In IgAN, IgA1 with Gal-deficient *O*-glycans in the hinge region (HR) is in the circulating immune complexes (IC) and in mesangial immunodeposits. Terminal *N*-acetylgalactosamine (GalNAc) in the Gal-deficient IgA1 is recognized by anti-glycan antibodies, resulting in formation of IC that may deposit in the kidney. HR of IgA1 has up to 6 of the 9 potential *O*-glycosylation sites occupied; some of these glycans may be Gal-deficient. *O*-glycosylation of IgA1 is initiated by a GalNAc-transferase (GalNAc-T), namely GalNAc-T2. As its abnormal localization or activity in IgA1-producing cells can lead to production of Gal-deficient IgA1, it is important to understand the kinetics and site-specificity of this enzyme. We produced recombinant GalNAc-T2 using insect cells and developed an *in vitro* system to study the kinetics of site-specific glycosylation using high-resolution mass spectrometry (MS). Time course of the enzyme reaction with synthetic HR (sHR) (VPSTPPTPSPSTPPTPSPSC) as acceptor was monitored by liquid chromatography (LC) coupled with Fourier transform ion cyclotron resonance (FT-ICR) MS and the glycosylated sites were determined by tandem MS. Our results showed that the number of GalNAc residues added to the sHR increased with time, the nonglycosylated sHR was completely consumed in 10 min; within 15 min, sHR had 3 to 6 GalNAc residues attached. Glycosylation sites were consistent with the sites previously described (VPS***T***PP***T***P***S***P***S***TPP***T***PSPSC; underlined S/T residues were glycosylated), and included those that are Gal-deficient in IgA1 (marked in bold and italics). Moreover, the two side-by-side S-T sites were alternatively glycosylated by one GalNAc each and were the last to be glycosylated. In summary, these data show that GalNAc-T2 can add GalNAc to all glycosylated sites in HR of IgA1, including those that are Gal-deficient. Thus, detailed studies of GalNAc-T2 kinetics and specificity will provide new information relevant to the pathogenesis of IgAN.

**TLR2 Induces Th17 Nephritogenic Myeloperoxidase Autoimmunity, While TLR9 Drives Th1 Autoimmunity** Shaun Andrew Summers, Oliver M. Steinmetz, Poh-Yi Gan, A. Richard Kitching, Stephen R. Holdsworth. *Medicine, Monash Medical Centre, Melbourne, Victoria, Australia.*

**Aim:** To define a link between infections and ANCA vasculitis, we explored the role of Toll-like receptor (TLR) 2 and TLR9 in experimental anti-myeloperoxidase (MPO) induced autoimmunity and glomerulonephritis.

**Methods:** To determine the role of TLR2 and TLR9 in anti-MPO autoimmunity C57BL/6 wild type (WT) mice were immunized with MPO alone, MPO+TLR2 ligand (L), Pam3CSK4, or MPO+TLR9(L), Cpg-ODN. Immune responses were studied on day 6 and 28. Anti-MPO glomerulonephritis was triggered by a sub-nephritogenic dose of nephrotoxic serum (NTS), glomerular injury was assessed 4 days later.

**Results:** Six days after immunization with MPO alone, MPO+TLR2(L) or MPO+TLR9(L) antigen-specific systemic production of IFNγ was increased only in mice immunized with MPO+TLR9(L) (MPO alone 336±291, MPO+TLR2(L) 830±172, MPO+TLR9(L) 3588±588pg/ml, $p<0.001$ compared to all other groups). Conversely, IL-17A production was increased only in WT mice immunized with MPO+TLR2(L), (MPO alone 24±10, MPO+TLR2(L) 1394±470, MPO+TLR9(L) 312±109pg/ml, $p<0.05$ compared to all other groups). There was no difference in IL-4 production between the groups. On day 28, IFNγ production in mice treated with MPO+TLR9(L) and IL-17A production in mice treated with MPO+TLR2(L) remained significantly elevated. On day 28 anti-MPO IgG was also increased in mice immunized with MPO and either TLR(L). Administration of a sub-nephritogenic dose of NTS resulted in increased albuminuria, (MPO alone 0.4±0.2, MPO+TLR2(L) 4.7±1.6, MPO+TLR9(L) 6.2±1.7mg/24hours, $p<0.05$) and histological renal injury in mice immunized with MPO + either TLR(L). TLR2(L)+MPO induced glomerulonephritis was neutrophil mediated and attenuated after treatment with monoclonal anti-IL17A neutralizing antibody (24±2% vs. 16±2% abnormal glomeruli, $p<0.05$). TLR9(L)+MPO induced glomerulonephritis was predominantly macrophage mediated, injury was attenuated after administration of anti-IFNγ therapy (25±3% vs. 18±1% abnormal glomeruli, $p<0.05$).

**Conclusion:** TLR2 induces Th17 mediated autoimmunity to MPO with neutrophil mediated glomerular injury. Conversely TLR9 induces Th1, macrophage mediated glomerulonephritis.

**Different Disease Phenotypes by Activation of TLR9 on Dendritic Cells (DC) and B Cells in Murine IgA Nephropathy** Tadahiro Kajiyama, Yusuke Suzuki, Hitoshi Suzuki, Satoshi Horikoshi, Yasuhiko Tomino. *Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan.*

[Background and Purpose]

Pathological roles of dendritic cells (DC) and B cells in mucosal immunity have been discussed. Recently, we demonstrated that Toll-like receptor 9 (TLR9), especially in

mucosa, has a crucial role in the pathogenesis of both human and murine IgA nephropathy (IgAN) (J Am Soc Nephrol 19: 2384-95, 2008). In the present study, we examined whether activation of TLR9 on mucosal DC and B cells contributes in different ways to the pathogenesis of murine IgAN using different cell-specific types of CpG-ODN, which is a ligand of TLR9.

[Methods]

For this study, we used three CpG-ODN, types A, B and C, which bind to TLR 9 on DC, B cells and both cells, respectively. IgAN prone mice (gddY) at 4 weeks of age were each nasally challenged with 10 ug of types A, B and C CpG-ODN at weekly intervals for 8 consecutive weeks. Blood and urine samples were collected before and after each administration. At 8 weeks after mucosal immunization, kidney samples were also collected and evaluated histopathologically.

[Results]

Urinary protein was aggravated after each administration of CpG-ODN in all mice. Serum IgA-IgG2a immune complexes were elevated in mice treated with types A and C, while serum IgA was increased in mice treated with type B. Interestingly, the mice treated with type A predominantly showed mesangial proliferative glomerular lesions, while sclerotic glomerular damage mainly with sclerotic lesions was observed in those treated with type B, suggesting that different disease phenotypes were induced.

[Conclusion]

It appears that the mucosal activation of TLR9 on DC and B cells may induce different types of glomerular damage in murine IgAN.

**Colon Cancer-Burden Experimental Rats Develop Marked Proteinuria; a Possible Research Tool for Paraneoplastic Glomerulopathy** Shin-Ichi Takeda,[1] Junko Chinda,[1] Akihiko Numata,[1] Takashi Murakami,[2] Masafumi Takahashi,[2] Eiji Kusano.[1] *[1]Division of Nephrology, Department of Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan; [2]Division of Bioimaging Sciences, Center for Molecular Medicine, Jichi Medical University, Shimotsuke, Tochigi, Japan.*

**Background.** Cancer patients occasionally develop renal disorders independently of direct tumor burden. In fact, a recent study (Kidney Int 70:1510-,2006) demonstrated that 10% of patients with membranous nephropathy had malignancies. We have also reported a case of crescentic glomerulonephritis who showed amelioration of renal impairment after resection of rectal cancer (Nephrol Dial Transplant Plus 3:330-,2010). However, this clinical entity remains mysterious, especially due to the lack of research tool. **Aim.** The objective of this study is to investigate whether cancer-bearing rats develop overt glomerulopathy. **Methods.** RCN-9 rat colon cancer cells ($1x10^7$) were injected into male 6-to-8-week-old F344 rats (n=6) and immunodeficient F344 rats (nude rats; n=3) via the portal vein. Urinalysis and histological examinations were performed in comparison with the control rats (n=6) that received vehicle-injection. **Results.** Metastatic growth of RCN-9 cells exclusively in the liver was observed in the cancer-injected rats, whereas direct invasion into the kidney was not evident (even microscopically). All of the cancer-injected F344 rats showed marked proteinuria (up to 158.0 mg/day) by 6 wks after cancer-injection in contrast to the controls (no more than 25.0 mg/day; $p<0.01$). Although microscopic morphological change was not evident, a large quantity of IgG was delineated by immunohistochemistry in the glomerular basement membrane zone of the proteinuric rats. Of particular interest is that none of the nude rats showed proteinuria despite of cancer growth, suggesting that T-cell-mediated immune responses are involved. **Conclusions.** As expected from the clinical perspectives, the cancer-bearing rats developed features of glomerulopathy such as proteinuria and deposition of immunological substance. Consequently, the present animal model should provide a new platform to address the underlying mechanism of paraneoplastic glomerulopathies.

### SA-PO2843

**The ASC-Dependent Inflammasome Protects Against Tubular Injury and Induces Inflammation Following Progressive Renal Injury** Wilco Pulskens,[1] Loes Butter,[1] Gwendoline J. D. Teske,[1] Nike Claessen,[1] Richard A. Flavell,[2] Fayyaz Sutterwala,[3] Sandrine Florquin,[1] Jaklien Leemans.[1] *[1]Pathology, AMC, Netherlands; [2]Immunobiology, Yale University; [3]Internal Medicine, University of Iowa.*

Tubulo-interstitial injury is a common finding in the chronically failing kidney and characterized by inflammation and fibrosis. The intracellular inflammasome contributes to the induction of inflammation through maturation of effector cytokines. Although the mechanism of activation is still unclear, several endogenous danger ligands are identified that can activate the inflammasome upon tissue injury. Furthermore, it is known that inflammasome components, NLRP3 and ASC are expressed in both inflammatory and epithelial cells. However, the role of the inflammasome in progressive renal injury is yet unknown.

C57Bl/6J wild type and ASC-/- mice (n=7/group) were subjected to unilateral ureter obstruction (UUO) by a permanent double ligation of the right ureter. Mice were subsequently sacrificed 1, 3, 7 and 14 days post-UUO to determine renal injury, inflammation and renal fibrosis. Renal mRNA levels were determined by quantitative RT-PCR and renal cytokines were measured by ELISA.

Following UUO, ASC mRNA remained constitutively present, whereas a strong increase of NLRP3 mRNA was observed compared to contralateral kidneys. Interestingly, ASC-/- mice displayed significantly enhanced levels of renal injury 1, 3 and 7 days post-UUO compared to wild type mice. In addition, ASC-/- mice had significantly less apoptotic tubular epithelial cells (t=14, and a tendency at t=3). Moreover, ASC deficiency resulted in reduced granulocyte influx (t=1 and 14), a reduced renal IL1β concentration (t=1) but did not affect accumulation of macrophages or myofibroblasts, total collagen deposition or renal TGFβ concentration. Preliminary data revealed that NLRP3-/- mice also had enhanced tubular injury compared to wild type mice 1, 3 and 7 days post-UUO.

The ASC-dependent inflammasome protects against tubular injury following UUO, associated with less apoptic epithelial cells. Moreover, the ASC-dependent inflammasome contributes to renal inflammation but does not affect fibrosis.

### SA-PO2844

**PPARδ Agonist Exerts Anti-Inflammatory Effect in Renal Proximal Tubular Cells** Xu Yang,[1,2] Shinji Kume,[1] Keiji Isshiki,[1] Masami Kanasaki,[1] Shin-Ichi Araki,[1] Toshiro Sugimoto,[1] Ping Han,[2] Detian Li,[2] Daisuke Koya,[3] Masakazu Haneda,[4] Hiroshi Maegawa,[1] Takashi Uzu.[1] *[1]Medicine, Shiga University of Medical Science, Otsu, Shiga, Japan; [2]Medicine, ShengJing Hospital of China Medical University, Shen Yang, China; [3]Medicine, Kanazawa Medical University, Kahoku-Gun, Ishikawa, Japan; [4]Medicine, Asahikawa Medical College, Asahikawa, Hokkaido, Japan.*

PPARs are the nuclear receptor family of ligand-inducible transcription factors, and exert multiple effects in various organs. PPARα and γ agonists have renoprotective effects in proteinuric kidney disease, but the therapeutic potential of PPARδ agonist remains unclear. Thus, we examined a renoprotecitve effect of GW501516, a PPARδ agonist, in free fatty acid (FFA)-bound albumin-overload model, a model to evaluate tubulointerstitial lesion in proteinuric kidney disease, and tried to indentify its molecular mechanism by in vitro study. Mice were fed on either standard diet (SD) or SD with GW501516, and intraperitoneally injected with FFA-bound albumin or PBS for 4 d. In SD group, FFA-bound albumin caused tubular damages and macrophage infiltration, and increased mRNA expression of inflammatory cytokines, TNFα and MCP-1. These alterations were all prevented by the treatment with GW501516 in vivo. Furthermore, we identified the molecular mechanism underlying the anti-inflammatory effect of GW501516 by using the cultured proximal tubular cells. GW501516 attenuated both TNFα- and FFA-bound albumin-induced MCP-1 expression through the inhibition of TAK1 activation, a downstream molecule of both toll-like receptor-4 and TNFα receptor, and subsequent NFkB(p65) nuclear translocation. These results indicate that PPARδ agonist exerted anti-inflammatory effect in renal tubular cells both in vivo and in vitro and may serve as a therapeutic candidate to attenuate the tubulointerstitial lesion in proteinuric kidney disease.

**The Antigens Recognized by Anti-Glomerular Basement Membrane Antibodies Undetectable by Enzyme-Linked Immunosorbent Assays** Zhao Cui,[123] Xiao-Yu Jia,[123] Zhen Qu,[123] Rui Yang,[123] Juan Zhao,[123] Ming Hui Zhao.[123] *[1]Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China; [2]Institute of Nephrology, Peking University, Beijing, China; [3]Key Laboratory of Renal Disease, Ministry of Health of China, Beijing, China.*

**Background:** Cases with anti-glomerular basement membrane (GBM) disease have been reported with linear deposition of IgG along GBM, but undetectable anti-GBM autoantibodies in circulation by ELISA. We speculated that the structure of antigens recognized by these antibodies may contribute to the negative results of ELISA.

**Methods:** Sera from four patients were collected, with typical linear deposition of IgG along GBM but no anti-GBM reactivity by ELISA. Circulating anti-GBM antibodies were detected by indirect immunofluorescence. Antigen specificity was identified by ELISA and Western-blot analysis, using purified bovine α(IV)NC1 and recombinant human α1~α5(IV) NC1 as antigens. The conformational structure of antigens was investigated by Western-blot analysis by preparing antigens under different conditions.

**Results:** The presence of circulating anti-GBM antibodies was confirmed by indirect immunofluorescence with linear deposition of IgG towards the cryptic epitopes along GBM on normal kidney sections. These antibodies did not recognize purified bovine α(IV)NC1 or recombinant human α1, α2, α4 or α5(IV)NC1 by ELISA and Western-blot analysis, but could blot recombinant human α3(IV)NC1 under non-reducing non-boiling condition, under such condition, the conformational epitope(s) on α3(IV)NC1 were thought to be preserved. When α3(IV)NC1 was prepared under reducing condition with β-mercaptoethanol and/or boiled to destroy the disulfide bonds, the binding with these antibodies disappeared.

**Conclusion:** Anti-GBM autoantibodies in circulation could recognize the cryptic and conformational dependent epitopes on α3(IV)NC1, which were pathogenic and may contribute to the negative results of ELISA.

**SA-PO2846**

**RNase 7 Expression in the Human Kidney and Urinary Tract** John D. Spencer, Andrew L. Schwaderer, Kirk M. McHugh, David S. Hains. *The Research Institute, Nationwide Children's Hospital, Columbus, OH.*

**Background**: Urinary tract infections (UTI) are a common bacterial infection. While many consider the urinary tract sterile, little is known how the body maintains sterility. Recent studies stress the importance of antimicrobial peptides (AMP) in preventing infection. Ribonuclease 7 (RNase7) is an important AMP that has been studied in the skin. RNase7's role in the epithelium of the urinary tract is unknown.

**Objective**: To characterize gene and protein expression of RNase 7 in the human kidney and urinary tract

**Design/Methods**: *Gene expression*: We isolated RNA from human kidney, ureter, and bladder tissue harvested from non-infected surgical pediatric patients. Isolated mRNA was reverse transcribed and quantified using real-time PCR. *Protein expression*: RNAse 7 expression was localized using immunohistostaining. To examine RNase7 protein expression in the urine, we developed a sandwich ELISA using two distinct antibodies to RNase7 and normalized urine concentrations to mg of creatinine.

**Results**: *Gene expression*: Constitutive *RNase7* mRNA expression was detected in human kidney, ureter, and bladder tissue. Absolute quantification using real-time PCR and a standard curve revealed that *RNase7* is expressed (ng RNase7/ 10 ng total RNA) in the renal cortex at 270, outer medulla 190, and renal pelvis 170. *Protein expression*: Immunohistochemistry localized RNase 7 to the urothelium of the bladder, ureter, and a subset of cells in the collecting duct. Specifically, immunofluorescence localized RNase7 to intercalated cells of the collecting duct. RNase 7 was detected in non-infected human urine samples. Control urine normalized to urine creatinine demonstrated RNase7 protein expression ranging from 1.5 to 6.6 (mcg/mg creatinine) with a mean SD of 4.1 +/- 1.9.

**Conclusion**: Our results characterize the expression a novel AMP, RNase 7, in the human kidney and urinary tract. *RNAse7* is expressed in the kidney, ureter, and bladder. Within the kidney, mRNA expression is greatest in the renal cortex. This potent AMP is specifically expressed in intercalated cells. In addition to maintaining acid-base homeostasis, intercalated cells have a role in the innate defense of the urinary tract.

**Ontogeny of the Goodpasture Autoantigen: Structural Alterations of Collagen IV Decrypting NC1 Autoepitopes during Glomerular Aging** Dorin-Bogdan Borza,[1] Yoshikazu Sado,[2] Wentian Luo.[1] *[1]Dept of Medicine (Nephrology), Vanderbilt University School of Medicine, Nashville, TN; [2]Shigei Medical Research Institute, Okayama, Japan.*

In Goodpasture (GP) disease, autoantibodies targeting the noncollagenous (NC1) domain of α3(IV) collagen in the glomerular basement membrane (GBM) mediate rapid progressive glomerulonephritis. How GP autoantibodies are elicited is unclear since their autoepitopes are cryptic within the NC1 hexamers formed by canonical assembly of α3α4α5(IV) collagen in the GBM. Because GP autoantibodies bind to the GBM of adults but not infants, we tested the hypothesis that the native GP autoantigen arises from age-dependent structural alterations of α3(IV) collagen. We found that α3-α5NC1 epitopes cryptic in the infant GBM were naturally unmasked in the adult GBM, which also contained a higher proportion of NC1 monomers. These differences were due to the occurrence in the adult but not infant GBM of distinct collagen IV isoforms, characterized by predominantly monomeric NC1 domains not assembled into hexamers, which included α3NC1 isoforms with naturally decrypted GP autoepitopes. Similar age-associated alterations of GBM collagen IV were observed in squirrel monkeys but were minimal in mice. These findings establish that structurally distinct isoforms of collagen IV are naturally produced and accumulate in the GBM during glomerular aging, without eliciting autoimmune pathology in most individuals. However, α3(IV) collagen isoforms with decrypted autoepitopes have the hallmark features of the autoantigen inciting the production of GP autoantibodies that they natively bind, presumably due to a breach in peripheral immune tolerance.

**SA-PO2848**

**Therapeutic Potential of Adipose-Derived Stem Cells for Anti-GBM Glomerulonephritis** Kazuhiro Furuhashi, Naotake Tsuboi, Hansu Kim, Takayuki Katsuno, Yosuke Saka, Takenori Ozaki, Waichi Sato, Enyu Imai, Yasuhiko Ito, Seiichi Matsuo, Shoichi Maruyama. *Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.*

**Introduction:** We have reported that adipose tissue-derived stem cells (ASCs), or mesenchymal stem cells (MSCs) form fat, promote regeneration in a rat model of acute kidney injury. More recently, MSCs have been shown to modulate immune reaction, suggesting that ASCs can be applied to the treatment for immune-mediated diseases. In the present study, we examined the renoprotective effects of ASCs focusing on their immunomodulatory properties.

**Methods:** Necrotizing crescentic glomerulonephritis was induced in WKY rats by intraperitoneal injection of anti-rat GBM mAb. Rat ASCs or control media were intravenously given everyday from day 0 through day 5. Renal function and renal histology were assessed on day 7. For cell tracking experiment, ASCs were stained with CFSE, and then were injected into animals.

**Results:** Intravenous injection of ASCs significantly prevented rats from renal dysfunction and proteinuria after administration of anti-GBM IgG. The number of glomeruli with crescent formation was significantly decreased in the ASCs group compared to control group. Interestingly, infiltration of ED2-positive immunoregulatory macrophages (M2) in glomerular crescents was increased in ASCs group despite comparable number of ED1-positive cells (M1) to control group. IL-10 concentration in renal cortex in diseased animal was higher in ASC group than in control group. IL10 concentration correlated closely with the number of ED2. Prominent number of CSFE-positive exogenous ASCs was observed in lung and spleen in contrast to their faint infiltration into kidneys, suggesting that ASCs can centrally demonstrate their immunoregulatory properties.

**Conclusion:** ASCs exert profound immunoregulatory properties especially on macrophages and ameliorate glomerular injury in a rat model of anti-GBM glomerulonephritis. The present study suggests that ASCs may provide a novel therapeutic approach for human crescentic glomerulonephritis.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2849**

**Tolerance Mechanisms Regulating Goodpasture Anti-Collagen Autoimmunity** Amy G. Clark,[1,2] Melissa L. Weston,[1,2] Mary H. Foster.[1,2] *[1]Medicine, Duke University Medical Center, Durham, NC; [2]Medicine, VAMC, Durham, NC.*

Organ deposition of autoantibodies against the NC1 domain of the alpha3 chain of type IV collagen leads to severe kidney and lung injury in Goodpasture Syndrome and anti-GBM nephritis. The origin of these highly pathogenic autoantibodies remains unknown. Recent analysis of an anti-alpha3(IV)NC1 H+L chain autoantibody transgenic model revealed that anti-alpha3(IV)NC1 B cells are normally regulated by receptor editing and deletion, suggesting that these tolerance mechanisms must be overcome or bypassed for disease initiation. To better define the mechanisms and role of receptor editing in autoimmune nephritis, we adopted a genetic approach. Editing is a process by which the autoreactive B cell receptor is rendered non-autoreactive by replacement of either the Ig heavy or light chain with a second chain generated by additional gene rearrangements at the Ig loci. We eliminated such rearrangements by breeding anti-alpha3(IV)NC1 Ig transgenic mice with MuMT and kappa-KO mice bearing targeted deletions of the endogenous (non-transgenic) IgM heavy chain and Ig kappa light chain, respectively. Spleen B cells were enumerated in the mutant transgenic progeny (millions±SD, n=4/group): 22.6±6.7, k+/Mu+; 24.7±4.6, kKO/Mu+; 5.0±1.7, k+/MuKO; and 2.5±0.8, kKO/MuKO, where +=sufficiency and KO=deficiency. Flow cytometry confirmed transgene Ig expression, and in kKO/Mu+ transgenic mice revealed lambda light chain editing. Thus, extensive editing involving both Ig chains occurs during development of anti-alpha3(IV)NC1 B cells, without which most cells are deleted. Nonetheless, recovery of IgM+kappa+ cells expressing the anti-alpha3(IV)NC1 transgene from kKO/MuKO mice indicates escape or persistence of a small population of potentially nephritogenic B cells.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2850**

**Deletion of Inhibitory Fc gamma Receptor 2B on Myeloid Cells Rather Than B Cells Enhances Murine Immune Complex Glomerulonephritis** Ruth M. Tarzi,[1] Javier Martín Ramírez,[2] Phoebe E. H. Sharp,[1] Charles D. Pusey,[1] H. Terence Cook,[1] Sjef Verbeek.[2] *[1]Imperial Kidney and Transplant Institute, Imperial College London, London, United Kingdom; [2]Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands.*

Fc gamma receptor 2B (CD32) is an inhibitory receptor for the Fc portion of IgG. It is expressed on B cells, where it regulates antibody production, and myeloid cells, where it regulates inflammatory responses to immune complexes. Nephrotoxic nephritis (NTN) is a model of immune complex glomerulonephritis, induced by the injection of sheep anti-mouse glomerular basement membrane antibody to preimmunized mice. We have created mice lacking CD32 on a pure C57BL/6 background, and confirmed that these mice have enhanced disease in NTN. In order to determine the relative contributions of CD32 on B cells and myeloid cells in NTN, we have induced NTN in mice with reduced FcgR2B expression on selective cell types, generated by crossing floxed FcgRIIB mice ($FcgRIIB^{fl/fl}$) with cell type specific Cre expressing transgenic mice. In $FcgRIIB^{fl/fl}$ X CD19Cre mice FcgR2B was reduced by 90% on B cells. FcgR2B expression was reduced 90% in Gr1+ neutrophils and 60% in Mac1+ cells using Lysozyme M Cre. Five days after induction of NTN, mice with myeloid deletion of CD32 ($LysMCreCD32^{-/-}$) and the full knockout $CD32^{-/-}$ mice had clinical signs of disease, whilst the $CD19CreCD32^{-/-}$ and floxed (WT) mice appeared well. There was significantly more glomerular thrombosis in the $LysMCreCD32^{-/-}$ and full $CD32^{-/-}$ mice compared with the $CD19CreCD32^{-/-}$ mice ($p<0.01$ and $p<0.05$ respectively). $CD19CreCD32^{-/-}$ mice had no more glomerular thrombosis than WT. Similarly, serum urea was raised in the full $CD32^{-/-}$ and $LysMCreCD32^{-/-}$ mice compared with the $CD19CreCD32^{-/-}$ mice ($p<0.05$), whilst the $CD19CreCD32^{-/-}$ mice had no more disease than the floxed (WT) mice.

Our results show that in this non-autoimmune model of immune complex glomerulonephritis, myeloid rather than B cell expression of the inhibitory Fc gamma receptor is responsible for protection from disease. These results give direct in vivo evidence for a protective role of the inhibitory Fc gamma receptor on myeloid cells in glomerulonephritis.

**Contact between Neighbouring Podocytes Forming Tight Junctions Precedes Glomerular Basement Membrane Thickening and Foot Process Effacement in Early Experimental Crescentic Glomerulonephritis** Lena Succar,[1] David J. Nikolic-Paterson,[2] David C. Harris,[1] Ross A. Boadle,[3] Gopala K. Rangan.[1] *[1]Renal Medicine Dept, Westmead Millennium Institute, The University of Sydney, Westmead Hospital, Sydney, NSW, Australia; [2]Nephrology Dept , Monash Medical Centre, Monash University, Clayton, VIC, Australia; [3]Electron Micropscopy Unit, Institute of Clinical Pathology & Medical Research, Westmead Hospital, Sydney, NSW, Australia.*

Podocytes contribute to crescents by forming bridges between the glomerular capillary tuft and Bowman's capsule in crescentic glomerulonephritis (CGN). However, the early ultrastructural alterations of podocytes in CGN have not been characterized. This study aims to investigate podocyte alterations by transmission electron microscopy (TEM) in early rat anti-GBM CGN. Anti-GBM was induced in pre-immunized male Wistar-Kyoto rats by sheep anti-rat GBM serum i.v.i. day 0 (d0) and examined d1,2,3,5,7,14. GBM-thickness; foot process effacement (FPE) assessed by filtration slit frequency(FSF)/µm GBM length; distances between neighbouring podocytes and podocyte to parietal basement membrane (PBM) were measured on randomly selected glomeruli in TEM digital images (anti-GBM, n=50; control n=25 glomeruli/time-point). On d1, there was widespread formation of focal contacts between podocyte cell bodies, resembling tight junctions at high magnification (20000x). Microvillous transformation at site of podocyte contact was frequent. By morphometric analysis, neighbouring inter-podocyte distance decreased (1.5±0.4; 2.4±0.2µm; mean±SEM; P<0.01 for anti-GBM vs. control groups) despite normal foot processes and GBM-thickness. By d2, inter-podocyte distance decreased further (1.1±0.2; 2.2±0.2 µm; P<0.01), GBM-thickness increased 4-fold (P<0.01) and FPE was segmental. By d5, FPE was extensive (1.5±0.1; 2.2±0.07 FSF/µm) accompanied by podocyte-bridge formation, as shown by decrease in podocyte to PBM distance (1.7±0.1; 3.4±0.9 µm; P<0.01). At d7 and d14 glomeruli had fibrinoid necrosis and cellular crescents. Podocyte cell bodies form focal contact prior to formation of podocyte-PBM bridges, suggesting potential cross-talk between neighbouring podocytes early in CGN.

**SA-PO2852**

**Rapamycin Causes Alterations of Podocytes Even without Proteinuria** Kostas Stylianou,[1] Ioannis Petrakis,[1] Vasiliki Mavroeidi,[1] Stavros Stratakis,[1] Theodora Katsarou,[1] Eleftheria A. Vardaki,[1] Spyros Stratigis,[1] Kostas Perakis,[1] John Kyriazis,[2] Eugene Daphnis.[1] *[1]Nephrology, University of Crete, Heraclion, Greece; [2]Nephrology, General Hospital of Chios, Chios, Greece.*

Introduction: Rapamycin can cause or ameliorate proteinuria. This contrasting behavior maybe due to either the dose used or the duration of administration. The current study was undertaken to examine whether or not rapamycin exerts direct toxicity on podocytes.

Methods: Balb/c mice were given either 3 different rapamycin doses for 1 week (low dose LD:1, intermediate dose ID:1.5 and high dose HD:3mg/kg/day i.p, -dose model) or an ID of rapamycin (1.5mg/kg) for 3 different periods (1, 4 and 8 weeks, time model). Six Balb/c mice injected with the rapamycin solvent (DMSO) served as controls.

Kidney morphology was examined by photon and electron microscopy. Expression of nephrin, podocin, Akt-kinase and Ser473pAkt was examined by WB, RT-PCR and IF.

Results

None of the mice developed proteinuria. Nevertheless, we noticed a dose and time dependent increase in the mean foot process width (FPW). On the first week FPW was as follows: controls 335nm, LD:385nm, ID:420nm, HD:420nm. FPW further increased from 420nm on week-1 to 456nm on week-2, and finally improved on week-8 (401nm). Both Podocin and Nephrin mRNA levels showed a significant decrease on week-1 (3 times lower vs. control, p<0.001), which improved on week-4 and was restored to normal on week-8. Nephrin and podocin protein levels didn't show significant alterations on WB or IF. Akt phosphorylation increased (fourfold vs. controls), in the HD and the week-4 groups (p<0.005).

Conclusions

Although rapamycin induced proteinuria was not detected, significant alterations were noticed in podocytes architecture, slit diaphragm proteins transcription and glomerular Akt activation. These alterations happened early on treatment and improved in the long term, indicating that a rapamycin "escape phenomenon" may exist.

**Different Podocyte Expression of Apelin in Focal and Segmental Glomerulosclerosis and Minimal Change Disease** Jan U. Becker,[1] Friedrich Modde,[1] Mario Schiffer,[2] Clemens L. Bockmeyer,[1] Catherine Meyer-Schwesinger,[3] Verena Broecker.[1] *[1]Medizinische Hochschule Hannover, Institut für Pathologie, Hannover, Lower Saxony, Germany; [2]Medizinische Hochschule Hannover, Klinik für Nieren- und Hochdruckerkrankungen, Hannover, Lower Saxony, Germany; [3]Universitätsklinikum Hamburg-Eppendorf, III. Medizinische Klinik, Hamburg, Germany.*

INTRODUCTION:

Apelin is a peptide which is known to directly induce contraction in smooth muscle cells and as a cofactor for VEGF.

Recently we found glomerular expression of Apelin and its receptor APJ exclusively in podocytes. To investigate the role of Apelin and APJ in podocytes, its expression in renal biopsies with podocyte injury and in normal kidneys was examined.

METHODS:

36 formalin fixated and paraffin embedded biopsies, 12 minimal change disease (MCD), 10 focal segmental glomerulosclerosis (FSGS), 3 IgA glomerulonephritis, 4 membranous glomerulonephritis, 4 diabetic glomerulosclerosis and 3 normal controls were examined. Immunhistochemistry for Apelin and APJ was quantified as positive and negative.

mRNA levels of Apelin and APJ were quantified by real time PCR in laser micro-dissected glomeruli as relative expression levels compared to normal controls.

RESULTS:

All normal kidneys (3/3) and most of the FSGS biopsies (8/10) had positive Apelin immunostaining of podocytes, while most MCD biopsies (9/12) were negative (p=0.0102). In contrast relative Apelin mRNA levels were significantly higher in glomeruli of MCD compared to FSGS (p=0,0409).

Immunostains and real time PCR of APJ showed positive podocytes in all specimens examined and no differences in mRNA levels.

CONCLUSION:

Podocytes in most cases of FSGS seem to retain the normal Apelin immunostaining while it is lost in most cases of MCD.

This contrasts with significantly increased mRNA levels of Apelin in MCD compared to FSGS.

Taken together, these data could indicate more rapid secretion of Apelin by podocytes in MCD, making it undetectable by immunostaining and a secretion defect with retained immunoreactivity in FSGS.

Further studies are needed to explore the possibility of impaired Apelin secretion by and autocrine effects of Apelin on podocytes.

**Upregulation of Calcineurin Is Involved in the Development of PAN Nephropathy, an MCNS Model** Masayuki Tomita, M. D. Murad Hossain, Mihoko Yamazaki, Hiroshi Kawachi. *Department of Cell Biology, Institute of Nephrology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

We have previously reported that the treatment with a calcineurin inhibitor (CNI), tacrolimus reduced the amount of proteinuria in Thy1 GN (Kidney Int 61:1139, 2002). We have also reported that the podocyte dysfunction is involved in the development of proteinuria in Thy1 GN (Kidney Int 60:2192, 2004, JASN 14:3111, 2003). Recently it is reported that another CNI stabilizes the actin cytoskeleton of podocyte, and protect podocyte from injury. These observations indicated that the alteration of calcineurin is involved in podocyte injury. In this study, first we analyzed whether the alteration of calcineurin is involved in the development of PAN nephropathy, a mimic of MCNS, and we also analyzed the effect of CNI on PAN nephropathy. At the peak of proteinuria in PAN nephropathy (day 10), the glomerular expression of calcineurin remarkably increased (519% to normal). Then, we analyzed the effect of tacrolimus on proteinuria in PAN nephropathy. The rats were treated with tacrolimus (0.2 mg/kg) from one day before PAN injection. The tacrolimus treatment reduced the amount of proteinuria (day 10: 207 ± 25 mg/day vs. 378 ± 34, P<0.01, day 24: 17 ± 6 vs. 75 ± 15, P<0.01). The staining of nephrin was clearly reduced in the vehicle-treated control group, but the reduction of nephrin staining was inhibited by the tacrolimus treatment (Score (0-4): 1.68 ± 0.15 vs. 1.15 ± 0.10, P<0.05). Next, the protective effect of tacrolimus was analyzed with cultured podocyte (The cells were kindly donated by Dr. Mundel). The cells were treated with PAN (5 mg/mL) for 72 hr in the presence or absence of tacrolimus (100 nM). Treatment with PAN increased the mRNA expression of calcineurin (817%) and FKBP12 (524%) in cultured podocyte. PAN caused cortical F-actin ring formation and stress fiber attenuation in those cells. Treatment with tacrolimus prevented PAN-induced cytoskeletal rearrangement in podocyte. In conclusion, calcineurin is involved in the development of proteinuria in PAN nephropathy, and CNI has a protective effect for podocyte.

**Significant Role of Glomerular CD44 Expression in Adriamycin-Associated Nephropathy** Takayuki Okamoto, Satoshi Sasaki, Yasuyuki Sato, Hironobu Ito. *Pediatrics, Hokkaido U Grad Sch Med, Sapporo, Japan.*

***PURPOSE (INTRODUCTION).***

Pivotal functions of cell adhesion molecule CD44 include signal transduction of osteopontin (OPN) and macrophage migration inhibitory factor (MIF). Because recent studies have indicated significant roles of OPN and MIF in the progression of glomerulosclerosis, we examined the roles of CD44 as a key molecule for these cytokines using adriamycin (ADR)-associated nephropathy.

***Methods.***

Male 12-week-old Balb/c mice and MIF-deficient Balb/c mice were used. After the injection of 12mg/kg of ADR at day 0, histological and functional data were sequentially collected from day 1 to day 28. Glomerular expression of CD44, OPN, and MIF were immunohistochemically evaluated together with the markers for podocytes and parietal epithelial cells (PECs).

***RESULTS.***

Wild mice showed focal reduction of the expression of podocyte markers, synaptopodin and podocin, from day 10. Preceding the reduction of the podocyte marker expression, CD44 staining became positive in claudin-1-positive PECs in a few corticomedullary

glomeruli from day 7. Thereafter the number of CD44-positive cells increased in both PECs and proliferating glomerular cells with an upregulation of the staining intensity. OPN also showed positive staining in some PECs from day 14. Confocal microscopic analysis showed perinuclear OPN expression in most PECs with perimembranous CD44 expression; moreover, in a few PECs in the glomeruli showing segmental reduction of podocyte markers, OPN was co-localized with CD44 in focal deposits at the leading edge of the cells, and these findings are likely to be implicated in migratory effects of CD44/OPN interaction. MIF-deficient mice showed significantly less histological and functional injuries after ADR injection. In addition, the CD44 and OPN expression was significantly less in MIF-deficient mice compared to wild mice and perimembranous co-localization of CD44/OPN was not observed.

***CONCLUSION.***

CD44 is a key molecule that reflects podocyte injuries in the progression of focal segmental glomerulosclerosis. CD44-mediated cell motility may have a significant role in PEC migration through the interactions with functionally related molecules such as OPN and MIF.

**TRPC6 Expression Was Suppressed by 1, 25-Dihydroxyvitamin D3 in the Rat Kidney of Puromycin Aminonucleoside Nephropathy** Houqin Xiao, Yong Zhang, Qinhong Zhang. *Department of Nephrology, Taihe Hospital of Yunyang Medical College, Shiyan, Hubei, China.*

Accumulating evidence suggests that vitamin D is renoprotective. However, the precise mechanisms and the molecular targets by which active vitamin D exerts its beneficial effects remain obscure. Mutations of TRPC6 gene as cause for hereditary FSGS as well as the localization of TRPC6 at the slit diaphragm indicate that TRPC6 plays a pivotal role in genetic and acquired forms of proteinuric kidney disease. The objective of this study was to evaluate the TRPC6 expression effect of active vitamin D on rats with puromycin aminonucleoside (PAN) nephropathy.

PAN rat model were constructed by consecutive three times intravenous injection PAN of 100 $mg.kg^{-1}$ body weight every ten days and 1,25-dihydroxyvitamin D3 ($0.2\mu g.kg^{-1}.d^{-1}$) were gavaged. The rats were sacrificed at one and three months after PAN injection respectively. 24-hour urinary protein, renal function and morphologic parameters in glomeruli were evaluated. Expressions of nephrin, TRPC6, TGF-β1, VDR mRNA were examined by RT-PCR. The protein expression and location of nephrin, TRPC6, VDR were decided by western blot and confocal microscope respectively.

PAN administration caused serious proteinuria, hydroperitoneum, hyperlipoidemia, hypoproteinemia and glomerular sclerosis. Compared with vehicle controls, 1, 25-dihydroxyvitamin D3 significantly attenuated proteinuria, gloumeruslerosis, restored renal function after PAN administration. In PAN model rat, TRPC6 protein expression were significant increased and merged with synaptopodin on one months and decreased on three months with a granular patter. Compared with vehicle controls, TRPC6 expression was significantly decreased and VDR expression was significantly increased after 1, 25-dihydroxyvitamin D3 treament. Significantly negative correlation was found between TRPC6mRNA and VDR mRNA. In addition, 1, 25-dihydroxyvitamin D3 suppressed renal TGF-β1 expression, restored the loss of nephrin after podocyte injury.

In conclusion, 1, $25(OH)_2 D_3$ can significant attenuate the PAN-induced podocyte injury and proteinnuria. The beneficial effects of 1, $25(OH)_2 D_3$ on podocyte may be partly attributable to suppression of TRPC6.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2857**

**The Balance of Thymosin β4 and Its Metabolite Ac-SDKP Regulates Profibrotic Factors** Yiqin Zuo, Haichun Yang, Li-Jun Ma, Agnes B. Fogo. *Pathology, Vanderbilt University, Nashville, TN.*

We previously showed that the G-actin sequestering protein thymosin β4 (Tβ4) is remarkably increased in the obstructed kidney in the unilateral ureteral obstruction (UUO) model of tubulointerstitial fibrosis. Tβ4, which is postulated to be profibrotic, is degraded by prolyl oligopeptidase (POP) to the anti-fibrotic Ac-SDKP peptide. Our study further revealed that inhibition of POP shifted the balance of Tβ4 and Ac-SDKP and exacerbated fibrosis in obstructed kidneys. We now investigated whether the altered balance of Tβ4 vs Ac-SDKP affects profibrotic molecules in the UUO kidneys.

Male C57BL/6 mice underwent UUO and were treated as follows: UUO without treatment, UUO+POP inhibitor (S17092, 40mg/kg per day, by gavage), UUO+Tβ4 (150μg/d, i.p.), UUO+combination (POP inhibitor and Tβ4), and UUO+Ac-SDKP (1.6 mg/kg/d, delivered by minipump). Mice were sacrificed at day 5.

POP activity was significantly lower in the obstructed kidneys of mice treated with POP inhibitor or combination (POP inhibitor, 2.1±0.3; combination, 5.7±1.6; vs untreated UUO, 27.6±2.3 pmol/min*mg tissue, both $p<0.05$; Ac-SDKP, 31.9±1.2, pNS vs untreated UUO). Consequently, the Ac-SDKP concentration was significantly lower in POP inhibitor and combination treatment groups but dramatically higher in Ac-SDKP group vs. untreated UUO (POP inhibitor, 0.66±0.08; combination, 0.86±0.09; Ac-SDKP, 2.41±0.08; vs. untreated UUO, 1.40±0.19 pmol/mg tissue, $p<0.05$). Neither POP activity nor Ac-SDKP was affected by Tβ4 treatment (21.2±1.6 pmol/min*mg tissue and 1.09±0.12 pmol/mg tissue, respectively). Plasminogen activator inhibitor (PAI-1), transforming growth factor (TGF)-β1, Tβ4, collagen I and III expression assessed by real time PCR were all dramatically reduced vs. untreated UUO by Ac-SDKP treatment. By contrast, PAI-1, TGF-β1 and collagen III expressions were significantly increased by POP inhibitor.

Our study suggests that exogenous administration of Ac-SDKP inhibits profibrotic factors. We propose that a shift from thymosin β4 to Ac-SDKP is crucial in modulating profibrotic molecules and eventually determining tubulointerstitial fibrosis.

**Topoisomerase 2 (Top 2)-DNA Covalent Complex Mediated Adriamycin-Mediates Podocyte Injury** Pu Duann,[1] Lisa Y. Lyu,[3] Ling-Mei Chiang,[2] Elias A. Lianos.[1] *[1]Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ; [2]Pediatrics, Chang-Gung Memorial Hospital, Keelung, Taiwan; [3]Pharmacology, Robert Wood Johnson Medical School, Piscataway, NJ.*

Adriamycin (ADR, doxorubincin) is a frequently used anticancer drug. In the mouse ADR causes proteinuria due to podocyte injury, an underlying mechanism being overproduction of reactive oxygen species (ROS). ADR kills tumor cells by complexing with the ADR specific target, Topoisomerase(Top)-2α.There are two Topoisomerase isozymes: a) Top2α, which is induced in actively proliferating states and is highly abundant in cancer cells, and b) Top2β, which appears only in terminally differentiated cells, e.g. adult cardiocytes and podocytes. We previously reported that the tumoricidal effect of ADR is mediated by trapping Top2-DNA covalent adducts (Top2 cleavage complexes) while ADR-mediated cardiotoxicity is mediated through Top2β. In the present study, we tested the hypothesis that Top2β is the target for ADR-mediated podocyte injury. In a culture system, we observed DNA damage after ADR treatment in wild type controls but not Top2β KO (Top2β-/-) cells, suggesting that DNA-damage is Top2β mediated. The proteasome core component 20S has been shown to work with Ump1/POMP. Using POMP-siRNA we demonstrated that etoposide (a Top2 drug)-mediated Top2β downregualtion was completely abrogated, suggesting the involvement of the 20S proteasome in mediating drug-induced Top2β downregulation. In addition, POMP siRNA treatment blocked the etoposide-induced DNA damage signal γ-H2AX suggesting that proteasomal degradation of Top2β can lead to permanent DNA breakage and activation of double strand break (DSB) signals (e.g. γ-H2AX) Dexrazone, an established ADR chemical inhibitor, antagonized formation of Top2α and Top2β-DNA covalent adducts, and blocked ADR-mediated DNA damage. In ADR-treated mice, we observed (immunohistochemistry) Top2-beta level induction. These observations point to Top2β as a mediator of ADR-mediated cytotoxicity in podocytes by: 1) interfering with formation of Top2-DNA covalent complex, and 2) depleting Top2β through the proteasome pathway.

**Matrix Metalloproteinase-12 (MMP-12) Deficiency Attenuates Crescent Formation in Anti-GBM Glomerulonephritis** Abu P. Abraham,[1,2] Greg Tesch,[1,2] Frank Yuanfang Ma,[1,2] William Richard Mulley,[1,2] David J. Nikolic-Paterson.[1,2] *[1]Nephrology, Monash Medical Centre, Clayton, Victoria, Australia; [2]Medicine, Monash University, Clayton, Victoria, Australia.*

MMP-12 is an enzyme that can cleave various extracellular matrix proteins and is required for macrophage infiltration and pulmonary fibrosis in experimental emphysema. We have shown previously that MMP-12 is highly up-regulated in experimental anti-GBM disease. The aim of this study was to determine whether MMP-12 (macrophage elastase) is required for glomerular macrophage infiltration and crescent formation in anti-GBM glomerulonephritis. Accelerated anti-GBM disease was induced in groups of 5 to 6 MMP-12 gene deficient mice (MMP-12-/-) and wild type C57BL/6J (WT) controls, which were killed 12 days after serum injection. WT and MMP-12-/- mice developed glomerular damage and glomerular tuft adhesions to Bowman's capsule. Both groups developed severe proteinuria. WT mice also developed crescents characterized by macrophage infiltration, epithelial cell proliferation, fibrin deposition and Bowman's capsule rupture. In contrast, MMP-12-/- mice were protected from crescent formation (3.1±1.4% vs. 24±2.7% in WT; $P<0.01$). This was associated with a significant reduction in macrophage infiltration in both glomeruli (1.4±0.2 vs. 3.1±0.2 CD68+ cells/gcs; $P<0.01$) and the interstitium (16±2 vs. 26±3 CD68+ cells/hpf), with a 90% reduction in renal TNF-α mRNA levels in MMP12-/- mice. Semi-quantitative assessment also showed a reduction in peri-glomerular macrophage infiltration in MMP12-/- compared to WT mice (1.5±0.2 vs. 2.5±0.2; $P<0.01$). The degree of tubular damage was reduced in MMP-12-/- mice based upon KIM-1 mRNA levels (60% reduction vs WT; $P<0.05$). In conclusion, these data demonstrate that endogenous MMP-12 is required for glomerular crescent formation in anti-GBM glomerulonephritis. This most likely operates via macrophage recruitment and activation.

**SA-PO2860**

**Lymphangiogenesis during the Development of Chronic Kidney Disease in Rat Anti-GBM Glomerulonephritis** Maki Tanabe, Akira Shimizu, Yukinari Masuda, Emiko Fujita, Shinya Nagasaka. *Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Lymphangiogenesis is the growth and formation of new lymphatic vessels. In renal diseases, lymphatic vessels develop during tubulointerstitial fibrosis. However, little is known about the lymphangiogenesis during the development of glomerulonephritis (GN) with chronic kidney injury. Progressive necrotizing and crescentic GN was induced in rats by intravenous injection of anti-GBM antibody. We assessed the distribution and pathologic characterizations of lymphatic vessels during the progression to end stage renal failure. In addition, we examined the expression of VEGF-C in the kidney. After anti-GBM antibody injection, necrotizing and crescentic GN developed with mecophage infiltration by day 7.

Newly formed necrotizing lesions reoccurred by week 3 with the development of glomerular sclerosis. Subsequently, intersitial fibrosis developed with mononuclear cell infiltration. Before anti-GBM antibody administration, podoplanin+ lymphatic vessels were located mainly around arcuate arteries. In renal cortex, a few lymphatic vessels were present around interlobular arteries, but not around glomeruli. However, after induction of anti-GBM GN, several podoplanin+ branches extended to cortex and located around inflamed glomeruli by week 2. At week 2, glomerular infiltrated macrophages expressed VEGF-C, and glomerular VEDG-C was upregulated by western blotting, suggesting that inflamed glomeluri induced lymphangiogenesis in interstitium before the development of interstitial fibrosis. Subsequently, interstitial fibrosis developed with irregular enlarged and increased number of lymphatic vessels. In this phase, VEGF-C expressed injured tubular epithelial cells and infiltrating cells. Importantly, lymphatic vessels during lymphangiogenesis in kidney were characterized by immunostaining with podoplanin+, Prox-1+, MIB-5 (proliferation maker)+ and type IV collagen (basement membrane)(-) vessels. In conclusion, in severe glomerular inflammation may lead to interstitial lymphangiogenesis by VEGF-C expression in glomeluar inflammation, before the development of interstitial fibrosis with VEGF-C expression in tubules and infiltrating cells.

## SA-PO2861

**Coronin 1a Deficiency Reduces T-Cell Recruitment in Anti-GBM-Nephritis** Christoph Daniel,[1] Laura Königer,[1] Christina Grigo,[1] Silke Meister,[3] Charlotte Starke,[3] Reinhard Voll,[3] Christian Hugo.[2] *[1]Nephrology and Hypertension, University of Erlangen, Erlangen, Germany; [2]Nephrology, University of Dresden, Dresden, Germany; [3]Immunology, University of Erlangen, Erlangen, Germany.*

Coronins are cytoskeletal, actin binding proteins involved in regulation of actin bundling. Using microarray analysis we identified Coronin 1a as a potential marker for glomerular reserve/precursor cells repopulating the glomerulus after severe mesangial injury. To characterise Coronins role in early anti-GBM nephritis we investigated disease progression 7 days after disease induction using coronin 1a deficient mice. We analysed renal function, histological changes and inflammation. In addition, inflammatory cells were analysed in blood, spleen, regional lymph nodes and bone marrow using flow cytometry. Interestingly, IgG antibody titers generated against the disease inducing sheep antibody were markedly reduced in Coronin 1a deficient mice (ELISA OD: 1,7±0,4 vs. 0,2±0,11) compared to wt mice. In contrast, number of IgG-secreting plasma cells was similar in both groups. Only in bone marrow, B220 positive B-cells were significantly lower in coronin 1a deficient mice compared to wt controls. Renal infiltration with CD4 positive T-cells of wt mice was about 4 times higher in anti-GBM-nephritic mice whereas the increase in Coronin 1a deficient mice was only the half (20,3±4,8 vs. 9,8±1,1 cells per high power field). Significantly lower CD4 positive T-cells were also detected in all investigated compartments. In contrast, percentage of CD8 positive T-cells was significantly lower in the nephritic kidney (13,1±2,0 vs. 8,8±2,4 cells per high power field) and regional lymph node (11,1±2,3% vs. 3,8±1,5%) but comparable in blood, and spleen. However, both coronin 1a deficient and wt mice developed anti-GBM-nephritis with comparable crescent formation and only a tendency to reduced proteinuria in the Coronin 1a deficient mice.

In conclusion, during early GBM-nephritis Coronin 1a is involved in regulation of T-cells and humoral response with minor effects on kidney function and renal damage.

## SA-PO2862

**Effects of Long- and Short-Term Treatment with Imatinib in the Progression of Renal Dysfunction and Fibrosis in Established Experimental Anti-GBM Nephritis** Masayuki Iyoda, Takanori Shibata, Yoshihiro Kuno, Yuki Hirai, Tadao Akizawa. *Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan.*

Introduction: Imatinib (IM) is a selective tyrosine kinase inhibitor that can block PDGF receptor (PDGFR) activity. In this study, whether long-term or short-term IM treatment (Tx) could prevent the progression of chronic kidney disease (CKD) was investigated in order to determine whether IM may have potential to treat patients with CKD. Methods: Nephrotoxic serum nephritis (NTS-N) was induced in Wistar-Kyoto (WKY) rats on day 0. Groups of animals were given either IM (25 mg/kg) or vehicle daily by intraperitoneal injection, from day 7 to day 49 for 43 days in the long-term Tx study (Long Tx), and from day 7 to 20 for 14 days in the short-term Tx study (Short Tx); all rats were sacrificed at day 50. Vehicle-treated groups received an equal volume of sterile water. Seven, female, 14-week-old WKY rats were used as normal controls (WKY-NTS (-)). Proteinuria (U-P), serum creatinine (Cr), and body weight (BW) were measured periodically. Morphological investigations were performed at sacrifice. Results: Cr levels were significantly lower in the IM-treated rats than in the vehicle-treated rats in the Long Tx group (Long Tx: 0.39 ± 0.01 vs. 0.28 ± 0.01 mg/dL, $p < 0.01$; Short Tx: 0.40 ± 0.05 vs. 0.35 ± 0.03 mg/dL, NS). When compared to vehicle Tx, IM-treated rats had reduced U-P at the end of the study (Long Tx: 175.38 ± 15.71 vs. 103.86 ± 17.79 mg/day, $p < 0.001$; Short Tx: 161.72 ± 9.79 vs. 131.93 ± 9.69 mg/day, $p < 0.05$). Imatinib Tx also decreased kidney weight (Long Tx: 2.09 ± 0.04 vs. 1.68 ± 0.03 g, $p < 0.001$; Short Tx: 1.91 ± 0.07 vs. 1.75 ± 0.05 g, $p < 0.05$; 1.63 ± 0.03 g in WKY-NTS (-)) and reduced glomerulosclerosis and tubulointerstitial damage scores. Renal cortical mRNA for collagen type I (collagen type I/GAPDH mRNA: Long Tx: 9.92 ± 2.52 vs. 2.14 ± 0.40, $p < 0.01$; Short Tx: 11.84 ± 1.48 vs. 5.31 ± 0.96, $p < 0.01$) was also significantly decreased in the IM-treated group. Conclusion: These results suggest that IM may prove useful in limiting the progression of chronic renal disease to end-stage renal failure.

## SA-PO2863

**p53 Deficiency Exacerbates Progression of Immune-Mediated Glomerulonephritis** Ryota Kimura,[1] Ryota Shirai,[1] Yuki Udagawa,[1] Yuki Tokui,[1] Takashi Okude,[1] Shiro Ueda,[1] Yoshihiko Ueda,[2] Osamu Yokosuka,[3] Makoto Ogawa,[4] Yuki Hamano.[4] *[1]Graduate School of Pharmaceutical Sciences, Chiba University, Japan; [2]Dokkyo Medical University Koshigaya Hospital, Japan; [3]Graduate School of Medicine, Chiba University, Japan; [4]Chiba University Hospital, Japan.*

**Objective:** p53 tumor suppressor is a key regulator of the response to cellular stress or DNA damage. p53 activation leads to cell cycle arrest, apoptosis, or senescence. p53 has been shown to be an important regulator of renal tubular cell viability in the animal models of ischemic and toxic acute kidney injury. In theses models, p53 activation induced proapoptotic pathways in renal tubular cells which contributed to kidney dysfunction. In this study, we investigated whether genetic inhibition of p53 provided a protective effect in a model of immune-mediated glomerulonephritis.

**Methods:** p53-null (KO) and wild-type (WT) mice were immunized subcutaneously with normal rabbit IgG in complete Freund's adjuvant, followed by intravenous injection of rabbit anti-mouse GBM serum. On days 6 and 9, blood and urine samples were collected and mice were sacrificed for the histological assessment.

**Results:** Upon induction of anti-GBM glomerulonephritis in WT mice, p53 expression was upregulated within the glomeruli and tubulointerstitium. Unexpectedly, the serum creatinine level and urine albumin excretion were significantly increased in KO mice compared with WT mice. KO mice displayed significant increase in the number of proliferating mesangial cells and macrophages in the glomeruli and proliferating macrophages in the tubulointerstitium, mesangial expansion and interstitial fibrosis. The expression of CDK2, cyclin E1 and E2 was upregulated in the cortex of KO mice compared with WT mice. In contrast, there were no significant differences in the number of apoptotic cells in the glomeruli and tubulointerstitium and expression of TNF-α and Bcl-2 in the cortex between KO and WT mice.

**Conclusion:** p53 plays an important role in altering renal inflammation by inhibiting proliferation of intrinsic and infiltrating cells in the glomeruli and tubulointerstitium and has a protective effect against progressive glomerulonephritis.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2864

**Clearing of Apoptotic Mesangial Cells and Associated Debris by Mesenchymal Stem Cells: A Crucial Step in Mesangial Repair Monitored with a 6D (Dimensional) – Live Cell Model** Jiamin Teng, Elba A. Turbat-Herrera, Guillermo A. Herrera. *Pathology, Nephrocor, Tempe, AZ.*

**Background:** Mesangial repair remains a poorly understood, yet very important step in glomerular recovery after an injurious event. Mesangial damage is often associated with mesangial cell (MC) apoptosis. Repair of the damaged mesangium may require exogenous cellular elements that can repopulate and rebuild the injured mesangial areas.

**Materials and methods:** An in-vitro platform using a 6D cell live model allows monitoring the sequential steps that must take place for mesangial repair to occur. Rat mesangial cells (RMCs) were cultured on Matrigel loaded glass bottomed multi-well plates with 10% FBS/RPMI 1640 until confluence. MCs were then made quiescent by incubating them first with 0.5% FBS/ RPMI for 48 hours and afterwards with glomerulopathic light chains (GLCs) (10 ug/ml, 48 hours X 2) purified from the urine of patients with light chain deposition disease and AL(light chain-associated) amyloidosis. Rat mesenchymal stem cells (RMSCs) were stained with PKH-2 fluorescence dye (green) and / or with Lysotracker Texas Red (red) and placed 96 hours later into the wells of GLCs-treated MCs for up to 2 weeks. MC cultures were maintained alive and 15 different locations were monitored simultaneously with sequential photos every 15 minutes using this system.

**Results:** Before the RMSCs were added to the system, most if not all MCs were in various stages of apoptosis. The various steps in the apoptotic process were monitored. RMSCs rapidly migrated towards the areas with the most damage and phagocytosed the fragments of apoptotic cells and debris. Not until mostly all of the damaged mesangial cells and surrounding debris, including damaged matrix, were cleared, the RMSCs began differentiating and transforming into mature MCs, establishing contacts with adjacent cells, and producing new matrix.

**Conclusions:** RMSCs actively participate in disposing of the damaged MCs and surrounding affected matrix. This appears to be an initial crucial step for the repair of the mesangium to occur. The findings indicate that exogenous MSCs may play an important role in clearing the injured mesangium prior to remodeling.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2865

**PIASy Regulates SM α-Actin Expression by Interacting with E12 in Mesangial Proliferative Glomerulonephritis** Kazuo Torikoshi,[1] Makoto Araki,[1] Takeshi Matsubara,[1] Akira Mima,[1] Takahiro Hirano,[2] Hideharu Abe,[2] Atsushi Fukatsu,[1] Hidenori Arai,[3] Toshio Doi.[2] *[1]Nephrology, Kyoto University, Kyoto, Japan; [2]Clinical Biology and Medicine, Tokushima University, Tokushima, Japan; [3]Innovation Unit for Near Future System and Technology, Kyoto University, Kyoto, Japan.*

α-Smooth muscle actin (SMA) is known to be a crucial marker for phenotypic transformation of glomerular mesangial cells. The SMA promoter contains two E-boxes, where the E2A binds and regulates the transcription.In this study, we tried to identify

a novel E2A binding protein and to examine its role in glomerulonephritis.Yeast two-hybrid screening using the cDNA library derived from mouse mesangial cells identified PIASy as an E12-interacting protein. The binding of PIASy to E12 was confirmed by co-immunoprecipitation in COS7 cells overexpressing both proteins. A small interfering RNA (RNAi) for PIASy significantly increased SMA mRNA expression, while RNAi for E12 reduced its expression in mesangial cells. Overexpression of E12 enhanced the SMA promoter activity approximately by 3 times, and the increase was blocked by co-transfection of PIASy in mesangial cells. Next, we examined the effects of TGF-β on PIASy in mesangial cells. The levels of PIASy mRNA were increased 12, 24, 48 hours after administration of 1ng/ml of TGF-β (1.36±0.32, 1.38±0.17, 1.72±0.22, respectively, $p<0.05$, vs. control). TGF-β also increased the levels of E12 and SMA in a time dependent manner consistent with PIASy. In vivo, we utilized an acute model of mesangial proliferative glomerulonephritis, Thy1 glomerulonephritis. Quantitative RT-PCR showed that glomerular PIASy, E12, TGF-β, and SMA mRNA were increased at days 6 (1.81±0.30, 2.95±0.62, 3.54±1.8, 32.4±30.3, respectively). Glomerular PIASy protein was also significantly increased at days 6 (1.77±0.45). Immunohistochemical analysis confirmed that PIASy was expressed in the mesangial area mainly at day 6. These results suggest that PIASy plays a critical role in experimental mesangial proliferative glomerulonephritis by modulating SM α-actin expression upon the interaction with E12.

**A Mouse Model of Spontaneous Mesangio-Proliferative Glomerulonephritis Linking Hyperlipidemia and Renal Disease** Harini Bagavant, Yogesh M. Scindia, Amanda Doran, Seshagiri Rao Nandula, Saleh Mohammad, Paromita Dey, Alexis Cutchins, Dominika Nackiewicz, Stephanie Oldham, Coleen Mcnamara, Umesh Deshmukh. *Division of Nephrology and 2 Cardiovascular Medicine, University of Virginia, Charlottesville, VA.*

Purpose: Hyperlipidemia is associated with chronic kidney disease, but per se does not cause renal failure. Animal and human studies suggest that renal disease in hyperlipidemia is determined by additional factors. We describe a mouse model of C57BL/6 (B6) mice, genetically deficient in Apolipoprotein E ($ApoE^{-/-}$) and a transcription regulator "Inhibitor of differentiation 3" ($Id3^{-/-}$) that can be used to investigate these factors.

Methods: It was recently shown that $ApoE^{-/-}Id3^{-/-}$ double knockout (DKO) develop hyperlipidemia and accelerated atherosclerosis. To study renal disease, male and female mice were maintained on regular mouse chow and sacrificed at 16 and 24wks. Renal pathology was evaluated by light and electron microscopy. Cell infiltrates and immune complex deposits were studied by immunostaining. Mesangial cell proliferation was studied by staining for Ki67 antigen and mesangial matrix expansion by fibronectin deposits. Proteinuria and serum creatinine levels were monitored for renal function. Gene expression in isolated glomeruli was studied using Affymetrix microarrays.

Results: DKO mice develop glomerular immune complex deposits, macrophage infiltration, and mesangio-proliferative glomerulonephritis (GN). DKO mice also develop loss of renal function. This was not seen in hyperlipidemic $B6.ApoE^{-/-}$ mice or normolipidemic $B6.Id3^{-/-}$ mice. Glomerular gene expression analyses indicate a dominant contribution of macrophage products in GN.

Conclusions: Results from DKO mice suggest that genetic factors like Id3 deficiency influences development of renal disease in hyperlipidemia. Recently, participants of a Diabetes Heart Study showed linkage of a functionally deficient Id3 SNP variant with atherosclerosis. Preliminary analyses also showed an association of the same variant with reduced glomerular filtration rate. Thus, pathways regulated by Id3 may also be important in human renal disease associated with elevated lipids.

**Impairment of Macrophage Function Resulting from Fc Receptor gamma Chain (FcRγ) Deficiency Causes the Development of Lipoprotein Glomrulopathy (LPG)** Kenji Ito, Maho Watanabe, Hitoshi Nakashima, Yasuhiro Abe, Takao Saito. *Div. of Nephrol. and Rheumatol., Dept. of Int. Med., Fukuoka University, Japan.*

[Purpose] LPG is a unique renal disease characterized by intraglomerular lipoprotein thrombi. In human, several novel apolipoprotein E(apoE) mutations and dyslipidemia were identified in patients with LPG. While, Kanamaru et al. reported LPG developed in chronic GVHD induced FcRγ-deficient mice. We attempted to clarify which has a principle role in development of LPG, dyslipidemia or FcRγ insufficiency. [Methods] Human apoE3 gene was introduced by adenovirus-mediated gene transfer into 20 week-old apoE and FcRγ double knockout(DKO), apoE knockout(AKO) and wild type(WT) mice, respectively. Blood sample were collected each time point, and kidneys were dissected after 3 weeks of apoE3 introduction. The specimens were stained with Oil Red O after lipid fixation in osmium tetroxide and were immuno-stained with CD68. For evaluation of macrophage function, peritoneal macrophages harvested from each genotype mice were cultured with oxidized LDL, and observed by light microscopy with Oil Red O stain. [Results] LPG-like lesions were observed in DKO and AKO, and the positive rate was significantly higher in DKO than that of AKO. The number of CD68 positive cells in glomerulus was significantly less in DKO than that in AKO. The oxidized-LDL uptake of macrophage was significantly reduced in DKO compared with macrophage from AKO. Serum total cholesterol(TC) levels of AKO and DKO were significantly higher than that of WT at baseline. After apoE3 introduction, serum TC levels were improved to normal level but triglyceride levels transiently increased in both mice. [Conclusion] Similar serum lipid alterations by human apoE3 administration were seen in DKO and AKO. While macrophage functions such as migration to glomeruli and uptake of oxidized LDL were significantly impaired in DKO. The fact that LPG was clearly frequently developed in DKO rather than AKO suggests that FcRγ impairment plays more important role in the development of LPG than dyslipidemia does. These results indicate that the pathogenesis of LPG may be related to macrophage dysfunction.

**Impaired Glomerular Adaptability Against Subtotal Nephrectomy after Conditional Knock-Out of Platelet-Derived Growth Factor Receptor (PDGFR)-β in Mice** Taizo Nakagawa,[1] Kumi Ichikawa,[1] Hidenori Yamazaki,[1] Takeru Hamashima,[2] Jie Shen,[2] Yoko Ishii,[2] Fumihiro Tomoda,[1] Hiroshi Inoue,[1] Masakiyo Sasahara.[2] *[1]The Second Department of Internal Medicine, University of Toyama, Toyama, Japan; [2]Department of Pathology, University of Toyama, Toyama, Japan.*

Background and Aim: Mesangial cell functions are critically regulated by PDGFR-βsignals. At ASN-Renal Week 2009, we have reported about systemically depleted PDGFR-β mice (Deletant). After 2 weeks of subtotal nephrectomy (SN), Deletant have shown increase of albuminuria. So we have hypothesized that the glomeruli have altered response to reduce renal mass under PDGFR-β depleted condition. To inspect the hypothesis, we have analyzed the pathology of remnant kidney(RK) at this phase.

Method: Deletant were obtained by giving tamoxifen to the mutant mice harboring both the PDGFR-β floxed allele and the transgenes encoding Cre recombinase with a tamoxifen-sensitive mutated estrogen receptor at 4 weeks of age. Mice with conserved PDGFR-β expression (Floxed) were used as controls. SN was carried out at 13 weeks of age, and RK were harvested after 2 weeks of SN.

Result: In RK of Floxed, the glomerular structures were preserved with dilated capillary lumina. On the other hand, in Deletant, abnormal glomeruli were focally detected, in which glomerular cells were distributed at higher density. In morphometry, although glomerular size similarly increased in both lines, Deletant included glomeruli with higher ratio of glomerular cell number for glomerular size (cellular density). As a result, the average of cellular density was significantly higher in Deletant than in Floxed. In electron microscopical observations (EM), mesangial cells formed branch-like structures to support the capillary lumina in Floxed. In contrast, collapsed glomeruli with hypertrophic podocytes were detected in Deletant. These changes were detected in 11 glomeruli of Deletant but none of Floxed within 34 glomeruli which were randomly selected from 4 mice of each line.

Conclusion: These glomerular changes were similar to collapsing glomerulopathy. This indicates the inhibition of PDGFR-β could induce impaired glomerular adaptability to massive nephron loss.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2869

**Proximal Tubular Injury and Rapid Formation of Atubular Glomeruli in Adult Mice with Unilateral Ureteral Obstruction: A New Look at an Old Model** Robert L. Chevalier, Michael S. Forbes, Barbara A. Thornhill. *Pediatrics, University of Virginia, Charlottesville, VA.*

Unilateral ureteral obstruction (UUO) is widely used as a model of progressive renal injury and fibrosis, with the mouse as the species of choice to study molecular mechanisms. While many renal disorders, including diabetes, lead to widespread formation of atubular glomeruli (ATGs) (JASN 19:197-206, 2008), identification of ATGs has been limited by the use of labor-intensive techniques (microdissection and serial sectioning). In rat models of renal disease (Heymann nephritis and polycystic disease), ATGs evolve over 6-8 months. Adult male mice were subjected to sham operation or complete UUO for 1 to 14 days. Kidneys were removed for determination of cell death (TUNEL), autophagy (LC3B) and collagen (Sirius); tubular atrophy and ATGs were identified by loss of *Lotus tetragonolobus* lectin staining from the epithelial cells of Bowman's capsule (normally present in 86%). After 7 days UUO, only 56±7% of glomeruli remained lectin-positive ($p<0.001$ vs. sham), and by 14 days, this fraction decreased to 18.5±3% ($p<0.001$ vs. sham and 7-day UUO). Integrity of the glomerulotubular junction of kidneys following 14 days UUO was validated in serial sections of 125 glomeruli: only 15% retained normal connections with proximal tubules (correlating with 18.5% lectin-positive); 46% were connected to atrophic proximal tubules, and 39% were ATGs. As a result of UUO, epithelial cells of the glomerulotubular junction die by apoptosis, autophagy and necrosis. Remaining cells at the glomerulotubular junction become flattened, the lumen collapses, followed by separation of glomerulus from tubule. While interstitial collagen deposition is largely limited to the medulla, and accounts for less than 5% of the fractional volume of the kidney, after 14 days of UUO over 80% of proximal tubules are atrophic or have separated from glomeruli. Thus, in addition to studying fibrogenic pathways in the mouse model of UUO, attention should be focused on the integrity of the glomerulotubular junction, which can be rapidly measured by Lotus lectin staining. This approach should lead to new insight in the pathogenesis of chronic kidney disease.

**Acute Kidney Injury during Hepatic Failure in Rats** Akira Shimizu, Yukinari Masuda, Shinya Nagasaka, Emiko Fujita. *Pathology, Nippon Medical School, Bunkyo-ku, Tokyo, Japan.*

Acute kidney injury (AKI) is a common complication in the acute liver dysfunction, posing an enormous obstacle to treatment efficiency and patient survival. However, little is known about the pathomechanisms of AKI during the development of acute liver dysfunction, in part due to the lack of an animal model. In this study, we characterize a rat model of AKI during the development of acute liver dysfunction following liver transplantation. Orthotopic liver transplantation was performed from DA (RT1a) to Lewis (RT1l) rats without immunosspression. In this combination, animal will die around day 11 with severe acute liver dysfunction. We studied kidney samples at day 5, day 7, and day 9 to 11, focusing on the cellular infiltrate and tubular injury. In addition, we also examined capillary injury in interstitium with the alteration of angiogenic growth factors.In the liver graft, a progressive acute cell- and antibody-mediated rejection developed leading to irreversible graft failure by day 11. During the progression of rejection of hepatic graft, acute liver dysfunction developed (T-Bil 6.4±2.8). During the development of liver dysfunction, AKI gradually developed in rats and is characterized by renal tubular degeneration with loss of brush border, KIM-1 expression, and severe disruption of renal proximal tubule epithelial filamentous-actin. In interstitium, focal interstitial edema occurred with neutrophil and mononuclear cell infiltration. In peritubular interstitial capillaries, endothelial dysfunction developed with decrease expression of eNOS. In addition, downregulation of VEGF, angiopoietin-1, and angiopoietin-2 was detected by immunohistochemistry and western blotting in renal cortex. In conclusion, AKI developed in rats during the development of acute liver dysfunction and was characterized by renal tubular degeneration and peritubular interstitial capillary endothelial dysfunction with decrease expression of angiogenic growth factors. Our rat model of AKI during liver injury closely mimics human AKI associated with acute liver injury and may be useful in delineating the mechanisms and potential therapies for this common clinical condition.

**SA-PO2871**

**A Murine Model of Phosphate Nephropathy** Philipp Eller, Kathrin Eller, Alexander R. Rosenkranz. *Innsbruck Medical University.*

Hyperphosphatemia is crucial since it correlates with all-cause mortality in patients with end stage renal failure. Acute hyperphosphatemia can result from ingestion of excessive amounts of phosphate-containing laxatives and results in an acute renal failure due to tubular precipitation of calcium phosphate deposits forming crystals of hydroxyapatite.

Db/db leptin-receptor deficient mice, which develop obesity and type II diabetes mellitus, were uninephrectomized at the age of 5 weeks and were either fed with standard chow or phosphorus-rich diet for the next 8 weeks. After 8 weeks renal cryosections of db/db mice treated with phosphorus-rich diet showed abundant tubular casts of calcium phosphate crystals with a strong histochemical reaction in the von Kossa stain as compared to controls. The acute degenerative tubular changes were accompanied by peritubular infiltration of CD4+, CD8+ T cells and macrophages as well as by interstitial fibrosis. Serum-phosphate levels significantly increased, whereas serum-calcium levels decreased in db/db mice treated with phosphorus-rich diet as compared to db/db mice on standard diet. Interestingly, db/db mice on phosphorus-rich diet had less body weight, significantly lower fasting blood glucose levels and a lower HOMA insulin resistance index. Moreover, they performed a significantly improved glucose as well as insulin tolerance test and had significantly smaller adipocyte diameters in the visceral adipose tissue. Significantly decreased numbers of CD8+ T cells, monocytes/macrophages, but increased numbers of CD4+FoxP3+ T cells were detected in the visceral fat of mice fed with a phosphorus-rich diet. Contrary, no difference in the size of subcutaneouse adipocytes or in the infiltration of inflammatory cells into the subcutaneous fat was observed between db/db mice on phosphorus-rich or standard diet. Additionally, mice with acute phosphate nephropathy displayed significantly thicker myocardial septal wall and smaller interior diameter of the left ventricle.

We here provide a murine model of phosphate nephropathy, which can be used for future pharmacological and pathophysiological studies analyzing the effect of hyperphosphatemia on renal, metabolic and cardiovascular phenotypes.

**Activation of Hypoxia-Inducible Factor Protects Against Cyclosporine A Induced Chronic Nephrotoxicity** Sewon Oh,[1] Jeongmyung Ahn,[2] Yun Mi Lee,[1] Su Jung Ha,[1] Ho Jun Chin,[1] Dong Wan Chae,[1] Ki Young Na.[1] *[1]Department of Internal Medicine, Seoul National University Bundang Hospital; [2]Department of Internal Medicine, Maryknoll Hospital, Busan, Democratic Peoples Republic of Korea.*

**Background:** Chronic cyclosporine A (CsA) nephropathy is characterized by interstitial fibrosis, arteriopathy and inflammatory cell infiltration. The main mechanism of Chronic CsA nephropathy is a chronic hypoxic injury and promotes apoptosis on renal tubular cells. Hypoxia-inducible factor (HIF) is a transcription factor which allows cells to adapt hypoxia, and it is known as a target to protect kidney from hypoxia. We investigated the hypothesis that HIF activation could attenuate the renal injury in chronic CsA nephropathy.

**Methods:** Male Sprague Dawley rats kept on a 0.05% low salt diet were treated with CsA for 28 days (15mg/kg/day, subcutaneous). Rats received a continuous infusion of cobalt chloride (CoCl) (10mg/kg/day) and dimethyloxalyglycine (DMOG) (100mg/kg/day) via osmotic minipump during the whole experimental period to activate HIF.

**Results:** CoCl or DMOG infusion did not significantly improve creatinine clearance (0.040± 0.004; CsA, 0.035±0.004; CoCl, 0.032±0.005 ml/min/100g; DMOG) and proteinuria (77.59±41.48; CsA, 55.82±7.03; CoCl, 33.82±8.44 mg/day; DMOG). Rat kidney treated with CoCl or DMOG showed the improvements of arteriopathy (1.75±0.25; CsA, 0.75±0.14; CoCl, 0.75±0.14; DMOG, $P<0.05$ vs. CsA) and tubulointerstitial fibrosis (2.83±0.58 vs. 1.25±0.35, CsA vs. DMOG; $P<0.05$). CoCl or DMOG increased renal HIF-1α protein, as manifested by western blot of nucleus extracts in the kidneys. Immunohistochemical evaluation revealed that the number of infiltrating glomerular and interstitial macrophages were significantly higher in CsA treatment group and this increase was attenuated by CoCl (12.94±2.04 vs. 4.62±0.99, CsA vs. CoCl, $P<0.05$) and DMOG treatment(1.3±0.85, $P<0.05$ vs. CsA). Enhanced apoptotic cell death in CsA- treated rat was decreased with CoCl treatment (76.03±13.11 vs. 10.65±7.28, CsA vs. CoCl , $P<0.05$).

**Conclusion:** Activation of HIF by CoCl or DMOG attenuates renal injury through anti-inflammatory and anti-apoptotic effect.

**Tubular Angiogenic Response after Glomerular Injury Is Modified by Pigment Epithelium Derived Factor** Davide Pietro Cina,[1] Hui Xu,[2] Limin Liu,[3] Laszlo Farkas,[4] Daniela Farkas,[4] Peter Margetts.[3] *[1]Medicine, University of Toronto, Toronto, ON, Canada; [2]Nephrology, Xiangya Hospital, Changsha, China; [3]Medicine, McMaster University, Hamilton, ON, Canada; [4]Internal Medicine, Virginia Commonwealth University, Richmond, VA.*

Peritubular vascular changes and hypoxia in the setting of glomerular injury may explain subsequent tubulointerstitial injury and fibrosis. We used a common model of glomerular injury in rats in order to assess vascular changes and to identify potential factors associated with regulating the angiogenic response. Further, we evaluated the effect of hypoxia on cultured renal tubular epithelial cells (HK2). Anti-Thy1.1 antibody administration (1 or 4 weekly doses) led to a dose dependent renal damage characterized by glomerulonephritis, elevated serum urea, and tubulointerstitial fibrosis. Using laser capture microdissection, we demonstrated an early induction of fibrogenic and angiogenic factors in the glomeruli and a subsequent dysregulated angiogenic response in the tubulointerstitial compartment in animals that developed glomerulonephritis. This was associated with peritubular capillary rarefaction assessed by CD34 and CD31 staining. Proximal tubules of anti-Thy1.1 treated animals demonstrated an increase in the angiostatic pigment epithelial derived factor (PEDF). Temporally associated with PEDF expression was a transient downregulation of tubular hypoxia inducible factor (HIF)1α. In HK2 cell culture, hypoxia induces HIF1α expression and this was down regulated by PEDF. Hypoxia also induced prolyl hydroxylase (PHD) 2 and PHD3 expression, but PHD expression was not differentially regulated by PEDF. PEDF expression was not regulated by hypoxia, and transforming growth factor β significantly suppressed PEDF expression.

In anti-Thy1.1 glomerulonephritis, there is aberrant tubular angiogenesis associated with glomerular injury and tubulointersititial fibrosis. We showed that PEDF may be involved by downregulating HIF1α. Further work is needed to elucidate the mechanism of PEDF upregulation and action in the tubules.

**SA-PO2874**

**TGFβ Differentially Regulates Expression of Cadherins in Proximal Tubule Cells** Nileshkumar Shah,[1] Iain Macphee,[2] Mark Edward Dockrell.[1] *[1]SW Thames Institute for Renal Research, London, United Kingdom; [2]Renal Medicine, St George's, University of London, London, United Kingdom.*

Adherens junctions and their constituent cadherins mediate adhesion between cells and maintain local intracellular concentrations of scaffolding and signaling molecules. They are key in regulating differentiation and polarisation of epithelial cells. E-cadherin (CDH1) has been much studied in the loss of renal epithelial integrity and the development of tubulointerstitial fibrosis, particularly in the context of TGFβ1. Our current studies of expression of cadherins in human biopsies (submitted in a separate abstract) indicate that CDH1 is not expressed in the human proximal tubule but that CDH2 (N-cadherin) and CDH6 (K-cadherin) are the predominant isoforms there.

Hence, we have investigated the CDH expression and regulation by TGFbeta. in human proximal tubule epithelial cells (PTEC) in culture.

Three cell models were used; primary cultures, SV 40 transformed HKC, and HPV transformed HK-2, cells. Cells were grown to 75% confluence and treated with TGFβ1 in a dose (1.25-5.0 ng/ml) and time (1-72 h) dependent manner. CDHmRNA was studied by RT-qPCR; and protein by immunoblotting.

In HKC CDH1 protein was readily detectable along with CDH2 but not CDH6. In contrast, in primary PTEC all 3 CDHs were detected. qPCR demonstrated higher expression of CDH6 and lower expression of CDH1 in primary cells compared to HKC. HK-2 cells had a similar profile to primary cells.

CDH1 mRNA and protein was down-regulated by TGFβ1 in all cell lines, as expected.

In contrast CDH2 was consistently up-regulated in all models.

In Primary cells TGFβ1down-regulated CDH6 protein but this was not reflected by reduction in mRNA. In contrast, in HK-2 cells CDH6 was upregulated both at protein and mRNA level.

Our results show that although TGFβ1 does down regulate CDH6 in primary cultures, unlike CDH1 this is not transcriptionaly regulated and therefore may not involve traditional TGFβ1 signaling. The TGFβ1-inudced increase in CDH2 is consistent with

the association of CDH2 with a migratory phenotype. The "natural" CDHs of the human proximal tubule do not respond to TGFβ1 in a manner predicted from murine or existing cell culture models.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2875**

**Altered Expression of the LIM Protein Hic-5 in Glomerular and Tubular Cells during Unilateral Ureteral Ligation** Nick Hornigold,[1] Madeleine Anne Vernon,[2] Jeremy Hughes,[2] Andrew F. Mooney.[3] *[1]CRUK Clinical Research Centre, St James's University Hospital, Leeds, West Yorkshire, United Kingdom; [2]Queen's Medical Research Institute, University of Edinburgh, Edinburgh, Scotland, United Kingdom; [3]Renal Unit, St James's University Hospital, Leeds, West Yorkshire, United Kingdom.*

The LIM protein, Hic-5, has an established role in experimental glomerular scarring (KI 2010). In vitro, mesangial cell attachment to collagen I upregulates Hic-5, initiating a pro-sclerotic phenotype with increased susceptibility to apoptosis (ASN 2008). Hic-5 is also expressed in normal distal tubular cells but its role here is unknown. We have now studied the tubular and glomerular expression of Hic-5 during unilateral ureteral ligation.

Rats underwent unilateral ureteral ligation by standard methods and were sacrificed at days 0, 7, 14 and 21. Immunohistochemical analysis of Hic-5 expression was undertaken and quantified by a blinded observer.

At day 0, there was no glomerular Hic-5 expression, as previously reported, but widespread expression in distal tubular cells. During progression of the disease, this pattern reversed. Using semi-quantitative scoring on a scale of 0-5, Hic-5 expression in glomeruli increased from 0.05 +/- 0.1 at day 0, to 0.14+/-0.02 at day 7, 1.57+/- 0.39 at day 14 and 1.69+/- 0.81 at day 21 despite no obvious changes in glomerular morphology.

To assess tubular expression, consecutive random cortical cross-section high-power fields were counted for Hic-5 positive cells. These changed from 140.6 +/- 7.7 at day 0, to 29.5 +/- 9.5 at day 7, 43.7 +/- 20.7 at day 14 and 36.8 +/- 3.8 at day 21.

These data suggest an important role for Hic-5 in tubular disease as well as glomerular disease. Experiments are underway to understand the consequences for tubular cells of reduced Hic-5 expression.

This work was supported by KRUK and the Yorkshire Kidney Research Fund.

**SA-PO2876**

**A Novel Benzylidene-Thiazolidinedione with Specific and Partial Agonist Activity on PPARγ** Angélica Amorim Amato,[1] Senapathy Rajagopalan,[5] Bruno M. Carvalho,[2] Mario Saad,[2] Marie Togashi,[1] Luiz A. Simeoni,[1] Igor Polikarpov,[3] Maria Carmo Alves Lima,[4] Suely L. Galdino,[4] Ivan R. Pitta,[4] Paul Webb,[5] Kevin Phillips,[5] Francisco R. Neves.[1] *[1]Pharmaceutical Sciences, University of Brasilia, Brasilia, Federal District, Brazil; [2]Internal Medicine, State University of Campinas, Campinas, Sao Paulo, Brazil; [3]Physics, University of Sao Carlos, Sao Carlos, Sao Paulo, Brazil; [4]Antibiotics, University of Pernambuco, Recife, Pernambuco, Brazil; [5]Center for Diabetes Research, The Methodist Hospital Research Institute, Houston, TX.*

Thiazolidinediones (TZDs) can improve whole body insulin sensitivity and ameliorate glucose metabolism in many animal models of obesity and diabetes, and also in humans. Despite the established therapeutic value of TZDs, their clinical use is limited by a number of adverse effects. Aiming to identify novel peroxisome proliferator-activated receptor-gamma (PPARgamma) ligands, synthetic benzylidene-TZDs were screened for PPAR agonist activity using reporter gene assay in U-937 human pro-monocytes. GQ-16 (5-(5-bromo-2-methoxy-benzylidene)-3-(4-methyl-benzyl)-thiazolidine-2,4-dione) was the only compound found to have agonist activity on PPARgamma. This compound displayed features of a partial and specific agonist for the receptor. It also repressed TNF-alpha promoter in human mesangial cells in a concentration-dependent manner, with reduced potency but with a comparable maximal response to rosiglitazone. GQ-16 bound PPARgamma with reduced affinity when compared to rosiglitazone, induced a protease digestion pattern similar to rosiglitazone, and SRC1 recruitment similar to troglitazone. The adipogenic potential of GQ-16 was less pronounced than that of rosiglitazone in vitro. Studies in obese Swiss mice indicated GQ-16 treatment results in insulin sensitization comparable to rosiglitazone, but with no weight gain. The cocrystal structure of GQ-16 with PPARgamma ligand-binding domain revealed a different binding mode when compared to that of rosiglitazone. These data establish GQ-16 as a novel PPARgamma agonist with promising therapeutic utility with the potential for less weight gain.

**Eicosapentaenoic Acid Restores Diabetic Tubular Injury through Regulating Oxidative Stress and Mitochondrial Apoptosis** Sekiko Taneda,[1] Kazuho Honda,[1] Chiharu Aoki,[1] Saeko Kanai,[1] Kosaku Nitta,[2] Hideaki Oda,[1] Kenta Uto.[1] *[1]Department of Pathology, Tokyo Women's Medical University; [2]Department of Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

**Objective:** The present study was designed to elucidate the mechanism of early diabetic tubular injury which is important in the pathogenesis of diabetic nephropathy, and to examine a therapeutic potential of dietary eicosapentaenoic acid (EPA) for the prevention of diabetic nephropathy. **Research design and methods:** Utilizing streptozotocin (STZ)-induced diabetic mice, albuminuria and the extents of histological injuries were monitored at 2 weeks after diabetes induction. Reactive oxygen species (ROS) production, apoptosis and hypoxia in the kidney were evaluated by immunohistochemistry and western blotting. In vitro study was performed using rat proximal tubular cells (NRK-52E) to confirm the protective effects of EPA for methylglyoxal (MG)-induced ROS generation and mitochondrial apoptosis. **Results:** The extents of albuminuria and histological tubular injuries were significantly lower in EPA-treated diabetic mice compared to the untreated diabetic mice. The levels of lipid peroxidation product (4-hydroxy-2-nonenal), oxidative DNA damage (8-hydoxy-deoxyguanosine), and mitochondrial apoptosis (TUNEL, caspase-9, cleaved caspase-3 and cytochrome C release) in the tubular cells were also significantly lower in EPA-treated diabetic mice. Furthermore, HIF-1α expression was significantly up-regulated in kidney tissues from EPA-treated mice than from untreated diabetic mice, although both diabetic groups were at similar levels of pimonidazole. NRK-52E cells incubated with MG induced ROS overproduction and apoptosis, and both of which were significantly reduced by the EPA treatment. **Conclusions:** Our results indicated that the ROS generation and mitochondrial apoptosis were involved in hyperglycemia-induced tubulopathy and EPA has a beneficial effect by suppressing ROS formation and apoptosis partly through the augmentation of HIF-1α response in diabetic tubular injury.

**SA-PO2878**

**Sildenafil, a Phosphodiesterase Type 5 Inhibitor, Attenuates Diabetic Nephropathy in Non-Insulin-Dependent Otsuka Long-Evans Tokushima Fatty Rats** Yoshihiro Kuno, Masayuki Iyoda, Takanori Shibata, Yuki Hirai, Tadao Akizawa. *Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan.*

Background. It is well established that the pathogenesis of diabetic nephropathy (DN) is associated with abnormalities of renal nitric oxide (NO) generation. Many of the biologic actions of NO are mediated by cGMP, which is rapidly degraded by phosphodiesterases (PDE). In this study, we evaluated the renoprotective effects of sildenafil (SIL), an inhibitor of PDE-5, in type 2 diabetic rats. Methods. Male Otsuka Long-Evans Tokushima Fatty (OLETF) rats, a non-insulin-dependent diabetes model, and Long-Evans Tokushima Otsuka (LETO) rats, a non-diabetic control, were treated with either SIL (2.5 mg/kg in drinking water) (OLETF-SIL) or undosed water (OLETF-CON) for 28 weeks, starting at 20 weeks of age; all rats were sacrificed at week 48. Albuminuria, BP, and BW were measured periodically. Results. SIL treatment significantly decreased albuminuria (36.19 ± 6.35 vs. 48.01 ± 8.21, $p < 0.05$), attenuated glomerular hyperfiltration, and resulted in a decrease in glomerular hypertrophy (glomerular size: 9921.71 ± 266.60 vs. 10856.60 ± 206.65 mm2, $p < 0.05$), in addition to a reduced glomerulosclerosis score (semiquantitative score: 0.89 ± 0.13 vs. 1.42 ± 0.13, $p < 0.05$) and a dramatic decrease in the number of glomerular and tubulointerstitial PCNA-positive cells in OLETF rats (PCNA+ cells in glomerulus: 0.043 ± 0.02 vs. 6.68 ± 0.37, $p < 0.0001$; PCNA+ cells in tubulointerstitium (0.5mm2): 4.60 ± 0.50 vs. 63.90 ± 16.00, $p < 0.001$). This was accompanied by a significant reduction in renal cortical mRNA levels of collagen types I ($p < 0.05$) and III ($p < 0.05$). The increased mRNA levels of matrix metalloproteinase (MMP)-2, MMP-9, tissue inhibitors of MMPs (TIMP)-1, and TIMP-2 in the OLETF rats were significantly or partially attenuated by SIL treatment (MMP-2, $p < 0.01$; MMP-9, $p < 0.01$; TIMP-1, $p < 0.05$; TIMP-2, NS, OLETF-SIL vs. OLETF-CON). Conclusions. This study suggests that SIL attenuated DN by its potent antiproliferative effects and by regulating extracellular matrix by affecting the balance between MMPs and their inhibitors.

**Precedent Anti-Inflammation and Suppression of Subsequent Interstitial Fibrosis in the Kidney by Non-Smooth Muscle Calponin (Calponin-h2) in Diabetic Mice Are Independent of Both Glucose Metabolism and Expression of Its Related Molecules** Kiyoko Inui, Takahiro Nakayama, Yoshihiko Inoue, Ashio Yoshimura. *Division of Nephrology, Showa University Fujigaoka Hospital, Yokohama, Kanagawa, Japan.*

Neutral calponin (Calponin-h2, CN2) is a non-smooth muscle isoform, and suppresses smooth muscle cell migration in addition to physiological roles in cytoskeletal organization. We established CN2 transgenic (CN2-Tg) mouse with the CRE-loxP site-specific recombination system, in that CN2 expression is induced only during the treatment of cadmium sulfate (0.5mg/kg BW/day) and we studied participation of CN2 in diabetic interstitial injury. Diabetes was induced by streptozocin (STZ, 100mg/kg BW x 2 times/3days) on both of CN2-Tg mouse and wild type ones (WT). Cadmium sulfate intraperitoneal treatment was started 5 days before the first STZ injection. Nephrectomy was done on 8 and 30 days after disease induction as well as on day 0 (n=6 in each). Immunostaining showing below was performed for evaluation of interstitial inflammation and all data were evaluated by computer-analysis system. The interstitial cell proliferation (ki-67$^+$ cells/high power field, hpf) was significantly suppressed in CN2-Tg at day 8 (3.7±0.5 (m±SE) in CN2-Tg, vs 5.7±0.4 in WT, $p<0.05$), and reduction of macrophages recruitment in the interstitium (F4/80$^+$ cells/hpf) was induced in CN2-Tg at day 8 (3.7±0.1 vs 6.9±1.3 , $p<0.02$), and day 30 (2.2±0.7 vs 5.4±0.5, $p<0.01$). Interstitial fibropsis was also significantly suppressed in CN2-Tg. There was no significant diffetrence in serum levels at day 8 for glucose (500.9±25.2 vs 444.3±76.9 mg/dl), insulin (0.5±0.02 vs 0.5±0.03 ng/ml), reptin (68.3±2.5 vs 68.4 ±2.6 pg/ml) and adiponectin (37.9±4.1 vs 48.0±4.0 ng/ml), those were all

studied by EIA. In conclusion, CN2-Tg mice showed precedent anti-inflammatory property and suppressed subsequent development of interstitial renal fibrosis in diabetes mellitus, those were independent of glucose metabolism and expression of its related molecules.

**Identification of Periostin as a Novel Matricellular Protein Linked to Progression of Glomerulonephropathies** Kontheari Sen,[1] Maja Lindenmeyer,[1,2] Ariana Gaspert,[3] Felix H. Eichinger,[4] Matthias Kretzler,[4] Stephan Segerer,[2] Clemens D. Cohen.[1,2] *[1]Institute of Physiology, University of Zurich, Zurich, Switzerland; [2]Division of Nephrology, University Hospital Zurich, Zurich, Switzerland; [3]Institute of Surgical Pathology, University Hospital Zurich, Zurich, Switzerland; [4]Department of Medicine, University of Michigan, Ann Arbor.*

Matricellular proteins (MP) are known to be involved in the pathogenesis of chronic nephropathies. To identify MP contributing to the progression of glomerulonephropathies (GN), glomerular gene expression was studied by microarrays on patients with focal-segmental glomerulosclerosis (FSGS, n=19), membranous GN (MGN, n=21), minimal change disease (MCD, n=5) and confirmed by real-time RT-PCR on additional biopsies. Immunohistochemistry (IHC) was performed on routine kidney biopsies.

Fifteen out of 19 known MP were found to be induced on transcriptional level in proteinuric GN. The highest induction was seen for periostin (POSTN), specifically in the progressive diseases FSGS and MGN. Real-time RT-PCR on glomerular samples confirmed the POSTN mRNA induction in progressive GN (lupus nephritis (LN, n=20) 12.9±33.8, $p<0.001$, FSGS (n=16) 2.3±1.9, $p<0.05$, MGN (n=14) 1.9±1.9, $p<0.1$). POSTN mRNA expression showed a negative correlation with renal function in a larger set of glomerular and tubulointerstitial specimen ($r=-0.18$, p=8.1E-03, $r=-0.47$, p=6.9E-14, respectively; n=221). By IHC on healthy kidneys a discrete positivity for periostin was found in the glomerular tuft, surrounding the vascular pole, and along the Bowman's capsule; no expression in the tubulointerstitium was detected. A prominent mesangial periostin staining was present in biopsies with progressive GN. Furthermore, periostin was found in areas of interstitial fibrosis. Co-immunofluorescene for smooth muscle actin and periostin revealed no overlap but a clear proximity suggesting mesangial cells (MC) as the source of glomerular periostin. This was supported by the detection of periostin by western blot on a MC line and its supernatant.

In sum, periostin is constitutively expressed in healthy glomeruli and is linked to progression of GN and renal failure.

**Adiponectin Regulates Bone Marrow-Derived Fibroblasts in Renal Fibrosis** Song-Chang Lin, Gang Chen, Feixia Dong, Jie Du, William E. Mitch, Yanlin Wang. *Department of Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Progressive renal fibrosis is the final common manifestation of chronic kidney disease resulting in irreversible loss of kidney parenchyma and renal function. Myofibroblasts play a critical role in the pathogenesis of renal fibrosis. Their origin remains controversial. Recent evidence suggests that bone marrow-derived fibroblasts can be detected in the kidney leading to renal fibrosis. In this case, the stimulus for recruitment of bone marrow-derived fibroblasts into the kidney is not clearly defined. Adiponectin (APN) is a circulating adipokine that can influence the migration of progenitor cells. Since APN levels are elevated in chronic kidney disease, we investigated the role of adiponectin in regulating the uptake of bone marrow-derived fibroblast into the kidney in a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO). Wild type (WT) and adiponectin knockout (APN-KO) mice were subjected to UUO and maintained for up to 2 weeks. Bone marrow-derived fibroblasts, identified as cells positive for both CD45 and collagen I or cells positive for both CD11b and collagen I, were accumulated in obstructed kidneys of WT mice in a time-dependent manner, reaching a peak at 5 days after UUO, which were significantly reduced in obstructed kidneys of APN-KO mice. Furthermore, the number of bone marrow-derived myofibroblasts that are positive for both CD45 and α-SMA were significantly decreased in obstructed kidneys of APN-KO mice compared to those of WT mice. Compared to contralateral kidneys, obstructed kidneys of WT mice showed increases in type I collagen and α-SMA as determined by immunohistochemical staining and Western blot analysis and total collagen as detected by picrosirius red stain. All of these parameters were attenuated in obstructed kidneys of APN-KO mice. These data indicate that APN can play a significant role in the recruitment and activation of bone marrow-derived fibroblasts during the pathogenesis of renal fibrosis.

**Analysis of GDNF-Inducible Zinc Finger Protein 1 Expression in Human Diseased Kidney** Shoji Saito,[#1,#2] Shoichi Maruyama,[#1] Seiichi Matsuo,[#1] Masahide Takahashi.[#2] *[1]Nephrology, Nagoya University, Nagoya, Aichi, Japan; [2]Tumor Pathology, Nagoya University, Nagoya, Aichi, Japan.*

The glial cell-line-derived neurotrophic factor (GDNF)-RET signaling pathway plays an important role in kidney development. We have previously identified a novel zinc finger protein, GZF1 (GDNF-inducible zinc finger protein 1), whose expression was induced in the human neuroblastoma cell line TGW expressing RET by GDNF stimulation and also detected in mouse metanephric kidney. In the present study, we examined the immunohistochemical expression of GZF1 in normal human kidney and various kidney diseases including chronic kidney disease (CKD) and cancers, and assessed the clinical significance of GZF1 expression. In the normal kidney, GZF1 was highly expressed only in the proximal tubular epithelial cells that were also positive for angiotensin-converting enzyme. We also evaluated GZF1 expression in various kidney diseases including membranous nephropathy, minimal change nephrotic syndrome, IgA nephropathy, diabetic nephropathy, acute tubular necrosis and ANCA-related glomerulonephritis. We found that decreased expression of GZF1 was associated with an increase in tubulointerstitial damage and serum creatinine levels. In addition, GZF1 expression was undetectable or very low in most cases of renal cell carcinomas and Wilms tumors. These findings suggest that GZF1 represents a new marker for renal proximal tubules and that there is an inverse correlation between the expression level of GZF1 and tubular function.

**Expression of P311 and Transforming Growth Factor-β1 in the Inflammatory Injured Human Kidneys** Feng Ping Wang, Zi Li, Junming Fan, Ping Fu. *Department of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

***Background:*** By binding to the transforming growth factor-β1 (TGF-β1) latency associated protein (LAP), P311 can induce myofibroblast phenotype in NIH3T3 cells *in vitro*, which suggested P311 involves in the fibrosis progression. This study was to detect the expression of P311 and TGF-β1 in the inflammatory injured human kidneys. ***Methods:*** 57 immunoglobulin A nephropathy (IgAN) patients, 11 membranoproliferative glomerulonephritis(MPGN) patients, 10 minimal-change nephrotic syndrome(MCNS) patients, 10 lupus nephropathy (LN) patients and 10 controles from partial nephrectomy were included. Clinical data from these patients at renal biopsy are shown in Table 1. In IgAN, the relevant clinical data of subgroups according to Katafuchi pathological cumulative scores were expressed in Table 2. P311 and TGF-β1 protein expression were detected by immunohistochemistry. Clinical data such as proteinuria quantification, serum creatinine level were analysized. The relationship between P311 and TGF-β1 in IgAN was analysized. ***Results:*** In normal human kidneys, anti-P311 antibody and anti-TGF-β1 antibody detected negative or weak immunoreactivity in renal tubular cells (Fig.1: a, b). In inflammatory injured human kidneys, intense P311 immunoreactivity was localized to distal tubules and collecting ducts (Fig.2: a,c,e,h), whereas TGF-β1 showed intense staining in both distal and proximal tubules (Fig.2: b,d,e,g). In addition, there was significant difference in P311 protein expression among different pathological grading subgroups in IgAN (Table 3; Fig.3). P311 protein expression in tubulointerstitial tissue was correlated with TGF-β1 in IgAN ($r = 0.921$, $P < 0.001$). ***Conclusions:*** These results indicate P311 and TGF-β1 was expressed in inflammatory injured human kidneys. P311 might be a key cytokine and be involved in the progression of renal fibrosis by binding to the TGF-β1 LAP.

**Role of Epithelial Mesenchymal Transdifferentiation (EMT) in Pathogenesis of Collapsing Focal Segmental Glomerulosclerosis in Children** Hanan K. Tawadrous,[1] Raafat Gorgy,[3] Sonal Bajaj,[1] Anthony D. Nicastri,[1] Morris J. Schoeneman,[1] Pravin C. Singhal,[2] Anil K. Mongia.[1] *[1]Pediatrics, Downstate Medical Center, Brooklyn, NY; [2]Medicine, Long Island Jewish Medical Center, New Hyde Park, NY; [3]Medicine, Trinitas Regional Hospital, Elizabith, NJ.*

*Background:* Collapsing focal segmental glomerulosclerosis ( CFSGS) is characterized by severe nephrotic syndrome, collapse and sclerosis of the glomerular tuft with prominent podocyte alterations and extensive tubulointerstitial lesions. Although there is an agreement on glomerular proliferative phenotype, the type of cells contributing to this phynotype remains controversial. Epithelial mesenchymal trans differentiation (EMT) is a process in which renal epithelial cells lose their epithelial phenotype and attain new characteristic features of mesenchymal cells. EMT has been reported to contribute to the progression of renal fibrosis in animal models. Increase expression of proliferating cell nuclear antigen (PCNA), α-smooth muscle actin(α-SMA), fibroblast-specific protein-1(FSP1) increase in EMT.

*Design:* We studied the role of EMT in the pathogenesis of collapsing type of FSGS. To determine the transformation of epithelial cells to myofibroblasts, we immunolabeled renal cortical sections from 8 patients with CFSGS and 3 controls for -SMA, PCNA, FSP1, E-cadherin. The number of positive cells in 10 random fields was counted, and the mean numbers of cells were calculated per glomerulus and per tubule. The results were compared with historical controls.

*Results:* Our data showed an increase of α- SM-actin, PCNA, FSP-1 positive stain in CFSGS pts in comparison to the controls. SMA means per glomerulus (SMA 28.6±8.75 vs1.5±1.1 p 0.0007 , PCNA17.3±6.58 vs 1.8±1.2, p 0.0035 FSP1 2.42 ±0.76 vs 0.5± 0.1 p 0.002) and per tubules SMA 17.42 ± 6.63 vs 1.5±1.1 p0.002 PCNA 6.16±3.05 vs 1.4±0.5p 0.009 FSP1 2.22±0.76 vs 1.25±1 p_0.11. E-cadherin was diminished for glomerulus 4.21±2.68and per tubules 1.66±1.41p <000.1

*Conclusion:* We conclude that renal cell EMT plays a role in the development of collapsing FSGS and increased intensity of SMS, PCNA, or FSP might correlate with *Conclusion:* We conclude that renal cell EMT plays a role in the development of collapsing FSGS and increased expression of SMS, PCNA, or FSP might correlate with intensity of the disease.

**Oral Iron Chelator – Deferiprone Prevents Nephrogenic Systemic Fibrosis in Mice** Chhanda X. Bose,[1] Sudhir V. Shah,[1] Kim M. Hiatt,[2] Sundararaman Swaminathan.[1] *[1]Nephrology, University of Arkansas for Medical Sciences, Little Rock, AR; [2]Dermatopathology, University of Arkansas for Medical Sciences, Little Rock, AR.*

**Background**: Nephrogenic Systemic Fibrosis (NSF) is associated with tissue accumulation of iron. Gadolinium contrast agents induce iron mobilization. However, role of endogenous iron in the pathophysiology is NSF has never been examined before. We examined this by using an oral iron chelator- deferiprone in a murine model of NSF.

**Methods:** In BalbC mice, we performed staged 5/6 nephrectomy to induce chronic kidney disease (CKD). Omniscan was administered intravenously, in various dosages (0.1, 0.5 and 2.5 mmol/Kg) and frequency (5 days a week to thrice a week) to CKD and sham-operated mice. Mice were sacrificed at varying time points (4 weeks to 18 weeks) after completing the Omniscan treatments. Once the murine NSF model was established, experiments were repeated in which oral iron chelator-deferiprone was administered along with IV Omniscan in a subgroup of mice. After 4-18 weeks of treatment, histologic analyses were performed.

**Results:** Omniscan treatment induced ulceration and sloughing of tail. No overt skin changes were observed in other areas of the skin. Progressive weight loss was observed in the Omniscan-treated mice. Early skin biopsies revealed mast cell and macrophages accumulation and increase in dermal collagen. Low doses (0.1 mmol/Kg) of Omniscan) induced NSF-like skin changes in CKD mice evaluated at 18 weeks. Iron chelator treated mice exhibited less tail ulceration, decreased weight loss with preservation of adipose tissue and diminished mast cell and macrophage infiltration and substantially decreased dermal fibrosis.

**Conclusion:** Prevention of NSF in this mice model suggests an important role for iron in the pathogenesis of gadolinium toxicity and NSF.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2886**

**Cutaneous Toxicity of Various Gadolinium Chelates in a Rat Model of Nephrogenic Systemic Fibrosis** Nathalie Fretellier,[1] Patrick Bruneval,[2, 3] Chantal Mandet,[2] Nejma Bouzian,[1] Jean-Marc Idee.[1] *[1]Research Department, Guerbet, Roissy, France; [2]INSERM U970, INSERM, Paris, France; [3]Pathology, University Paris Descartes, Paris, France.*

Nephrogenic systemic fibrosis (NSF) is a severe side effect of gadolinium chelates (GC) used as contrast agents for MRI in patients with end stage renal failure. The aim of this study was to test the cutaneous toxicity of various GC in a sensitized rat model of NSF.

Chronic renal failure was induced in male Wistar rats by 5/6 nephrectomy. Rats were sensitized by high phosphate diet (1%). Rat groups (n = 8/group) received single daily intravenous injections for 5 days either of saline for the control group or various GC at 2.5 mmol/kg (mL/kg of body weight): gadodiamide (Omniscan®), gadoterate (Dotarem®), gadobenate (MultiHance®), or gadobutrol (Gadovist®). Skin biopsies were performed at days 1, 8, and 25 ( or at premature animal sacrifice). Clinical and histological analysis were assessed blindly.

In all the rat groups, no early skin lesion were observed at days 1 and 8. In the gadodiamide-treated group, ulcerative and squamous skin eruptions appeared in 5 rats out of 8, from Day 8 until Day 23, and worsened in 4 animals or improved in 1 rat. Four rats were sacrificed for ethical reasons. No clinical skin lesions were observed in the other GC-treated groups or in controls. Skin histology was abnormal in 6 rats out of 8 in the gadodiamide-treated group, while no histological skin changes were observed in the other groups. Lesions consisted of bands of inflammatory dermal fibrosis. ED1-positive macrophages accumulated in the involved dermis and expressed TGFβ1. They were associated with an increased density of fibroblasts expressing TGFβ1, CD34, and S100A4 (equivalent to FSP1). Interestingly no myofibroblasts expressing α-smooth muscle actin were detected. In all the other GC-treated groups and in controls, histological and immunohistochemical patterns were normal.

In conclusion, the nonionic, linear GC gadodiamide is associated NSF-like skin lesions in hyperphosphoremic rats with advanced chronic renal failure.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2887**

**A Mineralocorticoid Receptor Antagonist Prevents Chronic Cyclosporine A Nephropathy in the Rat** Finn Thomsen Nielsen,[1,2] Boye Jensen,[1] Pernille B. Hansen,[1] Peter Bie.[1] *[1]Inst. of Molecular Medicine, University of Southern Denmark, Odense, Denmark; [2]Nephrology Clinic P, Copenhagen State Hospital, Copenhagen, Denmark.*

Aldosterone is suspected to aggravate cyclosporin A (CsA)-induced nephrotoxicity. We hypothesized that the mineralocorticoid receptor (MR) blocker eplerenone (EPL) prevented chronic CsA-induced renal functional decrease and tissue injury in rats.

Sprague-Dawley rats received CsA (15 mg/kg/day i.p.) and/or EPL (100 mg/kg/day p.o.) for 12 w. At 11 w, arterial and venous catheters were implanted. Rats were housed individually and were able to move freely during blood sampling and on-line measurement of BP. Inulin was infused for 24 h. At termination, one kidney was rapidly frozen and the contralateral kidney was perfusion fixed and divided in 1 mm slices, embedded in paraffin. Random sections were stained with PAS. Stereological analysis allowed blinded calculation of the volumes of tubuli ($V_{tub}$) and of the interstitial space ($V_{int}$).

CsA treatment showed significantly lower $V_{tub}$ and larger $V_{int}$ compared to controls ($p<0.001$); these changes were attenuated by EPL treatment ($p<0.001$). Hyaline vacuolization in tubules and vascular depositions in arterioles were seen in CsA treated rats but less pronounced after combination therapy. Inulin clearance, plasma sodium and potassium, or kidney weight/body weight ratio displayed no significant changes between groups. CsA reduced weekly body weight gain: 13.4±5.2 vs. 23.0±5.0 g, increased mean day-time BP: 125.8±6.4 vs. 108.0±9.8 mmHg and mean night-time BP: 124.3±6.6 vs.112.4±6.1 mmHg compared to controls ($p<0.01$ in all cases). These changes were prevented by EPL treatment: weight gain: 22.2±4.0 g, mean day-time BP: 109.7±7.5 mmHg and mean night-time BP: 112.4±6.1 mmHg (NS compared to controls). P-renin was elevated in CsA-treated groups compared to controls ($p<0.05$), P-aldosterone was higher in the EPL-treated group compared to both the CsA-alone treated group and controls ($p<0.02$). Whole blood CsA concentrations were not different between groups.

MR blockade by EPL prevented kidney tissue injury and hypertension by chronic CsA. It is concluded that the aldosterone-MR pathway contributes to chronic CsA-mediated nephrotoxicity.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2888**

**Inhibition of Renin Retards Progression of HIVAN** Dileep Kumar,[1] Ankita Sagar,[2] Shabina Rehman,[1] Ashwani Malhotra,[1] Praveen N. Chander,[2] Pravin C. Singhal.[1] *[1]Medicine, Long Island Jewish Medical Center, New Hyde Park, NY; [2]Pathology, New York Medical College, Valhalla, NY.*

Inhibition of the production of Ang II as well as blockade of AT1 receptors has been reported to slow down the progression of HIVAN. However, the role of renin inhibition has not been examined in the progression of HIVAN. We asked whether HIVAN mice had enhanced expression of renin. If yes, would the inhibition of renin would modulate the progression of HIVAN.

Six Vpr mice were either fed doxycycline (doxy) or vehicle in their drinking water for six wks (6 wks of doxy will allow them to develop HIVAN). Subsequently, kidneys were harvested and RNA was extracted, followed by probing for renin. A total of 24 (aged six wks) Vpr mice were fed doxycycline for six weeks followed by kidney biopsy for confirmation of the development of HIVAN and baseline kidney lesions. Subsequently, mice in groups of six were administered either normal saline or aliskiren (50 mg/Kg/day, by miniosmotic pump) for either 4 weeks (protocol A) or eight weeks (protocol B). At the end of experimental periods, blood and urine samples were collected and kidneys were harvested for renal histology. Vpr mice fed doxy showed 2-3 fold greater expression of renin expression. All mice showed overt HIVAN phenotype in the form of FSGS and microcystic dilatation of tubules at the end of the doxy therapy. In protocol A, mice receiving aliskiren showed 24.2% increase in number of sclerosed glomeruli (from the baseline value at 6 wks doxy) when compared to 139.2% increase in sclerosed glomeruli in saline receiving mice ($P<0.01$). In protocol B, mice receiving aliskiren showed 26.4% increase in number of sclerosed glomeruli (from the baseline value at 6 wks doxy) when compared to 124.6% increase in sclerosed glomeruli in saline receiving mice ($P<0.01$). Similar pattern was noted in the progression of tubular injury in both the protocols. Aliskiren also diminished urinary protein creatinine ratio (Protocol A, saline, 51.5 vs. aliskiren, 8.8, $P<0.01$). These findings indicate that renin inhibition slows down the progression of HIVAN.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2889**

**Aldosterone Contributes to the Progression of Renal Lesions in HIV-Associated Nephropathy (HIVAN) Mice** Dileep Kumar,[1] Ankita Sagar,[2] Divya Salhan,[1] Ashwani Malhotra,[1] Praveen N. Chander,[2] Pravin C. Singhal.[1] *[1]Nephrology, North Shore LIJ Health System, Great Neck, NY; [2]Pathology, New York Medical College, Valhalla, NY.*

Aldosterone has been reported to modulate the progression of renal lesions in several models of chronic kidney diseases. Since renin-angiotensin-aldosterone has been reported to play a role in the pathogenesis of HIVAN, we examined the contributory role of aldosterone in the pathogenesis of HIVAN.

To evaluate the effect of aldosterone on HIVAN, three weeks old control (FVB/N) or Tg26 mice (n=6) were administered either normal saline (FVBN, CS;Tg26, TgS), aldosterone (2 µg/day, FVBN, CA; Tg26, TgA), spironolactone (an aldosterone antagonist, FVBN, CSP; Tg26, TgSP), or aldosterone + spironolactone (FVBN, CA-SP;Tg26, TgA-SP) via miniosmotic pumps for four weeks. Every week blood pressure (BP) was recorded. At the end of the experimental period, blood and urine samples were collected and kidneys were harvested for grading the severity of renal lesions.

TgA mice showed higher ($p<0.01$) blood pressure when compared with TgS (TgA, 159/114; TgS, 118/80 mm Hg). However TgA-SP showed comparable blood pressure to TgS. Similarly, TgA mice showed higher urinary protein creatinine ratio (UP/CR) than to TgS (TgA, 38.5; TgS 27.5; CS, 6.9); whereas, spironolactone attenuated this effect of aldosterone on proteinuria. CS showed segmental sclerosis only in 2.5 ± 1% glomeruli and 0 to 1 + dilatation of tubules. In contrast, CA showed segmental glomerulosclerosis in 22.5 ± 2% of glomeruli. TgS displayed 12. 8 ± 2% segmentally sclerosed glomeruli and grade 2-3 dilated tubules; on the other hand, TgA showed 32.7 ± 3% segmentally sclerosed glomeruli and grade 3-4 dilated tubules. However, TgSP showed only 9.1 ± 0.8% segmentally sclerosed glomeruli and 0 to 1 dilated tubules. Since administration of aldosterone accelerated progression of HIVAN and inhibition of aldosterone by spironolactone slowed down the progression of HIVAN, it suggests that aldosterone contributes to the pathogenesis of HIVAN.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2890**

**Sirolimus Retards Development and Progression of Renal Lesions in HIV-Associated Nephropathy (HIVAN) by Altering HIV-1 Gene Transcription**
Dileep Kumar, Divya Salhan, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Long Island Jewish Medical Center, New Hyde Park, NY.*

Sirolimus has been demonstrated to modulate the development of renal lesions in animal models of glomerulosclerosis such as diabetic nephropathy as well as cystic diseases such as polycystic kidney disease. Interestingly, HIVAN is characterized by both glomerulosclerosis and microcystic tubular dilatation of tubules. On that account, we hypothesize that sirolimus would also modulate the development of renal lesions in HIVAN. To prove our hypothesis we have used HIV-1 transgenic mice (Tg26).

Four weeks old Tg26 animals (n=6) were administered either vehicle or sirolimus (5 mg/kg/day, intra-peritoneally) for 14 days (Group A). In another set of experiments, 4 wks old Tg26 mice (n=6) were administered either vehicle or sirolimus for two weeks followed by no treatment for the next two weeks (Group B). At the end of experimental periods, total RNA was extracted and HIV-1 gene transcription was measured by real time PCR. Renal lesions were graded for sclerosis and tubular dilatation. In *in vitro* studies, human podocytes were transduced either with HIV-1 or vector, followed by treatment with either vehicle of sirolimus for 72 h. Subsequently RNA was isolated and HIV-1 gene expression was measured by RT-PCR.

In group A, the vehicle treated mice showed 1+ to 2+ glomerulosclerosis and 2+ to 3+ tubular dilatation, two sirolimus-treated mice showed no glomerular sclerosis and only mild dilatation of tubules and one sirolimus treated mouse showed 0 to 1+ glomerulosclerosis and 1+ to 2+ tubular dilatation. In group B, vehicle treated animals showed two-fold advanced glomerular and tubular lesions vs. sirolimus-treated animals. Renal cortical sections of sirolimus treated animals showed attenuation of PCNA + ive cells, expression of TGF-β, α-SMA, cTGF, VEGF-R1, and MCP-1 when compared with vehicle-treated animals. Sirolimus also decreased transcription of HIV-genes both in renal tissue as well as in HIV-1 transduced podocytes. These findings indicate that sirolimus-induced altered HIV-1 gene transcription could be contributing to its disease modulating effects in HIVAN mice.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2891**

**Coumarin-Induced Intimal Plaque Calcification in ApoE Knock-Out Mice**
Leon J. Schurgers,[1] Cees Vermeer,[2] Willi Jahnen-Dechent,[3] Chris Reutelingsperger.[1] *[1]Biochemistry, Maastricht University, Maastricht, Netherlands; [2]VitaK, Maastricht University, Maastricht, Netherlands; [3]Biomaterials, RWTH Aachen, Aachen, Germany.*

Vascular calcification (VC) is generally regarded as an independent risk factor for cardiovascular morbidity and mortality. Coumarin treatment has been demonstrated to increase medial elastocalcinosis in both experimental animal models and man by impairing the vitamin K-dependent matrix Gla-protein (MGP), a potent inhibitor of VC. However nothing is known about a potential effect of coumarin treatment on atherosclerosis. We used an animal model for atherosclerosis and investigated the effect of coumarin on intimal plaque calcification. ApoE-/- mice received a western diet for three month to induce atherosclerotic plaques. Next, they were randomized to receive a diet containing vitamin K (VK; 1.5mg/g) or VK plus warfarin (VK&W; 1.5 mg/g & 3.0 mg/g). Animals were sacrificed at baseline (t = 0), one week or four weeks after treatment. Mice treated with VK&W had significantly more VC as measured by both atomic absorption spectroscopy (quantitative) and von Kossa staining (qualitative). Moreover, in the intimal plaque of coumarin treated animals a substantial part of the intimal cells displayed a chondrocytic phenotype. This was consistent with the presence of collagen type II, a marker for chondrocytes, and von Kossa staining. Coumarin also induced phosphatidylserine (PS) exposure of endothelial cells covering the plaque, as measured by in vivo annexin A5-biotin binding.

This is the first study demonstrating that coumarin treatment causes an increase of intimal plaque calcification; moreover, the plaque calcification was associated with an increase of apoptotic cells, suggesting accelerated progression towards a vulnerable plaque.

**Dedifferentiation of Medial Smooth Muscle Cells Is Associated with Transplant Vasculopathy in Rat Renal Allografts**
Miriam Boersema,[1] Kirankumar Katta,[2] Heleen Rienstra,[3] Gerjan Navis,[2] Jacob Van den Born,[2] Jan-Luuk Hillebrands,[1] Eliane R. Popa.[1] *[1]Pathology and Medical Biology, UMC Groningen; [2]Nephrology, UMC Groningen; [3]Cell Biology, UMC Groningen, Netherlands.*

**Background.** Chronic transplant dysfunction (CTD) is the leading cause of renal allograft loss. CTD is, among others, characterized by transplant vasculopathy (TV), i.e. occlusive neointima formation with smooth muscle cells (SMCs) resulting in ischemic graft failure. We recently demonstrated α-SMA$^+$ neointimal SMCs in rat renal allografts to be solely graft-derived. In the current study we hypothesized that neointimal SMCs are derived from dedifferentiated medial SMCs by analyzing SMC (de)differentiation marker gene expression levels in microdissected tissue. Dedifferentiated SMCs are able to migrate, proliferate and secrete matrix molecules thereby forming a putative source for neointimal cells.

**Methods.** Using laser dissection microscopy neointimal and medial tissue was isolated from Dark Agouti (DA)-to-Wistar Furth renal allografts (n=5, with CTD & TV) and DA-to-DA isografts as well as non-transplanted DA renal tissue (control groups, both n=5, no CTD & TV). Low density qPCR was used to analyze gene expression of SMC (de)differentiation markers.

**Results.** Compared to both control groups, medial expression of SMC-specific differentiation marker SM22α was downregulated, suggesting dedifferentiation. In line with this, KLF4 (inducer of dedifferentiation) was upregulated. Furthermore, medial expression of the matrix molecules Coll1α1 and Coll4α1 and the profibrotic factors TGF-β1 and CTGF was increased in allografts (vs. both controls). Compared to medial SMCs in allografts, neointimal SMCs displayed a further decrease and increase of SM22α and KLF4 expression, respectively. PDGF-B was solely expressed in the neointima, whereas its receptor PDGFRB was upregulated in the allograft media (vs. media both controls).

**Conclusions.** Medial SMCs in rat renal allografts are dedifferentiated thereby potentially providing a source for neointimal SMCs. Neointimal PDGF-B expression might serve as a chemoattractant for medial SMCs. Prevention of medial SMC dedifferentiation is a potential target for prevention of TV.

**Cardioprotection in Chronic Kidney Disease – The Role of Erythropoietin**
Sebastian Markus Schaefer,[1] Nadezda Koleganova,[1] Grzegorz Piecha,[1] Eberhard Ritz,[2] Marie-Luise Gross.[1] *[1]Institute of Pathology, University of Heidelberg, Heidelberg, Germany; [2]Dept. Internal Medicine, University of Heidelberg, Heidelberg, Germany.*

Cardiovascular disease is the primary cause of mortality in patients with chronic kidney disease (CKD). Heart remodeling develops in CKD comprising of interstitial fibrosis and capillary loss.

12-weeks old male Sprague-Dawley rats were randomized to 5/6 nephrectomy (NX) or sham operation and subsequently received murine erythropoietin (2.5 µg/kg/week), enalapril (12 mg/kg/day), erythropoietin plus enalapril, erythropoietin plus dihydralazine (25 mg/kg/day), or vehicle for 16 weeks. Volume density of capillaries, interstitium, and fibrocytes as well as length density of capillaries were analysed in the myocardium using stereology.

Left ventricle fractional shortening (by echocardiography) was reduced in vehicle treated NX (66.3%) compared with sham-op (81.2%) and this was ameliorated by erythropoietin (72.6%) and prevented by enalapril (80.6%). Capillary length density was lower in vehicle treated NX (3631±466 mm/mm3) compared to sham-op (4264±442), and the capillary rarefaction was prevented in NX treated with erythropoietin plus enalapril (4298±576) and reduced in NX treated with enalapril (3908±383), and erythropoietin plus dihydralazine (3949±355), but not with erythropoietin (3697±565; ANOVA $p<0.02$). In parallel expression of the p47phox NADPH oxidase was higher in untreated NX and most effectively reduced in NX treated with erythropoietin plus enalapril. In basal condition, there was no difference between the groups regarding myocardial hypoxia, reflected by pimonidazole staining.

Erythropoietin in combination with enalapril additively reduce cardiac fibrosis and microvessel disease in 5/6 nephrectomized rats presumably by decreasing myocardial oxidative stress.

**Erythropoietin Does Not Prevent Albuminuria in 5/6 Nephrectomized Rats**
Firas Aldebssi,[1] Grzegorz Piecha,[1] Nadezda Koleganova,[1] Sebastian Markus Schaefer,[1] Eberhard Ritz,[2] Marie-Luise Gross.[1] *[1]Institute of Pathology, University of Heidelberg, Heidelberg, Germany; [2]Dept. Internal Medicine, University of Heidelberg, Heidelberg, Germany.*

Chronic kidney diseases progress over time irrespective of the primary insult. Erythropoietin not only promotes erythrocytes production, but also acts as an anti-apoptotic cytokine. We hypothesize that treatment with erythropoietin in subtotally nephrectomized rats may slow down the progression of renal damage.

12-weeks old male Sprague-Dawley rats were randomized to 5/6 nephrectomy (NX) or sham operation and subsequently received murine erythropoietin (2.5 µg/kg/week), enalapril (12 mg/kg/day), erythropoietin plus enalapril, erythropoietin plus dihydralazine (25 mg/kg/day), or vehicle for 16 weeks.

The albumin excretion was significantly higher in untreated NX (48.6±43.0 mg/24h) compared to sham-op (0.8±0.7), and this was reduced in NX treated with enalapril (3.6±3.1) and erythropoietin plus enalapril (12.7±10.2) but was not changed in NX treated with erythropoietin (50.1±34.7) and erythropoietin plus dihydralazine (85.2±59.9). Systolic blood pressure was higher in NX treated with erythropoietin but not in NX treated with erythropoietin plus enalapril and erythropoietin plus dihydralazine compared to untreated NX. Treatment of NX rats with erythropoietin resulted in lower expression in the kidney of p47phox NADPH oxidase, glutathione peroxidase 3, eNOS, iNOS, and β2 subunit of the soluble guanyl cyclase.

Treatment with erythropoietin failed to decrease albuminuria in 5/6 nephrectomized rats regardless of the blood pressure.

**SA-PO2895**

**BAMBI Is Expressed in Endothelial Cells and Is Regulated by Lysosomal/ Autolysosomal Degradation** Sandhya Xavier,[1] Victoria Gilbert,[1] Maria Pia Rastaldi,[3] Anand C. Reddy,[1] Stefanie Krick,[1] Dmitrij Kollins,[1] Clemens D. Cohen,[2] Erwin P. Bottinger,[1] Detlef O. Schlondorff.[1] *[1]Mount Sinai School of Medicine, New York, NY; [2]University of Zurich, Zurich, Switzerland; [3]Milan, Italy.*

BAMBI (**B**MP and **A**ctivin **M**embrane **B**ound **I**nhibitor) is considered to influence TGFß and Wnt signaling, and thereby fibrosis. Surprisingly data on cell-type specific expression of BAMBI are not available. **Purpose**: examine the localization, the gene regulation, and protein turnover of BAMBI in kidneys. **Methods and Results**: By immunofluorescence microscopy and by mRNA expression BAMBI is restricted to endothelial cells of the glomerular and peritubular capillaries, and of arteries and veins in both murine and human kidneys. TGFß upregulated mRNA of BAMBI in murine glomerular endothelial cells (mGEC). LPS did not downregulate mRNA for BAMBI in mGEC or in HUVECs. BAMBI mRNA had a half-life of only 60 min and was stabilized by cycloheximide indicating post-transcriptional regulation due to AU-rich elements, which we identified in the 3' untranslated sequence of both the human and murine BAMBI gene. BAMBI protein turnover was studied in HUVECs with BAMBI over-expression using a lentiviral system. Serum starvation as an inducer of autophagy caused marked BAMBI degradation, which could be totally prevented by inhibition of lysosomal and autolysosomal degradation with bafilomycin, and partially by inhibition of autophagy with 3-methyladenine, but not by proteasomal inhibitors. Rapamycin activates autophagy by inhibiting TOR, and resulted in BAMBI protein degradation. Both serum starvation or rapamycin increased the conversion of the autophagy marker LC3 from LC3-I to LC3-II and also enhanced costaining for BAMBI and LC-3 in autolysosomal vesicles. **Summary:** 1. BAMBI localizes to endothelial cells in the kidney and to HUVECs. 2. BAMBI mRNA is regulated by post-transcriptional mechanisms. 3.BAMBI protein is regulated predominantly by autolysosomal and lysosomal degradation. **Conclusion**: The endothelial localization and the quick turnover of BAMBI may indicate novel, yet to be defined, functions of this modulator for TGFß and Wnt protein actions in the renal vascular endothelium in health and disease.

**Conditional Ablation of Glycogen Synthase Kinase 3b in Postnatal Mouse Kidney** Rujun Gong, Lance D. Dworkin. *Brown Medical School, Providence, RI.*

Glycogen synthase kinase (GSK) 3 is a ubiquitously expressed serine/threonine kinase existing in two isoforms, GSK3a and GSK3b. Aside from the long-recognized role in regulating insulin signal transduction and glycogen biosynthesis, a growing body of evidence has coined GSK3b as a master control molecule of NFkB activation and renal injury. Nevertheless, previous data are less conclusive because they relied greatly on small molecule inhibitors, which lack selectivity and barely distinguish between the GSK3 isoforms. In addition, early embryonic lethality of the global knockout of GSK3b precludes the interrogation of the biological role of GSK3b in adult kidney. To circumvent this issue, the Cre/loxP system for tissue-specific gene targeting was employed to generate a conditional knockout mouse model in which the GSK3b gene was specifically deleted in kidney cortical tubules at postnatal mature stage. Kidney specific ablation of GSK3b resulted in a phenotype no different from the control littermates. Knockout mice were viable and exhibited normal gross appearance, behavior, and development as well as normal kidney physiology in terms of kidney function, urine albumin excretion and urine concentrating ability. Of note, apart from normal glomerular and tubulointerstitial morphology, kidneys from knockout mice demonstrated more glycogen accumulation in the brush border of renal cortical tubules as assessed by both periodic acid-Schiff staining for light microscopy and direct biochemical assay, consistent with an elevated glycogen synthetic activity as evidenced by diminished inhibitory phosphorylation of glycogen synthase that occurred subsequent to GSK3b ablation. This finding was further validated by electron microscopic observations of increased deposition of glycogen particles in renal tubules of knockout mice, suggesting that GSK3a could not fully compensate for the loss of GSK3b in regulating glycogen metabolism in the kidney. In summary, kidney specific ablation of GSK3b results in increase renal tubule glycogen accumulation but has minimal effects on kidney function and histology. These mice should provide a powerful tool to uncover the role of GSK3b in the pathophysiology of kidney disease.

**SA-PO2897**

**Peritoneal Adipocyte Is Not Just an Innocent Bystander but Act as a Pivotal Cell of PD-Induced Peritoneal Membrane Damages** Talerngsak Kanjanabuch,[1,2] Sirigul Kanchanabuch,[2] Wasin Manuprasert,[2] Somchai Eiam-Ong.[1] *[1]Kidney&Metabolic Disorders Research Center, Chulalongkorn University, Thailand; [2]Medicine, Chulalongkorn University, Thailand.*

Continuous exposure of the peritoneal membrane to unphysiologic PD fluids (PDF) during long-term dialysis results in peritoneal damages. The role of adipocytes in PDF-induced membrane injury was investigated in both *in vivo* and *in vitro* studies.

**Methods:** 20 male Sprague-Dawley rats were subjected to twice daily perioneal injections with 4.25%PDF or 0.9% NSS. After 4- and 12-wk injections, histologies of omental&parietal peritoneal fats were assessed. Omental-derived primary pre-adipose cell and murine 3T3-L1 pre-adipocytes were used for *in vitro* study. Differentiations of both pre-adipocytes to adipocytes were induced by addition of an adipogenic hormonal cocktail. Fully differentiated adipocytes were incubated with conventional glucose-based, 1.1%amino acid, and 7.5%polyglucose PDF for 12 hr. The cell injuries and cell death were assessed. Cytokine and matrix protein expressions, including TGF-β, PAI-1, and collagen I were investigated using quantitative real time PCR and ELISA techniques.

**Results:** In *in vivo* studies, submesothelial fat tissues had increased adipocyte size at 4 and 12 wk when compared with control. This occurred in correspondence with thickening of submesothelial loose CNT layer and up-regulation of TGF-β. Adipocytes cultured with conventional PDF showed time and dose-dependent morphological changes, which were accompanied by cell injury, apoptosis, and loss of differentiation markers. Using of 7.5%polyglucose and 1.1%amino acid solutions significantly abrogated all of above changes in response to the PDF. TGF-β, PAI-1, and collagen type I were up-regulated in fully differentiated adipocytes after incubation with conventional PDF but were attenuated by changing to non glucose-based PDF.

**Conclusion**: Peritoneal fat cells are not just an innocent bystander but act as a pivotal cell of PD-induced peritoneal membrane injuries which may be mediated partly by manipulating TGF-β and PAI-1 expressions, and matrix production. Using of non glucose-based PDF can prevent PD-mediated fat cell injury.

**Transcutaneous Measurement of Renal Function in Freely Moving Rats** Daniel Schock-Kusch,[1] Qing Xie,[1] Yury Shulhevich,[2] Jürgen Werner Hesser,[2] Dzmitry Stsepankou,[2] Maliha Sadick,[3] Stefan Koenig,[4] Friederike Hoecklin,[5] Johannes Pill,[6] Norbert Gretz.[1; 7] *[1]Medical Research Centre; Medical Faculty Mannheim; University of Heidelberg, Germany; [2]Experimental Radiation Oncology, Medical Faculty Mannheim University of Heidelberg, Germany; [3]Freudenberg Forschungsdienste KG D-69465 Weinheim, Germany; [4]Freudenberg MekTek Europa GmbH 69465 Weinheim, Germany; [5]Institute for Clinical Radiology and Nuclear Medicine, Medical Faculty Mannheim, University of Heidelberg, Germany; [6]Roche Diagnostics GmbH, Sandhofer Str. 116, Mannheim, Germany; [7]Institute for Medical Technology of the University Heidelberg and the University of Applied Science Mannheim, Germany.*

A convenient method for the assessment of renal function using exogenous clearance marker is still missing. We describe a novel device, allowing determination of renal elimination kinetics of FITC-labelled renal markers in freely moving rats. The device excites an injected fluorescent marker and measures the concentration dependent fluorescent signal. Data transfer from the device to a host computer is accomplished by a RF sending device. The small size of the device allows measurements on the back of a rat. In contrast to classical clearance procedures the method is independent of blood and/or urin samples, moreover, as the clearance is measured in awake rats it is not influenced by anaesthesia as other published transcutaneous methods. As proof of principle, comparative measurements of transcutaneous and plasma elimination kinetics of FITC-sinistrin were performed in seven healthy, freely moving rats. Results show highly comparable elimination rate constants (m: transcutaneous: -0.026 ± 0.004 min-1; plasma: -0.027 ± 0.002 min-1) and elimination half-lifes (t1/2: transcutaneous: 27.3 ± 3.9 min; plasma: 25.3 ± 1.5 min). These data demonstrate that renal function can be measured in freely moving rats.

**Development of a Novel Mass Spectrometry-Based Method for Serum Creatinine Measurement in Rodents** Kevin Wyatt McMahon,[1] Masoud Zabet-Moghaddam,[2] Sharma S. Prabhakar.[1] *[1]Internal Medicine, Texas Tech University HSC, Lubbock, TX; [2]Center for Biotechnology and Genomics, Texas Tech University, Lubbock, TX.*

The measurement of serum creatinine in rodents has been plagued by interference from confounding compounds. We have developed a simple method for measuring creatinine in rat serum using matrix-assisted laser desorption/ionization- time of flight (MALDI-TOF) mass spectrometry. Sera (n=6) were collected from obese ZSF rats at 26 weeks of age given either plain water or water containing curcumin (1 mg/L – Pandey et al., ASN abstract, 2009). The calibration curve (R2= 0.997) was obtained using 2H3-creatinine as an internal standard (IS) by mixing a constant amount of IS with various amounts of creatinine (3.5-226 pg). The amount of 3.5 pg indicates 5-fold improvement in detection compared to similar approach using LC-MS. Sample preparation involves mixing one µL of serum sample with of a known amount of internal standard (99 µL, at C= 4 µM) followed by brief centrifugation through a centrifugal filter (Amicon Ultra-0.5 mL, 3,000 MWCO). The flow-through samples are then mixed with α-cyano-4-hydroxycinnaminic acid (CHCA) as the MALDI-matrix and subjected to MALDI-analysis. Spectra showed a strong peak at m/z= 114 Da corresponding to the mass of protonized creatinine, indicating that the sample clean up method adequately removed confounding molecules. The serum creatinine level was then calculated using the calibration curve. Using our new method, serum creatinine levels were found to be lower in obese ZSF rats given curcumin-containing compared with those given plain water, consistent with reported results. In addition, use of a creatinine autoanalyzer to measure serum creatinine showed good correlation with the results using our method ($r2 = 0.74$, $p<0.05$) indicating the reliability of the method. This simple, sensitive and fast technique could be a useful alternative to both enzymatic and HPLC-based methods. To our knowledge, this is the first time that MALDI has been suggested as a method for measuring serum creatinine in rodents.

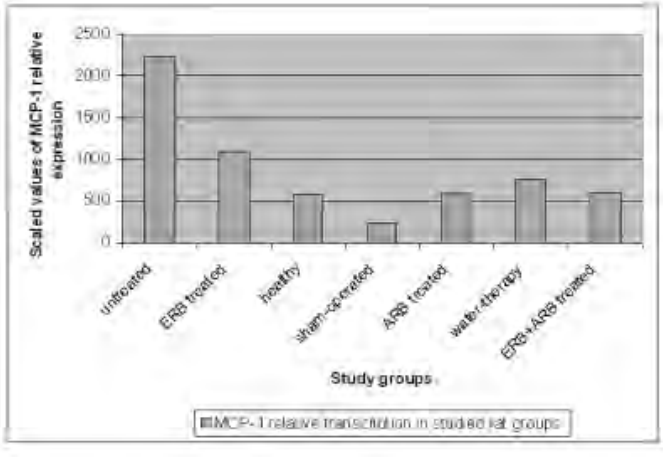
***CCL2/MCP-1* and *NF-κB* Gene Transcription in Remnant Kidneys after Physical Exercise** Mai Ots-Rosenberg,[1] Ülle Pechter,[1] Kylli Kõlvald,[1] Jana Uhlinova,[1] Ingrid Kalev.[2] *[1]Internal, University of Tartu, Estonia; [2]General and Molecular Pathology, University of Tartu, Estonia.*

Physical exercise has been shown to have positive influence on physical capacity, hypertension, left ventricular function etc. We have shown the positive effect of aquatic exercise on the chronic kidney disease (CKD) progression. Aim of the study was to investigate the effects of aquatic exercise to the gene expression in experimental CKD and compare with endothelin and angiotensin receptor blockers treatment. Wistar rats were divided into matched groups after renal ablation and studied during 12 weeks. Exercise group was subjected to thermoneutral water immersion and swimming without exhaustion 30 min daily. Chronic studies of systolic blood pressure and urinary protein excretion rate were performed. QPCR was performed for the transcription of intrarenal *CCL-2/MCP-1* and *NF-κB*. For quantification of rat *CCL2/MCP-1*, β-actin (*NF-kB*) mRNA we used a SYBR Green real-time quantitative RT-PCR method based on the TaqMan fluorescence method with the ABI Prism 7000 Sequence Detection System. Results revealed that the degree of hypertension was significantly higher in sedentary animals (177,8±4,9 vs 135,5±5,8). Proteinuria was reduced significantly (2,9±0,7 vs 10,1±3,1) in trained compared to sedentary rats. Deterioration of renal function were ameliorated significantly after physical activity.



*CCL2/MCP-1* renal abundance were all increased in the remnant kidney of the rats without physical activity and were reduced significantly by aquatic exercise treatment. QPCR transcription differences between study groups (Mann-Whitney test). *NF*κ*B* transcription was not significantly suppressed by treatments. Conclusion. Aquatic exercise improves the course of experimental CKD. These results point on the additional renoprotective properties of long-term water immersion and daily exercise in CKD rats.

**PTH Effects on Osteocytes in Uremia** Michael Pazianas,[1] Rachel M. Locklin,[1] Philippa Hulley,[1] Stelios A. Panagoutsos,[2] Ploumis Stavros Passadakis,[2] Graham Russell,[1] Vassilios A. Vargemezis.[2] *[1]The Botnar Research Centre and Oxford University Institute of Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom; [2]Nephrology, Thrace University, Alexandroupolis, Greece.*

A central role for osteocytes in the physiology of bone metabolism has been suggested. Osteocytes express the PTH receptor 1. Therefore, we assessed the effects of serum from long-term dialysis patients (pts) with high (78.8 to 81 pmol/l) or 'normal' PTH (1.1-6.9 pmol/l) & healthy controls (CTRs) on the growth of osteocyte-like MLO-Y4 cells in culture. The biochemical bone profile of the serum was remarkable for high FGF-23 (range: 816-1368 RU/mL) & low $1,25(OH)_2D_3$ (range: 22-43 pmol/l) concentrations for all of the uremic pts compared to the CTRs (FGF-23: 32-99 RU/mL & $1,25(OH)_2D_3$: 91-131 pmol/l). Serum calcium & phosphate in the 'normal' PTH (n-PTH) group were similar to those of the CTRs & elevated in the high PTH (h-PTH) group. 5% serum from dialysis pts with either n-PTH or h-PTH levels reduced significantly the cell number & viability within 24 hours compared to CTRs. Furthermore, the cell numbers were lower in the n-PTH than the h-PTH group & the number of normal cells in the n-PTH group was generally less than half that of the CTRs. However, adding back 40 pg/ml of recombinant 1-34 PTH (equivalent to the concentration in cultures using serum from h-PTH pts) failed to reverse the discrepancy in cell numbers between n-PTH & h-PTH osteocyte cultures. Analysis of the cultured cells by nick translation assay, which specifically measures the proportion of apoptotic cells, showed no increase in apoptosis in cultures fed with serum from dialysis pts up to 72 hours. **U**remic serum from dialysis pts reduced the growth of osteocyte-like MLO-Y4 cells through an apoptosis-independent mechanism. Although differences were seen between cultures treated with h-PTH & n-PTH serum, this may not to be the main factor affecting osteocyte survival in uremic conditions.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2902**

**Osteocyte Pathways Are Altered Early in *Jck* Mice, a CKD-MBD Model** Yves Sabbagh,[1] Wen Tang,[1] Stephen O'Brien,[1] Lucy A. Phillips,[1] Susan Ryan,[1] Luciene M. dos Reis,[2] Fabiana G. Graciolli,[2] Vanda Jorgetti,[2] Rosa Ma Moyses,[2] Shiguang Liu,[1] Susan Schiavi.[1] *[1]Endocrine, Genzyme Corp, Framingham, MA; [2]Nephrology Div, University of Sao Paulo, Sao Paulo, Brazil.*

Chronic kidney disease-mineral bone disorder (CKD-MBD) is defined by abnormalities in mineral and hormone metabolism, bone histomorphometric changes and/or the presence of vascular or soft tissue calcification. Emerging evidence suggests that features of CKD-MBD may occur early in disease progression and limited data raises the possibility that decreases in bone formation and/or mineralization may precede the onset of high turnover bone disease. To identify early pathophysiological changes in bone, we utilized the *Jck* mouse, a genetic model of polycystic kidney disease that exhibits progressive biochemical features of CKD-MBD. In our current study we investigated temporal bone changes in *Jck* relative to wild-type (WT) mice from 6 through 18 weeks of age. The development of osteitis fibrosis was observed as early as 9 weeks based on increased BFR in *Jck* ($0.57\pm0.04\mu m^3/\mu m^2/yr$) relative to WT mice ($0.36\pm0.02\mu m^3/\mu m^2/yr$) with a significant increase in bone volume by 12 wks (WT 8.9±0.4% vs *Jck* 6.8±0.5%). Parameters associated with mineralization rates were not substantially altered in *Jck* mice at any time point indicating a mineralization defect is absent in these mice. To capture the early molecular and cellular events in the progression of CKD-MBD we have begun to examine specific biochemical pathways associated with osteocyte function and bone remodeling beginning with analysis of the osteocyte specific Wnt-antagonist, sclerostin (SOST). The number of SOST positive osteocytes was significantly elevated in *Jck* mice at 9 weeks of age (48±9%) prior to the appearance of osteitis fibrosis, compared to WT age-matched mice (23±9%). A significant drop in the number of osteocyte positive cells was observed in *Jck* mice at 18 weeks (12±5%). As PTH rises, SOST expression may be down-regulated further contributing to high turnover disease. These data provide evidence for early bone changes in osteocytes that may negatively influence osteoblast function during progression of CKD-MBD.

**SA-PO2903**

**Osteocytic Osteolysis Is More Active in Woven Bone in Patients with Secondary Hyperparathyroidism** Aiji Yajima,[1] Masaaki Inaba,[2] Shigeru Otsubo,[3] Yuko Iwasa,[1] Yoshihiro Tominaga,[4] Kosaku Nitta.[5] *[1]Nephrology, Towa Hospital, Tokyo, Japan; [2]Metabolism, Endocrinology and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan; [3]Nephrology, Sangenjaya Hospital, Tokyo, Japan; [4]Transplant Surgery, Nagoya Second Red Cross Hospital, Nagoya, Japan; [5]Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

Purpose; Woven bone is fragile and is abundant in patients with secondary hyperparathyroidism. We investigated whether or not osteocytic osteolysis is more active in woven bone as compared with lamellar bone.

Methods; Ten hemodialysis patients with secondary hyperparathyroidism (age; 59.1 ± 8.4 years, duration of dialysis; 11.3 ± 7.5 years, serum intact PTH; 1264.5 ± 416.8 pg/ml) were investigated. The lacunae were classified into three groups (Renal Week 2009) and the parameters were calculated as follows; Woven or lamellar bone volume referent number of Lc with a predominantly eroded surface (ES) (N.ES.Lc/Wo.BV or N.ES.Lc/Lm.BV; N/mm$^2$), number of Lc with a predominantly quiescent surface (QS) (N.QS.Lc/Wo.BV or N.QS.Lc/Lm.BV; N/mm$^2$), and number of Lc with a predominantly osteoid surface (OS) (N.OS.Lc/Wo.BV or N.OS.Lc/Lm.BV; N/mm$^2$). Thereafter, the relationships between these parameters were analyzed by Wilcoxon's signed rank test.

Results; In woven bone, N.ES.Lc/Wo.BV was significantly greater than N.ES.Lc/Lm.BV (465.2 ± 88.5 versus 123.9 ± 66.8 N/mm$^2$, P=0.007). And N.ES.Lc/Wo.BV was greater than N.OS.Lc/Wo.BV (465.2 ± 88.5 versus 37.1 ± 87.0 N/mm$^2$, P=0.007) and N.QS.Lc/Wo.BV (465.2 ± 88.5 versus 67.0 ± 57.2 N/mm$^2$, P=0.007). N.OS.Lc/Wo.BV was not different from N.OS.Lc/Lm.BV(37.1 ± 87.0 versus 2.3 ± 5.1 N/mm$^2$, P=0.144). Both N.OS.Lc/Wo.BV and N.OS.Lc/Lm.BV was 0 N/mm$^2$ in 7 patients.

Conclusions; Osteocytes apparently resorb woven bone actively as compared with lamellar bone in patients with secondary hyperparathyroidism. It seems that bone formation is dependent on osteoblast function in these patients, but bone formation by the osteocyte may be activated by the reduction of serum PTH levels (JBMR in press).

**SA-PO2904**

**Bone Collagen Degeneration and Calcification Disorder Are Critical Phenomena in Adenine-Induced Renal Failure Rat** Chiharu Aoki, Kazuho Honda, Kenta Uto, Saeko Kanai, Sekiko Taneda, Hideaki Oda. *Department of Pathology, Tokyo Women's Medical University, Tokyo, Japan.*

**Background and Objective:** Molecular mechanism of renal osteodystrophy (ROD) is still uncertain and closely associated with the pathogenesis of chronic kidney disease-mineral bone disorder (CKD-MBD). The present study is designed to elucidate the essential phenomena in ROD focusing on the bone matrix collagen and its calcification process using adenine-induced renal failure rat model.

**Methods:** Renal failure was induced in 8-week-old male SD-Jcl rats by feeding 0.75% adenine-containing diet for 6 weeks. Serum parameters, body weight and bone

histopathology were examined at 2, 4, 6 weeks after adenine administration. Micro CT (μCT) analysis and stress analysis of bone were also evaluated.

**Results:** Serum creatinine, inorganic phosphate and intact PTH were progressively increased, and body weight, serum calcium and 1, 25$(OH)_2D_3$ were decreased concomitantly. The bone morphometric parameters showed increased bone formation (osteoblast surface / bone surface) and resorption (osteoclast surface / bone surface) until 2 weeks with increased peritrabecular fibrosis. Thereafter, bone resorptive parameters oppositely decreased at 4 weeks with massive increasement of osteoid tissue, indicating a severe calcification disorder. The μCT analysis of the femur showed decreased bone mineral density and increased osteoporosity in trabecular bone (control: 168mg/cm$^3$, adenine: 78.5mg/cm$^3$), and in cortical bone (control: 753mg/cm$^3$, adenine: 486mg/cm$^3$). Furthermore flexural strength was decreased in femur (control: 232N, adenine: 150N). Scanning electron microscopy revealed that an irregularity of collagen fiber arrangement and width at 6 weeks accompanying disappearance of periodic striation of collagen fibers. Western blot analysis of OPN and collagen I showed impaired production from 4 weeks to 6 weeks.

**Conclusion:** Ultra-structual abnormalities of bone matrix collagen associated with osteoblast dysfunction preceded a severe calcification disorder of the bone in the experimental model of ROD. The calcification process regulated by osteoblast/bone matrix interaction can be a clue for the pathogenesis of CKD-MBD.

**Association of Secondary Hyperparathyroidism with High Mortality and Morbidity in Dialysis Patients** Patricia T. Goldenstein, Lilian P. F. Carmo, Fernanda O. Coelho, Karina F. Pinheiro, Rosa Ma Moyses, Vanda Jorgetti. *Nephrology, University of São Paulo, São Paulo, Brazil.*

Bone abnormalities are found almost universally in patients with CKD requiring dialysis. Studies have shown associations between disorders of mineral metabolism and fractures, cardiovascular disease, and mortality. We retrospectively evaluated 300 outpatients with CKD on dialysis that were sent to a referral center for CKD-MBD from January 2005 to December 2009. The aim of this study was to compare morbidity and mortality in patients with secondary hyperparathyroidism (SHPT) that were submitted or not to parathyroidectomy (PTx). Their mean age was 48 ± 13 yrs, median dialysis time was 54.5 (36-108) months, 54% were female, and only 10% diabetic. Pain was the most common symptom (63%), followed by fracture (13.2%). Serum Ca, P and alkaline phosphatase were 9.9 ± 0.9 mg/dL, 5.5 ± 1.7 mg/dl, 208 U/L (120 - 442), respectively, whereas median PTH and 25vitamin D were 1217 pg/ml (IQR ; 656-1815) and 24 ng/mL (16-35). SHPT, defined as PTH >500, was detected in 82% of them. Patients with a severe SHPT (PTH ≥ 800 pg/ml) compared to those with PTH < 800 pg/ml more commonly presented pain (67 vs. 52% ; p<0.05), whereas a similar fracture rate was found between them (14 vs. 8% ; ns). PTx was indicated in 73% of the patients, but only performed in 38% of the patients with severe SHPT. PTx was associated with a decreased mortality (12.2% in PTx vs. 30.7% in non-PTx patients, RR = 0.51 ; 95% CI = 0.27-1.02 ; p = 0.05). In this study, the low prevalence of patients with low PTH levels in our cohort suggests that they are less often symptomatic. On the other hand, our results confirm the high morbidity and mortality associated with SHPT, emphasizing the need for early referral, as well as for other therapeutic interventions that would certainly benefit our patients.

**Impaired Cortical Bone in Pre-Dialysis CKD Patients Is Even More Marked in Those with Fragility Fracture** Stephanie Boutroy, Thomas L. Nickolas, Emily Stein, Adi Cohen, Elizabeth Shane. *Columbia University Medical Center, New York, NY.*

Cortical (Ct) bone comprises the majority of the appendicular skeleton and supports the majority of axial loads. Although alterations of Ct bone have been reported in CKD patients, there are no methods to depict accurately the microstructural properties of Ct bone in vivo. We applied a new quantitative computational method to high-resolution peripheral quantitative computed tomography (HR-pQCT, Scanco Medical AG, resolution ~82μm) images of the distal radius and tibia to measure both intra-cortical porosity (CtPo) and cortical thickness (CtTh) (Burghardt et al and Nishiyama et al - JBMR 2010). Our goal was to evaluate Ct bone characteristics at these sites in pre-dialysis CKD patients and controls and to determine whether CtTh and CtPo discriminate between CKD patients with and without a history of fragility fracture (FX).

We evaluated 3 groups of 17 patients: a control group (68±10 yrs) and CKD patients with (74±9 yrs) and without FX (73±8 yrs), matched for gender, race and ethnicity. Each patient was scanned at the radius and tibia by HR-pQCT and CtPo and CtTh were measured.

The groups did not differ by age, height and weight. eGFR and intact PTH did not differ between CKD patients with and without FX (respectively eGFR=24[13:44] and 28[17:46]; PTH=54[27:283] and 58[36:95], median[IIQ]). At the tibia, CtTh did not differ between CKD patients and controls (-7%, p=0.4). However CtPo was significantly higher in CKD patients (40%, p=0.004). CKD with FX tended to have thinner Ct bone than CKD without FX (-12%, p=0.08); although CtPo was 13% higher, the difference was not significant (p=0.3). At the radius, CtPo was 32% higher (p=0.2) and CtTh 16% lower (p=0.06) in CKD patients than controls. CKD with FX had significantly lower CtTh (-19%, p=0.02) than CKD without FX, but CtPo did not differ.

Using a novel method to assess CtPo and CtTh, we confirmed that the integrity of Ct bone is impaired in pre-dialysis CKD patients compared to controls. In addition, lower radius CtTh differentiated CKD patients with FX from those without FX. Larger, prospective studies are needed to determine whether Ct bone impairment predicts FX in CKD.

**The Pathogenesis of the CKD-MBD in Stage 2 CKD** Yifu Fang, Suresh Mathew, Keith A. Hruska. *Division of Pediatric Nephrology, Washington University School of Medicine, St. Louis, MO.*

In CKD, osteoblastic differentiation of cells in the neointima causes calcification of atherosclerotic plaques stimulated by hyperphosphatemia and inhibited by Pi binders. Vascular calcification (VC) is an important cause of CV morbidity in CKD. Hyperphosphatemia induces the expression of osterix, an osteoblast specific transcription factor, in the aorta. However, the CKD-MBD begins early in CKD as shown by in studies demonstrating abnormal trabecular architecture by HR qCT in stage 2 CKD patients (Bacchetta J et al JBMR 2009), increased FGF-23 (Pereira RC et al Bone 2009), and decreases in vascular smooth muscle contractile phenotype markers (Kokubo et al, JASN 2009). The loss of both the anabolism of bone and the vascular smooth muscle phenotype before abnormalities of mineral metabolism in the early phases of the CKD-MBD make it necessity to define a new molecular regulatory system underlying the condition. Here we tested the hypothesis that CKD induces the CKD-MBD prior to the onset of positive phosphate balance and stimulates vascular calcification in early CKD. *Ldlr-/-* mice fed high fat diets were subjected to renal cortical electrocautery and contralateral nephrectomy at 14 weeks of age to produce CKD –MBD, euthanasia was at 28 weeks. A relatively mild reduction in the glomerular filtration rate was seen with 76 % of normal (GFR (ml/min/kg): 1.36±0.13 (CKD) vs. 1.79±0.39 (WT) P<0.01) at 22 weeks of age (equal to stage-2 CKD). Serum assays of BUN, Ca, Pi and PTH were normal. CKD stimulated accumulation of aortic Ca levels at 28 weeks of age (0.52±0.19 (CKD) vs. 0.26±0.14 (wt) and 0.32±0.23 (sham) mg/g dry weight, p<0.05). Osteoblast surfaces and bone formation rates were reduced, which showed an inverse relationship between VC. Dickkoff -1 (Dkk-1), a circulating inhibitor of bone formation, levels were increased from normal wt 1868±772 or sham 1650±882 to 3132±1590 (pg/ml, p<0.01). Increased serum levels of FGF-23 were also detected (1154±763 (CKD) vs. 342±126 (WT) or 299±164 (sham) pg/ml, P<0.01). We conclude that the CKD-MBD is stimulated early in response to kidney injury with decreased bone formation, increased VC, and elevated FGF23 and Dkk-1 levels.

**Wnt Pathway Inhibition: Another Actor in CKD-MBD Pathophysiology?** Fabiana G. Graciolli,[1] Rodrigo B. Oliveira,[1] Luciene M. dos Reis,[1] Ana L. E. Cancela,[1] Lilian Cuppari,[2] Maria Eugenia F. Canziani,[2] Aluizio B. Carvalho,[2] Yves Sabbagh,[3] Vanda Jorgetti,[1] Susan Schiavi,[3] Rosa Ma Moyses.[1] *[1]Nephrology Division, University of Sao Paulo, Sao Paulo, Brazil; [2]Nephrology Division, Federal University of Sao Paulo, Sao Paulo, Brazil; [3]Renal and Endocrine Sciences, Genzyme Corp, Framingham, MA.*

CKD bone disease is complex and multifactorial. Recent studies have demonstrated that some proteins, such as Sclerostin (SOST) and DKK1 (Dickkopf-1), are able to inhibit bone formation in other diseases. We asked whether these proteins are involved in CKD-MBD pathophysiology. Toward this end, we measured the serum levels of SOST and DKK1 in 40 predialysis CKD patients [50 ± 11 yrs., creatinine clearance (CrCl) = 35 ± 16 ml/min] that were randomized to receive calcium acetate (Ca) or sevelamer hydrochloride (Sev) during 6 weeks. At baseline, serum SOST was elevated [0.8 ng/ml (0.4-1.1); ref. range = 0.3 (0.2-0.4)], as well as DKK1 [17.1 ng/ml (14.5-20.7); ref. range = 0.9 (0.3-2.3)]. We found significant correlation between SOST and serum FGF 23 (R= 0.48), phosphate (P; R=0.35) and CrCl (R=-0.43), as well as between DKK1 and P (R=0.39) and leptin (R=0.46). After 6 wks on P binder therapy, we observed a significant decrease of SOST in the Sev-treated patients (0.83 vs. 0.65 ng/ml; p < 0.05), whereas this effect was not observed in the Ca-treated patients (0.8 vs. 0.79 ng/ml, ns). These data suggest that, in CKD, there is an impairment of the Wnt pathway, confirmed by the elevated levels of SOST and DKK1. In addition, these preliminary results open the possibility of modulating their serum levels through the use of P binders.

**Plasma Fetuin-A May Not Be Associated with Inflammatory Status in CKD Stages 3 & 4** Martin L. Ford,[1] Edward R. Smith,[2] Laurie A. Tomlinson,[3] Chakravarthi Rajkumar,[1] Stephen Holt.[4] *[1]Brighton & Sussex Medical School, Brighton, United Kingdom; [2]Dept of Clinical Biochemistry, Brighton & Sussex University Hospitals NHS Trust, Brighton, United Kingdom; [3]Clinical Pharmacology Unit, Addenbrooke's Hospital, Cambridge, United Kingdom; [4]Dept of Nephrology, Brighton & Sussex University Hospitals NHS Trust, Brighton, United Kingdom.*

Introduction

Fetuin-A, a 62kDa protein, is synthesized in the liver. Fetuin-A is as an inhibitor of ectopic calcification, but is also thought to be a negative acute-phase reactant. Low circulating fetuin-A concentrations have been associated with aortic stiffening and adverse cardiovascular outcomes in both pre-dialysis and dialysis Chronic Kidney Disease (CKD). This association is potentially confounded by inflammation

Methods

170 stable outpatients with CKD stages 3 & 4 were enrolled in a prospective study of cardiovascular risk. Plasma and serum samples were taken on recruitment and stored at -70°C. Plasma fetuin-A was measured by ELISA (Biovendor, CZ). Serum hsCRP was

measured using particle enhanced nephelometry (Siemens, UK). Serum IL-1β & IL-6 & TNF were measured using ELISA (RnD Systems, UK).

Results

Mean MDRD eGFR was 32 (±11ml/min/1.73m²). Age 69 (±12 yrs). Male:female 119:51 . Non:diabetic:diabetic 128:42. Mean fetuin-A was 0.236 (±0.072g/l). Fetuin-A was significantly higher in the diabetic patients compared to the non-diabetics (0.290 ± 0.080g/l v 0.218 ± 0.060g/l, p<0.001)

Median hsCRP was 5.66 (IQR 5.01mg/l), median IL-1β 2.97 (IQR 1.30pg/mL), median IL-6 6.51 (IQR 5.02pg/mL) and median TNF was 16.72 (IQR 9.38 pg/mL). Fetuin-A did not correlate with log hs-CRP (r=0.045, p=0.559) logIL-1β (r=0.081, p=0.295), logIL-6 (r=-0.019, p=0.804) or logTNF (r=0.054, p=0.488). Subgroup analysis using fetuin-A by tertile or diabetic status did not demonstrate any significant relationship with inflammatory mediators.

Log hsCRP correlated significantly with log IL-1β (r= 0.183, p=0.017) and IL-6 (r=0.158, p=0.039) but there was no significant correlation with TNF (r=-0.139, p=0.070).

Conclusions

In this cohort of stable pre-dialysis CKD patients, fetuin-A was not associated with sensitive markers of inflammation.

### Role of Osteoprotegerin (OPG) in Predicting Loss of Foot Pulse and Development of Foot Ulcer in Type 1 Diabetic Patients with and without Diabetic Nephropathy

Maria Lajer,[1] Anders Jorsal,[1] Lise Tarnow,[1] Lars Rasmussen,[4] Hans-Henrik Parving,[2,3] Peter Rossing.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Dep. of Medical Endocrinology, Rigshospitalet, University Hospital of Copenhagen, Copenhagen, Denmark; [3]Faculty of Health Science, University of Aarhus, Aarhus, Denmark; [4]Dep. of Biochemistry, Pharmacology and Genetics, University Hospital of Odense.*

The bone-related peptide osteoprotegerin is produced by vascular cells and is involved in the process of vascular calcification previously shown to predict mortality and cardiovascular events. We investigated the predictive value of plasma OPG in relation to development of foot complications in patients with type 1 diabetes (T1DM) with and without diabetic nephropathy.

Prospective observational follow-up study of 397 type 1 diabetic patients with overt diabetic nephropathy (243 men; age [mean ± SD] 42.1 ± 10.5 years, duration of diabetes 28.3 ± 8.9 years, GFR 76 ± 33 ml/min/1.73 m²) and a control group of 176 patients with longstanding type 1 diabetes and persistent normoalbuminuria (105 men; age 42.6 ± 9.7 years, duration of diabetes 27.6 ± 8.3 years). p-OPG was measured by ELISA.

The median OPG for the 573 patients was 2.8(1.3-11.4)µg/L.

During 15.5 (0.2-17.0) years (median (range)) of follow-up, 107 (40%) with OPG levels above the median *vs*. 76 (27%) below developed a foot ulcer, $p$=0.001. This corresponds to a hazard ratio (HR) of 1.7[1.2-2.2] and covariate adjusted (sex, age, nephropathy status, smoking, $HbA_{1c}$, systolic BP, eGFR, and CRP) HR 1.5[1.0-2.1],($p$=0.04). Furthermore, 42 (16%) patients with higher OPG *vs.* 15 (5%) with lower lost foot pulse, adj. HR 2.2[1.0-4.6],($p$=0.04). Similarly, 51 (18%) with higher OPG levels *vs*. 21 (7%) with lower had vascular surgery or amputation performed, HR 2.9[1.7-5.0],($p$<0.001), however after adjustment this was no longer significant ($p$=0.53). In contrast, OPG levels were not related to loss of vibration perception or development of a Charcot foot, ($p$=0.11 and 0.27, respectively).

In conclusion, OPG remained an independent predictor of lost foot pulse and development of foot ulcer during follow-up in patients with T1DM.

## SA-PO2911

### Prevalence and Risk Factors for Coronary Artery Calcification Progression over Five Years in Pre-Dialysis CKD Patients

Jocelyn S. Garland,[1,2] Alexander R. Morton,[1,2] Robert Louis Nolan,[4] Wilma M. Hopman,[3] Rachel M. Holden.[1,2] *[1]Medicine, Queen's University, Kingston, ON, Canada; [2]Queen's University Vascular Calcification Investigators; [3]Community Health and Epidemiology, Kingston General Hospital; [4]Radiology, Queen's University.*

Coronary artery calcification (CAC) is common in chronic kidney disease (CKD). Not all patients demonstrate CAC despite a similar risk profile. We sought to determine risk factors for CAC progression (increase in CAC ≥ 30 Agatston units or increase in Agatston CAC category) in 95 stage 3-5 CKD patients over 5 years. At baseline, mean eGFR 25 ml/min/1.73m², 58% male, 40% diabetic, and 82% had BMI > 25 kg/m². [sup]M[/sup]edian baseline CAC was 83 *vs* 184 at study end (P<0.0001). 63% of participants had progressive CAC; progressors were older (68 *v* 58 years; p < 0.0001), had lower diastolic blood pressure (70 *v* 77 mmHg; p=0.002); higher fasting glucose (7.2 *v* 5.8 mmol/L; p=0.02), higher serum osteoprotegerin (OPG) (4.5 *v* 3.6 pmol/L; p=0.02) and lower serum fetuin (0.64 *v* 0.58 g/L; p=0.02). Baseline CAC score was important in determining risk of CAC progression. An adjusted logistic regression model with CAC progression as the dependent variable, and baseline CAC categories as covariates (CAC = zero as the referent group), CAC score categories of 101 to 400 and > 401 were associated with an increased risk of CAC progression (CAC 101-400: OR 27.2; 95% CI 2.4 to 312; p=0.008), (CAC ≥ 401: OR 5.1; 95% CI 0.97 to 27.4; p=0.056). In a separate multivariable logistic regression model adjusted for traditional cardiovascular risk factors (as a composite score) and eGFR, both serum OPG, and low serum fetuin (OR 0.008; 95% CI 0.000 to 0.387; p=0.01) were associated with CAC progression. There was a significant interaction between OPG and BMI, so that the greatest risk of progressive CAC was demonstrated in those who had higher levels of each variable (OR 1.4; 95% CI 1.11 to 1.8; p=0.005). In summary, CAC progression was common in many patients, yet individuals largely protected from CAC at baseline remained protected over 5 years. Important inhibitors to vascular calcification were demonstrated as pertinent factors in predicting those at risk for CAC progression.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2912

### Vitamin D Receptor and Osteoprotegerin Gene Promoter Polymorphisms Are Not Associated with Coronary Artery Calcification in Stage 3-5 CKD

Jocelyn S. Garland,[1] Rachel M. Holden,[1] Robert Louis Nolan,[2] Wilma M. Hopman,[1] Harriet Feilotter,[3] Xiao Zhang,[3] Alexander R. Morton.[1] *[1]Vascular Calcification Investigators, Department of Medicine Queen's University; [2]Radiology, Queen's University; [3]Pathology and Molecular Medicine, Queen's University.*

In CKD patients, derangements within the vitamin D endocrine system may incite the process of vascular calcification. Moreover, vascular calcification inhibitor function (such as osteoprotegerin (OPG)) is defective. Genetic polymorphisms have been identified in the vitamin D receptor (VDRP) and OPG gene promoter region (OPGP). Data on the association between VDRP and osteopenia are conflicting, but suggest the presence of BsmI bb may be protective. Furthermore presence of the 950 T→C allele of the OPG gene promoter region has been associated with increased vascular intima-media thickness. Given the association between osteoporosis and vascular calcification, we hypothesized 1) presence of the BsmI *bb* allele may protect against vascular calcification, 2) the OPG *CC* genotype might be associated with increased vascular calcification, 3) a combination of BsmI *BB/Bb* and 950 T→C might be associated with a greater risk of vascular calcification. We enrolled 95 stage 3-5 CKD patients (58% male, 40% diabetic) and identified the prevalence of OPG 950 T→C and VDR BsmI polymorphisms. We investigated whether particular genotypes were associated with varying severity of coronary artery calcification (CAC), FGF-23 or 25-OH D.

| Variable | OPG TT/TC n=70 | OPG CC n=23 | Bsm BB/Bb n=66 | Bsm bb n=28 |
|---|---|---|---|---|
| CAC median | 136 | 200 | 157 | 188 |
| 25 Vitamin D | 59.4 | 56.5 | 60.1 | 54.2 |
| log FGF 23 | 2.2 | 2.1 | 2.2 | 2.2 |
| OPG | 4.2 | 3.4 * | 3.75 | 4.74 * |
| PTH | 15.3 | 16.4 | 14.3 | 18.9 |
| Calcium | 2.3 | 2.3 | 2.3 | 2.2 |
| Phosphorus | 1.27 | 1.28 | 1.25 | 1.32 |

* P < 0.05

For hypothesis #3, CAC, FGF-23 and 25-OH D were compared in individuals with the combination of BsmI *BB/Bb* and 950 T→C genotypes (n=19) *v* BsmI *bb* and *CC* (n=75). No differences were identified, although patient numbers were limited. In summary, in this cohort of CKD patients, approximately 30% of patients possessed recessive genotypes of OPG and VDR polymorphisms. No differences were demonstrated with respect to the polymorphism and CAC, or FGF-23 and 25-OH D. However, lower OPG levels were observed in those with the OPG *CC* genotype.

## SA-PO2913

### Assessment of Bone Quality in Renal Transplant Patients by DXA and µCT

Astrid Starke,[1] Alf Corsenca,[2] Thomas Kohler,[3] Rudolf P. Wuthrich,[2] Ralph Müller,[3] Patrice M. Ambühl.[1] *[1]Renal Division, Stadtspital Waid Zurich, Zurich, Switzerland; [2]Division of Nephrology, University Hospital Zurich, Zurich, Switzerland; [3]Institute for Biomechanics, ETH Zurich, Zurich, Switzerland.*

Renal transplant patients (RTP) are at risk of developing bone abnormalities due to preexisting renal osteopathy and immunosuppressive therapy. The changes in bone structure and their pathogenesis are poorly described so far.

Bone quality was investigated in 29 RTP with stable graft function (mean eGFR 54±16 ml/min) in the context of an interventional study aimed at correction of metabolic acidosis. Bone mineral density (BMD) was assessed by dual energy x-ray absorptiometry (DXA) and compared to cancellous bone micro-architecture of iliac crest bone biopsies analyzed by micro-computed tomography (µCT). Follow-up (FU) DXA measurements and biopsies were performed 1 year after baseline (BL) evaluation.

Cumulative BL and FU assessments resulted in 46 pairs of DXA and µCT measurements. Comparative analysis by linear regression of BMD at lumbar spine, hip and femoral neck determined by DXA versus µCT revealed no significant correlations. None of the other micro-architectural parameters including cancellous bone volume density, bone surface density, connectivity density, trabecular number, separation and thickness obtained by µCT correlated with BMD from DXA measurements. BL and FU DXA measurements revealed individual changes in absolute BMD ranging from -5 to +11% for all sites and patients. Nevertheless, these relative alterations did not result in significant shifts in the WHO classifications of osteoporosis (T-score, Z-score). In contrast, FU biopsies of 18 patients showed prominent quantitative micro-architectural changes ranging from -42 to +288% versus BL for some parameters.

In conclusion, DXA and µCT analyses revealed changes in bone mineral density and cancellous bone micro-architecture of RTP within a 1 year FU. The findings suggest that assessment by DXA does not adequately reflect the type, degree and dynamics of structural bone alterations in these patients. Further studies will clarify which method is more suitable to evaluate bone quality to predict fracture risk in RTP.

**SA-PO2914**

**Sclerostin Serum Levels Correlate Positively with Bone Mineral Density and Structure in Hemodialysis Patients** Daniel Cejka, Danielle Diarra, Martin Haas. *Department of Nephrology and Dialysis, Medical University Vienna, Vienna, Austria.*

Context

Sclerostin is a soluble inhibitor of wnt signaling, which is crucial for bone biology. Sclerostin is down-regulated by the parathyroid hormone (PTH). Secondary hyperparathyroidism in dialysis patients might influence bone metabolism through regulation of Sclerostin.

Objective

We investigated whether Sclerostin levels in dialysis patients are influenced by iPTH, and whether Sclerostin is associated with bone turnover, structure and mass.

Design: Cross-sectional study

Setting and patients

76 dialysis patients and 45 healthy controls were included in this study. Sclerostin, Dkk-1, intact PTH (iPTH), bone alkaline phosphatase (bAP), type I collagen c-terminal telopeptide (CTX) and vitamin D were measured in all participants. Dual x-ray absorptiometry (DXA) of the lumbar spine, femoral neck, distal radius, and high resolution peripheral quantitative computed tomography (HR-pQCT) at the tibia and radius were performed in 37 dialysis patients.

Results

Dialysis patients had significantly higher Sclerostin levels than healthy controls (1257 pg/ml vs. 415 pg/ml, $P<0.001$). A significant correlation was found between Sclerostin and gender ($R=0.41$), iPTH ($R = -0.28$), 25(OH)D3 ($R=0.27$) and calcium ($R=0.25$) in the bivariate analysis. Gender and iPTH remained significantly associated with Sclerostin in the multivariate analysis. Sclerostin was associated with bone mineral density of the lumbar spine ($R=0.46$), femoral neck ($R=0.36$) and distal radius ($R=0.42$). Significant positive correlations between Sclerostin and HR-pQCT measurements were found predominantly in trabecular structures. Dkk-1 was neither related to bone measures nor to serologic parameters.

Conclusion

Sclerostin is increased in end stage renal disease. Sclerostin is positively associated with bone mineral density and bone structure in dialysis patients, and may prevent bone loss in renal osteodystrophy.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2915**

**Novel Markers for Renal Osteodystrophy (ROD)** Vincent Brandenburg,[1] Gunter B. Wolf,[2] Gabriele Lehmann.[2] *[1]Cardiology, RWTH University Hospital Aachen, Aachen, Germany; [2]Nephrology, University Hospital Jena, Jena, Germany.*

**INTRODUCTION AND AIMS:** Different subtypes of renal osteodystrophy are associated with significant morbidity. Bone biopsy is the gold-standard for the diagnosis of ROD subtypes. We evaluated the role of novel serum biomarkers for ROD diagnosis in ESRD patients.

**METHODS:** 56 ESRD pts underwent iliac bone biopsy for histomorphometry. In parallel serum samples were analyzed for fibroblast growth factor 23 (FGF23), osteoprotegerin (OPG), sclerostin, PTH, bone alk phos (BAP), TRAP5b, cross-linked N-terminal telopeptide of type I collagen (NTX) and other serum markers of bone metabolism. The aim of the study was to investigate the prognostic value of novel biochemical markers in the diagnosis of ROD subtypes. Serum sclerostin was measured by ELISA**.**

**RESULTS:** We investigated 56 Causasian ESRD pts (54 HD pts, 70% males; median age 50 yrs, median time on dialysis 35 months (range 2 to 119), diabetic nephropathy in 20%. Low-turnover ROD (LTO) was present in 20%, high turnover ROD in 80% - mild osteitis fibrosa in 43% and severe osteitis fibrosa in 37%. Osteocyte counts per bone volume correlated significantly with other cellular bone metabolism makers (ObS/BS and OcS/BS). Moreover, osteocyte counts were significantly higher in HTO than in LTO and correlated positively with FGF23 but not sclerostin in serum. Median serum sclerostin level was 0.99 ng/mL (range 0.14 to 2.98, median of normal range 0.71) in the entire group. Only in females sclerostin levels were significantly different depending on ROD subtype: higher in LTO than in HTO. In the entire group, ROC analyses revealed AUC with $p<0.05$ for PTH, TRAP5b, NTX and BAP for differentiation of LTO from HTO. Mean levels of these markers were all significantly higher in HTO pts than in LTO.

**CONCLUSIONS:** Osteocyte count per bone volume is markedly increased in HTO compared to LTO bone biopsies. In general, serum levels of osteocyte markers FGF23 and sclerostin do not help in differentiating ROD subtypes in HD pts. In addition to PTH, BAP, and TRAP5b, NTX serum levels may also play a role as a biomarker for ROD in ESRD.

**SA-PO2916**

**Raman Spectrum Properties and Morphological Characteristics in Human Uremic Bone Samples** Junichiro J. Kazama,[1] Yoshiko Iwasaki,[2] Hideyuki Yamato,[3] Ichiei Narita.[1] *[1]Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Biological Science, Oita University of Nursing and Health Science, Oita, Japan; [3]Blomedical Research Laboratories, Shinjuku, Japan.*

Raman spectroscopy is a non-destructive examination method, which detects molecular/crystal structural properties by analyzing frequencies of incoming laser beam to and scattering ray from the target sample. We compared Raman spectroscopic properties and morphological characteristics determined by bone histomorphometry in biopsied human uremic bone samples. Iliac bone samples were obtained from 48 CKD5D patients (M22:F26, 50.8±14.7 yo, HD duration 38.1±66.1M). Samples were embedded in MMA resin, and conventional bone histomorphometry was performed on the processed sections. Coherent laser beam was shot into the surface of remaining block, and the specific Raman spectrum was obtained by analyzing scattering ray. The area of .354 mm square with highest phosphate content was designated for the analyses. In this study, hydroxyproline/proline ratio (H/P), mineral/matrix ratio (M/M), mature collagen cross-links/immature collagen cross-links ratio (M/I) and hydoxylapatite crystallizing ratio (HC) were analyzed. In result, conventional bone histomorphometry categorized those 48 samples into 5 groups (mild change (ML) 11, adynamic bone (AB) 13, osteitis fibrosa (OF) 11, osteomalacia (OM) 6, mixed type (MX) 7). Significant negative correlations were found between FbV/TV and H/P($p<.01$, $r^2=.150$), FbV/TV and M/I($p<.005$, $r^2=.177$), intact PTH and H/P($p<.05$, $r^2=.130$), intact PTH and M/I($p<.005$, $r^2=.175$), OV/BV and M/I ($p<.005$, $r^2=.185$), respectively. OM showed lower M/M than others. ML and AB showed higher M/I, however, HC was low in AB. The relationships between PTH·FbV/TV and H/P·M/I suggested the disturbed matrix protein maturation in woven bone. Mild abnormal mineralization was found in calcified bone besides at calcified front in OM, which may also be related to immaturity of matrix protein. No matrix protein abnormality was detected in AB, while the development of hydroxyl apatite crystal was disturbed.

**Sclerostin – A Marker Superior to iPTH for Assessment of Bone Turnover in Dialysis Patients** Hartmut H. Malluche,[1] Daniel Cejka,[2] Johann Herberth,[1] Adam Branscum,[3] Danielle Diarra,[2] Martin Haas,[2] Marie-Claude M. Faugere.[1] *[1]Nephrology, Bone and Mineral Metabolism, University of Kentucky, Lexington, KY; [2]Nephrology, Medical University of Vienna, Vienna, Austria; [3]Biostatistics, Statistics and Epidemiology, University of Kentucky, Lexington, KY.*

**Background:** Sclerostin, a protein produced by osteocytes and circulating in blood, was recently identified as a component of parathyroid hormone (PTH) signal transduction. The current study was conducted to compare the value of determinations of blood concentrations of sclerostin versus intact PTH (iPTH) for assessment of bone turnover in stage 5 chronic kidney disease patients on dialysis (CKD-5D).

**Materials and Methods:** In a cross sectional study, 60 CKD-5D patients underwent bone biopsies after tetracycline double labelling followed by bone histomorphometry. Blood samples were drawn at time of bone biopsy. Levels of sclerostin were determined by ELISA and iPTH by IRMA. Associations between biochemical and histomorphometric parameters were evaluated by correlation and multiple linear regression analyses.

**Results:** Serum levels of sclerostin and iPTH correlated negatively ($rho=-0.34$, $p=0.01$). In unadjusted and adjusted analyses, serum sclerostin levels were strongly associated with histomorphometric parameters of bone turnover at the tissue level (measured by activation frequency [Ac.f] and bone formation rate/bone surface [BFR/BS]; Ac.f. β-estimate -0.000248, $P<0.001$; BFR/BS β-estimate -0.000235, $p=0.003$), while serum iPTH levels showed stronger associations than sclerostin with cellular parameters of bone formation and resorption (number of osteoblasts / bone perimeter β-estimate 0.0017, $p<0.001$ and number of osteoclasts / bone perimeter β-estimate 0.000809, $p<0.01$).

**Conclusions:** In CKD-5D patients, determinations of iPTH give information on number of bone forming and resorbing cells. Bone turnover at the tissue level is the result of both, number and activity of bone forming and resorbing cells. In the studied patient cohort, sclerostin is superior to iPTH for predicting bone turnover at the tissue level.

**Low Levels of 25-Hydroxyvitamin D and High Levels of Fibroblast Growth Factor-23 Are Associated with Calcitriol Deficiency in Patients with Severe CKD** Jessica B. Kendrick,[1] Alfred K. Cheung,[2,4] James S. Kaufman,[3] Tom H. Greene,[4] William L. Roberts,[4] Gerard John Smits,[1] Michel B. Chonchol.[1] *[1]University of Colorado Denver Health Sciences Center, Denver, CO; [2]VASLCHCS, Salt Lake City, UT; [3]VA Boston Healthcare System, Boston, MA; [4]University of Utah, Salt Lake City, UT.*

Purpose: Factors other than loss of renal mass may contribute to low calcitriol levels. We tested the hypothesis that high plasma fibroblast growth factor-23 (FGF-23) levels are associated with decreased calcitriol levels independent of 25-hydroxyvitamin D (25(OH) D) and kidney function.

Methods: This study was conducted on 1099 patients with severe CKD not on dialysis who participated in the HOST study. Calcitriol, 25(OH)D, intact parathyroid hormone levels

(iPTH), and FGF-23 levels were measured in stored plasma samples. Analysis was done using multiple linear regressions.

Results: Participants had a mean (SD) age and eGFR of 69±11 years and 18 ±6.5 mL/min/1.73m2, respectively. The median (IQR) calcitriol, 25(OH)D, iPTH and FGF-23 levels were 18 [12-26] pg/mL, 19 [13-27] ng/mL, 147 [90-246] pg/mL and 380 [216-945] RU/mL, respectively. In univariate [(R2 =0.20; p< 0.0001 for 25(OH)D and R2 =0.16; p< 0.0001 for FGF-23)] and multivariable analyses, 25(OH)D and FGF-23 were the strongest determinants of calcitriol levels. Coefficients shown in Table 1 represent changes in calcitriol levels per unit increase of the variable.

Table 1

| Independent Variables | β (95% CI) | P-value |
|---|---|---|
| eGFR (mL/min/1.73m2) | 0.007 (0.005, 0.009) | <0.0001 |
| Log10 25(OH)D (ng/mL) | 0.45 (0.40, 0.50) | <0.0001 |
| Log10 FGF-23 (RU/mL) | -0.13 (-0.16, -0.11) | <0.0001 |
| Log10 iPTH (pg/mL) | 0.09 (0.06, 0.12) | <0.0001 |
| Calcium (mg/dl) | -0.01 (-0.03, 0.01) | 0.2 |
| Phosphorus (mg/dl) | -0.016 (-0.03, -0.01) | 0.0005 |

Conclusion: Low 25 (OH) D and high FGF-23 levels are strongly associated with low calcitriol levels in patients with CKD.

## SA-PO2919

**Bone Turnover Markers Discriminate Fracture Status Non-Dialysis CKD Patients** Thomas L. Nickolas,[1] Elzbieta Dworakowski,[1] Valerie Thomas,[1] Emily Stein,[1] Adi Cohen,[1] Stephanie Boutroy,[1] Ryan Chauncey,[1] Mary B. Leonard,[2] Serge Cremers,[1] Elizabeth Shane.[1] *[1]Medicine, Columbia Univeristy, NY, NY; [2]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA.*

It is not known if bone turnover markers (BTMs) predict fracture (FX) in patients with predialysis chronic kidney disease (CKD). To address this question, we compared BTMs and measures of areal bone mineral density (aBMD) by dual energy X-ray absorptiometry (DXA) and bone geometry and microarchitecture by high resolution pQCT (HRpQCT, resolution ~82µm) for discrimination of FX in predialysis CKD.

Intact parathyroid hormone (iPTH), markers of bone formation (bone alkaline phosphatase [BSAP] and osteocalcin [OC]) and resorption (tartrate-resistant acid phosphatase 5b [Trap5b] and C-terminal telopeptides [CTX]) were measured in CKD patients with (n=26) and without (n=56) FX. aBMD was measured at the one-third and ultradistal radius (1/3R and UDR), total hip (TH), femoral neck (FN) and lumbar spine (LS). Cortical area, density and thickness (Ctarea, Dct, CTh) and trabecular density, number, thickness and separation (Dtb, TbN, TbTh, TbSp) were measured by HRpQCT at the distal radius (RAD) and tibia (TIB). All comparisons were adjusted for age, gender, body mass index (BMI) and diabetes.

FX and nonFX groups did not differ by kidney function, gender, race or ethnicity. Patients with FX were older (74±10 vs. 69±8 years, p=0.03), had lower BMI (28±4 vs. 30±5 years, p<0.05) and were more likely diabetic (58% vs. 32%, p0.03). In the FX group, OC, Trap5b and CTX were 36%, 28% and 31% higher (all p<0.05). By DXA, aBMD was 20% and 14% lower at UDR and LS (p=0.007 and 0.04; respectively). By HRpQCT at the RAD, Dtb and TbTh were 25% and 14% lower (p=0.02 and 0.008; respectively) and at the TIB, Ctarea and CTh were 30% lower (both p<0.05). Other BTMs or imaging measures did not differ. Areas under the ROC curves ranged from 0.61 (CTX) to 0.76 (UDR BMD); none differed significantly from a reference of LS BMD (AUC 0.70).

BTMs discriminate FX status in patients with CKD comparably to DXA or HRpQCT. Longitudinal studies are required to determine if BTMs can predict FX in patients with predialysis CKD.

## SA-PO2920

**Tests of Neuromuscular Function Discriminate among Those with and without Fractures in Chronic Kidney Disease** Charmaine E. Lok,[1,2] Sarah West,[2] Sophie Jamal.[2,3] *[1]Toronto General Hospital, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Women's College Hospital, Toronto, ON, Canada.*

**Background**: Fractures occur at a high frequency in patients with chronic kidney disease (CKD), with ~40% having sustained a fracture prior to initiating dialysis.

**Purpose:** Tests of neuromuscular function (NMT) have discriminated fracture status in dialysis patients; however, the ability of NMT to discriminate among fractured and non-fractured patients with stages 3 to 5 CKD has not been reported.

**Methods:** Baseline data from an ongoing prospective observational study of adult patients with stages 3-5 (pre-dialysis) CKD was used to determine if tests of neuromuscular function, as indicated by the timed up and go test (TUG), and the 6 minute walk test (6MW), could discriminate between those with and without self-reported low trauma fractures occurring after age 40. Results are expressed as areas under the receiver operating characteristic curves (AUC) with 95% confidence intervals (CI).

**Results:** Data was available for 71 men and 45 women. They were primarily Caucasian (62.9%) with a mean age of 62±16 yrs and weight of 78.7±17.6 kg. The most common cause of CKD was diabetes (43.4%). The mean eGFR (MDRD) was 19.1±11.0 ml/min/1.73m$^2$, with most (85.1%) patients categorized as stage 4 or 5 CKD. Almost half (46.4%) had a history of fractures and 34.6% reported a fall in the past year. Additionally, over half (54.5%) of all patients were sedentary, with less than 25% reporting that they engage in activity that causes them to sweat. The TUG was able to discriminate among those with and without fractures (AUC: 0.65 [95% CI: 0.49-0.81]), as was the 6MW test (AUC: 0.71 [95% CI: 0.53-0.90]). There were no statistical differences in the performance characteristics of the TUG and 6MW.

**Conclusions**: Among adult patients with stages 3 to 5 CKD not on dialysis, the majority of patients are inactive. Tests of neuromuscular function, i.e., the TUG and 6MW, are able to discriminate among those patients with and without fractures occurring after the age of 40. NMT is an easy and cost effective way to identify patients at risk of fractures for whom preventative strategies may be beneficial.

## SA-PO2921

**Osteoprotegerin Is Associated with Cardiac Dysfunction and Vascular Damage in Predialysis Patients** Shirley Yumi Hayashi,[2] Marcelo M. Nascimento,[1] Astrid Seeberger,[1] Britta Lind,[2] Anna Bjällmark,[2] Miguel C. Riella,[3] Lars-Åke Brodin,[1] Bengt Lindholm.[1] *[1]School of Technology and Health, KTH, Royal Institute of Technology, Stockholm, Sweden; [2]Baxter Novum & Renal Medicine Karolinska Institute, Stockholm, Sweden; [3]Pontifícia Universidade Católica do Paraná.*

Atherosclerosis and vascular calcification(VC) contribute to the high risk of cardiovascular disease (CVD) in chronic kidney disease (CKD) patients. Osteoprotegerin (OPG) has been associated to VC and mortality in CKD patients. The objective of the present study was to evaluate the relationship between VC markers and cardiac dysfunction parameters in pre-dialysis patients.. Fifty four (34 male, 60.0 ±11.2 yr) CKD patients stages 3 and 4 were evaluated. VC markers( fetuin and OPG) were analysed as well as cardiac function through conventional echocardiography and measurements of myocardial velocities using tissue Doppler echocardiography (TDE). Moreover, atherosclerosis was evaluated by measurements of carotid intima media thickness, and vascular elasticity using a new described technique called ultrasound strain imaging which measures the deformation or strain of common carotid artery by speckle tracking technique. No significant difference in OPG levels were observed between patients with CKD stage 3-4 (6.9±2.5 vs. 7.1±2.5 pmol/l)(p>0.05).Furthermore, OPG levels were negatively correlated with isovolumetric contraction velocities (IVCv) (Rho -0.45, p<0.001), peak systolic velocities (Rho -0.37, p<0.01) and positively with left ventricular (LV) end diastolic pressure (E/E´) (Rho 0.34, p<0.05), indicating the possible association between OPG and cardiac dysfunction. OPG levels were positively associated with IMT (Rho 0.48, p<0.001), common carotid artery strain (Rho – 0.32, p<0.05) and strain rate (-0.32,p<0.05). On the other hand, no associations were found between fetuin, cardiac function and vascular damage.In a stepwise multiple regression model, OPG was an independent predictor of IVCv, IMT,carotid strain and strain rate. In conclusion, in pre-dialysis patients OPG showed significant association with cardiac dysfuntion and vascular damage.These results suggest its role on VC and CVD in CKD patients.

## SA-PO2922

**Bone Histomorphometry and Biochemical Markers across CKD Stages** Katia R. Neves,[1] Rosa Ma Moyses,[1] Fellype Barreto,[2] Daniela Veit Barreto,[2] Cristianne Tomiyama,[2] Andrea Higa,[2] Fabiana G. Graciolli,[1] Luciene M. dos Reis,[1] Maria Eugenia F. Canziani,[2] Vanda Jorgetti,[1] Aluizio B. Carvalho.[2] *[1]Nephrology, Universidade de São Paulo, Brazil; [2]Nephrology, Universidade Federal de São Paulo, Brazil.*

CKD-MBD is characterized by early changes in bone histology, as well as in serum biochemistry. However, few studies have simultaneously evaluated biochemical markers and bone histomorphometry across CKD stages. In a cross-sectional study, we evaluated 148 adult CKD patients (CKD 2-5), and observed a progressive decrease in serum Ca, and a progressive increase in serum P, alkaline phosphatase (AP), PTH and FGF 23.

Bone Histomorphometry analysis disclosed decreased bone formation and mineralization in dialysis patients despite higher PTH levels. No differences were seen in bone volume (BV/TV).

| | CKD 2-3 (n=32) | CKD 4 (n=18) | CKD 5 (n=98) |
|---|---|---|---|
| Age | 50.0±9.5 | 54.4±11.8 | 48.5±13.1 |
| iPTH | 75 (42-89)[a,b] | 272 (120-398) | 242(113- 589) |
| iCa | 1.3±0.0[a,b] | 1.3±0.1 | 1.2±0.1 |
| P | 3.6 (3.2-3.8)[a] | 4.5 (4.0-4.8)[a] | 6.7(6.2-7.8) |
| AP | 109 (66-160)[a] | 119 (77-164)[a] | 203(158-282) |
| 25-OH Vitamin D | 42.3±19.9[a,b] | 25.0±10.3 | 31.9±15.7 |
| FGF 23 | 43 (25-62)[a] | 84 (48-138)[a] | 18,260(5,705-45,298) |
| BV/TV | 17.6 (12.9-21.1) | 17.9 (10.6-22.2) | 16.5 (12.2-21.9) |
| BFR | 0.005 (0.005-0.02) | 0.01 (0.007-0.04)[a] | 0.0004 (0.0004-0.03) |
| Mlt | 113 (31-655)[a] | 103 (33-273) | 656 (40-656) |

Mean ±SD except those in median (interquartile range). P < 0.05: a vs. CKD 5; b vs. CKD 4

Bone formation rate (BFR/BS) correlated with FGF 23 (R = -0.20), age (R = -0.24), PTH (R = 0.20) and Cr clearance (R = -0.16), whereas mineralization lag time (Mlt) correlated with FGF 23 (R= 0.22), age (R = 0.22), Ca (R = -0.16) and Cr clearance (R = -0.24). In conclusion, the natural course of CKD-MBD does not seem to influence BV/TV, but is associated with effects on bone turnover and mineralization. Although a significant correlation was found between some biochemical markers and bone turnover and mineralization, the exact role of some of them, such as FGF 23, requires further investigation.

**SA-PO2923**

**Higher Estradiol (E2) and Lower Sex Hormone Binding Globulin (SHBG) Levels in CKD Are Associated with Greater Bone Mineral Density (BMD) Compared with Controls: A CRIC Study** Takayuki Hamano, Matthew T. White, Thomas L. Nickolas, Raymond R. Townsend, Harold I. Feldman, Lucy W. Kibe, Michael Sulik, Mary B. Leonard. *CRIC.*

Sex hormone associations with estimated GFR (eGFR) and BMD have not been established.

This cross-sectional study examined 487 controls and 249 CRIC subjects [eGFR: median 47], age 21-80 yrs, excluding those on sex hormones, raloxifene, prednisone, or bisphosphonates. BMD was measured by DXA at the 1/3rd and ultradistal radius, and lateral lumbar spine. Total E2, testosterone (T), SHBG, 1-84PTH, and BSAP levels were obtained.

Total E2 levels were greater ($p < 0.001$) and SHBG levels were lower in CKD ($p < 0.05$) compared with controls, adjusted for age, sex, race, BMI, T levels and sex-age interactions. CKD effects were comparable in men and women. Within CKD, serum E2 levels were negatively associated with eGFR ($p < 0.001$), adjusted for age, sex, race, and T levels. BSAP levels were independently and negatively associated with E2 ($p < 0.01$), and positively associated with PTH ($p < 0.001$), adjusted for sex, race, and age in CRIC and controls.

Compared to controls, CKD participants had higher BMD Z-score at 1/3 radius and lumbar spine.

| **Distal 1/3 Radius Z-score** | **CKD Effect [95%C.I.]** | **P-value** |
|---|---|---|
| unadjusted | 0.30 [0.15, 0.46] | <0.0001 |
| adjustment for BMI | 0.22 [0.05, 0.38] | <0.01 |
| adjustment for BMI + E2 | 0.19 [0.12, 0.36] | 0.04 |
| **Lateral Spine Z-score** | **CKD Effect [95%C.I.]** | **P-value** |
| unadjusted | 0.56 [0.39, 0.73] | <0.0001 |
| adjustment for BMI | 0.46 [0.28, 0.63] | <0.0001 |
| adjustment for BMI + E2 + SHBG | 0.43 [0.24, 0.61] | <0.0001 |

Adjustment for BMI, E2 and SHBG attenuated the CKD effect. At the ultradistal radius, E2 was associated with greater BMD and SHBG with lower BMD, in CKD and controls. These data suggest that greater bioavailable E2 levels in CKD partly explain the higher BMD. The positive effect of E2 on BMD was independent of BSAP at radius, implying the beneficial effect of E2 was not mediated only through reduced bone turnover.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2924**

**Predictive Value of Biomarkers for Bone Turnover in ESKD** Hartmut H. Malluche,[1] Ezequiel R. Bellorin-Font,[2] Eudocia Rojas,[2] Aluizio B. Carvalho,[3] Patrick C. D'Haese,[4] Tilman B. Drueke,[5] Manuel A. Ferreira,[6] Vanda Jorgetti,[7] Sharon M. Moe,[8] Stuart M. Sprague.[9] *[1]Univ of Kentucky, Lexington, KY; [2]Hospital Universitario de Caracas, Caracas, Venezuela; [3]Federal Univ of São Paulo, São Paulo, Brazil; [4]Univ of Antwerp, Antwerp, Belgium; [5]Hôpital Necker, Paris, France; [6]Hospital Curry Cabral, Lisbon, Portugal; [7]Univ of São Paulo, São Paulo, Brazil; [8]Indiana Univ, Indianapolis, IN; [9]NorthShore Univ HS, Evanston, IL.*

Management of CKD-MBD requires assessment of bone turnover. The utility of serum biomarkers to discriminate bone turnover is unclear. An international cross-sectional, retrospective study to determine whether serum biomarkers could assess bone turnover was performed in 647 HD patients. PTH, intact (i) & whole (w), bone-specific alkaline phosphatase (BSAP), and procollagen type-1 N-terminal propeptide (P1NP) were measured in serum drawn at the time of bone biopsy. Bone turnover was determined as BFR/BS. Receiver operator curves were developed to assess minimal discriminating (AUC>0.70) or diagnostic (AUC>0.85) ability. Median iPTH, wPTH, BSAP and P1NP were different among categories of turnover ($p<0.0001$). None of the biomarkers achieved an AUC>0.70 to separate low or high from normal except for BSAP which discriminated low from normal (AUC>0.738). The combination of iPTH or wPTH and BSAP discriminated low from normal (AUC 0.702 & 0.726, respectively). Neither combination discriminated high from normal turnover. iPTH, BSAP, P1NP, and combination of iPTH and BSAP were able to discriminate high from nonhigh BFR/BS (AUC>0.70-0.743). Discrimination between low and nonlow BFR/BS was achieved with iPTH, wPTH, BSAP, and the combination of BSAP with either iPTH or wPTH (AUC>0.701-0.757). There were differences between iPTH, wPTH, BSAP, and P1NP across BFR/BS; no marker singly or in combination was robust enough to diagnose low, normal or high turnover. There was significant ROC based discrimination in differentiating low from nonlow and high from nonhigh, however, it did not reach acceptable levels for cross sectional diagnosis. Further prospective studies are required to assess their value for trend analysis.

**Serologic Diagnosis of Bone Turnover after Kidney Transplantation** Danielle Diarra,[1] Daniel Cejka,[1] Martin Haas.[1] *[1]Internal Medicine III, Nephrology, Medical University Vienna, Vienna, Austria; [2]Internal Medicine, KH der Elisabethinen Linz.*

BACKGROUND. Current guidelines suggest to maintain PTH levels in the upper range of normal in kidney transplant recipients with CKD stages 3-5T. Evidence in support of this recommendation is lacking.

METHODS. Bone biopsies were performed in 39 kidney transplant recipients. Renal osteodystrophy (ROD) was classified according the Delling classification as either type I (fibrosteoclasia and marrow fibrosis), type II (osteoidosis with low bone turnover) or type III (osteoidosis and fibrosis with increased bone turnover). Serologic bone markers (c-telopeptide [CTX], osteocalcin [OC], bone alkaline phosphatase [bAP]), intact (i) PTH, electrolytes and vitamin D status were obtained. Serologic values of patients with normal histology and ROD type II were combined for receiver operating characteristic (ROC curve).

RESULTS. Mean estimated GFR was 49±37ml/min. Nine patients had normal bone morphology, 13 ROD type II and 17 ROD type III. Median iPTH level did not differ between the groups and was above normal in all. There was no difference in median eGFR, median serum levels of calcium and phosphate, and median vitamin D or calcitriol levels between the groups. Patients with ROD type III had significantly higher CTX values than patients with normal bone histology, and significantly higher OC and bAP values than both other groups. The ROC curve of OC had the highest area under the curve (0.90) followed by bAP (0.82), PTH (0.73) and CTX (0.73). An OC level of 46ng/ml had a sensitivity of 88% and a specificity of 85% to differentiate high turnover from normal/low turnover ROD.

CONCLUSION. Measurement of intact PTH is an unsuitable means to assess bone turnover in post-transplant renal osteodystrophy and should not be used for treatment considerations. Osteocalcin has the best predictive value for the diagnosis of increased bone turnover in transplant recipients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2926**

**Sensitivity and Specificity of Guideline PTH Targets To Differentiate High and Low Bone Turnover** Sharon M. Moe,[1] Ezequiel R. Bellorin-Font,[2] Aluizio B. Carvalho,[3] Patrick C. D'Haese,[4] Tilman B. Drueke,[5] Hongyan Du,[6] Manuel A. Ferreira,[7] Hartmut H. Malluche,[8] Stuart M. Sprague,[6] Vanda Jorgetti.[9] *[1]Indiana Univ, Indianapolis, IN; [2]Hospital Universitario de Caracas, Caracas, Venezuela; [3]Federal Univ of São Paulo, São Paulo, Brazil; [4]Univ of Antwerp, Antwerp, Belgium; [5]Hôpital Necker, Paris, France; [6]Univ of Chicago, Evanston, IL; [7]Hospital Curry Cabral, Lisbon, Portugal; [8]Univ of Kentucky, Lexington, KY; [9]Univ of São Paulo, São Paulo, Brazil.*

To determine whether guideline values for PTH can differentiate high and low turnover (TO) bone disease, an international cross-sectional analysis of PTH targets to predict bone TO was performed. Bone biopsy and serum PTH (intact [i] & whole [w]) were analyzed in 647 subjects. PTH was stratified based on KDOQI (150-300 pg/ml) and KDIGO (2-9 times upper limit of normal [ULN]) targets. TO was based on BFR/BS being either low or high. KDOQI iPTH of <150 pg/mL had sensitivity/specificity of 68.6/61.2% for low TO. iPTH >300 pg/mL had a sensitivity/specificity of 58.0/77.7% for high TO. For KDIGO, an iPTH of less than 2X ULN had a sensitivity/specificty of 65.0/67.3% for low TO. An iPTH >9X ULN had a sensitivity/specificty of 37.0/85.8% for high TO. A wPTH of <2X ULN had a sensitivity/specificity of 73.5/56.7% whilst a wPTH of greater than 9X ULN had a sensitivity/specificity of 30.7/87.9% for low and high TO, respectively. Calculated ROC's predict the optimal iPTH for low TO would be <103.7 pg/mL with an averaged sensitivity/specificity (AUC 0.701) and to predict high TO would be an iPTH >242.7 pg/mL (AUC 0.701). A wPTH <47.1 pg/mL would predict low TO (AUC 0.712), however, there was not a wPTH that would achieve the minimally acceptable criteria (AUC >0.7) to predict high TO. Thus, the iPTH cutoffs for KDOQI and KDIGO had relatively high specificity, but low sensitivity to differentiate high TO, but were inadequate to predict low TO. However, wPTH can be predictive only of low TO with a threshold lower than proposed by KDIGO and KDOQI. In summary, iPTH can predict both low and high TO, but the diagnostic performance of this biomarker to reflect bone TO remains suboptimal.

**SA-PO2927**

**Cortical Bone Analysis in CKD Patients – A New Approach** Catarina Carvalho,[1] Katherine Wesseling-Perry,[2] Isidro B. Salusky,[2] R. C. Pereira.[2] *[1]Nephrology, Hospital Sao Joao, Porto, Portugal; [2]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

ROD diagnoses are defined by trabecular bone parameters. Cortical bone is the major determinant of bone strength, but the relationship between cortical bone, trabecular bone, and biochemical parameters in CKD pts remains unknown. Thus, 22 pts age 10.4±0.7 yrs treated with CCPD underwent double labeled BBx. Cortical bone was compared to biochemical values and traditonal trabecular TMV parameters. S-values were: Ca 9.3±0.2 mg/dl, P 5.7±0.2 mg/dl, Alk P-tase 380±41 IU/l, 1st PTH-IMA 524±86 pg/ml. Cortical porosity (Po) and osteonal osteoid surface (OS) were related to Ca (r= -0.30 and r= -0.42;

p=0.05), PTH (r=0.43 and r=0.40; p<0.01), and Alk P-tase (r=0.48 and r=0.48; p<0.01). Trabecular BFR correlated with PTH (r=0.88; p<0.01) and Alk P-tase (r=0.68; p<0.01) and trabecular osteoid volume (OV) with Ca, PTH and Alk P-tase (r= -0.63, r= 0.93, r=0.61; p<0.01).

| Cortical Parameter | Trabecular Parameter | | | | | | |
|---|---|---|---|---|---|---|---|
| | Bone Volume (BV/TV) | Osteoid Volume (OV/BV) | Osteoid Surface (OS/BS) | Osteoid Thickness (O.Th) | Bone formation rate (BFR/BS) | Eroded Surface (ES/BS) | Mineralization Lag Time (MLT) |
| Channel Diameter | NS | NS | NS | NS | NS | NS | NS |
| Osteon Diameter | NS | NS | NS | NS | NS | NS | NS |
| Porosity | NS | 0.518 P=0.000 | 0.490 P=0.001 | 0.509 P=0.000 | 0.457 P=0.001 | NS | 0.509 P=0.000 |
| Cortical Thickness | NS | NS | NS | NS | NS | NS | NS |
| Bone Formation Rate | NS | NS | NS | NS | NS | NS | NS |
| Osteoid Volume | 0.324 P=0.034 | 0.344 P=0.024 | 0.331 P=0.030 | 0.362 P=0.017 | 0.344 P=0.027 | 0.486 P=0.001 | NS |
| Osteoid Surface | NS | 0.488 P=0.001 | 0.425 P=0.005 | 0.368 P=0.015 | 0.358 P=0.021 | NS | NS |
| Eroded Surface | NS | NS | NS | NS | NS | 0.423 P=0.006 | NS |

Po and cortical OV correlated with trabecular bone formation, likely due to the action of PTH on both cortical and trabecular bone. Lack of correlation between cortical and trabecular BFR suggests that additional factors modulate cortical modeling in pediatric CKD. Understanding of cortical abnormalities may have therapeutic implications in the prevention of skeletal morbidity of CKD.

### SA-PO2928

**FRAX and Fracture Risk in Patients with Chronic Kidney Disease** Sophie Jamal,[1] Lisa Langsetmo,[2] Sarah West,[1] Sandhya S. Thomas,[3] Ryan Chauncey,[3] Thomas L. Nickolas.[3] *[1]Medicine, University of Toronto, Toronto, ON, Canada; [2]Statistics, McGill University Research Institute, Montreal, QC, Canada; [3]Medicine, Columbia University, NY, NY.*

Half of osteoporotic (OP) fractures (Fx) occur in patients with bone mineral density (BMD) above the OP diagnostic threshold. The FRAX risk assessment tool uses both BMD and other clinical risk factors for Fx to improve absolute Fx risk determination. In chronic kidney disease (CKD), BMD poorly identifies Fx risk. We hypothesized FRAX would improve Fx risk assessment in CKD.

We combined data from two cross-sectional studies of men and women, ≥18 yrs with pre-dialysis CKD Stages 3 to 5. We evaluated the ability of FRAX, with and without femoral neck (FN) BMD and assuming no prior Fx history, to discriminate prevalent OP Fx status. We also evaluated the ability of FRAX, with and without BMD and including prior clinical Fx, to determine prevalent spine Fx. The discrimination of age alone for Fx was used as a reference. Results are presented as AUCs with 95% confidence intervals (CI).

We enrolled 109 men and 81 women of whom 187 had BMD measurements. Mean age was 66.5 yrs, BMI was 28.5 kg/m2, and FN BMD was 0.722 g/cm2; 49 had OP Fx, 44 had spine Fx, 20 had a family history of Fx, 19 were taking steroids, 3 had RA, 15 were smokers and one person consumed ≥3 units of alcohol/day. FRAX both with and without BMD and excluding prior clinical Fx discriminated OP Fx status with AUC=0.67 (95% CI:0.58-0.75) and AUC=0.63 (95% CI:0.54-0.71) respectively, compared to AUC=0.60 (95% CI:0.52-0.69) for age. FRAX with and without BMD and including prior clinical Fx discriminated spine Fx status with AUC=0.66 (95% CI:0.57-0.75) and AUC=0.70 (95% CI:0.62-0.78), respectively, compared to AUC=0.68 (95% CI:0.59-0.77) for age.

FRAX, with or without BMD, had moderate ability to discriminate Fx status in pre-dialysis CKD patients. For spine Fx, FRAX performed similar to age. For clinical Fx, evaluation of other clinical risks for Fx modestly improved Fx risk assessment. Larger, longitudinal studies are needed to determine if assessment of clinical risk factors for Fx, in addition to BMD, improve Fx prediction in CKD.

### SA-PO2929

**Bone Mineral Density and Bone Structure Discriminate among Those with and without Fractures in Chronic Kidney Disease** Sophie Jamal,[1,2] Sarah West,[2] Charmaine E. Lok.[2,3] *[1]Women's College Hospital, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada.*

**Purpose:** The ability of bone mineral density (BMD) by dual x-ray absorptiometry (DXA) and bone structure by high resolution peripheral quantitated computed tomography (HR-pQCT) to discriminate among fractured and non-fractured patients with stages 3 to 5 chronic kidney disease (CKD) has not been well studied.

**Methods:** Baseline data from an ongoing prospective study of adult patients with stages 3-5 CKD was used to determine if BMD by DXA (Hologic) at the lumbar spine (LS), total hip (TH), ultradistal radius (UDR); and/or bone cortical area, density & thickness, trabecular density, thickness, separation & number by HR-pQCT (XtremeCT) at the radius could discriminate between those with and without self-reported low trauma fractures occurring after age 40. Results are expressed as areas under the receiver operating characteristic curves (AUC) with 95% confidence intervals (CI).

**Results:** Data was available for 71 men and 45 women. They were primarily Caucasian (62.9%) with a mean age of 62±16 yrs and weight of 78.7±17.6 kg. The most common cause of CKD was diabetes (43.4%). Almost half (46.4%) had a history of fractures and 34.6% reported a fall in the past year. BMD by DXA was able to discriminate among those with and without fractures at all sites (AUC for LS: 0.72 [95% CI: 0.61-0.84]; AUC for TH: 0.74 [95% CI: 0.61-0.88]; AUC for UDR: 0.69 [95% CI: 0.57-0.81]). HR-pQCT also performed well for cortical measures (AUC for area: 0.63 [95% CI: 0.49-0.78]; density: 0.65 [95% CI: 0.53-0.78] and thickness: 0.65 [95% CI: 0.53-0.78]) as well as trabecular measures (AUC for density: 0.69 [95% CI: 0.55-0.82]; number: 0.73 [95% CI: 0.61-0.86]; thickness: 0.65 [95% CI: 0.53-0.78], and separation: 0.69 [0.56-0.83]). There were no statistical differences in the performance characteristics of any of these tests.

**Conclusions**: Among adults ≥40 years old with stages 3 to 5 CKD not on dialysis, BMD by DXA and HR-pQCT parameters are able to successfully discriminate among those patients with and without self-reported low trauma fractures.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2930

**Characterization of Bone Loss in Patients with Chronic Kidney Disease Stage 5 on Dialysis (CKD 5 D) by High Resolution Peripheral Quantitative Computed Tomography (HR-pQCT)** Armando Luis Negri,[1] Elisa Elena Del Valle,[1] María B. Zanchetta,[1] Marcelo Puddu,[2] Roberto Barone,[3] Cesar Bogado,[1] José R. Zanchetta.[1] *[1]Nephrology, Instituto de Investigaciones Metabolicas, Buenos Aires, Argentina; [2]FMC-Caballito, Buenos Aires, Argentina; [3]STR Hurlingham, Hurlingham, Argentina.*

Patients with CKD 5D are at increased risk of fragility fractures. Recently HR-pQCT, a new non-invasive 3D bone imaging modality has been developed, to more accurately estimate bone quality and strength. The aim of this study was to assess whether volumetric bone mineral density (vBMD) and bone microstructure are impaired in dialysis patients using HR-pQCT bone imaging (XtremeCT, Scanco Medical AG) at the tibia and radius. HRpQCT has a resolution of <100um versus 350um of the standard pQCT machines allowing better analysis of trabecular microstructure. We examined 48 CKD 5D patients, 20 men and 28 women; mean time in dialysis was 65.6 ± 51 months. Mean age was 58.6 ± 11.1y for men and 53.5 ± 9.8 y for women. Mean serum iPTH level was 699 pg /mL (range: 79 - 2453 pg/ml). Both CKD men and women experienced significant trabecular (Tb) and cortical (Ct) impairment. CKD men vs. healthy controls at the radius: Tb vBMD: 138.9+/-45.8 vs. 188.4+/- 29.8 mg HA/cm(3)(p=0.001); Tb BV/TV(Bone volume/Total volume): 0.11±0.03 vs 0.15±0.02 (p=0.001); Tb number 1.72+/-0.39 vs. 2,00+/-0.27 mm(-1) (p=0.03) and Tb separation 564+/-307 vs. 429+/-67 mum. Cortical parameters in CKD men were also significantly decreased compared with healthy controls at the tibia: Ct thickness (ThK) 859+/- 260 vs. 1251+/-404mum (p=0.002); Ct vBMD 783.5±102 vs. 853.6± 56.2 mgHA/cm$^3$ (p=0.03); Ct area 90.3 ± 36.3 vs. 140.8 ± 32.5 mm$^2$ (p<0,001). Tibial CtThK had a positive significant correlation with Tb vBMD (r=0.62; p<0.001), Tb number (r=0.64; p<0.001) and a negative correlation with Tb separation (r=-0.55; p<0.001). In conclusion, this study shows an important impairment of trabecular microstructure in CKD 5D patients in addition to important alterations in cortical parameters with good correlations between them. Further longitudinal studies should be performed to validate HR-pQCT as a useull tool for predicting the fracture risk in CKD patients.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2931

**Diagnostic Usefulness of Bone Mineral Density in Predicting Vertebral Fracture and Abdominal Aortic Calcification in CKD Stage 5D Patients** Soichiro Iimori,[1] Sei Sasaki,[2] Yusuke Tsukamoto.[1] *[1]Department of Nephrology, Shuwa General Hospital, Kasukabe-shi, Saitama, Japan; [2]Department of Nephrology, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan.*

[Background] We previously reported that bone mineral sensity (BMD) was useful in predicting symptomatic any fracture (ASN 2009, abstract No. SA-PO2814). Since many cases of asymptomatic vertebral fracture (VF) co-existed, we analyzed usefulness of BMD by DEXA on VF and also examined the relationship with abdominal aortic calcification (AAC).

[Methods] Hemodialyzed patients (n=485) were enrolled from April/2003 to March/2008. Annual lateral abdominal X-ray was utilized to diagnose VF and AAC. Laboratory data was chosen from immediate previous examination before the X-ray showed VF or AAC (non-VF case), otherwise the first data.

[Results] 29 cases of VF and 277 cases of AAC were recorded. (1) Between VF and non-VF there was no difference in diabetes prevalence, dialysis vintage, hemoglobin, calcium, phosphorus nor intact PTH, but was different in female (<0.01), younger (p<0.001), lower BMI (p<0.01) and lower serum albumin (p<0.001). Among BMD measurements, 1/3 distal radius (1/3R), lateral lumbar spine (LS), femoral neck (FN) and femoral trochanter (FT) showed significant differences between the two groups (p<0.01). (2) ROC analysis on predicting VF, AUC was significant in FN (0.83), FT (0.78), 1/3R (0.72) and LS (0.67). When this result was stratified by gender, AUCs increased at FN (0.9), FT (0.83) and 1/3R (0.75) in male but decreased in female (FN: 0.73, FT: 0.70, 1/3R: 0.68). (3) Logistic regression analysis revealed lower BMD T-score at 1/3R (OR 0.63), LS (OR 0.7) and FN (OR 0.26) were significant predictor of VF (p<0.01). (4) Lower BMD T-score at 1/3R

(OR 0.87), LS (OR 0.80) and FN (OR 0.68) were significant predictor of AAC ($p<0.01$), and the presence of VF also predicted AAC (OR 6.04, $p<0.05$). (adjusted by age, gender, HD vintage and diabetes)

[Conclusions] BMD at femoral neck (t-score≤-2.4) was the best useful predictor of fracture not only in symptomatic any fracture but also in asymptomatic VF. This study suggested that loosing bone mineral caused vascular calcification in CKD stage 5D.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2932

**Comparison of Changes in DXA and Peripheral Quantitative Computed Tomography (pQCT) Measures of Bone Mineral Density (BMD) Following Renal Transplantation (RTxp)** Mary B. Leonard,[1] Hesham Shaban,[2] Babette Zemel,[1] Debbie Foerster,[1] Simin Goral,[2] Felix Wehrli.[2] *[1]Children's Hospital of Philadelphia; [2]University of Pennsylvania, .*

The structural basis of bone loss after RTxp has not been established. QCT provides discrete measures of trabecular and cortical volumetric BMD (vBMD, $g/cm^3$) while DXA measures areal BMD (aBMD, $g/cm^2$) of superimposed cortical and trabecular bone. QCT and DXA were compared at RTxp and 6 months later in 29 subjects (age 41±11 yr). Tibia QCT measures included trabecular vBMD in the metaphysis and cortical vBMD and thickness in the diaphysis. DXA aBMD was measured in the AP and lateral spine and total hip. Race, sex, and age-specific Z-scores were generated using reference data in 540 controls. Trabecular and cortical vBMD, and lateral spine and hip aBMD Z-scores decreased significantly.

| Z-Scores | Baseline | 6 Months | p |
|---|---|---|---|
| pQCT | | | |
| Trabecular vBMD | -0.63 ± 1.02 | -0.78 ± 1.02 | 0.0001 |
| Cortical vBMD | 0.14 ± 1.70 | -0.04 ± 1.54 | < 0.01 |
| Cortical Thickness | -0.72 ± 1.38 | -0.73 ± 1.45 | 0.70 |
| DXA | | | |
| AP Spine aBMD | -0.27 ± 1.42 | -0.44 ± 1.27 | 0.26 |
| Lateral Spine aBMD | -0.07 ± 1.28 | -0.40 ± 1.39 | 0.001 |
| Total Hip aBMD | -0.80 ± 0.96 | -0.91 ± 0.95 | 0.04 |

At baseline the significant correlations between QCT and DXA measures were: trabecular vBMD with AP spine ($r=0.46$; $p<0.01$), lateral spine ($r=0.50$, $p<0.01$) and hip aBMD ($r=0.67$, $p<0.0001$); cortical vBMD with AP spine aBMD ($r=0.51$; $p < 0.01$); and cortical thickness with AP spine ($r=0.58$, $p<0.001$), lateral spine ($r=0.40$, $p=0.04$) and hip aBMD ($r=0.56$, $p<0.001$). Correlations at 6 months were similar. Changes in trabecular vBMD were associated with changes in hip aBMD ($r=0.46$, $p<0.02$) but not with changes in AP or lateral spine aBMD. Changes in cortical vBMD and thickness were not associated with changes in DXA aBMD. These data demonstrated good correlations at each time point between QCT and DXA BMD. Total hip aBMD showed the strongest association with trabecular vBMD. Moreover, only total hip aBMD demonstrated good agreement with trabecular vBMD for changes over time.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2933

**International Assessment of TMV Classification of Bone Biopsy in ESKD** Stuart M. Sprague,[1] Hongyan Du,[1] Thomas L. Manley,[2] Aluizio B. Carvalho,[3] Patrick C. D'Haese,[4] Tilman B. Drueke,[5] Manuel A. Ferreira,[6] Vanda Jorgetti,[7] Sharon M. Moe,[8] Hartmut H. Malluche,[9] Ezequiel R. Bellorin-Font.[10] *[1]NorthShore Univ HealthSystem, Evanston, IL; [2]NKF, NY, NY; [3]Federal Univ of São Paulo, São Paulo, Brazil; [4]Univ of Antwerp, Antwerp, Belgium; [5]Hôpital Necker, Paris, France; [6]Hospital Curry Cabral, Lisbon, Portugal; [7]Univ of São Paulo School of Medicine, São Paulo, Brazil; [8]Indiana Univ School of Medicine, Indianapolis, IN; [9]Univ of Kentucky Medical Center, Lexington, KY; [10]Hospital Universitario de Caracas, Caracas, Venezuela.*

To determine whether serum biomarkers could predict bone disease, an international, multi-center, cross-sectional, retrospective analysis of the correlation between serum biomarkers and histologic bone disease was performed. Subjects (n=647) had a bone biopsy within the previous 10 years and blood obtained at the time of the biopsy; stored continuously at ≤ -20°C. PTH, intact (i) and whole (w), bone-specific alkaline phosphatase (BSAP), and procollagen type I intact N-terminal propeptide (P1NP) were measured in a central laboratory. Bone histomorphometery was classified using the KDIGO TMV system based on bone volume/tissue volume (BV/TV), mineralization lag time (MLT), osteoid thickness (Oth), and bone formation rate (BFR/BS). Demographic data, biochemistries (including original iPTH [OiPTH]) and treatment information at the time of the biopsy were collected. All 3 PTH assays were highly correlated (iPTH vs wPTH, $r=0.926$; iPTH vs OiPTH, $r= 0.629$; wPTH vs OiPTH, $r=0.670$; $p < 0.001$). Bone biopsy were classified by Mineralization (M), Turnover (T), and Volume (V). 55% of the biopsies demonstrated abnormal mineralization; 25% with abnormal mineralization, low turnover, and low volume; 17% with high turnover and 7% with normal bone. A weak correlation was observed between TMV score and BSAP ($r=0.333$, $p < 0.0001$), whereas no association between TMV score and other biochemical parameters. TMV classification of bone as described by KDIGO appears to be a valid means of classifying bone lesions; however, the biomarkers assessed in this study could not discriminate between various bone lesions.

## SA-PO2934

**Vertebral Bone Mineral Density Is Associated with Histomorphometric Bone Structure Parameters but Not with Serum Bone Markers in Hemodialysis Patients** Graziella M. Leme,[1] Ricardo Carneiro,[2] Rosa Ma Moyses,[3] Vanda Jorgetti,[3] Raul D. Santos Filho,[2] Carlos Eduardo Rochitte,[2] Maria Eugenia F. Canziani,[1] Aluizio B. Carvalho.[1] *[1]Nephrology, Federal University of São Paulo, São Paulo, São Paulo, Brazil; [2]Heart Institute (INCOR), University of São Paulo, São Paulo, São Paulo, Brazil; [3]Nephrology, University of São Paulo, São Paulo, São Paulo, Brazil.*

**Introduction**: Renal osteodystrophy (ROD) is a common feature in hemodialysis (HD) patients. ROD is frequently accompanied by low bone mass which can be assessed by vertebral computed tomography (vCT). The aim of this study was to evaluate the relationship between vertebral bone mineral density (BMD) assessed by vCT with serum bone markers and bone biopsy in HD patients.

**Methods:**One hundred patients (48.513 ys; 65% male; 57% white; mean length on HD: 31±24.8 mo) were evaluated. They underwent vCT, undecalcified bone biopsy and serum bone markers. Vertebral BMD was obtained at the trabecular bone of the middle section of one thoracic vertebra at the level of aortic arch, expressing in Housefield Units (HU). Transiliac bone biopsy was analyzed by histomorphometry (Osteomeasure®).

**Results:** Intact-PTH was 359.3±319.8pg/mL, osteoprotegerin 172.3±70.3pg/mL, deoxypyridinoline (DPD) 108.9±142.4nmol/mL, bone-specific alkaline phosphatase (BAP) 29.4±29.4U/L and 25OHvitamin D 31.8±15.5ng/dL. Bone volume (BVTV) was 17.4±6.4%, trabecular separation (Tb.SP) 602±238µ, trabecular thickness (Tb.Th) 113.2±19.6µ and trabecular number (Tb.N) 1.5±0.72/mm.

Correlations of vertebral BMD with serum bone markers and histomorphometric bone structure parameters

| | r | p |
|---|---|---|
| intact-PTH | 0.13 | 0.23 |
| OPG | - 0.13 | 0.23 |
| DPD | 0.21 | 0.46 |
| BAP | 0.06 | 0.58 |
| 25OHD | - 0.15 | 0.89 |
| BVTV | 0.41 | <0.001 |
| Tb.Sp | - 0.35 | 0.001 |
| Tb.Th | 0.34 | 0.001 |
| Tb.N | 0.31 | 0.004 |

**Conclusions**: vCT is a useful tool for the evaluation of bone structure in HD patients. However, it does not give any information regarding bone metabolism in that population.

Disclosure of Financial Relationships: nothing to disclose

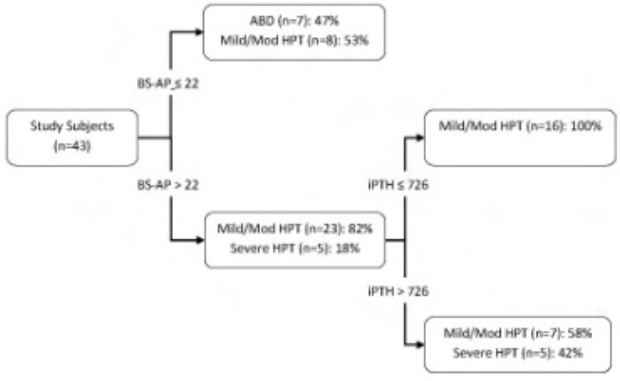
## SA-PO2935

**Determining the Optimal Predictor of Bone Histology in African-American (AA) Hemodialysis (HD) Subjects: A Classification and Regression Tree (CART) Analysis** Carol L. Moore, Beth Adams, Jerry Yee. *Nephrology/ Hypertension, Henry Ford Hospital, Detroit, MI.*

**Background:** Bone biopsy is the gold standard for determining bone histology. Non-invasive measures of bone activity include iPTH, CAP, CIP, total alkaline phosphatase (T-AP) and bone-specific alkaline phosphatase (BS-AP). We conducted CART analysis to determine which is the best predictor for classification of biopsy findings.

**Methods:** Bone biopsies were obtained in stable AA HD subjects. Lab markers for CKD-MBD were collected at time of biopsy. CART analysis determined the strongest predictors of biopsy findings and classified subjects based on the cutoff points found by the analysis.

**Results:** Pts (n 43) had an average age of 53.7 (11.6) yrs, dialysis vintage of 40.4 (24.5) mos, 30% with diabetes and 51% male. Biopsy results were classified as either adynamic bone disease (16%), mild/moderate (72%) and severe (12%) hyperparathyroidism (HPT). At the time of biopsy, mean iPTH was 225, 566, and 975 pg/mL ($p=0.006$), mean CAP was 125, 321, 534 pg/mL ($p=0.009$), mean CIP was 101, 245, 442 pg/mL ($p=0.010$), mean total alkaline phosphatase (T-AP) was 75, 150, 246 IU/L($p=0.001$) and mean bone-specific alkaline phosphatase (BS-AP) was 16, 34, 64 ng/mL ($p<0.0001$). The strongest predictor of biopsy findings was BS-AP. When BS-AP was > 22, the iPTH was useful in further classifying biopsy findings. With BS-AP > 22 and iPTH ≤ 726, 100% of subjects had mild/moderate HPT.



**Conclusion:** These results indicate that BS-AP, not iPTH, was the best predictor of biopsy findings with an optimal cut at 22. iPTH was able to further classify biopsy findings in those with a BS-AP > 22. No subjects with adynamic bone disease were found when BS-AP was >22. In those with BS-AP >22 and iPTH ≤ 726, all had mild/moderate HPT. BS-AP is an inexpensive, readily available assay that can assist clinicians in guiding therapy for CKD-MBD.

## SA-PO2936

**Paricalcitol Reduces Bone Alkaline Phosphatase (BAP) in Patients with Diabetic Nephropathy: Results from the VITAL Study** Daniel W. Coyne,[1] Dennis L. Andress,[2] Michael Amdahl,[2] Utpaul Audhya,[2] Eberhard Ritz,[3] Dick De Zeeuw.[4] *[1]Washington University; [2]Abbott Laboratories; [3]University of Heidelberg; [4]University Medical Center Groningen.*

**Introduction:** Observational studies in CKD patients show elevated levels of serum alkaline phosphatase and PTH predict all-cause mortality and elevated BAP predicts cardiovascular (CV) outcomes independent of PTH levels. Because treatment with vitamin D receptor activators to lower PTH associates with improved survival in CKD, we examined BAP after paricalcitol therapy to determine if the expected BAP reduction is primarily PTH-independent.

**Methods:** VITAL was a randomized, double-blind clinical trial that enrolled 281 subjects with type 2 diabetic nephropathy (DN) and iPTH 35 to 500 pg/mL. Subjects were randomized to placebo (n=93), 1 µg (n=93) or 2 µg paricalcitol (n=95) daily for 24 weeks to assess change in urinary albumin. Serum PTH and BAP were measured monthly and again 60 days after drug withdrawal.

**Results:** The mean baseline BAP and PTH were 25 U/L and 98 pg/mL and were evenly distributed among the groups. 52% of subjects had a PTH <70 pg/ml. Analyses of change from baseline in BAP and an evaluation of PTH dependence are shown in Table 1. Sixty days after stopping paricalcitol mean BAP levels remained significantly lower than baseline in the 1 and 2 µg groups (15% and 10%, P< 0.001 and P=0.003 vs. placebo) while mean PTH had risen to 28% and 18% above baseline levels (P=NS vs. placebo in both groups).

**Conclusion:** Paricalcitol has a direct effect on BAP reduction in DN CKD patients by PTH-independent mechanisms. Mean BAP reduction was sustained for as long as 60 days after stopping therapy despite the return of PTH levels to baseline. Future studies should examine a potential role for paricalcitol to reduce CV outcomes by a BAP-dependent mechanism.

Table 1. Analyses of Change from Baseline in BAP and an Evaluation of PTH Dependence

| | N | Mean % Change in BAP from baseline | P value (vs. Placebo) | Change in iPTH and BAP Correlation Coefficient* | P value |
|---|---|---|---|---|---|
| Placebo | 75 | -3% | | 0.17 | 0.154 |
| Paricalcitol 1 µg | 75 | -26% | P<0.001 | 0.27 | 0.017 |
| Paricalcitol 2 µg | 73 | -27% | P<0.001 | 0.45 | <0.001 |
| Subjects with baseline PTH <70 pg/mL | | | | | |
| Placebo | 41 | 2% | | 0.16 | 0.379 |
| Paricalcitol 1 µg | 36 | -20% | P<0.001 | -0.14 | 0.428 |
| Paricalcitol 2 µg | 39 | -26% | P<0.001 | 0.07 | 0.672 |
| Subjects with baseline PTH ≥70 pg/mL | | | | | |
| Placebo | 34 | -8% | | 0.26 | 0.141 |
| Paricalcitol 1 µg | 39 | -33% | P<0.001 | 0.22 | 0.178 |
| Paricalcitol 2 µg | 34 | -34% | P<0.001 | 0.36 | 0.035 |

## SA-PO2937

**Racial Differences in the Clinical Use of Cinacalcet among Hemodialysis Patients** Britt B. Newsome,[1] Craig Solid,[3] David A. Zaun,[3] Ryan D. Kilpatrick,[2] Jiannong Liu,[3] Kimberly M. Nieman,[3] Wendy L. St. Peter.[3,4] *[1]Denver Nephrologists, P.C., Denver, CO; [2]Amgen, Inc., Thousand Oaks; [3]Chronic Disease Research Group, MMRF, Minneapolis, MN; [4]Univ. of Minnesota.*

**Background:** African American (AA) patients with End Stage Renal Disease (ESRD) on dialysis are known to have more severe secondary hyperparathyroidism (SHPT) as reflected by higher levels of parathyroid hormone as well as requirements of higher doses of activated vitamin D. Despite these prior observations, racial differences in the clinical use of cinacalcet in the control of SHPT have not been examined. **Methods:** Data for this retrospective cohort study were from DaVita Inc. for 45,589 prevalent hemodialysis patients in August 2004 linked to Centers for Medicare and Medicaid Services data with follow-up through July 2007. Patients were included who had Medicare as primary payer and used IV vitamin D in baseline period (Aug. 1, 2004-Oct. 31, 2004). Patients with modality change, kidney transplant before Nov. 1, 2004 were excluded. Patients were grouped by parathyroid hormone (PTH) level <150, ≥150-≤300, >300-≤600, >600 pg/mL at baseline. Adjusted Cox regression was used to predict time to cinacalcet initiation, titration and discontinuation. **Results:** Of the 25,250 patients included in this analysis, 9474 (37.5%) were AA, 13632 (54.0%) were white (W) and 2144 (8.5%) were other race. Among cinacalcet users, 49.8% were AA. Among AA, 40.3% were prescribed cinacalcet compared to 24.4% of C and 24.7% of individuals classified as other race. Within each PTH strata, a greater percentage of AA, compared to the other race groups, was prescribed cinacalcet, and AA were prescribed higher doses. After covariate adjustment, AA, compared to W, were more like to be initiated on cinacalcet [AA:W hazard ratio (HR) 1.17; 95% confidence interval (CI) 1.11, 1.23] and less likely to be discontinued (AA:W HR 0.78; 95% CI 0.70, 0.85). There was no significant difference between the two race groups with respect to up titration of cinacalcet (AA:W HR 1.08; 95% CI 0.99, 1.18). **Conclusion:** AA patients more commonly are prescribed cinacalcet and at higher initial doses than other race groups in the management of SHPT.

## SA-PO2938

**Parathyroid Hormone (PTH) and Phosphorus (P) Trends after Cinacalcet Initiation in Hemodialysis (HD) Patients** Ryan D. Kilpatrick,[1] David A. Zaun,[2] Craig Solid,[2] Britt B. Newsome,[3] Jiannong Liu,[2] Kimberly M. Nieman,[2] Wendy L. St. Peter.[2,4] *[1]Amgen, Inc., Thousand Oaks, CA; [2]Chronic Disease Research Group, MMRF, Minneapolis, MN; [3]Denver Nephrologists, P.C., Denver, CO; [4]U of MN.*

**Background:** Cinacalcet response, i.e. change in secondary hyperparathyroidism (SHPT) lab values, has not been well characterized in real-world settings. Two response indicators may be disease severity at cinacalcet initiation and need for upward dose titration. We explored descriptive trends in PTH and P over 12 mos following cinacalcet initiation by baseline PTH category to describe real-world response. **Methods:** Data were from 45,589 prevalent DaVita Inc. HD patients (pts) in facilities on 8/2004. Pts had Medicare as primary payer and used IV vitamin D during baseline (8/04-10/04). 7,674 pts were identified who initiated cinacalcet between 11/04-8/07. To determine trends, Cinacalcet users remaining on therapy for ≥12 mos (n=4,177) were examined. Cohort was separated into pts who remained on their initial dose for first 12 mos (n= 2,196) and pts who had ≥1 upward dose titration (n = 1,981). Monthly median PTH and mean P values pre-initiation and in each mo. for 12 mos were calculated and stratified by baseline PTH (≥150-≤300, >300-≤600, >600 pg/mL). **Results:** Reductions in absolute PTH and P were larger for pts initiating at PTH levels >600 pg/mL. Pts receiving dose titration(s) had higher pre-initiation PTH and P levels and smaller reductions in PTH over 12 mo. period as compared to no-titrate pts. Overall, PTH and P reductions were sustained over 12 mos and for higher PTH initiators, continued decline in PTH and P was observed, possibly due to addition or adjustment of other therapies. **Conclusion:** Despite larger reductions in PTH and P for pts initiating in PTH >600 group, after 12 mos, PTH and P values remained higher than in pts initiating at lower PTH.

**Persistent Secondary Hyperparathyroidism: The Relationship between FGF23 and Cinacalcet** Magdalene M. Assimon,[1] Roy Mathew,[2] Darius Mason.[1] *[1]Albany College of Pharmacy & Health Sciences, Albany, NY; [2]Stratton VAMC, Albany, NY.*

Fibroblast growth factor 23 (FGF23) regulates phosphate excretion, vitamin D metabolism and directly reduces parathyroid hormone (PTH) secretion. PTH levels may remain elevated in dialysis patients despite elevated FGF23 levels and use of therapy to control secondary hyperparathyroidism (SHPT). Limited data exists regarding the association between cinacalcet and FGF23 in persistent SHPT. The aim of this study was to explore the association between cinacalcet use, FGF23 and SHPT in hemodialysis (HD) patients.

**Methods:** Adults receiving HD for ≥3 months were enrolled in this cross-sectional study. Patient demographics, laboratory values and medication lists were obtained. Pre-dialysis levels of intact FGF23 were measured by ELISA. Stepwise linear regression was used to identify factors associated with FGF23.

**Results:** Subjects' (n=118, 57.6% male, 46.6% diabetic etiology) mean age = 63.5±16.3 years, HD vintage = 3.3±2.9 years and log FGF23 = 2.50±0.36 pg/ml. Log FGF23 levels positively correlated with calcium [r=0.25, p=0.0063], phosphorus [r=0.56, p<0.0001], PTH [r=0.28, p=0.0022] and HD vintage [r=0.26, p=0.0026] and negatively correlated with age [r=-0.27, p=0.0006]. Log FGF23 levels were higher in cinacalcet users (n=38, mean dose = 51.5±41.3 mg/day, mean length of use = 6.9±6.3 months) compared to cinacalcet non-users (n=80) [2.62±0.41 pg/ml vs. 2.44±0.31 pg/ml, p=0.0185]. Use of cinacalcet [β=0.14, p=0.0052], calcium [β=0.19, p<0.0001], phosphorus [β=0.11, p<0.0001] and dialysis vintage [β=0.27, p=0.0013] were associated with log FGF23. Patients taking cinacalcet had higher median (IQR) PTH levels [431.7 (321.8–669) pg/ml vs. 301.7 (173.4-368.6) pg/ml, p=0.006] and received greater doses of IV calcitriol [3.6±3.6 mcg/week vs. 2.0±2.1 mcg/week, p=0.0185] compared to non-cinacalcet users.

**Conclusions:** Log FGF23 was positively associated with cinacalcet use, calcium, phosphorus and HD vintage. Subjects taking cinacalcet had worse SHPT and required larger doses of calcitriol, despite a 6.9 month mean duration of cinacalcet therapy. Cinacalcet use may be a surrogate marker for refractory SHPT resulting in the observed association with log FGF23.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2940**

**Comparison of Lanthanum Carbonate with Calcium Carbonate on Biomarkers of Bone Turnover in Hemodialysis Patients: A Cross-Over Study** Tatsunori Toida,[1] Keiichi Fukudome,[1] Shouichi Fujimoto,[2] Kazuhiro Yamada,[2] Susumu Chiyotanda,[1] Kazuo Kitamura.[2] *[1]Chiyoda Hospital, Hyuga, Miyazaki, Japan; [2]Dialysis Division, University of Miyazaki Hospital, Miyazaki, Japan.*

Lanthanum carbonate (LC) is a new non-calcium-containing phosphate binder. However, there are few comparative studies of the efficacy on bone turnover between LC and calcium carbonate (CaC). The aim of this cross-over study was to compare the effects of these drugs on biomarkers of bone turnover in hemodialysis (HD) patients.Fifty patients undergoing maintenance HD with bicarbonate dialysate containing 2.5 mEq/L of calcium were investigated. Following washout (2 weeks), these patients were randomized (1:1) to receive LC or CaC for 3 months. Thereafter, patients underwent a second washout (2 weeks) and switched to the alternative binder for 3 months. In addition of Ca, P and intact PTH, several bone turnover markers were measured using ELISA kits. Use of other phosphate binders and cinacalcet were prohibited during the study periods.Clinical characteristics and laboratory data were not different between group LC and CaC at the start of the study. Serum P levels were equally decreased in both groups (0M vs 3M; LC, 7.1+/-1.7 vs 5.5+/-1.3, p < 0.01; CaC, 7.1+/-1.8 vs 5.6+/-1.2 mg/dL, p < 0.01), but Ca levels were clearly increased in group CaC (0M vs 3M; 8.7+/-0.8 vs 9.1+/-0.7mg/dL, p < 0.01) 3 months after the treatment. The concentrations of intact PTH at pre- and post-treatment were not different between both groups, but the reduction with CaC was greater than with LC (CaC vs LC, -73.9+/-80.2 vs -12.9+/-78.7 pg/mL, p < 0.001). The levels of serum BAP and TRAP5b were significantly elevated in group LC (0M vs 3M; BAP, 23+/-8.9 vs 35+/-20 U/L, p < 0.001; TRAP5b, 768+/-304 vs 992+/-457 mU/dL, p < 0.01 ), but not in group CaC. In both groups, serum FGF23 levels were significantly decreased 3 months after the treatment, while osteoprotegerin levels did not change during the study periods. In conclusion, LC effectively reduced serum P levels in HD patient and raised the bone turnover without the change of PTH levels. LC may have advantages in the treatment of CKD-MBD in comparison with CaC.

**SA-PO2941**

**The Effects of Magnesium Carbonate/Calcium Acetate on Experimental CKD-MBD** Guaraciaba O. Ferrari,[1] Juliana C. Ferreira,[1] Katia R. Neves,[1] Cássia M. Puci,[1] Raquel T. Cavallari,[1] Wagner V. Dominguez,[1] Fabiana G. Graciolli,[1] Luciene M. dos Reis,[1] Jutta Passlick-Deetjen,[2] Vanda Jorgetti,[1] Rosa Ma Moyses.[1] *[1]Nephrology, Universidade de Sao Paulo, Brazil; [2]Fresenius Medical Care, Germany.*

Adequate phosphate (P) control is still a challenge in CKD-MBD. In this study, we evaluated the effects of a new P binder on parathyroids, bone and vascular calcification (VC). Rats were fed normal chow or an adenine(AD) diet for 4 wks, followed by 4 weeks of therapy with Ca (calcium acetate); CaMg [Ca/magnesium carbonate (Osvaren®)]; or Untreated. After that, we performed biochemical and bone histomorphometric analyses, as well as von Kossa staining of aortic sections and observed that P binders decreased fractional excretion of P (FeP) and FGF23. In the CaMg group, Mg was slightly elevated, whereas iPTH and FGF23 were lower than in the other AD-groups. P binders therapy was able to decrease bone resorption, but with a trend to an increase in mineralization defect. Despite a lower PTH, CaMg group presented an increase in parathyroid PCNA positive cells. VC was less commonly observed in CaMg than in Ca-treated rats (1/9 vs. 3/10).

| | Control Diet | Untreated | CaMg | Ca |
|---|---|---|---|---|
| Ionized calcium(mmol/L) | 1.15±0.08[b] | 1.07±0.07 | 1.07±0.11 | 1.12±0.10 |
| iPTH(pg/ml) | 125±79[bc] | 630±354[c] | 362±122 | 688±778 |
| Mg(mg/dL) | 1.8±0.1[abc] | 2.4±0.4[ac] | 3.2±0.6 | 2.6±0.4[c] |
| P(mg/dL) | 5.6±0.9[abc] | 7.4±0.7 | 7.6±1.2 | 7.2±1.7 |
| FeP(%) | 9.1±4.8[abc] | 21.2±10.9[ac] | 2.5±1.5 | 3.7±4.0 |
| PCNA(cells/mm2) | 2.4±4.1[bc] | 31.4±35.4[ac] | 201.2±137.0 | 4.0±9.8 |
| Bone volume(%) | 27.4±5.0 | 31.1±6.7 | 30.3±9.3 | 26.8±11.7 |
| Osteoid Thickness (μm) | 1.9±0.4[ac] | 2.6±1.3[a] | 5.3±2.8 | 7.3±2.4 |
| Bone Formation Rate(μm3/μm2/d) | 0.04±0.04 | 0.11±0.08 | 0.05±0.03 | 0.05±0.03 |
| Mineralization Lag Time(d) | 7±6[a] | 36±57 | 44±26 | 59±47 |

Mean ± SD; P< 0.05 = a vs Ca; b vs untreated; c vs CaMg.

In conclusion, in this model of CKD-MBD, CaMg was able to decrease PTH, FGF23 and VC prevalence compared to Ca. The mechanism that underlies the Mg effects on parathyroid proliferation should be elucidated in further studies.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2942**

**Comparison of Oral and Intravenous Alphacalcidol in Chronic Hemodialysis Patients** Myriam Lessard, Annie-Claire Nadeau-Fredette, Robert Bell, Jean-Philippe Lafrance, Vincent Pichette, Michel Vallee. *Nephrology, Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

BACKGROUND: It is well known that activated vitamin D is the mainstay of treatment for secondary hyperparathyroidism in chronic hemodialysis patients. However, the optimal route of administration of activated vitamin D is still debated.

OBJECTIVES: The aims of our study were to compare efficacy and side effects of intravenous (IV) versus oral administration of alfacalcidol in hemodialysis. Our secondary objective was to determine if oral administration has a cost-effectiveness advantage compare to IV administration.

METHODS: 88 chronic hemodialysis patients receiving IV alfacalcidol 3 times a week for at least 3 months were included in the study. All were switched to the same dose of oral alfacalcidol administered 3 times a week in the hemodialysis unit. Alfacalcidol dose was then adjusted according to K/DOQI recommendations. Annual costs and nursing time were calculated for both oral and IV routes of administration. Parameters at baseline and 3 months after the switch were compared using a Student's paired t-test.

RESULTS: Mean patient age was 64 years old and 43% were males. Three months after switching from IV to oral alfacalcidol, PTH levels significantly decreased from 754 to 538 pg/mL (p<0.001), total calcium levels increased from 9.36 to 9.60 mg/dL (p=0.001), whereas phosphorus levels remained stable (from 4.61 to 4.86 mg/dL, p=0.19). Compared to IV, oral administration was associated with an annual cost reduction of 187 000 $CAN and an annual nursing time reduction of 25 days.

CONCLUSION: Our study suggests that switching from IV to oral administration of alfacalcidol during hemodialysis sessions may lead to better secondary hyperparathyroidism control. Finally, oral administration of alfacalcidol has a major cost advantage and reduces the nursing time required.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2943

**Effect of Cinacalcet on the Change of Bone Mineral Density and Bone Markers in Hemodialysis Patients with Secondary Hyperparathyroidism** Yuki Tsuruta,[#1] Kazuhiro Okano,[#1] Naoki Kimata,[#2] Takashi Akiba,[#2] Kosaku Nitta.[#1] *[1]Department of Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan; [2]Departmente of Blood Purification, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Cinacalcet markedly reduces serum intact parathyroid hormone (iPTH) in hemodialysis (HD) patients with secondary hyperparathyroidism (SHP). Previous studies reported that HD patients have higher risk for hip fracture and higher rate of 1 year mortality after the fracture compared with general population. Parathyroidectomy reduces serum iPTH levels and increases bone mineral density (BMD) in HD patients. However, there is few reports about effect of cinacalcet on BMD and bone markers in HD patients.

Patient and method: We performed a 1 year cohort study included 21 HD patients who had serum iPTH more than 300pg/ml under conventional therapies included vitamin D. The patients with or without cinacalcet treatment are defined as cinacalcet (10 patients) and control (11patients) group, respectively. BMD of femoral neck and alkaline phosphatase (ALP) were measured at baseline and after 1 year treatment.

Result: There is significant reduction of serum iPTH and ALP levels for cinacalcet group, not for control group. BMD significantly increased 6.4% per year for cinacalcet group and decreased 6.2% per year for control group (p=0.0001). The changes of serum ALP levels during observation has negative correlation with the changes of BMD ($R^2$=0.629, p<0.0001).

Bone mineral density and bone markers

| | | Cinacalcet(n=10) | | | Control(n=11) | |
|---|---|---|---|---|---|---|
| | Before | After | p value | Before | After | p value |
| BMD | 0.573±0.125 | 0.604±0.109 | 0.0082 | 0.644±0.150 | 0.606±0.155 | 0.0011 |
| iPTH | 687.8±268.4 | 163.8±109.0 | <0.0001 | 316.7±106.2 | 334.4±163.8 | NS |
| ALP | 657.7±344.4 | 297.3±105.3 | 0.0096 | 326.0±126.5 | 361.4±173.5 | NS |

Conclusion: One year treatment of cinacalcet for HD patients with SHP reduced serum iPTH levels markedly and increased BMD of femoral neck. Furthermore, our study suggests that dynamics of ALP levels are a useful predictor for change of BMD in HD population.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2944

**Calcium (Ca) and Phosphate (P) Changes in Diabetics Receiving Moderate to High Doses of Paricalcitol: Results from the VITAL Study** Daniel W. Coyne,[1] Dennis L. Andress,[2] Utpaul Audhya,[2] Michael Amdahl,[2] Eberhard Ritz,[3] Dick De Zeeuw.[4] *[1]Washington University; [2]Abbott; [3]University of Heidelberg; [4]University Medical Center Groningen.*

**Introduction:** Increased serum P and Ca associate with increased mortality in CKD patients. CKD-related low calcitriol levels associate with poor outcomes, while use of vitamin D receptor activators (VDRA) associates with improved outcomes. Calcitriol therapy carries risks of elevated P and Ca. This analysis examined subjects receiving a selective VDRA, paricalcitol, for albuminuria reduction, to determine risk of elevated P and Ca.

**Methods:** VITAL was a randomized trial enrolling 281 type 2 diabetic subjects with CKD corrected serum Ca level <9.8 mg/dL and iPTH 35 to 500 pg/mL. Subjects received placebo (pbo, n=93), paricalcitol 1 µg (n=93), or paricalcitol 2 µg (n=95) daily for 24 weeks. Dose reductions to TIW occurred if elevated calcium was confirmed or if PTH <15 pg/ml.

**Results:** 43% of subjects had PTH in the normal range at baseline: mean PTH in pbo, 1µg and 2 µg groups were 105.3±91.2 pg/mL, 97.4±77.2 pg/mL, and 90.9±65.1 pg/mL. PTH increased 23% in the pbo group and declined by 21 and 48% in the1 µg and 2 µg groups (p<0.001, both). Mean changes in P and Ca during treatment are shown in Table 1. Despite increases in Ca, only 1 subject in the 1 µg group and 3 subjects in the 2 µg group experienced hypercalcemia, versus 1 in pbo (P=NS). Dose reductions of paricalcitol occurred in 14 and 42% in the 1 µg and 2 µg groups, primarily for PTH suppression.

**Conclusions:** Paricalcitol resulted in significant but modest increases in Ca and few episodes of hypercalcemia despite meaningful reductions in PTH consistent with previous studies. The finding that urinary P excretion was unchanged despite potent PTH suppression with paricalcitol suggests intestinal P absorption may not be enhanced by this selective VDRA.

Table 1. Change from Baseline to Last On-Treatment Observation in Ca and P

| | Placebo Mean (SD) | Paricalcitol 1 µg Mean (SD) | Paricalcitol 1 µg p vs. placebo | Paricalcitol 2 µg Mean (SD) | Paricalcitol 2 µg p vs. placebo |

**Pharmacokinetics of Alendronate Sodium in End-Stage Renal Disease Patients** Methee Chanpitakkul, Amnart Chaiprasert. *Department of Medicine, Phramongkutklao Hospital, Bangkok, Thailand.*

Osteoporosis is a worldwide public health problem. Bisphosphonates (e.g. alendronate sodium) are widely used for the treatment of osteoporosis. Alendronate sodium is not recommended in patients with creatinine clearance less than 35 mL/min due to lack of experience in renal failure. Until now, pharmacokinetics of alendronate sodium in end-stage renal disease (ESRD) patients are unknown.

**Objective**

To study the pharmacokinetics of oral alendronate sodium in ESRD.

**Method**

ESRD patients treated with regular hemodialysis three times a week for at least three months with no residual urine were enrolled. Exclusion criteria were history of drug allergy to alendronate sodium, intact parathyroid hormone < 150 pg/mL. After fasting at least 10 hours, the day after hemodialysis, single oral alendronate sodium 70 mg was taken. The plasma samples were drawn at 0, 0.5, 1, 2, 3, 4, 6, 8, and 10 hours after medication and were analyzed for alendronate concentration by high performance liquid chromatography method.

**Results**

Seven ESRD patients were studied. All were male, mean±SD age 54.1±5.9 years. The baseline calcium, phosphate, albumin and intact parathyroid hormone were 9.36±0.95 mg/dL, 5.13±1.59 mg/dL, 4.36±0.33 g/dL and 228.4±66.1 pg/mL, respectively. Pharmacokinetics of alendronate sodium in ESRD patients were as following; maximal concentration ($C_{max}$) 80.3±51.7 ng/mL, time of $C_{max}$ ($T_{max}$) 0.89±0.32 hour, area under the curve ($AUC_{0-inf}$) 195.6±93.3 ngxh/mL and half-life 4.36±4.99 hours. Clearance of alendronate, non-renal and non-dialysis, divided by fractional of bioavailability was 469.2±287.0 L/h.

**Conclusion**

Pharmacokinetics of oral alendronate sodium in end-stage renal disease patients are different from studies of healthy subjects.

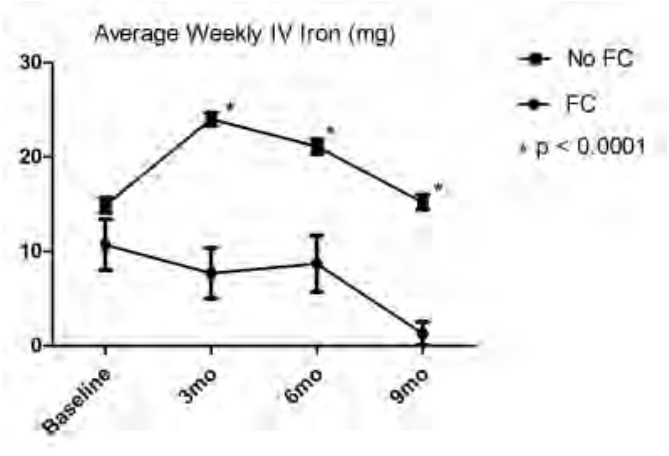
## SA-PO2946

**Prolonged Use of Ferric Citrate (FC) as a Phosphate Binder Reduces IV Iron Use in Pts with ESRD** Mohammed Sika,[1] Marvin V. Sinsakul,[2] Robert M. Niecestro,[3] Shou-Shan Chiang.[4] *[1]Vanderbilt University, Nashville, TN; [2]Edmund Lewis&Assoc, Chicago, IL; [3]Keryx Biopharmaceuticals; [4]Shin Kong Wu Ho-Su Memorial Hospital, Taiwan.*

FC is being evaluated as a phos binder in pts with ESRD. Studies have shown possible iron absorption with short-term use of FC. After completing a double-blind, placebo-controlled, dose-ranging study for 28 days, pts enrolled in an open-label extension study at a single center. Pts were started on 2-6gm of FC (500mg) used to maintain phos at 3.5-5.5mg/dL. IV iron and erythropoeitin stimulating agents(ESA) were continued based on protocol. Hct, Fe, ferritin, TSAT, average weekly IV iron and ESA dosages were recorded at baseline, 3, 6 and 9 mo. 28 pts (9M/19F, age 54±14yrs) received FC and followed for 306±85 days and were compared to 385 ESRD pts not on FC. The average dose of FC at 3,6,9 mo. was 4.8±1.4, 4.7±1.5, and 4.8±1.5 gm/d. Pts who received FC had a significant decrease in IV iron use compared to pts not receiving FC, while maintaining iron parameters and Hct (Figure,Table). Pts receiving FC tended to use less ESA compared to those that did not receive FC. We observed that long term use of FC as a phosphate binder not only controls phos, but may also maintain all iron parameters allowing for a decrease in IV iron and ESA use over time and this warrants further study.



FC vs. No FC

**Short Term Effect of 25-Hydroxy Vitamin D Supplementation in Hemodialysis-Patients** Jean-Christophe Szelag, Alejandra Lenz, Myriam Pastural, Carlos Cardozo, Nouredine Boumendjel, Ignace Mpio, Elias Abdullah, Walid Arkouche. *AURAL Villon, AURAL, Lyon, France.*

Vitamin D deficiency is involved in overall morbidity of ESRD patients. We studied the frequency of 25-hydroxyvitamin D deficiency and the effects of its correction in 148 HD-patients (58 women, 90 men, 61,4yr) for a period of 3 months

**Patients and methods:** Usual parameters of mineral metabolism was determined on monthly (total calcium, phosphorus) or quarterly (25-OHvitaminD (2+3), PTH) basis between winter and the end of last spring. Every treatment of interest (oral calcium, sevelamer hydrochloride, lanthanum carbonate, cinacalcet, calcitriol, and cholecalciferol) were listed during the study. 25-OHvitamin D deficiency (< 30 ng/mL) was treated with cholecalciferol (100000IU one or twice a month) or calcidiol (600 to 1000 IU/day). A supplementation was already proposed in 56 % of the patients before the study.

**Results:** The frequency of vitamin D deficiency at month 0 was 66,8% (99 patients) in spite of a supplementation in 49,4% of the cases. At month3, the institution or the intensification of the supplementation to 81 of these patients were associated with an increase of vitaminD levels (17,4+/-6,6 vs 32,3+/-14,9 ng/mL, p<0,0001, Wilcoxon rank test). Supplementation was associated with a slightly but significantly decrease of PTH level (423+/-322,9 *vs* 381,3+/-289,9 ng/L, p=0,0317). We observed a better control of serum phosphorus (1,58+/-0,5 vs 1,47+/-0,46 mmol/L, p=0,012) without any change on serum calcium (2,18+/-0,17 *vs* 2,18+/-0,16 mmol/L, p=0,76). There was no significant change of CRP ( 11,8+/-17,1 vs 8,9+/-9,8 mg/L, p=0,26) and serum albumine (38,9+/-3,6 vs 38,5+/-3,7 g/L, p=0,065). The only significant change in treatment was a reduction of alfacalcidiol dose and administration (58 to 53%). In patients without deficiency (49, supplementation 70%), 25-OHvitaminD, serum phosphorus and PTH remained stable.

**Conclusion:** This short term single center study confirms the high frequency of vitamin D deficiency in HD-patients. The supplementation with cholecalciferol or calcidiol allowed a decrease of PTH level, a better control of serum phosphorus with a reduction of calcitriol administration.

**Discovery of a Calcimimetic with Differential Effects on PTH and Calcitonin Secretion** Charles M. Henley III,[1] James R. Davis,[1] Sean Morony,[1] Wei Fan,[1] Monica Florio,[1] Banghua Sun,[1] Edward Shatzen,[1] William G. Richards,[1] Christopher Fotsch,[3] Jeff D. Reagan.[2] *[1]Metabolic Disorders, Amgen, Inc., Thousand Oaks, CA; [2]Metabolic Disorders, Amgen, Inc., South San Francisco, CA; [3]Medicinal Chemistry, Amgen, Inc., Thousand Oaks, CA.*

Calcimimetics are positive allosteric modulators of the calcium-sensing receptor (CaSR). Activation of the CaSR inhibits the secretion of parathyroid hormone (PTH), stimulates the secretion of calcitonin (CT) and decreases blood ionized calcium ($Ca^{2+}$). Cinacalcet, a second generation calcimimetic, is used therapeutically to reduce serum PTH, calcium, phosphate and calcium x phosphorous product in patients with secondary hyperparathyroidism on dialysis. The purpose of this research was to identify molecules that have divergent activities from current calcimimetic effects in uremic rats with partial ($1/6^{th}$) renal function. Towards this end, we developed a third generation calcimimetic and determined the molecular pharmacological properties of it using an operation model of allosteric modulation/agonism. We also measured compound effects on serum PTH, calcitonin and blood ionized $Ca^{2+}$ in 5/6 nephrectomized rats. We observed that the new molecule effectively reduced PTH levels without promoting CT secretion and thus had limited effects on $Ca^{2+}$ homeostasis in this uremic rodent model. These studies demonstrate the possibility of developing a calcimimetic with divergent activities on CT secretion. Whether these activities result from utility of different signaling pathways remains to be determined.

**Continuous Erythropoietin Receptor Activator (CERA) Ameliorates Sepsis-Induced TLR4 Pathway-Mediated Downregulation of AQP2 Expression and Acute Kidney Injury** Camila Eleuterio Rodrigues,[1] Talita R. Sanches,[1] Rildo A. Volpini,[1] Maria Heloisa M. Shimizu,[1] Patricia Semedo Kuriki,[3] Niels Olsen Saraiva Camara,[2, 3] Antonio C. Seguro,[1] Lucia Andrade.[1] *[1]Nephrology Department, University of São Paulo, São Paulo, SP, Brazil; [2]Immunology Department, University of São Paulo, São Paulo, SP, Brazil; [3]Nephrology Department, UNIFESP, São Paulo, SP, Brazil.*

During bacterial sepsis, TLR4 expression mediates interstitial leukocyte infiltration and tubular injury. TLR4 activation on tubular epithelial cells stimulates the NFkB pathway, leading to the production of cytokines that downregulate AQP2 in kidney medulla. In sepsis, erythropoietin (EPO) can be renoprotective, although the mechanism has yet to be elucidated. We used a cecal ligation and puncture (CLP) model to investigate the role that CERA, an EPO with a unique pharmacologic profile and long half-life, plays in sepsis-related AKI. Wistar rats were randomly divided into 3 groups: control (sham-operated); CLP; and CLP+CERA. CERA (5 µg/kg BW, i.p.) was administered 24 h before CLP. We measured creatinine clearance (Ccr), urinary volume (UV), MAP, serum Ht, and FENa. Immunoblotting for NFkB, TLR4, AQP2 and NKCC2 was performed in kidney tissue. Serum IL-2, IL-1b, IL-6, IFN-γ and TNF-α were measured by multiplex cytokine detection. Data are expressed as mean ± SEM.

| | Control (n = 5) | CLP (n = 7) | CLP+CERA (n = 7) |
|---|---|---|---|
| Ccr (mL/min)/100gBW | 0.73±0.05 | 0.32±0.10[a,b] | 0.70±0.07 |
| MAP (mmHg) | 112±2.5 | 111±11.2 | 115±8.3 |
| UV (mL/24h) | 11.9±5.3 | 4.6±1.5[b] | 16.3±3.3 |
| Ht (%) | 42±1.3 | 41±1.8 | 38±1.8 |
| FENa | 0.26±0.03 | 0.69±0.13[c,d] | 0.30±0.09 |
| NFκB | 100±0.0 | 158±4.8[a,b] | 110±10.0 |
| TLR4 | 100±0.0 | 170±7.9[c,d] | 120±14.7 |
| AQP2 | 96.8±2.6 | 36.7±4.2[e,f] | 101.3±3.0 |
| NKCC2 | 95.7±2.5 | 20.6±3.1[e,f] | 98.7±7.2 |

[a]p<0.01 vs. Control; [b]p<0.01 vs. CLP+CERA; [c]p<0.05 vs. Control; [d]p<0.05 vs. CLP+CERA; [e]p<0.001 vs. Control; [f]p<0.001 vs. CLP+CERA

Levels of all measured cytokines were lower in CLP+CERA rats than in CLP rats. CERA renoprotection is TLR4-dependent and is partly due to inhibition of the inflammatory response.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2950

**Amplification of Nrf2 Signaling by CDDO-Imidazolide Improves Outcomes in Ischemic Acute Kidney Injury in Mice** Manchang Liu,[1] Narsa Machireddy,[1] Thomas W. Kensler,[2] Michael B. Sporn,[3] Lorraine C. Racusen,[1] Sekhar P. Reddy,[1] Hamid Rabb.[1] *[1]Medicine, Environmental Health Sciences and Pathology, Johns Hopkins University, Baltimore, MD; [2]University of Pittsburgh, Pittsburgh, PA; [3]Dartmouth Medical School, Hanover, NH.*

Rationale: Acute kidney injury (AKI) caused by ischemia-reperfusion (IR) is a major clinical problem in both native and transplanted kidney. Oxidative stress induced by IR contributes to the pathogenesis of AKI. We have shown that genetic disruption of Nrf2 transcription factor enhances susceptibility to experimental ischemic AKI in mice (*Kidney Int*:76:277-85, 2009). We hypothesized that amplification of Nrf2 signaling with the synthetic compound CDDO-Imidazolide (CDDO-Im) would confer protection against AKI. Methods: CDDO-Im (30 µmol/kg bw) or vehicle was administered to mice by gavage at 24 h and 3 h prior to and at 24 h after undergoing 30 min bilateral kidney ischemia followed by reperfusion for 72 h. Serum creatinine (SCr) was measured at 0 h, 24 h, 48 h and 72 h post ischemia and the kidney was examined for histology and genes expression. Results: Mice treated with CDDO-Im had significantly improved renal function after ischemia compared to vehicle-treated IRI mice (SCr in mg/dL: CDDO-Im vs. vehicle, 1.36 ± 0.67 vs. 3.82 ± 0.16, p=0.017, n=5). Tubular injury in CDDO-Im treated mice was less severe than vehicle treated group (necrosis: CDDO-Im vs. vehicle, 43% ± 16 vs. 11% ± 6, p=0.06; Regeneration: 30% ± 8 vs. 74% ± 13, p<0.05). CDDO-Im significantly improved survival of mice from AKI (Survival time: CDDO-Im vs. vehicle, 72 h ± 0.0 vs. 57.6 h ± 10.5, p<0.05 by Log-Rank test). To verify that CDDO-Im activated Nrf2-dependent gene transcription in the kidney as the likely mechanism of protection, we analyzed Nrf2 target gene expression at 72 h post ischemia in the kidney of mice treated with CDDO-Im or vehicle. CDDO-Im significantly increased the expression of *Gclc*, *Gpx2*, and *Hmox1*genes compared to vehicle (p<0.01, n=3). Conclusion: These data suggest that amplification of Nrf2 signaling by a synthetic triterpenoid CDDO-Im confers protection against AKI, and exploiting this pathway could provide a novel therapeutic approach to ischemic AKI.

