressure (HBP) and office blood pressure (OBP).

Methods: This single center study enrolled all prevalent PD from 2014 to 2016. Patients recently started on PD (<3 m) or with recent peritonitis (<2 m) were not included. A bioimpedance monitor (BCM®, Fresenius Medical Care, Germany) was used to assess body composition. Demographic data, blood, 24-h dialysate and urine samples were collected. HBP and OBP measurements were collected the same day. Multivariate analysis was used to determine the relationship between HBP, OBP and extracellular fluid volume/total body water ratio (ECV/TBW). Potential cofounders included age, diabetes, Charlson comorbidity index, PD method (CAPD, APD), and residual renal function (RRF) were identified.

Results: 63 PD were included (59.7 ± 13.4 y; average follow-up 13.6 ± 5.2 m). Systolic OBP (sOBP) and systolic HBP (sHBP) were correlated with ECV/TBW. It was a very strong relationship between sHBP and ECV/TBW (p<0.001) with sHBP, RRF and serum BNP being the independent predictors (table 1)

Conclusions: Systolic HBP, decreased RRF and serum BNP were major independent predictors of expanded ECV. In daily practice, expanded ECV should prompt to check home blood pressure.

Funding: Government Support - Non-U.S.

Table 1. Predictors of % ECV/TBW

	Slope (95% CI)	p
sHBP	-0.07 (-0.12 to -0.03)	<0.001
RRF	-0.28 (-0.45 to -0.12)	<0.001

PD Patients Undergoing CABG: Modality Change and Complications Matthew J. Diamond,[1,2] Jennifer L. Waller,[1] Mufaddal F. Kheda,[1] Stephanie L. Baer,[2] Rhonda E. Colombo,[1] Lu Huber,[1] John J. White,[1,2] Matt Day,[1] Troy J. Plumb,[4] N. Stanley Nahman.[3] *[1]Augusta University, Augusta, GA; [2]Augusta VA Medical Center, Augusta, GA; [3]Medical College of Georgia at Augusta University, Augusta, GA; [4]University of Nebraska Medical Center, Omaha, NE.*

Background: Efforts to continue PD when patients undergo CABG may minimize infectious and thoracic complications of temporary HD, alleviate interruptions in therapy, and be more cost effective. To investigate patterns of modality change and post-op complications in PD patients undergoing CABG, we queried the USRDS.

Methods: Incident PD patients from 2004 – 2011 (n=56,192) who underwent CABG were studied. Groups included: no interruption of PD (PD); planned temporary (PT) HD then back to PD ($_{PT}$HD-->PD); permanent switch (PS) to HD ($_{PS}$HD); urgent temporary (UT) HD then back to PD ($_{UT}$HD-->PD); or urgent (U) HD with PS to HD ($_{U}$HD-->$_{PS}$HD). Demographics and outcomes were determined. The relative risk (RR) of complications of interruption of PD vs. no interruption of PD up to 90 days post-op were estimated.

Results: 1259 PD patients had CABG, 63% men, 79% White, with mean±SD age 61±2 years, and time on dialysis of 24.1±2.7 months. Readmissions 90 days post-op (Re-adm90, number), and group comparisons by complication, are shown in the table. Continuing PD, and planned temporary HD ($_{PT}$HD-->PD), were the most common forms of dialysis in PD patients with CABG. However, planned or urgent HD that returns to PD had the most readmissions, and when compared to those staying on PD, had the greatest risk of complications.

Conclusions: Continuing PD during CABG appears safe. A planned permanent switch to HD had the fewest readmissions and a non-significant tendency toward lower complication rates. Restarting PD after planned or urgent HD has a high complication rate. Risk stratification my help identify the best candidates for returning to PD post-CABG.

TH-PO866

Burkholderia Cepacia: An Outbreak in the Peritoneal Dialysis Unit Sarah Gleeson, Hari M. Talreja. *Middlemore hospital, Auckland, New Zealand.*

Background: Introduction *Burkholderia cepacia* is a, gram negative, opportunistic, environmental bacillus which commonly affects cystic fibrosis and immunocompromised patients. Rarely, it can cause peritoneal dialysis exit site infection (ESI). Data on predisposing factors, clinical course and treatment options is limited. Although a common cause of nosocomial infections, no nosocomial outbreaks in peritoneal dialysis (PD) patients have previously been reported. A recent outbreak of *B. cepacia* ESIs in our PD unit provided a unique opportunity to gain more information on *B. cepacia* ESIs and to outline an approach to investigating an outbreak in the PD unit. Eight such cases were identified.

Methods: Case description Following the identification of *B. Cepacia* as the causative organism in PD catheter exit site infection in three patients over an eleven week period, we began screening our PD population for *B. cepacia* exit site colonisation. Over the following sixteen weeks, a further three patients were identified as having asymptomatic colonisation, and a further two patients suffered symptomatic *B. cepacia* ESI. Of the five symptomatic ESIs, three developed tunnel infections requiring multiple courses of antibiotic treatment and eventual catheter removal. Isolated ESIs were treated with oral and topical antibiotics with full resolution. Five of eight patients were female, three had proud flesh at the exit site, three were diabetic (all of the asymptomatic infections were in non-diabetics; two of the three tunnel infections developed in diabetic patients). A thorough investigation into the likely source of the outbreak implicated the 4% chlorhexidine handwash used by the patients. However, samples from the manufacturer did not contain *B. cepacia* suggesting mishandling of the product by the patients may have contributed

Results:

Conclusions: Discussion This is the first reported outbreak of *B. cepacia* PD exit site infections. A number of interesting observations were made. Firstly, diabetes may potentially be a risk factor for refractory or more extensive infection. Secondly, treatment should be individualised according to the extent of the infection; our cohort suggests that an isolated ESI can be treated successfully with oral antibiotics whereas tunnel infections generally require catheter removal.

TH-PO867

The Lower Left Quadrant Incision Significantly Reduced Catheter Tip Migration in Peritoneal Dialysis – A Single Center Retrospective Analysis Yaohui Chen, Lin Yang, Chunyan Lang, Lili Yang, Zhenhua Liu, Yun Li. *Jiangxi Provincial People's Hospital, Nanchang, China.*

Background: The reported rate of catheter tip migration in peritoneal dialysis(PD) is 5-35%. In order to reduce it, a modified catheter implantation incision was studied.

Methods: One hundred and seventy-six of Han Chinese end stage renal disease(ESRD) patients were implanted with Tenckhoff double cuff straight catheter to carry out PD from November 2010 to September 2016. The patients were divided into two groups, 40 in the conventional group and 136 in the modified group. In the conventional group, the incision for the catheter implantation was at 9-13cm above pubic symphysis, left or right paramedian. In the modified group, the incision was at 6-9cm above pubic symphysis and about 2cm left paramedian in the lower left quadrant. It was also the position for catheter pouch. All operations were performed by one physician. The dialysate inflow and outflow times, ultrafiltration volume, urine volume, body weight and edema changes, leakage, infection, bleeding, intestinal obstruction, and catheter tip migration were observed.

Results: Within six months of implantation, 6(15%) patients in the conventional group *vs* 4(2.94%) patients in the modified group had catheter tip migration. Compared with the conventional group, the incidence of catheter tip migration was significantly lower in the modified group (p=0.01). In addition, in the conventional group, all 6 patients who had catheter tip migration needed surgical repositioning after conservative treatment to restore the catheter function. In the modified group, non-surgical repositioning in 1 of the 4 patients with catheter tip migration was achieved while the rest needed surgical repositioning. There were no significant differences in the dialysate inflow and outflow times, ultrafiltration volume, urine volume, body weight between two groups. There were no obvious leakage, infection, bleeding, intestinal obstruction and other complications.

Conclusions: The modified incision at 6-9cm above pubic symphysis and about 2cm left paramedian in lower left quadrant significantly reduced catheter tip migration in peritoneal dialysis in Han Chinese.

TH-PO868

Feasibility of Urgent-Start Peritoneal Dialysis in Older Patients with ESRD: A Single-Center Experience Haijiao Jin,[1] Zhaohui Ni.[2] *[1]Department of Nephrology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; [2]None, Shanghai, China.*

Background: Patients with end-stage renal disease (ESRD) frequently require urgent-start dialysis. Recent evidence suggests that peritoneal dialysis (PD) might be a feasible alternative method of urgent dialysis, including in older patients.

Methods: This retrospective study enrolled patients aged >65 years with ESRD who underwent urgent dialysis without functional vascular access or PD catheter at a single-center, from January 2011 to December 2014. Patients were grouped based on their dialysis modality (PD or hemodialysis [HD]). Patients unable to tolerate PD-catheter insertion or wait for PD were excluded. Each patient was followed for at least 30 days after catheter insertion. Short-term (30-day) dialysis-related complications and patient survival were compared between the two groups.

Results: A total of 94 patients were enrolled, including 53 (56.4%) who underwent PD. The incidence of dialysis-related complications during the first 30 days was significantly lower in PD compared with HD patients (3 [5.7%] vs. 10 [24.4%], P=0.009). Logistic regression identified urgent-start HD as an independent risk factor for dialysis-related complications compared with urgent-start PD (odds ratio 4.760 [1.183–19.147], P=0.028). The 6-, 12-, 24-, and 36-month survival rates in the PD and HD groups were 92.3% vs. 94.6%, 82.4% vs. 81.3%, 75.7% vs. 74.2%, and 69.5% vs. 60.6%, respectively, with no significant differences between the groups (log-rank=0.011, P=0.915).

Conclusions: Urgent-start PD was associated with fewer short-term dialysis-related complications without affecting survival compared with urgent-start HD in older patients with ESRD. PD may thus be a safe and effective dialysis modality for older ESRD patients requiring urgent dialysis.

Poor Early Exit Site Condition Was Associated with Subsequent Exit Site Infection and Catheter Loss of Peritoneal Dialysis Masaki Uehara, Takafumi Yamakawa, Takehiko Kawaguchi, Toshiyuki Imasawa, Moritoshi Kadomura. *Department of Nephrology, National Hospital Organization Chiba-East Hospital, Chiba, Japan.*

Background: Exit site infection (ESI) is a common complication for peritoneal dialysis (PD) patients. A previous study reported that the first ESI before eight month post-implant period was a higher risk of PD related infections. However, it is unclear whether an early condition of exit site after PD initiation is associated with subsequent ESI and PD catheter loss.

Methods: We retrospectively examined 46 patients who started PD from 2010 to 2015 at Chiba East Hospital in Japan. The patients were divided into two groups, good or poor exit site condition group (G or P group), according to ISPD exit site scoring system. We defined the poor exit site as the score more than 2 points on the first outpatient visit after PD initiation, or the worse score on the second visit. We compared episodes of ESI more than twice (E), peritonitis (P) and catheter loss (L) between the groups. Cox regression was used to estimate hazard ratios (HRs) adjusting for age and diabetes as primary disease.

Results: The patients were mostly male (69.6%), with a mean age of 61.0 years, and 50% of patients had diabetes. There were no statistical differences in baseline characteristics between the two groups. During the median follow-up of 719 days, we observed 13 of Es, 15 of Ps, and 13 of Ls. In unadjusted analyses, we found no statistical difference in P free survival rates, but E and L free survival rates were significantly lower in P group than in G group (Figure). In multivariable analyses, the adjusted HRs (95% CI) for E, P, and L in P group were 29.5 (2.62-331.61), 1.90 (0.61-5.94), and 3.00 (1.01-8.95), respectively.

Conclusions: Poor early exit site conditions were associated with subsequent ESIs and PD catheter losses. It may be crucial to keep good exit conditions after PD initiation. Further studies are needed to verify that early screening and interventions for poor exit sites can improve the outcomes.

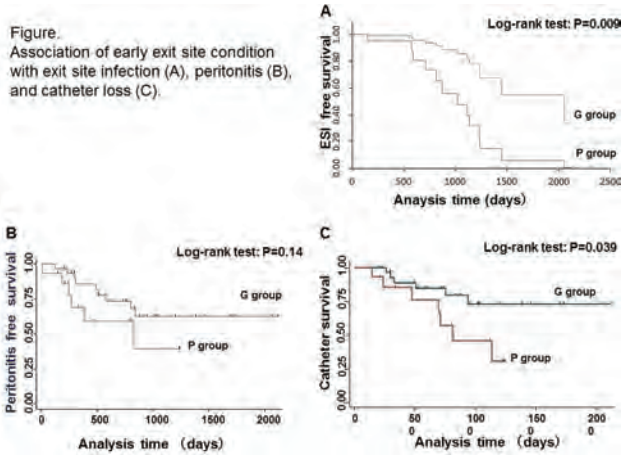

Figure.
Association of early exit site condition with exit site infection (A), peritonitis (B), and catheter loss (C).

Evaluating Bacterial Flush Efficiency and Touch Contamination Across 3 Different Twinbag Systems Paul Straka, James A. Sloand. *Baxter Healthcare Corporation, Deerfield, IL.*

Background: Peritonitis is a significant complication of peritoneal dialysis (PD). PD system design to reduce touch contamination by at-home PD patients is critical in reducing peritonitis risk. Impact of connection-design differences on contaminant flush efficiency among three different Twinbag CAPD system was assessed by examining differences in the amount of bacteria entering the fluid path under worse case touch contamination.

Methods: 3 studies were performed: A1, A2, and B, with details as follows: A1) Touch contamination at the transfer set connector adapter (TSCA) and the patient connector adapter (PCA) ends, each connector quantified. A2) Touch contamination simulated as in A1, connected and flushed to quantify the bacteria transferred into the fluid path. B) Known levels of bacterial contamination were inoculated into the fluid path, performed CAPD procedure and quantified the patient infusion fluid. Three different commercially available PD delivery systems (System 1, 2, 3) were tested using the above (27 times over a 4 day period) that differed in location of the frangible, the Y-configuration and the size of the shrouds (short: Camex; long: Hytrel) on the PCA.

Results: For touch contamination evaluation (A1), the TSCA had a significant (p-values <0.0001) lower mean bacterial level compared to the PCA. For touch contamination evaluation (A2), system 2 had a significantly higher mean count than systems 1 and 3 (p-value <0.001). For the flush efficiency evaluation (B), the three systems were compared within each day. There were no significant differences in the mean log base 10 values among the three systems within days 1, 3 and 4 (p-values ≥0.05). For day 2, system 3 mean was significantly higher than system 2 mean (p-value = 0.0031).

Conclusions: Touch contamination studies show that when contaminated, the smaller surface area of the TSCA when compared to the PCA resulted in lower bacterial counts. Despite what would appear as a more protective design, the deeply recessed Hytrel shroud resulted in significantly higher bacterial transfer into the fluid path than the shallow recessed Camex shroud. These differences are immaterial given no difference between "Flush before Fill" efficiency of the 3 systems, irrespective of frangible location or asymmetric Y position. This highlights the importance of redundancy in connection design features to reduce PD touch contamination.

TH-PO871

Peritoneal Membrane Transport Characteristics in Uni-Peritoneal Equilibration Test (PET) with Preceding Icodextrin Dwell as Compared to Classic PET with Preceding Glucose Dwell: A Pilot Study Harbir S. Kohli,[1] Gaurav Vohra,[1] Vivek Kumar,[3] Krishan Lal L. Gupta.[2] *[1]Post Graduate Institute of Medical Education and Research (PGIMER), CHANDIGARH, India; [2]Postgraduate Institute of Medical Education & Research, Chandigarh, India; [3]Postgraduate Institute of Medical Education and Research, Chandigarh, India.*

Background: In subjects on CAPD who use icodextrin for long night dwell, it has been recommended that nocturnal icodextrin exchange be replaced by dextrose dwell whenever PET is to be performed. This is because it has been thought that preceding exchange with icodextrin temporarily increases peritoneal membrane permeability and therefore, gives high dialysate/plasma creatinine (D/P cr) and low dialysate glucose at end of PET/dialyste glucose in fresh solution (D/D0) value. Whether this temporary change is also seen with use of Uni-PET (which involves one hour dwell of 1.5% dextrose followed by 4-hour dwell of 4.25% dextrose) is not known.

Methods: In this self, controlled study, subjects on CAPD, who were using icodextrin for long nocturnal dwell for at least 3 months, were screened for enrolment. Pregnancy or lactation, history of any PD related infectious complication in the past one month, present or past malignancy, and poor functional status were exclusion criteria. On day 1 enrolled subjects underwent classic PET with preceding 2.5% dextrose long nocturnal dwell and on day 2 Uni-PET was done with preceding 7.5% icodextrin long nocturnal dwell. Difference in D/P cr and D/D0 glucose between the two PETs were primary objectives. The study was approved by Institute Ethics Committee.

Results: Of 26 screened subjects 15 were enrolled over a period of 18 months (July 2015-December 2016). The mean (±SD) age of study population was 60.8±9.1 years. Majority were males and diabetes was the most common cause of CKD. Mean D/P cr were 0.68 ± 0.11 and 0.64 ± 0.08 in classic PET and Uni-PET, respectively. The difference between the two values was not significant [mean difference between D/P cr (classic PET-Uni-PET): 0.040 ± 0.86; 95% CI (-0.007 to 0.088); p=0.09]. Similarly, D/D0 glucose between classic PET and Uni-PET were also similar [mean difference between D/D0 glucose (classic PET-Uni-PET): -0.02 ± 0.09; 95% CI (-0.06 to 0.03); p = 0.448].

Conclusions: Peritoneal membrane small solute transport characteristics in Uni-PET with preceding icodextrin dwell are similar to classic PET with preceding glucose dwell. If Uni-PET is used, it is not necessary to replace preceding nocturnal exchange of icodextrin with that of dextrose

TH-PO872

Increasing Peritoneal Inflammation Over Time Drives Increasing Peritoneal Solute Transport: Results from the Global Fluid Study Vasileios Zavvos,[1] Emma H. Elphick,[2] Simon J. Davies,[2] Nicholas Topley,[1] Mark Lambie,[2] Donald Fraser.[1] *[1]Cardiff University, Cardiff, United Kingdom; [2]Keele University, Crewe, United Kingdom.*

Background: Local peritoneal inflammation is a feature of peritoneal dialysis (PD) treatment and high concentrations of dialysate IL-6 (dIL6) are a strong determinant of solute transport (PSTR). PSTR is associated with patient survival and increases during long term PD but it is not known to what extent the rise is driven by dIL-6.

Methods: We conducted a longitudinal analysis of the Global Fluid study, a multinational cohort study from UK, Canada and Korea. All incident patients with 3 or more paired dialysate/plasma samples were assayed for IL-6 by electrochemiluminescence. A linear mixed model with random intercept/slopes assessed associations with pIL6. Covariates included time on PD, centre, glucose exposure, icodextrin use, dIL6, gender, baseline age, comorbidity and urine volume in an adjusted model with backwards selection. pIL6 and dIL6 were log transformed. PSTR was assessed by modified peritoneal equilibration testing to calculate the dialysate to plasma creatinine ratio.

Results: There were 217 patients with 1274 measurements, with a median follow up time of 2.2 years from 6 centres. PSTR increased from a mean value of 0.715 within the first 6 months to 0.741 after 3.5 years, whilst dIL6 increased from 6.0 pg/ml to 12.0 pg/ml over the same period. When adjusted for centre, icodextrin use, urine volume and dIL6 were significant predictors of PSTR (β=0.069 95% CI 0.056 to 0.083 p<0.001). Time varying dIL6 was a better predictor than baseline dIL6 (AIC -1377 vs. AIC -1342). Time became insignificant with both varying and baseline dIL6. The effect of urine volume and icodextrin was reduced over time. Random slopes were significant for time (LRT 19 d.f.=2 p=<0.0005).

Conclusions: Both dIL6 and PSTR increase with duration of PD. The increase in PSTR over time is mostly accounted for by changes in dIL6 and urine volume.

Predictors of PSTR over time

	Coefficient	p value/95% Confidence Intervals
Time on PD	0.0091	0.000040 to 0.018
Centre	χ 2 = 44.5, d.f. = 5	p =<0.001
Urine Volume (L)	-0.040	0.0025 to 0.055
Urine Volume Time Interaction	-0.010	-0.017 to -0.003
Use of Icodextrin	0.023	0.0031 to 0.041
Icodextrin Time Interaction	-0.011	-0.021 to 0.002
Time varying dIL6 (log transformed pg/ml)	0.064	0.047 to 0.083

Table showing adjusted multilevel model for PSTR

TH-PO873

Transversus Abdominis Plane Block Relieves Perioperative Pain on Peritoneal Dialysis Catheter Insertion Kenji Harada. *Division of nephrology, Kokura memorial hospital, Kitakyusyu city, Japan.*

Background: The effectiveness of Transversus Abdominis Plain (TAP) block has been reported in the pain control at abdominal operation. However, its usefulness in pain management remains unclear in peritoneal dialysis (PD) patients undergoing catheter insertion. We investigated the effectiveness and safety of TAP block for perioperative on PD catheter insertion.

Methods: The present study is a single-centred, prospective, randomised study of initiated PD patients between from April 2016 to March 2017. VAS (Visual Analogue Scale), which is often used around anesthesiology and pain management field, was measured as pain assessment. VAS was measured at two points, right after and 24 hours after operation, using t-test with P values.

Results: Overall, 66 PD patients were included (mean age; 67.2 year old, male/female; 42/24, average eGFR 7.63±2.81). Patients were divided into two groups TAP block (n=31) and non-TAP block(n=35). There were significant low VAS in TAP block group right after operation (1.06 vs 3.47, p<0.0001). Furthermore, even at 24 hours after operation VAS in TAP block was lower (1.55 vs 2.59, p=0.041). There were no cases needed for ventilation and anesthetic drug such as morphine. TAP block-related adverse events were not found.

Conclusions: TAP block technique was significantly associated with relief from post-operative pain in PD catheter insertion. This treatment procedure might be a minimally invasive and effective therapeutic option for perioperative pain management on PD catheter insertion.

TH-PO874

Peritoneal Dialysis Is Associated with Lower Mortality Compared to Hemodialysis in Patients with Low Serum Albumin Sana Waheed,[3] Brad C. Astor,[2] Tripti Singh.[1] *[1]None, Madison, WI; [2]University of Wisconsin, Madison, WI; [3]Medicine, University of Wisconsin School Of Medicine and Public Health, Madison, WI.*

Background: Low serum albumin is associated with high mortality in patients on chronic dialysis. Clinicians are reluctant to offer peritoneal dialysis (PD) as an option for dialysis for patients with low serum albumin due to concerns of loss of albumin with PD. We evaluated mortality based on dialysis modality in patients with low serum albumin (<2.5 gm/dL)

Methods: We analyzed USRDS data from 2010-2015 to assess mortality by modality type adjusted for age, sex, race, employment, comorbidities and the year of dialysis initiation.

Results: Low serum albumin (<2.5 gm/dL) was present in 78,625 (19.9%) of 395,656 patients. Those with low serum albumin were less likely to use PD as their first modality than those with higher albumin (3.1% vs. 10.9%; p<0.001). Use of PD was associated with lower mortality compared to HD (hazard ratio [HR]= 0.86, 95% CI 0.80-0.93, p< 0.05) in patients with low serum albumin. This difference was more pronounced in patients who had glomerulonephritis (HR= 0.70) or hypertension (HR=0.79) than in those with end-stage renal disease (ESRD) due to diabetes mellitus or other causes [Table 1].

Conclusions: PD is associated with lower mortality than HD in patients with low serum albumin. Therefore, it is of concern that the rate of PD utilization is lower in these patients. We recommend advocating the use of PD in patients with low serum albumin as is associated with a lower mortality rate.

Table 1: Hazard ratio for mortality associated with PD compared to HD in patients with low serum albumin, by cause of ESRD

Cause of ESRD	HR (PD/HD)	CI (95%)	P-interaction
Glomerulonephritis	0.70	0.54-0.92	Reference
Hypertension	0.79	0.64-0.97	0.53
Diabetes Mellitus	0.92	0.83-1.02	0.04
Others	1.03	0.85-1.25	0.01
Overall	0.86	0.8-0.93	

TH-PO875

Race-Ethnicity and Mortality Associated with Serum Potassium in Peritoneal Dialysis Patients Rieko Eriguchi,[1] Yoshitsugu Obi,[2] Elani Streja,[2] Melissa Soohoo,[2] Connie Rhee,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[2] *[1]Kaizuka Hospital, Fukuoka, Japan; [2]UC Irvine, Orange, CA; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Abnormalities in serum potassium are risk factors for sudden cardiac death and arrhythmias among dialysis patients. A previous study showed that lower potassium is associated with mortality in peritoneal dialysis (PD) patients. However, it remains unknown whether the impact of serum potassium levels on mortality may be different according to race-ethnicity in PD patients.

Methods: We retrospectively examined 19,131 PD patients with available serum potassium data during treatment in a large dialysis organization from January 1, 2007 and December 31, 2011. Using a time-dependent Cox model and splines, we explored the association between monthly-averaged serum potassium level and cause-specific deaths potentially caused by dyskalemias (defined as deaths attributed to hypokalemia, hyperkalemia, cardiac arrhythmia, or cardiac arrest) across race-ethnicity with adjustments for case-mix variables (demographics and comorbidities).

Results: Mean age was 56±16 years, 44% were women, 57% were non-Hispanic white, 23% were African-American, and 12% were Hispanic. Compared to non-Hispanic white patients, African-Americans had lower serum potassium levels, and Hispanics had higher serum potassium levels at baseline. In the total cohort, serum potassium levels less than 3.5 mEq/L were significantly associated with higher cause-specific deaths. In regards to potential potassium-related deaths, hypokalemia was associated with mortality in both non-Hispanic whites and Hispanics. Hyperkalemia was not associated with mortality in Hispanics, only in non-Hispanic whites and African-Americans.

Conclusions: Among PD patients, lower serum potassium levels were associated with cause-specific deaths. The impact of serum potassium levels on potential potassium-related deaths varied according to race-ethnicity.

TH-PO876

Barriers to Peritoneal Dialysis in Kenya Ahmed P. Sokwala. *Aga Khan University Hospital, Nairobi, Kenya.*

Background: Peritoneal dialysis (PD) is not commonly practiced in Kenya. Kenya has approximately 4000 patients on hemodialysis (HD) with less than 20 patients on PD. The perception and attitude of both the patient and the doctor on the modality of chronic renal replacement therapy determines what type of dialysis the patient will be started on. Increase in PD in developing countries with poor infrastructure for HD, will increase the number of patients who can access renal replacement therapy for both acute kidney injury and end stage renal disease.

Methods: A questionnaire was formulated and mailed to the nephrologists to determine their attitude towards PD and to bring out the reasons why they are reluctant to start peritoneal dialysis. A total of 22 questions were formulated and the questionaires mailed to the 25 nephrologists in the region. Questions were about the nephrologists' opinions on reasons that limited patients and doctors selection of peritoneal dialsis as initial therapy. After analyzing the reasons, interventions can be put into place to improve the numbers of patients on peritoneal dialysis.

Results: Twenty three out of twenty five (93%) nephrologists responded to the questions. Only 38% of the nephrologists took care of patients on peritoneal dialysis and out of those 55% of the nephrologists had less than 2 patients on PD. Despite that 70% of the nephrologist thought that more than 20% of end stage renal disease patients should be on PD. Most of the doctors said they had adequate training and exposure to peritoneal dialysis in their training. Lack of nursing expertise was one of the main reasons stated by the nephrologist as being the main chalenge of starting peritoneal dialysis. Lower physcian reimbursement for peritoneal dialysis vis a vis haemodialysis was another point brought out, the Government had started paying for hemodialysis rather than peritoneal dialsysis The other major hinderance was insertion and care of the peritoneal dialysis catheter. Most nephrologists thought patients do well on peritoneal dialysis with no mortality difference between PD and HD.

Conclusions: There is positive attitude about PD amongst the nephrologist. Training more nurses on peritoneal dialysis and training doctors on bedside insertion of peritoneal dialysis catheres will probably increase the uptake of peritoneal dialysis in our country. Nephrologists should be equally reimbursed for PD as for HD or even better.

TH-PO877

Burden on Caregiver and Risks of Patients in Peritoneal Dialysis Marica Mulè,[3] Valerio Vizzardi,[2] Anna Bertoni,[4] Sara Molgora,[5] Massimo Sandrini.[1] *[1]Spedali Civili, Brescia, Italy; [2]University and Spedali Civili, Brescia (BS), Italy; [3]Università Cattolica, Milano, Italy; [4]Università Cattolica, Milano, Italy; [5]Università Cattolica, Milano, Italy.*

Background: This qualitative research aims to assess the psychological aspects about the caregivers of patients with Chronic Kidney Disease (CKD) in Peritoneal Dialysis (PD). This study has two goals: to observe the role of caregiver in PD; to compare fatigues, resources of dialysis team, patients and partners.

Methods: Two Focus Groups have been conducted: The first one with PD team and the second one with patients and their caregivers. Focus Groups were videotaped and transcribed. The transcripts were analyzed using the textual analysis software T-LAB. It has been performed a thematic analysis of elementary contexts.

Results: The thematic analysis implemented overall corpus of interviews showed a four-cluster solution. Clusters identify four thematic areas about PD team, patients and caregivers perceptions. We labeled these cluster respectively: "The relationship: the best possible support"; "Burden caregiver"; "Patient and Caregiver engagement" and "Quality of life in CKD". Clusters explain respectively 32,3%, 27,3%, 25% and 15,4% of the data variance. For the first aim the analysis showed as the caregiver is the best resource for the PD team and for the patients. In addition, the analysis shows as one of the possible risks of peritoneal dialysis that the caregiver feels more responsibility and fatigues than the patient does. This could bring the caregiver towards the burnout and dehumanizing behavior. In fact the CKD seems removing the patient freedom and looks like a cage for the caregiver. Regarding the second aim the clusters evidence as strength the relationship as the best chance in process of care in CKD. The greatest difficulty for PD team is recognizing when the caregiver becomes a "patient" and when the caregiver is a resource. In the same way the most fatigue for the caregivers is to recognize their role and their limits in patient caring. Last but not least the most difficult challenge for patients is going beyond their demotivation to be engaged in the care process.

Conclusions: The study shows as the CKD is a couple matter and a daily challenge for PD team. All clusters concern the burden caregiver may be one possible factor contributing to poor quality of life and depression in both family and patients.

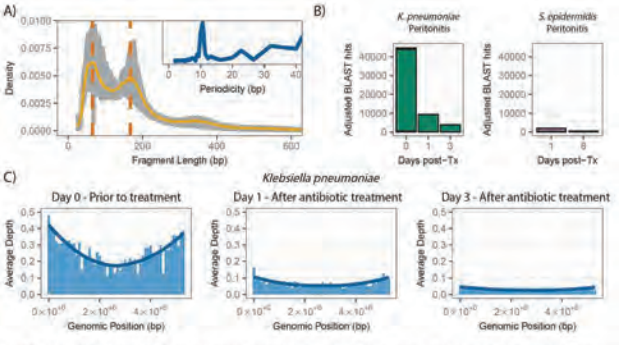
Metagenomic Sequencing of Cell-Free DNA in Peritoneal Fluid: A Novel Strategy to Identify Pathogens and Characterize Bacterial Growth Dynamics and Antibiotic Resistomes in Peritonitis John R. Lee,[3] Philip Burnham,[1] Amanda D. Renaghan,[3] Jeffrey I. Silberzweig,[2] Vesh Srivatana,[2] Darshana Dadhania,[3] Thangamani Muthukumar,[3] Manikkam Suthanthiran,[3] Iwijn De Vlaminck.[1] *[1]Cornell University, Ithaca, NY; [2]The Rogosin Institute, New York, NY; [3]Weill Cornell Medicine-, New York, NY.*

Background: Peritonitis is a devastating complication in peritoneal dialysis (PD) patients. Newer techniques are needed to predict peritonitis development and to characterize pathogen dynamics.

Methods: In this first-in-kind study, we recruited 4 ESRD PD patients; 2 subjects had peritonitis at the time of recruitment and the remaining 2 did not. We collected serial peritoneal fluid (PF) specimens from these subjects. We performed metagenomic sequencing on PF under single-stranded DNA library preparation using an Illumina NextSeq platform (2x75 bp).

Results: A mean of 3.6 million cfDNA fragments was obtained per specimen (N=7 specimens) and these fragments had peaks at 65 bp and 167 bp (Fig A). cfDNA profiling confirmed 2 cases of peritonitis (*Klebsiella pneumoniae, Staphylococcus epidermis*). Serial profiling showed decreasing adjusted BLAST hits after antibiotic treatment (Fig. B). Alignment of cfDNA fragments to the reference genome of *K. pneumoniae* revealed disproportionate coverage over the replication origin, highlighting active growth of *K. pneumoniae*, and subsequent decrease in growth activity after antibiotic treatment (Fig. C). Antibiotic resistance determination revealed the presence of PmrE, PmrF, oqxB, mfd, FosA5, cpxAR, PatA-PatB, and msbA, which provide resistance to colistin, novobiocin, ciprofloxacin, and norfloxacin.

Conclusions: Our first-in-kind study demonstrates that cfDNA profiling of peritoneal fluid is an all-inclusive approach to comprehensively identify pathogens, bacterial growth dynamics, and antibiotic resistomes, which may be useful in culture-negative peritonitis and recurrent peritonitis.



A) Cell free DNA fragments in PD fluid with fragment length on the x axis and density on the y axis. Peaks are noted at 65 bp and 167 bp, resembling patterns in the urine and plasma. The upper box represents peaks at 10 bp (representing breakpoints between nucleosomal wrapping). B) Microbial profiling of the 2 subjects with peritonitis after treatment. On the left is the subject diagnosed with *Klebsiella pneumoniae* peritonitis (green) and on the right the subject diagnosed with *Staphylococcus epidermis* (purple). Days after treatment are on the x axis and adjusted blast hits are on the Y axis. C) Disproportionate coverage over the origin site of replication (a parabola shape) is correlated with active bacterial growth rate based on Korem et al., Science 349(6252):1101, 2015. We applied this principle to the cfDNA metagenomic sequences prior to treatment (left) and after treatment (center and right panel). The genome position with 0 as site of origin is on the x axis and the depth of coverage is on the y axis. As shown, there is increasingly more even coverage over the origin site which is correlated with a non-dividing bacterial population.

TH-PO879

The Involvement of p38MAPK in Impaired Neutrophil Bactericidal Activity of Hemodialysis Patients Yasutaka Kamikawa,[1] Norihiko Sakai,[1] Yasuyuki Shinozaki,[1] Shinji Kitajima,[1] Tadashi Toyama,[1] Akinori Hara,[1] Yasunori Iwata,[1] Miho Shimizu,[1] Kengo Furuichi,[1] Takashi Wada.[1,2] *[1]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Japan; [2]Department of Nephrology and Laboratory Medicine, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan.*

Background: Mortality from infections has been reported to be higher in hemodialysis (HD) patients than that in healthy subjects. Previous studies reported that vascular access was the main route of bacterial infection in HD patients and also pointed that the most common micro-organism were staphylococcus aureus (*S. aureus*). To protect the host from bacterial infection, neutrophils have been thought to play central roles in the pathogenesis of the infection. This far, the dysfunction of neutrophils against bacterial infection in HD patients was reported. However the precise mechanism of neutrophil dysfunction in HD patients against bacteria remains unclear. In this study, we investigated the impacts of neutrophil inflammatory signaling against bacterial infection in HD patients.

Methods: Comprehensive analyses of intracellular signalings were performed in whole blood of HD patients and hypertensive (HT) patients as control using microarray system. None of patients had diabetes, cardiovascular disease and cancer. To confirm the contribution of the signaling to bactericidal activity in neutrophils, we examined the

phosphorylation, bacterial killing function, reactive oxygen species (ROS) production and myeloperoxidase (MPO) release in neutrophils against *S. aureus*.

Results: There were no difference at age and nutrition states such as serum albumin levels, cholesterol profile between HD and HT patients. RNA microarray analysis showed the suppression of p38 mitogen activated protein kinase (MAPK) signaling in HD patients. Neutrophils in HD patients showed the impairment of bactericidal activity against *S. aureus* compared to healthy subjects. Phosphorylation rate of p38MAPK of neutrophils in response to *S. aureus* was lower in HD patients than healthy subjects. The levels of ROS produced by neutrophils after co-culture with *S. aureus* were lower in HD patients, on the other hand, there was no difference of MPO release between HD patients and healthy subjects. A selective pharmacological inhibitor of p38MAPK suppressed bacterial killing function as well as ROS production in neutrophils of healthy subjects.

Conclusions: Impairment of p38MAPK signaling pathway might contribute to the suppression of neutrophil bactericidal activity in HD patients through the less production of ROS.

TH-PO880

Seasonal Variations in Blood Stream Infections in Hemodialysis Patients in the Midwest Marta Reviriego-Mendoza,[1] Sophia Rosen,[1] Hao Han,[1] Tommy C. Blanchard,[1] Jerry W. Jackson,[2] Julia I. Brennan,[4] John W. Larkin,[1] Len A. Usvyat,[1] Peter Kotanko,[3] Jeffrey L. Hymes,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]FMC Patient Safety Council, Mountain Brk, AL; [3]Renal Research Institute, New York, NY; [4]Spectra Laboratories, Rockleigh, NJ.*

Background: Blood stream Infections (BSIs) are the most common cause of morbidity and second leading cause of mortality in hemodialysis patients (HD). Environmental variations, particularly heat and humidity, are known to promote pathogenic growth and be associated with the incidence of BSIs and the worsening of clinical conditions. We aimed to study whether seasonal changes in the Midwestern area of the United States are associated with the variations in BSI rates in hemodialysis patients.

Methods: We collected data from HD patients treated at Fresenius Kidney Care clinics in the Midwest region from Jan-2014 through Dec-2016. This region was selected due to its more demarcated seasonal changes. Clinics included were those from the following states: Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin. The average monthly BSIs were calculated for HD patients and the association between the mean BSI rate and season was analyzed and plotted using a seasonally varying function that was optimized to the data using a least-squared method (Figure 1).

Results: We observed a distinct seasonal variations in BSI rates with a mean fluctuation of 9.25% below and above during July versus February of 2014-2016, respectively. Although BSI rates appeared to increase during warmer months, we observed a 34.3% decrease in BSI rates in the Midwest from 2014 to 2016.

Conclusions: Our findings suggest that seasonal variability is associated with alterations in BSI rates. In the Midwest, the highest BSI rates were observed during warmer months. The downward trends in BSI rates may be representative of improvements in infection control in HD facilities. Further analyses are warranted to confirm these results.

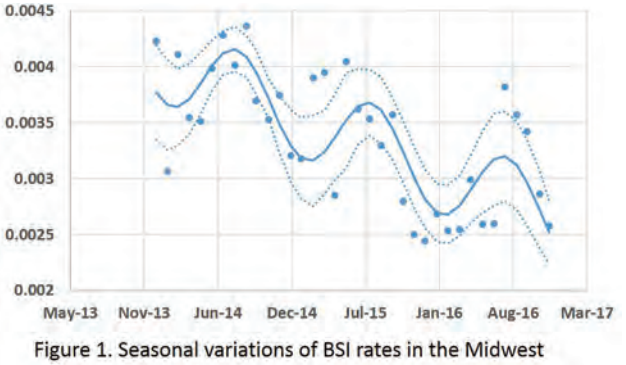


Figure 1. Seasonal variations of BSI rates in the Midwest

TH-PO881

Sex-Specific Differences in Blood Stream Infection and Hospitalization Rates in Hemodialysis Patients Marta Reviriego-Mendoza, Sophia Rosen, Dugan Maddux, John W. Larkin, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care, Waltham, MA.*

Background: It is known that men and women have physiological, hormonal, and genetic differences that can impact treatment regimens and clinical outcomes. Investigations on sex-specific differences in patients undergoing hemodialysis (HD) are limited. We performed a cross-sectional analysis to investigate if there are sex specific differences in systolic blood pressure (SBP) levels, blood stream infection (BSI) rates and hospitalization rates.

Methods: We analyzed data from all Fresenius Medical Care North America HD patients in 2016. Patients were grouped in 17-age categories from 18 years to 95 based on their age at initiation of dialysis. Yearly average SBP was calculated for each patient and averaged for each age-group. Hospitalization rates per patient year (ppy) and rate of admissions ppy were calculated for each age-group. We identified patients who had 1 or more BSIs during 2016 and calculated the percent of patients with at least 1 infection in that particular age group.

Results: Overall, we studied data from 230,091 patients; 43% were female. We used linear and quadratic regressions with an interaction term for Sex to study the sex-specific differences. From our analysis we noted: i) SBP remained stable for women at 139 (+/- 1) mmHg in all age groups, while males showed a steady decline from 143 mmHg to 130 mmHg from the age of 25 to 90 ($p<.0001$). ii) For both genders, BSIs are most common at a young age (between 25 and 40) and decline later in life. However, women exhibited a significantly higher percentage of BSIs compared to men with 9.2% vs 7.5% at age 25-30 ($p<.0001$). iii) Hospital admission rates ppy were significantly higher for women when compared to men, peaking at age 25 with nearly a 2 fold higher admission rates than men (3.0 vs 1.7 admissions ppy). Admission rates for women declined with age and equaled those of men by the age of 90 ($p<.0001$).

Conclusions: Our analysis shows that women, in particular those of a younger age, are at a significantly higher risk of BSIs and hospitalization than men. The characterization of these health disparities between the sexes may aid in identifying patients at risk of poorer outcomes.

TH-PO882

Association of Low Molecular Weight Heparin Compared to Unfractionated Heparin and the Risk of Dialysis-Related Infection and Septicemia among Hemodialysis Patients Hind H. Lazrak,[1] Emilie Rene,[1] Naoual Elftouh,[1] Annie-Claire Nadeau-Fredette,[1,2] Louis-Philippe Laurin,[1,2] Jean-Philippe Lafrance.[1,2] *[1]Research center, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada; [2]Division of nephrology, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada.*

Background: Hemodialysis patients have a higher risk of infection compared to the general population. The administration of low molecular weight heparin (LMWH) for the extracorporeal circuit anticoagulation requires less manipulation in comparison with unfractionated heparin (UFH), which may result in a reduced bacterial contamination. The aim of this study is to evaluate the association between the use of LMWH and dialysis-related infection and septicemia compared to UFH among chronic hemodialysis patients.

Methods: We conducted a retrospective cohort study of 6012 adult chronic hemodialysis patients (prevalent and incident) using an administrative database in Quebec, Canada. Hospitalizations due to dialysis-related infections or septicemia were identified using ICD-10 codes. Patients' exposure to LMWH or UFH was determined at the facility level. Infection rates were calculated as person-year and risk of infection was estimated using Cox proportional hazard ratios (HR) and 95% confidence interval adjusting for demographics, prior hospitalizations, comorbidities and steroids use.

Results: The incidence rate of hospitalizations for dialysis-related infections and septicemia was 0.044 patient-year. From the total cohort, 37% of patients were exposed to LMWH. Compared to UFH, LMWH was associated with a statistically significant decrease of infection risk (HR=0.79, 95%CI: 0.64-0.96). Moreover, younger age (HR=0.99, 95%CI: 0.98-1.00), hospitalization in prior year (HR=1.26, 95%CI: 1.00-1.58), chronic pulmonary disease (HR=1.36, 95%CI: 1.09-1.70) and diabetes (HR=1.26, 95%CI: 1.03-1.54) increased the infection risk among chronic hemodialysis patients.

Conclusions: Among hemodialysis patients, LMWH use decreased the risk of hospitalization for dialysis-related infection and septicemia compared to UFH.

TH-PO883

An Outbreak of Catheter-Related Bacteremia on Hemodialysis Patients Caused by Serratia marcescens Omar I. Delgado, Javier Soto-Vargas, Heriberto R. López, Jorge fernando Topete reyes, Ma anabel Salazar lopez, Oscar C. Martinez Garcia, Leonardo Pazarin-Villase?or. *Nephrology, Regional General Hosptial 46, Mexican Institute of Social Security, Guadalajara, Mexico, Guadalajara, Mexico.*

Background: Catheter related infections in hemodialysis patients are associated with a great morbidity, hospitalization, and death. *Serratia marcescens* it has been reported to cause nosocomial infection due to their ability to colonize antiseptic soaps. Our objective was to present an outbreak of S. marcescens in HD patients.

Methods: In our HD unit there are 27 HD machines, with a total of 945 treatments at week, we have 370 maintenance HD patients with 2 or more sessions per week. During the period of April to May 2015 ninety-five HD patients reported a bacteremia episode during, of which 56 cases were positive to *S. marcescens*. An epidemiologic search was conducted finding positive cultures on antiseptic soap used by medical personal.

Results: There were 95 cases of bacteremia, of which *S. marcescens* represented the 58.9% (56) of the cases, 14 (16.1%) we were unable to localize and agent, and other pathogens had a frequency no bigger than 2%. The median age was 35 years (IQR 25-53), 62 (65.33%) were male, 65 (68.4%) patients had HD thrice weekly, and 30 (31.6%) had twice or less HD sessions per week, 46 (48.4%) patients received their treatment on nocturnal hours, 27 (28.4%) on the morning hours and 12 (12.6%) on the evening and there were no association between the time of the HD sessions and the need for hospitalization and catheter removal. Seventy-one percent of the patients had a non-tunneled catheter, 29% had a tunneled catheter, and there were no cases in patients who had FAV as theirs venous access. The antibiotic treatment was standardized according to sensibility analysis of the cultures consisting of amikacin in lock therapy and systemic ciprofloxacin. There were no fatal cases, but the infection results in the need of hospitalization and access removal in four cases (4.2%).

Conclusions: The appearance of S. marcescens in blood cultures of HD patients units should alert the possibility of an outbreak, given its ability to colonize antiseptic substances. Early and targeted antibiotic treatment as well as rutinary microbiology screening is recommended for the prevention of outbreaks.

TH-PO884

Epidemiology and Outcomes of Infective Spondylodiscitis in Hemodialysis Patients Yuehan Lu, George Kuo, Chao-Yu Chen, Hsiang-Hao Hsu. *Kidney Research Center, Department of Nephrology, Linkou Chang Gung Memorial Hospital; College and School of Medicine, Chang Gung University, Taiwan, Taoyuan, Taiwan.*

Background: Infective spondylodiscitis, defined as the pathogenic invasion of vertebra and intervertebral disc, is an uncommon but serious disease. As the disease progresses, patients develop neurological deficits, sepsis, and even mortality. Microorganisms reach vertebra and intervertebral discs in different ways, including antegrade bacteremia from the blood stream, retrograde infection from the urinary tract and direct invasion from contiguous tissue or a surgical procedure. Patients on maintenance hemodialysis (HD) have additional risk factors that contribute to blood stream infection because of the repeated vascular puncturing, long-term catheter or Gore-Tex graft indwelling, and contamination of dialysis water purification system. The characteristics and outcomes of infective spondylodiscitis in HD patients may be different from those in the general population.

Methods: The cases of 1,402 patients who were hospitalized for infective spondylodiscitis in a 13 year period in a tertiary hospital were retrospectively reviewed. Of these, 102 patients on maintenance HD were enrolled in this study. Cox's proportional hazard model was used to evaluate the risk factors of mortality and recurrence.

Results: The 102 enrolled patients had an average age 63.3±11.2 years old and male-to-female ratio of 1:1.04. Back pain was present in 75.5% of patients and the most commonly infected site was the lumbosacral spine. Infection associated with vascular access was identified in 31.4% of patients and the use of dialysis via central venous catheters was three times higher than in outpatient cohort. Methicillin-resistant *S. aureus* was the most common pathogen, followed coagulase-negative staphylococci. The patients' in-hospital survival rate was 82.4%; their vascular access survival was 75.5% their one-year survival was 78.4% and their one-year recurrence rate was 20.2%. Congestive heart failure was associated with an increased one-year mortality. Other variables exhibited no significant relationship with patients' in-hospital mortality, one-year mortality or recurrence.

Conclusions: The characteristics and outcomes of infective spondylodiscitis in HD patients were elucidated. Most of the demographic and clinical variables, evaluated upon admission, did not predict mortality or recurrence. An algorithm for the diagnosis and treatment of infective spondylodiscitis in an HD cohort is provided.

TH-PO885

Epidemiology and Outcomes of Endophthalmitis in Chronic Dialysis Patients: A 13-Year Experience in a Tertiary Referral Center in Taiwan George Kuo,[1] Hsiang-Hao Hsu.[2] *[1]Chang-Gung Memorial Hospital, Taiwan, Taoyuan City, Taiwan; [2]Kidney Research Center, Department of Nephrology, Linkou Chang Gung Memorial Hospital; College and School of Medicine, Chang Gung University, Taiwan, Taoyuan, Taiwan.*

Background: Endophthalmitis is a severe eye infection leading to disabling outcome. we would like to investigate the epidemiology and clinical features of endophthalmitis in chronic dialysis patient in a tertiary referral center.

Methods: We perfoemed chart review and searched discharge diagnosis with ICD9 encoding endophthalmitis during Jan. 2002 to Dec. 2015.

Results: In total 32 patients, 25 were endogenous and another 7 were exogenous endophthalmitis. Most patients presented with ophthalmalgia and periocular swelling, whereas half of the patients suffered blurred vision (n=16, 50%). *S. aureus, K. pneumoniae,* and *P. aeruginosa* were the most frequent causative pathogens. Dialysis vascular infection was an important focus. The final visual outcomes in both groups were worse in the chronic dialysis patients compared with previous studies of general population

Conclusions: This is the first and the largest case series focusing on endophthalmitis in chronic dialysis patients. Our study showed different pathogen spectrum, an unique bacterial origin and worse visual outcome in these group of patients. Prompt referral to ophthalmologists is important.

Funding: Government Support - Non-U.S.

Characteristic of dialysis patient with endophthalmitis

	Endogenous (N = 25)	Exogenous (N = 7)
Days from symptoms onset to ophthalmoogist visit	1-30 (median: 2)	1-7 (median: 2)
Recent trauma or surgery	0 (0%)	7 (100%)
Days post trauma or surgery		3-20 (median: 4)
Blurred vision	14 (56%)	2 (28.5%)
Ophthalmalgia	25 (100%)	7 (100%)
Periocular swelling	25 (100%)	6 (85.7%)
Fever	8 (32%)	0 (0%)
Septic shock	2 (8%)	0 (0%)
Respiratory failure	2 (8%)	0 (0%)
Dialysis access infection	4 (14.8%)	0 (0%)
White blood cell counts	11 (+/- 5)	10 (+/- 6)
CRP level	71 (+/- 75)	16 (+/- 10)
Bacteremia	8 (32%)	0 (0%)
Fungemia	0 (0%)	0 (0%)

TH-PO886

Reduction in Rates of Blood Stream Infection Associated with Adoption of TeamSTEPPS as a Framework for Improved Hemodialysis Facility Workflows Jerry W. Jackson,[1,3] Norma J. Ofsthun,[3] Carol Meredith,[2] Marcy E. Goldberg,[3] Uddar Onta,[3] Franklin W. Maddux.[3] *[1]FMC Patient Safety Council, Mountain Brk, AL; [2]Fresenius Kidney Care, Downers Grove, IL; [3]Fresenius Medical Care North America, Waltham, MA.*

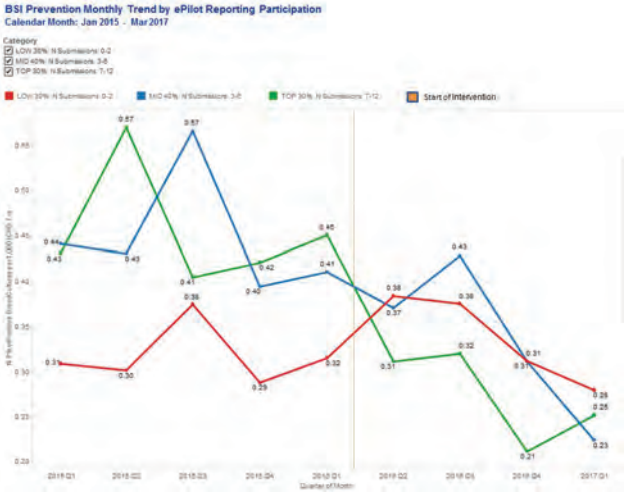
Background: Blood Stream Infection (BSI) remains one of the most serious adverse events affecting end stage renal disease (ESRD) patients. Multiple barriers and situational factors impede infection control in ambulatory hemodialysis (HD) facilities. We implemented a Quality Improvement Project (QIP) and analyzed its impact on BSI rates in HD facilities.

Methods: We deployed the QIP in 97 Fresenius Kidney Care facilities from January 2016 through March 2017. After performing a Failure Mode and Effects Analysis, we identified 55 HD workflow steps (distributed throughout the HD treatment) with high-risk for infection. The QIP design included training and observational auditing for the high-risk steps, use of TeamSTEPPS training to instill team-oriented care and to reduce barriers to infection control, ongoing coaching and feedback for caregivers in the use of TeamSTEPPS tools, incorporation of an infection control data set for analysis and action-planning during QAPI, and closed-loop communication pathways. The facilities were divided into Low, Mid and Top participatory subgroups based on monthly reported process metrics. Mean BSI rate by subgroup during 2015 was used for baseline. Implementation BSI rates by subgroup were followed Q1 2016 through Q1 2017.

Results: We studied data from a mean census of 10,988 patients. Mean baseline BSI rates (expressed as BSI episodes/1,000 HD treatments) by subgroup were: Low, 0.32; Mid, 0.46; Top, 0.46. Data collected at the end of the QIP showed changes in mean BSI rates of (+) 4.6%, (-) 23.7%, and (-) 32.2% for the Low, Mid and Top subgroups, respectively (Figure 1).

Conclusions: These findings suggest the use of TeamSTEPPS combined with the other interventions of this QIP might be associated with a reduction in dialysis associated blood stream infections.

Funding: Commercial Support - Fresenius Medical Care North America



TH-PO887

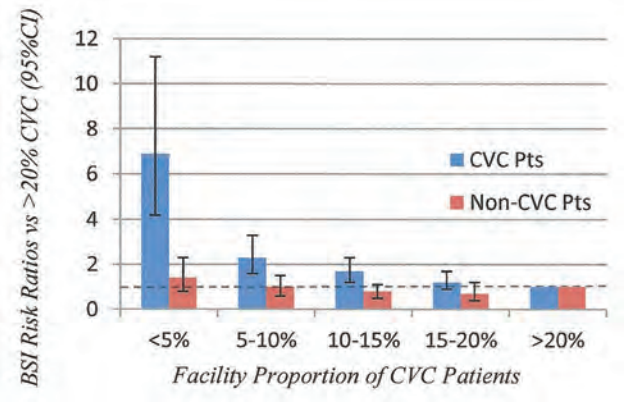
Bloodstream Infection (BSI) Rates in Catheter Patients Are Markedly Higher in Hemodialysis Facilities with Lower Proportions of Catheters Robert S. Brown,[1] Kristin M. Brickel,[2] Roger B. Davis.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]DaVita, Naugatuck, CT.*

Background: BSI rates of HD patients with catheters (CVC) are greater than with other accesses. Medicare assesses financial penalties and lower Five-Star ratings to high CVC facilities, prompting a study of BSI rates in CVC patients relative to facility CVC percentages.

Methods: CROWNWeb and NHSN data from all 171 Medicare facilities providing adult outpatient HD in the IPRO ESRD Network of New England throughout 2015 (mean, 12,626 patients/mo) compared BSI rates of CVC and non-CVC patients based upon facility proportion of CVCs, patient census, batch submitting organization and season.

Results: There were an average of 74±40 HD patients with 9±6 (13%) having CVC accesses per facility. Mean BSI/100 pt-mo was 0.50±1.0 for all accesses, 3.0±8.7 for CVC, and 0.21±0.72 for non-CVC patients (relative risk of BSI for CVC vs non-CVC patient, 10.7, 95%CI 8.7, 13.2, P=<0.0001). Surprisingly, annual BSI rates in CVC patients were negatively correlated with the facility's proportion of CVCs (–0.247, P=0.001) but positively correlated in non-CVC patients (0.147, P=0.056). Facilities with <5%, 5-10%, 10-15%, 15-20%, >20% CVCs have BSI rates of 11.7, 3.5, 2.5, 1.8, 1.6 per 100 pt-mo, respectively, in CVC patients (P=<0.0001). This striking difference was not seen in non-CVC patients (P=0.07, risk ratios in figure). Smaller providers have 1.3-2.6 times the BSI rates of the 4 large dialysis organizations (4.6 vs 1.8-3.6 BSI/100pt-mo, P=0.01) despite similar CVC proportions. There was no effect of facility census or season.

Conclusions: HD facilities with the lowest proportion of CVCs have significantly higher BSI rates (up to 6.9 times) in their CVC patients. This large difference may be explained by "dilution" of CVC patients with those in the lower risk non-CVC pool and by better training and experience in facilities with higher CVC proportions and the larger dialysis organizations. BSI rates in CVC patients may be a better quality parameter than CVC percentage.



TH-PO888

Tunnelled Hemodialysis Catheter Care Practices and Blood Stream Infection Rate in Children: Results from the SCOPE Collaborative Olivera Marsenic Couloures,[4] Jonathan Rodean,[1] Troy Richardson,[1] Bradley A. Warady,[3] Alicia Neu.[2] *[1]Children's Hospital Association, Overland Park, KS; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]The Children's Mercy Hospital, Kansas City, MO; [4]Pediatric Nephrology, Yale University, New Haven, CT.*

Background: The Standardizing Care to Improve Outcomes in Pediatric End-stage renal disease (SCOPE) collaborative seeks to reduce hemodialysis (HD) catheter associated blood stream infections (CA-BSI) by increasing implementation of standardized HD catheter care bundles. We report on HD catheter care practices and HD CA-BSI rates from SCOPE.

Methods: Catheter care practices and HD CA-BSI reported between 6/2013 and 3/2017 are included. Catheter care bundle compliance is monitored across the reporting period on a sample of patients at each center. Compliance with each element in the care bundle is evaluated as is overall compliance, which is scored as "all or none", ie each element must be performed to be compliant. For catheters with multiple observations compliance is reported as a percent compliance across observations. Only observations prior to the CA-BSI are included for catheters with infections. Results are reported as median and interquartile range (IQR) and compared by CA-BSI status with Wilcoxon Rank Sum tests. Associations between CA-BSI status and categorical characteristics are compared with chi-square tests.

Results: 427 catheters in 424 children [median (IQR) age 12.5 years (6,16), M: 54%, F: 46%] at 27 centers were included. 3569 catheter care observations were submitted with median (IQR) 4 (1,12) observations per catheter. 111 CA-BSI from 66 catheters were reported, yielding a rate of 2.0 infections/100 catheter months. Bundle compliance [%, median (IQR)] in catheters with and without CA-BSI and their comparisons are presented in the Table.

Conclusions: Compliance with an HD catheter care bundle was relatively high among SCOPE centers, and the overall CA-BSI rate is low. The low number of CA-BSI limits the ability to detect significant associations between compliance with care practices and CA-BSI. A comparison of CA-BSI rates before and after implementation of care practices is required to evaluate the impact of SCOPE on CA-BSI rates.

Care practice	No CA-BSI	CA-BSI	P

TH-PO889

Infection Rates in ESRD and Renal Transplant Patients Using Real World Claims Data Katherine Belenduik,[1] Richa Rajwanshi,[1] Yingjie Ding,[2] Kelly Kwon,[1] Dominic Borie,[1] Matthew Cascino,[1] Jay P. Garg,[1] Thomas Schindler,[3] Ha N. Tran.[1] *[1]Genentech, Inc., South San Francisco, CA; [2]Genesis Research, Hoboken, NJ; [3]F. Hoffmann - La Roche Ltd., Basel, Switzerland.*

Background: End stage renal disease (ESRD) patients (pts) are at increased risk of infections due to immune dysregulation, malnutrition, and indwelling dialysis access. After transplant (tx), pts are at further risk due to immunosuppressive therapy. Characterization of infections in large, real world samples will allow clinicians to better evaluate and understand infection risks in their patients. The objective of this study was to characterize the rates of serious and opportunistic infections in ESRD and renal tx pts.

Methods: We conducted a retrospective cohort study using the Truven Healthcare MarketScan® Commercial Claims and Encounters and Medicare Supplemental and Coordination of Benefits database between 2000 and 2014. The ESRD cohort index date was the first of either an ESRD or dialysis claim, separated by ≥7 days. The tx cohort index date was the first of ≥2 claims related to kidney tx, separated by ≥7 days.

Results: 23,433 ESRD pts on dialysis and 18,660 renal tx pts were identified. One year following the index date, the rates of serious infections were higher in ESRD than tx pts. Most serious infections required hospitalization in both groups and opportunistic infection rates were comparable (Table 1).

Conclusions: ESRD and post-tx pts experience serious infections with high rates of hospitalization indicating high burden of illness. Physicians should carefully evaluate infection risks when considering pre- and post-tx immunosuppressive regimens.

Funding: Commercial Support - Genentech, Inc./F. Hoffmann-La Roche

Advocating for a Unique ICD-10 Code for ESRD Tunneled Catheter Bacteremia Taurino N. Avelar, Katya Corado calvo, Sharon G. Adler. *Harbor-UCLA Medical Center, Torrance, CA.*

Background: In ESRD, infections account for 8% of cause-specific mortality. Hospitalizations are frequent, prolonged, and impair quality of life. Inpatient cost is ~$2.7 billion/yr. ICD-10 coding is intended to specifically characterize hospitalization clinical events. We tested whether ICD-10 coding accurately captures and distinguishes bloodstream infections (BSI) in ESRD patients with tunneled HD catheters from BSI in patients with other implanted devices.

Methods: This is a single-center retrospective chart review in patients with BSI from 10/1/15–12/31/16. Subjects were grouped: (Gp1) ESRD BSI from tunneled dialysis catheter infection; (Gp2) ESRD BSI with AV fistula (AVF) or graft (AVG); and (Gp3) Non-ESRD BSI from an implanted device (PICC lines, ICD/pacer leads, bioprosthetic/mechanical heart valves, orthopedic hardware, and non-HD grafts/stents (vascular, ureteral). Groupings were based on: (Gp1) Infectious Diseases Society of America Guidelines for Intravascular Catheter-Related Infection (CID 2009:49); (Gp2) Positive blood cultures in ESRD with AVF or AVG; and (Gp3) Positive blood/wound cultures, physical exam, radiological assessments, and biopsy results. We descriptively compared the use of ICD-10 codes among the clinical groups.

Results: Table shows ICD-10 codes used to classify the BSI events in these 3 groups. For some, >1 ICD-10 code was used. In 12, no code was used. There is substantial overlap in the ICD-10 codes used to describe BSI in patients with ESRD tunneled catheters, AVFs, and AVGs, and non-ESRD BSIs associated with other implantable devices.

Conclusions: In this "Discovery" cohort, the lack of a unique ICD-10 identifier for BSI due to tunneled dialysis catheters makes it difficult or impossible to distinguish these clinical events from other BSIs. "Validation" cohorts at other centers is in progress. A unique code is needed to quantify the burden of this devastating clinical entity.

ICD-10 codes in patients with BSIs

ICD-10 diagnosis	ICD-10 code	Gp1, n=19	Gp2, n=7	Gp3, n=17
BSI due to central venous catheter	T80.211A	0	0	1
Bacteremia/Sepsis	A41.01, A41.02, A41.89, A41.9, R65.20, R65.21, R78.81	18	5	5
Infection, inflammation, or other reaction/complication of vascular or cardiac valvular devices, implants, grafts	T82.898S, T82.6XXS	0	0	2
Infection, inflammation, from other complication of vascular or cardiac valvular devices, implants, grafts	T82.7XXA, T82.7XXS	0	0	0
Acute or subacute endocarditis	I33.9, I38	2	0	1
Abscess, discitis	K65.1, L02.91, M46.46	2	1	0

Comparison of National Healthcare Safety Network Dialysis Event Validation in Georgia and Tennessee Gianna S. Peralta,[1,3] Ashley Fell,[2] Elizabeth N. Smith,[1] Jeanne Negley,[1] Marion Kainer.[2] *[1]Georgia Department of Public Health, Atlanta, GA; [2]Tennessee Department of Health, Nashville, TN; [3]CDC/CSTE Applied Epidemiology Fellowship, Atlanta, GA.*

Background: 370,000 people in the United States rely on hemodialysis and are at risk for developing serious infections. Outpatient hemodialysis (OHD) facilities are required to report dialysis event (DE) data to the National Healthcare Safety Network (NHSN) including intravenous antimicrobial starts (AMX), positive blood cultures (PBC), and pus, redness, or increased swelling at the vascular access site (PRS). The Georgia Department of Public Health (GDPH) and Tennessee Department of Health (TDH) validated NHSN DE data to assess data quality and identify common reporting errors.

Methods: Sixty OHD facilities were selected for data validation (30 each in TN and GA). Facilities were selected due to having few reported PBCs, or at random. TDH validated data from January-June 2014, while GDPH validated DE data from January-June 2015. Both states followed the CDC DE Data Quality Evaluation Guide to select up to 30 patients per facility for medical record review to identify DEs, conduct a concordance check, and survey staff members responsible for NHSN DE data collection and reporting.

Results: Record review TDH reviewed a total of 790 patient records; GDPH reviewed 876. TDH identified 272 (34%) patients with at least one DE for a total of 497 events; GDH identified 201 (23%) patients with least one DE for a total of 332 events. Under-reporting of DEs was common (TN: 28%; GA: 39%). Over-reporting of DEs was more frequent in GA (12%) than TN (5%). **Survey** Compared to TN, a higher proportion of facility administrators in GA had read the CDC NHSN DE reporting protocol (79% vs. 51%). In TN, 55% of facility administers could not correctly describe how to count patients for the denominator, compared to 35% in GA. A majority of facility administrators in both states did not know how to correctly assign vascular access category (59% in TN; 78% in GA).

Conclusions: Validation of NHSN DE data provided valuable insight about data quality and common reporting errors that can be addressed through education and training. Reporting deficiencies were identified among all types of DEs. All facilities should have a strong working knowledge of the CDC DE Protocol. Consistent and accurate documentation of DEs can help facilities detect problems, identify trends, evaluate infection prevention activities, and engage staff in quality improvement.

TH-PO892

National Healthcare Safety Network Dialysis Bloodstream Infection Data—2016 Duc B. Nguyen,[1] Shunte Moon,[1] Taylor Guffey,[1] Christi Lines,[1] Preeti Rvindhran,[2] Jonathan Edwards,[1] Priti R. Patel.[2] *[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]Centers for Disese Control and Prevention, Atlanta, GA.*

Background: Among hemodialysis (HD) patients, bloodstream infections (BSIs) are often severe adverse events. The Centers for Disease Control and Prevention (CDC) conducts surveillance for these events through the National Healthcare Safety Network (NHSN). We summarized 2016 BSI data submitted to NHSN Dialysis Event Surveillance and compared to data from previous years.

Methods: A BSI is defined in the NHSN surveillance protocol as a positive blood culture collected in an HD outpatient or within 1 calendar day of a hospitalization. Access-related BSIs (ARBSI) are positive blood cultures with either a suspected vascular access source or uncertain source as indicated on the event reporting form. Denominator data consist of the number of HD outpatients treated at the facility during the first two working days of each month. BSI rates were stratified by vascular access type (e.g., arteriovenous fistula [AVF], arteriovenous graft [AVG], central venous catheter [CVC]). We compared BSI rates during 2014–2016 controlling for access type using generalized linear models.

Results: In 2016, 6,437 outpatient HD facilities reported 151,943 dialysis events to NHSN, including 27,108 BSIs, of which 20,375 (75.2%) were ARBSI. Most BSIs (62.7%) and ARBSIs (70.2%) occurred in patients with a CVC. Hospitalization and death associated with events occurred among 52.9% and 2.8% of BSI, respectively. The rate of BSI per 100 patient-months was 0.56 (0.22 for AVF, 0.37 for AVG and 1.84 for CVC) with 25th and 75th percentile of 0.2 and 0.79, respectively. During 2014–2016, the yearly reduction in rates controlling for access type was 7.1% (95% confidence interval [CI]: 5.9–8.2) for BSI and 8.3% (95% CI: 7.0–9.6) for ARBSI.

Conclusions: Rates of BSI were highest among patients with CVC. BSI and ARBSI appeared to have decreased during 2014–2016, possibly due to nationwide prevention efforts. Our results suggest that even though progress towards BSI prevention has been achieved, opportunities exist to reduce rates of BSIs and ARBSIs among HD patients.

AVG	0.27	0.26	0.25
CVC	1.83	1.68	1.56

TH-PO893

Bloodstream Infections in Pediatric Hemodialysis Outpatients: National Healthcare Safety Network, 2013-2015 Mark K. Weng,[1] Duc B. Nguyen,[1] Alicia Neu,[2] Ibironke W. Apata,[1] Bradley A. Warady,[3] Priti R. Patel.[1] *[1]Division of Healthcare Quality Promotion, Centers for Disease Control and Prevention, Atlanta, GA; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]University of Missouri, Kansas City School of Medicine, Children's Mercy Kansas City, Kansas City, MO.*

Background: Compared to adults, children on chronic hemodialysis (HD) are more often dialyzed via a central venous catheter (CVC), which poses a high risk of infection. However, data on bloodstream infections (BSIs) in the outpatient pediatric HD population are sparse. To characterize these infections, we analyzed 2013-2015 BSI data that outpatient HD centers reported to the Centers for Disease Control and Prevention's (CDC's) National Healthcare Safety Network (NHSN), a widely used healthcare-associated infection surveillance system.

Methods: The NHSN dialysis event surveillance protocol defines a BSI as a positive blood culture collected as an outpatient or within 1 calendar day of a hospitalization. Access-related BSIs are positive blood cultures with a suspected vascular access source or uncertain source. Up to 3 organisms per BSI can be reported. Pediatric BSIs were defined as those occurring in patients < 18 years of age at the time of event, and these BSIs could be reported by any participating HD center (adult or pediatric). Events in patients with a calculated age < 1 year were excluded due to data quality concerns. We categorized BSI by highest-risk vascular access type present (CVC > graft > fistula).

Results: During 2013 to 2015, 634 BSIs occurred in pediatric patients > 1 year of age. Of the 634 BSIs, 588 (93%) occurred in patients with CVC; 542 (85%) of the BSIs were classified as access-related. A total of 384 (61%) BSIs resulted in hospitalization, and 10 (2%) resulted in death. The most common pathogens identified were *Staphylococcus aureus* (30%), coagulase-negative Staphylococci (23%), and Enterococci (8%).

Conclusions: Catheters account for the majority of pediatric HD BSIs reported to NHSN, demonstrating the importance of interventions targeting catheter care and use of permanent vascular access, when possible. Further characterization of the incidence of BSIs in the pediatric outpatient HD population may yield additional opportunities for prevention. A limitation of the analysis is reliance upon calculated age, which may be subject to data entry error.

TH-PO894

Age-Dependent Production of Highly Apoptosis-Resistant CD31 – Memory-Tresps May Cause Chronic Inflammatory Conditions in Dialysis Patients Matthias Schaier,[1] Angèle Leick,[1] Florian Kälble,[1] Christian Morath,[1] Claudia Sommerer,[1] Martin G. Zeier,[1] Andrea Steinborn-Kroehl.[2] *[1]Nephrology, University of Heidelberg, Heidelberg, Germany; [2]Gynecology, University of Heidelberg, Heidelberg, Germany.*

Background: Dialysis patients have an increased susceptibility for chronic inflammation. In addition, an increased risk for virus-associated cancers and atherosclerotic diseases are documented.

Methods: We analyzed whether age-related differences in the differentiation of both recent-thymic-emigrant-(RTE)- regulatory (Tregs) and RTE-responder T cells (Tresps) into CD31--memory Tregs/Tresps led to differences in the suppressive activity of naïve and memory Tregs on autologous Tresps between healthy volunteers (n= 89) and dialysis patients (n=80).

Results: Our findings suggest, that the thymic release of RTE-Tregs decreases with age and thereby causes their enhanced differentiation via $CD31^+$-memory Tregs into $CD31^-$-memory Tregs, so that the suppressive activity of both naïve and memory-Tregs is maintained with age in healthy controls. In addition, the decreasing thymic release

of RTE-Tresps may cause their enhanced differentiation via MN-Tresps into CD31$^-$-memory-Tresps. Thus, the reactivity of the total Tresp pool may be weakened with age, as the resulting CD31$^-$-memory- Tresps may be much more sensitive to apoptosis. Presumably, both effects contribute to the fact that the functional activity of Tregs increases with age in healthy volunteers. Dialysis patients exhibit an increased RTE-Treg differentiation via CD31$^+$-memory Tregs which may enhance the suppressive activity of both naïve CD45RA$^+$- and CD45RA$^-$-memory-Tregs, especially in young individuals. However, the differentiation of RTE-Tresps via MN-Tresps, seen in healthy volunteers, could not be detected in dialysis patients. Instead, there was an age-dependent increase in the differentiation via CD31$^+$-memory Tresps into CD31$^-$-memory Tresps in dialysis patients. This effect may strengthen the functionality of Tresps with age and explain why Tregs of elderly dialysis patients show difficulties suppressing autologous Tresps, but preserve the ability to suppress non-autologous Tresps of healthy volunteers.

Conclusions: The aging immune system sustainably suppresses autoimmunity, but favors the incidence of inflammation. In contrast, the increased age-dependent production of highly apoptosis-resistant CD31$^-$-memory-Tresps in dialysis patients may cause chronic inflammatory conditions in these patients.

TH-PO895

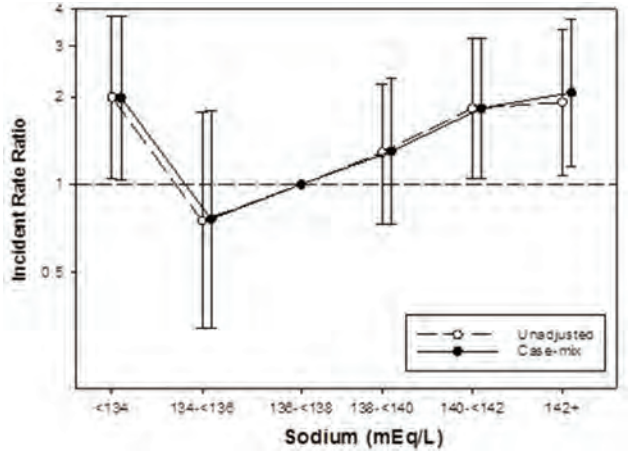
Serum Sodium and Bacteremia Risk in Dialysis Patients Connie Rhee,[4] Amy S. You,[6] Elani Streja,[2] Juan Carlos Ayus,[3] Hamid Moradi,[6] Steven M. Brunelli,[1] Csaba P. Kovesdy,[7] Danh V. Nguyen,[6] Kamyar Kalantar-Zadeh.[5] *[1]DaVita Clinical Research, Needham, MA; [2]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [3]Renal Consultants of Houston, Houston, TX; [4]University of California Irvine, Huntington Beach, CA; [5]University of California Irvine, School of Medicine, Orange, CA; [6]University of California, Irvine, Orange, CA; [7]University of Tennessee Health Science Center, Memphis, TN.*

Background: Hyponatremia is a potential risk factor for infection, which may be due to impairment of IL-17 producing helper T cells that function in host immunity, and concomitant mucosal membrane and cellular edema leading to breakdown of microbial barrier function. While dysnatremia and infection-related mortality are common in dialysis patients, little is known about the association between serum sodium levels and bacteremia in this population.

Methods: Among 823 dialysis patients from the national Biospecimen Registry Grant Program (BioReG) who underwent serum sodium testing over 1/2008-12/2014, we examined the relationship between sodium level and risk of bacteremia using case-mix adjusted Poisson regression models adjusted for age, sex, and race/ethnicity.

Results: In the overall cohort, the mean±SD and minimum-maximum serum sodium values were 138±3mEq/L and 115-154mEq/L, respectively; approximately 10% of all patients experienced one or more bacteremia events during the follow-up period. Patients with both lower sodium <134mEq/L and higher sodium ≥140mEq/L had higher incident rates of bacteremia in case-mix models (ref: 136-<138mEq/L): adjusted IRR [aIRR] 1.99 (1.04-3.81), 0.76 (0.32-1.80), 1.30 (0.73-2.31), 1.83 (1.05-3.18), and 2.07 (1.15-3.72) for sodium levels <134, 134-<136, 138-<140, 140-<142, ≥142mEq/L, respectively.

Conclusions: Both lower and higher serum sodium levels were associated with higher incident rates of bacteremia in dialysis patients. Further studies are needed to determine whether correction of dysnatremia ameliorates infection risk in this population.



TH-PO896

Impact of Pre-ESRD Nephrology Care on Early Post-Dialysis Sepsis-Related Hospitalizations Robert Nee,[2,3] Christina M. Yuan,[2,3] Lawrence Agodoa,[1] Kevin C. Abbott.[1] *[1]NIDDK, National Institutes of Health, Bethesda, MD; [2]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [3]Medicine, Uniformed Services University, Bethesda, MD.*

Background: Pre-end-stage renal disease (ESRD) nephrology care has been reported to improve morbidity and mortality in dialysis patients. However, its impact on infectious complications in dialysis patients has not been studied. Herein we assessed the association between pre-ESRD nephrology care and hospitalizations for sepsis within 12 months after initiation of dialysis.

