Results: Recipients received kidneys from: 73 older-living donors, 1187 younger-living donors, and 1400 deceased SCDs. Older-living kidney recipients were often older, but had similar co-morbidity scores. Baseline GFR of older-living kidneys was 13 ml/min per 1.73 m2 lower than younger-living kidneys. Time after transplant was 4 (IQR: 2-5) years. There was no significant difference in recipient death or graft loss between recipients of older or younger living donor kidneys (23 vs. 15%, adjusted HR (95%CI): 1.56 (0.98-2.49)). However, this hazard may increase with time (time-dependent interaction: p=0.01). Recipient death was higher for older-living kidney recipients (15 vs. 6%, HR: 2.73 (1.39-5.35)). Associations were not modified by recipient age or donor GFR (all interactions tested: p<0.05). Survival of older-living kidneys was similar to kidneys from deceased SCDs (HR: 0.98 (0.95-1.02)). This hazard may increase with time (p=0.01).

Conclusions: Accepting older-living kidney donors results in acceptable outcomes for the recipient. Continued and expanded use may help with the demand for transplantation.

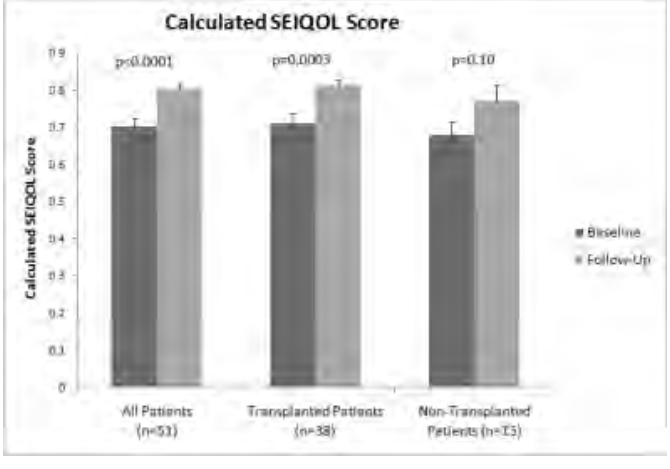
**A Novel Measure of Individualized Quality of Life in Patients Being Evaluated for Kidney Transplant** Jay A. Shah,[1] Khaled Abdel-Kader,[1] Irina Karpov,[3] Larissa Myaskovsky,[2] Rachel Hess,[2] Mark L. Unruh.[1] *[1]Renal Division, Department of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Department of Medicine, University of Pittsburgh School of Medcine, Pittsburgh, PA; [3]Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Health-related quality of life (HRQOL) is important in kidney transplant. The Schedule for the Evaluation of Individual Quality of Life (SEIQOL) is a novel tool to evaluate individualized quality of life (IQOL). It allows patients to nominate domains they view as valuable to their IQOL. The SEIQOL has previously been studied in various patient populations, including a cohort of patients with chronic kidney disease (CKD). We followed the change in SEIQOL score in patients being evaluated for kidney transplant. A cohort of 51 patients with CKD who were undergoing evaluation for kidney transplant completed the SEIQOL at baseline and a single 6-12 month follow up. We considered two separate groups: 38 patients who received a kidney transplant between assessments and 13 who did not. The average age of the cohort was 49 years, 66% were men, 27% were black, 31% had diabetes, 39% were on dialysis, baseline glomerular filtration rate among non dialysis patients and hemoglobin were 17.9 and 11.8, respectively. The baseline characteristics were similar in both groups. Domains of importance on the SEIQOL included family, health, leisure, and relationships. On follow up, finance became a prominently listed domain, while leisure became less frequently listed among transplanted patients. The SEIQOL score improved significantly in the transplanted group.



Future work should examine if the SEIQOL better correlates with health outcomes in this population. We conclude the SEIQOL is an effective tool for assessing change in IQOL in kidney transplant patients.

**Reaching the Original GFR of a Single Kidney after Living Donor Transplantation: Impact of Donor and Recipient Characteristics** Bertram Hartmann,[1] Christiane Manderscheid,[2] Ulf Schoenermarck,[2] Markus Guba,[3] Michael Fischereder,[2] Holger Schmid.[2] *[1]Medical Department I, Section of Nephrology, Ulm University, Ulm, Germany; [2]Medical Department I, Section of Nephrology, Munich University Hospital, Campus Grosshadern, Munich, Germany; [3]Department of Surgery, Munich University Hospital, Campus Grosshadern, Munich, Germany.*

Background

The aim of the study was to analyze living donor (LD) and recipient's characteristics after kidney transplantation (KT) and their impact on reaching the original donated GFR of the kidney.

Methods

242 consecutive living donor kidney recipient/donor pairs from 1997 – 2007 were included. Pairs were comparable concerning HLA match, ischemia time, operative time, and induction immunosuppressive treatment. GFR of the transplanted kidney was evaluated by using creatinine-based estimation equations (MDRD2 formula) at 3, 10 and 180 days after KT.

Results

A total of 45.9% of recipients reached the original donated GFR already 3 days after LD KT and 64.9% 10 days after LD KT. Significant predictors for not reaching the transplanted GFR in the early posttransplant period were older age of the donor (mean 52±9 vs. 49±10 years, $p<0.05$), a higher weight of the recipient (mean 74±10.7 vs. 67±12 kg, $p<0.001$) and a higher recipient´s BMI (24.3±3 vs 23±2.5 kg/m², $p<0.01$), as well as the gender constellation of a male donation to a female recipient ($p<0.01$). Adaptive hyperfiltration (GFR >60 ml/min) of the recipient after transplantation was a frequent finding.

Conclusions

The findings suggest that donor's age, recipient's weight, and the gender disparity of the donor-recipient pair should be considered as a criterion in the choice of donor and recipient pairs for successful short-term outcome in living donor renal transplantation. The problem of hyperfiltration in the early posttransplant period that may have a pivotal long-term prognostic impact deserves further exploration.

**F-PO2013**

**Older Dialysis Patients Are Unlikely To Receive a Deceased Donor Transplant, Even If Listed for Transplantation** Kathryn K. Stevens,[1] John Douglas Mcclure,[2] Marc J. Clancy,[1] Jonathan Fox,[1] Colin C. Geddes.[1] *[1]Western Infirmary, Glasgow, United Kingdom; [2]University of Glasgow, Glasgow, United Kingdom.*

**Introduction:** Most transplant centres have no upper age limit for transplantation, unless there is a clear contra-indication. The probability of older patients actually receiving a deceased donor (DD) kidney transplant is unclear preventing informed choice about the option of transplantation.

**Aim:** To determine the probability of receiving a DD kidney transplant in patients commencing RRT categorised by age.

**Methods:** Patients commencing dialysis in our centre between 1992 and 2009 were identified. Time to listing on the DD transplant waiting list (WL) and to first DD transplant were determined by Kaplan Meier analysis for patients, categorised by age, with censoring at the date of first living donor kidney transplant, death or last dialysis.

**Results:** 1513 patients were categorised into groups by age in years (1:<35 (n=134), 2:35-49.9 (n=207), 3:50-64.9 (n=415), 4:>65-74.9 (n=438) and 5:≥75 (n=319)). The probability of being listed for DD transplant was 75%, 54%, 27%, 4%, and 0.8% in groups 1-5 respectively. If listed, the probability of receiving a DD transplant within 5 years of starting RRT was 81%, 48%, 26%, 8% and 0% in groups 1-5. 93% (n=63), 87% (n=65), 76% (n=45) and 100% (n=7) of patients in groups 1-4 respectively who received a DD transplant were alive and off dialysis 1 year after transplant. The reason patients who were listed did not receive a transplant was usually death on the WL.

**Conclusion:** The likelihood of being listed for DD transplant falls with increasing age at the time of starting RRT. Even for patients listed for transplant, the probability of older patients actually receiving a transplant is lower than for younger patients. Death on the WL offers some explanation for this and organ allocation policies (e.g. matching by age of donor and recipient) may also contribute. Assessment for possible DD transplantation involves a considerable investment for both patient and healthcare resources. A patient's decision to proceed with assessment should be informed by similar local data.

Disclosure of Financial Relationships: nothing to disclose

**HLA Frequency Differences in Mexican-American and Caucasian** Steve Ogechi Egwuonwu,[1] Kantibhai M. Patel,[2] Zuber D. Mulla,[3] Ramin Tolouian.[1] *[1]Nephrology and Hypertension, Texas Tech University Health Sciences Center, El Paso, TX; [2]HLA Lab, Las Palmas Medical Center, El Paso, TX; [3]Obstetric and Gynecology, Texas Tech University Health Sciences Center, El Paso, TX.*

**Introduction**: We have learned during the years that Hispanic patients with renal transplant needs more immunosuppressants compared to Caucasian patients. Although the exact mechanism of this difference is not clear, we hypothesize that the differences in the HLA of these populations could have some role. As HLA frequencies differ from one ethnic group to another, there is a paucity of literature regarding HLA frequencies in the Mexican American (MA) population residing on the US-Mexico border.

**Methods**: We determined the distribution of HLA Class I and Class II antigen frequencies in Mexican American (MA) and compared it with Caucasian subjects from the kidney transplant program in El Paso, Texas, from 1987 to 2007.

Our analysis included 1455 donors and recipients: 1106 MA and 349 Caucasians. The HLA Class I (HLA-A, HLA-B, and HLA-C locus) and Class II (HLA-DR and DQ locus) typing were performed using Dynalbead HLA Cell Prep I and HLA Cell Prep II serology technique and Terasaki HLA Tissue Typing Class I and Class II Trays. Comparison of the HLA frequencies between these two racial/ethnic groups was done using the chi square test.

**Results**: The B7 antigen was significantly most frequent among Caucasians than among MA: ($p<0.0001$). In the Mexican American group HLA B35 appeared to be most significant ($p<0.0001$). Other antigens that were common among the MA compared to the Caucasians include A24 ($p<0.0001$), A31 ($p<0.0001$), and A68 ($p<0.0001$). Neither B4005 nor B48 were found in Caucasians but were detected in MA. In HLA class II locus, HLA DR4 was significantly most common in MA.

**Conclusion**: In our knowledge this is the largest study about the frequency of HLA in MA in US-Mexico border region. This study reveals clear differences in the distribution of HLA frequencies between Mexican Americans and Caucasians. Further studies should be conducted to determine if HLA differences have a role in different immune response in these two populations.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2015**

**Clinical Impact of Kidney Living Donors with Thin Basement Membrane Compared to Normal Donors** Monica X. Inofuentes, Francisco E. Rodríguez Castellanos, Patricia C. Ruiz Palacios, Bernardo Moguel, Maria Carmen Avila-Casado. *Nephropathology, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico.*

We have previously presented studies of Asymptomatic Mexican patients with Thin basement membranes (TBM) diagnosed at time-0 biopsy.

**AIMS.**

The aim of the present study was to assess the outcome at one-year follow up of patients with thin basement membrane (TBM) diagnosed at time-zero biopsies (TZB) compared to normal basement membrane (NBM) donors.

**METHODS.**

We analyzed the clinical and histopathological characteristics of the TZB from January 2007 to January 2008; 30 subjects in total divided in two groups- Group 1(n=15) TBM and Group 2 (n=15) NBM donors. The biopsies were processed for light microscope and electron microscopy.

**RESULTS.**

The basal serum Cr were different in both groups ($p=0.24$), at the end of the follow up period the comparison of the different parameters with significance in both groups were Creatinine clearance (CrCl) ( $p=0.19$), proteinuria ($p=0.10$) and systolic blood pressure ($p=0.19$). Serum Cr (SCr) and diastolic blood pressure showed a tendency for significance.

Group 2 and Group 1 in basal (prenephrectomy) SCr and CrCl and at the end of the year of follow up had differences ($p=0.001$) in both parameters. But for the development of Proteinuria postnephrectomy only de group Group 1 showed differences ($p=0.33$).

Interstitial inflammatory cells, tubulointerstitial Fibrosis and glomerular sclerosis weren't different in both groups.

**CONCLUSIONS.**

We find differences for CrCl and SCr in both groups, with worst outcome for TBM.

The most important finding in this trial was the association of TBM and the development of Proteinuria. This could be relevant in naturally occurring renal injury.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2016**

**Information Needs of Living Kidney Donors To Improve the Informed Consent Process: A Qualitative Study** Elisa J. Gordon,[1,3] Elizabeth A. Reddy,[1] Jeffrey Beaubien,[2] Jane L. Holl,[1] John J. Friedewald.[3] *[1]Institute for Healthcare Studies, Northwestern University; [2]Aptima, Inc; [3]Surgery, Northwestern University.*

Informed consent is ethically and legally required for living donation. Transplant clinicians must disclose sufficient information for living kidney donors (LKDs) to make an informed decision and feel adequately prepared to donate. We investigated LKDs' information needs. A random sample of LKDs who donated in the past year was interviewed

via telephone about their information needs, perceptions of the informed consent process and about the independent donor advocate (IDA). Interviews lasted 20 minutes. Responses were recorded by hand-written notes and analyzed by content for repetitive themes and patterns. The response rate was 75% (15/20 LKDs). LKDs desired more information about: recovery duration and experience; impact of donation on long-term health (i.e., side effects, medications, diet, having children); surgical logistics; recipient's health; scar size; and donor testing process. Most LKDs (n=12) viewed information about short- and long-term recovery as most crucial. LKDs suggested improving the informed consent process by: providing more information about recovery, long-term health effects of donation, the donor evaluation process, and showing the donation informational video earlier. Most LKDs felt the IDA helped protect their interests (n=14) and was a good source of information (n=6), but two did not appreciate the IDA's help.

Table 1. Illustrative Quotations of LKDs' Information Needs

| |
|---|
| "Things you have to do after surgery. I underestimated how long it would take my body to readjust. I was kind of tired. Even recently, I'm just getting back." |
| "I needed to know if there would be issues getting insurance later in life and if there might be health problems early on like diabetes or kidney failure." |

Greater efforts are needed to inform LKDs about all steps involved in donation early in the evaluation process and post-operative donor health and recovery via video and IDA to ensure realistic expectations and optimize informed consent. As this was a single center study, further research is needed to more generally assess LKDs' information needs.

### F-PO2017

**Long-Term Outcomes in Highly Sensitized and ABO Incompatible Patients Undergoing Kidney Transplants** Kumar Gaurav, Rasheed A. Balogun, Douglas Scott Keith, Scott Leonard Sanoff, Peter I. Lobo. *Division of Nephrology, University of Virginia, Charlottesville, VA.*

**Introduction**: There is no consensus on how low the anti-HLA antibodies need to be reduced prior to transplant so as to avoid post-transplant rejection in highly sensitized and ABO incompatible patients. Similarly there is no data regarding the level of maintenance immunosuppression required to prevent chronic graft loss.

**Methods**: Since May 1st 2006, we performed 20 kidney transplants in highly sensitized patients who were crossmatch positive against their living donor and in 8 patients who were ABO incompatible with their living donors. All these patients underwent a desensitization protocol treatment which included the use of Cellcept, Rituximab, as well as Plasmapheresis and IVIG to decrease antibody levels such that they may only be detectable by either the flow crossmatch or by the single antigen Luminex beads but not detectable by the cytotoxic assay. Post transplant, patients were maintained on higher doses of prednisone, CellCept and Prograf.

**Results**: Out of the 20 patients who underwent the treatment protocol and subsequently the transplant, 18 still have a functioning graft at an average follow-up of 27.7 months with a mean serum creatnine of 1.3 mg/dL and no albuminuria. 7 of 9 patients with a positive flowcrossmatch had humoral rejection episodes resulting in loss of 1 allograft. None of the 11 patients that had antibodies detectable only by Luminex had a rejection episode. The difference in rejection episodes between the flow crossmatch positive patients and flow crossmatch negative patients is statistically significant ($p<0.0003$). 2 of these 20 patients died after one year of follow-up, 1 with severe heart failure and other with sepsis. All 8 ABO incompatible patients have a functioning graft after a mean follow-up of 27 months and a mean serum creatnine of 1.1 mg/dL. Only 1 of these 8 patients had a rejection episode.

**Conclusion**: Our data indicates that for successful long-term outcome in highly sensitized and ABO incompatible patients, it would be beneficial to significantly reduce antibodies pre-transplant as well as maintain these patients on more immunosuppression.

Disclosure of Financial Relationships: nothing to disclose

### F-PO2018

**Impact of the Model for End-Stage Liver Disease Allocation Policy on Patient Survival after Liver Transplantation** Aastha Sethi,[1] Michelle M. Estrella,[2] Mohamed G. Atta.[2] *[1]Renal Division, Johns Hopkins Bayview Medical Center, Baltimore, MD; [2]Renal Division, Johns Hopkins Hospital, Baltimore, MD.*

To determine the effect of implementing the model of end-stage liver disease (MELD) among liver transplant individuals on all-cause mortality, we performed a survival analysis from the time of transplant to death in individuals who underwent orthotopic liver transplantation (OLT) at a tertiary referral hospital from 05/16/1995-04/22/2009. Individuals who were <18 years old, received multiple organs, underwent status 1A transplantation, or had no follow-up 3 months after the transplant were excluded (n=199). For the remaining 419 individuals (163 in pre-MELD era, 256 in MELD era) included in the analysis, hazard ratios (HR) and 95% confidence intervals (CI) were estimated using Cox proportional hazard models. Participants were censored at the time of last follow-up or 12/31/09. Socio-demographic characteristics were similar between the two groups. Mean follow-up times post transplant in the pre-MELD and MELD patients were 8.4 and 3.1 years, respectively, with 120 deaths observed. Adjusting for age, gender, race, pre-transplant renal replacement therapy (RRT), hepatitis C status, hypertension, diabetes, and time-varying binary estimated glomerular filtration rate [eGFR < 60 vs. ≥ 60 ml/min/1.73 $m^2$], there was no survival difference between patients transplanted in the pre-MELD versus the MELD era. However, need for pre-transplant RRT (HR=2.90, CI 1.24–6.80) and low eGFR post-transplant (HR= 1.53, CI 1.10–2.13) were adversely associated with worse survival in the adjusted analyses. These estimates were unchanged even when observation time was truncated to allow similar follow-up times between the pre-MELD and MELD era groups. In conclusion, patient mortality remains high after OLT. However, there is no difference in patients' survival between the pre-MELD and MELD era. The need for RRT prior to liver transplantation and impaired kidney function after transplantation are associated with increased mortality risk after liver transplantation.

Disclosure of Financial Relationships: nothing to disclose

### F-PO2019

**Similar 10-Year Graft Survival of Living Related and Unrelated Donor Kidney Transplantation, in Spite of Differences in HLA-Matching** Igor Marques, Gustavo Ferreira, Clarice Park, Lilian P. F. Carmo, Elias David-Neto. *Nephrology, University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Aim of the study: Living unrelated donors (LUD) constitute an incremental source of kidneys for transplantation at a global level. This study examines the outcome of allograft and patient survival in LUD transplantation compared with living related donor kidney transplantation (LRD) and analyzes influencing factors. Methods: We retrospectively analyzed 389 first living donor kidney transplantations performed between 1998 and 2007 in a single center, 281 recipients from LRD and 108 from LUD. Results: In the LRD group 50 patients (17.8%) were HLA-identical siblings, 181 (64.4%) had parent donor with haploidentical HLA and the other 50 patients (17.8%) had a distinct HLA-matching. The LUD group differed from the LRD group in age, gender and HLA-matching. The patients who received a kidney from a relative were younger at the time of transplantation. The female gender represented more than half of the patients in the LRD group, while in the LUD group represented close to a third part. As expected, the LUD group had a poor HLA-matching. All the other variables had a similar distribution in both groups, including: cause of end-stage renal disease, preemptive transplantation, donor age and gender, panel reactive antibodies and immunosuppression. The incidence of acute rejection was similar in both groups (LRD 25% and LUD 26%, p=0.89). There was no significant difference in patient survival when analyzed from the time of transplantation. The 1-year patient survival in the LUD and LRD groups was 96% and 95.3%, 5-year 91.6% and 92.4% and 10-year 89.1% and 84.7%, respectively. The death-censored graft survival rates for LUD transplants were 94.8% at 3 years, 91.7% at 5 years and 68.9% at 10 years, comparable to those for LRD transplants (excluding HLA-identical siblings), which were 92.5% at 3 years, 88.9% at 5 years and 81.1% at 10 years (p=0.77). Conclusion: In spite of poor HLA-matching, long-term graft survival of LUD kidney transplantation is similar to haploidentical and distinct LRD transplantation.

Disclosure of Financial Relationships: nothing to disclose

### F-PO2020

**Designation of Long Term Outcome Program for Iranian Living Unrelated Kidney Donors (LURD): Update Report** Ali Nobakhthaghighi, Ezzatollah Abdi, Tahereh Malakoutian, Ehsan Nobakht, Mohammad Kamgar, Niloofar Nobakht, Varshasb Broumand, Laila Nobakhthaghighi, Monir Sadat Hakemi, Behrooz Broumand, Iraj Fazel. *Academy of Medical Sciences of Iran.*

Introduction:The government-regulated compensation for LURD transplantation has decreased the waiting time and the number of patients in Iran national waiting list. However, the long term outcome of living donors is not well understood. A 10 year controlled cohort study has been started by Academy of Medical Sciences in cooperation with Charity Foundation for Especial Diseases since June 2006 to evaluate long term medical complications of kidney donors.

Methods: LURDs who had donated their kidneys after1995 were asked to participate in the study. Age, gender, BMI, systolic blood pressure(SBP), diastolic blood pressure(DBP), blood sugar(BS), hemoglobin, BUN, creatinine,lipid profile, urinalysis, urine albumin/creatinine and GFR are recorded.

Results: 1616 donors have been registered so far. 963 underwent nephrectomy between 2006 -2007. 97 donors underwent nephrectomy between1995-2003. The average time between nephrectomy and the study enrolment was 316.7 days. Mean age at the time of first visit was 30.4± 6.1 with 1333 (82.5%) male and 283(17.5%) female with mean BMI 23.5 ± 4.4 mean SBP 107 ±12.2 and mean DBP 75.3± 7.7. Mean GFR was 87.6±24 at the time of enrolment. Mean LDL was 98.12±32.2. Mean urine albumin/creatinine ratio was 6.1± 9.1mg/gram.67 of the kidney donors who underwent nephrectomy at least 5 years before the first visit and had at least 2 annual visits were selected. No statistically significant differences in BMI, SBP,DBP, BS, hemoglobin, LDL, urine albumin/creatinine ratio and GFR were observed in their follow up visits.

Conclusion: Most of the study participants were young with normal BMI and SBP. No worsening of SBP,GFR and proteinuria was observed in donors who had at least two annual follow up, however those are only small percentage of our study population.Most of the donors underwent nephrectomy within 1 year of study enrollment and long term follow up is needed to assess their prognosis. Further monitoring and comparison to normal subjects will be reported in future.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2021**

**Characteristics of an Online Renal Data-Sharing Initiative – The PatientsLikeMe Transplants Community** C. Brownstein,[1] P. Wicks,[1] T. Vaughan,[1] M. Massagli,[1] G. Junge.[2] *[1]Research and Development, PatientsLikeMe, Cambridge, MA; [2]Global Program, Novartis Pharma AG, Basel, Switzerland.*

PURPOSE: Renal transplant patients face medical and personal challenges such as monitoring their health, adhering to medication, and coping with emotions. While well-supported during the immediate post transplant period by healthcare professionals, patients may benefit from other means of support in the long term, such as peer to peer networking.

METHODS: The PatientsLikeMe Transplants Community allows patients to share detailed information about medical history, diagnosis leading to end stage renal disease, health-related quality of life, lab values (including blood pressure, serum creatinine, and GFR-4D), symptoms, and treatments with other patients.

RESULTS: Since its launch in Spring 2010, PatientsLikeMe hosted data from 681 kidney transplant recipients (792 transplants). Mean current age is 42±11 years, with 66% females. Mean age at transplant is 36±12 years; patients report spending a median of 11 months on the waiting list (range 0–11.8 years). Of those reporting a causative condition (N=566, 83%), the most common are hypertension (50%), diabetes (21%), glomerulonephritis (18%), and PKD (13%). 714 organs are of known origin (90%). 53% of organs were donated by living donors (81% related), 47% were from cadaveric donors. HLA mismatch data is available for 393 kidneys (50%) [Table 1]; there are significant differences in HLA mismatch between deceased (1.5±1), living (2.3±2), and living-related donors (1.9±1, respectively, F=6.5, df=2, p=0.002). Sibling-donated kidneys have the fewest HLA mismatches (1.4±1, N=79), followed by parents (2.0±1, N=36), children (2.1±1, N=19), and any other relation (2.5±2, N=48) (F=5.4, df=3, p=0.001).

CONCLUSION: Many patients who experience a life-changing event such as a renal transplant are willing to share detailed health data. This growing Community may advance scientific and medical research efforts as well as provide educational and support opportunities for patients willing to participate.

Table 1. HLA-A, B, DR mismatches

| Mismatches | N | % |
|---|---|---|
| 0 | 113 | 29 |
| 1 | 66 | 17 |
| 2 | 87 | 22 |
| 3 | 80 | 20 |
| 4 | 23 | 6 |
| 5 | 24 | 6 |
| 6 | 0 | 0 |
| Total | 393 | 100% |

Disclosure of Financial Relationships: Employer: PatientsLikeMe; Ownership: PatientsLikeMe.

**F-PO2022**

**Serum Angiotensin Converting Enzyme-2 Activity as a Marker of Cardiovascular Risk in Kidney Transplant Patients** Maria Jose Soler, Marta Riera, Marta Crespo, Judit Rigol, Marisa Mir, Eva Rodriguez, Josep M. Puig, Julio Pascual. *Nephrology, Hospital del Mar. Parc de Salut Mar. Fundació IMIM, Barcelona, Spain.*

Angiotensin converting enzyme(ACE)-2 is an enzyme that counterbalances ACE activity. The role of ACE2 in kidney transplant(KT) patients is unknown. The aim of this study is to investigate whether ACE2 activity is altered in KT patients as compared with controls. In addition, we studied the correlation between serum ACE2 activity and age, gender, graft function and analytical cardiovascular risk markers in KT patients.

ACE2 activity was assessed using a fluorescent assay in 113 KT patients(age 55±12yr, GFR-MDRD 44.8±11.3mL/min). Chronic kidney disease(CKD)-Stage 3 patients(n=27, age 57±10yr, GFR-MDRD 41.4±8.6)age, gender and MDRD-matched served as controls.

Serum ACE2 activity was decreased in KT patients as compared to CKD patients(35.4±2.8 vs 67.6 ±13 RFU/mL/h, p<0.05). In the univariate analysis, ACE2 activity was increased in KT patients with ischemic heart disease as compared with KT without ischemic heart disease (45.1±7.6 vs 34.3±2.9, p<0.05). In addition, ACE2 activity was increased in male as compared with female KT patients (42.7±3.7 vs 21.9±2.8, p<0.05). Renin angiotensin system blockade did not influence serum ACE2 activity. In multiple regression analysis, creatinine, LDL-cholesterol, gamma glutamyl transferase, gender, and hemoglobin were independent predictors of serum ACE2 activity.

Multiple linear regression analysis of independent predictors of serum ACE2 activity in KT patients.

| Risk factor | Standardized coefficient (Beta) | p-value |
|---|---|---|
| Gender | -0.284 | 0.002 |
| Serum creatinine (mg/dL) | 0.223 | 0.014 |
| Gamma glutamyl transferase (UI/L) | 0.222 | 0.008 |
| LDL-cholesterol (mg/dL) | 0.182 | 0.029 |
| Hemoglobin (g/dL) | 0.209 | 0.020 |

Data are expressed as regression coefficients and p-values. Dependent variable: serum ACE2 activity RFU/µL/h expressed in lnACE2; multiple r2 = 0.34, p < 0.001.

In conclusion, serum ACE2 activity in KT patients is increased when graft function is decreased and it is directly correlated with clinical and biochemical cardiovascular risk markers.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2023**

**Gonadal Dysfunction Associated with mTOR Inhibitor Treatment Is Reversible** Jordi Rovira, Barbara Vodenik, Maria J. Ramirez-Bajo, Elisenda Banon-Maneus, Daniel Moya-Rull, Marta Arias, Luis F. Quintana, Fritz Diekmann, Josep M. Campistol. *Nephrology and Renal Transplantation, Laboratori Experimental de Nefrologia I Trasplantament (LENIT), Hospital Clinic de Barcelona, Fundacio Clinic per la Recerca Biomedica, Barcelona, Spain.*

Recent studies observed an association of SRL treatment with gonadal dysfunction in transplant recipients.

The aim of this study is to characterize the effect of mTOR inhibition on spermatogenesis, showing the morphology changes on seminiferous tubules and sexual hormone profile, as well as to analyze the withdrawal of mTOR inhibition.

**Material and methods:**

Adult male *Wistar* rats were distributed in two groups according to intraperitoneal administration of vehicle (VEH; n=8), SRL (n=24) 1mg/kg three times a week. VEH group was treated for 12 weeks. Rats treated with SRL were sacrificed at 4, 8 and 12 weeks. A group of rats was treated with SRL for 4 weeks and then continued with vehicle injection during 8 weeks. This group was used to analyze the possible reversibility of the effect of mTOR inhibition. Body and testicular weight, testosterone, FSH and LH levels were measured. The testes were collected to perform histological measurements; seminiferous tubules area and inner diameter. The proliferation was performed by immunohistochemistry using Ki67 and PHH3 stain.

**Results:**

Testosterone levels were decreased after sirolimus treatment and recovered after withdrawal. The testes weight was significantly lower in SRL groups compared with VEH group. 8 weeks after a 4 cycle of SRL treatment permitted testicular weight had partially recoverd. The spermatogenesis was totally blocked on the spermatogonial level by SRL treatment. Withdrawal of treatment led to complete recovery spermatogenesis.

**Conclusions:**

mTOR inhibition in healthy animals produces sexual hormone dysfunction, a seminiferous tubule dystrophy and the blockade of spermatogenesis. This blockade is reversible.

**Effect of Blood Transfusions on Mortality and Long Term Renal Graft Outcome in Renal Transplant Patients** Frank J. O Brien, James Lineen, Claire Kennedy, Peter J. Conlon. *Department of Nephrology, Beaumont Hospital, Dublin, Ireland.*

Background

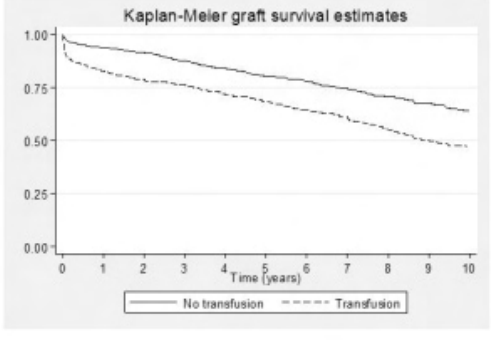
It has been established that patients who receive blood transfusions pre transplant spend a longer time on the transplant pool, and have higher rates of rejection. Little evidence exists on the long term graft outcomes in patients who receive transfusions at the time of transplant. This study aims to establish if there is a relationship between the receipt of blood transfusions at time of transplant and long term graft survival.

Methods

This was a single center, national, retrospective cohort study. Data was collected on patients who received kidney transplants over a 14 year period(n=2013). The primary outcomes were graft survival and mortality in patients who received blood transfusions compared to those that did not. Subsequent multi variate analysis using Cox's proportional hazard model was used to examine the effect of hemoglobin, donor and recipient age, CMV status, acute rejection, PRA and HLA. Log rank test was used to compare the two groups and Kaplan Meier survival curves were subsequently created.

Results

In the first year post transplant there was a lower rate of graft survival in those that received a blood transfusion compared to those that did not, p<0.001.



There was a strong association between number of units transfused and graft survival. Patients who received one blood transfusion had a ten year graft survival of 52%, while those that received four had a graft survival rate of 41% at ten years.

Using a Cox's proportional hazard model, perioperative blood transfusions had an independent negative effect on graft survival when adjusted for donor and recipient age, acute rejection and PRA group. Hemoglobin levels prior to transfusion did not have an influence on graft outcome.

Conclusion

Perioperative blood transfusion is associated with adverse effects on long term graft outcome.

**Endothelin Receptor Plays Role in BK Polyoma Virus Infection of Renal Epithelial Cells** Andrey Sorokin,[1] Bradley S. Miller,[1] Takahito Moriyama.[2] *[1]Department of Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Department of Medicine, Tokyo Women's Medical University, Tokyo, Japan.*

Although potent immunosuppressive therapies are useful for acute and chronic rejection, they become a risk factor for the progression of latent BK virus (BKV) to BKV nephritis after renal transplantation. Little is known about the mechanisms for BKV entry into human tubular epithelial cells (natural target of BKV), but it is likely that virus initially attaches to the α(2,3)-linked sialic acid of an N-linked glycoprotein of unknown nature. Expression of endothelin receptors is markedly higher in proximal tubular epithelial cells in transplanted kidney. We have established that antagonist of Endothelin Receptor B (ETRB) BQ788 prevented BKV infection of cultured human renal proximal tubular epithelial cells (HRPTEC). The percentage of infected cells and the cellular levels of BKV large T antigen expression were significantly decreased in HRPTEC treated with BQ788, but not in HRPTEC treated with BQ123 (antagonist of Endothelin Receptor A). In order to confirm that BQ788 decreases BKV entry into HRPTEC we have analyzed distribution of Alexa Fluor 488 labeled BKV particles in HRPTEC after 4 hours incubation. We observed that in control HRPTEC labeled BKV particles were located mostly in the cytoplasm, whereas in HRPTEC treated with BQ788 a significant portion of BKV particles was located on the cell surface indicating that BQ788 interferes with entry pathway of BKV. We also tested ability of PD145065, an unselective antagonist which blocks both ETRB and ETRA, for its ability to prevent infection by BKV. It appears that PD145065 was unable to mitigate infection, suggesting that inhibition of endothelin signaling is not sufficient to prevent BKV infection. Thus, BQ788 acts not through inhibition of signaling from ETRB, but because it possesses the unique ability to interfere with BKV infection likely by preventing viral particles from attachment to cellular BKV receptor. Further studies are necessary to test whether blocking ETRB could represent a simple feasible alternative strategy to treat BKV infection without any long-term negative impact to renal allograft.