**SA-PO2951**

**Calpastatin Overexpression Decreases Sepsis-Induced Organ Damage** Lara Zafrani,[2] Xuzhen Hu,[1] Zachary Dezman,[1] Hua Zhou,[1] Asada Leelahavanichkul,[1] Joelle Perez,[2] Emmanuel Letavernier,[2] Takayuki Tsuji,[1] Robert A. Star,[1] Laurent Baud,[2] Peter S. Yuen.[1] *[1]NIDDK, NIH, Bethesda, MD; [2]INSERM U702, Hopital Tenon, Paris, France.*

Mortality from sepsis is increased dramatically when complicated by multiple organ failure. Multiple pathophysiologic mechanisms have been proposed for sepsis-induced organ damage: systemic inflammation, necrosis/apoptosis, and lymphocyte apoptosis. Calpains, calcium-activated cysteine proteases, can increase inflammation, apoptosis and necrosis. Therefore, we hypothesized that inhibition of calpains might have a protective effect on multiple organ function in sepsis. To test our hypothesis, we used a model of polymicrobial sepsis induced by cecal ligation and puncture (CLP) in wild type (WT) mice and transgenic (TG) mice overexpressing calpastatin, a calpain-specific inhibitor. In WT mice, sepsis transiently increased calpain activity in kidney, liver and spleen peaking at 6 hr after CLP surgery. CLP increased plasma calpain activity at 6h (0.05 vs 0.21U) in WT mice. All subsequent studies compared CLP in WT vs TG mice. Plasma calpain was significantly lower in TG vs WT mice (0.15 vs 0.21U). Tissue calpain activity in TG mice was significantly diminished at 6 hr vs WT. Serum LDH levels were decreased at 6h in TG mice (2208±600 U/L versus 3600±816 U/L), consistent with a contribution of calpain to cellular death. We then determined whether calpain promotes generalized tissue damage or has differential effects on individual organs. TG mice had lower BUN (101±11 mg/dl vs 75±12 mg/dl in WT and TG mice, respectively) 24 hr after CLP surgery. Injury was also less extensive in TG liver (including hepatocyte glycogen stores, focal necrosis) and spleen (lymphocyte apoptosis, as measured by caspase 3 antibody staining). Furthermore, serum IL-6 was significantly decreased after sepsis in TG mice. These results indicate that calpains are activated early in septic plasma, kidney, liver, and spleen and can enhance the severity of multiorgan failure in sepsis. Therefore, systemic inhibition of calpains is beneficial with respect to sepsis outcome, and plasma calpain may be an early sepsis biomarker.

**Peptide Bβ15-42 Attenuates Kidney Ischemia/Reperfusion Injury and Improves Renal Allograft Survival** Inga Soerensen,[1] Song Rong,[1] Nathan D. Susnik,[1] Faikah Gueler,[1] Nelli Shushakova,[1] Peter Petzelbauer,[2] Hermann G. Haller,[1] Roland Schmitt.[1] *[1]Department of Nephrology, Hannover Medical School, Hannover, Germany; [2]Medical University Vienna, Austria.*

Renal ischemia/reperfusion (IR) injury is a major cause of acute kidney injury in native kidneys, and it is associated with delayed graft function, increased allograft rejection and reduced graft survival in renal transplantation. In this study we tested the efficacy of the Bβ15-42, a fibrin-derived peptide known to ameliorate cardiac IR injury, in a murine model of IR caused by renal artery clamping and in allogenic kidney transplantation (C57BL/6 into BALB/c). Intravenous Bβ15-42 was administered during surgery at the time of renal reperfusion. Animal survival and renal function were monitored for 7 days in the IR model and for 28 days in the transplantation model. Additional mice from both models were used to study renal pathology employing histology, immunohistochemistry, qPCR and immunoblot. Treatment with Bβ15-42 in the IR injury model resulted in improved 1-week survival and better renal function. Similarly, allograft recipients with intravenous Bβ15-42 treatment showed a significantly better survival during the 28 day follow-up. Recipient survival was further improved if grafts were additionally flushed with a Bβ15-42 containing solution prior to implantation (60% survival vs. 10% in the control group). Renal pathology revealed that IR kidneys and allografts from Bβ15-42 treated mice had less infiltrating leukocytes and lower levels of endothelial activation at day 1 and 6. This was associated with an improved integrity of tubular epithelium. Flow cytometry and mixed lymphocyte reaction assays analyzing recipient splenocytes at day 6 post-transplantation showed that protective effects of Bβ15-42 were associated with reduced alloreactive T cell priming. In summary we demonstrate that Bβ15-42 treatment provides protection from renal IR injury by inhibiting early inflammatory processes such as leukocyte infiltration and endothelial activiation. In the renal transplantation model these early effects lead to an attenuated subsequent alloimmune response and to a significant prolongation of allograft function.

**SA-PO2953**

**Economic Evaluation of Different Treatment Modalities in Acute Kidney Injury** Monique M. Elseviers,[1] Delphine De Smedt,[2] Lieven Annemans.[2] *[1]Univ. Antwerp, Belgium; [2]Ghent Univ., Belgium.*

The SHARF4 study investigated outcome of acute kidney injury (AKI) in 1303 ICU patients. A cost-effectiveness evaluation of conservative treatment (CONS), intermittent (IRRT) and continuous renal replacement therapy (CRRT) was performed.

An area under the curve model was used, whereby patients were simulated using time-to-event data, combined with direct medical costs per day. SHARF4 contains data on hospitalization costs, length of stay and hospital mortality. In addition follow up cost, mortality and SF-36 data were available for 2 years. All analyses used PASW Statistics 18 and were corrected for disease severity using the SHARF score. To calculate the Quality Adjusted Life Years (QALYs), the SF-36 raw scores were converted to a utility value, representing the quality of a life year by using Braziers' algorithm. The outcome is described as the ratio of the incremental costs to the incremental QALYs, also called the incremental cost-effectiveness ratio (ICER). In Belgium, a treatment is considered cost-effective if this ratio does not exceed 30,000 € per QALY.

Analyses indicated that the mortality rate, the cost and the length of stay differed significantly between treatment modalities during hospitalization. During the follow-up period however, no significant difference in mortality rate and cost per day could be observed. Utility values, which improved gradually after hospital discharge, revealed no significant differences, neither during hospitalisation nor during follow up time, between the three treatment options. CONS was associated with a cost of 34,090 EUR and 0.49 QALYs. CRRT was the most expensive therapy with a cost of 51,664 EUR and 0.52 QALYs. Compared to CRRT, IRRT was less expensive (43,711 EUR) however IRRT also led to less QALYs (0.46). The ICER of CRRT vs. IRRT was 131,604 EUR/QALY. The ICER of CRRT vs. CONS was 651,318 EUR/QALY.

In conclusion this study indicated that the additional cost of approximately 7,952 EUR associated with CRRT versus IRRT generates only a minor increase in QALYs of 0.06 making CRRT cost-ineffective compared to IRRT. Additionally, both RRT modalities were more expensive and IRRT even less effective than CONS.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2954**

**Endogenous IL-10 Attenuates Cisplatin Nephrotoxicity: Role of Dendritic Cell IL-10** William Brian Reeves, Raghu K. Tadagavadi. *Division of Nephrology, Penn State College of Medicine, Hershey, PA.*

Sterile inflammation is associated with tissue injury and organ failure. Recent studies indicate that certain endogenous cytokines and immune cells may limit tissue injury by reducing immune-mediated inflammatory responses. Cisplatin is a commonly used anticancer chemotherapeutic agent but causes acute kidney injury and dysfunction. We recently showed that renal dendritic cells attenuate cisplatin-induced kidney injury by reducing inflammation. Here we investigated the effect of endogenous IL-10 and dendritic cell IL-10 in cisplatin-mediated kidney injury. Cisplatin treatment caused increases in renal IL-10R1 expression and STAT3 phosphorylation. IL-10KO mice showed earlier and greater increases in BUN and serum creatinine after cisplatin treatment compared with WT mice, indicating that endogenous IL-10 ameliorates kidney injury in cisplatin nephrotoxicity. Renal expression levels of the chemokines IP-10, KC and MCP-1 were significantly higher in IL-10KO mice than WT mice. Renal infiltration of IFNγ-producing neutrophils was markedly increased in IL-10KO mice compared with WT mice. However, neutralization of IFNγ did not affect cisplatin-induced renal injury. Cisplatin treatment caused an increase in IL-10 expression by renal dendritic cells. The role of dendritic cell-derived IL-10 in cisplatin nephrotoxicity was investigated using a conditional cell ablation approach. Mixed chimeric mice lacking IL-10 in dendritic cells showed moderately greater renal dysfunction than chimeric mice positive for IL-10 in dendritic cells, suggesting that dendritic cell-derived IL-10 provides partial protection from cisplatin nephrotoxicity. These data demonstrate that endogenous IL-10 reduces cisplatin nephrotoxicity and associated inflammation. Moreover, a portion of the protective effect of dendritic cells in cisplatin nephrotoxicity is mediated by IL-10 produced by dendritic cells themselves. In addition, although IFNγ-producing neutrophils are increased in the absence of IL-10, IFNγ production itself does not contribute to cisplatin-induced renal injury.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2955**

**Protection Against Sepsis-Induced Acute Kidney Injury (AKI) Including the Inhibition of p53 by Pifithrin-α (PIF)** Rildo A. Volpini, Ana C. de Bragança, Talita R. Sanches, Maria Heloisa M. Shimizu, Lucia Andrade, Antonio C. Seguro. *Nephrology, School of Medicine, University of São Paulo, São Paulo, São Paulo, Brazil.*

AKI is a clinical problem typically associated with sepsis. Sepsis-induced AKI (SI-AKI) involves ischemic and toxic injury to the renal tubule epithelium. Sepsis is also a transcriptional activator of p53 which controlls the activation of Bax and p21. We investigated the role of PIF, a specific inhibitor of p53, in SI-AKI using a cecal ligation and puncture (CLP) model. Wistar rats were divided into 3 groups: Control (n=5); CLP (n=8); and CLP+PIF (n=8). PIF was given via 3 i.p. injections (2.2 mg/kg): 24h and 1h before CLP and 24h after CLP. We measured blood pressure, inulin clearance (CIn) and renal interstitial area (RIA) at 24h after CLP. Kidney tissue samples were also submitted to immunohistochemistry for p53, Bax, ED1 and PCNA, as well as to immunoblotting for cytoplasmic p21.

| Variable | Control | CLP | CLP+PIF |
|---|---|---|---|
| CIn (mL/min/100g BW) | 0.84±0.04 | 0.46±0.06[a] | 0.67±0.10[c] |
| MAP (mmHg) | 108.0±2.08 | 91.75±3.65[b] | 103.43±3.43[d] |
| p53 (score) | 0.56±0.07 | 0.80±0.05[a] | 0.52±0.06[d] |
| ED1 (+cells/grid field) | 4.52±0.25 | 8.3±0.12[b] | 4.87±0.66[e] |
| PCNA (+cells/grid field) | 1.27±0.27 | 3.08±0.25[a] | 1.79±0.36[c] |
| p21 (% of control) | 98.96±2.11 | 59.67±1.66[b] | 82.77±3.62[e] |
| RIA (%) | 5.44±0.88 | 12.55±0.72[b] | 8.97±0.32[b,e] |

[a] p<0.01 vs. Control; [b] p<0.001 vs. Control; [c] p<0.05 vs. CLP; [d] p<0.01 vs. CLP; [e] p<0.001 vs. CLP. Data are expressed as mean±SEM. Score range from 0 to 4. Grid field, 0.087 μm$^2$.

PIF treatment improved the GFR and MAP; the RIA increased in the CLP group but not in the CLP+PIF group. In the CLP+PIF group, the p53 staining score and the infiltration by macrophages were lower. PIF improved p21 expression, resulting in fewer PCNA+ cells. Our results show that PIF treatment protected the renal function of SI-AKI animals, and that it did so by suppressing p53 and inducing p21, thereby reducing cell proliferation. Our data provide a novel description of the mechanisms by which sepsis causes kidney injury. FAPESP 06/56320-0.

**SA-PO2956**

**Administration of Allogeneic, Human Mesenchymal Stem Cells to Phase I Human Study Subjects Does Not Elicit an Immune Response, but Does in Rats with AKI** Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Florian E. Toegel,[2] Christof Westenfelder.[1,3] *[1]Medicine, University of Utah and VA Medical Centers, Salt Lake City, UT; [2]Medicine, Cornell College of Medicine, New York, NY; [3]Physiology, University of Utah, Salt Lake City, UT.*

Human Mesenchymal Stem Cells (hMSC) do not express DR and blood group antigens, and are negative for co-stimulatory CD40, -80 and -86, predicting that infused allogeneic MSC should not elicit an antibody response. However, since hMSC are routinely cultured in FBS, retained bovine antigen may induce an allo-response. To avoid this possibility, we cultured hMSC without animal products for our recently completed Phase I Clinical Trial in which allogeneic hMSC were infused to open heart surgery patients beeing at high risk for post-op AKI (Nat Rev Nephrol 6:179, 2010). The administration of hMSC was safe, and no study subject developed post-op AKI or CKD, while ~ 20% of closely matched case controls experienced post-op AKI and CKD. We obtained identical beneficial outcomes in rats in which AKI was treated with allogeneic rat MSC (Stem Cells Dev 18: 475, 2009). Although unlikely, it is unknown whether hMSC administered in a xenogeneic protocol (hMSC into rats with AKI) are similarly hypoimmunogenic. Accordingly, hMSC from the Phase I Trial were first incubated with study subject sera collected 40 days post cell infusion. Serum exposed hMSCs were then incubated with FITC-labeled anti-human IgG antibodies and FACS analyzed, which failed to detect, in all subjects, antibodies to allogeneic hMSC. Next, rat sera, collected 14 days after AKI treatment with hMSC, were tested in identical fashion, using FITC labeled anti-rat IgG. This demonstrated, in all animals, robust antibody responses to hMSC. In summary, allogeneic hMSCs cultured without animal serum, infused at incremental doses, do not elicit an antibody response in humans, while they do in rats, the latter despite MSCs' known inhibitory effects on antibody production. In conclusion, these data confirm the immunologic safety of clinically used allogeneic hMSC when cultured without animal serum, while xenogeneic uses of these cells appear not advisable.

**Platelet Inhibition by Clopidogrel Protects Against Renal Ischemia-Reperfusion Injury** Joris J. Roelofs, Gwendoline J. D. Teske, Nike Claessen, Sandrine Florquin. *Department of Pathology, Academic Medical Center, Amsterdam, Netherlands.*

*Background*

Acute Kidney Injury (AKI) is a life-threatening condition, which is often the result of ischemia-reperfusion (I/R) injury. For patients in shock, I/R is associated with a mortality rate of more than 50%. Currently, treatment options remain largely supportive. Two important hallmarks of I/R injury are activation of coagulation and inflammation, which synergistically cause tissue damage.

Although blood platelets are best known for their pivotal role in hemostasis, mounting evidence shows that platelets are active players in various inflammatory processes as well.

*Aim*

The aim of this study was to examine the role of platelets during experimental I/R injury.

*Methods*

C57Bl6/J mice (n=8 per group) were treated with Clopidogrel or saline for 5 days, after which renal ischemia was induced by clamping off both renal arteries for 45 minutes, followed by reperfusion. Mice were killed 24hrs after I/R.

Effectiveness of platelet inhibition was evaluated by standardized tail bleeding. Renal tissue damage was determined on PAS stained paraffin sections. Renal function was determined by measuring BUN and plasma creatinine. Infiltrating neutrophils were counted manually in Ly6-G immunostained sections.

*Results*

Treatment with Clopidogrel resulted in longer bleeding times during standardized tail bleeding experiments, confirming the effectiveness of platelet inhibition by Clopidogrel.

Clopidogrel treatment resulted in significantly lower levels of renal tissue damage, accompanied by significantly lower BUN and creatinine levels than control mice after I/R (BUN: 23.5 ± 4.1 (Clopidogrel) vs. 38.7 ± 5.2 (control) mmol/L – creatinine: 33.4 ± 9.3 (Clopidogrel) vs. 86.8 ± 12.9 (control) µmol/L; $P<0.05$).

Clopidogrel treated mice showed significantly lower numbers of infiltrating neutrophils after I/R than control mice (15.2 ± 4.2 (Clopidogrel) vs. 58.6 ± 11.7 (control) Ly6G positive cells/HPF; $P<0.01$).

***Conclusion***

We conclude that platelet inhibition by Clopidogrel results in effective protection against renal I/R injury. Therefore, platelet inhibition may prove to be an interesting novel therapeutic intervention for patients with ischemia-induced AKI.

**Abstract Withdrawn**

**SA-PO2959**

**Conditional Knockout of Smad1 Ameliorates Glomerulosclerosis in Progressive Glomerulonephritis** Makoto Araki,[1] Hideharu Abe,[3] Kazuo Torikoshi,[1] Akira Mima,[3] Takeshi Matsubara,[1] Noriyuki Iehara,[1] Atsushi Fukatsu,[1] David J. Salant,[4] Hidenori Arai,[2] Toshio Doi.[3] *[1]Department of Nephrology, Kyoto University, Kyoto, Japan; [2]Department of Human Health Sciences, Kyoto University, Kyoto, Japan; [3]Department of Clinical Biology and Medicine, Tokushima University, Tokushima, Japan; [4]Boston University Medical Center, Boston, MA.*

A link between mesangial cell proliferation and subsequent glomerulosclerosis has been established in progressive glomerular injuries. However, its molecular mechanism has not been fully elucidated. We have reported that Smad1 is a key signaling molecule which regulates the transcription of type IV collagen (Col IV) in mesangial matrix expansion. We also showed that Smad1 is downstream of platelet-derived growth factor (PDGF)-BB in an acute model of glomerulonephritis. In this study we tried to delineate the signaling cascades involved in glomerulosclerosis by using conditional Smad1 knockout mice. C57BL/6 mice (7 weeks old) were injected nephrotoxic serum (NTN). After 21 days, mice were sacrificed, and the kidneys were removed for the analysis. In NTN mice, Col IV and PDGF-BB expression was increased in glomeruli along with induction of Smad1/5 phosphorylation. We then used the Cre-loxP system and Rosa22-Cre ERT2mice to conditionally knock out Smad1 by feeding them with tamoxifen. In Rosa22-CreERT2; Smad1fl/- mice (Smad1CKO), we found 70 % less expression of Smad1 than wild type (WT) mice in the kidneys. PAM-positive areas in Smad1CKO mice were significantly smaller than those in WT mice, which was consistent with the Col IV mRNA expression. We also examined the relationship between Smad1 and PDGF-BB in Smad1 CKO, and found that both mesangial proliferation and sclerosis were significantly reduced along with the decreased expressions of phosphorylated Smad1/5 and PDGF-BB. In conclusion, Smad1 also plays a pivotal role for development of in glomerular sclerosis in progressive glomerulonephritis.

**The Protective Effect of N-Acetylcysteine in Rats with Sepsis Submitted to Non-Lesive Mechanical Ventilation** Renata Campos, Maria Heloisa M. Shimizu, Rildo A. Volpini, Ana C. de Bragança, Fernanda D. T. Q. S. Lopes, Clarice R. Olivo, Antonio C. Seguro. *Nephrology, School of Medicine, University of Sao Paulo, São Paulo, São Paulo, Brazil.*

Patients with severe sepsis frequently present acute kidney injury (AKI) and needs mechanical ventilation. Experimental studies showed a protective effect of the antioxidant, N-acetylcysteine (NAC), in AKI models. We evaluated the effects of NAC on renal and pulmonary function in CLP-rats (cecal and ligation puncture) submitted to non-lesive mechanical ventilation (tidal volume: 8 ml/kg, PEEP: 6 $cmH_2O$ and $FiO_2$: 50%) for 2h. Three groups of male Wistar rats were studied 24h post-CLP: control, CLP and CLP+NAC. NAC was given in drinking water (4.8g/L) from 2 days before CLP until 24h after CLP, when we measured inulin clearance (GFR, ml/min/100gBW). In a 2nd set of experiments by using a Flexi-Vent, airway resistance (RAW), pulmonary elastance (HTIS), pulmonary resistance (GTIS) and airway peak pressure (PP) were determined. Data are mean±SEM. GFR was lower in CLP (0.45±0.08, n=12) when compared with 6 control-rats (0.83±0.04, p<0.01). NAC treatment prevented this alteration (0.78±0.12; p<0.01; n=6). As described in table 1, all ventilatory parameters were increased in CLP-rats and were normalized in CLP+NAC animals.

| Groups | RAW ($cmH_2O$.s/ml) | HTIS ($cmH_2O$/ml) | GTIS ($cmH_2O$/ml) | PP ($cmH_2O$) |
|---|---|---|---|---|
| Control (n=6) | 0.014±0.001 | 1.73±0.20 | 0.39±0.02 | 9.4±0.20 |
| CLP (n=6) | 0.028±0.001 * | 2.71±0.14 ♦∞ | 0.53±0.02 † | 12.1±0.20 † |
| CLP+NAC (n=6) | 0.015±0.001 | 2.08±0.15 | 0.40±0.01 | 9.1±0.18 |

*p<0.001, †p<0.01 vs. other groups; ∞p<0.01 vs. control, ♦p<0.05 vs. CLP+NAC.

The beneficial effect of NAC on respiratory mechanics was associated with a decrease in the perivascular edema evaluated by lung histology (CLP+NAC=12,4±0.7 µm; CLP=18.9±1.71 µm, p<0.001). Survival analysis followed every 12h after CLP for a total of 72h showed that NAC improved survival in septic rats (66% vs. 24%, p<0.01). In conclusion, NAC has a protective effect in respiratory mechanics and renal function of septic rats and reduces mortality.

**Fluid Balance, Diuretic Use, and Mortality in Critically Ill Patients with Acute Kidney Injury: A Secondary Analysis of the Fluid and Catheter Treatment Trial** Morgan E. Grams,[1] Michelle M. Estrella,[1] Josef Coresh,[1] Roy G. Brower,[1] Kathleen D. Liu.[2] *[1]Johns Hopkins University; [2]University of California, San Francisco.*

We evaluated whether fluid balance or diuretic use is associated with mortality in critically ill patients with acute kidney injury (AKI). Using data from the Fluid and Catheter Treatment Trial (FACTT, NEJM 2006; 354: 2564-75), a multicenter, randomized, controlled trial evaluating a conservative vs. liberal fluid management strategy in 1000 patients with acute lung injury, we evaluated the association between fluid management, fluid balance, and diuretic use with 90-day mortality in patients developing AKI, defined as a 50% or 0.3 mg/dl increase in serum creatinine by study day 4. Of the 300 patients with AKI, 244 patients survived 7 days of protocolized therapy and were included in the analysis. Baseline characteristics were similar between the 107 patients in the liberal group and the 137 patients in the conservative group. Positive fluid balance was significantly associated with mortality in both the crude analysis and that adjusted for demographics, severity of illness, day of AKI, diuretic dose, and randomization group (adjusted odds ratio [OR] 1.79 per L/day, 95% CI: 1.38-2.32, p<0.001). Higher furosemide doses had a protective effect on mortality in the unadjusted analysis (OR 0.45 per 100 mg/day, 95% CI: 0.28-0.75, p=0.002) but no significant effect after adjustment for fluid balance. There was no threshold dose above which mortality increased. The fluid management strategy had no significant effect on mortality by either analysis. Stratification by fluid management and AKI severity, and repeat analysis including the full cohort of patients with AKI (N = 300), showed similar results. We conclude that fluid balance is strongly associated with mortality in AKI, independent of liberal or conservative fluid management. Diuretic therapy, even in relatively high doses, had no adverse impact on short-term patient survival in patients with AKI.

**Acute on Chronic Renal Failure in Rats Is Treatment Resistant to Erythropoietin but Effectively Reversed by Mesenchymal Stem Cells: Relevance to Clinical Trials** Christof Westenfelder,[1,2] Anna Gooch,[1] Ping Zhang,[1] Zhuma Hu,[1] Leanne Swenson,[1] Jon D. Ahlstrom,[1] Florian E. Toegel.[3] *[1]Medicine, University of Utah and VA Medical Centers, Salt Lake City, UT; [2]Physiology, University of Utah, Salt Lake City, UT; [3]Medicine, Cornell College of Medicine, New York, NY.*

A vast variety of interventions protect kidney function and accelerate repair in healthy animals with normal renal function. However, EPO, IGF-I or ANP and others, all renoprotective in healthy animals, have not been helpful in patients with AKI. We believe that this difference in outcomes is due to the fact (1) that the efficacy of such interventions was not tested in experimental models with important co-morbidities, such as underlying CKD, a known risk factor for clinical AKI; and (2) that pharmacological agents can only temporarily target a limited number of the complex components of AKI's pathophysiology & repair mechanisms, while Mesenchymal Stem Cells (MSC) are able to beneficially affect the entire spectrum of involved processes. These issues were tested in rats with stable CKD (5/6th NX; decreased function, proteinuria, hypertension). AKI (pedicle clamp) was superimposed on CKD, and rats were either treated with human EPO (300 U/kg sc x 3 days, renoprotective in normal rats with AKI) or with 2x10E6/kg of allogeneic MSCs infused post reflow (renoprotective in normal rats with AKI). Controls received vehicle. EPO was ineffective while MSC infusion significantly protected renal function and accelerated repair. Preliminary efficacy data from our recently completed Phase I Trial show that MSC treatment of open heart surgery patients with underlying CKD prevented post-op AKI and subsequent CKD, while ~20% of closely matched case controls developed AKI & progressively lost renal function. Conclusion: these data demonstrate that pre-clinical studies with novel interventions should be first investigated in clinically relevant animal models, e.g., with underlying CKD, before they are tested clinically. This has generally not been done. In addition, MSC-based therapies appear to be superior to pharmacological interventions both in animals and study subjects with underlying CKD.

**The Effect of Endogenous (Physiologic) and Exogenous (Pharmacologic) Angiotensin 1-7 (Ang1-7) on Ischemia/Reperfusion-Induced Acute Kidney Injury (I/R-AKI), and Its Associated Adaptive Responses** Arnaldo F. Lopez-Ruiz, Kiran B. Chandrashekar, Ruisheng Liu, Luis A. Juncos. *Medicine-Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Ang1-7 has vasodilator and cytoprotective effects, that protect against chronic renal injury. However, its effect on I/R-AKI is unknown. We determined the effects of endogenous and exogenous Ang1-7 on I/R-AKI, and its resulting renal inflammation, apoptosis and expression of cytoprotective factors. Male rats were treated daily for 3 days with vehicle, A779 (Ang1-7 antagonist; 1120 Ug/kg ip) or Ang1-7 (560 Ug/kg ip), and then subjected to 40 minutes of I/R. They were followed for 3 days post I/R during which time they continued to receive their treatment. We determined the extent of AKI by measuring renal function (plasma creatinine) and injury (urine NGAL). In addition, we measured renal inflammation (TNFα) and apoptosis (cytochrome-C), as well as adaptive cytoprotective factors, heme oxygenase-1 (HO-1), vascular endothelial growth factor (VEGF), and prostacyclin (PGI2).

| | Creat mg/dl | NGAL UI/ml | TNFα pg/ug | Cyt-C ng/ug | HO-1 ng/ug | VEGF pg/ug | PGI2 ng/ml |
|---|---|---|---|---|---|---|---|
| SHAM | 0.6±0.03 | 120±5 | 0.4±0.1 | 0.2±0.02 | 0.1±0.1 | 33±1.2 | 2.3± 0.1 |
| I/R-Veh | 1.9±0.1* | 1730±3* | 4.9±0.3* | 4.2±0.4* | 0.7±0.03* | 8.7±0.6* | 0.7± 0.07 |
| I/R-A779 | 3.3±0.1*# | 2265±141*# | 4.6±0.4* | 4.2±0.03* | 0.65±0.05* | 10.7±0.7* | 0.6±0.04 |
| I/R-Ang1-7 | 1.2±0.04*# | 629±42*# | 2.4±0.2*# | 2.8±0.1*# | 1.1±0.1*# | 18±0.6*# | 3.5±0.06 |

Data: Mean±SEM, *p < 0.05 vs. Sham; #p< 0.05 vs. I/R-AKI; (n=6/group)

Blocking endogenous Ang1-7 exacerbated I/R-AKI (creatinine and NGAL increases were augmented), without altering the expression of the renal inflammatory or cytoprotective factors. Whereas, administering exogenous Ang1-7 blunted I/R-AKI, reduced renal inflammation and apoptosis while increasing HO-1, PGI2 and VEGF. Our results suggest that endogenous and exogenous Ang1-7 reduce I/R-AKI; however, the predominant mechanisms for the physiologic vs pharmacologic Ang1-7-induced protection may differ.

**Isoflurane Anesthesia Activates Intestinal Sphingosine Kinase To Protect Against Renal Ischemia Reperfusion Induced Liver and Intestine Injury** Minjae Kim,[1] Sang Won Park,[1] Jinu Kim,[1] Mihwa Kim,[1] Vivette D. D'Agati,[2] H. Thomas Lee.[1] *[1]Anesthesiology, Columbia University, New York, NY; [2]Pathology, Columbia University, New York, NY.*

Acute kidney injury (AKI) often leads to multi-organ dysfunction and systemic inflammation. We recently showed that AKI led to hepatic dysfunction mediated by cytokine release from the small intestine. We also previously showed that the volatile anesthetic isoflurane (Iso) protects against renal ischemia-reperfusion injury (IRI) via sphingosine kinase-1 (SK1) activation. We aimed to determine whether Iso protects against renal IRI-induced liver and intestinal injury and the mechanisms involved in this protection. After pentobarbital (PB) anesthesia and right nephrectomy, mice were subjected to 30 min of left renal ischemia followed by exposure to 4 h of equi-anesthetic doses of PB or Iso and then allowed to awaken from anesthesia. Mice exposed to PB after renal IRI developed severe AKI (Cr=2.39±0.05, N=10, p<0.01) and hepatic injury (ALT=238±18, N=10, p<0.01) compared with sham mice (Cr=0.47±0.03, N=6; ALT=61±8, N=4) 24 h after injury. The rise in ALT was associated with focused peri-portal hepatocyte necrosis, vacuolization, neutrophil infiltration, and pro-inflammatory mRNA upregulation. Iso exposure protected against AKI (Cr=1.61±0.17, N=8, p<0.01) and reduced hepatic injury (ALT=140±16, N=7, p<0.05) compared to PB exposure. Mechanistically, Iso induced liver protection via induction of small intestinal crypt SK1 as SK1 mRNA, protein expression, and enzymatic activity all increased. Intestinal sphingosine-1-phosphate (S1P) levels also increased with Iso exposure. We confirmed the importance of SK1 as mice treated with an SK inhibitor (SKI-II) or mice deficient in SK1 enzyme were not protected against hepatic and intestinal dysfunction with Iso exposure. Taken together, our model of renal IRI caused rapid hepatic and intestinal injury in mice. We show that Iso protects against this renal IRI-induced injury via upregulation of SK1/S1P in small intestinal crypts. Modulation of the SK1/S1P pathway may have important therapeutic implications to reduce extra-renal complications arising from AKI.

**Serum Cystatin C as a Biomarker of Sepsis-Induced Acute Kidney Injury in Mice** Asada Leelahavanichkul, Hua Zhou, Christoph Eisner, Lingli Li, Xuzhen Hu, Takayuki Tsuji, Kent Doi, Jurgen B. Schnermann, Robert A. Star, Peter S. Yuen. *NIDDK, NIH, Bethesda, MD.*

Mortality from sepsis is increased dramatically when complicated by acute kidney injury (AKI); hence, early detection of AKI is important in septic patients. Unfortunately, serum creatinine (Scr) has several limitations that delay recognition of AKI. We sought to explore the usefulness of serum cystatin C (CysC), which has been proposed as an alternative biomarker. We measured CysC, Scr, and BUN and compared them to a gold standard FITC-inulin GFR in CD-1 mice before and 3, 6, 12, and 18 hr after cecal ligation and puncture (CLP) induced sepsis. Bilateral nephrectomy (BN) and bilateral ureteral obstruction (BUO) were also used to determine the renal contribution to CysC handling, alone or in combination with CLP. CysC peaked more rapidly (12 hrs) than Scr or BUN after CLP, BN, or BUO; Cys C also correlated better than Scr or BUN with inulin GFR at 12 or 18 hrs after sepsis. Additionally, CysC was higher in BN model than BUO, confirming renal clearance by the nonexcreting kidney. Both CysC and Scr decreased after CLP/BN and CLP/BUO (vs CLP with 2 normal kidneys) despite increases in inflammatory and non-renal organ damage markers. This suggests decreased production, increased clearance and/or increase in volume of distribution (Vd). We measured CysC clearance and Vd following injection of exogenous CysC at 12 h after CLP (when CysC was otherwise stable). We found that CysC clearance was increased in sepsis with BN with a similar Vd, suggesting that sepsis increases extrarenal clearance. We conclude that CysC was a better overall kidney injury biomarker than Scr or BUN for sepsis AKI but still not an ideal marker because sepsis increases non-renal clearance by an unknown mechanism. Direct injury markers might be a more sensitive approach to the early detection of early sepsis-induced AKI.

**SA-PO2966**

**Combining Early and Late Remote Ischemic Preconditioning Strategies Confers Greater Tissue Protection Than Early Remote Ischemic Preconditioning Alone** Kieran Mccafferty, Conor Byrne, Julius Edward Kieswich, Martin J. Raftery, Magdi Yaqoob. *William Harvery Research Institute, Queen Mary university London, London, United Kingdom.*

Remote ischemic preconditioning (RIPC) is a process by which brief sub lethal episodes of ischaemia and reperfusion to an organ render distant organs resistant to subsequent lethal injury. RIPC confers 2 distinct phases of protection, the early phase (0-4h) and a late phase (24-72h). It is unknown whether additional protection can be achieved by summating early and late RIPC strategies. We hypothesized that combining these 2 strategies could reduce AKI following renal ischemia reperfusion injury.

Methods

Male Wistar rats were divided into 2 groups: Group 1 underwent a RIPC protocol consisting of 3 cycles of 5 minutes ischemia and reperfusion to the left leg using occlusion and reperfusion of the femoral artery. Group 2 underwent a sham RIPC protocol. 48 hours later both groups underwent a RIPC protocol as before, immediately followed by a right nephrectomy and 45 minute left renal artery occlusion to induce severe AKI. After a further 48 hours the animals were sacrificed and blood was taken for analysis.

Results:

| | Group 1 (n=8) | Group 2 (n=7) | p value |
|---|---|---|---|
| Creatinine (umol/l) | 243 (185-379) | 408 (366-549) | 0.05 |
| Urea (mmol/l) | 43.8 (36.7-51.2) | 63.9 (52.8-84.3) | 0.02 |
| Phosphate (mmol/l) | 3 (2.93-3.47 | 5.15 (4.44-6.07) | 0.01 |
| Base deficit (mEq/l) | 2.5 (0.05-4.25) | 4.5 (3.3-10.3) | 0.08 |

All values given as median (25th-75th Centile), with p values calculated using the Mann-Whitney test

The summation preconditioned (Group 1) had significantly better renal function than group 2 which had received only early RIPC.

Group 1 had 40% a lower median plasma creatinine, a 30% lower plasma urea, a 40% lower plasma phosphate and a 44% lower base deficit.

Conclusions

These results show for the first time that summation RIPC provides additional tissue protection when compared to early RIPC phase alone. Summation preconditioning may be an advantageous strategy for providing additional tissue protection in future clinical trials of RIPC, particularly applicable in the arena living kidney donation.

**SA-PO2967**

**P2X$_7$ Receptors Mediate a Deleterious Renal Epithelial-Fibroblast Crosstalk** Shougang Zhuang. *Department of Medicine, Rhode Island Hospital and Warren Alpert Medical School of Brown University, Providence, RI.*

Peritubular fibroblasts in the kidney are the major erythropoietin (EPO) producing cells and also contribute to renal repair following acute kidney injury (AKI). Although a reduced number of renal fibroblasts is frequently observed in the interstitium adjacent to damaged tubular epithelium in the early phase of AKI, the underlying mechanism remains unknown. In this study, we tested the hypothesis that damaged renal epithelial cells directly induce renal interstitial fibroblast death via release of intracellular ATP and activation of purinergic signaling. Exposure of a cultured rat renal interstitial fibroblast cell line (NRK-49F) to necrotic renal proximal tubular cell (RPTC) lysate or supernatant induced NRK-49F cell death by apoptosis and necrosis. A high level of ATP was detected in necrotic RPTC supernatant. Depletion of ATP with apyrase or inhibition of P2X purinergic receptor with PPADS blocked the deleterious effect of necrotic RPTC supernatant. P2X$_7$, an ATP-sensitive purinergic receptor, was not detected in cultured NRK-49F cells but was inducible by necrotic RPTC supernatant. Treatment with A438079, a highly selective P2X$_7$ receptor inhibitor, or knockdown of P2X$_7$ receptor with siRNA, also diminished renal fibroblast death induced by necrotic RPTC supernatant. Conversely, over-expression of P2X$_7$ receptor potentiated this response. Collectively, these findings provide strong evidence that damaged renal epithelial cells can directly induce renal interstitial fibroblast death. The findings further suggest that this deleterious crosstalk arises via ATP action on the P2X$_7$ receptor.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2968**

**Chronic Nicotine Exposure Exacerbates Acute Renal Ischemic Injury** Istvan Arany,[1] Samira C. Grifoni,[2] Jeb S. Clark,[1] Luis A. Juncos.[2] *[1]Pediatrics, University of Mississippi Medical Center, Jackson, MS; [2]Physiology and Biophysics, University of Mississippi Medical Center, Jackson, MS.*

The association between long-term smoking and renal dysfunction has only been recently recognized. Smoking-mediated damage of the renal proximal tubules contributes to tubulointerstitial injury and progression to chronic renal disease but it may also exacerbate acute kidney injury (AKI). Nicotine (NIC) is believed to link smoking to injury of the kidney. Here, we tested the hypothesis whether chronic NIC exposure exacerbates renal ischemia/reperfusion (IR) injury in mice. Accordingly, 10-14-week-old male C57BL/6J mice were administered by NIC (200 mg/ml in 2% saccharine) in their drinking water for 3-4 weeks resulting in high levels of cotinine in the serum and the kidneys of mice that were comparable to that found in chronic smokers. The control group received 2% saccharine. Acute renal ischemic injury (15 minutes of warm ischemia followed by 24 hours reperfusion) was significantly higher in the NIC group compared to the controls as revealed by serum creatinine and renal KIM-1 expression. Also, the extent of oxidative stress (malondialdehyde content of the kidney and renal HO-1 expression) was significantly higher in the NIC group. *In vitro* experiments on cultured mouse renal proximal tubule cells (TKPTS) recapitulated this phenomenon: chronic (24 hours) exposure to NIC exacerbated hydrogen peroxide ($H_2O_2$)-induced reactive oxygen species (ROS) production, LDH release, mitochondrial depolarization, cell permeability and collapse of the actin cytoskeleton. Pre-treatment with the antioxidant N-acetyl-cysteine (NAC) attenuated NIC-induced injury *in vitro*. These results suggest that smoking increases oxidative stress in the kidney and thus, smokers are likely exhibit more severe response to acute kidney injury than non-smokers.

**SA-PO2969**

**Increased Renal CYP4A Expression and 20-HETE Production Promotes Resistance to Renal Rschemia-Reperfusion Injury in Rats** Brodie Marthaler,[1] Sarah M. White,[1] Scott K. Van Why,[2] Michael R. Garrett,[1] Richard J. Roman,[3] Kevin R. Regner.[1] *[1]Nephrology, Medical College of Wisconsin; [2]Pediatrics, Medical College of Wisconsin; [3]Pharmacology and Toxicology, University of Mississippi Medical Center.*

20-Hydroxyeicosatetraenoic acid (20-HETE) is a product of cytochrome P450 4A (CYP4A) mediated metabolism of arachidonic acid. We previously demonstrated that analogues of 20-HETE mitigate renal ischemia-reperfusion injury (IRI) in rats. However, the role of endogenous 20-HETE in renal IRI has not been well characterized. In the present study, we first determined whether IRI alters endogenous renal tissue levels of 20-HETE in Sprague-Dawley rats. Compared with sham-operated controls, renal 20-HETE levels were significantly increased following 30 min of renal ischemia. Renal 20-HETE returned to control levels at 24 hrs reperfusion. To determine whether endogenous 20-HETE plays a protective role following renal ischemia, we compared the susceptibility of SS.5LEW 4A+ and SS.5LEW 4A- congenic rats to renal IRI. These congenic strains were previously generated by introgression of a region on rat chromosome 5 that includes (4A+) or excludes (4A-) the CYP4A genes from the Lewis rat to the Dahl S (S) genetic background. The renal expression of CYP4A protein and the production of 20-HETE is greater in the 4A+ strain compared with the S and 4A- strains. Baseline renal function was similar in the S, 4A+ and 4A- strains. Following 30 min bilateral renal ischemia and 24 hrs reperfusion, plasma creatinines in the S, 4A- and 4A+ rats were $3.8 \pm 0.4$, $4.1 \pm 0.4$, and $1.4 \pm 0.5$ mg/dl, respectively. Renal 20-HETE levels were significantly higher in the 4A+ compared to the 4A- rats following ischemia. Administration of the 20-HETE antagonist, 6,15-20-HEDE, abolished the resistance to renal IRI in the 4A+ rats (plasma creatinine at 24 hrs reperfusion = $4.0 \pm 0.5$ mg/dl). Taken together, these data indicate that over expression of CYP4A protein and increased renal 20-HETE production confers resistance to renal IRI.

**SA-PO2970**

**Pharmaceutical Induction of Heme Oxygenase 1 by Retinoic Acid Ameliorates Ischemic Acute Kidney Injury** Li-Wen Lai,[1] Kim-Chong Yong,[1] Serrine S. Lau,[1] Terrence J. Monks,[1] Yeong-Hau Howard Lien.[2] *[1]Pharmacology and Toxicology, University of Arizona, Tucson, AZ; [2]Medicine, Arizona Kidney Disease and Hypertension Center & University of Arizona, Tucson, AZ.*

Heme oxygenase 1 (HO-1) is the major stress protein in kidney and controlled up-regulation of HO-1 has been shown to exert anti-oxidant and anti-inflammatory activities and renoprotection against acute kidney injury (AKI). All-trans retinoic acid (ATRA), an active vitamin A metabolite, has multiple biological functions including cell growth and differentiation. We investigated protective effects of ATRA against ischemic AKI in mice. A single dose of ATRA (1mg/kg, i.p.) given 3-6 h prior to ischemia reperfusion injury (IRI) provided renoprotection with improved renal function (BUN: 19±1 vs. IRI: 121±19; serum Cr: 0.25±0.05 vs. IRI: 0.99±0.17, $p<0.01$), reduced tubular necrosis scores, neutrophil infiltration, and renal proinflammatory cytokine TNF-$\alpha$ mRNA abundance at 24 h of reperfusion. Importantly, ATRA treatment alone transiently induced HO-1 (3-4 folds increase in mRNA in 1-3 hrs). Moreover, a HO inhibitor, stannous mesoporphyrin, administered 90 min and 30 min before ischemia, completely abolished ATRA-mediated renoprotection, suggesting that HO-1 is the key effector of ATRA-mediated renoprotection. In contrast to the modest ATRA mediated HO-1 induction, IRI-mediated HO-1 induction is fulminant: 14-fold, 94-fold, and 4-fold at 1, 4, and 24 hr of reperfusion, respectively. ATRA pretreatment reduced IRI-mediated HO-1 induction by 70%, 55%, and 100% at 1, 4, and 24 hr of IRI, respectively. The expression of HO-2, a constitutively expressed HO was unchanged by ATRA, IRI or the combination treatment. Dual immunofluorescence

staining studies revealed that the induction of HO-1 occurs mainly in the proximal tubular cells. In conclusion, we have discovered ATRA as a novel pharmaceutical inducer for HO-1, demonstrated the potent efficacy of ATRA in protection against ischemic AKI at dosages commonly used in humans, and identified HO-1 as the key underlying effector of such protection. ATRA could be developed into a preventive agent for ischemic AKI and other AKI such as contrast nephropathy.

**Pretreatment with Sodium Cromoglicate Attenuates Renal Ischemia/ Reperfusion in Rats** Felipe Caetano Beraldo, Marilda Mazzali. *Division of Nephrology, State University of Campinas UNICAMP, Campinas, Sao Paulo, Brazil.*

Mast cells [MC] are rarely found in normal kidney. However, studies have shown the increase of these cells in inflammatory models of acute and chronic kidney injury, as well as in exta-renal models of ischemia reperfusion [I/R]. Blockade of MC degranulation was associated with regression of injury in different models. The aim of this study was to investigate the effects of pre treatment with sodium cromoglicate [SC] in inflammation and cell proliferation in a model of renal I/R in rats. Methods: 36 male Wistar rats were assigned to 9 groups with 4 animals each: 4 control groups, 4 treated groups and Sham. I/R was obtained by bilateral renal arterial clamping during 45 minutes. Treated animals received 160 mg/kg of SC, IP, immediately after reperfusion. Animals were sacrificed at days 1, 3, 5 and 7 after reperfusion. Renal function was measured by serum creatinine. Acute tubular necrosis [ATN] was analyzed by PAS staining. The proliferative response and inflammatory infiltration were quantified by immunostaining. Results: No difference in renal function was observed between treated and untreated animals. SC treated animals showed less severe ATN, with a marked reduction in tissue lesion at day 5 [3.5±0.6 vs 1.0±0.7 percent of denuded tubules, C5 vs T5, $p<0.05$]. Inflammatory cells followed the same pattern, with a significant lower macrophage infiltration after 1 and 5 days after I/R in treated animals [55.8±1.2 vs 26.3±0.9 cells/mm2, C1 vs T1; 121.87±5.9 vs 44.37±1.6 cells/mm2, C5 vs T5, $p<0.05$]. T cell infiltration was significantly reduced in early time points [D1] in treated animals [53.37±0.15 vs 26.87±0.5 cells/mm2, C1 vs T1, $p<0.05$]. The proliferative response to I/R injury was also more intense in non-treated groups, early after reperfusion [326.87±4.0 vs 216.25±2.4 cells/mm2, C1 vs T1, $p<0.05$]. Conclusions: The administration of a mast cell degranulation inhibitor, SC, prior to reperfusion attenuates ATN, inflammation and cell proliferation in an experimental model of renal ischemia reperfusion, suggesting that mast cell proteases can have a pivotal role in inflammatory cells attraction and maintenance of interstitial balance after acute ischemic injury.

## SA-PO2972

**Aldosterone Mediates Renal Dysfunction and Arteriolopathy in Cyclosporine (CsA) Nephropathy** Daniela Trujillo-Silva, Victoria Ramirez, Cristinoc Cruz, Rosalba Pérez-Villalva, Norma Bobadilla. *Molecular Physiology Unit, Instituto de Investigaciones Biomedicas, UNAM and Instituto Nacional de Ciencias Médicas y Nutrición Salvado Zubiran, Mexico, Mexico.*

We previously shown that aldosterone (Aldo) blockade prevented renal dysfunction and reduced structural injury in the model of chronic CsA nephrotoxicity, under low sodium diet (LSD) used to activate RAAS. To dissect the specific contribution of Aldo in inducing renal injury, rats treated with CsA on normal salt diet, received Aldo by infusion pumps to reach those levels found in rats feeding with LSD.

Twenty male Wistar rats were divided in: group receiving vehicle (V), rats receiving Aldo (175 µg/dia), rats treated with CsA (10 mg/Kg) and group simultaneously treated with CsA+Aldo for 15 days. Mean arterial pressure, glomerular filtration rate (GFR) and renal blood flow (RBF) were measured, and the percentage of arteriolopathy (Art) was quantified. In addition, Kim1 and TGFβ mRNA levels were evaluated and urinary $H_2O_2$ was assesed.

Results

| Group | Serum Aldo pg/ml | RBF ml/min | GFR ml/min | Urinary H2O2 nM/24h | Art % | Kim1/18s | TGFβ/18s |
|---|---|---|---|---|---|---|---|
| V | 332 ± 44 | 7.2 ± 0.7 | 2.2 ± 0.3 | 0.8 ± 0.2 | 5 ± 1 | 1 ± 0.1 | 1 ± 0.1 |

*$p<0.05$ vs. V, † $p<0.05$ vs. CsA Ψ $p<0.05$ vs. Aldo

Aldo infusion was associated with a significant reduction of RBF and GFR, together with an elevation of TGFβ mRNA levels. Low dose of CsA induced Art, an effect that was related with an increment in oxidative stress, as well as in TGFβ and Kim1. Aldo potentiated CsA toxicity, thus a greater reduction of GFR, together with enhanced arteriolopathy and TGFβ and Kim1 mRNA levels, were observed.

These results show that aldosterone contributes to renal dysfunction and structural injury in CsA nephrotoxicity, in absence of elevated angiotensin II, through increasing oxidative stress and TGFβ up-regulation.

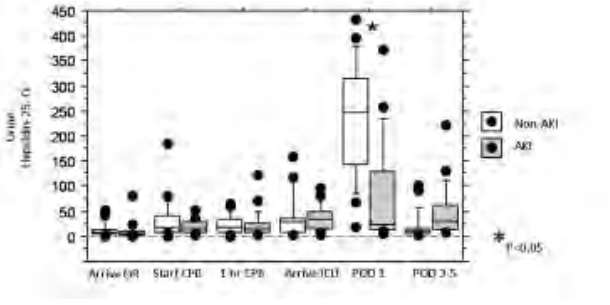
**Is Hepcidin-25 Protecting from Acute Kidney Injury Following Cardiopulmonary Bypass?** Martina Reslerova,[2] Julie Ho,[1,2] Claudio Rigatto.[2] *[1]Manitoba Centre for Proteomics and Systems Biology, University of Manitoba, Winnipeg, MB, Canada; [2]Section of Nephrology, University of Manitoba, Winnipeg, MB, Canada.*

Acute kidney injury (AKI) is a serious complication of cardiopulmonary bypass (CPB) resulting in increased short- and long-term morbidity and mortality. Urinary hepcidin-25 has been identified and shown to be elevated non-AKI versus AKI patients undergoing CPB using semi-quantitative mass spectrometry techniques (SELDI TOF-MS). The goal of this study was to validate these findings utilizing quantitative ELISA. In this prospective cohort, 250 CPB patients underwent a nested, case-controlled analysis of urinary hepcidin-25. Urines from Patients with (n=22) and without (n=22) AKI were collected at six time points: pre-operative, start of CPB, 1 hour on CPB, arrival to ICU, post-operative day 1 and days 3-5. Hepcidin-25 was found to be significantly elevated in non-AKI versus AKI patients at post-operative day 1,confirming the previously reported semi-quantitative mass spectrometry findings.



We postulate that hepcidin-25 may be protective in renal ischemia-reperfusion injury via iron sequestration mechanisms and that further studies are warranted to determine its overall utility as a biomarker in AKI.

**Pre-Conditional but Not Post-Conditional HIF Activation Protects Against Acute Ischemic Kidney Injury** Zhendi Wang, Gunnar Schley, Carsten Willam, Kai-Uwe Eckardt, Wanja M. Bernhardt. *Department of Nephrology and Hypertension, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany.*

**Background.** Inhibition of the Prolyl Hydroxylase Domain-Proteins (PHD) 6 hours prior to renal injury has been shown to protect the kidney via activation of hypoxia-inducible transcription factors (HIF) and HIF target genes. It remains unclear whether HIF activation at the time of injury (post-conditioning) also affects renal function.

**Methods.** A model of warm renal ischemia/reperfusion injury (IRI) was used in Sprague-Dawley rats. Right nephrectomy was performed before clamping the left renal artery for 40 minutes. Groups were treated with either 25mg/kg or 50mg/kg b.w. of a PHD-Inhibitor (PHD-I) or vehicle (Veh) 6 hours prior to ischemia (pre-conditioning) or with 25mg/kg of the PHD-I at the beginning of reperfusion. Serum creatinine were measured before, 24 hours and 72 hours after initiation of IRI. The rats were sacrificed at 72 hours and left kidneys were processed for histology and mRNA expression studies. mRNA levels of HIF target genes, including erythropoietin (EPO) were determined using real-time-PCR.

**Results.** Pre-conditional activation of HIF by the PHD-I significantly improved serum creatinine levels in comparison to Veh ($p<0.05$), with 25mg and 50mg/kg b.w. having the same effect, while no differences in renal function were found between Veh and PHD-I application just prior to reperfusion.

EPO was found to be strongly upregulated after PHD-I treatment compared to Veh with significantly higher expression in response to 50 mg /kg compared to 25 mg/kg group.

**Conclusion.** In order to achieve renal protection against ischemic injury the PHD-I had to be applied before the ischemic insult and was ineffective when given just prior to reperfusion. These findings are in line with the concept that PHD-I exert their protective effects through accumulation of HIF target gene products, with time requirements for increased transcription and translation of HIF dependent genes. Moreover increased expression of EPO at a higher dosage of the PHD-I did not lead to better preservation of kidney function, suggesting that PHD-I mediated protection is not proportional to EPO gene expression.

**Over-Expression of Protein Kinase G Reduced Ischemia/Reperfusion Induced Renal Injury** Yanzhang Li, Shuxia Wang. *Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY.*

Protein Kinase G (PKG) is a cGMP-dependent protein kinase that can be activated by cGMP. There are two PKG genes: PKG-I and PKG-II. Alternatively spliced exons of PKG-I results in two specific PKG-I isoforms: PKG-1α and PKG-1β. Recently, it has been shown that PKG-1α attenuates necrosis and apoptosis in cardiomyocytes following ischemia / reoxygenation. However, whether PKG has protective role in ischemia/reperfusion (I/R) induced kidney injury is unknown. Therefore, we performed the following studies to test whether PKG can protect I/R induce kidney injury by using PKG transgenic mice that are generated by our lab. Overexpression of the constitutively active PKG-I was achieved in PKG transgenic mice. The kidney I/R injury was induced in PKG transgenic mice and wild type control mice by removing the right kidney and clamping the pedicle of left kidney for 45min. After 24 h of reperfusion, the mice were sacrificed and left kidneys were harvested for further analysis. Our data demonstrated that the expression of PKG-Iα in the kidney was down-regulated in control mice after I/R injury as compared to sham group. Kidney functional and histological analysis showed that I/R induced kidney injury was significantly attenuated in PKG transgenic mice as compared to control mice. Together, our studies suggest that increasing PKG activity protects ischemia/reperfusion induced kidney injury.

**The Sustained Renal NFκB Activation Contributes to Acquired Resistance in Cisplatin-Induced Acute Kidney Injury** Jinghui Luo,[1] Hideo Yasuda,[1] Tomoyuki Fujikura,[1] Akihiko Kato,[2] Yoshihide Fujigaki,[1] Akira Hishida.[1] *[1]First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; [2]Division of Blood Purification, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan.*

The activation of NFκB after cisplatin administration has been shown to be implicated in acute tubular injury. The role of NFκB in acquired resistance in cisplatin-induced acute kidney injury, in which the rechallenge with the same dose of cisplatin day 14 after the first dose of cisplatin induced significantly less injury in rats, remains to be elucidated. Rats injected with cisplatin (5mg/kg) were divided into 3 groups: followed by the same dose injection of cisplatin day 14 (group1), the same dose injection of cisplatin day 14 with daily injections of pyrrolidine dithiocarbamate (PDTC) (a functional NFκB inhibitor, 80mg/kg/day) from day 12 (group2), and the same volume injection of vehicle day 14 with daily injections of PDTC (80mg/kg/day) from day 12 (group3). The renal NFκB activation after the first injection of cisplatin was sustained until day 14, which was attenuated by PDTC administration. Serum creatinine and renal apoptosis, evaluated by TdT-mediated dUTP nick-end labeling, was worsened day 17 and 19 in group 2 when compared to group 1.The expression of PCNA, a DNA repair marker, and heat shock protein (HSP) 72 were decreased form day 14 to day 17 in group 2 when compared to group1. The renal toxicity of PDTC was not found in group 3. These data imply that the sustained activation of NFκB after cisplatin injection contributes to acquired resistance in cisplatin-induced acute kidney injury via assembly of PCNA and HSP72.

**When Should We Stop Dialysis in Acute Kidney Injury: An Assessment of Peritoneal Dialysis, Urine Output, and Urinary NGAL in the Setting of Congenital Heart Surgery** Alyssa A. Riley,[1] Joshua Blinder,[1] John L. Jefferies,[1] David P. Nelson,[2] Stuart Goldstein.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Cincinnati Children's Medical Center, Cincinnati, OH.*

Acute kidney injury (AKI) after cardiopulmonary bypass (CPB) to correct congenital heart disease (CHD) is common. We use early continuous peritoneal dialysis (CPD) to prevent fluid overload and further cardiac compromise in oliguric pts. The effect of CPD on AKI recovery is unknown, thus indications for discontinuing CPD are unclear. While change in urine output (UOP) may suggest recovery, urinary biomarkers are earlier, more sensitive indicators of AKI than serum creatinine, may or may not be affected by CPD, and have not been evaluated to predict AKI recovery. We aim to determine how CPD affects UOP recovery and if urinary NGAL (UNGAL) levels are associated with CPD provision and/or UOP recovery. Pts <90 days old undergoing CPB treated with CPD are randomized, matched for CHD physiology. At the clinical time of CPD discontinuation (DC) determination, pts either 1) DC CPD or 2) continue CPD for an additional 24 hours. UOP (ml/kg/hr) and total output (TOP) (urine, dialysate, chest tubes) (ml/kg/hr) is measured throughout the study period. UNGAL is assessed 6 hour post-CPB, then at 12 hour intervals until CPD catheter removal. Eleven pts have been randomized, 6 DC and 5 continuing CPD. At 8 hour intervals after randomization, average UOP (ml/kg/hr) and TOP (ml/kg/hr) were compared (Table 1). Median UNGAL levels did not differ in the 24 hours after randomization (Table 2). Our data show that while UOP recovers significantly after CPD discontinuation, UNGAL levels are not affected. We suggest that decreasing UNGAL levels may provide earlier evidence of renal recovery and be used to guide discontinuation of dialysis.

**Table 1.** Average Urine and Total Fluid Output After Randomization

| | DC CPD | | Continue CPD | | |
|---|---|---|---|---|---|
| | UOP (ml/kg/hr) | ±SD | UOP (ml/kg/hr) | ±SD | p-value |
| Hr 1-8 | 3.9 | 0.8 | 0.9 | 0.1 | <0.001 |
| Hr 9-16 | 5.2 | 0.4 | 1.8 | 0.3 | <0.001 |
| Hr 17-24 | 5.5 | 0.8 | 2.1 | 0.3 | <0.001 |
| | TOP (ml/kg/hr) | ±SD | TOP (ml/kg/hr) | ±SD | p-value |
| Hr 1-8 | 4.5 | 0.5 | 5.6 | 0.1 | 0.5 |
| Hr 9-16 | 5.6 | 0.4 | 5.4 | 0.2 | 0.4 |
| Hr 17-24 | 5.8 | 0.8 | 4.7 | 0.3 | 0.8 |

**Table 2.** Median Urinary NGAL Pre/Post Randomization

| | DC CPD | | Continue CPD | |
|---|---|---|---|---|
| Time (hr) | Median NGAL/Cr (ng/mg) | (25%, 75%) | Median NGAL/Cr (ng/mg) | (25%, 75%) |
| -18 | 319 | (94, 673) | 218 | (106, 1259) |
| -6 | 180 | (75, 352) | 149 | (61, 999) |
| 0 | Randomization | | | |

**Repulsive Guidance Molecule C Is an Early Predicted Biomarker in Diagnosis of Acute Kidney Injury** Guang-Huar Young,[1] Vincent Wu,[2] Hung-Bin Tsai,[3] Wen-Je Ko.[1] *[1]Traumatology, National Taiwan University Hospital, Taipei, Taiwan; [2]Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [3]Internal Medicine, Buddhist Dalin Tzu Chi General Hospital, Chiayi, Taiwan.*

**Introduction:**

Free iron plays roles in models of ischemia-reperfusion (I/R) induced acute kidney injury (AKI) which elevated the production of reactive oxygen species (ROS). The up-regulated of hepcidin modulated iron homeostasis and prevent the perpetuation of ROS injury. Repulsive guidance molecule c (RGMc) is a key regulator of hepcidin and is up-regulated in conditions of iron deficiency/hypoxia.

**Methods:**

Urinary RGMc was identified via proteomic method from cardiopulmonary bypass (CPB)-associated AKI according to RIFLE criteria. Male wistar rats received unilateral renal I/R injury, serum and urine samples were collected on several post-ischemic reperfusion time points (40 min, 3 h, 6 h, 12 h, 24 h and 48 h). Human proximal renal tubular cells (HK2) and mice distal renal tubular cell (DCT) were treated with $H_2O_2$-induced injury.

**Results:**

RGMc and hepcidin were detected at rat kidney tubules by PCR, western blotting and immunochemistry staining. Both RGMc and hepcidin were up-regulated in renal I/R injury rats compared with sham-operated group on mRNA level in acute phase (40 min vs. sham operated in RGMc: 1.52 fold, $p<0.05$; 3 hr vs. sham operated in hepcidin: 2.9 fold, $p<0.05$). Here we demonstrate that RGMc is up-regulated prior to hepcidin on mRNA level in rat kidney under I/R injury. Moreover, we show that urinary RGMc excretion in protein level was increased significantly in early phase of I/R injury rat (3 hr vs. shamed operated: 2.42 fold) and CPB-associated AKI patients (post-operative 24 hr urine from patients with AKI vs. without AKI: 2.07 fold, $p<0.05$). Renal tubule cell treated with additional recombinant RGMc could stimulate hepcidin gene expression under $H_2O_2$-induced injury.

**Conclusion:**

Here we identified at the renal tubules, hepcidin and RGMc were expressed and elevated after I/R injury. We further found that urinary RGMc was elevated at CPB associated AKI patients. These finding indicate that hepcidin and RGMc are early biomarkers in acute kidney injury.

**L-NAME Abolishes Compensatory Mechanisms of Potassium ($K^+$) Secretion in Acute Kidney Injury Due to Ischemia and Reperfusion** Eliana Rachamimov,[1] Vered Avidan,[1] Hannah Wald,[2] Dvora Rubinger.[1] *[1]Nephrology and Hypertension Services, Hadassah University Medical Center, Jerusalem, Israel; [2]Gene Therapy Department, Hadassah University Medical Center, Jerusalem, Israel.*

During renal ischemic-reperfusion injury (IRI), increased nitric oxide (NO) production may affect tubular transport. The large-conductance $Ca^{+2}$-activated $K^+$ (BK) channels mediate flow-stimulated $K^+$ secretion.The present study was undertaken to define the role of NO system on $K^+$ handling and on BK channels expression in rats with IRI after bilateral renal artery occlusion, without (L-NAME (-)), and with (L-NAME (+)) pretreatment with the non-selective NO synthase inhibitor L-NAME. Plasma (P) creatinine levels were 160± 53 and 188± 40 µmol/l at 24hr and 62±30 and 279±61 µmol/l at 48hr reperfusion (p NS and p<0.001), in L-NAME (-) and L-NAME (+), respectively. L-NAME (+) animals were oligo-anuric, and had higher P $K^+$ and aldosterone levels than L-NAME (-). P $K^+$ levels were in correlation with urine flow rate (r=0.531, p<0.05). In L-NAME (-), IRI was associated with significant increases in protein (immunoblotting) and tissue (immunohistochemistry) expression of BK α subunit (functional channel) in renal cortex (3-4 fold), medulla and papilla (2-3 fold), and in colon (2 fold). These increases were blunted in L-NAME (+). The expression of FXYD4 (CHIF) , a protein involved in $K^+$ transport, was decreased in the kidney and increased in the colon in L-NAME (-) . In L-NAME (+) a more severe decrease in the renal expression and a decrease in colonic expression of FXYD4 was noted at 24hr reperfusion. The protein and tissue expression of α and β subunits of Na, K- ATPase were also markedly decreased after IRI, especially in L-NAME (+). These results show: 1.IRI is associated with significant increases in renal and colonic BK channel and colonic FXYD4 expression to maintain $K^+$ balance; 2. L-NAME administration is associated with delayed recovery of renal function, protracted hyperkalemia and abolishment of compensatory increases in BK channel and FXYD4; 3.These alterations are not related to aldosterone. Thus, in IRI, the compensatory increases in proteins involved in $K^+$ secretion are dependent on the integrity of NO system.

**Renal Metabolism of IL-6 Is Impaired in Acute Kidney Injury (AKI), but Not Pre-Renal Azotemia, in Mice** Nilesh Ahuja, Chris Altmann, Ana Andres-Hernando, Sarah Faubel. *Renal, University of Colorado Denver, CO.*

The proinflammatory cytokine IL-6 is increased in the serum of patients with AKI and predicts increased mortality and prolonged mechanical ventilation. The aim of this study was to examine the renal handling of IL-6. Since numerous proteins, including cytokines, are filtered by the glomerulus and metabolized by the proximal tubule (PT), we hypothesized that serum and urine IL-6 would increase in AKI due to impaired PT metabolism. Mouse models of pre-renal azotemia after 0.5 mg IP furosemide injection (no tubular injury) and ischemic AKI (tubular injury) (22 minutes of bilateral renal pedicle clamp) were studied. Renal histology 6 hours after furosemide injection was normal but was characterized by patchy tubular necrosis in AKI. BUN (mg/dL) was 15±1 in vehicle, 52±3 in pre-renal azotemia (P<0.0001, N=9-10), 24±1 in sham operated, and 60±1 in AKI (P<0.0001 vs sham; P=NS vs pre-renal azotemia, N=5-10). Urine IL-6 increased 6 hours after AKI but not pre-renal azotemia. To determine if circulating IL-6 appears in the urine in AKI, 200 ng of recombinant human (h)IL-6 was injected IV 5 hours post-procedure and urine collected for 1 hour; urine hIL-6 increased in AKI, but not pre-renal azotemia. Serum hIL-6 (pg/mL) was determined 1 hour post-injection and was 323±68 after vehicle injection, 394±40 in pre-renal azotemia (P=NS vs vehicle, n=3-4), 265±57 after sham operation, 4,609±1052 after AKI (P<0.001 vs sham, N=3-4), and 16,115±862 after bilateral nephrectomy (P<0.0001 vs sham, N=3-4). These data demonstrate that IL-6 elimination is intact in mice with functional kidneys (vehicle, pre-renal azotemia, and sham operation) but is greatly impaired in mice with impaired or absent kidney function (AKI and bilateral nephrectomy). To examine IL-6 metabolism, hIL-6 was added to the media of normal and hypoxic isolated PT; in normoxic PT, media IL-6 (pg/mL) was 773±22, in hypoxic PT media, IL-6 was 869±44 (P<0.05). In summary, reduced PT metabolism of IL-6 results in increased serum and urine IL-6. Impaired IL-6 metabolism leading to increased serum IL-6 may contribute to the deleterious systemic effects and increased mortality associated with AKI.

**A Cross-Talk Pathway between Epithelial Adenosine Transporters (ENT1) and Vascular A2B Adenosine Receptors Conveys Potent Protection from Acute Kidney Injury** Julee Dalton,[1] Jessica Bauerle,[1] Hartmut Osswald,[2] Holger Eltzschig,[1] Almut Grenz.[1] *[1]Dept of Anesthesiology, UC Denver, Denver, CO; [2]Dept of Pharmacology, University of Tuebingen, Tuebingen, Germany.*

Introduction: Previous studies indicated that extracellular adenosine generation and signaling protects from acute kidney injury (AKI) [1]. Once generated into the extracellular milieu, adenosine is rapidly cleared through uptake by equilibrative nucleoside transporters (particularly ENT1 and ENT2) [2-3]. Therefore, we hypothesized that targeting renal adenosine transporters could convey protection from ischemic AKI by enhancing extracellular adenosine signaling events.

Methods: Human proximal tubular cells (HK-2) were exposed to hypoxia to measure expression and function of renal adenosine transporters. Adenosine transport was assessed in vitro utilizing radio-actively marked adenosine derivates. Gene targeted mice ($ENT1^{-/-}$, $ENT2^{-/-}$ or for individual adenosine receptors) were studied in an ischemic model of AKI. Adenosine levels were measured via HPLC. Renal function was determined by FITC-labeled inulin clearance. Renal blood flow was measured by renal ultrasound.

Results: Initial studies of renal adenosine levels, or kidney function following treatment with the non-selective ENT-inhibitor dipyridamole revealed elevated renal adenosine levels in conjunction with kidney protection from ischemia. Molecular studies pointed towards a prominent role of ENT1 as main adenosine transporter of the kidneys. Consistent with these findings, studies utilizing gene-targeted mice for ENT1 or ENT2 confirmed a selective role for ENT1 in kidney protection from ischemic AKI. Additional studies in gene-targeted mice for individual adenosine receptors suggested that dipyridamole-dependent kidney protection involves signaling events through vascular A2B adenosine receptors (A2BAR) by increasing renal blood flow following ischemia particularly in the cortex.

Conclusion: Our results indicate a selective role for ENT1 in kidney protection from ischemia via enhancing vascular A2BAR signaling events, and suggest off-label use of dipyridamole to prevent or treat kidney injury from ischemia.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2982**

**Inhibition of Soluble Epoxide Hydrolase Does Not Prevent Acute Renal and Hepatic Injuries in Septic Mouse Model** Cuong D. Nguyen,[2] Toshinori Aoyagi,[2] Tianxin Yang,[2] Bradley C. Baird,[2] Bruce D. Hammock,[3] Alfred K. Cheung.[1,2] *[1]Medicla Service, VASLCHCS; [2]Medicine, University of Utah, Salt Lake City, UT; [3]Entomology, University of California, Davis, CA.*

In response to stimuli, arachidonic acid (AA) is metabolized by cytochrome *p*-450 epoxygenase to form epoxyeicosatrienoic acids (EETs). Soluble epoxide hydrolase (sEH) degrades EETs to a less biologically active product, dihydroxyeicosatrienoic acids (DHETs). Previous studies showed that EETs possess anti-inflammatory effects in the vasculature and particularly in the kidney. We therefore hypothesize that inhibition of sEH would prevent sepsis-induced acute kidney and hepatic injuries in a murine cecal ligation-and-puncture (CLP) model.

Male, 10-to-12-week-old C57BL/6 mice (n= 10) were treated subcutaneously with a sEH inhibitor, *trans*-4-[4-(3-Adamantan-1-yl-ureido)-cyclohexyloxy]-benzoic acid (*t*-AUCB), at 1mg/kg for 1 day before and 2 days after the CLP procedure. Compared to the control group, *t*-AUCB treatment did not decrease mortality (survival rate 3/15 vs. 2/15, n=15) nor prevent hypotension (SBP 69.0 ± 13.0 mmHg vs. 61.3 ± 10.5 mmHg). Furthermore, there was no significant difference between the *t*-AUBC and control groups in plasma levels of creatinine (0.38 ± 0.06 mg/dL vs. 0.41± 0.08 mg/dL) or hepatic injury markers (ALT 258.2 ±7.5 U/L vs. 64.0 ± 9.0 U/L, AST 654.0 ± 38.5 U/L vs. 626.2 ± 46.8 U/L). Similarly, *Ephx2-/-* mice without the sEH expression did not provide the protective benefits from CLP-induced acute injuries.

Despite of previous reports on the anti-inflammatory effects of EETs, our data suggest that inhibition of sEH *in vivo* was not associated with attenuation of organ injury and mortality in CLP-induced sepsis model. This difference could potentially be attributed to the severity insults observed in the CLP model. Additional work will be needed to clarify the implications of the anti-inflammatory actions of EETs in acute kidney injury.

**SA-PO2983**

**Comparison of Oral and Intraperitoneal Administration of Exogenous Reduced Glutathione (GSH) on Mitochondrial GSH Levels in Rat Kidney Cortex and Medulla** Marianna J. Zamlauski-Tucker, Josef M. Hannah. *Physiology & Health Science, Ball State University, Muncie, IN.*

GSH is the principal antioxidant inside cells and increasing the GSH level protects the cell against oxidative stress. The present study was undertaken to determine whether oral adminstration of GSH is as effective as intraperitoneal (i.p.) administration of GSH in increasing the mitochondrial GSH level in kidney cortex and medulla from ~ 9 month-old female Lewis rats. The Oral Group rats (n = 6) were given GSH (625 mg/Kg body wt) via gavage for two weeks. The i.p. Group rats (n = 7) were given GSH (250 mg/Kg body wt) via i.p. injection for two weeks. The Control Group rats (n = 9) were not given any exogenous supplementation. The kidneys were harvested at the end of the treatment period and separated into cortical and medullary tissue sections. The sections were further separated into cytosolic and mitochondrial fractions by differential centrifugation. GSH levels in the fractions were determined using a spectrophotometric assay. Statistical comparisons were done using ANOVA followed by the Fisher's LSD post hoc test.

Table 1

| | | Oral Group | | i.p. Group |
|---|---|---|---|---|
| | | GSH - µmol/g kidney wet wt | | |
| Cytosol | | | | |
| | Cortex | 4.7 ± 0.2 [a] | | 9.4 ± 0.9 [a,b] |
| | Medulla | 3.1 ± 0.1 [a] | | 6.2 ± 0.7 [b] |
| Mitochondria | | | | |
| | | GSH - nmol/g kidney wet wt | | |
| | Cortex | 127± 10 [a] | | 121 ± 11 [a] |
| | Medulla | 162 ± 17 [a] | | 107 ± 6 [b] |

Data expressed as X ± SEM; a - significantly different (p < 0.05) from Control Group; b - significantly different (p < 0.05) from Oral Group

Oral administration was as effective as i.p administration of GSH in increasing GSH levels in mitochondria from kidney cortex and medulla. However, a significant increase in GSH levels in the cytosol from kidney cortex and medulla was observed only with i.p administraton of GSH. Oral GSH admininstration significantly decreased GSH levels in cytosol in both kidney cortex and medulla. Thus, the route of administration of exogenous GSH does have different effects on cytosolic GSH levels in rat kidney cortex and medulla.

**Isolated Kidney Injury Aggravates Effects of Secondary Lung Insult in a Two-Hit Mouse Model** Rajit K. Basu,[1] Alvin G. Denenberg,[1] Hector R. Wong,[1] Prasad Devarajan.[2] *[1]Critical Care, Cincinnati Children's Hospital, Cincinnati, OH; [2]Nephrology, Cincinnati Children's Hospital, Cincinnati, OH.*

Acute kidney injury (AKI) independently increases morbidity and mortality in hospitalized patients, possibly by detrimentally affecting distal organ homeostasis. Renal ischemia alters neutrophil chemotaxis and water permeability in the lung, but little is known about host response to secondary pulmonary insult after AKI. Using a novel mouse model, we hypothesized that primary non-lethal kidney ischemia followed by a secondary direct lung insult would worsen host lung injury. From preliminary data, we determined that 30 minutes of bilateral renal pedicle clamping (AKI) optimally 'primed' lungs at 24 hours. Thus, our two-hit model incorporated surgery (sham or AKI) at time zero, intratracheal inoculations (IT) at 24 hours, and sacrifice at 48 hours. We compared 4 groups: Sham + IT saline (Sham+PBS), Sham + 50 µg lipopolysaccharide IT (Sham+LPS), AKI + PBS, and AKI + LPS. Creatinine levels increased in AKI groups, but all mice survived. Serum inflammatory cytokines KC and MCP-1 significantly increased with AKI+LPS versus Sham+LPS. Cytosolic kidney cytokine levels were not significantly different. Lung inflammation by myeloperoxidase (MPO) synergistically increased and lung cytosolic MCP-1 and MIP-2 trended upwards with AKI+LPS versus Sham+LPS. Taken together, we demonstrate that AKI leads to a sub-lethal renal "distress" state that primes a host for heightened responses to subsequent lung challenge, a likely under appreciated phenomenon which may often occur in the clinical arena.

Effects of AKI followed by LPS Challenge

| | Sham | | AKI | | |
|---|---|---|---|---|---|
| **Serum** | PBS | LPS | PBS | LPS | p value |
| Creatinine | 0.14 ± .03 | 0.19 ± .13 | 0.5 ± 0.2 | 0.3 ± .05 | 0.22 |
| KC | 414 ± 161 | 526 ± 52 | 601 ± 146 | 1730 ± 151 | <.001 |

**Estrogen Alters Ischemia-Reperfusion Injury Induced Glomerular Barrier Failure *In Vivo* and *In Vitro*** Michael Hutchens,[1] Yasuhara Kosaka,[1] Paco S. Herson,[1] Patricia D. Hurn,[1] Sharon Anderson.[2] *[1]Anesthesiology & Perioperative Medicine, Oregon Health & Science University, Portland, OR; [2]Division of Nephrology and Hypertension, Oregon Health & Science University, Portland, OR.*

**Introduction:** Estrogen is renoprotective after cardiac arrest (CA). Investigation into renal ischemia has focused on tubular epithelium, but estrogen is active on endothelium. Glomerular endothelium forms part of the filtration barrier and is damaged by ischemia. We hypothesized that CA damages the glomerular barrier, and that estrogen protects it.

**Methods:** Ovariectomized female C57BL/6 mice received vehicle (VEH) and underwent sham or received VEH or estradiol (EST) and underwent 10 min CA, then cardiopulmonary resuscitation (CPR). 24h later, fluorescent-conjugated Ficoll-70(FITC-Ficoll), was given intravenously. 1h later, mice were killed, and BUN, creatinine, and urine fluorescence measured. Mouse glomerular endothelial cells were raised on membrane supports (Corning, Lowell, MA). Medium containing 1 uM EST or VEH was applied and cells subjected to 3h oxygen-glucose deprivation(OGD). Medium was then replaced with color/drug-free media with FITC-Ficoll in the upper chamber. After 4h, fluorescence of lower chamber media was measured.

**Analysis:** Data are reported as mean±SEM. Significance was set at $p<0.05$.

**Results:** CA/CPR increased glomerular ficoll-70 flux (sham 0.061±0.010, CA/VEH 0.510±0.033, CA/EST 0.390±0.072, mcg/hr, $p<0.05$ v sham, n=3-4/group) *in vivo*. There was a trend toward reduced flux in EST treated animals. *In vitro*, OGD increased macromolecular flux. EST treatment during OGD reduced flux compared with VEH (EST 0.1085±0.002, VEH 0.1159±0.003 g/cm$^2$,*=$p<0.05$, figure).

**Discussion:** We found that function of glomerular endothelium is altered after ischemia reperfusion. In addition we found that estrogen protects barrier function *in vitro*.

**Application of NMR-Based Metabonomics in the Study of Rat Renal Ischemic-Reperfusion Injury** Nan Chen, Jun Wang, Xia Liu, Wen Zhang. *Department of Nephrology, Shanghai Ruijin Hospital, Shanghai, China.*

**Background:** Acute kidney injury is increasing obviously in recent years. The mechanism of acute kidney injury is still unclear. The metabolism of renal cell plays an important role in acute kidney injury and the study of renal metabolism is of great importance. The renal ischemia reperfusion injury rat model is the most often used animal model for acute kidney injury study. So we performed the metabonomics research in the ischemia reperfusion injury rat model to clarify the metabolic response to renal ischemic-reperfusion injury.

**Methods:** The rat renal ischemic-reperfusion model was studied by an integrated metabonomics strategy, utilizing $^{1}$H NMR and $^{31}$P NMR spectroscopy of kidney. Male Sprague-Dawley rats were subjected to either clamp of both sides of renal artery, sham operated (SO) surgery, or no treatment (n=5/group) and samples collected over 6 hours, 24 hours, 48 hours, 72 hours and 168 hours. The renal ultrastructure could be observed with transmission electron microscope. The data from NMR was analysed with SIMCA-P 10.5 software. The PCA map and OPLS-DA map were acquired. After data analysis by statistician the change of metabolite from renal tissue and serum were observed.

**Results:** A number of renal metabolic perturbations were observed in I/R rats compared with SO animals, including elevated isobutyrate, lactate, Sn-glycero-3-phosphocholine and hippurate while betaine, taurine, creatine and NADP were reduced. Scores plot of pattern recognition analysis were capable of distinguishing I/R from SO. The ATP level of renal tissue was decreased in the I/R group. By the same time the renal stucture was estimated under microscope with PAS and HE staining. The ultrastructure of renal tissue was detected by transmission electron microscope. The observed metabolic perturbations were consistent with the morphological change of kidney including the damaged membrane of renal tubular cell and the decreased density of mitochondria in tubular cells.

**Conclusions:** The observed changes in $^{1}$H and $^{31}$P NMR spectroscopy and morphology confirm the decreased energy metabolism and suggest the protection of mitochondria may be a strategy for prevention and treatment of AKI.

### SA-PO2987

**Effect of DPP4 Inhibition on Ischemia Reperfusion Injury (IRI)-Induced Loss of Renal Function** Lorenzo Glorie,[1] Annelies De Beuf,[1] Anja Verhulst,[1] Marc E. De Broe,[1] Benjamin B. Vervaet,[1] Veerle Matheeussen,[2] Ingrid De Meester,[2] Patrick C. D'Haese.[1] *[1]Laboratory of Pathophysiology, University of Antwerp, Wilrijk, Belgium; [2]Laboratory of Medicinal Biochemistry, University of Antwerp, Wilrijk, Belgium.*

Inhibitors of dipeptidyl peptidase 4 (DPP4) exhibit a protective effect on IRI of heart and lung through increased half-life of DPP4 substrates. In this study, the effect of the commercially available DPP4 inhibitor vildagliptin (VG) on renal function after IRI was assessed.

This effect of VG was tested in a unilateral 30' IRI rat model, in which contralateral kidney was removed after release of renal pedicle clamp. Saline or VG (1 mg/kg and 10 mg/kg) was administered iv prior to sham operation or IR. Rats were sacrificed and the ischemic kidney was removed after 2h/12h/48h of reperfusion. Inhibition of DPP4 was confirmed by decreased DPP4 activity in serum and kidney segment homogenates. Measurement of serum creatinine revealed significant dose-dependent protection of renal function in VG vs saline treated IR rats (0.7 mg/dl and 1.3 mg/dl for 10 mg/kg and 1 mg/kg VG respectively, vs 1.9 mg/dl for saline at 12h reperfusion; p=0.0003 and p=0.0022, respectively). Interestingly, VG treatment did not have a significant effect on tubular morphology as shown by PAS-PCNA staining. mRNA expression of DPP4, SDF-1α (DPP4 substrate), CXCR4 (SDF-1α receptor), HO-1 (heat shock protein), IL-1β (pro-

inflammatory) and IL-10 (anti-inflammatory) was evaluated by real-time RT-PCR and showed increased expression of CXCR4 and SDF1α at 48h in VG treated sham-operated rats as compared to saline treated sham-operated rats, whereas this was not seen after IR. mRNA expression of DPP4, HO-1, IL-1β and IL-10 was not altered by administration of VG. Increased infiltration of macrophages was reported in IR rats treated with 10 mg/kg VG at 2h and 12h reperfusion as compared to the saline IR rats.

In conclusion, DPP4 inhibition with VG results in a significant functional protection against IRI, this however without having any effect on IR-induced morphological changes, suggesting other mechanisms (e.g. by hemodynamic effects) to be responsible for the protective effect on renal function.

**SA-PO2988**

**Spermidine/Spermine-N1-Acetyltransferase (SSAT) in Acute Kidney Injury in Humans and Rodents: Role in Pathophysiology and Use as a Biomarker** Kamyar A. Zahedi, Amit Govil, Sharon L. Barone, Charuhas V. Thakar, Manoocher Soleimani. *Medicine, University of Cincinnati, Cincinnati, OH.*

Renal ischemia reperfusion injury (IRI) is a major cause of acute renal failure (ARF) in native and the foremost cause of delayed graft function (DGF) in transplanted kidneys, and ranks among the leading causes of morbidity in hospitalized patients. The expression and activity of SSAT and spermine oxidase (SMO) increase in the kidneys of rodents subjected to renal IRI, indicating the onset of enhanced polyamine catabolism. Expression of SSAT in cultured cells leads to DNA damage and growth arrest. Furthermore, the inactivation of SSAT gene significantly reduces the severity of tubular damage and renal dysfunction in animals subjected to kidney IRI. Studies described here were designed to examine the role of SSAT expression by the proximal tubule epithelium and flavin adenine dinucleotide (FAD)-dependent polyamine oxidases, PAO and SMO, in the etiology of IRI. Our studies indicate that the specific ablation of SSAT gene in mouse renal proximal tubules and inhibition of PAO and SMO reduce the severity of renal IRI. In order to determine the clinical relevance of our experimental observations and assess the utility of measurement of urinary polyamine levels as biomarkers of renal injury we examined the expression of SSAT and SMO in the kidney and determined the putrescine levels in the urine of patients with DGF. Using specific antibodies and biopsy sections, immunohistochemical staining demonstrated that the expression of SSAT and SMO is significantly enhanced in the kidneys of patients with acute renal failure in DGF but not in non-ischemic models. Measurement of urinary putrescine, a metabolite of SSAT-mediated polyamine catabolism, indicated significant elevation in patients with DGF but not in patients with renal failure secondary to non-ATN causes. We propose that the activation of SSAT plays an important role in the pathogenesis of acute ischemic renal failure in humans and rodents. We further propose that SSAT expression in the kidney and measurement of its metabolite (putrescine) in the urine can be used as novel biomarkers in AKI.

**Cyclosporine-Induced Modifications of Proximal Tubule Actin Organization and tPA Expression May Contribute to the Interstitial Fibrosis during Chronic Allograft Dysfunction** Virginie De Merindol,[1,3] Elodie Mestre,[1,3] Marie Essig.[1,2,3] *[1]UMR-S850, Inserm, Limoges, France; [2]Nephrology Dialysis Transplantations, CHU Limoges, Limoges, France; [3]Université de Limoges, Limoges, France.*

Recent studies focusing on non-immunological actions of cyclosporine A (CsA) have demonstrated its role in the control of actin organization in podocytes. We investigated whether a similar effect can be observed in proximal tubular cells which possess a highly organized cytoskeleton and if this effect could be involved in the interstitial fibrosis of kidney grafts observed in the long term.

Methods: Pig proximal tubular cells (LLC-PK1 cells) were incubated for 24h with 5μM CsA. Cytoskeleton organization was analyzed by immunofluorescence. Expression and activity of extracellular matrix proteases [tissue-type plasminogen activator (tPA), plasminogen activator inhibitor (PAI-1) and metalloproteases (MMP2, MMP9)] and the role of NFAT and cofilin pathways were analyzed.

Results: In LLC-PK1 cells, CsA induced a strong rearrangement of the actin cytoskeleton with a reinforcement of the lateral network. As observed when the actin cytoskeleton of proximal cells is rigidified by mechanical stress (Essig et al, AJP, 2001), CsA-induced actin reorganization was associated with an inhibition of the expression and activity of tPA, independent of its inhibitor PAI-1. No modification of the expression and activity of MMP2 and MMP9 could be observed. CsA induced an increase in pNFAT-NFAT ratio, however the VIVIT peptide, a specific inhibitor of NFAT, did not reproduce the effects of CsA on actin and tPA expression. CsA also induced an increase in pCofilin/Cofilin ratio and the S3R peptide, a specific inhibitor of cofilin phosphorylation, increased tPA activity suggesting that the effects of CsA on actin and tPA expression are mediated through the modification of cofilin activity.

Conclusion: In proximal tubular cells, CsA induces reorganization of the actin network and inhibits tPA expression and activity independently of NFAT inhibition and maybe through modification of cofilin activity. The decrease in tPA activity may contribute to the interstitial fibrosis of the graft observed in the long term in CsA-treated patients.

**Molecular Patterns in Protocol Biopsies at 3 Months Predict Acute Rejection Episodes** Bernd Krüger,[1,2] Yi Luan,[1] Yi Cai,[1] Weijia Zhang,[1] Bernd Schroppel,[1,3] Barbara T. Murphy.[1,3] *[1]Mount Sinai School of Medicine, Division of Nephrology, New York, NY; [2]V. Medizinische Klinik, Universitätsklinikum Mannheim, Medizinische Fakultät der Universität Heidelberg, Mannheim, Germany; [3]Mount Sinai School of Medicine, The Transplantation Institute, New York, NY.*

Background: Protocol biopsies offer the potential to identify subclinical events that predate functional events. However, renal pathology can fail to predict future graft events. Microarrays offer the ability to examine intragraft activity at a molecular level and the potential to predict clinical events prior to clinical graft injury.

Methods: We analyzed 3 months post-transplantation protocol biopsies from the GoCAR study cohort. We performed microarray analysis (Affymetrix GeneChip Human Exon 1.0 ST Array) with subsequent hierarchical clustering on 48 protocol biopsies and examined the association between gene clusters and clinical outcomes. Follow-up time was at least 9 months. Statistical analyses were performed using the SPSS statistical package.

Results: Hierarchical clustering revealed two patient groups based on differential gene expression patterns in genes related to immune response, muscle/collagen/fibrosis, transport/metabolism, and cell adhesion. Demographic, and clinical parameters including kidney function and histopathological findings were not different between the different clusters at the time of biopsies. However, patients clustered to the group with the highest expression of immune response genes, had a significant higher risk of future acute rejection episodes (p=0.002).

Conclusion: These data suggest that molecular changes within the graft are a more sensitive marker of subsequent pathological events and may be potentially used to stratify patients prior to the development graft injury, allowing individualized tailoring of immunosuppressive therapies.

**Urinary B Cell Attracting Chemokine 1 (BCA-1) Is a Sensitive Marker of Acute Humoral Rejection** Wenhan Peng, Dajin Chen, Jianghua Chen. *The Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

In previous studies, we found urinary fractalkine was a better marker of acute rejection, but urinary biomarkers of acute humoral rejection (AHR) were still unknown. The aim of this study was to investigate whether urinary B cell attracting chemokine 1 (BCA-1) was a useful noninvasive marker for detection of AHR in renal transplant recipients. Urinary C4d, fractalkine, chemokine monokine induced by IFN-γ (Mig), IFN-γ-inducible protein 10 (IP-10), granzyme B and perforin were also assessed. Urinary concentration of these markers was determined by ELISA technique in 323 recipients from June, 2001 to Dec, 2008 and 80 healthy controls. These urinary markers excreted by 115 patients with AR were at higher levels than those of healthy controls, 156 patients with stable renal function and 33 patients with chronic allograft nephropathy (P<0.001). Urinary fractalkine could also distinguish AR from acute tubular necrosis (N=19) (P<0.001). Only changes in urinary BCA-1 and C4d distinguished 37 patients with AHR from 78 patients with acute cellular rejection (ACR) (BCA-1: 20.99±3.57 vs. 1.99±0.41 ng/mmol creatinine, P<0.001; C4d: 27.21±6.13 vs. 11.62±2.22 μg/mmol creatinine, P=0.005, respectively). For distinguishing AHR from ACR, area under the conventional receiver operating characteristic curve of BCA-1 was greater than that of C4d (0.877 vs. 0.66). When BCA-1 was 5.64ng/mmol creatinine, the sensitivity was 83.3% and the specificity was 83.7% to diagnosis of AHR (P<0.001). The study shows that urinary BCA-1 and C4d were useful biomarkers for acute humoral rejection. The former was much better than C4d in predicting AHR.

**SA-PO2992**

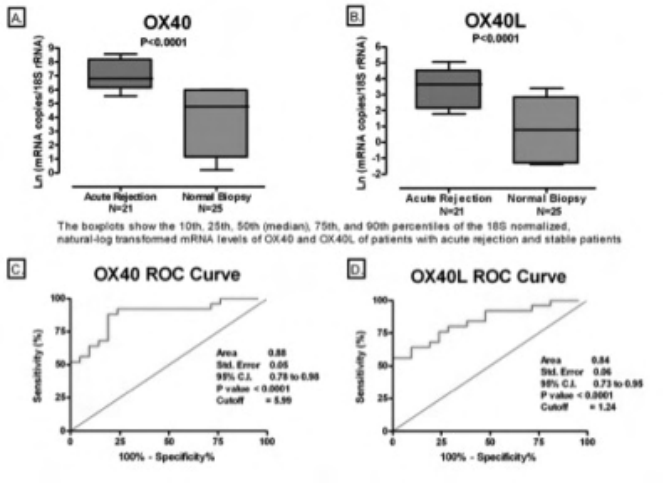
**Identification of High Levels of mRNA Encoding T Cell Co-Stimulatory Proteins OX40 and OX40L during Episodes of Acute Rejection of Human Renal Allografts** Michelle L. Lubetzky, C. Afaneh, Thangamani Muthukumar, Darshana M. Dadhania, Surya V. Seshan, Manikam Suthanthiran. *Division of Transplantation Medicine, New York Presbyterian-Weill Cornell, New York, NY.*

Acute rejection (AR) of human renal allografts remains a major cause of allograft failure. The development of novel urinary biomarkers for AR aids in diagnosis of rejection episodes. OX40 and its ligand (OX40L) are members of the TNFR superfamily and have been shown to be critical for T-cell co-stimulation and accelerated rejection in experimental models. Our goal was to investigate whether OX40 and OX40L contribute to AR in humans.

We studied urine samples from 21 patients with biopsy-proven AR and 25 patients with stable renal allograft function and normal biopsies. RNA was isolated from urinary cells, reverse transcribed to cDNA, preamplified with gene specific primers, and absolute mRNA copy numbers were quantified using RTQ- PCR assays.

The natural log-transformed mean (±SE) ratio of OX40 mRNA copies to 18S rRNA copies was higher in the urine of AR patients (6.98±0.26) compared to stable group (3.88±0.50) (P<0.0001) (Fig 1A) The ratio of OX40L mRNA to 18S rRNA was also higher in the urine of AR patients (3.37±0.28) compared to stable (0.72±0.41) (P<0.0001) (Fig 1B). Analysis of ROC curves demonstrated that AR can be predicted with a 88% sensitivity

and a 81% specificity using 5.99 as cutoff for OX40 mRNA (AUC: 0.88, P< 0.0001), and 56% sensitivity and 100% specificity using 1.24 as cutoff for OX40L mRNA (AUC: 0.84, P<0.0001) (Fig 1C & D).



Urinary cell mRNA levels of OX40 and OX40L are higher during episodes of AR in human renal allografts and can be noninvasive diagnostic biomarkers. Our report of altered levels of mRNAs for encoding OX40/OX40L in human transplantation advances these co-stimulatory molecules as potential drug targets in organ transplantation.

## SA-PO2993

**Unsupervised Analysis of Kidney Transplant Microarray Data Identifies Subgroups of Acute Rejection** Ken J. Park, Ying Huang, David L. Perkins. *Nephrology, University of California, San Diego, La Jolla, CA.*

**Introduction:** Based on multiple types of evidence, kidney transplant rejection is a heterogeneous diagnosis. We hypothesized that using unsupervised analysis of 2 publicly available kidney transplant microarray datasets, we could identify subsets of acute rejection (AR) based on molecular criteria of gene expression.

**Methods:** Data were downloaded from Gene expression Omnibus (GEO) microarray repository for "Paris" set (GSE9493) and from transplants.med.ualberta.ca for the "Alberta" set. Data was normalized with GCRMA in R and filtered by selecting genes with coefficient of variation of >10%. To build a classifier, we used the Alberta data as a test set. Significant genes were selected with p< 0.005 between AR and borderline TCMR (BL) vs. no rejection (NR) using t-test corrected with FDR. The number of clusters was determined using partition around medoids (PAM) for all AR and BL. Significant gene ontology (GO) biologic processes and KEGG pathways were identified using DAVID v6.7 (david.abcc.ncifcrf.gov/home.jsp). The classifier was then evaluated in the Paris validation set.

**Results:** 983 probe sets were significant between AR/BL vs. NR in the Alberta set. Clustering using PAM for AR and BL samples showed that two clusters had the best average silhouette width. 171 genes were significant between the two clusters. GO biologic processes and KEGG pathways were significantly different between the 2 subsets of rejection. Interestingly, comparison of histologic scores between the two groups showed increased glomerulitis and interstitial inflammation scores in the first cluster. Using the Paris set as an independent data set for validation, AR and BL samples also clustered into two groups using these 171 genes. Heat map showed differential expression of the genes between the 2 subsets. Importantly, Banff scores were higher in the group with higher expression of the classifier genes.

**Conclusion:** Based on comparison with histologic scores, unsupervised clustering of microarray data reveals two distinct groups of rejection which may represent different grades of severity of rejection.

## SA-PO2994

**Donor Specific Low Level C3d Fixing Anti-HLA Antibodies before Kidney Transplantation Are a Risk Factor for Early Rejection Episodes** Ulf Schoenermarck,[1] Markus Guba,[3] Teresa Kauke.[2] *[1]Medical Clinic I, Nephrology Div., University Hospital Munich-Grosshadern, Munich, Germany; [2]Laboratory of Immunogenetics, University Hospital Munich-Grosshadern, Munich, Germany; [3]Department of Surgery, University Hospital Munich-Grosshadern, Munich, Germany.*

Introduction:

The clinical relevance of anti-HLA antibodies only detected in solid phase assays (SPA) before kidney transplantation is discussed controversial. The aim of our study was to investigate the risk of early rejection in case of donorspecific low level C3d fixing (DSA+/C3d+) HLA-antibodies detected in pretransplant sera.

Patients and Methods:

219 consecutive patients with a deceased kidney allograft were retrospectively analysed. All patients were transplanted with a negative crossmatch. Patients with high immunological risk (e.g. with cytotoxic HLA-antibodies or with high level SPA+ antibodies) were not recommended for transplantation. 55/219 patients were positive in SPA before transplantation. SPA+ sera were measured by means of Luminex Single Antigen (LSA) beads with standard IgG conjugate and additionally with anti-C3d conjugate. Rejection episodes within the first 3 weeks after transplantation were correlated with the presence of DSA+/C3d+ HLA-antibodies.

Results:

Acute rejection (AR) occurred in 21/219 patients (9.6%) within the first 3 weeks after transplantation. AR was seen in 16/55 SPA+ patients (29%), but only in 5/145 SPA- patients (3.4%). DSA+/C3d+ HLA-antibodies were detected in 24/55 SPA+ patients (44%). AR occurred with higher frequency in patients with DSA+/C3d+ HLA-antibodies (13/24, 54%) than in DSA/C3d- patients (3/31, 9.7%; p<0.001).

Conclusion:

According to our preliminary data the presence of low level DSA+/C3d+ HLA-antibodies prior to transplantation is a risk factor for early rejection episodes. Further investigation using a combination of assays to determine specificity and function is necessary to evaluate the role of these low level HLA-antibodies on long-term graft survival.

## SA-PO2995

**Molecules Selectively Expressed in T Cell-Mediated Rejection: Comparison with Antibody-Mediated Rejection** Declan G. de Freitas, Jeff Reeve, Joana Sellares, Konrad S. Famulski, Luis G. Hidalgo, Gunilla Einecke, Dina F. Badr, Banu Sis, Michael Mengel, Philip F. Halloran. *ATAGC, University of Alberta, Edmonton, AB, Canada.*

The alloimmune response damages organ allografts by either T cell-mediated rejection (TCMR) or antibody-mediated rejection (ABMR), which share features because both induce inflammation (e.g. interferon-gamma effects). Distinguishing TCMR from ABMR is important for understanding mechanisms and guiding treatment strategies.

Methods: We studied 403 consecutive kidney biopsies for cause in 315 patients by histopathology, microarray analysis and alloantibody status. We defined the molecules expressed in biopsies labelled C4d$^+$ ABMR and C4d$^-$ABMR to those labelled TCMR using both class comparison and Predictive Analysis of Microarrays (PAM). PAMR$^+$ cases were identified using a previously published rejection classifier.

Results: 28 cases of TCMR, 17 cases of C4d$^+$ABMR and 47 cases of C4d$^-$ABMR were identified using histopathology and HLA antibody status. In comparison, 30 cases of TCMR and 13 cases of C4d$^+$ABMR were identified when PAM was applied to the histological diagnoses. TCMR, defined both clinically and molecularly, was characterized by a higher burden of selected T cell transcripts (e.g. GZMK, CD8A, CD2) and macrophage transcripts (e.g. ADAMDEC1, CXCL13). Table 1 lists the top 10 genes in each class comparison. Few interferon-gamma induced transcripts were identified reflecting the rejection vs rejection analysis. Marked overlap occurred between the gene lists as determined by both class comparisons. CXCL13 and ADAMDEC1 were the top performing genes in all comparisons and were highly correlated with the lesions of TCMR. Thus although TCMR and C4d$^+$ABMR share features, TCMR can be distinguished by a combination of a high T cell transcript burden and selected macrophage genes.

**Urinary NGAL and IL-18 Predicts Graft Function within Hours after Renal Transplantation** Kalathil K. Sureshkumar,[1] Chirag R. Parikh,[2] Richard J. Marcus.[1] *[1]Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA; [2]Nephrology, Yale University, New Haven, CT.*

In renal transplantation, delayed graft function portends adverse long-term graft and patient survival. Early diagnosis is essential for any intervention to be successful. Serum creatinine is a poor maker for early diagnosis of allograft injury.

We performed a prospective observational cohort study of deceased-donor kidney transplant recipients to evaluate urinary neutrophil gelatinase-associated lipocalin (NGAL) and IL-18 as biomarkers for earlier prediction of adverse graft outcome. Graft function recovery was classified as delayed graft function (DGF-dialysis requirement within first week), slow graft function (SGF-<40% reduction in serum creatinine by post-operative day 3 and no dialysis requirement), or immediate graft function (IGF-remaining patients). Biomarker levels at different post-transplant time points in 89 patients are shown below.

| Urinary biomarker | Post-transplant hour | DGF(n=37) | SGF(n=26) | IGF(n=26) | p-value |
|---|---|---|---|---|---|
| NGAL (ng/ml) | 0 | 762(94-2832) | 576(99-2000) | 566(45-921) | 0.106 |
| | 6 | 947(213-3667) | 712(41-1658) | 262(18-1202)* | 0.001 |

| | 6 | 219.2(53.1-946.4) | 65.2(25.6-2037.9) | 75.5(25.6-541.1) | 0.058 |
| | 12 | 351.5(77.3-2125.4) | 106.8(25.6-2247.6) | 98.1(25.6-417.0) | 0.005 |
| | 24 | 295.3(73.5-982.5) | 126.6(25.6-1143.2) | 73.2(25.6-939.6) | 0.002 |
| | 48 | 196.4 (53.9-938.1) | 106.9(25.6-711.5) | 69.2(25.6-939.6) | 0.017 |

Values expressed as median (10th to 90th percentile); *= p<0.05, IGF vs. SGF

Starting 6 hours post-transplant, urinary NGAL and IL-18 predicted DGF while NGAL also differentiated IGF from SGF. Our study supports the validity of these noninvasive tests for the early detection of allograft dysfunction which carries long-term adverse impact on graft and patient survival.

**Renal Protection from Extreme Cold Ischemia in Hibernating Squirrels** Alkesh Jani, Elaine Epperson, Jessica Martin, Arijana Pacic, Sandy Martin, Danica Ljubanovic, Charles L. Edelstein. *U of Colorado.*

We have shown that cold ischemia (CI) results in increased caspase-3 activity, tubular apoptosis, and brush border injury (BBI) in mouse kidneys. The 13-lined ground squirrel (GS) undergoes hibernation and torpor, when core temperature (CBT) falls to 4C for 7-18 days, accompanied by profound bradycardia and low-level *in vivo* perfusion. Torpor is therefore a natural model of organ preservation. We hypothesized that torpid GS kidneys were protected from prolonged CI. Our aim was to determine if protection required low-level *in vivo* perfusion or was intrinsic to the kidney (ex vivo experiment). Methods: Radiotelemeters were implanted in 1 yr old GS, and CBT was remotely monitored. Animals were sacrificed during late torpor when CBT was 4C for ≥ 7 days. Both kidneys were then perfused with cold UW solution. For the *in vivo* experiment one kidney was immediately processed. For the *ex vivo* experiment, the contralateral kidney was perfused with UW and stored *ex vivo* in UW for 72 hours at 4C. % tubules with BBI and apoptotic cells/hpf were counted by a pathologist in a blinded manner. Caspase-3/7 activity was measured using fluorescent substrates Results (Table): Neither apoptotic cells/hpf nor caspase-3/7 activity differed significantly between *in*- and *ex vivo* kidneys. BBI was significantly worse in *ex vivo* kidneys but affected < 10 % of tubules. Conversion of pro- to active-form caspase-3 did not occur in either *in*- or *ex vivo* kidneys.

| | Apoptosis (cells/hpf) | BBI (% tubules affected) | Caspase-3/7 activity (nmol/min/mg) | Immunoblot | |
|---|---|---|---|---|---|
| | | | | Pro-form Caspase-3 | Active-form Caspase-3 |
| In vivo torpid kidney | 0.10 | 0 | 6.5 | ++ | ND |
| Ex vivo torpid kidney | 0.03* | <10 ** | 13.6* | ++ | ND |

* p =NS vs in vivo; **p < 0.0002 vs. in vivo; ND = not detected; n = 3 in all groups

Conclusion. We have shown that torpid kidneys are remarkably resistant to apoptosis during severe, prolonged CI both *in*- and *ex vivo*. The protection is associated with a failure to convert pro-caspase-3 to its active form. These findings indicate that torpid ground squirrel kidneys are intrinsically protected even *ex vivo* and are not reliant upon the low-level *in-vivo* perfusion.

## SA-PO2998

**Effect of Erythropoietin on Graft Function and Kidney Injury Biomarkers Following Deceased Donor Kidney Transplantation** Richard J. Marcus,[1] Sabiha M. Hussain,[1] Chirag R. Parikh,[2] Ngoc L. Thai,[3] Kalathil K. Sureshkumar.[1] *[1]Nephrology, Allegheny General Hospital, Pittsburgh, PA; [2]Nephrology, Yale University and VAMC, West Haven, CT; [3]Transplantation, Allegheny General Hospital, Pittsburgh, PA.*

There is evidence that erythropoietin attenuates ischemia reperfusion injury, a factor implicated in the development of delayed graft function (DGF) following kidney transplantation. The objectives of the current study are to assess the impact of epoetin alfa on: 1) DGF incidence and 2) levels of urinary biomarkers of acute kidney injury (AKI) following deceased donor kidney transplantation (DDKT).

Patients undergoing DDKT underwent double blinded randomization to receive either 40,000 units of epoetin alfa or saline into the ipsilateral iliac artery proximal to the allograft anastomosis site immediately after reperfusion. Patients were followed for 30 days. DGF was defined as the need for dialysis in the first post transplant week. Immediate graft function (IGF) was defined as no requirement of dialysis in the first post-transplant week and a creatinine fall of >40% by post operative day three.

Out of 72 patients enrolled into the study, 36 received epoetin and 36 received saline. DGF developed in 15/36 (42%) in the epoetin group compared to 17/36 (47%) in the saline group (p=0.635). IGF was observed in 12/36 (33%) and 6/36 (17%) in the epoetin and saline groups respectively (p=0.1025). The average number of dialysis treatments in the first post-transplant week were 1.3±2.0 and 1.4±2.0 in the epoetin and saline groups respectively (p=0.898).

IL-18 and NGAL were assayed in urine samples at post-transplant hours 0, 6, 12, 24 and 48. IL-18 and NGAL levels were similar between the groups at all time points.

Safety analysis of the data revealed the following: 7 cardiac related adverse events in the epoetin group compared to 6 in the saline group. There was 1 thrombosed allograft in the epoetin group and 2 peri-transplant hematomas in the saline group. There were no deaths.

In conclusion, epoetin alfa did not decrease the incidence of DGF but showed a trend towards an increase in IGF after DDKT. Epoeitin alfa had no influence on urinary biomarkers of AKI.

## SA-PO2999

**Cellular Presensitization Converges with Ischemia Reperfusion Injury To Increase the Risk of Acute Rejection after Kidney Transplantation** Donald E. Hricik,[1] Aparna Padiyar,[1] Kenneth A. Bodziak,[1] Peter S. Heeger,[2] Joshua J. Augustine.[1] *[1]Medicine, University Hospitals Case Medical Center, Cleveland, OH; [2]Medicine, Mt. Sinai School of Medicine, New York, NY.*

Recent studies suggest that an interplay between innate and alloimmunity can influence early outcomes after kidney transplantation. Innate immunity may be triggered by ischemia reperfusion injury (IRI). Alloimmune responses vary among individuals. Humoral alloimmunity is conventionally assessed by detecting preformed anti-HLA antibodies (panel reactive antibodies (PRA)). We previously have described the ELISPOT assay for interferon gamma as a measure of T cell alloimmunity. To determine the interplay between presensitization and IRI and their effects on early acute rejection, we studied 79 consecutive recipients of deceased donor kidney transplants from our center for whom pretransplant donor specific ELISPOT and PRA were available. Characteristics of the patients: age 46.1±12 yrs, 49% male, 50% African American, HLA mismatches 3.9±1.8, time on dialysis 47.2±31 mos. 28% had positive pretransplant ELISPOT (≥25/300K cells); 6% had peak PRA≥80%; 23% had delayed graft function (DGF) (need for dialysis in first week); 22% had biopsy-proven acute rejection (AR) in the first year. The incidence of AR was 39% vs 16% in patients with and without DGF (p=0.042), and 36% vs 16% in patients with and without a positive pretransplant ELISPOT. The incidence of AR was 67% for patients with a combination of DGF and a positive pretransplant ELISPOT vs 18% in those without DGF and with a negative ELISPOT (p=0.005). Logistic regression showed that the combination of DGF and a positive pretransplant ELISPOT was a significant correlate of AR (odd ratio 9.2, 95% CI 1.53-55.9, p=0.016) independent of age, ethnicity, gender, HLA mismatch, time on dialysis, PRA, or either DGF or a positive ELISPOT alone. The results suggest that heightened pretransplant cellular alloimmune responses measured by the ELISPOT assay for interferon gamma increase the risk of AR in patients with DGF. The ELISPOT assay may play an important role in pretransplant immune risk assessment, especially in patients at risk for DGF.

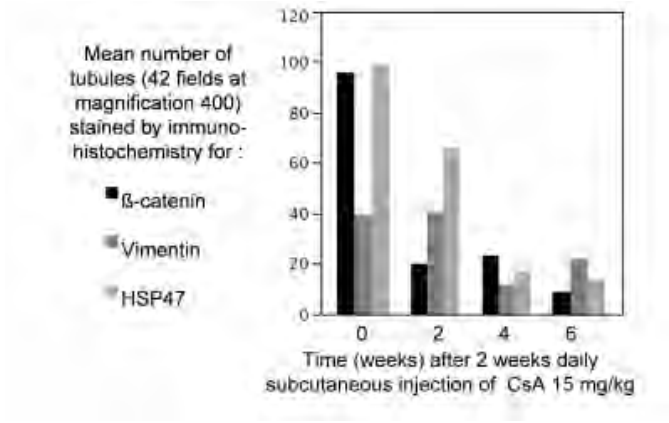
## SA-PO3000

**Epithelial to Mesenchymal Changes Are Early and Reversible Markers of Cyclosporine Nephrotoxicity In Vivo** Pierre Galichon,[1,2,3] Nathalie Vittoz,[1,2] Emilie Cornaire,[2] Edith Baugey,[2] Sophie Vandermeersch,[2] Marie-Christine Verpont,[2] Laurent Mesnard,[1,2,3] Yi-Chun Xu-Dubois,[1,2] Alexandre Hertig,[1,2] Eric Rondeau.[1,2] *[1]UNTR, APHP, Paris, France; [2]U702, INSERM, Paris, France; [3]ED394, UPMC, Paris, France.*

A widely used immunosuppressant, cyclosporine A (CsA) conveys long-term nephrotoxicity (interstitial fibrosis and tubular atrophy) through unknown mechanisms. No specific marker is hitherto available to measure CsA toxicity in exposed individuals. In native and transplanted human kidneys, Epithelial to Mesenchymal Transition (EMT) markers are expressed by tubular epithelial cells (TEC) in various nephropathies and -in grafts- predict evolution towards interstitial fibrosis. We hypothesized that CsA could activate EMT pathway in TEC with subsequent renal fibrosis. We studied the kinetics of the expression of EMT markers β-catenin, vimentin, and HSP47 at the protein and mRNA level in the kidneys from rats injected 15 mg/kg/day of CsA or its vehicle for 2 weeks, and followed for 6 weeks after CsA wash-out. By 2 weeks, CsA had induced histological changes (tubular dilation and vacuoles) contemporarily of the expression of EMT markers by TEC. Interestingly, CsA wash out lead to gradual regression of these tubular lesions, however EMT markers were persistently expressed 4 and 6 weeks later in those tubules that were surrounded by de novo fibrosis. Angiotensin 2 and endothelin receptor antagonists were tested for their ability to prevent CsA-induced EMT, but to no avail. Our study suggests that EMT markers could help to identify and localize ongoing CsA-induced toxicity in TEC. Whether or not EMT fully occurs in human kidneys is still debated, yet the durable expression of EMT markers by rat TEC exposed to CsA in vivo, and the coincidence of fibrosis around those TEC, encourages to further explore their value as markers of CsA toxicity and their role in human graft fibrosis.



Disclosure of Financial Relationships: nothing to disclose

**SA-PO3001**

**Agonistic Antibodies to the Angiotensin AT1-Receptor after Kidney Transplantation** Martina Guthoff,[1] Falko Fend,[2] Silvio Nadalin,[3] Nils Heyne.[1] *[1]Dept. of Diabetes and Endocrinology, Angiology, Nephrology and Clinical Chemistry, University of Tuebingen, Tuebingen, Germany; [2]Dept. of Pathology, University of Tuebingen, Tuebingen, Germany; [3]Dept. of General-, Visceral- and Transplantation Surgery, University of Tuebingen, Tuebingen, Germany.*

Agonistic antibodies to G-protein coupled receptors form an alternate pathway of receptor activation, distinct from ligand interaction. AT1-receptor agonistic antibodies (AT1-RAA) have been described in the setting of preeclampsia, arterial hypertension and kidney transplantation. We report clinical course and histopathological findings of early antibody-mediated rejection (AMR) and malignant hypertension in a renal allograft recipient secondary to non-HLA AT1-RAA.

A 48-yr. old patient underwent first kidney transplantation in a standard immunologic risk situation. Despite primary function, the patient became anuric on day 2 with loss of diastolic flow in the transplanted kidney. Serial renal biopsies revealed massive congestion of large vessels and glomeruli with progressive endothelialitis and atypical positive C4d staining, sparing peritubular capillaries. Plasmapheresis and a course of corticosteroids was initiated without improving renal function. Subsequently, malignant hypertension developed requiring i.v. antihypertensive therapy. No donor-specific HLA antibodies were detectable. In search of non-HLA antibodies, agonistic antibodies to the angiotensin AT1-receptor were detected.

Within 48 hours upon initiation of AT1-receptor blockade by losartan, malignant hypertension and allograft perfusion normalised and the patient developed polyuria. Renal outcome at nine months is excellent under continuous AT1-receptor blockade. Follow-up biopsy revealed no signs of AMR.

In conclusion, non-HLA AT1-RAA are a rare cause of AMR in kidney transplantation. Underlying pathomechanisms include endothelial activation, interaction of recipient preformed AT1-RAA with naïve donor endothelium and altered AT1 receptor signalling. Both, functional hemodynamic and histopathological alterations are responsive to AT1-receptor blockade. Screening for AT1-RAA prior to transplantation could identify patients at risk for non-HLA AMR.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3002**

**The Effect of Cyclosporine-Induced Renal Injury on *Klotho* Gene Expression in Reduced Renal Mass** Hye Eun Yoon,[1] ShangGuo Piao,[2] Jungyeon Ghee,[2] Ji-Hyun Song,[2] Seok Joon Shin,[1] Chul Woo Yang.[2] *[1]Internal Medicine, Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, Republic of Korea; [2]Transplant Research Center, The Catholic University of Korea, Seoul, Republic of Korea.*

We have previously shown that *Klotho* expression is suppressed in an experimental model of chronic cyclosporine (CsA) nephropathy (Transplantation 2010 in press), but it is unclear whether decreased *Klotho* expression is influenced by CsA toxicity per se or is secondary to renal insufficiency independent from CsA. Under a low-salt diet, mice underwent sham-operation (Sham) or 5/6 nephrectomy (5/6NX), and were daily administered subcutaneously olive oil (1mg/kg) or CsA (30mg/kg) for 4 weeks. We performed Western blot and immunohistochemistry for *Klotho* in kidney. The results showed that KLOTHO significantly decreased in the Sham+CsA (41.0±5.2%) or 5/6NX groups (33.7±7.1%) compared with the Sham group (111.3±11.3%), and further decreased in the 5/6NX+CsA group (9.2±4.3%) compared with the Sham, Sham+CsA or 5/6NX groups ($P < 0.05$). This finding clearly demonstrates that KLOTHO expression is decreased in kidney with reduced mass or chronic CsA nephropathy, and addition of CsA treatment further decreases it. In conclusion, reduction in KLOTHO expression observed in chronic CsA nephropathy depends upon CsA-induced renal injury.

**Diminished Met Signaling in Podocytes Contributes to the Development of Podocytopenia in Transplant Glomerulopathy** Putri Andina Agustian,[1] Mario Schiffer,[2] Wilfried Gwinner,[2] Irini Tossidou,[1] Clemens L. Bockmeyer,[1] Verena Broecker,[1] Jan U. Becker.[1] *[1]Medizinische Hochschule Hannover, Institut für Pathologie, Hannover, Lower Saxony, Germany; [2]Medizinische Hochschule Hannover, Klinik für Nieren- und Hochdruckerkrankungen, Hannover, Lower Saxony, Germany.*

Introduction:

Transplant glomerulopathy (TxG) can show secondary focal and segmental glomerulosclerosis (FSGS). While TxG is generally accepted to be primarily due to glomerular endothelial cell (GEC) damage, FSGS in native kidneys is caused by podocytopenia. The present study shall demonstrate podocytopenia in TxG and examine the role of decreased paracrine Met activation on podocytes by decreased HGF secretion of damaged GECs in the development of podocytopenia in TxG.

Methods:

Podocytes were counted in 10 zero hour biopsies and specimens with and without TxG.

HGF/Met signaling was examined in immunostains and quantitative RT-PCR in a set of biopsies from 10 patients with TxG including the diagnostic biopsy (DiagnBx) and two preceding biopsies (1stPrevBx and 2ndPrevBx). The effect of HGF on immortalised mouse podocytes was examined in vitro.

Results:

Podocyte counts were lower in TxG, glomerular size larger, than in the specimens without TxG.

Less of the two preceding biopsies of the patients than of the controls contained phospho-Met(Tyr1349) positive podocytes (2/8 vs. 7/7, p=0.0070; 4/9 vs. 9/9, p=0.0249). Glomerular HGF mRNA levels were lower in the 1stPrevBx of the patients (0.049 ± 0.083 vs. 0.284 ± 0.331; p=0.0185).

HGF stimulation of podocytes caused phosphorylation of AKT and ERK and induction of XIAP in vitro.

Conclusion:

Decreased podocyte density, caused by a combination of podocyte loss and glomerular hypertrophy is a feature of TxG. Decreased antiapoptotic Met signaling in podocytes, probably due to decreased HGF secretion by GECs could contribute to podocyte loss and FSGS in TxG.

**SA-PO3004**

**Subclinical Rejections and Inflammation Are Still Prevalent after Renal Transplantation** Willy Aasebo,[1] Anna Reisaeter,[2] Karsten Midtvedt,[2] Finn P. Reinholt,[2] Christina Dörje,[2] Hallvard Holdaas.[2] *[1]Akershus University Hospital, Oslo, Norway; [2]Oslo, University Hospital, Rikshospitalet, Oslo, Norway.*

**Background**. Although the prevalence of subclinical rejections has declined with "modern" immunosuppressive regimes including tacrolimus and mycophenolate mofetil (MMF) there is a great variability in reported incidence.

**Objective:** In a large transplant unit we introduced in 2009 protocol biopsies at week 6 after renal transplantation. We wanted to assess the incidence of subclinical rejection in renal recipients receiving regimen consisting of basiliximab, cyclosporine/tacrolimus, MMF and prednisolone. CNI allocation to Cya or Tac was based on age, body mass index, and pretransplant oral glucose test.

**Results:** A total of 262 surveillance renal transplant biopsies were performet. We excluded patients with donor specific antibodies, AB0 incompatibility, combined pancreas and kidney and biopsies for cause (n=83). Biopsies were classified according to Banff criteria. In the remaining 179 low-risk patients with protocol biopsy during one year 10% of the patient had subclinical rejections (1 case of subclinical humoral rejection). Including borderline findings 36% of the patients had sign of inflammation/rejection at week 6.

Subclinical rejections

| | Negative | Borderline | Rejection |
|---|---|---|---|
| | n = 115 | n = 46 | n = 18 |
| Recipient age | 56.9 (13.5) | 50.9 (14.6) | 51.4 (14.5) |
| Donor age | 49.0 (15.5) | 52.1 (17.7) | 43.4 (16.0) |
| HLA-mismatch | 2.5 (1.4) | 3.3 (1.1) | 2.9 (1.4) |
| Living donor, number (%) | 42 (36.5) | 21 (45.7) | 6 (33.3) |
| Creatinine, µmol/L | 118 (35) | 125 (59) | 129 (42) |
| Protein/creatinine ratio | 30 (31) | 30 (33) | 76 (95)• |
| Interstitial fibrosis (0-3) | 0.56 (0.53) | 0.84 (0.42) | 1.14 (0.68)• |
| Cyclosporine as CNI | 73 (64) | 30 (65) | 11 (61.1) |

• = p<0.05

**Conclusion:** Biopsy findings of subclinical rejections were frequent in a selected low risk transplant population 6 weeks after transplantation. Although the presence of interstitial fibrosis overall was moderate patients with subclinical rejection demonstrated significantly more fibrosis than patients with no or borderline rejections. Subclinical rejection was associated with an increase in protein excretion.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3005**

**Matrix-Gla-Protein, Fetuin and Osteopontin in Calcification of Renal Allografts** Johan Lorenzen M. Lorenzen, Hermann G. Haller, Wilfried Gwinner. *Nephrology, Hanover Medical School, Hanover, Germany.*

Background: Calcification of renal allografts is not uncommon in the first year after transplantation and is related to hyperparathyroidism. It is associated with an impaired long-term outcome (Am J Transplant 2005;5:934-41).

Aim of this study is to examine surrogate factors in blood and urine which are related to renal allograft calcification.

Methods: We analyzed blood and urine samples of 30 patients with and 30 patients without allograft calcification taken at 6 weeks, 3 and 6 months after transplantation. To dissect factors for calcification besides hyperparathyroidism, patients were matched for their parathyroid hormone levels. Analyses included serum and urine electrolytes, Matrix-Gla protein, fetuin, FGF-23 in serum/plasma and osteopontin (OPN) in urine. Patient demographical data, cold ischemia time, initial graft function and donor characteristics were comparable between the two groups.

Results: In patients with calcification, matrix-Gla protein levels were significantly higher (25%) at 6 weeks compared to control patients without calcification, but decreased thereafter, reaching levels that were 27.5% lower than that of the controls at 6 months. There was no difference in FGF-23 levels. Fetuin levels were higher in patients with calcification (16.2% at 6 weeks; p=0.021 and 22.9% at 3 months; p=0.06) (Fig 1). Urinary OPN was considerably lower compared to the control group at 6 weeks after transplantation (by 66.4%; p<0.001), but increased by 6.2-fold, reaching values 75.6% over the controls at 6 months after transplantation. Using immunohistochemistry we could demonstrate that Matrix-Gla protein, osteopontin and fetuin are specifically expressed in the vicinity of calcified areas of renal allografts. Vitamin D and PTH levels were not different between the groups.

Conclusions: The striking differences in serum Matrix-Gla-protein and fetuin, and urinary OPN point to an important involvement of these factors in the process of allograft calcification.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3006**

**Exploring Kidney Microbiome and Its Role in Transplant (Graft) Survival** Vasuki N. Venkat, Ying Huang, David L. Perkins. *Division of Nephrology-Hypertension, University of California, San Diego, San Diego, CA.*

Metagenomics is a powerful tool for microbial and viral discovery,as nucleic acids can be isolated directly from environmental samples and sequenced without a priori knowledge or having to culture or clone. Advances in DNA sequencing technologies such as high throughput sequencing methods allow for the relatively inexpensive and rapid acquisition of millions of base pairs of high quality sequence data from various metagenomic communities. Using these methods, our objective is to identify the renal microbiome following kidney transplantation, and investigate their role in graft function and survival. Hypothesis: Changes in the metagenome following transplantation modulate renal injury and function. Urine provides a nonvasive biological sample to study the kidney microbiome. Methods: Urine collected from normal control and transplanted kidneys was pretreated with polyethylene glycol to concentrate the viral like particles (VLPs). Next,the VLPs were extracted by performing cesium chloride density gradient ultracentrifugation. Nucleic acids were then extracted by formamide/Cetyltrimethylammonium bromide methods using the standard Sambrook's protocol. The resulting purified DNA was then sequenced using Illumina Genomic DNA preparation kit. Using our purification protocol, we identified particles staining for DNA by epifluoresence microscopy, while no particles were detected in the supernatant from the same subject prior to centrifugation.

Results: DNA sequencing results from the preliminary samples indicate the presence of viruses both in renal transplant and normal controls. The following viruses have been identified in the urine samples collected after transplantation - BK polyomavirus, JC polyomavirus, Simian virus 12, Simian agent 12, Simian virus 40, Encephalomyocarditis virus, Macacine herpesvirus and Pepino mosaic virus. The significance of these viruses as related to their contribution towards graft survival is yet to be studied.

**DSAb Positive Acute Cellular Rejection Is Associated with Increased Risk of Subsequent Antibody Mediated Rejection, Transplant Glomerulopathy and Allograft Loss** Michelle Willicombe, Jack W. Galliford, Paul Brookes, Adam Mclean, Candice A. Roufosse, H. Terence Cook, Tom Cairns, David Taube. *Imperial College Kidney and Transplant Institute, London, United Kingdom.*

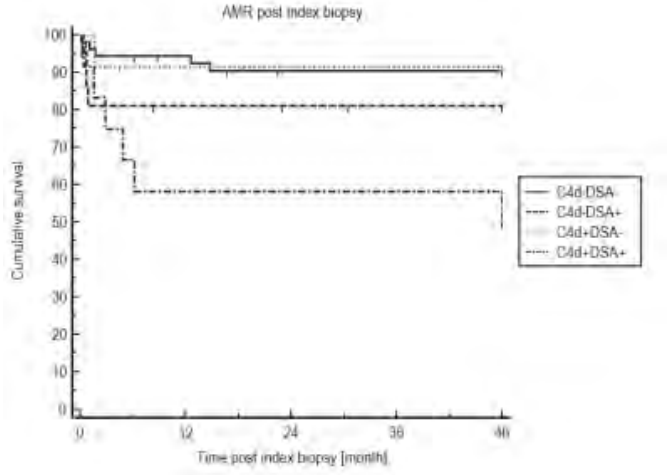
Although most T cell rejection [TCR] is rapidly and successfully reversed, there are a subgroup of patients who develop recurrent rejection and lose their allografts.

In this study, we have used C4d staining and Luminex single antigen bead screening for donor specific antibodies [DSAbs] to identify patients with TCR who may be at increased risk of further rejection and graft loss.

We retrospectively identified 100 patients [m: f, 76:24; mean age 43.96 ±13.11years; deceased: live donor 54:46; first: regraft 86:14; mean HLA mismatch 3.48 ±1.72] with histologically proven TCR. All patients received monoclonal antibody induction with tacrolimus, mycophenolate mofetil [MMF] and a steroid sparing regime. ACR was treated conventionally with iv methyl prednisolone and oral steroids. Mean follow up post TCR was 18.2 ±12.66 months.

54/100 patients were C4d-DSAb-, 22/100 patients were C4d-DSAb+, 12/100 were C4d+DSAb- and 12/100 were C4d+DSAb+. 3 year patient survival was similar in all groups. Compared with C4d-DSAb- patients, C4d+DSAb+ patients had inferior 3 year allograft survival [90.7%, 58.3%, p=0.023] and an increased risk of subsequent AMR [90.4%, 50.0%, p=0.005, Figure 1].

5/12 [41.67%] C4d+DSAb+ patients compared with 3/54 [5.56%] DSAb-C4d- went on to develop transplant glomerulopathy [p=0.0034].



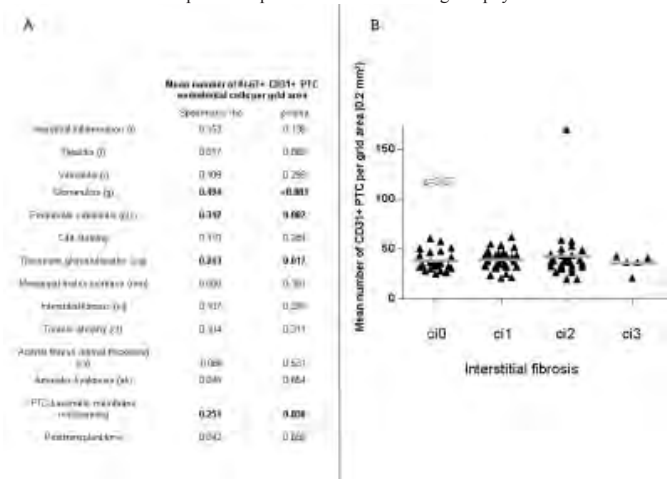
This is the first reported study showing that DSAb screening at the time of TCR predicts subsequent AMR, transplant glomerulopathy and graft failure. DSAb+ patients with TCR may benefit from enhanced surveillance and pre emptive augmented immunosuppression.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3008**

**Peritubular Capillary Endothelial Cell Cycling Is Selectively Increased in Antibody-Mediated Rejection of Kidney Transplants, but Not in Other Diseases** Stephen Adebayo Osasan, Jessica Chang, Yasemin Ozluk, Michael Mengel, Philip F. Halloran, Banu Sis. *University of Alberta, Edmonton, AB, Canada.*

Microcirculation endothelium is the main target of antibody-mediated rejection (ABMR). We hypothesized that ABMR is associated with a greater endothelial repair response compared to other diseases operating in kidney transplants. We related peritubular capillary (PTC) endothelial cell cycling and density of PTCs to histopathological Banff lesions and diagnoses, and whole-genome microarrays in 96 non-selected kidney transplant biopsies for cause. We performed double-immunostaining to label PTCs with anti CD31 and cycling cells with anti Ki-67. The PTC density and proliferating PTC endothelial cells were quantified by counting the number of CD31+ PTCs and Ki-67+CD31+ PTC endothelial cells, respectively, in the entire cortical biopsy area. The PTC endothelial cell cycling was selectively increased in C4d positive ABMR and C4d negative ABMR, but not in other diseases i.e. TCMR, acute tubular necrosis, glomerulonephritis (p=0.005). Increased PTC endothelial cell proliferation correlated with microcirculation lesions: glomerulitis, peritubular capillaritis, transplant glomerulopathy, and PTC basement membrane multilayering, but not with other lesions or C4d staining. Furthermore, transcript sets representing the molecular burden of active ABMR (endothelial cell-, macrophage-associated transcripts, IFNG regulated transcripts) correlated with increased PTC endothelial cell cycling (p<0.05). However, the PTC density did not differ among diagnoses and was not correlated with time post-transplant or lesions including atrophy and fibrosis.



Our results indicate that endothelial repair response is selectively increased in kidneys with ABMR, and there is no evidence for reduced PTC density among diseases, even with ABMR or significant scarring.

### SA-PO3009

**Relationship between Albuminuria and Allograft Pathological Changes Associated with Diabetic Kidney Disease** Izumi Nyumura,[1] Tetsuya Babazono,[1] Kazuho Honda,[2] Yasuhiko Iwamoto.[1] *[1]Department of Medicine, Diabetes Center, Tokyo Women's Medical University, Tokyo, Japan; [2]Department of Pathology, Tokyo Women's Medical University, Tokyo, Japan.*

**Background and aims:** Albuminuria is a fundamental manifestation of diabetic kidney disease (DKD); however, information regarding relationship between urinary albumin excretion and recurrence and severity of DKD in the renal allograft has been scarce. We therefore conducted this study to highlight the relationship between urinary albumin excretion and clinical or histological parameters associated with DKD in renal allograft in diabetic patients.

**Materials and methods:** 37 diabetic renal allograft recipients who underwent allograft biopsies 2 to 16 years after transplantation were studied. Patients were classified into the following two groups according to the urinary albumin-to-creatinine ratio (ACR) at kidney biopsy: those with normo- or microalbuminuria (ACR < 300 mg/g, N=21) and those with macroalbumiruia (ACR ≥ 300 mg/g, N=16). Histological glomerular changes including mesangial/glomerular areas and glomerular capillary number were analyzed by a computer-assisted image analyzer. Thickness of glomerular basement membrane (GBM) was evaluated by an electron microscopy.

**Results:** There were no significant differences between the two groups in terms of recipient age, posttransplant duration, blood pressure and hemoglobin A1C. Serum creatinine was significantly higher in macroalbumiruic patients than normo- and microalbuminuric patients. In the univariate correlational analysis, ACR was significantly related with serum creatinine (rs=0.42, p=0.01). Pathological changes in the allograft that are characteristic of DKD; *i.e.*, mesangial/glomerular areas, glomerular capillary number, and thickness of GBM were not different in the two groups. In contrast, the grade of tubulo-interstitial lesions were significantly higher in macroalbuminuia group (p=0.005).

**Conclusions:** Albuminuria was not associated with the clinical and histological parameters of DKD but with the renal function and tubulo-interstitial lesions of renal allograft in diabetic transplanted patients.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO3010

**Effect of Cholecalciferol Supplementation on Renal Allograft Structural and Functional Deterioration** Marie Courbebaisse,[1] Yi-Chun Xu-Dubois,[2] Eric Thervet,[3] Gerard Friedlander,[4] Christophe M. Legendre,[3] Eric Rondeau,[2] Nicolas Palllet.[3] *[1]Nephrology and Dialysis Unit, Hopital Tenon APHP, Paris, France; [2]Transplantation Unit, INSERM U702, Hopital Tenon APHP, Paris, France; [3]Transplantation Unit, Hopital Necker APHP, Paris, France; [4]Renal Physiology Unit, Hopital Necker APHP, Paris, France.*

Beneath their important role in mediating calcium homeostasis, vitamin D receptor (VDR) agonists inhibit renin angiotensin system, inflammation and fibrosis. Renal models of chronic kidney injury and some clinical observational studies showed that VDR agonists could afford nephroprotection. The aim of this study is to test whether vitamin D3 (cholecalciferol, CLC) supplementation may confer structural and functional nephroprotection during the first year after renal transplantation. We analyzed glomerular filtration rate (GFR) using iohexol plasma clearance, urinary procollagen III aminoterminal propeptide excretion (uPIIINP), tubular vimentin expression and nuclear beta-catenin staining as markers of epithelial to mesenchymal transition (EMT) by immunohistochemistry and Banff scores of interstitial fibrosis (IF) and tubular atrophy (TA) at 3 months (M3) and M12 post transplantation in 32 renal transplant recipients (RTR) supplemented with CLC between M3 and M12 (100 000 UI every other week during 2 months and 100 000 UI every other month thereafter) and compared with an historical control group of 32 RTR. Clinical and biological characteristics of the two groups were similar at M3. At M12, serum 25(OH)vitamin D was higher (31.8±7.1 vs 16.6±6.6 ng/ml, p<0.0001) and serum parathormone was lower in the treated group. During the follow-up period, we found no difference regarding the incidence of biopsy proven acute rejection, new onset diabetes or hypertension between both groups. Mean GFR and uPIIINP remained stable and similar in both groups. Between M3 and M12, IF/AT and EMT scores increased similarly in the two groups. We show that CLC supplementation in these stable RTR does not prevent EMT, IF and TA. Our results suggest that this dosage of CLC does not afford major nephrotection during the first year after renal transplantation.

**The Effect of Bafilomycin A1 on Apoptosis and Autophagy in Cold Preservation Ischemia** Kultigin Turkmen, Ali Akcay, Jessica Martin, Iram Zafar, Quocan Nguyen, Dong Won Lee, Zhibin He, Alkesh Jani, Charles L. Edelstein. *Univ of Colorado.*

Apoptosis and autophagy are the two fundamental types of genetically controlled cell death. The aim of our study was to determine the connection between autophagy and apoptosis in a mouse model of cold preservation ischemia (CPI). C57BL/6 mice weighing 20-25 g were used. Kidneys were perfused via the left ventricle with cold University of Wisconsin (UW) solution with/without bafilomycin A1 (2 mg/kg), an autophagy inhibitor. One kidney was preserved in $4^0$ for 48 hours and the other kidney was the control. Immunoblotting was used to detect LC-3, ATG-5 and Beclin-1 as markers of autophagy and BID, Bax and Caspase-3 as markers of apoptosis. Caspase-3 activity was measured using fluorescent substrates. Table 1 shows the results of immunoblotting and caspase activity. In summary, in CPI, proapoptotic markers BID, Bax and caspase-3 and autophagy markers LC3, ATG-5 and beclin-1 are increased. Bafilomycin inhibits both apoptosis and autophagy markers. Bafilomycin may prove useful in cold preservation of organs for transplant.

Table 1

| Markers | Vehicle 0 hr | Vehicle 48 hr | Bafilomycin A1 2mg/kg 48 hr | P value |
|---|---|---|---|---|
| Caspase-3 (active 17 kDa) | + | +++ | 0 | P<0.005 |
| BID (22 kDa) | 0 | ++++ | 0 | P<0.005 |
| Bax (20 kDa) | + | +++ | 0 | P<0.005 |
| LC-3-I (19kDa) | + | +++ | 0 | P<0.05 |
| LC-3-II (active 17kDa) | + | +++ | 0 | P<0.05 |
| ATG-5 (33 kDa) | + | ++++ | 0 | P<0.005 |
| Beclin-1 (55 kDa) | + | +++ | 0 | P<0.005 |
| Caspase-3 (nmol/min/mg) | 4.0 | 9.6 | 4.3 | P<0.05 |

+, 1-fold increase; +++, 3-fold increase; ++++, 4-fold increase

### SA-PO3012

**Primary Glomerular Disease among 1006 Adult Kidney Transplant Recipients: A Single Center Experience** Aaron M. Dommu, Rupesh R. Mehta, Thangamani Muthukumar, Meredith Aull, Surya V. Seshan, Manikkam Suthanthiran. *Cornell University, New York, NY.*

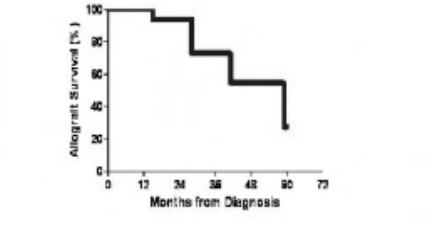
Our purpose was to identify the incidence of primary glomerular disease (PGD) in our transplant center and its impact on graft outcome.

We performed a chart review of all for-cause adult kidney transplant biopsies from our pathology records from 2003-2008 to look for PGD as the diagnosis. Allograft survival was defined as the time from diagnosis of PGD to ESRD. Patients (pts) who did not reach the endpoint were censored at their last follow up.

There were 1006 pts transplanted at our center during 2003-2008. A total of 451 for-cause biopsies were performed on 294 pts (29%). PGD was the 6th most frequent diagnosis (6%), after ATN (25%); Cellular Rejection (19%); CNI toxicity (14%); AMR (11%); and IFTA (7%). In the 19 pts with post-transplant PGD, the diagnosis was made at median of 9.5 months (range: 0-66) after transplantation. The mean (±SD) age was 41±15 years. 47% of the pts received living donor transplants. The median creatinine was 2.20 (range: 0.7-6.3) mg/dl and proteinuria was 4.3 (range: 0.7-22) gm/day. Ten of the 19 pts had native kidney biopsies prior to their transplants.

| Patient | Age | Sex | Race* | ESRD Cause | Donor Type | Allograft Biopsy | Graft Loss |
|---|---|---|---|---|---|---|---|
| 1 | 33 | F | H | FSGS | Deceased | FSGS | No |
| 2 | 20 | M | AA | FSGS | Living Related | FSGS | No |
| 3 | 12 | M | C | FSGS | Deceased | FSGS | No |
| 4 | 60 | M | AA | FSGS | Living Related | FSGS | No |
| 5 | 21 | M | AA | FSGS | Living Unrelated | FSGS | No |
| 6 | 30 | M | C | FSGS | Living Related | FSGS | No |
| 7 | 60 | M | AA | unknown | Deceased | FSGS | No |
| 8 | 18 | M | H | unknown | Deceased | FSGS | No |
| 9 | 60 | M | AA | unknown | Deceased | FSGS | Yes |
| 10 | 45 | M | AA | unknown | Deceased | FSGS | Yes |
| 11 | 36 | M | AA | unknown | Living Related | FSGS | Yes |
| 12 | 28 | F | H | unknown | Living Related | FSGS | No |
| 13 | 31 | F | C | unknown | Deceased | Minimal Change | No |
| 14 | 30 | M | H | Membranous | Deceased | Membranous | No |
| 15 | 40 | M | H | Membranous | Living Related | Membranous | No |
| 16 | 66 | M | C | unknown | Living Unrelated | Post infectious GN | No |
| 17 | 55 | M | C | unknown | Deceased | Post infectious GN | Yes |
| 18 | 44 | F | H | MPGN | Living Related | MPGN | Yes |
| 19 | 40 | M | O | IgM nephropathy | Deceased | IgM nephropathy | No |

* AA-African-American, C-Caucasian, H-Hispanic, O-Other



Five pts (26%) reached ESRD after a median of 40 months from the diagnosis (range: 16-49). The 3 year allograft survival after the diagnosis of PGD for the entire cohort was 73%. One pt died with a functioning allograft. The remaining 13 living pts with a functioning graft had a median creatinine of 1.7 (range: 0.9-5.1) mg/dl and median proteinuria of 0.64 (range 0-7.4) gm/day at most recent follow-up, 25 months (median) from the diagnosis. FSGS was the most common diagnosis and was found in 12 pts (63%).

PGD constitutes 7% of histologic diagnoses among transplant pts who undergo for-cause biopsies, and FSGS is the commonest lesion. A significant proportion of pts with PGD lose their graft.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3013**

**Cigarette Smoking Effects on a Chronic Cyclosporine Nephrotoxicity Model**
Sueli Alves,[1] Gloria E. Mendes,[1] Marcos Luz,[1] Rafael Souza,[1] Rael Matimoto,[1] Terezila Machado Coimbra,[2] Emmanuel A. Burdmann.[1,2] *[1]Sao Jose do Rio Preto Medical School; [2]University of Sao Paulo, Brazil.*

The aim of this study was to assess the effects of cigarette smoking (CS) on chronic cyclosporine (CsA) nephrotoxicity. Male rats were exposed to CS (smoking chamber) or sham procedure (smoking chamber without CS) for 10 min, twice a day for 20 weeks (w). From the 16 to the 20th w rats received low salt diet and on the 17th w they were given CsA 2.5 mg/day or vehicle (VH) for 3 w. Final groups were CS+VH, sham+VH, CsA+CS (CsACS) and CsA+sham (CsA). On day 141, GFR (inulin clearance, ml/min/100g), RBF (Doppler ultrasound, ml/min), RVR (mmHg/ml/min), tubulointerstitial fibrosis (TIF, score 0-4), CsA blood level (ng/ml) and immunohistochemistry for α-SMA, nitrotyrosine (Ny) and vimentin (Vi) were assessed.

Results for rats receiving VH with or without CS were identical, so they were presented as a single group. Data (mean±SE) were analyzed by one-way ANOVA with post-test. CsA caused GFR decrease (0.53±0.05 vs. 0.83±0.15 in VH, p<0.001), which was enhanced by CS (0.39±0.03, p<0.05 vs VH and CsA). CsA alone or with CS decreased RBF (CsA 3.81± 0.59, CsACS 3.91±0.59 and VH 6.68±1.0, p<0.01 VH vs. CsA and CsACS) and increased RVR (26.7 ± 3.2 in CsA, 26.1 ± 2.5 in CsACS and 16.8 ± 3.1 in VH, p<0.001, VH vs CsA and CsACS). CsA promoted TIF, not affected by CS: CsA 0.21 ± 0.08, CsACS 0.17±0.03 and VH 0.03 ± 0.02 (p<0.001, CsA and CsACS vs VH). CS did not affect CsA blood levels (CsA 1888 ± 334 and CsACS 1601 ± 577). CsA enhancement of TI α-SMA was not influenced by CS (CsA 1.7±0.4, CsACS 1.8±0.3 and VH 0.77±0.3, p<0.001, CsA and CsACS vs VH). CS increased CsA-induced α-SMA expression in the periglomerular area (CsA 0.52±0.1 vs. VH 0.27±0.1, p<0.05 and CsACS 1.0±0.4, p < 0.001 vs VH and p<0.01 vs CsA). CsACS rats increased the expression of Ny when compared to CsA and VH (CsACS 2.96±0.3, CsA 2.45±0.2 and VH 2.35±0.4, p<0.01 CsACS vs. VH and p<0.05 CsACS vs. CsA). Only CsA-treated rats expressed VI (CsA 0.49±0.6, CsACS 0.44±0.4 and VH 0).

In conclusion, CS aggravated significantly CsA-induced GFR decrease, periglomerular structural lesion and oxidative stress in a model of chronic CsA nephrotoxicity.

**The Response of *Klotho* Gene Expression Against Cyclosporine-Induced Renal Injury**
Hye Eun Yoon,[1] Jungyeon Ghee,[2] ShangGuo Piao,[2] Ji-Hyun Song,[2] Chul Woo Yang.[2] *[1]Internal Medicine, Incheon St. Mary's Hospital, Incheon, Republic of Korea; [2]Transplant Research Center, The Catholic University of Korea, Seoul, Republic of Korea.*

*Klotho* gene is an antiaging gene which has an antioxidant property. This study evaluated the response of *Klotho* gene expression against cyclosporine (CsA)-induced renal injury with different dosages and durations of CsA treatment.

First, under a low-salt diet, mice were daily administered olive oil (1mg/kg) and CsA (7.5mg/kg, 15mg/kg, and 30mg/kg) subcutaneously for one for 4 weeks. Second, mice were daily administered olive oil and CsA (30mg/kg) for one or 4 weeks. We performed RT-PCR, Western blot and immunohistochemistry for *Klotho* in kidney.

Short-term (1week) treatment with low-dose CsA (7.5mg/kg and 15mg/kg) increased *Klotho* expression in a dose-dependent manner, but long-term (4weeks) treatment with low-dose CsA decreased it. In contrast, treatment with high-dose CsA (30mg/kg) decreased *Klotho* expression in a time-dependent manner.

The response of *Klotho* expression was different against CsA-induced renal injury according to the dosages and durations of CsA. This suggest that adaption occurs in low-dose CsA by upregulating *Klotho* gene, but chronic CsA nephrotoxicity occurs in high-dose CsA by downregulating *Klotho* gene.

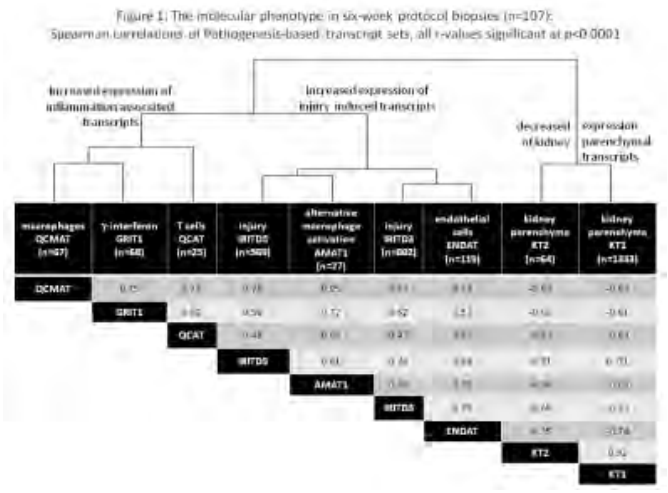
**SA-PO3015**

**The Molecular Phenotype of Six-Week Protocol Biopsies from Human Renal Allografts Reflects Prior Injury but Does Not Predict Outcome**
Michael Mengel,[1] Jeff Reeve,[1] Wilfried Gwinner,[2] Gunilla Einecke,[2] Declan G. de Freitas,[1] Anke Schwarz,[2] Banu Sis,[1] Hermann G. Haller,[2] Philip F. Halloran.[1] *[1]ATAGC, University of Alberta; [2]Division of Nephrology, Hannover Medical School.*

The rationale for protocol biopsies is to detect disease processes earlier, i.e. subclinically and thus putatively at a stage more amenable to treatment. We assessed the molecular phenotype in 107 six-week protocol biopsies from human renal allografts using Affymetrix microarrays. We summarized genome-wide expression data as pathogenesis based transcript sets (PBTs) reflecting inflammation, injury and loss of function in the kidney parenchyma. The molecular phenotype emerged as a robust correlation of increased inflammatory PBTs with increased injury PBTs and decreased expression in transcripts sets associated with normal nephron function.



Correlating this molecular phenotype to clinic-pathological variables before, at, and after the six-week protocol biopsy revealed it to be strongest associated with prior injury i.e. delayed graft function (r=0.41, p<0.001). A significant correlation between the six-week molecular phenotype with progression in interstitial fibrosis / tubular atrophy and persistence of inflammation between six-week and six-month protocol biopsies was found which did not translate into functional deterioration or allograft loss.

We conclude that in renal allografts the six-week subclinical molecular phenotype reflects prior injury to the graft but does not predict future outcome.

**SA-PO3016**

**Early High Dose Erythropoietin in ECD or NHBD Kidney Transplant Recipients Does Not Influence the Rate of Delayed Graft Function**
Declan G. de Freitas, Beatrice Coupes, Ian Read, Linda Birtles, Hany N. Riad, Paul Brenchley, Michael L. Picton. *Manchester Institute of Nephrology and Transplantation, Manchester Royal Infirmary, Manchester, United Kingdom.*

Non-heart-beating donor (NHBD) and extended criteria donor (ECD) renal transplant recipients are at increased risk of delayed graft function (DGF) in the post-operative period. Both human and animal models suggest that high dose erythropoietin (EPO) may confer protection from reperfusion injury. However, the efficacy and safety of high doses of EPO in renal transplant recipients has not been established.

We performed a single centre, randomised, double-blind, placebo-controlled trial in 39 recipients of an ECD or NHBD kidney. Patients randomised to the treatment group (n=19) received 3 IV injections of erythropoietin beta (33,000iu each), beginning prior to reperfusion and at 24 and 48 hrs post-operatively. The control group (n=20) received 0.9% saline. DGF was defined as the need for dialysis post-transplantation.

At baseline, there were no differences in patient age, donor characteristics or ischaemic time between the two groups. DGF occurred in 10/19 (52%) EPO recipients and 11/20 (55%) placebo recipients (p=0.88). The median number of dialysis episodes did not differ between groups (1 vs 1.5, EPO vs placebo, p=0.78). Rejection at 3 months occurred in 26% of EPO treated patients and 15% of placebo patients (p=0.28). Renal function was similar in both groups at 3 months (152.4umol/l ± 60.9 *vs* 175.6umol/l ± 83.68, $p$=0.33) and 1year (144.3umol/l ± 54.5 *vs* 150.6umol/l ± 64.6, $p$=0.78). Two deaths with a functioning graft occurred after 6 months in the placebo group due to septic complications. One graft was lost in the EPO group due to severe renal artery stenosis after 9 months. High dose erythropoietin was well tolerated with no drug related adverse events noted. Mean arterial pressure was similar at the end of the 3rd infusion (median 97mmHg for both groups). Haemoglobin levels and EPO usage were similar between the groups at all time points.

High dose erythropoietin administered IV peri-operatively was safe but did not confer protection from delayed graft function or influence graft function at 3 months or 1 year.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3017**

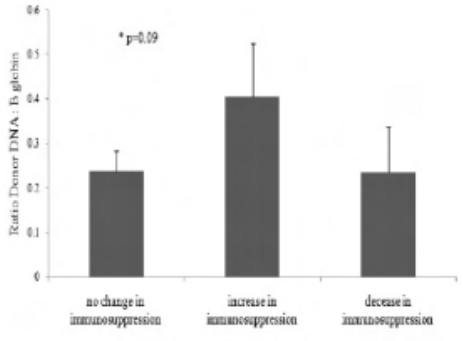
**Urinary Microchimerism Detection Predicts Allograft Injury**
Niamh E. Kieran,[1] Biswajit Paul,[2] Nicolae Leca,[1] Connie L. Davis,[1] Kimberly A. Muczynski,[1] Vijayakrishna K. Gadi.[2] *[1]Department of Medicine, University of Washington, Seattle, WA; [2]Clinical Research Center, Fred Hutchinson Cancer Research Center, Seattle, WA.*

Renal transplantation is the treatment of choice for many patients with end stage renal disease. Significant progress has been achieved in improving short-term outcomes, but long-term graft survival has only marginally improved. One reason for this is a lack of tools to accurately monitor for allograft injury. As transplantation is a form of iatrogenic chimerism, soluble donor DNA released as a result of allograft injury could serve as a quantifiable marker for rejection.

We prospectively recruited renal allograft recipients to provide urine at the time of biopsy procedures. Urine was processed for total genomic DNA and assayed for donor and total DNA by quantitative PCR. Donor DNA was amplified using HLA specific

primers non-shared with the recipient, total DNA with beta globin primers. Using change in immunosuppression as a clinical marker of biopsy outcome, we categorized the donor DNA:total DNA ratios into 3 groups (no change, immunosuppression either increased or decreased).

At this interim, clinical data and urinary chimerism results are available for 60 events in 48 patients. The majority of renal biopsies were performed for cause (n=54). Thirty-three recorded events were associated with no management change; 20, increase in immunosuppression (because of concern for rejection); 7, decrease in immunosuppression. There was no difference in creatinine between the groups. Interestingly, the mean urinary donor DNA:total DNA ratio was 0.24 (sem 0.05) in patients with no change in immunosuppression compared to 0.41(sem 0.12) in patients with increases in immunosuppression, *p*=0.09.



These preliminary results suggest a role for monitoring urinary donor-derived DNA as a marker of allograft injury post transplantation.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3018**

**Peritubular Capillary Basement Membrane Multilaminations in Renal Allografts: Typical but Not Pathognomonic for Antibody Mediated Injury** Georgios Liapis,[1] Harsharan K. Singh,[1] Vimal K. Derebail,[2] Tomasz Kozlowski,[3] Volker Nickeleit.[1] *[1]Pathology, UNC, Chapel Hill, NC; [2]Medicine, UNC; [3]Surgery, UNC.*

Peritubular capillary basement membrane laminations (PTCL) in transplants (tx) are thought to indicate chronic antibody mediated rejection. We aimed at determining the diagnostic significance of PTCL.

547 renal biopsies were analyzed (360 native,187 tx). PTCL was evaluated by electron microscopy, and cases with major changes (≥5 circumferential basement membrane layers - PTCL group B) were identified. PTCL-B was correlated with histologic findings/diagnoses and donor specific antibody titers (DSA).

PTCL-B was seen in 6.4% of native kidneys. It significantly correlated only with thrombotic microangiopathies (39% showing PTCL-B changes), and chronic tissue injury ($p<0.05$). In contrast, 36% of transplant biopsies showed PTCL-B ($p<0.05$), in particular late after grafting (5% in year-1, 61% after year-10). PTCL-B was associated with acute and chronic rejection (all $p<0.05$ by univariate analysis): peritubular capillaritis (61%), tx glomerulopathy (64%), glomerulitis (75%), endarteritis (38%), C4d positivity (61%), chronic vascular rejection (67%), elevated DSA (48%), and calcinurin-inhibitor toxicity (CNI 36%). PTCL-B was most tightly correlated with chronic antibody and/or T-cell mediated rejection (38-79% of cases, $p<0.05$). In a logistic regression model, the odds ratio (OR) for PTCL-B was 3.7 in cases with C4d positivity and 3.8 in biopsies taken >24 months post grafting (control group OR 0.24). Using the control group as reference, a diagnosis of CNI toxicity raised the OR for PTCL-B to 11, of acute cellular and/or antibody mediated rejection to 5-16, and chronic inactive or active cellular and/or antibody mediated rejection to 12-76.

PTCL-B is mainly found in tx biopsies post year-1 and in chronic active T-cell and/or antibody mediated rejection. Although PTCL-B is typical for an antibody mediated alloresponse, it is not pathognomonic. Between 21% and 62% of chronic rejection episodes do not show PTCL-B. However, if present, PTCL-B can serve as an adjunct marker of "rejection" and help avoid diagnoses of "CAN" or "IFTA".

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3019**

**Non-Immunological Factors and Non-Classical HLA Class I in Chronic Allograft Injury** Hitoshi Yokoyama. *Division of Nephrology, Kanazawa Medical University, Uchinada, Ishikawa, Japan.*

Background. Although the risk for morbidity and mortality is studied in subjects with renal transplantation, there are limited data to access the allograft survival in dyslipidemia, adiponectins and non-classical HLA class I. Methods. We investigated the alteration of estimated glomerular filtration rate (eGFR) based on the new 3-variable GFR-estimating equation for Japanese (194 x Serum Creatinine $(SCr)^{-1.094}$ x $Age^{-0.287}$ x 0.739, if female), and factors affecting the eGFR. We studied 120 adult subjects (age 19- to 72-year old; 77 males, 43 females; 23 cadaveric donors) for since January 2004. We examined clinical backgrounds, HLA matching, ischemic times, treated drugs, blood pressure, body mass index, and blood chemistry including lipids, total and high-molecular adiponectin (ADPN) levels, and circulating HLA-G5. Results. During the study periods, 5 years renal survival rate was 89.2%, and 15 subjects dropped out, because of end-stage renal failure in 6, death with a functioning kidney in 7, and moving in 2. Initial mean eGFR was 50.3 ml/min/1.73 $m^2$. The alteration of eGFR (ΔeGFR) was at -2.2 ml/min/1.73 $m^2$/year, which was higher in living donors than those of cadaveric donors (-2.8 vs. 0.1 ml/min/1.73 $m^2$/year, $p=0.002$). In single analyses, both LDL-C/HDL-C ratio below 2.0 and statin treatment decreased ΔeGFR at -1.4 and -1.0 ml/min/1.73 $m^2$/year, respectively. Serum high-molecular ADPN levels were reversely correlated with both eGFR and ΔeGFR (-0.240, $p=0.013$; -0.210, $p=0.031$, respectively). On the other hand, higher circulating HLA-G5 was selected as a renoprotective factor as well as statins in multivariate regression analysis (0.213, $p=0.038$; 0.258, $p=0.013$, respectively). The estimated equation of ΔeGFR (ml/min/1.73 $m^2$/year) was -6.710 + 2.138 x [donor type] (if cadaveric donor, 2; if living donor, 1) + 1.941 x [statin] (if treated by statin, 1) + 0.010 x [HLA-G] (serum HLA-G5 levels, U/ml) ($r=0.478$, $p<0.001$). Conclusion. Higher circulating HLA-G5 and statin could preserve the renal function judged by ΔeGFR in Japanese transplanted subjects, however. Total and high-molecular ADPN levels were reversely correlated with eGFR and ΔeGFR reported as an ADPN paradox.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3020**

**Everolimus (E) vs Enteric Coated Mycophenolate Sodium (EC-MPS): Proteomic and Pathologic Aspects** Elisabetta Bertoni,[1] Gianmarco Ghiggeri,[2] Marco Prunotto,[2] Solange Moll,[2] Maurizio Salvadori.[1] *[1]Renal Unit, Careggi University Hospital, Florence, Italy; [2]Division of Nephrology, Gaslini Hospital, Genova, Italy.*

Recent observations ascribe proteinuria after PSI use to apoptosis both of tubular and podocyte cells. Aim of this study was to compare by proteomic approach and protocol biopsies the effect of E vs EC-MPS in renal transplant (tx) recipients.

In a prospective, randomized, monocentric study 19 renal tx patients were enrolled to receive either E (8) or EC-MPS (11). E patients received high dose everolimus (C0 8-10 ng/ml) with CyA very low dose and steroids. The other group received EC-MPS (720 mg bid) with CyA standard dose and steroids. Urinary parameters were followed using proteomics for 1 year (quantitative assays, two dimensional electrophoresis, MALDI-TOF, Western blot).A protocol biopsy was performed at day 15 after tx. Immunochemistry for CD3,CD68, VEGF-A,Ki67 was performed. Apoptosis was evaluated by TUNEL. CD3,CD68,Ki67 expression was evaluated through computerized morphometrical analysis.

EC-MPS patients had higher DGF rate:RR=1.43, acute rejection rate :RR=1.41, lower eGFR at 1 year (66.18±4.5 vs 79.25±9.9 ml/min). E patients presented an increase of proteinuria reaching the highest level 15 days after tx ($p<0.03$).Proteomics showed in E patients an unselected increment of the high/medium and low molecular weight proteins. Biopsies in EC-MPS group showed a moderate/severe inflammation of lymphocytes and histiocytes. Expression of CD3 and CD68 on total area evaluated by morphometry was lower in E patients than EC-MPS patients: CD3 was 1.9±0.4% vs 4.4±0.5%,$p<0.05$ and CD68 was 5±1% vs 14±2%,$p<0.05$. Ki67 revealed a higher proliferation of tubular cells in the EC-MPS group: 2±1.3% vs 0.2±0.3% of total tubular cells in E patients;$p<0.05$. TUNEL showed a large number of glomerular and tubular apoptotic cells in the E group.

Our data confirm: a)E therapy with low CyA dose is safe and effective; b)EC-MPS vs E is associated to a higher RR of DGF and BPAR; c)Proteinuria in E group reversed after the first month to nornal levels; d)Biopsies documented a higher apoptosis in E patients as possible cause of proteinuria and higher immunological reactivity in EC-MPS patients.

**Renal Allograft Loss in the First Post-Operative Month: Causes and Consequences** Paul J. Phelan, James Lineen, Frank J. O Brien, Peter J. Conlon. *Department of Nephrology, Beaumont Hospital, Dublin, Ireland.*

Early transplant failure is a devastating outcome after kidney transplantation. We report the causes and consequences of deceased donor renal transplant failure in the first 30 days at our centre between January 1990 and December 2009.Controls were adult deceased donor transplant patients in the same period with an allograft that functioned greater than 30 days. Multi-factorial analysis was performed to test for independence of early allograft failure on patient outcome in the presence of several confounding variables. The incidence of early graft failure in our series of 2381 consecutive deceased donor transplants was 4.6% (n=109). The causes of failure were allograft thrombosis (n=48; 44%), acute rejection (n=19; 17.4%), death with a functioning allograft (n=17; 15.6%), primary non-function (n=14; 12.8%) and other causes (n=11; 10.1%). Mean time to allograft failure was 7.3 days. There has been a decreased incidence of all cause early failure from 7% in 1990 to <1% in 2009. Patients who developed early failure were older and had longer cold ischaemia times when compared to patients with allografts lasting > 30 days. Early allograft failure was strongly associated with reduced patient survival ($p<0.001$). In conclusion, early renal allograft failure is associated with a survival disadvantage but has thankfully become less common in recent years.

**Association between Interleukin 3 Gene Polymorphisms and Acute Rejection Following Kidney Transplantation** Dongyoung Lee,[2] Se-Bin Song,[1] Ju-Young Moon,[2] Kyung-Hwan Jeong,[1] Chun-Gyoo Ihm,[1] Tae Won Lee.[1] *[1]Internal Medicine, Division of Nephrology, KyungHee University Medical Center, Seoul, Republic of Korea; [2]Internal Medicine, Division of Nephrology, KyungHee East-West Neo Medical Center, Seoul, Republic of Korea.*

Acute rejection (AR) after kidney transplantation resulting from alloimmune responses has a negative effect on graft survival. AR is mainly caused by T-cell immune responses in renal allograft and many cytokines contributes to the activation of T-cell. Interleukin (IL) 2, 4, and 7 are well known cytokines related to AR. Many reports showed that single nucleotide polymorphisms (SNPs) of these cytokines can affect the occurrence of AR. IL3, which is secreted by activated T cells, contributes to T-cell activation and can mediate AR in kidney transplantation. This study aimed to investigate the association between SNPs of *IL3* and the occurrence of AR because there is no report about that. We analyzed three SNPs of *IL3* (rs181781, rs2073506, and rs40401) among 330 renal recipients, 60 of whom had developed AR. SNPs of *IL3* gene are one exonic SNP (rs40401) and two regulatory SNPs (thought to be the promoters, rs181781; rs2073506). The genotyping of the 60 AR patients and the 270 patients without AR demonstrated a significant relationship between genotype frequencies and the SNPs. The occurrence of AR was associated with rs181781 ($P$ = .021, codominant model; $P$ = .041, dominant model), rs2073506 ($P$ = .001, codominant model; $P$ = .0012, dominant model), and rs40401 ($P$ = .018, recessive model). Among haplotypes, a haplotype (AAT) showed a significant association with AR ($P$ = .0033). Our results suggest that *IL3* gene polymorphisms are associated with the development of AR.

**Blood Oxygen Level-Dependent MR Imaging (BOLD MRI) Early Post Kidney Transplantation Could Predict Acute Renal Rejection and Allograft Function** Ying Xu, Fei Han, Jianghua Chen. *The Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

**Purpose:**

Our previous study has concluded that blood oxygen level-dependent magnetic resonance imaging (BOLD MRI) could be a valuable method to discriminate between acute rejection and acute tubular necrosis by measuring tissue oxygen bioavailability in early kidney allograft dysfunction [1]. Mean R2* values in the medullary regions (MR2*) of transplanted kidneys with BOLD-MRI could represent the oxygenation state of renal allograft. This study was designed to identify the significance of BOLD MRI in prediction of acute renal rejection and long-term allograft function.

**Methods:**

Eighty-two patients with normal functioning grafts underwent BOLD MRI within 2 to 3 weeks post kidney transplantation. According to our previous results, they were divided into two groups: lower medullary R2* value group (MR2*<14.9/sec, n=23) and higher medullary R2* value group (MR2*>14.9/sec, n=59). The clinical data during the follow-up time (45.9±6.9 months) were recorded from our electronic database.

**Results:**

The baseline data of two groups had no significant difference. Patients with lower medullary R2* values had higher acute rejection rates than those with higher medullary R2* values in the first 6 months post transplantation, but the difference between two groups was not significant (17.39% vs 8.47%, P=0.259). The simplified equation of MDRD calculated estimated Glomerular filtration rate (eGFR) at the end of follow-up was inferior in lower medullary R2* value group than higher medullary R2* value group (77.14±22.76 ml/min vs 89.29±24.02 ml/min, P=0.037).

**Conclusions:**

Blood oxygen level-dependent MR imaging (BOLD MRI) could predict acute renal rejection and long term allograft function for patients with normal functioning grafts early post kidney transplantation.

**Impact of Luminex Solid Phase Screening on Recipient Selection and Renal Allograft Outcomes** Abdelaziz A. Elsanjak, Nabil Mohsin, Isabelle G. Wood, Helen Mah, Nidyanandh Vadivel, Edgar L. Milford, Anil Chandraker. *Brigham & Women's Hospital, Boston, MA.*

Aim: The aim of this study was to identify whether allocation of deceased donor kidneys by luminex solid phase screening of renal transplant candidates leads to a reduction of rejection episodes and an improvement in allograft function at one year.

Methods: Charts of 145 deceased donor kidney allograft recipients, transplanted between 12/2004 and 09/2009 were reviewed retrospectively. At the time of transplant, complement-dependent cytotoxic T-cell screening was used for 101 patients (transplanted between 12/04 - 04/07) and luminex solid phase screening technique was used for 44 patients (transplanted between 05/07-09/09). Of the 101 patients transplanted prior to adoption of luminex solid phase screening,73 stored pre-transplant sera sample were available for re-screening by luminex.

Result: Twenty five percent of patients (25 of 101) of the pre-luminex patients who underwent deceased donor renal transplantation had an episode of acute allograft rejection within one year, compared to 9% (4 out of 44) of patients in the post-luminex period. Of the 73 samples available in the pre-luminex patients only 7 had a rejection episode within one year (28 other samples including 18 patients with rejection were unavailable). Out of these 7 patients with allograft rejection, 4 had class I donor specific antibodies by luminex. However 12 (18%) out of 66 patients who were free from rejection were also noted to have class I DSA. The mean 1 year creatinine of pre luminex screened kidney transplant recipients was 2.0 mg/dl compared to 1.75 mg/dl in post luminex kidney transplant recipents.

Conclusion: We conclude that the introduction of luminex solid phase screening as a method for allocation for deceased donor kidney transplants, significantly reduced one year renal allograft acute rejection rates, and improved overall allograft function. It should however be noted that had luminex solid phase screening been in use in our center during the period 12/2004 through 5/2007, 18% of the 66 patients who were rejection free within the first year of transplantation would have been excluded from transplantation.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3025**

**Secondary Hyperparathyreoidism in Renal Transplant Recipients** Christian Marx,[1] Martin Busch.[2] *[1]Nephrological Center and Dialysis, Nordhausen, Germany; [2]Internal Medicine/ Nephrology, Friedrich Schiller University, Jena, Germany.*

**Introduction:** The calcimimetic Cinacalcet may be used to treat secondary hyperparathyreoidism occuring during chronic kidney disease (CKD). After kidney transplantation (TX) hyperparathyreoidism often persists or relapses. Presently there is little data on the off-label use of cinacalcet in these patients. **Patients and methods:**We retrospectively examined the course of intact parathyroid hormone (iPTH), the occurrence of hypercalcemic episodes and prescription of cinacalcet in 54 renal transplant recipients (18 females, 36 males) over a period of 36 months after TX. **Results:** At the time of TX, the K/DOQI- target values for iPTH in patients with CKD-stage 5 (150-300ng/l) were only met in 12/ 54 patients (22%). 5 patients had very low iPTH-levels (<35ng/l). 11/ 54 patients (20%) were partially or totally parathyreoidektomized. 3 of them developed iPTH-levels of >300ng/l within 3 years after TX. Patients with an iPTH of 150-300 ng/l at time of TX were 14-fold more likely to have an iPTH of >300ng/l after TX compared to patients with iPTH <150ng/l at the time of TX. Patients with an iPTH of >300ng/l at the time of TX were 20-fold more likely to have a persisting iPTH of >300ng/l after TX. The probability to develop hypercalcemia and the need for cinacalcet treatment were 8- and 11-fold increased after TX in those having an initial iPTH >300 ng/l compared to patients with iPTH <150ng/l. **Discussion:** Patients reaching the K/DOQI- target values for iPTH are at risk for a worsening of hyperparathyreoidism. Therefore for patients on the waiting list new target values could be necessary. Already prior to TX a straight therapy of hyperparathyreoidism is required. Hyperparathyreoidism may also relapse after parathyreoidectomy in transplant recipients. The treatment with drugs such as cinacalcet is a safe and effective option in transplant recipients with hypercalcemia and hyperparathyreoidism.

**Intravenous Iron Supplementation for Kidney Transplant Recipients** Benaya Rozen-Zvi, Uzi Gafter, Ruth Rahamimov. *Neprology and Hypertension Department, Rabin Medical Center, Petah Tikva, Israel.*

Background:

Iron deficiency is common among kidney transplant recipients (KTR), but data concerning the efficacy and safety of intravenous (IV) iron in this population are sparse. We aimed to evaluate the effect of IV iron in a cohort of KTR who were treated with at least one dose of IV Iron sucrose.

Methods:

Data from KTR who had been treated with IV iron sucrose were retrospectively analyzed. Hemoglobin level was determined at the time of the first iron dose infusion and at three month to evaluate efficacy. The efficacy analysis included only patients who were not treated with erythropoietin or were treated with a stable dose for at least 3 months. Safety data included adverse events, hospitalizations infections and creatinine values before and after the IV iron treatment. Data are presented as mean ±SD. Paired t-test was used for comparisons.

Results:

Between 1/2000 and 12/2009 eighty four patients were treated with 709 doses of IV iron, with average dose of 766±363 mg at 3 month. Mean age was 49.9±14.1 years and 83% had eGFR less than 60 ml/min/1.73 $m^2$. Mean transferrin saturation (TSAT) was 13.9±8%, 81% had TSAT lower than 20%. Five episodes of adverse events were reported, all resolved without treatment. There were no reports of anaphylactic reactions and all patients resumed treatment with IV iron without further events. In the 60 patients who were included in the efficacy analysis hemoglobin level rose from 10.01±1.42 gr/dL to 11.24±1.56 mg/dL at 3 months ($p<0.001$). Creatinine levels were stable at three month (2.36±1.23 to 2.42±1.5 ($p=0.40$)) and there was no increase in hospitalizations and infections.

Conclusion:

IV iron was safe and effective in KTR with iron deficiency and anemia. To the best of our knowledge, this is the largest series of IV iron treatment in kidney transplant recipients. Controlled trials should evaluate IV iron in this important and distinctive group of patients.

**SA-PO3027**

**Absence of Influence of Polymorphism -308A *TNFA* on Renal Graft Histopathologycal Findings in Mexican Mestizo Adults One Year after Transplant** Jose De la Cruz Moreira-Hernandez,[1] Caridad Aurea Leal,[2] Francisco Ramos Solano,[1] Eliseo Portilla-de Buen,[2] Benjamin Gomez-Navarro.[1] *[1]Nephrology and Transplant, Hospital de Especialidades del Centro Medico de Occidente, IMSS, Guadalajara, Jalisco, Mexico; [2]Biomedical Research Center West, Hospital de Especialidades del Centro Medico de Occidente, IMSS, Guadalajara, Jalisco, Mexico.*

BACKGROUND: Despite improvements in medical and pharmacological management chronic allograft nephropathy (CAN) remains the main cause of graft loss. Tumor necrosis factor alpha (TNFa) plays a central role as proinflammatory molecule. We analyzed the possible influence of polymorphism -308A of gene *TNFA*, which is known to produce high levels of TNFa, on the presentation of acute rejection or CAN currently interstitial fibrosis and tubular atrophy.

OBJECTIVE: To explore if the presence of high-production *TNFA* genotype or alleles in renal graft recipients is associated to acute rejection or CAN one year after transplant in a defined population.

MATERIALS AND METHODS: A cross-sectional study in 131 Mexican mestizo patients (89 male) 16 years or older who received a related living donor graft between January 2008 and March 2009. All had pre-implant biopsy. Variant -308A of gene *TNFA* was genotyped using allele-specific polymerase chain reaction. Clinical data were obtained from patient charts and the effect of the polymorphism on acute rejection or CAN was analyzed with Pearson´s and Spearman´s correlations, adjusting for demographic, biochemical and clinical variables.

RESULTS: At one year after transplant, 41 (31.0%) patients had acute rejection and 62 (47.3%) had calcineurin inhibitor toxicity. Overall, 57 (43.5%) patients showed CAN, but with mean creatinine 1.27 ± 0.79 mg/dl and mean GFR measured by creatinine clearance 77.32 ± 22.67ml/min. No influence of the polymorphism was found on any of the variables studied. Correlation with CAN was only found for calcineurin inhibitor toxicity ($r = 0.202$, $p = 0.05$) and acute cellular rejection ($r = 0.285$, $p = 0.005$).

CONCLUSIONS: Polymorphism -308A*TNFA* has no influence on acute rejection or chronic graft nephropathy one year after transplant in Mexican mestizo patients from Western Mexico.

Disclosure of Financial Relationships: nothing to disclose

**Is It Useful To Study Renal GFR and ERPF Determined by Renal Scintigram in the First Week To Predict Kidney Graft Function?** Nuno Figueiredo. *Nephrology, Hospitais Universidade Coimbra, Coimbra, Portugal.*

Introduction-The evaluation of glomerular filtration rate (GFR) and effective renal plasmatic flux (ERFP) are important methods in the management kidney transplant recipients.

Methods-From January to October of 2009, a renal scintigram was performed in the first week post-transplant in 63 patients, and the GFR and the ERPF were determined by DTPA-Tc99 and Tc99-MAG-3 respectively. They were followed up until 31/05/2010. Then we assessed the correlation between the observed GFR and RPF determined in the first week and the serum creatinine at the present time.

Results: Sample characterized by 63 kidney transplanted patients, with a mean age of 50,55 +/- 13,46 years, 97,1% were Caucasian and 2,9% Africans. The mean donor age was 52,48+/-16 years, 62 transplants were from deceased donors and 54,3% were from extended criteria donors(ECD). The mean cold ischemia time was 16,75+/- 4,9 hours. The mean HLA match was 2(28,6%), with a minimum of 0 in 8,6% and a maximum of 5 in 4,3%. About 55,6% received induction (36,5% Thymoglobulin and 19,1% Basiliximab). All had a calcineurin inhibitor (61,9% FK and 38,1% cyclosporine). Among the 63 patients, it was only possible to assess Tc99-MAG-3 ERPF in 46 patients. The mean DTPA-Tc99 GFR was 56,7 +/-29 ml/min/1,73M2. The overall mean ERPF was 344+/- 199.4 ml/min/1,73M2. At the present time the mean serum creatinine is 1,42 +/- 0,77 mg/dL. In our results there was no correlation between ERPF and the serum creatinine at the present time. We also did not find any correlation with the donor age, cold ischemia time or ECD ($p>0.05$). However we found a strong negative correlation between DTPA-Tc99 GFR with serum creatinine at the present time ($p<0.05$, Spearman coefficient factor of -0.455) and donor age ($p<0.01$, Pearson coefficient factor of -0.529).

According to our results the assessment DTPA GFR in the first week seems to be a good predictor of graft function however the same conclusion was not observed for effective renal plasmatic flux.

**SA-PO3029**

**Effect of Donor Vasopressor Support on Renal Allograft Function** Prasanna S. Srinagesh, William Yang, Aniruddha V. Palya, Parmish Lalit Kohli, Alden Michael Doyle, Karthik M. Ranganna. *Medicine, Drexel University College of Medicine, Philadelphia, PA.*

The outcome of cadaveric renal allografts procured from donors requiring inotropic support has been a subject of controversy. Prior studies have shown poorer outcomes in renal allografts obtained from donors requiring inotropic support, whereas one recent study reported beneficial effects on acute allograft rejection, and graft survival after cadaveric renal transplantation. Our study aims to determine whether the number of inotropic agents required by the donor prior to procurement affects both the short and long term outcomes of the renal allograft.

We reviewed data on recipients who recieved cadaveric renal transplantation from 2000 to 2004. There were 134 recipients from donors who were on donor inotropic support ranging from the use of one agent to three or more. Kidney function based on serum creatinine levels was followed at regular intervals. At 1 month follow up, serum creatinine was elevated in those recipients who received renal allografts from donors requiring 3 or more inotropic agents, compared to those who required inotropic support with only one agent. At 3 months post-transplantation, serum creatinine levels corresponded very closely regardless of the number of inotropic agents used in the donor. The difference in kidney function was not significant at 12 month follow-up.

| | Number of Pressors 1 | Number of Pressors 2 | Number of Pressors 3 | P value |
|---|---|---|---|---|
| Recipient Age M:F | 61.2 : 58.2 | 51.9 : 50.1 | 51.3 : 54.7 | |
| Gender M: F | 40 : 18 | 42 : 10 | 18 : 6 | |
| Donor Start Creatinine | 1.38±0.9 | 1.2±0.82 | 1.15±0.7 | 0.002 |
| Donor Final Creatinine | 2.30±2.29 | 1.57±1.4 | 1.71±1.0 | 0.106 |
| 1 Month | 2.95±2.45 | 2.84±2.56 | 3.24±3.38 | 0.85 |
| 3 Month | 2.22±1.6 | 2.13±1.7 | 2.31±1.42 | 0.90 |
| 6 Month | 2.08±1.31 | 2.24±2.29 | 2.16±1.31 | 0.91 |
| 12 Month | 2.22±1.63 | 1.93±1.01 | 1.88±0.8 | 0.46 |
| DGF M : F | 23 : 12 | 23 :4 | 13 : 5 | 0.18 |

Our study concludes that although initial kidney function may be lower in the initial post-transplantation period in those requiring more inotropic support, long term outcomes in these groups were relatively similar.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3030**

**Light Microscopic Features Do Not Distinguish between C4d Negative and C4d Positive Biopsies with Advanced Transplant Glomerulopathy** Kuang-Yu Jen, Jean L. Olson, Zoltan G. Laszik. *Department of Pathology, University of California San Francisco, San Francisco, CA.*

**Background:** Chronic antibody-mediated rejection with transplant glomerulopathy (TxGP) is an increasingly recognized cause of late allograft loss. Although the pathologic changes of TxGP are well characterized it is still uncertain whether light microscopic morphologic findings in patients with advanced C4d-negative TxGP reveal any distinguishing features from those with C4d positivity.

**Design:** The aim of the study is to quantitatively assess morphologic variables in 20 consecutive transplant kidney biopsies featuring advanced TxGP (Banff 07 cg3) with first time TxGP diagnosis. Eleven C4d positive and 9 C4d negative biopsies were scored for glomerular, tubulointerstitial, and vascular lesions according to the recommendations of Banff 07 Classification of Renal Allograft Pathology. The percentage of glomerular capillary double contours (CDC) in the most severely affected glomerulus was also recorded in each case. In addition, the proportion of non-globally sclerotic glomeruli featuring TxGP was calculated. The morphological findings in the C4d negative and C4d positive biopsies were correlated with each other and also with relevant clinical variables.

**Results:** Demographic and clinical variables, including post transplantation time and serum creatinine levels were similar in the C4d negative and C4d positive groups. None of the morphological variables of the Banff classification were statistically different in the two groups. Furthermore, the proportion of the non-globally sclerotic glomeruli affected by TxGP was similar between the two groups. However, the extent of the glomerular CDC (97.2%) in the most severely affected glomeruli in the C4d negative biopsies was significantly higher than in the C4d positive biopsies (69.5%) ($p=0.01$).

**Conclusion:** Our results indicate that the light microscopic features are highly similar in transplant biopsies showing advanced TxGP with and without C4d positivity. The difference observed in the extent of glomerular CDC in the two groups should be verified in a larger cohort of biopsies.

Disclosure of Financial Relationships: nothing to disclose

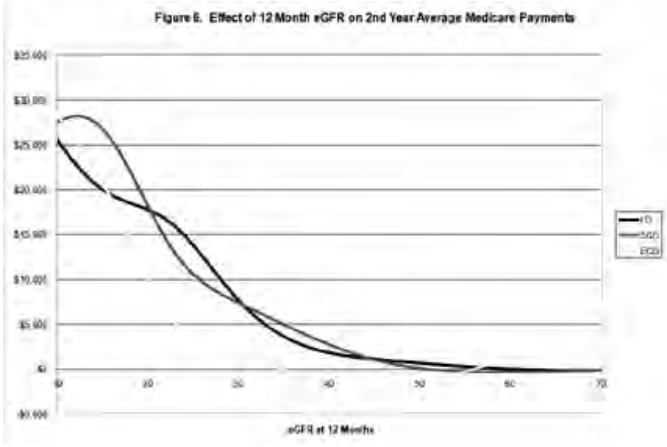
**SA-PO3031**

**Impact of Renal Function on Health Care Costs by Donor Type Following Kidney Transplantation in Medicare Patients** Mark Schnitzler,[1] Digisha Trivedi,[2] Krista L. Lentine,[1] Gilbert J. Litlaien.[2] *[1]Saint Louis University; [2]BMS.*

**Purpose:** To determine effects of renal function on cost by donor type.

**Methods:** The study included all recipients of single-organ kidney transplants in the United States between 1995 and 2003 recorded in the United States Renal Data System (USRDS) database. The predictor variable was renal function as measured by estimated Glomerular Filtration Rate (eGFR), calculated using the abbreviated Modification of Diet in Renal Disease equation including serum creatinine, age, gender and race. Estimated GFR in mL/m per 1.73 m2 was considered as a continuous variable at 1 year post-transplant. The total cost measure was actual payments made by Medicare for all health care services and was evaluated at yearly intervals up to three-years post-transplant. Linear regression was used to develop separate models for total costs during the second and third years post-transplant for each donor type.

**Results:** There were 32,681 LD, 49,551 SCD, and 5,343 ECD kidney transplant recipients included. Lower eGFR was a statistically significant predictor of increased cost of care during the second year post-transplant for each donor type (LD, $p<0.0001$; SCD, $p<0.0001$; ECD, $p=0.0001$) (See Figure). Similar eGFR/cost relationships were observed in the third post-transplant year for LD ($p<0.0001$) and SCD ($p<0.001$)While the . ECD eGFR/cost relationship was similar in the third post-transplant year as well, it was not statistically significant. The lack of significance for ECD is likely due to the skewed nature of cost data and small sample size.



**Conclusions:** In the three-year post-transplantation, there is a strong relationship between renal function as measured by eGFR and health care costs. This relationship is similar across donor types. Strategies that help patients maintain their eGFR at higher levels may provide cost savings to society.

**The Complete Correction of Post-Transplant Anemia Improves Graft Survival: Results of a Multicentre Randomized Study** Gabriel Choukroun,[1] Nassim Kamar,[2] Bertrand Dussol,[3] Isabelle Etienne,[4] Azmi Al Najjar,[5] Philippe Lang,[6] Antoine Thierry.[7] *[1]SUD Hospital; [2]Rangueil Hospital; [3]Conception Hospital; [4]Bois Guillaume Hospital; [5]Bretonneau Hospital; [6]Henri Mondor Hospital; [7]Miletrie Hospital, France.*

Retrospective studies suggested that chronic allograft nephropathy (CAN) might progress more rapidly in pts with post-Tx anemia. CAPRIT is a multicentre, randomized study, to investigate the effect of SC epoetin beta to normalize Hb values (target Hb 13.0-15.0 g/dl, Gr A, n = 63), compared with partial correction of anemia (target Hb 10.5-11.5 g/dl, Gr B, n = 62) on the progression of CAN.

125 pts (mean age 48.9 yrs, 61M) were included. They were on Tx for at least 12 months, with a Hb less than 11.5 g/dl and an estimated GFR (MDRD formula) between 50 to 20 ml/min at inclusion. Baseline Hb level and eGFR were similar in both groups, 10.4 ± 0.9 g/dl and 10.6 ± 0.7 g/dl for Hb, 34.4 ± 10.0 ml/min and 33.7 ± 10.8 ml/min for eGFR in Gr A and B. After 12 months, Hb level was 13.4 ± 4.1 g/dl in Gr A, 11.2 ± 0.9 g/dl in Gr B ($p < 0.001$) ; 12.9 ± 2.1 g/dl and 11.3 ± 1.1 g/dl respectively at the end of the 2-yrs follow-up ($p < 0.001$). At one yr, eGFR was significantly higher in Gr A (35.9 ± 17.2 vs 30.8 ± 12.1 ml/min, $p < 0.025$). This difference was also significant after 2 yrs (32.6 ± 12.7 vs 27.9 ± 13.7 ml/min; $p < 0.05$). 16 pts reach ESRD before the 2 yrs follow-up, 3 in Gr A and 13 in Gr B ($p < 0.01$). 4 pts died during the study, 1 in Gr A and 3 in Gr B. The Kaplan-Meier cumulative death-censored graft survival was 20 % higher in Gr A ($p < 0.01$). At the end of the study, 89 % of pts in Gr A and 61 % of pts in Gr B were on epoetin beta. Weekly doses were 5600 UI and 4600 UI respectively, by SC. There was no significant difference in the incidence of adverse events between groups and no severe side effect was related to the treatment by epoetin beta. The number of cardiovascular events was low and similar between groups.

This prospective randomized study is the first to demonstrate that targeting a serum Hb level of 13 g/dl or above had a nephroprotective effect in kidney transplant recipient.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO3033

**3 Year Results of a Randomised Controlled Trial of Alemtuzumab and Low Dose Tacrolimus Monotherapy Compared with Daclizumab, Tacrolimus and Mycophenolate Mofetil** Kakit Chan, Jack W. Galliford, Dawn Goodall, David Taube, Adam Mclean. *Imperial College Kidney and Transplant Institute, Hammersmith Hospital, London.*

In this study, we present the 3 year results of our randomised controlled trial [(RCT) Clinical Trials.gov: NCT00246129] of Alemtuzumab induction and low dose Tacrolimus [Tac] monotherapy, compared with Daclizumab induction, conventional dose Tac and Mycophenolate Mofetil [MMF] in renal transplantation.

Recruitment into this trial was completed in April 2008 and mean follow up is 37.5 months.

82 patients [54m, 28f; mean age 47.3+13.4 years] received Alemtuzumab, low dose Tac [0.1mg/kg; target level 5-8 ng/mL] and 41 patients [27m, 14f; mean age 47.0+10.6 years] received Daclizumab, Tac [0.15mg/kg; target level 8-12 ng/mL] and MMF [target level: 1.5-3.0 mg/L]. Both groups received our steroid sparing regime [prednisolone 60mg daily day 1-3; 30mg daily day 4-7 and then stopped] .

Rejection was diagnosed by biopsy and treated with steroids and the addition of MMF to the Alemtuzumab group.

Table 1 shows that patient, graft and rejection free survival were similar in the 2 groups. There was no difference in the cumulative risk of rejection and no increased late rejection in the Alemtuzumab group.

Allograft function [MDRD eGFR] was 5.6 ml/min [95%CI: 2.3,8.9; p=0.001] and 4.4 ml/min [95%CI: 2.0, 6.7, p<0.001] better at 1 and 3 years. [Bootstrap method] in the Alemtuzumab group

75.4% and 69.7% of the Alemtuzumab group remained on Tac monotherapy at 1 and 3 years.

Infection rates [positive bacterial and viral isolates, expressed as incidence/100 patient months] were similar in both groups.

This RCT shows that at 3 years, Alemtuzumab induction and low dose Tac monotherapy provides excellent patient and allograft, rejection and infection free survival similar to a conventional Daclizumab, Tacrolimus and MMF protocol.

Furthermore, allograft function is significantly better in the Alemtuzumab, low dose Tac group.

| | | Alemtuzumab | Daclizumab |
|---|---|---|---|
| Patient Survival | 3 year | 97.4% | 97.5% |
| Graft survival | 3 year | 92.2% | 97.6% |
| Rejection free survival | 3 year | 88.5% | 79.5% |
| MDRD eGFR [Mean±1SD] | 3 year | 52.0±15.1 | 47.6±18.4 |
| Infection free survival | 1 year | 70.0% | 60.0% |

Disclosure of Financial Relationships: nothing to disclose

### SA-PO3034

**African-American vs. Non-African American *De Novo* Renal Transplant Recipients Receiving Everolimus Versus Mycophenolate: Results from a Pooled Analysis** Fuad S. Shihab,[1] Diane M. Cibrik,[4] S. P. Mulgaonkar,[2] Dharmesh Patel.[3] *[1]University of Utah, School of Medicine; [2]Saint Barnabas Medical Center; [3]Novartis Pharmaceuticals Corporation; [4]University of Michigan.*

African-american (AA) de novo renal transplant recipients (RTs) are considered at higher risk for graft loss and rejections than non-African-americans (nonAA). Everolimus (EVR) comparative risk assessment of AAs vs. non-AAs between EVR and MPA is warranted.

Data on 2004 RTs from three EVR studies B201(N = 588), B251(N = 583), and A2309 (N = 833), were analyzed to identify impact of AA vs. non-AA on efficacy outcomes across both EVR dosing groups and mycophenolate (MPA) control groups. EVR groups received either 1.5 mg/day, or 3 mg/day; with either standard (SD-CsA) or reduced dose cyclosporine (RD-CsA). All control groups received MPA (1.44g/day) with ST-CsA. Composite efficacy end-point for the pooled analysis was graft loss, death, treated biopsy-proven acute rejection, or lost to follow up. Odds ratios (ORs) were calculated using a logistic regression model with treatment, study and AA (Yes or No) as independent variables.

MPA-treated RTs who experienced a composite end-point were 44.6% vs 30.7% for AA vs. non-AA subgroups respectively. EVR 1.5 mg-treated RTs who experienced a composite endpoint for AA vs. nonAA, similarly, were 44.1% vs. 31.2%; for EVR 3.0 mg values were 41.2% and 31.4%.

Likelihood of a Composite End-Point Event based on Treatment or AA vs nonAA

| | Odds Ratio (OR) | 95% C.I. | P-value |
|---|---|---|---|
| EVR 1.5 vs. MPA | 1.019 | 0.8090, 1.2835 | NS |
| EVR 3.0 vs. MPA | 1.0077 | 0.8006, 1.2684 | NS |
| AA vs. non-AA | 1.7915 | 1.3515, 2.3748 | P<0.0001 |

In this pooled data analysis in over 2000 RTs EVR treatment vs MPA resulted in similar composite end-point incidence events across AAs and non-AAs confirming no treatment effect. This result is expected as these studies were powered for non-inferiority. However, overall risk for experiencing a composite end-point in AA RTs was significantly higher compared to non-AA RTs. This pooled analysis confirms that AA recipients are at higher risk for poorer efficacy outcomes, irrespective of treatment.

### SA-PO3035

**Benefits and Risks of Surveillance Biopsies in Stable Renal Transplant Recipients** Prashant Pendyala,[1] Neha Nainani,[1] Kathleen M. Tornatore,[2] Mareena Susan Zachariah,[1] Rocco C. Venuto.[1] *[1]Renal and Pancreas Transplant Unit, Erie County Medical Center and University at Buffalo, Buffalo, NY; [2]Department of Pharmacy Practice, School of Pharmacy & Pharmaceutical Sciences, University at Buffalo, Buffalo, NY.*

**AIM:** To assess the value of surveillance biopsies (SB) in the management of stable renal transplant recipients (RTR).

**METHODS:** SB are being used commonly in RTR for early detection and treatment of subclinical acute rejection and of interstitial fibrosis and tubular atrophy. Biopsies carry the risk of various complications. We assessed the frequency with which unsuspected diagnoses were detected in the SB and the occurrence rate of complications. In this prospective study, RTR underwent SB at 3, 9-12 and 24 months (mo) after transplantation. SB performed between the years 2006-2008 were included.

**RESULTS:** A total of 202 biopsies were performed on 98 RTR. Twenty nine (14.3%) subclinical rejections (SC REJ) were detected. Nine (4.4%) biopsies showed acute calcineurin (CNI) toxicity and 19 (9.4%) showed disease recurrence (DIS R). A total of 45 (22.2%) treatment changes (RX) resulted from SB. A total of 16 (7.9%) hospital admissions followed the SB due to bleeding. Eight patients had an increase of creatinine of 0.3mg/dl or more that reverted to baseline. No grafts were lost and no patient needed surgical

intervention. SB were sub analyzed based on the time post transplant. There were 83 biopsies at 3 mo, 74 at 9-12mo and 45 at 24mo. In the 3 mo SB, 13 had SC REJ, 7 had DIS R and 5 had CNI toxicity. There were a total of 19 RX (23%) and the complication rate was 3.6%. At 9-12 mo 14 SC REJ and 9 DIS R were detected and 4 had CNI toxicity. These findings directly resulted in 21 (28%) RX with a complication of 8.1%. RX resulted in histologic improvement in the majority of the cases. At 24 mo biopsies, there were only 2 SC REJ and 3 DIS R. There were 4 (8.8%) RX whereas 7 (15.5%) RTR had complications.

**CONCLUSION:** SB done up to Year 1 are useful in the management of RTR and were associated with minimal morbidity. The risk benefit ratio for Year 2 SB requires further definition as complications at this time might outweigh the benefit from the SB.

## SA-PO3036

**Renal Function of an Everolimus Based Therapy after Calcineurin Inhibitor Withdrawal in Maintenance Renal Transplant Recipients One Year after Conversion** Claudia Sommerer,[1] Klemens Budde,[1] Wolfgang Arns,[1] Stefan Kramer,[2] Eva-Maria Vogel,[2] Frank B. Pietruck,[1] Thomas Rath,[1] Hermann G. Haller.[1] *[1]The APOLLO Study Group; [2]Novartis Pharma, Nuremberg, Germany.*

Objective: Renal function, safety and efficacy of an Everolimus regimen was assessed 12 months after Calcineurin-Inhibitor (CNI) withdrawal in maintenance kidney allograft patients (pts).

Methods: In an open-label, randomized, controlled, multi-center study 93 renal maintenance pts with a stable renal function (creatinine < 2.5mg/dl) and on a therapy consisting of CNI, Enteric-coated mycophenolate sodium (EC-MPS) with or without steroids were randomized to either continue CNI treatment (n=47) or b) convert to an Everolimus based (n=46) regimen.

Results: 93 pts were randomized to either Everolimus or CNI group (29 CsA/17 Tac; C0: CsA 98.0±25.6ng/mL; Tac 5.7±2.2ng/mL). Mean of years since the most recent transplantation was higher in the Everolimus compared to the CNI group (7.0±5.2 vs. 5.8±5.6). Renal function expressed as calculated GFR (Nankivell method) improved from conversion to M12 by 3.6mL/min/1.73m2 in favor of the Everolimus regimen (ns). The observed GFR slope from conversion to M12 was +3.4[-0.2;+7.0] for Everolimus and -0.2[-3.9;+3.5] mL/min/1.73m2 for CNI patients (ns). One death occurred in both groups and no graft loss or BPAR was observed in either group. Proportion of pts discontinued study regimen due to AE was 15(32.6%) in the Everolimus and 5(10.6%) in CsA group. Safety parameters related to study medication are listed below.

| | CNI | Everolimus |
|---|---|---|
| Hyperlipidaemia[%] | 0 | 6.5 |
| Total Cholesterol[mmol/L] | 5.2 | 6.1 |
| LDL[mmol/L] | 3.1 | 3.7 |
| HDL[mmol/L] | 1.3 | 1.5 |
| Triglycerides[mmol/L] | 2.6 | 2.5 |
| Anaemia[%] | 0 | 6.5 |
| Leucopenia[%] | 2.1 | 10.9 |
| Thrombocytopenia[%] | 0 | 4.3 |
| Mouth ulceration[%] | 0 | 26.1 |
| Diarrhoea[%] | 4.3 | 6.5 |
| Any infections[%] | 53.2 | 63.0 |
| Serious infections[%] | 10.6 | 17.4 |

Conclusions: Late conversion to an Everolimus/EC-MPS treatment in maintenance renal transplant pts after CNI withdrawal leads to a better renal function. Overall late conversion was safe although more side effects were reported. For a complete risk/benefit assessment a long term follow-up is needed which will be attempted.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO3037

**Dosing Modifications Are Required for Concomitant Administration of Colchicine and Cyclosporine** Matthew W. Davis,[1] Suman Wason,[1] Jennifer L. Digiacinto.[2] *[1]URL Pharma, Inc, Philadelphia, PA; [2]Salamandra, LLC, Bethesda, MD.*

**PURPOSE:** Cyclosporine potently inhibits P-glycoprotein membrane transporter and CYP3A4 enzyme required for metabolism of colchicine. This study was conducted to determine whether cyclosporine substantially increases exposure to colchicine when the two are coadministered, as may occur in renal transplant patients who develop gout.

**METHODS:** Twenty-four healthy volunteers received single-dose colchicine (0.6 mg) alone and in combination with single-dose cyclosporine (100 mg). On Day 1, volunteers received colchicine. Blood samples for pharmacokinetic analysis were collected predose and 0.5, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 6.0, 8.0, 12.0, 24.0, 36.0, 48.0, 72.0, and 96.0 hrs postdose. After a 14-day washout, volunteers (fasted conditions) received colchicine plus cyclosporine followed by blood sample collection for pharmacokinetic assessment as described.

**RESULTS:** Twenty-three volunteers completed the study. One volunteer discontinued because of elevated creatine kinase that resolved without treatment. Coadministration of colchicine with cyclosporine resulted in 224% increase in colchicine mean $C_{max}$ compared with colchicine alone (8.82 ng/mL *versus* 2.72 ng/mL, respectively). Colchicine $AUC_{0-\infty}$ increased approximately 215% when coadministered with cyclosporine (47.3 ng·hr/mL *versus* 15.0 ng·hr/mL for colchicine alone). Colchicine $T_{max}$ was unaffected by coadministration with cyclosporine. Total apparent oral clearance of colchicine decreased by 72% following coadministration compared with colchicine alone (13.4 L/hr *versus* 48.2 L/hr, respectively). Across the study, the most common adverse event following colchicine administration was headache (n=4, 16.7%). All adverse events were mild to moderate in severity.

**CONCLUSIONS:** These findings indicate a significant drug interaction occurs when colchicine and cyclosporine are coadministered. Therefore, dose reduction for colchicine (for prophylaxis, reduction to 0.3 mg [1/2 tablet] once daily or once every other day; for acute flare, 0.6 mg [1 tablet] repeated no earlier than every third day) should be made in patients requiring coadministration of colchicine and cyclosporine.

Disclosure of Financial Relationships: Employer: I am the Chief Medical Officer of URL Pharma; Ownership: I have stock options in URL Pharma; Patent: I have two patents pertaining to colchicine dosing with clarithromycin. I do not receive royalties. These patents have been assigned to URL Pharma.

## SA-PO3038

**A Multicenter Experience of Kidney Transplantation in ANCA-Associated Vasculitis (AAV) in the Era of Modern Immunosuppression** Duvuru Geetha,[1] Alfonso Eirin,[2] Karin A. True,[3] Maria V. Irazabal-Mira,[2] Ulrich Specks,[2] Philip Seo,[1] Patrick H. Nachman,[3] Fernando C. Fervenza.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]Mayo Clinic, Rochester, MN; [3]UNC Kidney Center, Chapel Hill, NC.*

We report our experience with a multicenter cohort of AAV patients who underwent kidney transplantation (KTX) at our institutions from January 1996 to March 2010. A total of 85 patients (45M/40F; mean age 49 years) received a KTX for ESRD secondary to biopsy proven microscopic polyangiitis (n=39), Wegener's granulomatosis (n=42), or renal limited vasculitis (n=4). Twenty-four patients were transplanted preemptively and 61 were on dialysis. Sixty-nine patients received a living donor KTX and 16 received a deceased donor KTX after a mean of 24 months from the start of dialysis. All patients were in clinical remission at time of KTX, with 57/85 (67.0%) in remission for more than 12 months. Fifty-eight patients received induction therapy. Sixty-four patients received maintenance immunosuppression with prednisone, mycophenolate mofetil and tacrolimus. Patients were followed up for a median of 64 months after KTX. At the time of KTX, 29 patients were ANCA-positive. Nine relapses occurred in 8 patients (6 WG; 2 MPA) resulting in graft lost in only one. Five of these patients were ANCA positive at the time of transplant. The vasculitis relapse rate was 0.2 per 1000 patient-years. There were 23 rejection episodes in 13 patients. Graft loss resulted from non-compliance with immunosuppression in 3 patients and from unrelated causes in 4. Six patients developed BK nephropathy. The median serum creatinine at 1 year was 1.3 mg/dl in the 75 patients who had more than one year of follow-up. The median serum creatinine at last follow up was 1.4 mg/dl. There was no difference in serum creatinine at last follow- up between patients with WG versus MPA (1.2 versus 1.3, P=0.09). Eight patients had post transplant malignancies (3 skin cancer, 1 bladder cancer, 1 renal cell carcinoma, 1 gastric carcinoma, 1 lung carcinoma, 1 head and neck carcinoma). KTX is a safe and effective option for treating ESRD secondary to AAV and relapses are rare with current immunosuppression regimens.

Disclosure of Financial Relationships: nothing to disclose

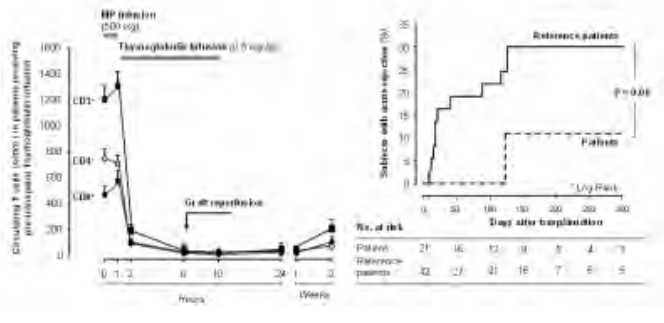
## SA-PO3039

**Pre- vs Post-Surgery Low-Dose Rabbit Thymoglobulin (RATG) Plus Basiliximab Induction in Renal Transplantation: A Prospective, Matched Cohort Study** Alessia Gennarini, Paolo Cravedi, Maddalena Marasa', Annalisa Perna, Giuseppe Remuzzi, Piero Ruggenenti. *Department of Medicine and Transplantation, Ospedali Riuniti di Bergamo and Mario Negri Institute for Pharmacological Research, Bergamo, Italy.*

Background: In high-risk kidney transplant recipients, low-dose RATG plus basiliximab prevented acute rejection as effectively as standard RATG induction, but was safer and cheaper (CJASN 2006,1:546).

Methods: In a single-center, prospective, matched-cohort study, we compared the outcome of 21 consecutive patients induced with a 6-day low-dose (0.5 mg/kg/day) RATG course started on average 6 h before graft reperfusion with that of 42 gender- and age- (±5 years) matched reference-patients given the same RATG course started post-surgery. All subjects were managed by the same team and received the same concomitant therapy with basiliximab (20 mg on day 0 and 4 post-transplant), cyclosporine and mychophenolate mofetil or azathioprine, without steroids. Each couple of reference patients had the same observation period of corresponding patient.

Results: Baseline characteristics, including HLA matching and cold ischemia time, of study groups were comparable. At graft reperfusion, all patients had their CD3+, CD4+ and CD8+ T cells fully depleted from the circulation.



Over a median (interquartile range) follow-up of 126 (40-198) days, 1 patient (4.8%) vs 11 reference patients (26.2%) had a biopsy-proven acute rejection. No patient compared to 5 reference-patients (11.9%) required dialysis therapy within 1 week post-transplant. Both treatment strategies were well tolerated.

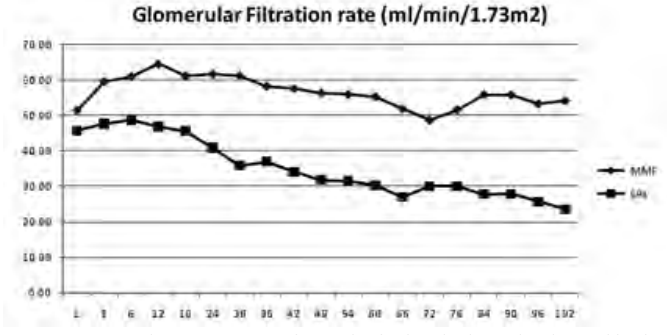
Conclusions: In renal graft recipients, pre-transplant RATG infusion further enhanced the protective effect of low-dose RATG plus basiliximab induction against acute allograft rejection and delayed graft function, possibly through T cell depletion at the time of grafting.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3040**

**Long Term Renal Allograft Function and Graft Survival Comparing Two Pred-Free, CNI Based Maintenance Immunosuppression: FK/MMF vs. FK/SRL** Lorenzo G. Gallon,[1] Darshika Chhabra,[1] Nader Najafian,[2] Pranav Dalal,[3] Gaurav R. Shah,[3] Joseph Ross Leventhal,[1] Anton I. Skaro.[1] *[1]Medicine/Nephrology, Northwestern University Medical School, Chicago; [2]Medicine/Nephrology, Harvard Medical school, Boston; [3]Medicine, Mt Sinai Hospital, Chicago.*

Background and Methods: The present prospective single center study was designed to compare the long term impact on renal allograft survival and function of two tacrolimus (Tac) based, pred-free maintenance immunosuppressive protocols: Tac/Sirolimus (SRL) vs. Tac/MMF. Renal transplant patients, after given induction with IL2-RA and rapid steroid elimination, were prospectively randomized to Tac/SRL (n=37) or Tac/MMF (n=45). Mean post-transplant follow-up 8.5 yrs. During the entire study, the following data were collected: patient and graft survival, incidence of ACR, glomerular filtration rate (GFR) at different time points post-tx, incidence of infections, malignancies, cardiovascular events, hypertension, hyperlipidemia, post-tx anemia and DM. Results: There were no significant differences between the two groups when comparing pt demographics and characteristics except for the mean age of donor that was significantly lower in the Tac/MMF than in the Tac/SRL group (3311 vs.3913 yrs, p=0.02). The Kaplan-Meier graft survival rates at 8.5 years post-tx were significantly different ( 91.1% in the Tac/MMF vs. 70.3% in the Tac/SRL, p=0.02). GFR measured at different time-points post-tx (up to 66 months post-tx) was consistently lower in the Tac/SRL than in Tac/MMF and the slope of GFR decline per month was significanltly steeper (p<0.0001) in the Tac/SRL vs. Tac/MMF.



Conclusions: The present prospective randomized study shows that the combination Tac/SRL in a pred-free regimen is associated with significantly lower long term graft survival and significantly worse renal transplant function when compared to the combination Tac/MMF.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3041**

**Alemtuzumab Induction in Renal Transplantation: A Single Center Experience** Jeannie P. Co,[1] Jessica G. Lucas,[1] Imran Dosani,[1] Uzoamaka T. Nwaogwugwu,[1] Rahul Bhardwaj,[1] Richard J. Marcus,[1] Kalathil K. Sureshkumar,[1] Sabiha M. Hussain,[1] Tina Y. Ko,[1] Ngoc L. Thai.[2] *[1]Nephrology, Allegheny General Hospital; [2]Transplantation, Allegheny General Hospital, Pittsburgh, PA.*

Alemtuzumab is increasingly used as an induction agent in renal transplantation. We aimed to compare retrospectively the safety and efficacy of induction with alemtuzumab, rabbit antithymocyte globulin (r-ATG) and basiliximab in renal transplant recipients on a calcineurin inhibitor-based steroid withdrawal protocol. Patients received induction with either single dose of alemtuzumab 30 mg intra-operatively, 4 consecutive 1.5 mg/kg doses of r-ATG or basiliximab 20 mg intra-operatively and on post-operative day 4. Results are as follows:

| | Alemtuzumab (n=71) | r-ATG (n=71) | Basiliximab (n=71) | p-value |
|---|---|---|---|---|
| DGF (%) | 27 | 28 | 38 | 0.286 |
| AR rate (%) | 13 | 11 | 28 | 0.013 |
| Number of Infections | 29 | 20 | 28 | 0.226 |
| LOS (days) | 6.2 | 7.1 | 8.1 | 0.013 |
| Admissions/patient/6mos | 0.6 | 0.9 | 0.9 | 0.226 |
| 1-year graft survival (%) | 85 | 85 | 87 | 0.371 |
| 1-year patient survival (%) | 97 | 99 | 96 | 0.426 |

DGF=delayed graft function; LOS=length of stay; AR=acute rejection

Leukopenia defined as a WBC count <4400/μL was observed in 24%, 16% and 2.8% among alemtuzumab, r-ATG, and basiliximab groups respectively (p=0.001) at post-operative day 7. WBC counts were similar at all other time points. Incidence of thrombocytopenia (defined as platelet count <145,000/μL) was similar between the groups at all time points. The reported cases of skin cancers were 0, 3 and 4 and solid tumors were 1, 1 and 0 in the 3 groups respectively. Cost analysis showed significant financial advantage with induction using alemtuzumab ($9,621) compared to r-ATG ($17,737) and basiliximab ($14,340).

In conclusion, alemtuzumab induction is associated with similar graft and patient outcomes in renal transplantation when compared to r-ATG and basiliximab. Alemtuzumab induction was also associated with lower AR rates and shorter LOS compared to basiliximab. Cost benefit analysis favored alemtuzumab use. Therefore, we feel that alemtuzumab provides a safe and effective approach to induction therapy in a cost-conscious health care environment.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3042**

**Does Rituximab Usage Improve the Likelihood of Recurrent FSGS Response?** Carlos E. Araya, Eduardo H. Garin, Richard E. Neiberger, Vikas R. Dharnidharka. *Pediatric Nephrology, University of Florida, Gainesville, FL.*

**Background:** Recurrence of primary FSGS in the allograft occurs in 30 to 50% of cases and is associated with early graft failure. Therapies are not well established and in many cases fail to induce remission. Rituximab has been used in recurrent FSGS with variable success.

**Methods:** We analyzed the existing literature in children and adults with recurrence of FSGS who were treated with rituximab, to determine factors associated with a response to treatment. Analyses were performed with Chi-Square testing or Fisher's exact test for categorical variables and Mann-Whitney test for non-normally distributed variables. Variables with p value <0.10 in univariate analysis for a relationship with development of a primary outcome were entered into multivariate logistic regression analysis.

**Results:** 34 renal transplant patients (16 pediatric) were treated with a mean of 3 rituximab doses (range 1-6). By univariate analysis for two outcomes (no response to therapy vs any response to therapy), a lower number of rituximab infusions (p = 0.008) and a normal serum albumin level (p = 0.039) were associated with a higher frequency of response to rituximab therapy. The patients who improved with therapy were younger at the time of transplant (19.2 vs 28.5 years), but this did not reach statistical significance (p = 0.095). By univariate analysis for 3 outcomes (no response, partial and complete remission) a lower number of rituximab infusions (p=0.03), shorter time to rituximab treatment from relapse (p = 0.02), and normal serum albumin (p = 0.007) were associated with a higher frequency of achieving remission. In multivariate analyses only a normal serum albumin level was significantly associated with a positive response to rituximab therapy (p = 0.007).

**Conclusion:** Adjuvant therapy with rituximab for recurrence of FSGS may be beneficial in only a small subgroup of patients and the response will likely be evident after the initial medication doses. A normal serum albumin is the main determinant of response.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3043**

**Risk for Delayed Graft Function in *De Novo* Renal Transplant Recipients Receiving Everolimus Versus Mycophenolate: Results from a Pooled Analysis** S. P. Mulgaonkar,[1] Diane M. Cibrik,[2] K. Mange.[3] *[1]Saint Barnabas Medical Center; [2]University of Michigan; [3]Novartis Pharmaceuticals Corporation.*

Delayed graft function (DGF) is a risk factor impacting efficacy outcomes in de novo renal transplant recipients (RTs). Everolimus (EVR) is an immunosuppressant used in cyclosporine (CsA) reduction and withdrawal protocols, and comparative risk assessment for DGF between EVR and MPA is warranted.

Data from 2004 de novo renal transplant recipients (RTs) from three EVR studies B201(N = 588), B251(N = 583), and A2309 (N = 833), were analyzed to identify the impact of DGF on efficacy outcomes across both EVR dosing groups and mycophenolate (MPA) control groups. In all studies, EVR groups received either 1.5 mg/day, or 3 mg/day; with either standard or reduced dose CsA depending on the individual study protocol. All control groups received MPA (1.44g/day) with standard dose CsA. Steroids were given as per center practice. Composite efficacy end-point for the pooled analysis was graft loss, death, treated biopsy-proven acute rejection, or lost to follow up. Odds ratios (ORs) were calculated using a logistic regression model with treatment, study, and DGF (Yes or No) as independent variables.

MPA-treated RTs who experienced a composite end-point were 29.3 vs.56.6% for no-DGF vs. DGF subgroups respectively. EVR 1.5 mg and 3.0 mg-treated RTs who experienced a composite endpoint for no-DGF vs. DGF, similarly, were identical at 29.8 vs. 50.6%.

Likelihood of a Composite End-Point Event based on Treatment or DGF

| | Odds Ratio (OR) | 95% C.I. | P Value |
|---|---|---|---|
| EVR 1.5 vs. MPA | 0.9868 | 0.7820, 1.2452 | NS |
| EVR 3.0 vs. MPA | 0.9868 | 0.7825, 1.2445 | NS |
| DGF vs. no-DGF | 2.5686 | 1.9579, 3.3699 | P<0.0001 |

In this pooled data analysis in over 2000 RTs EVR treatment resulted in similar composite end-point events confirming no treatment effect. This result is expected as these studies were powered for non-inferiority. However, risk for experiencing a composite end-point in those RTs with DGF increased significantly compared to those RTs who did not have DGF. This pooled analysis confirms that DGF is a risk factor for poorer efficacy outcomes, irrespective of treatment.

Disclosure of Financial Relationships: Research Funding: Novartis Pharmaceuticals Corporation.

**SA-PO3044**

**IL2ra Induction Therapy in the Prevention of Acute Rejection with TAC/MPA-Based Immunosuppression: Differential Effect by Type of Donor**
Jane Gralla, Alexander C. Wiseman. *University of Colorado.*

**Background:** IL2 receptor anatagonist (IL2ra) induction therapy has an excellent safety profile and improved outcomes in randomized trials using CsA-based immunosuppression. However, there have been no large randomized trials or retrospective analyses examining the effect of IL2ra vs. no induction using tacrolimus and mycophenolate (TAC/MPA)-based therapy.

**Methods:** A retrospective analysis of the SRTR database of adult, primary kidney transplant recipients from 2000-2008 with initial immunosuppression of TAC/MPA/prednisone, who received IL2ra induction therapy or no induction therapy (N=28,686) was performed. Acute rejection at 1 year and graft and patient survival at 1 and 3 years were compared by type of donor.

**Results:** There was no significant difference in 1- or 3-year graft or patient survival for IL2ra vs. no induction therapy, overall or by deceased donor (DD) or living donor (LD). Acute rejection at 1 year was significantly lower with IL2ra (11.6%) vs. no induction therapy (13.0%, relative risk (RR) 0.89, p<0.001, number needed to treat to prevent one episode of acute rejection (NNT)=71). Acute rejection with IL2ra for LD's was 10.8% vs. 12.7% with no induction therapy (RR=0.85, p<0.001, NNT=53) and 12.2% vs. 13.2% for DD's (RR=0.92, p=0.047, NNT=100). Accounting for other risk factors for rejection, the impact of IL2ra remained significant only for LD's.

Table 1: Overall Graft and Patient Survival and Multivariable Analysis of Acute Rejection at 1 Year

| | 3-Yr Graft Survival | 3-Yr Patient Survival | RR of Acute Rejection with IL2ra (95% CI) |
|---|---|---|---|
| All Donors (N=28,686) | 87.5% vs. 87.8% (p=0.50) | 92.8% vs. 93.2% (p=0.16) | 0.90 (0.85-0.96) (p=0.001) |
| DD (N=16,305) | 84.4% vs. 84.5% (p=0.85) | 90.6% vs. 91.2% (p=0.20) | 0.95 (0.87-1.03) (p=0.23) |
| LD (N=12,381) | 91.8% vs. 91.8% (p=0.91) | 95.8% vs. 95.7% (p=0.73) | 0.82 (0.74-0.90) (p<0.001) |

**Conclusion:** The benefit of IL2ra induction with TAC/MPA/prednisone maintenance immunosuppression is less than reported for CsA (baseline acute rejection rates are lower), but may still be of value particularly in LD recipients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3045**

**Bortezomib Therapy for Antibody-Mediated Rejection**
Masahiko Nagahama. *Division of Nephrology, Virginia Commonwealth Univ, Richmond, VA.*

**Introduction**: Although, it is true that abrogating antibody production is essential for antibody-mediated rejection (AMR), current therapies for AMR do not target the primary antibody producing cells, the plasma cells. Bortezomib is a first protesomal inhibitor, which is FDA approved, for the treatment of plasma cell-derived tumors. Only a few case reports and case series of Bortezomib therapy for AMR in renal transplant patients have been reported and there is little information available. The purpose of this case report is to describe the clinical experience with Bortezomib therapy for refractory AMR.

**Methods**: Two renal transplant patients with refractory AMR, who failed to alternate day 200 mg/kg intravenous cytomegalovirus immunoglobulin and plasmapheresis (CMVIG+PP) for 6 cycles, were treated with Bortezomib (1.3 mg/m$^2$, twice weekly for 4 doses) along with methylpredonisolone (250mg). Serial measurements of Flow cytometry crossmatch (FCXM) and donor-specific antibodies (DSA) were conducted by single antigen bead on Luminex platform.

**Results**: (Case 1) A 56 year-old African American (AA) male developed delayed graft function with AMR. He was treated with CMVIG+PP for 6 cycles. However, his FCXM remained positive with increased DSA levels (HLA A24: 10454 SFI; B32: 14426 SFI; B65: 13666 SFI, SFI:standard fluorescence intensity). He underwent Bortezomib therapy, which decreased DSA levels (HLA A24: 8368 SFI; B32: 11024 SFI; B65: 11141 SFI) and FCXM became negative. He came off dialysis and his serum Cr is stable for 6 months after Bortezomib therapy. (Case 2) A 44 year-old AA female developed AMR 6 months after transplant. She did not respond to CMVIG+PP for 6 cycles, and her FCXM remained positive with elevated DSA levels (HLA B44: 3199 SFI; DR15: 5957 SFI; DR4: 1778 SFI). Following Bortezomib therapy, FCXM was still positive and DSA levels were unchanged (HLA B44: 2332 SFI; DR15: 5921 SFI; DR4: 1000 SFI). Her renal function deteriorated and she returned to dialysis.

**Conclusion**: Bortezomib therapy may provide effective reduction in DSA levels and resolution of refractory AMR. However, this is not true for all patients and the prediction of sensitivity to this plasma cell targeted therapy should be investigated by clinical trials.

**6-Months Low-Sub-Therapeutic Dose of Valsartan-Therapy Improves Kidney β-ATP/Pi Levels in Stable Normotensive Kidney-Transplanted Patients: A 31P-MRS Study**
Roberto Bassi,[1,2] Paolo Fiorina,[1,2] Andrea Vergani,[1,2] Alessandro Del Maschio,[3] Antonio Secchi.[2] *[1]Nephrology Division, Transplantation Research Center, Children's Hospital/Harvard Medical School, Boston, MA; [2]Medicine, San Raffaele Scientific Institute, Milan, Italy; [3]Radiology, San Raffaele Scientific Institute, Milan, Italy.*

The effect of angiotensin receptor antagonists on kidney metabolism has not been fully studied. We took advantage of a new technique, 31P-Magnetic Resonance Spectroscopy (31P-MRS), to non-invasively study the effect of a low-sub-therapeutic dosage of the angiotensin receptor antagonist Valsartan treatment on kidney high-energy phosphate metabolism as evaluated with 31P-MRS. Twenty consecutive kidney-transplanted stable patients were enrolled and received Valsartan (80 mg/day) for six months or nothing. Kidney high-energy phosphate metabolism was evaluated both at baseline and after treatment by 31P-MRS with a 1.5T system (Gyroscan Intera Master 1.5 MR System; Philips Medical Systems, Best, the Netherlands). Valsartan-treated patients (n=9) showed a significant increase in ß-ATP/Pi ratio, a marker of kidney high-energy phosphate metabolism (baseline=1.03±0.08 vs. 6 months=1.26±0.07, p=0.03). In contrast, the ß-ATP/Pi ratio in the control group (n=11) did not change (baseline=0.85±0.10 vs. 6 months=0.89±0.08, ns). The improvement in ß-ATP/Pi ratio was not associated with a reduction in arterial blood pressure or in urinary albumin excretion.

Short-term and low-sub-therapeutic dose of Valsartan improves high-energy phosphate kidney metabolism in stable normotensive patients as assessed by kidney-localized 31P-Magnetic Resonance Spectroscopy regardless from any anti-hypertensive or anti-proteinuric effect.

**Outcomes of Kidney Transplant in Highly Sensitized Patients. Single-Center Experience**
Maria Joao Carvalho Azevedo Rocha,[1,2] António Cabrita.[1,2] *[1]Nephrology, Hospital Santo António- Centro Hospitalar do Porto, Porto, Portugal; [2]Transplant, Hospital Santo António- Centro Hospitalar do Porto, Porto, Portugal.*

Transplantation on hypersensitized patients (HSP) is a major challenge for any transplantation team. Portuguese law change in 2007, increased the incidence of (HSP) recipients from 1.3% to 7,6%.Our purpose is to analyze clinical outcomes of HSP.We retrospectively analyzed demographic and clinical data of all HSP transplanted between 2007 and 2009 in our unit.25 HSP (PRA>50%) 14 female,11 male,mean age 48,9±11,3 years received an isolated kidney graft.Mean dialysis time was 148,8±94,5 months.Average PRA was 70,8±17,1% by Luminex.Average donor age was 47,3±10y.CDC cross-match was negative in all cases.All received tacrolimus,MMF and prednisone,21 received ATG and 4 antiCD25 antibodies.Five patients received IVIG,one with plasmapheresis.Delayed graft function (DGF) occurred in 36%(75% in the antiCD25 group vs 28% in the ATG group; p=1,00).Six patients experienced one episode of acute biopsy proven rejection (ABPR),all antibody-mediated (AM),1 with superimposed cellular rejection.Time until ABPR was 16.6±6,9 days,4 patients presented acute graft dysfunction and 2 DGF.All received IVIG and plasmapheresis,one received ATG,3 received Rituximab.Discharge mean plasma creatinine (PCr) was1,83±0,9 mg/dL.Three allografts where lost,1 because of receptor death,1 primary non-function and 1 due to acute allograft thrombosis without AR.There were 36 hospital readmissions,13 caused by severe bacterial infection. With a mean follow-up of 24,9±9,4 months,22 allografts are functioning with a mean Pcr of 1,51(mg/dl] 0,77 mg/dL.The average PCr of patients who had ABPR is 2,31[]0,98 mg/dL and 1,1±0,44mg/dL in those who didn't(p=0,0015).HSP had a higher incidence of ABPR compared to the general transplant population(10,2%).Rejection episodes occurred soon after transplant and were antibody mediated.Despite this,there was no graft loss attributed to ABPR, although it seems to have a negative impact on graft function.Transplant is a good therapeutical option for these patients.Dessensitization therapies may further improve outcomes.

**A Randomized Clinical Trial Comparing Tacrolimus and Sirolimus Maintenance Monotherapy Following Kidney Transplantation** Monique E. Cho,[1] Xiongce Zhao,[2] Michael S. Ring,[1] Roslyn B. Mannon,[3] Allan Kirk.[4] *[1]Kidney Disease Branch, NIDDK; [2]Office of the Director, NIDDK, NIH, Bethesda, MD; [3]University of Alabama, Birmingham, AL; [4]Emory University, Atlanta, GA.*

Background: Both sirolimus (Rapa) and tacrolimus (FK) are effective in preventing renal allograft rejection when used as part of a multidrug regimen, but there have been no studies directly comparing these agents as monotherapies. Methods: In order to investigate whether there was a clear advantage to either drug, we enrolled 31 patients in a phase II trial using Thymoglobulin and methylprednisolone induction followed by combination therapy with both Rapa and FK for 6 months. At 6 months, those without rejection on protocol biopsy with good tolerance to both drugs were randomized either Rapa or FK monotherapy. Primary outcome was renal graft function over time, using linear mixed model to calculate the least mean square values of serum creatinine. The secondary outcomes included safety and tolerability profiles and renal graft biopsy results. Results: Out of 31 patients, 7 were randomized to Rapa and 8 to FK. The remaining 16 patients could not be randomized due to Rapa intolerance {oral ulcers (1); hyperlipidemia (2); arthropathy (3)}, rejection on protocol biopsy (4), or unrelated issues (6). The mean follow-up was 4 yrs post randomization. Their mean nadir serum Cr (mg/dL) was 1.03 in Rapa group and 1.17 in FK group and remained stable over 54 months without significant increase. There were no differences in the rates of biopsy diagnoses of IF/TA, rejection, or BK nephropathy in the two groups, based on a mean of 3.5 biopsies per patient over a mean of 1.4-year period. Serum triglycerides levels were significantly higher in the Rapa group between months 6-24, and the absolute lymphocyte count remained significantly lower in Rapa group between months 12-30. The incidence of post transplant diabetes was similar in both groups. Conclusion: In patients selected for their stability and tolerance to either drug, both Rapa and FK monotherapy provided similar prophylaxis from rejection without differing long-term consequences over a 4 year follow-up period. FK was associated with fewer dose limiting consequences.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3049**

**Everolimus Plus Reduced CsA Exposure: Preserved Efficacy and Renal Function from 12 to 24 Months** Fuad S. Shihab, Diane M. Cibrik, Yu Seun Kim, R. Walker, G. Zibari, C. Cornu-Artis, C. Panis, H. Jiang, Helio Tedesco-Silva. *For 2309 Study Group.*

Everolimus is an mTOR inhibitor that has immunosuppressive and anti-proliferative properties. The efficacy and safety of everolimus with cyclosporine (CsA) minimization was assessed in 833 de novo renal transplant recipients.

A2309 is a 24-month, randomized, multicenter, open-label study comparing 2 targets of everolimus (EVR) (C0 3 – 8 ng/mL or C0 6 – 12 ng/mL) with reduced CsA exposure versus a control group receiving enteric-coated mycophenolate sodium (MPA) 1.44g/day with standard exposure CsA. The endpoints at 24M were composite efficacy (incidence of graft loss, death, BPAR, loss to followup-LTF), plus renal function and safety comparisons between the EVR groups and the MPA control.

Donor and recipient characteristics were comparable between the groups. Around a 60% reduction in CsA exposure for both EVR groups continued to be maintained from 12M to 24M versus MPA control group (mean C0 at 24M: 52, 50 & 135ng/mL for EVR 3-8ng/ml, 6-12ng/ml & MPA groups, respectively). Mean 24M calculated GFR (MDRD) values were 52.2, 49.4 and 50.5 mL/min/1.73m2 for EVR 3-8, EVR 6-12 and MPA respectively, and comparable renal function was maintained from 12M to 24M.

Results for the ITT population at 24M by treatment group*. All values are n (%)

| | EVR 3-8ng/mL | EVR 6-12ng/mL | MPA 1.44g |
|---|---|---|---|
| Primary Composite Efficacy** | 91 (32.9) | 75 (26.9) | 76 (27.4) |
| Death | 9 (3.2) | 10 (3.6) | 8 (2.9) |
| Graft Loss | 16 (5.8) | 17 (6.1) | 11 (4.0) |
| Death, or Graft Loss | 23 (8.3) | 26 (9.3) | 18 (6.5) |
| Loss to follow up | 21 (7.6) | 14 (5.0) | 12 (4.3) |
| Treated BPAR** | 55 (19.9) | 42 (15.1) | 53 (19.1) |
| On-treatment Primary Composite Efficacy* | 72(26.0) | 56(20.1) | 74(26.7) |

**Only the first treated BPAR event included in composite score.

The incidence of notable AEs was higher in the EVR 6-12ng/mL group at 24M (75%), but the incidences for EVR 3-8ng/mL vs MPA were comparable, (68 vs 66%).

This analysis confirms that efficacy parameters and renal function achieved at 12M with a combination of EVR and 60% lower exposure to CsA as compared to MPA control were maintained at 24M.

**ABO Incompatible Living Donor Kidney Transplantation (ABOI-KT) without Splenectomy: Single Center Experience** Jeongmyung Ahn,[1] Dong Ryeol Lee,[1] Mi Young Jeon,[2] Byung Chang Kim,[3] Jin M. Kong.[1] *[1]Division of Nephrology, Internal Medicine, Maryknoll Medical Center, Busan, Republic of Korea; [2]Department of Pathology, Maryknoll Medical Center, Busan, Republic of Korea; [3]Department of Clinical Laboratory, Maryknoll Medical Center, Busan, Republic of Korea.*

**Introduction:** ABOI-KT seems a valuable option to overcome global organ shortage. With the recent protocol with no splenectomy, excellent graft outcome equivalent to ABO-compatible transplantation has been reported.

**Method:** Twenty-one ABO-I KT without splenectomy has been performed in our center since 2007. Rituximab was given 1 month prior to transplantation. Plasmapheresis was done to lower anti-ABO antibody to ≤8 on transplantation day. Number of HLA mismatch was 3.86(0-6). Anti-IL2 antibody induction and tacrolimus-based triple drug was used. Median IgG anti-ABO antibody titer initial, on transplant day and at last follow up was 32(8-512), 2(1-8) and 2(1-32), respectively. Posttransplant plasmapheresis was done not routinely but selectively in 7 patients with high initial ABO antibody titer, rapidly rising antibody titer during 2 weeks posttransplantation or rising serum creatinine.

**Result:** Median follow up was 20(2-41) months. One episode of ABO-antibody mediated acute rejection occurred in a patient, recovered by treatment. One patient developed leukoencephalopathy at 10Mo. post transplantation. But, his neurologic problem recovered after immunosuppressant reduction. No patient or graft was lost to date. There was no major infection requiring hospitalization. **Conclusion:** ABOI-KT has excellent outcome, and is a good way to increase donor availability.

**One-Year GFR as a Surrogate for Long Term Allograft Survival: Estimated Versus Measured GFR** Nicolas Maillard,[1] Olivier Moranne,[2] Christopher R. Mariat.[1] *[1]Service de Néphrologie et Laboratoire d'Explorations Fonctionnelles Rénales, CHU Saint Etienne, Saint Etienne, France; [2]Service de Néphrologie et Département de Santé Publique, CHU Nice, Nice, France.*

An increasing number of clinical trials use one-year GFR as an endpoint to estimate the risk of long-term allograft dysfunction. Several registry studies have recently questioned the real performance of the estimated GFR as a valid surrogate marker since the main estimation formulas exhibited only weak predictive values. This point could be explained by the inability of these creatinine-based equations to accurately estimate the true GFR in this population. The aim of our study was to evaluate whether a direct measure of GFR by inulin clearance could be more efficient than the MDRD equation to predict long term allograft survival.

We retrospectively analyzed all transplant recipients with a minimum follow-up of 10 years who had a one-year post-transplantation inulin clearance measurement (measured GFR) and a MDRD assessment (estimated GFR). The respective performances of these GFR evaluations were compared using multivariate analysis with adjustment on main co-variables known to impact allograft survival (Cox proportional model and ROC curves analysis).

Two hundred and twenty nine patients were retained for the analysis. While the one year inulin-based GFR was significantly associated with the 10-year graft loss for the CKD stages 3 (Hazard Ratio 2.9; CI95% [1.1-8.2] and 4 (HR 6.9 [1.2-40.1]), the MDRD-assessed GFR was only for stage 4 (HR 5.6 [1.3-23.9]. The multivariate ROC analysis tended to confirm the superiority of the one-year measured GFR, albeit its predictive performance still remained limited (Inulin and MDRD Area Under Curve respectively 0.65 vs. 0.60; ns)

Our results suggest that the one-year measured GFR is a better predictive factor of the long term allograft outcome than the creatinine-based GFR estimation. However, this parameter, when considered alone, cannot be considered as a valid surrogate marker of the long term allograft survival. Whether other parameters (e.g. proteinuria, histology) combined to the GRF evaluation would improve the prediction needs to be studied.

Disclosure of Financial Relationships: nothing to disclose

**It's Not Who You Know, It's What Who You Know Knows: The Role of Dialysis Teams and Social Networks in Improving Kidney Transplant Parity** Teri Browne. *College of Social Work, University of South Carolina, Columbia, SC.*

PURPOSE: Research has shown that black dialysis patients are significantly less likely than their white peers to be evaluated and listed for a kidney transplant. The contribution of the present study is to investigate previously unconsidered social network factors that might influence the racial composition of kidney transplant-patient populations. METHODS: Surveying 228 black hemodialysis patients in Illinois, the following research questions were addressed using an original survey: (1) What is the role of social networks in providing information about kidney transplantation to black hemodialysis patients? (2) What is the relationship between social networks and a patient's likelihood of being seen at a kidney transplant center? RESULTS: 94% of patients surveyed were interested in a kidney transplant, and 98% percent had insurance that would pay for a kidney transplant, but only 9% were active on a transplant waiting list. Black hemodialysis patients with lower incomes were less likely to be seen at a kidney transplant center (OR 1.38, 95%CI: 1.09-1.76, p<.01), and patients who have people in their social network with information about kidney transplant are significantly more likely to be seen at a kidney transplant center. Specifically,

black dialysis patients who get informational social support from their dialysis team (OR 1.76, 95%CI: 1.5-2.1, p<.001) and social networks (OR 1.63, 95%CI: 1.2-2.3, p<.001) are significantly more likely to be seen at a kidney transplant center. IMPLICATIONS: Kidney transplant disparity is a multifaceted social problem, and considering black dialysis patients' social milieu can be complimentary to the important existing research regarding this public health crisis. The logistic regression models imply that correct information about a kidney transplant and success of being seen at a kidney transplant center can be differentiated on the basis of considering social network informational attributes and income. Dialysis health teams can augment patients' social networks through their own interventions or by linking patients with mentors or patient navigators.

## SA-PO3053

**Peginterferon Alfa-2A Plus Ribavirin Combination Treatment in Chronic H C V Post Renal Transplantation: An Interim Analysis** Dujanah Hassan Mousa,[1] Faisal Sanai,[2] Hassan A. Aleid,[3] Hamad Ibrahim Al-Ashgar,[4] Khalid Abdulmohsen Almeshari,[3] Khalid I. Bzeizi.[2] *[1]Renal Department, Renal Transplant Program, Riyadh Military Hospital, Riyadh, Saudi Arabia; [2]Hepatology Department, Riyadh Military Hospital, Riyadh, Saudi Arabia; [3]Renal Transplant Program, King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia; [4]Hepatology Devision, King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia.*

Chronic liver disease has a significant impact on the survival of renal transplant recipients. At present, there is no safe and efficacious therapy of chronic HCV after renal transplantation. Interferon (IFN)-based therapy in renal transplant recipients remains a controversial issue, as it has been associated with a high risk of graft rejection and poor efficacy. Aim: To assess the safety and efficacy of PEG-IFN and ribavirin combination therapy in post-renal transplant HCV-infected patients. Methods: 28 adult renal transplant recipients at 2 centers in Saudi Arabia,12 months after surgery with confirmed HCV and evidence of histological disease were recruited in a prospective, pilot, open-label trial with PEGIFN-alpha-2a (135-180 micg/week) plus ribavirin (200-1200 mg/day)GFR base dose. Safety and laboratory assessments were performed periodically. more male (57%), mean age 47y, genotype 1&4,and mean HCV RNA 6.4 log10 IU/mL. Renal biopsy was performed in patients with a 20% increase in s creatinine. Results: 26 patients completed study. Dose reductions of PEGIFN and ribavirin were required for hematological side effects. Overall, 55.6%, 37% and 32% achieved EVR, end-of-treatment and SVR, respectively. No documented rejection episodes. Non-renal complications were seen in 3 patients.There was no difference in the pre-treatment and end-of-assessment serum creatinine. Conclusions: PEGIFN/ribavirin therapy in renal recipients is safe with no rejection episodes, but has limited efficacy in the treatment of chronic HCV.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO3054

**Area under the Curve (AUC) Bioequivalence (BE) of Mycophenolate Mofetil (MMF): CellCept® vs. Generic** Ian C. Doyle,[1] Ahmed M. Zikri,[2] William M. Bennett,[3] Michal J. Figurski,[4] Leslie M. Shaw.[4] *[1]School of Pharmacy, Pacific University Oregon; [2]Pharmacy Services; [3]Transplant Services, Legacy Good Samaritan Hospital; [4]Pathology Laboratory Medicine, University of Pennsylvania Medical Center.*

Purpose: Determine BE of generic MMF (Mylan) compared to CellCept (innovator MMF) in renal transplant (RT) recipients based on limited sampling mycophenolic acid (MPA) AUC.

Methods: During 5/09 to 4/10, we established an MMF therapeutic drug monitoring (TDM) program utilizing simultaneous multi-linear regression (MLR) (using SAS) and Bayesian kinetics (BAY) (using NONMEM). Currently, MLR and BAY models have been developed using CellCept. Since 5/09, 7 FDA-approved generic formulations of MMF have become available. Six RT patients were prospectively enrolled in an open-label, crossover design study to compare MPA AUCs of CellCept and the generic MMF formulation (Mylan) most often dispensed in our area. The 250mg capsule of each product was used. MPA levels were drawn at 0/40/240 min. and 0/40/120 min. for FK and CSA patients respectively. Patients consumed a minimum of 6 days of drug during crossover.

Results: MPA AUC

| Dose (mg) | CNI | Day | CellCept AUC BAY | Cellcept AUC MLR | Day | MMF AUC BAY | MMF AUC MLR |
|---|---|---|---|---|---|---|---|
| 500 BID | FK | 201 | 47.25 | 61.14 | 208 | 38.02 | 48.89 |
| 750 BID | FK | 64 | 86.77* | N/A* | 71 | 88.57 | 112.81 |
| 1000 BID | CSA | 57 | 38.67 | 39.77 | 64 | 38.53 | 44.51 |
| 500 BID | FK | 67 | 28.86 | 35.18 | 74 | 36.1 | 47.02 |
| 1000 BID | FK | 56 | 61.72 | 67.95 | 63 | 55.01 | 63.85 |
| 750 BID | FK | 82 | 28.52 | 35.16 | 76 | 43.82 | 62.87 |

* 240-minute sample not available (broken during shipping)

Conclusions: The FDA approves drugs as bioequivalent using data from healthy subjects who achieve a range of 80-125% AUC of innovator. MMF (Mylan) was approved as BE, with AUC 100% and Cmax 89% of CellCept. In our study, 4 of 6 patients had generic MMF AUC levels within 90%-110% AUC of innovator, and 5 of 6 patients were within 80-125%. Since AUC monitoring is subject to a high degree of intra- and inter-patient variability, AUC BE testing for RT patients is warranted. Current CellCept-based MLR and BAY models might not be applicable to patients taking generic MMF.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO3055

**1 Year Results of an Intensified Dosing of Enteric-Coated Mycophenolate Sodium in Renal Transplant Patients Results in Improved Efficacy without Compromising Safety: 1 Year Follow-Up Results** Klemens Budde,[1] Claudia Sommerer,[2] Petra Glander,[1] Toofan Ariatabar,[3] Stefan Kramer,[4] Eva-Maria Vogel,[4] Martin G. Zeier,[2] Wolfgang Arns.[3] *[1]University Hospital Charité, Berlin; [2]Nierenzentrum, University Hospital Heidelberg; [3]Transplantationszentrum, Dept. of Nephrology, Koeln-Merheim; [4]Novartis Pharma, Nuremberg, Germany.*

**Objective:** The influence of an intensified dosing (ID) regimen with enteric-coated mycophenolate sodium (EC-MPS) compared to EC-MPS standard dosing (SD) on efficacy and safety 12 months after renal transplantation was assessed.

**Methods:** De-novo kidney transplant recipients were treated with basiliximab, steroids and cyclosporine and randomized to EC-MPS standard (SD: 1440mg/d) or to EC-MPS intensified dosing regimen (ID: 2 weeks: 2880 mg/d; subsequent 4 weeks: 2160 mg/d; followed by 1440 mg/d). After completion of the core study at month 6, patients (pts) were included in an observational follow-up until month 12.

**Results:** 128 patients were randomized to either SD (n=65) or ID (n=63), 101 (78.9%) pts (n=49 ID vs. n=52 SD) completed the follow-up analysis at month 12. The incidence of BPAR was lower in the ID compared to the SD group (12(23%) vs. 3(6.1%); p= 0.025) at month 12 with one additional BPAR in ID vs 2 BPAR in SD pts in the follow-up period. Patient survival was 98.0% in the ID and 96.2% in the SD group, and 3 graft losses were observed in ID and 5 graft losses in SD pts. In the follow-up period the ID regimen was not associated with a higher rate of hematological side effects (11 ID vs. 15 SD pts). Slightly more infections (29 ID vs. 24 SD pts) and gastrointestinal symptoms (19 ID vs. 15 SD) were reported in the ID group. Safety parameters are listed below:

| | SD | ID |
|---|---|---|
| Anaemia [% of pts] | 12 | 8 |
| Leucopenia [% of pts] | 15 | 4 |
| Thrombocytopenia [% of pts] | 2 | 2 |
| Constipation [% of pts] | 2 | 4 |
| Diarrhea [% of pts] | 10 | 12 |
| Hemoglobin [g/dl] | 12.8 | 12.8 |
| Leukocytes [/nl] | 7.5 | 7.2 |
| CMV infection [% of pts] | 2 | 8 |
| BKV infection [% of pts] | 8 | 8 |
| Pneumonia [% of pts] | 4 | 6 |
| Serum creatinine [mg/dl] | 1.6 | 1.8 |

**Conclusion:** An intensified dosing regimen of EC-MPS was associated with a significantly lower BPAR rate at month 12 without compromising tolerability and safety.

## SA-PO3056

**Steroid Withdrawal in Renal Transplant Recipients after Conversion from a Cyclosporine Based Immunosuppressive Regimen to Tacrolimus Monotherapy; a Prospective Multicentre Trial** Lars Backman. *Uppsala University Hospital, Dept of Transplantation surgery, Uppsala, Sweden.*

Inspite of the introduction of new immunosuppressive (IS) agents and regimens, steroids (st) are still used widely. St are associated with an increased incidence of diabetes, hypertension and hyperlipidemia, aggravated by the use of Cyclosporine (CsA). Aim: to evaluate whether conversion from a CsA based IS to Tacrolimus (Tac) monotherapy resulted in improvements of these side-effects.

**Methods:** 79 renal transplant recipients (58M/21F) from 9 centres, with mean age of 59 (range 25-80) years with CsA and st associated side-effects were included. The patients were converted to a Tac based regimen with the subsequent withdrawal of st with a f-u of 24 months. Baseline results were compared to 24-month results with paired t-test. Levels are expressed as mean ± SD.

**Results**: 62 of the 79 patients (78%) completed the study and 43 (69%) were completely off st after 24 months (nopred), whereas 16 were still treated with prednisolone (pred), 2.5-7.5 mg/day. 2 patients died (lymphoma and heart failure) and 3 grafts were lost. 10 additional patients were withdrawn. None experienced acute rejection or developed diab during the follow-up.

| | s-crea | s-chol | s-trig | BP |
|---|---|---|---|---|
| Pred BL(n=19) | 140 ±32 | 5.18 ±1.50 | 1.99 ±0.85 | 140/75 |
| Pred 24months | 167 ±69 | 4.96 ±1.04 | 1.89 ±0.95 | 135/77 |
| P value | 0.05 | ns | ns | ns |
| Nopred BL(n=43) | 127 ±37 | 5.33 ±1.54 | 1.76 ±0.86 | 137/80 |
| Nopred 24months | 134 ±45 | 4.58 ±1.28 | 1.53 ±0.85 | 135/80 |
| P value | 0.044 | 0.011 | 0.042 | ns |

**Conclusion:** Conversion from a Cyclosporine based IS was safe and well tolerated. No patient had acute rejection or developed diabetes. The conversion from Cyclosporine resulted in a significant decrease in s-chol. Discontinuation of pred and Tacrolimus monotherapy resulted in a significant decrease in both chol and trig levels with a lower, but increase in crea levels over 24-months. Conversion from Cyclosporine based IS in renal transplant recipients with the subsequent withdrawal of steroids was possible in 73% of the patients and may result in a more favourable cardiovascular risk profile after renal transplantation.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO3057**

**Mycophenolate Mofetil (MMF) Therapeutic Drug Monitoring (TDM): Combined Multi-Linear Regression (MLR) and Bayesian (BAY) Area under the Curve (AUC) vs. Standard Care (SC)** Ian C. Doyle,[1] Ahmed M. Zikri,[2] William M. Bennett,[3] Leslie M. Shaw,[4] Michal J. Figurski.[4] *[1]School of Pharmacy, Pacific University Oregon; [2]Pharmacy Services; [3]Transplant Services, Legacy Good Samaritan Hospital; [4]Pathology Laboratory Medicine, University of Pennsylvania Medical Center.*

Purpose: Compare outcomes of renal transplant (RT) recipients following establishment of a mycophenolic acid (MPA) AUC TDM program to a concurrent fixed-dose, SC cohort.

Methods: From 5/09 to 4/10, 29 RT were prospectively enrolled into a study of CellCept®, having MPA levels monitored & doses adjusted to achieve AUC of 45 mg•hr/L (range 40-50). Initial MMF doses were 1000 mg BID for FK patients and 1500 mg BID for CSA patients. Limited sampling MPA levels were drawn on days 7, 30, & 60, at 0/40/240 min. and 0/40/120 min. for FK and CSA patients respectively. Final AUC was determined by averaging MLR and BAY AUCs. Doses were adjusted using AUC results, in conjunction with a transplant nephrologist. Side effects were assessed on AUC sampling days. Surveillance biopsies were performed, unless clinically contraindicated, at 6-8 weeks & 6 months post RT. SC patients were assessed via retrospective chart review (RT 4/09 to 11/09).

| # dose changes per AUC | 13 | 16 | 11 | - | - | - |
| # dose decrease | 8 | 13 | 8 | 0 | 2 | 1 |
| Mean WBC | 8.64** | 5.66* | 5.5* | 11** | 6.49* | 5.7* |
| Mean Hgb* | 11 | 11.8 | 12.9 | 10.7 | 11 | 11.8 |
| GI intolerance* | 3 | 2 | 2 | 2 | 3 | 1 |
| BK viruria by 3 mo* | | | 4/24 | | | 2/26 |
| Acute Rej. cumulative by 8wk & 3mo* | | | 0/24, 3/24 | | | 3/27, 7/26 |

*NS, **p=0.017

Conclusions: The low rate of in-range AUC values on day 30 might indicate more frequent AUC monitoring is needed during this time period. The large proportion of MMF dose decreases on day 30 & 60 is consistent with literature that MPA AUC increases with time. Many patients can have MMF dose decreased without increasing risk of AR. MPA TDM is associated with a non-significant decreased rate of AR at 3 months. An increased rate of BK infection was observed.

**Maintaining a Short and Stable Waiting List for Renal Transplant Candidates** Hallvard Holdaas. *Department of Medicine, Oslo University Hospital, Rikshospitalet, Oslo, Norway.*

**Introduction.** A universal and profound problem in nephrology is the increasing number of patients on waiting lists for renal transplantation. In most countries there is a critical organ donation shortage.

**Method.** We examined listing for renal transplantation and time on the waiting list for endstage renal disease (ESRD) patients in Norway during the last decade.

**Results**. The incidence of ESRD increased from 89 per million per year (pmp) in 2000 to 116 per million inhabitants per year in 2008. Mean age at start of renal replacement therapy was 65.2 years (9 – 88) and 64.8 years (7 – 95) in 2000 and 2008 respectively. During the years 2000 to 2006 the waiting list increased from 35 to 48 pmp with a transplant rate of 46.0 and 45.7 pmp respectively. Kidney grafts from living donors were stable in this period, 17 – 20 pmp. The supply from deceased donors was suboptimal and stable, 27.3 and 26.9 pmp in 2000 and 2006 respectively. However, after establishment of specific donor responsible doctors and a Governmental directive coupled with financial resources to hospitals providing deceased donors, the numbers of deceased donor increased to 35.4 in 2008 and 35.8 pmp in 2009. We also liberally accept extended criteria donors. Theare is also steady supply of living donors is provided by local nephrologist with no financial incentive to choose dialysis as the preferred treatment of ESRD. Overall transplantation rates in 2008 and 2009 were 58.3 and 60.9 pmp versus 46 pmp in 2000. The waiting list is now reduced to 37.3 pmp which is similar to 2000. The current median waiting time for first and secondkidney from deceased donor is about 10 months.

**Conclusion.** Sufficient supply for renal grafts may be obtainable by a combined utilization of kidneys from deceased and living donor sources. This national strategy for ESRD has resulted in a stable waiting list. Of all patients in ESRD in Norway 70% is transplanted and 30% in dialysis treatment.

**Kidney Transplant Candidates' Information Needs and Perceptions about OPTN-Defined High Risk Donor Organs** Elisa J. Gordon,[1,2] Elizabeth A. Reddy,[1] Daniela Ladner,[1,2] John J. Friedewald,[2] Michael Ison.[2] *[1]Institute for Healthcare Studies, Northwestern University; [2]Surgery, Northwestern University, Chicago, IL.*

OPTN-policy requires special consent for recipients of organs from OPTN-defined "high risk" donors (HR) but it is unknown what information patients need to make an informed decision about accepting HR organs. We investigated kidney transplant candidates' understanding of, information needs about, and willingness to accept HR donor kidneys. A consecutive sample of kidney transplant candidates underwent a 20-minute telephone interview. Open-ended responses were analyzed for repetitive themes and patterns. The response rate was 83% (147/177 patients). Candidates perceived 'high risk donor' to mean that the donor: was older (39%), had a general health problem (33%), had an infectious disease (29%), used drugs or alcohol (8%), or that the donor kidney would not function well or match well with the recipient (7%). Candidates wanted to know "everything" about the HR donor's: risky behaviors (smoking, drinking, drug use) (41%), medical conditions (16%), age (8%), how donors died, how well the graft would function (17%) and match (7%), and the statistical likelihood of transmitting infectious disease (39%). Candidates were unwilling (47%) or unsure (21%) to accept a HR kidney because they were concerned about getting an infection and endangering health (31%), the kidney would not function well or last (29%), doing well on dialysis (21%), and do not have enough information (11%).

Table 1. Information Needs about HR Kidneys

| |
|---|
| "Wouldn't it be a good thing to know what it was that killed the donor? What made [the organ] high risk? How long would it last?" |
| "What's wrong with the organ and how can it effect your body … Will it be rejected? That would be the major thing. I don't want to go through two surgeries." |

Transplant candidates for other organs may differ in willingness to accept HR organs as they may not have alternative therapy but certain death. Greater efforts are needed to educate kidney transplant candidates about what HR donor organs are, how well they function, and the donor's behaviors to optimize their informed treatment decisions.

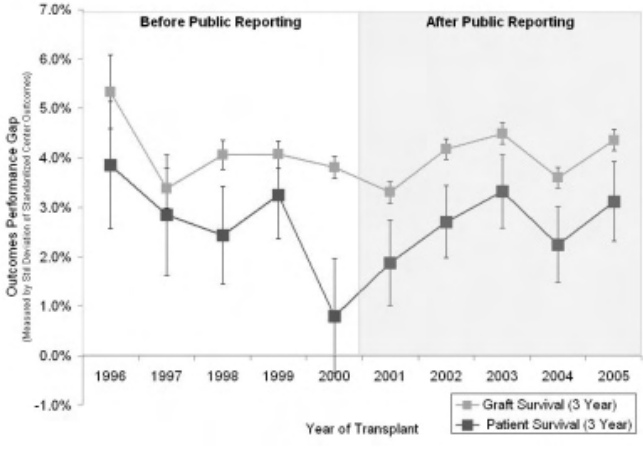
**Public Reporting Has Not Reduced the Performance Gap across Kidney Transplant Centers** Constantia Petrou,[1] Stefanos Zenios.[1,2] *[1]Culmini Inc; [2]Graduate School of Business, Stanford University.*

**Purpose:** To determine whether public reporting of kidney transplant center performance has reduced the outcomes gap across centers.

**Methods:** We used a mixed effects approach to provide robust estimates of the performance gap across transplant centers. Unlike current methods, this approach is not susceptible to generating extreme estimates of the performance gap due to random chance. Data were obtained from the USRDS. All adult patients who received a transplant between 1/1/95 and 9/30/05 were included. 3-year patient survival and 3-year graft survival were modeled using generalized linear mixed effect models with a logit link. Risk factors at the time of transplant were the fixed effects and transplant centers were the random effects. The outcomes gap across transplant centers was measured by the standard deviation of standardized outcomes derived from the models.

**Results:** Using the mixed effects method, the typical performance gap across centers was: 4.2 % for graft survival and 2.5% for patient survival (p-value < 0.01). Methods currently used in public reports exaggerated the performance gap: 8.6% gap for graft survival and 7.7% gap for patient survival. The effect of our more conservative estimate is clinically significant. If the performance gap would be completely eliminated (by worse centers matching the outcomes of the better ones), 25% of all graft failures and 20% of all deaths in the first three years after transplant could be averted. However, the figure below shows that the performance gap did not decrease after the introduction of public reports in 2001.



**Conclusions:** Public reporting of transplant center performance has not reduced the outcomes gap across centers. For all patients receiving a kidney transplant in any given year and followed for 3 years post-transplant, reducing this center gap is expected to save up-to 278 patient lives and 670 grafts.

## SA-PO3061

**Treating Post Transplant Anaemia Does Not Affect Progression of Chronic Kidney Disease: A Pilot Randomised Controlled Trial** Taryn Pile,[1] Martin J. Raftery,[1] Magdi Yaqoob.[2] *[1]Department of Renal Medicine and Transplantation, Barts and the London NHS Trust, London, United Kingdom; [2]Department of Translational Medicine and Therapeutics, William Harvey Research Instituite, Queen Mary, University of London, United Kingdom.*

Background

Post Transplant Anaemia (PTA) affects 30-45% of renal transplant recipients. The treatment of PTA has not been well studied in randomised controlled trials (RCT). A pilot study to assess the effect of treatment with Epoetin beta on renal progression, blood pressure and proteinuria in anaemic renal transplant recipients was performed.

Methods

A RCT was performed in a single renal transplant centre. Renal transplant patients more than 3 months post transplant with an Hb between 9 and 11.5g/dl were recruited. The treatment arm received Epoetin beta (EB) starting at a dose of 50U/kg/week to achieve a target of 11.5-13.5g/dl. The No Treatment group (NT) was treated with EB if the Hb fell below 9g/dl. The primary end-points were progression of CKD, blood pressure and proteinuria.

Results

55 patients were recruited (NT N= 27, EB N=28) and were followed up for a median of 23.34 months. The demographics and baseline biochemistry was similar in both groups at initiation of the study. At the end of the study the Hb was significantly higher in the EB group (EB: 12.3 ± 0.18 vs. NT: 9.99 ± 0.22 g/dl, $p < 0.001$). Protein:Creatinine Ratio was similar in both groups (EB 45.74 ± 12.07 vs. NT: 34.8 ± 6.84 mg/mmol, p=0.64). Average of 3 blood pressures was not significantly different at the end of the study (SBP: EB 130.9 ± 2.1 vs. NT: 127.3 ± 2.2, p=0.45; DBP 82.95 ± 1.4 vs. NT: 82.1 ± 1.4 mmHg, p=0.48). Rate of progression, determined by slope of eGFR by MDRD7, was not significantly different between the two groups (EB: -0.09 ± 0.1 vs. NT: -0.12 ± 0.15 mLs/min, p=0.78).

Conclusion

The treatment of anaemic transplant patients with EB in this small pilot RCT did not have any significant effect on renal progression. There is however no evidence of harm done to these patients treated to a target of 11.5-13.5g/dl. A large, multi-centred RCT is warranted to study the effects of erythropoietin treatment in PTA.

Disclosure of Financial Relationships: nothing to disclose

**High-Dose Erythropoietin (EPO) and Graft Function after Cadaveric Kidney Transplantation** Carsten Hafer,[1] Jan T. Kielstein,[1] Thomas Becker,[3] Hermann G. Haller,[1] Danilo Fliser.[2] *[1]Internal Medicine / Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; [2]Internal Medicine / Nephrology and Hypertension, Saarland University Medical Centre, Homburg / Saar, Germany; [3]Transplantation Surgery, Hannover Medical School, Hannover, Germany.*

**Background**: In experimental studies administration of erythropoietin (EPO) revealed tissue-protective effects and prevented renal tissue damage after ischemia-reperfusion injury.

**Methods**: We evaluated short- and long-term effects of high dose EPO on kidney function after renal transplantation in a prospective double-blind placebo controlled study. Ninety patients with CKD stage 5 D receiving a cadaveric kidney allograft were randomized to 3 x 40.000 IU EPO alpha (1st injection intra-arterial immediately after opening the transplant artery, 2nd and 3rd were given 3 and 7 days after successful transplantation) or placebo. Primary endpoint was estimated glomerular filtration rate (eGFR/CKD-EPI) 42 days after transplantation. Secondary endpoints were incidence of delayed graft function, i.e. dialysis dependency during the first 7 days after transplantation, and eGFR at 6 and 12 month.

**Results**: Eighty-eight patients were included in the intention to treat analysis. eGFR after 42 days was similar in both groups: 46.6 ± 28.3 ml/min (EPO) vs. 45.7 ± 21.6 ml/min (placebo), (p=0.78). The results were similar (p=0.24) after 12 months: 39.7 ± 3.4 (EPO) vs. 44.56 ± 3.6 ml/min (placebo). There was no significant difference between groups with respect to the incidence of delayed graft function (EPO: 10 of 44 pts. [22.7%]; placebo: 14 of 44 pts. [31.8%]). Transplant biopsies 6 weeks and 6 months after transplantation showed no significant differences in all histological indices. Number and severity of adverse events were comparable between both groups as was patient survival after 12 months, i.e. 97.7 % (EPO) vs. 95.5 % (placebo).

**Conclusion**: Administration of EPO after cadaveric kidney transplantation was well tolerated, but did not have a significant effect on graft histology or function in cadaveric allograft kidney transplants.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO3063

**Urinary NGAL-Ratios as a Non-Invasive Biomarker for Acute Tubular Injury in Kidney Transplant Patients** Jessica K. Kaufeld,[1] Wilfried Gwinner,[1] Irina Scheffner,[2] Hermann G. Haller,[1] Mario Schiffer.[1] *[1]Department of Nephrology, Medical School Hannover, Hannover, Germany; [2]Department of Statistics, Medical School Hannover, Hannover, Germany.*

Urinary neutrophil gelatinase-associated lipocalin (NGAL) has been recognized as an early and sensitive biomarker of kidney injury. It has been shown to predict dialysis and delayed graft function after kidney transplantation in deceased-donor kidney transplant recipients. In our study, we addressed the question whether urinary NGAL could predict the long-term graft function of renal allograft recipients (living-donor and deceased-donor) that were enrolled in the protocol-biopsy program of our center.

Protocol biopsies (pBx) were taken at 6 weeks, 3 months and 6 months after kidney transplantation. Urinary NGAL was measured in the spot urine at the time of the biopsy, normalized to urinary creatinine excretion and correlated to biopsy findings according to the current BANFF-classification such as acute tubular injury (ATI) and rejection as well as eGFR. Controls included 9 healthy individuals (2-kidney controls) and 12 individuals after kidney donation (1-kidney control) with normal kidney function. We screened 5 ICU patients with acute kidney failure to confirm the sensitivity of our assay.

Renal transplant recipients had 1.9-fold higher urinary NGAL ratios compared to the 2-kidney controls. Transplant patients with ATI or CNI-toxicity had only a numerical trend towards higher NGAL-ratios compared to those without. Patients with multiple findings of ATI did not have higher urinary NGAL compared to those with only one ATI finding in the pBx. No differences were found between moderate and severe ATI. Notably, when 1-kidney controls were analyzed, we found a significantly reduced urinary NGAL-ratio compared to 2-kidney controls (59%) and to the transplanted patients (32%). ICU-patients had 105-fold higher NGAL-ratios compared to the 2-kidney controls ($p<0.001$).

We conclude that urinary NGAL-ratios are apparently not sensitive enough as a non-invasive biomarker to monitor ATI in kidney transplant recipients. The differences seen between 1- and 2-kidney controls point to a confounding effect of renal mass on the urinary NGAL excretion.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO3064

**Novel Quantitative Virtual Microscopy-Based Method To Evaluate GL-3 Inclusions in Renal Peritubular Capillaries in Patients with Fabry Disease** Laura M. C. Barisoni,[1] J. Charles Jennette,[2] Robert B. Colvin,[3] Sheela Sitaraman,[4] Jeff Castelli,[4] Pol Boudes.[4] *[1]New York University School of Medicine; [2]University of North Carolina; [3]Harvard Medical School; [4]Amicus Therapeutics.*

Introduction: Renal failure is a major cause of morbidity and mortality in patients with Fabry disease (FD). Levels of GL-3 cytoplasmic inclusions in peritubular capillaries (PTCs) of renal biopsies are considered the most useful pathologic measure of therapeutic efficacy. Previous trials of enzyme replacement therapy used a semi-quantitative light microscopy (LM) approach to measure GL-3 inclusions in PTCs; however, limitations in quantifying low levels of GL-3 using this method were identified. Here we describe a novel virtual microscopy (VM) quantitative method to measure GL-3 inclusions in PTCs.