Methods: Using the US Renal Data System database, we identified 282, 571 Medicare primary patients initiated on maintenance dialysis from 1 January 2009 through 1 June 2013, and followed until 31 December 2013. We abstracted Medicare hospital claims for "septicemia" as primary discharge diagnosis, using the International Classification of Diseases, Ninth revision, Clinical Modification (ICD-9-CM) codes 038. xx (x = 0 to 9 inclusive). We conducted Cox regression analyses for sepsis, adjusted for demographic characteristics, cause of ESRD, dialysis modality, comorbidities, vascular access and other clinical variables.

Results: 11,614 (5.4%) patients were hospitalized for sepsis within 12 months after start of dialysis, 33% of whom had more than one hospitalization. Patients with pre-ESRD care had a lower incidence rate of early sepsis compared to those without pre-ESRD care (78.4 per 1,000 patient-years (PY) vs. 111.3 per 1,000 PY, respectively; p<0.001). Hospital length of stay was shorter in patients with pre-ESRD care compared to those without pre-ESRD care (13.7 days vs. 17.6 days, p<0.001). In fully adjusted Cox models, pre-ESRD care was associated with significantly lower likelihood for early sepsis (adjusted hazard ratio [aHR] 0.86, 95% CI 0.80-0.91). Compared to patients without pre-ESRD care, those with > 12 months of pre-ESRD care were significantly less likely to be hospitalized for early sepsis (aHR 0.78, 95% CI 0.71-0.86) but the association with those who had 6-12 months of pre-ESRD care was nonsignificant (aHR 0.95, 95% CI 0.86-1.05).

Conclusions: Pre-ESRD nephrology care was associated with lower risk of sepsis-related hospitalizations within 12 months of dialysis initiation. *Disclaimer: The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of the Army/Navy/Air Force, the Department of Defense, National Institutes of Health, or the United States government.*

TH-PO897

Incidence, Risk Factors, and Distribution of Syphilis in the ESRD Population in the United States Erena Weathers,[2] Jennifer L. Waller,[2] N. Stanley Nahman,[2,1] Rhonda E. Colombo,[2] Jake E. Turrentine,[2] Mufaddal F. Kheda,[2] Stephanie L. Baer.[1,2] *[1]Augusta VA Medical Center, Augusta, GA; [2]Augusta University, Augusta, GA.*

Background: The incidence of syphilis has increased 67% in 4 years to 7.5 per 100,000 in the US, but is undefined in the end stage renal disease (ESRD) population. This study examined diagnoses of syphilis and associated risk factors in ESRD patients to identify opportunities for improving screening and risk modification.

Methods: All incident ESRD patients from 2004-2010 in the USRDS were queried. ICD-9 codes were used to determine syphilis diagnosis and related comorbidities. Neurosyphilis (NS) was defined with both an ICD-9 code and an associated lumbar puncture CPT code. The geographical distribution was determined by number of cases per 100,000 ESRD patients in each state. A 5% random sample of patients without syphilis was used for analysis. Statistical analysis was performed using SAS 9.4 and a generalized linear model was used to examine the adjusted relative risk (aRR).

Results: Of 773,600 patients, 585,072 had complete data for analysis. 383 diagnoses of syphilis were identified. The incidence of syphilis diagnosis increased yearly from 2004-2011, with a peak incidence in 2011 of 54 per 100,000. The syphilis diagnoses were: 59% other unspecified, 22% NS and other types 1% or less. Associated risk factors included: hepatitis B (aRR=1.75 95% confidence interval (CI) 1.12-2.71), hepatitis C (aRR=3.60 95% CI 1.99-6.51), herpes simplex virus (aRR=2.05 95% CI 1.46-2.87), and HIV (aRR=7.55 95% CI 5.42-10.52). Demographic risk factors included black (aRR=4.96 95% CI 3.85-6.40) and other (non-white) race (aRR=1.99 95% CI 1.14-3.47). The highest rates were in the southeast followed by the northeast and west coast.

Conclusions: In the ESRD population, the incidence of syphilis was over 3 fold greater than in the general population in 2011, with the majority coded as unspecified syphilis followed by NS. The trend of rising incidence from 2004-2011, associated risk factors, and the geographic spread of syphilis in ESRD reflects the general population. These data suggest that routine screening for syphilis in the ESRD population may be beneficial.

TH-PO898

A Case of Leclercia Adecarboxylata Hemodialysis Catheter-Related Bacteremia Yasir Alfi, Ashte K. Collins. *Division of Renal Diseases & Hypertension, George Washington University, Washington, DC.*

Background: *Leclercia adecarboxylata*, formerly known as *Escherichia adecarboxylata*, was first identified by Lecrerc in 1962. It is a motile Gram-negative rod that is considered an uncommon opportunistic human pathogen. Here we describe a case of *L. adecarboxylata* bacteremia as part of a polymicrobial infection in a dialysis patient with a tunneled catheter.

Methods: A 50 year-old male with ESRD on HD for 7 months via left internal jugular tunneled catheter, HTN, and DM type II, who was admitted to the hospital with 1 day of subjective fever, chills, and malaise, all of which exacerbated by his dialysis treatment. He reported taking showers while the dialysis catheter is in place, but stated he only lets the water land below his chest. On admission, he was afebrile and hemodynamically stable. Lab results were remarkable for WBC of 19.6 x 10^3/µl. Vancomycin and piperacillin-tazobactam were started. Blood cultures grew *Staphylococcus epidermidis* (oxacillin-resistant), methicillin-sensitive *Staphylococcus aureus, Pseudomonas floures* (resistant to trimethoprim-sulfamethoxazole), *Escherichia coli* (pansensitive), *Serratia marcescens* (resistant to ampicillin and first generation cephalosporins) and *Leclercia adecarboxylata* (pan-sensitive). Antibiotic regimen was changed to vancomycin, gentamicin and levofloxacin. The tunneled catheter was removed and a new right internal jugular tunneled

catheter was placed 4 days later, after clearance of blood cultures. He was maintained on the above antibiotics for another 14 days, and recovered without long-term sequelae.

Results:

Conclusions: *L. adecarboxylata* is a ubiquitous organism and has been isolated from water sources including drinking water in the US. Water exposure is a possible source of infection in the patient presented above. Although there are several case reports of clinically significant infections with *L. adecarboxylata* in immunocompromised patients, it has been mostly isolated from post-traumatic flora in immunocompetent individuals. ESRD patients may be susceptible to *L. adecarboxylata* infection as they are relatively immunosuppressed. Only four previous reports were found on a PubMed literature search of tunneled hemodialysis catheter-related bacteremia with *L. adecarboxylata*. This infection can be treated successfully with catheter removal and a course of appropriate IV antibiotics. Most isolates are susceptible to all available antimicrobial agents.

TH-PO899

Mortality Risk and Cause of Death Following Staphylococcus aureus Endocarditis in a Danish Hemodialysis Population Mavish Chaudry,[6] Gunnar Gislason,[9] Anne-Lise Kamper,[1] Marianne Rix,[2] Anders Dahl,[7] Trine K. Lauridsen,[5] Louise B. Oestergaard,[3] Christian Hassager,[2] Christian Torp-Pedersen,[4] Niels E. Bruun.[8] *[1]Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark; [2]Rigshospitalet, Copenhagen, Denmark; [3]Aalborg University, Aalborg, Denmark; [4]Aalborg University Hospital, Aalborg, Denmark; [5]Copenhagen University Hospital, Charlottenlund, Denmark; [6]Department of Cardiology, Copenhagen, Denmark; [7]Gentote University Hospital, Hellerup, Denmark; [8]Herlev-Gentofte Hospital, Hellerup, Denmark; [9]Gentofte Hospital, Copenhagen, Denmark.*

Background: Staphylococcus aureus endocarditis has increased over the past decades and is a contributing factor to high mortality and morbidity. Outcome data are sparse. The study aimed to investigate causes and risk factors of mortality subsequent to staphylococcus aureus (S. aureus) IE in a hemodialysis- and a non-hemodialysis population.

Methods: S. aureus IE in hemodialysis patients was identified in The Danish National Registry on Regular Dialysis and Transplantation and The Danish National Patient Registry, and in non-hemodialysis patients in The East Danish Database on Endocarditis which contains data on consecutive patients with S. aureus IE from tertiary centres in the eastern part of Denmark. Independent risk factors of outcome were identified in multivariable Cox regression models.

Results: The cohorts of S. aureus IE included 121 hemodialysis patients and 197 non-hemodialysis patients from the period 1996-2012 and 2002-2012, respectively. The all-cause in-hospital mortality was 22.3% in hemodialysis- and 24.8% in non-hemodialysis patients. At one-year follow-up the all-cause mortality, excluding in-hospital mortality, was higher in hemodialysis patients 26.4% compared to non-hemodialysis patients 15.2% (p=0.017). In hemodialysis- and non-hemodialysis patients, the cardiovascular in-hospital mortality was 20.7% and 21.7% and one-year mortality, excluding in-hospital mortality, was 21.5% and 12.2% (p=0.030), respectively. In patients with S. aureus IE, hemodialysis was associated with an increased risk of all-cause mortality at >74 days after admission with S. aureus IE with a hazard ratio of 2.71 (95% CI 1.78-4.16). Age and diabetes mellitus were identified as independent risk factors of all-cause mortality. Hemodialysis treatment was also associated with an increased risk of cardiovascular death at >56 days after admission with a hazard ratio of 2.76 (95% CI 1.74-4.40).

Conclusions: In hemodialysis patients, the short-term in-hospital mortality rates are similar to the non-hemodialysis population whereas the long-term mortality rates are markedly increased in the hemodialysis population. Further investigations are needed to identify direct IE related reasons for these findings.

TH-PO900

Dialysis Access and Risk of Staphylococcus aureus Bacteremia – A Nationwide Study Mavish Chaudry,[3] Gunnar Gislason,[8] Anne-Lise Kamper,[2] Marianne Rix,[6] Paal S. Andersen,[7] Henrik Westh,[5] Henrik C. Schønheyder,[1] Christian Torp-Pedersen,[1] Niels E. Bruun.[4] *[1]Aalborg University Hospital, Aalborg, Denmark; [2]Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark; [3]Department of Cardiology, Copenhagen, Denmark; [4]Herlev-Gentofte Hospital, Hellerup, Denmark; [5]Hvidovre hospital, Hvidovre, Denmark; [6]Rigshospitalet, Copenhagen, Denmark; [7]Statens Serum Institut, Copenhagen S, Denmark; [8]Gentofte Hospital, Copenhagen, Denmark.*

Background: Staphylococcus aureus bacteremia (SAB) is a high-risk infection. This study aimed to investigate incidence and risk factors of SAB with various modalities of dialysis.

Methods: The end-stage renal disease population was retrieved from The National Registry on Regular Dialysis and Transplantation, in the period from January 1st 1996 to December 31st 2011. Information on SAB was obtained from the nationwide SAB Database. Patients were followed until death, the first episode of SAB, end of study (December 31st 2011), or a maximum of 16 years of follow-up. Independent risk factors were assessed by multivariable Cox regression.

Results: In the study period, 9997 patients commenced renal replacement therapy. The initial modality was hemodialysis in 6826, peritoneal dialysis in 2882 and 289 patients had a pre-emptive kidney transplantation. Changes in renal replacement therapy modality and vascular access was identified and entered time-updated during follow-up, allowing for time-updated exposure. SAB was found in 1278 patients (12.8%). The incidence rate of SAB was highest in uncuffed central venous catheter (CVC) (10.20/100 person-years) followed by cuffed CVC (9/100 person-years), arteriovenous graft (4.98/100 person-years) and arteriovenous fistula (4.93/100 person-years). The adjusted hazard ratio for SAB was: in cuffed CVC, 5.77 (95% CI 4.45-7.49), in uncuffed CVC, 7.13 (95% CI 5.39-9.42), in arteriovenous graft, 4.54 (95% CI 2.11-9.77) and in arteriovenous fistula, 3.40 (95% CI 2.78-4.14) compared to peritoneal dialysis. There was no difference in risk of SAB between uncuffed- and cuffed CVC. The first 1.5 months in renal replacement therapy in particular in CVC, diabetes mellitus and male gender were additional risk factors of SAB.

Conclusions: Patients in hemodialysis have a high incidence of SAB, in particular with CVC. In this study, the risk of SAB was similar in cuffed- and uncuffed CVC. The first 1.5 months in renal replacement therapy in particular in CVC, diabetes mellitus and male gender were independent risk factors of SAB.

Latent Tuberculosis in Dialysis Patients: Prevalence, Risk Factors, and Inflammatory Markers Randah A. Dahlan, Mahmoud M. Shaheen, Mostafa A. Abd_elkhalek, Abdulkareem Alsuwaida. *Davita KSA, Jeddah, Saudi Arabia.*

Background: Dialysis patients are more susceptible to infections than the general population as they have a dysfunctional immune system. Therefore, various prevention and screening strategies must be implemented in dialysis units to decrease the rate of infection. Screening for latent tuberculosis (LTB), is an important preventative strategy in countries with moderate or high disease burden. We conducted this continuous quality improvement project to ensure the process of screening for LTB is being appropriately implemented as per our dialysis unit policy, to know the prevalence of LTB using interferon—γ release assay (IGRA), and to determine if certain patients' variables may play a role as a risk factor or as a disease marker.

Methods: We reviewed the clinical data of all patients dialyzing at DaVita dialysis units in Jeddah, SA to abstract data about IGRA test, patients demographic, laboratory, radiological and clinical status.

Results: 302 dialysis patients were screened for LTB using the IGRA, and 92 patients (30.5%) were positive. All positive patients were assessed for presence or absence of suspicious symptoms and a chest X-ray (CXR) was obtained to rule out active disease. Active TB was thought to be unlikely in all patients. When patients with positive test were compared to those who tested negative, they were older (54.74 ± 16.05 versus 50.4 ± 16.2 years,*p* value = 0.033), more likely to have had a previous history of TB (*p* value = 0.0014), less likely they had received the BCG vaccine in the past (*p* value = 0.0003), and had a higher ferritin (*p* value = 0.45). There was no difference between the 2 groups in terms of sex, dialysis vintage, the background rate of DM, HCV, or HBV, lymphocytes count, neuropils, platelets, neutrophil to lymphocyte ratio, platelets to lymphocytes ratio, transferrin saturation, or albumin level.

Conclusions: Elderly, those with a past history of TB, and those who have no past history of BCG vaccination are all potentially at risk of LTB. Although many inflammatory markers are not characteristically high in patients with LTB, high ferritin level is commonly seen. This is the first study to describe simple inflammatory markers in dialysis patients with LTB. Screening dialysis patients who have persistent unexplained high ferritin level for LTB should be considered in appropriate settings.

TH-PO902

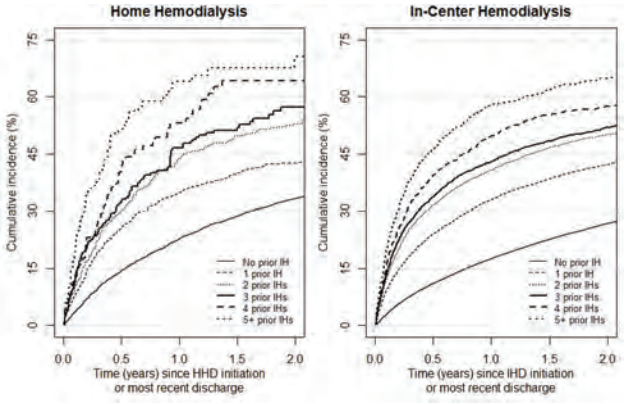
First and Recurrent Hospitalized Infections in Home and In-Center Hemodialysis Patients Eric D. Weinhandl,[1,2] Allan J. Collins.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Compared to thrice-weekly in-center hemodialysis (IHD), daily home hemodialysis (HHD) is associated with higher risk of infection-related hospitalization (IH). Strategies to reduce risk of infectious complications on HHD are needed to improve clinical and economic outcomes. We aimed to estimate the incidence of first and recurrent IHs in HHD and IHD patients with a fistula.

Methods: We analyzed data from the United States Renal Data System. The HHD cohort comprised patients who completed HHD training with the NxStage System One in 2006-2012 and who carried Medicare as primary payer (MPP). The IHD cohort comprised patients who initiated IHD in 2006-2012 and who carried MPP. We followed patients until the earliest of modality change, death, or December 31, 2012. We ascertained IHs from principal discharge diagnoses on Medicare claims. We estimated the cumulative incidence of IH, stratified by the cumulative number of prior IHs on HHD or IHD, and the hazard ratio of IH for HHD versus IHD, with adjustment for age, race, sex, ESRD duration, and primary cause of ESRD.

Results: We identified 4304 HHD and 46,988 IHD patients. On both HHD and IHD, the cumulative incidence of IH increased with each additional IH discharge (figure). For HHD versus IHD, the adjusted hazard ratio (AHR) of first IH was 1.24 (95% confidence interval, 1.07-1.44); the AHR of second IH, following discharge from the first IH, was 1.01 (0.86-1.19); and the AHR of each subsequent IH, following discharge from the preceding IH, was 0.92 (0.78-1.09).

Conclusions: Compared to IHD patients with a fistula, HHD patients with a fistula had higher risk of a first IH, but similar or slightly lower risk of recurrent IHs. However, in both dialytic settings, each additional IH discharge increased the risk of another IH. Less time to first IH in HHD patients prematurely sets in motion the cycle of increasing risk, ultimately manifesting as a higher IH rate on HHD versus IHD. Attention should be devoted to prevention of the first infection on HHD.



TH-PO903

Circulating Interferon-λ3, HBV Vaccination, and HBV/HCV Infections in Hemodialysis Patients Alicja E. Grzegorzewska,[4] Monika K. Swiderska,[3] Adrianna Mostowska,[2] Pawel P. Jagodzinski.[1] *[1]PUMS, Poznan, Poland; [2]PUMS, Poznan, Poland; [3]PUMS, Poznan, Poland; [4]Poznan University of Medical Sciences (PUMS), Poznan, Poland.*

Background: Interferon (IFN)-λ3 gene (*IFNL3*) is known from its crucial role in HCV clearance. Our aim was to investigate circulating IFN-λ3 and single nucleotide polymorphisms (SNPs) of *IFNL3* in hemodialysis (HD) patients who differed in response to HBV vaccination and status of HBV/HCV infections.

Methods: In 201 HD patients and 28 controls, plasma IFN-λ3 (ng/L) was determined using ELISA. *IFNL3* SNPs (rs12979860, rs8099917) were genotyped using HRM analysis.

Results: HBV vaccine responders among HD patients showed higher IFN-λ3 than healthy responders (120, 36–233 vs 62, 12.3–280, P=0.0004). In HD group, significant differences in circulating IFN-λ3 were shown between responders and non-responders to HBV vaccination (120, 36–233 vs 43, 15.9–77.4, P=1.0E-7) as well as between HBsAg positive patients and those who developed anti-HBs and became HBsAg negative after HBV infection (39.1, 10–83.4 vs 125, 35–215, P=0.010). Responders to HBV vaccination, who resolved HCV infection, did not differ in circulating IFN-λ3 from non-infected responders (133, 14.8–400 vs 120, 36–233, P=0.714), whereas responders to HBV vaccination, who did not show spontaneous HCV resolution, revealed lower IFN-λ3 than non-infected responders (74, 4.9–275 vs 120, 36–233, P=0.013). In patients with both infections, HBsAg positive/HCV RNA positive subjects showed lower IFN-λ3 (13.3, 9–21.6) than only HCV RNA positive patients (57.5, 13.7–203, P=0.031) and lower compared with patients who resolved both infections (88.5, 16.0–300, P=0.020). Circulating IFN-λ3 showed independent positive association with anti-HBs titer (β±SE 8.4±1.1, P=4.0E-13) and negative associations with HCV RNA (β±SE -32.5±11.4, P=0.005) and HBsAg (β±SE -45.3±22.9, P=0.049) positivity. Non-responders to HBV vaccination, patients HBsAg positive, and subjects replicating HCV composed a group with unfavorable outcomes. The remaining patients were analyzed as having favorable outcomes. The latter showed higher IFN-λ3 (120, 14.8–400 vs 50.7, 4.9–275, P=1.0E-11), but did not differ in distribution of *IFNL3* SNPs compared with subjects with unfavorable outcomes.

Conclusions: Higher IFN-λ3 concentrations are associated with response to HBV vaccination, self-limited HBV infection, and spontaneous HCV resolution.

TH-PO904

High Dose and Quadrivalent Influenza Vaccine Safety and Efficacy in Dialysis Patients: Interim 2016-17 Flu Season Analysis Harold J. Manley,[2] Eduardo K. Lacson,[1] Hocine Tighiouart,[3] Daniel E. Weiner,[3] Dana Miskulin,[3] Klemens B. Meyer.[3] *[1]Dialysis Clinic Inc, Boston, MA; [2]Dialysis Clinic Inc, Albany, NY; [3]Tufts Medical Center, Boston, MA.*

Background: Dialysis patients have high morbidity and mortality risk from influenza. During the 2016-17 flu season, Dialysis Clinic, Inc. administered Quadrivalent (Quad) and High Dose (High) flu vaccines. We compared safety and efficacy associated with each vaccine type.

Methods: All patients administered vaccine in clinic between 8/1/2016 and 12/31/2016 were followed thru 3/13/2017. Safety signal events were death, hospitalization, urgent care/ED visit or practitioner visit within 3 days of vaccination. Efficacy measures were death, hospitalization, and urgent care/ED visits ≥14 days post dose. Cox models were constructed for the entire population and within age subgroups (<65, ≥65 yrs old).

Results: There were 9393 patients vaccinated, 3646 (39%) with Quad and 5747 (61%) with High. Older patients were more likely to receive High flu vaccine (p<0.001). Hemodialysis was principal modality (90.2%). Safety signals were insignificant between vaccine type except for practitioner visit (1.6% v 0.5% in Quad and High patients, respectively (p<0.001). Vaccine hazard ratio (95% CI) and p-values regarding long term outcomes are shown in table. Kaplan-Meir survival curve for hospitalization is shown in figure.

Conclusions: Interim 2016-17 flu season analysis demonstrated that dialysis patients tolerated High and Quad vaccines similarly. High was associated with fewer hospitalizations in patients overall and ≥65 yrs old. High vaccine use also trended towards fewer hospitalizations in patients < 65 yrs old. No differences were noted in mortality rates. Dialysis providers should consider High flu vaccine in patients ≥65 yrs old.

Outcome	Age <65 group		Age≥ 65 group		Overall	
	HR (95% CI)	P value	HR (95% CI)	P value	HR (95% CI)	P value

TH-PO905

Accelerated Vaccination Schedule against HBV with Combined Hepatitis A and B Vaccine among Hemodialysis Patients: Does It Work? Mahmoud H. Imam. *Internal medicine Department, Faculty of Medicine Benha University, Benha, Egypt.*

Background: Hemodialysis patient possesses particular attributes which increase susceptibility to HBV infections. HBV vaccination significantly decreased the number of new HBV-infected patients. Using the conventional dosage schedule requires six months of vaccination. The aim of this study is to examine the result of seroprotection using the accelerated vaccination schedule in vaccination of hemodialysis patient through using combined hepatitis A and B vaccine.

Methods: In this study, 114 consecutive hemodialysis patients at New Jeddah hospital were enrolled. Their age ranged from 18 to 71 years. The inclusion criteria were [1] Age was above 18 years, [2] All patients had undetectable HBV surface antigen and antibody. Exclusion criteria included [1] A positive serum HBV surface antigen and antibody; [2] patient received a previous course of HBV vaccine, [3] patient positive for HBV surface Ag. Patients were sequentially randomized to receive either Hepatitis B recombinant DNA vaccine or to receive combined hepatitis A and B vaccine injection. Testing for HBV surface antibodies was done one and three months after completion of the mentioned dosage schedule. The primary outcome was the detection of seroprotection using serum HBV surface antibodies ≥ 10 mIU/mL. Adverse reactions were evaluated regarding both fever and post-injection pain scale.

Results: After one and three months of completion of the vaccination schedule, there were no statistically different proportion of positive seroprotected patients among both groups.

Conclusions: Accelerated vaccination schedule using combined hepatitis A and B vaccine may be equivalent to the conventional dosage of Hepatitis B.

TH-PO906

Hepatitis B Prevention in Dialysis – Needs Reconsideration Sonalika Agarwal. *Hnery Ford Hospital, Detroit, MI.*

Background: Hepatitis B virus (HBV) infection is a significant cause of morbidity in end stage renal disease (ESRD) patients undergoing hemodialysis (HD). A significant reduction in the incidence of HBV has occurred by segregating patients with the disease from those who are at risk for contracting it. We report a case of a patient on HD who developed seroconversion to hepatitis B surface antigen (HBsAg) positivity with viremia despite presumed natural immunity to HBV.

Methods: Our patient is a xx-year-old female who was started on HD in 2012. At that time, her serum HBsAg was negative, hepatitis core antibody (HBcAb) was positive and hepatitis b surface antibody titer >150 mIU/ml implying a prior history of infection with natural immunity. She lacked risk factors for contracting the HBV infection and was dialyzed with the general population in our dialysis unit. Routine annual screening yielded a positive HBsAg despite having negative levels in the past; however, she maintained a high titer of HBsAb. Additional testing revealed a negative IgM HBcAb, positive HBeAb and normal transaminase levels reflecting the absence of a new infection. Given low-grade viremia (1,489 IU/ml), the decision was made to relocate her to a dedicated dialysis machine in the unit isolation area. Hepatology diagnosed her with a

chronic inactivated form of hepatitis infection. A month later her repeat hepatitis panel showed seroconversion back to HBSAg negativity.

Results:

Conclusions: HBeAg negative patients with normal serum transaminases and low (<2000 IU/mL) or undetectable HBV DNA are considered to be in an inactive carrier state. According to Center for Disease Control (CDC) guidelines updated in 2016, patients who are HBsAg negative and HBsAb positive are not considered infectious. Annual HBsAb testing confirms that immunity is not lost in this population. The CDC does not recommend rechecking HBSAg on HD patients once antibody screen establishes immunity. This case highlights the importance of recognizing the chronic inactive hepatitis B infection state in HD patients. Given potential for transmission of infection during transient viremia, these patients should be isolated from the general population during HD. Although current guidelines do not recommend routine testing for HBsAg in HD patients with known immunity, addition of antigen testing to routine surveillance may be warranted to reduce the risk of HBV transmission in this population.

TH-PO907

Extreme Duration of Positive Hepatitis B Surface Antigen (HBsAg) after Vaccination in a Hemodialysis Patient Robert H. Barth,[1,2] Amar V. Patel.[2,1]
[1]Medicine, VA NY Harbor Healthcare System, Brooklyn, NY; [2]Medicine, SUNY Downstate College of Medicine, Brooklyn, NY.

Background: Patients with end stage renal disease (ESRD) without immunity to hepatitis B virus (HBV) frequently receive vaccines containing purified non-infectious subunits of HBsAg. The two vaccines available in the U.S., Engerix-B (ENG) and Recombivax HB (REC), are both produced by cloning HBV DNA into the yeast Saccharomyces cerevisae and harvesting and purifying the resultant HBsAg expressed by the yeast. There have been many reports of transient positivity of HBsAg assays in patients who have received these vaccines, almost always lasting less than 14 days, with several case reports of HBsAg positivity of 28 to 48 days' duration.

Methods: We report a case of extremely long-term HBsAg positivity apparently induced by vaccination. The patient was a man with ESRD secondary to diabetes. After beginning hemodialysis he received 3 doses of ENG in 2003-2004, and within one month developed a positive assay for antibodies (Ab) to HBV (HBsAb). HBsAg was never positive, but the assays were obtained 15-40 days after the vaccinations. He continued to have positive assays for HBsAb for 33 months, after which the Ab gradually became undetectable, and in 2007 a new series of vaccinations, this time with REC, was begun. 30 days after the first vaccination HBsAg and HBsAb had simultaneously become weakly positive, and 32 days after the second dose both antigen (Ag) and Ab assays were fully positive. The patient was clinically stable, LFTs were entirely normal, and HBV DNA, core antibody, e antibody and e antigen were repeatedly negative. No further vaccinations were given. Concurrent HBsAg and HBsAb positivity persisted for 4.3 years, with reduction of HBsAg titers after 1.5 years, but with weak positivity persisting until the patient's death from an unrelated cause in 2011.

Results:

Conclusions: The mechanism for this persistent Ag positivity is not clear, but was almost certainly not active HBV infection, and was temporally very closely correlated with REC vaccination. The sequential use of two different vaccines may have played a role through differences in their antigenic structure, but this is not certain. Explanation of this phenomenon will require further study, but this case illustrates the extreme variability of HBV Ag/Ab assay results after HBV vaccination in patients on hemodialysis.

TH-PO908

Comparison of Outpatient Antibiotic Use in Dialysis Units of NY State Ilay Rakhman,[4] Aaron S. Stern,[4] Tina Adjei-Bosompem,[4] George N. Coritsidis,[2,4] Teresa Lubowski,[3] Ti-Kuang Lee,[3] Carol Lyden.[1]
[1]ESRD Network 2, Lake Success, NY; [2]Elmhurst Hospital Center, Elmhurst, NY; [3]IPRO, Lake Success, NY; [4]Mount Sinai Hospital, Elmhurst, NY.

Background: Little information is available regarding oral antibiotic use in outpatient clinical dialysis settings. Our study compares different prescribing practices in end stage renal disease (ESRD) patients and non-ESRD patients in both rural and urban areas.

Methods: 2015 IPRO Medicare part D data from all 62 New York State (NYS) counties were reviewed to obtain oral antibiotic (ABX) prescription information for the ESRD and non-ESRD populations. The average number of prescribed ABX per patient and average number of prescription days were compared between rural and urban areas as well as ESRD and non-ESRD populations.

Results: We found that ESRD patients were prescribed significantly more ABXs than non-ESRD patients in NYS regardless of urban or rural setting. The average number of ABX prescription days was greater with ESRD patients compared to non-ESRD patients, primarily in urban areas. Urban patients were prescribed Ampicillin (p=0.0295), Cefeclor (p=0.464), Cefadroxil (p=0.003), Dicloxacillin (p=0.018), and Metronidazole (p=0.0078) more often. Rural patients were prescribed Cefpodoxime 3.5 times more often than urban ESRD patients.

Conclusions: ESRD patients are prescribed more antibiotics for a longer duration when compared to the general population. Differences in prescribing patterns could be explained by more judicious prescription practices, less diversity of prescribers, fewer individual prescribers or the clinical status of ESRD patients. We cannot yet answer the question of appropriateness of antibiotic prescriptions, but these data can help establish prescription patterns, which can then be applied more broadly. Ultimately the data can be used to modify prescribing practices using evidence based recommendations to decrease inappropriate antibiotic use and promote antibiotic stewardship.

Table 1. Comparison of Antibiotics Prescribing Patterns Between ESRD Non-ESRD Patients

	Non-ESRD	ESRD	p
Avg ABX prescribed per patient	0.89 ± 0.02	1.66 ± 0.06	<0.001
Rural	0.87 ± 0.04	1.79 ± 0.25	0.003
Urban	0.89 ± 0.02	1.63 ± 0.04	<0.001
Avg days ABX prescribed per patient	10.27 ± 0.92	13.30 ± 0.41	<0.001
Rural	10.61 ± 0.18	12.70 ± 1.43	0.171
Urban	10.17 ± 0.10	13.46 ± 0.37	<0.001

TH-PO909

Sustained Low Central Venous Catheter-Related Bloodstream Infection Rates in HD Patients with an Antibiotic Lock over a 3-Year Period Sumi J. Sun,[1] Norma Gomez,[1] Fang Yang,[1] Graham E. Abra,[1,2] Brigitte Schiller.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Stanford University, Palo Alto, CA.*

Background: CVCs are associated with catheter-related bloodstream infection (BSI) resulting in increased morbidity and mortality. Following our report of significantly reduced infection when 320 μg/mL gentamicin in 4% citrate is used as the CVC locking solution (Moran AJKD 2012), this has remained the standard of care in patients dialyzing with a CVC, unless physician order requested otherwise. The infection rates were monitored through an internal QC program developed for National Healthcare Safety Network (NHSN) reporting.

Methods: This study evaluated NHSN data with self-reported infection rates from January 2014 to December 2016 in a non-profit dialysis provider with a total of 57 free-standing dialysis facilities serving more than 5000 HD patients. BSI was reported according to NHSN criteria. Data were audited through comparison to an internal infection control report and discrepancies reconciled prior to final NHSN submission. Blood cultures were mandated before any antibiotic administration for suspected BSI, and 85% or more are sent to one internal lab (Ascend).

Results: The rate of catheter-related bloodstream infection over the three years was 1.00 episodes/100 patient months, 54% lower than the national average of 2.16 for CVC-related BSI (2014 NHSN BSI Pooled Mean Rate/100 patient-months). Monthly BSI rates showed minor fluctuations, however none exceeded the national average in any given month.

Conclusions: Gentamicin 320 μg/mL in 4% sodium citrate as a routine catheter lock demonstrated sustained low CVC-related BSI rates in HD patients, with approximately half the infection rate compared with the national average. Gentamicin-citrate lock should be considered the standard of care in patients with CVC access.

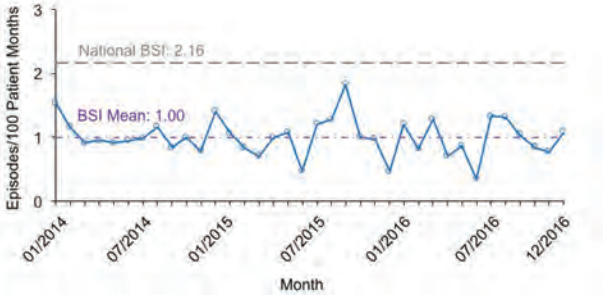

Figure 1: Monthly Bloodstream Infection Rates for Patients with Any CVC Access from 01/2014 to 12/2016

TH-PO910

First Treatment of Human Bacteremia during Dialysis Using a Biomimetic Sorbent Hemoperfusion Device Jan T. Kielstein,[2] Kathleen A. White,[1] Keith McCrea,[1] Robert S. Ward.[1] *[1]ExThera Medical, Martinez, CA; [2]Academic Teaching Hospital Braunschweig, Braunschweig, Germany.*

Background: Blood stream infections are the 2nd leading cause of mortality among CKD5D patients. To subvert the host immune response many pathogens bind to heparan sulfate, a key receptor on cell surfaces. The Seraph® 100 Blood Filter (Seraph) uses this affinity to bind and remove pathogens, toxins, and cytokines from flowing blood.

Methods: The first patients treated with the Seraph as part of an ongoing first-in-man study (www.clinicaltrials.gov. NCT02914132) are presented. The Seraph was placed in series, upstream from a FX80 high-flux dialyser (FMC), during a regular hemodialysis procdure with a 5008H dialysis machine (FMC) (Qb 300 mL/min; Qd 500 mL/min).

Results: Two male hemodialysis patients 57 and 82 years of age presented with S. aureus bacteremia. In adjunction to antibiotic therapy they were treated with Seraph concurrent with hemodialysis. As measured by automated blood culture, post-Seraph/pre-dialyzer blood samples had increased time to positivity (TTP) relative to contemporaneous pre-Seraph samples, indicating reduced concentration of bacteria. As estimated from TTP, mean incoming blood-borne bacteria decreased by 99% and 47% respectively per pass through the Seraph cartridge. During the 4-hour in-series treatment with Seraph and a dialyzer both patients remained hemodynamically stable and showed no adverse reactions.

Heart rate, blood pressure, and cardiac output were stable and reproducible. No clinically significant post treatment-changes in hematology or clinical chemistry occurred.

Conclusions: Seraph appears to be well tolerated by patients, and is capable of quickly removing pathogens from blood. It's rapid, broad-spectrum binding and inherent blood compatibility suggest future use as a prophylactic, or at the first sign of bloodstream infection, even before pathogen identification.

TH-PO911

Effectiveness of Direct-Acting Antiviral Regimens in the Treatment of Hepatitis C Virus Infection in a Diverse Dialysis Population Michelle T. Martin,[2,1] Ignatius Y. Tang,[2] Todd Lee.[1] [1]*University of Illinois at Chicago, Chicago, IL;* [2]*University of Illinois Hospital and Health Sciences System, Chicago, IL.*

Background: Direct-acting antiviral (DAA) regimens offer high sustained virologic response (SVR) in patients infected with the hepatitis C virus (HCV). However, clinical trial data in dialysis patients and real-world data in a multi-ethnic dialysis population are limited.

Methods: All HCV-infected dialysis patients who received DAA therapy at an urban academic medical center from 1/1/2014 to 12/1/2016 and had SVR data available were included in this single center retrospective review. Data collection included demographics, comorbidities, treatment regimen, and laboratory data. Descriptive statistics, Fisher's exact test, and Pearson's chi-square test were used for analysis.

Results: A total of 17 patients started treatment; SVR data were not available for 2 patients. Among the remaining 15 patients, the mean age was 63.1 (±6.9) years and BMI was 26.3 (±4.7) kg/m^2, 80% were male, 60% African American, 67% cirrhotic, 80% treatment-naive, 27% had diabetes, and 20% had psychiatric illness. The HCV genotype mix was 67% 1a, 27% 1b, and 6% 2b. Forty percent had received organ transplants: 33% liver and 7% liver + kidney; 83% of transplant patients received tacrolimus for immunosuppression. Sixty-seven percent of patients received elbasvir/grazoprevir, 20% elbasvir/grazoprevir + ribavirin, and 13% ledipasvir/sofosbuvir. SVR was achieved in all 15 patients (100%). Fatigue was reported by 20% of patients. All 3 patients who received ribavirin experienced anemia. One patient received additional erythropoietin during dialysis and had a ribavirin dose reduction. The SVR rates did not differ by genotype, regimen, cirrhosis, treatment history, ethnicity, gender, age, BMI, diabetes, psychiatric history, or transplant status. The SVR rates also did not differ by adherence; 13% of patients reported missing 1 dose of HCV medication during treatment.

Conclusions: Despite a high proportion of cirrhotic patients, all patients achieved SVR in this diverse dialysis patient population. While ledipasvir/sofosbuvir is not recommended for HCV-infected dialysis patients, both patients treated with this regimen achieved SVR. The SVR rates did not differ by treatment or demographics due to the 100% cure rate, and conclusions across groups are limited due to the small numbers. DAA regimens were well tolerated except for anemia in patients receiving ribavirin.

TH-PO912

Incidence of Dialysis-Related Infections in the Automated Peritoneal Dialysis Population in the United States Eric D. Weinhandl,[1,2] Allan J. Collins.[1,2] [1]*NxStage Medical, Inc., Victoria, MN;* [2]*University of Minnesota, Minneapolis, MN.*

Background: Infection increases risks of peritoneal dialysis technique failure and death. However, data about the magnitude of and trends in the incidence of all-setting peritoneal dialysis-related infection (DI) in the US are lacking. We estimated incidence of both hospitalized and non-hospitalized DI in the automated peritoneal dialysis (APD) population.

Methods: We analyzed United States Renal Data System records. From 2006 to 2013, we collected cohorts of end-stage renal disease patients on APD. We identified hospitalized and non-hospitalized cases of DI from Medicare claims with ICD-9-CM diagnosis codes [a] 567.x (peritonitis), [b] 996.68 (infection due to peritoneal dialysis catheter), and [c] 038.x (septicemia). We estimated incidence rates with definitions of diagnosis code [a], codes [a]-[b], and codes [a]-[c], and with only principal or with both principal and secondary diagnosis codes.

Results: In 2013, the incidence rate was 11.2 (annualized rate of change between 2006 and 2013, -6.3%), 25.1 (-4.7%), and 35.1 (-3.1%) events per 100 patient-years with diagnosis code [a], codes [a]-[b], and codes [a]-[c], respectively, as a function of only principal diagnosis codes. In contrast, as a function of both principal and secondary diagnosis codes, corresponding rates were 45.7 (-3.3%), 55.1 (-2.7%), and 66.3 (-2.1%) events per 100 patient-years. These rates corresponded to one DI case per 26, 22, and 18 patient-months, respectively. With DI defined by both principal and secondary diagnosis codes, hospitalized cases comprised between 53% and 61% of all cases.

Conclusions: Between 2006 and 2013, the incidence of DI decreased among APD patients in the US. However, the absolute magnitude of the incidence of DI was uncertain, as rates defined by an array of diagnosis code sets and diagnosis code positions varied by a factor of nearly 6 in 2013. The incidence rate associated with broader claims-based definitions indicated that DI remains a common complication in 2013; for frame of reference, the incidence of all-setting peritonitis ranged from 35 to 40 events per 100 patient-years in Australia between 2012 and 2015. In addition, more than half of DI cases involved hospitalization, a possible marker of inadequate monitoring in the outpatient setting. With continued growth of PD utilization in the US, novel tools to reduce risk of DI on APD are needed.

TH-PO913

Comparison of CAPD and APD Peritonitis in a Nephrology Reference Center in Mexico City Ruben Garrido,[2] Julio C. Arriaga,[2] Bernardo Moguel,[1] Francisco Rodriguez.[2] [1]*Instituto Nacional de Cardiologia, Mexico City, Mexico;* [2]*Instituto Nacional de Cardiologia Ignacio Chavez, Tlalpan, Mexico.*

Background: Peritonitis is a major cause of morbidity, mortality and increase health care cost in patients on peritoneal dialysis (PD). PD infection is associated with peritoneal membrane loss, technique failure and mortality. Following an episode of peritonitis, the risk of more peritonitis episodes, hemodialysis switch and death increased during the first month and during the next 6 months.

Methods: We evaluated retrospectively all patients with peritonitis episode from October 2014 to December 2016 in the "National Institute of Cardiology Ignacio Chávez" in Mexico City on different PD modalities: Continuous Ambulatory Peritoneal Dialysis (CAPD) and automated peritoneal dialysis (APD).

Results: 71 patients were evaluated, 36 (50.7%) of female sex with a median age of 50 years. 54 (76.1%) on CAPD and 17 (23.9%) on APD. The main cause of renal failure were diabetic nephropathy in 34 patients (45.1%). On 28 patients (39.4%)no history of peritonitis and the comorbidities were chronic hypertension (47.9%), ischemic heart disease (16.9%) and chronic heart failure (8.5%). The most frequent organism identified on cultures were S aureus in 23 (32.4%) patients, E coli in 7 (9.9%), S marcescens in 5 (7%), S epidermidis with 5 (7%) cases and Candida in 5 patients (7%).

Conclusions: The CAPD group presented more frequently peritonitis episodes. Most frequent infection was gram positive organisms: S. aureus in 39.4%. Mechanical dysfunction presented only in 1 patient of APD patients, and also only 1 patient died in this group. The level of albumin and BUN demonstrated a statistical significance and are associated with worst outcome in all patients.

Table. Clinical and biochemical outcomes APD and CAPD patients

Mechanical dysfunction	n	%
Yes	10	14.1
No	61	85.9
Final outcome	**n**	**%**
Live	63	88.7
Death	5	7
Lost to follow up	3	4.2

Outcome	n	%

Effects of Prospective Improvement Trail to Reduce the Incidence of Peritonitis in a Peritoneal Dialysis Population in Qatar Mohamed amin Khalil elesnawi,[1] Fadwa S. Al-Ali,[1] Abdullah Hamad,[1] Vimala K. Lonappan,[1] Sahar Aly,[2] Rania A. Ibrahim,[1] Ahlam Ali,[3] Tarek A. Fouda,[4] Hanaa Ahamed.[1] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Hamad medical corporation, Doha, Qatar; [3]hamad medical corpartion, Doha, Qatar; [4]Hamad medical cooperation, Doha, Qatar.*

Background: Peritonitis is the major complication in patients on peritoneal dialysis (PD). Peritonitis carries high morbidity and mortality. In addition it carries an economic burden of increasing hospitalization. We have 180 PD patients and over the period of 6 months in 2016 the peritonitis was average 4%. With this high incidence we decided to run a prospective improvement trial to reduce the incidence

Methods: We conducted a random survey for 60% of patients to determine daily practice. Root cause analysis for each case in the 6 months trial to identify risk factors. Based on the data, procedure check list created during monthly visits and re-training at same time. Regular home visit assessment and questionnaire taking for environmental evaluation and daily practice. All aspects of the trial were planned and drawn by Multidisciplinary team (MDT).

Results: 110 Patients took part in the survey and after analysis of the data using pareto chart, 24% had poor hand hygiene, 22% not using mask, 20% had constipation, 14% had an unsuitable environment at home, 8% had poor personal hygiene, 7% traveled abroad and 5% did not have adequate time to undertake the procedure properly. The incidence of peritonitis in the 6 months of the trial has fallen from average 4% to 1.4% which presents a 65% reduction of peritonitis. Furthermore there was 51.6% reduction in the overall medical cost

Conclusions: In this prospective trial we have demonstrated that peritonitis can be significantly reduced by MDT approach and monthly retraining of patients. Although there is medical and economical benefit, there is some cost implication for the monthly retraining. More work is needed to establish what would be the most effective frequency of training

TH-PO915

Microbiologic Surveys and Resistance Profiles in Mexican PD Patients Martín D. Vargas ezquivel,[2] Javier Soto-Vargas,[2] Heriberto R. López,[2] Ana L. Garc?a-Vera,[2] Carlos Daniel Jiménez Mejía,[2] Alfonso Ramos,[1] Mario A. Garc?a C?rdenas.[2] *[1]Baxter Mexico, San Jer?nimo Chicahualco, Mexico; [2]Regional General Hospital 46, Mexican Institute of Social Security, Guadalajara, Mexico.*

Background: Guidelines that recommend specific antibiotics for empiric treatment of peritonitis are not specific to populations and time variable microbiology. Our objective was to present the microbiologic change and antibiotic resistance in a reference center in México.

Methods: We recorded the cultures from PD patients with peritonitis from 2008-2015, an analysis was performed of resistance profile to different antibiotics according to their Gram stain and species.

Results: A total of 1814 samples were obtained, the more prevalent bacteria were *Staphylococcus* coagulasa negative (ConN) (23.7%), *S. aureus* (16.5%), *Escherichia coli* (12.2%) and *Enterococcus* spp (9.2%). The distribution of agents according to Gram stain between the years studied were no different (p=0.214), being Gram positive responsible of 70 to 64% of the cases of peritonitis. It was observed an increase of cases due to *S. aureus* and *Klebsiella* spp, as well to *E. coli* without a specific patron. The majority of the cases were in the ambulatory setting (73.5%). 60.3% of the infections caused by *Staphylococcus* were methicillin resistant. Of importance, 76% of CoNS had methicillin resistance and only 28.1% of *S. aureus*. The prevalence of Vancomycin resistant *Enterococcus* was 18%, with no difference between acquisitions on community or nosocomial setting. In the Gram negative bacilli group, 72.5% of the *E. coli* and 35.1% of the *Klebsiella* spp were BLEE-producing, but the susceptibility to carbapenems reached 98%. In respect to fluoroquinolones, *E. coli* resistance reached 77.8% of the cases, and *Klebsiella* spp only 20.9%. Surprisingly there were no differences between the resistance and the ambulatory or hospital setting of the infection.

Conclusions: The agents responsible of peritonitis during this 8 year study were primarily Gram positive coccus, with a high prevalence of methicillin resistance in both ambulatory and nosocomial setting. The presence of BLEE-producing Gram negative bacilli was high as well as the resistance to quinolones and aminoglycosides with a little variation over time.

TH-PO916

Services Associated with Increased Cost of Hospitalization for Peritonitis in Pediatric Patients Receiving Chronic Peritoneal Dialysis Allison C. Redpath,[4] Troy Richardson,[1] Alicia Neu,[2] Bradley A. Warady.[3] *[1]Children's Hospital Association, Overland Park, KS; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]The Children's Mercy Hospital, Kansas City, MO; [4]University of Wisconsin School of Medicine & Public Health, Madison, WI. Group/Team: SCOPE Collaborative.*

Background: Peritonitis is a leading cause of hospitalization in children on chronic peritoneal dialysis. The Standardizing Care to improve Outcomes in Pediatric ESRD (SCOPE) Collaborative has demonstrated a reduction in peritonitis rates and associated hospitalizations resulting in over $7million in cost-savings. Prior investigation has demonstrated that ICU stay and fungal peritonitis are associated with high-cost hospitalizations. The objective of this analysis is to describe service-line utilization associated with high-cost hospitalizations for peritonitis.

Methods: Peritonitis episodes reported by 24/29 SCOPE centers between 10/2011 and 9/2015 were linked with data in the Pediatric Health Information System (PHIS) database. Linkage was performed on the basis of sex, birth month and year, and date of peritonitis episode and hospitalization. Charges in PHIS were adjusted for cost-of-living differences and converted to costs. Detailed billing information was used to compare service-line utilization among the top 25 % of infection episodes by cost with bottom 75% and to compare fungal infection episodes to other types of infections.

Results: During the first 48 months of SCOPE, 266 peritonitis episodes were linked to 278 hospitalizations in PHIS. Detailed billing data was available for 246 hospitalizations and 238 peritonitis episodes. The proportions of hospitalization costs were similar between the top 25% of peritonitis episodes (N=66) and the lower 75% (N=180) for pharmacy (p=0.63), lab (p=0.30), imaging (p=0.85), supply (p=0.98), clinical (0.33) and other (p=0.18) service lines. Cost per case was significantly higher (p<0.001) for all service lines in the top 25% group. Compared with other types of infections (N=215), fungal peritonitis episodes (N=23) had elevated costs per episode (p<0.001) in lab, imaging, supply, room and board costs (including ICU costs) and costs associated with hemodialysis (HD).

Conclusions: The increase costs attributed to the top 25% of peritonitis hospitalizations can be attributed to all service lines. Increased hospitalization cost per case among fungal peritonitis infections is driven by increased room and board costs associated with prolonged length of stay, costs associated with HD, and lab costs.

TH-PO917

Comparison in Mortality in Dialysis Requiring AKI (AKI-D) in Native versus Kidney Transplant Recipients Tripti Singh,[1] Sana Waheed,[1] Arjang Djamali,[1] Neetika Garg,[1] Kristen Sipsma.[2] *[1]School of Medicine and Public Health, University of Wisconsin, Madison, WI; [2]UW Health, Madison, WI.*

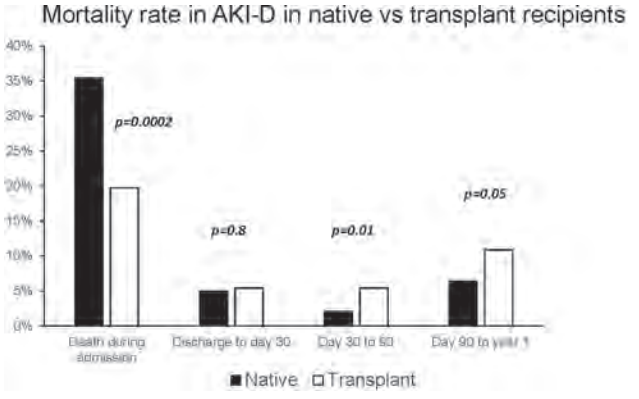
Background: There is limited information on mortality rates in patients with native versus transplant kidneys requiring renal replacement therapy (RRT) for acute kidney injury (AKI).

Methods: We compared one-year patient outcomes in a retrospective single center analysis of all adult patients with acute kidney injury requiring dialysis (AKI-D) admitted between February 2012- June 2016.

Results: 962 patients with native kidney (AKI-N) and 147 patients with kidney transplant (AKI-T) with AKI-D were admitted during the study period. Mean age was 57.6 years for AKI-N and 52.6 years for AKI-T patients (p=0.0001). 63% were males and 88% were Caucasians (p=ns). Serum creatinine at admission was significantly higher in AKI-T compared to AKI-N kidney patients (4.4 vs 3.2 mg/dL, p<0.0001). Length of stay was similar for both groups (21.6 vs 21.2 days). Continuous renal replacement therapy (CRRT) was utilized in 65% of AKI-N compared to 36.7% of AKI-T (p<0.0001).

Mortality at discharge was significantly higher for AKI-N compared to AKI-T (35% vs 19.8%, p = 0.0002). However, 1 year mortality for AKI-D was not different between native and kidney transplant recipients (49% vs 41%, p=0.09) because of poor late outcomes in transplant recipients (Fig 1). Logistic regression analyses determined CRRT (HR 3.6, 95% CI 2.8-4.7, p<0.0001), serum creatinine (HR 0.87 CI .82-.92, p<0.0001), LOS (HR 0.98 CI .98-.99, p<0.0001), and age (HR 1.01 CI 1.00-1.02, p<0.005), as significant predictors of one year mortality.

Conclusions: In patients with AKI requiring RRT early mortality is higher in native kidney disease while late mortality is greater in kidney transplant recipients. Overall, AKI requiring RRT is associated with nearly 40-50% mortality at one year, regardless of transplant status.



TH-PO918

A Multi-Platform Approach for the Noninvasive Differential Diagnosis of Acute Dysfunction of the Kidney Allograft Thangamani Muthukumar,[6] Carol Y. Li,[2] Catherine Snopkowski,[4] Hua Yang,[5] Liana S. Perry,[6] Steven Salvatore,[2] John R. Lee,[3] Surya V. Seshan,[1] Darshana Dadhania,[2] Manikkam Suthanthiran.[2] *[1]Weill Cornell Medical Center, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Weill Cornell Medicine-, New York, NY; [4]Weill Medical College of Cornell University, New York, NY; [5]Weill-Cornell, New York, NY; [6]Weill Cornell Medicine, New York, NY.*

Background: We tested a multi-platform approach for the noninvasive differential diagnosis of acute dysfunction of the kidney allograft.

Methods: We studied 118 kidney transplant recipients with acute kidney allograft dysfunction. All had kidney allograft biopsy done that were studied by light, immuno and electron microscopy and were stained for C4d and SV40 large T antigen. Serum samples were obtained at the time of biopsy for detecting donor-specific anti-HLA antibodies by Luminex single antigen bead assay (DSA). Urine specimen was obtained at the time of biopsy for urinary cell mRNA profiling. Using preamplification enhanced real-time quantitative PCR assays, we quantified CXCL10 mRNA, and CD3e mRNA levels as well as 18S rRNA levels and expressed their abundance as copies/ug total RNA. Using these three transcript levels, we derived our 3-gene molecular signature (Suthanthiran et al. N Engl J Med 2013). We also quantified BK virus VP1 mRNA levels (Ding et al. Transplantation 2002) in the biopsy matched urinary cells.

Results: Among the 118 kidney transplant recipients, biopsy revealed acute cell-mediated rejection (ACR) in 22 biopsies, acute antibody-mediated rejection (AMR) in 10 biopsies, acute tubular injury (ATI) in 49 biopsies, or polyomavirus nephropathy (PVAN) in 37 biopsies. All biopsies classified as ACR, AMR and ATI were negative for SV40. The first step in the differential diagnosis was the identification of the patients based on DSA. This identified the 10 patients with AMR. The next step in the differential diagnosis was the measurement of urinary cell VP1 mRNA. Based on our previously published cutoff value of 6.5 x 10^8 BKV VP1 mRNA copy number, 77 of the 81 patients who did not have PVAN were identified and excluded, with a negative predictive value (NPV) of 95%. In the final step, ACR and ATI were distinguished based on our previously published cutoff value of -1.213 of the 3-gene signature. Based on this cutoff value, the NPV was 83%.

Conclusions: A multi-platform approach, which involves testing DSA in the serum, BK virus VP1mRNA in urinary cells and the 3-gene signature in the urinary cells, offers a noninvasive method for the differential diagnosis of acute dysfunction of the kidney allograft with a high degree of accuracy.

Delayed Graft Function in Living Donor Kidney Transplantation – Risk Factors and Outcomes Manohar Reddy Mogulla, Philip A. Clayton. *Central and Northern Adelaide Renal and Transplantation services, Adelaide, SA, Australia.*

Background: Delayed graft function (DGF) is associated with poorer outcomes in deceased donor renal transplantation recipients. The association of DGF in living donor kidney transplantation has not been well studied. This study reviews the risk factors for DGF in Australia and New Zealand living donor kidney transplant recipients and its association with short and long term outcomes.

Methods: Data that had been prospectively collected in the Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry was reviewed. The inclusion criteria were all adult living donor kidney transplants performed between 2004 and 2015. Data from pediatric recipients (<18 years) and donors with pre-existing renal pathology (n=404), with incomplete data (n=46) and those with early graft loss (graft loss within 1 week of implantation) (n=38) were excluded. The variables studied included multivariable logistic regression to identify the risk factors for DGF and the association between DGF and rejection at 6 months; linear regression model to examine the association with eGFR at 1 year; and Cox proportional hazards models to examine the relationships between DGF and patient and graft survival.

Results: We observed DGF in 77 (2.3%) of 3358 transplants. Risk factors for DGF included right-sided kidney (odds ratio [OR] 2.00 [95% CI 1.18-3.40]); donor BMI (OR 1.06 [95% CI 1.01 - 1.12]); increasing time on dialysis and total ischemia time (OR 1.09 per hour [1.00-1.17]). DGF was associated with increased risk of rejection, worse patient and graft survival, and lower renal function at 1 year (Table).

Conclusions: In living donor kidney transplants DGF is uncommon but associated with significantly worse outcomes. The only modifiable risk factor identified was total ischemia time. Attention towards minimization of ischemia time in high-risk patients is recommended.

outcomes

Outcome	Estimate type	Estimate	95% CI	p-value
Rejection	Odds Ratio	2.37	1.41 - 3.97	0.001
Patient survival	Hazard ratio	2.14	1.21 - 3.10	0.009
Graft survival	Hazard ratio	1.98	1.27 - 3.10	0.003
eGFR at 1 year	Coefficient	-9.57	-13.5 - -5.64	<0.001

TH-PO920

Comparison between Delayed Graft Function and Slow Graft Function in Predicting Outcomes amongst Kidney Transplant Recipients Brittany L. Schreiber, Rohan Patankar, Vishy Chaudhary, Sujan P. Shah, Muhammad A. Mujtaba. *University of Texas Medical Branch, Galveston, TX.*

Background: Allograft dysfunction in the immediate post transplant period, commonly referred to as delayed graft function (DGF), has been associated with poor outcomes including acute rejection and decreased allograft longevity. Defining DGF continues to remain controversial with multiple definitions in literature. The United Network for Organ Sharing (UNOS) defines DGF as dialysis within the first week of transplantation (UNOS-DGF), leaving other measures of allograft dysfunction under the umbrella of slow graft function (SGF). Initiation of dialysis remains subjective and varies in different institutions. We aim to compare UNOS-DGF with SGF in predicting poor patient outcomes and long-term allograft dysfunction.

Methods: Our study was a single center, retrospective study that included 154 renal transplant recipients from January 1, 2015 - May 1, 2017. The patients were divided into 4 groups based on graft function: i) DGF, ii). SGF (creatinine reduction ratio <0.3 in the first 48 hours post transplant), iii). combined group and iv). immediate graft function (IGF). Chart review was performed and data collected including patient demographics, length of stay (LOS), 30-day-readmission rates, incidence of graft loss, and creatinine at 1 month post transplant.

Results: Of the 154 patients, 34 were included in the DGF group, 71 in the SGF group, 23 in the combined group, and 72 in the IGF group. Patients in the DGF and combined groups were noted to have significantly increased LOS by more than 200% and higher 30 day readmission rates compared to the IGF group with a relative risk increase of 1.68 and 1.57 respectively. Creatinine at 1 month post-transplant was significantly higher amongst the DGF, SGF and combined groups, with the greatest statistical difference in the SGF. Graft loss was seen in 13% of patients in the combined group as compared to 9%, 6%, and 3% in the DGF, SGF, and IGF groups respectively.

Conclusions: We observed that while the UNOS-DGF definition correlated with worse patient outcomes and impaired allograft function at 1 month post-transplantation, the SGF criteria identified patients at risk that were not defined by UNOS-DGF and therefore may better predict poor patient outcomes and long-term allograft dysfunction.

TH-PO921

Acute Kidney Dysfunction with No Rejection (ADNR) Is Associated with Poor Outcomes in Kidney Transplant Recipients François Paquot,[1] Hans Pottel,[2] Catherine Bonvoisin,[1] Laurent E. Weekers,[1] Francois Jouret.[1] *[1]University of Liege Hospital (ULg CHU), Liege, Belgium; [2]KULeuven, Kortrijk, Belgium.*

Background: The entity "acute kidney dysfunction with no rejection (ADNR)" has been proposed for kidney transplant recipients (KTR) presenting with acute elevation of serum creatinine without histological evidence of acute rejection (AR). The prognosis of ADNR has not been studied thus far.

Methods: From 2007 to 2015, we retrospectively categorized all KTRs with a *for-cause* kidney biopsy within 12 months post-kidney transplantation (KTx) into 2 groups: ADNR and biopsy-proven AR. Control group (C) included KTR with no ADNR or AR within 24 months post-KTx. BK virus nephropathy and primary nonfunction were excluded. Estimated glomerular filtration rate (eGFR) was determined using the Modification of Diet in Renal Disease (MDRD) equation. Linear mixed models established intercepts and slopes of eGFR decline from 6 to 24 months post-KTx. Cubic

spline analysis calculated the percentage of patients with a ≥30% reduction of eGFR from 6 to 24 months post-KTx.

Results: The mean age (years) at KTx was 50.2±14.2, 47.9±17.8 and 53.6±12.4 for ADNR (n=93), AR (n=22) and C (n=135), respectively. The female/male ratio was 39.8% (ADNR), 45.5% (AR) et 34.1 (C). The rate of delayed graft function was not significantly different among groups, and reached 26.9% (ADNR), 22.7% (AR) and 14.1% (C). The median time for *for-cause* graft biopsy was 22 [10-70] and 13 [7-43] days post-KTx for ADNR and AR, respectively. Of note, ADNR included 21 (22.6%) patients with "borderline" histology. At 6 months post-KTx, eGFR was higher in C (55.2±1.6 mL/min) *vs.* ADNR (45.5±1.9 mL/min; *p<0.05*) and *vs.* AR (48.6±3.9 mL/min; *p, 0.13*). The eGFR slope from 6 to 24 months post-Tx was positive in C (0.16±0.06mL/min/month) compared to negative slopes in ADNR (-0.04±0.08mL/min/month, *p<0.05*) and in AR (-0,04±0.16mL/min/month, *p, 0.26*). The proportion of KTR presenting with a ≥30% reduction of eGFR from 6 to 24 months post-KTx reached 7.4% in C *vs.* 25.8% in ADNR (*p<0.05)* and 19.1% in AR (*p<0.05)*.

Conclusions: In the present monocentric cohort, ADNR occurs frequently and early *post* KTx, and is associated with a significantly lower eGFR at 6 months and a significantly faster eGFR decline from 6 to 24 months post-KTx, in comparison to controls.

TH-PO922

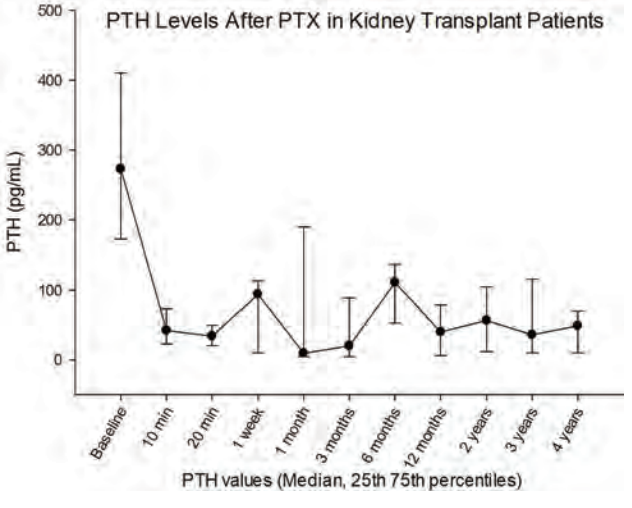
Value of Intra-Operative PTH Assay during Parathyroidectomy in Renal Transplant Recipients with Secondary and Tertiary Hyperparathyroidism Kevin Wang, Adeleye A. Edon, David Saxon, Florence Lima, David Sloan, B. Peter E. Sawaya, Amr E. Mohamed. *University of Kentucky, LEXINGTON, KY.*

Background: In renal transplant patients with secondary and tertiary hyperparathyroidism (HPT), the association between intra-operative parathyroid hormone (ioPTH) levels during parathyroidectomy (PTX) and long-term PTH is unknown. The present study aims at evaluating the value of ioPTH measurements on long-term outcome of PTX in renal transplant recipients in a single center study.

Methods: The ioPTH was measured in 18 renal transplant recipients (12 males and 6 females) who underwent PTX from 2005 to 2015 because of persistent hyperparathyroidism post-transplant. Near-total PTX was performed in 13 patients and total PTX in 5 patients. The ioPTH monitoring included 3 samples: pre-intubation (pre-ioPTH), 10- and 20-minute post parathyroid gland excision (10-ioPTH and 20-ioPTH). Patients were followed for up to 5 years (mean ± SD: 2.5 ± 1.6 years).

Results: The median (25^{th}-75^{th} percentile) pre-, 10- and 20-ioPTH levels were: 273 pg/ml (173-411), 42 pg/ml (22-73) and 34 pg/ml (20-50), respectively. All patients had a functional kidney transplant at time of surgery with a median serum creatinine of 1.3 mg/dl (1.2-1.7) and eGFR of 55 ml/min (40-60). The median time between renal transplant and PTX surgeries was 22 months (7-81). The median last follow-up PTH level was 59 pg/ml (17-83). There was no significant difference between 20-ioPTH and follow-up PTH measurements (*P*=0.6). The pre- PTX and follow-up PTH levels are shown in the Figure. Three patients (17%) were readmitted within 90 days because of hypocalcemia. Apart from easily treated hypocalcemia, the PTX surgeries were uneventful. No patient required repeat PTX because of recurrent HPT.

Conclusions: The 20-ioPTH is a good indicator of long-term PTH measurements. There were minimal complications associated with the procedure.



TH-PO923

A Prospective and Randomized Trial of Zoledronic Acid to Prevent Bone Loss in the First Year after Kidney Transplantation Igor Marques,[9] Maria Julia C. Araujo,[2] Fabiana Graciolli,[6] Luciene dos Reis,[7] Rosa M. Pereira,[1] Melani Custodio,[5] Vanda Jorgetti,[4] Rosilene M. Elias,[4] Rosa M. Moyses,[3] Elias David-Neto.[8] *[1]Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil; [2]None, Sao Paulo, Brazil; [3]Universidade Nove de Julho, São Paulo, Brazil; [4]Universidade de Sao Paulo, Sao Paulo, Brazil; [5]Universidade de São Paulo, São Paulo, Brazil; [6]University of Sao Paulo, Sao Paulo, Brazil; [7]University of Sao Paulo - Medical School - Nephrology Division, Sao Paulo, Brazil; [8]University of São Paulo School of Medicine, São Paulo, Brazil; [9]Unidade do Sistema Urinario, Hospital Universitario da UFPI, Teresina, Brazil.*

Background: Bone and mineral disorders occur frequently in kidney transplant (Ktx) recipients and have been associated with a high risk of fracture, morbidity, and mortality. Bisphosphonates may prevent or treat the bone loss promoted by the immunosuppressive regimens used in Ktx.

Methods: We conducted an open-label, prospective, randomized trial to assess the efficacy and safety of zoledronate to prevent the bone loss in the first year after Ktx. Ktx recipients were randomized 1:1 to receive zoledronate (5 mg at baseline) or no treatment (control group). Both groups received vitamin D supplementation. We evaluated bone mineral density (BMD) and microarchitecture with dual-energy X-ray absorptiometry (DXA) and with high-resolution peripheral quantitative computed tomography (HR-pQCT). Bone histomorphometric analyses were done at the time of Ktx and after 12 months of therapy.

Results: Differing from previous studies, after Ktx, neither zoledronate nor control group presented bone loss. Ktx has promoted an increase of BMD in both lumbar spine and total femur ($p<0.0001$). The late was more pronounced in the zoledronate group ($p<0.05$). Out of 34 patients, 29 had baseline and follow-up bone biopsies. On histomorphometry, we found that Ktx, but not zoledronate, suppressed bone activity without causing adynamic bone disease. Bone trabecular volume decreased only in zoledronate group ($p<0.05$). There was an improvement in cortical bone, as depicted by an increase in cortical thickness and a decrease in cortical porosity, in both groups.

Conclusions: In conclusion, we have confirmed that Ktx is not associated with significant bone loss, based on histomorphometric data. Therefore, although zoledronate had a beneficial effect in total femur BMD, the inclusion of bisphosphonates to prevent bone loss should be reconsidered in face of a contemporary immunosuppressive therapy.

Efficacy and Safety of Different Bisphosphonates for Bone Loss Prevention in Kidney Transplant Patients: A Systematic Review and Network Meta-Analysis Yan Yang,[1] Shi Qiu,[4] Xi Tang,[3] Ping Fu.[2] *[1]Kidney Research Institute, Division of Nephrology, West China Hospital, Sichuan University, Chengdu, China; [2]West China Hospital of Sichuan University, Chengdu, China; [3]west china hospital, sichuan university, Chengdu, China; [4]Department of Urology, Institute of Urology, West China Hospital, Sichuan University, Chengdu, Sichuan, P.R. China, Chengdu, China.*

Background: Because the preferred bisphosphonate regimen for kidney transplantation (KT) patients is still controversial, we aimed to compare different bisphosphonate treatments.

Methods: We searched PubMed, Embase, CENTRAL and reference lists of relevant articles up to April 1, 2017. We included RCTs comparing bisphosphonates in adult KT patients. The primary outcome was BMD change at the lumber spine and femoral neck. We performed pairwise meta-analyses by random effect model and network meta-analysis (NMA) by Bayesian model. We used the GRADE framework to assess the quality of evidence.

Results: A total of 21 RCTs involving 1332 patients with 6 bisphosphonate regimens were included in the NMA. At the lumber spine (Figure 1A), calcium alone showed significantly lower percent change in BMD compared to combination with vitamin D analogs or other bisphosphonates except clodronate. Pamidronate with calcium and vitamin D analogs showed improvemed BMD in comparison to clodronate with calcium. The combination of calcium and vitamin D analogs had a significantly lower influence than adding pamidronate or alendronate. Considering absolute terms (Figure 1B), zoledronic acid and calcium outperformed calcium alone. In terms of percent change in BMD at femoral neck (Figure 1C), both pamidronate and ibandronate combined with calcium revealed a remarkable gain compared with calcium. In absolue terms (Figure 1D), alendronate with or without vitamin D analogs, displayed a significant increase compared to calcium alone. Ibandronate with calcium demonstrated advantages than any other treatments.

Conclusions: New generation bisphosphonates were more favorable in KT patients to improve BMD. Bisphosphonate therapy was well-tolerated without increasing the frequency of adverse events and graft loss.

Funding: Government Support - Non-U.S.

TH-PO925

Prevalence of Vitamin D Deficiency after Kidney Transplantation and Its Association with Clinical Outcomes Puneet Bedi,[1] Nicole A. Hayde,[1] Maria Ajaimy,[1] Enver Akalin.[2] *[1]Montefiore Medical Center, Bronx, NY; [2]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY.*

Background: Kidney transplant recipients usually have low vitamin D levels, especially in the early posttransplantation period. Vitamin D deficiency is recognized as a risk factor for progression of kidney disease in general population. However, its association with graft outcomes in renal transplant patients is not well established.

Methods: We measured 25-hydroxyvitamin (OH) D levels and intact-Parathyroid hormone (i-PTH) levels at 6, 12, 24 and 36 months post-transplant in patients transplanted at our center between Jan 2009 and Dec 2014 and measured the association between 6 month post-transplant 25-OH-vit D and i-PTH levels and clinical outcomes.

Results: Prevalence of 25-OH-vit D levels <15, 15-19.9, 20-29.9, and > 30 ng/ml, was (29.2%, 22.2%, 34.7%, 13.3%) at 6 months, (21.4%, 23.7%, 35.0%, and 19.7%) at 1 year, (14.9%, 21.9%, 41.3%, 21.8%) at 2 years, and (16.8%, 18.5%, 38.5%, 26.2%) at 3 years, respectively. A total of 383 patients were followed up for 3.8 (2.4-5.3) years. There was no difference between the 4 groups in terms of age, sex, race, type of transplant, donor age, donor final creatinine, KDPI score, PRA levels, pretransplant DSA, and type of induction. A negative correlation between 25-OH-vit D and i-PTH levels at 6 months was found to be statistically significant (P<0.0001). Lower 25-OH-vit D levels did not increase risk of graft loss. Patient survival, incidence of acute antibody or T cell mediated rejection, transplant glomerulopathy, development of de novo DSA, incidence of opportunistic viral (CMV and BKV) and fungal infections, malignancy, proteinuria and serum creatinine levels at 1,2 and 3 years post-transplant were found to be similar in the 4 groups.

Conclusions: 25-OH-vit D deficiency is common after kidney transplantation and has a negative correlation with post-transplant i-PTH levels. Low 6 months post renal transplant 25-OH-vit D levels are not associated with decreased allograft survival or function or with increased risk for opportunistic infections/malignancy.

TH-PO926

Validation of Body Composition by Dual-Energy X-Ray Absorptiometry and Bioelectrical Impedance Analysis in Renal Transplant Recipients Thomas J. Wilkinson,[3] Danielle Richler-Potts,[2] Jill Neale,[2] Alice C. Smith.[1] *[1]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom; [2]Leicester Kidney Exercise Team, Leicestershire, United Kingdom; [3]University of Leicester, Leicester, United Kingdom.*

Background: Renal transplant recipients (RTR) experience adverse body composition (BC) changes including obesity and muscle wasting. Aberrant BC is associated with poor physical function and graft recovery, and increased mortality. Measuring BC is vital to understanding health status and comorbidity prognosis. Whilst dual-energy x-ray absorptiometry (DXA) is seen as the gold-standard, bioelectrical impedance analysis (BIA) may be an accessible and cheaper alternative. Formulas using anthropometric data that estimate BC may provide an alternative where DXA or BIA is not available. However, due to fluid and metabolic disturbances as a result of renal impairment, these methods need to be validated. We aimed to assess the validity of BIA and the Hume formula against DXA in RTR.

Methods: 36 RTR (12 females; 52±12 years; eGFR 54±21ml/min/1.73m^2) were measured using DXA and BIA. Estimated lean mass (LM), fat mass (FM), and FM% were compared using regression and Bland-Altman plots. Using only age, sex, height and weight, BC was estimated using the Hume (1966) formula.

Results: BIA showed 'excellent' agreement against DXA (LM *r*=.98, FM .95, FM% .92). Bland-Altman bias showed that BIA tended to marginally overestimate LM (+2.1kg 95% limits of agreement -3.9-8.1), and underestimate FM (-2.1kg -8.6-4.3) and FM% (-3.8% -11.7-4.0). The Hume formula performed exceedingly well against DXA. Regression revealed 'good' to 'excellent' agreement for LM (*r*=.94), FM (.92), and FM% (.79). Like BIA, the Hume formula overestimated LM (+3.5kg -4.7-11.6) and underestimate FM% (-3.8% -11.7-4.0). Remarkably, FM from the Hume was nearly identical to DXA.

Conclusions: Compared to DXA, BIA is a valid and accurate measure of BC. Interestingly, BC (in particular, FM) can be accurately estimated using just age, sex, height and weight. Due to its ease, the Hume formula may provide another method using routinely collected data. As unfavourable BC is associated with adverse outcomes in RTR, it should be routinely measured. In the absence of DXA, BIA or the Hume formula are valid alternatives to estimate BC. Research should investigate the sensitivity of these methods following interventions.

Restless Legs Syndrome (RLS): An Unresolved Uremic Disorder after Successful Renal Transplantation (TXR) Secundino Cigarran,[2] Jesus Calvino,[3] Lourdes Gonzalez tabares,[3] Monica Guijarro,[4] Nicolas Menendez,[2] Carmen R. Cobelo casas,[3] Beatriz Millan,[3] Ana maria Sanjurjo amado,[2] Sonia Cillero,[3] Juan Latorre,[2] maria-jesus Sobrido.[1] *[1]IDIS. Sergas, Santiago Compostela, Spain; [2]Nephrology, Eoxi Cervo-Lugo-Monforte, Burela, Spain; [3]Nephrology, Eoxi Cervo-Lugo-Monforte, Lugo, Spain; [4]Neurology, Eoxi Cervo-Lugo-Monforte, Lugo, Spain.*

Background: RLS is a common disorder of uremia that may improve after TXR. However, RLS frequency might not be as low as expected as some uremic disturbances related with RLS may continue even after a successful graft. The **aim** of this study was to assess the prevalence and related conditions for RLS in TXR.

Methods: A validated questionnaire for RLS study group diagnostic criteria was self-administered by 129 TXR, 82 men and 47 women, aged 57 ± 12.8 years followed in the nephrology clinic for more than one year and with stable renal function (creatinine 1.5 ± 0.54 mg/dL). Patients classified as probable RLS according to the questionnaire underwent a systematic neurological examination in order to exclude RLS mimics.