**F-PO2026**

**Everolimus May Reduce Need for Cytomegalovirus Infection Prophylaxis Versus Mycophenolate in *De Novo* Renal Transplant Recipients: Results from a Pooled Analysis of Three Prospective Studies** Fuad S. Shihab,[1] K. Mange.[2] *[1]University of Utah School of Medicine; [2]Novartis Pharmaceuticals Corporation.*

**Purpose**: Organ transplant recipients at risk for cytomegalovirus **(**CMV) infections typically require prolonged antiviral prophylaxis therapies that increase the economic burden in post-transplant care. Use of everolimus (EVR) with cyclosporine (CsA) in renal transplant (RTx) patients decreases the incidence of CMV, which may translate as an economic benefit of EVR vs. mycophenolate (MPA).

**Methods:** CMV data from 2004 *de novo* RTx recipients from three EVR studies A2309 (N = 833), B201 (N = 588) and B251 (N = 583) were analyzed to identify differences between EVR dosing groups and MPA control groups. In all studies, EVR groups received either 1.5 mg/day, or 3 mg/day with either standard or reduced dose cyclosporine based on individual study designs. All control groups received MPA with standard dose CsA. Steroids were given as per center practice. CMV events were reported as per local center evaluations.

**Results**: CMV prophylaxis was used in approximately 30% of all RTx recipients, primarily in those with D+R- serology. Time to first CMV event (infection/syndrome, viremia, or disease) was analyzed between two treatment groups: EVR group (EVR 1.5 and 3.0 mg combined, N=1335) vs. MPA group (EC-MPA or MMF, N=669). Mean time to first CMV event for EVR 1.5 mg, EVR 3.0 mg and MPA groups were 194, 190 and 124 days after transplant. Hazard ratio (HR) adjusted for study effect and donor/recipient serology was 2.214 for MPA vs. EVR ($p<0.0001$). In the populations who did not receive prophylaxis, adjusted HR was 2.769 for MPA vs. EVR ($p<0.0001$). An analysis of the D+R- serology subgroup who did not receive prophylaxis identified a HR of 2.167 for the MPA vs. EVR ($p<0.0179$).

**Conclusion**:This pooled analysis documents significant reduction in risk (measured as HR) for CMV events in EVR-treated *de novo* RTx recipients compared with the MPA control group. In addition, time to first CMV event is prolonged for EVR vs. MPA, and although this additional analysis is not rigorous, this delay in onset of CMV may positively impact the economic burden of post-transplant management.

**F-PO2027**

**Diagnosis and Monitoring of UTIs in Renal Transplant Recipients: A Higher Than Expected Incidence of Shed Urothelial Cell Colonization by Bacteria** Holly R. Courtneidge,[1] Alberto Contreras-Sanz,[1] Rita La Rovere,[1] Rebecca Birch,[1] Chloe J. Goonewardene,[2] Chris Mark Ambrose,[2] Harry Horsley,[2] James Malone-Lee,[2] Scott S. P. Wildman,[1] Mark A. Harber.[2] *[1]Royal Veterinary College, London, United Kingdom; [2]UCL Medical School, London, United Kingdom.*

Renal transplant recipients (RTRs) are susceptible to recurrent UTIs. It is acknowledged that there is considerable insensitivity of routine urinalysis when screening for UTIs. A large number of patients with genuine urine infections go undiagnosed and develop chronic recalcitrant infections; which can be associated with morbidity and graft loss. We investigated alternative UTI detection techniques and used these to investigate the natural history of UTIs in a cohort of RTRs.

MSUs were collected from 113 RTRs and 31 controls. Microscopic pyuria counts (in 1μl) and ATP measurements (normalised to creatinine levels), were performed on fresh unspun samples and compared to conventional nitrite and leukocyte dipsticks and bacterial culture results. Cytospun urine samples were stained with acridine orange (and crystal violet) to identify intracellular bacteria (IB) in shed urothelial cells.

Of the RTRs, 22.6% were deemed to have a UTI by 'gold standard' conventional culture, whereas 7.5% and 69.8% had UTIs according to nitrite and leukocyte dispsticks, respectively. Significant pyuria (≥10 wbc in 1μl urine [1]) revealed 84.9% of RTRs had a UTI. ATP levels were found to be 6.7±3.6 nM and 4.5±0.5 nM in RTRs deemed to have a UTI (by conventional culture) and those that did not, respectively. In controls 3.2% had significant pyuria,and ATP level was 3.8±2.1 nM. IB were visualised in shed urothelial cells in 45.3% of RTRs, and 0% of controls. Only 1.8% of RTRs with IB were deemed to have a UTI by conventional culture.

It is apparent that standard bedside tests for UTIs give variable results and that quiescent bacteria in urothelial cells is more common in RTRs than previously thought. Our results suggest that measuring urinary ATP is not an alternative test for UTI detection, but significant pyuria (≥10 wbc in 1μl fresh unspun urine) may be a more sensitive test to determine UTIs and quiescent IB.

**Risk Factors for Post Renal Transplant BKV Infection** Ankit Sakhuja, Kumar Sujeet, Y Ran Zhu, Brahm S. Vasudev, Ehab Saad, Barbara Bresnahan, Sundaram Hariharan. *Division of Nephrology, Medical College of Wisconsin, Milwaukee, WI.*

Introduction: BKV infection can progress to BKV nephritis leading to graft failure. This study evaluated our ability to predict BKV infection.

Methods: This prospective study was undertaken at our center after a formal IRB approval. A total of 189 renal transplant recipients from July 2007 – Sept 2009, followed till May 2010. All subjects were screened for quantitative BKV DNA (blood and urine) at 1, 3, 6,and 12 months post-tx. Detection of BKV in plasma and or urine was defined as BKV infection. Immunosuppressive therapy consisted of MMF, Tac and Pred. Recipient, Donor demographics, transplant and post transplant variables were correlated to post-transplant BKV infection. ANOVA and Chi Square tests were used for statistical analysis.

Results: A total of 65/189 (34%) had BKV infection, 48 (25%) BK viremia and viruria; and 17 (9%) BK viruria alone. The following table shows the results of univariate analysis for various risk variables to post-transplant BKV infection.

Table 1

| | BK viremia and viruria (n =48) | BK viruria alone, (n = 17) | No BKV infection, (n = 124) | P |
|---|---|---|---|---|
| Recipient: Mean Age (yrs) | 51.6 ±10.7 | 46.3 ± 11.0 | 50.7 ± 11.9 | 0.222 |
| Sex (M/F) | 34/14 | 11/6 | 73/51 | 0.252 |
| Race (W/B/O) | 31/6/10 | 14/2/1 | 70/44/10 | **0.003** |
| PRA Class I (Mean, %) | 16.8 ± 31.6 | 22.7 ±381. | 10.8 ± 24 | 0.686 |
| PRA Class I (Mean, %) | 7.3 ± 20.9 | 13.7 ± 30.9 | 8.2 ±22.8 | 0.814 |
| CIT - minutes | 930 ± 399 | 840 ± 506 | 815 ±396 | 0.401 |
| HLA AB mismatch | 2.7 ±1.2 | 1.9 ±1.4 | 2.8 ± 1.2 | 0.05 |
| HLA DR mismatch | 1.3 ±0.59 | 1.1 ± 0.66 | 1.3 ± 0.65 | 0.372 |
| Induction Ab (Thymo vs IL2 R blocker vs none) | 19/26/3 | 5/11/1 | 54/63/7 | 0.514 |

In addition, donor demographics, donor source (LD vs DD), Kidney vs Kidney/Pancreas Txs, post-transplant variables (DGF, acute rejection) did not correlate with BKV infection (data not shown).

Conclusion: The current study shows a lower prevelance of BKV infection in African Americans as opposed to Caucasians. However, there was no other overt risk factors identified to the occurrence of BKV infection.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2029**

**Impact of Steroid Avoidance on BK Virus Infection in Renal Transplantation**
Maria Marin, Saurabh K. Goel, Robert A. Sessions, Mohamed A. El-Ghoroury. *Dept of Nephrology, St John Hospital and Medical Center, Detroit, MI.*

Polyomavirus-associated nephropathy (PVAN), caused by BK virus, is an increasingly recognized cause of renal allograft dysfunction and graft loss. While the only widely accepted risk factor for PVAN is the degree of overall immunosuppression, the specific role for different immunosuppressants remains poorly characterized. We sought to determine if steroid use impacts the incidence of BK virus infection.

We retrospectively reviewed the charts of 101 consecutive renal transplant recipients screened for BK virus by plasma/urine PCR. Screening was performed at 1, 3, 6, 12 months after transplantation. BK virus infection was defined as plasma viral load of ≥ 10,000 DNA copies/ml and/or urine viral load of ≥ 10,000,000 DNA copies/ml. All patients received induction with rabbit ATG. Immunosuppression at hospital discharge included tacrolimus, mycophenolic acid ± prednisone, per institution protocol. Mean follow-up was 18.5 months. Total of 19 patients (18.8%) had evidence of BK virus infection including 12 (11.9%) with significant viremia. Renal biopsy performed (for increasing creatinine by >25%) in 7 patients with viremia showed PVAN in 6 cases.

BK viremia, viremia and/or viruria and PVAN depending on the steroid treatment (ITT population)

| | Patients on steroids (n=57) | Patients not on steroids (n=44) | p-value |
|---|---|---|---|
| Viremia n (%) | 6 (10.5%) | 6 (13.6%) | 0.632 |
| Viremia+/viruria n (%) | 12 (21.1%) | 7 (15.9%) | 0.512 |
| PVAN n (%) | 3 (5.3%) | 3 (6.8%) | 0.743 |

Viremia was defined as > 10,000 DNA copies /ml, viruria as >10,000,000 DNA copies/ml, PVAN was defined by renal allograft biopsy positive immunohistochemical staining for BK virus

eGFR was significantly lower at 18 months in patients with BK virus infection than in those without infection (41.3 vs. 57.5 ml/min; p=0.05). Two patients with PVAN progressed to ESRD. One patient needed ureteral stent placement for ureteral stenosis.

In conclusion, treatment with steroids does not appear to increase the incidence of BK virus infection in renal transplant patients. Larger, prospective studies are needed to address the specific effect of steroids on the incidence and outcome of BV virus infection.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2030**

**Circulating Endothelial Cells Are Elevated in Cytomegalovirus Infection in Transplantation**
Uta Erdbruegger,[1] Emily Dey Hazra,[2] Barbara Hertel,[2] Alexander Woywodt,[3] Torsten Kirsch,[2] Hermann G. Haller,[2] Marion Haubitz.[2] *[1]Dep. of Medicine, Div. of Nephrology, University of Virginia Health System, Charlottesville, VA; [2]Dep. of Medicine, Div. of Nephrology, Hannover Medical School, Hannover, Germany; [3]Lancashire Teaching Hospitals NHS Foundation Trust, Nephrology, Lancashire, United Kingdom.*

Cytomegalovirus (CMV) infection is a frequent complication in the early post-transplant period. CMV pp65 antigenemia testing and CMV PCR are used to diagnose and monitor disease activity. However, additional markers to better predict the clinical course are needed. Since CMV infection is associated with endothelial damage we hypothesize that circulating endothelial cells (CEC) are elevated in CMV infection and correlate with disease activity.

The study cohort consisted of 11 transplant recipients with CMV (2 bone marrow transplant recipients, 6 renal -, one liver-, one heart- and one lung transplant), 11 disease controls (DC) (renal transplant recipients without CMV, matched per age and transplant age) and 11 healthy controls (HC).

CEC were isolated with anti-CD146 driven immunomagnetic isolation and counted after staining with Ulex Europaerus lectin 1. CEC were measured once a patient was found to have active CMV disease reflected by positive CMV PCR and CMV antigenemia testing and repeated every 4 to 5 days until a negative result for CMV antigenemia and CMV PCR testing was obtained.

CEC were significantly elevated in patients with CMV (155.6/ml ±158 STD) compared to DC (33.6/ ml ±14.9, p=0.0324) and HC (10.9/ml ±6.0, p=0.0112). CEC levels between DC and HC also differed significantly (p=0.0026). 32 serial measurements of CEC were obtained in patients with active CMV. CEC correlated significantly with CMVpp65 (R 0.46, p=0.008), but not with CMV PCR (R 0.249, p=0.264) whereas CMVpp655 and CMV PCR correlated significantly (R 0.993, p=0.0001).

CEC are elevated in CMV infection after transplantation and correlate with CMV antigenemia. This might reflect endothelial damage caused by CMV. Routine and serial testing of CEC needs to be done to establish CEC as a sensitive clinical marker compared to CMV pp65 and CMV PCR which reflect only virus replication.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2031**

**Correction of Metabolic Acidosis with Potassium Citrate in Renal Transplant Recipients**
Alf Corsenca,[1] Astrid Starke,[2] Rudolf P. Wuthrich,[1] Patrice M. Ambühl.[2] *[1]Division of Nephrology, University Hospital Zurich, Zurich, Switzerland; [2]Renal Division, Stadtspital Waid Zurich, Zurich, Switzerland.*

Persisting disturbances in acid/base homeostasis may negatively impact on several metabolic pathways in renal transplant patients (RTP), specifically in muscle and bone mineral metabolism. The aim of this study was to prospectively examine the efficacy and safety of potassium citrate (K-Cit) versus potassium chloride (K-Cl) with regard to normalization of acid/base derangements in RTP with chronic metabolic acidosis.

30 RTP with chronic metabolic acidosis (serum bicarbonate < 24 mmol/L) and stable renal graft function were randomized to receive an individualised dose of either K-Cit (N=19) or K-Cl (N=11) to achieve a bicarbonate level of ≥ 24 mmol/L over 12 months of treatment.

| | Baseline | | Month 1 | | Month 6 | | Month 12 | |
|---|---|---|---|---|---|---|---|---|
| | K-Cit | K-Cl | K-Cit | K-Cl | K-Cit | K-Cl | K-Cit | K-Cl |
| Bicarbonate, mM/L | 21.3±2 | 20.4±2 | 24.9±2* | 21.8±2 | 24.1±3* | 21.6±2 | 24.3±3* | 21.4±2 |
| Potassium, mM/L | 4.2 | 4.1 | 4.7 | 4.4 | 4.7* | 4.2 | 4.4 | 4.3 |
| eGFR, ml/min | 51±13 | 60±19 | -- | -- | -- | -- | 50±11 | 56±14 |
| Citrate dosage, gr | 0 | 0 | 3.3±0.4 | 0 | 4.0±2.3 | 0 | 4.7±2.1 | 0 |
| Potassium dosage, mmol | 0 | 0 | 58±7* | 25.4±9 | 71±41* | 27.3±10 | 83±37* | 28.2±10 |

*) P < 0.05 vs. K-Cl

Serum potassium did not reach critical concentrations at any time point in either treatment group. Adverse treatment effects consisted mainly of mild gastrointestinal symptoms in both groups.

This is the first study demonstrating that metabolic acidosis can effectively and safely be normalized in patients with a renal graft. K-Cit was associated with a trend to slightly better preservation of renal graft function. In analogy to demonstrated benefits in patients with native CKD improving acid/base homeostasis may be advantageous in preserving GFR of grafted kidneys too. Further analysis of our data will focus on the impact of K-Cit on bone structure, mineral metabolism, physical performance and quality of life in RTP.

**F-PO2032**

**Factors Relating Renal Resisitive Index in Renal Transplant Recepients**
Siren Sezer, Sebnem Karakan, Nurhan Ozdemir. *Nephrology, Baskent University Hospital, Ankara, Turkey.*

**Background:** An increased renal allograft renal resistive index (RRI), which represents the percentage reduction of the end-diastolic flow as compared with the peak systolic flow, is associated with long-term greft survival. We aimed to find the clinical and laboratory parameters correlated with RRI measurements.

**Method:** We included 82 patients at the first year of transplantation and followed for 5 years prospectively. We recorded parameters as demographic and clinical features, laboratory values including rutine parameters with fetuin-A and HOMA index. Patients RRI was measured with Doppler ultrasonography.

**Results:** Baseline GFR was estimated as 82.4±11.3 mL/min/1.73 m². Fifty-nine (71,9%) had low RRI and 23 patients (29.1%) had high RRI according to the accepted RRI cut off 0.70. There were positive correlations between Fetuin A (r=+0.22, p=0.04), HOMA index (r=+0.24, p=0.02), systolic blood pressure (r=+0.53, p=0.00), diastolic blood pressure (r=+0,04, p=0,00) and proteinuria (r=+0.01, p=0.03), phosphorous (r=+0.19, p=0.04), C-reactive protein (r=+0.13, p=0.02). Comparison of variable factors in patients with low and high RRI is shown in table [table]. In linear regression analysis, independent factors affecting RRI were systolic BP (β=+0,36, p=0,00), serum CRP(β=+0,21, p=0,02), albumin(β=+0,29, p=0,00) and phosphorus (β=+0,21, p=0,00). At the end of five years follow up, increased RRI was associated with poor renal outcome (19% vs 8%, p=0,00) and had lower survival (p<0.05, log-rank test).

Comparison between patient groups

| | Low RRI(<0,70) | High RRI(≥0,70) | p |
|---|---|---|---|
| Fetuin A(g/L) | 43,1±21,1 | 53,6±20,4 | 0.02 |
| HOMA index | 2,2 ±1,0 | 2,8±1,1 | 0.00 |
| Systolic blood pressure(mm/Hg) | 113,3±8,1 | 126,6±13,7 | 0.00 |
| Diastolic blood pressure(mm/Hg) | 77,6±6,6 | 86,2±9,5 | 0.00 |
| Proteinuria(mg/d) | 282,2±167,7 | 668,7±364,7 | 0.01 |
| Albumin (g/d) | 3,7±0,3 | 3,9±0,2 | 0.02 |
| C-reactive protein (mg/l) | 2,1 ±0,7 | 2,6±1,2 | 0.01 |

none

**Conclusion:** RRI is a valuable tool for evaluating intrarenal damage, target organ damage and subclinical atherosclerosis. RRI should be monitored and it should be included in the routine investigations of renal allograft recipients during follow-up period.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2033**

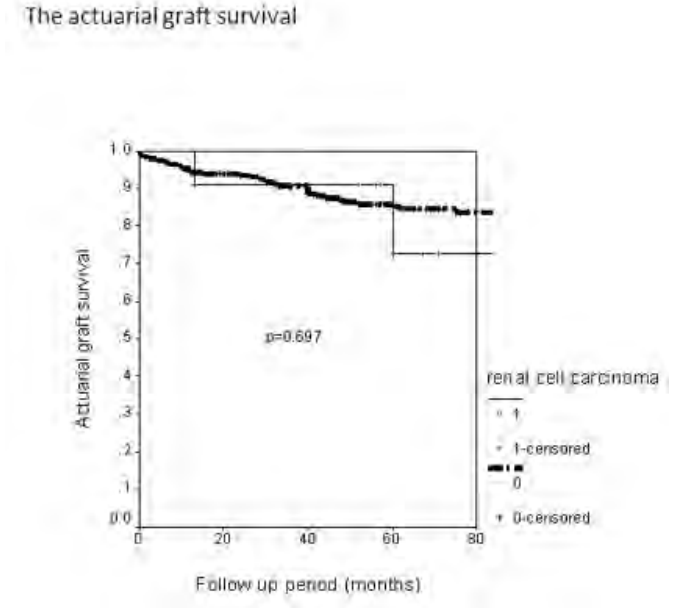
**Accidental Discovery of Renal Cell Carcinoma in Patients with ESRD at Time of Renal Transplantation: Impact on Transplant Outcome**
Hussein M. A. Sheashaa, Helmut G. Rennke, Helen Mah, Edgar L. Milford, Anil Chandraker, Abdelaziz A. Elsanjak. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: Renal tumors are common in the pre-transplant ESRD population. Their impact on transplant outcome has not been well addressed.

Methods: Our study is a retrospective follow-up observational study conducted in 258 renal transplant recipients. All of them had an ipsilateral native nephrectomy at the time of transplantation. We reviewed the histopathology of their native nephrectomies to measure

the prevalence of renal cell carcinoma (RCC) and to address the impact of accidental discovery of RCC on graft and patient outcome.

Results: RCC was found in 12 cases (4.7%); clear type in 9 cases, chromphobe and combined clear and papillary type in 1 and 2 cases respectively. There was no significant difference in HLA mismatch, primary immunosuppression, occurrence of rejection, graft function and patient and graft survival between patients with or without RCC (Figure 1). RCC presented in the other native kidney in 3 cases (25%) post-transplantation and one of them developed metastasis 4 years after renal transplantation in RCC group in comparison to 8 cases in the control group (3.3%) one of which developed metastasis 7 years after renal transplantation ($p<0.001$). The median follow up was period was 56 months for RCC group and 65 months for the control group.



Conclusions: We found that renal transplant outcome is not adversely affected by the presence of accidently discovered RCC at the time of transplantation. Patients with an accidentally discovered RCC at time of renal transplantation appear to be at significantly higher risk of the occurrence of RCC in the remaining native kidney. Further studies are warranted to confirm our results.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2034**

**Urinary Free Light Chains in Patients with Kidney Transplant Rejection** Min Li, Kanwaljit K. Chouhan, Kristine E. Gullo, Altaf-M. Khan, Nazih L. Nakhoul, Eric E. Simon, Rubin Zhang, Vecihi Batuman. *Section of Nephrology and Hypertension, Department of Medicine, Tulane University School of Medicine, New Orleans, LA.*

Urinary levels of polyclonal *kappa* and *lambda* free light chains (FLC) were evaluated as a potential novel biomarker for kidney transplant rejection. FLC were measured with a nephelometric immunoassay and correlations with kidney function were sought in 103 patients. Urinary FLC- to -creatinine ratios were compared with other low-molecular weight urinary biomarker proteins, including retinol-binding protein (RBP), β2-microglobulin (β2M), cystatin C (CSC), and immunoassayed urinary microalbumin to creatinine ratio (UACR). As controls, urinary FLC levels were obtained from healthy individuals. In kidney transplant rejection, patients with a biopsy diagnosis of acute tubular necrosis (ATN), chronic allograft nephropathy (CAN) and acute rejection (AR) exhibited highly increased urinary κFLC and λFLC and as well as urinary total (κ+λ) FLC/creatinine and FLC/CSC ratios. UACR, β2M and RBP fluctuated widely in subjects with ATN, CAN and AR. β2M and RBP showed no significant difference among groups compared to normal individuals. Significant correlations were noted with urinary FLC/creatinine and kidney function (serum creatinine and estimated glomerular filtration rate) in the ATN, CAN and AR groups. However, the urinary FLC/CSC ratio did not correlate with kidney function. In acute kidney rejection, urinary total (κ+λ) FLC/creatinine was markedly increased and correlated highly with UACR. Among all potential biomarkers examined for AR, FLC yielded the best predictive value at 87.8%, with 61% sensitivity and 78.3% specificity, RBP was the second best predictor (78.1% positive predictive value, 58.2% sensitivity and 66.7% specificity) and UACR was the third, while β2M and CSC were not significantly correlated with AR. These results suggest that monitoring the levels of urinary FLC would be useful for predicting early allograft rejection.

**Influence of Different HAART Regimen on Interstitial Fibrosis and Tubular Atrophy in HIV Kidney Transplant Recipients** Lissa B. Levin, Gregory Malat, Blair Weikert, Alden Michael Doyle, Karthik M. Ranganna. *Medicine, Drexel University College of Medicine, Philadelphia, PA.*

Transplantation in HIV+ recipients is safe and effective, but a high degree of awareness of complex pharmacology is required. Cyclosporine, sirolimus and prednisone is our maintenence immunosuppression regimen in HIV recipients. There is known to be interaction between the protease inhibitors (PI) and the differential metabolism of immunosuppressants, which may potentiate the calcineurin-inhibitor nephrotoxic effect. Protease inhibitors are known to be potent inhibitors of CYP3A4. Cyclosporine and sirolimus are CYP3A4 substrates, administration of these immunosuppressants with an inhibitor like any of the aforementioned protease-inhibitors decreases the dosage requirement of the immunosuppressants and increases the potency and possible toxicity of a comparable immunosuppressant dose.

We hypothesized that the the biopsies of the patients on PI therapy would show more severe IFTA (interstitial fibrosis and tubular atrophy) scores than patients on non-nucleoside reverse transcriptase inhibitor based regimen (NNRTI). At our institution, we have transplanted 92 HIV-positive patients since 2001. Of those patients, 50 were on PI-based regimens and 29 patients were on NNRTI-based regimens. We excluded those patients on combination of PI and NNRTI, or on neither a PI or NNRTI. Surveillance and for-cause allograft biopsies were graded using the Banff classification schema for interstitial fibrosis (ci) and tubular atrophy (ct), with scores ranging from 0-3 for both parameters. The sum of ci and ct scores provided the basis for analysis between the two groups.Analysis of the biopsy data from the two groups showed no difference between the average scores of subjects on PI vs. and those on NNRTI-based regimens. One year IFTA scores within the PI-based group averaged 1.8 vs. average scores within the NNRTI group of 2.1 ($p=0.592$). Three year IFTA scores within the PI-based group averaged 2.3 vs. average scores within the NNRTI group of 2.6 ($p=0.39$). Our analysis indicates that NNRTI-based and PI-based regimens are similar with respect to chronic allograft injury.

**F-PO2036**

**ImmuKnow™ (Cylex) Assay Results in the First Year Post-Transplant and Relationship to BK Virus Infection and Acute Rejection** Jane Gralla, Janna L. Huskey, Alexander C. Wiseman. *University of Colorado.*

**Background:** The ImmuKnow Assay is a functional T cell assay (TCA) that may quantify cellular immune responsiveness following renal transplantation. Using a standard protocol of TCA sampling in the first year post-transplant (tx), we hypothesized an association between TCA and BK virus infection (BKV) and acute rejection (AR) events.

**Methods:** We performed a single-center retrospective analysis of 897 TCA results in 414 renal tx recipients obtained at 0 (N=122), 1 (N=316), 6 (N=258), and 12 (N=201) months post-tx from 2005-2009 with concurrent urine and blood BKV PCR measurements.

**Results:** Mean TCA values were similar 0 to 1 month (419 ng/ml vs. 441 ng/ml, $p=0.32$), decreased 1 to 6 months (466 ng/ml vs. 356 ng/ml, $p<0.0001$), and remained stable 6 to 12 months post-tx (357 ng/ml vs. 370 ng/ml, $p=0.33$) "Low" TCA values (≤225 ng/ml) at 12 months were associated with a diagnosis of BKV reactivation (urine BKV PCR $>10^8$ copies/ml or detectable BKV viremia by blood PCR)($p=0.006$), but not at 1 or 6 months. Reductions in TCA of 100, 150 or 200 ng/ml over time were not predictive of BKV. "High" values of TCA (≥525 ng/ml) were not predictive of AR.

Table 1: BKV diagnosed at time of protocol test and corresponding TCA value

| TCA value | N | BKV+ | BKV- | p-value |
|---|---|---|---|---|
| 1 month TCA≤ 225 ng/ml | 29 | 1 (3%) | 28 (97%) | 0.99 |
| 1 month TCA >225 ng/ml | 287 | 13 (5%) | 274 (95%) | |
| 6 month TCA ≤ 225 ng/ml | 55 | 2 (4%) | 53 (96%) | 0.26 |
| 6 month TCA >225 ng/ml | 190 | 18 (9%) | 172 (91%) | |
| 12 month TCA ≤ 225 ng/ml | 37 | 6 (16%) | 31 (84%) | 0.006 |
| 12 month TCA >225 ng/ml | 142 | 4 (3%) | 138 (97%) | |

**Conclusions:** In this large single-center series, 1) TCA values were shown to significantly decrease from 1-6 months but not thereafter, 2) changes in TCA were not predictive of BKV reactivation, 3) low absolute TCA values (≤ 225 ng/ml) at 12 months were more commonly noted in patients with BKV reactivation. These findings suggest that TCA monitoring is not warranted prior to 6 months post-transplant, but patients with low TCA values at 6 months may benefit from potential tailoring of immunosuppression or more aggressive monitoring for infections between 6 and 12 months post-transplant.

**Intense C4D Staining and Presence of Donor Specific Antibody Is Associated with Higher Proteinuria in HIV Positive and HIV Negative Renal Transplant Recipients** Aniruddha V. Palya, Parmish Lalit Kohli, Gregory Malat, Simi Shahabdeen, William Yang, Blair Weikert, Alden Michael Doyle, Karthik M. Ranganna. *Medicine, Drexel University College of Medicine, Philadlphia, PA.*

HIV positive kidney transplant recipients have lower long term renal allograft survival compared with HIV- recipients of allograft. C4D positivity on biopsy has been found to be a known prognostic indicator for long term allograft outcome.

Our study analyzed the degree of proteinuria in relation to C4d deposition in renal biopsy specimens and donor specific antibodies in plasma (DSA) in HIV+ and HIV- recipients. 27 HIVpositive and 167 HIV negative renal transplant recipients transplanted between March 2005 and September 2008 were included.

C4d was positive in 100 biopsy specimens. Proteinuria data was obtained on all patients at the time of renal biopsy. HIV positive recipients had a higher incidence of C4D positivity. Increasing proteinuria was noted in both HIV positive as well as HIV negative renal transplant recipients (p-trend 0.01) with increasing intensity of C4D staining. HIV positive renal transplant recipients had a higher proteinuria when compared with HIV negative recipients across different C4D intensities (p value 0.01).

Presence of DSA was associated with significantly higher proteinuria (p value <0.001). Higher proteinuria was noted in HIV positive renal transplant recipients with DSA. Both C4D positivity and DSA remained significant in a multivariate analysis after adjusting for known confounders.

From our study we found that increasing intensity of C4D staining and donor specific antibodies appear to be associated with increasing proteinuria in both HIV positive and negative renal transplant recipients.

TABLE: Mean urine protein to creatinine ratio across HIV Positive and HIV Negative renal Transplant recipients

| | HIV positive(N=27) | HIV negative(N=167) | Unadjusted p-value | Adjusted p-value* |
|---|---|---|---|---|
| Recipients with C4D1 | 1.2 | 0.8 | 0.07 | 0.01 |
| Recipients with C4D2 | 1.9 | 1.7 | | |
| Recipients with C4D3 | 2.4 | 2.1 | | |
| DSA positive | 1.7 | 1.3 | <0.01 | <0.001 |

* Included in the final model: Hepatitis C, Graft or patient survival, Immunosuppression

Disclosure of Financial Relationships: nothing to disclose

## F-PO2038

**An Increase in Body Mass Index Is a Risk Factor for Persistent New Onset Diabetes after Transplantation in Renal Transplant Recipients** Yoonjung Kim, Junam Shin, Hye Ryoun Jang, Jung Eun Lee, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh, Wooseong Huh. *Nephrology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea.*

The association of an increase in BMI with the development of type 2 DM is well known , but it has not been clear in renal transplant recipients. This study investigated the relationship between an increase in BMI after kidney transplantation(KT) and the development of persistent new onset diabetes after transplantation (P-NODAT) in recipients treated with tacrolimus. Study design was retrospective case-matched control(1:3) study. Thirty-four patients developing P-NODAT were identified among 186 adult renal transplant recipients with no evidence of pre-transplant DM, who underwent KT from September 1997 to March 2008 and were treated with a triple regimen including tacrolimus. The controls were selected by pre-transplant BMI, age at transplant (±5 years) and date of transplantation(±12 months). Finally, 21 P-NODAT patients and 63 controls were enrolled. The pre- and post-transplant BMI data were collected every 16 weeks until 80 weeks. Between the two groups, the proportion of deceased donor was higher in P-NODAT patients (38.1%, vs.15.9%, $p$=0.02). There were no significant differences in sex, family history of DM, pre-transplant BMI, HCV infection, donor age, acute rejection rate, CMV infection, and tacrolimus levels. Pre-transplant BMI was 23.7±3.0 Kg/m$^2$ in P-NODAT group and 23.2±2.2 Kg/m$^2$ in the control group. BMI was decreased to 22.5±3.3 Kg/m$^2$ in P-NODAT group and to 22.0±2.2 Kg/m$^2$ in control group 16 weeks after KT. And then, in P-NODAT group, BMI was rapidly recovered to 23.4±3.3 Kg/m$^2$ at 32 weeks. However, in control group, BMI was recovered to 22.9±2.1Kg/m$^2$ at 80 weeks (ANOVA for repeated measures $p$=0.03 for between groups analysis). Logistic regression analysis revealed a significant association between weight gain from 16 weeks to 32 weeks and development of P-NODAT. The odds ratio was adjusted for donor type. Adjusted odds ratio was 1.37 (95% CI, 1.10-1.72) for every 1 kg increase in body weight from 16 weeks to 32 weeks (P=0.006). The increase in BMI after KT was related to a higher incidence of P-NODAT.