Methods: Renal biopsies were collected from 17 patients with variable FD severity enrolled in Phase 2 studies of AT1001, a pharmacological chaperone in clinical development for the treatment of FD. Biopsy samples were scanned at 100X magnification into whole slide digital images to enable virtual annotation of PTCs and scoring of GL-3 inclusions. For each digitally-imaged biopsy sample, a minimum of 50 PTCs were annotated by one pathologist. GL-3 inclusions in each annotated PTC were recorded by the other two pathologists using identical duplicates of the annotated virtual images. The final score for each sample was calculated as the average number of GL-3 inclusions per PTC.

Results: Using the published, semi-quantitative LM method, two pathologists scored 4/17 and 7/17 pre-treatment samples as "0" (using a scale from 0-3+), making it difficult to assess the effect of therapeutic interventions. Using the new quantitative VM method, GL-3 inclusions were detected in all samples tested, and the average number of GL-3 inclusions at baseline per PTC varied between 0.2 and 4.3.

Conclusions: The VM-based quantitative scoring improves sensitivity of measuring GL-3 inclusions in PTCs. Other advantages include the ability to annotate images, allow multiple pathologists to access the same slides from remote locations, and create an auditable archive of data for clinical trials.

**Improved Gastrointestinal Symptoms and Health-Related Quality of Life after Conversion from Mycophenolate Mofetil to Enteric-Coated Mycophenolate Sodium in Renal Transplant Patients Receiving Tacrolimus**

Hyeonseok Hwang,[1] Ha Young Oh,[2] Yon Su Kim,[3] Joong Kyung Kim,[4] Yeong Hoon Kim,[5] Yong-Lim Kim,[6] Chul Woo Yang.[1] *[1]Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [2]Internal Medicine, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, Republic of Korea; [3]Internal Medicine, Seoul National University College of Medicine, Republic of Korea; [4]Internal Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea; [5]Internal Medicine, Busan Paik Hospital College of Medicine, Inje University, Republic of Korea; [6]Internal Medicine, Kyungpook National University School of Medicine, Daegu, Republic of Korea.*

Background: The benefit of conversion from mycophenolate mofetil (MMF) to enteric-coated mycophenolate sodium (EC-MPS) in terms of gastrointestinal (GI) symptom burden and health-related quality of life (HRQoL) is unclear in renal transplant recipients receiving tacrolimus. This study was performed to determine whether tacrolimus-treated patients experience these benefits of EC-MPS conversion.

Methods: The study consisted of multi-center, open-label trial. Patients were categorized into two groups by a simple questionnaire for GI symptom. Patients with GI complaints were converted to equimolar EC-MPS (n=175) and the others continued on MMF (n=83). Gastrointestinal Symptom Rating Scale (GSRS) and Gastrointestinal Quality of Life Index (GIQLI) were evaluated at baseline and measured for one month. Patients and physicians completed Overall Treatment Effect (OTE) at one month.

Results: EC-MPS-converted patients had worse GSRS and GIQLI scores at baseline than MMF-continued patients (all $p < 0.01$). Significant improvements in GSRS and GIQLI scores were observed for EC-MPS patients at the end of one month, but MMF patients showed worsened GSRS scores (all $p < 0.05$). OTE scale indicated that EC-MPS-converted patients made more improvements in overall GI symptoms and HRQoL than MMF-continued patients did ($p < 0.001$).

Conclusions: In tacrolimus-treated renal transplant recipients with GI burdens, conversion from MMF to EC-MPS improves GI-related symptom and HRQoL.

Disclosure of Financial Relationships: Research Funding: The study was funded by Novartis Pharma.

**SA-PO3066**

**Validation of the Cystatin C as a Diagnostic Tool for Estimating Glomerular Filtration Rate in Donors One Year Post-Donation**

Miguel Angel González Alfaro,[1] Luz Adriana Balderas,[3] Mario Sandoval Sandoval,[1] Enrique Rojas-Campos,[2] Francisco Monteon,[1] Abel Puentes Camacho,[1] Benjamin Gomez-Navarro.[1] *[1]Nephrology and Organ Transplant, Hospital de Especialidades IMSS, Guadalajara, Jalisco, Mexico; [2]Clinical Researche Unit in Epididemiologic, Hospital de Especialidades IMSS, Guadalajara, Jalisco, Mexico; [3]Medical Research Unit In Renal Diseases, Hospital de Especialidades, Guadalajara, Jalisco, Mexico.*

Introduction: serum creatinine(SCr) is the most widely test, to estimate the glomerular filtration rate (eGFR). However SCr is less sensitive to detect early renal disease. Cystatin C (CyC) is a protein with a constant production rate, therefore is a potential good marker to estimate GFR.

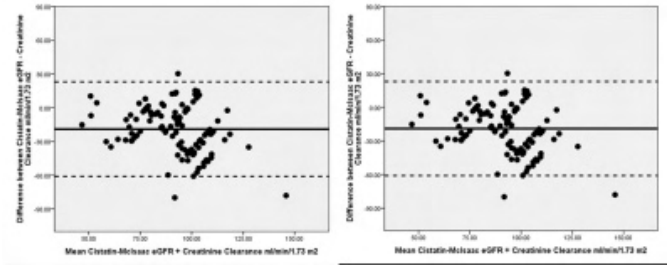
Aim: To determine the sensitivity, specificity of serum CyC as a marker of GFR in kidney donors vs CrCl and MDRD.

Methods: cross-sectional study of 125 stables kidney donors; to determine the levels of SCr, CrCl and CyC. Estimation of GFR by MDRD and McIsaac formulas (CyC) compared to CrCl, discordances between tests were done by Bland-Altman.

Cut-off 60ml/min

| | GFR McIsaac | GFR CrCl | GFR MDRD |
|---|---|---|---|
| Sensitivity | 44.82% | 13.79% | 13.79% |
| Specificity | 97.9% | 100% | 100% |
| PPV | 86.67% | 100% | 100% |
| NPV | 85.45% | 79% | 79% |

RESULTS. Sensitivity and other results are shown in table. Bland-Altman comparisons are shown in the graphic.



Conclusion: The correlation between estimated glomerular filtration rate by MDRD and McIssac calculated and the serum cystatin C is r=0,744 (P 0.000), with CrCl correlation drops to r=0,455 (P 0.000). Bland – Altman, showed that CcCl C vs Cystatin C underestimates and GFR MDRD vs Cystatin C overestimates GFR

**SA-PO3067**

**Everolimus Ascertain: Multivariate Analyses Identified High Baseline GFR as a Major Factor for Improving Renal Function**

L. Rostaing,[1] Philip O'Connell,[2] Hallvard Holdaas.[3] *[1]Department of Nephrology, Dialysis and Organ Transplantation, CHU Rangueil; [2]Centre for Transplant and Renal Research, Westmead Millennium Institute; [3]Medical Department, Oslo University Hospital.*

Early switch to an Everolimus (EVR) CNI elimination regime has demonstrated improved renal function in de novo renal transplant patients (RTs). This subanalysis of ASCERTAIN, a prospective, multicenter, open-label, three-arm study investigated the impact of CNI withdrawal or reduction by the addition of EVR in maintenance RTs on renal function (mGFR) at 24 months (M).

RTs (N=398) with renal impairment (est. GFR 30-70 mL/min) post-6M receiving CNIs, with MPA (72.6%) or AZA (27.4%) were randomized to Group (Gp) A (N=125): continued treatment with CNIs, GpB (N=128): EVR (8-12 ng/mL + CNI elimination, or GpC (N=145): EVR 3-8 ng/mL + CNI 70-90% reduction. An on-treatment (OT) univariate analysis of mGFR at 24M identified baseline risk factors. Further OT multivariate (MV) analysis of the factors showed the statistical significance of baseline mGFR, donor age and time since transplantation for mGFR at 24M across Gps. Baseline mGFR was a significant risk factor across treatment Gps.

Multivariate risk factor OT analysis of mGFR at 24M on per protocol population (N=385)

| RISK FACTOR | REGRESSION | P-VALUE |
|---|---|---|
| Recipient age (years) | -0.040 | 0.782 |
| Donor age (years) | -0.320 | 0.0089 |
| Time since transplantation (years) | -0.986 | 0.047 |
| History of diabetes mellitis (yes/no = y/n) | -0.060 | 0.989 |
| Calcium channel blockers at baseline (y/n) | 0.442 | 0.891 |
| Baseline mGFR mL/min/1.73m2 | 0.683 | <0.0001 |
| Lipid modifying agents at baseline (y/n) | -1.562 | 0.634 |
| Baseline urine protein/creatinine ratio (mg/mmol) | -0.066 | 0.271 |
| Baseline arteriolar hyaline thickening (lesion score ah) | -2.498 | 0.195 |
| Baseline severity grade of CAN | -2.240 | 0.279 |

This multivariate analysis identified time since transplantation and donor age as significant risk factors contributing to further reduction of GFR in maintenance RTs. A high baseline mGFR at time of EVR use was a significant benefit for GFR improvement at 24M.

**Effects of (+)-Catechin on the Progression of Diabetic Nephropathy in Rats** Sudha Chennasamudram,[1] Majid Moridani,[2] Shashi Kudugunti,[2] Tetyana L. Vasylyeva.[1] *[1]Department of Pediatrics, School of Medicine, Texas Tech University Health Sciences Center, Amarillo, TX; [2]Department of Pharmaceutical Sciences, School of Pharmacy, Texas Tech University Health Sciences Center, Amarillo, TX.*

**Purpose:** to investigate the role of (+)-catechin in the prevention of diabetic nephropathy in the streptozotocin-induced (STZ) diabetic rat.

**Methods:** Groups of control and STZ rats (n = 6) received 30-40 mg of (+)-catechin in the drinking water daily for 12 weeks. Additional groups received plain water. Urine was collected weekly and analyzed for albumin and creatinine. Plasma was collected weekly to monitor liver function (alanine aminotransferase [ALT]) and oxidative stress by assessing the thiobarbituric acid reactive substances (TBARS) test for lipid peroxidation and the concentration of free thiols. The effects of (+)-catechin on several inflammatory and growth factors were investigated. Lipid peroxidation and thiol content were also measured in liver and kidney tissue at necropsy.

**Results:** After 12 weeks of treatment, the 24-hours mean urinary albumin and albumin:creatinine ratio were significantly lower in diabetic rats treated with (+)-catechin compared to appropriate controls ($p < 0.05$). Additional indicators of renoprotection were observed, but none reached statistical significance. ALT was lower in the (+)-catechin-treated STZ animals. Lipid peroxidation was reduced four–fold and the thiol content was depleted by 51% in the control STZ group opposed to only 15% depletion in the (+)-catechin STZ group. Preliminary work indicated that Interleukin 6, tumor necrosis factor a, and soluble intercellular adhesion molecule-1 were elevated in the STZ model.

**Conclusion:** Our study demonstrated that (+)-catechin was non-toxic to liver and prevented oxidative stress in STZ diabetic rats. The renoprotective properties of (+)-catechin appeared to halt the progression of diabetic nephropathy in this model.

**Mechanisms Critical in the Induction of Functional Renal Tubules** Katherine J. Kelly,[1] Jesus H. Dominguez,[1,2] Jizhong Zhang,[1] Barbara Kluve-Beckerman.[3] *[1]Medicine/Nephrology, Indiana University School of Medicine, Indianapolis, IN; [2]Medicine/Nephrology, Roudebush VA Medical Center, Indianapolis, IN; [3]Pathology and Laboratory Medicine, Indiana University School of Medicine, Indianapolis, IN.*

Recovery from an acute renal insult recapitulates components of embryonic tubulogeneis, an elegant and complex process during which branching tubules that maintain solute and water homeostasis are formed. We have demonstrated robust expression of the acute phase reaction protein serum amyloid A (SAA) during tubule formation in embryogenesis and during regeneration after an acute renal insult in adult life. SAA expression in cultured renal tubule (NRK52E) cells induces the formation of functioning tubules. Recovery from established, experimental acute kidney injury induced by diverse insults in rats is accelerated by intravenous transplantation of renal tubule cells overexpressing SAA. The mechanism of tubule formation includes redistribution of the actin cytoskeleton with changes in cell shape, motility, adhesion and cell-matrix interaction. Decreased activation of extracellular signal regulated kinase (ERK) is associated with changes in the actin cytoskeleton. Tubule formation also results from increased proliferation of tubule cells expressing SAA. These studies support our hypothesis that serum amyloid A initiates a critical program in renal morphogenesis. They show that renal tubular cell re-differentiation is a complex response that involves changes in extracellular matrix as well as rearrangement of actin cytoskeleton. These effects might also take part in renal recovery following injury.

**Kidney Pericytes Stabilize Vascular Tubes in 3D Collagen Matrices** Claudia Schrimpf, Jeremy S. Duffield. *Renal Division, Brigham and Women's Hospital Harvard Institutes of Medicine, Boston, MA.*

We have recently described kidney pericytes, mural cells of the peritubular capillaries and their key role as myofibroblast progenitors (Humphreys B. D. et al. AJP 2010 176 (1); Lin S. L. et al. AJP 2008 173 (6)). However pericyte function in kidney tissue regeneration is unknown. To study their function in vasculogenesis and vascular stabilization after injury we developed a 3D assay of capillary tube formation in a collagen matrix. Capillary tubes are unstable and regress in the presence of serine proteases, but pericytes from other tissues are known to stabilize capillaries. We purified kidney pericytes, established and characterized primary cultures. Kidney pericytes attached to forming endothelial tubes and prevented capillary regression similarly to human vascular brain pericytes. Here we establish a hitherto unknown function for kidney pericytes that links pericyte detachment following injury to capillary rarefaction.

**A Study of Nondiabetic Renal Disease (NDRD) in Type 2 Diabetes Mellitus (DM) Patients in Indian Population** Vishwanath Siddini, Sudarshan H. Ballal. *Nephrology, Manipal Hospital, Bangalore, Karnataka, India.*

**Introduction and Aims**:

Wide spectra of nondiabetic renal disease are reported to occur in patients with type 2DM. we evaluated the prevelance and spectrum of NDRD in biopsied Type 2 DM. its correlation with diabetic retinopathy(DR) and rapid decline of renal function was also studied. **Methods**:

Between January 2001 and june2010, 120 patients underwent renal biopsy based on standard clinical indicators for NDRD. Clinical records and hisyopathological reports were reiviewed.

**Results**:

Major indications for biopsy were rapidly progressive renal failure (RPRF) and proteinuria in absence of diabetic retinopathy. Renal histology showed pure NDRD in 44, mixed NDRD-Diabetic nephropathy in 43 and pure DN in 33. DR was seen in 5(11%), 24(55%) and 23(70%) in patients with pure NDRD, mixed NDRD-DN and pure DN respectively. Negative predictive value of DR for predicting NDRD was 86% (58/68)

Of total 87 cases with NDRD:

48(52%) were tubulointerstitial lesions namely acute interstitial nephritis (AIN) – 32, chronic interstitial nephritis- 9 and acute tubular necrosis- 7.

37(44%) were glomerular lesions namely PIGN-12, MGN-8, IgA Nephropathy -6, FSGS-5, MCNS-3, Lupus Nephritis-1 , Idiopathic crescentic GN -1, and amyloid -1.

3(4%) were vascular lesions namely Atheroembolic ARF – 2 and scleroderma-1

Total 86 patients were identified as having RPRF/unexplained advanced renal failure. Pure NDRD was seen in 26(29%), mixed NDRD-DN in 37(44%) and pure DN in 23(27%). Positive predictive value of RPRF in predicting NDRD was 73 %( 63/86). Of these 63 patients patients, commonest lesion was AIN-32(50%) followed by PIGN-12(19%), CIN-7(13%), the majority of which had background DN. Rest of lesions were ATN, atheroembolic, scleroderma, lupus and crescentic GN. History of NSAIDs/native medications was available in more than half of cases of AIN. Skin infection was seen in 70% of PIGN cases.

**Conclusions**:

Prevalence of NDRD was 72% in biopsied type 2 diabetics. 73% of patients with Type 2DM and RPRFshowed NDRD. High incidence of AIN is probably related to increasing use of NSAIDS/native medications in such patients.

**PUB005**

**Polymyxin B: A Nephrotoxic Drug in Fact** Maria De Fatima Vattimo,[1] Bruce A. Molitoris.[2] *[1]School of Nursing, University of Sao Paulo, Sao Paulo, SP, Brazil; [2]Nephrology Division, Indiana University Purdue University, Indianapolis, IN.*

Polymyxin B (PmxB) is a nephrotoxic drug used to treat multiresistent Gram-negative bacteria infection. Its main side effect, the nephrotoxicity, reduces its clinical use. The objective of this study was to evaluate its nephrotoxicity and citotoxicity . Studies of renal function (creatinine clearance, crCl/100g), urinary peroxides (UP, nmol/g creat), TBARS (nmol/g creat), catalase activity (CA, nmol/degraded $H_2O_2$/mg total protein), thiols (nmol/mg total protein), LHD (%) and histology of renal tissue were performed in wistar rats. Cell culture studies evaluated apoptosis and viability (72h, Hoescht 33342,Acridine orange/Ethydium bromide, %). Mitochondrial function on LLC-$PK_1$ cells (MF, 4h, %) after the treatment with RhodaminePmxB (375 M) was also performed. Data are presented as mean±standard deviation (X±SD).

Results of renal function, lipid peroxidation and LLC-PK1 cell culture.

| Rats | crCL | UP | TBARS | CA | Thiols |
|---|---|---|---|---|---|
| CTL | 0.70±0.08 | 5.0±1.3 | 34.4±8.0 | 5.6±1.2 | 28.9±6.1 |
| PmxB | 0.30±0.33* | 35.6±9.9* | 98.1±18.0* | 1.2±0.4* | 15.7±1.3* |
| Cells | Apoptosis | Viability | LHD | MF | |
| CTL | 5±1 | 81±3 | 2.0±0.1 | 45.1±4.5 | |
| PmxB | 30±3* | 41±7* | 10.6±1.7* | 40.5±3.5* | |

* $p < 0.05$ vs Control (CTL)

PmxB induced acute kidney injury with the increment in UP and TBARS, and reduction in CA and thiols. It also increased the fractional interstitial area of renal tissue with acute tubule necrosis in renal cortex.The PmxB citotoxicity was confirmed with the increase in apoptosis, reduction in viability and elevation in DHL levels. MF was reduced and associated with the elevation of the dose, what suggests that the ATP dysfunction precedes cell injury. Thus, it can be concluded that PmxB induces acute kidney injury, with lipid peroxidation and renal cell death. Mitochondria plays a crucial role in the endogenous pathways of apoptosis in a dose paired manner.

**Hsp70 Expression in Septic Critically Ill Patients and Relation with the Severity of Cases and Acute Kidney Injury** Itir Yegenaga,[1] Murat Kasap,[2] Aylin Kanli,[2] Nur Baykara.[3] *[1]Nephrology, Kocaeli University Medical School, Kocaeli, Turkey; [2]Medical Biology, Kocaeli University Medical School, Kocaeli, Turkey; [3]Intensive Care, Kocaeli University Medical School, Kocaeli, Turkey.*

Acute kidney injury (AKI) especially in sepsis in intensive care units (ICU) is an important problem with serious consequences. Recently it is suggested that HSP 70(heat shock) protein family which is known to rescue the cells against the stress, might play a crucial role on the severity of sepsis and worse output.

Aim of this study is to search if there is a relationship between HSP70 protein expressions in the cells of urine sediment and mononuclear cells in blood of AKI and non-AKI patients with sepsis in the ICU and compared to the healthy individuals.

Clinical features of patients were shown in Table 1.

Clinical feature of patients

| | Mean age/SD | Gender/male | Mean SOFA | Mean APACHE II |
|---|---|---|---|---|
| AKI(n=5) | 77,75+3,30 | 3 | 15,25+1,71 | 30,50+8,10 |
| Non-AKI(n=5) | 44,33+17,39 | 2 | 8,00+2,00 | 15,33+7,09 |

Western blotting was used to study HSP70 expression by using a monoclonal HSP70 antibody (Biovision, USA). HSP*70* gene expression was studied by quantitative real time PCR(polymerase chain reaction) using a 5'-FAM labeled hydrolysis probe.

Although HSP*70* expression was present by PCR; HSP 70 protein was not determined in the cells of urine sediment. But there were no differences between groups. In blood samples, HSP*70* expression was 2.8-fold up-regulated in non-AKF patients then AKF patients. Furthermore, HSP*70* expression in non-AKI patients were up regulated (1.2-fold), while a 1.6-fold down regulation was observed in AKI patients when compare to the healthy control group. However, to see the capacity of HSP*70* expression, samples were heated 42°C 30 min, HSP*70* induction were 19.6-fold, 61.1-fold and 91.9-fold up-regulated in non-AKI, AKF and control sample, respectively.

This finding might suggest that non-AKF patients were more capable of protecting their cells, and the level of basic HSP 70 level might be related to the severity of sepsis in human in vivo.

**Overexpression of Cyclin-Dependent Kinase Inhibitor p18$^{INK4C}$ Protects Cisplatin-Induced Renal Tubular Epithelial Cell Injury** Zhang Yi,[1] Li Yuan,[2] Changlin Mei.[3] *[1]Nephrology Department of Changzheng Hospital, The Second Military Medical University, Shanghai, China; [2]Nephrology Department of Changzheng Hospital, The Second Military Medical University, China; [3]Nephrology Department of Changzheng Hospital, The Second Military Medical University, China.*

**Objective:**

We postulated that INK4 family members should have protective effects against AKI and used P18 as the main subject to explore its protective actions in cisplatin-induced AKI.

**Methods:**

We overexpressed P18 in renal tubular cells (LLC-PK1) and observed the effect of p18 overexpression on the LLC-PK1 cells by proliferation assay and the cell cycle analysis. Renal cell injury was induced by cisplatin (100μM) incubation for 24h and LDH release, caspase 3 activity and the splice fragments of caspase 3 and PARP, a caspase 3 substrate, were detected in the vehicle and p18 plasmid transfected cells after cisplatin administration. In order to identify the possible mechanism of p18 protection, we also detected the difference of endoplasmic reticulum stress (ERS) degree between the vehicle and p18 plasmid transfected cells after cisplatin administration.

**Results:**

After P18 plasmid transfection, P18 expression in LLC-PK1 cells increased markedly, and blocked the cell cycle and inhibited proliferation of LLC-PK1 cells. After cisplatin incubation, P18 overexpression did not affect cell necrosis significantly but reduced cell apoptosis markedly. Activation of caspase 3 and the splice fragments of caspase 3 and PARP were also reduced markedly in p18 plasmid transfected cells. Further, p18 overexpression reduced the upregulation of chaperone grp78, attenuated the degree of caspase 12 activation and decreased the level of PERK/eIF2α phosphorylation after cisplatin administration.

**Conclusions:**These results showed that P18, an INK4 family member, was also involved in cisplatin-induced renal cell injury and played protective actions via affecting the ERS pathway in addition to the cell cycle regulation.

**P2X7R and Acute Tubular Injury** Nishkantha Arulkumaran,[1] Simona Deplano,[1] Reiko Hewitt,[1] Alex Dyson,[2] Robert J. Unwin,[3] Mervyn Singer,[2] H. Terence Cook,[1] Frederick W. K. Tam.[1] *[1]Department of Nephrology, Imperial College Kidney and Transplant Institute, London, United Kingdom; [2]Department of Intensive Care Medicine, University College London, London, United Kingdom; [3]Department of Nephrology, University College London, London, United Kingdom.*

Purpose:

The P2X7 receptor (P2X7R) plays a key role in inflammatory cytokine release (IL-1β, IL- 18) and apoptosis. We determined the pattern of renal P2X7R expression in 2 rat models of acute kidney injury (AKI). In vitro work was done ascertain the functional significance of the P2X7R.

Methods:

(1). Rat model of haemorrhage and resuscitation

Forty percent of circulating volume of anaesthetised rats was shed. After 30mins, shed blood was re-infused over 2- hours. Rats were given 21% (n=5) or 100% oxygen (O2) (n=8).

(2). Rat model of sepsis

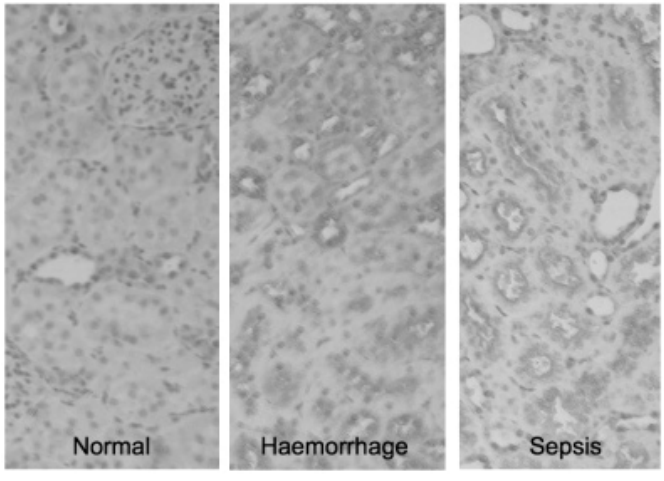
Sepsis was induced by injection of faecal slurry into the peritoneal cavity. Rats were fluid resuscitated for 6 hours.

(2). Cell culture

NRK 52E rat tubular epithelial cells were cultured. Cells were primed with LPS (1μg/ml) for 24 hours. Western blot was used to detect P2X7R and IL-1 expression.

Results:

(1). Immunohistochemistry (IHC) showed upregulation of P2X7R in renal tubules that correlated with the degree of acute tubular injury (see figure). There was no difference in acute tubular injury between rats receiving 21% and 100% O2.



(2). IHC demonstrated upregulation of P2X7R in renal tubules that correlated with the degree of acute tubular injury [figure 1].

(3). P2X7R protein was not detected under basal conditions. LPS stimulation resulted in a significant upregulation of P2X7R and pro- IL-1β protein as detected by Western Blot.

Conclusion:

Upregulation of P2X7R plays a crucial role in septic and ischaemic AKI. Tubular epithelial P2X7R expression has been demonstrated in both in vivo and in vitro work. Further work is required to determine the functional significance of tubular P2X7R.

**Results of Open Heart Surgery in Jehovah´s Witnesses: Incidence of Acute Kidney Injury and Mortality Compared with a Control Group** Carmen Bernis,[1] Ana Perez de José,[1] Rosario Madero,[2] Pablo Alonso,[3] Juan Bustamante,[4] Jose-Antonio Sanchez-Tomero.[1] *[1]Nephrology, HUPrincesa, Madrid, Spain; [2]Biostatistics unit; [3]ICU; [4]Cardiac surgery, .*

Acute kidney injury (AKI) is one of the most serious complications occurring after cardiac surgery (ACS) and is associated with increased mortality. Cardiac surgery often requires blood transfusion but some patients, such as Jehovah´s Witnesses refuse to use blood products.

The objective of this study is to evaluate the incidence of AKI (defined by RIFLE and AKIN ) and the mortality in Jehovah´s Witnesses undergoing cardiac surgery

**Methods**

All Jehovah´s Witnesses undergoing cardiac surgery in a reference Hospital, between January 2003 and July 2009 were retrospectively evaluated (n=67). All these patients refused any form of blood transfusion by signing a special consent. Data were prospectively collected. We evaluate the incidence of AKI using RIFLE and AKIN classification and in-hospital mortality . The statistical package SPSS (version 15 for windows) was used. Crude and adjusted dates for age, sex, type of surgery and baseline renal function ( CKD< ó >60 ml/min) are expressed.

**Results**

67 patients (mean age 62.19 ± 10.9 years; 53.7% females; mean Cleveland Score 3.66 ± 1.6 and SRI score 2.13 ± 0.93, 83.6% valvular surgery and 16.4% coronary artery bypass) were evaluated. Mean baseline creatinine 1.06 ± 0.29 mg/dl and maximum creatinine 1.13 ± 0.32 mg/dl.

The incidence of AKI defined by AKIN classification in Jehovah´s Witnesses was 13.4% (n=9) and in the control group 16.6% (n=100) (p=0.603).Defined by RIFLE the incidence was 9% (n=6) in Jehovah´s Witnesses and 7.2% (n=43) in the control group (p 0.619). Mortality in Jehovah´s Witnesses was 10% (n=7) and in the control group 8% (n=48) (p 0.481). Crude and adjusted dates were not statistically significant

Mortality was 10.4% in Jehovah´s Witnesses and 8% in control group (p 0.48)

**Conclusions**

AKI incidence (defined by RIFLE or AKIN ) and mortality were similar in Jehovah´s Witnesses and in the control group.

**Bif-1/Endophilin B1 in ATP Depletion-Induced Renal Tubular Cell Apoptosis** Sunggyu Cho,[1] Craig R. Brooks,[2] Zheng Dong.[1] *[1]Department of Cellular Biology and Anatomy, Medical College of Georgia and Charlie Norwood VA Medical Center, Augusta, GA; [2]Renal Division, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Bif-1 was originally identified as a Bax interacting protein via yeast two hybrid screening. Due to its sequence and structural homology to endophilins, Bif-1 is also called endophilin B1. More recent studies suggest that in addition to Bax, Bif-1 may also regulate mitochondrial dynamics and autophagy. Whether Bif-1 contributes to the regulation of renal pathophysiology is unclear. Here we have established stable Bif-1 knockdown renal proximal tubular cell lines by transfecting shRNA. The knockdown cells were resistant to apoptosis following ATP-depletion. Mechanistically, we found that Bif-1-knockdown did not affect Bax translocation to mitochondria during ATP-depletion, but it prevented Bax oligomerization in mitochondria. As a result, cytochrome c release from mitochondria was partially blocked. The results have demonstrated evidence for a role of Bif-1 in renal cell injury and death.

**Acute Trypanosoma cruzi Induce Renal Kidney Injury (AKI) in Mice** Gabriel Melo De Oliveira,[1] Nestor Schor.[2] *[1]Medicine-Nephrology Division, UNIFESP, São Paulo, São Paulo, Brazil; [2]Laboratorio de Biologia Celular, Fiocruz, Rio de Janeiro, Brazil.*

Experimental acute infection with Trypanosoma cruzi in mice promotes an intense myocarditis and other systemic changes. The aim of this study was to investigate the mechanisms of AKI in mice during experimental acute phase as well as the potential vulnerability of renal cells lines by the parasite. Infected mice showed significant increase ($p<0.05$) in creatinine (2.0 vs. 0.4 mg/dl,) and urea (40 vs.80 mg/dl) serum levels on the 6th day post infection (dpi) vs. control group. Also, histopathology analysis characterized AKI, but not related to the presence of the parasite. Proximal tubular injury presented cloudy swelling of the cytoplasm, increased tubular light and loss of cytoplasmic substance. The interaction between the parasite in renal cell lines (HMC, MDCK and LLC-PK1) was observed and it was disclosed that human mesangial cells (HMC) are the most resistant to infection with only 3.4 % infected cells, vs. 7.6% and 13%, respectively ($p<0.05$). However, HMC presented higher impairment, with 50% decreases in the viability and integrity after 72h of infection. Also, only HMC cells presented significant ($p<0.05$) increases in the NO expression (0.01 vs. 0.17 uM/mg), TNF-$\alpha$ (14.3 vs. 4.3 pg/dl) and IFN-$\gamma$ (5.7 vs. 106 pg/dl) vs. control group. Thus, these data suggested that AKI, in this model, are mainly due to inflammatory mediators released by parasite infection.

**Effects of Pre-Treatment with a High Dose of Methylprednisolone on Renal Ischemia/Reperfusion Injury** Ida M. Fernandes,[1] Gloria E. Mendes,[1] Terezila Machado Coimbra,[2] Emmanuel A. Burdmann.[1,3] *[1]Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto; [2]University of Sao Paulo Medical School, Ribeirao Preto; [3]University of Sao Paulo Medical School, Sao Paulo, Brazil.*

**Introduction:** Renal ischemia is the most important cause of acute kidney injury. Methylprednisolone (MP) has been shown to protect against ischemia/reperfusion injury (I/R) in other organs. **Objective**: To examine the effects of MP in renal I/R. **Methods**: 24 male Wistar rats received 30mg/kg of iv MP or saline 1 hour before 30 min of renal ischemia (RI). They were divided into 3 groups (n=8, each): control (C, sham surgery, no RI), I/R (saline infusion pre-RI), and MP (MP infusion pre-RI). GFR (inulin clearance, ml/min/100g) and sodium fractional excretion (FENa, %) were assessed 2 days after I/R. In the same time, macrophages (ED-1), neutrophils (No), lymphocytes (Lo) and nuclear factor-kappa- B (NFκ-B) were assessed by immunohistochemistry and scored according to the extent of tubulointerstitial immunostaining in the cortex and outer medulla (OM) areas. Results (mean±SD) were compared by ANOVA followed by Bonferroni test ($p<0.05$). **Results:** GFR was 0.92±0.3 in the MP group, 0.90±0.3 in the C group, and 0.47±0.2ml in the I/R group, ($p<0.05$ vs. MP and C). The FENa was similar in the MP (0.19) and C groups (0.35), and higher in the I/R group (0.57, $p<0.05$ vs. MP and C). Tubulointerstitial staining for Lo was significantly more intense in the I/R group when compared with C and MP groups in the cortex (14.4±3 vs. 6.7 ±1 and 5.3±1.6, respectively, $p<0.05$ I/R vs C and MP) and OM areas (10.6±3 vs. 4.3±1 and 3.7±0.6, $p<0.05$ I/R vs. C and MP). Similar results were observed for OM staining of ED1 (9.8±3 in I/R vs. 4.6±1 in C and 4.1±2 in MP, $p<0.05$) and No (3.1±2 in I/R vs. 1.1±0.3 in C and 1.4±1 in MP, $p<0.05$). NFκ-B immunostaining was significantly more intense in the OM of the I/R group compared with the sham and the MP groups (0.6±0.3 in I/R vs. 0.03±0.03 in C and 0.1±0.1 in MP, $p<0.05$). **Conclusion:** These results demonstrated that pre-treatment with high doses of MP conferred protection against renal I/R and suggested that this action is likely related to modulation of I/R-induced inflammatory mechanisms.

**Retroperitoneal Sarcoma Presenting as AKI Secondary to Bilateral Renal Artery Invasion** Amit Kumar Gupta,[BCM] Abdul A. Abdellatif.[BCM] *[1]Department of Medicine, Baylor College of Medicine, Houston, TX; [2]Department of Nephrology, Baylor College of Medicine, Houston, TX.*

62 yr female with baseline creatinine of 1 presented to the emergency department with sudden onset of anuria and 20-25 lbs weight loss in the last six months. Prior to presentation, she was started on Lisinopril 5 mg daily for hypertension. On physical examination blood pressure was mildly elevated to 150/86 with negative orthostatic changes. The laboratory findings were significant for: serum BUN 42mg/dl, Cr 5.1mg/dl, Sodium 126mmol/l, Potassium 5.4mmol/l, Serum osmolality 264, and calculated Fractional excretion on sodium was <1%. Urine analysis showed 50 RBC, 400mg/dl protein, no casts and urine osmolality of 229.

Lisinopril was discontinued and Doppler Renal Ultrasound to rule out renal artery stenosis showed the right kidney being 3 cm smaller than the left kidney and normal resistive indices. Within two days therapy, electrolyte abnormalities improved but the BUN and creatinine continued to get worse (BUN 78mg/dl and Cr 9.8mg/dl). Further laboratory workup including ANA, ANCA, C3, C4, Anti GBM antibodies was normal. Kidney biopsy was performed to rule out rapidly progressive glomerular nephritis which was normal.

Secondary to the high suspicion of a pre-renal etiology and to avoid the risk of Nephrogenic Systemic Fibrosis (NSF) a time-of-flight noncontrast MR angiogram was performed, which revealed an irregular, heterogeneous 3x5x5 cm mass in the para-aortic region encasing the origin of bilateral renal arteries and superior mesenteric artery (SMA). Flow in SMA and right renal artery was markedly reduced and complete cut-off of flow in left renal artery after its origin from aorta was noted.

CT guided biopsy of the mass revealed high grade liposarcoma. The mass was surgically excised with positive margins and vascular reconstruction was done. Patient recovered renal function after 6 weeks of intermittent dialysis with new baseline for creatinine of 2.5.

Conclusions:

==========

Noncontrast time-of-flight MR angiography is sensitive for evaluation of renal artery stenosis [90% sensitive compared to Renal angiogram] without the risk of NSF in patients with chronic kidney disease.

**PUB014**

**Henoch-Schonlein Purpura: Still a "Childhood" Disease?** Tarek Hamieh,[1] Manish K. Saha,[1] Vesselin Dimov.[2] *[1]Department of Medicine, Regions Hospital, University of Minnesota, Saint Paul, MN; [2]Department of Allergy and Immunology, Creighton University, La Vista, NE.*

Case Presentation: A 72-year-old female presented with one week history colicky abdominal pain, hematochezia, arthralgia and rash. The rash started on her elbows and extended to the legs and thighs. She denied recent use of antibiotics or anti-inflammatory medications. Patient was afebrile, normotensive, and palpable purpura was noted on the extensor surface of the arms and lower extremities. She had a normal hemogram and renal function. Urinalysis was positive for microscopic hematuria and trace proteinuria. Cryoglobulins were negative. Skin biopsy of the rash demonstrated leukocytoclastic vasculitis with IgA deposition on immunofluorescence consistent with Henoch-Schonlein Purpura. Patient's symptoms improved markedly with initiation of corticosteroids.

Discussion: Henoch-Schonlein Purpura (HSP) is a systemic vasculitis characterized by purpuric rash, abdominal pain, arthralgia, and renal involvement. It is characterized by the tissue deposition of IgA-containing immune complexes. Although it is commonly reported to be a "childhood" disease, it is increasingly reported in adults. The rash is typically purpuric and symmetric, often located on the extensor surfaces of the extremities. Renal involvement is common, and usually mild, however in severe cases, can progress to end-stage renal disease. When HSP is suspected, a urinalysis should be done promptly to check for active sediment consisting of red cell casts, which would suggest glomerulonephritis. Evidence suggests that glucocorticoids enhance the rate of resolution of the arthritis and abdominal pain and may prevent delayed-onset HSP nephritis. This case serves to illustrate the need to include HSP in the differential diagnosis in the appropriate setting (rash, arthralgias, renal involvement) when caring for adult population with abdominal symptoms or gastrointestinal bleeding.

**Sex Differences in the Regulation of the Vasodilator/Vasoconstrictor Balance in the Renin Angiotensin System Contribute to Sex Differences in Renal Interstitial Fibrosis** Hong Ji, Wei Zheng, Jun Liu, Xie Wu, Bilkish Bajaj, Jeffrey Seiden, Kathryn Sandberg. *Medicine, Georgetown University, Washington, DC.*

Renal disease progression is faster in men compared to women in numerous non-diabetic diseases. This sex difference is also observed in models of chronic and acute renal disease including unilateral ureteral obstruction (UUO), a model of tubulointerstitial fibrosis. We investigated the expression of key components of the vasoconstrictor and vasodilator arms of the renin angiotensin system (RAS) male and female mice subjected to UUO. One week after surgery, there was no effect of UUO nor were there sex differences in renal angiotensin type 1 receptor mRNA [$AT_1R$ (AU): M-Sham, 1.10±0.51; M-UUO, 0.92±0.23; F-Sham, 1.28±0.36; F-UUO, 1.01±0.14]. Compared to the female, angiotensin converting enzyme (ACE) mRNA in the male was 3.1-fold ($p<0.01$) and 1.7-fold higher in the sham and UUO kidneys, respectively [ACE (AU): M-Sham, 2.59±0.34; M-UUO, 1.00±0.28; F-Sham, 0.83±0.08; F-UUO, 0.58±0.14]. The female down-regulated renal expression of renin mRNA after UUO to a 1.9-fold ($p<0.05$) greater extent than the male [Renin (AU): M-Sham, 0.91±0.02; M-UUO, 0.87±0.09; F-Sham, 1.51±0.24; F-UUO, 0.78±0.08]. Furthermore, UUO-induced a 2.4-fold ($p<0.05$) greater increase in renal ACE2 in the female compared to the male [(AU): M-Sham, 1.34±0.81; M-UUO, 1.54±0.29; F-Sham, 0.69±0.22; F-UUO, 1.64±0.04] and a 2.2-fold ($p<0.03$) greater increase in the $AT_2R$ in the female kidney compared to the male [$AT_2R$ (AU): M-Sham, 0.67±0.54; M-UUO, 0.88±0.50; F-Sham, 1.23±0.32; F-UUO, 2.68±0.27]. These data suggest the female kidney is protected from UUO-induced renal injury compared to the male because the female is able to down-regulate the vasoconstrictor arm (renin and ACE) and up-regulate the vasodilator arm (ACE2 and $AT_2R$) of the RAS cascade in response to the UUO insult to a greater extent than the male. Supported by NIA R01 AG019291.

**Erythropoietin (EPO) Protects the Kidney Against the Injury and Dysfunction Caused by Ischemia-Reperfusion (I/R) in Diabetic Rats** Julius Edward Kieswich, Ananda Chapagain, Martin J. Raftery, Magdi Yaqoob. *Centre for Translational Medicine and Therapeutics, William Harvey Research Institute, London, United Kingdom.*

There is a growing body of evidence to suggest that EPO is tissue protective against I/R injury of kidneys, heart, brain and liver through its potent anti-apoptotic properties. Diabetic patients are at a high risk of acute kidney injury (AKI) following ischemic or nephrotoxic insults which are associated with increased morbidity and mortality.

We have previously shown that a single systemic administration of EPO pre-ischemia prevents AKI in rats and mice through the inhibition of apoptosis. The aim of this study was to investigate the ability of EPO to attenuate this injury in diabetic rats.

Rats weighing 200g were divided into four groups. Diabetes was induced in two of the groups through intraperitoneal injection of streptozotocin (50mg/kg). After 17 days EPO (300U/kg) was administered to one non-diabetic and one diabetic group. One hour after EPO injection, the I.R. protocol was performed. I/R. injury was achieved by clamping both renal arteries for 45 minutes.

The results showed that EPO reduced AKI similarly in both diabetic and non diabetic groups as evidenced by significant reductions in serum creatinine and urea levels ($p<0.05$). Ex vivo analysis of kidney protein by Western blotting showed upregulation of anti-apoptotic molecules such as Bcl-XL and XIAP in both EPO treated groups.

We conclude that EPO administration is equally effective in preventing I/R injury in both diabetic and non diabetic rats. The results of these investigations have implications for the prevention of AKI in diabetic patients undergoing high risk surgical procedures.

**Contrast Induced Nephropathy Following Intravenous Contrast Administration: A Meta-Analysis** Judith Kooiman,[1] Sharif M. Pasha,[1] Olaf Dekkers,[1] Yvo W. J. Sijpkens,[2] Aart J. van der Molen,[3] Menno V. Huisman.[1] *[1]Department of General Medicine, Leiden University Medical Center, Leiden, Netherlands; [2]Department of Nephrology, Bronovo Hospital, The Hague, Netherlands; [3]Department of Radiology, Leiden University Medical Center, Leiden, Netherlands.*

**Introduction** Contrast induced nephropathy (CIN) is defined by an increase in serum creatinine > 25% or > 0.5 mg/dL 48-72 hours after administration of iodinated contrast media (CM). Although generally mild and reversible, in rare cases CIN can lead to a need for renal replacement therapy (RRT). In literature, the incidence of CIN ranges between 1-25%. The aim of this meta-analysis was to asses the incidence of CIN and the need for RRT in patients undergoing IV CM administration prior to CT-scanning.

**Methods** Studies evaluating renal function after IV CM administration published after 2000 were searched for in Medline, Cochrane, Web of Science and EMBASE.

Primary endpoint was the weighted pooled incidence risk of CIN defined by an increase in serum creatinine> 25% or > 0.5 mg/dL. Secondary endpoint was the incidence of RRT after CM administration. Prespecified subgroup analyses were performed in patients with diabetes mellitus (DM) and pre-existent renal failure. All analysis were performed in a random effects-model.

**Results** Twenty prospective and 20 retrospective studies including a total of 19585 patients were included. In 75% of studies including patients with chronic renal failure preventive hydration regimes were advised. The weighted pooled incidence risk of CIN was 7.2% (95% CI 6.0-8.9) in a random-effects model. There was considerable between-study heterogeneity ($I^2$ 87%). Renal replacement therapy was needed in 0.6% (95% CI 0.4-1.0) of patients following CM administration. The incidence for CIN was 10.4% (95% CI 7.4-14.5) in patients with chronic renal failure and 10.4% (95%CI 6.6-16.1) in patients with DM.

**Conclusion** CIN occurred in about 7% of patients after IV CM administration, which is in the lower range reported by previous studies. The incidence of CIN was higher in subgroups of patients diagnosed with chronic renal failure or DM. The need for RRT is rare and occurs in 0.6% of all patients after administration of IV contrast.

**The Role of Bile Acids in Cryopreservation Injury of Kidney** Shunan Li,[1,2] Lawrence Wang,[1] Kajohnsak Noppakun,[1,2] Sandeep Gupta.[1,2] *[1]Stem Cell Institute; [2]Department of Medicine, University of Minnesota, Minneapolis, MN.*

**Background:** Prolonged cryopreservation of donor kidney decreases graft function and increases patient mortality. Kidney cells die by necrosis during cryopreservation and apoptosis during warm reperfusion phase. Delayed cell death by apoptosis during the reperfusion phase provides a window of opportunity for reducing cryopreservation injury. Tauroursodeoxycholic acid (TUDCA), a hydrophilic bile acid, prevents cell death by inhibiting apoptosis and upregulating survival pathways. We hypothesized that TUDCA can prevent cryopreservation injury by inhibiting apoptotic cell death.

**Objective:** The purpose of this study is to determine the protective effects of TUDCA in an in vivo model of cryopreservation injury of kidney.

**Methods:** Cell line: We used primary human renal proximal tubular epithelial cells (RPTEC) in a validated in vivo model of cryopreservation injury. Cryopreservation injury: RPTEC were grown to confluence in complete medium. The complete medium was subsequently replaced with UW (University of Wisconsin) cryopreservation solution with or without 50 to 1200 µM TUDCA, and the culture plates were incubated at 4°C for 48 hours. To simulate warm reperfusion phase of the transplantation, we replaced UW solution with complete medium and cultured cryopreserved cells for an additional 24 hours at 37°C. We determined apoptotic cell death by caspase-3 assay and upregulation of survival pathway by Western blot analysis. Caspase-3 Assay: We measured caspase-3 activity by using fluorometric substrate-Z-DEVD-Rhodamine 110. Survival pathway analysis: We determined activation of survival pathway by using specific antibodies against activated forms of p38, JNK, and ERK protein and standard Western blot techniques, and confirmed visual results by densitometry normalized for b-actin.

**Results:** Pretreatment of RPTEC with 150-1200 µM TUDCA significantly protected against cryopreservation injury by inhibiting caspase-3 activation and upregulating of ERK survival pathway.

**Conclusions:** TUDCA protected against cryopreservation injury and is a promising therapeutic agent for improving patient and graft outcome following cryopreservation of donor kidneys.

**Effect of Mesenchymal Stem Cells on Renal Tubular Epithelial Cells' Self-Recovery in Mice under Ischemia/Reperfusion and Possible Mechanism** Nanmei Liu, Jinyuan Zhang. *Jimin Hospital of Shanghai.*

**Objective:** Establish mice's acute renal injury model,exogenous intervened by mesenchymal stem cells(MSCs),observing its effect on renal tubular epithelial cells'(RTECs) regeneration of model mice.

**Methods:**45 healthy male C57BL/6 mice were scattered into control group(15),I/R group(15, clamping bilateral renal pedicles and then reopening after 30 minutes), I/R+mMSCs group(15, the same to I/R group, meanwhile,injected mMSCs through caudal vein into the body). 1 day,2days,3 days,7 days,14 days after, killed them(3/each group). Detected Scr and BUN, mice kidneys were dyed with HE to observe their pathological changes, evaluated their acute tubular necrosis score.The proportions of RTECs' proliferation were assessed by IHC of PCNA, apoptosis were detected by TUNEL. the protein level of Caspase-3,Bcl-2 in renal tubules were detected by Western blot. The levels of TNF-α,IL-1β,MCP-1, IL-10, HGF, BMP-7 were detected by ELISA.

**Results:**Comparing with I/R group, the level of BUN and Scr in I/R+mMSCs were much lower,at the same time ,this group's renal tubule's pathological changes mitigated significantly. ATN score was also significantly lower. The immunohistochemical staining of PCNA demonstrated that the positive expression of RTECs was increased significantly after intervention of mMSCs($P<0.05$). I/R could induce RTECs' apoptosis, mMSCs' intervention could significantly relieve its apoptosis($P<0.05$ or $P<0.01$). Western blot analysis revealed:contrasted with I/R group, the level of Caspase-3 in I/R+mMSCs group decreased notably(1.16±0.33, $P<0.01$),while the level of Bcl-2 increased significantly(0.94±0.27, $P<0.01$). ELISA result showed that the levels of TNF-α,IL-1β,MCP-1 in I/R group's renal tissue homogenate were increased significantly,while the levels of IL-10,HGF,BMP-7 decreased notably. While mMSCs' intervention could change these cytokines levels to the opposite direction.

**Conclusion:**MSCs can contribute to RTECs' regeneration,inhibit their apoptosis.The possible mechansim may be that MSCs can regulate cytokines secretion in renal tissues under ischemia/reperfusion,and then contribute to RTECs'self-recovery by paracrine.

**Significant Microalbuminuria May Portend AKI in Sepsis** Arghya Majumdar.[1] *[1]Nephrology, AMRI Hospitals, Kolkata, West Bengal, India; [2]Pharmacology, Jadavpur University, Kolkata, West Bengal, India.*

Introduction:

Sepsis leads to diffuse endothelial dysfunction; the glomerular manifestation of which is microalbuminuria (MA). Recent evidence indicates that the pathophysiology of sepsis induced acute kidney injury (AKI) is unique. Histo-pathological evidence of extensive glomerular capillary infiltration by leucocytes has been observed in septic AKI. Further, animal models of hyperdynamic sepsis have shown that AKI can occur in the absence of hypotension. These findings suggest that endothelial dysfunction may play a prominent role in septic AKI in comparison to patients of AKI due to other causes. Markers of endothelial dysfunction such as microalbuminuria may therefore have a potential diagnostic role in septic AKI.

Methods:

Prospective observational study in a 20 bed Intensive Care Unit (ICU) in a tertiary care hospital. MA estimated as spot urine albumin-creatinine ratio (ACR, mg/g) was measured on ICU admission. Between Jan 2007 and Dec 2008, 266 patients were recruited. Patients with ICU stay of less than 24 hrs and other confounding factors were excluded. Sepsis was diagnosed by the ACCP/SCCM criteria; AKI identified by the RIFLE criteria.

Results:

Of the 266 patients studied 130 patients had AKI as classified by the RIFLE criteria. Median age was 61.5 yrs, 61% were male, median APACHE II score was 15. The median level of ACR [204.1 mg/g, (IQR 119.7 – 402.0)] of patients with septic AKI (n=66) was significantly greater ($p<0.0001$) than the median ACR level of 67.1 mg/g (IQR 32.99 – 129.9) of patients who had AKI from other causes (n=70). Patients of sepsis who had developed AKI also had higher ACR than those who did not (n=51) [ACR 119.3 mg/g (IQR 37.02 – 354.3)] ($p=0.0137$).

Conclusions:

Microalbuminuria is a cheap point of care bed-side test which might help to preempt development of AKI in sepsis patients. This might help in guiding management strategies in remote resource poor areas and prioritizing transfer to a tertiary care centre with dialysis facility.

**Preliminary Results of the Clinical Trial: Prevention of Contrast-Induced Nephropathy by Oral or Intravenous Hydration. Evolution of Renal Function According to Levels of Creatinine and Cystatin C** Paloma L. Martin Moreno,[1] Nuria Garcia-Fernandez,[1] Nerea Varo,[2] Laura Montero,[2] Francisco Javier Lavilla,[1] Jorge M. Nunez-Cordoba.[3] *[1]Nephrology, Clinica Universidad de Navarra, Pamplona, Navarra, Spain; [2]Laboratory of Biochemistry, Clinica Universidad de Navarra, Pamplona, Navarra, Spain; [3]Department of Preventive Medicine and Public Health, Clinica Universidad de Navarra, Pamplona, Navarra, Spain.*

Objective: To compare the efficacy of hydration with IV bicarbonate or oral serum in the prevention of contrast-induced nephropathy. To study the usefulness of Cystatin C for monitoring renal function.

Material and methods:

Prospective, randomized, single-centre trial in hospitalized non-diabetic patients with estimated glomerular filtration rate (eGFR) calculated by MDRD-4 $\geq$ 30 ml/min, undergoing procedures with contrast media.

Patients were randomized in three groups: G1: IV bicarbonate, G2: Oral serum and G3: control. Variables studied before and 24 hrs after: creatinine, cystatin C and eGFR.

Results:

So far 67 patients have been enrolled. There were no significant differences ($p>0.05$) between groups regarding their baseline characteristics. The change in creatinine, cystatin and eGFR 24 hrs after contrast media administration was non-significant ($p>0.05$) within as between groups.

| | G1 | G2 | Control |
|---|---|---|---|
| Creatinine (mg/dL) | | | |
| Baseline | 0.98 (0.35) | 0.8 (0.24) | 1.39 (1.56) |
| 24 h after | 1.01 (0.35) | 0.85 (0.3) | 0.86 (0.23) |
| Cystatin C (mg/L) | | | |
| Baseline | 0.83 (0.34) | 0.82 (0.3) | 0.66 (0.15) |
| 24 h after | 0.82 (0.35) | 0.83 (0.32) | 0.65 (0.15) |
| eGFR by MDRD-4 (ml/min) | | | |
| Baseline | 85.1 (27.78) | 109.05 (47.91) | 78.47 (28.16) |
| 24 h after | 84.57(30.48) | 101.1 (37.35) | 92.17 (20.15) |

Data expressed as means and standard deviation of means

Conclusions:

The effect of contrast media in renal function of hospitalized non-diabetic patients with eGFR $\geq$30 ml/min is non-significant after 24 hours independently of the protocol of hydration. Creatinine, cystatin C and eGFR could be similar parameters for monitoring renal function.

Disclosure of Financial Relationships: nothing to disclose

**Preliminary Results of the Clinical Trial: Prevention of Contrast-Induced Nephropathy by Oral or Intravenous Hydration. Evolution of Markers Related to Oxidative Stress** Paloma L. Martin Moreno,[1] Nuria Garcia-Fernandez,[1] Nerea Varo,[2] Laura Montero,[2] Francisco Javier Lavilla,[1] Jorge M. Nunez-Cordoba.[3] *[1]Nephrology, Clinica Universidad de Navarra, Pamplona, Navarra, Spain; [2]Laboratory of Biochemistry, Clinica Universidad de Navarra, Pamplona, Navarra, Spain; [3]Department of Preventive Medicine and Public Health, Clinica Universidad de Navarra, Pamplona, Navarra, Spain.*

Objective: To study the erythrocyte superoxide dismutase (SOD) activity and levels of F2-isoprostanes in urine of patients who have received contrast media with different hydration protocols.

Material and methods:

Prospective, randomized, single-centre trial in hospitalized non-diabetic patients with estimated glomerular filtration rates $\geq$ 30 ml/min (eGFR) calculated by using the MDRD-4 equation, undergoing procedures with contrast media.

Patients were randomized in three groups: G1: IV bicarbonate, G2: Oral serum and G3: control. Variables studied before and after contrast media administration: erythrocyte SOD activity and F2-isoprostanes in urine.

Results:

So far 67 patients have been enrolled. There were no significant differences ($p>0.05$) between groups regarding their baseline characteristics, neither in the erythrocyte SOD activity nor in the level of F2-isoprostanes in urine within as between groups before and after contrast media administration.

Erythrocyte superoxide dismutase (SOD) activity and levels of F2-isoprostanes in urine before (baseline) and after contrast media administration

| | G1 | G2 | G3 |
|---|---|---|---|
| Erythrocyte SOD (U/mL) | | | |
| Baseline | 5 (3.92) | 4.64 (2.79) | 4.43 (1,14) |
| 4 h after contrast administration | 7.29 (13.39) | 7.58 (13.66) | 4.6 (1.68) |
| Isoprostanos F2 orina (pg/mL) | | | |
| Baseline | 11474.39 (11467.71) | 9726.11 (11358.03) | 18527.36 (18626.01) |
| 12 h after contrast administration | 11922.07 (11326.98) | 11110 (12328.13) | 12659.55 (12595.18) |

Data expressed as means and standard deviation of the means

Conclusions:

The administration of contrast media with different protocols of hydration to hospitalized non-diabetic patients with eGFR $\geq$ 30 ml/min does not bring about significant changes in the erythrocyte SOD activity or F2-isoprostanes levels in urine.

Disclosure of Financial Relationships: nothing to disclose

**Preliminary Results of the Clinical Trial: Prevention of Contrast-Induced Nephropathy by Oral or Intravenous Hydration. Evolution of Serum and Urine Markers of Renal Damage: Neutrophil Gelatinase-Associated Lipocalin (NGAL) and Interleukin-8 (IL-8)** Paloma L. Martin Moreno,[1] Nuria Garcia-Fernandez,[1] Nerea Varo,[2] Laura Montero,[2] Francisco Javier Lavilla,[1] Jorge M. Nunez-Cordoba.[3] *[1]Nephrology, Clinica Universidad de Navarra, Spain; [2]Laboratory of Biochemistry, Clinica Universidad de Navarra, Spain; [3]Department of Preventive Medicine and Public Health, Clinica Universidad de Navarra, Spain.*

Objective: To compare the effectiveness of IV and oral hydration in prevention of contrast-induced nephropathy through measurements of NGAL and Il-8.

Material and methods:

Prospective, randomized, single-centre trial in hospitalized non-diabetic patients with estimated glomerular filtration rate (eGFR) $\geq$ 30 ml/min calculated by MDRD-4, undergoing procedures with contrast media.

Patients were randomized in three groups: G1: IV bicarbonate, G2: Oral serum and G3: control. Variables studied serum and urine NGAL and IL-8.

Results:

So far 67 patients have been enrolled. There were no significant differences ($p>0.05$) between groups regarding their baseline characteristics, neither between groups in NGAL and serum Il-8 levels before and after contrast media administration ($p>0.05$). The change of urine Il-8 level after contrast media administration was significant ($p=0.033$) and different between groups ($p=0.035$).

NGAL and Il-8 levels

| | G1 | G2 | G3 |
|---|---|---|---|
| Serum NGAL (ng/ml) | | | |
| Baseline | 210.74 (229.99) | 201.05 (214.47) | 157.45 (40.49) |
| 4 h after | 276.39 (394.03) | 230.6 (313.06) | 159 (87.7) |
| Urine NGAL (ng/ml) | | | |
| Baseline | 76.79 (133.22) | 57.13 (91.51) | 105.67 (307.11) |
| 4 h after | 90.39 (162.36) | 46.57 (66.61) | 30.31 (62.09) |
| Serum Il-8 (pg/mL) | | | |
| Baseline | 151.52 (170.81) | 87.52 (116.54) | 164.95 (255.12) |
| 12 h after | 181.75 (199.12) | 77.43 (91.48) | 133.59 (227.01) |
| Urine Il-8 (pg/mL) | | | |
| Baseline | 175.75 (371.6) | 164.25 (285.96) | 395.92 (793.29) |
| 12 h after | 138.16 (211.44) | 192.46 (357.65) | 173.19 (321.68) |

Data expressed as means and standard deviation

Conclusions:

Urine Il-8 level changes in the first hours following administration of contrast media and this effect seems to depend on the protocol of hydration applied. This result is not observed in serum Il-8 or NGAL levels.

**Sevoflurane Induced Severe Acute Renal Failure Requiring Hemodialysis** Penchala S. Mittadodla, Robert S. Gayner. *St Luke's Hospital, Bethlehem, PA.*

Drug induced nephrotoxicity is common in clinical practice and accounts for up to 25% of all cases of acute renal failure. It is important for clinicians to be aware of nephrotoxic drugs and take necessary steps to prevent renal insult. We report a case of Sevoflurane precipitated severe acute renal failure in a patient who had multiple operations and Sevoflurane exposure.

A 73-year old Caucasian male was admitted following a motor vehicle accident and found to have a large laceration to the right thigh requiring debridement. Two weeks later, his right thigh wound got infected with S. aureus and E. coli for which he was treated with vancomycin and piperacillin/tazobactam. Subsequently, he had further debridement of the wound under general anaesthesia with Sevoflurane. He had a CT scan of chest with contrast to investigate an episode of dyspnea one day prior to the debridement. He did not have any documented episode of hypotension during his entire hospital stay. He developed severe acute renal failure with an elevated BUN and creatinine of 40 mg/dl and 8.0 mg/dl respectively and ultimately required hemodialysis.

His past medical history included type 2 diabetes mellitus, hypertension and hypothyroidism but no evidence of chronic kidney disease with a baseline creatinine of 1.0 and an estimated GFR > 60 ml/min/1.73 sq m. His medications included glyburide, pioglitazone, synthroid and SQ heparin.

Physical exam was significant for bibasilar crackles, 2+ bilateral pedal edema with normal blood pressure and he was nonoliguric. Serologic workup was normal and LFTs/CPK were normal. Urinalysis was positive for trace blood and protein and negative for eosinophils. A renal ultrasound was normal. Renal biopsy revealed acute tubular necrosis.

Sevoflurane, an inhaled anaesthetic agent, is metabolised into Compound A, which can have a tubulotoxic effect leading to ATN. It can be worsened by nephrotoxic drugs like contrast dye, renal insufficiency, volume depletion, diabetes, heart failure, sepsis or age >60. Repeated exposure to Sevoflurane should be avoided especially, with recent use of contrast dye.

**Overlapping Lupus Myocarditis and Nephritis: A Diagnostic and Therapeutic Challenge** Lawand A. Saadulla,[1] Giselle Baquero,[2] Navin Verma.[1] *[1]Nephrology, PSU/Hershey Medical Center, Hershey, PA; [2]Internal Medicine.*

We describe a case of a young woman presenting with fulminant heart failure, myocarditis and nephritis as first manifestation of SLE which represented a diagnostic and therapeutic challenge. To our knowledge a few similar cases have been reported in the literature.

A previously healthy 22 year old Hispanic female was transferred to our institution after she developed cardiogenic shock and hypoxemic respiratory failure requiring inotropic support and mechanical ventilation. Initial EKG showed non-specific T wave abnormalities with prolonged QT. Echocardiography demonstrated global hypokinesis with severe systolic dysfunction and left ventricular ejection fraction 15%. The patient developed a non-oliguric acute renal failure. Right heart catheterization was consistent with cardiogenic shock. Laboratory tests revealed high titers of ANA and dsDNA. Levels of C3 and C4 complement were markedly low. Clinical and laboratory findings were suggestive of lupus myocarditis as an etiology for her heart failure. A subsequent renal biopsy for her worsening acute renal failure showed diffuse proliferative glomerulonephritis. Treatment for SLE with pulse intravenous cyclophosphamide and methylprednisolone was initiated resulting in near complete organ recovery. The patient was discharged home to continue monthly cyclophosphamide maintenance therapy, with progressive improvement in her cardiac and renal function.

Acute lupus myocarditis leading to heart failure complicated by nephritis is uncommon but a potentially fatal initial manifestation of SLE. The diagnosis is challenging due to the higher prevalence of viral myocarditis and idiopatic dilated cardiomyopathy among patients presenting with newly diagnosed heart failure. Lupus myocarditis should be considered, diagnosed and treated promptly to avoid fatal consequences. Immunosuppressive agents are the mainstay therapy. The choice of regimen is controversial due to the paucity of literature on the treatment of lupus myocarditis overlapping with nephritis. Our patient responded well to combined cyclophophamide and steroid therapy, with induction of remission and improvement of her overall clinical condition.

**Outcomes of Acute Kidney Injury in Bone Marrow Transplant Patients** Ankit Sakhuja, Abhishek Deshmukh, Nilay Kumar, Aaron T. Dall, Gagan Kumar, Rahul S. Nanchal. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

**Background:**

Acute kidney Injury (AKI) has shown to be independent predictor for adverse outcomes in many diseases. Bone marrow transplant (BMT) patients constitute a unique group of patients exposed to multiple drugs that can worsen kidney function. There is limited literature on the development of AKI in the BMT population. We sought to investigate the frequency and associated outcomes of patients with BMT developing AKI.

**Methods**

Using Nationwide Inpatient Sample 2007, patients aged 18 years and above, discharged with any diagnosis of bone marrow transplant were identified through appropriate ICD-9 codes. The primary outcomes measured were frequency of AKI, all cause in hospital mortality and length of stay (LOS). Pearson correlation and Chi square were used to compare the variables for unadjusted analysis and logistic regression was used to obtain adjusted odds ratios. $\alpha$ was set at 0.05.

**Results**

There were an estimated 44,630 BMT patients admitted to the hospital in 2007. Of those 8.5% developed AKI and 2.8% had pre-existing chronic kidney disease (CKD).

After multivariate logistic regression and controlling for demographic characteristics and co-morbid conditions, patients with BMT developing AKI had significantly higher in-hospital mortality (OR 2.95; 95%CI 2.18-4.02) when compared to those with normal kidney function. BMT patients with CKD had significantly higher frequency of AKI (OR 5.8; 95%CI 4.12-8.24).

LOS was 6.2 days longer (95%CI 5.1-7.4 days) in BMT patients with AKI when compared to those with normal renal function.

**Conclusion**In BMT patients, AKI predicts higher all cause in-hospital mortality and longer LOS.

**Role of Statins in Prevention of Contrast Induced Nephropathy** Majed Samarneh, Norbert Shtaynberg, Morton J. Kleiner, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background:

Studies in animal models have suggested that there is a role for statins, acting as free radical scavengers, in the prevention of contrast-induced nephropathy (CIN). However, the effect in humans is not known.

Materials and methods

We carried out a retrospective chart review at our institution. 282 charts of patients who underwent a cardiac catheterization or a CT scan with an intravenous contrast were reviewed. Patients presenting with acute renal failure before the radiological study or who have end stage renal disease were excluded. We defined contrast-induced nephropathy as an increase in serum creatinine from baseline by greater than 0.5 mg/dL or an increase of 25% within 72 hours following the procedure.

Results

The Fisher's test was used to test for significant associations between categorical variables. The t-test or Mann-Whitney test was used as appropriate for continuous variables. Age, creatinine at baseline, and peak creatinine post percutaneous coronary intervention (PCI) were all significantly different between CIN groups. Subjects who had CIN were significantly older (69.6 +/- 11.9 vs. 63.2 +/- 14.7; p=0.0006), had significantly higher creatinine levels at baseline (1.6 +/- 0.84 vs. 1.14 +/- 0.98; p<.0001) and had significantly higher peak creatinine levels post-PCI (3.01 +/- 1.70 vs. 1.23 +/- 0.85; p<0.0001). Subjects with hypertension were 4.6 times more likely to develop CIN compared to subjects who did not have hypertension[95% CI: (2.4, 8.6). Subjects with all three risk factors, including hypertension, diabetes mellitus, and age greater than 65 were 11.6 times more likely to develop CIN. Patients who were on statin therapy were not protected from CIN (65 patients vs 92 patients; p=0.08).

Conclusion

Statin therapy was not effective in prevention of CIN in our study. However, these subjects who were on statins had higher prevalence of risk factors such as hypertension, age greater than 65, and a higher baseline creatinine which may have contributed to the higher incidence on CIN. A larger randomized sample size may elucidate the beneficial effects of statins in prevention of CIN.

**Cardiopulmonary Bypass Causes Short Term, but No Long Term Alterations in Healthy Rat Kidney** Maria Schenk, Iryna V. Samarska, Hjalmar R. Bouma, Robert H. Henning, Leo E. Deelman. *Clinical Pharmacology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands.*

**Background:** Cardiopulmonary bypass (CPB) is a commonly used technique in cardiac surgery. Clinical studies show both acute and long term effects on kidney function and a higher mortality in patients treated with CPB compared to patient treated without CPB. To obtain more insight into the pathogenesis of impaired renal function following CPB, we recently established a rat CPB model. In the present study we characterized the short-term effects of CPB on the kidney.

**Methods:** Rats underwent CPB or Sham procedure and were sacrificed at 60 min, 1, 2 and 5 days following the procedure. Subsequently, blood and urine samples were taken and the kidneys were removed. Renal gene expression was studied by Rt-PCR targeted to markers of ischemia, inflammation and fibrosis. Blood analyses were performed for several markers of the kidney function.

**Results:**

HO-1, TNF-alpha, Vcam, E-selectin and Pai-I gene expression were all upregulated at 60 min. after CPB. Immunohistochemistry demonstrated HO-1 upregulation in the renal tubuli. Almost all parameter normalized at 1 day after CPB. Cd68 expression and staining were upregulated at day 1 after CPB, indicating the influx of macrophages. Sham animals did not show significant changes. Blood analyses did not demonstrate impaired kidney function at any of the time points. Troponin levels were increased in the sham and CBP group at 60 min indicating cardiac damage by the procedure.

**Conclusion:** Our study demonstrates that CPB in healthy rats causes mainly acute alterations in the kidney, but no deterioration in kidney function. No long term effects were found in the healthy rat kidney. Long term effects in the kidney of patients are most likely caused by a combination of underlying pathophysiology and CPB treatment.

## PUB029

**Dose Dependent Renal Protection by iNOS Inhibition in Ischemic Acute Kidney Injury (iAKI) with Impact on Organic Cation Transporters** Reinhard Schneider, Marcus Meusel, Michael Kersten, Christoph Wanner. *University Hospital, Dept. Medicine, Div. Nephrology, Wuerzburg.*

Induction of inducible nitric oxide (NO) synthase (iNOS) is known as an important player in the pathomechanism of AKI. A dysbalance of NO isoforms, the postulated protective endothelial (e)NOS and the rather destructive inducible iNOS, might be causal. NO mediated effects e.g. on regulation of vasodilation, renal hemodynamics, glomerular filtration and tubuloglomerular feedback as well as inflammation is well described, but effects on alteration of tubular transporter mechanisms are lacking. Here we analyzed effects of iNOS inhibition by L-NIL [L-N6-(1-Iminoethyl)lysine] regarding iAKI damage and hypothesized impact on regulation of organic cation transporters (OCT).

Bilateral clamping of Aa. renales for 45 min followed by reperfusion resulted in iAKI in our animal model in rats. Beginning with ischemia L-NIL (in various doses) or saline was applied intraperitoneally. Corresponding sham served as control. Regarding renal functional parameters we determined inulin-/PAH-clearance and PAH netsecretion (NS) after iAKI. Cortical expression of eNOS and phos-eNOS(Ser1177) as counterpart of iNOS and expression of OCT1/2 was analyzed in kidney cortex.

Ischemia dependent reduction of inulin-/PAH-clearance and PAH-NS was improved by low dose application of L-NIL in our iAKI model. Using this dosage we detected an additional increase of eNOS overexpression while phos-eNOS(Ser1177) expression was not altered. Increased iNOS induction was unchanged by L-NIL. This was combined with a reversal of OCT1- as well as OCT2-downregulation using low dose L-NIL after iAKI.

Low dosage of L-NIL turned out to be protective in iAKI regarding renal functional parameters. eNOS upregulation might probably not be a the crutial factor of renal protection due to its unchanged activation via Ser1177 phosphorylation. iNOS inhibition itself seems to be a relevant issue, especially as no additional iNOS expression follows L-NIL application. Interestingly, abrogated OCT downregulation by L-NIL might indicate an important regulatory role of iNOS derived NO after iAKI, which has to be confirmed in future studies.

## PUB030

**Identification and Evaluation of Rat Urinary Biomarker Candidates for Drug-Induced Nephrotoxicity** Justyna Siwy,[1] William Mullen,[2] Harald Mischak,[1,2] Peter Rossing,[3] Parvaneh Espandiari,[4] Sharron R. Stewart,[4] Rodney L. Rouse,[4] Joseph Peter Hanig.[4] *[1]Mosaiques Diagnostics GmbH, Hannover, Germany; [2]University of Glasgow, Glasgow, United Kingdom; [3]Steno Diabetes Centre, Gentofte, Denmark; [4]U.S. Food and Drug Administration, Silver Spring.*

In an effort to identify biomarkers for drug-induced renal damage, we have previously identified potential urinary proteomic biomarkers for cisplatin-induced nephrotoxicity in rats, using the CE-MS (capillary electrophoresis coupled to mass spectrometry) technology. In a dataset consisting of 25 controls and 14 cases after treatment with cisplatin, 321 potential marker candidates could be identified as being significantly altered (p-value <0.05 as significance level after Benjamini and Hochberg multiple testing corrections). We now extend these findings by investigating the distribution of these biomarkers in urine from a longitudinal study of rats receiving gentamicin. Groups received three consecutive daily doses of 0, 75, 150, or 300 mg/kg gentamicin. Urine samples (4 per group) were collected on days 1, 5, 8, 13, 16, 20, 27, 34, and 41. All samples were analyzed using CE-MS. We analyzed the distribution of the 321 potential biomarkers of cisplatin-induced nephrotoxicity in urine samples from the gentamicin study. Thirty-two biomarker candidates were clearly associated with gentamicin induced injury, as indicated by significant changes following gentamicin treatment. In a second set of experiments, we examined the data for potential gentamicin-induced biomarkers of renal injury by identifying molecules with transient and dose-dependent changes following gentamicin administration. Of 368 candidates, 66 showed a transient and dose-dependent change. Of these, 6 were also indentified in the cisplatin study rendering these six excellent potential biomarkers for chemical-induced renal damage. We will disclose the identity of these potential biomarkers and give potential links to pathophysiology of renal injury. Collectively, these studies have demonstrated the potential of urinary proteomic biomarkers in assessing drug-induced renal damage and enabling advancements in preclinical safety testing.

## PUB031

**Non-Dilated Obstructive Uropathy: A Clinical Pitfall in the Investigation for Renal Failure** Dilip Unnikrishnan,[2] Hugo J. Villanueva,[1] Jinil Yoo.[1] *[1]Nephrology, Montefiore Medical Center North Division, Bronx, NY; [2]Nephrology Associates, Evansville, IN.*

Urinary tract obstruction is one of the important causes of acute renal failure (ARF) and failure to relieve obstruction expeditiously can permanently impair renal function. A dilated urinary system is used in most diagnostic procedures as a sign indicating obstruction. However, non-dilated obstructive uropathy (NOU) has been reported and is creating a clinical pitfall in the investigation for renal failure. We present a patient with NOU due to retroperitoneal fibrosis (RPF) who developed ARF requiring dialysis.

A 58-year-old male with hypertension on metoprolol presented with anuria. Renal ultrasound with doppler study showed normal sized kidneys without hydronephrosis. His renal functions worsened to serum creatinine (SCr) 14.5 mg/dL requiring hemodialysis. A retrograde cystoureterography was performed and demonstrated minor narrowing of the mid ureters without any ureteral obstruction. MRI showed no hydronephrosis but revealed a mantle of adenopathy encasing the abdominal aorta above its bifurcation. Because of strong clinical suspicion for obstructive uropathy, bilateral ureteric stents were placed. He subsequently underwent exploratory laparotomy, which confirmed the presence of RPF but no lymphadenopathy, and the open kidney biopsy showed histologic findings compatible with obstructive ARF. On the day of his discharge, renal functions improved to SCr 1.5 mg/dL.

NOU has been described with certain medications, in patients with RPF, and malignancies involving pelvis/ retroperitoneum. Our patient has RPF, idiopathic or related to use of beta blockers. About 2.5% patients with RPF are reported to have no dilatation of urinary system on sonogram. CT scan and MRI offer better anatomic delineation. Our case illustrates that a non-dilated urinary system on an imaging study or on retrograde cystoureterogram may not rule out the presence of obstruction. If clinical suspicion for urinary obstruction is high, expeditious further testing should be pursued to rule out obstructive ARF.

**Mitochondrial Injury and Tubular Apoptosis during Renal Ischemia-Reperfusion Are Suppressed in Bak-Knockout Mice** Qingqing Wei, Zheng Dong. *Department of Cellular Biology and Anatomy, Medical College of Georgia and Charlie Norwood VA Medical Center, GA.*

Renal tubular cell apoptosis via the intrinsic or mitochondrial pathway contributes to ischemic acute kidney injury (AKI). A key event of the mitochondrial pathway of apoptosis involves the activation of Bax and Bak, two multidomain proapoptotic Bcl-2 proteins. However, the specific roles played by Bax and Bak in mitochondrial injury and tubular cell apoptosis during ischemic AKI has not been established. In this study, we determined the role of Bak using gene-knockout mouse models. We tested two strains of mice with Bak knockout. One strain was purchased from Jackson Laboratory (B6 strain) and the other was derived from Bax(flox/flox)Bak(-/-) mice (BBC strain) . The mice were subjected to 30 min bilateral kidney ischemia followed by 48hrreperfusion. Compared with wild-type, the Bak-KO mice from both strains were significantly more resistant to ischemic AKI. For the B6 stain, Bak-KO mice showed BUN and serum creatinine of 229.8 and 2.32 mg/dL mg/dL vs.119.7 and0.91 mg/dL in wild-type mice. For the BBC strain, Bak-KO mice showed BUN and serum creatinine of 249.1 and 1.8 mg/dL vs. wild-type 114.2 and0.6 mg/dL. Ischemic AKI induced mitochondrial fragmentation in 41.4% proximal tubular cells in wild-type mice, which was suppressed to 15.9% in Bak-KO mice. Cytochrome c release was also significantly decreased in Bak-KO mice, so was tubular cell apoptosis. However, tubular necrosis shown by histological damage scores was not ameliorated in Bak-KO mice. Bak-KO mice survived better after ischemic AKI. Together, the results suggest that Bak mediates mitochondrial damage and tubular cell apoptosis, contributing to ischemic AKI.

## PUB033

**High Fat Diet Induced Proteinuria and Renal Insufficiency in Sprague-Dawley Rats** Jinn-Yang Chen. *Division of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.*

Backgrounds

Obesity is established independent risk factors for the development of chronic kidney disease. The mechanisms obesity induced renal insufficiency is investigated.

Methods

Eight weeks male Sprague-Dawley rats with (Sham) or without unilateral nephrectomy (UNX) received 60% high fat diet (HFD) or standard chow for 3 months. The oral glucose tolerance test (OGTT) was performed in the morning after an overnight 10- to 12-h fast once every month. Fasting blood samples were taken for measurement of glucose, insulin, total cholesterol, triglyceride, creatinine, BUN, HDL cholesterol. Urine protein was measured with spot urine protein/creatinine ratio. The abdominal fat distribution and

area were measured by CT scan. After 3 months of treatments, all rats were sacrificed. Epididymal fat, liver, heart, kidney and muscle were removed for immunohistochemistry and real-time quantitative PCR.

Results

After 3 months of experiments, sham rats taking standard chow weight 582.13 ± 39.2 gm and HFD rats weight 685.5 ± 87.5 gm. HFD rats developed increased insulin resistance, serum creatinine, leptin, urine protein/creatinine ratio and decreased serum adiponectin. Rats receiving both NPX and HFD had largest increase of proteinuria. HFD rats also have increased visceral fat/subcutaneous fat ratio. Surprisingly, UNX rats have increased sensitivity to insulin. Light microscopic investigation showed a dilatation in blood vessels and Bowman's space, mononuclear cell infiltration, degeneration in nephrons, including glomerulosclerosis and tubular defects, and an increase in the connective tissue in the kidneys in the treatment group. UNX rat has significant heart fibrosis.

Conclusion

Fatty diet is responsible for the rats' obesity and may lead to proteinuria, renal insufficiency, renal deformities as a result of histopathological changes such as dilatation, tubular defects, inflammation and connective tissue enlargement of the kidney.

**PUB034**

**Effects of *Fangjihuangqitang* on the Expressions of MCP-1 in Renal Cortex of Adriamycin-Induced Nephropathy (AIN) Rats** Hongyu Chen, Qin Zhu, Yongyun Wang. *Nephrology, Hangzhou Hospital of Traditional Chinese Medicine (TCM), Hangzhou, China.*

**Aims:** The purpose of study is to observe effects of *fangjihuangqitang* on the expressions of MCP-1 in renal cortex of AIN rats.**Methods:** 21 rats were divided into three groups randomly (normal group, AIN group and treatment group). Adriamycin was given (6.5mg/kg) to the AIN group and treatment group through the caudal vein, while isometric physiological saline was injected to the normal group. Treatment group were feed with *fangjihuangqitang* as the same time, while normal group were feed with isometric physiological saline. The quantitative detection of 24-hour proteinuria was been done on the second and eighth week respectively. Renal cortexes were taken at the end of experimentation. The expression of MCP-1 was tested by immunohistochemisty and RT-PCR.**Results:**Two weeks later, the quantitations of proteinuria in normal group, AIN group, and treatment group were 19.10±3.93mg/d, 408.85±149.27mg/d, and 489.10±296.20mg/d in the experiment.The values of the AIN group and the treatment group were much higher than the normal group($P$<0.05). Eight weeks later, the quantitations of proteinuria in normal group, AIN group, and treatment group were 42.03±9.58mg/d, 615.33±48.32mg/d, and623.86±146.22mg/d, and there was no significant difference between AIN group and treatment group.Tested by immunohistochemisty, the expression of MCP-1 in renal cortex in normal group, AIN group and treatment group were 0.04±0.01, 0.11±0.01, and0.07±0.01. Tested by RT-PCR. The expression levels of MCP-1 in renal cortex in normal group, AIN group and treatment group were 13.05±0.27, 34.51±1.20, and28.57±0.11. Both the values of the AIN group and the treatment group were much higher than the normal group($P$<0.05), while the treatment group was much lower than the AIN group($P$<0.05).**Conclusion:** The expression of MCP-1 mRNA and protein in Adriamycin-induced nephropathic rats was abnormal. The increase of MCP-1 expression is likely to be related to the mass of proteinuria. The reason for *fangjihuangqitang* which has gotten some effects on chronic kidney disease is possibly related to decreasing expressions of MCP-1 in renal cortex.

**PUB035**

**The Role of Protease Activated Receptor 4 in Renal Fibrosis** Chee Kay Cheung,[1] Ai Yen Chin,[1] Timothy Scott Johnson,[2] Simon P. Hart,[1] Sunil Bhandari.[1] *[1]Centre for Clinical Sciences, Hull York Medical School, Hull, East Yorkshire, United Kingdom; [2]Sheffield Kidney Institute, University of Sheffield, Sheffield, South Yorkshire, United Kingdom.*

The protease activated receptors are a novel group of G-protein coupled receptors which have been implicated in a range of diseases including inflammatory, fibrotic and coagulation disorders. 4 receptors (PAR1-4) have been identified, which are activated by various proteases. PAR1 and 2 have been studied extensively in kidney but the role of PAR4 is unknown. In lung fibroblasts, our group previously showed that PAR4 was upregulated in response to inflammatory cytokines, and targeting PAR4 led to a reduction in fibroblast number. We aimed to see whether a similar process occurred in renal fibroblasts, in cell culture and a model of renal fibrosis.

Primary human renal fibroblasts, the NRK49F rat fibroblast cell line and the NRK52E rat tubular cell line were used to identify PAR4, by RT-PCR and Western blotting. A rat 5/6ths nephrectomy model was used to assess distribution of PAR4 in the kidney, by RT-PCR and immunohistochemistry.

Renal fibroblasts constitutively expressed PAR1 and 2, but not PAR3 and 4 mRNA. PAR4 mRNA levels were not significantly upregulated in response to tumour necrosis factor (TNF)-α or lipopolysaccharide (LPS) in primary renal fibroblasts and NRK49F cells. PAR4 mRNA was expressed in sham kidney (n=5) and was significantly upregulated in the 5/6ths nephrectomy model (n=6) at day 90 by 2.2 (SEM ± 0.4) fold. PAR4 stained positively in proximal and distal tubules in sham kidney and 5/6ths nephrectomy, and negatively in fibroblasts, with no difference in intensity of staining between conditions. PAR4 mRNA and protein expression were confirmed in NRK52E cells by RT-PCR and Western blotting.

We have demonstrated distribution of PAR4 in the kidney for the first time. PAR4 expression was not increased in renal fibroblasts in response to inflammatory mediators or in a model of CKD, thus is unlikely to be a suitable target for apoptosis. Studies are ongoing to assess the effects of PAR4 stimulation on tubular cells, specifically if this promotes pro-fibrogenic cytokine release, as demonstrated previously for PAR1 and PAR2.

**PUB036**

**Combined Losartan (L) and Furosemide (F) Treatment Is Less Renoprotective Than L+Hydrochlorothiazide (H) in the 5/6 Renal Ablation Model (Nx)** Simone R. Costa, Renata A. Souza, Carla Romagnoli, Marcela C. Morais, Claudia R. Sena, Camilla Fanelli, Bianca H. Ventura, Denise M. Malheiros, Clarice K. Fujihara, Roberto Zatz. *Univ of Sao Paulo, Brazil.*

We showed (AJP 292:F1810) that LH association arrested renal injury for at least 7 months in Nx. Here we investigated if equal protection can be obtained by combining L with F instead of H. Nx was performed in 59 Munich-Wistar rats. One month later, tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/d), left kidney weight/body weight (LKW/BW), glomerular volume ($V_G$, x$10^6$µm$^3$), glomerulosclerosis index (GSI), interstitial macrophage infiltration (Mø, cells/mm$^2$) and tubulointerstitial (TI) proliferating cell nuclear antigen (PCNA+, cells/mm$^2$) were measured in 17 rats (**$Nx_{pre}$**). The remaining 42 rats were distributed into: **Nx** (untreated); **$Nx_{LH}$**, (L, 50 mg/Kg/d + H, 6 mg/Kg/d); and **$Nx_{LF}$** (L + F, 20 mg/Kg/d, the highest nontoxic dose). Results after 7 months (Mean ± SE, S, sham-operated, [a] p<0.05 vs. S; [b] p<0.05 vs. $Nx_{pre}$; [c] p<0.05 vs. Nx, [d] p<0.05 vs. $Nx_{LH}$):

| | TCP | ALB | LKW/BW | $V_g$ | GSI | Mø | TI PCNA+ |
|---|---|---|---|---|---|---|---|
| S | 149±3 | 28±6 | 0.49±0.1 | 0.7±0.1 | 1±1 | 36±5 | 26±5 |
| $Nx_{pre}$ | 198±5[a] | 91±8[a] | 0.53±0.1[a] | 0.8±0.1 | 16±3[a] | 104±10[a] | 142±16[a] |
| Nx | 200±14[a] | 203±26[ab] | 0.53±0.1[a] | 1.4±0.1[ab] | 328±38[ab] | 217±19[ab] | 163±21[a] |
| $Nx_{LH}$ | 146±5[bc] | 26±4[bc] | 0.46±0.1[bc] | 1.3±0.5[ab] | 12±4[abc] | 87±7[ac] | 34±3[abc] |
| $Nx_{LF}$ | 167±6[abcd] | 90±18[acd] | 0.56±0.1[ad] | 1.6±0.1[abd] | 38±12[acd] | 121±11[acd] | 86±10[abcd] |

Survival was 35% in Nx, 100% in $Nx_{LH}$ and 82% in $Nx_{LF}$. LH treatment arrested GSI, Mø and interstitial expansion, and reversed TCP, ALB, renal hypertrophy and TI hyperplasia. Though beneficial, LF treatment failed to normalize TCP or ALB, reverse renal growth or TI hyperplasia or detain GSI and INT progression. Mechanisms for the lower efficacy of LF may include increased glomerular stress from tuft hypertrophy and inflammation linked to TI hyperplasia. The clinical implications of these results remain to be investigated.

**Up-Regulation of miR-29c Suppresses Tropomyosin 1a Expression in the Remnant Kidney Model with Short Term Activation of Hyopoxia-Inducible Factor** Yi Fang,[1] Xiaofang Yu,[1] Jiaming Zhu,[1] Xialian Xu,[1] Mingyu Liang,[2] Yong Liu,[2] Alison J. Kriegel,[2] Xiaoqiang Ding.[1] *[1]Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China; [2]Physiology, Medicial College of Wisconsin, Milwaukee, WI.*

MicroRNAs (miRNAs) are small regulatory RNA molecules that modulate the activity of specific mRNA targets and play important roles in a wide range of physiologic and pathologic processes. We hypothesized that miRNAs might be involved in the progression of CKD. After 5/6 subtotal nephrectomy, male Sprague-Dawley rats were treated with intraperitoneal injections of L-mimosine(L-Mim), an inhibitor of prolyl 4-hydroxylase domain (PHD), at a dosage of 50 mg/kg every other day from wk 5 to wk 12 to inhibit PHD activity. L-Mim treated rats had lower BUN, Scr and Ualb, higher Hb and less severe tubular interstitial injury than control. Nuclear staining of HIF-1α and HIF-2α in the tubulointerstitial area in the L-Mim group is stronger than that in the control group. We found miR-29c in renal cortex was up-regulated in L-Mim groups compared with the control using Agilent miRNA microarrays. Of the microRNAs and proteins that exhibited reciprocal changes in expression following the L-Mim treatment, miR-29c and tropomyosin 1a (TPM1), which is involved in stress fiber function, met the sequence criteria for microRNA-target interaction, which was later confirmed by 3'-untranslated region reporter analyses. Real time PCR re-confirmed that miR-29c levels in rat cortex was up-regulated after short term L-Mim treatment while TPM1 was down-regulated at the protein level. TGFb1 treatment (3 ng/ml, 24 hours) decreased miR-29c expression and up-regulated protein expression of TPM1 in human renal epithelial cells. Overexpression of miR-29c significantly attenuated TGF-b1 induced increase in TPM1 in vitro. The results suggest that short term stabilizing of HIF up-regulates miR-29c, which contributes to suppression of TPM1 and amelioration of CKD progression.

**Introducing a CD for the Instruction of the Surgical Procedures Recommended for the Induction of a Mouse Model of Chronic Kidney Disease (CKD) (The So-Called Electrocautery Mouse Model)** Raymonde Gagnon. *Departrment of Medicine, McGill University Health Centre - Montreal General Hospital, Montreal, QC, Canada.*

The purpose of this CD is to facilitate the teaching of the 2 surgical procedures required for the induction of this proven mouse model of CKD i.e. electrocautery of the surface of the right kidney followed by a left nephrectomy 2 weeks later. The first author had been involved previously in the teaching of the 2 surgical procedures to various interested research groups. This new teaching tool includes the following 3 parts: 1) 200 professional

grade photographs of all aspects of the 2 surgical procedures (from skin-to-skin) and of important related information, e.g. the handling of the electrocautery apparatus; 2) an accompanying text provided detailed information related to the photographs and to a few drawings to accompany key photographs for special emphasis (i.e. the actual electrocautery procedure); and 3) additional relevant information on details of procedures used in our Center, particularly the special care of the mice immediately before and after the 2 surgical procedures. Ths mouse model of CKD presents distinct advantages in that it can provide different degrees of CKD (i.e. mild, moderate or severe) carried over various time periods as required by the chosen experimental protocol. By providing all the necessary information in this CD format, it is expected that CKD can be induced safely and efficiently in mice thereby promoting its use to conduct basic research in CKD.

**Effects of High Glucose and Mannose-Binding Lectin on the Activation of Lectin Complement Pathway in Human Renal Glomerular Endothelial Cells** Songmin Huang, Wenxing Fan, Wanxin Tang, Ping Fu, Fang Liu, Hongyu Qiu. *Department of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan Province, China.*

***Aim:*** To investigate the effects of high glucose and mannose-binding lectin (MBL) on the activation of lectin complement pathway (LCP) in human renal glomerular endothelial cells (HRGECs).

***Methods:*** HRGECs were guaranteed to culture in endothelial cell medium (ECM) *in vitro*. First, for the effects of high glucose on the activation of LCP, cells were cultured in ECM containing high glucose for different times (0-72 hours) or in different concentrations of glucose (0-60 mmol/L). Second, for the effects of exogenous MBL on the activation of LCP, cells were cultured in ECM plus exogenous MBL for different times (0-16 hours) or at different concentrations of MBL (0-8μg/ml). Third, for the effects of anti-human MBL monoclonal antibody (anti-MBL-mAb) or C1-esterase inhibitor (C1-INH) on the activation of LCP, cell-surface MBL, C3 and C5b-9 deposition were detected by flow cytometry, immunofluorescence and Western blot, respectively. NF-κB DNA-binding activity was evaluated by electrophoretic mobility shift assay (EMSA).

***Results:*** MBL or/and C3 deposition stimulated by high glucose were observed in both time and dose dependent manners. MBL or/and C3 deposition stimulated by exogenous MBL were also observed in both time and dose dependent increase manners, and peaked at 4 hours, then decreased. After treating with anti-MBL-mAb or C1-INH, both MBL and C3 deposition were significantly reduced. Treatment with anti-MBL-mAb or C1-INH could significantly attenuate the cell-surface C5b-9 staining, and obviously decrease NF-κB DNA-binding activity in HRGECs (all $P<0.05$).

***Conclusions:*** High glucose and exogenous MBL might mediate the activation of LCP in HRGECs, the mechanism by which may be associated with the cell-surface glycosylation and the level of exogenous MBL. C5b-9 deposition caused by the activation of LCP might strongly induce NF-κB DNA-binding activity in HRGECs, which may lead to endothelial cell injury. Both anti-MBL-mAb and C1-INH treatment could significantly inhibit the activation of LCP mediated by high glucose and exogenous MBL.

**Erythropoiesis-Stimulating Agent Aggravates Vascular Endothelial Function in Normal and Chronic Renal Failure Rats** Chieko Ihoriya, Minoru Satoh, Naruya Tomita, Tamaki Sasaki, Naoki Kashihara. *Division of Nephrology and Hypertension, Department of Internal Medicine, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Recent studies show erythropoietin has a wide variety of nonhematopoietic effects. However, it is still controversial whether these activities are beneficial in terms of the cardio-vascular protections. Erythropoietin acts through the erythropoietin receptor (EpoR) present in erythroblasts and also in the vascular endothelium. The binding affinity to EpoR differs depending on the erythropoiesis-stimulating agent. The binding affinity with Darbepoetin a (D-EPO) is lower than that with erythropoietin (EPO), thus it is possible that D-EPO has different effect on endothelial function. Normal male SD rats were treated with either EPO (20 IU/kg/week) thrice weekly or D-EPO (0.1 μg/kg/week) once weekly for 4 weeks. Endothelial-dependent vasodilatory response, gene expression of ICAM1 and TNFa, and NADPH oxidase activity were then assessed. The dosages of EPO and D-EPO were determined so as to have no effect on hemoglobin level. Next, adenine-induced uremic rats were divided into five groups: (1) no treatment, (2) low dose EPO treatment (20 IU/kg/week), (3) high dose EPO treatment (600 IU/kg/week), (4) low dose D-EPO treatment (0.1 μg/kg/week), and (5) high dose D-EPO treatment (3.0 μg/kg/week). EPO or D-EPO was administered for 4 weeks and survival rate was evaluated. In normal SD rats, the acetylcholine-dependent vasodilatory response decreased significantly in both EPO and D-EPO treatment groups. NADPH oxidase activity increased in both groups. Aortic gene expression of ICAM1 and TNFa similarly increased in both groups. There was no difference between EPO and D-EPO. In adenine-induced uremic rats, body weight and blood pressure were similar in the five groups. All rats had high blood pressure due to chronic renal failure compared to normal rats. Some rats died within one week after treatment. High-dose EPO and D-EPO groups had a low survival rate. In conclusion, administration of EPO and D-EPO increased oxidative stress and impaired endothelial function in normal rats. Administration of high-dose EPO to chronic renal failure rats further worsened prognosis.

**Metabolomic Search for Biomarkers of the Effect of a Spherical Carbon Adsorbent by Liquid Chromatography/Electrospray Ionization-Tandem Mass Spectrometry** Kaori Kikuchi,[1] Yoshiharu Itoh,[1] Kenjiro Murakami,[1] Toshimitsu Niwa.[2] *[1]Kureha Corp., Tokyo, Japan; [2]Advanced Medicine for Uremia, Nagoya Univ. Graduate School of Medicine, Nagoya, Japan.*

We searched biomarkers of the effect of a spherical carbon adsorbent by metabolomic study using liquid chromatography/electrospray ionization-tandem mass spectrometry (LC/ESI-MS/MS).

Serum metabolites in normal and chronic renal failure (CRF) rats before and after administration of a spherical carbon adsorbent for 3 days were analyzed by LC/ESI-MS/MS and principal component analysis. Further, serum and urine levels of the biomarkers were quantified by the selected reaction monitoring of LC/ESI-MS/MS. Indoxyl sulfate was the first principal serum metabolite, which could differentiate CRF from both normal and adsorbent-administered CRF rats, followed by hippuric acid, phenyl sulfate and 4-ethylphenyl sulfate. CRF rats showed increased serum levels of indoxyl sulfate, hippuric acid, phenyl sulfate, 4-ethylphenyl sulfate and *p*-cresyl sulfate, and administration of the spherical carbon adsorbent for 3 days to the CRF rats reduced the serum and urine levels of the metabolites.

Indoxyl sulfate is the best biomarker of the effect of the spherical carbon adsorbent in CRF rats. Hippuric acid, phenyl sulfate and 4-ethylphenyl sulfate are suggested as the additional biomarkers.

**The Prevalence of Chronic Kidney Disease (CKD) among Elderly People in Jiangsu, China: A Population-Based Cross-Sectional Epidemiologic Study** Bi-Cheng Liu, Hong Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China.*

**Background:** Chronic kidney disease is a growing problem among aging populations. However, few studies have focused on the prevalence of CKD in the elderly population. This study was performed to survey the prevalence, awareness and the risk factors of CKD among the elderly Chinese people.

**Methods.** A total of 1316 adults aged 60 years or older was investigated based on the stratified randomized sampling method from two city of Jiangsu province, southeast China (664 from Huaian and 652 from Suzhou) . All were screened for morning spot urine albumin-to-creatinine ratio, serum creatinine (Scr), uric acid (UA), cholesterol (TCh), triglyceride (TG), low density lipoprotein-cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C) and fasting blood glucose (FBG). Glomerular filtration rate (GFR) was estimated according to MDRD formula. CKD was defined as K/DOQI guideline.

**Results.** The overall prevalence of CKD was 32.3%. The distribution of CKD stages were as following: 16.6% at stage 1, 12.5% at stage 2, 3.0% at stage 3, 0.1% at stage 4, and 0.2% atstage 5. Albuminuria was detected in 30.2% of subjects, and the prevalences of microalbuminuria and macroalbuminuria were 29.3% and 0.9%, respectively. Reduced eGFR was found in 3.2% of all studied subjects. The awareness rate of CKD was only 9.6%. The logistic regression showed that age, gender, hypertension, systolic blood pressure (SBP), diabetes mellitus, fasting blood glucose, hypercholesterinemia, metabolic syndrome and hyperuricaemia were the independent factors related to the presence of CKD. Age, gender, hypertension, systolic blood pressure (SBP), fasting blood glucose and hyperuricaemia were independently associated with albuminuria.

**Conclusion.** This is the first community-based epidemiological study data on elderly Chinese people. The prevalence of CKD is 32.3%, while the awareness is only 9.6%, suggesting more attention should be paid to this specific group of people.

**Heat Shock Protein 72 Induced by Heat Shock Treatment May Function as a Novel Therapeutic Target in the Prevention of Vascular Calcification** Tzong-Shi Lu,[1] Kenneth Lim,[1,2] Guerman Molostvov,[2] Daniel Zehnder,[2] Li-Li Hsiao.[1] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Clinical Science Research Insitute, Warwick Medical School, Coventry, United Kingdom.*

Vascular calcification (VC) is a significant contributor to cardiovascular mortality in patients with chronic kidney disease (CKD) and coronary artery disease (CAD). Osteo/chondrocytic transformation and simultaneous dedifferentiation of smooth muscle cells (SMC) are important in the pathogenesis of VC. Heat shock protein 72 (HSP72) is a cardio-protective inducible heat shock protein that functions as a molecular chaperone. However, little is known about its effects in VC. We have established a long-term calcification and heat shock treatment (HST) model using human aortic-smooth muscle cells (HA-SMCs); calcification was achieved using 5mM $CaCl_2$ and 5mM β-Glycerolphosphate for 21 days and for HST, daily hyperthermia treatment at 43ºC for 30 minutes. Our results show for the first time that induction of HSP72 by HST significantly prevented the development of calcification in HA-SMCs, and these effects were abolished by the HST inhibitor, quercetin, *in vitro*. We next showed that HSP72 suppressed osteo/chondrocytic transformation markers, core binding factor α-1, Osteocalcin and Alkaline Phosphatase. Furthermore, we show that HSP72 upregulated the expression of myocardin and serum response factor (SRF), regulators of SMC contractile genes; co-immunoprecipitation studies demonstrated the association of myocardin-SRF-HSP72 complex. We also describe for the first time marked reduction of HSP72 expression in arteries from patients with CKD and CAD, compared to healthy controls, *in vivo*. In addition, organ culture of arteries from CKD and CAD

patients, confirmed that despite initially reduced expression, retained their ability to induce HSP72 following HST at 41ºC for 30 minutes. In conclusion, our study showed that HSP72 may function as a central regulator of molecular pathways involved in the development of VC, by suppression of osteo/chondrocytic transformation and stabilization of smooth muscle cell phenotype. We suggest treatment strategies that up-regulates HSP-72 as a new approach to inhibit VC.

**Renal Disease, Oxidative Stress, Inflammation Markers in Patients with Familial Lecithin-Cholesterol Acyltransferase Deficiency** Przemyslaw Miarka, Barbara Idzior-Walus, Marek Kuzniewski, Malgorzata Walus-Miarka, Wladyslaw Sulowicz, Przemyslaw Witek. *Dept of Nephrology, Metabolic Diseases, Jagiellonian University, Poland.*

Familial LCAT deficiency (FLD) is genetic disorder of lipid metabolism, characterized by low plasma HDL-cholesterol, proteinuria, haemolytic anaemia, corneal opacities. HDL functions including reduction of oxidative stress, anti-thrombotic, anti-inflammatory activity could be impaired in these patients. Usually patients with FLD develop renal failure during 3rd decade of life, but pathogenesis isn't known. There is growing evidence of inflammatory role, oxidative stress in development of renal disease. In study we assessed parameters of oxidative stress, inflammation and coagulation in 2 patients with LCAT deficiency due to Val309Met mutation of LCAT gene.

Material include 2 siblings with FLD (WX;SY) and control group. We also examined 5 other siblings, who were heterozygous (HTZ). Levels of IL6, IL10 and TNF were measured with ELISA, coagulation factorVII (FVII), and antithrombin III (A-TIII) activities by chronometric method and PAI-1 by chromogenic method.

Results: In 2 patients with FLD plasma thiobarbituric acid reactive substances (TBARS) levels were 1.55 times higher and paraoxonase (PON) activity was 2.4 times lower than in HTZ and controls. TNF and IL6 levels were lower and IL10 concentrations higher in FLD patients in comparison to healthy and HTZ persons.

FLD patients with renal disease are characterized by increased oxidative stress indicated by elevated TBARS and decreased PON activity. However, lower values of inflammatory cytokines, such as IL6, TNF and FVII and higher values of anti-inflammatory IL10 in comparison to controls were observed. The results indicate that low HDL levels are associated with low antioxidant defences, so oxidative rather than pro-inflammatory stress might be relevant in progression of renal disease in these patients.

| | WX | SY | HTZ | Controls | p |
|---|---|---|---|---|---|
| TRABS | 5.56 | 5.56 | 4.51 | 3.58 | 0.05 |
| PON | 285 | 415 | 421 | 698 | 0.01 |
| TNF | 2.86 | 2.71 | 2.52 | 3.58 | 0.05 |
| IL6 | 0.28 | 0.56 | 0.73 | 0.5 | 0.05 |
| IL10 | 0.63 | 2.0 | 0.65 | 0.17 | 0.05 |
| FVII | 76 | 68 | 126 | 112 | 0.05 |

**Urinary NGAL as a Marker for Early Stages of Chronic Kidney Disease in 5/6 Nephrectomised Rats** Martin Skott,[1] Rikke Norregaard,[1,2] Tae-Hwan Kwon,[3] Jorgen Frokiaer,[1,2] Soren Nielsen.[1] *[1]Water & Salt Research Center, Faculty of Health Science, Aarhus University, Aarhus, Denmark; [2]Institute of Clinical Medicine, Arhus University, Aarhus, Denmark; [3]Biochemistry and Cell Biology, School of Medicine, Kyungpook National University, Taegu, Korea.*

The aim of this study was to assess whether neutrophil gelatinase associated lipocalin (NGAL) could represent a novel marker of kidney function during the early stage of chronic kidney disease (CKD) in 5/6 nephrectomised rats.

CKD was induced by excision of ~ 2/3 of the left kidney and right 1/1 nephrectomy using the excision remnant kidney model. Sham operations were also performed.

Creatinine, urea and albumin were determined on 24 hr urine & serum samples. Direct ELISA was performed on 24 hr urine to detect NGAL.

Fourteen days after 5/6 nephrectomy, polyuria, polydipsia, azotaemia & proteinuria were observed in the rats with CKD. Urinary excretion of NGAL was increased in 5/6 nephrectomised rats.

| | Nephrectomy (n=10) | Sham (n=10) |
|---|---|---|
| **P-Creatinine(μmol/L)** | 71.64 ± 4.19* | 37.10 ± 1.23 |
| **P-Urea(mmol/L)** | 18.40 ± 1.58* | 6.06 ± 0.59 |
| **U-Albumin (g/L)** | 0.32 ± 0.13 | < 0.036 |
| **Creatinine clearance (ml/min)** | 0.72 ± 0.06* | 1.54 ± 0.12 |
| | Nephrectomy (n=25) | Sham (n=24) |
| **U-NGAL(Units/day)** | 18071.74 ± 1.16* | 5584.70 ± 1.13 |
| **Body weight (gram)** | 266.2 ± 6.0* | 300.46 ± 5.38 |
| **Urine output (μl/min/kg BW)** | 112.18 ± 8.79* | 36.46 ± 2.43 |
| **Water intake (μl/min/kg BW)** | 144.13 ± 6.26* | 61.87 ± 3.12 |

Values are calculated as means (±SE). * P < 0.05 compared to Sham

Pearsons correlation analysis (n=10) showed, as expected, that both plasma creatinine & urea correlated significantly with creatinine clearance (CLcr) (r=-0.66, p<0.05 & r=-0.84, p<0.05 resp.). Unexpectedly urinary NGAL concentrations did not correlate with plasma creatinine & urea (r=-0.55, p>0.05, r=-0.60, p>0.05 resp.), CLcr (r=0.41, p>0.05) & proteinuria (r=0.16, p> 0.05).

These data suggest that NGAL can serve as a novel urinary biomarker of CKD in rats exposed to 5/6 nephrectomy. However NGAL might not be able to assess the severity of CKD in this animal model, as opposed to conventional biomarkers of CKD.

**Hematological Parameters in Patients Treated with MIRCERA® after Conversion from rHuEPO** N. J. Vega, Gloria Antón Pérez, Raquel Santana Estupiñán, Patricia Pérez Borges, Roberto Gallego Samper, Fernando Henríquez Palop, Faina González Cabrera, Leocadia Palop Cubillo. *Department of Nephrology, Dr. Negrin University Hospital of Gran Canaria, Las Palmas de Gran Canaria, Spain.*

**Objectives**: To analyze whether conversion from weekly rHuEPO to monthly MIRCERA® is a safe option in patients with chronic kidney disease (CKD) on renal replacement therapy (hemodialysis (HD) and peritoneal dialysis (PD)) and those attending the advanced CKD (ACKD) unit (stages IV and V). **Methods:** 102 patients (39 HD, 37 PD, and 26 ACKD) were evaluated at baseline and after conversion during 6 months of follow-up regarding hematological parameters and anaemia treatment. Administration route was intravenous in HD and subcutaneous in PD and ACKD patients. **Results:** Mean age was 61.8±14.3 years and 59.8% of patients were men. The most frequent aetiology of CKD was diabetic nephropathy (45.1%), followed by CKD of unknown cause (15.7%) and chronic glomerulonephritis (12.7%). The 6.9% of patients were naive for erythropoiesis stimulating agent administration, 93.1% had received previously a rHuEPO. The results for hemoglobin (Hb) and the MIRCERA® dose over time are shown in the table below.

| Patients | Parameters | Baseline | 2 months | 4 months | 6 months |
|---|---|---|---|---|---|
| HD (n=39) | Hb (g/dL) | 11.51 ± 1.33 | 11.33 ± 1.13 | 11.28 ± 1.22 | 11.46 ± 1.18 |
| | MIRCERA (μg) | 157.69 ± 77.19 * | 157.69 ± 84.13* | 179.49 ± 84.25 | 179.48 ± 75.84 |
| PD (n=37) | Hb (g/dL) | 12.14 ± 1.32 | 11.52 ± 1.51 | 11.60±1.39 * | 11.94 ± 1.50 |
| | MIRCERA (μg) | 123.65 ± 55.88 * | 143.24 ± 50.17 * | 156.03±60.78 | 162.84 ± 76.06 |
| ACKD (n=26) | Hb (g/dL) | 12.29 ± 1.27 | 12.30 ± 1.56 | 12.62±1.63 | 12.64 ± 1.53 |
| | MIRCERA (μg) | 95.19 ± 38.09 ** | 119.23 ± 54.45 * | 126.92±56.97 | 133.65 ± 58.84 |

*p < 0.05; **p < 0.01

**Conclusions:** Conversion to MIRCERA® effectively and safely maintained the mean Hb level between 11 and 13 g/dL throughout the follow-up period. Upward dose adjustment of MIRCERA® was required over time in all patient subgroups, the largest dose increases being required in HD followed by PD and ACKD.

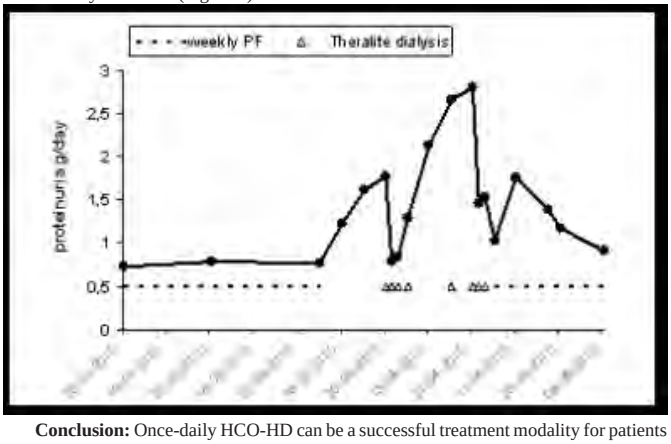
**Reduction of Proteinuria in Recurrent Focal Segmental Glomerulosclerosis after Renal Transplantation with High Cut-Off Hemodialysis** Marike Wabbijn, Dennis Alexander Hesselink, Michiel G. H. Betjes. *Nephrology, Erasmus MC, Rotterdam, Netherlands.*

**Background:** Timely treatment with plasmapheresis (PP) may lead to remission of recurrent idiopathic focal segmental glomerulosclerosis (iFSGS). A circulating permeability factor of 30-50 Kd has been postulated to be present in iFSGS, but has never been fully characterized. Recently, high cut-off (HCO) dialyzers have become available that allow for removal of molecules with a Mw up to 100 Kd. HCO-dialyzers have been used successfully to remove light chain immunoglobulins in patients with myeloma cast nephropathy We tested whether HCO dialyzers can be effective in the treatment of recurrent iFSGS after renal transplantation.

**Patient case:** A 28-yr old male underwent a 2nd kidney transplantion from a living-related donor. Proteinuria developed shortly after the 2nd kidney transplantation and recurrence of iFSGS was diagnosed on renal biopsy. PP treatment was started and stable remission of proteinuria was achieved. For the past two years, he has remained in an excellent clinical condition with low grade proteinuria, however dependent on once-weekly PP.

Recently, we started to treat this patient with HCO-HD, hoping the proteinuria would remain <0.5 gr/day and frequency of treatment could be decreased. The protocol was started 2 weeks after the last PP, when his proteinuria increased from 0.5 gr to >2 gr/day. Initially, we treated with HCO-HD every other day which lead to a rapid remission of proteinuria. However, once-weekly treatment lead to increasing proteinuria. We repeated this treatment schedule and confirmed the results: rapid remission but reappearance of proteinuria with once-weekly treatment (Figure 1).



**Conclusion:** Once-daily HCO-HD can be a successful treatment modality for patients with recurrent iFSGS after renal transplantation, supporting the hypothesis of a circulating permeability factor.

**Peroxisome Proliferator Activated Receptor Gamma Agonist Inhibits Lipopolysaccharide-Induced the Expression of Chemokines in Renal Tubular Epithelial Cells** Weiming Wang, Ying Lu, Xu Hao, Qiao Zhou, Cong Li, Nan Chen. *Ruijin Hospital.*

**Objective** The aim of this study is to investigate the anti-inflammatory actions of PPARgamma agonist in LPS-stimulated renal tubular epithelial cells and further to clarify the mechanisms. **Methods** HK-2 cells were divided into four groups: control, LPS (1μg/ml), 15d-$PGJ_2$( 5μM)**,** LPS (1μg/ml)+ 15d-$PGJ_2$(5μM). The expression of MCP-1 and IL-8 were measured using Real-time PCR and ELISA . To determine whether the inhibitory effects of 15d-$PGJ_2$ were PPARγ-dependent or not, RNAi experiments were performed. The location of NF-κB and the IκB phosphorylation was detected by immunofluorescence and western blot methods respectively. **Results** The IL-8 and MCP-1 protein expressions were increased by 1.6 and 2.3 times, respectively, in LPS-stimulated HK-2 cells ($p<0.05$), and the level of p-IκB in cytoplasm was significantly increased compared with control group. In 15d-$PGJ_2$-pretreated cells, IL-8 and MCP-1 were decreased by 74%, 79% in mRNA level and 69%, 49% in protein level compared with LPS group($p<0.05$). In 15d-$PGJ_2$ -pretreated PPARγ negtive cells, the levels of IL-8 and MCP-1 still was reduced by 59%, 44% in mRNA level and 47%, 39% in protein level compared with LPS group. 15d-$PGJ_2$ significantly reduced LPS-induced IκB phosphorylation and NF-κB nuclear translocation in PPARγ negative cells. **Conclusions** 15d-$PGJ_2$ could inhibit LPS-induced chemokines expression, and are not entirely dependent on PPARγ, which may be related to inhibition of IκB phosphorylation.

**Effect of Aggregated IgA1 from IgA Nephropathy Patients on Podocin Expression in Podocytes** Cheng Wang,[1] Xun Liu,[1] Zengchun Ye,[1] Hui Peng,[1] Hua Tang,[1] Hui Zhang,[2] Tan-Qi Lou.[1] *[1]Deparment of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; [2]Department of Medicine, Thomas Jefferson University, Philadelphia, PA.*

Background: Abnormal-galactosylated immunoglobulin (Ig)A1 play a pivotal role in pathogenesis of IgA nephropathy, and podocin is an important marker in podocyte and function in maintaining the glomercular basement membrane.We used mouse podocytes as the experimental model to investigate the effect of aggregated IgA1 (aIgA1) isolated from IgA nephropathy (IgAN) patients on podocin expression in podocytes through different pathways.

Methods: Jacalin affinity chromatography and Sephacryl S-200 molecular sieve chromatography were used to isolate IgA1 from blood of IgAN patients which was therefore became aIgA1 by heating. Podocytes were incubated with aIgA1 or special mesangial medium, which was supernatant of mesangial cells cultured with aIgA1 from IgA patients or healthy control. Podocin expression in podocytes was measured by real-time polymerase chain reaction, immunofluorescence and western blot analysis.

Results:AIgA1 from IgAN patients or healthy controls didn't show any effect on podocin expression in podocytes at mRNA and protein levels when compared with podocytes incubated with control medium (RPMI-1640 with 0.5% foetal bovine serum) ($P>0.05$). While medium from mesangial cells incubated with aIgA1 from IgAN reduced podocin expression in podocytes at mRNA and protein levels when compared with podocytes incubated with medium from mesangial cells with aIgA1 from healthy controls ($P<0.05$), and these podocytes pretreated with enalaprilat or valsartan cann't restored podocin expression to the level as control.

Conclusion: Our findings implicate that aIgA1 from IgAN patients could inhibit podocin expression by cross-talk, and renin-angiotensin system inhibitor cann't improve podocin expression, these mechanisms remain to be clarified.

**Mesangial Medium with IgA1 from IgA Nephropathy Inhibit Podocytes Adhesive Capacity through Local Renin Angiotensin System** Cheng Wang,[1] Zengchun Ye,[1] Hui Peng,[1] Xun Liu,[1] Hui Zhang,[2] Tan-Qi Lou.[1] *[1]Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; [2]Department of Medicine, Thomas Jefferson University, Philadephia, PA.*

Background: Podocytes numbers in urine is closely related with severity of IgA nephropathy, and some of them in urine were viable, which suppose detachment of podocytes may be a major cause of podocytopenia. We used mouse podocytes to investigate the effect of aggregated IgA1 (aIgA1) isolated from IgA nephropathy (IgAN) patients on podocytes adhesive capacity .

Methods:Jacalin affinity chromatography and Sephacryl S-200 molecular sieve chromatography were used to isolate IgA1 from blood of IgAN patients which was therefore became aIgA1 by heating. Podocytes were incubated with mediumof mesangial cells co-incubated with aIgA1 which was isolated from IgAN patients, and enalaprilat(10–5 M) and valsartan(10–5 M) and separately. Adhesive capacity of podocytes was assessed by cell counting manually and hexosaminidase assay.

Results: The level of angiotensinogen and angiotensin-converting enzyme mRNAs in podocytes, as well as angiotensinII, was also increased by mesangial medium of mesangial cells co-incubated with aIgA1 from IgAN patients($P<0.05$). The special mesangial medium induced more detachment of podocytes and enhancd ILK expression when compared with podocytes incubated with medium from mesangial cells with aIgA1 from healthy controls ($P<0.05$). Enalaprilat or valsartan partly improved adhesive capacity of podocytes and lower ILK expression when compared with podocytes exposed to the special medium ($P<0.05$), while Enalaprilat plus valsartan can restore adhesive capacity and ILK expression of podocytes to the level of podocytes exposed to medium of mesangial cells stimulated by aIgA1 from healthy control ($P>0.05$).

Conclusion: Our findings implicate that local renin angiotensin system activation in podocytes involved in down-regulation of adhesive capacity by mesangial medium in IgA nephropathy, which help to understand the pathogenesis of IgA nephropathy.

**Role of Non-Glucose Based Solution in Lipopolysaccharide (LPS)-Induced Epithelial Mesenchymal Transformation in Human Peritoneal Mesothelial Cell** Tae-Hyun Yoo, Bo Young Nam, Jwa-Kyung Kim, Jung Tak Park, Shin-Wook Kang. *Brain Korea 21 Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Peritoneal fibrosis is one of the most common complications of peritonitis which often leads to changes in peritoneal characteristics. Moreover, high glucose conditions are known to be associated with poor outcome in infection. Therefore, it is assumed that the glucose based peritoneal dialysis (PD) solution itself could aggravate the complications of peritonitis. Recently, non-glucose PD solutions have been proved to improve metabolic derangements and have been shown to preserve residual renal functions better than glucose based solutions. However, it is not clear whether non glucose solutions have a protective role against peritoneal fibrosis after peritonitis in CAPD patients. The aim of this study was to evaluate the effect of high glucose or non-glucose based PD solutions on lipo-polysaccharide (LPS) induced human peritoneal mesothelial cell (HPMC) epithelial-mesenchymal transformation (EMT).

Methods: HPMCs were isolated from a piece of human omentum and were exposed to 5.6 mmol/L glucose (NG), NG+1.5% and 4.25% Dianeal, or Extraneal PD solution with or without 2μg/L LPS. E-cadherin/α-SMA and fibronectin mRNA and protein were determined by real-time PCR and western blot.

Results: α-SMA and fibronectin mRNA and protein expression were significantly increased in LPS-treated group compared to NG group. E-cadherin mRNA and protein expression were significantly decreased in LPS group compared to NG group. 4.25% PD solutions were more increased in the α-SMA/E-cadherin mRNA and protein expression ratio. These high glucose associated changes were significantly lower in Extraneal+LPS group. EMT associated markers were similar between 1.5%+LPS and Extraneal+LPS. Morphological changes as EMT were seen in LPS+NG group and were more prominent in 4.25%+LPS group compared to 1.5%+LPS or Extraneal+LPS groups.

Conclusion: This study suggests that non-glucose based PD solution may be beneficial to prevent EMT in acute peritoneal inflammatory states such as CAPD peritonitis.

**β3-Integrin Inhibit Skeletal Muscle Fibrosis during Muscle Regeneration through Suppress TGF-β Signaling Pathway** Liping Zhang,[1] Jie Du,[1] Xiaonan H. Wang,[2] William E. Mitch.[1] *[1]Internal Medicine, Baylor College of Medicine, Houston, TX; [2]Internal Medicine, Emory University, Atlanta, GA.*

CKD impairs the actions of muscle progenitors/Satellite cells, interfering with the maintenance of muscle mass. These cells control skeletal muscle regeneration through their activation, proliferation and fusion. Mechanisms leading to satellite cell dysfunctions are unknown. Satellite cells are in intimate contact with the specialized component of the extracellular matrix (ECM) composing the basement membrane of myofibers. Integrin are cell surface adhesion molecules that bind a large array of ECM ligands including collagens, fibronectin, tenascin and laminin; these cells play a central role in translating mechanical and structure cues into intracellular molecular signals that affect satellite cell behavior and function. For example, the α1 and β3 subfamily of integrins reportedly play a critical role in muscle cell differentiation and β3 could be a trigger of myogenesis since αvβ3 interacts with fibronectin, laminin and collagens I and IV. These proteins are major constituents of the ECM for skeletal muscle development. In this study, we demonstrated that satellite cells express β3 integrin, and its expression is significantly increased in injured muscles. In a mouse model of β3 integrin knockout (KO), muscle regeneration was decreased and this was accompanied by reduced expression of myogenic genes including MyoD, Myf5 and Myogenin. There also was significantly increased expression of TGF-β1 in injured muscles of β3 integrin KO mice. On these mice, there was stimulation of TGF-β1 signaling, including an increase in Smad2 and Smad3 phosphorylation in both intact and injured muscle. In isolated satellite cells, TGF-β1 treatment or β3 KO suppressed satellite cell differentiation. In an effort to identifying the mechanism for these response,we found that β3 integrin associated with a latent form of TGF-β1 by immunoprecipitation . When TGF-β1 was suppressed, there was reduced fibrosis formation and improved muscle regeneration in injured muscle of β3 integrin KO mice. These results identified a novel mechanism by which β3 integrin influence muscle regeneration.

**Inhibitory Effect of Vascular Endothelial Growth Factor on Tubulointerstitial Fibrosis and Epithelial-Mesenchymal Transition in UUO Mice** Falei Zheng, Yaoguo Lian. *Div. of Nephrol, Peking Union Medical College Hospital, Beijing, China.*

**Aim:** Epithelial-mesenchymal transition (EMT) is an important event in renal interstitial fibrosis (RIF). This study is designed to determine the effect of vascular endothelial growth factor (VEGF) on RIF and EMT in unilateral ureteral obstruction (UUO) mice and on the expressions of TGF-β1, CTGF and BMP-7.

**Methods:** 36 male mice were divided into three groups: sham group(A) ,UUO group(B), and UUO+VEGF group(C ). The mice of group C were subjected to left ureteral ligation and received $VEGF_{121}$ (100 μg/kg/d, subcutaneously) from the first day after operation. Mice were sacrificed at day 3, 7 and 14 after operation, respectively. The histologic degree of RIF was determined by pathologic techniques. The expressions of α-smooth muscle actin (α-SMA), E-cadherin, TGF-β1, CTGF and BMP-7 in the kidneys were determined by Western blot and RT-PCR.

**Results:** Morphology changes were distinguished after UUO operation: accumulation of extracellular matrix in tubular-interstitial areas, atrophy of tubules. RIF in UUO mice was markedly distinct compared with that in sham mice, and significantly aggravated from day 3 to day 14 after operation. The degree of RIF, the expressions of α-SMA, TGF-β1, and CTGF increased significantly in UUO group, while E-cadherin and BMP-7 expressions decreased significantly in UUO group, compared with those in sham group at day 3, 7 and 14, respectively ($P$<0.05). VEGF treatment reduced RIF, expressions of α-SMA, TGF-β1 and CTGF, but increased the expressions of E-cadherin and BMP-7, compared with UUO mice at day 3 and 7, respectively ($P$<0.05). No differences in the expressions of these markers were found between the VEGF-treated and UUO mice at day 14 after operation except for CTGF expression.

**Conclusions:** VEGF administration may ameliorate RIF at the early stage in UUO mice. This effect may be probably related with inhibition of EMT by VEGF.

**Ets-1 Is a Regulator of LOX Expression in Hyperuricemia Nephrosis** Yang Zhou, Ruoyun Tan, Junwei Yang. *Center for Kidney Disease, the 2nd Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China.*

Hyperuricemia is reported to induce renal fibrosis and progressive renal disease. Lysyl oxidase (LOX), which plays pivotal roles in extra cellular matrix (ECM) maturation, is a critical mediator of hyperuricemia induced renal sclerosis. However, the molecular events underlying LOX expression in response to uric acid treatment are poorly understood. The transcription factor Ets-1 is rapidly induced both in kidneys of hyperuricemia mice and in proximal tubule cells (NRK-52E) incubated with uric acid. As compared with control, ECM expression and deposition after uric acid treatment are significantly diminished in NRK-52E cells transfected with Ets-1 siRNA. We have identified LOX as a novel target for Ets-1. Expression of LOX is similarly reduced in NRK-52E cells transfected with Ets-1 siRNA compared with control after uric acid treatment, which results in significantly diminished deposition of fibronectin in vitro. In summary, our results support a critical role for Ets-1 as a transcriptional regulator of LOX expression in hyperuricemia renal fibrosis.

**Fatty Acid-Binding Protein 3 in db/db Mouse Kidney: A New Insight for the Treatment of Diabetic Nephropathy** Hui-Mei Chen, Qing Gao, Wen-Wen Shen, Ming-Chao Zhang, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu, China.*

Previous studies from our laboratory showed that Chinese herbs were suggested to be the new drugs for diabetic nephropathy (DN), including Triptolide and Rhein. The kidney metabolizes actively lipophilic molecules, and our previous gene chip screening identified a novel DN-associated lipid-binding protein, fatty acid-binding protein 3 (FABP3). In this study, we determined the expression of FABP3 in db/db mice and the association with therapeutic effects. db/db mice with DN were administrated with Triptolide or Rhein. After 4, 8 and 12 weeks of treatment, 24-h urine albumin level, blood lipid parameters and podocyte changes were measured. FABP3 was quantitatively evaluated using immunohistochemistry and image analysis. We found that protein expression of FABP3 significantly increased in the glomeruli of db/db mice, when compared with that of db/m mice. It further increased with age in db/db mice, accompanied with albuminuria, hyperlipidemia and podocyte lesions. Immunohistochemistry revealed that FABP3 was mainly present in the podocyte cells. After either Triptolide or Rhein treatment, urinary albumin excretion was reduced and plasma levels of cholesterol, triglyceride, and low density lipoprotein cholesterol were decreased, and podocyte density and foot process were improved. Moreover, the positive expression area of FABP3 was markedly increased in glomeruli. The efficacy increased with the prolonging of the both treatment. In conclusion, the Chinese herbs, Triptolide or Rhein, may improve DN in db/db mice due to alleviated podocyte injury, while the lipid protein in plasma and FABP3 in glomeruli might mediate such process. Our results expand the understanding of the new approaches in the treatment of DN, but underlying mechanisms await further investigation.

**Effects of Irbesartan on the Expression of Integrin-Linked Kinase and Its Relationship with Podocyte Injury in Rats with Diabetic Nephropathy** Hou-Yong Dai,[1] Rining Tang,[1] Kun Ling Ma,[1] Jie Ni,[1] Bi-Cheng Liu.[1] *[1]Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China; [2]China.*

**Objective:** Recent studies suggested that integrin-linked kinase (ILK) expression might play a role in the podocyte injury and production of albuminuria in diabetic nephropathy, which renin angiotensin system has been involved. In this study, we investigated the influence of irbesartan, an angiotensin II receptor antagonist, on ILK expression and podocyte injury in experimental DN.

**Methods:** After induction of diabetes by combination of high-sucrose, high-fat diet and intraperitoneal injection of low dose of streptozotocin (35 mg/kg) in spontaneously hypertensive rats (SHRs), rats were randomly divided into two groups: diabetic SHRs (DN, $n$=8) and diabetic SHRs treated with irbesartan (50 $mg.kg^{-1}.day^{-1}$ by gavage, DN+Irb, $n$=9) for 8 weeks. Non-diabetic normotensive Wistar-Kyoto rats (WKYs) were used as controls (controls, $n$=11). The expression of ILK was determined via immunohistochemistry, RT-PCR and western blot. The typcial changes of podocyte injury were shown by light microscopy and electronic microscopy.

**Results:** Compared to the controls, the rats in DN were associated with hyperglycaemia, hypertension, hyperlipidaemia, insulin resistance, and albuminuria, which were similar to the presentation of human T2DN. In addition, these rats were presented with expansion of mesangial matrix, loss of podocyte and podocyte injury. More importantly, both mRNA and protein expression of ILK in DN were upregulated, which could be significantly prevented by the treatment with irbesartan, along with the decrease of albuminuria, reduction of blood pressure. Furthermore, the morphological study showed irbesartan treatment could significantly prevent the podocyte injury and inhibition of mesangial matrix expansion.

**Conclusion:** Irbesartan could downregulate the overexpression of ILK in diabetic kidney, which could be related with its renoprotective effect via prevention of podocyte injury.

**Angiotensin II Receptor Antagonist Ameliorates the Phenotypic Alterations of Podocytes in Early Diabetic Nephropathy** Hou-Yong Dai, Rining Tang, Kun Ling Ma, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China.*

**Objective**: Diabetic nephropathy (DN) as the leading cause of end-stage renal disease, the precise pathogenesis is still unclear. Emerging evidence has indicated that podocyte injury is a crucial event in the early stage of diabetic nephropathy, which angiotensin II has been involved. In this study, we firstly investigated the influence of irbesartan on the phenotypic alterations of podocyte in experimental DN model.

**Methods:** Experimental DN was induced by high-scrouse, high-fat diet (HSFD) and intraperitoneal injection of low dose of streptozotocin (35 mg/kg) in spontaneously hypertensive rats (SHR). This special model presented with hyperglycemia, hypertension, hyperlipidemia and insulin resitance. Diabetic rats were either treated with irbesartan (50mg/kg/day by gavage for 8 weeks) or vehicle. The pathological changes were investigated by light and electron microscope. Expression of nephrin and desmin were detected by real time RT-PCR and western blot.

**Results:** It was found that diabetic rats presented with a significantly loss of podocytes, effacement of foot process, thickening of the glomerular basement membrane (ECM) as well as mesangial matrix deposition. Furthermore, the expression of nephrin was significantly reduced while expression of desmin was significantly increased compared to that in control. More interestingly, it was demonstrated that irbesartan treatment not only lowered blood pressure and proteinuria, but also significantly attenuated the phenotypic changes of podocytes in this animal model.

**Conclusion**: This study provided novel data that inhibiting the early phenotypic change of podoctye might be an important mechanism of irbesartan to prevent the development of diabetic nephropathy.

**Treatment of Liver Abnormalities in Obesity/Diabetes** Jesus H. Dominguez,[1,2] Katherine J. Kelly.[1] *[1]Medicine/Nephrology, Indiana University School of Medicine, Indianapolis, IN; [2]Medicine/Nephrology, Roudebush VA Medical Center, Indianapolis, IN.*

Diabetic nephropathy is accompanied by cardiovascular and hepatic complications that increase morbidity and mortality. We have found abnormalities in liver function in obese/diabetic ZS rats with nephropathy. For example, serum aspartate aminotransferase was 219 ± 22 units/L in obese/diabetic Zs rats vs 113 ± 10 in lean littermates (p<0.02). This was accompanied by hepatic fibrosis in the obese group. We hypothesized that the oxidized low density lipoprotein (LDL) receptor LOX-1 is critical in these abnormalities as LOX-1 functions to internalize oxidized lipids, which are increased in diabetes and the metabolic syndrome. We further postulated that systemic blockade of LOX-1 with specific antibody would reduce hepatic toxicity. We have demonstrated renal protection with LOX-1 blockade (AJP 294:F110, 2008). We studied 4 groups of ZS rats 6 to 21 weeks of age: lean controls (L), obese/diabetic (O), obese/diabetic rats injected weekly with normal rabbit IgG (OS) or obese/diabetic rats injected weekly with anti-LOX-1 IgG (OLOX). The three obese/diabetic groups were equally obese, hyperglycemic and dyslipidemic throughout

the study. Hepatic LOX-1 expression was markedly increased in the obese/diabetic rats by 21 weeks of age and could be blocked with anti-LOX-1 treatment. Liver triglycerides (mg/20mg tissue) were 414±104 in L, 1008 ±89 in O, 1046 ± 35 in OS, and 850 ± 35 in OLOX ($p < 0.03$, OLOX vs O and OS). In the same groups, mean reduced glutathione level (umol/mg tissue) were 49 ± 5; 29 ± 4; 27 ± 2, and 41 ± 2 respectively ($p < 0.001$ OLOX vs O and OS). We conclude that early hepatic lipotoxicity in rats with diabetic nephropathy is extensive, manifested by lipid loading, abnormal liver function tests, fibrosis and decreases in glutathione levels which may have profound effects on drug metabolism. Blockade of the proinflammatory receptor, LOX1 blockade is remarkably protective.

**Evaluation of Podocin as an Early Biomarker of Diabetic Nephropathy in db/db Mice** Anette E. Ericsson, Annett Ferm, Anne-Cristine Carlsson, Camilla Johansson, Gerhard Bottcher. *Bioscience and Safety Assessment, AstraZeneca R&D Molndal, Sweden.*

High glucose levels may injure the podocyte by altering the expression of structural proteins such as podocin. To investigate if podocin is a useful biomarker for early development of diabetic nephropathy we characterized podocin by immunohistochemistry in the kidneys of male non-diabetic db/m mice (n=10), diabetic db/db mice (n=15) and PPARγ agonist (rosiglitazone, n=15) treated db/db mice. At 21 weeks of age db/db mice exhibited marked albuminuria and hyperglycemia compared with lean db/m mice (plasma glucose 41.6±0.9 mM versus 9.4±0.3 mM). Plasma cystatin C and creatinine were significantly lower in db/db mice (308±20ng/ml and 0.23±0.01 mg/dl, respectively) as compared to lean controls (507±30 ng/ml and 0.27±0.01mg/dl) indicating renal hyperfiltration. In the group treated with rosiglitazone from 8-21 weeks of age, plasma glucose was 23.3±1.4 mM i.e. a clear anti-hyperglycemic effect. In addition, albuminuria was lower (159±29 mg/mg creatinine) as compared to the untreated db/db mice (374±41 mg/mg creatinine). Despite glucose lowering effect of rosiglitazone no effect on plasma creatinine or cystatin C was found compared to db/db controls. Podocin was a sensitive marker for structural podocyte rearrangement and glomerular mesangial expansion, but semi-quantitative analysis of podocin staining intensity did not reveal any clear differences between db/db and lean db/m mice, indicating that neither high plasma glucose levels nor albuminuria might alter podocin in this early phase of diabetic nephropathy. However, rosiglitazone treatment slightly increased podocin staining, which may suggest a role in restoring or protecting glomerular integrity, and the structural podocin pattern and glomerular morphology was similar to that of db/m controls.

In conclusion, in contrast to reported *in vitro* data, podocin *in vivo* in the kidney appeared to be unaltered by plasma glucose level and albuminuria. Therefore, altered podocin may not be amongst the earliest events in the pathogenesis of diabetic nephropathy. Interestingly, anti-hyperglycemic treatment with a PPARγ agonist seems to restore the podocin staining pattern and morphology.

**Cannabinoid Receptor1 Antagonist Attenuates Insulin Resistance and Diabetic Nephropathy in Type 2 Diabetic Mice** Young Sun Kang,[1] Young Youl Hyun,[1] Jinjoo Cha,[1] Ji Eun Lee,[2] Hyunwook Kim,[2] Kum Hyun Han,[3] Hyoung-Kyu Kim,[1] Dae R. Cha.[1] *[1]Nephrology, Korea University, Ansan, Republic of Korea; [2]Nephrology, Wonkwang University, Gunpo, Republic of Korea; [3]Nephrology, Inje University, Goyang, Republic of Korea.*

The cannabinoid 1(CB1) receptor has an important role in the pathogenesis of obesity and insulin resistance. Recent studies suggest that the glomerular expression of CB1 receptor is increased in obese zucker rats, and associated with abnormal renal lipid metabolism. However, the exact mechanism for the effect of CB1 receptor inhibition on type 2 diabetic nephropathy is uncertain. We investigated the effect of CB1 receptor antagonist (CB1RA, SR141716: 10mg/kg/day in drinking water) on insulin resistance and diabetic nephropathy in type 2 diabetic db/db mice. Interestingly, CB1RA treatment significantly decreased food intake. Although FPG did not show significant difference, intraperitoneal insulin tolerance/oral glucose tolerance test were significantly improved. Plasma insulin levels and HOMA-IR were also improved by CB1RA treatment. In accordance with these metabolic improvements, plasma cholesterol, triglyceride and isoprostane levels were markedly decreased by CB1RA. In addition, its treatment decreased epididymal fat mass and induced the phenotypic change of adipocyte, and decreased hepatic steatosis. Simultaneously, LPO levels in adipose tissue and liver also showed significantly lower values in treated mice than that in control mice. Furthermore, CB1RA improved renal hypertrophy and decreased urinary albumin excretion by only 1 month of treatment, and showed significantly decreased serum creatinine level. Interestingly, CB1RA markedly suppressed urinary isoprostane, LPO levels, cholesterol and triglyceride contents of kidney, with an improvement of renal glomerulosclerosis in diabetic mice. From these results, we suggest that CB1RA improves insulin resistance and oxidative stress in adipose and hepatic tissues, and improves renal function through both metabolic and direct effect in the kidney, finally leading to the protective effect for the progression of diabetic nephropathy in type 2 diabetic mice.

**Gamma Linolenic Acid Can Prevent Extracellular Matrix Accumulation Via Anti-Inflammatory Effects in Diabetic Nephropathy** Hye-Young Kang, Jwa-Kyung Kim, Jung Tak Park, Shin-Wook Kang, Tae-Hyun Yoo. *Brain Korea 21 Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Recent studies suggest that inflammatory mechanism may contribute to the development and progression of diabetic nephropathy. Gamma linolenic acid (GLA), one of polyunsaturated fatty acids (PUFAs), have a positive effect on health by generating modulatory molecules for inflammatory responses. Previous studies have shown that GLA have protective properties in diabetic neuropathy, but the effect of GLA on diabetic nephropathy has been largely unexplored. This study was undertaken to investigate the effect of GLA on inflammation and ECM accumulation in experimental diabetic nephropathy. In vitro, rat mesangial cells (RMCs) and NRK-52E cells were exposed to media containing 5.6 mM glucose (NG), NG+24.4mM mannitol (NG+M), and 30mM glucose (HG) with or without GLA (10 or 100 μM). In vivo, 24 Sprague-Dawley rats were injected either with diluent (n=8, C) or streptozotocin intraperitoneally (n=16, DM), and 8 rats from diabetic group were treated with evening primrose oil (EPO) by gavage (450 mg/kg/day) for 3 months. RT-PCR and Western blot were performed for monocyte chemoattractant protein-1 (MCP-1), intercellular adhesion molecule-1 (ICAM-1) and fibronectin (FN) mRNA and protein expression, respectively, and immunohistochemical staining (IHC) for ICAM-1, and FN and Masson's trichrome staining with renal tissue was also performed. GLA significantly inhibited the increase in ICAM-1 mRNA expression and protein levels under diabetic conditions both in vitro and in vivo. MCP-1 and FN expression showed a similar pattern to the expression of ICAM-1. Twenty four hour urinary albumin excretion was significantly increased in DM rats and GLA treatment significantly reduced albuminuria ($p<0.05$). On Masson's trichrome staining, the extent of tubulointerstitial fibrosis was significantly higher in DM compared to C kidney ($p<0.005$), and this increase was significantly attenuated by EPO treatment ($p<0.01$). In conclusion, GLA prevents not only inflammation via inhibition of enhanced MCP-1 and ICAM-1 expression, but also ECM accumulation in diabetic nephropathy.

**Advanced Oxidation Protein Products Inhibite Insulin Secretion Via Activating of Renin-Angiotensin System in Rat Pancreatic Islet** Min Liang, Lei Yang, Fan Fan Hou. *Nephrology, Nanfang Hospital, Guangzhou, Guangzhou, Guangdong, China.*

Diabetes mellitus (DM) is a common endocrine metabolic disease, which is increasingly concerned in the medical field. Decreased insulin secretion due to islet cells injury is one of the most important reasons in the development of diabetes, however, the exact pathogenesis of dysfunction of islet remains unclear. Advanced oxidation protein products (AOPPs), which were found to be elevated in the plasma of DM, chronic kidney disease (CKD), obesity and hypertension patients, are relative with oxidative stress and inflammation. In this study, the effects of AOPPs on islet insulin secretion and its pathogenic mechanisms were evaluated. Insulin release index of rat islet cells decreased after stimulating with AOPPs modified rat serum albumin (AOPPs-RSA). Upreglulation of expression of angiotensin receptor 1 (AT1R) mRNA and protein, angiotensingen (AGT) mRNA and angiotensin converting enzyme (ACE) mRNA, and increase of angiotension II (Ang II) concentration of islet cells were observed after AOPPs-RSA stimulation. AOPPs-RSA also induced increase of intracellular reactive oxygen species (ROS) production detected by a flow cytometry of fluorescence intensity of 2',7'-dichlorodrofluorescein diacetate. Pre-incubation of islet with cytoplasmic super oxide dismutase (C-SOD) and the NAD(P)H oxidase inhibitors apocynin inhibited upexpression of AT1R, AGT, ACE and Ang II. Renin–angiotensin system inhibitor (RASI), lisinopril and telmisartan, and C-SOD and apocynin can improve insulin secretion dysfunction of islet induced by AOPPs-RSA. These results documented that AOPPs decrease rat pancreatic islet cells insulin release through activating local RAS mediated by oxidative stress.

**Dysregulation of Apoptosis and Angiogenic Growth Factors in a Podocyte Model of Diabetes and High Protein Diet** Rick L. Meek,[1] Robert J. Anderberg,[1] Sheryl K. Cooney,[1] Katherine R. Tuttle.[1,2] *[1]Research Department, Providence Medical Research Center, Sacred Heart Medical Center, Spokane, WA; [2]Division of Nephrology, Department of Medicine, University of Washington School of Medicine, Spokane and Seattle, WA.*

Advanced glycation end products (AGE) are pro-inflammatory metabolites that incite cellular injury leading to diabetic complications. High dietary protein, a rich source of AGE and their precursors, can induce or exacerbate albuminuria. In response to injury, glomerular podocytes decrease in number and reduce production of angiogenic growth factors, both mechanisms for albuminuria. The aim of this study was to determine if conditions modeling diabetes and high protein diet lead to production of AGE as well as podocyte apoptosis and reduction in angiogenic growth factor expression. Conditionally immortalized mouse podocytes were exposed for up to 2 weeks to an amino acid mixture designed to mimic high protein diet (AA), high glucose (30mM, HG), the combination (AA/HG), or AGE-bovine serum albumin (AGE-BSA). Podocyte phenotype was confirmed by Wilms Tumor antigen-1 and synaptopodin mRNA (RT-PCR) and protein (immunocytochemistry)

expression. Carboxymethyllysine (CML), a prominent AGE, increased in conditioned media from AA, HG, AA/HG, and AGE-BSA conditions. Podocyte number decreased by 2 weeks of culture in the experimental conditions together with increased indicators of apoptosis including: TUNEL staining, caspase 3/7 activity, and caspase 4 mRNA (gene expression array confirmed by RT-PCR). Podocyte expression (RT-PCR) of connective tissue growth factor (CTGF) mRNA declined in AA, AA/HG, and AGE-BSA conditions, while vascular endothelial growth factor-A (VEGF-A) mRNA decreased in AA/HG and AGE-BSA conditions. Conclusions: Conditions characteristic of diabetes and high dietary protein lead to increased AGE exposure along with podocyte apoptosis and reduced angiogenic growth factor expression.

Disclosure of Financial Relationships: nothing to disclose

**Differential Expression of Cyclin-Dependent Kinase Inhibitors (CKIs) and Apoptosis-Related Molecules in Diabetic Kidney Disease** Bo Young Nam, Hye-Young Kang, Tae-Hyun Yoo, Shin-Wook Kang. *Brain Korea 21 Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Kidney size is increased in diabetes primarily due to glomerular and tubular hypertrophy, principally mediated by CKIs. Additionally, CKIs also play an important part in the development of apoptosis, which has been considered one of the underlying causes of mesangial cell and podocyte loss in diabetic nephropathy (DN). We have previously shown that the nephrin expression was different between relatively small and large glomeruli isolated from early diabetic rats. Moreover, prior studies have suggested that glomerular hypertrophy in diabetes does not develop in all glomeruli concurrently. Based on these findings, it is supposed that apoptosis may also occur differentially in diabetic glomeruli. In this study, we hypothesized that more hypertrophied glomeruli rather than less hypertrophied glomeruli may undergo apoptosis. Rats were injected either with diluent (n=15, C) or STZ IP (n=15, DM). Glomeruli were isolated using sieves with pore sizes of 250, 150, 125, and 75μm after 3 months, and classified into large glomeruli (on 125μm sieve, LG) and small glomeruli (on 75μm sieve, SG) groups. The ratio of Bax/Bcl-2 protein expression and active caspase-3 protein expression were significantly increased in DM-LG compared to DM-SG and C-SG ($p<0.01$). In contrast, Akt activity was significantly increased in DM-SG, while it was significantly decreased in DM-LG ($p<0.05$). p27 and p21 expression were significantly increased in DM-SG compared to DM-LG and C-SG ($p<0.05$), but there was no difference in p27 and p21 expression between DM-LG and C-SG. The numbers of total glomerular cells in DM-SG and C-LG were significantly higher than that in C-SG ($p<0.05$). In contrast, there were significantly less total glomerular cells in DM-LG compared to the other groups ($p<0.05$). Apoptosis-related molecules and CKIs were differentially expressed according to glomerular size in DN, suggesting that hypertrophic process is ongoing only in less hypertrophied glomeruli and once they become large enough, the hypertrophic mechanism seems to be replaced by apoptosis.

**Simvastatin Ameliorates High Glucose Induced Glomerular Endothelial Cells Hyperpermeability and Tight Junction Disruption by Inhibiting RhoA Activation** Hui Peng,[1] Pengli Luo,[1] Zengchun Ye,[1] Yan-Ru Chen,[1] Cheng Wang,[1] Canming Li,[1] Farhad R. Danesh,[2] Tan-Qi Lou.[1] *[1]Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, GD, China; [2]Department of Medicine, Baylor College of Medicine, Houston, TX.*

High glucose has been showed to increase endothelial cells monolayer permeability in diabetes mellitus. We hypothesis high glucose may induce endothelial cells hyperpermeability by disrupting tight junctions, and statin could inhibit this effect through inhibiting RhoA activity. For this purpose, rat glomerular endothelial cells (rGEnCs) were cultured for 12h, 24h, and 48h in control medium (5mM D-glucose) or high glucose medium (30mM D-glucose). Mannitol was used as high osmotic control. The permeability of rGEnCs was evaluated by trans-endothelial electrical resistance (TEER). TEER was significantly decreased in high glucose compared with control or mannitol group from 2h. It reached the lowest level at 24h ($P<0.01$). Tight junction proteins was evaluated by Western blot. It showed that occludin was significantly decreased while claudin-5 increased after exposed to high glucose for 24h and 48h. However, ZO-1 and JAM-A did not change in high glucose. Pre-incubated with simvastatin(2.5μM) could partly reverse the hyperpermeability effect of high glucose($P<0.05$) as well as the change of proteins. But when cells co-incubated with simvastatin and mevalonate, simvastatin did not reverse the effect of high glucose. Pull-down assay indicated RhoA was significantly activated in high glucose for 24h compared with control group. Simvastatin could inhibit high glucose induced RhoA activation, while mevalonate reversed this effect of simvastatin. Taken together, these data suggest that high glucose may induce glomerular endothelial hyperpermeabilty by injuring tight junction integrity, and simvastatin could reverse this effect to protect endothelial permeability. Protection effect of simvastatin may be partly mediated through inhibition of mevalonate and subsequent inhibiting RhoA activated. The result implied a new mechanism of hyperglycemia damages glomerulis and a new protection mechanism of statins in diabetic mellitus.

**PUB066**

**The Effect and Mechanism of Norcantharidin on Tubulointerstitial Fibrosis of Diabetic Nephropathy** Youming Peng, Qiong Chen, Ying Li, Guanghui Ling, Fu-You Liu. *Nephrology, Second Xiangya Hospital, Center of Kidney Disease and Dialysis in Hunan Province, Central South University, Changsha, Hunan, China.*

Our studies previously found that NCTD inhibited the tubulointerstitial lesions in protein-overload nephropathy and NCTD could attenuate the tubulointerstitial fibrosis and inhibit tubular cell EMT (AJKD). However if NCTD could inhibits tubulointerstitial fibrosis in diabetic nephropathy (DN) is unknown. To investigate the effect of NCTD in tubulointersitial firosis of DN and its related mechanism, the type I of DN model was established by STZ injection and treated by NCTD for 8 weeks. Results shown that the ECM deposition and tubulointerstitial fibrosis and increased CaN expression were observed in diabetic kidney, while the pathological changes were inhibited in treated by NCTD ( n=20, $P<0.05$).,which was consistent with the decreased in the mRNA and protein expressions of FN, collagen IV and TGF-β1 and CaN ($P<0.05$). In vitro study, the mRNA and protein expression of FN, collagen IV, TGF-β1 and CaN increased in HK-2 cells exposed to with 30mM D-glucose in a time-depedent manner, but reduced in treated by 5μg/ml of NCTD ($P<0.05$). To verify the mechanisms of which factors involved this process, the CaN and NFATc expression was determined. HK-2 cells treated by NCTD (5μg/ml) a exhibit decreased in NFATc nuclear translocation induced by 30 mM D-glucose was seen compared to control($p<0.01$),Moreover, CaN-siRNA increased the protein and mRNA level of FN , collagen IV and TGF-β1 induced by HG, whereas significantly decreased in that of treated by NCTD ($P<0.05$). These data indicated that NCTD may have a positive effect in attenuating tubulointerstitial fibrogenesis in the early stage of DN rats. However it is not mediated through down-regulating CaN/NFATc pathway.

**Sucrose Induces Fatty Liver and Type II Diabetes in Rats Independent of Energy Intake** Carlos Alberto Roncal-Jimenez,[1] Miguel A. Lanaspa,[1] Christopher J. Rivard,[1] Takahiko Nakagawa,[1,2] L. Gabriela Sanchez-Lozada,[1,3] Diana I. Jalal,[1] Ana Andres-Hernando,[1] Katsuyuki Tanabe,[1] Magdalena Madero,[3] Yuri Y. Sautin,[2] Richard J. Johnson.[1] *[1]Medicine-Division of Renal Diseases and Hypertension, University of Colorado, Aurora, CO; [2]Medicine-Division of Nephrology Hypertension, University of Florida, Gainesville, FL; [3]Medicina, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico.*

Recent studies have implicated a role for fructose-containing sugars, such as sucrose and high fructose corn syrup, in the epidemic of obesity and diabetes. However, experimental studies are often criticized for using only purified fructose, often at clinically irrelevant concentrations, or for failing to control for energy intake. We therefore tested the hypothesis that a diet of 40% sucrose might induce metabolic abnormalities independent of energy intake. Rats were pair fed 40% sucrose or 40% starch for 4 months. Sucrose fed rats developed features of metabolic syndrome, with postprandial elevations in blood pressure, hypertriglyceridemia, and insulin resistance. Sucrose fed rats developed fatty liver with evidence for increased fat synthesis and decreased fat oxidation. Sucrose fed rats also developed variable hyalinization of pancreatic islets with low grade inflammation and a reduction in insulin levels and the development of frank type II diabetes. Finally, sucrose feeding was associated with increased expression of the fructose transporter, Glut5, in the jejunum and with increased expression of fructokinase in the jejunum and liver. In conclusion, sucrose, at concentrations ingested by a subset of Americans, can induce metabolic syndrome, fatty liver and type 2 diabetes, and this is independent energy intake. These data support a role for fructose-containing sugars in the epidemic of obesity, fatty liver, and metabolic syndrome.

**Adrenocorticotropic Hormone Attenuates Diabetic Nephropathy in Zucker Diabetic Fatty Rats Via Inhibition of Oxidative and Inflammatory Responses** Haiping Wang, Zhanjun Jia, Gang Liu, Tianxin Yang. *Internal Medicine, University of Utah, Salt Lake City, UT.*

Clinical evidence suggests a potent anti-proteinuric effect of adrenocorticotropic hormone (ACTH) in patients with various chronic kidney diseases including diabetic nephropathy. The objective of this study was to evaluate the therapeutic potential and safety profile of a natural source $ACTH_{1-39}$ peptide formulation, Acthar Gel (Acthar, Questcor Pharmaceuticals, Inc.) in Zucker diabetic fatty (ZDF) rats. Three cohorts (n=8-9 per group) of ZDF rats were created: 1 vehicle-treated and 2 Acthar-treated (5 or 20 units/kg IM, 3 times/ week, for 3 months). Vehicle-treated lean rats (n=4) served as controls. Physiologic and morphological measures were performed immediately after the 3 month Acthar treatment. There was a trend of reduced urine albumin and total urine protein for both doses of Acthar ($p=0.06$-$0.08$); the effect reached statistical significance ($p<0.05$) when the Acthar data were pooled. Histological analysis revealed evidence of renal fibrosis, protein casts, and infiltration of inflammatory cells in the diabetic kidney, which were significantly attenuated with either dose of Acthar ($p<0.05$). Compared to lean rats, there was a dose-dependent effect on renal concentration of thiobarbituric acid-reactive substances (TBARs) and suppression of NOX-1, TNF-α, and TGF-β renal mRNA level, with complete normalization with the high dose of Acthar. Both Acthar doses significantly reduced kidney hypertrophy ($p<0.05$). Acthar resulted in reduction of hypertrophy in other organs (including liver, heart, spleen),

as well as plasma triglyceride and plasma free fatty acid levels at the trend level. Acthar did not affect food and water intake nor urine volume. Plasma glucose and K+ also remained stable in Acthar treated rats. Together, these data suggest that Acthar protects against diabetic nephropathy via inhibition of oxidative and inflammatory responses and also provides an additional beneficial effect on the metabolic profile.

**Sulodexide Reduces Proteinuria and Abnormal Matrix Protein Accumulation in C57BL/6 Mice with Streptozotocin-Induced Diabetes** Susan Yung, Mel Chau, Qing Zhang, Owen Chan, Daniel Tak Mao Chan. *Department of Medicine, University of Hong Kong, Hong Kong.*

Diabetic nephropathy (DN) manifests with proteinuria and histopathologic abnormalities characterized by abnormal matrix deposition. Sulodexide is a mixture of purified glycosaminoglycans. It has been reported to reduce proteinuria in patients with diabetic nephropathy, but the mechanism of action remains unclear. We investigated the effect of sulodexide on proteinuria and renal histology in an experimental model of type I diabetic nephropathy.

C57BL/6 mice were rendered diabetic by 5 consecutive intraperitoneal injections of streptozotocin (50mg/kg). Blood glucose levels and proteinuria were monitored weekly. Once proteinuria (>100mg/dl) was established, mice were randomized to receive either saline or sulodexide (1mg/kg/day) treatment by oral gavage for selective time periods up to 12 week (n=6 for each time point), after which time mice were sacrificed, and urine, blood and kidney samples collected for analysis.

Sulodexide had no effect on blood glucose level, but significantly decreased urine albumin-to-creatinine ratio after 12 weeks. (8.96±4.10 vs 105.30±51.47g/μmol, with vs without sulodexide treatment, $P<0.001$). Diabetic mice developed glomerular hypertrophy, thickening of the GBM and Bowman's capsule, PKC-α activation, increased glomerular expression of TGF-β1, fibronectin, collagen type I, and decreased perlecan expression. Sulodexide treatment resulted in less glomerular hypertrophy, a progressive reduction in glomerular expression of matrix and fibrous tissue components or mediators with increasing treatment duration, and restoration of perlecan expression.

Our data demonstrate that sulodexide treatment improves phenotypic and histopathologic manifestations of nephropathy in diabetic mice, which could be mediated in part through increased renal perlecan expression.

**Measuring Carnosinase Activity in Diabetic Nephropathy** Ana Zutinic, Antien Mooyaart, Jan A. Bruijn, Emile De Heer, Hans J. Baelde. *Department of Pathology, Leiden University Medical Centre, Leiden, Netherlands.*

A relationship has been shown between carnosinase activity and the amount of leucine repeats in exon 2 of the *CNDP1* gene. A relationship between higher amounts of leucine repeats in *CNDP1* and increased risk of developing diabetic nephropathy has also been shown. In our study we investigated the optimal assay method for determining carnosinase activity in serum and heparin plasma, with the aim of accurately investigating the direct relationship of carnosinase activity with diabetic nephropathy.

The carnosinase assay method was adapted from Schoen *et al*. and Verena Peters. Samples were diluted in reaction buffer containing carnosine and the histidine release was quantified. In order to determine optimal incubation time, multiple carnosinase assays were carried out at: 0, 10, 20, 30 and 40 minutes of healthy serum incubation with carnosine at 37°C. Additionally, to test the optimal serum or heparin plasma concentration, eight different concentrations were tested ranging from sample:buffer ratio of 2:1 to 1:12. A serum:buffer ratio of 4:1 was used in previous studies. To compare carnosinase activity in heparin plasma and serum, both kinds of samples from healthy volunteers were tested for carnosinase activity.

In both serum and heparin plasma, carnosinase activity was linear from 0 to 10 minutes of sample incubation with reaction buffer. The optimal concentration to determine carnosinase activity accurately was a 1:1 ratio of sample:buffer . This means less material can be used for this assay than used in previous studies. The intra-assay variation was 6% and inter-assay variation was 16%. Carnosinase activity in serum and heparin plasma was comparable ($R^2$=0.9112). This means that both serum and heparin plasma can be used to accurately determine carnosinase activity of a subject. The described optimalisation of the carnosinase assay can lead to clarifying the relation between carnosinase activity and diabetic nephropathy due to being able to accurately measure carnosinase activity.

**A Method To Control the Rate of Administration of Venofer®** Mary M. Showers,[1] Jose A. Diaz-Buxo.[2] *[1]Renal Solutions Inc.; [2]Fresenius Medical Care-NA.*

**Background** Administration of Venofer® (iron sucrose) is an effective treatment for iron deficiency anemia.

**Method** We conducted usability testing of a novel Venofer Pump Module (VP), developed by Renal Solutions, Inc. in a simulated chronic hemodialysis use environment The module was used with the Fresenius 2008 T dialysis machine. Following visual prompts on the screen of the Venofer Pump Module, tubing made specifically for the Venofer Pump was snapped into place, threaded past the fluid detector through the pump, and leur locked to the port of the venous chamber of the dialysis blood tubing. A 100mg vial of Venofer® was inverted and attached to the tubing by pushing the spike through the rubber stopper of the vial. The Venofer Pump Module is capable of delivering 100mg, 75mg, or 50mg set doses of Venofer® at a rate of 34mg/min. Users were trained in the procedure and then asked to give 3 set doses of the Venofer®.

**Results** In-vitro testing completed with 34 end users, including 18 registered nurses, showed successful delivery of 100mg. 75mg. and 50mg. doses of Venofer® at 34mg/minute via the VP. Over 90% of the tasks associated with Venofer® delivery were successfully completed by the registered nurses and patient care technicians. 100% of users were able to self-correct any error that could result in an unacceptable risk, according to the VP Risk Analysis.

**Conclusion :**. The study showed adequate automated in-vitro delivery of Venofer® by all users. The VP may diminish human factors from the delivery of Venofer®

*Venofer Pump Module is pending FDA approval.

**"Unifying Vasculogenic Hypothesis" for Kidney and Solid Organ Regeneration** Leon G. Fine. *Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA.*

All examples of chronic solid organ fibrosis with loss of function show progressive loss of the interstitial microvasculature. In the kidney the initial insult to the organ usually leads to local areas of hypoxia. Hypoxia, per se, is a profibrogenic stimulus which leads to scar formation. Scars, in turn, obliterate microvessels, leading to a downward spiral of decreased function. Substantial evidence has accrued to show that the "Chronic Hypoxia Hypothesis" has been substantiated for chronic renal diseases (Fine LG and Norman JT, *Kidney International, 74:867-872, 2008*).

Attempts to regenerate chronically-diseased solid organs, by the transfer of progenitor cells which differentiate into the parenchymal phenotypes of the organ, are likely to fail in the long-term, since these cells will not survive the hypoxic environment. Resident progenitor cells suffer the same fate. Furthermore, even if transferred parenchymal cells were to survive, they would be unlikely to be able to recreate the complicated internal architecture of an organ (e.g. new nephrons, each containing up to 30 different phenotypes, cannot be formed in the adult kidney).

The Unifying Vasculogenic Hypothesis for Solid Organ Regeneration states: "Regeneration of solid organs after chronic injury and scarring, can be achieved solely by restoring the microvasculature. This can be achieved by adoptively transferring endothelial progenitor cells into the organ. The ensuing improvement in microvasculature, with relief of hypoxia, will stimulate resident progenitor cells to reconstitute the vascular network of the organ. Resident parenchymal progenitor cells and differentiated cells will consequently be restored to function, which will regenerate the parenchyma of the organ, including partial remodelling of scarred areas, within its existing architectural structure."

In summary, to restore solid organ function after chronic injury, it is hypothesized that all that is required to initiate the process, is a restored microvascular circulation. There should be no need to generate and transfer stem/progenitor cells of the specialized phenotype of each organ. This would apply to organs such as kidney, liver, lungs and heart. This hypothesis should be tested.

**A Markov Model Study on the Hierarchical Prognosis and Risk Factors in Patients with Chronic Kidney Disease** Xun Liu, Cheng Wang, Chenggang Shi, Cailian Cheng, Hua Tang, Zhujiang Chen, Tan-Qi Lou. *Division of Nephrology, Department of Internal Medicine, The Third Affiliated Hospital of Sun Yet-Sun University, Guangzhou, Guangdong, China.*

Background: Chronic kidney disease (CKD) has been identified as a public health problem. The hierarchical prognosis and risk factors in patients with CKD is, however, less well studied. Method: 272 outpatient CKD patients were investigated. Mean serum creatinine level of enrolled patients was 1.33 mg/dL (range 0.34-6.62). Mean GFR was 87.0 ml•min-1•(1.73m2)-1 (range 6.8-342.0). Markov model including six states [CKD1 stage, CKD2 stage, CKD3 stage, CKD4 stage, CKD5 stage as well as death/ end-stage renal disease (ESRD) stage] was established. Results: The mean following period was 2.0 years. 16 (5.9%) patients were lost at follow-up. 14 patients reached composite endpoint (death/ ESRD stage). The causes of death included severe pneumonia (N =2) and septic shock (N =1). Transition rate from CKD1 stage to CKD2 stage, from CKD2 stage to CKD3 stage, from CKD3 stage to CKD4 stage, from CKD4 stage to CKD5 stage and from CKD5 stage to death/ESRD stage were 9.2%/year, 10.9%/year, 13.2%/year, 16.1%/year and 47.1%/year respectively. The mean duration in CKD1 stage, CKD2 stage, CKD3 stage, CKD4 stage and CKD5 stage were 8.4 years, 5.8 years, 4.0 years, 1.8 years and 0.8 years respectively. Mean renal survival time or dialysis free period was 20.8 years. Multivariates analysis of Markov model showed the impact factors of prognosis. Old age, high diastolic blood pressure and hyperuricemia were the independent prognostic factors for the transition from CKD1 stage to CKD2 stage. Smoking and low hemoglobulin level were the independent prognostic factors of the transition from CKD2 stage to CKD3 stage. History of cardio-cerebral-vascular disease and low hemoglobulin level were the independent prognostic factors of the transition from CKD3 stage to CKD4 stage. RAS blockade therapy was the independent prognostic factors of the transition from CKD4 stage to CKD5 stage. Conclusions: Evaluation of severity and the treatment of CKD patients should be made according to the prognosis and influencing factors of different stage in CKD patients.

**Computational Systems Biology in the European Union Research Project on Chronic Kidney Disease – SysKid** Paul Perco,[1,2] Irmgard Muehlberger,[1] Raul Fechete,[1] Gil Stelzer,[3] Doron Lancet,[3] Gert J. Mayer,[4] Rainer Oberbauer,[2,5] Bernd Mayer.[1] *[1]Emergentec Biodevelopment GmbH; [2]Medical University of Vienna; [3]Weizmann Institute of Science; [4]Medical University of Innsbruck; [5]KH Elisabethinen Linz.*

We present a computational Systems Biology framework for integrating clinical data, Omics data, as well as results from functional studies aimed at characterizing molecular processes associated with diabetic nephropathy (DN).

SysKid (Systems Biology towards novel chronic kidney disease diagnostics and treatment) is a large-scale integrating research project funded by the European Union within the 7th framework programme. The consortium encompasses clinical, molecular and epidemiological research forming the basis for integrative approaches as epitomizing Systems Biology.

Major aims of SysKid are defined as (i) identifying of persons at risk of developing chronic kidney disease (CKD), (ii) deciphering of molecular processes leading to CKD and the identification of associated biomarkers, and based on these results (iii) developing of novel diagnostic and therapeutic strategies for prevention or control of disease progression. To accomplish these aims, broad Omics screening covering transcriptomics, proteomics, metabolomics, GWAS, and microRNAs, utilizing clinically well-defined samples from patients with DN along with functional experiments in cell culture and animal models is driven. For enabling an integrated analysis of such heterogeneous data sets, a dedicated Systems Biology pipeline has been implemented.

Sample specifications, study plan documents, Omics data files, as well as analysis reports from functional studies are managed in an object-centered record management system combined with a molecular feature database holding full human genome/proteome annotation. Explicit as well as automated inference is implemented for allowing persistent linkage of clinical data categories and molecular pathways ascribable to the pathophysiology of DN.

As implementation of the individual Omics regimes for significant sample numbers has become feasible concepts for data management, annotation and integration are needed, as exemplified by SysKid for chronic kidney disease.

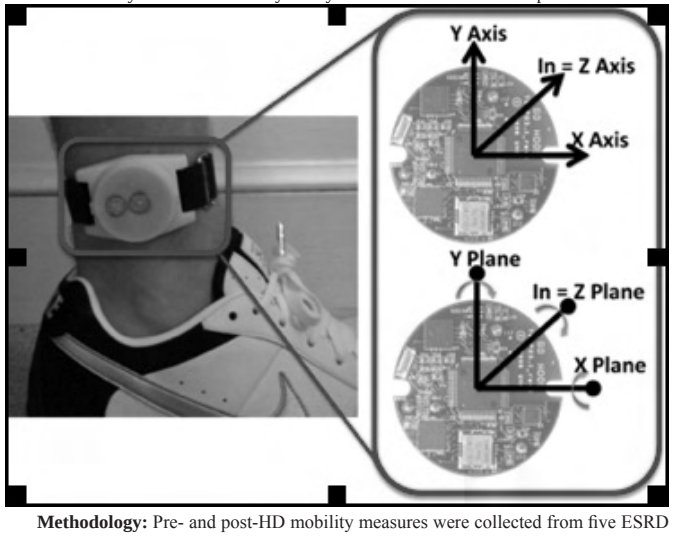
**Identifing Mechanisms of Falls in ESRD Patients on HD Using Non-Invasive Portable Device** Emaad M. Abdel-Rahman,[1] John Lach,[2] Rasheed A. Balogun.[1] *[1]Nephrology, UVA, Charlottesville, VA; [2]Electrical and Computer Engineering, UVA, Charlottesville, VA.*

**Introduction:** Falls are highly prevalent in patients with ESRD on HD and are associated with poor outcomes. To prevent falls, mobility mechanisms contributing to falls must be understood. The TEMPO (Technology-Enabled Medical Precision Observation) is a wireless body sensor network platform that provides precise human motion and orientation data continuously and non-invasively in any location over an extended period of time.



**Methodology:** Pre- and post-HD mobility measures were collected from five ESRD patients on HD over the course of 5 months. To assess the effects of post-HD-fatigue on fall risk , participants were asked to perform the same 4 tasks both before and after their HD treatment: 2 minutes of walking, 3 Get-Up & Go tests, 3 Postural Locomotion and Manual (PLM) control tests, and 3 tests of foot strength using a custom made measurement device. Additionally, the effects of inter-HD periods (two days vs. three days) were investigated. **Results:** While HD treatment influenced strength and mobility (i.e., weaker and slower after the dialysis) , there was no significant differences in dynamic stability between the pre- and post-HD sessions. Furthermore, mobility was better after the three-day interdialytic period than the two-day interdialytic period. **Conclusion:** Problem of fall-risk in HD patients is unique, with post-HD fatigue playing a role in falls in this population increasing the susceptibility to falls while returning home. Furthermore, the inter-dialytic period influenced pre-HD profiles increasing the susceptibility to falls before they come in for a HD treatment with the two-day interdialytic period suggesting that the residual effects of post-HD fatigue was still evident. Further study is planned with more participants and with longer data collections.

**Bioengineering of Bioactive, Hierarchical Kidney Membranes** Patricia Y. W. Dankers. *Institute for Complex Molecular Systems, and Laboratory of Chemical Biology, Eindhoven University of Technology, Eindhoven, Netherlands.*

Novel strategies to treat patients with kidney failure include the use of a bioartificial kidney set-up applied in conjunct with a conventional dialysis system. This bioartificial kidney should be composed of renal cells maintained on a membrane. The cells are proposed to additionally clear the blood from waste products. However, conventional membranes do not provide the organotypical environment the cells need, to be phenotypically preserved, and to properly function.

Here, we disclose the development of novel bioactive, supramolecular membranes that are proposed to be eminently suitable for this purpose. Especially, because they can be prepared as two-layered constructs with epithelial cells at one side, and endothelial cells or a non-fouling surface at the other side.

We developed these supramolecular membranes in order to mimic the natural basement membrane and its underlying extracellular matrix in a hierarchical fashion. The membranes are composed of supramolecular polymers based on hydrogen bonding moieties coupled to short oligomers. They self-assemble into nanofibers that can be processed into microfibers, resulting in hierarchical fibrous membranes. Bioactivity was introduced into these nanofibers by intercalation of bioactives modified with similar hydrogen bonding units. In addition, we developed new chemical strategies to post-modify these nanofibers with the bioactives.

Furthermore, our supramolecular strategy allows us to easily incorporate epithelial-specific bioactives at one side, and endothelial-specific bioactives or non-fouling agents at the other side. In this way we envision specific interactions of either epithelial or endothelial cells with the membranes. The non-fouling surface would be imperative in preventing unwanted interactions of blood constituents with the membrane, when no endothelial cells are applied at the blood side. We were able to prepare these different membranes, and we showed increase in function of renal epithelial cells, and adhesion of endothelial cells. Currently, we are studying the performance of different cell types on the novel membranes in a newly developed culture system in which we can monitor cell function.

**Pediatric Urolithiasis and Obesity: Are They Related?** Uri S. Alon,[1] Bryn C. Dekosky,[1] Ashley K. Sherman.[2] *[1]Pediatric Nephrology, Children's Mercy Hospital and Clinics, University of Missori at Kansas City School of Medicine, Kansas City, MO; [2]Medical Research, Children's Mercy Hospital and Clinics, University of Missori at Kansas City School of Medicine, Kansas City, MO.*

*Introduction:* There is evidence that in adults, obesity promotes stone formation. There is also evidence of increased incidence of urolithiasis in children concomitantly with increasing incidence of obesity. It is unclear if the latter two are related by cause and effect.

*Objective:* The aim of the study was to examine if there is an association between the incidence of kidney stones and that of obesity in children.

*Methods:* We retrospectively reviewed the data on children presented to the Renal Clinic due to urolithiasis between 5/12/2004 to 5/18/2009. Data collected included patients' gender, age and BMI, and when available stone chemistry analysis. Data were compared with three recent local and national studies on the incidence of pediatric obesity.

*Results:* Total number of patients of 139 which included 74 females with mean age of 11.3 and 65 males with mean age of 10.6 years (NS).

table 1. Obesity incidence in children with urolithiasis

| Study | | | Controls | | |
|---|---|---|---|---|---|
| | Percent | CI | | Percent | CI |
| BMI>85 | | | BMI>85 Locally | | |
| Both Sexes | 30.22 | 22.58 - 37.85 | | | |
| Female (n=74) | 27.03 | 16.91 - 37.15 | Female | 38 | No data |
| Male (n=65) | 33.85 | 22.34 - 45.35 | Male | 40 | No data |
| BMI>95 | | | BMI>95 Locally | | |
| Both sexes | 16.55 | 10.37 - 22.72 | Both Sexes | 17 | No data |
| BMI>95 | | | BMI>95 Nationally | | |
| Both Sexes | 17.99 | 11.60 - 24.37 | Both Sexes | 16.9 | 14.1 - 19.6 |
| Female (n=74) | 10.81 | 3.73 - 17.89 | Female | 15.9 | 12.6 - 19.1 |
| Male (n=65) | 26.16 | 15.47 - 36.84 | Male | 17.8 | 14.7 - 20.8 |

Of the 38 stones analyzed, the composition was: calcium-based 34, uric acid 2, Struvite 1 and cystine 1.

*Conclusions:* In our population, children afflicted by urolithiasis show the same trends towards obesity as the general population; thus it seems that obesity *per se* does not promote pediatric urolithiasis. This may be explained by the fact that in our patients the vast majority of stones continue to be calcium-based which are not known to be caused by obesity.

Disclosure of Financial Relationships: nothing to disclose

**PUB078**

**Calcium-Phosphorus Product and Blood Pressure in CKD** Ziad Maurice Ashkar. *Acadiana Renal Physicians, Lafayette, LA.*

Hypertension is very common in chronic kidney disease(CKD) with prevalence increasing with severity of renal failure. Disorders of mineral metabolism and increased calcium-phosphorus product have been associated with increased mean arterial pressures (MAP) in dialysis patients. There are scarce data looking into the association of calcium-phosphorus product with blood pressure in CKD.

85 patients with CKD stages 2,3 and 4 were included in a cross-sectional study over a two-year period. Linear regression analysis was done between the averages of calcium-phosphorus product(caxph) and blood pressures. There was no association detected between MAP and caxph (p=0.223) or between pulse pressures(PP) and caxph(p=0.924).

Multi-linear regression analysis was then done between caxph and blood pressures adjusting for age,sex,race, erythropoesis stimulating agents (ESA) use, diabetic status(Dm),PTH levels and average blood pressure meds per patient.

No association was found between blood pressures and caxph.

MAP was positively associated with PTH level(p=0.015,R squared=0.249), and male sex(p=0.01). PP was significantly associated with age(p<0.0001) and Dm(p=0.01).

Multilinear regression between MAP and caxph

| | p value | coefficient |
|---|---|---|
| caxph | 0.319 | -0.22 |
| PTH | 0.015* | 0.059 |
| age | 0.2 | -.0115 |
| male sex | 0.01* | 5.83 |
| race | 0.179 | -3.07 |
| Dm | 0.633 | -1.09 |
| BPmeds | 0.664 | 0.368 |
| ESA | 0.707 | 0.98 |

*statistically significant

The study findings suggest no association between calcium-phosphorus product and blood pressure in CKD.

The significant association of MAP with PTH in CKD suggest an early role of PTH in hemodynamic vascular effects, before caxph and phosphorus roles are manifested in end stage renal disease.

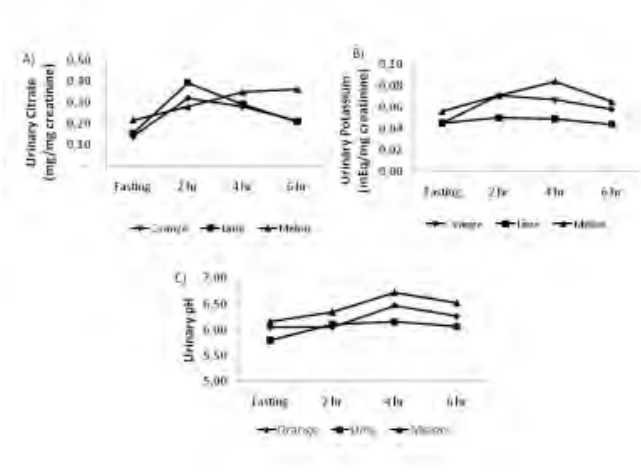
**Acute Effects of Fruits upon Citrate and Potassium Excretion in Hypocitraturic Stone Formers** Leandro Cunha Baia, Alessandra Calábria Baxmann, Ita Pfeferman Heilberg. *Nephrology Division, Federal University of São Paulo, São Paulo, Brazil.*

Numerous studies have reported increases in 24-hour urinary citrate excretion induced by orange or lemon juices, but it has been observed that because citrate in orange is complexed mainly by potassium, the resultant alkali-load provides better citraturic effects. The aim of the present study was to compare the acute effects of dietary potassium supply alone, from non-citrus sources (melon), with the effect provided by citric (orange, lime) natural juices. METHODS: Hypocitraturic stone-forming patients collected two-hours urine samples after an overnight fast (baseline), 2, 4 and 6 hours after consumption of either a fresh melon juice (n=10, 3M/7F, 48±13yrs), freshly squeezed orange juice (n=10, 1M/9F, 48±11yrs) or freshly squeezed lime juice (n=10, 4M/6F, 49±12 yrs), for determination of urinary parameters. Results are shown in the table and figure below:

Dietary contents and urinary parameters

| | | Melon | Orange | Lime |
|---|---|---|---|---|
| Juice Citrate Content (mEq) | | - | 50 | 50 |
| Juice Potassium Content (mEq) | | 19.7 | 19.7 | 2.5 |
| Juice pH | | 5.71 | 3.78 | 2.46 |
| Urinary Citrate | AUC | 0.32 | 0.27 | 0.30 |
| | Δ | 159* | 200* | 193* |
| Urinary Potassium | AUC | 0.08 | 0.06 | 0.05 |
| | Δ | 133* | 140* | 10 |
| Urinary pH | AUC | 6.46 | 6.23 | 6.08 |
| | Δ | 9.8* | 6.9* | 6.4 |

AUC (mg/mg creatinine); (* p<0.05) *vs* baseline



A significant percentual (%) increment (Δ) of urinary citrate was observed for melon, orange and lime after 4 hrs *versus* baseline, while Δ for potassium and pH were statistically significant only for melon and orange. However, the mean AUC (area under curve) did not differ between groups. CONCLUSION: Dietary potassium from non-citrus sources may provide equivalent amounts of increase in urinary citrate compared to citric sources due to its alkalinizing effects.

**PUB080**

**Effect of Cystone® over One Year on Urine Cystine and Stone Formation** Stephen B. Erickson,[1] Terri J. Vrtiska,[2] Vincent J. Canzanello,[1] John C. Lieske.[1,3] *[1]Division of Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]Department of Diagnostic Radiology, Mayo Clinic, Rochester, MN; [3]Department of Laboratory Medicine & Pathology, Mayo Clinic, Rochester, MN.*

Cystine kidney stones frequently recur because inadequate prevention exists. We recruited 10 documented recurrent cystine kidney stone formers into a 2 phased study to assess safety and effectiveness of Cystone®, an herbal treatment for prevention of kidney stones. The first phase was a randomized double-blinded 12 week cross over study assessing the effect of Cystone® vs. placebo on urinary chemistries. The second phase was an open label one year study of Cystone® to determine if renal stone burden decreased, as assessed by quantitative and subjective assessment of CT. Results revealed no statistically significant effect of Cystone® on urinary composition short (6 weeks) or long (52 weeks) term. Average renal stone burden increased rather than decreased on Cystone®. Therefore, this study does not support the efficacy of Cystone® to treat cystine stone formers.

**Increased Sensitivity to 1,25(OH)$_2$Vitamin D$_3$ in Genetic Hypercalciuric Stone-Forming Rats** Kevin K. Frick,[1] John R. Asplin,[2] Murray J. Favus,[2] Christopher David Culbertson,[1] Stephanie Yee,[1] Nancy Krieger,[1] David A. Bushinsky.[1] *[1]University of Rochester School of Medicine; [2]University of Chicago.*

Genetic hypercalciuric stone-forming (GHS) rats have been selectively bred to excrete more urine (U) calcium (Ca) than Sprague-Dawley (SD) controls. GHS rats uniformly form kidney stones and express an increased number of vitamin D receptors (VDR) in kidney, intestine and bone. To assess the biological activity of the GHS VDR, we injected 25(OH)D$_3$ replete GHS or control Sprague-Dawley (SD) rats, fed a Ca replete (1.2% Ca) diet, with either 25 ng/d 1,25(OH)$_2$D$_3$ (Vit D) or vehicle (Veh) for 7d. Administration of Vit D to both SD and GHS rats increased serum Ca equally (increase of ~1.5 mg/dl) and suppressed PTH to undetectable levels in each. UCa in GHS+Veh (10.5 mg/d) was elevated compared to SD+Veh (1.7 mg/d); UCa was increased in SD+Vit D (24.4 mg/d), and further increased in GHS+Vit D (41.9 mg/d; all groups n=8, all comparisons p<0.01). To examine gene expression important for renal tubular Ca reabsorption, total kidney RNA was isolated and analyzed by QRT-PCR. VDR was increased in SD+Vit D and GHS+Vit D relative to respective Veh. Expression of the distal luminal renal Ca transporter TRPV5, Ca binding protein calbindin D$_{28K}$ and the basolateral Na/Ca exchanger NCX were all similarly increased in SD+Vit D and GHS+Vit D. Expression of klotho, which activates TRPV5, was decreased only in GHS+Vit D. The Ca transporter TRPV6 was increased in SD+Vit D and further increased in GHS+Vit D. Levels of the basolateral Ca ATPase PMCA were inhibited in GHS+Vit D but not in SD+Vit D. There were no differences in expression of thick ascending limb paracellular protein claudin 16, Na/K/2Cl transporter NKCC2 and K channel ROMK between the SD+Vit D and GHS+Vit D groups. Thus the greater increase in UCa with Vit D in GHS compared to SD indicates that the enhanced number of VDR in GHS amplifies the biological response to administered Vit D. The mechanism of the

increased UCa in GHS+Vit D may involve a reduction in klotho, which activates TRPV5, and/or a reduction in PMCA, resulting in less renal tubular Ca reabsorption and greater hypercalciuria in GHS+Vit D as compared to SD+Vit D.

**Factors Involved in Changes of Serum Magnesium (sMg) Levels in Hemodialysis (HD) Patients and the Impact of Treatment of Secondary Hyperparathyroidism (SHP) in Magnesium Levels** Emilio E. Gonzalez-Parra, Beatriz Fernández, Catalina Martin Cleary, Pablo Justo Avila, Jesus Egido. *Nephrology, Fundacion Jimenez Diaz, Madrid, Spain.*

Magnesium (sMg)is increased in HD patients. It has some similar homeostatic mechanisms to calcium and is influenced by treatments like cinacalcet and paricalcitol are not well known. ¿That these treatments may influence sMg?.

**OBJECTIVES**

Determine sMg in different techniques of HD

Influence of treatment with phosphate binders in serum sMg

Influence of treatment for SHP with Cinacalcet, paricalcitol and 25 OH vitamin D in sMg .

**MATERIAL AND METHODS**

59 patients on HD (23 w, 36 m), mean age 70.3. 13 in HDFonline and 46 in high flow conventional HD (CHD).sMg in the dyalisate was 0.5 mmol / L. 27 of these patients were diabetic.

Paricalcitol was held in 15 cases and 5 cases were treated with cinacalcet. 18 patients were treated with oral calcidiol (0,266 mg / week). The paricalcitol mean dose of 3.2 mGR / week, cinacalcet daily dose of 60 mg / day.

**RESULTS**

Mean sMg was 2.066 ± 0.038 mg / dl. sMg did not correlate with sCa (r 0,075), p 0.482.

sMg was lower in CHD than in olHD ; 2.02 ± 0.25 vs 2.2 ± 0.304, p <.032.

No correlation with phosphate binders, neither its doses. sMg not correlated with sPTH or with 25 OH vit D. Calcidiol correlated with Ca and P, p <.05, sMg has not the same behavior to similar cations.

No differences between sMg in diabetics and non-diabetic patients; 2107 ± 0.3 vs 2023 ± 0.24 (ns) .

sMg quartiles, higher level of sMg, increased level of calcidiol, but that was not significant. Higher sMg quartile corresponded to higher PTH than lower sMg (0-1.9 mg / dl), but non-significant.

No significant differences in sMg between patients treated or not with paricalcitol (2.15 ± 033 vs 2.02 ± 0.24 mg/dl); calcidiol (2.11 ± 0.27 vs 2.04 ±0.30 mg/dl) and cinacalcet (2.3 ± 0.25 vs. 2.04 ± 0.27 mg/dl).

**CONCLUSIONS**

1. - Magnesium behaves differently to calcium, there is no correlation with PTH, 25 OH vitamin D, calcium and phosphate.

2. – No influence of Paricacitol or Cinacalcet treatment on sMg was observed

3. - In olHD sMg is higher than in CHD.

4. – Calcidiol level is higher on patients with higher sMg but this is non-significant.

**PUB083**

**A New Model of Quantifying Phosphate Removal in Conventional Hemodialysis Therapy** Chuan-Ming Hao. *Huashan Hospital, Fudan University.*

**Background** Hyperphosphatemia is closely associated with mortality in patients on hemodialysis. We report a simple formula to estimate phosphate removal by each hemodialysis session to develop therapeutic strategies and analyze the factors that may affect removal. **Methods** 167 MHD patients were enrolled in this study. They had received the following dialysis treatment:4-hr each session, 3 times per week, Polysulfone 1.2$m^2$ or Triacetate 1.3$m^2$,Dialysate flow was 500ml/min. The out-flow dialysate samples were collected every 15min during 4 hours to measure the concentration of phosphate. Total amount of phosphate removal was estimated by area under the curve of dialysis volume (x) and dialysate phosphate concentration (y). This estimation was very close to the actual phosphate removal. The levels of serum phosphate, Hct, PTH, $TCO_2$ (all before treatment)and kt/v(urea), ultrafiltration rate, dry weight, blood flow were also recorded. 137 data sets were randomly selected to generate a model and the remaining 30 data sets were used to validate. **Results** The total amount of phosphate clearance by four-hours dialysis treatment was mostly between 600-900mg. By backward stepwise regression, the best model to describe the removal of phosphate per 4h dialysis as a function of treatment variables was: total amount

=79.6´T45(mmol/L)-0.023´age(years)+0.065´Weight(kg)-0.12´TCO2+0.05´Clearance(ml/min)-3.44. T45 represented phosphate concentration of dialysate after 45min of treatment; Clearance represented the phosphate clearance of dialyser when blood flow was 200ml/min. The validation results showed that the residual were all within 3mmol, indicating that the error would not exceed 10% of the real value. MSE and MSPR were very close suggesting the model was highly accurate. **Conclusions** This study derived a new approach to quantify phosphate removal of conventional hemodialysis by a simple formula, which may be helpful for clinicians to evaluate the phosphate balance in MHD patients.

Disclosure of Financial Relationships: nothing to disclose

**PUB084**

**Not All 25 OH Vitamin D Defiency Is True Vitamin D Deficiency: Syndrome of Excess Endogenous 1,25 Vitamin D: Nephrolithiasis, Nephrocalcinosis, Osteopenia, Growth Retardation, Hypoparathryoidism** Jessica G. Lucas, Barbara A. Clark. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Clinicians are increasingly aware of the ubiquitous nature of vitamin D deficiency in the general population and measurement of 25 OH Vitamin D levels are becoming more routine. This may present a clinical dilema in patients with calcium nephrolithiasis with hypercalciuria. Idiopathic hypercalciuria has been, in some cases, attributed to excess endogenous 1,25 vitamin D. However, this is not widely appreciated, levels are not routinely measured and the extreme clinical manifestations of this disorder are even more under appreciated. A 17 yo male with a history of recent nephrolithiasis was referred by his endocrinologist to determine the risk/benefit of vitamin D therapy for his newly diagnosed osteopenia, growth retardation (bone age of 14) and low 25 OH Vit D levels, prior to initiating growth hormone therapy. Testing revealed nephrocalcinosis, serum calcium of 9.9 mg/dl. phosphorus of 3.8 mg/dl, HCO3 27 mmol/L, creatinine 0.7 mg/dl, 25 OH Vit D level 14ng/ml (nl 20-100), intact PTH < 3.0 pg/ml (nl 9-69), urine calcium 457 mg/d (normal <300), phosphorus 492 mg/gm creatinine (nl 210-750), citrate 1938 umol/d, oxalate 14 mg/d , urine pH 6. A 1,25 Vit D level returned at 160 pg/ml (nl 15-60). Family history was notable for nephrolithiasis in father and paternal GF. The patient was treated with HCTZ, high fluid intake, low salt intake and somatropin injections (for his growth retardation). Vitamin D therapy was not recommended. Repeat urine calcium/creatinine ratios were 135-238 mg/gm, Dexa scan showed improved bone mineralization and the patient grew 2 inches over 8 months. The hypercalciuria and marked suppression of PTH secretion were attributed to the excess 1,25 Vit D levels and the bone demineralization was attributed to the renal calcium loss. In summary, low 25 OH vitamin D levels should not lead to automatic repletion of exogenous vitamin D in calcium stone formers. Increased vigilance for idiopathic hypercalciuria with endogenous 1,25 Vitamin D excess, especially with a positive family history, is indicated.

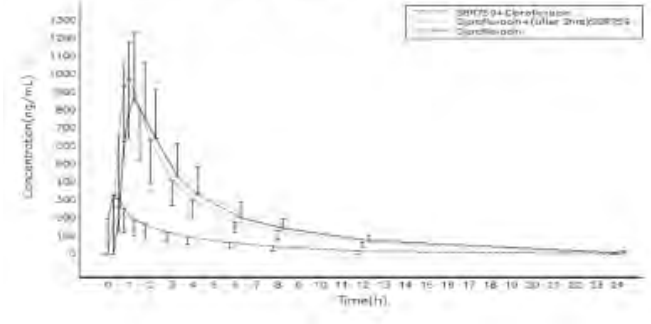
**SBR759 Drug Interaction with Ciprofloxacin: Separating Administration by 2 Hours May Avoid Need for Therapeutic Substitution** Alan J. Slade,[1] Sayaka Shimada,[1] Stephan De la Motte,[2] Robert L. Schmouder.[1] *[1]Novartis Institute for Biomedical Research; [2]Harrison Clinical Research.*

SBR759 is a novel, calcium-free, polymeric, iron (III)-based phosphate binder being developed for the treatment of hyperphosphatemia in patients with chronic kidney disease. SBR759 is an orally-dosed, powder that effectively binds phosphorus in the GI tract. As expected, due to the class interaction between fluoroquinolone antibiotics and di- and tri-valent metal cations, an interaction between SBR759 and ciprofloxacin was detected during *in vitro* testing. This Phase I study was conducted in healthy volunteers to characterize the pharmacokinetics (PK) of ciprofloxacin when administered with or 2 hours before SBR759. **METHODS:** An open-label, 3-period, single-dose, cross-over study design was utilized. Volunteers received 250 mg ciprofloxacin alone, 2 hours before and in combination with 5 g SBR759. Ciprofloxacin PK samples were collected through 24 hours post dose. **RESULTS:** 36 volunteers were enrolled in the study. The most common AEs were discolored stool (11/36), diarrhea (8/36) and flatulence (8/36). The PK time-concentration curves for the three treatment arms are shown below.

Figure 1: SBR759 Drug Interaction: Ciprofloxacin time-concentration profile (arithmetic mean (SD)(*n=36*)



When SBR759 was administered with ciprofloxacin (dashed line), there was a 68% decrease in the ciprofloxacin geometric mean ratio of Cmax (0.32) and AUC0-inf (0.31). Alternately, when ciprofloxacin was administered 2 hours prior to SBR759 (dotted line) there was no discernible interaction (Geo. mean ratio - Cmax: 1.04 and AUC0-inf: 0.96). **CONCLUSIONS:** Simultaneous administration of ciprofloxacin and SBR759 leads to a significant PK interaction. Administration of ciprofloxacin 2 hours prior to SBR759 allows adequate time for absorption thus no interaction was measured in healthy volunteers. These data suggest that with care and counseling, clinicians can use ciprofloxacin in patients receiving SBR759.

**Improved Management of Mineral Metabolism in Hemodialysis Patients; Sevelamer-Carbonate (SC) Versus Sevelamer-Hydrochloride (SH)** Brett W. Stephens,[1] Donna Roy,[2] Donald A. Molony.[1] *[1]Renal Diseases and Hypertension, University of Texas Houston Medical School, Houston, TX; [2]DaVita PDI South Dialysis, Houston, TX.*

Successful management of hyperphosphatemia amongst dialysis patients remains an important but incompletely achieved goal. Recent evidence supports the view that the concurrent achievement of KDOQI targets for $PO_4$, Ca, iPTH is associated with the best patient survival. An important barrier to successful management is the need to take $PO_4$ binders. As part of the quality improvement process, we evaluated the achievement of KDOQI mineral metabolism goals in a single dialysis center, for the six months before initiation of and after full conversion of all patients from SH (Renagel®) to SC (Renvela®) as their phosphate binders. All other aspects of the dialysis care remained unchanged. The table lists the data from these two periods.

| | % of patients with PO4 of >3.5 to < 5.5 mEq/L | % of patients with iPTH of 150 – 300 pg/ml | % of patients with Ca of > 8.2 to <9.5 mEq/L | % of patients with all three parameters within the KDOQI target range |
|---|---|---|---|---|
| 7/1/2007 to 12/31/2007 | 69.4 ± 8.7 | 60.6 ± 8.5 | 81.3 ± 7.3 | 46.3 ± 2.8 |
| 1/1/2009 to 6/30/2009 | 76.8 + 5.6± | 61.3 ± 6.4 | 95.5 ± 3.0 | 54.2± 7.3 |
| p | NS | NS | p = 0.07 | p < 0.05 |

86% and 98% of patients were treated with SH and SC as their primary binder in the first and second time periods, respectively. Significantly, more patients achieved the 3-KDOQI goals during period two. Although changes in either $PO_4$ or Ca did not quite reach statistical significance, improvements in either or both likely accounted for the observed improvement in the number of patients achieving the 3-KDOQI goals concurrently. The possibility of temporal trends accounting for the observed improvement can only be excluded by a randomized controlled clinical trial. These observations, however, support the view that phosphate binder type may influence importantly whether clinical goals are achieved. In this single practice, SC appeared to offer an advantage over SH for achieving KDOQI mineral metabolism goals.

Disclosure of Financial Relationships: nothing to disclose

**Effect of Diet Sunkist Orange Soda on Urinary Lithogenicity** Nicola T. Sumorok,[1] Brian H. Eisner,[4] Marshall L. Stoller,[2] John R. Asplin,[3] David S. Goldfarb.[1] *[1]Nephrology, New York University School of Medicine, New York, NY; [2]Urology, University of California-San Francisco, San Francisco, CA; [3]Litholink Corporation, Chicago, IL; [4]Urology, Massachusetts General Hospital, Harvard Medical School, Boston, MA.*

**Purpose:** Studies have shown that certain beverages decrease urinary lithogenicity by increasing urine citrate excretion. Citrate and total alkali concentrations in 12 diet sodas showed that Diet Sunkist Orange soda has the highest concentration of potential base. We studied the effect of Diet Sunkist Orange soda consumption on urinary chemistry.

**Methods:** 9 healthy men and women ages 26-54 completed the study. During the control period, subjects drank 32 oz. of water for 3 days in addition to their own, ad lib diet and recorded a food diary. During the study period, the subjects drank 3-,12-oz cans of Diet Sunkist Orange soda a day instead of water, and replicated their diets from the control period. In each period, the subjects performed 24-hour urine collections on days 2 and 3. Urine chemical analysis was performed, including urinary citrate levels and pH.

**Results:** Diet Sunkist Orange soda increased urinary citrate excretion by 24.8 mg/day, which was not statistically significant (95% CI –71.5 to 121.1, p-value 0.57). There was no significant change in pH from the control period to the study period (pH 6.27 to 6.22; 95% CI –0.111 to 0.202, p=0.52). Urine volumes and creatinine excretions were not significantly different between the control and study periods.

**Conclusions:** Despite the relatively high citrate and total alkali content of Diet Sunkist Orange soda, there is not enough citrate content to affect the urinary chemistry in healthy subjects who have normocitraturia at baseline. The positive effect that was seen in a prior study looking at Performance, a sports drink, can be attributed to the higher content of citrate in an alkaline form and the higher pH of Performance. The effect of Diet Sunkist Orange soda on the urinary chemistry in patients with hypocitraturia and nephrolithiasis is not likely to have a clinically significant effect to prevent calcium or uric acid stones.

**Assessment of Bone Mineral Density (BMD) and Structure in Children with Idiopathic Hypercalciuria (HC)** Shamir Tuchman,[1] Babette Zemel,[2] Mary B. Leonard.[2] *[1]Pediatric Nephrology, Children's National Medical Center, Washington, DC; [2]The Children's Hospital of Philadelphia, Philadelphia, PA.*

DXA studies have reported BMD deficits in children with HC. Peripheral quantitative CT(pQCT) provides discrete measures of trabecular(Trab) and cortical(Cort) volumetric BMD and cortical dimensions. The purpose of this pilot study was to use pQCT/DXA to characterize differences in BMD in HC differentiated based on a calcium restricted diet. 13 subjects were categorized as absorptive HC (AH; n=7) or renal HC (RH; n=6) based on urinary changes after a 300mg/day, 3-week calcium restricted diet (AH urine calcium decreased to < 4 mg/kg/d). Tibia QCT measures included Trab_BMD(distal metaphysis) and Cort_BMD and Section Modulus($Z_p$; summary measure of cortical dimensions and strength in torsion)(mid-diaphysis). DXA measures include AP_spine_BMD, whole body(WB)_BMD and width-adjusted spine BMD(WA_BMD; estimates vertebral volumetric BMD using AP and lateral scans excluding spinous processes). Z-scores were generated using reference data in over 600 controls. The results are summarized below. The overall results and results in AH and RH subjects did not differ significantly from controls or between each group (p>0.05). However, the data demonstrated (1) a pattern of greater Trab_BMD, WB_BMD, and WA_BMD in AH subjects, and (2) a pattern of lower Trab_BMD, WB_BMD, and spine_BMD in RH subjects. These data suggest that assessment of bone health in children with HC should consider distinct differences in measures of BMD between AH and RH. Larger studies are needed to determine if this results in clinically significant alterations in bone health.

| Z-score | Overall (n=13) | Renal HC (n=7) | Absorptive HC (n=6) |
|---|---|---|---|
| pQCT | | | |
| Trab_BMD | -0.04+/-1.02 | -0.46+/-0.94 | 0.38+/-1.00 |
| Cort_BMD | -0.25+/-0.83 | 0.05+/-0.73 | -0.56+/-0.87 |
| Zp | -0.08+/-0.87 | -0.12+/-0.66 | -0.04+/-1.11 |
| DXA | | | |
| WB_BMD | 0.13+/-1.20 | -0.35+/-1.26 | 0.61+/-1.02 |
| AP_spine_BMD | -0.06+/-1.18 | -0.33+/-1.38 | 0.20+/-0.99 |

**Hormonal and Dietary Determinants of Urinary Phosphate Excretion in Healthy Volunteers and Patients with Chronic Kidney Disease Stage 1-4** Liesbeth Viaene, Bjorn K. I. Meijers, Vanrenterghem Yves, Pieter Evenepoel. *Nephrology, University Hospital Gasthuisberg, Leuven, Belgium.*

Introduction: Phosphate homeostasis is disrupted in chronic kidney disease (CKD). In steady-state, 24-hour urinary phosphate excretion (24h-$Ur_{Phos}$) corresponds to net daily intestinal absorption. We aimed to identify hormonal and dietary determinants of 24h-$Ur_{Phos}$ and 24 hour urinary fractional excretion of phosphate ($FE_{phos}$). Methods: 20 healthy volunteers (HV) (age 34 ±10 year) and 170 stable CKD stage 1-4 patients (age 59±15 year) were studied. Fasting blood and 24-hour urine samples were analyzed for parameters of mineral metabolism including calcidiol, calcitriol, FGF-23 and PTH. Dietary data were available in all HV and in 72 CKD patients. Results: Table1 summarizes relevant dietary and biochemistry data.

Relevant biochemistry data

| | HV | >60 ml/min/m² | 30-60 ml/min/m² | 15-30 ml/min/m² | p-value |
|---|---|---|---|---|---|
| Phosphate (mg/dl) | 3.5 | 3.1 | 3.3 | 3.2 | 0.06 |
| Biointact PTH (ng/l) | 17 | 10 | 18 | 29 | <0.0001 |
| Calcitriol (ng/l) | 59 | 64 | 41 | 38 | <0.0001 |
| FGF-23 (ng/l) | 28 | 33 | 64 | 69 | <0.0001 |
| FEphos (%) | 16 | 20 | 30 | 36 | <0.0001 |
| 24h-UrPhos (mg/day) | 895 | 791 | 792 | 726 | 0.27 |
| Dietary phosphate intake (mg/day) | 1513 | 1315 | 1191 | 1247 | 0.11 |

Median values are shown.

Only dietary phosphate intake was independently associated with 24h-$Ur_{Phos}$ ($R^2$=0.20, p<0.0001). 24-Hour $FE_{phos}$significantly increased along the progression of CKD. In multivariate analysis, high 24h-$Ur_{Phos}$, high PTH, high FGF-23, low serum phosphate, low calciuria and low eGFR were independently associated with high $FE_{phos}$ ($R^2$= 0.60; p<0.0001). Conclusions: Our data confirm and extend previous experimental and clinical findings. The inverse association between calciuria and $FE_{phos}$supports the notion of regulation of proximal tubule phosphate transport by a calcium-sensing receptor. 24h-$Ur_{Phos}$ and $FE_{phos}$ are readily available and inexpensive measures of dietary phosphate exposure and renal phosphate handling. They may prove to be of added value for monitoring phosphate homeostasis in CKD.

**A Multi-Center Randomized Double-Blind Placebo-Controlled Trial on Chewing Effect of a Chitosan Loaded Gum HS219 for the Control of Serum Phosphorous in Maintenance Hemodialysis (HD) Patients** Tadao Akizawa,[1] Yoshinari Tsuruta,[2] Yoichi Okada,[3] Yoshihiro Miyauchi,[4] Akio Suda,[5] Hirosi Kasahara,[6] Nobuhiro Sasaki,[7] Yoshitaka Maeda,[8] Takako Suzuki,[9] Noriaki Matsui,[10] Jun Niwayama,[11] Toshiaki Suzuki,[12] Hideaki Hara,[13] Yasushi Asano,[7] Masafumi Fukagawa.[14] *[1]Showa University School of Medicine; [2]Meiyo Clinic; [3]Maruko General Hospital; [4]Asahi General Hospital; [5]Suda Clinic; [6]Japanese Red Cross Suwa Hospital; [7]Japanese Red Cross Koga Hospital; [8]Toride Kyodo General Hospital; [9]Komagome Kyouritsu Clinic; [10]Tsuchiura Kyodo General Hospital; [11]Sumiyoshi Clinic Hospital; [12]Asagaya Suzuki Clinic; [13]Gifu Pharmaceutical University; [14]Tokai University School of Medicine, Japan.*

Background: Control of serum phosphate level is a critical step in management of CKD-MBD. HS219 is a chewing gum designed to trap salivary phosphorous, which is an alternate source of phosphorous with higher concentration than serum. Aim: To evaluate the efficacy and safety of HS219 when given three times a day for 3 weeks to the HD patients with hyperphosphatemia. Method: 68 HD patients maintained on calcium carbonate (33 subjects) or sevelamer (35 subjects) were enrolled. The major inclusion criteria required serum phosphorous of >5.5 and < 9.0 mg/dL. The primary end point was the changes from baseline in serum phosphorus. Secondary end points included change from baseline in salivary phosphorous, serum calcium, PTH and FGF23. Results: 63 patients chewed at least one gum: 35 HS219 and 28 placebo. HS219 was well tolerated and safe. No significant

effects of HS219 on reduction of serum and salivary phosphorous were observed. There was no correlation between salivary and serum phosphorous. However, statistically significant difference was observed in change from baseline to end of chewing for iPTH (P=0.018), particularly in sevelamer group (P=0.001). Effect on iPTH was correlated to serum phosphorous reduction whilst not changing serum calcium. Conclusion: HS219 has no effects on serum and salivary phosphorous, but reduces PTH in sevelamer group. Further exploratory study is needed to evaluate its efficacy.

**A Bioimpedance Study on Factors That Influence Bone Health in a Haemodialysis Population** Julie E. Browne, Caroline McConnell, Charlotte Griffin, Ying Kuan. *Renal Unit, Altnagelvin Hospital, Londonderry, Northern Ireland, United Kingdom.*

**Introduction:** Patients with end stage renal failure have altered bone metabolism and are at increased risk of spontaneous fracture compared to the general population. Dual energy X-ray absorptiometry (DXA) is commonly used to evaluate bone health but involves radiation exposure. Multifrequency bioimpedance analysis (MF-BIA) measurements can provide a non-invasive method for assessing body composition that has been found to correlate closely with values measured by DXA. Bone Mineral Content (BMC), measured by BIA, may provide an indication of bone health. This study assesses the factors that influence BMC in a Hemodialysis (HD) population, and the possible utility that this measurement may have as a screening tool.

**Method:** BMC was measured using a MF-BIA analyzer (InBody S20, Biospace) in 50 HD patients in a single renal unit (Altnagelvin Hospital, Londonderry, UK). Date of test, body weight (kg), BMI and BMC (kg) was recorded in addition to sex and length of time on renal replacement therapy (RRT). Maximum values of PTH (PTHmax) in the 12 months preceding the study were also recorded as surrogate biochemical measure of metabolic bone health. The results were analysed using Medcalc (MedCalc Software, Inc, Mariakerke, Belgium), by correlating BMC, as percentage of body weight (%BMC), with age, gender, time on RRT and PTHmax.

**Results:** 30 males and 20 females were included in the study. Mean time on dialysis was 4.8 years (range 0.2-31.5 years). Other results are shown in Table 1. Multivariate analysis suggests that %BMC correlates negatively with time on dialysis ($p<0.05$).

Table 1.

| Variable | Mean | ± 1SD* |
|---|---|---|
| Age (years) | 61 | 16 |
| Weight (kg) | 74.5 | 13.2 |
| PTH max (ng/l) | 646 | 392 |
| BMC (kg) | 3.6 | 0.8 |
| %BMC | 4.8 | 1.0 |

*SD=standard deviation

**Conclusion:** MF-BIA offers a non-invasive measurement of body composition, yielding important information, including nutritional status in the HD population. BMC estimated in our study suggests a detrimental impact of long term RRT on bone health. This finding is similar to that found from other studies with DXA, and suggests that further studies on MF-BIA as a screening tool in this population should be pursued.

**PUB092**

**Vertebral Trabecular Bone Attenuation, Mineral Metabolism and Coronary Artery Calcification in Patients with Normal Renal Function** Ana L. E. Cancela,[1] Raul D. Santos Filho,[2] Silvia Titan,[1] Carlos Eduardo Rochitte,[2] Russell Gotschall,[3] Brian S. Kelley,[3] Susan Schiavi,[3] Vanda Jorgetti,[1] Rosa Ma Moyses.[1] *[1]Nephrology, Universidade de São Paulo, Brazil; [2]Instituto do Coração, Universidade de São Paulo, Brazil; [3]Genzyme Co.*

This study explores the relationships among vertebral trabecular bone attenuation (TBA), coronary artery calcification (CAC) and mineral metabolism markers in 271 patients with suspected coronary artery disease (CAD) and normal renal function (MDRD >60 ml/min/1.73 $m^2$) submitted to multislice CT (MSCT) to assess CAC. Agatston Scores (AS) were assigned. CT images were analyzed to measure thoracic TBA (mean of 3 measures), which was obtained in Housfield Units (HU). We also analyzed serum P, ionized Ca (iCa), lipid profile, alkaline phosphatase (AP), PTH, 25-vitamin D [25(OH)D] and intact FGF-23. Patients were considered to have CAC when AS was >10 (CAC group; $n$=155) and when AS was ≤ 10 they were assigned to the non-CAC group ($n$=116). Mean age was 58.17± 9.4 years, 57.2% were male, 65.3% white, 81.1% were hypertensive and 35.8% diabetic. Mean serum P was 3.57±0.54 mg/dl, median FGF-23 and Creat clearance were 59.3 pg/ml and 92.4 ml/min/1.73 $m^2$. Median TBA and AS were 200.9 HU (interquartile range:163.9-241.7) and 40.0 HU (interquartile range: 0-275.0). TBA was lower in women (p= 0.046) and white patients (p=0.01).There were negative correlations between TBA and AS ($r$=-0.211; $p$<0.0001) and TBA and age ($r$=-0.419; $p$<0.0001). There was a trend towards a correlation between TBA and FGF23 ($r$=-0.10; $p$=0.10) and between TBA and PTH ($r$=-0.111; $p$=0.069). We found no correlation between TBA and iCa, AP, P or 25(OH) D. Compared to the non-CAC group, CAC group had lower TBA (median 184.1 vs 211.0 HU, $p$=0.004). Multivariate analysis revealed that TBA was dependent on age ($p$<0.0001, CI -3.42-1.52) and FGF-23 ($p$=0.04, CI -0.053-0.001). In conclusion, we found that TBA was negatively correlated to coronary calcification, age and serum FGF-23 in a population with normal renal function and suspected CAD. Interactions between vascular and bone physiology and common pathogenetic factors for bone loss and CAC may be responsible for these associations.

**PUB093**

**Variability of Serum Phosphate in Patients on In-Center or Home Hemodialysis** Katie E. Cardone,[1] George R. Bailie,[1] Rachid Daoui,[2] Shari A. Meola,[2] Christopher D. Hoy.[2] *[1]ANephRx, Albany College of Pharmacy and Health Sciences, Albany, NY; [2]Hortense and Louis Rubin Dialysis Centers, Saratoga Springs, NY.*

Background: Limited data exist regarding extent of variability in serum phosphorus concentrations ([P]) amongst those on different dialysis modalities. Despite this, clinicians frequently rely on these values to make clinical decisions in patients on dialysis. The purpose of this study was to retrospectively examine the extent and magnitude of variability in monthly, routine estimates of [P] over a 1 yr period in a cadre of patients at an outpatient dialysis facility.

Methodology: A retrospective chart review of [P] was conducted amongst patients with end stage kidney disease receiving renal replacement therapy. All adult patients who received treatment at the facility between 1/1/2009 and 12/31/2009 whose records were available for review, & who had ≥2 [P] lab values were included. Patients may have received either in-center intermittent hemodialysis (HD) or frequent home hemodialysis (≥5 days/wk) (FHH).

Results: A total of 153 patients were included (HD: n=118; FHH: n=35).

| | HD (n=118) | FHH (n=35) |
|---|---|---|
| DEMOGRAPHIC | | |
| Mean±SD Age (yr) | 65.5±16.4 | 57.8±11.6 |
| % Caucasian | 80 | 88.6 |
| % Male | 53 | 63 |
| LABORATORY DATA | | |
| Mean±SD number of laboratory orders | 12.9±7.3 | 15.7±7.0 |
| Geometric Mean±SD [P] (mg/dL) | 5.0±1.2 | 5.1±1.2 |
| Mean±SD Intrapatient [P] Range | 3.2±1.7 | 3.7±1.4 |
| Mean±SD Intrapatient [P]: | | |
| % of values ≥6.5 mg/dL | 17.2±25.6 | 19.0±27.3 |
| % of values >5.5 mg/dL | 31.9±32.2 | 34.5±31.5 |
| % of values 3.5-5.5 mg/dL | 54.9±28.2 | 51.6±25.5 |
| % of values <3.5 mg/dL | 13.2±19.6 | 13.9±19.6 |
| % of values ≤2.5 mg/dL | 3.3±10.1 | 3.1±6.7 |

*p<0.05

Conclusion: Intrapatient variation in [P] is not different amongst those on HD or on FHH. This may be due to differences in management of [P], including diet, extent of phosphorus restriction, and medication use. For the average patient, [P] remains within the range of 3.5-5.5 more than half the time.

**Calcification in Abdominal Aorta and in Coronary Arteries in Hemodialysis Patients Is Not Directly Related to Plasma Concentration of Fibroblast Growth Factor 23** Jerzy Chudek,[1,2] Marcin Adamczak,[1] Andrzej Wiecek,[1] Przemyslaw Pencak,[3] Joanna Witkowicz,[1] Beata Czerwienska.[1] *[1]Department of Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland; [2]Department of Pathophysiology, Medical University of Silesia, Katowice, Poland; [3]Division of Radiology, SPSK-M, Katowice, Poland.*

**Introduction:** Fibroblast growth factor 23 (FGF-23) is recognized as a circulating phosphaturic hormone which suppresses the proximal tubular Na/Pi-2a and Na/Pi-2c cotransporters. FGF-23 deficient mice develops severe vascular calcification, however the role of FGF-23 in the development and progression of vascular calcifications in chronic renal failure (CKD stage 5) remains unknown. The aim of this cross-sectional study was to analyse the interrelation between plasma concentration of FGF-23 and calcifications in abdominal aorta and coronary arteries in hemodialysis patients applying multislice computer tomography.

**Patients and methods:** Seventy five patients (37 M, 38 F; aged 56, range 23-83 years) hemodialysed three times a week for 2-228 months (mean±SD 36±46) were enrolled into this study. In all patients coronary calcium score (CCS) and calcium score of abdominal aorta (AoCS) using multislice computer tomography were performed. Plasma intact FGF-23 concentrations were measured by ELISA (Immutopics, CA, USA). Data are presented as means and 95% CI.

**Results:** Coronary arteries and abdominal aorta calcifications were detected in 57 (76%) and 61 patients (81.3%), respectively. The mean CCS and AoCS were 1014 (640-1388) and 2704 (1906-3502), respectively. There was a strong correlation between CCS and AoCS (R=0.721, p<0.001) and between CCs or AoCS and time of dialysis therapy (R=0.256, p=0.03 and R=0.281, p=0.02, respectively). There was no correlation between CCS or AoCS and plasma intact FGF-23 concentration (also after logarithmic transformation). There was a strong correlation between serum phosphate and intact FGF-23 concentration (R=0.513; p<0.001)

**Conclusion:** Plasma FGF-23 is not related to the intensity of vascular calcifications in hemodialysis patients.

**Comparative Effects of Phosphate Binders in Experimental Adynamic Bone Disease** Juliana C. Ferreira, Guaraciaba O. Ferrari, Raquel T. Cavallari, Cássia M. Puci, Wagner V. Dominguez, Luciene M. dos Reis, Fabiana G. Graciolli, Rosa Ma Moyses, Katia R. Neves, Vanda Jorgetti. *Nephrology Division, Universidade de São Paulo, Brazil.*

Despite the increasing prevalence of adynamic bone disease (ABD), there are no studies of the effects of P binders on ABD. Rats submitted to 5/6 Nx+PTx were divided into: Ca ($CaCO_3$); Sev (Sevelamer $CO_3$); CKD (untreated); and control (sham). After 8 wks, we performed biochemical and histomorphometric (BHist) analyses, as well as von Kossa staining in aortic sections. All Nx rats showed higher creatinine and P and lower Ca than did control rats. Serum P was similar in all Nx groups, but fractional excretion of P (FeP) was significantly lower in the treated groups. Calciuria was higher in the Ca group than in the Sev group. A non-significant decrease in serum FGF-23 was seen in Sev group. None of the rats developed VC. BHist revealed ABD in all Nx groups, as confirmed by lower bone formation rates, as well as decreases in osteoid volume, osteoblast surface and osteoclast surface and absence of fibrosis. We found no differences among the study groups in terms of BHist parameters, except for greater eroded surface in the Ca group.

| | Ca (n=7) | Sev (n=5) | CKD (n=7) | Control (n=5) |
|---|---|---|---|---|
| Creatinine (mg/dl) | 1.4±0.5 | 1.5±0.4 | 1.4±0.2 | 0.6±0.1[a] |
| ionized Ca (mmol/L) | 0.5±0.1 | 0.5±0.3 | 0.6±0.2 | 1.1±0.0[a] |
| P (mg/dl) | 11.5±2.2 | 10.6±3.5 | 11.3±3.0 | 5.2±0.2[a] |
| FeP (%) | 1.8±1.7[a] | 23.1±12.1[a] | 53.8±23.3[a] | 6.1±3.0[a] |

**Paricalcitol (Pc) Therapy Upregulates Bone Fibroblast Growth Factor 23 (FGF23) and Improves the Mineralization Defect in Experimental Uremia** Michael Freundlich,[1] Ezequiel R. Bellorin-Font,[2] R. C. Pereira,[3] Evelyn Alonzo,[2] Yasmir Quiroz,[4] Janaury Bravo,[4] Eudocia Rojas,[2] Orlando Suniaga,[2] Isidro B. Salusky,[3] Bernardo Rodriguez-Iturbe,[4] Jose R. Weisinger.[2] *[1]Pediatric Nephrology, University of Miami, Miami, FL; [2]Nephrology and Renal Transplant, Hospital Universitario, Caracas, Venezuela; [3]Pediatric Nephrology, UCLA, Los Angeles, CA; [4]Renal Service, Hospital Universitario, Maracaibo, Venezuela.*

FGF23 may directly impact skeletal mineralization independent of systemic phosphate (P) homeostasis and $1,25(OH)_2D_3$ stimulates osteoblast and osteocyte FGF23 production, but little is known on the skeletal response of both hormones in CKD. We evaluated bone expression of FGF23 by immunohistochemistry and bone histomorphometry in 5/6-nephrectomy rats. Treatment (Rx) 8 weeks with Pc or enalapril (E) similarly atenuated renal insufficiency vs. vehicle-treated controls (U) (creatinine 0.76±0.1 and 0.76±0.06 vs. 1.67±0.75 mg/dl, respectively, p<0.05). Plasma Ca was similar in all groups and P remained unchanged (Pc 6.46±1.83, En 6.34±1.7, U 7.31±1.89 mg/dl). Osteocyte FGF23 expression was↑in U vs. sham-operated rats (S) and even more prominently following Pc Rx. Bone histomorphometry (Table) revealed indices of defective mineralization, markedly attenuated with Pc. In addition, Pc improved significantly eroded surfaces (ES/BS). In contrast, E displayed↓bone FGF23 expression with less attenuated %OS/BS and %ES/BS (p<0.05 vs.Pc). In summary, in experimental uremia a mineralization defect is highly prevalent and associated with↑bone FGF23 expression despite normal P levels; Pc Rx upregulated bone FGF23 expression and partially improved the mineralization defect and bone resorption. The effects of the different vitamin D sterols on osteocyte function remain to be defined in CKD.

**Metabolic Syndrome Is a Risk Factor for Coronary Artery Calcification Severity in Stage 3-5 CKD Patients** Jocelyn S. Garland,[1,2] Rachel M. Holden,[1,2] Wilma M. Hopman,[3] Robert Louis Nolan,[4] Alexander R. Morton.[1,2] *[1]Medicine, Queen's University, Kingston, ON, Canada; [2]Queen's University Vascular Calcification Investigators; [3]Community Health and Epidemiology, Kingston General Hospital; [4]Radiology, Queen's University.*

Few studies have investigated chronic kidney disease patients (CKD) for the presence of metabolic syndrome, and its relationship to coronary artery calcification (CAC). The primary research objective was to determine the cross-sectional associations of metabolic syndrome (defined as per NCEP ATP III 2004 criteria), insulin resistance (assessed by HOMA IR) and CAC (quantified by MSCT) risk factors in 95 stage 3-5 CKD patients. Biochemical risk factors for CAC including FGF-23 and osteoprotegerin (OPG) were measured. Mean age was 64 years, 40% had diabetes, 57 % male, mean BMI 31.8 kg/m$^2$ and mean eGFR 25 ml/min/1.73m$^2$. Metabolic syndrome (3 of 5 criteria) was identified in 80%. Median CAC was higher in those with metabolic syndrome (239 *v* 10; P=0.001). By multi-nomial logistic regression, with CAC categories as the dependent variable and CAC = 0 as the reference group, an increased risk in CAC severity was demonstrated in those with metabolic syndrome. This relationship remained when adjusted for age and eGFR. By linear regression with all five metabolic syndrome criteria as covariates, hyperglycemia, hypertriglycidemia and low HDL were the most important risk factors in predicting logCAC. Considering insulin resistance, HOMA IR was measured in 72 of 95 patients who were not receiving insulin therapy. Median HOMA IR was higher in those with metabolic syndrome (2.5 *v* 1.1; P=0.001), and was positively correlated with log FGF 23 (r = 0.25; p = 0.04). HOMA IR inversely correlated with 25-OHD level (r = 0.22; p = 0.06), OPG (r = -0.20; p = 0.08) and OPG corrected for BMI (r = -.47; p < 0.001). In conclusion, metabolic syndrome was found to be highly prevalent in this cohort of stage 3-5 CKD patients, and there was an increased risk of CAC severity in metabolic syndrome patients. Insulin resistance was associated with risk factors for CAC. Studies are needed to identify whether treatment of metabolic syndrome improves CAC severity and progression.

**Intravascular Treatment to Symptomatic ADPK(L)D** Rikako Hiramatsu, Yoshifumi Ubara, Junichi Hoshino, Takafumi Toyohara. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

(Introduction) Since kidney and liver in ADPKD patients are usually supplied by well-developed arteries, we have attempted to contract enlarged kidney and liver in ADPKD patients by transcatheter arterial embolization (TAE) method using intravascular coils.

(Method)From 1996 to 2010, 785 patients with ADPKD were treated for abdominal distension due to renal enlargement and hepatomegaly. (Results)Kidney-dominant enlargement was present in 69% of ADPKD patients. The kidney and liver were similarly enlarged in 18%. Liver-dominant enlargement was present in 13 %. We have tried renal TAE in 653 patients with intractable enlarged kidneys. After TAE till today 587 patients showed a favorable clinical course. On 66 patients concomitant complications of other organs, such as cancer and cardio-cerebral vascular diseases became the cause of death. After renal TAE, 18 patients underwent renal transplantation without nephrectomy. Next, we have tried hepatic TAE in 282 patients with intractable symptomatic polycystic liver. 247 out of 282 patients have had a favorable clinical course. However, we could not cure 35 patients with severe hepatic failure and peritonitis with massive ascites, and hepatic cystic infection.(Conclusion)No major complications related to the TAE procedure have been encountered for either the kidney or the liver. Our treatment thus far may be less effective in reducing total liver volume than surgical hepatectomy. On the otherhands, our treatment should be safe even when performed repeatedly or after a relapse following surgical therapy. We are preparing for further TAE in patients with a poor initial result. TAE also may be an option for treatment of patients with symptomatic polycystic liver as well as kidneys in poor general medical condition who are not candidates.

**Histomorphometrical Analysis of Ectopic Ossification in a Hemodyalisis Patient** Rikako Hiramatsu, Yoshifumi Ubara, Junichi Hoshino, Takafumi Toyohara. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

A 55-year-old Japanese woman receiving hemodialysis during 5-years was admitted to our hospital for the evaluation of hypercalcemia and the ectopic calcinotic lesion in June 2009. Radiography revealed massive metal-density deposition on soft tissue near the bilateral hips, bilateral shoulders and left forearm. Because histology of ectopic calcinotic lesion showed bone tissue, histomorphometric examination using undecalcified thin sections was performed on iliac bone as well as ectopic bone on outer side of the iliac bone, and was compared with each other. Both specimens showed osteitis fibrosa, but bone formation rate was accelerated in ectopic bone than in iliac bone by using dLS/BS (39.9/17.2=2.3) and BFR/BV (798.5/214.0=3.7). The rate of bone formation to bone resorption was accelerated in ectopic bone (81.6/14.6=5.59) than in iliac bone (53.8/22.8=2.35) by using the rate of OS/BS to ES/BS. Woven bone formation was more prominent in ectopic bone. Trabecular bone structure was revealed to continue to layers of unmineralized osteoid lesion including mineralized island bones independently on areas different from calcification(Fig).

The mechanism how bone arises from multipotential mesenchymal cells in soft tissue could not yet be proved. However, once bone formation is initiated, bone formation would be accelerated due to this driving force of hyperparathyroidism, resulting in an increase of bone volume.

**Bone Mineral Density Can Predict Bone Loss after a Well-Functioning Kidney Transplantation** Carolina Lara Neves, Luciene M. dos Reis, Katia R. Neves, Rosa Ma Moyses, Vanda Jorgetti. *Nephrology, University of São Paulo, São Paulo, São Paulo, Brazil.*

**Introduction:**Post-transplant bone disease is a complex disorder that extends beyond simple alterations BMD. Low BMD had not enough predictive value of fracture and bone histology.The KDIGO suggest that DXA screening should only be done in individuals with a well-functioning allograft (CKD stages 1-3T).**Objectives:** Evaluate BMD after stable kidney transplantation (KT) and determine factors associated to bone loss. Ensure the predictive value of BMD on bone histology.**Methods:** Patients were 36.4 ± 8.9 years and CKD 1-3T.They were receiving low prednisone dosis and the same immunosuppressive therapy since KT. We excluded patients with gonadal disfunction, parathyroidectomy or with calcium, vitamin D or bisphosphonates treatment. They were submitted to clinical and biochemical evaluation, DXA and transiliac bone biopsy with histomorphometric analysis. We classified patients with bone loss through DXA T score < -1,0 SD, on femur or lumbar.**Results:** Hypercalcemia was observed in 40.7%, hypophosphatemia in 26%. Users of tacrolimus had lower phosphorus than users of cyclosporine(p=0.019). PTH > 65 pg/ml in 30% of them. 85% and 95% presented elevation of osteoprotegerin and deoxypyridinoline, respectively. 63% of our patients had 25(OH) < 30ng/mL. 57% of the patients had osteopenia or osteoporosis by DXA. Mean BV/TV was not decreased, but 30% presented low bone volume. Low BFR was seen in 60% of the patients, 46% presented enlarged MLT. All patients with 25 (OH) D insufficiency/deficiency had enlarged MLT. PTH was the only predictor of serum phosphorus (p=0.042), lumbar BMD (p=0.044) and osteoid volume (p=0.001). Patients with bone loss according to DXA presented lower BMI (p=0.02), BV/TV (p=0.03) and TbN (p=0.01), and higher TbSp(p=0.009).**Conclusion:** After stable and well-functioning KT, patients still presented abnormalities of mineral metabolism and bone histology. The predominance of mixed bone disease are related to immunosuppressive drugs, hypophosphatemia, persistence of hyperparathyroidism and 25 (OH) D insufficiency. BMD through DXA evaluation showed a good predictive value to structural and statics parameters of bone histology.

**Efficacy of Weekly (QW) or Bi-Weekly (BIW) IV Vitamin D Analog Therapy in Hemodialysis Patients** Neeta O'Mara,[1] Amelia Gajary,[1] Toros Kapoian,[2] Lois E. Lamanna,[1] Diane M. Brink,[1] Christine L. Velsor.[1] *[1]Dialysis Clinic, Inc (DCI), North Brunswick, NJ; [2]Med/Neph, UMDNJ-RWJ Med School, New Brunswick, NJ.*

**BACKGROUND**: Secondary hyperparathyroidism is a common complication in dialysis patients. Management includes methods to reduce serum phosphate and vitamin D analog therapy such as calcitriol, doxercalciferol, or paricalcitol. However, these agents are supplied in a limited number of dosage strengths in single-dose vials. **METHODS**: In order to minimize waste, we designed a protocol to align the dose and dosing interval with vitamin D analog vial size. This resulted in a number of patients receiving QW or BIW IV vitamin D rather than the usual thrice weekly (TIW) dosing. Less frequent vitamin D dosing has previously been reported to be effective in a limited number of dialysis patients. **RESULTS**: Twelve patients (mean age 66 years; mean dry weight 80.4 kg; 8 M, 4 F; 7 black, 5 white; 5 diabetes) received QW (n=10) or BIW (n=2) IV vitamin D analog therapy. Nine patients received doxercalciferol (mean dose 3.9 mcg/week; range 1.5-8 mcg/week), and 3 received paricalcitol (1 mcg/week). Results provided in table below. We defined responders as those patients who either had an elevated PTH (>300) which declined with therapy, or who had a PTH in target (150-300) that remained in target.

| | Baseline | 3 months |
|---|---|---|
| | mean (±SD) | mean (±SD) |
| **iPTH (pg/mL) all** | 370 (254) | 492 (311) |
| iPTH (pg/mL) responders | 324 (223) | 303 (158) |
| iPTH (pg/mL) non-responders | 433 (331) | 755 (279) |
| **cCa (mg/dL)** | 9.4 (0.45) | 9.0 (0.55) |
| **PO4 (mg/dL)** | 5.5 (1.6) | 5.1 (1.4) |

Of the 12 patients, 5 patients demonstrated significant increase in PTH value (non-responders) and were subsequently changed back to TIW dosing. The need for more frequent dosing did not appear to be dependent on initial PTH level, specific vitamin D analog, or dose of vitamin D used. **CONCLUSIONS**: Less frequent IV (BIW or QW) vitamin D analog dosing appears to be an acceptable option in some patients. However, more information is needed to better prospectively identify patients in whom this regimen will be effective.

**CKD Is Associated with Increased Serum Levels of Energy-Regulating Hormones** Rodrigo B. Oliveira,[1] Luciene M. dos Reis,[1] Fabiana G. Graciolli,[1] Ana L. E. Cancela,[1] Maria Eugenia F. Canziani,[2] Aluizio B. Carvalho,[1] Lilian Cuppari,[2] Yves Sabbagh,[3] Vanda Jorgetti,[1] Susan Schiavi,[3] Rosa Ma Moyses.[1] *[1]Nephrology, University of Sao Paulo, Brazil; [2]Nephrology, Federal University of Sao Paulo, Brazil; [3]Genzyme Co.*

Recent studies have shown that bone and energy metabolism are balanced with each other and are likely co-regulated. Serum proteins, such as Leptin (Lep), Adiponectin (Adip) and Serotonin (Ser) regulate energy metabolism, as well as bone mass. Previous studies have shown an increase of Lep and Adi in CKD, but there is no data regarding Ser. We evaluated serum levels of Lep, Adip and Ser in 40 predialysis CKD patients [50 ± 11 yrs., creatinine clearance (CrCl) = 35 ± 16 ml/min] that were randomized to receive calcium acetate (Ca) or sevelamer hydrochloride (Sev) during 6 weeks. At baseline, median serum Lep was 19.7 ng/ml (5.6-54.1) and correlated significantly with BMI (R=0.55), serum phosphate (R=0.38) and 25 vitamin D (R = -0.49). Median serum Adip was 11.0 mg/ml (8.1-13.9. Serum Ser was elevated (220 ± 102 ng/ml), and correlated with BMI (R = -0.39) and CrCl (R = -0.42). After 6 wks on P binder therapy, we observed a significant decrease of serum Lep in the entire study population (19.7 vs. 14.9; $p < 0.05$). However, although presenting non-different baseline values, a significant decrease was observed only in Sev-treated patients (9.8 vs. 7.4 ng/ml; $p < 0.05$), whereas this was not found in Ca-treated patients (26.5 vs. 26 ng/ml, ns). We found no differences between the intra-group changes in serum Lep. No significant changes were seen in serum Ser after P binder therapy. Our results confirm that hormones that regulate energetic metabolism are dysregulated in CKD. The correlation between Lep and phosphate, and the apparent reduction of serum Lep after P binder therapy suggest that pharmacological inhibition could be achieved in CKD.

**Phosphate Binding by Sevelamer: Effects of HCl, Carbonate, Tablet, Powder & pH** Edward A. Ross,[1] Jennifer Paugh-Miller,[1] Chris Batich,[2] Sam Popwell.[2] *[1]Division of Nephrology, Univ. of Florida; [2]Dept of Materials Science & Engineering, Univ. of Florida, Gainesville, FL.*

**Background & Aims:** The amount of phosphate (P) bound by sevelamer is dependent on 1) uptake of aqueous P-containing solution into the expanding hydrogel, and 2) its cationic charge due to protonation during manufacture and that resulting from the milieu's acidity. With the importance of pH and physical properties of gel-expansion, we questioned whether there would be differences in P binding *in vitro* between sevelamer HCl and carbonate, and whether they were in tablet or powdered formulations.

**Methods:** We incubated sevelamer HCl (tablets or laboratory crushed) and carbonate (tablets or factory-powdered) for 1 hr at pHs 1, 2.3 or 7 (simulating degrees of gastric acidity), stirred at 37° C. They were then stirred at pH 7 for 3 hrs in a 20 mM P solution (simulating small bowel conditions). Atomic absorption quantified [P] for calculating P bound per gm binder.

**Results:** The sevelamer HCl *v.* carbonate compounds had statistically ($p>0.8$) similar P binding for every experimental condition. For tablets there was greater P binding with increasing levels of incubation acidity: for pH 7, 2.3 and 1 there was, respectively, 1.42, 2.97, and 4.22 meq P bound/g sevelamer HCl tablet; compared to 1.61, 2.26, and 4.61 meq/g sevelamer carbonate tablet ($p<0.001$), representing up to approx 200% greater binding between pH 1 and 7. While there was no difference in P binding powder *v.* tablet at pH 7, acidity had less of an effect on powders: 1.36, 1.78, and 2.73 meq/g sevelamer HCl powder *v.* 1.30, 1.51, and 3.29 meq/g sevelamer carbonate powder. Longer acid incubations at 3 hrs had no greater effect than that at 1 hr (p=NS).

**Conclusions:** Despite differences in the synthesis of sevelamer (HCl *v.* carbonate) and its formulation (tablet *v.* powder) there is similar P binding that has a significant dependency on pH in incubation conditions that we believe simulate exposure to gastric acidity in vivo. These *in vitro* findings support clinical P-binding equivalency between sevelamer HCl and carbonate; however, we believe hydrogel diffusin kinetics affect the pH dependency of P binding by tablets *v.* powdered formulations.

**Sevelamer Improves Serum Electrolyte Profile, Metabolic and Cardiovascular Markers and Survival in ESRD Patients on Hemodialysis Treatment** Siren Sezer, Sebnem Karakan, Nurhan Ozdemir. *Nephrology, Baskent University Hospital, Ankara, Turkey.*

**Background:** This study prospectively evaluated the 2 years impact of sevelamer hydrochloride and calcium acetate on the metabolic indices in HD patients.

**Methods:** 126 HD patients were included between 2007 to 2009. HD patients with serum phosphate levels more than 5.5 mg/dl were randomly assigned to sevelamer hydrochloride (group 1, n=63) or calcium acetate (group 2, n=63). Baseline laboratory and demographic features of the patient groups were similar.

**Results: P**atients in group 1 exhibited lower levels of serum potassium, total cholesterol, serum low-density lipoprotein and homocysteine and higher HDL and vitamin B12 levels. All cause of mortality was 8% in sevelamer and 11% in calcium acetate group (log-rank $p<0.05$).

Comparison between groups

| Parameter (serum) | GROUP 1 | | GROUP 2 | |
|---|---|---|---|---|
| | Baseline-24 month | p | Baseline-24 month | p |
| Phosphorus (mg/dL) | 8.0 ±3.2-6.1 ± 1.6 | <0.05 | 7.4± 1.5-5.7±1 | <0.05 |
| Alkaline phosphatase (UI) | 227±69-195±81 | <0.05 | 275 ±130-198 ±78 | <0.05 |
| Calcium (mg/dL) | 9.3±0.1-9,1±0.2 | <0.05 | 9.2± 0,8-9,7 ± 0,4 | <0.05 |
| iPTH (pg/mL) | 367.5±306.2 -385.5±298.4 | <0.05 | 492.6±384.2 -321.5 ± 199.7 | <0.05 |
| Ca x P product | 74,4±12.88 -55,51±11.8 | <0.05 | 68.08± 14,56 -55.25 ±10,9 | <0.05 |
| K (mmol/dL) | 4,95±0,65 -3,86±0,78 | <0.05 | 5,29±0,80- 5.14 ±0,73 | non significant |

## PUB105

**Efficacy and Tolerability of Lanthanum Carbonate in Clinical Practice. Retrospective Multicenter Study** Jose-Vicente Torregrosa,[1] M. T. Gonzalez,[2] Jorge B. Cannata-Andia,[3] Dolores Arenas,[4] Jesus Montenegro,[5] Jose Mora-Macia,[6] Emilio E. Gonzalez-Parra,[7] F. Rios.[8] *[1]H Clinic; [2]H Asturias; [3]H P Socorro; [4]H Galdakao; [5]FMC Granollers; [6]FJ Díaz; [7]FMC S Luciano; [8]H Belvitge.*

Introduction: Lanthanum Carbonate (LC) is an effective and well tolerated noncalcium-based phosphate binder to treat hyperphosphatemia in CKD patients. The efficacy and tolerability of LC therapy was assessed in daily clinical practice

Methods: Retrospective multicenter study recording data of patients starting LC and a follow-up 12 months from 65 Spanish HD units. Blood levels of P, Ca, PTH, AST, ALT, GGT were collected before starting LC and at 1,3,6,9 and 12 months. Adverse events (AEs) were recorded.

Results: 622 (406 male-216 female) were analyzed, mean age 61(22-94) years, time on dialysis 77±68,3 months, 23% diabetics. Evolution of P and Ca are shown in the Table 1. There was a statistically significant decrease in levels of P between basal visit and the follow-up analyzed visits ($p<0.01$)* with a total reduction of 25.2% from basal to final visit. No significant changes in PTH levels. Mean AST, ALT and GGT blood at starting and after 12 months were respectively (U/l): 17.1±10.3 vs 16.1±10.6, 16.5±11.8 vs 15.5±8.9 and 35.8±51.4 vs 41.4±83.8 (p=ns in all of them). 124 (19.3%) patients reported AEs. The most frequent AEs (%) were: nausea (16), flatulence (14), dyspepsia (13), constipation (13), abdominal pain (13), diarrhea (6), vomiting (5) and anorexia (5). None was of seriously intensity. The mean dose of CL was progressively increased during the first 6 months but not significantly.

| Visit (Months) | CL Average Dosage(mg) Mean±SD | P Levels ( mg/dl) Mean±SD | Ca Levels ( mg/dl) Mean±SD |
|---|---|---|---|
| Basal | 1906.9±603 | 6.47±1.4 | 9.00±1.29 |
| 1 | 2008.5±639 | 5.48*±1.5 | 9.00±0.9 |
| 3 | 2189.4±671 | 5.36*±1.5 | 8.98±1.24 |
| 6 | 2297.0±749 | 5.03*±1.4 | 8.99±1.24 |
| 9 | 2318.6±821 | 5.04*±1.3 | 9.00±0.89 |
| 12 | 2290.6±783 | 4.84*±1.3 | 8.90±0.91 |

Conclusion: In clinical practice, LC was significantly effective since the first month, showing a progressively reduction of P levels. LC showed acceptable tolerance and safety profile.

## PUB106

**Non-Invasive Assessment of Renal Osteodystrophy: Comparison of Bone Histology with Quantitative Computed Tomography (QCT)** Katherine Wesseling-Perry,[1] Harald Jueppner,[2] Vicente Gilsanz,[3] Kevin V. Lemley,[3] Joshua Zaritsky,[1] Barbara Gales,[1] Isidro B. Salusky.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Endocrine Unit, Harvard Medical School/Mass General Hospital, Boston, MA; [3]Children's Hospital Los Angeles, Los Angeles, CA.*

The need for non-invasive assessment of bone has been emphasized by KDIGO. Thus, femoral shaft and lumbar vertebral structure were characterized by QCT in 28 CKD pts. (19M/9F, 23 CKD5/5 CKD2-4, age 16±2 yrs). Values were compared to healthy children of similar age and size. Biochemical values (SD) were: Ca: 8.9±0.9 mg/dl; P:5.8±1.3 mg/dl; Alk P'tase: 267±190 IU/L; tCO2: 22±4 mEq/L; PTH: 549±324 pg/ml. Both lumbar and femoral bone density were greater in patients than in normal controls (cancellous bone Z: 1.7±2.1(SD) ($p<0.05$ from control), cortical bone Z: 0.9±1.4 ($p<0.05$ from control)). 16 subjects underwent BBx within 2 wks of imaging and histomorphometric parameters were compared to QCT measures [table 1]. Femoral CBD was inversely correlated with trabecular separation but directly related to osteoid accumulation. Femoral CBD was inversely correlated with Alk P-tase (r= - 0.38, z=1.91). Thus, defects in bone structure and mineralization may be detectable by QCT; further studies are warranted.

Correlation between Bone Histology and QCT

| QCT | Bone Histology | | | | |
|---|---|---|---|---|---|
| | Bone volume (BV/TV) (%) | Trabecular number (Tb.N) (n) | Trabecular Separation (Tb. Sp) (um) | Osteoid volume (OV/BV) (%) | Osteoid thickness (O.Th) (um) |
| Vertebral cancellous bone density | r=0.24, NS | r=0.27, NS | r= - 0.33, NS | r=0.30, NS | r=0.27, NS |
| Vertebral cross sectional area | r= - 0.12, NS | r= - 0.04, NS | r= -0.11, NS | r=0.10, NS | r=0.17, NS |
| Femoral cortical bone density | r=0.07, NS | r=0.43, p=0.09 | r= - 0.21, NS | r= - 0.01, NS | r= - 0.04, NS |
| Femoral cross sectional area | r=0.24, NS | r=0.39, p=0.13 | r= - 0.62, p=0.01 | r=0.24, NS | r=0.42, p=0.10 |
| Femoral cortical bone area | r=0.35, NS | r=0.41, p=0.12 | r= - 0.67, p<0.01 | r=0.35, NS | r=0.40, p=0.12 |

## PUB107

**Cinacalcet Hydrochloride with Very Low Doses of Vitamin D Does Not Reduce the Poorly Mineralized Bone Areas in Patients with Secondary Hyperparathyroidism** Aiji Yajima,[1] Masaaki Inaba,[2] Shigeru Otsubo,[3] Kosaku Nitta,[4] Tadao Akizawa.[5] *[1]Nephrology, Towa Hospital, Tokyo, Japan; [2]Metabolism, Endocrinology and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan; [3]Nephrology, Sangenjaya Hospital, Tokyo, Japan; [4]Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan; [5]Nephrology, Showa University, School of Medicine, Tokyo, Japan.*

Purpose; The increase of poorly mineralized bone areas will lead to high fracture rate. Direct mineralization around lacunae was seen and the poorly mineralized areas were significantly reduced after parathyroidectomy (Renal Week 2009, JBMR in press). We investigated changes in poorly mineralized areas after the treatment with cinacalcet hydrochloride (HCl).

Methods; Seven hemodialysis (HD) patients received 12.5-50 mg/day of cinacalcet HCl with 0.5-1.5 µg/day of oral alfacalcidol for 1 year (Group I) to reduce serum PTH levels. In addition, three other HD patients received cinacalcet HCl with 2.5-5.0 µg/day of Maxacalcitol intravenously for 1 year (Group II). Transiliac bone biopsy specimens were obtained before and after the treatment to measure the poorly mineralized area in basic multicellular unit (PM.BV/BV(BMU)) and bone structural unit (PM.BV/BV(BSU)).

Results; PM.BV/BV(BMU) before and after the treatment were 15.6 ± 11.2 and 15.0 ± 14.6 % in Group I, but were reduced from 4.5 to 1.3 %, from 0.9 to 0.5 %, and from 0.7 to 0.5 %, in the 3 Group II patients, respectively. PM.BV/BV(BSU) before and after the treatment were 5.0 ± 12.7 and 7.9 ± 4.6 % in Group I, but were reduced from 11.3 to 1.6 %, from 6.4 to 1.1 %, and from 5.5 to 2.4 %, in the 3 Group II patients.

Conclusions; Plasma $1,25(OH)_2D_3$ levels measured from 7 to 10 days after the initial administration of 2.0 µg/day of alfacalcidol were below the upper limit of the normal range (20 to 60 pg/mL) (AJKD 2003). Oral administration of 0.5-1.5 µg/day of alfacalcidol may not be effective to mineralize the uncalcified matrix and poorly mineralized areas could not be reduced after the treatment with cinacalcet HCl, though 2.5µg/day or more of Maxacalcitriol is sufficient to reduce the poorly mineralized areas in patients receiving cinacalcet HCl.

Disclosure of Financial Relationships: nothing to disclose

## PUB108

**Severe Hypercalcemia on Osteoporosis Prevention with Calcium-Vitamin D Supplements in Elderly Patients with Chronic Kidney Disease** Yisfalem W. Alamdew, Hugo J. Villanueva, Lin N. Lwin, Jinil Yoo. *Nephrology, Montefiore Medical Center North Division, Bronx, NY.*

One of the most prevalent and disabling medical conditions in elderly women is osteoporosis for which daily supplement of cacium-vitamin D (Ca-Vit D) is recommended. In a sub group of elderly women with chronic kidney disese(CKD), severe symptomatic hypercalcemia is observed without a clear etiology even after extensive diagnostic work-ups for malignancies, hyperparathyroidism, and granulomatous diseases, but with clinical evidences of low bone turnover and on daily dose of Ca-Vit D.

We illustrate 2 cases who were on Ca-Vit D for osteoporosis. Case I who was on metolazone for fluid overload presented initially with hypercalcemia (18.5mg/dL), and metabolic alkalosis ($HCO_3$ 31 mEq/l and PH=7.51), suggestive of milk-alkali syndrome. Case II had several episodes of symptomatic hypercalcemia of undetermined etiology and underwent a bone biopsy, diagnostic of adynamic bone disease. The following is a summary of clinical features.

| | Case I | Case II |
|---|---|---|
| Age/Gender | 79/Female | 76/Female |
| CKD stage/etiology | III to IV/type II DM | IV to V/hypertension |
| Serum calcium (mg/dL) (8.5-10.5) | 18.5 | 13.3 |
| Phosphate (mg/dL) (2.5-4.5) | 3.5 | 5.8 |
| Albumin (g/dL) (3.2-4.8) | 4.1 | 3.3 |
| Intact PTH * (pg/dL) (10-65) | 4.7 | 12.3 |
| 25(OH) Vit-D (ng/dL) (10-55)** | 38 | 16 |
| 1,25(OH)$_2$ Vit-D (pg/dL) (20-76) | 14 | 16 |

* Parathyroid hormone ** The Laboratory's reference range

The hypercalcemic episodes were resolved quickly with treatment and not recurred by avoiding Ca-Vit D supplements. The PTH rose gradually above normal levels. A subgroup of elderly patients with CKD have low to normal levels of PTH, decreased urinary calcium excretion because of decreased GFR but normal intestinal calcium absorption in presence of normal 25-OH Vit D and/or 1,25(OH)$_2$ Vit D, especially on Ca-Vit D supplements. In these cases, a low bone turnover induced by relatively suppressed PTH, can cause hypercalcemia because of its decreased calcium buffering capacity.

We present our cases to heighten awareness of the disorder, "hypercalcemia and low bone turnover in CKD" on elderly women with Ca-Vit D supplements for osteoporosis.

## PUB109

**Paricalcitol Use Allows Greater Exposure to Vitamin D Receptor Activation Compared to Doxercalciferol in Hemodialysis Patients** Utpaul Audhya, Samina Khan, Beverly A. Johns, Steven E. Marx. *Abbott, Abbott Park, IL.*

INTRODUCTION: Vitamin D receptor (VDR) activators have a suppressive effect on the RAAS, as well as anti-inflammatory and anti-fibrotic effects, which most likely accounts for their overall mortality benefit. Improved survival with higher dose of VDR activators has previously been established. The objective of this study is to compare VDR activation by using dose exposure between paricalcitol and doxercalciferol in adult hemodialysis patients.

METHODS: A cohort analysis from 2004 through 2009 was conducted in a large dialysis organization in adult hemodialysis patients. Cohorts were based on adult patients receiving a minimum of 10-consecutuive doses of paricalcitol or doxercalciferol. Consecutive was defined as simultaneous dialysis session. The index date was the first dose of paricalcitol or doxercalciferol. Generalized linear models with a log link Poisson regression, adjusting for age, gender, race, diabetes status, study entry period, and iPTH was conducted. A propensity matched (age, gender, race, diabetes status, iPTH) analysis was conducted as described above. An additional subanalysis was conducted including baseline albumin in the propensity match.

RESULTS: Multivariate analysis of paricalcitol-treated patients (n=39,476) vs. doxercalciferol-treated (n=2,681) demonstrated statistically significant greater number of doses administered with paricalcitol: 1.12, p<0.0001. Propensity matched analysis (n=2,671 per cohort) demonstrated similar results: 1.10, p<0.0001 more doses administered in the paricalcitol cohort compared to doxercalciferol cohort. The subanalysis including baseline albumin demonstrated the same results: 1.10, p<0.0001.

CONCLUSION: This study demonstrated that in both a multivariate and a propensity matched analysis patients received more doses in paricalcitol treated cohort compared to the doxercalciferol cohort. More VDR activator doses administered may lead to greater vitamin D receptor activation, which may improve clinical outcome. Further research is needed to confirm these results.

## PUB110

**Anemia and Vitamin D Deficit in Chronic Kidney Disease Stage 2-5nd: A New Vitamin D Pathogenic Role?** Secundino Cigarran,[1] Emilio E. Gonzalez-Parra,[3] Guillermina Barril,[4] Francisco Coronel,[2] Montserrat Pousa.[1] *[1]Nephrology, Hospital Da Costa, Burela, Lugo, Spain; [2]Nephrology, Hospital Clinico San Carlos, Madrid, Spain; [3]Nephrology, Fundación Jimenez Díaz, Madrid, Spain; [4]Nephrology, Hospital Universitario de La Princesa, Madrid, Spain.*

Patients with chronic kidney disease (CKD) are at high risk for cardiovascular disease, and despite recent advances in hypertension control, anemia management, mortality remains high. Vitamin D deficiency is high at early stages of CKD and plays a biologic role, independiently associated to decrease glomerular filtration rate (GFR), as a pleitropic hormone. The aim of this, cross-sectional, study is to assess the vitamin D influence on anemia in CKD patients.

563 pts were enrolled,mean age 68-±13 years, mean GFR 46.67± 23.9 ml/min/1.73m$^2$, 38% female and 30% DM, mean Hb level 13.16 ± 1.68 gr/dl. Anemia defined as Hb level<12.5 gr/dl was met in 201 patiens (35.9%), Parameters analyzed were, Hb, eGFR, nutritional (albumin, prealbumin), inflammation (C reactive protein, fibrinogen) and cardiovascular (Uric acid, urinaryAlb/ creatinin index) parameters and mineral bone markers. Data were analyzed with SPSS 15 for Windows (SPSS, Chicago ILL. USA).

Compared with non anemic patients, anemic were older (71.17± 11.79 vs 66.03±13.7 years , P< 0.001), diabetic (35.6 vs 25.7% , P<0.001), lower GFR (36.54±17.9 vs 52.36 ± 25.0, p< 0.001).

T paired test

| Variable | Anemic ( N=201) | Non Anemic N=359 | P |
|---|---|---|---|
| Serum Albumin (gr/dl) | 4.18 ±0.41 | 4.34±.30 | .001 |
| Prealbumin (mg/dl) | 29.93±6.96 | 31.62±7.13 | .001 |
| Calcium (mg/dl) | 9.20±.53 | 9.38±.41 | .001 |
| Phophorous (mg/dl) | 3.76± .83 | 3.41±..61 | .001 |
| Parathormone (pg/ml) | 100±96.8 | 68±57.3 | .001 |
| CaxP (mg2/dl2) | 34.59±8.11 | 32.52±6.66 | .001 |
| 25 vit D (ng/ml) | 16.7±9.47 | 18.6±10.7 | .043 |
| 1, 25 D3 (pg/ml) | 34.6±14.24 | 40.85±16.43 | NS |
| Urinary Alb/Cr Index (mg/gr crea) | 541.63±1260 | 295.2±598 | .001 |

NS = Not Significance

Conclusion: Vit D has influence on anemia. Given the high prevalence of anemia and 25 D deficiency, further studies should explore the effects of 25D nutritional replacement on erythropoiesis in CKD patients.

## PUB111

**Comparison of Diasorin LIAISON Vitamin D Assay Against LC-Tandem MS in a CKD Cohort from the CanPREDDICT Study** Daniel T. Holmes, Suzette M. Walsh, Hans Frykman, Ognjenka Djurdjev, Adeera Levin. *University of British Columbia.*

The purpose was to compare an automated 25(OH)VitaminD (VitD) method with a reference method in patients with CKD. A 416 pt cohort was taken from the Canadian Study of Prediction of Risk and Evolution to Dialysis, Death and Interim Cardiovascular Events Over Time (CanPREDDICT) study. Serum was collected at 25 Canadian sites and stored at -80°C until analysis. LCMSMS was performed on the Applied Biosystems API5000 using a modification of their iMethod. Automated VitD, Bone ALP (BAP), and 1-84PTH analysis was performed using the Diasorin LIAISON analyzer (kits provided by Diasorin). Passing Bablok regression was: LIAISON=0.980[CI 0.932-1.031]xLCMSMS-2.89[CI -5.45,-0.134]nM. Correlation between methods was:ρ=0.90 overall, 0.55 for definite deficiency (<25nM,n=27),0.77 for moderate deficiency (25-75nM,n=227), and 0.57 for VitD sufficient pts (>75nM,n=162). Interpretive concordance rates (CI) in these 3 categories were: 0.85(0.65-0.95), 0.88(0.83-0.92), and 0.80(0.73-0.86). Discrepancies did not appear related to eGFR. The Diasorin LIAISON VitD method produces more accurate results compared to LCMSMS than has been previously reported, with slightly lower ρ. Clinical concordance rates of LCMSMS and LIAISON VitD results were reasonable to good.

## PUB112

**Intraperitoneal Paricalcitol Therapy in CAPD Patients with Secondary Hyperparathyroidism** Ji-Min Jeon, Yong-Ki Park. *Divison of Nephrology/ Internal Medicine, DongRae BongSeng Hospital, Busan, Korea.*

Secondary hyperparathyroidism(2HPT) is a major complication in ESRD patients undergoing dialysis. In hemodialysis patients with secondary hyperparathyroidism, intravenous administration of paricalcitol became widely utilized. In CAPD patients, however, the intravenous administration of paricalcitol which requires frequent visits to the clinic is not practical. The purpose of this study was to determine the safety and effect of intraperitoneal paricalcitol therapy in CAPD patients. The subjects of this study were two CAPD patients with 2HPT . They had already received oral calcitriol pulse therapy for 3 months. and they had refused parathyroidectomy and intravenous paricalcitol which require frequent visit to the hospital. and It is not introduced paricalcitol capsule in korea yet. so, We have experimentally tried the intraperitoneal paricalcitol therapy. Two patients were taught to inject the paricalcitol(5μg) directly into the dialysate three times per week before bedtime. Blood samples for measurement of intact parathyroid hormone(iPTH),

serum ionized calcium, serum phosphate, serum total alkaline phosphatase levels were obtained at baseline and 1,2,3 months of treatment. If hypercalcemia(>10.5 mg/mL) and hyperphosphatemia(>6.5 mg/dL) developed, the patients were stopped from treatment. After intraperitoneal paricalcitol for 3 months, there was a significant drop of iPTH leve.

Table 1.Patients characteristics and serial change of intact parathyroid hormone

| | Age(years) | Sex | Duration of CAPD(months) | Baseline(pg/mL) | 1 month | 2 months | 3 months |
|---|---|---|---|---|---|---|---|
| Case 1 | 55 | Male | 98 | 924 | 684 | 621 | 598 |
| Case 2 | 70 | Male | 82 | 870 | 852 | 764 | 707 |

There were no definite hypercalcemia and hyperphosphatemia. In conclusion, Intraperitoneal paricalcitol therapy might be effective for suppressing iPTH in CAPD patients with 2HPT. A large-scale and longterm study must be conducted for safety and clinical effect

Disclosure of Financial Relationships: nothing to disclose

**Racial Differences in Vitamin D, Parathyroid Hormone and Fibroblast Growth Factor-23 Levels in Chronic Dialysis Patients** Anna Jeanette Jovanovich,[1] Michel B. Chonchol,[1] Alfred K. Cheung,[2,4] James S. Kaufman,[3] Tom H. Greene,[4] William L. Roberts,[4] Gerard John Smits,[1] Jessica B. Kendrick.[1] *[1]University of Colorado Denver Health Sciences Center, Denver, CO; [2]VASLCHCS, Salt Lake City, UT; [3]VA Boston Healthcare System, Boston, MA; [4]University of Utah, Salt Lake City, UT.*

Purpose: Abnormalities of mineral metabolism have not been described across races in patients requiring dialysis.

Methods: Study was conducted among 654 dialysis patients who participated in the Homocysteine in Kidney and End Stage Renal Disease study. 25-hydroxyvitamin D [25(OH)D], calcitriol, intact parathyroid hormone (iPTH), and fibroblast growth factor (FGF-23) levels were measured in plasma samples. Multivariable regression analyses were performed to investigate the association between race and levels of vitamin D, iPTH, and FGF-23 levels.

Results: There were a total of 654 patients on chronic dialysis. 51% was non-Hispanic black (NHB), 38% was non-Hispanic white (NHW) and 11% were categorized as other races. NHB had the lowest 25(OH) D levels when compare to NHW and others (15.0±10.0 vs. 21±31 vs. 24±25 ng/mL respectively; p<0.0001). There was no significant difference in calcitriol levels among races. NHB had higher iPTH concentrations than NHW and others (326±299 vs. 232±263 vs. 275±246 pg/mL respectively; p<0.0001). The median [IQR] FGF-23 levels among NHB, NHW and those of other race were 3914 [1350-13682], 4036 [1393-12878] and 5658 [1916-16017] RU/mL, respectively (p=0.14). After adjustment for demographics and cardiovascular risk factors, NHB was independently associated with lower 25(OH)D (β= -0.12; p=0.009) and higher iPTH (β=0.12; p=0.005) levels than non-Blacks. NHB was independently associated with increased iPTH when further adjusted for calcium, phosphorus, 25(OH)D, calcitriol and FGF-23 suggesting other mechanism play a role in elevated iPTH levels in NHB on dialysis. There were no racial differences for FGF-23 levels in multivariable-adjusted models.

Conclusions: Disorders of mineral metabolism, particularly low 25(OH)D and elevated iPTH levels are more severe in NHB when compare to non-blacks requiring dialysis.

**Role of Teriparatide in the Treatment of Hypocalcemia Related to Hypoparathyroidism Post-Renal Transplantation** Estela Nogueira, Alice Santana, José Guerra, Sonia Silva, Clara Mil-Homens, Antonio Gomes da Costa. *Nephrology, Hospital Santa Maria, CHLN, EPE, Lisbon, Portugal.*

The aim of this study was to retrospectively analize the efficacy and safety profile of teriparatide use, in patients with severe hypocalcemia post kidney transplant, due to previous parathyroidectomy. Teriparatite is a recombinant human PTH that was approved by U.S FDA for the treatment of osteoporosis with high risk of fracture. Additionally, some studies have suggested a role in the management of iatrogenic hypoparathyroidism post kidney tranplantation.

Efficacy was evaluated by calcium and phosphorus serum levels, calcium carbonate and calcitriol doses administrated and safety profile by serum creatinine levels and secondary effects pre and post therapy with teriparatide (Forteo®), at 20µg/day administred subcutaneously.

5 patients (3F and 2M), with 52±9,2 years (mean±SD) developed severe hypocalcemia (5,6±0,9mg/dl) immediately following renal transplantation, requiring high doses of calcium gluconate at 10% (4,4±1,5 vials/day). PTH levels were under the normal range (5,3±7,7pg/ml) and as hypocalcemia persisted, teriparatide was administred 33±11days post transplant. After therapy, calcium levels increased (7±1.2 vs 8.5±1.2mg/dl) and phosphorus levels declined (5,4±1.5 vs 4 ±0.9 mg/dl). Simultaneously, calcium carbonate (12,2±7,2 vs 6±2 g/day) and calcitriol (4±1.5 vs 2.5±1 cp/day) required doses decreased and intravenous calcium was suspended in all patients. Teriparatide therapy was maintained during 13.8±10,8 months. In 2 patients it was not possible to suspend it (at 17 and 30 months respectively) and another patient required it after a withdrawal period, due to persistent hypocalcemia. No secondary effects were reported and serum creatinine levels remained stable after teriparatide administration.

Our data suggest that teriparatide use was safe and efficient to stabilize calcium levels and decreased calcium and calcitriol requirements in patients with iatrogenic hypoparathyroidism post-kidney transplant.

**Hypophosphatemia and Secondary Hyperparathyroidism Associated with Bisphosphonate Use** Uzoamaka T. Nwaogwugwu, Barbara A. Clark. *Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.*

Maintaining normal phosphorus is essential for cellular function. Hypophosphatemia may present as nonspecific symptoms of myalgias/ weakness. There are very few reports of acquired drug induced hypophosphatemia and hyperphosphaturia and most of these are attributed to direct proximal tubular toxicity. We report a case of symptomatic hypophosphatemia attributed to secondary hyperparathyroidism associated with chronic use of alendronate. A 55 yo woman with osteopenia maintained on alendronate for 4 years presented with several months of unexplained fatigue and myalgias. Serum phopsphorus levels were repeatedly less than 2.3 mg/dl over a 4 month period despite attempts to replete with oral phosphate. She was referred for further evaluation. She was vitamin D replete (on weekly vitamin D3 50,000 IU weekly for the past 4 years) (25 OH vitamin D levels 45-53 ng/ml; 1,25 vitamin D level 31 pg/ml). Urine phosphorus was 1500 mg/24h; urine calcium 408mg/24h, corrrected serum calcium 8.9-9.7 mg/dl and intact PTH levels were persistently mildly elevated (71-80 pg/ml). Alendronate was held for one month without any improvement in the lab values or symptoms. Work up for primary hyperparathyroidsim with neck CT scan, US and sestamibi scan were unrevealing. A trial of cinacalcet corrected the hypophosphatemia and hyperparathyroidism (phosphorus 2.9 mg/dl; calcium 8.6 mg/dl, iPTH 58 pg/ml) and the patient felt better. The cinacalcet was discontinued after 8 months and all parameters remained normal an additional 8 months later. This is consistent with the known delayed clearance of alenodrante from bone stores. We present a case of symptomatic hypophosphatemia occuring after long term bisphosphonate use that took months to resolve. The correction with cinacalcet confirms the mechanism as secondary hyper parathyroidism, but was not related to hypocalcemia or vitamin D deficiency, as our patient had neither. We recommend periodic screening of serum phosphorus and PTH with chronic bisphosphonante use, especially if there are complaints of muscle pain or weakness. The mechanism for the hyperparathyroidism remains to be elucidated but can occur in the absence of hypocalcemia.

**PUB116**

**Is Pamidronate More Effective Than Alendronate in Adult Patients for the Prevention of Bone Loss after Kidney Transplantation?** Rasika A. Sirsat, Vipla S. Puri, Sandeep Dasharath Holkar, Alan F. Almeida, Amit Chandrakant Langote, Jatin Piyush Kothari, Rajaram R. Jagdale. *Nephrology, P D Hinduja Hospital, Mumbai, Maharashtra, India.*

Purpose: A randomized non blinded study comparing safety and efficacy of Pamidronate versus Alendronate for the prevention of bone loss after renal transplantation in adult patients.

Methods: A total of 41 patients were randomly assigned to receive either Alendronate (70 mg/wk for 1 year) or Pamidronate (60 mg IV injection at baseline and at 6months post transplantation. All patients were also given oral calcium 1 g and 500 IU vitamin D supplements daily. Estimates of BMD by DEXA , Sr Calcium, Sr Phosphorus, Sr albumin, Sr Alkaline phosphatase, PTH , vitamin D, Osteocalcin, Urine crosslaps were done at baseline and at one year.