Results: The frequency of probable RLS according to the questionnaire results was 29.5% (18 men and 20 women). After thorough neurological examination, the diagnosis of RLS was confirmed in 18 patients providing an overall definitive RLS frequency of 14.5% (above the average prevalence reported for the general population). Therefore, RLS diagnosis was established for six men (7.5%) and 12 women (27. 3%). These results rendered a positive predictive value for the self-administered questionnaire remarkably higher for women (60%) than for men (33%) pinpointing a higher rate of RLS mimics among men. Besides gender differences, confirmed RLS cases showed no differences regarding age, diabetes, comorbid disorders, BMI, anticalcineurin therapy, renal function, anemia and time from transplantation. Neither blood pressure nor number of antihypertensive drugs was statistically different though RAAS blockade was significantly less frequent among the confirmed RLS cases (22.2% versus 47.2%). Because of the clear-cut preponderance of women, we performed a separate analysis for females. A poorer renal function estimated by CKD-EPI (52 ± 17.5 vs 42 ± 13.9 ml/min) and a lower phosphate tubular reabsorption rate (75 ± 10.5 vs 65 ± 9.2) characterized women with RLS.

Conclusions: RLS prevalence after transplantation (14.5%) remains high. This condition is twice more prevalent for females. Contribution of RAAS, graft function impairment and phosphate overload for this remarkable prevalence requires further investigation.

Chymase and Neprilysin: Key Regulators of the Renin-Angiotensin System (RAS) in Kidney Allografts Johannes J. Kovarik,[2,5] Christopher Kaltenecker,[2] Chantal M. Kopecky,[3] Oliver Domenig,[6] Marlies Antlanger,[2] Johannes Werzowa,[2] Farsad A. Eskandary,[1] Renate Kain,[2] Marko Poglitsch,[6] Georg Bohmig,[1] Marcus Saemann.[4] *[1]Medical University Vienna, Vienna, Austria; [2]Medical University of Vienna, Vienna, Austria; [3]University of New South Wales, Sydney, NSW, Australia; [4]Wilhelminen Hospital, Vienna, Austria; [5]Division of Clinical Pharmacology, Vanderbilt University, Nashville, TN; [6]Attoquant Diagnostics, Vienna, Austria.*

Background: Angiotensin-converting enzyme inhibitors (ACEis) are well established to be beneficial in patients with heart failure and chronic kidney disease (CKD). Their role after kidney transplantation (KTx), however, remains ambiguous, and the effects of ACEis on plasma and intrarenal metabolites of the 'classical' and 'alternative' renin-angiotensin-system (RAS) in KTx recipients have not yet been studied.

Methods: This prospective study, which was designed to investigate allograft-specific RAS metabolism, included 48 kidney transplant recipients subjected to allograft biopsy for graft dysfunction, progression of proteinuria, and/or DSA detection early (0-24 months; n=14), intermediate (24-144 months; n=18) or late post-KTx (>144 months; n=16).

Results: Patients on ACEi therapy (n=24) had lower plasma levels of angiotensin (Ang) II (p<0.01), but higher levels of Ang I (p<0.05) and Ang-(1-7) (p<0.01) than patients without RAS blockade (n=24). Mass spectrometry-based renal biopsy analysis displayed a 2.8-fold increase in renal Ang II formation, with a stepwise increase from the early to the late biopsy group (p<0.005), paralleled by enhanced chymase activity (early group: 34±29%; late: 54±32%, p<0.005). Renal Ang-(1-7) formation via neprilysin (NEP) was dominant (59±13%) over Ang II-mediated Ang-(1-7) formation (15±10%).

Conclusions: Our study reveals a profound tissue-specific distortion of the RAS within renal allografts in a time-dependent fashion, with chymase and neprilysin being the predominant regulators of the RAS in kidney allografts. While the clinical significance

of these results remains to be determined, a conspicuous role of chymase and neprilysin determining allograft survival may be hypothesized.

Cardiovascular Risk Prediction in Renal Transplant: Post-Hoc FAVORIT Trial Analyses Theresa I. Shireman,[2] Basma O. Merhi,[1] Jessica A. Ogarek,[2] Andrew Bostom.[3] *[1]Nephrology, Rhode Island Hospital, East Greenwich, RI; [2]Center for Gerontology and Health Care Research, Brown University, Providence, RI; [3]Memorial Hospital of Rhode Island, Chepachet, RI.*

Background: Cardiovascular disease (CVD) is the leading cause of mortality and kidney graft failure in renal transplant recipients (KTR), but predictive risk algorithms consistently underestimate the incidence of arteriosclerotic outcomes.

Methods: We conducted a secondary analysis of data from the Folic Acid for Vascular Outcome Reduction in Transplantation (FAVORIT) randomized clinical trial. Measures included traditional CVD risk factors along with an expanded list of variables clinically important for KTRs, such as baseline phosphorus, cholesterol (HDL, LDL, remnant), triglycerides, graft vintage, donor type, glomerular filtration rate (eGFR), albumin-to-creatinine ratio (ACR), and diastolic (DBP) and systolic blood pressure (SBP). The cohort was split into training (2/3) and validation (1/3) samples after excluding individuals with pre-existing CVD. After deriving the most parsimonious risk calculator for the clinically adjudicated CV endpoint (CVE) in the training sample, we then applied the risk score to the validation sample and assessed model fit with area under the curve (c-statistic). Secondary outcomes, all-cause mortality (ACM) and graft failure, were also modeled using the CV risk score.

Results: From the training sample (n=1,892), key variables associated with CVD endpoint were age, smoking status, diabetes, living donor, eGFR ≥ 45, ln(ACR), DBP (<70) and SBP (>140). Combined with race and gender, the c-statistics for the training model was 0.754 for CVD endpoint, 0.762 for all-cause mortality, and 0.83 for graft failure. The model results from the validation sample generated c-statistics of 0.666 (CVE), 0.682 (ACM), and 0.643 (graft failure).

Conclusions: Important kidney transplant related risk factors (donor type, eGFR, and ACR) add significantly to cardiovascular risk prediction that include more typical measures. Further testing in other cohorts is needed to validate our findings and strengthen the model.

Hospital Readmissions in Kidney Transplant Recipients with Peripheral Vascular Disease Michelle L. Lubetzky,[3] Layla Kamal,[4] Maria Ajaimy,[4] Puneet Bedi,[1] Enver Akalin.[2] *[1]Brookdale University Hospital Medical Center, Brooklyn, NY; [2]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY; [3]Medicine, Montefiore Medical Center, New York, NY; [4]Montefiore Medical Center, Bronx, NY.*

Background: The benefits of kidney transplantation (KTx) in diabetic patients with peripheral vascular disease (PVD) are unclear. While patients may have improved survival compared to dialysis, the burden of care post KTx has not been assessed.

Methods: We performed a review of diabetic patients with and without PVD transplanted from January 2012 to June 30, 2015. Data on readmissions, re-operations and length of stay was collected. Patient and graft survival was assessed.

Results: Of 203 diabetic patients reviewed 56 (27.6%) had PVD and 147 no PVD. There was no difference in age, sex, race, or type of KTx between the two groups. At a median of 3.14 years follow up (range 30, 1947) there was no difference in 30 or 90 day readmissions between the groups, however significantly more PVD patients were admitted at 1 year (p=0.03), Figure 1. Additionally, PVD patients spent significantly more time in hospital at 1 year (p=0.03). More patients with PVD had re-operations at 90 days and 1 year (p<0.01, p<0.01). Overall graft survival was worse in diabetic patients with PVD although this was not significant (93.2% versus 85.7% p=0.1). Patients with PVD who were re-admitted had significantly worse graft survival than patients with PVD who were not readmitted (100% vs 78.9% p=0.04, Figure 2).

Conclusions: Diabetic patients with PVD have worse graft survival than those without PVD and utilize more resources after KTx with significantly longer length of stays and more re-operations. Readmission in KTx patients with PVD portends poor graft survival.

Table 1

	NO PVD	PVD	P value
Time to first readmission (days, mean±SD)	192±272	217±268	0.59

De Novo Heart Failure after Kidney Transplantation: Trends in Incidence and Outcomes Colin R. Lenihan,[3] Sai Liu,[2] Anita Deswal,[1] Maria E. Montez-Rath,[3] Wolfgang C. Winkelmayer.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Stanford University, Santa Clara, CA; [3]Stanford University School of Medicine, Palo Alto, CA.*

Background: Older US data indicate that heart failure (HF) occurs in 18% of patients in the 3-years following kidney transplant. Herein, we sought to explore secular trends in the incidence of de novo post-kidney transplant HF and its associated mortality.

Methods: We identified adult patients who underwent their first kidney transplant in the US between 1998 and 2010. We required that patients had ≥6 months of continuous Medicare parts A and B coverage prior to transplant. HF diagnosis was ascertained using ICD-9 diagnosis codes. Patients with a diagnosis of HF prior to transplant were excluded from the cohort. Cox models were employed to examine secular trends in 1) de novo post-kidney transplant HF and 2) mortality following de novo post-transplant HF diagnosis. Calendar year of transplant was the primary exposure of interest.

Results: 48,771 patients met the study inclusion criteria. Age at transplant, BMI, dialysis vintage and the prevalence of several baseline comorbidities increased between 1998 and 2010. 7269 patients developed HF within 3 years of kidney transplantation with a median time to HF of 0.76 years and an incidence rate of 6.2 per 100 person-years. When adjusted for demographic, comorbid, and transplant-related characteristics the incidence of de novo post-transplant HF was 31% lower for patients transplanted in the year 2010 compared to those transplanted in 1998 (HR 0.69; CI 0.60-0.79; **Figure 1**). However, we observed no temporal trend in adjusted mortality following de novo post-transplant HF diagnosis.

Conclusions: When adjusted for demographic and clinical characteristics, the incidence of de novo post-kidney transplant heart failure has declined significantly during the period from 1998 to 2010, with no apparent change in subsequent mortality.

TH-PO932

NT-proBNP as a Predictor of Major Cardiac Events in Renal Recipient Patients Carola-Ellen Kleine,[3] Roxana Werberich,[4] Louisa Werberich,[5] Dominik Boes,[6] Felix Hundt,[2] Rainer Woitas.[1] *[1]Nephrology, University Hospital of Bonn, Bonn, Germany; [2]Nephrology, University Hospital of Bonn, Bonn, Germany; [3]Nephrology, University Hospital of Bonn, Bonn, Germany; [4]Nephrology, University Hospital of Bonn, Bonn, Germany; [5]Nephrology, University Hospital of Bonn, Bonn, Germany; [6]Nephrology, University Hospital of Bonn, Bonn, Germany.*

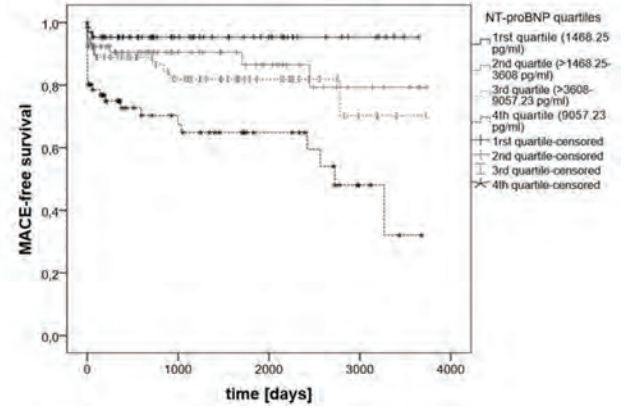
Background: Patients on renal replacement therapy have an increased cardiovascular risk. NT-proBNP is an established marker for cardiovascular risk and mortality in the general population. In a small cohort of kidney transplant patient NT-proBNP was significantly higher in patients suffering from major cardiac events (MACE). We aimed to further investigate NT-proBNP as a predictor of MACE in renal transplantation.

Methods: The study cohort consisted of 264 patients that were kidney transplanted between 01/2005-05/2015. MACE was defined as myocardial infarction (ST-segment elevation (STEMI) or non ST-segment elevation (NSTEMI)), stroke, intervention requiring coronary artery disease (CAD) or cardiovascular death. Blood samples were drawn prior to the kidney transplantation. Mann-Whitney *U* tests, multivariate Cox regression and Kaplan-Meier survival analysis were performed. Before, age, NT-proBNP, creatinine and C-reactive protein (CRP) were logarithmic transformed.

Results: The cohort consisted of 60.6% male patients, median age was 54 years. Mean observation time lasted for 3.2 years. 17.4 % of the patients suffered of MACE: 74% NSTEMI, each 11% STEMI and CAD and 2% cardiovascular death. Recipients with preoperative NT-proBNP greater 9057.3 pg/ml (4th quartile) had a significant greater risk to develop MACE (p<0.05) (Figure 1). After adjustment to age, sex, diabetes mellitus, preexisting CAD, hypertriglyceridemia, cholesterolemia, peripheral occlusive disease, atrial fibrillation, arterial hypertension, creatinine and CRP, NT-proBNP remained an independent risk factor (HR 3.81, 95% CI 2.04-7.12, p=0.000).

Conclusions: In our cohort of renal transplant recipients NT-proBNP proved to be an independent predictor of MACE. NT-proBNP level at the time of transplantation may identify patients at greater risk for cardiovascular complications.

Figure 1. MACE-free survival according to NT-proBNP quartiles



TH-PO933

Early Initiation of ACE Inhibitors in the Post Renal Transplant Period: A Study from a State Run Tertiary Care Centre Umesh L. *NEPHROLOGY, INSTITUTE OF NEPHROUROLGY, BANGALORE, India.*

Background: Angiotensin converting enzyme inhibitors (ACEI) comprise drug class, which inhibit the effects of angiotensin II by blocking the synthesis of same. Angiotensin converting enzyme inhibitors (ACEI) are well documented to be potent anti-hypertensives with renoprotective effects but are grossly underutilized in renal transplant recipients. However, these drugs have been reported to cause elevated potassium and creatinine levels in some renal transplant patients. There have been no reports of prospective studies of ACEI in renal transplant patients in the early posttransplant period. The purpose of this study is to assess the safety of an ACEI class, when started in early posttransplant period.

Methods: This study is a Prospective observational study. We reviewed 78 kidney transplant patients during the period of January 2012 to march 2017 at our institution. 64 patients were initiated on ACEI therapy within a month of post- transplant. Patients were considered to be enrolled when they met the following criteria: Declining serum creatinine, improving urine output and serum potassium < 5.5 mEq/L. Exclusion criteria: anaphylaxis to ACEI, use of ACE or ARB for treatment of posttransplant erythrocytosis and serum potassium >5.5 mEq/L.

Results: 64 Patients were studied, 53(83%) were male and 11(17%) were females. Mean age was 32±15 years (12-56). Minimum duration of follow up was 6 months. For each patient haemoglobin, serum creatinine and potassium levels were analyzed at the beginning of ACE inhibitors and at the end of the first, third, sixth month. Average potassium levels, hemoglobin levels did not differ significantly between groups and were in normal clinical ranges. While incidence of graft failure did not differ, death with functioning graft was lower in the ACEI group.

Conclusions: ACEI can be used successfully in post-renal transplant with beneficial long term impact on renal function. There is need for further randomized controlled studies to see the effect of ACEI on Graft function and its survival.

Funding: Government Support - Non-U.S.

TH-PO934

Changes in Renal Function in Patients Bridged to Heart Transplantation with a Continuous-Flow Left Ventricular Assist Device (LVAD): Analysis of 2480 Patients Nissreen Elfadawy,[1] Sadeer Al-Kindi,[2] Anne M. Huml,[1] Guilherme H. Oliveira.[2] *[1]Division of Nephrology, Department of Medicine, University Hospitals Cleveland Medical Center, Cleveland, OH; [2]Harrington Heart and Vascular Institute, University Hospitals Cleveland Medical Center, Cleveland, OH.*

Background: Left ventricular assist devices (LVADs) have become an established option for patients with end-stage heart failure. The impact of LVAD on renal function is not widely studied and remain controversial. **Objectives:** The aim of this study was to determine the impact of LVAD implantation on renal function in patients with end-stage heart failure and discover risk factors associated with renal dysfunction in these patients

Methods: We used the United Network Of Organ Sharing registry (UNOS) to identify adult patients who are bridged to heart transplantation with HeartMate II or Heartware continuous-flow LVADs from 2007-2015. We excluded patient on dialysis, intra-aortic balloon pumps, extra-corporeal membrane oxygenation, or inotropes. Calculated glomerular filtration rate (GFR) using CKD-EPI formula was assessed at listing and prior to heart transplantation. Significant change in GFR at time of transplantation was defined ≥10 ml/min/1.73 m2 change from baseline. Predictors for worsening in GFR were examined by multivariable logistic regression model.

Results: A total of 2480 patients were included, mean age 54±12 years, 80% were male, 36% were status 1A, and 45% had ischemic cardiomyopathy. Mean time on wait-list was 192 days. Mean baseline GFR was 76±26, mean GFR at time of HTx was 72±26 (p<0.001). Overall, 31% (n=788) showed significant worsening in GFR. Risk factors for worsening GFR were older age (1.03 [1.02-1.04] per year, P<0.001), longer time on wait-list (1.001 [1.000-1.001] per day, P=0.001), higher PCWP (1.02 [1.01-1.03] per 1 mmHg, P<0.001), and higher baseline GFR (1.04 [1.03-1.04] per 1 ml/min/1.73 m2, P<0.001)

Conclusions: Approximately one third of candidates for heart transplantation experience significant GFR worsening after LVAD implantation. Older age, longer wait time, and higher baseline GFR are significant risk factors

TH-PO935

The Change in Carotid Arterial Inflammation in De Novo Renal Transplant Recipients as Assessed by 18F-FDG PET/CT Hye Eun Yoon,[1,3] Yaeni Kim,[1,3] Chul Woo Yang,[2,3] Yong-Soo Kim,[2,3] Seok Joon Shin.[1,3] *[1]Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, INCHEON, Republic of Korea; [2]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [3]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Chronic kidney disease (CKD) is associated with an increased risk of cardiovascular disease, and characterized by increased inflammation. Inflammatory activity of the arterial wall can be assessed by measuring ^{18}F-fluorodeoxyglucose (^{18}F-FDG) uptake with positron emission tomography computed tomography (PET/CT). Data on change in arterial inflammation in CKD patients after renal transplantation are not available to date. This study investigated the change in the inflammatory activity in carotid artery after renal transplantation in CKD patients.

Methods: We assessed ^{18}F-FDG uptake, quantified as target-to-background ratio (TBR), in the right and left carotid arterial walls in 10 CKD patients. ^{18}F-FDG PET/CT was performed before transplantation and at post-transplantation 4 months. TBR was evaluated in the whole carotid artery (WH) and most diseased segment (MDS). Most diseased segment (MDS) was defined as the 1.5-cm arterial segment, centered on the slice of artery demonstrating the highest ^{18}F-FDG uptake at baseline. WH-TBRmax was calculated as the mean of maximum TBR values for all of the whole carotid artery segments, and WH-TBRmean was calculated as the mean of averaged TBR values of the whole carotid artery segments. MDS-TBRmax was calculated as the mean of maximum TBR values derived from 3 contiguous axial segments of the MDS, and MDS-TBRmean was calculated as the mean of averaged TBR values of the MDS segment.

Results: Eight patients showed a reduction in right Whole-TBRmax and WH-TBRmean, and left MDS-TBRmean, WH-TBRmax, and WH-TBRmean. Seven patients showed a reduction in right MDS-TBRmax and MDS-TBRmean, and left MDS-TBRmax. There was a tendency of reduction in right WH-TBRmax MDS-TBRmax, and MDS-TBRmean (% reduction [95% CI]: -6.50% [-12.81, 1.54]; -4.06% [-13.42, 9.38]; -4.47% [-13.64, 7.29]) and in left WH-TBRmax, WH-TBRmean, MDS-TBRmax, and MDS-TBRmean, (% reduction [95% CI]: -6.13% [-15.17, 8.32]; -8.37% [-17.62, 6.56]; -6.14% [-14.53, 7.01]; -7.29% [-17.91, 4.18]). The right Whole-TBRmean was significantly reduced from baseline (% reduction [95% CI]: -5.74% [-15.37, -0.02], P = 0.047).

Conclusions: The ^{18}F-FDG uptake of WH and MDS were reduced after renal transplantation. Renal transplantation may confer an anti-inflammatory effect on carotid atherosclerosis in CKD patients.

Extracellular Fluid Excess Is Significantly Associated with Coronary Artery Calcification in Kidney Transplant Recipients Seohyun Park,[2] Arum Choi,[1] Heebyung Koh,[2] Jaeyeol Kwon,[2] Tae-Hyun Yoo.[2] *[1]Department of Internal Medicine, College of Medicine, Severance Biomedical Science Institute, Brain Korea 23 PLUS, Yonsei University, Seoul, Republic of Korea; [2]Department of Internal Medicin, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Republic of Korea.*

Background: Coronary artery calcification (CAC) is associated with increased mortality in CKD patients and does not regress after kidney transplantation. Extracellular fluid excess measured by bio-impedance analysis (BIA) is also associated with adverse clinical outcomes in kidney transplant recipients (KTR). Present study is aimed to identify the relationship between extracellular volume status and CAC in KTR.

Methods: We evaluated 123 KTR of CMERC-HI (Cardiovascular and Metabolic Disease Etiology Research Center-High Risk, NCT02003781), a prospective observational cohort study of high risk patients with cardiovascular disease. Extracellular volume status was assessed by BIA and extracellular fluid excess (EFE) was defined if the ratio of extracellular water and total body water (ECW/TBW) was more than 0.390. CAC was measured by multi-detector CT and CAC ≥400 was considered as a calcified coronary artery.

Results: In this study, fifty-four (43.9%) patients showed excess with body fluid. Compared with non-EFE group, EFE group was older and had a longer time on KT, a longer duration of previous dialysis, and a lower estimated glomerular filtration rate (eGFR). The CACS and the proportion of calcified coronary artery were significantly higher in the EFE group. In logistic regression analysis, EFE was significantly associated with calcified coronary artery. Moreover, EFE was found to be independently associated with calcified coronary artery after adjustment for multiple confounders (Odds ratio; 4.327, 95% confidence interval; 1.309 – 14.298, P = 0.016).

Conclusions: Our study demonstrated that extracellular volume excess was significantly associated with CAC in KTR. Present study suggests that EFE might be a risk factor for cardiovascular disease in KTR.

TH-PO937

Hypertension, Renal Function, and Histologic Changes in Living Kidney Transplant Recipients from Hypertensive Donors Thomas Dienemann,[4] Jana Schellenberg,[2] Kerstin U. Amann,[5] Christoph Daniel,[3] Katharina M. Heller.[1] *[1]Friedrich - Alexander University Erlangen - N?rnberg, Erlangen, Germany; [2]Uniklinikum Erlangen, Nürnberg, Germany; [3]University Erlangen-Nürnberg, Erlangen, Germany; [4]Nephrology and Hypertension, University of Erlangen, Erlangen, Germany; [5]Department of Pathology, University of Erlangen, Erlangen, Germany.*

Background: Due to the ever-increasing organ shortage, centers increasingly accept living kidney donors with preexisting hypertension despite concerns over donor safety for over two decades. Data on outcomes in recipients of such kidneys of hypertensive living donors is very limited. In the present study, we examined we examined whether use of hypertensive living kidney donors associates with kidney function, blood pressure and histologic changes at transplantation and one year after transplantation in living kidney transplant recipients

Methods: Retrospective single center analysis of 182 living kidney transplant recipients (age>18; transplant date 2008-2015). Hypertension in donors was defined as ABPM above 135/85 or ≥1 BP medication. Recipients eGFR was measured at 1 year using the MDRD equation. All renal biopsies were examined by a blinded pathologist using the recently advocated total renal chronicity score (TRCS). Logistic regression models adjusted for multiple potential confounders were used to examine the relationship of hypertensive donor on blood pressure and renal function in recipients.

Results: One year follow up was complete in 180 patients including a biopsy at transplant, in 131 patients a protocol biopsy 12 months after transplant was also available. 138 recipients had normotensive donors (dNT), 42 recipients had hypertensive donors (dHT). There were no differences in age, sex, BMI, and eGFR between recipients from dNT and dHT. Average systolic and diastolic blood pressure in dHT was significantly higher (131/76 vs 119/72 mmHg in dNT, p < 0.001 for both). Adjusted for multiple confounders there was no difference in blood pressure, number of antihypertensive drugs, and eGFR in recipients at 1 year. The TRCS showed no difference at time of transplant and at 1 year after transplantation

Conclusions: In our cohort, recipients of a living kidney transplant from hypertensive donors showed no differences in blood pressure, renal function or the TRCS after a 1 year follow up. Prudent selection in terms of accepting hypertensive donors remains mandatory. However longer follow up data is needed to assess potential long term effects which might affect the commonly superior results of living kidney transplantation in recipients of such kidneys.

TH-PO938

Allograft Rescued from Pseudo Transplant Renal Artery Stenosis Gunjan Garg, Laura H. Mariani, Milagros D. Samaniego-Picota. *University of Michigan, Ann Arbor, MI.*

Background: Transplant renal artery stenosis (TRAS) is a common vascular complication typically occurring 3-24mos post-transplant and may be due to surgical technique or size discrepancy between donor and recipient arteries. As the transplant population ages, there is increasing recognition of pseudo-transplant renal artery stenosis, in which vascular disease proximal to the arterial anastomosis results in graft failure. Here we present a rare case of late acute allograft failure secondary to pseudo-TRAS.

Methods: A 53 yo woman with diabetes, hypertension, smoking, without known peripheral vascular disease, who underwent a living unrelated kidney transplant 5yrs ago for PKD, presented with 4 days of graft tenderness and decreased urine output. Physical exam showed BP of 183/94 and tenderness over the left lower quadrant allograft. UA was negative for blood, protein or leukocytes. Serum Creatinine was 7.1 mg/dL (baseline 1.2 mg/dL). She reported compliance with immunosuppressants. A transplant ultrasound with Doppler showed 11.4cm kidney without hydronephrosis, although a parvus tardus waveform (Fig) was seen in the transplant renal artery with low resistive indices. A CO2 angiogram showed complete left common iliac (CIA) and proximal external iliac artery (EIA) occlusion with almost no flow to the transplant renal artery. Left CIA was stented with improved flow to the graft without any pressure gradient. Within 72 hrs, creatinine was 1.8 mg/dL and 1.2 mg/dL in 2 wks.

Results:

Conclusions: TRAS is a potentially reversible cause of graft dysfunction in early post transplant period, but patients with CVD risk factors can develop pseudo-TRAS in the iliac vessels as a late complication. Early detection can prevent complete graft loss. Transplant renal artery Doppler can show parvus tardus waveform, prolonged systolic acceleration with small amplitudes and blunting of the systolic peak suggesting poor arterial inflow to the kidney. Prompt intervention within 24 hrs of initial presentation, in our case, successfully rescued the allograft.

TH-PO939

Sodium/Glucose Cotransporter 2 (SGLT2) Inhibitor for Diabetic Kidney Transplant (KT) Patients Hyuk yong Kwon, Jin M. Kong. *Nephrology, BHS-Hanseo hospital, Busan, Republic of Korea.*

Background: SGLT2 inhibitor is a newly introduced hypoglycemic drug that inhibits glucose reabsorption at proximal tubule. A recent RCT in diabetic CKD patients showed a long-term renoprotective effect, by a decrease in hyperfiltration as a consequence of increased distal sodium delivery with tubuloglomerular feedback. This result seems relevant to KT patients where reduced nephron mass may suffer from hyperfiltration that jeopardizes long term graft survival. But the experience of this drug in KT patients is limited and there are concerns of lower urinary tract infection and acute graft dysfunction due to volume depletion by osmotic diuresis as well as reduction in intraglomerular pressure. The aim of this study is to evaluate the safety and efficacy of SGLT2 inhibitor in KT patients.

Methods: Twenty-five KT patients were treated with dapagliflozin 5mg/d. Three patients had type 1 DM and 7 had NODAT. Sixteen patients were on insulin with or without oral agents. Median posttransplant months were 72(9-262). Diuretics were stopped before the initiation of study drug.

Results: Baseline HbA1c was 7.9±1.3%, decreased significantly at 3(7.4±1.1%, p=0.01) and 6(7.4±1.0%) months(M). Body weight decreased significantly from 72.2±22.1 to 68.1±22.0(p=0.001)kg at 12M. Two patients could stop insulin and another 4 patients could reduce ≥20% dose of insulin. eGFR did not change significantly (71.1±20.1ml/min at baseline, 71.5±25.8 at 12M). Clinically apparent acute graft dysfunction was not observed. Office blood pressure also was not changed significantly but 10 of 24 patients had a decrease in number and/or dose of anti-hypertensives. No significant change in urine albumin-creatinine ratio at 1 year. Six patients discontinued study drug due to acute cystitis in 2, weight loss in 1 and lack of efficacy in 3.

Conclusions: SGLT2 inhibitor seems to be beneficial in glucose control of KT patients, with acceptable safety profile. Further studies are clearly needed to determine the possible long-term renoprotective effect in this patient population.

TH-PO940

Diabetes Weighted Genetic Risk Scores and Prediction of New Onset Diabetes after Kidney Transplantation Kelly A. Birdwell,[1] M. Lee Sanders,[2] Digna R. Velez edwards,[1] Talat Alp Ikizler,[1] Ayush Giri.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: New onset diabetes after transplantation (NODAT) is associated with increased cardiovascular events and mortality, but the underlying pathogenesis is not well understood. We examined the genetics of NODAT in kidney transplant recipients using genetic risk scores constructed from previously identified single nucleotide polymorphisms (SNPs) for type 1 and type 2 diabetes in the general population to observe if NODAT overlaps with these disorders genetically.

Methods: Our study cohort included 54 cases and 248 controls, all European American, identified through our prior genome-wide association study completed using Illumina OMNI1 or OMNI5 platforms. Genetic risk scores (GRS) for type 1 and type 2 diabetes were created using SNPs published in the literature. GRS are used as a tool to summarize risk-associated SNPs across the genome to improve prediction of polygenic diseases. For type 1 diabetes, 3 GRS were created: 1) Full, with 25 type 1 SNPs and 3 HLA SNPs 2) Non-HLA, with 25 type 1 SNPs 3) HLA-only, with 3 HLA SNPs. For type 2 diabetes, 65 SNPs were used. All SNPs were from independent loci. Both non-weighted and weighted GRS were created. Logistic regression models were run using NODAT as the dependent variable and GRS as independent variables, with and without adjustment for covariates (sex, BMI, steroid use, and CMV infection).

Results: The cohort mean age was 42.4 years and 59.9% female. Weighted type 1 GRS, both Full and HLA-only, were significantly associated with NODAT in unadjusted and adjusted analyses. The odds of having NODAT was 1.25 times higher (OR 1.25, 95% CI 1.03-1.53, p = 0.03) in the weighted adjusted Full model, and similarly was 1.25 times higher (OR 1.25, 95% CI 1.01-1.534 p = 0.04) in the weighted adjusted HLA-only model, for each unit increase in weighted GRS score. Noteworthy associations were not observed using the type 1 Non-HLA GRS or the type 2 GRS.

Conclusions: Kidney transplant recipients with NODAT have genetic variants that are associated with those SNPs that predict type 1 diabetes but not type 2. This suggests the underlying pathogenesis might reflect more of a type 1 mechanism.

Advanced Glycation End Products (AGEs) by Skin Autofluorescence (SAF) in Renal Transplant (TxR): Risk and Influence in Clinical Practice Secundino Cigarran,[1] Lourdes Gonzalez tabares,[2] Nicolas Menendez,[1] Juan Latorre,[1] Carmen R. Cobelo casas,[2] Beatriz Millan,[2] Nuria C. López,[1] Sonia Cillero,[2] Ana maria Sanjurjo amado,[1] Jesus Calvino.[2] *[1]Nephrology, Eoxi Cervo-Lugo-Monforte, Burela, Spain; [2]Nephrology, Eoxi Cervo-Lugo-Monforte, Lugo, Spain.*

Background: AGEs accumulation constitute a vascular pathogenic mechanism involved in aging, diabetes and chronic kidney disease (CKD) moreover of being a measure of cumulative metabolic stress. Despite removal of uremic toxins&AGEs after a succesful TxR, cardiovascular disease (CVD) remains the leading cause of mortality. Our aim was to evaluate AGEs by SAF in TxR and its relation with markers associated to CV risk.

Methods: 191 stable TxR were analyzed (38.7% women, aged 56±13.1 years). All were on CKD stages1-4 and > 12 months of transplantation. Variables assessed: diabetes, CVD history, subclinical atheromatosis by arm-ankle-index and allograft resistivity index, 24-h ABPM, anthropometric and nutritional markers (including dynamometry), biochemical (hemoglobin, albumin, transferrin, CKD-EPI, Ca, P, iPTH, vitamin D and C reactive protein). Urinalysis included ACR (mg/gr) and phosphorus tubular reabsortion (RTP,%). AGEs were measured by SAF. Vascular age was estimated by Koetsier formula (AFD-0.83/0.024) and estimated 10-years cardiovascular death risk by REGICOR formula.

Results: Mean SAF was 2.99±0.83 UA and estimated vascular age was 90±34.6 years (30 years above biological). After univariable analysis, SAF was higher in men (3.1±0.90 vs 2.8±0.67, p<.001), diabetic (3.2±0.86 vs 2.9±0.81, p<.001) and steroids use (3.1±0.91vs2.7±0.71 p<.001). A positive correlation with night SBP (r=0.240 p<.005), iPTH (r=0.210 p<.001), P (r=0.300 p<.005) and negative with hemoglobin (r=-0.310 p<.005), CKD-EPI (r=-0.350 p<.005) & RTP (r=-0.263 p<.005). Nutritional parameters&AGEs showed a negative correlation with albumin, transferrin, arm circumference & dynamometry (r=-0.200 p<.005). AGEs also showed correlation with subclinical vascular atheromatosis as well as with REGICOR scale (r=0.400 p<.001). After multivariate analysis significant variables were:age, male, steroid use, P and dynamometry.

Conclusions: SAF is a validated, economic, and non-invasive tool to assess cardiovascular risk in TxR.Besides age and male gender, our results suggest that P overload, steroid use and nutritional status are the main significant determinants that promote AGEs accumulation. Further longitudinal studies are required in order to confirm this hypothesis.

The Impact of Hyperuricemia in Transplanted Kidney in Women Yasuyuki Nakada,[1] Izumi Yamamoto,[1] Haruki Katsumata,[1] Kohei Unagami,[2] Masayoshi Okumi,[2] Hideki Ishida,[2] Takashi Yokoo,[1] Kazunari Tanabe.[2] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Department of Urology, Tokyo Women's Medical University, Tokyo, Japan.*

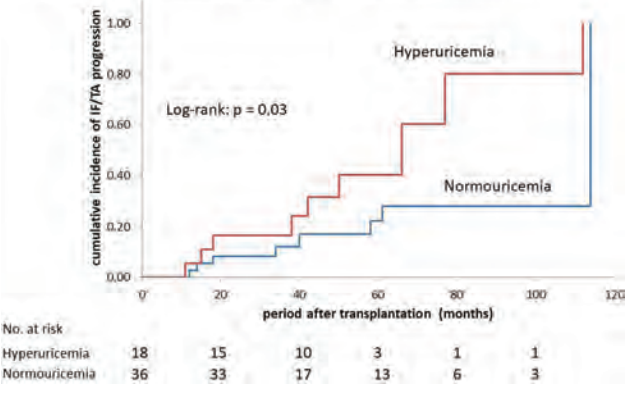
Background: The progression of arteriolar hyalinosis (AH) and interstitial fibrosis / tubular atrophy (IF/TA) is closely associated with graft failure in patients with kidney transplantation. Several clinical factors (aging, hypertension, diabetes, calcineurin inhibitor) influence this mechanism but the significance of hyperuricemia (HUA) was not fully understood. We here postulated that the HUA could influence AH and IF/TA progression in kidney allograft recipients.

Methods: We evaluated 126 recipients who received kidney transplants from January 2005 to December 2009 at the Department of Urology, Tokyo Women's Medical University. Patients with diabetes mellitus were excluded. AH and IF/TA progression were defined if Banff scores inceased more than one. HUA was defined as serum UA >7.0 mg/dL in males and >6.0 mg/dL in females. Survival analysis methods including Kaplan-Meier and Cox Proportional Hazard Model were used to evaluate the independent association of the UA burden over time (the average annual level of s-UA) with pathological progression, after adjustment for baseline covariates (age, gender, BMI, blood pressure, serum CNI concentration, baseline UA in serum).

Results: Hyperuricemic recipients were shown to have a higher cumulative progression of IF/TA (log-rank: $p = 0.01$) but not AH (log-rank: $p = 0.76$). HUA was found to be a significant predictor for the progression of IF/TA (HR: 1.71, p = 0.01). These trends were observed only in females (log-rank: $p = 0.03$) but not in males (log-rank: $p = 0.19$).

Conclusions: The impact of HUA on pathological deterioration is greater in females than males, suggesting the importance of more cautious management of HUA in females.

Figure. 1 The cumulative incidence of IF/TA progression in females



TH-PO943

Physical Frailty and Cognitive Change Among Kidney Transplant Recipients Nadia M. Chu,[1] Alden L. Gross,[1] Qianli Xue,[2] Karen J. Bandeen-roche,[1] Richey Sharrett,[2] Michelle C. Carlson,[1] Dorry L. Segev,[2] Mara McAdams-DeMarco.[2] *[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD.*

Background: With restoration of kidney function, kidney transplant (KT) recipients may experience preserved or improved cognitive function. However, KT recipients have a higher burden of frailty at the time of KT, and frail recipients may not experience this potential benefit. The goal of this prospective study was to assess post-KT cognitive trajectories by frailty status (12/2008 – 12/2016).

Methods: Participants completed a physical frailty exam (five Fried criteria) and global cognitive testing (3MS) at time of KT-admission, as well as at least one cognitive test during post-KT. We used a mixed effects model adjusted for follow-up time, age, sex, race, donor type, and 3MS score at time of KT with a random slope (time) and intercept (person) to describe multiple 3MS scores post-KT by frailty status.

Results: Of 665 KT recipients (mean age 52 years) followed for a mean of 2.2 years (3.7 visits), 15.2% were frail, and the mean 3MS score was 92.5 at time of KT. In the first month post-KT, non-frail recipients experienced a significantly greater rate of cognitive improvement (0.53 points-per-week, 95% CI: 0.33, 0.73), however there was no evidence

of such an improvement among frail recipients (0.20 points-per-week, 95% CI: -0.35, 0.75). Rates of cognitive change among non-frail KT recipients continued to increase 1-3 months post-KT, and plateaued thereafter through 1 year post-KT. Frail individuals did not significantly improve anytime during the year post-KT.

Conclusions: In conclusion, frailty is associated with mitigated improvement in global cognition post-KT. Frail recipients may benefit from interventions to improve cognitive function after KT.

Funding: NIDDK Support

TH-PO944

High Hemoglobin Levels Maintain Graft Function in Japanese Kidney Transplant Recipients Makoto Tsujita. *Nagoya Daini Red Cross Hospital, Nagoya, Japan.*

Background: Post transplant anemia is an important factor for graft survival in kidney transplant recipients. But how we should manage hemoglobin (Hb) values for better graft survival in Japanese recipients, remains unknown.

Methods: This was an open-label, randomized controlled trial to demonstrate high Hb values on graft function. One hundred twenty six stable recipients were randomized into two groups - Hb normal group (12.5-13.5 g/dL, n=65) and Hb subnormal group (10.5-11.5 g/dL, n=61). Either Darbepoetin alfa or Epoetin beta were included in the study from January 2012 to March 2014 at Nagoya Daini Red Cross Hospital and Masuko Memorial Hospital. Primary endpoint was the difference between both groups rate of decline in kidney function.

Results: During the course of this study, 12 patients dropped out. At baseline, the mean age was 49.7 and 49.6 years old, eGFR was 35.4 and 35.9 ml/min/1.73m2, and Hb 11.3 and 11.2 g/dL in Hb normal group (n=59) and subnormal groups (n=55), respectively. After 24 months(M), the mean Hb was 12.6 and 11.2 g/dL(p<0.001), the eGFR was 34.8 and 32.7 ml/min/1.73m^2 (p=0.27). Figure1 showed a change of eGFR from baseline eGFR (ΔeGFR). From baseline to 24M, the eGFR decreased by a mean 0.1 and 3.7 ml/min/1.73m2(p=0.02). Patients who doubled their serum creatinine levels and reached end stage renal disease were not found. Also no cardiovascular event and acute rejection occurred in both groups.

Conclusions: This study shows that high Hb values might be more impactful on graft function in Japanese kidney transplant recipients.

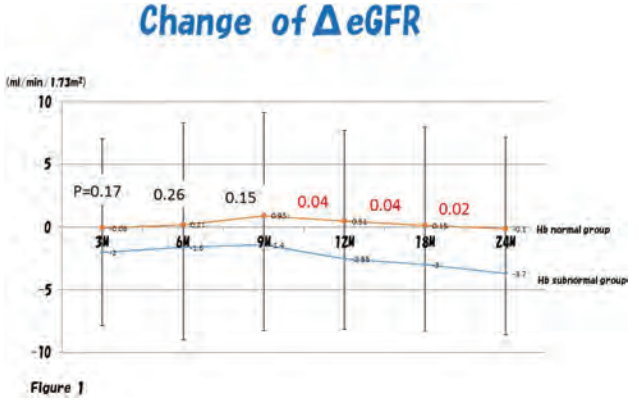

Figure 1

TH-PO945

Relationship of Magnesium and Insulin Resistance in Living Donor Kidney Transplant Recipients Joy V. Nolte,[2] Biruh Workeneh,[3] Linda W. Moore,[2] Marie C. Gabour,[4] Ahmed O. Gaber,[2] William E. Mitch.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Houston Methodist Hospital, Houston, TX; [3]MD Anderson Cancer Center, Houston, TX; [4]UMASS Boston, Lexington, MA.*

Background: Magnesium (Mg) is an important cofactor for blood glucose control and energy metabolism. Decreased Mg stores have been correlated with increased insulin resistance (IR) in diabetes and chronic kidney disease. It is difficult to assess total magnesium stores because serum Mg does not necessarily correlate with total body magnesium. Dietary intake of Mg before and after kidney transplant (KT) has not been heretofore described.

Methods: We sought to determine differences in Mg intake before and after KT. We analyzed 31 subjects who completed the ASA24 24hr dietary recall and oral glucose tolerance tests (OGTT) <1 month prior to transplant and 3 months post-transplant. Subjects were noninsulin dependent at KT, mostly male (84%) and an average age of 48yo. IR was indicated by Matsuda Index (MI). Spearman's correlation (ρ) and mixed model statistics were used.

Results: Dietary recalls revealed most subjects consumed inadequate Mg pre- and post-KT(Table 1); however, serum Mg (SMg) remained within range for 83% pre-KT and 90% post-KT. Mean SMg decreased 0.23mg/dL despite increased dietary intake. Neither calcinuerin dose nor trough correlated with SMg post-KT. SMg, but not dietary Mg, correlated with fasting insulin and MI at baseline but did not reach significance (ρ= -0.346, P=0.056 and ρ=0.332, P=0.068). IR significantly correlated with weight (PE= -0.087, P=0.0003), waist circumference (PE= -0.096, P<0.0001), and BMI (PE= -0.119, P=0.032) over time but not serum or dietary Mg intake (ρ=0.001, P=0.61).

Conclusions: We found that pre-KT patients do not consume sufficient dietary Mg and a significant number were insulin resistant. Post-KT insulin resistance worsened despite increased Mg intake, but we speculate that treatment with calcinuerin inhibitors and other undetermined mechanisms could be depleting total Mg stores and potentially contributing to the insulin resistance observed post-KT. More accurate biomarkers for total body Mg and overall dietary Mg intake are needed to further examine magnesium's role in IR.

TH-PO946

Proton Pump Inhibitors versus Histamine 2 Receptor Antagonists in Transplant Patients Julio L. Chevarria, Hannah M. O'Keeffe, Ecaterina Berzan, Neil L. Thompson, Maura Looney, George S. Mellotte, Catherine A. Wall, Peter J. Lavin. *Trinity Health Kidney Centre, Tallaght Hospital, Dublin, Ireland.*

Background: Proton pump inhibitors (PPIs) are among the most commonly prescribed drugs. It has been estimated that two-thirds of those on PPIs do not have a verified indication. Recent literature has related their use with acute and chronic renal impairment. Therefore it is important to determine if PPIs are being used appropriately. The purpose of this work was to evaluate the appropriateness of PPI use in prevalent kidney transplant patients.

Methods: We performed a cross-sectional study in prevalent transplant patients from January to December 2016. We reviewed their records during that timeframe. We recorded demographic characteristics, principal comorbidities, creatinine and CKD-EPI, PPIs or H2RAs, indication, time of use, steroid dose. For the statistical analysis we used SPSS19. We carried out descriptive and inferential analysis, accepting a p<0.05 as significant.

Results: 282 patients were included. 57(20%) were on steroid free regimens and 210(69.7%) were on 5mg or less. The mean dose was 3.9mg(SD 2.1). A total of 120(42.6%) were on PPIs, 87(30.9%) on Ranitidine and 75(26.6%) on neither. The most common was Omeprazole(43.3%) followed by Lansoprazole(25.8%), and 99.03% for more than 90 days. Only 14(6.7%) had a clearly documented indication for their use. The use of PPIs was greater in hypertensive patients(p:0.02, OR 2.05, CI 95% 1.11-3.77), older patients(56.3 vs 51.8 years, p:0.023). The use of PPIs compared to ranitidine was greater in patients with diabetes(p:0,03, OR 2.30, CI95% 1.08-4.90), older patients(56.3 vs 52.3years, p:0.04) and longer transplant vintage(11.9 vs 7.3years, p:0.01) and there was no difference in the creatinine or CKD-EPI (p:0.24) at the time of review. The use of Ranitidine over PPIs was more frequent in heavier patients(79.0 vs 73.1 Kg, p:0.04).

Conclusions: A large number of patients are being treated with PPIs or Ranitidine without a documented indication. These findings highlight the importance of evaluating appropriate therapy and recommending discontinuation if a clear indication does not exist. Reducing inappropriate prescribing of PPIs in kidney transplant patients can minimize potential for adverse events, and foster controllable cost expenditure.

TH-PO947

Higher Risk of Mortality Among Girls with ESRD Is Mediated by Lower Access to Transplant Patrick Ahearn, Kirsten L. Johansen, Barbara A. Grimes, Elaine Ku. *UCSF, San Francisco, CA.*

Background: Although women live longer than men in the general population, survival in the adult ESRD population does not appear to differ by sex. Few studies have focused on differences in survival by sex among children with ESRD.

Methods: Using data from the United States Renal Database Service (USRDS) we performed a retrospective cohort study of children between the ages of 2 and 19 years who required their first RRT between January 1, 1995 and December 31, 2011. We examined the association between sex and mortality using a Cox proportion hazards model adjusted for demographic characteristics, cause of ESRD, socioeconomic status, calendar year of ESRD onset, and BMI.

Results: We included 13,087 children, of whom 1694 died during 7.4 years of mean follow-up. In unadjusted analysis, risk of death was 45% higher for girls than boys (95% CI 1.32-1.60). In fully adjusted analyses, risk of death remained 35% higher for girls (95% CI 1.22-1.48). This higher risk of death was present regardless of initial RRT modality but was more marked in older girls (≥13 years, p<0.05 for interaction). The risk

of death for girls was higher both on dialysis and after transplant (p>0.05 for interaction by treatment modality). Girls were also less likely to receive kidney transplant than boys (adjusted HR 0.93 [95% CI 0.90-0.97]). In mediation analysis, when we further adjusted for transplant as a time-dependent covariate in our models for mortality risk, the risk of death in girls was partially attenuated [HR 1.28, Table].

Conclusions: Mortality risk is substantially higher for girls with ESRD than for boys. This risk of death is partially attributable to lower access to transplant among girls. However, even after adjustment for transplant access, risk of death remains higher for girls treated with either dialysis or transplant. Further investigation is needed to determine reasons for these observations.

Funding: NIDDK Support, Other NIH Support - NHLBI

Risk of death comparing girls versus boys in unadjusted and adjusted analyses.

Overall cohort (N=13,087)	Girls N= 5,951 Hazard ratio (95% CI)	Boys N=7,136 Hazard ratio (95% CI)
Total follow-up time, person-years	43,323	53,513
Follow-up time attributable to dialysis	18,177	20,021
Unadjusted model	1.45 (1.32-1.60)	1.0 (Ref)
Adjusted model	1.35 (1.22-1.48)	1.0
Adjusted model with transplant as time-dependent covariate	1.28 (1.16-1.41)	1.0
Risk of death during follow-up time attributed to dialysis	1.30 (1.16-1.44)	1.0
Risk of death during follow-up time attributed to transplant	1.28 (1.03-1.60)	1.0

Hospitalisations Following Kidney Transplantation in Children Siah Kim,[2,4] Rebecca A. Spicer,[1] Hugh J. Mccarthy,[3] Fiona Mackie,[2] Sean E. Kennedy.[2] *[1]None, Sydney, NSW, Australia; [2]Sydney Children's Hospital, Newtown, NSW, Australia; [3]Syndey Children's Hospital Network, Westmead, NSW, NSW, Australia; [4]School of Women's and Children's Health, University of NSW, Randwick, NSW, Australia.*

Background: Although there is extensive published information about graft survival and acute rejection among paediatric kidney transplant recipients, there a paucity of published data on hospitalisations within the first twelve months post kidney transplant.

Methods: We performed a retrospective review of children who received kidney transplants at Sydney Children's Hospital from 2009 to 2015. We collected data on length of stay (LOS) in hospital immediate post-transplant, LOS in intensive care, elective and non-elective readmissions over the first twelve months following kidney transplant.

Results: 35 children received kidney transplants over 2009 to 2015, 20 female (57%) and 15 male (43%). 20 received deceased donor grafts, 15 living related including one ABO incompatible and one paired kidney exchange. Mean age of the kidney transplant recipients was 10 years (sd 5 years). Median length of stay was 15 days (IQR 11 to 22 days), with median intensive care LOS 4 days (IQR 3 to 6 days). There were 136 admissions to hospital within the first twelve months with 80 (59%) elective and 56 (41%) non-elective. 22 (63%) of children had non-elective admissions post transplant. Planned admission was due to biopsy (40 admissions) and stent removal (25 admissions). The most common cause for unplanned admission was AKI (14 admissions), UTI (13 admission) and infective illness (23 admissions). Median cumulative days of hospital admission over the first twelve months was 5 days (IQR 1 day to 16 days) for patients.

Conclusions: Hospitalisation within the first year post kidney transplant is common, however cumulative inpatient days in hospital in the first year post-transplant is relatively short for most children. Our data shows that kidney transplantation is associated with low levels of hospitalisation within the first twelve months and will help counsel children and their families about their post-transplant course.

TH-PO949

Results of a Pediatric Transplant Program in a Low Income Country: 10 years of Guatemalan Experience Angie L. Aguilar,[2] Sindy Soveranis,[2] Edgar E. Reyes,[1] Randall M. Lou-Meda.[2] *[1]Hospital Roosevelt, Guatemala, Guatemala; [2]FUNDANIER, Guatemala, Guatemala.*

Background: ESRD rates appear to be increasing for many developing countries, becoming more challenging to get access to Renal Replacement Therapy and transplant in particular. Guatemala, situated in Central America, has an incidence of ESRD in children of 4.6 pmarp and a transplant rate of 6.9 pmp including children and adults. FUNDANIER (Foundation for Children with Kidney Diseases) has become the only center that provides free access to RRT to Guatemalan Children and during the last decade has performed and follow up close to 80 transplants. Hereby we analyzed our program database

Methods: We retrospectively described the results of all transplanted patients between 2007 and 2017. Data including demographic characteristics of recipients and donors were obtained from FUNDANIER data base. Variables like immunosuppression, reasons for discharge of the program, graft loss causes, No. of rejections, acute complications, patient and graft survival at 1 year were analyzed

Results: 78 patients were transplanted. The mean age was 12.6ys(SD3.12),54% were male and the etiology of ESRD was unknown in 65%, followed by CAKUT in 21% of patients. Regarding donors, the mean age was 33ys(SD7.62) and 37% were male. Most of the donations were from living donors (88%). The maintenance immunosuppression used in 91%(n=71) of the patients was Tacrolimus, Mycophenolate and Prednisone. The most common acute complication after transplant was infections (19%). In total 26% of patients (18/70) experience at least 1episode of rejection after 12mo post transplant. Of 43 episodes of rejection reported, 53%(23/43) were after 1year post transplant. The mean time of follow up was 3.5 years (SD1.97).8(23%) patients discharged from the program were moved to other type of RRT due to graft loss. The patient and graft survival at 1 year was 89% and 88%. When divided by type of donation, the 1year graft survival for living and deceased donor was 89% and 70%

Conclusions: After the first decade of the program this is the 1st analysis. Most of the transplants are from young and living donors. Increasing the number of deceased donor is mandatory in order to improve the transplant rate in a country with a high rate of ESRD with unknown etiology. The overall graft survival is 88% at 1 year. The main cause of graft loss is rejection due to poor compliance and acute vascular complications

TH-PO950

Time to Second Kidney Transplantation after Failed Pediatric Kidney Transplant: A Retrospective Cohort Analysis Korntip Phonphok,[2] Yong W. Cho,[1] Suphamai Bunnapradist.[2] *[1]Mendez National Institution of Transplantation, Los Angeles, CA; [2]UCLA, Los Angeles, CA.*

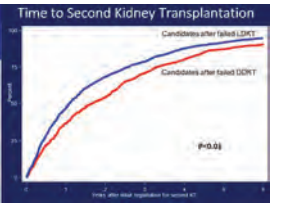
Background: With the prioritization of age ≤ 18 years old at time of registration on the kidney transplant waiting list, deceased donor rates have increased. Majority of these patients require subsequent transplantation at later time. Waiting periods before re-transplantation may vary in length, depend on donor type, PRA, and HLA mismatch. We hypothesized that candidates of those after failed first pediatric DDKT would have greater time to subsequent KT than those after failed first living donor KT (LDKT).

Methods: We used data from the Organ Procurement Transplant Network (OPTN/UNOS) as of December 8, 2016. A retrospective cohort analysis was created to examine time to second KT in 1,935 candidates listed at age 18-30 from January 1, 2000 to September 30, 2015 with previous KT at age ≤ 18. Those with > 2 KT episodes or multiorgan transplant were excluded. Patients were divided into 2 groups according to donor type of first KT; 1) those with failed first DDKT and 2) those with failed first LDKT.

Results: Median time to second KT were 646.5 days and 412.0 days in those candidates with failed first DDKT and those with failed first LDKT, respectively. (p<0.01) First LDKT recipients were more likely to have subsequent LDKT than those with failed DDKT. Median PRA were 85% and 68% (p<0.01), and high PRA (PRA≥98%) were found 26.0% and 16.0% (p<0.01) in recipients of second KT after failed first DDKT and those after failed first LDKT, respectively.

Conclusions: Candidates with previously failed pediatric DDKT had significant greater time to subsequent KT than those with failed first LDKT as well as higher PRA value. Pediatric KT recipients prioritize DDKT in the past could face a challenge with greater waiting time and PRA before re-transplantation.

	Group1 First DDKT (n=796; 41.14%)	Group2 First LDKT (n=1139; 58.86%)	P value
Second Donor type			<0.01
DDKT	625 (78.51%)	655 (57.50%)	
LDKT	171 (21.48 %)	484 (42.49%)	
Time to second KT (days) median (min-max)	646.5 (1-4762)	412 (1-5128)	<0.01
PRA median (min-max)	85 (0-100)	68 (0-100)	<0.01
PRA=0	120 (15.07%)	243 (21.33%)	0.01
PRA>=98%	207 (26.00%)	182 (15.98%)	<0.01



TH-PO951

The Incidence of Chronic Changes in Protocol Biopsies in Asymptomatic Young Pediatric Renal Transplant Recipients Sunee Panombualert, Patricia L. Weng, Robert B. Ettenger. *Mattel Children's Hospital at UCLA, Los Angeles, CA.*

Background: Previous studies of protocol biopsies (Bx) in stable pediatric kidney transplant (KTx) patients have found a high incidence of interstitial fibrosis (ci) and tubular atrophy (ct), but the effect of recipient age as a continuous variable is unclear.

Methods: We examined the relationships between recipient age (1-10 yrs vs 11-20 yrs) at Bx and the results of protocol Bxs at 6 months, 1 and 2 years in stable pediatric KTx patients from 2005-2016. Bxs were evaluated for subclinical rejection and ci/ct by Banff 2013 criteria.

Results: A total of 506 protocol Bxs were performed. Subclinical rejection was found in 5.5%, 3.8%, and 2.5% at 6 months, 1 and 2 years, respectively of all Bxs and did not differ significantly by time post-Tx or by patient age. In all Bxs, ci ≥ 1 was detected in 15.1% and ct ≥ 1 was found in 16.3% at 6 months. There was no relationship between time after transplant or subclinical rejection and the incidence of ci or ct. However, in the 6 months Bxs, the frequency of ci score was 26.8% in patients 1-10 yrs and only greater than 9.5% those 10-20 yrs (p=0.003). Similarly, ct scores were 28.6% vs 10.3% (p=0.002) at 6 months. By 1 year, ci and ct had increased in both age groups but continued to be significantly higher in patients 1-10 yrs (Table).

Conclusions: Young age as a continuous variable is significantly associated with a higher incidence of chronic tubulointerstitial damage in early protocol biopsies, and this is unrelated to subclinical rejection.

Histology scores	ci score ≥ 1			ct score ≥ 1		
	6 mo Bx	1 yr Bx	2 yr Bx	6 mo Bx	1 yr Bx	2 yr Bx
Age 1-10	15(n=56) 26.8%	23(n=51) 45.1%	19(n=41) 46.3%	16(n=56) 28.6%	24(n=51) 47.1%	18(n=41) 43.9%
Age 11-20	11(n=116) 9.5%	24(n=100) 24%	17(n=56) 30.4%	12(n=116) 10.3%	25(n=100) 25%	16(n=56) 28.6%

TH-PO952

Effect of Pregnancy Post-Transplant on Rejection and HLA-DSA Development Nadeen J. Khoury, Andrea G. Kattah, Fernando G. Cosio. *Mayo Clinic, Rochester, MN.*

Background: Pregnancy is known to be a sensitizing event; however, most studies have suggested that allograft function is not impaired. We looked at our transplant cohort to assess for rejection post-pregnancy and development of de Novo donor specific antibodies (DSA).

Methods: We used our transplant database to identify the female patient population who were 16-46 years old at the time of transplant. We included transplants which occurred between 1996 to 2014. Patients with a functioning graft for at least 2 years post-transplant were included in our data analysis. We then used pregnancy codes to select those who had a pregnancy or pregnancy-related event.

Results: We identified 47 patients with pregnancy-specific codes from an initial cohort of 412 patients. After excluding patients who had pregnancies prior to transplant and multiorgan transplants, we were left with 11 patients with appropriate pathology and DSA data. These patients were all Caucasian and received living kidney transplants. Thymoglobulin and alemtuzumab were used for induction. Triple immunosuppression was used initially with mycophenolate mofetil switched to azathioprine prior to pregnancy. Age at the time of pregnancy was between 27 and 38 and primary kidney disease included: HTN nephrosclerosis, reflux disease, IgA and anti-GBM disease. Serum creatinine at the time of transplant was 0.9-2.1 with proteinuria ranging between 31 to 157 mg/24h. 8 had a single pregnancy post-transplant and 3 had two pregnancies. Post-pregnancy biopsies were performed at 2-12 months post delivery. None of the patients had evidence of acute rejection, 8 had mild to moderate arteriosclerosis and arteriolar hyalinosis and 3 had features of chronic antibody mediated rejection, including transplant arteriopathy and glomerulopathy. The women with chronic antibody mediated rejection all had de novo DSA and were the ones with 2 pregnancies.

Conclusions: Most pregnancies post-transplant carry a benign course; it does appear however, that multiple pregnancies might trigger de novo DSA and chronic antibody mediated rejection. It would be important to have larger studies to further delineate this phenomenon and help counsel women who desire to conceive after transplant.

TH-PO953

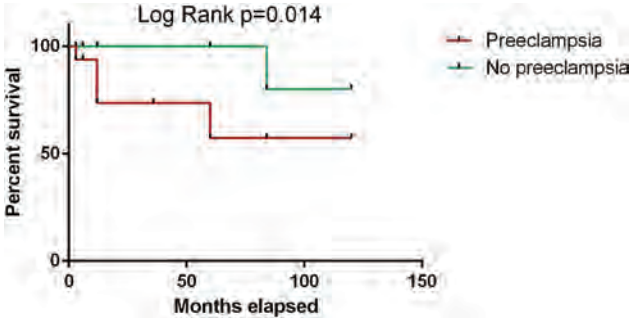
Preeclampsia Predicts Chronic Dysfunction in Kidney Transplantation Javier Soto-Vargas,[2] Karla L. Lemus,[2] Efrain CHAVARRIA-AVILA,[1] Renato Parra.[2] *[1]UNIVERSIDAD DE GUADALAJARA, GUADALAJARA, Mexico; [2]Nephrology, Regional General Hospital 46, Mexican Institute of Social Security, Guadalajara, Mexico.*

Background: The goal was to evaluate the renal and obstetric outcomes in pregnancy after kidney transplantation in a Mexican center

Methods: Kidney transplant recipients who underwent pregnancy after transplantation at Regional General Hospital of the IMSS between January 1997 and January 2016 were identified. Data on demographics, comorbidities and clinical and graft outcomes were collected with a median follow up of 61.3 months post-partum.

Results: There were 41 pregnancies identified in 34 recipients. The median age of recipient at childbearing was 26.5 years (IQR, 22.7-30.5) and the median interval from transplantation to conception was 84.4 months (IQR, 43-106). There was a difference between the median pre-pregnancy estimated glomerular filtration rate (eGFR) (91.0 mL/min/1.73 m(2); IQR, 71.0-106.0) and median eGFR at time of last post-partum follow up (66.0 mL/min/1.73 m(2); IQR, 37.0-87.5, P<0.001). 31 (75.6%) pregnancies ended in singleton live births. Pre-eclampsia occurred in 16 pregnancies (39.0%). There were 7 (17.1%) patients with chronic dysfunction during the follow up, 4 (9.8%) lost their graft, and only one death was recorded, attributed to histoplasmosis. Only the occurrence of preeclampsia was associated with the development of chronic dysfunction and loss of graft (p=0.009 and p=0.018 respectively) independent of the presence of rejections.

Conclusions: Post-transplantation pregnancies with preeclampsia are associated with the development of chronic dysfunction and loss of graft.



TH-PO954

Endothelin-1 Type A Receptor Antibodies Are Associated with Arteritis and Functional Decline in Pediatric Renal Transplantation Meghan Pearl,[1] Jonathan Grotts,[1] Maura Rossetti,[1] Qiuheng J. Zhang,[1] Patricia L. Weng,[1] Elaine F. Reed,[1] Eileen W. Tsai.[2] *[1]UCLA, Los Angeles, CA; [2]Duke University, Durham, NC.*

Background: We recently found that the non HLA antibody, Angiotensin II Type 1 Receptor Antibody (AT_1R-Ab) is associated with poor outcomes in pediatric kidney transplant recipients (KTRs); however, the role and clinical impact of other non-HLA antibodies such as endothelin-1 Type A receptor Antibody (ETAR-Ab) remains unknown.

Methods: 65 pediatric patients were monitored for 2 years after transplantation from August 2005 to November 2014. ETAR-Ab (ELISA), AT_1R-Ab (ELISA), and HLA DSA (Luminex bead assay) were measured pre-transplant, 6 months (m), 12m, 24m post-transplant and during episodes of rejection. Based on a receiver operating curve analysis, > 10 and >17 units/ml was considered positive for ETAR-Ab and AT_1R-Ab respectively while MFI cut off ≥1000 was considered positive for HLA DSA. Biopsies were performed at 6m, 12m, 24m post-transplant per protocol and for clinical suspicion of rejection and evaluated by 2013 Banff criteria. Clinical risk factors and renal function (MDRD for >18 and updated Schwartz Equation for <18 years old) were assessed.

Results: The prevalence of ETAR-Ab was 32%. Risk factors for ETAR-Ab included younger age (p=0.038), steroid free immunosuppression (p=0.038), and AT_1R-Ab (p<0.001), but not HLA DSA (Figure 1a). ETAR-Ab was associated with greater median declines in renal function (p=0.034, Figure 1b) and arteritis on biopsy (p=0.011), but not acute rejection (data not shown).

Conclusions: In pediatric KTRs, ETAR-Ab is highly prevalent and associated with AT_1R- Ab, vascular inflammation, and worsening renal function. This suggests that ETAR-Ab and AT_1R-Ab monitoring may be warranted in children, especially those on steroid-free immunosuppression. Dual blockade may attenuate allograft injury and improve renal function.

Creatinine Monitoring by Remote Blood Spot Testing in Pediatric Kidney Transplant Recipients Marian Sinkey,[2] Jane Dickerson,[3] Jodi M. Smith.[1] *[1]Children's Hospital & Regional Medical Center, Seattle, WA; [2]Seattle Children's, Seattle, WA; [3]Seattle Children's Hospital, Seattle, WA.*

Background: Pediatric kidney transplant patients are monitored frequently with laboratory testing to assess kidney transplant function and optimize therapeutic drug doses. Dried blood spots could reduce the number of lab trips, benefiting those who are remote, elderly, working, or unable to travel.

Methods: We collected 35 samples via phlebotomy from 30 participants for simultaneously paired venous and finger-poke (capillary) to assess the correlation of venous plasma creatinine with capillary dried blood spot creatinine (DBS had already been validated for immunosuppression levels (1)). This method uses creatinine-d3 as the calibrators, and creatinine-13C3-d3 as internal standard measured with a SCIEX QTRAP 6500. Limits of detection and quantitation were determined on the equivalent of 3 μL dried blood spot extractions.

Results: We demonstrate a strong correlation between venous and capillary (DBS) creatinine values when the creatinine was less than 1.5 mg/dl. There was a small negative bias of -0.1 mg/dL for samples less than 1.5 mg/dL. When the Cr was greater than 1.5 mg/dl we observed a larger negative bias of -0.7 mg/dL in capillary specimens (DBS).

Conclusions: The study established that remote (home) dried blood spot testing (DBS) is a logistically possible method of monitoring both creatinine and immunosuppression levels on the same card when the expected creatinine concentration is less than 1.5 mg/dL. Detecting sudden increases in creatinine may result in more immediate actions prolonging the life of the graft. Eliminating barriers to timely lab draws may improve adherence, decrease costs, and improve overall quality of life. Results greater than 1.5 mg/dl should be confirmed with venous plasma method. Further investigation is on-going to improve the method's accuracy at high creatinine concentrations. 1. Dickerson, J.A.; Sinkey, M.; Jacot, K.; Stack, J.; Sadilkova, K.; Law, Y.M.; Jack, R.M. Tacrolimus and sirolimus in capillary dried blood spots allows for remote monitoring. Ped Trans. 2015, 19(1): 101-6.

PACT Score Identifies Nonadherence and Acute Rejection in Pediatric Renal Transplantation Kyle Freischlag,[2] Vivian M. Chen,[1] Shashi K. Nagaraj,[1] Annabelle N. Chua,[1] Eileen W. Tsai.[1] *[1]Duke University, Durham, NC; [2]Duke University School of Medicine, Durham, NC.*

Background: In this pilot study, we examined the utility of a pre-transplant Psychosocial Assessment of Candidates for Transplantation (PACT) score to identify at-risk pediatric patients.

Methods: Patients were <21 year-old renal transplant recipients at our institution between 2005 and 2017. Pre-transplant psychosocial evaluation was standardized in 2011 utilizing PACT scores to assesses candidates (0-5) on social support, psychological health, lifestyle factors, and understanding. Demographics and clinical outcomes were analyzed by low PACT score (≤2), high PACT score (≥3), and no PACT score.

Results: 61 pediatric patients were identified: 7% low PACT score, 33% high PACT score, and 61% no PACT score (Table 1). High PACT scores were associated with lower rates of medical non-adherence (Low 75% vs High 15% vs No 51.4%, p=0.01) and acute rejection (0% vs 20% vs 50.0%, p=0.025) (Figure 1). Controlling for HLA mismatch, PACT score reduced (OR 0.15 95% CI 0.03-0.83) while non-adherence increased (OR 5.72 95% CI 1.35-24.28) the chances of acute allograft rejection.

Conclusions: PACT was associated with less medical non-adherence and fewer incidences of acute rejection. Our study highlights PACT score in risk stratifying candidates, which warrants prospective validation.

A Modified "Teach Back" Method to Improve Self-Management in Youth with Kidney Transplants Jayanthi Chandar, Adela D. Mattiazzi, Malgorzata N. Bielecka, Marissa J. Defreitas, Alan M. Delamater. *University of Miami Miller School of Medicine, Miami, FL.*

Background: Kidney transplant recipients require adherence to a strict medical regimen. Higher rates of non-adherence are reported among adolescents, often resulting in transplant loss. Inadequate functional health literacy is one of the factors affecting adherence. Teach Back' is a verbal literacy tool that facilitates patient understanding and knowledge retention.

Methods: We performed a quasi-experimental pilot study using a modification of the 'Teach Back' method, in which the patient used digital media to answer basic questions regarding their health and medication regimen while waiting to be seen by the health care provider (HCP) in clinic. The HCP then created a corrected version during the encounter and gave it to the patient. Rapid assessment of literacy-TEEN score was assessed at baseline. Knowledge of names and purpose of medications used were assessed by digital capture and by questionnaire, at baseline, upon introduction of the program with access to the patient for 1 month, and after taking away the program for one month. Knowledge was scored as 0-100% with 0 indicating no answers were correct and 100 indicating all were correct.

Results: Sixteen patients (10 male, 6 female) were recruited to the study. Mean age was 17.3± 2.4 years and 94% were ethnic minority (Black or Hispanic). Seven of 16 patients (43.75%) had an academic achievement below grade level. REALM-TEEN score was < 65% in 3/16 (18.75%) patients. At the end of the study period, there was a trend towards improvement in knowledge of medications (see figure). Only one patient used the program at home.

Conclusions: A significant proportion of adolescent transplant recipients are disadvantaged by low academic achievement. Digital technology used during clinic visits appears to be useful in improving knowledge and purpose of medications in adolescents with kidney transplants. This is an important self-management tool for transitioning adolescents to adult HCPs.

Impact of Immediate Post-Transplant Parenteral Iron Therapy on Prevalence of Anemia and Short-Term Allograft Function in a Cohort of Pediatric Renal Transplant Recipients Oluwatoyin F. Bamgbola,[2] Diego H. Aviles,[3] Franca M. Iorember.[1] *[1]Phoenix Children's Hospital, Scottsdale, AZ; [2]SUNY Downstate Medical Center, Brooklyn, NY; [3]Dept of Pediatrics, Louisiana State University Health Science Center, New Orleans, LA.*

Background: Anemia is common but under-diagnosed and is often inadequately treated in renal transplant {KTX} recipients. Due to high turn over rate during chronic dialysis and blood loss during KTX surgery, iron deficiency (ID) is the major determinant of early-onset (< 6 mo) post-transplant anemia (PTA). We sought to examine the clinical benefit of routine use of parenteral (IV) iron in patients who had KTX surgery.

Methods: Subjects aged 2 -18 yrs who had KTX between 2011 & 2015 received 1-2 mg/kg of diluted iron sucrose over 1 hr in the first week of surgery. Historical control was their counterparts between 2005 & 2010. We determined i) the prevalence rate (PR) and predictors of early- (6 mo) and late-onset (12 mo) anemia, ii) relationship between IV iron therapy and anemia; and iii) association of IV iron treatment with the rates of acute rejection (ARE), allograft dysfunction, infection, erythropoietin (EPO) use and hospitalization (HOS).

Results: Prevalence rate of anemia for the cohort (n = 79): 85% at 1 mo, 74% at 3 mo, 55% at 6 mo, 60% at 12 mo & 47% at 24 mo. There was greater PR of anemia at 3 (p = 0.01), 6 (p = 0.03) and 12 mos. (p = 0.03) in the Controls (n = 42). The best set of predictors in multiple regression analysis for early anemia were poor donor quality and no IV iron treatment; $R^2 = 0.13$; p = 0.01. Predictors for late-anemia at 12 mo: anemia at 6 mo, steroid use, allograft, previous KTX, and no IV iron treatment (p = 0.001). Although not significant, there was greater frequency of allograft dysfunction, ARE, and hospitalization in the Controls. There was greater number of anemia treated with EPO rescue in the Controls (p = 0.03).

Conclusions: - Post-surgery treatment with IV iron reduces the rate of anemia up to 12 mo after KTX - Post-surgery IV iron use reduced the need for later EPO rescue treatment for anemia - Early anemia is predominantly due to iron deficiency and poor donor quality - Late anemia is due to pre-existing anemia, steroid use, previous KTX and allograft dysfunction - Literatures support association of early and late anemia with lower graft and patient survival - Randomized controlled trials are needed to determine the scope of evaluation for PTA and cost benefit analysis of therapeutic options including EPO, oral iron and/ or IV iron

TH-PO959

Malignancies after Pediatric Kidney Transplantation: A Long Term Single-Center Experience in Japan Tomoo Yabuuchi,[1] Ken-ichiro Miura,[1] Shoichiro Kanda,[1,2] Yohei Taniguchi,[1] Takeshi Nagasawa,[1] Ryutaro Hisatomi,[1] Hideki Ban,[1] Yoko Shirai,[1] Yoko Takagi,[1] Naoto Kaneko,[1] Kiyonobu Ishizuka,[1] Hiroko Chikamoto,[1] Yuko Akioka,[1] Motoshi Hattori.[1] *[1]Department of Pediatric Nephrology, Tokyo Women's Medical University, Tokyo, Japan; [2]Department of Pediatrics, University of Tokyo, Tokyo, Japan.*

Background: Kidney transplantation (KTx) is the preferred treatment option for children with end-stage renal disease. Today, approximately 11.3% of all deaths after pediatric KTx are related to cancer. With improved graft survival and overall survival, this proportion is likely to rise. Increased cancer risks are well documented in adult KTx recipients. However, the spectrum of malignancies and risk in the pediatric KTx population, particularly in Asia, are less well described.

Methods: We retrospectively reviewed medical charts of all consecutive pediatric KTx patients aged less than 20 years in our center between April 1983 and December 2016.

Results: During maximum 31 years of follow-up, 13 out of 363 patients (3.6%) developed malignancy, which included 3 EBV-associated posttransplant lymphoproliferative disorder (PTLD), 1 EBV-associated post-transplant smooth muscle tumor (PTSMT), 2 brain tumors, 1 B-cell lymphoma, 1 renal cell carcinoma, 1 thyroid carcinoma, 1 lung cancer, 1 bladder cancer, 1 breast cancer, and 1 Wilms tumor. Patients diagnosed with EBV-associated PTLD, EBV-associated PTSMT, and Wilms tumor were mostly transplanted at younger ages and the median age at diagnosis of malignancy was 6.6 years (range 5.5-11.5), with a median time to diagnosis of 1.2 years (range 0.6-1.2). In contrast, the median age at diagnosis of other malignancies was 27.6 years (range 20.4-31.8), and the median time from KTx to diagnosis of malignancy was 15.2 years (range 10.6-17.1). No EBV-associated PTLD has occurred since 2005, when we started regular screening of EBV-DNA load in children at risk for developing PTLD.

Conclusions: This is the first study which investigated occurrence of malignancies in pediatric KTx recipients in Asian populations. EBV-associated PTLD and PTSMT occurred during early periods from KTx. Regular screening of EBV-DNA load might be helpful to prevent EBV-associated PTLD. Other malignancies were diagnosed during early adulthood, emphasizing the need for long term surveillance of these patients.

Pubertal and Growth Development of Children and Adolescents Following Renal Transplantation Rainer Büscher, Deniz Serdar, Cordula Kiewert, Peter F. Hoyer, Anja K. Büscher. *University of Duisburg-Essen, Pediatrics 2, Essen, Germany.*

Background: Children with chonic kidney disease often show a delayed pubertal development and growth restriction, which is an enormous psycho-social stress factor. The improvement of renal function following RTx seems to positively influence some of the involved mechanisms. We analyzed pubertal development and growth in children following RTx in order to identify potential risk factors.

Methods: Data of 90 children (0-18 years, 32 ♀) from our center who underwent RTx between 2000-2015 have been retrospectively analyzed. Mean observation time was 6.7 years. We studied the influence of gender, age, underlying disease, mode and duration of dialysis, glucocorticoid and growth hormone therapy prior to RTx, renal function and immunosuppression on the annual course of weight and growth, bone age, testicle volume, estradiol/testosterone levels, age at onset of menarche and change of pubertal Tanner-stage.

Results: Mean age at RTx was 6.8 years (±4.7 years). Length (-1.6SD) and weight (-0.9SD) were reduced prior to RTx and we found a pronounced dissociation between skeletal and chronological age. While all patients gained weight ($p=0.007$) following RTx, length and dissociation of bone age showed no improvement ($p=0.032$). On the contrary, the dissociation was more pronounced in the group of patients between 7-12 years ($p<0.05$). Patients receiving growth hormone therapy prior to RTx showed a negative dissociation and reduced length at time of RTx and presentd an accelerated catch-up-growth with no further significant differences after RTx. Living kidney donation was associated with a significantly enhanced length (-0.9SD vs. -1.7SD, $p=0.025$). Age at onset of menarche (12.98±1.64 years, normal range 11.2-15.6 years) and change from Tanner-stage P1 to P2 (11.2±15.6, normal range 8-12.6 years) were in the upper normal range. Boys were 12.3±1.5 years old (normal range 9.2-15.2 years) at transition to P2. No dependancy on gender, disease, duration and mode of dialysis, immunosuppression or prior glucocorticoid therapy could be observed.