Disclosure of Financial Relationships: nothing to disclose

## F-PO2039

**Severe Vascular Lesions and Poor Functional Outcome in Kidney Transplant Recipients with Lupus Anticoagulant Antibodies** Guillaume Canaud,[1] Bienaime Frank,[3] Laure-Helene Noel,[2] Dany Anglicheau,[1] Eric Thervet,[1] Christophe M. Legendre,[1] Julien Zuber.[1] *[1]Service de Transplantation, Hôpital Necker, Paris, France; [2]Laboratoire d'Anatomopathologie, Hôpital Necker, Paris, France; [3]Service d'Explorations Fonctionelles, Hôpital Necker, Paris, France.*

Antiphospholipid syndrome (APS), the leading cause of acquired thrombophilia, has been associated with severe vascular changes in native kidney. However, the impact of anti-phospholipid antibodies (APA) on clinical outcome and graft histology following renal transplantation remains poorly known and controversial. Therefore, we retrospectively explored, using a nested case-control study, the functional and histological significance of APA, primarily lupus anticoagulant, in kidney transplant recipients, systematically evaluated with 3- and 12-month post-transplant screening biopsies and measured glomerular filtration rate (mGFR).

Among 1359 kidney transplant recipients during the study period, 37 had APA (2.7%), primarily lupus anticoagulant, and 12 fulfilled APS diagnostic criteria (0.8%) at the time of transplantation. During the early post-transplant course, 4 of the 12 APS patients died. Early thrombosis of graft vessels and deep venous thrombosis occurred more frequently in APA+ patients than in controls (27 vs 7%, p<0.05 and 35 vs 14%, p<0.05, respectively). The patient survival rate was significantly lower in patient with APS than in the controls. Strikingly, hallmark lesions of APS-associated nephropathy (APSN) were found in most of screening graft biopsies in APA+ patients but not in the controls. Accordingly, APA+ patients had a dramatic increase of chronic vascular cv and ah scores and a faster decline in mGFR at one year. In conclusion, renal transplantation may be life-threatening in APS patients, and the presence of lupus anticoagulant at the time of transplantation is associated with a high rate of allograft APSN and a poor transplantation outcome.

Disclosure of Financial Relationships: nothing to disclose

## F-PO2040

**Malignancies Confined to Disused Brachiocephalic Arteriovenous Fistulae in Renal Transplant Patients: A Rare but Important Differential** Philip Webster, Lareina Wujanto, David Taube, Neill D. Duncan. *Imperial College Kidney and Transplant Institute, Hammersmith Hospital, London, United Kingdom.*

**Background**

Swelling in an arteriovenous fistula (AVF) is commonly due to thrombosis, aneurysm and infection. However due to the significantly increased risk of malignancy after transplantation, this should also be considered. We present 4 patients, all of whom had renal transplants at our centre, who developed malignant change confined to their AVF.

| Patient | Diagnosis | Immunosuppression | Treatment | Outcome |
|---|---|---|---|---|
| 1. Male, 59yrs, Caucasian | Angiosarcoma | Mycophenolate mofetil (MMF)/steroids for underlying glomerulonephritis. Rituximab/plasma exchange/ daclizumab/steroids/ tacrolimus for ABO incompatible transplant. | Arm amputation | Alive 2 years after presentation, no metastasis |
| 2. Female, 41yrs, Afro-Carribean | Angiosarcoma | Alemtuzumab/steroids/ tacrolimus for transplant | Nil | Died 4 months after presentation with lung metastases |
| 3. Male, 44yrs, Caucasian | T-cell Lymphoma | Steroids/tacrolimus for transplant. MMF/steroids for rejection | Reduction of immunosuppression | Alive 3 months after presentation, under close monitoring |
| 4. Male, 56yrs, Caucasian | Diffuse Large B-cell Lymphoma with Epstein-Barr virus | Steroids/tacrolimus/MMF for transplant | Reduction of immunosuppression. Rituximab | Alive 3 months after presentation undergoing treatment |

**Discussion**

Predilection for malignancy at the site of an AVF is not understood. Turbulent blood flow within a fistula leads to endothelial shear stress causing up-regulation of growth peptides, heightening proliferative responses. Angiosarcoma behaves aggressively with a poor outcome. There are 6 similar cases previously reported. All were initially thought to have thrombosed, aneurysmal fistulae. 5 died within 16 months of diagnosis. The other had lung metastases at time of publication. Surgical resection of a non-metastasized lesion offers the only chance of cure at present. There is no previous documentation of post-transplant lymphoproliferative disease confined to AVFs.

**Conclusion**

Whilst rare, malignancy should be considered when a new swelling occurs at a haemodialysis fistula in immunosuppressed patients. Further research into pathogenesis is required.

Disclosure of Financial Relationships: nothing to disclose

## F-PO2041

**Hypercalcemia after Kidney Transplantation in Patients with ou without Cinacalcet before Transplantation** Amélie Belloi,[1] Emmanuel Villar,[1] Marie-Christine Carlier,[2] Anne Charrie,[3] Rémi Cahen,[1] Claire Pouteil-Noble.[1] *[1]Néphrologie, CHLS, Pierre-Bénite, France; [2]Biochimie, CHLS, Pierre-Bénite, France; [3]Radioanalyse, CHLS, Pierre-Bénite, France.*

Use of phosphate binders or calcimimetics in dialysis have modified phosphate and calcium balance after transplantation. The aim of this prospective study was to compare the evolution of phosphate and calcium balance after transplantation and parathyroidectomy incidence between D0 and M1, M3, M6, M12 in patients with or without cinacalcet on the day of transplantation. All the patients transplanted between 01.01.00 and 12.31.08 with a functioning graft more than 1 month were included(n = 338). Serum phosphate and calcium balance (PTH, Ca, P and 25OHD), graft function, calcium and vitamin treatment, parathyroidectomy history were collected until M12 and compared between 2 groups : without (group 1, n = 310) and with (group 2, n = 28) cinacalcet. After transplantation, mean calcemia in group 2 (between 2.53± 0.21mmol/L and 2.57±0.12mmol/L) was significantly increased at M1, M3, M6, M12 in comparison with group 1(between 2.37±0.20mmol/L and 2.45±0.17mmol/L) (p<0.0005) while on D0, calcemia was no different. Mean PTH was significantly higher in group 2 than in group 1 at M3, M6 and M12 (p<0.05). Graft function was not different in the 2 groups. The rate of hypercalcemia was significantly more common in group 2 than in group 1 at M1(36% vs9%), M3(39% vs15%), M6(32% vs15%), M12(32% vs10%) (p<0.05). Cinacalcet treatment was required in 25% of patients of group 2 and only 0.65% of patients of group 1. Parathyroidectomy was performed in 7% of patients of group 2 vs 0.65% of patients of group 1. During the first year of transplantation, hypercalcemia is more common in patients with cinacalcet treatment before transplantation and may require cinacalcet treatment or parathyroidectomy. Cinacalcet represents a suspensive treatment of hyperparathyroidism in dialyzed patients. Side effects of cinacalcet (hypercalciuria,

nephrocalcinosis, bone mineralization) are not well known on the long term kidney graft function. The cost-benefit of cinacalcet treatment after transplantation must be evaluated in comparison with parathyroidectomy.

**F-PO2042**

**Impact of Polymorphisms of the Renin-Angiotensin-Aldosterone System on Renal Transplantation** Magdalena Siekierka-Harreis, Christos Bantis, Christina Schwandt, Lars C. Rump, Katrin Ivens. *Department of Nephrology, Heinrich-Heine University, Düsseldorf, Germany.*

In the present study we evaluated the impact of the three major polymorphisms of the renin-angiotensin-system on long-term outcome after renal transplantation.

We studied n=205 consecutive patients, who underwent renal transplantation in our center from 1998 to 2001 (cadaveric: n=161, living related: n=44), followed up for 5.0±2.0 years. One hundred healthy volunteers were analyzed as controls. Aldosterone synthase gene C-344T, angiotensinogen gene M235T and angiotensin converting enzyme gene I/D polymorphisms were determined by PCR.

The genotype distribution was similar in patients and control subjects (ns). During follow up n=103 (50.2%) patients had at least one episode of acute rejection and n=28 (13.7%) experienced graft failure. No association between the polymorphisms and the incidence of acute rejection was detected (ns). Patients carrying the aldosterone synthase CT/TT genotypes experienced graft failure more frequently (16.1%) compared to the CC genotype (4.5%, $x^2$: 4.0, OR: 1.22, 95%CI: 1.07-1.39, $p<0.05$). An increased frequency of graft loss was also observed among the patients carrying the angiotensinogen TT genotype (27.8% vs. 10.7% in MM/TT, $x^2$: 7.4, OR: 2.43, 95%CI: 1.32-4.48, p=0.007). Combined analysis of the polymorphisms allowed a more precise identification of patients predisposed to graft loss: patients with the genotype combination of aldosterone synthase CT/TT and angiotensinogen TT had an almost three times higher risk for graft loss (31.3% vs. 10.4% in the other genotype constellations, $x^2$=10.0, OR=2.87, 95% CI: 1.53-5.41, p=0.002). The Kaplan Meier analysis confirmed the impact of C-344T ($p<0.05$) and M235T (p=0.005) polymorphisms as well as their combined analysis ($p<0.001$) on graft survival. This effect was prominent after the first two years after renal transplantation. No association between angiotensin converting enzyme gene I/D polymorphism and any of the parameters studied was observed.

Our results suggest that aldosterone synthase gene C-344T and angiotensinogen gene M235T polymorphisms influence the long-term graft survival in renal transplantation.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2043**

**Copeptin in Heart Transplant Recipients and Hemodialyzed Patients Is Dependent on Kidney Function and Heart Structure, but Not in Kidney Transplant Recipients** Jolanta Malyszko,[1] Jacek S. Malyszko,[1] Piotr Przybylowski,[2] Ewa Koc-Zorawska,[1] Michal Mysliwiec.[1] *[1]Nephrology Department, Medical University, Bialystok, Poland; [2]Cardiac Surgery and Transplantation, Jagiellonian University, Cracow, Poland.*

Introduction: Copeptin is cosynthesized with vasopressin, thereby directly mirroring vasopressin levels – but copeptin is more stable in plasma and serum. Chronic heart failure-CHF is present in more than one-third of incident dialysis patients as well as in kidney allograft recipients. The aim of the study was to assess copeptin in kidney allograft recipients kidney, orthotopic heart recipients and hemodialyzed in relation to NYHA class and kidney function.

The studies were performed on 136 prevalent patients after orthotopic heart transplantation- OHT, 100 prevalent kidney allograft recipients and 100 HD patients. Plasma copeptin was measured using a commercially available kit.

Results: Copeptin correlated with parameters of kidney function: creatinine, eGFR by MDRD, eGFR by CKD-EPI, cystatin C (r=0.46, $p<0.001$), and HDL, NT-proBNP (r=0.25, $p<0.01$), IVS (intraventricular septal diameter) (r=-0.30, $p<0.01$), EF, ferritin. In multiple regression analysis predictors of copeptin were cystatin C and IVS explaining 51% of copeptin variations. In kidney allograft recipients copeptin was significantly lower than in orthotopic heart transplants. Lower NYHA classes were more prevalent in kidney allograft recipients. Copeptin was higher in CKD stage 4 when compared to stage 2, similarly it was higher in NYHA class III than I. However, all the correlation did not reach statistical significance. Copeptin correlated with age, residual renal function, HD dose, heparin dose, Kt/V, pH, TSAT, ferritin, presence of CAD, hsCRP, IL-6, NYHA. In multiple regression analysis NYHA class, Kt/V and IL-6 predicted copeptin levels in HD.

Copeptin in heart transplant population is independently associated with kidney function and heart structure but not in kidney allograft recipients. Copeptin in HD population is independently associated cardiac function, but additionally may be associated with dialysis adequacy and chronic inflammation.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2044**

**Association of Aldosterone Synthase Gene Polymorphisms and Histopathology of Calcineurin-Inhibitor Toxicity in Renal Transplant Patients** Patricia C. Ruiz Palacios,[1] Monica X. Inofuentes,[1] Rafael G. Toledo,[1] Francisco E. Rodríguez Castellanos,[1] Eduardo Mancilla Urrea,[3] Maria Carmen Avila-Casado.[2] *[1]Nephrology, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, DF, Mexico; [2]Nephropathology, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, DF, Mexico; [3]Renal Transplant, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, DF, Mexico.*

INTRODUCTION. Recent observations suggest that aldosterone plays a central role in the pathogenesis of Calcineurin Inhibitors (CI) nephrotoxicity. The aim of this work was to test the association of polymorphisms in the aldosterone synthase (AS) gene with the histopathology of CI toxicity in renal transplant patients.

METHODS. A renal biopsy and blood sample was taken from 50 male and 33 female patients treated with CI, to determine histophatological findings secondary to CI nephrotoxicity and their polymorphisms in the AS gene. The -344T/C, Int 2W/C polymorphisms were screened by modification of standard PCR-RFLP. Renal biopsies were analyzed by light microscopy.

RESULTS. The patients with nephrotoxicity (group A) had higher systolic and diastolic blood pressure than patients without nephrotoxicity (group B): 140±26.1 mmHg vs 124±18.6 (p= 0.011), and 87±13.7 vs 77±12.6 (p=0.003), respectively. The uric acid tended to be higher in group A than group B (8.2±2.3 vs 6.7±1.9 mg/dL, p=0.008). CI levels were higher in the group A than group B (114 vs 54 ng/ml, p = 0.02). Development of arterial hypertension occurred in 71% of patients in group A and 53% of patients in group B (p=NS). There was a trend of higher levels of aldosterone in patients with genotype CC of the polymorphism Int 2W/C and the genotype TC of the polymorphism -344 T/C. There was no significant difference in the genotypes between group A and group B. Also, there was no difference in the grade of interstitial fibrosis between groups.

CONCLUSION. This study proves that there is no association between polymorphisms of AS gene and histopathological findings of CI toxicity in patients with renal transplant. The potential involvement of the aldosterone in the development of nephrotocixity due to CI may not be dependent of the specific polymorphisms of the AS gene.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2045**

**New Manifestation of Henoch-Schönlein Purpura Following Renal Transplantation Due to IgA Nephropathy** Ulf Schoenermarck, Simon Rau, Michael Fischereder. *Medical Clinic I, Nephrology Div., University Hospital Munich-Grosshadern, Munich, Germany.*

Henoch–Schönlein purpura (HSP) is a rare systemic small vessel vasculitis, typically presenting with palpable purpura, arthralgia, abdominal pain and renal disease. Renal histology shows a similar picture as in IgA nephropathy, the most common glomerulonephritis in adults. Recurrence of IgA nephropathy or HSP after renal transplantation is frequent. Here, we report on a patient with first manifestation of HSP following a renal transplantation due to IgA nephropathy.

We report the case of a 69-year-old male who underwent cadaveric renal transplantation 21 months prior to admission due to a bioptically proven IgA nephropathy. The immunosuppressive regimen consisted of tacrolimus, mycophenolate mofetile and steroids. Steroids were tapered and finally stopped completely a few months after transplantation. Baseline creatinine was ~1.6 mg/dl.

The patient was admitted with palpable purpura of all limbs, skin ulcerations and diffuse arthralgias. Serum creatinine was 2.1 mg/dl with mild proteinuria (0.3 g/l) and hematuria (50/µl). The skin biopsy showed a classical leukocytoclastic vasculitis with deposition of complement C3, IgA and fibrinogen which is pathognomonic of HSP. Steroid therapy was reintroduced (starting with 100 mg/d prednisolone p.o.). Skin lesions and kidney function rapidly improved. The patient was discharged from hospital after 13 days with a serum creatinine of 1.4 mg/dl. On a follow-up examination 4 weeks after discharge, serum creatinine was 1.5 mg/dl and the skin lesions were hardly visible. Hematuria or proteinuria was no longer detectable.

Recurrence of preexisting IgA nephropathy or HSP is frequent after renal transplantation. In contrast, HSP with cutaneous leukocytoclastic vasculitis following a renal transplantation due to IgA nephropathy has not been described yet. In this case remission of HSP could be rapidly achieved by steroid therapy. The withdrawl of steroids after renal transplantation due to isolated IgA nephropathy might have favoured the occurence of HSP in this patient.

**F-PO2046**

**Predictors of Serum Hepcidin Levels in Renal Transplant Patients** Stephan Brincat,[1] Chris Jones,[1] Jolanta Malyszko,[2] Iain C. Macdougall.[1] *[1]Department of Renal Medicine, King's College Hospital, London, United Kingdom; [2]Department of Nephrology and Transplantology, Medical University, Bialystok, Poland.*

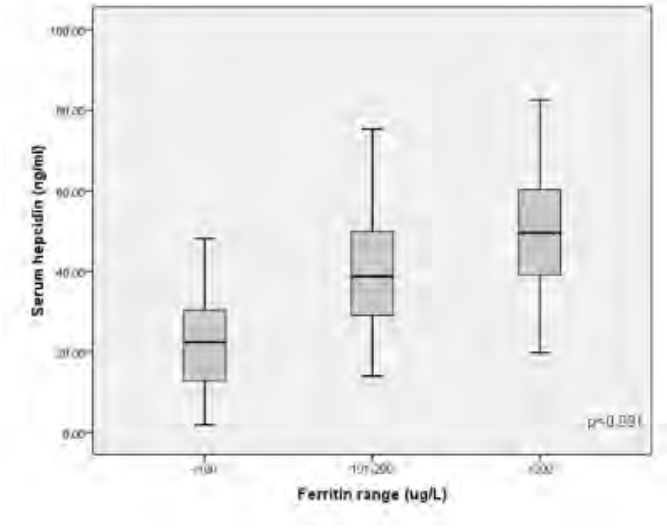
Introduction: Hepcidin, a 25-amino acid peptide, is a key regulator of iron metabolism. It is modulated in response to anaemia, inflammation, and hypoxia. Post-transplant anaemia is common with a multifactorial aetiology.

Aim: To identify predictors of serum hepcidin levels in renal transplant patients.

Methods: Using a commercially available ELISA, serum levels of hepcidin were measured in a cohort of stable renal transplant patients and compared to markers of anaemia, inflammation and iron status. Variables were log transformed to satisfy normality assumptions.

Results: In 96 transplant patients (aged 23-86 years, 63 male, 62 Caucasian, 14 diabetic, mean eGFR=53ml/min/1.73m$^2$), serum hepcidin levels were higher than healthy controls (36.8+/-19.4 v 20.6+/-10.0ng/ml; p<0.001). 49% of patients were anaemic (WHO classification). Higher hepcidin levels were observed in anaemic patients, compared to non-anaemic patients (43.9+/-16.9 v 29.1+/-19.2ng/ml; p<0.001). Hepcidin levels were positively correlated with ferritin (r=0.62, p<0.01) and interleukin-6 (r=0.265, p=0.02) and negatively correlated to haemoglobin (r=-0.44, p<0.01) and eGFR (r=-0.27, p<0.01). Mean hepcidin levels showed a stepwise increase with 3 different ferritin ranges (p=<0.001) [Figure 1]. Using multiple linear regression ($R^2$=0.5), the only independent predictors for hepcidin were ferritin (p<0.001), haemoglobin (p=<0.005) and raised C-reactive protein (p<0.02).

Conclusions: Serum hepcidin levels are independently predicted by ferritin, haemoglobin, and raised C-reactive protein, but not kidney function in renal transplant patients. Further studies are required to characterise the role of serum hepcidin in post-transplant anaemia.



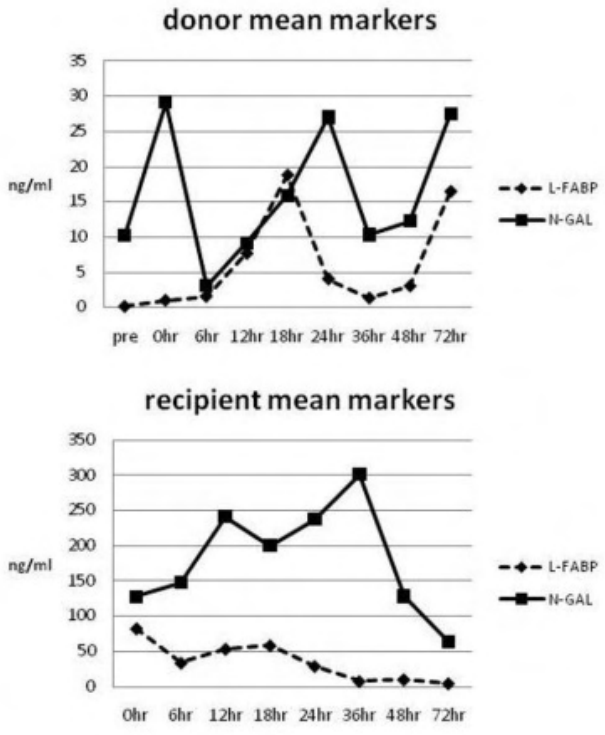
Disclosure of Financial Relationships: nothing to disclose

**F-PO2047**

**Trend Differences between Two Urinary Biomarkers in Living Donated Kidney Transplant Donors and Recipients during the Perioperative Period**

Junko Kohei, Kosaku Nitta, Ken Tsuchiya, Takumi Yoshida, Shunji Shiohira, Hidekazu Sugiura. *Nephrology, Tokyo Womens Medical University, Shinjuku, Tokyo, Japan.*

Urinary liver-type fatty acid binding protein (L-FABP) and neutrophil gelatinase-associated lipocalin (N-GAL) variations have previously been associated with acute kidney injury in perioperative period, however the trend of these variations post renal surgery has not been studied in depth. This study's objective is to examine whether there are differences in the variations between the two markers during the perioperative period in both donor's and recipient's urine pre, post and during living-donor transplantation. We randomly selected 10 donors and their recipients undergoing kidney transplantation to use as test samples for a prospective investigation. Urinary samples were collected immediately before surgery and 0, 6, 12, 18, 24, 36, 48, and 72 hours post operation. L-FABP and N-GAL from these test samples were measured with a standard commercial ELISA kit. In the results that followed from recipients, within a three day post operative period, there were no cases demonstrating delayed graft function and in every case serum creatinine levels fell below 2.0mg/dl. Mean donor L-FABP and N-GAL were different between the peak time. Furthermore 72hour after surgery both markers had risen. On the other hand, mean recipient markers were also different between the peak time, their score was gradually decreased form 36hours after surgery.



N-GAL drastically changed after donor and recipient surgery and elevated early postoperative period with some peak; it tended to reflect the surgical kidney injury rather L-FABP. N-GAL will not be a reliable marker alone to help identifying acute kidney injury or delayed graft function.

Disclosure of Financial Relationships: nothing to disclose

**F-PO2048**

**Influence of Different HAART Regimen on the Incidence of C4D Deposition and Donor Specific Antibodies in HIV Positive Renal Transplant Recipients**

Aniruddha V. Palya, Blair Weikert, Gregory Malat, Suganthi Soundararajan, Nauman Shahid, Alden Michael Doyle, Karthik M. Ranganna. *Medicine, Drexel University College of Medicine, Philadelphia, PA.*

It is increasingly being noted that HIV+ renal transplant recipients tend to have more rejection. We have been seeing increased antibody mediated rejection in them. C4D deposition in the biopsy and donor specific antibodies are features of antibody mediated rejection. HIV recipients have previously been reported to have a significantly higher incidence of C4D positivity and DSA than non-HIV recipients. We decided to look whether there is any difference in their incidence when the recipients are on different HAART regimen. Induction agent we use is basiliximab and the mainetenence immunosuppression include cyclosporine, sirolimus and prednisone. There was no difference between the two groups as far as demographics were concerned.

We studied 71 biopsies which included surveillance and indication biopsies and panel reactive antibody titers performed between March 2005 and September 2008 on 27 HIV positive renal transplant recipients. 21 out of 71 biopsies (29%) were indicated biopsies.

Degree of C4D positivity in biopsies and incidence of DSA

| | PI based (n=9) | NNRTI based (n= 14) | Combination (N = 4) | P value |
|---|---|---|---|---|
| Recipients with C4D negative | 8 | 2 | 2 | |
| Recipients with C4D 1 | 3 | 1 | 2 | 0.17 |
| Recipients with C4D 2 | 0 | 1 | 0 | |
| Recipients with C4D 3 | 3 | 5 | 0 | |
| DSA positive | 4 | 7 | 0 | 0.013 |
| DSA negative | 10 | 2 | 4 | |
| Serum Creatinine | 3.1±2.2 | 2.2±1.3 | 2.7 ± 1.6 | 0.49 |
| Urine Protein/Creatinine ratio | 1.34 | 1.07 | 0.88 | 0.82 |

| Functioning graft | 6 | 12 | 3 | 0.64 |

non-nucleoside reverse transcriptase inhibitor based regimen (NNRTI); protease inhibitor based regimen (PI).Donor specific antibody (DSA)

We found that there was no significant difference in the incidence of C4D deposition across the different HAART regimen. We also found no significant difference with respect to serum creatinine and graft survival. However, NNRTI based HAART regimen appeared to be associated with higher incidence of DSA.

**Incidence of BK Viremia and BK Nephropathy in Renal Transplant Patients Induced with Alemtuzumab or Antithymocyte Globulin: Single Center Experience** Farnaz Mohammadi, Abdul Moiz, Nadia W. Iqbal, Krista L. Lentine, Bahar Bastani. *Division of Nephrology, Saint Louis University School of Medicine, Saint Louis, MO.*

**OBJECTIVES:** To evaluate the incidence of BK viremia (BKV), BK nephropathy (BKVN), renal transplant outcomes and predictors for developing BKVN.

**METHODS:** We retrospectively analyzed 306 consecutive renal transplant patients (pts) from 2006 to 2010. Pts had received either alemtuzumab (30mg, one dose) or antithymocyte globulin (ATG; 1.5mg/kg, 5 doses) or basiliximab as induction therapy. Maintenance regimen comprised of tacrolimus and mycophenolate-mofetil (MMF). Prednisone was used only in ATG and basiliximab groups. Serum BK PCR was serially monitored post-transplant. Reduction in immunosuppression was carried upon diagnosis of BKV. Leflunomide replaced MMF in cases with concomitant rejection and BK infection.

**RESULTS:** Mean (±SD) age of pts at BKV was 52±12 yrs, of whom 78% were male. For induction 236(77.1%) pts had received alemtuzumab, 68(22.2%) pts ATG and 2 basiliximab. Total number of BKV pts was 40 (13.1%). Time from transplant to serum BK PCR positivity was 9±9 months. BKV lasted for a mean of 5.3±5 months. Out of 40 pts with BKV, 27(67.5%) had received alemtuzumab and 12(30%) ATG. BKVN was noted in 5 pts; concomitant acute rejection was present in 2 pts. Mean tacrolimus trough level was 9.2±3.1ng/ml at the time of BKV. Tacrolimus dose was reduced in 19(41.3%) pts. MMF dose was decreased in 38(96%) pts and it was discontinued in remaining 4%. Biopsy proven acute rejection during follow-up was seen in 17(42.5%) pts; leflunomide replaced MMF in 14 of them. Four pts lost allograft (10% of those with BKV). In 5(12.5%) pts BKV lasted for more than 6 months. There was no statistically significant difference in the incidence of BKV in alemtuzumab vs ATG (11.4% vs 17.6%, P=0.14).

**CONCLUSION:** Early diagnosis of BKV based on serial monitoring of serum BK PCR and pre-emptive reduction of immunosuppression resulted in resolution of BKV and reduced progression to BKVN. Substitution of MMF with leflunomide in patients with concomitant BKV and rejection was associated with progressive decrease in viral load and stabilization of allograft function.

Disclosure of Financial Relationships: nothing to disclose

**An Adjuvanted Influenza A H1N1 Vaccine Does Not Provide a Protective Immune Response in the Majority of Renal Transplant Recipients** Susanne Brakemeier, Petra Glander, Fritz Diekmann, Hans-Hellmut Neumayer, Klemens Budde. *Nephrology, Charite, Berlin, Germany.*

In the course of the Influenza A H1N1 pandemic especially immunocompromised patients were recommended to receive vaccination. In healthy controls, between 80% and 95% of adults develop a sufficient immune response after a single vaccination, however no data are available for immunosuppressed patients so far, therefore we evaluated the immune response to an adjuvanted Influenza A H1N1 vaccine (Pandemrix®) in renal transplant patients.

A total of 60 patients (12 female/48 male) aged 52 ± 14 years who received a transplant at least six months ago agreed to participate in the study. 22 healthy subjects served as controls.

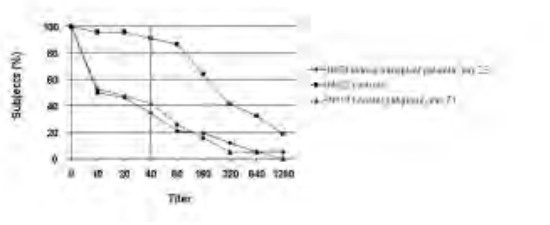
A single dose of Pandemrix® (3,75µg per dose, adjuvanted) was administered at day 0. In a subgroup of 19 patients, booster vaccination was performed after a median of 21 days and booster titers were analysed at a median of 71 days after the second vaccination.

Two patients had an elevated titer before vaccination, although being completely asymptomatic.

Of the remaining 58 patients, after a median of 25,8 days only 34,5% developed a titer of 1:40 or more, which is considered as a sufficient immune response. The other 38 patients (65,5%) showed no or only a weak response. In contrast to this 91% of the control group developed a protective titer of 1:40 or more.

In the booster subgroup, a titer of 1:40 or more was present in 42% after the second vaccination.

Figure 1



Immunosuppressive regimens consisted of mycophenolate in combination with either tacrolimus, cyclosporine, everolimus, or sirolimus, with a median through level of 5.5 ng/ml, 92.4 ng/ml, 6.9 ng/ml, and 7,4 ng/ml, respectively. 50% of patients were off steroids.

These data suggest that in renal transplant patients a single dose of Pandemrix® as well as booster vaccination is not sufficient to induce a protective immune response.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2051**

**Fool's Gold: Creatinine as the Diagnostic Standard for AKI Biomarker Studies** Sushrut S. Waikar,[1] Rebecca A. Betensky,[2] Joseph V. Bonventre.[1] *[1]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Biostatistics, Harvard School of Public Health, Boston, MA.*

Serum creatinine concentration (SCr) has been used as the diagnostic test for acute kidney injury (AKI) for decades, despite being an imperfect gold standard due to limited sensitivity and specificity. Novel tubular injury biomarkers may revolutionize the diagnosis of AKI and eventually replace SCr in the evaluation of patients at risk for AKI. However, if novel biomarkers are compared against SCr as the gold standard, then errors in SCr's diagnostic performance may adversely affect the apparent sensitivity and specificity of the biomarkers. The apparent sensitivity and specificity of a biomarker depend not only on the biomarker's test characteristics but also on disease prevalence, sensitivity and specificity of the gold standard, and the conditional dependence between the tests. Assuming conditional independence (i.e., the gold standard and the biomarker are independent given the disease status), the apparent sensitivity and specificity of a biomarker can be calculated for different estimates of disease prevalence and gold standard performance characteristics. The following table shows how varying estimates of disease prevalence and SCr's sensitivity and specificity affect the apparent sensitivity and specificity of a novel biomarker that is assumed to be perfectly accurate for the diagnosis of AKI.

Apparent performance of a perfect biomarker compared to an imperfect gold standard

| Gold standard | Prevalence | Apparent Sn | Apparent Sp |
|---|---|---|---|
| | 0.1 | 31% | 97% |
| SCr rise of 0.3 mg/dL (Sn 80%, Sp 80%) | 0.2 | 50% | 94% |
| | 0.3 | 63% | 90% |
| | | | |
| | 0.1 | 100% | 91% |
| Need for dialysis (Sn 10%, Sp 100%) | 0.2 | 100% | 82% |
| | 0.3 | 100% | 72% |

Sn, sensitivity; Sp, specificity

Misclassification of AKI may lead to substantial misinterpretations of the diagnostic ability of novel biomarkers. Biomarkers that perform best relative to SCr may in fact be conditionally dependent and recapitulate the shortcomings of SCr. Our findings suggest that small changes in SCr should not be used to define AKI in biomarker or interventional AKI studies.

**Pattern of Change in Serum Creatinine Predicts Need for Dialysis in Acute Kidney Injury (AKI)** Yang Luo,[1] Etienne Macedo,[1] Josee Bouchard,[1] Sharon Soroko,[1] Glenn M. Chertow,[2] Jonathan Himmelfarb,[3] T. Alp Ikizler,[4] Emil P. Paganini,[5] Ravindra L. Mehta.[1] *[1]University of California San Diego; [2]Stanford University School of Medicine; [3]University of Washington; [4]Vanderbilt University School of Medicine; [5]Cleveland Clinic Foundation.*

*Background:* The course of AKI is characterized by the rate, magnitude and duration of serum creatinine (Scr) change. These changes are affected by comorbidities, and nature and timing of acute insults. We hypothesized that pattern of Scr increase is associated with need for RRT. *Methods:* Using data from 351 out of 618 PICARD study (KI, 2004, 66: 1613-1621) patients whose Scr (corrected for fluid balance) increased consecutively for 3/+ days, we determined the pattern of AKI during the development phase before dialysis. The slope, Scr delta and area under curve (AUC) of Scr were calculated for the 1st 3 days after ICU admission and at peak value (Max). The predictive ability of these variables was assessed with a ROC analysis and cut-off points established. Patients were assigned to categories based on the cut points to compute odds ratios. *Results:* Daily slope and delta Scr of the 1st 3 days were similar in the 2 groups. Dialyzed patients had higher peak Scr (delta max Scr p=0.04). Increases in AUC in the 1st 3 days and at peak were predictive of need for RRT.