Results: Baseline characteristics in both groups were similar with respect to immunosuppressive protocols, calcineurin exposure, steroid use, age, calcium, phosphorous and Vitamin D levels. In both Alendronate and Pamidronate groups, a mean rise in BMD of femur and spine, osteocalcin and a decrease in serum PTH was seen but failed to reach statistical significance. Parameters such as albumin, Calcium, Phosphorus and Vitamin D showed significant increase from baseline among both the groups .Other parameters such as Sr Calcium, Alkaline phosphatase, Osteocalcin, PTH, Urinary crosslaps were comparable but the difference was not statistically significant. There was statistically significant increase in mean femur T score of 20.2% in Alendronate group which was statistically significant( P< 0.05 ). None of the patients had to discontinue bisphosphonates due to any adverse effects during the study period.

Conclusions : Our study confirms that bisphosphonate use is safe and efficacious for the prevention of bone loss in renal transplant patients. Alendronate group showed statistically significant increase in femur T score as compared to Pamidronate group and needs further study as to whether additional doses of pamidronate need to be given.

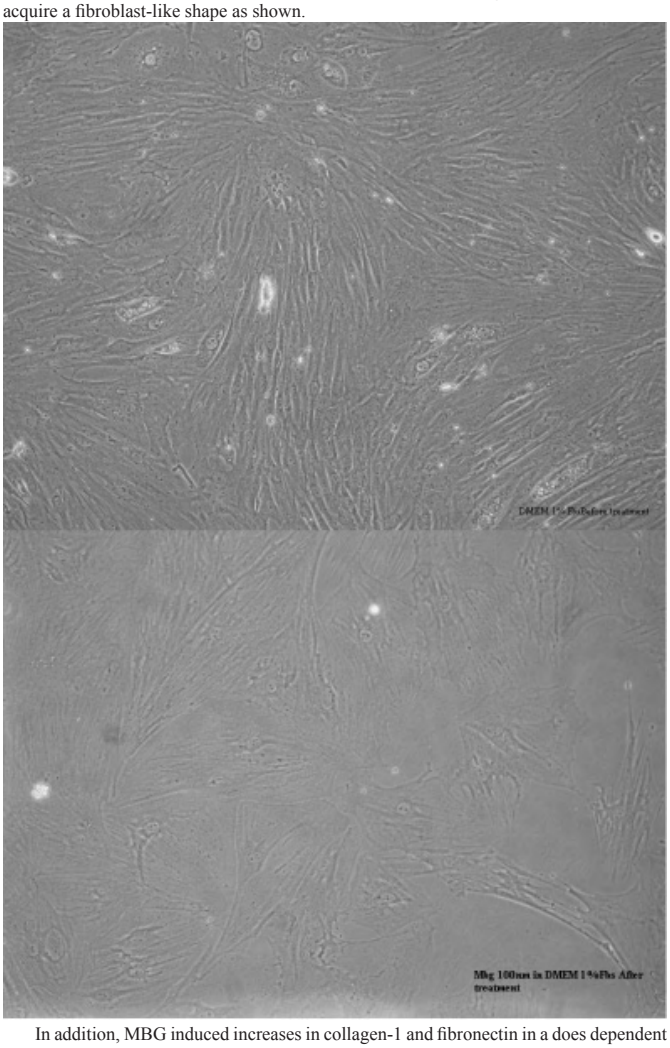
**Rat Bone Marrow Derived Mesenchymal Stem Cells Differentiate into Fibroblast-Like Shaped Cells in the Presence of Marinobufagenin** George Budny,[1] Sankaridrug Periyasamy,[1] Alexei Bagrov,[2] Olga Fedorova,[2] Christopher J. Cooper,[1] Nader Abraham,[1] Joseph I. Shapiro.[1] *[1]Medicine and Physiology/ Pharmacology, University of Toledo Medical Center, Toledo, OH; [2]National Institute of Aging, Baltimore, MD.*

We recently demonstrated that the cardiotonic steroid marinobufagenin (MBG) induces cardiac and renal fibrosis in vivo as well as directly stimulates collagen type I secretion by isolated fibroblasts. However, it is unclear how much fibrosis is due to the activation of resident fibroblasts in tissues as opposed to other processes. In this study, the effect of MBG on differentiation of bone marrow derived mesenchymal stem cells in rats was investigated. Mesenchymal stem cells (MSCs) are multipotent stem cells that can differentiate into a variety of cell types including renal tubular epithelium and fibroblasts. To examine whether MBG alone can trigger MSC differentiation into fibroblasts, we used

MSCs prepared in our lab from bone marrow which was extracted from Sprague-Dawley rat's tibia and femur bones. The cells were cultured and subcultured in DMEM with 15%FBS until they reached confluence. We then treated the MSCs with MBG in different concentrations. Digital photographs were taken 24 hours after adding the MBG to the cell culture media (DMEM with 1%FBS). Cells were also collected and protein expression was measured with Western blot. MBG (100 nM) caused MSCs grown to confluence to acquire a fibroblast-like shape as shown.



In addition, MBG induced increases in collagen-1 and fibronectin in a does dependent fashion. Our data suggest that cardiotonic steroids such as MBG may be an important factor in inducing MSCs differentiation into fibroblasts and, through this mechanism, may play a role in progressive renal fibrosis.

**Leptin Exerts a Pro-Apoptotic Effect on Rat Renal Tubular Cells Via Prostaglandin $E_2$ Aggregation** Yen Cheng Chen,[1] Yung-Ho Hsu,[2] Cheng-Hsien Chen,[1] Tso Hsiao Chen.[1] *[1]Division of Nephrology, Taipei Medical University-Wan Fang Medical Center, Taiwan; [2]Division of Nephrology, Taipei Medical University-Shuang Ho Hospital, Taiwan.*

Leptin, a circulating hormone secreted mainly from adipose tissues, is reported to act on kidney in pathophysiological states. However, the influence of leptin on renal tubular epithelial cell is still unclear. In the present study, we intended to investigate the influence of leptin on gentamicin-induced aoptosis in rat renal tubular cells. Gentamicin-induced apoptosis in renal tubular cells (NRK-52E) was examined using terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick end-labeling. We found that the 48-h treatment of leptin with a high dosage (from 50 to 250 ng/ml) exerted a pro-apoptotic effect on gentamicin-induced apoptosis in NRK-52E cells although an anti-apoptotic effect was found at 24 h. Leptin obviously reduced the expression of Bcl-$x_L$, and increased cleaved caspase-3 in 48-h treatment. In caspase-3 activity assay, the gentamicin-induced activity of caspase-3 was also reduced by leptin treatment at 24 h, but enhanced at 48 h. We also found that leptin induced the expression of cyclooxygenase-2, prostacyclin ($PGI_2$) and prostaglandin $E_2$ ($PGE_2$) in a dose-dependent manner. The siRNA transfection for $PGI_2$ synthetase diminished the anti-apoptotic effect of leptin at 24 h, and enhanced the pro-apoptotic effect at 48 h. Additionally, NS398 blocked $PGE_2$ augmentation and the pro-apoptotic effect of leptin at 48 h. Our results reveal that a long-term treatment of leptin exerts a pro-apoptotic effect on rat renal tubular cells through $PGE_2$ aggregation.

**Hyperosmolal Microenvironments Induce Differentiation of Bladder Epithelial Cells in Culture** Bradley P. Dixon, Jeff Henry, John J. Bissler. *Division of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Urinary bladder epithelium is chronically exposed to a hyperosmolal microenvironment. Superficial urothelial cells adapt to this microenvironment through the accumulation of organic osmolytes and formation of the asymmetric unit membrane comprised of uroplakins on the apical cell surface. Failure to activate such differentiation in cells repairing inflammatory or surgically created defects in the bladder epithelium and exposed to hyperosmolality may lead to osmotic stress, an aberrant DNA damage response, and apoptosis.

We cultured a novel urothelial cell line, ULTI, under isoosmolal culture conditions as well as gradually adapted these cells to osmolalities of both 450 mOsm/kg and 600 mOsm/kg by addition of either sodium chloride or urea. Cell proliferation was measured by both trypsin detachment and counting with a hemocytometer, and by crystal violet DNA staining. Cells were lysed, RNA and protein were isolated, and RT-PCR was performed to detect markers of urothelial differentiation such as cytokeratin 18, cytokeratin 20 and uroplakin II. Western blot was used to measure activation of apoptosis through cleavage of PARP and caspase-3.

ULTI cells demonstrated robust proliferation under isoosmolal conditions, but arrested proliferation following adaptation to hyperosmolal conditions. Markers of apoptosis were not present in cells gradually adapted to hyperosmolality. Under both isoosmolal and hyperosmolal conditions, ULTI cells express cytokeratin 18 indicating their epithelial nature. However, only cells gradually adapted to hyperosmolal conditions demonstrated both cytokeratin 18 and 20 expression, indicative of an "umbrella cell" phenotype.

These results demonstrate that a hyperosmolal microenvironment can facilitate urothelial cell differentiation. Failure of cells to activate this differentiation program may lead to osmotic stress, aberrant DNA damage response, and ultimately apoptosis or carcinogenesis.

**Protease-Activated Receptor-2 in Renal Cell Carcinoma** Glenda C. Gobe,[1] Retnagowri Rajandram,[1] Jacky Yung Suen,[2] David Fairlie,[2] David W. Johnson,[1] David A. Vesey.[1] *[1]Centre for Kidney Disease Research, The University of Queensland, Brisbane, Queensland, Australia; [2]Institute for Molecular Bioscience, The University of Queensland, Brisbane, Queensland, Australia.*

Protease Activated Receptor-2 (PAR2) is a G protein-coupled receptor that is activated by trypsin-like proteases. It is implicated in the progression of pancreatic, colon and stomach cancers where its expression is often enhanced and one of its natural ligands trypsin, is frequently over produced. Its role in clear cell renal carcinoma (ccRCC) has not been investigated. The aims of this study were to examine: 1. PAR2 and trypsin/trysinogen (TRY) expression in ccRCC tissue and 2. The effect of PAR2 activation on RCC cell proliferation.

A tissue microarray (TMA) consisting of 67 confirmed archived cases of ccRCC and paired uninvolved cortical renal tissue was constructed. Sections were stained for PAR2 and TRY. Cell surface PAR2 was examined in the RCC cell lines Caki-1, ACHN, SN12K1, 786-O A498 and primary cultures of human proximal tubule cells (PTC) by an intracellular $Ca^{2+}$ mobilization assay (fluo-3 fluorimetry). TRY expression was measured by immunoblotting and DNA synthesis by $^3$H-thymidine incorporation.

PAR2 expression was greater and more intense in the normal tissue, (proximal tubules), than ccRCC tissue (84.4% vs 59.7%). There was negligible staining in distal tubular cells (DTC). TRY staining was greater in the ccRCC tissue than the normal tissue (94% vs 85.7%). Both PTC and DTC showed cytoplasmic staining. Cultured PTC showed the highest level of PAR2 cell surface expression, similar in magnitude to the colon carcinoma cell line, HT29. The other RCC cells showed decreasing levels of cell-surface PAR2 (Caki-1>ACHN>786-O>A498>SN12K1). By immunoblotting all the cell lines showed some TRY expression including the PTC. Trypsin (5nM) but not the PAR2 activating peptide, 2f-LIGRLO-$NH_2$ (2μM), increased DNA synthesis Caki-1 cells.

Both PAR-2 and TRY are expressed in ccRCC tissue and may contribute to cancer progression. TRY induces DNA synthesis in Caki-1 cells by a PAR2 independent mechanism.

**The Direct Effects of Hepcidin-25 on Human Proximal Tubular Epithelial Cells** Steven Michael Harwood, Elizabeth Miller, Martin J. Raftery, Magdi Yaqoob. *Translational Medicine and Therapeutics, Queen Mary, University of London, London, United Kingdom.*

Hepcidin is a peptide hormone primarily synthesized in the liver that is a key mediator of iron homeostasis. Hepcidin concentrations are elevated in CKD and may be suppressed in response to erythropoietin therapy. Recent work has suggested that hepcidin is localized

in other organs including the kidney and that proximal tubular epithelial cells (PTEC) can actively absorb hepcidin from the renal filtrate. We hypothesized that hepcidin might in addition to its recognized role have other directly mediated cell functions. To study these putative effects we incubated active hepcidin-25 peptide on cultures of human PTEC (HK-2) in the absence and presence of cellular injury. Hepcidin (0-200ng/mL) was found to cause a linear dose-response increase in cell cytotoxicity within 2h with a two-fold rise in cytotoxicity induced fluorescence found with 75ng/mL hepcidin (n=8, $p<0.05$). Cytotoxicity was determined using a CytoTox-Fluor cytotoxicity assay using the dead cell substrate bis-AAF-R110 with similar results obtained with LDH methods. No rise in caspase-3 activity was seen indicating that cell death was necrotic and not apoptotic in nature (n=5, P=NS). Proliferation (viability) was determined by MTS assay with the finding that low concentrations of hepcidin having a profound effect after just 2.5h (2-fold increase at 50ng/mL, n=8, $p<0.05$). However, the rise in MTS was not sustained at higher hepcidin concentrations. Further work then examined the effect of hepcidin on peroxide induced injury (1 and 2mM $H_2O_2$ for 2h) and ATP depletion injury (50μM antimycin A and 10μM deoxyglucose for 1h). Both injury models produced highly significant reductions in proliferation. However hepcidin at 100ng/mL at the time of insult was found to have no additive injurious effect. On the contrary, when cultures were pre-incubated with 100ng/mL hepcidin for 1h prior to ATP depletion injury, a highly significant cytoprotective effect was seen (n=6, $p<0.0002$). We conclude that hepcidin is likely to be more than just an iron regulator in patients with CKD and that the direct effects upon PTEC in the clinical setting may be both cytoprotective and cytotoxic.

**Rapamycin Induced Nuclear Sequestration of mTOR May Control Downstream Signaling in Primary Vascular Smooth Muscle Cells** Yuxia He,[1] Christi M. Terry,[1] Mary Carlson,[1] Alfred K. Cheung.[2,1] *[1]Dept. of Medicine, Univ. of Utah, SLC, UT; [2]Medical Service, VA Healthcare System, SLC, UT.*

Dysregulated proliferation of vascular smooth muscle cells (VSMC) contributes to the failure of vascular stents and hemodialysis vascular accesses. Rapamycin (RAP) is used to inhibit restenosis after angioplasty and is under investigation for treatment of vascular access stenosis. RAP inhibits the phosphorylation of mammalian target of rapamycin (mTOR). Activated mTOR regulates VSMC proliferation through phosphorylation (and activation) of the cytoplasmic target P70S6 kinase. Previous studies in transformed cell lines or cancer cells showed that mTOR shuttled between the nucleus and cytoplasm and that nuclear sequestration may also be a cellular means to regulate mTOR. In this study, we showed by immunocytofluorescence (ICF) and western blotting that in proliferating cultured primary VSMC, mTOR was localized in both the cytoplasm and nucleus. RAP treatment (100 nM) inhibited the phosphorylation of mTOR and cell proliferation as expected, but it also promoted mTOR nuclear accumulation by 6h that was maintained up to 48h, as determined by western blotting of nuclear fractions. Further, exposure of VSMC for 24h to 20 ng/ml of leptomycin B (LMB), a specific inhibitor of nuclear export, resulted in enhanced mTOR nuclear sequestration, as determined by ICF, indicating that mTOR is actively shuttled between nucleus and cytoplasm. RAP exposure markedly reduced phosphorylation of Thr389 in the catalytic domain by 6h that was maintained up to 48h. RAP inhibited the phosphorylation of Thr421 in the P70S6 kinase auto-inhibitory domain at 1h, but in contrast to Thr389, phosphorylation levels of Thr421 returned to pre-treatment levels by 24h. Thus, phosphorylation of specific sites with different functions in the P70S6 kinase, is differentially affected by RAP. These data suggest that the intranuclear sequestration of mTOR induced by RAP in primary VSMC may be a means to separate mTOR from its cytoplasmic targets, such as P70S6 kinase, and this mechanism may play a role in RAP-induced inhibition of VSMC proliferation.

**Reactive Oxygen Species Contribute to Hypertrophy and Vascular Thickening in Remaining Renal Mass after Unilateral Ischemia, but Not Uninephrectomy** Hee-Seong Jang,[1] Jinu Kim,[2] Jee In Kim,[1] Min Hyun Cho,[3] Kwon Moo Park.[1] *[1]Anatomy and BK21 Program, Kyungpook National University School of Medicine, Daegu, Republic of Korea; [2]Department of Anesthesiology, College of Physicians and Surgeons of Columbia University, New York, NY; [3]Department of Pediatrics, Kyungpook National University hospital, Daegu, Republic of Korea.*

Undesirable alterations of remaining renal mass following renal mass reductions induced by unilateral renal ischemia (UI) or unilateral nephrectomy (Ux) have been shown to induce long-term renal insufficiency. However, the molecular mechanisms underlying these alterations remain to be clearly elucidated. We then evaluated the involvement of reactive oxygen species (ROS) in alterations of the contralateral kidneys (CKs) after UI and Ux. Ux is relatively less pathologic than UI. Mice were subjected to either 30 min of UI or Ux. Some mice were treated with Mn(III) Tetrakis (1-methyl-4-pyridyl) porphyrin (MnTMPyP, a superoxide dismutase (SOD) mimetic) daily beginning 1 day after the operations. Ux and UI resulted in hypertrophy and medial thickening renal cortical artery of the CKs at 9 days after the operations. UI increased superoxide levels and reduced manganase SOD (MnSOD) expression in the CKs, but Ux did not. MnTMPyP-administration blocked kidney hypertrophy and UI-induced increases in the medial area of CK along with reductions in superoxide production, but it did not affect any of the Ux-induced phenomena. In conclusion, ROS contributes profoundly to changes in the CK after UI, but not to changes in the CK after Ux, thereby suggesting that long-term renal insufficiency occurring after renal mass reductions should be treated differently, depending on the cause of the insufficiency.

**An Antiapoptotic Role of Cadmium in Human Renal Epithelial Cells** Nileshkumar Shah,[1] Iain Macphee,[2] Mark Edward Dockrell.[1] *[1]SW Thames Institute for Renal Research, London, United Kingdom; [2]Renal Medicine, St George's, University of London, London, United Kingdom.*

$Cd^{2+}$ is an important pollutant that poses a significant health risk currently ranking 7th in the Agency for Toxic Substances and Disease list of hazardous substances. The NHANES study (1999-2006)demonstrated high levels of serum $Cd^{2+}$ are associated with chronic kidney disease (CKD) and albuminuria. $Cd^{2+}$ has also has teratogenic and carcinogenic activities. Studies on renal proximal tubule epithelial cells(PTEC) have shown relatively specific effects on the cadherin(CDH)-dependent cell junctions. CDH are trans-membrane proteins which regulate epithelial integrity by the formation of extracellular complexes and modulation of intracellular signaling. CDH2 (N cadherin) is associated with migration and considered a hallmark of fibrosis and metastasis.

The aim of current study was to investigate the mechanism of cadmium toxicity on human PTEC with regard to cadherin expression and induction of apoptotis.

Transformed human PTEC (HKC-8) were treated with $CdCl_2$ (5-50 uM) for 1-24 h. Cell morphology was studied and CDH1 (E cadherin) and CDH2 were studied by immunoblotting along with mediators of apoptosis (Cleaved caspase 3, pERK5 and pAKT).

$Cd^{2+}$ caused concentration dependent morphological changes in PTECs; cells became round, detached from each other and at higher concentrations, from the basal surface .

In contrast to our hypothesis, Cd2+ caused a transient reduction in CDH1 at 6 h but not at 24 h with a persistent rise in CDH2.

Following a transient rise, cleaved caspase 3 was reduced in a dose dependent manner with a sustained rise in pERK5. There was a fugacious rise in pAKT.

$Cd^{2+}$ is an important pollutant associated with CKD and carcinogenesis, however the mechanism of cadmium toxicity is not fully understood. Surprisingly, in these experiments $Cd^{2+}$ was associated with a reduction in apoptosis at 24 h along with induction of CDH2, which may explain its carcinogenic potential. Although the concentrations used here are relatively high, chronic exposure to lower concentrations may have similar effects and therapeutic intervention to block pERK5 may allow apoptosis and reduce the carcinogenic potential of $Cd^{2+}$ in the kidney.

**Effects of the *Echinacea purpurea* as Anti-Proliferative on Renal Adenocarcinoma Cells (CAKI-1) in Culture** Renata Cristina Tassetano, Marcelo Andery Naves, Maria Dalboni, Fernanda Teixeira Borges, Nestor Schor. *Medicine, University Federal of Sao Paulo, Sao Paulo, Brazil.*

Renal cell carcinoma (CR) is rare compared to other cancers. Angiogenesis is an important route of tumor growth which is regulated by numerous pathways, especially Ras and Akt, which are targets of many therapeutic agents. Due to the resistence of CR to conventional treatments is increasing interest in alternative treatments. The Ep is used as an alternative treatment for some cancers. The aim is analyze the effect of *E.p.* on the RAS and Akt signaling pathway in tumor angiogenesis.

**METHODS**: Sorafenib (Sor 3uM) and Ep150ug/ml were added to culture for analysis: apoptosis (f. cytometry), protein expression of Ras and Akt (W.blot), performed after 24, 48 and 72 hours of treatment. Analyzed by One Way ANOVA, $p<0.001$ vs CT.

**RESULTS:** We observed that both the Sor as Ep demonstrated significant anti-tumor activity with increased apoptotic cells and decrease Ras and Akt proteins in both treatments.

Table 1

| | Ep 24h | Ep 48h | Ep 72h | S 24h | S 48h | S72h |
|---|---|---|---|---|---|---|
| Apo C | 7.2 ± 0.8 | 7.5 ± 0.3 | 4.7 ± 0.4$& | 7.2 ± 0.8 | 7.5 ± 0.3 | 4.7± 0.4$& |
| Apo T | 9.3 ± 0.6* | 6.8 ± 0.4$ | 7.6±0.7*#$& | 10.1 ±1.2* | 5.6 ± 0.9*$ | 9.2±0.6*$& |
| RAS C | 0.484±0.05 | 0.208±0.01# | 0.117 ± 0.02#$ | 0.95±0.05 | 0.869±0.01# | 0.353±0.02#$ |
| RAS T | 0.289±0.02* | 0.27±0.01*# | 0.183±0.009*#$ | 0.423±0.02* | 0.672±0.01*# | 0.397±0.009*#$ |
| AKT C | 0.280 ± 0.05 | 0.343± 0.01# | 0.301 ± 0.02$ | 0.956 ± 0.05 | 0.350 ± 0.01# | 0.868 ± 0.02#$ |
| AKT T | 0.207± 0.02* | 0.223± 0.01* | 0.193 ± 0.009* | 0.964 ± 0.02 | 0.128 ± 0.01*# | 0.518±0.009*#$ |

*P=<0.001 vs CT, # vs Sorafenib, $ vs 24 h, & vs 48 h

So we conclude that the E.P. is a promising complementary treatment in the CR since activity has anti-proliferative and anti-angiogenesis in vitro.

**Whether and How MDM2 (Murine Double Minute 2 Oncogene) Was Involved in Aldosterone-Induced Human Mesangial Cell Lines (HMCLs) Proliferation** Haiyun Wang, Limeng Chen, Xue-Wang Li, Xuemei Li. *Nephrology Department, Peking Union Medical College Hospital, Beijing, China.*

**Objective** To investigate whether and how MDM2, the p53 binding protein, a negative regulator of p53, was involved in HMCLs proliferation induced by aldosterone. **Methods** RT-PCR, immunoflourescence and Western blot were used to make sure the expression of MDM2 in HMCLs, and the relationship among time, dose and MDM2 expression. Proliferation of HMCLs was evaluated by flow cytometry. Small interference RNA of MDM2 was invocated to confirm the relationship among aldosterone, MDM2 expression and proliferation of HMCLs. Spironolactone, a mineralcorticoid receptor (MR) blocker was used to estimate the role of whether MR was involved in aldosterone inducing MDM2 elevation; cycloheximide, a protein synthesis inhibitor was inducted to estimate whether the

rapid nongenomic mechanisms regulate aldosterone inducing MDM2 expression directly. **Results** Both MR and 11β-HSD type 2 mRNAs were detected implied the reactive potency to aldosterone in HMCLs . MDM2 protein expression was detectable in both the nucleus and the cytoplasm. Aldosterone significantly increased MDM2 expression in a dose and time-dependent manner compared with control ones. The percentage of S phase increased in HMCLs stimulated with certain concentration of aldosterone at 24 hours ($P<0.05$). A reduction of MDM2 protein was dose-dependent confirmed by transfection of MDM2 siRNAs. Under the transfection of MDM2 siRNA, aldosterone did not promote the HMCLs proliferation. All these implied MDM2 participates in aldosterone inducing HMCLs proliferation. As aldosterone with spironolactone did not promote expression of MDM2 mRNA and protein, MR involved in this process was identified. Aldosterone with CHX did not increase expression of MDM2 protein indicated it is not directly regulated by the rapid nongenomic mechanisms. **Conclusion** MDM2 participates in aldosterone inducing HMCLs proliferation. MDM2 is significantly induced by aldosterone via MR and inhibited by spironolactone. The increase expression of MDM2 protein induced by aldosterone is not directly regulated by the rapid nongenomic mechanisms.

**Mizoribine (MZR) Suppresses Proliferation of Rat Glomerular Epithelial Cells (GEC) in Culture and Inhibits Increase of MCP-1 and MIP-2 Stimulated by Thrombin** Hideaki Yamabe, Michiko Shimada, Reiichi Murakami, Yuko Shimaya, Takeshi Fujita, Norio Nakamura. *Department of Nephrology, Hirosaki University Hospital, Hirosaki, Japan.*

Glomerular crescents play an important role in progressive glomerular injury. The lesions consist of GEC, macrophages and fibrin deposition. MCP-1 is a chemoattractant of monocytes, which have a procoagulant activity. MIP-2 is a chemoattractant of neutrophils, which mediate acute necrotizing injury in crescentic glomerulonephritis. MZR is an immunosuppressive drug, which inhibits selectively inosine monophosphate dehydrogenase, has been used for organ transplantation. The aim of this study is to investigate the effects of MZR on GEC. Cultured rat GEC were used. GEC proliferation was determined by using MTT assay. MCP-1 and MIP-2 were quantified by ELISA in culture supernatants and their mRNA expressions were analyzed by real-time RT-PCR. NF-kappa B in GEC was examined by immunofluorescence study. The proliferation of GEC was suppressed by MZR in a dose-dependent manner in the range of 1.0-100.0 μg/ml. These concentrations of MZR had no toxic effect to GEC. Thrombin (0.5-5.0 U/ml) enhanced the production of MCP-1, MIP-2 and their mRNA expressions. The stimulatory effect of thrombin on the productions of MCP-1 and MIP-2 was inhibited by addition of MZR (MCP-1; control: 0.20±0.07 pg/μg cell protein, thrombin: 0.52±0.03 pg/μg, thrombin+MZR: 0.40±0.02 pg/μg, $p<0.01$ vs thrombin, MIP-2; control: 4.06±0.08 pg/μg, thrombin: 11.67±0.54 pg/μg, thrombin+MZR: 8.77±1.40 pg/μg, $p<0.001$ vs thrombin). The relative mRNA expressions of MCP-1 and MIP-2 stimulated by thrombin were also inhibited by addition of MZR (MCP-1; control:1.00 ±0.1, thrombin: 9.75±0.4, thrombin+MZR: 7.52±0.8, $p<0.01$ vs thrombin, MIP-2; control: 0.99±0.2, thrombin: 17.9±1.0, thrombin+MZR: 9.53±1.0, $p<0.001$ vs thrombin). MZR (10 μg/ml) suppressed the thrombin-induced translocation of NF-kappa B into the nucleus of GEC. These data demonstrated a suppressive effect of MZR on the proliferation of GEC and the production of MCP-1 and MIP-2 stimulated by thrombin possibly via inhibition of NF-kappa B. It is suggested that MZR may be useful for the treatment of crescentic glomerulonephritis.

**Altered Exon 4 KIM-1 Gene Sequence in Renal Cell Carcinoma (RCC) and Concordant Expression of KIM-1 and CD68** Ping L. Zhang,[1] Venkata Sabbisetti,[2] Joseph V. Bonventre.[2] *[1]Department of Anatomic Pathology, William Beaumont Hospital, Royal Oak, MI; [2]Renal Division, Brigham and Women's Hospital, Boston, MA.*

KIM-1 is a type I transmembranous protein which is a sensitive and specific marker of proximal tubule (PT) injury. Our studies demonstrates that KIM-1 confers a phagocytic phenotype on injured PT cells. KIM-1 is also upregulated in human PT-derived renal cell carcinomas (RCC) including clear cell RCC and papillary RCC. The goals of this study were to determine whether human RCC had altered KIM-1 gene sequence and whether there was concurrent expression of KIM-1 and another phagocytic factor CD68, a transmembrane glycoprotein mainly present in macrophages. Genomic DNA was prepared from paraffin-embedded tumor tissue containing 3 clear cell RCC and 3 papillary RCC. Using the purified DNAs as the template, PCR was performed to amplify each of the nine major coding exons of the KIM-1 gene. Each PCR product then went through a cloning and sequencing (GENEWIZ) process. Vector NTI software was used to compare exon DNA sequence to the published sequence of KIM-1 (HAVCR-1;NM_012206). There were mutations in exon 4 in 4 of 6 patients (the mucin-like domain), but not in the remaining eight exons.

A tissue microarray containing 42 RCC derived from PTs and 48 tumors derived from distal nephron tubules were analyzed for KIM-1 (AKG7 antibody) and CD68 (KP1 clone) expression using immunohistochemistry. KIM-1 was expressed in 18/20 papillary RCC and 18/22 clear cell RCC, but not in distal nephron tubules derived renal tumors (0/25 chromophobe RCC and 0/23 oncocytoma). Expression of CD68 was similar to that of KIM-1 (positive in 17/20 of papillary RCC and 13/22 of clear cell RCC, but negative in chromophobe RCC (0/25) and oncocytomas (0/23)). There was a significant correlation between staining intensity (graded 0 to 3+) of KIM-1 and CD68 ($r = 0.56$ and $p = 0.001$).

In summary, gene sequence changes were found in exon 4 of human RCC derived from PTs. There was concurrent expression of KIM-1 and CD68 in PT-derived RCC. Both membrane proteins facilitate phagocytosis in RCC and may be important for immunological modulation that may enhance RCC resistance to therapy.

**$GABA_B$ Receptor Mediated Chemotaxis and Cytoskeleton Rearrangement Are Dependent on Signaling Via PI3-K/Akt and Src Tyrosine Kinases** Michelle T. Barati, Janice Scherzer, Madhavi J. Rane, Jon B. Klein. *Kidney Disease Program, Univeristy of Louisville, Louisville, KY.*

Chemotaxis is essential to numerous biologic and pathophysiologic processes, including inflammation, neuronal development, and cancer cell metastasis. We have previously reported g-amino butyric acid (GABA) type B receptors ($GABA_BR$) to be present in and function as chemoattractant receptors in response to GABA agonists, in human neutrophils. The $GABA_BR$ is a metabotropic G protein-coupled receptor comprised of a heterodimer of $GABA_{B1}$ and $GABA_{B2}$ subunits interacting via leucine zipper motifs in the C-terminal domains. The goal of this study was to define signaling mechanisms regulating $GABA_BR$-mediated chemotaxis. We used rat basophilic leukemic cells (RBL-2H3 cells) stably transfected with human $GABA_{B1b}$ and $GABA_{B2}$ receptors. The $GABA_BR$ agonist baclofen induced chemotaxis that was dependent on $GABA_BR$. To define the cell signaling mechanisms regulating this chemotaxis, cells were treated with inhibitors to Phosphatidylinositol 3-Kinase (PI3-K), Akt, and Src kinases, prior to chemotaxis assays. Signaling via all three pathways regulated baclofen-induced chemotaxis. In addition, baclofen-induced Akt activation was dependent on both PI3-K and Src kinase-dependent signaling. Directed cell migration requires substantial rearrangement of the cytoskeleton. Cortical actin polymerization was increased suspended RBL cells subject to a baclofen gradient, and exposure of adherent RBL cells to baclofen caused cell spreading with increased actin polymerization and localization in membrane ruffles. Baclofen stimulation of RBL cells also increased formation of microtubules as determined by fractionation of cells and quantitation of soluble / free tubulin and insoluble microtubules. Treatment of RBL cells with either cytochalasin D or nocodazole to inhibit actin or tubulin polymerization, respectively, completely abolished baclofen-mediated chemotaxis. In conclusion, $GABA_B$ receptor stimulation causes cytoskeletal rearrangement and chemotaxis in RBL cells. These data suggest a role for $GABA_B$ receptor stimulation in cellular response to injury and disease.

**Inhibition of PAI-1 Protects Glomerular Endothelial Cells Against Pro-Apoptotic Effects of Adipocyte-Derived Media** Bridgette Corsa,[1] Dan Gao,[1,2] Agnes B. Fogo,[1] Li-Jun Ma.[1] *[1]Department of Pathology, Vanderbilt University Medical Center, Nashville, TN; [2]Department of Nephrology, First Affiliated Hospital, Zhengzhou University, Zhengzhou, China.*

Background: Chronic kidney disease (CKD) is increased in obesity. A hallmark of CKD is progressive glomerulosclerosis with loss of capillary loops. We have shown that adipocyte-derived factors induce apoptosis of glomerular endothelial cells. Plasminogen activator inhibitor-1 (PAI-1) is a potent inducer of apoptosis. We hypothesized that targeting endogenous PAI-1 in glomerular endothelial cells (GENs) protects against the pro-apoptotic effects of the adipocyte-derived media.

Methods: Apoptosis was induced in mouse GEN either by adding recombinant human PAI-1 (rhPAI-1, 22.7nM, 48 hours) or by adding adipocyte-derived media to GEN with knockdown of PAI-1 or intact PAI-1. Endogenous PAI-1 in GENs was knocked down by transfecting with PAI-1 siRNA and compared to scrambled RNA transfected GENs. Cleaved caspase-3 and tight junction protein ZO-1 were assessed by Western blot. Data are expressed as mean±SE.

Results: Mouse GENs treated with exogenous rhPAI-1 showed a 2-fold increase in cleaved-caspase-3 expression when compared to untreated GENs. PAI-1 siRNA effectively knocked down PAI-1 expression by 90% in GENs. Adipocyte-conditioned media vs. normal media induced a 5.4-fold increase in cleaved caspase-3 expression in GENs treated with scrambled RNA. In contrast, GENs with knockdown of PAI-1 were protected against adipocyte-conditioned media effects, with only minimal induction of cleaved caspase-3 (only 9% vs. scrambled RNA treated GENs). ZO-1 expression was not different between groups.

Conclusions: Inhibition of endogenous PAI-1 protects glomerular endothelial cells against the pro-apoptotic effects of adipocyte-derived media. Our data suggests that modulation of endothelial PAI-1 may provide protection against obesity-induced chronic kidney disease.

**Dorsal Root Ganglion Neurons Exibit Specific Firing Patterns Due to Different Electrophysiolgical Properties of Voltage Activated Ion Channels** Wolfgang Freisinger, Tilmann Ditting, Kristina Rodionova, Sonja Heinlein, Peter Linz, Karl F. Hilgers, Roland Veelken. *Nephrology, Friedrich-Alexander University Erlangen Nürnberg, Erlangen, Germany.*

PURPOSE: We could characterize recently a special group of medium-sized neurons with renal afferents (ARN) that exhibited significantly more frequently a tonic firing pattern upon stimulation than controls without projections from the kidney. We tested the hypothesis that a different firing pattern is related to changes in voltage activated sodium channels.

METHODS: 114 dorsal root ganglion (DRG) neurons from Th11-L2 (8 SD-rats) were investigated with whole cell patch clamp technique. ARN were identified by retrograde fluorescent labelling (DiI). All neurons were characterized by action potential generation due to current injection (40-12000 pA, 600 ms), tonic cells exhibited persisting AP, phasic 1to6/600ms. Static membrane properties were recorded; cells underwent voltage changes (-100 to 60 mV, 1 Step 10mV, 50ms) to investigate voltage activated channels.

RESULTS: We examined 114 DRG neurons, of which 76 stained positively for DiI. Cells with tonic firing pattern were found in 34% of DiI positive renal DRG neurons vs. 13% in non-renal DRG neurons. After depolarizing current injection (dDCI), over all 73% showed a phasic, 27% a tonic firing pattern. Voltage activated Na+-currents showed a significantly smaller inward current between -100mV to 20mV(e.g. at -40mV -7520±1988 pA vs. 20589±1162,6374, p<0,0001) in tonic firing cells. Furthermore, the voltage of half activation of the sodium channels was significantly higher in tonic vs. phasic cells (-40mV vs. -60 mV).

CONCLUSION: Cells with tonic firing pattern are found more frequently among ARN. All cells with tonic firing pattern after dDCI showed a significant change of voltage induced currents. In tonic firing neurons, Na+-channels exhibited lower inward currents being activated at higher voltage changes. As tonic neurons are more frequently found in renal afferents, we suppose that renal neurons may exhibit different subtypes of voltage dependent Na+-channels.

**Fluvastatin Attenuates High Glucose-Induced Fibronectin Expression by Inhibiting the Signal Pathway of Rho-Kinase in HK-2 Cells** Jia Liu, Changying Xing. *Dept of Nephrology, First Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China.*

Objective: To explore the effect of Rho-kinase signal pathway in renal interstitial fibrosis of diabetic nephropathy (DN) and the mechanism of fluvastatin in the prevention of renal interstitial fibrosis of DN. Methods: Human renal proximal tubular epithelial cells (HK-2 cells) were cultured in vitro. Rho-kinase activity was expressed as phosphorylation of myosin-phosphatase target 1 (p-MYPT1). The level of p-MYPT1 and fibronectin (FN) stimulated by high glucose was determined by Western blot at the time of 0h, 6h, 12h, 24h, 48h. Same marks were detected when high glucose cultured HK-2 cells treated with different concentrations (10-7, 10-6and 10-5 mol/L) of fluvastatin for 12h and when treated by lysophosphatidic acid (LPA) further. Result: High glucose enhance the expression of p-MYPT1 and FN at the time of 6h, 12h, 24, 48h compared with the time of 0h in culured HK-2s. The increase of FN expression stimulated by high glucose was in time-dependent fashion and the increased level of p-MYPT1 reached the peak at 12h. Fluvastatin decreased high glucose-mediated level of p-MYPT1 and FN in dose-dependent manner. The inhibitory effect of fluvastatin on up-regulation of p-MYPT1 and FN stimulated by high glucose was reversed by LPA. Conclusions: Rho-kinase may be one of the initiation signals of renal interstitial fibrosis of DN. Fluvastatin can prevent the development of renal interstitial fibrosis of DN by inhibiting Rho-kinase signaling pathway.

**Constitutive Gene Expresion in Renal and Vascular Cells Is Regulated by Basal Levels of Reactive Oxygen Species** Gemma Olmos,[1] Marta Gonzalez,[1] Maria Del Nogal,[1] Susana Marquez,[1] Ines Mora,[1] Manuel Rodriguez-Puyol,[1] Diego Rodriguez-Puyol.[1-2] *[1]Physiology, Universidad de Alcala, Alcala de Henares, Madrid, Spain; [2]Nephrology Section and Research Unit, Hospital Principe de Asturias, Alcala de Henares, Madrid, Spain.*

Genes are considered as constitutive when they are detected in cells in basal conditions. Stimuli such as reactive species oxygen (ROS) may up-regulate the expression of these genes but the mechanisms involved in their continuous basal expression are unknown. As ROS concentrations are tightly maintained at intracellular level because the equilibrium between synthesis and degradation, we hypothesized that the basal levels of ROS could be responsible for the expression of these constitutive genes in renal and vascular cells. We analyzed the expression of some genes in cultured cells after decreasing intracellular ROS concentration and we explored the mechanisms involved.

In different human cell types (mesangial cells HMC; umbilical vein endothelial cells HUVEC; fibroblasts IF) exogenous catalase (CAT) addition produced an increased intracellular CAT activity and a decreased intracellular ROS concentration. Basal TGF-β1 and eNOS protein content decreased in HMC and HUVEC, respectively. In contrast, no changes were detected in other proteins:erythropoietin (IF), COX1 (HMC) or protein kinase G (HMC). As the presence of AP-1 responsive elements is one of the differential characteristic between the catalase-inhibited or non-inhibited genes, we analysed the relationship between the basal activity of AP-1 and ROS deprivation. Catalase decreased the whole TGF-β1 promoter activity and this effect disappeared when AP-1 binding site of TGF-β1 promoter was removed. Although the intracellular ROS concentration was inhibited to a similar level by diphenyleneiodonium (DPI, NADPH oxidase inhibitor), rotenone (R, mitochondrial complex I inhibitor) and allopurinol (xanthine dehydrogenase inhibitor) only DPI and R decreased TGF-β1 promoter activity.

That suggest low levels of ROS could be essential for the basal expression of constitutive AP1-dependent genes in kidney and vascular cells. Several systems involved in the synthesis of ROS could play different roles on this regulation.

**Uric Acid Induces Lipid Accumulation in Liver Cells** L. Gabriela Sanchez-Lozada,[1,2] Miguel A. Lanaspa,[2] Carlos Alberto Roncal-Jimenez,[2] Richard J. Johnson.[2] *[1]Nephrology, INC Ignacio Chavez, Mexico City, DF, Mexico; [2]Renal Dis & Hypertens, U. of Colorado, Aurora, CO.*

Hyperuricemia has been associated with hepatic steatosis in several studies. In rats, the experimental elevation of serum uric acid was associated with increased deposition of intrahepatic lipids; these findings suggest a causative role of UA on the abnormal accumulation of fat within liver cells. To better understand the cellular mechanisms implicated in this outcome, we examined the effect of UA on fat accumulation as well as in specific enzymes involved in fat metabolism in human hepatoma cells (HepG2).

HepG2 cells (ATCC, USA) were cultured with uric acid (UA, 12 mg/dL) for 48 hr. Intracellular triglycerides (TG) were quantified by an enzymatic-coupled colorimetric assay. Fatty acid synthase (FAS) and enoyl-CoA-hydratase-2 (ECoAH) expressions were evaluated by western blot. In addition translocation of carbohydrate responsive element binding protein (ChREBP) was evaluated in nuclear and cytoplasm fractions.

UA induced a 20% increment in intracellular TG; this rise was similar in magnitude as the induced by fructose (5 mM), a known stimulator for TG synthesis in liver cells. Co-incubation of UA with fructose further increased TG synthesis. UA is a byproduct of intrahepatic fructose catabolism; as such the synergistic effect of UA and fructose suggests that UA derived from fructose contributed, at least partially, to further rise intracellular TG. In addition, UA dose dependently decreased the mitochondrial enzyme enoyl-CoA-hydratase-2 (ECoAH) an essential enzyme for b-oxidation. On the other hand UA increased the cytosolic enzyme fatty acid synthase (FAS), which is central in the pathway of the novo lipogenesis. ChREBP nuclear translocation is a strong regulator of FAS expression, as such we found that UA significantly increased the nuclear translocation of this transcription factor.

These findings supports that UA is acting to induce liver steatosis by at least two mechanisms: lowering the disposal of intracellular lipids by reducing the expression of ECoAH and through inducing the nuclear translocation of ChREBP with a secondary overexpression of FAS.

**Overexpression of Nitric Oxide Synthase and Soluble Guanylate Cyclase and Inhibition of Urea Cycle in Platelets from Hemodialysis Patients** Sergio F. F. Santos,[1] Monique B. Moss,[2] Tatiana M. C. Brunini,[2] Mariana A. S. Siqueira,[2] Antônio Cláudio Mendes-Ribeiro.[2] *[1]Disciplina de Nefrologia, UERJ, Rio de Janeiro, Brazil; [2]Farmacologia, UERJ, Rio de Janeiro, Brazil.*

**Background:** Chronic renal failure (CRF) is characterized by the presence of endothelial dysfunction and platelet activation. Nitric oxide (NO), a potent inhibitor of platelet function, is synthesized from the amino acid L-arginine. Arginase competes with nitric oxide synthase (NOS) for the substrate L-arginine, modulating its activity. Our group has previously demonstrated an activation of L-arginine-NO pathway in blood cells from uraemic patients. The aim of this study was to investigate the effects of CRF in the activity and expression of arginase and expression of inducible (iNOS) and endothelial (eNOS) NOS and soluble guanylate cyclase (sGC) in human platelets.

**Methods:** In this study, 13 uraemic patients under hemodialysis and 12 healthy controls matched for sex and age were included. The expression of iNOS, eNOS, sGC and arginase I and II expressions was accessed by Western Blotting. Arginase activity was analysed through the conversion of [$C^{14}$]-L-arginine into [$C^{14}$]-urea. Mann Whitney test was used for statistical analysis.

**Results:** It was demonstrated an overexpression of both iNOS and eNOS in platelets from CRF patients. The expression of sGC was also increased in CRF patients compared to controls. In contrast, there were no alterations in the expression of both isoforms of arginase in patients with renal failure, although arginase activity was decreased (2.8±0.5 vs 1.3±0.1 pmol urea/ mg protein/2h) in these patients.

**Conclusion:** The present study suggested that the increased of NO synthesis previously observed in CRF may be explained by an overexpression of eNOS and iNOS in platelets. Moreover, the expression of sGC, was also increased in CRF, which could lead to generation of cGMP and inhibition of platelet function. Nevertheless, impairment of arginase activity may provide more substrate for NO production. In this context, the rise of NO bioavailability may contribute to the prolonged bleeding time and bleeding tendency in uraemic patients under hemodyalisis.

**Macrophage Migration Inhibitory Factor (MIF) Activates the PI3K/mTOR Signalling Pathway in Renal Tubular Epithelial Cells** Anisha Tanna, Simona Deplano, Frederick W. K. Tam. *Imperial College Kidney and Transplant Institute.*

**Purpose:**

The phosphoinositide-3-kinase/mTOR signalling pathway plays a crucial role in the cellular response to growth factors and is a key regulator of cell metabolism, proliferation and survival. Macrophage migration inhibitory factor (MIF) is a proinflammatory cytokine which has been associated with chronic inflammatory diseases such as glomerulonephritis

and recently with tumorigenesis. However, there is limited understanding of the downstream signalling pathways. In this study we investigated the cell signalling cascade following stimulation with recombinant MIF in renal tubular epithelial cells.

**Methods:**

*(1). Cell culture and immunoblotting*

Rat tubular epithelial cells (NRK 52-E) were stimulated with recombinant rat MIF at different concentrations (50-100 ng/ml) and for various time periods (5'- 240') and changes in protein phosphorylation were examined by Western blotting.

*(2). Measurement of rat Monocyte Chemoattractant Protein-1 (MCP-1)*

Rat tubular epithelial cells were treated with different concentrations of recombinant rat MIF (1-50 µg/ml) for 24 hours in the presence or absence of the PI3 kinase inhibitor Wortmannin. MCP-1 production was measured by sandwich ELISA.

**Results:**

(1).At low concentrations, in the range of nanograms per mililitre, MIF induces an increased phosphorylation of Akt and S6 ribosomal protein in a time and dosage-dependent manner.

(2). At higher concentrations, in the range of micrograms per millilitre, MIF leads to significant secretion of MCP-1 in a dose-dependent manner. The presence of the PI3 kinase inhibitor Wortmannin does not appear to affect the production of MCP 1.

**Conclusion:**

Low concentration of MIF is able to upregulate the PI3K/mTOR signalling pathway in renal tubular epithelial cells and at higher concentrations also leads to the production of MCP-1 in renal tubular epithelial cells. This implicates MIFas a potential link between cell proliferation and inflammation and hence an important potential therapeutic target.

## PUB137

**Repression of Tumor Necrosis Factor alpha Promoter in Human Mesangial Cells by Peroxisome-Proliferator Activated Receptor gamma and Thyroid Hormone Receptor** Angélica Amorim Amato,[1] Flora A. Milton,[1] Juana B. Woitechumas,[1] Marie Togashi,[1] Luiz A. Simeoni,[1] Guilherme M. Santos,[2] Francisco R. Neves.[1] *[1]Pharmaceutical Sciences, University of Brasilia, Brasilia, Federal District, Brazil; [2]Laboratory of Molecular Biology, Medical Research Council, Cambridge, United Kingdom.*

Glomerular mesangial cells have been shown to play critical roles in renal physiology, such as regulation of glomerular filtration, clearance of immunocomplexes and extracellular matrix production. Histopathological findings frequently correlate mesangial cell proliferation and extracellular matrix accumulation to glomerulopathies. Among the etiologic factors of glomerulopathies, it is well known that grow factors and cytokines have a great importance, in particular tumor necrosis factor alpha (TNF-). Antidiabetic drugs such as thiazolidinediones (TZDs), which act as PPAR gamma agonists, have been recently shown to prevent glomerulopathy in animal models by repressing the transcription of many genes involved in renal damage. We investigated whether pioglitazone, a TZD, decreased the mesangial cell proliferation induced by TNF- and if this effect could be attributed by transcriptional repression by the receptor of pioglitazone on TNF- promoter. We also investigated if thyroid hormone influenced TNF- promoter activity. Our results showed that pioglitazone decreased mesangial cell proliferation induced by TNF-. Moreover, it was shown that in these cells pioglitazone repressed the activity of TNF- promoter. We identified that the site for this repression was between -125 and -82 upstream the TATA box and the IC50 was 1,7 x 10-7 M. This effect was not observed in another cell line, namely U937 promonocytes. These results suggest possible mechanisms to explain how TZDs may prevent glomerular injury.ααααααα

## PUB138

**Losartan Reverts the Mesangial Cell-Myofibroblast Transdifferentiation Induced by High Glucose and Angiotensin II** Mirian A. Boim, Carine Prisco Arnoni, Edgar Maquigussa, Luciana Guilhermino Pereira, Clévia Dos Santos Passos. *Medicine - Renal Division, Federal University of São Paulo, São Paulo, São Paulo, Brazil.*

Diabetic glomerulosclerosis is initiated by mesangial cell (MC) activation, resulting in mesangial matrix expansion and production of pro-fibrotic cytokines. This activation is accompanied by a cell transdifferentiation process, where the MC presents myofibroblastic characteristics, like the expression of smooth muscle α-actin (αSMA) and acquired migration capacity. Angiotensin II (AngII) AT1 receptor blocker, losartan has been shown to revert the renal fibrosis in diabetic animals. The aim of this study was to evaluate the effect of the losartan, on the regression of the MC to myofibroblast transdifferentiation, induced *in vitro* by high glucose environment (HG, 30 mM) and by AngII ($10^{-7}$M). MCs were stimulated with HG and AngII or glucose and AngII simultaneously during 4 days (4d G+AngII) or 6 days (6d G+AngII) to induce the cellular transdifferentiation. The expressions of the αSMA, collagens I and IV, fibronectin and growth factors, including transforming growth factor β1 (TGF-β) and connective tissue growth factor (CTGF) were evaluated by real time PCR and Western blot. Cells of the group 4d G+AngII presented myofibroblastic transdifferentiation characteristics that were even more evident in group 6d G+AngII with migration capacity more than 100% compared with the control cells. This group was used to evaluate the effect of growing doses of losartan ($10^{-4}$-$10^{-6}$M) during the last 48 hr of stimulation. All doses of losartan significantly reduced the expression of the mesangial matrix components, αSMA and cell migration but the highest dose of ($10^{-4}$M) was the more effective to induce reversion of MC to myofibroblast transdifferentiation in the present *in vitro* model. Results suggest that the renin angiotensin system inhibition can be a potential strategy, not only to avoid the progression of the diabetic glomerulosclerosis, but also to reverse the fibrogenic process typical of the diabetic nephropathy.

## PUB139

**Importance of Podocyte B7-1 Expression in Hypoxic Injury and Its Salvage by siRNA Knockdown and Antioxidants** Jer-Ming Chang.[1,2,3] *[1]Department of Internal Medicine, Kaohsiung Municipal Hsiao-Kang Hospital, Kaohsiung, Taiwan; [2]Division of Nephrology, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; [3]Faculty of Renal Care, Kaohsiung Medical University, Kaohsiung, Taiwan.*

**Background/Aim** Hypoxia is a well-recognized factor for renal functional deterioration. We had shown that the hypoxia-induced damage was correlated with cytoskeletal disruption and B7-1 expression in podocytes. It's not clear if inhibition of B7-1 expression may prevent the hypoxia-induced damages and if antioxidants can relieve the injuries.

**Materials and methods** Podocyte cell line derived from H-2K$^b$-tsA58 transgenic mice was cultured. Hypoxic stimuli to podocytes were done by putting cells in the 1% $O_2$ incubator. Molecular cloning of B7-1 and hypoxia-inducible factor (HIF) into plasmids were done with standard method and protein interaction was proved by co-immnunoprecipitation. PCR/Western blot and immunohistochemistry were performed with proper methods. Stress fiber was evaluated by stainingwith rhodamine-phalloidine. RNA knockdown was done by introducing lentiviral plasmid into podocytes. Oxidative injuries were assessed by probing nitrotyrosine production. ADMA (asymmetric dimethylarginine) and aminoguanidine were used to reduce oxidative injuries by LPS-induced iNOS expression.

**Results** Our experiments showed that HIF was stably expressed in podocytes and was enhanced by hypoxic and LPS stimuli, along with the expression of B7-1 (both mRNA and protein). B7-1 and HIF interacts each other by co-IP and endogenous IP. Stress fibers of podocytes were disrupted by either LPS or hypoxic stimuli, demonstrated by merging B7-1 and HIF fluorescence images. iNOS and nitrotyrosine levels were both increased significantly by LPS treatment and moderately by hypoxia. The above changes in podocytes after hypoxic stimuli were prevented by lentiviral-B7-1 RNA interference. However, aminoguanidine and ADMA fail to relieve the oxidative injuries provoked by nitroprusside effectively.

**Conclusion** We found that hypoxia-induced podocyte injuries are B7-1-dependent. Effect of antioxidants has to be re-evaluated in our system. Animal studies concerning development of proteinuria will be our next step to verify our cellular finding.

## PUB140

**Ghrelin Suppresses Angiotensin II-Induced Renal Tubular Scenscence by Blocking p38-MAP Kinase Pathway** Keiko Fujimura, Shu Wakino, Koichi Hayashi. *Department of Internal Medicine, School of Medicine, Keio University, Tokyo, Japan.*

(Objectives) Renal cell senescence is one of the main pathways for deterioration of renal function. Both in cellular and organ system, it is believed that environmental stress induces senescence. However, cellular mechanism(s) involved in this signaling have not been fully elucidated. Ghrelin is a growth hormone secretagogue which derived from stomach and has been suggested to exert tissue protective effects. In this study, we examined the mechanisms of angiotensin II (AngII)-induced renal tubular cell senescence and the effects of novel peptide, ghrelin on this cellular change. (Methods) Cultured human proximal cell line, HK-2 cells were utilized. 72 hours after cells were stimulated with 1 mM of AngII, cells were assayed with scenscence-associated b-Gal staining (SA-bGAL staining). Expressions and phosphorylation levels of several molecules involved in cellular senescence were analysed by Immunoblotting. The effects of Ghrelin on AngII-induced senescence were tested by 30 minutes pretreatment with Ghrelin. (Results) In HK-2 cells, the expression both Ghrelin and AngII receptors were expressed. SA-bGal assay demonstrated that AngII induced renal tubular cell senescence, which was attenuated by Ghrelin. AngII activated p38 MAP kinase and the expression of p21 and p53 were increased by Ang II. These molecular changes were also blocked by ghrelin. (Conclusions) Our data indicated that ghrelin suppressed AngII-induced renal tubular senescence by blocking p38-MAP kinase pathway. Ghrelin could be a novel therapeutic strategy against senescence-associated kidney damages including renal atherosclerosis or diabetic kidney disease.

## PUB141

**Angiotensin II Stimulation of Aquaporin-2 Expression and Trafficking Involves cAMP, PKA, PKC, and Calmodulin-Dependent Signaling Pathways Via AT1 and V2 Receptor** Chunling Li, Weidong Wang, Christopher J. Rivard, Miguel A. Lanaspa, Robert W. Schrier. *Division of Renal Diseases and Hypertension, Univercity of Colorado Denver, Aurora, CO.*

Angiotensin II (ANG II) plays a major role in renal water and sodium regulation. In the immortalized mouse renal collecting duct principal cells ($mpkCCD_{cl4}$) cell line, we treated cells with ANGII and examined AQP2 protein expression, trafficking, and mRNA levels, by immunoblotting, immunofluorescence, and reversed transcription-polymerase chain reaction. After 24 hr incubation, ANGII-induced AQP2 protein expression was observed at the concentration of $10^{-10}$ M and increased in a dose-dependent manner. ANG II ($10^{-7}$ M) increased AQP2 protein expression and mRNA levels at ½, 1, 2, 6, 24 hrs.

Immunofluorescence studies showed that ANGII increased the apical membrane targeting of AQP2 from 30 min to 6 hr. Next, the signaling pathways underlying the ANGII-induced AQP2 expression were investigated. The PKC inhibitor RO 31-8220 ($5\times10^{-6}$ M) and the PKA inhibitor H89 ($10^{-5}$ M) blocked ANGII-induced AQP2 expression, respectively. Calmodulin inhibitor W-7 markedly reduced ANGII and/or dDAVP-stimulated AQP2 expression. ANGII ($10^{-9}$ M) and/or dDAVP ($10^{-10}$ M) stimulated AQP2 protein levels and cAMP accumulation, which was completely blocked by pretreatment with the vasopressin V2 receptor (V2R) antagonist SR121463B ($10^{-8}$ M). Pretreatment with angiotensin AT1 receptor (AT1R) antagonist losartan ($3\times10^{-6}$ M) blocked ANGII ($10^{-9}$ M) stimulated AQP2 protein expression and cAMP accumulation, and partially blocked dDAVP ($10^{-10}$ M) and dDAVP+ANGII induced AQP2 protein expression and cAMP accumulation. In conclusion, ANG II regulates AQP2 protein, trafficking and gene expression in renal collecting duct principal cells. ANGII-induced AQP2 expression involves cAMP, PKC, PKA, and calmodulin signaling pathways via V2 and AT1 receptors.

## PUB142

**The $EP_4$ Receptor Antagonist L-161 982 Reduces the Expression of $Na^+/K^+$-ATPase and Increases the Apoptotic Response in Hypertonic Mouse M-1 Cortical Collecting Duct Cells** Genevieve Paris, Rania Nasrallah, Richard L. Hebert. *Cellular and Molecular Medicine, Kidney Research Centre, University of Ottawa, Ottawa, ON, Canada.*

Prostaglandin (PG) $E_2$, is highly produced in the kidney and regulates sodium reabsorption, which is driven by the $Na^+/K^+$-ATPase (NKA) pump. It has been reported that high salt (HS) affects the activity of NKA in the cortical collecting duct. The current study addresses the role of $PGE_2$ in the modulation of NKA in a hypertonic environment for 24 hours. We demonstrated by immunoblotting a 2-fold increase in NKA expression and activity following hypertonic conditions (240mMol/L of NaCl, choline chloride, mannitol). Hypertonicity also stimulated cyclooxygenase (COX)-2 expression and $PGE_2$ production as measured by EIA. We detected by real-time PCR an increase in $EP_3$ receptor mRNA, but $EP_1$ and $EP_4$ were unaltered by HS. COX inhibition (indomethacin and ibuprofen) and EP antagonists (L-161 982 ($EP_4$), SC 51089 ($EP_1$)) did not reverse the increase in NKA expression or activity, suggesting that $PGE_2$ is not responsible for the high expression of NKA in HS. However, the $EP_4$ antagonist L-161 982 decreased the expression of NKA α-1 in HS. This effect might result from apoptosis of the cells in the presence of L-161 982, since we demonstrated that anisomycin decreases NKA α-1 expression. Also, we observed that L-161 982 in HS increases the expression of cleaved caspase-3 (2-fold), increases caspase activity (2-fold), decreases AKT phosphorylation (30%), and increases the number of apoptotic nuclei with Hoechst 33342. Additionally, $^3$H-leucine and $^3$H-thymidine incorporation were reduced by 50 % in HS conditions and with L-161 982. None of these apoptotic effects were reversed by $PGE_2$ treatment in HS. These data suggest that L-161 982 can affect cell growth and apoptosis independent of the $PGE_2/EP_4$ system. Further analysis is needed to determine how the $EP_4$ antagonist L-161 982 induces apoptosis in these cells. In summary, we demonstrated that the elevated $PGE_2$ production in HS does not regulate NKA expression and activity or apoptosis, future studies will determine the role of HS-induced $PGE_2$.

## PUB143

**Does Untreated Obstructive Sleep Apnea Speed-Up Progression of Chronic Kidney Disease in Patients Who Are Not on Dialysis?** Ashok K. Ananthasayanan,[1] Ahmad Kilani,[1] Arash Rashidi.[1,2] *[1]Dept of Internal Medicine, Fairview Hospital, A Cleveland Clinic Hospital, Cleveland, OH; [2]Nephrology & Hypertension, Ohio Medical Group, Westlake, OH.*

Sleep apnea (SA) is common in general population. SA correlates with diseases such as coronary heart disease, arrhythmias, pulmonary hypertension, cor pulmonale, and systemic hypertension. SA has a highly prevalent in patients with end stage renal disease (ESRD), but it is not clear whether SA is a risk factor for progression of chronic kidney disease. We are reporting a case on untreated SA with progressive worsening of kidney function, who responded to SA treatment. A 50 year old Caucasian female with hypertension, diabetes, SA, hypothyroidism, hepatitis C and morbid obesity admitted with heart rate of 35/min and was in renal failure on admission with BUN of 39 and creatinine of 2.18. Her baseline creatinine level prior to this admission was 0.99 to 1.58. She had been diagnosed to have obstructive sleep apnea based on polysomnography. Detailed nephrology workup and investigation pertaining to renal failure was negative, except strong evidence of ischemic kidney. Renal biopsy not done as there was no clear indication and additional benefit. She was given intravenous fluid initially, which did not show any improvement in her renal function. Kidney function continued getting worse and eventually she was started on hemodialysis as her renal function deteriorated. Once she was started on oxygen and BiPAP, her renal function started improving and her dialysis gradually weaned and stopped. Her renal function improved to its baseline and remained stable without a need for dialysis after treating her SA. We like to stress the importance of untreated SA in CKD patients as it can cause ischemic kidney and kidney failure with combination of other factors such as bradycardia, which potentially can diminish oxygen delivery to kidney.

## PUB144

**Mortality Prediction for Patients with APACHE IV System for ICU Patients Requiring Emergent Hemodialysis** Vijaya Surekha Bhamidipati,[1] Winston Lee,[2] Sheldon Greenberg.[3] *[1]Internal Medicine, Christiana Care Health System, Newark, DE; [2]Nephrology, Maimonides Medical Center, Brooklyn, NY; [3]Nephrology, Maimonides Medical Center, Brooklyn, NY.*

**PURPOSE**

To determine outcome correlation with APACHE IV (Acute Physiology & Chronic Health Evaluation) scores at admission & 24 hours prior to emergent Renal Replacement Therapy (RRT) in patients with Acute Renal Failure in ICU (Intensive Care Unit).

**METHODS**

• Retrospective chart review of single center Medical ICU database of all patients who underwent emergent RRT over 18 months.

• Data was collected to calculate the APACHE IV score on admission to the ICU and 24 hours prior to RRT.

• Correlation between the 2 APACHE IV scores and the outcomes of these patients (death or survival to discharge) was determined.

• Exclusions: ESRD patients, palliative care patients receiving RRT, subsequent ICU admissions.

**RESULTS**

· A total of 70 patient charts were reviewed. 43% (n=30) of the patients died during hospitalization after receiving RRT and 57% (n=40) of patients survived.

· Cox regression analysis was performed with both scores and the APACHE scores 24 hrs prior to RRT correlated better with outcome compared to APACHE score at ICU admission.

· The p value was 0.045 for the analysis with scores at ICU admission and was 0.003 for analysis with scores 24 hrs prior to RRT.

· The hazard ratio increases by 2.1% for every 1 point increase in APACHE I score at ICU admission and increases by 3.2% for every 1 point increase in APACHE score 24 hrs prior to RRT.

**CONCLUSIONS**

· The patients in medical ICU with ARF requiring emergent RRT continue to have very high mortality rates. We have previously submitted results showing that APACHE scores at ICU admission correlate strongly with outcomes after RRT in this subset of patients.

· Calculating scores at admission is standard of care in ICUs, however determining the APACHE IV score 24hrs prior to RRT may be a better guide for predicting outcomes in this group of patients. Further studies are needed with larger patient populations to propose a scoring system that can be used for this group of patients and APACHE IV may be a useful tool for such studies.

Disclosure of Financial Relationships: nothing to disclose

## PUB145

**Comparison of 4 Severity Scoring Systems for Predicting Outcomes in ICU Patients with Acute Renal Failure** Vijaya Surekha Bhamidipati,[1] Winston Lee,[2] Sheldon Greenberg.[3] *[1]Internal Medicine, Christiana Care Health System, Newark, DE; [2]Nephrology, Maimonides Medical Center, Brooklyn, NY; [3]Nephrology, Maimonides Medical Center, Brooklyn, NY.*

**PURPOSE**:

To compare APACHE IV(Acute Physiology & Chronic Health Evaluation), SOFA(Sequential Organ Failure Assessment), MODS (Multi Organ Dysfunction Score ) and SAPS II ( Simplified Acute Physiology Score) scores to predict outcomes in patients in the ICU(Intensive care Unit) with acute renal failure needing emergent Renal replacement therapy (RRT).

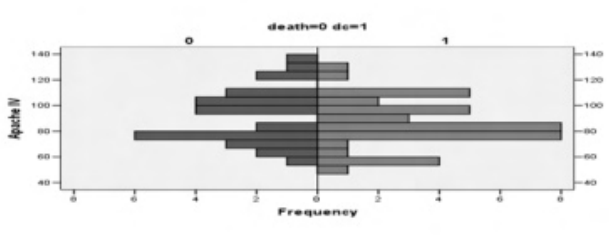
**METHODS**:

· Retrospective chart review of single center Medical ICU database of patients who underwent emergent RRT over 18 months.

· Data was collected to calculate the 4 scores on ICU admission.

· Correlation between the above mentioned scores and the outcomes of patients (death or survival to discharge) was determined after RRT.

Exclusions: ESRD, palliative RRT, subsequent ICU transfers.



**RESULTS**:

· 70 charts reviewed.

· Group 0(Death) =30; Group 1(Survival to discharge)=40

· APACHE IV: Mean in Group 0=92; Group 1= 86.6

· MODS: Mean in Group 0 =9.53; Group 1=8.93( Nonsignificant)

· SAPS II: Mean in Group 0=53.76; Group 1=58.39

· SOFA: Mean in Group 0=10; Group 1=10.44 (Nonsignificant)

· Cox Regression analysis was performed with all 4 scores and APACHE IV score correlated highest with mortality.

**CONCLUSIONS**:

· We have previously presented the correlation between APACHE IV score with outcomes and compared MODS and SAPS II scores with APCAHE IV which was found to have the strongest correlation. We now have similar results with another scoring system, SOFA. We think that the complexity of this system accounts for the strongest correlation.

· Further studies are needed with larger patient populations to propose a scoring system that can be used for this group of patients and APACHE IV may be a useful tool for such studies.

**PUB146**

**B-Type Natriuretic Peptide and Acute Kidney Injury in Critically Ill Patients** Massimo De Cal,[1] Paolo Lentini,[1] Grazia Maria Virzì,[2] Dinna N. Cruz,[2] Claudio Ronco.[2] *[1]Nephrology, University of Padua, Padua, Italy; [2]Nephrology, San Bortolo Hospital, Vicenza, Italy.*

AKI is a common clinical problem in ICU patients and independently predicts poor outcome. AKI can affect the heart through several pathways, whose hierarchy is not yet established. BNP has diagnostic and prognostic utility in patients with acute decompensated heart failure, and it is an independent predictor for cardiovascular events and overall mortality in various patients group including those with chronic kidney disease.

Our study aimed at investigating whether BNP levels in the first 48 hours may be useful in detecting and/or predicting AKI. We studied a cohort of 26 consecutive patients admitted to ICU of our Hospital. Primary outcome was presence of AKI during admission or development of AKI during ICU stay. Plasma BNP was measured with fluorescence-based immunoassay with Triage point-of-care analyzer (Biosite Inc., USA).

In patients with AKI on admission we found a higher SOFA score (10.0±2.4 vs 6.1±2.1; p=.002) and, as expected, higher creatinine levels (1.85 vs 0.82; p=.001) compared to No-AKI patients. Moreover, AKI patients had higher BNP values on admission compared to No-AKI patients: 510 vs 197 pg/mL, respectively. Plasma BNP levels were also statistically significantly higher for AKI patients at 24 and 48 hours after admission compared to No-AKI patients (p<.05). Moreover, increase in BNP of AKI patients during 48 hours was significant (p=.012).

We also analyzed levels of creatinine and BNP in all patients (9) developing AKI at any point during 48 hours.

For those patients, the difference in BNP versus Non-AKI patients at admission was even more pronounced (p=.05). Moreover, for these patients, creatinine and BNP levels at baseline, and at 24 and 48 hours were significantly higher compared to No-AKI patients (p<.05).

This is the first investigation about BNP levels in AKI or Non-AKI ICU patients. We have shown that patients with AKI have high levels of Creatinine and BNP. Moreover, we found a significant increase of BNP levels in patients with AKI at admission during 48 hours. High levels of plasma BNP may help identify patients with elevated risk of AKI in the ICU setting.

**Renal Safety of Ibandronate 6 mg Infused over 15 Minutes Versus 60 Minutes in Breast Cancer Patients with Bone Metastases: A Randomized Open-Label Equivalence Trial** Luc Frimat,[1] Alain Lortholary,[2] Sophie Abadie Lacourtoisie,[3] Fawzia Mefti,[4] Eric Pujade Lauraine,[5] Pascal Bleuzen,[6] Philippe Morvan,[6] Sandrine Kraemer,[6] Xavier Pivot.[7] *[1]Nancy University, France; [2]Catherine de Sienne, Nantes, France; [3]Paul Papin, Angers, France; [4]René Huguenin, Saint-Cloud, France; [5]Hôtel Dieu, Paris, France; [6]Roche, Neuilly-sur-Seine, France; [7]Jean Minjoz, Besançon, France.*

Ibandronate (IB) is indicated to prevent skeletal complications in patients (pts) with breast cancer and bone metastases. A short term infusion could help to overcome time and cost health care issues. The aim of the study is to demonstrate the renal safety equivalence of IB 6 mg infused over 15 min versus 60 min. Pts were women having breast cancer with bone metastasis. Exclusion criteria were renal failure (Cockcroft-Gault < 30mL/min), tooth/jaw disorder or uncontrolled severe diseases. Eligible pts were randomly assigned to receive nine IB 6 mg i.v. infusions over either 15 min or 60 min every 3 weeks for 24 weeks. The primary criterion was creatinine clearance (CC), 28 days after the last infusion. Clinical equivalence was demonstrated if 95% confidence interval (95CI) is in the range [-8,8] mL/min. Out of 334 randomized pts (165 in 15-min group vs 169 in 60-min group), 325 (159 vs. 166) and 312 (151 vs. 161) were respectively included in intent to treat (ITT) and in per protocol (PP) analysis. The difference of CC (95CI) between groups were respectively -2.91 [-7.99, 2.16] and -3.00 [-8.18, 2.18] in ITT and PP, whereas after post-hoc adjustment according to age, the CC are equivalent in both PP and ITT populations. Death and serious adverse event rates did not differ between groups. Three serious adverse events were considered related to IB: an osteonecrosis of the jaw (15-min group), a pain in jaw and an enamel cracking (60-min group). Two renal failures, reported in the 60-min group, were not considered related to IB. None occurred in the 15-min group. In conclusion, IB may be infused over 15 min for 6 months without clinically significant consequence on renal function.

**Eculizumab for Atypical Hemolytic-Uremic Syndrome (aHUS) in an Infant Reverses Renal Failure and Need for Dialysis** Christian Hanna, Randa Razzouk, Scott Schurman, James Listman. *Department of Pediatrics, State University of New York, Upstate Medical University, Syracuse, NY.*

Objectives: The aHUS is a clinical triad of microangiopathic hemolytic anemia, thrombocytopenia, and renal impairment. aHUS is a rare and life-threatening disorder associated with congenital or acquired uncontrolled activation of the complement system that leads to thrombotic microangiopathy and acute renal failure. Plasma infusions have variable efficacy, and end-stage renal disease often develops in treatment failure. Eculizumab (Ecu) is a humanized monoclonal antibody that binds to C5 and inhibits terminal complement activation. We describe here the youngest reported case of aHUS who responded to treatment with Ecu. The patients coures and serologic monitoring of Ecu therapy will be discussed.

Case design: A 10-month old infant girl was hospitalized with severe relapsing aHUS. Plasma infusion therapy initially seemed effective during the first 2 months of her presenting diagnosis. However, she subsequently became more recalcitrant to therapy with rapid deterioration necessitating initiation of hemodialysis as well as switch from plasma infusion to plasma exchange. After start of Ecu intervention, she showed rapid response in clinical and serologic parameters. As of two months of Ecu treatment, she continues with sustained response that includes normalization of renal and hematological parameters without the aid of burdensome plasma therapy or dialysis.

Result: Complete control of a plasma-resistant form of aHUS was achieved over a few weeks and sustained following initiation of chronic treatment with Ecu.

Conclusions: Ecu intervention appears to be more effective and simpler treatment option for aHUS than plasma-based approaches, including affecting reversal of renal failure.

**Extramedullary Hematopoiesis: A Rare Cause of Acute Kidney Injury** Jay S. Hochman,[1] Stephen D. Vaughan,[1] Suchin Worawichawong,[2] James C. Gough,[2] Hallgrimur Benediktsson,[2] Farshad Sepandj.[1] *[1]Internal Medicine, University of Calgary, Calgary, AB, Canada; [2]Pathology, University of Calgary, Calgary, AB, Canada.*

Extramedullary hematopoiesis (EMH) is a recognized complication of adults with myeloproliferative disease, but renal impairment is rare. We present two cases of biopsy-proven renal EMH, which presented with acute kidney injury (AKI).

The first case involved a 73 year old woman with a known history of myelodysplastic syndrome (MDS) who presented with subacute renal failure. Her history, exam and biochemical investigations did not reveal a diagnosis. She therefore underwent renal biopsy, which showed renal EMH and acute tubular injury. To our knowledge this is the first reported case of renal EMH in a patient with MDS. As no ischemic or toxic insult could be indentified, we hypothesize that renal EMH may lead to acute tubular injury. Prior to the biopsy results, this patient received an empiric course of high-dose steroids and had a biochemical improvement in renal function. As there is little evidence to suggest a beneficial effect of steroids in EMH we hypothesize that steroids may have had a non-specific anti-inflammatory effect, which halted the renal tubular injury.

The second case involved a 62 year old female with myelofibrosis and subacute renal failure. Similar to the first case, this patient's renal biopsy demonstrated EMH and acute tubular injury. In review of her history, there were several factors that may have contributed to her renal failure including a lower GI Bleed. However, we suspect that renal EMH contributed to her tubular injury adding supportive evidence to our interpretation of the first case.

In conclusion, renal EMH is a rare finding that may cause or contribute to development of acute tubular injury in patients with certain hematologic disorders.

**The Profile of Acute Kidney Injury in Patients with Acute Viral Hepatitis A on Recent Endemic Outbreaks: A Single Center Experience in Korea** Moon-Jae Kim, Woo Chul Joo, Joon Ho Song, Seoung Woo Lee. *Division of Nephrology & Hypertension, Inha University Hospital, Incheon City, Korea.*

**Background:**

Flu-like outbreaks of viral hepatitis A(VHA) were occured in South Korea for recent years. The existence of VHA-related renal failure as a distinct disease entity is controversial. The purpose of this study was to analyze the clinical features of acute renal injury(AKI) in adults with hepatitis A.

**Methods:**

Clinical and laboratory data of patients with AHA from January 2005 to December 2009 were analysed in our hospital. The diagnosis of AKI was based on appropriate laboratory investigations and RIFLE criteria.

**Results:**

Total 795 patients with VHA were admitted during 5 years and the incidence of AHA was explosively increased since 2008. AKI was noted in 39 cases in those hepatitis A patients(4.9%). Mean ages of AKI patients were in the middle of 4th decade, male was 33 (82.5%). In AKI group serum creatinine levels were peak (6.3 ± 5.7 mg/dl) at 3rd hospital day. Serum AST, ALT and total bilirubin were 2353 ± 2547 IU/l, 2887 ± 2052 IU/I, and 9.3 ± 5.4 mg/dl respectively at that time. The serum creatinine(11.4 ± 5.5 vs 3.1 ± 1.8 and total bilirubin(8.7± 4.6 vs 4.5 ± 2.1mg/dl) were significantly higher in patients of AKI

group than non-AKI group. Oliguria was seen in 85 % of AKI group, and three patients died with fulminant hepatic failure. Mean 4.3 ± 2.3 sessions of HD were performed in oliguric AKI with high level of bilirubin, renal function was completely recovered early than liver function.

**Conclusion:**

AKI is not rare complication of viral hepatitis A. The renal function and mortality were associated by the liver dysfunction in hepatitis A, and the high level of total bilirubin seems to be related to severity of AKI. But any renal injury was not obesrved.

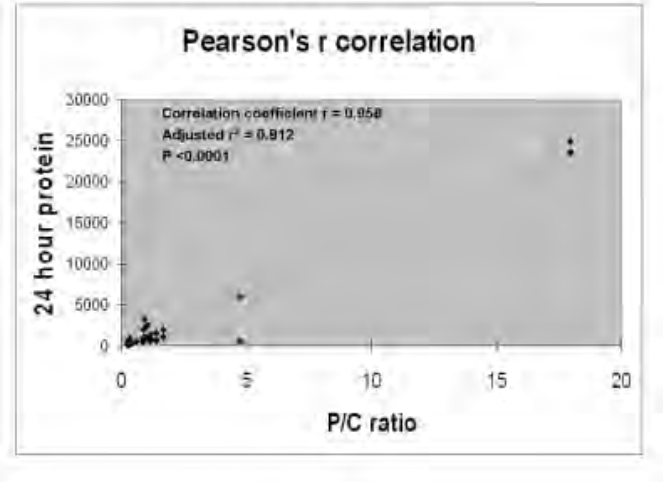
**Correlation of Spot Urine Protein/Creatinine (P/C) Ratio to 24-Hour Urinary Protein in Patients with Acute Kidney Injury (AKI)** Ayman Layka,[1] Mihail Ion Soare,[1] Mauro Braun,[1] Beth L. Fromkin,[1] Rute C. Paixao,[1] Dianne T. Sandy,[1] Gian M. Novaro.[2] *[1]Department of Nephrology, Cleveland Clinic Florida; [2]Department of Cardiology, Cleveland Clinic Florida, Weston, FL.*

Objective: To determine the correlation of random single voided P/C ratio to measurement of protein in 24 hour urine collection in group of inpatients with acutely compromised glomerular filtration Rate (GFR).

Methods: Spot urine P/C ratio and 24-hour urinary protein were measured by standard methods in group of inpatients with non-oliguric AKI not undergoing renal replacement therapy. AKI is defined as an abrupt (within 48 hours) absolute increase in the serum creatinine concentration (Scr) of ≥0.3 mg/dL from baseline. The correlation between the two methods of measurement of proteinuria was calculated by using Pearson correlation coefficient (r).

Results: A total of 17 patients were available for assessment; 13 males and 4 females with total mean age of 66 ± 14 years. 14 patients had hypertension, and 7 patients had diabetes. Mean baseline Scr was 1.5 ± 0.9 and mean Scr on day of urine collection was 3.7 ± 1.9. Mean GFR estimated by MDRD formula was 24 ± 14 mL/min/1.73m² and mean creatinine clearance calculated from 24 hour urine collection was 36 ± 29 ml/min. Mean 24 hour protein was 2490 ± 5832 mg/24 h and mean P/C ratio was 2.1 ± 4.2 mg/g. The bivariate comparison between the the P/C ratio and 24 hour protein collection, using Pearson's r correlation, demonstrated highly positive correlation, which was statistically significant [adjusted r2 = 0.958; p < (2-tailed) 0.0001].



Conclusion: The correlation between spot urine P/C ratio and 24-hour urinary protein is maintained when GFR is abruptly decreased, and this ratio in random single voided urine may serve as reliable surrogate of a timed protein excretion in patients with AKI.

**PUB152**

**64 Year Old Woman with Shortness of Breath, Weight Loss, Fatigue and New Onset of Proteinuria, Hematuria and Renal Failure** Snezana H. Mijovic-Das. *Division of Nephrology, Albany Medical College, Albany, NY.*

Hepatitis C (HCV) infection is by far the most common cause of Mixed Cryoglobulinemia (MC). Cryoglobulinemic glomerulopathy is well described in patients with known Hepatitis C infection. By contrast, renal involvement in patients with Mixed Cryoglobulinemia ( MC ) not associated with HCV is less known and it has been poorly described with only a few cases reported.

We were consulted on a 64 year old, African American woman, treated with Methotrexate and Imuran for Polymyositis for more than ten years, for increased shortness of breath, fatigue and weight loss of 80 lbs, new onset of microscopic hematuria , subnephrotic range proteinuria with acute rise in creatinine to 1.2 ( base line 0.6). The serology revealed anemia, increased creatinine to 1.2, ANA > 5000, and >300 anti ds ab, low complements, elevated anti SSa ab and anti RNP ab ; positive cryoglobulins, but negative for Hepatis C. Both IgM and IgG were elevated and SPEP revealed an IgM kappa paraprotein. Renal biopsy was done and all features of cryoglobulinemic glomerulopathy were present. Neither renal biopsy nor bone marrow revealed presence of lymphoma. We treated the patient with Rituximab with obvious improvement of renal function ( Cr 0.6) and decreased proteinuria.

We concluded that the patient had mixed cryoglobulinemic glomerulopathy likely associated with presence of lupus. We believe that mixed cryoglobulinemia in patients without Hepatitis C is of importance because number of patients with Type II Mixed Cryoglobulinemia and IgM kappa component as a marker of B cell proliferation almost exclusively associated with renal involvement is high mostly in regions where the prevalence of HCV infection is relatively low. Occurrence of overt B cell lymphoma later on in the course of disease is well known and repetitive clinical evaluation of the patients is important.

**Anti-GBM Disease with Normal Renal Function – 6 Cases Report** Lijun Mou, Limeng Chen, Yan Qin, Yubing Wen, Mingxi Li, Hang Li, Xuemei Li, Xue-Wang Li. *Nephrology Department, Peking Union Medical College Hospital, Beijing, China.*

**Objective** To investigate the clinical and pathologic characteristics of anti-GBM disease with normal renal function. **Methods** In the past 11 years, clinical and pathology data of 35 hospitalized patients with anti-GBM disease in Peking Union Medical College Hospital were reviewed retrospectively. The circulating anti-GBM antibodies were detected by enzyme-linked immunoassay (ELISA). All the patients received the pulmonary CT scan and kidney biopsy. **Results**: 6 of 35 (17.1%) patients, who kept normal renal function for 26m (8m to 129m) were enrolled in this study. The average age of the 4 male and 2 female patients were 32.50±8.12 years old. All of the 4 male had pulmonary hemorrhage, with smoking history. 5 patients were accompanied with renal impairment, microhematuria, proteinuria or nephrotic syndrome. One patient had pulmonary hemorrhage only. The antineutrophil cytoplasmic antibody (ANCA) serology was negative of all. Renal biopsies from 5 patients revealed linear deposition of IgG along the GBM, 1 patient showed linear deposition of IgG along the tubular basement membrane accompanied by granular mesangial C3 deposits, by immunofluorescence. Mild mesangial proliferation and crescents formation in 3 patients , normal lightmicroscopy in two patients and endothelial proliferative glomerulonephritis in one patient were observed. Immunosuppression and/or Plasmapheresis were given to 6 patients. The follow-up of patients (8m-129m) revealed a good prognosis, 4 patients achieved complete remission, 2 had mild proteinuria and microhematuria. Compared with the other 30 anti-GBM disease with renal dysfunction patients, the titers of anit-GBM antibody, ratio of percentage of crescents and anemia of the patients with normal renal function were less severe, prognosis is better. **Conclusion** Anti-GBM disease with normal renal function is not uncommon in younger patients. Under the aggressive treatment, a good prognosis of maintaining normal renal function can be expected, in spite of mild proteinuria or hematuria may leave in some patients.

**PUB154**

**Clinical Analysis of 35 Cases with Anti-Glomerular Basement Membrane Disease** Lijun Mou, Limeng Chen, Yubing Wen, Yan Qin, Wenling Ye, Jianling Tao, Wei Ye, Hang Li, Xuemei Li, Xue-Wang Li. *Nephrology Department, Peking Union Medical College Hospital & Chinese Academy of Medical Science, Beijing, China.*

**Objective** To investigate the clinical features, treatment and prognosis of anti-glomerular basement membrane (GBM) disease, examine the efficiency and safety of double filtration plasmapheresis (DFPP). **Methods** A total of 35 hospitalized patients diagnosed as anti-GBM disease were recruited in our center. All patients were divided into 3 groups as the manifestation at admission. Group I: patients with severe pulmonary hemorrhage or RPGN were treated with pulse methylprednisone with or without DFPP, then followed by prednisone and CTX (n=24). Group II: patients without severe pulmonary hemorrhage and RPGN were treated with prednisone and CTX (n=5). Group III: 5 ESRD patients and 1 normal renal function patient (n=6) were not received immunosuppression thearapy. Anti-GBM antibody titers of pre and post-DFPP in 4 patients were measured consectively, removal rates were calculated. **Results** The mean age of all patients was 41.1±16.6 y. 45.7% presented with pulmonary-renal syndrome. 20% patients had positive P-ANCA serology. 54.2% crescentic glomerulonephritis and 8 with other types of glomerulonephritis were revealed by kidney biopy (n=24). Patients in Groups I showed more severe manifestation at admission: higher concentration of serum creatinine, peak titers of anit-GBM antibody, percentage of crescents, with the follow-up 7 died, but 50% patients avoided death and/or dialysis-dependent end-stage renal disease. No patient died in group II and III. The older age, anemia, higher Scr(>300μmol/L), oligouria or anuria and immediate HD required at admission, more glomerular sclerosis, but not the percentage of crescent and therapy strategy, predicted poor prognosis. The anti-GBM antibody was negative after 4-6 times of DFPP , the median removal rate was 55%. During total 94 DFPP sessions, there were no unacceptable morbidity. **Conclusions** Different thearapy strategy is necessary for anti-GBM disease with different clinical manisfestation. DFPP is an effective and safe way to clear the anti-GBM antibody.

**Anuric Acute Kidney Injury Induced by Acute Mountain Sickness Prophylaxis with Acetazolamide** Javier Neyra,[1] James Castle,[3] James E. Novak.[2] *[1]Department of Internal Medicine, Henry Ford Health System, Detroit, MI; [2]Division of Nephrology and Hypertension, Henry Ford Health System, Detroit, MI; [3]Division of Nephrology and Hypertension, British American Hospital, Lima, Peru.*

Acetazolamide (ACZ) is a carbonic anhydrase inhibitor used as a diuretic, anticonvulsant, and antiglaucoma agent. ACZ is also used as prophylaxis for acute mountain sickness before ascent to high altitude. A 55-year-old healthy man with a history of incidentally-detected kidney stones traveled to Peru. He took 2 doses of ACZ 250 mg before ascent to Ancash, Peru (4500 meters above sea level) and 3 doses of 250 mg while at peak ascent, all at intervals of 12 h. He had taken similar prophylaxis without incident on previous trips. 24 h after peak ascent, he developed headache, nausea, bilateral low back pain, and oliguria. Renal ultrasound showed uncomplicated right-sided nephrolithiasis without obstruction and an empty bladder, confirmed by bladder catheterization. Creatinine and BUN were 9.5 mg/dL and 94 mg/dL, respectively. Blood tests showed mild leukocytosis, high anion gap metabolic acidosis, and hyperphosphatemia. The patient received normal saline with minimal response and subsequently required 2 sessions of hemodialysis for anuric acute kidney injury (AKI). Renal Doppler ultrasound, serum complement, ASO, CPK, and myoglobin were normal. UA showed pH 6, urine protein:creatinine ratio 0.24, and fractional excretion of sodium 22%. Urine microscopy showed isomorphic RBCs (12-15/hpf) but no eosinophils, casts, or crystals. Renal function returned to baseline after 96 h of supportive care and the patient was discharged. 24-h urine collection after recovery revealed normal excretion of electrolytes, creatinine, and uric acid. The pathogenesis of AKI was attributed to ACZ crystalluria causing tubular obstruction. This classic presentation of anuria and renal colic has been described previously in patients receiving ACZ for glaucoma and epilepsy. However, ours is the first report of AKI after exposure to prophylactic doses of ACZ to prevent acute mountain sickness. This case highlights the risk of adverse outcomes even in previously healthy individuals and suggests that increased fluid intake may be advisable in travelers taking ACZ prophylaxis.

**Non-Dilated Obstructive Uropathy – An Unrecognized Cause of Acute Renal Failure in Hospitalized US Patients** Macaulay A. Onuigbo,[1,2] Kayode C. Lawrence,[3] Nnonyelum T. Onuigbo.[4] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Midelfort Clinic, Eau Claire, WI; [3]Nephrology, Elmhurst Hospital Center, New York, NY; [4]IT, NT Systems, Eau Claire, WI.*

Background/Objective

The syndrome of non-dilated obstructive uropathy (NDOU) and ARF is well reported. However, the literature suggests that this syndrome is rare, accounting for less than 5% of cases of urinary obstruction. Our recent experience with three cases of NDOU seen within a space of months suggests otherwise.

Methods

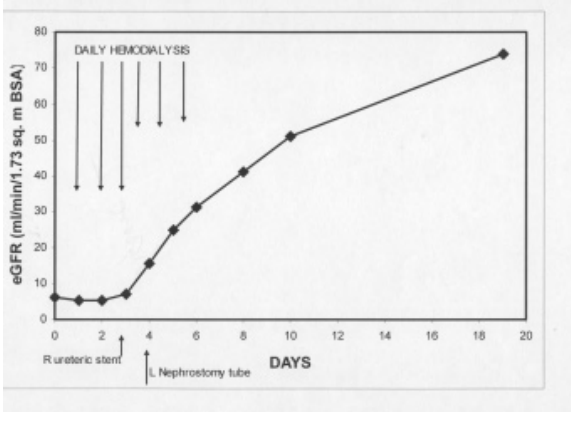
Between March 2009 and October 2009, in a small Mid-western American town Nephrology practice, we successfully managed three cases of NDOU. They all presented with newly symptomatic ARF.

Results

Renal imaging revealed no dilatation in both kidneys in one, unilateral dilatation only in the second, and dilatation was absent in a single functioning kidney in the third. Two males, three females, mean age 61 years. Peak creatinine, 320–880 umol/L. Despite absence of dilatation on renal imaging, strong suspicion for NDOU led to decompression procedures with prompt recovery of kidney function in all three patients – two required percutaneuous nephrostomy tube placements and/or ureteric stents and one responded to simple Foley catheter drainage. One required temporary hemodialysis (Table 1, Figure 1).

Conclusion

We submit that NDOU may be more common than previously speculated. A high index of suspicion is warranted as significant renal salvage can often be achieved by timely decompression procedures.



Charateristics of 3 patients with NDOU

| AGE/SEX | Peak S Cr (mg/dL) | New S Cr (mg/dL) | Cause of Non-dilatation | Hemodialysis | Treatment |
|---|---|---|---|---|---|
| 56/M | 10.3 | 1.2 | Metastatic bladder cancer | YES | R Ureteric stent + L perc Nephrostomy |
| 59/F | 4.4 | 1.08 | Metastatic uterine cancer | NO | L perc Nephrostomy |
| 67/M | 4.0 | 1.8 | BPH, short duration | NO | Foley Catheter |

**N-acetyl Cysteine in the Management of Carboplatin- and Ifosfamide-Induced Nephrotoxicity** Rasmi Palassery, Osvaldo Regueira, Curtis W. Turner, Tetyana L. Vasylyeva. *Department of Pediatrics, Texas Tech University Health Sciences Center, Amarillo, TX.*

**Background**: Carboplatin and ifosfamide are alkylating chemotherapeutics used to treat solid tumors. N-acetyl cysteine (NAC) was protective in ifosfamide-induced nephrotoxicity *in vitro*, but its clinical use for carboplatin nephrotoxicity has not been described. We report the case of NAC treatment for acute renal injury in an adolescent who received ifosfamide, carboplatin, and paclitaxel. **Case Report:** A 15-year-old male received chemotherapy for abdominal recurrence of a mixed germ cell tumor of the testis. The primary tumor was treated with cisplatin, etoposide, and bleomycin eight-months earlier. Serum creatinine after the first chemotherapy cycle ranged between 1.05 and 1.61 mg/dL. The day before initiating the second course of chemotherapy, the patient's serum creatinine was 1.23 mg/dL. After hydration with IV fluids, he received paclitaxel (257 mg), carboplatin (653 mg), and ifosfamide (3400 mg) admixed with mesna (684 mg) on day 1. He received ifosfamide (3420 mg/day) admixed with mesna (684 mg), with appropriate hydration for 4 subsequent days. During the week, urinary output decreased and serum creatinine steadily increased to 2.06 mg/dL by day 7. NAC (600 mg PO BID) was initiated. Creatinine rose to 2.25 mg/dL the next day and then began to fall. NAC was discontinued on day 11 and the patient was discharged on day 15 when his creatinine was 1.12 mg/dL. **Conclusion:** NAC ameliorates chemotherapy-induced nephrotoxicity. The observed effect may be due to alterations in mitochondrial apoptotic pathways and/or glutathione replenishment. NAC's antioxidant properties are known to reverse free-radical-mediated cell damage and mitochondrial injury, both possible pathways of carboplatin and ifosfamide renal injury. Prophylactic or concomitant NAC treatment with carboplatin and ifosfamide should be considered to prevent nephrotoxicity.

**PUB158**

**Acute Tubular Necrosis Associated with Vancomycin Alone: Is It so Uncommom?** Mohammad A. Quasem. *Internal Medicine, United Health Services Hospitals, Binghamton, NY.*

***Introduction:*** Vancomycin is nephrotoxic. Nephrotoxicity was reported in 0-5% in 1980s. However recent reports indicate higher incidence of nephrotoxicity. It is more nephrotoxic in combination with other nephrotoxic medications particularly aminoglycosides. According to recent publications, nephrotoxicity of vancomycin alone as high as 19% and as high as 28% in combination with aminoglycosides.. The most common type of toxicity is acute interstitial nephritis (AIN). Acute tubular necrosis (ATN) from vancomycin alone is very rare. Some earlier literatures report vancomycin alone never causes ATN.

***Case:*** We present a biopsy-proven case of ATN from vancomycin alone. Our patient, a 63 yr old female admitted with left hip cellulitis. She was put on iv vancomycin. After 5 days, she was discharged home with administration of iv vancomycin at home by home care nurse. Vancomycin (random) level was 84 mcg/ml after 10 days and she developed acute kidney injury(AKI) with serum creatinine of 4.6 mg/dl (baseline 0.8 mg/dl). She was re-admitted to hospital and kidney biopsy showed tubular injury without any inflammation to suggest AIN. Vancomycin was stopped and the patient had full recovery of renal function after 4 weeks.

***Conclusion:*** Vancomycin associated ATN probably more common than anticipated as biopsies are rarely done.

**PUB159**

**Unusually Slow Recovery from Acute Tubular Necrosis Due to Zoledronic Acid. A Case Report** Frederic F. Rahbari-Oskoui,[1] Odicie O. Fielder,[3] Nima Ghasemzadeh,[1] Randolph A. Hennigar.[2] *[1]Medicine, Emory University, Atlanta, GA; [2]Pathology, Emory University, Atlanta, GA; [3]Medicine, Kaiser Permanente, Atlanta, GA.*

**Background:** Dose dependant acute tubular necrosis (ATN) due to Zoledronic acid (Zometa) has been reported. Most cases have involved prostate cancer and multiple myeloma, where majority of patients required chronic hemodialysis. All reported cases of recovery, if present, occurred within 4 months of acute insult.

**The case:** A 59 year old white female with diabetes mellitus, hypertension and metastatic breast cancer and normal kidney function was treated with 15 monthly injections of Zometa for prevention of hypercalcemia and had developed two episodes of mild acute kidney injury (AKI) with serum creatinine levels of < 2 mg/dl, which had resolved by withholding the treatment. After the 16th injection, she developed severe AKI

due to ATN based on urine microscopy. Zometa was the only possible offender. Serum creatinine stabilized around 8.0 mg/dl without hyperkalemia, hypervolemia or uremic symptoms, therefore initiation of dialysis wasn't deemed necessary. But due to lack of significant improvement of kidney function, worsening of subnephrotic range proteinuria and appearance of eosinophiluria over the next 3 months, a kidney biopsy was performed to rule out other possible etiologies. Diagnosis of pure ATN was confirmed. The course was remarkable for an unusually slow and progressive recovery over more than 15 months, with stabilization of serum creatinine around 3.0 mg/dl without any need for dialysis. This slow pattern of recovery is extremely unusual for any cause of ATN.

**Conclusion:** Repeated injections of Zometa may result in severe AKI even if previous reversible episodes of mild AKI occurred. Presence of such episodes may represent a warning sign for development of severe ATN by cumulative dose toxicity and indicate the need for discontinuation of treatment. Even though most reported cases of ATN needed immediate initiation of dialysis without any reported recovery, in the absence of absolute indications, dialysis may not be necessary and progressive recovery of renal function may occur up to 15 months after the original insult.

## PUB160

**Granulomatous Interstitial Nephritis: A Rare Presentation of Crohn's Disease** Manish K. Saha, Tarek Hamieh, Vishal Sagar. *Department of Medicine, Regions hospital, University of Minnesota, Saint Paul, MN.*

Case Presentation: A 17-year-old male with Attention Deficit Hyperactivity Disorder was admitted with generalized weakness and malaise. Work-up revealed a creatinine of 4.0 mg/dL. Urinalysis was negative for RBC, cast or significant proteinuria. Hepatitis panel was nonreactive. A percutaneous kidney biopsy revealed noncaseating granulomas, acute on chronic tubulointerstitial nephritis (TIN) with normal glomeruli . A diagnosis of granulomatous interstitial nephritis (GIN) was made and prednisone was started. Two weeks later, creatinine decreased to 2.8 mg/dL.However patient developed diarrhea when prednisone was tapered. Colonoscopy was consistent with Crohn's disease (CD). He was restarted on prednisone with improvement of his GI symptoms and stable creatinine. He did not tolerated higher doses of prednisone and attempts at tapering prednisone resulted in worsening of kidney function. Subsequently he also failed azathioprine. Infliximab was started with improvement in his creatinine to 2.6mg/dl and resolution of diarrhea.

Discussion: We present this case of granulomatous interstitial nephritis (GIN) as the initial manifestation of Crohn's disease (CD). Historically, most cases of TIN associated with CD have been strongly attributed to aminosalicylates (5-ASA) exposure. Our case was unique in that the initial manifestation of CD was renal insufficiency secondary to GIN. The GIN found on kidney biopsy subsequently raised the suspicion for inflammatory bowel disease (IBD) in our patient when he presented with diarrhea. Additionally, this case highlights the need to consider TNF-alpha inhibitors before pursuing further aggressive measures such as renal replacement therapy, transplant, or proctocolectomy. Since it may be the same immune mechanism causing intestinal inflammation and interstitial nephritis, infliximab may play a role in renal insufficiency in patients refractory or intolerable to corticosteroids/aminosalicylates. Infliximab may also be better at controlling diarrhea than other immunomodulators thus decreasing the prerenal effects of hypovolemia on existing CKD.

## PUB161

**Biopsy-Proven Acute Tubular Necrosis in High Vancomycin Level Associated Acute Kidney Injury: Case Series** Ganesh B. Shidham,[1] Ravish Shah,[1] Anil K. Agarwal,[1] Tibor Nadasdy.[2] *[1]Internal Medicine, Ohio State University Medical Center, Columbus, OH; [2]Pathology, Ohio State University Medical Center, Columbus, OH.*

**Purpose of study:** To our knowledge this is the first case series reporting biopsy-proven acute tubular necrosis (ATN) associated with high levels of vancomycin. Recently there has been a 10- to 20-fold increase in vancomycin use. Outpatient vancomycin therapy, higher trough levels, longer treatment duration, concomitant nephrotoxic agents, and chronic kidney disease are among the risk factors for nephrotoxicity. Although allergic interstitial nephritis is a well-known complication, vancomycin induces oxidative stress, resulting in ATN as shown in animal studies. Human cases with biopsy-proven vancomycin-associated ATN have been rarely reported in the literature. **Methods:** A retrospective chart review was performed on patients who underwent a kidney biopsy for acute renal failure (ARF) and high levels of vancomycin with clinical suspicion of vancomycin-associated ARF. Fifteen cases were identified from Nov 2008 to Dec 2009.

**Results:**

| Number of biopsies | Age (years) | Creatinine baseline (mg/dl) | Creatinine peak (mg/dl) | Creatinine at recovery (mg/dl) | Vancomycin Level* (mcg/ml) | Biopsy Findings | |
|---|---|---|---|---|---|---|---|
| | mean: 58.4 | mean: 1.04 | mean: 6.5 | mean: 1.5 | mean: 48.8 | ATN | ATN + TIN |
| 15 | range: 22-83 | range: 0.5 to 2 | range: 3.8-14 | range: 0.8 to 2.2 | range: 22 to 149 | 5 | 10 |

TIN: Tubulointerstial nephritis. * Vancomycin therapeutic level 15-20 mcg/ml

**Conclusion:** Our retrospective review of kidney biopsies in patients with ARF and high levels of vancomycin shows universal evidence of ATN and in some cases mild to moderate tubulointerstitial nephritis. Though a few patients needed renal replacement therapy, prognosis of vancomycin-associated ARF is uniformly good with improvement of creatinine to baseline. We recommend close monitoring of trough levels of vancomycin, particularly in those with risk factors such as chronic kidney disease, advanced age, liver disease, and after exposure to contrast agent to prevent vancomycin-associated ARF.

## PUB162

**How Safe Is Exenatide in Type2 Diabetics with Renal Impairment?** Rajesh Shrivastava, Ashraf I. Mikhail, Sadananda V. Aithal. *Morriston Hospital, United Kingdom.*

The management of type 2 diabetes mellitus in patients with renal impairment is complicated by weight gain and hypoglycaemic events.Incretin-mimetics hoped to address these issues. Exenatide is licenced for use in type2 diabetes mellitus in patients with mild renal impairment(crcl 50-80ml/min) and with caution in moderate renal impairment (crcl 30-50ml/min).

We report the effects of exenatide in a 63year old male with poorly controlled type2 diabetes, obesity (Wt 105.5 Kgs, BMI 34.4),hypertension,hyperlipidaemia and stable chronic kidney disease(creatinine 138µmols/l,eGFR 45mls/min/1.73m2) with microabuminuria. He commenced Exenatide 5µg twice daily, increased to 10µg in four weeks. He developed nausea and intermittent vomiting with the increased dose. His glycaemic control improved and weight dropped to 99.6Kgs. He presented 2months later with a creatinine of 1393µmol/L. He appeared euvolaemic and maintained a urine output of 2l/day. His BP was 145/70. Urinalysis was normal. He commenced haemodialysis 48hrs later.

Renal biopsy showed mild diffuse mesangial sclerosis.The striking feature was proximal tubular dilatation with hydropic vacuolation and features of acute tubular necrosis(ATN).

Exenatide, ramipril, metformin, frusemide and rosuvastatin were discontinued. His renal function improved as shown and he was off dialysis after 3weeks.

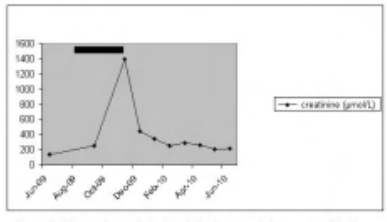

Figure 1. Change in creatinine in relation to exenatide exposure (black rectangle)

The potential natriuretic action of exenatide along with diuresis and ACE inhibition may have compounded the effects of subclinical volume depletion in causing ATN in our case.This highlights the need to exercise extreme caution with the use of exenatide even in patients with stable early CKD in the presence of other risk factors for renal injury. Exenatide induced renal injury requiring dialysis has been reported to FDA. However there are no published reports describing the natural course of patients needing dialysis following acute kidney injury post exenatide use.

**Coexisting IgA Nephropathy and Antiglomerular Basement Membrane (Anti-GBM) Disease** Vishwanath Siddini, Sudarshan H. Ballal. *Nephrology, Manipal Hospital, Rustom Bagh, Bangalore, Karnataka, India.*

BACKGROUND: Antiglomerular basement membrane (GBM) disease is characteristically described with linear deposition of IgG along glomerular basement membrane. Concurrence of IgA nephropathy and anti-GBM disease is very rare. Here is a case report of a patient who was diagnosed to have concurrent anti-GBM disease and IgA nephropathy

CASE: A 31 yr old female with no previous comorbidities presented with history of hematuria, oligoanuria and nausea and vomiting. On examination she had features of volume overload. Investigations showed serum creatinine of 7mg/dl and Hemoglobin of 8.4 gm/dl. Urinalysis showed 3+ protein with 10-15 RBCs. Ultrasound abdomen showed normal sized kidneys. Serum C3, ANA and ANCA was negative and serum Anti-GBM antibody was positive. She underwent renal biopsy after initiation of hemodialysis. LM showed enlarged glomeruli with cellular and fibrocellular crescents, mesangial proliferation and mild irregular basement membrane thickening. IF revealed linear IgG deposits and significant mesangial IgA deposits. Serum Anti-GBM antibody was positive. She was diagnosed to have antiGBM disease with IgA nephropathy. She received total 3 gms of iv methyl prednisolone followed by oral steroids. She also received 8 sessions of plasmapheresis, intermittent hemodialysis and 500 mg of IV cyclophosphamide. She continued to be anuric. Currently, she is on maintenance hemodialysis and the oral steroid has been stopped.

CONCLUSIONS: Concurrence of anti-GBM disease with other IgA nephropathy is very rare. After extensive search we could find only 2 case reports of coexisting IgA nephropathy and anti-GBM disease. To our knowledge this is the first case report of IgA nephropathy with anti-GBM disease from India.

**PUB164**

**Plasmapheresis in Non-Diarrhoeal HUS Patients** Vishwanath Siddini, Sudarshan H. Ballal. *Nephrology, Manipal Hospital, Bangalore, Karnataka, India.*

**AIM**: To study clinical profile and role of Plasmapheresis in atypical HUS.

**MATERIALS AND METHODS:** 11 patients between 4 and 15 years of age with non-diarrhoeal HUS were studied. The clinical profile and severity of lesions on renal biopsy were studied. Plasmapheresis (single volume) was instituted soon after diagnosis and continued till hematological parameters were near normal and stable. Efficacy of PP was assessed based on duration and severity of illness, number of sittings required and time for normalization of hematological and renal parameters.

**RESULTS:** There were 8 males and 3 females with mean age of 9.4 years (range 4 to 15). Patient's parameters are in the table.

Table 1

| Age (years) | Duration of Illness | Urine Output | Hb% | Platelet Count | LDH | Peak S. Cr. (mg/dL) | Renal Biopsy |
|---|---|---|---|---|---|---|---|
| 5 | 1 month | Oliguric | 6.5 | 50,000 | 1754 | 5.2 | Glomerular |
| 11 | 1 month | anuric | 7.6 | 41,000 | 1007 | 6.8 | Arteriolar |
| 8 | 3 days | non-ologuric | 5.7 | 20,000 | 2691 | 3.8 | Glomerular |
| 4 | 1 week | Oliguric | 6.2 | 30,000 | 2340 | 4.5 | Glomerular |
| 6 | 10 days | oliguric | 7.5 | 55,000 | 1608 | 2.4 | not done |
| 9 | 1 week | non-oliguric | 8.5 | 20,000 | 1998 | 9.8 | Glomerular |
| 11 | 2 days | Oliguric | 9.3 | 83,000 | 5623 | 4.9 | not done |
| 13 | 1 week | non-oliguric | 6.6 | 67,000 | 1156 | 3 | glomerular |
| 11 | 2 days | Oliguric | 5.3 | 65,000 | 2718 | 16.8 | Arteriolar |
| 12 | 1 week | Oliguric | 4.3 | 92,000 | 3084 | 5 | not done |
| 15 | 6 weeks | Oliguric | 7.3 | 18,000 | 1898 | 7.1 | Arteriolar |

All patients except 2 required dialytic support. Patients required a mean of 11.4 sittings of PP to normalize and stabilize their haematologic parameters. One patient had recurrence of renal and haematologic abnormalities after 10 days and received another sitting of 5 cycles of PP. Another patient had recurrence after 5 days requiring 6 sittings of PP. Renal parameters took longer (> 4 weeks) to recover and all except 3 have normal renal functions on follow up. One patient expired. Two patients are still dialysis dependent.

**CONCLUSIONS**: PP is an effective form of therapy in atypical HUS and we found it to be useful even with a long duration of disease and severe lesions (arteriolar) on biopsy.

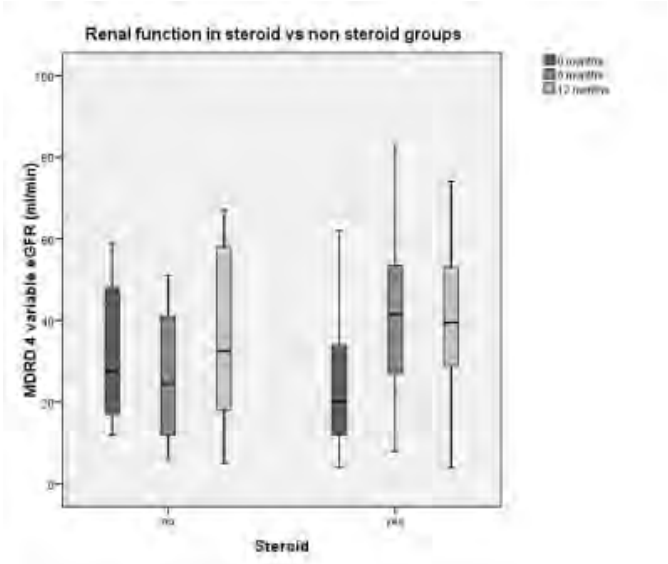
**PUB165**

**Long Term Outcome in the Largest Single Centre Study of the Effect of Steroids in Acute Idiopathic Interstitial Nephritis** Anisha Tanna, Jenny Rayner, Alan D. Salama, Frederick W. K. Tam, David Taube, Seema Singh, Charles D. Pusey, H. Terence Cook, Neill D. Duncan. *Imperial College Kidney and Transplant Institute, Hammersmith Hospital, London, United Kingdom.*

There are no prospective randomised control trials of steroid treatment for Acute Idiopathic Interstitial Nephritis [AIIN], and retrospective studies to date are very limited. This pathology is relatively common, AIIN was found in 271/2855 native renal biopsies at our centre 2000-2010.

**Methods:** This is a retrospective longitudinal study of all patients with biopsy proven acute interstitial infiltration in the absence of additional renal pathology. Patients on maintenance steroid treatment for proven vasculitis or other chronic inflammatory condition were excluded. Treated patients received oral Prednisolone ≥0.5mg/kg, an intention to treat analysis was performed.

**Results:** Eighty one patients were treated with steroids: 48 male, 51±17yrs, follow-up 32±26 months. Sixteen patients were not treated with steroids: 13 male, 55±17yrs, follow-up 37±26 months. Compared to eGFR at initiation of treatment, there was a significant difference in the steroid group at 6 and 12 months (paired t-test, p<0.001). In the non-treated group there was no significant difference in GFR at 6 or 12 months.



The mean change in EGFR to six months was plus 16.3 ml/min/month for the steroid group and minus 14.0 ml/min/month for the non-treated group (unpaired ttest, p<0.05). There was no significant difference in the proportion of patients on RRT at last follow between the two groups (Chi squared P=0.86)

**Conclusion:** Corticosteroids were beneficial in the treatment of AIIN, however despite the size of this study there are limitations of retrospective analysis, and treatment bias must be taken into account. A prospective randomised controlled trial into the use of corticosteroids in this condition is urgently needed.

**A Case of Acute Renal Failure with Rapidly Enlarging Kidneys** Lakshmi Turlapati, Tejas P. Desai, Karlene O. Hewan-Lowe. *Department of Nephrology, East Carolina University, Greenville, NC.*

**Case Information:** A 52-year-old obese female admitted for pancreatitis was treated empirically with vancomycin and piperacillin-tazobactam. Her renal function at admission was normal. A week into her hospitalization, she developed progressively worsening renal failure and generalized macular blanching rash. She became oliguric and required dialysis support. Her urine microscopy revealed many monomorphic red blood cells. She had proteinuria (1 gram/24 hours). Her serological work up was significant for low complements. Serial non-contrast CT scans showed rapidly increasing kidney size from 12.6 cm to 16 cm bilaterally within 8 days. Subsequently she had renal biopsy which showed dispersed interstitial mononuclear inflammatory infiltrate with rare eosinophils and tubular damage. She was diagnosed as having acute interstitial nephritis secondary to piperacillin which was discontinued. She was treated with steroids resulting in clinical improvement.

**Discussion:** Acute interstitial nephritis is a known reversible cause of acute renal failure. Major secondary causes of acute interstitial nephritis include drugs, infections and autoimmune disorders. Most cases are idiopathic. Symptoms of AIN usually start approximately 3 weeks after the drug exposure but may range from 1 day to 2 months. Clinical manifestations may vary from asymptomatic elevation of BUN/creatinine or abnormal urinary sediment to generalized hypersensitivity syndrome with fever, rash, eosinophilia and oliguric renal failure. Our patient had fever, rash and oliguric renal failure but did not have peripheral eosinophilia or eosinophiluria. It has been reported that kidneys may be normal or enlarged in size. In our case we report a significant acute enlargement in kidney size on serial scans which could increase the positive predictive value for acute inflammatory processes affecting the kidneys. Supportive treatment with withdrawal of the causative agent usually results in improvement of renal failure. The role of steroids still needs to be defined.

**Acute Tubulo-Interstitial Nephritis in a Patient with Hepatitis B on Tenofovir** Hima Bindu Yalamanchili,[1] Sandeep Ravi,[1] Yue Shen,[1] Gilbert W. Moeckel,[2] George Abdelsayed,[1] James P. Gavin.[1] *[1]Internal Medicine/ Nephrology, Bridgeport Hospital/Yale University, Bridgeport, CT; [2]Department of Pathology, Yale University School of Medicine, New Haven, CT.*

Introduction: Acute Interstitial Nephritis (AIN) has been reported in Human Immunodeficiency Virus patients on atazanavir and tenofovir. We present a patient with Hepatitis B on tenofovir monotherapy presenting with acute renal failure secondary to acute tubulo-interstitial nephritis.

Case: A 67-year-old African American male with past medical history of chronic active Hepatitis B infection treated with tenofovir and hypertension was admitted with generalized weakness,nausea for one week. His medications were atorvastatin, hydrochlorothiazide, and atenolol. There were neither any new medications nor any dosage changes prior to

current presentation. Initial serum chemistry revealed Blood urea nitrogen of 173 mg/dl, Creatinine 18.6 mg/dl, bicarbonate 22 meq, Phosphorus level 12.5 mg/dl, (a baseline creatinine 1.23) and Creatinine phosphokinase of 741 IU/l. Urine analysis demonstrated specific gravity 1.014, no casts, negative for urinary glucose with rare urine eosinophils. 24 hr urinary protein was 830 mg/day. Investigations for HIV and cryoglobulins were negative. Renal ultrasound demonstrated normal sized kidneys. Biopsy demonstrated acute tubulo-interstitial nephritis with focal glomerulosclerosis. His renal function gradually improved with transient hemodialysis(10 days),Tenofovir discontinuation and 3-day course of pulsed methylprednisolone followed by prednisone taper.

Unique features: To our knowledge acute tubulo-interstitial nephritis was not previously described on tenofovir monotherapy. Few previous case reports of AIN were reported in patients with HIV on combination of tenofovir and atazanavir. Tenofovir alone was associated with Fanconi's syndrome and proximal tubular dysfunction. Due to the temporal association and improvement of renal function off tenofovir, tenofovir is the most likely cause of acute renal failure in this patient.

Objective: This case highlights the importance of awareness that tenofovir might be a rare cause of acute tubulo-interstitial nephritis.

**Stage 3 Chronic Kidney Disease (CKD): Aliskiren and Proteinuria** Marcos Luis Álvarez Alejandre,[1] Consolación Rosado Rubio,[1] Raquel López de la Fuente,[2] Jose L. Lerma,[1] Cyntia Gonzalez Álvarez,[1] José Luis Rodríguez Commes.[1] *[1]Servicio de Nefrología, Hospital Clínico de Salamanca, Salamanca, Spain; [2]Centro de Salud Santa Elena, Zamora, Zamora, Spain.*

Introduction:

Block early proteinuria is an effective mechanism to slow the progression of renal damage and reduce cardiovascular morbidity, greatly increased in the ERC. One of the fundamentals is to inhibit angiotensin Rennin axis. However, the dual blockade with ACEI + ARB, can impair kidney function and induce hyperkalemia, especially in the elderly.

Recently it has aliskiren, direct renin blocker, but is unknown effect on proteinuria and progression of CKD in the elderly when added to ACEI / ARB.

Objectives:

1. To assess the antiproteinuric effects of aliskiren for 6 months.
2. To determine the impact on renal function
3. Establish clinical and metabolic side effects

Methods:

We studied prospectively a population of 44 patients (mean age 70 +/- 5) CKD stage III treated with ACEI and/or ARBs 150-mg/dia Aliskiren was added. Each patient was in control of himself and used a control group of 12 patients with similar characteristics treated with ARB (olmesartan) was determined microalbuminuria, serum K, serum Cr. Ccr (MDRD) The statistical analysis was conducted using as variance using the Student t test or Kruskal-Wallis test, depending on variables.

Results:

There was a significant reduction from 1012 to 875 microalbuminuria ($p < 0.002$)

The average concentration of serum K was 4.5 mg / dl, unchanged throughout the study. ($p = 0.86$)

There was a significant reduction in serum Cr from 1.98 to 1.94 mg / dl ($p < 0.003$) and Ccr increased from 36.61 to 37.8 ml/min ($p < 0.013$).

Conclusions:

1. Microalbuminuria Aliskiren significantly reduced in elderly patients with CKD stage III, previously treated with ACE inhibitors and / or ARB.

2. The good tolerability of aliskiren, the lack of metabolic adverse effects (hyperkalemia) and the moderate increase in glomerular filtration allow its use in this population with close monitoring, but requires long-term randomized studies to verify these results.

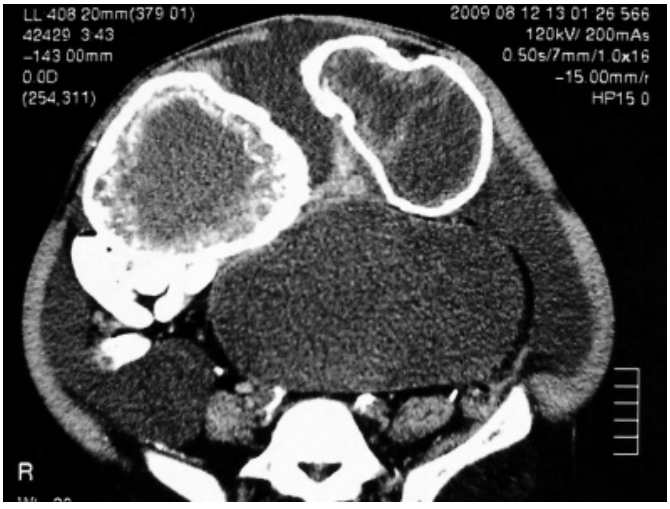
**Unusual Calcified Mesenteric Pseudocysts in a Chronic Hemodialysis Patient** Heino R. Anto,[1,2] Suk Chul Kim,[1] Anatole Hounnou,[2] Richard Steinberg.[2] *[1]Nephrology, Saint John's Episcopal Hospital, New York, NY; [2]Nephrology, Peninsula Hospital Center, New York, NY.*

A 32 y/o male on hemodialysis for 8 years and whose renal replacement was exclusively hemodialysis, developed nephrogenic ascites over a 7 year period. During his dialysis tenure, the patient was poorly compliant in keeping his dialysis sessions, following his diet, or taking his phosphate binders. His serum phosphorous was frequently over 5.5 mg/dl, and serum intact PTH over 1000 pg/ml. A 2009 CT of his abdomen revealed calcified mesenteric pseudocysts which were not present on a 2003 CT scan.



We believe that the structure of these pseudocysts are extremely unusual, and have never been reported in the medical literature. In conclusion, we postulate that these pseudocysts are the result of ectopic calcification, possibly related to a high calcium x phosphorous product, fetuin-A , and undercarboxylated Gla-protein deficiencies.

**Pitfalls in Managing Cardiovascular Risk of Young Patients with Chronic Kidney Disease Stages III and IV** Rammohan Sripad Bhat,[1] Ajay Prabhakar Dhaygude,[2] Christopher Federick Wong,[1] Christopher John Goldsmith,[1] Edmond O'Riordan,[4] Poonam Batra,[2] Prasad Rajendran,[1] Anindya Banerjee.[3] *[1]Nephrology, University Hospital Aintree, Liverpool, Cheshire, United Kingdom; [2]Nephrology, Royal Preston Hospital, Preston, United Kingdom; [3]Nephrology, Arrowe Park Hospital, Wirral, United Kingdom; [4]Nephrology, Salford Royal Hospitals NHS Trust, Manchester, United Kingdom.*

Purpose of the study was to assess the prevalence and management of cardiovascular risk in young adult population with Chronic Kidney Disease stages III and IV

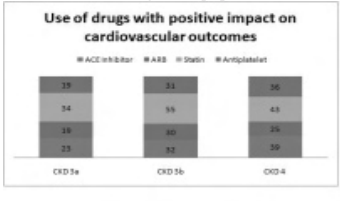
We collected demographic, clinical and lab data on patients aged 65 years or less with CKD stage III and IV attending nephrology outpatients at 4 different hospitals across the North-West of England. Results were compared with Renal Association standards.

Data was collected on 217 patients of whom 60 belonged to CKD stage IIIa, 77 to stage IIIb and 80 to stage IV. Males constituted 36% of the study population. We found that significant proportion of patients were still hypertensive and obese, whilst smoking habit and cholesterol level were not checked or documented in medical notes in substantial number of patients.

Prevalence of poorly addressed cardiovascular risk factors in study population

| Risk Factor | No of Patients (%) | Data not recorded in medical notes (%) |
|---|---|---|
| Diabetes (HbA1c > 7.5%) | 70 (32.2%) | 0 |
| Hypertension (BP > 130/80) | 164 (75.5%) | 17 (7.8%) |
| Obesity (BMI > 25.0) | 78 (35.9%) | 22 (56.2%) |
| Smoking | 35 (16.12%) | 22 (56.22%) |
| Cholesterol > 4.0mmol/L | 80 (36.86%) | 97 (44.7%) |
| Protenuria (ACR > 3.5 or PCR > 15) | 106 (48.84%) | 31 (14.28%) |

Figure 1 shows use of medications which can positively impact on cardiovascular outcomes of this high risk population.



Whilst various guidelines recommend that we address cardiovascular risk factors during every outpatient contact, we found less than acceptable attention to them.

Disclosure of Financial Relationships: nothing to disclose

**PUB171**

**A Prospective Observational Multicenter Study To Evaluate the Effectiveness and Safety of Methoxy Polyethylene Glycol-Epoetin Beta (Mircera®) in Patients with Anemia Secondary to Chronic Kidney Disease. MINERVA Study** Aleix Cases,[1] J. M. Portolés,[2] J. Calls,[3] Alberto M. Martinez-Castelao.[4] *[1]Hospital Clinic, Barcelona, Spain; [2]Hospital Fundación Alcorcón, Spain; [3]Hospital de Manacor, Mallorca, Spain; [4]Hospital de Bellvitge, Barcelona, Spain.*

**Background:** Mircera® is a continuous erythropoietin receptor activator approved for the treatment of anaemia associated with chronic kidney disease (CKD) in patients on dialysis and patients not on dialysis with once-monthly maintenance dosing.

**Objective:** This study examined the effectiveness and safety of Mircera® when administered in patients with anemia secondary to CKD in routine clinical practice.

**Methods:** A prospective observational multicenter study. Information about patients on haemodialysis and conservative therapy were collected. The results of a preliminary analysis of the 3-month follow-up are presented.

**Results:** A total of 240 patients were evaluated (56.3% male): mean age: 70.8±14.7years. Diabetic nephropathy was the most common etiology (23.3%). 60.8% of patients were in IV-V stage, 27.7% were naïve and 33.1% converted patients. Of patients on haemodialysis (39.2%), 11.4% were naïve and 27.7% converted patients Among converted patients, 64.5% previously received epoetin beta and 32.9% darbepoetin alpha; mean weekly doses 7,122±6,660.3IU and 38.9±37.8µg, respectively. Median doses of Mircera® at baseline and 3 month were 87.5(75-150)µg/month and 112.5(75-162.5)µg/month in naïve patients, and 100(75-150)µg/month and 100(75-175)µg/month in converted patients, without significant differences between groups during this period. Mean Hb levels in converted patients were 11.4±1.3g/dL at the time of conversion and 11.4±0.7g/dL after 3 months. No differences between groups in Hb levels were detected during the evaluation period. 68% of converted patients at baseline and 72.2% in month 3 presented Hb levels ≥11mg/dL. Only a non-drug related adverse event was reported.

**Conclusions:** The preliminary results appear to indicate that Mircera® is an effective and safe election for correct and maintenance of stable Hb levels. Further analyses will be needed to confirm these data.

Disclosure of Financial Relationships: nothing to disclose

**PUB172**

**Is It Possible To Control Dyslipidemia Using Atorvastatin in Patients with Chronic Kidney Disease?** Eleni Chelioti, Athanasios Georgiou, Antonios Zagorianos, Prokopis Papazafeiris, Sotiris Mikrow, Gabriel Papadakis. *Dept. of Nephrology and Renal Unit, General Hospital of Piraeus, "Tzaneio", Athens, Greece.*

Purpose: Dyslipidemia is proposed to be a secondary cause of renal damage. Using of statins ameliorates renal function and reduces the cardiovascular risk in patients with stage 3 and 4 chronic kidney disease (CKD). This analysis looked at lipid profile in patients with stage 3 and 4 CKD who were receiving atorvastatin and which of them had lipid levels according to published guidelines.

Method: A comparative study was performed in Outpatient Clinic. Participants were 109 (50 female/ 59 male, age range 55-85 years) patients with CKD (clearance creatinine range 30-60 ml/min/1.73m2). The group of patients who were received atorvastatin, had a dose range 10-40mg. Laboratory parameters were evaluated for total cholesterol (tChol), triglycerides (TG), low-density lipoprotein (LDL) and high-density lipoprotein (HDL). The CKD was identified using the MDRD equation. Statistical analysis based on percentage evaluation.

Results: The patients using atorvastatin had a mean eGFR 48 ml/min/1.73m2 and them without statins had mean eGFR 34 ml/min/1.73m2 ($p<0.05$). Fifty nine percent of patients not used statins and 41% were receiving atorvastatin with a mean dose 20±10mg. The percentage of patients without statins had tChol <200mg/dl, TG <150mg/dl, LDL <100mg/dl, and HDL >35mg/dl was 45%, 35%, 37% and 39% respectively and patients using atorvastatin had 64% of tChol <200mg/dl ($p<0.001$) , 60% TG <150mg/dl ($p<0.001$), 56% LDL<100mg/dl ($p<0.001$) and 44 % HDL >35mg/dl (p=NS).

Conclusion: It is difficult to control dyslipidemia in patients with stage 3 and 4 CKD despite the fact that more half of apparently controlled patients using atorvastatin had lipid levels below targets in compare to patients without statins. Although, the patients who receiving atorvastatin had a better renal function. These observations may help to render plausible a strategy for a strength use of statins.

Disclosure of Financial Relationships: nothing to disclose

**PUB173**

**Primary Physicians Rarely Detect Chronic Kidney Disease in Type 2 Diabetic Patients** Laura Cortes Sanabria, Héctor R. Martínez Ramírez, Alfonso M. Cueto-Manzano, Enrique Rojas-Campos. *Unidad de Investigación Médica en Enfermedades Renales, UMAE, HE, IMSS, Guadalajara, Jalisco, Mexico.*

Type 2 diabetes mellitus (DM2) is the most common cause of end-stage renal disease (ESRD) in many parts of the world. A large number of individuals at early stages of chronic kidney disease (CKD) are largely undiagnosed and untreated; consequently, ESRD is continuously increasing. Primary physicians (PP) are the most indicated to perform the measures for preventing, diagnosing and treating CKD at early stages.

***Aim:*** To determine the frequency with which PP identify risk factors and establish the diagnosis of CKD in DM2 patients.

***Methods:*** Six hundred twenty seven patients were randomly selected from the total DM2 population ≥18 years attending to 11 primary health-care units. Clinical charts were reviewed searching for clear evidence of CKD diagnosis, classification and risk factor identification. CKD was defined according to K/DOQI criteria.

***Results:*** Patients were 63±13 years, 56% female, and had 11±7 years of DM2 vintage. Age >60 years was present in 63%, smoking in 38%, obesity in 59%, dyslipidemia in 48%, hypertension in 58%, use of nonsteroidal anti-inflammatory drugs in 24%, and urinary tract infection in 10%. Inadequate control was observed for blood glucose in 53%, for hypertension in 71%, and for serum lipids in 21%. None of the latter variable was identified as risk factor for CKD. Serum creatinine was measured in 354 patients (56%) within the previous 18 months; from these, only 11 patients had an estimated GFR. Using clinical record data, CKD stages 3-5 was present in 21% of the sample; however, in none of the cases CKD diagnosis and classification were established by PP.

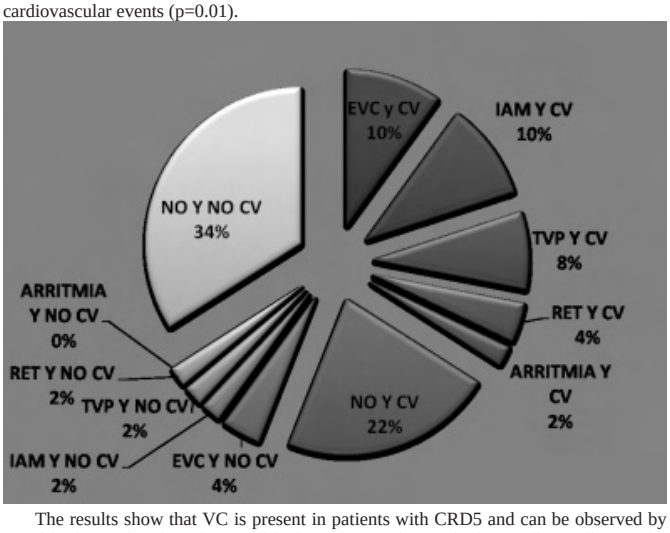
***Conclusions:*** CKD was neither diagnosed nor classified in this sample of patients (in spite of being present in a 21% of them). A high frequency of CKD risk factors was present, but in no case they were clearly identified in the clinical records. Despite PP were taking care of DM2 patients at high risk for CKD, they rarely requested-calculated indicators of renal function. Efforts have to be done to increase the clinical competence of PP for diagnosing CKD.

Disclosure of Financial Relationships: nothing to disclose

**PUB174**

**Survey of Vascular Calcification and Atherosclerosis in Patients with Chronic Renal Disease in Dialysis by Carotid Echography** Luis Gerardo D'Marco, Dayana J. Olmos, Lurlinys Flores, Liana Brito, Lisbeth Martinez. *Nephrology, Ruiz y Paez University Hospital, Bolivar, Venezuela.*

Clinic and epidemiological studies have shown that cardiovascular disease is related to an increase in the mortality rate of patients with chronic renal disease (CRD). Vascular complications are mainly secondary to calcification and atherosclerosis. CV does not only involve passive calcium and phosphorus deposits in atherosclerotic blood vessels but also active 'ossification' of vascular structures. High phosphate levels and the increased Ca x P play an important role in this process, and seem to be associated with an increased mortality. **OBJECTIVE**: The purpose of this study was to determine the presence of VC and atherosclerosis by means of carotid echography in 50 patients with CRD5 in dialysis. **METHODS**: Fisher Test was used to determine whether or not the differences were significant, which was decided based on p–value obtained in the test (<0.05). **RESULTS**: The age of patients averaged 45.34 years and most of patients were female (56%). The predominant dialysis method was hemodialysis (52%) for an average period of 23.38 months (SD: ± 29.52). The average laboratory test values were: hemoglobin (9.8 g/%), urea (141.3 mg/dl), creatinine (7.4 mg/dl), uric acid (6.9 mg/dl) (p=0.050), cholesterol (188.2 mg/dl), triglycerides (206.5 mg/dl), albumin (3.47 mg/dl), calcium (8.69 mg/dl), phosphorus (6.5 mg/dl), and Ca x P (55.4). VC was observed in 56% of patients; 46% had echographic criteria for atherosclerosis (intima-media thickness ≥ 0.9 mm) with an overall average of 0.89 mm (SD: ±0.28) (p=0.0006). The group with VC had more adverse cardiovascular events (p=0.01).



The results show that VC is present in patients with CRD5 and can be observed by carotid echography; thus, the use of the latter as a routine method to predict cardiovascular events in this group.

Disclosure of Financial Relationships: nothing to disclose

**Association between Hemoglobin (Hb) Stability and Clinical Outcomes in Patients Receiving Erythropoiesis-Stimulating Agents (ESAs)** Angel Luis M. De Francisco. *Servicio de Nefrologia, Hospital Universitario Marques de Valdecilla, Santander, Spain.*

**Purpose:** To investigate the specific effect of Hb variability on cardiac and other safety outcomes.

**Methods:** Data from Phase III trials with methoxy polyethylene glycol-epoetin beta (a continuous erythropoietin receptor activator [C.E.R.A.]) were used to assess associations between Hb variability and clinical outcomes. A total of 1879 patients (pts) on dialysis and not on dialysis receiving C.E.R.A. every 2 weeks (Q2W) or once monthly (Q4W), or comparator ESA treatments (epoetin alfa or beta, darbepoetin alfa) were included in the analysis. Hb levels were to be maintained between 10.5-13 g/dL. Logistic regression was used to analyze the association between Hb values and adverse event (AE) occurrence.

**Results:** During the studies, 25% of pts had ≤47.2% of Hb values within ±1 g/dL of baseline (pre-treatment), 25% had >47.2% and ≤62.8%, 25% had >62.8% and ≤77.3%, and 25% had >77.3%. A total of 783 pts had 1136 AEs: vascular access thrombosis (n=220), arrhythmia (n=168), congestive heart failure (n=92), sepsis (n=84), cerebrovascular accident (n=53), and cardiac arrest (n=50). There was a significant association between Hb stability and a reduced incidence of several categories of AEs.

| Adverse events | Odds ratio (95% confidence interval) |
|---|---|
| Arrhythmia | |
| Q2 | 0.98 (0.64, 1.49) |
| Q3 | 0.75 (0.48, 1.16) |
| Q4 | 0.62 (0.39, 0.99) |
| Cardiac arrest | |

## PUB176

**Widespread Pain, Depression, Sleep Disturbance, and Quality of Life in Dialysis Patients** Ma. Clarissa H. Del Rosario, Afton L. Hassett, Malathi Chamarthi, John A. Walker, Naomi Schlesinger. *Medicine, UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ.*

**Background:** End Stage Renal Disease (ESRD) is often accompanied by multiple co-morbidities, including sleep disturbances, depression, chronic pain, and fatigue. Few studies have evaluated whether fibromyalgia (FM) occurs concomitantly with these symptoms.

**Objective:** To evaluate the prevalence of depression and sleep disturbance in ESRD patients requiring renal replacement therapy (RRT) and whether these are associated with concomitant FM.

**Methods:** Outpatients at two dialysis facilities were invited to participate in this study. Patients who did not speak English or who were severely demented were not invited to participate. Of those invited, 48 patients gave informed consent and completed the Quick Inventory of Depressive Symptomatology, the Pittsburgh Sleep Quality Index, and the SF-36. All were evaluated for FM using American College of Rheumatology criteria with tender point examination.

**Results:** Of the 48 patients who completed the study protocol, 26 (56.5%) were men. Mean patient age was 62.1 years (SD±15.6) and mean years of education was 14.3 (SD±3.2). None of the participants met criteria for FM although one patient had widespread pain. Depression was common amongst patients; 22 (45.8%) earned scores consistent with at least mild depression. Most patients (53.1%) also earned scores consistent with likely sleep disturbance. Those with at least mild depression were more likely to have sleep disturbances than those without depression (t= 3.961, P>0.001). Health related quality of life was within the mean expected for patients with medical illness (Physical Component Scale score=47.7[SD±19.3] and Mental Component Scale score= 59.1[SD±18.5]).

**Conclusions:** In this study, patients receiving RRT commonly suffered from depressive symptoms. Sleep disturbances also were common and associated with the presence of depression. Despite this, patients' health related quality of life was similar to that of other medical patient populations. Our findings suggest that routine screening for depression and sleep disturbance should be an important part of the management of patients receiving RRT.

## PUB177

**Influence of Serum Magnesium Levels on the Prevalence and Progression of Vascular Calcification in CKD 4 and Dialysis Patients** Philip D. Evans,[1] Mhairi K. Sigrist,[2] Chris W. McIntyre.[1,3] *[1]Royal Derby Hospital, Derby, United Kingdom; [2]University of British Columbia, Vancouver, Canada; [3]School of Graduate Entry Medicine, University of Nottingham, Derby, United Kingdom.*

Magnesium (Mg) has been implicated as a factor associated with reduced levels of vascular calcification (VC). The aim of this study was to investigate if serum Mg levels characteristically seen in a CKD population treated with non-Mg based phosphate binders and conventional lower Mg concentration dialysate was associated with the prevalence, or development, of progressive VC.

We studied 134 patients (60 on hemodialysis [HD], 28 on peritoneal dialysis [PD], and 46 with stage 4 CKD). Predialysis serum Mg levels were measured and VC assessed at baseline, 12 and 24 months. A calcification score (CaSc) was generated by quantifying the calcification in a standardized section of the superficial femoral vein from multislice CT. A standard diasylate magnesium concentration of 0.5mmol/L was used for both HD and PD patients, no oral Mg salts were used in this population.

The groups were well matched for age, gender, diabetic status, smoking status, body mass index and dialysis vintage (where appropriate). There was no significant difference in mean serum Mg (HD[±SD]: 1.04±0.16mmol/L; PD: 0.9±0.15mmol/L; CKD4: 0.93±0.12mmol/L; p=NS).There was a statistically significant difference between baseline prevalent CaSc (HD [median +IQR]: 121 [0 to 610]; CKD4: 2 [0 to 197]; p=<0.05; PD: 21 [0 to 343]; p=NS) and no difference in mean CaSc progression (HD[±SD]: 123.8±213.5; PD: 101.6±194.1; CKD4: 121.1±250.1; p=NS). There was no association of serum Mg as a continuous or categorical (converted into tertiles) variable with either prevalent or progressive CaSC.

We were unable to demonstrate an association with serum pre-dialysis Mg levels and any measure of prevalent or progressive VC in CKD patients characterised by Mg levels largely within the normal range.

## PUB178

**The Usefulness of Serum Cystatin C for Prediction of Microvascular Complications in Type 2 Diabetic Patients** Sung-Kyu Ha,[1] Sung Jin Moon,[1] Sung Chang Bae,[1] Jwa-Kyung Kim,[1] Sang Hun Lee,[1] Jung Eun Lee,[2] Hyeong Cheon Park.[1] *[1]Internal Medicine, Gangnam Severance Hospital, Seoul, Korea; [2]Internal Medicine, Yongin Severance Hospital, Yongin, Korea.*

Introduction: The objective of this study was to evaluate the prognostic value of cystatin C for macro- and micro-vascular complications in type 2 diabetic patients.

Methods: A total of 300 patients (200 men, mean age 62.9±8.7 years) with type 2 diabetes at Gangnam severance hospital were included. Receiver operator characteristics (ROC) analyses of cystatin C to detect major adverse cardiac events (MACE), retinopathy, and microalbuminuria were conducted.

Results: ROC curve analyses demonstrated cystatin C 1.285 and 0.96 as the cutoff levels to predict retinopathy (AUC: 0.694) and microalbuminuria (AUC: 0.684), respectively. On multivariate logistic regression analysis adjusted by age, sex, DM duration, and HbA1C, cystatin C levels ≥ 1.285 (OR: 3.419, 95% CI 1.741-6.716, p-value <0.001) and ≥ 0.96 (OR: 2.464, 95% CI 1.082-5.610, p-value =0.032) were independent predictors for retinopathy and microalbuminuria, respectively. However, cystatin C could not detect the MACE.

Colclusion: This study demonstrates that cystatin c may predict the retinopathy and microalbuminuria in type 2 diabetic patients.

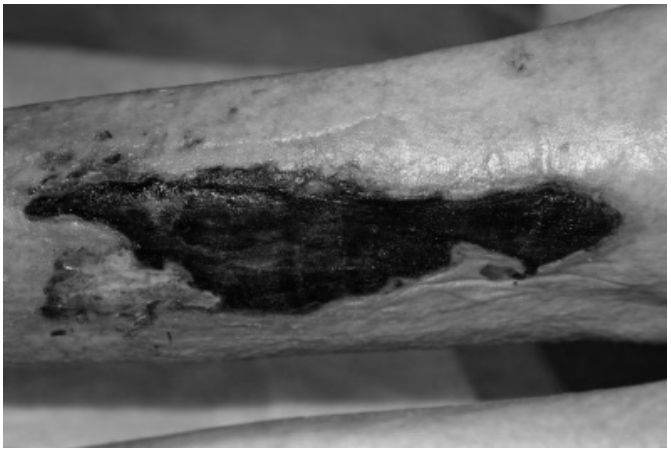
## PUB179

**Presenting an Unusual Case of Calciphylaxis in a 64 Year Old Female Hemodialysis Patient Despite Normal Clinical Markers and Negative Skin Biopsy** Hooman Hajian. *Division of Nephrology, University of Washington, Seattle, WA.*

Calciphylaxis is an extra-osseous vascular calcification which can occur in end-stage renal disease (ESRD). It is a rare but serious condition due to systemic medial calcification of the arterioles leading to ischemia and subcutaneous necrosis. Microscopically, there is small vessel mural calcification with or without endovascular fibrosis, extravascular calcification, and thrombotic occlusion. It most commonly occurs in ESRD patients on Hemodialysis (HD) or after kidney transplant, although it may also happen without ESRD. It manifests as areas of painful ischemic necrosis usually over the abdomen, buttock, and thigh. Some of the risk factors for Calciphylaxis in ESRD are female sex, obesity, elevated phosphorus, co-administration of certain medications, autoimmune disorders, and hypercoagulable states.

We present a case of a 64 year old Caucasian female with hypertension, Diabetes Mellitus type 2, DVTs, hypothyroidism, CVA, myocardial infarction, paroxysmal atrial fibrillation on no anticoagulation, and ESRD who presented with multiple ulcers on bilateral upper and lower extremities (LE) and right hip. The LE ulcers were well demarcated with thick black eschar and painful.



A LE skin biopsy a week earlier did not show Calciphylaxis. Serum calcium and phosphorus levels were 7.7 and 3.7 mg/dL, respectively. Intact PTH was 139 pg/mL (normal 9-73). Cryoglobulin, Cryofibrinogen, and ANCA screen were negative. Given the clinical suspicion, a repeat skin biopsy was done which confirmed Calciphylaxis and proper management was initiated.

Given its low incidence and high mortality, timely diagnosis of Calciphylaxis is crucial. While the importance of skin biopsy to establish diagnosis is uncertain, it is commonly used to confirm the diagnosis. However, it should not over-rule or replace a clinician's clinical assessment or suspicion.

**Antihypertensive Therapy Modulates Markers of Cardiovascular Disease Risk in Older People with Chronic Kidney Disease** Stephen G. John,[1] Paul J. Owen,[1] Jane H. Youde,[1] Chris W. McIntyre.[1,2] *[1]Royal Derby Hospital, Derby, United Kingdom; [2]University of Nottingham, Derby, United Kingdom.*

Chronic kidney disease (CKD) is highly prevalent in older people and is associated with changes in cardiovascular (CV) function and elevated CV risk. Whilst aggressive blood pressure (BP) control is the cornerstone of CKD management, doubt exists concerning the current optimal BP targets in this group, primarily due to falls risk. As part of a prospective study of CV function and falls in response to the introduction and escalation of antihypertensive therapy (AHT) we assessed systemic markers of CV health in older (>70 years) non-diabetic patients with CKD 3/4.

We recruited 61 subjects (including non-CKD controls). AHT was fully withdrawn for 2 weeks before initial assessments of skin Advanced Glycation End-products (AGE) as a measure of cumulative metabolic stress, routine bloods and proteinuria (UPCR). AHT was restarted to a target BP of 130/80mmHg. Assessments were repeated at four weeks after full titration of medication (AHTr), and after a further 12 months follow-up (FU).

Mean age was 76±4yrs, mean eGFR in the CKD group was 42±14ml/min/1.73m$^2$. AHT used was in line with current guidelines and predominantly based on RAAS inhibition (mean achieved BP 128/69 mmHg). Significant proteinuria was present in 18%. Skin AGE, haemoglobin, albumin and proteinuria did not change. Serum sodium fell with AHTr (median 141±3 to 140±3mmol/l; p<0.001), but rose over one year (140±3mmol/l; p=0.017). Whilst CKD did not progress in the CKD group, serum creatinine rose at FU in non-CKD patients (76±19 to 84±25mmol/l; p=0.038). Increased serum corrected calcium at AHTr did not further change at FU (2.34; 2.38; 2.36mmol/l; p=0.005; p=ns). An initial rise in serum phosphate with AHT was normalised by one year (1.11; 1.17; 1.10mmol/l; p<0.001; p=0.004). 25-OH vitamin D fell over the study (58 to 42 ng/ml; p<0.001).

AHT introduction rapidly causes alteration of humoral markers of CV health, which are partially reversed over time. There is no appreciable change in tissue AGE levels as marker of cumulative metabolic stress over a one year period in either CKD patients or hypertensive subjects with normal renal function.

**A Study of the Seasonal Change in Albuminuria** Koichi Kanozawa, Tokushi Nakajima, Hajime Hasegawa. *Division of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama, Japan.*

Background: Microalbuminuria is important not only for early diabetic nephropathy but the early diagnosis of CKD that it is the risk factor of a cardiovascular disease or end stage renal disease from the first. Glomerular hyperfiltration, some problems of blood vessel side including the the impaired endothelial function and the oxidative stress, and reabsorption in the renal tubules are suggested to the appearance mechanism of urinary albumin excretion (UAE), and also being associated with blood pressure (BP) is known. On the other hand, BP is influenced of temperature and a seasonal variation exists.

Aims: It is examined whether a seasonal change exists in UAE.

Methods: For the outpatient during hypertensive medical examination, we measured UAE, office and home BP for all seasons. We distributed them in each season, and analyzed. Furthermore, we evaluated seasonal variation in hemoglobin (Hb), HbA1c, estimate glomerular filtration rate (eGFR), and serum 8-hydroxy-2'deoxyguanosine (8-OHdg) level.

[Results] This study was performed in a medical center and a clinic of Saitama in Japan. There is no change in the dose of anti-hypertensive agents during observation, and UAE evaluated a total of 1286 measurement by 178 patients who had normo- or microalbuminuria (less than 300 mg/gCr). The UAE of the summer was significantly low in comparison with the UAE of other seasons (autumn; 43.1±58.8 mg/gCr, winter; 45.0±55.4 mg/gCr, spring; 38.0±55.1 mg/gCr, summer; 29.1±40.8 mg/gCr, respectively. This variation was accepted each in the non-diabetes-mellitus (DM) and in DM group. On the other hand, UAE correlated also with which each systolic and diastolic BP. The seasonal change existed in each BP. In the systolic home BP, the group which was more than an average accepted the seasonal change of UAE strongly compared with the group which was below an average. In Hb, HbA1c, eGFR, and serum 8-OHdg level, the seasonal variation was not accepted.

Conclusion: There is a seasonal change in UAE and it was suggested that it was influenced of the seasonal variation of BP. In evaluation of the UAE, seasonal variation should be considered.

**Effects of IV Iron Use in Non Dialysis CKD** Margaret Knight,[1] Hongyan Du,[2] L. Tammy Ho,[1] Stuart M. Sprague.[1] *[1]Division of Nephrology and HTN, Northshore University HealthSystems, Evanston, IL; [2]Center on Outcomes, Northshore University HealthSystems, Evanston, IL.*

The use of intravenous iron (IVfe) is a cornerstone of anemia management in the dialysis population. IVfe is not well studied in nondialysis CKD (NDCKD) patients (pts). Limited studies have shown that IVfe can raise iron saturation (%fe) and improve hgb, however effects of longer term use in NDCKD pts receiving EPO is not known.

Methods: 112 pts with NDCKD receiving IVfe were retrospectively studied using a system wide electronic medical record, available since 2006 for both inpatient and outpatient care. Utilizing billing records, pts receiving IVfe were identified from 2006-2009. Pts with estimated GFR (eGFR) above 60 ml/min were excluded, as well as pts identified with active malignancy and GI bleeding. Frequency of IVfe, effect on hemoglobin (hgb), %fe, BP and eGFR were determined before/after IVfe. Effects of IVfe on EPO dosing over a mean followup period of 8.55 (1.5-40)months were determined. Effects of individual fe formulations were also assessed.

Results: 49 % of pts were male with mean eGFR 32 ± 21 ml/min. About 25% of pts receiving IVfe were not followed in a CKD clinic. These pts were more likely to receive IVfe as an inpt p<0.0001, to receive a transfusion for anemia p<0.027, had less hgb correction, and received less IVfe, p<0.0007. The remaining pts, part of a CKD clinic, receiving EPO, were given total mean fe dose of 1.18 g per course. Mean hgb increase(↑) was 1.1 ±1.2 g/dl, p<0.0001. After IVfe, there were significant ↑'s in %fe, ferritin and eGFR, p<0.0001. Change of %fe positively correlated with hgb, ferritin and negatively correlated to serum PTH p<0.048. No changes in BP were noted before/after dosing. No differences between fe formulations were noted. In NDCKD receiving EPO, mean interval of dosing of IVfe was 235.3 ± 137.7 days, with ↓ EPO dosing at 0-6 weeks and 3-6 months following IVfe, p<0.1, 0.02. At 3-6 months, EPO dosing decreased by 2000 units per week.

Use of IVfe appears effective in ↑ %fe and ↓ epo requirements in NDCKD for a mean interval period of almost 8 months. Effective managment of IVfe, anemia in CKD appears best in a CKD clinic setting.

**Trial Announcement: Vitamin K2 To Slow Vascular Calcification in Hemodialysis Patients, "VitaVasK"** Thilo Krueger,[1] Ralf Westenfeld,[9] Georg Schlieper,[1] Mario Cozzolino,[2] Johannes Jacobi,[3] Michel Y. Jadoul,[4] Markus Ketteler,[5] Lars C. Rump,[6] Peter Stenvinkel,[7] Andrzej Wiecek,[8] Karel M. Leunissen,[10] Ralf-Dieter Hilgers,[12] Leon J. Schurgers,[11] Jurgen Floege.[1] *[1]Nephrology, University of Aachen, Aachen, Germany; [2]Renal Division, S. Paolo Hospital, Milan, Italy; [3]Nephrology, University of Erlangen-Nuremberg, Erlangen, Germany; [4]Nephrology, University of Louvain, Brussels, Belgium; [5]Nephrology, Klinikum Coburg, Coburg, Germany; [6]Nephrology, University of Duesseldorf, Duesseldorf, Germany; [7]Nephrology, Karolinska Institute Stockholm, Stockholm, Sweden; [8]Nephroloy, University of Katowice, Katowice, Poland; [9]Cardiology, University of Duesseldorf, Duesseldorf, Germany; [10]Nephrology, University of Maastricht, Maastricht, Netherlands; [11]CARIM, University of Maastricht, Maastricht, Netherlands; [12]Biostatistics, University of Aachen, Aachen, Germany.*

Patients on hemodialysis (HD) exhibit an increased cardiovascular mortality associated with vascular calcification (VC). Matrix Gla protein (MGP) is a powerful vascular wall-based inhibitor of VC. MGP needs activation by vitamin K-dependent carboxylation.

The ERA/EDTA sponsored "VitaVasK" study will be the first clinical trial in HD patients to target the progression of VC using vitamin K-containing supplements. VitaVasK is a randomized, double-blind, placebo-controlled trial with parallel groups. Participants are recruited from nine European nephrology centers. Multislice spiral computed tomography (MSCT) will be used to screen for coronary artery calcification (CAC). Stable HD patients with CAC scores >100 will be randomized to a daily oral supplementation of vitamin K2 (n=178) or placebo (n=178) for 18 months. Primary outcomes will be attenuation of progression of coronary and aortic calcification at 12 and 18 months using volume scores determined by MSCT. Secondary outcomes will be regression of VC, attenuation of

progression of aortic and mitral valve calcification, major adverse cardiovascular events, mortality, and change in plasma levels of undercarboxylated and carboxylated MGP. Patients will be followed beyond the primary study duration to determine the mortality at three and five years.

Disclosure of Financial Relationships: nothing to disclose

**PUB184**

**QM C.E.R.A. Is as Effective as QW or Q2W Darbepoetin Alfa (DA) in Correcting Hemoglobin (Hb) Levels in Chronic Kidney Disease (CKD) Patients Not on Dialysis, Regardless of Etiology of CKD** Maurice Laville. *Claude Bernard University, Lyon, France.*

**Purpose:** This post hoc analysis assessed the impact of the etiology of CKD on anemia correction in CORDATUS, a randomized, multicenter study, which demonstrated the non-inferiority of once-monthly (QM) methoxy polyethylene glycol-epoetin beta (a continuous erythropoietin receptor activator [C.E.R.A.]) vs once-weekly (QW) or once every 2-weekly (Q2W) DA in the correction of anemia in CKD patients not on dialysis.

**Methods:**

Patients with CKD (n=307) were randomized to receive QM C.E.R.A. or DA QW/Q2W for 20 weeks followed by an 8-week evaluation period. Primary efficacy analyses (Hb response defined as increase in Hb ≥1 g/dL from baseline and a concentration >10.5 g/dL; non-inferiority (NI) test for Hb change from baseline in group comparison) were repeated in the 4 most common etiologies of CKD: diabetes (DM); hypertension/large vessel disease (HTN); glomerulonephritis (GN); interstitial nephritis/pyelonephritis (IN/PN).

**Results:** Response rates were similar for QM C.E.R.A. vs QW/Q2W DA regardless of the etiology of CKD. The NI test for Hb change from baseline was also significant for each etiology, with the exception of GN, where the response rate was 100% in both groups but the p-value for NI test was not significant, primarily because twice as many Hb values in patients treated with DA were >12 g/dL.

| Etiology of CKD | Hb response rate (%) | | NI test for the difference between groups in Hb change from baseline to evaluation | |
|---|---|---|---|---|
| | C.E.R.A. | DA | Difference in mean Hb (g/dL) | p-value |
| DM | 94.3 | 94.2 | 0.001 | <0.0001 |
| No DM | 94.0 | 92.9 | -0.052 | <0.0001 |
| HTN | 94.7 | 92.1 | -0.044 | <0.0001 |
| No HTN | 93.6 | 94.5 | -0.051 | <0.0001 |
| GN | 100.0 | 100.0 | -0.579 | 0.2299 |
| No GN | 93.3 | 92.8 | 0.009 | <0.0001 |
| IN/PN | 95.0 | 76.9 | 0.048 | 0.0281 |
| No IN/PN | 94.0 | 95.0 | -0.037 | <0.0001 |
| Any of the above | 94.2 | 92.9 | -0.075 | <0.0001 |

**Conclusion:** Regardless of the etiology of CKD, QM C.E.R.A. provides similar efficacy in correcting Hb levels when compared with QW/Q2W DA in CKD patients not on dialysis.

Disclosure of Financial Relationships: nothing to disclose

**PUB185**

**Revisiting Guidelines on Screening and Monitoring of Calcium, Phosphate and Haemoglobin Abnormalities in Chronic Kidney Disease Stage 3** Ping Tyug Loh, Katrina Koh, Vathsala Anantharaman. *Division of Nephrology, Department of Medicine, National University Hospital, Singapore, Singapore.*

**Objective**: We aim to examine the incidence and prevalence of Chronic Kidney Disease (CKD) complications, specifically serum calcium and phosphate abnormalities as well as anaemia in patients with moderate CKD (CKD stage 3).

**Methods**: 226 patients with CKD stage 3 (Age 66±13, eGFR 40±8, Male 65%, Chinese 70%) based on estimated Glomerular Filtration Rate (eGFR) by Modification of Diet in Renal Disease (MDRD) formula who were referred to National University Hospital Renal Division in 2009 were studied. Patients were further categorized into CKD3a (eGFR45-59mL/min) and CKD3b (eGFR30-44mL/min). Serum calcium, phosphate, and haemoglobin levels from their first visit until May 2010 were recorded.

**Result:** Result is as shown in Table 1. 2% of these patients did not have data on serum calcium, phosphate, or haemoglobin within the evaluation period.

Incidence and Prevalence of Hypocalcaemia, Hyperphosphataemia, and Anaemia in CKD Stage 3.

| | CKD3a | | CKD3b | |
|---|---|---|---|---|
| | Incidence (per 100 patient months) | Prevalence (%) | Incidence (per 100 patient months) | Prevalence (%) |
| Hypocalcaemia (<2.15mmol/L) | 2 | 4.8 | 2 | 4.3 |
| Hyperphosphataemia (≥1.45mmol/L) | 2 | 3.2 | 3 | 4.9 |
| Anaemia (<10.5g/dL) | 2 | 6.3 | 5 | 16.0 |

**Conclusion**: Hypocalcaemia and hyperphosphataemia are rare in CKD3a and CKD3b. Hence, screening and monitoring for hypocalcaemia and hyperphosphataemia at CKD stage 3 may not be cost effective. Similarly, anaemia is also rare at CKD3a. Screening and monitoring for anaemia may not be necessary until CKD3b, when it is more common.

**A Multiple-Intervention Model May Preserve Better the Renal Function of Patients with Type 2 Diabetes Mellitus and Early Nephropathy Compared to Conventional Health-Care Model** Héctor R. Martínez Ramírez, Laura Cortes Sanabria, Ivan E. Perales Rodriguez, Erika Gomez Garcia, Alfonso M. Cueto-Manzano. *Unidad de Investigación Médica en Enfermedades Renales, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

To determine the effect on renal function of patients with type 2 diabetes mellitus (DM2) and early nephropathy (EN), a Primary Care Unit with a multiple-intervention (MI) model *vs* another with conventional health-care model were compared. All FP received training on EN (40h). Patients in MI model received an educative intervention (2 h/wk) by multidisciplinary team over 4 wks, including the following sessions: emotional management (social worker), nutritional counselling (dietitian), exercise (physical trainer), health-related problems (FP).

One-hundred six patients have been included; 25 in MI and 35 in conventional model have concluded 6 months of follow-up. Main results are shown in the table. No difference in medical treatment was observed between groups.

Comparison of delta results between groups at the end of follow-up.

| Lifestyle Questionnaire§ | Multiple-Intervention (N 25) | Conventional (N 35) |
|---|---|---|
| Knowledge of disease | 2.4±2.3†* | 0.9±2.8 |
| Adherence to treatment | 1.4±5.5 | 0.7±4.9 |
| Emotion management | 3.3±3.6†* | 0.2±3.2 |
| Exercise | 0.1±4.0 | 0.6±3.2 |
| Tobacco Consumption | 0.2±0.9 | 0.3±1.0 |
| Alcohol Consumption | 0.3±2.7 | 0.6±2.0 |
| Diet | 3.8±4.2* | 2.2±4.6* |
| Total | 8.5±10* | 6.5±11.7* |
| Clinical/Biochemical Variables | | |
| Body mass index (Kg/m2) | -14±15* | -17±16* |
| Waist circumference (cm) | -5±11 | -8±10* |
| Systolic BP (mmHg) | -0.7±1.4* | -0.2±0.9 |
| Diastolic BP (mmHg) | -1.6±4.2 † | -0.5±4.5 |
| HbA1c (%) | -0.6±1.6 | 0.2±2.0 |

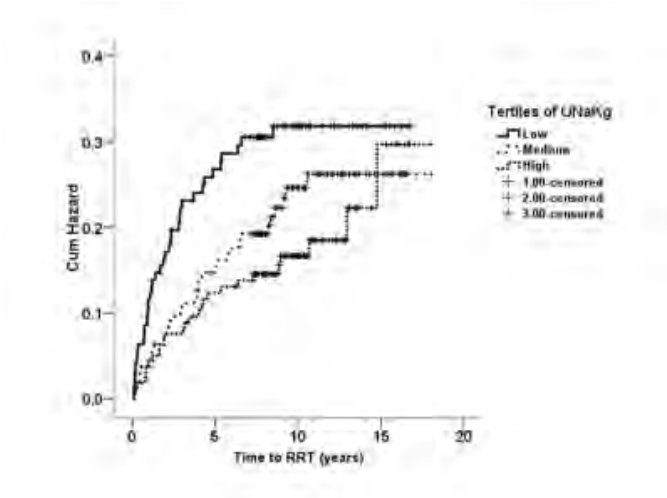
**Low Urinary Sodium Predicts Progression to RRT in Patients with CKD** Emily P. Mcquarrie,[1] Patrick Barry Mark,[1] Jamie P. Traynor,[2] Jonathan Fox,[3] Alan G. Jardine.[1] *[1]University of Glasgow, Glasgow, United Kingdom; [2]Monklands Hospital, Airdrie, United Kingdom; [3]Glasgow Royal Infirmary, Glasgow.*

Aim: To establish whether 24h urinary sodium excretion (UNa), a marker of dietary sodium intake, determines long-term risk of requiring renal replacement therapy (RRT).

Methods: Adult CKD patients with at least one UNa measurement were identified. Patients were excluded if: receiving RRT at time of measurement; no simultaneous eGFR measurement and at least one further reading; decline in eGFR >10ml/min/yr or UNa <70mmol. UNa was adjusted for weight (UNaKg) due to the high correlation between measures (r=0.384, p<0.001). Kaplan Meier survival analysis was performed comparing time to RRT by tertile of UNaKg. Binary logistic regression was performed to determine independent predictors of requirement for RRT.

Results: 488 patients were identified with median 8.6y(IQR 4.2-11.4) follow-up. 50.4% were male, mean age 51.8y(SD 16.7), mean weight 78.0Kg(18.0), baseline eGFR 48.4ml/min(25.6), SBP 139mmHg(24), DBP 79(13), UNa 159.3mmol(63.7). 103 patients required RRT at a median of 9.3y. UNa correlated significantly with weight, SBP, DBP and eGFR. Male gender and requirement for RRT were also significantly associated. No correlation seen with diuretic therapy. Using Kaplan Meier analysis, patients in the lowest tertile of UNaKg were significantly more likely to require RRT than those in the highest tertile (p=0.024).



[Hazard plot of time to RRT by tertile of UNaKg], independent of sex. On univariate analysis UNaKg was a significant predictor of requiring RRT (ExpB = 0.678 (95% CI 0.5-0.92) p=0.011) however on multivariate analysis only eGFR remained a significant predictor.

Conclusions: Low urinary sodium excretion is a significant predictor of requirement for RRT but not independent of renal function. High dietary sodium does not have a detrimental effect on renal outcome.

**Salmonella Empyema in End Stage Renal Disease Patient** Penchala S. Mittadodla, Robert S. Gayner, Nicole Denise Gray, Swapnil Khare, Fabio Dorville. *St Luke's Hospital, Bethlehem, PA.*

Pulmonary infections account for up to 25% of infections in end stage renal disease (ESRD) patients and confer a 14-16 fold higher mortality compared to general population. We report a rare case of pleural involvement of group B salmonella in an ESRD patient receiving hemodialysis, which has not been previously reported in ESRD patients.

A 49-year old Caucasian male was admitted to the intensive care unit with respiratory distress requiring BIPAP. He had a one-week history of worsening dyspnea, cough and fever. One month ago, he had self-limiting diarrhea lasting 3 days. His past medical history included end stage renal disease, on hemodialysis, hypertension, diabetes mellitus, coronary artery disease and asthma. He was not on any immunosupressant medications.

His vital signs were notable for T-102.2 F, HR-115/min, BP-91/64 mm Hg, RR-24/min and initial O2 sats-83% on room air. Physical examination revealed crackles with reduced air entry in right base and bilateral wheezing. He also had bilateral lower extremity edema. Workup revealed elevated segmented neutrophils, elevated BUN 44 mg/dl and creatinine 6.7 mg/dl. Arterial blood gas analysis showed a mild mixed respiratory and metabolic acidosis. Chest x-ray and a CT scan of chest revealed right lower lobe consolidation with pleural effusion. Thoracocentesis revealed exudative pleural fluid, which grew group B salmonella. A chest tube was placed to drain the empyema and a 14-day course of ceftriaxone was completed.

According to the literature, up to 33% of patients with extraintestinal salmonella infections have a recent history of gastrointestinal symptoms like our patient. Salmonella can spread hematogenously from the gastrointestinal tract or may remain dormant in the reticuloendothelial system, later seeding the pleural space. Immunocompromised conditions like HIV, malignancy, steroid use, sickle cell disease and diabetes mellitus have increased risk for salmonella infections. Prompt administration of antimicrobials and drainage is recommended.

**Retinal Vessel Narrowing Is Not Reversed with Renal Transplantation** Qi-Lun Ooi,[1] Foong Kien Newk-Fon Hey Tow,[1] Mohd Afzal Alias,[1] Rajeev Deva,[1] Ryo Kawasaki,[2] Tien Y. Wong,[2,3] Deb J. Colville,[1] Anastasia F. Hutchinson,[1] Judith A. Savige.[1] *[1]The University of Melbourne, Northern Health, Melbourne, VIC, Australia; [2]Centre for Eye Research Australia, The University of Melbourne, Royal Victorian Eye and Ear Hospital, Melbourne, VIC, Australia; [3]Singapore Eye Research Institute, Singapore National Eye Centre, Singapore.*

**Background and Objectives:** Small vessel disease contributes to stroke, and possibly vascular dementia, and diastolic dysfunction. Retinal arteriole and venule calibre reflect systemic small vessel changes, and these vessels are narrowed in hypertension and chronic kidney disease (CKD). This study examined whether renal transplantation reversed the narrowing seen in CKD5.

**Design, setting, participants and measurements:** This was a cross-sectional study of 100 patients who had a renal transplant for a median of 6.4 years (range 0.8 - 28.8) and 70 patients with CKD5. Nineteen (19%) transplant patients had normal renal function, 75 (75%) had CKD 3 or 4 and 5 (5%) had CKD5. In addition, 5 patients were studied pre- and 18 months post-transplant. Retinal vessel diameters were measured from digital fundus images (Canon CR5-45NM non-mydriatic camera) by a trained grader using a computer-assisted grading method (Univeristy of Wisconsin, Maddison, WI, USA) and Knudtson's formula. These were summarized [TW1] as the central retinal arteriolar equivalent (CRAE), central retinal venular equivalent (CRVE) and arteriole-to-venule ratio (AVR).

**Results:** Patients with a transplant were younger than patients with CKD5, and were just as likely to have hypertension (85% versus 84.3%, OR 1.06, CI 0.45 - 2.46, p=1.000), but had less diabetes (21% versus 39%, OR 0.42, 0.21 – 0.84, p=0.015). The mean CRAE in patients with a transplant was 134.8 $\pm$7.6 um versus 137.9 $\pm$ 14.9 um in patients with CKD5 (p = 0.086). Mean CRVE was 198.5 $\pm$17.8 um versus 202.4 $\pm$ 27.8 um (p=0.265). CRAE and CRVE did not change significantly in the 5 individual patients studied post-transplant.

**Conclusions:** The retinal microvascular narrowing seen in CKD5 persists after renal transplantation. These results suggest systemic microvascular disease is not modified by renal transplantation.

**Once-Monthly C.E.R.A. Administration Maintains Stable Hemoglobin Concentrations in Dialysis Patients with Varying C-Reactive Protein** Nicolas D. Papagalanis. *(on Behalf of the ML20952 Study Group) Nephrology Department, Red Cross Hospital, Athens, Greece.*

**INTRODUCTION AND AIMS:** Continuous erythropoietin receptor activator (C.E.R.A.) is a novel agent with unique receptor activity, allowing once-monthly (Q4W) administration for effective maintenance of stable hemoglobin (Hb) in patients with chronic kidney disease (CKD). We examined the effect of C-reactive protein (CRP) levels and dialysis conditions on the maintenance of Hb concentrations, and the relationship between CRP levels and C.E.R.A.dose.

**METHODS:** This prospective, multicentre, single arm, open label study assessed the efficacy, safety and tolerability of once-monthly administration of C.E.R.A. for the maintenance of Hb levels in dialysis patients with chronic renal anemia. Patients (n=188) in Greece (≥18y) receiving adequate dialysis and intravenous epoetin or darbepoetin with stable baseline Hb (10.5-12.5 g/dL) entered a 16-week C.E.R.A. dose titration phase (DTP) followed by an 8-week efficacy evaluation period (EEP). At DTP (week 16) and EEP (week 24) the efficacy parameters and exposure were analyzed by baseline CRP (≤6.0 mg/L, >6.0 mg/L), using an ANOVA test.

**RESULTS**: Mean baseline, week 16 and week 24 Hb concentrations for patients on C.E.R.A Q4W with baseline CRP levels ≤6.0 mg/L was 11.6 (SD=0.57) g/dL, 11.9 (0.97) g/dL and 11.6 (1.09) g/dL and for patients with CRP levels >6.0 mg/L were 11.5 (0.55) g/dL, 11.6 (0.97) g/dL and 11.4 (1.14) g/dL, respectively. The table below shows that patients with CRP levels >6.0 mg/L were exposed to a higher C.E.R.A. dose than patients with CRP ≤6.0 mg/L (DTP *p=0.028*, EEP *p=0.085*).

| CRP | N (DTP) | DTP mean (SD) dose (µg) | N (EEP) | EEP mean (SD) dose (µg) |
|---|---|---|---|---|
| ≤6.0 mg/L | 119 | 152 (63.4) | 103 | 139 (95.5) |
| >6.0 mg/L | 58 | 176 (80.3) | 50 | 170 (124.3) |

**CONCLUSIONS:** Dialysis patients with elevated CRP levels are exposed to more C.E.R.A than to patients with CRP ≤6.0 mg/L. However once-monthly C.E.R.A. administration effectively maintains stable Hb levels in dialysis patients with CKD, despite CRP levels.

**PUB191**

**Vegetarian Low Protein Diets Supplemented with Chetoanalogues. Is It Feasible in the Routine Clinical Practice?** Giorgina B. Piccoli,[1] Valentina Consiglio,[1] Maria Chiara Deagostini,[1] Stefania Scognamiglio,[1] Rossella Attini.[2] *[1]SS Nefrologia, ASOU San Luigi, Orbassano, Turin, Italy; [2]Maternofoetal Unit, OIRM S Anna University of Torino, Torino, Italy.*

**Background.**

Vegetarian supplemented diets are cited as promising tolls for slowing CKD progression. The opinion that they are scarcely feasible in the clinical practice limits their use.

**Aim** of the study was to assess the feasibility of the diet in a new Nephrology Unit, where it was routinely prescribed to stage 3-5 CKD patients.

**Methods**

Prospective analysis: December 2007-April 2010. Diet composition: Vegan diet with Protein content 0.6 g/Kg/day; supplementation: Ketosteril 1 every 10 Kg; 1-3 free meals/week, monthly follow-up, simplified schema based upon " allowed " and "forbidden" food. Side effects and compliance were recorded at the visits. Progression was evaluated as loss of GFR (Cockroft formula) in patients with at least 6 months of follow-up. Logistic regression was performed on SPSS.

**Results**

Out of over 1500 patients followed since the start of the Unit (December 2007), 84 non pregnant adult patients started the supplemented low protein diet(median age 67 years, 38% diabetics, multiple comorbidities in 42%, educational level >12th grade 18%). Median data at start: proteinuria 1.3 g/day, GFR 20 mL/min, creatinine 3.5 mg/dL.

At April 2010, 42 patients were continuing the diet, 10 discontinued it (5 for personal preferences, 5 for side effects), 2 died, started dialysis, 2 dropped out from follow-up, 3 improved and discontinued the diet, 25 started dialysis (planned in 19; acute cardiovascular or infectious problens led to emergency start in 6 cases). The main side effect was poor

gastrointestinal tolerance; severe oedema was recorded in 1. No baseline data correlated with "succesful follow-up", defined as at least 6 months on the diet, in uni and multivariate analysis. In the subset of cases followed for at least 6 months, median GFR decrease was -2 ml/min/year.

**Conclusion**

Vegetarian, supplemented low protein diets are routine feasible in non selected CKD patients. A trial period may help identifying patients who can benefit from this regimen.

Disclosure of Financial Relationships: nothing to disclose

## PUB192

**Cancer History among Persons with Chronic Kidney Disease in the United States** Laura C. Plantinga,[1] Chi-Yuan Hsu,[1] Vahakn B. Shahinian,[2] Rajiv Saran,[2] Meda E. Pavkov,[3] Sharon Saydah,[4] Neil R. Powe.[1] *[1]University of California, San Francisco, CA; [2]University of Michigan, Ann Arbor, MI; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]Centers for Disease Control and Prevention, Hyattsville, MD.*

Certain cancers are more common in ESRD patients, but less is known about its association with earlier stages of CKD. In the 1999-2006 National Health and Nutrition Examination Surveys, 22,540 adult participants (≥20 years) were surveyed regarding their history of cancer, including type(s) and age(s) at diagnosis. CKD was defined as a urinary albumin:creatinine ratio of ≥30 mg/g (stages 1 and 2) or MDRD-estimated GFR of 15-59 ml/min/1.73 m$^2$ (stages 3 and 4). Adjusted prevalence of cancer history was calculated using multivariable logistic regression with U.S. population-based weighting. Among those with no CKD, CKD stages 1 and 2, and CKD stages 3 and 4, the unadjusted prevalence of self-reported history of any cancer was 6.7%, 10.5%, and 21.3%, respectively ($P$<0.001). With adjustment for current age, however, there was no significant association of history of any cancer with current CKD status (8.1%, 7.8%, and 8.5%, respectively; P=0.66). Among those with CKD stages 3 and 4 and a history of cancer, the age-adjusted prevalence of kidney or bladder cancer was 4.8% among those with CKD, compared to 2.3% of those with no CKD ($P$=0.02). Similarly, with age adjustment, 9.1% (CKD stages 3 and 4) vs. 6.1% (no CKD) reported having had gastrointestinal cancer ($P$=0.05). Skin cancer was less commonly reported in those with CKD stages 1 and 2 (29.3%) compared to those with no CKD (38.8%; P=0.04), but no other specific type of cancer examined differed significantly by CKD status with age adjustment. Additional adjustment for gender, race/ethnicity, and smoking did not alter the results. While the unadjusted prevalence of self-reported cancer is >3 times higher in those with moderate to severe CKD compared to no CKD, much of this observed association appears to be due to older age, a risk factor for both conditions. CKD may, however, be associated with greater prevalence of specific types of cancer, including kidney, bladder, and gastrointestinal cancers.

## PUB193

**Effects of Plasma Calcium and Phosphorus Levels outside Target Ranges as Proposed by KDOQI and KDIGO in Pre-Dialysis Patients** Iris Postmus,[1] Dinanda J. De Jager,[1] Nynke Halbesma,[1] Elisabeth W. Boeschoten,[2] Friedo W. Dekker,[1] Diana C. Grootendorst.[1] *[1]Clinical Epidemiology, LUMC, Leiden, Netherlands; [2]Hans Mak Institute, Naarden, Netherlands.*

In dialysis patients disturbed mineral metabolism has been associated with poor outcome. Aim of this study was to assess the effect of calcium (Ca) and phosphorus (P) levels outside the targets as proposed by KDOQI and KDIGO, on time to initiation of dialysis in pre-dialysis patients.

*Methods*

237 Incident adult pre-dialysis patients (71% M, 65±15 yrs, P 4.46±1.05 mg/dl, Ca 9.39±0.63 mg/dl) from the prospective Dutch PREPARE-2 cohort were included. The effects of P and Ca levels below, within, and above target ranges on time to dialysis initiation were assessed using Cox regression.

*Results*

Patients achieving target ranges and the associated incidence rates and hazard ratios (HRs) for initiation of dialysis treatment

a. Target: KDOQI: CKD3-4: 2.7-4.6 mg/dl, CKD5: 3.5-5.5 mg/dl, KDIGO: 2.5-4.5 mg/dl; b. Adj. for age, sex, primary kidney disease, eGFR, SBP and Hb; c. Target: KDOQI: 8.4-10.2 mg/dl, KDIGO: 8.5-10.0 mg/dl; d. same as b. + P

*Conclusion*

P levels above both the KDOQI and KDIGO target ranges are associated with a higher risk of dialysis initiation. No association was found between Ca and the risk of dialysis initiation. Therefore, successful maintenance of P levels might be beneficial in postponing dialysis.

Disclosure of Financial Relationships: nothing to disclose

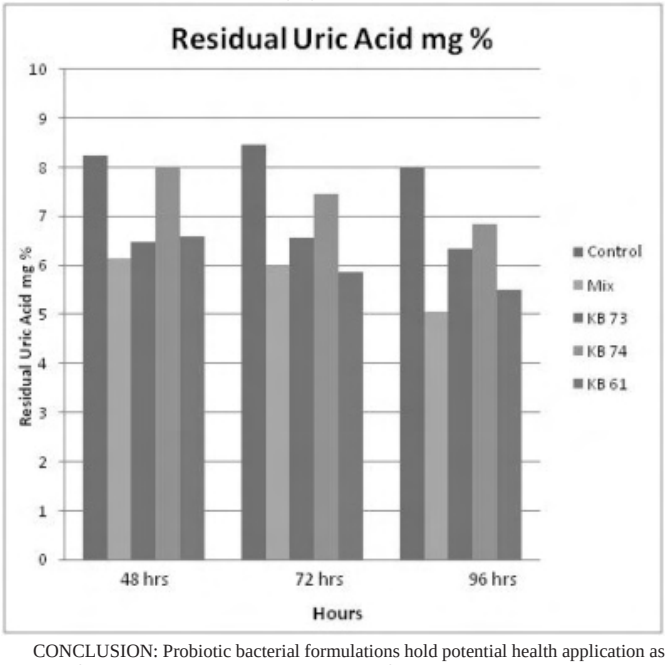
## PUB194

**A Novel Approach of Uric Acid Removal with a Probiotics Dietary Supplement Product Formulation (In-Vitro Studies)** Natarajan Ranganathan,[1] Pari Ranganathan,[1] Usha N. Vyas,[1] Eli A. Friedman.[2] *[1]Kibow Biotech Inc, Newtown Square, PA; [2]Down State Med Ctr - SUNY, Brooklyn, NY.*

PURPOSE: Over 5 years have been devoted to continuous in vitro design and testing of novel probiotic product formulations based on the concept that substituting a usual bowel function for reduced or absent kidney function (with various generally accepted biomarkers) may preempt the clinical consequences of chronic kidney disease (CKD). The present report recounts our exploratory studies aimed at reducing plasma uric acid biomarker levels as a means of preventing symptomatic hyperuricemia and/or gout in patients with CKD.

METHODS: An Artificial Intestinal Fluid (AIF) was prepared according to US pharmacopeia standards. To this, uric acid was added as a potassium or sodium urate salt at concentrations of 8.34 mg%. Over 50 different well characterized probiotic strains - both aerobes and anaerobes - with a known concentration of Colony Forming Units (CFU's) in multiple of billions were added individually and collectively to a 100 ml aliquot of AIF. Each text mixture was individually incubated in a shaker at 37$^0$C and 50 rpm. Control volumes without added probiotic bacteria were also incubated in the same manner. 1.0 ml samples were withdrawn every 24 hours for a period of 96 hours. These samples were then centrifuged for 10 minutes at 8000 rpm to settle the biomass. Residual uric acid in the supernatant was quantified using a Quantichrom Uric Acid kit from Bio-assay System, CA.

RESULTS: Of the bacteria studied, three Lactobacillis strains (KB 61, KB 73 and KB 74) individually and together demonstrated specific utilization of Uric acid as biomarker with varied and different affinities ranging from 15% to 40%.



CONCLUSION: Probiotic bacterial formulations hold potential health application as a means of reducing intra-intestinal concentration of uric acid.

## PUB195

**Elderly Patients with Stage 3 Chronic Kidney Disease (CKD): Eplerenone. Drug Effectivity and Safety** Consolación Rosado Rubio,[1] Marcos Luis Álvarez Alejandre,[1] Raquel López de la Fuente,[2] Jose L. Lerma,[1] Cyntia Gonzalez Álvarez,[1] José Luis Rodríguez Commes.[1] *[1]Servicio de Nefrología, Hospital Clínico de Salamanca, Salamanca, Spain; [2]Centro de Salud Santa Elena, Zamora, Zamora, Spain.*

Introduction:

An early blocking of proteinuria is an effective mechanism to slow the progression of renal damage. However, as evidenced by the ONTARGET study, a dual blockade that combines ACEI and ARB is not without risks and can result in further deterioration of the

renal function and hyperkalemia, especially in the elderly. Direct blockers of aldosterone and eplerone are antifibronegic and beneficial for the cardiovascular system. Theoretically, they lack hormonal or metabolic adverse effects. However, their effect on proteinuria and CKD progression in the elderly is still unknown.

Objectives:

1.To assess the antiproteinuric effect of eplerenone

2.To identify its influence on renal function

3.To establish its clinical and metabolic side effects

Material/Methods:

We performed a prospective study of 46 patients (age 69 +/-5) with stage 3 CKD under treatment of ACEI and/or ARBs who started taking 25 mg/day of eplerenone. Each patient served as own control. We assessed proteinuria, serum K and serum Cr. The statistical study was performed with analysis of variance with Student's t-test or Kruskal-Wallis test, depending on the variables.

Results:

74% of the patients showed a reduction of proteinuria from 1.53 to 1.12 ($p<0.02$).

The average concentration of serum K was 4.4 mg/dl, and the concentration at the end of the follow-up was 4.5 mg/dl. This difference was not statistically significant ($p=0.83$). No cases of severe hyperkalemia were observed.

The initial mean value of serum Cr in the sample is 1.6 mg/dl, and the final value is 1.8 mg/dl. This deterioration was not statistically significant ($p=0.52$).

Conclusions:

- Eplerenone reduced proteinuria significantly in elderly patients with stage 3 CKD who had been previously treated with ACE inhibitors and/or ARB.

- The good tolerance of eplerenona, the absence of hyperkalemia and the moderate increase in glomerular filtration support the conclusion that it can be used with close monitoring in these patients, although randomized studies are required.

Disclosure of Financial Relationships: nothing to disclose

## PUB196

**Urinalysis as a Predictor of Microalbuminuria in Stage 3 CKD** Shayan Shirazian, Jai Radhakrishnan, Herbert S. Chase. *Nephrology, Columbia University Medical Center, New York, NY.*

Purpose: NKF guidelines recommend quantitative urine protein (QUP) assessment in patients with Stage 3 CKD. The purpose of this study was to determine the proportion of Stage 3 CKD patients with urine protein measurement and to test the effectiveness of urinalysis as a screening test for microalbuminuria.

Methods: Patients enrolled in this study were ambulatory clinic patients followed consistently over a four year period (registered > 10 times at the Columbia University Medical Center clinic from 2004-2008). Demographic information, diabetic and hypertensive status, serum creatinine values and urine protein values were extracted from the clinical data warehouse. A minimum of 4 creatinine values separated by at least one year were required for study inclusion. Stage 3 CKD status was assigned if eGFR was between 30 and 60 for at least 3 months. eGFR was calculated using the MDRD formula. Urinalysis (UA) and urine microalbumin-creatinine ratio (UACR) results were compared using UACR as the 'gold standard' for microalbuminuria.

Results: 1160 adult patients were classified as Stage 3 CKD (69% female, 61% diabetic, 98% hypertensive, 24% Black or Hispanic). Of these, 1020 had UA or QUP measurement, 741 (65%) had QUP measurement, 538 had UACR, 459 had spot urine protein and 28 had 24hr urine protein or albumin measurement. 140 patients (12%) did not have qualitative or quantitative urine protein testing. 466 patients had both UA and UACR testing. UA testing correlated poorly with UACR in evaluating for microalbuminuria in both diabetics (Sensitivity=0.71, Specificity=0.76) and non-diabetics (Sensitivity=0.6, Specificity=0.83). Patients with true positive UA results had a significantly faster rate of GFR decline than those with false positive UA results (-2.95 vs. -1.48 ml/min/year, $p<0.05$).

Conclusions: A large percentage of patients with Stage 3 CKD, followed consistently in a tertiary care ambulatory clinic, lack quantitative urine protein testing. UA does not accurately predict microalbuminuria in Stage 3 CKD and and has limited utility in determining the risk of GFR decline.

Disclosure of Financial Relationships: nothing to disclose

## PUB197

**Involvement of Serum Indoxyl Sulfate in Development of Anemia in Non-Dialysis CKD Patients: A Retrospective Cohort Study** Tatsuya Shoji,[1] Naohisa Tomosugi,[2] Takuya Uehata,[3] Yusuke Sakaguchi,[1] Akira Suzuki,[1] Yoshiharu Tsubakihara.[1] *[1]Department of Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan; [2]Division of Advanced Medicine, Medical Research Institute, Kanazawa Medical University, Kahoku, Ishikawa, Japan; [3]Department of Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

**Background:** Role of uremic toxins in exacerbating renal anaemia is still unclear. In CKD patients, serum indoxyl sulfate, a uremic toxin, is markedly accumulated and was shown to accelerate the progression of renal dysfunction and vascular disease. This retrospective observational study examines whether serum indoxyl sulfate is involved in development of anaemia in non-dialysis CKD patients.

**Methods:** Study design: Retrospective cohort study. Setting & Participants: Consecutive 357 non-dialysis and erythropoietin-naive CKD patients were recruited from single outpatient nephrology clinic at referral hospital. Predictor: serum indoxyl sulfate. Outcomes: Primary end point was initiation of erythropoietin treatment.

**Results:** Participants were predominantly man (56.6%), and non-diabetic (82.1%); participant mean age was 61.9 years [SD, 14.9]. Mean eGFR was 47.4 ml/min/1.73m$^2$ [SD, 25.0], mean hemoglobin was 12.7 g/dL [SD, 1.9], and median indoxyl sulfate was 0.24 mg/dL [interquartile range, 0.12-0.46]. 25 events occurred in each gender over a mean follow-up of 22.9 months. One of the covariates, gender, violated the proportional hazard assumption of Cox's model, so we constructed Cox's model in each gender separately. The limited number of events did not allow us to include more than three variables for each model. The table shows hazard ratios (HR) associated with serum indoxyl sulfate (mg/dL) in each gender model.

HR associated with serum indoxyl sulfate (mg/dL)

| | HR (95% CI) | |
|---|---|---|
| | Male | Female |
| Unadjusted | 10.0 (5.4-18.5) | 3.0 (1.9-4.6) |
| Adjusted for age | 10.0 (5.4-18.6) | 2.5 (1.9-4.6) |
| Adjusted for estimated GFR | 4.4 (1.9-9.9) | 0.7 (0.4-1.4) |

**Conclusion:** These results suggested that serum indoxyl sulfate was involved in development of anemia in non-dialysis CKD patients, at least in male.

Disclosure of Financial Relationships: nothing to disclose

## PUB198

**Once-Monthly C.E.R.A. Administration Maintains Stable Hemoglobin Concentrations in Dialysis Patients Regardless of Age, Gender or Diabetes** Kostas I. Sombolos. *(on Behalf of the ML20952 Study Group) Renal Unit G.H. "G. Papanikolaou", Thessaloniki, Greece.*

**INTRODUCTION AND AIMS:** Continuous erythropoietin receptor activator (C.E.R.A) is a novel agent with unique receptor activity, allowing once-monthly administration for effective maintenance of stable hemoglobin (Hb) in patients with chronic kidney disease (CKD). Since males, patients >65 years (y) and patients with diabetes are an expanding CKD population, we examined the effect of age, gender and diabetes on the maintenance of Hb concentrations with C.E.R.A. over time.

**METHODS:** This prospective, multicentre, single arm, open label study assessed the efficacy, safety and tolerability of once-monthly administration of C.E.R.A. for the maintenance of Hb levels in dialysis patients with chronic renal anemia. Patients (n=188) in Greece (≥18y) receiving adequate dialysis and intravenous epoetin or darbepoetin with stable baseline Hb (10.5-12.5 g/dL) entered a 16-week C.E.R.A. dose titration phase (DTP) followed by an 8-week efficacy evaluation period (EEP). At DTP (week 16) and EEP (week 24) the efficacy parameters were analyzed by age (<65y, 65-75y, >75y), gender and diabetes (yes/no), using an ANOVA test.

**RESULTS**: Mean Hb concentration at baseline, week 16 and week 24, for patients <65y, 65-75y, >75y, male (M) and female (F), diabetic or non-diabetic are shown in the table below. No statistically significant differences were found between the sub-populations or study phases.

| | N | Baseline mean (SD) (g/dL) | Hb Week 16 Hb mean (SD) (g/dL) | Week 24 Hb mean (SD) (g/dL) |
|---|---|---|---|---|
| Age y | | | | |
| <65 | 89 | 11.7 (0.58) | 11.8 (0.92) | 11.5 (1.11) |
| 65-75 | 65 | 11.5 (0.51) | 11.8 (1.06) | 11.6 (1.14) |
| >75 | 34 | 11.6 (0.63) | 11.7 (1.01) | 11.7 (1.14) |
| Gender | | | | |
| M | 115 | 11.6 (0.58) | 11.9 (0.89) | 11.6 (1.13) |
| F | 73 | 11.6 (0.58) | 11.6 (1.10) | 11.5 (1.12) |
| Diabetes | | | | |
| Yes | 35 | 11.7 (0.51) | 11.6 (1.10) | 11.4 (1.34) |
| No | 153 | 11.6 (0.58) | 11.8 (0.95) | 11.6 (1.07) |

**CONCLUSIONS:** Regardless of age, gender, or diabetes, once-monthly C.E.R.A. administration in dialysis patients can effectively maintain Hb stability.

## PUB199

**Low Glomerular Filtration Rate in Normoalbuminuric TypeII Diabetic Patients Is Related with Aging Kidney** Oonishi Takahiro. *Nephrology, Yamada Red Cross Hospital, Ise, Mie, Japan.*

Some diabetic patients have low GFR with normoalbuminuria. The aim of this study was to identify a group of normoalbuminric type 2 diabetic patients with low GFR and compare them with normoalbuminuric patients with normal GFR.Altogether,147 normoalbuminuric type 2 diabetic patients with average 10 years of diabetes duration that patients were divided these patients into elderly group (E group, average age 68.9 years old) and the non-elderly group under 65 years old(N group, average age 51.1 years old) and examined blood pressure, HbA1c, creatinine clearance (Ccr),estimated GFR and pulse wave velocity(PWV), LV mass index and relative wall thickness (RWT) by echocardiogram.

Result: Ccr of E group deteriorated significantly than N group(69.2 +- 26.0 ml/min vs 86.2 +- 25.0 ml/min,$p<0.01$), and E group was higher than N group in comparison of blood pressure and PWV.In addition,RWT of E group was significantly lager than N group. Conclusion: Some of the elderly diabetic patients with normoalbuminuria reduced the GFR. It was related that the atherosclerosis and left ventricule hypertrophy. It might be that GFR in elderly diabetic patients dose not show only renal function but also cardiovascular disease.

**Pulmonary Hypertension in Patients with Chronic Kidney Disease** Eranga S. Wijewickrama,[1] Wasantha Kapuwatte,[2] Hasantha Ranawaka,[2] Thamal Vithanage,[3] Mihirini Abeywickrama,[3] S. Naranthiran,[2] Anuja Abeyadeera,[4] Godwin Constantine,[3] Rushika D. Lanarolle.[3] *[1]University Medical Unit, National Hospital of Sri Lanka, Colombo, Sri Lanka; [2]Institute of Cardiology, National Hospital of Sri Lanka, Colombo, Sri Lanka; [3]Department of Clinical Medicine, Faculty of Medicine, Colombo, Sri Lanka; [4]Department of Surgery, Faculty of Medicine, Colombo, Sri Lanka.*

Background

High prevalence of pulmonary hypertension had been observed in patients with end stage renal failure undergoing chronic haemodialysis. The objective of this study was to evaluate the prevalence of pulmonary hypertension (PH) among the pre-dialytic chronic kidney disease (CKD) patients.

Methods

The prevalence of PH was evaluated in 32 randomly selected patients with CKD who were attending an outpatient renal clinic at the National Hospital of Sri Lanka. Pulmonary artery pressures were evaluated by two cardiologists using a single Doppler echocardiography machine. All patients with PH were screened for secondary causes.

Results

Six patients (18.8%) had PH as defined by pulmonary artery systolic pressure (PAP) >35mmHg. PAP was >45mmHg in 4 of these patients which constituted 12.5% of all patients. None of these patients were having functioning arterio-venous fistulae. Three of these patients had left ventricular diastolic dysfunction but the remaining 3 patients had no clinical or echocardiographic evidence of a cause for PH. The mean serum creatinine concentration in the study population was 3.8mg/dl and the mean haemoglobin concentration was 9.6g/dl. The aetiology of CKD, the degree of renal dysfunction and the levels of haemoglobin, calcium and phosphate were no different in the group of patients with PH compared to patients without PH.

Conclusion

There is a high prevalence of PH even among patients in the pre-dialytic stages of CKD. Further studies need to be carried out to identify factors which predispose these individuals to development of PH.

**Once-Monthly C.E.R.A. Is Non-Inferior to Darbepoetin alfa for Correcting Anemia in Patients (pts) with Chronic Kidney Disease (CKD) Regardless of Age, Gender, Diabetic Status, Hypertension, or Presence of Hyperlipidemia** Rainer Woitas. *Department of Internal Medicine I, University of Bonn, Germany.*

**Purpose:** The CORDATUS study showed that the continuous erythropoietin receptor activator (C.E.R.A.) effectively corrected anemia when administered once monthly (Q4W) to pts with CKD not on dialysis. A subgroup analysis was performed to establish whether these data were dependent on age, gender, or presence of diabetes, hypertension, or hyperlipidemia.

**Methods:** Adult pts with stage 3/4 CKD not on dialysis received either subcutaneous C.E.R.A. Q4W with a starting dose of 1.2 „g/kg or darbepoetin alfa (DA) once weekly (QW) or once every 2 weeks (Q2W) according to local labeling. The primary efficacy analyses (Hb response, defined as increase in Hb ≥1 g/dL from baseline and a concentration ≥10.5 g/dL; non-inferiority (NI) test for Hb change from baseline in each group) were repeated for the subgroups defined according to gender, age, diabetic status, hypertension, or presence of hyperlipidemia.

**Results:** Hb response rates were similar for Q4W C.E.R.A. and QW/Q2W DA, irrespective of gender, age, or the presence of diabetes, hypertension, or hyperlipidemia. The NI test for Hb change from baseline was significant for each category analyzed, with the exception of the 'no hypertension' group, which included only 10 patients.

| Variable | Hb response rate (%) | | Non-inferiority for the difference between groups in Hb change from baseline to evaluation | |
|---|---|---|---|---|
| | C.E.R.A. | Darbepoetin alfa | Difference in mean Hb (g/dL) | p-value |
| Male | 95.5 | 94.0 | 0.174 | <0.0001 |
| Female | 93.0 | 93.1 | -0.182 | 0.0002 |
| Age ≤65 years | 93.2 | 95.9 | 0.062 | <0.0001 |
| Age >65 years | 94.7 | 92.4 | -0.049 | <0.0001 |
| Diabetes | 94.2 | 95.1 | 0.010 | <0.0001 |
| No diabetes | 94.0 | 91.8 | -0.078 | <0.0001 |
| Hypertension | 94.0 | 93.9 | -0.015 | <0.0001 |
| No hypertension | 100.0 | 85.7 | -0.941 | 0.0003 |
| Hyperlipidemia | 94.3 | 93.5 | -0.021 | <0.0001 |
| No hyperlipidemia | 93.6 | 93.6 | -0.090 | 0.0026 |

**Conclusion:** In this study, C.E.R.A. Q4W was statistically non-inferior to DA for correcting anemia in pts with CKD, regardless of age, gender, diabetic status, hypertension, or presence of hyperlipidemia.

**The Effect of Cardiac Resynchronization Therapy on Cardio-Renal Anemia Syndrome** Takeshi Yokoyama, Katsuomi Matsui, Yugo Shibagaki, Takashi Yasuda, Kenjiro Kimura. *Nephrology and Hypertension, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan.*

Background: Chronic kidney insufficiency and anemia are often present in the severe heart failure (HF) patient. Cardio-renal anemia (CRA) syndrome is medically intractable and develop into end stage renal failure. Although Cardiac resynchronization therapy (CRT) is known to improve cardiac functional status and symptom in severe HF patients with ventricular dyssynchrony, there is a paucity of data whether CRT have an salutary effect for CRA syndrome.

Purpose: To determine if CRT improves renal function and anemia in patients with chronic kidney disease (CKD) and severe HF.

Methods: All the patients who were treated with CRT in our hospital were reviewed retrospectively and 22 patients with CKD stage 3 or above were selected. Renal function and anemia, cardiac function before and after CRT were compared.

Results: Of the 22 subject, there are 15 patients were with CKD stage 3 (stage 3 group), and 7 patients with CKD stage 4 (stage 4 group) pre-CRT. HF symptom of both groups improved significantly. Estimated GFR (eGFR) did not significantly improved in stage 3 group, but in stage 4 group, it improved significantly ($p < 0.05$). Slope of approximate line of time to eGFR tended to increase in stage 3 group and it increased significantly in stage 4 group. Slope of aooroximate line of time to hemoglobin tended to increase in both groups.

Conclusion: CRT may cotribute to amelioration of CRA syndrome in patients with advanced CKD. Especially, hemodynamic improvement by CRT may contribute to amerioration of renal function.

**Awareness of Kidney Disease among Black Africans Living in the UK** Adekunle Bamidele Adesina,[1] Samuel Abiamuwe,[2] Gillian Olumide.[2] *[1]Renal Unit, Morriston Hospital, ABM University Health Board, Swansea, United Kingdom; [2]School of Health Sciences, University of Wales, Swansea, United Kingdom; [3]School of Health Sciences, University of Wales, Swansea, United Kingdom.*

BACKGROUND: Chronic kidney disease leads to end stage renal failure (ESRF) and it is a global growing epidemic. ESRF leads to death unless treated by dialysis or kidney transplant. In the UK, Black Africans have a fourfold incidence of ESRF compared to Whites due to their higher rates of diabetes and hypertension.

PURPOSE : To investigate the knowledge and perceptions of kidney health among people of Black African origin living in the city of Swansea.

METHODS : The study adopted a qualitative design which used semi-structured individual interview as the tool for data collection.

RESULTS :The sample comprised of a balanced number of eight individuals (four men and four women) aged between 23 to 58 years, drawn from various locations within the city and county of Swansea. Data were analyzed using thematic content analysis. Overall, we found that current level of knowledge of kidney health and related issues of renal diseases including its primary risk factors was generally very low. Perceived risk of predisposition to kidney disease was also poor. These findings hold for both men and women. Reason such as lack of information and education regarding kidney disease, access to health services and mistrust in the health professionals and value of treatment were frequently cited.

CONCLUSIONS :These findings underscore the need for increased public health measures to raise awareness, stimulate early detection among blacks and manage risk factors in this community.

Disclosure of Financial Relationships: nothing to disclose

**PUB204**

**A Five-Factor Behavioural Intervention Study of Risk Modification on Kidney Disease Prevention in Black British Populations – Rationale and Design** Adekunle Bamidele Adesina,[1] Sally Altree,[2] George Karani,[3] Fope Adesina,[4] Kofi Obuobie.[5] *[1]Renal Unit, Morriston Hospital, Swansea, United Kingdom; [2]Renal Dietetics, University Hospital of Wales (UHW), Cardiff, United Kingdom; [3]Cardiff School of Health Sciences, University of Wales Institute (UWIC), Cardiff, United Kingdom.*

**RATIONALE** There is a well recognised excess prevalence of kidney disease amongst UK ethnic minorities notably black African-Caribbean. Although studies such as the AASK have addressed specific risk factor modification amongst American blacks, there is relative paucity of similar data among Black British populations.

**Purpose of study**

To examine the impact of modifying multiple risk factors for kidney disease including salt, but also sugar/calorie intake, smoking, stress/social isolation and a sedentary lifestyle.

**DESIGN**

Prospective cohort study of >/=5000 subjects in community adults (18-65 years), of black-African and African-Caribbean descent residing g in five cities of South Wales and West of England. duration 5 years.

**Interventions**

Salt Restriction (≤5g/day)

Sugar & alcohol reduction, accoding to UK standards

Structured (planned) >/=30 min./day and 'opportunistic' exercises at least 5 days of the week

· Brisk walking, dancing or jogging

Social support through enhanced contacts with relatives and friends.

Smoking cessation through enhanced access to existing programmes of local UK agencies

**Evaluations**

Questionnaire survey on personal medical/drug history and family history of kidney and related chronic health conditions, awareness of dietary risk factors, stress and social well-being, Weight, Height, Eating habits, Urinalysis (dipstick and spot urine) on two samples over a three month interval, Blood pressure, fasting serum creatinine, lipids and glycaemia on two measurements over a two to three-month interval 24-hour urinary measurements of sodium and potassium at baseline and three monthly intervals.

The analyses would focus on time-trends of incidence and prevalence of kidney disease, high blood pressure, and weight in all subjects and by sub-groups' pre-defined levels of compliance with each of the five components of the behavioural intervention.

**MPO-ANCA Associated Vasculitis with Pulmonary Fibrosis** Nishkantha Arulkumaran,[1] Naomi Periselneris,[1] Nicola H. Strickland,[3] Philip W. Ind,[2] Charles D. Pusey,[1] Alan D. Salama.[1] *[1]Department of Nephrology, Imperial College Kidney and Transplant Institute, London, United Kingdom; [2]Department of Respiratory Medicine, Imperial College, London, United Kingdom; [3]Department of Radiology, Imperial College, London, United Kingdom.*

Purpose: The occurrence of Anti-neutrophil cytoplasm antibody (ANCA) associated vasculitis (AAV) and pulmonary fibrosis (PF) in the same patient is rare. We ascertained characteristics and clinical outcomes of patients with AAV and PF.

Methods: A retrospective observational cohort study of 500 patients (142 with microscopic polyangiitis; MPA) attending our nephrology clinic from 1974-2009

Results: 15 AAV patients had PF. Eleven were male and 4 were female- all with MPA. Those tested were MPO-ANCA positive (n=14). Mean age was 66.5 (52-86) years. Two were smokers, 8 ex-smokers. PF diagnosis was concurrent with AAV in 9, preceded AAV in 2 and followed AAV in 4 patients. Ten patients had a renal biopsy that showed FSGN, with glomerular tuft necrosis in 7. Mean serum creatinine on presentation was 5.85mg/dL (median 4.35mg/dL). Induction was with steroids and cyclophosphamide (CyP) in 9. In addition to this, 4 had plasma exchange, and 1 had rituximab. One patient had steroids alone. Respiratory complications were the commonest cause of mortality (5 out of 10). There was no significant difference in survival between patients with MPA with PF and those without PF (p=0.127).

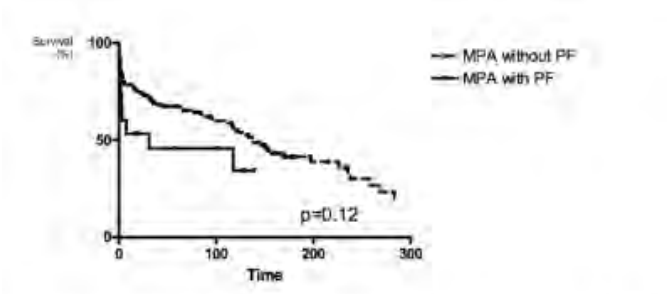

Figure 1: Kaplan Meier survival curve comparing the cohort of patients with MPA and PF and patients with MPA alone

Survival was worse in MPA patients with serum creatinine >5mg/dL at presentation compared to those with creatinine <5mg/dL (p<0.0001). Mean creatinine at follow up in 11 patients who achieved remission was 2.55mg/dL (median 2.15mg/dL).

Conclusion: AAV and PF may occur concurrently. Degree of renal impairment at presentation is a stronger predictor of survival than presence of PF, though morbidity from PF is significant. Optimum treatment of PF in MPA needs to be determined.

## PUB206

**Spectrum of Renal Diseases in a Tertiary Care Hospital of Pakistan** Syed Rizwan Bokhari, Hafiz I. Ahmad, Muhammad Awais. *Nephrology Department, Allama Iqbal Medical College, Lahore, Pakistan.*

Patients with renal diseases make a large group among patients presenting to our tertiary care hospital in Pakistan. We aimed at studying the spectrum and etiology of renal diseases referred for Nephrology consultation from inpatient floors and emergency department. PLACE AND DURATION OF STUDY: The study was conducted in the Department of Nephrology over a period of three and half months (Feb to May, 2010). DESIGN: A single center based prospective observational study RESULTS: A total of 202 patients were studied. Of these 100 were males and 102 females. Mean age of the patients in this series was 32.7 years with a range of 14 to 85 years. Of these 202 patients 59(29.2%) had acute renal failure (ARF) / Acute Kidney Injury (AKI), 141(69.8%) had chronic kidney disease (CKD) and 2 (1%) had transplant dysfunction.

Out of 59 ARF/AKI patients, etiologies included peri-partum ARF 20 (34%), sepsis 19(32%), nephrotic syndrome 10 (17%), non nephrotic protienuria 4 (7%), post surgical ATN 7 (12%), hypovolemia 5 (8.4%), drug induced 4(7%), acute Glomerulonephritis 4(7%), hepetorenal 4 (7%) and obstructive uropathy 2 (3.3%).

Out of 141(69.8%) patients with CKD18 (13%) had CKD 4, 74 (52%) had CKD 5 and 49(35%) had ESRD. Causative factors for CKD included HTN 108 (77%), DM 48 (34.5%), combined HTN and DM 33(24%), obstructive uropathy 12(8.6%), nephrotic syndrome 2 (1.4%) and Lupus Nephritis 2 (1.4%).

CONCLUSION: This study highlighted two important issues. Peri-partum renal failure makes the largest group of ARF patients and a large number of patients present with advanced CKD (stages 4 &5) as their first presentation of renal disease. These findings underscore the need for improved obstetric care and launching of intensive efforts for early screening strategies and risk factor management for diagnosis and treatment of Chronic Kidney Disease.

## PUB207

**Hepatitis B Virus Infection Is Associated with Lower Renal Function in Chinese Adults of Beijing** Jianfang Cai, Xiaohong Fan, Hang Li, Xuemei Li, Xue-Wang Li. *Nephrology, Peking Union Medical College Hospital, Beijing, China.*

**AIM:** To explore the association between Hepatitis B virus (HBV) infection and renal function and urinary albumin excretion.

**DESIGN AND METHODS:**In this cross-sectional study, a random sample of 6856 Chinese rural adults aged 30 to 75 years were selected in Beijing during 2008 to 2009. HBV infection was defined as serum HBsAg positivity. Estimated glomerular filtration rate (eGFR) was calculated with the estimating equation developed by CKD-EPI. The estimated marginal means (EMMs) and standard error of means (SEMs) of eGFR, the logarithm of serum creatinine (Cr) and the logarithm of urinary albumin-creatinine ratio (ACR) by HBV infection status were calculated and compared with generalized linear models, adjusted for age, gender and other confounding factors (e.g. hypertension, diabetes, dyslipidemia, obesity, smoking, nephrolithiasis). All statistical analyses were conducted with SPSS14.0 and results were expressed as EMMs±SEMs.

**RESULTS:** HBV infection had an overall prevalence of 4.90% in the study population. The unadjusted EMM of eGFR was lower (92.39±0.85 vs. 94.62±0.19 ml/min/1.73m2, p=0.010) and that of logarithm of Cr (1.905±0.004 vs. 1.893±0.001, p=0.002) was higher in persons with than in those without HBV infection. So were multivariate-adjusted EMM of eGFR (89.52±0.95 vs. 91.78±0.71 ml/min/1.73m2, p=0.001) and that of logarithm of Cr (1.917±0.005 vs. 1.907±0.004, p=0.002), after adjusted for age, gender, and other confounding factors (e.g. hypertension, diabetes, dyslipidemia, obesity, smoking, nephrolithiasis).However, there was no difference in the multivariate-adjusted EMMs of logarithm of ACR between persons with and those without HBV infection.

**CONCLUSIONS:** HBV infection is associated with lower renal function, but not with urinary albumin excretion in Chinese general population of Beijing.

## PUB208

**The Prevalence of Type 2 Cardio-Renal Syndrome in Inpatients with Chronic Heart Disease** Xi Chen, Zhaohui Ni, Shan Mou, Qin Wang. *Renal Division, Renji Hospital Shanghai Jiaotong University School of Medicine, Shanghai, China.*

***Instruction*:** Recent studies have showed that patients with chronic heart disease (CHD) are at high risk of chronic kidney disease, which is defined as type 2 cardio-renal syndrome (type 2 CRS). The high prevalence and early diagnosis of type 2 CRS in CHD population don't gain enough attention of clinicians. In this study, we aim to investigate the prevalence of type 2 CRS in CHD patients and find out the related factors of type 2 CRS.

***Methods:*** A retrospective, cross-sectional analysis of 1275 CHD inpatients of Cardiology Department from July 2008 to July 2009 was conducted. Estimated glomerular filtration rate (GFR) was calculated using the simplified Modification of Diet in Renal Disease (MDRD) equation. Baseline characteristics including age, gender, lifestyle, medical history, physical examination, laboratory variables were collected and analyzed.

***Results:*** Of all the 1275 CHD inpatients, the prevalence of type 2 CRS was 18.4% (235/1275). Patients with type 2 CRS were older than patients without CRS. Compared to study patients without CRS, type 2 CRS patients were more likely to have medical history of diabetes mellitus (28.9% vs 21.8%, $P$ <0.05), hyperuricemia (41.3% vs 26.4%, $P$ <0.001) and cerebrovascular disease (9.8% vs 5.7%, $P$ <0.001). Univariate analysis showed the significant correlation between type 2 CRS and lactate dehydrogenase(LDH) ($r$= 0.127, $P$=0.042), type B natriuretic peptide(BNP)($r$= 0.182, $P$<0.001), blood urea nitrogen(BUN)($r$= 0.298, $P$<0.001), serum creatinine(SCr)($r$= 0.301, $P$<0.001), uric acid(UA)($r$= 0.142, $P$<0.001), eGFR($r$= -0.334, $P$<0.001). Moreover, age (odds ratio [OR] 1.038, 95% confidence interval [CI] 1.025-1.051) and hyperuricemia (OR 1.855, 95% CI 1.380-2.494) were risk factors of type 2 CRS.

***Conclusion:*** This study suggested that the prevalence of type 2 CRS was high in CHD patients and some cardio-renal related markers like LDH, BNP, SCr, BUN, UA and eGFR were associated with type 2 CRS. Especially for CHD patients with advanced age and hyperuricemia, early diagnosis and treatment of type 2 CRS were needed.

**Comparison of Three Methods of Estimation of Glomerular Filtration Rate with Creatinine Clearance in Kidney Transplant Recipients** Lukasz B. Chrobak,[1] Alicja Debska-Slizien,[1] Andrey Petranyuk,[2] Magdalena Maria Jankowska,[1] Boleslaw Rutkowski.[1] *[1]Nephrology, Transplantation and Internal Medicine, Medical University of Gdansk, Gdansk, Poland; [2]English Division of Medical University School, Medical University of Gdansk, Gdansk, Poland.*

Background:

Estimation of glomerular filtration rate (GFR) after renal transplantation is performed with the use of methods which are standardized for population of non-transplant patients with chronic kidney disease. Results of estimation of GFR may be different in population of kidney recipients due to comorbidities, altered nutritional status, residual clearance and donor specific factors affecting graft function. So far there are very few studies comparing creatinine based GFR estimation methods with creatinine clearance or isotope based methods in this population.

Aim:

The aim of the study was to compare creatinine clearance with three GFR estimation methods in group of kidney transplant recipients.

Patients and methods:

We calculated eGFR with 4-variable Modification of Diet in Renal Disease (MDRD) formula, Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation and Cockroft-Gault (C-G) formula in 226 consecutive kidney graft recipients transplanted in Medical University of Gdansk in years 2007-2009. These results were analyzed against creatinine clearance. Patients with unstable creatinine concentration were excluded from the study.

Results:

We have noticed significantly different results of assessment of GFR depending on calculation method. The median values were: 56.6 ml/min, SD=17.6 for creatinine clearance; 48.6 ml/min/1.73/m(2), SD=19,9 for MDRD eGFR; 42,3 ml/min/1.73/m(2), SD=18.9 for CKD-EPI equation and 55.3 ml/min, SD=18.6 for C-G formula. Pearson's correlation analysis showed that C-G formula correlates best with creatinine clearance in our group of patients (r=0.67).

Conclusions:

Our results confirm that C-G formula correlates best with creatinine clearance in our cohort of kidney transplant recipients. Use of appropriate formula for estimation of kidney function in this group of patients is essential for proper drug dosage and decision-making.

**Study of Early Screening of Chronic Kidney Disease (CKD) in the Population of Palmas/Tocantins-Brazil: An Appliance of the Scored Compared to the Conventional Methods** Itágores Hoffman II Coutinho,[2] Joao Egidio Romao, Jr.,[1] Manuel C. Castro,[1] Ibsen S. Trindade,[2] Balduino F. Andrade.[2] *[1]University of São Paulo, São Paulo; [2]Federal University of Tocantins, Palmas, Brazil.*

The determination of the risk of development and the early diagnosis of CKD offer opportunities of treatments that block the progression of the nephropathy and reduce its morbidity and mortality. Objectives: To make an early screening of the CKD in adult population of Palmas/Tocantins-Brazil through the Scored questionnaire, and compare it to conventional diagnosis methods. Methods: The Scored provides 20% of CKD's hidden chance when ≥4. Randomly 707 participants of general population who lived or worked in the raffled domicile were selected. A questionnaire with the 11 questions of the Scored, and others important risk factors for CKD, weight, height, abdominal circumference, blood pressure, capillary glucose, fasting glucose, serum creatinine and urinalysis were evaluated. CKD was defined as estimated creatinine clearance (eGFR - Cockcroft-Gault equation) <60 mL/min/1.73 m². The frequency of all variables were determined and the bivariated analyses, through the crossing of the independent variables with the denouement Scored and CKD, determining the odds ratio (OR). Results: Mean age was 40.1±15.6 (range 18-87) yr and 63% were female. Scored was positive in 27.7% of the participants and CKD diagnosis was established in 3.4%. In group with eGFR <60 mL/min/1.73 m², mean eGFR was 42.2±12.7 (range: 18.4 to 59.6). Comparing the results of the Scored with the CKD, we observed OR=20.3 (p <0.00001). Analyzing the Scored with the age ≥65 yr, diabetes mellitus (DM) and hypertension (HTN), we observed OR of 28.8 (p <0.00001), 5.1 (p <0.00001) and 3.4 (p <0.00001), respectively. In comparison of CKD with the age ≥65 yr, DM and HTN, we found OR of 42.5 (p <0.00001), 21.2 (p <0.00001) and 3.2 (p =0.004), respectively. Conclusion: The Scored shown strong relationship with CKD and its risk factors, being useful on CKD's screening of the general population. Due its easy applicability, it could be implemented in public health politics, and the physicians should be encouraged to use this tool as initial screening.

Disclosure of Financial Relationships: nothing to disclose

**PUB211**

**Comparison of the CKD-EPI and the MDRD Equations for Estimating GFR and the Prevalence of CKD in Icelandic Adults** Sverrir I. Gunnarsson,[1] Runolfur Palsson,[1,3] Gunnar Sigurdsson,[2,3] Olafur S. Indridason.[1] *[1]Division of Nephrology; [2]Division of Endocrinology, Landspitali University Hospital; [3]University of Iceland, Reykjavik, Iceland.*

The CKD-EPI equation has been proposed as a replacement for the MDRD equation to generate the estimated glomerular filtration rate (eGFR) from serum creatinine. In this study, we examined the performance of these two equations in a large cohort of community-dwelling adults.

We examined data from a large cross-sectional study on bone health conducted in 2001-2003, that included IDMS-standardized serum creatinine values for 1628 randomly recruited Caucasian subjects from the Reykjavik area. The eGFR was calculated by the MDRD and the CKD-EPI equations and the relative performance of the equations examined. The prevalence of CKD (eGFR <60 mL/min/1.73 m²) obtained by the two equations was compared.

The mean age of the subjects was 59.7 ± 14.8 years and 63.8% were women. The median (range) eGFR by the CKD-EPI equation was higher than by the MDRD equation, 97.0 (21.2-136.1) vs. 95.9 (22.6-213.9) mL/min/1.73 m² (p<0.001), respectively. Correlation between the CKD-EPI and MDRD equations was strong (r=0.871; p<0.01) and excellent for those with CKD (r=0.987; p<0.01). The median of the difference in eGFR obtained with the two equations (CKD-EPI eGFR minus MDRD eGFR) was 0.32 (-98.2–18.6) mL/min/1.73 m². For individuals with eGFR <45, 45-59, 60-74, 75-90 and >90 mL/min/1.73 m², the median and percent difference in eGFR by the two equations (CKD-EPI minus MDRD) was -0.79 (-2.24%), 0.37 (0.81%), 2.82 (3.98%), 5.24 (6.32%) and -4.64 (-4.40%) mL/min/1.73 m², respectively (p<0.001). The CKD-EPI equation yielded a lower prevalence of CKD for women than the MDRD equation (5.6% vs. 6.2%; p<0.001) but for men the prevalence was equal (3.9%). Agreement between the equations was good with only 8% of the patients diagnosed as having CKD by the MDRD equation having eGFR >60 by the CKD-EPI equation.

In healthy subjects, the correlation between the CKD-EPI and MDRD equations is very good. The difference in eGFR by the two equations varies by kidney function and is minimal at lower levels of eGFR. The CKD-EPI equation may be less prone to overestimate CKD in women.

**Percutaneous US-Guided Renal Biopsy Experience from a Single-Center in China: A Retrospective Study Comparing Two Different Nurses' Method** Xuelin He, Huijuan Ye, Heng Li, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital of Medical College, Zhejiang University, Hangzhou, Zhejiang, China.*

Renal biopsy is essential for the diagnosis of kidney diseases, but complications and the degree of comfort, remain problematic. To improve the comfort and acceptability we upgraded our nurses' method, and we conducted a retrospective observational study on the rate of major and minor complications in our kidney disease center to assess the safety and comfort profile of the two different nurses' method.

2220 biopsies performed in our kidney diseases center from Aug 2006 to Oct 2009 was undertaken. The patients were divided in two groups: group A(Aug 2006 to Sep 2007, 702 biopsies) was treated by abdominal bandage with sandbag pressure dressing in 6 hours and kept strictly in prostration position 24 hours; group B(Oct 2007 to Oct 2009, 1518 biopsies) was treated by abdominal bandage without sandbag pressure dressing in 6 hours and only kept strictly in prostration position 6 hours. The major complications (perinephric hematoma, gross hematuria) and minor complications (postural hypotension due to vasovagal response, urinary retention, back pain, insomnia, and gastrointestinal symptoms such as nausea, vomiting and abdominal distention ) were observed in two groups.

There was no significant difference on gross hematuria (group A 3.1% vs group B 3.5%, P>0.05) and perinephric hematoma (group A 11.2% vs group B 10.9%, P>0.05) in two groups. Compared with group A, group B had lower rate of postural hypotension (group A 10.8% vs group B 7.2%,P<0.05), urinary retention needed urinary catheter (group A 20.8% vs group B 9.3%, P<0.01), back pain (group A 26.1% vs group B 11.5%, P<0.01), gastrointestinal symptoms (group A 39.5% vs group B 16.8%,P<0.01), and insomnia(group A 31.6% vs group B 21.1%,P<0.01).

The rate of minor complications was decreased, without increase the rate of major complications in percutaneous renal biopsy after nurses' method improvement. However, the degree of comfort and acceptability was increased.

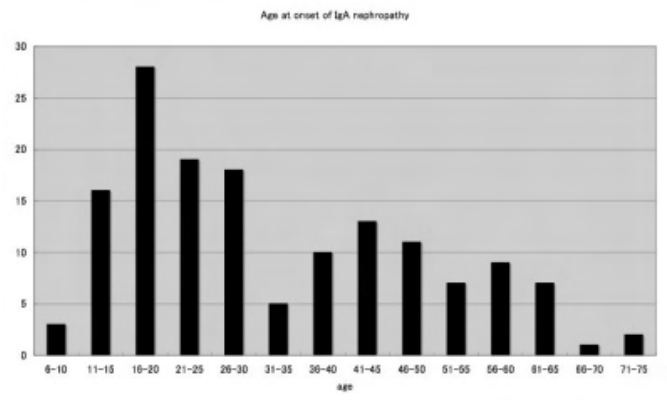
**Clinical and Histological Differences by the Age-at-Onset of Primary IgA Nephropathy in a Single Center Japanese Population** Makoto Inoue, Shin-Ichi Takeda, Shigeaki Muto, Eiji Kusano. *Nephrology, Jichi Medical University, Shimotsuke, Tochigi, Japan.*

PURPOSE: IgA nephropathy is the most common primary glomerulonephritis in Japan and the patients may present at any age. When we retrospectively reviewed 149 patients with primary IgA nephropathy who had been admitted to Jichi Medical University hospital from January 2005 to November 2009, there were two peak incidence in 16-20 and 41-45 years.



The aim of this study was to define the clinical and histological differences in IgA nephropathy between the two groups; young patients group (YG) and non-young group (NYG).

METHODS: Data were obtained on 89 YG patients under 35 years (mean age 21 years, 8-35) and 60 NYG patients over age 35 (50 years, 36-75).

RESULTS: The NYG more frequently had hypertension ($p<0.0001$). Compared with YG, NYG patients had higher blood pressure (BP); mean systoric BP was 138 mmHg vs 121 mmHg ($p<0.0001$), mean diastoric BP was 81 mmHg vs 69 mmHg ($p<0.0001$), serum creatinine was 85.8 µmol/L vs 62.8 µmol/L ($p<0.0001$), serum IgA was 344 mg/dl vs 311 mg/dl ($P<0.05$) and urinary protein: creatinine ratio was 137.9 mg/mmol vs 87.0 mg/mmol ($p<0.05$). Renal pathological investigation showed the chronic lesions were dominated in NYG. YG had significantly less glomerular sclerosis ($P<0.005$), renal tubule atrophy ($P<0.05$), and arteriolosclerosis ($P<0.0001$).

CONCLUSION: IgA nephropathy patients were more likely to suffer from hypertension, renal insufficiency and chronic pathologic lesions depend on the age, which might be the risk factors for the patient's unfavorable prognosis.

**PUB214**

**Nicaragua Revisited: Prevalence of CKD in a High Altitude, Coffee Growing Village** Timothy S. Laux,[1] Philip Bert,[2] Gerardo Barreto,[2] Mark L. Unruh,[1] Aurora Aragon,[2] Cecilia Torres.[2,3] *[1]Renal-Electrolyte, University of Pittsburgh Medical Center, Pittsburgh, PA; [2]Center for Research in Health, Work, and Environment, National Autonomous University of Nicaragua at Leon, Leon, Nicaragua; [3]Occupational and Environmental Medicine Sciences, Uppsala Universitet, Uppsala, Sweden.*

Purpose/Background: Chronic kidney disease (CKD) has been documented as widespread in parts of Central America, but knowledge gaps remain concerning CKD's prevalence in regions located at higher altitudes where coffee is grown.

**Methods**

Study Design: Cross-sectional study using an interviewer administered questionnaire covering demographic information, lifestyle, diseases, medications and measures quantifying serum creatinine (SCr) values >1.2 mg/dL for men and >0.9 mg/dL for women, estimated glomerular filtration rate <60 mL/min/1.73 $m^2$, dipstick proteinuria stratified as microalbuminuria (30-300 mg/dL) and macroalbuminuria (300+ mg/dL), hypertension, and BMI.

Setting and Participants: Total population between the ages of 20-60 years in one coffee growing village in Nicaragua located at 1,000 meters elevation. 267 participants (120 men, 147 women, 82% response).

Predictor or Factor: Participant sex, age, occupation; conventional CKD risk factors and factors suggested by previous surveys in Central America.

Results: Prevalence of abnormal SCr levels was low: 1 male (0.4%) and 4 females (1.5%). Prevalence of estimated GFR < 60 mL/min/1.73 $m^2$ was 0 (0%) of men and 2 (1.4%) of women. Overall proteinuria rate among men was 27.5% (33 individuals), with 27 having low (81.8%) and six having high range (18.2%). The overall rate among women was 21.4% (32 individuals), all having low range. There was a difference between proteinuria distributions and sex ($p=0.019$) as well as age ($p=0.042$).

Conclusions: The GFR rates and CKD prevalence in this village are comparable to a previously studied Nicaraguan coffee farming region and different than either the 1988-1994 or 1999-2004 NHANES study. This data can be used to guide Nicaraguan CKD screening criteria and further refine hypotheses about the process(es) behind the high rates of CKD seen in other regions of the nation.

**A Comparison of Prediction Equations for Estimating Glomerular Filtration Rate in Chinese Patients with Chronic Kidney Disease** Xun Liu, Cheng Wang, Hua Tang, Chenggang Shi, Cailian Cheng, Zhujiang Chen, Tan-Qi Lou. *Division of Nephrology, Department of Internal Medicine, The Third Affiliated Hospital of Sun Yet-Sun University, Guangzhou, Guangdong, China.*

Background Accurate measurement of renal function is important for the detection of chronic kidney disease (CKD). We sought to evaluate the applicability of formulas based on serum creatinine (SC) levels in Chinese patients with CKD.

Materials and methods 327 CKD patients who had undergone 99mTc-DTPA-glomerular filtration rate (GFR) estimation were enrolled. Average sGFR measured by 99mTc-DTPA GFR estimation was 44.5±26.9 ml/min/1.73 m2. The Cockcroft-Gault-equation, MDRD1-equation, abbreviated MDRD-equation, Jelliffe-1973-equation, Mawer-equation, Hull-equation, Jelliffe-1971-equation, SC-reciprocal-equation, Gate-equation and Bjornsson-equation were tested. Using the 99mTc-DTPA-GFR as the reference standard GFR (sGFR), the accuracy of estimated GFR (eGFR) was compared with sGFR in various stages of CKD.

Results Bland-Altman analysis demonstrated that Cockcroft-Gault-equation, Bjornsson-equation and Hull-equation were better than the other equations. However, the agreement limits of all the equations exceeded the prior acceptable tolerances defined as 60 ml/min/1.73 m2. Linear regressions showed that the slopes of Jelliffe-1973-equation and Cockcroft-Gault-equation were closer to the identical line. The median of difference of Jelliffe-1973-equation, Bjornsson-equation and abbreviated MDRD-equation were smaller. The median % absolute difference of MDRD1-equation, Bjornsson-equation and Cockcroft-Gault-equation were smaller. Accuracy of Bjornsson-equation, Jelliffe-1973-equation and Cockcroft-Gault-equation were higher than those of the other equations. But 30% accuracies of all the equations were less than 70%. When compared the bias as well as accuracy of eGFR with sGFR in different stages of CKD, GFR estimated by Bjornsson-equation, Cockcroft-Gault-equation and Jelliffe-1973-equation showed good results.

Conclusion When SC was measured by enzymatic method, GFR estimation equations may show great bias in Chinese CKD patients. Further improved formulas are needed to assess GFR in Chinese CKD patients.

**PUB216**

**Rigorous Derivation of a Formula for Estimation of Average Creatinine Clearance (CCA) in the Non-Steady State** Douglas L. Somers. *Internal Medicine, University of Iowa, Iowa City, IA.*

In clinical care or research, it is sometimes useful to estimate intrinsic renal function while serum creatinine (sCr) is changing, for instance in the interdialytic period in End Stage Renal Disease, or in Acute Kidney Injury. In the face of changing sCr, an estimator sometimes used for CCA over the time of urine sample collection is : CCA = (Urine creatinine excretion/sample collection duration)/( sCr at start of collection + sCr at end of collection)/2). To understand the limitations of this equation, it was rigorously derived from a differential equation describing non-steady state accumulation and excretion of body creatinine. This derivation requires the following assumptions: 1)Single pool kinetics, 2)No extrarenal losses, 3)The patient's volume is approximately constant, 4) Creatinine Generation Rate is approximately constant over the collection time, 5)Volume of Distribution of Creatinine= Body water, 6)Serum Creatinine increases or decreases in a monotonic manner, and , 7)The mass of creatinine in the urine collection is small, (compared to twice the time-averaged mass of creatinine in the body). The final assumption means that the estimator is in error when the renal function is improving, and the remaining assumptions suggest other limitations. Nonetheless, comparison to numeric solutions of the original differential equation shows that the simple estimator of CCA is usually within a few percent of the true CCA, when sCr is rising.

**PUB217**

**Kidney Function in Patients with Abdominal Multivisceral/Small Bowel Transplantation** Michiko Suzuki, Muhammad Ahmad Mujtaba, Asif A. Sharfuddin, Muhammad S. Yaqub, Dennis P. Mishler, Tim E. Taber. *Nephrology, Indiana University/ Clarian Transplant Institute, Indianapolis, IN.*

**Background:** Renal dysfunction is a recognized complication seen after transplantation of gastrointestinal organs, which may require renal replacement therapy. In multivisceral transplantation (MVT), etiologies of acute kidney injury (AKI) include hypovolemia, drug-induced nephrotoxicity, acute tubular necrosis, portomesenteric thrombosis, and hyperbilirubinemia.

**Methods:** Renal function at the two different time points, pre-transplant and one year post-transplant, was assessed by estimated Creatinine Clearance (ClCr) calculated by Cockcroft-Gault formula and Schwartz formula for adult and pediatric subjects, respectively. One year post-transplant kidney function was analyzed with demographic and clinical variables, including pre-transplant risk factors for kidney disease and post-transplant sequential laboratory data. AKI was defined as serum Cr greater than 2.0-fold increase from baseline.

**Results:** The final cohort included 48 patients, 25 multivisceral (liver, pancreas, and small bowel), 15 isolated small bowel, and 8 modified multivisceral (small bowel combined with liver or pancreas) transplants. The average age of the study subjects was 33.7±22.6 years old. The mean level of pre-transplant serum Cr (sCr) was 0.7±0.7 mg/dl with 69% (n=33) of patients having ClCr greater than 80ml/min. One year after transplant, 58% of

patients (n=28) had ClCr less than 80ml/min, 46% of patients (n=22) had ClCr less than 60ml/min. In linear regression analysis, age at transplant, baseline sCr, pre-transplant ClCr, sCr at 1 months, 3months, 6 months and 9 months after transplant, mean Tacrolimus level at post operative day (POD) 7, and AST at POD180 showed significant correlation with post-transplant ClCr. Pre-existing hypertension and AKI after transplant were also correlated with post-transplant ClCr (P<0.05).

**Conclusion:** In MVT/ small bowel transplant patients, risk factors for post-transplant chronic kidney disease include older age, pre-existing kidney dysfunction, pre-existing hypertension, and AKI after transplant.

**SDMA Outperforms CKD-EPI and MDRD Derived eGFR for the Assessment of Renal Function in Patients with Adult Congenital Heart Disease** Oktay Tutarel,[1] Agnieszka Denecke,[1,2] Stefanie M. Bode-Böger,[3] Jens Martens-Lobenhoffer,[3] Mechthild Westhoff-Bleck,[1] Jan T. Kielstein.[2] *[1]Cardiology, Hannover Medical School, Hannover, Germany; [2]Nephrology, Hannover Medical School; [3]Clinical Pharmacology, Otto-von-Guericke University, Magdeburg, Germany.*

*Purpose*

Adults with congenital heart disease exhibit a 3-fold higher mortality in the presence of moderate or severe chronic kidney disease. However formulas for the estimation of glomerular filtration rate (GFR) have not been evaluated in this special patient population. The aim of this study was to compare different markers and equations for the estimation of renal function in adults with congenital heart disease.

*Methods*

Renal function was assessed in 102 patients using the MDRD equation, the simplified MDRD equation, the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation, the Cockcroft-Gault formula and the Larsson equation. Additionally, symmetrical dimethylarginine (SDMA) was measured.

*Results*

GFR estimated by the original MDRD (Pearson r = 0.465, p<0.001) and the CKD-EPI equation (r = 0.462, p<0.001) showed a similar strong correlation with the eGFR based on a Cystatin C based equation. While GFR according to the simplified MDRD equation showed a weaker correlation (r = 0.439, p<0.001). Creatine clearance according to the Cockcroft-Gault formula showed no correlation at all to the Cystatin C based eGFR (r = 0.144, p = 0.17). The strongest correlation was observed for SDMA and Cystatin C based eGFR (r = -0.552, p<0.001).

*Conclusion*

GFR in adults with congenital heart disease should be estimated using the original MRDR or the CKD-EPI formula. SDMA seems to be a promising marker of renal function for this patient group and should be further evaluated in the future.

**Is eGFR Representative for the Retention of Other Uremic Solutes in CKD before Start of Dialysis?** Raymond C. Vanholder,[1] Eva Schepers,[1] Daniela Veit Barreto,[2] Fellype Barreto,[2] Griet Lrl Glorieux,[1] Ziad Massy,[2] Sunny Eloot.[1] *[1]Department of Internal Medicine - Nephrology, Ghent University Hospital, Gent, Belgium; [2]Clinical Pharmacology, Amiens University Hospital, Amiens, France.*

The severity of chronic kidney disease (CKD) can be expressed in terms of Glomerular Filtration Rate (GFR), which can be determined directly or calculated/estimated according to different formulae based on creatinine and/or cystatin C (eGFR). The aim of our study was to investigate whether the currently used eGFR-values are representative for the progressive increase of concentration of uremic retention solutes with different degrees of renal dysfunction.

The association with eGFR was evaluated for a broad set of uremic solutes [creatinine (Crea), uric acid (UA), symmetric dimethyl arginine (SDMA), asymmetric dimethyl arginine (ADMA), and free and total fractions of hippuric acid (HA), 3-carboxy-4-methyl-5-propyl-2-furanpropionic acid (CMPF), indoxyl sulfate (IS), indole acetic acid (IAA), and p-cresylsulfate (pCrS)] in a group of patients with different degrees of kidney failure, i.e. CKD stage 2 to 5, not on dialysis. Concentration was correlated with eGFR calculated with formulae based on creatinine (MDRD), cystatin C (Le Bricon et al, Filler et al, Rule et al), and the combination of both (epi-GFR).

Creatinine showed the best fit (MDRD $R^2$=0.833) followed by total IS ($R^2$=0.416), SDMA ($R^2$=0.237), free pCrS ($R^2$=0.150), and free IAA ($R^2$=0.123). There was a substantial disparity in significance of fits among solutes. There was a substantial disparity in significance of fits among solutes. The formulae only based on cystatin C did not show different correlations versus the epi-GFR or the MDRD formula, even for solutes other than creatinine. Free fractions of protein bound solutes showed better correlations compared to the total fractions, except for indoxyl sulfate.

Hence, eGFR is only partially representative for the progressive increase of concentration with worsening kidney function for all studied retention solutes, with borderline significance for UA and even no significance for CMPF.

**The Chronic Disease Nephropathy Prevention Clinic in Siksika Nation: A Quality Improvement Project** David Ward,[1] Ellen M. Novak,[1] Sony Brar,[2] Brenda Hemmelgarn.[1] *[1]Department of Medicine, University of Calgary, Calgary, AB, Canada; [2]Alberta Kidney Disease Network, AB, Canada.*

**Background:** The prevalence of ESRD is higher amongst the Aboriginal population. Diabetes, access to health care services, and limited ongoing assessment and follow-up may contribute to this increased risk.

**Objective:** To determine whether a community-based clinic led by a nurse practitioner will improve the management of Aboriginal People at risk of developing kidney disease.

**Methods:** The study population included Aboriginal patients from Siksika Nation with diabetes or difficult to control blood pressure (BP). Patients were assessed by a nurse practitioner who provided ongoing management of BP, blood sugar, and lipid control; according to national clinical practice guidelines. Outcome variables of interest were reduction in haemoglobin A1C (HbA1C), BP, and LDL, as well as the proportion of patients initiated on medications indicated (ACE-I or ARB, statins and ASA). Differences between groups were analyzed using paired T-test and Chi-square as appropriate.

**Results:** A total of 78 patients were followed regularly in the clinic (62% female; mean age 56 years). Amongst those above target at baseline, there was a significant reduction in mean HbA1C (0.96%; p<0.01), LDL (0.62mmol/L; p<0.01), systolic BP (15.9 mmHg; p<0.01), and diastolic BP (9.7 mmHg; p<0.01). Additionally, there was a significant increase in the proportion of subjects initiated on an ACE-I or ARB (42.4%; p<0.01), statin (35.9%; p<0.01), and ASA (35.9%; p<0.01).

**Conclusions:** Adequate management of patients at high risk of developing kidney disease has been shown to reduce progression of kidney disease and development of ESRD. Although limited by lack of a comparison group, our data suggest that a community-based, nurse-practitioner led clinic can significantly improve management in many clinically relevant areas. The impact of these interventions has been shown in other studies to reduce the risk of death and cardiovascular events; the effect in the Aboriginal population on these hard clinical endpoints remains to be determined.

**PUB221**

**Estimation of Glomerular Filtration Rate Based on Serum Cystatin C Concentration in Old and Very Old Subjects – PolSenior Study** Andrzej Wiecek,[1] Jerzy Chudek,[1,2] Marcin Adamczak.[1] *[1]Department of Nephrology Endocrinology and Metabolic Diseases, Medical University of Silesia in Katowice, Katowice, Poland; [2]Department of Pathophysiology, Medical University of Silesia in Katowice, Katowice, Poland.*

**Introduction:** Cystatin C-based Hoek' equation, applicable for estimation of glomerular filtration rate (eGFR) does not include age, unlikely those routinely used, creatinine-based (Cocroft-Gault, MDRD and CKD-EPI equations). Thus the estimation of eGFR by this method is not influenced by age and could be more accurate in very old people. The assessment of eGFR based on cystatin C equations has not been performed in very old population yet.

Aim: The estimation of frequency of chronic kidney disease - CKD (stage 3-5) based on Hoek' equation in older than 65 years.

**Patients and methods:** Study was performed in 113 subjects in age 55-60y. and 565 in age 65-101y. from the PolSenior study population. Subjects in age 65-101y. were divided into three subgroups (65-75; 76-85 and over 85y.). Serum cystatin C concentration was assessed by enzyme-linked immunoabsorbent method. eGFR was estimated with cystatin C-based Hoek' equation.

**Results:** Serum cystatin C concentration was increasing in subsequent age subgroups (mean±SD) (0.78±0.17mg/ml in 55-60y. subgroup, 0.94±0.30mg/ml in 65-75y. subgroup, 1.06±0.26mg/ml in 76-85y. subgroup and 1.22±0.35mg/ml in older than 85y. subgroup). The frequency of subjects with eGFR<60 ml/min (cystatin C-based equation) was increasing with age, from 0.9% in 55-60y. subgroup through 8.5% in 65-75y. subgroup and 23.0% in 76-85y. subgroup to 41.1% in over 85y. subgroup. In the oldest subgroup the prevalence of subjects with eGFR<60ml/min estimated with cystatin C-based equation was significantly higher (p<0.01) than estimated in subjects with MDRD formula (41.1% vs. 35.5%).

There was a strong correlation between serum cystatin C concentration and age (r=0.480, p<0.001) in the whole group of analyzed subjects. Serum cystatin C concentration was not related to BMI (r=0.026 p=0.51).

**Conclusion:** Cystatin C-based Hoek' equation for estimation of glomerular filtration rate seems to be very useful and accurate for diagnosis of chronic kidney disease in old and very old subjects.

**PUB222**

**Kidney Disease Is Independently Associated with Increased Risk of Hospitalization and Death in the US Veteran Population** Ziyad Al-Aly, Michael I. Rauchman, Tarek M. Elachkar. *Division of Nephrology, Saint Louis Veterans Affairs Medical Center, Saint Louis, MO.*

We wanted to examine the effect of kidney disease on the risk of hospitalization and death among United States veterans. Using the Department of Veterans Affairs national databases, we built a cohort of 28,980 patients who have at least 2 eGFR measurements that are at least 3 months apart in fiscal year 2000. Patients were followed until the end of fiscal year 2008. Patients were categorized into the non-CKD group if the 2 eGFRs were above 60 ml/min, and into CKD stage 3a, 3b, 4, and 5 if these eGFRs were between

45-59, 30-44, 15-29, and <15 ml/min; respectively. We then built separate Cox survival models to examine the effect of kidney disease on the risks of hospitalization and death. Compared to patients without kidney disease, patients with kidney disease had significantly increased risk of hospitalization; HR=1.190 (CI=1.140-1.242), HR=1.412 (CI=1.343-1.484), HR=1.705 (CI=1.592-1.826) and HR=2.201 (CI=2.000-2.424), for CKD stage 3a, 3b, 4, and 5; respectively. We then examined the effect of kidney disease on the risk of death and found that declining kidney function is associated with increased risk of death; HR=1.540 (CI=1.453-1.633), HR=2.460 (CI=2.314-2.615), HR=3.508 (CI=3.250-3.786) and HR=3.673 (CI=3.297-4.092), for CKD stage 3a, 3b, 4, and 5; respectively. The results show a differential risk of hospitalization and death among patients with CKD stage 3a and 3b; suggesting perhaps that CKD stage 3 is too broad and should be subdivided into stage 3a and 3b. Furthermore, the results indicate that there is an independent and graded association between kidney function and the risks of hospitalization and death in US veterans.

## PUB223

**Peripheral Vascular Disease in Chronic Kidney Disease Patients** Behnoud Beroukhim, Jose Jesus Perez, Ojas Naik, Venkataraman Ramanathan. *Nephrology, Michael E DeBakey VA Medical Center, Baylor College of Medicine, Houston, TX.*

INTRODUCTION: Peripheral vascular disease (PVD) coexists in patients with chronic kidney disease (CKD) and is associated with significant morbidity and mortality. However, disparities exist in the diagnosis and management of symptomatic PVD in this population.

METHODS: In this retrospective study, we reviewed the charts of consecutive veterans who underwent vascular ultrasound evaluation in a 6-month period for symptoms suggestive of PVD. Patients with prior history of PVD including those who underwent amputation or percutaneous or surgical revascularization were excluded. We measured ABI, segmental pressures in high and low thigh, calf and ankle, digital pressures and qualitative waveform in each extremity. MDRD GFR was estimated and patients were stratified into 2 groups: Group A - eGFR <60 ml/min and Group B - eGFR >60 ml/min. .

RESULTS: A total of 187 patients underwent vascular evaluation for symptoms suggestive of PVD and significant PVD was noted in 114 veterans (61%). As shown in the table, proportion of veterans who had significant PVD was higher in Group B.

| | Group A (eGFR<60) | Group B (eGFR>60) | p value |
|---|---|---|---|
| n | 57 | 130 | |
| Significant PVD (doppler) | 28 (49%) | 86 (66%) | 0.03 |
| Surgery consult | 23 (82%) | 51 (59%) | 0.04 |
| Revascularization | 12 (43%) | 51 (59%) | ns |
| Amputation | 6 (21%) | 4 (5%) | 0.01 |
| Re-hospitalization | 19 (68%) | 8 (9%) | <0.0001 |
| 1-yr mortality | 14% | 8% | ns |

Surgery consult was requested more frequently in Group A patients, but revascularization procedures were performed less often in this group. During follow up, the rate of atraumatic lower extremity amputation was significantly higher in patients with eGFR <60 ml/min. Similarly, re-hospitalization for PVD symptoms were significantly higher in this group. One-year mortality rate was also higher in Group A, but it failed to reach statistical significance.

CONCLUSIONS: Among veterans with symptomatic PVD, eGFR <60 ml/min is associated with higher rate of amputations and re-hospitalizations.

## PUB224

**Anemia Management with Methoxy Polyethylene Glycol-Epoetin Beta in Routine Clinical Practice: Preliminary Results of the OCEANE Study in Patients with Chronic Kidney Disease (CKD) Not on Dialysis** Gabriel Choukroun,[1] Christopher R. Mariat,[2] Marc C. Froissart,[3] Paul Landais,[4] Luc Frimat.[5] *[1]Nephrology, CHU Amiens; [2]Nephrology, CHU Saint-Etienne; [3]Nephrology, HEGP Paris; [4]DIM, Necker; [5]Nephrology, Nancy.*

Methoxy polyethylene glycol-epoetin beta (MPGE) is a new Erythropoiesis Stimulating Agent (ESA) licensed in Europe since 2007. We aim to describe anemia management with MPGE in routine practice and its accordance with European recommendations (EMEA 2007).

**Methods:** OCEANE is a one-year french multicentre prospective observational study. 605 patients (515 CKD patients not on dialysis, 90 transplanted patients) initiating MPGE were included. The primary endpoint is the proportion of patients with hemoglobin (Hb) level within 10-12 g/dL at 6 months. Here are the first results for the 515 CKD patients not on dialisis.

**Results:** The population included 53% men, with a mean age of 72±14 years and a CKD stage 2 (1%), 3 (29%), 4 (55%) and 5 (15%). Main etiologies of CKD were vascular (47%) and diabetic nephropathies (27%). Estimated GFR was 25±12 mL/min/1.73m$^2$, transferrin saturation was 24%, serum ferritin 218 ng/mL and 73% of the patients had a CRP<10 mg/L. Iron therapy was ongoing in 34% of the patients. At baseline, 248 patients (48%) were ESA-naive, 126 patients (25%) were previously treated with darbepoetin alfa, 103 patients (20%) with epoetin beta, and 31 patients (6%) with epoetin alfa. In ESA-naive patients, mean Hb level was 10.0±0.9 g/dL and the median starting dose of MPGE was 50 $\mu$g per injection (range: 30-150). In non ESA-naive patients, mean Hb level was 11.3±1.4 g/dL and the median starting dose of MPGE was 100 $\mu$g per injection (range: 30-360). The administration frequency was monthly in 46% of ESA-naive patients and 84% of non-ESA naive patients. The administration type was self-injection (14%), injection by a relative (4%) or a nurse at home (82%).

**Conclusion:** In current practice, MPGE is used in ESA-naive and non ESA-naive CKD patients regardless of the previous ESA treatment. At initiation, lower doses seem to be used rather than theorical ones, and a monthly dosing seems to be used immediatly in almost 50% of ESA-naive patients.

## PUB225

**Quality Assessment and Performance Improvement (QAPI) in a Pediatric Dialysis Unit: Taking Control of Phosphorus** Sheila Jones Coakley, Marie Y. Saint-Vil, Myerly Kertis, Alexandrina Pop, Gaston E. Zilleruelo, Carolyn L. Abitbol. *Pediatric Dialysis, University of Miami/Holtz Children's Hospital, Miami, FL.*

Quality Assessment/Performance Improvement (QAPI) projects are required by the Conditions of Coverage issued by the Center for Medicaid and Medicare Services (CMS) for all dialysis facilities in the U.S. In pediatric dialysis patients, phosphorus (P) targets have been one of the most difficult clinical measures to achieve. At the Holtz Children's Hospital pediatric dialysis unit, located in a multiethnic urban community, hyperphosphatemia was identified as a major deficiency of quality control compared to adult units in Florida Network 7. Our objective was to develop a QAPI multidisciplinary program focused on improving and sustaining serum P levels within target for the majority of pediatric patients on hemodialysis. A unit based assessment and improvement program was developed with the nursing manager and staff, social, dietary and physician services. Attention focused on education and adherence to diet and P binder medications. Incentive tools included individual dietary counseling, puzzles and games, weekly and monthly report cards, and friendly competition among patients. Rewards included meal vouchers with a grand prize of an Itunes card. P levels were monitored weekly with review of diet and medications. During a period of 1 year from May 2009 through May 2010, 33 patients (15 Males) with an average age of 16.9±3.8 years were hemodialyzed 3 times weekly. Progressive tactics were employed from October 2009 through May 2010. For the 3 years prior to the QAPI, only 18 % of the Holtz patients achieved the target P goal compared to 52% of Network patients. With the introduction of QAPI strategies, the quarterly percentage of patients within the P target increased from 25% to 88% with an average of 33% per month. In conclusion, significant improvement in P levels can be achieved in a pediatric dialysis unit, although sustainability is difficult. Patient education and motivational strategies that are ongoing and age appropriate are required.

## PUB226

**'Reverse Epidemiology' of Blood Pressure in Elderly Pre-Dialysis Patients** Moniek C. M. de Goeij,[1] Nynke Halbesma,[1] Dinanda J. De Jager,[1] Nora Voormolen,[2] Diana C. Grootendorst,[1] Elisabeth W. Boeschoten,[3] Friedo W. Dekker.[1] *[1]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands; [2]Department of Clinical Radiology, Leiden University Medical Center, Leiden, Netherlands; [3]Hans Mak Institute, Naarden, Netherlands.*

In dialysis patients and in the elderly population reverse epidemiology has been found, where low blood pressure is associated with higher mortality and high blood pressure has a survival advantage. This study aimed to investigate whether reverse epidemiology is already present before the start of dialysis, by analyzing the association between systolic (SBP) and diastolic (DBP) blood pressure and time to renal replacement therapy (RRT) in elderly (≥65 years) pre-dialysis patients.

Methods:

In the retrospective PREPARE cohort 547 incident pre-dialysis patients were included when referred to pre-dialysis outpatient clinics between 1999 and 2001. The clinical status of the patients was followed through medical charts until start of RRT, mortality, or end of study (1 January 2008). Patients were stratified for age into <65 years and ≥65 years. Cox regression for time to RRT was used (a) during first year, (b) conditional on not starting RRT the first year on pre-dialysis, and (c) total follow-up.

Results:

Time to RRT was decreased in elderly patients (n=240) with SBP <140 or ≥160 mmHg compared to patients with 140-159 mmHg, resulting in a U-shaped association; for first year, after first year, and entire follow-up. For DBP, only the patients with 70-79 mmHg had a decreased time to RRT compared to patients with 80-89 mmHg during the first year of follow-up; adjusted HR (95% CI) of 1.85 (0.99-3.46). After the first year of follow-up, patients with DBP <70 mmHg or DBP ≥100 mmHg had a faster start of RRT compared to patients with 80-89 mmHg; adjusted HR (95% CI) of 4.92 (1.75-13.86) and 4.30 (1.28-14.42) respectively.

Conclusion:

Indications of reverse epidemiology are already present in elderly pre-dialysis patients. In this patient group both low and high SBP and DBP decreased the time to RRT. Future research is necessary to find a biological explanation.

## PUB227

**Systematic Evaluation of Loss to Analysis in Randomized Controlled Trials in Chronic Kidney Disease** Aneet J. Deo,[1] Christopher H. Schmid,[2] Katrin Uhlig.[1] *[1]Division of Nephrology, Tufts Medical Center, Boston, MA; [2]Institute for Clinical Research and Health Policy Studies, Tufts Medical Center, Boston, MA.*

**Objective:** To systematically evaluate the treatment of missing outcome data for primary outcome analysis in randomized controlled trials (RCTs) of patients with chronic kidney disease (CKD) by assessing the amount and reporting of loss to analysis, evaluate the use of intention to treat (ITT) analysis and report the methods used to handle missing outcome data.

**Methods:** MEDLINE search for English-language reports of RCTs of adults with CKD (including dialysis and transplantation) published from January 1st, 2007 through December 31st, 2008. Loss to analysis was present if the number of participants included in the main pre-specified analysis of the primary outcome was less than the number randomized. ITT use was judged to be complete if the study included all randomized participants by their originally allocated groups in the analysis of the primary outcome

**Results:** We found 196 eligible RCTs. Twenty seven percent of these studies did not clearly describe a primary outcome. Sixty-seven (61%) of 110 studies with complete data on outcomes had loss to analysis, among which the median number of patients lost was 9%. Only 50% of the trials that claimed primary outcome analysis by ITT actually included all randomized participants in outcome analysis. The method of imputation for missing outcome data was only described in 4 (4%) of 110 studies.

**Conclusion:** The quality of reporting of trials in patients with CKD remains sub-optimal, especially with respect to reporting of missing outcome data, use of ITT analysis and outcome data imputation. This impedes critical appraisal of study quality. Explicit description of reasons for loss of outcomes data and of how this is handled is needed.

## PUB228

**Is Red Cell Distribution Width (RDW) Associated with Renal Function or Renal Anemia?** Mireille E. Emans,[1] Wouter W. van Solinge,[4] Karlijn L. van Rooijen,[4] Maarten Jan M. Cramer,[1] Pieter Doevendans,[1] Branko Braam,[3] Carlo A. Gaillard,[2] Johanneke L. Breeijen Den.[4] *[1]Cardiology, University Medical Center Utrecht, Utrecht, Netherlands; [2]Nephrology, VU University Medical Center, Amsterdam, Netherlands; [3]Division of Nephrology and Immunology, University of Alberta, Edmonton, Canada; [4]Clinical Chemistry and Hematology, University Medical Center Utrecht, Utrecht, Netherlands.*

RDW is associated with mortality in a community based cohort (PMID19307522) and in heart failure (HF). In HF, chronic kidney disease (CKD) and anemia correlate with RDW (PMID19781428). We studied determinants of RDW, focussed on renal function and renal anemia.

Data from the Utrecht Patient Oriented Database, an infrastructure of relational databases, were used. Of all adult patients of whom RDW was performed in 2008 as part of the hematology measurement, we ascertained data about renal function (MDRD), haemoglobin (Hb), immature reticulocyte fraction (IRF), reticulocyte count, leucocytes and C-reactive protein (CRP). Subpopulations were defined as: CKD (MDRD<60ml/min/m2), anemia (Hb<12.6 g/dL men, Hb<11.9 g/dL women) and both. Multiple linear regression models for RDW were generated using a stepwise selection process.

RDW was higher in anemia, CKD and both. Only in non-anemic patients MDRD was a weak predictor for RDW. Remarkably, IRF was the strongest predictor for RDW.

Markers for the degree of red cell turn over (IRF) rather than renal function (red cell production) predict RDW. These data may elucidate some of the mechanisms causing the association between RDW and risk.

Multilinear regression analysis for RDW

## PUB229

**Age and Gender Comparisons between 1,971 Patients Reaching Stage 5 CKD and 2,122 Patients Commencing RRT at 7 UK Renal Centers** Daniel Ford,[1,3] Dirk J. Van Schalkwyk,[1] David Ansell,[1] Charles Tomson,[1,2] Yoav Ben-Shlomo,[3] Damian G. Fogarty.[1,4] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Southmead Hospital, Bristol, United Kingdom; [3]University of Bristol, Bristol, United Kingdom; [4]City Hospital, Belfast, United Kingdom.*

**Introduction** The UK Renal Registry (UKRR) has shown that the male to female ratio starting RRT is 1.6:1. Other studies have shown that this ratio is reversed (1:1.85) for patients with an eGFR <30. The aim of this study was to compare the gender and age differences of patients with CKD stage 5 (not on RRT) with those commencing RRT.

**Methods** All adult patients reaching CKD stage 5 (two eGFR results <15ml/min/1.73m², >90 days apart with no intervening result ≥15) during 2006-7 at 7 UK renal centers were included. Baseline data including: age, gender, ethnicity, renal disease and socioeconomic deprivation were extracted direct from the centers' IT systems. Results were compared with UKRR data from patients commencing RRT at the same centers during 2007-8.

**Results** 1,971 adult patients reached CKD stage 5 during 2006-7. 2,122 patients commenced RRT during 2007-8. The M:F ratio of patients reaching CKD5 was 1.29:1. This was lower than the ratio of patients starting RRT (1.62:1, p<0.001) (Figure 1).

The population reaching CKD5 was significantly older than the incident RRT population (median age 69.7 vs. 64.9 years, p<0.001) (Figure 2).

**Conclusion** These results show that there are both gender and age differences between patients reaching CKD stage 5 and those accepted on to RRT. There are a number of possible explanations for these differences including: differing rates of kidney function decline, starting RRT at different levels of function, differing mortality rates, differing conservative care policies and differing RRT acceptance policies and access. The reasons for these differences are under investigation.

## PUB230

**Extent of Abdominal Aortic Calcifacation on X-Ray Predicts the Presence of Significant Coronary Artery Disease in Dialysis Patients** Arien Gaasbeek,[1] Mihaly K. De Bie,[2] Joanne D. Schuijf,[2] Ton J. Rabelink,[1] Martin J. Schalij,[2] Jeroen J. Bax,[2] J. Wouter Jukema.[2] *[1]Nephrology, Leiden University Medical Center; [2]Cardiology, Leiden University Medical Center.*

**Introduction:**

Coronary Artery Disease (CAD) is highly prevalent in asymptomatic dialysis patients. Given their poor prognosis identifying these patients is relevant. The extent calcified lesions in the aorta may correlate with the extent of atherosclerosis in the coronary arteries. The aim of this study was to evaluate the association of the extent of abdominal aortic calcification (AAC) as assessed on abdominal X-ray and the presence of significant CAD in dialysis patients.

**Methods:**

A total of 43 consecutive dialysis patients (23 male, avg. age 66 ± 8yrs), currently participating in the ICD2 trial with no history of CABG or PCI were included. The presence of significant CAD (≥50%luminal narrowing one of the major epicardial vessels) was assessed with CT-Angiography. The extent of calcification of the abdominal aorta was assessed on lateral X-ray and was graded using a previously validated grading system, resulting in a score ranging from 0-24 points.

**Results:**

Two patients were excluded from due to poor scan quality. Significant CAD was present in 15 (36.8%) patients. The extent of calcification in the abdominal aorta, assessed on X-ray, was significantly higher in patients with significant CAD (AAC-score 12.4 ± 4,9 vs. 5.4 ± 3.9 p<0,001). Using binary logistic regression controlling for age and gender the association of the AAC score and the presence significant CAD was assessed: every point increase in the AAC score was associated with an 1.4 (95% CI 1,1 - 1,8) fold higher chance of having significant CAD. ROC analysis of the AAC score resulted in an area under the curve of 0.87.

**Conclusions:**

The extent of calcification of the abdominal aorta is associated with the presence of significant coronary artery disease in dialysis patients. A simple lateral X-ray of the abdomen, on which the extent of calcification can be quantified, may therefore be a useful tool to identify dialysis patients at high risk for having significant coronary artery disease.

**CKD-3 and CKD-4 Patients Have More Probability To Initiate Dialysis Than Die. MERENA Study (Morbimortality in Chronic Kidney Disease Patients). Final Results after Five Year Follow-Up** Jose L. Gorriz,[1] Alberto M. Martinez-Castelao,[2] J. M. Portolés,[3] Aleix Cases,[4] Jose Luno,[5] Juan F. Navarro,[7] Fernando Dealvaro-Moreno.[6] *[1]Servicio de Nefrologia, Hospital Universitario Dr Peset, Valencia, Spain; [2]Servicio de Nefrologia, Hospital Bellvitge, Barcelona, Spain; [3]Servicio de Nefrologia, Fundacion Hospital Alcorcon, Alcorcon, Madrid, Spain; [4]Servicio de Nefrologia, Hospital Clinic, Barcelona, Spain; [5]Servicio de Nefrologia, Hospital Gregorio Marañon, Madrid, Spain; [6]Servicio de Nefrologia, Hospital Infanta Sofia, Madrid, Spain; [7]Servicio de Nefrologia, Hospital Nra Sra de la Candelaria, Tenerife, Canary Islands, Spain.*

The MERENA study, is a 5-year follow-up prospective, observational, multicenter study aimed to assess renal disease and morbi-mortality in CKD patients stages 3 or 4.

**Patients** & **method**: Inclusion criteria : CKD-stage 3 or 4, life expectancy >1 year after inclusion. We included 1129 consecutive patients visited in the outpatient clinic of 54 Spanish Nephrology centres.

**Results:** After five year follow-up, 542 patients (37.9 %) reached the primary end–point of the study (need for renal replacement therapy or death) (16.1 % and 21.9 respectively). 182 patients dead (16.1%), 195 initiated hemodialysis (17.3 %), 44 peritoneal dialysis (3.9%), and 8 received an preemptive kidney transplant (0.7%). 22 patients were transferred to other unit (1.9%) and 91 were lost for follow-up (8.1%).

In non-diabetic CKD-3 patients mortality rate was 7.5 %, in diabetic CKD-3, 12.7 %, in non-diabetic CKD-4 22.2%, and in diabetic CKD-4, 24 % ($p<0.01$, log rank test). KM survival at five years was 90 %, 80%, 67% and 61% respectively in those groups.

Causes of death: cardio-vascular (47.2%), neoplasms (16.7%), infections (14.3%), hepatic or gastrointestinal diseases (3.8%) or other and unknown (18%).

**In conclusion**: After 5-year follow up, the MERENA study shows that CKD patients have high mortality rates, especially in diabetics CKD-4. In our patients, contrary to other studies, the probability of initiating renal replacement therapy was more frequent than the risk of dying.

**Race/Ethnicity, Poverty, and the Association between Periodontal Disease and CKD** Vanessa Grubbs,[1] Deidra C. Crews,[5] Kirsten Bibbins-Domingo,[1] Elizabeth Hedgeman,[3] Rajiv Saran,[3] Priti Patel,[4] Kristina L. Ernst,[4] Neil R. Powe.[2] *[1]University of California, San Francisco, CA; [2]San Francisco General Hospital, CA; [3]University of Michigan, Ann Arbor, MI; [4]Centers for Disease Control and Prevention, Atlanta, GA; [5]Johns Hopkins University, Baltimore, MD.*

Recent studies suggest an overall association between chronic kidney disease (CKD) and periodontal disease, but it is unknown whether this association varies by race/ ethnicity or poverty status. We sought to examine this using 1999-2004 National Health and Nutrition Examination Survey data, which included11,400 dentate, adult participants (aged 21-75) with periodontal exams. CKD was defined as urinary albumin:creatinine ratio of >30 mg/g or estimated glomerular filtration rate of 15-59 ml/min/1.73 m2. Adjusted odds ratios (AORs) were calculated using multivariable logistic regression with U.S. population-based weighting. The estimated prevalence of moderate/severe periodontal disease was 4.6% among whites, 8.6% among blacks, and 5.5% among Mexican-Americans ($p<0.001$). CKD prevalence was 10.8% among whites, 12.6% among blacks, and 9.4% among Mexican-Americans ($p<0.001$). Periodontal disease was independently associated with CKD (AOR 1.51, 1.20-1.91) after adjusting for race/ethnicity, age, gender, hypertension, diabetes, education, and poverty index ratio (PIR). Although there were no statistically significant interactions between periodontal disease and race/ethnicity or poverty, subgroup analyses showed the most profound association of periodontal disease and CKD among the very poor (PIR<=1; AOR 2.38, 1.23-4.58) and, particularly, among very poor whites (AOR 3.15, 1.27-7.82). Further study is needed to understand whether periodontal disease is a CKD risk factor and, if so, whether targeted treatment could improve disparate CKD outcomes.

**Low Dose Losartan/Benazepril Alone or Combination in Primary Glomerulonephritis with Proteinuria but Intolerance to Large or Regular Dose Renin-Angiotensin Antagonists** Qiang He, Lina Shao, Xiayu Li, Jianghua Chen. *Kidney Disease Center, the First Affiliated Hospital, Medical College, Zhejiang University, Hangzhou, Zhejiang, China.*

To observe the efficacy and safety of low-dose losartan / benazepril alone or combination in primary glomerulonephritis patients with proteinuria but intolerance to large or regular dose rennin-angiotensin antagonists. 27 patients were recruited during January 2007 to February 2009 in our hospital. All diagnoses were confirmed by renal biopsy, including 21 cases of IgA nephropathy, 6 cases of non-IgA mesangial proliferative glomerulonephritis. All patients were normal blood pressure, proteinuria <2.0g / d, eGFR> = 60ml/min, without the history of immunosuppressants application. All patients could not tolerate even though a single dose of ACEI or ARB before recruit. The patients were divided into 3 groups: A group :16 cases, as low dose losartan group (12.5-25mg / d); B group : 7 cases, as low doses benazepril group (2.5mg / d); C group: 4 cases, as low dose of losartan combined with low dose of benazepril group (losartan 12.5mg / d + Benazepril 2.5mg / d). All Patients were followed 6 months, The 24-hour urine protein, β2-microglobulin (MG), eGFR, mean arterial pressure (MAP) and symptom dizziness were evaluated each month. We found that 27 patients could well tolerate low dose losartan / benazepril alone or in combination therapy, After 6 months, Urinary protein were all significantly decreased: A group: 43.5% ($p = 0.01$), B Group: 36% ($p = 0.012$), C group: 56.3% ($p = 0.001$); 6 cases in A group of, 2 cases in B group and 2 cases in C group showed complete remission. The urinary β2- MG were also significantly decreased in all groups, A group: 68% ($p = 0.001$), B group: 63.7% ($p = 0.01$), C group: 75.2% ($p = 0.001$). The decline of urinary protein and β2-MG were not significant different among the 3 groups ($p> 0.05$; ANOVA). And the eGFR, MAP were not significant different during the follow-up. We made the conclusion that: The normotensive patients with primary glomerulonephritis who not tolerate high-dose or conventional dose ACEI / ARB , may be still effective and well tolerance by low-dose losartan / benazepril alone or combination therapy.