Conclusions: The majority of our patients showed a timely pubertal development following RTx. Despite a improved renal function, growth and bone age remained retarded.

TH-PO961

Donor and Recipient Size Mismatch Is Associated with Graft Survival in Pediatric Living Donor Kidney Transplantation Heather L. Wasik, Rebecca Ruebner, Cozumel S. Pruette, Dorry L. Segev, Allan Massie. *Johns Hopkins University, Baltimore, MD.*

Background: Studies in adults and adolescents have shown that a small donor body size in relation to recipient body size is associated with increased risk of graft loss following kidney transplantation. Little is known about this relationship in young children undergoing living donor kidney transplantation (LDKT) in whom greater size mismatch is possible.

Methods: We studied first-time LDKT recipients 1995-2015 aged <11y at transplant using SRTR data. Patients were divided into two groups based on donor/recipient body surface area ratio (D/R BSA ratio): BSA ratio ≤ 2 and BSA ratio > 2. Multivariable Cox models were used to compare time to death-censored graft failure (DCGF) between patients in the two BSA ratio groups, adjusting for recipient, donor, and clinical characteristics including recipient age at transplant, recipient BSA, sex, race, cause of ESRD, years of dialysis prior to transplant, donor age, donor/recipient sex mismatch, number of HLA mismatches, and year of transplant.

Results: Of 1,948 pediatric patients undergoing LDKT, 352 (18%) had a D/R BSA ratio ≤ 2. Patients with BSA ratio ≤ 2 had a higher incidence of DCGF compared to those with a BSA ratio > 2 (32.3% at 10 years vs. 15.4%, logrank p <0.001). After adjustment, D/R BSA ratio ≤ 2 remained associated with an increased risk of DCGF (aHR (95% CI)=1.62 (1.10-2.39), p=0.01).

Conclusions: Low D/R BSA ratio is associated with increased risk of DCGF in children undergoing LDKT. Donor size may be an important factor to consider when selecting organs for pediatric LDKT.

Long-Term Neurodevelopmental and Anthropometrical Outcome of Children Born to Female Kidney Transplant Recipients Natalja Haninger,[1] Apostolos Vacariu,[2] Alice Schmidt,[1] Gere Sunder-Plassmann.[1] *[1]Department of Medicine III, Division of Nephrology and Dialysis, Medical University of Vienna, Vienna, Austria; [2]Medical University of Vienna, Vienna, Austria.*

Background: Pregnancy rates have increased during the last years among kidney transplant recipients and live birth rate is high. These pregnancies are deemed high risk, with many obstetric complications and negative delivery outcomes. No long-term data of neurodevelopmental and anthropometrical outcome in this high risk population are available.

Methods: We retrospectively analyzed neurodevelopmental and anthropometrical long-term outcome data of 36 children born to 29 female kidney transplant recipients between 1989 and 2017. Data were collected from chart reviews (including Bayley Scales of Infant Development, percentile lines by WHO growth charts adjusted to expected height), personal interviews of the mother, and the Austrian Mother Child Booklet.

Results: We evaluated a total of 51 pregnancies. Pre-eclampsia was observed in 5 pregnancies (10%). Live birth rate was 71% (n=36), rate of abortion 29% (n=15), including 2 stillbirths. 34 singletons and one set of twins were born after organ transplantation (19 females, 17 males; 2 singletons after IVF). 83% required C-section, 16 infants were born term, 20 (56%) premature; 16 of them had low birth weight, including 6 with very low and 4 with extremely low birth weight. 11 (31%) were small for gestational age. Mean gestational week at delivery was 35±4. 14 children required neonatal intensive care treatment. One child was born with renal pelvic dilatation (4%). Mean age of children was 11,3±8,2 years at assessment for physical, social, and psychomotor skills. Growth retardation was seen in 9 children (25%); 5 (14%) were above normal range; 22 (61%) as expected. Hyperactivity disorder (n=2), poor fine motor skills (n=3), delayed speech development or speech abnormalities (n=3), and cognitive developmental disorder (n=1) were diagnosed.

Conclusions: We observed an enhanced rate of neurodevelopmental delay and anthropometrical abnormalities in this high risk population. Obstetric and delivery complications might influence neurodevelopmental and anthropometrical outcome in children born to female kidney transplant recipients.

TH-PO963

Improving Identification and Documentation of Urinary Tract Infection Risk after Renal Transplantation in Children Marie-Michele Gaudreault-Tremblay,[2] Damien G. Noone,[2] Rory F. McQuillan,[3] Diane Hebert,[2] Rulan S. Parekh.[1] *[1]The Hospital For Sick Children, Toronto, ON, Canada; [2]The Hospital for Sick Children, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada.*

Background: Urinary tract infection (UTI) is the most frequent infectious complication after kidney transplantation in children. Trimethoprim-Sulfamethoxazole is standard UTI prophylaxis in all transplant recipients, irrespective of pre-transplant diagnosis or post-transplantation UTI risk factors. Identification and documentation of patient's risk of post-transplantation UTI is often lacking, which complicates the choice of appropriate prophylaxis. The aim of this quality improvement project is to improve documentation and categorization of post-transplantation UTI risk for transplant recipients, with a target screening rate of 90%.

Methods: In our Centre, the model for improvement (Plan-Do-Study-Act) was used to sequentially implement an educational initiative and a checklist to facilitate systematic review of UTI history and risk factors. The purpose of the intervention was to allow clinicians to categorize children's post-transplantation UTI risk. Documentation in patients' medical records was assessed at each clinic visit. Parameters analyzed were:

appropriate identification/documentation of post-transplantation UTI risk, UTI history and risk factors. The medical team satisfaction regarding the intervention and the supplementary time used to document was also assessed. A *u* chart was used for analysis.

Results: A total of 14 renal transplant outpatient clinics (77 patients; 126 medical visits) were reviewed from February to May 2017. The baseline documentation of UTI history in the patient's medical record was 45% and of UTI risk factors 25%. After the medical team educational session, an increase of the documentation of UTI risk factors was observed (47% of documentation following educational session) but no significant change in documentation of UTI history (41%). Following implementation of the checklist, documentation of UTI history and risk factors improved by 21% and 17% respectively. However, categorization of patient's post-transplantation UTI risk was almost always missing.

Conclusions: UTI is a major clinically significant complication following pediatric kidney transplantation. Implementation of a checklist significantly improved documentation of UTI history and risk factors in children after renal transplantation.

TH-PO964

CMV Viraemia Is Associated with Decline in Graft Function in Paediatric Renal Transplant Recipients Shazia Adalat, Martin Garcia-Nicoletti, Nabil Z. Melhem, Grainne M. Walsh, Helen E. Jones, Jelena Stojanovic. *Evelina London Children's Hospital, London, United Kingdom.*

Background: Little is documented about impact of post-transplant CMV viraemia on graft function in paediatric renal transplant recipients.

Methods: A retrospective analysis of CMV viral loads, graft outcomes, amendments in immunosuppression (IS) and rejection episodes in renal allografts in a large paediatric transplant centre. CMV donor/recipient status, timing of CMV viraemia, duration of any antiviral therapy and time to CMV seroconversion were analysed. Rejection episodes were noted with correlation to IS changes and decline in GFR was calculated annually using the Schwartz formula.

Results: Of 101 paediatric renal transplants performed over a 5 year period (2010-15), data was analysed for 76 followed-up patients. Follow up ranged 1.3-7.3 years at time of review (mean 4.2 years). Two thirds of all transplants came from living donors and two thirds followed a standard IS protocol of basiliximab, tacrolimus, azathioprine and tapering prednisolone. In 43% both donor and recipient were CMV naive; both were CMV seropositive in 23% and in 25% the donor was positive while recipient was naive. In 9% recipient positive only. Of CMV naïve recipients with CMV positive donor(n=19), all received 3 months of prophylactic valganciclovir. Despite prophylaxis, 52% developed CMV viraemia at a median of 4.3mo (range 1.4-7mo). 3 of these developed CMV disease (1 hepatitis, 1 enteritis and 1 fever with neutropenia). Of the remaining 7, who had viraemia with no systemic features, 6 were on standard IS. Median time to seroconversion was 3.3 (range 0.6-54) months. Decline in graft function was 2-66 ml/min/1.73m^2 (median 21). Of those who didn't develop viraemia, two grafts were lost. Of CMV seropositive recipients, 59% (n=10/17) developed CMV viraemia 0-26 (median 1.9) months post-transplant. 9 patients were on standard IS. Decline in graft function ranged from -8 to 42 (median 8) ml/min/1.73m^2 from first to last follow up, compared to median decline in GFR in those without viraemia of 2(range-27 to 42) ml/min/1.73m^2. No primary infection in CMV-/- or reactivation of latent infection in CMV -/+allografts was found.

Conclusions: There is a greater decline in graft function in CMV naive patients who develop viraemia regardless of seroconversion. There is no evidence that this is related to changes in immunosuppression at the time of the CMV viraemia.

TH-PO965

Tubular Cell Senescence in the Donated Kidney Predicts Allograft Functions, but Not Donor Remnant Kidney Functions, in Living Donor Kidney Transplantation Tadashi Sofue,[1] Yoshio Kushida,[2] Taro Ozaki,[1] Masahiro Moritoki,[1] Yoko Nishijima,[1] Akira Nishiyama,[3] Tetsuo Minamino.[1] *[1]Department of CardioRenal and Cerebrovascular Medicine, Kagawa University, Kagawa, Japan; [2]Department of Pathology, Kagawa University, Kagawa, Japan; [3]Department of Pharmacology, Kagawa University, Kagawa, Japan.*

Background: It is uncertain whether kidneys from marginal donors are suitable for living kidney transplantation. In deceased donor kidneys, tubular cell senescence in the donated kidney is reported to affect allograft functions. However, the degree of cell senescence in a living donor kidney with marginal factors has not been reported so far. In this study, we assessed the association of tubular senescence with allograft and remnant kidney functions in living donor kidney transplantation by a prospective observational clinical study.

Methods: Thirty-eight living donor kidney transplantations were analyzed prospectively. Tissue sections obtained from pre-implantation kidney biopsies were immunostained for p16^{INK4a} to indicate tubular senescence. Various kidney biomarkers were analyzed in urine and blood samples. The protocols and informed consent forms were reviewed and approved by the Ethics Committee of Kagawa University (#H22-056) and registered in the UMIN Clinical Trials Registry (UMIN000004905).

Results: Of the 38 donors, 21 had marginal factors. Severe tubular senescence was found in living donors with overlapping marginal criteria. Tubular senescence in living donor kidneys was significantly related to donor age and lower recipient kidney functions at 1 year after transplantation independently of donor age (β = -0.281; P = 0.050), but did not affect remnant kidney functions after donation. Pre-transplant donor factors, such as pre-eGFR, hypertension, systolic blood pressure, and albuminuria, did not show any significant AUC for prediction of high tubular cell senescence. High plasma soluble αKlotho levels were associated with a higher predictive value for low tubular cell senescence with an area under the curve of 0.78 (95% confidence interval 0.62–0.93; P < 0.01).

Conclusions: The nuclear p16-staining rate in donated kidney tubules is a predictor for allograft kidney functions, but not donor remnant kidney functions in living donor kidney transplantation. Detection of tubular cell senescence may facilitate selection of appropriate living donor candidates.

Validation of Living Donor Nephrectomy Codes Ngan Lam,[7] Krista L. Lentine,[5] Scott Klarenbach,[7] Manish M. Sood,[4] John Paul Kuwornu,[8] Kyla L. Naylor,[1] Greg A. Knoll,[3] Joseph Kim,[6] Amit X. Garg.[2] *[1]Institute for Clinical Evaluative Sciences, University of Toronto, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]Ottawa Hospital, Ottawa, ON, Canada; [4]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [5]Saint Louis University, St. Louis, MO; [6]Toronto General Hospital, University Health Network, Toronto, ON, Canada; [7]University of Alberta, Edmonton, AB, Canada; [8]Institute for Clinical Evaluative Sciences, London, ON, Canada.*

Background: Use of administrative data for outcomes assessment in living kidney donors is increasing given the rarity of post-donation complications and challenges with loss to follow-up.

Methods: Using linked healthcare administrative databases in Ontario, Canada, we conducted a retrospective cohort study to determine the validity of diagnostic and procedural codes for living donor nephrectomies. The reference standard was living kidney donation events identified through the province's tissue and organ procurement agency, with verification by manual chart review. All living kidney donors from 2003 to 2010 who had donated at one of five major transplantation centers in Ontario were included. Operating characteristics (sensitivity and positive predictive value, PPV) of various algorithms using diagnostic, procedural, and physician billing codes were calculated.

Results: During the study period, there were a total of 1199 living donor nephrectomies performed. Overall, the best algorithm for identifying living kidney donors was the presence of one diagnostic code for kidney donor (ICD-10 Z52.4) and one procedural code for kidney procurement or excision during a hospital admission (1PC58, 1PC89, 1PC91). Compared to the reference standard, this algorithm had a sensitivity of 97.4% and a PPV of 90.1%. The diagnostic and procedural codes performed better than the physician billing codes (sensitivity 60.1%, PPV 78.3%).

Conclusions: An algorithm consisting of one diagnostic and one procedural code accurately identified living kidney donors in administrative databases. This algorithm can be used to identify and follow living kidney donors for post-donation outcomes.

TH-PO967

Nephrosclerosis beyond That Expected for Age Is Predictive of Early New-Onset Hypertension in Living Kidney Donors Naim S. Issa,[2] Lisa E. Vaughan,[2] Aleksandar Denic,[2] Venkata vamsi Nagineni,[2] Harini A. Chakkera,[3] John C. Lieske,[2] Lilach O. Lerman,[2] Sandra J. Taler,[2] Mark D. Stegall,[2] Emilio D. Poggio,[1] Andrew D. Rule.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Mayo Clinic, Rochester, MN; [3]Mayo Clinic Arizona, Scottsdale, AZ.*

Background: Nephrosclerosis on kidney biopsy of living donors is known to associate with older age and hypertension (HTN). Whether nephrosclerosis is also predictive of adverse kidney function changes early after donation is unclear.

Methods: We retrospectively studied living kidney donors who had an implantation renal biopsy as part of the Aging Kidney Anatomy study. Age-based thresholds (95th percentile for 18-75 yo) were defined for glomerulosclerosis percentage (8-30%), cortical fibrosis (1-10%), number of fibrosis foci (1-6) and arteriosclerosis (60-76%). A Nephrosclerosis Index was defined assigning a value of 1 for each parameter that was abnormal. The Nephrosclerosis Index was assessed as a predictor of residual eGFR, eGFR<60 ml/min/1.73 m^2, elevated 24-hour albumin excretion, and new onset HTN (defined as SBP>140 or DBP>90 mm Hg or use of anti-hypertensive medications) after donation.

Results: There were 1409 donors available to define age-based thresholds of which 741 returned for a follow-up visit 2-24 months after donation (mean and median # months). The Nephrosclerosis Index was 0 in 65.3%, 1 in 26.2%, 2 in 6.3%, and 3 or higher in 2.2%. After adjusting for clinical predictors, baseline characteristics that associated with Nephrosclerosis Index were age (p<0.001) and HTN (p=0.003). After adjusting for age at donation, pre-donation HTN, and follow-up time, the Nephrosclerosis Index was not predictive of change in eGFR (p=0.89) at follow-up, a follow-up eGFR<60 ml/min/1.73 m^2 (p=0.56), or change in urine albumin (p=0.70). After excluding baseline HTN and adjusting for age and follow-up time, the Nephrosclerosis Index per level increase associated with new-onset HTN at follow-up (OR=1.9, p=0.021). A Nephrosclerosis Index of 2 or higher was also associated with new-onset HTN at follow-up (OR=4.2, p=0.017). An alternative analysis using single-thresholds rather than age-based thresholds for Nephrosclerosis Index found no association with new-onset HTN at follow-up.

Conclusions: Although uncommon, nephrosclerosis beyond that expected for age in a living kidney donor is associated with both prevalent HTN at donation and new-onset HTN at short-term follow-up.

TH-PO968

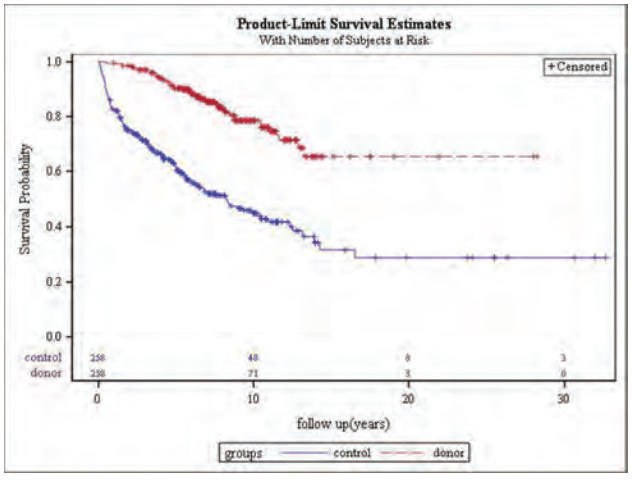
Mortality in Living Kidney Donors with ESRD: A Propensity Score Analysis Using the United States Renal Data System Robert Nee,[3,4] Amarpali Brar,[1] Dimitre Stefanov,[1] Rahul M. Jindal,[2] Madhu R. Joshi,[1] Bair Cadet,[1] Moro O. Salifu.[1] *[1]SUNY Downstate Medical Center, Brooklyn, NY; [2]USU-Walter Reed Department of Surgery, Uniformed Services University, Bethesda, MD; [3]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [4]Medicine, Uniformed Services University, Bethesda, MD.*

Background: Living kidney donation has been performed with the premise of acceptable safety of kidney donors. Although a very small percentage of living donors progress to end-stage renal disease (ESRD) after donor nephrectomy, evidence suggest that the rate of ESRD is comparable to that in the general population. However, for those donors who develop ESRD, their survival on dialysis has not been systematically assessed.

Methods: We used the United States Renal Data System (USRDS), and abstracted 274 prior living kidney donors (cases) between 1995 to 2009. There were 609,398 on dialysis without kidney donation (controls). Univariate analysis was used to test differences between the unmatched groups. We used propensity score matching to identify 258 cases and 258 controls. Time-dependent Cox proportional hazards model, adjusted for demographic factors and comorbidities, was used to compare survival between the two matched cohorts.

Results: In the propensity score-matched cohort, mortality was lower in cases compared with controls (19% vs 49%, p<0.0001). Cox model results demonstrated that cases had significantly lower mortality compared with controls (adjusted hazard ratio [AHR] 0.20, 95% CI 0.14-0.28, p<0.0001). Time-segmented analyses showed cases with significantly lower mortality 0-5 years (AHR 0.15; 95% CI 0.10-0.24; p<0.0001), and 5-10 years since start of dialysis (AHR 0.26; 95% CI 0.14-0.48; p<0.0001). After 10 years, the difference in survival was nonsignificant (AHR 0.48; 95% CI 0.17-1.32; p=0.15), likely due to the small sample size of patients in this time interval.

Conclusions: We observed a lower mortality rate in living donors with ESRD compared to matched non-donors. This data will guide clinicians in the informed consent process with prospective donors.



Survival curves of donors vs. matched non-donors with ESRD

TH-PO969

Dynamic Contrast Computed Tomography as a Separate Renal Function Test for Living Renal Transplantation Donors Midori Hasegawa, Jin Iwasaki, Kazuo Takahashi, Hiroki Hayashi, Shigehisa Koide, Daijo Inaguma, Yukio Yuzawa. *Fujita Health University School of Medicine, Toyoake, Japan.*

Background: Non-ionic contrast agent is stable in vivo and is eliminated without being metabolized, exclusively by glomerular filtration. The purpose of this study is to establish the method of measurement of glomerular filtration rate (GFR) and effective renal plasma flow (ERPF) by dynamic computed tomography (CT), for use in accurate separate renal function evaluation.

Methods: When preoperative abdominal contrast-enhanced CT of renal transplant donor candidates was performed, low level radiation (8 mSv) dynamic CT images were added every 2 for 30 seconds. The region of interest (ROI) was set at the right and left renal artery just before branching, and the CT value in the ROI was obtained. A time-density curve was derived from the CT value and photographing time. ERPF was calculated using the Patlak plot method. GFR was calculated using a 3-compartment model (intra-arterial, extracellular space, glomerulus) analytic method. CT based GFR was compared with inulin clearance results.

Results: Table 1 shows the results in 5 renal transplant donors. CT-based GFR closely coincided with inulin clearance. The filtration fraction (GFR/ERPF) was 0.22±0.03. Figure 1 shows the images of ERPF and GFR.

Conclusions: This method can be clinically applied for separate renal function evaluation.

Gender		Female	Female	Female	Male	Male

A Multivariate Model to Predict Post-Donation Kidney Function and Outcomes in Living Kidney Donors Sophie Limou,[2,3] Lola Jacquemont,[1] Edouard Gardan,[1] Simon Nusinovici,[1] Matthieu Hanf,[1] Maryvonne Hourmant.[1] *[1]CHU de Nantes, Nantes, France; [2]Inserm UMR1064, Center for Research in Transplantation and Immunology, Nantes, France; [3]Ecole Centrale de Nantes, Nantes, France.*

Background: Predicting kidney function after donation is a major challenge in living kidney donors. The aim of this study was to assess a wide range of demographics and clinical variables as non-invasive preoperative markers of post-donation kidney function.

Methods: 110 French living kidney donors who had a 51Cr-EDTA scintigraphy and a measured glomerular filtration rate (mGFR) pre- (D0) and one-year post-donation (Y1) were included. Over 15 characteristics were collected for each subject before and after nephrectomy (*e.g.* sex, age, hypertension, creatinine and lipids levels). Kidney volume was quantified using three methods: total parenchymal three-dimensional renal volume (3DRV), total parenchymal renal volume contouring (RVCt), and renal cortical volume (RCoV). We tested each variable for association with Y1 mGFR using univariate and multivariate regression models. Finally, we produced receiver operating characteristic (ROC) curves to assess the performance of our model in discriminating chronic kidney disease (mGFR<60mL/min) at Y1.

Results: The mean mGFR was 105.2±17.7 mL/min at D0 and 68.1±12.8 mL/min at Y1. Total parenchymal volume measurements exhibited a high correlation with RCoV (R2=0.92 for 3DRV and 0.84 for RVCt). In univariate models, the correlation between kidney volume and mGFR was the highest for the RCoV measures with R2=0.44 ($P=2x10^{-6}$) at D0 and R2=0.59 ($P=3x10^{-11}$) at Y1. Y1 mGFR was also strongly associated with age (R2=-0.62, $P=7x10^{-13}$) and D0 mGFR (R2=0.68, $P=4x10^{-16}$). Using stepwise regressions, we developed a model integrating 5 non-invasive preoperative markers (D0 mGFR, age, RCoV, triglycerides level and birth weight) predicting Y1 mGFR with a R2=0.68. Finally, the ROC curve analysis showed that this multivariate model could reliably predict chronic kidney disease at 1-year post donation (area under the curve [AUC]=0.92).

Conclusions: The integration of non-invasive preoperative characteristics in one statistical model can accurately predict post-donation kidney function and outcomes in French living kidney donors. These results warrant validation in an independent population. Our report therefore opens the way for developing a predictive risk score that would be easily implemented in clinics.

TH-PO971

Liberalization of Living Kidney Donor Selection Criteria and Long-Term Outcomes Marco van Londen, Anthony B. Wijninga, Maarten A. de Jong, Stefan P. Berger, Gerjan Navis, Martin H. De Borst. *University Medical Center Groningen, Groningen, Netherlands.*

Background: To meet the increasing demand for donor organs, selection criteria for living kidney donors have been liberalized. The impact of this liberalization is largely unknown. We compared long-term outcomes of living kidney donors over different time periods.

Methods: In this single-center prospective cohort study, we divided 323 living kidney donors into two groups according to the year of donation (1987-2004, n=81 vs. 2005-2012, n=242). We analyzed differences in age, sex, measured GFR (mGFR, continuous iothalamate), systolic blood pressure, proteinuria, BMI, and number of antihypertensives among the two groups (1987-2004 vs. 2005-2012) at baseline and at 5 years post-donation, using Student's t-test and Pearson's Chi-square test.

Results: At donation, sex (41% vs. 50%, p=0.13) and mGFR (105±14 vs. 103±16 ml/min/1.73m^2, p=0.23) were similar among both groups. However, donors who donated after 2004 were older (46±10 vs. 53±10, p<0.001), had a higher systolic blood pressure (122±11 vs. 129±14 mmHg, p<0.001), and BMI (25±4 vs. 27±4 kg/m^2, p=0.002), and more often used antihypertensives (5% vs. 15%, p=0.04). At 5 years post-donation, individuals who donated after 2004 had a lower mGFR (72±11 vs. 68±12 ml/min/1.73m2, p=0.01) and a more pronounced mGFR reduction compared with pre-donation (-35±12 vs. -39±15 ml/min, p=0.01). There were no differences in systolic blood pressure (126±13 vs. 128±14 mmHg, p=0.44), proteinuria (1.1±2.0 vs. 0.8±1.0 g/24h, p=0.34), BMI (27±4 vs. 27±4 kg/m^2, p=0.19) or number of antihypertensives at 5 years post-donation.

Conclusions: Our study confirms a trend in the liberalization of living kidney donors, at least regarding age and blood pressure at donation. Moreover, we observed a small but significant reduction in long-term renal function in living kidney donors who donated more recently. Future studies with longer follow-up should address the impact of donor liberalization on outcomes.

TH-PO972

Long-Term Renal and Non-Renal Morbidities in Living Kidney Donor Yaerim Kim, Hyunjin Ryu, Young Lee Jung, Jae shin Choi, Cheolgu Hwang, Mi-yeon Yu, Yon Su Kim, Hajeong Lee. *Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Kidney transplantation (KT) is the best treatment option for end-stage renal disease (ESRD). Safety of kidney donor has become an overarching theme according to increase of KT from living donor. However, risk factors for renal and non-renal morbidities were not clearly identified.

Methods: We observed 1,238 living kidney donors who underwent nephrectomy from January 1986 to February 2016 in a single tertiary hospital retrospectively. We estimated overall incidences of renal morbidities including ESRD and non-renal morbidities: hypertension (HTN), prediabetes, diabetes and malignancy. In addition, we analyzed significant risk factors for renal and non-renal morbidities.

Results: A total of 901 donors who were followed up more than 1 month were finally included. Median age was 42 (IQR, 18-65) years and 47.2% was women. Preexisting HTN was found in 47 (5.2%) donors. Only three donors had impaired glucose tolerance or diabetes at the time of donation. After 27 months of follow-up, final estimated glomerular filtration rate (eGFR) was 71.3 ± 14.36 ml/min/1.73m^2. One donor progressed to ESRD. Total 20.3% of donors failed to recover up to eGFR ≥ 60 ml/min/1.73m^2. Seventy eight (8.7%) of 901 donors presented new onset HTN, 43 (4.8%) prediabetes or diabetes, and 17 (1.9%) malignancy after donation. Interestingly, donors with preexisting HTN or diabetes did not show increased inadequate renal recovery. In the multivariate analysis, women, higher BMI and lower initial eGFR contributed to new onset hypertension independently. In addition, older age, higher BMI and inadequate renal recovery elevated new onset diabetes. Malignancy after donation was affected by older age, lower serum uric acid and albumin levels. Finally, inadequate renal recovery was associated with older age, higher BMI and lower initial eGFR.

Conclusions: Post-donation renal and non-renal morbidities are not rare. In our study, donors with older age, higher BMI and lower initial GFR should be monitored meticulously for developing renal and non-renal complications after donation. It is important to control adjustable risk factors strictly such as BMI and uric acid before and after donation to maintain their residual kidney function well.

TH-PO973

Hemodialysis Patient Social Networks Promote Living Donor Transplant Discussions Avrum Gillespie,[1] Swati Rao,[3] Sarah E. Dawson,[2] Heather M. Traino,[2] Peter P. Reese,[4] Zoran Obradovic,[2] Crystal A. Gadegbeku,[3] Edward L. Fink.[2] *[1]None, Philadelphia, PA; [2]Temple University, Levittown, PA; [3]Temple University School of Medicine, Philadelphia, PA; [4]University of Pennsylvania, Philadelphia, PA.*

Background: Social contagion theory posits that ideas, attitudes, and behaviors spread within social networks. However, little is known about the structure and influence of social networks within the unique setting of hemodialysis (HD) clinics. We examine the role of patient HD social networks and discussing living donor kidney transplantation (LDKT), a well-known barrier to renal patients' access to transplantation.

Methods: Survey and observational data collected between 8/2012 and 2/2015 were used to characterize the social network of 46 hemodialysis patients in a newly opened clinic.

Results: The mean age of participants was 54yrs, 58% were male, 39% Hispanic and 30% African Americans and 65% had discussed transplant with clinic nephrologist. Thirty-two (70%) patients interacted with others to form a social network, with 44% discussing transplantation with other patients. Patients who discussed transplant with others in their network were 19 times more likely (OR 18.7; 95% C.I. 3.4-101.5; p = 0.001) to request consideration of living donation from family/friends than those who were not connected through the clinic network. Patients who discussed transplant with HD staff were also more likely to discuss the possibility of live donation (OR 5.1 C.I. 1.5-18.1, p = 0.01). Patient demographic characteristics were not associated with discussions about living donation with individuals outside the clinic setting.

Conclusions: This study found that patients who discuss transplant with other patients and staff in the hemodialysis clinic are more likely to request consideration of living donation from member of their extra-clinic networks. These findings suggest HD patient social networks are potential target for social network interventions. This research also challenges the current ecological approach to barriers to transplantation which attributes only a small role to the HD clinic and often neglects the role of patient interactions.

TH-PO974

Racial/Ethnic Differences in Barriers to Kidney Transplant Evaluation among Hemodialysis Patients Derek R. Jones,[3] Zhiying You,[1] Jessica B. Kendrick.[2] *[1]UC Denver, Aurora, CO; [2]University of Colorado Denver and Denver Health Medical Center, Denver, CO; [3]University of Colorado School of Medicine, Denver, CO.*

Background: Only a small percentage of patients with end stage renal disease receive a transplant and this is particularly the case for racial/ethnic minorities. Our objective was to identify barriers to transplant evaluation in our dialysis centers.

Methods: We conducted a survey of adult hemodialysis patients in the Denver Metro area. Participants completed an 11-item survey with demographic information and questions regarding time on dialysis, if a provider ever spoke to them about a transplant and whether they had been evaluated for a transplant. Reasons for not having an evaluation were explored. Descriptive statistics were used to provide summaries of the responses.

Results: 167 patients completed the survey (response rate 63.9%). The majority of participants were male between the ages of 50-79 years and were Hispanic (49%) or Non-Hispanic Black (31.7%). 140 patients (84.0%) reported having a discussion about kidney transplantation with their doctor but only 53% (N=89) reported having a transplant evaluation. Fewer Non-Hispanic Blacks reported having a transplant evaluation than Non-Hispanic whites or Hispanics (43.4% vs. 57.7% (Whites) and 59.7% (Hispanics)) which trended towards statistical significance, p=0.07. The most frequent responses of the patients who had not been evaluated were: not referred by their provider (46%), did not know how to proceed (43.4%) or did not understand the benefits (39.5%) or transplant process (38.2%). Additionally, compared to Non-Hispanic whites, Blacks and Hispanics reported less understanding of the benefits and/or process of transplant.

Conclusions: Improved patient-provider communication and kidney transplantation education may reduce disparities in access to kidney transplantation.

TH-PO975

Care and Outcome of Refugees Kidney Transplant Patients in Jordan Kamel Hatahet,[3] Mohamed A. Sekkarie,[2] Sami Alasfar.[1] *[1]John Hopkins University Hospital, Baltimore, MD; [2]Nephrology and Hypertension Associates, Bluefield, WV; [3]Syrian American Medical Society, Waldorf, MD.*

Background: Taking care of displaced Kidney Transplant recipients (KTRs) is a big challenge and requires having a sustainable infrastructure. The Syrian American Medical Society (SAMS) shares its experience in managing these patients who are refugees camps in Jordan.

Methods: The screening process started by organizing medical missions to Jordan through SAMS established mobile clinic. SAMS medical missions were held every 3 months. The mission included one nephrologist from the US assigned to examine all KTRs, evaluate their recent labs, and to modify their immunosuppressants (IS) regimen. Others aims of the missions are to assure access and coverage for IS medications and to assess barriers for care.

Results: In July 2016, missions started providing care and medications for 17 KTRs and the number of patients has increased up to 41 patients April 2017. IS were provided and shipped from the U.S and given to the KTRs without charges with 3 months' worth of IS with each medical mission. No graft loss was noted throughout this period. There was one death due to pancreatic cancer. Figure 1 shows that serum Creatinine measurements have remained stable since mission started. Patients' characteristics is shown in table 1 Barriers included lack of a dedicated local nephrologist to address urgent medical problems, lack of affiliation with a nearby hospital to provide additional care such as renal biopsies, and costs of the IS and their shipments.

Conclusions: Medical missions to Syrian refugees' camps in Jordan seem to achieve a good outcome in KTRs. More work is needed to reach out to patients in other camps and countries and to overcome barriers. Future steps may include hiring a local nephrologist or developing affiliations with local hospitals.

Kidney Donor Risk Index Is a Good Prognostic Tool for Prediction of Early Post-Transplant Kidney Function and Graft Survival in a Korean Population Han Ro,[3] Miyeun Han,[4] Jong Cheol Jeong,[1] Ji Yong Jung,[3] Wookyung Chung,[2] Curie Ahn.[5] *[1]Ajou University Hospital, Suwon, Republic of Korea; [2]Gachon University Gil Hospital Nephrology, Incheon, Republic of Korea; [3]Gachon University Gil Medical Center, Incheon, Republic of Korea; [4]SEOUL NATIONAL UNIVERSITY HOSPITAL, SEOUL, Republic of Korea; [5]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Kidney donor risk index (KDRI) is used in the United States to estimate the deceased donor kidney. However, KDRI is not yet used in Asian population. We tried to validate KDRI in assessment of deceased donor kidney in a large number of Korean population group.

Methods: The data of Korean Organ Transplantation Registry (KOTRY) between 2009 to 2012 was used in the analysis. Among 1924 deceased donor kidney transplantation, 1582 cases in which KDRI score could be calculated were included in this study. We investigate the impact of KDRI on the graft function and graft survival.

Results: We divided the donors by KDRI tertile (T1: range, 0.6432~1.17025, T2: range, 1.17057~1.48566, T3: range, 1.48630~3.80629). The recipients of T1 were younger and had less diabetes. Mean estimated glomerular filtration rate at post transplant 1 year of each group was 76.1 ±21.0, 64.7 ±20.3, 55.5 ± 21.0 ml/min/1.73m^2 respectively. In the Cox regression analysis, KDRI showed good association with death censored graft survival, of which median follow up duration was 24.6 months (hazard ratio 1.778, 95% confidence interval 1.087-2.906, p=0.022).

Conclusions: KDRI is a good tool for estimation of early posttransplant outcomes in Korean population.

Defining the Delays to Kidney Transplant among American Indian Patients with Kidney Disease Mira T. Keddis,[1] Muneeb Ilyas,[1] Nan Zhang,[2] Raymond L. Heilman,[3] Amit Sharma.[1] *[1]Mayo Clinic, Phoenix, AZ; [2]Mayo Clinic Arizona, Scottsdale, AZ; [3]None, Phoenix, AZ.*

Background: The purpose of this study is to examine differences in the time from kidney transplant (KTx) evaluation to wait-listing and KTx rates in a cohort of American Indian (AI) patients compared to whites from 2012 to 2016 at a single center.

Methods: All AI patients presenting for KTx evaluation at Mayo Clinic Arizona from 2012 to 2016 were included (n=300). A random sample of non-Hispanic white controls matched for year of KTx evaluation was included (n=300).

Results: Compared to white controls, AI patients were younger (mean age 53±12.2 vs 57.2±13.4 years, p=0.0001), more likely to have diabetes (79 vs 41%, p<0.0001) and diabetic kidney disease (66.3 vs 35.7%, p<0.0001) and require dialysis at the time of evaluation (88 vs 58.3%, p<0.0001). They were more likely to have limited functional capacity at the time of KTx evaluation compared to white controls (55.3 vs 26.6%, p<0.0001). Several socioeconomic variables differed between the two groups with AI patients more likely to have the following associations: less than high school education (24.9 vs 7.3%, p<0.0001), single or widowed (32.6 vs. 17.8, p=0.008), and unemployed (81.7 vs 68.7%, p=0.001), There was no difference in the rate of prior history of cardiovascular disease between the two groups. AI patients had significantly lower rates of cancer diagnoses compared to white controls (3.3 vs 20.1%, p<0.0001). The time from initial KTx evaluation to selection conference decision regarding candidacy was delayed by 38 days for AI patients (mean 83 vs 45 days, p=0.0001) and they were more likely to be denied KTx compared to white controls (28.7 vs 19.2%, p=0.04). Reasons for denial did not differ between the two groups. Among patients deemed acceptable for KTx, AI patients were less likely to be listed on UNOS (84.2 vs 92.1 %, p=0.019), experienced longer delays from the time of approval for KTx to UNOS listing (median 42 vs 16 days, p<0.0001), and had longer waiting time from UNOS listing to receiving KTx (median 499 vs 380, p<0.0001) compared to whites. Transplant rates were significantly lower among AI compared to whites (25.5 vs 62%, p<0.0001).

Conclusions: Our study confirms that AI patients presenting for KTx suffer from significant delays in all steps of KTx evaluation and KTx rates in current times and highlights several clinical and socio-economic differences that may explain this disparity.

TH-PO1000

High Levels of Parathyroid Hormone after One Month of Renal Transplantation Are Related to Long Term Graft Loss Carlo M. Alfieri, Maria Teresa Gandolfo, Valentina Binda, Donata Cresseri, Mariarosaria Campise, Anna Regalia, Maria Meneghini, Piergiorgio Messa. *Fondazione IRCCS Ca' Granda Ospedale Policlinico Milan, Milan, Italy.*

Background: Renal transplantation (RTx) only partially corrects certain metabolic alterations, especially in mineral metabolism (MM). Our aim was to examine the effect of RTx during the 1styear of RTx on MM parameters and to evaluate the factors mostly related to long term graft outcome.

Methods: In 531 RTx pts (age:48[39;58]yrs–303males), transplanted in our unit between 2004 and 2014, clinical parameters, blood and urinary samples were collected before RTx and at 1, 6, 12 mths after RTx. Median follow up was 7[2-12]yrs.

Results: 84% of pts received a RTx from a deceased donor; 72% and 20% of pts were treated with haemodialysis and peritoneal dialysis before RTx. Time of dialysis was 48[30-71]mths. In the overall cohort MM parameters before RTx were: Ca 9.3[8.8-9.8] mg/dL, P 5.0[4.05-5.85] mg/dL, iPTH 205[123-443]pg/mL, ALP 106[66-170] U/L. Cold ischemia time (CT) was 13[11-16]h. In 13% of pts DGF was reported, and 13% of pts had a rejection during the 1st year of RTx. During the 1st year of RTx, 6% of pts received cinacalcet. Thirty-five% of pts were treated with active vitamin D, whereas in 11 % were supplemented with natural vitamin D alone. In the 1st year of RTx, a reduction of iPTH levels was observed(p=0.005). During follow up time, 66 pts restarted dialysis (D+). Compared to pts with a functioning graft (D-), D+ had longer CT(p=0.01) and at the 3-timepoints considered, worst renal function, higher urinary protein excretion and of iPTH. A difference in 1st year rejection prevalence was found (p=0.001) between the two groups. In multivariate analysis only iPTH at 1st mth and not iPTH at 12th mth resulted independently related with graft loss(p=0.03). Using ROC curve, the the discriminatory power in predicting graft outcome was tested for: 1st mth eGFR (AUC 0.37±0.04 – p=0.003), 1st mth Prot-U(AUC 0.62±0.04 – p=0.002) and 1st mth iPTH (AUC 0.62±0.05 – p=0.01 – cut-off value 75 pg/mL). The inclusion of iPTH to eGFR and Prot-U provided an increase in discriminatory power which was +30% for eGFR + iPTH (AUC from 0.37 to 0.67 –p<0.001) and +3% for Prot-U + iPTH (AUC from 0.62 to 0.65 –p=0.002).

Conclusions: Our data confirm that RTx is able to influence MM from the beginning, and that early elevated iPTH levels at 1st month of RTx may play a role on long-term graft outcome.

TH-PO1001

Impact of Elevated PSA on Time to Kidney Transplant and Mortality in ESRD Patients Nagaraju Sarabu,[2] Nicholas K. Schiltz,[1] Donald E. Hricik.[2] *[1]Case Western Reserve University, Cleveland, OH; [2]University Hospitals Case Medical Center, Rocky River, OH.*

Background: Conflicting opinions and practices exist about screening for prostate cancer prior to kidney transplant with a PSA because of the concern that it might delay transplant causing more harm than benefit.

Methods: This study included incident male ESRD patients over 45 years from the 1999-2012 United States Renal Data System, linked with Medicare claims data. Our main study variable of interest was elevated prostate specific antigen (PSA) as indicated through an ICD-9-CM diagnosis code. Primary outcomes of interest were time to kidney transplant and mortality. We used propensity score matching to control for selection bias, and Cox proportional hazards models and Kaplan Meier curves to compare the risk between men with elevated and non-elevated PSA.

Results: 2789 of 64307 (4.3%) of the patients had elevated PSA. Figure 1 shows the baseline characteristics of 2789 patients with elevated PSA and 2789 propensity based matched controls. Elevated PSA was associated with lesser mortality (HR:0.66; CI: 0.62-0.70), and did not significantly increase time to transplant (HR: 0.80; CI: 0.80-1.06). Kidney transplant significantly improved survival regardless of the PSA status prior to transplant.

Conclusions: Elevated PSA is not a contraindication for kidney transplant, and therefore should not be delayed.

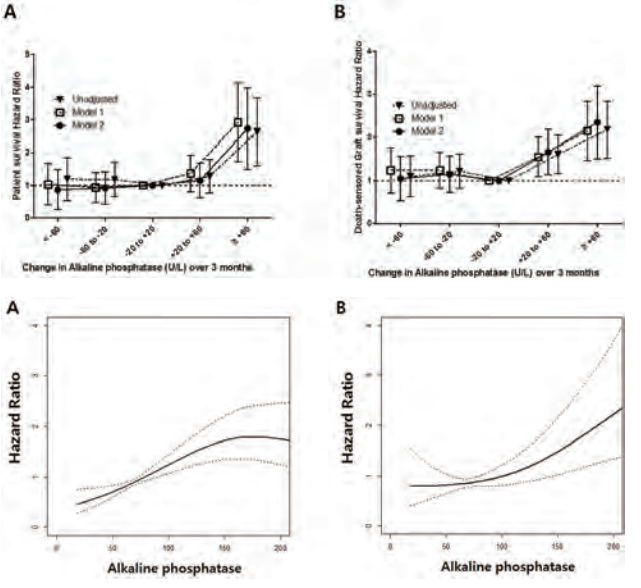
Pre- and Post-Transplant Serum Alkaline Phosphatase Predicts Graft Failure and Mortality in Kidney Transplant Recipients Yong Chul Kim,[1] Seokwoo Park,[1] Hajeong Lee,[1,2] Chun Soo Lim,[2,3] Yon Su Kim,[1,2] Jung Pyo Lee.[2,3] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Recent studies showed that high levels of serum alkaline phosphatase (AlkPhos) are associated with all-cause or cardiovascular death in chronic kidney diseases. However, there are apparently no data on the effect of AlkPhos in kidney transplant recipients (KTRs). The aim of this study was to evaluate whether serum AlkPhos is associated with graft failure and mortality after kidney transplantation.

Methods: Among the 3029 kidney transplant recipients (KTRs) who were enrolled in a multicenter cohort, we examined the association of pre- and post-transplant serum AlkPhos levels and long-term outcomes in KTRs.

Results: Pre-transplant serum AlkPhos ≥ 80 IU/L was associated with a hazard ratio (HR) for graft failure of 1.571 (95% CI 1.146-2.152, P = 0.005) in a fully adjusted model. Death-censored graft failure (DCGF) rate in kidney recipients gradually increased along the increments of AlkPhos. Also, a rise in serum AlkPhos by 40 IU/L during the first 3 months after kidney transplantation was associated with higher rates of DCGF (HR 2.353, 95% CI 1.506-3.676) and higher rates of mortality (HR: 2.733, 95% CI 1.479-5.050). Cox regression models using time-varying AlkPhos for initial 3 months after transplantation demonstrated significant relationships between AlkPhos and DCGF (HR 1.39, 95% CI 1.04-1.84) or mortality (HR 2.14, 95% CI 1.39-3.27).

Conclusions: Increased pre- and post-transplant serum AlkPhos and a rise of serum AlkPhos during early period after kidney transplantation is associated with graft failure and mortality in kidney transplant recipients.



TH-PO1003

High-Resolution Digital Analysis of Leukocyte Densities in Early Surveillance Biopsies Significantly Improves Prediction of Kidney Transplant Function after Four Years of Follow-Up Sibylle Von Vietinghoff,[1] Jan H. Braesen,[3] Abedalrazag A. Khalifa,[3] Jessica Schmitz,[1] Gunilla Einecke,[2] Bernhard M. Schmidt,[1] Anke Schwarz,[1] Hans H. Kreipe,[1] Hermann G. Haller.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Medical School Hannover, Hannover, Germany; [3]Medizinische Hochschule Hannover, Hannover, Germany.*

Background: Minor histopathological changes are difficult to quantify by eye. The impact of inflammation on renal allograft survival has been demonstrated in grafts with rejection, and, on a molecular level, also in early surveillance biopsies. We assessed leukocyte abundance in early surveillance biopsies by digital image analysis and analyzed impact on outcome.

Methods: In 67 surveillance biopsies six weeks after transplantation a full Banff classification was performed. T cell (CD3), B cell (CD20), macrophage (CD68) and dendritic cell (CD209) densities and CD206 and HLA-DR markers were assessed by digital image analysis (Definiens system).

Results: An average surface area of 4.7±2.4 mm^2 renal cortex was assessed, with average 1.7%CD3, 0.5%CD20, 0.3%CD68, 0.2% CD209. CD3, CD20 and CD68% were significantly higher in grafts with histological rejection. High CD68 density associated with lower combined patient and graft survival after four years. CD20 and CD68 densities inversely correlated with eGFR. CD68 correlated with eGFR loss. $CD68^+$ macrophages were localized mainly in the interstitium. Tubular macrophages increased in grafts with rejection. HLA-DR and CD206 were assessed for M1 and M2 polarization with more M1 positivity in the cortex, and more M2 in the medulla. Among histological measurements including a complete Banff classification, only CD68 density was a significant predictor of CKD IV after four years. It also significantly contributed to the best eGFR prediction set in multivariable linear regression analysis of clinical and pathological parameters. The original CD68 median maintained its discriminative power for survival and eGFR in a second independent cohort.

Conclusions: In comparison to other histopathological markers and as an addition to known clinical risk factors, $CD68^+$ macrophage density measurement significantly improves prognostic value of early surveillance biopsies.

Renal Parenchymal Calcifications in a Cohort of Renal Transplanted Patients and Their Correlations with Long Term Graft Outcome Carlo M. Alfieri, Gabriella Moroni, Donata Cresseri, Anna Regalia, Francesca Zanoni, Valentina Binda, Maria Teresa Gandolfo, Mariarosaria Campise, Paola Simonini, Masami Ikehata, Maria Meneghini, Piergiorgio Messa. *Fondazione IRCCS Ca' Granda Ospedale Policlinico Milan, Milan, Italy*.

Background: Renal calcifications(RC) have been described in kidney transplantation(KTx), but the aetiology and significance of this finding are still unclear. Our aim is to evaluate the prevalence an the clinical impact on long term graft prognosis of RC.

Methods: 95 KTx pts, submitted to renal biopsy(RBx) on clinical indication from 2009 to 2012 were followed up until 2016 (FU time:(5[4-6]yrs). Clinical and biochemical data were collected at the time of RBx(TBX),12mth before(T-12) and after(T+12) the RBx. Exposition to Ca, P and PTH during the year before RBx was calculated by averages of the observed values. In yrs after T+12(Tfu), creatinine, Ca, P, PTH, ALP, Prot-U were recorded annually and analyzed as averages of observed values. RBx were studied for general histology and for RC by Von Kossa(VK) staining. In pts with more than one RBx, only the 1st one was considered. Pts in which VK was negative or slight positive were defined as group1(VK-1:n 68;46 slightly positive), while pts with moderate or severe VK positivity were included in group2(VK-2:n=27;8 high VK positive).

Results: The pts were 51 males and 44 females, age 50±12 yrs. VK groups did not differ for gender, age, type of KTx, VK-2 had longer time of KTx(p= 0.03). At T-12, TBX and T+12, renal function was similar between the groups. No differences were found in mineral metabolism(MM) at TBX, while VK-2 had a lower exposition to PTH during the year before RBx(p<0.001). VK-2 had higher glomerulosclerosis(GS;p=0.04). During Tfu, VK-2 pts had worst sCr(p=0.04) higher PTH and ALP(p=0.03;p=0.002). 33 pts have lost their graft during the F-U time, with a higher prevalence in VK-2(p=0.0006). By means of Cox regression and Kaplan Meier analysis belonging to VK-2 was the stronger independent parameter related to graft loss (HR=3.49–p=0.001;K-M p<0.0001).

Conclusions: The prevalence of RC in RBx is quite high. RC correlated with PTH exposition during the year before RBx, but not with Ca and P levels. Time of KTx and GS also were related to RC, assigning to RC a significance of chronic damage rather than a simply result of MM imbalance, at least in the RBX performed on clinical indication. A relation between VK positivity at TBX and long term graft loss was also found.

TH-PO1005

Dynamics of DNA Methylation in Renal Allograft: From Early Ischemia/Reperfusion Injury to Late Fibrosis Response Sai Vineela Bontha, Valeria Mas. *University of Virginia, Charlottesville, VA.*

Background: The mechanisms of development of fibrosis post-transplantation are not completely understood. Early graft insults like ischemia/reperfusion injury followed by course of its response/repair could involve changes in molecular determinants including DNA methylation (DNAm) which influence long term allograft function. In the current study we assessed the dynamics of DNAm across 1) pre-implant biopsies post-ischemic injury (PI) 2) post-reperfusion (PR) and 3) >24 months post kidney transplantation (KT).

Methods: Infinium 450K methylation (n = 96) and gene expression (n = 182) arrays were performed in PI, PR and KT renal allograft biopsies and analyzed. Genome runner was used to assess distribution and enrichment of Dme CpG sites along regulatory features. Integrative analyses of differentially methylated (Dme) CpGs and corresponding differential gene expression were performed at each matched time points.

Results: PI allografts classified based on progression to allograft dysfunction showed 1,188 Dme CpGs mapped to genes involved in inflammation and metabolism. When paired PI and PR allografts were compared there was apparent change in DNAm of genes involved in pathways like *NRF2* mediated oxidative stress response and functions like cellular assembly and organization, cell death and survival. Integration analysis showed Dme and expression of genes involved in energy metabolism, transporters and transcription factors important in regulation of immune response. Further, comparison of post-KT allografts with differential outcomes revealed 21,351 Dme CpG sites. The Dme CpGs observed at early time points were mostly hypomethylated and promoter associated. However, a shift in the pattern was observed in later stages. Dme CpGs were interestingly located in gene bodies and in evolutionarily conserved tissue specific regions. Integration analysis corroborated with findings as gene expression changes in kidney tissue specific regions like tubular epithelium was observed.

Conclusions: Shift in DNAm pattern over time in renal allograft is evident with corresponding change in gene expression pattern. It is important to study closely the sequential changes to evaluate timely therapeutic intervention based on the pathways dysregulated at different molecular levels.

Investigating Angiotensin II-Regulated Proteins as Biomarkers of Fibrosis in Kidney Transplant Recipients Zahraa Mohammed-Ali,[4] Shelby Reid,[2] Tomas Tokar,[6] Paul M. Yip,[4] Alexandre Tavares-Brum,[1] Heloise Cardinal,[1] Joseph Kim,[3] Ana Konvalinka.[5] *[1]Centre Hospitalier de l'Université de Montréal, Montral, QC, Canada; [2]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [3]Toronto General Hospital, University Health Network, Toronto, ON, Canada; [4]University Health Network, Toronto, ON, Canada; [5]University Health Network, University of Toronto, Toronto, ON, Canada; [6]Princess Margareth Cancer Center, Toronto, ON, Canada*.

Background: AngiotensinII, the main effector of the renin-angiotensin system (RAS), causes kidney interstitial fibrosis/tubular atrophy (IFTA). However, specific markers of kidney AngII activity remain unknown. Here we report on the urine excretion of 6 AngII-regulated proteins (BST1, GLNA, LAMB2, LYPLA1, RHOB and TSP1), and show that 1) they reflect IFTA in kidney transplant recipients; 2) they are modified by RAS inhibition.

Methods: A previously developed mass spectrometry-based assay was used to quantify 6 AngII-regulated proteins in urine of 2 cohorts of kidney transplant recipients from a single Canadian centre: 1) 19 patients with IFTA and 19 stable controls with concomitant urine and biopsy samples; 2) 20 patients with urine and biopsy samples before and after RAS inhibition. Differences in creatinine-adjusted urine levels of AngII-regulated proteins between IFTA and control patients were assessed using two-tailed t-test. Correlations between AngII-regulated proteins and traditional markers of kidney graft function were evaluated using Spearman's rank correlation. Fixed-effects model was used to assess changes in AngII-regulated proteins following RAS therapy.

Results: Urine excretion of all AngII-regulated proteins was significantly higher in IFTA compared to control (ln fmol/µmol of creatinine ± SD, BST1: 17.46±0.65 vs 9.76±0.20, p=0.01; GLNA: 9.73±0.52 vs 1.62±0.17, p=0.009; LAMB2: 90.22±2.99 vs 54.05±1.55, p=0.03; LYPLA1: 6.61±0.77 vs 2.13±0.05, p=0.0002; RHOB: 9.02±3.42 vs 1.10±0.13, p=0.004; TSP1: 8.05±0.81 vs 3.47±0.16; p=0.002). These proteins correctly separated IFTA and control patients in unsupervised hierarchical clustering analysis. Urine excretion of all AngII-regulated proteins correlated with each other, but not with serum creatinine and total urine protein. All AngII-regulated proteins negatively correlated with RAS inhibitor use over time (fixed effects coefficient<0); however, GLNA and TSP-1 were most significantly decreased (p<0.05).

Conclusions: Urine excretion of AngII-regulated proteins was significantly increased in patients with IFTA and was modified by RAS inhibition. These proteins may represent coveted markers of kidney fibrosis, and may be valuable in guiding therapy with RAS inhibitors.

TH-PO1007

Clinical and Histologic Review of Transplant Nephrectomy Cases in a Single Center Soo Ya Bae,[1] Chung Hee Baek,[2] Su-Kil Park.[2] *[1]Asan Medical Center, Seoul, Republic of Korea; [2]Asan Medical Center, Songpa-gu, SEoul, Republic of Korea*.

Background: Despite advancement in the management of kidney allograft, several indications for transplant nephrectomy still exists. Chronic allograft intolerance syndrome is the most common reason of transplant nephrectomy (TN). Recent studies reported antibody mediated rejection (ABMR) plays an important role in chronic allograft injury and subsequent graft failure. There is few studies about histopathology of TN, resulting lack of knowledge about predominant type of rejection resulting chronic allograft intolerance syndrome. We investigated clinical indications and histologic diagnosis of TN cases, especially the type of rejection.

Methods: From January 1995 to March 2016, 96 cases of TN were done in Asan Medical Center. We reviewed 88 cases of TN for baseline clinical characteristics, clinical indication of TN and histologic diagnosis after TN.

Results: Most common cause of end stage renal disease (ESRD) were primary glomerular nephritis (23.9 %) and hypertension (23.9 %). Most common clinical indication of TN was chronic allograft intolerance syndrome (43.3%). Rejection was the most common histologic diagnosis of TN (73.1%), of chronic allograft intolerance syndrome cases either (92.1%). Among 24 rejection cases diagnosed by Banff 2007, 13 cases were T cell mediated rejection (TCMR), and 10 cases were mixed rejection. Among 10 rejection cases by Banff 2013, 2 cases were TCMR, and 8 cases were mixed rejection. Among 14 cases of chronic allograft intolerance syndrome by Banff 2007 and 2013 classifications, 6 cases were TCMR, and 8 cases were mixed rejection. 9 cases showed discrepancies between clinical indication and histologic diagnosis (10.2 %), 7 cases showed discrepancies in the type of rejection (8.0 %).

Conclusions: Chronic allograft intolerance syndrome was the leading clinical indication for TN, and rejection was the most common histologic diagnosis. By Banff 2007 and 2013 classification, pure TCMR and mixed rejection cases were predominant. Some discrepancies between clinical indication and histologic diagnosis existed, with discrepancies in the type of rejection as well.

TH-PO1008

Uncovering the Association between Early Histological Features of Diabetic Kidney Disease and Renal Allograft Outcomes Jacob Cho, Chelsea C. Estrada, Sandeep K. Mallipattu. *Stony Brook Medicine, Stony Brook, NY.*

Background: Diabetes Mellitus is a risk factor for worse renal allograft survival, but patients typically do not lose their allograft due to diabetic kidney disease (DKD). However, it remains unclear whether early diabetic changes in the transplanted kidney are associated with worse outcomes. The objective of this pilot study is to determine whether histological features consistent with early DKD are predictive of subsequent graft loss.

Methods: We reviewed consecutive, clinically indicated, renal allograft biopsies performed at Stony Brook University Hospital from 2010 to 2015. Biopsies with either mesangial matrix expansion (MME) or thickened basement membrane (TBM) were classified as early DKD (eDKD). Patients with a final diagnosis of transplant glomerulopathy (TG) or overt DKD were excluded. Graft failure, creatinine, and eGFR were also collected at 6 months, 1 year and 2 years post biopsy. All data was assessed for normality, and then parametric or non-parametric tests were employed for data analysis.

Results: In total, 247 renal transplant biopsies were reviewed. Biopsies were performed at a mean of 3.98 ± 0.93 years post-transplantation. In total, 83 were excluded for either overt DKD or TG. Of the remaining 164 biopsies, 89 (54.2%) were classified as eDKD and the rest (45.7%) as non-diabetic kidney disease (NDKD). Baseline demographics for the two groups are in **Table 1**. Mean HbA1C was 6.0 ± 0.1% in the eDKD group and 6.2 ± 0.2% in the NDKD group. In all, 25/89 (28.1%) patients in the eDKD had graft failure at a mean of 0.9 years post biopsy, as compared with 16/75 (21.3%) patients in the NDKD group (p= 0.368).

Conclusions: In this small cohort, these data suggest there is a trend towards worse renal allograft outcomes in patients with early histological features of DKD. Further analysis of eGFR trends and a larger sample size are required to determine the significance of early DKD changes on allograft outcomes.

The Association of Calcium Oxalate Deposition in Kidney Allografts with Graft and Patient Survival Ragnar Palsson,[1,2] Anil K. Chandraker,[1,2] Gary C. Curhan,[1,2] Gearoid M. McMahon,[1,2] Sushrut S. Waikar.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Oxalate is a dicarboxylic anion that can precipitate with calcium and cause kidney injury. Patients with end-stage renal disease (ESRD) have elevated plasma levels of oxalate. After kidney transplant (Tx), hyperoxaluria ensues, increasing risk of calcium oxalate deposition (CaOxD) in the allograft. Few studies have examined risk factors for CaOxD in this setting and its association with patient outcomes.

Methods: We performed a retrospective cohort study of patients who had allograft biopsies at our hospital within 3 months of Tx, from 10/1999–2/2015. The presence or absence of CaOxD was extracted from biopsy reports. We determined risk factors for CaOxD and evaluated its association with the composite outcome of graft failure or death at 2 years.

Results: 68 of 346 patients had CaOxD in allograft biopsies. Factors associated with CaOxD in multivariable models adjusting for serum calcium, black race and donor type (living vs. deceased) were: dialysis vintage (odds ratio (OR) 1.15, 95% CI 1.01-1.30 per additional year), diabetes as a cause of ESRD (OR 2.67, 95% CI 1.26-5.63) and elevated serum creatinine at the time of biopsy (OR 1.31, 95% CI 1.16-1.48 per additional mg/dL). After further adjusting for delayed graft function (DGF), these associations became non-significant with only DGF remaining a significant predictor of CaOxD. CaOxD was associated with 2.56-fold (95% CI 1.20-5.45) increased odds of graft failure or death at 2 years in a multivariable model adjusted for black race, donor type, dialysis vintage and acute rejection. After adjusting for DGF, the association between CaOxD and graft failure or mortality became non-significant (OR 1.56, 95% CI 0.68-3.57).

Conclusions: CaOxD is common in patients with early graft dysfunction after Tx, and is strongly associated with DGF and poor graft and patient survival. Whether CaOxD in the allograft contributes to poor outcomes through DGF or other mechanisms is a possibility that could be tested in trials involving oxalate lowering therapies prior to Tx.

Urinary Microvesicles in Kidney Transplantation: A Source for Novel Early Biomarkers for Delayed Graft Function and Overall Outcome Fabian Braun,[1] Markus M. Rinschen,[1] Corinna Klein,[2] Denise Buchner,[3] Roger Wahba,[3] Dirk L. Stippel,[3] Christine E. Kurschat,[1,2] Bernhard Schermer,[1] Andreas Beyer,[2,4] Thomas Benzing,[1,2] Roman-Ulrich Mueller.[1,2] *[1]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University Hospital Cologne, Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, University of Cologne, Cologne, Germany; [3]Department of General, Visceral and Cancer Surgery, Division of Transplantation Surgery, Transplant Center Cologne, University Hospital of Cologne, Cologne, Germany; [4]Systems Biology of Ageing Cologne, SyBaCol, University of Cologne, Cologne, Germany.*

Background: Microvesicles (MVs) are a promising source for cellular material comprising specific proteins and nucleic acids that can be isolated easily from most body fluids. This is especially true for urinary microvesicles, yet their implementation in routine diagnostics is still subject to investigation. We hypothesize that the diagnosis of kidney transplant failure by kidney biopsy could in particular benefit from the addition of novel noninvasive biomarkers for the prediction of graft survival.

Methods: We established a protocol of differential centrifugation, to isolate MVs from urine collected from living kidney transplant recipients and their corresponding donors over the course of 20 kidney transplantations. We collected whole urine samples on day -1 (donor sample), 0, 1 and 3 months after transplantation (recipient sample). MV pellets were analyzed using quantitative mass spectrometry based proteomics. We used linear regression models to find proteins which linearly change their abundance in correspondence to clinical parameters, e.g. GFR measured at 6 and 12 Months after transplantation.

Results: With our approach we were able to identify >1500 proteins present in at least 50% of the collected samples. Strikingly, using hierarchical cluster analysis we detected a clear clustering of the sample proteomes by time point of urine collection. Furthermore we detected specific proteomic time course patterns over the course of transplantation, with complement and serum-bourne proteins peaking shortly after transplantation. Also, MV proteins of glomerular or tubular origin were regulated distinctly over the course of transplantation. We chose 64 candidate proteins that showed low statistical error and high stability in the leave-one-out cross-validation of the linear models with GFR values measured after 6 and 12 months or that were either only or not detected in samples depicting delayed graft function.

Conclusions: Our analysis represents the first concise data set depicting the changes in the human urinary MV proteome over the course of kidney transplantation. Ongoing experiments will focus on the validation of candidate proteins correlating with long term outcomes and the analysis of their clinical implementation.

TH-PO1011

Dynamic Creatinine Clearance Calculation Enables Early Assessment of Kidney Function and Advances Detection of Functional Decline After Renal Transplantation Paul Beele, Arjan D. Van Zuilen, Maarten B. Rookmaaker. *UMCU, Utrecht, Netherlands.*

Background: Immediately after renal transplantation (RTX), graft function can be compromised for which early intervention can be crucial. However, the rapid fall

in plasma creatinine concentration immediately after RTX can conceal graft function decline. We present a strategy to estimate creatinine clearance (C_{Cr}) immediately after RTX and advance detection of functional decline.

Methods: C_{Cr} was derived from 2 subsequent plasma creatinine levels over time using a newly developed method for Dynamic Creatinine Clearance Calculation (D3C) (Fig1A). We estimated C_{Cr} one day (T1) after RTX by D3C and correlated this to the estimated C_{Cr} using CG at T12 in 154 uncomplicated RTX patients. We also investigated whether monitoring of D3C could advance detection of functional decline in patients with early rejection.

Results: Average plasma creatinine at T1 was 350±204μM and 155±75μM at T12. D3C at T1 was 50±22ml/min whereas CG estimated C_{Cr} was 59±21ml/min at T12. D3C at T1 correlated to GC estimated C_{Cr} at T12 (R=0.741, R^2=54,9%, p=0.000) (Fig1B), improving upon plasma creatinine correlation at T1 and T12 (R=0.661, R^2=43.7%, p=0.000). Detection of functional decline was advanced by identifying a decreasing D3C over time as compared to an increase in plasma creatinine concentration over time. This is illustrated by 2 patients with biopsy proven rejection (Fig1C,D) and 2 uncomplicated transplantations (Fig1E,F).

Conclusions: One day after RTX D3C significantly correlates to CG estimated C_{Cr} at T12 in uncomplicated RTX patients. Moreover, monitoring of renal function using D3C after RTX advances detection of functional decline on average by 2 days, expediting therapeutic intervention and conceivably improving clinical outcome.

TH-PO1012

Proposal of Score to Predict Outcome of Deceased Donor Renal Transplantation Carlos rafael A. Felipe,[3] Andre S. Alvarenga,[3] Silvana Maria C. Miranda,[1] Gerson M. Pereira jr,[3] Pedro Augusto M. Souza,[2] Izabela L. Piana,[4] Ana elisa S. Jorge.[3] *[1]Hospital Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [2]None, Belo Horizonte, Brazil; [3]Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [4]Faculdade de Minas Faminas BH, Belo Horizonte, Brazil.*

Background: Kidney Donor Profile Index (KPDI) correlated with graft loss and death. However, patients who received kidneys with the same KDPI may have different outcomes.

Methods: We developed a score system based on data of 113 deceased donor renal transplants (DDRT) from 01/2013 to 02/2016: mean age 50.7 years; mean cold ischemia time was 13.4 hours; 62% presented delayed graft function; the median of the KDPI was 53.5%. The score was calculated assigning one point for KDPI ≥ 70%, donor serum creatinine ≥ 2.0mg/dL and donor age ≥ 50 years (table 1). Patients were divided in 4 groups according to the sum of points (0, 1, 2, 3 points) and graft survival was evaluated for each group.

Results: Distribution of patients by points categories: 0 points - 47.8%; 1 point - 27.4%; 2 points - 19.5%; 3 points - 5.3%. One year graft survival was 88.4% for 0 points, 73.6% for 1 point (p = 0.0735 vs 0 pts), 61.5% for 2 points (P = 0.0076 vs 0 pts) and 0% for 3 points (p <0.0001 vs 0 pts). Combining kidneys with a score of 0 and 1 point, 1-year graft survival was 82.9%, significantly higher than kidneys with 2 points (p = 0.0368) and 3 points (p <0.0001) [figure 1].

Conclusions: Kidneys with 0 or 1 point had better survival, being acceptable for most transplant candidates. Kidneys with 2 points presented intermediate survival, and may be more suitable for candidates with a low expectation of obtaining a better graft in a timely manner. None of the 6 recipients who received 3-point kidneys had a functioning graft after 1 year, raising serious concerns about the acceptability of these organs.

Scoring points system

Criteria	Points
KDPI > 70%	1
Final Donor creatinine > 2.0mg/dL	1
Donor age > 50 years	1
Total	

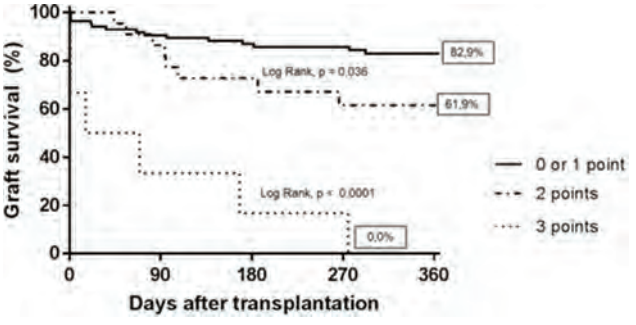

Figure 1. Graft survival according to scoring points groups

TH-PO1013

Development of a New Prediction Model for Graft Function in Living Donor Kidney Transplantation Yuta Matsukuma,[1] Kosuke Masutani,[1] Shigeru Tanaka,[2] Akihiro Tsuchimoto,[1] Kohei Unagami,[3] Masayoshi Okumi,[3] Kazunari Tanabe,[3] Kazuhiko Tsuruya,[1] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Fukuoka, Japan; [2]Fukuoka Dental College, Fukuoka, Japan; [3]Tokyo Women's Medical University, Tokyo, Japan.*

Background: In recent years, there has been an increase in usage of grafts from marginal donors in living donor kidney transplantation. Such donors have several co-existing atherosclerotic factors such as aging, hypertension, dyslipidemia, and relatively low renal function. A simple prediction model for post-operative graft function may help to determine whether marginal donors are suitable in clinical settings of living donor kidney transplantation.

Methods: We conducted a single-center retrospective cohort study using clinical and laboratory measurements to construct a prediction model for graft function at 1 year. Low graft function was defined as estimated glomerular filtration rate (eGFR) ≤ 45 mL/min/1.73m^2 at 1 year. A risk prediction model for low graft function was developed using multivariable logistic regression model with a stepwise backward elimination method.

Results: A total of 343 living donor kidney transplantation procedures were performed between January 2006 and May 2016. 123 patients had eGFR ≤ 45 mL/min/1.73m^2 at 1 year after transplantation. Risk prediction model for low graft function was developed using donor age, pre-operative eGFR, hypertension, and donor/recipient body weight mismatch. The incidence of low graft function increased linearly with increase in total risk scores (p for trend <0.01). This model demonstrated modest discrimination (c-statistics = 0.75) and good calibration (Hosmer–Lemeshow test: p=0.77).

Conclusions: A new prediction model computed from four pre-operative variables created in this study is simple and useful system in clinical settings for prediction of graft function at 1 year in living donor kidney transplantation.

TH-PO1014

Patients with ESRD Secondary to a Plasma Cell Dyscrasia: The Combined Transplantation Is a Good Option Beatriz Redondo navarro, Candela Moliz, Maria Molina, Enrique Morales, Manuel Praga, Esther Gonzalez monte, Amado Andres. *Nephrology Department, Hospital 12 de Octubre, Madrid, Spain.*

Background: Plasma cell dyscrasias (PCD) are due to an abnormal proliferation of a single clone of plasma or lymphoplasmacytic cells leading to secretion of immunoglobulin (Ig) or an Ig fragment and are a known cause of end stage renal disease (ESRD). Traditionally, renal transplantation (RT) has been avoided in these patients due to the poor patient survival, the risk of recurrence in renal allograft and the high incidence of life threatening infections. However, the improving result of stem cell transplantation (SCT) in combination with the new drug in PCD patients with ESRD has encouraged to considerer in them a RT therapy.

Methods: We performed a retrospective study that included all patients with PCD who have received both SCT and RT in our hospital. We reviewed renal and haematological evolution, infections complications and recipient and RT survival after 3 year of follow-up.

Results: We included 6 patients: 4 (67%) males, median age 55 years old (49-57). The causes of ESRD were: 2 cast myeloma, 2 light-chain diseases, 1 primary amyloidosis and 1 focal segmental glomerulosclerosis. The causes of PCD were: 5 multiple myeloma and 1 primary amyloidosis. 4 (67%) of the patients received SCT 4 before RT and 2 (33%) after RT. The median creatinine at 1 and 3 year were 1.6 (1.1-1.9) and 1.3 (1.1-1.9) mg/dl, respectively. After 3 years of follow-up, renal graft survival non-death censored was

83 %. 5 episodes of infections that need admission occurred in 3 patients: 2 Aspergillus, 2 viral infections and 1 urinary infection. 3 patients developed a recurrence of their PCD: 2 had a remission after treatment with lenalidomide (one partial and the other one complete remission) and 1 patient finally died 15 months. Patient survival at the end of follow-up was 83%.

Conclusions: Sequential SCT and RT could be a suitable option for patients with PCD and ESRD. The patient and renal graft survival arte conditioned to the relapse of hematological disease and infections complications. The high incidence of fungal infection will require special prophylaxis measure. These results highlight the importance of declaring more number of patients in this situation and with longer follow-up to elucidate the best management of PCD with ESRD.

TH-PO1015

Assessment of a Dedicated Transplant Low Clearance Clinic and Patient Outcomes on Dialysis after Graft Loss at Two UK Transplant Centres Rhys D. Evans,[3] Soliana Bekele,[2] Sarah G. Clark,[2] Lauren Harris,[4] Samantha M. Campbell,[4] Alice Thomas,[2] Gareth L. Jones,[4] Raj Thuraisingham.[1] *[1]Barts Health NHS Trust, London, United Kingdom; [2]Barts Health NHS trust, London, United Kingdom; [3]UCL Centre for Nephrology, London, United Kingdom; [4]Royal Free Hospital, London, United Kingdom.*

Background: Recipients with a failing kidney transplant (RFKT) receive worse care than those with native disease and outcomes on dialysis after graft loss (DAGL) are poor. Dedicated low clearance transplant clinics (LCTC) are recommended for the management of RFKT but data to support their use is limited. We assessed the management of RFKT at two London transplant centres, one with a dedicated LCTC (Centre A) and one without (Centre B).

Methods: Transplant patients at Bart's Health (Centre A) and the Royal Free Hospital (Centre B) who transitioned to an alternative form of renal replacement therapy (RRT) between 01/01/2012-30/11/2016 were included. Patients with graft failure within a year of transplantation or due to an unpredictable acute event were excluded. Data were recorded after review of medical records.

Results: 179 patients were included; mean age at dialysis restart was 48.6 (+/- 13.4) years, 99 (55.3%) were male, and mean transplant duration was 3678 (+/- 2851) days. Pre-dialysis counseling was documented in 79 (91%) and 68 (74%) patients at Centre A and B respectively (p=0.003). Listing for re-transplantation at restart occurred in 61 (34.1%) patients across both groups. Table 1 outlines clinical parameters at restart and modes of RRT restarted. Outcomes at 1 year after initiation of DAGL were determined in 136 patients; 1-year mortality was 6.6% overall.

Conclusions: A dedicated LCTC improved pre dialysis care. Rates of pre-emptive re-transplantation were low, but 1-year mortality across both centres was better than published estimates.

Clinical parameters at restart and modes of RRT restarted

Parameter at restart (mean; SD)	Centre A (n=87)	Centre B (n=92)	p-value
Haemoglobin (g/L)	89.4 (15.3)	96.1 (17.1)	0.007

TH-PO978

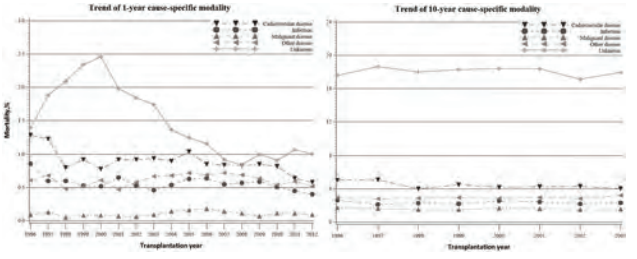
Causes of Death among Kidney Transplant Recipients in the United States Sankar D. Navaneethan,[1,3] Jingbo Niu,[1] Sreedhar A. Mandayam,[2] Saed Shawar,[1] Jenny S. Pan,[1] Kevin F. Erickson,[1] Wolfgang C. Winkelmayer,[1] Venkat Ramanathan.[1] *[1]Baylor College of Medicine, Houston, TX; [2]None, Bellaire, TX; [3]Michael E.DeBakey VA Medical Center, Houston, TX.*

Background: Mortality rate among kidney transplant recipients is lower than the dialysis population. However, except for single center studies, comprehensive examination of reasons for death among those with functioning allograft is lacking. Herein, we studied the causes of death among those who underwent kidney transplantation in the United States.

Methods: We examined United States Renal Data System (USRDS) database to identify patients (age ≥18 years) who received their first kidney transplantation between 1996 and 2012, and subsequently died with functioning graft. Deaths were classified into: a) cardiovascular, b) infectious, c) malignancy, d) others and e) unknown reasons. We examined the trends for 1-year and 10-year risk of death due to above mentioned causes for the study population. We also used competing risk models to assess the associations between transplantation year and each cause-specific mortality during 10-year follow-up.

Results: We included 196,748 transplant recipients and among them, 40,742 died with functioning allograft. Of these, cause of death was reported as unknown for 64% of patients. For those with reported cause of death, cardiovascular deaths accounted for 37%, malignancy: 14%, infection: 21% and other causes: 28% of deaths. One and 10-year trends for these various causes of deaths are shown in Figure 1. Patients who underwent transplantation in later years had lower hazards of death (for various causes) compared to patients who underwent transplantation in 1996 (Figure 2).