Table

| | Dialyzed(n=141) | Non-dialyzed(n=210) | ROC curve | Cut-Off value | OR (95%CI) |
|---|---|---|---|---|---|
| AUCmedian (IQR) (mg*day/dl) | | | | | |
| 1st day | 3.9(2.7-5.7) | 3.5(2.7-4.9) | 0.84 | 5.9 | 2.0(1.1-3.7) |
| 2nd day | 7.1(5.0-9.7) * | 5.9(4.7-8.1) | 0.81 | 5.9 | 2.1(1.4-3.3) |
| 3rd day | 11.0(8.1-14.3) * | 9.0(7.2-11.6) | 0.79 | 11.3 | 2.3(1.5-3.6) |
| to Max | 19.6 (13.0-37.4) * | 15.4 (11.5-25.9) | 0.81 | 27.8 | 1.9(1.2-2.9) |
| delta Max median (IQR )(mg/dl) | 2.7 (1.6-4.2) * | 2.1 (1.2-3.2) | 0.56 | 2.8 | 1.7(1.1-2.6) |

*P<0.05 compared with non-dialyzed group

*Conclusion.* Patterns of serum Scr change can identify patients who will need RRT. AUC Scr relative to other parameters may facilitate optimal timing of dialysis in AKI patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2053**

**Glomerular Filtration Rate, Proteinuria, and the Incidence and Outcomes of Acute Kidney Injury** Matthew T. James,[1,2] Brenda Hemmelgarn,[1,2] Natasha Wiebe,[3] Neesh I. Pannu,[3] Braden J. Manns,[1,2] Scott Klarenbach,[3] Marcello Tonelli.[3] *[1]Medicine, University of Calgary, Canada; [2]Community Health Sciences, University of Calgary, Canada; [3]Medicine, University of Alberta, Canada.*

Lower levels of estimated glomerular filtration rate (eGFR) predispose to acute kidney injury (AKI), and modify the risks of death and kidney failure following AKI. Proteinuria is also a marker of kidney disease but whether it is associated with the risk and subsequent outcomes of AKI is unknown. We performed a cohort study of 920,985 adults residing in Alberta, Canada between 2002 and 2007 to examine how proteinuria modified the associations between eGFR and AKI, as well as the risks of adverse clinical outcomes following AKI. Participants not requiring chronic dialysis at baseline and with at least one outpatient measurement of both serum creatinine and proteinuria (using urine dipstick or albumin-creatinine ratio) were included. We assessed hospitalization with AKI using validated administrative codes. Over median follow-up of 35 months (range, 0-59 months), 6,520 (0.7%) participants were hospitalized with AKI. Among those with eGFR ≥ 60 mL/min/1.73m$^2$, the adjusted rate of hospitalization with AKI was 4.4-fold higher among those with heavy proteinuria by dipstick (rate ratio 4.4 vs no proteinuria, 95% CI 3.7-5.2). The adjusted rates of hospitalization with AKI remained up to 3.7 fold higher in participants with heavier proteinuria across lower levels of baseline eGFR. Similar findings were observed when urine albumin-creatinine ratio was used to assess proteinuria, or when AKI was defined by receipt of dialysis. Further, compared to participants without proteinuria, the adjusted rates of death and end-stage renal disease or doubling of serum creatinine following AKI were up to 1.6-fold and over 3-fold higher, respectively, in participants with heavy proteinuria but similar baseline eGFR. At all levels of eGFR, people with proteinuria are at markedly higher risk of developing AKI and of death or advanced kidney disease after experiencing AKI. These findings suggest that proteinuria, in addition to baseline eGFR, should be incorporated into systems for assessing the risk or outcomes of AKI.

**SA-PO2054**

**Accuracy of Morning Urine Protein-to-Creatinine Ratio in Acute Kidney Injury** Jonathan J. Taliercio, Susana Arrigain, Jesse D. Schold, James F. Simon. *Department of Nephrology and Hypertension, Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, OH.*

The purpose of the study was to assess the accuracy of proteinuria quantification using a morning urine protein-to-creatinine (PC) ratio compared to 24-hour urine collection in hospitalized patients with non-oliguric acute kidney injury (AKI).

The 24-hour urine collection is the gold standard for quantifying protein excretion. The first morning urine PC ratio has been validated as an alternative to the 24-hour collection in stable kidney function. While the PC ratio has not been validated in AKI, practitioners are using it in this setting.

This was a prospective cohort study of adult subjects who had non-oliguric AKI (≥2-fold rise in serum creatinine and urine output ≥400 cc/day) and ≥ +1 proteinuria admitted to the Cleveland Clinic main hospital. Exclusion criteria included CKD stage ≥ 4, initiation of hemodialysis, and AKI recovery before consent. Morning urine samples were obtained before noon the day of enrollment or the following morning. Lin's concordance coefficient was used to analyze the linear association and deviation from the 45 degree line between 24-hour protein and the PC ratio.

175 subjects were screened; 35 subjects met inclusion criteria and were enrolled in the study. The median and interquartile range for the 24-hr protein and the PC ratio were 0.47 (0.26, 1.33) and 0.89 (0.33, 2.07) respectively. Only 4 patients had >2 grams of proteinuria. Lin's concordance coefficient was 0.85 (95% CI 0.74-0.91) using all raw data, and a more conservative 0.72 (0.52-0.85) using log transformed values and excluding 3 influential data points. The PC ratio tended to overestimate the 24-hour collection, with the difference increasing with greater proteinuria.

The morning urine protein-to-creatinine ratio is strongly associated with 24-hour urine protein collections in patients with non-oliguric AKI and <2 gram proteinuria. The accuracy is poor with a bias toward over-estimation of proteinuria, potentially limiting its utility in patients with heavier proteinuria. The 24-hour urine collection should remain the standard practice for proteinuria quantification in AKI.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2055**

**Pre-Operative Proteinuria and Adverse Renal Outcomes in Patients Receiving Coronary Artery Bypass Grafting Surgery** Tao-Min Huang, Vincent Wu, Guang-Huar Young, Fan-Chi Chang, Pi-Ru Tsai, Wen-Je Ko, Kwan-Dun Wu. *Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.*

Background: Proteinuria has been recognized as an independent risk for adverse outcomes in patients with chronic kidney disease (CKD), However, the effect of preoperative proteinuria on renal outcome after cardiac surgery has never been evaluated. We hypothesized that preoperative proteinuria (detected by dipstick test) is predictive of cardiac surgery associated acute kidney injury (CSA-AKI).

Methods:Data was obtained from a teaching hospital and its two affiliate hospitals. From 2003 to 2007, all adult patients undergoing coronary artery bypass grafting surgery

(CABG) were included. Patients with stage 5 CKD or previous dialysis were excluded. Proteinuria was defined as mild (trace to 1+) or heavy (2+ to 4+) according to dipstick tests. Multiple stepwise logistic regressions were used to assess the factors associated with CSA-AKI (defined by Acute Kidney Injury Network criteria) and postoperative renal replacement therapy (RRT).

Results:A total of 1052 patients were enrolled with a mean age of 65.7±11.0 years; 75.7% were male. CSA-AKI developed in 183 (17.4%) patients, of which 50 (4.8%) underwent RRT. Mild proteinuria (OR = 1.576, p = 0.043) and heavy proteinuria (OR = 2.041, p = 0.0110) were associated with CSA-AKI, independent of CKD stages and the presence of diabetic mellitus.

Factors associated with post-operative acute kidney injury

| Variables | OR (95%CI) | p |
|---|---|---|
| Age | 1.04 (1.02-1.06) | <0.001 |
| DM | 2.22 (1.49-3.31) | <0.001 |
| Recent MI | 1.84 (1.19-2.83) | 0.006 |
| IABP | 6.17 (3.49-10.90) | <0.001 |
| Proteinuria | | |
| No proteinuria | 1 | - |
| Mild | 1.58 (1.02-2.45) | 0.043 |
| Heavey | 2.04 (1.18-3.54) | 0.011 |
| CKD stage | | |
| <3 | 1 | - |
| 3 | 1.65 (1.08 - 2.52) | 0.021 |
| 4 | 2.61 (1.31 - 5.19) | <0.001 |

Heavy proteinuria was also associated with postoperative RRT (OR = 3.440, p = 0.0036), independent of serum creatinine.

Conclusion:This study demonstrates that proteinuria, detected with urine dipstick, is an important predictive factor of mild and severe CSA-AKI in patients undergoing cardiac surgery.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2056

**Plasma NGAL for Diagnosis of Established AKI** Dinna N. Cruz,[1] Sergio Gaiao,[1,2] Francesco Garzotto,[1] Massimo De Cal,[1] Claudio Ronco.[1] *[1]S Bortolo Hosp, Vicenza, Italy; [2]Sao Joao Hosp, Porto, Portugal.*

The conceptual model of AKI is a rapid worsening of kidney function from pre-morbid levels. Therefore ideally a baseline serum creatinine (sCr) should be known; unfortunately this is not always possible. Diagnosis of AKI present on ICU admission is frequently done retrospectively, when old records are obtained or when a significant decrease in sCr from the admission value is seen in subsequent days. In some studies renal SOFA (rSOFA) score has been used to define AKI using a single sCr value. NGAL has been shown to be an early marker of AKI; however, our aim was to use it for discrimination of established AKI on ICU admission.

**METHODS**

We selected 90 ICU patients who had AKI on ICU admission and 168 ICU patients who never had AKI. Diagnosis was based on RIFLE, using a baseline sCr retrospectively obtained from hospital records. Plasma NGAL and sCr were measured on the first ICU day; rSOFA was calculated based on admission sCr. Patients were considered rSOFA(+) if rSOFA>1 and NGAL(+) if NGAL>150ng/ml. We then constructed a "panel" based on sequential approach using both rSOFA and NGAL. Patients were considered panel (+) if (rSOFA>1) or (rSOFA≤1 but NGAL>150ng/ml); and panel (-) if both rSOFA(-) and NGAL(-). We compared the diagnostic test accuracy of the 3 methods for AKI diagnosis.

**RESULTS**

Median sCr on admission were 1.7 (IQR 1.2,2.6) mg/dl and 0.9 (IQR 0.8,1.1) mg/dl in AKI and nonAKI groups, respectively. The diagnostic test accuracy of each method is reported in Table 1.

Table 1: Diagnostic test accuracy (with 95%CI)

| | rSOFA | NGAL | rSOFA-NGAL panel |
|---|---|---|---|
| SENSITIVITY (%) | 38.9 (29.0-49.8) | 68.9 (58.1-78.0) | 71.1 (60.5-79.9) |
| SPECIFICITY (%) | 96.4 (92.0-98.5) | 80.4 (73.4-85.9) | 80.4 (73.4-85.9) |
| PPV (%) | 85.4 (70.1-93.9) | 65.3 (54.7-74.5) | 65.9 (55.6-75.1) |
| NPV (%) | 74.7 (68.2-80.2) | 82.8 (76.8-88.1) | 83.9 (77.0-89.0) |

**CONCLUSION**

rSOFA alone has high specificity but low sensitivity for AKI on ICU admission. When NGAL is used together with it, the panel has acceptable specificity but higher sensitivity. When the baseline sCr is not readily available, NGAL may provide additional information to the physician and help in recognizing established AKI.

Disclosure of Financial Relationships: Honoraria: Speaker Honoraria for Biosite/ Inverness Medical.

## SA-PO2057

**Neutrophil Gelatinase Associated Lipocalin (NGAL) as a Biomarker of Acute Kidney Injury (AKI) after Cardiac Surgery in Adults** Rafael Carlos Miranda, Thayza Lopes, Emmanuel A. Burdmann, Emerson Quintino Lima. *Nephrology Division, Hospital de Base - Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Sao Paulo, Brazil.*

**Introduction:** Acute kidney injury following cardiac surgery is associated with high morbidity and mortality. The aim of this study was to evaluate the utlity of urinary NGAL excretion as an early biomarker for AKI after cardiopulmonary bypass (CPB) in adults. **Methods:** Patients submitted to elective coronary artery bypass or valve surgery requiring CPB were enrolled. Patients with ongoing AKI, baseline GFR < 30 ml/min (MDRD equation) or renal transplant were excluded. AKI was defined as an increase of 50% or at least 0.3mg/dL in baseline serum creatinine level within 4 days after surgery (AKIN criteria). Urinary NGAL was measured by an ELISA kit (BioPorto, Denmark) before surgery and 2, 4, 6, 12, 24, 48, 72 and 96 hours after CPB. Preoperative, intraoperative and postoperative data were evaluated by unpaired t-test, Mann Whitney and Fisher's exact tests. The performance of urinary NGAL as a biomarker for AKI was evaluated by ROC curve. P<0.05 was considered as significant. **Results:** 103 patients, 58 males, 55 ± 14 years, were submitted to 75 coronary artery bypass and 28 valve surgeries. AKI developed in 28 (27%) patients (19 males, 58 ± 12 years, preoperative serum creatinine 1.2 ± 0.3 mg/dL). There was no difference regarding age, gender, preoperative serum creatinine, EuroSCORE, surgical, anesthesia and CPB times and hospital length of stay between AKI and non AKI patients. Mortality (32% vs 2.7%, P<0.001) was higher in AKI patients. The median NGAL after 4 h (73 ng/ml [8-398] vs 11 ng/ml [(2-63]; P=0.008), 6 h (39 ng/ml (3-253) vs 9 ng/ml [3-27]; P= 0.009) and 12h (19 ng/ml [6-50] vs 6 ng/ml [3-30]; P=0.02) after CPB were higher in AKI group and preceded the rise in serum creatinine in at least 12h. The ROC curve area for urinary NGAL 4 h, 6 h and 12 h after CPB were 0.66 (95% CI 0.54-0.79; P=0.008), 0.66 (95% CI 0.53-0.79; P=0.009) and 0.64 (95% CI 0.52-0.76;P=0.02). **Conclusions:** These results suggest that NGAL might be a useful tool for the early identification of cardiac surgery patients who will develop AKI.

## SA-PO2058

**Performance of Plasma Neutrophil Gelatinase-Associated Lipocalin (pNGAL) as Marker of Acute Kidney Injury. A Prospective Study in Emergency Department** Karina Soto,[1] Silvia Coelho,[1] Ana Luisa Papoila,[2] Qing Ma,[3] Bruno Rodrigues,[1] Pedro Fidalgo,[1] Michael R. Bennett,[3] Prasad Devarajan.[3] *[1]Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal; [2]Biostatistic, Faculdade de Ciências Médicas, Lisbon, Portugal; [3]Nephrology, Cincinnati Children's Hospital, Cincinnati, OH.*

**Background**: The search for early and accurate biomarkers of acute kidney injury (AKI) is currently a top priority, particularly in the emergency department (ED), where an immediate approach is crucial. In a prospective cohort study we evaluated the discriminative and predictive ability of pNGAL for AKI diagnosis.

**Methods**: Patients (>18y - <80y and CKD<stage IV) admitted to the ED of Fernando Fonseca Hospital, were classified according to clinical criteria. pNGAL was measured at 0, 6, 12, 24 and 48 hours from admission (Triage® NGAL Device; Biosite). Diagnosis of AKI was based on RIFLE and AKIN criteria. To determine the predictive and discriminative power of pNGAL, the area under the receiver operating characteristic curve (AUC) and predictiveness curves were used. Cut-off values were determined through Generalized Additive Models.

**Results**: Patients (n=616) mean age of 59.1y, were adjudicated to have AKI (21.1%), pre-renal azotemia (preR- 25.8%), stable chronic kidney disease (CKD-2.4%) and normal function (NF- 50.7%). The highest levels of pNGAL were shown in the AKI group, differentiating AKI patients from preR and NF (p<0.001). The discriminative ability of pNGAL was good, reaching AUCs from 0.77 to 0.80 (CI 0.77 to 0.84). Increasing levels of pNGAL were associated with increasing risk of AKI and with higher grades of AKIN and RIFLE classifications, showing better performances with AUCs 0.88; 0.86; 0.89; 0.87; and 0.85 at different study times (AKIN>2 grade). At a cut-off of 100 ng/mL, pNGAL showed specificity and sensitivity values of 70.2 and 78.3%, respectively at 12h of admission.

**Conclusions**: pNGAL is a useful biomarker for diagnosis of AKI in a heterogeneous ED population, with good discriminative ability, reliably differentiating AKI from preR azotemia. pNGAL is also an excellent marker of AKI severity.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2059

**Plasma Neutrophil-Gelatinase-Associated Lipocalin (pNGAL) for the Prediction Risk of Acute Kidney Injury, in the Presence of Comorbidities. *A Prospective Study*** Silvia Coelho,[1] Qing Ma,[2] Pedro Fidalgo,[1] Bruno Rodrigues,[1] Michael R. Bennett,[2] Ana Luisa Papoila,[3] Prasad Devarajan,[2] Karina Soto.[1] *[1]Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal; [2]Nephrology, Cincinnati Children's Hospital, Cincinnati, OH, Portugal; [3]Biostatistics, Faculdade de Ciências Médicas, Lisbon, Portugal.*

**Background:** In the emergency department (ED) a prompt diagnosis and appropriate treatment for acute kidney injury (AKI) could improve patient's outcome. A multivariable (clinical and biomarkers) approach could tremendously improve diagnosis accuracy.

The purpose of this study was to evaluate the pNGAL performance associated with clinical risk factors of AKI in a heterogeneous ED population.

**Methods**: Patients (>18y - <80y; CKD stage <IV) admitted to the ED were included. AKI was defined according to the RIFLE and AKIN criteria. pNGAL was measured (by Triage® NGAL Device; Biosite) at 0, 6, 12, 24 and 48h from admission. Significant AKI risk factors were selected and a multifactorial analysis was developed associating with pNGAL levels.

**Results**: 616 patients (mean age 59.1 y) were classified by clinical criteria as AKI (21.1%), pre-renal azotemia (PreR-25.8%), stable CKD (2.4%) or normal kidney function (NF- 50.7%), and were assigned as I to IV stages of susceptibility (on the basis of baseline kidney function): 66.9%, 21.5%, 4.9%, and 6.6%, respectively. Most stages III-IV corresponded to AKI patients and median values of pNGAL increased with grade of susceptibility (p<0.001).

The risk of developing AKI was associated with increasing stages of susceptibility, cardiovascular disease (CVD), and older age (≥75 y) and pNGAL discriminatory performance was better in presence of these variables. Multiple logistic regression model

at T12 showed that patients with pNGAL>100 ng/mL had 7-fold higher risk of AKI (OR 7.4), with an OR=2.7 for CVD; an OR=4.1 for >III susceptibility; and OR=1.8 for older age. (Hosmer-Lemeshow p-value=0.616; AUC 0.83).

**Conclusions**: The presence of elevated pNGAL levels in ED is associated with heightened risk of developing AKI, even more so in patients with risk factors such as CVD, previous renal dysfunction and older age.

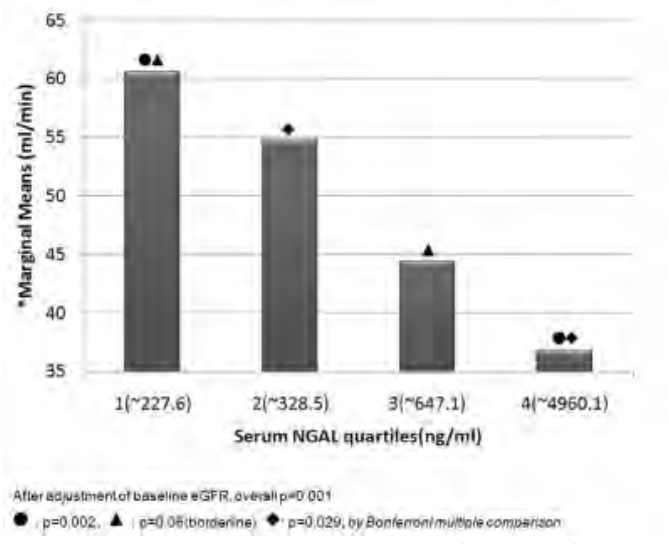
**Serum Neutrophil Gelatinase-Associated Lipocalin Predicts Long-Term Renal Outcomes in Patients with Acute Kidney Injury** Kichul Yoon, Eunjung Cho, Sang-Kyung Jo, Won-Yong Cho, Hyoung-Kyu Kim. *Division of Nephrology, Department of Internal Medicine, Korea University College of Medicine, Seoul, Korea.*

**Background :** There has been insufficient research on long-term renal prognosis of AKI patients. Objectives of this study were to determine long-term renal outcome in patients with AKI and to find factors that can predict long-term renal function. **Methods:** Out of 100 hospitalized AKI patients who were enrolled in this prospective, observational, cohort study, 55 patients who had a mean follow-up of 506 days were included in the analysis. The serum and urine neutrophil gelatinase-associated lipocalin (NGAL) levels were measured at the time of AKI diagnosis. Patients were divided into 'worsened' or 'preserved' renal function group at 6 month by criteria of 25% reduction in eGFR from baseline. Variables associated with the groups and the factors that might predict eGFR at 6 months and 1 year were also determined. **Results:** Thirty two percent of the patients fell into the 'worsened' group at 6 months. Baseline eGFR, initial serum & urine NGAL and initial presence of proteinuria were associated with 'worsened' renal function. Baseline eGFR was the strongest predictor in predicting eGFR at 6 months, followed by initial serum NGAL. Serum NGAL was found to be a useful predictor of 6 month eGFR.

Figure 1. Estimated marginal means of 6 month eGFR outcome(ml/min/1.73m$^2$) for serum NGAL in quartiles



After adjustment of baseline eGFR, overall p=0.001

● : p=0.002, ▲ : p=0.06(borderline), ◆ : p=0.029, by Bonferroni multiple comparison

The serum NGAL level was also a good diagnostic marker for prediction of the 6-month eGFR <30ml/min/1.73m$^2$, based on area under the receiver operating characteristic curve analysis. **Conclusion:** Significant proportion of this cohort who suffered AKI episode had worsened long-term renal function after AKI. Initial serum NGAL level might be a useful independent biomarker for predicting long-term renal function after AKI.

### SA-PO2061

**Serum Neutrophil Gelastinase-Associated Lipocalin (NGAL) and Cystatin C (CyC) Are Early Biomarkers of Contrast Induced Nephropathy (CIN) in CKD Patients after Coronary Catheterization** Norella C. T. Kong. *Medicine, Hospital Universiti Kebangsaan Malaysia, Cheras, Kuala Lumpur, Malaysia.*

Purpose: We investigated whether serum NGAL and CyC are early predictive biomarkers of CIN in CKD patients undergoing coronary catheterization.

Methods: CIN was defined as a rise in serum creatinine ≥25% above baseline levels in the absence of other aetiology. Serum creatinine levels were measured (and eGFR, MDRD, calculated) at baseline, 24 hrs and 48 hrs post-procedure. Blood for serum CyC were collected at baseline and 24hrs and for serum NGAL pre-, at 4 hrs post- and at 24 hrs post-procedure.

Results: CIN was diagnosed in 11/100 (11%) patients and one patient required dialysis. We found a significant rise in serum NGAL ≥25% from baseline at 24 hrs in 7 of these CIN patients(Z=-1.97, p = 0.04*) but NGAL did not change in the other four. Serum CyC at 24hrs was increased ≥25% from baseline in 4 of CIN patients (4/11) (Z=-2.76, p=0.008) - these patients also had a rise in serum NGAL. Serum CyC did not change in the other 7 of the 11 CIN patients. Serum NGAL also rose ≥25% in 12 of the 89 non-CIN patients and one subsequently developed CIN. This patient also had a rise in serum CyC level. The remaining patients were discharged at 48 hrs. This subgroup could well have had 'incipient CIN'. Receiver operating characteristic curve (ROC) showed that both NGAL and CyC could diagnose CIN 24hrs earlier than serum creatinine. The areas under the ROC curves for serum CyC and for serum NGAL between 0-24 hrs were 80.7% (p =0.001**; 95% CI= 0.68– 0.93) and 85.1% (p <0.001**; 95% CI=0.75– 0.952) respectively. An increase in serum NGAL ≥ 25% from baseline at 24 hrs post-procedure and advanced age were independent predictors for the development of CIN (OR=1.012, p=0.005**), (OR =1.188, p=0.019*) respectively.

Conclusions: Both serum NGAL and serum CyC were earlier predictive biomarkers for CIN than serum creatinine and the use of either would enhance CIN diagnosis for this at-risk population.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2062

**Serum Neutrophil Gelastinase-Associated Lipocalin (NGAL) as an Early Marker of Contrast Induced Nephropathy (CIN) in CKD Patients after Coronary Catheterization** Norella C. T. Kong.[Hospital Unive] *[1]Medicine, Hospital Universiti Kebangsaan Malaysia, Cheras, Kuala Lumpur, Malaysia; [2]Inst#1; [3]Inst#1; [4]Inst#1; [5]Inst#1.*

Purpose: To investigate whether serum NGAL is an early predictive biomarker of CIN compared with serum creatinine in CKD patients who undergo coronary catheterization.

Methods:

This prospective study involved patients with CKD Stages 2-4 who underwent coronary catheterization. CIN was defined as an increase of ≥25% in the baseline serum creatinine within 48 hours (hrs) of exposure to contrast medium in the absence of an alternative aetiology. All patients received IV N saline and oral N acetylcysteine prophylaxis. Serum creatinine levels were measured at baseline, 24 hrs and 48 hrs post- procedure. Blood samples for serum NGAL were collected pre-, at 4 hrs and at 24 hrs post- procedure.

Results:

100 patients completed the study. The frequency of CIN was 11% and one patient required dialysis. In patients with CIN, serum creatinine started to rise at 24 hrs but achieved significance only at 48 hrs (Z=0.155, p =0.006). Serum NGAL increased ≥25% from baseline at 24 hrs in 7 of the CIN patients (7/11) (Z = -1.97, p = 0.04) but did not change in the other 4 (4/11). However, serum NGAL also rose ≥25% in 12 of the 89 non-CIN patients, one of whom subsequently developed CIN but the rest were discharged at 48 hrs. This subgroup may have had 'incipient CIN'. At both baseline and at 24 hrs, serum NGAL correlated with serum creatinine (r1=0.42, p1 <0.005; r2 =0.423, p2 <0.001) and eGFR (r1 = -0.356, p1 <0.005; r2 = -0.399, p2 <0.001 respectively). It was also highly associated with CKD stages at both time points (p=0.01 and <0.001 respectively).Using ROC curves, the area under the curve was 85.1% (p <0.001; 95% CI = 0.75– 0.952)giving a sensitivity and specificity for serum NGAL of 81.0% and 75.3% respectively. Risk factors for CIN in CKD patients included age, female gender, Indian ethnicity, diabetes mellitus and anaemia. Age alone was the independent risk predictor (p=0.026).

Conclusions: Serum NGAL was an early predictive biomarker for CIN in the said patient population.

**Increased IL-6 and NGAL with Transaminitis after Laparoscopic Donor Nephrectomy** Steven C. Yap, Sang Won Park, H. Thomas Lee. *Anesthesiology, Columbia University College of Physicians and Surgeons, New York, NY.*

Patients with AKI frequently sustain extra-renal organ dysfunction. We showed previously that murine models of AKI led to increased IL-6 and TNF-α that directly contributed to hepatic dysfunction. Despite the large number of nephrectomies performed in the United States, the impact of these findings in humans is unclear. In this study, we examined whether patients undergoing laparoscopic donor nephrectomy show increased postoperative IL-6 and TNF-α levels with injury to the liver and whether the remaining kidney sustains injury. Serial serum and urine samples were collected from 25 laparoscopic donor nephrectomy patients and 13 control patients subjected to non-renal laparoscopic surgery. IL-6, TNF-α and NGAL were quantified by ELISA. Serum was also analyzed for creatinine (Cr), AST and ALT. Our results show that patients after nephrectomy not only show increased Cr, but also have increased serum IL-6, AST (Figure 1) and ALT (not shown) compared to patients after control laparoscopic surgery. Increases in serum TNF-α did not reach significance most likely due to small sample size. Elevated serum cytokines correlated with transaminitis (IL-6 vs. ALT, Pearson r=0.42, P=0.02). Donor nephrectomy patients had increased urine NGAL normalized to urine Cr at 24 hours (0.22±0.05, N=19 for donor nephrectomy vs. 0.10±2.2, N=7 for control laparoscopy, p<0.005). Increases in urine NGAL directly correlated with age (Figure 1D) suggesting that decreased renal reserve resulting in tubular stress may occur in the remaining kidney in older nephrectomy patients. Taken together, these findings suggest that donor nephrectomy results in increased production of cytokines, possibly explaining the relationship between AKI and hepatic dysfunction. In addition, patients with advanced age may sustain additional injury to the remaining kidney after nephrectomy.

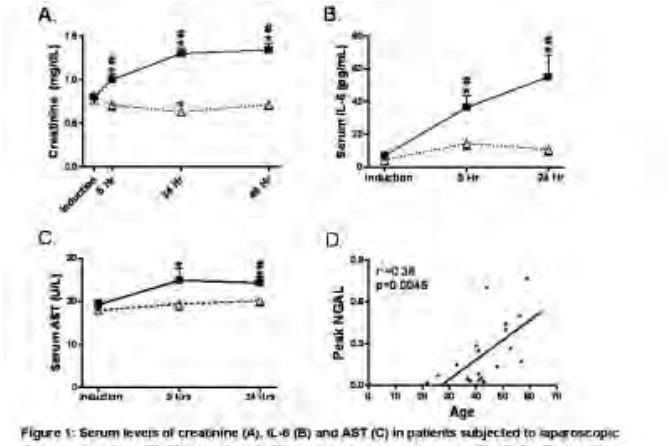

Figure 1: Serum levels of creatinine (A), IL-6 (B) and AST (C) in patients subjected to laparoscopic donor nephrectomy (N=25, ●) and control laparoscopic non-renal surgery (N=13, △). Peak urine NGAL corrected for urine creatinine after laparoscopic donor nephrectomy (N=19, ●) correlated with patient age (D). *P<0.05 vs. Control, #P<0.05 vs. Induction. Error bars represent SEM.

**Test Characteristics of Urinary Neutrophil Gelatinase-Associated Lipocalin (uNGAL) for Differential Diagnosis and Risk Stratification in Patients with Established Acute Kidney Injury** Eugenia Singer,[1,2] Antje Elger,[1] Saban Elitok,[2] Ralph Kettritz,[1,2] Thomas L. Nickolas,[3] Jonathan M. Barasch,[3] Friedrich C. Luft,[1,2,4] Kai M. Schmidt-Ott.[1,2,4] *[1]Charité – Universitaetsmedizin, Berlin, Germany; [2]Helios Clinics Berlin, Germany; [3]Columbia University College of Physicians and Surgeons; [4]Max-Delbrueck Center for Molecular Medicine, Germany.*

Background: Serum creatinine dynamics are used for the diagnosis of acute kidney injury (AKI) in current classification schemes (e. g. RIFLE), but are temporally and diagnostically poor. Urinary NGAL, a biomarker of nephron damage, may help to differentiate intrinsic kidney damage from prerenal AKI. Methods: The relationship between uNGAL levels at the time of diagnosis of AKI and outcomes was evaluated prospectively. uNGAL levels were determined on the Abbott ARCHITECT(R) standardized clinical platform. The primary outcome was worsening of AKI (progression to higher RIFLE category, dialysis initiation, or death) during hospitalization. In those patients with a likely or definitive diagnostic attribution based on clinical criteria, we tested uNGAL in distinguishing intrinsic from prerenal AKI. Results: We studied 162 hospitalized AKI patients. We excluded 17 with postrenal obstruction or insufficient clinical information. From the remaining 145 patients, 75 patients had a clinical diagnosis of intrinsic AKI, 32 patients had prerenal AKI, and 38 patients had an uncertain or ambiguous diagnosis. We found that uNGAL levels effectively discriminated intrinsic AKI from prerenal AKI (ROC 0.87, CI 0.81-0.94). NGAL levels at a cutoff > 100 ng/ml had a sensitivity of 0.75, a specificity of 0.88, a positive predictive value of 0.93, and a diagnostic accuracy of 0.78 in separating intrinsic AKI versus prerenal AKI. Patients with the primary endpoint had significantly higher uNGAL levels ($p<0.001$). In logistic regression analysis, uNGAL levels independently predicted worsening AKI, when corrected for demographics, comorbidities, serum creatinine, and RIFLE class. Conclusion: uNGAL is useful in the differential diagnosis and prognostic stratification of patients with established AKI.