**Effect of KDOQI Guidelines on Patient Awareness of CKD** Tarundeep Kaur,[1] Ajay Singh Behl.[2] *[1]Renal Diseases and Hypertension, University of Minnesota, Minneapolis, MN; [2]HealthPartners Research Foundation, HealthPartners, Minneapolis, MN.*

**Purpose of study:** To test awareness of CKD among patients after introduction of the KDOQI guidelines.

**Background:** End Stage Renal Disease (ESRD) is the most public form of Chronic Kidney Disease (CKD). Studies suggest that clinical practice guidelines of the National Kidney Foundation Disease Outcomes Quality Initiative (NKF KDOQI) ™ formed in 1997 and the relation of CKD with Cardio-Vascular Disease (CVD) have increased the recognition of CKD amongst primary physicians. Two studies based on the National Health and Nutrition Examination Survey (NHANES) reported low awareness amongst patients regarding their CKD status.

**Significance and Hypothesis:** The studies based on NHANES were done using the 1999-2000 dataset, which was soon after the KDOQI guidelines were issued for the first time. We believe that awareness among patients is representative of the communication by the physician and the patient. We test this by analyzing the self-reported awareness amongst patients regarding their Chronic Kidney Disease (failing or weak kidneys) in the NHANES 2005-2006 dataset.

**Methods:** NHANES 2005-2006 data is used. We use complex survey design based multivariate logit regression with the awareness levels as the dependent variable and lab values and socioeconomic variables as the explanatory variables.

**Results**: There were 4965 respondents who replied either a yes or a no to the question regarding awareness about their having failing or weak kidneys. 136 (2.7%) of them reported being told that they had failing or weak kidneys. Of the total respondents 383 (93.73%) had CKD stage 3, 24 (4.26%) had CKD stage 4 and 11 (2.01%) had stage 5. Of these, 354/383, 13/24 and 1/11 were unaware about their CKD. Compared to the findings from the 1999-2000 datasets, the awareness did not increase.

**Conclusions**: We need to rethink and improve the communication and dissemination techniques regarding clinical guidelines for CKD management. Unless the patients know about their kidney disease, the guidlines will not be helpful in imparting education and taking measures to decrease the progression of the disease at the primary care level.

**Distance-Counselling on Drug Dosage Adjustments (DDA) in Patients with Renal Insufficiency: The 10-Year Experience of "Service ICAR" in France** Vincent Launay-Vacher, Sarah Zimner-Rapuch, Nicolas Janus, Sabine Amet, Gilbert Deray. *Service ICAR Department of Nephrology, Pitie Salpetriere Hospital, Paris, France.*

**Background**: Drug Dosage Adjustment (DDA) in renal insufficiency (RI) is crucial to avoid overdosage from non-adjustment or underdosage from empirical dose reduction. All drugs may require dosage adjustment, even if the main elimination pathway is non-renal. Several studies indeed reported the need for DDA for drugs that are hepatically metabolized, due to reduced metabolism from interactions with uremic toxins and enzyme activity or hepatocyte transport. The "Service ICAR", founded in 1999, provides physicians with advices on DDA, based on evidence from the international literature. A dedicated team of physicians and pharmacists (5 full-time) prospectively searches and analyzes the literature to elaborate recommendations. Responses include specific drug pharmacokinetic considerations, subsequent DDA and schedule, adverse effects, specific monitoring in case of overdosage and data on potential drug transfer through the dialysis membrane and consequent optimal time of administration.

**Results**: From March 1999 to December 2009, 17'847 requests have been carried out, on 970 different drugs. Questions were asked by 3'398 physicians, mainly nephrologists, but also infectiologists, hematologists, and oncologists, for 8'758 patients. Patients were on hemodialysis in 56.3%, peritoneal dialysis in 4.2%, non dialyzed in 37.9% and on continuous veno-venous hemodialysis in 1.6%. Anti-infectious agents (43%) and anti-cancer agents (29%) were the drugs most frequently involved.

**Conclusion**: The activity of our Service ICAR shows that drugs' handling in RI patients is a critical clinical problem, especially in dialysed patients. From these data, it is suspected that in the general population, where fine renal function evaluation is usually not performed, the risk for drug inappropriate dosage and the need for DDA is also critical. Our Service ICAR is currently developing a website on which clear data will be available, and access restricted to health care professionals, physicians and pharmacists.

The Service ICAR receives unrestricted educational grants from Roche and Gilead.

### C.E.R.A. Efficiently Corrects and Controls HB in Chronic Kidney Disease Patients Not on Dialysis Independent from Pre-Treatment and Specified Administration Aspects – Analysis of the Non-Interventional Study SUPRA

Frank Leistikow. *Nierenzentrum Mannheim, Mannheim-Käfertal, Germany.*

**INTRODUCTION AND AIMS:** The SUPRA trial was designed to investigate the use of once-monthly (QM) C.E.R.A. in every day clinical practice in anemic chronic kidney disease (CKD) patients (pts) not on dialysis without the constraints of an interventional protocol. The study investigated if C.E.R.A. corrects and maintains Hb in defined targets.

**METHODS:** This non-interventional study (NIS) was conducted in 46 German centers. Data of 335 pre-dialysis pts treated with QM C.E.R.A. were collected over a 9-month-treatment period. Analysis of the collected data were performed in a descriptive way.

**RESULTS:** 335 pts were treated and formed the safety population. We present data from 259 (77.3%) pts from whom at least one Hb measurement was available in month 7-9 (evaluation period) . Pts who had been previously switched (n=124) from frequent-applicable ESA to C.E.R.A., and pts who had been started *de novo* on C.E.R.A. (n=125) were included. Main reason for CKD was hypertensive nephrosclerosis (38.6%). Baseline Hb was 10.2 ±0,9 g/dL in ESA naive pts and 11.3±1.0 g/dL in ESA pretreated pts. At study end Hb had been 11,3 ±0,7 g/dL. In month 7-9 43,6% and 68,6% of ESA-pretreated and 45,9% and 69,6% of ESA naive pts had all measured Hb values in the ranges of 10-12/10-13 g/dL. 76 pts had been treated with C.E.R.A. with a frequency > QM with Hb values in the above mentioned ranges of 43,4% and 67,11%. From the 147 at home treated pts 45,6% and 70% reached the described Hb-targets. In month 7-9 the hemoglobin fluctuation < = 1g/dl had been 91,9% in ESA pre-treated pts and 92,61% in ESA naive pts. 28,2%, 32%, 21,6%, 3,5%, 10%, 2,3% and 2,3% required <= 50, <= 75, <= 100, <= 120, < = 150, <=200 and >200 µg C.E.R.A. per month during month 7-9. There were 13 pts experiencing adverse drug reactions during the study.

**CONCLUSIONS:** Data collected within this NIS on CKD pts exposed to C.E.R.A. therapy indicate good efficacy on a once monthly and > once monthly schedule, administered at practice and at home, in ESA naive and in ESA treated pts and exhibit a low incidence of drug-related events.

### Renin-Angiotensin System Blockade Contributed to Severe Hyponatremia in the Outpatients without Diuretics

Jun Matsuda,[1] Ryohei Yamamoto,[2] Daisuke Ito,[1] Daisuke Mori,[1] Hiroyuki Kadoya,[1] Hisako Murata,[1] Masanobu Takeji,[1] Yasuyuki Nagasawa,[2] Yoshitaka Isaka,[2] Hiromi Rakugi,[2] Atsushi Yamauchi.[1] *[1]Nephrology, Osaka Rosai Hospital, Sakai, Osaka, Japan; [2]Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background: Hyponatremia (hypoNa) is one of the most common electrolyte disorders in clinical practice. However, little information on the contributors of hypoNa is available except older age and use of diuretics, which were exclusively assessed in the hospitalized patients. The aim of the present study was to identify the contributors to hypoNa in the outpatients without diuretics.

Design: A single-center cross-sectional study. Patients: Medical records of 20964 outpatients who visited Department of Internal Medicine, Osaka Rosai Hospital between April 2007 and November 2009 were assessed. Among a total of 114 patients with severe hypoNa (sNa≤125 mEq/L), 61 patients received no diuretics at the onset of hypoNa (hypoNa group), who were compared with 61 age- and sex-matched patients without diuretics during the study period (normal group). Outcome: HypoNa (sNa≤125 mEq/L). Independent variables: BMI, BP, eGFR, serum albumin, use of renin-angiotensin system (RAS) blockade and calcium channel blockade, and past histories of diabetes (DM), cardiovascular diseases (CVD), and hepatic diseases. Statistics: multivariate conditional logistic regression models

Results: Clinical characteristics between hypoNa and normal group were as follows; age 71±13 vs. 70±12 yr (mean±SD), male 65.6 vs. 65.6%,BMI 20.2±3.8 vs. 23.1±2.7 kg/m2, serum albumin 3.6±0.7 vs. 4.2±0.4 g/dL, systolic BP 130±17 vs. 135±14 mmHg, eGFR 81 (61-109) vs. 69 (57-82) mL/min/1.73m2 (median (interquartile range)), DM 23.0 vs. 27.9%, CVD 16.4 vs. 23.0%, hepatic disease 9.8 vs. 4.9%. Multivariate analyses revealed that RAS blockade was significantly associated with hypoNa (odds ratio 8.93 [95%CI 1.38 - 57.9], P = 0.022), along with BMI (0.67 [0.51 - 0.88], P = 0.004), serum albumin (0.03 [0.00 - 0.29], P = 0.002), and past history of CVD (9.53 [1.03 - 87.9], P = 0.047).

Conclusion: RAS blockade contributed to hypoNa, besides BMI, serum albumin, and past history of CVD.

## PUB238

### CKD in Primary Care: Baseline Data from the Renal Risk in Derby ($R^2$ID) Study

Natasha J. Mcintyre, Richard J. Fluck, Chris W. McIntyre, Maarten W. Taal. *The Department of Renal Medicine, The Royal Derby Hospital, Derby, Derbyshire, United Kingdom.*

**INTRODUCTION:** Most patients with CKD3 are managed in primary care but there are few data regarding their characteristics. Previous studies have largely excluded patients >75yrs, who make up a large proportion. We undertook a study of these patients with the long-term goal to define risk of cardiovascular disease (CVD) and CKD progression.

**METHODS**: Participants with KDOQI defined CKD stage 3 were recruited from 33 Primary Care Practices between July 2008 and March 2010. Adult patients of any age were invited. Medical history and demographic data were obtained as well as a clinical assessment including urine and serum biochemistry tests.

**RESULTS**: 1741 participants were recruited: mean age of 73(±9)yrs; 60%(n=1052) female; 98%(n=1698) white; 17%(n=294) had diabetes;17%(n=293) had microalbuminuria; 76%(n=1329) had CKD3a; 65%(n=1123) used ACEi/ARB; 22%(n=387) had a history of CVD. Baseline data and analysis of clinically relevant subgroups are shown below.

Baseline data

| | Total n=1741 | No Diabetes n=1447 | Diabetes n=294 | <75yrs n=917 | ≥75yrs n=824 |
|---|---|---|---|---|---|
| BMI (± SD) | 29 ±5 | 28.6 ±5 | 31.1 ±6* | 29.7 ±6 | 28.3±5* |
| SBP (mmHg; ± SD) | 134 ±18 | 134 ±18 | 135 ±19 | 131 ±17 | 137 ±19* |
| DBP(mmHg; ± SD) | 73 ±11 | 74 ±11 | 68 ±10* | 75 ±11 | 71 ±11* |
| PWV (m/sec; mean ± SD) | 9.9 ±2.0 | 9.8 ±2.0 | 10.3 ±2.0* | 9.2 ±1.7 | 10.6±2.1* |
| UACR (mean ± SD) | 4.6 ±33 | 3.2 ±25 | 11.6 ±57* | 5.7 ±44 | 3.5 ±13 |
| eGFR (mL/min/1.73m)² | 53 ±10 | 53 ±10 | 49 ±10* | 55±10 | 50 ±10* |
| Hb (g/dL) | 13.2±1.5 | 13.3±1.4 | 12.6±1.5* | 13.4±1.5 | 13 ±1.4* |

ΔAlbuminuria >microalbuminuria threshold. *p=<0.05 vs comparitor group.

**CONCLUSION**: Patients with CKD in primary care, in Derbyshire, are mainly elderly, female and overweight or obese. The majority fall into CKD stage 3a and significant albuminuria uncommon. BP was well controlled but PWV was elevated. Sub-group analysis revealed those with CKD 3b, diabetes and those >75 yrs had a higher risk profile. 10 yr follow-up will afford a unique opportunity to study CKD 3 and its consequences in patients often excluded from other studies, and will provide an important comparison with CKD cohorts recruited from secondary care, including the CRIC study.

## PUB239

### Renal Granulomatous Sarcoidosis: A Long Term Follow Up of 33 Patients

Fabrice Mihout,[1] Rafik Mesbah,[2] Raymond Azar,[3] Christian Noel,[4] Jean-Jacques Boffa,[5] Philippe J. Vanhille.[1] *[1]Nephrology, Hopital, Valenciennes, France; [2]Nephrology, Hopital, Boulogne/mer, France; [3]Nephrology, Hopital, Dunkerque, France; [4]Nephrology, Hopital, Lille, France; [5]Nephrology, Hopital Tenon, Paris, France.*

Sarcoidosis is a systemic inflammatory disease of unknown pathophysiology. Renal failure can occur by several mechanisms, but the most typical is granulomatous interstitial nephritis.

We present a retrospective series of 33 patients (pts, 23 men), mean age 60+/-13 y, with histological proven granulomatous interstitial nephritis due to sarcoidosis. We studied clinical and biological parameters at presentation and during follow-up (mean 69 ± 54 months) and compared long-term renal outcomes in 2 groups of pts: 17 pts treated with methylprednisolone pulses (MP) followed by oral corticosteroids (CS) and 16 pts on oral CS alone. Adverse effects of steroids were also recorded.

At presentation, mean eGFR was 19±14 mL/min/1.73m², mean proteinuria 1.1g/d, microhematuria and leucocyturia were found in 50% pts. Ten pts had hypercalcemia. Transient hemodialysis was necessary in 3 cases. Extra-renal manifestations were: fever 20%, chest abnormalities 79%, cholestasis 36%, lymphopenia 90%, and elevated ACE 61%. All pts received oral prednisone 0.5-1.0 mg/kg/d for 2 months, then progressively tapered. Renal function improved with a mean eGFR increase of 19.5ml/min/1.73m2 with maximal response at the end of the first month of treatment. At the end of follow up, mean eGFR was 41±16 mL/min/1.73m². Pts who were treated with MP + oral CS had a better renal outcome compared to those treated by oral CS without MP (Δ eGFR: +27±15 mL/min/1.73m² *vs* Δ eGFR: +14±7 mL/min/1.73m²; p=0.04). Twenty four percent of pts had a renal relapse, either during CS tapering or after their withdrawal. CS side-effects were observed in 45% pts: hypertension 21%, diabetes 24%, cardiovascular events 15% (3 deaths), infection 18% and osteoporosis 18%.

Renal sarcoidosis is characterized by severe renal failure and systemic manifestations. Better long-term renal outcomes are obtained with MP followed by oral CS than with oral CS alone. The high incidence of steroid-adverse events emphasizes the need for steroid-sparing regimens.

**Effects of Mono- and Dual Blockade of RAS on Escape Phenomenum** Takanori Nagai,[1] Kahori Hori,[1] Yushi Nakayama,[2] Yukiko Hasuike,[1] Yuichiro Izumi,[3] Masayoshi Nanami,[1] Takahiro Kuragano,[1] Yoshinaga Otaki,[1] Hiroshi Nonoguchi,[1] Takeshi Nakanishi.[1] *[1]Division of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [3]LKEM, NHLBI/NIH, Bethesda, MD.*

The renin-angiotensin-aldosterone system (RAS) blockers have renoprotective effects in proteinuric CKD patients. However, rebound increase of proteiuria after 3-4 years' treatment with ACE inhibitors (ACE-I) is known as an escape phenomenunon. We retospectively examined whether monotherapy with ARB or dual blockade with ARB plus ACE inhibitor cause rebound increase in proteiuria in CKD patients. 54 CKD patients (mean age of 58 years old, 32 IgA nephropathy, 17 diabetic nephropathy, 5 non-IgA nephropathy) with initial decrease in proteinuria (larger than 50 %) by the treatment with RAS blckers were selected and the presence/absence of rebound increase in proteiuria (larger than initial level of proteinuria) was examined. Basal proteinuria was 1.4 and 1.9 g/day in ARB (n=23) and ARB/ACE-I (n=31) treated patients, respectively. Peak reduction of proteinuria was observed at 18 and 23 months after the start of the treatment in patients treated with ARB alone and dual blockade, respectively. Proteinuria was reduced to 22±10 (mean±SD) and 15±12% of the basal level by ARB and ARB/ACE-I, respectively. Rebound increase in proteinuria was observed in 7 (30%) patients with 16 months after the start of the treatments in ARB treated patients. In contrast, rebound increase in proteinuria was seen in 4 (13% ) with 26 months after the start of the treatment in dual blockade with ACE-I and ARB. In remaining patients, rebound increase in proteinuria was not oberved during 51 and 49 months follow-up in ARB and ARB/ACE-I, respectively. These data show that 1) rebound increase in proteinuria was observed in patients treated with ARB or ARB plus ACE-I, and 2) dual blckade with ARB and ACE-I should be considered to reduce the risk of rebound increase in proteinuria in patients with CKD.

**Urine Cotinine in Adolescents with Chronic Kidney Disease: A Report from the Chronic Kidney Disease in Children (CKiD) Cohort Study** Abiodun A. Omoloja,[1] Judith Jerry-Fluker,[2] Alison G. Abraham,[2] Derek Ng,[2] Bradley A. Warady,[2] Susan L. Furth,[2] Mark Mitsnefes.[3] *[1]Pediatrics, Wright State University, Dayton, OH; [2]The CKiD Study Investigators; [3]Cincinnati Children's Hospital Meidcal Center, Cincinnati, OH.*

Second hand smoking (SHS) has been associated with cardiac disease. The goal of this study was to determine the relationship between exposure to SHS and clinical and laboratory parameters of adolescents at baseline in CKiD, an observational cohort study of 586 children (aged 1-16 yrs) with Schwartz estimated GFR of 30-90 ml/min/1.73m$^2$. Urine cotinine concentration [Uc] was used to determine exposure to SHS.

Of the 239 adolescents who had self-reported data on smoking and SHS exposure, 149 had Uc data available. Seven subjects were excluded because they had Uc levels ≥ 75 ng/ mL consistent with active tobacco use. In the remaining 142 subjects, Uc ≥ 1 ng/ mL was considered as evidence of exposure to SHS. Analysis was performed using Fisher's Exact Test for categorical variables and Wilcoxon Rank Sum scores for continuous variables.

There were 39 subjects (27%) exposed to SHS and 103 who were not. There was no racial, age, or gender differences between both groups. Baseline wide range C reactive protein, lipid profile, iohexol GFR and hemoglobin were not statistically different between groups. The group exposed to SHS had a higher median SBP percentile (70%) compared to unexposed group (50%) [P < 0.01]. Those exposed to SHS had a higher prevalence (29%) of left ventricular hypertrophy compared to 10% in those not exposed [P = 0.04]. Nephrotic range proteinuria (Up/c ≥ 2.0) was more prevalent in children exposed to SHS (34%) in comparison to 10% in those not exposed [P < 0.01].

These results suggest that in non-smoking adolescents with CKD, SHS exposure, as measured by Uc, may be an unrecognized variable that may adversely affect CKD progression and cardiovascular outcome.

**Is Vitamin D Deficient in the Sunshine State of Florida?** Umabala Pasupala, Rute C. Paixao, Mauro Braun, Dianne T. Sandy, Beth L. Fromkin, Noelle Barrera. *Nephrology and Hypertension, Cleveland Clinic Florida, Weston, FL.*

Vitamin D deficiency has been increasingly recognized as an important public health problem and has been associated with multiple extra skeletal functions. One of the major risk factors for vitamin D deficiency is Chronic Kidney Disease (CKD). Recent studies have been challenging the assumption that vitamin D deficiency may be less prevalent in people living in sunny climate; however limited data is available so far.

To verify the prevalence of Vitamin D deficiency in sunny areas and its association with other co-morbidities, we conducted a cross sectional descriptive study at Cleveland Clinic Florida on patients with CKD stage III to V from spring 2008 to winter 2009. Patients with malignancy-related hypercalcemia, secondary hyperparathyroidism, multiple myeloma, Sarcoidosis, or Paget's disease were excluded.

2010 patients admitted to Internal Medicine and its subspecialties were screened, from those 97 with eGFR < 60 (MDRD equation) met the inclusion criteria, but 11 were excluded due to acute renal failure, and 2 due to unavailable Vit D levels. The remaining 84 patients were checked for 25-hydroxy vitamin D, 1,25-dihydroxy vitamin D, and intact parathyroid hormone levels. According to KDOQI guidelines, 25-OH vitamin D levels below 30 ng/ ml were considered to be insufficient, and below 15 ng/ml as deficient.

Hypovitaminosis D was prevalent in 70% of the study group (52% vitamin D insufficient and 18% vitamin D deficient). The mean 25-OH Vit D level was 24.7 ng/ml. The majority of patients were CKD stage 3, and 75% of those were vitamin D deficient. Also hypovitaminosis D showed significant association with Diabetes Mellitus (p= 0.03), and some association with anemia (p=0.437), and with cancer (p= 0.221).

In conclusion, Vitamin D deficiency is highly prevalent in CKD patients admitted to a South Florida Hospital and is significantly correlated with Diabetes Mellitus. Routine monitoring of vitamin D levels in early stages CKD and in diabetes can be beneficial even in sunny areas. Larger multi-center population-based studies are needed to verify the prevalence and outcomes of vitamin D deficiency.

**Association of CHF and LVH with Mortality in Men with Moderate-to-Advanced Non-Dialysis Dependent Chronic Kidney Disease** Jason J. Payne,[1,2] Smriti I. Sharma,[1,2] Dexter G. De Leon,[1,2] Jun Ling Lu,[3] Fregenet A. Alemu,[2] Rasheed A. Balogun,[4] Sandra M. Malakauskas,[2] Kamyar Kalantar-Zadeh,[5] Csaba P. Kovesdy.[2,4] *[1]Carilion Clinic, Roanoke, VA; [2]Salem VA Medical Center, Salem, VA; [3]Salem Research Institute, Salem, VA; [4]University of Virginia, Charlottesville, VA; [5]Harbor-UCLA, Torrance, CA.*

The interrelationship of left ventricular hypertrophy (LVH) with congestive heart failure (CHF) and their impact on mortality in non-dialysis dependent CKD (NDD-CKD) is unclear.

We examined associations of echocardiographycally measured ejection fraction (EF) and LVH with all-cause mortality in a historic cohort of 650 men with moderate-to-advanced NDD-CKD (mean eGFR: 37±21 ml/min/1.73m2). EF and LVH were examined separately and after categorizing patients by combining their EF and presence/absence of LVH. Associations with mortality were examined in Cox models with adjustments for potential confounders.

EF <50% was associated with higher all-cause mortality (hazard ratio, 95%CI: 1.61 (1.21-2.15), p=0.001) even after adjustment for age, race, comorbidities (including coronary artery disease), smoking status, blood pressure, eGFR, albumin, bicarbonate, cholesterol, calcium, phosphorus, hemoglobin, white blood cell count and percent lymphocytes in white blood cell count, proteinuria and medication use. LVH in itself was not associated with mortality (0.95 [0.72-1.25], p=0.7), but the presence of LVH combined with an EF<50% was associated with a 2.4-fold greater death risk after multivariable adjustments (Table).

Mortality associated with CHF and LVH

| | EF>50%, No LVH Reference Group | EF>50%,LVH | EF<50%, No LVH | EF<50%, LVH |
|---|---|---|---|---|
| Unadjusted | 1 | 0.92 (0.73-1.17) | 1.38 (1.08-1.75) | 1.33 (0.96-1.85) |
| Case-mix adjusted | 1 | 0.91 (0.67-1.22) | 1.32 (0.97-1.79) | 1.24 (0.83-1.89) |
| Case-mix + labs + BP adjusted | 1 | 0.97 (0.86-1.39) | 1.33 (1.0-2.06) | 2.38 (1.41-4.02) |

HR, 95%CI

Low EF is associated with higher mortality in patients with NDD-CKD. In the presence of a low EF, LVH is also associated with higher mortality. Clinical trials are needed to determine if interventions targeting patients with low EF and LVH can lower mortality in NDD-CKD.

**The Clinical and Imaging Presentation of Acute "Non-Complicated" Pyelonephritis** Giorgina B. Piccoli, Valentina Consiglio, Stefania Scognamiglio, Rossella Attini, Maria Chiara Deagostini. *SS Nephrology, ASOU San Luigi, Torino, Italy.*

**Background.** Acute pyelonephritis (APN) is differently defined according to imaging data (CT scan or Magnetic resonance) or clinical criteria (tetrad of fever, costovertebral pain, lower urinary tract symptoms, positive urinary cultures). In adults updated information on the relationship between imaging and clinical data is lacking.

**Aim**: to analyze the relationship between the clinical and imaging presentation of APN, defined according to imaging criteria (CT or Nuclear Magnetic Imaging), in a single setting where patients undergo routine imaging studies.

**Methods.** All consecutive patients hospitalized for "non-complicated" (primary, with the exclusion of local or systemic predisposing factors) APN in our institution in June 2005-December 2009 were considered. Clinical, biochemical and imaging data at hospitalization were analyzed by univariate and logistic regression analysis (SPSS vers 17.0). The main outcome variable considered was the presence of abscessed lesions.

**Results**. There were 119 patients, all females, median age 32 years (15-72). Non typical presentations were common. At hospitalization, fever was absent in 6.7%, pain in 17.8% and lower urinary tract infection symptoms in 52.9%; 42% had taken antibiotics in the previous 3 days; the median interval before referral was 3 days. Inflammatory markers were elevated (CRP median: 12.1 mg/dL (0.2-39); WBC mean 12528±4127). Urinary and blood cultures were positive in a minority of cases (23.5%; 12.6%). Lesions were bilateral in 12.6%, multiple in 79.8%; abscesses were present in 39.5%. Renal scars were present at diagnosis in 18 patients (15.1%), prosumably sign of previous APN. APN was however undiagnosed in 15/18. No presenting sign/symptom discriminated between small lesions, abscesses or multifocal involvement, with the exception of positive cultures, correlated with multiple infectious foci (multivariate OR 4.2; CI 1.139-15.515).

**Conclusions.**
The presentation of APN is protean, with high prevalence of non typical oligosymptomatic presentations. In the absence of clinical or biochemical markers, imaging studies are required to assess the severity of kidney involvement.

**PUB245**

**Adherence to K/DOQI Practice Guidelines for Bone Metabolism and Disease in Patients with CKD in an Academic Internal Medicine Clinic** Milap Pokharel. *Department of Internal Medicine, Saint Joseph Mercy Hospital, Ann Arbor, MI.*

Chronic kidney disease (CKD) is associated with a variety of bone disorders and disorders of calcium and phosphorus metabolism. Elevated plasma parathyroid hormone (PTH) levels have been linked to adverse clinical outcomes which can be prevented through early detection and treatment. Guidelines recommend checking serum calcium, phosphorus and intact PTH in all patients with CKD stage 3 and higher plus vitamin D levels in patients with elevated PTH. The aim of our study was to assess the adherence to above guidelines in an Academic Internal Medicine (AIM) clinic.

Among all patients 18 years or older that visited AIM clinic between September 1, 2006 and August 31, 2008, a random sample of 400 eligible patients was included in the study based on a sample size calculation. A retrospective chart review was done and specific variables such as age, sex, calcium levels, phosphorus levels, PTH, vitamin D were collected and analyzed.

51% were women, 56% were white and the mean age was 43.7 years. 315(78.75%) had a glomerular filtration rate (GFR) evaluation. 169 of the 315 patients who were tested had a previous GFR measurement. 31(8%) patients of the total sample had a GFR below 60. Of the 31 patients, 5 (1.58%) did not have a previous test result reported, 14 (4.44%) had an abnormal GFR on both measurements and 12 (3.8%) of the patients with abnormal GFR did not have a GFR below 60 on the previous measurement.

Of 31 patients with an abnormal GFR on the index visit, 29 (94%) had serum calcium evaluated and 20 (65%) had a serum PO4 reported. 4 (13%) had both PTH and 25OH-vitamin D level reported. Of the 14 with confirmed CKD by definition, all had corrected serum calcium, 9 (64%) had a PO4, and 3 (21%) had both PTH and 25OH-vitamin D levels reported.

Our study shows that adherence to guidelines related to bone metabolism is not adequate in the AIM clinic. This study will increase physicians awareness regarding the management of bone metabolism in patients with CKD, and remind them that current practice falls short of meeting the guidelines.

**The Slight Increase in Urine Albumin and beta 2-Microglobulin Are Independently Related with Blood Pressure in General Japanese Population: The Takahata Study** Kazuko Suzuki, Ami Ikeda, Yusuke Mashima, Kazunobu Ichikawa, Satoshi Takasaki, Tsuneo Konta, Isao Kubota. *Department of Cardiology, Pulmonology, and Nephrology, Yamagata University School of Medicine, Yamagata, Japan.*

**Background:** Essential hypertension is a multifactorial disorder and a risk factor for renal failure and cardiovascular diseases. Recently it is advocated that subtle acquired renal injury such as renal microvascular and tubulointerstitial damage evokes salt-sensitive hypertension. The objective of this study is to examine the relation between blood pressure and these renal abnormalities in general population.

**Methods:** The participants of this community-based, cross-sectional study were 1,965 subjects over 40 years old, without antihypertensive medication or renal insufficiency. Urine albumin-creatinine ratio (UACR) and beta 2 microglobulin-creatinine ratio (UBCR) obtained from single spot urine were used as markers of renal microvascular and tubulointerstitial damage, respectively.

**Results:** Multiple linear regression analysis showed a significant positive correlation between systolic blood pressure and UACR, and UBCR, but not estimated glomerular filtration rate. In multiple logistic regression analysis the increase in UACR and UBCR levels were independently related with hypertension after adjustment with possible confounders and slight increases of UACR (5-9 mg/g) and UBCR (100-199 μg/g) showed a significantly higher risk for hypertension, compared with UACR <5mg/g and UBCR <100μg/g, respectively. Furthermore the positive relation between urine sodium excretion and blood pressure was observed in subjects with low UACR and all UBCR levels, but not high UACR levels (≥5 mg/g).

**Conclusions:** This study revealed that the slight increases in urine albumin and beta 2-microglobulin were independently related with blood pressure in general Japanese population. These renal abnormalities might differently affect the development of hypertension.

**PUB247**

**Lupus Nephritis in the Elderly** Tanyarat Teerapornlertratt. *Department of Medicine, Faculty of Medicine, Siriraj Hospital, Bangkok, Thailand.*

**Background** The patients are now getting older as well as SLE patients. We describe the prevalence, clinical manifestations and prognosis in lupus nephritis patients of ≥ 50 years.

**Material and Methods** Thirty lupus nephritis patients of ≥ 50 years were analyzed retrospectively for 17 years.

**Results** Of 30 patients (male 7, female 23) the average age was 56.6 ± 4 years (range 50-72 years). Follow up period was 25.8 months, the major extrarenal manifestations were anemia (39.3%) and musculoskeletal (33.3%). Renal manifestations were hypertension 66.7%, nephrotic range proteinuria 62.9%, azotemia 41.3%. Renal biopsy revealed LN WHO type 4 for 63.3%, the overall probability of one year survival was 94.1%, 3 years for 68.6%. The cause of death was infection.

**Conclusion** The elderly LN patients who presented with arthritis, anemia and renal involvement were not uncommon in ≥ 50 years. The prompt diagnosis and treatment will rescue and prolong good quality of life in these patients.

**Management of CKD and Clinical Guidelines in France: Results of PREPARE Study** Malik Touam,[1] Paul Stroumza,[2] Eric Daugas,[3] Bertrand Dussol,[4] Laurent Juillard,[5] Patrick Henri.[7] *[1]AURA, Paris, France; [2]Résidence du Parc, Marseille, France; [3]Hôpital Bichat, Paris, France; [4]Hôpital de la Conception, Marseille, France; [5]Hôpital E.Herriot, Lyon, France; [6]Hôpital Clemenceau, Caen, France.*

In this transversal study we analysed the quality of CKD management before dialysis or transplantation in France. During the week 23- 27 nov. 2009, 2190 CKD pts (GFR <60 ml/min/1,73 m², without history of dialysis or transplantion) were included by 301 nephrologysts. The characteristics of 2089 pts by CKD stage (119 excluded, missing datas or GFR>60) are:

| | st III | st IV | st V | Total+st II |
|---|---|---|---|---|
| N-median age,yrs | 688-73 | 746-73.5 | 314-69 | 2089-72 |
| Sexe F-Diabetes,% | 39.2-35.2 | 40.9-41.6 | 42.7-36 | 40.6-36.9 |
| IC,HF,St*,% | 38.1 | 46.5 | 37.9 | 39.3 |
| CKD vintage-Nephrol referral, months | 40-16 | 44-19 | 61-22 | 43-18 |
| Hypertension>130/80 mm Hg,% | 39.9 | 46.9 | 49.9 | 62.2 |
| HbA1c>8%,% | 17.6 | 19.5 | 16.9 | 18.9 |
| RAS blockers-Statines,% | 73.1-56.4 | 70.6-57 | 65.9-51.6 | 70-55.2 |
| Vit D-Ca salts-P binders, % | 28-9.6-1 | 39-24.5-6 | 55-42.4-20 | 35-19.6-5.6 |
| ESA,% | 12.9 | 34.6 | 55.1 | 26.1 |
| Hbs vaccine-AVF creation,% | - | 31.3-17.4 | 46.1-35.8 | - |

*IC ischemic cardiopathy, HF heart failure, St stroke

Hypertension was found in 87.7% and treated in 84.9% of cases. The dyslipidemia was present in 53.2% of cases, with a median of LDL> 2.70 mmol/l (st III to V). At st V, iPTH was <150 (25%),>300 (37.9%) and >600 pg/ml (7%). At st IV-V, Hb target [10-12g/dl] was found in 52.8% of pts. The nephrology referral is a late at st IV-V. At st V the monitoring was monthly (71.7%) and quarterly (25.3%). Age and cardiovascular morbidity were lower at st V, suggesting that the setting on dialysis was early, or/and the mortality was higher. ESRD was expected in 1398 pts with a orientation to hemodialysis-peritoneal dialysis in 84% -16% of cases.The Hbs vaccine and the creation of AVF were performed in a small percentage of pts, while the hemodialysis treatment is planned for a majority of pts.
Disclosure of Financial Relationships: nothing to disclose

**Profile of Patients Oriented Exclusively to Conservative Treatment of ESRD** Malik Touam,[1] Eric Daugas,[3] Bertrand Dussol,[4] Patrick Henri,[5] Laurent Juillard,[6] Paul Stroumza.[7] *[1]AURA, Paris, France; [2]Hôpital Bichat, Paris, France; [3]Hôpital de la Conception, Marseille, France; [4]Hôpital Clemenceau, Caen, France; [5]Hôpital E. Herriot, Lyon, France; [6]Clinique de la Résidence du Parc, Marseille, France.*

***Background:*** The characteristics of pts with CKD progressing to ESRD and oriented exclusively to conservative treatment (CT) are poorly understood.

***Methods:*** As part of an french study PREPARE, one day in november 2009, 301 nephrologists have described the characteristics and their intent to treat 2089 pts with a GFR <60 ml/min/1,73 m2 (not on dialysis or transplantation).

***Results:*** The ESRD was expected in 1382/2089 (68.5%) pts, and CT were the preferred orientation in 7% (n = 97/1382) of cases. This option was selected by 23.2% of nephrologists (n = 70/301) while the CKD was at stage 5 (15.5%), 4 (51.5%) or 3 (33%). The main reasons for this choice were the great age (67%), cardiovascular comorbidity (21.6%), neoplasia (16.5%), psychiatric disorders (11.3%), or for other reasons whose refusal of dialysis by pts(24.7%).

The comparative characteristics of pts referred to dialysis (without transplantation, n = 863) and those to CT are:

| | CT n=97 | Dialysis n=863 | p |
|---|---|---|---|
| Age, years | 82,4 ± 9.1 | 74.4 ± 10 | < 0.0001* |
| Denutrition,% | 31,5 | 6.1 | < 0.0001* |
| BMI, kg/m2 | 24.8 ± 5.2 | 27.9 ± 5.7 | < 0.0001 |
| Nephrol. monitoring, years | 1.7 ± 3.7 | 1.3 ± 3.6 | 0.31 |
| IC, HF, St **,% | 62.9 | 47.2 | 0.003 |
| Solid Tumor,% | 20.6 | 12.4 | 0.02 |
| Diabetes,% | 28.9 | 41.5 | 0.02 |
| Charlson score modified | 7.2±2.3 | 6.5 ± 1.9 | 0.004 |

*Univariate and multivariate analysis ** IC ischemic cardiopathy , HF heart failure, St stroke

The distinctive parameters of pts oriented to CT are a great age and a poorer nutritional status, regardless of duration of follow-up and co-morbidities. Nearly 25% of nephrologists give other non-physical reasons for this choice. This suggests that factors such as social isolation or rejection of dialysis treatment, involved in a crucial decision. Further studies are needed to clarify this.

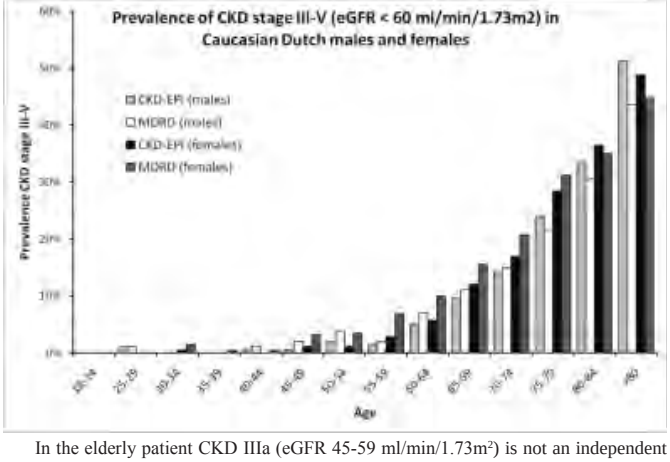
**The Effect of the CKD-EPI Equation To Estimate Glomerular Filtration Rate: Does the Patient Benefit?** Jan A. J. G. van den Brand, Jack F. Wetzels. *Department of Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

A reduced glomerular filtration rate (GFR) below 60 ml/min/1.73m$^2$, is sufficient to diagnose chronic kidney disease (CKD) stages III-V. Recently the CKD-EPI equation to estimate GFR was developed. We assessed the consequences of its introduction on CKD prevalence in our population.

We calculated $eGFR_{CKD\text{-}EPI}$ and $eGFR_{MDRD4}$ for 2 823 and 3 272 age stratified randomly selected Caucasian males and females. We obtained information on health status and medication use through a questionnaire. Serum creatinine was measured with a Jaffé assay calibrated versus isotope diluted mass spectrometry.

The CKD-EPI equation generally gave higher estimates of GFR than the $MDRD_4$ formula did. Change in prevalence of CKD III-V was dependent on age and gender (see figure). Thus, introduction of the CKD-EPI formula resulted in a lower prevalence in younger persons, but a higher prevalence in the elderly. In the general population the overall result is a reduction in the number of persons identified with CKD III-V. However the benefit for the individual patient can be questioned.



In the elderly patient CKD IIIa (eGFR 45-59 ml/min/1.73m$^2$) is not an independent risk factor, rather an indicator of cardiovascular risk profile. Use of the CKD-EPI formula would thus unnecessarily increase the number of patients referred for nephrology care. In contrast, for young patients CKD IIIa is an independent risk factor, eGFR being well below the fifth percentile of normal kidney function. The CKD-EPI equation would result in classifying these young persons upward, thus lead to under diagnosis of CKD.

In conclusion, introduction of the CKD-EPI formula leads to higher estimates of GFR on a population level. However, redefining CKD stages is needed to improve risk stratification and care for the individual patient.

**PUB251**

**Rural-Urban Disparities in Health Related Quality of Life (HRQoL) in Chronic Kidney Disease (CKD): The Study of Treatment for Renal Insufficiency: Data and Evaluation (STRIDE)** Tiffany C. Veinot,[1] Anca Tilea,[1] Brenda W. Gillespie,[1] Margaret A. Kiser,[2] Fredric O. Finkelstein,[3] George Eisele,[4] Peter Kotanko,[5] Rajiv Saran.[1] *[1]U. of Mich., Ann Arbor, MI; [2]U. of N. Carolina, Chapel Hill, NC; [3]Hospital of St. Raphael Yale U., New Haven, CT; [4]Med. College of Albany, Albany, NY; [5]RRI, New York, NY.*

Research in HRQoL among CKD patients by rural versus urban residence has been limited. We examined differences in HRQoL among urban and rural residents in a national CKD cohort. The STRIDE is a prospective cohort study at 79 US renal clinics (n=1,502). Patients were categorized as rural (n=234) or urban (n=1,268) using the zipcode-based Rural-Urban Commuting Area (RUCA) classification. The two groups' baseline Kidney Disease Quality of Life Short Form-36 (KDQoL) scores were compared (see Table) using 2-sample t-tests (unadjusted) and linear regression (adjusted for age, gender, race, education, diabetes, hypertension, hemoglobin and eGFR).

Rural and urban patients were similar, with a mean age of 63±12, and a mean eGFR (MDRD) of 24±10 ml/min/1.73m$^2$, but there were significantly more rural whites (80% *vs.* 66%, p<0.0001).

Rural patients had statistically significant lower scores for:energy/fatigue, physical component summary, general health and burden of kidney disease. There were no statistically significant differences in other KDQoL scores. After adjustment, rural patients had significantly worse scores for: energy/fatigue, the kidney disease component summary and burden of kidney disease. Rural patients reported significantly better cognitive functioning.

| KDQoL-SF36 Measure | Urban* (n = 1,268) | Non-Urban* (n = 234) | P-value Unadjusted | P-value Adjusted |
|---|---|---|---|---|
| Mental Component Summary | 50±10 | 50±10 | 0.90 | 0.77 |
| Energy/Fatigue | 48±24 | 43±24 | 0.01 | 0.005 |
| Physical Component Summary | 38±12 | 36±12 | 0.02 | 0.07 |
| General Health | 47±19 | 44±17 | 0.02 | 0.11 |
| Kidney Disease Component Summary | 57±10 | 56±11 | 0.36 | 0.04 |
| Burden of Kidney Disease | 61±26 | 56±26 | 0.01 | 0.04 |
| Cognitive Functioning | 52±38 | 56±37 | 0.14 | 0.04 |

*Urban defined as RUCA 1-3, non-urban defined as RUCA 4-10

Rural residence may confer HRQoL challenges for CKD patients related to access to care or other factors. Given known associations between HRQoL, morbidity and mortality, further research is needed in this area.

**Chronic Kidney Disease in Queensland (CKD.QLD)** Sree Krishna Venuthurupalli,[1] Robert G. Fassett,[2, 3] Tracy A. Lowis,[2] Wendy E. Hoy.[2] *[1]Renal Medicine, Rockhampton Hospital, Rockhampton, Queensland, Australia; [2]Centre for Chronic Disease, University of Queensland, Brisbane, Queensland, Australia; [3]Renal Medicine, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia.*

Aim: To establish a practice network, registry and research platform for chronic kidney disease (CKD) in Queensland (QLD) Australia.

Background: CKD is a leading cause of morbidity and mortality in Australia with huge economic implications. However, definitions, staging and predictions of course are all imperfect. Varying models of CKD service delivery are evolving but are not yet rigorously evaluated. CKD.QLD is a multidisciplinary CKD research group, established in September 2009 in QLD, a state with a multiethnic population of 4.5 million people, and a single public health provider (Queensland Health).

Methods: The first phase consisted of a cross-sectional profile of CKD activity in all renal practices in QLD, both hospital based and community-based, conducted between December 2009 and January 2010.

Results: Sixteen separate public renal practices were surveyed, where 10,469 CKD patients were identified as attending. All services collected patient data but usually in a service designed excel spreadsheet. Models of CKD care varied greatly from nurse-practitioner-led multidisciplinary community clinics to hospital based renal clinics. Specialist clinics in hospitals focussed mainly on stages 4-5 CKD but community clinics included management of earlier stages. Stages 1-2 CKD were frequently referred back to primary care. Estimates suggested equal or greater numbers of patients in private practice as in the public setting.

Conclusions: CKD is a common disease and many cases are followed within Queensland renal clinics. However, stage of CKD patients seen and models of care vary considerably across the sites. We plan more detailed review of services, establishment of a registry, sampling of CKD patients in other practice settings, including primary care, and development of a research agenda, which will include outcomes research, biomarkers, clinical trials, and models of care.

**The Epidemiology of Metabolic Syndrome in Sichuan and Relationship between Chronic Kidney Disease and Metabolic Syndrome** Li Wang. *Department of Nephrology, Sichuan Provincial Hospital, Chengdu, Sichuan, China.*

Objective: To investigate the epidemiology of metabolic sydrom an it's relationship and chronic kidney diseaes.Method:3024 people older than 18 years were enrolled by cluster random sampling.This reseach included a questionnaire,physical exminations and laboratory examinations . CKD was diagnosed by decreased eGFR(<60ml/min/1.73m$^2$) or presentation of microalbuminuria, macroalbuminuria, proteinuria or hematuria. MS was diagnosed according to IDF standard . Result:The prevalence and age-and-sex-standardized prevalence of hypertension was 16.5% and 11.9% respectively with a higher prevalence in Guanghan than in Chengdu(22.0% vs 11.0%, p<0.001). The prevalence and age-and-sex-standardized prevalence of diabetes was 6.6% and 5.1% respectively with a higher prevalence in Guanghan than in Chengdu(9.2% vs 4.0%, p<0.001), The prevalence and age-and-sex-standardized prevalence of hyperlipidemia was 53.4% and 50.76% respectively with a higher prevalence in Guanghan than in Chengdu(57.5% vs 49.3%, p<0.05), The prevalence and age-and-sex-standardized prevalence of obesity was 60.0% and 65.30% respectively with a higher prevalence in Chengdu than in Guanghan (65.8% vs 54.1%,

p<0.001), The prevalence and age-and-sex-standardized prevalence of hyperuricemia was 14.4% and 15.13% respectively with a higher prevalence in Chengdu than in Guanghan (18.3 vs 10.4%, p<0.001), The prevalence and age-and-sex-standardized prevalence of metabolic syndrome was 10.0% and 8.57% respectively without difference in Chengdu and Guanghan (9.9% vs 10.0%, p>0.05).the prevalence of CKD was higher in MS people than non-MS people(26.2% vs 18.4, p<0.001). Low HDL-c[OR0.524(0.432~0.636)], high FPG[OR3.499(2.838-4.312], hypertension[OR2.138(1.771-2.582], Centralobesity [OR1.502(1.234-1.828] are risk factors. Based on central obesity, prevalence of CKD increases as the number of abnormal metabolic components increases. When the number increases to 1,2,3 or 4, the OR1.737(1.105~2.731),2.236(1.542~3.509),2.093(1.263~3.466 )or2.700(1.279~5.698)respectively.Conclusion:The prevalence of metabolic syndrome and its components is high in Sichuan Province. Prevalence of CKD are higher in MS patients than in general population in Sichuan.

**Once Monthly C.E.R.A. Provides Stable Hb-Values in CKD-Patients; Results from a Metaanalysis of 3 Studies** Thomas Weinreich,[1] Danilo Fliser,[2] Stefan N. Heidenreich.[3] *[1]Dialysezentrum, Villingen-Schwenningen, Germany; [2]Innere Medizin IV, Universitätsklinikum des Saarlandes, Homburg/Saar, Germany; [3]KfH Dialyse, Aachen, Germany.*

INTRODUCTION AND AIMS: CERA (Mircera®) was approved as a long acting ESA for patients (pts.) suffering from renal anemia. The studies SESAM, SUPRA and MIRACEL haven been conducted in CKD pts of stages IV and V in germany. Given the large no. of pt. data and similar time schedules of these studies, the pooled data offered the chance for subgroup analyses.

METHODS: Data from all 3 studies were pooled in a common database and analyzed with respect to individual Hb-fluctuation, reaching of target Hb-range and number of dose adaptations needed. Separate analyses were performed for the following subgroups:

Route of admin. (i.v./s.c.)
Age (<=65/>65)
Gender (male/female)
Previous ESA treatment (Epoetin/Darpeoetin/CERA)
Diabetic pts (yes/no)

RESULTS: Study population consisted of 1343 hemodialysis pts (MIRACEL study 424 pts; SESAM 919 pts.) and 335 CKD 4 and 5 pts (SUPRA). When comparing the various subgroups the following results were observed:

Table 1: Results of the subgroup analysis (% pts)

| | Hb-Fluctuation from individual mean | | | Patients in target range | | Dose adaptations | |
|---|---|---|---|---|---|---|---|
| | <= 1 g/dl | 1-2 g/dl | > 2 g/dl | 10-12 g/dl | 10-13 g/dl | <=2 | >2 |
| Route of admin (i.v./s.c.) | 84.8 / 84.8 | 13.7 / 13.8 | 1.5 / 1.4 | 37.3 / 44.1 | 66.4 / 68.3 | 66.1 / 59.5 | 33.9 / 40.5 |
| Age (<=65/>65) | 82.1 / 86.6 | 16.7 / 11.7 | 1.1 / 1.7 | 34.9 / 42.2 | 64.9 / 68.4 | 63.8 / 64.1 | 36.2 / 35.9 |
| Gender (f/m) | 83.9 / 85.5 | 13.8 / 13.7 | 2.3 / 0.8 | 39.8 / 38.9 | 63.4 / 69.8 | 63.1 / 64.7 | 36.9 / 35.3 |
| Previous ESA trt (Epoetin/Darbepoetin /CERA) | 86.1 / 82.6 / 83.0 | 12.7 / 15.1 / 14.3 | 1.2 / 2.3 / 2.7 | 36.9 / 44.2 / 36.7 | 68.4 / 66.4 / 63.3 | 65.1 / 63.8 / 56.7 | 34.9 / 36.2 / 43.3 |
| Diabetic pts (no/yes) | 83.7 / 85.7 | 14.2 / 13.4 | 2.0 / 1.0 | 37.4 / 40.9 | 63.2 / 70.1 | 63.2 / 64.6 | 36.8 / 35.4 |

Evaluation Phase (V7-V9)

CONCLUSIONS: Once monthly CERA trt maintained stable Hb-values with most pts having only a minimal Hb-fluctuation. These results could be confirmed for various subgroups, thus demonstrating that once monthly CERA is a suitable trt for pts suffering from CKD related anemia whith only few dose-changes needed.

**Bioimpedance Measurement for Volume in Patients with Chronic Kidney Disease Participating in the CanPREDDICT Study: Design of a Prospective Study and Results of a Single Centre Pilot** Trevor J. Wilkieson,[1] Mukesh Khandelwal,[1] Cathy Z. Kotsamanes,[1] Adeera Levin,[2] Azim S. Gangji,[1] Catherine M. Clase.[1] *[1]Medicine, McMaster University, Hamilton, ON, Canada; [2]Medicine, University of British Columbia, Vancouver, BC, Canada.*

**Background.** Volume status is difficult to assess clinically. Hypervolaemia may predispose patients to congestive heart failure (CHF) in the short term and in the longer term cause arterial changes and cardiac remodelling that lead to myocardial infarction (MI), stroke, and sudden death. Data on volume status in patients with chronic kidney disease (CKD) not on dialysis are sparse.

**Methods.** Nested in the multi-centre CanPREDDICT study, we conducted a single-centre pilot to examine the feasibility of conducting a substudy measuring bioimpedance in prevalent patients with CKD who were already participating in CanPREDDICT. We measured bioimpedance in triplicate on a single occasion. We analyzed the data according to the method of Piccoli, classifying patients based on the resistance (R) – reactance (Xc) graph. Primary outcomes for the pilot were the proportion of CanPREDDICT participants who were eligible and consenting to the substudy, and the proportion of substudy participants who were volume overloaded. For the main study, we plan to recruit 500 of 1136 CanPREDDICT participants in 7 to 9 centres and examine whether volume overload, assessed by bioimpedance predicts a primary outcome composite of stroke, MI, amputation for peripheral vascular disease, CHF or vascular death, with power of 0.7 to detect hazard ratios of 1.6 or greater.

**Results.** From 2009 December 09 through 2010 June 03, 57 consecutive CanPREDDICT participants were approached at their first return visit. Of these, 46 participants were eligible, 36 (78%) participated and 10 declined. Participants were 39% women, mean age 67 years, 44% were volume overloaded by RXc graph.

**Conclusions.** The study appears feasible; volume overload by RXc graph is prevalent.

**Association of Microalbuminuria with Family History of Renal Disease in Pediatric Nephrology Patients** Robert Woroniecki,[12] Karolina I. Woroniecka.[23] *[1]Pediatric Nephrology, Children's Hospital at Montefiore, Bronx, NY; [2]Center For Pediatric Kidney Diseases and Hypertension, Flushing, NY; [3]Undergraduate Studies, Brown University, Providence, RI.*

Microalbuminuria (MA) is a biomarker of subclinical cardiovascular disease, endothelial dysfunction and is a prognostic marker of kidney disease in patients (PTs) with diabetes mellitus (DM) and hypertension (HTN). MA has been associated with glomerular hyperfiltration (GHF) found in DM, metabolic syndrome (SX), sickle cell disease (SCD), and reported in children with chronic kidney disease, HTN, vesicoureteral reflux (VUR), single kidney, etc. However, it is unclear if MA in children is a marker of genetic predisposition to kidney disease, i.e. is associated with family history of renal disease/HTN. We examined the records of 35 PTs who were tested for MA due to following clinical indications: HTN (n=11), aplasia/hypoplasia (n=4), obstruction/dysplasia/reflux/pyelonephritis (n=10), cystic disease (n=6), and GHF (n=4) in SX, SCD and DM.

| | MA (n=14) | No MA (n=21) | P value |
|---|---|---|---|
| Age (years) | 12.9± 4.4 | 13.7±4.6 | 0.61t |
| Female (%) | 7 (50) | 9 (43) | 0.74f |
| Height percentile | 72.6±29.2 | 69.4±32.5 | 0.71t |
| MAP (mmHg) | 78.7±10.5 | 79.8±14.3 | 0.80t |
| SCr (mg/dl) | 0.65±0.21 | 0.71±0.21 | 0.39t |
| Birth weight (kg) | 3.27±0.59 | 3.45±0.37 | 0.47t |
| Positive FX (%) | 11 (78.6) | 9 (42.8) | 0.046f |
| Positive FX-HTN (%) | 9 (64.3) | 3 (14.3) | 0.004f |

MAP-mean arterial pressure, SCr-serum creatinine, FX: family history of dialysis, renal stones, cystic disease, and HTN, FX-HTN: family history of renal disease excluding idiopathic HTN, t-test, f-Fisher's exact, ± standard deviation.

We found an association between MA and FX, and no association with other tested variables. The association of MA with FX was stronger if idiopathic HTN was excluded from FX (table). PTs with FX had odds ratio (OR) of 4.9 (CI 1.05-22.84) of having MA, while there was no association of MA with PTs renal diagnosis, p=0.74. OR for PTs with FX-HTN having MA was 10.8 (CI 2.1-55.7). PTs with FX-HTN may be at risk of GHF and may benefit from early screening for MA.

Disclosure of Financial Relationships: nothing to disclose

**Wide Range Overt Proteinuria in Chronic Kidney Disease Patients with Diabetes Has Different Predictive Value for Renal and Cardiovascular Outcome** Keiko Yasuda, Koichi Sasaki, Masaki Hatanaka, Terumasa Hayashi. *Nephrplogy, Izumisano Municipal Hospital, Rinku General Medical Center, Izumisano, Osaka, Japan.*

Purpose: Recently, significance of proteinuria in chronic kidney disease (CKD) has been reevaluated since estimated glomerular filtration rate was adopted as the definition of CKD. Although CKD patients with diabetes mellitus (DM) have wide range overt proteinuria, its predictive value for renal and cardiovascular, has not been fully clarified.

Methods: 221 diabetic patients with CKD stage 2-5 not on dialysis were prospectively enrolled as a hospital cohort since August 2004. Exclusion criteria was age over 90, malignancy, active infection, low cardiac ejection fraction (<40%). Primary outcome was combined renal outcome of serum creatinine (Cr) doubling or end stage renal disease requiring dialysis. Cardiovascular events was also defined as secondary outcome. Valuables such as proteinuria and other established predictive factors were incorporated into Cox proportional hazards analysis to determine the independent predictors for renal and cardiovascular outcome.

Results: Mean follow-up period was 3.4±1.5 years. Mean age was 63.8±11.1 and 66% were men. Mean serum Cr and proteinuria level were 2.27±1.35mg/dl and 3.99±3.74g/day. The amount of proteinuria was significantly greater among 133 patients who reached the combined renal endpoint compared with 88 patients who did not (5.33±3.95g/day vs 1.95±2.19g/day, P<0.001). After adjustment with other established predictive factors, proteinuria (HR 1.190, 95%CI 1.103-1.284) and serum Cr (HR 1.466, 95%CI 1.178-1.824) were strongly and independently associated with renal outcome. In contrast, there was no significant difference in proteinuria level between patients with (4.20±4.01g/day, N=72) and without secondary outcome (3.88±3.61g/day, N=149). Cox univariate proportional hazard model revealed that proteinuria (HR 0.910, 95%CI 0.766-1.081) tended to be associated with secondary outcome.After adjustment, proteinuria (HR 0.937, 95%CI 0.781-1.123) was independently associated with secondary outcome.

Conclusion: Wide range overt proteinuria in CKD patients with DM has different predictive value for renal and cardiovascular outcome.

**Clinical and Pathological Analysis in the Serum HBV Antigen Negative and Antibody Positive Patients with Kidney Injury** Shengqiang Yu, Yuxian Zhu. *Institute of Nephrology, Shanghai Changzheng Hospital, Shanghai, China.*

**Objective:** To investigate the clinical and pathological characteristics in the serum HBV antigen negative and antibody positive patients with kidney injury. **Methods:** A total of 21 serum HBV antigen negative and antibody positive patients with kidney injury were included into this study. All of them were accepted routine laboratory analyses and renal biopsy. HBV-antigens (HBsAg and HBcAg) in renal tissues were detected by indirect immunofluorescence assay. **Results:** 7 of the patients revealed severe proteinuria which was diagnosed as nephrotic syndrome, 14 of them revealed non-nephrotic proteinuria. 3 of the patients were only serum HBcAb positive, 10 of them were serum HBsAb+HBcAb positive, 7 of them were HBsAb+HBeAb+HBcAb positive and 1 of them was HBeAb+HBcAb positive. All the patients' HBV-DNA copies were lower than 500 copies/ml. According to the renal biopsy, there were 7 patients diagnosed as HBV associated glomerulonephritis. **Conclusions:** The results suggested that renal biopsy, especially the HBV-antigen detection in renal tissue were very important to the patients with kidney injury whose serum HBV antigen negative and antibody positive.

**Do the Costs Born by the Nephrology Department in the Hospital Justify Its Transfer to a Health Establishment with a Short Stay Unit?** Juan Abascal Ruiz. *Nephrology, "Lozano Blesa" Universitary Hospital, Zaragoza, Spain.*

**OBJECTIVES:** The work developed by our department and its assistance complexity do not require all the necessary processes for the optimal functioning of a modern hospital. On the other hand, the work legislation makes the costs of specialized staff be larger if the work is done within a hospital or if it is done in another Health establishment.

**MATERIAL AND METHODS:** Throughout the years 2000-2008 we have studied the whole health activity of our department and the costs it generates. We have done the same with the Hospital general costs and their fraction assigned to our department. The established method has been: For Human Resources the distribution of work loads measured in hours considering the hour as the unit of technical value. For the health assistance we have applied microeconomics techniques (analytical management) and established the doctrine of homogeneous functional group.

**RESULTS:** They are exposed for each homogeneous functional Group (hospitalization, consultations and its areas, interventionist Nephrology, hypertension maps, intravenous iron, haemodialysis and peritoneal haemodialysis and intra-hospital and emergencies. The cost of staff in our department is 47.61%; The functioning costs are 31.32%; The costs of using other services are 17,15% and the structure costs of other services are 3.65% of our budget.

**DISCUSSION:** Considering another alternative in the use of public financing in Health is simple possible with a more rational use of resources and looking for the achievement of its cost-effectiveness with the application of technical criteria and social management mechanisms of the resources disregarding its finalist pre-assignment.

**SUMMING UP:** The ability to negotiate is possible in the 83.85% of our Department ´s budget considered as final cost unit. The possibility of negotiating, with existing work legislation can be done above the 47.61%. The saving percentage of 10 points is possible on the 10.90% of present budget.

**PUB260**

**Australian Home Dialysis Uptakes Vary Markedly, State by State and within States. Better High-to-Low Home-Achiever Protocol Sharing Is Required** John W. M. Agar, Carmel M. Hawley. *Home Dialysis Advisory Group, Kidney Health Australia, Melbourne, Victoria, Australia.*

**Introduction:** Australian home-based dialysis therapy (HBDT) uptake varies markedly, state by state. Individual renal unit home haemodialysis (HHD) utilisation ranges 1% to 22% while peritoneal dialysis (PD) ranges 15-46% while the national mean is 10% (HHD) and 22% (PD). Despite this known interstate data, intra-state unit vs unit HBDT utilization has not been documented.

**Aim:** To document unit-by-unit HBDT uptake for all major Australian dialysis services and to determine if HBDT utilisation is uniform within each state or if it also varies widely.

**Method:** Using ANZDATA (December 2008), we compared the % of facility-based HD (FHD) with the % of HBDT (both HHD and PD) for all 32 Australian units with >100 total all-modality dialysis patients, both inter-state across all states and territories and intra-state within each state.

**Results:** While some states were uniformly low HBDT achievers – in part explained by geographic and demographic differences – within states with the highest HBDT achieving units were other units which ranked among the lowest HBDT achievers. While the unit with the highest HBDT [one of the largest units in Australia] recorded 20% HHD and 46% PD (66% HBDT) and only 34% FHD, several large units recorded total HBDT rates of <20%. A unit-by-unit breakdown of HBDT uptake within each state confirmed similar marked intra-state variability with some renal units within the same state achieving HBDT penetration rates of 2-3 times those of other like renal units within that state. This variable high-to-low HBDT utilisation pattern recurred across most states.

**Conclusion:** State vs state variability in HBDT uptake may be due to state-specific demographics and geography or to differing state funding models or unit/patient-directed incentive programs. However, inter-unit variations within individual states are more likely the result of local, unit-specific medical and/or nursing expertise or bias, home training logistics or HBDT emphasis during pre-dialysis education. We believe that HBDT uptake may be improved by high to low achiever inter-unit protocol-sharing and staff education.

**Lessons from Implementing the Advanced CKD Patient Management Toolkit (ACPMT)** Jameta N. Barlow,[1] William E. Haley,[2] Uptal D. Patel.[1] *[1]Duke Univ, Durham, NC; [2]Mayo Clinic, Jacksonville, FL.*

**Background:** Management of advanced CKD can be facilitated by improvements in care processes; however, successful implementation of quality improvement (QI) interventions is challenging. During a QI study of the Renal Physicians Association's ACPMT (consisting of 16 management tools) in 10 community nephrology practices, we sought to assess lessons learned by practices from the implementation experience.

**Methods:** After completion of the 6 month intervention, we conducted 13 semi-structured interviews of key clinical or managerial personnel (medical/physician assistant, nurse, nephrologist, office manager, and social worker) from 8 study sites (2 pending). Interviews were recorded, transcribed, and qualitatively analyzed using the constant comparative method to assess practices' experience with implementing the ACPMT.

**Results:** Interviewees' responses revealed 3 lessons related to their implementation experience. Facilitators that optimized the practice to the QI intervention included ensuring ongoing engagement across all staff, defining and measuring local goals, and customizing QI processes and components of the ACPMT. Barriers to implementing the QI intervention included limited ability to use ACPMT components with electronic medical records, low perceived value of some tools by physicians, exigencies of clinical work flow, and limited patient interest in patient-specific tools. Finally, the dedicated QI effort prompted increased team spirit surrounding the management of advanced CKD care. Consequently, despite expressed disappointment upon finding that there were limited improvements in performance measures across all study sites, strong endorsement for the QI experience remained with all sites stating that they have continued using the ACPMT.

**Conclusion:** A diverse sample of community nephrology practices was able to implement the ACPMT after customizing some components of the intervention. The barriers and facilitators encountered were common to QI implementation. Despite minimal impact on improving performance measures, this QI experience has catalyzed ongoing continuous QI efforts within participating practices.

**Captopril Mitigates Chronic Renal Failure after Bone Marrow Transplant: Extended Follow-Up of a Randomized Trial** Manpreet Bedi,[2] John E. Moulder,[2] Eric P. Cohen.[1] *[1]Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Radiation Oncology, Medical College of Wisconsin, Milwaukee, WI.*

We have tested captopril compared to placebo in adults and children undergoing radiation-based bone marrow transplant (BMT, hematopoietic stem cell transplant). There is better kidney function and better patient survival in subjects on captopril (n=28) compared to placebo (n=27) (Int J Radiat Biol Oncol Phys, 2008). Use of captopril was as a mitigator, not as a radioprotector, i.e. the drug was started one month after irradiation and continued for up to one year thereafter. We have extended this study by longer follow-up and by addition to it of contemporaneous subjects eligible for the study but who did not enroll (n=74). This non-study cohort is added to the placebo group to create a larger no-drug group for this analysis. Endpoints are BMT nephropathy/HUS and patient survival. The captopril group had only one case of BMT nephropathy, while there are 11 in the combined no-drug group. Patient survival is better in the subjects on captopril compared to the no-drug subjects (p=0.07 for the actuarial curves). Median days of patient survival are 309 in the combined no-drug group, and 724 days for those on captopril. Safety analysis showed no difference in adverse event rates between the captopril and the placebo groups, and there was no difference in cancer relapse rates. We conclude that captopril is an effective and safe mitigator of chronic renal failure after radiation-based BMT.

**The Experiences of Close Persons of ESKD Patients on Maximum Conservative Management: A Narrative Study** Aine Burns,[1] Joe T. Low,[2] Jason Myers,[2] Sheila J. Johnston,[1] Louise Jones.[2] *[1]Centre for Nephrology, University College London, London, United Kingdom; [2]Marie Curie Palliative Care Research Unit, University College London, London, United Kingdom.*

Background: Close persons play an important role in the care of elderly renal patients, though few studies have looked at the impact on those caring for patients who have elected not to dialyze and are following a maximum conservative management (MCM) care pathway. Such patients do not undergo dialysis, but are offered other medical support to prolong life and alleviate symptoms. Aims: To explore (i) the impact of end stage kidney

disease (ESKD) on the main close persons of patients with chronic kidney disease stage 5 who opt for MCM and (ii) how support for close persons can be improved. Methodology: Qualitative interviews were carried out with 26 purposefully sampled close persons across five London renal centers, using a narrative approach. Findings: The following key themes were identified: the specific diagnosis of ESKD had little impact on close persons as patients already had other chronic health problems; close persons understood patients' decisions to not dialyze, but had little influence in the final decision; close persons only had a vague understanding of the nature and implications of MCM; the quality and depth of the relationship between the close person and patient determined what care was provided with other family members and friends playing supporting roles; close persons appreciated the support provided by the renal teams, though they identified areas for improvement such as out of hours advice; there was less satisfaction with the continuity in the general provision of health care; close persons experienced uncertainty about the long term future, and only a few discussed end of life issues with patients. Conclusion: Close persons were satisfied with care provided by renal services, though areas for improvement included "out-of hours" support, better continuity of care across medical specialties, handling of crisis situations and uncertainty about the future. This unique examination of close person experiences provides evidence for the development of interventions to improve the lives of this important group.

Disclosure of Financial Relationships: nothing to disclose

## PUB264

**A Narrative Study of the Experiences of Patients with Kidney Disease on a Maximum Conservative Management (MCM) Programme** Aine Burns,[1] Joe T. Low,[2] Sarah Davis,[2] Henry W. L. Llewellyn,[2] Louise Jones,[2] Sheila J. Johnston.[1] *[1]Centre for Nephrology, UCL, London, United Kingdom; [2]Dept of Mental Health Science, UCL, London, United Kingdom.*

Dialysis treatments are widely available, but for elderly patients with multiple co-morbidities, they may have no benefit to quality of life or survival. For these patients, Maximum Conservative Management (MCM) is becoming more widely available across the UK, wherein renal teams have responsibility for providing a generalist palliative approach with input from palliative care specialists. Little is known about the experiences of patients on MCM and about how they make and cope with the decision not to have dialysis. This qualitative study explores narratives of patients on MCM programmes about their illness and experiences of the care they receive. Semi-structured interviews aim to elicit patients' narratives on their illness, coping styles, decisions around care (especially with reference to their decision not to have dialysis) and their experiences of MCM itself. Verbatim transcripts are analysed thematically using a constant comparative approach. Recruitment is ongoing with 10 patients of 25 recruited. Emerging themes reveal the complexity of perceived clinical, psychological and social factors in decisions regarding care, and the pervasiveness of typically negative second-hand experiences of dialysis. Equanimity around death in this population may explain their rejection of life-prolonging treatment in favour of less invasive care. However, most patients do not consider their decision to be final, even though dialysis would no longer be clinically appropriate for some in the very late stages of disease. Patients consider the decision to be theirs, though welcome guidance from their clinical teams and families. Despite some vagueness in patients' definition and description of the MCM programme, they feel well-supported by the approach's holistic structure. This study thus confirms the viability of MCM and underscores the importance that clinicians are aware of the weight and complexity of decisions regarding care.

## PUB265

**Carotid Atherosclerosis (CA) and Body Composition Assessment by Bioelectrical Vectorial Impedance (BIVA) in Chronic Kidney Disease (CKD) Patients Stage 2 – 5nd** Secundino Cigarran,[1] Francisco Coronel,[3] Montserrat Pousa,[1] Ignacio Docal,[1] Guillermina Barril,[4] Emilio E. Gonzalez-Parra.[2] *[1]Nephrology, Hospital Da Costa, Burela, Lugo, Spain; [2]Nephrology, Fundación Jimenez Díaz, Madrid, Spain; [3]Nephrology, Hospital Clinico Universitario de San Carlos, Madrid, Spain; [4]Nephrology, Hospital Universitario de la Princesa, Madrid, Spain.*

Evidence suggests atherosclerotic vascular diseases are a major cause of morbi-mortality in CKD patients. The prevalence of CA by ultrasonoghraphy was significant higher in CKD than general population. The aim of corss-sectional study is to assess the relationship of CA with body composition markers. 227 pts with CKD stage 2-5, were examined by high-resolution B-mode ultrasonography (USBM) with a 7.5MHZ linear array probe ( LogiQ PRO, GEE . USA). Body composition assessment was performed by whole tetrapolar bioelectrical vectorial impedance analysis (BIVA) ( EFG, Akern Firenza Italy). Data derived derived from BIVA were Na-K exchange, Phase angle, body cell mass /ecw ratio, PA standarized (PA and PA± std derived from healthy population).Data were analyzed by SPSS15.0. 58 pts had not CA. 168 (74.4%) had CA and compared with non CA were older (68.66±10.1 vs 54.34 ±10.5 years, P<0.001), Diabetic (36.1 vs 17.3% , p<0.001).

T-Paired test

| Variable | Non CA (N=58) | CA (N=169) | P |
|---|---|---|---|
| Na-K exchange | 0.96±.14 | 1.05±.19 | .001 |
| Body Cell Mass (%) | 50.91±5.48 | 49.64±6.22 | .001 |
| ECW (%) | 46.96±4.62 | 48.96±4.68 | .001 |
| ICW (%) | 53.03±4.62 | 51.04±4.69 | .001 |
| Resting Energy Expenditure (cal/day) | 1510.1±254.8 | 1430±272.3 | .046 |
| BCM/ECW (Kg/L) | 1.46±.30 | 1.32±.31 | .001 |
| Phase Angle(º) | 5.81±.9 | 5.42±.92 | .001 |
| PA standarized | -.62±.82 | -.98±.83 | .001 |
| Hb (gr/L) | 13.70±1.49 | 13.14±1.54 | .001 |
| Albumin (gr/dl) | 4.45±.29 | 4.30±.31 | .001 |

CA= Carotid Atehosclerosis. ECW extracellular water. ICW intracellular water.

No other significance was met.

CA is associated to older, lower GFR , diabetic and cellular damage expresed by increased Na-K exchange, lower PA, PA std, and BCM/ECW ratio. Further clinical trials are required to explain this biologic significance.

Disclosure of Financial Relationships: nothing to disclose

## PUB266

**Cost-Effectiveness of Adding Aliskiren to Losartan and Optimal Antihypertensive Therapy in Patients with Hypertension, Type 2 Diabetes, and Nephropathy with Residual Proteinuria** Thomas E. Delea,[1] Aaron Moynahan,[1] Charu Taneja,[1] Helen Lau,[2] Jean Lian,[2] Hans-Henrik Parving,[3] Sean D. Sullivan.[4] *[1]PAI (Policy Analysis Inc.), Brookline, MA; [2]Novartis Pharmaceuticals Corp., East Hanover, NJ; [3]Rigshospitalet, University Hospital of Copenhagen, Copenhagen, Denmark; [4]University of Washington, Seattle, WA.*

**Background**: AVOID was a randomized, double-blind, 6-mo. study of adding aliskiren to losartan and optimal antihypertensive therapy (AHT) in patients with hypertension, type 2 diabetes, and nephropathy with residual proteinuria (urinary albumin creatinine ratio [UACR]>100 mg/g) after ≥3 mo. of 100 mg/d losartan. Aliskiren reduced mean UACR by 20% vs placebo (P=.009).

**Methods**: A Markov model was used to project lifetime incidence of myocardial infarction (MI), stroke, heart failure (HF) and end-stage renal disease (ESRD), life years (LYs), quality-adjusted life years (QALYs), and expected lifetime costs (US healthcare system perspective) with losartan + AHT with or without aliskiren. Albuminuria progression by treatment was projected by generalized linear model regression equations fit to UACR data from AVOID. Probabilities of CVD/ESRD by UACR and death without CVD/ESRD by age were obtained by calibrating the model to yield results for losartan and placebo in the RENAAL study. Other probabilities, costs, and utilities were based on published sources.

**Results**: If effects of aliskiren on progression of UACR observed in AVOID are maintained while on treatment, adding aliskiren is projected to reduce lifetime incidence of ESRD by 5% and MI/stroke/HF by 4% vs. losartan and AHT only. LYs are increased by 0.17; QALYs by 0.09. Savings from averted MI/stroke/HF ($5400) and ESRD ($11,800) more than offset additional cost associated with aliskiren treatment. Savings in total lifetime costs with aliskiren are $7500. Findings are sensitive to the assumed duration of aliskiren benefit.

**Conclusion**: Adding aliskiren to losartan + AHT in patients with hypertension, type 2 diabetes, nephropathy and residual proteinuria is projected to reduce costs and increase QALYs and may be cost-effective from a US healthcare system perspective.

## PUB267

**Supporting Pathways to Palliative Care for People Diagnosed with Chronic Kidney Disease** Robert G. Fassett,[1,2] Helen G. Healy,[1] Iain Robertson,[3] Loren M. Youl,[4] Sarah Anne Challenor,[5] Rose Mace,[5] Rosalind M. Bull.[4] *[1]Renal Medicine, Royal Brisbane Hospital, Brisbane, Queensland, Australia; [2]Medicine, University of Queensland, Brisbane, Queensland, Australia; [3]School of Human Life Sciences, University of Tasmania, Launceston, Tasmania, Australia; [4]Nursing and Midwifery, University of Tasmania, Launceston, Tasmania, Australia; [5]Renal Unit, Launceston General Hospital, Launceston, Tasmania, Australia.*

Aims;To identify current practice of offering palliative care and compare with evidence-based best practice and determine associations between initiation of palliative care and predictors of uptake of conservative care.

Background: The increasing acceptance of elderly onto dialysis programs has heightened interest in and study of the process of end-of-life decision-making in ESKD, and the role of palliative care in the later stages of treatment. A chart review was conducted as part of a wider research program to describe current clinical practice.

Methods: A chart review of the 45 CKD and dialysis patients who died in 2006-2008 in North Tasmania aimed to determine the associations between patient or family request, or actual withdrawal of RRT and/or referral for palliative care, and recorded potential predictors of withdrawal in the last 12 months of life. Qualitative and quantitative analysis was performed.

Results: The presence of, advanced health care directives, patients wish to die, and stroke were associated with family request for withdrawal. The loss of will to live, behavioural changes, severe pain, loss of ADLs were associated with patient request for

withdrawal. Expressed need to die, behavioural changes, loss of ADLs and appetite were associated with actual withdrawal. There was a cycle of ambiguity as patient and families change their minds about treatment withdrawal. Who controls this process fluctuates from time to time. A limited range of language is used to express the recognition of the need to die.

Conclusion: Loss of function, particularly from stroke, and severe pain are interpreted as representing levels of suffering which would justify the need to withdraw. The influence of patient, family and clinicians on this decision involves negotiation and equivocation.

**Measure of Satisfaction with Body Image of Patients Undergoing Chronic Hemodialysis** Simone Adriana Guaraldo,[2] Geison Stein Meirelles Ramos,[1] Clarissa B. B. Uezima,[1] Bárbara Margareth Menardi Biavo,[2] José Adeirton Bezerra da Silva,[1] Everton Aparecido Teodoro,[1] Mary E. C. Costa,[1] Camila Machado de Barros,[2] Elzo R. Junior,[2] João Paulo L. B. Martins,[1] Elvino Barros,[3] Carmen B. Tzanno-Martins.[1] *[1]Integrated Center of Nephrology, Guarulhos, São Paulo, Brazil; [2]Home Dialysis Center, São Paulo, São Paulo, Brazil; [3]Federal University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil.*

**Objective**: To evaluate satisfaction with body image concerning the general characteristics of this population.

**Methodology:** Cross-sectional study with 73 patients undergoing chronic hemodialysis, with preserved cognition, confirmed by the Modified Mini-Mental (3MS) test application. 39 of them were male (53.4%) and 34 female (46.6%). Demographic data (gender, age, dialysis time), body mass index (BMI) and silhouette scale were evaluated in order to assess body image (current silhouette, ideal silhouette and one year ago silhouette - Sunkard and Sorensen, 1993).

**Results:** The mean age was 52.18 ± 14.87 years, hemodialysis time was 25.64 ± 25.30 months, mean BMI was 24.5 ± 5.18 kg / m². 39 patients (53.4 %) were well nourished. Most male (74.4%) and female (73.5%) were dissatisfied with their body image. Patients dissatisfied with their body image were those in the beginning of hemodialysis and those with more than 2 years of treatment. The group that showed higher satisfaction were the eutrophic ones. However 64% of them were dissatisfied. All groups showed a high percentage of dissatisfaction regardless of the compared variables.

**Conclusion:** Most patients undergoing chronic hemodialysis are dissatisfied with their body image, regardless of the compared variable. Thus, we suggest that aesthetic, nutritional and physical education interventions are implemented in order to bring benefits to this population.

**Participate in Activities of Daily Living Scale and Nutritional Assessment of the Elderly** Yukihiro Nishimoto. *Dept. of Nephrology and Dialysis, Chukyo-Kosei Clinic, Nagoya, Aichi, Japan.*

Activities of daily living scale (ADL) deterioration in the elderly patients has influence on an action in eating, transference of walking or wheelchair. However, its utility in the relation with biochemical parameter are not elucidated clearly for circumstances, respectavily. In this study it was to investigate the relation of nutritious state to eating condition, transference, age, nursing level and biochemical parameters.

ADL was evaluated at three classified eating actions, six classified transfer conditions, five classified nursing levels. Albumin, pre-albumin, retinol binding protein, cholinesterase and transferrin were measured (n=84; 25male and 59female)

Both eating actions and transfer ability level decreased, albumin level (3.9+/-0.1 vs. 3.6+/-0.1 g/dl, p<0.01), pre-albumin level (21.8+/-0.8 vs. 18.0+/-1.4 mg/dl, p<0.05), cholinesterase level (256+/-9.4 vs. 185+/-14.3 U/l, p<0.01) and transferrin level (221+/-6.0 vs. 179+/-9.5 mg/dl, p<0.01) decreased significantly. There were no significant differences between age and biochemical analysis. Pre-albumin, retinol binding protein, cholinesterase along with transferrin and albumin in particular decreased significantly in relation to higher required levels of nursing support. Data from hemodialysis patients is still under analysis. ADL, albumin and transferrin levels were quantitative correlation. In addition, long half-time assay were significant differences. These results suggested that long half-time studies are relatively adequate and valuable in the index.

**Examination of Understanding of Prognosis and Disease Progression in Elderly Patients with Advanced Kidney Disease** Jane O. Schell,[1] Uptal D. Patel,[1] James Tulsky.[2] *[1]Nephrology, Duke University, Durham, NC; [2]Center of Palliative Care, Duke University, Durham, NC.*

CKD is a common condition in an aging population. Elderly patients who progress to kidney failure suffer increased disability, morbidity, and mortality. Yet, little is known about how well these patients understand their diagnosis and its prognosis in order to plan for the future. Our goal was to describe, through focus groups and in-depth interviews, how elderly patients at different CKD stages understand their disease course.

**Methods:** From one academic and one community nephrology practice, we recruited 23 subjects over age 65 who were receiving dialysis or had documented CKD. Patients participated in either an in-depth interview (n=11) or focus group (n=22 in four groups). All interviews were audio-recorded and transcribed. We used qualitative content analytic methods with open and axial coding to identify common and recurrent themes describing how disease progression is explained, understood and experienced by the patient.

**Results:** Patients reported that kidney disease was frequently explained to them using medical terminology and blood chemistry levels with considerably less emphasis on prognosis. Patients described their experience with CKD and impending dialysis as one of fear and worry. Many of them had thought little about the future, either because they were unaware of how ill they were, or simply chose not to. When they did, their thoughts about the future were dominated by uncertainty and lack of knowledge of what the future might hold.

**Conclusions:** Because elderly CKD patients are at high-risk for increased disease burden and disability, understanding of disease progression may assist in goals of care planning and preparation for the future. This study highlights limitations in how patients understand and are prepared for their kidney disease course. Improved communication techniques may enhance elderly CKD patient understanding and experience.

**How Do Nephrologists Discuss Prognosis and Disease Progression with Chronic Kidney Disease Patients?** Jane O. Schell,[1] Uptal D. Patel,[1] James Tulsky.[2] *[1]Nephrology, Duke University, Durham, NC; [2]Center of Palliative Care, Duke University, Durham, NC.*

End stage renal disease (ESRD) is a chronic life-limiting illness that impacts patient survival, quality of life and functional status. Despite the tremendous effect ESRD has on patients' lives, we know little about how nephrologists discuss prognosis and disease progression with patients. Our goal was to document from nephrologist descriptions, through focus groups and in-depth interviews, how they communicate prognosis and disease progression to their patients.

**Methods:** We conducted focus group and in-depth interviews with 12 nephrologists from two nephrology practices (one academic and one community). All interviews were audio-recorded and transcribed. We used qualitative content analytic methods with open and axial coding to identify common and recurrent themes of how nephrologists discuss prognosis and disease progression with patients.

**Results:** Discussions of disease progression depended upon patient factors, including comorbidities and age, and clinical factors, such as rate of renal function decline. Discussions of prognosis were noted to be infrequent, especially within the advanced CKD population. When these conversations did occur, they were generally prompted by the patient or a decline in clinical status. All nephrologists expressed that it was their role to have these discussions with their patients. Nevertheless, nephrologists described perceived barriers to engaging in these conversations including insufficient time to spend with patients, the potential negative impact on patient hope, and the lack of privacy for conducting discussions with ESRD patients in dialysis units.

**Conclusions:** Discussions of disease progression and prognosis in patients with chronic life-limiting disease such as ESRD can be challenging. How nephrologists engage in these conversations may impact patients' experience and preparation. This study describes nephrologists' perceptions about discussions of disease progression and prognosis. By studying how nephrologists talk to patients, future communication techniques can be developed to improve patient care.

**PUB272**

**How Many Courses of Steroid Pulse Therapy Are Necessary for the Induction of Remission in IgA Nephropathy? A Retrospective Study on Tonsillectomy Plus Steroid Pulse Therapy** Takahiro Uchida,[1] Takashi Oda,[1] Keishi Higashi,[1] Kojiro Yamamoto,[1] Taketoshi Kushiyama,[1] Toshitake Hyodo,[1] Naoki Oshima,[1] Soichiro Miura,[2] Hiroo Kumagai.[1] *[1]Department of Nephrology, National Defense Medical College; [2]Department of Internal Medicine, National Defense Medical College, Tokorozawa, Saitama, Japan.*

Recently, tonsillectomy plus steroid pulse therapy has been reported to be quite effective for the treatment of IgA nephropathy, however, no data is available regarding the optimal number of courses of steroid pulse therapy in the protocol. We therefore conducted a retrospective study as to the relation between the number of courses of steroid pulse therapy and the therapeutic effects. Between 2002 and 2009, we identified 159 patients as IgA nephropathy by renal biopsy in our renal department and 34 of them received tonsillectomy plus steroid pulse therapy. Twenty-three patients received 3 courses of steroid pulse therapy, 1 patient received 2 courses, and 10 patients received 1 course. We compared therapeutic effects between those patients received 3 courses and 1 course. No significant basal difference was found between the two groups in terms of gender, age, urinary protein, hematuria, serum creatinine or estimated GFR. In 23 patients treated with 3 courses of steroid pulse therapy, 13 patients obtained clinical remission (complete disappearance of urinary abnormalities, including proteinuria and hematuria) and 18 patients experienced disappearance of hematuria. On the other hand, in 10 patients treated with 1 course of steroid pulse therapy, 4 patients obtained clinical remission and 9 patients experienced disappearance of hematuria. No statistical difference was found in clinical remission or in disappearance of hematuria between the two groups ($p$=0.25, and $p$>0.99, respectively). These data suggest that only one course of steroid pulse therapy may be necessary and sufficient for the induction of remission in IgA nephropathy treated with tonsillectomy plus steroid pulse therapy.

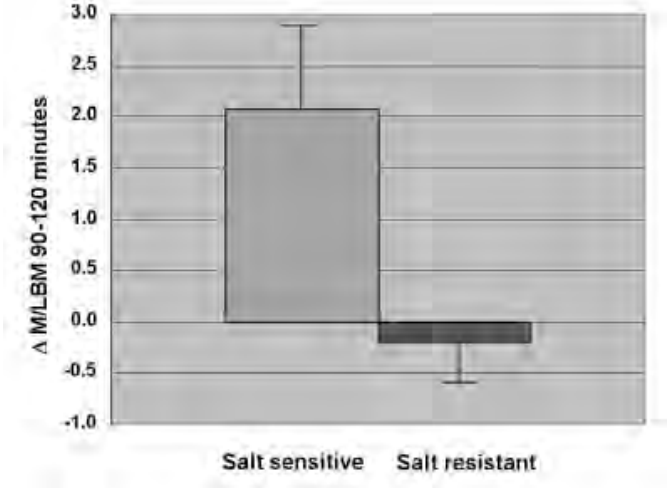
**Type 2 Diabetics (T2D) with Salt-Sensitivity (SS) Substantially Improve Lipid Control and Insulin Sensitivity on a Paleolithic-Type Diet** Lynda A. Frassetto, Shelley L. Mccoy, Anthony Sebastian. *University of California San Francisco.*

**Background:** Dietary salt can induce insulin resistance in rats and men. In soleus muscle, salt loading induced significant insulin resistance in the Dahl-SS, but not Dahl-SR (salt resistant) rats. In normal weight men on a 200 mmoL salt diet for 5 days, insulin sensitivity [mean insulin mediated glucose disposal (M values)] measured by euglycemic hyperinsulinemic clamp (EHC) decreased 15%.

**Methods:** T2D patients on their usual diets were randomized to a lower salt diet, either a "Paleo"-diet (excludes dairy, legumes and grains, n=9) or an ADA diet (n=6) for 2 weeks. Subjects had one EHC and flow mediated dilation of the brachial artery (BAR, a measure of elasticity), and repeat fasting lipid, glucose and BP measures on the last 3 days of their usual and study diet. BPs were measured after 5 minutes sitting, in triplicate. Subjects were considered SS if BP decreased ≥ 5 mmHg. All measures were averaged, results reported as mean±SD.

**Results:** Both study diets improved glucose and lipid values. The Paleo diet induced *greater improvements* in glucose (p=0.04) and total cholesterol (TC, p=0.006) compared to the ADA diet, as well as in MAP (p=0.05). BP did not fall with the ADA diet (=SR). BP fell with the Paleo-diet in 7 subjects (=SS) and not in 2 (=SR) (MAP -5±3 vs +4±2 mmHg, p=0.003). With the Paleo-diet, SS compared to SR subjects had lower TC (-39±30 vs -18±15 mg/dL), LDL-chol (-25±20 vs -6±2 mg/dL), glucose (-27±30 mg/dL vs -20±33 mg/dL) and fructosamine (-37±33 vs -15±35 mmol/L). SS T2Ds had greater improvement in insulin sensitivity (M value +2.1±2.8 vs -0.2±0.6) and a 19 % improvement in BAR vs 10 % in the SR group (SR, 5.1 ±0.3 to 5.7±0.6%; SS, 5.2±0.7 to 6.2 ±1.2%).



**Conclusions:** A Paleo-diet is superior to an ADA diet in improving metabolic abnormalities in T2D; SS T2Ds particularly benefit from a low salt Paleo-diet.

**Comorbidities and Survival of Patients with Type 1 Diabetes on Renal Replacement Therapy** Jaakko Helve,[1] Mikko Haapio,[2] Per-Henrik Groop,[3] Carola Gronhagen-Riska,[2] Patrik Finne.[1] *[1]Finnish Registry for Kidney Diseases, Helsinki, Finland; [2]Division of Nephrology, Helsinki University Central Hospital, Helsinki, Finland; [3]Folkhälsan Research Center Biomedicum Helsinki, Folkhälsan Institute of Genetics, Helsinki, Finland.*

**Objective:** To estimate effect of comorbidities on survival of patients with type 1 diabetes on renal replacement therapy.

**Research design and methods:** An incident cohort of all patients with type 1 diabetes entering chronic renal replacement therapy (n=656) in Finland between 2000 and 2008 was followed until death or the end of follow-up on 31 December 2008. All data were obtained from the Finnish Registry for Kidney Diseases, which collects information on comorbidities at the start of renal replacement therapy. Main outcome measure was relative risk of death according to comorbidities.

**Results:** At start of renal replacement therapy, 22% of patients had coronary artery disease, 18% peripheral vascular disease, 10% cerebrovascular disease, 33% left ventricular hypertrophy, and 7% heart failure. All these comorbidities were significant predictors of death in univariate analysis (RR 1.6-4.9). The 5-year survival probability of patients without comorbidities was 74%, while it was 56% and 37%, respectively, for those with one or more than one comorbidity. When the comorbidities were studied in a multivariate model, adjusting for age and gender, peripheral vascular disease (RR 1.9), left ventricular hypertrophy (RR 1.7) and heart failure (RR 2.5) remained independent risk factors of death. One third of deaths in the study population could be attributed to comorbidities.

**Conclusions:** Among patients with type 1 diabetes entering renal replacement therapy, comorbidities are common and strong predictors of death. Therefore, it is essential to identify and adequately treat comorbidities.

**Clinical Significance of Urinary Fibrin/Fibrinogen Degradation Product (u-FDP) in Diabetic Nephropathy: Correlation with Proteinuria, and Effectiveness of Anticoagulant Therapy** Takehiko Kawaguchi, Yasuhiro Ohtsuka, Keiji Horike, Daijo Inaguma, Asami Takeda, Kunio Morozumi. *Department of Nephrology, Japanese Red Cross Nagoya Daini Hospital, Nagoya, Japan.*

Background: Coagulation/fibrinolysis system is involved in intraglomerular inflammation of kidney diseases. It is assumed that urinary fibrin/fibrinogen degradation products(u-FDP) be associated with the pathogenesis and activity of diabetic nephropathy(DMN), and that anticoagulant therapy be effective for the reduction of proteinuria.

Method: Data on 18 DMN patients with nephrotic syndrome, who anticoagulant therapy with heparin and the sebsequent warfarin were newly initiated for, were analyzed. All the patients had already taken angiotensin-converting enzyme inhibitors(ACEI) or angiotensin II receptor blocker(ARB) for renoprotection before the anticoagulation. The treatment target was to prolong the activated partial thromboplastin time(aPTT) with unfractionated heparin to 2 times the mean of the control value, and to prolong prothrombin time international normalized ratio(PT-INR) with warfarin to 2.0. Pearson's correlation coefficient(r) was used to identify cross-sectionally the relationship between u-FDP and urinary protein(u-Pro). Paired t-test was also used to examine the difference in u-FDP and u-Pro between means in patinets before and after the anticoagulation.

Results: The mean age of the patients was 62±11 years, and 56% were female. The mean values of mean blood pressure, serum creatinine, eGFR, serum albumin, u-Pro and u-FDP were 95±10mmHg, 2.8±1.4mg/dl, 25±17ml/min/1.73m$^2$, 2.8±0.6g/dl, 6.5±2.8g/gCr, 18,000±25,000ng/ml, respectively. A significant positive correlation was observed between u-FDP and u-Pro both at baseline(r=0.77, p=0.0005) and one month after the treatment(r=0.84 , p<0.0001). The mean u-FDP and u-Pro after the treatment was both significantly reduced from baseline(uFDP: 12,100±20,200ng/ml, p=0.02, u-Pro: 4.6±2.3g/dl, p=0.001).

Conclusion: This preliminary analysis on DMN suggested that u-FDP was highly correlated with u-Pro, and that anticoagulant therapy could have an impact on renoprotection. Further studies are needed to confirm the effectiveness of anticoagulation for DMN.

**The Remedial Effect of Strict Diet Treatment and Exercise Therapy Using Information Technology (IT) on Metabolic Syndrome** Hideyasu Kiyomoto,[1, 5] Tadashi Sofue,[1] Daisuke Nakano,[2] Kumiko Moriwaki,[3] Atsuhiro Ichihara,[4] Akira Nishiyama.[2, 5] *[1]Division of Nephrology and Dialysis, Department of CardioRenal and CerebroVascular Medicine, Faculty of Medicine, Kagawa University, Kagawa, Japan; [2]Department of Pharmacology, Faculty of Medicine, Kagawa University, Kagawa, Japan; [3]Division of Nephrology & Hypertension, University of Miami, Leonard M. Miller School of Medicine, Miami, FL; [4]Department of Endocrinology & Anti-Aging Medicine, Keio University School of Medicine, Tokyo, Japan; [5]Team Kagawa, Consortium to Conquer Diabetes, Kagawa, Japan.*

[Background] The number of metabolic syndrome (MS) patients is increasing exponentially in the modern society. MS causes chronic kidney disease, but early aggressive intervention prevents it from progressing to renal failure. In this prospective study we examined if the supporting system of strict diet treatment and exercise therapy using IT is effective in treating metabolic syndrome. [Method] We divided 60 untreated MS patients into 4 groups of exercise therapy, diet treatment, combination therapy of them, and their own effort by the lot. We obliged them to carry pedometers managed on the internet and report their meals by signing up for accounts on the website, and conducted the anti-obesity program under strict direction of trainers and nutritionists for 6 weeks. Insulin resistance of every subject was estimated by tolerance to meal before and after the program to reduce their weight for 6 weeks. [Results] The remedial effects on MS such as significant reduction in BMI, leptin, MDA-LDL, glucagon, and insulin resistance were observed in every group except the one of their own effort. There was no change in renal function, urinary albumin excretion, plasma renin activity, and serum aldosterone level, however a positive correlation between improvement of BMI and decrement of systolic blood pressure was observed. In 6 weeks of short-term program, sole therapies of exercise or diet treatment were less effective, but the combination therapy of them showed the prominent additive effect. [Conclusion] Strict correction of lifestyle using IT is useful in treating MS.

**The Pattern of Clinical Practice Affects on the Outcome in Diabetes Mellitus** Ho Seok Koo,[1] Sewon Oh,[3] Yunjung Oh,[1] Dong Ki Kim,[1] Ho Jun Chin,[3] Kook-Hwan Oh,[1] Ki Young Na,[2] Kwon Wook Joo,[1] Chun-Soo Lim,[4] Yon Su Kim,[1] Dong Wan Chae,[3] Curie Ahn,[1] Jin Suk Han,[1] Suhnggwon Kim.[1] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Department of Internal Medicine, Catholic University College of Medicine, Seoul, Republic of Korea; [3]Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul, Republic of Korea; [4]Department of Internal Medicine, Seoul National University Boramae Hospital, Seoul, Republic of Korea.*

Background:The diabetic nephropathy is the leading cause of ESRD.Many guidelines are published for DM,CKD but they are not always followed by clinicians.We analyzed the adherence to guidelines and patients' outcome.Methods:We searched all patients with DM who visited to single center in 1yr and checked whether patients were tested and was prescribed medication as in guidelnies.Results:Among5,623 DM patients,physicians tested HbA1c in4,524paitents(80.5 %),total cholesterol,83.4%,LDL,44.5 %,serum creatinine,79.2 %,urine protein(dipstick),66.9 %,UACR,31.6 %.The rate of appropriate control of BP was 27.3%,HbA1c(<7%); 45.4%, LDL(<100 mg/dL);49.1%.The ACEI(ARB) was prescribed in63.9%,statin,31.1%,EPO,66.2% among a recommended group as in guidelines.During follow-up,602 patients were dead and 93patients were progressed to ESRD.674 patients reached to the composite outcome (12.1%/5567 patients).The univariate risk factors to outcome were gender,level of cholesterol, HbA1c,presence of (cholesterol,HbA1c,UACRor Cr) data, and use of ACEI(ARB),antiplatelet agent.With Cox's hazard proportional model, appropriate control of cholesterol(<200 mg/dL) reduced outcome risk to81.5%(68.4-97.1%),HbA1c<7% reduced the risk to 80.9% (67.4-97.1%), usage of antiplatelet agent reduced the risk to83.1%(69.5-99.5%), and presence both of renal functional data reduced the risk to71.7%(59.0-87.1%).The patients with the data of renal function had taken the medicine of ACEI,ARB,statin more frequently.Conclusion:Testing HbA1c and renal function in DM patients was related to better prognosis in death rate and ESRD rate and might be important to improve the prognosis of renal function and mortality.

**Discovery and Early Development of Bardoxolone Methyl (BARD), an Antioxidant Inflammation Modulator (AIM) Targeting the Keap1-Nrf2 Pathway** Colin Meyer,[1] Christian Wigley,[1] Deborah A. Ferguson,[1] James Warren Huff,[1] Robin Kral,[1] Karen Liby,[2] Michael B. Sporn.[2] *[1]Reata Pharmaceuticals, Inc., Irving, TX; [2]Dartmouth Medical School, Hanover, NH.*

Bardoxolone methyl (BARD) and related analogs in the AIM class are the most potent known inducers of the Keap1-Nrf2 pathway. AIMs were discovered through a medicinal chemistry campaign designed to identify novel molecules to inhibit inflammation-induced carcinogenesis. Oleanolic acid, a triterpenoid natural product, was selected as the initial scaffold due to its weak anti-inflammatory and anti-carcinogenic activity. Synthetic derivatives were evaluated by measuring suppression of NO production in activated macrophages; BARD was one of the most potent analogs ($IC_{50}$=0.11 nM). Biochemical assays subsequently established that BARD directly interacts with regulatory cysteine residues on Keap1, which play a key role in regulating inflammation and oxidative stress. Activation of Keap1 promotes accumulation of Nrf2 in the nucleus, inducing transcription of genes that increase antioxidant capacity, induce glutathione synthesis, and conjugate and export potentially harmful molecules from the cell. In addition to inducing Nrf2, activation of Keap1 appears to suppress the transcriptional activity of NF-κB resulting in reduction of inflammation. The BARD structure and activity profiles resemble that of the endogenous activators of Nrf2 which play an important role in the resolution of inflammation. BARD protects against pro-inflammatory stimuli *in vitro* and *in vivo* in an Nrf2-dependent manner. BARD and related analogs have also been shown to improve endothelial dysfunction, suppress mesangial cell contraction, and increase inulin clearance in preclinical studies. Clinical trials with BARD were initiated in oncology patients; substantial improvements in measures of kidney function occurred in 80% of patients and were sustained in patients treated for six months. In a subsequent Phase 2 clinical trial, BARD significantly increased glomerular filtration rate and improved other renal function markers (BUN, Uric Acid, Phosphorus) in patients with Stage 3b/4 chronic kidney disease. A 12-month pivotal study of BARD is underway in this same patient population.

**HOMA Test in Patients with Simultaneous Kidney Pancreas Transplant** George A. Osuchukwu, Adeel Ahmad, Tina Kochar. *Nephrology and Hypertension, University of Texas Medical Branch, Galveston, TX.*

Objective

The aim of this study is to evaluate the usefulness of the HOMA (homeostasis model of assessment) to determine insulin secretion and insulin resistance in diabetic patients with a functioning kidney-pancreas transplant.

Research Design and Methods

43 Kidney-Pancrease transplants done in our center in 2 years were followed over a period of time 2 – 18 months. Serial fasting glucose, insulin and C. peptide levels were obtained for Estimation of the Beta cell function HOMA-B and insulin resistance HOMA-%S using the HOMA2 calculator. These values were compared to the normal expected values for the general population.

Results

HbA1C and fasting glucose levels were within normal limits for all subjects. Beta cell function was higher than 100% the value usually reported in the normal population. Insulin resistance was persistent but did worsen over the period of follow up.

Conclusion

This study shows that the HOMA score can be a valuable tool in the assessment of metabolic function in patients with a functioning pancreas transplant. Due to the systemic delivery of insulin there is an over estimation of beta cell activity.Insulin resistance was high and persisted throughout the period of follow up. More research will be needed to assess its application to predict impending graft failure by worsening insulin resistance or decreasing beta cell activity.

**BNP as a Novel Cardiovascular Risk Factor in Stage 3 Chronic Renal Patients with Diabetes Mellitus Type 2** Ana Paula Silva, Ana Cabrita, Anabela Malho, Ana Pinho, Pedro Neves. *Nephrology, Hospital de Faro, Faro, Portugal.*

The diabetic cardiomyopathy is a myocardial disease caused by diabetes mellitus (DM) unrelated to vascular and valvular pathology or systemic arterial hypertension.

The introduction of novel molecular biology techniques offers new diagnostic approaches. The most promising application is the analysis of the B-type natriuretic peptide (BNP).

The BNP is released by the cardiac ventricles in response to myocardial stretch, and the clinical effects of this peptide are mainly vasodilatation and increase of diuresis. The BNP values reflect the baseline myocardial conditions and the degree of neurohormonal activation.

The aim of this study was to examine the influence of inflammation, oxidative stress, and renal function on BNP levels in patients with diabetes mellitus type 2.

This observational cross-sectional study included 25 patients (w=11, m=14) from our diabetic nephropathy outpatient clinic, with a eGFR (MDRD) of 55 ml/min/1.73 $m^2$ and a mean age of 66.2 years.

The exclusion criteria were: antioxidant therapy during the previous 6 months, clinical cardiovascular disease and uncontrolled hypertension (pressure values ≥140/90 mmHg)

Several laboratorial parameters were evaluated, including serum BNP, high-sensitive C reactive protein (hsCRP), oxidative stress (malondialdehyde) and glomerular filtration rate (eGFR)

We found that BNP levels were influenced, in a single regression model, by malondialdehyde (r=0,505 p=0,001), CRP (r=0,966 p=0,003) and eGFR (r=0,505 p=0,014). In a multiple regression model ($R^2$= 0,932 p=0,001) we found that only malondialdehyde (β=0,643 p=0,001) and CRP (β=0,293 p=0,033) independently influenced the BNP levels.

In this study with stage 3 chronic renal patients with diabetes mellitus type 2, inflammation and oxidative stress were associated with higher BNP values. Further studies, with more patients, are needed to evaluate the potential role of BNP, as an early biomarker of cardiovascular disease in chronic renal patients.

**Vitamin D Levels and Microalbuminuria-to-Creatinine Ratio in Type 2 Diabetic Patients** Ana Paula Silva, Ana Cabrita, Ana Pinho, Pedro Neves. *Nephrology, Hospital de Faro, Faro, Portugal.*

The active vitamin D (aVD) has many important functions including immunomodulation, anti-proliferation and potentially renoprotective functions.

Earlier studies have demonstrated that glomerular haemodynamic changes, podocytes abnormalities and mesangial activation are associated with proteinuria in diabetic patients. The growing amount of evidence of the beneficial effect of aVD on glomerular structures, is reinforced by clinical studies showing that aVD decrease proteinuria in renal patients.

The aim of this study was to examine the association between active vitamin D blood levels and microalbuminuria-to-creatinuria ratio in patients with type 2 diabetes mellitus.

This observational cross-sectional study included 50 type 2 diabetic patients, from our renal outpatient clinic (f=18, m=32), mean age = 66.9 years and a mean eGFR (MDRD) of 50 ml/min/1.73 $m^2$.

The exclusion criteria were: Hg A1c ≥7,5 %, BMI > 27, vitamin D therapy during the previous 6 months, uncontrolled hypertension (pressure values ≥140/90 mmHg), previous physical activity, and infection, neoplasic or psychiatric disease.

Several laboratorial parameters were evaluated: microalbuminuria-to creatininuria ratio in the stop morning sample, active vitamin D levels and the glomerular filtration rate (eGFR).

We found a strong direct correlation between the microalbuminuria-to creatininuria ratio and the vitamin D blood levels (r= - 0,786 p=0,001).

In our study, the vitamin D blood levels were predictive of increased proteinuria in type 2 diabetic patients. Further studies, with greater number of patients and with therapeutic intervention with vitamin D analogues should be carried, to confirm this beneficial role of aVD.

**Acute Renal Failure in Diabetes: Etiology and Outcome** Saubhik Sural, Sandip K. Bhattacharya. *Nephrology, Peerless Hospital & B K Roy Research Center, Kolkata, West Bengal, India.*

**Purpose:**Some studies have shown that diabetic patients are more prone to develop ARF. An analysis was done in diabetic patients who developed ARF to determine the etiological spectrum, to find out various variables affecting the outcome and compare it with ARF in non diabetics.

**Methods:**All diabetic patients who suffered from ARF during last 3 years at the institute were studied. The patients who presented with multiorgan failure, severe shock, or expired within 24 hours of admission were excluded from the study. The study sample was divided into two groups- group1- patients with overt proteinuria (stage IV) and group2- patients without overt proteinuria. The demographic profile, cause of ARF, need for dialysis, duration of oliguria, time of recovery, degree of recovery of renal function , other complications , mortality and other variables affecting the outcome were noted. All these factors were statistically compared between group1 and group 2, and also compared with non diabetic ARF.

**Result:**Of 88 patients suffering from diabetic ARF 57 patients had overt proteinuria(group1 ) and 31 were in group2. The various causes of ARF were urosepsis (15 in group1&9 in group2), other sepsis (9 in group1 and 6 in group2, fungal infection (5 in group1 and 2 in group2), obstructive uropathy including papillary necrosis (7 in group1 and 4 in group2), drugs (9 in group 1 and 5 in group2), contrast (4 in group1 and 1 in group2), vasculitis (3 in group1 and 1in group2), other toxins like consumption of raw fish gall bladder(5 in group1 and 3 in group2). On statistical analysis papillary necrosis, Non Steroidal Anti Inflammatory Drugs(NSAIDS) and conrtast were found to be significantly more common in group1. Overall mortality was 11%. Sepsis was only significant factor predicting mortality. There was no difference in outcome between group2 and non diabetic ARF. Delayed recovery and partial recovery were more common in group1.

**Conclusion:**Diabetic patients with overt proteinuria are more prone to develop ARF, most significantly from NSAIDS compared to non diabetics and diabetics without overt proteinuria. Delayed and partial recovery is more common in this group. Mortality depends on underlying condition like sepsis.

**Liver Enzymes Are Associated with Diabetic Nephropathy and Kidney Function in Patients with Diabetes** Dorien M. Zelle,[1] Alaa Alkhalaf,[1] Nicole Deetman,[1] Eva Corpeleijn,[2] Reinold O. B. Gans,[3] Ronald Stolk,[2] Gerjan Navis,[1] Stephan J. L. Bakker.[1] *[1]Kidney Centre, Unversity Medical Centre Groningen, Netherlands; [2]Epidemiology, Unversity Medical Centre Groningen, Netherlands; [3]Internal Medicine, Unversity Medical Centre Groningen, Netherlands.*

**Background**

Diabetes is associated with many metabolic disturbances, including fatty liver, which may lead to development of diabetic nephropathy (DN). To assess the influence of metabolic abnormalities regarding the liver, we studied the liver enzymes alanine aminotransferase (ALT), gamma glutamyl transferase (GGT), alkaline phosphatase (AP) and bilirubin (BIL) in type 2 diabetic patients (DMT2) with and without DN.

**Methods**

In this case-control study, cases with DN were matched for age, sex and duration of diabetes with controls without DN. Diabetes was defined according to WHO criteria. Liver enzymes and BIL were measured by routine assays. GFR was estimated by MDRD.

**Results**

We included 32 cases and 32 controls. Median [interquartile range] duration of diabetes was 15 [10-20] , age 64±9 years and 54% male. Estimated GFR was 65±23 mL/min/1.73m² in cases vs 84±15 mL/min/1.73m² in controls (p<0.001). Urinary albumin concentration was 752[239-1074] mg/l in cases vs 3[3-6] mg/l in controls (p<0.001). In logistic regression analyses, risk for DN increased with each doubling of GGT (OR=1.85[1.0-3.4], P=0.045) and AP (OR=6.9[1.5-31.6],P=0.01), but not ALT(OR=0.9[0.4- 2.0],P=0.9). BIL (OR=0.25[0.1-0.8],P=0.03) was inversely associated with DN. This was independent of age, sex, BMI, HDL-cholesterol and blood pressure. In linear regression analyses GGT and AP were inversely associated with eGFR (GGT:$R^2$=0.33, $\beta_{STD}$=-4.8,P=0.01 ; AP:$R^2$=0.33, $\beta_{STD}$=-12.6,P=0.009), whereas BIL was positively associated with eGFR ($R^2$=0.34 $\beta_{STD}$= 9.2,P= 0.009).

**Conclusions**

GGT and AP, but not ALT, were positively associated with DN and inversely associated with kidney function. BIL was negatively associated with DN and positively associated with kidney function. Further research is needed to elucidate the mechanisms behind the protective association of endogenous BIL and the relationship between liver enzymes and DN.

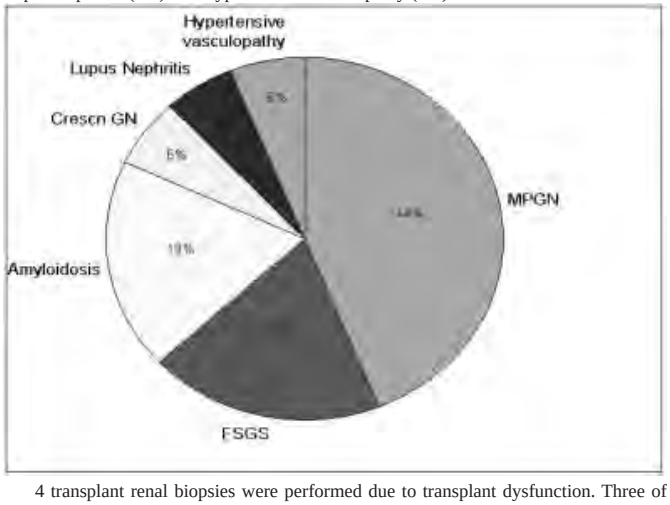
**Spectrum of Renal Diseases Observed Through Renal Biopsy** Hafiz I. Ahmad, Syed Rizwan Bokhari, Muhammad Awais. *Department of Nephrology, Allama Iqbal Medical College, Lahore, Pakistan.*

We analyzed 19 serial Renal Biopsies carried out at Division of Nephrology Jinnah Hospital, Lahore over a period of 1 year from March 2009 to May 2010.Due to resource limitations only light microscopy was employed to evaluate the biopsy specimens.

Out of 19 patients 14 were male and 5 female with average age 23.9 (range 16-58). The male to female ratio was 2.8:1. Serum Creatinine ranged from 1.1 to 13.9 mg/dl (mean 3.65). Proteinuria in Nephrotic syndrome patients ranged from 3.5 to 12.7gm/24hrs (mean 5.12). All kidney biopsies were done by experienced nephrologist with automated 18 gauge biopsy needle (Bard- Monopty) using ultrasound guidance under aseptic conditions.

Out of 19 procedures 15 were performed on native kidneys and 4 on transplanted ones. The most common indication in native kidneys was Nephrotic Syndrome (80%). Three others were Nephritic Syndrome , RPGN & Lupus Nephritis; 6.6% each .The histological diagnoses were MPGN (44%), FSGS (19%), Crescentic GN (19% ), Amyloidosis (6%), Lupus Nephritis (6%) and Hypertensive Vasculopathy (6%).



4 transplant renal biopsies were performed due to transplant dysfunction. Three of them showed acute cellular rejection and one was cyclosporine toxicity.

We compared our biopsy findings with studies done in South Asian, Mid Eastern and European countries. The spectrum of our findings was most consistent with that of Nepal, i.e. membranoproliferative glomerulonephritis (MPGN) being the commonest lesion in nephrotic syndrome patients.

Our study provides an insight in the pattern of various glomerulonephritides in this country and underscores the need for more extensive data collection for optimizing management strategies.

**Collapsing FSGS: A Clinicopathological Study** Mohammed A. Al-Ghonaim,[1] Hala M. Kfoury,[1] Abdulkareem Alsuwaida.[1] *[1]King Saud University; [2]King Saud University; [3]King Saud University.*

Background:

Collapsing FSGS is one of the recognized type of FSGS it is tend to be related to HIV infection and or IV drug use. However, no HIV related collapsing FSGS rate is increasing.It is characterized clinically by marked proteinuria and renal insufficiency and histologically by global or segmental wrinkling of glomerular basement membrane, glomerular capillary collapse, severe podocyte injury, and glomerular epithelial cell proliferation.

Method:

We reviewed renal biopsy records between 2005 and 2010 in two tertiary hospitals in Riyadh, Saudi Arabia, and identified 13 cases of Collapsing FSGS. Patients' demographic, clinicopathologic data, treatment and outcome were collected from medical records. Renal biopsies were studied by light, immunofluorescence, and electron microscopy, The histological selection criteria for Collapsing FSGS were performed according to the Columbia classification.

Result:

All the patient were young (mean age of 28 +/- 15 years), there were 7 male. All presented with nephrotic range proteinuria (24-h urinary protein: 3.5 +/- 4.9 gm/day) and the serum creatinine on presentation 171+/- 124 µmol/l. Mean follow up duration is 2.3 years. 4 patients developed end stage renal disease (ESRD). The mean serum creatinine in patient who did not develop ESRD is 132+/- 73 µmol/l.

Conclusion: the incidence of collapsing form of FSGS is increasing, clinical course tend to be variable with worst renal survival in patient presenting with high serum creatinine.

**Recovery of Renal Function in ANCA Vasculitis Continues throughout the 1st Year of Immunosuppressive Therapy** Isabelle Chapdelaine, Remi Goupil, Josee Bouchard, Clement Deziel, Stephan Troyanov. *Medicine, Hôpital du Sacré-Coeur de Montréal, Montreal, QC, Canada.*

The time to maximal renal recovery in ANCA-associated vasculitis (AAV) is uncertain. Prolonged immunosuppression can lead to severe complications while abandoning prematurely such treatments can deny patients vital renal function. We sought to determine the time course of renal recovery in patients presenting with an eGFR below 30 ml/min/1.73m2 at onset.

We identified AAV patients by reviewing all ELISA ANCA measurements performed since February 2004. Demographics, clinical and laboratory assessment at diagnosis and during follow-up were collected from medical records.

Of the 39 patients identified, 22 had an eGFR below 30 ml/min/1.73m2 at onset. Their eGFR was 13 ± 8 ml/min/1.73m2 with an age of 58 ± 16 years. The median follow-up was 36 months. All patients received oral corticosteroids, 19 pulse methylprednisolone, 20 cyclophosphamide and 12 plasmapheresis. Nineteen patients had a renal biopsy showing, on median, moderate interstitial fibrosis, 20 and 7 percent of glomeruli with crescents and global glomerulosclerosis, respectively. Over time, the eGFR slowly increased from 13 ± 9 at onset to 19 ± 11, 21 ± 13, 25 ± 15, 25 ± 15 and 28 ± 16 ml/min/1.73m2 at 1, 3, 6, 12 and 24 months, respectively ($p<0.001$ for within-subject effect) with every post-hoc pairwise comparison (by LSD method) significant except for 6 vs. 12, 6 vs. 24 and 12 vs. 24 months ($p>0.1$, 0.06 and 0.08, respectively). Ten required dialysis, 3 of which were able to exit at 5, 7 and 14 months while 4 died within the first year.

This small cohort of AAV patients with severe renal insufficiency but relatively preserved renal parenchyma displayed slow but progressive and significant eGFR improvement over at least the first year. Prudence and patience is warranted in assessing renal response to therapy.

**Type I Membranoproliferative Glomerulonephritis as the Initial Presentation of Waldenstrom Macroglobulinemia** Emanuela Didita, Qamar Iqbal, Mirela A. Dobre, Andrew Lazar. *Internal Medicine, Huron Hospital, East Cleveland, OH.*

Introduction

Nephrotic range proteinuria is rare in patients with Waldenström macroglobulinemia. When present, it is usually due to amyloid light-chain deposition. We present the first case, to our knowledge, of type I membranoproliferative glomerulonephritis as the initial presentation of Waldenstrom macroglobulinemia.

Case report

A 61 year old female with hypertension for 10 months presented with proteinuria and the progressive deterioration of her kidney function. She had 30 pound weight loss over two years, but no gross hematuria, foamy urine, chest pain, shorthness of breath, skin changes, hemoptysis, joint pain, or headache. She was taking triameterene/hydroclorothiazide 37.5/25 mg daily, omega-3 fatty acids 1000 mg three times daily, and multiple vitamins and mineral supplements daily. Physical examination showed only trace edema in the legs. Laboratory data revealed creatinine 1.95 mg/dL, urine protein 4.38 g/24 hours, cholesterol 331 mg/dL, low density lipoprotein 232 mg/dL. Urinalyis revealed proteinuria and hematuria without casts. Cryoglobulins, rheumatoid factor, hepatitis C, antinuclear, anti-DNA and anti-neutrophil cytoplasmic antibodies, were negative. The complement levels were normal: C3 70 mg/dL and C4 14 mg/dL. Serum protein immunelectrophoresis revealed a IgM/Kappa monoclonal protein. Kappa/Lambda ration was 2.29. The kidney biopsy revealed type I membranoproliferative glomerulonephritis. The bone marrow biopsy was diagnostic of Waldenstrom macroglobulinemia. The patiend was treated with the chemotherapeutic agents Rituximab, Bendamustine and the kidney function much improved.

Conclusion

Waldenstrom macroglobulinemia should be included in the diferential diagnosis of type I membranoproliferative glomerulonephritis with negative cryoglobulins. Prompt diagnosis and treatment of macroglobulinemia is essential for the prognostic of membranoprolipherative glomerulonephritis type I, as the patients left untreated will rapidly progress to end stage renal disease.

**Cyclosporine Therapeutic Drug Monitoring in Nephrotic Syndrome: Which Time Point To Use for a Generic Product?** Xiaoli Du,[1] Haiyun Wang,[2] Qiang Fu,[1] Limeng Chen,[2] Zhu Zhu,[1] Xuemei Li.[2] *[1]Pharmacy Department, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China; [2]Department of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China.*

***Background*** Although C2 monitoring has been accepted as the optimal TDM strategy for cyclosporine (CsA) in organ transplantation, but there is limited information in nephrotic syndrome (NS). In China, most NS patients were prescribed generic product of CsA, and monitored by C0, without data supporting this practice. ***Objective*** To investigate the appropriate monitoring method for generic CsA product in NS patients. ***Methods*** An open-label, prospective study was carried out at Peking Union Medical College Hospital in NS patients receiving generic CsA product, Tianke®. The dose was 3-4 mg/kg/d given in two divided doses before meal. Blood samples were collected prior to (t=0), and at 1, 2, 3, and 4 h following a steady-state morning dose. CsA concentrations were assayed by HPLC. $AUC_{0-4}$ was calculated using trapezoidal method. Limited sampling strategies (LSSs) for $AUC_{0-4}$ were determined using multiple regression analysis. ***Results*** 16 patients were enrolled in this study. The C0, C1, C2, C3 and C4 were 76.6±40.0, 791.0±408.0, 574.2±284.7, 342.4±151.3, and 236.9±111.4 ng/ml, respectively. The $AUC_{0-4}$ was 1828.4±775.4 ng·h/ml. The $t_{max}$ was 1.3±0.5 h, shorter than that reported for Neoral®. C0 had the worst correlation with $AUC_{0-4}$ ($r^2$= 0.38, 0.64, 0.68, 0.76, and 0.72 for C0, C1, C2, C3, and C4, respectively). For the prediction of $AUC_{0-4}$, the LSS incorporating C1 and C2 gave the best result among the LSSs including two blood samples ($r^2$=0.99). Among the 5 time-points, only C2 showed significant difference between the patients with normal and abnormal BUN or Ccr levels ($P$<0.05). ***Conclusion*** For the investigated generic CsA product, C2 was the best single time-point sample for the prediction of CsA exposure and renal toxicity. To achieve more accurate prediction of $AUC_{0-4}$, the LSS incorporation C1 and C2 could be adopted. It is suggested that LSSs specific to brand be developed in different countries.

**Renal Limited "Lupus-Like" Glomerulonephritis** Ana Huerta,[1] Vassilios Liakopoulos,[2] Amudha Palanisamy,[1] Andrew S. Bomback,[1] Jai Radhakrishnan,[1] Glen S. Markowitz,[1] Gerald B. Appel.[1] *[1]Columbia Univ. College of Physicians and Surgeons, NY; [2]Univ. of Thessalonika.*

***Bacgkround:*** The histopathology of proliferative lupus nephritis (LN) may be confused with other immune complex (IC)-mediated glomerulonephritides (GNs). In general, though, proliferative LN is marked by the following histolopathologic findings: 1) a "full house" IF pattern; 2) extraglomerular deposits (EGDs); 3) electron dense deposits (EDDs) at mesangial, subendothelial, and subepithelial locations; and 4) tubuloreticular inclusions (TRIs). It remains unclear whether a LN diagnosis should be given to pts with inconclusive SLE serologies and no clinical SLE symptoms when a renal biopsy shows the classical patterns of LN.

***Methods:*** We reviewed the courses of 3 pts with "lupus-like" GN. All pts had at least 3 of the above 4 histopathologic criteria for LN. Their course and serologies, however, never confirmed the diagnosis of SLE despite long-term follow.

***Results:*** Pts were all female and aged 19, 37, and 50 yrs at presentation. Biopsies were read as IC-mediated diffuse proliferative GN with dominant IgG glomerular immune deposits and variable codeposits of IgA, IgM, C3 and C1q. All biopsies showed EDD at mesangial, subendothelial and subepithelial locations, and TRIs; 2 pts' biopsies also displayed a "full house" IF pattern and/or extraglomerular deposits. All of the pts maintained negative/inconclusive serologic SLE tests and no extrarenal symptoms of SLE over mean follow-up of 3.4 yrs. All 3 pts were treated with steroids; 2 pts also received MMF or CTX. Despite therapy, all pts had a progressive decline in renal function leading to ESRD in 2 pts and CKD stage 4 in 1.

Biopsy findings

| Case | IF staining | EGDs´ location | mesangial,subendothelial & subepithelial EDD | TRIs |
|---|---|---|---|---|
| 1 | IgG,C3,C1,κ,λ | TBM & interstitial | + | + |
| 2 | IgG,IgA,IgM,C3,C1,κ,λ | - | + | + |
| 3 | IgG,IgA,IgM,C3,C1,κ,λ | TBM | + | + |

***Conclusion:*** Pts with biopsy patterns resembling LN but without extrarenal SLE manifestations or SLE-consistent serologies at diagnosis and during follow-up may constitute a unique group. These pts may be less responsive to therapy than typical LN pts. Awareness of "lupus like" GN will clarify the incidence and significance of this population.

**PUB290**

**Plasmapheresis in the Hemodialysis Unit: Single Center Experience** Rumeyza Kazancioglu, Meltem Gursu, Serhat Karadag, Zeki Aydin, Savas Ozturk, Sami Uzun, Emel Tatli. *Nephrology, HaseKi Training and Research Hospital, Istanbul, Turkey.*

**INTRODUCTION:** Theurapeutic plasma exchange (TPE; plasmapheresis) is a mode of extracorporeal therapies applied by membrane separation or centrifugation method; the first method more commonly used. We present the analysis of plasmapheresis results of our unit.

**METHODS:** Patients who had plasmapheresis within 2009 were included. Age, gender, primary disease, number of series and sessions, replacement fluid, complications and the outcome were recorded.

**RESULTS:** 41 patients had plasmapheresis with mean age and male/female ratio of 45.17±16.49years and 18/31, respectively. The indication for plasmapheresis was crescentic glomerulonephritis(GN) in 8, post-transplant GN in 6, Wegener's granulomatosis(WG)/microscopic polyangiitis(MPA) in 6, pre-transplant PRA(panel reactive antibody) positivity in 5, HUS(Hemolytic uremic syndrome)/TTP(Thrombotic thrombocytopenic purpura) in 5, neurological demyelinating diseases in 3, multiple myeloma(MM) in 3, systemic lupus erythematosus(SLE) in 1, FSGS(focal segmental glomerulosclerosis) resistant to conventional treatments in 2 patients and FSGS prior to transplantation in 1 patient. 35 patients had 1 (5.9±3.3 sessions), 5 patients had 2 series(5.5±4.5 sessions) and 1 patient had 10 series(4.2±2.3 sesions) of plasmapheresis. The replacement fluid was fresh frozen plasma in 34 and human albumin in 7 patients. The outcomes are presented in Table 1.

Table-1

| | Complete response | Partial response | No response |
|---|---|---|---|
| Crescentic GN | 1 | 3 | 4 |
| Post-transplant GN | 0 | 3 | 3 |
| WG/MPA | 0 | 5 | 1 |
| Pre-transplant PRA positivity | 0 | 3 | 2 |
| HUS/TTP | 2 | 1 | 2 |
| MM | 1 | 2 | 0 |
| FSGS resistant to other treatments | 0 | 2 | 0 |
| FSGS prior to transplantation | 1” | 1 | 0 |
| Neurological demyelinating disease | 2 | 0 | 1 |
| SLE | 1 | 0 | 0 |

Outcome of the primary disease

**DISCUSSION:** Although plasmapheresis has been used mostly for non-nephrological diseases; it is a procedure convenient to use in hemodialysis units due to similarities regarding technique and complications. In cities where there is no unit specialized for extracorporeal treatments as in our city; HD units may improve their practice about TPE and provide early treatment of mentioned diseases.

## PUB291

**Clinical Characteristics of Patients with MPO-ANCA-Positive Interstitial Pneumonia with or without Glomerulonephritis** Kiyoki Kitagawa,[#1] Akinori Hara,[#1] Kengo Furuichi,[#1] Takashi Wada.[#2] *[1]Department of Disease Control and Homeostasis, Kanazawa University, Kanazawa, Japan; [2]Department of Laboratory Medicine, Kanazawa University, Kanazawa, Japan.*

Lung and kidney are two major target organs in patients with MPO-ANCA related vasculitis. In this study, we investigated the clinical characteristics of MPO-ANCA-positive interstitial pneumonia (IP) Japanese patients with or without glomerulonephritis (GN). A total of 7 patients who were diagnosed as MPO-ANCA-positive IP in Kanazawa University Hospital was examined in this study. The patients were followed based on the diagnosis as IP to onset of GN or May 31, 2010 (mean period 1541±470 days). Three patients (43%) developed GN during the follow-up period (GN group: mean age 57.0±9.4, female 2, male 1). The others never showed renal involvement until May 31, 2010 (non-GN group: mean age 59.0±3.4, female 3, male 1). A mean period from diagnosis of IP to onset of GN was 1927±1025 days. The levels of MPO-ANCA during follow-up period were higher in GN group (at diagnosis of IP : 178±48 EU vs. 34±15 EU, p=0.02, at end point : 295±94 EU vs. 75±49 EU, p=0.07). However, at the time of the diagnosis of IP, none of urinary findings, renal function, serum CRP, respiratory function tests, Birmingham vasculitis activity score and vasculitis damage index had statistical difference between GN group and non-GN group. At the end point of this study, neither respiratory function tests nor doses of prednisolone differed between both groups.

In conclusion, the level of MPO-ANCA may be a predictive factor for subsequent onset of GN in patients with MPO-ANCA-positive IP.

## PUB292

**Characteristics of Patients Seen in Combined Renal-Rheumatology Clinic at Royal Brisbane and Women’s Hospital, Brisbane, Australia** Thaminda Liyanage, Helen G. Healy, Dwarakanathan Ranganathan. *Department of Renal Medicine, Royal Brisbane and Women’s Hospital, Brisbane, Queensland, Australia.*

Background

Patients with connective tissue diseases with multisystem involvement require long term follow up in different sub speciality clinics simultaneously. Royal Brisbane and Women’s Hospital combined Renal-Rheumatology clinic was implemented in July 2009 in an attempt to improve patient care and satisfaction, reduce burden of attending too many clinics, improve quality of clinical training and trainee satisfaction.

Aim

This descriptive study looked at patient characteristics in renal-rheumatology clinic from July 2009 to January 2010.

Method

Case notes of all patients followed up at Renal-Rheumatology clinic up to January 2010 were reviewed. Patients’ demographics, diagnosis at referral, dependency on maintenance dialysis were recorded. Descriptive statistics included number of subjects (n), age range, mean and standard deviation for age.

A patient satisfaction survey conducted with anonymous questioner.

Results

46 patients included- 29 females and 17 males; 30 had Systemic Lupus Erythematosus (SLE), 6 had other connective tissue disorders, 7 had vasculitis and diagnosis was uncertain in 3 patients. 20/30 (66%) of SLE patients were females. Only 7 (15%) required maintenance dialysis and most of them had SLE (5/7).

Overall age ranged from 18-82 years with mean age of 47.89 years (SD 17.00 years). Age of females ranged from 21-77 years with mean age of 47.96 years. Age of males ranged from 18-82 years with mean age of 47.76 years.

26/46 took part in patient satisfaction survey.

Patient satisfaction survey results

| Question | Mean score |
|---|---|
| Provides better care | 3.10 |
| Saves time | 3.86 |
| Saves money | 4.10 |
| Gets quick clinical decisions | 2.90 |
| Better than attending 2 different clinics | 4.40 |

Table 1

Conclusion

Patients and trainees expressed satisfaction in the combined clinic. As this is a monthly clinic most patients were seen only once or twice hence too early to assess clinical improvement. Patients have to be followed up for a longer period before one can establish whether combined clinic improves quality of care and clinical outcomes.

## PUB293

**Membranous Lupus Nephritis: A Single Center Experience** Smaragdi Marinaki,[1] Chrysanthi Skalioti,[1] Irene Synodinou,[1] Argyrios Georgalis,[1] Lydia Nakopoulou,[2] Charalambos Moutsopoulos,[3] John Boletis.[1] *[1]Nephrology and Transplantation Unit, Laiko Hospital, Athens, Greece; [2]Pathology Department, University of Athens, Athens, Greece; [3]Pathophysiology Department, University of Athens, Athens, Greece.*

Purpose: To evaluate the clinical characteristics, the therapy and the outcome of patients with membranous lupus nephritis.

From a single center cohort of 195 patients with biopsy proven lupus nephritis performed between 2000 and 2009, 29(15%) patients had pure membranous lupus nephritis (class V). We retrospectively analyzed the data that were available in 14(13 women,1 man) of them. Mean follow-up was 28.4 months, mean age was 39±9 years and mean SLE duration 55±51 months. In 10/14 patients membranous was the first manifestation of lupus nephritis, whereas in 4/14 patients it was conversion from another class. All patients but two (86%), had normal renal function at presentation. Nine patients (64%) presented either with nephrotic syndrome or with nephrotic range proteinuria while 5/14 had proteinuria <3g/24h at diagnosis. Complement levels were normal. Three patients underwent a second renal biopsy, one because of ongoing activity and two because of relapse after complete remission. There was no conversion to other classes of lupus nephritis. Eleven patients were treated with an ACE inhibitor. A total of seventeen episodes were treated in 14 patients. Most of them (12/17,71%) with MPA (2-3mg/day) and corticosteroids (0.5-1mg/Kg/day for the 1st month). In 5/12, the anti CD-20 mAb Rituximab was added. Two were treated with iv monthly pulses of cyclophosphamide and corticosteroids, 1/17 with corticosteroids only, one with Rituximab and corticosteroids, while one patient received no immunosuppression. Partial remission was achieved in 4/14(28.6%) patients after 4.5 months and complete remission in 10/14(71%) after 12 months. Complete remission was sustained in 9/10 patients. No episode of infection that needed hospitalization occurred. In conclusion, in our cohort, we observed the same rate of membranous lupus nephritis (15%)as reported in other series. MPA based therapy seems to be safe and effective with a complete remission rate of 71%.

## PUB294

**Increased Activity of (pro) Renin – Angiotensin System in Patients with Primary Chronic Glomerulonephritis** Magdalena Mostowska, Elzbieta Pawliczak, Andrzej P. Oko, Ilona Piechocka, Stanislaw Czekalski. *Department of Nephrology, Transplantology and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland.*

Introduction and aims:

Abnormal activation of (pro) renin – angiotensin system ((P)RAS) is involved in kidney damage in patient with primary chronic glomerulonephritis (GN). Not only angiotensin II (Ang II), but also prorenin and renin as agonists of prorenin - renin receptor can induce glomerulosclerosis, interstitial fibrosis and pathological proliferation. Till now, elevated plasma level of prorenin was detected in patients with diabetes mellitus and it was considered as an early indicator of development of diabetic kidney disease. The aim of the study was an evaluation of plasma (P)RAS components and to determine their relationship with largenes of proteinuria in primary chronic GN.

Material adh methods:

Fifty five (31 woman, 24 men) untreated patients (without immunosupressive and antihypertensive drugs) aged 39.9 ± 14.8 years with primary chronic GN in stages 1 – 3 of chronic kidney disease and 20 healthy persons (10 woman, 10 man) aged 36.8 ± 9.3 years participated in the study. Prorenin and Ag II levels in plasma were measured by ELISA while renin plasma concentration was measured by radioimminological method. In all patients 24 – hour urinary protein excretion was also evaluated.

Results:

Significantly higher plasma prorenin and Ang II levels ($p = 0.0003$ and $p = 0.002$, respectively) in patients with primary GN when compared to healthy controls were found. In contrast there was no difference in renin concentration in plasma between both groups. In patients with primary GN, plasma prorenin concentration was significantly correlated with 24 – hour urinary protein excretion ($r = 0.406$, $p = 0.002$).

Conclusions

In patients with primary chronic GN plasma concentrations of prorenin and Ang II are increased. Positive correlation between plasma prorenin concentration and proteinuria may suggest the role of this prohormone in glomerular damage.

**A Case of Membranous Nephropathy Due to Antiphospholipid Antibody Syndrome** Saurabh A. Pande,[1] Khurram Mumtaz,[1] Kanwal Raghav,[2] Eric J. Bloom,[1] Rasib Raja.[1] *[1]Nephrology, Albert Einstein Medical Center, Philadelphia, PA; [2]Internal Medicine, Albert Einstein Medical Center, Philadelphia, PA.*

Introduction: Membranous nephropathy (MN), the most common cause of nephrotic syndrome in adults is classified as either primary or secondary. We report a case of secondary MN due to a rare etiology.

Case: 48-yr-old African American man presented with headache and blurry vision for a day. He also reported lower extremity swelling, foamy urine and chronic back pain for which he was using ibuprofen for the past year. Labs were consistent with nephrotic syndrome with a serum creatinine of 1.4mg/dL, serum albumin of 1.7g/dL and spot urine protein and creatinine ratio of 9mg/g. MRI of brain showed multiple acute posterior circulation infarcts. CT of abdomen revealed left renal vein thrombosis. Anticoagulation was started and a work-up for a hypercoagulable state was ordered.

Renal biopsy showed membranous nephropathy. Serologies for hepatitis B and C, HIV, syphilis, cryoglobulinemia and lupus were negative. Anti-phospholipid antibody titer was elevated. In the absence of other secondary etiologies, he was diagnosed as a case of membranous nephropathy (Grade 2 by Ehrenreich and Churgs classification) secondary to anti-phospholipid antibodies or NSAIDs use. The former is likely since the proteinuria did not resolve after cessation of NSAIDs use.

Discussion: MN has an identifiable cause in only 20% of cases. Minimal change glomerulopathy is often associated with NSAIDS use but association between NSAIDS and MN is uncommon. Several cases of NSAIDs induced MN have been reported, but most of them revealed a clear temporal association between NSAIDs cessation and resolution of proteinuria, which did not happen in our case. Fakhouri et al. reviewed kidney biopsies of 29 patients with primary antiphospholipid syndrome in the absence of associated systemic diseases, mainly SLE. Of these, 20 showed typical features of vascular APS nephropathy while the 9 showed predominant pathological features distinct from the vaso-occlusive disease characteristic of common vascular APS nephropathy. These atypical biopsies included 3 cases of membranous nephropathy.

**Cyclosporin A Therapy for Henoch-Schönlein Nephritis with Nephrotic-Range Proteinuria** Jee Min Park,[1] Ki Soo Pai,[1] Jae Il Shin.[2] *[1]Department of Pediatrics, Ajou University School of Medicine, Suwon, Republic of Korea; [2]Department of Pediatrics, Yonsei University College of Medicine, Seoul, Republic of Korea.*

To evaluate the therapeutic role of cyclosporin A (CyA) for the treatment of Henoch-Schönlein nephritis (HSN), twenty nine patients (18 boys, 11 girls) with nephrotic-range proteinuria were analyzed retrospectively. Mean age was 8.6 years (range 2.0-15.5 years) at diagnosis of Henoch-Schönlein purpura (HSP). All patients had developed the nephrotic-range proteinuria at a mean interval of 4.4 months (range 0-50.7 months) after the diagnosis of HSP. Mean duration of CyA treatment were 12.3 months (range 2.6-55.0 months). Mean follow-up times were 3.7 years (range 1.2-12.9 years) from the beginning of the CyA treatment. Steroids had tapered and stopped gradually after initiation of CyA. All patients responded to the CyA treatment within a mean of 1.8 months (range 1 weeks to 3.5 months). Twenty three patients achieved a stable remission with mean follow-up duration of 3.2 years and 6 patients seemed to become CyA dependent, since they developed proteinuria when the treatment was stopped. Renal function was preserved in all patients but one who developed to end stage renal disease because of poor compliance of CyA. We conclude that CyA treatment for HSN showing nephrotic-range proteinuria is effective and safe although some patients seem to develop CyA dependency.

**Renal Outcome in Minimal Change Disease Associated with Mysthenia Gravis: A Case Series Report** Lawand A. Saadulla, Navin Verma. *Nephrology, PSU/ Hershey Medical Center, Hershey, PA.*

Minimal change disease (MCD) is the most common lesion observed in patients with thymoma-associated autoimmune disorders, such as myasthenia gravis (MG). It can also present few years after removal of thymomas. Long-term renal prognosis and outcome following immunosuppressive therapy are largely unknown. We present two cases of MCD and MG with varying response to immunosuppressive agents and renal outcome.

The first patient is a 63-year-old male with three year history of MG admitted to our hospital with acute renal failure (ARF) and anasarca. His urine protein to creatinine (UPC) ratio was 13g/day. Renal biopsy revealed MCD, and he was treated with various immunosuppressive regimen, including corticosteroids, calcineurin inhibitors and rituximab. Unfortunately, his renal function deteriorated, and he required hemodialysis and has been dialysis dependent since then.

The second patient is a 68-year-old male with MG for two years presented with ARF, nephrotic syndrome and anasarca. His UPC ratio was 14g/day. Renal histology revealed features of MCD. He was treated successfully with high dose corticosteroid and mycophenolate mofetil (MMF). He achieved complete remission in a few weeks and remains in remission for nine months now.

To our knowledge, the literature contains only a few other published cases of glomerulopathy associated with thymic-disease. This association is most likely underdiagnosed. The role of T-cell immune disorder and circulating cytokines has been postulated as a possible pathogenesis of selective proteinuria associated with MCD. The beneficial response to immunosuppressive therapy in one of our patients supports this theory. Various immunosuppressive regimens-other than MMF- have been used. However, a definitive conclusion cannot be drawn regarding the effectiveness of one treatment over another in improving the renal outcome due to the limited numbers of identified cases in the literature. Our report is the first to suggest the combination of MMF and prednisone as a viable treatment option in treating patients with MCD associated with MG.

Disclosure of Financial Relationships: nothing to disclose

**PUB298**

**Immunotactoid Glomerulopathy (Chronic Lymphocytic Leukaemia Associated): Response to Treatment with Rituximab-Cyclophosphamide, Vincristine and Prednisolone** Vikas Srivastava. *Renal Unit, Flinders Medical Centre, Adelaide, SA, Australia.*

Background – Immunotactoid (or fibrillary) glomerulopathy is a very rare cause of glomerulonephritis, with deposition of fibrillar material, renal impairment and/or proteinuria. It can be associated with lymphoproliferative disorders, but optimal treatment strategies have not been defined. We describe a case in which treatment was associated with remission of proteinuria and stabilisation of renal function.

Case report- A 66 year old female presented with renal impairment (Creatinine 154 µmol/L, eGFR 29ml/min), hypertension (160/100), nephrotic range proteinuria (5.5g /24 hours), anaemia and lymphocytosis. Renal biopsy revealed an immunotactoid glomerulopathy with mesangiocapillary glomerulonephritis on light microscopy and fibrils visualised on electron microscopy of 20-30 nm in diameter, some with a microtubular appearance. Bone marrow biopsy showed cellular infiltrates, 90% consisting of mature lymphocytes consistent with B-cell CLL. Our patient received four cycles of Rituximab/ Cyclophosphamide, Vincristine and Prednisolone at three weekly intervals with anti-hypertensives. With this treatment her proteinuria has reduced significantly to 0.19 g/24 hours, she has normal normal blood pressure and renal function (creatinine 100 µmol/L), and a recent bone marrow biopsy confirmed marked depletion in B cells (<1% by flow cytometry).

Conclusion - Whilst most cases of fibrillary glomerulonephritis and immunotactoid glomerulopathy are idiopathic, some cases are associated with chronic lymphocytic leukaemia (CLL) or other B-cell lymphomas. In such patients, therapy directed at the underlying disorder may be effective and despite the striking fibrillary deposition can be associated with marked improvements in renal disease. This case illustrates an excellent outcome of a treatment strategy in a disease whose rarity precludes large scale randomised trials and concurs with other reports of benefit of Rituximab in this condition (Collins et al, Am J Kidney Dis. 2008 Dec;52(6):1158-62).

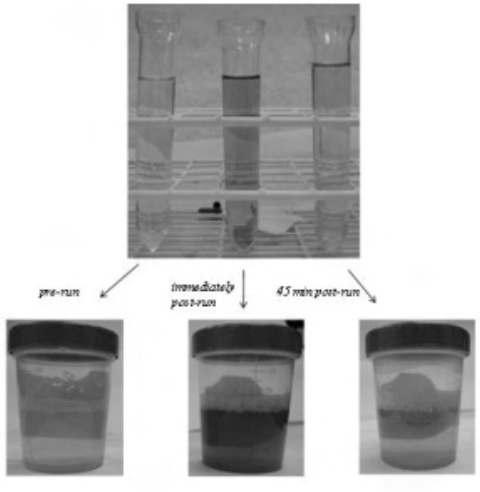
**Operation Iraqi Freedom Amputee with Running Induced Pigmenturia** Pallavi Belur,[1] Meagan M. Rizzo.[2] *[1]Department of Medicine, Walter Reed Army Medical Center (WRAMC); [2]Nephrology Service, WRAMC, Washington, DC.*

Reports of exercise induced concomitant hemoglobinuria and myoglobinuria are rare. Furthermore there are no reports of it in amputees in the literature. A healthy 29-year-old Operation Iraqi Freedom (OIF) soldier had a left below the knee amputation (BKA) in January 2005. In September 2005 he developed transient red urine after running with his prosthesis for ≥ 20 minutes. In 2010 he presented to Nephrology with persistent symptoms. His urine was initially unremarkable but post-run was grossly red and positive for blood and protein on dipstick; microscopy showed granular casts.



After centrifugation the supernatant remained red leading to the diagnosis of pigmenturia. Urine myoglobin and hemoglobin were markedly elevated post run. Urinary findings improved after 45 minutes. He was never anemic and had normal renal

function.

Laboratory Data

| Urine | Pre-run | Post-run | 45 min post run | Reference |
|---|---|---|---|---|
| Myoglobin | <27 | 1220 | 806 | <28mcg/L |
| Hemoglobin | 1.1 | 8.6 | 2.2 | < 1mg/dL |
| Spot protein/creatinine | 0 | 1.116 | 0.481 | <0.300 (ratio) |
| Microscopy | no casts | moderate granular casts | few granular casts | |

In conclusion, this soldier developed myoglobinuria, hemoglobinuria, protienuria and granular casts after a short run with his prosthesis. After reviewing the limited literature available, we recommended obtaining a new prosthetic with more shock absorbing ability and encouraged non-erect exercises (i.e. biking or swimming). We also advised decreasing running or running on softer surfaces such as a treadmill or on the grass to reduce the local trauma to the stump. Recognition of this process is important given the number of soldiers returning from deployments with amputations after improvised explosive device (IED) blast injuries. Questions still remain about the long term renal prognosis for such patients with transient, recurrent pigmenturia.

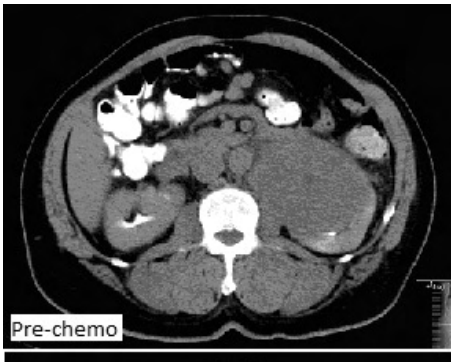
Disclosure of Financial Relationships: nothing to disclose

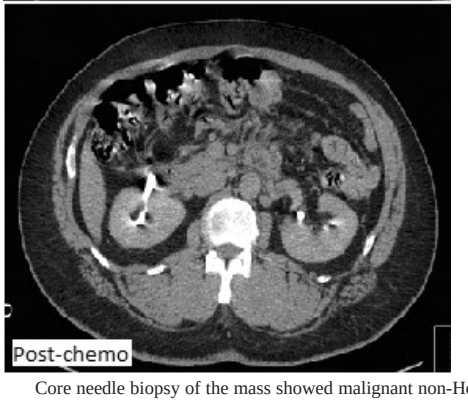
**PUB300**

**A Rare Cause of a Large Unilateral Renal Mass** Amarpali Brar, Moro O. Salifu, Syed I. Shah, Getinet Ayalew, Gurinder S. Sidhu. *Medicine, SUNY Downstate, Brooklyn, NY.*

Renal masses are a frequent incidental radiological finding. Renal cell carcinoma (RCC) is the most common primary renal malignancy, however primary renal lymphoma (PRL) is rare.

We report a case of a 73-year-old man who presented with left flank pain. He had no hematuria, and other than 20 lb weight loss, had no other complaints. On examination, he had no palpable flank mass, no temporal wasting and no palpable lymphadenopathy. CT scan revealed a large soft tissue mass measuring 11 cm in the upper pole of the left kidney. The mass abutted the aorta and surrounded the left renal vessels.





Core needle biopsy of the mass showed malignant non-Hodgkin lymphoma, large B cell type. The malignant cells stained positive for lymphocyte common antigen and CD-20; and negative for CD-3. Bone marrow biopsy didn't show any involvement by lymphoma. Positron Emission Tomography (PET) showed intense uptake in the left kidney (SUV-26). He was started on multi-agent chemotherapy with rituximab, cyclophosphamide, vincristine, doxorubicin and prednisone (R-CHOP). Soon after starting chemotherapy, patient's pain improved. Patient tolerated chemotherapy well, except for mild sensory peripheral neuropathy. He had complete resolution of the renal mass on CT scan and repeat PET scan 6 months later showed physiologic distribution of radiotracer. Two years after initial presentation he continues to do well and remains disease free.

PRL is a rare tumor of the kidney. The prognosis of PRL is poor in the cases reported in the literature. Our case demonstrates the effectiveness of R-CHOP in treatment of PRL, and that prognosis can be good after completion of chemotherapy. Chemotherapy can be safely administered despite large tumor involving the kidney. This case also demonstrates the usefulness of PET scan in assessing initial disease staging and then the response to chemotherapy.

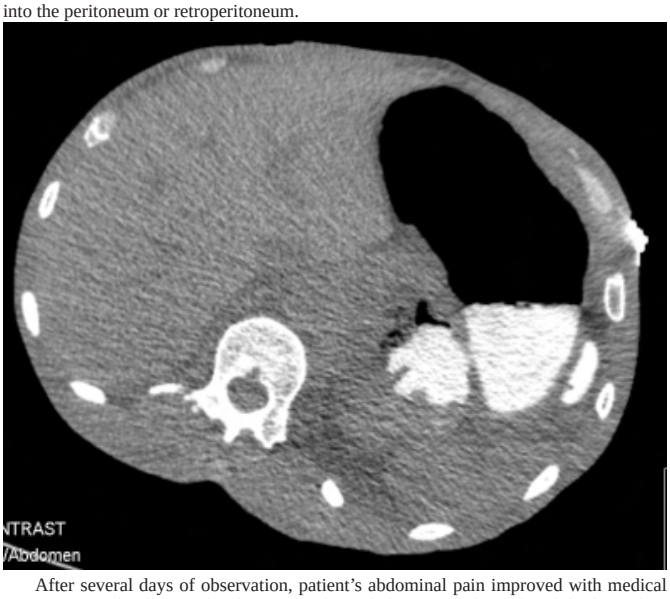
Disclosure of Financial Relationships: nothing to disclose

**PUB301**

**A Rare Complication Following Treatment of Left Sided Renal Cell Carcinoma (RCC)** Amarpali Brar, Ratesh Khillan, Getinet Ayalew, Gurinder S. Sidhu. *Medicine, SUNY Downstate Medical center, Brooklyn, NY.*

RCC is the most common cancer of the kidney. Radical nephrectomy (RN) can be curative for localized RCC and may improve survival in metastatic disease.

We report a case of a 52-year-old woman who presented with left flank pain and 20 lb weight loss. Her physical exam was unremarkable except for bitemporal wasting. CT scan revealed a large left upper pole renal mass. The mass was 7 cm, inseparable from the adrenal, abutting the pancreas and left renal vessels; with retroperitoneal lymphadenopathy. Percutaneous biopsy showed RCC, clear cell type. She was found inoperable at the time of surgery; and was started on sorafenib with control for several months; and then sunitinib. Upon increase in the mass, she was switched to temsirolimus. After having had temsirolimus for 12 weeks, she returned with abdominal pain and nausea. Physical exam was unremarkable but her performance status was poor. CT scan showed that the renal mass was smaller than before, had central necrosis and had eroded into the posterior wall of the stomach; and no other distant metastases. The oral contrast was seen in the stomach with direct flow into the necrotic center of the mass; with no extravasation of the contrast into the peritoneum or retroperitoneum.



After several days of observation, patient's abdominal pain improved with medical management; she did not develop any peritoneal signs and tolerated oral feeds. Patient chose non-surgical management and was transferred to a hospice.

This case illustrates the local problems that may result from an unresected RCC, despite absence of distant metastasis. The stomach invasion could be due to tumor necrosis as a result of temsirolimus or direct tumor extension. RCC can have severe local complications even in the absence of metastases; RN at initial presentation should be considered to prevent local complications.

**PUB302**

**Mycophenolate (Myfortic®) in Autoimmune Diseases: Effect on Clinical Course and Chemical Parameters** Helga Frank,[1] Sabine Seibel,[1] Martin Wittner,[2] Uwe Heemann.[1] *[1]Nephrology, Technical University Munich, Munich, Germany; [2]Dialyse Ebersberg, KfH, Ebersberg, Germany.*

Background:

The enteric-coated formulation of mycophenolate sodium (EC-MPS; Myfortic®), a reversible inhibitor of inosine monophosphate dehydrogenase with delayed release of MPS, is used to prevent rejection of renal allografts.

The objective of our prospective non-randomized open pilot phase III longitudinal study was to evaluate the effect of EC-MPS in antibody-associated autoimmune diseases with respect to the function of the affected organs, and immunserological course of antibodies.

Methods

Twenty-five patients (10 males; mean age: 49.3±12 years) with new-onset or relapsed autoimmune disease were consecutively enrolled. Underlying diseases were: ANCA-associated vasculits (n=7; c-ANCA: n=5, p-ANCA: n=2), IgA-nephritis (n=7), systemic lupus erythematodes/SLE (n=4), sclerodermia (n=2), membranous glomerulonephritis (n=2), dermatomyositis (1), sharp syndrome (1), focal glomerulosclosis with psoriasis (1). Patients received EC-MPS with a target daily dose of 2 x 720 mg/day combined with orally corticosteroids. Primary endpoints were function of the affected organ, course of chemical and immunserological results (ANA; ANCA; c3, c4) and self-assessment by questionary (SF 36) 3 (A) and 12 months (B) after treatment start.

Results:

After a mean follow-up of 45±12 weeks, creatinin-clearance (CCl) rose in patients with renal affection (n=11) from 87±50(baseline) to 92±50 (A) and 113±41 ml/min (B). Proteinuria decreased from 1.95±1.57 to 1.4±0.9 (A) and 1.24±0.7 g/gCrea (B). In patients

with extrarenal affections(n=19), symptoms (arthralgia, scleritis, cutaneous/muscular/neurological manifestations) improved in n=17 patients. ANA/ANCA (initially positive in n=14/7) improved in n=6/5. During the study period, 6 patients were hospitalized due to infections (urinary/respiratory tract: n=3/3). Two patients with cANCA-vasculitis and 1 with sclerodermia progressed and treatment was extended to cyclophosphamide. One patient with SLE died from cardiovascular disease. EC-MPS was well tolerated in terms of GI side effects.

Conclusion

EC-MPS can be a useful and steroid-sparing immunosuppressant in various autoimmune diseases.

**The Trend of Anti-Hypertensive Agents of Incident Dialysis Patients Prior to Regular Hemodialysis** Yen Ni Hung,[1] Yee-Yung Ng,[2] Shiao Chi Wu.[1] [1]*Institute of Health and Welfare Policy, National Yang Ming University, Taipei, Taiwan;* [2]*Division of Nephrology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background

The ACEI and ARB have been reported to be beneficial to slow down the deterioration of renal function even in the patients with renal failure. The condition of administration of these agents in incident patient prior to regular dialysis is seldom investigated.

Methods

We retrospectively enrolled 23907 adult incident patients who began regular dialysis between January 1 2004 and December 31, 2006. All incident patients with first payment code for ACEI and ARB before 3 years of beginning regular dialysis were identified to analyze the condition of ACEI and ARB administration.

Results

In this study, we found that there is a trend of reducing administration of these agents for the incident dialysis patients closing to the regular dialysis.

The 3-years antihypertensive agents of incident patients before regular dialysis

| | Total | year 2004 | year 2005 | year 2006 |
|---|---|---|---|---|
| | number (%) | number (%) | number (%) | number (%) |
| The 1st year of anti-hypertensive agents prior to HD | | | | |

| ARB (%) | 1156 (4.84) | 378 (4.93) | 398 (4.69) | 380 (4.9) |
| The 2nd year of anti-hypertensive agents prior to HD | | | | |
| ACEI inhibitors (%) | 847 (3.54) | 282 (3.67) | 314 (3.7) | 251 (3.24) |
| CCBs (%) | 3759 (15.7) | 1235 (16.09) | 1283 (15.12) | 1241 (16.02) |
| ARB (%) | 1777 (7.43) | 522 (6.8) | 644 (7.09) | 611 (7.89) |
| The 3rd year of anti-hypertensive agents prior to HD (%) | | | | |
| ACEI inhibitors (%) | 1156 (4.84) | 383 (4.99) | 439 (5.17) | 334 (4.31) |
| CCBs (%) | 4043 (16.91) | 1356 (17.67) | 1450 (17.09) | 1237 (15.97) |
| ARB (%) | 1864 (7.8) | 501 (6.53) | 695 (8.19) | 668 (8.62) |
| Total | 23907 | 7674 | 8485 | 7748 |

In conclusion, the reason of decreasing trend of ACEI and ARB administration in incident dialysis patients prior to regular dialysis should be further investigated in order to keep thses agents for slowing down the deterioration of renal function, and then delay the dialysis.

**Acute Diabetes Insipidus in Tramatic Brain Injury** Kyung Soo Kim, Min Ji Lee, Bernice Kim, Eun Jin Kwon, Sung Zoon Shin. *Division of Nephrology, Department of Medicine, Dongguk University Ilsan Hospital, Goyang City, Kyunggi-do, Korea.*

**Aim**

Although Central Diabetes Insipidus (CDI) is a well-known complication, which is caused by a lack of the vasopressin, and induces severe dehydration, electrolyte imbalance, and cardiovascular collapse, almost all of research papers have been reported without making any mention of a contribution of nephrologist care or it's effect on the outcome.

The aim of this study was to evaluate the incidence and risk factors for acute CDI in traumatic brain injury, and assess the effect of nephrologist care on the morbidity and mortality.

**Method**

We reviewed medical data, retrospectively, of patients with CDI complicated in traumatic brain injury from Jan 2007 to Dec 2009. CDI was diagnosed if plasma sodium was > 150 mmol/L in the presence of polyuria of > 3 L/24 hours in the acute clinical setting, or if, after an overnight water deprivation test or an 8-hour observed water deprivation test, urine osmolality was > 600mOsmol/kg, and desmopressin acetate was used.

**Results**

CDI occurred in 34 (11%) patients among 300 patients who diagnosed of traumatic brain injury. The mean age(±SD) was 51.5(±15.8) years old, and the number of male gender was 20 (58.8%) in CDI patients. Independent risk factors for CDI in traumatic brain injury were cerebral edema, low Glasgow coma scale, and hypotension needed more than 2 inotropics. On 34 CDI patients, the 8 were under nephrologist care with other specialties including neurologists or neurosurgeons, and they demonstrated better survival rate (15 deaths in 26 CDI patients without nephrologist care (58%) vs. 3 deaths in 8 with nephrologist care (38%)), but not a statistically significant.

**Conclusion**

The CDI in traumatic head injury is not an unusual complication. Cerebral edema, low Glasgow coma scale, and severe hypotension were associated with development of CDI among the patients with traumatic brain injury.

Although CDI is associated significantly with increased morbidity and mortality, nephrologist care might have a beneficial effect on the outcome. It will be needed of nephrologists to take an active part for the proper management of CDI patients in these critically ill settings.

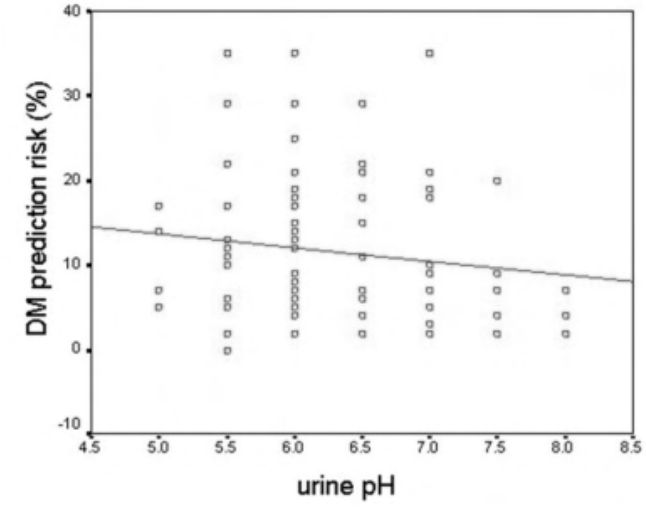
**Urine pH as a Predictor of Developing Type 2 Diabetes** Omar H. Maarouf, Majed Samarneh, Layla Kamal, Isabelle Ayoub, Rabih Nasr, Samer El Zarif, Marie Abdallah, Suzanne E. El Sayegh. *Medicine, Staten Island University Hospital, Staten Island, NY.*

The role of urine pH in predicting the risk for developing diabetes mellitus remains unclear. We hypothesize that as urine pH increases, the risk of developing diabetes mellitus decreases. We performed a retrospective cohort study of patients admitted to Staten Island University Hospital during the period from June 2008 to June 2009. Patients with conditions that are known to influence the urine pH were excluded: CKD (defined as GFR< 60 for over 3 months), urinary tract infection, acute kidney injury, and chronic indwelling bladder catheter. The final study cohort included 92 subjects who had an appropriate database to use the Atlanta diabetes risk prediction model for estimation of the diabetes risk score. Urine pH was inversely correlated with the diabetes risk prediction score but this was not statistically significant (r= -0.14, p=0.20). Univariate analysis showed that BMI ≥ 30 kg/m$^2$ was associated with a lower urine pH but this was not statistically significant. There was no association between urine pH and hypertension, low HDL or elevated TG. Our study had a few limitations. First, it is a retrospective cohort without a long term follow-up. Another limitation is the limited number of participants in the final cohort. Moreover, we have not validated the accuracy of a urine dip in calculating the urine pH for this study. Our study is the first to examine the relationship between urine pH as a marker of insulin resistance and the risk of developing diabetes. We found an inverse relationship between urine pH and the risk of developing diabetes although not statistically significant.



Urine pH is a promising marker of insulin resistance. If validated, urine pH has the potential to become one of the screening tools for diabetes in the primary care setting.

**PUB306**

**Non-Embolic Renal Infarction: Association with Fibromuscular Dysplasia: 16 Year Experience with 22 Patients, 1994-2010** Lionel U. Mailloux,[1] Susana Hong,[1] Craig Greben,[2] Eric John Gandras.[2] [1]*Department of Medicine/Nephrology, North Shore University Hospital, Port Washington, NY;* [2]*Department of Interventional Radiology, North Shore University Hospital, Manhasset, NY.*

Renal infarction (RI) has been seen in 22 patients with renal artery stenosis. Fibromuscular dysplasia (FMD) was present in 18 patients. Demographics: 16 female, 21 Caucasians, ages 31-81, median age 54. These patients presented to the Emergency Department with excruciating flank pain. Imaging was performed: CT studies in all patients were suspicious for RI. Diagnostic angiography was then performed with a diagnosis of FMD in 18 patients in addition to confirming the RI in all patients.

At the time of angiography, angioplasty and stent deployment were performed when fibromuscular dysplasia with any significant obstruction of blood flow was seen. The patients have been followed up for at least one year and there have been no further renal infarcts;

some patients have been followed for as long as 10 years. Three patients had previously developed total occlusion of the renal arteries, but prior to the time that the current infarcts were diagnosed. These 3 patients had FMD in their non-infarcted kidney. Three patients had intimal dissections of their renal arteries diagnosed at the time of angiography. All patients undergoing angioplasty and/or stent deployment were treated with clodiprogel for one year and either an ACE inhibitor or ARB for their blood pressure. Sequential follow up by renal Doppler ultrasound has been performed to determine the patency of the stent, and renal function is being monitored.

**Conclusion:** Although renal infarction is not rare, its association with the presence of fibromuscular dysplasia of the renal artery has previously not been reported in a series of patients. This is a series of cases in both men and women who have now been followed for a long period of time and who have subsequently done well after intervention. No one has developed progressive renal disease during the follow up period.

Disclosure of Financial Relationships: nothing to disclose

## PUB307

**A Retrospective Study of the Renal Biopsies Realized in Native Kidneys at the Cleveland Clinic Florida from 2000 to 2010** Julianne M. Parente, Mauro Braun, Ayman Layka, Rute C. Paixao, Dianne T. Sandy, Beth L. Fromkin. *Nephrology Department, Cleveland Clinic Florida, Weston, FL.*

**Introduction**: Renal biopsy is an invaluable tool in the diagnosis, prognosis and management of patients with kidney disease. The main indications for this procedure include establishment of the exact diagnosis, determine the nature of therapy, decide when treatment is futile or evaluate for potentially reversible changes.

**Objectives:** This study was conducted to determine the results of percutaneous renal biopsies realized in native kidneys during the last 10 years by the Nephrology group of Cleveland Clinic Florida. Investigate the characteristics of the population referred for biopsies in terms of age, sex distribution, presence of renal failure, presence of proteinuria and its range (nephrotic vs non-nephrotic) and diagnosed pathologies. Obtain epidemiologic data and compare to similar studies available on the literature.

**Material and Methods:** Results of 184 renal biopsies with definitive diagnosis realized in Cleveland Clinic Florida from 2000 to 2010 were retrospectively analyzed for age, sex distribution and diagnosis using Epi Info software.

**Results:** Among the 184 patients analyzed, the mean age was 53 ±17 years (range between 16 and 91) and 47.8% (88 patients) were male. Renal failure was present in 79.3% (146) of the patients and 95.7% (173) had proteinuria. Among those, 44.9% (79 patients) had nephrotic range proteinuria. The most frequent diagnoses encountered were Focal Segmental Glomerulosclerosis (FSGS) (35 patients, 19%); Lupus Nephritis (21 patients, 21.4%) and Acute Interstitial Nephritis (AIN) (20 patients, 10.9%). The gender distribution showed that Lupus Nephritis was the most common diagnosis in females (16.7%, 16 patients) and FSGS was the most common diagnosis in males (25%, 22 patients).

**Conclusion:** In our results, FSGS, Lupus Nephritis and AIN were the most frequent biopsy-proven renal diseases. In comparison to previous studies reported on the literature that showed IgA nephropathy as the most common diagnosis, our epidemiology seems to differ. We suggest the establishment of a national US registry database for future epidemiological analysis.

## PUB308

**Clinical Effects of CCB and RAAS-I on ΔeGFR in ADPKD Patients Was Assessed by Analysis of Covariance (ANCOVA)** Ken Tsuchiya, Michihiro Mitobe, Takumi Yoshida, Hidekazu Sugiura, Shunji Shiohira, Kosaku Nitta. *Department of Medicine IV, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan.*

Intracellular Ca level is likely to play critical roles in the cyst formation in the ADPKD patients. Although *in vitro* and *in vivo* study using an animal model of ADPKD showed that CCB might accelerate the cyst progression, the possibly unfavorable effects of CCB on the pathophysiological status of PKD have not been examined using a clinical approach. Previously we investigated about this issue using conventional statistical method, in this study, analysis of covariance (ANCOVA) was used to evaluate the influence of CCB and renin- angiotensin-aldosterone system inhibitors (RAAS-I; including ACEI and ang II receptor blocker) with respect to the decrease of the eGFR. This model has included following confounding factors, baseline eGFR, mean SBP, and mean DBP. The effects of profile, linearity, interaction, and co linearity in ANCOVA were examined using regression diagnostic analysis. Two-tailed P-values of less than 0.05 were considered to be significant. Periods during which the antihypertensive drug prescriptions for CCB and/or RAAS-I had not been changed for at least one year were selected from among the clinical histories of the 32 outpatients. The mean values were; treatment duration,2.4 years; age, 49.5 years; SBP/DBP, 125 and 78 mmHg, respectively. The mean baseline eGFR was 34.4 mL/min/1.73 $m^2$ and the mean change in eGFR per year (ΔeGFR) was -2.7 mL/min/1.73 $m^2$/year. Only CCB significantly contributed to a reduction in ΔeGFR in both a univariable ANCOVA (crude coefficient: -2.00, 95%CI: -3.29 to -0.71, p=0.004) and a multivariable ANCOVA (crude coefficient: -1.79, 95%CI: -3.28 to -0.30, p=0.020). In contrast, none of the other confounding factors, RAAS-I, the baseline eGFR, SBP, DBP, contributed to reductions in ΔeGFR in both a univariable and multivariable ANCOVA. There has been no evidence that CCBs directly influence on the polycystin protein, nevertheless CCB might have a unfavorable effect on renal function in ADPKD patients, to whom RAAS-I should be the first choice. To establish these results further randomized studies with larger sample sizes are required.

## PUB309

**Long Term Follow Up of Renal Function in Patients with Cystic Fibrosis** Marius C. Florescu,[1] Elizabeth Lyden,[1] Diana F. Florescu,[1] Jennifer A. Fillaus.[2] *[1]University of Nebraska Medical Center, Omaha; [2]Sioux Fall.*

**Background**

Cystic fibrosis (CF) patients have numerous infections requiring prolonged antibiotic treatments, some of them nephrotoxic. Inhaled antibiotics can reach detectable levels. The aim of our study was to determine the impact of long term antibiotics use on the kidney function in CF population.

**Methods**

Data was retrospectively collected for 113 adults over 8 years. Spearman correlation coefficients were used to look at associations of continuous variables and Wilcoxon rank sum test to compare kidney function with various covariates.

**Results**

57(50.4%) patients were males and 56(49.5%) females, [mean age 31.7 years (SD 9.68)] of which 31% had DM, 9.7% HTN and 8.8% renal stones.

Over 8 years follow-up there were no significant changes in BUN (p0.92) or creatinine (p0.2); the presence of DM or contrast use was not associated with changes in renal function.

22% of the group had ≥ 1 episodes of ARF. The presence of ARF was associated with increased BUN (p0.002) and creatinine (p0.056) at 8 years.

Use of intravenous colistin (COL), gentamicin (Gm) or tobramycin (Tob) did not correlate with increased BUN (p0.64; p0.49; p0.51) or creatinine (p0.43; p0.49; p0.17). Documentation of elevated Tob peak and through levels did not correlate with increased BUN or creatinine. The use of intravenous vancomycin did not significantly increase BUN (p0.47) or creatinine (p0.2).

Inhaled COL and Gm correlated with increased BUN (p0.009; p0.02) but not creatinine (p0.45;p0.46). Inhaled Tob did not correlate with increased BUN (p0.17) or creatinine (p0.58). Only inhaled COL correlated with episodes of ARF (p0.03).

Episodes of ARF and renal function did not correlate with none of the major CF genetic mutations.

**Conclusion**

This is the first study to assess the impact of antibiotic use on renal function in CF population. The use of nephrotoxic antibiotics in CF patients is not associated with significant renal toxicity over 8 years. Intravenous COL, Gm, Tob and vancomycin were not associated with elevated BUN and creatinine. Only inhaled COL and Gm were associated with increased BUN, but not creatinine.

## PUB310

**New Markers of Inflammation-Induced Renal Injury Subside When Endotoxin Tolerance Develops in Humans as Measured by Urine Proteomics** Suzanne Heemskerk,[1,2] Annelies Draisma,[1] Martijn P. W. J. M. Bouw,[1] Coby M. M. Laarakkers,[3] Johannes G. van der Hoeven,[1] Rosalinde Masereeuw,[2] Peter Pickkers.[1] *[1]Intensive Care Medicine, Radboud University Medical Center Nijmegen, Nijmegen, Netherlands; [2]Pharmacology and Toxicology, Radboud University Medical Center Nijmegen, Nijmegen, Netherlands; [3]Clinical Chemistry, Radboud University Medical Center Nijmegen, Nijmegen, Netherlands.*

**Background**

Sepsis has been identified as the most common cause of renal injury in the ICU. No large clinical studies are available that show an improvement of renal function in patients with sepsis and this may be related to the lack of early diagnostic tests that indicate the onset of renal injury.

**Objective**

The aim of the current study was to search for potential new early markers of renal injury during acute endotoxemia and to investigate whether renal injury can be ameliorated by the induction of lipopolysaccharide (LPS) tolerance.

**Methods**

Healthy males (n=5) received iv bolus injections of 2 ng/kg/day *E. coli* LPS for 5 consecutive days. We used Surface enhanced Laser Desorption/Ionization Time-of-Flight Mass Spectrometry (Seldi-TOF MS).

**Results**

Repeated LPS administrations induced a diminished GFR of 33±7% (p=0.02) on day 2 and an increase in serum creatinine of 11±3% (p=0.002) on day 3, which was associated with the appearance of 15 peak intensities in the urinary protein profile including an increase in β2-microglobuline levels (p=0.04) 6 hours after the first LPS administration. Four of the 15 peak intensities on day 1 correlated with serum creatinine levels on day 3; 3950, 4445, 6723 and 7735m/z (p=0.03; 0.01; 0.02 and 0.05 respectively). With the development of LPS tolerance, renal function restored, reflected by a decrease in serum creatinine and β2-microglobuline levels to baseline (p=0.2 and 0.4 respectively, between day 1 and 5), and by attenuated peak intensities in the urinary protein profile (p<0.0001 for all 15 peak intensities).

**Conclusion**

In conclusion, renal injury occurs during repeated endotoxemia and can be predicted by new urinary markers using proteome research. The inflammation-induced renal injury subsided when LPS tolerance developed after 5 consecutive days of LPS administrations.

**The Effects of Different Solvents on the Amount and the Efficiency of Glycoprotein Enrichment Using Concanavalin A** Xuejiao Liu,[1] Mingxi Li,[1] Bixia Gao,[1] Xiaohong Fan,[1] Xuemei Li,[1] Youhe Gao,[2] Xue-Wang Li.[1] *[1]Nephrology, Peking Union Medical College Hospital, Beijing, China; [2]Peking Union Medical College, Beijing, China.*

**Objective:** Glycoprotein is one of the most important post-translational modification proteins in urine. This study evaluates the effects of different solvents on the amount and the efficiency of glycoproteins enrichment using Concanavalin A (Con A) in urinary glycoproteome. **Methods:** The morning urine samples of six healthy donors (3M/3F, 20-30 year old) were collected and pooled together. The proteins were precipitated by acetone. The samples were divided into 4 groups according to different solvents: [circ1]25mM $NH_4HCO_3$,[circ2]Lysis buffer (7M Urea, 2M Thiourea, 1%DTE and 5%Tris-base), [circ3] Lysis buffer diluted five times, [circ4]Buffer of ConA-agarose. The same amount (1300mg) of proteins solved by different solvents were loaded on ConA-agarose and incubated at 4°C overnight. The sample of control was solved by 25mM $NH_4HCO_3$, loaded on Agrose and incubated at 4°C overnight. Bradford method was used to measure the concentration of proteins. The 1D-SDS-PAGE electrophoresis was used to compare the inter-group differences in glycoprotein bands. **Results**: Lysis buffer solved the most amount of proteins (2621mg) compared to that solved by 25mM $NH_4HCO_3$ (1987mg) and ConA-agarose (1536mg). Lysis buffer diluted five times(G3) captured the most amount of glycoproteins (75mg) among solvents (50mg in G1, 45mg in G2 and 56mg in G4). Agarose did not enrich any glycoproteins. The 1D-SDS-PAGE electrophoresis showed the glycoprotein bands of G2 and 3 were more than that of G 1 and 2.

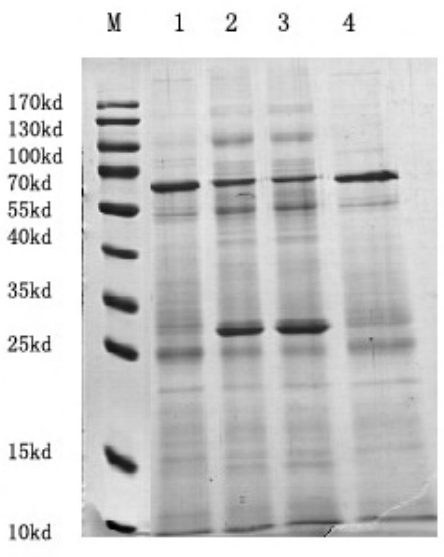

Figure 1:Glycoprotein captured by ConA in Group 1, 2, 3, 4 respectively (M:marker)

**Conclusion:**Among these solvents, lysis buffer solves the most amount of urinary proteins, and lysis buffer diluted five times captures the most amount of glycoproteins. This solvent also improves the efficiency of glycoproteins enrichment by Con A in glycoproteome study.

**Dermal Hyperplasia in a Renin Secreting Transgenic Mouse: A Potential Animal Model for Nephrogenic Systemic Fibrosis (NSF)** Mandip Panesar,[1] Sandra Buitrago,[2] George Hajduczok,[2] Craig A. Jones,[2] Kenneth W. Gross.[1,2] *[1]Medicine, Physiology, State University of New York at Buffalo, Buffalo, NY; [2]Molecular and Cellular Biology, Roswell Park Cancer Institute, Buffalo, NY.*

NSF is a systemic fibrosing disorder occurring in renal failure patients and may be triggered by exposure to gadolinium-based contrast agents (GBCA). Given the ethical dilemma of administering GBCA to renal failure patients, an animal model is needed to better understand NSF. The purpose of this study was to determine whether an established transgenic mouse is a suitable animal model of NSF. We previously developed a transgenic (RenTag) mouse model in which the control region of the renin gene is used to promote expression of a viral oncogene. The mouse was created by fusing 4.6Kb of the 5'-flanking region of the mouse Ren2 gene to the SV40 T antigen structural gene. We previously reported a dramatic and spontaneous restructuring of the renal vascular bed consisting of hyperplasia of medial smooth muscle cells within the vascular wall leading to occlusion of the lumen as evinced by paleness consistent with low renal perfusion and was clearly evident by 12 weeks. The pathology progressed to encompass intimal lesions, inflammatory infiltrates in interstitial tissue, focal obstruction of collecting tubules, dilatation and degeneration of proximal tubules and hypercellular glomeruli with features of renal failure. We now report the skin of these transgenic animals to be non-elastic, tight, and thick. Histological analysis revealed thickened dermis with densely staining collagen bundles at 12 weeks. BUN was consistently elevated at 6, 8, 10 and 12 weeks. Collectively, these findings are suggestive of NSF in humans which is characterized by thickening and hardening of the skin. We also determined whether the dermal pathology was an outgrowth of impaired renal function. RenTag mice (6-10 weeks) with impaired kidney function were exposed to gadodiamide (0.3 mmol/kg, iv) to determine whether gadolinium exacerbated the NSF characteristics similar to the human clinical condition. This animal model may provide insights into the biological mechanisms underlying NSF.

**Report of a Male Italian Imerslund-Grasbeck Patient with an Effective Null Mutation of the *CUBN* Gene** Tina Storm,[1] Francesco Emma,[2] Pierre J. Verroust,[1] Jens Michael Hertz,[3] Rikke Nielsen,[1] Erik I. Christensen.[1] *[1]Anatomy, Aarhus University, Denmark; [2]Nephrology and Urology, Ospedale Bambino Gesú, Italy; [3]Clinical Genetics, Aarhus University, Denmark.*

**Background:** Imerslund-Gräsbeck syndrome is a rare autosomal recessive disorder characterized by selective, intestinal, intrinsic factor-vitamin $B_{12}$ malabsorption. An additional proteinuria is frequently observed in these patients. The disease can be caused by mutations in the *CUBN* and *AMN* genes encoding the cubam receptor partners cubilin and amnionless. **Aim:** The aim of this study was to describe the functional renal phenotype of an Imerslund-Gräsbeck Syndrome patient. **Methods:** Mutation detection was performed through direct sequencing of the *CUBN* gene of a male Imerslund-Gräsbeck patient born from consanguineous parents. Immunohistochemistry of a renal biopsy collected from the patient, together with immunoblotting analyses of collected urine was used for phenotypic determination. **Results:** We identified a homozygous guanine for thymine exchange in the conserved donor splice site of exon 23 of the *CUBN* gene. No cubilin was detected in the renal biopsy suggesting an effective null mutation. Amnionless displayed an abnormal cytoplasmic localization in the proximal tubule cells demonstrating the interdependent relationship of the two receptor proteins, for the first time, in man. The patient´s urinary excretion pattern furthermore indicated a selective tubular proteinuria. **Conclusions:** We established direct correlations between the immunohistochemical data and the urinary protein excretion in an Imerslund-Gräsbeck patient hereby demonstrating the role of cubilin in handling of filtered proteins in the human kidney. Furthermore, no developmental abnormalities or physical defects of the patient suggest that cubilin is not essential for human embryonic development.

**Effects of Uremic Toxins on Gene Expression in Human Renal Tubular Cells** Daniel M. Torres, Francisco Ramirez-Valle, Hania Kassem, Jiri Zavadil, Jerome Lowenstein. *Medicine, New York University Langone Medical Center, New York, NY.*

To test the hypothesis that uremic toxins are excreted by active renal tubular transport, and that the genes controlling these putative transporters might be upregulated in uremia (as a compensatory mechanism), we compared gene expression (using Affymetrix HG-U133 Plus 2.0 arrays) in cultured normal human renal tubular cells exposed for 24 or 48 hours to plasma from normal donors (N, n=2) or plasma obtained pre- and post-dialysis in patients with stable end-stage renal disease (ESRD, n=3).

Results: 527 genes were detected as significantly modulated in cultured cells incubated in N and in ESRD plasma. Comparing the gene expression in N and ESRD plasma, among the array of genes encoding putative transporters, we identified 16 genes whose expression were differentially effected by uremic plasma. Of these 6 were upregulated. Among these were genes encoding for a K conductance calcium channel (SLC23A2) and a calcitonin receptor (CALCA). A gene encoding the organic anion transporter SLC22A6 was downregulated.

178 genes believed to be associated with inflammatory responses were identified. Of these, these several genes related to TGF-beta signaling and its downstream profibrotic and promigratory effects (LTBP2, LAMC2, MMP9, SERPINE1, TGFBI) and other genes related to inflammation ,(CXCL2, CXCR7, IL6ST, TNFRSF19, TNFSF15) were upregulated on exposure to uremic plasma. The overexpression of the TGF beta signature was normalized following 3-3.5 hour hemodialysis.

Conclusions This pilot project appears consistent with our hypothesis that substances that are not completely removed by hemodialysis accumulate in the plasma of uremic patients and may play a role in the regulation of selected transport proteins serving as a compensation for the reduced nephron mass. Further, the increase in proinflammatory and profibrotic signaling may be implicated in the ongoing inflammation that characterizes the uremic state; normalization of the expression of these genes suggests that this increase may be attenuated at the molecular level by hemodialysis.

**Renal Cyst Number Measured on MR Images in ADPKD Kidneys: Inter-Reader Variability and the Total Renal Cyst Number Estimated from the Cyst Number on a Single Mid-Slice Image** Kyong Tae Bae,[1] Cheng Tao,[1] Amol A. Patil,[1] Arlene B. Chapman,[2] Jared J. Grantham,[3] Vicente E. Torres,[4] Lisa M. Guay-Woodford,[5] Peter C. Harris,[4] Marva M. Moxey-Mims,[6] William M. Bennett,[7] Jin Hong Wang,[1] Diana Kaya,[1] James E. Bost.[1] *[1]U Pittsburgh; [2]Emory U; [3]U Kansas; [4]Mayo Clinic; [5]UAB; [6]NIDDK; [7]Legacy Good Samaritan.*

In ADPKD, renal cyst number is likely associated with the genotype, renal volume progression and ultimate decline in GFR. The purpose of the study is to evaluate inter-reader variability of measuring renal cyst number and to estimate the total renal cyst number from a single mid-slice MR image.

Two radiologists counted cysts with diameters ≥ 2 mm in each kidney on a mid-section of coronal T2 MR images (12- 65 sections) in 221 ADPKD CRISP subjects. Inter-reader reliability was assessed with intraclass correlation coefficient (ICC). Differences in total cyst count, averaged over the two readers, between gender and genotype (PKD1, PKD2) were assessed with t-tests. Pearson correlation coefficient of reader bias with total kidney volume was also determined. Furthermore, in 16 of 221 subjects, the two readers reviewed the entire set of images of each kidney and counted the total number of cysts (TNC). Association between TNC and the product of the mid-section cyst count (MNC) and the number of sections (NS) in each kidney was evaluated with correlation coefficients.

The inter-reader reliability of measuring MNC was extremely high (ICC=0.99). Reproducibility was within ±10% for 94% of the cases. Overall bias and variability (mean ± SD), as measured by the difference in cyst number between the two readers, was negligible at -0.26 ± 3.79. Cyst numbers were significantly higher in subjects with PKD1 than PKD2 (mean 63±28.4 vs 37±22.4; p< 0.001) but no difference was noted by gender. Bias was not significantly affected by genotype (p=0.664) or kidney volume (p=0.433). TNC correlated strongly ($r^2$=0.50) with MNCxNS and may be estimated from a regression relationship (TNC = 0.127xMNCxNS).

Cyst numbers measured in a mid-section of MR images are highly reliable and reproducible and may be used to estimate the total cyst number within the kidney.

**Vitamin A Deficiency with Decreased Serum Retinol Binding Protein in Dent's Disease** Rachel Becker-Cohen, Choni Rinat, Efrat Ben Shalom, Sofia Feinstein, Yaacov Frishberg. *Division of Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel.*

Dent's disease is an X-linked renal proximal tubular disorder manifesting as low molecular weight proteinuria, hypercalciuria, nephrocalcinosis and progressive renal impairment. Three patients with Dent's disease presented with complaints of impaired night vision, and xerophthalmia. Laboratory evaluation showed severely decreased serum vitamin A concentrations. Retinol binding protein (RBP) is a transport protein for vitamin A, delivering it from the liver to target organs. The retinol–RBP complex is filtered at the glomerulus and normally undergoes reabsorption at the proximal tubule. Our hypothesis was that renal losses of RBP in Dent's disease could be responsible for decreased serum retinol. We investigated vitamin A status and RBP in serum and urine of 8 patients with genetically confirmed Dent's disease. We found that in addition to the 3 boys with clinical vitamin A deficiency, 3 others had asymptomatic deficiency with a normal ophthalmologic examination, all had normal renal function. Two young men with Dent's disease and impaired renal function had normal serum vitamin A concentrations. Serum RBP concentrations were low in patients with vitamin A deficiency, and were correlated with vitamin A levels. Urinary RBP concentrations were increased in all patients (2000 fold), regardless of vitamin A status. We compared these results to patients with nephrotic range proteinuria due to glomerular disease and patients with advanced nephropathic cystinosis, another proximal tubulopathy. Patients with glomerular proteinuria had only mildly increased urinary RBP with normal serum RBP and vitamin A. Patients with cystinosis and impaired renal function had massive urinary RBP losses, but without a decrease in serum RBP or vitamin A levels, similarly to the adult patients with Dent's disease and low GFR. Treatment with moderate dose vitamin A supplements in 5 patients with vitamin A deficiency resulted in rapid resolution of ocular symptoms and an increase in serum vitamin A concentrations. We recommend screening patients with Dent's disease for vitamin A deficiency, and treating before the appearance of visual symptoms.

**Endothelial Cell Proliferation after Cysteamine Exposure** Martine T. Besouw,[1,3] Lambertus V. Heuvel,[1,3] Mieke Dewerchin,[2] Elena N. Levtchenko.[1,3] *[1]Dept of Pediatric Nephrology, University Hospitals Leuven, Leuven, Belgium; [2]Vesalius Research Center, VIB-KULeuven, Leuven, Belgium; [3]Laboratory of Pediatrics, KULeuven, Leuven, Belgium.*

**Background**

Cysteamine is used to treat cystinosis, an autosomal recessive disease caused by intralysosomal cystine accumulation due to mutations in the *CTNS* gene. Recently 8 patients with cystinosis were reported with muscular-skeletal weakness, skin striae and bruising-like lesions on elbows after administration of high doses of cysteamine. Skin biopsies of the elbow lesions showed vascular endothelial cell proliferation called angioendotheliomatosis and a variability of collagen fiber caliber on electron microscopy. We aimed to study the mechanisms of these side effects *in vitro*.

**Methods**

Human microvascular endothelial cells (HMVEC) and human fibroblasts were incubated with a range of cysteamine concentration (0-10 mM) during 6 or 24 hours. Medium and cysteamine were refreshed every 6 hours. Cell viability was measured using WST-1, which represents cleavage of the tetrazolium salt WST-1 to a formazan-class dye by viable mitochondria. Next, we measured cell proliferation by BrdU, which is incorporated in the DNA of dividing cells.

**Results**

After 6 hours, cell viability did not differ significantly between specific cysteamine concentrations or cell types; cell proliferation increased significantly in HMVEC after exposure to concentrations between 0.03-3.0 mM. After 24 hours, a significant rise in WST-1 signal was found in both cell types and a significant rise in BrdU incorporation was found in HMVEC at concentrations between 0.03-1.0 mM. A concentration of 10 mM was toxic in all cell types.

**Conclusion**

Exposure to cysteamine at concentrations found in patient's plasma can increase proliferation of HMVEC, both measured by cell viability and proliferation assays. This is in line with the *in* vivo finding of cysteamine induced angioendotheliomatosis in cystinosis patients. The rise in WST-1 signal without a rise in BrdU signal seen in fibroblasts could be due by cysteamine increasing mitochondrial activity, rather than stimulating cell proliferation. These results are the first step in unraveling the mechanisms of newly reported cysteamine toxicity.

**Novel Renin Gene Mutation Causes Autosomal Dominant Chronic Kidney Failure and Anemia and Responds to Fludrocortisone Treatment in Childhood** Anthony J. Bleyer,[2] Martina Zivna,[1] Katerina Hodanova,[1] Petr Vyletal,[1] Helena Hulkova,[1] Milan Elleder,[1] Stanislav Kmoch.[1] *[1]Charles University in Prague, Prague, Czech Republic; [2]Wake Forest University School of Medicine, Winston-Salem, NC; [3]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.*

Background: A novel mutation (c.58T>C) resulting in the amino acid substitution of cysteine for arginine in the signal peptide of renin was identified in a father and daughter with chronic kidney disease. Methods: Clinical laboratory studies were performed before and after administration of fludrocortisone, 0.1 mg orally each day. Laboratory investigations were performed. Results: The daughter presented at age 6 years with a persistently elevated serum creatinine (1.2 mg/dl). The blood pressure was 82/52 mm Hg, with serum Na 140 mEq/l, K 5.5 mEq/l, urate 6.3 mg/dl with urate fractional excretion 5.2% (normal 6-20%), hemoglobin 10.5 g/dl. The plasma renin activity level was <0.5 ng/ml/h (normal 0.5-5.9 ng/ml/hr) with corresponding low aldosterone level. At age 10 years, the patient was started empirically on fludrocortisone, 0.1 mg orally each day. There was an increase in the baseline eGFR from 45 ml/min to 75 ml/min, which was sustained after four months of chronic treatment. The father suffered from more advanced chronic kidney disease, and his eGFR (35 ml/min) did not increase with fludrocortisone. Laboratory Investigations: Wild type (WT REN) and mutant (C20R REN) eukaryotic expression vectors were transfected into HEK 293 cells. In cell lysates, WT REN produced the fully glycosylated prorenin and successfully completed ER translocation and underwent cleavage of its signal sequence, whereas C20R REN produced only the non-glycosylated preprorenin. Immunofluorescence analysis demonstrated that the C20R REN protein did not form cytoplasmic granules and instead had intense diffuse cytoplasmic staining. CONCLUSION: Mutations affecting the renin signal peptide alter ER processing of preprorenin and result in hyporeninemia, anemia, hyperuricemia and CKD. Fludrocortisone treatment started in childhood improves eGFR.

**Prevalence of Vitamin D Deficiency in Children and Young Adults with Autosomal Dominant Polycystic Kidney Disease** Melissa A. Cadnapaphornchai, Berenice Y. Gitomer, Michel B. Chonchol, Kim Mcfann, Wei Wang, Robert W. Schrier. *Department of Medicine, University of Colorado Denver, Aurora, CO.*

**Purpose:** Autosomal dominant polycystic kidney disease (ADPKD) is known to occur in childhood and to affect 1 in 400 live births. Borderline hypertension (75-95 percentile) and hypertension (>95 percentile) in children with ADPKD have been associated with larger kidney volumes and increased left ventricular mass index (LVMI) when compared to normotensive ADPKD children. Inhibition of the renin-angiotensin-aldosterone system has been shown to improve renal function and prevent the rise in LVMI in children with ADPKD compared to untreated children. Since active vitamin D is one of the most potent hormones for down-regulating renin expression in the kidney, we determined vitamin D status in young subjects with ADPKD.

**Methods:** We measured baseline serum 25(OH)D levels total in 105 (60 female and 45 male) young subjects with ADPKD aged 8-24 years. 25(OH)D was measured by ELISA assay.

**Results:** Subjects mean (SD) age and creatinine clearance were 16 (4) years and 129 (34) ml/min/1.73m² respectively. The study group comprised 94 Caucasian, 9 Hispanic and 2 African American subjects. The mean (SD) serum 25(OH)D level was 31.9(17.9) ng/ml. 53.4 % of these children had serum 25(OH)D levels < 30 ng/ml, and 25% of patients had vitamin D deficiency defined as a serum 25(OH)D level < 20 ng/ml. In these ADPKD children renal function was normal [mean (SD); 129(27) ml/min/1.73m²]. Mean (SD) 25(OH)D level was highest in 31 children whose samples were collected during the summer months, 46 (22) ng/ml, as compared to those patients whose samples were collected during winter months , 23 (13) ng/ml, p < 0.001.

**Conclusion:** In summary, vitamin D deficiency/insufficiency is prevalent among young patients with ADPKD despite normal kidney function. Vitamin D supplementation may be beneficial in patients with ADPKD however, future studies will be necessary to further address this issue.

**Coexistence of a Novel *GLA* Mutation and *COL4A3* Variant in Two Chinese Females** Zhi-Yong Cai,[1,3] Su-Xia Wang,[1] You-Kang Zhang,[1] Yu-Qing Chen,[1] Lin-Chang Liu,[1] Yu Huang,[2] Hong Zhang.[1] *[1]Renal Division, Peking University First Hospital; [2]Department of Medical Genetics, Peking University Health Science Centre; [3]Department of Internal Medicine, Beijing Gongan Hospital.*

Fabry disease(FD) is an X-linked lysosomal storage disease caused by mutations of *GLA* gene. Thin basement membrane nephropathy (TBMN) is usually characterized by hematuria with uniformly thinned glomerular basement membrane (GBM).Mutations of *COL4A3* or *COL4A4* were identified in some TBMN patients. We observed a family with both phenotypes. The proband(II-1) was a 41-year-old Chinese female with proteinuria(0.75g/24hr), microscopic hematuria, Scr 81umol/l, and hypertention(BP 160/100mmHg).She also presented angiokeratomas,hypohidrosis and tinnitus.Her renal biopsy revealed vacuolization of podocytes and 7/35 glomeruli with segmental or global sclerosis.Electron microscopy indicated concentric lamellated inclusions in podocytes, parietal epithelial and distal tubular epithelial cells. Diffuse thinning of GBM with a mean thickness of [sup]216[/sup]±[sup]31nm[/sup] was identified and staining for α3(IV) and α5(IV) were positive. Her daughter(III-1) showed hematuria, neuropathic pain, hypohidrosis, and TIA. One of her sister(II-3) only presented with hematuria without signs of FD. The α-galactosidase A activity of II-1 and III-1 were 33 and 75 unit respectively, lower than normal range(100-500 unit). A novel mutation of 1208 ins 21bp in *GLA* gene was detected in II-1 and III-1. And a new variant of *COL4A3* gene (M1209I) was also confirmed in II-1 and III-1. However in II-3,with hematuria only, *COL4A3* M1209I was identified.The *COL4A3* M1209I polymorphism may be associate with TBMN. The co-occurrence of *GLA* mutation and *COL4A3* variant in II-1 and III-1 contributed to both FD and TBMN. The outcome for the coexistence of FD and TBMN need longer period of follow-up.

**PKD1 and PKD2 Gene Variants in Italian Patients Affected by Autosomal Dominant Polycystic Kidney Disease (ADPKD)** Paola Carrera,[1] Francesca Rigo,[1] Cristina Montrasio,[1] Silvia Calzavara,[1] Lucia Palmieri,[3] Piergiorgio Messa,[2] Alberto Edefonti,[2] Francesco Scolari,[4] Paolo Manunta,[1] Alessandra Boletta,[1] Maurizio Ferrari.[1] *[1]San Raffaele Scientific Institute, Milano, Italy; [2]IRCCS Policlinico, Milano, Italy; [3]University of Modena, Italy; [4]Spedali Civili, Montichiari (BS), Italy.*

ADPKD is the most common genetic nephro-pathology in humans (about 1/1000). Aim of our work was to identify variants of *PKD1* and *PKD2* genes in Italian ADPKD patients. Analysis of gene variation would allow to: confirm the diagnosis in clinically uncertain/atypical cases; offer genetic counseling in at risk families; exclude mutation in related donors for kidney transplantation; define molecular spectrum of *PKD1* and *PKD2* in Italian patients.

A semi-automated Sanger direct sequencing protocol has been developed for detection of variants in exons and flanking regions. Specific amplification of PKD1 was achieved by previously published and by new protocols.

We analyzed 124 unrelated patients belonging to 108 families, 42 relatives and 16 patients with no reported familiarity. In the majority of patients (115/124) variants were found: 94(81%) PKD1; 11(10%) PKD2; 10(9%) both genes. In 2 familial and 7 sporadic cases no variants were found.

In 98% (106/108) of familial cases variants were found in PKD1 and/or PKD2. In sporadic cases, 53% (8/15) were positive. Based on the ADPKD Mutation Database, the majority of variants were not described (163/189). By combining results for truncating and known variants we identified pathogenic mutations in 73/115 (63%) patients. For variants not yet determined with respect to their pathogenicity a classification was not always feasible. We were able to assign as likely pathogenic 9 variants (7.8%) reaching a total 71% of affected alleles. When applicable, intra-familial segregation, frequency analysis in 200 DNA from >56 years health individuals, evaluation of type of substitution, conservation among orthologous, in-silico evaluation of intronic variants helped interpretation, nevertheless this issue remains cumbersome. Harmonization of criteria for interpretation of unclassified variants will improve counselling to patients and their relatives.

**Long-Term Outcome in Children with Unilateral Multicystic Renal Dysplasia. Is the Contralateral Kidney Normal?** Jayanthi Chandar,[1] Carolyn L. Abitbol,[1] Maria Matilde Rodriguez,[2] Wacharee Seeherunvong,[1] Michael Freundlich,[1] Gaston E. Zilleruelo.[1] *[1]Department of Pediatrics, Division of Pediatric Nephrology, University of Miami, Miller School of Medicine, Miami, FL; [2]Department of Pathology, Division of Pediatric Pathology, University of Miami, Miller School of Medicine, Miami, FL.*

The clinical spectrum of renal dysplasia includes the non-functioning kidney with multicystic dysplasia (MCDK). We report our experience of the outcome of unilateral MCDK and its contralateral kidney in 101 children with the diagnosis of MCDK from 1985 to 2009. Demographics and data collected included urine protein/creatinine ratio, estimated GFR (eGFR), blood pressure, surgical intervention, renal length and abnormalities of the contralateral kidney, and involution rate. There was a predominance of left sided MCDK. Diagnosis was made prenatally in 86.7%. Contralateral abnormalities included vesicoureteral reflux (14%), UPJ obstruction (4.1%) and megaureter (2.4%). Complete involution of MCDK occurred within 5 years in 57%. Compensatory hypertrophy of the contralateral kidney to >97% occurred in 74.1%. Nephrectomy was performed in 19.8%. Chronic kidney disease (CKD) stage ≥2 was observed in 9.7%, proteinuria in 17% and hypertension in 6.9%. Hyperfiltration with mean eGFR of 149±13 ml/min/1.73m² was seen in 37.8%. There was a significant correlation between proteinuria and decreased eGFR, and hyperfiltration and increased contralateral kidney size (p<0.0001 and 0.003 respectively). Those with CKD ≥2 had contralateral abnormalities either at birth, or later.In conclusion, there is an increased risk of CKD in children with unilateral MCDK associated with hyperfiltration and proteinuria. Thus long-term follow up is recommended.

**Progession of ADPKD: Importance of Follow-Up** Valentina Corradi,[1,2] Fiorella Gastaldon,[1] Anthi Panagiotou,[1,2] Grazia Maria Virzì,[1,2] Dinna N. Cruz,[1,2] Claudio Ronco.[1,2] *[1]Nephrology, San Bortolo Hospital, Vicenza, Italy; [2]IRRIV, International Renal Research Institute Vicenza, Vicenza, Italy.*

**Background**:ADPKD is the common genetic renal disorder and it is an important cause of CKD stage V. In dialysis population in Vicenza prevalence of ADPKD accounts for 13.4% versus 8.2% in Italy. In our previous epidemiological study we identified the presence of three different haplotypes to support the hypothesis of a founder effect in our region, suggesting the presence of a strong linkage-specific gene.The purpose of this study was to evaluate the progression of the disease in the pre-dialysis ADPKD out-patients (pts) in terms of the estimated GFR (eGFR/yr).

**Materials and Methods**:Three years follow-up was conducted (N=45). Pts were evaluated with Magnetic Resonance (MR) to measure the total kidney volume (TKV), eGFR (ml/min/1,73m²) was measured by the MDRD equation. Creatinine and blood pressure were registered on the first investigation (t0) and following control (t1). We calculated the difference of eGFR (ml/min/1,73m²)for year, between t0 and t1(Δmedian eGFR/1yr). Categorical data were expressed as percentages and continuous variables by median and interquartile range (IR) compared by Sign-test.

**Results**:Characteristics of ADPKD patients at t0, belong to 31 families, are shown on the table.

| Demographic Data | Median (IR) or N (%) |
|---|---|
| Age at first investigationl, years | 51 (43-57) |
| Age of diagnosis, years | 34 (26-45) |
| Male (%) | 24 (53,3%) |
| **Comorbidities** (%) | |
| Hypertension | 34 (75,5%) |
| Renal Stones | 11 (24,4%) |
| Diabetes Mellitus | 3 (6,7%) |
| **Kidney function parameters** | |
| CKD at first investigation | 26 (57,8%) |
| CKD stage 5 at interview (%) | 2 (4,4%) |
| Crea (mg/dL) t0 | 1,48 (1,04-2,10) |
| Crea (mg/dL) t1 | 1,69 (1,02 to 3,10) |
| eGFR (ml/min per 1,73m²) t0 | 48 (28-73) |
| eGFR (ml/min per 1,73m²) t1 | 45 (20-66) |
| max cysts diameter in right kidney (cm) | 4,0 (3,3-5) |
| max cysts diameter in left kidney (cm) | 4,0 (3-5,4) |

We calculated the Δ median eGFR/1yr (ml/min per 1,73m²):-2,0 (-5,5 – 0)and the difference for this period was found statistically significant (p=0.0009*).

**Conclusions**:ADPKD patients were younger than CKD pts. They had modestly enlarged kidneys in terms of max cysts diameter and moderate progression of CKD (expressed as a decrease of eGFR). These data suggest the importance of life style and diet behavior, control of blood pressure and a frequent follow-up in ADPKD patients, in order to preserve kidney function.

## PUB325

**Neuroimaging Findings of Children with Autosomal Dominant Polycystic Kidney Disease** John F. S. Crocker, Philip D. Acott. *Pediatrics, IWK Health Center, Halifax, NS, Canada.*

We previously reported autosomal dominant polycystic kidney disease (ADPKD) first presentation characteristics in a cohort of 55 children showing a significant prevalence of modifiable risk factors (hypertension = 22%; proteinuria > 150 mg/day = 7%; hyperlipidemia = 54%) despite normal renal function in 98% at diagnosis (AJKD 2004: 43-2, 296-303). This study evaluates the neuroimaging findings of a subset of ADPKD children presenting with headaches and/or family history of cerebral aneurysms from our expanded cohort.

63 ADPKD children (age 1 – 20 years; 25% < 1 year) are followed based on family history, ultrasound confirmation of cysts, and/or linkage analysis. Twenty ADPKD children (31.7%) age 3-20 years had central nervous system (CNS) investigation with CAT or MRI angiography after presentation with headaches. No child had focal neurological deficits, cognitive impairment, or other medical diseases or syndromes with the exception of one child with spina bifida and a ventriculo-peritoneal (VP) shunt.

No cerebral vascular aneurysms were found in the 20 children with CNS imaging (MRI angiography, n = 17; CAT scans, n = 3). Five (25%) ADPKD children (3 ♀; 2 ♂) showed a variety of CNS abnormalities including: a) areas of cerebral hemisphere white matter demyelination (n = 1), b) focal frontal cortex white matter demyelination (n = 1), c) cerebral and cerebellar atrophy with partial atrophy of posterior corpus callosum (n = 1), d) a 3 mm periventricular cyst (n = 1), and CNS lesions typical of known spina bifida with VP shunt placement (n=1). All children were from different families.

This pediatric ADPKD patient database is the first to document CNS neuroimaging anomalies before adulthood in 4 children (exclusive of expected findings of VP shunted child). These findings are likely developmental and are not in a vascular pattern. It is noted that ADPKD during early development has abnormal cilary function and primary cilia are critical to neural stem cell development as demonstrated by mice with Kif3A or Smo protein anomalies who demonstrate failure of radial astrocytes responsible for adult neurogenesis. Screening large groups of children will define the extent of the CNS lesions in ADPKD.

## PUB326

**Temporal Retinal Thinning Is Common in Alport Syndrome** Martin C. Gregory,[1] Faisal Ahmed,[2] Kandon K. Kamae,[2] Paul S. Bernstein.[2] *[1]Division of Nephrology, University of Utah Health Sciences Center, Salt Lake City, UT; [2]Department of Ophthalmology, University of Utah Health Sciences Center, Salt Lake City, UT.*

X-linked Alport Syndrome (XLAS) is an inherited nephropathy that commonly causes hearing loss and less commonly includes pathognomonic ocular findings such as anterior lenticonus and perimacular retinal flecks. We performed detailed ophthalmological examination including high-definition spectral-domain optical coherence tomography in 29 male and female patients with XLAS. Temporal retinal thinning was assessed as the proportional reduction of temporal compared to nasal retinal thickness using normative data from Grover et al (2009). Although lenticonus was present in only 2 eyes and retinal flecks in only 10 eyes, severe (> 2 SD) temporal retinal thinning was found in 37/55 (67%) and moderate (1-2 SD) temporal retinal thinning was found in 6/55 (11%) of eyes satisfactorily examined. Retinal thinning appeared similar in degree with mutations causing juvenile forms of XLAS as in those causing adult onset forms of XLAS (C1564S and L1649R).

Opthalmic manifestations with different COL4A5 Mutations

| Mutation | # of eyes | Nasal retinal thickness μ OD/OS | Temporal retinal thickness μ OD/OS | Anterior lenticonus | Retinal dots or flecks |

| G1060S | 2 | 321/311 | 286/383 | 0/2 | 0/2 |
| C1564S | 6 | 292±49/296±52 | 270±37/269±36 | 0/6 | 0/6 |
| L1649R | 22 | 323±22/320±23 | 296±16/292±16 | 0/22 | 2/22 |
| Unknown | 6 | 331±25/320±23 | 289±11/289±9 | 2/6 | 2/6 |

OCT is increasingly available and is a rapid, inexpensive, and noninvasive method that merits further study as a diagnostic marker for XLAS in patients who lack other ophthalmologic features.

**Study of P53 Codon 72 Polymorphism & Clinico-Radiological Correlations in ADPKD Patients** Krishan L. Gupta,[1] Swarnjeet Kaur,[1] Rajindra Prasad,[2] Anupam Lal,[3] Vinay Sakhuja.[1] *[1]Deparment of Nephrology and; [2]Biochemistry; [3]Radio-Diagnosis, Postgraduate Institute of Medical Education and Research, Chandigarh, India.*

Although much is known about molecular genetics of ADPKD, recently a tumour suppressor gene, P53 has been identified as an endogenous negative regulator of PKD1. Present study analysed the clinical profile of 50 ADPKD patients, correlated the kidney volumes assessed on non contrast computerized tomography with creatinine clearance (CCl), estimated by Cockroft and Gault formula, and studied polymorphism at codon 72 of P53 gene. Mean age of diagnosis was 40 12.4years, clinical features were flank pain (80%), UTIs (34%), nephrolithiasis (32%), gross haematuria (30%), and proteinuria (56%) of patients. 64% had liver cysts, and 2% of subjects had pancreatic cysts and intracranial aneurysms. Hypertension was seen in 94%, chronic renal failure in 56%, 42, 85% of whom had ESRD. Mean estimated CCl, was 50.8537.38ml/min.

Mean total kidney volume on CT scan was 779.43409.98 ml. Kidney volumes had significantly negative correlation with CCl, (correlation coefficient-.718, significant at 0.01 level) even after adjustment for age, values were higher among males and subjects with proteinuria. Polymorphism at codon 72 of P53 gene was studied using polymerase chain reaction. 76% and 20% of patients were homozygote for pro/pro and arg/arg variant respectively, 4% heterozygote for arg/pro. Arg/arg variants had non significant trend towards higher kidney volumes. Conclusions: Renal volumes estimated by non contrast CT is a surrogate marker for disease progression in ADPKD. Arg/arg/ variant may be a risk factor for higher kidney volumes, underlying mechanism colud be higher rate of cellular proliferation in this variant. Larger studies however needed to confirm these results.

**Renal Manifestations of Patients with *MYH9*-Related Disorders** Kyoung Hee Han,[1] Hyun Kyung Lee,[1] Yun Hye Jung,[1] Hee Gyung Kang,[1] Il-Soo Ha,[1] Hae Il Cheong.[1,2] *[1]Department of Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Research Center for Rare Diseases, Seoul National University Hospital, Seoul, Republic of Korea.*

*MYH9*-related disorders are a group of autosomal dominantly inherited disorders caused by mutations of *MYH9*, which encodes the non-muscle myosin heavy chain IIA (NMMHC-IIA). May-Hegglin anomaly and Sebastian, Fechtner and Epstein syndromes belong to this group. While megathrombocytopenia is the common characteristic finding of *MYH9*-related disorders, basophilic cytoplasmic inclusion bodies in leukocytes (Döhle-like body), deafness, cataract and nephritis are found only in some patients.

In this study, renal manifestations of MYH9-related disorders were analyzed in seven genetically confirmed, unrelated Korean patients.

Among the seven patients with *MYH9* mutations, four cases had renal manifestation; one with positive family history (Patient 1) and three without (sporadic cases). All the three sporadic cases had severe renal involvement with rapid progression to end-stage renal disease (ESRD) except Patient 4, who is still young (now 7 years old), and their mutations were in the motor domain of NMMHC-IIA. The familial case (Patient 1) had milder renal involvement without progression to ESRD by his 30s, and his mutation was in the tail domain of the protein.

Clinical features of 4 patients with renal involvement

| Patient | FHx | Age at Dx | Kidney involvement | | Other Organs | | Mutation |
|---|---|---|---|---|---|---|---|
| | | | Kidney Bx / GBM change | ESRD | WBC | Deaf / Eye | (exon, domain) |
| 1 | (+) | 30 yrs | FSGS / (-) | (-) | (+) | (-) / (-) | D1424N (30, tail) |
| 2 | (-) | 22 yrs | FSGS / (+) | (+) | (-) | (+) / (+) | S96L (1, motor) |
| 3 | (-) | 12 yrs | Not done | (+) | (-) | (+) / (-) | S96L (1, motor) |
| 4 | (-) | 14 mos | Mesangial expansion / (+) | (-) | (+) | (-) / (-) | R718W (16, motor) |

The remaining three cases with *MYH9*-related disorders did not have renal manifestation, or ear and eye involvement. All of them had positive family history and their mutations were in the tail domain of NMMHC-IIA (E1841K, R1165C, and K373N, respectively).

In summary, renal involvement was found in 4 of 7 cases with *MYH9*-related disorders, and the patients with a mutation in the motor domain of NMMHC-IIA had more severe renal manifestation.

## PUB330

**Evaluation for the Effectiveness of Proteinuria to the Progression of Renal Dysfunction for Female Fabry Patients** Kazushige Hanaoka,[1] Mahiro Kurashige,[1] Toya Ohashi,[2] Hiroshi Kobayashi,[2] Yoshikatsu Eto,[2] Hiroyuki Ida,[2] Tatsuo Hosoya.[1] *[1]Devision of Kidney and Hypertension, Department of Internal Medicine, The Jikei University, School of Medicine, Minato, Tokyo, Japan; [2]Department of Pediatrics, The Jikei University, School of Medicine, Minato, Tokyo, Japan.*

Purpose: Nephropathy is one of the major and life-threatening complications of Fabry disease. The main signs of Fabry nephropathy are reduction of glomerular filtration rate (GFR) and proteinuria. The major signs of Fabry nephropathy are reduction of glomerular filtration rate (GFR) and proteinuria. Renal function progressively decreases when proteinuria is overt for male Fabry patients. However, correlation between proteinuria and renal function is still unclear for female Fabry patients. This study aimed to evaluate the effectiveness of proteinuria to the progression of renal dysfunction for female Fabry patients.

Methods: This was single center, retrospective study. The data were collected from 15 female patients treated by Enzyme replacement therapy (ERT) at least 30 months. Recombinant α-galactosidase B was administered in a dosage of 1 mg/kg body weight every other week. The estimated GFR (eGFR) was used for evaluating renal function. Proteinuria measured by urine collection and described protein/creatinine ratio.

Results: A mean age of 15 patients was 48±15 years. Mean observation time was 47±14 months. eGFR was declined from 87±22 to 79±22 ml/min/1.73m$^2$ (p=0.39). Reduction rate of eGFR was -1.9±2.2 ml/min/1.73m$^2$/year. Proteinuria was 204±110 mg/gCr. None of 15 patients had urine abnormalities except proteinuria. There was no correlation between proteinuria and eGFR (rs= -0.19). Neither reduction rate of eGFR correlated to proteinuria (rs=0.29).

Conclusion: Our results indicated that, unlike male patients, proteinuria did not correlate with progression of renal dysfunction in female Fabry patients.

## PUB331

**Natural History and Immunohistochemical Study of Japanese Male X-Linked Alport Syndrome** Yuya Hashimura,[1] Kandai Nozu,[1] Hiromi Otsubo,[1] Fusako Hashimoto,[1] Shingo Ishimori,[1] Koichi Nakanishi,[2] Norishige Yoshikawa,[2] Hiroshi Kaito,[1] Kazumoto Iijima,[1] Masafumi Matsuo.[1] *[1]Pediatrics, Kobe Univ, Kobe, Hyogo, Japan; [2]Pediatrics, Wakayama Medical Univ, Wakayama, Japan.*

Introduction

X-linked (XL) AS is caused by mutations of COL4A5 encoding α5 chains of type IV collagen. It has been reported that clinical severity in male XLAS patients depends on mutation types. In USA, 64% of XLAS males showed missense mutations and 15% of patients showed Glycine-X-Y mutations. The median age of ESRD was 37 years for those with missense mutations and 25 years for those with truncating mutations. Immunohistochemically, 80% of XLAS males showed complete absence of α5 expression in renal tissues, and 20% of them showed α5 positive in several staining patterns. Our objective was to evaluate the natural history and the α5 expression pattern in renal tissues of Japanese male XLAS.

Method

Fifty-six male patients with genetically defined XLAS and 47 their male families with urinary abnormalities and/or ESRD were included in this study. Mutational analyses of COL4A5 were carried out by using (1)PCR and direct-sequencing of genomic DNA, (2) RT-PCR of mRNA and direct sequencing and (3) multiplex ligation-dependent probe amplification. Renal survival rates were analyzed by Kaplan-Meier method.

Result

Forty-five percent of XLAS males had missense mutations and 92% of the missense mutations were Glycine-X-Y mutations. The median age of ESRD was 35 years for those with missense mutations and 24 years for those with other mutations. 25% of XLAS males showed atypical α5 staining patterns and 81% of them had a missense mutation and others had an in-flame deletion. Interestingly, there were three pairs of patients showed different staining patterns in spite of the same mutations, and one of those cases was familial.

Conclusion

Japanese male XLAS patients showed different proportion of genotype, but similar renal survival rates compared to the previous study in USA. Immunohistochemical studies of α5 staining of renal tissues were useful tool for diagnosis of male XLAS, but we should consider some cases show atypical immunohistochemical patterns, which do not depend on solely their mutations.

## PUB333

**Genetic Aberrations in Proteins of the Alternative Complement Pathway in Patients with Atypical HUS** Lambertus V. Heuvel,[1,2] Dineke Westra,[1] Elena Volokhina,[1] Nicole Van De Kar,[1] Marleen Huigen.[3] *[1]Pediatric Nephrology, Radboud University Nijmegen Medical Centre, Netherlands; [2]Pediatrics, University Hospital Leuven, Belgium; [3]Laboratory Medicine, Radboud University Nijmegen Medical Centre, Netherlands.*

**Objectives:** Defective complement control on the surface of host cells is thought to have an important role in the pathogenesis of atypical hemolytic uremic syndrome (aHUS). The disease is associated with predisposing mutations in complement (regulating) proteins and with autoantibodies against CFH (αFH). The presence of mutations might be a prognostic factor for the outcome of renal transplantations and kidney donation.

**Methods:** Mutational screening, by means of PCR and DNA sequencing, is performed on the genes encoding complement C3 (*C3*), complement factor D (*CFD*), decay accelerating factor (*DAF*), and clusterin (*CLU*) in a group of 65 aHUS patients. In previous studies, a mutation in *CFH*, *IF*, *MCP*, or *FB*, or the presence of αFH was found in 36.9% (24/65) of these patients. Influence of mutations on protein structure is analyzed with respect to available structural data.

**Results:** Two heterozygous missense mutations (p.Lys65Gln; p.Glu1258Ala) were found in *C3* in four aHUS patients. Furthermore, one strongly predisposing SNP (p.Arg161Trp) was found heterozygously in twelve patients and in only three healthy controls (95% CI: 0.029-0.130). Analysis of available structural data indicates that the amino acids altered by the two missense mutations and the predisposing SNP might be located in the proximity of the C3b interface with CFH. Prediction models for interaction between CFH and C3 will be displayed. No genetic aberrations were found in *CFD*, *DAF*, or *CLU*.

**Conclusions:** Three novel potentially pathogenic alterations were found in *C3* in 24.2% (16/ 66) of the patients. These alterations might be located near the binding site of CFH, thereby influencing the interaction between this protein and C3b. This might lead to an increased activity of the alternative complement pathway. No mutations were found in *CFD*, *DAF*, and *CLU*, but the role of these genes in the pathogenesis of aHUS cannot be excluded yet, as a larger cohort needs to be screened.

## PUB334

**Accumulation of Glycosphingolipids in Cystic Epithelial Cells Affects Molecular Pathways of Cystogenesis** Herve Husson,[1] Thomas A. Natoli,[1] Ryan J. Russo,[1] Bing H. Wang,[2] Yeva Budman,[2] Steven R. Ledbetter,[1] John P. Leonard,[3] Oxana Beskrovnaya.[1] *[1]Cell Biology, Genzyme Corp., Framingham, MA; [2]Analytical Research & Development, Genzyme Corp., Waltham, MA; [3]Pharmacology, Genzyme Corp., Waltham, MA.*

Polycystic kidney disease (PKD) is characterized by the progressive growth of cysts in the kidney and other organs. Cyst formation is associated with increased rates of epithelial cell proliferation, apoptosis and dysregulation of multiple signaling pathways. Glycosphingolipids (GSL) and sphingolipids (SL) are emerging as major regulators in many of these cellular processes. GSL are also key components of membrane rafts, and can modulate the function of cell-surface receptors. Alterations of GSL metabolism have been previously documented in human ADPKD and the *cpk* mouse model of PKD, suggesting that these changes may play a role in disease progression. We set out to explore a link between cystogenesis and GSL. We found that glucosylceramide (GlcCer) and ganglioside GM3 levels are elevated in ADPKD kidneys and in kidneys from several mouse models of PKD, including *Pkd1* conditional knock out, *pcy* and *jck* animals. We also showed upregulation of GlcCer Synthase mRNA in human and mouse cystic epithelial cells by SAGE analysis and real time quantitative PCR analysis respectively. To examine a link between GSL levels and cystogenesis, we analyzed the effect of GSL modulation on cell cycle progression in cultured epithelial cells. Inhibition of GlcCer accumulation with either GlcCer Synthase siRNA or a small molecule inhibitor caused delay in the cell cycle progression. Furthermore, we showed that activated Akt/mTOR signaling pathway in cultured cystic epithelial cells is directly affected by inhibition of GlcCer Synthase upon IGF-1 stimulation. These data support a molecular link between elevated GSL levels and cystogenesis, thus suggesting GSL metabolism as a new target for PKD therapy.

**PUB335**

**Survey of Unruptured Intracranial Aneurysm in Autosomal Dominant Polycystic Kidney Disease Patients in Japan** Mahiro Kurashige,[1] Kazushige Hanaoka,[1] Yuichi Murayama,[2] Tatsuo Hosoya.[1] *[1]Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University, School of Medicine, Minato, Tokyo, Japan; [2]Department of Neurosurgery, The Jikei University, School of Medicine, Minato, Tokyo, Japan.*

Background: Intracranial aneurysm (ICA) is one of the most common complication of autosomal dominant polycystic kidney disease (ADPKD). Almost 10 percent of the ADPKD patients was affected. We investigated the characteristics of ICA and the correlation between frequency of ICA and renal function in ADPKD patients.

Methods: We performed a retrospective chart review of 152 ADPKD patients who visited the Jikei University hospital from April 2007 to September 2009. There were 79 male (52%) and 73 female (48%) with mean age of 49 yr. The information evaluated for the study was sex, age, presence of hypertension, renal function at the time of MRA. The estimated GFR (eGFR) was used for evaluating renal function. All patients were screened by magnetic resonance angiography (MRA) for ICA. The two-sample t test and $\chi^2$- test were used as statistical analysis.

Results: Thirty-one ICAs were detected in 24 of 152 ADPKD patients (15.8%). Four patients had multiple ICAs. The frequency of ICA was 13% in male (10 out of 79) and 19% (14 out of 73) in female, showing no statistical difference. The frequency of ICA was higher in hypertensive ADPKD patients; 19% in hypertension patients vs 9% in normotension patients. Eight ICAs were > 5mm in diameter. The localization of ICA was as follows; 19% in anterior cerebral artery, 16% in middle cerebral artery, 42% in internal carotid artery, 13% in basilar artery, and 10% in vertebral artery. Correlation between the frequency of ICA and renal function was listed in Table1. We found that the frequency of unraptured ICA was high in ADPKD patients in CKD stage1-2 than normal population, and increased, according to progression of CKD stage.

frequency of ICAs and CKD stage

| | aneurysm | no aneurysm | total |
|---|---|---|---|
| CKD stage 1-2 | 7 (9.8%) | 64 (90.2%) | 71 |
| CKD stage 3-4 | 6 (12.8%) | 41 (87.2%) | 47 |
| CKD stage 5-5D | 11 (32.4%) | 23 (67.6%) | 34 |

$\chi$-square P<0.01

Conclusion: The results indicated that ICA screening and follow-up study by MRA may be important for ADPKD patients.

**PUB336**

**Case of Accelerated ADPKD in a Lupus Nephritis End Stage Renal Disease Patient** Hemant Magoo, Roger F. Carbajal Mendoza, Donald I. Baumstein, Alf M. Tannenberg. *Nephrology, Metropolitan Hospital Center/New York Medical College, New York, NY.*

**Introduction:** Autosomal dominant polycystic kidney disease (ADPKD) is an inherited systemic disorder occuring in 1 in 800 live births and accounts for 7 to 10% of the dialysis population. There have been isolated case reports of nephrotic range proteinuria secondary to lupus nephritis in ADPKD patients with rapid progression to kidney failure. The converse of this has never been reported. We present a case of a chronic dialysis patient with end stage renal disease (ESRD) secondary to lupus nephritis that developed accelerated ADPKD.

**Case:** A 33 year female with ESRD secondary to lupus nephritis since 2001 was evaluated for epigastric pain and dyspepsia. She started chronic hemodialysis at age of 24 in 2001. Her past medical history was significant for hypertension, Class IV and Class V lupus nephritis with high chronicity index diagnosed on renal biopsy in 1999 and 2001. Renal cystic disease was absent at the time of biopsy in 2001 and a right upper quadrant ultrasound in 2004 revealed absence of any cysts in the right kidney. Work up for dyspepsia in December 2009 with computed tomography of the abdomen revealed bilateral kidneys of 14 cm length with multiple bilateral renal cysts compatible with ADPKD. Repeat ultrasound of the kidney 6 months later revealed classic ADPKD pattern with bilateral enlarged kidneys of 18 cm length and loss of corticomedullary differentiation.

**Discussion:** While lupus nephritis is an autoimune disease, ADPKD occurs due to a germ line mutation in a single gene. The nature of inherited mutation, genetic factors, and associated conditions such as hypertension and interstitial fibrosis influence the rate of progression of ADPKD. The link between lupus nephritis and ADPKD, if it exists, is not known. The accelerated progression of ADPKD in our patient raises the possibility of interstitial fibrosis secondary to lupus nephritis as a trigger factor hastening this progression.

**Whole Gene Deletion of *ATP6V1B1*: A Novel Disease Mechanism for Autosomal Recessive Distal Renal Tubular Acidosis** Elizabeth Norgett,[1] Anthony Yii,[1] Katherine G. Blake-Palmer,[1] Ariana Kariminejad,[2] Fiona E. Karet.[1] *[1]Medical Genetics, University of Cambridge, Cambridge, United Kingdom; [2]Kariminejad-Najmabadi Path. & Genetics Center, Tehran, Islamic Republic of Iran.*

Distal Renal Tubular Acidosis (dRTA) is a disorder of acid-base regulation caused by functional failure of alpha-intercalated cells in the distal nephron. Where it is inherited in a recessive manner, it is usually severe and often associated with sensorineural hearing loss. To date, mutations that underlie recessive dRTA have been found in the two genes that encode protein subunits a4 and B1 of the alpha intercalated cell's apical $H^+$ATPase: *ATP6V0A4* and *ATP6V1B1*.

Here, we describe a consanguineous kindred in which dRTA was diagnosed in the proband at age 2 months following failure-to-thrive. Nephrocalcinosis was present in infancy, and he was noted to be deaf at 2y. The parents and a sibling are clinically normal. Linkage to *ATP6V0A4* was excluded, but attempts to PCR-amplify *ATP6V1B1* from the proband's genomic DNA failed for all exons. A complete deletion of the whole gene was identified. Gene dosage was halved in both parents.

Mapping of the deletion breakpoints revealed the 5' end to fall in intron 1 of the ventral anterior homeobox 2 gene *VAX2*, which lies immediately 5' of *ATP6V1B1*, while the 3' breakpoint lies within the intragenic region between *ATP6V1B1* and *ANKRD53*, the gene immediately 3' of *ATP6V1B1*. The 56.8 Kb genomic fragment represented by this deletion is replaced in this family by 2 nucleotides (GG). This appears to be a unique genetic phenomenon, and has not previously been reported in any INDEL mutation.

This is the first time a whole gene deletion has been described as a mechanism for dRTA. In addition to delineating this novel deletion, our findings suggest functional redundancy of *VAX2* in humans; the homeobox protein encoded by this 3-coding-exon gene is essential for establishing the dorsal-ventral axis of the eye in mouse (Barbieri et al, Development 129:805-13, 2002), but the child described here does not display any ocular phenotype despite missing most of the coding portion of the gene.

**Mutational Analysis of *NPHS1* in a Worldwide Cohort of CNS Patients** Bugsu Ovunc,[1] Shazia Ashraf,[1] Virginia Vega-Warner,[1] Friedhelm Hildebrandt.[1,2] *[1]Departments of Pediatrics and of Human Genetics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute, .*

Congenital nephrotic syndrome (CNS) is defined as nephrotic syndrome which manifests within the first 3 months of life. Mutations in *NPHS1* gene encoding nephrin, are a major cause for CNS. Currently, more than 170 different mutations of *NPHS1* causing CNS have been published, affecting most exons.

We performed mutation analysis of *NPHS1* in a worldwide cohort of children with CNS. All 29 exons were examined using direct sequencing. New mutations were confirmed by showing their absence in 96 healthy control individuals.

We were able to detect disease causing mutations in 9/31 families (29%). 7 of the families showed a homozygous mutation, while 2 were compound heterozygous. In another two families, single heterozygous *NPHS1* mutations were detected. Out of 13 mutations discovered, 3 of them were novel, consisting of 1 splice site mutation and 2 missense mutations. Novel mutations occurred in individuals in whom both recessive disease alleles were discovered.

Our data demonstrate that the spectrum of *NPHS1* mutations is still expanding, involving new exons, in patients from a diverse ethnic background.

**Bronchiectasis and Pulmonary Function Test (PFT) Abnormality in ADPKD** Qi Qian, Ladan Zand, Robert Hartman, Teng Moua, Xiangling Wang, Tobias Peikert, Kaiser Lim. *Mayo Clinic, Rochester, MN.*

**Backgrounds:** ADPKD, characterized by polycystic kidney dysfunction, is a systemic disease with multiple extra-renal manifestations. ADPKD patients exhibit an increased prevalence of radiographic bronchiectasis. The functional significance of such abnormality has not been defined. We examined the occurrence of pulmonary function test (PFT) abnormalities in a cohort of ADPKD patients with and without radiographic bronchiectasis.

**Methods:** Clinical records of adult ADPKD patients seen at Mayo clinic with both chest CT scan and PFT from year 1998 to 2008 were reviewed. A total of 65 patients were enrolled after excluding those with acute pneumonia or other acute pulmonary infiltrative processes. CT criteria for diagnosis of bronchiectasis included enlarged internal bronchial diameter, failure of airway tapering for at least 2 cm beyond the last branch point, and airway wall thickening in the lung periphery. PFT abnormalities were classified to five patterns: obstructive, restrictive, mixed (obstructive and restrictive), non-specific, and isolated reduction of diffusion lung capacity for carbon monoxide (DLCO).

**Results:** Thirty-two of the 65 (49.2%) ADPKD patients exhibited radiographic bronchiectasis. PFT abnormalities were noted in 24 of the 32 (75.0%) patients with and 16 of 33 (48.5%) without radiographic bronchiectasis (P<0.03). Mean age and eGFR were not statistically different between patients with and without PFT abnormalities. Except for the isolated reduction in DLCO, the distribution of PFT abnormalities was similar: 11 of the 24 (with bronchiectasis) vs. 7 of the 16 (without bronchiectasis) had an obstructive pattern; 3 of the 24 vs. 4 of the 16, restrictive pattern; 1 of the 24 vs. 1 of the 16, mixed pattern; and, 3 of the 24 vs. 4 of the 16, nonspecific pattern. The isolated DLCO reduction was noted exclusively in those with bronchiectasis, 6 vs. 0 in those without bronchiectasis.

**Conclusion:** In this cohort, ADPKD patients with radiographic bronchiectasis had a higher occurrence of PFT abnormalities, suggesting a functional significance of radiographic bronchiectasis in ADPKD.

**The Primary Cilium Is Required for Vasopressin Mediated Aquaporin-2 Trafficking** Takamitsu Saigusa,[1] P. Darwin Bell,[1] Robert J. Kolb.[2] *[1]Division of Nephrology, Department of Medicine, Medical University of South Carolina, Charleston, SC; [2]Pediatrics, Medical University of South Carolina, Charleston, SC.*

PCDNA (cilia -) and Bap2 (cilia +) are collecting duct cell lines derived from a PKD mouse model (orpk) and were used here to determine the role of the primary cilium in vasopressin (AVP) mediated aquaporin 2 (AQP2) trafficking and fluid absorption. Upon apical AVP addition, cilia (-) cells grown on impermeable supports had an increased net fluid absorption, as evident by the formation of epithelial domes, which were absent in cilia (+) cells. Immunofluorescence studies showed AQP2 localizes to cilia and in a subapical membrane compartment in cilia (+) cells. Upon AVP treatment, there was an increase in AQP2 at the apical membrane in cilia (-) but not in cilia (+) cells. Biotinylation and Western blot analysis confirmed this and also showed increased levels of a glycosylated form of AQP2 in cilia (-) vs. cilia (+) cells. Interestingly, in cilia (-) cells there was basolateral membrane insertion of AQP2 at a high level. In the absence of cilia, there appears to be an AVP mediated targeting of the V2 receptor to the apical membrane and enhanced AQP2 localization at both apical and basolateral membranes. We used electrophysiology to characterize V2R signaling and activation of ENaC by recording changes in amoliride/benzamil equivalent short-ciruit current (Isc). Addition of vasopressin to the apical membrane resulted in an increased equivalent Isc in cilia (-) cells; whereas only a minimal increase in Isc was found in the cilia (+) cells. To determine if apical V2R mediated water transport in cilia (-) cells also utilizes cAMP and PKA we pretreated cilia (-) cells with H89, an inhibitor of PKA. Treatment with H89 abolished changes in Isc in cilia (-) cells with addition of apical vasopressin. Thus, we propose AQP2 trafficking requires a normal cilium and when absent, the collecting duct cells becomes dedifferentiate leading to enhanced salt and water absorption which may contribute to the hypertension observed in PKD patients.

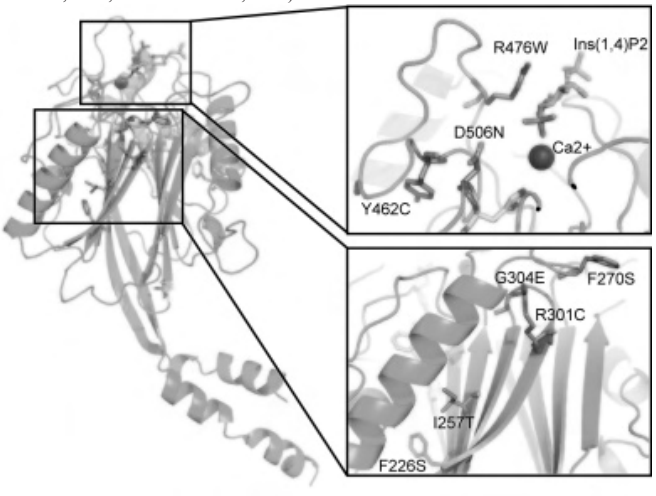
**Structural Modeling of *OCRL1* Mutations in Patients with Dent 2 Disease** Steven J. Scheinman, Fosheng Hsu, Yuxin Mao.

The oculocerebrorenal syndrome of Lowe (LS) features proximal tubulopathy, cataracts, and mental developmental delay, with mutations in *OCRL1*. That gene is also mutated in 15% of patients with Dent disease (Dent 2), without eye or neurologic abnormalities. The majority of *OCRL1* missense mutations in both LS and Dent 2 occur in the phosphatase domain of the protein. We located 9 reported *OCRL1* missense mutations in patients with Dent 2 and 10 in LS on the computationally modeled 3-dimensional structure of the catalytic domain of the human OCRL1 protein based on the known structure from pombe yeast (Tsujishita, et al., Cell 105:379, 2001) and the C-terminal ASH-RhoGAP domains (Erdmann, et al., Dev Cell 13:377, 2007).



The figure shows 8 Dent 2 missense mutation on the catalytic domain of OCRL. These residues are shown in sticks and colored in grey. Two were located in loops close to the phosphatase catalytic site and predicted to alter substrate binding (Cat). Five were distant from the catalytic site in the protein interior and likely to alter protein stability (Stab); 2 of these had been reported to reduce protein abundance (Hoopes, et al., Am J Hum Genet 76:260, 2005). One (F270S) was located in an exposed region of a flexible loop; the functional consequences of this mutation are not clear. One was at the boundary of ASH-RhoGAP domains and expected to alter protein interactions (Int). Three of these were associated with cataracts: 1 Cat, 1 Stab and 1 Int. A similar spectrum was seen among the missense mutations in patients with LS, all of whom had cataracts and mental developmental delay. Differences in extrarenal phenotype between Dent 2 and LS may reflect variations in tissue-specific compensatory mechanisms rather than direct consequences of changes in protein structure by mutation.

**PUB342**

**Klotho Expression Is Reduced in Human Kidneys from Patients with Autosomal Dominant Polycystic Kidney Disease** Robert W. Schrier, Wei Wang, Michel B. Chonchol, Melissa A. Cadnapaphornchai, Kim Mcfann, Xiang-Dong Yan, Berenice Y. Gitomer. *Department of Medicine, University of Colorado Denver, Aurora, CO.*

**Purpose:** Autosomal dominant polycystic kidney disease (ADPKD) affects an estimated 600,000 patients within the U.S. Complete loss of renal function occurs in 50% of affected patients by age 60. The recently discovered FGF-23-Klotho axis is an important endocrine regulator of phosphate homeostasis and vitamin D levels. Klotho functions as an obligate co-receptor for FGF-23 binding in the kidney. Hence, deficiency of either FGF-23 or Klotho results in a similar phenotype characterized by premature aging and hyperphosphatemia. Significantly, angiotensin-II down-regulates renal expression of Klotho which may aggravate angiotensin-II induced renal injury. As angiotensin-II is up-regulated early in the course of ADPKD we hypothesized that expression of human Klotho would be reduced in human ADPKD kidneys and that the serum level may correlate with impaired renal function.

**Method:**[/bold] We measured expression of human membrane bound Klotho mRNA by quantitative PCR in 5 normal and 7 ADPKD kidneys. Serum Klotho level was measured in 40 ADPKD adults, comprising 17 women and 23 men [mean (SD) age: 30(12) years] by ELISA (Cubasio Biotech, Japan).

**Results**:[/bold] Mean(SD) expression of Klotho/GAPDH was significantly lower in ADPKD kidney compared to control kidney, ADPKD 0.13(0.10) vs. control 1.62(0.49), p =0.002. Mean (SD) serum level of Klotho was 28.6(30.3), however, no correlation between serum Klotho level and renal function over estimated glomerular filtration range 42-136 ml/min/$m^2$ was found.

**Conclusion:**[/bold] Klotho mRNA level is severely reduced in human ADPKD kidney and may exacerbate renal injury. The circulating form of human Klotho detected by ELISA assay does not correlate with renal function in ADPKD.

**PUB343**

**Clinical Features in Patients with Autosomal Recessive Alport Syndrome** Vanessa Sivakumar, Mardhiah Binti Mohammad, Yanyan Wang, Hayat Dagher, Deb J. Colville, Judith A. Savige. *Medicine (Northern Health), The University of Melbourne, Melbourne, VIC, Australia.*

**Background and Objectives:** Most patients with Alport syndrome have X-linked disease, and the clinical features are well-described with this mode of inheritance. We have reviewed clinical features in our families with genetically-proven autosomal recessive disease who have presented over the past 20 years.

**Patients and Methods:** Alport syndrome was diagnosed on the basis of a lamellated GBM in a renal biopsy from the affected individual or a family member. Autosomal recessive inheritance was confirmed with the demonstration of *COL4A3* or *COL4A4* mutations or the exclusion of linkage to the *COL4A5* locus using haplotype analysis. Clinical features were noted and fundus photographs obtained in most cases.

**Results:** Of the 51 families with Alport syndrome we have seen, 8 (16%) had autosomal recessive inheritance demonstrated genetically. Two families (25%) were consanguineous. Fifteen affected individuals were identified, including 7 (47%) females. Three families (38%) had only one affected family member in a single generation. All 15 affected individuals developed endstage renal failure in adulthood at a median age of 28 years (range 23 - 38). Fourteen (93%) had hearing loss, 10 (10/13, 77%) had lenticonus, 9 (9/11, 82%) had a central retinopathy, and 9 (9/9, 100%) had a peripheral retinopathy. In contrast, only 2 females in the 42 families with X-linked Alport syndrome developed renal failure before 40 years of age. One of these had Alport syndrome, and the other was unaffected and had an unrelated disease.

**Conclusions:** Most individuals with autosomal recessive Alport syndrome develop renal failure in early adulthood together with hearing loss, lenticonus, and retinopathy. A female who presents with renal failure, hearing loss, lenticonus and retinopathy is very likely to have autosomal recessive Alport syndrome.

**Inpatient Healthcare Utilization and Costs of Polycystic Kidney Disease** Cheryl L. Tran, Emily G. Herreshoff, Patrick Gipson. *University of Michigan, Ann Arbor, MI.*

Purpose: To investigate inpatient healthcare costs of polycystic kidney disease (PKD) in the United States.

Methods: Using the 2006 cohort from the Healthcare Cost and Utilization database, US Agency for Healthcare Research and Quality, we searched for all discharges with PKD as either a primary or secondary diagnosis. ICD 9 codes used were 753.12 (PKD NOS), 753.13 (Autosomal Dominant PKD), and 753.14 (Autosomal Recessive PKD). For discharges with PKD as the primary diagnosis, additional data were available on average hospital charges, aggregate (estimated national) charges, length of stay, and associated secondary diagnoses and procedures.

Results: In 2006, there were 20,441 hospital discharges with a diagnosis of PKD NOS, with 686 (3.4%) having this as the primary diagnosis; 8,230 with ADPKD, 1647(20%) as primary diagnosis; and 1,104 with ARPKD, 92 (9.1%) as primary diagnosis. The median charge per hospitalization for PKD NOS was $24,470, ADPKD was $13,520, and ARPKD was $27,179. However, when comparing the aggregate charges ("National Bill"),

ADPKD had the highest charges of $45,549,971. Charges for PKD NOS and ARPKD were $29,290,234 and $4,191,567, respectively. For ARPKD, the most common age of hospitalization was infants <1yr with 426 (55%), though 22.4% of hospitalizations were for patients ages 18-64yrs. Among pediatric hospitalizations for ARPKD or PKD NOS, 50 and 55% respectively were at Children's hospitals. Among pediatric hospitalizations for ADPKD, 80% were at Children's hospitals.

Conclusion: Most admissions for patients with PKD have a primary discharge diagnoses other than PKD. Seventy percent of admissions in patients with PKD have a discharge diagnosis of PKD NOS, not the more specific ADPKD or ARPKD. The cost of inpatient care for patients with PKD as the primary diagnosis is $79,000,000, but this accounts for only 8% of all inpatient hospital charges related to PKD. Children's hospitals care for the majority of inpatients under age 17 with PKD.

**Lipocalin 2 Is a Critical Mediator of Polycystic Kidney Disease Progression** Amandine Viau,[1] Khalil El Karoui,[1] Denise Laouari,[1] Clement Nguyen,[1] Martine Burtin,[1] Bertrand Knebelmann,[1] Jonathan M. Barasch,[2] Fabiola Terzi.[1] *[1]INSERM U845, Paris, France; [2]Medicine, Columbia University, NYC, NY.*

Polycystic cystic disease (PKD) is characterized by the development and growth of cysts that progressively lead to the destruction of the surrounding normal parenchyma and end stage renal failure (ESRF). Although the majority of PKD are hereditary, multiple renal cysts may develop as a result of developmental abnormalities, aging, drug or dialysis. The mechanisms of PKD progression are poorly understood. It has been suggested that cell proliferation may participate, but the signaling cascades involved remain to be elucidate.

We have recently shown that Lipocalin 2 (Lcn2), a siderophore chelating protein, markedly increased in acquired cysts after 3/4 nephrectomy. Here, we show that Lcn2 was also overexpressed in cystic tubular epithelia of jck (juvenile cystic kidney) mice, an inherited model of PKD similar to the human autosomal dominant polycystic cystic disease (ADPKD). Notably, Lcn2 was not simply a marker of renal lesions, but a crucial mediator of cyst progression. In fact, inactivation of Lcn2 gene dramatically prevented cyst progression in both acquired and inherited experimental PKD. The beneficial effect was associated to a marked decrease of cell proliferation in cystic epithelia. In addition, we discovered that Lcn2 was a critical transcriptional target of EGFR and mediated its mitogenic effect. EGFR inhibition prevented Lcn2 up-regulation and protected the kidney from cyst progression in mice expressing a dominant negative EGFR isoform. In this context, HiF1-a was crucially required for EGFR-induced Lcn2 overexpression. These data were relevant to human ADPKD where urinary Lcn2 was increased particularly in patients who rapidly progressed to ESRF.

In conclusion, our results uncover a novel function of Lcn2 and a critical pathway leading to progressive cystogenesis and renal failure. Lcn2 acts, therefore, as a tubular growth regulator, the overexpression of which identifies patients with progressive PKD and, more importantly, regulates cyst growth.

**Ectodysplasin A2 Receptor (EDA2R), a Gene Implicated in Male Pattern Baldness Is Underexpressed in *Cilia (-)* Oakridge Polycystic Kidney (orpk) Mice Cell Line** Soundarapandian Vijayakumar, Soumyaroop Bhattacharya, Aditi Mulgund. *Pediatrics, University of Rochester Medical Center, Rochester, NY.*

Oakridge polycystic kidney mice *(orpk)* with mutation in a protein involved in cilia formation called IFT88/polaris develop polycystic kidney disease. *Tg737orpk* mutants also exhibit defects in the patterning of the skull and teeth. Recent studies show that primary cilia may regulate sonic hedgehog (Shh) activity in the control of molar tooth number. *Cilia (-) orpk* mutant cells (pCDNA) and *cilia (+)* rescued cells that had stable transfection of polaris gene (BAP2) were obtained from Dr. Bradley Yoder (University of Alabama at Birmingham). Matrigel cysts from rescued cells had a well defined lumen whereas cysts from mutant cells had multiple lumens or no defined lumen. These results suggested that these two lines are phenotypically different and hence we investigated the two cell lines using genome-wide expression profiling to identify novel genes regulated by IFT88. We performed genome-wide expression profiling from high quality RNA extracted from pCDNA (orpk mutant; n=3) and BAP2 (rescued; n=3) cell lines, using Affymetrix GeneChip® mouse Gene 1.0 ST Array. Preliminary analysis using Significance Analysis of Microarrays (SAM) on normalized expression intensities identified 14 probe sets representing 5 annotated genes (Xsist, Aldh1a1, A1g2, Ttc39b and Ncl) as overexpressed in pCDNA samples while 1 gene (Eda2r) was underexpressed in the same when compared to BAP2. Preliminary immunostaining studies show that EDA2R may be localized in the basal bodies of rescued (BAP2) cell lines and its expression is severely decreased in mutant (pCDNA) cells. EDA/EDA2R is implicated in the regulation of shh signaling in the context of hair follicle, salivary gland and tooth development. This novel finding is very significant in the understanding of how primary cilia may regulate shh signaling. Also, recent gene linkage studies implicate the role of EDA2R in male-pattern baldness (androgenetic alopecia), and this raises the possibility that EDA2R could also be one of the "second hit" factors in PKD cystogenesis.

**NGAL in ADPKD Families: A Genotype-Phenotype Correlation** Grazia Maria Virzì,[1] Valentina Corradi,[1] Fiorella Gastaldon,[1] Massimo De Cal,[2] Dinna N. Cruz,[1] Claudio Ronco.[1] *[1]Nephrology, S Bortolo Hospital; [2]Medical Surgical Sciences, University Padua.*

Autosomal dominant polycystic kidney disease (ADPKD) represents 8-10% of the causes of ESRD in the world. The rate of progression of renal insufficiency is variable, and ESRD occurs in only 50% of affected subjects.

There are few biomarkers for quantification or monitoring kidney function. Creatinine (Cr) is an unreliable parameter to describe kidney function.

One of the most promising biomarkers in clinical nephrology is NGAL, massively released from kidney tubular cells after harmful stimuli.

Recent studies suggest a possible role for NGAL in CKD.

Our aim was to investigate the role played by NGAL and its correlations with CysC, Cr, Urea, eGFR in ADPKD families.

We measured NGAL, CysC, Cr, Urea in 18 ADPKD patients on dialysis (ADPKD-RRT), 36 of their relatives not on dialysis (ADPKD-NoRRT), 38 wild-type relatives (WT) and 30 healthy controls (Ctr).

Plasma NGAL was measured using point-of care test. CysC, Cr and Urea were measured with standard methods in clinical laboratory.

| | ADPKD-RRT | WT | ADPKD-NORRT | P |
|---|---|---|---|---|
| NGAL pg/mL | 611(537,676) | 60(60,61) | 66(60,113) | <.001 |
| Cr mg/dL | 8.8(6.9,10.2) | 0.8(0.8,0.9) | 1.1(0.8,1.5) | <.001 |
| CysC mg/L | 6.08(5.6,6.5) | 0.71(0.6,0.8) | 0.84(0.7,1.5) | <.001 |
| Urea mg/dL | 127(109,141) | 33(30,40) | 41(31,70) | <.001 |

Plasma NGAL and CysC values in ADPKD-RRT were significantly higher than Ctr (median 61.7 pg/ml, p<.001).

ADPKD-RRT pts had significantly higher NGAL, CysC, Cr and Urea levels compared to ADPKD-NoRRT and WT.

ADPKD-NoRRT pts had higher NGAL, CysC, Urea and Cr levels compared to WT relatives.

NGAL levels were similar between WT group and Cont (p>.05).

A strong correlation between NGAL and RRF was observed (NGAL/eGFR: r=-0.81; NGAL/Cr:r=.89; NGAL/Urea:r=.7; NGAL/CysC:r=.95, all with p<.001).

In conclusion, we studied NGAL in the context of genotype-phenotype. In ADPKD, NGAL was higher in patients already on RRT compared to their affected relatives not on RRT. WT group had normal NGAL levels; so WT relatives could be a better Ctr group because they share same genes.

**PUB348**

**Development of a High Resolution Melt (HRM) Method for Mutation Screening in PKD2 Gene in ADPKD Families** Grazia Maria Virzì,[1] Alice Bruson,[2] Valentina Corradi,[1] Fiorella Gastaldon,[1] Massimo De Cal,[3] Dinna N. Cruz,[1] Maurizio Clementi,[2] Claudio Ronco.[1] *[1]Nephrology, S Bortolo Hospital; [2]Pediatrics-Clinical Genetics, University Padua; [3]Medical and Surgical Sciences, University Padua.*

Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common hereditary diseases. Mutations of 2 genetic loci (PKD1 and PKD2) can lead to renal cysts. Mutations in PKD2 are expected to be responsible for 15% of cases of ADPKD. The PKD2 gene consists of 15 exons in the 4q21.2 region; it encodes a 5.4 kb transcript; polycystin-2 consists of 968 amino acids.

We apply high-resolution melt analysis (HRM) as a new method of mutation scanning in the PKD2 gene prior to sequencing to select only mutation positive samples.

The method is based on DNA amplification in the presence of a double stranded DNA (dsDNA) intercalating fluorescent dye and on the transition of the double-stranded DNA molecule to its two single strands. DNA denaturation or melting has been used for many years to study DNA structure and composition. Initially, fluorescence is high in a Melt analysis because the sample starts as dsDNA, but fluorescence increases as the temperature is raised and DNA dissociates into single strands. The observed melting behavior, typical of each sample, can be discriminated according to sequence and length. Amplification and HRM conditions for 16 fragments of the PKD2 gene were optimized. HRM analysis were performed with the Rotor Gene 6000 (Qiagen).

Regions where the patient and control samples produce a common profile were not further evaluated, while those regions where the patient profile deviates from the control were assessed by DNA sequencing.

In conclusion, we developed a screening method using HRM analysis prior to direct sequencing, where only positive samples (according to reference) are further sequenced. With this approach, all positive and negative patients were successfully distinguished, and the results obtained were in absolute concordance with the direct sequence analysis.

HRM for the PKD2 genotyping is a simple and sensitive technique, to detect known and unknown variants, that could significantly reduce the time and cost of screening for mutations.

**Autophagic Dysfunction Is Associated with Autosomal Recessive Polycystic Kidney Disease** Shixuan Wang,[1] Xuefeng Su,[1] Maoqing Wu,[1] Ayumi Takakura,[1] Patricia D. Wilson,[2] Jing Zhou.[1] *[1]Medicine, Brigham and Women's Hospital, Boston, MA; [2]Pediatrics, Medical College of Wisconsin, Milwaukee, WI.*

Autophagy is a catabolic process for cells to respond to stressful conditions such as starvation and hypoxia. It has been linked to many types of human disorders. Thus far, no reports have been published about the association between autophagy and either autosomal dominant (AD) or recessive (AR) polycystic kidney diseases (PKD), the most common inherited kidney disorders. Here, we demonstrate dysregulation of autophagy in patients with ARPKD. Compared to that in normal individuals, LC3 expression level and LC3 II/I ratio were reduced in ARPKD patients, indicating defective autophagy. Furthermore, mTOR signaling was activated, as p70 S6 kinase was hyper-phosphorylated at site T389. In conditional knockout (CKO) mice of Pkd1, mTOR signaling was also activated; however, autophagy regulation exemplified by ratio of LC3 II/I and expression level of beclin 1 seemed normal. Taken together, these data suggest that mTOR-autophagy axis may play a distinct role in AD- and ARPKD and autophagy may be potentially a way for therapeutic intervention.

**Type II Diabetes in Patients with Autosomal Dominant Polycystic Kidney Disease** Wei Wang, Berenice Y. Gitomer, Kim Mcfann, Xiang-Dong Yan, Robert W. Schrier. *Department of Medicine, University of Colorado Denver, Aurora, CO.*

**Purpose:** Autosomal dominant polycystic kidney disease (ADPKD) is the most common potentially lethal genetic disorder affecting 1 in 400 live births. Diabetes is also very common affecting 7.8% of the United States population. Type II diabetes mellitus accounts for more than 90% of patients. Moreover, the epidemic of obesity and diabetes is increasing within the US and worldwide. In this regard, there is information from our ADPKD center that body mass index has increased significantly in ADPKD subjects (1985-1992 vs. 1992-2001). However, the impact of type II diabetes in ADPKD patients has not been well studied.

**Methods:** In order to assess the effect of Type II diabetes on severity of ADPKD we undertook a survey of patients from our ADPKD clinical database. Forty-four ADPKD patients with type II diabetes and available clinical information were identified. Eighty-eight patients with ADPKD but without diabetes who were age and sex matched to those with diabetes were selected for comparison.

**Results:** Those patients with diabetes had significantly larger kidney volumes than those with ADPKD alone [Geometric mean (95% CI)],2456(1510-3992)$cm^3$ vs. 1358(1186-1556)$cm^3$, p=0.02. There were no statistical differences between comparison groups based on occurrence of hypertension, ESRD or death. However, among those whose age at hypertension was known, the patients with both ADPKD and diabetes had earlier median(95% CI) age at onset of hypertension compared to those with ADPKD alone, 31(23-40) vs.38(35-42) years, p=0.04. Patients with ADPKD and diabetes tended to have an earlier median age of death than those with ADPKD alone 63(49-no upper) vs. 65(61-71) years, p=0.09.

**Conclusion:** Patients with ADPKD and type II diabetes have larger renal volumes and tend to die at a younger age compared to those patients with ADPKD alone. Exercise and weight loss should therefore be a particular recommendation in patients with ADPKD.

**Caspase 3 Stimulates Migration and Cord Formation of Ureteric Bud Cells: A Potential Role in Reduced Ureteric Bud Branching by Maternal Nutrient Restriction** Midori Awazu,[1] Michio Nagata,[2] Mariko Hida.[1] *[1]Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan; [2]Department of Pathology, Tsukuba University, Tsukuba, Ibaraki, Japan.*

We previously reported that maternal nutrient restriction (50%, NR) reduces the size of metanephroi and inhibits ureteric bud branching in the offspring. While developmentally regulated signaling molecules such as ERK, p38, PI3K/Akt, and ß catenine are downregulated and upregulated at embryonic day 15 and 18, respectively, cleaved caspase 3 is down regulated at both time points in metanephroi from the offspring of NR. Inhibition of caspase 3 is reported to suppress metanephros growth and ureteric bud branching, but the mechanism remains unclear. Recently, caspase 3 is implicated in functions other than apoptosis including cell proliferation and motility. We therefore examined the role of caspase 3 in cord formation, migration, proliferation, and apoptosis using a mice ureteric bud cell line. Ureteric bud cells were cultured in 3D collagen type 1 gels with FGF2 100 ng/ml in the presence or absence of specific caspase 3 inhibitors Ac-DNLD-CHO or Ac-DEVD-CHO at 2, 20, and 200 µM. Cord formation was observed after several days of culture. Both the length and the number of cord structure were significantly decreased by Ac-DNLD-CHO or Ac-DEVD-CHO in a dose dependent manner. Total cell number was not affected by caspase 3 inhibition. Apoptotic cells detected by Hoechst staining were rarely observed (0.8±0.6%) and the number was also not altered by caspase 3 inhibition. FGF2-stimulated cell migration assessed by a modified Boyden chamber method, was inhibited significantly by Ac-DNLD-CHO in a dose dependent manner (2 µM 36±3, 20 µM 28±2, 200 µM 2±1 vs vehicle 84±6). The expression of cleaved caspase 3, assessed by immunoblot was more intense in the fetal rat kidney and decreased by neonatal day 7. The expression was significantly less in the NR kidney, but the difference disappeared by neonatal day 7. In conclusion, caspase 3 may promote ureteric bud branching by stimulation of cell migration not apoptosis. Reduced ureteric branching in maternally nutrient deprived offspring may be mediated by suppressed caspase 3 activity.

**Dysregulation of mTOR Signaling Pathway in Rat Metanephros by Maternal Nutrient Restriction** Mariko Hida,[1] Michio Nagata,[2] Midori Awazu.[1] *[1]Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan; [2]Department of Pathology, Tsukuba University, Tsukuba, Ibaraki, Japan.*

Maternal nutrient restriction produces offspring with fewer nephrons. While apoptosis has been suggested to be the cause, the mechanism is not fully elucidated. We previously reported that signaling pathways important for kidney development, ERK, p38, PI3K/Akt, and ß catenin were downregulated and upregulated by maternal nutrient restriction at embryonic day 15 (E15) and 18 (E18), respectively, in rat fetal kidney. Mammalian target of rapamycin (mTOR) is a kinase downstream of PI3K/Akt that integrates growth factor stimulation and nutrient availability with protein synthesis and cell growth. We examined the expression of activated mTOR in rat fetal kidney under nutrient-restricted conditions. The role of mTOR on proliferation was also investigated in a metanephric mesenchymal cell line MS7. The offspring of dams given food ad libitum (CON) and those subjected to 50% food restriction throughout pregnancy (NR) were examined. Metanephros size became significantly smaller in NR after E14. At E18, total kidney protein, DNA content, and protein/DNA were significantly decreased in NR (62%, 70%, and 87%, respectively). The expression of phosphorylated mTOR (Ser2448, P-mTOR), assessed by immunoblot, was decreased (0.4-fold) and increased (1.8-fold of CON), at E15 and E18, respectively, in NR. Immunohistochemically, P-mTOR expression was found in metanephric mesenchyme and glomerular precursors. In NR kidney, P-mTOR expression was decreased at E13 and E15, but was increased at E18 in the nephrogenic zone in association with increased expression of Ki67. Rapamycin, an inhibitor of mTOR, at 1 µM inhibited serum-stimulated proliferation of cultured metanephric mesenchymal cells by 30%. The expression of L-type amino acid transporter LAT1, a known activator of mTOR, was decreased at E15 in NR (0.4-fold of CON), but the difference was no longer observed at E18. In conclusion, the decreased mTOR activity at E15 may have a role in the inhibited metanephros growth under maternal nutrient restriction. Increased activity at E18 is thought to be a compensatory response which may be mediated by increased LAT1.

**PUB354**

**Reprogramming Human Kidney Epithelial Cells to Nephron Progenitors Requires More Than Epigenetic Destabilization with Growth Factors or Small Molecules** Caroline E. Hopkins, Jessica Ineson, Melissa H. Little. *Institute for Molecular Bioscience, University of Queensland, Australia.*

The adult kidney has a limited capacity to repair. Reprogramming adult kidney cells to a nephron progenitor-like phenotype may represent an alternative for cell therapy purposes. In this study, we have investigated whether adult kidney cells can be reprogrammed to a nephron progenitor-like state via growth factor signaling, small molecules and nuclear reprogramming. Our results show that the human proximal tubular cell line HK2s can be reprogrammed to undergo an epithelial to mesenchyme transition in response to TGFB1, however this does not lead to a kidney progenitor cell phenotype based on in vitro assays of renal potential. In contrast, we have found that treatment of HK2s with VPA, a HDAC inhibitor associated with reprogramming leads to increased expression of kidney progenitor markers assessed via qRTPCR. VPA treated HK2 cells upregulated key CM transcription factors, including Six2, Pax2, Osr1, Eya1 and Hoxa11, and underwent a mesenchymal morphological transition. However, when assessed for their ability to contribute to a CM field within a developing kidney ex vivo, these cells could not act as nephron progenitors. In order to deepen the CM attractor state, we have undertaken a screen for reprogramming factors via sequential pooling of 15 kidney developmentally-specific transcription factors. In this way, we have identified several pools of transcription factors that, together with VPA treatment, lower E-cadherin expression whilst inducing most elements of a genuine CM gene regulatory network. We are currently evaluating the relative renal potential of each positive pool to identify the most efficient transcription factor combination for reprogramming renal epithelial cells to a CM phenotype. This is the first report demonstrating targeted reprogramming within the kidney field. These results concur with the observations of the field that reprogramming involves overcoming multiple epigenetic barriers in order to both destabilize the gene regulatory network specific to the initiating cells and fully activate the network required for the desired attractor endpoint.

**Reactive Oxygen Species (ROS) Produced by NADPH Oxidase Contribute Ureteric Bud Branching and Nephrogenesis** Sato Matsuura, Shuji Kondo, Kenichi Suga, Yukiko Kinoshita, Maki Urushihara, Toshiaki Tamaki, Shoji Kagami. *Department of Pediatrics and Pharmacology, University of Tokushima, Tokushima-city, Tokushima, Japan.*

Ureteric bud branching and nephrogenesis are performed through large-scale proliferation and apoptosis during renal development. ROS produced by NADPH oxidase considered to be involved in cell behaviors including proliferation and apoptosis. However the role of ROS remains to be determined during renal development. We first investigated

the expression of NADPH oxidase and ROS production in rat embryonic (E14, E15, E16, and E18) and postnatal (P1, P7, P20, and P42) kidneys. We further determined the role of ROS in ureteric bud branching and nephrogenesis using NADPH oxidase inhibitors. Immunohistochemistry revealed that the NADPH oxidase components (Nox1, 2, 3, 4, p22phox, p47phox, and p67phox) were expressed on epithelial cells in ureteric bud branches and immature glomerular cells and epitherial cells in nephrogenic zone. Western blotting also demonstrated all of these components were expressed in embryonic and postnatal kidneys. ROS production detected by DHE assay was strongly observed in ureteric bud branches and nephrogenic zone corresponding with NADPH oxidase localization. Organ culture of E14 kidneys for 2 days showed that the inhibition of NADPH oxidase with diphenyleneiodonium (DPI) ($1x10^{-5}$ M) and apocynin ($1x10^{-3}$ M) significantly decreased the number of ureteric bud branches (71.4%, $p<0.05$) and tips (66.7%, $p<0.05$) associated with reduced level of ROS production. This was also associated with decreased level of phosphlylated ERK1/2 and increased level of cleaved caspase-3 ($p<0.05$). Organ culture of E18 kidneys for 2 days showed that its inhibition reduced the size of nephrogenic zone ($P<0.01$) accompanied with reduced levels of ROS production, pax-2 expression, PCNA positive cells, and p-ERK1/2, and increased level of cleaved caspase-3. These results first demonstrate that ROS produced by NADPH oxidase might play an important role in ureteric bud branching and nephrogenesis through regulation of proliferation and apoptosis.

## PUB356

**NR3 Subtypes of the N-methyl-D-aspartate (NMDA) Receptor Expression in Developing Male and Female Rat Kidneys** Karen A. Munger,[1,2,3] Laura Mandler,[1,3] Rachel F. Reynen,[3,4] Jason L. Petersen.[1,2,3] *[1]Basic and Applied Research, Avera Research Institute, Sioux Falls, SD; [2]Internal Medicine, University of South Dakota, Sioux Falls, SD; [3]Research and Development, VAMC, Sioux Falls, SD; [4]Biology, Augustana College, Sioux Falls, SD.*

The NMDA receptor is a widely recognized glutamate receptor in the brain. NMDA receptors are positive ion channels for the net influx of calcium. Kidney function is largely unknown. The NR3 subtype of the NMDA receptor is only found in developing brain. Interestingly, the NR1/NR3 receptor complex requires only glycine rather than a combination of glycine and glutamate to activate the channel.