Conclusions: In this national registry of kidney transplant population, cause of death is unknown for substantial proportion of patients dying with functioning allografts. Risk for deaths due to cardiovascular disease and other causes have decreased over time.



Transplantation year and 10-year cause-specific mortality (adjusted for age, sex and race)

	Cause-specific mortality, sub-hazard ratio (95% CI)				
Year	Cardiovascular	Infection	Malignancy	Other	Unknown
1996	1.0 (referent)	1.0 (referent)	1.0 (referent)	1.0 (referent)	1.0 (referent)
1997	0.93 (0.81, 1.06)	0.71 (0.58, 0.87)	0.90 (0.70, 1.15)	0.86 (0.72, 1.03)	1.00 (0.94, 1.07)
1998	0.69 (0.60, 0.80)	0.82 (0.67, 1.00)	0.87 (0.68, 1.11)	0.86 (0.72, 1.03)	0.96 (0.90, 1.01)
1999	0.77 (0.67, 0.89)	0.74 (0.61, 0.90)	0.86 (0.68, 1.10)	0.83 (0.70, 0.99)	0.89 (0.84, 0.95)
2000	0.70 (0.61, 0.80)	0.72 (0.59, 0.87)	0.81 (0.64, 1.03)	0.76 (0.64, 0.91)	0.85 (0.80, 0.91)
2001	0.65 (0.57, 0.75)	0.71 (0.59, 0.86)	0.79 (0.62, 1.00)	0.77 (0.65, 0.91)	0.76 (0.72, 0.81)
2002	0.64 (0.56, 0.73)	0.62 (0.51, 0.76)	0.69 (0.54, 0.88)	0.68 (0.57, 0.81)	0.67 (0.63, 0.71)
2003	0.57 (0.50, 0.66)	0.62 (0.51, 0.75)	0.66 (0.52, 0.85)	0.75 (0.63, 0.88)	0.63 (0.59, 0.67)

TH-PO979

Correlation of Pre Kidney Transplant Psychosocial Factors with Post-Transplant Kidney Graft Survival Brittany L. Schreiber, Ramon Noriega, Ann Kathleen N. Gamilla-Crudo, Sujan P. Shah, Flor Espinoza, Rohan Patankar, Wayne G. Fischer, Muhammad A. Mujtaba. *University of Texas Medical Branch, Galveston, TX.*

Background: Pretransplant psychosocial and nutritional factors are important aspects of kidney transplant evaluation as they may be associated with post-transplant outcomes; however there is scant data on this topic. The aim of the study was to determine the correlations between pretransplant, nonclinical and psychosocial factors to post-transplant kidney allograft survival.

Methods: We selected the following pre-transplant factors: race, gender, food stamp, marital relationship, family support, income status, insurer, education, Karnofsky score, history of depression, active clinical follow up, dialysis compliance, serum albumin level, history of substance abuse, distance from transplant center etc. One year kidney allograf survivalwas selected as an outcome. The study involved retrospective analysis of 131 kidney transplant patients. There were 56 female patients and 75 male patients. There were 56 female patients and 75 male patients. We had 72 Hispanics (53%), 33 African Americans (24%), 22 Whites (16%), 9 Asians (7%). Patients age ranged from 25 years to 77 years. Nominal logistic regression analysis and multinominal logistic regression analysis were used to identify the significant relationship between one dependent nominal variable and one or more continuous-level independent variables. A p-value of ≤ 0.05 was considered significant

Results: Female gender (p .02), active pre listing clinic follow up (p=0.04), stronger immediate family support(p=0.06), proximity to primary transplant center (p 0.0012), pre transplant nutrional status as evidenced by serum albumin >3.5 gm/dl, was associated with a better one year graft survival, however food stamps status (p 0.004), repeat transplant status (p 0.05) was associated with poor allograft survival. Remaining variable's did not show a significant relationship.

Conclusions: Pretransplant psychosocial assessment is an important component of kidney transplant work up as it is associated with one year kidney allograft survival. More studies are needed to confirm our findings.

TH-PO980

Health Literacy and Inequity in Access to Transplantation: Results from the ATTOM Study Dominic Taylor.[1,2] *[1]University of Southampton, Southampton, United Kingdom; [2]North Bristol NHS Trust, Bristol, United Kingdom. Group/Team: On behalf of ATTOM investigators.*

Background: Access to kidney transplantation is reduced among people with low socioeconomic status, a component of which is low educational level. Transplant preparation requires patients to understand complex concepts, demanding adequate health literacy (HL). In the Access to Transplant and Transplant Outcome Measures (ATTOM) study, low HL was associated with low educational level and was more common in incident dialysis patients compared to wait-listed or transplanted patients. We hypothesised that HL mediates the association between low educational level and reduced access to transplantation.

Methods: ATTOM recruited UK incident dialysis patients, 2011-13. Data collected included the exposure (no educational qualifications vs any), outcomes (time to transplant wait listing/time to live donor transplant censored at 2 years), the mediator (HL, defined by 'Single Item Literacy Screener' on a five-point scale, 5 indicating lowest HL), and covariates (age, ethnicity, comorbidity by Charlson index). Structural Equation Modelling was used to calculate effect sizes for the exposure on the mediator, the mediator on the outcome and the exposure on the outcome, adjusted for the covariates. From these, the *total effect* of education on access to transplant and the *indirect effect* mediated by HL were calculated. Weibull AFT models were used and effect size expressed as time-to-event ratio (TR). $p<0.05$ was deemed significant.

Results: 2463 of 2621 recruited patients responded to the SILS, and were included. A 1-point increase in HL score was independently associated with 15% increased time to wait listing (TR 1.15;95% CI 1.07-1.25) and 25% increased time to live donor transplant (TR 1.25;95% CI 1.06-1.47). In the mediation model, the *total effect* of low educational level was to increase time to wait listing by 22% (TR 1.22;95% CI 1.02-1.48) and time to live donor transplant by 47% (TR 1.47;95% CI 1.04-2.08). The *indirect effect* mediated by HL accounted for 35% of the increase in time to wait listing and 30% of the increase in time to live donor transplant.

Conclusions: In this large UK cohort study, HL mediated a substantial proportion of the effect of low educational level on reduced access to deceased-donor transplant wait listing and live donor transplantation. Interventions to improve patients' understanding of the transplantation process have potential to reduce socioeconomic inequity in access to transplantation.

TH-PO981

Effectiveness of iChoose Kidney Decision Aid on Kidney Transplant Knowledge Rachel E. Patzer,[2] Laura J. McPherson,[2] Mohua Basu,[3] Sumit Mohan,[1] Stephen O. Pastan.[2] *[1]Columbia University, New York, NY; [2]Emory University, Atlanta, GA; [3]None, Peachtree City, GA.*

Background: We developed a shared mobile decision aid (iChoose Kidney) that displays individualized risk estimates of survival and mortality for dialysis vs. kidney transplant for patients with end-stage renal disease (ESRD). We examined whether use of iChoose Kidney was associated with improved gains in transplant knowledge.

Methods: In a randomized controlled trial, 470 patients at 3 centers were randomized to receive education with (intervention) or without (standard of care) iChoose Kidney during their transplant evaluation. Patients completed surveys immediately before and after evaluation and gain in transplant knowledge (9 item scale) from pre- to post-evaluation was calculated by subtracting mean pre-survey from post-survey scores. Knowledge gains were assessed by study group and by race, health literacy and numeracy levels.

Results: Among 443 patients completing both surveys, mean age was 51 years, with 63% male, and 48% black. The mean pre- and post-evaluation transplant knowledge scores were 5.1 ± 2.1 and 5.8 ± 1.9, respectively, with a mean difference of 0.7 ± 1.7 points. Change in knowledge during the visit was significantly greater among iChoose (1.0 ± 1.8) vs. control (0.3 ± 1.4) for all patients ($p<0.0001$) (Figure 1) as well as for black (1.1 ± 1.7 vs. 0.4 ± 1.4; $p=0.04$) and white (1.5 ± 1.8 vs. 0.2 ± 1.9; $p=0.003$) patients. Intervention (vs. control) patients with moderate (1.2 ± 1.7 vs. 0.4 ± 1.1; $p=0.02$) and high (1.0 ± 1.8 vs. 0.2 ± 1.5; $p=0.001$) literacy and moderate (1.3 ± 1.9 vs. 0.2 ± 1.4; $p=0.0001$) and high numeracy (0.8 ± 1.4 vs. 0.2 ± 1.1; $p=0.02$) benefited most from the tool; while patients with low literacy (1.0 ± 1.9 vs. 0.7 ± 1.4; $p=0.41$) and low numeracy (1.0 ± 1.9 vs. 0.7 ± 1.6; $p=0.39$) had non-significant improvements.

Conclusions: The iChoose Kidney decision aid was effective in improving ESRD patient transplant knowledge among patients undergoing transplant evaluation. Similar shared decision aids could help clinicians better inform patients about transplant.

Impacts of Options Education on Modality Choice in Incident ESRD Patients Yue Jiao, Marta Reviriego-Mendoza, John W. Larkin, Rob Lynch, Len A. Usvyat, Jeffrey L. Hymes, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Dialysis education programs that teach chronic kidney disease (CKD) patients about their renal replacement therapy (RRT) options may help patients to make informed decisions. The impact of educational programs on kidney modality choice is unknown. We analyzed the impacts of an options educational program on incident modality choice for hemodialysis (HD), peritoneal dialysis (PD), or transplant in patients who progressed to ESRD.

Methods: For this analysis, we collected data from Fresenius Kidney Care (FKC) patients who progressed to ESRD and started RRT between 2009 and 2016. Patients were categorized into groups depending on whether they received options education and if they started dialysis as outpatient or inpatient. We determined the annual percentage of ESRD patients who initiated RRT by modality choice (HD, PD, or transplant) in the first 120 days of RRT.

Results: A total of 300,818 patients who progressed to ESRD and initiated a RRT were included in the study; 68,721 patients received options education. In 2016, education prior starting RRT was associated with more patients (1 percentage point) receiving a transplant in the first 120 days of RRT, as compared to those without options education. Concurrently, in patients who received options education and started with outpatient dialysis for RRT, there were 16 percentage points more who utilized PD and 17 percentage points less treated by HD when compared to patients without options education. In patients who received options education and started dialysis as an inpatient in 2016, there were 3 percentage points more who were treated with PD and 2 percentage points less treated by HD when compared to patients without options education. Similar findings were observed in during every year in the study period.

Conclusions: These findings suggest that options education prior starting RRT may lead to a higher proportion of patients choosing a transplant or home dialysis when progressing to ESRD. Further analysis are needed to confirm these findings.

Experiences of Kidney Transplant Recipients as Patient Navigators Anne M. Huml,[6] Catherine M. Sullivan,[3] Adam T. Perzynski,[3] Kitty V. Barnswell,[4] Kate A. Greenway,[1] Cindy Kamps,[5] Marquisha Marbury,[3] Julie A. Pencak,[3] Derrick L. Wilson,[2] Jacqueline Dolata,[3] Ashwini R. Sehgal.[6] *[1]Comprehensive Transplant Center, The Ohio State University Wexner Medical Center, Salem, VA; [2]Luthren Hospital Kidney Transplant Center, Fort Wayne, IN; [3]MetroHealth Medical Center, Cleveland, OH; [4]University Of Louisville, Louisville, KY; [5]University of Kentucky, Richmond, KY; [6]Center for Reducing Health Disparities, Division of Nephrology, Case Western Reserve University, Cleveland, OH.*

Background: The use of trained kidney transplant recipients as patient navigators resulted in increased completion in steps in the transplant process by dialysis patients (1). We sought to understand the experiences of these patient navigators.

Methods: Six kidney transplant recipients were hired and employed by transplant centers in Cleveland, OH, Columbus, OH, Fort Wayne, IN, Lexington, KY, and Louisville, KY. The transplant navigators received formal training as peer educators, met with dialysis patients on a regular basis, and provided tailored education and assistance about transplantation to each patient. In addition, they worked closely with the pre-transplant coordinators and social workers to learn the details of each patient's transplant work-up. We queried navigators using open-ended questions delivered by email to learn about their experiences. We used qualitative analyses to compile and code navigator responses and identify and categorize common themes. A thematic auditor reviewed and refined the coding.

Results: Two primary categories of themes emerged from the data about the navigator experience: 1) practical comments that supported programmatic or implementation observations of the navigators, and 2) affective comments that reflected a shared experience among the navigators and patients. The navigators were able to fill voids in the transplantation and dialysis care process that were not fulfilled by other dialysis caregivers. This was accomplished by a natural bond based upon a shared experience (of dialysis and kidney failure) between the navigator and the patient. The patient and navigator effectively were experiential partners.

Conclusions: Kidney transplant recipients trained as patient navigators fill the role of a non-traditional medical provider, offer support during the transplant process, and from the navigator perspective, provide an added-benefit to complement routine dialysis and nephrology care. TH-PO984

Patient and Provider Perceptions of Medication Safety Issues in Adult Kidney Transplant Recipients Bashir Hamidi, David J. Taber. *Medical University of South Carolina, Charleston, SC.*

Background: Medication safety adverse events (AEs), which include non-adherence to drug regimens and adverse drug events, are associated with graft loss following transplantation. Although kidney transplant recipients are considered high-risk for developing these issues, there are limited studies analyzing long-term patient and provider perceptions of medication safety issues in this population.

Methods: This was a prospective, cross-sectional study of 176 stable kidney transplant recipients which assessed patient self-reported medication adherence and adverse drug events through surveys and compared these to blinded provider assessments occurring during a coinciding routine clinic visit.

Results: In the 176 patients, self-reported medication adherence was 38%, 45%, and 17% for high, medium, and low categories, as measured by a validated survey. AEs were common, with 96% of patients reporting at least one and a mean of 5.9 AEs per patient-visit across the entire study population. Self-reported AE burden was significantly correlated with medication non-adherence with a one unit increase in self-reported patient AE burden (measured by the validated Memphis score) increasing the odds of patients being in a lower adherence category by a factor of 1.35 (CI 1.13 to 1.62, P<0.001). The analysis of clinic assessments revealed that providers only assessed 49% of participants to have at least one AE, with a mean count of 0.8 per patient-visit. Patient self-reported AE burden had a weak positive correlation (Kendall tau= 0.15, P=0.008) with providers' assessment of patient AEs during routine visits.

Conclusions: These results indicate a significant relationship between between AE burden and medication adherence in kidney transplantation. Further, providers tended to under-assess medication AEs during routine clinic visits, when compared to patient assessments. Improving recognition and management of AEs in kidney transplant recipients may impact medication adherence.

TH-PO985

Knowledge and Attitude of Medical Students towards Organ Transplantation Alicja Rydzewska-Rosolowska,[3] Milena Jamiolkowska,[2] Tomasz Hryszko,[3] Szymon Brzosko,[1,3] Beata Naumnik.[3] *[1]DaVita Poland, Bialystok, Poland; [2]Medical University of Bialystok, Bialystok, Poland; [3]I Department of Nephrology and Transplantation with Dialysis Unit, Medical University of Bialystok, Bialystok, Poland.*

Background: In modern era transplantation has become an important mean of treatment. Although it is widespread and medically accepted, certain controversies still exist. The aim of this study was to evaluate attitudes toward organ transplantation among students from Medical University of Bialystok.

Methods: The anonymous survey was conducted among 273 students (medicine, dentistry, nursing and physiotherapy). The questionnaire was self-designed and contained 15 dichotomous questions regarding the attitude towards transplantation from deceased donors, living donors, the definition of brain death and whether the family was made aware of students' beliefs.

Results: 99.6% of students accepted organ transplantation as a therapeutic method. Living transplantation was accepted by 98.9% of students and transplantation from unrelated donors by 92.6% and 87.6% (respectively depending on the existence of an emotional bond between the donor and the recipient). Interestingly 12.8% of students approved selling of organs as a means of expanding the donor pool with significant differences between different divisions (medicine 18.4%, dentistry 6.1%, nursing 7.4% and physiotherapy 19.2%, p<0.05). On average 90.1% of students declared that they know the definition of brain death and again there were statistically significant differences between groups (medicine 96.5%, dentistry 74.2%, nursing 95.6% and physiotherapy 84.6%, p<0.01). Unfortunately, only 81.3% of students accepted the concept of brain death (medicine 91.2%, dentistry 66.1%, nursing 77.9% and physiotherapy 79.2%, p<0.01). Noteworthy 98.5% of students would accept an organ if needed but only 93.8% declared willingness to donate organs after death. Interestingly 26.4% of subjects stated that family should decide whether organs can be retrieved (medicine 17.5%, dentistry 37.9%, nursing 27.9% and physiotherapy 30.8%, p<0.01). Only 69.2% of respondents talked to their family about their attitudes concerning transplantation.

Conclusions: Although organ transplantation is widely accepted by medical students from different faculties and divisions there are still certain areas were controversies exist (e.g. definition of brain-death and the subject of organ selling). A structured, well-planned educational program should be implemented to improve the awareness and attitude, especially among medical students.

TH-PO986

The Effects of Marriage Duration after Transplantation on Graft Outcomes in Spousal Donor Kidney Transplantation Mi-yeon Yu,[3] Ji In Park,[2] Hyunjeong Cho,[1] Yon Su Kim,[1] Hajeong Lee.[1] *[1]Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Kangwon National University Hospital, Chuncheon-si, Republic of Korea; [3]Seoul national university hospital, Seoul, Republic of Korea.*

Background: It is well known that graft survival rate in spousal donor kidney transplantation (SKT) is similar to that of living related donor kidney transplantation (LRKT) despite poor histocompatibility and older age. Marriage is a distinctive feature of spousal kidney donation and other living unrelated kidney donation. Although married people live longer and healthier than singles due to their closest environmental and habitual relationship, the effect of marriage on graft outcome has not been evaluated.

Methods: In a retrospective cohort study, we recruited patients undergone living donor kidney transplantation at Seoul National University Hospital between January 2000 and February 2016. We divided patients into three groups as follows: SKT, LRKT and other living unrelated kidney donor transplantation (LURKT). For spousal donors, the marriage duration after transplantation (MDAT) was surveyed by both personal interview and telephone questionnaire. Outcome was biopsy proven acute rejection (BPAR), graft survival (GS) and patient survival (PS).

Results: A total of 824 living donor kidney transplantation recipients were included. Among them, LRKT was most common with 68.8 %, followed by SKT with 22.3 %, and LURKT with 8.9 %. SKT group received their allografts from donors with older age (median age 46.0), more female sex (65.8%), more ABO incompatibilities and higher HLA mismatches than LRKT or LURKT groups. They tended to receive more preemptive transplantation. In[S1] the Kaplan-Meier curve, SKT revealed lower BPAR free survival rate than LRKT, whereas GS and PS were not different. Among SKT, longer MDAT was demonstrated as a novel protective factor for BPAR even after adjustment (adjusted HR 0.244, 95% CI 0.121-0.493, P<0.001), although it did not affect GS or PS.

Conclusions: We demonstrated that graft and patient survival rate of SKT was not inferior to LRKT, despite their immunologic risk. Moreover, we found that longer MDAT was a novel protective factor for BPAR free survival rate. Not only immunologic similarity but also habitual similarity between donor and recipient may influence on graft outcome after kidney transplantation.

TH-PO987

Cannabis Dependence or Abuse before and after Kidney Transplantation: Implications for Post-Transplant Outcomes Krista L. Lentine,[6] Tarek Alhamad,[9] Ngan Lam,[7] Abhijit S. Naik,[3] Farrukh M. Koraishy,[5] David A. Axelrod,[2] Dorry L. Segev,[1] Vikas R. Dharnidharka,[8] Daniel C. Brennan,[9] Mark Schnitzler.[4] *[1]Johns Hopkins University, Baltimore, MD; [2]Lahey Hospital and Clinic, Burlington, MA; [3]None, Ann Arbor, MI; [4]Saint Louis Univ, St Louis, MO; [5]Saint Louis University, Saint Louis, MO; [6]Saint Louis University, St. Louis, MO; [7]University of Alberta, Edmonton, AB, Canada; [8]Washington University School of Medicine, St Louis, MO; [9]Washington University in St. Louis, St. Louis, MO.*

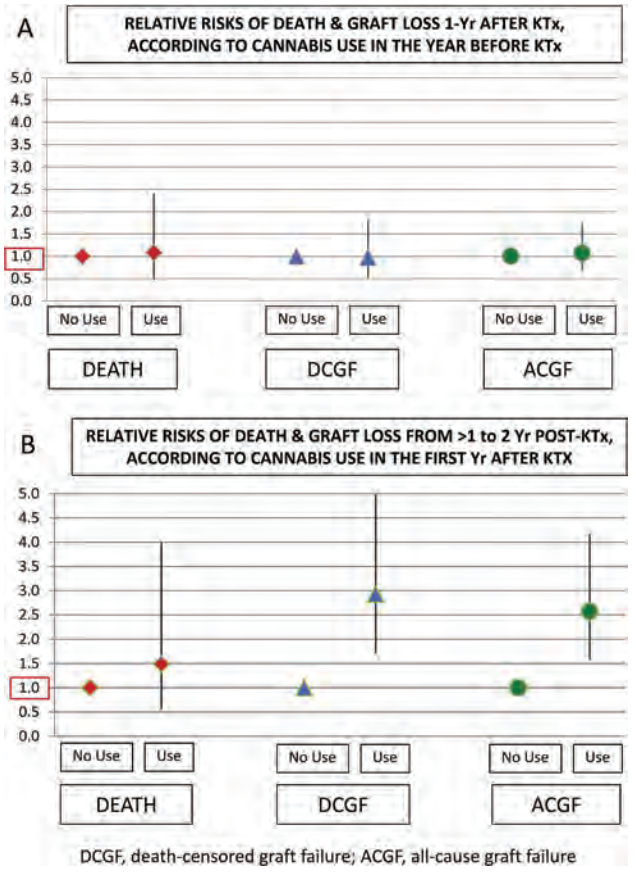
Background: Currently, transplant centers vary in screening practices for marijuana use and requirements for abstinence in kidney transplant (KTx) recipients.

Methods: We examined billing claims for 52,689 Medicare-insured KTx recipients to identify diagnoses of cannabis dependence or abuse (CDOA, International Classification of Diseases-9 diagnosis codes 304.3, 305.2) in the year before and after KTx. Associations of CDOA with post-KTx death and graft failure (adjusted hazard ratio, 95% $_{LCL}$ aHR 95% $_{UCL}$) were quantified by multivariate Cox regression including adjustment for recipient, donor and transplant factors, and propensity for CDOA.

Results: CDOA diagnoses were uncommon, found in 0.5% and 0.3% in the year before and after KTx, respectively. The likelihood of CDOA diagnosis before and after KTx declined with older recipient age, and was increased in men, African Americans, those with less than a college education and unemployed patients. After multivariate and propensity adjustment, CDOA in the year before KTx was not associated with increased risk of death or graft survival in the year after KTx (**Fig 1A**). However, CDOA in the first year post-KTx was associated with three-times the risk of death-censored graft failure (aHR $_{1.72}2.93_{4.99}$) and 2.5-times the risk of all-cause graft loss (aHR $_{1.59}2.57_{4.17}$) in the subsequent year (**Fig 1B**).

Conclusions: Diagnoses of CDOA are uncommon among KTX recipients, and likely reflect a select subgroup of cannabis users who reach clinical attention. While associations likely in part reflect associated conditions or behaviors, clinical diagnosis of CDOA in the year after transplant appears to have prognostic importance for subsequent allograft survival.

Funding: NIDDK Support



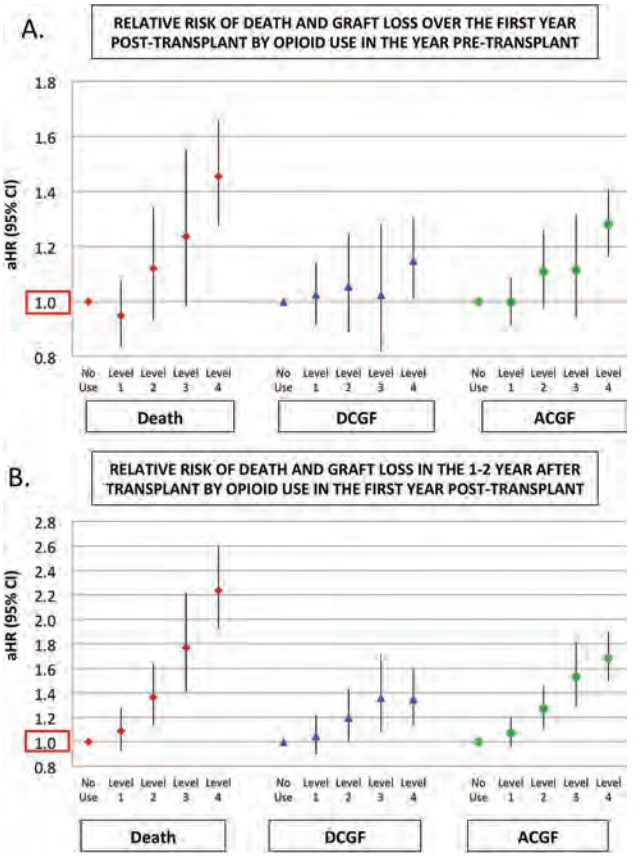


Figure. Adjusted associations of Level 1-4 prescription opioid use before and after transplant and death and graft failure (referent=no use). Abbreviations: ACGF, all-cause graft failure; CI, confidence interval; DCGF, death-censored graft failure.

TH-PO988

Prescription Opioid before and after Kidney Transplant Ngan Lam,[7] Krista L. Lentine,[5] Zidong Zhang,[5] Dorry L. Segev,[2] Vikas R. Dharnidharka,[8] Gregory P. Hess,[3] Radhika Devraj,[6] Bertram L. Kasiske,[1] Daniel C. Brennan,[9] Mark Schnitzler.[4] *[1]Hennepin County Medical Center, Minneapolis, MN; [2]Johns Hopkins University, Baltimore, MD; [3]LDI University of Pennsylvania/ IMS, Plymouth Meeting, PA; [4]Saint Louis Univ, St Louis, MO; [5]Saint Louis University, St. Louis, MO; [6]Southern Illinois University Edwardsville, Edwardsville, IL; [7]University of Alberta, Edmonton, AB, Canada; [8]Washington University School of Medicine, St Louis, MO; [9]Washington University in St. Louis, St. Louis, MO.*

Background: An evolving body of literature suggests the epidemic of prescription opioid use has impacted the transplant population.

Methods: We examined a novel database wherein national U.S. transplant registry identifiers were linked to records from a large pharmaceutical claims warehouse (2008 to 2015) to characterize antidepressant use before and after kidney transplantation, and associations (adjusted hazard ratio, $_{95\%\ LCL}aHR_{95\%\ UCL}$) with death and graft failure.

Results: Among 75,430 eligible patients, 43.1% filled opioids in the year before kidney transplantation, and use was more common among recipients who were women, white, unemployed, publicly insured, and those with longer pre-transplant dialysis. The majority of recipients (60%) with the highest level of pre-transplant opioid use continued high-level usage post-transplant. Pre-transplant opioid use bore graded associations with 1-year post-transplant outcomes, with the highest level use predicting 45% increased risk of death (aHR $_{1.28}1.45_{1.66}$) and 28% increased risk of all-cause graft failure (aHR $_{1.17}1.28_{1.41}$). High-level opioid use in the first year after transplant was associated with twice the risk of death (aHR $_{1.93}2.24_{2.60}$) and 68% higher risk of all-cause graft failure (aHR $_{1.50}1.68_{1.89}$) over the subsequent year.

Conclusions: While associations may, in part, reflect underlying conditions or behaviors, opioid use history appears relevant in assessing and providing care to transplant candidates and recipients.

TH-PO989

Provision of Highly Specialized Aftercare by the Transplant Center Strongly Improves Patient and Allograft Survival in Long-Term Follow-Up After Kidney Transplantation Thomas Schachtner,[1] Natalie M. Otto,[2] Petra Reinke.[3] *[1]Charite Campus Virchow Clinic, Berlin, Germany; [2]Charité Berlin, Berlin, Germany; [3]Charité, Campus Virchow Klinikum, Berlin, Germany.*

Background: Despite rapid medical advancements in the field of transplantation, mean kidney allograft survival remained at a standstill. If and to what extent a highly specialized and experienced aftercare of kidney transplant recipients (KTRs) impacts patient and allograft outcomes in long-term follow-up, however, remains mostly unknown.

Methods: We retrospectively analyzed 1328 KTRs between 1998 and 2015 with respect to patient and allograft survival. KTRs treated regularly in our transplant center in long-term follow-up were compared with KTRs followed by local nephrologists and general practitioners. KTRs that make no use of the transplant center provided aftercare, were assessed by a questionnaire-based survey with respect to allograft survival and their reasons not to make use of it.

Results: In total 824 KTRs (62.0%) were followed in our transplant center and 504 KTRs (38.0%) were followed by local nephrologists. Multivariate analysis identified shorter distance to the transplant center (p<0.001), living donation (p<0.001), early registration to the waiting list (p=0.009), and shorter initial hospital stay (p=0.004) as independet factors for strong adherence to the transplant center. KTRs followed in our transplant center showed significantly better patient (72.7% vs. 50.4% after 15 years; p=0.001) and death-censored allograft survival (85.0% vs. 64.4% after 15 years; p<0.001) compared to KTRs followed by local nephrologists. These differences were equally observed in deceased and living donation. Reasons not to make use of the transplant center provided aftercare included distance (47%), prohibitively expensive costs (37%), no identifiable advantages (34%), and negative experiences (7%).

Conclusions: Our data strongly indicate that provision of aftercare by the transplant center is highly associated with superior patient and allograft survival. The observed wide differences may be attributed to highly specialized screening protocols, careful and critical guidance of immunosuppression, and more comprehensive medical care. Despite long distances, transplant centers, local nephrologists, and health insurances must encourage patients to make use of transplant center provided aftercare.

TH-PO990

The Impact of Donor BMI on Outcomes after Deceased Kidney Transplantation Adam Arshad,[4] Imogen Chappelow,[4] James Hodson,[5] Andrew Ready,[2] Jay Nath,[3] Adnan Sharif.[1] *[1]Queen Elizabeth Hospital, Birmingham, Birmingham, United Kingdom; [2]University Hospital BIrmingham, Birmingham, United Kingdom; [3]University Hospital Birmingham, Birmingham, United Kingdom; [4]University of Birmingham, Stoke on Trent, United Kingdom; [5]University Hospital Birmingham NHS Trust, Biostatistics, Birmingham, United Kingdom.*

Background: The shortage of available donor organs means we must reconsider our current policies on donor selection. There is variation in practice between centers as to the acceptable limit to donor BMI in deceased kidney transplantation, with no recommendations in American or UK guidelines.

Methods: Data from the UK National Health Service Blood and Transplantation register was analysed for all patients receiving deceased donor kidney transplants (Jan 2003 - Jan 2015). Transplants were separated into 5 categories depending on the donor's body mass index (BMI) (kg/m^2): < 18.50 (underweight), 18.50 – 25.00 (normal), 25.01 – 30.00 (overweight), 30.01 – 35.00 (obese) and > 35.00 (morbidly obese). Risk-adjusted outcomes were assessed by multivariable analysis, adjusting for donor, recipient and peri-operative characteristics.

Results: Data for 17,590 transplants were assessed (donor BMI < 18.50 kg/m^2 in 380, 18.50 kg/m^2 – 25.00 kg/m^2 in 6890, 25.01 kg/m^2 – 30.00 kg/m^2 in 6692, 30.01 kg/m^2 – 35.00 kg/m^2 in 2503 and > 35.00 kg/m^2 in 1148). On multivariable analyses, increasing donor BMI was found to be an independent risk factor for delayed graft function (p<0.001), with rates of 27.8%, 31.4% and 32.8% for normal, obese and morbidly obese patients, respectively. However, no evidence of significant differences in longer term outcomes such as patient survival (p= 0.109), graft survival (p= 0.093) or 12-month creatinine values (p= 0.550) were detected between donor BMI groups. A subgroup analysis of DCD recipients was performed (n = 3593). Whilst increasing donor BMI was found to be associated with an increase the functional warm ischaemia time (WIT) and standard WIT by an average 1.80 (p = 0.030) and 2.19 minutes (p = 0.015) respectively, this was not found to have a significant impact on the incidence of delayed graft function (p= 0.464, p= 0.520) or graft survival (p= 0.760, p = 0.423) on multivariable analysis.

Conclusions: In this large national cohort study, we found that there was no evidence of significant differences in long-term outcomes between deceased donor kidneys from different BMI groups. Rejection of kidneys based upon donor BMI alone does not appear to be justified.

TH-PO991

The Impact of Recipient BMI on Outcomes after Kidney Transplantation Adam Arshad,[3] Imogen Chappelow,[3] James Hodson,[4] Jay Nath,[2] Adnan Sharif.[1] *[1]Queen Elizabeth Hospital, Birmingham, Birmingham, United Kingdom; [2]University Hospital Birmingham, Birmingham, United Kingdom; [3]University of Birmingham, Stoke on Trent, United Kingdom; [4]University Hospital Birmingham NHS Trust., Biostatistics, Birmingham, United Kingdom.*

Background: A high recipient BMI is still considered a contraindication for transplantation across many centres. However, there is inconsistent evidence as to the influence of recipient BMI on post-transplant outcomes.

Methods: Data from National Health Service blood and transplantation was analysed for all patients receiving deceased donor kidney transplantations between January 2003 to January 2015. Transplants were separated into 5 categories depending on the recipient's body mass index (BMI) (kg/m^2): < 18.50 (underweight), 18.50 – 25.00 (normal), 25.01 – 30.00 kg/m^2 (overweight), 30.01 – 35.00 (obese) and > 35.00 (morbidly obese).

Results: Data for 11,916 transplants were analysed (recipient BMI < 18.50 kg/m^2 in 300, 18.50 kg/m^2 – 25.00 kg/m^2 in 4730, 25.01 kg/m^2 – 30.00 kg/m^2 in 4270, 30.01 kg/m^2 – 35.00 kg/m^2 in 2132 and > 35.00 kg/m^2 in 480). In multivariable analysis, obese and morbidly obese recipients were seen to have impaired graft outcomes, with risk-adjusted rates of delayed graft function of 33.0% and 33.1%, relative to 25.3% in normal BMI recipients (p < 0.001). Obese and morbidly obese BMI were also found to be at increased risk of graft failure (death-censored), with adjusted rates of 1-year and 5-year (in brackets) graft survival of 92.8% (86.0%) and 91.6% (84.4%), relative to 94.4% (88.2%) in normal BMI recipients (p < 0.001). Interestingly, the only group found to be at increased risk of death were the underweight recipients, with adjusted 1- and 5- year survival of 95.1% and 83.5%, compared to 97.0% and 90.6% in normal BMI recipients and 97.2% and 89.7% for morbidly obese recipients (p = 0.005).

Conclusions: Raised recipient BMI increases the risk of graft failure in long-term. Overall, methods to reduce this increased risk of graft failure should be explored.

TH-PO992

Alteration in Body Mass Index and Estimated Glomerular Filtration Rate after Kidney Transplantation Ekamol Tantisattamo,[1] Possawat Vutthikraivit.[2] *[1]Multi-Organ Transplant Center, Division of Nephrology, Department of Internal Medicine, Oakland University William Beaumont School of Medicine, Royal Oak, MI; [2]PHRAMONGKUTKLAO COLLEGE OF MEDICINE, BANGKOK, Thailand.*

Background: The pattern of post-transplant weight change and renal allograft function is unclear. We aim to determine this association.

Methods: A retrospective cohort study of 70 renal transplant recipients was divided into 3 groups (BMI <25, 25 to <30, and ≥30 kg/m2). Changes in the mean BMI compared to pre-transplant BMI (ΔBMI) every 3-month follow-up periods up to 96 weeks post-transplant were correlated with post-transplant eGFR and changes in mean eGFR (ΔeGFR) during the corresponding 3-month follow-up.

Results: Compared to pre-transplant BMI, BMI at the time of discharge from the transplant admission increased in 3 groups (p=0.003, 0.000, and 0.514). In normal and overweight groups, BMI was lower during the first 4- and 12-week post-transplant compared to BMI at the time of transplant, respectively (p=0.236 and p=0.012-0.069) and then became persistently higher through 96 weeks post-transplant (p=0.001-0.122 and p=0.004-0.299). Mean eGFR continued trending up post-transplant until 24-week post-transplant and appeared to be plateau among all 3 BMI groups (Figure). By comparing mean eGFR every 12-week interval during post-transplant, there was no difference among 3 groups. In addition, ΔBMI between consecutive 3-month follow-up period did not associate with ΔeGFR at the corresponding 3-month follow-up period (p=0.104-0.922). The probability of developing worsening CKD stage was higher in overweight and obese groups compared to normal weight group, but there was no statistical significance (HR 0.697 (CI 0.296 to 1.641) for overweight and HR 0.695 (CI 0.279-1.728) for obese compared to normal weight group - Figure).

Conclusions: eGFR appears to increase with weight loss during the first 24-month post-transplantation in all BMI strata; however, it does not significantly change and not associated with BMI alteration thereafter. Pre-transplant obesity may not be the main determinant for post-transplant renal allograft function during early and late post-transplant periods.

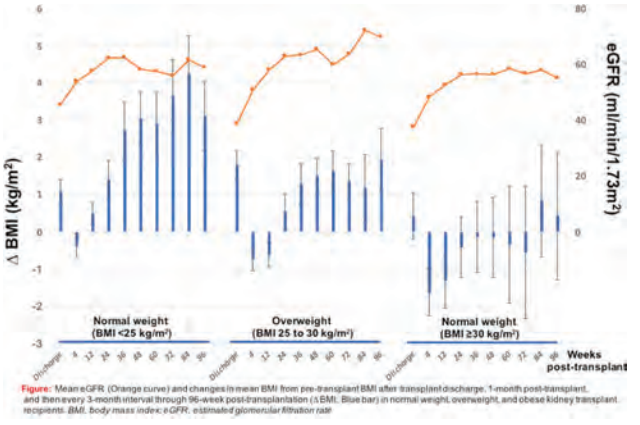

Figure: Mean eGFR (Orange curve) and changes in mean BMI from pre-transplant BMI after transplant discharge, 1-month post-transplant, and then every 3-month interval through 96-week post-transplantation (Δ BMI, Blue bar) in normal weight, overweight, and obese kidney transplant recipients. *BMI, body mass index; eGFR, estimated glomerular filtration rate*

TH-PO993

Is Body Mass Index a Significant Independent Risk Factor for Graft Failure and Patient Death in the Modern Immunosuppressive Era? Ho Sik Shin,[2,1] Anil K. Chandraker.[2] *[1]Kosin University College of Medicine, Gospel Hospital, Busan, Republic of Korea; [2]Harvard Medical School, BWH, Transplantation Research Center, Boston, MA.*

Background: In previous studies, kidney transplant recipients with high body mass index (BMI) had inferior or superior outcomes compared to patients with lower BMI, and thus it remains unclear whether BMI is a significant independent risk factor for graft failure and patient death in the modern immunosuppressive era. We used United Network for Organ Sharing (UNOS) data to determine whether obesity affects patient and graft outcome following kidney transplantation.

Methods: From the UNOS database, we identified patients who underwent primary kidney-only transplantation between 1987 and 2016. The study sample consisted of 69,749 from 1987-1999 and 197,986 from 2000-2016. We correlated BMI with graft and patient survival, and created multivariate models to evaluate the independent effect of BMI on graft and patient outcomes, adjusting for factors known to affect graft success and patient survival.

Results: Mean BMI shifted from 25 kg/m^2 in 1987-1999 to 27 kg/m^2 in 2000-2016. Higher BMI was associated with significantly worse graft, patient and patient with functioning graft survival from 1987-1999. Lower and higher BMI were also associated with significantly worse graft, patient and patient with functioning graft survival from 2000-2016. In the same BMI group, graft and patient survival rates from 2000-2016 were higher than in 1987-1999. Cox regression modeling hazard ratios showed that obesity also increased the risk of graft failure and patient death.

Conclusions: BMI is a significant independent risk factor for graft failure and patient death in the modern immunosuppressive era.

Table 1. Patient characteristics according to era.

Characteristics	Year 1987-1999 (n = 69,749)	Year 2000-2016 (n = 197,986)
Recipient age (years)*	45.6 ± 12.7	51.2 ± 13.4
BMI (kg/m²)*	25.4 ± 4.6	27.7 ± 5.1
Donor age (years)*	34.6 ± 16.4	39.6 ± 15.2
Cold ischemic time (hours)*	19.4 ± 11.5	13.5 ± 10.8
Ethnicity (number/%)		
White	41,312/59.2	99,909/50.5
African American	17,316/24.8	52,899/26.7
Hispanic	7,171/10.3	29,706/15.0
Asian	2,627/3.8	11,495/5.8

Obesity: A Risk Factor for Hypertension after Kidney Transplantation Ekamol Tantisattamo,[1] Possawat Vutthikraivit.[2] *[1]Multi-Organ Transplant Center, Division of Nephrology, Department of Internal Medicine, Oakland University William Beaumont School of Medicine, Royal Oak, MI; [2]PHRAMONGKUTKLAO COLLEGE OF MEDICINE, BANGKOK, Thailand.*

Background: Hypertension (HTN) after kidney transplantation is common. Underweight leads to unfavorable outcomes in ESRD. The magnitude of risk factors including obesity after kidney transplantation is unclear.

Methods: Seventy kidney transplant recipients were enrolled in a retrospective closed cohort study. Post-transplant HTN is defined as SBP ≥ 140 mmHg first detected after 1-month post-transplantation. The incidence of HTN and the association between potential risk factors and post-transplant HTN were determined.

Results: Mean age was 52.66±1.43 years old and 41 patients (58.6%) was male. There were 49 patients (70%) diagnosed with post-transplant HTN, which was an account of the incidence of post-transplant HTN was 48.67 person-year. Mean SBP and DBP at the time of diagnosis were 151 mmHg; whereas, SBP and DBP of the remaining 21 patients (30%) without post-transplant HTN were 119 mmHg, respectively (p= 0.0167, mean difference 31.79, CI 5.9367 to 57.6433). Several traditional risk factors for HTN were examined and pre-transplant obesity (BMI ≥30 kg/m^2) and old age (≥ 65 years old) were significantly associated with post-transplant HTN (RR 1.382 (CI 1.050 to 1.819) and RR 1.6 (1.306 to 1.96); Table)). By using binary logistic regression analysis, post-transplant HTN was 1.140 times greater in obese than in non-obese patients after adjusted for age, gender, race, pre-transplant BMI, and eGFR at transplant discharge (CI 1.006 – 1.291, p=0.040).

Conclusions: Although the reverse epidemiology of non-obesity leading to potential harmful effect in ESRD patients, pre-transplant obesity can lead to poor post-transplant cardiovascular outcomes. Since obesity continues carrying and remains one of the traditional risk factors of HTN after successful kidney transplantation, pre-transplant weight control is still warranted.

Association between systolic hypertension beyond 1-month post-kidney transplantation and its potential risk factors

	RR	CI
Pre-transplant BMI	1.382	1.050 to 1.819
Age ≥65 years old	1.600	1.306 to 1.960
Male	1.218	0.873 to 1.700
African American	1.214	0.904 to 1.629
eGFR ≥ stage 3 CKD	1.064	0.716 to 1.580

TH-PO995

Metabolic Responses to Kidney Transplantation: Is Early Weight Gain Benign? Biruh Workeneh,[3] Joy V. Nolte,[2] Linda W. Moore,[2] Roman Shypailo,[1] Ahmed O. Gaber,[2] William E. Mitch.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Houston Methodist Hospital, Houston, TX; [3]MD Anderson Cancer Center, Houston, TX.*

Background: It is widely assumed that modest weight gain following kidney transplantation (KT) is advantageous to patients. However, there is no consensus about what constitutes appropriate degree of weight gain nor has there been rigorous explorations about the nature and metabolic implications of changes in body composition.

Methods: We analyzed 31 living kidney transplant (KT) recipients. Subjects were 18-65yrs old, noninsulin dependent, and received tacrolimus-based immunosuppression. All measurements were obtained <1mo prior to and 3mo post-KT. DXA and BodPod were used to measure body mass and define body compartments. Resting energy expenditure (REE) was obtained by indirect calorimetry and physical activity was assessed by accelerometory. Insulin resistance (IR) was determined by HOMA-IR and dietary intake determined ASA24 dietary recall.

Results: We observed significant increases in body weight and fat (Table1). DXA revealed fat accumulation primarily in the truncal region. Visceral and subcutaneous fat volumes increased significantly, and visceral fat volume positively correlated with IR (r=0.452, p=0.012). REE did not change significantly and there was no relationship with fat or muscle mass. Accelerometry showed subjects were more ambulatory post-KT, 5201 vs 6515 average daily steps(p=0.034). Vector magnitude (total axis activity) also increased. Food recalls showed more calories comprised of fat and protein are consumed post-KT(42% and 17% of total kcals).

Conclusions: We conclude that only 3 months after KT there are small but significant increases in adipose deposition and have reported adverse responses including insulin resistance. Even at this early stage, patients accumulate total body fat and importantly, visceral fat. The changes we observed could not be attributed to changes in other body compartments, decreased metabolic rate, or physical activity but dietary factors may influence orexigenic factors and adipose tissue accumulation.

Android Obesity and NT-ProBNP in Kidney Transplant Patients Magdalena B. Kaziuk. *Chair and Department of Nephrology, Jagiellonian University Medical College, Kraków, Poland.*

Background: Adipose tissue is a typical location for storage of water-insoluble toxins in a body. An excess of adipose tissue may be either systemic or local. According to a pattern of fat distribution in the body, we distinguish two types of obesity: android (visceral, abdominal) and gynoid (around bottom and tights, peripheral). The obesity increases a risk of the kidney failure and cardiovascular complications in a group of kidney transplant patients (KTx). An attempt was made to evaluate a relationship between the amount of adipose tissue, obesity type, and NT- proBNP level in KTx patients.

Methods: The study covered 128 patients (60 women and 68 men, average age 49.5 ± 10.8 years) with a functioning renal transplant more than 3 months after the transplant. The amount of adipose tissue was determined using the bioelectrical impedance analysis (BIA) and anthropometric measurements, nutrition status and the obesity type were established by Waist to Height Ratio (WHtR) and Waist to Hip Ratio (WHR), the function of the transplanted kidney was evaluated by calculation of the estimated glomerular filtration rate (eGFR) using the MDRD formula, and their relation with the N-terminal pro-brain natriuretic peptide (NT- proBNP) was studied.

Results: In the study group, 22.7% of patients were classified as having a correct body weight, while 56.7% and 20.6% of participants had an android and gynoid type, respectively. In the logistic regression analysis, an increase by 0.2% in a risk of abdominal obesity in KTx patients (OR=1.002 95% CI: 1.001–1.003; p< 0.001) was associated with an increase in NT- proBNP by 100 pg/ml. An increase in eGFR by 1ml/min/1,73m2 was associated with a reduction in the androidal obesity risk by 4.5% (OR= 0.955 95% CI: 0.923–0.984; p=0.005). The higher the NT-proBNP value, the higher the percentage content of adipose tissue (Spearman rank correlation coefficient: 0.473; p<0.001) in KTx patients.

Conclusions: A large amount of adipose tissue, particularly in a case of androidal obesity, may be a predictor of kidney or cardiovascular system. Furthermore, high NT-proBNP levels may be associated with an increased risk of obesity in KTx patients; therefore, correct diet and pharmacological management, and physical activity adapted to the physical fitness level of a patient are necessary.

TH-PO997

Waist to Hip Ratio (WHR) as a Predictor of Increased Length of Stay Post Kidney Transplantation Flor Espinoza, Rohan Patankar, Ramon Noriega, Brittany L. Schreiber, Vishy Chaudhary, Muhammad A. Mujtaba. *University of Texas Medical Branch, Galveston, TX.*

Background: Objective: To determine if WHR vs body mass index (BMI) could be used as a reliable predictor of increased length of stay from transplant to first discharge, defined as 7 days or more, in a group of first time kidney transplant recipients. Background: Prolonged hospitalizations in renal transplant patients continues to be a concern due to its potential effect on health care costs and patient satisfaction scores. Various factors including BMI are considered while establishing suitability for kidney transplantation. However, BMI has its limitations as it does not take into account body fat distribution. WHR may provide an alternative tool for pre-transplant candidate selection. We aimed to assess if WHR could to be used to predict increased length of stay (LOS) post kidney transplantation.

Methods: This is a single center retrospective analysis of deceased and living donor kidney transplants performed through the period of May 2015 to March 2017. Increased LOS was defined as 7 days or more. A multivariate linear regression analysis was performed comparing BMI and WHR, and results were reviewed. A p-value of ≤ 0.05 was considered significant.

Results: A total of 69 patients were included, 60 of which received deceased donor kidney transplants and 9 received living donor kidneys. All patients were first time kidney transplant recipients. Patients WHR ranged from 0.78 – 1.07. The LOS ranged from 5 to 22 days. Increased WHR was significantly assocated with LOS (P-value = 0.04), whereas BMI was not (P-value = 0.84).

Conclusions: Our results suggest that WHR can be used as an accurate tool to predict increased length of stay in first time kidney transplant recipients. Further collaborative efforts and research are needed to fully elucidate the relationships between WHR and increased length of stay with respect to cost, patient satisfaction and graft outcomes

TH-PO998

Genome Wide Non HLA Alloimmunity Contributes to Graft Loss after Kidney Transplantation Rainer Oberbauer,[3] Roman Reindl-Schwaighofer,[3] Alexander Kainz,[1] Andreas Heinzel,[4] Kira Jelencsics,[2] Petra Hruba,[6] Ondrej Viklicky,[1] Georg Bohmig,[2] Gottfried Fischer,[3] Brendan Keating.[1] *[1]Department of Nephrology, Vienna, Austria; [2]Medical University Vienna, Vienna, Austria; [3]Medical University of Vienna, Vienna, Austria; [4]Medical University of Vienna, Vienna, Vienna, Austria; [6]Institute for Clinical and Experimental Medicine, Prague, Czech Republic.*

Background: HLA alloimmunity is the main cause of renal transplant loss but the contribution of nonHLA donor recipient mismatches on a genome wide basis has not been elucidated thoroughly yet.

Methods: We made use of the iGeneTrain consortium and genotyped 753 donors and 863 corresponding recipients using the Affymetrix Axiom Tx GWAS Array (Affymetrix). Raw genotypes were after an initial quality control phased and imputed with impute2 using GoNL and 1KG data as reference panels. The ensemble Variant Effect Predictor and ANNOVAR were used for SNP annotation. The number of recipients with a median follow up of 6.5 years were obtained from the Vienna and Prague transplant cohort study. The main available outcomes are death censored graft loss and eGFR slope after transplantation. HLA incompatibility and other clinical variables known to influence these outcomes are available. In a first preliminary analysis elucidating the effect of donor recipient non-synonymous SNP (nsSNP) mismatches (MM) on graft survival a Cox model was employed to analyze the association of nsSNP MM with graft survival. For this preliminary analysis 180 donor recipient pairs with 36 events were available.

Results: The association of nsSNP MM with graft survival showed a trend towards elevated risk for death censored graft loss (table). Table: Multivariable Cox model relating the time of graft survival to donor recipient HLA MM and nsSNP MM. A follow up study utilizing the full cohort and imputation results will be performed in the next months prior to the meeting. Further custom peptide arrays (NimbleGen/Roche) holding 172,943 features will be employed to uncover the formation of antibodies in case of donor recipient LoF and nsSNP MM.

Conclusions: NonHLA alloimmunity independently contributes to graft loss after kidney transplantation.

Cox model

Parameter	HR	95CI lower	95CI higher	p-value
HLA MM	1.29	1.05	1.60	0.017
SNP a 100	1.58	0.78	3.21	0.201

TH-PO999

Effect of Human Leukocyte Antigen Mismatching on the Outcomes of Kidney Transplantation: A Systematic Review and Meta-Analysis Xinmiao Shi,[1] Rui Liu,[3] Jicheng Lv,[2] Xinfang Xie,[2] Xuhui Zhong,[1] Jie Ding.[1] *[1]Peking University First Hospital, Beijing, China; [2]Renal Division, Peking University First Hospital, Beijing, China; [3]The First Hospital of Tsinghua University, Beiijng, China.*

Background: The impact of HLA mismatching on kidney transplantation(KT) remains controversial. We aimed to evaluate the effect of HLA mismatching on KT.

Methods: We systematically searched PubMed, EMBASE, and the Cochrane Library for relevant studies.

Results: For adults, every HLA mismatch(mm) increase was associated with increased risk of overall graft failure (HR=1.06;95%CI,1.05-1.07), death-censored graft failure (HR=1.09;95%CI,1.06-1.11) and mortality (HR=1.05;95%CI,1.02-1.07). Moreover, HLA-DR mismatching was associated with significantly inferior graft survival(HR=1.08; 95%CI,1.05-1.11), but not HLA-A (HR=1.06;95% CI,0.98-1.14) or HLA-B (HR=1.01;95%CI,0.89-1.14). For children, compared with 0–1 HLA-DR mm, 2 mm significantly increased the risk of graft failure at 1 year (RR=1.41,95%CI:1.11–1.80),3 years (RR=1.28,95%CI:1.08–1.52),5 years(RR=1.21,95%CI:1.04–1.41), and 10 years (RR=1.30,95%CI:1.02–1.67). For HLA-A+B, the 5-year graft failure risk was higher for 2–4 compared with 0–1 mm (RR=3.17,95%CI:1.20–8.36), but not for 3–4 compared with 0–2 mm (RR=1.49,95%CI:0.79–2.80).

Conclusions: For adults, HLA mismatching is an independent factor affecting graft failure and mortality. HLA-DR appears to be more essential than HLA-A or -B. For children, HLA-DR and HLA-A+B are important factors affecting graft failure.

Effect of Hyperkalemia on Renal Ammonia Metabolism Autumn N. Harris,[1] P. R. Grimm,[2] Hyun-Wook Lee,[1] Eric J. Delpire,[3] Paul A. Welling,[2] Jill W. Verlander,[1] I. D. Weiner.[1,4] *[1]Nephrology, University of Florida, Gainesville, FL; [2]University of Maryland School of Medicine, Baltimore, MD; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Nephrology, NF/SGVHS, Gainesville, FL.*

Background: Type IV Renal Tubular Acidosis (RTA) is characterized by metabolic acidosis and hyperkalemia, but the mechanism(s) through which the metabolic acidosis

develops remains in question. In particular, hyperkalemia's role in the pathogenesis of the metabolic acidosis has been unclear. This is because in vivo models testing the effects of hyperkalemia are difficult to perform because of robust renal K excretory mechanisms that limit development of chronic hyperkalemia. To obviate this limitation, we used a genetic model of hyperkalemia that does not target the proximal tubule (PT) or collecting duct, does not directly target proteins involved in ammonia metabolism and does not involve altered K intake to determine hyperkalemia's effect on acid-base homeostasis and ammonia metabolism.

Methods: We used a recently reported DCT-specific constitutively active SPAK (DCT-CA-SPAK) mouse model and compared it with wild type (WT) littermates. We used thiazide administration to block the NCC over-activity and correct the hyperkalemia.

Results: Under basal conditions DCT-CA-SPAK mice exhibited hyperkalemia and metabolic acidosis. Despite the metabolic acidosis, they had decreased urine ammonia excretion compared to WT mice. Titratable acid excretion was not altered. Thiazide administration, to reverse the effect of DCT-CA-SPAK on NCC, corrected the hyperkalemia and increased ammonia excretion, but had neither effect in WT mice. Phosphoenolypyruvate and phosphate-dependent glutaminase, key ammonia generating proteins, expression was significantly less in DCT-CA-SPAK PT. Glutamine synthetase, which recycles ammonia, was significantly greater in DCT-CA-SPAK cortical PT. NKCC2 and Rhbg expression were unchanged. Thus, hyperkalemia in a genetic model that does not alter K intake, does not directly involve the PT and does not directly alter proteins involved in ammonia metabolism, alters expression of multiple proximal tubule proteins involved in ammonia generation, leading to decreased ammonia excretion, which is reversible with correction of the hyperkalemia.

Conclusions: Hyperkalemia can directly inhibit proximal tubule ammonia metabolism, decreasing ammonia and net acid excretion, and leading to metabolic acidosis. Moreover, the effects of hyperkalemia on ammonia metabolism to suppress ammonia excretion are greater than those of metabolic acidosis to stimulate it.

Diabetes-Induced Ammoniagenesis and Kidney Growth Are Independent of Acidosis and Increased Filtered Load of Glutamine Hassane Amlal,[1] Cara E. Molulon,[2] Sritej Devineni.[1] *[1]University of Cincinnati, Cincinnati, OH; [2]University of Cincinnati College of Medicine, Cincinanti, OH.*

Background: Studies have shown that total ammonia ($NH_4^+ + NH_3$) causes renal cell hypertrophy. We have previously demonstrated that diabetes-induced kidney growth occurs early during the onset of hyperglycemia and is associated with the stimulation of ammonia synthesis in the proximal tubule (*J Am Soc Nephrol* 27: 652A, 2016). However, whether the stimulation of ammoniagenesis is secondary to the development of acidosis and/or increased filtered load of glutamine remain unknown.

Methods: The inhibition of carbonic anhydrases by acetazolamide (ACTZ) in the proximal tubule activates the tubulo-glomerular feedback and induces metabolic acidosis by increasing NaCl delivery to macula densa and by increasing bicarbonate wasting in the urine, respectively. Rats were housed in metabolic cages with free access to food and water for water balance studies and urine collections. After acclimation, rats were divided into 4 groups, and treated with vehicle, ACTZ, Streptozotocin (STZ) to induce type 1 diabetes or STZ + ACTZ for 7 days. Blood chemistry and urinary NH_4^+ excretion were analyzed and kidney mass (kidney weight/body weight) was measured.

Results: As indicated by serum [HCO3-], significant metabolic acidosis was developed in rats treated with ACTZ or ACTZ + STZ but not in STZ-treated rats as compared to vehicle group. NH4+ excretion increased by 3-fold, 10-fold and 15-fold in ACTZ, STZ alone and ACTZ+STZ animals, respectively vs. Control group. Kidney mass increased slightly in ACTZ group (15%) and sharply in STZ alone (42%) and ACTZ+STZ (60%) groups, as compared to Controls. ACTZ did not alter food intake but significantly reduced body weight loss in ACTZ+STZ rats (-3g) vs. STZ alone (-20g). This correlated with improved levels of blood volume markers (BUN, Hct and Hb) and reduced urine output in ACTZ + STZ, indicating a reduction in glomerular filtration rate by ACTZ vs. STZ alone.

Conclusions: The stimulation of ammoniagenesis and increased renal mass are more profound in STZ-induced diabetes than in ACTZ-induced metabolic acidosis. Moreover, acidosis and diabetes exert an additive effect on both parameters, indicating that the signaling mechanism mediating the effects of acidosis and diabetes are different. Lastly, the stimulation of ammonia synthesis in diabetes is independent of increased filtered load of glutamine.

Sex Differences in Renal Ammonia Metabolism Autumn N. Harris,[1] Gunars Osis,[1] Hyun-Wook Lee,[1] Kierstin L. Webster,[1] Jill W. Verlander,[1] I. D. Weiner.[1,2] *[1]Nephrology, University of Florida, Gainesville, FL; [2]Nephrology, NF/SGVHS, Gainesville, FL.*

Background: Renal ammonia excretion is an important component of acid-base homeostasis. Previous studies indicate that sex impacts multiple aspects of renal function. This study's purpose was to investigate gender differences in renal ammonia metabolism.

Methods: We compared 4-month-old male (M) and female (F) C57Bl/6 mice, with measurement of plasma electrolytes, urinary ammonia excretion, and evaluation of changes in key proteins involved in ammonia metabolism using immunoblot analysis and immunohistochemistry.

Results: Under basal conditions, female mice excreted significantly more urine ammonia than male mice (F, 71.9±22.9; M, 46.1±18.6 μmol/day; $P \leq 0.02$) and had significantly lower plasma bicarbonate concentrations than male mice (F, 18.1±1.6; M, 19.9±1.5 mmol/L; $P \leq 0.02$). Titratable acid excretion (F, 63±42; M, 78±17 μmol/day), urine pH (F, 6.40±0.18; M, 6.36±0.14), plasma Na^+ and K^+ concentrations, and food intake (F, 8.9±0.9; M, 9.6±1.2 g/day) did not differ significantly. Total expression of key ammonia generating proteins, phosphoenolypyruvate and phosphate-dependent glutaminase were significantly greater in the cortex of female than male mice. Expression of glutamine synthetase, which recycles ammonia, was significantly greater in the cortical proximal tubules (PT) of female mice. Expression of NBCe1, a basolateral PT bicarbonate transporter, recently shown to regulate PT ammonia metabolism, did not differ significantly between sexes. Expression of the ammonia transporter family member, Rhbg, was significantly greater in connecting segment cells and intercalated and principal cells in the collecting duct in the cortex and inner stripe of the outer medulla (ISOM) in female mice. Expression of Rhcg was significantly greater in female mice in connecting segment cells and in the basolateral membrane of intercalated and principal cells in the collecting duct in the ISOM.

Conclusions: Despite similar levels of food intake and thus protein intake, which is the primary determinant of endogenous acid production, female mice excreted higher amounts of basal ammonia, but not titratable acid. This increase in ammonia excretion was associated with differences in the expression of several proteins involved in ammonia generation and transport. Thus, there are sex-dependent differences in basal ammonia metabolism and acid-base homeostasis.

Hypercapnia Increases Urinary Ammonium Excretion and Upregulates Expression of the NH3/NH4+ Transporters Rh Glycoproteins Nazih L. Nakhoul,[1] L. Lee Hamm,[1] Kathleen S. Hering-Smith,[1] Mohammed T. Islam,[1] Solange Abdulnour-Nakhoul.[1,2] *[1]Tulane Medical School, New Orleans, LA; [2]SLVHCS, New Orleans, LA.*

Background: Hypercapnia and subsequent respiratory acidosis is a serious complication observed in patients with respiratory disorders such as chronic obstructive pulmonary disorder (COPD) and acute respiratory distress syndrome. A recent study shows that the presence of COPD in patients with CKD greatly increases the risk of death. The acute response to hypercapnia is buffering of H^+ by hemoglobin and other cellular proteins but this effect is limited. The chronic response (usually complete in 3-5 days) is renal compensation that increases HCO_3^- reabsorption, mostly in the proximal tubule, and stimulates urinary excretion of titratable acids (TA) and NH_4^+. However, the main effective pathway is the excretion of NH_4^+ in the collecting duct. Our hypothesis is that the renal NH_3/NH_4^+ transporters Rhbg and Rhcg in the collecting duct mediate this response. The effect of hypercapnia on these transporters is unknown.

Methods: We conducted *in-vivo* experiments on mice subjected to induced respiratory acidosis. We placed two groups of mice in special chambers where breathing gas mixtures can be controlled. One group breathed 8% CO_2 (21% O_2 & 71% N2) to induce respiratory acidosis and the other breathed normal air as control. After 5 days, the mice were euthanized and kidneys, blood and urine samples were collected. We used immuno-histochemistry, Western analysis and qRT-PCR to determine how breathing high CO_2 levels affects localization, abundance and gene expression of the Rh proteins.

Results: Western analysis showed a significant increase in expression of Rhbg (by 43% ± 3.3) and Rhcg (by 12.6% ± 3.0) in animals that breathed 8% CO_2, ($P<0.01$, n=10). In addition, carbonic anhydrase (CA-IV) expression was increased significantly in hypercapnia (by 51% ± 14, $P<0.005$). In hypercapnic animals, there was a significant increase in urinary NH_4^+ excretion (by 50% ± 3.2, $P<0.01$) but the change in TA was not statistically significant.

Conclusions: These data suggest that hypercapnia (for 5 days) leads to compensatory upregulation of Rhbg & Rhcg proteins that contributes to excretion of NH_3/NH_4^+ in the kidney. These studies are the first to show a link between hypercapnia, NH_4^+ excretion and Rh expression.

The A-Splice Variant of NBCe1 Is Necessary for Basal and Acidosis-Stimulated Renal Ammonia Metabolism Hyun-Wook Lee,[1] Gunars Osis,[1] Autumn N. Harris,[1] Lijuan Fang,[1] Heather L. Holmes,[2] Adam J. Rossano,[2] Michael F. Romero,[2] Jill W. Verlander,[1] I. D. Weiner.[1,3] *[1]Nephrology, University of Florida, Gainesville, FL; [2]Mayo Clinic, Rochester, MN; [3]Nephrology, NF/SGVHS, Gainesville, FL.*

Background: Renal ammonia excretion is the largest component of net acid excretion during both basal conditions and metabolic acidosis. Proximal tubule (PT) ammonia generation is critical for normal renal ammonia excretion, but the mechanisms through which external stimuli alter PT ammonia metabolism are incompletely understood. This study's purpose was to determine the role of the predominant proximal tubule NBCe1 (SLC4A4) splice variant, NBCe1-A, in ammonia metabolism under basal conditions and in response to metabolic acidosis.

Methods: We used mice with specific deletion of the NBCe1-A splice variant generated using TALEN gene editing. Mice were fed normal diet or were acid-loaded by adding HCl to chow. All studies compared homozygous deletion (KO) mice with wild-type (WT) littermates.

Results: Under basal conditions, KO mice had spontaneous metabolic acidosis, consistent with proximal RTA from impaired proximal tubule bicarbonate reabsorption. Despite this acidosis, urinary ammonia excretion was not elevated in KO mice. Urine pH was lower in KO than WT mice, indicating that the failure of basal acidosis-stimulated

ammonia excretion was not due to impaired urine acidification. Immunoblots and immunohistochemistry (IHC) showed KO mice, despite their acidosis, expressed less phosphate-dependent glutaminase (PDG) and phosphoenolpyruvate carboxykinase (PEPCK), key ammonia generating enzymes, throughout the entire PT, and expressed more glutamine synthetase (GS) in cortical PT segments than did WT. After acid-loading, the ability to increase ammonia excretion was impaired significantly, by ~70%, in KO mice. Immunoblots and IHC showed less change in PEPCK, PDG and GS in the proximal convoluted tubule (PCT) of KO than WT mice. However, in the proximal straight tubule (PST) in the outer medulla, where in the normal mouse NBCe1-A expression is less than in the PCT, PDG and PEPCK upregulation and GS downregulation were greater in KO than in WT mice.

Conclusions: (1) NBCe1-A is a key protein in the signaling pathway through which PCT ammonia metabolism is regulated during basal conditions and metabolic acidosis; and, (2) In the PST, one or more additional mechanisms enable responsiveness to exogenous acid-loading, but not to the spontaneous metabolic acidosis, in KO mice.

TH-PO1021

The A-Splice Variant of NBCe1 (NBCe1-A) Regulates Citrate Excretion and NaDC1 Expression Gunars Osis,[1] Kierstin L. Webster,[1] Heather L. Holmes,[2] Adam J. Rossano,[2] Michael F. Romero,[2] Jill W. Verlander,[1] I. D. Weiner.[1,3] *[1]Nephrology, University of Florida, Gainesville, FL; [2]Mayo Clinic College of Medicine, Rochester, MN; [3]Nephrology, NF/SGVHS, Gainesville, FL.*

Background: Urinary citrate affects several critical kidney functions, including acid-base homeostasis and prevention of calcium nephrolithiasis. Proximal tubule (PT) NaDC1 is believed to be the major regulator of urinary citrate excretion. These studies examined the role of the A-splice variant of NBCe1 (NBCe1-A) in basal and acidosis-stimulated citrate excretion and NaDC1 expression.

Methods: We used recently developed NBCe1-A-specific deletion (KO) mice and their wild-type (WT) littermates. We performed exogenous acid-loading with dietary HCl loading for 7 days. We used quantitative immunohistochemistry (qIHC) to examine NaDC1 expression in proximal convoluted tubule in the cortical labyrinth (PCT), proximal straight tubule (PST) in the medullary ray (PST-MR) and PST in the outer medulla (PST-OM). Urinary citrate was measured using ^{1}H-NMR.

Results: In WT mice under basal conditions, NaDC1 immunolabel intensity exhibited significant axial heterogeneity, PCT < PST-MR < PST-OM. Under basal conditions, NBCe1-A deletion induces spontaneous metabolic acidosis. Despite the acidosis, which in normal conditions decreases citrate excretion, citrate excretion was significantly greater in KO than WT mice (~3x-fold). Quantitative IHC showed NaDC1 expression was significantly less in KO than WT mice in all PT sites. Exogenous acid-loading decreased urinary citrate excretion >98% in both genotypes such that final urinary citrate did not differ significantly between WT and KO mice. Exogenous acid-loading increased NaDC1 expression in WT mice in the PCT and PST-MR, but not the PST-OM. In KO mice, in contrast, exogenous acid-loading did not alter PCT NaDC1 expression significantly, but did increase expression significantly in both PST-MR and PST-OM.

Conclusions: 1) Under basal conditions NBCe1-A expression is critical to the normal regulation of citrate excretion and NaDC1 expression; 2) in WT mice, there is significant axial heterogeneity of both basal NaDC1 expression and its response to acid-loading; and, 3) during exogenous acid-loading alternative signaling pathways in NBCe1-A KO mice increase NaDC1 expression with a different axial pattern than in WT mice. We conclude that NBCe1-A is critical for citrate metabolism through its regulation of normal NaDC1 expression under basal conditions and in response to acid-loading.

TH-PO1022

Exploring the Exchangeability of Transmembrane Segments between Na/HCO3 Cotransporter NBCe1-A and Cl-HCO3 Exchanger AE1 Seong-Ki Lee, Walter F. Boron. *Physiology and Biophysics, Case Western Reserve University, Cleveland, OH.*

Background: The SLC superfamily of transport proteins comprises >300 genes in 52 families. Here we study 2 SLC4 family members: electrogenic NBCe1 (SLC4A4) and electroneutral Cl-HCO_3 exchanger AE1 (SLC4A1). NBCe1-A is predominantly expressed in the renal proximal tubule basolateral membrane, where it reabsorbs HCO_3^- into the blood. The erythrocyte variant of AE1 is important for CO_2 carriage in blood. Recently, Arakawa et al. published the crystal structure of human AE1, which has 14 transmembrane segments (TMs). They classified the TMs into a core domain (CD; 8 TMs) and a gate domain (GD; 6 TMs). They proposed that conformational changes of the GD allow transport of substrate, whereas the CD provides substrate specificity.

Methods: Guided by this new AE1 structure, we defined NBCe1's TMs (~25-30% amino-acid identity to AE1). We hypothesized that NBCe1-A will work when implanting gate TMs of AE1 into NBCe1-A, whereas NBCe1-A will not work when implanting core TMs of AE1 into NBCe1-A. We generated 14 NBCe1-A chimeras, 1 for each TM. We assessed NBCe1-A's electrogenic activity by two-electrode voltage-clamping *Xenopus* oocytes expressing each mutant. We checked surface expression (SExp) by biotinylation.

Results: Data is summarized in Table. We found that, in general, implanting gate TMs induces SExp, whereas implanting core TMs does not. We also found that some mutants show robust electrogenic activity (I_{NBC}, NBCe1-A current, or ΔV_m upon HCO_3^- addition).

Conclusions: Our findings suggest that the CD of NBCe1-A cannot tolerate swapping of individual TMs because of coordination with substrates, whereas the GD of NBCe1-A generally expresses after such swaps, and even shows robust electrogenic activity in some cases presumably because the swapped TM still works as a structural component.

ΔTM	1st	2nd	3rd	4st	8st	9st	10st	11st	5st	6st	7st	12st	13st	14st

TH-PO1023

Novel Point Mutation in NBCe1/SLC4A4 Displays Dominant-Negative Inhibition of Wild-Type NBCe1A Activity in Mammalian Cells and Xenopus Oocytes Adam J. Rossano, Heather L. Holmes, Michael F. Romero. *Mayo Clinic College of Medicine, Rochester, MN.*

Background: NBCe1 (electrogenic Na^+/HCO_3^- cotransporter 1; SLC4A4) is present at the proximal tubule basolateral membrane where it controls systemic pH by reclaiming HCO_3^-. Human recessive NBCe1 mutations cause proximal renal tubular acidosis, cataracts, and glaucoma. A recently discovered novel point mutation (NBCe1-Mut) produces similar clinical findings, but its biophysical characterization is lacking.

Methods: NBCe1A activity was assessed by voltage clamp in *Xenopus* oocytes. Membrane trafficking was followed using HA-tagged constructs. NBCe1A activity was also assayed in human trabecular meshwork cells (NTM-5) and retinal pigment epithelia (RPE) by co-transfecting GFP-tagged NBCe1 constructs with pHire (RFP-based pH indicator) to monitor intracellular pH.

Results: In oocytes, CO_2/HCO_3^- (CB) addition elicited strong inward currents with NBCe1A-WT (WT). Currents in E91R (low-function) and Mut injected oocytes were indistinguishable from water controls. WT/E91R coinjections produced currents similar to WT, but co-injection of WT/Mut reduced maximum current to ~35% of WT-alone. HA tracking revealed that Mut trafficking to the plasma membrane was impaired compared to WT/E91R, and co-injection of WT/Mut constructs decreased successful trafficking to ~50% of WT-alone. Exposure of human cells expressing pHire to CB solutions produced a characteristic fall in pH followed by a gradual Na^+-sensitive pH increase (HCO_3^- entry) via endogenous NBCe1. Cells transfected with WT displayed more rapid HCO_3^- entry than neighboring untransfected cells as well as dramatic acidification upon Na^+ removal. pH transients in E91R transfected cells were indistinguishable from those in untransfected neighbors while expression of Mut slowed HCO_3^- entry and diminished the rate of acidification upon Na^+ removal in both cell types studied.

Conclusions: NBCe1A-Mut displays poor transport and trafficking to the plasma membrane. Surprisingly, Mut can impair WT function and localization when co-expressed in amphibian and human cells. These results suggest a unique dominant-negative phenotype which requires further mechanistic analysis.

TH-PO1024

Expression of Phosphate-Dependent Glutaminase (PDG) in Normal and Neoplastic Human Kidney Hyun-Wook Lee,[1] William L. Clapp,[2] Dara N. Wakefield,[2,3] Jill W. Verlander,[1] I. D. Weiner.[1,4] *[1]Nephrology, University of Florida, Gainesville, FL; [2]Pathology, University of Florida, Gainesville, FL; [3]Pathology, NF/SGVHS, Gainesville, FL; [4]Nephrology, NF/SGVHS, Gainesville, FL.*

Background: Phosphate-dependent glutaminase (PDG) is a mitochondrial protein that has a critical role in renal ammonia metabolism, catalyzing the initial step in ammoniagenesis, and may have a role in glutamine-derived ATP generation. The cellular distribution of PDG in the human kidney is currently unknown. This study's purpose was to determine PDG's cellular expression in normal and neoplastic human kidney.

Methods: We used human kidney tissues from unused portions of nephrectomy specimens removed during routine treatment of renal cell carcinoma for immunohistochemistry studies. Three separate PDG antibodies were used; all gave similar results. Normal human kidney protein lysates were obtained from commercial sources.

Results: Immunoblot analysis of both human whole kidney and cortical protein revealed an ~63 kDa protein. Immunohistochemistry showed PDG immunolabel throughout the nephron and in arterial walls in a granular pattern consistent with mitochondrial expression. Glomerular label was punctate and weak compared to tubules. Tubule distribution of PDG was verified using H^+-ATPase and NKCC2 as markers. Strong PDG expression was present in proximal tubule, descending and ascending thin limb, thick ascending limb, distal convoluted tubule, connecting segment (CNT), and throughout the collecting duct (CD). Cellular heterogeneity in label intensity was evident in CNT and CD profiles. PDG expression in kidney neoplasms varied among tumor types. In tumors of presumed proximal tubule origin, clear cell and papillary renal cell carcinoma (RCC), weak, 1+, PDG immunolabel was present. In tumors of presumed intercalated cell tubule origin, oncocytoma and chromophobe RCC, PDG immunolabel was substantially more intense, 2-3+, and immunolabel intensity was greater in oncocytoma than in chromophobe RCC.

Conclusions: 1) PDG is widely expressed in epithelial and non-epithelial cells in the human kidney. 2) PDG expression in RCC varies with tumor type; it is weakly expressed in clear cell and papillary RCC, whereas in oncocytoma and chromophobe RCC it is expressed more strongly. 3) This wide-spread expression suggests PDG may have critical roles both in ammoniagenesis and glutamine-derived ATP generation.

TH-PO1025

Axial Heterogeneity of Phosphate-Dependent Glutaminase Expression and Response to Metabolic Acidosis Hyun-Wook Lee,[1] Gunars Osis,[1] Autumn N. Harris,[1] Lijuan Fang,[1] Jill W. Verlander,[1] I. D. Weiner.[1,2] *[1]Nephrology, University of Florida, Gainesville, FL; [2]Nephrology, NF/SGVHS, Gainesville, FL.*

Background: Phosphate-dependent glutaminase (PDG) is critically important in renal ammoniagenesis and may also contribute to 2-oxoglutarate generation used for TCA-derived ATP generation. Although increased proximal tubule (PT) PDG expression during metabolic acidosis is well-recognized, its expression and regulation in other renal tubule cells is not well-characterized. This study's purpose was to determine PDG's cellular expression in the kidney and the cell-specific response to metabolic acidosis.