**SA-PO2065**

**Urinary L-FABP Predicts Recovery from Severe Acute Kidney Injury in Critically Ill Patients** Kent Doi,[1] Hiroko Yamamoto,[1] Kousuke Negishi,[1] Tomoko Ishii,[1] Toshiro Fujita,[1] Takehiro Matsubara,[1] Naoki Yahagi,[1] Takeshi Sugaya,[2] Eisei Noiri.[1] *[1]University of Tokyo; [2]CMIC, Co. Ltd.*

Acute kidney injury (AKI) is one of the serious complications for critically ill patients in intensive care unit (ICU). New AKI biomarkers including urinary L-type fatty acid-binding protein (L-FABP) have been developed mostly for early detection and severity prediction. However, their prognostic utility for severe and established AKI remains unclear. This study is aimed to evaluate whether urinary L-FABP can predict renal recovery from AKI that requires continuous renal replacement therapy (CRRT). Urinary L-FABP was measured at the initiation of CRRT in 34 critically ill patients treated at a mixed ICU of our university hospital. In 22 patients (64.7%), CRRT was discontinued because of renal recovery, whereas 12 patients needed CRRT until they died. There were significant differences between the recovery group and the non-recovery group in urinary L-FABP [75.0 (IQR 10.5–260.8) ng/ml versus 251.9 (52.0–5785.9) ng/ml, $p<0.05$] and blood lactate level (2.4±0.9 mmol/l versus 6.6±1.3 mmol/l, $p<0.05$). The non-renal SOFA score in the recovery group was significantly lower than the non-recovery group (7.9±0.6 versus 11.3±0.8, $p<0.05$). However, distributions of RIFLE criteria classes based on serum creatinine and urine output were variable and failed to predict renal recovery. Receiver operating characteristic (ROC) analysis revealed urinary L-FABP had a good performance for predicting renal recovery [area under the ROC curve 0.71 (95%CI 0.51–0.86)], which was improved by being combined with non-renal SOFA score [area under the ROC curve 0.85 (0.61–0.96)]. Six patients in the recovery group with the higher urinary L-FABP values than the cut-off value (103.2 ng/ml) showed significant reductions of urinary L-FABP at one day prior to CRRT termination [263.5 (IQR 259.9–2109.2) ng/ml → 54.0 (10.0–133.4), $p<0.05$]. In conclusion, urinary L-FABP measured at CRRT initiation and sequentially can predict renal recovery.

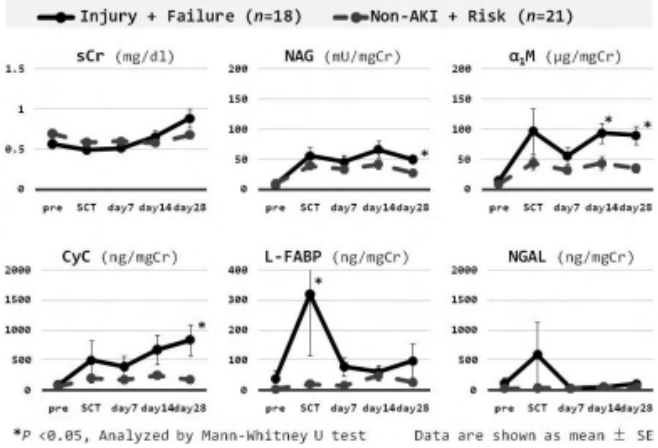
**Highly Elevated Levels of Urinary Liver-Type Fatty Acid Binding Protein Is Likely To Be an Early Warning Sign of Acute Kidney Injury Following Hematopoietic Stem Cell Transplantation** Taku Morito,[1,2] Minoru Ando,[2] Ken Tsuchiya,[2] Kosaku Nitta.[1] *[1]Department IV of Internal Medicine, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan; [2]Department of Nephrology, Tokyo Metropolitan Komagome Hospital, Bunkyo-ku, Tokyo, Japan.*

INTRODUCTION: Acute kidney injury (AKI) is a common complication after myeloablative allogeneic hematopoietic stem cell transplantation (SCT). The use of urine as a diagnostic medium may allow the non-invasive detection of incipient nephropathy.

METHODS: A prospective cohort study was conducted in 39 patients (48.1±13.1 years) receiving SCT. To detect subclinical tubular damage, urinary biomarkers such as N-acetyl-β-glucosaminidase (NAG), $\alpha_1$ microglobulin ($\alpha_1$M), Neutrophil gelatinase associated lipocalin (NGAL), Liver-type fatty acid binding protein (L-FABP) and cystatin C (CyC) were consecutively measured before and 4 points after SCT. AKI was classified by the RIFLE criteria.

RESULTS: Incidence of any AKI was 76.9% after SCT (10.3% within 14 days and 15.4% within 28 days), and high-grade AKI (≥ Injury) was 46.2%. Changes of 5 biomarkers were compared between patients with and without the emergence of high-grade AKI (Figure1). While serum Cr remained statistically constant until day 28, in high-grade AKI group, any biomarker manifested the first peak at SCT, which was followed by a transient decrease at day 7 and a subsequent increase up to day 28. Only the peak value at SCT of L-FABP was statistically significant. These results suggested that: (1) subclinical tubular damage is induced likely by pre-conditioning regimens, the degree of which could be involved in the emergence of high-grade AKI, and (2) L-FABP may be most sensitive for early detection of tubular damage in the setting of SCT.

CONCLUSIONS: L-FABP has shown promise as a marker of identification of patients at risk for high-grade AKI following myeloablative allogeneic SCT.



Disclosure of Financial Relationships: nothing to disclose

**SA-PO2067**

**Urinary IL-18 and L-FABP as Early Predictive Biomarkers in Contrast-Induced AKI (Acute Kidney Injury) on Chronic Kidney Disease (CKD) Stage 3 Patients** Kosuke Inoue. *Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Nankoku, Japan.*

BACKGROUND/AIMS: Contrast-induced nephropathy (CIN) is the important cause of hospital-acquired AKI on CKD patients. However, some urinary biomarkers for AKI were reported to be high in CKD patients. Thus, sensitivity and specificity of these urinary biomarkers are not determined for the diagnosis of AKI in CKD patients. This study was designed to investigate whether human urinary IL-18, neutrophil gelatinase-associated lipocalin (NGAL), and liver-type fatty acid binding protein (L-FABP) are early predictive markers for CIN after coronary angiography (CAG) in CKD patients. METHODS: 24 patients of CKD Stage 3 undergoing CAG were enrolled. Urine samples were collected before, 3h, 6h, 24h after CAG and IL-18, NGAL, and L-FABP levels measured by using an ELISA kit. Urinary creatinine values were measured and the values of urinary biomarkers were corrected by the creatinine concentration because of oligohydruria. This study was approved by Kochi Medical School review boards. All patients provided written informed consent. RESULTS: eGFR (Estimated glomerular filtration rate) decreased more than 5ml/min in 12 patients (decreased eGFR group) and did not decrease in remaining 12 patients (non-decreased group) after CAG. At 3h, 6h, and 24h after the procedure, the ratio with the previous value of the urinary IL-18 and L-FABP were significantly increased in the decreased eGFR group, but not in the non-decreased group. In contrast, NGAL are rapidly

increased in both group, however, no statistically significant difference of NGAL was observed between two groups. When we used uncorrected biomarker values by creatinine, the specificity and sensitivity were significantly decreased.

CONCLUSIONS: We conclude that urinary IL-18 and L-FABP could be early biomarkers of CIN in CKD Stage3 patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2068**

**IL-18 Is the Best Predictor of Renal Replacement Therapy after Cardiac Surgery from among a Panel of Markers** John M. Arthur,[1,5] Evelyn C. Lewis,[1] Timothy P. Taylor,[1] Michael G. Janech,[1,5] James A. Tumlin,[3] Lakhmir S. Chawla,[2] Andrew Shaw.[4] *[1]MUSC, Charleston, SC; [2]George Washington University, Washington, DC; [3]UT Chattanooga, Chattanooga, TN; [4]Duke University, Durham, NC; [5]Ralph H Johnson VA Medical Center, Charleston, SC.*

Acute kidney injury (AKI) has a high mortality but treatments to prevent it have not been identified. Markers that can predict which patients will require renal replacement therapy (RRT) are needed to help develop new therapies. Urine samples from 117 patients who developed at least stage I AKI after cardiac surgery were collected at 4 centers. Mean bypass time (2:47±0:07 vs 2:36±0:22), preoperative creatinine (1.2±0.05 vs 1.3±0.11 mg/dl) and time after surgery of urine collection (1.4±0.07 vs 1.8±0.23 days) were not different between the groups. The increase in serum creatinine was greater in the RRT group (0.7±0.06 vs 1.4±0.28 mg/dl, p<0.05). We measured 27 analytes in urine obtained after the patients met criteria for AKI. Receiver Operator Characteristic curves were created to determine the ability of the analytes to predict RRT. Adjusting the concentration of the analyte by dividing by urine creatinine concentration improved the ability of the analytes to predict RRT. Urinary IL-18 was the best predictor of RRT with an AUC value of 0.86. Using a cutoff value of 249 pg/mg Cr, the RRT outcome of 101 of the 117 patients was correctly predicted. The sensitivity was 73% and the specificity was 87%. The AUC values for the remaining markers was VCAM-1 (0.82), NAG (0.82), IL-6 (0.82), NGAL (0.80), L-FABP (0.80), Cystatin C (0.79), HGF (0.79), Clusterin (0.78), IL-1ra (0.77), albumin ((0.77), MCP-1 (0.76), IL-8 (0.75), Fetuin A (0.74), Urine protein (0.72), VEGF (0.69), LIF (0.69), GROα (0.67), RBP (0.67), β2 microglobulin (0.66), IL-10 (0.65), Eotaxin (0.65), Netrin 1 (0.63), MIP1α (0.58), TRAIL (0.55), RANTES (0.54) and TNFα (0.43). We conclude that IL-18 is the best predictor of the need for RRT after cardiac surgery from among a panel of commonly used markers. The predictive value in this population of post surgery patients is good enough to help select patients for clinical trials in AKI.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2069**

**Utility of Urine Biomarkers for Differential Diagnosis of Acute Kidney Injury in Cirrhotic Patients** Won K. Han, Svastijaya Daviratanasilpa, Bonita E. Falkner. *Medicine/Division of Nephrology, Thomas Jefferson University, Philadelphia, PA.*

The purpose of this study was to evaluate the diagnostic utility of urinary hepatocyte growth factor (HGF), kidney injury molecule-1 (KIM-1), and N-acetyl-β-D-glucosaminidase (NAG) for detection of established acute kidney injury (AKI) in a cross-sectional study and then to differentiate the cause of AKI among patients with cirrhosis in a case-control study. In the cross-sectional study, spot urine samples were collected from 79 patients with established AKI and from 233 non-AKI subjects. The case-control study included urine samples from 48 cirrhotic patients (31 AKI and 17 non-AKI). AKI was defined as ≥ 50% increase in serum creatinine from baseline. Biomarkers were measured at 3 time points during hospitalization and normalized to the urine creatinine concentration. Receiver-operating characteristic curves were generated and the areas under the curve (AUC) compared for performance of biomarkers. In the cross-sectional study, urinary HGF, KIM-1, and NAG had an AUC of >0.90 to detect the established AKI. In the prospective study of patients with cirrhosis, the AUCs to differentiate acute tubular injury (n=10) from prerenal azotemia (n=10) at 24 and 48 hours after enrollment were 0.90 and 0.98 for HGF; 0.82 and 0.89 for KIM-1; 0.76 and 0.84 for NAG, respectively. The AUCs to differentiate acute tubular injury (n=10) from hepatorenal syndrome (n=11) at 24 and 48 hours after enrollment were 0.65 and 0.83 for HGF; 0.56 and 0.77 for KIM-1; 0.66 and 0.89 for NAG, respectively. Our results demonstrate that urinary biomarkers can aid to differentiate the cause of AKI in patients with cirrhosis.

**Early Elevation of Urinary α1 Microglobulin Following Myeloablative Allogeneic Hematopoietic Stem Cell Transplantation Patients Predicts Incidence of High-Grade Acute Kidney Injury** Taku Morito,[1,2] Minoru Ando,[2] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Department IV of Internal Medicine, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan; [2]Department of Nephrology, Tokyo Metropolitan Komagome Hospital, Bunkyo-ku, Tokyo, Japan.*

INTRODUCTION: Allogeneic myeloablative (m-allo) hematopoietic stem cell transplantation (SCT) involves a great risk of acute kidney injury (AKI). Early detection and treatment of AKI is necessary to improve the outcome.

METHODS: A prospective cohort study was conducted in 27 patients (46.3±13.4 years) receiving m-allo SCT between Dec 2008 and Oct 2009. We measured urinary biomarkers for renal tubular injury such as N-acetyl-β-glucosaminidase (NAG), $\alpha_1$ microglobulin ($\alpha_1$M), Neutrophil gelatinase associated lipocalin (NGAL), Liver-type fatty acid binding protein (L-FABP) and cystatin C (CyC) levels before and 4 points after SCT. AKI was classified by the RIFLE criteria. Discriminative power of biomarkers for emergence of AKI was evaluated using area under the ROC curve. Variables relevant to emergence of AKI were analyzed using multivariate logistic regression analysis.

RESULTS: Any AKI occurred at day 51 (median) following m-allo SCT. Incidence of any AKI and high-grade AKI (≥ Injury), which is associated with 1-year mortality for post-SCT patients, was 66.7% and 40.7%, respectively. Among biomarkers we measured, $\alpha_1$M at day 14 and 28 had moderate power to discriminate subsequent high-grade AKI (figure 1). Multivariate logistic regression analysis showed that only $\alpha_1$M level at day 14 and 28 were associated with the emergence of high-grade AKI. ($\alpha_1$M at day 14: OR; 1.039, 95%CI; 1.005-1.113, $P$ = 0.0177 and $\alpha_1$M at day 28: OR; 1.122, 95%CI; 1.023-1.442, $P$ = 0.0007, respectively).

CONCLUSIONS: Among currently-available biomarkers, urinary $\alpha_1$M could be useful for identification of patients at risk for subsequent high-grade AKI following m-allo SCT.

**Soluble Thrombomodulin Levels in Acute Kidney Injury** Josee Bouchard,[1] Rakesh Malhotra,[1] Sharon Soroko,[1] Akanksha Gupta,[2] David T. Berg,[2] Ashita J. Tolwani,[3] Ravindra L. Mehta.[1] *[1]University of California San Diego; [2]Eli Lilly Research Laboratories; [3]University of Alabama at Birmingham, .*

*Background.*

Markers of endothelial dysfunction have been implicated in the pathophysiology of acute kidney injury (AKI) in septic animal models. There are limited data on markers of endothelial dysfunction in clinical AKI. We hypothesized that soluble thrombomodulin (sTM) is involved in the development of AKI in critically ill patients and that sTM levels can predict AKI.

*Methods.*

We conducted a prospective, multicenter observational study to evaluate the role of sTM levels as an early biomarker for AKI in critically ill patients. AKI was defined according to the AKIN criteria. Samples were collected every 12 hours after ICU admission for ≥48 hours and up to 10 days.

*Results.*

From the 80 patients enrolled, 18 developed AKI on average 1.5 ± 1.7 days after ICU admission. Mean sTM levels were higher in patients who developed AKI compared to patients without AKI over the study (6.5 ± 7.5 ng/ml vs. 1.7 ± 2.0 ng/ml; p < 0.001). The area under the curve (AUC) to predict AKI using sTM was 0.729 (95% CI, 0.630 to 0.828). STM levels were also significantly higher in patients with sepsis than without sepsis (3.6 ± 5.9 ng/ml vs. 2.3 ± 3.2 ng/ml; p= 0.005). In septic patients, sTM levels were higher in patients who developed AKI than in those who did not over the study (7.4 ± 9.2 ng/ml vs. 2.1 ± 2.6 ng/ml; p < 0.001) and the AUC to predict AKI in this group was 0.709 (95% CI 0.578-0.839).

*Conclusion.*

Soluble thrombomodulin is a biomarker of endothelial dysfunction potentially involved in the pathophysiology of AKI and which can help to predict AKI. Further studies are required to evaluate its role in endothelial dysfunction, sepsis and AKI.

**Serum Nutritional Markers Are Predictors of Early Mortality in Hospital-Acquired Acute Kidney Injury** Chuan-Ming Hao. *Huashan Hospital, Fudan University.*

**Background:** Preexisting malnutrition is common in patients with acute kidney injury (AKI), but few studies have shown the relationship between the changes of nutritional status and the outcomes of these patients. **Methods:** 194 patients with hospital-acquired AKI, as determined by RIFLE staging criteria were included. Nutritional evaluations, including Subjective Global Assessment (SGA), anthropometric and laboratory evaluations were conducted. The primary outcome was early mortality (<7 days) and late mortality (>7 days, <28 days) after inclusion into the study. **Results:** AKI patients at enrollment were characterized by a high prevalence of malnutrition. Univariate analysis showed that the SGA, serum prealbumin, cholesterol and total lymphatic cells, and the Maastricht index were significantly different among early mortality, late mortality and survival groups. The serum prealbumin and cholesterol levels in the early death group were significantly lower than those in the survival and late death groups ($p < 0.05$). Multivariate analysis revealed that SGA, albumin, prealbumin and cholesterol remained independently and significantly associated with early mortality after adjusting for age, sex, dialysis, ventilation, hemoglobin, platelets, bilirubin, and Glasgow coma score. The ROC area value to predict early mortality for albumin, prealbumin and cholesterol were 0.591, 0.736 and 0.603, respectively, with that of prealbumin significantly higher than others ($p < 0.05$). **Conclusions:** Lower levels of serum prealbumin, albumin and cholesterol at enrollment were independently associated with increased early mortality in hospital-acquired AKI patients.

**Serum Uric Acid Level as a Marker for Mortality and Acute Kidney Injury in Patients with Acute Paraquat Intoxication** Sujin Seok, Junghoon Kim, Su-Ji Kim, Hyo-Wook Gil, Jong-Oh Yang, Eun-Young Lee, Sae-Yong Hong. *Internal Medicine, Soonchunhyang University, Cheonan, Korea.*

Paraquat (PQ) is a non-selective herbicide that generates reactive oxygen species (ROS) *in vivo*. Uric acid emerged as a marker of oxidative stress, and may enhance ROS-mediated injury. Therefore, we investigated the association between uric acid levels and mortality and acute kidney injury (AKI) in patients with acute PQ intoxication.

**Methods:** From January 2007 to December 2008, 513 patients arrived at our hospital with acute PQ intoxication. We excluded the patients of initial serum creatinine >1.2 mg/dL, arrival at hospital more than 24 hours after PQ ingestion, death on the day of admission, and those who left the hospital against medical advice. Subsequently, a total of 247 patients were included in the study. Patients were divided into two groups (hyperuricemia *vs.* non-hyperuricemia) based on uric acid levels. Mortality and AKI were analyzed in reference to uric acid level.

**Results:** The mean serum uric acid level was 5.6±1.6 mg/dL in men, 4.1±1.3 mg/dL in women and the mean serum creatinine level was 0.7±0.2 mg/dL. Patient mortality was higher in hyperuricemia group than in non-hyperuricemia group (68.4% *vs.* 38.3%, $p<0.05$). Hyperuricemia significantly increased the risk of mortality and the adjusted odds ratio for mortality was 3.67 (1.35-9.98) with hyperuricemia. The frequency of AKI was higher in the hyperuricemia group (78.9% *vs.* 61.2%, $p<0.05$). The mortality in the kidney failure group was 75.7%, while that of the counterpart was 17.9%. After adjustments for age, gender, and the amount of PQ ingestion, hyperuricemia was still significantly associated with an increased risk of kidney failure (OR, 3.30; 95% CI, 1.33-8.20). There was an increased prevalence of respiratory failure associated with hyperuricemia. The incidence of liver injury and pancreatic injury were not statistically significant. The mean uric acid level increased in association with an increase in the number of organ injuries.

**Conclusions:** Baseline serum uric acid level might be a good clinical marker for patients at risk of mortality and AKI after acute PQ intoxication.

**Urinary Kallikrein Activity and Tissue Kallikrein Promoter DNA Methylation Analysis in Acute Kidney Injury** Sunwoo Kang,[1] Pei-An (Betty) Shih,[2] Roy Mathew,[3] Fangwen Rao,[2] Rakesh Malhotra,[2] Ravindra L. Mehta,[2] Daniel T. O'Connor.[2] *[1]Nephrology, College of Medicine, Inje University, Busan, Korea; [2]Medicine, University of California San Diego, Lajolla, CA; [3]Veteran's Affair Medical Center, Albany, NY.*

Transplanted subjects with acute kindy injury (AKI) excreted less kallikrein. Kallikrein gene transfer protected against AKI by inhibiting apoptosis and inflammation without affecting blood pressure. Therefore, we hypothesized that changes in urine epigenetics for kallikrein could be a biomarker approach during the AKI.

We examined the DNA for aberrant methylation of the promoter KLK1 gene and LINE-1 elements by pyrosequencing from 20 AKI patients and 38 healthy controls. Results were compared with clinical data and the urine activity of the kallikrein.

The AKI patients had lower systolic blood pressure than controls (119.8 ± 4.4 vs. 131.7 ± 1.7 mmHg; p = 0.02) and higher heart rate (89.3 ± 3.6 vs. 68.0 ± 1.6 bpm; p = 1.73E-05). Unexpectedly it turned out that our AKI subjects have high kallikrein excretion, about 10 times higher than controls ( 6.74 ± 1.92 vs. 0.63 ± 0.08 mU/mg creatinine; p < 0.001). Our AKI subjects had high epinephrine excretion, about 3 times higher ( 20.1 ± 2.4 vs. 7.5 ± 1.1 ng/mg creatinine; p < 0.001). Urinary kallikrein excretion was controlled by urinary epinephrine excretion in these samples. Promotor KLK1 specific methylation was high in blood. But, it was significantly lower in urine (66.38 ± 1.00 vs. 33.43 ± 4.67%; p < 0.001). KLK1 methylation in blood DNA was significantly higher in the AKI patients than controls (70.32 ± 2.27 vs. 65.36 ± 1.05%; p = 0.011). However, KLK1 methylation in urine DNA trended higher in the AKI patients (40.95 ± 7.06 vs. 30.35 ± 5.88%; p = 0.22).

In conclusion, increased epinephrine production under hypotensive condition induced significant increase in urinary kallikrein excretion in AKI. KLK-1 promoter DNA methylation study confirmed that this gene is the kidney specific expressed one because it was lower in urine. Since KLK1 promotor methylation was higher in the AKI patients than controls, KLK1 promoter CpG methylation may have potentially pathogenic role on AKI susceptibility.

**Urine Sediment from Patients with Acute Kidney Injury Contains Potential Biomarker Proteins** Robert Arthur,[1] Michael G. Janech,[1,2] Benjamin Neely,[1] John M. Arthur,[1,2] Juan Carlos Q. Velez.[1] *[1]MUSC, Charleston, SC; [2]Ralph H Johnson VA, Charleston, SC.*

Acute kidney injury (AKI) is an important clinical problem. Many potential biomarkers have been proposed in the urine but the urine sediment has not been investigated as a potential source of biomarkers. The sediment is used to help diagnose acute tubular necrosis and is a likely source of informative biomarkers. We compared the proteins in the urine supernatant to those in the urine sediment using 2D gel electrophoresis. Patterns of proteins were strikingly different between the sediment and supernatant. Uromodulin (Tamm Horsfall Protein) was far more abundant than any other protein on the sediment gels. Carbonic anhydrase, keratin, alpha and beta actin were also identified. Albumin, zinc α2 glycoprotein, α-1-microglobulin and prostaglandin H2 isomerase were most abundant in the urine supernatant. To further characterize the proteins present in the sediment, we performed two dimensional chromatography tandem mass spectrometry on tryptic peptides from sediment proteins. 578 proteins were identified with high confidence. Protein abundance was determined using Scaffold by dividing number of assigned spectra by number of total spectra to give a percent total spectra. Uromodulin, several histone proteins, keratin, hemoglobin subunits and protein S100-A8/9 were the most abundant proteins. Gene Ontology (GO) terms were assigned to the proteins. 21% of the proteins were assigned to cellular processes. Protein phosphorylation and proteolysis were the most common cellular processes with 10 proteins each. Proteins involved in signal transduction, DNA processes, cell adhesion, nucleosome assembly, signal transduction and transcription were also abundant. 16% of the proteins were assigned to GO terms associated with biological regulation. Regulation of cell growth and transcription were the most common terms in this group. For the cellular component GO terms, 72% of proteins were unassigned, 15% were in intracellular organelles, 11% were in membrane and 9% each were in cytoplasm and nucleus. These proteins in the urine sediment of patients with AKI are candidates to be used as diagnostic and prognostic markers.

**Diagnostic Marker Pattern of Sequenced Urinary Peptides for Early and Accurate Detection of Acute Kidney Injury** Jochen Metzger,[1] Torsten Kirsch,[2] Marion Haubitz,[2] Harald Mischak,[1,3] Peter Rossing,[4] Stefan Herget-Rosenthal.[5] *[1]Mosaiques Diagnostics GmbH, Germany; [2]Hannover Medical School, Germany; [3]University of Glasgow, United Kingdom; [4]Steno Diabetes Centre, Denmark; [5]Rotes Kreuz Krankenhaus, Germany.*

Acute kidney injury (AKI) is a common condition in intensive care unit (ICU) patients and associated with high mortality. In order to prevent its progression and to improve its outcome, early and accurate detection of AKI is crucial. In pilot studies kidney injury molecule 1 (KIM-1) was proposed as a promising early marker for AKI. However, latter studies could not confirm these findings making it necessary to search for other, more predictive markers.

We used capillary electrophoresis mass spectrometry to identify urinary peptide markers predictive for AKI in urine samples obtained from indwelling bladder catheters of ICU patients who later developed AKI (maximum 5 days prior AKI) defined by a serum creatinine increase ≥ 50% in ≤ 48 hours or maintained normal kidney function. The statistically most significant markers were combined and validated on a blinded set of ICU patient samples. Classification accuracy of the proteomic model in this patient collective was compared to that based on urinary KIM-1 levels.

A combination of 20 peptides allowed classification of a blinded test set of ICU patient samples (n=20) with 89% sensitivity and 82% specificity. In order to evaluate general applicability, the urinary proteomic model was further applied to the classification of single-void urine samples from hematopoietic stem cell transplanted patients of which 13 developed AKI after transplantation and 18 did not. AUC in this validation set was 0.90 with sensitivity and specificity values of 94 and 82 %, respectively. Compared to the proteomic model, ROC curve analysis revealed poorer classification accuracy of KIM-1 with the respective AUC values being outside the statistical significant range (0.67 for the ICU and 0.57 for the HSCT validation set).

In contrast to KIM-1, the proteomic marker pattern allowed accurate detection of AKI as early as 5 days in advance of serum creatinine irrespective of the patient population in whom AKI occurred.

**Clinical Significance of Tubular and Podocyte Biomarkers in Acute Kidney Injury** Katsuomi Matsui,[1] Atsuko Kamijo,[1] Masanori Hara,[2] Takashi Yasuda,[1] Kenjiro Kimura,[1] Takeshi Sugaya.[1] *[1]Department of Nephrology and Hypertension, Internal Medicine, St. Marianna University School of Medicine, Kanagawa, Japan; [2]Department of Pediatrics, Yoshida Hospital, Niigata, Japan.*

*Background*: Acute kidney injury (AKI) is a common complication in critically ill patients. Urinary excretion of liver-type fatty acid-binding protein (L-FABP), which is expressed in the proximal tubules, reflects the presence of tubular injury. Urinary excretion of podocalyxin (PCX), a glycoprotein prominently expressed on podocytes, is associated with podocyte injury. Our aims were to evaluate the utility of urinary L-FABP for the early detection of AKI and to examine whether podocyte injury is present in AKI patients using the biomarker of urinary PCX.

*Methods*: Patients admitted to the intensive care unit (ICU) were divided into the AKI group (n=14) and non-AKI group (n=11), according to the occurrence of AKI during hospitalization in the ICU. Changes in various biomarkers were evaluated.

*Results*: In the AKI group, elevation of urinary L-FABP level [maximum value of L-FABP, 199.0 (92.5–433.6) μg/g creatinine, median (25%–75% interquartile range)], which reflects tubular injury (area under the curve 0.95, cut-off value 44.1 μg/gCr), occurred between -30 and 0 hour before the occurrence of AKI (i.e., the time at which serum creatinine peaked), and elevation of urinary PCX level [maximum value of PCX, 389.5 (267.0–501.0) μg/g creatinine; upper limit of reference value, 160 μg/g creatinine] occurred during the time of recovery from AKI when serum creatinine levels were decreasing between 34.0 and 72.0 hours after the occurrence of AKI.

*Discussion and Conclusions*: Our study suggests that L-FABP is a useful biomarker for early detection of AKI and that podocyte injury was induced during the recovery phase of AKI. Moreover, podocyte injury observed by elevation of urinary PCX was induced even in patients with mild or moderate AKI. It is speculated that the more severe the episode of AKI, the more severe is the podocyte injury. Because a recent study revealed that AKI is associated with increased risk for CKD, podocyte injury may be closely related to renal impairment after AKI.

**SA-PO2078**

**Time-Dependent Changes of Urinary Biomarkers in Lung Cancer Patients after Cisplatin-Based Chemotherapy** Tomoko Sato,[1] Satohiro Masuda,[1] Aiko Ozawa,[1] Yosuke Togashi,[2] Young Hak Kim,[2] Michiaki Mishima,[2] Takaharu Ichimura,[3] Joseph V. Bonventre,[3] Ken-Ichi Inui.[1] *[1]Department of Pharmacy, Kyoto University Hospital, Kyoto, Japan; [2]Department of Respiratory Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

**[Backgrounds]** Acute kidney injury occurs after cisplatin-based chemotherapy with about 20% of patients with lung cancer. Therefore, serial monitoring of kidney function is crucial in patients with lung cancer treated with cisplatin. Because the classical biomarkers for renal function such as serum creatinine (Scr) and blood urea nitrogen (BUN) are insensitive and nonspecific, some algorithm(s) should be established in combination with some urinary biomarkers specific for cisplatin-induced nephrotoxicity. **[Aim]** The aim of the present study is to identify useful urinary biomarkers for the monitoring of the kidney damage in the lung cancer patients treated with cisplatin. **[Methods]** The urine samples were collected at the day before the administration of cisplatin (60mg/m$^2$) and at days 3, 7, 14 and 21. The urinary neutrophil gelatinase-associated lipocalin (NGAL), Liver-type fatty acid-binding protein (L-FABP) and osteopontin were measured by commercially available ELISA kits. The urinary Kidney Injury Molecule-1 (KIM-1) and forty cytokines/chemokines were also measured by microbead-based sandwich ELISA with the Bio-Plex® system. Eight patients were enrolled in this study with written informed consent. **[Results]** In the case with severe nephrotoxicity after the cisplatin-based chemotherapy with elevated Scr, most of the urinary biomarkers examined were markedly increased at day 3. However, the urinary KIM-1 and NGAL, but not L-FABP or osteopontin, were increased up to 3-fold in four patients without change in Scr. Because the pre-treatment urinary KIM-1 and NGAL was increased at the second course of chemotherapy, cumulative nephrotoxicity was suggested in the patients receiving repeated cisplatin-based chemotherapy. **[Conclusion]** Urinary KIM-1 and NGAL can be sensitive and specific biomarkers reflecting the cisplatin-induced kidney injury in lung cancer patients.

**Changes in Urinary Cytokines during 3 Days after Ischemia-Reperfusion Predict Renal Functional Outcome on Day 7 and 1, 2, and 3 Later** Osun Kwon, Binzhi Zhang. *Medicine/Nephrology, Penn State College of Medicine, Hershey, PA.*

Acute kidney injury (AKI) is a common disorder associated with high morbidity and mortality. Ischemia is the leading cause of AKI. To date, however, no specific treatment modalities are available to treat sustained AKI. Noninvasive parameters which reliably reflect the ongoing phenomenon in the kidney and predict renal functional outcome are required to facilitate improved management and decrease the morbidity and mortality of the patients. We recently reported that urinary IP-10, IL-8, VEGF, TGF-alpha and EGF may predict renal functional outcome during the first week of diagnosis of ischemic AKI. In the current study, we questioned whether changes in multiple urinary cytokine levels early after an ischemic insult predict long-term as well as short-term renal functional outcome. Fifteen recipients of a renal allograft were studied since freshly transplanted kidneys are known to be an optimal model for pure postischemic AKI in humans. Urine samples were obtained about 4 hrs after reperfusion of the renal allograft and 3 days later. Markers of inflammation and regeneration were assessed in the urine samples. During 3 days after ischemia-reperfusion, high proinflammatory cytokine levels tended to decrease and low EGF levels tended to increase, especially in subjects with recovering renal function compared to the subjects destined to have sustained AKI. The sum of the changes (% increase or decrease) in 8 urinary proinflammatory cytokine levels; IL-1beta, IL-6, IL-8, MCP-1, IP-10, RANTES, TGF-alpha, VEGF, and the change in urinary EGF between day 0 and 3 were analyzed for renal outcome on postoperative day 7 and year 1, 2, and 3. More than 53.3 % and -48.3 % increase in urinary EGF between day 0 and 3 predicted renal recovery (s-Cr ≤ 1.3 mg/dl) 1 and 2 years later, and 3 years later, respectively. Less than 709.3 % decrease in the sum of 8 urinary cytokine changes tends to predict no renal recovery on day 7 and 1 and 2 years later. We suggest that increase in urinary EGF and decrease in multiple urinary proinflammatory cytokines over 3 days after an ischemic insult may predict renal functional outcome on day 7 and 1, 2, and 3 years later.

**Association of Urinary Alpha-GST and Pi-GST with Dialysis Requirement in Acute Kidney Injury** Victor F. Seabra,[1,3,4] Mary Celine R. Perianayagam,[1,3] Hocine Tighiouart,[2,3] Orfeas Liangos,[3] Oscar Pavao Dos Santos,[4] Bertrand L. Jaber.[1,3] *[1]Kidney and Dialysis Research Laboratory, St. Elizabeth's Medical Center, Boston, MA; [2]Biostatistics Research Center, Tufts Medical Center, Boston, MA; [3]Department of Medicine, Tufts University School of Medicine, Boston, MA; [4]Division of Nephrology, Federal University of Sao Paulo, Sao Paulo, SP, Brazil.*

**Background.** There is lack of information on the potential usefulness of single measurements of urinary alpha glutathione S-transferase (GST), a proximal tubular injury marker, and pi-GST, a distal tubular injury marker, for the prediction of dialysis requirement in acute kidney injury (AKI).