Male and female rat kidneys were examined at post-partum day 1, 7, 14 and 21 for NMDA content. Protein was isolated from kidneys and run on an 8% SDS Page gel and transferred to nitrocellulose membrane. Antibodies to the NMDA receptor subtype NR3A and B were applied to the membrane, followed by secondary antibodies. Positive bands were visualized with a chemiluminescent probe. Histological sections were examined in Bouins fixed tissues, sectioned at 7 microns and probed with primary anti-NR3 antibodies with CY5 labeled secondary probes. Sections were photographed on a fluorescent confocal microscope. PCR was conducted for NR3A and B message in kidney tissues.

RESULTS:

NMDA NR3 receptor subtypes are found in developing rat kidney. Interestingly, the NR3A is only found in the collecting ducts, whereas NR3B is widely expressed in all tubules EXCEPT the collecting duct. In addition, the NR3 subtype is expressed early in kidney development and protein expression peaks at 7-14 days after birth and then disappears. There are also gender-dependent differences in NR3B expression, with females having lower levels and peaking at day 7, whereas males have higher levels of NR3B expression and peak expression later, at day 14. RT-PCR results parallel the protein expression. These results echo our previous results of higher NR2A expression in males and also point to possible developmental differences in the NR3 expression. Future studies will focus on the regulation of the renal NR3 receptors and functional differences.

Disclosure of Financial Relationships: nothing to disclose

## PUB357

**Intrauterine Programming of Tubular Sodium Reabsorption in a Rat Model of Placental Insufficiency** Kai D. Nüsken,[1] Kerstin U. Amann.[2] *[1]Department of Pediatric Nephrology, University of Cologne, Cologne, Germany; [2]Department of Nephropathology, University of Erlangen-Nuremberg, Erlangen, Germany.*

**Introduction:** Bilateral ligation of the uterine arteries in rats (LIG) serves as a model of placental insufficiency. The offspring shows both intrauterine growth restriction (IUGR) and developmental programming, including persisting alteration of renal function.

**Methods:** Parameters of kidney function and morphology in offspring of dams which underwent either LIG or sham operation (SOP) were compared with those of untreated controls (C). Weight gain, blood and urinary parameters were recorded regularly up to the age of 30 weeks. Glomerular, tubular, interstitial and vascular characteristics and markers of inflammation (ED-1) and proliferation (PCNA) were determined at the age of 30 weeks. Renal gene expressions were quantified by RT-PCR.

**Results:** At puberty (age 7 weeks), both LIG and SOP offspring showed catch-up growth, decreased urinary sodium and increased urinary potassium and aldosterone ($p<0.001$). Concomitantly, plasma sodium was increased and potassium reduced. However, adult LIG offspring (age 30 weeks) showed an elevated urinary loss of sodium despite an increased renal gene expression of the mineralocorticoid receptor, the 11β-hydroxysteroide dehydrogenase type 2 and the β-subunit of the epithelial sodium channel. PCNA protein expression in the thick ascending loop of Henle (TAL) was concomitantly increased.

**Conclusions:** In puberty, SOP activates tubular sodium reabsorption similar to LIG, which may contribute to catch-up growth. In adult LIG offspring, increased PCNA in the TAL indicates need for tubular repair processes. As the TAL is crucial for sodium reabsorption, tubular damage in this part of the nephron may outweigh the activation of the ENaC, thus resulting in a loss of sodium.

## PUB358

**Maternal Undernutrition Dysregulates Apoptosis in Offspring Kidneys** Cynthia C. Nast,[1] Sanaz Tafti,[2] Mina Desai,[2] Michael Ross,[2] Thomas R. Magee.[2] *[1]Pathology, Cedars-Sinai Medical Center, Los Angeles, CA; [2]Ob-Gyn, Harbor-UCLA Medical Center, Torrance, CA.*

**Background:** Maternal undernutrition (MUN) induces offspring kidney nephron deficits by uncertain mechanisms. We evaluated MUN-induced kidney RNA, then protein expression before and after birth to assess the role of apoptosis. **Design:** Pregnant rat dams were 50% food restricted from embryonic day (E)10. Male offspring E20 and postpartum day (P) 1 kidneys were removed. E20 whole kidney RNA was hybridized using rat Agilent DNA microarrays. E20 and P1 kidneys were analyzed by Western blot and slides stained by TUNEL for morphometry and WT1 and Pax2 for apoptosis localization.

**Result:** E20 kidney microarray showed 198 known genes with ≥1.5 fold change. Analysis of ontological groups and signaling pathways revealed 4 significantly upregulated genes in apoptotic signaling pathways; Fas ligand (7.0 fold), TNFα (1.6 fold), TNFR1a(1.6 fold), and AKT2 (1.5 fold). Apoptosis protein expression was altered as shown below.

E20 and P1 Western Blot Data

| | E20 Kidney | E20 Kidney | P1 Kidney | P1 Kidney |
|---|---|---|---|---|
| | Fold Change | P value | Fold Change | P value |
| Fas Ligand membrane | 1.4 | 0.14 | 1.3 | 0.98 |
| Fas Ligand soluble | Not detected | -- | 1.0 | 0.93 |
| FAS | 2.2 | 0.002 | 1.9 | 0.05 |
| BAX | 0.9 | 0.52 | 4.5 | 0.01 |
| Bcl2 | 1.8 | 0.003 | 0.6 | 0.03 |
| Caspase 3 | 1.2 | 0.69 | 1.6 | 0.03 |
| p53 | 1.4 | 0.28 | | |

Kidney TUNEL showed significantly increased apoptosis in the P1 nephrogenic zone (NZ) (MUN 2.2 ±.3 vs C 1.6 ±.5, $p < 0.05$), primarily in mesenchyme and renal vesicles; E20 TUNEL trended upward ($p<0.07$)

**Conclusion:** Apoptosis is upregulated in P1 MUN offspring kidneys in NZ mesenchyme and renal vesicles, thus impairing postpartum nephron formation. Pro- and anti-apoptotic proteins are increased at E20; however ↑BAX and ↓Bcl-2 at P1 suggest parturition effects cell survival. MUN increased apoptosis may be a direct effect and/or due to dysregulated developmental signaling pathways such as Notch, which we previously have shown to be reduced by MUN at E20. Therefore P1 upregulated apoptosis likely is an important mechanism inducing nephropenia in MUN progeny.

## PUB359

**Von Hippel Lindau Syndrome: A Review of Patients Attending the Irish National Tertiary Referral Center over the Past Twenty Years** Frank J. O Brien, Peter J. Conlon. *Department of Nephrology, Beaumont Hospital, Dublin, Ireland.*

Introduction

Von Hippel-Lindau disease (VHL) is a syndrome characterized by variety of tumours. This disease is genetic and can present in childhood, adolescence or in adult life. This study aims to characterize the presentation, natural history and renal manifestations of patients attending our institution with this condition. We also examine changes in method of presentation over the past 20 years.

Methods

A retrospective chart review was carried out on all patients coded as having VHL by the Hospital Inpatient Enquiry Scheme (HIPE) at Beaumont Hospital. Age, sex, mode of presentation, presence or absence of end stage kidney disease (ESKD) and genotype were recorded. Presence or absence of the characteristic tumours of VHL was also noted, as were the initial presenting features of these tumours.

Results

18 patients were identified has having VHL. The most frequent mode of presentation was altered neurological signs (56%), with a proportion presenting with haematuria (33%). Patients diagnosed prior to 2000 were more likely to have presented with significant complications of VHL, while those diagnosed after this time were more likely to have been diagnosed via screening. Five patients (27%) developed end stage kidney disease as a result of nephrectomy for bilateral renal cell carcinoma. These patients all required haemodialysis. The average time spent on dialysis was 1.8 years (range 6 months-5 years). Three of these subsequently received a transplant, two cadaveric and one living donor. Two patients developed unilateral renal cell carcinoma. Nine patients (50%) had coincidental central nervous system haemangioblastomas. One person was noted to have died secondary to metastatic renal cell carcinoma.

Conclusion

Our institution is unique in Ireland, consisting of tertiary referral centres for nephrology, urology/transplant and neurosurgery. The prevalence of VHL noted above is similar to that described internationally. Our patient group has similar rates of ESKD, but higher rates of transplantation when compared to similar studies. This study highlights the significant renal burden of this illness. It also highlights the importance of screening.

**Counting Glomerular Number in Developing Mice** Jianyong Zhong,[1] Haichun Yang,[2] Valentina Kon,[1] Agnes B. Fogo,[2] Iekuni Ichikawa,[1] Ji Ma.[1] *[1]Pediatrics, Vanderbilt University, Nashville, TN; [2]Pathology, Vanderbilt University, Nashville, TN.*

Attenuation in acquisition of normal nephron number *in utero* has been linked to a variety of diseases and may be compensated by postnatal interventions. Abnormal kidney size/nephron number *in utero* also characterizes some mice generated by transgenic technologies. These novel biologic insights and animal models require a reproducible and practical approach to determine the number of nephrons at various stages from a limited amount of tissue. Although the literature contains a few studies, they report a wide range of glomerular number. Further complicating this issue is the fact that traditional methods for glomerular number counting were developed primarily in adult rats and have not been validated in developing mice which are characterized by small and rapidly growing glomeruli. In the present study we tested the hypothesis that a stereological approach utilizing 2-dimentional sections to estimate the nephron number in the whole kidney encompassed in the Weibel-Gomez method can be used to obtain reliable and reproducible data in the developing kidney of the mouse.

Serial sections of mouse kidneys revealed that starting from 7 dpp, almost every glomerulus can be identified by WT-1 and synaptopodin staining. Despite continued increase in age, kidney weight and glomerular size, the number of glomeruli assessed by Weibel-Gomez method remained stable at 7, 10, 14, 18, 21, 25 and 28 dpp, averaging 19495±534 glomeruli per kidney (mean±SE, n=4-5 mice for each time point). There was no difference in glomerular number between the left and right kidneys. A small adjustment of the coefficient in the Weibel-Gomez equation was required for assessments in mice. These results were confirmed by using the fractionator/dissector method as well as by different examiners using the Weibel-Gomez method.

We conclude that, the Weibel-Gomez method is a reliable and reproducible method of counting the glomerular number in developing mice. The reference equation can be used as a practical alternative for the fractionator/dissector procedure and emerging imaging technologies that both require exhausting the small amount of tissues in mice.

**Association of Vascular Endothelial Growth Factor Gene Polymorphisms and Vascular Complications in Patients with Type 2 Diabetes According to Heritage** Kenneth Earle,[1] Karima Zitouni,[2] Diane Harry,[2] Kamini Kalidas,[2] Lorna Tinworth,[2] Steve Jeffery.[2] *[1]St George's Hospital NHS Trust London, United Kingdom; [2]St George's University London, United Kingdom.*

**Introduction and aim**

Deregulation of vascular endothelial growth factor(VEGF) is associated with coronary syndromes and microvascular diabetes complications. It is unknown if genetic determinants of VEGF are related to the epidemiological observation of a greatly increased risk of renal and cardiovascular disease(CVD) in Indo-Asian(IA) and African-Caribbean(AC) patients with type 2 diabetes compared with those of Caucasian(CAN) heritage in the UK

**Methods**

We genotyped 369 consecutive clinic attendees in North London,UK of AC(n=90), IA(n=47) and CAN(n=232) heritage for the -460(C/T) and +405(G/C) VEGF polymorphisms by polymerase chain reaction-restriction fragment length polymorphism. Presence of CVD, retinopathy determined by direct fundoscopy, and nephropathy according to serial urinary albumin:creatinine ratios>3mg/mmol and/or pre-end-stage renal dysfunction, hemoglobin A1c(HbA1c) blood pressure and serum cholesterol was obtained from medical records

**Results**

The mean(SD) age and duration of diabetes of the AC, IA and CAN groups were, 58.3(12.2), 59.5(10.8), 57.4(15.3) years and 16.3(9.0), 17.9(7.5), 17.0(10.4) years respectively. There were no differences in HbA1c, blood pressure or total cholesterol.There was no difference in the distribution of the TC, TT, CC and the CG, GG, CC genotypes of the -460 and +405 VEGF polymorphisms between the groups

The proportion of patients with CVD(n=31) carrying the CC genotype was higher than those carrying the TC and TT genotypes (24vs 5vs 10%; p=0.01).There was an association of CVD with carriage of the CC genotype in the IA subgroup(p<0.01). In the whole cohort, the GG genotype was associated with retinopathy(p=0.01) and with marginal significance with nephropathy(p=0.05)

**Conclusion**

In these patients with type 2 diabetes, a genetically determined disturbance of VEGF regulation may be of relevance to the higher incidence of CVD in the IA heritage group, but appears not to relate to differences in renal complications in either the AC or IA groups compared with those of CAN heritage

**TaqMan Genotyping Analysis of NADPH Oxidase Gene Locus in Acute Kidney Injury** Mary Celine R. Perianayagam,[1] Hocine Tighiouart,[2] Daniel T. O'Connor,[3] Bertrand L. Jaber.[1] *[1]Department of Medicine, St. Elizabeth's Medical Center, Boston, MA; [2]Biostatistics Research Center, Tufts Medical Center, Boston, MA; [3]Center for Human Genetics and Genomics, University of California, San Diego, CA.*

**Background**. Although oxidative stress plays an important role in acute kidney injury (AKI), the association of oxidative stress-related genetic variants and clinical outcomes are unknown.

**Methods**. We examined the association of 4 tag-single nucleotide polymorphisms (SNPs) (Ref-SNP No. rs8854, rs4673, rs37946244 and rs4782390) in the NADPH oxidase gene locus with dialysis requirement or the composite of dialysis requirement or in-hospital death in 262 hospitalized adults with AKI. Dominant and additive multivariable logistic regression analyses were performed.

**Results.** Observed and expected genotype frequencies were not different and allele frequencies met Hardy Weinberg equilibrium (P>0.05). Within each SNP, baseline characteristics were not different between genotype groups in respect to age, sex, race, and APACHE II score. In the dominant model, on univariate analysis, the rs8854 A-allele group experienced 50% and 59% lower odds for dialysis requirement or the composite outcome, respectively, as compared to the GG genotype group. This association with the composite outcome persisted after adjustment for sex, race, and APACHE II score. In the additive model, there was no independent association between each copy of the rs8854 minor A-allele and outcomes, suggesting lack of a gene dose effect. The remaining 3 tag-SNPs were not associated with the outcomes of interest.

| rs8854 A-allele (vs GG genotype) | OR | 95%CI | P |
|---|---|---|---|
| Dialysis requirement | | | |
| -Unadjusted | 0.50 | 0.22,1.11 | 0.09 |
| -Adjusted | 0.52 | 0.22,1.19 | 0.12 |
| Dialysis requirement or in-hospital death | | | |
| -Unadjusted | 0.41 | 0.19,0.89 | 0.02 |
| -Adjusted | 0.40 | 0.17,0.93 | 0.03 |

**Conclusion.** Of the 4 tag-SNPs in the NADPH oxidase gene locus examined in this pilot study, only one SNP located in the promoter region (rs8854) was associated with lower requirement for dialysis or in-hospital death. Larger studies are needed to confirm these relationships.

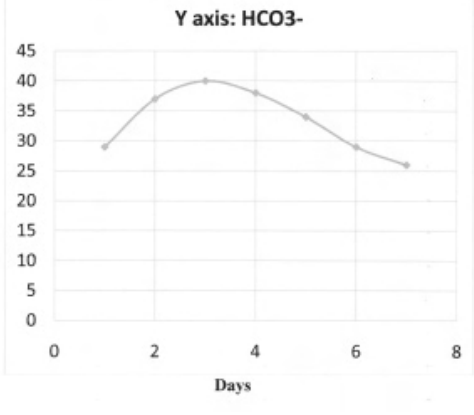
**Regional Citrate Anticoagulation for Slow Continuosus Ultrafiltration (SCUF) Complicated by Severe Metabolic Alkalosis** Mourad Alsabbagh,[1] Edward A. Ross.[1] *[1]Division of Nephrology, University of Florida, Gainesville, FL; [2]Division of Nephrology, University of Florida, Gainesville, FL.*

Slow Continuous Ultrafiltration is a safe and efficient treatment for patients with fluid overload who are hemodynamically unstable, have low urine output, and don not need dialysis or hemofiltration (HF) for solute clearance.Anticoagulation needs to be sustained for these long treatments, and this can be clinically challenging as many patients have contraindications to systemic anticoagulation with heparin. Regional Citrate Anticoagulation would be an alternative option; however, we believe this can be problematic due to citrate kinetics. We present two cases in which patients received Anticoagulant Citrate Dextrose Solution A (ACD-A 225 ml/hr) pre-filter and had net UF of approximately 300 ml/hr: severe metabolic alkalosis developed with serum bicarbonate levels rising from 24-25 to 39-41 mmol/l [PH =7.70, PCO2=29.7, HCO3=37.3.



This is in contrast to our CVVH protocol using the same rate of ACD-A, in which there is approximately 2 L/hr of HF and no alkalosis; In this paper we discuss with detailed calculations how the metabolic alkalosis develops with using SCUF to emphasize the importance of accounting for the kinetics of citrate clearance into the HF, thereby avoiding acid base disturbances. Clinicians need to be aware of the risk of metabolic alkalosis when

using modalities with low rates of ultra- or hemofiltrate, and decrease or discontinue the citrate. In SCUF modality (compared with CVVH) the considerable net positive balance of citrate accumulate results in the development of severe metabolic alkalosis, despite net losses of bicarbonate into the ultrafiltrate.

Citrate Balance in SCUF in 3 days

| SCUF | Day 0 | Day 3 |
|---|---|---|
| Bicarb Balance (g/D) | -1.1 | -1.8 |
| Citrate Balance ( mmol/D) | +584.6 | +570.2 |

Net positive balance of citrate accumulate results in the

**Microbiologic Treatment Efficacy in Continuous Renal Replacement Therapy (CRRT)** Daniel A. Caroff, Francis P. Wilson, Jeffrey S. Berns, Peter P. Reese. *Renal, Electrolyte, and Hypertension, University of Pennsylvania, Philadelphia, PA.*

Background: Despite theoretical and practical advantages, studies have not found that CRRT confers improved survival compared to intermittent hemodialysis (IHD) for acutely ill patients with AKI. We postulated that higher antibiotic clearances with CRRT cause low blood levels leading to poorer bacteriologic and clinical outcomes. This study aims to identify differences in treatment of bloodstream infection between patients on continuous venovenous hemodialysis (CVVHD) and IHD.

Methods: ICU patients receiving CVVHD (≥ 48 hrs) or IHD (≥ 2 treatments over 72 hrs) and positive blood cultures were identified over a 2-yr period. We studied the duration of positive cultures from initial IV antibiotic dosing, type of vascular access, antibiotic regimen, frequency of obtaining blood cultures, and microbiologic data.

Results: We identified 27 CVVHD and 21 IHD patients. The CVVHD cohort had a longer average duration of bloodstream infection than the IHD cohort (66.3 hrs vs. 56.9 hrs; p=0.08) that approached statistical significance. There was no significant difference in the rates of Gram-positive or Gram-negative infections between the cohorts. There was a higher rate of fungemia in patients with non-tunneled dialysis catheters compared to patients with tunneled catheters (p=0.04). The most commonly used antibiotics were Vancomycin, Cefepime, and Linezolid with similar usage in both groups. 61% of CVVHD patients died compared to 63% of IHD patients. On average, CVVHD patients had fewer blood cultures drawn after the first positive culture than IHD patients (0.61 vs 0.74 per day; p=0.07).

Conclusions: Our results suggest a longer average duration of bloodstream infection in patients on CVVHD compared to IHD. This may in part account for poor outcomes in septic CRRT patients. There was a higher incidence of fungemia in patients with NTDCs. Also, blood cultures were drawn at a lower rate in the CVVHD cohort, perhaps related to lower body temperature in CRRT than IHD. Future studies should explore whether more aggressive antimicrobial therapy during CRRT is necessary to improve treatment and survival of infected patients on CRRT.

**Vancomycin Dosing in Morbidly Obese Patients Undergoing CVVHD** Wei Chen, Julie L. Chen, Danielle Garcia, Payal Lakhani, Ladan Golestaneh. *Department of Medicine (Renal Division) and Pharmacy, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY.*

This study is to evaluate serum vancomycin removal in morbidly obese patients receiving continuous venovenous hemodialysis (CVVHD). Three morbidly obese patients with body mass indices (BMI) > 35 and oliguric renal failure were enrolled in a prospective, observational study. CVVHD was initiated 2 hours after the administration of a vancomycin loading dose. The loading dose of 20 mg/kg was given to achieve a target concentration of 25-30 mcg/ml. Blood flow, ultrafiltration and dialysate flow rates were individualized by the renal service. Vancomycin levels were measured at time 0, 2, 4, 8 hours. All three patients were obese, with BMI of 45, 70 & 36. The dialysate flow rate was 2 L/hr for all three patients, but blood flow and ultrafiltration rates varied within a limited range. The calculated half-life of vancomycin was 10.7, 14 & 11.7 hours, and the clearance was 72.4, 62.2, 73.6 ml/min. Vancomycin levels fell by 40.4%, 32.8%, 37.7% after 8 hours of CVVHD. When the data is extrapolated to 24 hours using calculated half-life, vancomycin levels fell below the therapeutic range (15 mcg/ml) after 12 hours. This study shows that vancomycin is effectively cleared by CVVHD in morbidly obese patients. Based on our results, we make the following recommendations: 1)for anuric or oliguric patients, to maintain therapeutic vancomcyin levels during CVVHD, an adequate loading dose is indicated to ensure a vancomycin level of 25 to 30 mcg/ml before the initiation of CVVHD; 2)in obese patients, we recommend a loading dose of 20 mg/kg based on adjusted body weight instead of actual weight; 3)vancomycin 1 gm q12hr or 750 mg q8hr is required to maintain a vancomycin trough of 15 to 20 mcg/ml during CVVHD; and the dosing regimen should be modified if there is any interruption in CVVHD.

**Figure 1. Recommended dosing regimen**

**PUB367**

**Genius® Dialysis System (Genius): A Safe and Efficient Method for Critically Ill Patients** Veronica T. Costa e Silva, Regina C. R. M. Abdulkader, Luis Yu, Gillene S. Ferreira, Renato Antunes Caires. *Nephrology Service, University of S Paulo School of Medicine, Sao Paulo, Brazil.*

Genius is well suited for hybrid therapies especially for critically ill patients. Adequacy and complications have not been studied. Thus, we retrospectively analyzed all dialysis with Genius system performed in adult ICUs during March 2010. The following complications were evaluated: hypotension, coagulation system (leading to dialysis interruption), cardiac arrhythmia, reduction of prescribed blood flow and no attainment of prescribed ultrafiltration (UF). Data are presented as mean ± SD or %. During the studied period, 195 dialysis were performed in 40 patients (4±3/patient). *Patients' characteristics*: age 58 ± 14 years, 55% male, 60% on vasopressors, 70% septic, 73% with acute kidney injury. *Dialysis' characteristics*: venous access by temporary catheter in 95% (51% femoral and 41% internal jugular veins), high-flux membrane in all (FS80 in 68%), blood flow = dialysate flow (250 mL/min in 68% of dialysis), no anticoagulation in 65% and duration of 6 hours in

58%. *Adequacy*: blood urea decreased from 118 ± 58 to 78 ± 41 mg/dL (P<0.01, 69 ± 27% reduction), and potassium decreased from 4.2 ± 0.8 to 4.0 ± 0.7 mEq/L (P<0.01). Prescribed UF was 1.6 ± 0.9 L which was not attained in 27% of dialysis. However, patients had their volume balance decreased from 1.6 ± 1.4 L in pre-dialysis day to 0.2 ± 1.6 L in dialysis day (P<0.01). *Complications:* 78% of the dialysis did not present any complication and 6% presented more than one complication. Main complications were hypotension in 20% (7% required introduction or increase in vasopressors), access problems in 32%, reduction in prescribed blood flow in 9% and clotting of the system in 17%. Clotting was associated (Fischer´s test) with access not working well (P<0.01) and with the need for decreasing blood flow (P<0.01) but not with the absence of anticoagulation (P=0.68). Cardiac arrhythmia occurred in 3 dialysis and bacteremia in 1. *In conclusion*, Genius may be an alternative for dialysing critically ill patients, allowing reduction of positive fluid balance. Complications are infrequent and mainly associated with problems of vascular access.

## PUB368

**Transition from Continuous to Intermittent RRT: Analysis of an International ICU Cohort** Dinna N. Cruz,[1] Roberto Fumagalli,[2] Manuel E. Herrera-Gutiérrez,[3] Paola Inguaggiato,[4] Detlef Kindgen-Milles,[5] Aníbal Defensor Marinho,[6] Rene Robert,[7] Claudio Ronco.[1] *[1]S Bortolo Hosp, Vicenza, Italy; [2]Milano Bicocca Univ, Monza, Italy; [3]Carlos Haya Hosp, Malaga, Spain; [4]S Croce e Carle Hosp, Cuneo, Italy; [5]Univ Hosp, Dusseldorf, Germany; [6]Santo Antonio General Hosp, Porto, Portugal; [7]Univ Hosp, Poiters, France.*

**Background**

In the management of Acute Kidney Injury (AKI) in the ICU, it is common practice to transition from CRRT to intermittent RRT (IRRT) as the patient clinically improves but continues to need renal support. However, there are no published data on this practice. Our aim was to describe the clinical circumstances present when patients are shifted to IRRT.

**Methods**

We identified 26 ICU patients in the DoReMi study who were started on CRRT then subsequently shifted to IRRT. We compared their characteristics on the first and last day of CRRT (i.e. the day before starting IRRT) using paired tests.

**Results**

The cohort was 69% male, median age 70 yr; SAPS II and SOFA scores on ICU admission were 49 and 12, respectively; pre-morbid serum creatinine (sCr) was 1.1 mg/dL. After a median of 6 (IQR 3-12) days on CRRT, they were transitioned to IRRT. On the last day of CRRT, they were less likely to be on vasopressors, and had significantly improved MAP, SOFA, urea, sCr and PaO2/FiO2 (Table 1). However, urine output was low. Two of 26 patients had to shift back to CRRT within 7 days, of whom 1 died in the ICU.

**Conclusion**

Patients are shifted from CRRT to IRRT when hemodynamic and metabolic status have improved. Patients with low urine output need continued renal support, albeit at lower intensity, and transition to IRRT may be an appropriate choice.

Table 1

| | First CRRT day | Last CRRT day | p |

## PUB369

**How To Dialyze a Whale** Andre A. Kaplan,[1] Allison Tuttle.[2] *[1]Dept Med, UConn Hlth Ctr, Farmington, CT; [2]Mystic Aquarium, a Division of Sea Research, Inc., Mystic, CT.*

We report our efforts in providing renal replacement therapy for a 1050 kg. Beluga whale with AKI. Given the likely increased adipose stores we estimated total body water of 500 liters, thus calculating that dialytic requirements would be approximately 10 times that of a human. Hemodialysis did not appear a rational choice due to the anticipated difficulty in providing prolonged hemoaccess. PD had been previously tried unsuccessfully in a pilot whale (Ward DM, Proc Int Assoc Aquatic Animal Med, 1994 (abs). We therefore considered intestinal dialysis. Projected goal was to provide 30 liters/day of mannitol at 20% and to replace diarrhea output with 100 liters per day of hypotonic saline with bicarbonate. The whale had been trained to swallow a gastric tube and infusions were provided 5 times daily. It became quickly evident that the maximum tolerated gastric infusion was only 10 liters daily, with a concomitant 30 liters per day of parenteral fluid replacement with D5W, NS and bicarbonate. Lab values were obtained twice daily.

Results over a 15 day period:

Intestinal Dialysis in a Beluga Whale

| | day 1 | day 4 | day 7 | day 10 | day 13 | day 15 |
|---|---|---|---|---|---|---|
| **BUN** | 186 | 180 | 160 | 140 | 140 | 136 |
| **CR** | 13.3 | 14.5 | 14.7 | 16.6 | 18.3 | 19.4 |
| **K** | 6.9 | 6.1 | 4.8 | 4.4 | 4 | 4.1 |
| **HCO3** | 10.3 | 14 | 17.5 | 25.4 | 27.2 | 29.4 |
| **pH** | 6.99 | 7.04 | 7.08 | 7.22 | 7.32 | 7.38 |
| **Ca** | 8 | 8.9 | 9.2 | 9 | 9.1 | 9 |
| **Phos** | 10.4 | 11.8 | 11.1 | 10.4 | 10.3 | 9.5 |

As previously described with intestinal dialysis, removal of creatinine was inefficient. Continued increase in creatinine also supports our contention that improvements in nitrogen, potassium and acid base balance were the result of the treatment and not a return of endogenous renal function. Despite apparent success in dialytic goals, the whale expired on day 15. Preliminary postmortem evaluation confirmed clinical diagnosis of ATN. The cause of the ATN has not yet been identified. Although a definitive cause of death has not yet been determined, we believe intestinal dialysis represents a reasonable option in the treatment of AKI in the whale.

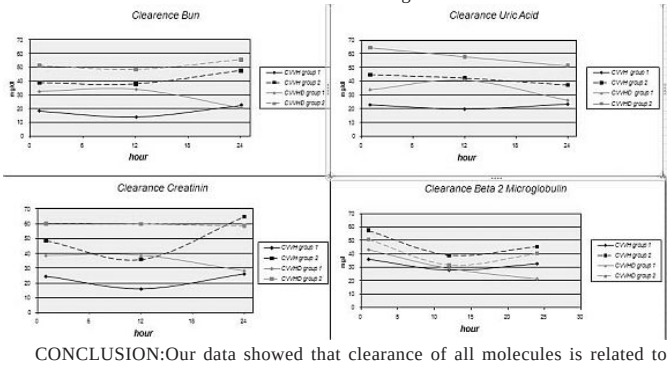
**Solutes Removal during Continuous Renal Replacement Therapy in Critically Ill Patients with a New High Polysulfone-Based Hemofilter (CUREFLO®): Convenction Versus Diffusion** Nicola Marchionna,[1,3] Matteo Floris,[1,3] Alessandra Brendolan,[1] Federico Nalesso,[1] Monica Zanella,[1] Claudio Ronco.[1,3] *[1]Nephrology, St Bortolo Hosp, Vicenza, Italy; [2]IRRIV, Italy.*

BACKGROUND:Solutes removal during continuous renal replacement therapy(CRRT) can be obtained by convention,diffusion and membrane adsorption.The best modality for CRRT is currently uncertain and it is poorly understood how transport of different solutes,changes over time.

METHODS:We compared,in critically ill patients,small molecular(creatinine,BUN,uric acid)and middle molecular weight(b2 microglobulin)solutes clearance and filter lifespam,during 7 continuous veno-venous dialysis(CVVHD)and 7 continuous veno-venous hemofiltration(CVVH)sessions.ACF-130W hollow-fiber dialyzer(1.3sqm,Asahi Kasei Kuraray Medical co.Ltd)was used.Patients were treated by CRRT using the Multifiltrate Fresenius machine.We compared different treatment conditions in CVVH(Group 1:Qb200 ml/min,Qr1500 ml/h in postdiluition,Qf -100 ml/h vs Group 2:Qb250 ml/min,Qr2500 ml/h in postdiluition,Qf -200 ml/h)and CVVHD(Group 1:Qb200 ml/min,Qd2500 ml/h,Qf -100 ml/h vs Group 2:Qb250 ml/min,Qd3500 ml/h,Qf -200 ml/h).Samples were collected before sessions and after 1,12 and 24h from the beginning.We also evaluated sieving coefficient of BUN,creatinine,uric acid,albumin,B2 microglobulin,myoglobin,alfa 2 macroglobulin

RESULTS:All sessions reached targeted 24h duration and at the end hemofilters displayed no clotting with a very low blood residual in the filter both in CVVH than in CVVHD treatments.Mean clearances are shown in Figure 1.



CONCLUSION:Our data showed that clearance of all molecules is related to filtration dose.Small molecular clearances are better in CVVHD during all long treatment. Moreover,middle molecular weight are better removed during CVVH.CUREFLO® filter is safe and its removal performances are suitable for the most advanced techniques in CRRT.

## PUB371

**Diffusive and Convective Solute Clearance during Continuous Renal Replacement Therapy with a New High Polysulfone-Based Hemofilter (CUREFLO®)** Nicola Marchionna,[1,3] Matteo Floris,[1,3] Alessandra Brendolan,[1] Federico Nalesso,[1,3] Monica Zanella,[1] Francesco Garzotto,[1,3] Dinna N. Cruz,[1,3] Pasquale Piccinni,[2] Claudio Ronco.[1,3] *[1]Nephrology, St Bortolo Hosp, Vicenza, Italy; [2]ICU, St Bortolo Hosp, Vicenza, Italy; [3]IRRIV, Vicenza, Italy.*

BACKGROUND: Solute exchanges during continuous renal replacement therapy (CRRT) can be obtained by convention, diffusion and membrane adsorption.The purpose of the study is the assessment of safety and efficacy of post-dilution continuous hemofiltration (CVVH) and hemodialysis (CVVHD) with CUREFLO®, a new high-flux polysulfone-based hemofilter

METHODS: Ten treatments (5 CVVH, 5 CVVHD) were performed in critically ill patients with acute kidney injury. ACF-130W hollow-fiber dialyzer (1.3 sqm, Asahi Kasei Kuraray Medical co.Ltd) was used. Patients were treated by CRRT using the Multifiltrate Fresenius machine. The treatment conditions were: CVVH(Qb 200 ml/min;Qr 1500 ml/h in postdiluition;Qf -100 ml/h) CVVHD(Qb 200 ml/min;Qd 2500 ml/h;Qf -100 ml/h. Samples were collected before the sessions and after 1, 12 and 24h from the beginning. We evaluated the clearance of BUN, creatinine, uric acid and sieving coefficient(SC)of BUN,creatinin,uric acid,albumin,B2microglobulin,myoglobin,alfa 2 macroglobulin.We also assessed the thrombogenicity through phothos of dialyzer for residual blood

RESULTS:Clearances for both treatments and SC of CVVH are showed.

| CVVH | | | |
|---|---|---|---|
| *Clearances* | *1h* | *12h* | *24h* |
| BUN | 18.3±10 | 14±12.8 | 22.5±4.9 |
| Creatinin | 24.4±11.9 | 16±17.1 | 26±6.8 |
| Uric Acid | 22.9±13.2 | 19.8±13.1 | 23.4±8.4 |
| *Sieving Coefficents* | *1h* | *12h* | *24h* |
| BUN | 1±0.08 | 1±0.07 | 1±0.04 |
| Creatinin | 1±0.07 | 1.1±0.07 | 1.1±0.04 |
| Uric Acid | 1.1±0.01 | 1.1±0.07 | 1.1±0.05 |
| Albumin | 0±0.01 | 0±0.01 | 0±0.01 |
| Beta 2 Microglobulin | 0.9±0.08 | 0.89±0.14 | 1±0.16 |
| Myoglobin | 0.58±0.26 | 0.38±0.16 | 0.31±0.15 |
| Alfa 2 Macroglobulin | 0.25±0.10 | 0.21±0.05 | 0.22±0.07 |
| | | | |
| CVVHD | | | |
| *Clearances* | *1h* | *12h* | *24h* |
| BUN | 18.3±10 | 14±12.8 | 22.5±4.8 |
| Creatinin | 24.4±11.9 | 16±17.1 | 26±6.8 |
| Uric Acid | 22.9±13.2 | 19.8±13.1 | 23.4±8.4 |

No adverse reactions were observed during the study.All sessions reached targeted 24h duration and at the end hemofilters displayed no clotting with a very low blood residual in the filter

CONCLUSION:The clearances for small molecules is greater in CVVHD than in CVVH as it is expected and the CUREFLO® shows a sieving profile suitable for removal of larger solutes through high filtration rate.The use of CUREFLO® is safe and its removal performances are suitable for the most advanced techniques in CRRT.

**Outcomes in Intensive Care Unit Patients with Elevated Serum Lactate Requiring Renal Replacement** Robert M. Murithi, Warangkhana Wongba, William S. Burtnett, Mohamed Saad, Rosemary Ouseph. *Medicine, University of Louisville, Louisville, KY.*

Acute kidney injury (AKI) increases the mortality in patients in the intensive care unit. The mortality of AKI from sepsis is 75%. Methods: This study is a retrospective chart review of patients admitted to the intensive care units at local tertiary care centers from January 1, 2007-December 31, 2009. Inclusion criteria included age ≥ 18 years, diagnosis of sepsis, lactate level ≥ 2mmol/L, and acute kidney injury defined as an increase of 30% in serum creatinine or if baseline value was unknown a creatinine ≥ 1.5 mg/dL. Logistic regression was performed to see if there is a difference in patient survival in patients with lactate levels ≥ 2 mmol/L who require renal replacement therapy (RRT). Data is shown as mean ± s.d. Results: 51 cases were identified. The demographics of the population were 63% men, 76.5% Caucasian, 76% on pressors, average age 60 ± 17 years, baseline creatinine 1.42 ± .76, lactate 6 ± 4 mmol/L, and bicarbonate 20 ± 6 mEq/L. The overall mortality rate was 37%. Among patients requiring RRT (18% of study group) mortality was 67%. The mean time to initiate RRT was 2±1.7 days (3.3 ± 3.2 in survivors vs 1.5 ± .54 in nonsurvivors) . The mean time on RRT was 5.6 ± 4 days among survivors and 3.6 ± 2.8 days in patients who died. The overall withdrawal of care rate was 35%, among RRT it was 50%. Among patients who died 3 had an increase in lactate levels and 5 required increasing pressor support. There was no statistically significant difference in demographics or initial laboratory data between survivors and nonsurvivors. Conclusion: There was aggressive withdrawal of care by intensive care teams in patients determined to have low survival. Despite earlier initiation of renal replacement therapy nonsurvivors had increasing lactate levels and required increasing pressor support. The effect of interventions outlined by the Surviving Sepsis Campaign on outcomes in patients requiring RRT need further study.

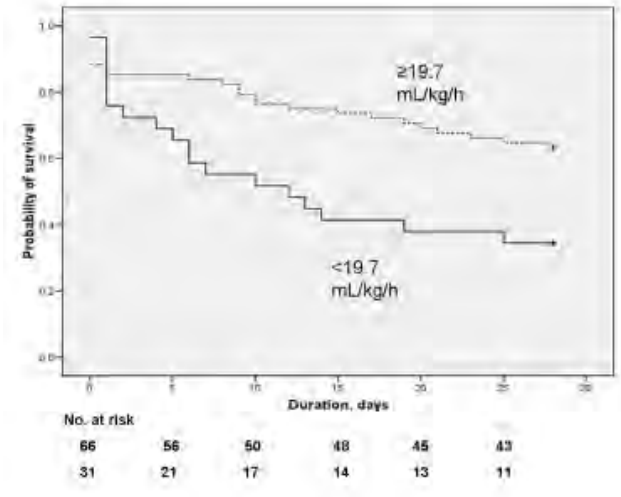
**Delivered Dose of Continuous Venovenous Hemofiltration Predicts Outcome in Septic Patients with Acute Kidney Injury: A Retrospective Study** Shaikh Azam Nurmohamed,[1] Mark Koning,[2] Marc G. Vervloet,[1] Johan Groeneveld.[2] *[1]Nephrology, VU University Medical Center, Amsterdam, Netherlands; [2]Intensive Care, VU University Medical Center, Amsterdam, Netherlands.*

**Background:** The leading cause of acute kidney injury (AKI) in the intensive care unit is sepsis and its occurrence contributes to mortality and morbidity. Timing and dose of continuous venovenous hemofiltration (CVVH) remains controversial, particularly in sepsis. The objective of this study is to examine which CVVH characteristic best predicts mortality in sepsis-induced AKI.

**Methods:** We retrospectively studied all consecutive patients with sepsis-induced AKI requiring CVVH in a 1.5-year period. Patient, sepsis and CVVH characteristics, including timing, dose, mode, type of substitution fluid and of anticoagulation, and azotemic control were evaluated. Primary outcome was survival at day 28 after start of CVVH.

**Results:** Of the 97 patients, 43 (44%) died up to day 28 after start of CVVH. In univariate analyses, the delivered dose of CVVH was about 10% higher in survivors than non-survivors (median 23 vs 20 mL/kg/h, P=0.01), because non-survivors had a higher body weight, while the substitution fluid flow rate is fixed in our institution. In multivariate analyses, a lower delivered CVVH dose contributed to predict higher mortality, independently of non-renal organ failure, type of substitution fluid and azotemic control. In a Kaplan-Meier curve, a delivered dose <19.7 mL/kg/h was associated with shorter survival (P=0.006).



**Conclusion:** Our retrospective data suggest that in sepsis-induced AKI requiring CVVH, the delivered dose, rather than timing, mode of administration and azotemic control by CVVH, and organ failure are independent predictors of mortality. This argues for prospective studies on the effect of doses >19.7 mL/kg/h during CVVH in septic patients with AKI.

**Value of Troponin (Tn) T as a Marker of Ischemic Heart Disease in Patients on Hemodialysis (HD). A Case Report** Ma del Carmen Prados Soler, Mª Dolores Del Pino Pino, Remedios Garofano, Clara Moriana, Manuel Ángel Rodríguez. *S. Nephrology, C. H. Torrecárdenas, Almería, Andalucía, Spain.*

**Introduction:**

Patients with chronic kidney disease (CKD) have a high rate of mortality associated with cardiovascular disease. The cardiac troponins (Tn) are biomarkers with great specificity for myocardial damage; their elevation is a criterion for the diagnosis of acute myocardial infarction (AMI)

Measurement of baseline TnT values in patients on hemodialysis is of great interest given the greater likelihood that these patients have elevated baseline levels. This non-specific increase may indicate less myocardial damage, an inflammatory response or a state of chronic volume overload

**Case Report:**

An 82-year-old man with stage 5 CKD on HD since January 08. He had a history of hypertension, type 2 diabetes mellitus and hypercholesterolemia. Ischemic cardiopathy: AMI, with a double coronary bypass and a pacemaker due to AV block

As an innovation, HD patients have their baseline Tn measured each 4 months. In this case, the serial baseline values of TnT were: 0.06, 0.1 and 0.09 ng/mL

He was admitted to the Cardiology Service with progressive dyspnea. Physical examination is normal. Cardiac markers: progressive elevation of TnT: 0.17 – 5.05 – 6.13 ng/mL. ECG: Pacemaker rhythm, with no capture or stimulation failure. Diagnosis: AMI of undetermined location

Forty-eight hours later the patient presented to the Emergency Service with sudden dyspnea. Auscultation: Bibasal crepitations up to the midfields. Cardiac markers: myoglobin 202, TnT 6.71 ng/mL. Echocardiogram similar : Left ventricle not dilated, walls not thickened, weight loss and septoapical dyskinesia. Diagnosis: Acute pulmonary edema. Given an emergency HD session – ultrafiltration, but died 60 minutes later; the ECG showed electrical beat due to pacemaker with electromechanical dissociation

**Conclusions:**

- In patients on HD, baseline measurements of TnT levels represent an improved strategy, as in a particular patient with symptoms of ACS, it is fundamental to compare the TnT value at that time with baseline figures

- Baseline measurement of TnT is particularly interesting in patients with a pacemaker, as ECG is not useful in these patients

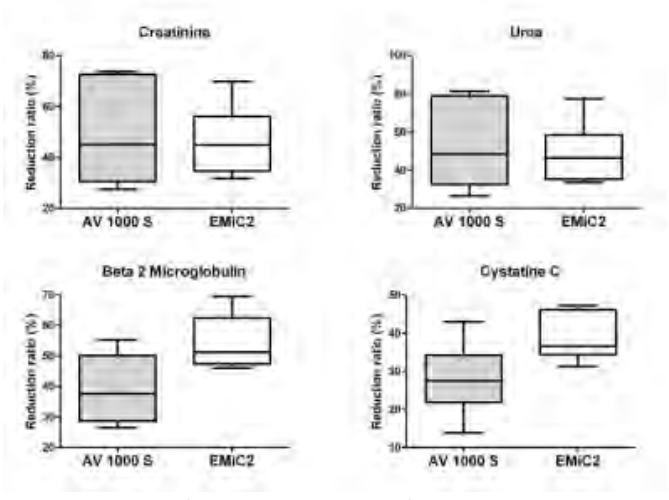
**Superior Elimination of Middle Molecules by the EMiC2 Dialyzer in Comparison to the AV 1000 S Dialyzer – A Prospective Comparative Cross-Over Study** Julius Schmidt, Carsten Hafer, Sajoscha A. Sorrentino, Hermann G. Haller, Jan T. Kielstein. *Department of Nephrology and Hypertension, Medical School Hannover, Hannover, Germany.*

**Background:** Removal of middle molecules is suggested to be advantageous in critically ill patients. Aim of the study was to compare middle molecule clearance of two dialyzers identical in surface area and material but different membrane porosity. **Methods:** Randomized cross-over trial. 10 ICU patients with AKI received two consecutive extended dialysis (ED) sessions starting either with EMiC2 dialyzer (Polysulfone, 1.8 $m^2$, Fresenius Medical Care (FMC) Germany) or AV1000S dialyzer (1.8 $m^2$, Polysulfone, FMC) using the GENIUS system®. All patients were treated using the 90 L GENIUS batch dialysis system (FMC). Blood / dialysate flow: 150 ml/min, treatment time 10 h. **Results:** Treatment with both dialyzers was well tolerated by all patients (4F/6M, mean age 43 years). There was a marked difference in dialyzer clearance of the middle molecules beta2-microglobulin (EMiC2: 51.4 ± 1.8 ml/min, AV 1000S: 40.5 ± 1.9 ml/min, p=0.0003) and cystatin c (EMiC2: 46.1 ± 1.4 ml/min, AV 1000S: 33.3 ± 1.7 ml/min, p=< 0.0001) **)** was also reflected by the more pronounced reduction of serum levels of these compounds ([b2M] EMiC2: 54.3 ± 3.6 %, AV 1000S: 39.1 ± 4.5 %, p=0.025, [cysc] EMiC2: 38.9 ± 2.6 %, AV 1000S: 28.0 ± 3.9 %, p=0.043).



In line with this we found a higher total amount of middle molecules in the collected ultrafiltrate and dialysate in the EMiC2 group ([b2M] EMiC2: 122.1 ± 17.3 mg, AV 1000S: 71.2 ± 11.9 mg, p=0.033, [cysc] EMiC2: 26.1 ± 4.3 mg, AV 1000S: 12.7 ± 3.1 mg, p=0.027)**.** There was no difference in the total amount of eliminated albumin per ED. **Discussion:** The EMiC2 dialyzer is more effective in eliminating middle molecules as compared to the AV1000S dialyzer. The clinical relevance of this finding should be evaluated in the future.

**Different Modes of Blood Purification for Acute Kidney Injury Following Multiple Bee Stings** Ling Zhang, Li Zhou, Ping Fu. *Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

**Correspondence :** Prof. Ping FU

**Objective** This study is to investigate the effect of different modes of blood purification for the treatment of acute kidney injury (AKI) following multiple wasp stings.

**Methods** 87 patients with AKI due to wasp stings during 2001-2009 were retrospectively analyzed. 82 cases with AKI were recieved blood purification: (1)CVVH group:early intervention of continuous venovenous hemofiltration (CVVH) for at least 48h was performed, then replaced by intermittent hemodialysis (IHD) when conditions of patients were stable. (2)CVVH+PE group: plasmapheresis was performed on Day 1 and Day 2 in addition to CVVH. (3)IHD group: IHD was performed three times per week. (4) PD group: continuous ambulatory peritoneal dailysis (CAPD) was performed.

**Results** (1)CVVH group: 33 cases (91.7%) discharged improved, but 3 case died. (2)CVVH+PE group: 9 cases (90%) discharged improved, but 1 case died. (3)IHD Group: 22 cases (73.3%) improved but 3 cases died, 2 cases progressed to end stage renal disease(ESRD) and 3 cases withdrawed. (4)PD group: no patients improved, 2 cases died, 3 cases progressed to ESRD and 1 case withdrawed. Survival rate and recovery of the renal function in groups of CVVH, CVVH+PE and IHD groups were better than PD group. There was no significant differences of survival rate and recovery of the renal function among CVVH, CVVH+PE and IHD groups. But in the early stage, the decrease in total bilirubin, creatine kinase and white blood cells are more significant in groups of CVVH and CVVH+PE than IHD group. Adverse events (low blood pressure) in CVVH and CVVH+PE group were less than IHD group (P<0.05). Patients in CVVH+PE group progressed into polyuria (16.1±8.3 vs.23.2±11.2 days) and normal renal function (26.4±11.8 vs.34.2±16.1 days) earlier than CVVH group (P<0.05).

**Conclusions** Results from this study indicate that early CVVH treatment might be helpful in patients with impaired organ function and might reduce hospitalization days. But whether it can increase the survival rate of patients needs to be confirmed by further studies. CVVH combined PE might represent as a novel approach. CAPD may not be the first choice because of the low clearance rate.

**Epoetin Alfa SQ Dosing May Be Reduced to Once Per Week in Hemodialysis Patients** Alexandre S. Ackad,[1] Christopher D. Parisi,[2] Julius M. Gardin.[1] *[1]Medicine, Hackensack University Medical Center, Hackensack, NJ; [2]Department of Patient Care, Hackensack University Medical Center, Hackensack, NJ.*

Purpose: To assess the feasibility of reducing the frequency of SQ EPO dosing, while maintaining a hemoglobin target of 11 to 12 gm/dl.

Methods: Retrospectively studied were (n= 299) prevalent HD patients from 1/1/09 through 12/31/09. Patients were gradually switched from the conventional EPO administration of 3 doses per week SQ to a once per week dose that was equivalent to the sum of their previous weekly EPO doses. Concurrent iron replacement protocol was unchanged. Excluded were incident HD patients less than 2 months on HD, those requiring more than 90,000 iu EPO/w, and patients with a mean Hb =>of 13 gm/dl. Hb values were the average of all 2009 end-of-the-month values. The EPO dose and Ferrous Gluconate (FERR) dose per week were computed from the cumulative monthly EPO dose and the total number of outpatient treatments.

Patients were divided into three groups: Group A (n= 124) received 1 or less injection/w, Group B (n= 137) between 1 and 2.5 doses/w, and Group C (n= 38) 3 or more doses per week. One way ANOVA followed by a Tuckey post-test was used for statistical analysis.

Results:

Table 1

| | Group A | Group B | Group C | P value |
|---|---|---|---|---|
| Mean Hb gm/dl | 11.69(11.61-11.79) | 11.30(11.10-11.33) | 11.18(10.80-11.21) | <0.001 |
| Mean EPO iu/wk | 2907(2580-3234) | 4782(4225-5338) | 8250(6176-10325) | <0.001 |
| Mean FERR iu/wk | 17.18(15.28-19.07) | 18.91(16.91-20.91) | 18.29(15.50-21.09) | 0.4167 |

Conclusion: Reducing SQ EPO administration from 3 times per week to 1 time per week in our chronic prevalent HD population was done without compromising the overall Hb target, and was accompanied by a substantial reduction in average weekly EPO dosage.

**Iron Sucrose Maintenance Therapy in Hemodialysis (HD) Patients and Erythropoiesis-Stimulating Agent (ESA) Sparing** George R. Aronoff,[1] Michael Brier,[1,2] Claudy Mullon,[3] Phaneth Keo,[3] Ann Mooney,[3] Norma J. Ofsthun,[3] Jose A. Diaz-Buxo.[3] *[1]Department of Medicine, Univ. of Louisville Sch. of Med, Louisville, KY; [2]Dept. of Med., VA Medical Center, Louisville, KY; [3]Fresenius Medical Care NA, Waltham, MA.*

**Background:** The treatment of anemia in HD patients includes the administration of an ESA and iron. In addition to IV iron replacement, HD patients also need maintenance IV iron to sustain iron sufficiency and Hgb levels within recommended limits. To test the hypothesis that HD units giving maintenance IV iron and having a higher percentage of patients with transferrin saturation (TSAT) between 20-50% would use less ESA to maintain desired Hgb levels, we examined iron usage, ESA doses and Hgb levels from a large hemodialysis data base.

**Methods:** We compared facility level data from 153 Fresenius dialysis clinics with 40 patients using 80% iron sucrose from Jan-Dec 2008. A subset of facilities with a greater-than-median % patients with Hgb 10-12 g/dL and less-than-median Epo dose was identified (N=49). The average quarterly % of HD patients with 3-month average TSAT in range 20-50% was used to rank facilities. Based on this method, 16 of 49 clinics (group 1) had a higher % TSAT in range and 9 of 153 clinics (group 2) with lower % TSAT. Algorithms, iron indices, Hgb levels, Epo doses were compared for all 25 facilities.

**Results:**

Average quarterly % of patients and 3-month average TSAT, Ferritin, Hgb and Epo

| Group | % Pts w/TSAT 20-50% | TSAT (%) | Ferritin (ng/ml) | Hgb (g/dl) | % Pts w/Hgb 10-12 g/dl | Epo units/ Administration |
|---|---|---|---|---|---|---|
| 1 | 90 | 30.4 | 674 | 11.6 | 62.5 | 6,412 |
| 2 | 69 | 26.6 | 540 | 11.5 | 59.9 | 7,665 |

Iron replacement doses were used in both groups, however, Group 1 used iron maintenance of 100mg every other week (N=5), 100 mg q month (N=8), and either 25 or 50 mg q week (N=3). Group 2 used smaller maintenance doses of 25 or 50 mg q week (N=8). The maintenance algorithms targeted TSAT 20-50% and serum ferritin 100-800 ng/ml.

**Conclusion:** A higher % of patients with a 3 month average TSAT of 20-50%, higher mean TSAT and ferritin but comparable hemoglobin levels were achieved with 16% less Epo using iron sucrose maintenance doses of 100 mg every other week or 100 mg once a month.

**Transfusion Practices of In-Hospital Hemodialysis Patients in the Past 5 Years** George N. Coritsidis, Saad A. Bhatti, Kayode C. Lawrence, Salwa Rhazouani. *Division of Nephrology, Elmhurst Hospital Center-Mt Sinai School of Medicine, Elmhurst, NY.*

Introduction

With the upcoming bundling process the issue of possible increases in transfusions of ESRD patients has arisen. In-hospital transfusion practices have much improved in the last 5-10 years after the TRICC trial (N Engl J Med. 1999). Given the importance of avoiding transfusions in ESRD we were interested to see if there have been changes in transfusion practice for these patients.

Methods

Medical records were reviewed for all dialysis patients admitted to Elmhurst Medical Center for the periods of 2004/2005 and 2009/2010. For those patients that received transfusions the following were recorded: reasons for transfusion (H=hemorrhage, C=cardiac, A=anemia of chronic disease), transfusion trigger hemoglobin levels (Hb) and number of units given.

Results

Between 2004 and 2005, 158 patients on dialysis were admitted of which 22 were transfused: 46% H; 46% A and 9% C. 54 units were given in total. Between 2009 and 2010, 239 patients on dialysis were admitted of which 19 were transfused: 58% H; 42% A; 0% C. 46 units were given in total.We present our findings.

Comparison of transfusion practices: 2004/05 vs 2009/10

| | 2004-05(n=158) | 2009-10(n=239) | p value |
|---|---|---|---|
| Age (yrs) | 57.8±3.38 | 51.3±3.33 | NS |
| Hb trigger for transfusion (g/dL) | 6.61±0.132 | 6.74±0.057 | NS |
| Units Transfused (per patient) | 2.45±0.19 | 2.48±0.26 | NS |
| TRc | 6.96 | 5.61 | NS |

NS=non significant; TRc=ESRD patients transfused per 100 ESRD patient admissions per year

Conclusions

Over the last five years there has been a trend towards decreased transfusion of ESRD patients admitted to our hospital. Furthermore, fewer units were given for reasons other than hemorrhage, though this did not reach significance. On average, there was no difference in the trigger HB levels over the years. However, in both time periods they were below that of the TRICC trial of 7 g/dl. Limiting transfusions in ESRD patients, where reasonable, has benefical effects for future transplantation.

**Once Monthly C.E.R.A. in Hemodialysis Patients Provides Stable Hb Levels in All Patient Groups – Results from the SESAM Study** Frank Dellanna,[1] Thomas Weinreich,[2] Frank Leistikow.[3] *[1]Dialysezentrum Karlstrasse, Düsseldorf, Germany; [2]Dialysezentrum, Villingen-Schwenningen, Germany; [3]Nierenzentrum Mannheim, Mannheim, Germany.*

**INTRODUCTION AND AIMS:** CERA (Mircera®) was approved as a new long acting ESA for patients (pts.) suffering from renal anemia. The SESAM trial was one of the first observational studies to test stability of anemia control of CERA in routine clinical practice in hemodialysis pts.

**METHODS:** This non-interventional study was conducted in 92 German centers. Data of 924 hemodialysis pts. were collected over 8 months/9 visits. Analysis of the data was done in a descriptive way.

**RESULTS:** 910 pts. formed the Full Analysis Set (FAS), and for 710 pts. (Per Protocol Set, PPS), data on application of CERA and Hb measurements at least twice between visits 7 and 9 were available. In 856 pts. information about previous ESA trt. was recorded. Most pts were pretreated with Epoetin beta and Darbepetin alfa(42.7% / 22.7%). Although not for all pts. of the PPS unique identification for a subgroup was possible or information was missing, the pt. numbers with data available were sufficent for subgroup analysis:

- Route of admin.: 124 (s.c.) / 394 (i.v.)
- Age: 201 (<=65) / 342 (>65)
- Gender: 296 (m) / 247 (f)
- Previous ESA trt.: 373 (Epoetin) / 133 (Darbepoetin)
- Diabetic pts: 205 (yes) / 338 (no)

Results from subgroup analysis (PPS) for the evaluation period are given in Table 1:

Table 1: Individual deviation from mean during evaluation period in different subgroups (% of pts)

| | | **<= 1 g/dl** | **1-1,5 g/dl** | **1,5-2 g/dl** | **>2 g/dl** |
|---|---|---|---|---|---|
| Route of admin. | s.c./i.v. | 95.2/87.8 | 3.2/7.6 | 0.8/3.8 | 0.9/0.8 |
| Age | <=65/>65 | 88.1/90.4 | 7.0/6.4 | 4.5/2.3 | 0.5/0.9 |
| Gender | m/f | 90.9/87.9 | 6.1/7.3 | 3.0/3.2 | 0.0/1.6 |
| Previous ESA trt | Epoetin/Darbepoetin | 89.5/89.5 | 7.0/4.5 | 2.9/4.5 | 0.5/1.5 |
| Diabetic pts | yes/no | 90.7/88.8 | 6.3/6.8 | 2.4/3.6 | 0.5/0.9 |

**CONCLUSIONS:** Once monthly CERA trt. maintained stable Hb values with low intraindividual variability in this non-interventional study. Although some minor differences could be observed, results were consistent throughout all subgroups, thus showing that once-monthly CERA is suitable for all pts. on hemodialysis.

**CKD Epidemiology and Renal Anemia Treatment with NeoRecormon in Everyday Clinical Practice in Haemodialysed Patients in Latvia, Poland and Serbia. The Results of Non-Interventional, Observational Study** Maciej Drozdz,[1] Boleslaw Rutkowski,[2] Jolanta Malyszko.[3] *[1]Nephrology Department, Collegium Medicum Jagiellonian University, Cracow, Poland; [2]Nephrology, Transplantology and Internal Diseases Department, Medical University of Gdansk, Gdansk, Poland; [3]Department of Nephrology and Transplantology with Dialysis Unit, Medical University of Bialystok, Bialystok, Poland.*

ESA are routine treatment for renal anemia.However the approach toward renal anemia may differ in different countries.The aim of the study was to compare the retrospective data on CKD epidemiology and renal anemia management and prospective data on 12 months of standard ESA therapy between the countries. It was a non-interventional,observational study.Data of 383 patients were analysed.The most common reasons of CKD were:pyelonephritis in Latvia,hypertensive nephrosclerosis and glomeluronephritis in Serbia,diabetic nephropathy and pyelonehritis in Poland.Mean serum creatinine and eGFR at CKD diagnosis were similar in all countries.Patients from Serbia had significantly higher creatinine concentration and lower creatinine clearance at predialysis care,hemodialysis start and at start of ESA therapy.The rate of patients with early ESA therapy (>3 months before start of hemodialysis)was 11,6% in Serbia,6,2% in Latvia,11,2% in Poland.In Serbia 74,4% of patients started ESA therapy after hemodialysis start.During the retrospective period the mean weekly doses of ESA were comparable in Poland and Serbia (5470±2670 vs 4485±2234 units/week)and higher in Latvia(9323±3627 units/week).Patients from Poland had higher than patients from Serbia and Latvia hemoglobin values at start of CKD(10,6±2,3 vs 10±2,1 and 9,6±2,2 p=0,02),at predialysis care(11,2±1,8 vs 10,2±2,4 and 10±1,6 p=0,02)at start of hemodialysis 9,4±1,6 vs 8,7±1,6 and 9,2±2;p=0,02).During prospective phase the mean weekly dose of epoetin beta remained statistically higher in Latvia.The rate of patients with blood transfusions was highest in Poland(44%)(Serbia 7%,Latvia6% p<0,001).Results:There are country specific differences in the renal anemia management.Patients in Latvia received higher doses of ESA.Patients from Poland more often receive blood transfusions.

**No Malnutrition, No Chachexia Is Feasible in Chronic Dialysed Children: Apply Daily On-Line Hemodiafiltration** Michel Fischbach. *Children's Dialysis Unit, University, Strasbourg, France.*

Despite major advances in the understanding and management of uremic growth failure, 35 % to 50 % of children with chronic kidney disease (CKD) still grow up to become adults of small stature. The final adult height achieved is correlated with the height deficit recorded at the time of kidney transplantation. A degree of catch up growth does occur after kidney transplantation in childhood, but it is often limited. Growth retardation in children with CKD causes significant difficulties in their daily lives, often limiting psychosocial integration. Additionally, growth retardation is associated with a greater number of hospital admissions and an increased risk of mortality. Growth failure is the common end point of a variety of pathologies which result in growth hormone resistance including. In children on chronic dialysis, linear growth may be improved by ensuring optimal clinical care is given. This includes maximising nutritional support in order to prevent malnutrition. Further management options include the administration of rhGH treatment and the use of more frequent and intensive dialysis sessions i.e. daily on line hemodiafiltration (D-OL-HDF), which combines increased dialysis convective flow with ultrapure dialysate, in order to limit cachexia. Since 2002 (N=21children) we deliver D-OL-HDF in children, 6 times a week 3hours, convective flow of 18 to 27 L/m². Despite normal/free diet, no need for phosphate chelators, normal blood pressure with 3/21children needing one drug, normal echcardiac function, and catch up growth. This "perfect" growth package is in part related to reduced inflammation (CRP, beta 2 microglobulin), normal diet/appetite, and overall a low time average deviation of bicarbonate (optimal control of acidosis). No malnutrition, no cachexia is faesible in chronic dialysed children. The only limitation should be costs (human, economical)of in centre intensive daily HDF.

**Treatment of Anaemia in Patients on Haemodialysis (HD) in Catalonia: Relationship between Dosis of Erythropoiesis Stimulating Agents (ESA), Haemoglobin (Hb) and Mortality** Joan Fort,[1] Aleix Cases,[2] Alberto M. Martinez-Castelao,[3] Roser Deulofeu Vilarnau,[4] Emma Arcos Fuster,[4] Jordi Comas Farnes.[4] *[1]Nephrology, Hospital Vall Hebron, Barcelona, Spain; [2]Nephrology, Hospital Clinic, Barcelona, Spain; [3]Nephrology, Hospital Bellvitge, Barcelona, Spain; [4]Catalan Health Service, Catalan Renal Registry Committee, Barcelona, Spain.*

Objective

Relationship with mortality and Hb levels and ESA treatment in patients on HD

Methods

An observational, prospective study using data from the Catalan Renal Registry. Patients who began HD in Catalonia between 2004 and 2007 (n=3.904). To analyse both types of ESA together (Epoetin and Darbepoetin Alpha) we used conversion factor Darbepoetin Alpha, in mcg, to Epoetin (in IU) 1:200. The Resistance Index (RI); quotient between the dosis of ESA adjusted for weight and Hb level. Andersen-Gill model, with robust variance

estimation, adjusted according to the ESA dosis, HB level, RI and other known risk factors, to study the relationship between mortality risk, Hb level and the dosis of ESA.

Results

The mean age of the patients was 65.5 years of whom (64% male). The mean Hb during follow-up decreased as of 2005, from 12.2 g/dl to 11,7 g/dl in 2007 ($p < 0.05$). A negative relationship between ESA weekly doses and Hb levels was found. Patients with doses over 16.000 IU had a lower average Hb level of 2.22 units ($p < 0.05$).

The relative mortality risk in patients with Hb level < =11 g/dl was significantly higher than the risk in patients with over 11 g/dl ($p < 0.005$). There was no decreased mortality risk in the groups with higher Hb levels ($p > 0.05$). Regarding ESA, there were no significant differences between the non-treated patients and the rest.

The relative mortality risk in patients with RI over 10 was greater than in patients with RI under 10. This risk increased progressively as the patients became more resistant. There were no differences in mortality risk between the groups with lower RI ( < =5 and > 5-10).

Conclusions

Patients with the highest Hb levels, had better survival rates (cut-off point Hb > 11 g/dl) and required lower ESA doses. The patients with greatest mortality risk were those who showed the most resistance to treatment.

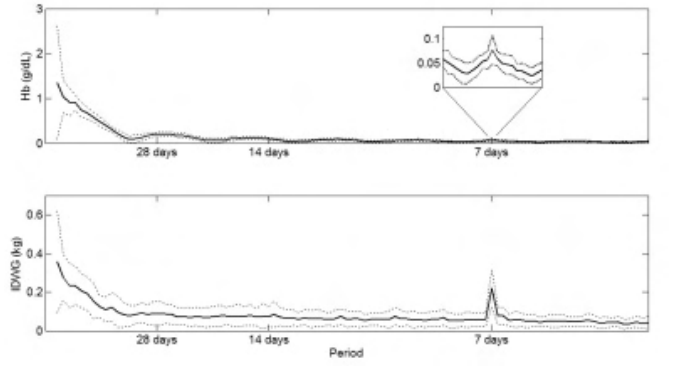
**Association between Interdialytic Weight Gain and Hemoglobin Variability**
Adam Gaweda,[1] Brian Harris Nathanson,[4] Michael J. Germain,[3] George R. Aronoff,[1] Alfred A. Jacobs,[1] Michael Brier.[2] *[1]Department of Medicine, University of Louisville, Louisville, KY; [2]Department of Veterans Affairs; [3]Baystate Medical Center, Springfield, MA; [4]OptiStatim, LLC, Longmeadow, MA.*

Hemoglobin (Hb) variability is common in ESRD patients. It is caused by multiple factors, including interdialytic weight gain (IDWG). In this retrospective cohort study, we quantify the association between IDWG and Hb variability.

We studied 49 ESRD patients treated at Baystate Medical Center, Springfield, MA between March 2007 and July 2008. The Hb was measured every treatment using Crit-Line III (Hemametrics Inc.). IDWG was defined as a difference between the current pre-dialysis and the preceding post-dialysis weight. To analyze the variability of Hb and IDWG we used Fourier series. It represents longitudinal data as a series of periodic components of different amplitude and frequency (frequency spectrum). We compared the frequency spectra of Hb and IDWG using mixed effect regression.

The mean IDWG within the study population was 2.70 (±0.15) kg. Regression analysis revealed positive correlation between IDWG and Hb variability ($R^2 = 0.49$). The IDWG has a significant periodic component with periodicity of 7 days and amplitude of 0.22 (±0.01) kg. The amplitude of the corresponding Hb component is 0.07 (±0.004) g/dL per kg.



Mean frequency spectra (continuous line) and 95% CI (dotted line) for Hb and IDWG.

Interdialytic weight gain associated with increased Hb variability varies prominently on a weekly basis consistent with weekend weight gains. From a population perspective, intraweek weight gains have limited impact on Hgb variability, however this impact may be significant in a few patients. This supports mid- or late week Hb determinations for anemia management.

## PUB385

**Protein Energy Wasting (PEW) in Hemodialysis: A Mediterranean Perspective**
Carolina Gracia-Iguacel, Jorge Enrique Rojas-Rivera, Beatriz Fernández, Jesus Egido, Alberto Ortiz. *Nephrology, Fundacion Jimenez Diaz, Madrid, Spain.*

**Background:**

Malnutrition is common in hemodialysis (HD) patients and is associated with increased morbidity and mortality.Until recently, there was not a common nomenclature that allow a detailed study of the problem.The purpose of the present cross-sectional study was to asses for the first time in a Southern European country the prevalence of the recently defined PEW and to study determinants of PEW in this population since most published information in Europe has been obtained in Northern Europe, which has different dietary and social habits.

**Patients and methods:**

Eighty-eight stable HD patients from a single unit were studied.Clinical, biochemical and anthropometric measurements which are criteria of PEW were studied.Statistical analyses were performed using statistical software spss 5.version.

**Results:**

PEW was present in 36% of the patients. PEW patients presented a significantly higher EPO resistance index (ERI) (15.8 ±11.3 vs 9.38 ± 7.7 UIEPO/kg/week/hb, p=0.006) and lower levels of transferrin (161 ±42 vs 162 ± 33 mg/dl, p=0.046); and triglycerides (122 [81–160] vs 166 [112 – 227] mg/dl ,p=0.009).In the univariate analysis: age (p=0.006),CO2 (p=0.014),hsCRP (p=0.035) and 25 hidroxyvitamin D (p=0.006) levels were associated with the presence of PEW.In a multinomial logistic regression analysis higher age and the presence of metabolic acidosis were independently associated to higher odds of having PEW,we found non significant trend for hsCRP (table 1).

| | Odds ratio ( 95%CI) | P |
|---|---|---|
| CO3H-≤17mEq/L | 0.15(0.03-0.63) | 0.01 |
| Age≥72 years | 6.80(1.66-27.78) | 0.008 |
| hsCRP≥0.9 ng/mL | 0.31(0.09-1.05) | 0.06 |
| 25 hydroxi≤15ng/mL | 1.18(0.22-6.30) | 0.11 |
| Hb≤9.5g/dL | 0.45(0.081-2.49) | 0.36 |

**Conclusions:**

This observational study indicates that the prevalence of PEW in HD patients from a Southern European country is high.The presence of PEW is a determinant of EPO resistance.We identify a correctable factor that increased the risk of PEW: metabolic acidosis.Further studies should address the influence of correction of metabolic acidosis on the prevalence of PEW.

**Endotoxaemia in Haemodialysis: A Novel Factor in Erythropoetin Resistance**
Laura E. A. Harrison,[1] James O. Burton,[1] Cheuk-Chun Szeto,[2] Philip K. T. Li,[2] Chris W. McIntyre.[1,3] *[1]Department of Renal Medicine, Royal Derby Hospital, United Kingdom; [2]Medicine & Therapeutics, Chinese University of Hong Kong, Hong Kong; [3]School of Graduate Entry Medicine and Health, University of Nottingham, United Kingdom.*

Endotoxin (ET) derived from gut translocation is a driver of systemic inflammation, and more directly, a wide variety of other pathophysiological responses. Severe endotoxaemia is an underappreciated, but common finding, in haemodialysis (HD) patients. Resistance to erythropoietin (EPO), previously identified as a predictor of mortality risk, and associated with inflammation and malnutrition, is also wide spread. This study aims to explore the potential link between previously unrecognised endotoxaemia and EPO Resistance Index (ERI) in HD patients.

50 established HD patients were studied at a routine HD session. Data collection included weight, BMI, ultrafiltration volume, weekly EPO dose and blood sampling pre and post HD. ERI was calculated as ratio of total weekly EPO dose to body weight (U/kg) to haemoglobin level (g/dL).

Patient age was 62±14 yrs and dialysis vintage 38 months [IQR 18-70]. Mean Hb was 11.3±1.3g/dL with a median EPO dose of 10,000 [IQR 7,500-20,000] u/wk and ERI of 13.7 [IQR 6.9-23.3] (U/Kg)/(g/dL). Mean pre-HD serum ET levels were significantly elevated at 0.69±0.30 EU/ml.

Natural logarithm of ERI correlated to predialysis ET levels (r=0.324, p=0.03) with only relatively weak association with hsCRP (r=0.280, p=0.07). Log ERI also correlated with UF volume, a driver of circulatory stress (r=0.295, p=0.046) previously identified to be associated with increased intradialytic endotoxin translocation. There were no significant correlations with BMI, ktV, albumin, PTH or ferritin levels in this group characterised by good control of these important clinical variables.

This is the first evidence that endotoxaemia driven by HD-induced circulatory stress may play a role in ERI and its associated mortality. It raises the possibility that elevated EPO doses may in part merely be identifying patients subjected to significant circulatory stress and suffering the myriad of negative biological consequences arising from sustained systemic exposure to ET.

## PUB387

**Protein Nutrition in Patients Switching Low-Flux to High-Flux Hemodialysis**
Tai Yeon Koo,[1] Jung-Sik Park,[1] Gheun-Ho Kim.[2] *[1]Department of Internal Medicine/Divison of Nephrology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; [2]Department of Internal Medicine/Divison of Nephrology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; [3]Department of Internal Medicine/Divison of Nephrology, Hanyang University College of Medicine, Seoul, Korea.*

**Background**:Malnutrition is related to morbidity and mortality in dialysis patients. High-flux dialyzer has been used to improve nutritons in hemodialysis patients. However,several clinical trials have shown conflicting results regarding impact of flux intervention on nutritons.**Methods**:We retrospectively evaluated effects of changing membrane flux on nutriton in 29 hemodialysis patients who switched low-flux to high-flux membranes.After flux intervention, patients were followed for 24 months and parameters were compared with basal values.Dry weight,serum albumin,total protein,cholesterol and normalized protein catabolic rate(nPCR) were obtained quarterly and predialysis β2-microglobulin(β2MG),cystatinC,hs-CRP,Kt/Vurea, urea reduction ratio(URR) and β2MG reduction ratio yearly.**Results**:During follow-up,Kt/Vurea,URR, hs-CRP,serum cholesterol

and dry weight wasn't significantly affected by flux intervention.However,predialysis β2MG and cystatinC were significantly decreased and β2MG reduction ratio was significantly increased.Serum albumin was significantly declined early,but recovered. Serum total protein decreased early but significantly increased, and nPCR significantly increased after 1 year.

Comparison of nutritional parameters between low-flux and high-flux hemodialysis

| | -3month | 6month | 12month | 18month | 24month |
|---|---|---|---|---|---|
| Albumin(g/dL) | 4.8±0.3 | 4.3±0.4* | 4.5±0.4* | 4.5±0.4* | 4.7±0.3 |
| Protein(g/dL) | 7.2±0.4 | 7.0±0.6 | 7.1±0.5 | 7.3±0.5 | 7.6±0.5* |
| nPCR(g/kg/day) | 1.1±0.2 | 1.1±0.3 | 1.2±0.4* | 1.2±0.4* | 1.3±0.3* |

Values are described as mean±SD.*p<0.05 by paired t-test.

**Conclusion:**Flux intervention may produce biphasic response in nutrition, initial decline and final improvement, in hemodialysis patients.The nutrition may have been aggravated in early by enhanced middle molecular clearances but improved in late by increasing protein intake.

Disclosure of Financial Relationships: nothing to disclose

**Factors Predicting Erythropoietin Resistance among Maintenance Hemodialysis Patients** Salman Rasheed Mallick,[1] Anca C. Rafiroiu,[1] Saima Iqbal,[1] Mahboob Rahman,[2] Charity Kankam,[1] Malik Ladha,[1] Gita Verma,[1] Osama W. Amro.[1] *[1]Internal Medicine, Saint Vincent Charity Medical Centre, Cleveland, OH; [2]Division of Nephrology, University Hospitals of Cleveland, Case Western Reserve University, Cleveland, OH.*

Individual response to erythropoietin-stimulating agents among end stage renal disease patients is affected by multiple factors, many of them still poorly quantified. The aim of this study was to identify and quantify potential factors that can modify the response to erythropoietin (EPO) in hemodialysis patients. The study used a retrospective, longitudinal, multicenter design and included in its final sample 1456 patients from 15 hemodialysis units in Northeast Ohio that were followed up to two years. The outcome measure used to evaluate the dose–response effect of EPO therapy was the erythropoietin resistance index (ERI), calculated as the weekly weight-adjusted dose of EPO divided by the hemoglobin level. Mean ERI for the entire group was 15.11±14.26 U/kg/week/g per 100 ml. ERI was negatively impacted by being a female, having a low body mass index, low serum iron, low serum ferritin and low albumin levels. Antecedents of diabetes, congestive heart failure or neoplasm, or the normalized protein catabolic rate had no effect on ERI. Angiotensin converting enzyme inhibitor or angiotensin receptor blocker use, alkaline phosphatse, intact parathyroid hormone and, urea reduction ratio were also significantly associated with ERI but Statin use and K t/v were not. This study has several strengths, including its unique nature based on a large population-based sample, the diversity of the HD population analyzed and the variety of biological markers assessed. Clarifying the predictors of ERI among ESRD patients can be of tremendous importance given the magnitude of this problem in the US population.

**PUB389**

**Clinical and Biochemical Correlates of Extracellular Mass (ECM)/ Body Cell Mass (BCM) Ratio in Hemodialysis (HD) Patients (Pts)** Neal Mittman, Rakesh R. Sheliya, Meghna M. Desai, Brinda Desiraju, Jyotiprakas Chattopadhyay, Morrell M. Avram. *Avram Division of Nephrology, Long Island College Hospital, Brooklyn, NY.*

Malnutrition is a strong predictor of mortality in hemodialysis (HD) pts. Bioimpedance analysis (BIA) has been validated as a useful tool to measure body composition in dialysis pts. Extracellular mass (ECM)/ body cell mass (BCM) ratio is a highly sensitive index of malnutrition, i.e. increased ECM/BCM ratio (EB ratio). We have previously reported that a single hemodialysis treatment does not change extracellular water/intracellular water ratio. The objective of the present study was to explore the relationship between EB ratio, clinical and biochemical parameters in our HD pts. We enrolled 49 pts, recorded demographic, clinical and biochemical data, and followed them over 9 years. BIA was used to determine ECM and BCM pre-dialysis. The mean age was 51 years. Fifty-five percent were women. The majority (81%) were African-American, and 40% were diabetic. The mean EB ratio was 1.37 ± 0.3 (range: 0.70-2.42). Pts with EB ratio in the highest tertile had significantly poorer survival than pts with EB ratio in the lowest tertile (2.4 vs 4.2 yrs; p=0.031). The results of univariate regression analysis is shown below.

Univariate regression analysis: predictors of ECM/BCM ratio

| Variables | Beta Coefficient | p values |
|---|---|---|
| Age (years) | 0.43 | 0.002 |
| Gender (Female) | -0.53 | <0.0001 |
| Months on dialysis | 0.29 | 0.046 |
| Albumin (g/dL) | -0.295 | 0.068 |
| Creatinine (mg/dL) | -0.55 | <0.0001 |

Higher EB ratio was associated with female gender, with increased age and greater months on dialysis at enrollment, and with lower somatic protein stores (serum creatinine). In conclusion, EB ratio is a strong independent risk factor for mortality, most likely due to its association with nutritional status, and therefore may be a useful prognostic tool in HD pts. The use of serial measurements to impact survival, ideally in association with aggressive management of protein energy malnutriton, needs to be evaluated in prospective trials.

**Repatriation of ESA Prescribing and Administration in Haemodialysis (HD) Patients Reduces Cost without Affecting the Efficacy of Erythropoiesis Response** Reena A. Popat,[1] Christopher J. Kirwan,[2] Martin J. Raftery,[2] Magdi Yaqoob.[2] *[1]Pharmacy & Medicines Management, Barts and The London NHS Trust; [2]Nephrology and Transplantation, Barts and The London NHS Trust.*

After a London wide initiative to create savings on the procurement of ESA therapy, we undertook a process of repatriation to bring back the prescribing and administration of ESA therapy from community to the hospital for HD patients under our care. We investigated whether repatriation of ESA therapy maintained or improved anaemia management whilst creating savings for the health economy.

**Method:** Patients analysed were those maintained on the same ESA preparation and on HD for 6 months pre and post repatriation. Hb, ESA dose, PTH, CRP and ferritin levels were recorded for the study period and type of vascular access. Mean Hb and ESA dose per patient pre and post repatriation and percentage of Hb measurements greater than 10.5g. dL pre and post repatriation was compared.

**Results:** 210 patients (127 male) with a mean age of 57.3 years were recruited. 74 patients were Asian, 73 Caucasian 61 Afro Caribbean and 2 other. 133 patients had permanent vascular access.

There was no statistical difference in Hb pre and post repatriation in all patients (10.8g. dl and 11g.dl respectively) and when analysed according to vascular access: Pre repatriation permanent: 10.8g.dl, temporary 10.9g.dl; post repatriation both permanent and temporary access patients mean Hb was 11g.dl. The percentage of patients with an Hb of greater than 10.5g.dl prior to repatriation was 61% vs. 63.6% post repatriation (NS).

There were no difference in the ESA dose between all groups pre and post repatriation: 10831iu vs. 104262iu respectively (NS) and when analysed according to access: Pre repatriation permanent: 10223iu, temporary: 11881iu and post repatriation permanent: 10256iu, temporary: 10860iu (p 0.059).

CRP, PTH and ferritin were similar in all groups' pre and post repatriation.

Approximately $3 million has been saved as a result of repatriation.

**Conclusion:** Repatriation of ESA prescribing has made significant cost savings whilst maintaining Hb control at similar ESA requirements suggestive of no compromise in the efficacy.

**The Changes of Insulin (Ins) Resistin (Rs) and Adiponectin (Adp) Concentrations and the Changes of HOMA-IR (H-IR) in 4-Hour Hunger Test (HT) in Malnourished (MN) and Obese (OB) HD Pts in Comparison with the Control Group (CG)** Katarzyna Romejko-Ciepielewska, Katarzyna Szamotulska, Zbigniew Bartoszewicz, Stanislaw Niemczyk. *Nephrology, Military Institute of Medicine, Warsaw, Poland.*

1. Evaluation if there are diff. in Ins, Rs, Adp conc. changes and in H-IR in 4-hour HT between HD MN, normal-weight(NW) and OB pts and HD pts and the CG.

87 pts. Group 1-37 HD: 12 pts BMI < 21,0, 12 - 21,0 – 25,9, 13 ≥ 30,0. CG-50 pts: 13 pts BMI < 21,0, 15- 21,0–25,9, 22 ≥ 30,0.We ex. the Ins, Rs, Adp and glucose conc. in fasting state(FS) at 8:00 a.m. (the last meal at 8:00 p.m. the prev. day) at 12.

Ins in FS was significantly(SS) higher in MN HD in comp. with MN CG: 9,19 vs 5,24, p=0,008. In HD Ins in FS falls with the rise of BMI, vs to CG.

In FS the fall of H-IR value with the rise of BMI in HD: 1,68, 1,22, 0,95. In the CG IR rose with the rise of BMI: 1,21, 1,70, 3,86. The SS diff. bt HD OB and CG : p<0,001.

Rs in FS was SS higher in HD pts vs CG: 15,06 vs 4,72 p<0,001 in MN pts; 17,87 vs 5,73 p<0,001 in NW pts; 17,53 vs 5,22 p<0,001 in OB pts.

Adp in FS bt HD and healthy pts. Adp conc. in FS fall with the rise of BMI: 247,61, 149,50, 123,21 in HD pts and 155,19, 101,62, 98,27 in CG pts.

In 4-hour HT Ins conc. falls SS in CG: 5,24 vs 2,93 p<0,001; 6,27 vs 4,54 p<0,001; 14,93 vs 9,34 p<0,001, The SS fall of Ins in 4-h HT was observed in MN HD pts 9,19 vs 7,01, p=0,005. In 4-h HT H-IR values fall SS in the CG: 1,21vs 0,64 p<0,001 in MN, 1,70 vs 1,13 p<0,001 in NW, 3,86 vs 2,40 p<0,001 in OB pts. In HD H-IR values fall SS in MN 1,68 vs 1,36 p=0,001 and in NW 1,22 vs 0,95 p=0,042.

In 4-HT test Rs conc. rises SS in the CG NW 5,73 vs 6,17 p=0,092, in OB pts 5,22 vs 6,11, p=0,020 and in HD NW : 17,87 vs 19,21 p=0,027. The fall of Rs in 4-HT in HD MN: 15,06 vs 14,16 and in HD OB pts:17,53 vs 17,13.

In 4-HT test the SS diff. in Adp conc. in the CG. In HD with correct BMI we observe the SS rise of Adp conc. (p=0,032) and in OB HD pts the SS fall of Adp conc. (p=0,033).

1. High Ins and high IR in FS and in 4-h HT in HD MN may be the hormonal cause of anorexia.

2. Rs and Ins chang and H-IR chang in FS and in 4-h HT do not confirm the hypothesis that Rs develops IR

**Renal Anemia Treatment with NeoRecormon in Everyday Clinical Practice in Haemodialysed Patients in Latvia, Poland and Serbia. The Results of Non-Interventional, Observational Study** Boleslaw Rutkowski,[1] Jolanta Malyszko,[2] Maciej Drozdz.[3] *[1]Nephrology, Transplantology and Internal Diseases Department, Medical University of Gdansk, Gdansk, Poland; [2]Department of Nephrology and Transplantology with Dialysis Unit, Medical University of Bialystok, Bialystok, Poland; [3]Nephrology Department, Collegium Medicum Jagiellonian University, Cracow, Poland.*

ESA are routine treatment for CKD anemia.However the approach toward renal anemia treatment may differ among countries.The aim of the study was to compare retrospective data and prospective data on 12 months of ESA therapy in ESRD patients in Latvia, Serbia and Poland.The study was conducted in 50 centers, 383 patients' data were analyzed(221 males,162 females;aged 19-90(57,4±14,9)years;259 from Poland,81 from Latvia,43 from Serbia).The percentage of patients with early ESA introduction(>3 months before hemodialysis start)was 11,6% in Serbia,6,2% in Latvia and 11,2% in Poland. In Serbia most of patients(74%)started ESA therapy after hemodialysis start.In Poland ESA therapy was introduced 32±172 days before dialysis start.This was earlier than in Latvia(23±251) and Serbia(4±206)(p<0,001).Patients from Poland had higher than patients from Latvia and Serbia Hb concentrations at CKD diagnosis and at predialysis care. During retrospective phase most patients in Serbia received NeoRecormon subcutaneously (95%),while in Poland subcutaneous route of administration was used in 51% of patients and in Serbia 69%(p<0,001).The dose of epoetin beta was higher in Latvia (9300±3600 units/week) than in Serbia (5600±3300)and Poland(4500±2200) during retrospective phase of the study and remained statistically higher during prospective phase.Patients from Latvia had signicantly higher than patients from Serbia and Poland Hb concentrations during all study visits (11,72g/gl (±1,3) vs 11,16g/dl(±1,3) and 11,0g/dl(±1,3)).The rate of patients with blood transfusions was higher in Poland (44%) (in Serbia(7%) and Latvia (6%)(p<0,001). Results:In Poland ESA therapy started earlier and patients had higher Hb levels on CKD diagnosis and predialysis care.The dose of epoetin beta and Hb levels were highest in Latvia.

**Safety of a Single Administration of 1 gram of IV Ferumoxytol in Hemodialysis Patients with Iron Deficiency Anemia (IDA)** Dawn M. Sabau,[1] Erin S. Nowak,[1] Joseph E. Bender III,[2] William Strauss,[2] Naghmana Bajwa.[2] *[1]Liberty Dialysis, Kokomo, IN; [2]AMAG Pharmaceuticals, Inc., Lexington, MA.*

Iron deficiency is the most common cause of anemia and is nearly universal in the hemodialysis population. Intravenous (IV) iron is commonly used for the management of iron deficiency anemia (IDA) in these patients. *Feraheme*® (ferumoxytol) Injection is a novel IV iron therapy that has been approved in the US for the treatment of IDA in adults with CKD. Ferumoxytol consists of an iron oxide core with a unique carbohydrate coating (polyglucose sorbitol carboxymethylether), that is isotonic, has a neutral pH and has lower free iron content than other IV iron products. Ferumoxytol is currently approved for an initial 510 mg IV injection followed by a second 510 mg IV injection 3 to 8 days later; a second course of therapy can be given to patients with persistent or recurrent IDA.

A small regional dialysis clinic has had recent experience administering 1.02 g of ferumoxytol (2 vials of 510 mg each), as a single injection in 12 hemodialysis patients. These patients were predominantly male (8/12) and ranged in age from 45-75 years. These administrations were well tolerated. There were no adverse reactions reported in these patients, including IV iron class reactions (e.g., hypotension or anaphylactoid reactions), except for one of the 12 patients who experienced a mild rash on the torso and legs 4 days post ferumoxytol administration; this event resolved within 10 days without any treatment. This patient is a 66-year-old male with a history of allergies to 6 classes of drugs and no previously reported reactions to IV irons. No adverse events were reported in the remaining 11 patients. Although the sample size is small, ferumoxytol demonstrated good tolerability when administered as a single injection of 1.02 g to these patients. These results suggest that further exploration of a 1 gram dosing paradigm is warranted.

**Once-Monthly Anemia Management Maintains Stable Hemoglobin Levels in Hemodialysis Patients – Results from the HbDay Study** Piotr Seniuta, Thierry Baranger, Valerie Drouillat, Frank Bergé. *Hemodialysis, Polyclinique Bordeaux Nord Aquitaine, Bordeaux, France.*

**Objective:** Methoxy polyethylene glycol-epoetin beta is a continuous erythropoietin receptor activator (C.E.R.A.) and provides the maintenance of stable hemoglobin (Hb) levels in hemodialysis patients with once-monthly administration. Chronic kidney disease patients with renal anemia undergoing treatment with an erythropoiesis stimulating agent (ESA) can be given supplementary iron to maintain the Hb target. The HbDay study evaluates the maintenance of stable Hb levels with an intravenous supplementary iron (iron hydroxy/dextran), on the same day as the subcutaneous administration of C.E.R.A. every 4 weeks.

**Material and Methods :** This "real life" observational study is based on a 9 month period in a single centre. The data on Hb level, iron status and ESA treatment was collected retrospectively for a 3 month period prior to the once-monthly anemia management and during the next 6 months. 125 hemodialysis patients were evaluated (48 % female), the mean duration on dialysis is 5 years and the mean age is 73 years. Age distribution is: < 65 years, 25%, 65-75 years, 21%, 75-85 years, 38%, ≥ 85 years, 16%.

**Results :** The Hb level and iron status are stable during the study. The mean Hb level is 11.1 ±1.33 g/dl in baseline (one week before the start of C.E.R.A.) and 10.9 ±1.21 g/dL, during the evaluation at W24 p=0.242. 56% of the patients are between 10-12 g/dL in baseline; and 66% during the evaluation. During the evaluation at W24, the mean serum ferritine is 363 µg/L, the mean transferrine saturation is 26%, the median dose of iron hydroxyl/dextran is 200mg/month and the median dose of C.E.R.A. is 150µg/month (45% patients with the same dose as the baseline, 33% decrease and 22% increase).

**Discussion :** The Hb levels can be maintained in hemodialysis patients with both administrations of iron supplementation and C.E.R.A. on the same day every 4 weeks. **Conclusions :** This "real life" study in a intensive dialysis center shows that the once-monthly anemia management can be effective. This is an opportunity to simplify the organization of dialysis centers and as a result make them more cost effective.

**Cumulative Safety Outcomes with Ferumoxytol in a Medium-Sized Dialysis Organization (MDO)** Amit Sharma,[1] Denise Vanvalkenburgh,[2] Kellie Y. Becker,[2] Betsy J. Lahue.[3] *[1]Boise Kidney and Hypertension Institute, Boise, ID; [2]Liberty Dialysis, Mercer Island, WA; [3]AMAG Pharmaceuticals, Lexington, MA.*

**Purpose:** Conduct a retrospective review of the safety and anemia outcomes associated with implementation of a ferumoxytol IV iron management protocol.

**Methods:** Anemia outcomes and lab values were collected across all clinics of a medium-sized dialysis organization (MDO) from April 2009 through April 2010. Adverse events (AEs) reported for patients receiving ferumoxytol treatments were summarized from first dose through June 13, 2010. The overall rate of adverse events was calculated and types of events were examined. Hemoglobin, TSAT and ferritin values were evaluated at the unit level for the 13 month period of observation.

**Results:** Starting in October 2009, nearly 54% (46/85) of the MDO clinics began administering doses of ferumoxytol, however ferric gluconate and iron sucrose made up >75% of the total IV iron grams used in 2009. Feraheme use increased from 22% of grams in Q4 2009 to 48% in Q1 2010, and in April, 84% (73/87) of MDO sites were administering ferumoxytol, comprising 63% of total iron grams used. To date (6/13/2010), 2515 patients have received 7457 doses of ferumoxytol. Forty-six (46) events were reported during this timeframe in 7457 doses (0.62%); these included nausea (16), hypotension (8), vomiting (7), dyspnea (7), rash (6), wheezing (1) and fatigue (1). Comparing 2009 to 2010 monthly anemia outcomes for the MDO clinics, there were no apparent differences in the proportion of patients with hemoglobins >12g/dL , TSATs >50% and ferritin >500 ng/dL.

**Conclusions:** This MDO has gained a large experience with ferumoxytol following successful implementation of a ferumoxytol IV iron management protocol. There were very few adverse events and the types of adverse events observed were as expected for IV iron products. Ferumoxytol appears to be well tolerated for the treatment of iron deficiency anemia in the dialysis population.

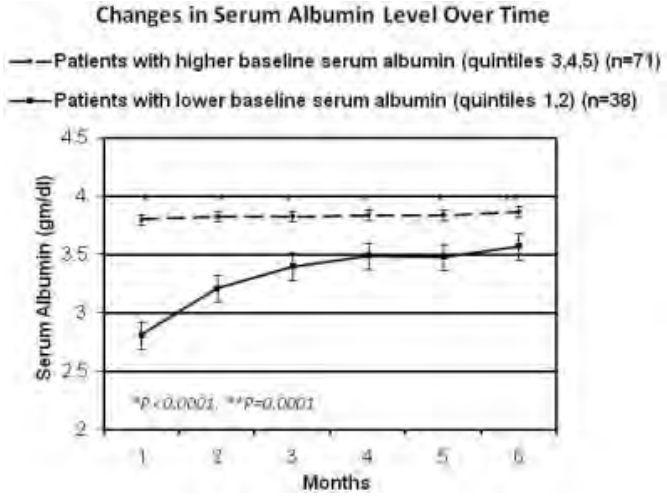
**Does Serum Albumin Level Improve in Hemodialysis Patients after Starting Dialysis?** Arif Showkat,[1] Fridtjof Thomas,[2] Elizabeth A. Tolley.[1,2] *[1]Medicine, University of Tennessee, Memphis, TN; [2]Preventive Medicine, University of Tennessee, Memphis, TN.*

Malnutrition is a common problem in chronic hemodialysis (CHD) patients (pts). The purpose of this study is to evaluate the changes in nutritional status as measured by serum albumin (SA) in mostly African-American (AA) CHD pts, during the first 6 months after starting dialysis.

Retrospective chart review study. 109 incident CHD pts, 98% were AA; 60% were male; 44% had diabetes mellitus (DM), and 10% had human immunodeficiency virus (HIV) infection. Mean age was 50.44±13.49 years.The following variables were used for nutritional parameters: SA, normalized protein catabolic rate, serum transferrin, serum creatinine, and body mass index. Values of the variables were collected on each pt for the first 6 months after starting dialysis. The repeated measures of SA were modeled utilizing the mixed-effects modeling approach.

Baseline SA level was predicted by the presence of DM and patient's age. During the 6-month follow-up period, most of the improvement in SA level was found among the pts with baseline SA level in the lower two quintiles.



Patient's age was the only significant predictor of the change in SA levels during the 6-month follow-up.

The Coefficent Estimates for the Fixed Effects in the Identified Model

| | Coefficients | S.E. | P |
|---|---|---|---|
| Variables affecting baseline SA | | | |
| Intercept | 3.55 | 0.06 | <0.0001 |
| Age | 0.101 | 0.04 | 0.012 |
| DM | -0.20 | 0.07 | 0.0064 |
| Variables affecting the changes in SA during 6 months | | | |
| Month | 0.05 | 0.009 | <0.0001 |
| Age | -0.01 | 0.007 | 0.0071 |

In incident CHD pts, SA level over time improved only in a small group of pts and was affected by patient's age and baseline SA level.

**Treatment of Confirmed B12 Deficiency in Hemodialysis Patients Improves Epogen Requirements** Norbert Shtaynberg, Majed Samarneh, Michael M. Goldman, Morton J. Kleiner, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

Background. Vitamin B12 deficiency may have deleterious effects on overall functionality and may increase erythropoietin stimulating agent (ESA) resistance in end stage renal disease (ESRD) patients on maintenance hemodialysis, yet little is known about its' prevalence in this population.

Methods. Vitamin B12 as well as MMA levels were drawn from ESRD patients prior to hemodialysis. All patients with MMA levels greater than 700nmol/L had peripheral smears evaluated for hyper-segmented neutrophils. Those who were positive were considered to be B12 deficient and underwent treatment with intramuscular vitamin B12 injections for a total of 4 months. Post treatment MMA levels and blood smears were obtained. Erythropoietin dosages were monitored pre and post treatment.

Results. There was a 58% (60/103) prevalence of vitamin B12 deficiency as defined by a positive MMA level and a positive blood smear. Out of 52 patients with positive smears, 36 (69.2%) were negative on repeat analysis after B12 treatment.

Mean epogen (EPO) dosages significantly decreased by 16,572±41,902 units from baseline to the post-B12 treatment period (p=.0082, Wilcoxon Signed Rank test). From June through August, the mean EPO usage was 82,066.7±47,906.3 and from January through March, the mean EPO usage was 65,495.0±39,690.7. Post-B12 treatment hemoglobin levels were 11.5 ± 1.1 g/dL. There were 26 patients (52%) receiving iron supplementation during the B12 treatment period and 24 (48%) not receiving supplementation.

Conclusion

Vitamin B12 supplementation was associated with a decrease in the mean dose of ESA administration while maintaining a stable hemoglobin level. Although there is a high variability in the dosing, this was also seen in the patients who were not B12 deficient. Maintaining serum vitamin B12 levels has been shown to improve functionality, and may allow a decrease in the use of ESA's and their toxicities and significant costs.

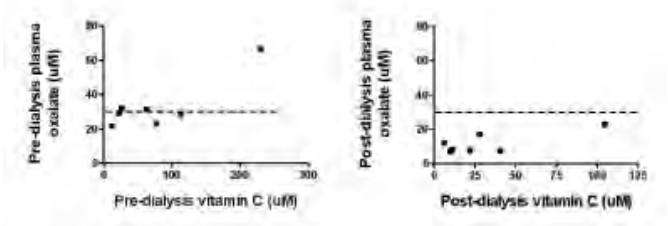
**Plasma Oxalate and Vit C Levels before and after Hemodialysis** William D. Sirover,[1] Thilagavathi Venkatachalam,[1] Robert L. Benz,[4] Lawrence S. Weisberg,[1] Nathan W. Levin,[2] Peter Kotanko,[2] Garry J. Handelman.[3] *[1]Cooper Medical Institute, Camden, NJ; [2]Renal Research Institute, New York, NY; [3]University of Massachusetts, Lowell, MA; [4]Lankenau Hospital, Wynnewood, PA.*

Plasma oxalic acid accumulates between treatments in HD patients, and is then cleared by hemodialysis. Although oxalate levels before treatment can exceed supersaturation (βCaOx>1), which usually occurs when oxalate is >30 μM, efficient hemodialysis is able to bring oxalate levels to <30 μM. At that concentration, oxalate can dissolve and permanent oxalate tissue deposits are unlikely. Supplemental vit C can increase pre-dialysate oxalate in HD patients, and is a cause for concern in the design of studies that use vit C for anemia management.

We screened 42 HD patients for pre-dialysis vit C level, and then identified a subset with either low (<30 μM) or high (>60 μM) plasma levels. Plasma vit C and oxalate were measured just before dialysis, right after dialysis, at 24 hours, and at then just prior to the next treatment. The graph shows oxalate and vit C measurements for 7 patients; the figure on the left is pre-dialysis, and the figure on the right is post-dialysis.



Predialysis, 3 of 7 patients were at βCaOx>1 (dotted line), but after dialysis all patients were below βCaOx. One patient had a Kt/V=1, predialysis oxalate 72 μM, and predialysis vitC 240 μM, but this patient also was below the oxalate saturation threshold following dialysis. Our findings indicate thathigh-flux dialysis effectively clears oxalate; however if patients are administered supplemental vit C, it would be prudent to ensure that Kt/V goals are met, and to make occasional determinations of pre and post dialysis plama oxalate levels. Patients in the therapeutic range of vitC (60-80 μM) to optimize EPO dose may not experience oxalosis, as plasma is cleared to below the oxalate supersaturation threshold, after adequate hemodialysis treatment (Kt/V>1.2).

Disclosure of Financial Relationships: nothing to disclose

**PUB399**

**Impact of Hospitalization on Hemoglobin (Hb) Levels and Erythropoietin Stimulating Agent (ESA) Use in Patients with ESRD on Hemodialysis: A Single Center Experience** Wojciech Sokolowski,[1,3] Vishalakshmi Batchu,[2] Jodumutt Ganesh Bhat,[1] Premila Bhat.[1,2] *[1]Atlantic Dialysis Management Services, LLC, Ridgewood, NY; [2]Wyckoff Heights Medical Center, Brooklyn, NY; [3]New York Medical College, Valhalla, NY.*

Variability in ESA responsiveness and dosage is of clinical and financial importance for the dialysis community. Hospitalization may lead to reduced Hb levels and increased Epoetin alfa (Epo) use. We reviewed the charts of patients at a large urban dialysis unit with a formal anemia management protocol targeting Hb 10-13 g/dL who missed dialysis due to hospitalization from 1/1/2007 through 12/31/2007. Patients were included in the analysis if hospitalized for ≥48 hours and returned to the dialysis unit for subsequent care. Patients who initiated dialysis <1 month prior to hospital admission were excluded and those with multiple admissions were included in the analysis for only the first of their series of hospitalizations. During the first three months of the study period, 60 patients were hospitalized 79 times. 49 patient admissions were included in this interim analysis (remainder not analyzed due to missing data (n=13), repeated hospitalization (n=9), death (n=6) or transfer (n=2) during follow-up period). Mean age was 63.0 years, 70% were male, and mean length of stay (LOS) was 9.4 days. Compared with baseline, mean Hb was unchanged in the 3 months after hospital stay (12.09 vs. 11.94 g/dL) but administered Epo dose was significantly increased (12,529 vs. 15,417 units/treatment, p=0.02). 30/49 patients had a net increase in mean dose of Epo and 13/49 patients had increases of ≥5000 units/treatment. This effect showed no significant interaction with age, sex, LOS, or serum albumin. In conclusion, hospitalization is associated with increased ESA use to maintain Hb at target levels.

**Prognosis of Hemodialysis Patients with Chronic Heart Failure Relates to Patient's Muscle Bulk** Oonishi Takahiro. *Nephrology, Yamada Red Cross Hospital, Ise, Mie, Japan.*

Purpose: Dialyzed patient's muscle bulk is related creatinine index (CrID). Moreover,CrID is not only related muscle mass of the patient but also their vital prognosis.

In general, the skeletal muscle blood flow and disturbances of peripheral circulation relate, and are said that it is important when the condition is understood in the state of chronic heart failure. We hypothyzed that the poor prognosis of herat failure was low CrID , but high CrID was related not poor prognosis. Method: The heart failure incidence of 1.5 years, serm albumin, CrID, BNP, Hb, and the left ventricle ejection fraction(LVEF) examined . For nine people (7 men, 2 women, and 12.8 average dialysis period years) who had been diagnosed as a chronic cardiac failure in January, 2009. Result: Three persons died during this studyperiod ,one person was acute respiratory failure ,one person was arrhythmia due to acute myocardial infarction,one person was septicemia due to ovarian abscess. The albumin and CrID of the case who had died were intentionally low, and BNP was intentionally high. As for Kt/V and PCR, a significant difference was not seen. Conclusions: It was thought that the muscle bulk took part patient with chronic heart failure's prognosis.

**The Combination Therapy of Intradialytic Parenteral Nutrition and Oral L-Carnitine Administration Could Prevent the Progression of Malnutrition-Inflammation – Atherosclerosis Syndrome** Masataka Tsunoda. *H.N.Medic Sapporo-Higashi, Hokkaido, Japan.*

**Backgrounds:** Chronic dialysis patients with protein energy malnutrition (PEM) have occasionally treated by intradialytic parenteral nutrition (IDPN), but controversial arguments still exist as to whether or not IDPN improves PEM. The lipid metabolism disorder caused by L-carnitine(LC) deficiency has supposed to lead the muscle loss in dialysis patients and to be related to the ineffectiveness of IDPN. In this study, we treated the patients with PEM by the combination of IDPN and LC. **Methods:** Six patients, whose nutritional conditions had not improved by IDPN, were enrolled to the study. 200ml of 6.1 % amino acids solution, 200ml of 50% dextrose solution and 100ml of 20% soy lipid solution were infused to the blood line throughout each entire dialysis session. 300mg of LC was orally administered for 20 minutes before each dialysis session. Total energy intakes including with IDPN ranged 30- 35Kcal/Kg/day, and it was recognized appropriate for dialysis patients. Body compositions by bioimpedance method, serum levels of C-reactive protein (CRP), and amino acid profile were evaluated every 3 months for 12 months. **Results:** During the IDPN treatment alone, the fat mass had gradually increased while the muscle mass had decreased. With LC add-on, however, the muscle mass dramatically increased. The levels of serum CRP significantly decreased 6 months after the administration of LC (0.058±0.033 to 0.038±0.020 mg/dl; $p<0.05$). Amino acid profile showed interesting changes; both levels of taurin(109±85.5 to 127±92.7 nmol/ml; $p<0.05$) and methionine(25.8±1.97 to 30.4±3.40nmol/ml; $p<0.01$) increased, and total homocysteine (tHcy) decreased significantly 6 months after the administration(65.2±46.5 to 50.7±34.8 nmol/ml; $p<0.05$). **Conclusions:** The combination therapy of IDPN and LC ameliorated the nutritional status of the patients through the improvement of lipid metabolism. Furthermore, it reduced the serum levels of CRP and tHcy, which is closely related to the acceleration of atherosclerosis in dialysis patients. The combination therapy could be a recommendable strategy for the prevention of Malnutrition-Inflammation-Atherosclerosis syndrome.

**PUB402**

**Intraobserver Validation of an Oscilometric Technician for Assessment of Ankle-Brachial Index** Zaida Noemy Cabrera Jimenez, Rosilene M. Elias, Isac Castro, Joao Egidio Romao, Jr. *Nephrology, University of Sao Paulo School of Medicine, Sao Paulo, SP, Brazil.*

**Background:** The easiest widely-used method for the diagnosis of peripheral arterial disease is the measurement of ankle-brachial index (ABI). ABI has been shown to be a good predictor of mortality among patients on hemodialysis. However, the variability intra-observer in measuring ABI among patients on hemodialysis has not been formally tested

**Methods**: We prospectively included 124 thrice-weekly incident hemodialysis patients (85 men; age 51 ± 20 years old). Two oscillometric devices were used to measure blood pressure in upper and lower extremities simultaneously. Measurements were performed on both sides pre and post dialysis (baseline), and were repeated in two consecutive dialysis sessions (time 1 and 2)

**Results**: The Friedman test showed no difference in across multiple measurements in right systolic blood pressure (SBP) and right diastolic blood pressure (DBP) ($p=0.205$ and $p=0.212$, respectively). The same was observed for left side SBP and DBP ($p=0.982$ and $p=0.160$, respectively). Wilcoxon test showed no difference between pre and post ABI (Table 1).

Pre vs post ABI

| | Right ABI pre dialysis | Right ABI post dialysis | p | Left ABI pre dialysis | Left ABI post dialysis | p |
|---|---|---|---|---|---|---|
| Baseline | 1.03 (1.18 , 1.33) | 1.09 (1.18 , 1.31) | 0.161 | 0.98 (1.20 , 1.31) | 1.08 (1.20 , 1.30) | 0.890 |
| Time 1 | 1.05 (1.18 , 1.29) | 1.03 (1.16 , 1.28) | 0.582 | 1.06 (1.20 , 1.30) | 1.08 (1.19 , 1.28) | 0.933 |
| Time 2 | 1.07 (1.18 , 1.29) | 1.08 (1.20 , 1.30) | 0.114 | 1.08 (1.19 , 1 .32) | 1.09 (1.22 , 1.34) | 0.623 |

DBP (time 2) and SBP (baseline) presented no self-correlation, and perfectly fit between confidence interval, generating the most reliable ABI (time 2 post and time 1 pre dialysis)

**Conclusion**: This prospective study showed a good intra-observer agreement in measuring blood pressure by an oscilometric device to calculated ABI, in incident patients in hemodialysis. The most reliable measurement could be determined to calculate the ABI. Further studies will be necessary to test the applicability of this method in identify cardiovascular risk in this population

**Effective Cardiac Therapy, Anemia Full Correction with Erythropoeitin, However Intensified Intravenously Iron Application Results in Significant Regression of Left Ventricular Hypertrophy (LVH) in Patients with Very Long Time Survival on Hemodialysis (HD)** Hannelore B. Hampl. *Internal Medicine, Nephrology, Charite University Berlin.*

**Aim** of the study was to find out the effect of adequate cardiac therapy in combination with full anemia correction on regression of LVH; because a suffered heart needs additionally energy (oxygen) to heal! Secondary question: What could be the reason for increased events in presence of normal hemoglobin (Hb) described by others?

384 patients (84 diabetics), (age 59.5±7.8 years/HD since 14.1±8.5 years; 260 female) were regularly echocardiographically controlled since II/97 until 12/08, the LVH as Mass index ($g/m^2$) was evaluated. During anemia correction on the way to normal Hb iron parameters (transferrin- saturation (TFS), ferritin, iron levels) and thrombocyte counts (ThCs) were checked 3- monthly. High target doses of β- blockers, ACE- inhibitors, ATI-receptor blockers, aldosteron blockers were given.

**Results:** before/after therapy: Blood pressure (mmHg) 162±13/87±16 to 132±12/81±5, $p<0.001$; Hb (g/dl) 11.6±2.2/14.3±1.5, $p<0.001$; ThCs ($mm^3$) 302 800±79 000/180 000±60 000, $p<0.01$; TFS (%) 16.5±5.3/45.5±5.2, $p<0.01$; iron (µmol/L) 9.6±3.4/21.3±5.4, $p<0.01$**;** ferritin (µg/L) 1 175±854/1 477± 1 101, n.s. LVH-Regression:total(48%);g/m2**:** 166.9±30.3/112.9±11.7, $p<0.001$**;** partial(26%), 212.1±40.7/158.6±37.7**,** $p<0.01$; not successful (26%), 176.5±40.4/184.39.2,n.s. Increase of 1g/dl Hb decreases LVH of 5.0 g/m2 in non-diabetics; however in only 2.5g/m2 in diabetics! Multivariate analysis**:** cardiac therapy ($p<0.03$),esp. β- blockers($p<0.01$), Hb correction ($p<0.01$) are independent, significant prognostic factors for LVH regression! Our cardiac/non cardiac mortality over time: 10/16%; no increase in events. **Conclusion:** Effective cardiac therapy decreases significant cardiac mortality. Iron therapy has to be intensified i.v. to prevent functional iron deficiency responsible for activated thrombocytosis inducing fatal strokes/cardiac events. Full anemia correction is not a risk factor for increased mortality and events. In contrast to non- diabetics, diabetics show in particular a higher dependency of their cardiac function on normal (!) oxygen availability.

Disclosure of Financial Relationships: nothing to disclose

**PUB404**

**Reactive Thrombocytosis Due to Iron Deficiency Anemia: Has an Aggravating Risk Factor for Cerebro/Cardio Vascular Events (CCVEs) during Full Renal Anemia Correction as Yet Not Been Taken into Consideration?** Hannelore B. Hampl. *Nephrology, University, Berlin, Germany.*

Randomized controlled trials(RCTs) in uremics have found an increased risk for CCVEs when hemoglobin targets >13g/dl during therapy with erythropoeitin/ESAs. The mechanism of these harmful events with erythropoeitin/ESA therapy to full anemia correction has not been elucidated. Aim of the study was to find out a relationship between iron deficiency and thrombocyte counts(**ThCs)** on the way to anemia correction. Erythropoiesis needs iron. **Oral iron absorption is disturbed in uremics .**

We reviewed(1998-2007) the iron status(transferrin g/L,-saturation, TSAT %, iron µmol/L, ferritin µg/L, Hb g/dl, mean corpuscular hemoglobin concentration, MCHC g/dl, hypochromic RBCs %, fibrinogen mg/dl) and correlated these factors to **ThCs /mm3 during anemia correction** in 384 HD-pats.; age 59.5±7.8 yrs; 176 f, time on HD 13.5±8.5 yrs. Intensified **iron application only intravenously** on the way to full anemia correction of Hb 14g/dl with epoietin β of 15 000 IU(correction phase); **only 5000 IU/pat./week(maintained phase) without increased CCVEs compared to RCTs** has had the following results(before/after correction): Remarkable, there is a significant negative correlation between iron parameters and ThCs: the higher the MCHC(29.9/**36.1,**$p<0.01$); the lower the hypochromic cells(16.9/**0.7,**$p<0.001$; the higher the TSAT(27.2/**46.6**, $p<0.001$); the higher the iron level( 52.6/**75.2**,$p<0.001$); the higher the ferritin values (500.1/**1537**,$p<0.001$); the lower fibrinogen levels(741.3/**189.4**,$p<0.001$), **the lower thrombocyte counts** 310 000/**187 522.** Absolut transferrin was diminished (167.6/148.5,$p<0.05$) due to chronic inflammation in uremics and therefore **faster** saturated. **Conclusion:** Iron status has to be intensified (TSAT>40%) and applicated only iv due to poor oral iron absorption during full anemia correction in uremics to prevent functional iron deficiency which is well known for inducing reactive thrombocytosis via thrombopoeitin receptor being responsible for severe CCVEs like in RCTs. **ESA therapy to raise Hb requires a large amount of iron iv, raising Hb to normal requires an even greater amount routinely causing functional iron deficiency.**

**PUB405**

**Analysis of the Causes of Death and Mortality Risk Factors in Patients Treated with Hemodialysis** Wenlv Lv, Xiaoqiang Ding, Jie Teng, Jianzhou Zou, Yimei Wang, Yihong Zhong. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

**Purpose:** To analyse the causes of death in maintenance hemodialysis patients and explore the risk factors affecting survival of hemodialysis patients. **Methods:** The data were retrospectively analysed during the periods 1 Jan. 1998 through 31 Dec. 2008. Cox regression analysis was used to find mortality risk factors**. Results:** 237 of 648 maintenance hemodialysis patients died in the study period. Their average age at the beginning of hemodialysis was 63(19-87) yeas old and men accounted for 60.8%. The median survival time was 9.6 (0.03-156.80)months. The main causes of death were cardiovascular disease (20.3%), cerebrovascular disease(16.5%) and infection (24.9%). 33.3% of the deaths occurred within 3 months of hemodialysis. Results of Cox regression analysis: (1) Age (HR=1.036, 95%CI 1.013-1.061, $P<0.01$), Charlson comorbidity index(CCI)≥5(HR=6.408, 95%CI 1.893-11.694, $P<0.01$) and baseline blood albumin(HR=0.943, 95%CI 0.895-0.993, $P<0.05$), history of congestive heart failure(HR=2.463, 95%CI 1.265-4.797, $P<0.01$) and cerebrovascular diseases (HR=2.532, 95%CI 1.084-5.912, $P<0.05$) were the mortality risk factors. (2) The history of cerebrovascular diseases(HR=7.741, 95%CI 2.817-12.273, $P<0.01$)and DN (HR=3.659, 95%CI 1.299-8.311, $P<0.05$) were the risk factors of death due to cardiovascular and cerebrovascular diseases. (3) Age(HR=1.075, 95%CI 1.004-1.151, $P<0.05$), blood albumin(HR=0.908, 95%CI 0.799-0.988, $P<0.05$) at the beginning of hemodialysis were the risk factors of death from infection. (4) Blood albumin(HR=0.883, 95%CI 0.819-0.953, $P<0.01$) and eGFR(HR=0.853, 95%CI 0.729-0.922, $P<0.01$) at the beginning of hemodialysis, the history of congestive heart failure before hemodialysis(HR=3.011, 95%CI 1.231-5.365, $P<0.05$) were the risk factors of death within 3 months of hemodialysis. **Conclusion:** Cardiovascular and cerebrovascular diseases, infection are the main causes of death in maintenance hemodialysis patients. Older patients, CCI≥5, lower blood albumin,DN, underlying cardiovascular and cerebrovascular disease, and late initiation may be the risk factors of Mortality.

Disclosure of Financial Relationships: nothing to disclose

**PUB406**

**Aortic Arch Calcification Score Predicts Mortality in Peritoneal Dialysis Patients** Francesca K. Martino, Ching Yan Goh, Ilenia Filippi, Pierluigi Di Loreto, Rossella Torregrossa, Maria Pia Rodighiero, Carlo Crepaldi, Claudio Ronco. *S Bortolo Hospital.*

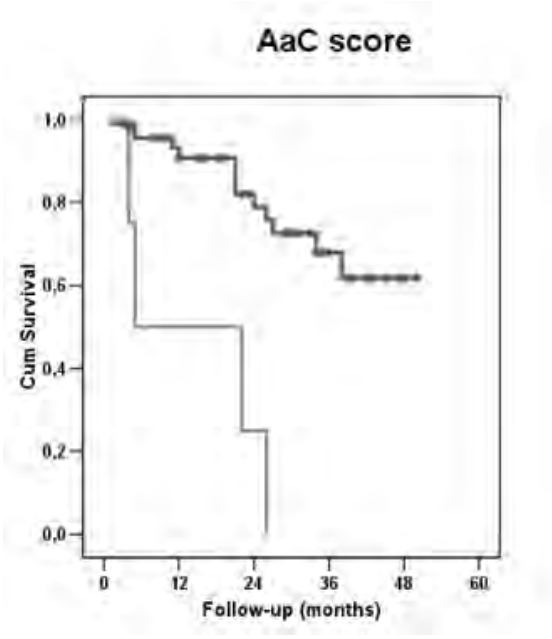
**Background:** Vascular Calcification (VC) is associated with cardiovascular disease (CVD) and mortality. Several radiological imaging are used to evaluate VC extension but some are expensive and not always easily accessible. However, quantification of aortic arch calcification (AaC) by chest Xray (CxR) is cheap and easily available. We aimed to access the prognostic role of AaC score in mortality of peritoneal dialysis patients (PD pts).

**Method:** We performed a retrospective study on 57 pts who started their PD in 2006 or 2007. We measured the AaC score (0:no calcification, 1:small spot of calcification, 2: one or more thick calcifications, 3: circular calcification) from pts CxR on their 1st clinic visit.

Baseline characteristics of pts were evaluated: age, primary renal disease (PRD), duration of RRT, history of CVD and biochemical parameters like Albumin, Hb, Ca, P and PTH.

Kaplan-Meier method was used to calculate the survival rate, and differences were assessed with log rank statistic. Multivariable Cox regression models addressed the time to death. All statistical tests were performed with SPSS version 16.

**Results:** The median follow-up period was 29 months (IQR17-36.5). All cause mortality was 29.8%. In univariable analyses, the age of pts at initiation of PD (p=0.0076), AaC score ≥2 (p=0.0001), PRD (p=0.0015), history of CVD (p=0.032) were significantly associated with mortality. In multivariable analyses, we found that high AaC score ≥2 (HR:4.058; p=0.035) and diabetic nephropathy (DN) (HR:7.332;p=0.007) were the only 2 independent predictors of all cause mortality.



**Conclusion:** In this analysis, we conclude that high AaC score ≥2 and DN are independent predictors of mortality in PD pts.

**PUB407**

**The Association of Prorenin and Biomarkers for Cardiovascular Disease in Non-Diabetic Normotensive Hemodialysis Patients** Yoshiyuki Morishita, Shiho Hanawa, Junko Chinda, Eiji Kusano. *Nephrology, Jichi Medical University, Shimotsuke, Tochigi, Japan.*

**Background.** Circulating prorenin contributes to the pathogenesis of tissue damages leading to cardiovascular disease (CVD) in diabetic mellitus (DM) and hypertension (HT) patients by activating tissue renin-angiotensin-aldosterone (RAS) system and intracellular signaling by binding (pro)renin receptor (PRR); however, little is known about its roles in hemodialysis (HD) patients.

**Aim**. We evaluated the association of circulating prorenin and CVD predictive biomarkers in non-diabetic normotensive HD (nonDM-NT-HD) patients.

**Methods.** We measured prorenin and PRR to investigate the association of prorenin and CVD predictive biomarkers, such as brain natriuretic peptide (BNP), high-sensitivity C-reactive protein (hs-CRP), 8-hydroxydeoxyguanosine (8-OHdG) and diacron-reactive oxygen metabolite (d-ROM) in fourteen nonDM-NT-HD patients and ten healthy volunteers (control).

**Results.** Prorenin did not increase in nonDM-NT-HD patients compared to control (nonDM-NT-HD: 175.7±131.6 pg/m vs. control: 164.7±109.9 pg/m, (N.S.)). *PRR mRNA* expression increased in nonDM-NT-HD patients (nonDM-NT-HD: 1.5 vs. control: 0.9 ($p<0.0001$)). Although prorenin was not correlated with hs-CRP, it was significantly correlated with BNP, 8-OHdG and d-ROM (BNP; r=0.766; $p<0.001$, 8-OHdG; r=0.712; p=0.003, d-ROM r=0.735; p=0.002) in nonDM-NT-HD patients. Prorenin was not correlated with plasma renin activity (PRA), angiotensin I (ATI), angiotensin II (ATII) and aldosterone (Ald), whereas PRA was significantly correlated with ATI and ATII in nonDM-NT-HD patients. PRA, ATI, ATII and Ald were not correlated with CVD predictive biomarkers in nonDM-NT-HD patients.

**Conclusions.** Circulating prorenin was associated with CVD predictive biomarkers independent of circulating RAS in nonDM-NT-HD patients. It may contribute to the development of CVD in HD patients.

**PUB408**

**Echocardiographic Changes after Conversion from Conventional Hemodialysis to In-Center Thrice Weekly Nocturnal Hemodialysis** Albert M. Osei, Lissa Sugeng, Jay D. Shah, Diane M. Fodor, Lynn Weinert, Bharathi V. Reddy. *Medicine, Section of Nephrology, University of Chicago, Chicago, IL.*

**Background:** Approximately 70-80% of stage V CKD patients have some features of left ventricular hypertrophy (LVH) before initiation of dialysis. Conventional 4-hour thrice weekly hemodialysis (CHD) fails to cause regression of LVH. There is evidence that a longer and or more frequent hemodialysis sessions as done in home hemodialysis (HHD) lead to regression of LVH. HHD may not be feasible for all dialysis patients. In-center nocturnal hemodialysis (INHD) is a new modality that is done three nights a week, 8 hours per session. The effect of INHD on left ventricular mass (LVM) and left ventricular ejection fraction (LVEF) is unknown.

**Design, setting, participants and measurement:** This retrospective analysis assessed the impact of conversion from CHD to INHD on LVH and LVEF. In 13 patients who switched from CHD to INHD, adequacy of dialysis, blood pressure (BP), calcium, phosphorous, protein catabolic ratio and hemoglobin (Hb) were determined before and 6 months after conversion. Changes in LVM and LVEF were reviewed in 6 patients who had 2D echocardiograms before and 1 year after conversion to INHD.

**Results:** Nine of 13 patients were converted to INHD because of volume overload. There was no significant difference in pre-dialysis systolic BP before and after conversion to INHD. However, there was a significant reduction in average post dialysis systolic BP from 134 (+/-22) mmHg to 113 (+/- 15) mmHg (P= 0.01). There was no significant difference in Hb before and after conversion. In six patients who had echocardiographic data, baseline mean LVM was 150(+/- 44) gm/m$^2$ and LVEF was 40(+/-14) %. After switching to INHD, 4 of 6 patients had regression of LVM to a mean of 106(+/-31) mg/m$^2$and 5 patients had improvement of LVEF to a mean of 53(+/-3) %.

**Conclusion:** Regression of LVM may be achieved with INHD and this could be related to improved fluid management with longer dialysis sessions. However, this is a small retrospective study. Prospective randomized trials comparing the effects of CHD and INHD on LVM and LVEF are needed.

## PUB409

**Concurrent Use of Clopidogrel and Proton Pump Inhibitors Does Not Influence Prognosis of Coronary Heart Disease in Hemodialysis Patients**

Yoshio Shimizu, Hiroaki Io, Shinji Hagiwara, Tomohito Gohda, Chieko Hamada, Satoshi Horikoshi, Yasuhiko Tomino. *Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan.*

**Background**: Dual antiplatelet therapy (APT) with aspirin and clopidogrel is recommended for patients with acute coronary syndromes (ACS) and/or percutaneous coronary intervention (PCI). Current consensus recommendations state that these patients should receive a proton pump inhibitor (PPI) to reduce gastrointestinal (GI) bleeding. Recent analyses have suggested that PPIs may weaken the antiplatelet effects of clopidogrel by involving CYP (cytochrome P450)2C19. Although ACS is common in hemodialysis patients and PCIs are widely performed, little attention has been paid to this point in hemodialysis patients.

**Design**: Retrospective cohort study using medical records of Juntendo University Hospital to identify who received coronary angiography (CAG) from January 2008 to December 2009.

**Patients**: Thirty-six hemodialysis patients who were hospitalized for CAG were examined.

**Measurements**: Baseline and follow-up drug use was assessed. Primary outcomes were re-hospitalizations for severe cardiovascular disease.

**Results**: During the observation period, 69% of concurrent users and 40% of non-concurrent users had cardiovascular events (p=0.169). There was no significant difference in the time to coronary events between concurrent users and non-concurrent users (p=0.27, log-rank test). The hazard ratio (HR) associated with concurrent use of clopidogrel and PPIs for serious cardiovascular disease was 1.13 (95% confidence interval (CI): 0.46 to 2.57). The significant factors for severe cardiovascular disease in hemodialysis patients were female gender (HR: 5.66, CI: 1.47 to 23.71), serum LDL-cholesterol (HR: 1.08, CI: 1.03 to 1.14) and serum phosphate (HR: 0.50, CI: 0.22 to 0.99).

**Limitations**: The selection bias by cardiologists and severity of coronary heart disease in each patient could not be assessed.

**Conclusion**: In hemodialysis patients with serious coronary heart disease treated with clopidogrel and PPIs, the corresponding point estimate for serious cardiovascular disease is not increased.

**Short-Term Outcomes of Cardiac Surgery in Patients on Chronic Dialysis**

Takeshi Yamamoto,[1] Jun Matsuda,[2] Hiroyuki Kadoya,[2] Masanobu Takeji,[2] Megumu Fukunaga,[1] Atsushi Yamauchi.[2] *[1]Nephrology, Toyonaka Municiple Hospital, Toyonaka, Japan; [2]Nephrology, Osaka Rosai Hospital, Sakai, Japan.*

*Background*. Long-term dialysis remains a major risk factor for cardiac surgeries, especially for those who have diabetic nephropathy. One of our strategies for these patients is an intensive perioperative management by the collaboration between the surgeons and the nephrologists. This study aimed to elucidate whether our strategy is appropriate.

*Methods*. Between 2005 and 2008, 36 chronic dialysis patients(36/460 total cardiac surgeries, 7.8%) underwent cardiac surgery, including coronary artery bypass grafting(CABG), valve surgery, combined CABG and valve procedures, and other cardiac surgeries, in our institution. The mean age was 64.8 years old (38 to 77 years). Twenty patients had diabetic nephropathy(group D) and 16 patients were without diabetic nephropathy(group ND). All patients were dialysed the day before surgery. In the postoperative period, we managed all the patients in ICU. In most instances, we started continuous hemodialysis(CHD) the day after the operation and controlled water and electrolyte balance appropriately until the circulatory conditions reached stable. Preoperative profiles and perioperative and short-term results were examined, with comparing group D with group ND.

*Results*. A part of results are shown in the Table.

*Conclusions*. With intensive perioperative management and advanced technology, cardiac surgery can be done in chronic dialysis patients safely with acceptable early mortality and morbidity.

**Provision of Dialysis Services in Libya**

Wiam A. Alashek,[1] Chris W. McIntyre,[1] Maarten W. Taal.[2] *[1]School of Graduate Entry Medicine, University of Nottingham, Derby, United Kingdom; [2]Department of Renal Medicine, Royal Derby Hospital, Derby, United Kingdom.*

**Purpose:** Dialysis is entirely funded by the public health care sector in Libya but there is no registry to gather national data. This study aimed to investigate dialysis provision and practice in Libya. **Methods:** A cross-sectional study of all Libyan dialysis facilities was undertaken from April to July 2009. Data were collected using a structured questionnaire. **Results:** 2430 patients were treated in 40 centres (adult population prevalence 624 per million). Thirty-two (80%) dialysis units were located in the north of the country where 88.5% of inhabitants live. Only 3 centres offered peritoneal dialysis. There were a total of 173 functioning haemodialysis (HD) stations (1 machine to 3.4 patients). Separate room/s were allocated for virus positive patients in 92.5% of units while dedicated machine/s were reserved in 7.5%. Hand wash facilities were available in each HD room in 22 centres (55%). No dialyzer reuse was permitted. The total number of doctors was 114 (doctor to patient ratio 1:22). Two remote centres were operating without doctors. The number of trained dialysis nurses was 639 (nurse to pateint ratio 1:3.8). 52.5% of patients were offered scheduled consultations in outpatient clinics. Patients received 4-12 h of HD per week. Kt/v was routinely calculated for some patients in 10% of centres, whereas urea reduction ratio was the main method of adequacy monitoring in 25%. 70% of centres used single pre-dialysis urea measurement monthly to monitor adequacy. Haemoglobin was monitored monthly in all units but only 50% monitored iron status. Serum calcium and phosphorus were measured in 85% of centres and serum calcium only in 5%. No assessment of blood minerals was performed in 10%. Monitoring of serum albumin was done in 57.5% of centres. 55% of centres experienced intermittent deficiency in laboratory supplies resulting in failure to perform required blood tests. **Conclusion:** Dialysis services are appropriately distributed. In general, the provision of dialysis is adequate but several areas for improvement have been identified. It is hoped that this study will facilitate the development of a Libyan Renal Registry.

## PUB412

**Could Hemodialysis Patients Maintaining a Low Phosphorus Diet?**

Eleni Chelioti,[1] Antonios Zagorianos,[1] Athanasios Georgiou,[1] Antonis Ntalianis,[2] Prokopis Papazafeiris,[1] Gabriel Papadakis.[1] *[1]Dept. of Nephrology and Renal Unit, General Hospital of Piraeus, "Tzaneio", Athens, Greece; [2]Dept. of Sociology, University of Crete, Crete, Greece.*

Purpose: In the majority of hemodialysis (HD) patients, phosphorous (P) intake largely exceeds the amount of P removed during HD. The use of P binders is universal in this population. The reduction of P intake is considered an additional measure for the prevention of P retention. Aim of this study was to evaluate the knowledge of low phosphorous diet, the compliance to intake daily a low phosphorous diet and the optimal reception of phosphate binders.

Method: A descriptive study was performed in our Renal Unit. Participants were 29 HD patients (21 males/8 females, mean age 61±14years, mean period on dialysis 98±77months, mean Kt/V 1.4±0.1), who were undergoing dialysis three times per week. All patients had been prescribed phosphate binders. According to an adjusted questionnaire from Kidney Early Evaluation Program-Quality of life, patients completed a questionnaire concerning compliance with phosphorous binders, knowledge of low phosphorous diet and if consumed daily a low phosphorous diet. Statistical analysis based on using descriptive statistics such as mean ±SD and percentages.

Results: The percentage of patients who had knowledge of a low phosphorous diet was 82.7%(24/29) but the majority of them continued to be on a high phosphorous diet. The frequency of HD patients who consumed daily a high phosphorous diet was 38%(11/29) and thrice a week was 55. 2%(16/29). Only, 6.8%(2/29) of HD patients were on a low phosphorous diet. Moreover,79.3% (23/29)of them received the prescribed phosphate binders and 82.6 %(19/23) were receiving phosphate binders regularly. The percentage of HD patients who received calcium carbonate, sevelamer or combinations of these was 43.5%, 34, 8% and 21.7% respectively.

Conclusion: The majority of HD patients had a very good knowledge of a low phosphorus diet but their compliance to a low phosphorous diet was poor. Moreover, the reported receiving of phosphate binders were good. It is necessary to optimize the compliance of a low phosphorus diet and the use of phosphate binders by hemodialysis patients.

**The Influence of Continuous Quality Improvement on Outcomes in Maintenance Hemodialysis Patients** Xian-Guang Chen, Hua Wu. *Nephrology Department, Beijing Hospital, Beijing, China.*

**Objective** To observe the influence of continuous quality improvement(CQI) on outcomes in maintenance hemodialysis patients. **Methods** According to the KDOQI guideline the CQI team improved the objective laboratory result from 2004 to 2009 using the four-step process called PDCA cycle-plan: plan, do, check and act and then analyzed the relationship between the improvement and mortality rate. **Results** There were 75 hemodialysis patients in 2004 and 117 patients in 2009. They had no significant difference in age and gender. The URR in 2009(69.6±8.74%) was higher than that in 2004(65.23±6.46%, p<0.001). In 2009 there were better levels of hemoglobulin(111.1±13.61g/L vs. 98±17.39g/L, p<0.001), serum phosphorus(1.56±0.49mmol/L vs. 1.77±0.61mmol/L, p=0.013) and albumin(39.1±2.81g/L vs. 37.86±4.31g/L, p=0.034)than those in 2004. Serum calcium (2.34±0.2mmol/L vs. 2.41±0.3mmol/L, p=0.081), iPTH (393.6±443.91pg/ml vs. 427.75±380.99pg/ml, p=0.615) and C-reactive protein(0.6±0.88mg/dl vs. 0.96±1.47mg/dl, p=0.081)had no difference in the two groups. According to KDOQI guideline, the rates of the result within the recommended range were showed in table1. Parts of the result were compared with DOPPS 2007. In 2009 there were longer hemodialysis time (57.67±51.06 months vs. 32.11±32.37 months, p<0.001) than that in 2004. Mortality rate in 2009 was slightly better than that in 2004(8.5% vs. 14.7%, p=0.185). **Conclusions** According to KDOQI guideline, continuous quality improvememt can improve anemia, serum phosphorus, nutrition levels and hemodialysis patients' outcomes.

Table1:the rates within the recommended range

**Immunogenicity and Efficacy of a Pandemic Influenza A (H1N1) 2009 AS03-Adjuvanted Vaccine in Patients with End-Stage Renal Disease** Ralf A. Dikow,[1] Isabella Eckerle,[1] Vedat Schwenger,[1] Martin G. Zeier,[1] Paul Schnitzler,[2] Claudia Sommerer.[1] *[1]Nephrology, University Hospital, Heidelberg, Germany; [2]Virology, University Hospital, Heidelberg, Germany.*

**BACKGROUND**

Patients with end-stage renal disease have a reduced response to vaccinations due to uraemia-related immune dysfunction. To increase immunogenicity of vaccines, antigens can be formulated with adjuvants. The new tocopherol-containing adjuvant system $AS03_A$ has not been tested in patients with end-stage renal disease so far.

**METHODS**

Patients on dialysis were immunized with an inactivated split-virion A/California/7/2009 H1N1v pandemic vaccine with the adjuvant system $AS03_A$, either only with a single dose at day 0 or with a second dose at day 21. Antibodies against pandemic influenza A (H1N1) 2009 were tested with an ELISA in every patient three months after vaccination and compared to non-immunized dialysis patients.

**RESULTS**

In total, 294 dialysis patients were enrolled. 169 patients were vaccinated with either one dose (64 patients) or two doses (105 patients) of pandemic H1N1 vaccine, 125 patients remained unvaccinated. Influenza A H1N1 vaccination resulted in 40/63 (63.5%) patients with one vaccination and in 93/105 (88.6%) patients with two vaccinations in a positive Pandemic New Influenza IgG ELISA > 11 AU. Multivariate regression analysis revealed (i.) former response to hepatitis B vaccination and (ii.) number of vaccination doses as independent factors for the response to influenza A H1N1 vaccination. No episode of influenza A (H1N1) illness occurred in any of the groups within the study period of six months after vaccination. Use of the adjuvant system $AS03_A$ caused only mild to moderate local symptoms in 143/169 (84.6%), but no serious adverse events.

**CONCLUSION**

We report the first study of pandemic H1N1 vaccine adjuvanted with $AS03_A$ in patients with end-stage renal disease. Influenza A (H1N1) AS03-adjuvanted vaccine is immunogenic, effective and save in these patients.

**Are Small Dialysis Organizations (SDOs) Prepared for Income Changes under the CMS Proposed Payment System?** Fredric O. Finkelstein, Alan S. Kliger. *Hospital of St. Raphael, Yale, New Haven.*

Background. The CMS Proposed Payment System for dialysis contained few concrete instructions for dialysis facilities. It has been suggested that small dialysis organizations (SDOs, Independents and Regionals with < 50 units) have fewer resources to prepare for the new payment model, placing them at risk when the final rule is published. Our objective in this study was to determine how SDOs were preparing for potential income losses.

Method. Using an SDO database developed from CMS files and other government data sources, we drew a quota sample of 75 SDO facilities designed to represent the population of SDO facilities in the 48 contiguous states by region, number of stations, rural/suburban/urban, and high/low minority location. Facility managers were queried in three separate interviews over a six week period about their awareness, preparation and potential changes. Interviews were part of a larger study designed to estimate PPS payments from patient data. Facilities were compensated for participation in the study.

Results. Of the more than 300 facilities contacted, 23% had joined Large Dialysis Organizations (LDOs), 42% were out of business or unreachable. Of the eligible facilities, nearly half declined to participate. Only 59% said they had read the CMS report, and only 24% said they understood the report very well; 47% looked up their estimated payments under the new bundle. Among those responding to detailed interviews, if their payments were 5% lower than expected, 45% said they would stay in business "only with deep cuts in costs", 30% said they would go out of business, and 25% said they would continue to operate without radical changes**.** If payments were cut 5% below current levels, 56% said they were "Very likely/ Likely" to lose experienced nurses, due to either staffing cuts or attrition.

Conclusions. The number of SDO facilities has declined sharply since 2007. A majority were unaware or unprepared for the changing payment model and anticipated a variety of cuts in their income, staff and operational capabilities. These results suggest the 2011 transition will not proceed smoothly.

**Evolution of Quality Parameters and Mortality in Haemodialysis Patients in Catalonia: Catalan Registry of Renal Patients** Joan Fort,[1] Aleix Cases,[2] Alberto M. Martinez-Castelao,[3] Roser Deulofeu Vilarnau,[4] Emma Arcos Fuster,[4] Jordi Comas Farnes.[4] *[1]Nephrology, Hospital Vall Hebron, Barcelona, Spain; [2]Nephrology, Hospital Clinic, Barcelona; [3]Nephrology, HUB, Barcelona, Spain; [4]Catalan Renal Registry Committee.*

Objectives

To study the evolution of some quality indicators for Haemodialysis (HD) and survival in patients initiating HD during the period 2002-2007.

To compare survival of patients returning to HD following a renal transplant (RT) with those initiating HD for the first time.

Methods

Using data from the Renal Catalan Registry,we studied patients initiating HD who did not die during the first 90 days of treatment (n=4,494). From the initiation of HD until the end of the follow-up period, univariate (by year of initiation) and bivariate (by year of initiation and year of follow-up) analyses were performed.We calculated a model of parametric survival adjusted by repeated-measure, time-dependent variables.

Results

From 2002 the mean (sd) Kt/V increased progressively until 2007 (1.30 (0.27) to 1.45 (0.27), together with the percentage of patients with Kt/V>1.3 (39.2% to 70.0%)and those undergoing 12 hours of HD weekly (51.1% to 60.0%.There was a progressive increase in tunneled catheter use (8.1% to 13.9%)while arteriovenous fistula (AVF) remained stable (76.8% to 76.4%). The mean (sd) Haemoglobin (Hb) increased from 2002 to 2005 (11.5 g/dl (1.69) to 12.4 g/dl (1.36)) and then decreased (11.9 g/dl (1.35) in 2007). We observed a progressive increase in the number of patients with Hb levels between 11 and 13 g/dl (46.5% to 56.4%). In 2005 and after adjusting for risk factors, there was a drop in the relative mortality risk compared to 2002 (RR=0.63). Patients with greater risk of death where those who had a Kt/V<1.3, were on dialysis <12 hours weekly, and who initiated HD with catheter and Hb<11 g/dl. The relative mortality risk was not significantly different for those patients returning to HD following RT.

Conclusions

Kt/V, weekly hours of HD and percentage of patients with Hb between 11 and 13g/dl improved during the studied period. The percentatge of AVF remain stable. From 2005 a reduction in mortality was observed. Patients reinitiating dialysis following renal transplant had similar evolution of HD quality parameters and survival to those initiating HD for the first time.

**Survival after Starting RRT in Patients with Adult Polycystic Kidney Disease (ADPKD)** Richard Haynes,[1] Farhad Kheradmand,[2] Christopher G. Winearls.[1] *[1]Oxford Kidney Unit, Oxford Radcliffe Hospitals NHS Trust, Oxford, Oxfordshire, United Kingdom; [2]Department of Urology, Oxford Radcliffe Hospitals NHS Trust, Oxford, Oxfordshire, United Kingdom.*

Aim: to investigate whether survival after beginning of RRT had improved for patients with ADPKD from 1971 to present day.

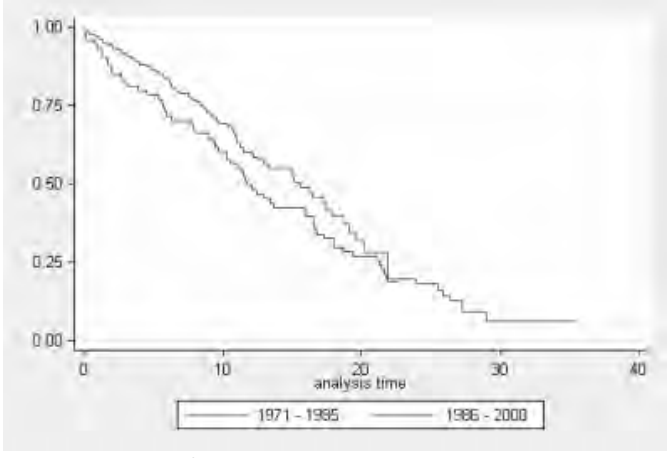
Methods: basic characteristics of all adult patients with ADPKD starting RRT in our unit from 1971-2000 were collected. Relative risk of death were estimated using Cox regression.

Baseline characteristics of study population, by period.

| | All patients | Period | | p value |
|---|---|---|---|---|
| | | 1971 - 1985 | 1986 - 2000 | |
| Number | 265 | 74 | 191 | |
| Age at start of RRT ± SD | 53.5 ± 10.0 | 51.1 ± 8.4 | 54.4 ± 10.4 | 0.017 |
| Number male (%) | 120 (45) | 38 (51) | 82 (43) | 0.22 |
| Number transplanted (%) | 192 (72) | 52 (70) | 140 (73) | 0.62 |
| Comorbidities (%): | | | | |
| Cardiac disease | 15 (6) | 7 (10) | 8 (4) | 0.10 |
| Cerebrovascular disease | 4 (2) | 0 (0) | 4 (2) | 0.21 |
| Peripheral vascular disease | 0 (0) | 0 (0) | 0 (0) | n/a |
| COPD | 2 (1) | 0 (0) | 2 (1) | 0.38 |

COPD = chronic obstructive pulmonary disease

Results: 265 patients with ADPKD started RRT of whom 152 died (median follow-up 11 years). Age (HR 1.08; 95% CI 1.06-1.10) and RRT mode (transplant v dialysis as time-varying covariate; HR 0.22; 95% CI 0.16-0.31) were associated with survival in unadjusted analyses. In adjusted model period was associated with survival (HR 0.67; 95% CI 0.47-0.97). Median survival increased from 11.7 to 15.5 years.



Over same period, life expectancy in general population had increased only slightly, suggesting improvements observed here were specific for ESRD population.

Conclusions: survival for patients with ADPKD on RRT has improved more than that expected from secular trends from 1971 to 2000. RRT now provides almost 2/3 of lifespan expected (from general population) compared to about 1/2 in 1971.

**Patient and Technique Survival among Independent and Assisted Peritoneal Dialysis Patients** Jay S. Hochman, Pietro Ravani, Rob Quinn. *Internal Medicine, University of Calgary, Calgary, AB, Canada.*

Peritoneal dialysis (PD) is an effective form of home based renal replacement therapy. As the dialysis population ages worldwide, there are an increasing number of patients with barriers to self care PD. Many of these barriers can be overcome by home care assisted PD. For this reason many centers have developed and implemented home care assisted PD programs. Despite the growing interest and utilization of assisted PD programs, little is known regarding technique and patient survival.

In this study, we will use data from a prospectively maintained dataset that captures baseline characteristics and outcomes of all incident dialysis patients between January 1, 2004 and the present. The adjusted PD technique survival of patients treated with assisted PD will be compared to those treated with self-care PD. Death and transplantation will be handled as competing risks for the purposes of our analysis. In addition, we will describe the reasons for technique failure and their relative frequency according to time on therapy. This work will help us better understand the outcomes of patients treated with home care assisted PD and will provide targets for future therapeutic interventions to improve outcomes among PD patients.

At the time of abstract submission ethics approval is pending. However, results will be available for presentation at renal week.

**Trends in Prevalence and Morbidity in HIV-Infected Dialysis Patients** Paul L. Kimmel, Paul W. Eggers. *NIDDK, NIH, Bethesda, MD.*

HIV infection is the fourth most common correlate of kidney disease in young male African American US ESRD patients. Previously we showed incidence remained stable and prevalence had increased through 2000, due to improved survival among HIV-infected (HIV+) dialysis patients, as the number of patients living with AIDS and in the US ESRD program increased, presumably because of availability of highly active antiretroviral therapies (HAART) in the US. Morbidity in this population has not been evaluated. Using previously developed methodology we evaluated trends in prevalence and morbidity of HIV+ patients in the ESRD dialysis program.

A retrospective cohort study was performed using the USRDS, analyzing patients receiving dialysis from 1995 to 2007. Presence of HIV/AIDS was ascertained through the CMS 2728 cause of ESRD code and by examination of billing codes, a method previously used by us and validated by Hebert et al. Hospitalization rates were calculated per 1,000 person years as in the USRDS Annual Data Report.

The prevalence of HIV+ patients increased from 2397 in 1995 to 8761 in 2007, while the percentage of HIV+ patients in the ESRD program has remained stable between 1.4 and 1.6% of the population since 2000. HIV/AIDS accounted for between 6.6 and 6.9% of black men aged 25 to 44 in the program from 2000 to 2007. Hospitalization rate in the ESRD program was 218/1000 in 2007, while that of HIV+ patients was 22.4% higher at 267/1000. There was an approximately 2.5 fold increase in the number of hospitalizations for infection in HIV+ patients compared to non-HIV/AIDS patients, a disparity not noted in other diagnostic groups.

HIV+ patients remain an important group in the ESRD program. The numerical prevalence of HIV infection has increased but the proportion has remained relatively stable. The morbidity of HIV+ patients is increased compared with uninfected patients, with the greatest disparity noted in rates of infectious causes of hospitalization.

Disparities in hospitalization for infections suggest better approaches to prevention, surveillance, prophylaxis and treatment interventions may reduce morbidity and improve survival of HIV+ ESRD patients.

**The Prevalence and Predictors of Anaemia in European Children with Established Renal Failure** Leah Krischock, Karlijn J. Van Stralen, Kitty J. Jager, Franz S. Schaefer, Enrico E. Verrina, Jaap Willem Groothoff, Eleanor Jane Tizard. *On Behalf of the ESPN/ ERA-EDTA Registry Study Group, Amsterdam Medical Centre, Amsterdam, Netherlands.*

Purpose of study: Determine the prevalence of anemia in European children with Established Renal Failure (ERF), identify risk factors for anemia in this patient population, and determine the adequacy of treatment of anemia.

Methods: Data were collected from 2028 patients on dialysis, and 2313 transplant patients aged 17 years or under from 2000 to 2009, from 20 European countries contributing to the ESPN/ERA-EDTA Registry. Percentages were weighted according to the number of hemoglobin (Hb) measurements available. There was an average of 3.8 measurements per patient. Linear mixed model analyses were used to determine effect of parameters on Hb levels.

Results: Comparing the results with European adult guidelines and British paediatric guidelines, 46% of dialysis and 26% of transplant patients were anemic. 90% of dialysis patients were treated with erythropoietin stimulation agents (ESA), while only 10% of transplant patients were on an ESA.

In dialysis patients, younger age was strongly associated with lower Hb levels. Haemodialysis (rather than peritoneal dialysis), and a primary diagnosis (PRD) of cystic kidney disease were also associated with lower Hb levels, while congenital anomalies of the kidneys and urinary tract were associated with higher Hb levels.

In transplant patients, predictors for a lower Hb level were again younger age as well as female gender. Patients with a PRD of HUS had higher Hb levels compared with all other PRDs.

Conclusions: We have identified anemia is a common and significant problem in European children with ERF. Children on haemodialysis are more prone to anemia than those on peritoneal dialysis and those who have been transplanted. Younger children, particularly those under six years of age, are most at risk. Evidence based European guidelines are needed to help paediatric nephrologists optimize management of anemia in children requiring renal replacement therapy. The management of anemia in those particularly at risk should be specifically targeted.

**Decrease in the Number of Undocumented Patients Starting Hemodialysis in a New York City Hospital over the Last Three Years** Mary C. Mallappallil, Reisha T. Browne, Win Kyaw, Moro O. Salifu. *Internal Medicine, Division of Nephrology, SUNY HSCB Downstate at Brooklyn, New York, NY.*

Purpose : We hypothesized that there is a change in the number of undocumented patients who present themselves to the inner city hospitals in New York City for hemodialysis over the past three years.

Methods: We looked at the number of incident patients starting hemodialysis in our center over the past three years from 2007 to 2009, analyzed physician and social worker notes, billing specialist input and social security numbers for all patients to determine their immigration status.

We are the largest Municipal hospital based dialysis center in New York City with a referral base of 22 community hemodialysis centers. Our hemodialysis population is unique with patients from the Caribbean ethnic minority, who are emergently started on hemodialysis in the hospital. With no prior medical care dialysis is started with a catheter after which, on discharge they are transferred to out patient hemodialysis units. They become eligible in New York State for emergency Medicaid which covers the cost of care for hemodialysis.

In 2007, we started 138 new patients on hemodialysis of which 58 (42%) were undocumented patients. In 2008, we started a total of 115 patients on hemodialysis of which 39 (34%) were undocumented and in 2009, we started 105 patients on hemodialysis of which 27 (26%) were undocumented patients with no medical insurance. Using chi square analysis the decrease in number of undocumented immigrant patient for the three years is significant with *p* value at 0.005, which is an unexpected decrease.

The average creatinine of patients starting hemodialysis in 2007 was 9.5mg/dL and in 2009 is 9.9mg/dL.

We correlated the decrease in the incident number of new undocumented immigrant dialysis patients to the trend of decrease in the illegal immigrant population reported by the center of immigration studies and data from Homeland Security from 2007 to 2009 due to economic reasons and increased immigration enforcement.

We still have a significant number of undocumented immigrant patients on hemodialysis compared to the most other institutions and the United States Renal Data System.

Disclosure of Financial Relationships: nothing to disclose

## PUB422

**Outcomes of Patients Starting Hemodialysis with Serum Creatinine Greater Than 30mg/dL** Mary C. Mallappallil, Reisha T. Browne, Win Kyaw, Moro O. Salifu. *Division of Nephrology, Department of Internal Medicine, State University of New York at Brooklyn, Downstate Medical Center and Kings County Hospital Center, Brooklyn, NY.*

We report 8 cases of patients with serum creatinine (SCre) > 30mg/dL (GFR < 2ml/min) who presented for initial hemodialysis (HD) in our hospital over the past 3 years. We analyzed the mortality of these patients at one year based compared to those with SCre <30md/dL.

Observational study of 149 patients who started hemodialysis over the past three years. We analyzed patient mortality at 1 year with serum creatinine >30mg/dL (n=8) and compared to all those with SCre<30mg/dL (n=141).

Many of our patients started HD in the hospital, without prior medical care. All belong to ethnic minority groups & are usually started on HD with a catheter.

After 1year on HD, 1 of the 8 patients with SCre > 30mg/dL died (12.5%) compared to 20 of 141 patients (15%) in the group with SCre < 30mg/dL. In the group with Scre > 30mg/dL, the mean SCre and Body Mass Index(BMI) was 34.2mg/dL and 30 respectively. With SCre < 30mg/mL, the subset that survived 1 year had a mean SCre and BMI of 10.3mg/dL and 27.9 and the subset that died had mean SCre and BMI of 7.3mg/dL and 25 respectively.

In those with SCre> 30mg/dL, 7 were placed on chronic HD, 2 had prior medical care and medical insurance at presentation. All spoke English & presented symptomatically to the hospital.

Clinical Characteristics of Patients with Serum Creatinine greater than 30mg/mL starting Hemodialysis

| patient number | Age and sex | serum creatinine md/dL at start of HD | GFR at start of HD ml/min | Body Mass Index | Alive/ one year | type 2 diabetes | Hypertension |
|---|---|---|---|---|---|---|---|
| 1 | 35M | 37.7 | 1.6 | 33 | yes | no | yes |
| 2 | 50F | 31.4 | 1.4 | 35 | yes | yes | yes |
| 3 | 47M | 30.5 | 1.9 | 30 | yes | no | yes |
| 4 | 56M | 30.5 | 1.9 | 22 | yes | no | yes |
| 5 | 52M | 36.7 | 1.5 | 34 | yes | no | yes |
| 6 | 28M | 33.5 | 1.9 | 31 | yes | no | yes |
| 7 | 51F | 30.3 | 1.4 | 29 | no | no | no |
| 8 | 22M | 42.5 | 1.5 | 26 | yes | no | no |

We found that very high serum creatinine > 30mg/dL with high BMI, had better one year mortality (12.5%) than the average patient starting hemodialysis our center (15%) and this may be due to the larger muscle mass. We need larger groups to determine the significance of our findings.

Disclosure of Financial Relationships: nothing to disclose

## PUB423

**A Survey of Influenza Vaccination Status among Dialysis Staff in the South Chicago Area** Albert M. Osei, Bharathi V. Reddy, Pradeep V. Kadambi, Michelle A. Josephson, Woojin James Chon. *Department of Medicine/ Nephrology, University of Chicago, Chicago, IL.*

**Background:** The advisory committee on immunization practices includes dialysis patients in the high risk category of those needing influenza vaccinations. Some studies have concluded that dialysis patients do not achieve the same level of protection after vaccination as non-dialysis patients. The use of antiviral medications in patients on hemodialysis is plagued with uncertainty about the optimal dosing. Thus, influenza infection prevention among dialysis patients must include reducing their viral exposure during outbreaks. Hemodialysis patients spend at least 12 hours each week in close proximity to nurses and technicians. The rate of influenza vaccination among the dialysis staff is unknown and so are the factors affecting the rate of vaccination.

**Design, Setting, and Participants:** We distributed a single page survey on influenza vaccination status, reasons for declining vaccination, facility policies and patient inquiries. The target group was dialysis nurses and technicians in the south side of the city of Chicago and the surrounding suburbs.

**Results:** In all, 108 individual responses representing 58% return rate were received from 10 different units that allowed their staff to participate. 62% of the respondents were dialysis technicians and 32% were nurses with 6% unknown. For the current influenza season, 55% received the seasonal influenza vaccine and 35% reported receiving the H1N1 vaccine. 22% reported having never received any type of influenza vaccine. The stated reasons for not receiving vaccination included: "never had the influenza vaccination" at 14%, "not in a high risk category" at 9%, and "previous skin reaction" and "vaccination not made available" at 6% each. 84% reported availability of vaccines from their facilities. 67% reported having been asked their opinion on influenza vaccination on at least one occasion by a patient. Of those asked, 81%recommended it, 7% advised against it and 12% offered no opinion.

**Conclusion:** Influenza vaccination among hemodialysis staff is suboptimal. Education of dialysis staff and a policy mandating vaccination may need to be considered.

Disclosure of Financial Relationships: nothing to disclose

## PUB424

**A Comprehensive Multicentric Assesment of Haemodialysis Facilities** Eduardo Parra,[1] Dolores Arenas,[2] Maria Fernanada Martínez,[3] Fernando Alvarez-Ude.[4] *[1]Nephrology, Hospital Reina Sofía de Tudela, Tuela, Navarra, Spain; [2]Nephrology, Hospital Perpetuo Socorro, Alicante, Elche, Elda, Spain; [3]Nephrology, Hospital Casa de la Salud, Valencia, Spain; [4]Nephrology, Hospital General de Segovia, Segovia, Spain.*

INTRODUCCTION:

Nowadays, we do not have a comprehensive system to assess haemodialysis (HD) facilities, considering clinical performance measures (CPMs), health related quality of live (HRQoL), patient´s satisfaction and costs, simultaneously. The aim of this study is to analyze the results of the HD therapy in 6 different facilities.

MATERIAL AND METHOD:

This is an observational and prospective study. Two centres were public and four private (with agreement with our National Health Service). We collected several HD results over 2008.

RESULTS:

Centres showed no significant differences in demographic, kind of renal disease and Charlson Co-morbidity Index. The table shows the results of each centre.

| CENTRES | | 1 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|---|
| Type of centre | | PUBLIC | PUBLIC | PRIVATE | PRIVATE | PRIVATE | PRIVATE |
| Mean of patient´s months on HD | | 37.3 | 30.6 | 47.0 | 167.4 | 39.9 | 27.9 |
| CLINICAL PERFORMANCE MEASUREMENTS | | | | | | | |
| | Kt/v (% > 1,2) | 90.0 | 88.2 | 81.4* | 94.0 | 96.3 | 87.8 |
| | Hb (% 11-13 gr/dl) | 51.2 | 62.2 | 51.1 | 66.2 | 61.1 | 56.1 |
| | Ca (% 8,4-9,5 mg/dl) | 68.3 | 75.7 | 60.0 | 69.2 | 68.5 | 58.5 |
| | P (% 2,7-5 mg/dl) | 68.3 | 70.3 | 46.7* | 69.2 | 72.2 | 51.2 |
| | VASCULAR ACCESS (% native arteriovenous fistula) | 48.8* | 73.0 | 71.7 | 79.7 | 77.8 | 75.6 |
| | ANNUAL MORTALITY | 16.1 | 22.9* | 19.1 | 11.4 | 10.0 | 10.8 |
| SATISFACTION AND QUALITY OF LIFE | | | | | | | |
| | SATISFACTION KBD | | | | | | |
| | ESCALE 0-100 | 91.6 | 97.6 | 87.5 | 85.1 | 89.0 | 87.3 |
| | HEALTH RELATED QUALITY OF LIFE | | | | | | |
| | SF-36 MSS | 53.1 | 46.8 | 45.8 | 46.5 | 49.1 | 51.1 |
| | SF-36 PSS | 31.7 | 33.0 | 32.5 | 37.0 | 35.4 | 35.9 |
| COST | | | | | | | |
| | ANNUAL COST PER PATIENT (€) | 42.574 | 39.289 | 32.872 | 29.786 | 35.461 | 35.294 |

*p < 0.05, MSS: mental summary score, PSS: physical summary score

CONCLUSION:

There were differences in some CPMs between centres but not in those related to HRQoL and patient´s satisfaction. There was a great variability in cost between different centres. In our study, lower cost and private management did not imply poorer outcomes.

Disclosure of Financial Relationships: nothing to disclose

## PUB425

**A Novel Comprehensive System To Assess Haemodialysis Facilities** Eduardo Parra,[1] Dolores Arenas,[2] Maria Fernanada Martínez,[3] Fernando Alvarez-Ude.[4] *[1]Nephrology, Hospital Reina Sofía, Tudela, Navarra, Spain; [2]Nephrology, Hospital Perpetuo Socorro, Alicante, Elche, Elda, Spain; [3]Nephrology, Hospital Casa de la Salud, Valencia, Spain; [4]Nephrology, Hospital General de Segovia, Segovia, Spain.*

INTRODUCCTION:

Nowadays, we do not have a comprehensive system to assess haemodialysis (HD) facilities. The aim of this study is to find a suitable, clear and acceptable way of assessing HD facilities.

MATERIAL AND METHOD:

This is an observational and prospective study. Several HD variables were collected over 2008 in 6 different facilities. The evaluation system gives, by consensus of investigators, a relative weight to each selected indicator. The maximum number of points was assigned to the facility with better results for each selected indicator and cero to the one with the poorest result. The other facilities get points proportionally to that clearly-defined range. HD variables considered and the points assigned were: A) clinical performance measurements (CPMs), which included Kt/v (10 points), haemoglobin (10), calcium (10), phosphorous (10), type of vascular access (10) and annual mortality (20), B) Health Related Quality of

Live (HRQoL), estimated using the SF-36® test (10), C) patients satisfaction, using KBD® test (10), D) annual cost per patient for each centre (10).

For instance, if a centre (the best one) has an 80% of patients with haemoglobin on target (11-13 g/dl), and another (the worst one) has 60%, they will get 10 and 0 points respectively; a center with a 70% will get 5 points.

RESULTS:

Centres showed no differences in age, sex, time on HD, kind of renal disease and Charlson Co-morbidity Index. The total score of each centre was 40.7, 53.5, 24.4, 76.8, 76.3 and 51.8.

CONCLUSION:

We believe that this way of assessing HD facilities may fulfil the requirements of simplicity, clarity, proportionality, discrimination, acceptability and comprehensiveness as well as correlation with CPMs and being focused into improvement of centres. The generalization of such a system of assessing HD centres may contribute to improve the outcomes and efficiency of the health system.

**PUB426**

**Outcome of Acute Admission in Haemodialysis or Transplant Patients over a 12 Month Period. Requirements for High-Dependency Care and the Effect of Ethnicity** Darren S. Parsons, Adam Mclean, Neill D. Duncan, David Taube, Tom Cairns. *Imperial College Kidney and Transplant Institute, West London Renal and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.*

**Background**

The West London Renal and Transplant Centre (WLRTC) serves a population of 2 million. It provides inpatient services for 2800 patients on renal replacement therapy: 1350 dialysis (HD/PD) and 1450 transplant patients (TX).

**Methods**

We have analysed the outcome of acute admission in patients on renal replacement therapy during a 12 month period to examine outcome, length of stay (LOS), requirements for additional organ support beyond dialysis (eg inotropic support, non-invasive ventilation) in our renal high-dependency ward (RHDU) and the effect of patient ethnicity on admission rates.

**Results**

From 31.5.2009 to 31.5.2010 there were 3873 elective and 2633 acute admissions to WLRTC. Acute admissions comprised: HD/PD 1270, TX 1038 and Nephrology 325. LOS was HD/PD 12 ± 20 (median 5, 1- 272) and TX 7 ± 16 (median 3, 1-273) days. Death during acute admission occurred in 98/1270 HD/PD (7.5%) and 15/1038 TX (1.4%). During the same time period outpatient deaths on renal replacement were 59 HD/PD and 14 TX. Overall death on the programme during 12 months: HD/PD 60/1350 (4.4%) and TX 29/1450 (2.0%). Of the acute admissions, 369/2308 (16.0%) episodes required 2 organ support (duration 1-45 days) and 101/2308 (4.4%) required 3 organ support (duration 1-29 days) beyond basic renal replacement therapy in RHDU.

| Ethnicty | HD/PD Programme | HD/PD Admissions | TX Programme | TX Admissions |
|---|---|---|---|---|
| Number | 1350 | 1270 | 1450 | 1038 |
| Caucasian | 34.3% | 37.4% | 51.5% | 46.3% |
| Afro-Caribbean | 17.5% | 19.4% | 10.8% | 16.0% |
| Indo-Asian | 23.8% | 19.5% | 20.8% | 20.5% |
| Other/Unknown | 24.3% | 23.7% | 23.7% | 17.2% |

Comparison of Ethnicity on Programme (HD/TX) compared to Acute Admissions

**Conclusions**

Our inpatient mortality rates are low in both HD/PD and TX acute admissions. A significant proportion of acute admissions required additional organ support beyond dialysis. Analysis by ethnicity showed little significant impact on the requirement for acute admission in HD/PD or TX patients.

**PUB427**

**Quality Accreditation of a Public Hemodialysis (HD) Unit in Spain. Our Experience** Mª Dolores Del Pino Pino, Ma del Carmen Prados Soler, Remedios Garofano, Clara Moriana, Manuel Ángel Rodríguez. *Nephrology, Complejo Hospitalario Torrecárdenas, Almería, Spain.*

In May 2006 the current HD unit was opened. It consists of 5 rooms, 41 monitors, 26 posts, three shifts a day (Mondays to Saturdays), 100 fixed patients, with 100% occupation of dialysis posts, 15.870 sessions performed during the last year and a total of 50 staff. Quality accreditation of the HD Unit aims to encourage the continued improvement of the Service, through three important points: "What is not recorded does not exist", "What is not measured cannot be improved", "Consider solely those records and documents that can benefit the Unit".

Accreditation Process: Evaluation by the Andalusian Health Care Quality Agency (AHCQA) performed of 86 standards, corresponding to four blocks: I. The citizen, center of the Health System, II. Organization of patient-centered activity, III. Professionals, IV. General support and safety processes, and V. Results. The development of the accreditation process was as follows: Phase 1: Preparation phase – March 2008; Phase 2: Self-evaluation and internal improvement – from March 2008 to June 2009; Phase 3: External evaluation – July 2009. Decision of the Certification Committee: Accreditation of Advanced Quality, thus becoming the only public HD Unit accredited in Andalusia. By complying with more than 90% of the standards, the AHCQA considered our strong points to be: user satisfaction, participation and rights, accessibility and continuity of care, activities related to the promotion of health care programs, structure and installation of general, support and safety processes; Phase 4: Follow-up self-evaluation during 5 years.

Conclusions: Being the sole public HD Unit accredited by the AHCQA has endowed our hospital with recognition by the Health Authorities; for the patients, we have surpassed their level of satisfaction, confidence and trust in us, and for our Service it has led us to seek out areas for improvement. We consider ourselves to be a solid working team, desiring continuous improvement and hoping to obtain even better accreditation levels. We encourage HD Units to follow our experience as it is the best way to promote continuous improvement.

**Demographics of Undocumented Residents with End-Stage Renal Disease in the Houston Community** Rajeev Raghavan, David Sheikh-Hamad. *Department of Medicine, Division of Nephrology, Baylor College of Medicine, Houston, TX.*

Introduction: Currently there is no uniform national policy regarding health care for undocumented residents (UR). Since both care delivery and compensation vary between states, confusion and ethical dilemmas are abound. The term UR include persons who have either crossed the U.S. border illegally or are immigrants who entered legally, but are now out-of-status. It is not known exactly how many UR require renal replacement therapy (RRT). Combining the Urban Institute estimate of 11 million UR with data from the United States Renal Data System (USRDS) database, at least 6000 UR in the U.S. require RRT. In this work, we sought to evaluate the demographics of this patient population in the Houston public hospitals and clinics.

Methods: One hundred and eighty-five UR currently receive dialysis in the Houston community. Sixty of these patients receive maintenance hemodialysis. Demographic information was obtained via patient interview and chart review.

Results: When compared to patients in the USRDS, this patient population is younger and demonstrates lower prevalence of diabetes (42.8 *vs* 60 years; and 37% *vs* 44%, respectively; $p<0.05$). 95% of the patients are Hispanic and only 23% graduated high school. Most patients have spent over 30% of their life in the United States before commencing dialysis (average 16.5 years); and 53% received pre-dialysis care. Only 3% of the patients had knowledge of their kidney disease prior to immigrating to the US. Importantly, none of the patients want to return to their home countries because of established roots here and perceived poor outcomes for patients on dialysis in their home countries.

Conclusions: The number of UR needing RRT in the Houston public hospital system is large and imposes a significant financial burden on the community. Adequate solutions require uniform policy nation-wide. The use of non-standard dialysis is one approach that may benefit these patients while containing costs. Immigration reform is critical if these patients were to benefit from the new health care reform.

**Successful Treatment of Colon Cancer with Oxaliplatin/5-Flurouracil/ Luecovorin in a HIV Positive Patient with End Stage Renal Disease on Hemodialysis** Divya Salhan, Abhijit Kontamwar, Kenar D. Jhaveri, Michael D. Gitman. *The Raggio Institute and the Division of Kidney Diseases and Hypertension, NSLIJ Health System, Manhasset, NY.*

Little is known about the dosing and efficacy of cancer treatment in hemodialysis (HD) patients. Here we report the successful use of oxaliplatin(OX) for the treatment of colon cancer in a HIV positive patient with end stage renal disease (ESRD) on hemodialysis (HD).

A 57 year old HIV positive Caucasian male with ESRD on HD was evaluated for the treatment of colon cancer. He had developed ESRD secondary to the use of tenovofir and NSAIDS and had been on HD for one and a half years. A CT scan revealed a large polypoid mass in the caecum and he was subsequently diagnosed with stage 3 A colon carcinoma. The carcinoembrionic antigen level was 2.1ng/ml. He was on antiretroviral therapy. The patient received modified FLOX chemotherapy which included: OX 40mg/m2, L-luecovorin(LV) 360 mg/m2, 5-Flurouracil(5FU) 400mg/m.The patient received 4 cycles of chemotherapy. Each cycle consisted of 6 weeks of chemotherapy with a 2 week break between the cycles. The OX and LV were administered over 2 hours and 5 FU was administered as an IV push 1 hour into the LV infusion. HD was performed within 1 hour of OX administration. The HD was done via Optiflux F160 dialyzer for three and a half hours with a blood flow rate of 400ml/min. The patients laboratory toxicity profile was followed closely throughout the course of chemotherapy. According to the National Cancer Institution toxicity criteria the patient tolerated the chemotherapy well with Grade 0 toxicity. He received full treatment without interruption. The most recent CEA level was 1.2ng/ml.The HIV viral load (vl) pre and post treatment was 50 and 93 RNA copies/ml respectively.

With the rising number of dialysis patients requiring chemotherapy, clinicians will need a safe and effective therapy to treat this population. We report that the reduced dose modified FLOX regimen was safe and effective in our HIV positive ESRD patient and should be considered as an option for other ESRD patients with colon cancer.

**Anemia Management in Hemodialysis Patients: A Report from Binocrit® Observatory Study (BOS)** Malik Touam,[1] Pablo A. Urena.[2] *[1]AURA, Paris, France; [2]Clinique du Landy, Levallois-Perret, France.*

This was prospective national observatory. 83 nephrologists described their practices when including hemodialysis pts (HD) during the period from april 2009 to april 2010. ESA treatment by Binocrit ® is initiated in HD adults, without iron deficiency and whose hemoglobin (Hb) is stable during the last three months before inclusion.

332 HD (mean age 65 y, male 55%, 9 y on dialysis, diabetes 24%) are included. At baseline the mean Hb, ferritin (Fe) and TSAT were respectively 10.8 ± 3 g/dl, 220 ± 56 µg/l and 21 ± 7%. The optimal Hb was [10-12 g/dL] or [11-13 g/dl] for 90.3% and 9.7% of nephrologists. This target relates to respectively 93% and 7% of HD. If Hb> 13 g/dl, 32.3% of nephrologists suspend ESA, while 67.7% reduce the dosage. In 87% of HD, iv route for iron therapy was used . Fe target is [200-500 mg / l] in 52.8% , and [500-800 mg / l] in 47.2% of cases. TSAT target is [15-30%] in 89.7% and> 30% in 10.3% of cases. When Fe is above the target, 81% of nephrologists suspend iron treatment, and 19% reduced dosage or frequency of administration. The interval between iron injection and blood sampling for iron status: 7 d in 16.1% , between 7-14 d in 12.9% and no standardised protocol in 51.6% of cases. At initiation of ESA therapy Hb is monitored weekly in 12.9%, every two weeks in 54.8%, every month in 32.4% of cases. In the maintenance phase, it is monitored every two weeks (35.5%) and monthly (64.5%). In multivariate analysis (taking into account age, sex, vintage on dialysis, diabetes, inflammation, Fe and TSAT target), there is no significant difference between the HD where the target Hb was 10-12 g/dl and those where the target Hb was 11-13 g/dl.

Conclusion: for 90% of nephrologists Hb target was 10 -12 g/dl for 93% of HD. A minority of nephrologists are choosing a high Hb target in 7% of pts, whose main characteristics are not different from the majority of HD. The iron therapy is administered iv in the majority of HD. However, its biological monitoring does not seem to obey a strict protocol in 51.6% of nephrologists. 30% of nephrologists believe that the optimal Fe is [500-800 mg / L], whereas only 10.3% are an TSAT> 30%.

**Effect of Regional Distribution of Dialysis Satelites on Travel Time and Access to Care** Lilyanna Trpeski,[1] Stanley S. Fenton,[2] Charmaine E. Lok.[2] *[1]Ontario Renal Network, Cancer Care Ontario, Toronto, ON, Canada; [2]Nephrology, Toronto General Hospital, Toronto, ON, Canada.*

Background: Providing dialysis care is influenced by direct and indirect patient factors. Access to dialysis care is an indirect factor that may affect long term patient outcomes. Rural satellite centers were designed to facilitate dialysis by reducing travel times for patients who live long distances from urban dialysis centers in Ontario, Canada.

The aim of this study was to explore the impact of having satellite centers on patients' commuting distances and travel times from their homes to their dialysis centers, almost 2 decades after satellite centers were first introduced in Ontario.

Methods: Prevalent dialysis patients at the end of 2009, abstracted from the Ontario Renal Reporting System, were analyzed. The patients' residential and the dialysis facilities' postal codes were used in the validated "Great Circle Distance" formula which calculates the shortest distance between 2 points using SAS software. The travel time was calculated based on the average driving speed of 70 km/h.

Results: At the end of 2009, 9,626 patients were receiving dialysis in 27 centers and 42 satellites in Ontario. The mean distance from home to the dialysis facility for all in-centre patients was 13.1km. In 10 of 14 Health Regions, 95% of patients live up to 50 km from the dialysis center. Travel time greater than 1 hour was observed in 0.8% to 15% of the patients by Health Region.

Conclusion: The regional distribution of dialysis centers is effective in ensuring timely access to care in the majority of the patients (90%) in Ontario. However, there are 3 regions where patients are more likely to travel >1 hour, one way, to receive dialysis. Additional strategies, such as telemedicine, is necessary to improve access and monitoring of dialysis care for patients with long commute times.

**Comparison of Two Models of Telemedicine in Remote Dialysis Units in Northern Quebec** Murray L. Vasilevsky,[1] Claude Sicotte,[2] Khalil Moqadem,[2] Johanne Desrochers,[1] Madeleine St-Gelais.[1] *[1]Nephrology, McGill University Health Centre, Montreal, QC, Canada; [2]Department of Health Administration, University of Montreal, Montreal, QC, Canada.*

Telemedicine was introduced to improve the surveillance of patient care in two remote satellite units serving First Nation Cree patients in the James Bay region of Northern Quebec. An electronic database (Nephrocare) accessible from the University center was operative in both sites and linked to the University center. The telemedicine model differed between sites. One model (Unit A) consisted of weekly or bi-weekly rounding on each patient by the nephrologist, using a mobile telemedicine station in the satellite unit. The second model (Unit B) consisted of a weekly videoconference between the nephrologist and satellite nurses to review charts and resolve problems. All Cree patients older than 18 and dialyzed for a minimum period of 9 months prior to and after introduction of telemedicine were included. The impact of telemedicine on outcome measures was compared between Unit A and Unit B. Data was extracted retrospectively from monthly lab tests and chart review and subjected to ANOVA with repeated measures. 28 patients were included in the analysis. There were no differences in pre-dialysis systolic and diastolic BP, serum Hb, serum albumin, phosphate, PTH, glucose, glycosylated Hb and KT/V between units. The number of prescription medication changes and transfers to the university center was the same. Telemedicine provides better security for patients and staff in remote settings. Different models of telemedicine to support dialysis in remote settings may be equally effective and should be adapted according to the local needs of the particular unit.

**Impact of Vascular Access Blood Flow Monitoring on Access Survival in Hemodialysis Patients** Amir Abdi Pour,[2] Seyed-Ali Sadjadi,[1] Navin Jaipaul,[1] James I. McMillan.[1] *[1]Nephrology Section, VA Loma Linda Health Care System, Loma Linda, CA; [2]Nephrology Division, Loma Linda University Department of Medicine, Loma Linda, CA.*

Vascular access thrombosis results in suboptimal outcome in patients on hemodialysis. Numerous studies have shown divergent results of the impact of monitoring on access survival. We conducted a retrospective review to determine failure rate of the first usable vascular access during the first year of use in 102 United States Veterans with (Group 1) and without (Group 2) blood flow monitoring, using the saline dilution technique over a 10 year period. Table 1 shows the demographics and impact of surveillance.

Table 1: Baseline Characteristics and Study Endpoints

| Variable | Group 1( N=48) | Group 2( N=54) | P value |
|---|---|---|---|
| Age (±SD), years | 69±9 | 63±11 | 0.40 |
| Male gender, n | 48 | 52 | 0.17 |
| Diabetes, n | 30 | 37 | 0.52 |
| Hypertension, n | 40 | 49 | 0.26 |
| Peripheral Vascular Disease, n | 7 | 10 | 0.59 |
| Coronary ArteryDisease, n | 24 | 21 | 0.25 |
| Congestive Heart failure, n | 21 | 27 | 0.65 |
| Access type, n | | | 0.27 |
| AV fistula | 26 | 35 | |
| AV graft | 22 | 19 | |
| Access failure, n | | | |
| Overall | 12 | 4 | 0.01 |
| AV fistula | 1 | 1 | |
| AV graft | 11 | 3 | |
| Infection, n | 6 | 2 | 0.09 |
| Revision, n | 14 | 5 | 0.01 |
| Thrombosis, n | 19 | 3 | <0.001 |
| Fistulogram, n | 18 | 34 | 0.01 |

**Results**: There was no significant difference in demographics, comorbidities, or type of access between the two groups. Overall access loss and revision were higher and statistically significant in group 1 vs. group 2 (Table 1). Access thrombosis was also significantly higher in group 1 vs. group 2 (Table 1). Graft failure was significantly higher in the first year compared to native fistula failure in both groups (n= 14 vs. 2; p value <0.001). Although not statistically significant, access infection tended to be higher in group 1 vs. group 2 (Table 1). **Conclusion**: Access surveillance decreases the rate of access thrombosis and failure but requires more procedures and interventions. It appears that access surveillance has a greater impact on preventing graft loss vs. native fistula loss during the first year of follow-up.

Disclosure of Financial Relationships: nothing to disclose

## PUB434

**Deadlock in Hemodialysis Angioaccess (DHDAA)** Thanh Cao Huu, Cridlig Joelle, Michele Kessler, Luc Frimat. *Nephrology, CHU Nancy, ??Vandoeuvre, France.*

The authors reported observations of deadlock in hemodialysis angioaccess (DHDAA) of 15 patients (9 F & 6 M) with mean age at 59±18 years , treated by hemodialysis for 127±86 months. Co-morbidity as diabetic mellitus and obesity were noted in 8 patients, arteriopathy and coronaropathy in 12, calciphylaxis and chronical inflammatory diseases in 4. Risk factors incriminated of DHDAA were: high incidence of central veins catheterism (CVC) (6±4 catheters per patient including 4±3 non-tunnelled-catheters and 3±3 permanent tunnelled catheters (PTC) (Canaud) per patient.. Only 1 patient did receive 2 subclavian catheters before DHDAA situations. They received up to 11±6 surgical angioaccess failures including fistula, PTFE, or shunt. Only 3 patients received radio-cephalic in forearms as the first angioaccess while 12 did receive proximal fistula or PTFE. Femoral accesses including catheters, PTFE and saphen vein bypasses were attempted in 9 patients. Stenoses of cave system-central veins occurred in most of the patients (stenoses of internal jugular veins:13, brachio-cephalic veins:13, subclavian veins:10, femoral & iliac veins: 3). Thank to Angioplasties,11 permanent tunnelled catheters were inserted and 6 new angioaccess operated. Without the need of angioplasty, 3 s/clavian PT catheters, 2 femoral vascular accesses and 1 brachial PTFE bypass were performed. These last angio-access comprised aggressive but still fragile solutions since: 1 patient was to be transplanted in emergency, 7 still kept PT catheters, 7 could receive proximal Fistula or PTFE AA (including 2 ligations, 2 stenoses treated by angioplasties and 2 stenoses treated by PTFE bypass). Peritoneal dialysis were contraindicated or failed in all and transplantation was possible in another patient. Hospitalisations were frequent, unpredictable and stressful. 4 Patients died 1 to 6 months after the last AA. In conclusion, the situation of DHDAA in our 15 patients was the combination of numerous angioaccess failures and CV catheters & stenoses. Management of DHDAA are time consuming. Multi-disciplinary efforts and patience are needed.

**Percutaneous Trans-Lumbar (PTL) Dialysis Catheter Placement, Unto Superior Vena Cava (SVC), Guided by Computed Tomography, a Case Report** Javier Castillo Tapia,[1] Alejandro Chavez,[1] Salvador Mendoza,[1] Patricia Peña,[1] Armando Avila,[2] Juan Rochin Teran,[2] Leticia Marquez,[1] Luis Alberto Evangelista Carrillo,[1] Abel Puentes Camacho,[1] Jorge Andrade-Sierra,[1] Leonardo Pazarin,[1] Mario Sandoval Sandoval,[1] Enrique Rojas-Campos,[3] Alfonso M. Cueto-Manzano,[3] Benjamin Gomez-Navarro.[1] *[1]Nephrology and Organ Transplant, IMSS, Guadalajara, Jalisco, Mexico; [2]Radiology and Imagenology, IMSS, Guadalajara, Jalisco, Mexico; [3]Medical Research Unit in Renal Diseases, IMSS, Guadalajara, Jalisco, Mexico.*

**Introduction**: In HD when common vascular accesses (VA) are unavailable it is necessary to consider other sites.The first Latin-American, PTL placement unto SVC, CT guided. **Case**. Female 28 yrs. ESRD (vesicoureteral reflux). 2 renal transplants (1992,1999), from LRD (father) and CD, lost for AR at 36 and 16 mo. HD since Feb-2002, 18 VA (6 mahurkar (MAH), 6 tunelized catheters, 3 native and 3 graft fistulas [GF]). Hepatitis B and C positive; cross-match positive (99%), PRA HLA C-I (100%) and C-II (100%). Last VA lost (GF-right femoral ), perforation and bleeding (August 28 2009) at HD. We placed a MAH useful for 1 week in a subclavian branch (Sept. 2, 2009). We planned a PTL catheter placement unto SVC, guided by CT, as a last option. **TECHNIQUE**: Initial CT to measure distance skin-IVC. Punction at the lumbar back between the iliac ridge-lumbar spine; IVC was reached after 3-attempts using the Seldinger technique; corroborated by pulsation absence and CT. Using a hydrophilic wire (guide), catheter was introduced from IVC to SVC, CT-corroborated . Skin tunnelization to the right flank. The catheter max. flux reached was 450 ml/hr, recirculation 5%, Kt/V 1.6. June 15, 2010: SCr 12.2mg/dL, Uric acid 9.5mg/dL, P 3.8 mg/dL, Ca 8.5mg/dL, Hb10.5g/dL, Alb 3.6g/dL. It has 120 catheter/days, with no complications in flux, infections, thrombosis, bleeding, migration and hematoma.

## PUB436

**Case Study: HeRO Vascular Access Device Long-Term Outcomes in Renal Transplant Patient with Multiple Co-Morbidities** Howard E. Katzman. *Department of Vascular Surgery, University of Miami, Miami, FL.*

**Purpose:** To report long-term outcomes 47 months after implant of the novel HeRO vascular access device in a catheter-dependent Hispanic male with a history of two renal transplants and multiple co-morbidities.

**Methods:** The HeRO device was implanted July 25, 2006, in a 31 year-old Hispanic male as part of the HeRO Food and Drug Administration clinical trial. This catheter-dependent patient required dialysis since the age of 8 due to congenital deformity. His exhaustive vascular access history included multiple fistulas, grafts and catheters at the time of HeRO implant. Co-morbidities included hypertension, hepatitis C, central venous stenosis in both brachiocephalic locations, thyroid papillary carcinoma and total thyroidectomy with no history of smoking or diabetes. This patient continues to be followed beyond the clinical trial requirements for evaluation of long-term outcomes.

**Results:** A HeRO device was successfully placed over-the-wire utilizing the existing dialysis catheter tract in the right internal jugular vein. A femoral bridging catheter was placed and used for acute dialysis until the HeRO device could be cannulated, approximately one month post implant. To-date, this patient has been followed for 47 months post HeRO implant. Two percutaneous HeRO interventions have been required to maintain patency, the first at 42 months post implant and the second at 44 months post implant. At approximately 46 months post implant, the original HeRO graft was replaced with a new HeRO graft due to pseudoaneurysms in the graft segment, which resolved the thrombosis issues. No infections have been reported to-date.

**Conclusion:** This case report demonstrates that patients ineligible for an upper extremity access due to central venous stenosis may experience the long-term benefits of a subcutaneous arteriovenous access by receiving the HeRO device.

Disclosure of Financial Relationships: nothing to disclose

## PUB437

**Early Thrombectomy of Arteriovenous Dialysis Grafts: Is It Worthwhile?** Vijay Mudunuri, Jeremy C. O'Neal, Michael Allon. *Nephrology, University of Alabama at Birmingham, Birmingham, AL.*

Introduction:

In spite of the National Kidney Foundation's initiative to increase use of autogenous fistulas for vascular access, many patients continue to undergo hemodialysis with arteriovenous (AV) grafts. Clotted AV grafts are treated with endovascular or surgical thrombectomy. The outcomes of thrombectomies performed within 2 months of graft creation were assessed.

Methods:

We retrospectively analyzed the outcomes of all AV grafts placed at our medical center over a 5 year period that required thrombectomy within 60 days of creation. Technical success was defined as the immediate restoration of graft patency. Primary patency was calculated from declot to first intervention and cumulative patency from declot to permanent graft failure. We also compared the outcomes for grafts undergoing thrombectomy at ≤30 days vs 31-60 days.

Results:

Of 709 AV grafts placed, 98 grafts (14%) clotted within 60 days of creation and underwent percutaneous or surgical thrombectomy, including 63 (9%) within 30 days of graft creation, and 35 (5%) at 31-60 days after creation. Grafts clotting within 30 days of creation typically underwent surgical thrombectomy and those clotting after 30 days usually underwent percutaneous thrombectomy. The immediate technical success was 82%. The median primary graft patency was 14 days and median cumulative graft patency was 38

days, and was similar at ≤ 30 vs 31-60 days. Thrombosis within 30 days was likely due to poor arterial inflow and thrombosis at 31-60 days was commonly due to stenosis at the venous anastomosis.

Outcomes of early declot of AV grafts

| | <=30 days | 31-60 days | p value |
|---|---|---|---|
| No. of patients | 63 | 35 | |
| Anatomic abnormalities | Laceration of graft wall-1, Redundant graft-2, Kinked graft-1, Adherent clot-1 | Stenosis at venous anastomois-23 | |
| Declot- Surgery/ Interventional Radiology | 60/ 3 | 10/ 25 | <0.001 |
| Primary patency | | | |
| Median, days | 11 | 23 | 0.46 |
| 90 days | 19% | 31% | |
| 180 days | 17% | 22% | |
| Cumulative patency | | | |
| Median, days | 27 | 163 | 0.29 |
| 90 days | 34% | 51% | |
| 180 days | 32% | 45% | |

Conclusion:

Thrombectomy within 2 months of graft creation is associated with poor primary and cumulative patency, and may not be worthwhile.

Disclosure of Financial Relationships: nothing to disclose

**PUB438**

**Superior Vena Cava Syndrome Secondary to Permcath Catheter for Hemodialysis (HD)** Ma del Carmen Prados Soler, Mª Dolores Del Pino Pino, Remedios Garofano, Clara Moriana, Manuel Ángel Rodríguez. *S. Nephrology, C. H. Torrecárdenas, Almería, Andalucía, Spain.*

**Introduction:** Thrombosis or stenosis of the superior vena cava (SVC) and/or brachiocephalic trunk (BCT) in patients with central catheters for HD is frequently, secundary to alterations of hemostasis and barotrauma, whether or not accompanied by endovascular infection. The symptoms are shoulder girdle edema, dyspnea and jugular vein ingurgitation. Angioplasty, endoluminal treatment of the stenosis requires implantation of a stent to prevent restenosis

**Case Report:** 72-year-old woman with chronic kidney disease, on HD since 05, via a Permcath catheter.On 07 she required a change of the permanent catheter due to failure of the previous one. In November 09 she presented catheter dysfunction due to lack of flow, for which she was given urokinase. Physical examination of note showed: facial and cervical edema, rest of the examination are normal and vital constants too. Laboratory studies are normal. A superior cavography showed: stenosis of the SVC in the upper third, no filling of the right BCT due to thrombosis, with abundant collateral circulation via the intercostal braches to the azygos vein, which in turn drained into the SVC, and partial thrombosis of the left BCT. Given that stent implantation requires withdrawal of the permanent catheter and that in this case there was great difficulty obtaining another vascular access, it was initially decided to systemic anticoagulation for 6 months. Later, depending on the findings of a radiological control and the clinical situation the possibility of endoluminal treatment will be assessed

**Conclusions:**

- Controversy exists in the superior vena cava syndrome concerning the treatment of choice. Conservative treatment with oral anticoagulation may be a good alternative in some cases, sometimes achieving clinical and radiological resolution of the syndrome, with endoluminal treatment being reserved as a second choice

- Given the increased frequency of the use of central venous catheters for HD for long periods of time and that venous stenosis or occlusion is usually asymptomatic, early diagnosis is important to permit its resolution

**Proactive Monitoring of Hemodiaysis Vascular Accesses Reduces Declot Procedures at an Out-Patient Vascular Center** Jack E. Rubin.[1] [1]*Los Angeles Vascular Center, Inglewood, CA;* [2]*J. Joseph Hewett, Los Angeles Vascular Center, Inglewood, CA.*

Proactive monitoring by nephrologists in their dialysis centers as well as routine vascular access flow rate determination at Los Angeles Vascular Center (LAVC) was responsible for reducing the incidence of declot procedures in vascular accesses of patients sent there. In 2007, 36% of all vascular salvage procedures performed there were declots, this percentage fell to 31% in 2008 and settled at 24% in 2009. This was a reduction of 31% in the number of declots done from 2007 to 2009. In conjunction with this fall in declot procedures, there was also an increase in the percentage of angioplasties done at LAVC. In 2007, 30% of vascular salvage procedures done there were angioplasties, it rose to 37% in 2008 and it reached 46% in 2009. This was a increase of 51% in the number of angioplasties done in 2009 compared to 2007.

PERCENTAGE OF DECLOTS AT LAVC

| | | |
|---|---|---|
| 36 | 31 | 24 |
| 2007 | 2008 | 2009 |

This reduction in the number of declot procedures was due to proactive montioring of patients' vascular accesses by their attending nephrologists and the nursing staff at the patients' dialysis centers as well clinic visits at LAVC to check blood flow rates of their accesses. Patients were referred to LAVC for consistent reductions of KT/V measurements, evidence of access blood flow rates < 600 ml/min, increased venous pressure found while patients were on dialysis, and post-dialysis bleeding, all of which are compatible with a stenosis forming their vascular access. The restult of this proactive monitoring was both lower costs to insurers both due to the fact that angioplasties are not as costly to perform and there were fewer in- hospital admissions for patients due to their not being able to be declotted in time, in a hospital setting, to return to their dialysis centers for their scheduled dialysis sessions.

Disclosure of Financial Relationships: Ownership: I am a shareholder in Los Angeles Vascular Center.

**Reasons Why and Ways How To Convert an Access Center to a Vascular Center** Jack E. Rubin,[1] Samuel Awuah,[2] J. Joseph Hewett.[1] [1]*Los Angeles Vascular Center, Inglewood, CA;* [2]*RMS Lifeline, Vernon Hills, IL.*

Los Angeles Vascular Access Center (LAVAC) opened in June of 2007 to perform vascular salvage procedures on hemodialysis patients. Within 3 months of its opening it performed it first lower extremity angiogram (LEA). This was done as the number of people with peripheral arterial disease (PAD), between 10-20 million, was much larger than the number of patients with ESRD, 425,000. LEA's are in table 1.

Number of Lower Extremity Angiograms Done at LAVC

| | | |
|---|---|---|
| 10 | 73 | 163 |
| 2007 | 2008 | 2009 |

LAVAC did 13 renal angiograms in 2008 and in 2009 it did 37 and changed its name to Los Angeles Vascular Center (LAVC) to better reflect its performing procedures other than vascular salvage. LAVC started doing venous ablation (VA) procedures and in 2009 and performed 14. In 2009 pain management done by implantation of spinal column stimulators as well as epidural injections of steroids was started.

LAVC was able to diversify due to its having a practice model different from most other vascular access centers. It always had an IR, rather than an IN performing its procedures because an IR is better equipped to perform procedures on the larger sized arteries of the legs and kidneys. Additionally, IN's are not trained in vein ablation techniques. LAVC was fortunate to have an IR that had training in pain management and has successfully placed spinal column stimulators (SCS) for patients with chronic pain in the past.

In summary, by employing an IR, a vascular access center can become a vascular center which can perform an increased number of cases apart from merely doing vascular salvage. This allows a wider range of patients which can be treated there to correct both PAD and RAS as well as doing VA procedures. In addition to the larger number of patients aso available for treatment, the number of referring medical personnel can be increased. Instead of having referrals only from nephrologists, the center's referrals can then come from podiatrists, wound care centers, internists as well as gynecologists for VA's. An additional service line, pain management, can also be done, as it is in LAVC, by an IR trained in pain management.

Disclosure of Financial Relationships: Ownership: I am a shareholder in Los Angeles Vascular Center.

**PUB441**

**Clinical Outcomes of Arteriovenous Grafts (AVG) Placed Prior to Hemodialysis (HD) Initiation** Roman A. Shingarev, Ivan D. Maya, Michael Allon. *Medicine, University of Alabama at Birmingham, Birmingham, AL.*

Pre-HD patients usually receive an arteriovenous fistula (AVF) as their first vascular access, with AVG placement reserved for HD patients who have had a failed AVF. Little is known about the outcomes of AVG placed in pre-HD patients. We compared the outcomes of AVG placed pre-HD with those placed post-HD at a large dialysis center.

We retrospectively queried a prospective, computerized vascular access database, to identify 417 patients with a new AVG placed during a 5-year period, including 69 placed pre-HD and 348 post-HD. We compared baseline demographic and clinical characteristics, cumulative AVG survival (from surgical placement to permanent failure), and primary AVG patency (from surgical placement to first intervention) between the two AVG groups.

The two patient groups were similar in baseline demographics (age, sex, race) and co-morbidities (diabetes, hypertension, coronary artery disease, peripheral vascular disease, and cerebrovascular disease). Of the 65 patients with pre-HD AVG who eventually started HD, 39 (or 60%) were able to use the AVG at a median of 60 days after AVG surgery. Cumulative AVG survival was similar in patients with pre-HD and post-HD AVG (median, 583 vs 657 days; HR 1.21 (95% CI, 0.86-1.75), p = 0.25; 1-yr patency 57 vs 60%; 2-yr patency 39 vs 48%; 3-yr patency 31 vs 40%). Primary graft patency was also similar in patients with pre-HD and post-HD AVG (median, 155 vs 99 days; HR 0.84 (95% CI, 0.65-1.11), p = 0.23; 1-yr patency 26 vs 20%; 2-yr patency, 11 vs 11%).

AVG placed pre-HD have similar clinical outcomes to those placed pre-HD, with comparable cumulative survival and primary patency. Pre-HD AVG placement is a viable option in selected CKD patients.

**Can In-Center Intermittent Peritoneal Dialysis (IPD) Provide the Necessary Adequacy for New Dialysis Patients?** Alp Akonur,[1] Steven Guest,[1] Arshia Ghaffari,[2] James A. Sloand,[1] J. Ken Leypoldt.[1] *[1]Renal Division, Baxter Healthcare Corporation, McGaw Park, IL; [2]Department of Medicine, University of Southern California, Los Angeles, CA.*

Although national and international expert nephrology groups have published recommendations to initiate dialysis when the glomerular filtration rate (GFR) falls within 6-10.5 ml/min/1.73m², no clinical trials have compared outcomes in patients starting dialysis with full versus incremental dialysis dose (Pollock et al, 2007). We used the 3-pore model to evaluate the combined effectiveness of increasing doses of three times per week in-center intermittent PD and residual GFR in achieving the recommended urea clearances.

Two dialysis modalities were examined: 6 dwells / 12L total volume (low-dose IPD) and 50% tidal / 24L total volume (high-dose IPD). 8-hour dialysis duration and 1.5% dextrose solution were assumed with 2L fill volume except in tidal mode. PD Adequest 2.0 (Baxter Healthcare, Deerfield, IL, USA) and typical patient kinetic parameters were used to model urea clearances. The minimum residual GFR required to achieve a total weekly urea Kt/V of 1.7 was calculated.

In the absence of any dialysis, the minimum residual GFR necessary to achieve a weekly urea Kt/V of 1.7 was calculated to be approximately 10 ml/min/1.73m². We found the 12L, low-dose IPD modality to be adequate for patients with GFR greater than 6.8 ml/min/1.73m². The 24L, high-dose tidal IPD modality was adequate for patients with GFR greater than 5.5 ml/min/1.73m². These results suggest that in-center intermittent PD may be a viable option for patients with residual GFR greater than approximately 5 ml/min/1.73m² and could serve as a bridge when new patient training is delayed or home support is temporarily lost. Compared with full-dose PD (i.e. 24-hour, 7 days per week), intermittent PD may help eligible patients achieve the recommended clearance targets while minimizing excessive glucose exposure.

| | No Dialysis | Low-Dose IPD | High-Dose IPD |
|---|---|---|---|
| Calculated IPD Kt/V | 0 | 0.5 | 0.7 |
| Residual Kidney Kt/V | 1.7 | 1.2 | 1.0 |
| Residual GFR, ml/min/1.73m² | 9.7 | 6.8 | 5.5 |

**Hiccups as Sole Symptom of Peritonitis in a Peritoneal Dialysis Patient: Case History and Discussion** Sholey Argani. *Renal Section, Veteran's Affairs Medical Center, Washington, DC.*

A 60 year old diabetic patient whose history included mild retinopathy, hepatitis C virus infection, and hypertension, commenced peritoneal dialysis (PD) for his chronic kidney disease stage 5. Initial PD prescription provided 4 exchanges of 2.5 % dextrose on cycler at night, with a last fill of icodextran. Approximately five months after initiating peritoneal dialysis, the patient presented with four days of persistent hiccups. Physical examination at this time revealed an afebrile well nourished man with blood pressure 105/62 mm Hg, heart rate 72 beats/min. His abdomen was soft with no erythema at the PD catheter site.

On blood chemistry, glucose measured 76 mg/dl, BUN 40 mg/dl, creatinine 10.6 mg/dl, sodium 132 mmol/L, Potassium 2.8 mmol/L, Chloride 94 mmol/L, and bicarbonate 26 mmol/L.

Peritoneal dialysate appeared faint yellow, with 561 non red blood cells/cub mm. On differential, there were 70% segmented neutrophils, 14% lymphocytes, 15 % monocytes, and 1% eosinophils. The culture of peritoneal fluid was unrevealing, but intravenous vancomycin was administered. Within 24 hours the hiccups had completely resolved. This patient received intraperitoneal vancomicin for two weeks, as well as prophylactic oral fluconazole.

The myriad causes of hiccups (singultus) include irritation of the vagus or phrenic nerves, central nervous system pathology, and metabolic derangements such as alcohol intoxication, hyponatremia and uremia. [1,2] One case report [3]noted hiccups due to acidic lactate solution in a PD patient; these resolved with the change to a ph-neutral dialysate. However, in our review of the literature this is the only case of hiccups as the only presenting symptom of culture negative PD peritonitis.

**Peritoneal Dialysis Outcomes during First Year Treatment of Incident Diabetic Patients** Patricia Quadros Branco,[1] Anabela S. Rodrigues,[2] Maria Augusta Cabrita Silva Gaspar,[1] Ricardo Vizinho,[1] Maria João Carvalho,[2] Manuel A. Amoedo,[4] Rui Castro,[5] Ana Paula Bernardo,[6] Jose Diogo Barata,[1] António Cabrita.[2] *[1]Nephrology Department, Santa Cruz Hospital, Portugal; [2]Santo Antonio Hospital; [3]Sao Joao Hospital; [4]Espirito Santo Hospital; [5]Tras os Montes e Alto Douro Hospital; [6]Amato Lusitano Hospital.*

BACKGROUND: Whereas diabetes mellitus (DM) is not a consistent risk factor for peritoneal dialysis technical survival, other co-morbid diseases such as cardiovascular disease (CVD) are common in DM patients (pts) and may predict technical survival. AIM: Compare early technical survival of incident PD DM pts with non-DM pts. METHODS: Prospective multicentre, cohort study of every incident PD pts in a national public health care system, in a reference area of 10 million people. We collected baseline data, hospital admissions, peritonitis, transplants, CV events and deaths, PD prescription, dialysis efficacy, anaemia. Pts were followed for the first 12 months. Technique failure was defined as switching dialysis modality; we censored for death. RESULTS: 238 pts, 98 APD and 140 CAPD, were included. 24.8% DM. Age 53±15 years, 56.7% male; 12 pts died; 13 switched treatment dialysis modality (6 infection, 7 underdialysis). DM pts were older (57±12 vs 52±16 years, p =0.013) and had higher prevalence of CVD (55% vs 21% p<0.001). There were no differences in dialysis efficacy targets, peritoneal transport, anaemia, serum albumin, peritonitis rate. In multivariate analysis DM was positively (HR=10.1; p= 0.02) and daily fluid removal negatively (HR =0.9; p= 0.01) associated with mortality. After adjustment for age, non-optional PD, DM, daily fluid removal, icodextrin utilization, baseline CVD was associated with short-term technique failure (HR = 5.2; p=0.02 ). CONCLUSION: In this model DM was not predictor of early dialysis modality switch. Fluid removal optimization may influence the prognosis of these pts.

**Haemodialysis (HD) Patients Are Still Capable of Choosing Peritoneal Dialysis (PD)** Jean-Louis D. Christophe, Jean-Philippe Lengelé, Florence Hubert, Marylène Tarin. *Service de Néphrologie, GHdC - Hôpital St-Joseph, Gilly, Belgium.*

Once end-stage renal disease (ESRD) patients are in HD, they rarely choose to be transferred to PD. Those transfers mainly happen because of HD technique failure. We wanted to know how often and how our PD patients come from HD.

We retrospectively studied the 50 patients who started PD in our center between February 1996 and May 2010. Only two patients who started PD after long-term failure of renal transplantation following HD were excluded.

Of the 48 remaining patients, 15 (31 %) had been transferred to PD in spite of HD being their first mode of treatment. Of these, 5 were referred very late in the course of their renal disease or progressed rapidly and had to be taken urgently in HD before being informed on alternative techniques of renal replacement therapy (RRT). They later chose PD and were transferred after a mean time in HD of 122 days (range 44-322). Six other patients had received the information on the different modalities of RRT and had chosen PD before reaching ESRD, but had a rapidly progressive disease or an intercurrent event that urged us to start with HD. PD was initiated a mean of 69 days (range 11-247) later, one patient feeling so well in HD that he had an arteriovenous fistula before eventually asking to be transferred to PD.

Finally, four patients had deliberately chosen HD as their first mode of treatment but changed their mind later on (mean time in HD 434 days, range 216-861) : two did so after a local re-information meeting including current and former (transplanted) PD patients; one was psychologically intolerant to HD; another one was bored from travelling to the HD center. It is of note than none of the 15 patients was transferred to PD because HD was becoming practically impossible e.g. due to vascular access failure.

**Conclusions**: patients who are in HD may very well be transferred to PD on a voluntary basis, even after being treated for years in HD. Information on PD should be regularly given to HD patients, by doctors and nurses but patient-to-patient information should also be stimulated. The medical and paramedical staff must pay attention to HD patients' needs that might change in time and be met by PD.

**PUB446**

**Peritonitis Occurring Less Than 1 Month after Training Explained by Maladaptive Connector Set for Peritoneal Dialysis (PD)** George N. Coritsidis,[1] Dharmeshkumar V. Sutariya,[1] Barbara Beach.[2] *[1]Division of Nephrology, Mt. Sinai School of Medicine at Elmhurst Hospital Center, Elmhurst, NY; [2]Peritoneal Dialysis Unit, Elmhurst Hospital Center, Elmhurst, NY.*

Introduction

Early peritonitis in PD can be due to surgical complications. Any peritonitis is associated with diminished technique survival. We recently experienced an unusually high infection rate soon after commencement of PD in 4 patients. After reviewing our PD training process and having ruled out surgical issues, we examined the possibility of a malfunction within the system due to complaints of leakage.

Methods

After a review of charts, history and physical examinations of affected patients, the common finding was the evidence of leakage in 3 patients despite normal exit sites in all. The company of the plastic connector sets was contacted.

Results

All patients had catheter flushes by day 7. Infection was first identified by symptoms and abnormal cell count. On average, peritonitis occurred within 1 month of training and 2 months of catheter placement. Two patients had relapses. 5 of 6 episodes grew Staphylococcus Epidermidis.

Patient Characteristics

| Patient | Training Date | Infection date | Cell Count (per cu.mm.) | 2nd Episode of Peritonitis | Organism |
|---|---|---|---|---|---|
| 1 | Day 15 | Day 34 | 12240 | Day 79 | Staph. epidermidis (both episodes) |
| 2 | Day 20 | Day 17 | 950 | Day 72 | Staph. epidermidis (both episodes) |
| 3 | Day 12 | Day 21 | 330 | none | culture negative |
| 4 | Day 34 | Day 110 | 1600 | none | Staph. epidermidis |
| Average | Day 20.45 | Day 45.4 | 3780 | | |

Date of surgery is considered day 0

All patients were initially treated with vancomycin, ceftazidime and antifungal prophylaxis, with prompt resolution of the peritonitis. On contact with the manufacturer, it was revealed that similar episodes were reported but were resolved after structural changes. A repeat company investigation indicated a new error in the current connector size, and titanium connectors were dispatched. There were no new infections after the change to titanium connectors.

Conclusions:

In diagnosing early peritonitis soon after PD catheter placement, the possibility of a malfunction anywhere along the system should be entertained and examined.

**Peritonitis Prevention in Peritoneal Dialysis Patients with Domestic Animals**

Sunil George, Cheryl Laveglia, Nand K. Wadhwa. *Department of Nephrology, Stony Brook University Hospital, Stony Brook, NY.*

Evidence based literature suggests that a companion animal/pet can help a person better cope with stressful life events, prevent loneliness, decrease depression, improve activities of daily living, and increase social interactions. Many peritoneal dialysis (PD) patients keep pets as social support. However the close interaction with these pets can increase the risk for peritonitis particularly with Pasteurella multocida. In our dialysis unit we encountered a patient with recurrent peritonitis with this organism. This prompted us to evaluate the prevalence of pets in peritoneal dialysis patients and to incorporate a training session about pets when the patient initiates PD. Questionnaires related to the interactions of the patients with the domestic animals during treatments were distributed to all PD patients. The patient population included 17 males and 9 females with a mean age of 47 years. The patients were followed over 520 patient-months. The survey of our PD population showed that 23 % (6/26) have pets at home. Two patients including the patient with recurrent peritonitis reported that pets had frequent contact with the dialysis bags and tubing or direct contact with the patient during set up. Three patients allowed the pets to enter the room occasionally during treatment. One patient never allowed his pets to interact during connections, exit site care or while he was on automated PD. We instituted a training session for patients who kept domestic animals as pets. The training included interventions including patient education, counseling on hygiene and placement of barriers limiting the pet's access to the dialysis equipment. Appropriate interventions taken by the patient with recurrent peritonitis have kept him free of peritonitis for two years. Subsequently we have no episode of peritonitis related to pets in our unit. Thus we recommend a periodic questionnaire and an educational session for all PD patients who have or intend to have companion animals as social support.

**The Effect of Twenty Four Hour Peritoneal Rest in Peritoneal Dialysis Patient**

Takanobu Imada,[1] Sanae Kikuchi,[1] Hideki Yamahara,[1] Hiroya Masaki,[2] Mitsushige Nishikawa,[1] Toshiji Iwasaka.[1] *[1]Department of Internal Medicine II, Kansai Medical University, Osaka, Japan; [2]Department of Laboratory Medicine and Clinical Sciences, Kansai Medical University, Osaka, Japan.*

**Background:** Peritoneal dialysis (PD) is superior to hemodialysis (HD) in protection of residual renal function. The present study was conducted to evaluate whether peritoneal resting could improve continuous ambulatory peritoneal dialysis (CAPD) patient's peritoneal function. We assumed that patients who have some residual renal function may be able to choose whether normal dose daily PD or high dose PD and one day peritoneal rest. We investigated that whether twenty four hour peritoneal rest might lead to improve peritoneal methothelial cell and peritoneal membrane function. **Method:** As a single-center prospective observational study, we analyzed 5 PD patients. They kept residual renal function, and their peritoneal transport characteristics categories (checked using a peritoneal equilibration test: PET) were High average or High, from initiating dialysis therapy for more than six months. We adjusted the PD prescription to keep peritoneal rest and the minimal dose of total (peritoneal and kidney) Kt/Vurea of at least 1.7 per week. We reperformed a PET and examined a mean surface area of peritoneal mesothelial cell. **Results:** The mean PD period was 541±240 days. The mean enforcement period of peritoneal rest was 143±77 days. The mean surface area of peritoneal mesothelial cell was significantly improved (before peritoneal rest: 343.8±9.2μm$^2$ vsersus after peritoneal rest :300±11.2μm$^2$, P=0.019 ). Peritoneal membrane function did not change significantly in this study (the dialysate/plasma ratio of creatinine (D/P); P=0.19, the dialysate 240 min/ initial dialysate ratio of glucose (D/Do); P=0.18). **Conclusion:** In this study, the peritoneal rest improved a mean surface area of peritoneal mesothelial cell. This result clearly indicated that peritoneal rest improved morphological changes. Twenty four hour peritoneal rests may improve peritoneal dysfunctions in patients with residual renal function.

**A Comparison of Short Term Outcomes after Cardiothoracic Surgery (CTS) in End Stage Renal Disease (ESRD) Patients by Dialysis Modality**

Victoria A. Kumar, Scott A. Rasgon, Karen N. Dewar. *Nephrology, Southern California Permanente Medical Group, Los Angeles, CA.*

The number of ESRD patients undergoing CTS has increased over recent years, but concerns exist regarding the outcomes of patients treated with peritoneal dialysis (PD) during the immediate post surgical period. We sought to examine short term outcomes in both PD and hemodialysis (HD) patients who underwent CTS in this retrospective cohort study. We reviewed records for all ESRD patients who received CTS at our center between January 1, 1994 and December 31, 2008, including those who underwent coronary artery bypass grafting (CABG), valve replacement, and combined CABG/valve replacement. All PD patients who received CTS during the study period were included in our analysis. Two controls matched for age, sex, diabetes status and Charleston Comorbidity score (CCS) were obtained for each PD patient from the pool of HD patients who received CTS. The student's t-test, Wilcoxon rank sum, Fisher's exact test and Yates chi square corrected for continuity were used wherever appropriate.

| | PD (n=36) | HD (n=72) | p value |
|---|---|---|---|
| Mean age (years) | 58.8±9.4 | 59.3±9.1 | 0.78 |
| Males (%) | 24 (67) | 44 (61) | 0.73 |
| Surgery type (%) | | | 0.34 |
| CABG | 28 (78) | 48 (67) | |
| valve replacement | 5 (14) | 19 (26) | |
| CABG + valve replacement | 3 (8) | 5 (7) | |
| Diabetes Mellitus (%) | 26 (72) | 54 (75) | 0.92 |
| Mean CCS | 6.6±2.0 | 6.8±2.2 | 0.66 |
| Elective Surgery (%) | 13 (37) | 32 (45) | 0.57 |
| Median CSU LOS in days (IQR) | 2 (1.75-5) | 4(2-6.25) | 0.02 |
| Median hospital LOS in days (IQR) | 9.5 (7-13) | 11 (7-17) | 0.19 |
| Median intubation time in hours (IQR) | 24 (24-24) | 24 (24-48) | 0.07 |
| Post operative infection (%) | 2 (6) | 16 (22) | 0.03 |
| Death during hospitalization (%) | 3 (8) | 8 (11) | 0.33 |

CSU = cardiac surgical unit; LOS = length of stay; IQR = interquartile range; CRRT = continuous renal replacement therapy

Only 2 (6%) of our PD patients required conversion to HD during their hospital stay. The incidence of post-operative infection and median CSU LOS were lower for PD patients. Our findings suggest that PD patients undergoing CTS generally do not require conversion to HD and do not fare worse than similar HD patients.

**Fluid Overload – A Frequently Encountered, Easily Ignored and Difficultly Controlled Problem in Peritoneal Dialysis Patients Associated with Cardiac Hypertrophy and High Pro-BNP and Adiponectin Levels**

Mei-Chuan Kuo, Shang-Jyh Hwang, H. C. Chen. *Nephrology, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan.*

**INTRODUCTION AND AIMS:** Fluid overload in dialysis patients may induce heart failure but fluid depletion may decrease residual renal function. This study is to evaluate fluid status in hemodialysis (HD) and peritoneal dialysis (PD) patients by chest X-ray, cardiac echo and body composition spectroscopy and the effect of fluid control in PD patients by dietary management and monitored by BCM.

**METHODS:** 96 regular HD patients and 98 PD patients were recruited. Body compositions were checked by BCM. Chest X-ray, Cardiac echo, blood biochemistry were checked concomitantly. For PD patients, they were further randomized into 2 groups (control and intervention). Body compositions were measured every month in intervention group and at enrolling and end point of study in control group. Chest X-ray, Cardiac echo, nutritional markers, pro-brain natriuretic peptide (BNP) and cytokines were checked at the point of enrollment and the end point of study. The statistic methods included unpaired t test, Chi-square test and person correlation.

**RESULTS:** There was no significance in cardio-thoracic ratio and percentage of cardiomegaly between PD and HD patients. However, PD patients had higher percentage of LVH . Besides, PD patients had significantly higher blood pressure than HD patients. The degree of overhydration was higher in PD patients . The degree of overhydration was associated with LV mass in PD patients. Despite of intensive diet education and monitored by BCM, fluid overload, evidenced by high Pro-BNP and adiponectin levels, is still a common problem in PD patients.

**CONCLUSIONS:** Fluid overload in PD patients is presented as higher BP, more usage of anti-HT agents, and higher overhydration measured by BCM. In comparison to chest-x-ray, BCM is a more sensitive and easy tool for control of fluid overload in PD patients. However, by dietary management it is still not satisfactory to achieve the goal despite of monitored by BCM. To decrease the complications in PD patients, we should pay more attention to the fluid status.

## PUB451

**Ten-Year Experience with Fungal Peritonitis in Peritoneal Dialysis Patients: Antifungal Susceptibility Patterns in a North-American Center** Jasmin Levallois,[1] Annie-Claire Nadeau-Fredette,[1] Denis Ouimet,[1] Michel Vallee.[1] *[1]Service de Nephrologie, Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Service de Microbiologie, Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Objective : To describe the clinical and microbiologic features associated with fungal peritonitis in peritoneal dialysis (PD) patients at Hopital Maisonneuve-Rosemont (HMR), from August 1996 to July 2006.

Methods : Cases were retrieved from the microbiology laboratory culture registry. Antifungal susceptibility was determined by the CLSI M27A2 method.

Results : Among 288 PD patients (total follow-up of 7258 patient-months), 9 patients were found with fungal peritonitis. Candida spp. were identified in all of them, with a majority of non-albicans Candida species. Resistance to fluconazole, itraconazole or voriconazole was as frequent as potential resistance to amphotericin B. No isolate was resistant to caspofungin and one was resistant to micafungin. Prior bacterial peritonitis was frequent (66%). All patients had their PD catheter removed and all of them survived.

**Table 1: Antifugal susceptibility of 9 cases of fungal peritonitis (MICs)**

| Sex/Age | Species | Ampho B | Fluco | Itraco | Vorico | Caspofung | Micafung |
|---|---|---|---|---|---|---|---|
| M/75 | *C. albicans* | 0.5 | 1 | 0.12 | 0.12 | 0.12 | 0.25 |
| M/51 | *C. glabrata* | **2 R** | **16 I** | **32 R** | **32 R** | 0.5 | 0.06 |
| M/67 | *C. krusei* | 1 | **R*** | 0.5 | 0.5 | 1 | 2 |
| M/78 | *C. parapsilosis* | 0.5 | 1 | 0.12 | 0.016 | 1 | **16 R** |
| M/69 | *C. parapsilosis* | 0.125 | 2 | 0.06 | 0.008 | 0.25 | 2 |
| F/62 | *C. parapsilosis* | **2 R** | 0.25 | 0.06 | 0.016 | 0.5 | 0.06 |
| F/56 | *C. tropicalis* | 0.25 | 0.5 | 0.12 | 0.03 | 0.03 | 0.25 |
| M/35 | *C. tropicalis* | 0.25 | 0.5 | 0.25 | 0.06 | 0.12 | 0.5 |
| M/61 | *C. tropicalis* | **2 R** | 4 | **1 R** | 0.5 | 1 | 0.25 |

**R** = resistant **I** = intermediate

**R*** = *C.krusei* are assumed to be intrinsically resistant to fluconazole.

Conclusions : In our institution, fungal peritonitis in PD patients is rare. All cases were caused by Candida species. Variable susceptibility patterns were observed, which may influence the initial empirical antifungal therapy and underscore the importance of individual speciation and susceptibility testing of invasive Candida isolates

## PUB452

**Serum Parathyroid Hormone Level (PTH) Varies with Vitamin D Dosing Schedule in Peritoneal Dialysis (PD) Patients** Susie Q. Lew. *Department of Medicine, George Washington University, Washington, DC.*

Oral vitamin D therapy is used in the management of secondary hyperparathyroidism in ESRD PD patients. Time dependent changes in PTH level following oral vitamin D ingestion is not known, but is important information used to adjust vitamin D dosage.

The aim is to determine the temporal change in PTH level following oral vitamin D administration in ESRD PD patients.

Blood samples for PTH were obtained either 1 day (A), 2 days (B) or 3 days (C) after oral vitamin D ingestion for 2 consecutive months, respectively. Results are given as mean ± SD. Significant if $p \leq 0.05$ #.

Results

| (n=22) | A | B | C | A vs B | B vs C | A vs C |
|---|---|---|---|---|---|---|
| PTH pg/ml | 382±264 | 447±312 | 451±319 | p<0.04 # | p<0.93 | p<0.18 |
| calcium mg/dl | 8.8±0.5 | 8.9±0.6 | 8.7±0.7 | p<0.10 | p<0.07 | p<0.70 |
| phosphorus mg/dl | 5.5±1.4 | 5.3±1.6 | 5.3±1.3 | p<0.40 | p<0.98 | p<0.39 |

PD patients have a lower PTH level when obtained the day after oral vitamin D ingestion. PTH level trends upward with longer intervals between ingestion and blood draw.

Larger prospective studies are required to identify the optimal time to sample blood for PTH level in PD patients.

**Estimated GFR as a Measure of Dialytic Clearance in Patients on Peritoneal Dialysis** Umair M. Malik,[1] Khurram Mumtaz,[1] Manish Jain,[1] Saurabh A. Pande,[1] Kanwal Raghav,[2] Imara Dissanayake,[1] Eric J. Bloom,[1] Rasib Raja.[1] *[1]Nephrology, Albert Einstein Medical Center, Philadelphia, PA; [2]Internal Medicine, Albert Einstein Medical Center, Philadelphia, PA.*

Background: In PD patients weekly Measured Creatinine Clearance (MCC) is an estimate of dialysis adequacy and correlates with long term patient well being and mortality. Currently, besides doing a 24 hour dialysate and urine collection to calculate MCC, there is no other practical way to estimate small molecule clearance provided by dialysis from readily available blood tests.

Objective: The goal of this study was to determine whether Modification of Diet in Renal Disease (MDRD) and Cockroft-Gault estimated GFR correlates with peritoneal dialysis delivered creatinine clearance.

Methods: Measured Creatinine Clearnce (MCC) for 34 patients was calaculted by collecting 24-hour peritoneal dialysate and residual urine and checking serum creatinine the following day. In our study, values for Measured Creatinine Clearance (MCC) are presented in ml/min/1.73 m2 and were obtained by dividing the weekly creatinine clearance by 10,080 (the number of minutes in a week) and normalizing for body surface area. SPSS software was used to compare mean Measured creatinine clearance (MCC) and estimated MDRD and Cockfoft-Gault GFR.

Results: For the group as a whole, the Modiication of Diet in Renal disease (MDRD) estimated GFR predicted the Measured creatinine Clearance (MCC) from the serum creatinine reasonably well. The mean Measured Creatinine Clearance (MCC) for the study group as a whole was 6.8 +/- 3.3 ml/min/1.73 m2, and the value predicted by the Modification of Diet in Renal Disease (MDRD) equation was 5.6 +/- 2.5 ml/min/1.73 m2. The Cockcroft-Gault equation predicted a mean value of 8.5+/-3.3 ml/min/1.73 m2.

Conclusions: Modification of Diet in Renal disease (MDRD) and Cockcroft -Gault estimated GFRs approxiamate closely with Measured Creatinine Clearance (MCC) and can therefore be used as surrogate measures of small molecule clearance in patients on peritoneal dialysis. The conclusions from this study need to be prospectively confirmed in a larger cohort of peritoneal dialysis patients.

## PUB454

**Clinical Impact of Complementary Therapy of Peritoneal Dialysis and Hemodialysis in Japan; a Retrospective Multicenter Study** Yukio Maruyama, Keitaro Yokoyama, Masaaki Nakayama, Chieko Higuchi, Tsutomu Sanaka, Yoshihide Tanaka, Ken Sakai, Sonoo Mizuiri, Yasushi Otsuka, Satoru Kuriyama, Teruhiko Maeba, Hideaki Iwasawa, Toshiyuki Nakao, Tatsuo Hosoya. *EARTH (Evaluation on the Adequacy of Renal Replacement Therapy) Study Group, Tokyo, Japan.*

Background and Aims: Although complementary therapy of peritoneal dialysis (PD) and hemodialysis (HD) is widely performed to correct underdialysis and/or overhydration in Japan, its clinical efficacy is still unknown.

Methods: In this retrospective multicenter study, we recruited 106 patients (57±11 years and 77 males) changed the therapy from PD alone to complementary therapy of PD and HD.

Results: The median duration of PD alone and subsequent complementary therapy were 3.0 and 1.3 years, respectively. During the first three months after changing the therapy, body weight, serum creatinine and the dialysate to plasma creatinine ratio decreased significantly. On the other hand, hemoglobin level elevated.

Conclusions: Complementary therapy of PD and HD is an effective way to control fluid status and correct inadequate solute removal. Additionally peritoneal transport rate was thought to be improved.

Time course changes

**Infected Titanium Adapter: A Common Cause of Relapsing Peritonitis** Gautam M. Phadke, Amandeep Gill, Diptesh Gupta, Kunal Chaudhary, Madhukar Misra. *Internal Medicine, Nephrology, University of Missouri, Columbia, MO.*

Relapsing peritonitis,is defined as an episode of peritonitis with the same genus/species that caused the preceding episode of peritonitis within 4 weeks after completing the course of antibiotics. We report a case-series of five patients with relapsing peritonitis due to infected titanium adapter.

Retrospective analysis of patients with relapsing peritonitis. Patients with pre-sternal Missouri Swan-neck Catheter were analyzed.

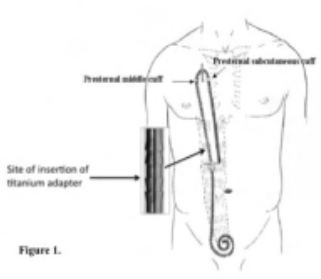

Figure 1.

All five patients had the first episode of peritonitis after 4 months of initiation of PD. In all five patients, first peritonitis presented with classical signs and symptoms of peritonitis viz. abdominal pain, cloudy effluent. Subsequent presentations were variable: asymptomatic with cloudy effluent, minimal abdominal discomfort. The commonest organism isolated was Coag. negative Staphylococcus (Epidermidis in 3/5 and Hominis is 1/5). 1 out of 5 patients had culture negative peritonitis. During relapses, none of the patients had clinical evidence of exit-site infections or subcutaneous tunnel infection. The average number of relapses prior to diagnosis of titanium adapter (TA) infection was 3. 1 patient had to be changed to HD due to catheter loss due to infection in the immediate proximity of the adapter. 4 patients successfully underwent change of TA and no subsequent episodes of peritonitis were reported for 6 months after the change of the adapter.

Infected TA is not an unusual cause of relapsing peritonitis. Non-diagnosis or delayed diagnosis of infected TA, is due to lack of awareness amongst providers who routinely take care of patients with pre-sternal catheter; and due to lack of diagnostic tools to detect this type of infection. Changing the TA, in most circumstances resolves the problem, thus preventing catheter replacement or catheter loss.Only 1 out of 5 patients was lost to HD.

**Effect of New PD Fluid Connecting System on the Prevention of CAPD Peritonitis** Young Rim Song,[1] Youngsu Kim,[1] Sung Gyun Kim,[1] Soo Jin Kim,[1] Sejoong Kim,[2] Hyung Jik Kim.[1] *[1]Department of Internal Medicine, Hallym Univ. Sacred Heart Hospital, Anyang, Gyeonggi-do, Korea; [2]Department of Internal Medicine, Gachon University of Medicine and Science, Incheon, Korea.*

Purpose: Continuous ambulatory peritoneal dialysis (CAPD) peritonitis increases mortality and morbidity of patients with peritoneal dialysis and has harmful effects on the adequacy of peritoneal dialysis. Main cause of peritonitis is contact contamination from catheter manipulation in exchanging fluid. This study was performed if the new developed transfer set (staysafe$^r$ Catheter Extension Luer-Lock, Fresenius Medical Care, Germany) could decrease the incidence of CAPD peritonitis.

Method: We compared control group with traditional transfer set and treatment group with new transfer set. Control group was enrolled patients on CAPD from January to June 2007 and treatment group was patients from May to October 2008. Follow-up period was 12 months. Primary end point was the incidence of CAPD peritonitis. Secondary end points were the incidence of exit site infection and peritonitis free survival.

Result: There were no differences of basic characteristics between 36 patients in control group and 32 in treatment group. The incidence of peritonitis in treatment group was significantly less than that in control group (0.30 vs. 0.70 episodes/year, respectively, p=0.021). The peritonitis free survival of treatment was also significantly better than that of control group (p=0.017). There was no difference in exit site infection rate between two groups (0.11 vs. 0.22, respectively, p=0.283). The causative microorganisms of both groups had no differences and the differences of the amount and duration of use of antibiotics were insignificant.

Conclusion: This study suggests that the use of the new transfer set could decrease the incidence of CAPD peritonitis and increase peritonitis free survival time.

**Barriers to International Peritoneal Dialysis Evidence-Based Medicine and Quality Practices: Implications for Guideline Development** Manish M. Sood,[1] Mauro Verrelli,[1] Gemini Tanna,[2] Paul Komenda,[1] Claudio Rigatto,[1] Daniel Schwartz.[3] *[1]Nephrology, University of Manitoba, Winnipeg, MB, Canada; [2]Nephrology, University of Toronto, Toronto, ON, Canada; [3]Nephrology, University of British Columbia, Abbotsford, BC, Canada.*

**Introduction:** Little is known regarding barriers to guideline implementation in the Nephrology community. We set out to identify barriers, specifically in evidence-based practice and measurement of quality indicators, in an international cohort of peritoneal dialysis (PD) Practioners.

**Methods:** Subscribers to an online nephrology education site (Nephrology Now) were invited to participate in an online survey. Nephrology Now is a non-profit, monthly mailing list that highlights clinically relevant articles in Nephrology. 475 physicians supplying PD care participated in an online survey assessing their use of evidence-based medicine (EBM) and continuous quality indicators (CQI) in their PD practice. Ordinal logistic regression was utilized to determine relationships between baseline characteristics and EBM and CQI practices.

**Results:** The majority of physicians were Nephrologists (89.7%). 50.4% worked in academic centres and 77.3% utilized a personal digital assistant (PDA) device. The geographic regions of our respondents were 13.5% Canadian, 34.5% USA, 19.4% European, 4.4% Australian, 5.3% South American, 10.7% African and 12.2% Asian. Adherence to PD clinical practice guidelines were generally strong however lower adherence was associated with countries with lower total health care expenditure as percentage gross domestic product, not using PDA, length of physicians practice and smaller (<20 patients per centre) PD practice.

**Conclusions:** International variation in guideline adherence may be influenced by a country's health care expenditure, physicians PDA use and experience and size of PD practice. These barriers may impact future guideline development and implementation

**A Rare Cause of Peritoneal Dialysis Related Peritonitis: Leclercia Adecarboxylata** Christin M. Spatz, Apurva Lapsiwala, William Brian Reeves. *Nephrology, Hershey Medical Center/PSU, Hershey, PA.*

A 38 year old male with end-stage renal disease on peritoneal dialysis secondary to diabetic nephropathy and prior failed renal transplantation presented with abdominal pain of two days duration. He was afebrile and his abdominal exam was remarkable for diffuse tenderness. Peritoneal fluid was cloudy with 3,499 nucleated cells 94% neutrophils. Fluid culture grew *Leclercia Adecarboxylata* and *Acinetobacter Baumanii*. *L. adecarboxylata* was pansusceptible to Cephalosporins and Aminoglycosides. *A. baumanii* was resistant to Cefazolin but susceptible to Cefepime and Aminoglycosides. He was treated with intraperitoneal Cefepime and 72 hours later his cell count had decreased to 1,943 nucleated cells, however, the patient had not clinically improved. Intraperitoneal Gentamicin was then added to Cefepime. After 48 hours, his abdominal pain resolved. Repeat fluid testing showed only 62 nucleated cells and peritoneal culture showed no growth. He was discharged home on hospital day 6 with intraperitoneal Gentamicin and Cefepime to complete 21 days of antibiotics.

*Leclercia adecarboxylata* is a gram negative bacillus usually found in the setting of polymicrobial infections. The rarity of infection alone may suggest *Leclercia* requires other pathogens to cause clinically significant disease. Literature review shows most cases of *L. adecarboxylata* are pan-susceptible. Although our patient's cultures were initially susceptible to beta lactams, it is likely resistance occurred leading to treatment failure. Our case had a good outcome with early broadened antibiotic coverage for presumed beta-lactamase resistance. This organism, although infrequently isolated, may represent therapeutic challenges in the future if not identified early and treated aggressively.

**Nephrologists' Perceptions Regarding the Eligibility Criteria for Peritoneal Dialysis (PD): A Conjoint Analysis Study** Hisako Yoshida,[1] Kazuhiko Tsuruya,[1] Shunsuke Yamada,[2] Toshiaki Nakano,[2] Masatomo Taniguchi.[2] *[1]Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

**Purpose**: The purpose of this study was to investigate nephrologists' perceptions regarding the eligibility criteria for PD.

**Methods:** We developed three types of questionnaires that can reveal the perception of the nephrologists as to PD using conjoint analysis (CA); 1) the eligibility criteria for PD, 2) the nephrologists' cognition for ''high self-care ability'' and 3) factors that determine ''clinical status of PD patients'' as good. These questionnaires were answered by 10 nephrologists (male: 9, age 35±13 years). The model of ''the eligibility criteria for PD'' was composed of 16 profiles of hypothetical patient with end-stage renal disease. They were designed to have seven characteristics (i.e. sex, age, diabetic status, weight, living situation, patients' compliance with treatment, cardiac function), as was referred to previous report (Thamer et al, Am J Kidney Dis, 2000). The following question was asked in each hypothetical patient; ''Do you recommend PD for this patient?''. Similarly,

we developed the other two questionnaires using the Self-Management Capacities Scale (Su et al. J Adv Nurs, 2009).

**Results:** CA revealed that ''compliance with treatment'' was the most important factor that affects eligibility criteria for PD, but failed to reveal the dominant factors regarding ''self-care ability'' that influence nephrologists' perception in the dialysis modality selection. However, as to the questionnaire of ''clinical status of PD patients'', the factors concerning ''fluid control'' (e.g. blood pressure level, sodium intake and BNP level) affected the nephrologists' perceptions in the assessment of PD patients.

**Conclusion:** This study revealed that the nephrologists' perception regarding the eligibility criteria for PD was most influenced by ''compliance with treatment''. In the future study, we want to clarify the association between the nephrologists' perceptions and the clinical practice in the actual patients.

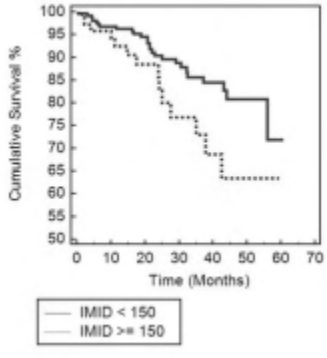
**Index of Mortality Bound to the Inflammatory Status in Dialysis (IMID): A New Predictive Index of Mortality in Dialysed Patient** Dumoulin Alexandre. *Nephrology, Centre de Dialyse, Beziers, France.*

**Introduction**: In spite of the progress in the hold in charge of the dialysis patients, the mortality of the dialysis patients remains always extremely elevated.The main objective of this survey is to determine an index of mortality clean to the dialysis based on characteristic elements of the chronic inflammation and notably on the ß2 Microglobulin (ß2M), raised in routine in dialysis allowing to define the IMID.

**Material and methods**: The survey rests on the assessment of nutritional and inflammatory parameters at a population of incidental dialysis patients on the period of the 01.01.2005 to the 01.01.2010. From these parameters: Albumin, Pre-albumin, C reactive protein, Orosomucoid and ß2M, the calculation of the IMID has been achieved to the hold in charge of the patient and way quarterly $IMID_{Max}$. The dialysis treatment (haemodialysis HD or haemodiafiltration HDF) prescribed has been considered like a therapeutic in intension to treat.

**Patient:** The survey is about 605 patients distributed in 229 women and 376 men whose respective middle age (year) is of 72.1±13.1 and 69.8±15.3. On the set of the incidental patients, 133 deceased patients permitted to determine the Lti (the life span).

**Results**: More the IMID is raised, the Lti more is short ($p<0.001$). The actuarial curve shows a meaningful difference between the patients having to the entry an IMID superior to 150 ($p<0.03$).



Among the deceased patients, the IMID is representative of neoplasy or an inflammatory death. Difference doesn't exist between both dialysis modality (HD vs HDF) concerning the $IMID_{Max}$ and the Lti for the deceased patients.

**Conclusion :** The IMID is an index of choice in the prognosis of mortality carriers of neoplasy or having an inflammatory syndrome (like infection). The HDFdoesn't bring an improvement in the prognosis of mortality.

**Rat Bladder as a Model for Oxidative Damage from Intravenous Iron (IVFe) Preparations** George R. Bailie,[1] Hsin Li,[2] Amy B. Pai,[1] Robert M. Levin.[2] *[1]Albany Nephrology Pharmacy Group, Albany College of Pharmacy & Health Sciences, Albany, NY; [2]Department of Pharmaceutical Sciences, Albany College of Pharmacy & Health Sciences.*

Background: Many serum biomarkers have been used to examine oxidative stress associated with IVFe. The rat bladder is sensitive to oxidative damage and might be a sensitive model. We examined bladder contractility responses after IVFe.

Methods: Five Groups of 6 adult SD rats received 1 or 5 mg/kg IVFe or saline intravenously each week for 4 doses. IVFe included iron sucrose (IS), ferric gluconate (FG), high MW iron dextran (ID), ferric carboxymaltose (FCM) and ferumoxytol (FMX). Animals were sacrificed 7 days after the last dose, serum obtained via cardiac puncture and 2 full thickness bladder strips were placed in baths containing Tyrode's solution for contractility studies. Strips were successively stimulated with 2, 8 or 32 Hz field stimulations (80 V, 1 msec duration; acts via synaptic transmission), carbachol (10 mM; acts via direct muscarinic cholinergic stimulation) and KCl (120 mM; acts via direct muscle depolaration - does not need synaptic transmission or receptor stimulation). All responses recorded as mg tension/100 mg strip weight.

Results: At 1 mg/kg, no changes in bladder weight were noted in any treatment group. There was an increased bladder weight at 4 weeks only in the FG 5mg/kg group vs. control ($p<0.05$). Contractile response to carbachol and KCl were significantly reduced in FG group and showed dose-response activity (Table shows 5 mg/kg responses only).

Contractile response (mg tension/100 mg strip weight) after 5 mg/kg IVFe doses

| Stimulus | Control | IS | FCM | FMX | ID | FG |
|---|---|---|---|---|---|---|
| 2 Hz | 15.3 | 12.1 | 12.3 | 13.4 | 12.7 | 14.3 |
| 8Hz | 39.2 | 35.7 | 33.3 | 39.3 | 40.0 | 39.1 |
| 32 Hz | 57.4 | 51.2 | 45.1 | 54.2 | 57.9 | 52.4 |
| Carbachol | 41.7 | 41.8 | 31.4 | 40.4 | 37.4 | 42.9^ |
| KCl | 23.3 | 22.2 | 22.1 | 27.6 | 27.0 | 29.7* |

^$p<0.05$ vs control. *$p<0.05$ vs FG 1 mg/kg

Conclusions: FG increased bladder mass and has a dose-dependent negative effect on the contractile responses on bladder smooth muscle vs. other IVFe products following carbachol and KCL. Future studies will investigate this mechanism further and determine if this can be a test for the oxidative properties of IVFe products.

**Assessment of CRP and ESR Measurement as Inflammatory Markers in ESRD Patients with Hyperferritinemia** Roger F. Carbajal Mendoza, Hemant Magoo, Donald I. Baumstein, Alf M. Tannenberg. *Nephrology, Metropolitan Hospital Center/New York Medical College, New York, NY.*

Introduction: There is no perfect marker for occult inflammation in patients on chronic hemodialysis. The serum measurements of inflammatory markers may help to determine whether the presence of hyperferritinemia in dialysis patients is due to iron overload or inflammation. Currently, no consensus exists regarding which marker should be used to designate inflammatory states versus non-inflammatory states in patients with end stage renal disease (ESRD). Considering C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) as markers of inflammation and erythropoeitin (EPO) hyporesponsiveness as a consequence of inflammation, our objective was to determine if high levels of CRP and ESR, as well as hyperferritinemia correlate with high level of erythropoeitin resistance index (ERI) as an indicator of poor response to EPO.

Method: This observational study included 50 chronic hemodialysis patients. We measured hemoglobin, hematocrit, serum albumin, transferrin saturation, ferritin, CRP, ESR in monthly laboratory evaluation. The ERI was calculated as weekly weight adjusted dose of EPO divided by the hemoglobin level. The average age was 52.6 years and 62% of patients were male. The ERI average was 12.9. The average ferritin, CRP and ESR levels were 803 ng/ml (range 21-1650 ng/ml), 12.3 mg/L (range 0.07- 88.6 mg/L), 22.2 mm/hr (range 1-60 mm/hr) respectively.

Results: We did not find a linear correlation between either CRP and ERI ($R^2$: 0.0005) or ESR and ERI. In addition there was no clinically significant correlation between ferritin and ERI ($R^2$: 0.1127), Transferrin saturation and ERI ($R^2$: 0.133). There was no correlation between ESR and Ferritin ($R^2$: 0.0493), nor CRP and Ferritin ($R^2$: 0.0033).

Conclusion: The data presented shows no correlation between CRP or ESR with ferritin as indicators of inflammation in our chronic hemodialysis patients. This suggests that higher levels of ESR and CRP may not be helpful to differentiate hyperferritinemia due to inflammation versus iron overload.

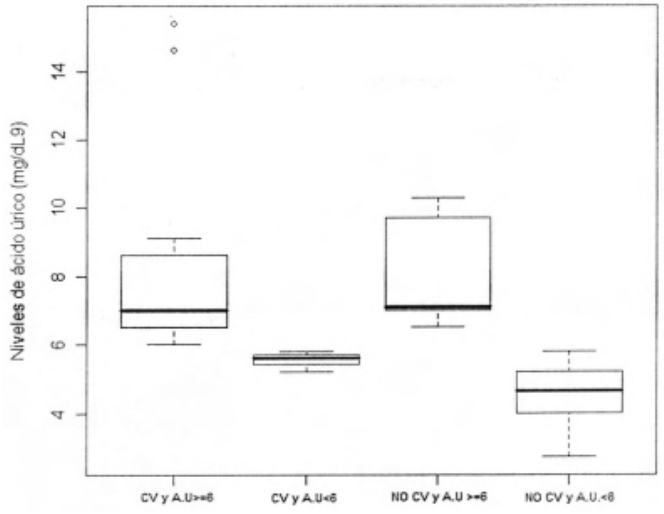
**PUB463**

**Uric Acid, Vascular Calcification and Atherosclerosis in Chronic Renal Disease** Luis Gerardo D'Marco, Dayana J. Olmos. *Nephrology, Ruiz y Paez University Hospital, Bolivar, Venezuela.*

Clinic and epidemiological studies have shown that cardiovascular (CV) disease is related to an increase in the mortality rate of patients with chronic renal disease (CRD). Uric acid (UA) is strongly associated with renal disease and CV risk, and its levels are especially increased in people with hypertension or patients undergoing dialysis. Interest in the association between UA levels and CV risk has been renewed in recent years. The mechanism by which UA can inflict damage is still unknown. **OBJECTIVE**: The purpose of this research was to relate the presence of vascular calcification (VC) and atherosclerosis studied by carotid echography, UA levels and other laboratory parameters in 50 patients with CRD undergoing dialysis. **METHODS:** Fisher Test was used to determine whether or not the differences were significant, which was decided based on p–value obtained in the test (<0.05). **RESULTS**: The age of patients averaged 45.34 years (SD: ± 17.2) and most of patients were female (56%). The predominant dialysis method was hemodialysis (52%) for an average period of 34.96 months (SD: ± 35.48). The average laboratory test values were: hemoglobin (8.6 g/%), urea (141.2 mg/dl) (p=0,012), creatinine (7.4 mg/dl), UA (6.9 mg/dl) (p=0.040), total cholesterol (188.1 mg/dl), triglycerides (206.5 mg/dl), albumin (3.4 mg/dl), calcium (8.6 mg/dl), phosphorus (6.5 mg/dl), and Ca x P product (55.4). VC was observed in 56% of patients; 46% had echographic criteria for atherosclerosis (intima-media thickness ≥ 0.9 mm) with an overall average of 0.89 mm (SD: ±0.28) (p=0.0006), being higher in patients with hypertension and diabetes Mellitus; this group also posed an increased predisposition to atherosclerosis and VC (p=0.01).



**CONCLUSIONS**: According to these results, we conclude that UA levels over 6 mg/dl pose an increased risk of VC and adverse CV events.

Disclosure of Financial Relationships: nothing to disclose

**PUB464**

**Influence of CKD, RRT, Inflammation and Proteolytic Enzymes on the Development of Atherosclerosis in Carotids** Wieslaw Klatko,[1] Stanislaw Niemczyk,[2] Katarzyna Szamotulska,[4] Tomasz Wisniewski,[1] Leszek Paczek.[3] *[1]Department of Nephrology, Regional Specialistic Hospital, Ciechanow, Poland; [2]Department of Nephrology, Military Medical Institut of Warsaw, Warsaw, Poland; [3]Department of Immunology, Trnsplantology and Internal Medicine, Medical University of Warsaw, Warsaw, Poland; [4]Department of Epidemiology, National Research Institute of Mather and Child, Warsaw, Poland.*

Atherosclerosis vascular disease is the most frequent complication in pts with chronic kidney desease undergoing hemodialysis and peritoneal dialysis. Intima media complex (IMC) measuring has been the non-invasive imaging test for evaluation of cardiovascular risk. Little is known how proteolytic enzymes activites influence on development of atherosclerosis.

The study was carried out on 60 pts in the following groups:

Group1 (n-30) undergoing HD

Group2 (n-10) undergoing PD

Group3 (n-10) pts with CKD without dialysis

Group4 (n-10) control group

Methods:

IMC of common carotid artery was measured bilaterally at the level 1cm from the bulb, two in each side on the far wall. The mean IMC was recorded as the average of the left and right IMC.

Blood samples were taken in the morning before dialysis, for pts undergoing hemodialysis before dialysis.

Results:

Medians

| Parameters\Groups | HD | PD | CKD | Controls |
|---|---|---|---|---|
| Collagenase mcU/ml | 36.89* | 51.89** | 35.83* | 30.59 |
| Cathepsin B mcU/ml | 45.83** | 45.67** | 37.63* | 21.43 |
| Elastase mcU/ml | 45.21** | 42.01* | 40.26* | 32.38 |
| CRP mg/l | 6.72* | 6.43 | 2.00 | 1.44 |
| IMC | 0.75*** | 0.65*** | 0.55 | 0.50 |

*)p< 0.05, ** )p<0.01, ***p)<0.001 for comparison to control group (t-test after logarithmic transformation)

Conclusion:

Relation between development of atherosclerosis in carotids and age was observed in all groups treated with dialysis. IMC among patient undergoing hemodialysis and peritoneal dialysis is higher and more related to age than among pts treated without dialysis and control group. Duration of RRT, urea, creatinine, albumin, cholesterol, TGL, troponin I serum concentration were not correlated with IMC.It has been observed that pts undergoing HD, PD and with CKD without dialysis have higher elastase, collagenase, cathepsin B activity and higher CRP concentration.

Disclosure of Financial Relationships: nothing to disclose

**Dry Weight, Pre-Dialysis Systolic Blood Pressure (SBP) and Intima-Media Thickness (IMT) Predict Pre-Dialysis Brain Natriuretic Peptide (BNP) Levels** Paolo Lentini,[1-2] Luca Zanoli,[3] Valentina Pellanda,[1] Vincenzo Catena,[1] Alexandra Chronopoulos,[1] Massimo De Cal,[2] Claudio Ronco,[4] Marco Baiocchi,[1] Roberto Dell'Aquila.[1] *[1]Nephrology-Intensive Care Unit, St. Bassiano Hospital, Bassano Del Grappa (Vi), Italy; [2]University of Padua, Padua, Italy; [3]Internal Medicine, University of Catania, Catania, Italy; [4]Nephrology, St Bortolo Hospital, Vicenza, Italy.*

Background: High BNP levels are correlated with cardiovascular (CV) damage and poor outcomes in hemodialysis (HD) patients. Aim: To determine the independent predictors of vascular damage in a population of chronic HD patients. Materials and Methods: All 74 patients enrolled in our HD program were included. Median pre-dialysis BNP (183 pg/mL) was used as a cut-off to create two subgroups. Hematological and biochemical variables were obtained by a pre-dialysis blood draw. All patients underwent a doppler of the supra-aortic blood vessels 30-45 days before BNP analysis. All dopplers were executed by the same operator. Student t test and chi-square test were used for comparison. Univariate predictors of BNP were studied in multivariate logistic regression analysis. The model was tested in ROC curve analysis. Results:Univariate analysis: Patients with BNP>183pg/ml had significantly lower Hgb, weight and dry weight,higher SBP,pulse pressure,IMT,carotid stenosis and CV events. Logistic regression analysis: Dry-weight(1kg increase,OR 0,93,95%CI 0.88-0.98,p<0.05), pre-dialysis SBP (1mmHg increase,OR 1.03,95%CI 1.01-1.06, p<0.05),and IMT (0.1mm increase, OR 1.21, 95%CI 1.04-1.40, p<0.05) were selected as independent predictors of pre-dialysis BNP>183 pg/ml.

Table 1.Logistic regression analysis for BNP pre dialysis > 183 (pg/ml)

| | OR | 95.0% CI | p |
|---|---|---|---|
| Dry weight (Kg) | 0,925 | 0,876 0,977 | 0,005 |
| SBP pre dialysis (mmHg) | 1,032 | 1,007 1,057 | 0,011 |
| IMT (0.1 mm) | 1,208 | 1,041 1,402 | 0,013 |

Hosmer-lemeshow Goodness-of-Fit test was not significant (p=0.264), Nagelkerke R-square was 0.33. The Area under ROC curve for the selected model was 0.78 (95%CI 0.67-0.88, p<0.0001). Conclusions: Dry weight, pre-dialysis SBP and IMT predict higher levels of pre-dialysis BNP.

**The Effluent Free Radical Level Is a Potential Predictor of Technique Failure and Mortality in Peritoneal Dialysis Patients** Hiroshi Morinaga,[1] Hitoshi Sugiyama,[2] Keiichi Takiue,[1] Masashi Kitagawa,[1] Tatsuyuki Inoue,[1] Shinji Kitamura,[1] Yohei Maeshima,[1] Hirofumi Makino.[1] *[1]Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Center for CKD and Peritoneal Dialysis, Kayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

INTRODUCTION AND AIMS: Residual renal function (RRF) is associated with oxidative stress and survival in peritoneal dialysis (PD). This study investigated the association between oxidative stress and renal anemia, RRF and prognosis in PD.

METHODS: The levels of free radical in the overnight dwell of peritoneal effluent from 45 patients were determined by electron spin resonance (ESR) spectrometry using α-phenyl-N-tert butylnitrone (PBN) as a spin trapping agent. The levels of hemoglobin, plasma level of β2-microglobulin (β2MG), the effluent level of 8-hydroxy-2´-deoxyguanosine (8-OHdG), the daily urine volume and adequacy of dialysis at the baseline were also measured. The effect of these factors on the composite endpoint (withdrawal from PD or mortality) in patients followed for twenty-four months was analyzed.

RESULTS: A significantly positive correlation was observed between the level of effluent free radicals (EFR) and plasma β2MG (R = 0.3708, P = 0.0122) or effluent 8-OHdG (R = 0.3676, P = 0.0130), and a negative correlation between the level of EFR and hemoglobin (R = -0.3393, P = 0.0226), daily urine volume (R = -0.3335, P = 0.0252) or re

Disclosure of Financial Relationships: nothing to disclose

**PUB467**

**Anti-Inflammatory Effects of Oral Paricalcitol in Hemodialysis Patients** Juan F. Navarro,[1,2] Carmen Mora,[2] María L. Méndez,[1] Mercedes Muros,[3] Javier García.[1] *[1]Nephrology Service, University Hospital Nuestra Señora de Candelaria (HUNSC); [2]Research Unit, HUNSC; [3]Clinical Biochemistry, HUNSC, Santa Cruz de Tenerife, Spain.*

Hemodialysis (HD) patients are affected by an inflammatory syndrome, which has been related to diverse complications. Moreover, inflammation is a strong factor in the development and progression of atherosclerotic disease. During the last years, a growing interest has developed related to the pleiotropic effects of vitamin D in CKD. Paricalcitol, a selective vitamin D receptor (VDR) activator, has demonstrated immunomodulatory effects in experimental studies. However, data clinical data about this effect are very scarce. The aim of the present study is to analyze in HD patients the anti-inflammatory effects of oral paricalcitol.

Eighty patients were initially considered for inclusion: 55 were excluded and 25 subjects (mean age, 62 years; mean HD time, 12 months; 56% diabetics) were included in the study. All of them were previously treated with intravenous calcitriol, and after a 4-weeks wash-out

period, oral paricalcitol (1 µg/day) was administered for 12 weeks. Baseline serum calcium (Ca), phosphorus (P), Ca-P product, and iPTH were 9.1 mg/dl, 4.8 mg/dl, 44.2 $mg^2/dl^2$ and 317 pg/ml, respectively. At the end of the study, these parameters did not change, except for iPTH, which decreased to 302 pg/ml ($p<0.05$). Serum concentrations of high-sensitive C-reactive protein (CRP), interleukins (IL)-1,6 and 10, and tumor necrosis factor-alpha (TNFa) were measured. After paricalcitol administration, serum IL levels did not change. However, CRP and TNFa experienced a significant decrease: 5.9±2.3 vs 7.2±3.4 mg/l ($p<0.001$), and 7.1±2 vs 7.6±2.6 pg/ml ($p<0.05$), respectively. The percent decrease of these parameters were 4% and 14%, respectively, respect to their basal values. The ratio between pro- (IL-1, IL-6 and TNFa) and anti-inflammatory (IL-10) cytokines experienced a beneficial change: IL-6/IL-10 ($p=0.05$) and TNFa/IL-10 ($p=0.01$). In conclusion, oral paricalcitol administration to HD patients is associated with modulation of inflammatory process, specifically with a reduction of CRP and TNFa, as well as an improvement of IL-6/IL-10 y TNFa/IL-10 ratios.

Disclosure of Financial Relationships: nothing to disclose

**Comparative Study between the Inflammatory and Metabolic Profile of Peritoneal Dialysis (PD) Versus Hemodialysis (HD)** Karina F. Pinheiro, Victor Sato, Bruno C. Silva, Márcia Fernanda Arantes Oliveira, Hugo Abensur. *Nephrology, Hospital das Clinicas - University of São Paulo School of Medicine, Sao Paulo, Brazil.*

Fibrinogen which is involved in the coagulation system and leptin which is directly correlated to the nutritional state and to body total fat are related to higher inflammatory state and consequently higher cardiovascular(CV)risks.To evaluate metabolic characteristics and inflammatory markers through fibrinogen, leptin and the C-reactive protein(CRP)in patient's maintained PD and HD.We studied 63 prevalent patients in dialysis at only one university center(48 patients on HD and 15 on PD).Fibrinogen, leptin, lipids, albumin and CRP were compared between the two groups.Statistic analyze between 2 groups was carried using chi-square test for qualitative variables and t-test or Mann-Whitney for quantitative variables with normal distribution or not, respectively.Clinical-laboratorial characteristics of the patients on PD compared to patients on HD were as follow: age 48±18 vs. 47±18($p>0.05$); hypertension 100% vs 69%($p=0.013$);obesity evaluated through body mass index(BMI) 25.67±6.9Kg/$m^2$ vs 22.39±3.9Kg/$m^2$($p = 0.012$); diabetes 27% vs. 4%($p=0.01$); fibrinogen 511±141mg/dL vs. 380±115mg/dL($p=0.001$); CRP 14.18±13.82 vs 4.18±5.01($p < 0,001$); albumin 3.87±0.46g/dL vs 4.16 ± 0.32g/dL($p = 0.011$) and hemoglobin 10.3±1.15g/dL vs 11.5±1.67g/dL($p < 0.001$). Leptin median was 35,6ng/mL on PD and 8,2ng/mL on HD patients($p=0.006$).The lipid profile among patients maintained PD and HD were: cholesterol 190±46mg/dL vs 154±36mg/dL($p = 0.003$); LDL 104.4±41.3mg/dL vs. 83.9±28.7mg/dL($p=0.035$); HDL 54.8±22.2mg/dL vs. 42±15.1mg/dL($p=0.014$) and triglycerides 156.8±115.2mg/dL vs. 140.8±61.8mg/dL($p>0.05$).There was no significant statistic difference regarding the number of CV events, nor as to the Kt/V standard.Statins use among patients maintained PD and HD was 53% and 19%($p=0.008$) .Patients maintained PD showed higher levels of fibrinogen, leptin and CRP when compared to patients on HD.Therefore, as these subjects were more hypertensive and presented worse lipid profile and higher BMI, it can be attributed to a higher inflammatory status and worse volume control.

**Arteriovenous Fistula Failure: Role of Cardiovascular Structure and Function** Zoe C. L. Pittman,[1] Shvan Korsheed,[1] Stephen G. John,[1] Chris W. McIntyre.[1,2] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]University of Nottingham, United Kingdom.*

Primary and secondary arteriovenous fistula (AVF) failure is a major barrier to increasing AVF utilisation. Previous observational studies of access failure have largely focussed on demographic factors, partially describing patients likely to suffer thrombotic loss of AVFs. Therefore, we have undertaken a further detailed study of access failure as a function of *pre-operative* vascular anatomy and cardiovascular performance (local and systemic).

We studied 43 patients, two weeks prior to AVF formation and followed up for at least a year. In addition to pre-operative vascular mapping, demographic and biochemical data, patients underwent a comprehensive cardiovascular assessment including transthoracic echocardiography, pulse wave analysis and pulse wave velocity (PWV). Factors associated with failure were identified by multivariate analysis.

Primary failure occurred in 13/43 patients, secondary failure occurred in 11/30 during the subsequent follow up period of 17.8 (± 8.8) months. Arterial diameter and arterial blood flow predicted primary failure ($r^2 = 0.254$, OR 1.096 (1.018–1.179) $p=0.004$ and $r^2=0.247$, OR 1.033 (1.004–1.062) $p=0.005$ respectively). The only other predictor was carotid radial (CR) PWV ($p= 0.052$). For secondary failure CR-PWV and carotid femoral PWV were tending to significance ($p=0.059$ and $p=0.065$ respectively). Despite a significant degree of cardiac contractile dysfunction (mean LVEF 44.9 ± 12.5%), no measures of systemic or central CV performance were found to be associated with risk of access failure.

Primary and secondary AVF loss is dependant on peripheral vessel size and viscoelastic properties, with reduced upper limb arterial compliance being associated with a reduced propensity for access failure. These data do not support the contention that poor cardiac contractile status is likely to result in failure to establish native vascular access.

**A Bioimpedance Study Assessing the Relationship between Inflammation and Body Composition in a Haemodialysis Population** Siddhesh Mukund Prabhavalkar, Julie E. Browne, Ying Kuan. *Renal Unit, Altnagelvin Area Hospital, Londonderry, United Kingdom.*

Introduction

Patients on maintenance haemodialysis (MHD) have excess morbidity and mortality in comparison to general population. The development of malnutrition, inflammation, and atherosclerosis (MIA) syndrome has been postulated to be a major reason for this. MHD is also associated with changes in body composition, with decrease in lean body mass, which may be a consequence of MIA. Multifrequency bioimpedance represents a novel and an accurate way of assessing body composition in this population. This is a cross-sectional study assessing the relationship between inflammation, as measured using C reactive protein and body composition.

Method

Data was collected from 54 patients on maintenance haemodialysis which included Gender, Age, duration on dialysis, CRP, albumin, total cholesterol, and HDL cholesterol. Bioimpedance measurements (% skeletal muscle mass (%SMM), % body fat mass (%BFM)) were obtained prior to dialysis from the subjects. Statistical analysis was performed using Medcalc Stat package.

Results

Data was obtained from 54 patients (34 males and 20 females). Mean age was 62.1 years +\- standard deviation (SD) 14.98. CRP positively correlated with %BFM ($p=0.005$, $r^2=0.14$) whilst negatively correlated with %SMM ($p=0.003$, $r^2=0.16$). In multiple regression model, CRP was shown to be independently associated with %BFM ($p=0.0069$) as well as %SMM ($p=0.0083$). However duration on dialysis, albumin, age of subjects and total cholesterol were not shown to be associated with body composition indexes.

Conclusion

The results of this cross-sectional study suggest that body composition of patients on MHD may be affected by inflammation. These changes can be postulated to be part of the phenomenon of MIA, and suggests that interventions that reduce inflammation and improve lean muscle mass may serve to improve prognosis of patients on dialysis. This study also supports the use of bioimpedance as a measure of nutrition, providing information on MHD patients independent of other clinical biomarkers.

**Effect of Atorvastatin on Cardiac Troponin-T and High Sensitivity C-Reactive Protein in Maintenance Hemodialysis Patients** John White,[1] Harold M. Szerlip.[2] *[1]Medicine, Medical College of Georgia, Augusta, GA; [2]Medicine, University of Arizona, Tucson, AZ; [3]Augusta, GA.*

In asymptomatic dialysis patients, elevated cardiac troponin T (cTNT) and hs-CRP levels are associated with increased cardiovascular events and may represent modifiable risk factors. We postulated that low level elevations in cTnT were related to chronic inflammation. The purpose of this study was to investigate the association of cTnT and hs-CRP over time in maintenance hemodialysis (HD) patients and to ascertain whether treatment with an HMG-CoA reductase inhibitor would reduce both cTnT and hs-CRP.

Methods: We conducted a prospective cohort study enrolling 42 asymptomatic HD patients at 2 outpatient dialysis facilities. Levels of cTnT and hs-CRP were analyzed at baseline, then weekly for 4 weeks to determine variability. Patients with elevated cTnT >= 0.1 ng/ml were then treated with atorvastatin x 6 months. The relation between clinical factors, cTnT, and hs-CRP were assessed as well as the effect of atorvastatin on final cTnT and hs-CRP.

Results: At baseline (n = 42), cTnT was detectable in 89% and 28.6% (n = 12) had cTnT >= 0.1. Measured levels of hsCRP (n = 31) were low risk in 29% (< 3.1 mg/L), high risk in 42% (3.1-10), and markedly elevated (>10) in 29%. Individual variability for cTnT was low with 80% of values within 0.02 from the mean. Contrastingly, hs-CRP individual coefficient of variation averaged 42%. There was no relation between cTnT and hs-CRP. Age (r = 0.33) and time on dialysis (r = 0.42) were moderately related to cTnT. Atorvastatin treatment had no effect on cTnT or hs-CRP levels in 8 patients.

Conclusions: Elevations in cTnT in patients on chronic hemodialysis do not vary significantly over time. In contrast there appears to be marked variation in hs-CRP indicating varying degrees of inflammation. There is no relationship between inflammation as assessed by hs-CRP and elevations in cTnT. Atorvastatin had no effect on either of these biomarkers.

**Immediate Inhibitory Effect of Acidic Electrolyzed Water on Respiratory Tract Infection (New Influenza H1N1pdm Virus) and Urinary Tract Infection In Vitro** Tokunori Yamamoto,[1] Masahiko Katayose,[2] Kyoichiro Yoshida,[2] Nobuo Achiwa,[2] Naoto Sassa,[1] Norihisa Matsukawa,[1] Masashi Katoh,[1] Yasushi Yoshino,[1] Kazuo Mizutani,[1] Ryohei Hattori,[1] Momokazu Gotoh.[1] *[1]Urology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Advanced Technology Development Section, Hoshizaki Electric Co., Ltd., Toyoake, Japan.*

Because of their low immunity, chronic kidney disease (CKD) patients have significantly higher risks of death and complications caused by infection than non-CKD patients. Urology department providing dialysis treatment, kidney transplantation, and urinary tract infection treatment is one of the departments where many compromised hosts can stay or visit as either inpatients or outpatients. Although vaccination is recommended to prevent pathogens with higher infection risks, CKD patients are less capable of obtaining and maintaining antibodies and likely to lose immunity earlier than healthy individuals.

In this study, acidic electrolyzed water generated by electrolysis technology (hereinafter called "electrolyzed water (EW)") was examined in vitro for respiratory tract infection (California/4/2009 (A-H1N1) pdm, obtained from US CDC) and urinary tract infection. EW was added with virus suspension and inoculated into embryonated eggs. The hemagglutinating properties observed after 2 days of incubation were used to calculate 50% egg-infective dose.

The experiment showed that EW (pH 2.7, available chlorine concentration 20 ppm) effectively inhibited more than 99.99% of H1N1 within 10 seconds. Similar efficacy was also observed for urinary tract infection. Low pH of EW has high and instant sterilizaiton effect against clinical isolated drug resistance bacterium (Staphylococcus aureus (MRSA), Enterococcus faecalis, Pseudomonas aeruginosa, Acinetobacter baumannii). It was suggested that EW is effective in preventing infection in urology clinics and hospitals apt to have many compromised hosts.

**Elevated Interleukin-18 in End-Stage Renal Disease Compared to Healthy Controls and Chronic Kidney Disease** Kenneth Yong. *Nephrology, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia.*

***Introduction***

Interleukin(IL)-18 is an inflammatory cytokine with pro-atherogenic properties that has been implicated in the pathogenesis of atherosclerosis and is an independent predictor of cardiovascular death in the general population. End-stage renal disease (ESRD) is a state of chronic inflammation characterised by accelerated atherosclerosis. Although serum IL-18 levels have been demonstrated to be elevated in dialysis-dependent ESRD patients, serum IL-18 level in chronic kidney disease (CKD) patients remains unknown.

***Methods***

This was a cross-sectional study of healthy controls, stage 3-4 chronic kidney disease (CKD) patients, and stage 5 pre-dialysis CKD patients. Fasting serum levels of IL18 were measured using a commercially available ELISA method (MBL Co, Ltd) with level of detection of 7.5pg/mL.