Methods: C57Bl/6 mice were fed normal diet or were acid-loaded by adding HCl to chow for 7 days. Three separate PDG antibodies were used; all gave similar results.

Results: Under basal conditions, immunohistochemistry (IHC) showed PDG immunolabel throughout the renal nephron, collecting duct and papillary surface epithelium. Immunogold electron microscopy confirmed mitochondrial localization; gold label density was generally greater in mitochondria in distal tubule and collecting duct cells than in PT cells. The cellular distribution of PDG expression was verified using double-immunolabel IHC with NHE3, AQP1, NKCC2, and H^+-ATPase. Cells with strong PDG expression were present in the proximal convoluted tubule, proximal straight tubule, descending and ascending thin limbs, thick ascending limb, distal convoluted tubule, connecting segment, and throughout the collecting duct. In the PT, label intensity was heterogeneous, with interspersed intensely- and weakly-labeled cells. In medullary collecting ducts, intercalated cells had greater expression than principal cells. In addition, intercalated cell expression was heterogeneous in CCD and CNT. Acid-loading increased the number of strongly PDG-positive PT cells, did not alter expression in cortical and medullary thick ascending limb (mTAL) in the OSOM or the entire collecting duct and decreased expression in mTAL in the ISOM.

Conclusions: (1) The finding of cellular heterogeneity in PT PDG expression, with acid-loading increasing the number of PT cells with intense PDG expression, identifies a new ammoniagenic regulatory mechanism. (2) The wide-spread expression of PDG in non-PT cells, which was not altered by acidosis, suggests PDG may contribute to glutamine-derived ATP generation via the TCA cycle.

TH-PO1026

Monophosphoryl Lipid A Prevents Sepsis-Induced Inhibition of HCO3- Absorption in Medullary Thick Ascending Limb Bruns A. Watts,[1] Thampi George,[1] Edward R. Sherwood,[2] David W. Good.[1] *[1]U TX Med Branch, Galveston, TX; [2]Vanderbilt U Med Center, Nashville, TN.*

Background: Sepsis impairs HCO_3^- absorption in the MTAL through two distinct mechanisms: 1) by decreasing the intrinsic HCO_3^- absorptive capacity, and 2) by enhancing inhibition of HCO_3^- absorption by LPS through upregulation of basolateral TLR4 signaling. Both effects depend on ERK activation. Monophosphoryl lipid A (MPLA) is a detoxified derivative of LPS that enhances innate host resistance to infection and improves survival following endotoxemia or sepsis. Recently we showed that pretreatment of MTALs with MPLA in vitro prevents LPS inhibition of HCO_3^- absorption by activating a TLR4-TRIF-PI3K-Akt pathway that prevents LPS-induced ERK activation. Here we examined whether pretreatment with MPLA in vivo would protect the MTAL against sepsis.

Methods: Mice were treated with vehicle or MPLA 48 h before sham or cecal ligation and puncture (CLP) surgery. MTALs were studied in vitro 18 h post-surgery.

Results: As shown previously, CLP decreased basal HCO_3^- absorption rate by 22% and increased inhibition by LPS from 21 to 41% vs sham controls ($P<0.05$). Pretreatment with MPLA prevented both the effects of sepsis to decrease the basal HCO_3^- absorption rate and to enhance inhibition by LPS. MPLA treatment increased Akt phosphorylation and prevented the CLP-induced activation of ERK that reduces basal HCO_3^- absorption rate in the MTAL. These effects of MPLA on Akt and ERK were eliminated in MTALs from CLP mice treated with a PI3K inhibitor and in MTALs from TRIF-deficient mice. Treatment of MTALs from CLP mice with MPLA in vitro reduced ERK activity through activation of PI3K. In addition, treatment with a PI3K inhibitor in vitro enhanced the ability of LPS to inhibit HCO_3^- absorption through ERK activation in MTALs from MPLA-treated CLP mice. MPLA attenuated the decrease in plasma [HCO_3^-] in CLP mice.

Conclusions: MPLA treatment prevents the effects of sepsis to impair MTAL HCO_3^- absorption. These protective effects are mediated through MPLA stimulation of a TRIF-PI3K-Akt pathway that downregulates ERK activation in the MTAL. These results identify TLR4-based immunomodulators such as MPLA as novel agents to treat or prevent sepsis-induced renal tubule dysfunction and identify pathways that can be targeted to preserve MTAL HCO_3^- absorption during bacterial infection.

Metabolic Acidosis Inhibits AMPK Function in Kidney Cells Nuria M. Pastor-Soler,[1] Hui Li,[1] Kazuhiro Omi,[2] Kenneth R. Hallows.[1] *[1]Keck School of Medicine of USC, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Background: AMP-activated protein kinase (AMPK) is stimulated by cellular metabolic depletion. We have shown that AMPK activation inhibits kidney membrane transport proteins, thus protecting cells from further metabolic depletion and damage. AMPK is tightly regulated, and when pharmacologically activated, can protect kidneys from superimposed injury. Conversely, AMPK is inhibited in chronic kidney disease (CKD) and pharmacologic AMPK activators are proposed as therapies to slow CKD progression. However, the mechanisms by which AMPK may promote kidney survival are unclear. CKD results in systemic metabolic acidosis (MA) due to the inability of the kidney to excrete non-volatile acid. MA often goes undetected and, if untreated, MA has severe health sequelae such as worsening glomerular filtration rate (GFR). We hypothesized is that there is cross-talk between acid-base status and AMPK signaling, and that dysregulation of AMPK function by MA disrupts kidney regeneration.

Methods: We used kidney epithelial cell lines in culture and adult male C57BL/6 mice for our experiments. Cells were exposed to media at either pH 7.3-7.4 (control) or 6.9-7.0 (acidic) for 3 d ± an AMPK activator for the last 16 h. Mice were given 1.5% saccharin ± 0.28 M NH_4Cl in the drinking water for 2 months. Mice also underwent uninephrectomy (UNX) as a model for CKD vs. sham surgery. To evaluate the AMPK pathway in tissue, we examined levels of phosphorylation of acetyl CoA carboxylase (pACC) by immunoblot.

Results: We found that as compared to cells grown at pH 7.4, kidney cells grown in acidic media have reduced baseline AMPK activity and blunted pharmacologic AMPK activation. Mice on the acidogenic diet developed MA without significant weight loss compared to mice on the control diet (blood pH 7.2 vs 7.3 ± 0.01). In mice after UNX, the superimposed MA induced a statistically significant decrease in pACC, compared to mice with UNX in a control diet.

Conclusions: Our results point to a direct inhibition of the AMPK pathway in the setting of combined CKD and MA. This AMPK inhibition may be detrimental to kidney regeneration in the setting of CKD and MA.

Acute Secretin-Induced Urinary HCO3- Excretion: A Function of Pendrin Peder Berg,[1] Casper K. Larsen,[1] Inês Cabrita,[2] Karl Kunzelmann,[3] Jens G. Leipziger.[1] *[1]Aarhus University, Aarhus, Denmark; [2]Physiology, University of Regensburg, Germany, Regensburg, Germany; [3]University of Regensburg, Regensburg, Germany.*

Background: The gastro-intestinal hormone secretin is able to acutely increase the amount of HCO_3^- in the urine by a currently unknown mechanism. The actions of secretin are well understood in gastro-intestinal physiology; among many functions it acts as an important activator of pancreatic HCO_3^- secretion. The secretin receptor (SCTR) is also expressed in kidney collecting ducts (CD), the function here is not well defined. The present study investigated the acute effects of bolus injections of secretin (i.p., 10μg) on urinary pH in Pendrin knockout (KO) and wildtype (WT) mice.

Methods: Real time monitoring of urine flow and urinary pH was performed by bladder catheterization and insertion of micro pH-electrodes in the outflow of the catheter in i.v. anaesthetized mice. Two different protocols were used to assess the functional effects of secretin on urinary pH: **1.** Mice were under a continuous i.v. infusion through a tail vein catheter. After 30 minutes the animals were injected with either secretin or vehicle. **2.** After a gavage load, mice were injected with furosemide (0.2μg/g BW, i.p.) and subsequently treated with secretin or vehicle.

Results: 1. WT secretin treated animals had a significant transient urinary alkalization, peak difference: 0.41 pH units (n=6, p=0.014), whereas no alkalization was observed in the secretin treated KO mice and neither in sham injected WT and KO mice. **2.** WT secretin treated animals had a significant transient urinary alkalization, peak difference: 0.64 pH units (n=6, p=0.002), whereas no alkalization was observed in the secretin treated KO mice and neither in sham injected WT and KO mice. Furthermore, SCTR mRNA was specifically localized only in isolated connecting tubules and collecting ducts. In IHC results the SCTR (basolateral) co-localized with Pendrin (apical).

Conclusions: Secretin is a potent activator of renal HCO_3^- excretion. Its mechanism requires functional Pendrin (SLC26A4) and is likely mediated via the SCTR in β-intercalated cells of the collecting duct.

Hydrochlorothiazide and Acute Urinary Acidification: The Voltage Hypothesis of ENaC-Dependent H+ Secretion Refuted Niklas Ayasse, Jens G. Leipziger. *Aarhus University, Aarhus, Denmark.*

Background: It has been assumed that furosemide-induced urinary acidification is due to the coupling between increased electrogenic sodium transport via the epithelial sodium channel (ENaC) in the collecting duct (CD) and a subsequent increased activity of the vacuolar H^+-ATPase, localized in the α-intercalated cells of the CD. However, we recently showed that urine acidification by furosemide occurs apparently independent of ENaC activity. We demonstrated that furosemide directly stimulates H^+ secretion in the thick ascending limb (TAL) via the Na^+/H^+ exchanger NHE3. Under the assumption that urinary acidification takes place in the TAL we expect that the administration of hydrochlorothiazide (HCT) does not cause an acute change in urinary pH. We investigated the effect of HCT both under conditions of low and high ENaC expression.

Methods: Mice having been subjected to either a control diet or a low-Na^+ diet were anesthetized and infused (0.5 ml/h) with a control solution. The urinary bladder was catheterized and urine pH was measured directly in the outflow of the catheter with an electrode. Mice received either HCT (30mg/kg/h) or a vehicle solution. Diuresis was simultaneously quantified. Urinary Na^+ and K^+ excretions were measured using flame

photometry. The kidneys were harvested to quantify ENaC expression by Western Blotting.

Results: (1) Mice having been fed a low-Na^+ diet showed a significant upregulation of ENaC. **(2)** After the administration of HCT urine output was increased in both groups. **(3)** HCT caused an increase in Na^+ excretion that did not reach significance. **(4)** K^+ excretion rates increased markedly after HCT administration from 18.55±3.83 to 31.67±7.62 in the control diet group and from 22.95±3.68 to 48.71±8.36 µmol/h in the low-Na^+ diet group. **(5)** Importantly, no changes in urine pH were observed after the administration of HCT in both groups.

Conclusions: Despite the induction of acute kaliuresis by HCT, indicating an increased electrogenic transport of Na^+ via ENaC, an acute increased H^+ secretion was not observed, neither under control conditions nor under conditions of marked ENaC upregulation. Thus, this study supports our previous finding that H^+ secretion by furosemide takes place in the TAL.

Two Year Follow Up on Chronic Hemodialysis (HD) Patients Prescribed Sucroferric Oxyhydroxide as Part of Routine Care

Stuart M. Sprague,[1] Vidhya Parameswaran,[3] Linda H. Ficociello,[3] Norma J. Ofsthun,[3] Claudy Mullon,[3] Robert J. Kossmann,[3] Daniel W. Coyne.[2] *[1]NorthShore University HealthSystem University of Chicago Pritzker School of Medicine, Chicago, IL; [2]Washington University School of Medicine, St. Louis, MO; [3]Fresenius Medical Care North America, Waltham, MA.*

Background: Controlling serum phosphorus (sP) in HD patients is challenging, in part, due to lack of compliance with the high pill burden typically associated with phosphate binder (PB) therapy. Sucroferric oxyhydroxide (SO) is a PB with a starting dose of 3 pills per day. The current analysis aimed to assess the long-term effectiveness of SO in lowering sP and PB pill burden.

Methods: Adult Fresenius Kidney Care HD patients switched during 1/1/14 -3/31/15 from PB monotherapy to SO monotherapy and continued on SO for two years were included (n=241). Baseline was defined as the 3 months before SO, when prior PB was used. Mean prescribed PB pills/day and sP levels were calculated using mixed effects linear regression. In-range sP was defined as sP ≤ 5.5 mg/dl.

Results: Patients had a mean age of 54 years and dialysis vintage of 57 months at baseline. The majority of patients (67%) were on sevelamer before switching to SO. Mean pill burden decreased by 48-53% from baseline (9.4 pills/day) to SO follow-up (4.4-4.9 pills/day). Prior to switching to SO, 15.8% of patients had a sP ≤ 5.5 mg/dl, after switch this increased to 30.8% at Q1 (a 95% increase or 1.9x from baseline) to 44.1% at 2 years (a 179% increase or 2.7x from baseline) [Figure].

Conclusions: During two year follow-up after switching PB to sucroferric oxyhydroxide, patients were 1.9x to 2.7x more likely to have sP ≤ 5.5 mg/dl (95%-179% increase from baseline) while being prescribed 50% less PB pills/day compared to baseline.

Effectiveness of Sucroferric Oxyhydroxide (SO) in Lowering Serum Phosphorus (sP) in 4,925 Chronic Hemodialysis (HD) Patients Prescribed SO as Part of Routine Care

Daniel W. Coyne,[1] Linda H. Ficociello,[2] Vidhya Parameswaran,[2] Norma J. Ofsthun,[2] Claudy Mullon,[2] Robert J. Kossmann,[2] Stuart M. Sprague.[3] *[1]Washington University School of Medicine, St. Louis, MO; [2]Fresenius Medical Care North America, Waltham, MA; [3]NorthShore University HealthSystem University of Chicago Pritzker School of Medicine, Chicago, IL.*

Background: Although the majority of HD patients are prescribed phosphate binders (PB), hyperphosphatemia is highly prevalent. A barrier to phosphorus control can be the high pill burden of most PB. The current analysis aimed to assess the effectiveness of SO in lowering sP and PB pill burden in a large patient population.

Methods: Patients included in the analysis were all Fresenius Kidney Care (FKC) patients switched during 1/1/14 -12/31/16 from PB monotherapy to SO monotherapy for at least three months. Baseline was defined as the 3 months before SO, when prior PB was used. Patients were followed until end of analysis period, end of monotherapy SO, or discharge from FKC. Mean prescribed PB pills/day and sP levels were calculated using mixed effects linear regression. In-range sP was defined as sP ≤ 5.5 mg/dl.

Results: Patients (n=4925) had a mean age of 55 years and dialysis vintage of 53 months. During baseline the majority of patients were hyperphosphatemic (only 18.9% had sP ≤ 5.5 mg/dl). Achievement of sP ≤ 5.5 mg/dl improved over SO from 28.5% at Q1 to 41% at Q8. Patients were prescribed, on average, 9.5 pills/day and this was reduced by >50% (4.2 to 4.7 pills/day) during SO follow-up. At baseline, patients were treated with sevelamer (Sev), calcium acetate (CaAc), ferric citrate (FC), or lanthanum carbonate (LC). Figures demonstrate the increases in patients achieving sP ≤ 5.5 mg/dl by the 4 baseline PB.

Conclusions: In a large cohort of patients switching to SO, improvements in achieving sP ≤ 5.5 mg/dl were observed across all baseline PB.

TH-PO1032

Changes in Mineral Bone Disease (MBD) Markers in Hemodialysis (HD) Patients Switched to Sucroferric Oxyhydroxide (SO) Sandeep Shori,[1] Vidhya Parameswaran,[2] Linda H. Ficociello,[2] Claudy Mullon,[2] Robert J. Kossmann.[2] *[1]None, Westlake, TX; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Elevated levels of MBD markers (sP, PTH, Ca) increase patient's risk of morbidity and mortality. This current analysis assesses the changes in MBD markers in patients who lower sP to ≤ 5.5 mg/dl when switching to SO.

Methods: Adult, baseline (BL) hyperphosphatemic (sP> 5.5 mg/dl) Fresenius Kidney Care HD patients switched to SO as part of routine clinical care during 1/1/14 -12/31/16 and maintaining sP ≤ 5.5 mg/dl for 2 quarters (Q1, Q2) after the switch were eligible. BL was defined as the 3 months before SO, when prior phosphate binders (PB) was used. Mean prescribed PB pills/day, sP, Ca, and PTH levels were calculated using mixed effects linear regression.

Results: At baseline the majority of patients were treated with sevelamer (66%), followed by calcium acetate (28%), lanthanum carbonate (5%) and ferric citrate (1%). MBD markers and number of phosphate binder pills/day at BL, Q1 and Q2 for 394 patients who achieved sP ≤ 5.5 mg/dl during Q1 and Q2 are presented in the table.

Conclusions: In a cohort of hyperphosphatemic HD patients switching to SO, improvements in achieving sP ≤ 5.5 mg/dl were accompanied by improvements in Ca and PTH and a 46% reduction in number of phosphate binder pills/day.

TH-PO1033

Serum Albumin and Serum Phosphorus among Hemodialysis Patients after Initiating Sucroferric Oxyhydroxide (SO) Kamyar Kalantar-Zadeh,[1] Linda H. Ficociello,[2] Vidhya Parameswaran,[2] Hasi Mondal,[2] Nicolaos V. Athienites,[3] Claudy Mullon,[2] Robert J. Kossmann.[2] *[1]University of California Irvine, School of Medicine, Orange, CA; [2]Fresenius Medical Care North America, Waltham, MA; [3]Renal Medical Care PC, Abington, MA.*

Background: Dietary protein intake may result in higher phosphorus burden and increases in serum phosphorus (sP) in hemodialysis (HD) patient, whereas restricting high-protein diet to control phosphorus may lead to hypoalbuminemia. This presents a challenge as both low serum albumin (sAlb) and high sP increase mortality risk. We hypothesized that under routine clinical care scenario, SO can lead to increase in sAlb, while lowering sP and pill burden.

Methods: All adult patients who completed 1 year of uninterrupted SO treatment (Q1-Q4) with sP and sAlb measurements were eligible for the analysis. Hypoalbuminemic patients (Low-Alb) had sAlb ≤ 3.5g/dl during at least one 3 month baseline interval and were matched on gender, race, diabetes status, and age (+/-5 years) to patients with normal sAlb during baseline (Match). 79 matched pairs were created.

Results: The two groups did not differ on matched baseline factors or BMI (31.1 vs 31.2 kg/m^2) but Low-Alb patients had a shorter dialysis vintage (32 vs 60 months) at baseline. Comparing baseline to Q4 of SO follow-up, PB pills/day decreased by 44.9 and 45.1% (both p<0.0001) and sP decreased by 0.7 and 0.5 mg/dl (both p<0.0001), for Low-Alb and Match, respectively. Mean sAlb stayed stable in Match, but increased significantly (p<0.0001) in the low sAlb group from 3.49 mg/dl at baseline to 3.71, 3.73, 3.74, and 3.69 mg/dl during Q1-Q4, respectively. Figure 1 shows monthly changes for sP and sAlb.

Conclusions: Lowering of sP and PB pills/day was observed in Low-Alb and Match patients after switch to SO. Low-Alb patients who received SO also experienced significant increases in sAlb.

Funding: Commercial Support - Fresenius Medical Care North America

TH-PO1034

Diet Induced Iron Deficiency Inhibits Intestinal Phosphate Absorption by a NaPi-IIb-Independent Mechanism Evans O. Asowata,[2] Surjit K. Srai,[3] Robert J. Unwin,[1] Joanne Marks.[2] *[1]Centre for Nephrology, University College London, London, United Kingdom; [2]Department of Neuroscience Physiology & Pharmacology, University College London, London, United Kingdom; [3]Department of Structural and Molecular Biology, University College London, London, United Kingdom.*

Background: Recent evidence suggests that iron-deficiency influences phosphate (Pi) homeostasis through altered transcription and processing of FGF-23 in osteocytes. In addition, older studies have provided conflicting data as to whether diet induced iron-deficiency impacts intestinal Pi absorption. We aimed to confirm if iron-deficiency alters intestinal Pi absorption, and if so, to investigate the underlying mechanisms.

Methods: Six-week old male Sprague-Dawley rats and C57Bl/6 mice were fed an iron-deficient (ID) diet (2-6 ppm iron) or control (C) diet (48 ppm iron) for 2-weeks, with both diets including 0.6% Pi. *In vivo* and *in vitro* Pi uptake experiments using a physiological Pi concentration (10mM) were used to examine changes in intestinal Pi absorption in these models. Western blotting, qPCR, and ELISAs were employed to understand the underlying mechanisms.

Results: Diet induced iron-deficiency inhibited Pi absorption in the rat duodenum *in vivo* (C: 6.0±0.6 *vs.* ID: 2.5±0.6 nmoles Pi in 1ml plasma/5cm, n=7, P<0.01), while FGF-23 and 1, 25$(OH)_2D_3$ levels were unaffected. In contrast, *in vivo* Pi absorption in the mouse ileum, which is known to be mediated predominantly by NaPi-IIb, was unaffected by iron-deficiency (C: 92.2±9.9 *vs.* ID: 98.3±8.5 nmoles Pi in 1ml plasma/5cm, n=6). In addition, the NaPi-IIb inhibitor, PFA (10mM), did not inhibit *in vitro* Pi absorption in the duodenum of control rats (C: 32.80±2.95 *vs.* C + PFA: 32.03±1.32 nmoles Pi/100mg, n=6), while iron-deficiency caused a significant reduction (ID: 10.04±1.21, P<0.0001, n=6), suggesting that this response is not dependent on NaPi-IIb. Interestingly, Western blotting showed that iron-deficiency significantly increased the expression of claudin 3 (C: 0.18±0.01 *vs.* ID: 0.37±0.07; P<0.05, n=6), as well as the apical membrane iron transporter, DMT1 (C: 0.10±0.02 *vs.* ID: 0.51±0.01; P<0.05, n=3).

Conclusions: We hypothesise that increased DMT1 expression may locally impact intestinal Pi absorption by a mechanism involving DMT1-induced accumulation of intracellular H^+ in the enterocyte resulting in increased claudin 3 levels, and subsequent sealing of the tight junction to reduce paracellular Pi absorption. Understanding how diet induced iron-deficiency affects intestinal Pi absorption may identify a novel target for the management of hyperphosphataemia in CKD patients.

TH-PO1035

Incidence, Predictors, and Therapeutic Consequences of Hypocalcemia in Patients Treated with Cinacalcet: The EVOLVE Trial Jürgen Floege,[5] Kate Tsirtsonis,[2] Jan Iles,[1] Tilman B. Drueke,[3] Glenn M. Chertow,[6] Patrick S. Parfrey.[4] *[1]Amgen Inc, Thousand Oaks, CO; [2]Amgen ltd, Uxbridge, United Kingdom; [3]Inserm UMR 1018, CESP, Université Paris-Sud, France; [4]Memorial University, St. John's, NL, Canada; [5]RWTH University of Aachen, Aachen, Germany; [6]Stanford University School of Medicine, Palo Alto, CA.*

Background: The calcimimetic cinacalcet is used to treat secondary hyperparathyroidism in patients receiving dialysis. Asymptomatic hypocalcemia is often observed following its initiation. Here we investigated the incidence, predictors and therapeutic consequences of hypocalcemia.

Methods: This was a post-hoc analysis of the randomized, double-blind, placebo-controlled EValuation Of Cinacalcet Hydrochloride Therapy to Lower CardioVascular Events (EVOLVE) trial. Hypocalcemia was classified as mild (total serum calcium 8.0 – 8.39 mg/dL), moderate (7.5 – 7.99 mg/dL) or severe (<7.5 mg/dL).

Results: At least one episode of hypocalcemia developed within 16 weeks after the first administered dose among 58.3% (1130/1938) patients randomized to cinacalcet versus 14.9% (286/1923) with placebo. Hypocalcemia in the cinacalcet group was severe in 18.4% of the patients versus 4.4% in the placebo group. Severe hypocalcemia following administration of cinacalcet was associated with geographic region (patients with Latin America and Russia had a higher risk relative to US), higher body mass index, higher baseline plasma PTH, lower corrected total serum calcium and higher serum alkaline phosphatase. Median cinacalcet dose immediately prior to the first hypocalcemia episode was 54-58 mg/day and similar in the three hypocalcemia categories. In the majority of patients, hypocalcemia resolved spontaneously within 14 days without modification of background therapy. Among patients who received an intervention, the most common was an increase in active vitamin D sterol dose.

Conclusions: The occurrence of hypocalcemia is a frequent effect following initiation of cinacalcet. The likelihood of developing hypocalcemia was related to the severity of secondary hyperparathyroidism. Hypocalcemia was generally asymptomatic and self-limited.

TH-PO1036

Intradialytic Change in Serum Calcium Concentration, but Not Dialysate Calcium Concentration, Is Associated with Cardiovascular Events in Hemodialysis Patients Miho Tagawa,[1] Takayuki Hamano,[2] Shinichi Sueta,[3] Satoshi Ogata,[2] Yoshihiko Saito.[1] *[1]Nara Medical University, Nara, Japan; [2]Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan; [3]Kyoto University, Kyoto, Japan.*

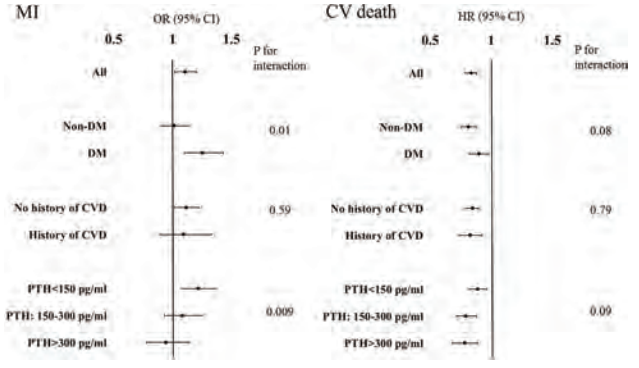
Background: Association of dialysate calcium (Ca) concentration and cardiovascular (CV) events has been studied but intradialytic change in serum Ca concentration has not been studied in detail.

Methods: This was a longitudinal study based on the Japan Renal Data Registry from 2008 to 2009. Predictor variable was deltaCa (postdialysis - predialysis serum Ca concentration). Outcome variable was CV events during 1-year observation period. Statistical analyses were performed using multivariate logistic regression or Cox regression model, adjusted for potential confounders.

Results: Among 301,649 patients on the database, data for 44,700 patients were available after excluding missing data. There were 844, 1,450, and 1,815 events of myocardial infarction (MI), ischemic stroke, and CV death, respectively. Delta Ca was associated with higher incidence of MI and lower incidence of CV death (Table). Additional adjustment for dialysate Ca yielded similar results. Delta Ca was not associated with ischemic stroke. Delta Ca was associated with MI especially among diabetics and patients with low PTH (Figure).

Conclusions: Intradialytic increase in serum Ca concentration was associated with higher incidence of MI and lower incidence of CV death and it was not mediated through dialysate Ca concentration. It is suggested that not only predialysis but also postdialysis serum Ca concentration should be evaluated carefully and both large increase and decrease in intradialytic serum Ca concentration should be avoided not to increase MI and CV death, respectively.

	MI (OR)	CV death (HR)
Intradialytic change in serum Ca concentration (per mg/dL)	1.11 (1.02-1.20)	0.83 (0.79-0.88)



TH-PO1037

Hidden Hypocalcemia at the Initiation of Dialysis Satoshi Yamaguchi,[1] Takayuki Hamano,[2] Karin Shimada,[1] Ayumi Matsumoto,[1] Nobuhiro Hashimoto,[1] Tatsufumi Oka,[1] Daisuke Mori,[1] Yusuke Sakaguchi,[2] Isao Matsui,[1] Yoshitaka Isaka.[1] *[1]Nephrology, Osaka Univ Graduate School of Medicine, Suita, Japan; [2]Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Japan.*

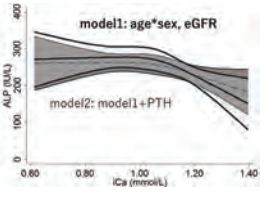
Background: Hypocalcemia (HypoCa) often leads to arrhythmia and heart failure. Our aims of this study are to reveal serum calcium abnormalities in incident hemodialysis (HD) patients and its clinical significance.

Methods: We performed a retrospective cohort study of incident HD patients. We collected the latest data just before the initiation of HD. We used logistic regression models to examine the factors associated with true HypoCa defined as ionized Ca (iCa) <1.15 mmol/L. We performed analyses to explore the association between the iCa levels and QTc prolongation in electrocardiogram, which was reported to be a predictor of cardiovascular death in CKD. Restricted cubic spline analyses were employed to explore potential nonlinear relationships between iCa and ALP or intact PTH (iPTH) levels.

Results: Among the enrolled 336 patients, the mean (SD) eGFR was 5.1 (1.9) mL/min/1.73m2. Eighty-one % of the patients showed true HypoCa, 60 % of whom showed normal corrected Ca (cCa), in other words, hidden HypoCa. Among patients with normal cCa levels, the ALP levels greater than upper normal limit were significantly associated with hidden HypoCa (Odds ratio; 8.4, 95%CI 1.1~64), accounting for 75% of normal cCa. Multivariate analysis showed the significant factors associated with true HypoCa were male, lower eGFR and serum albumin levels, higher serum phosphate levels, non-use of active vitamin D in pre-dialysis CKD, polycystic kidney disease, and high BNP levels (Fig.1). Moreover, lower iCa levels were associated with higher prevalence of QTc prolongation. A negative association between iCa and ALP were observed. Additional adjustment for iPTH did not change the relationship between iCa and ALP substantially (Fig.1), implying that osteomalacia induced by low iCa levels might explain high ALP levels.

Conclusions: Hidden HypoCa was prevalent just before the start of HD and associated with high ALP and BNP levels accompanied by QTc prolongation. High ALP levels despite normal cCa imply the presence of hidden HypoCa. The impact of pre-dialysis HypoCa on hard outcomes after HD initiation remains to be elucidated.

Variables	Odds Ratio	95 % CI
male	4.61	1.56-13.6
eGFR(per ml/min/1.73m²)	0.75	0.60-0.94
Alb (per g/dL)	0.23	0.07-0.70
Phosphate (per mg/dL)	1.84	1.20-2.84
active D user	0.32	0.12-0.88
ADPKD	19.3	1.20-311
BNP (per unit of logBNP)	1.55	1.01-2.38



TH-PO1038

Effect of an Individualized Therapy for Hyperphosphatemia in Hemodialysis Patients – A Single-Center, Open-Label Randomized Clinical Trial Xinyu Dong, Mengjing Wang, Qian Zhang, Jiaying Zhang, Minmin Zhang, Li Ni, Jing Chen. *Huashan Hosopital, Fudan Univeristy, Shanghai, China.*

Background: We hypothesized that estimation of phosphorus balance would improve the efficiency of treatment of hyperphosphatemia. Thus we compared individualized therapy with traditional therapy of hyperphosphatemia in maintenance hemodialysis (MHD) patients.

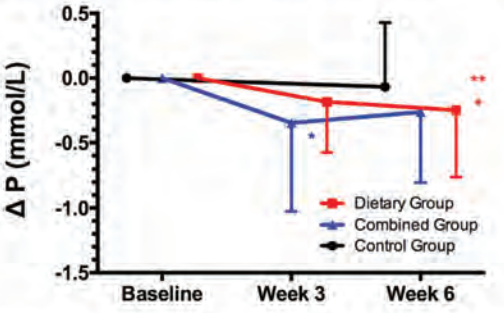
Methods: 67 eligible MHD patients with serum phosphate >1.45mmol/L were randomized into Control Group (n=20) and Individualized group (Dietary Group, n=23 and Combined Group, n=24) for 6 weeks. Phosphorus balance was achieved in Individualized group by the following equation: Diet Pi×60% = Pi removed by hemodialysis and phosphate binders. Patients in Dietary Group were assigned diet education and individualized diet for 6 weeks, while patients in Combined Group were assigned individualized diet for 3 weeks following correction of phosphate retention by increased hemodialysis sessions. No estimation of phosphorus balance was assessed in Control Group and patients were assigned conventional HD regimen and phosphate binders according to serum calcium and phosphate. Analysis was done among patients with good compliance.

Results: Mean age of the participants was 57.7±9.0 years old. Baseline serum phosphate was 1.96±0.38 mmol/L, 2.08±0.41 mmol/L and 2.13±0.47 mmol/L in Control, Dietary and Combined Group, respectively. Serum phosphate decreased significantly at Week 3 and Week 6 compared to Baseline in Dietary Group (Week 3: -0.18±0.39, *P*=0.113; Week 6: -0.41±0.42, *P*=0.004), and in Combined Group (Week 3: -0.35±0.68, *P*=0.045; Week 6: -0.26±0.54, *P*=0.056), but not in Control Group (Week 6: -0.09±0.50, *P*=0.556). No significant change was found in albumin, creatinine, calcium, iPTH, AKP, and nPCR during the follow-up period.

Conclusions: Individualized therapy was effective and safe in correcting hyperphosphatemia without inducing malnutrition. Current study provided a new and applicable approach in treating hyperphosphatemia in MHD patients.

Funding: Government Support - Non-U.S.

Change of serum phosphate level during 6-week follow-up in the Dietary Group, Combined Group, and Control Group.



* $P < 0.05$ compared with Baseline, ** $P < 0.05$ compared with Week 3. ΔP = Serum phosphate level (at Week 3 or Week 6) – Baseline phosphate level. Results are mean ± SD

TH-PO1039

Can CKD Patients Estimate Phosphate Content (PC) in the Food Correctly? Petr Taborsky. *Fresenius Medical Care, Praha, Czech Republic.*

Background: Hyperphosphatemia has been identified as a risk factor for survival of CKD patients. Food is the main source of increased serum phosphate in CKD. Patients are advised to control the amount of absorbed phosphate by phosphate binders. Reasonable PC estimate is a prerequisite for successful treatment with phosphate binders and for their adequate dosing.

Methods: Phosphate and protein content of 53 popular food items available on the market in Czech Republic were measured using standard chemical methods. Five typical Czech meals were prepared by nutritional specialist using recipes recommended for dialysis patients. The identical meals were purchased fresh in restaurant or frozen in supermarket and phosphate and protein content of all meals were measured. Virtual menu consisting of meal photos and short descriptions including information on the meal origin was compiled, nutrition facts were blinded. 23 predialysis patients CKD stage 3-5 were asked during their regular visit in nephrology clinic to go over the menu and put together the three days diet corresponding to their kidney function. Importance of low PC in the diet was repeatedly stressed. All patients were previously instructed in renal diet by nutrition specialist using the standard protocol. The optimal diet and the "worst" choice (the lowest and the highest possible content of phosphate) were calculated for comparison.

Results: Calculated PC in dietary regimens ranged from 730 to 1780 mg per day, all diets contained at least 60 g of protein per day. Phosphate to protein ratio in food varies much widely: from 9 mg/g in non-processed beef to 85 mg/g in some brands of spread cheese. PC in home-made meals was 1.2 to 2 times lower than in ready-to-eat meals. Food products labeled as "for children" contained less phosphate. Mean PC in diet chosen by patients was 1420 mg per day ranging from 920 to 1690 mg of phosphate per day. Difference in PC was done mainly by individual preferences of some sorts of dairy products and manufactured pastries.

Conclusions: PC is extremely variable, even within the same sort of food. For ordinary patient without special training the correct estimation of PC in food is very difficult even impossible. Traditional education based on close correlation between protein and PC in food should be changed because of widespread use of phosphate-containing additives.

TH-PO1040

Phosphate and Phosphate Changes Are Associated with Mortality in Dutch Dialysis Patients: A Registry Based Analysis Tiny Hoekstra,[1,2] Frans J. van Ittersum,[1] Marc H. Hemmelder,[2] Marc G. Vervloet.[1] *[1]VU University Medical Center, Amsterdam, Netherlands; [2]Nefrovisie Foundation, Utrecht, Netherlands.*

Background: Observational data suggest that an improvement over time of hyperphosphatemia in dialysis patients is associated with improved mortality. However it is unknown if an absolute or relative decline is optimal. This knowledge could have

clinical implications. Our aim is to associate the magnitude of changes in phosphate concentration with survival taking into account its initial value.

Methods: At quarterly intervals data on phosphate are available in a subset (N=5,487) of the Dutch renal replacement registry. Patients were followed from the date of the first available measurement until death or censoring (transplantation, recovery of renal function, lost to follow-up, end of study period). Time-updated cox regression analysis was performed with phosphate as well as changes in phosphate between subsequent measurements as continuous exposure variables. To allow for non-linear associations penalized splines smoothing was used. The analyses with changes were also performed stratified for categories of initial phosphate level. Adjustments were performed for age, sex, primary kidney disease, vintage, year of baseline, dialysis modality, previous transplantation.

Results: Both phosphate levels and phosphate changes showed a non-linear, U-shaped association with mortality. Lowest mortality was found for phosphate levels around 1.25 mmol/L. A gradually increase in benefit of phosphate decrease was observed across strata of initial phosphate level (from < 1.5 mmol/L to > 2.00 mmol/L), suggesting that a phosphate target of about 1.40 mmol/L is optimal. (Figure 1).

Conclusions: Patients with higher baseline phosphate concentrations appear to benefit form a greater absolute decline. Our data reinforce current clinical practice aiming at a target range for dialysis patients with hyperphosphatemia, instead of a fixed absolute decline.

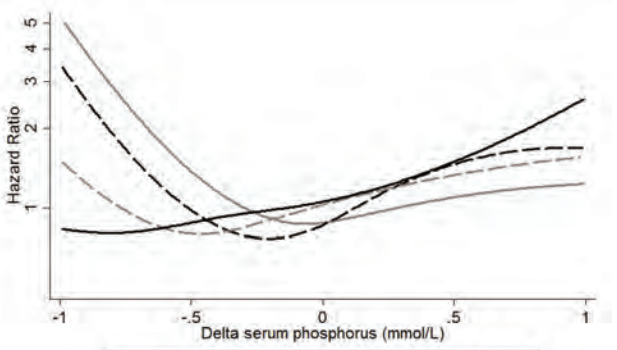


Figure 1. Changes in phosphate and mortality, stratified for categories of initial phosphate levels. The curves are adjusted for confounding factors.

Effects of Mineral Bone Disorder Medication Non-Adherence on Dialysis Patient Outcomes Yue Jiao,[1] Michelle Dias,[2] Savannah R. Clary,[2] Diane M. Rondeau,[1] Marta Reviriego-Mendoza,[1] John W. Larkin,[1] Len A. Usvyat,[1] Terry L. Ketchersid,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Rx, Franklin, TN.*

Background: Patients on dialysis are known to have a high medication burden, taking about 10 to 12 different medications. This burden has been associated with increased rates of medication non-adherence, especially for mineral bone disorder (MBD) therapies. It has been estimated that >50% of dialysis patients do not take their phosphate binders as prescribed (Ghimire et al. 2015). We aimed to characterize the outcomes of dialysis patients based on their MBD medication adherence levels.

Methods: In this retrospective cohort analysis, we included all patients dialyzed at Fresenius Kidney Care clinics between 2006 and 2016. Patients were characterized based on their MBD medication adherence levels per dietician assessment and categorized as: 1) "taking the medication as prescribed", and 2) "taking the medication inconsistently or not at all." The most recent MBD medication adherence assessment per patient was utilized for categorization. Rates of hospital admissions and mortality were calculated during the entire study period per patient basis.

Results: We analyzed data on 135,340 dialysis patients and identified that 9,929 (8%) took MBD medications inconsistently or not at all. Overall, we found lower rates of hospitalizations and mortality in patients who were determined to be adherent to their MBD medications versus those who were non-adherent. The hospitalization rate was 2.1 admissions per patient year (ppy) for the non-adherent group and 1.7 ppy for the patients taking MBD medication as prescribed ($p<0.001$ using Poisson regression). There were 9.3 deaths per 100 patient years (p100py) in the non-adherent group, and 8.8 p100py in the adherent group ($p=0.0013$ using a Kaplan Meier analysis).

Conclusions: In dialysis patients with bone disorders, MBD medication adherence appears to be associated with hospitalization and mortality outcomes. Importantly, these results are only reflective of patients with bone disorders and not the overall dialysis population. Further analyses are needed to understand root causes for dialysis patient medication non-adherence.

Coordination of Pharmaceutical Care in Dialysis Patients Is Associated with Lower Mortality and Hospital Admission Rates Sophia Rosen,[1] Marta Reviriego-Mendoza,[1] Savannah R. Clary,[2] Sheetal Chaudhuri,[1] Michelle Dias,[2] John W. Larkin,[1] Len A. Usvyat,[1] Terry L. Ketchersid,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]FreseniusRx, Franklin, TN.*

Background: It is estimated in the literature that >50% of ESRD patients do not take their phosphate binders as prescribed. The renal pharmacy FreseniusRx provides coordinated mineral and bone disorder (MBD) medication delivery and adherence support for enrolled patients. We investigated whether coordinated MBD pharmaceutical care is associated with improvements in hospital admission and mortality rates in dialysis patients.

Methods: We included data from hemodialysis patients in the network of Fresenius Medical Care North America clinics who were first enrolled into FreseniusRx pharmacy in January-February of 2016. This analysis utilized data on patients before and up to 9 months after pharmacy enrollment. We identified control patients not enrolled in the pharmacy by nearest neighbor 1:1 matching on the logit of the propensity score for demographics, comorbidities, state, insurance type, as well as, baseline lab values, vintage, access, hospitalization rates and other parameters. We compared hospital admission and mortality rates in 3, 6, and 9 months after enrollment.

Results: We analyzed data on 7116 patients (3558 in Rx and 3558 matched patients not in Rx). Rx patients had lower hospital admission rates per patient year (Rx vs non-Rx at 3, 6, and 9 months: 1.41 vs 1.54, 1.52 vs 1.62, 1.49 vs 1.60; $p=0.03$, $p=0.09$ and $p=0.065$ based on Poisson model). Mortality rates were also lower (HR for Rx vs non-Rx at 3, 6, and 9 months: 1.4, 1.4 and 1.3; $p=0.03$, $p=0.004$ and $p=0.003$ based on Cox model).

Conclusions: Coordinated pharmaceutical care is associated with lower hospital admission and mortality rates in the hemodialysis patient population. Further analyses are needed to understand what elements of this coordinated care are associated with improvements.

Four Times Daily versus Three Times Daily Dosing of Phosphorus Binders Does Not Improve Serum Phosphorus in Dialysis Patients Richard S. Muther.[1,2] *[1]Kidney Associates of Kansas City, Kansas City, MO; [2]Dialysis Clinics Inc., Kanssa City, MO.*

Background: Hyperphosphatemia associates with poor outcomes in ESRD patients. Dietary phosphorus restriction and phosphorus binding compounds taken with meals are the primary (though often ineffective) treatments to limit intestinal phosphorus absorption and lower serum phosphorus. Because phosphorus is known to undergo enterohepatic recirculation, a quality improvement project was conducted to determine whether bedtime administration of phosphate binder could favorably impact serum phosphorus.

Methods: Twenty-nine (29) dialysis patients with hyperphosphatemia received their daily phosphorus binding dose either 3 times a day with meals or 4 times a day with meals and at bedtime for 3 months, crossing over to the alternate dosing schedule for an additional 3 months. The type and total daily dose of binder was not changed and patients continued their usual phosphorus restricted diet.

Results: Standard of care data over the project period was available on 23 patients (3 expired, 2 withdrew, 1 transfer). Serum phosphorus did not change over the 3 month course of treatment, regardless of a 3 times daily with meals (5.63 ± 1.4 to 5.72 ± 1.49) or 4 times daily with meals and at bedtime (5.71 ± 1.01 to 5.95 ± 1.47) dosing schedule. The results were not influenced by baseline serum phosphorus (greater or less than 6.0 mg/dL) or the type of phosphorus binder.

Conclusions: If enterohepatic recirculation of dietary phosphorus affects serum phosphorus in dialysis patients, it does not appear to respond to increasing the frequency of administration of phosphorus binding compounds.

TH-PO1044

Association between Use of Phosphate-Binders and the Risk of Infection-Related Mortality in Hemodialysis Patients: The Q-Cohort Study Shunsuke Yamada,[1] Masanori Tokumoto,[2] Masatomo Taniguchi,[3] Hideki N. Hirakata,[3] Takanari Kitazono,[1] Kazuhiko Tsuruya.[4] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Medicine, Fukuoka Dental College, Fukuoka, Japan; [3]Fukuoka Renal Clinic, Fukuoka, Japan; [4]Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: Use of phosphate (P)-binders enables hemodialysis patients to take more protein, stay in a better nutritional status, and maintain serum P level in a recommended range. By contrast, dietary protein restriction often leads to protein-energy-malnutrition, which is closely related to the increased risk of infection-related deaths. However, it still remains unknown whether the risk of infection-related deaths is decreased in patients with P-binders compared with those without P-binders.

Methods: The present study was a prospective multicenter observational study consisting of 2926 hemodialysis patients registered to the Q-Cohort Study. The main exposure was use of P-binders and the main outcome was infection-related deaths. Patients' information was collected only at baseline. Propensity score (PS) for P-binder

use was created by multivariable logistic regression analysis. Multivariable-adjusted Cox proportional hazards models with or without PS-based approaches were used to estimate the risk of infection-related mortality.

Results: During the 3.9 years of median follow-up period, 106 patients died of infection. Patients with P-binders showed a higher body mass index and normalized protein catabolic rate and higher serum levels of creatinine and albumin compared with those without P-binders. Even after adjustment for confounding factors including serum levels of P, albumin, and creatinine, protein catabolic rate, and body mass index, the incidence of infection-relate deaths was significantly lower in patients with P-binders than those without P-binders; hazard ratio [95% confidence interval] for infection-related deaths was 0.63 [0.40–0.99]. The associations remained significant even after applying four different propensity score (PS) based adjustments; PS matching, PS stratification, PS covariate adjustment, and inverse probability weighting treatment.

Conclusions: Our results suggest that use of P-binders was significantly associated with a lower incidence of infection-related deaths in hemodialysis patients, even after accounting the nutritional factors and confounding by indication. Further studies are necessary to determine why P-binder users have the advantage of having a lower risk of infection-related deaths in hemodialysis patients.

TH-PO1045

Gastrointestinal Tolerability of Tenapanor to Treat Hyperphosphatemia in Patients on Hemodialysis Geoffrey A. Block,[2] David P. Rosenbaum,[1] Paul Korner,[1] Zhiwu Yan,[1] Glenn M. Chertow.[3] *[1]Ardelyx, Inc., Fremont, CA; [2]Denver Nephrology, Denver, CO; [3]Stanford University School of Medicine, Palo Alto, CA.*

Background: Hyperphosphatemia (HP) is common in ESRD and associated with morbidity and mortality. Phosphate binders are commonly associated with gastrointestinal (GI) side effects including diarrhea, nausea, vomiting, dyspepsia, constipation, abdominal pain, and abdominal bloating. Tenapanor (TEN) is a minimally absorbed small molecule NHE3 inhibitor that reduces GI sodium and phosphate absorption.

Methods: 8-week, double-blind, randomized treatment period (RT) with a 4-week placebo-controlled randomized withdrawal period (RW). Patients on hemodialysis (HD) with serum phosphate (sP) ≥6.0 mg/dL and a 1.5 mg/dL increase from baseline were randomized 1:1:1 to receive 3, 10 or 30 mg TEN twice daily. The 30 mg cohort was allowed to down-titrate weekly (30 to 20 to 15 to 10 to 3 mg twice daily) during the first 4 weeks of RT based on GI tolerability. At the end of RT, all patients were re-randomized 1:1 to either remain on TEN or placebo for RW. Patient reporting of loosened stool or increased frequency in bowel movements (BMs), regardless of magnitude, was classified as "diarrhea." Patients recorded daily BM frequency and form [Bristol Stool Form Score (BSFS)] using an eDiary.

Results: 219 patients were randomized to RT, 164 entered RW, and 152 completed the study. There was only one TEAE observed in >5% of patients during RT (diarrhea, 39%) and no TEAE >5% during RW. During RT, 7.8% (n=17) of patients discontinued due to diarrhea; one (3 mg TEN) with SAE; during RW there were no discontinuations due to diarrhea. During RW, diarrhea was reported by 1.2% of the TEN group vs 2.4% on placebo and there were no discontinuations. Mean BM frequency increased by 0.4/day (baseline of 1.5/day) during RT, and BM frequency was 0.3/day higher with TEN than with placebo during RW. Mean BM frequency was within the normal range in all groups. Mean BSFS scores increased by 0.9 (baseline 4.2) during RT, and there was a 0.7-point difference between placebo (4.4) and TEN treatment (5.1) during RW.

Conclusions: TEN was well-tolerated in HD patients; the only TEAE >5% was diarrhea, reflecting the pharmacodynamic mechanism of action of TEN, resulting in softer more frequent BMs that, on average, remained within the normal range with regard to both frequency and form.

Efficacy of Tenapanor to Treat Hyperphosphatemia in Patients on Hemodialysis Geoffrey A. Block,[2] David P. Rosenbaum,[1] Paul Korner,[1] Zhiwu Yan,[1] Glenn M. Chertow.[3] *[1]Ardelyx, Inc., Fremont, CA; [2]Denver Nephrology, Denver, CO; [3]Stanford University School of Medicine, Palo Alto, CA.*

Background: Tenapanor (TEN) is a minimally absorbed oral small molecule that blocks the sodium-hydrogen type 3 exchanger (NHE3) in the gastrointestinal (GI) tract inhibiting the absorption of dietary sodium and has been demonstrated to alter paracellular phosphate transport and reduce serum phosphate (sP) concentration in patients receiving hemodialysis (HD).

Methods: 8-week, double-blind, randomized treatment period (RT) with a 4-week placebo-controlled randomized withdrawal period (RW). Patients on HD with sP ≥6.0 mg/dL and a 1.5 mg/dL increase from baseline were randomized 1:1:1 to receive 3, 10 or 30 mg TEN twice daily. The 30 mg cohort was allowed to down-titrate weekly (30 to 20 to 15 to 10 to 3 mg twice daily) during the first 4 weeks of RT based on GI tolerability. At the end of RT all patients were re-randomized 1:1 to either remain on TEN or placebo for RW. The primary endpoint, based on the responder population (defined as patients demonstrating a ≥1.2 mg/dL decrease in sP during RT), was the difference in change in sP between pooled TEN and placebo from the end of RT to the end of RW.

Results: 219 patients receiving HD were randomized and 164 patients (75%) completed RT, of which 152 (93%) completed RW. Principal reasons for discontinuation included adverse events (8%), and hyperphosphatemia (5%). 80 patients were responders in whom the mean decrease in sP as compared to baseline during RT was 2.6 mg/dL. During RW, mean sP increased by 1.5 mg/dL in placebo treated patients and 0.5 mg/dL in TEN treated patients, resulting in a LS mean difference of –0.8 (95% CI: –1.4, –0.2, p=0.01). For the intent to treat (ITT) group (all 164 patients in RW), mean sP increased by 0.8 mg/dL in placebo treated patients and 0.1 mg/dL in those receiving TEN resulting in a LS mean difference of –0.7 (95% CI: –1.2, –0.3, p=0.003). TEN resulted in statistically significant reductions in sP during RT in all 3 TEN groups.

Conclusions: TEN, an oral small molecule NHE3 inhibitor that reduces intestinal phosphate transport, significantly lowers sP in patients receiving HD with hyperphosphatemia.

TH-PO1047

A Novel, Selective, and Non-Systemic Na+/H+ Exchanger 3 Inhibitor, TP0469711, Potently Enhances Phosphate Excretion with a Favorable Gastrointestinal Tolerability in Rats Eiji Munetomo, Tomohiro Abe, Hideki Tomoike, Hiromitsu Kajiyama, Saori Koyasu, Lisa Okumura, Shoichi Kuroda, Haruyuki Mori, Yasunobu Ushiki, Teisuke Takahashi, Koji Yamamoto. *Taisho Pharmaceutical Co., Ltd., Saitama, Japan.*

Background: Na^+/H^+ Exchanger 3 (NHE3) inhibitor is known to enhance the excretion of phosphate and expected as a new candidate for anti-hyperphosphatemia drug. However, NHE3 inhibitor also causes diarrhea frequently because of the excessive enhancement of Na excretion.

Methods: NHE1, NHE2 and NHE3 activities of TP0469711 (TP) were evaluated by measuring intracellular pH recovery in each NHE over-expressing cells. Na-dependent phosphate transporter 2b (NaPi2b) activity was evaluated by uptake of ^{33}P phosphate in NaPi2b over-expressing cells. To examine the effect of TP on the phosphate absorption and excretion, the radioactivity of ^{32}P phosphate in the blood and feces were measured after oral administration of TP. Inhibitory effects of NHE3 by TP were evaluated by measuring pH and luminal Na content in the intestinal tract. Na excretion and water content in feces up to 24 hours were evaluated after oral dosing of TP in rats.

Results: TP inhibited human and rat NHE3 activities with IC_{50} values of 2.2 and 2.1 nM, respectively. However, TP (3 μM) had no effects on human NHE1, NHE2 and NaPi2b activities. Oral administration of TP increased pH of luminal content in the upper intestine in a dose-dependent manner in rats. TP (0.1 mg/kg, p.o.) significantly decreased the area under the curve of plasma ^{32}P phosphate radioactivity by 40.7 ± 4.7 % (n=5, $P < 0.001$). TP (0.1 mg/kg, p.o.) significantly increased the fecal excretion of phosphate by 62 % (n=6, $P < 0.05$), without affecting Na excretion and water content in feces. TP significantly enhanced the excretion of Na and increased water content at a higher dose of 1 mg/kg (n=7, $P < 0.01$). Over dose of TP (30 mg/kg, p.o.) did not raise plasma concentration (< 1 ng/ml), which means TP is a non-systemic NHE3 inhibitor.

Conclusions: We discovered a novel, selective and non-systemic NHE3 inhibitor, TP0469711, which potently excreted phosphate into feces with a favorable gastrointestinal tolerability in rats. TP is suitable for a new therapeutic agent for the treatment of hyperphosphatemia in patients with end-stage renal disease.

VS-505: A Novel Phosphate Binder: First Clinical Experience in Haemodialysis Patients Johan Rosman,[1,4] Testuji Asao,[3] Mark A. Thomas,[4] Shitotomo Yamauchi.[2] *[1]School of Medicine, Curtin University, Perth, WA, Australia; [2]Ethic Co., Ltd., Chiyoda, Japan; [3]KDL Inc., Tokyo, Japan; [4]Royal Perth Hospital, Perth, NSW, Australia.*

Background: Phosphate binders (PB) side effects lead to non-compliance. Recently, iron-based PB were introduced, but absorption leads to high iron levels. VS-505 is a novel class PB where the iron ion (as ferric chloride) is bound to inert Arabic Gum. Animal studies showed superior efficacy and better tolerance without change in serum iron levels. This is the first study in haemodialysis patients to test safety, efficacy and tolerability.

Methods: This single arm, open label, dose escalation study used VS-505 in haemodialysis patients, stable on treatment for over 12 weeks. Plasma phosphate (Pi) level had to be between 6 - 10 mg/dl after a 2 weeks wash out from current PB. Other treatment, and dialysis modality remained unchanged. Treatment with VS-505 was 8 weeks with 2-weekly dose escalations, guided by Pi levels, from 1.5 g/day to 9.0 g/day. From screening to treatment day 22, lab parameters were followed weekly, then fortnightly. Primary Efficacy Endpoint was the Pi change during treatment. Secondary Efficacy Endpoints were Time Course of Pi to end of treatment and Plasma Calcium (Ca) change. Other criteria were trajectory of Iron Parameters, standard dialysis bloodtests, and Electro-Cardiograms. Tolerability was evaluated with questionnaires. Endpoints analysis by Intention to Treat/Full Analysis Set and a Per Protocol Set. A last Observation Carried Forward was applied for patients not completing the study.

Results: Sixteen patients were enrolled. 11 withdrew consent: 3 for diarrhea after dose escalation, 8 for medication-unrelated AE's. 30% of all patients reported black stools (iron). Only one subject received full dose escalation to 9 g/day, 4 reported abdominal dyscomfort after the escalation to 4.5 g/day. No changes of iron parameters were found. Routine parameters remained unchanged. Plasma Pi was significantly reduced in the treatment group, median Pi change -2.40 mg/dl (-30.9%), ($p<0.0001$). Significant lowering of Pi levels were already observed at the lowest given dose of VS-505. There was no change of Ca levels, but a significant reduction in iPTH over the treatment period.

Conclusions: VS-505 is a promising, effective, safe and well-tolerated PB for the treatment of hyperphosphatemia with advantages over current drugs. Further studies in larger numbers of patients are warranted to find its exact place in routine treatment.

TH-PO1049

Impact of Admission Serum Phosphate Levels on Mortality in Hospitalized Patients Michael A. Mao,[2] Wisit Cheungpasitporn,[2] Charat Thongprayoon,[1] Wonngarm Kittanamongkolchai,[2] Ankit Sakhuja,[3] Stephen B. Erickson.[2] *[1]Bassett Medical Center, Cooperstown, NY; [2]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [3]Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN.*

Background: The aim of this study was to assess the relationship between admission serum phosphate levels and in-hospital mortality in all hospitalized patients.

Methods: All adult hospitalized patients who had admission serum phosphate available between years 2009 and 2013 were enrolled. Admission serum phosphate was categorized based on its distribution into six groups (<2.5, 2.5-3.0, 3.1-3.6, 3.7-4.2, 4.3-4.8 and ≥4.9 mg/dL). The odds ratio (OR) of in-hospital mortality by admission serum phosphate, using the phosphate category of 3.1-3.6 mg/dL as the reference group, was obtained by logistic regression analysis. Pre-specified subgroup analysis stratified by chronic kidney disease (CKD) and cardiovascular disease (CVD) status was performed.

Results: 42,336 patients were studied. The lowest incidence of in-hospital mortality was associated with a serum phosphate within 3.1-4.2 mg/dL. A U-shaped curve emerged demonstrating higher in-hospital mortality associated with both serum phosphate <3.1 and >4.2 mg/dL. After adjusting for potential confounders, both serum phosphate <2.5 and >4.2 mg/dL were associated with an increased risk of in-hospital mortality with ORs of 1.60 (95% CI 1.25-2.05), 1.60 (95% CI 1.29-1.97) and 3.89 (95% CI 3.20-4.74) when serum phosphate were within <2.5, 4.3-4.8 and ≥4.9 mg/dL, respectively. Among subgroups of patients with CKD and CVD, the highest mortality was associated with a serum phosphate ≥4.9 mg/dL with ORs of 4.11 (95% CI 3.16-5.39) in patients with CKD and 5.11 (95% CI 3.33-7.95) in patients with CVD. While serum phosphate <2.5 mg/dL was associated with increased in-hospital mortality in patients with CVD (OR 3.24, 95% CI 1.82-5.58), the risk was not significantly increased among CKD patients with serum phosphate <2.5 mg/dL.

Conclusions: Hospitalized patients with admission serum phosphate <2.5 and >4.2 mg/dL are associated with an increased risk of in-hospital mortality. In addition, CKD and CVD patients with hyperphosphatemia at admission (≥4.9 mg/dL) carry the highest mortality risk.

TH-PO1050

Mineral Bone Disease after Kidney Transplantation Silvana Maria C. Miranda,[1] Ana elisa S. Jorge,[2] Gerson M. Pereira jr,[2] Pedro Augusto M. Souza,[1] Andre S. Alvarenga,[2] Carlos rafael A. Felipe,[2] Izabela L. Piana.[3] *[1]Hospital Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [2]Santa Casa de Belo Horizonte, Belo Horizonte, Brazil; [3]Faculdade de Minas Faminas BH, Belo Horizonte, Brazil.*

Background: Mineral bone disease (MBD) after kidney transplant (KT) is frequent and associated with pre-existing MBD, immunosuppressive therapy and graft function.

Methods: We analyzed the evolution of serum calcium (Ca), phosphorus (P) and parathyroid hormone (PTH) before and after KT from a retropective cohort of 39 KT patients in a Brazilian KT center.

Results: There was a significant reduction of P and PTH after KT, whereas Ca increased significantly (Table 1). At 1 year of KT, 17.9% of patients had hypercalcemia and 17.1%, hypophosphatemia. PTH above the normal range was observed in 68% of patients. Pre-transplant PTH was positively correlated with post-transplant PTH (r = 0.519, p = 0.001) and negatively correlated with post-transplant P (r = -0.450, p = 0.004). There was no correlation between pre-transplant PTH and post-transplant Ca (r = 0.174, p = 0.296) or eGFR (r = -0.035, p = 0.840). Figure 1 shows the positive correlation between post-transplant PTH and Ca; the negative correlation between post-transplant PTH and P. Interestingly, the only variable associated with post-transplant eGFR was pre-transplant P, with a negative correlation (r = -0.326, p = 0.042).

Conclusions: After KT, there were a significant increase in Ca and reduction of PTH and P levels. Post-transplant hyperparathyroidism, hypercalcemia and hypophosphatemia were frequent, and post-KT PTH correlated with Ca and P. Pre-transplant P correlated negatively with eGFR post-trasnplant.

Table 1: Evolution of mineral parameters after kidney transplant

Variable	Pre-transplant (n=39)	Post-transplant (n=39)	p
PTH (pg/mL) – median	340.8	91.6	<0.0001
P (mg/dL) - mean	5.27	3.02	<0.0001
Ca (mg/dL) – median	8.68	9.37	<0.0001

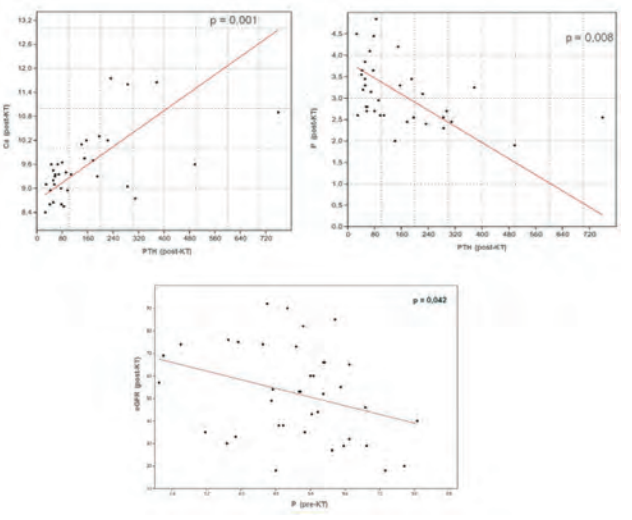

Figure1: Linear Regression for mineral parameters

TH-PO1051

Influence of Dialysis Vintage on Mineral and Bone Disorders after Kidney Transplantation Keiji Kono,[1] Hideki Fujii,[1] Kentaro Nakai,[2] Nozomi Hosokawa,[1] Shunsuke Goto,[1] Shinichi Nishi.[1] *[1]Kobe University Graduate School of Medicine, Kobe, Japan; [2]Fukuoka Red Cross Hospital, Fukuoka, Japan.*

Background: Mineral and bone disorder (MBD), such as hypercalcemia and hypophosphatemia, frequently occurs after kidney transplantation (KT), and its evidence has accumulated. However, the relationship between pre-KT dialysis vintage and post-KT MBD has not been evaluated in the detail.

Methods: Ninety-six patients who underwent KT were included. Patients with parathyroidectomy during pre-KT and the 12 months post-KT were excluded. We compared the natural history of post-KT MBD between pre-emptive KT (PKT) and non-PKT. Furthermore, non-PKT group was divided into 3 groups according to the dialysis vintage; <3years, 3-6years, >6years. Parameters of MBDs and kidney function were followed at pre-KT, 1 and 2 weeks, and 1, 2, 3, 6 and 12 months post-KT. We also checked pre-KT parathyroid enlargement by ultrasound evaluation.

Results: Serum calcium levels increased and reached a plateau at the 2 months post-KT in all the groups. Patients with longer dialysis vintage had higher serum calcium levels from the 1 week post-KT, and particularly the group with dialysis vintage > 6 years had persistent hypercalcemia, which was significantly higher serum calcium levels from the 1 month to 12 months post-KT compared to the other groups. Serum phosphate levels substantially decreased until the 1 week post-KT, after which it gradually increased in all the groups. The non-PKT group had significantly lower serum phosphate levels compared to the PKT group from the 1 week to 3 months post-KT, but there was no significant difference depending on dialysis vintage. PTH levels were significantly higher in the PKT group compared to the non-PKT group at pre-KT, but substantially decreased in the PKT group to almost the same levels as the other groups until the 1 month post-KT. The group with dialysis vintage > 6 years had higher prevalence of pre-KT parathyroid enlargement and persistent higher PTH levels during the 12 months post-KT, and its levels were significantly higher at the 12 months post-KT compared to the other groups. Kidney function was comparable among all the groups during the 12 months post-KT.

Conclusions: Our findings suggest that patients with longer dialysis vintage have persistent higher serum calcium levels just after KT, and its levels are significantly higher especially in dialysis vintage > 6 years probably due to persistent hyperparathyroidism.

TH-PO1052

Serum Lithium (Li) Values within Recommended Range May Induce Changes in Renal Tubular Function and Calcium Homeostasis in Patients with Bipolar Disorder (BD) Lucas D. Hortêncio,[2] Karla M. DE ALMEIDA,[2] Michelle Silva,[2] Beny Lafer,[2] Claudia Helou.[1] *[1]Lab Pesquisa Basica LIM12 Fac Medicina Univ Sao Paulo, SP, Brazil, Sao Paulo, Brazil; [2]Institute of Psychiatry of University of Sao Paulo, Sao Paulo, Brazil.*

Background: Li is the first choice for maintenance treatment of patients with BD. However, Li can induce nephrogenic insipidus diabetes and some patients may develop asymptomatic hypercalcemia because Li may cause primary hyperparathyroidism.

Methods: Thus, we studied 76 patients with BD treated with or without Li by a cross-sectional analysis. We collected blood (B) and 24-hour urine (U) samples to evaluate renal function, electrolyte homeostasis and serum (S) hormone levels.

Results: As shown in the Table, we studied more women than men, but they had similar age, eGFR, and S Li values were within recommended range. Both women and men treated with Li had higher U pH and lower U density than Non-Li-treated patients. Li-treated-women had also higher levels of S PTH, S ionized Ca (S iCa) than that of other

groups. Moreover, Li-treated-women showed a positive correlation between high levels of S iCa and increases of S PTH, diuresis and U pH and low U density when we plotted levels of S iCa≥5.47 mg/dL. On the other hand, only Non-Li-treated women showed low levels of S PTH, diuresis and U pH and high U density when we plotted levels of S iCa≤4.88 mg/dl. No patient showed any symptom and other ionic homeostasis disorder.

Conclusions: Li induced changes in both parathyroid and renal tubular function without clinical manifestations justifying a periodically monitored surveillance especially in women patients.

Association between Mineral Metabolism Parameters and Carotid Intima Media Thickness in a Cardiovascular Risk Population (CORDIOPREV Study) Maria Encarnacion Rodriguez Ortiz,[1] Francisco Gómez-Delgado,[2] Antonio Arenas-Larriva,[2] Antonio Canalejo,[3] Purificación Gómez-Luna,[2] Carmen maria Herencia,[1] Javier López-Moreno,[2] Mariano Rodriguez,[4] José López-Miranda,[2] Yolanda Almaden peña.[2] *[1]Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC). Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC). Reina Sofía University Hospital/University of Córdoba, Córdoba, Spain.*

Background: Cardiovascular diseases (CVD) are the main cause of mortality in patients with Mineral Metabolism (MM) alterations, as those with CKD. Thus, factors related to MM may play a key role in the onset and development of CVD. Carotid intima media thickness (IMT-CC) has shown strong associations with well-recognized risk factors of CVD and it is a predictor of coronary artery disease. The aim of this study was to assess whether there is an association between some key parameters of MM and the IMT-CC in a cardiovascular risk population.

Methods: This work was carried out in the setting of the CORDIOPREV study (Clinical Trials 128 Registry NCT0092493741), a prospective, randomized, controlled trial including 1,002 patients aged 20-75 years with coronary heart disease. Carotid arteries were examined bilaterally using a Doppler ultrasound high-resolution B-mode. IMT-CC was calculated as the mean of three measurements. Basal plasma levels of FGF23, Ca, P, creatinine (Cr), Mg, 25-OH and calcitriol (CTR) were measured.

Results: As shown in the table (mean±SE), a significant inverse relationship was observed between IMT-CC and eGFR and Mg, while Cr and FGF23 were directly associated with IMT-CC.

Conclusions: Even within the normal range, there was an association between some MM parameters and the IMT-CC in a cardiovascular risk population. Thus, these factors might be useful for the monitoring of CVD. Grant ISCIII (PI14/00872)

Functional Analysis of Gcm2 in Adult Gcm2 Conditional Knockout Mice Yamada Taku,[1] Norifumi Tatsumi,[3] Sahoko Kamejima,[3] Taketo Uchiyama,[2] Ichiro Ohkido,[2] Masataka Okabe,[4] Takashi Yokoo.[4] *[1]Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan; [3]Jikei University School of Medicine, Tokyo, Japan; [4]The Jikei University School of Medicine, Tokyo, Japan.*

Background: *Glial cells missing-2* (*Gcm2*) is exclusively expressed in the parathyroid gland (PTG). The specific role of mice *Gcm2* in the development of PTG from the third pharyngeal pouch has been further investigated, although its function in adult mice remains largely unknown. *Gcm2* directly regulates *calcium-sensing receptor* (*CaSR*) and transactivates it through *Gcm2* response elements in the *CaSR* promoter, which has important implications for the exacerbation of CKD-MBD. Accordingly, it is possible that *Gcm2* plays a crucial role in CKD-MBD and particularly, in secondary hyperparathyroidism (SHPT).

Methods: We generated *Gcm2* conditional knockout mice in which loxP sites flanked exons 2 and 3 in the *Gcm2* allele. We then crossed these mice with tamoxifen-inducible Cre strain. Next, we intraperitoneally injected 40 mg/kg of tamoxifen into 8-week-old mice for five days. The mice were sacrificed one (1KOmice) and seven (7KOmice) months after tamoxifen administration. We then investigated their serum biochemistry and performed histological analysis.

Results: Serum biochemical parameters of 1KOmice were not significantly different when compared with those of control mice. However, compared with control mice, a significant increase in the serum phosphate level and significant decrease in calcium and parathyroid hormone levels were confirmed in the 1KOmice. Staining of PTG with HE showed that normal structure was generally conserved in 1KOmice, except for the presence of a few follicles, whereas normal structure was not conserved in 7KO mice and their PTGs showed many follicles.

Conclusions: 7KOmice showed hypocalcemia, hyperphosphatemia, low parathyroid hormone level, and many follicles in PTG. In addition, normal PTG structure was not observed in these mice. These results suggest that the loss of function of *Gcm2* at an adult age leads to hypoparathyroidism, as observed in congenital *Gcm2* knockout mice. This animal model is useful to study distinct roles of *Gcm2* at different ages and the relationship between *Gcm2* and CKD-MBD, particularly SHPT.

3'UTR Regulates the Baseline Protein Abundance and Activity of Mouse NaPi-IIa Hassane Amlal, Sulaiman Sheriff, Perwez Alam. *University of Cincinnati, Cincinnati, OH.*

Background: The apical sodium-phosphate cotransporter NaPi-IIa plays an important role in the control of phosphate balance by regulating the rate of inorganic phosphate reabsorption in the kidney proximal tubule. We have previously shown that the 3'-untranslated region (3'UTR) of NaPi-IIa mRNA transcript plays an important role in the post-transcriptional regulation of NaPi-IIa in response to estrogen. However, whether 3'UTR regulates the baseline expression of NaPi-IIa has not been studied.

Methods: We have studied the role of 3'UTR in mNaPi-IIa expression and activity using OK cells transfected with mammalian expression plasmids containing the open-reading frame (ORF) 3'-UTR or 5'-UTR ORF or the full-length (FL) mouse NaPi-IIa transcript. Immunoblotting, Real-time PCR and ^{32}P uptake studies were performed. Further, the role of microRNAs (miRNA) in the function of mNaPi-IIa-3'UTR was examined by luciferase assay using the miRNA target expression vector. Full-length mNaPi-IIa 3'UTR or 4 overlapping (~250bp) fragments (F1-F4 from stop codon) were generated by PCR and individually sub-cloned into the miRNA target expression vector. Subsequently, chimeras of 5'UTR-ORF-(F1 to F4) were generated in mammalian expression vector and used to examine the expression of mNaPi-IIa protein in OK cells by immunoblotting.

Results: The protein abundance of mNaPi-IIa is increased by 3-fold in OK cells transfected with 3'UTR-free plasmid (i.e. 5'-ORF), as compared to FL or ORF-3'UTR. This correlates with 50% increase in Pi transport activity, as shown by a sharp increase in Na^+-dependent ^{32}P uptake in cells expressing 5'-ORF vs. ORF-3'UTR. Real-time PCR data showed no difference in the mRNA expression levels between the 3 plasmid constructs. Normalized luciferase activity was increase by 36%, 74%, 54% and 27% for F1 to F4 fragments, respectively, compared to 3'UTR. Interestingly, the protein abundance of NaPi-IIa was significantly reduced in cell transfected with all F1 to F4 chimeras, with a more profound reduction in chimera 5'UTR-ORF-F4, as compared to 5'UTR-ORF construct.

Conclusions: 3'UTR regulates the baseline expression of mouse NaPi-IIa protein abundance and activity in OK cells. This phenomenon is mediated through a sequence specific post-transcriptional mechanism involving microRNAs, which interact with *cis*-acting elements distributed throughout the 3'UTR.

Transition from Low to High Dietary Phosphate Reduces Serum Calcium but Increases Vascular Calcification in Experimental CKD Cynthia M. Pruss, Kimberly J. Laverty, Emilie C. Ward, Bruno A. Svajger, Paul S. Jeronimo, Mandy E. Turner, Martin P. Petkovich, Rachel M. Holden, Michael A. Adams. *Queen's University, Kingston, ON, Canada.*

Background: Chronic kidney disease (CKD) impairs phosphate (PO_4) homeostasis resulting in hyperphosphatemia, which is associated with cardiovascular events and vascular calcification (VC). Animal models of CKD demonstrate pathologies and outcomes similar to those of CKD patients. We examined the impact of dietary phosphate loading on markers of mineral metabolism in controlled adenine-induced CKD.

Methods: Sprague Dawley rats were fed a 0.25% adenine, 0.5% PO_4 diet for 4-5 weeks to induce stable CKD (creatinine >250 uM), then fed 0.5% PO_4 diet without adenine. At 5.5 weeks, rats were fed either s 0.5%, 1% or 1.5% PO_4 diet, N=9, 10, 6, while another group (N=21) was fed increasing dietary PO_4 every 4 days (0.5%→0.75%→1%→1.5%). Controls were fed 0.5% PO_4 diet (N=8). Serum calcium (Ca), PO_4, FGF-23, PTH, and tissue Ca and PO_4 were determined.

Results: At 5 weeks, CKD rats vs control had 3.2±0.6 vs 2.5±0.3 mM PO_4 and 2.8±0.2 vs 2.4±0.1 mM Ca. Off adenine, the 0.5% group was at control PO_4 levels but had elevated Ca at 6.5 weeks. At 7 weeks, the 1.0 and 1.5% groups had marked increases in PO_4, PTH, and FGF-23, while serum Ca dropped (table 1). VC was observed in 80% of high PO_4 rats (1 or 1.5%). In the increasing dietary PO_4 group, serum PO_4 (mM) increased with dietary PO_4: baseline(2.1±.3), 0.5%(2.7±0.7), 1%(4.2±0.5), 1.5%(4.8±1.3) PO_4. Fasting serum Ca (mM) increased in CKD rats given 0.5% PO_4 (2.1±0.2→3.1±0.3), but significantly declined when fed 1%(2.4±0.7) and 1.5%(2.2±0.9) dietary PO_4. PTH and FGF-23 both increased (4x, 2x) with the increased dietary PO_4 and VC was observed in all rats.

Conclusions: In our CKD model, 0.5% PO_4 diet increased serum Ca but did not induce VC. In contrast, dietary PO_4 of 1% or more led to significant decreases in serum Ca, but generated high serum PO_4, FGF-23, PTH and VC. These findings uncover a new link between dietary PO_4 and serum Ca.

Regulation of Intestinal Phosphate Transport in a Rat Model of CKD Komuraiah Myakala,[2] Evgenia Dobrinskikh,[4] Eileen M. Sutherland,[1] Moshe Levi.[3] *[1]Uniiversity of Colorado, Denver, CO; [2]University of Colorado, Aurora, CO; [3]University of Colorado Denver, Aurora, CO; [4]University of Colorado, Denver, Aurora, CO.*

Background: In chronic kidney disease (CKD) hyperphosphatemia is a common occurrence and plays important roles in cardiovascular and bone disease. The mechanisms however still remain unknown and the role of intestinal phosphate (Pi) transport is subject of ongoing debate.

Methods: We studied regulation of intestinal phosphate transport in a model of 5/6 nephrectomy (Nx) induced CKD in the rat fed a relatively high Pi diet (1.5% Pi, 0.6% Ca).