**Methods.** We examined the association of urinary alpha-GST and pi-GST levels with dialysis requirement or in-hospital death in 246 hospitalized adults with AKI using logistic regression analyses. A single urine sample obtained at the time of nephrology consultation was assayed by ELISA, and the results were normalized to urinary creatinine.

**Results.** Mean age was 66 years, 54% were men, mean APACHE II score 20, 44% had sepsis, 39% required dialysis, and in-hospital mortality was 22%. In unadjusted analyses, increases in pi-GST were associated with higher odds for dialysis requirement or the composite of dialysis requirement or in-hospital death. These associations were attenuated after adjustment for APACHE II score. Urinary alpha-GST was not associated with the outcomes of interest.

| | **Dialysis requirement** | | **Dialysis requirement or in-hospital death** | |
|---|---|---|---|---|
| | OR per doubling (95%CI) | | OR per doubling (95%CI) | |
| | alpha-GST | pi-GST | alpha-GST | pi-GST |
| **Unadjusted** | 1.10 (0.94,1.29) P=0.22 | 1.14 (1.01,1.29) P=0.03 | 1.11 (0.96,1.30) P=0.16 | 1.15 (1.02,1.29) P=0.02 |
| **Adjusted for APACHE II score** | 1.05 (0.89,1.24) P=0.57 | 1.11 (0.98,1.26) P=0.09 | 1.04 (0.88,1.23) P=0.64 | 1.12 (0.98,1.27) P=0.10 |

**Conclusion.** A single measurement of the distal urinary tubular marker pi-GST obtained at the time of nephrology consultation might provide prognostic discrimination for predicting dialysis requirement in AKI.

**SA-PO2081**

**Evaluation of Endotoxin Activity Assay in Acute Kidney Injury and Continuous Renal Replacement Therapy** Kent Doi, Takehiro Matsubara, Eisei Noiri, Toshiro Fujita, Naoki Yahagi. *University of Tokyo.*

Blood endotoxin level is one of the most important predictive factors for the outcomes of critically ill patients in ICU. The EAA™ Endotoxin Activity Assay is the only FDA approved rapid whole blood assay for detection of human endotoxemia. This assay is based on the ability of antigen-antibody complexes to prime neutrophils for an augmented respiratory burst response. Although neutrophil activation has been observed in acute kidney injury (AKI) and patients treated by continuous renal replacement therapy (CRRT), it is unclear whether the EAA assay will be influenced by these conditions. Blood endotoxin levels of 14 AKI patients who were treated by CRRT were measured sequentially (0, 24, 48 hr) by the EAA assay. All the patients were diagnosed as AKI by the AKIN criteria (BUN 66.9 ± 25.2 mg/dl, Cre 5.1 ± 2.5 mg/dl, plasma NGAL 533.1 ± 100.3 ng/ml). There was no significant correlation between the endotoxin activity (EA) values and BUN ($R^2$ = 0.1981), serum creatinine ($R^2$ = 0.088), or plasma NGAL ($R^2$ = 0.046). Four patients had severe gram-negative rod infections that eventually caused septic shock. In 10 AKI patients without septic shock, the EA values did not show any significant changes during the three different time-points. The highest EA values of the septic shock patients were significantly higher than the non-septic shock patients (0.81 ± 0.10 vs 0.37 ± 0.05, p<0.05). Plasma NGAL of the septic shock patients was also significantly higher than the non-septic patients (847.8 ± 163.1 ng/ml vs 407.2 ± 103.2 ng/ml, p<0.05). Combination of EA value (cut-off >0.40) and plasma NGAL (cut-off >500 ng/ml) could perfectly distinguish the septic shock patients. These data indicate that the EAA assay was not influenced by AKI/CRRT and that the EAA assay and plasma NGAL can detect severe sepsis in AKI/CRRT patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2082**

**Stroke Volume Variation (SVV) Monitoring and Acute Kidney Injury (AKI) in Abdominal Aortic Aneurysm (AAA) Surgery** Paolo Lentini,[1-2] Vincenzo Catena,[1] Rudi Stramanà,[3] Valentina Pellanda,[1] Massimo De Cal,[2-4] Alexandra Chronopoulos,[4] Claudio Ronco,[4] Marco Baiocchi,[1] Diego Cognolato,[3] Roberto Dell'Aquila.[1] *[1]Nephrology-Intensive Care Unit, S. Bassiano Hospital, Bassano Del Grappa (VI), Vi, Italy; [2]University of Padua, Padua, Italy; [3]Vascular Surgery, St. Bassiano, Bassano Del Grappa (VI), Italy; [4]Nephrology, St. Bortolo, Vicenza, Italy.*

AAA surgery patients are at high risk for AKI, which may be due to hypovolemia, haemorrhage, decreased cardiac output, vascular disruption, or inflammation. Large variations in SVV can predict volume responsiveness in mechanically ventilated patients. AIM: We conducted a pilot study to assess if patients with wide variations of SVV before and after clamping of the aorta are at higher risk of AKI development than those with lesser variations. MATERIALS AND METHODS: We enrolled 8 consecutive patients undergoing elective AAA surgery with supra-renal clamping. Patients were all on volume-control mechanical ventilation (8 ml/kg) and positive end expiratory pressure of 4 cmH20. Patients with sustained arrhythmias, spontaneous ventilations, and those extubated before 12 h post-operative were excluded. SVV was measured with the FlowTrack/Vigileo (Edwards®) device every 3 minutes during the procedure and for 24 h after surgery. A detailed log of ins and outs was kept. Patients received 70ml/kg/h of cristalloids, and fluid boluses and transfusions were given if needed according to medical team preference. Data was compared with non-parametric tests. RESULTS: Out of 8 patients, 3 developed AKI, defined as RIFLE Risk category. As compared to patients without AKI, AKI patients had a significantly larger SVV after aortic clamping (13.25% vs. 24.5%, p=0.01). The increase in SVV at aortic declamping time, as compared to SSV at clamping time, was also significantly higher in AKI patients (-3.75% vs. 12.5%, p=0.04). CONCLUSION: SVV monitoring during and after suprarenal AAA surgery is a feasible non-invasive tool that can help identify patients at risk for AKI. Particularly, an increase in SVV at aortic declamping time, as compared to SSV at clamping time, may be a marker for risk of AKI development that should be further studied.

**Urine Biomarkers Predict Acute Kidney Injury in Very Low Birth Weight Infants** David J. Askenazi,[1] Stuart Goldstein,[2] Prasad Devarajan,[2] Chirag R. Parikh,[3] Ravindra L. Mehta,[4] Anupam Agarwal.[5] *[1]Pediatrics, Univeristy of Alabama, Birmingham, AL; [2]Pediatrics, Cincinatti Children's Medical Center, Cincinnati, OH; [3]Medicine, Yale, New Haven, CT; [4]Medicine, University of California, San Diego, CA; [5]Medicine, University of Alabama, Birmingham, AL.*

Objective: Acute kidney injury (AKI) is a strong predictor of mortality in premature infants. Our objective is to determine the utility of 6 potential urine biomarkers to predict AKI in very low birth weight (VLBW, birth weight between 500-1500 g) infants.

Method: 78 VLBW infants were enrolled from a regional quaternary care NICU. Urine samples were collected on postnatal days 1 through 6 and the maximum concentration for each biomarker was determined. Candidate biomarkers evaluated include neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule -1 (KIM-1), interleukin-18 (IL-18), Osteopontin (OPN), β2 Microglobulin (β2 M), and cystatin C. As data was non-normally distributed, the Mann-Whitney U test was used to determine differences between groups.

Results: Urinary concentrations of NGAL, KIM-1, IL-18, OPN were increased in infants with AKI compared to those without AKI. No difference was seen with β2 M and Cystatin C. Similar findings were seen if values were corrected for urine creatinine (data not shown).

Urine Biomarkers Predict AKI in VLBW infants

| | No AKI ( n = 60 ) | AKI (n =18 ) | p | ROC AUC |
|---|---|---|---|---|
| NGAL (ng/mL) | 349 ( 168,651) | 562 (358,847) | <0.05 | 0.65 |
| KIM-1 (pg/mL) | 313 ( 129,592) | 711 ( 307,1190) | <0.01 | 0.73 |
| IL-18 (pg/mL) | 75 (26,385) | 192 ( 87,810) | <0.05 | 0.67 |
| Osteopontin (ng/mL) | 214 (136,329) | 379 ( 231,536) | <0.05 | 0.72 |
| Cystatin C (ng/mL) | 1776 (335,4560) | 2884 ( 1373,4545) | 0.39 | 0.58 |
| β2 Microglobulin (ug/mL) | 1.6 (0.9,2.4) | 1.7 ( 1.1,3.3 ) | 0.33 | 0.59 |

Median (25%,75%) AUC for AKI

Conclusion: Urine concentration of 4/6 candidate biomarkers are elevated in VLBW infants with AKI. Single or panel biomarkers may improve our ability to detect AKI, predict outcomes, and design interventions in this population.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2084**

**Urine Biomarkers of Acute Kidney Injury (AKI) Predict Mortality in Very Low Birthweight (VLBW) Infants** David J. Askenazi,[1] Stuart Goldstein,[2] Chirag R. Parikh,[3] Prasad Devarajan,[2] Ravindra L. Mehta,[4] Anupam Agarwal.[5] *[1]Pediatrics, University of Alabama, Birmingham, AL; [2]Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Medicine, Yale, New Haven, CT; [4]Medicine, University of California, San Diego, CA; [5]Medicine, University of Alabama, Birmingham, AL.*

Background: AKI is a strong predictor of mortality in VLBW infants. Novel urine biomarkers of AKI predict mortality in other populations. We evaluate the utility of 6 biomakers to predict mortality in VLBW infants.

Method: Urine samples were collected on postnatal days 1 through 6 for 105 VLBW infants in whom 13 died at (age 26 +/- 6 days). The maximum concentration for each biomarker was compared between survivors and non-survivors.

Results: Neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule 1 (KIM-1), interleukin 18 (IL-18) and osteopontin (OPN) levels were higher in non-survivors vs. survivors, while cystatin C and B2 M were not statistically different.

| | survived (n=94) | died (n=13) | p | ROC AUC |
|---|---|---|---|---|
| NGAL (ng/mL) | 376 ( 181,569) | 555 (300,1176) | <0.05 | .68 |
| KIM-1 (pg/mL) | 315 ( 146,611) | 384 ( 252,1215) | <0.01 | .66 |
| IL-18 (pg/mL) | 93 (54,353) | 114 (40,213) | <0.05 | .50 |
| Osteopontin (ng/mL) | 229 (169,354) | 480 (280,631) | <0.05 | .78 |
| Cystatin C (ng/mL) | 1938 (570,4469) | 1884 ( 400,4588) | 0.39 | .47 |
| β2 Microglobulin (ug/mL) | 1.7 (1.1,2.5) | 1.7 ( 0.9 ,2.9 ) | 0.33 | .51 |
| GA ( wks ) | 27 +/- 3 | 25 +/- 2 | < 0.01 | |
| BW (gm) | 1000 +/- 304 | 681 +/- 237 | < 0.01 | |

Median (25-75%) , AUC for Mortality

Conclusion: Urine AKI biomarkers predict survival in VLBW infants. Single or panel biomarkers may improve our ability to detect predict outcomes, and design intervention studies in this population.

Disclosure of Financial Relationships: nothing to disclose

**Urine Biomarkers for Gentamicin-Induced Acute Kidney Injury in the NICU** Suzanne Heemskerk,[1,2] Diana Jansen,[1] Linda Koster-Kamphuis,[3] Martijn P. W. J. M. Bouw,[1] Arno F. J. van Heijst,[4] Peter Pickkers.[1] *[1]Intensive Care Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Pharmacology and Toxicology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [3]Pediatric Nephrology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [4]Neonatal Intensive Care Unit, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

*Background:* Gentamicin (GM) is an aminoglycoside frequently used in the neonatal intensive care unit (NICU) to treat infections. Despite low resistance and costs, GM is also nephrotoxic and may cause acute kidney injury (AKI). Serum creatinine appears to be an insensitive and unreliable marker in this setting.

*Objective:* To determine whether urine biomarkers are useful for early detection of gentamicin-induced AKI in neonates in the NICU.

*Subjects:* Twenty-five neonates (18M/7F, gestational age 35.4 weeks) with a bladder catheter without pre-existent kidney disease were divided in a GM group (n=13) and a reference group (n=12).

*Study design and procedures:* A prospective, clinical observational trial with non-invasive procedures. Demographics, vital signs and clinical conditions were recorded. Every two hours, during the period of bladder catheter, urine samples were collected and renal injury biomarkers glutathione S-transferase A1-1 (GSTA1-1), GSTP1-1, Kidney Injury Marker-1 (KIM-1) and neutrophil gelatinase-associated lipocalin (NGAL) were determined. Residual blood samples were used to measure serum creatinine (sCr).

*Results:* Demographics were similar between both groups expect for gender. No significant differences were found in baseline kidney function, hemodynamics, ventilation support and reason for admission.Treatment with GM resulted in higher levels of sCr compared to the reference group (80[64-87] vs 60[55-76] µmol/L;P<0.05). The average time until the highest peak was shorter for all biomarkers compared with sCr (P<0.05). Furthermore, higher levels of sCr corresponded with higher levels of KIM-1, GSTA1-1 and GSTP1-1.

*Conclusion:* Treatment with GM results in higher levels of sCr. In addition, the urinary biomarkers KIM-1, GSTA1-1 and GSTP1-1 might be useful for early detection of AKI in the NICU.

**Predicting Acute Kidney Injury Development after Cardiac Surgery in Children Using Neutrophil Gelatinase Associated Lipocalin (NGAL)** Ana Carolina Kozak, Thayza Lopes, Emmanuel A. Burdmann, Emerson Quintino Lima. *Nephrology Division, Sao Jose do Rio Preto Medical School, Sao Jose Rio Preto, Sao Paulo, Brazil.*

**Introduction:** Serum creatinine is currently the most used biomarker for diagnosis of acute kidney injury (AKI). The aim of this study was to evaluate the role of urinary NGAL excretion as an AKI biomarker after cardiac surgery in children. **Methods:** Children (<18

y) submitted to elective cardiac surgery were enrolled. AKI was defined as a reduction in baseline estimated GFR (Schwartz formula) ≥25% (pediatric RIFLE) in the first 4 days after surgery. Urinary NGAL was measured by an ELISA kit (BioPorto, Denmark) before and 2, 4, 6, 12, 24, 48, 72 and 96 hours after surgery or cardiopulmonary bypass (CPB) beginning. Pre, intra and postoperative data were evaluated by unpaired t-test, Mann Whitney and Fisher's exact tests, as appropriated. The performance of urinary NGAL as an AKI biomarker was evaluated by ROC curve. P<0.05 was considered significant. **Results:** 96 children submitted to cardiac surgery were assessed. AKI developed in 19 (20%) patients. There was no difference regarding weight, preoperative estimated GFR and previous cardiac surgery between AKI and non AKI groups. Children who developed AKI were younger (29.8 ± 43.3 months vs 52.8 ± 51.7 months in non-AKI, P=0.01). The CPB duration (111 ± 51 min vs 67 ± 49 min in non AKI; P<0.001), surgery time (243 ± 78 min vs 170 ± 71 min in non AKI; P<0.001) and anesthesia time (332 ± 93 min vs 253 ± 88 min in non AKI; P=0.001) were higher in the AKI group. The median urinary NGAL was higher in AKI patients after 2 h (43 ng/ml [ 10-100] vs 4 ng/ml [0.9-22]; P=0.001), 4 h (27 ng/ml [3-300] vs 3.7 ng/ml [1.6-15.8]; P=0.005) and 6 h (11.7 ng/ml [2.4-33] vs 2.5 ng/ml [0.9-10.8]; P=0.03) following CPB or surgery beginning and preceded the rise in serum creatinine for at least 12h. The ROC curve areas for urinary NGAL 2 h, 4 h and 6 h after CPB were 0.74 (95% CI 0.62-0.87; P=0.008), 0.72 (95% CI 0.59-0.85; P=0.002) and 0.71 (95% CI 0.58-0.84; P=0.004), respectively. **Conclusions:** Urinary NGAL was an efficient and early biomarker for diagnosis of AKI development after heart surgery in children.

### SA-PO2087

**Renal Outcomes Following Acute Kidney Injury in the Pediatric Intensive Care Unit: A Prospective Cohort Study** Cherry Mammen,[1] Douglas G. Matsell,[1] Daniel S. Levine,[3] Helen Ruth Nadel,[3] Jean Paul Collet.[2] *[1]Division of Nephrology, UBC/BC Children's Hospital, Vancouver, BC, Canada; [2]Dept. of Pediatrics, UBC/BC Children's Hospital, Vancouver, BC, Canada; [3]Dept. of Radiology, UBC/BC Children's Hospital, Vancouver, BC, Canada.*

**Background**: The development of standardized AKI definitions has allowed for a better understanding of AKI epidemiology, but the long term renal outcomes of AKI in the pediatric critical-care setting have not been well-established. **Objectives**: 1) To determine the incidence of chronic kidney disease (CKD) in children who sustained AKI at a tertiary care PICU from 2006-2008 and 2) To explore the relationship between AKI severity and the probability of developing CKD 1-3 years following AKI. **Methods:** All AKI patients admitted to BC Children's Hospital's PICU from 2006-2008 were identified by their maximal AKI stage: 1 (mild), 2 (moderate) or 3 (severe), according to the Acute Kidney Injury Network (AKIN) definition. Patients were contacted for a renal assessment at either 1, 2, or 3 years following their AKI. The outcome of CKD was defined as the presence of either proteinuria, microalbuminuria, hypertension (HTN), or abnormal GFR through estimated or nuclear (DTPA) methods. The proportion of CKD patients from each AKI stage was compared by chi-square test. Multivariate logistic regression was used to model the association between several ICU admission characteristics (age, weight, diagnosis, PRISM score, use of acute dialysis, nephrotoxin use, lowest Hb and paO2) and the likelihood of developing CKD. **Results:** 31/108 (28.7%) patients revealed at least one sign of CKD (18: microalbuminuria or proteinuria, 16: abnormal GFR, 2: HTN). Incidence rate of CKD was 12 cases/100 person-years of follow-up. No significant differences were seen in the proportion of patients with CKD between the 3 AKI stages (p=0.332). None of the selected ICU admission factors predicted CKD. **Conclusions:** The severity of AKI, as defined by the AKIN classification system, does not predict long term renal injury in tertiary-care PICU patients. However, the high incidence of CKD in this population signifies that all critically-ill children should be followed-up regularly after an episode of AKI.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2088

**Degree and Outcome of AKI in Children and Neonates in a Single Pediatric Nephrology Center** Isabel Roberti, Shefali Vyas. *Pediatric Nephrology and Transplantation, Saint Barnabas Medical Center, Livingston, NJ.*

Data is sparse regarding the **degree and outcome of AKI in pediatrics** despite an increase in incidence of AKI in hospitalized children.

We reviewed consults between January 2008 and March 2010 with the diagnosis of AKI - 125 children (27 s/p kidney txp, 7 with known CKD and 91 with new onset AKI). Of these 91, 4 were lost to f/u. Demographic data, etiology of AKI, co-morbidities, clinical findings, need for dialysis and outcome were analyzed by location (ICU, PICU, Floor) for 87 children.

Seven of the 87 children had 2 or more episodes of AKI. Demographics: M/F = 47/40; Ethnicity: C/AA/H/O = 26/40/17/4; Age: 1 day - 19yrs (median NICU = 10d, PICU and Floor = 11yrs).

**Characteristics of AKI in 87 Children**

| Variable | NICU N= 34 | PICU N=17 | Floor N= 36 |
|---|---|---|---|
| AKI grade: R/I/F/L# | 0/3/27/4 * | 0/3/9/5* | 4/17/14/1 |
| Etiology: PR/R/PostR## | 18/11/5 | 7/9/1 | 24/9/3 |
| HTN | 2 (6%) | 7(41%)* | 5(14%) |
| Dialysis | 3(10%)* | 6(35%)* | 1(0.02%) |
| Outcome: D/R/CKD/ERSD### | 13*/17/4/0 | 2/10/3/2 | 1/31*/4/0 |

#=pRIFLE; ##PR=pre-renal, R=Renal, PostR= Post renal; ### D=death, R=complete recovery; *p<0.05

**Pre-Renal AKI (N=31):** NSAIDs induced AKI was seen in 1/7 (14%)(PICU) and 5/24 (21%)(Floor).

**Renal AKI (N=18)(Floor and PICU):** AGN (variable diagnosis) was the most common etiology -Floor (5/9 = 55%), PICU (4/9 = 44%) - Postinfectious GN - 2/18 (11%), HUS 4/18(22%).

As expected, **AKI grade was significantly higher in the PICU and NICU** compared to the Floor. However, 5/15 (29%) children with AKI on the Floor progressed to CKD or ESRD. Overall 13/87 (15%) had CKD or ESRD on f/u. **The grade of AKI did not correlate with outcome**. Among **children who required dialysis** (N=7) (PICU+Floor), 4 **(57%) developed CKD or ESRD - p<0.01**.

**AKI in the NICU cohort had multiple co-morbidities and significantly higher mortality** (38%); 6 had severe IUGR, 6 were twins or triplets, 19 were extreme premies with Bwt<1000g.

We conclude that **the grade of AKI presentation is high** in all the units and the prognosis is particularly poor in neonates due to multiple co-morbidities. The need of long-term f/u of AKI survivors is imperative in view of the high rate of CKD and ESRD.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2089

**Acute Kidney Injury in Congenital Diaphragmatic Hernia Requiring Extracorporeal Life Support: An Insidious Problem** David T. Selewski, Samir K. Gadepalli, Robert Drongowski, David B. Kershaw, George Mychaliska. *Mott Children's Hospital, University of Michigan, Ann Arbor, MI.*

**Purpose:** Patients with congenital diaphragmatic hernia (CDH) requiring extracorporeal life support (ECLS) are at increased risk for acute kidney injury (AKI.) We hypothesized that AKI would be associated with increased mortality. We also hypotesized that vasopressor requirement and nephrotoxic medication exposure would be associated with AKI.

**Methods:** This is a single center retrospective chart review in all patients with CDH requiring ECLS from 1999-2009 (n=68). Patient variables that could potentiate renal failure were collected. We used a rise in creatinine from baseline by the RIFLE (risk: 1.5x, injury: 2x, failure: 3x, loss, and end-stage renal disease) criteria to define AKI. Statistical analysis was performed via SPSS using student's t-test and Chi-square analysis with p < 0.05 considered significant.

**Results:** Survival to hospital discharge was 37/68 (54.4%). AKI was identified in 48/68 (71%) patients with 15 (22% of all patients) qualifying as injury and 33 (49% of all patients) qualifying as failure by the RIFLE criteria. Patients that qualified as failure by the RIFLE criteria had a significant decrease in survival (27.3% with failure vs. 80% without failure, $p$ =0.001.) This represents an absolute increase in mortality of 52.7% when patients qualified as failure. Patients who qualified as failure also had increased length of ECLS (314 ±145 vs. 197 ±115 hours, $p$=0.001) and decreased ventilator free days in the first 60 days (3.83±8.5 days vs. 25.21±17.8, $p$=0.001). There was no significant difference in survival when patients qualified as risk or injury. AKI was not associated with vasopressor requirements, diuretic exposure or antibiotic days.

**Conclusions:** This is the first report using a systematic definition of AKI in patients with CDH on ECLS. There is a high incidence of AKI in these patients and when it progresses to failure is associated with higher mortality, increased ECLS duration and increased ventilator days. This highlights the importance of recognizing AKI in CDH patients requiring ECLS and the potential benefit of preventing progression of AKI or early intervention.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2090

**Weight-Based Determination of CRRT Fluid Overload Status Predicts Pediatric ICU Mortality** David T. Selewski, Theresa Mottes, Rebecca M. Lombel, Mallika Kommareddi, Neal B. Blatt, Yong Y. Han, Michael Heung. *University of Michigan, Ann Arbor, MI.*

**Purpose:** In pediatric patients fluid overload (FO) at continuous renal replacement therapy (CRRT) initiation is an independent risk factor for mortality. Previous studies have calculated FO based on daily fluid balance during ICU admission, which is labor intensive and error-prone. We hypothesized that a simpler weight-based assessment of FO at CRRT initiation would be effective in predicting mortality.

**Methods:** This is a retrospective single-center review of all PICU patients requiring CRRT from 07/2006-02/2010 (n=119). Percent FO was determined by a published standard [Method 1: (fluid in-fluid out from ICU admission to CRRT start)/ICU admission weight] and by a weight-based method [Method 2: (CRRT initiation weight-ICU admission weight)/ICU admission weight]. We calculated %FO at CRRT discontinuation: (CRRT discontinuation weight-ICU admission weight)/ICU admission weight. Median [IQR] %FO was compared between survivors and non-survivors using Mann-Whitney U-test. Mortality odds ratios (OR) were determined by logistic regression modeling adjusted for age and PRISM score.

**Results:** ICU mortality for this cohort was 58%. Percent FO at CRRT initiation was significantly different between survivors and non-survivors (Method 1: 8.0% [2.0-14.0] vs 23.0% [12.0-37.0], $p$<0.001; Method 2: 3.0% [0-15.0] vs 16.0% [3.0-38.0], $p$=0.001). FO scores by each method were significantly correlated ($r$=0.77, $p$<0.001). The adjusted mortality OR for a 1% increase in FO was 1.05 (95%CI 1.01-1.09) by Method 1 and 1.04 (95%CI 1.01-1.07) by Method 2. At CRRT discontinuation survivors had lower %FO than non-survivors (2.7% [-4.7-9.7] vs 11.1% [-1.0-23.5], $p$=0.001).

**Conclusion:** Our results confirm that FO is associated with greater mortality in PICU patients requiring CRRT. We have extended the literature by demonstrating that weight-based assessments of both initial and discontinuation %FO have prognostic significance. We propose weight-based FO determination as a simple and effective way to routinely assess FO in the ICU setting.

**SA-PO2091**

**Impact of AKI on Development and Progression of CKD** Neville R. Dossabhoy,[1,2] Cherinet Adgeh,[1,2] Mukesh Sharma,[1,2] Sunanda J. Ram.[2] *[1]Medicine, VA Medical Center, Shreveport, LA; [2]Medicine, LSUHSC, Shreveport, LA.*

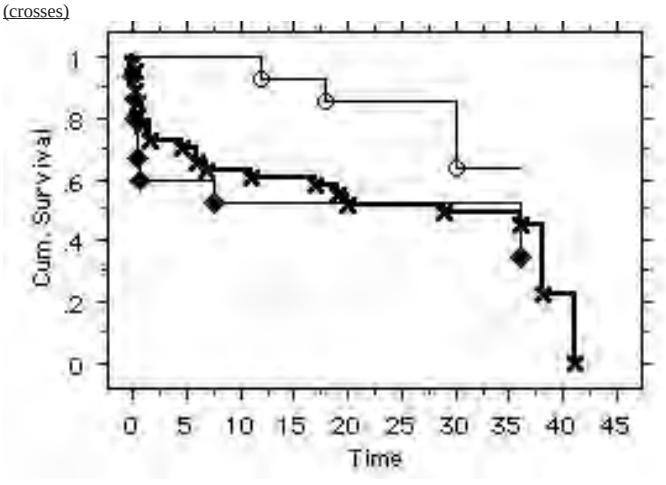
Background: Emerging evidence indicates that the incidences of Acute Kidney Injury (AKI) and CKD are rising. However, much of the growth of End Stage Renal Disease (ESRD) seems independent of the growth in CKD. Relatively little is currently known regarding the potential for evolution from AKI to CKD, or the impact of AKI on CKD progression.

Purpose: To study the impact of AKI episodes on development of CKD and on progression of preexisting CKD.

Methods: We conducted a retrospective analysis of clinical data spanning a 3 year period from 2006-09. Patients with CKD (stages 3 and 4) and AKI were identified using ICD codes. Patient demographics and comorbid conditions were noted. Lab values were recorded including baseline creatinine and GFR, and serial GFR's after AKI. Primary end points of this study were rate of progression of CKD after AKI insult; mortality; and incidence of ESRD in patient with AKI, CKD, and AKI on CKD. Kaplan-Meier survival curves were plotted for outcomes of ESRD and death.

Results: 80 patients with complete data were analyzed. Those with >1 episode of AKI were excluded. Mean age 67±1 years; all males; follow-up upto 38 months. 16 had AKI only, 16 CKD only, and 48 had AKI on CKD. AKI did not significantly impact on time to ESRD (P=NS). There was a trend towards AKI increasing patient mortality, regardless of presence of baseline CKD.

Survival curves for CKD only (open circles), AKI only (diamonds) and AKI on CKD (crosses)



Conclusion: AKI may worsen risk of death but did not significantly affect attainment of ESRD compared to patients with preexisting CKD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2092**

**Long-Term Clinical Outcomes in Patients with Chronic Kidney Disease Complicated by Dialysis-Requiring Acute Kidney Injury** Po-Hung Lee, Yung-Ming Chen, Tun-Jun Tsai, Kwan-Dun Wu. *Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.*

**Background**: Information is limited regarding the clinical outcome in patients with preexisting chronic kidney disease (CKD) who developed dialysis-requiring acute kidney injury (AKI). This study investigated the long-term outcome of these patients, with emphasize on patient overall survival and end-stage renal disease (ESRD).

**Patients and Methods**: Between January and June in 2002, we consecutively recruited patients with CKD stage 3 or worse who received emergent hemodialysis via a temporary catheter due to fluid overload or uremic emergency. These patients were monitored over a period of 5 years for all-cause mortality and ESRD till the end of 2007. All parameters and biochemical data were obtained by reviewing medical charts by a nephrologist. Factors predicting clinical outcomes were analyzed with appropriate statistics.

**Results**: Among the 131 patients investigated, 21 (16%) were successfully withdrawn from acute hemodialysis for at least 3 months after an average of 8 sessions of dialysis therapy (ranging from 1 to 44, group A). In contrast, 110 (84%) patients were unable to be withdrawn from acute hemodialysis (group B). Multivariate logistic regression revealed that larger kidney size, lower predialysis Cr levels, and not having diabetes were predictors for withdrawl from dialysis. During the subsequent 5 years, all patients in group B became ESRD requiring chronic renal replacement therapy (RRT), whereas only 8/21 (38%) patients in group A developed ESRD. Being diabetes and hyperkalemia at basal were predictors for ESRD in the latter group. Further analysis with Cox's proportional hazards model showed that older age, prerenal azotemia, and propensity score for assigning to dialysis withdrawl were independent risk factors for death from any cause. There was no statistically significant difference in all-cause mortality between groups A and B patients.

**Conclusion**: 10% (13/131) of our CKD patients with dialysis-requiring AKI could be removed from acute RRT and remain dialysis-free after 5 years. These patients were mainly nondiabetics, having larger kidney size, and displaying lower Cr and potassium levels at baseline.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2093**

**Is the Severity of Acute Kidney Injury (AKI) Associated with Long-Term Mortality?** Mariana B. Pereira,[1] Dirce M. T. Zanetta,[2] Regina C. R. M. Abdulkader.[1] *[1]Discipline of Nephrology, School of Medicine. University of S. Paulo, Brazil; [2]School of Public Health University of S. Paulo, Brazil.*

AKI increases long-term mortality. However, the causes and factors associated with long-term mortality have not been studied. We studied 530 patients 1 and 2 years after AKI, defined by AKIN criteria (creatinine). Exclusion criteria: age<18 years, presumed etiology other than acute tubular necrosis, baseline creatinine > 3.5 mg/dL, renal transplant and unknown outcome. Analyzed variables: age; gender; type of admission (medical or surgical); patient location (ward, emergency service or ICU); AKI etiology (ischemia, nephrotoxicity, sepsis); baseline and discharge GFR (evaluated by MDRD equation); AKIN classification(1, 2, 3); need for dialysis or mechanical ventilation; comorbidities (hypertension, diabetes, heart failure, cancer, chronic liver or pulmonary diseases). Causes of death were identified by death certificate and classified by ICD-10. Survivors and nonsurvivors were compared 1 and 2 years after hospital discharge. Multivariable logistic regression was used to analyze the independent variables associated with mortality, by backward stepwise method. Goodness of fit was evaluated by the Hosmer-Lemeshow test. One- and two-year mortality were respectively: 27% and 37%. Adjusted odds ratios (OR) and 95% confidence intervals (CI) are presented in the table.

| | OR (CI) | P |
|---|---|---|
| At 1 year | | |
| Clinical admission | 2.78 (1.68-4.60) | <0.01 |
| Chronic liver disease | 2.65 (1.30-5.42) | <0.01 |
| Heart failure | 1.69 (1.03-2.77) | 0.03 |
| Cancer | 3.44 (2.02-5.85) | <0.01 |
| At 2 years | | |
| Age >65 years | 1.54 (1.03-2.32) | 0.03 |
| Clinical admission | 2.23 (1.38-3.61) | <0.01 |
| Heart failure | 2.37(1.47-3.81) | <0.01 |
| Chronic liver disease | 3.05 (1.48-6.29) | <0.01 |
| Cancer | 3.40 (1.99-5.82) | <0.01 |

Causes of death were similar (P<0.05) at 1 and 2 years after discharge, respectively: diseases of circulatory (26 and 39%), pulmonary (15 and 17%), and digestive systems (12 and 5%), or malignant neoplasms (22 and 12%). In conclusion, long-term mortality after AKI is associated with previous patient´s condition, not with the AKI severity.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2094**

**Chronic Renal Replacement Therapy (C-RRT) after Acute Renal Failure (ARF) Treated with Acute Dialytic Support in a Big Population** Maria Teresa Tenorio,[1] Fernando Liano.[2] *[1]Nephrology, Hospital Universitario Ramon y Cajal; [2]On Behalf of the Madrid Acute Renal Failure Study Group (GEFRAM).*

The new ARF classification systems, the introduction of the use of AKI and the analysis of huge administrative data bases suggest that a great number of AKI patients could be on chronic dialysis in the future.