***Results***

Mean age was similar in all 3 groups. Serum levels of IL18 were significantly elevated in stage 5 CKD patients (n=15, mean±SD 413.5 ± 176.1 pg/mL) compared with stage 3-4 CKD patients (n=20, 260.8 ± 77.8 pg/mL; p=0.006) and healthy controls (n=20, 258.7 ± 132.6 pg/mL; p=0.005). IL18 levels were similar between the CKD and healthy control group (p=0.949).

***Conclusion***

Serum IL18 levels were significantly elevated only in advanced CKD patients and may in part explained the greater risk of atherosclerosis in the group of patients.

**Spondylodiscitis in Hemodialysis Patients – Still a Risk in an Era of Fistulas and Catheter Replacement** Masoud Afshar,[1,2] Robert F. Reilly.[1,2] *[1]Medicine, VA North Texas Health Care System, Dallas, TX; [2]Medicine, UT Southwestern Medical Center at Dallas, Dallas, TX.*

Spondylodiscitis (infection of the vertebral disc and adjacent vertebral bodies) is a devastating complication of access-related bacteremia in hemodialysis patients. We report a series of 13 patients seen in our unit with spondylodiscitis over the past 10 years. The most common presentation was back pain with localized tenderness over the spinal segment involved (11/13). The majority of patients were diabetic (10/13). Only 3 had fever and 5 an elevated WBC count on presentation. As previously reported the most common access was a permcath (9/13). Five of 9 permcath patients had a bacteremic episode in the preceeding 3 months. All were treated with permcath removal and placement of a new catheter after several days of antibiotic therapy. Catheter salvage was not attempted. Surprisingly an AV fistula served as vascular access for 3. Blood cultures were positive in 8 of 13 and all were Staphylococcal species (epidermidis-2, MSSA-3, MRSA-4). The lumbosacral spine was the most commonly involved spinal segment (9/13). An associated epidural or psoas abscess was present in 5. C-reactive peptide (CRP) levels were elevated, >10 mg/dL in 7 of 12 patients in which they were measured. Erythrocyte sedimentation rate (ESR) was measured in 10 and was >60 mm/hr except in one patient (42 mm/hr). Eight patients had an albumin concentration <3.2 g/dL and serum hemoglobin concentration <11 gm/dL. Most patients recovered fully, however, two were left with significant neurologic deficits. Three died within six months of initial presentation (two with continuing infection and one of coronary artery disease). The typical affected hemodialysis patient in our series was a diabetic presenting with back pain. Despite the fact that most laboratory tests showed evidence of an inflammatory state (elevated ESR, elevated CRP, decreased albumin, and decreased hemoglobin) fever and an elevated WBC count were often absent. Importantly, although most cases occurred in patients with permcaths, a significant number (3/13) had an AV fistula for their vascular access. In our hands replacement of infected catheters was not protective.

**Design of a Prospective Observational Study To Evaluate the Prospective Payment System (PPS) Impact on Small Dialysis Organizations (SDOs)** Irene Agodoa, Lei Lei, Denise Globe. *Amgen inc, Thousand Oaks, CA.*

**Background:** Beginning January 1, 2011, the Centers for Medicare and Medicaid Services (CMS) has proposed to implement a bundled prospective payment system that would establish a combined payment for composite rate and separately billable dialysis services. A case mix adjustment model has been developed to attempt to align reimbursement with costs. However, SDOs may not have a sufficiently large risk pool over which to spread and mitigate financial risk and may not have adequate resources to treat patients requiring high resource utilization. To understand the impact of the new policy on this vulnerable dialysis segment, a registry has been designed to describe trends in treatment patterns of SDOs prior to and during the implementation of the PPS. **Design:** A multi-center, multi-year observational study of End Stage Renal Disease (ESRD) patients receiving dialysis at SDOs (defined as part of a chain that has fewer than 50 dialysis units within the entire association). Enrollment begins in 2010 with ~4.5 to 6 months of subject data collection during this baseline year, and up to 48 months of subject data collected after the initiation of the PPS. Approximately 50 small dialysis units from throughout the United States (US) will be enrolled. Site selection will be geographically diversified by inclusion of interested facilities to represent the 9 US Census Bureau Divisions. Primary study endpoints are the proportion of patients within each facility meeting each of the CMS ESRD PPS quality metrics over time. Secondary endpoints include facility operating characteristics (ie ownership and closures) and patient characteristics, treatment patterns, and clinical outcomes reported in aggregate per facility over time. To maintain study integrity, participating facilities will not be individually identified. Descriptive analyses will be conducted to estimate treatment patterns and patient characteristics at the facility level before and during CMS reimbursement policy changes. This study will provide a comprehensive data repository that will enable real-time assessment of treatment trends in SDOs prior to and during the period of PPS implementation.

**Improved Blood Flow and Adequacy with Streamline Bloodlines** Joan E. Arslanian, Carl M. Lockman, Yvette C. Parker, Chaim Charytan. *NY Hospital of Queens, Flushing, NY.*

Dialysis adequacy (Kt/V) is a determinant of mortality. Kt/V is a function of blood flow (BF), dialysate flow, dialyzer type and treatment time. Increasing blood flow can be economically and logistically simple, but must be combined with attention to arterial pressure (AP).

We evaluated the Medisystems Streamline (SL) bloodline with improved hemodynamics (lower turbulence,no blood-air contact) by raising blood flows based on arterial pressures. We hypothesized that we would 1) improve Kt/V for patients with different vascular accesses and starting BF with little impact on AP; and 2) further improve Kt/V for patients with already high Kt/Vs.

In a cross-over evaluation of 202 patients, we compared Kt/V 1) on conventional bloodlines; and 2) on SL. We recorded spKt/V and treatment values for average delivered BF, average AP, actual treatment times, average dialysate flows, dialyzer types and accesses. We excluded patients with changes in treatment times, dialysate flows, dialyzers or accesses between periods. We calculated significance using paired t-test and McNemar's test.

With SL, we showed significantly increased BF with a minimal 4% increase in AP. Average Kt/V and the percent of patients with Kt/V >=2.0 also improved significantly, regardless of starting BF and access type.

**Bioimpedance Analysis and the Duration of the Hemodialysis Session** Carlo Basile, Pasquale Libutti, Anna Lucia Di Turo, Francesco Casucci, Nicola Losurdo, Annalisa Teutonico, Carlo Lomonte. *Division of Nephrology, Miulli General Hospital, Acquaviva delle Fonti, Italy.*

Bioelectrical impedance (BIA) is a measurable property of electrical ionic conduction of soft tissue. Impedance is composed of resistance (R) and reactance (Xc). Physiologically, measured R correlates strongly with total body water. In man, more than 90% of impedance is composed of R. Aim of this study was the investigate R and Xc during hemodialysis (HD) sessions of different duration.

This is a two-step crossover study. All HD sessions utilized high-flux FX80 dialyzers and the GENIUS® single-pass batch dialysis system (FMC, Germany), which consists of a closed dialysate tank of 90 l. **Step A:** 22 stable white prevalent anuric uremic patients underwent two standard (~ 4h) bicarbonate HD sessions in a random sequence. The sessions were pair-matched as far as the dialysate and blood volume processed (90 l), volume of ultrafiltration and dialysate Na+ (140 mmol/l) and K+ concentrations (2 mmol/l) are concerned. One HD session had the dialysate Ca++ concentration 1.5 mmol/l; the other 1.25 mmol/l. **Step B**: 11 out of the 22 patients underwent one standard (~ 4h) and one long-hours (~ 8h) slow-flow bicarbonate HD session in a random sequence. The sessions were pair-matched as described in step A with the only exception that dialysate Ca++ concentration was 1.5 mmol/l in both treatments. R and Xc were determined at the start and the end of each HD session, injecting 800 µA at 50 kHz alternating sinusoidal current with a standard tetrapolar technique.

Solute mass balances were not significantly different in both steps, except for Ca++ mass balance in step A. R and Xc values did not show any statistically significant difference in step A. Post-dialysis R, Δ R (the difference between post- and pre-dialysis) and percent increase of R values were significantly higher in the 8h sessions in step B ($P < 0.0001$, 0.02 and P 0.02, respectively).

In conclusion, 8h slow-flow bicarbonate HD sessions were associated with post-dialysis R values significantly higher than the corresponding ones of the 4h sessions. If higher R values may represent a proxy of a correct dry body weight, it remains a matter of future research.

Disclosure of Financial Relationships: nothing to disclose

**PUB478**

**Removal of Uremic Retention Solutes in Standard Bicarbonate Hemodialysis and Long-Hours Slow-Flow Bicarbonate Hemodialysis** Carlo Basile,[1] Pasquale Libutti,[1] Anna Lucia Di Turo,[1] Francesco Casino,[2] Luigi Vernaglione,[3] Sergio Tundo,[1] Pasquale Maselli,[1] Annalisa Teutonico,[1] Carlo Lomonte.[1] *[1]Division of Nephrology, Miulli General Hospital, Acquaviva delle Fonti, Italy; [2]Division of Nephrology, Matera, Italy; [3]Division of Nephrology, Manduria, Italy.*

Many studies already stressed the importance of hemodialysis (HD) time in the removal of uremic toxins. In those studies, however, also the amount of dialysate and/or processed blood was altered. Aim of this crossover study was to investigate the isolated effect of time on removal of uremic toxins.

Eleven anuric HD patients underwent 2 bicarbonate HD sessions (~ 4h and ~ 8h) in random sequence. The GENIUS® single-pass batch dialysis system and the high-flux FX80 dialyzers (FMC, Germany) were utilized. GENIUS® consists of a closed dialysate tank of 90 l, thus offering the opportunity of effecting mass balances of any solute in a very precise way. The volumes of blood and dialysate processed, of ultrafiltration and dialysate composition were prescribed to be the same. Small molecules (urea, creatinine, phosphorus and uric acid), the middle molecule $ß_2$M and protein-bound compounds (homocysteine, hippuric acid, indole-3-acetic acid and indoxyl sulfate) were investigated. Total solute removals (solute concentration in the spent dialysate x 90 l, i.e. the volume of dialysate) (TSR), clearances (TSR of a solute / area under the plasma water concentration time curve of the solute) (K), total cleared volumes (K*time) (TCV), and dialyzer extraction ratios (K/blood flow) (ER) were determined.

TSR, TCV and ER were statistically significantly larger during prolonged HD for all small and middle molecules (at least, $P = 0.01$). The percent increases of TSR were 26.6 % for phosphorus and 39.2% for $ß_2$M ($P = 0.005$). No statistically significant difference was observed for protein-bound solutes in any of the above parameters.

In conclusion, small and middle molecules are removed more adequately from the deeper compartments when performing a prolonged HD. Hence, factor time is very important for these retention solutes. The kinetic behavior of protein-bound solutes is completely different because of the strength of their protein binding.

Disclosure of Financial Relationships: nothing to disclose

**PUB479**

**Hemodynamic Stability in Long-Hours Slow-Flow Bicarbonate Hemodialysis** Carlo Basile, Pasquale Libutti, Anna Lucia Di Turo, Luigi Vernaglione, Francesco Casucci, Nicola Losurdo, Annalisa Teutonico, Carlo Lomonte. *Nephrology, Miulli Hospital, Acquaviva delle Fonti, Italy.*

The interplay of Na+, K+ and Ca++ mass balance (MB) with ultrafiltration volume ($V_{UF}$) is crucial in hemodynamic stability during hemodialysis (HD).

This two-step crossover study utilized high-flux FX80 dialyzers and the GENIUS batch dialysis system (FMC, Germany). **Step A:** 22 stable HD patients underwent two standard (4h) bicarbonate HD sessions in random sequence. The sessions were pair-matched for the dialysate and blood volume processed (90 l), $V_{UF}$ and dialysate Na+ and K+ concentrations ((140 and 2 mmol/l). One HD session had dialysate Ca++ concentration 1.5, the other 1.25 mmol/l. **Step B**: 11 patients underwent one 4h and one 8h slow-flow bicarbonate HD session in random sequence. The sessions were pair-matched as described in step A except for dialysate Ca++ concentration (1.5 mmol/l in both treatments). Na+, K+ and Ca++ concentrations were measured in fresh and spent dialysate to determine solute MB. Systolic (SBP), diastolic and mean arterial pressure (MAP) trends were analyzed. Plasma volume (PV) changes were computed from plasma total protein concentrations.

All dialysis sessions were uneventful. **Step A:** mean Na+ MB and K+ MB were not significantly different, whereas Ca++ MB was less positive with dialysate Ca++ concentration of 1.25 mmol/l. Intradialysis decreases of mean SBP, MAP, PV and $V_{UF}$ were not significantly different between the two treatments. **Step B:** all solute MBs were not significantly different between the two treatments. SBP decreased significantly during the 4h runs, whereas was stable during the 8h ones ($P<0.0001$ and P=NS, respectively). Significantly lower intradialysis decreases of mean SBP ($P<0.02$) and MAP ($P<0.04$) occurred in the 8h sessions, despite not different mean $V_{UF}$ (2.9 l). The slope of PV in the first 4 h was less steep during the 8h sessions ($P<0.0001$). PV decrease was significantly higher at the end of the 4h HD runs ($P<0.04$).

In conclusion, a better hemodynamic stability was achieved in the 8h sessions despite not different $V_{UF}$ and solute MBs. A better PV preservation can explain the better hemodynamic stability peculiar to long-hours HD treatments.

**Elevated Plasma Brain Natriuretic Peptide (BNP) Levels in Hemo-Dialysis (HD) Patients and Its Lack of Correlation with Volume Status** Robert L. Benz,[1,2,3] Rob J. Mathews,[1] Mark R. Pressman,[2,5] Michael M. Chernick,[4] Albert A. Keshgegian.[2,3,6] *[1]Nephrology, Lankenau Hospital, Wynnewood, PA; [2]Lankenau Institute for Medical Research, Wynnewood, PA; [3]Mainline Health, Wynnewood, PA; [4]Biostatistics, Lankenau Institute for Medical Research, Wynnewood, PA; [5]Pulmonary & Sleep Medicine, Lankenau Hospital, Wynnewood, PA; [6]Pathology, Lankenau Hospital, Wynnewood, PA.*

**Background**: In HD patients, BNP can be elevated in the absence of overt circulatory overload. We evaluated the presence of elevated BNP levels and it's correlation with pre/post HD volume status in ESRD patients.

**Methods**: 22 patients on maintenance high-flux HD without evidence of overt circulatory overload were studied. Volume status was assessed by history, clinical exam, and weight measurements. Pre/post-HD (1st of week) and pre- next HD (mid-week) measurements of BNP were collected and compared to patients' interdialytic weight gains (IDWG), weights pre/post/pre-HD, volume ultra-filtered (U.F.), and HD treatment variables.

**Results**: 19/22 HD patients had elevated BNP levels. Mean (1st of week) pre-HD BNP was 846.2pgm/ml; mean post-HD BNP was 895.4 pgm/ml; and mean pre mid-week BNP level was 755.2 pg/ml (nl<100pgm/ml). Mean group post-HD weights matched mean group EDW goal. Mean U.F. was 2.65 L and 2.55 respectively. Mean KT/V was 1.66. There was no significant change in pre/post/pre-BNP. There was no correlation with BNP and U.F. [p=0.615, 0.682, and 0.646 (pre/post/pre) respectively]. Post-HD BNP levels did not correlate with KT/V ($p = 0.927$).

**Conclusion**: BNP is elevated in HD patients. Despite patients achieving EDW, BNP did not change significantly pre/post-HD and did not correlate with total U.F. or KT/V. These results suggest volume may not be the causative factor for BNP elevation and that BNP is not cleared effectively with high-flux HD. Measuring BNP in HD patients may be misleading in assessing for circulatory overload states.

**PUB481**

**Circulatory Refilling Capacity of Patients in Hemodialysis** Olga R. Carmona. *Nephrology Center, University of Uruguay, Montevideo, Uruguay.*

**Background**. There is know that fluid overload require more ultrafiltration with the risk of lost of plasma volume preservation increasing the possibility of intradialytic hypotension(IH).The most common etiology of IH is the rapid fluid removal in a short time . Plasma Refilling Rate (PRR) mitigate the blood volume reduction by ultrafiltration.

**Objective**: Analize the correlation between PRR with IH and Hemodynamics Parameters at the end of Hemodialysis (HD).

**Methods**.29 patients on conventional HD were studied. Systolic Blood Pressure(SBP), Diastolic Blood Pressure (DBP), Heart Rate(HR), Ultrafiltration Rate (UFR) were measured at 10 minutes intervals throughout HD.Blood samples were obtained to measure Hematocrit used to calculate Plasma Volume (PV) pre ,second hour and at the end of HD. PRR was calculate with the difference between PV and UFR at the second hour and at the end of HD.Student t test was used to compare PRR at the second hour and the end of HD. Pearson correlation was used to establish the relation between the IH and hemodynamicsParameters,with PRR at the end of HD.

**Results**

A significant drop of PRR at the end of HD respect at the second hour were calculated:PRR,second hour :796,94ml±297,08ml;PRR at the end of HD:468,82ml±335,32ml (t= -3,74 ,p<0,001).

Correlation between Hemodynamics Parameters and PRR at the end of HD

| Hemodynamics Parameters | Mean ±StD | Correlation with PRRend | Significance:p<0,05 |
|---|---|---|---|
| IH | 0,38±0,49 | -0,788 | 0,0001 |
| PAS (mmHg) | 145,86±28,26 | 0,442 | 0,016 |
| PAD(mmHg) | 87,37±18,88 | 0,286 | 0,133 |
| HR (beats/min | 78±13,35 | 0,143 | 0,458 |
| UFR(ml/min | 891,03±26,921 | 0,455 | 0,013 |
| FR (ml) | 2867,86±858,10 | 0,400 | 0,032 |

38 % of the patients suffer hypotensive episodes at the end of HD.There was a significant negative Pearson Correlation between IH episodes with the PRR at the end of HD Besides there was a significative correlation between PAS , UFR and FR with the PRR .

**Conclusion**: A low Blood Pressure at the end of HD can be a sign of a too rapid Ultrafiltration in relation to the circulatory refilling capacity.

Disclosure of Financial Relationships: nothing to disclose

**Heparin Influence on the Lipid Profile in Dialysis** Maria Mar Castilla, Francisca Lopez, Juan Payan Lopez, Cayetana Moyano Peregrin. *Nephrology, Hospital Costa del Sol, Marbella, Malaga, Spain.*

Purpose of the study

To evaluate the variations in the lipid profile during 3 dialysis sessions performed with different regimens of anticoagulation (unfractionated heparin (UFH), low molecular weight heparin (LMWH) and without heparin).

Methods

Prospective, randomized, controlled trial in 12 chronic hemodialysis (HD) patients. Measurement of triglycerides (TG), cholesterol (Col), HDL and LDL pre-HD and post-HD, in 3 dialysis sessions with the same breakfast (25g fat) and different anticoagulation. Values expressed as mean ± standard deviation. Statistical analysis Wilcoxon test (comparing dialysis: UFH vs no Heparin, LMWH vs no Heparin and UFH vs LMWH).

Results

Results

| | Percentage of increase during a dialysis session (mg/dL) | | | |
|---|---|---|---|---|
| | TG | Total Cholesterol | HDL | LDL |
| Unfractionated heparin | 28%(±29) | 8%(±9) | -0.2%(±10)* | 1% (±22) |
| Bemiparina | 38%(±31) | 4 %(±10) | 8%(±15) | -4%(±35) |
| Without Heparin | 64%(±43) | 7%(±10) | 14%(±16)* | -9%(±12) |

*p= 0.036

UFH drops HDL, the opposite occurs with the LMWH and dialysis without heparin. These differences are significant only when comparing the variations of HDL on dialysis with UFH with those of no heparin dialysis.

The larger increase of TG in dialysis without heparin versus dialysis with UFH and LMWH, can be justified because of the vascular endothelial lipoprotein lipase (LPL) release induced by heparin.

Conclusions

1. Decreases HDL cholesterol in dialysis conducted with unfractionated heparin and increases in dialysis without heparin.

2. The type of heparin used (unfractionated heparin vs bemiparin) has not shown significant differences on the lipid profile during a single session of hemodialysis under the conditions of this study.

**End-Stage Renal Disease (ESRD) Prospective Payment System (PPS): Identifying and Assessing Impact on Hospital-Based Dialysis Centers (HBDCs)** George N. Coritsidis,[1] Anjali Acharya,[1] Ross Miller,[2] Kelly J. Ko,[2] Akhtar Ashfaq,[3] Irene Agodoa.[3] *[1]NYC Health and Hospitals Corporation, New York, NY; [2]Cerner LifeSciences, Beverly Hills, CA; [3]Amgen Inc, Thousand Oaks, CA.*

**Introduction:** HBDCs may be at increased financial risk under the proposed ESRD PPS. This has implications for quality and access to care for dialysis patients. This qualitative study was done to understand how HBDCs perceive the PPS. **Methods:** From 10/2009 to 2/2010, an online questionnaire targeted all HBDCs in the US (N=811) that provide outpatient and inpatient dialysis treatment to adults. Of these HBDCs, 698 were successfully contacted, 305 agreed to participate, and 127 completed the 37-question survey. Facilities could give multiple responses. To monitor consequences longitudinally, follow-up data will be collected over the next 3 yrs. **Results:** Hospital types included: community teaching (46), community non-teaching (36), academic (30), public (18), and other (7). Of these, 31% were affiliated with small hospitals (<200 beds) and 44% reported that other dialysis centers in the community were somewhat unavailable (9%) or scarcely available (35%). Mean reported distance to the nearest facility was 29 miles overall; 56 miles for those serving rural populations, and 24 and 42 miles for those reporting access as somewhat unavailable and scarcely available, respectively. The PPS was perceived as favoring large dialysis chains and potentially having a negative impact on quality and access to care. Dialysis centers affiliated with smaller hospitals were more concerned with financial risk *vs.* those affiliated with larger hospitals (85% *vs* 75%). There was concern that this may lead to closure, while those affiliated with larger hospitals were more concerned with being over-burdened due to closure of smaller nearby centers. Facilities treating <100 patients/yr reported they were at least somewhat unprofitable (57%) compared to facilities serving >100 patients/yr (31%). **Conclusions:** HBDCs believe they will be adversely affected by the PPS, which could potentially lead to decreased access to care for patients, especially smaller facilities serving rural populations.

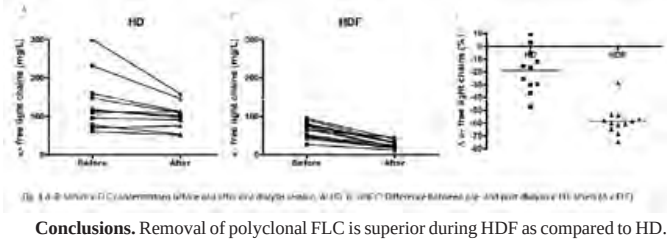
**Polyclonal Free Light Chains Are More Effectively Removed by Online Hemodiafiltration Than by Low-Flux Hemodialysis** Claire H. Den Hoedt,[1,2] Neelke C. Van Der Weerd,[3] R. W. Wulkan,[1] Albert H. Mazairac,[2] Muriel Grooteman,[3] E. Lars Penne,[2,3] Michiel Bots,[4] Peter J. Blankestijn,[2] Pieter M. Ter Wee,[3] Marinus A. Van Den Dorpel.[1] *[1]Maasstad Hospital, Rotterdam; [2]UMCU, Utrecht; [3]VUmc, Amsterdam; [4]Julius Center, Utrecht, Netherlands.*

**Background.** Serum κ- (22.5 kDa) and λ-FLC (45 kDa) concentrations increase with worsening renal function and have been associated with reduced neutrophil function. FLC may contribute to infection risk and inflammatory state in dialysis patients.

**Purpose.** To investigate whether polyclonal FLC are more effectively removed by online hemodiafiltration (HDF) than by low-flux hemodialysis (HD).

**Methods.** Blood samples were obtained in 12 HDF and 12 HD patients, at the beginning and end of 1 dialysis session. κ- and λ-FLC concentrations were determined by nephelometry with high-specificity immunoassays. Differences in FLC were compared by Mann-Whitney tests.

**Results.** κ-FLC changed from 116 mg/L (median, total range: 61-300) to 102 mg/L(51-158) in HD patients and from 66 mg/L (27-95) to 23 mg/L (12-46) in HDF. λ-FLC changed from 107 mg/L (58-201) to 103 mg/L (65-190) in HD and from 69 mg/L (37-336) to 50 mg/L (26-313) in HDF. Pre-dialysis levels were significantly different between the two groups (κ: p=0.002 and λ: p=0.03). The median difference in serum κ-FLC before and after dialysis was -17% (-47 to +9) in HD patients and -60% (-75 to -29) in HDF (p<0.001, for difference in Δ change). For λ-FLC this was -3% and -28% respectively (p=0.002). Weight change and residual kidney function did not differ between HD and HDF.



**Conclusions.** Removal of polyclonal FLC is superior during HDF as compared to HD. The lower pre-dialysis FLC levels in HDF suggest a sustained decrease in FLC. Further studies are needed to establish the association between FLC and clinical endpoints.

**High-Flux Membranes in "Standard" Hemodialysis Technique Versus On-Line Hemodiafiltration** Carlo Donadio, Angeliki Kanaki, Danika Tognotti, Valentina Batini, Elena Donadio, Raffaele Caprioli, Alberto Lippi, Ettore Balestreri. *Internal Medicine - Nephrology, University of Pisa, Pisa, Italy.*

Bicarbonate hemodialysis is often performed using low-flux membranes, which do not clear the blood from "middle" molecules. On-line hemodiafiltration (HDF) with high-flux (HF) membranes is needed to remove β2-microglobulin (β2M) and other middle molecules. On-line HDF is performed by means of sophisticated dialysis monitors.

Aim of this study is to compare dialytic efficiency in the removal of small and middle molecules of HF membranes in "standard" HD technique in comparison with the use in on-line HDF technique.

Patients and methods. Eight patients, 31-78 years, dialytic vintage 11-228 months, in stable conditions and nutritional status, treated with HDF technique with HF membranes (HDF100 Fresenius 3 pts, Polyflux 210H 5 pts).

Dialytic efficiency, tolerability, and effects on inflammation, and cardiovascular parameters were assessed using three HF dialyzers (Triacetate: Nipro N190FH; Helixone: Fresenius FX1000; Polyamide: Gambro Polyflux 210H) in "standard" HD in comparison with on-line HDF technique.

Patients were treated in randomized rotation with each HF dialyzer in HD and HDF technique for 2 weeks, after an equilibration period of 1 month with usual HDF treatment. Blood- and dialysate-flow were maintained constant. Reinfusion fluid, in post-dilution during HDF, was 19.5±2.8 L.

The removal of small molecules was very high (urea reduction ratio 76.2-78.8 %) and similar with all membranes either in HD or in HDF. Phosphate removal ranged 39.3-58.6%. The removal of β2M was very high, 62-75%, in HDF and 60-68% in HD. β2M removal was significantly higher in HDF vs HD only with Poly210H. A significant removal of myoglobin, homocysteine and BNP was found with all membranes in HD and HDF. TNF concentrations decreased after all HDF dialysis and after HD with Poly210H e N190FH. A slight increase in IL10 was found with N190FH. IL6 was unchanged. The analysis of ultrafiltrate fluid demonstrated occasionally a modest concentration of albumin.

Conclusion. HD performed with HF dialyzers could be a cost-effective and efficient alternative treatment, simpler and cheaper than HDF.

**Altered Sleep Architecture in Patients with End-Stage Renal Disease** Rosilene M. Elias,[1] Douglas Bradley,[2] Christopher T. Chan.[1] *[1]Nephrology, Toronto General Hospital, University Health Network, Toronto, ON, Canada; [2]Respirology, Toronto General Hospital, University Health Network, Toronto, ON, Canada.*

**Background and Hypothesis:** Although sleep disturbances in End Stage Renal Disease (ESRD) are widely recognized, the effect of uremia on sleep architecture is poorly investigated. We hypothesize that ESRD patients exhibit impaired sleep architecture independent of sleep-related breathing disorders.

**Methods**: We studied 57 ESRD patients (42 men) and 57 controls (46 men) who had undergone polysomnography. Control subjects were matched to the ESRD patients by age (52.9 ± 1.7 vs. 51.7 ± 2.2 yrs, p=0.67), body index mass (31.3 ± 0.8 vs. 29.4 ± 1.1 kg/m$^2$, p=0.18), periodic leg movement index (25.1 ± 4.4 vs. 27.7 ± 7.1 leg movements/hr sleep, p=0.75), and frequency of apneas and hypopneas/hr sleep (apnea-hypopnea index: 41.5 ± 3.9 vs. 41.0 ± 4.7, p=0.94). Sleep architecture was assessed by quantifying total sleep time, sleep efficiency (% of time asleep/sleep period time after lights out), amount and proportion of time spent in slow-wave (N3 sleep) and rapid-eye movement (REM) sleep, and the frequency of arousals from sleep (ArI).

**Results**: ESRD patients had shorter total sleep time, diminished sleep efficiency and reduced REM sleep (Table 1). Univariable analysis showed that total sleep time and REM sleep were independent related to ESRD (p=0.002 and p=0.008, respectively).

Sleep variables

| | Control (n=57) | ESRD (n=57) | p |
|---|---|---|---|
| Total Sleep Time (min) | 323.2 ± 10.22 | 276.9 ± 12.39 | 0.0018 |
| Sleep Efficiency (%) | 76.69 ± 2.07 | 69.61 ± 2.9 | 0.0497 |
| REM sleep (min) | 48.26 ± 3.29 | 34.46 ± 3.88 | 0.0078 |
| REM sleep (%) | 14.74 ± 0.98 | 11.09 ± 1.16 | 0.0175 |
| N3 sleep (min) | 37.9 ± 6.1 | 33.7 ± 4.0 | 0.5663 |
| N3 sleep (%) | 12.2 ± 1.7 | 11.5 ± 1.4 | 0.7716 |
| Arousals Index | 38.8 ± 24.6 | 49.0 ± 42.6 | 0.1210 |

**Conclusion:** ESRD patients exhibited impaired sleep architecture, independently of ssleep apnea, characterized by reduced sleep eiciency, total and REM sleep time. Prospective evaluation of the effect of intensifying uremia clearance on sleep morphology therefore warrants further examination.

Disclosure of Financial Relationships: nothing to disclose

**Evaluation of Alternative Epoetin alfa Dosing Regimens To Reduce Hemoglobin Variability Using Pharmacokinetic Pharmacodynamic (PKPD) Model-Based Simulation** Bill Frame,[1] Diane R. Mould,[1] Thomas Comstock,[2] Sameer Doshi,[2] Juan Jose Perez Ruxio.[2] *[1]Projections Research, Poenixville, PA; [2]Amgen Inc, Thousand Oaks, CA.*

**Purpose:** To assess the impact of alternative Epoetin alfa (EA) dosing algorithms on within subject hemoglobin (Hb) variability in patients on hemodialysis (HD) using PKPD model-based simulation. **Methods:** A validated PKPD model of Hb response to EA in patients on HD with anemia was used to simulate Hb profiles in a cohort of 3000 virtual subjects, from which patients with stable dose and Hb levels between 10-12 g/dL were selected and randomly assigned to each of the 3 dosing arms (N≥750 subjects per arm). For each arm, doses were simulated to be administered thrice weekly and adjusted monthly; reduced by 25% if the Hb increased >2 g/dL/month; held if Hb ≥13 g/dL until ≤12 g/dL, then resumed at 25% lower dose. Dosing per label was compared with Dosing Algorithms A and B, which simulated graded dose changes of 10% and 25% at defined Hb values. The target Hb ranges for arms A and B were set to 10-12 g/dL and 10.5-11.5 g/dL, respectively. Subject doses were simulated to be titrated per the assigned algorithm for 6 months followed by a 6 month evaluation period. After Hb simulation, Hb variability was determined as the within subject Hb standard deviation (SD) during the evaluation period and % of values within the Hb range of 10-12 g/dL. **Results:** 2613 simulated subjects were randomized to the 3 dosing algorithms. Summary statistics show similar within subject Hb variability for the 3 dosing algorithms.

| Statistic, Mean (SD) | Label Dosing | Dosing Algorithm A | Dosing Algorithm B |
|---|---|---|---|
| N | 853 | 837 | 923 |
| Hb mean (g/dL) | 11 (0.8) | 11 (0.88) | 11 (0.79) |
| Within subject Hb SD (g/dL) | 1 (0.4) | 1 (0.4) | 1 (0.38) |
| Proportion Hb within 10-12 g/dL (%) | 59.2 (23.8) | 58.3 (24.3) | 62.6 (23.5) |

**Conclusions:** Results suggest that graded dosing approaches for EA will not result in reduced Hb variability within subjects and that Hb variability observed in prevalent patients on dialysis is not due to the dosing algorithm, but may be due to patient factors including intercurrent clinical events, which were not considered in this simulation exercise.

**Evaluation of Inpatient Urea Reduction Ratios in Chronic Hemodialysis Patients** Meghana R. Gaiki, Maria V. Devita, Michael F. Michelis. *Division of Nephrology, Department of Medicine, Lenox Hill Hospital, New York, NY.*

End stage renal disease (ESRD) patients on hemodialysis (HD) are frequently admitted to the hospital for dialysis and nondialysis related medical issues. There are no guidelines to measure adequacy of the HD prescription in a hospital setting despite there being core measure requirements for other medical diagnoses.

We sought to measure hemodialysis adequacy using urea reduction ratios (URRs) in chronic hemodialysis patients upon admission to the hospital and compare each patient's data to their outpatient (OP) hemodialysis prescription (HDRx) and URR. Information regarding URRs, HD access, blood flow rate (Qb), dialyzer clearance, duration of the HD session, ultrafiltration volume and blood pressures was recorded for both settings. The dialysate flow rate was 500ml/min for all HD sessions.

Data was collected for 19 patients. In the hospital, fifteen patients (80%) had a lower HDRx and 12 (63%) patients had URRs < 65%. All 12 had a lower HDRx, in terms of lower dialyzer clearance (n=7), shorter duration of HD session (n=10), lower Qb (n=9) or a combination of these variables (n=11). Discernible reasons for lower HDRx included: postoperative pain (n=2), hemodynamic instability (n=4), access problems (n=2), patient request (n=3) or a combination of these issues (n=3). Four patients had lower HDRx due to unclear reasons. Of interest, 6 (50%) of the 12 patients had URRs < 65% in the OP setting in the month just prior to admission. The remaining 7 (37%) of the 19 patients maintained adequate URRs in both settings.

In conclusion, a majority of the patients had URRs <65% and lower HDRx in the hospital due to concurrent medical problems including hemodynamic instability, postoperative pain and access problems. In some instances there was no apparent justification for the lower HDRx. It is important to monitor changing patient variables before each HD session. It may be worthwhile to measure dialysis adequacy in the hospital several times to optimize clearances.

**Connective Tissue Growth Factor Is Effectively Removed by Online Hemodiafiltration, While It Is Not Removed by Low-Flux Hemodialysis** Karin G. Gerritsen,[1] Claire H. Den Hoedt,[1,3] Alferso C. Abrahams,[1] Tri Q. Nguyen,[2] Marinus A. Van Den Dorpel,[3] Muriel Grooteman,[4] Roel Goldschmeding,[2] Peter J. Blankestijn.[1] *[1]Nephrology, University Medical Center Utrecht, Netherlands; [2]Pathology, University Medical Center Utrecht, Netherlands; [3]Internal Medicine, Maasstad Hospital, Rotterdam, Netherlands; [4]Nephrology, VU Medical Center, Amsterdam, Netherlands.*

Connective tissue growth factor (CTGF) is an important profibrotic factor in chronic kidney disease (CKD). Previous studies also indicated pro-inflammatory properties and a potential role in atherosclerosis. The aminoterminal fragment (N-CTGF, 18 kD) is the predominant form in plasma. In CKD, CTGF accumulates in plasma. It is postulated that (N-) CTGF is a middle molecular weight uremic toxin, which could be removed by convective therapies. We investigated whether CTGF is removed by online hemodiafiltration (HDF) as compared to low-flux hemodialysis (HD).

We measured plasma CTGF at the beginning and end of 1 dialysis session in 12 HDF and 12 HD patients. CTGF levels are depicted as medians with ranges. Mann Whitney test was used for comparison of differences between pre- and post-dialysis CTGF levels.

Median pre-dialysis plasma CTGF was 2.6 nmol/L (1.0-7.0) in HD as compared to 2.7 nmol/L (1.4-4.7) in HDF (P=0.95). Median post-dialysis plasma CTGF was 2.8 nmol/L (1.1-7.3) in HD as compared to 0.91 nmol/L (0.31-2.6) in HDF. The median difference in plasma CTGF before and after dialysis was +13% (-30 to +37) in HD and -63% (-86 to -45) in HDF (P<0.001) (Fig. 1). Weight change, ultrafiltration volumes and residual kidney function did not differ between HD and HDF.

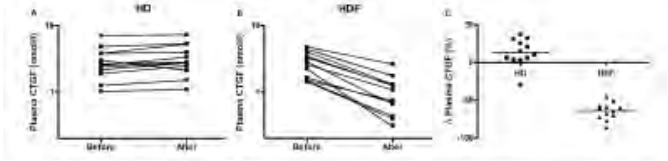

Fig. 1. A-B. Plasma CTGF levels before and after one dialysis session. A: HD. B: HDF. C: Difference between pre- and post-dialysis CTGF levels (Δ CTGF).

Our data show that CTGF is effectively removed by HDF while it is not removed by conventional low flux HD. Regarding the profibrotic and potential pro-inflammatory properties of CTGF, removal by HDF may have beneficial prognostic implications in dialysis patients.

**Impact of Phosphate Binder Choice on Missed In-Center Dialysis Treatments: The Perspective of a Small, Mid-Size, and Large Dialysis Organization in the US** Daniel Grima,[1] Jay B. Wish,[2] Lisa Bernard,[1] Elizabeth S. Dunn,[3] David C. Mendelssohn.[4] *[1]Cornerstone Research Group Inc., Burlington, ON, Canada; [2]University Hospitals Case Medical Center, Cleveland, OH; [3]Genzyme Corporation, Cambridge, MA; [4]Humber River Regional Hospital, Weston, ON, Canada.*

**Purpose:** Missed in-center dialysis treatments, including those due to hospitalization, have been associated with compromised patient outcomes and increased healthcare resource utilization. The objective of this study was to quantify the impact of sevelamer vs. calcium based binders (CBBs) on missed in-center dialysis treatments among hyperphosphatemic dialysis patients from the perspective of a small, mid-size, and large dialysis organization in the US. **Methods:** A model was developed in Excel to estimate missed dialysis sessions among three hypothetical cohorts of hyperphosphatemic patients treated with either sevelamer or CBBs. The cohorts were characterized by their size to represent a small, mid-size or large dialysis organization (75, 30,000 and 120,000 patients, respectively). In any given month, a patient in the model could receive dialysis treatments within the center, experience a hospitalization or die. Treatment-specific monthly survival rates, hospitalization rates, length of stay and binder dosages were derived from the published literature. A dialysis schedule of 3 treatments per week was assumed. Analyses were conducted for a time horizon of 1 year. **Results:** The use of CBBs was associated with an increased number of missed in-center dialysis treatments compared to the use of sevelamer over 1 year. The magnitude of sevelamer's impact on maintaining in-center dialysis treatments increased with the size of the dialysis population.

Missed In-Center Dialysis Treatments due to Hospitalization

| | Calcium | Sevelamer | Difference |
|---|---|---|---|
| Small (N=75) | 446 | 395 | 51 |
| Mid (N=30,000) | 178,714 | 158,142 | 20,572 |
| Large (N=120,000) | 714,857 | 632,571 | 82,286 |

**Conclusions:** Treatment of hyperphosphatemic dialysis patients with sevelamer relative to CBBs is associated with a reduction in missed in-center dialysis treatments across small, mid-size and large dialysis organizations.

Disclosure of Financial Relationships: Consultancy: Daniel Grima is an employee of and shareholder in Cornerstone Research Group, Inc. and as such, has received funds as an consultant to Genzyme Corporation.

**PUB491**

**Inclusion of Dialysis Costs in Cost-Effectiveness Analyses of Therapies for Patients on Dialysis: A Case Study of Sevelamer for the Treatment of Hyperphosphatemia** Daniel Grima,[1] David C. Mendelssohn,[2] Elizabeth S. Dunn,[3] Lisa Bernard.[1] *[1]Cornerstone Research Group Inc., Burlington, ON, Canada; [2]Humber River Regional Hospital, Weston, ON, Canada; [3]Genzyme Corporation, Cambridge, MA.*

**Purpose:** There is uncertainty as to whether the cost of dialysis is related to a therapy that extends the life of a patient on dialysis, but does not impact the need for or the extent of dialysis, and consequently, uncertainty around whether dialysis costs should be included in cost-effectiveness analyses (CEAs) of these therapies. This study examined the cost-effectiveness of sevelamer versus calcium-based binders (CBBs) as treatment for hyperphosphatemia in dialysis patients and, within this context, the suitability of including dialysis costs in such CEAs. **Methods:** A Markov model estimated life years, incremental cost per life year (LY) gained and incremental quality-adjusted life year (QALY) gained. Treatment-specific survival was derived from the Dialysis Clinical Outcomes Revisited (DCOR) study and extrapolated using Weibull regression. The base case analysis used resource use and survival data for patients ≥ 65 years combined with Canadian unit costs and utility weights from the literature. Analyses were conducted for a 10-year time horizon using the Alberta Health Care System perspective, with costs and outcomes discounted at 5% per year. **Results:** In the case where dialysis costs were excluded, sevelamer resulted in a gain of 1.02 LYs and 0.62 QALYs per patient compared with CBBs, producing ratios of $20,847/LY and $34,175/QALY gained. Inclusion of dialysis costs resulted in ratios above $90,000/LY and $150,000/QALY gained. **Conclusions:** No therapy that extends the life of dialysis patients, without decreasing the need for or the extent of dialysis, can be cost-effective if dialysis costs are included. As a result, patients requiring dialysis could be denied access to life-extending therapies, simply because dialysis is costly. We conclude that dialysis costs should not be included in CEAs of such therapies and recommend that health economic guidelines, practice and public policy in this area be consistent, ethical and non-discriminatory.

Disclosure of Financial Relationships: Consultancy: Daniel Grima is an employee of and shareholder in Cornerstone Research Group, Inc. and as such, has received funds as an consultant to Genzyme Corporation.

**PUB492**

**Endotoxaemia in Haemodialysis Patients Is Not Associated with Excessive Hydration** Laura E. A. Harrison,[1] Cian Chan,[1,2] James O. Burton,[1] Simon J. Davies,[2] Cheuk-Chun Szeto,[3] Philip K. T. Li,[3] Chris W. McIntyre.[1,4] *[1]Department of Renal Medicine, Royal Derby Hospital, United Kingdom; [2]Department of Nephrology, University Hospital of North Staffordshire, United Kingdom; [3]Medicine & Therapeutics, Chinese University of Hong Kong, Hong Kong; [4]School of Graduate Entry Medicine and Health, University of Nottingham, United Kingdom.*

Endotoxin (ET) has a wide range of adverse effects on cardiovascular function; driving inflammation, atherosclerosis and cardiovascular mortality. ET translocation from gut to circulation has been associated with fluid overload in heart failure and may be a factor in endotoxaemia in PD patients. ET levels are grossly elevated in haemodialysis (HD) patients, but assessment with indirect measures of fluid status (left atrial volume, BNP) has not demonstrated a relationship with endotoxaemia. We aimed to assess endotoxaemia with reference to absolute measures of body composition.

14 established HD patients were studied using a gold standard Deuterium dilution (De) method and Bioimpedance Analysis (BIA) to assess total body water (TBW) pre and post HD. Deuterium concentration was measured in breath by flowing-afterglow mass spectrometry, ensuring full equilibration. BIA was measured using a multifrequency, multisegmental device. Blood samples were taken pre and post HD.

Patient age was 65±15 yrs and dialysis vintage 19 months [IQR 9-60]. Mean ET pre-HD was 0.72±0.39 EU/ml, which inversely correlated to $TBW_{De}$ pre and post HD (r= -0.657 in both groups, $p<0.05$) as well as to BMI (r=-0.565, p=0.035). However, there was no relationship between TBW indexed to weight (TBW/body weight) and ET levels. $TBW_{De}$ and $TBW_{BIA}$ correlated pre and post HD (r=0.956 and 0.943, $p<0.001$).

HD results in severe endotoxaemia, but factors influencing this are not fully understood. In contrast to heart failure, excessive hydration does not appear to be a significant driver of endotoxaemia in HD. Furthermore, relative obesity appears to be associated with lower levels of serum ET. This may relate to lean/fat mass hydration or relative protection against bowel hypoperfusion as a result of omental tissue load and could be related to the observed positive effects of obesity on HD survival.

**Relative Blood Volume Monitoring during Hemodialysis: A Qalitative Indicator of Fluid Overload** Jasmine Ion Titapiccolo,[1] Manuela Ferrario,[1] Francesco Garzotto,[2] Maria Gabriella Signorini,[1] Dinna N. Cruz,[2] Flavio Basso,[2] Alessandra Brendolan,[2] Federico Nalesso,[2] Ulrich Moissl,[3] Ciro Tetta,[3] Sergio Cerutti,[1] Claudio Ronco.[2] *[1]Department of Bioengineering, Politecnico di Milano, Milano, Italy; [2]San Bortolo Hospital, Vicenza, Italy; [3]Fresenius Medical Care Deutschland GmbH, Germany.*

**Background.** Inadequately removed fluid volume may lead to chronic fluid overload which can lead to hypertension, left ventricular hypertrophy and heart failure. This exploratory study aims at identifying new parameters obtained from continuous Blood Volume Monitoring allowing an indirect evaluation of hydration status.

**Methods.** 33 chronic HD patients from the dialysis unit of the San Bortolo Hospital in Vicenza were enrolled. Before each HD treatment, fluid overload (FO) was assessed with a whole body bioimpedance spectroscopy device (BCM, Fresenius Medical Care). During HD, blood volume reduction (BVR%) was monitored by a real-time online ultrasonic blood volume monitor (BVM, Fresenius Medical Care). Over the first 30 minutes and the last 30 minutes the BVR% values were linearly interpolated and their slopes were assessed. The parameters considered in this work are: initial BVR% slope (slope$BV_0$), final BVR% slope (slope$BV_{end}$), and BVR% reduction, which corresponds to the difference between the initial value (100%) and the final value.

**Results.** Patients with higher FO (>2.5l) have a significantly lower slope$BV_0$ and lower BVR% reduction in respect with the patients with FO<2.5l, whereas the final slope was not significantly different between the two groups.

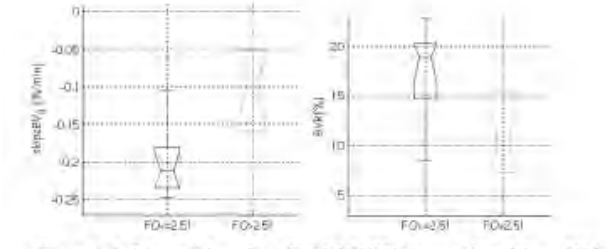

Figure 1. Left panel, boxplot of initial BVR% slope values (slope $BV_0$). Right panel, boxplot of BVR% reduction in the two populations: not overhydrated (FO≤2.5l) and overhydrated patients (FO>2.5l).

**Conclusion.** The slope of the RBV% values, estimated in the first 30 minutes of treatment, was found to be a useful parameter to identify previously unrecognized states of overhydration. The proposed parameter can be used as a qualitative indicator of fluid overload.

**Systematic Review of Effects of Erythropoiesis-Stimulating Agents (ESAs) on Fatigue among End-Stage Renal Disease (ESRD) Patients on Dialysis**
Kirsten L. Johansen,[1] Dennis A. Revicki,[2] Fredric O. Finkelstein,[3] Christopher Evans,[4] Shaowei Wan,[5] Irene Agodoa.[5] *[1]UCSF, San Francisco, CA; [2]United BioSource Corp, Bethesda, CA; [3]Hospital of St Raphael, Yale University, New Haven, CT; [4]MapiValues, Inc., Boston, MA; [5]Amgen Inc, Thousand Oaks, CA.*

**Purpose**: Improvement in health related quality of life remains an important goal of treating patients with ESRD. Recent data highlighted the impact of ESA therapy on improving physical function and exercise tolerance in this population. The purpose of the present study was to review the literature to better understand the effect of ESA therapy on dialysis patients' perception of fatigue. **Method:** A systematic literature review was conducted on the effects of ESAs on fatigue using MEDLINE and EMBASE, limited to articles published in English from 1988 to 2010. In addition, reference lists of identified papers were searched. To meet inclusion criteria, the studies had to report data on a measure of fatigue before and after an intervention with any ESA among adult patients undergoing dialysis. **Results:** 76 studies were identified; 13 examined the effects of ESAs on fatigue outcomes and met inclusion criteria. Of those, 3 randomized controlled trials (RCT) used Kidney Disease Questionnaire (KDQ) to measure fatigue. The incremental increase in KDQ fatigue score between baseline and follow-up (24 weeks or 48 weeks) was higher when baseline hemoglobin (Hb) level was lower. Mean KDQ fatigue score changes were 0.16 (median change), 0.46, and 1 in the ESA treatment group with achieved Hb level of 13.5 g/dL, 12.2 g/dL, and 10.2 g/dL (low)/11.7 g/dL (high) compared with baseline Hb level of 11.1 g/dL, 9-11 g/dL, and 7 g/dL respectively (clinically meaningful difference in KDQ score is 0.5). Four studies measured SF-36 vitality scores and found a 0.9 to 24.8% improvement in vitality at various follow-up times. **Conclusion:** Treating anemia is associated with an improvement in fatigue among dialysis patients. Additional research is needed to examine the benefit of treating anemia to current Hb targets on other anemia-associated symptoms among dialysis patients.

**Interdialytic Weight Gain: Predictors and Associations**
Kotagal Shashi Kant,[1,2] Heather Duncan,[1,2] Karthikeyan Meganathan,[3] Zona E. Saylor,[1,2] Mahmoud T. El-Khatib,[1,2] Abhijeet Goyal.[1,2] *[1]Nephrology and Hypertension, Univ Cincinnati Coll Med, Cincinnati, OH; [2]Dialysis Clinic, Inc, Cincinnati, OH; [3]Public Health Sciences, Univ Cincinnati, Cincinnati, OH.*

High cardiovascular morbidity and mortality remains a vexing problem for HD patients. High IDWG (interdialytic weight gain) is associated with increased mortality but also with better nutrition. Adherence to diet and HD time are factors controlled by patients. We assessed the contribution of dialysis time, microinflammation, demographic, laboratory and HD treatment specific factors on IDWG in a cohort of HD patients.

**Methods:** 97 HD pts treated for at least one month were included in this analysis of treatments Jan-Mar 2010. All treatments at one outpatient dialysis center, with an interdialytic interval of 2 or 3 days, were reviewed for IDWG, treatment duration, BVP (blood volume processed) & EPO dose given, as well as pre- and post-sitting blood pressures and weights. IDWG per day was estimated by dividing the IDWG by the interval; these values were then normalized (nIDWG) to the patient's EDW (estimated dry weight). The cohort was divided into two groups based on the median value, hi-nIDWG & lo-nIDWG. All treatment parameters, as well as common labs, EPO dose/kg and basic demographics were described for these two groups.

**Results:** nIDWG was positively correlated with number of BP meds and EPO dose/kg. Hi-nIDWG was correlated negatively with Hgb, corrected calcium, BVP & EDW. A multivariable logistic regression model showed that BVP and corrected Ca remained significantly associated with nIDWG. Comparison of the highest and lowest quartiles of nIDWG showed the same differences we found in analysis of the entire cohort.

**Conclusions:** Our results suggest that patient specific variables are associated with hi-nIDWG. Surprisingly patients with lower EDW had higher nIDWG, as well as lower BVP values despite equivalent HD times. Hemodynamic instability is possibly responsible for the lower BVP. We will examine echocardiographic parameters for further explication of this finding. Our results support the survival disadvantage of lower body mass in HD patients. Further study is needed of this problem.

**Adjustments of Dialysate Potassium Concentration in Response to Daily Changes in Serum Potassium in Chronic Outpatient Hemodialysis**
Csaba P. Kovesdy,[1,2] Jun Ling Lu,[3] Sandra M. Malakauskas.[1] *[1]Salem VA Medical Center, Salem, VA; [2]University of Virginia, Charlottesville, VA; [3]Salem Research Institute, Salem, VA.*

Abnormal serum potassium (SeK) is associated with increased mortality in dialysis patients. Dialysate potassium concentration (DiK) is adjusted based on monthly SeK measurements in chronic outpatient hemodialysis (HD). Short term fluctuations in SeK may require more frequent adjustments, but the ideal frequency of SeK measurement is unknown.

We measured SeK before each HD session for 4 weeks in 36 outpatients undergoing 3x/week HD, with adjustment of DiK as needed. We examined correlations of SeK and of the number of implemented adjustments in DiK with various clinical characteristics using Pearson correlation coefficients.

Patients were all males, mean (SD) age was 68.6 (9.9) years, 53% were black and mean (SD) baseline SeK was 4.9 (0.6) mmol/L. At baseline 47% and 53% of patients used a DiK of 2.0 and 3.0 mmol/L, respectively. Higher SeK was associated with dialysis on the first day of the week and with younger age, white race, lower KT/V and DiK, and higher protein catabolic rate. Changes in DiK were implemented 68 times (16% of all the treatments, median (range) of 2 (0-5) changes/month/patient). The number of changes/patient in DiK did not correlate with clinical characteristics (Table).

Adjustments in DiK are warranted in a significant proportion of outpatient dialysis sessions based on short term fluctuations in SeK. The current paradigm of once-a-month SeK monitoring is inadequate and could result in the application of inappropriate DiK concentrations, which could potentially contribute to a higher incidence of arrhythmias. Routine implementation of more frequent SeK monitoring should be considered in chronic outpatient HD.

Correlation of the number of DiK adjustments/patient/month with clinical characteristics

| | correlation coefficient | p value |
|---|---|---|
| Age | 0.26 | 0.13 |
| Race | -0.13 | 0.5 |
| BMI | -0.23 | 0.17 |
| Treatment time | -0.12 | 0.5 |
| Type of access | 0.03 | 0.8 |
| KT/V | -0.03 | 0.8 |
| nPCR | 0.01 | 0.9 |
| Serum K | -0.28 | 0.11 |

**Is Bioimpedance Spectroscopy (BIS) Useful in Determination of Dry Weight (DW) in the Elderly Dialysis Patients?**
Inger Laegreid,[1,2] Knut Aasarod,[1,2] Marit Jordhoy.[3] *[1]Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway; [2]Department of Nephrology, St. Olavs University Hospital, Trondheim, Norway; [3]Regional Center of Excellence in Palliative Care, Oslo University Hospital, Oslo, Norway.*

The aim of this pilot study was to test the applicability of bioimpedance spectroscopy (BIS) and to describe the hydration status and body composition (BC) of a cohort of elderly dialysis patients above 75 years in our dialysis unit.

A total of 34 pts > 75 years were registered, 10 were excluded (1 due to language problems, 4 were too ill, 1 transplanted and 4 due to practical problems), 24 pts included in the study. To quantify fluid status and assess BC (lean tissue mass and adipose tissue mass), whole body BIS assessments was made using the Fresenius Body Composition Monitor (BCM). Electrodes were placed on hand and foot, in a supine position, and the measurements were done before dialysis session.

BCM results.

| | |
|---|---|
| Age m | 81.4 years |
| Blood pressure (before dialysis) m | 158/76 mm/Hg |
| BMI Body mass index (after dialysis) m | 24.7 kg/m² |
| LTI (lean tissue index) m | 10.8 (10 pt < 10th percentile) |
| FTI (fat tissue index) m | 13.1 (8 pt > 90 th percentile) |

m= mean

Overhydration (OH) was registered in 17 pts, i.e. moderate in 9 ( OH > 1.0 L and < 2.5 L), serious in 8 (OH > 2.5 L). Only four pts in each groups was planned for ultrafiltration. Residual renal function: diuresis (D)> 1 L/ 24 h in 9 pts, 7 pts D: 0.5 - 1 L/ 24 h and 8 pts anuric. Se-albumin 37.5 g/l (36 - 45). According to BMI, 1 pt had underweight (< 18.5), 15 pts had normal weight (18.5 – 24.9), 6 pts overweight (25.0 – 29.9) and 2 pts were obese (BMI > *30).* The BCM revealed a low mean LTI (very low LTI in 10 pts) whereas the mean FTI was high (very high FTI in 8 pts) indicating protein energy wasting (PEW) with muscular depletion combined with fat gain. The BCM enables more precise estimates of the pts's nutritional status than se-albumin and BMI, indicating PEW in a substantial proportion of elderly dialysis patients.The results indicate that the BCM may be helpful to detect overhydration (OH > 2.5L) and to determine dry weight in elderly dialysis patients.

**Does Hemodiafiltration Alter Protein Binding of Drugs Compared to Conventional Hemodialysis?**
Louis-Philippe Laurin, Louise Roy, Renee Levesque. *Nephrology Service, Centre Hospitalier de l'Université de Montréal, Montréal, QC, Canada.*

BACKGROUND: Online high efficiency hemodiafiltration (ol-he-HDF), which combines convection and diffusion, showed improved clearance of middle weight molecules and protein-bound solutes compared to conventional hemodialysis (HD), and better control of the inflammatory state. This may interfere with drug protein binding. METHODS: We compared protein binding of phenytoin (an acidic drug bound to albumin) and quinine (a basic drug bound to alpha-1 acid glycoprotein) in predialysis serum of 25 patients on chronic renal replacement therapy for at least 6 months (12 ol-he-HDF patients with reinfusion

volume >23 liters per dialysis session and 13 conventional hemodialysis patients; all with *Kt/V* ≥1.2) and 11 healthy control volunteers. Protein binding was measured using in vitro equilibrum dialysis with radiolabeled $^{3}$H-Quinine and $^{14}$C-Phenytoin added to each subject's serum.

Percentage of free phenytoin and quinine

| | Albumin (g/L) | AAG (g/L) | % free phenytoin | % free quinine |
|---|---|---|---|---|
| PreHDF | 37±3* | 1.1±0.4* | 17.2±1.3* | 12.2±2.8 |
| PreHD | 35±3* | 1.3±0.3* | 19.1±4.5* | 12.8±4.8 |
| Controls | 41±2 | 0.7±0.2 | 11.9±0.5 | 13.7±2.0 |

Data are presented as group mean ± SD; *p<0.05 versus normal subjects (two-sample t-test); AAG, alpha-1 acid glycoprotein; HDF, online high efficiency hemodiafiltration; HD, conventional hemodialysis.

RESULTS: Levels of free phenytoin were increased in end-stage renal disease patients compared with controls. No differences were observed between HD and ol-he-HDF patients for protein binding with phenytoin. Levels of free quinine were similar in ol-he-HDF patients, HD patients and controls. CONCLUSIONS: Online high efficiency hemodialfiltration does not seem to alter significantly predialysis protein binding of drugs compared to conventional hemodialysis.

Disclosure of Financial Relationships: nothing to disclose

**PUB499**

**Assessment of Hemoglobin (Hb) Responsiveness to Epoetin alfa (EPO) in Patients on Hemodialysis (HD) Using a Population Pharmacokinetic Pharmacodynamic (PKPD) Model** Diane R. Mould,[1] Thomas Comstock,[2] Sameer Doshi,[2] Juan Jose Perez Ruxio.[2] *[1]Projections Research, Phoenixville, PA; [2]Amgen Inc, Thousand Oaks, CA.*

**Purpose**: Develop a population PKPD model describing the effect of EPO on Hb response in HD patients for use in simulation of alternative EPO dosing. **Methods**: A PKPD model was developed using patient demographics, clinically relevant covariates, and EPO and Hb concentrations from 4 clinical trials (15 subjects with PK and 118 subjects with Hb). EPO PK were described using an open 2 compartment model with linear elimination; predicted individual time courses served as the input function to the PD model. A maturation-structured cytokinetic model consisting of 5 compartments linked in a catenary fashion was used to describe the time course of Hb, following a zero-order process and stimulated by EPO according to an Emax function. Visual predictive checks using data from 3 studies were performed to qualify the model. **Results**: The PK and PD of EPO were well described by the model. PK parameter estimates were similar to values previously reported. Population mean (%CV) parameters were clearance (L/h)0.64(27); central volume (L)9.4(49); intercompartmental clearance (L/h)0.12(52); and peripheral volume (L)3.7(67). The PD model described two subpopulations: i. with Hb based on their EPO dosing and ii. with Hb not apparently related to their EPO dosing. The second subpopulation accounted for 18.6% of the subjects and included those who experienced serious infections, bleeding or other intercurrent events that could cause a substantial change in Hb. Parameter estimates from the PD model were physiologically reasonable and consistent with published reports. Population mean (%CV) parameters were maximum effect (g/dL/d)0.17(5.7); $SC_{50}$(Units/L)11(32); and red blood cell lifespan (d) 73(2.8). **Conclusions:** Hb response to EPO in stable patients on HD is successfully described using a population PKPD model. The model provides a platform for simulation of Hb using different dosing strategies. Further work is needed to model the variability observed in patients with intercurrent events, such as infection and inflammation that can influence Hb response to EPO.

**Distributions of and Correlations among Retained Organic Solutes in Hemodialysis Patients: The Retained Organic Solutes and Clinical Outcomes in Hemodialyis (ROSCO) Study** Laura C. Plantinga,[1] Timothy W. Meyer,[2] Thomas H. Hostetter,[3] Josef Coresh,[4] Michal L. Melamed,[3] Nancy E. Fink,[4] Natalie Plummer,[2] Zhe Quan,[3] Pooja C. Oberai,[4] Neil R. Powe.[1] *[1]University of California, San Francisco, CA; [2]Stanford University, Palo Alto, CA; [3]Albert Einstein College of Medicine, Bronx, NY; [4]Johns Hopkins University, Baltimore, MD.*

The accumulation of organic waste products is thought to contribute to poor outcomes in hemodialysis (HD) patients, but little is known about the distributions and inter-correlations of these putative uremic toxins. In a cohort of 521 incident HD enrolled 1995-1998 from 71 US clinics, we measured and compared levels of unique organic solutes [p-cresol sulfate (PCS), indoxyl sulfate (indican), methylamine (MMA), and dimethylamine (DMA)]. Using thawed plasma samples from ~6 mo after start of dialysis, we measured the solute levels by high-performance liquid chromatography with fluorescence detection. Quality control analyses with duplicate samples showed good agreement for all five solutes (r=0.89-0.99, P<0.001 for all). Median (interquartile range) values were: PCS, 3.1 (1.9-4.3) mg/dl; indican, 1.6 (1.0-2.4) mg/dl; MMA, 49.6 (43.2-56.2) μg/L; and DMA, 18.3 (16.1-20.5) μM; all levels were far greater than those in healthy individuals. Most inter-correlations were statistically significant (P<0.05) but weakly positive, with PCS and indican being the most highly correlated (r=0.33), followed by DMA and indican (r=0.19) and MMA and indican (r=0.18). PCS levels were higher in patients who were male, non-obese, without history of gastrointestinal disease, and with baseline creatinine ≥7 mg/dl and BUN ≥50 mg/dl. Indican levels were higher in those with fewer comorbidities; higher creatinine and BUN; and lower white blood cell counts. Higher MMA and DMA were associated with higher creatinine; higher DMA was additionally associated with no residual urine at baseline, obesity, and non-white race. In summary, levels of retained organic solutes vary markedly by HD patient and the solutes are only weakly correlated with each other. Individual solute levels are associated with different patient factors and may contribute to variation in patients' symptoms.

**Hemodialysis Prescription Optimization Decreases Intradialytic Hypotension: A Quality Assurance Study** Davina J. Tai, Joslyn D. Conley, Jennifer M. MacRae. *Medicine, University of Calgary, Calgary, AB, Canada.*

Intradialytic hypotension (IDH) is a common complication of hemodialysis (HD). We have previously shown that preventative strategies for IDH are underutilized (Tai ASN 2008). In this quality assurance/quality improvement (QA/QI) study, we determined the effect of deliberate HD prescription optimization on the incidence of IDH and the prevalence of IDH-prone patients in the Foothills Medical Centre HD unit in Calgary, AB. Two 4 week study periods were compared: the control period (Aug 19-Sept 15, 2007) and the intervention period (Sept 6-Oct 3, 2009). The intervention period occurred after 2 months of weekly didactic education for rounding HD physicians and focused HD prescription optimization during bedside HD rounds. HD prescriptions were modified as deemed clinically appropriate by rounding HD physicians. IDH was defined as a drop in systolic blood pressure (SBP) ≥ 20 mmHg (if the pre-HD SBP was ≤ 100mm Hg, then IDH was defined as a drop in SBP ≥ 10 mmHg) with associated symptoms or intervention. Patients were classified as IDH-prone if IDH occurred in 30% of their HD sessions over 4 weeks. The control and intervention groups consisted of 91 and 82 patients, respectively. Patients in the intervention group were younger (62 years vs 70 years, p=0.01) and had less diabetes (43% vs 59%, p=0.03). The incidence of IDH was 11% in the intervention group vs 17% in the control group (p=0.0002). 13% of patients in the intervention group were IDH-prone vs 23% in the control group (p=0.10). Patients in the intervention group were prescribed multiple preventative strategies more frequently than in the control group (p=0.02). HD prescriptions in the intervention group utilized lower dialysate temperatures (89% vs 55%, p<0.001) and combination sodium and ultrafiltration profiling (20% vs 8%, p=0.02) more frequently than in the control group. At present, there is no standard of care in managing IDH. Our results illustrate that a QA/QI program to optimize HD prescriptions significantly decreases the frequency of IDH in chronic HD patients. More studies are needed to identify superior prophylactic and therapeutic options for IDH.

**Exercise Increases Intradialytic Urea Clearance in Chronic Hemodialysis Patients** Davina J. Tai,[1,2] Kristen Parker,[2] Joslyn D. Conley,[1,2] Jennifer M. MacRae.[1,2] *[1]University of Calgary, Calgary, AB, Canada; [2]Southern Alberta Renal Program, AB, Canada.*

Hemodialysis (HD) adequacy is based on urea kinetics and urea clearance. Low blood flow to muscles during HD is a rate-limiting factor to urea clearance. Theoretically, intradialytic exercise increases muscle perfusion, thereby increasing urea clearance and HD adequacy. We performed a retrospective study to determine the effect of active intradialytic exercise on intradialytic urea clearance in patients from 2 community HD units in Calgary, AB. Patients were eligible if they were on HD at least 3 times per week for at least 3 months and were participating in a voluntary intradialytic exercise program consisting of active stationary cycling supervised by an exercise therapist. The primary outcome was change in average intradialytic urea clearance (ΔKurea) with exercise as measured by ionic dialysance during HD. Thirty-one patients with a mean age of 70 years were included in the study. Intradialytic exercise began at a mean time of 61 minutes into HD, with a mean total exercise time of 34 minutes. The average Kureas pre-exercise, during exercise, and post-exercise were 220mL/min, 245mL/min, and 220mL/min, respectively. With intradialytic exercise, there was a significant increase in Kurea (ΔKurea = +25mL/min [95% CI 15 to 36; p<0.0001]) which returned to baseline once exercise was stopped (ΔKurea= -24mL/min [95% CI -34 to -16; p<0.0001]. Our study illustrates that intradialytic exercise is associated with increased intradialytic urea clearance. More studies are needed to determine if intradialytic exercise translates into improved clinical outcomes for HD patients.

**PUB503**

**Effects of Protein-Leaking Dialyzer on Plasma Pentosidine Concentration, a Marker of Carbonyl Stress, in Hemodialysis Patients** Hidenori Yamazaki, Fumihiro Tomoda, Tsutomu Koike, Takeshi Hayashi, Hiroyuki Kinuno, Satoshi Kagitani, Taizo Nakagawa, Hiroshi Inoue. *The Second Department of Internal medicine, University of Toyama, Toyama, Japan.*

Objective: Over 90% of plasma pentosidine (PEN), a marker of carbonyl stress is bound to albumin. Because only the free fraction of PEN is available for diffusion through dialysis membrane, the removal of PEN is low in conventional hemodialysis (HD). However, the effects of protein-leaking dialyzer on albumin-bound solutes such as PEN remained to be elucidated in hemodialysis patients.

Design and Methods: In the present study, the removability of PEN was compared between two types of triacetate dialyzer with different membrane pore sizes, FB-UH and FB-G (having pore radius of 76 and 60Å, respectively). Eight HD patients were treated with FB-UH and FB-G by crossover manner in the same condition for three months each.

Plasma PEN and the leakage of albumin into dialysate effluent were measured at the end of each treatment. Removal rate of solutes was calculated from their pre-HD and post-HD blood levels.

Results: Although the removal rate of small molecular solutes such creatinine and urea did not differ between the two dialyzers, $\beta_2$-microglobulin was removed more efficiently by FB-UH compared with FB-G. At pre-HD levels, plasma PEN was lower in FB-UH compared with FB-G. Plasma PEN decreased after HD in FB-UH, but did not change in FB-G (0.35±0.10 to 0.26±0.07 vs 0.70±0.09 to 0.70±0.14 μg/mL; HD × dialyzer interaction, $p<0.05$). Consequently, the removal rates of PEN were greater in FB-UH than in FB-G (24.7±2.5 % vs 4.9±7.0 %, $p<0.05$). The leakage of albumin into dialysate effluent was also greater in FB-UH compared with FB-G (2.41±0.41 g vs 0.51±0.02 g, $p<0.05$). Additionally, the removal rate of PEN was correlated positively with the leakage of albumin into dialysate effluent ($r=0.56$, $p<0.05$) in the combined measurements of both dialyzers.

Conclusion: The protein-leaking dialyzer, FB-UH reduced carbonyl stress efficiently in HD patients. The reduction of carbonyl stress in FB-UH was attributed to the removal of albumin-binding PEN via leakage into dialysate effluent.

Disclosure of Financial Relationships: nothing to disclose

**Effect of Different Dialyzers on Clearance of beta-2 Microglobulin and Small Weight Molecule Toxins in Hemodialysis Patients** Jihong Yang, Hua Wu, Tianqing Tang, Xian-Guang Chen. *Department of Nephrology, Beijing Hospital, Beijing, China.*

**Objective:** To compare effect of different dialyzers on clearance of beta-2 microglobulin(β2-MG) and small weight molecule toxins in maintain hemodialysis patients. **Methods:** Sixty-seven stable Chinese hemodialysis (HD) patients were recruited into this one time HD or hemodialysisfiltration (HDF) study in January, 2010. The exclusion criteria were: on HD less than 3 months; central venous catheter; heart failure and acute infection. The patients were divided into B1-1.6H (PMMA membrane) HD, F7APS (Fresenius Polysulfone) HD, FX60(Helixone) HD and APS900 (ASAHI Polysulfone) HDF four groups by different dialyzers. They had 3 times HD per week, each HD lasted 4 hours. Blood chemistry, hemoglobin and β2-MG were measured before and after HD or HDF session. **Results:** Of the 67 patients, average age was 60.8±3.4 years , ratio of male to female was 36 to 31, duration on HD was 65.2±46.2 months, body weight was 64.4±10.7kg, hemoglobin was 115.0±11.6g/L, serum albumin was 39.9±2.34g/L. The age, gender, proportion of patients with diabetic, body weight, hemoglobin and serum albumin was not significantly different among four groups. Reduction rate of serum urea in B1-1.6H,F7APS, FX60 and APS900 group was 66.9%, 68.8%, 69.2% and 69.0% respectively; Reduction rate of creatinine was 63.3%, 66.2%, 63.2% and 61.5%; And reduction rate of serum phosphorus was 48.6%, 54.6%, 53.1% and 53.2% . There was no significantly difference in the reduction rate of urea, creatinine and phosphorous among four groups. The value of KT/V of FX 60 group was highest, APS 900 group ranked second, F7APS group third and B1-1.6H group was lowest, difference between highest group and lowest group was significant; Reduction rate of β2-MG in APS900, FX60, B1-1.6H group was 77.7%, 52.3% and 29.8% respectively, whereas concentration ofβ2-MG in F7APS group increased 15.4% after dialysis. Difference between each two groups was significant. **Conclusions:** High flux HD had the best effect on the clearance of small weight molecule toxins; Except HDF could effectively reduced the concentration of β2-MG, high flux and special middle flux (PMMA membrane) HD also had the same role.

Disclosure of Financial Relationships: nothing to disclose

**PUB505**

**Severe Lactic Acidosis with Renal Failure in Multiple Mieloma (MM): A New Case Report** Antonio Di Felice, Emiliana Ferramosca, Lucia B. De Sanctis, Antonio Santoro. *Division of Nephrology Dialysis and Hypertension, St. Orsola-Malpighi University Hospital, Bologna, Italy.*

Type B lactic acidosis has been rarely described in association with MM. Only 2 case reports has documented lactic acidosis in MM.

CASE REPORT: The patient, male, 51 year old, was admitted in our hospital because of increasing bone pain and rapidly worsening of renal failure. MM with severe bone lesions was diagnosed in 2003. He underwent 2 autologous and 1 allogenic bone marrow transplantation. After transplant failure he was treated with cycles of chemotherapy (thalidomide, dexamethasone, bortezomib) and radiation therapy, interrupted for intolerance signs. His MM was deemed to unresponsive to therapy. On admission patient was non toxic, Blood Pressure 130/80 mmHg, heart rate 80 bpm, diuresis 2.500 ml. Laboratory tests showed creatinine 4.8 mg/dl, BUN 230 mg/dl, Glicemia 96 mg/dl, Hb 10.9 gr/dl, WBC 9.500/mmc, PLT 254.000/mmc, PTT-ratio 1.0, INR 1.11, Na 132 mEq/lt , K 6.0 mEq/lt, Ca 8.6 mg/dl, CPK 135 U/L. Arterial blood gas determination showed a severe metabolic acidosis with $HCO3^-$ 4.0 mMol/lt; arterial lactate level was 132 mg/dl. After i.v. bicarbonate administration, continuous renal replacement treatment with CVVHDF was started in order to obtain a rapid removal of lactate and a better control of bicarbonate levels; contemporarily a new course of dexamethasone and thiamine treatment were started. However, in spite of the treatment and the presence of normal diuresis, lactic acid levels increased up to >230 mg/dl, with persisting acidosis and progressive worsening of general conditions. No other causes of lactic acidosis than MM were found (neither prolonged hypoxia, nor particular pharmacological treatment or thiamine deficiency). The course was complicated by a severe sepsis and the patients deceased after 15 days without recovering of renal function.

In *conclusion*, our case is very probably the third case of type B lactic acidosis associated with MM. This disease, often with severe prognosis, rarely described in patients with rapidly progressive and refractory MM, may be underestimated. Therefore it should be interesting to dose lactate in all patients with severe MM.

**Mechanisms of Aldosterone Action in the Intercalated Cells of the Collecting Ducts** Kahori Hori,[1] Takanori Nagai,[1] Yuichiro Izumi,[2] Yushi Nakayama,[3] Yukiko Hasuike,[1] Masayoshi Nanami,[1] Yoshinaga Otaki,[1] Katsumasa Kawahara,[4] Takeshi Nakanishi,[1] Hiroshi Nonoguchi.[1] *[1]Division of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]LKEM, NHLBI, NIH, Bethesda, MD; [3]Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [4]Physilology, Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan.*

Aldosterone palys a major role for urine acidification and acid excretion in the collecting ducts. Aldosterone receptor, namely mineralocorticoid receptor (MR), has been believed to be localized in the principal cells and non-type A intercalated cells but not in the type A intercalated cells of the collecting ducts. We have established a new cell line of the intercalated (IN-IC) cells from SV40 transgenic rats. We examined the mehcanisms of aldosterone action via MR in the IN-CI cells. RT-PCR revealed that IN-IC cells have MR, 11ß hydroxysteroid dehydrogenase type 2 (11ß HSD2), vasopressin V1a receptor, H-ATPase, HK-ATPase, Rhesus blood group C glycoprotein (Rhcg), AE1, pendrin but not vasopressin V2 receptor, aquaporin 2 and ENaC, showing the characteristics of type A intercalated cells. The effects of aldosterone on MR, 11ß HSD2, H-ATPase, HK-ATPase, Rhcg, AE1, and pendrin were examined using real time PCR and Western blot. Aldosterone dose-dependently increased mRNA and protein expressions of MR, 11ß HSD2, HK-ATPase, Rhcg, AE1 and pendrin. In contrast, aldosterone decreased H-ATPase protein expression. Gene silencing of MR by 5 nM siRNA with 80 nM oligofectamine abolished the effects of aldosterone on mRNA and protein expressions of MR, 11ßHSD, H-ATPase, HK-ATPase, Rhcg, AE1 and pendrin. Vasopressin also increased H-ATPase, HK-ATPase and Rhcg but not AE1and pendrin expressoins. In contrast, aldosterone decreased mRNA expresson of V1a vasopressin receptor. These data show that 1) type A intercalated cells have MR, 11ß HSD2 and vasopressin V1a receptor, 2) effects of aldosterone on acid-base regulation is completely through MR and there are no non-MR pathway in the type A intercalated cells, 3) vasopressin via V1aR modulates aldosterone action on acid-base regulation.

**Regulation of the SAT1 (SLC26A1) Transporter in Kidney by Acid-Base Status and Dietary Sulfate Intake** Nilufar Mohebbi,[1,2] Ming Zeng,[1] Wolfgang Krick,[3] Gerhard Burckhardt,[3] Birgitta C. Burckhardt,[3] Carsten A. Wagner.[1] *[1]Institute of Physiology, University of Zurich, Zurich, Switzerland; [2]Division of Nephrology, University Hospital Zurich, Zurich, Switzerland; [3]Institute for Vegetative Physiology and Pathophysiology, University of Göttingen, Göttingen, Germany.*

The SAT1 anion exchanger is expressed basolaterally in the renal proximal tubule and the liver and in vitro is able to mediate transport of anions such as sulfate, chloride, bicarbonate, or oxalate. In the kidney the transporter has been implicated into the basolateral release of reabsorbed sulfate into blood. We have previously observed in microarray and proteome studies that 2 and 7 days of $NH_4Cl$-induced acidosis increased SAT1 mRNA and protein in mouse kidney. Here we studied the in vivo regulation of SAT1 in rat kidney and liver. Rats were given NaCl, $Na_2SO_4$, NaCl + $NH_4Cl$, or $Na_2SO_4$ + $NH_4Cl$ for 7 days to dissect the regulation by acidosis or sulfate repletion/depletion. $NH_4Cl$ induced similar metabolic acidosis in both groups with increased urinary acid excretion. $NH_4Cl$ together with NaCl as well as dietary sulfate alone stimulated urinary sulfate excretion. Addition of sulfate to the diet reduced mRNA expression of SLC13A1 (NaSi) but had no effect on renal SAT1 mRNA and protein. $NH_4Cl$-loading with NaCl reduced NaSi mRNA but did not alter SAT1 mRNA. Combined $Na_2SO_4$ and $NH_4Cl$ loading decreased NaSi mRNA but again did not affect SAT1 mRNA. In kidney, $NH_4Cl$ enhanced SAT1 protein expression 3-4 fold. In contrast, in liver, $Na_2SO_4$ or $NH_4Cl$ alone increased SAT1 mRNA whereas the combination had surprisingly no effect. Thus, regulation of SAT1 by sulfate and acidosis may be organ-/cell-specific. The exact role of SAT1 in the transport of sulfate or other substrates requires further elucidation.

**PUB508**

**Defining the Buffering Process by a Triprotic Acid without Relying on Stewart-Electroneutrality Considerations** Minhtri K. Nguyen, Liyo Kao, Ira Kurtz. *Medicine, UCLA, Los Angeles, CA.*

Upon the addition of protons to an aqueous solution, a component of the $H^+$ load will be bound i.e. buffered. In an aqueous solution containing a triprotic acid, $H^+$ can be bound to 3 different states of the acid as well as to $OH^-$ ions that are derived from the auto-ionization of $H_2O$. In quantifying the buffering process of a triprotic acid, one must define the partitioning of $H^+$ among the three states of the acid and also the $OH^-$ ions in solution in order to predict the equilibrium pH value. However, all previous quantitative approaches that model triprotic acid titration behaviour and used to predict the equilibrium pH rely on the mathematical convenience of electroneutrality/charge balance considerations.

This fact has caused confusion in the literature, and has led to the assumption that charge balance/electroneutrality is a causal factor in modulating proton buffering (Stewart formulation). However, as we have previously shown, although charge balance can be used mathematically as a convenient tool in deriving various formulae, electroneutrality per se is not a fundamental physicochemical parameter that is mechanistically involved in the underlying buffering and proton transfer reactions. The lack of distinction between a mathematical tool, and a fundamental physicochemical parameter is in part a reason for the current debate regarding the Stewart formulation of acid-base analysis. We therefore posed the following question: Is it possible to generate an equation that defines and predicts the buffering of a triprotic acid that is based only on $H^+$ partitioning without incorporating electroneutrality in the derivation? Towards this goal we derived our new equation utilizing: 1) partitioning of $H^+$ buffering; 2) conservation of mass; and 3) acid-base equilibria. In validating this model, we compared the predicted equilibrium pH with the measured pH of an aqueous solution consisting of $Na_2HPO_4$ to which HCl was added. The measured pH values agreed with the predictions of our equation within experimental error. Our results provide further important evidence that one can mathematically model the chemistry of acid-base phenomenology without relying on electroneutrality considerations.

**Renal Dysfunction in American Cutaneous Leishmaniasis (ACL)** Rodrigo Alves de Oliveira,[1] Lucia Andrade,[3] Antonio C. Seguro,[3] Talita R. Sanches,[3] Leonardo Oliveira Teotonio,[1] Claudio Gleidiston Lima Silva,[1] Lucyo Flavio Bezerra Diniz,[1] Elizabeth De Francesco Daher.[2] *[1]Internal Medicine, Federal University of Ceará - School of Medicine - Campus Cariri, Barbalha, Ceara, Brazil; [2]Internal Medicine, Federal University of Ceará - School of Medicine - Campus Fortaleza, Fortaleza, Ceara, Brazil; [3]Nephrology Department, University of São Paulo School of Medicine, Sao Paulo, Brazil.*

Renal dysfunction in ACL has been attributed to antimonial treatment but might be attributable to ACL itself. To test this hypothesis, we evaluated 37 ACL patients before treatment. We tested glomerular and tubular renal function, comparing the results with those obtained for 8 control subjects. We also tested urine and plasma osmolality (Uosm and Posm) before and after administration of desmopressin (after a 12-h fast), as well as plasma bicarbonate (Pbic), urinary pH (UpH) and plasma pH (PpH) before and after oral administration of $CaCl_2$ (acidification test). In addition, we quantified AQP2, NHE3, NKCC2, H-ATPase and pendrin. None of the patients had glomerular dysfunction (ClCr, 109±31 ml/min). Urinary concentrating defect was identified based on a post-test U/Posm ratio <2.8 in 27 patients (77%) or Uosm <700 mOsm/kg in 22 (63%). There was no statistical difference between pre- and post-test osmolality. Urinary AQP2 expression was significantly lower in patients than in controls (99.5±0.5 vs. 38.5±12%, p=0.006), whereas that of NKCC2 was significantly higher (102±2.5 vs. 147±12%, p=0.02). Urinary acidification defect (post-test UpH >5.45) was seen in 17 patients (46%; p=0.006 vs. controls). Pre-test Pbic was <21 mEq/L in 12 patients (32.5%), and pre-test PpH was <7.35 in 14 (38%). NHE3 expression was significantly higher in patients than in controls (100±0.6 vs. 176±15%, p=0.015), as was that of H-ATPase (98±0.2 vs. 190±8%, p=0.04) and pendrin (110±7.0 vs. 152±10%, p=0.05). The urinary concentrating defect is likely caused by downregulation of AQP2 expression, and the increased NKCC2 expression probably represents a compensatory mechanism. ACL is associated with dysregulation of major acid-base transporters and may thus impair urinary acidification.

**Application of a New Delta Current Method for Determining the Substrate Stoichiometry of Electrogenic Sodium Bicarbonate Cotransporters NBCe1-A and NBCe2-C** Xuesi Max Shao,[1] Liyo Kao,[2] Ira Kurtz.[2] *[1]Neurobiology, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

The stoichiometry of electrogenic NBC transporters is an important determinant of their function. If an electrogenic transporter has a fixed stoichiometric ratio q, q can be determined by the reversal potential $E_{rev}$ with known intra- and extra-cellular concentrations of the transported species if a specific blocker is available. If there are other transporters/channels in the membrane, a widely used approach is to calculate delta $E_{rev}$ by altering concentrations of the transported species. This approach is based on the assumption that the effects of other channels and transporters on $E_{rev}$ are additive. However, the Goldman-Hodgkin-Katz (GHK) equation suggests otherwise: $E_{rev}$ is a *logarithmic* function of the sum of different conductances rather than being additive. In the present study, we therefore developed a new delta current (ΔI) method to estimate q based on a general model of transporter function (including symporters and antiporters) that does not require a blocker. ΔI instead of delta $E_{rev}$ is determined by altering the external concentration of a transported ion thereby eliminating other currents. The ratio of ΔIs at membrane voltages $V_2$ and 0 is: $\Delta I_2/\Delta I_o = (\exp(FV_2/2RT))^{q-1}$. Therefore, $q = (2RT/FV_2)\ln(\Delta I_2/\Delta I_o)+1$. We tested this ΔI methodology in patch-clamp experiments of HEK-293 cells expressing NBC1e1-A or NBCe2-C. Our data show that the ΔI equation accurately calculates a stoichiometry ratio of $HCO_3^-:Na^+$ of 2 demonstrating the utility of this new methodology for measuring the stoichiometry of electrogenic transporters.

**PUB511**

**Effects of Respiratory and Metabolic Acidosis on Transcription, Expression, and Distribution of NHE3 in OKP Cells** Pedro Henrique I. Silva, Nancy A. Reboucas. *Physiology and Biophysics, University of São Paulo, Sao Paulo, Brazil.*

The $Na^+H^+$ exchanger isoform 3, NHE3 (Slc9-a3), is essential for $H^+$ secretion and $HCO_3^-$ reabsorption in renal proximal tubules. Our goal in the present study was to evaluate the influence of respiratory (RA) and metabolic acidosis (MA) on expression and sub-cellular localization of NHE3 in opossum kidney proximal tubule cells (OKP).

Confluent OKP cells were submitted to acidosis for 24 h, either by addition of HCl to the medium or by increasing $pCO_2$ (80 or 160 mmHg) in the incubator chamber. Control cells were grown at pH 7.4, $[HCO_3^-]$ 24 mM, and $pCO_2$ 40 mmHg. MA: mild, pH 7.21±0.02, $[HCO_3^-]$ 15.4±0.9; severe, pH 6.95±0.07, $[HCO_3^-]$ 8,5±1.8. RA: mild, pH 7.11±0.03, $[HCO_3^-]$ 24.5±0.3; severe, 6.86±0.01, $[HCO_3^-]$ 29.7±1.0. NHE3-mRNA levels, measured by real time RT-PCR, was similarly increased in mild (46±10.8%) and severe (35.7±8.4%) MA, although it remained unchanged in both types of RA. NHE3-mRNA stability, measured after inhibition of transcription with actinomycin D, did not change in either types of acidosis. Increased activity of the promoter gene, evaluated by the expression of the reporter gene Firefly luciferase, was observed in severe MA when the region spanning -2,095 to +55 was evaluated, but remained unchanged on the segment -152/+55.

A 58.4±6.8% increase in the relative NHE3 protein abundance, evaluated by Western blot of total proteins, was detected in severe MA and remained unchanged in mild or severe RA. Also, an increase of 107±15.4% in the amount of cell-surface NHE3-protein, evaluated by biotin binding, was observed in severe MA, and by 51.0±25.5% in severe RA, but the latter was not significant.

We conclude that metabolic acidosis increases the expression of NHE3 gene by mechanisms that alter the transcription efficiency, but not the mRNA stability. The transcriptional activity seems to be affected not by the low pH, but by the low levels of $HCO_3^-$, since respiratory acidosis with equal low pH had no effect on the promoter activity. Metabolic acidosis, in addition to increasing NHE3 expression at mRNA and protein levels, also increases NHE3 recruitment to the apical membrane, an effect that was not significant in respiratory acidosis.

Disclosure of Financial Relationships: nothing to disclose

**PUB512**

**Sodium Bicarbonate and Progression to Renal Failure in a Majority African American CKD Patient Population** Lakshmi Turlapati, Raeesa Mirza, Rania Abdel-Rahman, Rachel Ward, Travis Kauffmann, Meredith Whitacre, Susan Tober. *Division of Nephrology & Hypertension, Brody School of Medicine at East Carolina University, Greenville, NC.*

**Background**

A study by de Brito-Ashust et al demonstrated that sodium bicarbonate may delay the progression of renal failure to end stage renal disease (ESRD) among chronic kidney disease (CKD) patients. However, this study was conducted on a largely Caucasian patient population located in the U.K. The purpose of this study was to examine the effect of sodium bicarbonate (NaHCO3) on the rate of progression to ESRD among a predominately African American population in an academic medical center in the southeastern U.S.

**Methods**

We conducted a retrospective cohort study to examine the impact of NaHCO3 on the rate of change in GFR. Inclusion criteria consisted of patients older than 18 years with a GFR ≤35. The primary endpoint was the rate of change in GFR. Data was collected until the patient's most recent clinic visit or start of dialysis. The treatment group included patients receiving NaHCO3, and the controls were patients who were not treated but had serum bicarbonate levels similar to those of the treatment group. Independent sample t-tests were used to compare the mean rate of change in GFR between groups.

**Results**

Two hundred charts were reviewed. Of these, 60.5% were African American and 30.8% were Caucasian. The average patient was 62.5 (±14.78) years and most patients were female (54.5%). Average serum bicarbonate level at initiation of treatment with NaHCO3 was 19 mmol/l. Thirty-five patients were in the treatment group, and there were 28 controls. Compared to the control group, the mean rate of change in GFR was slower among patients treated with NaHCO3 (-4.07 ± 6.83 vs. -3.94 ± 7.65), but the difference was not statistically significant (95% CI-2.71-4.77, p>.05).

**Conclusion:**

This retrospective study indicates that NaHCO3 is not associated with decreased progression of ESRD among predominately African American CKD patients. Population differences may account for the findings in this trial compared to previous reports. This finding needs to be confirmed in a prospective, randomized trial.

**PUB513**

**SIADH Due to Neurocysticercosis with a Novel Treatment Strategy** Jenny Blau,[1] Julianna Barsony,[2] Joseph G. Verbalis.[2] *[1]Internal Medicine, Georgetown University, Washington, DC; [2]Division of Endocrinology and Metabolism, Georgetown University, Washington, DC.*

We report a case of SIADH as a result of neurocysticercosis for the first time, and highlight the application of the new V2 receptor antagonist tolvaptan for long-term control of symptomatic SIADH. The larval stage of the pork tapeworm preferentially invades the central nervous system causing neurocysticercosis (NCC), with potential for associated

endocrine disruptions due to inflammatory and mass effects. NCC associated syndrome of inappropriate antidiuretic hormone secretion (SIADH), presenting as hyponatremia, has not been reported. A 33-year old Mexican male presented with headache, nausea, vomiting, altered mental status and gait instability that progressively worsened. MRI imaging revealed a 3.5x3.2 cm cyst occupying the third ventricle with hydrocephalus and thickening of the superior and mid portions of the infundibulum with a left shift. CSF ELISA was positive for anti-cysticercus antibody. SIADH was diagnosed based on euvolemic hyponatremia ([Na+]=123 mmol/L), hypoosmolality (273 mOsm/kg H2O), inappropriately elevated urine osmolality (685 mOsm/kg H2O), and urine sodium (UNa=168 mmol/L), with normal thyroid and adrenal function. The patient underwent surgery and received antihelmintic therapy with abendazole and dexamethasone. Pathology demonstrated absence of direct invasion of the hypothalamus or the pituitary, and noted astrocyte inflammatory reaction. After initial trials of fluid restriction and hypertonic NaCl, persistent hyponatremia responded to escalating doses of tolvaptan (from 15 mg to 60 mg final). Follow-up for 3 months demonstrated normal serum [Na+] (141-143 mmol/L) on tolvaptan 60 mg daily, with no side-effects. This first case presentation of NCC associated SIADH addresses an emerging problem in the U.S., due to rising immigration rates from endemic countries in Latin America, Asia and Africa. The lessons learned from the application of tolvaptan for control of symptomatic SIADH extend beyond NCC. In addition to fluid and electrolyte control, the long-term adverse consequences such as osteoporosis and fractures should also be preventable.

**A Case of Upward Reset Osmostat** Martin D. Brzoska, Ernst H. Scheuermann, Christoph Betz. *Medicine, Division of Nephrology, Johann Wolfgang Goethe-Universität, Frankfurt am Main, Germany.*

We present a case of upward reset osmostat in a 34 year old male with type 1 diabetes mellitus. At the time of clinical workup of the disorder the patient was asymptomatic with no excessive thirst and had a hypernatriemia of 165 mmol/l.

The photograph shows the patient reading a magazine in spite of the severe hypernatremia. However, he had experienced slight disturbances of speech and gait when a serum sodium of 180 mmol/l had been detected two months before.

Our workup included a fluid deprivation test with measurement of serum and urine electroytes, urine osmolarity, plasma ADH concentration and adrenal hormones. Pituitary and hypothalamic lesions as well as solid tumors were ruled out with radiographic imaging.

Producing a urine osmolarity of 900 mosmol/l the patient showed intact renal and hypothalamic reaction to fluid deprivation. We detected no osmotic diuresis or associated chronic kidney disease whatsoever. Volume expansion in turn led to the excretion of a dilute urine and showed no effect on serum sodium concentrations and osmolarity.

We therefore made the diagnosis of upward reset osmostat, which is described as a rare selective disorder of the osmoreceptors with ADH secretion being primarily governed by changes in volume.

**Severe Hyponatremia Caused by Portal Vein Thrombosis without Cirrhosis of Liver – A Hope with Tolvaptan!** Penchala S. Mittadodla,[1] Robert S. Gayner.[1] *[1]St Luke's Hospital, Bethlehem, PA; [2]Bethlehem, PA; [3]Bethlehem, PA.*

Hyponatremia is commonly seen in patients with cirrhosis of the liver with up to 50% of patients having a sodium level less than 135 meq/l. Hyponatremia is a predictor of death with cirrhosis of liver highlighting the need for adequate treatment or correction. We report a rare case of a post-splenectomy patient who developed treatment unresponsive hyponatremia caused by portal vein thrombosis without cirrhosis of the liver ultimately treated with tolvaptan successfully.

A 55-year-old Caucasian male was admitted with a 2-week history of progressively worsening lethargy and abdominal distension secondary to ascites. The patient had a serum Na of 116 meq/l on admission. An extensive workup was performed including a serum osm of 264 mmol/kg, TSH of 2.2 uIu/ml, cortisol level of 14.7 mcg/dl, urinary osmolarity of 337 mmol/kg, urine sodium of 14 mmol/l, normal ejection fraction by echo, normal LFTs (except elevated alkaline phosphatase) and creatinine of 0.9-1.3 mg/dl.

The patient had a splenectomy for hypersplenism, secondary to chronic myelomonocytic leukemia (currently in remission), four weeks prior to this presentation. His baseline serum sodium pre-operatively and up until 4 weeks post operatively ranged between 134 to140 meq/l. Past medical history was notable for ascites, hypertension and anemia.

A CT of the abdomen and abdominal ultrasound revealed portal vein thrombosis with portal hypertension and ascites. His liver appeared normal. A Liver biopsy was performed and showed moderate portal inflammation with mild piecemeal necrosis and bridging fibrosis suggestive of portal vein thrombosis but no evidence of cirrhosis. Transsinusoidal pressure gradient was measured at 7 mmHg.

His hyponatremia was very resistant to fluid restriction, lasix, and aldactone. Tolvaptan, a vasopressin 2 antagonist, was administered in the hospital and his sodium improved to 134 meq/l after 4 days and thereafter ranged between 129 to 133 meq/l with tolvaptan treatment. Additionally, he was treated with warfarin for portal vein thrombosis.

**PUB516**

**A Weakness of Cola** Penchala S. Mittadodla,[1] Robert S. Gayner,[1] Gloria Fioravanti.[1] *[1]St Luke's Hospital, Bethlehem, PA; [2]Bethlehem, PA; [3]Bethlehem, PA.*

Although the effects of caffeine intake have long been recognised, there is very little published literature about chronic excessive intake of cola causing severe electrolyte disturbances. We report a case of cola induced hypokalemia leading to severe muscle weakness. The importance of a detailed history and systematic approach in the investigation of hypokalemia is discussed.

A 43-year old Caucasian male was admitted with 2-week history of escalating weakness and inability to ambulate. He denied any other symptoms. His past medical history was non-contributory and he was not taking any medications. He consumed alcohol occasionally. Physical examination revealed normal blood pressure and was significant only for symmetrically reduced 3/5 strength in all extremities. Lab data revealed hypokalemia with serum potassium of 2.3mmol/l; all other labs were normal except elevated serum CK at 2814 U/l with a normal TSH, random cortisol, aldosterone and sedimentation rate. Urinary electrolytes were not done prior to supplementation of pottasium. His dietary history obtained the next day revealed that patient consumed 5-6 liters of cola/day. With the cessation of cola consumption and administration of potassium supplements, the hypokalemia and muscle weakness resolved.

Caffeine, an ingredient of cola, is known to have a weak diuretic action and can cause hypokalemia if consumed in excess of 500-600mg/day. Cola has 10-15mg of caffeine per 100ml, therefore our patient had been consuming at least 800-1000mg/day for the last 4-6 months. Inadequate dietary intake of potassium along with excessive renal loss due to diuresis would have led to his presentation. Many potential causes of hypokalemia can be eliminated after a detailed history, dietary review and laboratory evaluation. Measurement of blood pressure, serum electrolytes, urine electrolytes and evaluation of acid-base status should be the initial step in the diagnosis of hypokalemia. Subsequent evaluations such as measurement of serum aldosterone, renin and cortisol levels may be needed in certain cases.

Disclosure of Financial Relationships: nothing to disclose

**PUB517**

**Severe Acidosis Due to Propylene Glycol Overdose** Uma Krishna Pakkivenkata, Edward A. Ross. *Division of Nephrology, Univ. of Florida, Gainesville, FL.*

In cases of apparent overdose it is often challenging to ascertain the exact poison when laboratory results are not immediately available. Clinicians need to be aware that agents which are increasingly used as alternatives to ethylene glycol, may themselves

have toxicity. The case below illustrates severe acidosis in which treatment for suspected methanol or ethylene glycol overdose was also efficacious for the unexpected final diagnosis of propylene glycol (PG) poisoning.

A 58 year old male with alcohol dependence was admitted with altered mental status. He complained of blurred vision, dizziness and subjective fever. Physical exam was remarkable only for the impression of alcohol intoxication. Notable laboratory findings were: serum Na 135, K 3.3, Cl 83, $CO_2$ 5 meq/L; BUN 22, Cr 2.4 mg/dl; serum osmolality measured 360 and calculated 331 mOsm/kg, lactate 8.5 mmol/L, EtOH 185 mg/dl, salicylate undetectable; ABG pH 6.89, $HCO_3$ 3.2, $pCO_2$ 16; urinalysis no crystals. With increased anion and osmolal gaps methanol or ethylene glycol toxicity was suspected. He was started on fomepizole and was emergently hemodialyzed for 5 hours, normalizing the anion gap. Days later methanol and ethylene glycol levels returned undetectable, however the PG level was very high at 200 mg/dl making it the sole identifiable cause of the acidosis.

PG (mol wt 76) is used as an emulsifier for IV benzodiazepines, and toxicity due to excess dosing has been reported. It is also now used in antifreeze as a substitute for ethylene glycol. PG is metabolized to pyruvic acid, acetic acid and lactic acid. The parent compound is renally cleared and thought primarily responsible for toxicity, rather than metabolites: CNS depression, arrhythmias, ocular irritation, and GI disturbances. It is rapidly cleared by hemodialysis.

Our patient's altered mental status precluded a history of this overdose. It is imperative that clinicians be aware of growing industrial use of PG, and add this possibility to the differential diagnosis for patients in whom ethylene glycol or methanol toxicity are being considered. Fortunately hemodialysis will efficiently remove PG, as well as many other small suspected toxins, while final identification is awaited from the laboratory.

Disclosure of Financial Relationships: nothing to disclose

**PUB518**

**A Novel Case of Adult-Onset Bartter's Syndrome** Wiroon Sangsiraprapha, Daniel Addison, Evan A. Longfield, Biruh Workeneh. *Internal Medicine, Baylor College of Medicine, Houston, TX.*

Bartter's Syndrome is an autosomal recessive disorder marked by normal blood pressure with profound hypokalemia, metabolic alkalosis, hypomagnesemia, and hypercalciuria. This is caused by a range of mutations in genes encoding for ion transport proteins in the thick ascending limb of the loop of Henle. Although commonly a childhood disease, adult-onset Bartter's syndrome has been noted into the third decade of life. We present this case to add to the sparse literature available in this rare condition.

A 34 year-old Latin American female with a history of multiple DVTs, endometriosis, asthma, and chronic UTIs which was treated with chronic gentamicin presented with persistent hypokalemia that was resistant to replacement therapy. Physical examination revealed normal blood pressure, while laboratory investigation revealed profound hypokalemia with kaliuresis, hypocalcemia with hypercalciuria, hypomagnesemia, and metabolic alkalosis. Urine diuretic screen was negative and renal ultrasonography was normal. Based on the clinical and laboratory findings she was diagnosed with classical Bartter's syndrome.

Bartter's syndrome may present in both the antenatal period as well as in the more common neonatal form. Disease presentations well into the third decade of life have been reported but no reports describe chronic disease presenting after the third decade of life. Additionally, cases of transient Bartter's syndrome associated with aminoglycoside use have been described however aminoglycoside-associated disease lasted no longer than 6 weeks following the cessation of therapy. Our patient went on to have persistent Bartter's after more than a year of aminoglycoside discontinuation. This leads us to believe that our patient has disease consistent with classical Bartter's syndrome. We postulate that long-term use of gentamicin may have played a role in activating a disease-causing mutation leading to her unusually late disease-onset.

**Conclusion**: The classic form of Bartter's syndrome may present beyond the third decade of life, and adult-onset Bartter's syndrome may be associated with gene activating drugs.

**FGF23: An Indicator of Protein Intake in Children with Normal and Mildly Impaired Renal Function?** Justine Bacchetta,[1,2] Pierre J. Cochat,[1] Laurence Dubourg,[1] Isidro B. Salusky,[2] Katherine Wesseling-Perry.[2] *[1]Hospices Civils de Lyon & Universite de Lyon, Bron, France; [2]David Geffen School of Medicine, UCLA, Los Angeles.*

Fibroblast Growth Factor 23 (FGF23) is a phosphaturic factor and a suppressor of 1α hydroxylase activity in the kidney. Although its role in phosphate and vitamin D metabolism have been demonstrated in CKD patients, little is known in subjects with normal renal function or early CKD.

We performed a sub-group analysis of the INU23 study (influence of GFR and age on FGF23 levels in pediatric CKD) in the subgroup of children with renal risk but normal renal function or early CKD, after excluding patients. with solid organ transplantation, nephrotic syndrome and genetic disorders associated with specific bone abnormalities.

A total of 120 children (65 boys, age 10.7±3.9 yrs, BMI 17.4±3.6) were included. Mean±SD (range) for biological parameters were: GFR (inulin clearance) 109±18 (70-150) ml/min/1.73m$^2$, PTH 31±12 (7-86) pg/ml, 25OHD 25±10 (7-69) ng/l, C-terminal FGF23 (Immutopics$^R$) 38±41 (2-376) RU/ml, intact FGF23 (Kainos$^R$) 35±17 (2-78) pg/ml and uric acid (UA) 253±69 (95-452) µmol/l.Univariate Spearman analysis found significant associations between UA and GFR (r=-0.21; p=0.02), age (r=0.33; p<0.001), body weight (r=0.41; p<0.001), height (r=0.37; p<0.001), BMI (r=0.34; p< 0.001), PTH (r=0.34; p<0.001), C-terminal FGF23 (r=0.19; p=0.04), intact FGF23 (r=0.26; p=0.005), phosphate reabsorption rate (RRP, r=-0.36; p< 0.001), TmP/GFR (r=-0.28; p=0.02) and serum proteins (r=0.19; p=0.04). Multiple linear regression analyses using backward stepwise procedures demonstrated that uric acid could predict TmP/GFR, as well as PTH and C-terminal FGF23 serum levels. A similar trend was observed for intact FGF23. Since phosphate, protein, and purine intakes are closely linked, therefore the association between uric acid, markers of urine phosphate excretion and serum FGF23 suggests that circulating levels of FGF23 may be an early nutritional indicator of high protein and phosphate intakes in a pediatric population with normal or mildly impaired GFR.

**Shank2 Redistributes with NaPiIIa during Regulated Endocytosis** Evgenia Dobrinskikh, Hector Giral-Arnal, Yupanqui A. Caldas, Moshe Levi, R. Brian Doctor. *Medicine, University of Colorado, Denver, Denver, CO.*

Serum phosphate levels are acutely impacted by the abundance of sodium phosphate co-transporter IIa (NaPiIIa) in the apical membrane of renal proximal tubule cells.PDZ domain-containing proteins bind NaPiIIa and likely contribute to the delivery, retention, recovery and trafficking of NaPiIIa. Shank2 is a distinctive PDZ domain protein that binds NaPiIIa. To begin defining the role of Shank2 in regulating NaPiIIa activity, distribution and abundance, the present in vivo study followed the fates of NaPiIIa and Shank2 during regulated NaPiIIa endocytosis. Rats were maintained on a low phosphate diet and then plasma phosphate levels were acutely elevated by high phosphate feeding to induce the recovery, endocytosis and degradation of NaPiIIa. Western blotting of renal cortical tissue from mice given high phosphate feed showed NaPiIIa and Shank2 underwent degradation. Quantitative immunofluorescence analyses, including microvillar vs intracellular intensity ratios and intensity correlation quotients, showed that Shank2 redistributed with NaPiIIa during the time course of NaPiIIa endocytosis. Further, NaPiIIa and Shank2 trafficked through distinct endosomal compartments (clathrin, early endosomes, lysosomes) with the same temporal pattern. These in vivo findings indicate that Shank2 is positioned to coordinate the regulated endocytic retrieval and down regulation of NaPiIIa in rat renal proximal tubule cells.

**Down-Regulation of Paracellin-1 in Diabetic Rats as a Possible Cause of Hypomagnesemia in Diabetes** Kaori Takayanagi, Taisuke Shimizu, Takatsugu Iwashita, Yosuke Tayama, Juko Asakura, Koichi Kanozawa, Hajime Hasegawa. *Dept of Nephrol & Hypertens, Saitama Med Center, Saitama Med Univ, Kawagoe, Saitama, Japan.*

Hypomagnesemia is a well known clinical feature of diabetes mellitus, and is recently revealed to be involved in the development of insulin resistance. Although the hypomagnesemia in diabetes is known to be provoked by the decrease in the renal Mg reabsorption, its molecular mechanisms have not been elucidated. In this work, we studied the changes in the expression of Mg transporting molecules in diabetic rats.

Kidneys were sampled from male SD rats at 4 weeks after streptozotocin (STZ) injection (60 mg/kg, ip). Changes in the expression and distribution of Mg transporting molecules were studied by immunohistochemistry and real time PCR.

In results, fractional excretion of Mg (FEMg) was significantly decreased in STZ-rats (0.49±0.12% in STZ-rats vs 0.64±0.11% in control), although serum Mg concentration was not decreased. In STZ-rats, gene expression of paracellin-1 (PCLN), which is a principal Mg pathway in tight junction of ascending loop of Henle (TAL), was significantly decreased (68.6±14.9% in STZ-rats vs 100.7±6.7% in control rats), although gene expression of calcium sensing receptor (CaSR) was similarly down-regulated (46.2±3.2 in STZ-rats vs 106.7±17.7 in control rats). Gene expressions of TRPM6, TRPM7, NKCC2, ROMK and NCC were all unchanged in STZ-rats. Immunohistochemistry of PCLN showed diminished immunoreactivity in the superficial and juxtamedullary lesions of cortex in the STZ-rats. Similarly, immunoreactivity of CaSR was also diminished in the cortex.

Present study suggested that the hypomagesemia in diabetes might be provoked by the decreased reabsorption of Mg in TAL which might be principally resulted from down-regulation of PCLN. The decreased Mg reabsorption is known to be noticed in microalbuminuric stage of diabetic nephropathy. PCLN-related inhibition of Mg reabsorption may indicate the interstitial damage of early diabetic nephropathy.

**Renal Hypophosphatemia and SIADH Associated with Small Cell Carcinoma: Report of a Case and Review of the Literature of 9 Cases** Ekamol Tantisattamo, Roland C. K. Ng. *Department of Medicine, University of Hawaii, John A. Burns School of Medicine, Honolulu, HI.*

*Background*: Acquired isolated renal phosphate wasting associated with tumor known as oncogenic osteomalacia is a rare paraneoplastic syndrome caused by overproduction of fibroblast growth factor 23. Oncogenic osteomalacia is usually associated with benign mesenchymal tumors. Syndrome of inappropriate antidiuretic hormone secretion (SIADH), on the other hand, is a common paraneoplastic syndrome caused by small cell carcinoma (SCC). Concomitant oncogenic osteomalacia and SIADH associated with SCC is very rare with only 4 other cases reported in the literature. We report a case of SCC-related renal wasting hypophosphatemia and concurrent SIADH and review the literature reporting 9 other cases of SCC associated with oncogenic osteomalacia.

*Case report*: A 60-year-old Caucasian male presented with nausea, vomiting, and generalized malaise due to persistent hyponatremia for 2 months despite fluid restriction. Laboratory workup comfirmed SIADH. Serum phosphorus was less than 1 mg/dl and remained low in spite of phosphate replacement. Fractional excretion of phosphorus was 41% (normal < 5%) and renal tubular maximum resorptive capacity of phosphorus factored for GFR was 0.6 mg/dl (normal 2.5-4.2 mg/dl). Serum calcium was 9 mg/dl and total 25-Hydroxy vitamin D was 34 ng/ml. Chest x-ray was unremarkable. Chest and abdominal CT scan showed a left apical lung mass, left hilar adenopathy, and liver metastasis. Bronchoscopy with biopsy confirmed SCC. His serum phosphorus normalized after receiving the first cycle of chemotherapy.

*Conclusions*: Almost half of reported cases of renal phosphate wasting associated with SCC concomitantly presented with SIADH. These cases had initial serum phosphorus level lower and survival periods shorter than those without SIADH. This rare dual paraneoplastic syndrome and low serum phosphorus may be a poor prognostic sign. In addition, both renal phosphate wasting and SIADH usually occur in a short period of time before identification of SCC. Therefore, renal wasting hypophosphatemia with concomitant SIADH/hyponatremia should prompt a search for SCC rather than a benign mesenchymal tumor.

**Opossum Kidney (OK) Cells Demonstrate Molecular and Electrophysiological Properties Consistent with "Leaky" Proximal Tubular Epithelia** R. Todd Alexander, Jelena Borovac, Andrew C. Rasmussen. *Department of Pediatrics & Physiology, University of Alberta, Edmonton, AB, Canada.*

The proximal tubule (PT) reabsorbs the majority of glomerular filtrate. A significant amount of water and electrolytes are (re)absorbed from this nephron segment via the paracellular pathway. The molecular mechanisms mediating this are incompletely understood. This is in part explained by the lack of a well characterized cell culture model suitable to the study of paracellular transport across a leaky epithelia such as the PT. We therefore set out to develop and characterize a cell culture model with which to study PT paracelluar transport. To this end, we employed Opossum kidney (OK) cells. We first measured their transepithelial resistance, with a EVOM Epithelial Voltohmmeter, as they became polarized. We found, by 4 days after plating, a resistance of $9.78 \pm 1.52\ \Omega/cm^2$, that did not increase further. Next, we employed Ussing chambers to perform dilution potential measurements. Consistent with a fixed paracellular pore that is not altered by voltage, we observed a linear relationship between voltage and current applied across the monolayer. These studies demonstrated a pNa/pCl ratio of 0.962 ± 0.006, consistent with preferred paracellular anion flux. This was maintained across a range of dilutions between 0.25 – 4 (apical to basolateral). The absolute flux of $Na^+$ was found to be 4.9*10-8 ± 0.1*10-9 cm/s and $Cl^-$ to be 5.1*10-8 ± 0.1*10-9 cm/s. This is in keeping with the high conductance of this cell line (0.05 ± 0.01 S/cm²). We then employed a radiotracer to measure calcium diffusion across monolayers of OK cells and found a flux of 214 ± 43 nmol/hr/cm². In order to understand the molecular basis of these findings we set out to determine the expression of claudins (tight junction proteins implicated in paracellular ion fluxes) in this model system. We were able to identify and clone by homology claudin-4, -6, -11, -12, -15 and -20 from this cell line. In summary, we have characterized the molecular and electrophysiological phenotype of a low resistance, renal epithelial cell culture model with which to study PT paracellular transport.

**Evidences That Ser 418 Can Modulate hSGLT1 Distribution in MDCK Cells** Olivia Beloto-Silva, Maria Oliveira-Souza. *Physiology and Biophysics, University of Sao Paulo, Sao Paulo, SP, Brazil.*

The regulation of $Na^+$/glucose co-transporter (SGLT1) is essential for the provision of glucose to the body and, thus it is important for maintenance of blood glucose at near constant levels. The activity and cellular distribution of SGLT1 is modulated by the phosphorylation state of the protein involving protein kinases PKA or PKC. One of the known phosphorylation sites is at Serine 418 (S418). In this study we investigated the effect of cellular distribution of human SGLT1 (hSGLT1) and a mutation changing S418 to a histidine (hSGLT1-*S418H*). Endogenous SGLT1 and SGLT2 expression, in *wild type* MDCK cells (*wt*MDCK), was accessed by analysis of mRNA. The genes encoding for hSGLT1 and hSGLT1-*S418H* were ligated into the fluorescent vector pEGFP-N1 and transfected into *wt*MDCK cells. Immunoblotting was used to confirm if hSGLT1 and hSGLT1-*S418H* were being expressed after the transfection. Immunofluorescence was used to provide information about the cellular distribution of hSGLT1 and hSGLT1-*S418H*. Our results show no expression of mRNA for SGLT1 or SGLT2 was detected in *wt*MDCK cells (nontransfected), what makes this cell a model system for studying SGLT1 or SGLT2 co-transporters. The distribution of hSGLT1, in transfected cells, was predominantly in the plasma membrane. In contrast, the distribution of hSGLT1-*S418H* was predominantly in the cytosol, but will be further confirmed with experiments of biotinylation. Thus, this work demonstrates that presence of Serine 418 is required for proper cellular distribution of hSGLT1. Moreover, the phosphorylation of S418 appears to be necessary for the insertion of the protein into the plasma membrane of MDCK cells, which can probably modify the glucose transport by SGLT1. **Clinical Features of Hyponatremia: Changes Related to Increasing Use of Thiazide Diuretics** Inhye Cha, Won-Yong Cho, Sang-Kyung Jo, Hyoung-Kyu Kim. *Department of Internal Medicine, Division of Nephrology, Korea University Anam Hospital, Seoul, Republic of Korea.*

Background : Hyponatremia is the most frequent electrolyte disorder in clinical practice. Use of thiazide diuretics markedly increased, and thiazide-induced hyponatremia seems to be frequently encountered. Purpose : Evaluate the incidence, etiologies of hyponatremia for 6years(2004-2009). Assess the prevalence and characteristics of thiazide-induced hyponatremia. Methods : Retrospective cohort study. Total 322 patients who admitted with hyponatremia were included. Results : 174(54%) patients presented hyponatremia. 208(64.6%) were female, mean age was 69.9 years-old, average plasma sodium was 118.9mEq/L on admission. Most common current medical histories were hypertension(56.5%) and diabetes mellitus(29.8%). Most common causes were thiazide diuretics(37.6%) and SIADH(18.9%). Most common clinical manifestations were general weakness(44.4%) and nausea(22%). Thiazide-induced hyponatremia show a tendency to increase from 2004 to 2009(P<0.001), combination type drug use were also increasing. In thiazide-induced hyponatremia compare to those from other causes, portion of female was higher (73.6% vs 64.6%, P<0.001), mean age was older (74.7 vs 69.9 years-old, P<0.001) and incidence of cerebrovascular accident was higher (19.8% vs 11.5%, P<0.001). Conclusion : The number of hyponatremia increased for recent 6years. The percentage of thiazide-induced hyponatremia is still increasing, and thiazide-containing combination drug is becoming a main cause of thiazide-induced hyponatremia. Thiazide-induced hyponatremia seems to occur mainly in old age, female and who has history of cerebrovascular event. Therefore more cautions might be necessary in those patients with thiazide use.

**PUB526**

**RLY5016: A Novel Therapeutic Polymer To Control Serum Potassium: Physical, Chemical & In Vitro Properties** Jamie Cope, Kalpesh N. Biyani, Han-Ting Chang, Eric F. Connor, Angela Lee, Mingjun Liu, Deidre L. Madsen, Paul Mansky, Jonathan A. Mills, Florence Roger, Jerry Buysse. *Relypsa, Santa Clara, CA.*

Potassium (K) is the main intracellular electrolyte required for fundamental processes such as membrane activation, ion and solute transport, and the regulation of cell volume. Serum K levels ≥5.5mEq/L (hyperkalemia) can lead to muscle weakness, ventricular tachycardia and death. Precise control of K homeostasis, therefore, is critical. Acute or chronic hyperkalemia can arise from tissue trauma, renal insufficiency, insulin deficiency or resistance, conditions that interfere with the normal workings of the renin-angiotensin-aldosterone-system (RAAS) and/or the use of RAAS blocking drugs. For half a century, a cation exchange resin, sodium polystyrene sulfonate (Na-PSS; e.g. Kayexalate, Kionex), has been used to treat hyperkalemia. Recently its efficacy, as well as the safety of the doses of sorbitol with which it is most often co-administered, has been questioned.

RLY5016 is a new, high capacity, non-absorbed, cation exchange polymer intended for the control of serum K. The RLY5016 polymer comprises low swelling beads with an average diameter of 100uM. The counter-ion present on RLY5016 is calcium (rather than sodium), which is preferable for chronic heart failure or hypertension patients with chronic renal insufficiency in whom control of sodium intake is important.

RLY5016 releases most or all of its calcium under low gastric pH conditions and therefore becomes available for binding other cations when the pH increases upon exit from the stomach. Because of its novel chemical composition, RLY5016 has a binding capacity approaching double that of Na-PSS when tested in vitro at pH6-6.5 (Table).

RLY5016 binds up to 1.5mEq K per gram of polymer in human colonic and fecal extracts, where abundant interfering ions are available to compete for binding sites. This polymer is therefore capable of binding K in the complex milieu of the colon and increasing K excretion through this route.

| Polymer | Final pH | K Bound (mEq/g) |
|---|---|---|
| RLY5016 | 6.21 ± 0.02 | 8.53 ± 0.13 |
| Kayexalate | 6.35 ± 0.02 | 5.09 ± 0.05 |

**Acute Management of Patients with Hyperkalemia: A Systematic Review** Meghan J. Elliott,[1] Paul E. Ronksley,[2] Catherine M. Clase,[3,4] Sofia B. Ahmed,[1] Brenda Hemmelgarn.[1,2] *[1]Department of Medicine, University of Calgary, Calgary, AB, Canada; [2]Department of Community Health Sciences, University of Calgary, Calgary, AB, Canada; [3]Department of Medicine, McMaster University, Hamilton, ON, Canada; [4]Department of Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, ON, Canada.*

Hyperkalemia occurs commonly and, if left untreated, can lead to fatal cardiac arrhythmias. We undertook a systematic review of the randomized trial evidence supporting available therapies in the acute management of hyperkalemia.

A previous systematic review included studies to 2003 (Mahoney BA et al, 2005). We conducted an all-language search of MEDLINE and EMBASE from 2003 to 2009 that combined the search theme, hyperkalemia, with the sensitive RCT filter. Eligible articles included RCTs, quasi-RCTs and crossover studies of pharmacological and non-pharmacological interventions for hyperkalemia in adults.

Our search retrieved 2158 potentially relevant citations; 9 were reviewed in full text (Kappa=0.94). Five (n=164) of these in addition to 11 studies (n=212) from the previous review were included. There was insufficient data from studies for meta-analysis to be performed. Intravenous (IV) insulin and dextrose reduced serum $K^+$, on average, by 0.5 mmol/L within 15 minutes and persisted 1 to 2 hours. A similar decrease occurred within 30 minutes of treatment with both nebulized and IV beta$_2$-agonist formulations. Nebulized albuterol and IV insulin together were more effective than either alone (decrease in $K^+$ 1.2 + 0.87 mmol/L at 60 minutes). Results for IV bicarbonate were equivocal. There was no appreciable benefit to resin or fludrocortisone over placebo. No major adverse events were reported with any of the interventions. Most studies were small and of variable quality.

The evidence guiding emergency interventions for hyperkalemia is limited and based on small studies with poor reporting and methodological limitations. Based on this systematic review, appropriate first line therapies include nebulized or inhaled beta-agonists and IV insulin with dextrose. Combination therapy appears more effective than either intervention alone. Further well-designed studies in this area are needed.

## PUB528

**Analysis of Characteristrics of Hyponatremic Patients Hospitalized Via Emergency Department** Eun Hee Jang,[1] So Yeon Choi.[2] *[1]Nephrology, School of Medicine, Jeju National University Hospital, Jeju, Jeju-do, Korea; [2]Internal Medicine, Seoul Adventist Hospital, Seoul, Korea.*

Hyponatremia is the most common electrolyte disorder. We evaluated the causes and clinical manifestations of symptomatic hyponatremia. We retrospectively reviewed clinical records of the hyponatremic patients who had been admitted from January 2005 to June 2009. We enrolled 68 patients(22 male, age 67.8±15.9 years, mean±SD) without liver cirrhosis, heart failure, chronic kidney disease or septic shock. We analyzed data to evaluate the differences of clinical manifestations according the age, sex, symptoms, taking medications(especially diuretics such as thiazide), urine sodium concentrations and the degree of hyponatremia. Sodium concentration([$Na^+$]) was 116.9±7.1 mEq/L and serum osmolalilty was 247.8±19.4 mOsm/kg. Urine sodium concentration and osmolality were 68.0±55.7 mEq/L and 382.8±150.4 mOsm/kg respectively. There was no difference in serum [$Na^+$] according to age, sex. Thirty four patients (50%) had nausea and vomiting and 21(30.9%) patients showed neurologic symptoms. Patients with neurologic symtoms seemed to have lower serum osmolarity than patients without neurologic symptoms(242.9± 19.2 vs 250.21±19.5 mOsm/kg, $p = 0.08$). The main causes of symptomatic hyponatremia were diuretics(35, 51.4%), poor oral intake(17, 25.0%) and SIADH(6, 8.8%). Initial choice of fluid therapy were discontinuation of offending drugs with free water restriction(8, 11.7%), 0.9% normal saline infusion(33, 48.5%) and hypertonic saline(20, 29.4%). Thiazide-induced hyponatremia(35, 51.4%) was common in elederly female patients(24) and showed more hypo-osmolar than hyponatremia due to other causes(240.0±17.8 vs 256.5 mOsm/kg, $p < 0.05$). However, in 19 cases of thiazide-induced hyponatremia, serum [$Na^+$] was recovered quickly by isotonic fluid infusion, discontinuing thiazide without hypertonic saline with no neurologic complications. Thiazide diuretics may be the main cause of symptomatic hyponatremia. Especially in elderly patients, thiazide should be carefully administered with frequent electrolyte monitoring.

## PUB529

**Hyponatremia with Aliskiren: Pseudohyporeninemic Hypoaldosteronism** Rahul S. Koushik.[1,2,3] *[1]UTHSC, TX; [2]International Kidneycare Foundation, TX; [3]SAKDC, San Antonio, TX.*

Introduction: Direct rennin inhibition (DRI, Aliskiren, Tekturna®, Rasilez®) has supplemented ACEI, ARB and spironolactone in renin-angiotensin-aldosterone system (RAAS) antagonism. Long term side effects of this drug are unknown. Three cases of hyponatremia on aliskiren, are presented.

Case 1: A 72 year-old obese Latino woman with CKD IV, DM2, HTN, CHF and remote uninephrectomy presented with dizziness, confusion, weakness after a recent increase in loop diuretic. Fifteen months ago, alsikerin 300 QD was added to a regimen of irbesartan 300 QD, lisinopril 40 BID, metoprolol 100 BID, nifedipine 60 BID and furosemide 80 BID. Symptoms and sodium slowly normalized on holding ACEI, ARB and aliskiren.

Case 2: A 60 year-old Latino woman with CKD III, DM2, HTN and hypothyroidism presented with dizziness, weakness, atypical chest discomfort. Two years ago aliskiren 150 QD was started to supplement lisinopril 40 QD and HCTZ 12.5 QD. She responded to IV fluids and withholding aliskiren/ACEI.

Case 3: A 74 year-old African-American woman with CKD IV, DM2 and HTN presented with a subcutaneous abscess and uncontrolled diabetes. Two years ago, aliskiren 300mg was added to her regimen of olmesartan 40 BID, amlodipine 10 QD, furosemide 40 BID and clonidine 0.2 BID.

BP and labs

| Case | BP | Sr Na | Sr K | Ur Na | BNP | Sr urate | eGFR |
|---|---|---|---|---|---|---|---|
| 1 | 110/75 | 117 | 5.0 | 25 | 633 | 9.3 | 22 |
| 2 | 82/50 | 134 | 4.4 | 112 | 5 | NA | 23 |
| 3 | 134/70 | 131 | 4.6 | 64 | 44 | 10.5 | 29 |

Ur Na= urine sodium, BNP=brain natriuretic peptide, NA=not available

Discussion: Patients presented with diverse symptoms, pre-renal labs (high BUN/creatinine ratios and sr. uric acid) and hyponatremia long after aliskiren was started (mean 21.3 months). They responded to holding RAAS blockers. Aliskiren therapy may result in a physiological state of *pseudohyporeninemic hypoaldosteronism* that interferes with the protective, renin-mediated, 'aldosterone escape' of chronic diuretic use.

Conclusions: We have reached a new zenith in RAAS antagonism. Aliskiren with other RAAS blocking agents and diuretics may increase susceptibility to severe hyponatremia. Urine electrolytes may not be useful in assessing volume depletion in aliskiren treated patients

Disclosure of Financial Relationships: nothing to disclose

## PUB530

**Hospital Admissions for Hyperkalemia with Trimethoprim-Sulfamethoxazole – A Cohort Study of 267,212 Older Women with Urinary Tract Infections** Ngan Lam,[1] Matthew A. Weir,[1,2] Amit X. Garg.[1,2,3] *[1]Department of Medicine, Division of Nephrology, University of Western Ontario, London, ON, Canada; [2]Department of Epidemiology and Biostatistics, University of Western Ontario, London, ON, Canada; [3]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada.*

Background: Trimethoprim-sulfamethoxazole (TMP-SMX) is a commonly used antibiotic which may cause hyperkalemia by blocking the amiloride-sensitive sodium channels in the cortical collecting duct. This association has been described in case reports and small studies.

Objective: To obtain population-based estimates of the risk of hospital admissions for hyperkalemia following treatment with TMP-SMX in elderly women for urinary tract infection (UTI).

Design: Retrospective, population-based, cohort study.

Methods: We utilized linked health care administrative databases in Ontario, Canada from January 1, 1997 to March 31, 2009 to identify elderly women with simple UTIs who were treated with TMP-SMX. We compared their results to those treated with other antibiotics. The primary outcome was a hospital admission for hyperkalemia within 10 days of antibiotic initiation.

Results: The cohort consisted of 267,212 women. The primary outcome rate per 100,000 patients was 53.7 in the TMP-SMX group. This represented a 3.0-fold increased risk compared to amoxicillin, the referent drug. No such association was observed with the other antibiotics. Only 2.5% of women admitted for hyperkalemia had an outpatient potassium level measured in the days following their TMP-SMX initiation.

Conclusion: TMP-SMX therapy increases the risk of hospitalization for hyperkalemia. Physicians should be aware of this adverse event and consider a standing order to measure serum potassium three days after a TMP-SMX prescription in older patients at risk of hyperkalemia.

Association between antibiotic use and hospital admissions for hyperkalemia

| | Event rate (per 100,000 persons) | Odds Ratios [95% CI] | |
|---|---|---|---|
| | | Unadjusted | Adjusted |
| TMP-SMX | 53.7 | 2.30 [0.82, 6.51] | 3.05 [1.07, 8.67] |
| Ciprofloxacin | 15.5 | 0.66 [0.19, 2.35] | 0.66 [0.19, 2.36] |
| Norfloxacin | 9.0 | 0.38 [0.11, 1.31] | 0.46 [0.13, 1.58] |
| Nitrofurantoin | 9.8 | 0.42 [0.12, 1.43] | 0.45 [0.13, 1.55] |
| Amoxicillin (reference) | 23.3 | 1.00 | 1.00 |

## PUB531

**Spontaneous Severe Hypokalemia (HK) of Uncertain Etiology Presenting with Quadriplegia in a Rural South Indian Population** Sreejith Parameswaran,[1] Rathinam Swaminathan,[2] Jai Radhakrishnan.[3] *[1]Nephrology, JIPMER, Pondicherry, India; [2]Medicine, JIPMER, Pondicherry, India; [3]Medicine, Columbia U, NY, NY.*

Spontaneous, severe HK manifesting as quadriplegia in the absence of overt renal function abnormalities has been increasingly observed at our center( during just the months of May & June 2010, a total of 10 such pts were admitted to our center). In this preliminary report, we describe the clinical and biochemical features of 4 such pts (2F, age 34-44 yrs). 3 pts presented with flaccid quadriparesis and 1 pt with neck weakness. 2 pts reported nocturia. All pts were normotensive, none were diabetic. 2 pts experienced previous episodes and had discontinued K supplements.

Relevant biochemistries are shown:

Table 1:

| | Serum K (mEq/L) | Serum HCO3 (mEq/L) | Serum Creatinine (mg/dl) | Urine K (mEq/L) | Urine Osm (mosm/l) |
|---|---|---|---|---|---|
| Patient 1 | 2.1 | 27 | 1.0 | 8.6 | 204 |
| Patient 2 | 1.8 | 22 | 1.1 | 8.02 | 175 |
| Patient 3 | 1.9 | 36 | 0.8 | 12.7 | 457 |
| Patient 4 | 2.3 | 50 | 1.1 | 5.91 | 108 |

All the patients had normal s.creatinine, 2 of 4 patients had severe metabolic alkalosis, and developed low $iCa^{+/}$carpopedal spasm following K+ correction. All had low urine $K^+$ suggesting extrarenal loss or transcellular shift of $K^+$. None of the patients had h/o vomiting or loose stools, they denied h/o intake of drugs known to produce HK. Our center is located in southern peninsular India with a 'tropical dry climate' with high ambient temperatures.

March to June are hot and dry with temperatures up to 39$^0$C. All our patients lived in a rural setting and were of low socioeconomic status. . Rice was their staple diet, consumed three times a day; their financial status did not allow consumption of high $K^+$ foods(meat, vegetables and fruits). We hypothesize that extremely low dietary $K^+$ coupled with

excessive loss of $K^+$ in the sweat resulted in severe HK. Periodic paralysis is a possibility but is a rare entity.

In summary, we report, for the first time from our country, a high incidence of hypokalemic paralysis postulated to be from a very low consumption of $K^+$ coupled with excessive loss in sweat. Further studies on the epidemiology and etiology are underway.

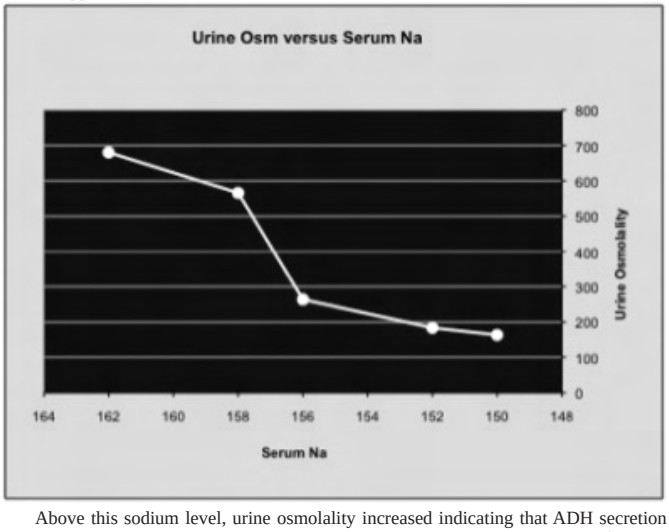
**Neurosarcoidosis Presenting as Hypernatremia: Interplay of Reset Osmostat and Relative Hypodipsia** Kanwal Raghav,[1] Saurabh A. Pande,[2] Nina Mingioni,[1] Eric J. Bloom.[2] *[1]Internal Medicine, AEMC, Philadelphia, PA; [2]Nephrology, AEMC, Philadelphia, PA.*

Preface: Pathophysiology underlying hypernatremia entails either excess salt intake or free water loss. Antidiuretic hormone (ADH) release and thirst center stimulation due to rising plasma osmolality, act as homeostatic mechanisms. Together, they minimize free water loss and increase fluid intake, maintaining serum sodium within a narrow range. Rarely, the problem lies within this regulatory system impairing either the thirst mechanism or osmotic regulation of ADH release.

Case: 32-year-old woman with sarcoidosis presented with generalized weakness. Labs showed serum sodium of 172mmol/L and urine osmolality of 1302mOsm/k. Trending serum sodium and urine osmolality revealed that osmolalities dropped dramatically when sodium approached 157mmol/L.



Above this sodium level, urine osmolality increased indicating that ADH secretion and its action on kidney was intact. MRI showed enhancement anterior and inferior to third ventricle suggestive of neurosarcoidosis. Desmopressin with increased water intake, stabilized serum sodium nearing 154mmol/L.

Hypothesis: Since patient showed signs of thirst, but resultant water intake was insufficient to manage the serum osmolality, a relative hypodipsia was proposed. Also since urine osmolality fell dramatically below a sodium concentration of 157mmol/L, a reset osmostat with the body recognizing higher than normal sodium as the norm was coexistent. Neurosarcoidosis affecting the thirst center [medial preoptic nucleus] and osmoreceptors [subfornical organ and organum vasculosum of lamina terminalis] was the culprit lesion.

Discussion: Hypodipsia with essential hypernatremia due to reset osmostat is a rare entity. There is an anomalous thirst mechanism along with defective osmoreceptors which results in a chronic, fluctuating hypernatremia. treatment is uncertain.

**Human Platelet Lysates as a Serum Substitute in Renal Epithelial Cell Culture** Caroline Rauch, Elisabeth Feifel, Gerhard Gstraunthaler. *Division of Physiology, Innsbruck Medical University, Innsbruck, Austria.*

Cultured renal epithelia form monolayers of differentiated, polarized cells. Grown on permeable supports, an apical and a basolateral compartment are separated by the cultured epithelium, that enable to study epithelial transport in vitro. Some requirements must be met by the in vitro system: retention of the polar cell architecture and junctional assembly, presence of vectorial transport, sidedness of cellular uptake routes, and retention of segment-specific metabolic and transport properties. Thus, culture conditions, culture media and supplements have a significant impact on in vitro epithelial function. In this respect, the quality of fetal bovine serum (FBS) seemed to be of major importance. In early studies a high lot-to-lot variablity of FBS was found that substantially influenced the differentiation of Xenopus laevis A6 epithelia and the generation of a transepithelial potential difference (PD) and resistance (TEER), and batch-testing of FBS was required.

We recently reported on the use of human platelet lysates (PL) as a replacement for FBS. PL preparation was optimized for growth factor content, quantified by ELISA. The growth promoting capacity of PL was tested on renal cell lines, for which growth characteristics, phenotypes, and differentiation end points are well established. PL support growth, proliferation and differentiation, as assessed by dome formation, of proximal tubule-like LLC-PK1, HK-2 and distal tubule-like MDCK cells. Proliferation was monitored by determination of cell density and by resazurin or WST-8 assays. Proliferation rates were identical in culture media with 10% FBS or 5% PL. To biochemically determine the mitogenic potential of PL, the stimulation of ERK1/2 MAP kinase was determined. Addition of PL to quiescent LLC-PK1 cultures resulted, like FBS, in specific phosphorylation, and thus activation, of ERK1/2. In addition, TEER was monitored in filter-grown LLC-PK1 and MDCK epithelia. Both epithelia generated a TEER of 150-250 Ω•cm2 in PL-supplemented media, comparable with FBS.

PL are a valuable, animal-derived component-free substitute for FBS in renal epithelial cell culture, with a proven high batch-to batch uniformity.

**Progesterone: The Missing Factor in Potassium Homeostasis in Mice and Men** Amel Salhi,[1] Anie Azroyan,[1] Aurelie Edwards,[2] Gilles Crambert.[1] *[1]Centre de Recherche des Cordeliers, INSERM/UPMC/CNRS, Paris, France; [2]Department of Chemical and Biological Engineering, Tuft University, Medford, MA.*

Modern dietary habits are characterized by high-Na+ and low-K+ intakes, each of which has been correlated with a higher risk for hypertension. In this study, we examined whether long-term variations in the intake of Na+ and K+ induce lasting changes in the plasma concentration of circulating steroids by developing a mathematical model of steroidogenesis in mice. An interesting finding of the mathematical model is that mice increase their plasma progesterone levels specifically in response to K+ depletion. This prediction was confirmed by experimental measurements in both male mice and men. We then focused on the putative role of progesterone as an in vivo modulator of renal function under potassium restriction conditions. Our results indicate that progesterone regulates renal K+ handling both in males and females, independently of its role in reproduction. We established that the increase in progesterone production by male mice is time-dependent and is correlated with decreased urinary K+ content. The progesterone-dependent ability to retain K+ efficiently is due to a RU486-sensitive stimulation of the "colonic" H,K-ATPase expressed in kidney. Our results suggest the existence of a hereto unknown regulatory process involving progesterone, its nuclear receptor, the colonic H,K-ATPase and renal K+ retention.

**PUB535**

**Involvement of H,K-ATPase Type2 in Renal Potassium Retention during Pregnancy** Amel Salhi, Gilles Crambert. *Centre de Recherche des Cordeliers, UPMC / CNRS, Paris, France.*

Progesterone, a steroid hormone involved in the female menstrual cycle, pregnancy (supports gestation) and embryogenesis, is also a neuromediator acting in the central nervous system, suggesting that this hormone may have other functions larger than those usually described. Moreover, different types of progesterone receptors are found in non reproductive tissues, such as kidney.

Previous studies from our group have recently shown that adrenal progesterone is a hormone produced in a chronic potassium deficient diet, and that it acts on kidney to allow optimal potassium reabsorption by stimulating the H,K-ATPase type 2 (HKA).

Our objective was to determine the role of progesterone in different circumstances known to induce renal potassium retention, for instance in pregnancy.

We have confirmed that a positive potassium balance is induced during pregnancy, regardless of food intake, and this retention is correlated to a stimulation of H,K-ATPase type2 expression (3 fold increase at day 16)

To examine the hypothesis that HKA is important during pregnancy, we have mated wild type mice and established a time course of serum progesterone level, urinary potassium excretion and renal expression of the HKA in female during pregnancy. We have also examined the phenotype of female deficient for HKA during pregnancy.

Preliminary results suggest that HKA is stimulated in kidney of pregnant females and that the lack of HKA results in hardship during parturition. These difficulties are not linked to the genotype of fetuses and potassium replenishment through absorption of enriched water will allow optimal gestation/delivery.

**Gordon's Syndrome: A Case Report of Normotensive Variant** Erdal Sarac. *Department of Internal Medicine, St. Elizabeth Health Center - NEOUCOM, Youngstown, OH.*

Gordon's syndrome, considered a monogenic form of low-renin hypertension, is a rare, autosomal-dominant disease characterized by hypertension, hyperkalemia, hyperchloremic metabolic acidosis and normal glomerular filtration rate.

Here we report an unusual presentation of Gordon's syndrome with normal blood pressure in a 42 year-old Caucasian female with persistent hyperkalemia. Past medical history included endocarditis, classic migraine, non-aneurysmal sub-arachnoid hemorrhage, bronchial asthma, and osteoporosis. The patient complained of muscle weakness and had unremarkable physical examination and normal blood pressure. Laboratory evaluation revealed: normal serum sodium, chloride. bicarbonate level and glomerular filtration rate. Baseline plasma renin activity, aldosterone and cortisol levels were within normal range. An ACTH stimulation essay was performed:

ACTH Stimulation Essay

| Laboratory Results | Baseline | Post-ACTH |
|---|---|---|
| Urine K (mmol/L) | 4.9 | 8.7 |
| Serum ACTH (ng/dl) | 19 | 9 |
| Serum aldosterone (ng/dl) | 2.1 | 26 |
| Urine Na (mmol/L) | 66 | 93 |
| Serum K (mmol/L) | 5.7 | 5.7 |

Additional testing revealed normal 24 h urine aldosterone, HbA1C, 1,25 (OH)2 Vitamin D, intact PTH level, CK total, CT abdomen and pelvis, renal ultrasound, and renal scan. A diagnosis of a primary selective defect in potassium secretion, such as the one associated with Gordon's syndrome, was made. Treatment with hydrochlorothiazide was started with subsequent return of serum potassium level to normal.

To date, about 100 cases of Gordon syndrome have been described in the literature. Both familial and sporadic forms have been seen. Normotensive forms of Gordon's syndrome were also described and is mostly seen in adults. This case demonstrates the need to be aware of a normotensive variant of Gordon syndrome especially in adult patients with unexplained hyperkalemia.

**Treatment of Hyponatremia Is Associated with Enhanced Cognitive Function** Rick P. Vaghasiya, Maria V. Devita, Georgia Panagopoulos, Michael F. Michelis. *Division of Nephrology, Department of Medicine, Lenox Hill Hospital, New York, NY.*

Hyponatremia occurs in 15% to 30% of hospitalized patients, making it the most common electrolyte abnormality in this population. Mild hyponatremia has generally been considered asymptomatic, however, a recent study showed that patients with mild to moderate chronic hyponatremia had an increased risk of falls, as well as gait and attention impairments. The present study was designed to assess cognition levels using the Mini-Mental Status Exam (MMSE) in patients with varying degrees of hyponatremia pre and post serum sodium (SNa) improvement.

Twenty-four hospitalized patients with SNa values $\leq$ 134 meq/L from a single center were included. The MMSE was administered to these patients and scores recorded out of a maximum of 30. The MMSE was repeated when the investigators felt the SNa improved appreciably. Initial SNa levels were approached therapeutically with 0.9% NS, fluid restriction, vasopressin receptor antagonists, withholding medications, or 3% NS as clinically indicated. The MMSE were administered at least 72 hours apart and the individual questions were altered when the test was repeated. Pre and post SNa improvement MMSE scores were compared.

The initial SNa levels of the 24 patients ranged from 117 to 134 meq/L with a mean of 124.3 meq/L (SD±4.4) and post-improvement SNa ranged from 127 to 143 meq/L with a mean of 133.7 meq/L (SD± 4.1, p=0.016). The mean SNa improvement was 9.4 meq/L. Overall, 21 of the 24 patients (88%) had an increase in MMSE score after improvement in SNa. Of those 21 patients, 7 patients had a pre SNa level $\geq$ 127 meq/L. Nine patients had a 4-10% increase in MMSE score, 8 patients had an 11-20% increase, 3 patients had a 21-35% increase and one patient had a 100% increase in the MMSE score after SNa improvement.

Treatment of hyponatremia at all levels was associated with improved cognitive function. These findings suggest that careful monitoring of serum sodium levels is important in all patients, even in those with a mild degree of hyponatremia. Attempting to correct hyponatremia to improve cognitive function should be encouraged.

**Diabetic Ketoacidosis in Haemodialysis-Dependent Patients-"A Rare Occurence"** Bhavani Adusumilli. *Internal Medicine, William Beaumont Hospital, Royal Oak, MI.*

The occurrence of diabetic ketoacidosis (DKA) in hemodialysis-dependent (HD) patients has been rarely reported in the literature and involves a different treatment algorithm compared to those with preserved renal function. Here, we present the clinical course and management of hypertension and DKA in a patient with end stage renal disease on chronic hemodialysis.

A 32-year-old African-American male with insulin dependent diabetes mellitus and chronic renal failure on hemodialysis presented with nausea and bilious vomiting. He reported not taking insulin for two days because of decreased appetite. On presentation his vital signs included a blood pressure of 180/125, respiratory rate of 22 breaths/min, and heart rate of 91 beats/min, temperature of 36.1 $^{o}$ C. Clinical examination revealed strong odor of ketones, dry mucous membranes, poor capillary refill and clear breath sounds. Serum biochemistry measurements showed serum glucose of 281mg/dl, sodium of 137 mEq/L, potassium of 3.9 mEq/L, chloride of 99 mEq/L, anion-gap of 21 with bicarbonate of 17 mEq/L, BUN of 31 and serum creatinine of 14.59 mmol/L. Other relevant results included beta-hydroxybutyrate level of 1.91 mmol/L, lipase of 37 units/L and serum osmolality of 300mosm/L. Chest X -ray and blood and urine cultures were unremarkable. He was started on regular insulin infusion with frequent monitoring of blood glucose and serum electrolytes. Hemodialysis was initiated with rapid correction of metabolic abnormalities.

This case illustrates the main issues facing clinicians managing DKA in HD patients. Unlike severe hyperglycemia in preserved renal function, which routinely causes clinically significant extracellular volume (EC) deficits, DKA in HD patients causes EC expansion. Furthermore, the same degree of hyperglycemia causes less rise in serum tonicity in HD patients compared to patients with preserved renal function primarily because of the absence of osmotic diuresis in dialysis patients. Although sole therapy with insulin infusion is adequate to treat severe hyperglycemia in majority of HD patients, associated high anion gap metabolic acidosis requires hemodialysis.

**Exploring Molecular Mechanisms behind the Aquaporin-2 Translocation in Renal Principal Cells Using Small Molecule Inhibitors** Jana Bogum,[1, 2] Vedrana Tabor,[1] Jens Furkert,[1] Jens von Kries,[1] Walter Rosenthal,[3, 4] Enno Klussmann.[1] *[1]Leibniz Institute for Molecular Pharmacology (FMP), Berlin, Germany; [2]Department of Biology, Chemistry and Pharmacy, Free University Berlin, Berlin, Germany; [3]Max Delbrueck Center for Molecular Medicine (MDC), Berlin, Germany; [4]Department of Molecular Pharmacology and Cell Biology, Charite - University Medicine, Berlin, Germany.*

Arginine-vasopressin (AVP) regulates aquaporin-2(AQP2)-mediated water reabsorption from primary urine by binding to the vasopressin V2 receptor on the surface of renal collecting duct principal cells. Stimulation of the receptor is followed by an increase in cAMP and activation of protein kinase A (PKA) that phosphorylates AQP2 at C-terminal Serine 256. This, in turn, leads to a redistribution of AQP2 from intracellular vesicles into the plasma membrane and facilitates water reabsorption from primary urine. Only few proteins involved in the control of AQP2 have been identified. Thus, molecular mechanisms underlying the transport of AQP2 are largely unknown. In a cell-based screening approach we identified novel small molecules inhibiting the cAMP-dependent AQP2 redistribution. Through detailed characterization of effects of the small molecules and identification of their targets we aim to discover proteins controlling the AQP2 translocation to the plasma membrane of renal principal cells. Such novel inhibitors of the AQP2 redistribution might be useful to develop an efficient therapy for diseases associated with excessive water retention, such as chronic heart failure (CHF), liver cirrhosis or SIADH (syndrome of inappropriate antidiuretic hormone hypersecretion).

**SIADH in a Patient with Fetanyl Patient-Controlled Analgesia** Roger F. Carbajal Mendoza, Hemant Magoo, Donald I. Baumstein, Alf M. Tannenberg. *Nephrology, Metropolitan Hospital Center/New York Medical College, New York, NY.*

Introduction: Hyponatremia is the most common electrolyte disorder in hospitalized patients. We report a case of hyponatremia secondary to syndrome of inappropriate secretion of antidiuretic hormone (SIADH) associated with Fentanyl Patient-Controlled Analgesia (PCA) in the setting of treatment of abdominal pain. To the best of our knowledge there is only one prior case report of fentanyl and SIADH which involved fentanyl transdermal patch.

Case: A 55 year old African American female patient was treated with fentanyl PCA pump for abdominal pain secondary to pancreatitis. The patient developed euvolemic hypoosmolar hyponatremia while receiving pain control with fentanyl PCA. Serum osmolality was 272 mOsm/kg while urine osmolality was 415 mOsm/kg suggesting inappropriate antidiuresis. Urine sodium of 139 mmol/L argues against volume contraction. Serum creatinine, thyroid function test and cortisol levels were normal consistent with adequate renal, thyroid and adrenal function.There was no recent use of diuretics.

Conclusion: We found an association between fentanyl PCA and hyponatremia with resolution of hyponatremia once the drug was discontinued.

**Pioglitazone-Induced Sodium Retention in Rat Is Independent of alpha Subunit of Epithelial Sodium Channel (ENaC$\alpha$) Expression in the Distal Nephron** Jinping Li, Bala Sundara Ponnam, Hongbao Ma, Shyan-Yih Chou. *Renal and Hypertension Division, Brookdale University Hospital, NY.*

***Purpose:*** To investigate the role of ENaC$\alpha$ in sodium retention induced by pioglitazone (PGZ).

***Methods:*** Male SD rats were maintained on a 1% NaCl diet; the experimental group was fed on the same diet plus PGZ. To suppress the production of aldosterone, a separate group of rats were maintained on a 3% NaCl diet with or without PGZ. To further suppress aldosterone production, an angiotensin converting enzyme inhibitor was combined with an angiotensin receptor antagonist. In this group, the rats were fed on a 3% NaCl diet and received enalapril plus olmesartan with or without PGZ. All PGZ-treated rats received PGZ at the dose of 40 mg/kg bw/day for 5 days. Western blotting was then performed and the data were expressed as mean ± SE in arbitrary densitometry units normalized to ß-actin signals.

***Results:*** In the group of rats maintained on a 1% NaCl diet, the protein expression for ENaC$\alpha$ in the medulla was similar between the control and PGZ-treated rats (band density, 0.536 ± 0.016 in PGZ-treated rats, *vs* 0.604 ± 0.040 in control). In the cortex, the band density for ENaC$\alpha$ was 0.676 ± 0.110 in PGZ-treated rats, similar to 0.746 ± 0.156 in pair-fed control rats. In PGZ-treated and control rats, there was a linear correlation between ENaC$\alpha$ and serum and glucocorticoid-induced kinase-1 protein expression (P = 0.01). In the group of rats maintained on a 3% NaCl diet, the expression for ENaC$\alpha$ in the medulla was 0.996 ± 0.182 in PGZ-treated rats, similar to 0.573 ± 0.049 in pair-fed control rats. In

the cortex, the band density for ENaCα was 1.256 ± 0.193 in PGZ-treated rats, similar to 1.320 ± 0.104 in pair-fed control rats. In PGZ-treated rats maintained on a 3% NaCl diet while receiving enalapril and olmesartan, the band density for ENaCα in the medulla was 0.604 ± 0.070, similar to 0.602 ± 0.032 in pair-fed rats receiving enalapril and olmesartan. In the cortex, the band density for ENaCα was 0.189 ± 0.016 in PGZ-treated rats, similar to 0.304 ± 0.050 in control rats.

***Conclusion:*** Sodium retention induced by PGZ is independent of expression of ENaCα in the apical membrane of the distal nephron.

**Drug Interaction between Celecoxib and Methotrexate (MTX) in Organic Anion Transporter 3-Transfected Renal Cells and in Rats** Akimitsu Maeda,[1] Shuichi Tsuruoka,[2] Kentarou Ushijima,[4] Yoshikatsu Kanai,[3] Hitoshi Endou,[5] Akio Fujimura.[4] *[1]Pharmacy, Aichi Cardiovascular and Respiratory Center, Ichinomiya, Aichi, Japan; [2]Nephrology, Univ. of Tsukuba, Tsukuba, Ibaraki, Japan; [3]Pharmacology, Osaka Univ., Osaka, Japan; [4]Pharmacology, Jichi Medical Univ., Shimotsukua, Tochigi, Japan; [5]Pharmacology, Kyorin Univ., Mitaka, Tokyo, Japan.*

MTX has a clinically important pharmacokinetic interaction with nonsteroidal anti-inflammatory drugs (NSAIDs) mainly through its competition for tubular secretion via the renal organic anion transporter 3 (OAT3). Celecoxib, cyclooxygenase 2 inhibiter, has not been reported to interact with MTX, but the mechanisms are unclear why the interaction is not occurred. We have previously reported the usefulness of human OAT3-transfected renal tubular cells for screening of the drugs which interfere with the pharmacokinetics of MTX. The purpose of this study was to evaluate the effect of celecoxib on MTX tubular secretion using a renal cell line stably expressing human OAT3 (S2-hOAT3), and to evaluate the pharmacokinetic interaction of the two drugs in rats. [$^3$H]MTX uptake into S2-hOAT3 cells was significantly inhibited by celecoxib in a concentration-dependent manner and the Ki value was 35.3 μM. However, MTX serum concentrations and urinary excretion of MTX over 24 h in rats were not affected by celecoxib (50, 200 mg/kg). Celecoxib serum concentrations in the rats were increased by the increase in celecoxib dosage and the maximum drug concentration (Cmax) was 20.6 μM (celecoxib 200 mg/kg), which did not reach the Ki value obtained in the in vitro study. These results indicated that celecoxib inhibited the secretion of MTX via hOAT3, which suggested that celecoxib was a substrate of hOAT3. However, co-administration of the two drugs at clinical dosage did not affect the pharmacokinetics of MTX, because the serum concentrations did not reach the Ki value. Although the accumulation study using S2-hOAT3 cells was useful to predict the interaction between the new drug and MTX in vivo, a comparison of the Ki value with the Cmax in clinical dosage was necessary to evaluate the degree of this interaction.

**Changes in Serum Aldosterone Relate to Reductions of Extracellular Volume in Hemodialysis Patients** Jochen G. Raimann,[1,2] Li Liu,[1,2,5] Fansan Zhu,[1] Stephan Thijssen,[1,2] Mary Carter,[1] Andrew S. Bomback,[4] Vimal K. Derebail,[3] Philip J. Klemmer,[3] Nathan W. Levin,[1] Peter Kotanko.[1,2] *[1]RRI, NYC; [2]BIMC, NYC; [3]UNC, Chapel Hill; [4]Columbia University, NYC; [5]Peking University First Hospital, Beijing.*

Background

Water and salt homeostasis in healthy subjects is tightly regulated by the renin - angiotensin -aldosterone system (RAAS). In hemodialysis (HD) patients (pts) a right-shifted relation between extracellular volume (ECV) and serum aldosterone was demonstrated (Bomback, 2009). This study aimed to investigate temporal changes of aldosterone following ECV reduction in HD pts.

Methods

Chronic HD pts (BMI < 40 kg/m2) underwent gradual reduction of post-HD weight. ECV, total body water (TBW) and aldosterone were measured pre-HD at baseline (BL) and after post-HD weight reduction. TBW and ECV were measured by segmental bioimpedance spectroscopy (Zhu, 2006). Serum aldosterone was determined by ELISA (Alpco Diagnostics). Changes in the aforementioned parameters were assessed by paired T-Test. Data are shown as mean±SD.

Results

Thirteen HD pts (age 55±14 yrs, 9 females, 8 blacks, BMI 27±6 kg/m2) were enrolled over a period of 53±39 days. ECV changed by -1.2±2.6 L (P=0.11), ECV/TBW (BL: 49.3±3.7%; end: 49.1±4.0%, P=0.8) and aldosterone (BL: 40.7±23.5 ng/dL versus 42.1±19.9 ng/dL, P=0.7) did not change significantly. Changes in aldosterone correlated significantly with changes of ECV/TBW ($R^2$=0.57, P<0.01; Figure 1).

Conclusion

Serum aldosterone levels are higher in HD pts compared to healthy controls (Figure 1) and its relationship to ECV/TBW is shifted to the right. The inverse relationship between changes of ECV/TBW and accompanying changes in aldosterone seen in HD pts suggests an intact RAAS sensitive to ECV changes.

Figure1: Serum aldosterone versus ECV/TBW in healthy subjects (data from Bomback, 2009) and the 13 HD patients in the present study.

**Prophylactic Tolvaptan for Chemotheraputic Hydration in a Central Nervous System Lymphoma Complicated by Syndrome of Inappropriate Antidiuretic Hormone** Maura A. Watson, Frank P. Hurst, Stephen W. Olson. *Medicine/Nephrology Service, Walter Reed Army Medical Center, Washington, DC.*

**Case:** A 59 year old female with primary central nervous system (CNS) lymphoma required high volume sodium bicarbonate infusion during rituxan and methotrexate infusion due to acute kidney injury (AKI) in the setting of prior treatment cycles. During the infusion, the patient developed symptomatic hyponatremia with a sodium nadir of 120. Urine and serum sodium, creatinine, and osmolarity were consistent with the diagnosis of syndrome of inappropriate antidiuretic hormone (SIADH). Serum sodium normalized and symptoms resolved after discontinuation of volume replacement and initiation of free water restriction. The V2-receptor antagonist tolvaptan was added to her subsequent chemotherapy cycle with prophylactic high volume sodium bicarbonate infusion and successfully prevented repeat symptomatic hyponatremia. There also was no repeat AKI. Urine osmolarity declined from 694 to 344 mOsm/kg over four days, suggesting effective urinary free water loss induced by tolvaptan.

**Discussion:** To our knowledge, this represents the first reported case of the successful use of tolvaptan to permit chemotherapeutic hydration in the setting of SIADH. SIADH is a common disorder seen in CNS malignancies and can complicate chemotherapeutic regimens requiring intravenous fluids. Tolvaptan is a selective oral vasopressin 2-receptor antagonist that increases free water excretion to reverse the effects of SIADH. Previous studies have focused on the potential clinical benefit of tolvaptan in cardiac heart failure, cirrhosis and acute brain injury. This case suggests a potential treatment niche for vasopressin receptor antagonists in patients with SIADH in the setting of disease processes that require aggressive hydration such as contrast prophylaxis, hypercalcemia, rhabdomyolysis and chemotherapeutic hydration.

**In Utero Exposure to Maternal Diabetes Lead to Glucose Intolerance and HTA without Major Effect on Lipid Metabolism** Bertrand Blondeau,[1] Celine Fassot,[1] Jean-Paul Duong van Huyen,[2] Martine D. Lelievre-Pegorier.[1] *[1]INSERM U872, Centre de Recherche des Cordeliers, Paris, France; [2]Departement de Pathologie, Hopital Europeen Georges Pompidou, Paris, France.*

We have previously demonstrated in the rat that in utero exposure to maternal diabetes impairs renal development leading to a reduction in nephron number (Nehiri et al, Diabetes 2008). Recent evidence shows that adult metabolic disease may originate from adverse fetal environment that will alter organ development and function in postnatal life. Here we analyzed the in utero exposure to maternal diabetes on the development of a metabolic syndrome in the offspring.

Pregnant rats were made diabetic (plasma glucose around 20 mM) with a single injection of streptozotocin injection on day 0 of gestation. Offspring from diabetic mothers (DMO) and from control mothers (CMO) were followed from birth to 12 months of age. In these animals, metabolic parameters such as glucose tolerance, insulin sensitivity as well as plasma lipid levels and pancreatic insulin and morphology were studied.

As compared to controls, DMO offspring had a normal birth weight and an impaired postnatal growth that persisted throughout life. Metabolic tests revealed that DMO offspring show an impaired glucose tolerance as soon as 6 months associated with a decreased insulin secretion but normal insulin sensitivity. In older animals (12 months of age), glucose intolerance and both impaired insulin secretion and sensitivity were still observed. In DMO offspring we measured high blood pressures, decreased fasting plasma triglycerides levels and normal plasma NEFA, HDL-cholesterol and total cholesterol.

Altogether, these results show that this model of in utero exposure to maternal diabetes leading to normal birth weight induced glucose intolerance and increased blood pressure,

without major effects on lipid metabolism. It is suggested that a fetal hyperglycaemic environment program hypertension and glucose intolerance but does not alter lipid metabolism.

**Renalase Belongs to a New Class of Catecholamines Metabolizing Enzymes** Gary V. Desir, Peili Wang, Guoyong Li, Lieqi Tang, Heino Velazquez. *Medicine, Yale School of Med, VACHS, West Haven, CT.*

Renalase is an FAD containing protein that is expressed in kidney, heart, skeletal muscle, and small intestine, and is secreted into blood. In vitro data suggest it specifically degrades catecholamines and functions as a soluble amine oxidase. However, recombinant renalase metabolized catecholamines at a rate low enough to cast doubt on its physiological relevance as an amine oxidase. To gain further insight into its kinetic properties, we performed additional computer-based domains analyses, and noted the presence of a Rossmann fold, and significant similarities with some members of the NADB_Rossmann superfamily, suggesting the presence of a NAD(P) binding site. In vitro assays revealed that hRenalase has intrinsic NADH oxidase activity in the absence of catecholamines (Km=9.39±0.87 μM, Vmax=17.19±1.22 nmol/min/mg protein). NADPH is not metabolized to a significant degree. A saturating concentration of NADH (250 μM) stimulated renalase-mediated epinephrine metabolism by 17.9±1.1 fold ($p<0.000001$). The estimated Km for epinephrine is 17.09±4.28 μM, with a Vmax of 22.18±0.11 nmol/min/mg protein. Epinephrine metabolism is autocalytic since the rate increases by 2 fold over the first 30 minutes. While catalase was ineffective, superoxide dismutase inhibited epinephrine metabolism completely, indicating a superoxide anion dependent mechanism. We conclude that recombinant hRenalase1 belongs to a new class of FAD-containing, NADH-dependent catecholamines metabolizing enzymes, and its kinetics parameters for epinephrine compare favorably to those of MAO-A and MAO-B. We speculate that renalase is a physiologically relevant modulator of epinephrine levels.

**Comparative Study of Additional Antihypertensive Effect of Magnesium Supplement with or without Angiotensin-II Receptor Blocker in Hypomagnesemic Rats** Yang Wook Kim,[1] Tae Hee Kim,[2] Hyun Seung Lee,[2] Kyu-Bok Jin.[1] *[1]Nephrology, Internal Medicine, Haeundae Paik Hospital, Inje University, Pusan, Korea; [2]Nephrology, Internal Medicine, Busan Paik Hospital, Inje University, Pusan, Korea.*

**Introduction;** Mg is an essential element critically involved in vascular function and influences blood pressure(Bp) regulation by modulating vascular tone and reactivity. Several studies have shown that serum Mg is inversely associated with blood pressure and plasma renin activity. The purpose of this study was to evaluate the additional effect of dietary Mg supplement with angiotensin receptor blocker on Bp in hypomagnesemic rats.

**Methods;** Fifty five S-D male rats were used. The rats were divided into Mg-deficient and control groups. Mg-free and Mg-contained diet was adminitrated. After 14 weeks, ten Mg-deficient and five control rats were treated with Mg. Another group of ten Mg-deficient rats were received angiotensin receptor blocker(ARB; losartan , 30 mg/Kg, intraperitoneal), and ten Mg-deficient rats received ARB plus Mg in the same way.

Systolic Bp was measured by tail-cuff method using a plethysmography. During this experimental period, serum Mg, calcium, potassium, angiotensin, aldosterone, 1,25-dihydroxyvitamin D and vasopressin were measured.

TGF-b1, AQP-2 of renal tissue extract and immunohistochemistry for TGF-beta1 were preformed.

**Results;** At 14 weeks, systolic Bp was significantly higher in Mg-deficient rats than in control rats ($P$=0.034).

In the hypomagnesemic rats, treatment with Mg resulted in a decrease of systolic Bp, which was further decreased by losartan and losartan/Mg combination. Treatment with losartan/Mg combination resulted in a decrease of systolic Bp most. However, the difference did not reach statistical significance. The serum calcium, angiotensin II, aldosterone and 1,25-dihydroxyvitamin D were higher while the vasopressin level lower in Mg-deficient rats. AQP-2 expression was increased in hypomagnesemic group, decreased in losartan group. There were no differences of pathological findings and expression of TGF-b in tissue of kidney and heart among groups.

**Conclusion;** The oral magnesium supplement can reduce the blood pressure in hypomagnesemic hypertension.

Also, Magnesium supplementation may enhance the effect of antihypertensive medication of angiotensin-II receptor blocker.

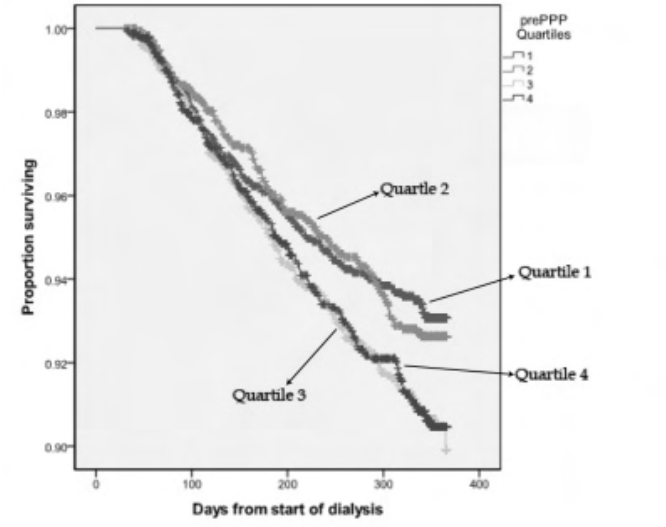
**Impact of Pulse Pressure on Patient Outcomes in Incident Hemodialysis Patients** Len A. Usvyat,[1] E. Lars Penne,[1,2] Olga Sergeyeva,[1] Stephan Thijssen,[1,2] Peter Kotanko,[1] Nathan W. Levin.[1] *[1]Renal Research Institute, NY, NY; [2]Beth Israel Medical Center, NY, NY.*

High pulse pressure is associated with increased mortality in general population. The aim of this study was to examine the specific effects of this relationship in hemodialysis (HD) patients while also adjusting for systolic blood pressure (SBP) and change in SBP over time.

All RRI in-center HD patients who initiated dialysis between Jan 2000 and Jan 2009 were included. Pre-HD SBP (preSBP) and diastolic blood pressure (preDBP) were recorded each treatment in the first year of HD. Mean preSBP (preSBP) and the pulse pressure as percent of preSBP (prePPP = 100%*[preSBP - preDBP]/ preSBP) of the first 30 days were calculated. The linear slope of preSBP (preSBPSLOPE) was computed per patient using all preSBP values in year one to demonstrate change in preSBP: increased, decreased, and stable. Patients were stratified based on quartiles of prePPP: quartile 1 (14-44%), 2 (44-48%), 3 (48-52%), 4 (52-74%).

7077 pts were included (56% male, 39% black, 53% diabetic, age [SD]: 62.2 [15.8] yr). Using Kaplan-Meier analysis, quartiles 1 and 2 of prePPP had the longest survival time while quartiles 3 and 4 shortest survival ($p<0.05$ using log-rank test).



Using Cox regression (adjusted for gender, race, diabetes, preSBP, preSBPSLOPE), quartile 4 had the highest risk of death (HR=1.36, 95% CI: 1.05-1.77), followed by quartile 3 (HR=1.26, 95% CI: 0.98-1.62). No differences were observed between quartile 1 and quartile 2.

The differences in prePPP groups disappeared after adjusting for age as a continuous variable. This finding was further confirmed by a subgroup analysis stratified by age groups, suggesting that prePPP does not alter patient outcomes in dialysis population.

In contrast to the general population, pulse pressure is not a significant predictor of mortality in HD patients.

Disclosure of Financial Relationships: nothing to disclose

**PUB549**

**Blood Pressure Characterization by Radiotelemetry in Rat Offspring after Maternal Low Protein Diet** V. Matti Vehaskari,[1,2] Tyrus Stewart,[1] Jeannine Ory Ascani,[2] Johnny Porter.[3] *[1]Pediatrics, LSU Health Sciences Center, New Orleans, LA; [2]The Research Institute for Children, New Orleans, LA; [3]Physiology, LSU Health Sciences Center, New Orleans, LA.*

Maternal protein restriction in rats has been widely used to induce intrauterine growth restriction (IUGR) and adult hypertension, usually measured by the tail cuff method, in the offspring. The present study was undertaken to characterize the BP profile in unstressed IUGR offspring by radiotelemetry.

Pregnant dams were subjected to 6% protein (LP) or control 20% protein (C) diet throughout second half of pregnancy. Radiotelemetry transmitter was implanted in subgroup of LP (N=7) and C (N=6) offspring at 7-10 months of age. Baseline telemetry recording was started 5 days later, followed by 1 week of recording on high Na (3%) diet. Renal cortical and medullary tissue for epinephrine and norepinephrine assay by HPLC was collected at sacrifice.

LP pups had 15% lower birth weight. By tail cuff method, elevated daytime systolic BP in LP pups was present by 8 weeks of age and persisted until 10 months of age (LP 133 vs. C 119 mmHg, P=0.014) but the difference disappeared under anesthesia (LP 119 vs. C 119 mmHg). Continuous telemetry monitoring in awake animals revealed no significant differences between LP and C pups during day or night in systolic (day 119 vs. 121, P=0.48; night 120 vs. 124 mmHg, P=0.33) or diastolic (day 90 vs. 89, P=0.77; night 94 vs. 92 mmHg, P=0.57) pressures. Appropriate BP dipping during inactive (day) period and decrease in heart rate was observed in both groups. High Na diet induced similar small BP increase (4-6 mmHg) in both groups. Norepinephrine content (ng/mg wet weight) was increased in LP kidneys but it reached statistical significance only in the cortex (P=0.033). There were no differences in renal epinephrine content.

In conclusion, continuous telemetry monitoring revealed no sustained hypertension in this model of IUGR. Higher tail cuff BP may be due to enhanced stress reactivity of LP rats during handling. Therefore, the reduced nephron number and later nephrosclerosis described in this model of prenatal programming may be dissociated from systemic hypertension.

**Nicorandil Has the Micociculatory Renoprotective Effect on Renal Ischemia-Reperfusion Model in Mice** Tokunori Yamamoto, Hideki Mizuno, Naoto Sassa, Norihisa Matsukawa, Masashi Katoh, Yasushi Yoshino, Kazuo Mizutani, Ryohei Hattori, Momokazu Gotoh. *Urology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.*

[Aim]
Nicorandil (Nic), an angina treatment which has ATP sensitive K channel opening and nitrate like activity, is known to have cardioprotective effect for ischemic cardiac disease. It is considered that angina and acute renal failure have a common point as ischemic disease. In this study, we investigated the protective effect of Nic on renal ischemia reperfusion model in mice.
[Method]
C57BL/6 mice (8 weeks old, male) were anesthetized by pentobarbital. After the uninephrectomized of right kidney, left renal artery and vein were clamped for 30 min. One day after reperfusion, serum creatinine (sCr) and urea nitrogen (sUN) were measured. Nic was administrated from one day before operation by drinking water (6, 30 mg/kg/day). peritubular capillary blood flow(PTC) and diameter of afferent arteriole (Af)were measured by intravital microscopy(Yamamoto T et al AJP Renal 2001).
[Result]
Nic slightly but significantly reduced sCr and sUN in a dose dependent manner (sCr, Control; 2.6±0.3, Nic 6; 2.3±0.1, Nic 30; 2.1±0.2, sUN, Control; 218.8±1.2, Nic 6; 191.4±7.8, Nic 30; 191.3±9.6, mean±SE, n=11-13). PTC significantly increased treatment group than control group( 0.41 plus minus0.09 VS 0.22 plus minus0.11micro/sec,$p<0.05$ ). Diameter of Af dilated treatment group than control group(15.2plus minus1.8VS 10.8plus minus2.1micrometer ,$p<0.05$ )
[Conclusion]
Nicorandil improved not only ischemic cardiac damage but also ischemic microcirculatory renal damage.

**Telmisartan Improves Metabolic Profile in Obese Patients with Arterial Hypertension** Marcin Adamczak,[1] Malgorzata Kubik,[1] Jerzy Chudek,[1, 2] Andrzej Wiecek.[1] *[1]Department of Nephrology, Endocrinology and Metabolic Diseases, Medical University of Silesia, Katowice, Poland; [2]Department of Pathophysiology, Medical University of Silesia, Katowice, Poland.*

Purpose of study: There are several lines of evidence suggesting that telmisartan may improve cardiometabolic profile. The aim of the study was to estimate changes of insulin resistance, plasma levels of adiponectin and of proinflamatory cytokines after long-term antihypertensive treatment with telmisartan in obese hypertensive patients.
Patients and methods: 34 previously untreated obese adults (BMI between 30 and 40 $kg/m^2$) with arterial hypertension were enrolled into the study. Euglycemic-hyperinsulinemic clamp technique was applied for measurement of glucose cells uptake (M value) and calculation of M to insulin plasma concentration ratio (M/I). M and M/I values, body fat content (by DEXA method), as well as plasma concentration of adiponectin, its high molecular weight fraction (HMW), leptin and markers of inflammation (hsCRP, TNFα, IL-6, IL-8) were estimated before and after 6-month telmisartan therapy.
Results: 25 patients completed the study. Telmisartan therapy was followed by 14.2% decrease of systolic and by 19.6% decrease of diastolic blood pressure. Body weight and fat mass did not change significantly. Both M and M/I values increased significantly (24.4% and 38.6%, respectively). Plasma concentrations of hsCRP and IL-8 decreased significantly, while plasma IL-6 and TNFα concentrations only tended to decline. Plasma levels of total adiponectin and its HMW fraction increased after treatment with telmisartan by 10.8% and by 23.5%, respectively.
Conclusions: 1. Telmisartan monotherapy improves insulin sensitivity in obese patients with hypertension. 2. The additional potential benefit of telmisartan therapy is the increase of plasma adiponectin concentration and suppression of microinflammation that may contribute to slowing of atherosclerosis development and reduction of cardiovascular risk in obese hypertensive patients.

**Gender Disparities in the Awareness and Control of Hypertension** Abdulkareem Alsuwaida, Mohammed A. Al-Ghonaim. *Medicine, King Saud University, Riyadh, Saudi Arabia.*

***Background***
Hypertension is an important risk factor for the commonest cause of death among men namely, cardiovascular diseases. The purpose of this study was to provide data concerning gender difference in the awareness, treatment, and control of hypertension in Adult men.
***Methods***
We conducted a cross sectional study in Riyadh, the capital of Saudi Arabia. Subjects were asked if they had been told by a physician that they had hypertension or were on a blood pressure medication. Blood pressure was measured using standardized Joint National Committee (JNC) protocol.
***Results***
The study sample consisted of 814 adults who were at least 18 years old. Of the estimated 27.6 % people with hypertension, 38.6 percent were unaware of their hypertension, 29.8% were aware of their condition but were not being treated, and among those whom been treated 40.8 percent remained uncontrolled. Independent predictors of a lack of awareness of hypertension were an age of at least 45 years, male sex, and BMI greater than 30. The extent of awareness and control of hypertension did not differ significantly by monthly income, educational level, physical activities or smoking status.
***Conclusions***
Awareness and control of hypertension is low in men, making them public health priorities. Achieving more stringent blood pressure control will require increased attention by physicians and public education to improve the awareness and control of hypertension.
Disclosure of Financial Relationships: nothing to disclose

**High Incidence of Albuminuria Associated with Cardiovascular Risk Factors in Japanese Hypertensive Patients: Cross-Sectional Study with a Nationwide Internet Survey (AVA-E Study)** Koichi Asahi,[1] Yoshihiro Tani,[1] Kenichi Tanaka,[1] Kenji Baba,[3] Yasushi Itakura,[3] Kunitoshi Iseki,[2] Tsuyoshi Watanabe.[1] *[1]Department of Nephrology and Hypertension, Fukushima Medical University, Fukushima, Japan; [2]Dialysis Unit, University Hospital of the Ryukyus, Nishihara, Okinawa, Japan; [3]Dainippon Sumitomo Pharma Co., Ltd., Tokyo, Japan.*

Objective: The present study aims to elucidate the real status and risk factors associated with abnormality of urinary albumin excretion (UAE) in Japanese hypertensive patients. Method: Demographic and clinical data on 8,963 hypertensive outpatients who underwent qualitative tests for urinary albumin/creatinine ratio (quali-ACR) from September 2009 to March 2010 were collected via the Internet from 639 nationwide registered physicians (AVA-E study conducted by Dainippon Sumitomo Pharma Co., Ltd.). Results: Mean office blood pressure and eGFR were 138.3/78.7 mmHg and 69.7 mL/min/1.73 m2, respectively. Qualitative urinary protein test (quali-UP: a dip-stick method) were simultaneously tested for 94.9% of the patients and revealed the incidence of (-), (±), (+), (++), and (+++) are 71.9%, 14.5%, 8.4%, 3.7%, and 1.4%, respectively. Quali-ACR showed the abnormally high range in 42.9% of overall patients and 35.4% of the 7,355 patients with (-) or (±) on quali-UP. The incidence of CKD (eGFR<60ml/min/1.73m2) was 20.8%. Reported comorbid risk factors were smoking (17.8%), diabetes (34.9%), high LDL-C, (41.0%), low HDL-C (10.9%), high TG (30.1%), dyslipidemia (57.2%) and histories of myocardial infarction (3.5%) and stroke(5.4%). Multivariate logistic regression analyses identified age, BP, BMI, diabetes, dyslipidemia, number of comorbidities and eGFR as risk factors for abnormalities in quali-ACR. Interpretation: Abnormal UAE are highly frequent and associated with cardiovascular risk factors in Japanese hypertensive patients on usual outpatient care.
Disclosure of Financial Relationships: nothing to disclose

**Combination of Irbesartan and Enalapril Versus Amlodipine on Hypertensive Retinopathy in Patients with Chronic Kidney Disease** Eleni Chelioti,[1] Antonios Zagorianos,[1] Adrianna Mitropoulou,[2] Athanasios Georgiou,[1] Prokopis Papazafeiris,[1] Gabriel Papadakis.[1] *[1]Dept. of Nephrology and Renal Unit, General Hospital of Piraeus, "Tzaneio", Athens, Greece; [2]Dept. of Ophthalmology, General Hospital of Piraeus, "Tzaneio", Athens, Greece.*

Purpose:Aim of this study was to evaluate the effect of combination of irbesartan and enalapril or amlodipine on retinal microvasculature changes in hypertensive patients with chronic kidney disease (CKD).
Method: Twenty-three patients (12males/11females, age range 45-85 years) with untreated hypertension (Systolic Blood Pressure, SBP>160 mmHg and Diastolic Blood Pressure, DBP >90 mmHg) and CKD stage 3(mean Clearance creatinine 39±7ml/min/1.73m2) were randomized to received a combination of irbesartan 150 mg/day and enalapril 10mg/day (n=13) or amlodipine 10mg/day (n=10) in a double-blind study for 12 months. Measurements of blood pressure, retinal microvasculature( arteriolar sclerosis and narrowing) using a fundoscopic exam and renal function were evaluated at baseline and at the end of the study.
Results: Both the combination of irbesartan and enalapril and single treatment with amlodipine reduced blood pressure (BP) in all patients (BP≤130/80mmHg $p<0.001$). Accompanying the reduction in BP, there were an improvement in arteriolar sclerosis and narrowing ($p<0.03$ and $p<0.02$ respectively). Although, both in group BP reduction was associated with a significant ameliorate of renal function, mean clearance creatinine 52±10ml/min/1.73m2 ($p<0.05$). Moreover, we found out an inverse relation between arteriolar narrowing and left ventricular hypertrophy.
Conclusion: Either double antihypertensive treatment or single treatment can induce regression of retinal microvascular abnormalities associated with reduction of BP. However, fundoscopy is a simple and non invasive exam that may be useful in the assessment of target organ damage. These results should be interpreted with caution because the sample is small and may limit the power of the study.

## PUB555

**A Dose-Response Relationsship between NOS-Inhibition with L-NMMA and Blood Pressure in Healthy Man** Frank H. Christensen, Thomas Larsen, Jesper N. Bech, Erling B. Pedersen. *Departments of Medical Research and Medicine, Holstebro, Denmark.*

**Purpose:** Nitric oxide is involved in the regulation of blood pressure, but the importance of this regulation in healthy man is still unclear. The present study investigated the effects of increasing doses of the Nitric Oxide synthase (NOS) inhibitor L-NMMA on blood pressure in healthy man.

**Methods:** Twelve healthy young men (18-30 years) were included in a cross-over, placebo-controlled, single-blinded study. On 4 separate study days, the subjects were randomised to receive placebo or one of 3 doses of L-NMMA: 3.0 mg/kg bolus IV injection followed by 2.0 mg/kg/hour IV infusion for one hour, 4.5mg/kg bolus injection followed by 3.0 mg/kg/hour IV infusion for one hour or 6.0 mg bolus IV injection followed by 4.0 mg/kg/hour IV infusion for one hour. Blood pressure (BP) and heart rate (HR) were repeatedly followed every 5 to 10 minutes during infusion period. Four days before each study day, the subjects were given 3 gr. NaCl pr day as a supplement to their usual diet.

The differences in BP and HR were assessed in steady state period using area under curve (AUC) in relation to baseline. Differences are presented in medians with interquartile ranges in brackets. Statistics were performed with Friedman's test

**Results:**

Baseline diastolic (DBP) and systolic blood pressure (SBP) and HR were not different between groups (119.5/62.1 ± 7.5/ 5.9 mmHg, 52.9 ± 7.5 beats/min, Mean ± SD). IV infusion of L-NMMA increased both DBP and SBP and decreased HR. From 20-60 min a stable BP and HR was observed with less than 10% difference in the variables. The calculated AUC increased in a dose-dependent way both for DBP and SBP (placebo: -28 (90) / 18 (217) , 3.0mg: 151 (103) / 71 (100), 4.5mg: 219 (113) / 68 (218), 6.0mg: 283 (51) / 217 (252) mmHg*min, $p < 0.001$, $p = 0.025$) The calculated AUC for heart rate decreased in a dose-dependent way (placebo: -21 ± (159), 3.0mg: -95 ± 192, 4.5mg: -163 (160) mmHg*min, 6.0mg: -178 (136) mmHg*min, $p = 0.021$).

**Conclusions:**

NOS inhibition with continuous L-NMMA infusion causes a dose dependent increase in DBP and SBP and a dose dependent decrease in heart rate.

**Discordant Changes in Vascular Compliance and Proteinuria with Drug Therapy in CKD Patients** Debbie L. Cohen, Kevin Sterling, Raymond R. Townsend. *Medicine, Renal Division, University of Pennsylvania, Philadelphia, PA.*

Chronic kidney disease (CKD), proteinuria and increased arterial stiffness are associated with increased cardiovascular disease (CVD) risk. We performed a prospective randomized trial of subjects with stage 1-3 CKD with proteinuria > 500 mg/dL. All subjects were already on renin angiotensin suppressing therapy with either an ACE ***or*** ARB prior to enrollment. Subjects were then randomized to 3 treatment groups in addition to their current treatment: group 1 - ACE+ARB, 2 - eplerenone, 3 - isosorbide mononitrate. Subjects were followed for a period of 4 months and had pulse wave velocity (PWV) and central pulse pressure measured (SphygmoCor PV device, AtCorMedical, Sydney, Australia] at baseline and 4 months to determine if changes in urine protein excretion resulted in changes in vascular compliance depending on drug therapy assignment in patients with CKD and proteinuria. Results (baseline minus 4 month value) are shown in the table below.

| | Group 1 (n=5) | Group 2 (n=13) | Group 3 (n=11) |
|---|---|---|---|
| Δ Urine Protein g/day | 0.32±0.2 | 1.04±0.4* | -0.2±0.3 |
| Δ SBP mm Hg | 13.4±14.9 | 9.7±6.4 | 1.0±5.4 |
| Δ PWV m/sec | 0.87±0.9 | -1.13±1.15 | 0.9±1.17* |

*p = 0.02

7 subjects were randomized to group 1 with dual RAAS blockade (with 2 drop outs), 13 subjects were randomized to RAAS + eplerenone, 11 subjects were randomized to RAAS + Nitrate. Urine protein excretion was decreased in group 1 and 2 but was increased with the addition of the nitrate in group 3. BP declined in all 3 groups over the treatment period however PWV decreased in group 1 and 3 but increased in group 2.

Conclusion:

1. Significant decrease in proteinuria in RAAS + eplerenone despite an increase in PWV.

2. Slight non-significant increase in proteinuria but significant decrease in PWV in RAAS and nitrate.

3. Changes in protein excretion on drug therapy added to RAAS foundation are not predicted by changes in PWV.

## PUB557

**Primary Hypertensive Nephrosclerosis Has Become a Less Common Cause of ESRD** Amit J. Joshi, George Dunea, Peter D. Hart. *Division of Nephrology, Stroger Hospital of Cook County, Chicago, IL.*

**Background:** The role of hypertension in hastening the progression of renal disease is undisputed, but the prevalence of hypertensive nephrosclerosis as a primary cause of end-stage renal disease (ESRD) continues to be overestimated.

**Methods:** We reviewed by clinical criteria the diagnoses of patients starting dialysis in the past 2 years (June 2006-May 2010) at a large inner city hospital. A presumed diagnosis of primary hypertensive nephrosclerosis was made on the basis of excluding other causes of ESRD and finding a long history (>10 years) of hypertension, gross cardiomegaly, relatively small kidneys on ultrasound, and proteinuria < 2g/d.

**Results:** The estimated overall prevalence of primary hypertensive nephrosclerosis was 7%. In African American patients 38% had diabetic nephropathy, 22% had glomerular disease, 14% had hypertensive nephrosclerosis, and 27% had other causes. In Hispanics, 57% had diabetic nephropathy, 27% had glomerular disease, 14% had other causes, and only 2% had primary hypertensive nephrosclerosis.

Table 1

| Etiology of ESRD | African American(n=129) | Hispanic (n=118) | Others (n=35) |
|---|---|---|---|
| Diabetes | 49 (38%) | 68 (57%) | 14 (40%) |
| Glomerular disease | 28 (22%) | 32 (27%) | 13 (37%) |
| Hypertensive nephrosclerosis | 18 (14%) | 2 (2%) | none |
| HIV | 11 (8%) | none | none |
| Lupus | 6 (5%) | 2 (2%) | 1 |
| Others | 17 (13%) | 14 (12%) | 4 |

**Conclusion:** We found that in the past 2 years the overall prevalence of primary hypertensive nephrosclerosis was 7%. In African Americans in our hospital, it has declined over the past 2 decades from 22% to 14%. We suggest that nephrologists reporting to networks and registries should alter their diagnostic criteria.

Disclosure of Financial Relationships: nothing to disclose

## PUB558

**Effect of Dietary Potassium Supplement on Blood Pressure, Augmentation Index and the Renin-Aldosterone System in Healthy Humans** Solveig K. Matthesen, Thomas G. Lauridsen, Erling B. Pedersen, Henrik Vase. *Departments of Medical Research and Medicine, Holstebro Hospital, Holstebro, Denmark.*

**Purpose:**

Animal experiments and studies in humans have shown that potassium treatment can reduce blood pressure due to a reduced contraction of vascular smooth muscle cells. We wanted to test the hypothesis that dietary potassium supplement would decrease peripheral and central blood pressure(CBP), pulse wave velocity (PWV) and augmentation index (AI) in healthy humans.

**Methods:**

The effect of potassium 100 mmol /day was measured in a randomized, placebo-controlled, cross-over study of 22 healthy humans. The treatment periods were 4 weeks separated by a 2 week wash-out period. The participants received a diet standardized according to weight and physical activity during the last four days of each treatment period. The diet was composed of 55 % carbohydrates, 15 % proteins and 30 % fat. Daily fluid intake was 250 ml/1000KJ, and sodium content in the diet was 150-200 mmol depending on the energy demand. We measured 24-hour-BP using Kiwex 2430, CBP, PWV and AI using Sphygmocor, GFR using the constant infusion technique with 51-Cr-EDTA, plasma concentrations of renin (PRC) and aldosterone (PAC) using RIAs, and fractional excretion of potassium ($FE_K$) and sodium ($FE_{Na}$).

**Results:**

Urinary potassium excretion increased during the intervention (placebo: 75± 22 mmol/24 hour versus potassium supplement: 168 ±37 mmol/24 hour, $p< 0.05$, means±SD). $FE_K$ increased (13±4 to 29±7, $p< 0.05$). $FE_{Na}$ , 24-hours BP, PWV, CBP, AI and GFR were not significantly changed. During potassium supplementation, an increase was measured in PRC (7±4 to 10±8 mIU/ l, $P<0.05$) and PAC (378±217 to563±362 pmol/l, $P<0.05$).

**Conclusions:**

Urinary potassium excretion was significantly increased during the intervention indicating that the participants complied with the diet. Neither 24-hours-BP, CBP nor AI changed significantly during intervention. The lack of decrease in blood pressure might be attributed to an antagonizing effect induced by the increase in the activity of the renin-aldosterone system.

## PUB559

**Plasma Nitrite in Patients with Renal Impairment: A Pilot Study** Daniel Schroeder, Jens Passauer. *Nephrology, University Hospital Carl Gustav Carus, Dresden, Germany.*

**Background:** Plasma nitrite (NO2) is now regarded as an important storage compound of nitric oxide (NO) which significantly contributes to vasodilatation and organ protection during ischemia. At present little is known about the status of this physiological principle in patients with renal impairment.

**Methods:** In a pilot study we determined baseline plasma nitrite levels in patients with renal insufficiency (RI, n=19), in patients on dialysis (D, n=30) and in healthy control subjects (C, n=11) by chemiluminescence (NOA280, Sievers instruments, CO). In addition we measured changes in NO2 levels during 8 minutes of complete forearm ischemia in HD (n=5) and C (n=5). Finally we determined changes in NO2 during a four-hour dialysis session in D (n=20).

**Results:** NO2 was 182±92 nmol/L in D, 162±95 in RI and 67±28 in C showing an inverse correlation to GFR (MDRD, $r=0.35$;$p<0.005$). During hemodialysis NO2 decreased to 82±25% (1h), 84±43 (2h) and 63±21 (4h) of the pre-dialysis baseline level. During forearm ischemia we observed a significantly more pronounced decrease in NO2 to 80±10% (2min), 73±12 (6min) and 59±11 (8min) of baseline in D compared to C (91±12 ; 84±15 and 82±13% ; $p<0,05$ by ANOVA).

**Conclusion:** 1) Renal impairment is associated with an increase in plasma nitrite. 2) The high NO2 plasma concentrations observed in D can not be explained by the dialysis procedure itself. 3) There are significant differences in nitrite metabolism during ischemia between dialysis patients and control subjects. Further studies have to clarify the significance of these observations and to unravel the underlying mechanisms.

**Role of CD4$^+$CD28$^-$ T Cells in Pathogenesis of Cardiovascular Events in Patients on Haemodialysis** Nihil Chitalia,[1] Behnam Zal,[2] Christina Baboonian,[2] Debasish Banerjee.[1] *[1]Renal Medicine, St. George's Hospital, London, United Kingdom; [2]CV Sciences, St. George's University of London, London, United Kingdom.*

**Background**

ESRD patients have a high cardiovascular (CV) mortality; not explained by traditional risk factors. Inflammation and macrophage activation have been proposed as a key pathogenic mechanism in the development and progression of atherosclerosis in these patients. A human heat shock protein 60 (hHSP60; a stress protein upregulated in inflammation) specific sub-population of CD4$^+$ cells, CD4$^+$CD28$^-$ , present in coronary artery disease (CAD) engage in vascular damage via Killer Immunoglobulin-like Receptor 2DS2 (KIR2DS2). Also, CD4$^+$CD28$^-$ cells produce IFN-γ which is a potent activator of macrophages contributing to plaque rupture.

This study investigated the expansion and activation of CD4$^+$CD28$^-$ cells in ESRD patients.

**Methods and Results**

15 patients (mean age 61.9±9), men 60%, DM 33%, hypertensives 94%, current smoking 0% and 10 healthy controls were studied. CD4$^+$CD28$^-$ cells were isolated from peripheral blood by FACS and cloned using irradiated allogeneic feeder cells.

Three patients (20%) had increased number of CD4$^+$CD28$^-$ cells that constituted 6-9% of the total CD4$^+$ count. None of the controls had CD4$^+$CD28$^-$ cells. Analysis of clones (n=112) by RT-PCR showed 45%, 49% and 51% of cells in each patient expressed the KIR2DS2, largely in the absence of the corresponding inhibitory KIRs (95%). KIR2DS2 positive clones exibited autoreactivity against target cells pulsed with hHSP60. As DAP-12 is essential for effector function, we tested the hHSP60 reactive cells for DAP-12 mRNA. 92% of 2DS2 positive clones expressed DAP-12 and were reactive to hHSP60. These clones produced IFN- γ upon antigen exposure.

Proportion of killer hHSP60-specific T cells in HD patients were notably higher compared to pre-dialysis patients (41% vs 15%; studied separately).

**Conclusion**

The higher frequency of killer CD4$^+$CD28$^-$ cells in these patients is of significance which may suggest their gradual expansion with progressive renal impairment. We therefore propose a mechanism outside the traditional risk factors that may account for CV events in these patients.

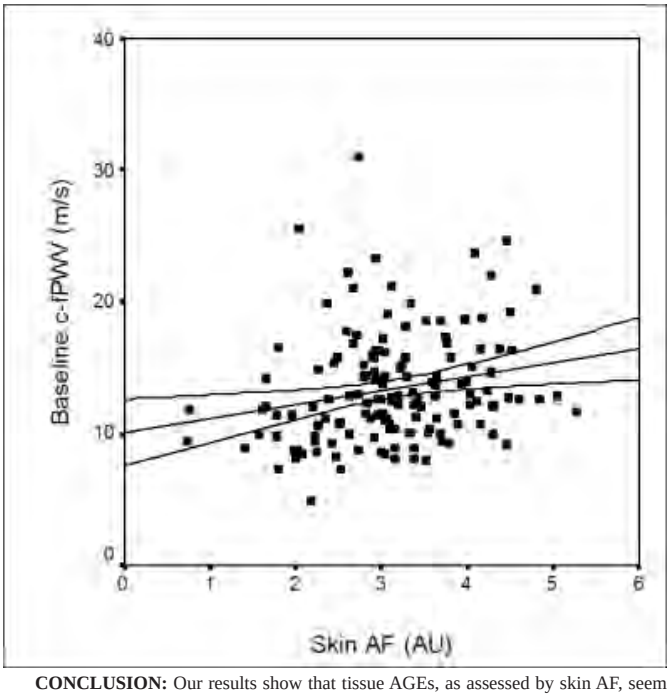
**Tissue Advanced Glycation End-Products Are Not Associated with the Progression of Aortic Stiffness in Hemodialysis Patients** Véronique Couture,[1,2] Mihai Silviu Utescu,[1,2] Simon Desmeules,[1,2] Karine Marquis,[1,2] Mohsen Agharazii.[1,2] *[1]Medicine, Université Laval, Québec, QC, Canada; [2]Medicine, CHUQ-HDQ, Québec, QC, Canada.*

**INTRODUCTION**: Among haemodialysis (HD) patients, an increased aortic stiffness is associated with increased cardiovascular disease (CVD). It has been suggested that skin autofluorescence (AF), a measure of tissue advanced glycation end-products (AGEs), predicts mortality in HD patients and is associated with arterial stiffness in patients with end-stage renal disease (ESRD). The purpose of this study is to examine whether there is an association between skin AF and aortic stiffness in HD patients and whether skin AF can predict the progression of aortic stiffness.

**METHODS:** This is a cross-sectional observational study with longitudinal follow-up in 205 (118 men) chronic HD patients. At baseline, skin AF was assessed by the AGE-Reader® and expressed as Arbitrary Units (AU) while aortic stiffness was evaluated before the second HD session of the week by the measurement of carotid-femoral pulse wave velocity (c-fPWV). A follow-up was also performed one year after the baseline examination in order to study the impact of tissue AGEs on the progression of aortic stiffness and merely 131 patients (70 men) completed the study.

**RESULTS:** Baseline values for skin AF and c-fPWV were 3.14±0.86 AU and 13.2±4.1 m/s respectively while c-fPWV at follow up was 13.9±4.2 m/s. Skin AF correlates positively with baseline c-fPWV (r=0.216, *p=0.009*). Conversely, there is no correlation between skin AF and the progression of aortic stiffness.



**CONCLUSION:** Our results show that tissue AGEs, as assessed by skin AF, seem to be associated with aortic stiffness at baseline in HD patients. However, skin AF is not associated with the rate of progression of aortic stiffness in this population. These results suggest that tissue AGEs may not be involved in the progression of aortic stiffness.

**The Utility of Ultrasonography To Show Arterial Media Calcifications (AMC) in Young People with End Stage Renal Disease Not Yet on Dialysis** Annibale Marinelli, Franco Della Grotta. *Nephrology and Dialysis, Riuniti Hospital Anzio, Anzio, Roma, Italy.*

In young people, arterial media calcifications are linked to diabetes and to vintage dialysis and they increase the risk of cardiovascular mortality. It is unknown if AMC are present in end stage renal disease before starting dialysis. We have evaluated the development of AMC and arterial intimal calcifications (AIC) with ultrasonography; infact, even if it isn' t used for this purpose, it permits a clear distinction between the two kinds of lesions besides showing AMC in an initial stage (linear deposition of calcium salts as spots or as segments). We have studied 44 subjects with the inclusive age between 25 and 55 years; 25 (15M/10F; mean age 41±9 years) were affected by chronic renal failure (MDRD 14±5 ml/min) and 19 were healthy volunteers (8M/11F; mean age 41±8 years). The exam was performed with trasversal and longitudinal scansions of the common and superficial femoral arteries (until the lower part of the thigh). The nephropaties were constituited by nefroangiosclerosis (4), diabetes type I (4), diabetes type II (1), chronic pyelonephritis (3), unknow etiology (4). In comparison to healthy subjects, patients were more hypertensive (22/25, p<0,001) and they had higher values of phosphate (4,8 mg/dl ± 0,9 vs. 3,6 ±0,4, p<0,001) and PTHi (318±258 pg/ml vs. 70±40, p<0,001). Vascular calcifications (AIC plus AMC) were evident in 44% of patients and in the 10% of the controls (p<0,05); isolated AIC were higher in chronic kidney disease patients although not in a significant way (6 vs 2). On the contrary, we observed AMC only in the end stage renal disease ( 7 cases,p<0,05). Taking into account all patients affected by renal damage, AIC and AMC were associated rispectively with age (49±4 y., vs 39±8, p<0,01) with and with diabetes (5/7, p<0,001). Although we have evaluated only a few patients, this study shows that, despite bone turn-over alterations, the development of AMC in young people with end stage renal disease is connected primarily with diabetes.

**Plasma Asymmetric Dimethyl L-arginine Levels in End Stage Renal Disease Patients with Pulmonary Hypertension** Jeffrey M. Turner,[1] Ariel Meyer,[1] Zhe Quan,[1] Daniel Spevack,[1] Michal L. Melamed,[1] Timothy W. Meyer,[2] Thomas H. Hostetter,[1] Amanda C. Raff.[1] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Stanford University School of Medicine, Palo Alto, CA.*

**Introduction:** End stage renal disease (ESRD) patients are at increased risk for developing pulmonary hypertension and those with pulmonary hypertension are at increased risk for mortality. Asymmetric dimethyl L-arginine (ADMA), an inhibitor of endogenous nitric oxide synthase, is associated with primary pulmonary hypertension and has previously been found to be elevated in some patients with renal failure. ADMA may contribute to endothelial dysfunction in ESRD patients with pulmonary hypertension. We

hypothesized that ESRD patients with pulmonary hypertension would have higher levels of plasma ADMA than ESRD patients without pulmonary hypertension as well as controls without renal disease.

**Methods:** We studied 20 ESRD patients that had available echocardiogram data from a single outpatient hemodialysis unit. Eleven patients with PASP > 35mmHg were selected from a previously identified pulmonary hypertension cohort and 9 patients without pulmonary hypertension were selected as a comparison group. In addition, plasma from 10 control subjects without renal disease was collected. Plasma ADMA levels were measured in each group.

**Results:** Patients with ESRD had significantly higher levels of ADMA than normal controls 0.722 +/- 0.143 μM/L vs. 0.484 +/- 0.072 μM/L (p<0.001). ADMA plasma levels in ESRD patients with and without pulmonary hypertension were 0.766 +/- 0.161 μM/L vs. 0.684 +/- 0.108 μM/L (p=0.21) respectively. These 2 groups were similar in regards to sex, age, PTH, calcium, phosphorous, and hemoglobin. The mean Kt/V was > 1.2 in both groups.

**Conclusions:** ADMA levels are increased in patients with ESRD as compared to normal controls without renal failure. However, we were unable to detect a difference in plasma ADMA levels in ESRD patients with and without pulmonary hypertension.

**Plasmatic Pentosidine Levels and Vitamin D Dosing Are Associated with Accelerated Progression of Aortic Stiffness in Hemodialysis Patients** Mihai Silviu Utescu,[1,2] Véronique Couture,[1,2] Karine Marquis,[1,2] Simon Desmeules,[1,2] Mohsen Agharazii.[1,2] *[1]Medicine, Université Laval, Québec, QC, Canada; [2]Medicine, CHUQ-Hôtel Dieu de Québec, Québec, QC, Canada.*

INTRODUCTION: Aortic stiffness as measured by carotido-femoral pulse wave velocity (c-f PWV) is associated with increased cardiovascular (CV) mortality in hemodialysis (HD) patients. However, the progression rate and the determinants of aortic stiffening in HD are not completely elucidated. The accumulation and generation of advanced glycation end products (AGEs), endothelial dysfunction and vascular calcification resulting from a disturbed calcium phosphate metabolism could play a role.

METHOD: The c-fPWV) was measured in 109 chronic (more than 3 months) HD patients (49 females). Fifteen months (14±5) after the baseline measurements we re-evaluated the c-fPWV. Demographic and anthropometric data (age, sex) , history of CV disease and diabetes, dialysis vintage, residual renal function, laboratory parameters (calcium, phosphate, PTH, albumin, CRP), plasmatic levels of pentosidine (AGEs) and endothelin-1 (endothelial dysfunction) and finally, medication dosage (alfacalcidol, sevelamer hydrochloride and calcium carbonate) were evaluated at baseline.

RESULTS: During the follow-up period, c-fPWV increased from 13.13±3.79 to 14.25±3.88 m/s (p<0.001). After adjustments for the changes in mean blood pressure and heart rate, the c-fPWV progression rate per year was of 0.54±1.19m/s (p<0.01). Determinants of adjusted c-fPWV progression rate per year expressed as percent value from baseline c-fPWV were assessed with a multivariate analysis using baseline clinical, dialysis, laboratory, medication dosage data, mean blood pressure and heart rate as independent variables. In this model, only Alphacalcidol dosing (R2 =0.095; p<0.005) and plasmatic pentosidine levels (R2=0.049; p<0.05) were retained as independent determinants of c-fPWV progression rate. Endotheline-1 plasmatic levels positively correlated with pentosodine levels (r=0.404; p<0.001) but were not retained as determinant.

CONCLUSION: Plasmatic levels of pentosidine and vitamin D dosing seem to be independent predictors of an accelerated progression of AS in HD patients.

## PUB565

**Resistive Index Measured by Renal Doppler Ultrasound Reflects Arteriolosclerosis in Renal Biopsy Specimen** Yohei Doi,[1] Fumiki Yoshihara,[1] Hatsue Ishibashi-Ueda,[2] Satoko Nakamura,[1] Yoshio Iwashima,[1] Hideaki Takata,[1] Takashi Fujii,[1] Takeshi Horio,[1] Yuhei Kawano.[1] *[1]Hypertension and Nephrology, National Cerebral and Cardiovascular Center, Suita, Oosaka, Japan; [2]Pathology, National Cerebral and Cardiovascular Center, Suita, Oosaka, Japan.*

**Background, Purpose**

Resistive index (RI), calculated from the renal doppler waveform, has been shown to be relevant to progression of renal dysfunction and survival rate. However, clinical significance or related factors of RI have not been fully clarified. The purpose of the present study was to clarify the correlation between RI , clinical parameters and renal histology.

**Materials and Methods**

Of 46 consecutive patients underwent renal biopsy, 35 patients who underwent renal doppler ultrasound were enrolled. Clinical diagnosis of the 35 patients were Mesangial proliferative glomerulonephritis(n=13), Membranous nephropathy (n=6), Diabetic nephropathy (n=6) and others (n=10). Biopsy specimens were evaluated as follows, 1. interstitial fibrosis was quantitated using a software for image analysis, 2. arteriolosclerosis was evaluated as the ratio of luminal diameter to the outer diameter, 3. glomerulosclerosis and tubular atrophy were assessed by means of a semi-quantitative method.

**Results**

The characteristics of participants were age 58.6±14.9 years, BMI 24.9±3.9, blood pressure 138.7±19.2 / 75.7±10.5 mmHg, blood urea nitrogen(BUN)19.9±6.8 mg/dL, serum creatinine (S-Cr) 1.29±0.59 mg/dL, hemoglobin (Hb) 12.8±2.4 g/dL, urinary protein excretion 3.3±3.0g/day, urinary N-acetyl-β-glucosaminidase 15.6±19.8 U/L, urinary β2-microgloburin 1309±4901 μg/dL, RI 0.68±0.09. In univariate regression analysis, RI was significantly and positively correlated with age (r=0.467), BUN (r=0.510), S-Cr (r=0.544), interstial fibrosis (r=0.348), tubular atrophy (r=0.340) and negatively with arteriolosclerosis (r=-0.408) and Hb (r=-0.335). Stepwise multiple regression analysis showed age, S-Cr, arteriolosclerosis were independent related factors for RI (β-coefficient=0.309, 0.444, -0.277, respectively).

**Conclusion**

RI was increased in associated with age, renal dysfunction and arteriolosclerosis. Arteriolosclerosis may be one of the determinants of RI.

## PUB566

**Rosiglitazone (RGZ) Improves the Natriuretic/Diuretic Response to Atrial Natriuretic Peptide (ANP) but Not cGMP-Mediated Renal Vasodilatation in Rats with Congestive Heart Failure (CHF)** Ilia Goltsman,[1] Elena Ovcharenko,[1] Zaid Abassi,[1] Aaron Hoffman,[1] Xinkang Wang,[2] Giora Z. Feuerstein,[2] Joseph Winaver.[1] *[1]Physiology and Biophysics, Faculty of Medicine, Technion-IIT, Haifa, Israel; [2]Translational Medicine, Pfizer, Collegeville, PA.*

**Background/Aims:** The natriuretic/diuretic response to ANP and endothelial-dependent (ED) and -independent (EI) vasorelaxation, both cGMP-mediated, are blunted in rats with aorto-caval fistula (ACF), an experimental model of CHF. Recently, we reported that chronic treatment with RGZ, a PPARγ-agonist, improved the natriuretic response to ANP in rats with CHF (Goltsman et al., ASN Renal Week 2009, abstract TH-PO063). In the present study we explored the effects of RGZ treatment on ED and EI renal vasodilatation in rats with ACF.

**Methods:** The natriuretic/diuretic responses and urinary cGMP (UcGMP) excretion in response to rat ANP (15 and 50 μg/kg/hr) were assessed by clearance methodology in CHF rats following 2-week RGZ (30 mg/kg/day, p.o) or vehicle (Ve) treatment, and in sham-operated controls (N=6-10). The capacity of isolated glomeruli and collecting ducts to generate cGMP in response to ANP ($10^{-11}$-$10^{-6}$M) was tested. The ED and EI renal vasodilatory responses to ACh (1-100 μg/kg/min) and SNAP (10, 30 μg/kg/min), respectively, were studied by ultrasonic flowmetry.

**Results:** CHF rats treated with RGZ exhibited significantly enhanced natriuretic and diuretic responses compared with Ve, as represented by peak $U_{Na}V$; control: 11.2±1.8 μEq/min, CHF+Ve: 3.66±1.2* μEq/min, CHF+RGZ: 11.2±2.3† Eq/min (P<0.05 vs. *control and †CHF+Ve). However, these improvements were not matched by increased UcGMP excretion. Also, RGZ treatment did not alter the capacity to generate cGMP in response to ANP in isolated renal tissues. Finally, the blunted renal vasodilatory responses to ACh and SNAP were not improved in CHF rats treated with RGZ.

**Conclusions:** In rats with CHF, chronic RGZ treatment enhances the natriuretic response to ANP, but not the blunted cGMP-mediated vasodilatation. The data may also suggest that RGZ selectively enhances signaling mediated by particulate rather than soluble guanylate cyclase, probably at a step beyond cGMP generation.

**Single Centre Study on Outcomes Following Renal Artery Stenting** David Makanjuola,[1] Matthew Lumley,[1] Hugh Gallagher.[1] *[1]Nephrology, St. Helier Hospital, Carshalton, United Kingdom; [2]Nephrology, St. Helier Hospital, Carshalton, United Kingdom; [3]Nephrology, St. Helier Hospital, Carshalton, United Kingdom.*

Background

Renal artery stenosis causes hypertension, renal dysfunction and is associated with cardiovascular events. We examined the results of all patients who had renal artery stenting for atherosclerotic disease since 2003 to present at our unit.

Methods

Data were collected on BP, antihypertensives taken, creatinine pre-procedure, at 6 months and at end of follow up; whether the patient was taking an ACE-I/ARB pre-procedure and if not, whether they had been introduced post procedure.

Results

48 patients had renal artery stenting. Mean age was 72.0+/-1.4years, mean follow up was 19.7+/-2.3months.

Outcomes following renal artery stenting

| | Change in Creatinine (μmol/L) | Change in Systolic BP(mmHg) | Change in Diastolic BP(mmHg) | Change in number of antihypertensive medications |
|---|---|---|---|---|
| 6 months | 12.4, CI -0.8 to 25.6, P value< 0.06 | -13.9, CI -5.6 to-22, P value< 0.002 | -7.3, CI -3.3 to -11.3, P value< 0.0007 | -0.2, CI -2.0 to 1.7, P value< 0.4 |
| End of follow up | 9.2, CI -2.0 to 20.4, P value< 0.1 | -7.9, CI -3.9 to -11.9, | P value< 0.0003 | -0.05, CI -0.5 to 0.4, P value< 1 |

17 were on ACE-I or ARBs pre-procedure, 26 were not and 5 patients had missing information. Of the 26 patients post procedure 9 were started on an ACE-I/ARB. Therefore, of the patients who were not on an ACE-I/ARB pre-procedure 39% were able to start following the procedure.

Discussion

Our findings show that in our patient group, renal artery stenting for atherosclerotic renovascular disease led to a significant reduction in systolic and diastolic BP at 6 months and end of follow up. Revascularisation however had no impact on the number of antihypertensive agents prescribed. The ASTRAL trial only included patients in whom

there was uncertainty whether or not they would benefit from revascularisation. Therefore, those patients most likely to derive benefit may have been excluded. Our experience suggests that revascularisation may enable a significant proportion of patients to be able to commence ACE-I/ARBs.

**Retinal Venules Dilate after an Episode of Haemodialysis in End-Stage Kidney Failure** Foong Kien Newk-Fon Hey Tow,[1] Qi-Lun Ooi,[1] Tien Y. Wong,[2, 3] Ryo Kawasaki,[2] Peter F. Mount,[4] Deb J. Colville,[1] Judith A. Savige.[1] *[1]Medicine, The University of Melbourne (Northern Health), Melbourne, VIC, Australia; [2]Center for Eye Research Australia, The University of Melbourne, Royal Victorian Eye and Ear Hospital, Melbourne, VIC, Australia; [3]Singapore Eye Research Institute, Singapore National Eye Centre, Singapore; [4]Department of Nephrology, Austin Health, Melbourne, VIC, Australia.*

**Background:** Retinal vessel appearance reflects changes in the systemic microvascular circulation. This study examined the effects of haemodialysis on retinal vascular caliber.

**Patients and Methods:** Twelve males and 12 females with a median age of 62.5 years (range 30-87) underwent routine haemodialysis using Gambro high-flux dialysis membranes. Twenty (83%) patients had hypertension and 10 (42%) had diabetes. Retinal images were recorded using a non-mydriatic camera (Canon CR5-45NM) immediately before and 30 minutes after dialysis. Retinal vascular calibers were measured by a trained grader using a computer-assisted vessel measurement system (University of Wisconsin, Maddison, WI, USA) and Knudtson's formula. Measurements were summarised as Central Retinal Artery Equivalent (CRAE) and Central Retinal Vein Equivalent (CRVE).

**Results:** Patients had a mean of 2.0 L fluid removed ($p<0.0001$), and their mean arterial pressures decreased from 91.5 mm Hg to 84.7 mm Hg ($p=0.058$). Retinal arterioles dilated in males (mean change 6.9 um, CI 1.30 - 12.5, $p= 0.020$) but not in females after dialysis. Retinal venules dilated in all patients (mean change 12.7 um, CI 7.3 - 18.3, $p<0.001$). The change in CRVE correlated positively with the volume of fluid removed per Kg body weight (coefficient 5.869, $p=0.042$), and negatively with the change in mean arterial pressure (coefficient - 0.364, $p= 0.046$). Vessel calibre returned to baseline by 2 hours.

**Conclusions:** Retinal vascular dilatation after dialysis probably occurs secondary to the release of systemic vasoactive factors that affect all microvascular beds and contribute to post-dialysis hypotension. Retinal vascular imaging allows the examination of dynamic physiological changes in the microvascular circulation.

**Uric Acid Is Causally Associated with Blood Pressure in a Controlled Setting: Results from a Mendelian Randomization Analysis of GLUT9** Afshin Parsa, Eric M. Brown, Matthew R. Weir, Braxton D. Mitchell, Patrick F. Mcardle. *Medicine, University of Maryland School of Medicine, Baltimore, MD.*

BACKGROUND: Elevated serum levels of uric acid (UA) are consistently associated with hypertension, but the directionality of the association remains debated. We used, in a controlled setting, a Mendelian randomization approach to demonstrate the direction of the association between UA and blood pressure (BP). Using a recently described functional single-nucleotide polymorphism, rs16890979 (Val253Ile), in the GLUT9 gene that is associated with lower UA levels, we examined the unconfounded association between genotype and BP.

METHODS: Genotyping was performed on 516 "healthy" participants in the HAPI Heart Study to identify variants of a genetic locus reliably associated with serum uric acid level (GLUT9). Participants were on prepared fixed standardized high and low sodium diets (280 and 40 meq per day) for 6 days each and BP measures were based on ambulatory mean 24 hour BP measures. All of our participants were free of diuretic or other anti-hypertensive medication use. Using Mendelian randomization analysis, relationships between genotype and both UA and BP were assessed.

RESULTS: Each copy of the minor Ile allele conferred approximately a 0.44 mg/dl reduction in uric acid ($p = 3.2x10-11$). On the high sodium diet each copy of the Ile allele was associated with a mean decreases in systolic BP of 2.2 mmHg ($p = 0.0058$). The effect of the genotype was attenuated, but still significant on the low sodium diet with a mean decreases in systolic BP of 1.48 mmHg ($p = 0.038$).

CONCLUSION: Decreases in serum uric acid concentration, as directly mediated by genetic variants of GLUT9, are causal of decreases in BP and may be modified by dietary sodium intake.

**ACE/ACE2 Ratio in Serum and Kidney Cortex Is Increased in Sexually Mature Male Mice** Marta Riera, Julio Pascual, Judit Rigol, Maria Jose Soler. *Nephrology, Parc de Salut Mar. Fundació IMIM, Barcelona, Spain.*

It has been shown that there are gender differences in the expression of some of the components of the Renin-Angiotensin System (RAS). Gender differences in renal and cardiovascular diseases seem to involve the overexpression of various components of the RAS, including angiotensin converting enzyme (ACE), the angiotensin II type 1 receptor, and angiotensinogen. Previous studies demonstrated that serum ACE activity is increased in 8-week old male mice as compared to female controls. We previously showed that serum ACE2 activity is altered in healthy male mice and human. Gender differences in ACE/ACE2 ratio have not been widely studied.

The aim of this study is to investigate whether there are differences between healthy male and female mice in ACE/ACE2 activity ratio in serum at different ages (1,3 and 6 month-old-mice). We also studied ACE/ACE2 ratio in kidney cortex from male and female mice at 1 and 3-months. For this purpose, serum and renal tissue was obtained from male and female mice at 1, 3 and 6 months of age. ACE and ACE2 activities were measured using respective fluorescent assays.

Serum ACE/ACE2 ratio was increased in males as compared to females at sexual maturity, 3 and 6 months of age (3 month-old:1.00±0.13 vs 1.31±0.09; 6 month-old: 1.00±0.06 vs 1.65±0.11 arbitrary units; $p=0.06$ and $p<0.05$, respectively). Additionally, ACE/ACE2 ratio in kidney cortex was increased in 3-month old male mice as compared to female mice (1.00±0.20 vs 2.39±0.67, $p<0.05$). We did not observe any difference in ACE/ACE2 ratio in serum and kidney cortex from 1-month old male mice as compared to females, when animals are sexually immature.

In conclusion, ACE/ACE2 ratio is increased in plasma and kidney cortex from sexually mature male mice as compared to female. ACE/ACE2 imbalance in male mice may increase Angiotensin II formation and decrease its degradation that will lead angiotensin II accumulation in serum and kidney in male mice. Angiotensin II accumulation in kidney and serum might be associated to the accelerated kidney disease progression and increased cardiovascular risk in males.

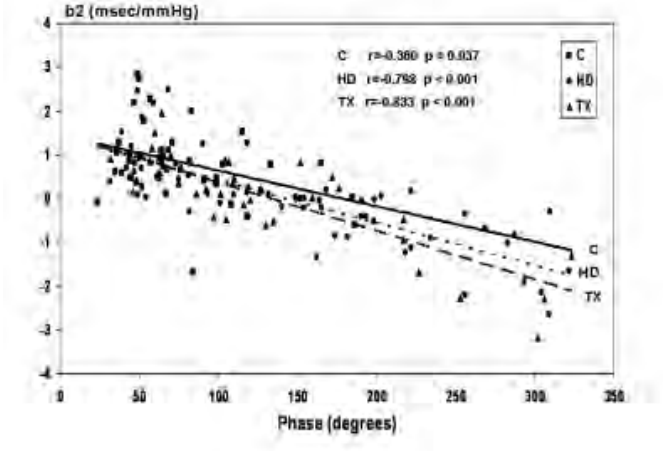
**Delayed Effect of Blood Pressure Fluctuations on Heart Rate in Patients with End-Stage Renal Disease** Dan Sapoznikov, Dvora Rubinger. *Nephrology and Hypertension Services, Hadassah University Medical Center, Jerusalem, Israel.*

The magnitude and the time delay of the baroreflex may be affected by decreased autonomic activity in the uremic state. The present study was undertaken to assess the delayed effect of systolic blood pressure (SBP) fluctuations on heart rate in patients with end stage renal disease. To evaluate the magnitude and the time delay of heart rate response, continuous interbeat intervals (IBI) and SBP were monitored in non-diabetic patients on chronic hemodialysis (HD, n=68), in patients after renal transplantation (TX, n=39) and in age-matched controls (C, n=34). A 4-term multivariate model for prediction of IBI differences from present and past SBP differences was calculated by the least square method. The frequency domain variables LF$\alpha$ , phase shift and lag time were also calculated. The $b_1$ model coefficient, representing the dependence of IBI difference with the first previous SBP difference, was markedly lower in HD patients than in controls, but increased after TX. $b_1$ strongly correlated with age and with the baroreceptor indices LF$\alpha$ coefficient and baroreflex slope. The correlations of $b_2$ coefficient, the 2nd model term, with the phase shift between SBP fluctuations and IBI are shown in Figure1:



Significant correlations were also found between $b_2$ and the lag time in both HD ($r=0.724$, $p<0.001$) and TX ($r=0.827$, $p<0.001$) patients. The lag time in controls (0.5-1.75 sec) was markedly lower than in HD and TX patients (up to 3.2 sec). These findings show: 1. In patients with end stage renal disease, there is a significant time delay in the heart rate response to the blood pressure variations. 2. Renal TX improves baroreceptor indices, but has no significant effect on the time delay of heart rate response to blood pressure oscillations. The prolonged delay may contribute to the circulatory instability in patients with chronic kidney disease.

**The Effect of Cyclooxygenase-2 Inhibition on Systemic and Renal Hemodynamic Function and the Renin Angiotensin System in Healthy Humans** Magdalena A. Sarna,[1] Brenda Hemmelgarn,[1,2] Daniel A. Muruve,[1,2] Jennifer M. MacRae,[1,2] Shubhra Singh,[1] Yan Shi,[1] Darlene Y. Sola,[1] Sofia B. Ahmed.[1,2] *[1]Department of Medicine, University of Calgary, Calgary, AB, Canada; [2]Alberta Kidney Disease Network, AB, Canada.*

Even in healthy humans, cyclooxygenase-2 (COX-2) inhibition results in loss of kidney function, though the mechanism by which this occurs is unclear. COX-2-derived vasodilatory prostaglandins play a prominent role in arterial vasoregulation through interactions with the renin angiotensin system (RAS). Accordingly, we examined the role of COX-2 in control of baseline systemic and renal hemodynamic function and in the response to angiotensin II (AngII) in healthy humans. We hypothesized that COX-2 inhibition would result in a decrease in GFR (glomerular filtration rate), RPF (renal plasma flow) and RAS components and would increase the pressor response to AngII challenge.

Nine healthy subjects (4 females and 5 males) were studied in high salt balance, a state of maximal RAS suppression. Circulating components of the RAS (plasma renin activity (PRA), AngII, and aldosterone), blood pressure (BP) and renal hemodynamics [GFR, RPF, filtration fraction (FF)] were measured at baseline and in response to graded AngII infusion pre- and post-14 days of COX-2 inhibition with 200 mg celecoxib daily. Compared to baseline, there was a decrease in all circulating components of the RAS (PRA (p=0.15), AngII (p=0.36) and aldosterone (p=0.03)) following COX-2 inhibition. Blood pressure was unaffected by COX-2 inhibition (p=0.37 MAP, p=0.30 systolic, p=0.90 diastolic BP). There was a decrease in GFR (p=0.03) and RPF (p=0.02) post COX-2 inhibition with a resultant increase in FF (p=0.02). Compared to baseline, GFR was maintained while RPF decreased and FF increased in response to AngII after COX-2 inhibition. There was no difference in the circulating RAS components or pressor response to AngII pre- vs post-COX-2 inhibition.

The results suggest that COX-2 modulates RAS activity and renal hemodynamics at baseline and in response to AngII in healthy humans. COX-2 inhibition is associated with glomerular hyperfiltration and this may represent the mechanism by which COX-2 inhibition predisposes to loss of GFR.

**Relation between Metabolic Abnormalities Associated with Arterial Dysfunction in Pediatric Dialysis and Transplant Patients** Hanan K. Tawadrous, Haroon Kamran, Anil K. Mongia, Louis Salciccioli, Morris J. Schoeneman, Jason Lazar. *Pediatric Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

Background

We previously demonstrated that higher augmentation index (AI), greater carotid intima-media thickness and endothelial dysfunction are present in patients with end stage renal disease on dialysis (D) compared to transplant recipients (Tx) and healthy controls. The etiology of increased arterial stiffness is uncertain but may be related to metabolic abnormalities present in D patients that improve after transplantation.

Objective

To assess metabolic abnormalities associated with increased arterial stiffness in pediatric D patients.

Methods

We studied 44 patients:15 on D,14 Tx (6 with living related donor (LRD), and 8 with deceased donor transplant (DDRT),and 15 healthy age, gender and ethnicity matched controls (C). CIMT and brachial artery flow-mediated increase in arterial diameter (FMD) was measured by high-resolution ultrasound. Heart rate corrected to 75 bpm (AI75) was measured by applanation tonometry. Hemoglobin (Hgb) and 25 hydroxy Vit D were obtained in all groups. PTH, calcium, phosphate and calcium x phosphate product (CaxP) levels were obtained in D. Mean values between groups were compared using ANOVA and pairwise comparisons.

Results

In all pts, FMD and PWV were each significantly correlated with Hgb, renal group (C,Tx,D) and with VitD on univariate analyses. AI75 was correlated with Hgb and renal group, but not Vit D. Hgb and Vit D were significantly correlated (r=.51,p=.001). On multivariate analyses, FMD was independently associated with renal group whereas PWV (p=.10) and AI75 (.005) were associated with Hgb. In the D group, AI75 was also correlated with P level(r=-.74, p=.004) and Ca x P (r=-.71, p=.007), but not with PTH or Ca. In D,cumulative Epogen dose was unrelated to any of the vascular parameters upon partial correlation with Hgb.

Conclusion

Metabolic and vascular parameters differ among D, Tx, and C. Anemia appears to play an important role in the development of arterial dysfunction in pediatric renal patients, whereas P and CaxP products may be contributory in those on D. High Epogen dosage does not appear to be detrimental.

**Prolonged Dual Antiplatelet Therapy Did Not Decrease the Incidence of Restenosis after PTRA-Stenting — A Six-Year Study** Xin Zhang,[1] Mei Wang,[2] Li Zuo,[1] Wei Qin,[1] Haiyan Wang.[1] *[1]Nephrology, Peking University First Hospital; Institute of Nephrology, Peking University, China; [2]Nephrology, Peking University People's Hospital, China.*

**Background**: Dual antiplatelet therapy for at least 1 month is recommended for post-PCI patients with bare metal stents, but it is not yet known if this period is optimal for post-PTRAS patients.

**Objective:** To test if a prolonged dual antiplatelet therapy can lower instent-restenosis in renal arteries.

**Method:** Data from 2003 to 2009 was retrieved from the ARAS register database.

Patients were included if they: had unilateral or bilateral renal artery stenosis≥50% by angiography and were implanted BM-Stents; took aspirin plus clopidogrel for at least 1 month post procedure; were regularly followed up for at least 12 months.

Paients were divided into 1-month group (dual antiplatelet therapy for 1 month) and prolonged group (dual antiplatelet therapy for longer than 1 month). Restenosis was defined as a combination of Peak Systolic Velocity>180 cm/s and Renal Aortic Ration(RAR)>2.5:1 on color duplex sonography.

**Results:** A total of 116 patients with 141 stents were analyzed. Mean age was 67.7±8.7 years, and 89 % were male. The mean time for follow up was 31.1±18.8(4~81)months. One patients died (0.9%) and 32 had non-fatal cardiovascular events (27.6%). Eighteen patients were dignosed restenosis(15.5%).

The 1-month group had 18 patients and the prolonged group had 98. Baseline data including age, gender, and atherosclerotic comorbities and the intervention parameters including percentage of stenosis, the reference vessel diameter, and the stent size were all comparable. The period of clopidogrel pretreatment was longer in prolonged group(3.3±4.2 *vs* 1.9 ±1.5days, P<0.05). At the end of follow up, the restenosis rate did not differ between two groups(17/98 *vs* 1/18, P>0.05). Incidence of bleeding events was comparable.

**Conclusion:** In our retrospective study, aspirin with prolonged clopidogrel did not lower the incidence of restenosis after PTRA-stents. The optimal period for dual antiplatelet therapy needs to be studied in prospective clinical trials.

**Spleen Tyrosine Kinase Inhibitor R788 Is Effective in Reducing the Severity of Late Stage Glomerulonephritis and That This Effect Persists after Treatment Is Withdrawn** John P. McDaid,[1] Jennifer Smith,[1] Gurjeet Bhangal,[1] Esteban S. Masuda,[2] H. Terence Cook,[1] Charles D. Pusey,[1] Frederick W. K. Tam.[1] *[1]Imperial College Kidney and Transplant Institute, Imperial College, London, United Kingdom; [2]Rigel Pharmaceuticals Inc, South San Francisco, CA.*

Spleen tyrosine kinase (Syk) is crucial tyrosine kinase in the regulation of signal transduction upon activation of Fc receptors by immune complexes leading to proinflammatory cytokine production. Immune complex deposition in the kidney is an important cause of renal failure and the induction of diseases such as crescentic glomerulonephritis. Using the Wystar Kyoto rat model of glomerulonephritis and the Syk inhibitor R788 (fostamatinib disodium), an oral prodrug of the selective Syk inhibitor R406, we have previously shown that Syk inhibition is effective in the reduction of severity of glomerulonephritis. In this study we demonstrate that Syk inhibition is effective in reducing the severity of late stage disease at 21 days and also that the reduction in proteinuria by 70% (p<0.0012) and glomerulular crescents by 50% (p<0.001) compared to vehicle control group was maintained even when the treatment was withdrawn at day 14. Further investigations into the effect of Syk inhibition on fibrosis, a key feature of this late stage disease, by examining fibrotic markers alpha smooth muscle actin, fibronection, type IV collagen and cytokines TGFβ and CTGF are ongoing.

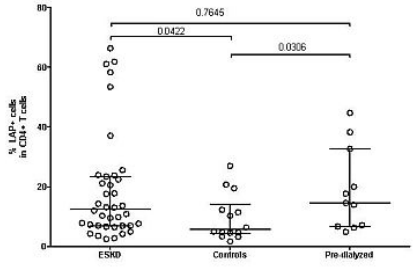
**Modulation of CD4$^+$/LAP$^+$ in Uremic Peripheral Blood** Pascal Meier,[1] Regine Audran,[2] Rachel Meier.[1] *[1]Nephrology, CHCVs, Sion, Switzerland; [2]Immunology, CHUV, Switzerland.*

CD4$^+$/CD25$^+$ regulatory T cells (Tregs) are essential for maintaining self-tolerance and immune homeostasis. Several molecules including transforming growth factor beta (TGF-β) have been linked to the function and differentiation of Tregs. We have demonstrated that some uremic toxins (i.e. oxidized LDL) may induce Tregs cell cycle arrest and apoptosis affecting their suppression capacity and finally promote a constant micro-inflammatory state in patients with end-stage kidney disease (ESKD). In this study, we analyzed markers of regulatory populations in human peripheral blood from ESKD patients. Frequency of natural Tregs CD4$^+$/FOXP3$^+$/CD25$^{hi}$/CD69$^-$ or CD45RO$^+$ or of CD4$^+$/CD127$^{lo}$/CD25$^{hi}$ was lower than in pre-dialyzed patients and controls.



On the contrary, we observed an increased frequency of a population of CD4$^+$ T cells expressing membrane TGF-β and of its latency-associated peptide (LAP) in ESKD and in pre-dialyzed patients (Mann-Whitney p values). The role of this population of CD4$^+$/CD127$^+$/CD25$^{lo/int}$ sequestering TGF-β on their surface, suggesting a regulatory function, is not yet elucidated. Thus, we have characterized in ESKD patients, the modulation of a population of LAP$^+$ and m TGF-β$^+$ CD4 T cells that is different from the classic dysfunctional CD4$^+$/FOXP3$^+$/CD25$^{hi}$ natural Tregs. Our findings provide the opportunity to identify CD4$^+$/LAP as a therapeutic target for the treatment of the micro-inflammatory state encountered in ESKD patients.

**Sirolimus Modulates Development and Progression of HIV-Associated Nephropathy (HIVAN) by Altering Plasminogen Activation Inhibitor (PAI)-1 Gene Expression** Shabina Rehman, Shitij Arora, Dileep Kumar, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Long Island Jewish Medical Center, New Hyde Park, NY.*

Renin-Angiotensin System (RAS) has been demonstrated to contribute to the progression of renal failure in several human and animal modes of chronic kidney diseases. Modalities which prevent the production or block the effect of Angiotensin (Ang II) have been demonstrated to slow down the progression of HIVAN. Recently, we reported that sirolimus attenuated the development of HIVAN (Am J Pathol. August, 2010). Since Ang II mediates it profibrotic effect through PA-1, we asked whether sirolimus modulated the progression of HIVAN by altering renal tissue expression of PAI-1.

Four weeks old Tg26 animals (n=6) were administered either vehicle or sirolimus (5 mg/kg/day, intra-peritoneal) for 14 days (group A) or 28 days (group B). To determine the role of Ang II in PAI-1 mediated mediated renal injury in HIVAN, Tg26 mice (n=3) were treated with either saline or telmisartan (300 µg/day, by miniosmotic pump) for two weeks. At the end of experimental periods, kidneys were isolated and prepared for histology. In addition, RNA was extracted evaluated for expression of PA-1 gene by RT-PCR.

In group A, the vehicle treated mice showed 1+ to 2+ glomerulosclerosis and 2+ to 3+ tubular dilatation, two rapamycin-treated mice showed no glomerular sclerosis and only mild dilatation of tubules and one rapamycin treated mouse showed 0 to 1+ glomerulosclerosis and 1+ to 2+ tubular dilatation. In group B, vehicle treated animals showed two-fold advanced glomerular and tubular lesions vs. rapamycin-treated animals. Rapamycin-treated animals showed 5-fold decrease in renal tissue PA-1 gene expression when compared with vehicle treated Tg26 mice. Tg26 mice showed enhanced tubular cell expression of PAI; however, telmisartan not only diminished development renal lesions in Tg26 mice but also inhibited tubular cell expression of PAI-1. These findings indicate Ang II contributes to the tubular cell expression of PAI-1 in HIVAN and rapamycin may be slowing down renal lesions in HIVAN by attenuating PAI-1 transcription.

**Thrombin Stimulates Synthesis of M-CSF, GM-CSF, MCP-1, and MIF in Human Proximal Tubular Epithelial Cells (PTEC) in Culture** Yuko Shimaya, Michiko Shimada, Hideaki Yamabe, Takeshi Fujita, Reiichi Murakami, Norio Nakamura, Ken Okumura. *Nephrology, Hirosaki University, Hirosaki, Aomori, Japan.*

Although Colony-stimulating factors (CSFs) were originally defined as haematopoietic cell growth factors, it has been suggested that CSFs are involved in various inflammatory conditions. However, it's role and expressions in the kidney has not well elucidated. We have been investigated the effect of thrombin in the kidney cells since thrombin exists in urine of the patients with glomerulonephritis, and urinary procoagulant activity has been suggested in the tubulointerstitial injury.

In this study, we used thrombin with or without argatroban which is a synthetic thrombin inhibitor to stimulate human PTEC and examined the expressions of Macrophage Colony Stimulationg Factor (M-CSF), Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF), Monocyte Chemoattractant Protein-1 (MCP-1) and Migration Inhibitory factor (MIF). Protein levels in the cell supernatants were measured by ELISA, and mRNA levels were quantified by realtime RT-PCR.

M-CSF, GM-CSF and MCP-1 protein levels were largely increased ($P$<0.01) and MIF were slightly increased ($P$<0.05) with thrombin (0.5-5.0u/ml, 24-72hours) in a dose and time dependent manner, and decreased with argatroban ($P$<0.01). Besides, 6h incubation with thrombin (1.0 or 5.0u/ml) increased mRNA levels of M-CSF, GM-CSF and MCP-1 dose-dependently($P$<0.05) and mRNA levels of MIF did not change.

Collectively, thrombin stimulated the production of M-CSF, GM-CSF, and MCP-1 by cultured PTEC and the possibly related to the tubulointerstitial injury in glomerulonephritis via blood coagulation process.

**Expression of the IL-2 Receptor in Murine Podocytes** Diego H. Aviles,[1] Jeannine Ory Ascani,[1] David J. Tate,[2] William E. Smoyer,[3] Arnold H. Zea.[2] *[1]Pediatrics, LSU Health Sciences Center/ Children's Research Institute, New Orleans, LA; [2]Stanley Scott Cancer Center, LSU Health Sciences Center, New Orleans, LA; [3]Pediatrics, Nationwide Children's Hospital, Columbus, OH.*

Nephrotic syndrome (NS) is a renal disease that results in massive proteinuria and edema. Patients with NS secondary to FSGS have poor responses to treatment and a high risk for developing renal failure. The renal podocyte plays an important role in maintaining the structural integrity of the glomerular filtration barrier. While mutations affecting the podocyte account for only a minority of the cases of NS, there is evidence that cytokines play a role in many forms of NS. We have shown that patients with NS due to FSGS have increased IL-2 production, although the underlying mechanism for IL-2 induced proteinuria is unknown. **Hypothesis**: IL-2 induced proteinuria is due to a direct effect on the podocyte. **Methods:** Differentiated murine podocytes were used to measure the IL-2 receptor expression in the presence and absence of IL-2 by qRT-PCR, flow cytometry and Western blotting. Apoptosis was measured by flow cytometry, while cytokine production was measured in supernatants with a Bioplex cytokine kit. **Results:** We found that murine podocytes expressed the IL-2 receptor, and that they produced IL-2 when stimulated with exogenous IL-2. IL-2 also induced podocyte apoptosis. **Conclusions:** We conclude that murine podocytes express a functional IL-2 receptor, and that they produce IL-2 in response to IL-2 exposure. Our results thus establish the ability of podocytes to both produce and respond to IL-2, a prime target to our current treatment for NS, although whether such stimulation in NS represents an autocrine or paracrine response to IL-2 remains uncertain.

**Vitamin D Antibacterial Activity in Cells from Peritoneal Dialysate Effluent**
Justine Bacchetta, Rene Chun, Katherine Wesseling-Perry, Martin Hewison, Isidro B. Salusky. *Orthopedic Hospital Research Center & Department of Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles.*

CKD patients are vitamin D deficient (precursor 25OHD and active $1,25(OH)_2D$) and both forms of the vitamin stimulate innate antibacterial activity in human monocytes. Infections are the main cause of morbidity in peritoneal dialysis (PD) pts. Thus, we hypothesized that peritoneal monocytes from PD pts may be targets for vitamin D therapy with potential unrecognized effects in the prevention of infections. Cells from 23 dialysate effluents (12 pts, age 16±3 yrs, serum 25OHD 29±9 ng/ml) were studied. Cells were isolated by centrifugation of 24 hour-dialysate effluent and evaluated for: 1) cell phenotype by flow cytometry; 2) baseline *in vivo* expression of genes associated with vitamin D function: vitamin D receptor (VDR], 24-hydroxylase (CYP24A1), 1α-hydroxylase (CYP27B1) and antibacterial cathelicidin (LL37); 3) gene expression following treatment of peritoneal monocytes *in vitro* with 25OHD (100 nM) or $1,25(OH)_2D$ (5 nM). There was a wide range of peritoneal cell number among pts (median 826,380; r 24,500-34,848,000 cells/l). Analysis of total cell populations from PD effluent before *in vitro* culture showed a significant correlation between the expression of CYP27B1 and LL37 ($r= 0.728$; $p<0.001$), and between the expression of CYP24A1 and both CYP27B1 and LL37 ($r= 0.698$ and 0.573, respectively, $p<0.01$). Serum 25 OHD levels did not correlate with the expression of vitamin D-dependent genes in PD cells. Crucially, expression of antibacterial LL37 by peritoneal monocytes was further enhanced after *in vitro* treatment with either 25OHD (10-fold) or $1,25(OH)_2D$ (100-fold).This is the first demonstration that, similar to peripheral blood monocytes, peritoneal monocytes have a functional system for vitamin D metabolism and activity. Induction of antibacterial LL37 by these cells appears to be dependent of expression of CYP27B1, and is enhanced by the addition of either inactive or active vitamin D. These data highlight a potentially important new function for vitamin D supplementation in the prevention of infectious related complications in PD patients.

**Differential Effects of Age and Cytomegalovirus-Seropositivity on Circulating T Lymphocyte Subsets of End-Stage Renal Disease Patients**
Michiel G. H. Betjes, Elly L. E. A. De Wit, Nicolle H. R. Litjens. *Nephrology, Erasmus Medical Center, Netherlands.*

**Background:** Patients with end-stage renal disease (ESRD) have an impaired T cell immunity which may be related to the profound changes in total number and distribution of their circulating T cell subsets. Cytomegalovirus (CMV)-seropositivity is increasingly recognized as a major determinant of accelerated T cell ageing and as such may contribute to impaired T cell immunity.

**Patients and Methods**: In a cross-sectional study the absolute numbers of circulating T lymphocytes and CD4pos and CD8pos T cells were determined of 139 ESRD patients (60% CMV-seropositive) and compared to healthy individuals matched for age and CMV serostatus. T cell subsets were further characterized by their differential expression of CD45RO and CCR7. Expression of the markers CD28 and CD57 on memory T cells was analyzed to establish the degree of T cell differentiation in more detail.

**Results:** CMV-seropositivity is associated with a significant expansion of both CD4 and CD8 memory populations in healthy individuals already at a young age. The total number of CD8 memory T cells is not affected by age in CMV-seropositive individuals and remains expanded by an average 60% compared to CMV-seronegative individuals. In addition, the degree of T cell differentiation is increased in CMV-seropositive healthy individuals. A modest age-related contraction of the naïve CD4pos T cell population was associated with CMV-seropositivity, in contrast to the CMV-independent pronounced decrease in the number of the CD8pos naïve T cells. ESRD patients showed a profound naïve T cell lymphopenia at all ages. Within their CD4pos T cell compartment, CMV-seropositivity aggravated the contraction of naïve T cells and increased the number of differentiated memory T cells. The remarkable CMV-seropositivity related expansion of memory CD8pos T cells was not observed, but the degree of terminal differentiation was increased.

**Conclusion:** CMV seropositivity is associated with pronounced age-related changes like expansion and increased differentiation of circulating CD4pos and CD8pos T cell populations, and aggravates the T cell dysregulation observed in ESRD patients.

**Synergistic Antifungal Effect of Caspofungin and Human Polymorphonuclear Leukocytes (PMNs) from Chronic Haemodialysed Patients and Renal Transplant Recipients Against *Candida albicans***
Franca Giacchino,[1] Giuliana Banche,[2] Valeria Allizond,[2] Daniela Scalas,[2] Janira Roana,[2] Giuseppe Garneri,[1] Rosaria Patti,[1] Rosanna Coppo,[3] Vivian Tullio,[2] Chiara Merlino,[2] Narcisa Mandras,[2] Anna Maria Cuffini.[2] *[1]Nephrology and Dialysis Unit, Civil Hospital, Ivrea, Turin, Italy; [2]Department of Public Health and Microbiology, University of Turin, Turin, Italy; [3]Nephrology Dialysis Transplant Unit, Regina Margherita Hospital, Turin, Italy.*

**Background.**Invasive fungal infections(IFIs) are difficult to eradicate especially in immunocompromised host: uremic patients are highly susceptible to fungal infections due to impaired phagocyte-dependent host defences. Hence, antifungal drugs that positively influence phagocyte activity may be crucial for IFI resolution.

**Objectives**.The aim of this study was to evaluate the effect of caspofungin, a new echinocandin, on the functions of PMNs from healthy subjects, haemodialysed patients and renal transplant recipients towards *Candida albicans*.

**Study design and Methods**.PMNs were separated from venous blood samples of 40 healthy donors, 68 haemodialysed patients and 65 renal transplant recipients. The effects of caspofungin on either phagocytosis or intracellular killing by PMNs towards *C.albicans* were investigated by incubating yeasts and PMNs with caspofungin. Drug-free controls were included.

**Results.**A diminished PMN efficiency was found in haemodialysed patient and renal transplant recipient PMNs, with reduced both phagocytosis and fungicidal activity towards intracellular yeasts, in comparison with healthy subject PMNs. As the majority of systemically acting antifungal drugs, caspofungin did not significantly improve phagocytic activity. Conversely, the fungicidal activity of uremic patient PMNs was significantly potentiated by caspofungin after 60'and 90' of incubation, in comparison with drug-free controls($p<0.01$).

**Conclusions.**Our findings provide evidence that caspofungin is able to restore the depressed intracellular killing by uremic patient PMNs, through a synergistic effect with PMNs towards *C.albicans* and may constitute effective therapeutic option for IFI treatment in patients with altered phagocyte-dependent innate immunity.

**Proliferation and Activation during Tubulointerstitial Injury in the Native Kidney**
Victoria J. Ingham, Neil S. Sheerin. *Institute of Cellular Medicine, Newcastle University, Newcastle-upon-Tyne, United Kingdom.*

Tubulointerstitial (TI) inflammation and fibrosis is seen with progressive renal failure and may be a common pathway to renal failure. The role and function of TI lymphocytes in the pathogenesis of injury is unknown.

Methods

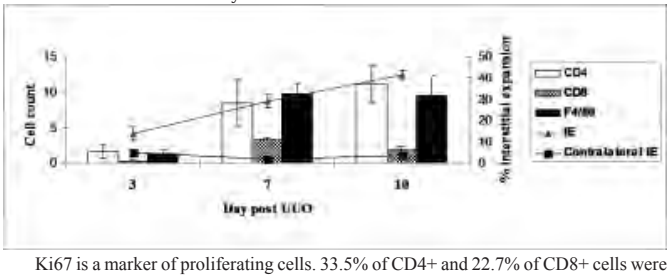
We used the unilateral ureteric obstruction (UUO) model of TI fibrosis to assess the composition and phenotype of infiltrating leukocytes.

Four animals were sacrificed at 3, 7 and 10 days after UUO. Tissue sections were analysed for:

- TI injury with Periodic acid Schiff and immunohistochemical (IHC) αSMA staining
- Cellular infiltration with quantification of CD4+, CD8+ and F4/80+ cells by IHC
- T cell proliferation by immunofluorescent dual staining of CD4+ or CD8+ cells with Ki67
- T cell activation by dual staining of CD4+ or CD8+ cells with CD69

Results

There was a positive correlation between cellular infiltration and injury. Few T cells were present at day 3 post UUO. By day 7, CD4+ and CD8+ T cells increased 6 and 11 fold compared to day 3. CD4+ T cell infiltration predominated over CD8+ cells with a CD4+: CD8+ ratio of 2.5:1 and 6:1 at days 7 and 10. There was negligible T cell infiltration in contralateral and normal kidneys.



Ki67 is a marker of proliferating cells. 33.5% of CD4+ and 22.7% of CD8+ cells were found to be Ki67+ at day 10 post UUO.

CD69 suggests lymphocyte activation. CD4+ activation peaked at day 7. More CD8+ lymphocytes were activated at later time points post UUO suggesting a requirement for initial CD4+ help ($p<0.05$).

Conclusions

Lymphocytes are not simply trafficking through injured kidney but show evidence of proliferation and activation. Since Chapman et al. (Virology 2005) showed that T cell proliferation only occurs in response to antigen recognition, this work suggests a loss of tolerance to self antigen in this non-immunologically mediated model of TI fibrosis. As yet the specific antigen(s) are unknown.

**Immune Response to Hepatitis B Vaccine in ESRD Population**
Lakshmi P. Nadimpalli,[1] Prajwol R. Pant,[1] Earl C. Smith,[1] Janos Molnar,[1] Ashok K. Singh,[2] Krishnamurthy P. Gudehithlu,[2] Andres Serrano.[1] *[1]Department of Nephrology, Mt. Sinai Hospital/Chicago Medical School, Chicago, IL; [2]Department of Nephrology, John H. Stroger Hospital of Cook County, Chicago, IL.*

End-Stage Renal Disease (ESRD) patients have a low seroconversion rate compared to the general population, following Hepatitis B vaccination (HBV). It has been reported an association between high TNFα levels, a marker of chronic inflammation, and immunocompromized state in chronic hemodialysis (HD) patients. We conducted a prospective study to identify clinical parameters that can predict seroconversion, and to

evaluate the possible association between inflammation (measured by inflammatory markers -TNFα, CRP & ferritin) and the immune response following HBV. Thirty five chronic HD patients who were negative for hepatitis B surface antigen and antibody, received 40 µg of HBV in the deltoid muscle at 0, 1 & 6 months. Immune response to HBV was evaluated 1 month after completion of the vaccination series by quantitative antibody (Ab) titers. Clinical parameters and inflammatory markers were compared between patients who responded and those who did not. Patients who responded to HBV (22 or 63%) were younger than those who did not (53.95 +/- 15.47 vs. 68.85 +/- 9.67, p=0.018). There were no differences in other parameters (sex, ethnicity, type of access, number of years on HD, urea reduction ratio, serum iron, hemoglobin, albumin, PTH, calcium, phosphorus and bicarbonate) and in the use of erythropoietin stimulating agents or vitamin D analogues between the two groups. We specifically evaluated the association of inflammatory markers (TNFα, CRP, ferritin) with seroconversion after HBV, but there were no differences between the two groups. Patients were also stratified according to their Hepatitis B Ab titers, but there were no differences in any of the parameters described.

***Conclusion:*** The immune response to HBV in chronic HD is low compared to the general population. Younger age seems to be associated with an adequate response to HBV. We did not identify any association between inflammation, measured by inflammatory markers (TNFα, CRP & ferritin), and the lack of seroconversion after HBV.

**Micro- and Macrovascular Dysfunction in Systemic Lupus Erythematosus** Susann Patschan, Martha Potulski, Daniel Patschan, Gerhard A. Mueller. *Department of Nephrology and Rheumatology, University Hospital Göttingen, Göttingen, Niedersachsen, Germany.*

Patients with systemic lupus erythematosus (SLE) suffer from vasculitis of small arteries/arterioles. The disease is associated with a 17-fold higher risk for artherosclerosis. Aim of the study was (I) to analyze the regenerative activity of the endothelial progenitor cell (EPC) system and (II) to measure pulse wave velocity in SLE.

A total of 39 SLE patients and 21 healthy controls were included into the study. EPC regeneration was evaluated by a colony-forming unit assay, total peripheral circulating EPCs were measured by cytometric analysis. Pulse-wave velocity (PWV) was quantified by tonometric analysis.

SLE patients, as compared to controls, displayed significant mobilization of total CD133+ and of CD133+/Flk-1+ cells (81 ±19 vs. 25 ±20%, p<0.001 and 0.92 ±0.84 vs. 0.46 ±0.47, p=0.02). In contrast, the regenerative activity of EPCs was markedly affected (25 ±29 vs. 45 ±31, p=0.01). Pulse wave velocity, a parameter of macrovascular damage, did not differ between patients with SLE and healthy controls (mean blood pressure levels in SLE patients were normotensive).

In summary our data show (I) a dramatic increase in circulating CD133+ cells and a significant increase in peripheral CD133+/Flk-1+ cells in SLE, reflecting intact EPC mobilization. (II) However, the regenerative activity of the EPC system was affected, which points towards the inability of adequate vascular repair. Since PWV analysis did not show differences between (normotensive) SLE and healthy controls, signs of microvascular dysfunction (e.g. dimished EPC proliferation) may not allow to conclude on structure/function of the larger arterial blood vessels and vice versa. Thus, both functional vascular elements must be analyzed separately.

Disclosure of Financial Relationships: nothing to disclose

**Risk Assessment and Renal Morbidity after Acute Stroke** Rupesh Raina. *Department of Nephrology and Hypertension, Cleveland Clinic Foundation, Cleveland, OH.*

Although acute stroke is an emergency disease and shares the same atherosclerotic risk factors with ischemic heart disease, the association of renal failure and stroke is poorly investigated.

We assessed the prevalence and predisposing factors for renal insufficiency in patients who sustained acute stroke and investigated outcomes (hospital discharge disposition (HDD) and length of stay (LOS)).

628 patients from a single center with acute ischemic and hemorrhagic stroke during 2007 and 2008 were evaluated. AKI, defined as serum creatinine.>0.3mg/dl or percentage increase of 50% from baseline on admission and discharge was assessed. Risk factors considered were age, gender, race, BUN value and history of hypertension, diabetes mellitus, hyperlipedemia ( HPL), coronary artery disease (CAD), and stroke. The mean age for all members was 63 years old, and the ages ranged from 18 to 96. The median length of stay was 6 days.

Of the 628 patients with acute ischemic and hemorrhagic 90 (14.3%) had renal insufficiency at admission. the prevalence of renal insufficiency at admission ranged from 4.1% (430) to 17.2% (431).

Multivariable models for renal insufficiency at admission showed males (p<0.001), those with hypertension (p=0.002), diabetes (p=0.003), stroke (p=0.027) and CKD (p<0.001) history had significantly higher risk of renal insufficiency at admission. No significant differences were observed in history HPL or CAD.

Of the those with hypertension (p=0.021)and CKD(p<0.001) also had significantly higher risk of renal insufficiency at discharge. In addition, non-whites (p<0.001) and older patients (p<0.01)also showed increased risk of renal insufficiency at discharge.

Conclusion: Renal failure is prevalent in acute stroke patients at time of admission and is associated with poor outcome at discharge. Consistent implementation of renal protective management and more broad use of drugs with potential renal protective properties may result in better outcome.

**HIVAN Phenotype Is Associated with Downregulation of MicroRNA-21 and MicroRNA-192** Divya Salhan, Dileep Kumar, Ashwani Malhotra, Pravin C. Singhal. *Medicine, LIJ Medical Center, New Hyde Park, NY.*

HIV-associated nephropathy (HIVAN) phenotype is characterized by proliferarion of podocytes and tubular cells. However, the exact pathophysiology of proliferative phenotype is not clear. Since, we recently reported that epithelial mesechymal transition (EMT) contributed to pathogenesis of HIVAN phenotype in Tg26 mice (AJP 2010), a mouse model of HIVAN, we asked whether microRNAs were associated with this process. Micro RNAs have been reported to be differentially expressed in various pathological and physiological states. The precise role of microRNAs, endogenous RNA oligonucleotides which specifically target mRNA and regulate gene expression in HIVAN is not known. Several studies have also identified micro RNAs as key regulators of EMT and may enforce the epithelial phenotype.

FVB/N (control) and Tg26 mice aged 16 wks (n=3) were sacrificed and kidneys were harvested for renal histology, immunohistochemical studies, and RNA extraction. Renal cortical sections were immunolabeled for EMT markers (α-SMA, vimentin, FSP1, ZEB2, and E-Cadherin).Total RNA from renal tissue (n=3) was isolated by Triozol reagent (Invitrogen).cDNA was synthesized using SuperScript Enzyme Mix (Invitrogen).Real-Time qPCR was performed (according to the manufacturer's instructions) to detect the Mir-192 and Mir- 21 by using SYBR Green Universal Kit (Invitrogen) using forward primers for Mir-21, Mir-192 and universal qPCR primers (Invitrogen).

Renal histology in TG26 mice showed classical HIVN phenotype in the form of collapsing variant of focal segmental glomerulosclerosis and microcystic dilatation of tubules. Moreover, in all Tg26 mice, variable numbers of glomerular and tubular cells showed expression of α-SMA, vimentin, FSP1, and loss of E-Cadherin; whereas, control mice did not show any abnormality. Renal tissue expression of Mir-21 and Mir-192 were decreased in Tg26 (Mir21, 5-fold and Mir 192, 4.5-fold; n=3) vs. control mice(n=3). These results demonstrate that downregulation of Mir-21 and Mir-192 was associated with the induction of EMT, a suggested feature of HIVAN phenotype.

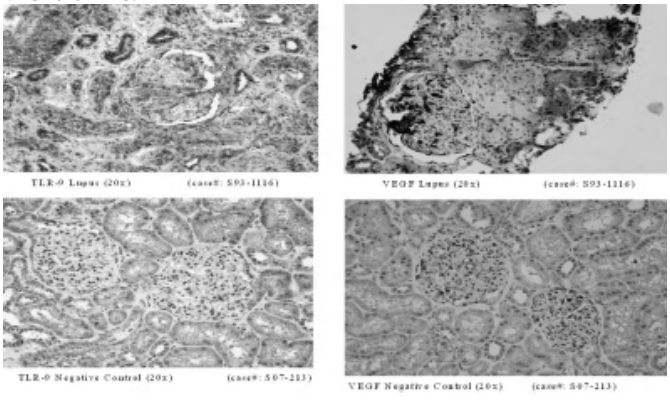
**Role of VEGF and TLR 9 in Lupus Nephritis** Mohammad A. Samih,[1] Sofia Rubinstein,[1] Leah Balsam,[1] Marianne Frieri,[1] Ahmad Aljada,[3] Hui Liu.[2] *[1]Department of Internal Medicine, Nassau University Medical Center, East Meadow, NY; [2]Department of Pathology, Nassau University Medical Center, East Meadow, NY; [3]Department of Biomedical Sciences, School of Health Professions and Nursing Sciences, Long Island University, CW Post C.W. Post Campus, Brookville, NY.*

Introduction: Vascular endothelial growth factor(VEGF) is a key regulator of angiogenesis, binds to receptors on all endothelial cells, including glomerular endothelial cells. TLR9, one of the Toll-like receptor family, implicated in pathogenesis of autoimmunity especially in SLE and the induction of T-helper 1 immune response.

Objective: We compared glomerular and tubulointerstitial expression of both proteins in biopsies from lupus nephritis with normal controls.

Methods: 10 lupus nephritis(LN) kidney biopsies were collected, with 10 normal controls. Immunohistochemistry was performed using the Vectastain Elite ABC kit. Slides were deparaffinized, dehydrated, permeabilized with 0.1% Saponin in PBS, treated with 0.3% hydrogen peroxide and blocked with serum containing PBS and 0.1% Saponin. Slides were incubated with antibodies against VEGF and TLR9 monoclonal antibody, incubated with biotin labeled anti-mouse for 0.5 hour followed by Vectastain ABC solution, incubated with ImmPACT DAB Substrate, stained with hematoxylin and eosin, mounted and microscopically score at 10x and 20x.Clinical renal scoring was also assessed.

Results: VEGF intensity score was greater in the glomeruli vs. the tubules. TLR9 intensity score was greater for renal tubules vs. VEGF. Both stains were negative in the healthy controls. There was no correlation with class severity and intensity of staining of VEGF and TLR9.



Conclusion: This is the first study that examined the combined expression of VEGF and TLR9 in LN in human samples. Both proteins could be a potential future therapeutic target.

**CCR5 Deficiency Aggravates Murine Lupus Nephritis** Jan-Eric Turner,[1] Hans-Joachim Paust,[1] Sabrina Bennstein,[1] Philipp Bramke,[1] Oliver M. Steinmetz,[1] Erik M. Disteldorf,[1] Joachim Velden,[2] Rolf A. Stahl,[1] Ulf Panzer.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Insitut für Pathologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

The recruitment of T cells and monocytes is a characteristic feature of human and experimental lupus nephritis and closely correlated to loss of renal function. The chemokine receptor CCR5 is expressed on monocytes and T cell subsets and is supposed to play an important role in recruiting these leukocytes into inflamed organs.

In this study, we investigated the functional role of CCR5 by using the MRL/MpJ-Faslpr (MRL/lpr) mouse model of systemic lupus erythematosus that resembles the human disease. CCR5-/- mice were backcrossed into the MRL/lpr background for at least seven generations. Analysis of 6-month-old CCR5-/- MRL/lpr mice showed aggravated nephritis with more glomerular tissue damage, increased albumin to creatinine ratio ($20.1 \pm 4.3$ vs. $0.9 \pm 0.43$; $P < 0.01$) and augmented T-cell recruitment ($9.9 \pm 1.4$ vs. $4.7 \pm 0.7$ CD3+ cells / high power field; $P < 0.01$) compared to their wild-type littermates. The relative distribution of IFNγ- and IL-17-producing CD4+ T cells, FoxP3+ regulatory T cells, and IFNγ-producing CD8+ T cells in the kidney and the secondary lymphoid organs of MRL/lpr mice were unaffected by CCR5 deficiency. The mechanism underlying the aggravation of the nephritis in CCR5-/- MRL/lpr mice remains to be elucidated.

**Neutrophils Are an Important Source of IL-17 in Human Inflammatory Diseases** Joachim Velden,[1] Hans-Joachim Paust,[2] Jan-Eric Turner,[2] Oliver M. Steinmetz,[2] Saskia Schröder,[2] Ursula Kneissler,[1] Elion Hoxha,[2] Erik M. Disteldorf,[2] Hans-Willi Mittrücker,[3] Rolf A. Stahl,[2] Udo Helmchen,[1] Ulf Panzer.[2] *[1]Nierenregister, Institut für Pathologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]Institut für Immunologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

BACKGROUND: The pathogenic role of interleukin-17A (IL-17) in autoimmune diseases has been demonstrated in numerous transgenic mouse models. It is further supported by a promising anti-IL-17 approach for the treatment of rheumatoid arthritis in humans. IL-17-driven inflammation has primarily been attributed to the actions of Th17 cells. However, the cellular sources of IL-17 in human tissues remain to be fully elucidated.

PURPOSE: The primary goal of this study was to identify and characterize intrarenal IL-17 containing ($IL\text{-}17^+$) cells in human ANCA-associated glomerulonephritis (ANCA-GN).

METHODS: Human kidney biopsies of ANCA-GN and tissue samples of other inflammatory diseases were analyzed by immunohistochemical and immunofluorescent microscopy co-localization studies. Neutrophils were isolated from healthy human blood and were either analyzed by immunofluorescent microscopy, or stimulated *in vitro* and analyzed by ELISA.

RESULTS: Neutrophils were by far the largest $IL\text{-}17^+$ cell population in acute necrotizing ANCA-GN, in chronic active Crohn's ileocolitis, in psoriasis dermatitis, and in non-autoimmune inflammatory diseases such as infectious tonsillitis. The second most frequent $IL\text{-}17^+$ species were mast cells, whose contribution was increased in chronic as compared to acute ANCA-GN. The amounts of $IL\text{-}17^+$ T cells were negligible throughout in all specimens. All neutrophils from healthy human blood constitutively contained IL-17, which they were able to release upon stimulation *in vitro*.

CONCLUSIONS: Neutrophils are the predominant IL-17-laden effector cells in human ANCA-associated glomerulonephritis, Crohn's disease and psoriasis. The concept of Th17 cells being the main source of IL-17, at least in these human autoimmune diseases, is thus challenged.

**Increased Levels of Anaphylatoxin (C5a) and Bradykinin in End-Stage Renal Disease Patients on Maintenance Hemodialysis** Vinod K. Bansal,[1] Evangelos Litinas,[2] Korosh Sharain,[2] Debra Hoppensteadt,[2] Jawed Fareed.[2] *[1]Department of Nephrology, Loyola University Medical Center, Maywood, IL; [2]Department of Pathology, Loyola University Medical Center, Maywood, IL.*

Besides the upregulation of inflammatory mediators end stage renal disease (ESRD) patients maintained on hemodialysis are subjected to periodic exposure to heparin and contact activation due to procedural settings. Recently the presence of a heparin contaminant, namely hypersulfated chondroitin sulfate was linked with the adverse reactions and deaths observed in these patients (Kishmoto, et al. N J Med 2008). To validate this report we measured both the C5a anaphlatoxin and bradykinin levels in ESRD patients prior and after maintenance hemodialysis. The control group comprised of 40 normal healthy individuals were included to establish the normal level of these mediators. Sandwich Elisa methods utilizing monoclonal antibodies which are specific for either human C5a or bradykinin were used in these studies. Both the C5a and bradykinin were elevated in pre-dialysis samples from ESRD patients (C5a: 3.2±0.6 ng/ml vs 14.2± 4.6 ng/ml, bradykinin: 6.4±1.8ng/ml vs 9.3±2.4ng/ml). Moreover, dialysis itself produced an increase in both the C5a and bradykinin levels. The postdialysis samples were further increased up to 60%, suggesting that dialysis and heparinization itself result in the up regulation of these mediators. Supplementation of heparin to the plasma also resulted in the generation of both C5a and bradykinin. The plasma samples included in these studies represents patients who were not treated with the contaminant heparin. These results suggest that both C5a and bradykinin are up-regulated in ESRD patients and this level can be further augmented by dialysis and heparinization. Therefore, additional factors may have contributed to the complex adverse reaction profiles and deaths in patients administrated with contaminated heparin.

**Penicillin G Reduces Podocyte Injury Induced by Puromycin Aminonucleoside: Role of Transmembrane Transporters** Mary Artero,[1] Cristina Zennaro,[2] Lorella Pascolo,[3] Marco Stebel,[2] Claudio Tiribelli,[2] Maria Pia Rastaldi,[4] Michele Carraro.[2] *[1]Azienda Ospedaliero-Universitaria, Trieste; [2]University of Trieste; [3]Sincrotrone SpA, Trieste; [4]Fondazione Policlinico, Milan, Italy.*

We evaluated the effect of penicillin G, which is a substrate for several families of small organic molecule transporters, on podocyte damage induced by puromycin aminonucleoside (PAN).

Sprague Dawley rats were injected with PAN or normal saline. Two subgroups of PAN rats were treated with penicillin G before PAN injection. After 10 days the rats were killed, and the kidneys were excised to determine filtration characteristics and for histologic and morphometric analysis. Glomerular adhesion and cell viability in podocyte culture were studied using both established lines of differentiated human podocytes and primary culture from isolated rat glomeruli. Transport in live cells was studied using fluorescent penicillin. Expression of podocyte membrane transporter messenger RNA was measured .