Results: Male rats with 5/6 Nx had a marked increase in serum BUN (37.7 ± 2.0 vs. 150.5 ± 29.8 mg/dl in sham control, p<0.02), serum creatinine (0.5 ± 0.06 vs. 1.65 ± 0.23 mg/dl in sham control, p<0.008), and serum Pi (7.48 ± 0.85 vs. 18.19 ± 1.84 mg/dl in sham control, p<0.001). We isolated apical brush border membrane vesicles (BBMV) from the duodenum and the jejunum and studied sodium gradient dependent Pi (Na^+/Pi) cotransport as a function of pH. Across every single pH studied, including 5.5, 6.0, 6.5, 7.0, and 7.5 Na^+/Pi transport activity was increased in BBM from 5/6 Nx rats. This was associated with a 2-fold increase in NaPi-2b protein abundance in the duodenum and a1.4-fold increase in NaPi-2b protein abundance in the jejunum. To determine if there are sex-dependent differences in CKD and intestinal Na^+/Pi transport, we also studied in parallel female rats with 5/6 Nx. We found that female rats with 5/6 Nx also had a marked increase in serum Pi (4.75 ± 0.39 vs. 10.7 ± 1.24 mg/dl in sham control, p<0.003). In addition, there were marked increases in intestinal Na^+/Pi transport activity paralleled by increases in NaPi-2b protein abundance.

Conclusions: Our study therefore indicates that in both male and female rats with CKD, the hyperphosphatemia is mediated by increased intestinal Na//Pi transport activity and increased NaPi-2b protein expression.

The Role of Gut Microbiota in Phosphorus Metabolism in Maintenance Hemodialysis Patients Yuanyi Miao,[1] Min Xia,[2] Yuqing Chen.[2] *[1]Peking University First Hospital, Beijing, China; [2]Renal Division, Peking University First Hospital, Beijing, China.*

Background: Disturbance of phosphorus metabolism is a risk factor associated with mortality in hemodialysis patients. Gut absorption is the major source of phosphorus. Recent studies indicated that the intestinal flora of uremic patients changed a lot. And phosphorus is an essential element of bacterial survival and reproduction. The purpose of the study was to explore the role of intestinal microbiota in the control of serum phosphorus.

Methods: Microbial DNA was isolated from the stools of 20 healthy controls and 21 maintenance hemodialysis patients from one hemodialysis center. 14 out of the 21 patients were treated with Lanthanum carbonate for 12 weeks, thus stools were also collected before and after the treatment. The bacterial composition was analyzed by 16S ribosomal RNA pyrosequencing. Bioinformatics tools, including abundance profiling, taxonomic diversity and correlation analyses were used in microbiome data analyses.

Results: Clinical biochemical traits were compared before and after the use of Lanthanum carbonate in MHD patients. The serum phosphorus decreased after using Lanthanum carbonate for 12 weeks (P<0.001). There was no difference in other traits. 13 genera were closely correlated with serum phosphorus and the correlation coefficient was above 0.4 (P<0.05). And 11 genera were positively related to serum phosphorus, suggesting that survival of the 11 genera were related to phosphorus. We also found that 2 genera were negatively related to serum phosphorus, indicating that the 2 bacteria may be involved in the absorption process of phosphorus. 58 bacterial operational taxonomic units (OTUs) were different before and after the use of phosphorus binder. More decreased OTUs were identified after using phosphorus binder. 7 genera were obviously reduced, including Centipeda, Chryseobacterium, Gemella, unclassified_ Rhodocyclaceae, Pelomonas, Curvibacter and Parvimonas. Furthermore, the microbial richness and diversity decreased in hemodialysis patients and declined further after phosphorus reduction.

Conclusions: Gut flora is related to phosphorus metabolism in hemodialysis patients, and improving intestinal microbiota may regulate the absorption of phosphorus in the intestine. The use of phosphorus reduction drugs lead to decreased microbial richness and diversity.

TH-PO1059

Vessels Are an Important Depot for Phosphate in Response to an Oral Load in an Experimental Model of CKD Mandy E. Turner, Paul S. Jeronimo, Emilie C. Ward, Kimberly J. Laverty, Rachel M. Holden, Michael A. Adams. *Queen's University, Kingston, ON, Canada.*

Background: Dysregulated phosphate (PO_4) homeostasis contributes to increased cardiovascular risk in CKD patients, in part due to vascular calcification. We sought to determine if tissue deposition of PO_4 following an oral PO_4 load was altered by level of kidney function and changes in dietary PO_4.

Methods: CKD was induced in rats using dietary adenine (0.25%, 0.5% PO_4). At 6 weeks, adenine was stopped and animals were fed either low phosphate (LP) (0.5%, N=48) or high phosphate (HP) (1.0%, N=24) diet for 2 weeks. Non-CKD animals followed a parallel protocol (0.5%, N=12 and 1.0%, N=12). Prior to sacrifice, 6 hr fasted animals consumed 0.1g of PO_4 spiked with ~5mil CPM of $^{33}PO_4$. Blood samples were drawn at 20 min up to 6 hrs after the PO_4 load for measurement of $^{33}PO_4$ and phosphate. Animals were sacrificed at 0, 2, and 6 hrs post-oral load. Various tissues were collected for radioactivity and PO_4 measurement.

Results: The pattern of tissue disposition of PO_4 was altered by kidney function and pre-existing level of dietary PO_4. An HP diet produced a greater increase in serum PO_4, parathyroid hormone and fibroblast growth factor 23 than the LP diet. Serum $^{33}PO_4$ was detectable within 20 min following the oral load. In control animals, vascular tissue levels of $^{33}PO_4$ fell between 2 hrs and 6 hrs indicating lack of retention. In contrast, in CKD rats, vascular tissue levels of $^{33}PO_4$ were markedly higher at 6 hrs compared to 2 hrs, indicating substantial accrual and retention of phosphate. Although both bone and blood vessels had greater phosphate accrual in CKD, only the HP diet induced a vascular-selective deposition. That is, the vascular tissue:bone ratio was more than twice that found in either controls or LP CKD (bone:vessel CPM, 2hr: 1.7±0.8 vs. 0.6±0.2, p=0.003; 6hr: 1.2±0.9 vs. 0.4±0.1, p=0.008). CKD rats exposed to the HP diet had higher levels of phosphate in arteries compared to the LP diet (74±176 v. 715±624 nmol/mg of tissue, p<0.0001) consistent with more severe vascular calcification.

Conclusions: Changing from an LP to a HP diet in experimental CKD produces maladaptive responses in vascular tissue resulting in preferential and sustained vascular deposition of phosphate that likely associates with the vascular calcification phenotype.

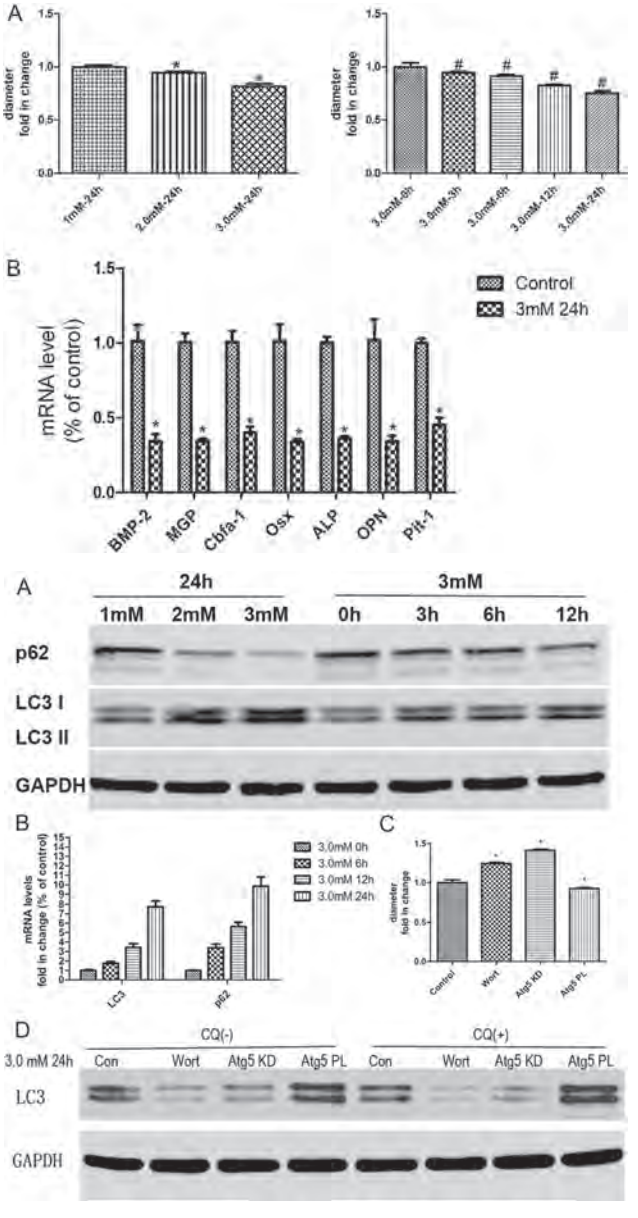
Phosphate Stimulates Myotube Atrophy through Autophagy Activation – Evidence That Hyperphosphatemia Contributes to Skeletal Muscle Wasting in CKD yue yue Zhang, Wei jie Yuan. *Shanghai General Hospital, Shanghai Jiaotong University School of Medcine, Shanghai, China.*

Background: Although evidence indicates that autophagy is involved in the maintenance of muscle homeostasis, it is unidentified if high phosphate could stimulate the activation of autophagy leading to muscle protein loss.

Methods: Immortalized rat L6 myotubes were exposed to a high concentration of phosphate with or without autophagy inhibition. Myotube atrophy was examined by phase contrast microscope. The autophagy activity was assessed by the expression of microtubule associated protein 1 light chain 3 (LC3) and p62 using quantitative real-time PCR and western blot.

Results: Phosphate induced cell atrophy in L6 myotubes with a dose- and time-dependent fashion and these response were not associate with the development of calcification or osteogenesis. Phosphate also dose- and time-dependently increased the ratio of LC3-II/LC3-I. Inhibition of autophagy with wormannin or knockdown of Atg5 significantly suppressed myotube atrophy caused by high concentration of phosphate.

Conclusions: High concentration of phosphate induces muscle cell atrophy through the activation of autophagy. Targeting autophagy could be a therapeutic strategy for muscle wasting caused by hyperphosphatemia.



TH-PO1061

Phosphate Retention Induces Growth Retardation in Adolescent Mice Marina Kohara,[1] Kazuhiro Shiizaki,[1] Yoshitaka Iwazu,[1] Yutaka Miura,[1] Kenichi Akiyama,[2] Toshihiro Nakano,[2] Ruri Kaneda,[1] Hiroshi Kurosu,[1] Makoto Kuro-o.[1] *[1]Jichi Medical University, Shitsuke, Japan; [2]Tokyo Women's Medical University, Tokyo, Japan.*

Background: Growth retardation is a major problem of chronic kidney disease (CKD) in adolescence. It is well known that the effect of supplementation of growth hormone (GH) is not sufficient, so more effective treatments have been requiring. CKD causes the phosphate retention and this control is very difficult due to the nutritional concern. We hypothesized that phosphate retention might be one of pathogenesis of growth retardation in adolescence with CKD.

Methods: Female C57BL/J6 mice were fed the regulated diets consists of various amount of phosphate from four to eight weeks old. Body weight, femur length and serum phosphate and insulin-like growth factor-1 (IGF-1) levels were measured. The target genes of GH including IGF-1, acid-labile subunit (ALS), major urinary proteins (MUP) 1 and 3, solute carrier organic anion transporter family member 1a1 (SLCO1A1), and hydroxysteroid dehydrogenase 3β5 (HSD3B5) mRNA, IGF-1 binding protein-1 (IGFBP-1) mRNA as an inhibitory marker of IGF-1 signaling and signal transducers and activators of transcription (STAT) 5 protein levels were evaluated in liver.

Results: The remarkable growth retardation with significantly high phosphate and low IGF-1 levels in serum were confirmed in mice fed the highest phosphate diet. The significantly lower expression levels in all of target genes of GH and STAT5 protein, and higher expression level in IGFBP-1 mRNA were also observed. The mice fed the middle phosphate diets showed the significantly lower levels in serum IGF-1 and in target gene expressions of GH compared with those fed the normal phosphate diet but not growth retardation.

Conclusions: The phosphate retention induces the growth retardation resulting from the inhibitions of both GH and IGF-1 signaling. Its moderate restriction might improve the growth retardation resulting from the improvement of the resistance to IGF-1 even though serum IGF-1 level was low. These findings suggest that the controlling phosphate retention using the phosphate binders and dietary restriction should be considered in adolescent CKD patients who require the supplementation of GH.

TH-PO1062

Alteration of Renal Claudins in Rats with Hypercalciuria Gheun-Ho Kim, Il hwan Oh. *Hanyang University College of Medicine, Seoul, Republic of Korea.*

Background: Ninety-eight to 99% of the filtered load of calcium is reabsorbed by the renal tubules. Whereas most of the calcium reabsorption passively occurs in the proximal tubule through tight junctions, the distal nephron has been known as the major site for regulation of calcium excretion. Claudins form the conductive and selective part of the tight junctions along the nephron and may be involved in regulatory events in the control of calcium transport. This study was undertaken to test if the renal expression of claudins are altered in the different settings of hypercalciuria.

Methods: Male Sprague-Dawley rats were used for three different animal protocols: $CaCO_3$, NaCl, and NH_4Cl loading. The rats were randomly divided into control (n=6) and treated (n=6) group in each experiment, and a daily fixed amount of food flurry was given to each rat. The control diet contained 0.8% calcium and 0.3% NaCl, and the treated diet had additional $CaCO_3$ (6%), NaCl (7%), or NH_4Cl (7.2 mmol/220 g BW) for 7 days. Plasma and urine data were followed, and kidneys were harvested for immunoblotting and qPCR analysis at the end of our animal experiment.

Results: Hypercalciuria was successfully induced by $CaCO_3$, NaCl, and NH_4Cl loading, and fractional excretion of calcium was significantly increased by the loading of $CaCO_3$ (5.00 ± 0.92 vs. 0.27 ± 0.08%, $P < 0.05$), NaCl (2.07 ± 0.57 vs. 0.25 ± 0.27%, $P < 0.05$), and NH_4Cl (0.90 ± 0.36 vs. 0.27 ± 0.12%, $P < 0.05$). The abundance of claudin-2 protein was not significantly altered by $CaCO_3$ or NaCl loading, but both claudin-2 protein (85 ± 9 vs. 100 ± 11%, $P < 0.05$) and mRNA (49 ± 23 vs. 100 ± 17%, $P < 0.05$) expression were significantly decreased by NH_4Cl loading. In response to $CaCO_3$ loading, the protein abundance of claudin-4 (47 ± 17 vs. 100 ± 12 %, $P<0.05$) and occludin (59 ± 17 vs. 100 ± 25%, $P<0.05$) were decreased, suggestive of changes in distal nephron. Interestingly, claudin-7 protein was decreased by NaCl loading (29 ± 14 vs. 100 ± 34%, $P<0.05$).

Conclusions: We confirmed that hypercalciuria in metabolic acidosis is associated with claudin-2 down-regulation in the proximal tubule. However, hypercalciuria induced by high calcium or salt intake was not accompanied by claudin-2 dysregulation. Further studies are required to investigate the regulatory role of paracellular calcium transport in the distal nephron.

TH-PO1063

Green Tea (GT) Increases Urinary Excretion of Calcium and Phosphorus, but These Effects Were Not Due to Caffeine (CAF) Claudia Helou,[1] Igor O. Da silva,[1] Talita R. Sanches,[2] Mirela Santinho,[1] Lucia Andrade.[2] *[1]Lab Pesquisa Basica LIM12 Fac Medicina Univ Sao Paulo, SP, Brazil, Sao Paulo, Brazil; [2]University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: The consumption of industrialized (i) or natural (n) GT increases worldwide because this beverage is rich in antioxidant. However, there is a lack of studies about GT effect on the renal tubular function and a possible role exerted by the presence of CAF.

Methods: Thus, we housed Male Wistar rats in individual cages and randomly assigned them to have ad libitum access to tap water (W), iGT (Feel Good©), nGT or 8 mg% CAF dissolved in tap water. On day 8, we moved them to metabolic cages and collected 24-h urine samples. The rats were then anesthetized, and we placed a catheter in abdominal aorta to measure blood pressure (BP) and collect blood samples. We quantified creatinine and electrolytes in urine and plasma samples. We removed the kidneys to quantify protein expression (PE) of ion transporters in the cortex (C) and outer medulla (OM), by Western blot. We used ANOVA followed by Newman-Keuls test for statiscal analysis.

Results: All groups showed all ion plasma concentration values within normal range. As shown in the Table, nGT decreased BP and increased liquid intake and urine output. However, both i and n GT increased urinary excretion (UV) of calcium (Ca), phosphorus (P) and magnesium (Mg) and CAF increased only UVMg. With regard to PE of ion transporters, we only evaluated PE of TRPM6 and Na-Pi type IIa in C and PE of NKCC2 and Na-Pi type IIa in OM, and we only found decrease in PE of TRPM6 in iGT when compared with nGT, $p<0.05$, until now.

Conclusions: Even though we have not yet identified the mechanism for which GT induced Ca and P urinary losses we suggest to add GT in the list of risks for lithiasis.

Determinants of Reduced Urinary Calcium Excretion in Patients with CKD: The Role for 1.25-VitD Janaina d. Ramalho,[1] Estela M. Duarte,[1] Ana P. Takeichi,[1] Alisson D. Machado,[1] Paulo Lotufo,[2] Isabela M. Bensenor,[2] Rosa M. Moyses,[1] Silvia M. Titan.[1] *[1]Nephrology Division, Faculty of Medicine, University of São Paulo, São Paulo, Brazil; [2]Clinical Research Center, Universitary Hospital, University of São Paulo, São Paulo, Brazil.*

Background: A positive calcium balance may contribute to the pathogenesis of vascular calcification, which is highly prevalent in CKD. Recent studies have shown that CKD is associated with a reduction in urinary calcium excretion (UCE), but determinants are not fully known. Our aim was to evaluate mineral metabolism biomarkers associated with UCE in a CKD population.

Methods: Clinical data, CKD-MBD biomarkers and 24h urinary calcium excretion from 412 participants in the Progredir Study were evaluated. Univariable and multivariable linear regression models were used to explore determinants of UCE expressed in mg/kg – log transformed.

Results: Median UCE was 0.48 mg/kg (IQR 0.28 – 0.82 mg/kg). In the descriptive analysis, calciuria was negatively related to age, serum phosphorus, serum potassium, PTH, FGF23, and acidosis, whereas positively associated to eGFR, serum calcium, and 1,25-vit D. In linear regression models, even after adjustment for age, sex and eGFR, only 1,25-vit D, serum calcium, serum potassium and acidosis remained significantly related to UCE. However, in the multivariable model (Table1), only age, eGFR, 1.25-VitD and serum calcium were independently related to UCE.

Conclusions: Our results show that eGFR decline is associated with a dramatic decrease in UCE. Age, 1.25-VitD and serum calcium are independently associated to this effect in this CKD population. Therapeutic measures on 1.25-VitD reduced levels could have an impact on UCE.

Funding: Government Support - Non-U.S.

The Plant 3,4,5-Tri-O-Galloyl Quinic Acid Methyl Ester Inhibits Calcium Oxalate Crystals Growth in a Drosophila Model and Decreases Renal Cell Annexin A1 Surface Expression and Crystal Adhesion Mohamed A. Abd El-Salam,[2,3] Jairo Bastos,[3] Jing jing Han,[5] Daniel Previdi,[4] Paulo Donate,[4] Michael F. Romero,[1] John C. Lieske.[2] *[1]Mayo Clinic College of Medicine, Rochester, MN; [2]Department of Internal Medicine, Division of Nephrology and Hypertension, Mayo Clinic College of Medicine, Rochester, MN; [3]Department of Pharmaceutical Sciences, School of Pharmaceutical Sciences of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil; [4]Department of Chemistry, Faculty of Philosophy, Arts and Sciences, University of Sao Paulo, Ribeirão Preto, Brazil; [5]Department of Internal Medicine, Division of Nephrology and Hypertension, Mayo Clinic College of Medicince, Rochester, MN.*

Background: The design of more effective therapies for urinary stone prevention depends on identifying critical pathogenic steps. Adherence and retention of crystals is one potential early event. Many studies have identified crystal-binding proteins (e.g. annexin A1, heat shock protein 90 (HSP90) and α-enolase) on the apical membranes of renal tubular epithelial cells. Agents that affect expression of these molecules could ameliorate crystal retention.

Methods: The plant metabolite 3,4,5-tri-*O*-galloyl quinic acid methyl ester (QAME) was prepared by total synthesis and its potential effect on calcium oxalate monohydrate (COM) crystal binding to the surface of Madin-Darby Canine Kidney Cells type I (MDCK I) and crystal growth in a *Drosophila melanogaster* (fruit fly) Malpighian tubule model were studied. Membrane, cytosolic, and total α-enolase, Annexin A1 and HSP90 levels were evaluated by subcellular fractionation followed by Western blot. Immunofluorescence staining and confocal microscopy were also performed on cultured cells.

Results: Pretreatment of MDCK 1 cells with QAME for up to 6 h significantly diminished crystal-binding in a concentration-dependent manner. QAME significantly reduced surface expression of Annexin A1 by immunofluorescence microscopy, whereas the intracellular level increased. Western blot analysis confirmed these changes in membrane and cytosolic fractions of QAME-treated cells, whereas total cell QAME remained unchanged. The compound also significantly decreased the size and growth of COM crystals induced *ex vivo* in the *Drosophila melanogaster* Malpighian tubule model.

Conclusions: These data indicate that QAME decreased binding of COM crystals to cells by decreasing the surface expression of Annexin A1 via changing localization of Annexin A1 from the plasma membrane to the cytosol. Thus, QAME may be useful for the prevention and modulation of stone formation. Further pre-clinical and clinical studies should be done for the use of this compound in urolithiasis.

TH-PO1066

Establishing a Drosophila Model System to Study the Molecular Function of Human Genes Identified from Patients with Nephrolithiasis/ Nephrocalcinosis Fujian Zhang, Qiuxia Fan, Xizhen Hong, Xiaoming Feng, Fan Fan Hou. *Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: Nephrolithiasis/nephrocalcinosis is a frequent condition that affects 15% of adults, causing a huge burden on health care systems globally. Calcium oxalate stones account for more than 75% of renal stone diseases. In recent years, more than 30 genes have been identified as novel monogenic causes of kidney stone disease by using whole exome sequencing. However, the pathological function of the majority of these novel genes have not been validated *in vivo*.

Methods: First, we established the principal cell-specific gene knock-down method using UAS-RNAi/Gal4 system and examined its effect on calcium oxalate stone formation. Then, we investigated the effect of fly homology of 30 human genes identified from patients with kidney stone disease on calcium oxalate stone formation. We also examined the effect of calcium oxalate stone formation on lifespan. Furthermore, we examined the effect of these genes on the metabolism of oxalate in malpighian tubule cells.

Results: In this study, we found that knockdown of genes encoding v-ATPase protein complex in malpighian tubule principal cells led to the formation of large calcium oxalate stones. We also found that defects in 80% (24 of 30) fly homology of 30 known nephrocalcinosis/nephrolithiasis genes led to the accumulation of calcium oxalate stone in malpighian tubule. We also observed that the formation of large kidney stones significantly shortened the lifespan in adult flies. Furthermore, we found that RNAi knockdown of these nephrolithiasis genes led to the accumulation of oxalate in malpighian tubules, suggesting that these nephrolithiasis genes in principal cells may affect the secrection of oxalate from malpighian tubule.

Conclusions: In this study, we present the first *Drosophila* model system to study the molecular function of human genes identified from patients with nephrolithiasis/ nephrocalcinosis. These results suggest that *Drosophila* malpighian tubules could be a very powerful system to screen genes involved in the formation of calcium oxalate stone *in vivo*, and small molecules that could be used to dissolve calcium oxalate stones in patients with nephrolithiasis/nephrocalcinosis.

TH-PO1067

Development of a Humanized Murine Model for Study of O. formigenes Intestinal Colonization Amanda Pebenito,[1] Lama Nazzal,[1] Menghan Liu,[1] Martin J. Blaser.[1,2] *[1]New York University School of Medicine, New York, NY; [2]New York Harbor V.A. Medical Center, New York, NY.*

Background: *Oxalobacter formigenes* (*O.f.*) are symbiotic bacteria in the human gut that degrade oxalate, a component of most kidney stones. Observational studies suggest that *O.f.* colonization reduces the risk for kidney stones. Given the importance of dietary oxalate and calcium levels, studies in mice are more practical than in humans; however, *O.f.* do not naturally colonize laboratory rodents. Our objective was to develop a humanized murine model to investigate the therapeutic potential of *O. formigenes* in its native microbiome.

Methods: To humanize mice, we transplanted feces from a pool of healthy human donors who were *O.f.*-negative (confirmed by PCR, qPCR, and oxalate degradation assay), supplemented with a human *O.f.* strain: OXCC13 (10^8 CFU/mL). The inoculum was introduced to C57BL/6J mice via esophageal gavage three times over six days. We compared two methods of humanization, transplanting inocula into mice that were (i) germ free; or (ii) treated with high-dose, broad-spectrum antibiotics (0.5g/L vancomycin, 1g/L ampicillin, 1g/L neomycin, 1g/L metronidazole in drinking water for 6 days) to suppress their native microbiome. As controls, one group received humanization with no pre-treatment and another received a sham gavage.

Results: Based on *oxc* qPCR and 16S rRNA sequencing, all humanized groups were stably colonized with *O.f.* through 8 weeks post-gavage, whereas mice that received sham gavage remained uncolonized ($p<0.001$). Humanization significantly changed microbial community structure as measured by unweighted UniFrac distances ($p<0.001$) and humanized germ-free and antibiotic-treated groups were highly similar in β-diversity. We also assessed humanization by the number of shared OTUs between treatment groups and donor inoculum over time. Both germ-free and antibiotic-treated mice had a significant increase in shared OTUs compared to sham ($p=0.024$, $p=0.036$). The number of shared OTUs was stable in each group through 8 weeks post-gavage without significant difference between germ-free and antibiotic-treated mice.

Conclusions: Our method of transplanting human feces and *O.f.* conferred a new microbial phenotype in mice that resembled a human microbiome and was stable over time. Antibiotic pre-treatment, a simpler alternative to germ-free mice, provided comparable results. This model may allow insights to *O.f.*'s role in preventing calcium oxalate stones.

Activation of the PKA Signaling Pathway Stimulates Oxalate Transport by Human Intestinal Caco2-BBE Cells Hatim A. Hassan, Donna L. Arvans, Altayeb Alshaikh, Mohamed Bashir. *University of Chicago, Chicago, IL.*

Background: Most kidney stones are composed of calcium oxalate, and small increases in urine oxalate affect the stone risk. The mammalian intestine plays a crucial role in oxalate homeostasis and we had recently reported that *oxalobacter*-derived factors stimulate oxalate transport by human intestinal Caco2-BBE (C2) cells through mechanisms including PKA activation. We therefore evaluated whether intestinal oxalate transport is directly regulated by activation of the PKA signaling pathway. To this end, PKA is activated with forskolin and IBMX (F/I). F/I significantly stimulated (4-fold) ^{14}C-oxalate transport by C2 cells (≥ 49% of which is mediated by the oxalate transporter SLC26A6 [A6]), an effect completely blocked by the PKA inhibitor H89, indicating that it is PKA-dependent. Utilizing selective pharmacological inhibitors in preliminary studies, we found that the PKC, ERK1/2, PI3K, P38, and Src kinases are not involved in the observed stimulation. Evaluating A6 total and surface (using brush border membrane vesicles) protein expression revealed that the observed stimulation is not due to changes in A6 total and surface protein expression. Assessing ^{14}C-oxalate transport as a function of increasing ^{14}C-oxalate concentration in the flux medium showed that the observed stimulation is due to F/I-induced increase (1.8-fold) in V_{max} (the maximal velocity) and reduction (2-fold) in K_m (the apparent affinity for oxalate) in preliminary studies. siRNA knockdown studies showed that significant components of the observed stimulation are mediated by the A6 and SLC26A2 (A2) oxalate transporters. Since F/I did not affect A6 total and surface protein expression, and in view of the reduced K_m (reflecting greater A6 affinity for oxalate upon PKA activation), it is likely possible that the observed stimulation is due to mechanisms including F/I-induced enhanced A6 transport activity resulting from an increase in the intrinsic activity of the preexisting A6 membrane transporters. We conclude that activation of the PKA signaling pathway significantly stimulates intestinal oxalate transport by C2 cells through mechanisms including increased intrinsic activity of preexisting A6 membrane transporters, as well as enhanced A2 transport activity (resulting from more A2 membrane transporters and/or increased intrinsic activity).

P2X7 Receptor Stimulation Is Not Required for Oxalate Crystal-Induced Kidney Injury Hannah L. Luz,[3] Martin Reichel,[3] Kai-Uwe Eckardt,[1] Robert J. Unwin,[4] Frederick W. Tam,[2] Felix Knauf.[1] *[1]Dept of Nephrology and Medical Intensive Care, University Hospital Charite Berlin, Berlin, Germany; [2]Renal and Vascular Inflammation Section, Hammersmith Hospital, Imperial College Kidney and Transplant Institute, London, United Kingdom; [3]Dept of Nephrology and Hypertension, University of Erlangen-Nuremberg, Erlangen, Germany; [4]Centre for Nephrology, Royal Free Hospital, University College London Medical School, London, United Kingdom.*

Background: Oxalate crystal-induced renal inflammation is associated with progressive kidney failure due to activation of the NLRP3/CASP-1 inflammasome. It has been suggested previously that purinergic P2X7 receptor signaling is critical for crystal-induced inflammasome activation and kidney injury. Therefore, we investigated the role of the P2X7 receptor in response to crystal-induced cytokine release, inflammation, and kidney failure using *in vitro* and *in vivo* models.

Methods: Bone marrow-derived dendritic cells (BMDC) from C57BL/6 (wild-type), Casp1$^{-/-}$ and P2X7$^{-/-}$ mice were stimulated with calcium-oxalate crystals, monosodium urate crystals or ATP. Interleukin-1beta (IL-1ß) release was measured using ELISA and western blot analysis. For studies *in vivo*, age- and gender-matched wild-type, Casp1$^{-/-}$ and P2X7$^{-/-}$ mice were placed on a high oxalate diet to induce oxalate nephropathy. Kidney sections were analyzed for crystal deposition, tubular damage, and macrophage infiltration using F4/80 staining. Renal function was monitored by changes in plasma creatinine sampled retro-orbitally.

Results: Stimulation of BMDC from wild-type mice with oxalate crystals, urate crystals or ATP induced a robust release of IL-1ß. Treatment with the P2X7 inhibitor A740003 selectively abrogated ATP-induced, but not oxalate and urate crystal-induced IL-1ß release. In line with this finding, BMDC from P2X7$^{-/-}$ mice released reduced amounts of IL-1ß following stimulation with ATP, while oxalate and urate crystal-induced IL-1ß release was unaffected. In sharp contrast, BMDC from Casp1$^{-/-}$ mice exhibited reduced IL-1ß release following either of the three stimulants. In addition, while Casp1$^{-/-}$ mice were protected from crystal-induced renal failure, P2X7$^{-/-}$ mice demonstrated similar degrees of crystal deposition, tubular damage and inflammation when compared with WT mice. In line with these findings, increases in plasma creatinine were no different between WT and P2X7$^{-/-}$ mice.

Conclusions: In contrast to previous findings, our results indicate that P2X7 receptor is not required for crystal-induced CKD and it is unlikely to be a suitable therapeutic target for crystal-induced progressive kidney disease.

Structural Alteration of Urinary Tamm Horsfall Protein under Hyperoxaluric Conditions in Rats: Role of Calnexin, a Glycoprotein Chaperone Rishi Bhardwaj,[1] Ankita Bhardwaj,[1] Chanderdeep Tandon,[2] Devinder K. Dhawan,[1] Tanzeer Kaur.[1] *[1]Department of Biophysics, Panjab University, Chandigarh, India; [2]Amity Institute of Biotechnology, Amity University, Noida, India.*

Background: Tamm Horsfall Protein (THP), a urinary glycoprotein has been studied extensively for its involvement in the progression or regression of renal stone formation. Also, some studies have pointed out the abnormality in structural conformation and glycosylation as the root cause for the altered nature of THP. Calnexin, an ER resident chaperone, deals with the proper folding of glycoproteins in order to ensure their structural and functional entity. Therefore, study was carried out to decipher the role of calnexin and THP under hyperoxaluric environment in rat model mimicing renal stone condition, if any.

Methods: Rats were randomly divided into four groups: control, hyperoxaluric groups i.e. ethylene glycol alone, ethylene glycol with ammonium chlroide and hydroxy-l-proline, respectively. After hyperoxaluric induction, urine from the rats was collected for THP isolation. Rats were then sacrificed and kidneys were removed for further investigations. Methods employed to carry out the investigations included protein expression analysis via Western Blot and Immunohistochemistry and gene expression analysis by mRNA studies. Fourier Tranform Infrared Spectroscopy and hydrophobicity analysis of isolated THP were carried out in order to demonstrate any structural changes. Sialic acid content was estimated both in renal tissues and isolated THP.

Results: Studies revealed a significant increase in the expression of calnexin as well as THP in the renal tissue of all the hyperoxaluric groups at both protein and gene level. Moreover, absence of peak at 1462 cm^{-1} in the FTIR spectrum of THP was also demonstrated by the hyperoxaluric animals with significant alteration in the extent of hydrophobicity. Also, sialic acid content of renal tissues and isolated THP was found to be significantly lowered in the animals subjected to hyperoxaluric insult.

Conclusions: Above mentioned finding suggests a possiblity that alteration in the working environment of glycoprotein chaperone, calnexin can greatly modulate the role of THP by regulating its structural, conformational and functional aspects. This could pave a path towards the development of novel therapeutic approaches targeting chaperone activity as well as stress thus generated under renal stone ailment.

TH-PO1071

ALLN-177, a Novel Oral Enzyme Therapy, Reduces Urinary Oxalate Excretion and Plasma Oxalate in Porcine Dietary Model of Severe Hyperoxaluria Danica Grujic,[1] Paulina Szczurek,[2] Nadia Mosiichuk,[2] Liudmyla Lozinska,[2] Stefan Pierzynowski.[2] *[1]Allena, Newton, MA; [2]Lund University, Lund, Sweden.*

Background: Hyperoxaluria (HO) is a chronic metabolic disorder and a major risk factor for nephrolithiasis and oxalate nephropathy. Secondary HO is caused by increased intestinal oxalate absorption from the diet due to enteric disorders or unexplained causes. There are no pharmacologic therapies approved for HO. ALLN-177 is an oral oxalate-specific enzyme therapy (Rx) that degrades oxalate in the gastrointestinal (GI) tract, decreasing oxalate absorption and thereby reducing urine oxalate. ALLN-177's ability to decrease oxalate burden as assessed by urine and plasma oxalate was tested in a porcine model of HO induced with high oxalate diet (HOD). Pigs were chosen due to physiological similarities to humans in GI and renal function.

Methods: To induce severe HO, 12 pigs were fed HOD for 7 days, followed by a 7-day treatment period continuing on HOD during which a daily oral dose of 22,500 units (u) ALLN-177 was given with feed 3x/day, 7,500 u/meal. HOD was a mix of a regular chow with 2.2 g/kg of Ca, 20% fat and frozen rhubarb (2:1 w/w). The primary endpoint was the within-pig difference in 24h urine oxalate (UOx) on HOD plus ALLN-177 compared to HOD alone, expressed as mg oxalate/g creatinine/24h (mg/gCr/d). Change in plasma oxalate was analyzed, and *Oxalobacter* colonization was assessed using PCR on fecal samples collected the last day of study treatment with primers designed to detect multiple species of Oxalobacter.

Results: Daily oral ALLN-177 with meals significantly reduced UOx by mean of 38.7 mg/gCr/d (39%) when compared to pre-treatment UOx on HOD (100.1±20.1 vs.: 61.5±14.3 mg/gCr/d on HOD+ALLN-177; $p<0.001$), returning UOx to the range recorded prior to HOD (61.3 ± 14.5 mg/gCr/d). In addition, mild hyperoxalemia while on HOD (plasma oxalate 13.9±0.9 umol/L) was significantly reduced with Rx to 9.9±2.3 umol/L, $p<0.001$. PCR of fecal samples was negative for Oxalobacter indicating absence of colonization. Therapy was well tolerated without adverse effects observed.

Conclusions: Orally administered ALLN-177 with meals was well tolerated and normalized UOx and plasma oxalate in a pig model of secondary HO.

TH-PO1072

Crystalluria and Monocyte Responses in Healthy Subjects Following a Single Dietary Oxalate Load Tanecia Mitchell, Mikita Patel, Vidhush Yarlagadda, Adam D. Ambrosetti, John Knight, Dean G. Assimos, Ross P. Holmes. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Dietary oxalate has been suggested to play an important role in the risk and progression of stone formation in patients with calcium oxalate (CaOx) kidney stone disease. Oxalate has also been associated with crystal formation and inflammation in renal cells. We have previously determined that monocyte mitochondrial function is altered in patients with CaOx kidney stone disease. The purpose of this study was to determine whether dietary oxalate causes crystal formation in the urine and alters monocyte mitochondrial responses in the circulation of healthy subjects.

Methods: Twenty healthy subjects (29.1 ± 1.7 years old) with an average BMI of 25.5 ± 0.8 kg/m^2 were enrolled in the study. Participants consumed a low oxalate diet for 3 days prior to consuming a single high dietary oxalate load (spinach smoothie; 8 mmoles). Urine and peripheral blood was collected prior to the load and five hours later. Crystalluria was quantified by measuring oxalate levels using ion-chromatography mass spectrometry (IC/MS) and a Nanosight nanoparticle counter. Monocyte mitochondrial responses were assessed using the Seahorse XF96 Analyzer.

Results: A single high dietary oxalate load in healthy subjects significantly increased total urinary oxalate levels (pre-oxalate 2.36 ± 0.6 vs. post-oxalate 35.35 ± 4.8 mg; $p<0.0001$). In addition, urinary crystals were observed following the load and determined to be approximately 180 nm in diameter via the Nanosight nanoparticle counter. The effect of the high dietary oxalate load on monocyte mitochondrial responses was variable among participants. Eleven of the healthy subjects (55%) had decreased monocyte mitochondrial function; whereas, 3 (15%) were not affected by the load and 6 (30%) had increased mitochondrial function following the load compared to pre-oxalate samples.

Conclusions: These findings suggest that a single high dietary oxalate load causes crystal formation and changes in monocyte mitochondrial responses in healthy subjects. Understanding these mechanisms further may aid in designing dietary recommendations to mitigate crystal formation in patients with CaOx kidney stone disease.

TH-PO1073

Results of a Phase 2 RCT of ALLN-177 in Patients with Secondary Hyperoxaluria Sagar U. Nigwekar,[2] James E. Lingeman,[1] James A. Bolognese,[3] Annamaria T. Kausz.[4] *[1]IU Health Physicians Urology, Indianapolis, IN; [2]Massachusetts General Hospital, Boston, MA; [3]Cytel inc, Cambridge, MA; [4]Allena Pharmaceuticals, Newton, MA.*

Background: Hyperoxaluria (HOx) is a metabolic disorder associated with increased risk of nephrolithiasis and other sequelae including oxalate nephropathy. Secondary HOx is caused by excess oxalate absorption from diet due to enteric disorders (enteric HOx, EH) or is unexplained (idiopathic). There are no approved pharmacotherapies for HOx. To address this unmet need, ALLN-177 was developed as a novel oral formulation of crystalline oxalate decarboxylase, an oxalate-specific enzyme that degrades oxalate in the gastrointestinal (GI) tract, thereby reducing urine oxalate (UOx).

Methods: This double-blind, placebo-controlled RCT randomized adult subjects with secondary HOx and UOx ≥50 mg/d 1:1 to ALLN-177 (7500 u/meal) or placebo taken orally with meals 3x/day for 28 days. Multiple 24-hr urine collections were obtained to determine change in UOx, and the primary analysis used a mixed effects repeated measures analysis of variance model.

Results: 67 subjects were randomized and treated (32 ALLN-177, 35 placebo); 18 had EH. The primary endpoint (EP) 24-hr UOx change from baseline to Week (Wk) 4 showed a trend favoring ALLN-177 (-5.4 mg/d; see Table). Key secondary EP were statistically significant, and a substantially greater, clinically meaningful treatment effect was seen in post-hoc analyses in the predefined EH subset, including the time-weighted average (TWA) assessing the aggregate effect across the study duration. Adverse events were reported by 50% of ALLN-177 subjects vs. 63% placebo, and GI AEs were the most frequently reported, 16% ALLN-177 vs 40% placebo. No subjects discontinued ALLN-177 for any reason.

Conclusions: ALLN-177 was well-tolerated and has potential to meaningfully reduce UOx in patients with EH, who have a substantially increased risk for renal complications and thus an unmet need for an effective therapy to reduce UOx.

Funding: Commercial Support - Allena Pharmaceuticals

Endpoints	All Comparison vs. Placebo mean (90% CI)	Enteric Comparison vs. Placebo mean (90% CI)

SLC26A6 Is the Principal Oxalate Transporter in Macrophages Teresa R. Wagner,[1,2] Louise M. Tonner,[3,1] Zhirong Jiang,[1] Robert B. Thomson,[1] Felix Knauf,[4,1] Peter S. Aronson.[1] *[1]Yale School of Medicine, New Haven, CT; [2]University Tübingen, Tübingen, Germany; [3]FAU Erlangen, Erlangen, Germany; [4]University Hospital Charite, Berlin, Germany.*

Background: Macrophages are able to phagocytose calcium oxalate crystals, dissolve the crystals into their molecular components, and discharge accumulated oxalate. The goal of this study was to identify the transporter(s) responsible for oxalate transport across the plasma membrane of macrophages. We specifically evaluated the potential role of SLC26A6 because of its known activity as a Cl^--oxalate exchanger in kidney and intestine.

Methods: Oxalate transport in macrophages was assessed by using the human monocytic THP-1 cell line and bone marrow-derived macrophages from mice in ^{14}C-oxalate transport assays. Immunoblotting and qPCR were used to detect expression of SLC26A6. The functional role of SLC26A6 in mediating oxalate transport was studied by siRNA knockdown in THP-1 cells and isolation of macrophages from Slc26a6$^{-/-}$ mice. Macrophage viability was measured by WST-1 assays.

Results: DIDS-sensitive Cl^- gradient-stimulated oxalate transport was detected in both THP-1 cells and mouse macrophages, consistent with Cl^--oxalate exchange activity. Expression of SLC26A6 in THP-1 cells and mouse macrophages was detected by qPCR and immunoblotting. Partial knockdown of SLC26A6 expression by siRNA in THP-1 cells caused significant reduction of Cl^--oxalate exchange activity. There was complete loss of Cl^--oxalate exchange activity in macrophages isolated from Slc26a6$^{-/-}$ mice. Prolonged incubation with ^{14}C-oxalate revealed significantly higher accumulation of oxalate in macrophages from Slc26a6$^{-/-}$ mice compared to wild-type mice, indicating that SLC26A6 plays a major role in mediating oxalate efflux under physiological conditions. Moreover, incubation in high oxalate media was found to cause significantly greater loss of viability of macrophages from Slc26a6$^{-/-}$ mice compared to wild-type mice.

Conclusions: We conclude that SLC26A6 is the principal oxalate transporter in macrophages and likely plays a role in mediating oxalate efflux and reducing cellular oxalate toxicity.

TH-PO1075

Urinary Stone Events Are Predicted by Urinary Oxalate Excretion in Enteric Hyperoxaluria Matthew R. D'Costa,[1] Annamaria T. Kausz,[2] Felicity T. Enders,[1] Kristin C. Mara,[1] Ramila A. Mehta,[1] John C. Lieske.[1] *[1]Mayo Clinic, Rochester, MN; [2]Allena Pharmaceuticals, Newton, MA.*

Background: Elevated urinary oxalate (UOx) excretion is considered an important pathologic contributor towards the development of renal complications of enteric hyperoxaluria (EH). Since there are limited outcomes data we assessed the relationship between UOx and kidney stone events in an EH cohort.

Methods: In all, 589 patients from Olmsted County, MN were identified who had 24h urine supersaturation test results and a diagnosis of malabsorption or bariatric surgery (defined as EH). "Baseline" was the date of the first available 24h urine. Urologic procedures and emergency department visits with diagnostic codes consistent with kidney stones ≥1 month after baseline were considered a stone event. Multivariate logistic regression was performed to predict a first stone event >6 months after index date.

Results: Median follow-up time was 4.2 yrs. Mean age was 50.2 yrs and 74% were female. Baseline UOx was associated with a first stone event in models adjusted for baseline urine calcium and citrate (Table). For each 10 mg/24h increase in UOx, odds of a

stone event was 1.15 (p=0.012). Similarly, among EH patients with baseline urine oxalate of 60 mg/24h or greater, odds of a stone event after six months was 2.75 times greater than for EH patients whose baseline urine oxalate was below 40 mg/24h (p=0.030); for baseline urine oxalate between 40 and <60 mg/24h this odds ratio was 2.69 (p=0.008).

Conclusions: Baseline UOx predicts risk of future stone events in a cohort of EH patients. This risk persists even after adjustment for other urinary stone risk factors, including calcium and citrate excretion. Thus strategies to reduce UOx in EH patients should also reduce kidney stone risk.

Predictors of first stone event six months or more after baseline

Model 1*	Odds Ratio	Lower 95% CL	Upper 95% CL	p-value

Relative Supersaturation of 24-Hour Urine and Likelihood of Kidney Stones Megan Prochaska,[4] Eric N. Taylor,[3] Pietro Manuel Ferraro,[2] Gary C. Curhan.[1] *[1]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; [2]Fondazione Policlinico Universitario A. Gemelli, Rome, Italy; [3]Maine Medical Center, Portland, ME; [4]Renal, Brigham and Women's Hospital, Boston, MA.*

Background: Relative supersaturations of calcium oxalate, calcium phosphate, and uric acid are used clinically in kidney stone prevention. However, the magnitudes of association between levels of relative supersaturation and stone risk require further quantification.

Methods: We performed a cross-sectional study using 24-hour urine collections from 2,505 stone formers and 1,267 controls from the Nurses' Health Study I (NHS I), Nurses' Health Study II (NHS II), and Health Professional Follow-up Study (HPFS) cohorts to quantify the association between level of calcium oxalate, calcium phosphate, and uric acid relative supersaturations and the likelihood of being a stone former.

Results: The relative risks (RR) for being a stone former were 5.85 (3.40 to 10.04) in NHS I and 6.38 (3.72 to 11.0) in NHS II for calcium oxalate relative supersaturation of 3.0 or greater compared with <1.0, and the RR was 6.95 (3.56 to 13.6) in HPFS for calcium oxalate relative supersaturation of 4.0 or greater compared with <1.0. The RR for being a stone former were 1.86 (0.92 to 3.71) for NHS I, 4.37 (2.68 to 7.10) for NHS II, and 3.59 (2.04 to 6.31) for HPFS for calcium phosphate relative supersaturation category of 4.0 or greater compared with <1.0. For uric acid relative supersaturation, the relative risks for being a stone former were 4.30 (2.34 to 7.90) for NHS I and 2.74 (1.71 to 4.40) for NHS II for the highest relative supersaturation category of 4.0 or greater compared with <1.0. In HPFS, uric acid relative supersaturation was not significantly associated with likelihood of stone formation.

Conclusions: The likelihood of being a stone former increases with higher calcium oxalate and calcium phosphate relative supersaturation levels in men and women, and higher relative supersaturation levels of uric acid in women. This increase begins at levels below the currently accepted 'normal' values.

Absolute Compared with Percentage Differences in 24-Hour Urine Oxalate and Likelihood of Being a Kidney Stone Former Gary C. Curhan,[1] Eric N. Taylor,[3] Pietro Manuel Ferraro.[2] *[1]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; [2]Fondazione Policlinico Universitario A. Gemelli, Rome, Italy; [3]Maine Medical Center, Portland, ME.*

Background: Higher absolute differences in 24-hour urine oxalate have been demonstrated to be associated with risk of kidney stone formation, but there are no published data about the magnitude and shape of the associations per 20% increase. For the latter, the change is dependent on the starting value, which has implications for intervention studies.

Methods: In three large cohort studies (Nurses' Health Study (NHS) I, NHS II and Health Professionals Follow-Up Study (HPFS)), we obtained 24-hr urine collections from individuals with and without a history of kidney stones. We calculated the likelihood of being a stone former per 10 mg/d and also per 20% higher 24-hour urine oxalate. For the former, logistic regression was used to calculate odds ratios of being a stone former. For the latter, we used a logarithmic approach such that the interpretation of the coefficient was the increase in risk per 20% higher urine oxalate (on a non-linear, continuous scale). The analyses adjusted simultaneously for age and all 24-hr urinary factors. The initial analysis used a single 24-hr urine (N=3775). A secondary analysis used the subset of participants who had completed two 24-hr urine collections (N=2426).

Results: Spline plots showed that the relation was not linear so the 'per 10 mg/d' results were biased. Using a non-linear model, the per 20% higher urine oxalate multivariable adjusted relative risk (MVRR) for the single urine collection was 1.15 (0.85, 1.57), p =0.37 for NHS I, 1.10 (0.81, 1.48), p=0.54 for NHS II, and 1.17 (1.00, 1.36), p =0.04 for HPFS. The per 20% higher urine oxalate MVRR for the average of two urine collections was 1.37 (1.23, 1.53), p <0.001 for NHS I, 1.22 (1.11, 1.33), p <0.001 for NHS II, and 1.17 (1.07, 1.29), p =0.001 for HPFS. When we pooled the estimates for the non-linear model, the MVRR using the single collection, was 1.15 (1.02, 1.31), p=0.02 and for the average of two collections was 1.25 (1.14, 1.36), p<0.001.

Conclusions: These data strongly support an independent non-linear association between higher 24-hr urine oxalate and likelihood of stone formation, which must be taken into consideration when designing oxalate reduction trials.

Determinants of Urine Chemistry in the Rare Kidney Stone Consortium (RKSC) Cystinuria Registry Frank Modersitzki,[2] David S. Goldfarb.[1,3] *[1]Nephrology Section, New York Harbor VAMC, New York, NY; [2]New York University School of Medicine, New York, AL; [3]Nephrology, NYU Langone Medical Center, New York, NY.*

Background: Urine chemistry is a determinant of stone formation in cystinuria. We previously showed that positive cystine capacity (CysCap), a measure of higher cystine solubility, led to fewer stone events. We queried the RKSC Cystinuria Registry to determine urinary and medication variables associated with positive (CysCap+), rather than negative (CysCap-) values.

Methods: This is the 1st report from the Cystinuria Registry, with data on 300 people with cystinuria (142 males, 158 females; age at enrollment 38 ± 17 years). 112 participants had 306 determinations of CysCap, measured by Litholink (Chicago, IL). In this cross-sectional study we compared variables associated with CysCap+ vs CysCap-.

Results: Lower urine Na (r=0.48; Fig 1A) and creatinine (r=0.62, not shown) were associated with lower 24h urine cystine (UC; P<0.001). Increasing CysCap values were seen with increasing urine pH (r_s=0.45, Fig 1B), volume (r_s=0.44) and decreasing UC (r_s=-0.44 Fig 1C; all P<0.001). Dividing Cyscap determinations into CysCap+ and CysCap- groups (Table), only higher urine volume and greater daily citrate doses were different. Relatively few participants were taking citrate or tiopronin.

Conclusions: Higher urine pH and volume and lower UC were associated with less lithogenic urine; lower UC was seen with less Na and creatinine. Higher volume and citrate doses distinguished patients with less lithogenic urine. Many patients with cystinuria may be undertreated and would benefit from better dietary adherence.

Urinary Cystine Excretion in an Adult Kidney Stone Cohort William E. Haley,[1] Felicity T. Enders,[1] Ramila A. Mehta,[3] David S. Goldfarb,[2] John C. Lieske.[1] *[1]Mayo Clinic, Jacksonville, FL; [2]New York Harbor VAMC, Hastings on Hudson, NY; [3]Mayo Clinic, Rochester, MN, Rochester, MN.*

Background: Cystinuria is caused by mutations in the amino acid transporter coded by *SLC3A1* and *SLC7A9*. Heterozygotes are not well defined or characterized. This study determined the distribution of urinary cystine (Ucys) in adult kidney stone formers and defined the prevalence of moderate to severe cystinuria.

Methods: Ucys, ornithine, lysine, and arginine (OLA) were analyzed by quantitative liquid chromatography – tandem mass spectrometry in all new adult patients in a tertiary stone clinic (2000 – 2014; N=1173; median follow up 1.4 yrs (IQR 2, 12)).

Results: Ucys excretion was abnormal in 15% (176/1173) of adult kidney stone formers. The majority were moderate, and 1% were severe (consistent with homozygous cystinuria). Patients with moderate Ucys differed from normal being more likely male with a greater percentage uric acid (UA) stones. Higher urinary levels of OAL were present with moderate and severe Ucys, suggesting the moderate group contains a subset of heterozygous cystinuria carriers. Non-cystine stones were present with moderate Ucys including a higher proportion UA stones compared to the normal Ucys group. Only a

minority with severe Ucys excretion had a family history of cystinuria. In univariate models, predictors of moderate Ucys (>115 µmol/24h) and severe cystinuria (>1000 µmol/24h) were higher UNa, sulfate and OAL (P<0.001). In multivariate models, Usulfate, Ulysine, Uornithine remained significant.

Conclusions: A high index of suspicion and low threshold for screening are necessary since cystinuria requires specialized treatment for best outcomes. Moderate cystinuria may confer UA stone risk and requires further study.

Interference of Tiopronin with Urine Cystine Measurement Is Assay-Dependent Callen D. Giesen,[1] Robin S. Chirackal,[1] Clayton Brady,[2] Nick Voskoboev,[1] Ryan M. Flanagan,[1] John C. Lieske.[1] *[1]Mayo Clinic, Rochester, MN; [2]None, Fairport, NY.*

Background: Patients with cystinuria often suffer frequent stone events, require multiple surgical interventions, and even develop CKD. When conservative measures fail (fluids and alkali), thiol drugs including tiopronin that reduce cystine to create tiopronin-cysteine dimers (and thus increase cystine solubility) are the next option. Urine cystine is often measured using a cyanide-nitroprusside colorimetric assay. Quantitation by liquid chromatography tandem mass spectrometry (LC-MSMS) is specific but not readily available. The present study compared urine cystine measurement by both methods to determine the relative effect of tiopronin.

Methods: Waste urine samples (n=16) from the Mayo Clinic Renal Testing Laboratory were spiked to expected therapeutic (0.1 mg/L) and super-therapeutic (1 mg/L) urine levels of tiopronin and a synthetically prepared tiopronin-cysteine complex. Neat and spiked samples were assayed by the cyanide-nitroprusside assay (modified for microplate settings) and by LC-MSMS.

Results: Tiopronin increased urinary cystine by the colorimetric assay but appropriately decreased it by LC-MSMS (Table). Tiopronin-cysteine complexes also increased values in the colorimetric assay, but had no effect on the LC-MSMS assay.

Conclusions: Tiopronin caused significant interference with the colorimetric assay, even when added as a tiopronin-cysteine complex. The underlying chemistry of the method, which effectively measures reduced cysteine monomers, is the likely reason. Conversely, LC-MSMS accurately detects a fall in intact cystine when tiopronin is added to urine, and is not affected by the resulting cysteine-tiopronin complexes. Thus patients on tiopronin should ideally be monitored using an MS-based assay of intact urinary cystine to ensure proper drug dosing and disease monitoring.

Spike Material	Level (mg/L)	Assay	Mean Difference (mg/L; %)		95%CI (mg/L; %)	
Tiopronin	0.1	Colorimetric	24	80%	0 to 48	26% to 135%
		LC-MSMS	-83	-32%	-154 to -12	-55% to -8%
	1	Colorimetric	323	906%	290 to 356	654% to 1158%
		LC-MSMS	-218	-96%	-350 to -86	-98% to -95%
Tiopronin + Cysteine	0.1	Colorimetric	28	62%	7 to 48	31% to 93%
		LC-MSMS	-34	8%	-87 to 19	-22% to 39%
	1	Colorimetric	234	645%	181 to 286	475% to 815%

TH-PO1081

ROKS II Nomogram: Predicting Future Symptomatic Stone Episodes Lisa E. Vaughan,[1] Felicity T. Enders,[1] John C. Lieske,[1] Terri J. Vrtiska,[1] Ramila A. Mehta,[2] Andrew D. Rule.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN, Rochester, MN.*

Background: We previously developed a prediction tool for symptomatic recurrence after the first stone event (ROKS nomogram). A more generalizable prediction tool is needed that can also be applied in stone formers with more than one prior stone episode.

Methods: We performed a population-based cohort study of validated incident kidney stone formers in Olmsted County, Minnesota, from 1984-2012 and followed them for all subsequent episodes through 2017. Predictors for symptomatic recurrence were identified from clinical characteristics at each stone episode. A nomogram was developed from a multivariable cox proportional hazards model using robust standard errors.

Results: There were 3,364 validated first-time kidney stone formers with 4,951 stone episodes. The stone recurrence rates per 100 person-years were 3 after the first stone episode, 7 after the second episode, 12 after the third episode, and 18 after the fourth episode or higher. A parsimonious model included the following risk factors for recurrence: younger age per 10 years (HR=0.88, p<0.001), male sex (HR=1.25, p=0.002), higher body mass index per 5 kg/m² (HR=1.07, p=0.004), family history of stones (HR=1.36, p<0.001), pregnancy during last episode (HR=1.82, p=0.005), asymptomatic stone prior to the first validated episode (HR=1.35, p=0.008), suspected stone episode prior to the first validated episode (HR=1.75, p<0.001), brushite, struvite or uric acid stone ever (HR=1.24, p=0.16), no known calcium oxalate monohydrate stone ever (HR=0.89, p=0.08), pelvic or lower pole stone (HR=1.39, p<0.001), no ureterovesicular junction stone on imaging (HR=0.84, p=0.01), number of kidney stones on imaging (0 ref.; 1 HR=1.30, p<0.001; 2+ HR=2.03, p<0.001), and diameter of largest kidney stone on imaging (<3 mm or none ref.; 3-6 mm HR=1.25, p=0.021, >6 mm HR=0.96, p=0.79). The risk of recurrence also increases with number of past episodes (p<0.001). The final model had a C-index of 0.653; with bootstrapping, the C-index corrected for optimism was 0.643.

Conclusions: The ROKS II nomogram was developed to aid physicians in identifying patients at high versus low risk for symptomatic stone recurrence and is more generalizable than the current ROKS nomogram. With an estimate of the risk of recurrence, physicians and patients can make informed decisions on dietary and medical interventions.

TH-PO1082

Recurrent but Not First-Time Symptomatic Kidney Stone Formers Are at Higher Risk for ESRD and Death Tsering Dhondup, Wonngarm Kittanamongkolchai, Ramila A. Mehta, LaTonya J. Hickson, Felicity T. Enders, John C. Lieske, Andrew D. Rule. *Mayo Clinic, Rochester, MN.*

Background: Prior studies reporting an increased risk of ESRD in kidney stone formers (SFs) are limited by the use of codes, lack of diagnosis validation, and short follow-up time. In this study we determined the incidence of ESRD and mortality in a cohort of carefully characterized SFs.

Methods: Coded SFs (ICD-9: 592, 594 & 274.11) in Olmsted County, Minnesota between1984-2012 were categorized after chart review into mutually exclusive groups: incident (first-time) symptomatic SF, recurrent symptomatic SF (first stone event prior to study period), asymptomatic SF, bladder SF, and miscoded (not a SF). Age and sex-matched controls were randomly sampled from the Olmsted County population (4:1 ratio). Cox proportional hazards models were used to determine the risk of ESRD (identified using the United States Renal Data System) and mortality (National Death Index) after adjustment for baseline comorbidities.

Results: The cohort of 7036 SFs and 28,136 controls (mean age 48 years and 58% male) had 94 and 183 ESRD events and had 1139 and 3923 deaths, respectively, over a mean follow-up of 9.4 years. After adjusting for baseline CKD, diabetes mellitus, hypertension, dyslipidemia, obesity and gout, recurrent SFs but not incident SFs were at higher risk of ESRD and mortality (Table). Asymptomatic SFs were also at higher risk of ESRD and mortality, while bladder SF were at higher risk of mortality and miscoded SF were at higher risk of ESRD.

Conclusions: The risk of ESRD and mortality may be higher in recurrent than incident symptomatic SFs due to more substantial renal injury from more severe stone disease. Thus efforts to reduce kidney stone recurrence may have beneficial impact on ESRD and mortality risk. Other disease that leads to kidney imaging (incidental detection of asymptomatic stones) or is miscoded as kidney stones can bias the risk of ESRD or mortality in code based studies that lack chart validation.

Funding: NIDDK Support

Risk of ESRD and death by SF groups compared to controls : HR with (95% CI)

Outcome	Incident SF	Recurrent SF	Asymptomatic SF	Miscoded	Bladder SF
ESRD	1.38 (0.87, 2.16)	3.32 (1.55, 6.99)	3.79 (1.66, 8.68)	6.52 (2.46, 19.08)	1.26 (0.28, 4.11)
Death	1.07 (0.96, 1.18)	1.21 (1.03, 1.41)	1.41 (1.18, 1.67)	1.07 (0.87, 1.3)	1.37 (1.11, 1.68)

TH-PO1083

Lower Than Normal Urine pH in Calcium Oxalate (CaOx) Stone Forming (SF) Women Is Due to Reduced Gastrointestinal (GI) Alkali Absorption Kristin J. Bergsland, Fredric L. Coe, Elaine M. Worcester. *University of Chicago, Chicago, IL.*

Background: We have previously found that in normal (N) men (M) and women (W) fed identical diets in a General Clinical Research Center (GCRC), the urine pH (UpH) of W exceeds that of M due to greater absorption of alkali from the GI tract. Since calcium (Ca) SF is often accompanied by altered UpH that reduces the solubility of SF salts in urine, we have similarly studied idiopathic hypercalciuric CaOx and CaP stone formers in the GCRC to identify whether differences in UpH regulation are associated with stone type within sex and if so, what components of acid-base metabolism are responsible for the differences.

Methods: We measured UpH and determinants of acid-base regulation in 25 N (13 M), 17 CaOx SF (11 M) and 15 CaP SF (8 M). We collected 15 urines and 20 blood samples over a 15 hour day in the GCRC; diet was fixed. GI anion excretion (GIAE) = [(Na + K + Ca+ Mg) - (Cl + P)] in urine (mEq/hr).

Results: W CaOx SF had lower UpH than other W during the fed period (Table). Lower UpH in CaOx W was accompanied by higher net acid excretion (NAE) and urine titratable acid (TA), and reduced urine CO_2 excretion and GIAE. In M CaP SF, GIAE was higher vs M N. Sulfate excretion (Sul) was reduced in all SF vs N.

Conclusions: The pathophysiology of Ca stone formation differs by sex. In the presence of hypercalciuria, normally high GIAE and UpH of W predisposes to CaP SF while higher TA and NAE and lower UpH in M favors CaOx SF. Exceptions are M CaP, with increased GIAE that correlates with a trend to higher UpH, and W CaOx, with lower than normal GIAE and higher NAE which translates into reduced urine CO_2 and lower UpH. These differences may have clinical implications for use of stone therapies that affect UpH.

An Association between the Genetic Hypercalciuric Stone-Forming Rat and the Gut Microbiome Joshua M. Stern,[2] Nancy S. Krieger,[3] Matthew K. Abramowitz,[1] David A. Bushinsky.[4] *[1]Albert Einstein College of Medicine, New York, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Univ. of Rochester, Rochester, NY; [4]University of Rochester Medical Center, Rochester, NY.*

Background: The Genetic Hypercalciuric Stone-forming (GHS) rat has been an established model of kidney stone disease. The rats have been selectively inbred for hypercalciuria for over 100 generations, originally from standard Sprague Dawley (SD) rats. All GHS rats make stones by 18 weeks of age. The model has been extensively studied and phenotyped. However, no study has previously examined differences in the rat's microbiome. In this study we characterize the gut microbiome (GMB) from GHS rats compared to age and sex matched SD controls.

Methods: 4 male GHS rats and 2 male SD rats were housed separately and fed similar diets of rat chow in the same animal room. Fresh fecal pellets were collected at one single time point, stored at -80ºC and sent to the Albert Einstein Department of Urology where the pellets were prepared for analysis by DNA extraction, amplification of the 16S rRNA V4 region using barcoded primers on an Illumina platform. QIIME was used for analyses.

Results: 16S rRNA analysis between the 2 groups found significant differences. *Bacteriodes genus* was 39% more abundant in the GHS. *Firmicutes Phylum* was 17.2% more abundant in the SD rats as compared to 5.7% in the GHS rats, a 67% increase in the SD rats. The alpha diversity of the GHS rats' GMB cluster well and are widely separated from SD. The GHS rats have a lower Shannon score diversity. *Roseburia genus*, known to contain species that produce beneficial short chain fatty acids was 70% more abundant in the SD group. Similarly *Faecalibacterium genus*, with known butyrate producers, was increased 35% in the SD rats.

Conclusions: We, for the first time, demonstrate that age and sex matched GHS rats carry a GMB that is distinct from its SD ancestors. Of particular interest is the decreased bacterial diversity seen in these rats at just 12 weeks of age. *Bacteroides genera* is significantly up-regulated in the GHS rats and similar to findings seen in human stone formers (Stern et al., Urolithiasis 44:399, 2016). Future studies to determine causality and directionality of this effect are warranted.

Tubular Crosstalk in Renal Calcium Handling Olivier Bonny,[1,2] Fanny Durussel,[1] Suresh Krishna Ramakrishnan.[1] *[1]Dpt Pharmacology and Toxicology, University of Lausanne, Lausanne, Switzerland; [2]Service of Nephrology, Lausanne University Hospital, Lausanne, Switzerland.*

Background: Calciuria is one of the main risk factors for kidney stone and the understanding of its regulation is essential for stone prevention. In the kidney, calcium tubular reabsorption is complex, starting in the proximal tubule (PT) with paracellular reabsorption, continuing in the ascending limb (TAL) with transepithelial paracellular transport through the claudin system and regulation by the basolateral calcium sensing receptor and ending by transcellular calcium reabsorption in the distal convoluted tubule (DCT). When calcium reabsorption is challenged in one specific part of the nephron, reaction in other segments of the nephron has been observed, but not studied systematically. We hypothesized that challenge in one segment is affecting calcium reabsorption in other segments through tubular crosstalk.

Methods: We used mice and challenged renal calcium reabsorption by furosemide (acutely at 4 hours and chronically at 7 days) and thiazide injections or by feeding them with cinacalcet. We microdissected tubular segments and studied the most relevant genes and proteins involved in calcium transport in each segment.

Results: We found that upon acute challenge with furosemide, Nhe3 was downregulated in the proximal tubule, while Cldn16 and 19 were upregulated in the TAL and Trpv5, Ncx1, Pmca4 and calbindin 28 and 9 were upregulated in the DCT. On chronic furosemide treatment, we observed a shift toward increased proximal and TAL calcium reabsorption, with higher levels of Nhe3, Nkcc2 and CaSR in addition to high levels of Cldn 16 and 19. Interestingly, chronic cinacalcet treatment was increasing NHE3 and CaSR expression. In the DCT, NCC was upregulated, but Trpv5 and other more distal genes involved in calcium transport were not changed. Thiazide challenge did not modify expression of the tested genes acutely (4 hours), but chronically was increasing NHE3 (protein level) and some distal genes.

Conclusions: Altogether, this data show that tubular crosstalk is part of the intrarenal regulation of calciuria. The precise mechanisms leading to tubular adaptation to a segment-specific calcium reabsorption challenge still need further studies.

Differential Expression of miRNAs from Urinary Extracellular Vesicles Identify Pathogenesis of Kidney Stones and Randall's Plaque in Humans Suchitra Sutthimethakorn,[1] Xiangling Wang,[2] Robin S. Chirackal,[1] Felicity T. Enders,[2] Andrew D. Rule,[2] Pritha Chanana,[2] Muthuvel Jayachandran,[2] John C. Lieske.[2] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN.*

Background: Kidney stone disease is a complex disease associating with various types of kidney cells. Activation of the kidney cells could influence the sorting of specific cargo, especially miRNAs into urinary extracellular vesicles (EVs) as well as the release of these EVs into urine, linking the patho- and physiological process of the kidney. However, the roles of miRNAs within urinary EVs of kidney stone disease remain largely unknown. The current study thus aimed to extensively define the changes of miRNAs in urinary EVs between varying degrees of stone formers and controls.

Methods: Bio-banked cells-free urine samples from kidney stone formers with low plaque (LP, n=4; < 5% papillary surface area coverage) and high plaque (HP, n=4; > 5% papillary surface area coverage), first-time stone formers (SF, n=4), and non-stone forming controls (n=4) were used in this study. Urinary EVs-derived miRNAs were extracted and analyzed by XRNA Exosome RNA-Seq Library Kit. Differentially expressed miRNAs (p-value < 0.05) between first-time stone formers and controls, and between HP and LP stone formers were validated by RT-qPCR method and submitted to DIANA-miRPath Bioinformatics tool for biological pathway prediction.

Results: Exosome RNA-Seq analysis revealed a total of 17 and 10 differentially expressed miRNAs between SF and controls, and between LP and HP stone formers, respectively. Pathway analysis demonstrated the involvement of these altered miRNAs in various cellular processes and signaling pathways such as endocytosis, TGF-beta signaling pathway, MAPK signaling pathway and focal adhesion. Interestingly, several altered miRNAs have been related to numerous kidney-related diseases, including kidney fibrosis, chronic kidney disease, and acute kidney injury. Thus far, RT-qPCR data confirmed the increased expression level of hsa-miR-1299 in the SF group, as compared to the controls.

Conclusions: These findings revealed the changes in miRNAs profile within urinary EVs and their possible roles in kidney stone pathogenesis as well as the formation of Randall's plaque. Further investigations of these potential miRNAs may lead to better understanding of pathogenic mechanism underlying calcium-based kidney stone disease.

TH-PO1087

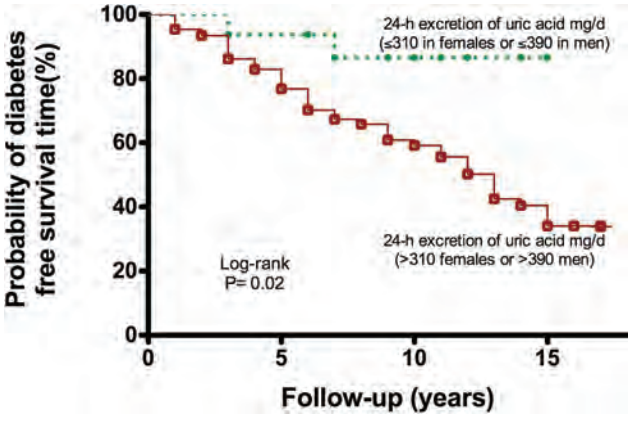
Association of Hyperuricemia and Higher Uricosuria and the Development of Prediabetes or Diabetes in Kidney Stone Formers Bernardo A. Martinez-Guerra,[1] Juan Carlos Ramirez-Sandoval,[1] María F. Castilla-Peón,[2] Alfonso Gulias-Herrero,[1] Cynthia Garcia,[1] Ricardo Correa-Rotter.[1] *[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [2]Hospital Infantil de Mexico Federico Gomez, Ciudad de México, Mexico.*

Background: Nephrolithiasis (NL) isassociated withinsulin resistance and may be a sentinel event before the diagnosis of diabetes mellitus (DM).

Methods: Demographics, associated medical conditions, laboratory data, including 24-h urine analysis, and treatment were obtained at least annually from records. We excluded from analysis KSF who were taking the following drugs that alter uric acid serum levels and excretion (thiazide diuretics, losartan, allopurinol).

Results: From 266 patients of the NL clinic, 118 non-diabetic KSF that fulfilled inclusion criteria were included, 73 (62%) were female, mean age 44±13 yrs, median baseline BMI 26 kg/m^2(IQR 23-31) and 12 (10%) were hypertensive. Median follow-up was 8.6 years (range 1.4-19.3). During follow-up, preDMwas diagnosed in 27(23%) and DM in 24 (20%). Median time to DM diagnosis was 6.4 yrs (IQR 3.8-13). Bivariate analysis showed thatage, serum uric acid (≥5.5 in females and ≥7 mg/dL in males), and total excretion of uric acid (>310 mg/day in females and >390 mg/day in males in 3 or more 24-h urine analysis; see figure)were risk factors for development of preDMor DM. Other variables such as baseline BMI, eGFR, triglycerides, cholesterol, blood pressure or other 24-h urine profile determinations were not associated with the occurrence of the event. After adjusting for age, sex, and hyperuricemia (HR:2.2;95%CI:1.3-3.8), higher uric acid excretion (HR:8.7; 95%CI:1.2-65) was a strongprognostic factor for DM developmentin KSF patients.

Conclusions: The present study is the largest known report exploring the effect of 24-h urine analysis characteristics of KSDand the risk of development preDM andDM. Older age and hyperuricemia, predicted development of preDM and DMyet a higher 24-h urine uricosuriawas thestrongest predictor for this outcome even several years before the diagnosis of preDM or DM.



TH-PO1088

Epidemiological Insight into Nephrolithiasis in Pakistan Ali Amar,[1,2] Amar J. Majmundar,[1] Ayesha Afzal,[2] Mumtaz Ahmad,[3] Shagufta Khaliq,[2] Friedhelm Hildebrandt.[1] *[1]Medicine, Div Nephrology, Boston Children's Hospital, Boston, MA; [2]University of Health Sciences, Lahore, Pakistan; [3]Fatima Jinnah Medical University & Sir Ganga Ram Hospital, Lahore, Pakistan.*

Background: Nephrolithiasis (NL) affects 1 in 11 individuals worldwide and causes high patient morbidity, frequent hospitalizations and surgical interventions. Pakistan resides within the Afro-Asian stone belt with a high NL prevalence of 12-15% (Rizvi *BJU Int* 89: S62, 2002). We have shown that a genetic cause in NL can be identified in about 11% of adult and 16-20% of pediatric stone formers (Halbritter *JASN* 26: 543, 2015; Braun *cJASN* 11: 664, 2016).

Methods: From 07/2014 to 12/2016, we recruited 242 families with NL, based on ultrasound finding of at least one renal stone, from 5 different tertiary care hospitals in Punjab, Pakistan, administrating a clinical survey that characterized age of onset, stone recurrence, and family history confirmed by their urologist and/or medical records. In 33 NL families, additional recruitments were made who had an average of 4 family members with at least one stone (range 1-28) and pedigrees were constructed.

Results: Our NL cohort consisted of 438 individuals (348 affected). The median age of onset of probands was 28 years (1-76 years, n = 123). 26% (32/123) presented at <18 years of age. There were 148 male and 94 female stone formers (M:F is 1.57:1). 50% (110/220) had >1 stone episode in their lifetime. Multiple stones at presentation were observed in 60.4% (134/222) of subjects. The family history of NL was positive in 48.6% (108/222) of cases. 50% (79/158) of subjects were born of consanguineous unions. 78.8% (26/33) of large multigenerational families for whom pedigrees were generated, exhibited multiple affected individuals in each generation, suggesting a strong genetic pattern of inheritance that is dominant or recessive with multiple consanguinity.

Conclusions: Here we describe a large cohort of Pakistani NL subjects with a high frequency of stone recurrence and familial cases. Pedigree analysis suggests a genetic causation. Whole exome sequencing to identify causative mutations in known or novel NL genes is underway.

TH-PO1089

Increasing Prevalence of Nephrolithiasis Correlating with an Increase in BMI – A Population Based Study of Israeli Children Hadas Alfandary,[4,5] Orly Haskin,[4] Miriam Davidovits,[3] Oren Pleniceanu,[2] Adi Leiba,[1] Amit Dagan.[4,5] *[1]None, Ramat Gan, Israel; [2]Pediatric stem cell research institute, Sheba medical center, Petach Tqiwa, Israel; [3]Schneider Children's Medical Center of Israel, Petah Tiqva, Israel; [4]Schneider Children's medical center of Israel, Petah Tiqva, Israel; [5]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.*

Background: Studies of adult and pediatric populations have shown a significant rise in nephrolithiasis incidence in recent decades. In adults, a clear association has been demonstrated between increasing BMI and a higher risk of kidney stone formation. Evidence is less conclusive for the pediatric population. This study examined the epidemiology of nephrolithiasis in the Israeli pediatric population during a 30-year period

Methods: We accessed data from the compulsory medical evaluations of 17 year olds in Israel, prior to enlistment for military service during 1980-2013. Candidates for the army with a history of stone disease were compared to those without such history.