The aim of this work is to test if this hypothesis is true in our community.

Methods: Observational, multicenter, retrospective study analyzing how many of the patients, who started chronic hemodialysis (C-HD) or peritoneal dialysis (CPD) in the Madrid region (6.328.106 inhabitants) along 2009, had an AKI episode that required acute RRT, either in 2008 or 2009. Only AKI patients having a free-dialysis period after hospital discharge or those who were on dialysis for more than 3 months were included. Twenty hospitals and 15 satellite units (SU) with c-RRT facilities covered these treatments in Madrid. The population served by each hospital was provided by local authorities. A simple questionnaire was mailed. Minimal disagreements were later resolved.

Results: Adequate information, corresponding to 91% of the Madrid population, was received from 19 hospitals and all the SU. On 2009 December 31st, 2040 patients were on CHD (339.9 pmp/y) and 341 on CPD (56.8 pmp/y). Along 2009, 790 patients started c-RRT (incidence:131 pmp/y) due to: diabetes, 24.3; glomerulonephritis (GN), 17.4; vascular dis, 17.1; interstitial dis, 8.8; PKD, 8.1; other congenital 1.1; others 9.6 and unknown 13.5 % respectively. Among the incident patients, 54 (7%) had needed acute RRT for an ARF episode in 2008 or 2009. This figure, representing an incidence of chronic RRT due to severe ARF of 9 cases pmp/y, has the following etiology: 13 acute tubular necrosis, 10 GN, 8 vasculitis, 7 other causes and unknown origin in 16. Of these patients,53 were placed on C-HD.

Conclusions: The contribution of the ARF needing dialytic treatment during the acute episode over the total incidence of c-RRT in Madrid is important, but that of the paradigmatic form of the syndrome, ATN is small (incidence 2 pmp/y). These data should be borne in mind when the new denomination, AKI, is used as its utilization is not uniform.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2095**

**Survival and Quality of Life in Patients with Acute Kidney Injury (AKI)** Denise H. M. P. Diniz,[1, 3] Marcelo Andery Naves,[1, 3] Nestor Schor,[1] Sergio L. Blay.[2] *[1]Division of Nephrology, Department of Internal Medicine, Federal University of São Paulo, São Paulo, SP, Brazil; [2]Departament of Psychiatric, Federal University of São Paulo, São Paulo, SP, Brazil; [3]Division of Stress and Quality of Life, Federal University of São Paulo, São Paulo, SP, Brazil.*

Background: Survival and Quality of life (QoL) has not been a priority goal for patients with AKI. Aim: To evaluate survival rate and QoL domains in patients with AKI in two public hospitals in Sao Paulo, Brazil. Methods: Study design: Case-control study. Setting: Hospital São Paulo-UNIFESP and Hospital dos Servidores do Estado –HSPE in São Paulo,Brazil. Study participants: Cases and controls were selected among patients admitted at ICU during 2008 and 2009. Patients were randomly selected after, inclusion and exclusion criteria were verified at an initial interview. Cases were patients at ICU with a confirmed diagnosis of AKI, with no chronic comorbities, that needed renal therapeutic support. The control group consisted of patients at ICU with acute diseases. Out of 579 patients initially identified, 372 (156 cases and 216 controls) survived up to the first application of SF-36, but 284 patients (142 cases and 142 controls) were matched according to age and gender. Main outcome measures: QoL was assessed through a Portuguese version of the SF-36 Health Survey. Results: Significant differences in mortality rate were observed between cases and controls. Out of 311 cases total number of identified cases), 155 died ( 49.84%) and 52 controls out of 268 (total of controls) died (19.40%). There was a significant correlation between AKI and death rate. Beside, there was also significant correlation between dialysis and death rate, in both hospitals. However, in the UNIFESP there was also association between death rate and health insurance (social security and private security). Other significant differences were observed according to QoL domains, like general health condition( 0.007), vitality ( 0.004), mental health (0.016).. Conclusion: Our data demonstrated that mortality rates are higher and QoL domains are significantly impaired among cases when compared to controls.

**AKI Accelerates Progression of CKD: Prospective Cohort Study** Ha Na Yang, Hye Won Kim, Eunjung Cho, Inhye Cha, Won-Yong Cho, Hyoung-Kyu Kim, Sang-Kyung Jo. *Department of Internal Medicine, Korea University Anam Hospital, Seoul, Korea.*

Although recent studies showed the important role played by acute kidney injury(AKI) in the progression of chronic kidney disease(CKD), lack of prospective controlled studies makes it difficult to reach a meaningful conclusion. The purposes of this study was to examine whether the presence of AKI accelerates progression of CKD and also to examine whether severity of AKI or new biomarkers could be served as useful predictor of CKD progression. We constructed a cohort of CKD patients who were hospitalized under diagnosis of AKI on CKD(n=93). We classified severity of AKI by RIFLE criteria and measured initial serum, urine NGAL and urine KIM-1. We also constructed an age-sex matched cohort for control of CKD patients without AKI episodes(n=89). We followed-up their clinical course every three months, and observed change of eGFR for primary outcome. The secondary outcome was defined as doubling of serum creatinine, initiation of maintenance renal replacement therapy or all-cause mortality. Kaplan-Meire curve was used to obtain probability to reach to the outcomes and we also assessed the prognostic value of RIFLE criteria and biomarkers of AKI by logistic regression. Mean age in AKI on CKD cohort were 65.14 ± 14.95 yrs(male:44.1%). The prevalence of diabetes and hypertension was 56.5 and 73.9% and the causes of AKI were ischemic 39.8%, septic 35.2% and toxic 13.6%. Severity of AKI were risk(33%), injury(26.1%), and failure(40.9%). Mean follow-up period were 116.24 ± 98.27days. Change of eGFR 6 months later were -3.54 in AKI on CKD cohort, and -0.17 mL/min/1.73 $m^2$ in stable CKD cohort ($p<0.05$). Kaplan-Meier curve showed significantly higher probability to reach to secondary outcome in AKI on CKD cohort compared to stable CKD cohort(p=0.03). Although failure in RIFLE criteria also tended to show higher probability of progression (p=0.07), initial NGAL or KIM-1 could not predict the progression. In conclusion, this prospective study shows that episodes of AKI definitely accelerate the progression of CKD and might also suggest the usefulness of RIFLE criteria in prediction of CKD progression.

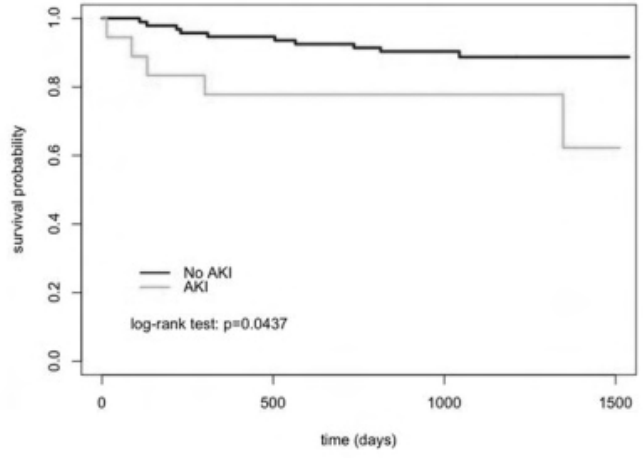
**SA-PO2097**

**The Long Term Impact on Survival of Acute Kidney Injury after Liver Transplantation** Elena Mancini,[1] Antonio Bellasi,[1] Alessia Mordenti,[2] Sandra Giannone,[2] Andrea Zanoni,[2] Antonio Santoro.[1] *[1]Nephrology Unit, Policlinico S.Orsola-Malpighi, Bologna, Italy; [2]Intensive Care Unit, Policlinico S.Orsola-Malpighi, Bologna, Italy.*

Data on long-term impact on survival of Acute Kidney Injury (AKI) after surgery are still scanty. In particular, only a few papers reported on a follow up longer than 1 year. Thus, we tested the association between AKI and the 4-year all-cause mortality in a cohort of patients undergoing Orthotopic Liver Transplantation (OLT), a procedure frequently complicated by AKI.

Demographic and clinical variables of all consecutive patients undergoing OLT between January 2006 and December 2007 at our institution were collected at study entry and during the first week after surgery. AKI was defined according to the AKIN criteria as a 50% o greater increase of serum creatinine during the first week after surgery. Patients were followed until study end or death.

We recruited 144 middle-age [53.4 (11.7)] male (74.7%) and female (25.3%) patients. The most common cause of liver failure was a hepatotropic viral infection (75.7%). The median MELD score was 21 [Interquartile Range (IQ): 12-27]. The median follow-up time was 37.2 [IQ: 28.7-44.4]. The overall incidence of AKI within 7 days from surgery was 16.2%. As illustrated in figure 1, patients who developed AKI were at increased risk of death (log-rank test $p<0.0437$).



Even after adjustment for age, sex, liver failure etiology and graft function, patients with AKI had a significant 268% increase in the risk of all-cause mortality (Hazard ratio 3.68; 95% confidence interval 1.15-11.71; p=0.02).

Early AKI complicating OLT has a strong impact on patient long-term survival. Concerted efforts should be undertaken to limit the occurrence of such devastating complication in the peri-operative period after OLT.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2098**

**Long Term Effect on Renal Function of Chronic Kidney Disease Patients by Radiocontrast Media** Il Young Kim, Soo Bong Lee, Jungmin Son, Harin Rhee, Jung Sub Kim, Sang Heon Song, Eun Young Seong, Ihm Soo Kwak. *Internal Medicine, Pusan National University School of Medicine, Busan, Republic of Korea.*

**Background**: The risk of acute kidney injury(AKI) by intravascular radiocontrast in patients with chronic kidney disease(CKD) has been well known, but long term effect on renal function in patients with CKD has been less evaluated.

**Methods**: We retrospectively reviewed medical records of 176 CKD patients with estimated glomerular filtration rates (eGFR) <60 ml/min/1.73$m^2$ who underwent computed tomography (CT) with intravenous radiocontrast at Pusan National University Hospital. Patients were divided into 3 groups(CKD stage 3, N=104; CKD stage 4, N=52; Peritoneal dialysis(PD), N=20). We used reciprocal of serum creatinine(1/sCr) as a parameter of renal function. Baseline 1/sCr and follow-up 1/sCr after CT was tracked in each patients. Follow-up 1/sCr values were assessed in monthly based manner(up to 8 months). Statistical analysis was performed by paired t-test using values before and after CT.

**Results**: In baseline characteristics, there are no significant differences among the 3 groups(CKD stage 3, stage4, PD) in variables of sex(Male(%); 47.2% vs 59.6% vs 60%, p=0.256), diabetes(40.3% vs 53.8% vs 55%, p=0.094), and age(68.29±10.21 vs 67.15±11.44 vs 65.00±9.62, p=0.448). There are no significant differences between values of 1/sCr before and after CT in each of 3 groups. (CKD stage 3: 0.6847 ± 0.1287 vs 0.6832 ± 0.1596, p=0.897, CKD stage 4: 0.4475 ± 0.1225 vs 0.4389 ± 0.0732, p= 0.474, Peritoneal dialysis: 0.1133 ± 0.0451 vs 0.1102 ± 0.0348, p=0.171). In each group, data analysis according to the presence of diabetes mellitus (DM) did not show significant differences of 1/sCr before and after CT

**Conclusion**: Overall, these results illustrate that intravenous contrast using in CT scan has no significant long term effect on renal function in CKD patients irrespective of DM. Large prospective study could give more solid evidence.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2099**

**Post-Operative Acute Kidney Injury in Patients with Renal Cell Carcinoma Is a Potent Risk Factor for New-Onset Chronic Kidney Disease after Radical Nephrectomy** Ajin Cho, Junseok Jeon, Hye Ryoun Jang, Wooseong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh, Jung Eun Lee. *Internal Medicine, Samsung Medical Centre, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Radical nephrectomy is a significant risk factor for chronic kidney disease (CKD). The aim of this study was to determine the incidence of AKI and whether post-operative AKI is associated with new-onset CKD after radical nephrectomy for renal cell cancer (RCC).

We conducted a retrospective study of 519 adult patients (>40 years old) with normal renal function who underwent unilateral radical nephrectomy for a solitary renal cortical tumor and were pathologically diagnosed with RCC between January 2000 and February 2007. Postoperative AKI was classed using risk, injury, failure, loss, and end-stage kidney disease (RIFLE) criteria. To evaluate the renal outcome of post-operative AKI, serum creatinine levels at 3 months, 12 ±3 months, and 36 ±3 months after the nephrectomy were recorded for all patients. CKD was defined as a decrease in estimated glomerular filtration rate (GFR) to less than 60 mL/min per 1.73 $m^2$. One hundred and seventy-five (33.7%) patients experienced post-operative AKI. Most of them (94%) fell into the AKI risk category. Older age [odds ratio (OR) 1.02, 95% confidence interval (C.I.) 1.00–1.05], male gender (OR 3.13, 95% C.I. 1.91–5.12), high body mass index (OR 1.08, 95% C.I. 1.01–1.15), small RCC size (OR 0.87, 95% C.I. 0.81–0.93), and high preoperative GFR (OR 1.04, 95% C.I. 1.03–1.06) were independent risk factors for postoperative AKI. CKD was more prevalent in the AKI group than in patients without AKI 3 years after surgery (50% vs. 32%, respectively; *P*=0.003). Patients who experienced postoperative AKI had a 4.24-fold higher risk of new-onset CKD after multiple adjustments were made to the data (95% C.I. 2.28–7.89, *P*<0.001). Postoperative AKI was a potent risk factor for new-onset CKD after radical nephrectomy in patients with RCC. Prevention of postoperative AKI is essential for reducing the incidence of CKD after nephrectomy.

## SA-PO2100

**Incidence, Etiology, and Outcome of Acute Renal Failure in Patients with Influenza A during 2009-2010 Season** Wiroon Sangsiraprapha,[1] Vikyath Prakash,[1] George M. Dolson.[1,2] *[1]Internal Medicine, Baylor College of Medicine, Houston, TX; [2]Nephrology, Houston Veteran Affairs Medical Center, Houston, TX.*

Influenza A uncommonly causes acute kidney injury (AKI). We described a patient with influenza A and AKI due to rhabdomyolysis (index case, Clin Micro Infect 16, 330, 2010), then retrospectively reviewed influenza A cases at 2 urban hospitals to determine the incidence, etiology, and outcome of AKI.

Positive influenza A was identified in 87 patients. Thirteen (14.3%) developed AKI (creatinine 0.9±0.1 mg/dL, increased to 4.9±1.0, p<0.02, mean±SE). AKI patients were older (50.2±3.7 years vs 32.4±2.1, p<0.001), had shortness of breath (92.3±7.7% vs 30.9±5.5 , p< 0.001), and pneumonia (76.9±12.1% vs 9.4±3.4, p< 0.001). HIV infection increased risk of AKI (30.7±13.3% vs 4.1±2.3, p<0.05). AKI patients more likely received antiviral medications (92.3±7.7% vs 52.8±5.9, P, <0.001). AKI increased risk of death (46.114.4% vs 4.12.3, p<0.01). Diabetes, obesity, coronary disease, chronic lung disease, malignancy, or immunosuppressiant did not increase risk of AKI.

Etiology and outcome of AKI varied among the 13 patients. Eight (61.5%) had acute tubular necrosis (ATN). Seven ATN patients had shock and ARDS with SOFA scores greater than 13. Rhabdomyolysis was present in 3 ATN patients. Six ATN patients died (46%). Five patients (38% of AKI, all with ATN) required renal replacement therapy (RRT). Among patients who received RRT, 3 died, 1 continued RRT, and 1 recovered renal function. AKI in 5 patients was prerenal (38.5%). All patients with prerenal AKI recovered.

In summary; 15% patients with influenza A developed AKI. These patients were older, had severe respiratory symptoms, and had a higher mortality than patients without AKI. Antiviral medications did not appear to decrease risk of AKI. Underlying HIV increased probability of AKI. ATN was the most common etiology of AKI associated with influenza A. Rhabdomyolysis occurred in 23% of the cases of AKI.

In conclusion, AKI developing during influenza A infection predicts a worse outcome with increased risk of death. Etiology of AKI appears multifactorial and associated with pulmonary and cardiovascular failure.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2101

**Acute Kidney Injury (AKI) at the Time of Nephrology Consultation (NC) in H1N1-Infected Patients** Márcia Fernanda Arantes Oliveira,[1] Regina C. R. M. Abdulkader,[1] Yeh Li Ho,[2] Sigrid S. Santos,[2] Renato Antunes Caires,[1] Lucia Andrade.[1] *[1]Nephrology Department, University of São Paulo School of Medicine; [2]Infectious Diseases Department, University of São Paulo School of Medicine, São Paulo, SP, Brazil.*

Early NC has been associated with a better prognosis in AKI. The characteristics of AKI that lead the intensivist to request a NC have not been studied. The H1N1 epidemic provided this opportunity. From July to August, 52 adult patients with H1N1 infection were treated in the intensive care unit (ICU). AKI was identified in 25 H1N1-infected patients. We defined AKI using the RIFLE criteria and based on an increase in serum creatinine ($S_{creat}$) level from baseline to 72 hours after ICU admission. We compared the patients to whom a NC was requested (NC+, n=16) with those who were never followed by the nephrologist (NC-, n=9). Continuous variables were compared by t-test or Mann-Whitney test, and presented as mean±SD or median (interquartile range). Categorical variables were compared by Fisher's exact test or qui-square test. NC+ patients were older (45 ±15 and 35±16 years, p=0.04) and 56% needed dialysis. NC+ patients had a trend to higher mortality (50% and 11%, P=0.08). Although the frequency of baseline GFR<75 mL/min/1.73$m^2$ was similar in both groups: 33% and 23%, NC+ patients had higher values of peak $S_{creat}$ up to 72 hs after ICU admission [2.89 (1.75-4.39) and 1.65 (1.57-2.84), p<0.01]. Other comorbidities had similar distribution in both groups.

| | NC+ | NC- |
|---|---|---|
| Mechanical ventilation (yes/no) | 13/3 | 6/3[a] |
| Vasopressor support (yes/no) | 10/6 | 9/0[b] |
| APACHE II | 18±6 | 15±3 |
| pH | 7.23±0.14 | 7.35±0.06[c] |
| Bicarbonate(mEq/L) | 20.4±6.6 | 21.7±4.2 |
| Creatine kinase (U/L) | 305 (139-788) | 160 (72-349) |
| LDH (U/L) | 959 (511-1951) | 1042 (559-2101) |
| C-reactive protein (mg/dL) | 177 (111-316) | 113 (90-156) |
| Lactate (mg/dL) | 25 (19-39) | 21 (14-34) |
| Bilirubin (mg/dL) | 0.8 (0.4-1.0) | 0.3 (0.2-0.7)[c] |

[a] p=0.02 vs. NC+; [b] p=0.05 vs. NC+; [c] p=0.04 vs. NC+

AKI was identified by 72 hours after ICU admission in 25 patients. However, only 64% of those were treated by a nephrologist. Those patients had higher baseline creat levels and were more severely ill.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2102

**Incidence and Clinical Characteristics of Acute Hepatitis A Complicated with Acute Renal Failure** So Yeon Choi,[2] Dong Hyun Sinn,[4] Eun Hee Jang,[3] Hyun-Jung Kim.[1] *[1]Medicine, Gyeongsang National University, Jin-Ju, Republic of Korea; [2]Medicine, Seoul Adventist Hospital, Seoul, Republic of Korea; [3]Medicine, Cheju National University, Cheju, Republic of Korea; [4]Medicine, Armed Forces Capital Hospital, Sung nam, Republic of Korea.*

Background/Aims: Acute renal failure (ARF) was regarded to be a rare complication of acute hepatitis A. However along with increase in the incidence of acute hepatitis A in Korea, more cases of ARF among acute hepatitis A patients are encountered nowadays. We aim to see the recent aspects of incidence and clinical characteristics of ARF in acute hepatitis A patients.

Methods: In overall, 363 patients (age; 27.6 ± 6.5, male; 263 (73%)) who had been diagnosed as acute hepatitis A at two local hospitals located in Korea (Seoul Adventist Hospital and Armed Forces Capital Hospital) during January 2002 to December 2009 were enrolled. Diagnosis of acute hepatitis A was made by confirmation of anti HAV-IgM antibody and corresponding symptoms and sign. ARF was defined by serum creatinine level above 1.5 mg/dL.

Results: ARF was noticed in the 14 of 363 (3.9%) patients. Five out of 14 patients (36%) with ARF required dialysis therapy, and all of the 14 patients with ARF recovered from ARF. Patients with ARF tend to be older (30.7 ± 6.7 vs. 27.5 ± 6.5, p = 0.074), and showed more prolonged prothrombin time (59.8% ± 28.5 vs. 77.8 ± 26.1, p = 0.011), higher peak of total bilirubin (13.2 ± 8.8 vs. 7.5 ± 4.9, p = 0.001), higher peak of alanine aminotransferase (4,447 ± 1,777 vs. 2,746 ± 1,939, p = 0.001), higher peak of aspartate aminotransferase (4,688 ± 3,146 vs. 2,746 ± 1,939, p = 0.006), and lower nadir level of platelet (136,857 ± 51,992 vs. 203,805 ± 139,478 p = 0.009) compared to patients without ARF. If ARF developed, days in hospital were significantly increased (32.1 ± 28.6 vs. 18.4 ± 15.0, p = 0.029). Proteinuria more than grade 1 was noticed in 239 of 340 (66%) patients who underwent urine analysis. But the degree of protienuria was not different between patients with ARF and without ARF.

Conclusions: We report the recent aspects of incidence and clinical characteristics of acute renal failure in acute hepatitis A patients.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2103

**Acute Kidney Injury (AKI) by Cortinarius Orellanus Intoxication – The Largest German Case Series** Stefan Herget-Rosenthal,[1] Duaa Aresmouk,[2] Martin Langenbeck,[1] Siegmar F. Berndt,[3] Andreas Schaper,[4] Scott O. Grebe.[2] *[1]Div. of Internal Medicine, Rotes Kreuz Krankenhaus, Bremen, Germany; [2]Dept. of Nephrology, Helios Klinikum, University of Witten/Herdecke, Wuppertal, Germany; [3]German Mycological Society, University, Kassel, Germany; [4]Poison Information Centre North, Georg-August-University, Goettingen, Germany.*

The fungus Cortinarius orellanus contains the tubulotoxin orellanine, which may cause AKI by interstitial nephritis and oxygen-free radicals. Besides case reports only 2 larger series have been reported in 1957 and 1990. We report current data on AKI, therapeutic options and outcome of orellanine intoxication.

We analyzed the largest German case series of AKI due to orellanine intoxication after mushroom ingestion confused with chanterelles. Renal biopsy was performed in 1 patient. Orellanine intoxication was confirmed by an expert of the German Mycological Society. Data are presented as mean ± SD. The semi-quantitative amount of ingested mushrooms, and the therapy with N-acetylcysteine (NAC) and steroids were correlated with chronic kidney disease (CKD) stages 12 months after intoxication.

All patients (n = 8, age 52±10 years, 50% male) presented with typical symptoms of orellanine intoxication (nausea, epigastric pain, headache) with a latency of 7±1 days after ingestion. None had preexisting CKD. At admission all patients showed severe AKI (S-Crea 10.0±6.5 mg/dl, Urea 177±68 mg/dl) and tubular proteinuria of 405±320 mg/d. In 5 patients (63%) AKI was oligo-anuric and immediate renal replacement therapy (RRT) was required. The biopsy showed severe acute tubular necrosis and interstitial nephritis. After 12 months, 3 patients (38%) still required RRT, 4 patients developed CKD stage 3 and 1 stage 4. CKD severity was correlated with the amount of ingested mushrooms (r = 0.8, p = 0.02) but not with the therapy with NAC and steroids (r = -0.1, p = 0.87).

Orellanine intoxication is a rare cause of severe AKI. Our limited data suggest, that orellanine intoxication is associated with poor renal outcome reflected by a high rate of advanced CKD. CKD severity correlates with the amount of ingested mushrooms and is not influenced by antioxidant or antiinflammatory therapy.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2104**

**Cortinarius Speciosissimus Mushroom Poisoning Causing Irreversible Renal Failure** Carol Brunton,[1] Colin G. Millar,[1] Christopher O. C. Bellamy.[2] *[1]Aberdeen Royal Infirmary, Aberdeen, United Kingdom; [2]Edinburgh Royal Infirmary, Edinburgh, United Kingdom.*

4 fit and healthy adults (2 male, 2 female) aged between 46-58yrs, presented to our unit 36 hrs after ingesting "wild mushrooms",subsequently identified as belonging to the Cortinarius species (Cortinarius Speciossimus)

Initial symptoms were vomiting and diarrhoea, "burning throat", headache and increasing oliguria. 3 were completely anuric on transfer. All were dialysed by day 6. There is no specific treatment although previous case reports suggest improved outcome with the use of N-acetyl cysteine [NAC], Selenium, and steroids. All patients received NAC infusion followed by oral therapy for 3 weeks, both iv and oral Selenium and Prednisolone 60mg daily with tapering doses. All were biopsied by day 17 post poisoning, and exhibited severe diffuse toxic tubular injury with associated interstitial inflammation and areas of fibrosis. Blood and urine samples were analysed for Orellanine but were all negative.

The Cortinarius genus has over 300 species, but 2 are highly poisonous. The toxic compound is Orellanine, a bipyridine similar in structure to paraquat. The charged nitrogen atoms confound important redox reactions. In vitro studies demonstrate increased reactive oxygen species and depletion of glutathione, hence the use of anti-oxidants as potential treatments. Orellanine appears to have a predilection for the proximal tubular epithelium and the exact mode of action is uncertain. It is not destroyed by heat, freezing, drying or cooking and once ingested cannot be removed. Acute renal failure has been reported, and often presents after a delay of 7-21days. It is irreversible in up to 70% cases depending on dose and individual sensitivity.

This is a rare cause of renal failure; the last reported cases in the UK were in 1980. The changing climate and encouragement of foraging may make this species more common. The cases we present had a much more rapid presentation, with very early requirement for renal replacement therapy. 2 years after ingestion, 3 of our patients remain dialysis dependant. One of the female patients recovered renal function after 4 months and has a current creatinine of 124µmol/l (1.4mg/dl).

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2105**

**Response to Vasoconstrictor Therapy in Hepatorenal Syndrome Parallels Increases in Mean Arterial Pressure: A Pooled Analysis of Clinical Trials** Juan Carlos Q. Velez, Paul J. Nietert. *Department of Medicine, Medical University of South Carolina, Charleston, SC.*

Hepatorenal syndrome (HRS) is an ominous complication of end-stage liver disease. Vasoconstrictor therapy has been advocated as a modality to revert HRS with mixed results. We hypothesize that, regardless of the pharmacological agent used, achievement of a substantial rise in arterial blood pressure is critical for the recovery of kidney function in HRS. Using PubMed search engine, we identified 28 studies on pharmacotherapy of HRS, including retrospective and prospective clinical trials. After the exclusion of 9 studies due to unavailable relevant data, we conducted an analysis of data pooled across 489 subjects from 17 eligible studies (12 tested terlipressin, 3 norepinephrine, 3 octreotide, 2 midodrine and 1 dopamine), 6 of which were randomized controlled trials. Means and standard errors were identified for the populations' mean arterial pressure (MAP), serum creatinine (sCr), and urine output (UOP) measurements at baseline and at varying subsequent time points during treatment (range = 3 to 14 days). When possible, values specific to study subgroups (e.g. responders vs. non-responders, active treatment vs. placebo or comparator) were abstracted. Inverse variance weighted regressions were conducted to estimate the mean change per day in MAP, sCr, and UOP for each of the study subgroups (n=32), since some measurements were conducted on 3 or more occasions. The associations between changes in MAP and changes in sCr and UOP were then assessed using Spearman rank correlations. Increases in MAP were strongly associated with declines in sCr (rho = -0.80, $p < 0.0001$) and moderately associated with increase in UOP (rho = 0.37, $p = 0.087$). The magnitudes of these associations were stronger when the correlations were restricted to randomized clinical trials (MAP vs. sCr: rho = -0.90, $p < 0.0001$; MAP vs. UOP: rho = 0.60, $p = 0.12$), and the findings were similar among populations whose mean baseline MAP was ≤75 mmHg or >75 mmHg. These results support consideration for a goal-directed approach to the treatment of HRS. A substantial rise in MAP may improve kidney function in HRS irrespective of baseline MAP.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2106**

**Clinical Characteristics and Renal Prognosis from 111 Patients with Acute Interstitial Nephritis** Tao Su, Liqiang Meng, Li Yang, Xiaomei Li. *Renal Division, Department of Medicine, Peking Universtity First Hospital, Institution of Nephrology, Beijing, China.*

Acute interstitial nephritis (AIN)is a common cause of acute renal dysfunction. However the true outcome may be underestimated by several reasons involving basal condition and factors during disease progress. In this study an attempt was made to find prognostic factors in AIN. **Methods:** Patients pathologically diagnosed as AIN 2002.1-2009.12 were analyzed. Assessment of renal function was defined as full-, partial- or no-recovery when Scr returned to normal, higher than normal but had a more than 50% decrease of highest level or had no change. Risk factors including etiology of AIN, offending drugs, history of essential hypertension(EHT), diabetes(DM) and chronic kidney disease(CKD) were enrolled into logistic regression analysis for long-term renal outcome prediction. **Results:** 111 patients were enrolled (41 male and 70 female), averaged 45.3 years old. 63 cases were followed up for average 29.0 months. Aetiology of AIN involved in drug (80.2%), TINU syndrome (11.7%), idiopathic (4.5%). Severe renal failure was the major clinical pattern. Hyperglobulinemia was observed in 27.9% of all, 53.9% of TINU. 42% of TINU showed uveitis 6 months later after occurrence of AIN. There were 22.5%, 27.9% and 14.4% of patients suffered from basal CKD, EHT and DM. Six patients had autoimmune thyroid disease (AITD), while three were TINU. Among 111 patients, cases with full-, partial- or no-recovery in a short-term (1-2 month) renal assessment was 36.0%, 18.9% and 45.0% respectively. From the followed-up 63 cases, 54(85.7%) patients got a final full renal recovery, including 21 cases recovered shortly and 33 cases gradually within 6 months. Only nine (14.3%) remained renal insufficiency, four of them with CKD history despite of normal Scr level before the onset of AIN. In risk factor analysis, CKD was the only factor associated with outcome (OR =4.53). **Conclusion:** From this analysis, AIN patients with hyperglobulinemia or history of AITD should be closely followed-up to rule out TINU. Most AIN patients show good prognosis within 6 months, but a few may progress into renal chronicity, especially in those with history of CKD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2107**

**Improving Renal Outcome in Multiple Myeloma and Acute Kidney Injury: Extracorporeal Elimination of Free Light Chains Using High Cut-Off (HCO) Hemodialysis** Nils Heyne,[1] Martina Guthoff,[1] Hans-Ulrich Haering,[1] Katja C. Weisel.[2] *[1]Department of Endocrinology and Diabetology, Angiology, Nephrology and Clinical Chemistry, University of Tübingen, Tübingen, Germany; [2]Department of Hematology, Oncology and Immunology, University of Tübingen, Tübingen, Germany.*

About 50% of multiple myeloma patients present with impaired renal function upon diagnosis, up to 10% are dialysis-dependent. Cast nephropathy is the most common form of light-chain associated acute kidney injury (AKI). Novel therapeutics have substantially improved outcome in multiple myeloma disease, nonetheless, renal function determines patient prognosis. Timely initiation of chemotherapy and reduction of serum free light-chain (sFLC) concentrations are paramount for renal functional recovery.

We and others shown extended high cut-off (HCO) hemodialysis an effective means for extracorporeal sFLC removal. Here we report outcome data from 19 patients with multiple myeloma and dialysis-dependent AKI, treated with chemotherapy and concomitant sFLC removal. 10 patients were newly diagnosed and 9 had relapsed or refractory disease. Median eGFR was 7.4 (range 3.3 - 10.9) ml/min/1.73m², median sFLC concentration was 9.680 (range 1.590 - 66.100) mg/l. Chemotherapy mainly included new therapeutic drugs. Follow-up > 3 months was obtained from 17 patients.

In parallel to chemotherapy, a median of 8 (range 3 - 23) HCO dialyses were required to reduce sFLC concentrations below 500 mg/l. Sustained renal functional recovery was achieved in 14 out of 17 patients (83.2 %) with a median time of 17 days until off hemodialysis. Patients who did not recover renal function suffered refractory myeloma disease. Response to chemotherapy and duration of AKI prior to initiation of therapy were independent predictors of renal functional outcome.