PAN treatment resulted in proteinuria and hypoalbuminemia, mitigated in rats pretreated with penicillin G. Kidney:body weight ratio and glomerular hypertrophy were reduced in pretreated animals. Albumin permeability correlated with proteinuria and was comparable to the control group in PAN rats pretreated with penicillin G. Healthy glomeruli pretreated with penicillin G demonstrated permeability characteristics which depended on the doses of both penicillin and PAN. PAN inhibited glomerular adhesion and podocyte outgrowth on collagen IV substrate in a dose-dependent fashion in cell cultures in which penicillin G was removed. Cultures in which penicillin G was not removed showed normal adhesion, according to the dose of the antibiotic. Penicillin G also increased podocyte viability 48 h after PAN exposure. Intracellular fluorescent penicillin was clearly visualized in podocytes after incubation. Podocyte gene expression was detected for OATP and P-glycoprotein transporters and the monoamine transporter PMAT.

Penicillin G reduces podocyte injury induced by PAN in the intact animal and in culture, possibly by blocking membrane transporters, particularly of the OATP family, or an intracellular target.

**Presence of C1q Deposits Is Associated with Better Prognosis in Children with Primary Focal Segmental Glomerulosclerosis (FSGS)** Nataliya Chorny, Morris J. Schoeneman, Anil K. Mongia, Sreevidya Kusuma, Shella Mongia. *Pediatric Nephrology, SUNY Downstate, Brooklyn, NY.*

Primary FSGS is the most common cause of steroid resistant nephrotic syndrome in children. Progression to ESRD (End Stage Renal Disease) is common (>60%), but some patients have prolonged remission with normal renal function. Prognostic indicators of FSGS have not been clearly defined. We performed a retrospective review of 44 children with primary FSGS diagnosed between 1996 -2009. Ages at onset ranged from 2.5 years to 19 years, and mean follow-up period was 6.3 years (1.5 -16) 33 were males and 11 were females. 27 patients were black, 9 Hispanic, 5 Caucasian and 4 other. 14 patients progressed to ESRD over 2 to 8 years. 30 patients (68%) entered prolonged remission, 14 in complete without proteinuria and 17 in partial remission with persistent proteinuria but without nephrotic syndrome. We examined clinical, laboratory and histologic variables at onset, in an attempt to determine prognostic indicators. Our data revealed that 3 variables at onset had a significant impact on prognosis. They were: presence of C1q deposits (p=0.002), GFR at presentation (p=0.002), and percentage of global glomerulosclerosis (p=0.045). Furthermore the patients with C1q deposits needed less immunosuppressive medications to achieve and stay in remission. Serum albumin, Urine PC ratio, Hemoglobin, and Cholesterol were not significantly associated with development of ESRD.

Characteristics of children with remission vs ESRD

| Features at onset | Remission (n=30) | | ESRD (n=14) | | |
|---|---|---|---|---|---|
| | Mean | S.D | Mean | S.D | p-value |
| GFR at presentation | 123 | 38 | 81 | 38 | 0.002 |
| C1q Deposits | N=8 | | 0 | | 0.002 |
| % of Global Glomerulosclerosis | 7.8 | 8 | 26 | 27 | 0.04 |
| Urinary P/C ratio | 4.9 | 6.3 | 8 | 10 | 0.23 |
| Normal blood pressure | n=23 | | n=9 | | 0.21 |

We conclude that presence of C1q deposits is associated with better prognosis and requires lesser immunosupression. This group of patients could represent a different variant of FSGS.These features may assist in guiding the type and intensity of initial immunosuppressive and/or vasoactive therapy.

**The Renoprotective Effect of Podocyte-Targeted HO-1 Expression Is Unsustainable Following Glomerular Immune Injury** Pu Duann,[1] Ling-Mei Chiang,[2] Elias A. Lianos.[1] *[1]Medicine, Robert Wood Johnson Med School, New Brunswick, NJ; [2]Pediatrics, Chang-Gung Memorial Hospital, Keelung, Taiwan.*

Induction of heme oxygenase (HO)-1 is a key defense mechanism against oxidative stress. Compared with tubules, glomeruli are refractory to HO-1 upregulation in response to injury. This can be a disadvantage as it may be associated with insufficient production of cytoprotective heme-degradation metabolites (biliverdin, CO). We, therefore, explored whether targeted HO-1 expression in glomeruli can reduce proteinuria in immune injury induced by an anti-glomerular basement membrane (GBM) antibody (Ab). We employed a 4.125-kb fragment of a mouse nephrin promoter downstream to which a FLAG-tagged human (h)HO-1 cDNA sequence was inserted and generated transgenic mice from the FVB/N parental strain, in which immunolocalization (using anti-FLAG antiboby) of the transprotein (FLAG-hHO-1) in glomerular epithelial cells (GEC) was validated. Urine protein (Up) factored by urine creatinine (Uc) excretion in transgenic (Tg) mice with anti-GBM Ab injury assessed on days 3 and 6 of injury was significantly lower compared with wild-type (Wt) controls. Up/Uc on day 3: Tg 2.62 ±1.41, Wt 5.48 ±2.56, (p=0.02). Day 6: Tg 3.43 ± 1.94, Wt 8.34 ± 4.76. (p= 0.019). This antiproteinuric effect dissipated at later time points. Up/Uc on day 9: Tg 41.51 ± 68.71, Wt 41.60 ± 58.2. Day 12: Tg 67.58 ± 38.71, Wt 71.60 ± 48.9 (p= 0.98). To explore the mechanism of this non-sustainable salutary effect, we explored changes in levels of the FLAG-hHO1 transprotein in the course of immune injury. Western blot analysis of FLAG-hHO1 in protein lysates coupled with densitometry revealed a progressive decrease in transprotein levels. Compared to levels prior anti-GBM treatment, FLAG-hHO1 was reduced to 62% on day 2, 23% on day 3 and became undetectable on days 6, 9 and 12. We conclude that the unsustainable salutary effect of GEC-targeted HO-1 expression is due to degradation of the transprotein, which occurs via an as yet unknown mechanism.

**Glucocorticoid Action in Podocytes Is Modulated by ABCB1 and Can Induce ABCB1 Activity** Tad Eichler,[1] Danica Petrovic-Djergovic,[1] Seetharamaih Chittiprol,[1] Richard F. Ransom.[1,2] *[1]Center for Clinical and Translational Research, The Research Institute at Nationwide Childrens Hospital, Columbus, OH; [2]Pediatrics, The Ohio State University School of Medicine, Columbus, OH.*

The primary treatment for nephrotic syndrome is oral glucocorticoids (GC), and we have previously reported that GCs can both protect from and ameliorate podocyte injury. GC are substrates for the ABC family of multiple drug resistance efflux pumps, primarily ABCB1. We previously found that ABCB1 is expressed in podocytes both *in vitro* and *in vivo*. In order to demonstrate a functional role for ABCB1 in GC action against nephrosis *in vivo*, we induced experimental nephrotic syndrome in rats puromycin aminonucleoside (PAN) injection. Separate groups of rats were injected daily with the ABCB1 inhibitor verapamil (VER), with the synthetic GC, methylprednisolone (MP), or with VER and then MP (VER+MP). Proteinuria was measured in 24 hr urine by the Bradford assay. The amount of protein in 24 h urine was similar in PAN, VER, MP groups at both 10 (372 ± 9 mg/24 h) and 12 days (289 ± 83 mg/24 h) after PAN injection, while proteinuria in VER+MP was dramatically reduced (97 and 44 mg/24 h at 10 and 12 d). The injurious effect of PAN on cultured podocytes was slightly reduced by low doses of either VER or the synthetic GC, dexamethasone (DEX), while a synergistic protective effect was evident in cells treated with VER+DEX. We further hypothesized that GC can increase the expression or activity of podocyte ABCB1, which may be a mechanism of induced steroid resistance in nephrotic syndrome. We found that the both the quantity and activity of ABCB1 protein increased (131% and 157% of controls) in cultured human podocytes increased after DEX treatment. In addition, the mRNA expression of the GC-regulated genes, FKBP5 and TSC22D3, was increased in a dose-dependent manner by DEX, and this induction was significantly greater in podocytes pre-treated with VER. These results suggest a significant role for ABCB1 in both the therapeutic action of GC in nephrotic syndrome and in the development of steroid resistance via enhancement of podocyte ABCB1 activity.

**Focal Segmental Glomerulosclerosis Induced by Lithium Treatment** Vince Faridani,[1,2] Csaba P. Kovesdy.[2,3] *[1]Cariolion Clinic, Roanoke, VA; [2]Salem VA Medical Center, Salem, VA; [3]University of Virginia, Charlottesville, VA.*

Lithium carbonate (Li) is a medication commonly used to treat bipolar affective disorder. The drug is known to produce a number of renal side effects, including nephrogenic diabetes insipidus, chronic interstitial nephropathy, renal tubular acidosis and minimal change disease. We report a rare case of focal segmental glomerulosclerosis (FSGS) in the context of chronic Li use.

We describe a 52 year old male with a history of hypertension and bipolar disorder, who presented with a gradual elevation in his serum creatinine and nephrotic range proteinuria. His medications included clonazepam, diltiazem, lamotrigine, paroxetine, simvastatin and lithium carbonate for the last 15 years. Physical examination was unremarkable. Initial laboratory workup showed serum creatinine 2.0 mg/dl (eGFR 35), blood cholesterol 264, triglycerides 460, HDL 42, LDL 144. Urine analysis showed a specific gravity of 1.004, large blood on dipstick, 30 mg/dl protein, pH of 5.5 and sediment showing 1-3 red blood cells, spot urine protein-creatinine ratio indicated 3 grams of protein/24hrs. Renal ultrasound showed normal sized kidneys and multiple small simple cysts. A kidney biopsy was performed which revealed FSGS and moderate patchy interstitial fibrosis.

FSGS associated with chronic Li exposure has only been described in 3 previous pediatric case reports. In our patient the histological finding of FSGS accompanied by limited foot processes effacement, glomerulomegaly and proteinuria without hypoalbuminemia suggests secondary FSGS, possibly related to Li exposure. It is unclear how lithium could induce FSGS. It has been theorized that lithium could interact with anionic sites of the glomerular capillaries known to limit the passage of molecules and thus cause proteinuria. Cessation of lithium can facilitate the resolution of nephrosis.

**Puromycin Aminonucleoside Increases Podocyte Intercellular Permeability Via Oxidative Stress** Tae-Sun Ha. *Pediatrics, Chungbuk National University, Cheongju, Chungbuk, Korea.*

Puromycin aminonucleoside (PAN)-induced nephrosis is a well-described model of human idiopathic nephrotic syndrome because PAN injection into rats results in increased glomerular permeability with the characteristic ultrastructural changes in glomerular epithelial cells (GEpC; podocytes) similar to human nephrosis. To investigate the role of zonula occludens (ZO)-1 and oxidative stress on PAN-induced podocyte phenotypical changes and hyperpermeability *in vitro*, we cultured rat GEpCs in media containing various concentrations of PAN. Morphological assessment revealed that *in vitro* PAN induced not only the ultrastructural changes of GEpC, such as shortening and fusion of microvilli, but also separation of the intercellular gaps and ZO-1 and polymerization of F-actin resulting in increased intercellular permeability. Oxidative stress level after PAN treatment was markedly higher than that of basal level. PAN induced the inner cytoplasmic translocation of ZO-1 protein and also reduced ZO-1 protein amount and mRNA expression in a dose-dependent manner. These phenotypical changes of podocyte caused by PAN were prevented by the antioxidative effect of vitamin C. Our results demonstrated that the glomerular hyperpermeability caused by intercellular ZO-1 disturbances via oxidative stress would be the mechanism of proteinuria in experimental PAN-induced nephrosis.

**Circulating Galactose-Deficient IgA1 in IgA Nephropathy: Findings from a Large Case-Control Cohort from North China** Ping Hou,[1,3] Krzysztof Kiryluk,[1] Yifu Li,[1] Zina Moldoveanu,[2] Bruce A. Julian,[2] Jan Novak,[2] Ali G. Gharavi,[1] Hong Zhang.[3] *[1]Medicine, Div. of Nephrology, Columbia University, NY; [2]Medicine and Microbiology, University of Alabama at Birmingham, AL; [3]Nephrology, Peking University First Hospital, Beijing, China.*

Gal-deficient IgA1 (Gd-IgA1) is a key pathogenic factor in development of IgA nephropathy (IgAN). The aims of this study were to evaluate levels of circulatory Gd-IgA1 as a predictor of IgAN and examine their clinical correlates.

We measured plasma Gd-IgA1 using HAA lectin-based ELISA in a large case-control cohort from Beijing (496 IgAN cases and 499 healthy controls). We calculated the ROC curve and estimated the sensitivity and specificity of Gd-IgA1 in the diagnosis of IgAN. In addition, we correlated high Gd-IgA1 levels with clinical characteristics of our patients.

Among cases, 52% were males; 89% had microscopic and 28% gross hematuria, 75% had mild (0.3-3 g/24h) and 20% severe (>3 g/day) proteinuria, 49% had hypertension on presentation. Average age was 32.5 years (+/-11.2) and eGFR was 83.5 +/- 33.9 ml/min/1.73 m2 at the time of biopsy. Plasma Gd-IgA1 level was significantly elevated in IgAN patients compared to controls (P=5.0x10-78); this difference was robust to adjustments for age and gender. The area under the ROC curve was 0.85 (95%CI: 0.83-0.88, p =1.9x10-82), with sensitivity and specificity of 74% and 81%, respectively. Among cases, high Gd-IgA1 levels were associated with a greater degree of renal dysfunction, as reflected by a significant inverse correlation of Gd-IgA1 with eGFR at biopsy (r=-0.2, P=9.9 x 10-6). On average, CKD stage IV-V patients had higher plasma Gd-IgA1 compared to patients with CKD stage I-III (P = 5.4 x 10-9). In addition, Gd-IgA1 level positively correlated with systolic BP (r=0.2, p=1.2x10-3) and diastolic BP (r=0.1, p=0.025). In contrast, associations of serum total IgA and IgA1 with either eGFR or BP were not significant. Gd-IgA1 level did not correlate with proteinuria or hematuria.

In summary, this is the largest study to date demonstrating that plasma levels of Gd-IgA1 are important predictors of IgAN and strongly correlate with the degree of renal dysfunction.

**Is Low Birth Weight a Signal for Podocyte Damage and a Risk Factor for Secondary Focal Segmental Glomerulosclerosis?** Yohei Ikezumi,[1] Toshiaki Suzuki,[1] Tamaki Karasawa,[1] Hiroya Hasegawa,[1] Hiroshi Kawachi,[2] Hiroko Nishimura,[3] Makoto Uchiyama.[1] *[1]Department of Pediatrics, Niigata University Medical and Dental Hospital; [2]Department of Cell Biology; [3]Institute of Nephrology, Niigata University Graduate School of Medical and Dental Sciences, Niigata-City, Japan.*

**Background:** Recent studies show an increased incidence of focal segmental glomerulosclerosis (FSGS) and that steroid-sensitive FSGS is often associated with enlarged glomeruli and a reduced number of nephrons. We examined in children whether secondary FSGS also shows these traits and whether low birth weight (LBW) may be a signal/risk factor for early FSGS.

**Materials and Methods:** We examined the birth weight of patients (n = 206) who received renal biopsy in our institute between 1993-2009. Fifteen patients were diagnosed with secondary FSGS, and 5 of these (33.3%, significantly higher than the overall LBW rate in Japan, 9.7%) had a record of LBW. We used PAS and/or PAM-stained paraffin-embedded tissues to quantify the glomerular cells, with separation of cells in the endocapillary, mesangial, and extracapillary (podocyte) areas. Cells were counted in at least six full-shaped glomeruli (visible vascular and urinary poles) without sclerotic lesion. Twelve biopsy specimens from age-matched non-FSGS patients (minimal pathology) with normal birth weight (NBW) were used as control.

**Results:** Glomeruli were significantly larger in LBW-FSGS vs. control (91% larger; $P < 0.001$) or vs. NBW-FSGS patients (75%; $P < 0.001$). The number of mesangial area cells was significantly lower (25%) in LBW-FSGS vs. NBW-FSGS ($P < 0.05$). The number of podocytes was 70% lower in LBW-FSGS vs. controls ($P < 0.001$) and 62% lower vs. NBW-FSGS ($P < 0.001$). NBW-FSGS patients vs. controls also showed 23% fewer podocytes ($P < 0.05$).

**Conclusion:** These results show that 1) LBW may correlate with development of early FSGS; and 2) in LBW-FSGS kidneys, there were fewer podocytes whereas the glomeruli were enlarged, suggesting that LBW (and prematurity) may predispose children to podocyte loss and to secondary FSGS. LBW may be deemed a risk factor and a means of its early discovery. (Supported by JSPS KAKENHI 22591177 and 21390307)

**Glomerular Volume and Mesangial C4d Deposition on IgA Nephropathy: Markers of Higher Risk of Progression to Renal Failure** Monica X. Inofuentes, Bernardo Moguel, Virgilia Soto, Maria Carmen Avila-Casado. *Nephropathology, Instituto Nacional de Cardiologia, Mexico City, Mexico.*

IgA nephropathy (IgAN) is the most frequent glomerulopathy worldwide has a wide spectrum of clinical presentation, and a similarly range of hystopathological findings.

Several previous studies had identified clinical and/or histopathological prognostic factors in IgAN, but the significance of these factors still controversial.

**AIMS.**

The aim of this study was to identify histopathological indicators of progression to ESRD, by means mesangial C4d deposition and glomerular volume (GV).

**METHODS.**

This retrospective cohort study included patients with IgAN who underwent renal biopsy at our center from January 2004 to December 2007. C4d was marked by immunohistochemistry in paraffin embedded tissue, then cut off into 3- to 4μm sections; and stained with PAS. Evaluation of glomerular volume were done with digital video camera coll-Snap with image analyzer Vx51

**RESULTS.**

Thirteen consecutive renal biopsies from clinical diagnosis of haematuria/proteinuria (mean age 38 ±10: male 69%/ female 31%) were included; 70% had mesangial C4d positive. Mean GV was $8.86\mu m^3 x 10^6 \pm 4\ \mu m^3$. .C4d positive, were associated with an increased in serum uric acid *(p=0.02)*, systolic blood pressure (*p=0.001)* and proteinuria (*p=0.04)* the group with an increased GV (47%) were associated with systolic hypertension (*p=0.05)*, hyperuricemia (*p=0.003) and* increased in serum creatinine (*p=0.03)*.

**CONCLUSION.**

C4d positive and increased GV are associated with progression of renal damage in IgAN. Such factors could be relevant in naturally occurring in IgAN.

**Expression of Phosphorylated (p) PKCε in Experimental Crescentic Glomerulonephritis (CGN)** Vassiliki N. Karavana,[1] Elias A. Lianos.[1,2] *[1]Medicine and Thorax Foundation, University of Athens, Athens, Greece; [2]Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ.*

PKCε, a DAG-dependent, $Ca^{2+}$- independent kinase attenuates extent of fibrosis following tissue injury, suppresses apoptosis and promotes cell quiescence. In CGN, glomerular epithelial cells (GEC) contribute to fibro-cellular crescent formation while they also transdifferentiate to a mesenchymal phenotype. To explore whether activated PKCε is expressed in these lesions, we employed a rat model of CGN. Administration of rabbit antibody against rat glomerular basement membrane (anti-GBM) in rats pre-immunized with rabbit Ig resulted in extensive CGN by day 10-12 and heavy proteinuria. Controls included animals that received: a) no anti-GBM Ab, and b) Puromycin Aminonucleoside (PAN) (15mg/100g) to cause non-immune GEC injury associated with comparable degree of proteinuria. Phosphorylation at $Ser^{729}$ of PKCε is critical for kinase activation and cellular compartmentalization. Using an antibody against PKCε phosphorylated (p) at $Ser^{729}$, we assessed immunolocalization of the kinase on days 10-12 of CGN. In glomeruli of control animals, pPKCε was undetectable. In glomeruli of animals with CGN, pPKCε was expressed exclusively in GEC. Marked pPKCε expression was also present in cells comprising fibrocellular crescents, which had acquired a mesenchymal phenotype (negative for GEC markers, positive for α-smooth muscle actin). In renal tubules, identified using lectin staining, there was weak to absent pPKCε expression in proximal tubular cells. In contrast, there was strong expression in distal convoluted tubules and in medulary and cortical collecting tubules. These were surrounded by inflammatory infiltrates and fibrosis. pPKCε localization in glomeruli following PAN was non specific. We conclude that pPKCε expression in GEC and crescentic lesions is specific for immune-mediated injury and may provide a defense mechanism against progression.

**Novel Expression of Claudin-5 in Glomerular Podocytes** Ryo Koda,[1,2] Linning Zhao,[1] Eishin Yaoita,[1] Yutaka Yoshida,[1] Sachiko Tsukita,[3] Atsushi Tamura,[3] Masaaki Nameta,[4] Ichiei Narita,[2] Tadashi Yamamoto.[1] *[1]Department of Structural Pathology, Institute of Nephrology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [3]Laboratory of Biological Science, Graduate School of Frontier Biosciences and Graduate School of Medicine, Osaka University, Osaka, Japan; [4]Cooperative Laboratory of Electron Microscopy, Niigata University, Niigata, Japan.*

Tight junctions are the main intercellular junctions of podocytes of the renal glomerulus under nephrotic conditions. Their requisite components, claudins, still remain to be clarified. We have measured the mRNA levels of claudin subtypes by quantitative RT-PCR using rat isolated glomeruli. Claudin-5 was found to be expressed most abundantly in glomeruli. Mass spectrometric analysis of membrane fractions from isolated glomeruli also confirmed only a predominant expression of claudin-5 without any detection of other claudin subtypes. In situ hybridization and immunolocalization studies revealed that claudin-5 was localized mainly in glomeruli where podocytes were the only cells expressing claudin-5. Claudin-5 protein was observed on the entire surface of podocytes including apical and basal domains of the plasma membrane in the normal condition, and was inclined to be concentrated on tight junctions in puromycin aminonucleoside nephrosis. Total protein levels of claudin-5 protein in isolated glomeruli were not significantly upregulated in the nephrosis. These findings suggest that claudin-5 is a main claudin expressed in podocytes and that the formation of tight junctions in the nephrosis may be due to local recruitment of claudin-5 rather than due to total upregulation of the claudin protein levels.

**Molecular Mechanism for Angiotensin II Induced Proteinuria** Eva Koenigshausen, Magdalena Woznowski, Ivo Quack, Sebastian A. Potthoff, Lars C. Rump, Lorenz Sellin. *Department of Nephrology, Heinrich Heine University, University Hospital, Duesseldorf, Germany.*

**Introduction**

Microalbuminuria serves as an early marker for glomerular injury in hypertensive and diabetic patients. Inhibitors of the renin-angiotensin-aldosterone system but not calcium channel blockers reduce albuminuria in these patients. Albuminuria results from a defect in the glomerular filter that is composed of endothelium, basal membrane and podocytes with slit diaphragms. A major component of the glomerular slit diaphragm is nephrin, that is endocytosed upon bindung to the adaptor protein β-arrestin2.

**Methods**

Cells expressing the AT1-receptor or its mutant D125AR126L, nephrin and β-arrestin2 were stimulated with Angiotensin II (Ang II). After cell lysis, co-immunoprecipitation with subsequent westernblot analysis was performed. For the inhibitor studies, cells were pretreated with the AT1-inhibitors 60 min before stimulation with Ang II. The effect of Ang II on the β-arrestin2 binding motif was studied by using two nephrin mutants. For the endocytosis assay, cells were stimulated with Ang II and incubated with biotin before cell lysis.

**Results**

Ang II stimulation increases the protein interaction between nephrin and β-arrestin2. This Ang II effect is dependent on the AT1-receptor and can be inhibited by AT1-receptor blockers. The G-protein signalling is essential for the Ang II effect, as the AT1-receptor mutant D125AR126L abolishes all G-protein signalling and inhibits the Ang II mediated increase of the nephrin β-arrestin2 interaction. Phosphorylation of T1120 and T1125 of the nephrin C-terminus is essential for the binding of β-arrestin2 even after stimulation with Ang II. Stimulation with Ang II increases endocytosis of nephrin.

**Conclusion**

Ang II weakens the integrity of the slit diaphragm through increase of nephrin endocytosis and is perceived to promote proteinuria. This previously unknown molecular effect of Ang II could help to understand the molecular mechanisms of Ang II induced proteinuria beyond hemodynamic effects.

**Angiotensinogen Copies Have Inverse Relationship with Podocyte Nephrin Expression** Dileep Kumar, Hersh Goel, Divya Salhan, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Long Island Jewish Medical Center, New Hyde Park, NY.*

Nephrin is reported to be an important constituent of slit diaphragm. It is widely believed that slit diaphragm acts as a glomerular filtration barrier for the filtration of mid and large molecular proteins. Loss of nephrin has been reported to contribute to the development of glomerular proteinuria in several models of chronic kidney diseases. We have previously demonstrated that chronic Ang II infusion in rats attenuated nephrin expression by podocytes (Am J Nephrol 28:500-507, 2008). Moreover, Ang II in *in vitro* studies promoted podocyte apoptosis (Am J Physiol 283:F173-80, 2002). In the present study we evaluated the effect of angiotensinogen (*Agt)* copies on podocyte expression of nephrin and associated renal injury.

Four months old FVBN mice with variable copies of *Agt* (*Agt*-2, *Agt*-3, *Agt*-4) were evaluated for their blood pressure levels, degree of proteinuria, blood urea nitrogen, serum Ang II levels. Kidneys were harvested and prepared for renal histology and immunohistochemical studies for nephrin expression, apoptosis and oxidative stress.

*Agt*-4 mice showed higher (P<0.01) levels of blood pressure when compared with *Agt*-2 mice. *Agt*-4 mice also showed an increase mean urinary protein-creatinine ratio when compared to *Agt*-2 mice. *Agt*-4 mice showed segmental glomerulosclerosis (15 ± 2.5% glomeruli) and tubulointerstitial fibrosis; whereas, *Agt*-2 mice did not show any overt renal lesions. *Agt*-4 mice showed enhanced renal tissue expression of oxidative stress and increased number of apoptotic cells when compared with *Agt*-2 mice. Interestingly, *Agt*-4 mice showed attenuated glomerular expression of nephrin when compared with *Agt*-2 mice. Mice with 3 *Agt* copies showed only mild attenuation of glomerular expression of nephrin. These studies suggest that higher *Agt* copies are associated with proteinuria and development of sclerosis by attenuating nephrin expression.

**Glomerulotubular Interaction in IgA Nephropathy Induces Apoptosis of Tubular Epithelial Cells: Role of Crosstalk between Angiotensin II and Aldosterone** Joseph C. K. Leung, Loretta Y. Y. Chan, Sydney C. W. Tang, Kar Neng Lai. *Department of Medicine, The University of Hong Kong, Pokfulam, Hong Kong.*

Glomerulotubular crosstalk network is pivotal in inducing tubulointerstitial damage in IgA nephropathy (IgAN). We had previously shown that polymeric IgA1 (pIgA1) from IgAN patients activated the renin-angiotensin system (RAS) in mesangial cells and up-regulated the inflammatory cascade in proximal tubular epithelial cells (PTEC). We further examined the role of aldosterone (Aldo) in tubular injury.

PTEC expresses only the mineralocorticoid receptor (MR), but not 11beta-hydroxysteroid dehydrogenase type II or aldosterone synthesis, suggesting the lack of aldosterone synthesis by PTEC. Apoptosis, measured by cleaved PARP expression and caspase 3 activity, was induced in PTEC activated by conditioned medium prepared from mesangial cells (HMC) cultured with pIgA1 from IgAN patients (n=35) but not from normal subjects (n=32). Exogenous angiotensin II (AngII) and Aldo, but not purified pIgA1 protein, induced PTEC apoptosis in dose- and time-dependent manner. Significant increased expression of NADPH oxidase and intracellular reactive oxidative species (ROS) formation were also detected in PTEC cultured with AngII, Aldo or conditioned media prepared from IgAN patients. Pre-incubation of PTEC with AngII receptor subtype-II (AT2R) antagonist (PD123319) or MR antagonist (eplerenone), but not AT1R antagonist (losartan), partially suppressed the pIgA1-conditioned media induced ROS generation (25%) and apoptotic events (< 35%). Combined blockade with PD123319 and eplerenone achieved more than 95% inhibition of ROS generation and apoptosis. Interestingly, AngII and pIgA1 conditioned media, but not Aldo, up-regulated the expression of AT2R and MR in PTEC. Pre-incubated PTEC with PD123319, but not losartan or eplerone, abrogated these up-regulated AT2R and MR expression.

In conclusion, our in vitro data suggest that AngII and aldosterone, released by pIgA1 activated HMC, served as the mediators for glomerulotubular crosstalk in inducing apoptosis of PTEC through generation of ROS species. In addition, crosstalk between AngII and aldosterone could play a role in pIgA1 induced PTEC apoptosis.

**Ethanol Alters Expression of Cytochrome P450 (CYP) Isoforms in Podocytes** Ellen T. McCarthy,[1] Jianping Zhou,[2] Shuhua Wang,[1] Ryan Eckert,[1] Tarak Srivastava,[3] Ram Sharma,[2] Virginia J. Savin,[2] Mukut Sharma.[2] *[1]Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [2]Kansas City VA Medical Center, Kansas City, MO; [3]Childrens Mercy Hospital, Kansas City, MO.*

Ethanol intake is associated with salutary effects on cardiovascular function as well as hypertension in larger doses. Likewise, 20-hydroxyeicosatetraenoic acid (20-HETE) has both anti- and pro-hypertensive effects. The effect of ethanol on podocyte expression of the CYP isoforms that make 20-HETE has not been described. We incubated immortalized podocytes with ethanol (1, 2, 5, 10 or 20 µl/ml) for 1, 8 or 24 hrs. We then examined expression of CYP4a12a, CYP4a12b and CYP4f13 using quantitative RT-PCR. Results were expresses as fold change over appropriate time controls. In preliminary studies we examined the effect of ethanol on podocyte cytoskeleton using fluorescence microscopy following actin staining. Ethanol (2, 5, 10 and 20 µl/ml) significantly increased expression of CYP4a12a in podocytes at 8 hr ($P$<0.05 vs control). The highest concentration of ethanol (20 µl/ml) caused a significant decrease in expression of CYP4a12a at 24 hr ($P$<0.02 vs control). Expression returned to baseline values by 24 hr at other concentrations. A similar pattern was seen in expression of CYP4a12b in podocytes, namely increased expression at 8 hr (5 and 10 µl/ml, $P$<0.01 vs control) and suppression by 20 µl/ml at 24 hr ($P$<0.001 vs control). Ethanol (20 µl/ml) increased expression of CYP4f13 in podocytes with a 2-fold increase being seen at 24 hr, though this did not reach statistical significance. Fluorescence microscopy showed marked derangement of the actin cytoskeleton after ethanol treatment (10 and 20 µl/ml) for 24 hr. In summary, we have shown that ethanol in meaningful concentrations induces podocyte expression of CYP450 isoforms capable of 20-HETE synthesis, namely CYP4a and 4f. We hypothesize that ethanol alters eicosanoid metabolism in glomerular cells, and that this effect varies with levels of ethanol exposure. The long-term effects of chronic ethanol exposure on podocytes is unknown. The effect of ethanol on eicosanoid metabolism in renal cells may in part explain the cardiovascular impact seen in humans.

**The Cytoskeleton and Mechancial Properteis of Renal Glomerular Capillaries and Glomeruli** R. Tyler Miller,[1] Joel M. Henderson,[2] Leslie A. Bruggeman,[1] Jung Hee Suh,[4] Jeffrey H. Miner,[4] John R. Sedor,[1] Martin R. Pollak.[3] *[1]Medicine, CWRU/Metrohealth, Cleveland, OH; [2]Pathology, BU, Boston, MA; [3]Nephrology, Harvard/BIDMC, Boston, MA; [4]Medicine, Washinton Univ., St. Louis, MO.*

The mechanical properties of tissues and cells are important determinants of their differentiated state, function, and responses to injury, but are not well characterized or understood. Renal glomeruli in particular, primarily the capillary walls, are exposed to significant hemodynamic forces and must have mechanical properties that permit them to withstand and accommodate these forces. Understanding their mechanics is an important step towards understanding renal diseases characterized by abnormal expression or assembly of structural proteins and abnormal hemodynamics. We use atomic force microscopy (AFM) to measure the elastic properties of rat glomerular capillaries, and a newly developed technique, capillary micromechanics, to measure the elastic properties of whole glomeruli. The baseline Young's moduli of the capillary walls and intact glomeruli were approximately 2,500 Pa. Treatment with the actin-depolymerizing agents Cytochalasin D and Latrunculin B reduced the elastic moduli of capillaries and whole glomeruli by approximately 50%. Inhibition of non-smooth muscle myosin activcity reduced the elastic moduli by approximately 35%. Cytochalasin D and Latrunculin B reduced the G/F actin ratios of glomeruli, but did not disrupt their architecture. AFM studies of glomeruli from HIVAN and Col4a3-/- mice reveal that these glomeruli are significanly softer than controls at a time when pathology by light microscopy is minimal. Glomeruli have tightly controlled mechanical properties, those properties are dependent on the state of the actin cytoskeleton and non-muscle myosins, glomerular capillaries contribute significantly to the mechanical properties of whole glomerluli, and abnormal mechanical properteis of glomeruli may contibute to glomerular disease.

**Novel Polarity Complex in Podocytes: Crumbs Homolog 2 and Its Interaction Partners** Masatoshi Nukui, Karl Tryggvason, Jaakko Patrakka. *Department of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden.*

Podocytes, glomerular visceral epithelial cells, are located on the outer part of the glomerular basement membrane found facing to the urinary space. They are highly polarized cells having extremely unique trait to maintain both a dynamic cell shape. Recent studies verify that conserved polarity protein complexes are fundamental regulators for podocyte morphology. These protein complexes include the Crumbs complex and the partitioning defective (PAR) complex.

Drosophila Crb is involved in the control of cell-cell adhesion and epithelial cell polarity. Crumbs homolog 2 (Crb2) is one of the three mammalian homologues of Drosophila Crb, and is a large transmembrane protein, whose function has been unknown. We confirmed that Crb2 is expressed mainly in the kidney and the brain by RT-PCR, and co-localizes with nephrin in podocyte foot processes by immunohistochemistry.

To investigate the function of Crb2, we started to look for interaction candidates of Crb2 by Y2H experiment using the intracellular part of Crb2 as a bait, and we found that Mmp5, Par6 and Lnx2 may interact with Crb2. Human kidney sections were stained with antibodies directed against these proteins, and the results confirmed that three candidates were present in podocyte foot processes. To confirm the interaction of Crb2, co-immunoprecipitation experiment was conducted. For further investigation, pull down experiment, using GST-Crb2 protein, accompanied with mass spectrometry analysis will be performed. Our result provides a new insight into protein complexes in podocyte, and shed new light on podocyte biology.

**Immunomodulation of Experimental Nephrotic Syndrome Induced by PAN in Rats** Danica Petrovic-Djergovic,[1] Seetharamaih Chittiprol,[1] Richard F. Ransom.[1,2] *[1]Center for Clinical and Translational Research, The Research Institute at Nationwide Childrens Hospital, Columbus, OH; [2]Pediatrics, The Ohio State University School of Medicine, Columbus, OH.*

A variety of experimental evidence supports the association of minimal change nephrotic syndrome (MCNS) with atopy and a Th2 cytokine bias. The puromycin aminonucleoside (PAN) model of experimental MCNS in rats is thought to exert direct toxic effects on glomerular podocytes, though the responsiveness of the PAN model to glucocorticoid therapy suggests there may be an unappreciated immune contribution. We therefore measured cytokines in rats in order to examine a potential immunological contribution to the proteinuria induced by PAN. Blood was withdrawn from rats 10 days after PAN injection, and total protein was measured in 24 h urine collections. Cytokine levels were measure using a custom 14-plex Luminex xMAP assay (Millipore MAP Cytokine Panel) both in plasma and in supernatants of 2 d cultures of isolated peripheral blood mononuclear cells (PBMC) treated with LPS, PMA+ionomycin, or without stimulation. Consistent with an association between proteinuria and Th2 cytokines, the plasma concentration of IL-4 and IL-13 were greater at 10 days post-injection in PAN-treated rats than in controls (123 ± 46 vs. 51 ± 10 pg IL-4/ml and 244 ± 42 vs. 125 ± 34 pg IL-13/ml). However, the plasma concentration of interferon-γ, a Th1 cytokine, was also greater in PAN-treated rats than controls (292 ± 52 vs. 17 ± 12 pg IFNγ/ml). The mean plasma concentration of CCL5 (RANTES) was lower in PAN-treated animals than controls (14,500 ± 1830 vs. 25,600 ± 7260 pg CCL5/ml), while plasma concentrations of other cytokines were not significantly different. Surprisingly, less IL-4, IL-13, and IFNγ were released by un- and stimulated PBMC isolated from PAN-treated rats than from controls. In summary, these results suggest that the nephrosis induced in rats by PAN injection may have a previously-unappreciated immune component, though the decreased capacity of PBMC from PAN rats to release cytokines suggests an alternate source, possibly the kidney, for effector cytokines.

**Are Circulating Fibrocytes an Indicator of Disease Severity in Proliferative Glomerulonephritis?** Christine M. Ribic, Limin Liu, Catherine M. Clase, Peter Margetts. *Division of Nephrology, McMaster University, Hamilton, ON, Canada.*

**Background:** Proliferative glomerulonephritis (GN) can be complicated by progression to end stage renal disease associated with interstitial fibrosis. Recent studies have postulated that circulating bone marrow derived progenitor cells called fibrocytes are recruited to injured tissue and contribute to fibrinogenesis. We aimed to quantify circulating fibrocytes in patients with newly diagnosed proliferative GN, and to examine fibrocytes as a biomarker of disease activity and prognosis. **Methods:** We recruited 11 patients in a single centre with proliferative GN undergoing renal biopsy and 6 volunteer healthy controls. Fibrocytes were defined as cells positive for CD45 and collagen-1 by flow cytometry and were quantified in enrolled patients and controls. The samples were run in replicates and the results with the most consistent control IgG staining were used. **Results:** Of the enrolled patients, 3 were women, mean age 58 (standard deviation [SD] 19) years; 8 had anti-neutrophil cytoplasmic antibody positive vasculitis, 1 had lupus, 1 had IgA nephropathy and 1 had immune-complex mediated GN. Renal biopsy confirmed proliferative GN in all cases. Median serum creatinine was 478 (SD 334) mmol/L. Fibrocytes were 4.9% of peripheral white cells in cases and 1.9% in controls (P = 0.36); absolute fibrocyte concentrations were 0.72 $x10^9$ cells/L in cases and 0.14 $x10^9$ cells/L in controls (P = 0.15). There was a significant association between serum creatinine and fibrocyte concentration (P = 0.03). There was also a significant correlation between follow-up serum creatinine and biopsy interstitial fibrosis score (P= 0.02). **Conclusion:** Our preliminary data show a 3-fold increase in circulating fibrocytes in patients with active proliferative GN compared with controls, and an association between fibrocytes and creatinine, that did reach statistical significance. Further work is needed to determine whether these suggestive findings indicate fibrocyte tissue injury and to develop the quanitification of fibrocytes as a biomarker for disease activity in active proliferative GN.

**Functional Consequences of NO Depletion on Glomerular Soluble Guanylyl Cyclase (sGC) and Protein Permeability** Mukut Sharma,[1] Ram Sharma,[1] Ellen T. McCarthy,[2] Virginia J. Savin,[1] Elias A. Lianos.[3] *[1]Nephrology Research, MBRF, KC VA Medical Center, Kansas City, MO; [2]Kidney Institute, KU Medical Center, Kansas City, KS; [3]Nephrology, UMDNJ-RWJMS, New Brunswick, NJ.*

In Chronic Kidney disease (CKD) circulating levels of asymmetric dimethylarginine (ADMA), a potent Nitric Oxide Synthase (NOS) inhibitor, increase. We have demonstrated that ADMA injures glomerular filtration barrier (GFB) by NO depletion thereby increasing superoxide ($O_2^{\cdot -}$) and decreasing cGMP. Further, GFB is protected by NO and cGMP, the ligand and product of sGC activation, respectively [KI 2005; AJP 2009]. NO-mediated activation of sGC requires reduced sGC heme iron ($Fe^{+2}$). However, NO depletion may affect GFB through additional mechanism(s). Presently we studied changes in albumin permeability ($P_{alb}$) in isolated rat glomeruli to determine whether ADMA injures GFB by altering the redox state of sGC heme iron. Glomeruli were incubated for 15 min at 37°C with ADMA at concentrations found in CKD patients, 2) ODQ, a potent oxidizer of NO-sensitive sGC heme iron, 3) a combination of ADMA (5μM) and ODQ (5μM). Results (Table 1), show that ADMA+ODQ had an additive effect on $P_{alb}$. HMR-1766 (1-10μM), an NO- and heme-independent sGC activator that stimulates sGC only when sGC heme-iron is oxidized, dose-dependently reversed the effect of ADMA+ODQ on $P_{alb}$. ADMA-induced increase in $P_{alb}$ was reversible by DETA-NONOate (NO donor), Tempol ($O_2^{\cdot -}$scavenger) and by 8-Br-cGMP (data not shown). Table 1.

| Group (n=15 each) | $P_{alb}$±SEM | Significance*P*value |
|---|---|---|
| Control | 0.005±0.09 | |
| ADMA 5μM | 0.65±0.05 | 0.001*vs.*Control |
| ODQ 5μM | 0.5±0.1 | 0.001*vs.*Control |
| ADMA 5μM+ODQ 5μM | 0.81±0.075 | 0.001*vs.*Control |
| ADMA 5μM+ODQ 5μM+HMR 1μM | 0.70±0.098 | |
| ADMA 5μM+ODQ 5μM+HMR 5μM | 0.51±0.056 | 0.001*vs.*ADMA+ODQ |
| ADMA 5μM+ODQ 5μM+HMR 10μM | 0.14±0.087 | 0.001*vs.*ADMA+ODQ |

We conclude that ADMA increases $P_{alb}$ by causing NO depletion. sGC heme iron oxidation, owing to the consequent $O_2^{\cdot -}$ excess, only partially accounts for this increase.

Disclosure of Financial Relationships: nothing to disclose

**Glomerular Protective 8,9-Epoxyeicosatrienoic Acid (8,9-EET) Is Not Metabolized by Soluble Epoxide Hydrolase (sEH) in Mouse Podocytes** Mukut Sharma,[1,3] Jianping Zhou,[1] Ram Sharma,[1,3] Virginia J. Savin,[1,3] Tarak Srivastava,[2] Ellen T. McCarthy.[3] *[1]Nephrology Research, KC VA Medical Center, Kansas City, MO; [2]Nephrology, Children's Mercy Hospital UMKC, Kansas City, MO; [3]Kidney Institute, KU Medical Center, Kansas City, KS.*

Preservation of podocyte structure and function in the glomerular filtration barrier is critical for the treatment and prevention of proteinuria. Four EET regioisomers namely, 5,6-, 8,9-, 11,12- and 14-15-EET, mediate several biological processes in an autocrine/paracrine manner. We have recently discovered a unique protective effect of 8,9-EET in the glomerular filtration barrier. Since EETs are readily metabolized to biologically active dihydroxyeicosatrienoic acids (DiHETrE) by soluble epoxide hydrolase (sEH), it is not clear whether 8,9-EET or its vicinal diol 8,9-DiHETrE is responsible for the observed glomerular protection. We compared the effect of 8,9-EET (100 nM) and 8,9-DiHETrE (50-200nM) on glomerular albumin permeability *in vitro* ($P_{alb}$). We used the circulating permeability factor (FSPF) in FSGS patient plasma (20μL) to cause glomerular injury indicated by increased $P_{alb}$. Summary of Results (Table 1) shows that only 8,9-EET protected against FSPF.

| Table 1: Group | $P_{alb}$ ±SEM (n=15 each) | *P* value |
|---|---|---|
| Control | 0.005±0.07 | |
| 8,9-EET 100nM | -0.24±0.12 | |
| 8,9-HETrE 100nM | 0.12±0.079 | |
| FSGS | 0.75±0.08 | 0.001*vs.* Control |
| 8,9-EET 100 nM+FSGS | 0.06±0.11 | 0.001*vs.* FSGS |
| 8,9-HETrE 200nM+FSGS | 0.5±0.07 | 0.1 *vs.* FSGS |

We next examined the expression of sEH protein in differentiated mouse podocytes and isolated rat glomeruli using immunoblotting. When compared with the renal cortex, both podocytes and glomeruli showed negligible expression of sEH. Metabolism of 8,9-EET in glomeruli and podocytes appears to be different from that in tubules and the interstitium. We conclude that the glomerular protective effect of 8,9-EET is not due to 8,9-DiHETrE and that sEH is unlikely to contribute significantly to 8,9-EET metabolism in podocytes.

**Coordinated Loss of Neuroglobin, Synaptopodin, and Nephrin in VHL-Deficient Podocytes** Brooke M. Steenhard, Kathryn S. Isom, Larysa Stroganova, Adrian T. Zelenchuk, Patricia St. John, Dale R. Abrahamson. *Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS.*

Neuroglobin (Ngb) is an ancient heme protein thought to bind or transport oxygen and/or reactive oxygen species. Discovered in brain, the function of Ngb is unclear, but a Ngb overexpressing transgenic mouse is protected from ischemia-induced injury to brain and heart. Ngb is expressed at either extremely low levels or absent in normal kidney. In isolated glomeruli from mice with a conditional deletion of von Hippel Lindau (VHL) in podocytes (Pod-Cre fVHL), Ngb is massively upregulated at both mRNA and protein levels. Glomeruli from Pod-Cre fVHL and wildtype littermates were isolated and assayed for other globin changes using quantitative real time RT-PCR. Compared to wildtype, cytoglobin (Cygb) mRNA levels are unchanged, but there is a small but significant decrease in alpha (Hba-a1) and beta (Hbb-b1) chains of hemoglobin in Pod-Cre fVHL glomeruli. Globin profiling was repeated in glomeruli from Alport mice lacking *Col4a3*, a component of the mature glomerular basement membrane. In contrast to Pod-Cre fVHL, there are no changes in Cygb, or Hbb-b1 in 4 week old Alport glomeruli, and Ngb is not upregulated (and only barely detectable). Ngb protein in Pod-Cre fVHL glomeruli is podocyte-restricted and overlaps with anti-synaptopodin and anti-nephrin labeling. Unlike Alport, where all glomeruli undergo rapid and diffuse fibrosis, kidneys from proteinuric Pod-Cre fVHL mice stained with Periodic acid-Schiff reveal a range of glomerular histology. Some glomeruli appear almost normal, with intense podocyte immunolabeling for Ngb, synaptopodin, and nephrin. Other glomeruli had degrees of fibrosis, with PAS-positive matrix in part or all of the glomerulus. Weak labeling for Ngb, synaptopodin and nephrin labeling are seen in less fibrotic regions, but all three markers are lost in areas of severe sclerosis. Our results suggest a possible reno-protective role for Ngb within Pod-Cre fVHL kidney.

**PUB614**

**Endoplasmic Reticulum (ER) Stress Precedes Podocyte Apoptosis at the Onset of Proteinuria in the db/db Mouse Model of Diabetic Nephropathy (DN)** Jianling Tao, Jie Ma, Hong Zhang, Jin Hong Li, Yubing Wen, Hang Li, Xuemei Li, Xue-Wang Li. *Division of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences.*

Objective: Podocyte apoptosis was indicated as an early phenomenon of DN. ER stress induced podocyte apoptosis contributes to proteinuria in some animal models of podocyte injury. We hypothesized in db/db mouse model of DN, ER stress is involved in podocyte apoptosis coincidently with the onset of proteinuria.

Methods: Six, nine, twelve-week-old male C57BLKS/J db/db mice (n=7) and age-matched db/m control mice (n=5) were studied. Twenty-four hour urine protein output (24UP), blood free fatty acid(FFA), HbA1c, and fast blood glucose(FBG) were measured. The ratio of the mesangial area to glomerular area (M/G) was calculated. The glomerular apoptosis was assayed by TUNEL. The intensity of Glucose-regulated protein 78(GRP78) was co-localized with synaptopodin by immunofluorescence stain. Indicators of ER-associated apoptosis GRP78, C/EBP homologous protein (CHOP), Bcl-2 and Bax of renal cortical tissues were assayed by WB.

Results: The body weight, 24UP, blood FFA, HbA1c, and FBG of db/db mice were significantly higher than each age matched control($p<0.05$). The kidney weight was significantly higher in 12w db/db mice compared with 12w db/m mice. 24UP was significantly higher in 9w and 12w db/db mice compared with that of 6w db/db mice ($p<0.05$). M/G in 9w db/db mice was significantly higher than that of 9w db/m mice ($p<0.05$). There were no significant changes of M/G among three control groups. There were no significant changes in glomerular apoptosis detected either among three db/m or db/db mice groups or between db/m and db/db mice($p>0.05$). But confocal microscopy showed steadly increased expression of GRP78 in podocytes only in db/db mice with age increase. There were no significant changes of GRP78, CHOP, Bax and Bcl-2 protein in renal cortical tissues either between db/db with db/m groups or among db/db or db/m mice groups.

Conclusions: ER stress precedes podocyte apoptosis at the onset of proteinuria in db/db mouse model of DN.

**Involvement of Endoplasmic Reticulum (ER) Stress in Podocyte Apoptosis Induced by Saturated Fatty Acid Palmitate** Jianling Tao,[1] Xiong Zhong Ruan,[2] Hang Li,[1] Yubing Wen,[1] Xuemei Li,[1] Xue-Wang Li.[1] *[1]Division of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China; [2]Centre for Nephrology, University College London Medical School, London, United Kingdom.*

Objective: Podocyte apoptosis was recently indicated as an early phenomenon of diabetic nephropathy.Pancreatic β-cells exposed to saturated free fatty acid paimitate undergo irreversible ER stress and consequent apoptosis, involving in the pathogenesis of insulin resistance. We hypothesized palmitate could induce podocyte apoptosis via ER stress.

Methods: Podocyte apoptosis was determined by DAPI stained apoptotic cell counting and TUNEL stain.The expressions of indicators of ER molecule chaperone and ER-associated apoptosis Glucose-regulated protein 78(GRP78),C/EBP homologous protein (CHOP),Bcl-2 and Bax were assayed by Western Blot and Real-time PCR.GRP78 and synaptopodin were co-localized by immunofluorescence stain.

Results: Palmitate significantly increased cultured murine podocytes TUNEL-positive cells and apoptotic cell percentage time-dependently when loading 0.5 mM (10h, 13h, and 15h compared with 0h, $p<0.05$) and dose-dependently when loading 0.25mM, 0.5 mM, 0.75 mM,and 1 mM of palmitate for 15h (compared with control, $p<0.05$). Palmitate time-dependently and dose-dependently increased the protein expression of GRP78,CHOP and BAX and decreased that of Bcl-2. Palmitate ranging from 0.25 mM to 1 mM loading for 12h significantly increased mRNA of GRP78,CHOP and BAX and decreased that of Bcl-2 compared with control($p<0.05$) with the maximum concentration in 0.75 mM. 0.5 mM of palmitate loading for 3h, 8h and 12h significantly increased mRNA of GRP78, CHOP and BAX and decreased that of Bcl-2 compared with 0h ($p<0.05$)with the maximum effect at 3h.Confocal microscopy demonstrated GRP78 expression was significantly increased when exposing to 0.5 mM of palmitate for 8h compared with control.

Conclusions: Palmitate could induce podocyte apoptosis via ER stress, suggesting podocyte apoptosis and consequent proteinuria caused by lipotoxic free fatty acid could be ameliorated by relief of ER stress.

**Silencing of Podocyte VEGF-A Induces Irreversible Glomerular Damage: Animal and Cellular Model** Delma Veron, Claudia A. Bertuccio, Pardeep Kumar Aggarwal, Alda Tufro. *Pediatrics, Yale University, New Haven, CT.*

Vascular endothelial factor-a (VEGF-A) is essential to the differentiation of endothelial cells and vascular morphogenesis. In the glomerulus, podocytes and endothelial cells express VEGF-A. Genetic deletion of VEGF-A in the endothelium leads to systemic endothelial degeneration, vascular thrombosis and swelling of glomerular endothelium, whereas VEGF-A knockout in podocytes caused thrombotic microangiopathy in mice. To study the mechanism involved in local injury induced by low glomerular VEGF-A we developed an inducible podocyte silencing VEGF-A mouse and cellular model.

We generated Tet-O-siVEGF transgenic mice by oocyte pronuclear injection of a Tet-On vector containing an shRNA targeting the first VEGF exon; their breeding with podocin-rtTA mice resulted double transgenic mice that silence VEGF-A in podocytes in a doxycycline-regulated manner.

Upon doxycycline induction for a week podocin-rtTA:tet-O-siVEGF mice decreased VEGF-A mRNA and VEGF-A protein levels to ~20% of single transgenic or non-induced controls, as determined by qPCR and ELISA in isolated glomeruli. Mice developed proteinuria, mesangial expansion, mesangiolysis, microaneurisms, and decreased glomerular volume. Glomerular ultrastructure evidenced endothelial cell swelling, GBM lamination, podocyte effacement and fusion. Both functional and structural damage was irreversible after removal of doxycycline.

In addition, we crossbred podocin-rtTA:tet-O-siVEGF mice with Immortomouse®, isolated and cloned conditionally immortalized podocytes, which expressed WT1, podocin, nephrin and CD2AP and silenced VEGF-A upon induction with doxycycline.

We conclude that both animal and cellular models are useful tools to study the pathophysiology and molecular mechanisms involved in the irreversible glomerular damage induced by low VEGF.

**Sirolimus Inhibits Development of HIV-Associated Nephropathy (HIVAN) by Inhibiting Epithelial Mesanchymal Transposition** Iti Yadav, Anju Yadav, Madhuri Adabala, Dileep Kumar, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Long Island Jewish Medical Center, New Hyde Park, NY.*

HIV-associated nephropathy (HIVAN) is characterized by proliferative phenotype in the form of collapsing glomerulopathy and microcystic dilatation of tubules. Recently, epithelial mesenchymal transdifferetiation (EMT) of renal cells has been demonstrated to contribute to the pathogenesis of proliferative HIVAN phenotype (Am J Physiol. 298:F734-44, 2010). We hypothesize that sirolimus will not only inhibit renal cells EMT but will also attenuate manifestation of proliferative HIVAN phenotype.

Age (three weeks old) and sex matched HIVAN (Tg26) or control (FVB/N) mice in groups of six were administered ether normal saline (normal saline receiving Tg26 mice, TgNS; normal saline receiving control mice, CNS) or sirolimus (5.0 mg/Kg, intraperitoneal, every other day; sirolimus receiving Tg26 mice, TgS; sirolimus receiving control mice, CS) for either two weeks (protocol A) or eight weeks (Protocol B). At the end of the scheduled periods, blood and urine samples were collected; kidneys were harvested and processed for renal histology, immunohistochemical and mRNA studies.

TgNS showed enhanced ($P<0.01$) proliferation of both glomerular and tubular cells when compared to CNS in both protocols, A and B; on the other hand, TgS showed attenuated renal cell proliferation when compared with TgNS. TgNS also showed increased number of α-SMA-, vimentin-, and FSP1 + ive cells (glomerular as well as tubular) when compared with CNS (protocols A and B); however, TgS showed reduced number of α-SMA, vimentin, and FSP1 + ive renal cells when compared to TgNS. Renal tissues of TgNS showed enhanced expression of PCNA, α-SMA, and FSP1 by immunoblotting studies when compared with CNS. However, sirolimus attenuated renal tissue expression of PCNA, α-SMA, and FSP1 in Tg26 mice (both in protocol A and B). Interestingly, sirolimus preserved renal epithelial cell expression of E-cadherin in TgS. Since sirolimus also attenuated renal cell ZEB expression (a repressor of E-cadherin transcription), it appears that sirolimus may be attenuating renal cell EMT by preserving epithelial cell E-cadherin expression.

**Role of Heparanase in the Pathogenesis of Minimal Change Nephrotic Syndrome Induced by Respiratory Syncytial Virus** Jinxiang Yu, Yuhong Tao, Zheng Wang. *Department of Pediatrics, West China Second University Hospital, Sichuan University, Chengdu, Sichuan, China.*

**Background:** Respiratory syncytial virus (RSV) is the most important triggering factor of minimal change nephrotic syndrome(MCNS).β-D-endoglycosidase heparanase is proposed to be important in the pathogenesis of proteinuria by selectively degrading the negatively charged side chains of heparan sulfate proteoglycans(HSPG) within the glomerular basement membrane(GBM).

**Objective:** to explore the role of heparanase in the pathogenesis of MCNS induced by RSV

**Methods:** SD rats were inoculated with $6\times10^6$PFU(plaque-forming unit) RSV, and killed on days 4,8,14,28,56 and 84 postinoculation ($RSV_4$, $RSV_8$, $RSV_{14}$,$RSV_{28}$, $RSV_{56}$ and $RSV_{84}$). The proteinuria and serum parameters were measured; renal histology was observed by light microscopy and transmission electron microscopy;RSV mRNA in the kidney and lung was confirmed by *in situ* hybridization. Anionic sites in GBM were quantitatively evaluated through polyethyleneimine(PEI) staining under transmission electron microscopy. Renal heparanase protein and mRNA expression level were determined by immunohistochemical staining and real-time quantitative reverse transcriptase polymerase chain reaction(real-time quantitative RT-PCR).

**Results:** After inoculation of RSV , the urinary protein increased, foot processes of glomerular epithelial cells were fusional and accompanied with hypoalbuminemia, particularly in rats inoculated with $6x10^6$PFU RSV on days 14-28 postinoculation when the changes of renal tissue under lightmicroscope and electron microscope (the fusion of foot processes were extensive) bear similarity to human MCNS essentially. Compared with those of normal control ,$RSV_{56}$ and $RSV_{84}$ groups, anionic sites in GBM significantly from $RSV_4$,

$RSV_8$, $RSV_{14}$ groups decreased ,and heparanase expression in $RSV_4$, $RSV_8$, $RSV_{14}$ group were elevated. There were a positive correlation between the expression level of heparanase and proteinuria, and a negative correlation between anionic sites and proteinuria.

**Conclusion:** Heparanase expression contributes to the pathogenesis of proteinuria in RSV nephropathy in rats.

**Tacrolimus Reduces Nephrotic-Range Proteinuria of IgA Nephropathy Via Podocyte Actin Cytoskeleton Maintenance** Qingxian Zhang,[1,2,3] Li Zhu,[1,2,3] Sufang Shi,[1,2,3] Lijun Liu,[1,2,3] Jicheng Lv,[1,2,3] Hong Zhang,[1,2,3] Hai Yan Wang.[1,2,3] *[1]Renal Division, Peking University First Hospital; [2]Peking University Institute of Nephrology; [3]Key Laboratory of Renal Disease, Ministry of Health of China.*

**Background:** Recently, it was reported the Calcineurin (CaN) induced synaptopodin dephosphorylation, which could damage podocyte actin cytoskeleton and induce proteinuria, could be blocked by CaN inhibitor, cyclosporine A, in cultured podocyte and mice model. Our previous clinical study showed tacrolimus (FK506), another inhibitor of CaN, improved the proteinuria remission of steroids or steroids with cyclophosphamide / mycophenolate resistant nephrotic-range proteinuria in IgA nephropathy (IgAN) patients . We speculated FK506 reduced proteinuria in patients with IgAN by maintaining podocyte actin cytoskeleton through inhibiting CaN.

**Methods:** 12 IgAN patients with persistant nephrotic-range proteinuria after three to six months treatment with steroids or steroids plus cyclophosphamide/mycophenolate were administrated with FK506 at least for six months and their renal specimens were evaluated. Among them, 3 patients received repeated renal biopsy. 4 cases of peritumoral normal kidney tissue were used as normal control. Expression of CaN and synaptopodin were evaluated by immunohistochemical staining. In vitro, human podocyte were treated with puromycin aminonucleoside (PAN) with or without FK506. Integrity of podocyte actin cytoskeleton, expression of CaN and synaptopodin were detected after 48 hours treatment by Immunofluorescent staining.

**Results:** Compared to control, patients with IgAN showed increased expression of CaN and decreased expression of synaptopodin, which mainly displayed in podocyte. In those patients received repeated renal biopsy after complete proteinuria remission with FK506 therapy, the expression of CaN reduced and synaptopodin increased. In vitro, PAN induced podocytes showed F-actin lost, synaptopodin expressed weakly and disorderedly after 48 hours, and it could be partial recovered by application of FK506.

**Conclusion:** These results indicated that FK506 can maintain the integrity of podocyte actin cytoskeleton to reduce nephritic-range proteinuria in patients with IgAN.

**Expression and Significance of Vascular Endothelial Growth Factor (VEGF) AND Its Receptor in Hepatitis B Virus-Associated Nephritis** Yongze Zhuang,[1] Xiaorong Zhong,[2] Yinghao Yu.[2] *[1]Nephrology, Fuzhou General Hospital, Nanjing Command PLA, Fuzhou, Fujian, China; [2]Pathology, Fuzhou General Hospital, Nanjing Command PLA, Fuzhou, Fujian, China.*

VEGF and its receptor may participate in the development and progression of chronic kidney diseases,but the role of VEGF and its receptor in HBV-associated nephropathy(HBV-GN)is unclear. The clinical and pathological data were retrospectively analyzed in 68 patients with HBV-GN diagnosed as by renal biopsy. The protein expression of VEGF,VEGF receptor 2(Flk-1) and thrombomodulin(TM)in renal biopsy specimens were determined by immunohistochemistry and tested by semi-quantitative method. VEGF and Flk-1 were weak or no expression in glomeruli of normal kidney tissues, while the expression of VEGF and Flk-1 were significantly increased in HBV-GN and significantly different among different pathological types. The expression of VEGF,Flk-1 and TM in sclerosing glomerulonephritis(SGN)group was significantly lower than those in other pathologic types. The expression of VEGF and Flk-1 were positively correlated in the degree of glomerular changes in the mild lesion group(57.35%), but was negatively correlated in the moderate and severe disease group; and that in sclerosis group (9cases,glomerular sclerosis rate>50%) were evidently decreased. 46cases(67.65%)of those patients had the renal vascular lesion, of which mild change in 21cases, moderate change in 17cases,severe lesion in 8cases. The expression of VEGF and Flk-1 in moderate and severe vascular lesions were significantly higher than those without vascular disease. The expression of VEGF and Flk-1 expression in 10 cases(eGFR <60ml/min)were significantly lower than other patients. The expression of VEGF and Flk-1 were positively correlated with the level of urine protein in the mild and moderate disease group. The percent of chronic renal insuffiiency in the group of VEGF<4points was obviously higher than 4-6 and >6points. In early lesions of HBV-GN, podocyte was injuried, promoting VEGF upregulation,which led to endothelial cell activation and Flk-1 upregulation and promote the formation of proteinuria; in late lesions,VEGF and its receptor were decreased, promoting glomerulosclerosis and progression of HBV-GN.

Disclosure of Financial Relationships: nothing to disclose

**PUB621**

**Clinical and Pathological Study on IgA Nephropathy with the Deposition of Hepatitis B Virus Antigens in Renal Tissue** Jian Chen,[1] Hongbin Zhong,[1] Yinghao Yu.[2] *[1]Nephrology, Dong Fang Hospital, Fuzhou, Fuzhou, Fujian, China; [2]Nephrology, Fuzhou General Hospital, Nanjing Command PLA, Fuzhou, Fujian, China.*

Objectives: To investigate the clinical and pathological characteristic, To evaluate whether there existed different subtypes of IgA nephropathy with the deposition of HBV antigens in renal tissue, and the pathological characteristics of it. Methods Retrospective study method was applied to analyze 120 IgA nephropathy accompanied by the deposition of HBV antigens and IgA nephropathy without deposition of HBV antigens. The control study was performed on clinical classification, histomorphology, immunological type, ultrastructure. The relevant factors were scored by semiquantitative analysis. Results Group A(37.5%) with massive proteinuria and nephrotic syndrome was significantly different from group B(19.17%)(P<0.05)and group A with haematuriu (7.5%) was significantly different from group B(19.17%)(P<0.05). Pathological Lee's classification of renal tissue:grade IV in group A(27.14%) was significantly higher than in group B(8.33%)(P<0.05),while grade II in group A(18.83%) was significantly lower than in group B(47.5%)(P<0.05). Immunohistochemical result: group A(60.0%) with IgA+IgG+IgM was significantly higher than group B(28.33%)(P<0.05);while group B(32.0%) with IgA+IgG was significantly higher than group A(10.83%)(P<0.05).The result of ultrastructure :51 cases of group A(42.5%) with Lesion of basement membrane was significantly more than only 3cases of group B(2.5%)(P<0.05);while 69 cases of group A(57.50%) with abnormality of foot cells was significantly more than 41 cases of group B(34.17%)(P<0.05);group A with much deposition under mesenterium, endothelium, basement membrane and epithelium was significantly more than group B(2.5%)(P<0.05). Conclusions Clinical presentation of IgA nephropathy with the deposition of HBV antigens in renal tissue is various. Massive proteinuria or nephrotic syndrome is the most common symptom, which pathological changes is more severity and type of IgA+IgG+IgM is more common. There are 42.5% cases companied with lesions of basement membrane.

**Anti-C1q Antibodies: Association with Lupus Nephritis in Afrocaribbean Population in a French West Indies Island** Maryvonne R. Dueymes,[1] Christophe Deligny,[2] Raluca Ples,[3] Jean-Marc Roger Dueymes-Laporte.[4] *[1]Immunology Department, CHU, Fort de France, Martinique; [2]Internal Medicine Department, CHU, Fort de France, Martinique; [3]Anatomo-Pathology Laboratory, CHU, Fort de France, Martinique; [4]Nephrology Department, Centre Hospitalier, Lamentin, Martinique.*

Introduction

Renal involvement is a major complication of systemic lupus erythematosus (SLE) and is a strong determinant of morbidity and mortality. The prognosis of lupus nephritis indicate a need for identifying early biomarkers that predict nephritis development. Autoantibodies against C1q have been described in SLE as well as in other connective diseases. They have been considered as a marker of disease activity and presence of nephritis.

Objectives

Our aim was to compare titers of anti-C1q and anti-DNA in afrocaribbean SLE patients with (n=30) or without (n=30) subsequent biopsy-proven lupus nephritis.

Methods

Sera from 60 SLE patients based on the American college of Rheumatology (ACR) criteria, 20 rheumatoid arthritis without nephritis and 20 controls without auto-immune disease and nephritis were collected. Anti-C1q were detected by ELISA Kit (Bioadvance) and anti-DNA antibodies were measured by IF and ELISA (Phadia).

Results

Anti-C1q were detected in 24/30 patients (80%) with nephritis (in majority class IV and class V) and in 8/30 patients (28%) without renal disease. No anti-C1q were found in the two other groups, rheumatoid arthritis and controls. Anti-C1q titers were higher in SLE patients with nephritis than without (p<0,02). Anti-DNA were positive in SLE patients with nephritis (90%) and without nephritis (78%) (p=NS). Anti-C1q did not correlate with anti-DNA in all groups.

Conclusion

The study in Afrocaribbean SLE patients confirms previous finding in other populations the association of anti-C1q antibodies with nephritis and disease activity. Their presence or absence represent an non invasive biological marker in the follow up of SLE patients.

**Sunitinib Induced Nephrotic-Range Proteinuria** Stacy Z. Ker,[1] Jason I. Biederman,[1,2] Khaled M. Ismail,[1,2] Michael T. Keefe.[1,2] *[1]Botsford Hospital, Farmington Hills, MI; [2]Hypertension Nephrology Associates, PC, Livonia, MI.*

Presented are two cases, an 85 year old female and a 66 year old male with renal cell carcinoma (RCC) treated with nephrectomy followed by sunitinib for recurrence. Both patients had no proteinuria prior to sunitinib therapy. Nephrotic-range proteinuria of 11.6 g/g and 9.8 g/g was detected 21 months and 24 months, respectively, after starting sunitinib on a 4-week-on, 2-week-off cycle. Both patients were also noted to have uncontrolled blood pressures during the 4-week-on cycle of their treatment. Reduced estimated glomerular

filtration rate (eGFR) was also noted in both patients. Serum creatinine increased from a pre-sunitinib level of 2.1 mg/dL to 3.2 mg/dL 24 months post-therapy in the female and 1.9 mg/dL pre-sunitinib therapy to 4.16 mg/dL 25 months post-treatment in the male. Serologic work-up of nephrotic-range proteinuria was negative, with the exception of a weakly positive ANA in the female. Neither patient was diabetic and random glucose levels were normal. Sunitinib was not discontinued in either of the patients due to excellent treatment responses. Because of the poor long-term outcomes of patients with stage 4 RCC and presence of a solitary kidney, renal biopsy was not performed in either patient.

Proteinuria and hypertension are well known side effects of bevacizumab, a vascular endothelial growth factor (VEGF) inhibitor. Sunitinib, which inhibits multiple tyrosine kinase receptors, including VEGF receptors, was not shown to induce proteinuria in clinical trials. This phenomenon has only recently been described in animal models as a preeclampsia-like syndrome induced by sunitinib and a similar drug, sorafenib. Previous case reports of sunitinib induced renal failure with renal biopsy data have shown thrombotic microangiopathy but have presented with sub-nephrotic range proteinuria. Due to the poor long term survival of these patients and the paucity of biopsy data, we believe this clinical syndrome is under reported. Clinicians should monitor patients treated with the aforementioned drugs for hypertension, proteinuria and renal dysfunction.

**The Gene Expression of TWEAK/Fn14 and IP-10/CXCR3 in Glomerulus and Tubulo-Interstitium of Patients with Lupus Nephritis** Jianxin Lu, Bonnie Kwan, Kai Ming Chow, Philip K. T. Li, Cheuk-Chun Szeto. *Department of Medicine & Therapeutics, Prince of Wales Hospital, The Chinese University of Hong Kong, HongKong, China.*

*Background* The role of TNF-like weak inducer of apoptosis (TWEAK)/Fn14 and interferon-inducible protein (IP-10) / CXCR3 axis in the pathogenesis of lupus nephritis remain elusive. *Methods* We quantified the mRNA expression of TWEAK, Fn14, IP-10 and CXCR3 in glomerulus and tubulointerstitium of 42 patients with lupus nephritis (LN group) and 10 healthy controls. *Results* As compared to controls, LN patients had higher glomerular expression of TWEAK and Fn14, but glomerular CXCR3 expression was lower in the LN group. Similarly, LN group had higher tubulointerstitial expression of TWEAK and Fn14, but lower tubulointerstitial expression of CXCR3, than controls. Glomerular TWEAK expression of class V nephritis was significantly higher than proliferative nephritis. Glomerular expression of CXCR3 significantly correlated with proteinuria (r=-0.532; p=0.019), whereas tubulointerstitial CXCR3 significantly correlated with serum creatinine (r=-0.447; p=0.029). *Conclusion* In patients with lupus nephritis, there is an increase in intra-renal expression of TWEAK and Fn14, and a decrease in CXCR3 expression. Intra-renal expression of CXCR3 correlates with proteinuria and renal function. Our findings suggest that TWEAK/Fn14 and IP-10/CXCR3 axis may contribute to the pathogenesis of lupus nephritis.

**The Gene Expression of NGAL and TLR9 in Glomerulus and Tubulo-Interstitium of Patients with Lupus Nephritis** Jianxin Lu, Bonnie Kwan, Kai Ming Chow, Philip K. T. Li, Cheuk-Chun Szeto. *Department of Medicine & Therapeutics, Prince of Wales Hospital, HongKong, China.*

*Background* The role of Neutrophil gelatinase associated lipocalin (NGAL) and Toll-like receptor 9 (TLR9) in the pathogenesis of lupus nephritis remain elusive. Methods Laser microdissection of the snap-frozen kidney biopsy specimens was performed using the PALM Microlaser System. We quantified the mRNA expression of NGAL and TLR9 in glomerulus and tubulointerstitium of 42 patients with lupus nephritis (LN group) and 10 healthy controls. *Results* As compared to controls, LN patients had higher glomerular expression of TLR9. Similarly, LN group had higher tubulointerstitial expression of NGAL and TLR9. Both of Glomerular(r=0.554; p=0.001) and tubulointerstitial (r=0.379; p=0.043) TLR9 significantly correlated with proteinuria. As for NGAL, only tubulointerstitial NGAL significantly correlated with proteinuria(r=0.492; p=0.003), GFR(r=-0.386; p=0.022) and Cl(r=0.54; p=0.004). *Conclusion* In patients with lupus nephritis, there is an increase in intra-renal expression of NGAL and TLR9. Intra-renal expression of NGAL and TLR9 correlates with proteinuria and renal function. Our findings suggest that NGAL and TLR9 may contribute to the pathogenesis of lupus nephritis.

**Effect of Rituximab on Resistant Idiopathic Membranous Glomerulonephritis (IMGN)** Filippo Mangione, Ciro Esposito, Francesca Castoldi, Luigi Villa, Clara Migotto, Nicoletta Serpieri, Noemi Maggi, Vittoria Esposito, Fabrizio Grosjean, Antonio Dal Canton. *Nephrology, Policlinico S.Matteo, Univ. of Pavia, Italy.*

IMGN may lead to progressive renal dysfunction. All the therapeutic strategies proposed for IMGN are burdened with side effects. Rituximab (RTX) has proven to be effective in patients with IMGN, however not in patients with refractory disease. We evaluated if RTX could be useful as a cyclosporine-sparing agent and in patients refractory to other treatments. RTX (1 g) was administered i.v. on day 1 and day 15. In cases of ongoing CYA therapy, CYA was tapered by 20% after the last infusion, and hence monthly if no increase in proteinuria was noted. Patients were followed up to 6 months. Complete remission was defined as proteinuria < 0.3 mg/24h; partial remission was defined as proteinuria < 1 g/24h. 6 patients (5 ♂, 1♀ ) were enrolled. 4 patients had CYA-dependent IMGN and 2 patients had refractory IMGN. Mean age was 52.8 years (range 40-77 y); mean time from first diagnosis of IMGN was 61.8 months (range 4-143 months). Mean baseline proteinuria was 3.06 ± 1.74 g/24h; 5/6 patients had proteinuria > 2 g/24h, and 2 of them had nephrotic proteinuria. Significant B cell (counted as CD19+ and CD20+ circulating cells) depletion occurred right after the first infusion and was maintained up to 6 months. At the end of the study, mean proteinuria levels were not significantly different from baseline (2.8 ± 2.7 g/24h; p=0.76). Only 1/6 patient (which was in the refractory group) reached complete remission. One patient in the CYA-dependent group discontinued CYA therapy with proteinuria steadily < 1 g/24h; another one afforded a 40% reduction in CYA dose, but with proteinuria > 1 g/24h. Two subjects remained nephrotic. There was a slightly increase of renal function at the end of the study period (77.67 ± 29.52 vs 88.17 ± 22.27 ml/min per 1.73 $m^2$, p = 0.24). Only two minor side effects were noted (pruritus without cutaneous rash, 1 hypotensive episode) during infusions. RTX can be safely used in patients with refractory IMGN or, as a cyclosporine-sparing agent, in cyclosporine-dependent IMGN however its efficacy remains to be proved.

**Red Cell Exchange in the Management of Malaria Falciparum** Raeesa Mirza, Rania Abdel-Rahman, Tejas P. Desai. *Nephrology and Hypertension, East Carolina University, Greenville, NC.*

Learning objectives:

Although common worldwide, malaria is an extremely unusual occurrence in the United States. Therefore it can present a diagnostic and therapeutic challenge. By describing this case, we hope to highlight the role of red blood cell exchange transfusion in the treatment of severe Malaria Falciparum.

Case Information:

A 27 year old female with a history of type 2 diabetes was admitted to an outside hospital, complaining of fevers, chills and myalgia for one week. Initally she was thought to have influenza and treated conservatively. However, her clinical condition continued to deteriorate with the development of jaundice, hepatic dysfunction and acute renal failure. She was empirically started on multiple intravenous antibiotics, and transferred to our facility.

It was noted that she had recently returned from India two weeks prior to this admission. She denied any illness while she was there besides traveler's diarrhea. In light of this information, a blood smear was performed which revealed *Plasmodium falciparum*. The patient was found to have a 23% parasitemic burden. At this point an infectious disease consult was obtained, and the patient was started on quinidine and clindamycin intravenously.

Nephrology was consulted for a red blood cell exchange transfusion. A 1.5 liter exchange was perfomed on the day of admission. Blood smears were monitored before and after treatments, with the goal of reducing parasitemic burden to less than 10 %. Smears were then followed every 12 hours, and the patient required one additional exchange transfusion to achieve our goal.

She tolerated and responded well to the treatment, and after several days in the ICU with ventilatory and dialytic support, she recovered completely.

Summary:

As malaria is encountered so rarely in this country, few guidelines exist regarding management. After reviewing the literature we found cases of severe malaria falciparum responding to exchange transfusion. This case illustrates the indication for cytapheresis in the setting of malaria falciparum causing severe malaria.

**A 120-Month Retrospective Analysis of De Novo HBV Infection in a Mayo Clinic Hemodialysis System – A Comparative Effectiveness Review and a Call for Change in Current US CDC Guidelines for HBV Immuno-Surveillance and Immuno-Prophylaxis** Macaulay A. Onuigbo,[1] Macaulay A. Onuigbo.[2] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Midelfort Clinic, Eau Claire, WI.*

Background

Infection with HBV is a serious public health issue. Complications of HBV infection include cirrhosis, liver failure and heptaocellular carcinoma. Hemodialysis (HD) exposes ESRD patients to significantly higher risk for HBV infection. Current US CDC guidelines and recommendations, practiced in US HD units, and worldwide, were established in 2001. A recent false positive HBsAg test following HBV immunization (Engerix B) led us to believe that changes to current guidelines are long overdue.

Objective

The aim was to determine the incidence/prevalence rates of de novo HBV infection among HD patients in five Mayo Clinic Hemodialysis units over a 120-month period and to assess the relative risks of a positive HBsAg test being a de novo HBV infection versus a false positive serology test following HBV immunization. A new patentable IT Software Program to help optimize immuno-prophylaxis and immuno-surveillance for HBV in HD patients and other high risk populations was to be developed. New changes to current US CDC guidelines would subsequently be enunciated.

Methods

A retrospectively acquired database of relevant HBV serology test results in the last ten years from patients attending five Mayo Clinic HD units was analyzed.

Results

Preliminary data show that we had a zero incidence of de novo HBV infection in our HD population during the last ten years. The only positive HBsAG test results were false positive following Engerix B vaccination.

Conclusion

Our preliminary data demonstrate that de novo HBV infection among HD patients in the US is very rare; it was absent in our unit over a 120-month period. False positive HBsAG tests may be more prevalent than de novo HBV infection. Current US CDC guidelines on HBV immuno-prophylaxis and immuno-surveillance, established in 2001, are due for a revision. Our new IT Software Program under development could maximize the efficacy and effectiveness of HBV immunoprophylaxis among high HD patients and high-risk populations, in general.

**The Experimental Treatment and Its Mechanism of Total Flavonoids of Ajuga (TFA) on Mesangial Proliferative Glomerulonephritis (MsPGN)** Weihua Peng. *Nephrology, DongFang Hospital, Fuzhou, Fujian P.R.C., Fuzhou, Fujian, China.*

To observe the effect of TFA on Rats with MsPGN and its mechanism, we established the improved animal model of chronic serum sickness MsPGN. The positive urinary protein rats were randomly divided into the model control group(normal rats), the tripterygium wilfordii polycoride(TPG) group(0.018g•kg$^{-1}$•day$^{-1}$),the TFA high-dosage group(2.16g•kg$^{-1}$•day$^{-1}$),the TFA mid-dosage group(1.08g•kg$^{-1}$•day$^{-1}$) and the TFA low-dosage group(0.54g•kg$^{-1}$•day$^{-1}$). After 6weeks,24h urinary protein,blood biochemistry were detected. Rats Mesangium,GMC and ECM accumulation were observated under the light microscope.The content of MDA and SOD activity was detected by chemical colorimetric assay,the concentration of IL-1,TNF-αby radio immunoassay,the expression of TGF-$\beta_1$ by ELISA,and the expression of NF-κBp$^{65}$ in rats nephridial tissue with immunohistochemistry.

The excretion of urine protein in TFA groups and TPG group were more significantly decreased than the model group(P<0.01 or P<0.05).GMC in model group increased significantly, mesangial region became obviously widen, groundsubstance increased,the capillaries were pressed into narrowing or disappearing,those pathomorphological changed in TFA groups dramatically lessen(P<0.01 or P<0.05).There were no statistics difference in urine protein excretion and pathomorphological change among the first two TFA groups and TWG group(P>0.05).SOD activity in TFA groups were obviously higher than model control group,the expression of MDA,IL-1,TNF-α,TGF-$\beta_1$ and NF-κB p$^{65}$ were obviously decreased(P<0.05 or P<0.01),and Nuclear translocation of NF-κB was significantly inhibited.The effect of increasing SOD activity and decreasing the content of MDA in TFA mid-dosage group were better than TPG group(P<0.05).The relative analysis shows the expression of NF-κB p$^{65}$ was significantly positive correlation with the expression of Serum IL-1,TNF-α,TGF-$\beta_1$(r=0.566, P<0.05; r=0.669, P<0.05; r=0.598, P<0.05),and was significantly negative correlation with SOD activity(r=-0.825, P<0.01).The research indicated that TFA had a certain therapeutical effect on MsPGN which might be related to resist oxidative stress and decrease the expression of NF-κB, IL-1, TNF-α, TGF-$\beta_1$.

**Occult Intrarenal Bacteria Cause Fibromyalgia: New Ideas of Pathogenesis** Russell E. Randall. *NA.*

Bacterial casts are pathognomonic for intrarenal infection. 278 patients (99% female) with a clinical diagnosis of fibromyalgia were studied. 65% were free of urinary symptoms but often had livido reticularis and palmar erythema, headaches, chronic fatigue, arthralgias and skin rashes. Low titer autoantibody (ana, anca, antithroid) positivity occured in 27%.

clean catch urines were cultured and the stained sediment examined using high power oil immersion and polarizing microscopy.

bacterial and/or celluar casts were present in 99%. Routine urine cultures identified organisms in only 80%. All urine specimens were further subjected to intentional dehydration and delayed microscopy at 30 minutes, one, three and 24 hours. 100% showed the formation of microcrystals, both free and within bladder or renal epithelial cells. These appeared to be derived from nuclear proteins from infected apoptotic cells. The precise composition of these crystals is being studied, but they resemble uric acid in a micro-form or amino acids from degradating nuclear proteins.

It is hypothesized that intrarenal reabsorption of bacterial-induced intracellular products of apoptosis initiates the symptoms known as fibromyalgia. The precice mechanisms are not yet known.

To be discussed: criteria that defines intrarenal infection, and the response to and the adequacy of antibiotic therapy.

**Decreased Numbers of Plasmacytoid Dendritic Cells but Normal Counts of Monocyte Subpopulations in ANCA-Associated Vasculitis during Remission** Marten Segelmark,[1,2] Thomas Hellmark,[1] Mohamed A. Abdgawad.[1,2] *[1]Department of Nephrology, Lund University, Lund, Sweden; [2]Department of Nephrology, Skane University Hosptial, Lund, Sweden.*

Introduction: In most chronic inflammatory diseases there are reports of increased numbers of pro-inflammatory monocytes (CD14low/CD16+). AASV patients in remission are at an high risk of relapse, and AASV remission have been shown to be associated with increased levels of circulating cytokines and increased proportion of PR3+/CD177+ neutrophils.

Methods: We analyzed monocyte subpopulations and plasmacytoid dendritic cells (PDC)complete as well as comolete white blood cell count in 29 stable AASV patiens, 24 healthy controls (HC) and 14 renal transplant recipients (Tp).

Results: Compared to HC AASV had significantly more PMNs, and less PDCs and lymphocytes. Tp patients also had high PMNs and low lymphocyte counts, suggesting this to be secondary to treatment. However AASV had significantly less PDCs compared to the Tp patients. Neither Tp nor AASV patients had any deviations in the three major monocyte subpoplations.

PDCs and monocyte subpopulations in AASV

| Cells 10*6/l | AASV (n=32) | HC (n=23) | Tp (n=14) |
|---|---|---|---|
| Total white cells | 7697 (±3169 | 6291±1841 | 7471±1264 |
| PMN | 5755±2926 | 3848±1809*** | 5107±1014 |
| Lymphocytes | 1179±884 | 1839±471*** | 1542±563 |
| Total Monocytes | 548±290 | 491±144 | 636±276 |
| CD14+/CD16low | 469±258 | 419±138 | 547±266 |
| CD14+/CD16+ | 48±38 | 34±16 | 52±55 |
| CD14low/CD16+ | 32±29 | 38±17 | 37±25 |
| PBC | 3.8±4 | 10.3±5*** | 6.8±4* |

*=p<0.05 vs AASV, ***=p<0.001 vsAASV

Disucssion: Low circulating PBCs may indicate an increased recruitment of such cells to target organs. PBCs are the main source of type 1 interferons, suggesting a role for these cytokines in AASV. The change in monocyte subpoplation reported from many other inflammatory states were not seen in AASV remission.

Disclosure of Financial Relationships: Research Funding: Funding from GAMBRO AB, about $30.000 per year from 2008-2011.

**Detection of PreS1/S2Ag and Other HBV Antigens in the Patients with HBV Associated Glomerular Nephritis** Chenggang Shi, Xiaolin Zeng, Hui Peng, Qiongli Yin, Chao Ma. *The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

**Background** PreS1 is an HBV envelope protein. Immunogenicity of PreS1 is strong, and at the same time the PreS1 antigen is an index of virus replication. Our aim is to detect the expression of PreS1/S2-Ag and other antigens of hepatitis B in renal tissues of hepatitis B virus associated nephritis.

**Methods** PreS1/S2Ag,HBeAg,HBsAg,HBcAg in renal paraffin sections were detected by immunohistochemistry in 59 Patients, including 49 HBV carring nephrosis, 5 minor changed disease, 5 renal calculus or renal carcinoma. The status of antigen expression and clinical feathers were given statistical analysis.

**Results** (1) The four antigens were expressed in the renal tissue. The positive rates of the Pre-s1/s2Ag, HBeAg, HBsAg, HBcAg in the 49 patients with HBV carring nephrosis were 32.7%(16 cases), 38.8%(19 cases), 14.3%(7 cases), 46.9%(23 cases), respectively. All four antigens positive rate was 70.2% (36 cases). (2)The expression of PreS1/S2-Ag in the renal was correlation with the expression of HBcAg in renal(r=0.459, P<0.01). It was located in the cytoplasm of renal tubular and glomerular epithelial cells, endothelial and mesangial cells. (3)In the 36 cases of HBVGN there were 14 cases (38.9%) of membranous nephropathy (MN), 4 cases (11.1%) of membranoproliferative glomerulonephritis (MPGN), 8 cases (22.2%) of IgA nephrosis (IgAN), 1 case (2.8%) of minimal change glomerulopathy (MCD), 3 cases (8.3%) of mesangial proliferative glomerulonephritis (MsPGN), 6 cases (16.7%) of proliferativesclerosing glomerulonephritis (PSGN). (4)The positive expression rates of HBcAg through megatemperature and high pressure with gastric enzyme or simple megatemperature and high pressure to restore antigens are 48.9%, 14.6%. There was significant difference (P<0.01); (5)The occurrence of HBVGN was correlated with the status of serum HBeAg (r=0.367, P<0.05).

**Conclusion** PreS1/S2-Ag expresses in renal tissues with HBVGN .The method of antigen restored through megatemperature and high pressure with gastric enzyme can raise the positive expression rates of HBcAg in renal. To detect the four antigens can elevate the rate of diagnose of HBVGN.

**Disseminated Herpes in a Patient Receiving Mycophenolate Mofetil and Prednisone for Membranous Nephropathy** Alejandro Solano Bayardo,[1] Sorour Rahgoshay,[1] Razi Syed,[1] Wajid M. Choudhry.[2] *[1]Internal Medicine, Unity Health System, Rochester, NY; [2]Nephrology, Unity Health System/University of Rochester, Rochester, NY.*

**Introduction**

Disseminated herpes has been associated in immunocompromised patients in general. Mycophenolate mofetil, has been rarely associated with disseminated herpes and its occurrence is mostly seen in patients with organ transplant.

**Case Discussion**

A 81 year old male with history of idiopathic membranous glomerulonephritis stage I-II, with 5.6 g/day proteinuria diagnosed in 2002; had been receiving treatment with mycophenolate mofetil at 2 g daily resulting in partial remission therefore dosage was reduced to 1 g a day in a year time. Later in 2008 the dosage was further reduced to 500 mg daily. He developed severe nephrotic syndrome 5 months later requiring increasing mycophenalate mofetil at 2 g a day and the addition of prednisone. Following this, the patient was admitted to the hospital with dyspnea and generalized pruritic and painful rash for 3 weeks and epigastric pain with vomiting for 2 days prior to admission. Physical exam revealed a diffuse erythematous papular rash with some vesicles involving his face, chest and back.

The skin biopsy showed multinucleated cells correlating with herpes infection and viral cultures were positive for varicella zoster virus. During hospitalization upper endoscopy showed multiple shallow ulcers and bronchoscopy showed mucosal ulcers with BAL positive for Aspergillosis. The patient received treatment with IV acyclovir and caspofungin with resolution of skin rash along with clinically recovery.

**Conclusion**

The presentation of our patient with disseminated herpes and pulmonary aspergillosis is most likely associated with immunosuppression caused by mycophenolate mofetil and prednisone in the setting of membranous nephropathy.

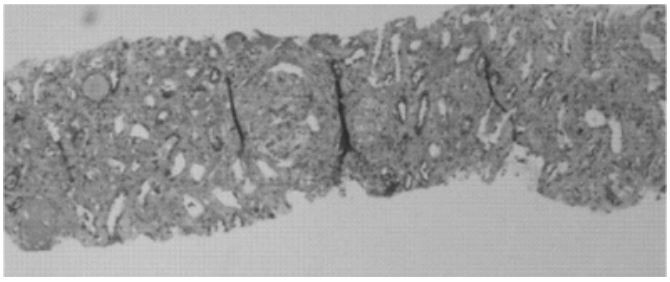
**P-ANCA Crescentic Glomerulonephritis Coincided Hodgkin Lymphoma with Renal Recovery after Lymphoma Treatment** Khaldoun Soudan, Sherry L. Werner, Seema S. Ahuja. *Nephrology and Pathology, The University of Texas Health Science Center and the South Texas Veterans Health Care System, San Antonio, TX.*

**Clinical case**

A 68 year-old male with history of diabetes mellitus and stage 3 chronic kidney disease developed worsening renal function (Creatinine 1.5 to 3.1 mg/dL) with nephrotic range proteinuria of 20g/day. Work-up was notable for a P-ANCA with a pauci-immune crescentic glomerulonephritis on renal biopsy. Due to the severe interstitial fibrosis he did not receive immunosuppressive therapy and was initiated on dialysis.

After one month, patient was diagnosed with Hodgkin Lymphoma [HL] by lymph node biopsy. Chemotherapy (Adriamycin, Bleomycin, Dacarbazine, Vinblastine) was administered with improving lymphadenopathy.

It was noticed after chemotherapy treatment that renal function improved based on an average urea-creatinine split clearance of 36mls/min, increasing urine output and a decrease in proteinuria to 10 g/day. Dialysis was discontinued with stable serum Creatinine of 1.3 mg/dL. P-ANCA titer became undetectable.



**Discussion**

Various solid and lymphproliferative malignancies have been associated with glomerular diseases to include membranous nephropathy, minimal change disease and focal segmental glomerulosclerosis. Effective treatment of the tumor generally leads to reversal of the glomerular injury.

ANCA have been described in HL patients, but is usually not associated with pathological complications such as antibody mediated systemic vasculitis or pauci-immune glomerulonephritis.

This patient had biopsy proven P-ANCA pauci-immune glomerulonephritis with renal failure requiring dialysis that responded to lymphoma treatment.

**Conclusions**

Hodgkins Lymphoma can present initially as P-ANCA pauci-immune crescentic glomerulonephritis.

Significant improvement in renal function is possible after lymphoma treatment even with advanced renal interstitial fibrosis.

**Twenty Year Profile of IgA Nephropathy in a Secondary Care Hospital** Sivakumar Sridharan, Vasantha M. Muthuppalaniappan, Michael K. Almond. *Renal Unit, Southend University Hospital, Westcliff-on-Sea, Essex, United Kingdom.*

Aim:

To evaluate the profile of IgA nephropathy cases and the outcomes over 20 years in a secondary care hospital.

Methods:

We identified IgA nephropathy patients from the histopathology reports for the period 1988 to 2008 and their case records were retrieved. Various clinical information pertaining to the study were collected from these records.

Results:

We had a total of 425 renal biopsies during this period, of which there were 40 IgA nephropathy cases. The commonest age group was 40-49 years (27.5% of patients). 75% of patients were males. The commonest presentations were isolated haematuria (35%), combined haematuria and proteinuria (17.5%) and proteinuria (15%). 42.5% of patients had raised creatinine levels at the time of presentation. Urine dipstick testing at the time of first presentation showed blood in 87.5% of patients and protein in 77.5%. Hypertension was present in 32.5% of patients and 25% had smoking history. The commonest histology found was mesangial proliferative type (37.5%) with 5% of patients with crescentic formation. Outcome evaluation showed 22.5% of patients had remission and an equal number developed CKD. 72.5% of patients were managed conservatively, 15% of patients had transplant and 20% of patients had dialysis at sometime during their treatment. Only one patient was treated with short course steroids and none of them had immunosuppressants. 20% of our cohort died over the last 20 years and all of them died of non-renal causes. Outcome was not known in 15% of patients due to non-attendance.

Discussion:

IgA nephropathy is the commonest glomerulonephritis worldwide and it was the commonest diagnosis in our hospital in the past 20 years. Our study showed the commonest age group affected was in the fifth decade of life in comparison to the second and third decades which is common worldwide. Haematuria remains the commonest reason for referral and is present in majority of patients. Crescentic formation predicted poor prognosis as they developed ESRD. Majority of our study patients were treated in a conservative approach and this approach coupled with regular follow-up was found to be successful from a secondary care point of view.

**PUB636**

**Hypoalbuminemia with Coexisting Protein-Losing Enteropathy and Membranous Nephropathy in a Patient with SLE-Like Mixed Connective Tissue Disease** Donjeta Sulaj, Lin N. Lwin, Hugo J. Villanueva, Jinil Yoo. *Nephrology, Montefiore Medical Center, North Division, Bronx, NY.*

We observed a patient with severe hypoalbuminemia who was found to have SLE - like mixed connective tissue disease (MCTD) with coexisting membranous nephropathy (MN) and protein - losing enteropathy (PLE). Initially she had trace proteinuria (< 0.5 g in 24 - hr urine), but severe hypoalbuminemia (< 1.0 g/dL). Under the presumptive diagnosis (Dx) of PLE, she was placed on methylprednisolone (Medrol) 48 mg p.o. daily. While serum albumin (Salb) level rose to 2.2 g/L in 4 weeks, her proteinuria increased > 3.0 g in 24 - hr urine. With the Dx of MN and persisting muscle weakness, mycophenolate (MMF up to 3.0 g/d) and a low dose of Medrol (18 mg/d) were started.

The case is a 43 - year - old obese lady who was admitted with abdominal pain and diarrhea, and found to have marked muscle weakness (bed-ridden), + pleural effusion, + ascites, serum creatinine (Scr) in ranges of 0.7 to 1.3 mg/dL, Salb 1.6 to 0.9 g/dL, total serum protein 2.2 g/dL, + proteinuria: 418 mg to < 1.0 g in 24 - hr urine, + ANA 1: 1260 speckled, (-) anti - ds DNA, + anti - Ro, + anti - RNP, low serum complement and normal liver enzymes. The kidney biopsy revealed MN Stage I-II and mesangial deposits. She had repeated upper GI endoscopy and colonoscopy which all showed edematous mucosa and nonspecific findings. The presumptive Dx of PLE was made in the view of severe hypoalbuminemia, in which other causes, such as protein malnutrition, heavy proteinuria, or liver diseases have been excluded.

The protein loss in PLE is considered due to increased permeability of intestinal mucosa and/or capillaries induced by inflammatory burden in SLE or MCTD, and responds dramatically to corticosteroids. The pathophysiology of protein loss in PLE is believed to be different from that in glomerular diseases, independent of molecular weight. In our patient, "nephrotic syndrome" due to MN was not evident by masquerading PLE, until her PLE was controlled with Medrol and Salb reached to 2.2 g/dL. Extra renal loss of protein may mask nephrotic syndrome.

**Novel Role for alpha-Galactosidase as a CKD Biomarker** Sapna Trivedi,[1] Mehmet M. Altintas,[2] Orlando M. Gutierrez,[2] Jochen Reiser.[2] *[1]Medicine, University of Cambridge, United Kingdom; [2]Medicine, Nephrology, University of Miami, FL.*

**Purpose**: Blood activity levels of alpha galactosidase (a-GAL) are usually measured in the context of diagnosing Fabry's disease. After reliably setting up the testing system, we sought to analyze the relationship of a-GAL activity levels in patients with different stages of Chronic Kidney Disease (CKD) independent of Fabry's disease, to evaluate its use as a potential biomarker in CKD.

**Method:** Patients with renal failure (CKD 2 - 60<GFR<89, CKD 3 - 30<GFR<59, CKD 4 - 15<GFR<29, CKD 5 - GFR<15) were identified. Blood samples were obtained by fingerprick testing and a-GAL measurement and analysis was undertaken using the protocol by Nestor Chamoles[1]. A-GAL activity was correlated with clinical data.

**Results:** eGFR was significantly associated with a-GAL levels in this dataset (P=0.04). The results demonstrate the relationship between eGFR and a-GAL levels (log transformed to achieve a normal distribution) is different by gender with men but not women showing a significant linear association between a-GAL and eGFR. Levels of a-GAL decrease with decreasing quartiles of eGFR in men (P = 0.03) but not women (*P* = 0.6).

Interaction between eGFR and gender

| Source | DF | Type III SS | Mean Square | F Value | PR>F |
|---|---|---|---|---|---|
| Sex | 1 | 2.76 | 2.76 | 4.56 | 0.0353 |
| eGFR | 1 | 1.14 | 1.14 | 1.88 | 0.1739 |
| eGFR*sex | 1 | 3.18 | 3.18 | 5.25 | **0.0242** |

**Conclusion:** In models stratified by gender, eGFR remained linearly associated with a-gal levels in men independently of age, race, body mass index, diabetes, and hypertension (a-gal levels increase 1.5 for every 10 ml/min/1.73 m² increase in eGFR, *P* = 0.004). In contrast, there was no relationship between eGFR and a-GAL levels among women in unadjusted or multivariable adjusted regression analyses (*P* = 0.9). This may in part be due to the known unreliability of the fingerspot testing method in females or due to the fact that two copies of alpha-galactosidase are able to compensate in conditions of CKD in women. In summary, our data suggests that a-GAL activity may have a role as a biomarker for CKD stage in males. We are currently exploring the molecular mechanisms that underlie our findingr]

**Localization of (Pro)renin Receptor in Glomeruli of IgA Nephropathy, Diabetic Nephropathy, and Minimal Change Nephropathy Using Renal Biopsy Specimen** Satoko Ueda. *1Department of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Nankoku, Kochi, Japan.*

Activated prorenin plays a key role in the regulation of the tissue RAS, and a direct renin inhibitor has been reported to reduce proteinuria in diabetic nephropathy through inhibiting the tissue RAS. However, little information is available regarding the localization of activated prorenin in human kidney under pathophysiological conditions. We examined the localization of activated prorenin in kidney biopsy specimens of the patients with IgA nephropathy(IgAN), diabetic nephropathy(DN), and minimal change nephropathy(MCN). The antiserum against activated prorenin was raised in a rabbit by injecting the peptide fragment corresponding to the gate region of human prorenin. The antibodies for nephrin and CD34 were used as markers for podocyte and endothelial cells, respectively. Immunohistochemical analyses were performed by confocal microscopy.

We analyzed 19 renal biopsy specimens (n=8 IgAN, n=4 DN, n=7 MCN). Immunohistochemistry with the anti-(P)RR antibody showed positive immunostaining in mesangial area in 13 patients (n=5 IgAN, n=4 DN, n=4 MCN) and podocyte area in 12 patients (n=6 IgAN, n=4 DN, n=2 MCN). These were no significant staining for activated prorenin in endothelial cell in glomeruli. These findings indicate that activated prorenin is observed in mesangial area and podocyte, and the staining pattern may be different.

In conclusion, activated prorenin is expressed in mesangial area and podocyte in human kidney and may contribute to the pathophysiology of IgANand DN.

**Unusual Presentation of Lupus Nephritis** Bhavani Adusumilli. *Internal Medicine, William Beaumont Hospital, Royal Oak, MI.*

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease, characterized by multisystem involvement. SLE predominantly affects women in childbearing age . Late onset SLE represents a specific subgroup and the studies of elderly patients with SLE are scarce. We report a case of lupus nephritis with an unusual presentation.

A, 79 year-old, female with only history of hypertension was admitted to our hospital with complaints of progressive malaise and rash which started over the bridge of the nose, ears eyebrows and dorsum of hands and symmetric polyarthritis involving the small joints of the hands and wrists. The patient was well until 2 months before admission when she began having weakness and was found to have neutropenia and anemia. The patient was not on any drugs likely to cause drug-induced lupus. On examination, she appeared unwell. There was an erythematous plaque like rash involving the face and ears and crusted lesions on the lip. Neck was supple without adenopathy. Joint exam revealed definite synovitis of MCP and MTP joints as well as PIP joints. Labs, showed a white count of 1.7 BIL/L, hemoglobin of 8.6 mg/dl, with serum creatinine of 1.01mg/dl, anti DsDNA positive greater than 1000,ANA titer greater than 1:1280,low C3 and C4, with negative ANCA, SS-A and SS-B.A thorough infection screen, including a viral panel for Herpes Simplex, Herpes Zoster, Epstein-Barr, Cytomegalovirus, Hepatitis B, Hepatitis C, HIV, Echo and Coxsackie viruses was negative. Urine and blood cultures were negative. Urine analysis showed active sediments with protein /Creatinine ratio of 9.7.A percutaneous needle kidney biopsy was performed and was consistent with diffuse proliferative lupus nephritis (WHO type 4 LUPUS). The patient was initiated on high-dose corticosteroid therapy with plan to start CellCept once her WBC count improved.

Late onset SLE is rare and the course of the disease is considered to be more benign. Skin manifestations, photosensitivity , arthritis and nephritis occur rarely in elderly patients . But here we present a case of late onset lupus presenting with skin manifestations and nephritis.There is less clinical awareness of late-onset lupus, leading to a delay between onset and diagnosis.

**Tubulointersticial Fibrosis: Potential Mechanisms of Induction and Repair** Mirian A. Boim, Edgar Maquigussa, Luciana Guilhermino Pereira, Carine Prisco Arnoni. *Medicine - Renal Division, Federal University of São Paulo, São Paulo, São Paulo, Brazil.*

Increased glomerular protein filtration, tubular reabsorption and traffic may have direct toxic effects on epithelial cells, which increase the production of chemokines and profibrotic cytokines, such as the transforming growth factor-beta (TGF-β), the most potent inducer of the epithelial-mesenchymal transition (EMT). On the other hand, the bone morphogenetic protein-7 (BMP-7) plays a critical role in the repairing processes of the damaged tubular cells. The endogenous activity of BMP-7 is controlled by BMP antagonists, such as gremlin. Our objective was to evaluate the role of these proteins in the induction of EMT and the reversion of tubulointerstitial fibrosis using models, in vivo (puromicin-induced proteinuria in rats) and in vitro (immortalized human proximal tubular cells, HK-2). HK-2 cells were stimulated with TGF-β (1ng/ml) for up to 48 hours. Adult male Wistar rats were treated with puromycin (100mg/kg, ip) and after 10 weeks the renal function and proteinuria were evaluated. The expression of EMT marker molecules (α-SMA, E-cadherin and FSP1), fibronectin, collagen, TGF-β, BMP-7 and gremlin were estimated by real time PCR, Western blot and immunohistochemistry. HK-2 cells stimulated with TGF-β expressed α-SMA and fibronectin with decreased expression of E-cadherin indicating that the cells were in EMT process. Gremlin expression also increased in cells incubated with TGF-β, suggesting inhibition of BMPs. Puromycin caused severe proteinuria and tubulointerstitial fibrosis evidenced by increases in expression of fibronectin and collagen associated with increased expression of TGF-β, FSP-1 and α-SMA, indicating the presence of EMT also in the in vivo model. There was a rise in BMP-7 and gremlin expression suggesting that despite the activation of a repair mechanism (BMP-7) is probably inhibited by gremlin, facilitating the fibrogenesis. Future experiments will determine the role of BMP-7 and gremlin in the process of reversion of the EMT at the prospect of developing strategies to control the mechanisms of induction and likely the treatment of tubulointerstitial fibrosis.

**Epithelial-to-Mesenchymal Transition Contributes to Aristolochic Acid Nephropathy-Induced Tubulointerstitial Fibrosis** Annelies De Beuf,[1] Joelle L. Nortier,[2] Marc E. De Broe,[1] Patrick C. D'Haese.[1] *[1]Laboratory of Pathophysiology, University of Antwerp, Antwerp, Belgium; [2]Nephrology, Université Libre de Bruxelles, Brussels, Belgium.*

Aristolochic acid nephropathy (AAN), due to the use of traditional Chinese medicine and characterized by progressive renal dysfunction and tubulointerstitial fibrosis, has become a worldwide disease. Using a well validated mouse model of AAN, the present study aimed to (i) identify important mediators leading to renal fibrosis and (ii) check whether epithelial-to-mesenchymal transition (EMT) plays a role herein. Male CH3/He mice were administered AA (2.5 mg/kg/day) up to 10 days whilst a group receiving vehicle served as controls. Animals were sacrificed after 1, 2 and 4 days of treatment, and 1 and 20 days posttreatment. The expression of several genes involved in renal fibrosis and the regulation of EMT was investigated using quantitative real-time RT-PCR. In the acute phase after AA treatment, tubular necrosis was observed, whilst renal fibrosis characterized by

lymphocyte/macrophage infiltration, tubular atrophy and collagen deposition, started to develop later and was maximal 20 days posttreatment. TGF-β/Smad and Wnt/β-catenin are two major intracellular signaling pathways involved in the regulation of EMT. The gradually increase of TGF-β and β-catenin during the development of renal fibrosis reaching maximal increases of 10.6 fold and 2.9 fold respectively 20 days posttreatment was accompanied with increased Smad3 and Smad7 expression (3.5 fold). Interestingly, the mRNA expression of two downstream targets of TGF-β/Smad signaling, namely connective tissue growth factor (CTGF), an EMT related key mediator of fibrosis, and CCN3, a negative regulator of CTGF, was significantly increased (9.9 and 5.3 fold respectively). Finally, the development of AA-induced renal fibrosis went along with a marked upregulation of the EMT markers N-cadherin (5.1 fold) and vimentin (19.8 fold). Results of this study suggest a central role for EMT in the development of AA-induced renal fibrosis and the use of this model allows to identify early mechanisms initiating the fibrotic process and to evaluate the effect of anti-fibrotic compounds.

**Dexamethasone Stimulates Fibrogenic Proteins in Rat Mesangial Cells** Noritaka Kawada, Toshiki Moriyama, Harumi Kitamura, Yoshitsugu Obi, Jun-Ya Kaimori, Yoshitsugu Takabatake, Masaru Horio, Hiromi Rakugi, Yoshitaka Isaka. *Division of Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.*

Background. Recent investigations have established the beneficial role of steroid therapy on several glomerulonephritis, including Lupus nephritis, IgA nephropaty and ANCA associated nephritis. The administration of steroid has been shown to reduce tissue inflammation and promote tissue repair. However, steroid, in particular situation, promotes tissue fibrosis, which causes to limit the application of steroid therapy on advanced IgA nephritis. In the present study, we investigated the molecular mechanisms of steroid-induced renal glomerular fibrosis. Results. The administration of Dexamethasone (Dex, 10-6M for 6hrs) in cultured rat mesangial cells reduced the expression of Monocyte chemotactic protein-1 (MCP1) and TGFβ mRNAs (MCP1: -70%, p<0.01, TGFβ: -30%, p<0.05), but increased the expression of fibrogenic protein mRNAs, including Plasminogen activator inhibitor-1 (PAI-1: +130%, p<0.01) and Lysyl oxidase (LOX: +20%, p<0.05). The protein expression of PAI-1 and LOX were not affected by Dex at 6hrs, but significantly induced at 16hrs (PAI-1: +53%, p<0.01, LOX: +79%, p<0.01). The combined administration of Dex and TGFβ (2ng/ml) further induced PAI-1 protein (TGFβ+Dex: +230%)and mRNA (TGFβ: +190%, TGFβ+Dex: +640%) and LOX protein (TGFβ+Dex: +110%) and mRNA (TGFβ: +8%, TGFβ+Dex: +60%). Dex reduced the expression of BMP-1 mRNA (-20%, p<0.05) and the combined administration of TGFβ blunted this response (TGFβ: +3%, TGFβ+Dex: +1%), which may explain a part of the synergistic stimulatory effect of Dex and TGFβ on the LOX protein expression. Conclusions. Dex may enhance fibrosis under the presence of TGFβ partly through the induction of PAI-1 and LOX protein.

**The Effect of C3-C3a-C3aR on Renal Epithelial Mesenchymal Transition and Its Possible Mechanism** Fang Liu, Rong Gou, Jun Huang, Ping Fu. *Division of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

**Objective**: The aim of this study is to investigate the effect of C3-C3a-C3aR pathway on renal tubular epithelial mesenchymal transition (TEMT) and its possible mechanism.

**Methods:** Renal proximal tubular cell line HK-2 were cultured in vitro and divided into six groups: control group,TGF-β1 positive control group,10nM anaphylotoxin C3a group,50nM C3a group,100nM C3a and 50 nM C3a+1μM C3a receptor inhibitor(C3aR, SB290257)group. The expressions of E-cadherin, α-SMA, TGF-β1, CTGF, Col-Iand β-catenin were detected by immunohistochemistry, Western blot and real-time PCR. Scanning electron microscope (SEM) was used to observe the cellular morphological changes.

**Results:** Normal HK-2 cells showed the classic cobblestone shape, and SEM showed a loss of apical-basal polarity and microvilli of the cells after stimulated by C3a, and the cells become elongated and invasive. Immunohistochemistry, RT-PCR and Western blot showed that C3a induced the loss of the epithelial marker E-cadherin and increased the expressions of α-SMA, TGF-β1, CTGF, Col-Iand β-catenin in dose-dependent and time-dependent manners. And C3aRA could partly block the decrease of E-cadherin and increase of α-SMA and TGF-β1.

**Conclusions:** C3a could induce tubular epithelial-to-mesenchymal transition, TGF-β1, β-catenin pathway may participate in the mechanism. And C3aRA could partly block the effect of C3a on renal tubular cells. These findings identified a novel pathway that may contribute to renal fibrosis associated with the over-activation of complement in renal injury.

Disclosure of Financial Relationships: nothing to disclose

**C5a Regulates Tubular Epithelial-Myofibroblast Transdifferentiation *In Vitro*** Fang Liu, Jun Huang, Rong Gou, Ping Fu. *Division of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

**Objective**:

Growing evidences indicated that the activation of complement system was involved in the development of tubulointerstitial injury. But the mechanism is not fully understood. We hypothesize that complement induce the tubular epithelial-myofibroblast transdifferentiation (TEMT) during the tubulointerstitial fibrosis. This study was to investigate the effect of anaphylotoxin C5a on TEMT in vitro.

**Methods**: Renal proximal tubular cell line HK-2 were cultured in vitro and divided into six groups: control group,TGF-β1 positive control group,25nM anaphylotoxin C5a group,50nM C5a group and 25 nM C5a+2.5μM C5a receptor inhibitor group. The expressions of E-cadherin, α-SMA, TGF-β1, CTGF, Col-Iand β-catenin were detected by immunohistochemistry, Western blot and real-time PCR. And scanning electron microscope (SEM) was used to observe the cellular morphological changes.

**Results:** Normal HK-2 cells showed the classic cobblestone shape, and SEM showed a loss of apical-basal polarity and microvilli of the cells stimulated by C5a, and the cells become elongated and invasive. Immunohistochemistry, RT-PCR and Western blot showed that C5a induced the loss of the epithelial marker E-cadherin and increased the expressions of α-SMA, TGF-β1, CTGF, Col-Iand β-catenin in dose-dependent and time-dependent manners. And C5aRA could partly block the decrease of E-cadherin and increase of α-SMA and TGF-β1.

**Conclusion:** C5a could induce TEMT. TGF-β1, β-catenin pathway may participate in the mechanism. And C5aRA could partly block the effect of C5a on renal tubular cells. These findings identified a novel pathway that may contribute to renal fibrosis associated with the over-activation of complement in renal injury.

**PUB645**

**Endothelial Lineage Impairment and Increased PR3 Expression on Peripheral Cells of Endothelial Phenotype in Wegener´s Granulomatosis** Susann Patschan, Daniel Patschan, Johannes Wessels, Sabine Blaschke, Gerhard A. Mueller. *Department of Nephrology and Rheumatology, University Hospital Göttingen, Göttingen, Niedersachsen, Germany.*

Wegener´s Granulomatosis (WG) is characterized by microvascular endothelial damage and alterations of the endothelial progenitor cell (EPC) system. Interactions between anti-Proteinase 3 antibodies and their antigens (PR3) on neutrophils are pathogenetically relevant in WG. Aim of this study was (I) to analyze total circulating EPCs and regenerative activity of blood-derived EPCs, and (II) to evaluate PR3 expression on circulating myelomonocytic and endothelial cells in WG.

Blood samples from WG patients were analyzed for total and for Flk-1$^+$ myelomonocytic cells. Healthy donors served as controls. For evaluating the proliferative activity of EPCs, a colony forming unit assay (CFU) was performed. PR3 expression by the cells was quantified by cytometric analysis. Serum Angiopoietin 1 was measured by ELISA technique.

A total of 21 healthy donors (12 female, 9 male [40.3 ±9.2 years]) and 31 WG patients (13 female, 18 male [59.2 ±15.3 years]) were included into the study. The total percentages of EPCs were not different between the two groups. WG patients displayed lower proliferate activity of EPCs (22.3 ±4.1 vs. 45.9 ±6.8, CFU-ECs, p=0.0027). In addition PR3 expression was significantly higher in the total as well as in the Flk-1+ (sub)population of myelomonocytic cells in WG (10.4 ±14.4% vs. 0.3 ±0.4%, p=0.02 bzw. 0.3 ±0.3% vs. 0.1 ±0.1%, p=0.04). Finally, WG patients showed lower serum levels of Angiopoietin 1 as compared to controls (689 ±224 pg/ml vs. 1542 ±315 pg/ml, p=0.034), the levels did not linearily correlate with either clinical activity or the total number of circulating EPCs or the numbers of colonies formed (EPC regeneration).

In addition to reduced EPC regeneration and decreased levels of Angiopoietin 1, both indicating impairement of the endothelial system, patients with WG show significantly increased expression of PR3 in the total and in the Flk-1$^+$ myelomonocytic cell population. Thus PR3 could be involved in the pathogenesis of microvascular endothelial damage in patients with WG.

**Association between Renal Tubular Expression of Alpha Five Integrin and Kidney Failure** Kathryn I. Scobie, Daniel A. Muruve, Rick Chin, Kiril Trpkov, Wenjie Wang, Brenda Hemmelgarn. *Nephrology, University of Calgary, Calgary, AB, Canada.*

Chronic kidney disease involves deposition of extracellular matrix and tubulointerstitial fibrosis. Integrins are heterodimeric cell surface proteins that mediate cell-extracellular matrix interactions, cell-cell interaction and adhesion. The α5-integrin subunit is the major fibronectin binding protein and its expression is induced on tubular epithelium during injurious conditions. The purpose of this study was to determine the relationship between tubular epithelial α5-integrin expression in kidney biopsies and risk of kidney failure.

A convenience sample of 158 frozen kidney biopsies from non diabetic patients from our institution were stained for α5-integrin using immunohistochemistry. Of these biopsies 55 did not have adequate tubular epithelial cells and were excluded from the study, for a final study population of 103 subjects. α5-integrin was evaluated by one reviewer and categorized as present (at least 25% of cells within one tubule stained positive) or absent. Patients were followed for a mean of 15.8 months for the primary outcome of development of kidney

failure (a composite of doubling of serum creatinine, end-stage renal disease or death).

Of the 103 biopsies 66 (64.1%) stained positive for α5-integrin. During follow-up 7.8% of patients had a doubling of serum creatinine, 12.6% developed ESRD, and 3.9% died. After adjusting for age, gender, baseline eGFR, diabetes and hypertension, the presence of α5-integrin staining was associated with an almost six-fold increased risk of kidney failure (Odds Ratio 5.9 (CI 1.1 - 30.5; p = 0.036). Our study is limited by its single location and small sample size.

We found a significant association between α5-integrin and development of kidney failure. Further studies are required to confirm these results, and determine the degree of α5-integrin expression which confers an increased risk of adverse clinical outcomes.

**CD248 Positive Stromal Cells Are Linked to Determinants of Progressive Chronic Kidney Disease in IgA Nephropathy** Stuart W. Smith,[1] Joel Ogunka Nwosu,[2] Alexander J. Howie,[3] Clare Isacke,[4] Christopher D. Buckley,[1] Caroline O. S. Savage.[1] *[1]Institute of Biomedical Research, University of Birmingham, United Kingdom; [2]University Hospital Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [3]Department of Pathology, University College London, United Kingdom; [4]Breakthrough Breast Cancer Research, The Institute of Cancer Research, United Kingdom.*

CD248 is a stromal marker that is expressed on fibroblasts and pericytes found in the human kidney. Expression is low in normal tissue but becomes upregulated at times of tissue remodelling. We therefore hypothesised that CD248 expression is upregulated in chronic kidney disease(CKD).

Methods: Renal cell populations were isolated from human kidney. CD248 expression was assessed using confocal microscopy, RT-PCR and Western blotting. CD248 expression was characterized in kidney biopsy samples taken from patients with IgA nephropathy using immunohistochemistry(n=93). CD248 staining was quantified using an image analysis system. The extent of chronic renal damage within each biopsy was assessed. CD248 expression was correlated against albuminuria, eGFR and chronic renal damage. Patients were followed up for 1095 days following diagnosis. Confocal microscopy was employed to localise CD248, alpha-smooth muscle actin(αSMA) and Fibroblast specific protein-1(FSP-1).

Results: CD248 was expressed by renal fibroblasts but not by other renal cell populations. CD248 localised to the peritubular and interstitial space in CKD. Expression correlated with albuminuria(0.500; p<0.0000), chronic renal damage (0.539;p<0.0000) and eGFR(-0.679; p<0.0000). This relationship was maintained in a multivariate analysis. In total 19 patients reached a renal endpoint(7 patients doubled their serum creatinine; 12 patients reached end-stage renal failure). Interstitial CD248 staining >9.8% was predictive of poorer renal outcome($\chi 2$=18.28, P=0.0001). Immunofluorescence failed to co-localise CD248 with αSMA or FSP-1.

Conclusion: CD248 defines a subset of renal fibroblasts that are linked to albuminuria and chronic renal damage and may be implicated in the tissue remodelling seen in IgA nephropathy.

Disclosure of Financial Relationships: nothing to disclose

**PUB648**

**Detection and Localization of Advanced Glycation End-Products (AGEs) in Diabetic Kidneys by Raman Microscopy** Vincent Vuiblet,[1] Olivier Piot,[2] Philippe Gillery,[3] Laure-Helene Noel,[5] Michel Manfait,[2] Philippe Birembaut,[4] Philippe Rieu.[1] *[1]Nephrology, University Hospital, Reims, France; [2]UMR 6237, CNRS, Reims, France; [3]Biochemistry Department, University Hospital, Reims, France; [4]Anapathomo-Pathology Department, University Hospital, Reims, France; [5]Unit 507, INSERM, Paris, France.*

While the biochemistry of Advanced Glycation End-Products (AGEs) is rather well defined, the clinical implication of the accumulation of these substances during diabetes and uremia still remains largely unknown. The difficulty to analyse AGEs in tissues is a major limitation to study the role of these pathogenic agents. We therefore investigated the potential of Raman microscopy to identify AGEs in tissues.

Methods: Raman signal of pure carboxymethyllysine (CML) and pentosidine were first obtained for reference. Raman spectral images acquired from renal biopsies of diabetic and non diabetic patients were examined to find out the AGE spectral "fingerprints". Tissue spectral imaging obtained by Raman spectroscopy were then compared with CML- and pentosidine-immunohistochimical staining of the same tissues.

Results: Raman signal of CML and pentosidine showed characteristic spectral "fingerprints" which were also found among the spectral images of diabetic kidneys but not in control kidneys. The tissue localisation of CML and pentosidine obtained by Raman spectroscopy were identical to the results found by immunolocalization.

Conclusion : In this work, we show that the Raman spectroscopy microsopy can detect and localize AGEs in tissues. With further development, this Raman-based approach has the potential for non-invasive examination of AGE adducts in living tissues and ultimately to assess their precise pathogenic role in diabetes-, age- and uremia-related diseases.

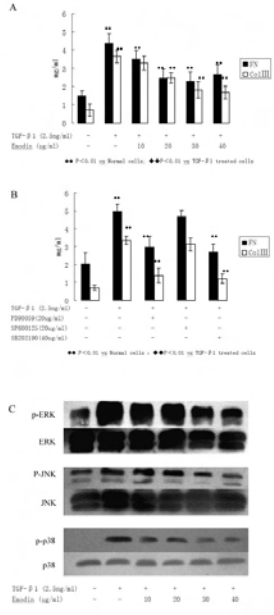
**PUB649**

**Emodin Inhibits ECM Synthesis by Repressing p38 and ERK1/2 in TGF-β1 Stimultated NRK-49F Cells** Bin Zhu, Caifeng Zhu, Yongjun Wang, Ying Lu. *Nephrology, Hangzhou Hospital of Traditional Chinese Medicine (Guangxing Hospital), Zhejiang Chinese Medical University, Hangzhou, Zhejiang, China.*

Objective: To observe the effects of emodin on synthesis of extracellular matrix (ECM) in TGF-β1 stimultated NRK-49F cells.

Methods: NRK-49F were divided into normal control cells; TGF-β1 treated cells and emodin (low, median and high concentration) interfered cells treated with TGF-β1; PD98059, SB202190 and SP600125 were adopted to inhibit ERK1/2, p38 and JNK respectively. Enzyme linked immunosorbent assay (elisa) was performed to detect the secrection of fibronectin (FN) and collagen III in supernatant of cells. Western blot was employed to analyze the phosphorylation of ERK, JNK and P38 respectively .

Results: FN, Collagen III as well as phosphorylation of ERK, P38 were increased in NRK-49F cells stimulated with TGF-β1 as compared with control cells(Fig.1.A); Pretreatment with emodin repressed the expression of FN and Collagen type III in a dose dependent manner in TGF-β1 treated cell(Fig.1.A). PD98059 or SB202190 but not PD98059 significantly attenuated the expression of FN and Collagen type III in TGF-β1 treated cells(Fig.1.B). Emodin also inhibited the phosphorylation of ERK and P38 significantly,but it decreased JNK phosphorylation without significant difference as compared with cells treated with TGF-β1(Fig.1.C).



Conclusions: Emodin inhibits ECM Synthesis by repressing p38 and ERK1/2 but not JNK in TGF-β1 stimultated NRK-49F cells.

Disclosure of Financial Relationships: nothing to disclose

**PUB650**

**Obesity in Patients with Chronic Kidney Disease on Hemodialysis** Bárbara Margareth Menardi Biavo,[2] Clarissa B. B. Uezima,[1] Mary E. C. Costa,[1] Camila Machado de Barros,[2] João Paulo L. B. Martins,[1] Elzo R. Junior,[2] Elvino Barros,[3] Carmen B. Tzanno-Martins.[1] *[1]Integrated Center of Nephrology, Guarulhos, São Paulo, Brazil; [2]Home Dialysis Center, São Paulo, São Paulo, Brazil; [3]Federal University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil.*

**Objective:** To determine the number of overweight and obese patients undergoing hemodialysis and verify their relationship to socio-demographic and clinical aspects.

**Methodology:** Cross-sectional study with 464 patients during the month of January 2010. Demographic, clinical and anthropometric data were recorded.

**Results:** Of 464 patients evaluated, 279 (60.1%) were male and 185 were female (39.9%). Patients' mean age was 54.25 ± 15.07 years and the highest prevalence was eutrophic patients (55.6%), followed by overweighed (24.83%), obese (9.9%) and malnourished (9.67%). Given only the obese, we found that the majority are male (62.2%), data that differs from the general population in Brazil. In this population, differences in obesity prevalence between the genres are not observed. For the total sample of patients studied, 153 (32.97%) were diabetics, a higher percentage than that found by the census of the Brazilian Society of Nephrology (SBN - 2008). Of these 32.7% (50/153) were overweighed and 15.03% (20/153) were obese. Assessing the elderly, who account for 23.28% (108/464) of the study population, half have diabetes (54/108). Comparing the elderly patients group with non-diabetics, we observed a higher prevalence of overweight and obesity in the first group - 50% (27/54), while the second group was 25.9% (14/54) of these elderly in these BMI strata.

**Conclusion:** These results demonstrate the relationship of overweight and obesity with DM and aging, both risk factors for the development of CKD. Furthermore, the coincidence of diabetes and CKD with modifiable risk factors (obesity, sedentary lifestyle, poor

dietary habits) increases morbidity and mortality in these patients. Therefore, assessment of nutritional status is important for an adequate clinical and nutritional intervention, in order to help reduce these rates.

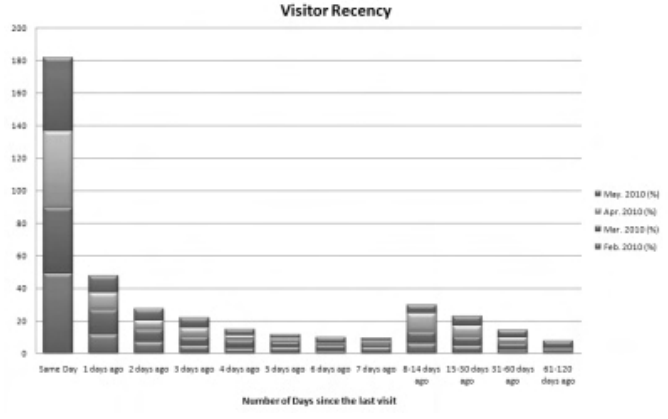
**Measuring User Interaction with a Nephrology Teaching Resource: Developing a Technologically Advanced Online Teaching Tool** Tejas P. Desai,[1] Cynthia R. Christiano,[1] Paul Bolin, Jr.,[1] Maria E. Ferris.[2] *[1]Medicine, ECU, Greenville, NC; [2]Pediatrics, UNC, Chapel Hill, NC.*

A number of online medical resources do not assess users' level of engagement. Without this information, online teaching tools will not be competitive or successful. We hypothesize that a technologically advanced website will yield, objectively, high user engagement.

Nephrology On-Demand (http://www.nephrologyondemand.org) is a multimedia teaching resource created on the Wordpress platform with direct hyperlink text items, slides available through Slideshare.net, and videos produced through Camtasia Studio 6 and stored on internal servers or YouTube.com. Google Analytics code was inserted into root files and captured data measuring user interaction from February to May 2010. We measured absolute unique visitors and location, duration of visits, visitor loyalty and frequency, and search patterns. Registration is voluntary.

2390 visitors (64 registered) from 84 countries made 3440 visits and viewed 8680 pages. The mean number of page views per visit was 2.59 (SD 0.34) with 61% from new visits. For return users, 47% had visited Nephrology On-Demand 7 times or more; 27% used the site 15 times or more. Many users performed same day returns.



Eighty-seven percent of visitors required 5 pageviews or less to find the desired information. The mean number of minutes required to find the desired information was 2:10 (SD 0:14).

Nephrology On-Demand has an increasing number of visitors who return to the site frequently. Users appear to find desired information with minimal clicks and time. These data suggest users are engaged with the teaching resources available on this website. Future efforts will involve measures to improve the low rate of voluntary registration and evaluations of usability and customer feedback.

**Washington University George M O'Brien Center for Kidney Disease Research** Marc R. Hammerman. *Internal Medicine, Nephrology, Washington University School of Medicine, St. Louis, MO.*

The overarching mission of the Washington University (WU) George M. O'Brien Center for Kidney Disease Research (CKDR) (P30 DK079333) is to support investigations designed to gain a better understanding of the way the kidney develops, including the role that particular genes play in the structure and function of the organ and thereby determine how abnormalities in genes and their expression increase an individual's risk of developing kidney disease. The Renal Organogenesis Core focuses on providing researchers access to tissues destined to become kidneys or endocrine pancreas from animal embryos and access to technology designed to transplant such tissues into adult animals as a tool to study kidney development, as a possible technique for replacing damaged kidneys in humans, or developing a viable treatment for diabetes, the major cause of ESRD. The Renal Disease Models Core and imaging center concentrates its efforts on developing transgenic or non-transgenic disease models of kidney disease in mice and rats and evaluating how particular genes and their expression affect kidney development and function. The Kidney Translational Research Core provides access to an established database of biological samples donated with the consent of kidney transplant patients and is expanding the database to include all patients with kidney disease who are treated at WU, St. Louis Children's Hospital and St. Louis University Hospitals. The database contains tissue, blood and DNA samples, which are made available to researchers studying abnormalities in gene expression that occur in kidney disease. Four pilot and Feasibility projects are supported through an Administrative Core. Proceedings of state-of-the-art conferences by invited speakers are published quarterly in the journal *Organogenesis*, as the WU CKDR sponsored Organogenesis Forum. The WUCKDR invites the participation of any qualified investigator. More detailed descriptions of Cores and applications are available on its website: http://renal.wustl.edu/OBRC.html.

**Feasibility Studies for Delivering Renvela® (Sevelamer Carbonate) for Oral Suspension Using a Feeding Tube** Chris Y. Ho, Abizer Harianawala, Martin Hanus, Suchitra Venugopal, Sunita Goyal, Hitesh Bhagat. *Drug and Biomaterial R&D, Genzyme Corporation, Waltham, MA.*

Purpose: To demonstrate that Renvela® for oral suspension can be administered to patients using a feeding tube. Sevelamer carbonate is a polymeric amine that binds phosphate and is indicated for the control of serum phosphorus in patients with chronic kidney disease on dialysis. Sevelamer carbonate is hygroscopic but insoluble in water.

Methods: The commercially available feeding tubes ranging from 3.5FR (opening)/58 cm length to 18FR/ 122 cm length composed of silicone, polyurethane or polyvinyl chloride (PVC) were selected for evaluation. To simulate the worst case scenario, for losses in delivery, 0.2 gm dose was used. For clogging studies, a high dose of 2.4 gm was used. The delivered drug was quantitated by using a total titratable amines procedure. The clogging end point was based on the inability of the Renvela® suspension to be delivered from the feeding tube.

Results: Clogging was observed with feeding tubes that had very small openings of 3.5 FR or were very long with length of 125 cm. Acceptable drug delivery (90 to 110% of target dose, with less than 6% RSD) was obtained with all of the feeding tubes that did not clog.

Conclusion: Sevelamer carbonate for oral suspension ranging from 0.2 gm to 2.4 gm dose can be delivered accurately using commercially available feeding tubes.

Disclosure of Financial Relationships: nothing to disclose

**PUB654**

**Investigation of Dose Dividing Techniques for Renvela® (Sevelamer Carbonate) for Oral Suspension 2.4 gm** Chris Y. Ho, Abizer Harianawala, Suchitra Venugopal, Martin Hanus, Sunita Goyal, Hitesh Bhagat. *Drug and Biomaterial R&D, Genzyme Corporation, Waltham, MA.*

Purpose: To develop dose dividing techniques for Renvela 2.4 gm packet using dosing options available over-the-counter.

Background: Each 2.4 gm packet of Renvela® powder contains 2.4 gm of sevelamer carbonate active moiety, which is a non-absorbed, phosphate binding, cross linked polymer. Sevelamer carbonate is indicated for the control of serum phosphorus in patients with chronic kidney disease on dialysis.

Methods: Two different dose dividing techniques were developed using either an oral syringe or a graduated dosing spoon. For the method using an oral syringe, an entire packet of Renvela® powder containing 2.4 gm of sevelamer carbonate was transferred to a cup. Sixty ml of water, measured by a 30 ml or 60 ml oral syringe, was added into the cup to form a suspension. Using the same syringe, 20 ml or 40 ml of the suspension was withdrawn to provide 0.8 gm or 1.6 gm of sevelamer carbonate for dosing, respectively. The remaining sevelamer carbonate suspension was discarded. For the method using a 10 ml over-the-counter graduated dosing spoon, Renvela® powder was poured into the dosing spoon to a specific volume, 2 ml for 0.8 gm and 4 ml for 1.6 gm of sevelamer carbonate. The measured powder was then transferred into a cup, hydrated with water for 5 minutes to form a suspension for dosing. The divided doses obtained by both methods were analyzed *in vitro* for reproducibility and average dose delivered.

Results: Both dose dividing techniques delivered results of 90 to 110% with acceptable % relative standard derivation (RSD) showing that both techniques deliver accurate quantity of sevelamer carbonate from a 2.4 gm Renvela® packet.

Conclusion: Two dose dividing techniques were developed using an oral syringe and graduated dosing spoon available at the pharmacy. *In vitro* testing confirmed that 0.8 gm and 1.6 gm of sevelamer carbonate powder could be dispensed accurately. These practical dose dividing techniques can provide flexibility for clinicians to administer 0.8 gm or 1.6 gm of sevelamer carbonate from a 2.4 gm Renvela® packet.

**Nephronpower and the Online Transplant Center; Blogging as an Educational Tool** Kenar D. Jhaveri. *Nephrology, North Shore/LIJ & Hofstra Medical School, Great Neck, NY.*

To help aid the educational material at the disposal to renal fellows in training and transplant physicians in training, I have created two web based teaching tools (blogs).

The first is www.nephronpower.com

The blog focuses on all aspects of nephrology and covers topics from history of nephrology to basic science to quizzes and puzzles. The point is to make short and easy to read blog posts to get the point across. There are several sections:

In the news: which discuss a recent publication of interest with a brief synopsis;

Topic discussion: a specific topic that is discussed in slightly more detail;

Consult rounds: a case based discussion of a specific question; Journal Club: A peer reviewed article that is of interest being discussed.;

Educational material such as quizzes and board type review questions also appear on it to make it a more interactive teaching tool. The entries are entered by faculty and fellows based on interesting topics being discussed in core lectures, consult cases or personal experiences.

The second blog is www.onlinetransplantcenter.blogspot.com ; a specific tool for transplant physicians with a similar educational focus but centered more around the field of transplantation medicine and surgery. There are numerous contributors in this blog from multiple institutions and allows for an educational dialogue of basic science to clinical topics.

These blogs were implemented less than a year ago and there are already 151 blog posts on nephronpower and 51 on the onlinetransplantcenter.

A site-meter reading on nephronpower shows that in the last few months, the average visits have increased from 100/month to 1500/month and the time spent per visit is on average 4 minutes. The world map depicts visitors from all continents visiting this site regularly.

I believe that tools like these allow fellows to actively learn and faculty to actively teach in a more creative manner. Links to other popular blogs that are internal medicine and nephrology related enhance the website and allow for cross transfer of knowledge.

Disclosure of Financial Relationships: nothing to disclose

## PUB656

**CROWNWeb – Expanding CPM Collections** Matthew J. Mcdonough. *Renal Requirements Communications and Training, FMQAI - The Florida ESRD Network, Tampa, FL.*

CROWNWeb software application is a mandatory-use ESRD data collection application developed by CMS for all Medicare-certified dialysis facilities.

The Centers for Medicare & Medicaid Service (CMS) will use the CROWNWeb data-collection system to provide the renal community information to help better gauge their facility's performance and patient outcomes by utilizing the system to collect an expanded list of clinical performance Measures (CPMs) including new CPMS related to patients' infections, medication allergies, and hospitalizations.

CROWNWeb currently collects data for the 26 CPMs adopted by CMS on April 1, 2008 to monitor the quality of care dialysis facilities administer to ESRD patients, and will utilize the new CPMs to help determine if these factors might impact a patient's course of treatment.

**Elements of the New CPMs**

Over 112 new CPM data elements have been created for data entry in CROWNWeb. Of those, 69 are mandatory for use in the future CPMs.

**Infections**

Twenty-Five (25) measures will be collected in CROWNWeb. These measures include, but are not limited to: the patient's dialysis access infection type, the source of vascular infection, and the date antibiotics were prescribed.

**Medication Allergies**

CROWNWeb will use over 31 new elements and measures to help report a patient's medication allergies. These refer to the possible Erythropoiesis Stimulating Agent (ESA), iron, vitamin D, etc. to which a dialysis patient may be allergic (i.e. Epoetin Alfa, Calcijex, Zemplar, etc.).

**Hospitalizations**

Fifteen (15) hospitalization attributes will be collected in CROWNWeb, including: the name of the hospital at which the patient was admitted, the hospital discharge date, and the hospital admission date.

**CROWNWeb Release Schedule**

CROWNWeb's second release is scheduled for January 2011. With the beginning of the expanded bundle and the impending national release of CROWNWeb, it is essential for Medicare-certified dialysis facilities to understand the scope of the project and the various gauges by which CMS will monitor facility performance.

## PUB657

**Prospective Evaluation for Treatment Compliance with Phosphate Binding Agents in Patients on Haemodialysis (HD): Preliminary Results of COMQUELFOS Study** Rafael Perez-Garcia,[1] Dolores Arenas,[2] Ana Blanco,[3] O. Reatiga,[4] M. C. Prados,[5] F. Rios,[6] Jose L. Lerma.[7] *[1]H Infanta Leonor; [2]H Perpetuo Socorro; [3]Dialcentro FMC Madrid; [4]FMC Reus; [5]H Torrecardenas; [6]FMC San Luciano; [7]H Salamanca.*

Introduction: The efficacy of phosphate binders (PB) is directly related with the treatment compliance (TC). Knobel and al. evaluated the Simplified Medication Adherence Questionnaire (SMAQ)[1]. With the criteria of TC and SMAQ, we evaluate the adherence of the patients on HD to PB treatment.

Methods: 288 patients were included in this multicenter, open-label trial, who met the indication for PB treatment. The patients had a basal phosphate (P) levels ≥5.5 mg/dl. It was considered "adherent treatment patients' those that had TC>75%, positive SMAQ and P≤ 5 mg/dl in the following visits (5 months). The therapeutic strategy to improve the adherence was studied.

Results: 105 patients were analyzed (62♂-43♀) with a means age and P were respectively; 61.3 (23-87) years and 6.3 (5.4-10.2) mg/dl. 56 patients (53.3%) were considered non adherent to treatment and continued at subsequent visits. The most common strategies to improve the adherence were: to insist in the compliance (51.4%), change to other PB (35.5%) and to increase the dose (15.9%). Finally, 85.2% of the total patients (56) were adherent. Table1 show, the PB used in these patients.

| Phosphato Binders (PB) | Non adherent patients' (Basal visit) (n=56) | Adherent patients' (5 months)(n=24)* |
|---|---|---|
| | Nº PB / % | Nº PB / % |
| Mean of P (mg/dl) | 6.3 | 4.9 |
| Calcium-based | | |
| Calcium Carbonate | 18 / 24.6% | 7 / 17.5% |
| Calcium Acetate | 7 / 9.6% | 2 / 5% |
| Non calcium-based | | |
| Lantanum carbonate | 17 / 23.2% | 14 / 35% |
| Sevelamer | 22 / 30.1% | 9 / 22.5% |
| Aluminum Hidroxide | 9 / 12.3% | 8 / 20% |
| Total | 73 / 100% | 40 / 100% |

*At the moment of the analysis only 27 completed patients were available.

Discussion: In these preliminary results, it could not possible to know the most efficacies therapeutic strategy to improve the adherence. At last visit, Lanthanum Carbonate was the most frequently PB used in the patients that achieve to become in adherent patients.

**Nutrition Education Program in Hemodialysis: Short and Long Term Impact on Hyperphosphataemia Control** Clarissa B. B. Uezima,[1] Bárbara Margareth Menardi Biavo,[2] Mary E. C. Costa,[1] Elzo R. Junior,[2] João Paulo L. B. Martins,[1] Elvino Barros,[3] Carmen B. Tzanno-Martins.[1] *[1]Integrated Center of Nephrology, Guarulhos, São Paulo, Brazil; [2]Home Dialysis Center, São Paulo, São Paulo, Brazil; [3]Federal University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil.*

**OBJECTIVE**

To evaluate the short and long term effect in the control of hyperphosphataemia of a nutrition education program performed with hemodialysis patients.

**METHODS**

In January 2009, a dietary intervention was conducted in hyperphosphataemia patients. Study participants were those who had, in the last three months, an average serum phosphorus ≥ 5.5 mg/dL.

In January 2010, the same activities were conducted with participants of the previous year that had showed increased serum phosphorus levels. Concomitantly, the demographic and laboratory parameters were reevaluated.

**RESULTS**

In 2009, 86 patients with hyperphosphatemia participated in the nutritional intervention. Of these, 10 currently are no longer in the clinic due to transfer to another center, transplant or death.

In 2010, 41 (54%) of 76 patients who participated in the first intervention phase showed increased serum levels of phosphorus and they were subjected to educational activities again. The other 35 (46%) had levels of this mineral within normal limits. Both groups make use of phosphate binder.

After the nutritional intervention, a decrease in serum phosphorus was observed from 6.8 ± 0.90 to 5.9 ± 1.35 mg/dL; P <0.001.

Regarding nutritional status, the average BMI of this population was 23.7 ± 3.9 kg/m².

Urea and albumin levels were stable before and after intervention and Kt/V increased (1.2 ± 0.30 to 1.4 ± 0.50 P 0.004).

After the educational plan, there was a decrease in the number of patients in precontemplation and relapse, and an increase in the action stage.

**CONCLUSION**

There is a known link between the attendance of patient groups who share the same problem and achieving positive results in programs to adopt proper eating habits. However, through this study, it was observed that these group activities should be carried out more frequently to ensure compliance to the dietary guidelines in the long run.

## PUB659

**Variables Associated with CMV Infections after Kidney Transplantation** Willy Aasebo,[1] Hallvard Holdaas.[2] *[1]Medical Depatment, Akershus Universtity Hospital, Lorenskog, Norway; [2]Medical Department, Oslo University Hospital, Rikshospitalet, Oslo, Norway.*

**Background**. Rejection episodes, recipient age and CMV IgG positive donors to CMV IgG negative recipients have been reported as risk factors for CMV infection after kidney transplantation. In this report associations between CMV infection and a wide variety of variables present at the time of transplantation (n = 32) and variables occurring during the first 10 weeks after transplantation (n = 10), were assessed.

**Methods**. All patients >18 years of age who received a kidney allograft in 2005, 2006 or 2007 were included (n = 593). The standard immunosuppressive protocol consisted of steroids, mycophenolate and CNI. Induction therapy with Basiliximab, in addition to lower doses of cyclosporine, was introduced in 2007. CMV-PCR was taken at least once a week during the first 10 weeks after transplantation. Odds ratio (OR) for CMV infection was explored with univarite and multivariate logistic regression. In the multivaiate regression variables from at transplantation and variables acquired during the first 10 weeks after transplantation were separated in analyses.

**Results**. In all 232 (39 %) had CMV infection. The following variables increased OR in univariate regression analysis: CMV IgG +/- (1.6, p = 0.022), recipient age (1.02, p = 0.0003), prophylactic antibiotics (1.8, p = 0.0006), living donor to deceased donor (1.5, p = 0.020), bacterial infections (1.5, p = 0.016), reoperation (1.8, p = 0.0072), rejection (2.7,

p <0.0001), the use of Cyclosporine (2.5, p <0.0001). The following variables decreased OR: Basiliximab induction therapy (0.6, p = 0.0002), use of immunosuppressants before Tx (0.5, p = 0.0007).

**Conclusion**. New variables associated with CMV infection were identified. Of special interest, and after multiple regression analyses, were: prophylactic antibiotics (OR: 1.4, p = 0.008), use of Cyclosporine (OR: 2.6, p <0.0001), Basiliximab (OR: 0.6, p = 0.002) and immunosuppressive treatment before Tx (OR: 0.5, p = 0.006).

**PUB660**

**Intra-Operative Ureteral Stents: An Overlooked Cause of Severe Proteinuria Following Kidney Transplantation** C. Afaneh,[1] D. Morrone,[2] David Serur,[2] M. Abreu-Goris,[1] Jun B. Lee,[2] Thangamani Muthukumar,[2] Choli Hartono,[2] D. Leeser,[1] S. Kapur,[1] Manikkam Suthanthiran,[2] Darshana Dadhania.[2] *[1]Transplant Surgery, Cornell Univ.; [2]Transplant Medicine, Cornell Univ.*

Post-transplant (txp) proteinuria is a commonly observed phenomenon. Nephrotic range proteinuria can be indicative of recurrent glomerulonephritis and necessitate early biopsy & intervention. Benign reversible causes of proteinuria are rare. However, encrustation of ureteral stents (US) has been associated with urinary protein excretion. It is of interest that US are commonly placed at the time of renal txp. In this study, we investigated the hypothesis that renal allograft recipients with US have increased levels of proteinuria in the early post-txp period & US removal is associated with prompt improvement in urinary protein excretion.

We retrospectively reviewed 19 renal allograft recipients who had US placed. Inclusion criteria was >2g/day of proteinuria in the early post-txp period. We compared proteinuria levels at 2 weeks (wks) post-txp with the US in place to proteinuria at 1 & 4 wks post-US removal.

The median proteinuria with US in place was 2.98 g/day (range 2.30-9.51) & was significantly reduced to 0.50 g/day 1 wk after US removal (P<0.0001) & remained low at 0.36 g/day 4 wks following removal (Fig.1A) The mean (±SE) serum creatinine (SCr) also significantly decreased from 2.19±0.15 mg/dL with US in place to 1.90±0.12 mg/dL at 1 wk & 1.75±0.11 mg/dL at 4 wks post removal (P<0.0001, Fig.1B). There was no correlation between SCr & level of proteinuria at 2 wks post-txp ($r_s$=0.19, P=0.43).

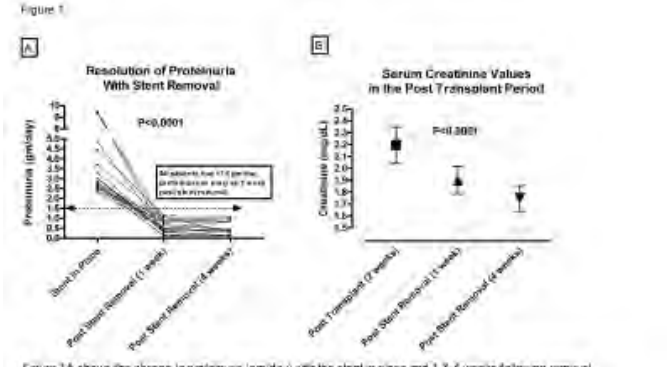

Figure 1A shows the change in proteinuria (gm/day) with the stent in place and 1 & 4 weeks following removal.
Figure 1B shows the mean and standard deviation of the serum creatinine (mg/dL) for the various time points.

Our findings demonstrate that US are associated with significant proteinuria in renal allograft recipients, and their removal is associated with prompt reduction in proteinuria. Thus, US appear to be a new and thus far unrecognized cause of significant proteinuria in renal allograft recipients.

**Incidence of BK Viruria in Renal Allograft Recipients with Hepatitis C and Its Correlation with Chronic Allograft Nephropathy** Sana R. Akbar,[1] Sadanand S. Palekar,[1] Sachin H. Sachdev,[1] Adeem Akbar.[2] *[1]Department of Nephrology and Renal And Pancreas Transplant, Newark Beth Israel Medical Center, Newark, NJ; [2]Internal Medicine, St. Luke's Hospital, Bethlehem, PA.*

INTRODUCTION: Chronic allograft nephropathy (CAN) is a major cause of renal allograft failure post renal transplantation. The purpose of our study was to look at patients with hepatitis C who are renal allograft recipients & to see the incidence of BK viruria in this cohort along with its association with CAN.

METHOD: We retrospectively reviewed charts of renal transplant recipients from 1995-2009 at our transplant center who were diagnosed with hepatitis C prior to transplantation. Primary outcome was overall incidence of BK viruria in patients with hepatitis C with renal allografts. Secondary outcome looked at the incidence of CAN in this cohort & presence of other viral infections. CAN was defined as per biopsy findings or creatinine ≥1.5mg/dL with proteinuria in those without a biopsy.

RESULTS: 38 patients with Hepatitis C between ages of 26-78 years were identified.81.6% were males. 9/38 (23.7%)had BK virus urine PCR > 10,000 copies, while 4 patients were not tested. Of 9/38 patients with BK viruria with Hepatitis C, 100% had CMV (IgG).Of these 5/9(55.6%)had CAN. Meanwhile 20/38 patients (52.6%)who had hepatitis C and CMV but no BK viruria, 35% had CAN. There were no cases of CAN in patients who had hepatitis C and BK viruria without CMV. 4/38 (10.5%) patients in this cohort had HIV & 2/4 (50%)had BK viruria & despite presence of hepatitis C & BK viruria did not develop CAN. Overall 15/38(39.5%) patients had CAN. 8/15 had biopsy proven CAN. Overall 3/38(7.9%) allografts were lost to CAN.

CONCLUSION: BK viruria incidence is not very high in renal allograft recipients with Hepatitis C, none the less renal transplant recipients with triple viral infections (hepatitis C, CMV, BK virus) have a much higher incidence with higher risk of CAN than those with dual infection with hepatitis C and CMV only. This also suggests that BK virus may be potentiating CAN in this cohort of patients who are already immunosuppressed & susceptible. The presence of HIV was not related to increased incidence of CAN.

**NGAL in Urinary Exosomes as a Source of Kidney Dysfunction Biomarker in Renal Transplantation** Andres Boltansky,[1] Sergio Alvarez,[1] Antonio Vukusich,[1] Margarita Hurtado,[1] Marcela Ursu,[1] Guilio Innocenti,[1] David Carvajal,[1] Cristian Suazo,[2] Sandra Villanueva,[2] Juan Carreno,[2] Rogelio Altuzarra,[2] Constanza Yen,[2] Denisse Tapia,[2] Carlos E. Irarrazabal.[2] *[1]Unidad de trasplante, Clinica Davila, Santiago, Chile; [2]Laboratory of Molecular Physiology, University of Los Andes, Santiago, Chile.*

The End Stage of Renal Disease (ESRD) require for its treatment of permanent dialysis or kidney transplantation (KT). The KT is the best clinical treatment; however, the early function of the allograft varies depending of multiple factors, associated with cold ischemia time (CIT) and the allograft rejection process. It is known that serum creatinine is a late marker for predicting graft recovery after kidney transplantation, mainly in patients with delayed graft function (DGF).

NGAL is produced in the distal nephron and it is one of the most promising novel biomarkers for acute kidney injury (AKI). NGAL has been proposed as a predictor of organ recovery from delayed graft function after kidney transplantation.

The exosomes are vesicles released into the urine from the kidney epithelium and it has been proposed as better source to explore biomarker of renal dysfunction. We propose that determination of NGAL in urinary exosomes is a better predictor of kidney dysfunction after KT than others urinary fractions.

We analyze 15 kidney-allograft recipients (16-60 years): 11 living (LD) and 4 deceased donors (DD). The average of CIT was 14 hours in DD and less than 1hr in LD. Three patient developed DGF. Using Western blot analysis NGAL was detectable from the first post operative day (POD) in cellular and exosomal fraction of the urine, but not in whole urine. The exosomes expressed higher levels of NGAL than cellular fraction. We noticed that NGAL expression in exosomas, but not in the cellular fraction, was elevated in the patients with DGF compared with non-DGF patients (p<0.05) from 1-3 POD and correlates with serum creatinine. This preliminary study suggests the exosomal fraction could be more sensitive substrate to evaluate early biomarkers of DGF after kidney transplantation.

**Synchronous Bronchogenic and Gastric Carcinoma in a Renal Transplant Recipient** Amarpali Brar,[1] Fasika M. Tedla,[1] Moro O. Salifu,[1] Dale Distant,[2] Syed I. Shah,[1] Gurinder S. Sidhu.[1] *[1]Medicine, SUNY Downstate Medical center, Brooklyn, NY; [2]Surgery, SUNY Downstate Medical Center, Brooklyn, NY.*

Solid organ transplant recipients (TR) are at increased risk of developing cancer; commonly Kaposi sarcoma and lymphomas. There are limited data to suggest increased risk of epithelial malignancies in TR.

A 60-year-old man with hypertension, diabetes, peripheral vascular disease, coronary artery disease and end stage renal disease underwent renal transplant 2 years prior to presenting with upper abdominal discomfort. He was an active smoker and had smoked for 100 pack years. He denied any family history of cancer. His physical exam at the time was remarkable only for obesity and left leg amputation. His medications included tacrolimus and prednisone. Upper gastrointestinal endoscopy showed a mass in the stomach and pathology revealed the diagnosis of gastric adenocarcinoma. Staging CT scan showed no evidence of metastatic disease in the liver or other parts of the abdomen, but a right upper lobe spiculated mass was found. Trans-thoracic needle biopsy of the lung mass showed a second malignancy- non-small cell lung cancer, TTF-1 positive. The lung cancer was morphologically distinct from the gastric cancer. Patient underwent gastrectomy and pathologic review showed adenocarcinoma of intestinal type with 4/8 nodes involved; T2b N1, TNM stage II. Subsequently he underwent right upper lobectomy with mediastinal and hilar lymph node sampling. The pathologic review showed squamous cell cancer and 0/8 nodes involved; TNM T2N0M0, Stage 1B. Patient did well after both surgeries and was then given adjuvant therapy for gastric cancer with 5-flourouracil and radiotherapy. One year after the initial diagnosis he continues to do well, and is disease free.

Unlike Kaposi sarcoma or lymphoma; epithelial malignancies are not known to be related to immunosuppressed state. This case illustrates a unique scenario with a patient on immunosuppressive therapy having developed two synchronous non-immunosuppression related cancers. The development of the two cancers in this case could be related to smoking. This case is the only known case of two synchronous primary cancers in a TR.

**Clinical Implications of Polyomavirus-Associated Nephropathy after Renal Transplantation** Helen P. Cathro,[1] Jason C. Gardenier,[2] Douglas Scott Keith,[3] Robert Sawyer,[2] Kenneth L. Brayman,[2] Hugo Bonatti.[2] *[1]Pathology, University of Virginia, Charlottesville, VA; [2]Surgery, University of Virginia, Charlottesville, VA; [3]Medicine, University of Virginia, Charlottesville, VA.*

BK virus nephropathy (BKVN) develops in ~5% of renal transplants (RT), causing graft loss in 15-80% of cases within 5 years. Most studies suggest that the majority of BKVN occurs during the first post-transplant (PT) year. We noticed an increasing number of cases of late-onset BKVN and conducted a retrospective study.

All renal specimens from patients with biopsy-proven BKVN from 2000-2009 at a single institution were reviewed.

Of 846 RT recipients, 18 had biopsy-proven BKVN (2.1%), 4 of whom had also received pancreatic transplants. The median age of 12 males and 6 females was 52.2 yr (range 27.9-63.8 yr), and the median time PT was 20.1 mn (range 3.2-80.4 mn), with only 4 or 22%, <1 yr out. Fourteen patients were on standard immunosuppression (IS). Screening for BK virus was erratically administered due to geographical/logistical constraints. Five patients had prior biopsy proven episodes of acute rejection and 13 patients (72%) had received intensive prior IS, usually for acute rejection (n=10) or for subsequent pancreas transplantation. Fourteen patients were treated with antiviral therapy, +/- IVIG, +/- IS taper, and single patients were treated with IVIG or IS taper alone. One patient died after returning to dialysis, and 17 were alive at an average of 3.4 yr follow up. Seven of these had returned to dialysis (41%), and 5 had a serum creatinine >2 mg/dL (29%). Only 5 patients had good graft function (29%).

Retrospective analysis of BKVN at a single institution during the current IS era demonstrated 78% of cases occurring after the first PT year, and 39% after the second PT year. Inconsistent screening and over-IS may be playing a role. The poor outcome of 72% of the BKVN cases is in part due to late diagnosis at a severe stage of disease. Late onset BKVN is an underrecognized cause of graft loss and dysfunction, and rigorous screening followed by tapering of IS on positive testing, should be emphasized beyond the first year post-transplantation.

**Expanded Criteria Donors and Histological Scoring: Impact on Graft Survival of Kidneys with Prolonged Ischemia and Delayed Graft Function** Carlos R. Chiurchiu,[1,2] Javier De Arteaga,[1,2] Verónica Riva,[3] Maria Virginia Burguesser,[3] Walter Guillermo Douthat,[1,2] Jorge Luis De la Fuente,[1,2] Ana Diller,[3] Pablo U. Massari.[1,2] *[1]Renal Transplant Program, Hospital Privado-Centro Medico de Cordoba, Cordoba, Argentina; [2]Postgraduate School of Nephrology, Catholic University of Cordoba, Cordoba, Argentina; [3]Pathology Service, Hospital Privado-Centro Medico de Cordoba, Cordoba, Argentina.*

The use of expanded donors or kidneys with preexisting chronic damage remains controversial but they offer the opportunity for donor pool expansion. We investigated the impact of these conditions as predictors of graft survival (GS) in a cohort of recipients with prolonged cold ischemia time (CIT) and high incidence of DGF.

Seventy consecutive cadaveric kidney allograft implanted between 2001 and 2005 with an early graft biopsy (mean 7.4 days post-Tx) were included in the study. All kidneys were preserved with Wilconsin and HTK solutions. Donor age was 40.4±15.6 y (37% >50 y), CIT: 22.2±9.6 hours, (median 20 hours, 41% >24 h), 63% with cerebrovascular accident, expanded donors 37%. DGF was present in 84% and oliguria was 13,5±12.5 days. Moderate-severe acute tubular necrosis was present in 71% of early biopsies; moderate histological scoring (MHS: 4-6) 63%, severe (SHS: ≥7) 27%, ideal (1-3) 0% and acute rejection 14,3%.

At 48 months GS was 73,3%, when stratified according MHS vs. SHS: 81% vs. 63% (p: n.s.), donor age (≤ 50 y vs. older): 89% vs 41% (p<0.002), cause of death (cerebrovascular vs. others) 62% vs. 92% (p<0.03), type of donor: (standard vs. expanded) 90% vs 41% (p<0.0003), CIT (>24 h vs rest) 73% vs. 74% (p:n.s.). Multivariate analysis for GS: SHS 1.23 (IC 95% 0.88-1.70, p<0.2), donor age 0.96 (IC 95% 0.87-1.05, p<0.4), death other cerebrovascular accident 0.43 (IC 95% 0.02-6.60, p< 0.5), standard donor 0.12 (IC 95% 0.01-0.87, p< 0.03), days of oliguria 1.02 (IC 95% 0.98-1.05, p< 0.3). Primary non-functioning kidneys were more frequent in expanded donors than standard (20.0 vs 0.0%, p<0.002)

Our results suggest that in allografts with prolonged ischemia and preexisting histological chronicity, only the presence of expanded criteria is a significant independent donor risk factor for graft outcomes.

**Deconvolution of the Molecular Mechanisms Underlying the Negative Effects of Calcineurin Inhibitors on the Kidney** Amanda E. Crunk,[1,2] Christopher J. Rivard,[2] Uwe Christians,[1] Jelena Klawitter.[1] *[1]Anesthesiology, University of Colorado Denver, Aurora, CO; [2]Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Modern immunosuppressive drug regimes have significantly increased the one year graft survival rate of kidney grafts, however chronic allograft dysfunction is still a serious problem. Immunosuppressant-mediated nephrotoxicity is one of the major limiting factors in terms of long-term survival. Calcineurin inhibitors (CNIs) like cyclosporine and tacrolimus are known to contribute to chronic allograft dysfunction. Even after 30 years of clinical use, surprisingly, the molecular mechanism of CNI nephrotoxicity is not yet fully understood. Despite the known risks of CNI use, most transplant patients today are still discharged with CNI-based immunosuppressive drug regimes. At an early stage, CNI seem to target proximal tubules, but the effects of CNIs on other regions of the kidney have never systematically been studied. The inner medulla of the kidney, containing the collecting duct cells, is under a significant amount of stress due to its function to concentrate urine and thus being exposed to very high tonicities. We hypothesize that these collecting duct cells are sensitive to CNIs since they require significant amounts of energy to survive in their environment, however, CNIs are known to derail energy metabolism. In order to test this hypothesis we exposed two rat cell lines, the immortalized rat proximal tubules (IRPTC) and the rat inner medullary collecting tubules (RIMCT), to various concentrations of tacrolimus and determined their survival using the Invitrogen Cyquant NF assay. The results showed that the collecting duct cells had an EC50 of 20 µg/ml and the proximal tubules cells had and an EC50 of 60 µg/ml. These data indicate that proximal tubules cells, and not the collecting duct cells, are more resistant to the effects of tacrolimus which is in contrast to histological observations. A systematic proteo-metabonomic approach has focused on the mechanisms of toxicity in RIMCT cells and the effect that CNI-induced endothelial dysfunction may have in sensitizing proximal tubules to CNI nephrotoxicity in vivo.

**Hypomagnesaemia after Renal Transplantation (R-TX)** Antonio Di Felice, Emiliana Ferramosca, Marialetizia Soverini, Benedetta Ferri, Antonio Santoro. *Division of Nephrology Dialysis and Hypertension, St. Orsola-Malpighi University Hospital, Bologna, Italy.*

**INTRODUCTION.** Hypomagnesaemia (Hypo-Mg) is an electrolyte disorder frequently present in R-TX, whose pathogenesis is unclear. It has been associated to a cyclosporine-related urine loss, but it can be induced by other drugs, like proton pump inhibitors (PPI), widely employed in gastric protection of R-TX. From the clinical point of view, H-Mg can determine arrhythmias, seizures, hypocalcemia; same experimental studies have suggested that Mg supplementation inhibits cyclosporin-induced chronic nephropathy in experimental animals. Aim of this study is to evaluate incidence of H-Mg after R-TX and its possible relationships with drug therapy.

**PATIENTS AND METHODS.** 96 renal transplanted patients have been studied, age 21-79 yrs; TX age 2-290 months. Creatinine was between 0.8 and 2.1 mg/dl. All patients were on immunosuppressive treatment with calcineurin inhibitors (CNIs), 62% cyclosporin (Cs-A) and 38 % tacrolimus (FK); 61 patients at least (74.4%) were on treatment with PPI.

**RESULTS**. Hypo-Mg was detected on 30 of the 96 examined patients (31.2%), age 56.6±12.6 years (31-76), age of TX 119.3±77.7 months (10-290). 17 of them (56.7%) were on Cs-A therapy (43.4%), and 13 (43.4%) with FK; 27 patients (90%) were on PPI therapy. Only one patient showed a high urinary excretion of Mg. In 10 patients Hypo-Mg persisted despite of oral supplementation. Serum creatinine was 1.34±0.46 mg/dl (0.81-2.36); CNI blood levels were all in therapeutic range.

**CONCLUSION**. 1) A significant incidence of Hypo-Mg after R-TX is confirmed. 2) Hypo-Mg does not appear to be determined exclusively by an elevated urinary loss, but other mechanisms have to be considered (altered abdominal absorption?). 3) Hypo-Mg is present both in Cs-A patients and in FK treated. 4) From the etio-pathogenic point of view, drug hypothesis seems to be relevant, particularly regarding PPI, as well as CNIs. It is therefore necessary to accurately evaluate the indication and the type of gastric protection in R-Tx. 5) More studies are needed to evaluate the possible impact of chronic Hypo-Mg on transplanted kidney long-term function.

**Swine Flu (H1N1) in a Liver and Kidney Transplant Patient: A Case Report** Remedios Garofano, Clara Moriana, Manuel Ángel Rodríguez, Mª Dolores Del Pino Pino, Ma del Carmen Prados Soler. *S. Nephrology, C. H. Torrecárdenas, Almería, Andalucía, Spain.*

INTRODUCTION

Swine flu (H1N1) is a new virus resulting from the association of RNA segments of the influenza virus of porcine, aviary and human origin. The incubation period is 1-7 days Contagion between persons occurs via the airway or by contact and is inactivated by desiccation, detergents, alcohol and bleach. Complications include decompensation of the underlying disease or development of viral pneumonia, with respiratory failure and acute respiratory distress syndrome.

CASE REPORT

An 17-year-old woman who received a liver and kidney transplant in June 06 and was being treated with tacrolimus, mycophenolate mofetil and steroids. She was referred to the hospital in July 09 with a diarrhea with mild anemia and leucopoenia and slight worsening of renal function. On admission, the dosage of MMF was reduced and the diarrhea ceased, coproculture and PCR-CMV were negative. The patient's status worsened progressively with onset of high fever, severe worsening of renal function with a plasma creatinine and moderate pancytopenia but with severe leucopoenia, requiring withdrawal of MMF and treatment with filgrastim, plus empiric antibiotic therapy. Blood and urine cultures were positive for E. coli. The infectious symptoms of urinary origin remitted with specific antibiotherapy, the fever ceased and the pancytopenia and renal function improved. Three days later she again had febrile peaks up to 40ºC, accompanied by irritative cough, myalgia and general malaise, compatible with pseudoinfluenza symptoms. PCR for influenza A was reported to be positive on the day the patient was discharged, fully recovered.

CONCLUSION

Since the start of the Swine flu pandemic in Mexico in March 2009, the prevalence of infection has continued to rise. The first confirmed case of Swine flu in Spain was in April 2009. Groups at risk include patients with mild-to-moderate kidney disease and transplant recipients. The most notable characteristics of our case were the early appearance and good evolution of the infection, with no relevant sequelae despite the presence of factors and complications that could give rise to it.

**Evaluation of Polyomavirus BK-Associated Nephropathy** Veronica M. Gonzales, Madeleine V. Pahl, Clarence E. Foster III, Renee R. Weng. *University of California, Irvine, Orange, CA.*

*Purpose.* To determine if proposed risk factors for developing polyomavirus BK-associated nephropathy (PVAN) from prior literature exist and what therapies were most effective at preventing graft deterioration in our transplant population. Prior studies have suggested that anti-thymocyte globulin induction, male gender, and deceased donor kidneys may predispose transplant recipients to develop PVAN.

*Methods.* A retrospective chart review was conducted of all renal transplant recipients who had a positive BK virus PCR from Jan. 1st, 2001 to Dec. 31st, 2009. Data collected include demographics, immunosuppression, serum creatinine, PVAN treatment, and renal biopsy results. Based on the identified risk factors and efficacy of treatment options, an evidence based guideline for the screening and management of PVAN will be developed.

*Results.* Twenty three patients were identified from 243 renal transplant recipients. The median time to the first detection of BK virus was 10 months post-transplant. In BK-positive patients, 61% received deceased donor kidneys compared to 72% in the overall transplant population. Basiliximab induction was more common in the positive BK virus group (65% versus 57%). A greater proportion of patients were male in the positive BK virus group (74% versus 62%). There was no association with age, BMI or ethnicity. Treatment of BK virus was reserved for the 16 patients who had viremia and consisted of reduction in immunosuppressive therapy. Eight patients received leflunomide in addition to immunosuppression reduction. Seven patients had BK virus first detected on biopsy and all of those patients progressed to graft dysfunction regardless of treatment.

*Conclusions:* Risk factors from prior studies did not always correlate in our transplant population. The greatest risk was among patients who were less than 12 months post transplant. Routine screening for BK virus allows for early intervention which is critical to treating BK virus and preserving graft function. Decreasing immunosuppressive therapy and the addition of leflunomide were beneficial to patients who were diagnosed early.

**Pandemic H1N1 Influenza A in Kidney Transplant Patients: Concerns on Clinical Management** Ana M. Gonzalez Rinne, Alejandra Alvarez, Patricia Delgado Mallen, Domingo Marrero, Lourdes Perez, Jose Gonzalez Posada. *Nephrology, Hospital Universitario Canarias, La Laguna, Tenerife, Spain.*

We studied the incidence, comorbidity and mortality of H1N1 influenza A in our renal transplant population from July to December 2009.

**Patients and methods:** Patients with influenza-like illness who seek medical assistance were tested to confirm diagnosis of pandemic H1N1 influenza A using real-time reverse transcriptase (rRT)-PCR from nasopharyngeal swabs. Prophylaxis with neuraminidase inhibitor (oseltamivir) was started at recommended doses at the begining of symptoms and mantained unless diagnosis was excluded. Only patients with expected complicated clinical course were admitted to Hospital.

**Results:** 12 (3,4%) out of 353 renal transplant patients followed in our center were diagnosed. Mean age was 42.9 years (19 to 69 years). Seven patients had associated comorbid illness and in most patients (75%) immunosuppression was based on combination therapy with prednisone, anticalcineurin inhibitor and mycophenolate. One patient got infected in the early post-transplant period (17 days), the remaining developed the infection in a later post-transplant stage (mean 82,3 months; 8 months to 17 years). Four (33%) cases showed a complicated evolution: one patient, in the early post-transplant period, heavily immunosuppressed for being highly sensitized, developed viral pneumonia with fatal outcome; two had superimposed bacterial infections which led to long hospital stay and in one patient with a severe acute rejection episode, concomitant H1N1 influenza A infection, delayed anti-rejection therapeutic strategy which contributed to graft loss.

**Conclusion:** Despite early treatment with antivirals, renal transplant patients are a population at high risk for serious complications in influenza epidemics. Special preventive strategies must be stressed in the early post-transplant period of highly sensitized (heavily immunossuppressed) patients.

**Clinical Relevance of Anti HLA Antibodies in Renal Transplantation in Living Donor Program: A Single Centre Study** Sanjay Gupta, Pranab Mahanta. *Nephrology, AIIMS, New Delhi, India.*

**Background:** Renal transplant recipients may develop de-novo anti HLA antibodies (HLA abs) that may lead to allograft dysfunction. Because of insufficient routine monitoring the exact incidence of humoral alloimmune responses during allograft dysfunction is still uncertain. Aim was to evaluate the clinical relevance of detection of de-novo HLA Abs during the episode of renal allograft dysfunction.

**Methods**: The study group consisted of 41 non HLA-identical living donor first renal transplant recipients (non-sensitized pre-transplant) with an episode of allograft dysfunction needing allograft biopsy. Anti-HLA class I antibodies (HLA-I Abs) and anti-HLA class II antibodies (HLA-II Abs) were tested by ELISA in study group and in the control group with stable graft function.

**Results**: Immunosuppressive regimen was in Tac/MMF/P in 17/41, Tac/Aza/P in 6/41, CsA/MMF/P in 10/41 and CsA/Aza/P in8/41. None received induction. Out of 41 allograft dysfunctions cases, acute cellular rejection (ACR) was seen in 10/41, C4d was positive in 2/10, Chronic rejection (CR) 9/41, Transplant glomerulopathy (TG) 4/41, Focal segmental glomerulosclerosis (FSGS) 7/41, Calcineurin Inhibitor toxicity (CNI) 8/41 and non specific changes 3/41. HLA-I Abs and HLA-II Abs were detected in 14/41 (34%) and 12/41 (29%) respectively. Ten cases had both Abs. Prevalence of HLA-I Abs was 70% in ACR, 44% in CR, 50% in TG, 14% in FSGS and nil in CNI and non specific histology. With HLA-I Abs, odd ratios (OR) for ACR was 8 [95% CI 1.4-157] and HLA-I Abs correlated negatively with CNI. Prevalence of HLA-II Abs was 50% in ACR, 44% in CR, 75% in TG and nil in FSGS, CNI and non specific histology. With HLA-II Abs, the OR for TG was 9 (95% CI 1.04-62.9). HLA-I Abs were present in 13/23 of immune mediated injury (ACR,CR,TG) vs 1/18 of non immune graft dysfunction (FSGS, CNI,non specific) with the OR for immune mediated graft dysfunction as 22 (95% CI 2.5-195).

**Conclusion**: Screening for HLA Abs during the episode of allograft dysfunctions discriminate between immune mediated rejection and non immune allograft dysfunction and help in tailoring immunosuppression. HLA Abs mediated allograft injury exists as a spectrum of renal injury.

**Secondary Hyperparathyroidism Due to Ectopic Gland** Clara Moriana, Manuel Ángel Rodríguez, Remedios Garofano, Ma del Carmen Prados Soler, Mª Dolores Del Pino Pino. *S. Nephrology, C. H. Torrecárdenas, Almería, Andalucía, Spain.*

INTRODUCTION:

Chronic kidney disease (CKD) is associated with a cascade of events with negative affects on bone and mineral metabolism. Successful renal transplantation normalizes most uremic disorders seen in patients on dialysis. The incidence of secondary hyperparathyroidism is of 30-50%

CASE REPORT:

The patient was a 64-year-old man with hypertension and CKD. He received a kidney transplant in January 96. In February 07 he was diagnosed with secondary hyperparathyroidism

Ultrasound and scintigraphy of the neck showed no pathological findings. Given the possibility of an ectopic gland the patient underwent a repeat scintigraphy with a thoraco-abdominal scan, again with no findings of note. Treatment of the hypercalcemia was started with cinacalcet up to two full doses of 180 mg/d and bisphosphonates. In December 08, faced with persistent high levels of calcium and intact parathyroid hormone (iPTH), the imaging tests were repeated (ultrasound and scintigraphy). The echogram showed a vascularized, hypoechoic nodule measuring 14x13x12 mm located in the posteroinferior part of the left thyroid lobe, which was reported as an enlarged parathyroid gland. In January 09 the patient underwent parathyroidectomy, no hyperplastic glands or adenomas were found. The hypercalcemia and high iPTH figures persisted, and a CT of the neck and chest showed an intrathoracic, ectopic parathyroid gland in the upper right paratracheal mediastinum, which was removed in July 09

The patient experienced severe worsening of renal function , severe hypocalcemia, anasarca, moderate-severe pericardial effusion, atrial fibrillation and dysphonía. The patient has now completely recovered

CONCLUSIONS:

Management of persistent hyperparathyroidism is an important therapeutic objective after renal transplantation. The cause is usually an occult adenoma, with an incidence of ectopic parathyroid glands of 6-25%, with 55% of these glands situated in the mediastinum. Preoperative scintgraphy with Technetium-99m-Sestamibi and CT can aid the surgeon plan the best initial surgical approach. The complications that can result from parathyroid surgery include hypocalcemia and adynamic bone disease

**Treatment of Recurrent FSGS Post Transplant with a Multi-Modal Approach Including High Galactose Diet and Oral Galactose Therapy** Tamim H. Naber,[1] Madhu C. Bhaskaran,[1] Xiaotong Wang,[3] Fouad Boctor,[3] Gregory P. Dilimetin,[5] Ernesto P. Molmenti,[4] Howard Trachtman,[2] Kenar D. Jhaveri.[1] *[1]Nephrology; [2]Pediatrics, NY; [3]Pathology; [4]Surgery, North Shore/LIJ, Hofstra School of Medicine; [5]Nassau Nephrology LLP, NY.*

**Introduction:** FSGS is a leading cause of steroid resistant nephrotic syndrome. 40% of patients with primary FSGS have elevated levels of a circulating factor that increases glomerular permeability to protein. FSGS recurs after transplant in about 30% of cases, with graft loss in up to 50% of these patients. Recurrence typically occurs early, often within hours post transplant, which suggests the causative role of the permeability factor (Palb).

**Case:** We report a case of a 46 year old caucasian woman with biopsy proven primary FSGS diagnosed in 1984 who had recurrence of her disease post living related renal transplant in December 2009. On a basiliximab induction and triple drug regimen, she developed massive proteinuria of 37gm/24 hours within two days after transplantation. This was followed by progressive deterioration in renal function with creatinine of 3.5mg/dL after a nadir of 1.5mg/dL. A kidney biopsy one week post transplant revealed

effacement of podocytes on EM, compared to the zero hour biopsy which was normal. Despite multimodal therapies with 15 treatments of plasmapheresis (TPE), 1 dose of IVIG, and 2 doses of rituximab (1gm); proteinuria remained in the nephrotic range (9 gm/24 hr). Three months after transplantation, she was started on a high galactose diet (Celery, Beets, fresh basil, milk & honey) and supplemental powder galactose 0.2g/kg PO BID. After 2 months, she came off TPE, her urinary spot protein to creatinine ratio stabilized at 0.5, despite a repeat biopsy that showed no change in EM findings. Her creatinine declined to 1.5mg/dL. Palb levels are pending.

**Conclusion:** This case report suggests that administration of galactose may be a safe and effective means of reducing proteinuria in patients with recurrent FSGS after kidney transplantation. The findings support the performance of randomized clinical trials to assess the efficacy of this novel therapy in patients with this clinical problem.

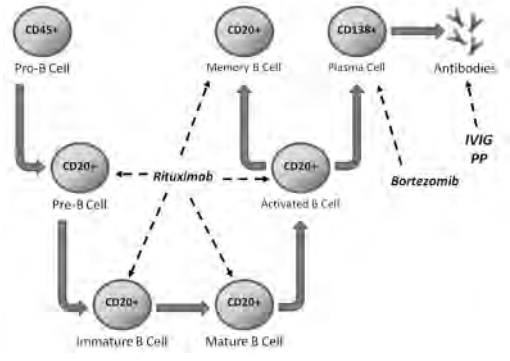
**Bortezomib in Kidney Transplantation: A Review** Rajeev Raghavan,[1] Abdallah Mohamed Jeroudi,[1] Katafan Achkar,[2] A. Osama Gaber,[3] Samir Patel,[3] Abdul A. Abdellatif.[1] *[1]Department s of Medicine and Nephrology, Baylor College of Medicine, Houston, TX; [2]Departments of Nephrology and Surgery, The Kidney Institute and The Methodist Hospital, Houston, TX.*

Introduction: Current therapies for pre-transplant desensitization and antibody mediated rejection (AMR) do not specifically deplete the plasma cells which produce anti-human leukocyte antigen (HLA) antibodies.



Bortezomib is a proteosome inhibitor which induces plasma cell apoptosis. It has been used off label in transplantation since 2005. We review this drug's biological effects, pharmacodynamics, and the current body of literature regarding its use for renal transplantation. Results: Bortezomib interferes with certain cell cycle regulatory proteins causing proteosome inhibition and apoptosis in CD138 positive plasma cells. Neurotoxicity is a dose-related side effect and may occur in up to 30% of treated patients. There are eight published case series using Bortezomib in kidney transplantation. Seven of the eight series show varying success in reducing donor specific antibodies or PRA.

Table 1: Characteristics and outcomes of published cases using Bortezomib as combination or solo therapy for AMR / desensitization (table abdridged for abstract).

| Author | N | Complete Therapy | Results |
|---|---|---|---|
| Wahrman et al (2010) | 2 | 2 cycles bortezomib and steroids | Decreased PRA |
| Walsh et al (2010) | 2 | 1 cycle boretzomib, pharesis, rituximab, and steroids | Reduction donor specific antibodies |
| Sberro-Soussan et al (2010) | 4 | solo therapy Bortzomib | No effect on antibody levels |
| Trivedi et al (2009) | 11 | 1 cycle bortezomib, pharesis, steroids | Reduction in donor specific antibodies |

Conclusions: Limited experience shows Bortezomib may have promise in manipulating the humoral arm of the immune system to manage desensitization and AMR; further clinical trials are needed.

**Cases of Swine Flu in Kidney Transplant Patients in Almeria** Manuel Ángel Rodríguez, Remedios Garofano, Clara Moriana, Mª Dolores Del Pino Pino, Ma del Carmen Prados Soler. *S. Nephrology, C. H. Torrecárdenas, Almería, Andalucía, Spain.*

INTRODUCTION

Since the outbreak of the Swine flu pandemic in March 09, the number of cases worldwide has continued to grow. It usually presents as a mild flu-like syndrome, with rapid onset of high fever accompanied by general asthenia, myalgia and respiratory symptoms. Among those at risk are patients with mild-to-moderate renal failure and immunosuppressed persons

CASE 1

17-year-old woman who received a liver and kidney transplant 37 months previously and was on treatment with tacrolimus, mycophenolate mofetil and steroids. She was admitted in July 09 with a febrile syndrome and diarrhea. During her admission she had acute pyelonephritis due to E. coli, severe pancytopenia and acute worsening of renal function. After her total recovery but prior to discharge, she again had high fever and mild respiratory symptoms. A PCR diagnosis of Influenza A was informed on the morning of her discharge

CASE 2

A 38-year-old woman with CRF received a kidney transplant 9 months previously and was on tacrolimus and mycophenolate sodium. She was admitted in October 09 with a history of febrile syndrome and respiratory symptoms, with extensive bilateral pneumonia and acute severe respiratory failure that required admission to the ICU, where she remained for 5 days being treated with intensive oxygen therapy, broad-spectrum antibiotics and oseltamivir. Her course was satisfactory

CASE 3

A 38-year-old woman with CRF received a kidney transplant 2.5 months previously and was on treatment with tacrolimus, mycophenolate mofetil and steroids. She was admitted in November 09 with a two-week history of fever, myalgia, general malaise, cough and expectoration. The patient also had positive blood and urine cultures for E. coli. She was treated with an antibiotic according to the antibiogram and oseltamivir. Her course was satisfactory

CONCLUSION

The three cases of Influenza A in kidney transplant patients recorded in the province of Almeria occurred in young women, shortly after kidney transplantation and with no other risk factors apart from those associated with the transplant itself. From the consideration of the respiratory and renal situation, their course was good

**Anemia Control in Kidney Transplant Patients Treated with Mircera® (Methoxy Polyethylene Glycol-Epoetin Beta)** A. Sánchez-Fructuoso,[1] L. Guirado,[2] J. C. Ruiz,[3] Jose-Vicente Torregrosa,[4] M. L. Suarez,[6] R. Gallego.[7] *[1]Hospital Clínico San Carlos, Madrid, Spain; [2]Fundación Puigvert, Barcelona, Spain; [3]Hospital Marqués de Valdecilla, Santader, Spain; [4]Hospital Clinic i Provincial, Barcelona, Spain; [5]Hospital Central de Asturias, Oviedo, Spain; [6]Hospital Dr. Negrín, Gran Canaria, Spain.*

**Background:** Kidney transplant (KT) is considered the gold standard treatment of chronic kidney disease (CKD) but anemia is an increasingly frequent complication after KT. Mircera® provides stable and sustained hemoglobin levels with once-monthly dosing in CKD patients.

**Methods:** Observational, retrospective study to evaluate anemia control in KT patients treated with Mircera® for correction or conversion from other ESAs. Information about demographics, CKD, anemia, blood analyses, treatment and adverse events were collected at baseline and months 1, 3 and 6.

**Results:** Between October 2009-May 2010, 292 patients were evaluated. Mean age: 52.9±13.9 years. Female: 50.7%. Stage 3 CKD: 54.4%. Forty-four(15.1%) patients were in the immediate post-transplant period, 49(16.8%) naïve-treatment and 199(68.2%) converted patients. Eighty-eight(48.9%) of converted patients previously received darbepoetin alfa, 82(45.6%) epoetin beta and 8(4.4%) epoetin alfa. Mean doses of Mircera® at baseline were 75.0±22.2µg/month, 97.0±46.4µg/month and 120.5±58.6µg/month in naïve, converted and immediate post-transplant patients, respectively. Mean Hb varied from baseline to month 6 between 10.2±0.7g/dL and 11.8±0.9g/dL in naïve patients ($p<0.001$), and between 11.4±1.3g/dL and 11.9±1.2g/dL in converted patients ($p<0.001$). In patients in the immediate post-transplant period, mean Hb was maintained between 10.4±1.7g/dL at baseline and 11.5±1.4g/dL in month 3. The only study-drug related adverse event was hypertension. No patient died during the study.

**Conclusions:** These preliminary results suggest that Hb stability can be achieved and maintained after correction or conversion to once-monthly Mircera® in KT recipients. It was well tolerated and the safety profile was as expected and comparable to shorter acting ESAs.

**PUB677**

**Post Transplant Lymphoproliferative Disorder – A Single Center Experience** Vishwanath Siddini, Sudarshan H. Ballal. *Nephrology, Manipal Hospital, Bangalore, Karnataka, India.*

We report 3 cases of post transplant lymphoproliferative disorders(PTLD) observed at our center.

**MATERIALS AND METHODS:** Retrospective evaluation of 750 renal transplant recipients from 1991 to 2010 was done. All 3 patients diagnosed to have PTLD were on regular follow up. A detailed study of dose and type of immunosuppression, rejection episodes, and clinical, radiological and histological presentation, treatment protocol and outcome was made

**RESULTS:** 3 patients were detected to have PTLD. All 3 were male. Mean age of patients was 40.33 yrs. Mean time of onset from transplantation was 5.6 years. Basiliximab induction was used in one patient. Maintenance immunosuppressions used in two were Cyclosporine, Azathioprine and steroid while Tacrolimus, Azathioprine and steroid was used in one. There were no episodes of rejection necessitating antirejection treatment. Pre-transplant EBV status was unknown in all 3 but post PTLD all had EBV positive status. Manifestation was with weight loss, abdominal pain and pleural effusion.All were extranodal and extrarenal tumors. Patients were treated by reducing the immunosuppression to only steroids along with chemotherapy. 2 patients expired, both within 4 months of diagnosis. One attained remission but relapsed within one month and expired subsequently. One patient is surviving after 3 months of diagnosis and is in remission.

**DISCUSSION:** NHL accounts for 93%. Clinical manifestations are variable. Risk factors are- Immunosuppression, EBV infection & other viral infection. Workup includes routine labs with LDH , histology with molecular genetics, EBV serology, EBV viral load , CMV serology, conventional and PET-CT, bone marrow smear and biopsy , CSF examination. Preventive measures include rapid withdrawal/tapering of agents required for graft acceptance and antiviral prophylaxis (Gancyclovir ). Treatment options include reduction of immunosuppression , chemotherapy (R-CHOP, ACBVP, Pro-MACE-CytaBOM), antiviral drugs (doubtful efficacy), interferon alpha, Rituximab. Prognosis varies with clonality and disease extent.

**CONCLUSION:** High index of suspicion is required. Preventive measures and appropriate treatment helps in improving the prognosis of the disease

**Corynebacterium Striatum: A Rare but Dangerous Cause of Infective Endocarditis in Renal Transplant Patients** Matthew A. Sparks,[1] Jason J. Eckel,[1] Eric W. Raasch,[1] Ruediger W. Lehrich,[1] Stephen R. Smith,[1] Todd V. Brennan,[2] Matthew Jay Ellis.[1,2] *[1]Division of Nephrology, Department of Medicine, Duke University; [2]Division of Abdominal Transplantation, Department of Surgery, Duke University.*

Typically, coryneform bacteria or diphtheroids are considered skin contaminates when isolated in blood or other cultures. However, in the setting of immunosuppression, this genus of bacteria can lead to serious, life threatening infections. We report two patients who developed C. striatum native mitral valve endocarditis 3-6 months after kidney transplantation, likely from surgical site infections. Ubiquitously found, including the skin and oropharynx, these bacteria are aerobically growing, non-spore forming, non-partially-acid-fast, gram-positive rods of irregular morphology. Specific coryneform species have been identified as important pathogens in both immunocompetent and immunocompromised patients. Previous case reports have identified C. striatum as the cause of endocarditis in immunocompetent hosts. C. jeikeium and C. urealyticum have been reported to cause infections in immunosuppressed patients (solid organ, non kidney transplants), particularly with indwelling devises (i.e. catheters, shunts, valves, urinary catheters etc). Several case reports document coryneform endocarditis in kidney transplant patients; however, no speciation was documented. To our knowledge, these are the first two documented cases of endocarditis caused specifically by C. striatum in kidney transplant recipients (MEDLINE search, 1966-2010, all languages). In conclusion, C. striatum when isolated in blood cultures from immunosuppressed patients should be investigated and treated aggressively, as fatal native or prosthetic valve endocarditis can be seen.

Patient Demographics

| Patient 1 | Patient 2 |
|---|---|
| 41 y/o White Man with DM1 on HD | 43 y/o Black Man with FSGS on PD |
| Living donor transplant | deceased donor transplant |
| Wound dehiscence | Wound dehiscence |
| Acute rejection Before IE | No rejection |
| IE 6 months after transplant | IE 3 months after transplant |
| Native mitral valve | native mitral valve |
| No emboli | Emboli to brain and joints |
| Survived | Died |

## PUB679

**Predictability of Risk of Infection and Rejection in Renal Transplant Patients Using Adenosine Triphosphate Release Assay** Anurag Tikaria,[Wayne State Uni] Sameh R. Abul-Ezz.[Univ. of Arkans] *[1]Nephrology, Wayne State University, Detroit, MI; [2]Renal Associates, Albaquerque, NM; [3]Nephrology, University of Arkansas for Medical Sciences, Little Rock, AR.*

Assessing the impact of immunosuppressive therapy on the immune system is a major challenge in renal transplant recipients. Currently the gold standard for differentiating rejection from infections associated with nephropathy is allogarft biopsy. Cyclex ImmunKnow assay measures cell mediated immunity by measuring ATP production of CD4+ T cells in response to mitogenic stimulation.

We retrospectively reviewed all kidney transplant recpients who had Cylex Immuknow testing done for allograft dysfunction from 2003- 2006, concurrent with allograft biopsy. Acute rejection of the allograft was diagnosed on histopathology according to the Banff criteria and viral infections with polyoma BK and CMV were tested by plasma PCR.

The number of patients with qualifying events were 136, mean age was 46, 66% were male and 57% were white. Infections were more common when ATP levels were less than 200 ng/ml (RR 2.8, p< 0.001). Acute rejection episodes were more common when ATP levels were more than 200 ng/ml (RR 1.8, p < 0.001).

CD4 + ATP Levels at the time of diagnosis

| ATP levels | Rejection | Infection | None |
|---|---|---|---|
| < 200 | 21(36%) | 14(24%) | 24(30%) |
| >200 | 10(14%) | 34(43%) | 34(43%) |

We conclude that Cylex Immuknow assay can help differentiate patients with acute rejection vs. infection in kideny transplant recipients with acute allograft dysfunction.

**Recurrence of Complement Factor H-Related Protein 5 Nephropathy in a Renal Transplant** Katherine Anne Vernon,[1] Daniel P. Gale,[2] Elena Goicoechea de Jorge,[1] Adam Mclean,[2] Patrick Maxwell,[3] Matthew C. Pickering,[1] H. Terence Cook.[1] *[1]Centre for Complement and Inflammation Research, Faculty of Medicine, Imperial College, London, United Kingdom; [2]Imperial College Kidney and Transplant Institute, Imperial College, London, United Kingdom; [3]Division of Medicine, University College, London, United Kingdom.*

Complement dysregulation is associated with C3 glomerulonephritis (C3GN). C3GN is characterized by glomerular deposits that contain C3 in the absence of immunoglobulin. A heterozygous internal duplication in the complement factor H-related protein 5 (*CFHR5*) gene has been associated with familial C3GN among Cypriot individuals. This disorder, designated CFHR5 nephropathy, is characterized by microscopic haematuria and renal failure. CFHR5, a plasma protein, has complement regulatory function *in vitro* and co-localises with renal complement deposits *in vivo*, suggesting that it may regulate complement activation within the kidney. The mechanism through which heterozygous internal duplication in CFHR5 predisposes to C3GN remains unknown. Here we report an individual with CFHR5 nephropathy and end-stage renal failure (ESRF) who developed rapid recurrence of CFHR5 nephropathy in an unrelated transplant kidney. A 53-year old Cypriot male with ESRF previously thought to be secondary to type I MPGN following two native renal biopsies, underwent a cadaveric renal transplant. Renal transplantation proceeded with no complications. Although his creatinine initially fell, it subsequently stabilised at 186µmol/l and he underwent a transplant biopsy 46 days after transplantation. The biopsy showed scattered subendothelial and mesangial electron dense deposits with isolated granular C3 staining, features consistent with C3GN. PCR of genomic DNA together with serum CFHR5 western blot analysis revealed heterozygous internal duplication of CFHR5, changes identical to those reported in familial Cypriot CFHR5 nephropathy. CFHR5 nephropathy rapidly recurred in the transplanted kidney, demonstrating that renal synthesis of wild-type CFHR5 cannot prevent the development of CFHR5 nephropathy.

**Protective Role of TNF-α Converting Enzyme in Rejecting Renal Transplant** Jun Wang, Juan Wang, Zilong Li, Hua Zhou, Lining Wang. *Department of Nephrology, First Affiliated Hospital of China Medical University, Shenyang, Liaoning, China.*

TNF receptors are differentially regulated in rejecting renal transplants. TNF-αconverting enzyme (TACE) regulates the membrane shedding of both receptors and TNF itself. We analyzed the expression and regulation of TACE in rejecting renal transplants. Using immunohistochemistry, epithelial cell culture and TACE plasmid transfection, immunoblotting and ELISA, we showed that TACE was up-regulated mainly in tubular epithelial cells in acute rejecting kidney, where it co-localized with TNFR2. Epithelial cells with increased level of TACE shed more soluble TNFR2 into culture media, and even more after PMA activation of TACE. The shedding could be completely blocked by TACE inhibitor TAPI. Up-regulation of TACE in epithelial cells in acute rejecting kidney could result in TNFR2 shedding and antagonize the pro-inflammatory effect of local TNF.

## PUB682

**Adherence/Non-Adherence in Renal Transplant Recipients Following Conversion from a Cyclosporine Based Immunosuppressive Regimen to Tacrolimus Monotherapy** Lars Backman. *Uppsala University Hospital, Dept of Transplantation Surgery, Uppsala, Sweden.*

Although difficult to study, non adherence with the immunosuppressive drugs after organ transplantation has been shown to result in significant morbidity and graft loss in organ transplant recipients. One aim of the present study was to evaluate adherence among patients who had converted from Cyclosporine based immunosuppression to Tacrolimus monotherapy.

Patients and methods: 79 renal transplant recipients (58M/21F) with a mean age of 59 (range 25-80) years with Cyclosporine and steroid associated side-effects began the study and 62 (78%) completed it. The patients were converted to a Tacrolimus based regimen with the subsequent withdrawal of steroids and follow-up during a 24 month period. They filled out questionnaires which included questions about their medication.

**Results:** In the first questionnaire in answer to the straightforward question as to how often they missed taking medications during the past 4 weeks, 27 (35%) of the patients who answered admitted to having missed at least once. A total of 51(67%) patients responded that they took their medicine at least 1 hour late. To follow-up questions as to the reasons for missing or taking medicine late, an even larger number, namely 56 patients answered that they just forgot.

Although none of the results were statistically significant would appear that younger patients, male patients, and patients who did not complete the study missed their medicine more often.

An analysis of the sixth questionnaire administered at the end of this 2 year study, showed very similar results with 24 (45%) responding that they missed some medications and 41 (77%) that they sometimes took their medicine more than an hour after the prescribed time.

**Conclusion:** In general our study supports other recent research indicating that despite the patients have undergone a kidney transplant for potentially life threatening condition, there is a large percentage of patients that are non-adherent with there prescribed immunosuppression, putting them at risk for a late rejection and a potential graft loss.

**PUB683**

**Modification of Cyclosporine-Based Therapy in Long Term Follow Up after Renal Transplantation** Veit Busch,[1] Bernhard Breil,[2] Uta Hillebrand,[1] Stefanie Hanna Reiermann,[1] Barbara M. Suwelack.[1] *[1]University Hospital, Muenster, Germany; [2]Departement of Medical Informatics and Statistics, Muenster, Germany.*

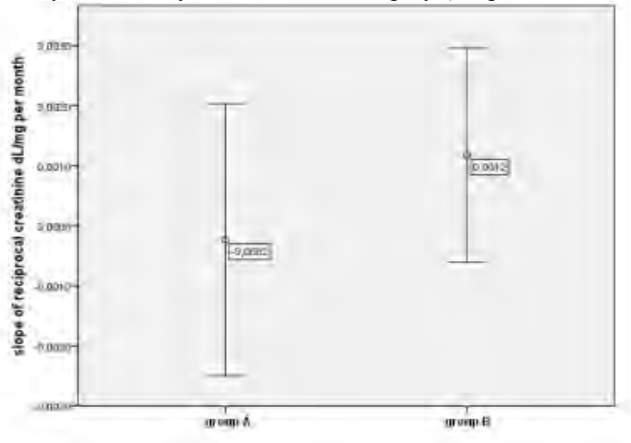
Introduction: In long term care after renal transplantation a modification of a cyclosporine (CSA) based therapy due to side effects, e.g. hyperlipidemia or allograft dysfunction often is necessary.

Methods: Caucasian renal transplant recipients were included into prospective open label trials 8 years after transplantation. In group A (n=54) CSA was replaced by tacrolimus (TAC). In group B (n=51) calcineurin inhibitor (CNI) was tapered and mycophenolate mofetil (MMF) therapy was started or intensified. Group B was subdivided depending on the type of CNI at baseline (Group B1: TAC, n=13; Group B2: CSA, n=38).

Renal function (by reciprocal of serum creatinine: crea-1) bloodpressure and lipid parameters were monitored for 24 months.

Results: At baseline patient and graft characteristics (e.g. crea-1 0,6 versus 0,61 dL/mg) as well as blood pressure, lipid parameters and count of statins and antihypertensive drugs were comparable in both groups.

Slope of crea-1 in 2 years was close to 0 in both groups (no significant difference).



In group A there was a significant drop of s-cholesterol, HDL-cholesterol and triglycerides (baseline vs postinterventional values p≤0,009). Compared to group B LDL-cholesterol-levels were significantly reduced (p=0,02) without an increase in statin therapy.

The subgroup analysis revealed a significantly higher slope of crea-1 in Group B2 as compared to group B1 (+0.0026 versus -0.0028 dL/mg per month, p=0.03) and to group A (p=0.05). Lipid parameters were not different in subgroups.

Conclusions: Even years after kidney transplantation switching to increased dose of MMF from CSA, but not from TAC may improve renal function. A switch from CSA to TAC ameliorates lipid metabolism while preserving renal function.

Disclosure of Financial Relationships: nothing to disclose

**The Efficacy and Safety of Double Filtration Plasmapheresis (DFPP) as Treatment of Transplantation** Yukiko Hasuike,[1] Naoki Suzuki,[2] Hiroshi Nonoguchi,[1] Takeshi Nakanishi.[1] *[1]Internal Medicine, Division of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]Division of Clinical Engineering, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

**Introduction**. DFPP is useful and often performed as a treatment of transplantation to remove pathological IgG. However, excess treatment of DFPP can reduce essential proteins such as albumin and fibrinogen (Fbg) since the reduction rate of Fbg is greater than that of IgG. A patient, who has an operation plan of transplantation, lack of Fbg leads to serious status. It is important to estimate the level of IgG, albumin, and Fbg after DFPP in advance as well as to decide appropriate treatment. To investigate the efficacy and safety of DFPP, a prediction formula for the change of these proteins was established and inspected the agreement.

**Methods**. A patient with acute myeloblastic leukemia who had undergone plasma exchange gave written informed consent to use the effluent of the plasma exchange. The plasma effluent was processed by plasma fractionater with closed circuit *in vitro*, and plasma parameters were determined during the processing. A prediction formula about the parameters was established on the basis of 1 compartment model. The prediction formula was prepared using the parameters before DFPP, circulating blood volume (BV), flow rate of plasma (QF) and drainage (QD), sieving coefficient of plasma separation (SC1) and fractionater (SC2). Using this formula, estimated data from applications the conditions *in vitro* were compared with measured data *in vitro* to inspect the agreement. Likewise *in vitro*, estimated data of clinical DFPP (18 treatments) *in vivo* were compared with measured data *in vivo*.

**Results**. The prediction formula; Concentration at t time = concentration at 0 time*exp [-SC1* {(QF-QD) (1-SC2)+QD}/BV]. The estimated data from the formula were consisted with measured data both *in vitro* and *in vivo* (R2>0.959).

**Discussion**. The formula of DFPP was available to predict the levels of albumin, IgG, and Fbg after DFPP in advance, and to remove IgG without lack of Fbg. Using the prediction formula, suitable DFPP for individual cases could be performed effectively and safely.

**Kidney Transplant Patients' Perception, Beliefs & Barriers Related to Regular Nephrology Outpatient Visits** Ajay K. Israni,[1,3] Kathryn R. Goldade,[2] Lisa L. Berndt,[3] Jennifer Vigliaturo,[3] Bertram L. Kasiske,[1,3] Jasjit S. Ahluwalia.[2] *[1]Medicine, Hennepin County Medical Center, University of Minnesota, Minneapolis, MN; [2]Medicine, University of Minnesota, Minneapolis, MN; [3]Minneapolis Medical Research Foundation, Minneapolis, MN.*

**Background:** Our previous work has shown substantial national variation in the frequency of nephrology visits after kidney transplantation. The low frequency of nephrology visits was associated with increased risk of allograft failure.

**Method:** A qualitative study that included interviews and 5 focus groups of transplant recipients.

The study took place at a transplant center in the Upper Midwest. Participants (n=39) were selected if they had at least one of the previously published risk factors for decreased nephrology visit: ethnic minorities, lower median household income, living less than 10 miles from the transplant center.

We assessed the patients' perceptions and beliefs and perceived barriers to regular nephrology outpatient visits.

**Results:** The transplant recipients understood the importance of keeping nephrology appointments and reflected positively on them. Regardless, they perceived barriers to adhering to these visits such as a value on self-reliance which they described increasing over time since transplant; a growing sense that they could interpret their bodies independently without needing to see the doctor as regularly; and, finally, the multitude of physical and mental health challenges post-transplant. There were other factors that motivated patients to keep their regular nephrology visits such as peer support relationships and talking with other patients on dialysis. Patients reported that talking to patients that had received a transplant before them helped them anticipate and cope with the mental and physical challenges inherent to life post-transplant.

**Conclusions:** Even though kidney transplant recipients understood the importance of keeping nephrology appointments, there were significant perceived barriers to these visits. Future interventions should address perceived barriers and motivate patients to keep regular nephrology visits post-transplant as a way to improve allograft outcomes.

**Perception Is Everything: The Opinions of Potential Renal Transplant Recipients to Non-Standard Donor Options** John F. Johnson, Andrew A. House. *Department of Medicine, Division of Nephrology, London Health Sciences Centre, London, ON, Canada.*

The demand for renal transplantation is much greater than the supply of available donors. Individuals with end stage renal disease often wait years to receive a "standard" deceased-donor transplant. To reduce transplant wait time four non-standard donor options are available; expanded criteria donor (ECD), living donor (LD), pair exchange and xenotransplantation. The last option, which involves the successful transplantation of an animal kidney into a human recipient, remains an experimental donor option. To date, there is limited research about the perception of non-standard donor options by potential recipients. Our study documented the attitudes of potential renal transplant recipients towards these four options. Of 155 individuals surveyed from a transplant waiting list at a single centre, 91 questionnaires were successfully completed (i.e. 59% response rate) and included in our study. The average age of the respondents was 50.41 ($\pm$ 13.53) years. The majority of respondents were (i) male, (ii) on renal replacement therapy for $\geq$ 2 years, and (iii) reported "good" or "very good" health status. We found that only 46% of the respondents would accept an ECD option. In fact, 81% of respondents against an ECD option would not change their opinion in exchange for a decrease in wait time. We also found that, if available, only 53% of respondents would accept an animal donor option. Of the 47% of respondents against xenotransplantation, 89% would not change their opinion in exchange for a decrease in wait time. However, 87% of respondents would accept either an LD or pair exchange option. In conclusion, only about 50% of the potential recipients surveyed would accept an ECD or animal donor option. On the other hand, the majority of potential recipients would accept an LD or pair exchange option. Based on our findings we suggest the following recommendations (i) maintain a separate waiting list for potential recipients who would accept an ECD option, (ii) educate potential recipients about the risks and benefits of an ECD option, and (iii) transplant programs should pursue an LD or pair exchange option wherever possible.

**Pilot Study To Evaluate the Efficacy and Safety of Enteric-Coated Mycophenolate Sodium (EC-MPS) in Combination with Sirolimus in *De Novo* Renal Transplant Recipients** V. Ram Peddi, Sofia Recalde, Jennifer Wilson, Lawrence H. Lu, Kimi Ueda Stevenson. *Department of Transplantation, California Pacific Medical Center, San Francisco, CA.*

EC-MPS has different pharmacokinetic and pharmacodynamic profile when compared to Mycopheonalte Mofetil (MMF). Although, there are several studies that have evaluated the safety of MMF and Sirolimus combination, no such data exists for EC-MPS and Sirolimus combination.

**Methods:** In this prospective study (IRB approved), pts received Tacrolimus and EC-MPS immunosuppression initially and were converted to Sirolimus from Tacrolimus between 3 and 6 m post-transplantation. Pts had calculated GFR (Nankivell) pre conversion (baseline) and at months 1, 3, and 6 post conversion. Patients also had measured GFR with radiopharmaceutical I-125 agent (Glofil®) at baseline and at month 6 after conversion.

**Results:** 26 patients consented to the study. Consent was obtained at the time of transplantation. 12 (46%) pts were converted to Sirolimus at a mean of 148 d post-transplantation. 14 pts were not converted and main reason (in 9/14 or 64%) was pts decision not to switch medications given stable allograft function. In this ongoing study all patients completed 1 month of follow-up post conversion. In patients who were switched the mean calculated GFR at baseline was 73.5 mL/m and 78.7 mL/m at 1 month post conversion (7% improvement; p=0.06). 7 pts completed the study and 5 pts are awaiting the month 6 GFR. Measured GFR in the 7 pts at baseline was 69.9 mL/m and 79.6 mL/min at 6 m after conversion (13.9% improvement in GFR; p=0.10). 1 pt had acute rejection 54 days after conversion and was treated successfully with Corticosteroids and remained on Sirolimus. 1 pt had severe edema after conversion and was switched back to Tacrolimus. The mean baseline calculated GFR in the 14 patients who were not converted was 76.2 mL/m at baseline and 79.1 mL/m at 1 month (3.8% improvement; p=0.21).

**Conclusions:** EC-MPS and Sirolimus combination provides safe and effective immunosuppression with low-incidence of complications. Renal function improves after conversion.

**Cyclosporine Versus Tacrolimus Maintenance Therapy in Renal Transplantation** Mamdouh N. Albaqumi.[1,2] *[1]Medicine, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; [2]Medicine, New York University Medical Center, New York, NY.*

**Background:** Cyclosporine and tacrolimus are important immunosuppressive agents for the prevention of acute rejection. Several studies have shown comparable results in long term graft and patients survival comparing a tacrolimus based therapy to a cyclosporine one while other studies have shown that tacrolimus based regimen had a better renal function, and less episodes of acute rejections. Most of these studies were in Caucasian population. In this study, we describe our experience comparing tacrolimus versus Cyclosporine maintenance therapy in a Saudi population.

**Material and methods:** All patients from 2003 until 2008 in our transplant clinic were identified. A retrospective analysis was carried out comparing patients and graft survival, kidney function, and metabolic profile between the two groups.

**Results:** There was no statistical difference in acute rejection rate between the cyclosporine group and the tacrolimus one (18.7% vs. 20.9% respectively, P=0.756). Mean serum creatinine was not statistically different between the two groups in the first month, 6 months, one year, and two years post transplantation. Patients and graft survival in one and two years were also similar in both groups. Although patient and graft survival were similar in both groups, the cyclosporine group had a higher level of cholesterol compared to the tacrolimus one (4.6±1.03 versus 4.1±0.80 respectively, P= 0.010).

**Conclusion:** In our population, there is no difference in one or two years patients and graft survival between patients on cyclosporine maintenance therapy versus tacrolimus. However, patients on cyclosporine had a higher blood pressure and serum cholesterol level.

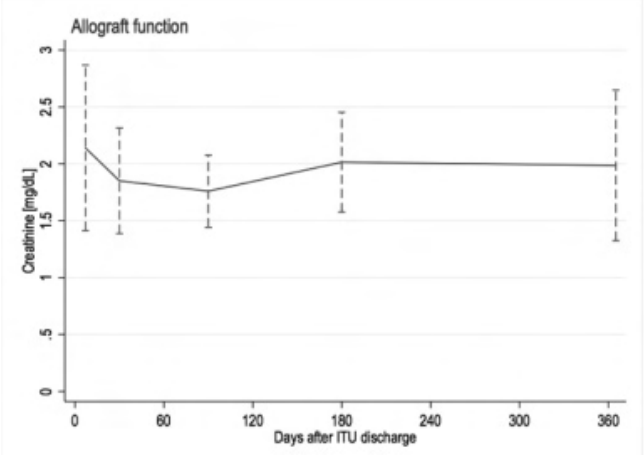
**Long-Term Outcome of Renal Transplant Recipients and Allograft Function after Survival in the ICU** Nishkantha Arulkumaran,[1] Stephen C. West,[1] Maie H. Templeton,[2] Stephen J. Brett,[2] Kakit Chan,[1] David Taube.[1] *[1]Nephrology, Imperial College Kidney and Transplant Institute, London, United Kingdom; [2]Intensive Care Medicine, Imperial College, London, United Kingdom; [3]United Kingdom.*

Purpose: To determine long- term renal transplant recipient survival and graft function after an intensive care unit (ICU) admission

Methods: Retrospective cohort study of renal transplant patients admitted to the ICU over a 4- year period in 2 medical ICUs in a tertiary renal centre

Results: 47 renal transplant patients were admitted to the ICU. The median duration from time of transplantation was 8.8 years. Mean baseline serum creatinine was 1.68mg/dL. Reasons for admission were intracranial pathology (5), cardiac instability (5), pulmonary oedema (4), chest sepsis (12), bacteraemia with septic shock (2), gastrointestinal bleeds and intra- abdominal crises (13), surgical (5), and others (1). Mean APACHE II score was 21, and ICU length of stay (LoS) was 10.5days.

Fifteen patients died on ICU (32%), whilst a further 9 patients (19%) died on the ward. 6 patients (24%) died over a 4 year follow up. Predictors of inpatient mortality were the presence of sepsis (p=0.032) and admission for chest sepsis (p=0.040). On ICU, duration of mechanical ventilation (p=0.019) and ICU LoS (p=0.014) were predictive of mortality. Among patients discharged from hospital, long- term survival was good with a 900- day 50% mortality. Death- censored allograft loss occurred in 5 patients (11%) over a maen of 103 days. Graft function remained stable a year post discharge with no significant change from the baseline creatinine. Mean 1- year creatinine was 1.98mg/dL.



Conclusion: Inpatient mortality of renal transplant recipients admitted to the ICU is significant, though patients who are discharged from hospital do well. Graft loss is not insignificant, though surviving grafts have preserved function.

Disclosure of Financial Relationships: nothing to disclose

**Retrospective Analysis of Factors Influencing Transplant Function and Survival of Patients with Low Immunological Activity** Cornelia Anneliese Blume, Wilfried Gwinner, Hermann G. Haller. *Nephrology, Medical School Hannover, Hannover, Lower Saxony, Germany.*

**Background:** Standard immunosuppressive regimen after NTX usually contains a calcineurin inhibitor (CNI), an antiproliferative agent and prednisolone. Due to the several side effects, minimization is attractive, but must be safe towards rejection. It remains a challenge to identify patients with low alloimmunity as candidates for minimization. In this study, we retrospectively identified patients with low alloimmunity by stable transplant function during CNI free dual immunosuppression. **Methods and patients:** 99 patients (59 m, 40 f; 54 ± 15 yrs.) transplanted between 1988 and 2006 in Hannover were reduced to mycophenolate and steroids after a mean of 115 ± 77 months. Renal function was analysed. Therapy was reduced in group A (71/99 patients) due to CNI toxicity, proven by biopsy in 43%. Group B patients (28/99) were reduced due to side effects of the CNI. Observation time was 45 ± 27 months. 27/99 patients were treated with mycophenolate directly after transplantation, whereas the rest received the drug at the time of CNI elimination. In 28/99 patients, we performed protocol biopsies within 6 months after NTX. For statistics, the two-sided Wilcoxon analysis was used. **Results:** The mean creatinine of group A was 245 ± 107 µM/l at minimization, whereas group B showed a significantly lower creatinine of 152 ± 73 µM/l ($p < 0.0001$). After an observation time of 45 ± 27 months, transplant function was stable in both groups (group A 289.9 ± 100 µM/l; group B 169.6 +/- 95 µM/l). 5/71 patients of group A lost transplant function in the following. Protocol biopsies in 14/28 patients of group B predicted absence of rejection as well as protocol biopsies in 7/71 group A patients. In 3 patients of group A, protocol biopsies showed signs of humoral rejection (3/5) as predictor of transplant glomerulopathy and chronic damage (c-grade 1-2 according to BANFF 97) or tubulitis as predictor of a chronic allograft failure. **Conclusions:** It is possible to define criteria for an immunologically inert transplant using protocol biopsies. Minimization to mycophenolate and steroids may be safe in a special patient cohort with low immunologic risk.

**Listing Pre Dialysis Patients for Transplantation: Is It Worthwhile?** Wendy Brown, Damien Ashby, Peter Hill, Megan Griffith. *Imperial College Kidney & Transplant Institute, London, United Kingdom.*

UK guidelines recommend that people with advanced CKD are activated for transplantation within 6 months of needing to start dialysis. Pre-emptive transplantation may have benefits over transplantation post dialysis. Pre dialysis transplant workup has increased in recent years with evidence that coronary angiography is not detrimental to the rate of decline of GFR. Increased live donor transplantation has also increased rates of pre-emptive transplantation.

Aim: To investigate the outcome of pre dialysis patients listed for transplantation.

Method. All patients deemed fit for transplantation were offered work up/listing for transplantation if anticipated to require dialysis in the next 6 months. The outcomes of those patients listed from Jan 2006 to April 2010 were analysed.

Results: 63/173 patient listed received pre-emptive renal transplants. 34/63 received kidneys from live donors, 29/63 received kidneys from deceased donors, of whom 8 underwent simultaneous kidney pancreas transplantation (SPK). The mean time to live donation was 164 days [14-755], to deceased kidney alone was 314 days [34-958] and to SPK was 198 days [5-754]. 69/173 patients commenced dialysis, the mean time to dialysis was 401 days, but there was great variation between patients [25-1896]. Of these 29 have been transplanted, 13 within 6 months of starting dialysis.

Forty one patients have not yet started dialysis; 10 of these have been suspended from the transplant list for medical reasons or renal function stabilisation; 31 remain active on the transplant waiting list. The mean time these patients have been listed is 392 days [42-1373].

Conclusions: Pre dialysis workup for renal transplantation successfully enables significant numbers of patients to receive pre-emptive renal transplants from both live and cadaveric donors, thus avoiding dialysis and its associated complications; and it also facilitates early transplantation post starting dialysis. However, predicting the start time of dialysis in individual patients is extremely difficult and better ways to assess this are required to optimise the time of listing.

**Does Allograft Failure Impact School Attendance in Children on Dialysis? A NAPRTCS Study** Ashton Chen, David B. Kershaw, John C. Magee, Panduranga S. Rao. *University of Michigan, Ann Arbor, MI.*

BACKGROUND: Allograft failure accounts for a significant number of pediatric patients commencing dialysis. There are limited outcomes data in children returning to dialysis after transplant failure. School attendance is an important outcome measure in the pediatric population. METHODS: Using the North American Renal Trials and Collaborative Studies (NAPRTCS) database, we identified school-age patients who initiated dialysis between January 1, 1992 and December 31, 2007 (N=3489). Patients were categorized by transplant history, those with previous allograft failure and those with no history of transplant (transplant naïve). There were 2849 patients of school age with school status data available at 6 months post dialysis initiation; 2262 were transplant naïve and 587 had allograft failure. There were 2052 school age patients with school status available at 12 months after dialysis initiation; 1578 were transplant naïve and 474 had allograft failure. Full-time school attendance at 6 and 12 months after dialysis initiation was compared between the transplant naïve and allograft failure groups using a Chi-square test. Multivariate analysis was performed to determine impact of transplant failure on school attendance. RESULTS: The difference in school attendance between the transplant naïve and transplant failure groups was statistically significant at 6 months (72.3% and 67.2%, p=0.0164), but not at 12 months (72.5% and 68.6%, p=0.103). After covariate adjustment, transplant failure had no impact on school attendance at either 6 or 12 month after dialysis initiation (HR 1.12, CI 0.91-1.39, HR 0.99, CI 0.78-1.27 respectively). CONCLUSION: Children with failed allografts who return to dialysis have comparable full-time school attendance compared to their transplant naïve dialysis counterparts a year after allograft failure. Allograft failure does not appear to be a significant factor impacting school attendance.

**Comparison between Direct Renal Measurement as Goal Standard vs Accurancy of Imaging Studies as Well as Renal Weight and Renal Function in Kidneys of Living Renal Donors** Fernardo A. Fajardo, Maria Carmen Avila-Casado. *Nephropatology, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico.*

Regardless immunological factors, number of nephrons can have an impact in the outcome of renal allografts. Using renal imaging: ultrasonogram (USG) and Computed tomography imaging (CTI) in the measurement of donor renal size can be inaccurate. The aim of this study was to compare the renal size by direct measurement of allografts from LRD used as Goal standard, and compare it with the USG and CTI.

**Material and Method**: Twenty-four kidney allografts from LRD were prospectively studied. Donor protocol included: Tc-99m DPTA, direct 24hrs CrCl and calculated MDRD (modification of diet in renal disease); USG and CTI. Number of nephrons was calculated by renal weight (grams). direct measurement of renal size using a rule in cm (metric system) during organ procurement. Renal imaging and renal weight were correlated with short purges of Tcc-99m DPTA. Purges were used for CrCl determination. **Results:** twenty-four kidney allografts from 12male and 12 female donors were included. There was significant correlation between the length by direct measurement with imaging studies (CTI and USG), but CTI was the most accurate imaging technique for the measurement of renal size, and correlated well with the value in length and AP axis (Rho = 0.08, 0.035 respectively). **Conclusions:** Although CTI and USG shown a significant correlation with the goal standard, CTI showed to be most accurate. There was not a significant correlation between kidney weight and 24-Hrs CrCl, MDRD and Tcc-99m DPTA (Rho = 0.189, 0.178, 0.359).

**Dermatological Lesions in Renal Transplant Recipients: A Retrospective Study** Marilena Gregorini,[1] Michela Castello,[2] Teresa Rampino,[1] Antonio Dal Canton,[1] Teresa Valsania,[1] Eleonora Pattonieri,[1] Chiara Rocca,[1] Camillo Carrara,[1] Francesca Bosio.[1] *[1]Unit of Nephrology, University and IRCCS Fondazione Policlinico S. Matteo, Pavia, Italy; [2]Unit of Dermatology, Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy.*

The chronic use of immunosuppressive drugs in transplantation patients (pts) predispose to opportunistic infections and malignancies. Reports on skin lesions are very few. The aim of our study was to evaluate the relation between immunosuppressive drugs, demographic characteristics and skin lesions.

A retrospective study was performed using medical records of 183 kidney transplant recipients followed for ten years in our Transplant Unit.

Induction therapy consisted of basiliximab and steroids (S); maintenance therapy included cyclosporine, tacrolimus, S, mycophenolate mofetil (MMF), micophenolic acid (MFA), rapamycine, everolimus. Anti-rejection therapy consisted of S and/or tymoglobulines.

The lesion diagnosis has been made by skin, mucous, nails and hair evaluation. Skin biopsies, cultures, serological tests were also performed. Lesions were reported in 95,7% of pts and 54.1% had more than one. 37,7% of pts showed viral lesions, 25,6% showed immunosoppression-related lesions, 20,2% bacterial lesions, 15,8% benign tumors, 14,2% mycosis, 11% precancerosis lesions, 9,2% cutaneous xerosis, 8,7% dermatitis, 8,2%malignant tumors**.** A significative correlation was found between calcineurin inhibitors and gengival hyperplasia ($p<0,001$); mTOR inhibitors and acne/folliculitis ($p<0,05$), MFA and herpes simplex lesions ($p<0,05$); MMF and warts ($p<0,05$). Anti-rejection therapy was related to precancerosis lesions ($p<0,001$), bacterial lesions ($p<0.05$) and gengival hyperplasia ($p<0.001$). Malignant tumors were more frequent in elderly pts ($p<0.001$). Herpes zooster was more frequent in the first two years post-transplant ( $p<0.05$), immunosoppression-related lesions appear in the first year post transplant ( $p<0.001$), precancerosis lesions and malignant tumors in pts after 67,5 months from transplantation. Cutaneous manifestations are frequent in kidney transplanted pts. Early and continuous monitoring is necessary for early diagnosis and an appropriate treatment.

**Successful Living Related Renal Transplantation in Factor H Antibody Associated Atypical Hemolytic Uremic Syndrome (aHUS)** Johannes Hofer,[1] Thomas Giner,[1] Therese Jungraithmayr,[1] Alejandra Rosales,[1] Magdalena Riedl,[1] Walter Mark,[2] Lothar Bernd Zimmerhackl.[1] *[1]Medical University, Innsbruck, Austria; [2]Medical University, Kaunas, Lithuania.*

A 12 year old boy presented with sudden onset of nausea, vomiting and deterioration of health. Laboratory examination showed hemolytic anemia (Hb 84 g/l, LDH 1662 U/l), thrombocytopenia (platelets 16 x $10^3$/µl) and acute renal failure (serum creatinine 11.36 mg/dl) indicating aHUS. C3 was decreased to 43 mg/dl. He initially received daily fresh frozen plasma (FFP) infusions over 10 days (5ml/kg), followed by one infusion per week over two weeks and afterwards every other week. The patient did not regain renal function and on the 7th day after disease onset peritoneal dialysis (PD) was started. After one month on PD he developed peritonitis and was switched to hemodialysis (HD). The patient was on HD until renal transplantation, receiving HD 3 times per week (4 hour sessions).

The patient was diagnosed with Factor H antibody (FH-Ab) associated aHUS. The FH-Ab level was initially high (1600 AU/ml). Renal function did not recover. Therefore living related renal transplantation was planned. To reduce FH-Ab titers prior to kidney transplantation one plasma exchange (PE) and a single infusion of IgG (2 g/kg body weight) on the day before transplantation was preformed. In 11/2009 a living related renal transplant from the father was done. Induction therapy with ATG and immunosuppression with Tacrolimus, MMF and Steroids was given. 4 months after transplantation terminal complement complex levels were normal and the antibody titers are in the very low range (<100 AU/ml).

At present many patients with FH-Ab positive aHUS are waiting for renal transplantation. Without evidence of the role of this aHUS subtype before, during and after transplantation they are at high risk for transplant failure because of recurrence of aHUS. IN this case report, the combination of plasma therapy, IVIG and induction therapy was successful. In order to follow these patients consequent evaluation in specific registries are recommended (www.hemolytic-uremic-syndrome.org).

**Successful Renal Transplantation in a 4-Year Girl with Renal Tubular Dysgenesis Due to Mutations of the Angiotensin-Converting Enzyme Gene**

Aya Inaba,[1] Hiroshi Hataya,[1] Yuko Hamasaki,[1] Kenji Ishikura,[1] Hiroyuki Satoh,[1] Kenichi Satomura,[2] Seiichirou Shishido,[3] Masataka Honda.[1] *[1]Nephrology and Transplantation, Tokyo Children's Medical Center, Fuchu, Tokyo, Japan; [2]Pediatric Nephrology, Osaka Medical Center for Maternal and Child Health, Izumi, Osaka, Japan; [3]Pediatric Nephrology, Toho University, Ota, Tokyo, Japan.*

Renal tubular dysgenesis (RTD) is a critical disorder characterized by the Potter sequence, severe hypotension and skull ossification defects. We report a successful renal transplantation in a 4-year-old girl with RTD due to mutations of the angiotensin-converting enzyme (ACE ) gene.

The patient, a Japanese girl, was born at 33 weeks gestation. A hypoplastic lung and diastasis of the cranial sutures were observed. Severe hypotension persisted during the neonatal period, which was treated with plasma expanders and catecholamines. However mild hypotension still persisted. Peritoneal dialysis was required from day 3 after birth. Histopathological findings in the kidney were compatible with RTD and gene analysis revealed compound heterozygotic mutations, two novel deletions in exon 1 and exon 25 of the ACE gene (Eur J Pediatr (2009) 168:207-209) . At 4 years, the patient received a living kidney transplant from her mother. Before transplantation her blood pressure was low (systolic, 60 mmHg) . During the perioperative period, blood pressure was well maintained by adjustment of fluid replacement and catecholamines. A postoperative study showed higher plasma angiotensin II (Ang II) concentrations (194ng/ml) than those measured before transplantation (50ng/ml) . The patient was discharged with a functioning graft on postoperative day 58. At discharge, her blood pressure was higher (systolic, 90mmHg) than that before transplantation.

The major periorperative problem of renal transplantation in our patient was the management of blood pressure and it was maintained successfully without the administration of Ang II. The increase in plasma concentrations of Ang II after transplantation suggests expression of ACE derived from the renal graft and this may have contributed to the perioperative management of blood pressure.

**Evaluation of Renal Transplant Recipient in a Single Centre of Bangladesh**

Shahidul Islam, Muhammad Rafiqul Alam, Habibur Rahman, Harun U. R. Rashid. *Department of Nephrology, Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh.*

Renal transplantation (Tx) is the treatment of choice for most patients with end stage renal disease. In our centre renal Tx. started and continue from 1988, but post Tx. Patient evaluation has been not well established.

Total 214 ESRD patients were transplanted from July 1995 to December 2005. All patients were live related donors, mothers were the major donor about 33% followed by brother 29%, sister 16%, father about 14%.

Among the transplanted patient 138 (64.48%) were survival, 19 (8.87%) under went graft failure put on dialysis and 57 (26.73%) were died.

Among the survival patients, 115 recipients were evaluated and reveled 83(72.17%) developed HTN, 32 (27.83%) chest infection (Specific and non-specific), 29 (25.22%) graft dysfunction, 29 (25.22%), 25 (21.70%) UTI, 22 (19.19%) diabetes, 18 (15.65%) having CMV carrier & 9 (7.83%) CVD having post Tx proteinuria.

Over all graft survival in 1st of year 85%, 3rd year 75%, 5th year 65% & 10 year 50%

In conclusion, results of renal Tx. is encouraging as compare to other countries. So, to increase number of transplantation needed to overcome the existing donor scarcity as well as to increase number of transplant centre in our country.

**Long-Term Graft Survival over 20 Years after Kidney Transplantation; a Single Center Experience**

Dong Jin Joo, Kyu Ha Huh, Tae-Hyun Yoo, Yu Seun Kim. *Transplantation Center, Yonsei University College of Medicine, Seoul, Korea.*

***Background***: Kidney graft survival has been improving last few decades. We analyzed the clinical differences of the long-term survival graft from others.

***Patients and Methods***: We retrospectively analyzed the 300 kidney recipients who underwent between April, 1979 and November, 1988, which were performed over 20 years ago. Among them, four groups were classified according to the duration of graft survival, which included 6 grafts in short-term survival group (under 1 year, Group 1), 63 grafts in intermediate-term survival group (5-10 years, Group 2), 54 grafts in long-term survival group (10-20 years, Group 3), and 107 grafts in extremely long-term survival group (over 20 years, Group 4). The 70 recipients who survived for 5-10 years and who died with functioning graft within 1 year were excluded.

***Results***: Donor age (30.8±8.8) of Group 4 was younger than other groups (33.7±13.2, 38.8±12.2 and 36.7±10.3; p<0.001). There were no significant differences in HLA mismatching but acute rejection episodes were significantly different (1.00±0.00, 0.59±0.93, 0.19±0.48 and 0.11±0.42; p<0.0001). All recipients in Group 1 were preemptive transplant cases, which was significantly different from others ($p$=0.004). Azathioprin-based immunosuppression was more used in Group 1 (83.3%) than others (20.6%, 29.6%, and 43.0%; $p$<0.0001). Except Group1, Group 2 showed more acute rejection episodes than others ($p$<0.0001; Table 1). Of these different factors, donor age (OR=1.034, $p$<0.0001) and acute rejection episodes (OR=1.461, $p$<0.0001) were significant risk factors that affected on the over-20-years graft survival rate according to the Cox-regression analysis.

***Conclusion***: Long-term graft survivors over 20 years after transplantation showed younger donor age and less acute rejection episodes.

**Predictors of Transplant Recipient Outcome after Renal Allograft Loss**

Hye-Young Kang, Jung Tak Park, Bo Young Nam, Jwa-Kyung Kim, Shin-Wook Kang, Tae-Hyun Yoo. *Brain Korea 21 Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.*

The number of patients who require dialysis after graft loss is growing with an increase in the number of renal allografts. Patients reinitiating dialysis after graft failure have different characteristics from transplant-naïve patients starting dialysis considering chronic inflammation from allograft rejection and exposure to prolonged immunosuppression. However, data regarding the outcomes of patients on dialysis after graft loss are limited. We therefore explored the characteristics and risk factors for mortality among patients returning to dialysis after graft loss. Study subjects consisted of 294 patients who reinitiated dialysis after graft loss between 1985 and 2006. Glomerular filtration rate (GFR) was calculated using the MDRD equation. New-onset diabetes after transplantation was defined as casual glucose ≥ 200 mg/dl and/or use of hyperglycemic medications. Comorbid conditions were expressed as the Charlson comorbidity index (CCI). Biochemical and clinical data at graft loss were considered as baseline. The mean age of patients at the time of graft loss was 39.7 ± 10.8 years, and 203 (69.5%) patients were male. The mean GFR at dialysis reinitiation was 9.1 ± 4.6 ml/min/1.73 $m^2$ and the most common comorbid conditions were diabetes (20.8%) and malignancy (15.0%). Cardiovascular disease was the most common cause of death during the 67.4 ± 50.6 months of follow-up (28.9%). History of diabetes (HR 6.88, $P$ < 0.001), new-onset diabetes after transplantation (HR 1.84, $P$ = 0.03), high CCI score (HR 1.83, $P$ = 0.02), and low serum albumin level (HR 2.93, $P$ = 0.01) were independent risk factors for mortality. However, GFR at dialysis reinitiation (HR 1.04, $P$ = 0.21), cumulative dose of cyclosporine (HR 1.00, $P$ = 0.33) or prednisolone (HR 1.01, $P$ = 0.16) were not. Comorbid conditions, new-onset diabetes after transplantation, and hypoalbuminemia predicted mortality in patients who returned to dialysis after graft failure. Improving nutritional status and treating comorbid conditions could ameliorate the outcome of these patients.

**Steroid Versus Non-Steroid Immunosuppression Protocols in Pediatric Renal Transplant: Comparison of Outcomes**

Juhi Kumar, Heejung Bang, Eduardo M. Perelstein, Valerie L. Johnson. *Pediatric Nephrology/Public Health, Weill Cornell Medical College, New York, NY.*

**Background:** Corticosteroids have been the mainstay of immunosuppression in pediatric renal transplant despite many side effects especially growth suppression in children. Since 2005 our center has been using steroids only as a premedication for thymoglobulin in the initial peri-operative and immediate post transplant period. Prior to that we used a steroid based protocol. Our induction protocol consists of 5 doses of Thymoglobulin and Methylprednisone. Mycophenolate Mofetil is given on day # 0 and Prograf is started on day # 1. Patients are maintained on Prograf and MMF long term.

**Objective:** To compare outcomes between patients on steroid (S) versus non-steroid (NS) based protocols.

**Methods:** Data on demographic, anthropometric, biochemical variables and medications were obtained from patient records. Comparisons between the S and NS groups were made for the following outcomes: graft survival, acute rejection, estimated GFR, height z scores, BMI, number of anti-hypertensives used and use of erythrocyte stimulating agents (ESA). Longitudinal data (at 3 time points up to 2 years) were available on acute rejection,

height z scores and BMI so these data were analyzed by generalized estimating equations accounting for within person correlation, while other cross-sectional data were analyzed by standard linear or logistic regression. In all regression analyses, potential confounders such as age, donor source and time trend were controlled.

**Results:** There were 49 subjects, 20 in the S and 29 in the NS group. Height z scores were significantly higher (p=0.02) and acute rejection rate (p=0.01) and the number of anti-hypertensives used (p=0.02) were significantly lower in the NS group. The differences in graft survival, eGFR, BMI, and use of ESA's were not significant, likely due to insufficient statistical power.

**Limitations:** small sample size, retrospective chart review, historic controls

**Conclusions:** Steroid free immunosuppression provides comparable outcomes in terms of graft survival and graft function but possibly better outcomes for linear growth and incidence of acute rejection in children.

## PUB701

**Pancreas-Kidney Transplantation: Experience at Single Center in Korea**

Hankyu Lee,[1] Kitae Bang,[1] Jongho Shin,[1] Jongwon Ha,[4] Jaeseok Yang,[3] Curie Ahn.[2] *[1]Nephrology, Internal Medicine, Eulji Hospital, Daejeon, Korea; [2]Department of Internal Medicine, Seoul National University, Seoul, Korea; [3]Transplantation Center, Seoul National University Hospital, Seoul, Korea; [4]Department of Surgery, Seoul National University, Seoul, Korea.*

Introduction. The pancreas transplantation is the curative treatment for diabetes. We report current result of pancrease-kidney transplantation and characteristics in Korea.

Methods. We retrospectively reviewed pancreas-kidney TPL from 2002 to 2010 in Seoul National University Hospital in Korea. 21 patients underwent pancreas transplantation; twenty patients were simultaneous pancreas-kidney and one pancreas after kidney transplantation from deceased donors. 8 patients suffered type 1 diabetes, whereas 13 patients type 2 diabetes.

Results. The mean recipient age was 42.9 years. The mean donor age was 28.5 years. The mean HLA mismatch was 3.9. Immunosuppressive treatment consisted of basiliximab induction followed by tacrolimus, MMF, and Pd. The After a mean follow-up of 45.2 months, survival rate of patients, kidney allograft and pancreas allograft survival rate were 95%, 90%, and 80%, respectively. One patient died of cerebral infarction and small bowel perforation. 2 pancreas allografts were lost due to CMV pancreatitis and small bowel perforation.; Beyond early postoperative period, allograft loss of pancreas and kidney was limited to 1 case of noncompliance to the medications. No more complications occurred during follow including cardiovascular and ophthalmologic ones.

Postoperative complications

| **In-hospital complication** | **36cases / 15pts** |
|---|---|
| Hematoma / Fluid collection | 3 / 3 |
| Small bowel perforation | 2 / 2 |
| Thrombosis in pancreas vein | 2 / 2 |
| Pancreatitis (Unknown, CMV) | 2 / 2 |
| Infection (PCD, Sepsis) | 2 / 2 |
| Cholecystitis | 1 / 1 |
| Urine leakage | 1 / 1 |
| Cerebral infarction | 1 / 1 |
| Bx proven kidney rejection | 11 / 10 |
| Bx proven pancreas rejection | 7 / 6 |
| **Alive at hospital discharge** | **20 pts / 21 pts** |

Conclusion. The pancreas-kidney transplantation is a well-established therapeutic option with tolerable outcomes for patients with diabetes. However, we should be careful about the complications in the immediate postoperative period.

**Functional Iron Deficiency and Hepcidin in Renal Replacement Therapy**

Jolanta Malyszko,[1] Jacek S. Malyszko,[1] Piotr Kozminski,[3] Michal Mysliwiec,[1] Iain C. Macdougall,[2] Ewa Koc-Zorawska.[1] *[1]Nephrology, Medical University, Bialystok, Poland; [2]Renal Unit, King'S College Hospital, London, United Kingdom; [3]Dialysis Unit, Mlawa, Poland.*

Hepcidin has emerged as a key regulator of iron homeostasis and is believed to play an important role in the functional iron deficiency. NGAL (neutrophil gelatinase-associated lipocalin) binds small-iron carrying molecules. We tested the hypothesis that hepcidin and/or NGAL is related to functional iron deficiency (defined as ferritin above 200 ng/ml with TSAT below 20%) in 200 haemodialysis patients and 160 kidney allograft recipients.

Methods: Serum iron, total iron binding capacity, ferritin, transferrin saturation-TSAT, complete blood count, creatinine, albumin were assessed using standard laboratory methods. Soluble transferrin receptor, hsCRP, were measured using commercially available kits. Hepcidin was assayed using kit from Bachem, UK. Serum NGAL was assessed using kits from BIOPORTO, Denmark.

Results: Functional iron deficiency was present in 21% of HD patients and in 23% of kidney allograft recipients. Serum NGAL, hepcidin, ferritin, ESA dose, hsCRP, prevalence of diabetes, use of ACE inhibitors were significantly higher in HD patients with functional iron deficiency, whereas serum albumin, serum iron, TSAT, residual renal function, Kt/V, and serum creatinine pre-and post HD were significantly lower in this population. In addition to a low TSAT and high ferritin, the presence of functional iron deficiency was associated with inflammation and high NGAL in multiple regression analysis. In kidney allograft recipients with functional iron deficiency, serum hepcidin, hsCRP, ferritin were significantly higher, whereas erythrocyte count, serum iron were significantly lower when compared to patients without functional iron deficiency.

Conclusions: Functional iron deficiency is common in patients on renal replacement therapy, and is associated with high hepcidin levels and inflammatory markers. These data support the concept that these patients are inflamed, and this population should be investigated for underlying and potentially reversible causes. Furthermore, hemodialysed patients may benefit from more aggressive dialysis treatment.

## PUB703

**Experience in the Kidney Transplant Program at the Hospital de Especialidades; Centro Médico de Occidente. IMSS. Guadalajara Jalisco, México**

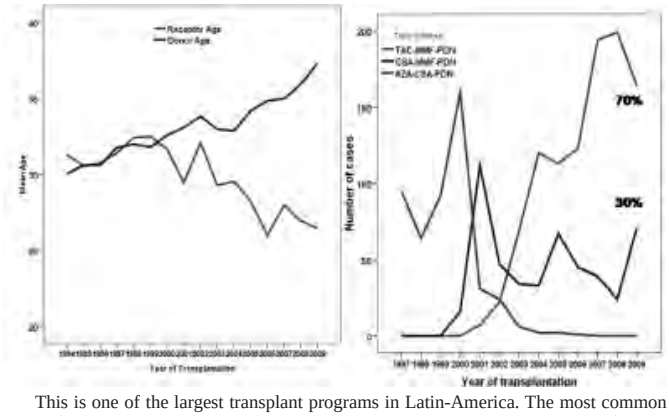
Abel Puentes Camacho,[1] Jorge Andrade-Sierra,[1,2] Enrique Rojas-Campos,[2] Francisco Monteon,[1] Mario Sandoval Sandoval,[1] Carlos Valdespino,[1] Miguel Medina Perez,[1] Luis Alberto Evangelista Carrillo,[1] Javier Castillo Tapia,[1] Alfonso M. Cueto-Manzano,[2] Benjamin Gomez-Navarro.[1] *[1]Nephrology and Organ Transplant, Hospital de Especialidades, Guadalajara, Jalisco, Mexico; [2]Medical Reseach Unit in Renal Diseases, Hospital de Especialidades, Guadalajara, Jalisco, Mexico.*

In the USRDS report, Jalisco (Mexican state) had the highest transplant rate in the world. Therefore this study describes the characteristics of our kidney transplant population.

Clinical charts of 2,319 recipients were retrospectively reviewed (Jan/94-Dec/09).

Main results in Table and Figure.

| Variable | 1994-1999 | 2000-2005 | 2006-2009 |
|---|---|---|---|
| Receptor Age (years) | 32±11 | 30±12 | 27±11 |
| ≤ 19 yrs | 57 (11) | 228 (25) | 261 (30) |
| 20-40 yrs | 346 (67) | 494 (54) | 491 (56) |
| 41-60 yrs | 112 (21) | 183 (20) | 114 (13) |
| ≥ 61 yrs | 3 (1) | 10 (1) | 9 (1) |
| Gender, F/M N(%) | 195(37) / 330(63) | 329(36) / 587(64) | 314 (36) / 564(64) |
| Donor Age(years) | 31±11 | 33±11 | 36±10 |
| Donor F/M N(%) | 261(50) / 260(50) | 475 (52) / 436(48) | 420 (48) / 456(52) |
| Unknown N(%) | 354(69) | 683(74) | 749(85) |
| HLA < 2 Ag | 285 (59%) | 508 (59%) | 203 (24%) |
| HLA ≥ 3 Ag | 125 (26%) | 252 (30%) | 556 (67%) |
| Identical N(%) | 76 (15%) | 95 (11%) | 74 (9%) |
| LRD N(%) | 420 (81) | 668 (73) | 690 (79) |
| Cadaveric D | 37 (7) | 149 (16) | 61 (7) |



This is one of the largest transplant programs in Latin-America. The most common cause of ESRD is unknown. Living donor continuous to be the most common type of donor. In the last decade recipients had shown the most important decrease in age whereas donors have been increasingly older; Immunosuppression have also change, currently the most common scheme is TAC+MMF+PDN .

Disclosure of Financial Relationships: nothing to disclose

## PUB704

**A Six-Year Single Center Experience with Rabbit Anti-Thymocyte Globulin (Thymoglobulin) Containing Induction Regimen in Lowering Acute Rejection Rates in Kidney Transplantation**

Vinayak Ramanath, Preethi Yerram, Diptesh Gupta, Khaled Mohamed. *Division of Nephrology, Univ. of Missouri-Columbia, Columbia, MO.*

**Introduction:** Rates of acute rejection in renal transplantation has been trending down over the last several years owing to more efficacious immunosuppressive regimen. Current acute rejection rate in the US approximates 10-15%.

**Aim:** To determine the acute rejection rate within first 12 months among patients undergoing renal transplantation at the University Hospital, Columbia-Missouri between 2003 and 2009 with Thymoglobulin containing induction regimen, and to compare it with the national average.

**Methods:** After obtaining IRB approval, medical records of all kidney transplant recipients at the University Hospital, Columbia-Missouri between January 2003 and January 2009 were reviewed. Data was collected regarding biopsy proven acute rejection in the first year of transplantation. We defined acute rejection as an episode of renal allograft dysfunction, proven by renal allograft biopsy. Demographic data, donor type, re-transplantation, cold and warm ischemic time, antigen mismatches, CMV status, renal

parameters, type and dose of induction therapy used (thymoglobulin vs other), and details of maintenance immunosuppression.

**Results:** Total of 160 renal transplants were done between January 2003 and January 2009. 26 were from living donors and the remaining 134 from deceased donors. 154 of the 160 patients received thymoglobulin as part of the induction therapy; while four patients did not receive thymoglobulin. No information was available on two patients. All the patients were maintained on a three-drug immunosuppressive regimen; a calcineurin inhibitor, prednisone and an antimetabolite. There were a total of 10 biopsy proven acute graft rejections within the first year, with the rejection rate being 6.2% which is lower than the national average. Four of the ten patients who had rejection were either non-compliant with their immunosuppression or had subtherapeutic levels of the calcineurin inhibitor.

**Conclusion:** Use of thymoglobulin as part of the induction therapy for kidney transplantation is associated with much lower rates of acute rejection.

**Higher Education Alleviates Racial Disparities in Access to Kidney Transplantation** Gurprataap Singh Sandhu,[2] Anna Barenbaum,[1] Preeti Rout,[2] Martha Pavlakis,[2,3] Hongying Tang,[3] Joo Heung Yoon,[4] Alexander S. Goldfarb-Rumyantzev.[2,3] *[1]Tel Aviv University, Tel Aviv, Israel; [2]Division of Nephrology, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA; [3]Transplant Institute, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA; [4]Internal Medicine, Massachusetts General Hospital, Boston, MA.*

Racial disparities in access to medical care have been demonstrated before and are difficult to eliminate. We hypothesize that higher education level might result in reduced disparities in access to transplantation.

We used data from the USRDS of incident ESRD patients ≥18 years of age, who started dialysis 1/1/1990-9/1/2007. The outcomes were the likelihood of (1) wait-listed or transplanted without being listed; and (2) of receiving kidney transplant for those patients who were previously listed.

We identified 3,224 ESRD patients for whom education information was available. A mean age of ESRD onset was 57.1 ± 16.2 years, 54.3% were male, 64.2% White, and 50.4% had diabetes. During the study follow-up 35.2% of patients were either listed or transplanted without being listed.

Compared to African Americans greater percentage of White patients graduated from the college (16.7% vs. 10%), smaller percentage of White patients never graduated from the high school (30.8% vs. 38.6%). Compared to Whites African American subjects had a lower likelihood of listed or transplanted without being listed (HR 0.7, p<0.001) and lower likelihood of being transplanted after placed on the waiting list (HR 0.58, p<0.001). When analyzed in groups divided by education level, compared to Whites the likelihood of African American patient being listed or transplanted without listing was lower in three less educated groups: HR 0.67 (p=0.005) for those never completed high school; HR 0.76 (p=0.02) for high school graduates; and HR 0.65 (p=0.003) for those with some college education. However, there was no significant difference in those with highest education level (HR 0.75, p=0.1).

In conclusion, while racial disparities in access to kidney transplantation do exist, the difference lose significance in highly educated individuals.

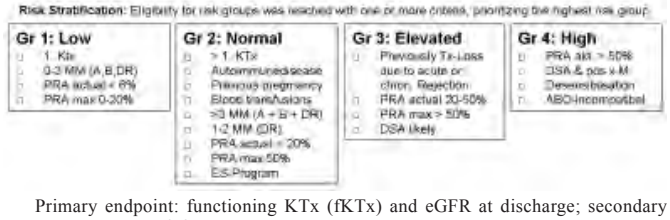
**Prospective Immunologic Risk Stratification in Kidney Transplant Recipients – Evaluation of Early Outcome** Lioba V. Schewior,[1] Rolf A. Stahl,[1] Christine Eulenburg,[3] Thomas Eiermann,[4] Lioba Schewior,[2] Björn Nashan,[2] Friedrich Thaiss.[1] *[1]Nephrology, University Medical Center Hamburg-Eppendorf, Germany; [2]Hepatobiliary/Transplantation Surgery, University Medical Center Hamburg; [3]Medical Biometry/Epidemiology, University Medical Center Hamburg; [4]Transplant Immunology/HLA-Laboratory, University Medical Center Hamburg.*

Presensitization of Kidney Transplant Recipients (KTR) has increasing impact on allograft outcome. Still, there is a lack of valid markers to predict the immunologic risk of the allograft/KTR match. The aim was to evaluate an immunologic stratification using established clinical and HLA-laboratory data.

Prior to Kidney Transplant (KTx) stratification was performed



Primary endpoint: functioning KTx (fKTx) and eGFR at discharge; secondary endpoint: delayed graft function (DGF), adverse events and health economic parameters. Immunosuppression (IS) for all KTR were steroids, Basiliximab and Tacrolimus (C0 4-6 ng/dl) or Cyclosporin (C0 80-120 ng/dl) with either MPA or Everolimus. Risk groups 3 and 4 did received additional IS.

N=79 KTR were enrolled. Baseline demographics were comparable (age, cold ischemic time coronary artery disease, diabetes, p=ns). Best KTx function was observed in group 1 and 2, lower in groups 3+4.

KTx function at time of discharge

| Group (n) | fKTx [%] | MDRD4 [mean ml/min] | [+/-sd] | DGF [%] |
|---|---|---|---|---|
| 1 (23) | 95.7 | 58.7 | 27 | 17.4 |
| 2 (44) | 86.4 p=0.008 | 56.5 | 23 ns | 22.7 |
| 3 + 4 (12) | 50.0 p=0.011 | 50.4 | 19 ns | 25.0 |
| Total (79) | 83.5 | 56.6 | 24 | 21.5 |

Two deaths occurred, both due to cardiovascular events (gr 1,2). Other complications were rare with no differences between groups. IS costs were highest in group 4.

In this cohort pretransplant immunologic risk stratification allowed to identify an important proportion of patients at immunologic risk (15%) with an incidence of early allograft failure of 50%.

Disclosure of Financial Relationships: nothing to disclose

**Comparisons of Enteric-Coated Mycophenolate Sodium (EC-MPS) and Mycophenolate Mofetil (MMF) in Renal Transplant Recipients (RTRs) with Diabetes Mellitus (DM) Prior to Transplant in the Mycophenolic Acid Observational Renal Transplant (MORE) Registry** Fuad S. Shihab,[1] Laurence Chan,[2] Mohanram Narayanan,[3] Michael J. Moritz,[4] Anne Wiland,[5] Kevin M. Mccague,[5] Cataldo Doria.[6] *[1]University of Utah, Salt Lake City, UT; [2]University of Colorado, Denver, CO; [3]Scott and White Clinic, Temple, TX; [4]Lehigh Valley Health Network, Lehigh Valley, PA; [5]Novartis, East Hanover, NJ; [6]Thomas Jefferson University Hospital, Philadelphia, PA.*

**Introduction:** The MORE Registry is a prospective, observational study of de novo RTRs designed to determine effectiveness, tolerability and safety of EC-MPS vs. MMF-based regimens. **Methods:** Based on standard-of-care at 40 US sites, outcomes analyzed included: graft survival (GS), patient survival (PS), first biopsy-proven acute rejection (BPAR), adverse event (AE) rates, serum creatinine (SCr) and percentages of RTRs maintained on at least full recommended mycophenolic acid (MPA) dose (1440/2000 mg/day, EC-MPS/MMF). Preliminary data {229 DM (159 EC-MPS/ 70 MMF), 454 non-DM (304 EC-MPS/ 150 MMF) RTRs; 100% tacrolimus; 58% maintenance steroids} were analyzed. **Results:** Interim results at 1, 3, 6 and 12 mo showed that more of the DM EC-MPS RTRs were maintained on at least full dose of MPA (EC-MPS/ MMF: 79.4/66.7%, p=0.05; 69.2/56.5%, p=0.08; 56.3/47.8%, p=0.38; 50.5/45.7%, p=0.69). The same trend was observed in the non-DM RTRs (EC-MPS/MMF: 81.6/73.0%, p=0.04; 74.5/61.2%, p=0.01; 57.2/44.8%, p=0.04; 47.8/41.9%, p=0.39). Comparable 6-month clinical outcomes were achieved for effectiveness, tolerability and safety in all RTRs. In the DM group of EC-MPS/MMF RTRs, there were no significant differences in GS (99.4/100%, p=0.82), PS (99.3/96.9%, p=0.06), BPAR (6.6/4.3%, p=0.88), mean SCr (1.44/1.54 mg/dL, p=0.33), early AEs by organ system, infections or neoplasia. Similar results were observed in the non-DM group (EC-MPS/MMF: GS 98.6/98.6%; PS 99.6/100%; BPAR 6.8/6.9%: SCr 1.44/1.56 mg/dL). **Conclusion:** A greater percentage of RTRs (± DM) treated with EC-MPS were maintained on full dose MPA, which was previously shown to be a good predictor of long-term graft outcomes.

**Prevalence of and Associations between Low 25-Hydroxyvitamin D Levels and Anemia in Renal Transplant Recipients** Michael Shye, Michal L. Melamed. *Albert Einstein College of Medicine/ Montefiore Medical Center.*

Low 25-Hydroxyvitamin D (25(OH)D) levels have recently been associated with poor outcomes including anemia, infection and all-cause mortality in the general population. Renal transplant recipients (RTR) are a specific population that is more susceptible to these poor outcomes.

We studied all RTR >21 years old who had 25(OH)D values within the first year of transplantation at the Montefiore Medical Center from 2000 to 2008 (n=251) using an electronic medical records database. The baseline 25(OH)D level was defined as the first value obtained after transplantation. We collected information on baseline demographics, co-morbidities, laboratory results and vitamin D use. In addition, infectious hospitalization and mortality was obtained from hospital records and via linkage to the Social Security Administration mortality registry.

Participants had a mean age 48.2 (standard deviation (SD) 13.2), 58% were male, 29% were African-American, 37% were Hispanic and 18% were white, median Charlson score was 3 (IQR 2, 5) and 38% had diabetes mellitus at baseline. Seven % had 25(OH)D levels >=30 ng/mL, 40% had 25(OH)D levels <30 but >=15 ng/mL and 53% had 25(OH)D levels <15 ng/mL. Twenty-eight % had levels <10 ng/mL. 25(OH)D levels were correlated with hemoglobin (hgb) levels (rho=0.18, p=0.003). After multivariable adjustment for demographics, co-morbidities and vitamin D use, for every 1 ng/mL higher 25(OH)D level, hgb was higher by 0.03 g/dL (0.004, 0.05). 119 patients were hospitalized for infectious causes. Patients with baseline 25(OH)D levels <10 ng/mL had a higher incidence rate ratio (IRR) for infectious hospitalization (IRR 1.38 (0.91, 2.12) and those with levels <15 ng/mL had an IRR of 1.28 (0.84, 1.94). Only 25 patients died over follow-up (4 years (IQR 2, 6)). There was no association between baseline 25(OH)D levels and mortality.

We found that in this consecutive sample of RTR with baseline 25(OH)D levels, lower 25(OH)D levels were associated with lower hgb levels. Further research is warranted in this area.

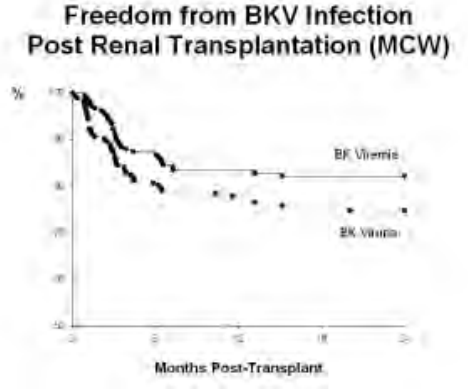
**Prospective Study of BK Virus Infection in Renal Transplant Recipients** Kumar Sujeet, Ankit Sakhuja, Y Ran Zhu, Brahm S. Vasudev, Ehab Saad, Barbara Bresnahan, Sundaram Hariharan. *Division of Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Introduction: BK virus infection is common in kidney transplant recipients.

Aim: The current prospective single center study evaluated the natural history of BKV infection after renal transplantation.

Methods: A total 189 subjects were enrolled from July 2007 to Sept. 2009. Subjects were followed till May 2010. Subjects were screened at 1, 3,6 and 12 months for viruria and viremia. Detection of BKV DNA in plasma and or urine was considered as BKV infection. Significant BKV infection is defined by BKV DNA copies >10,000/ml in plasma or >100,000 copies/ml in urine. Maintenance Immunosuppressive therapy consisted of MMF, Tacrolimus and Prednisone.

Results: A total of 65 subjects had BKV infection and 124 without. A total 48 had viremia and viruria, and 17 with viruria alone. The donor/recipient demographics, transplant (donor type, CIT, PRA, HLA mismatch) and post-transplant (DGF, induction antibody, acute rejection) variables were not substantially different in subjects with or without infection. Majority of BKV infection occurred six months post transplantation. Significant BKV viremia was seen in 21/189 (11%). These viremic subjects were submitted for transplant renal biopsy. Silent BKV nephritis was detected in 8/21 subjects. All subjects with significant viremia were treated successfully with reduction of immunosuppression without antiviral therapy. Details of appearance and decline in BKV DNA are not shown. Kaplan-Meier estimates of freedom from BKV infection is shown in figure 1.



Conclusion: In conclusion, in renal transplant recipients 1. BKV infection is common, 2. seen within six months post-transplant, 3. silent BKV nephritis can be seen without renal dysfunction, 4. reduction of immunosuppression alone can successfully treat BKV infection.

**Cardiovascular Disease Risk Factors in Postoperative Japanese Living Kidney Donors; a Cross-Sectional Study** Masahiko Yazawa,[1] Ryo Kido,[2] Takashi Yasuda,[1] Yugo Shibagaki,[1] Kenjiro Kimura.[1] *[1]Center for Kidney Diseases, St. Marianna University Hospital, Kawasaki, Kanagawa, Japan; [2]Department of Epidemiology and Healthcare Research, Kyoto University, Kyoto, Japan.*

[Background] It is reported that living kidney donors (LKDs) develop to have cardiovascular disease (CVD) risk factors post-donation, however, the prevalence of these risks have not been well studied.

[Purpose] We examined kidney function, albuminiuria and CVD risk factors in 36 prevalent Japanese LKDs to describe those prevalence in current practice.

[Methods] The study design was cross-sectional. All the thirty-six LKDs who underwent donor uninephrectomy in our hospital and agreed to the informed consent were selected. Their kidney functions measured by inulin crearance (Cin) and CVD risk factors (albuminuria, glucose / lipid metabolism, blood pressure by ambulatiory monitoring, uric acid, and BMI) were cross-sectionally evaluated.

[Results] The mean age at donation and at the study were 58.1±9.8 and 61.7±9.2, respectively. The median time from donation to the study was 944 days. The mean kidney function measured by Cin was 55.2±10.3 ml/min/1.73m$^2$, indicating 63.9% of donors were at CKD stage 3. Microalbminuria appeared in as much as 16.7% of LKDs. Prevalence of other CVD risk factors such as hypertension, non-dipper type blood pressure, dyslipidemia, glucose intolerance, and hyperuricemia were 22.2%, 40.6%, 41.7%, 19.4% and 27.8%, respectively, which were almost equal or lower than Japanese general population but still was significant considering that LKDs were cleared from pretransplant evaluation that they were "healthy".

[Conclusion] After kidney donation, although equally or less prevalent than general population, kidney donors have still relatively high prevalence of cardiovascular risk factors, indicating the importance of long-term follow up of donors with special attention to CVD risk factors.

**Relationship between Arginine Vasopressin and Aquaporin-2 in Early Postoperative Kidney Transplantation Patients** Yang Wook Kim,[1] Kyu-Bok Jin,[1] Hyun Seung Lee,[2] Tae Hee Kim.[2] *[1]Nephrology, Internal Medicine, Haeundae Paik Hospital, Pusan, Korea; [2]Nephrology, Internal Medicine, Busan Paik Hospital, Pusan, Korea.*

**Background:** The aquaporin-2 (AQP2) water channel is mainly located in the apical plasma membrane of epithelial cells in the collecting ducts in responses to arginine vasopressin (AVP). The level of AVP increases in chronic kidney disease, but mechanism remains unclear. There are few studies about AVP expression in kidney transplantation(KT). This present study was aimed at relationship with AVP and urine AQP2 expression in KT patients prospectively.

**Method:** Fourteen KT patients and eight healthy persons(control) were enrolled. To evaluate urine concentration, plasma AVP, urine AQP2 expression, serum osmolarity, urine osmolarity, urine specific gravity, serum sodium and urine sodium were measured before and after KT.

**Result:** KT did not produce a significant change in serum sodium, urine sodium, serum osmolarity, and urine specific gravity. The urine osmolarity increased significantly after KT but were low compared to control(p=0.002). Pre-KT p-AVP level was elevated inappropriately, but AVP declined to normal range after KT but was high compared to control(P=0.018). The urine AQP2 expression unrelated to the high p-AVP level was suppressed before KT, and increased after KT, however, low compared to control(p=0.005).

**Conclusion:** The relationship of urine AQP2 and p-AVP were almost normalized after KT, but urine AQP2 expression compared to P-AVP level was inappropriately decreased in early period after KT. These results suggest that the correlation between p-AVP and AQP2 expression are not yet regulated by normal feedback mechanisms in early KT period.

**Effect of Desensitization Therapy with High Dose IVIG on Anti-HLA Antibodies** Vinay Nair, Deirdre L. Sawinski, Peter S. Heeger, Bernd Schroppel. *Nephrology, Mount Sinai Medical Center, NY, NY.*

Purpose: The aim of this study was to determine the effect of high dose IVIG on anti-HLA antibodies in highly sensitized kidney wait-listed patients.

Methods: 15 patients with a cPRA>40% and high on the wait list were analyzed (12 adult, 3 pediatric). Patients received 2gm/kg IVIG per month for 4 months or until transplanted. HLA antibodies were determined before and after desensitization using Luminex single antigen beads. Antibodies > 10,000 MFI resulted in entering unacceptable antigens into UNOS. Eight patients had IgG subtyping performed. Statistical analysis was performed using Graphpad Prism software.

Results: 66% of IVIG treated patients had a decrease in antibody strength (median decrease 1908 MFI or 26.7% of baseline) while 26% had an increase (median increase 1203 MFI or 40.8% of baseline). Pooled analysis revealed a decrease of 837 MFI translating into an 11.2% decrease from baseline (p<0.0001). There was no difference when analyzing class 1 and class 2 separately. The number of class II antibodies with an MFI>10,000 decreased (7 vs. 3 antibodies; p=0.03) whereas there were more antibodies with an MFI from 1000 to 5000 after IVIG (26 vs. 31 antibodies; p=0.05). 5 patients had a change in calculated PRA greater than 10% (4 decreased (range 12-27%) 1 increased by 17%). If cPRA was less than 90% there was a greater likelihood that IVIG would result in a change. There were no differences in the response of IgG class 1 vs. class 2 after desensitization. The 5 patients subsequently transplanted had lower cPRA pre and post desensitization.

Conclusion: Desensitization with high dose IVIG did not result in a clinically meaningful reduction in antibody number, strength, or cPRA in the majority of patients. The effect of IVIG may be greater in patients with a lesser degree of sensitization. However IVIG may have other beneficial effects in highly sensitized patients and change in antibody strength should not be the only measure of successful desensitization.

**Tumorectomised ABO-Incompatible Renal Transplant Amidst Donor Specific Antibodies** Vinod Venkataraman. *Renal Medicine, Royal Melbourne Hospital, Melbourne, VIC, Australia.*

INTRODUCTION

The gulf between survival on dialysis and transplantation led to overcoming of ABO incompatibility and donor specific anti-HLA antibodies (DSAb) in live donor renal transplants. Eculizumab, an inhibitor of the C5 complement molecule has been used to prevent antibody mediated rejection (AbMR) associated with DSAb. Additional strategy was implantation of tumorectomised donor kidney. We describe a transplant of tumorectomised ABO incompatible (ABOi) kidney amidst positive flow crossmatch to DSAb.

METHODS

A 57 years old patient with a donor against whom she was both ABOi and had DSAb was planned for a paired kidney donation (PKD). An incidental small tumour of donor kidney prevented this. Alternatively she had pre transplant plasma exchanges and received tumorectomised kidney with Eculizumab infusions.

The anti-B ortho titre fell from 16 to 4 and the DSAb dropped from MFIs of 16848 to HLA- B50and 2327 to HLA- B38 to 5648 and 249 respectively post-plasmapharesis. The patient received Eculizumab and Basiliximab induction prior to theatre and maintained on Tacrolimus, Mycophenolate and Prednisolone.

After removal from the donor, the kidney was sighted to have the original lesion along with a second small tumour abutting the antero-medial border. Papillary renal cell cancer was found on complete excision.

RESULTS

There was immediate graft function and creatinine reached nadir of 115 umol/ l. ABO titres and DSAb remained low. Renal function was stable with no proteinuria but marginal microalbuminuria.

Protocol biopsies at 3 months showed no cellular rejection, though there were occasional areas of focal glomerulitis. There were no other features AbMR and C4d was negative. There were no evidence of transplant glomerulopathy**.** Eculizumab infusions finished 3 months post transplant after re-assurance from renal biopsy and low DSAb levels.

Surveillance imaging at 3 months showed no recurrence in transplant, but a lesion was seen in the native kidney. Nephrectomy showed clear cell renal cancer with no invasion of renal vein.

CONCLUSION

Innovative surgical techniques and new immunosuppressive therapies enables renal transplantation in previously unimaginable circumstances.

**Excessive Activation of the Complement System Underlies the Progression of Autosomal Dominant Polycystic Kidney Disease** Zhen Su,[1] Changlin Mei.[2] *[1]Nephrology, Changzheng Hospital, Second Military Medical University, Shanghai, China; [2]Nephrology, Changzheng Hospital, Second Military Medical University, Shanghai, China.*

**Objective** To explore the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD), and seek new therapeutic targets. **Methods** Urine glycoproteins were identified using mass spectrometry(MS). Urine glycoproteins was reconfirmed by western blot, in-gel digestion and MS. Complement factor B (CFB) and C9 were detected by immunohistochemistry and western blot. C3 and C4 were detected by immunoturbidimetry. Han:SPRD rats were interfered with rosmarinic acid. **Results** 113 glycoproteins and 261 peptide segments were identified, of which 39 glycoproteins expressed differentially in the urine of ADPKD patients. Compared with the normal control group, the expression of CFB, SERPING1 and C9 increased remarkably with the progression of ADPKD, while the expression of C1RL, CD55 and CD59 decreased gradually. Western blot, in-gel digestion and MS reconfirmed that the change of the 6 proteins was consistent with that of MS. Immunohistochemistry showed that CFB and C9 expressed highly in cyst-lining epithelial cells and renal tubular epithelial cells of ADPKD patients and rats. Western blot showed that the expression of C9 and CFB in the kidney of ADPKD patients and rats were increased. Serum C3 and C4 were normal in ADPKD patients. Rosmarinic acid was able to delay deterioration of renal dysfunction of rats. **Conclusion** The alternative complement pathway expressed highly in ADPKD kidney tissue, and complement inhibitor rosmarinic acid was able to delay the progression of renal dysfunction in Han: SPRD rats, suggesting that it participated in the progression of ADPKD, and implying that inhibiting complement activation may be a potential effective strategy for the treatment of ADPKD.