Results: Of 1,908,893 candidates, 1691 reported a history of nephrolithiasis before the age of 18 years; this yields an average incidence rate of 88.6 in 100.000. During 1980-1995 the average reported incidence of nephrolithiasis was 69 cases per 100,000 candidates. From 1995, reported incidence increased by an average of 6% per year, and reached 120 per 100,000 during 2010-2012. This increased incidence was observed for both males and females, but was more prominent among males. The mean BMI of stone formers was higher than that of the control group (22.7±3.5 vs. 22.1±3.9 kg/m2 p<0.001). The odds ratio for nephrolithiasis in candidates with BMI 25-30 kg/m2 was 1.3 (1.1-1.5) and for BMI>30 kg/m2, it reached 1.7 (1.4-2.1) compared to the control group (table 1). The trend of increasing BMI among male candidates during 1995 to 2012 parallels the trend of increasing reports of nephrolithiasis during these years, r=0.71 p<0.01

Conclusions: In conclusion, our study is the largest population based epidemiological analysis on nephrolithiasis in children. We were able to show that in the last 20 years the incidence of nephrolithiasis in children has risen significantly. In our study population males had higher rates of nephrolithiasis than did females, with no change in the difference between the genders in the last 20 years. We report a correlation between increasing BMI and increasing prevalence of nephrolithiasis in children. More prospective observational and intervention studies are needed to examine a pathophysiological explanation linking high BMI with nephrolithiasis

TH-PO1090

Inflammatory Markers in Pediatric Nephrolithiasis Kirsten Kusumi,[1,4] John Ketz,[2,3] Andrew L. Schwaderer.[2,3] *[1]Akron Children's Hospital, Akron, OH; [2]Nationwide Children's Hospital, Columbus, OH; [3]The Ohio State University, Westerville, OH; [4]Northeastern medical university, Rootstown, OH.*

Background: Kidney stones associate with higher rates of heart attack/stroke and low bone mineral density/fractures. The mechanism of this association remains unknown; inflammation may be key. Our objective is to determine if pediatric stone formers have inflammation.

Methods: Urine was collected from 11 stone formers and 16 controls; 12-17 years old with radiographic evidence of stones. Exclusion criteria: metabolic acidosis, CKD II or >, immobilization, hyperlipidemia, hypertension, diabetes, inflammatory bowel disease, rheumatoid arthritis, or lupus. Urine was tested via a Mesoscale V-Plex Human Cytokine panel inflammation array. Levels were normalized to creatinine to control for concentration. Statistics by paired T-Test; p value <0.05 was significant.

Results: Five inflammatory markers were significantly increased in stone children: Il-13, Il-1B, MIP-1B, Il-12/Il-23p40 and Il-16.

Conclusions: This is the first evidence of inflammation in pediatric stone formers; this population is free of confounding diseases that are common in adults. Identification of inflammation in pediatric stone formers may be the first step in delineating the molecular mechanisms linking stone, bone and cardiovascular disease.

TH-PO1091

Hidden Sources of Sodium: The Role of Water Purification and Hypernatriuria in Kidney Stone Formation Adedeji O. Sodeinde, Samir A. Brahmbhatt, Juan C. Calle. *Cleveland Clinic Foundation, Cleveland, Ohio, Beachwood, OH.*

Background: One of the mainstays of dietary modification for prevention of calcium-containing stone formation is salt intake restriction. This is usually achieved by reducing dietary intake of high salt containing foods like smoked, cured or salted foods and canned goods. However the purity of water consumed is usually not addressed. The case presented here highlights the difference of well water, which is purified by reverse osmosis, compared to bottled water, which is purified by distillation, and their effect on urinary sodium levels.

Methods: A 49 year old male with a history that is significant for recurrent urinary tract infections due to uric acid and calcium oxalate stones was being followed up in the outpatient setting for stone prevention. Initial 24-hour urine studies were positive for

hypercalcemia, hyperphosphatemia and hypernatruria, all while consuming well water purified by reverse osmosis. He was advised to drink and cook with bottled water which is purified by distillation. After the change, his initial urine sodium of 305 mmol/d decreased to 208 mmol/d. As a confirmation, it increased to 241 mmol/d when he asked to use well water again and back down to 177 mmol/d once back on bottled water.

Results:

Conclusions: As sodium restriction is one of the main therapies in preventing calcium-containing stones, there should be increased awareness about the routes with which it can be consumed. Reverse osmosis, though an efficient and economical method of water purification, may leave more sodium content in the water than distillation which is the purest form of water purification. If hypernatriuria remains an issue in a patient with persistent stone formation and well controlled dietary sodium ingestion, there might be benefits to assessing the water consumed and its purification process.

TH-PO1092

Longitudinal Assessment of Health-Related Quality of Life (HRQoL) in Rare Kidney Stone Formers (RKSF) Frank Modersitzki,[3,2] Mary I. McIntosh,[1] David S. Goldfarb.[2] *[1]Mayo Clinic, Rochester, MN; [2]New York Harbor VAMC, New York, NY; [3]New York University School of Medicine, New York, AL. Group/Team: Rare Kidney Stone Consortium.*

Background: The assessment of HRQoL in RKSF is important for following disease course and evaluating treatment. Previously, using a non-disease specific instrument we showed that RKSF present differently, with the worst domain scores in cystinuria. These are the first follow-up data based on summary scores for adults in a cross-sectional comparison.

Methods: RKSF were enrolled from 4 RKSC registries: primary hyperoxaluria, cystinuria, Dent disease and APRTd. HRQoL is measured with the generic non-disease specific SF-36v2. Results are norm-based scores (NBS) based on US Standard Population (Domain score mean = 50). Group means < 47 indicate the presence of impaired functioning in associated dimension.

Results: We scored 545 surveys of the adult population at different time points, adjusted for the last stone event and compared the Physical and Mental Component Scores (PCS and MCS). We found the lowest PCS in Dent, and the highest in PH. The lowest MCS was found in cystinuria, the highest was found in PH. Low PCS indicate restrictions in self-care, physical, social and role activities; bodily pain, tiredness and poor rated health. Low MCS are associated with frequent psychological distress, social and role disability due to emotional problems, and poor rated health. Participants with cystinuria reported more stone events with related procedures than other RKSF (X^2 (9) 23.375, p=.005).

Conclusions: HRQoL in RKSF is influenced by stone events and can be assessed with a non-disease specific SF-36v2. Adjusting for time between the survey and last event allows for the interpretation of more meaningful HRQoL profiles. The time from the last stone event and related procedures affect HRQOL in RKSF significantly.

Funding: NIDDK Support

TH-PO1093

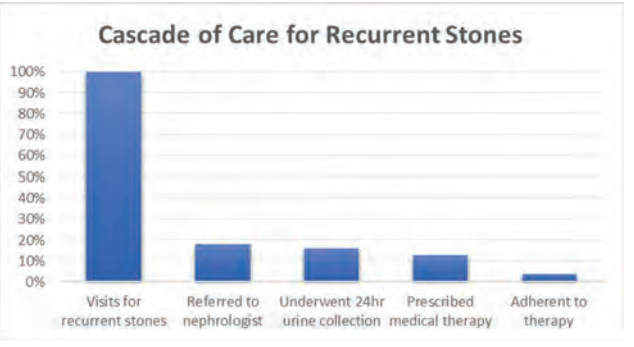
A Cascade of Care for Urinary Stone Disease (USD) Mansi Mehta, David S. Goldfarb. *Nephrology, NYU Medical Center, New York, NY.*

Background: USD is a preventable disease characterized by significant risk of recurrence. A "cascade of care" shows how many patients are lost to follow-up at diagnosis, referral, and treatment and is a useful tool in delivering HIV care. We can analyze our success, or failure, in the secondary prevention of kidney stones and retention of patients by constructing a cascade of care.

Methods: We abstracted data from observational studies to identify impediments to care of patients with USD

Results: In the US there are about 1.2 million ER visits per year. 37% of patients diagnosed with stones receive a follow-up consultation with a urologist and fewer see a nephrologist. Although 24h urine collection results may decrease stone recurrence rate, only 7.4% do them. 50% of patients experience a recurrent 2nd episode within 5 years. Of these 24% undergo a complete evaluation, 18% are referred to a nephrologist and 13.8% are prescribed medical therapy. 30% remain adherent to this pharmacotherapy. Of patients that are adherent 27% have lower odds of an ER visit than non-adherent patients. The cascade of care demonstrates that a low prevalence of patients receive proper follow-up. The impediments to the care of patients with kidney stones are (1) the unrecognized comorbidities of stones (2) disconnect between the ER and stone experts and (3) the low prevalence of 24h urine collections and prescribed medical therapy.

Conclusions: It is important to identify loci in the cascade of care that could represent opportunities to change practice. Prescription of appropriate fluid therapy and dietary changes and a referral to an expert should 1st be initiated by the ER. The low prevalence of 24h urine collections may reflect that the data are intimidating for some. Empiric therapy for calcium stones with fluids, diet, thiazides and potassium citrate may be a rational therapy to achieve significant supersaturation reductions and could be compared with targeted medical therapy in a randomized controlled trial. A greater effort needs to be devoted to develp a comprehensive flow of participants to retain patients in the cascade of care for USD.



TH-PO1094

Raman Chemical Imaging in Kidney Stone Analysis Vincent Castiglione, Pierre-Yves Sacré, Eric M. Ziemons, Etienne Cavalier, Philippe Hubert, Romy Gadisseur. *University of Liege, CHU Sart-Tilman, Liege, Belgium.*

Background: The structure of kidney stones might provide clinical useful information in addition to the stone composition. The Raman chemical imaging (RCI) is a new technology used for the production of two-dimensions maps of the constituents' distribution in samples. We aimed at determining the use of RCI in urinary stone analysis.

Methods: Twelve calculi were analyzed by RCI using a confocal Raman microspectrophotometer. They were selected according to their heterogeneous composition and morphology. Prior to the analysis, samples were sliced and milled in order to detect the nucleus of the stones and having a smooth surface. RCI was performed on the whole section of stones. Once acquired, the data were baseline corrected and analyzed by MCR-ALS. Results were then compared to the spectra obtained by Fourier Transform Infrared spectroscopy, the gold standard method for the determination of urolithiasis composition.

Results: RCI succeeded in identifying all the chemical components contained in each sample, including monohydrate and dihydrate calcium oxalate, anhydrous and dihydrate uric acid, apatite, struvite, brushite, whitlockite and ammonium urate. However, proteins couldn't be detected because of the huge autofluorescence background and the small concentration of these poor Raman scatterers. Carbapatite and calcium oxalate were correctly detected even when they represented less than 5 percent of the whole stones, allowing the detection of very small structures like Randall's plaques. Moreover, RCI provided the distribution of components within the stones. The nuclei were accurately identified, as well as thin layers of other components. Conversion of dihydrate to monohydrate calcium oxalate was correctly observed in the center of one sample.

Conclusions: RCI showed a good accuracy in comparison with infrared spectroscopy in identifying components of kidney stones. In addition, RCI is nondestructive enabling the storage of samples. This analysis was also useful in determining the organization of components within stones, which help locating constituents in low quantity, such as nuclei. However, this analysis is time-consuming, which makes it more suitable for research studies rather than routine analysis.

TH-PO1095

Unique Case Renal Failure with Severe Metabolic Alkalosis and Hypermagnesaemia Requiring Hemodialysis Ravi K. Thimmisetty,[1] Omer Alrawi,[1] Yahya M. Osman Malik,[2] Zeenat Y. Bhat.[1] *[1]Wayne State University, Detroit, MI; [2]Wayne State University Medical School, Detroit, MI.*

Background: We are presenting an interesting case of renal failure, severe metabolic alkalosis and symptomatic hypermagnesemia that required dialysis for correction.

Methods: 60-year-old African American male with history of metastatic sigmoid colon cancer s/p resection with end-colostomy and Hartmann's stump admitted with abdominal pain, vomiting and dyspnea. Other medical problems were hypertension

and left ureteral obstruction from colonic mass s/p left percutaneous nephrostomy tube. Home medications include flomax, protonix, over the counter Alka-seltzer. Admission vitals were -temperature 97.5 fahreinheit, blood pressure of 95/77, heart rate 98 beats per minute, respiratory rate 16 per minute and saturating 97% on 40% fiO2. On exam, he was cachectic, mild somnolent and dry. There was no edema. Laboratory values on admission revealed sodium 135, K is 4.7, chloride 80, bicarbonate >45, creatinine is 5.5 mg/dl (baseline Cr is of 1.5), calcium 9, magnesium 5.6 and phosphorus 9.9. ABG results showed pH is 7.59, pCO2 is 71, pO2 183, bicarb is 59.9. After volume resuscitation, patient became bradypnea, more somnolent and further worsening of respiratory status requiring intubation. Immediately hemodialysis was started for treating symptomatic hypermagnesemia and severe metabolic alkalosis in the setting of acute renal failure. Urine output started increasing. With 2 sessions of renal replacement therapy, patient improved significantly interims of mental status and biochemically. Creatinine down to 2.4 and pH is 7.37. All other electrolytes were normalized and patient was extubation. Severe alkalosis could have been multifactorial oral alkali intake and vomiting in setting of renal failure and week ago, had gastrograffin for small bowel obstruction which can sometime result in metabolic alkalosis.

Results:

Conclusions: Gastrograffin sometimes prepared with solutions containing alkali. Caution should be taken while giving these solutions containing alkali especially in the setting of renal failure. Concomitant severe metabolic alkalosis and hypermagnesemia can contribute to high mortality and poses a therapeutic challenge especially in the setting of renal failure. Renal replacement therapy is required in these cases.

TH-PO1096

A Case Report of Severe Hypokalemia Induced by Posaconazole Sreelatha Katari,[1] Daniel W. Coyne.[2] *[1]Barnes Jewish Hospital, St Louis, MO; [2]Washington University School of Medicine, St. Louis, MO.*

Background: Hypokalemia is not a very common electrolyte abnormality that has been recognized with azole antifungals.

Methods: A 66 year old man with history of Acute Myeloid Leukemia (AML) status post stem cell transplant in 6/2016 and chemotherapy presented with weakness, loss of appetite and failure to thrive on 1/2017. His current outpatient medications are tacrolimus, atovaquone, fluconazole, valacyclovir and budesonide. His blood pressure was 137/76 mm Hg, pulse 118, and BMI 24. Serum sodium 137 mmol/L, potassium (K) 4.1 mmol/L, chloride 107 mmol/L, urea nitrogen 9 mg/dL, and creatinine 0.85mg/dL. Chest and abdominal CT showed recurrence of AML, so he was started on dasatinib. On day 3 he developed neutropenic fever so he was started on vancomycin, meropenem and posaconazole. On day#11 he developed polyuria of more than 4L and profound hypokalemia. Serum K was 2.1 mmol/L, bicarbonate of 24 mmol/L, phosphorus 1.8 mg/dl and magnesium of 1.9 mmol/L. Urine analysis showed no glycosuria with a PH of 5. Urine K 42 mmol/L, sodium 105mmol/L, osmolality of 393 mOsm/kg, serum osmolality of 297mOsm/Kg, calculated potassium deficit daily was nearly 440meq. His workup showed renal wasting of potassium with no evidence of renal tubular acidosis. Given the timeline of events the electrolyte abnormalities were attributed to posaconazole, so it was discontinued and switched with micafungin. Over next 10 days his serum potassium promptly normalized and did not require further supplementation.

Results: Posaconazole has been increasingly used in the treatment of zygomycetes and asperillus infections in hematological malignancies. It works by inhibiting enzyme lanosterol 14α-demethylase leading to defective fungal cell wall and its death. Exact mechanism of hypokalemia is not clear but animal studies have shown inhibition of 11β-hydroxysteroid dehydrogenase type 2 dependent cortisol inactivation by posaconazole leads to excessive cortisol byproducts like cortisone, leading to apparent mineralocorticoid excess causing urine potassium losses and hypokalemia.

Conclusions: Posaconazole induced profound Hypokalemia is rare complication with only two other published cases in literature. So we suggest serum potassium be closely monitored in patient treated with posaconazole and the treatment is its prompt discontinuation

TH-PO1097

Severe, Symptomatic Hyponatremia in Patient Started on New Anti-VEGF Therapy Priyanka Jethwani,[2] Ari B. Geller.[1] *[1]None, West Hartford, CT; [2]Department of Medicine, University of Connecticut Health Center, Hartford, CT.*

Background: Hyponatremia is described as a side-effect of various chemotherapeutic agents. However severe, symptomatic hyponatremia can often limit use of those agents despite good overall outcomes.

Methods: This is the case of a 62-year-old Caucasian male with history of metastatic renal cell carcinoma with sarcomatoid features who presented to ED with one week of progressive fatigue, decreased energy levels, unsteadiness, lightheadedness and poor oral intake. Three weeks prior, he was started on Carbozantinib (new anti-VEGF agent) after failure of prior therapy. Fluid intake was at baseline and he was euvolemic on physical examination. Complete neurologic exam was normal despite known brain metastases. Labs revealed sodium 112 (131 two weeks ago), K 4.1, BUN 16, Cr 0.6, serum osm 229, urine osm 645, urine Na 125, TSH 2.42, AM cortisol 6.8, based on which he was thought to have SIADH. He was on long-term SSRI at a stable dose. Head imaging showed known metastatic brain lesions that had decreased in size. Despite fluid restriction, sodium dropped to 110. 3% hypertonic saline infusion was started, followed by torsemide and salt tablets. He underwent a co-syntropin stimulation test with inadequate response. However, he had been normotensive and did not receive corticoid therapy during hospitalization or at discharge. Despite this, sodium levels improved. Sodium was 133 at discharge and 137 two days later. He was challenged with dose-reduced Carbozantinib as outpatient, however, sodium dropped to 128 again within two weeks. Consequently, therapy was discontinued.

Results:

Conclusions: Carbozantinib was FDA approved in April 2016 for use in patients with advanced renal cell carcinoma who have failed prior anti-VEGF therapy. It improves progression-free survival in patients with advanced renal cell cancer with failure of prior therapy ($p<0.005$) when compared to Everolimus, which is standard of care. In the phase I trial of the drug, 2 out of 25 participants developed hyponatremia. In the phase II and phase III trials, hyponatremia was not reported. The most commonly seen adverse effects were diarrhea, fatigue, nausea, decreased appetite, palmar-plantar erythrodysesthesia syndrome, hypertension, vomiting, weight loss, and constipation. This is the first known reported case of severe, symptomatic hyponatremia secondary to SIADH attributed to carbozantinib therapy.

Ibuprofen Abuse – A Case of Rhabdomyolysis, Hypokalemia, and Hypophosphatemia with Drug Induced Mixed Renal Tubular Acidosis Shakuntala S. Patil,[1] Swathi Subramany,[3] Manisha Singh,[2] Michelle W. Krause.[3] *[1]UAMS, LITTLE ROCK, AR; [2]University of Arkansas For Medical Sciences, Little Rock, AR; [3]University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Drug induced renal tubular acidosis (RTA) can pose an uncommon, but important cause of severe potassium wasting and hypokalemia. We report a case of mixed RTA presentation causing severe hypokalemia and unexplained hypophosphatemia in a patient who consumed large amounts of Ibuprofen

Methods: A 48-year old previously healthy African American woman was admitted to the Medical intensive care unit with complaints of diffuse myalgias and severe generalized weakness for past few days. She was urinating a large volume (more than 2 liters) of dark colored urine with dysuria. Past history was significant for a distal tibio-fibular stress fracture 5 months ago complicated by delayed union. Her admission labs revealed severe hypokalemia, a non-anion gap metabolic acidosis with a positive urine anion gap (UAG) and a urine pH of 6.5 consistent with distal (Type I) RTA. She had spontaneous, non-traumatic rhabdomyolysis secondary to severe hypokalemia, but with hypophosphatemia resembling proximal RTA (Type 2). She had low 25-OH Vitamin D, mild transaminitis and E. coli cystitis. 24 hour urine potassium was 104 mmol(normal <30 mmol). Upon further questioning, the patient revealed that she had been taking about 20 tablets of Ibuprofen tablets daily (about 4 grams/day) for the past 3 months to control her ankle pain. She tested negative for Sjogren's disease, other autoimmune disorders and paraproteinemia. With continued aggressive fluid and electrolyte replacement, Vitamin D therapy and cessation of ibuprofen, her biochemistries normalized within 5 days. Repeat serum chemistries were noted to be normal in 1 week follow up in clinic.

Results:

Conclusions: Our patient developed severe but reversible hypokalemia with a mixed proximal and distal RTA like picture, most likely due to Ibuprofen use. A few cases have been reported of Ibuprofen preparations causing either proximal or distal type RTA. This is thought to be related to its inhibitory effect on Carbonic Anhydrase II. This case highlights the potential of Ibuprofen to cause type 3 RTA like picture, or a mixed type 1 and 2 RTA with life threatening hypokalemia to the extent of causing rhabdomyolysis.

TH-PO1099

Transient Hyporeninemic Hypoaldosteronism with Renal Salt Wasting: An Unusual Presentation Huda Arif,[1] David J. Leehey.[2] *[1]Loyola University, Chicago, IL; [2]Loyola University Medical Center, Oak Park, IL.*

Background: We are presenting a case of transient hypoaldosteronism with hyporeninemia presenting with orthostatic hypotension and renal salt wasting without cerebral disease. Adrenal insufficiency was ruled out by normal ACTH and cortisol levels

Methods: A 61-year-old gentleman with no significant medical history except for mild essential hypertension was referred to the renal clinic after multiple visits to the emergency room for symptomatic orthostatic hypotension requiring isotonic saline infusion. Evaluation in clinic showed orthostatic hypotension with an intact autonomic response. He reported polyuria with approximately 3-4L daily urine output. Laboratory evaluation revealed persistent hypoaldosteronism with plasma aldosterone levels <1 ng/dL, low plasma renin activity (0.23-1.10 ng/mL/h), and normal ACTH and cortisol levels. He had normal renal function and normal plasma potassium and total carbon dioxide levels. His plasma sodium levels were generally normal with occasional mild hyponatremia noted. He had persistently elevated urinary sodium concentrations (> 20 mmol/L) in the face of hypotension, and 24h urine sodium and aldosterone excretions were 164 mg and < 1 mcg, respectively. He was treated with fludrocortisone 0.1 mg daily with marked improvement in orthostatic symptoms. Over the course of years, his renin and aldosterone normalized and fludrocortisone was tapered to minimal dose. Attempts to stop fludrocortisone resulted in recurrence of symptoms.

Results:

Conclusions: Aldosterone causes reabsorption of sodium and chloride and excretion of potassium and hydrogen ions in the distal convulated tubule. Selective or isolated aldosterone deficiency can result from a deficiency in renin secretion or decreased adrenal synthesis. Hyporeninemic hypoaldosteronism is most common in patient with mild to moderate renal insufficiency due to diabetic nephropathy or chronic interstitial nephritis. It can also occur with acute GN and in patients taking NSAID and CNI. The characteristic electrolyte findings of this disorder are hyperkalemic hyperchloremic acidosis and occasionally mild hyponatremia, usually in the setting of impaired renal function. This

case illustrates the importance of considering the diagnosis of hypoaldosteronism in adult patients with symptoms and signs of renal salt wasting in the absence of hyperkalemic hyperchloremic acidosis.

TH-PO1100

Hyperkalemia and Megestrol Acetate: Related? Nikhil Agrawal,[1] Ilka A. Netravali,[1] Shimontini Mitra,[2] Stewart H. Lecker,[1] Melanie P. Hoenig.[1] *[1]Beth Israel Deaconess Medical Center, Brookline, MA; [2]None, Brookline, MA.*

Background: Megestrol acetate (MGA) is a synthetic progestin widely used as an appetite stimulant for patients with cancer. MGA binds to the glucocorticoid receptor with nearly twice the affinity as cortisol and can cause symptoms of glucocorticoid excess while suppressing endogenous glucocorticoid production. We report a case of concomitant mineralocorticoid deficiency in a patient taking MGA with evidence of glucocorticoid deficiency.

Methods: A 51-year-old woman with allogenic stem cell transplant 2 years prior for AML and subsequent relapse was admitted for a line infection. She was noted to have a refractory hyperkalemia a week after admission that required repeated interventions with insulin, dextrose, IV fluids, furosemide, and sodium polystyrene. She reported 3 cups of tomato juice daily and a history of hypokalemia. Medications: atovaquone, ciprofloxacin, daptomycin, famotidine, folic acid, ondansetron, posaconazole, valacyclovir, cefepime and allopurinol. Two days prior to admission, her MGA was increased from 400 to 800mg daily. She denied fatigue, weakness, or hyperpigmentation. She was normotensive and her examination was unremarkable. She had pancytopenia without evidence of tumor lysis. Serum chemistry showed Na 139, K 6.2, Chloride 110, Bicarb 21, BUN 21, Cr 0.8 Early am cortisol: 0.8 mg/dl (increased to 8.8mg/dl at one hour with high dose ACTH stimulation). ACTH <5 pg/mL (6-50). Renin 2.79 ng/mL/hr (0.25-5.82), Aldosterone 1.0 ng/dL (supine 3-16). A low potassium diet was begun but potassium remained high. Urine potassium excretion was low. MGA discontinued, and fludrocortisone and hydrocortisone were begun. Potassium normalized within 24 hr. Within 5 days, she became hypokalemic, and fludrocortisone was discontinued.

Results:

Conclusions: This is the first reported case of hyperkalemia in association with MGA. Although MGA is a well-known cause of adrenal insufficiency, this is usually restricted to the glucocorticoid axis. Here low ACTH level suggests secondary adrenal insufficiency which is typically not associated with defects in the mineralocorticoid axis. Yet low aldosterone level in the setting of hyperkalemia without suppression of renin and with reduced renal potassium excretion is consistent with mineralocorticoid deficiency. Since this resolved with discontinuation of MGA, this suggests that MGA may have an additional effect on the mineralocorticoid axis.

TH-PO1101

An Unusual Case of Peripheral Edema Due to Suspected Liddle's Syndrome Sadeem Ali,[1] Sri jegan Radhakrishnan,[1] Reginald I. Obi.[2] *[1]ECU, Greenville, NC; [2]ECU Physicians Nephrology, Greenville, NC.*

Background: Liddle's syndrome is a rare autosomal dominant disease affecting epithelial sodium channels in which there is a primary increase in collecting tubule sodium reabsorption and usually associated potassium wasting. Patient usually presents with hypertension, hypokalemia, and metabolic alkalosis, with an overall clinical picture mimicking mineralocorticoid excess. However, its presentation with a chief complaint of peripheral edema has not been reported to our knowledge.

Methods: We present a 47 years old female who has been hypertensive since the mid thirties of her age. She came for management of hard to control generalized edema, mostly in her lower extremities, for the last three years. No cardiac or liver etiology identified. She had tried several diuretics including hydrochlorothiazide, furosemide, spironolactone and was then on chlorthalidone 50 milligrams daily. She had been profoundly hypokalemic while on diuretics and requiring 80 milli equivalents daily replacement of potassium chloride. Her labs also showed metabolic alkalosis and relatively high sodium levels. We suspected a potassium wasting syndrome. After holding chlorthalidone for three days, with continued potassium replacement, her trans tubular potassium gradient was calculated at 7.9 confirming urinary potassium wasting. Her plasma aldosterone to renin activity ratio was 13.2, making primary hyperaldosteronism unlikely. We started her on amiloride as 5 mg twice a day due to clinical suspicion of Liddle's syndrome. After three weeks, her swelling has completely resolved and blood pressure also normalized. Her potassium supplementation and all antihypertensive medications were discontinued except for a reduced dose of amiloride. Her labs now show normal potassium and bicarbonate levels. Genetic testing for Liddle's syndrome has not been done in this patient because it will not change management.

Results:

Conclusions: Refractory peripheral edema could be an unusual presentation of this rare but treatable condition. Paying close attention for pathophysiologic clues of Liddle's syndrome will result in more specific management for subsets of patients presenting with edema, refractory to the commonly used loop and thiazide diuretics.

TH-PO1102

Relationship between Serum Potassium and Dose Modification and Discontinuation of Renin-Angiotensin-Aldosterone System Inhibitors in UK Patients with Heart Failure Lei Qin,[4] Philip McEwan,[2] Marc L. Evans,[3] Laura Horne,[1] Susan Grandy.[4] *[1]Global Medical Affairs, AstraZeneca, Gaithersburg, MD; [2]Centre for Health Economics, Swansea University, Singleton Park, United Kingdom; [3]Department of Medicine, University Hospital Llandough, Cardiff, United Kingdom; [4]Health Economics and Outcomes Research, AstraZeneca, Gaithersburg, MD.*

Background: Renin-angiotensin-aldosterone system inhibitors (RAASi) may be prescribed to heart failure (HF) patients, but discontinued due to concerns over hyperkalemia (HK). The real-world usage of RAASi in primary care was evaluated in UK HF patients with a range of serum potassium (K+) levels.

Methods: A retrospective observational study was conducted using primary care data from the Clinical Practice Research Datalink from Jan 2006 to Dec 2015. Patients (≥18 years) were included if they had a first diagnosis of HF during the study period. RAASi discontinuation was defined as a ≥90-day gap without a prescription using the medicines possession ratio, and dose reduction as a decrease to prescribed daily dose between successive prescriptions. Incidence rate ratios (IRRs) for discontinuation and odds of dose reduction were tested for association with time-updated serum K+ using Poisson and Logistic Generalized Estimating Equations respectively after adjustment for demographic and clinical covariates.

Results: Of the total HF population at baseline (n=23,541), 60.9%, 15.1%, 23.4% and 0.04% were taking angiotensin-converting enzyme inhibitors, angiotensin-II receptor blockers, mineralocorticoid receptor antagonists and renin inhibitors, respectively. A total of 7,527 RAASi discontinuations were estimated in 68,133 patient-years of follow-up, a reference rate of 110 discontinuations per thousand patient-years. A J-shaped association between adjusted IRRs and serum K+ was observed, with high serum K+ (≥6.0 mEq/L) being strongly associated ($p<0.001$) with incidence of discontinuation (Figure). Serum K+ ≥5.5 mEq/L was associated with an increased odds of dose reduction (OR=1.33, p=0.035) versus Serum K+ < 5.5 mEq/L.

Conclusions: Physicians were more likely to discontinue RAASi or reduce dose in HF patients with HK. Further research is warranted to determine the clinical impact of RAASi dose modification and discontinuation in the treatment of HK in the UK.

TH-PO1103

Relationship between Serum Potassium and Dose Modification and Discontinuation of Renin-Angiotensin-Aldosterone System Inhibitors in UK Patients with CKD Lei Qin,[4] Philip McEwan,[2] Marc L. Evans,[3] Eirini Palaka,[1] Susan Grandy.[4] *[1]Health Economics and Outcomes Research, AstraZeneca, Cambridge, United Kingdom; [2]Centre for Health Economics, Swansea University, Singleton Park, United Kingdom; [3]Department of Medicine, University Hospital Llandough, Cardiff, United Kingdom; [4]Health Economics and Outcomes Research, AstraZeneca, Gaithersburg, MD.*

Background: Renin-angiotensin-aldosterone system inhibitors (RAASi) may be prescribed to CKD patients, but discontinued or dose reduced due to concerns about hyperkalemia (HK). The real-world usage of RAASi was evaluated in UK CKD patients with a range of serum potassium (K^+) levels and severities of renal dysfunction.

Methods: A retrospective observational study was conducted using primary care data from the Clinical Practice Research Datalink from Jan 2006 to Dec 2015. Patients (≥18 years) were included if they had a first diagnosis of CKD stage 3 or higher during the study period. RAASi discontinuation was defined as a ≥90-day gap without a prescription using the medicines possession ratio, and dose reduction as a decrease to daily dose between successive prescriptions. Incidence rate ratios (IRRs) for discontinuation and odds of dose reduction were tested for association with time-updated serum K^+ using Poisson and Logistic Generalized Estimating Equations respectively adjusting for demographic and clinical covariates, including eGFR.

Results: Of the total CKD population at baseline (n=144,388), 37.6% were taking angiotensin-converting enzyme inhibitors, 14.7% were taking angiotensin-II receptor blockers, 2.4% were taking mineralocorticoid receptor antagonists, and 0.04% were taking renin inhibitors. A total of 53,587 RAASi discontinuations were estimated in 704,830 patient-years of follow-up. A J-shaped association between adjusted IRRs and serum K^+ was observed, with high serum K^+ (≥6.0 mEq/L) being strongly associated with

incidence of discontinuation (Figure). This pattern was consistent across eGFR strata. Serum K^+ ≥5.5 mEq/L was associated with increased odds of dose reduction (OR=2.24, p<0.001) versus Serum K^+ < 5.5 mEq/L.

Conclusions: Physicians were more likely to discontinue RAASi or reduce dose in CKD patients with HK. Further research is warranted to determine the clinical consequences of RAASi dose modification and discontinuation in the management of HK in the UK.

Metformin-Associated Lactic Acidosis in a Patient with Normal Renal Function Naushaba Mohiuddin,[2] Jian Li.[1] *[1]None, Detroit, MI; [2]Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Background: INTRODUCTION Metformin -associated lactic acidosis (MALA) in patients without renal impairment is an infrequent serious complication. In patients in whom development of renal dysfunction is anticipated, monitoring renal function more frequently and discontinuing Metformin at early renal impairment is crucial. We present a case of severe lactic acidosis in a patient who had no contraindication to Metformin prescription.

Methods: Case: Patient is a 58 year old female presented with abdominal pain and diarrhea. She has history of Diabetes, HTN, with prior normal renal function on Metformin, Lisinopril and Lasix. In Emergency department patient was hypotensive. She was started on Vasopressors and given IV fluids. ABGs showed severe high an ion gap acidosis, acute renal failure and Lactate level of 11. Despite aggressive IV hydration, her Lactate trended up to 17. Braod spectrum antibiotics started. She was admitted to ICU. Acute abdomen, septic and cardiogenic shock were ruled out. On further review, was noted, patient was admitted at outside hospital 3 weeks ago, with diarrhea, had negative work up. At that time she had CT abdomen with IV contrast. Metformin was held prior and 4 days after. Metformin was resumed on discharge. A week later, she had CTA of abdomen. Baseline creatinine was around 0.7mg/dl and GFR 88ml/min/1.73m2. Patient was started on sustained low-efficiency dialysis with regional citrate anticoagulation (SLED RCA), for MALA. A progressive recovery was observed, with initially weaning off pressors, lactate level improving and later complete recovery of her renal function.

Results:

Conclusions: Conclusion: 1. Identifying patients who are on metformin, at risk to develop Prerenal azotemia, or alteration in renal function can potentially prevent this life threatening condition.2. Presence of elevated lactic acidosis in a diabetic patient on metformin, even with baseline normal renal function, should trigger to consider MALA.

TH-PO1105

Low K, Not OK: Distal Renal Tubular Acidosis Associated with Autoimmune Thyroiditis Timothy Yen,[1] Roberto L. Collazo-Maldonado.[2] *[1]Internal Medicine, Methodist Dallas Medical Center, Dallas, TX; [2]Division of Nephrology, Methodist Dallas Medical Center, Dallas, TX.*

Background: Profound hypokalemia can present with hypokalemic paralysis. This is a rare but potentially fatal condition. Potassium wasting secondary to renal tubular acidosis (RTA) is a common cause of severe hypokalemia. RTAs are associated with multiple systemic diseases including autoimmune disorders and endocrinopathies.

Methods: A 43 year old Hispanic woman with a previous history of calcium phosphate renal stones presented to the ED after she awoke with generalized limb paralysis and inability to rise from bed. She denied having similar symptoms in the past, and review of symptoms was negative. She denied having a history of family illness, or using alcohol, tobacco or drugs. The patient did not take any medications or herbal supplements. Vital signs were normal on admission except for sinus bradycardia of 49 BPM. On examination, she had 3/5 strength in all extremities but normal sensation and reflexes. Her blood and urine investigations were suggestive of a distal RTA. The patient had a normal anion gap metabolic acidosis (pH 7.236, HCO3 15 mmol/L), severe hypokalemia (K 1.8 mmol/L), with normal serum calcium and magnesium levels. Urine studies revealed a urine pH of 7.5 and anion gap of 31 (Cl 90 mmol/L; K 15 mmol/L; Na 106 mmol/L). The patient was given IV and oral potassium replacement before being started on a bicarbonate infusion. By morning, her serum potassium level had risen to 3.6 mmol/L and her weakness had completely resolved. Investigations into the etiology of her RTA were performed. ESR and CRP levels were normal, and screening for ANA and Anti-SSA/SSB was negative. Thyroid function tests ordered to investigate her sinus bradycardia revealed subclinical hypothyroidism (TSH 14.0 uIU/L, free T4 1.10 ng/dL) with an elevated anti-thyroid peroxidase antibody (2729 IU/mL). The patient was discharged in stable condition and placed on a regimen of 1.6 mcg/kg/day of levothyroxine with oral bicarbonate and potassium supplements.

Results:

Conclusions: This is a case of a previously healthy middle aged woman who presented with hypokalemic paralysis caused by a distal RTA. The patient lacks any classical risk factors for acquired RTA except for elevated anti-thyroid peroxidase antibody. Internists and nephrologists must be aware of this rare but documented association between autoimmune thyroiditis and distal RTA.

TH-PO1106

Associations between Serum Potassium and Clinical Outcomes in Patients with CKD in a Real World Setting Philip McEwan,[2] Lei Qin,[4] Marc L. Evans,[3] Laura Horne,[5] Eirini Palaka,[1] Susan Grandy.[4] *[1]Health Economics and Outcomes Research, AstraZeneca, Cambridge, United Kingdom; [2]Swansea Centre for Health Economics, Swansea University, Singleton Park, United Kingdom; [3]Department of Medicine, University Hospital Llandough, Cardiff, United Kingdom; [4]Health Economics and Outcomes Research, AstraZeneca, Gaithersburg, MD; [5]Global Medical Affairs, AstraZeneca, Gaithersburg, MD.*

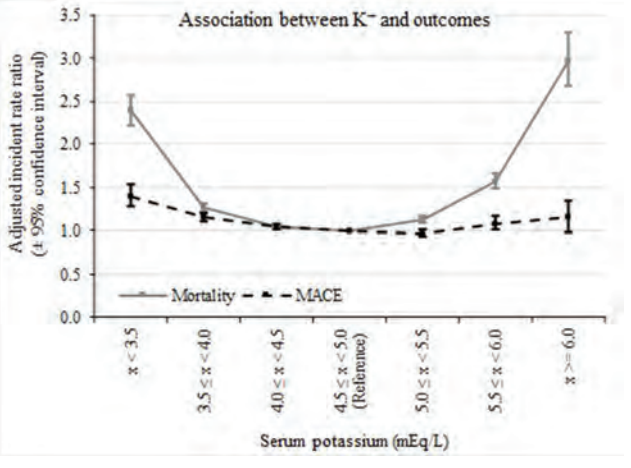
Background: The associations between serum potassium (K^+) and rates of mortality and serum K+ and rates of major adverse cardiovascular events (MACE) have previously been characterised using US healthcare data. This study assessed the generalisability of this finding and developed risk equations using UK real-world data on a cohort of chronic kidney disease (CKD) patients.

Methods: A retrospective observational study was conducted using the Clinical Practice Research Datalink from Jan 2006 to Dec 2015. Patients (≥18 years) with a first diagnosis of CKD stage 3 or higher during the study period were analysed with clinical outcomes of interest included all-cause mortality and MACE (arrhythmia, heart failure, myocardial infarction, stroke). Incidence rate ratios (IRRs) associated with time-updated serum K^+ were estimated using Generalized Estimating Equations adjusted for a broad range of demographic and clinical covariates.

Results: Analysis included 144,388 CKD patients with a mean follow-up of 4.9 years. Patients were predominantly female (60.4%) with a mean age of 73.7 years and mean eGFR of 49.7 mL/min/1.73m^2. Baseline ischemic heart disease, stroke, myocardial infarction and peripheral vascular disease were present in 11.5%, 6.6%, 3.4% and 2.6% of patients, respectively. There were 34,602 deaths and 71,607 MACE during the study period. U-shaped associations were observed between serum K^+ and IRRs for mortality and MACE (Figure), with low (<4.5 mEq/L) and high (≥5.5 mEq/L) K^+ concentrations being positively associated with incidence.

Conclusions: A real-world analysis of UK patients with CKD indicated associations between hypo- and hyperkalemia with risk of mortality and MACE. The observed U-shaped trends were consistent with previously reported US real-world studies.

Funding: Commercial Support - AstraZeneca



TH-PO1107

Prevalence of Hyperkalemia in Patients with ESRD Undergoing Hemodialysis Saravanan Balamuthusamy, Alagarsamy l Reddi, Sankarapandian Ponnaih, Ranjit K. Dhelaria, Balamurugan Sankarapandian. *Texas Research Institute and PPG Healthcare PA, Fort Worth, TX.*

Background: Adverse cardiovascular events are the most common reason for mortality and morbidity in patient with ESRD. Hyperkalemia is a well-known etiology of cardiac arrhythmias in ESRD and non-ESRD patients. We have analyzed the prevalence of hyperkalemia in prevalent hemodialysis patients dialyzed 3 times a week in an outpatient dialysis clinic.

Methods: Retrospective analysis of serum potassium levels in ESRD patients undergoing hemodialysis in 9 dialysis clinics. pre-dialysis Potassium levels were measured as per dialysis protocol. Based on serum potassium levels, patients divided into four groups i) Hypokalemia (Serum K level less than 3.5) ii) normokalemia (Serum K level between 3.6 to 5.4 mmol/lit), iii} moderate hyperkalemia (Serum K level between

5.5 to 5.9 mmol/lit), and iv) severe Hyperkalemia (Serum K level more than 6.0 mmol/lit). Institutional approval was obtained to review charts.

Results: 1022 ESRD patients undergoing hemodialysis were included in the analysis. 2.25% of these patients had severe and 6.75% had moderate hyperkalemia; 2.5% had hypokalemia and the remaining 88.5% had normokalemia.

Conclusions: We have estimated that 9% of HD patients either had moderate or severe hyperkalemia and 2.5% had hypokalemia. The risk of adverse cardiac events is greater when there are rapid fluctuations in serum K which is more likely to occur in hyperkalemic patients dialyzed with 2K baths. Ability to auto-titrate dialysis baths based on serum potassium levels might help mitigate the rapid fluctuations in serum potassium in hyperkalemic dialysis patients.

TH-PO1108

A Cause for Concern: RAAS Inhibitors Are Associated with Significant Risk of Hyperkalemia in Patients with Chronic Heart Failure: A Meta-Analysis Ankur Jain, Abhilash Koratala, Hesham Nasser, Amir Kazory. *University of Florida, Gainesville, FL.*

Background: Inhibitors of renin-angiotensin-aldosterone system (RAAS) are widely used in patients with chronic heart failure (HF). We previously reported that the impact of angiotensin converting enzyme inhibitors (ACE-I) and angiotensin receptor blockers (ARB) on renal function is distinct from that of downstream blockers of the RAAS (i.e. mineralocorticoid receptor antagonists [MRA]). In this study, we sought to evaluate the effect of these agents on the incidence of hyperkalemia in HF.

Methods: Articles cited in PubMed, EMBASE, and Cochrane database from 1987 to 2017 using key words: "heart failure", "angiotensin-converting enzyme", "angiotensin receptor blocker", and "mineralocorticoid receptor antagonist" were searched and those randomized controlled trials (RCTs) that addressed the impact of RAAS inhibition in HF were identified. Hyperkalemia, defined as serum potassium level >5.5 mmol/L, was considered the primary endpoint. A meta-analysis was performed. Mantel-Haenszel random-effects model was used to calculate risk ratios (RRs) with 95% confidence intervals (CIs).

Results: A total of 3389 studies were selected after extensive database search. After excluding duplicate and non-randomized trials, 14 RCTs with 29,433 participants were found eligible for analysis. Compared to placebo, ACE-I/ARB significantly increased the risk of hyperkalemia (RR 2.31 CI 1.77-3.02, p≤0.01). Addition of MRA to ACE-I/ARB further increased the risk (RR 2.19 CI 1.51-3.16, p≤0.01). When evaluated for severe hyperkalemia (i.e. serum potassium levels > 6 mmol/L), ACE-I/ARB increased the risk compared to placebo (RR 1.59, CI 1.13-2.25, p=0.01), and addition of MRA to ACE-I/ARB further increased it (RR 1.63 CI 1.13-2.35, p=0.01).

Conclusions: In patients with HF, ACE/ARB therapy increases the risk of hyperkalemia by more than two folds and downstream addition of MRA increases the risk further. RAAS inhibitors have been shown to improve outcomes including mortality in this patient population. Future studies are needed to evaluate therapeutic strategies (e.g. newer potassium binders) for prevention of hyperkalemia to avoid underutilization of RAAS inhibition.

TH-PO1109

Workup of Unexplained Renal Hypophosphatemia Anneke Bech,[3] Ewout J. Hoorn,[1] Robert Zietse,[1] Jack F. Wetzels,[2] Tom Nijenhuis.[4] *[1]Erasmus Medical Center, Rotterdam, Netherlands; [2]Radboud University Medical Center, Nijmegen, Netherlands; [3]Radboud University Nijmegen Medical Center, Nijmegen, Nijmegen, Netherlands; [4]Radboud university medical center, Lent, Netherlands.*

Background: Hypophosphatemia can be caused by renal phosphate loss. Increased renal phosphate loss can be inherited or acquired. The most common causes of acquired renal hypophosphatemia are medication, Fanconi syndrome, hyperparathyroidism and tumor induced osteomalacia (TIO). The clinical picture of these disorders varies widely and is non-specific. An increasing number of patients with unexplained renal hypophosphatemia is being referred to our clinics.

Methods: We retrospectively evaluated all patients who were referred in the period of 2013-2017 because of unexplained renal hypophosphatemia in two university hospitals in the Netherlands (N=13).

Results: The median age was 51 years and ten patients were male. They did not show any other signs of tubulopathy and did not use drugs known to be associated with hypophosphatemia. Baseline characteristic are shown in table 1. We performed an ^{111}Indium-pentetreotide SPECT/CT in 5 patients and a ^{68}Ga-DOTA-TOC PET/CT scan in 3 patients. One of these scans showed an increased uptake suggestive of TIO. Genetic testing, performed in all patients, did not show a mutation in genes that are known to be associated with renal phosphate wasting (*DMP1, FGF23, FGFR1, GALNT3, PHEX, SLC34A1, SLC34A3, SLC9A3R1*).

Conclusions: We have evaluated a group of patients with unexplained renal hypophosphatemuia. Despite extensive and expensive additional investigations, the cause of renal phosphate loss remained unexplained in the majority of patients. The pretest probability of finding a phosphaturic hormone producing tumor on a scan with radiolabeled somatostatin analogs or to find a mutation with genetic analysis in a patient with aspecific complaints and an (inappropriately) normal FGF23 level is low. We therefore advise not to perform scans and genetic analyses as a standard workup in these patients.

Table 1 Baseline characteristics

	Median	Range	Reference value
Serum phosphate (mmol/l)	0.61	0.36-0.77	0.80-1.40
TmP/GFR (mmol/l)	0.50	0.38-0.55	0.80-1.40
Serum creatinine (µmol/l)	81	53-142	60-110
PTH (pmol/l)	5.2	3.2-8.7	1.0-6.5
25OHD (nmol/l)	71	40-135	>50
cFGF23 (RU/ml)	92	53-202	<125

TH-PO1110

Correcting Serum Potassium ([K]) in Critical Care Philip Goldwasser,[2] Andrea Roche-Recinos,[1] Robert H. Barth.[2] *[1]SUNY Downstate, Brooklyn, NY; [2]VA NY Harbor Healthcare System, Brooklyn, NY.*

Background: High platelet counts (PLT) positively bias serum [K] in chemistry panels (C_K). Because the C_K assay uses indirect potentiometry, it should also be positively biased by low total protein (TP), common in critical care, but this is unproved. Neither bias should affect [K] measured in gas panels (G_K) in whole blood anticoagulated with electrolyte-balanced heparin. Since even a subtle bias in C_K might be important at a decision limit, we sought to derive a practical correction for commonly seen values of PLT on C_K - G_K (ΔK), as well as to confirm TP bias.

Methods: In our critical care database (Clin Biochem 2017), we found 710 patients who had C_K, G_K, TP, and PLT obtained < 20 min. apart (median: 4 min). We excluded 17 cases with PLT ≥500 (units:10^9/L), as such values (i) are already known to bias C_K, and, (ii) being extreme, might skew the estimated effect of more usual PLT values. The independent effects of PLT and TP upon ΔK were estimated with multivariate methods.

Results: Mean values (±SE) were: PLT, 209±3.5 [range: 4-497]; TP, 6.5 ±0.04 g/dL [2.1-10.1]; ΔK, 0.27± 0.01 mEq/L [-1.8 to +2.5; 21% of values ≥ 0.5]. PLT correlated with both ΔK (r=0.13 $p<10^{-3}$) and TP (r= 0.19 $p<10^{-6}$). TP and ΔK didn't correlate (r=-0.06 p=0.11), possibly the result of confounding by PLT. No nonlinear effects of PLT category (TABLE) on ΔK were detected by ANOVA with polynomial contrast. By multiple linear regression, ΔK rose 0.053±0.014 mEq/L with each PLT rise of 100 ($p=10^{-4}$) and by 0.026±0.011 (p=0.02) with each 1 g/dL fall in TP (model adj. R^2=.024).

Conclusions: The accuracy of C_K can be improved simply with a 0.05 mEq/L reduction per 100 PLT rise. The effect of TP on C_K is minor, but, proportionally, the same as its effect on serum [Na]. Much of the variation in C_K relative to G_K is unexplained.

Funding: Veterans Affairs Support

Mean Values by PLT Category

PLT Category (mean)	N	CK	GK	ΔK (% cases ≥ 0.5)	TP
0-99 (65)	65	4.24	4.00	.238 ± .031 (17%)	5.9

Post-Hyperkalemia Prescription Patterns for Renin–Angiotensin–Aldosterone System Inhibitors (RAASis) in England Laura Horne,[1] Robert J. LoCasale,[1] Sharon Maclachlan,[2] Marvin V. Sinsakul,[1] James B. Wetmore.[3] *[1]AstraZeneca, Gaithersburg, MD; [2]Evidera, London, United Kingdom; [3]Hennepin County Medical Center, Minneapolis, MN.*

Background: It is unclear how physicians may adjust RAASi prescriptions for patients with hyperkalemia (HiK; elevated serum potassium [K^+]). We evaluated whether RAASi use is modified after incident HiK in England.

Methods: A retrospective cohort analysis of the linked Clinical Practice Research Datalink (CPRD) and Hospital Episode Statistics (HES) databases identified RAASi prescription changes after HiK. Patients (≥18 years) with an incident HiK event (first measurement of K^+ ≥5.0 mmol/L or HiK diagnosis code) using RAASis from 2009–2013 were included. Change in next RAASi prescription was defined as dose increase, augmentation with diuretic, no change, switch to other RAASi, dose decrease, or interruption. HiK severity was defined as K 5.0–≤5.5 (K^+ 5.0–≤5.5 mmol/L or CPRD diagnosis code with no lab results); K 5.5–≤6.0 (K^+ >5.5–≤6.0 mmol/L); or K >6.0 (K^+ >6.0 mmol/L or HES diagnosis code, regardless of K^+). Frequencies of post-HiK RAASi use were calculated overall, by clinical comorbidities, and by HiK severity.

Results: An HiK event was experienced by 59,465 RAASi users. Most patients (74.6%), including most with CKD (72.2%), continued the same RAASi drug/dose after HiK, even after K 5.5–≤6.0 (67.9%) and K >6.0 (45.6%). Augmentation with diuretics was uncommon, occurring in only 4.8% of the overall cohort, 10.4% of patients with heart failure (HF) and 13.0% of patients with K >6.0. Patients with HF more often switched RAASi and patients with K >6.0 more often interrupted treatment (**Table**).

Conclusions: Most patients continued the same RAASi drug and dose after incident HiK, even with K >6.0 and when renal function was likely reduced; addition of diuretics was uncommon. Whether this represents an optimal HiK treatment strategy needs further study.

Maintained Efficacy and Safety of Sodium Zirconium Cyclosilicate for Hyperkalemia: 12-Month, Open-Label, Phase 3 Study Steven Fishbane,[8] Pablo E. Pergola,[15] David K. Packham,[6] Simon D. Roger,[9] Edgar V. Lerma,[2] Javed Butler,[11] Stephan Von haehling,[12] Bruce S. Spinowitz,[1] Geoffrey A. Block,[5] Scott H. Adler,[13] Bhupinder Singh,[7,14] Philip T. Lavin,[4] Peter A. McCullough,[3] Mikhail Kosiborod.[10] *[1]New York-Presbyterian/Queens and Weill Medical College of Cornell University, Flushing, NY; [2]UIC/ Advocate Christ, Oak Lawn, IL; [3]Baylor University Medical Center, Dallas, TX; [4]Boston Biostatistics Research Foundation, Framingham, MA; [5]Denver Nephrology, Denver, CO; [6]University of Melbourne, Melbourne, NSW, Australia; [7]ZS Pharma Inc., part of AstraZeneca, San Mateo, CA; [8]Hofstra Northwell Health School of Medicine, Great Neck, NY; [9]Renal Research, Gosford, NSW, Australia; [10]Saint Luke's Mid America Heart Institute, Kansas City, MO; [11]Stony Brook University, Stony Brook, NY; [12]University of Göttingen Medical Centre, Göttingen, Germany; [13]AstraZeneca, Gaithersburg, MD; [14]University of California, Irvine, Irvine, CA; [15]Renal Associates PA, San Antonio, TX.*

Background: We evaluated sodium zirconium cyclosilicate (ZS), an oral, highly selective potassium (K) binder for hyperkalemia over 12 mo.

Methods: This international, multicenter, open-label, single-arm phase 3 trial enrolled 751 outpatients (≥18y) with K≥5.1mEq/L. In acute phase (AP), patients (pts) received 10g ZS TID for 24–72h until K ≤5.0mEq/L by point-of-care device (iSTAT). 746 pts with K 3.5-5.0mEq/L by iSTAT entered an extended phase (EP) and received ZS titrated to K ≤5.0mEq/L (5g to start, min 5g every other day, max 15g daily) for ≤12mo without diet or RAASi restrictions. Primary endpoints were measured by central laboratory: % with normal K acutely; % with K≤5.1 or ≤5.5mEq/L during 3-12mo; mean K; adverse events (AE).

Results: Pts had a median age of 64y, 74% had eGFR <60, 38% had heart failure and 70% were on RAASi. During AP, baseline mean K decreased from 5.6 to 4.8 mEq/L; K 3.5-5.0mEq/L was achieved in 99% and 78% of pts when assessed by i-STAT and central lab, respectively; K 3.5-5.5mEq/L was achieved in 99% (central lab). Overall, 466 (62.5%) completed EP. Mean daily ZS dose was 7.2g. Normokalemia was maintained up to 12 mo [Figure]. During EP, mean K ≤5.1 or ≤5.5mEq/L was achieved in 88% and 99% of pts over 3-12 mo, respectively; 489 (65.5%) pts experienced an AE and 21.6% a serious AE. There were 8 (1.1%) deaths. Common AEs (>5%) were hypertension, peripheral edema, urinary tract infection, constipation, and anemia. Laboratory-determined hypokalemia (<3.5mEq/L) occurred in 5.8% (1.2% with K 2.5-<3.0).

Conclusions: ZS treatment rapidly reduced K in pts with hyperkalemia and maintained normokalemia for up to 12 mo; safety profile was consistent with prior studies and acceptable for this patient population.

Acute Efficacy of Sodium Zirconium Cyclosilicate for Hyperkalemia in Outpatients with Potassium ≥6.0 mEq/L: Post-Hoc Subgroup Analysis of a Phase 3 Trial David K. Packham,[3] Simon D. Roger,[6] Pablo E. Pergola,[9] Edgar V. Lerma,[1] Scott H. Adler,[8] Bhupinder Singh,[4,10] Philip T. Lavin,[2] Steven Fishbane,[5] Mikhail Kosiborod.[7] *[1]UIC/ Advocate Christ, Oak Lawn, IL; [2]Boston Biostatistics Research Foundation, Framingham, MA; [3]University of Melbourne, Melbourne, NSW, Australia; [4]ZS Pharma Inc., member of the AstraZeneca Group, San Mateo, CA; [5]Hofstra Northwell Health School of Medicine, Great Neck, NY; [6]Renal Research, Gosford, NSW, Australia; [7]Saint Luke's Mid America Heart Institute, Kansas City, MO; [8]AstraZeneca, Gaithersburg, MD; [9]Renal Associates PA, San Antonio, TX; [10]University of California, Irvine, Irvine, CA.*

Background: Treatment for patients (pts) with potassium (K) ≥6.0 mEq/L is often hospital-based. Sodium zirconium cyclosilicate (ZS) is an investigational, oral, highly selective K-binder shown to restore normokalemia in hyperkalemic pts. We report subgroup results for outpatients with K ≥6.0 mEq/L during acute treatment in a 12 mo Phase 3 study.

Methods: We performed a post-hoc analysis of an international, multicenter, open-label, single-arm trial that enrolled 751 pts (≥18y) with point-of-care (iSTAT) K ≥5.1mEq/L. Immediate treatment decisions were based on iSTAT K data, and confirmed by central laboratory serum K. During acute phase, pts received 10g ZS TID (24–72h) until K 3.5–5.0 was achieved by iSTAT K. Post-hoc endpoints were: final K, change in K from baseline, achievement of K 3.5–5.0 and adverse events (AE) during acute phase. Proportions were calculated using last observation carried forward.

Results: At baseline, 126 (17%) of pts had serum K ≥6.0mEq/L. 99% completed the acute phase. Most pts (71%) had CKD and 74% used RAASi with no discontinuations observed. Median acute phase treatment duration was 1 day; median ZS dose was 30g. Mean (95% CI) baseline serum K was 6.2 (6.2, 6.3), final K was 4.6 (4.5, 4.7), with mean K change of -1.6 (-1.7, -1.5). The majority of pts achieved normokalemia; no patients had K >6.0 at 24h (Figure). Serum K values were higher than i-STAT K values. AEs were observed in 11 of 126 pts including 3 gastrointestinal disorders, 3 infections, 2 musculoskeletal disorders, 1 peripheral edema. No AEs were serious. There was 1 report of hypokalemia (3.0–<3.5 mEq/L) in the acute phase.

Conclusions: Oral outpatient treatment with ZS rapidly normalized K in pts with baseline K ≥6.0mEq/L with few adverse events and may be a viable therapy for this high-risk pt population.

*100% of patients had a baseline i-STAT reading of ≥6.0 mmol/L

TH-PO1114

Risk Factors and Outcomes of Rapid Correction of Severe Hyponatremia Jason C. George,[2] Ion D. Bucaloiu,[2] Waleed Zafar,[1] Alex R. Chang.[2] *[1]Geisinger, Dnville, PA; [2]Geisinger Medical Center, Danville, PA.*

Background: Rapid correction of serum sodium is a concern in patients with severe hyponatremia and can have serious clinical consequences, including central pontine myelinolysis (CPM). Clinical risk factors of rapid correction and incidence of CPM has not been well-studied among patients with severe hyponatremia.

Methods: Using data from 1,352 inpatients in Geisinger Health System from 2001-2016 with serum sodium ≤120 mEq/L on admission, we examined possible predictors of overcorrection (demographics, comorbidity, medication, lab, and physical measurement data). Rapid correction of sodium (≥10mEq/L) was determined using sodium values closest to the 24 hour timepoint. CPM was determined by diagnostic codes and chart review of all brain MRIs.

Results: Mean age was 65.2 (SD 15.5) years, 54.9% were female, and 65.1% had a history of chronic hyponatremia (last outpatient sodium <135 mEq/L). The median change in sodium at 24 hours was 7.1 mEq/L (IQR 3.6–11.0), and 396 (29.3%) patients had rapid sodium correction. After multivariate adjustment, risk factors for overcorrection included female gender, schizophrenia, hypo- and hyperkalemia on presentation, and repletion of other electrolytes **(Table)**. History of chronic hyponatremia, outpatient loop diuretic use, and treatment at an academic center were associated with lower risk for rapid sodium correction. A total of 357 (26.4%) patients had brain MRIs completed during follow-up with 10 patients showing evidence of CPM (7 had documented rapid correction).

Conclusions: Consideration of various contributing factors, including age, gender, medications and co-morbidities could provide useful risk stratification for preventing rapid sodium correction and CPM.

Treatment of dRTA with an Innovative Combination Product as Compared to Current Standards of Care Aurélia Bertholet-Thomas,[1] Catherine Guittet,[2] Maria A. Manso,[2] Luc andre Granier.[2] [1]*Centre de référence des maladies rénales rares, Bron, France;* [2]*Advicenne, Nîmes, France. Group/Team: B21CS study investigators*.

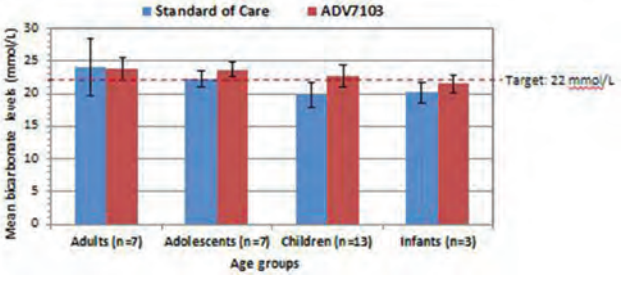
Background: Patients suffering from distal renal tubular acidosis (dRTA) require long-term treatment in order to restore and maintain physiological blood pH values. Products currently used as standards of care (SoC) require several daily administrations and are characterised by gastro-intestinal (GI) tolerability issues and bitter taste. A new innovative age-adaptable prolonged-release granule combination product (ADV7103), achieving adequate bicarbonataemia (blood bicarbonate ≥22 mM) with only two daily doses, together with improved tolerability and palatability, is proposed as an alternative. The objective of this work is to discuss the ability to restore bicarbonataemia with ADV7103 in comparison with SoC in dRTA patients.

Methods: A multicentre (N=13), open-label, non-inferiority, sequential study was performed. Adult and paediatric dRTA patients (N=37, 30 evaluable for bicarbonataemia) received their SoC and then ADV7103 at the most appropriate doses, both during 5-day periods. The alkali doses administered and the blood bicarbonate levels at steady state treatment conditions were compared. GI tolerability, palatability, easiness of administration and swallowing, were evaluated using visual analogue scales or 5-point facial hedonic scales.

Results: Blood bicarbonate levels were suboptimal in children and infants with the SoC and improved with two daily administrations of ADV7103. Less variability was observed with ADV7103 in adults and similar results were obtained with both treatments in adolescents. Improved GI tolerability, palatability and easiness of administration were observed in all age groups with ADV7103 compared to SoC. The improved ability to correct metabolic acidosis of ADV7103 was associated to the possibility of optimising dosing, while poor tolerability and acceptability appeared to limit further dosing increases with SoC.

Conclusions: ADV7103 is the first prolonged-release alcalinizing product improving bicarbonataemia control in dRTA patients compared with SoC, with less GI side effects and very good acceptability.

Funding: Commercial Support - Advicenne



TH-PO1116

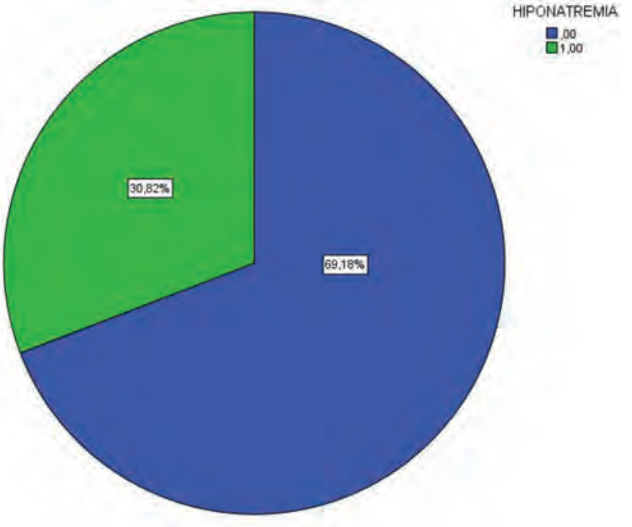
Prevalence of Hyponatremia in Dengue Infected Patients Daniel Caputo,[1] Armando L. Negri,[3] Juan Carlos Ayus,[4] Carlos Eghi,[2] Graciela E. Cabral,[2] Ydania Fernandez carreño.[2] [1]*Hospital Nacional Alejandro Posadas, El Palomar. Buenos Aires, Argentina;* [2]*Hospital Posadas, Buenos Aires, Argentina;* [3]*Instituto de Investigaciones Metabólicas, Buenos Aires, Argentina;* [4]*Renal Consultants of Houston, Houston, TX*.

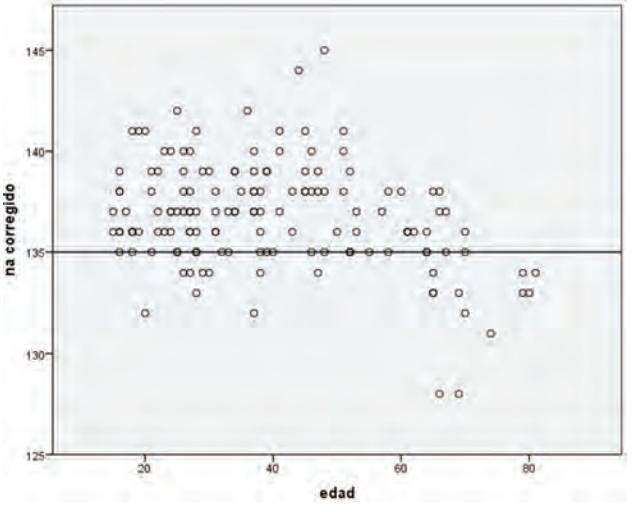
Background: PHO-WHO (Dengue guidelines 2016), and CDC recommended high water intake in patients with dengue. However, no information exists about the prevalence of hyponatremia in newly infected patients.

Methods: Cross-sectional study in patients with newly diagnosed dengue infection in Argentina from January 2016 to April 2016. Hyponatremia was defined as serum sodium concentration <=135 mEq/L. Natremia was corrected in patients with hyperglycemia. Patients with creatinine greater a 1,6 mg/dl were excluded.

Results: We evaluated 146 patients with dengue diagnosis confirmed by IgM serology or PCR. Hyponatremia was present in 30.8% of the patients **Figure 1**. In the multivariate logistic regression model, the OR of hiponatremia adjusting for age and sex was significant in the group of over 65 years; OR 9.2 (IC95 2.9-28.9) p= 0,001. **Figure 2**

Conclusions: The prevalence of hyponatremia in newly infected patients with dengue, especially in older patients is high. Electrolyte evaluation should be done at admission in all patients with dengue and routine use of hypotonic fluids should be avoided in these patients.





TH-PO1117

Safety and Efficacy of ADV7103, an Innovative Prolonged-Release Oral Alkalising Combination Product, after 6-Months of Treatment in Distal Renal Tubular Acidosis (dRTA) Patients Aurélia Bertholet-Thomas,[1] Catherine Guittet,[2] Maria A. Manso,[2] Luc andre Granier.[2] [1]*Centre de référence des maladies rénales rares, Bron, France;* [2]*Advicenne, Nîmes, France. Group/Team: B21CS study investigators*.

Background: A new innovative age-adapted prolonged-release granule combination of potassium citrate and potassium bicarbonate, ADV7103, has been developed in order

to achieve sustained physiological blood pH values in dRTA patients with a simplified dosing regimen. The current standards of care (SoC) require multiple administrations and are not always well tolerated. The objective of this clinical study was to assess safety of ADV7103 after treatment for 6 months as well as to follow-up bicarbonate levels and evaluate patient's satisfaction.

Methods: Adult and pediatric dRTA patients (N=30) were included in a multicentre (N=12), open-label, 24-month study. They received ADV7103 twice a day at appropriate doses. Preliminary data after 6 months of treatment were analysed, including adverse events and bicarbonataemia. Improvement of quality of life was evaluated at by patients and/or their parents using a 100-mm visual analogue scale.

Results: A total of 17 patients presented adverse events. Among the 45 adverse events observed, 40 were unrelated, 1 (abdominal pain) was unlikely related, 3 (alopecia, dyspepsia and abdominal pain) were possibly related, and 1 (diarrhea) was probably related to the treatment. The 5 latter adverse events were all of mild intensity. There was only one serious adverse event unrelated to the product (wisdom teeth removal). Efficacy was maintained after 6 months treatment, with blood bicarbonate levels above 21 mM in 79% of the patients. Only three patients presented bicarbonatemia levels below 20 mM. ADV7103 doses ranged from 1.3 to 7.2 mEq/kg/day. Patients and/or their parents were extremely satisfied with ADV7103. The change of alkalising treatment from the their SoC to ADV7103 allowed an average improvement of their quality of life of 80.5%, ranging from 76 to 98% depending of the age group considered.

Conclusions: The present preliminary results confirm the excellent safety and efficacy of ADV7103, a combination product allowing treatment with only 2-daily doses. The level of satisfaction of the patients is very high and clinicians are expecting registration of the product for first-line treatment of dRTA.

Prognostic Factors in Sepsis Patients Who Have Undergone Direct Hemoperfusion with Polymyxin B-Immobilized Fibers Aiko Okubo, Ayumu Nakashima, Shigehiro Doi, Toshinori Ueno, Takao Masaki. *Hiroshima University Hospital, Hiroshima, Japan.*

Background: In 2016, the definitions of sepsis and septic shock were reviewed by the Society of Critical Care Medicine and Sequential Organ Failure Assessment (SOFA) and a quick SOFA score was added to those definitions. Direct hemoperfusion therapy with polymyxin B-immobilized fiber cartridge (PMX-DHP) has been widely used to treat sepsis and septic shock. However, prognostic factors are not well understood. We retrospectively assessed the prognostic factors of patients who had received PMX-DHP for sepsis and septic shock.

Methods: Data on 71 patients with severe infection who had undergone PMX-DHP from January 2006 to August 2015 were included in this study. Participants were re-evaluated according to the criteria of the Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3) and all were confirmed to satisfy the new definition of sepsis. The patients were divided into groups based on having survived (n=59) or not survived (n=12) for 28 days after PMX-DHP. Clinical data before and after PMX-DHP were compared between the two groups.

Results: In the non-survivor group, the Glasgow Coma Scale score before PMX-DHP was significantly lower than in the survivor group (12 [6 to 14] vs 14 [12 to 15], P<0.01). Furthermore, pH after the first PMX-DHP session was significantly lower in non-survivors than in survivors (7.28±0.23 vs 7.39±0.06, P=0.03). The only factor identified by multivariate analysis as significantly associated with 28-day mortality was pH after the first PMX-DHP session (odds ratio, 0.93; 95% CI, 0.83–0.99; P=0.02).

Conclusions: pH after the first PMX-DHP session is an independent risk factor for mortality in patients receiving PMX-DHP for sepsis and septic shock.

TH-PO1119

Urinary Acid Excretion in Overweight Patients with CKD Yuichiro Izumi,[3] Koji Eguchi,[5] Yushi Nakayama,[3] Hideki Inoue,[6] Hiroshi Nonoguchi,[2] Yutaka Kakizoe,[1] Takashige Kuwabara,[4] Masashi Mukoyama.[4] *[1]Department of Nephrology, Kumamoto university graduate school of medical sciences, Kumamoto, Japan; [2]Kitasato University Medical Center, Kitamoto, Japan; [3]Kumamoto University, Kumamoto, Japan; [4]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [5]Kumamoto University Graduate School of Medicine, Kumamoto, Japan; [6]Kumamoto University School of Medicine, Kumamoto, Japan.*

Background: Urinary ammonium excretion, which reflects acid excretion by the kidney, has been suggested as a predictor for the chronic kidney disease (CKD) outcome. Overweight is one of the risk factors for progression of CKD. We examined urinary acid excretion in overweight CKD patients.

Methods: 25 Japanese out-patients with CKD who were treated with diet and medical therapy in our hospital were enrolled to evaluate acid excretion by the kidney. A 24-h urine collection was performed one day before visiting our hospital to determine excretion of creatinine, protein, urea, ammonium, pH, titratable acid (TA) and other electrolytes. Blood test was performed at visiting day. Their creatinine clearance (Ccr) corrected by body surface area was from 10 to 120 ml/min. For further analysis, patients, whose Ccr was > 30 ml/min, were divided into two groups: 11 normal (BMI 21 ± 2 kg/m^2) and 10 overweight (28 ± 3 kg/m^2) patients. Acid excretion between two groups was compared.

Results: Both ammonium (Figure 1) and TA excretions decreased with the decrease of Ccr (r^2 = 0.31, P = 0.0036 and r^2 = 0.20, P = 0.028). Between two groups, ammonium excretion was significantly decreased in overweight patients compared to that in normal weight patients (Figure 2). TA excretion tended to be increased in overweight group, resulting in no difference of total acid excretion (calculated by ammonium + TA) between the two groups. While protein and sodium chloride intakes were greater in overweight, net endogenous acid production (NEAP) and Ccr were not different between the two groups.

Conclusions: There might be a modulation of acid excretion mechanism in overweight patients with CKD.

Thiazide Test in CKD: Variable Test Results Due to Differences in Thiazide Excretion Anneke Bech,[2] Tom Nijenhuis,[3] Jack F. Wetzels.[1] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]Radboud University Nijmegen Medical Center, Nijmegen, Nijmegen, Netherlands; [3]Radboud university medical center, Lent, Netherlands.*

Background: The thiazide test is used to test the functionality of the sodium-chloride co-transporter (NCC). The test is used in the diagnostic work-up of patients with suspected Gitelman syndrome. Reference values for the thiazide test are based on small studies in young healthy volunteers. Patients presenting with tubular disorders however frequently are older and/or have a compromised kidney function. We observed a lower increase in fractional chloride excretion (delta FeCl) in patients with CKD and a remarkable variation in this parameter. In this study, we evaluated urinary thiazide excretion as an explanatory variable.

Methods: We performed thiazide tests in 10 individuals with CKD. Mean age was 65 years, mean serum creatinine was 124 μmol/l and seven individuals were male. Hydrochlorothiazide was measured in urine samples by LCMS.

Results: The median delta FeCl was 2.1% (range 0.0-3.9%). In 7 patients with CKD, the delta FeCl was below our threshold of 2.5% in healthy volunteers. CKD patients had a lower median thiazide excretion than young healthy individuals (33 μg/min vs 65 μg/min, p=0.01). There was a correlation between thiazide excretion and chloride excretion (Figure).

Conclusions: The standard thiazide test cannot be used in patients with CKD to evaluate the function of NCC. Our study indicates that invalid test results are likely explained by reduced tubular secretion of hydrochlorothiazide. Additional studies are needed to see if e.g. chloride excretion factored for thiazide excretion is a useful alternative parameter. Figure**:** urine hydrochlorothiazide concentration at maximal FeCl (closed circles CKD subjects, open squares young healthy individuals)

Proximal Tubular Function in Patients with Multiple Sclerosis Andrew S. Allegretti,[3] Nydjie Payas,[1] Scott Krinsky,[2] Ravi I. Thadhani,[3] Ishir Bhan.[4] *[1]Biogen, Cambridge, MA; [2]Mass General Hospital, Boston, MA; [3]Massachusetts General Hospital, Boston, MA; [4]Biogen, Inc, Cambridge, MA.*

Background: A recent database study revealed evidence of a higher than expected prevalence of Fanconi syndrome diagnosed in patients with multiple sclerosis (MS) relative to the general population. Proximal tubular function, which is altered in Fanconi

syndrome, has not been evaluated in patients with MS. Our objective was to compare the patterns of urinary electrolyte and amino acid excretion between MS and age- and gender-matched non-MS controls.

Methods: Subjects aged 18 or older with a diagnosis of MS were eligible to participate as cases; controls were age- and gender-matched individuals without MS. Exclusion criteria included known chronic kidney disease or kidney transplantation, use of a drug known to inhibit renal carbonic anhydrase, or use of a drug known to cause Fanconi syndrome. A blood sample was collected for a basic metabolic panel plus phosphorus. Urinalysis was performed and urine was assayed for electrolytes, glucose, creatinine and a panel of 28 amino acids. Univariate analysis was performed using Chi square and Wilcoxon testing.

Results: 11 MS patients (10 females, 1 male) participated, age and gender matched to 20 non-MS controls (17 females, 3 males). 10/11 MS patients were on disease-modifying therapy, including dimethyl fumarate (4/11), glatiramer (2/11), fingolimod (2/11), interferon (1/11), and natalizumab (1/11). Median age among MS patients and controls was 45 [IQR 32, 59] and 53 [IQR 31, 63] years, respectively. Race, ethnicity and gender were similar between groups. Mean levels of 17 /28 (61%) urinary amino acids were higher in MS patients than controls ($p < 0.05$ for carnosine, glutamate, hydroxyproline, and proline). Urinary amino acids were generally in the normal range, but abnormal levels were more common in MS patients for 8 amino acids and normal in all individuals for the remainder. Increased urinary amino acids were not associated with a particular MS treatment. MS patients had greater urine sodium levels (97 [IQR 73, 125] vs. 55 [IQR 29, 75] mmol/L; $p = 0.03$) and similar levels of urine potassium, chloride and phosphorus.

Conclusions: MS patients with normal kidney function may be at higher risk of urinary amino acid wasting. Future studies are needed to verify these findings and to elucidate whether MS or its treatment predispose to previously unrecognized proximal tubular dysfunction.