In combination with effective chemotherapy, extracorporeal elimination of sFLC by HCO hemodialysis enables renal functional recovery of dialysis-dependent AKI in a high proportion of myeloma patients. A prospective, randomized European multicenter trial (EuLITE), adressing the influence of extracorporal sFLC elimination on renal and patient outcome in multiple myeloma and cast nephropathy is ongoing.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2108**

**Diagnostic Uncertainty of Kidney Biopsy for Evaluation of Renal Sarcoidosis in Patients with Acute Renal Failure and Sarcoidosis – A Case Report and Series** Ravish Shah,[1] Alia S. Albawardi,[2] Anil K. Agarwal,[1] Tibor Nadasdy,[2] Ganesh B. Shidham.[1] *[1]Internal Medicine, Ohio State University Medical Center, Columbus, OH; [2]Pathology, Ohio State University Medical Center, Columbus, OH.*

**Purpose of study**: Sarcoidosis is an idiopathic multisystem disease characterized by noncaseating granulomatous inflammation. The incidence of kidney involvement ranges from 3-23%. We hereby report a case of acute renal failure (ARF) in a patient with sarcoidosis, and review 21 kidney biopsies in patients with history of sarcoidosis. **Method**: A 63-year-old Caucasian male was treated for pulmonary sarcoidosis with a 6-month course

of prednisone. Two months after finishing treatment, he presented with creatinine of 4 mg/dl (baseline 1.5 mg/dl) for which no obvious etiology could be identified. A kidney biopsy was performed. This showed nonspecific changes without evidence of epitheloid granulomata. Even though the biopsy was negative for renal sarcoidosis, he was empirically started on high-dose prednisone for a clinical diagnosis of renal sarcoidosis. Serum creatinine improved to 2 mg/dl within a month of treatment. Patient continues to be stable on low-dose prednisone. This case shows the importance of prednisone trial for clinical diagnosis of renal sarcoidosis in patients with an inconclusive renal biopsy.

To further investigate the incidence of inconclusive renal biopsies and absence of epitheloid granuloma (hallmark of renal sarcoidosis) we performed a retrospective review of 21 renal biopsies in patients with ARF and sarcoidosis.

| Kidney biopsy results | N = 21 |
|---|---|
| Granulomatous interstitial nephritis | 4/21 (19%) |
| Membranous GN | 4/21 (19%) |
| Diabetic nephropathy | 4/21 (19%) |
| Nonspecific changes of chronic renal injury | 9/21 (43%) |

**Conclusion**: These data underscore the diagnostic uncertainty of renal biopsy for ARF in the setting of sarcoidosis, as classical granulomatous changes are seen in only a minority of cases. It is possible that biopsy sampling error is higher in sarcoidosis as granulomatous lesions are focal. Empiric treatment with steroids may be initiated in cases in which there is a strong clinical suspicion of renal sarcoidosis even with a non-diagnostic biopsy.

**Clinical Features and Outcome of Anti-Glomerular Basement Membrane Disease in Older Patients** Zhao Cui,[123] Juan Zhao,[123] Xiao-Yu Jia,[123] Ming Hui Zhao.[123] *[1]Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China; [2]Institute of Nephrology, Peking University, Beijing, China; [3]Key Laboratory of Renal Disease, Ministry of Health of China, Beijing, China.*

**Background** Anti-glomerular basement membrane (GBM) disease is increasingly recognized in older patients. The difference in disease presentation and outcome between older and younger patients remains controversial. It makes treatment difficult to the older patients. We conducted the current study to analyze the characteristics of patients over 65 years with anti-GBM disease and to compare the younger and older cohorts.

**Methods** 221 consecutive Chinese patients with anti-GBM disease diagnosed from 1998 to 2008 in our referral center were recruited. Clinical and pathologic characteristics as well as outcomes were analyzed retrospectively.

**Results** The 50 (22.6%) older patients had a male predominance (male/female = 1.9:1). In comparison with the 171 younger patients, the older patients had higher proportion of positive ANCA ($p<0.001$), lower prevalence of hemoptysis ($p=0.011$), lower urine protein excretion ($p=0.001$) and lower initial serum creatinine ($p=0.001$). During follow-up, patient survival was worse in older patients ($p=0.007$) and renal survival was similar to the younger patients ($p>0.05$). Multiple regression analysis showed that the serum level of anti-GBM antibodies was the independent predictor for patient death ($p=0.004$) and the initial serum creatinine was the independent predictor for renal failure ($p<0.001$). Plasma exchange combining with corticosteroids and cyclophosphamide was the independent factor to improve both patient survival ($p=0.001$) and renal survival ($p=0.016$).

**Conclusions** Older patients with anti-GBM disease had milder renal damage and less pulmonary involvement, but with similar renal outcome and worse patient survival. It implied that early diagnosis and intensive therapy were crucial to improve the outcome of older patients.

**Outcome of Chinese Patients with Anti-Glomerular Basement Membrane Disease Receiving Different Therapeutic Regimens: A Large Cohort Study from a Single Center** Zhao Cui,[123] Juan Zhao,[123] Xiao-Yu Jia,[123] Qi-Zhuang Jin,[123] Xu-Yang Cheng,[123] Ming Hui Zhao.[123] *[1]Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China; [2]Institute of Nephrology, Peking University, Beijing, China; [3]Key Laboratory of Renal Disease, Ministry of Health of China, Beijing, China.*

Anti-glomerular basement membrane (GBM) disease usually presents with rapidly progressive glomerulonephritis, accompanied by pulmonary hemorrhage. The low incidence and fulminant course of disease prevent any large randomized control study defining the benefits of any given therapy. We conducted a retrospective survey of 221 consecutive patients from 1998 to 2008 in our hospital, with an aim to elucidate the effect of different therapeutic regimens on the outcome. Disease presentation and outcomes were compared among patients received different treatments. We found that the initial serum creatinine and positive ANCA were independent predictors for patient death. The initial serum creatinine and percentage of crescents in glomeruli were independent predictors for renal death. The combination therapy, plasmapheresis plus corticosteroids and cyclophosphamide, had an overall benefit effect on both the patient survival ($p=0.016$) and renal survival ($p=0.008$), particularly to the patient survival of Goodpasture disease ($p=0.015$) and the renal survival of anti-GBM nephritis with initial serum creatinine over 600μmol/L ($p=0.014$). Treatment using corticosteroids alone was a predictor for patient and renal death ($p<0.001$). Corticosteroids plus cyclophosphamide had no effect on patient or renal outcome ($p>0.05$). In conclusion, the combination therapy was preferred, especially in patients with pulmonary hemorrhage or severe renal damage. Early diagnosis was crucial to improve the outcome.

**SA-PO2111**

**Phase 1 Evaluation of the Novel C5aR Antagonist CCX168** Daniel Dairaghi, Daniel A. Johnson, Kara Deshayes, Shichang Miao, Lisa C. Seitz, Yu Wang, Manmohan Reddy Leleti, Jay P. Powers, Pirow Bekker, Thomas J. Schall, Juan C. Jaen. *ChemoCentryx, Inc.*

Purpose

CCX168 is an orally active C5aR antagonist. A Phase 1 study has been conducted in healthy volunteers (HVs) to establish the safety, tolerability, pharmacokinetic (PK) and pharmacodynamic (PD) profile of oral CCX168. This work has paved the way for clinical evaluation of CCX168 in patients with ANCA-associated vasculitis/glomerulonephritis (GN).

Methods

In the Phase 1 program, 40 male or female HVs received either placebo or 1 – 100 mg CCX168 orally, in a single-dose or a multiple-dose (7 days) regimen. Blood was collected at pre-specified time points for PK and PD analyses. Ex vivo analysis of C5aR receptor coverage on blood neutrophils was performed based on C5a-induced CD11b expression. A similar PD assay was performed on blood samples from mice dosed orally with CCX168. PK/PD requirements were defined for complete inhibition of C5aR-mediated neutrophil activation and anti-MPO-induced GN by CCX168 in mice.

Results

CCX168 potently blocks C5a-mediated chemotaxis of human neutrophils in human blood (IC50 2 nM) and CD11b upregulation (IC50 4 nM). CCX168 was well tolerated, with excellent oral bioavailability and dose-proportional increases in exposure in both periods of the Phase 1 study. There were no serious adverse events (AE) or withdrawals due to AE. Plasma levels of CCX168 of 197 ng/mL (~400 nM) were reached after a 100-mg dose, 12 hrs after which there was a 94% reduction in CD11b upregulation (ex vivo PD assay). Similar plasma levels of CCX168 were required in the anti-MPO mouse model for near-maximal prevention of GN (see related abstract). Plasma distribution half-life was 7.8 hours and terminal half-life was 29 hours.

Conclusions

CCX168 showed an excellent safety and tolerability profile in HVs. PK and PD data indicate that 30-50 mg CCX168 bid in humans should result in greater than 90% C5aR coverage in blood at all times, considered optimal for CCX168 evaluation in Phase 2 trials in vasculitis.

**AQP2 Affects Renal Epithelial Cell Adhesion, Migration and Tubule Formation by Interacting with Integrin β1 Via an External RGD Motif** Ying Chen,[1] William Rice,[1] Wei Li,[1] Yawei Kong,[1] Robert A. Fenton,[2] Jian Li,[3] Victor Hsu,[3] Dennis Brown,[1] Hua Ann Jenny Lu.[1] *[1]Program in Membrane Biology/Divison of Nephrology, Massachusetts General Hospital and Harvard Medical School, Boston, MA; [2]The Water and Salt Reaserch Center, Department of Anatomy, Aarhus University, Aarhus, Denmark; [3]Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Aquaporin 2 (AQP2) is a classic water channel that mediates water reabsorption by principal cells of collecting duct (CD) of mammalian kidney in response to vasopressin. However, we and others have observed an unexpected phenotype in AQP2 knockout animals, with severe tubular defects, renal failure and neonatal mortality. Here, we report the discovery of a conserved Arg-Gly-Asp (RGD) sequence, an integrin-binding motif, in the second external loop of AQP2. AQP2 was able to interact with integrin β1 via this RGD motif in co-immunoprecipitation assays. AQP2 colocalized with integrin β1 on the basal and lateral membranes in CD of wild type mouse kidneys. A synthetic peptide consisting of the entire 2nd external loop of AQP2 bound to integrin β1 on overlay assays, and blocked migration and tubule formation by cultured AQP2 expressing cells. Mutation of this AQP2 RGD motif to RGA in AQP2 expressing cells resulted in significant defects in cell adhesion, migration and in vitro tubule formation. RGA expressing cells formed cyst-like structures in 3D cultures. The functional significance of the interaction of AQP2 and integrin β1 was further investigated. Alteration of the AQP2-RGD motif led to a significant increase in integrin β1 accumulation at the plasma membrane in cell cultures. To summarize, we have shown that AQP2 interacts with integrin β1 via its RGD motif and modulates the trafficking of integrin β1. We propose that AQP2 may affect important cellular functions related to epithelial cell/matrix interactions that are mediated by integrin β1.

**Vasopressin-Induced Phosphorylation of S261 in AQP2-P262L, a Mutant in Recessive Nephrogenic Diabetes Insipidus, May Underlie Recessive Nephrogenic Diabetes Insipidus** Peter M. T. Deen, Christiane Trimpert, Lise M. Verhoef. *Physiology, Radboud Univ. Nijmegen Med. Centre, Nijmegen, Netherlands.*

Vasopressin regulates water homeostasis through insertion of aquaporin-2 (AQP2) water channels in the apical plasma membrane of renal cells. AQP2 mutations cause nephrogenic diabetes insipidus (NDI), a disease in which the antidiuretic response is lacking, resulting in polyuria and polydipsia. While most AQP2 mutants in recessive NDI are misfolded, retained in the endoplasmic reticulum and unable to interact with wild-type (wt)-AQP2, cell culture studies suggest that AQP2-P262L in recessive NDI folds properly and interacts with wt-AQP2 in healthy parents, but is impaired in its vasopressin-induced translocation from

vesicles to the apical membrane in NDI patients. The underlying mechanism, however, is unknown. As it was recently shown that, besides S256, vasopressin-induced translocation of AQP2 also coincides with AQP2 phosphorylation at S264 and S269 (pS269), and de-phosphorylation at S261, and P262 lies adjacent to S261, we tested vasopressin-induced phosphorylation of AQP2-P262L. In MDCK cells, wt-AQP2 only shows an unglycosylated 29 kDa band, while AQP2-P262L is expressed as a 29 and 30 kDa band. Using AQP2 antibodies insensitive to phosphorylation, dDAVP increased the presence of the 30 kDa band. This band felt back to 29 kDa upon treatment with phosphatases, indicating that phosphorylation of AQP2-P262L underlies the appearance of the 30 kDa band. Using phosphor-specific antibodies, it appeared that, similar to wt-AQP2, dDAVP increased pS256 and pT269 in human AQP2-P262L. however, in contrast to wt-AQP2, pS261 was hardly detectable with control AQP2-P262L, and was extensively increased with dDAVP. Moreover, compared to the 29 kDa band, 30 kDa AQP2-P262L was strongly phosphorylated at S256 and S261. Our data reveal that vasopressin induces pS261 in AQP2-P262L and that this difference from wt-AQP2 may underlie its inability to sort to the plasma membrane and to cause NDI in the AQP2-P262L NDI patients.

**Transient Receptor Potential Classic Channel 6 Activation Participates in the Regulation of Aquaporin-2 Trafficking** Vedrana Tabor,[1] Doerte Faust,[2] Jelena Milic,[2] Aline Kirschner,[2] Beate Eisermann,[1] Anita Neumann,[1] Andrea Geehlhaar,[1] Janin Junker,[1] Walter Rosenthal,[2,3] Enno Klussmann.[1] *[1]Signal Transduction, Leibnitz Institute for Molecular Pharmacology, Berlin, Germany; [2]Max Delbrueck Center for Molecular Medicine, Berlin, Germany; [3]Charite University Medicine, Berlin, Germany.*

Transient receptor potential classic 6 (TRPC6) channels belong to a superfamily of transient receptor potential (TRP) channels. Proteins from this family form cation channels permeable for Ca2+ and Na+. TRPC 6 can be specifically and selectively activated by hyperforin, one of two main constituents of St. Johns wart. TRPC6 is co-expressed with aquaporin-2 (AQP2) in renal collecting duct principal cells. It has been suggested that the arginine vasopressin (AVP)-induced redistribution of AQP2 acts not only through elevation of cAMP levels, but also through the increase of cytosolic Ca2+. These Ca2+ influxes might be controlled by TRPC6 channels.

We observed that by activating TRPC6 channels AQP2 changes it localization from cytoplasmic to predominant plasma membrane in rat primary inner medullary collecting duct (IMCD) cells. Further, we have shown that V2R stimulation and consequent rise in the cAMP levels induce the TRPC6 redistribution from intracellular domains to the plasma membrane. We have tested the potential co-localization of AQP2 and TRPC6 on AQP2 bearing vesicles as one of the possible reasons for the coordinated trafficking. However, our results strongly suggest that TRPC6 does not reside on the AQP2 bearing vesicles.

Specific TRPC6 activation changed the phosphorylation patterns of AQP2.

In addition, we have identified two drug-like small molecules inhibiting TRPC6, and tested their impact on AQP2 and TRPC6 trafficking in rat primary IMCD cells as well as in the mouse model of syndrome of inappropriate secretion of antidiuretic hormone (SIADH). The compounds inhibited TRPC6 activity, this was associated with the inhibition of the AVP-induced redistribution of AQP2, and in addition normalization of Na+ levels in vivo. Thus inhibition of TRPC6 with the small molecules may pave the way to a new concept for the treatment of diseases associated with excessive water retention.

**Dislocation of Mouse Collecting Duct Aquaporin-2 by Metabolic Acidosis: Role of Vasopressin V1a Receptor** Yukiko Yasuoka,[1] Mizuka Kobayashi,[2] Yuichi Sato,[3] Hiroshi Nonoguchi,[4] Akito Tanoue,[5] Katsumasa Kawahara.[1] *[1]Physiology, Kitasato U. Sch. of Med, Sagamihara, Kanagawa, Japan; [2]Anesthesiology, Kitasato U. Sch. of Med, Sagamihara, Kanagawa, Japan; [3]Mol. Diagnostics, Kitasato U. Sch. of Allied Health Sci., Sagamihara, Kanagawa, Japan; [4]Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [5]Pharmacology, National Research Institute for Child Health and Development, Okura, Tokyo, Japan.*

Metabolic acidosis decreases urine concentrating ability by interfering with aquaporin-2 (AQP2) translocation in the luminal membrane of the principal cell (PC) through the kidney collecting duct (CD). However, the cellular mechanisms involved in urinary AQP2 excretion are still controversial. We determined whether vasopressin V1a receptor (V1aR), localized in the CDs and stimulated by acidosis, played key roles in the luminal AQP2 translocation. Wild (WT) and V1aR knockout (KO) mice were placed in metabolic cages and subjected to normal diet (control) and dietary $NH_4Cl$ loading (acidosis) with free access of water for 6 d. Some of them were treated without water for additional 1 d (dehydration). Urinary excretion of AQP2, estimated by Western blotting analysis, was 2.2% and 25% of control, respectively, in WT and KO mice (n=8, each) after 6-d metabolic acidosis, although it was markedly (160%) increased in WT, but remained unchanged in KO mice after dehydration (1 d) (n=3, each). Immunocytochemistry of the kidney cortex (WT) showed the diffuse presence of AQP2 in the cytoplasm of the PC (control, acidosis) and the dense staining in the apical membrane (dehydration). On the other hand, in the KO mice CDs, it showed weak staining of AQP2, with mainly staining in the apical membrane in the above three conditions. By using highly sensitive *in situ hybridization* technique, a level of the V2R mRNA expression remained unchanged during acidosis. We conclude that luminal AQP2 translocation in the mice kidney CDs is inhibited by metabolic acidosis even in the absence of V1aR signaling, and that V1aR may be essential for expression of AQP2, especially its upregulation during dehydration.

## SA-PO2116

**Crucial Role of p38MAPK in Control of Aquaporin-2 Abundance in Renal Principal Cells** Vedrana Tabor,[1] Pavel I. Nedvetsky,[1] Grazia Tamma,[2] Philipp Skroblin,[1] Aline Kirschner,[3] Beate Eisermann,[1] Andrea Geehlhaar,[1] Burkhard Wiesner,[1] Walter Rosenthal,[3,4] Enno Klussmann.[1] *[1]Signal Transduction, Leibniz Institute for Molecular Pharmacology, Berlin, Germany; [2]General and Environmental Physiology, University of Bari, Bari, Italy; [3]Max Delbrück Center for Molecular Medicine, Berlin, Germany; [4]Molecular Pharmacology and Cell Biology, Charité University Medicine, Berlin, Germany.*

The water channel aquaporin-2 (AQP2) is mediating arginine-vasopressin (AVP)-dependent increases in water reabsorption in renal collecting duct principal cells by binding to vasopressin V2 receptors (V2R) expressed on the basolateral cell surface. This leads to activation of adenylyl cyclase and elevation of cAMP levels. cAMP activates protein kinase A (PKA) which phosphorylates AQP2 at serine 256 (AQP2-Ser256). Short term stimulation with forskolin (FSK), another cAMP elevating agent induces increases in AQP2 abundance in primary IMCD cells. Recently, it was discovered that Ser261 within the C-terminus of AQP2, is phosphorylated under the resting conditions. This phosphorylation decreases in response to cAMP elevation induced by AVP or FSK. We observed that p38MAPK is phosphorylating Ser261 in vitro. Phosphorylation by p38MAPK represents a hallmark for ubiquitination and proteasomal degradation of its targets, indicating that it might regulate AQP2 protein levels in renal principal cells.

According to our in vivo studies in cells and mice, within 30 minutes of exposure to AVP and FSK the abundance of AQP2 increased by decreasing the extent of AQP2-pUb, thus decreasing its proteasomal degradation. This event is associated with a decrease of p38MAPK-induced Ser261 phosphorylation in a PKA-dependent manner. Physiologically, hitherto this unrecognized regulatory mechanism of AQP2 expression might play a key role in rapidly increasing water reabsorption.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2117

**Abnormal Function of the Vasopressin-Cyclic-AMP-Aquaporin2 Axis during Urine Concentrating and Diluting in Patients with Reduced Renal Function** Ingrid Moeller Thomsen,[1] Thomas G. Lauridsen,[1] Erling B. Pedersen.[1,2] *[1]Departments of Medicine and Medical Research, Holstebro Hospital, Holstebro, Denmark; [2]University of Aarhus, Aarhus, Denmark.*

*Background*

The kidneys ability to concentrate and dilute urine is deteriorated during progressive renal insufficiency. We wanted to test the hypothesis that these phenomena could be attributed to an abnormal function of the principal cells in the distal part of the nephron.

*Methods*

Healthy control subjects and patients with chronic kidney diseases were studied. Group 1 comprised healthy subjects, n=10. Groups 2-4 comprised patients with chronic kidney disease (Group 2, n=14, e-GFR ≥ 90 ml/min; Group 3, n=11, 60 ml/min ≤ e-GFR < 90 ml/min; and Group 4, n= 16, 15 ml/min < e-GFR ≤ 60 ml/min). The subjects collected urine during 24 hours. A urine concentrating test was done by thirsting during the following 12 hours. Thereafter, a urine diluting test was performed with a water load of 20 ml / kg body weight. The effect variables were urinary excretions of aquaporin2 (u-AQP2), cyclic-AMP (u-c-AMP), urine volume (UV), free water clearance ($C_{H2O}$), urine osmolarity (u-Osm), and plasma arginine vasopressin (p-AVP).

*Results*

After fluid deprivation, u-Osm increased. In all groups, UV and $C_{H2O}$ decreased and u-AQP2 and u-c-AMP increased in Groups 1and 2, but were unchanged in Group 3 and 4. P-AVP was significantly higher in Group 4 than in the other groups. During urine diluting, UV and $C_{H2O}$ reached significantly higher levels in Groups 1-3 than Group 4. Both before and after water loading, u-AQP2 and p-AVP were significantly higher and u-c-AMP was significantly lower in Group 4 than the other groups. Estimated-GFR was correlated negatively to p-AVP and positively to u-c-AMP during the diluting test.

*Conclusion*

Patients with moderately severe chronic kidney disease have a reduced renal concentrating and diluting capacity compared to both patients with milder chronic kidney disease and healthy control subjects. These phenomena can be attributed, at least partly, to an abnormally decreased response in the AVP-c-AMP-AQP2 axis.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2118**

**Renal Aquaporin Expression and Osmotic Water Permeability Is Altered in Mice Fed a High Fat Diet** Grazia Tamma, Patrizia Gena, Domenica Lasorsa, Lisa Mastrofrancesco, Anna Rosito, Maria Svelto, Giuseppe Calamita, Giovanna Valenti. *Department of General and Environmental Physiology, University of Bari.*

The prevalence of obesity, one of the metabolic syndrome forms, has increased dramatically during the past decade with an estimated incidence of over 300 million adults worldwide. Obesity is an established independent risk factor for the development of chronic kidney disease. On the other hand, activation of the sympathetic nervous system and the renin-angiotensin system, leading to renal sodium and water retention, links obesity with hypertension. Considering these particular clinical features, in this study we focused our attention on the potential dysregulation of renal aquaporins (AQPs) in the kidney of a mouse model of obesity and type 2 diabetes mellitus (T2DM).

Mice were fed a high fat (HFD) or normal (ND) diet for 20 weeks. The expressions of AQP1, 2, 3 and 4 were analyzed by Western blotting and the subcellular distribution was investigated by immunocytochemistry. The osmotic water permeability (Pf) of the whole renal plasma membranes was evaluated by stopped flow light scattering.

Western blotting of total lysates from HFD mice revealed higher immunoreactivity for AQP1, AQP2 and AQP4 compared to mice fed a normal diet; no change was detected for AQP3. However, AQP1, AQP2, AQP3 and AQP4 abundance decreased in a crude kidney membrane preparation suggesting a reduced cell surface expression of these AQPs. Immunolocalization experiments confirmed an altered subcellular distribution of renal AQPs in HFD mice kidney.

Stopped flow light scattering showed a reduced Pf from 254.8±30.5 μm/s to 169.8±16.2 (P<0,0001) in membrane from ND versus HFD mice, respectively, consistent with the observed decrease in AQPs cell surface expression.

Altogether, these data reveal altered AQPs expression and osmotic water permeability of HFD mice kidney. These observations suggest a patho-physiological relevance for aquaporins in renal complications associated with metabolic syndrome.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2119**

**Urinary Exosomal (Microvesicular) Aquaporin-2 Is a Possible Early Biomarker for Cisplatin-Induced Acute Kidney Injury** Hiroko Sonoda,[1] Hiroaki Kondo,[1] Naoko Yokota-Ikeda,[2] Masahiro Ikeda.[1] *[1]Veterinary Pharmacology, University of Miyazaki, Miyazaki, Japan; [2]Nephrology, Miyazaki Prefectural Miyazaki Hospital, Miyazaki, Japan.*

Cisplatin, an antineoplastic agent, is known to cause acute kidney injury (AKI). The lack of appropriate biomarkers has hampered initiation of potential therapeutics in cisplatin-induced AKI in a timely manner. Of the known aquaporins (AQPs), water channel proteins, AQP1 and AQP2 have been found in the urinary exosomes (microvesicles) that are secreted from tubular epithelial cells. It was reported that cisplatin-injured rats showed urinary concentrating defect associated with down-regulation of AQP1 and AQP2 proteins levels in the kidney. In order to evaluate urinary exosomal AQP2 as an early noninvasive biomarker for cisplatin-induced AKI, this study examined the effect of the treatment of rats with cispaltin on the excretion of exosomal AQP2. Cisplatin (7.5 mg/kg) or saline was administered intraperitoneally in rats. Urine and blood samples were collected at various time points after the injection. Urinary exosomes were isolated from the collected urine by differential centrifugation. Plasma creatinine concentration of cisplatin-injected rats significantly increased 72 to 168 hours after the injection, compared to that of control rats. Urinary exosomal AQP2 abundance, judged by immunoblotting, was significantly lower in cisplatin-injected rats than in control rats 24 to 168 hours after the injection. Renal AQP2 protein level tended to be increased 24 hours, and was significantly decreased 168 hours after the injection. RT-PCR analyses showed that the renal AQP2 mRNA level was not changed at 24 to 72 hours and was significantly decreased 168 hours after the injection. Based on these data, we conclude that urinary AQP2 may represent an early to later noninvasive biomarker for cisplatin-induced AKI. Furthermore, we speculate that the reduction of urinary exosomal AQP2 level by cisplatin was due to retention of renal AQP2 abundance in early phase of cisplatin-induced kidney injury and due to lowered renal AQP2 level in later phase.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2120**

**Angiotensin (1-7) Induces Downregulation of AQP1 in Rat Proximal Cell Via Release of Bradykinin and Prostaglandin** Zaira Palomino Jara,[1] Richard Bouley,[2] Dulce Elena Casarini,[1] Flavia F. Jung.[3] *[1]Department of Medicine, Federal Univerisity of São Paulo, São Paulo, Brazil; [2]Nephrology Division, Massachussetts General Hospital and Harvard Medical School, Boston, MA; [3]Division of Pediatric Nephrology, Georgetown University, Washington, DC.*

Aquaporin 1 (AQP1) is the major constitutively expressed water channel in the renal proximal tubule and thin descending limb where nearly 80% of water is reabsorbed. However, the factors regulating its expression are still elusive.

We previously showed that Angiotensin II (AngII) $10^{-8}$M upregulated the AQP-1 expression in immortalized rat proximal tubule cells (IRPTC). We now show that Angiotensin-(1-7) (Ang(1-7) downregulated AQP1 in IRPTC. Ang(1-7) $10^{-8}$M downregulated AQP-1 mRNA and protein expression ( p<0.01,n=4) and these inhibitory effects were completely blocked by $10^{-5}$M D-[Ala$^{7}$]- Ang-(1-7) (p<0.001,n=4). Therefore in this study, we investigated Bradykinin (Bk), Prostaglandin E2 (PGE2), Angiotensin Converting Enzyme (ACE) and ACE2 as possible mediators of Ang (1-7) effect on AQP1 expression. IRPTC were treated with $10^{-8}$M Ang(1-7) for 0, 5, 15, 30, 60 and 120 min. After each time point, the release of Bk and PGE2 induced by Ang(1-7) stimulation were measured by both HPLC and by ELISA while the enzymatic activity of ACE and ACE2 were measured by fluorometric assay. At 15 min there was a significant elevation of Bk release compare to in absence of Ang(1-7) (time 0) (1.53 vs. 0.43 nM/mg; p<0.01, n=5). PGE2 release was significantly higher after 30 min of stimulation (169,10 vs. control 23,30 pg/mL, p<0.01, n=3). Interestingly, the presence of Ang(1-7) inhibited the enzymatic activity of ACE (ZPhe-HL – control: 0,46 ± 0,02 vs 5min: 0,04 ± 0,001 nM/min/mg, p<0,01, n=4;) while it stimulated ACE2 activity (control: 180 ± 33,88 vs. 120 min: 1041,9 ± 77,2 nM/min/mg, p<0,01, n=4). This study suggest that Ang(1-7) effect on AQP1 downregulation is mediated by release of BK and PGE2, as well as, inhibition of ACE and stimulation of ACE2. This mechanism may play a important role in the homeostasis of water reabsortion in proximal tubule.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2121**

**AQP5: Renal Aquaporins Family Got a New Member** Giuseppe Procino,[1] Lisa Mastrofrancesco,[1] Fabio Sallustio,[2] Vincenzo Costantino,[2] Francesco Paolo Schena,[2] Maria Svelto,[1] Giovanna Valenti.[1] *[1]Department of General and Environmental Physiology, University of Bari, Bari, Italy; [2]Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy.*

In an attempt to investigate the regenerative potential of adult multipotent renal progenitor/stem cells (ARPCs) isolated from human kidneys (Sallustio et al., 2009) we characterized them for the expression of aquaporins. ARPCs expressed measurable levels of the proximal tubule-specific AQP1, both at mRNA and protein levels. When ARPCs were differentiated in vitro into epithelial cells, the expression of the collecting duct-specific AQP2 was also induced.

Surprisingly, ARPCs also expressed measurable levels of AQP5, an aquaporin known to be selectively expressed in lung, salivary and lachrymal glands in mammals. This evidence prompted us to investigate the presence and the localization of AQP5 in the mammalian kidney.

Total RNA was isolated from adult human, rat and mouse kidneys and subjected to RT-PCR. Interestingly, AQP5 transcripts were found in all the species tested.

Western blotting analysis, revealed an AQP5 band of 27 kDa as well as a glycosylated form. Consistent with that, neither the transcript nor the protein was found in AQP5 null mice. AQP5 abundance was higher in the renal cortex than in the medulla.

Immunolocalization indicated that AQP5 was expressed at the apical membrane of the cortical collecting ducts (CCDs) epithelial cells with negligible staining in the inner medulla. Triple immunostaining indicated that, in rat CCDs, AQP5 did not colocalize either with AQP2 or with the intercalated cells marker V-ATPase, suggesting a cell specific expression of AQP5 in cells not expressing AQP2 but likely involved in water reabsorption. The ratio between AQP2- and AQP5-expressing cells was approximately 3:1.

In conclusion, the expression of AQP5 in the ARPCs, might suggest a role in the differentiation/regeneration processes of the collecting duct epithelial cells. Moreover, its constitutive expression at the apical membrane in the CCD, renders AQP5 a possible target for improving water reabsorption in the collecting duct when AQP2 apical expression is unpaired as in nephrogenic diabetes insipidus.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2122**

**Systemic Distribution of AQP11 and Phenotypic Analysis of AQP11-Null Mice** Kenichi Ishibashi. *Pathophysiology, Meiji Pharmaceutical University, Kiyose, Tokyo, Japan.*

AQP11 is a member of a new aquaporin subfamily with unusual NPA boxes, but has a high water permeability. AQP11 is expressed widely most abundantly in testis, thymus and moderately in liver, kidney, intestine and brain. However, its cellular localizations other than kideny are poorly characterized. Little is known about the phenotypes of AQP11 knockout mice other than polycystic kidney disease which is fatal due to uremia within a month. In this study, we examined AQP11 distribution and extrarenal phenotypes of AQP11-null mice. In situ hybridization analyses revealed that AQP11 was expressed at epithelial cells in the small intestine, hepatocytes, lymphocytes in the thymus and spermatocytes in the testis. Immunohistochemical analyses revealed that AQP11 was expressed intracellularly in the epithelial cell of the choroid plexus, vascular endothelial cells in the brain and the spinal cord, epithelial cells in the small intestine, and lymphocytes in the thymus. In AQP11-null mice, we observed intracellular vacuoles in hepatocytes around portal area, spermatocytes, and the epithelial cells of the choroid plexus and the small intestine. However, other cells expressing AQP11 appeared unchanged in AQP11-null mice.The vacuoles of hepatocytes (postnatal day 6) and proximal tubular cells (postnatal day 3) were compared by staining with an early endosome marker (EEA1), a lysosome marker (M6PR), and an ER marker (KEDL) and microarray analyses. Both vacuoles were strongly stained with M6PR and KEDL but weakly with EEA1, suggesting a common defect in endocytosis in these organs. The microarray analyses in both organs showed the absence of the enhanced expression of ER-stress related genes which has been observed at postnatal day 7 in the kidney. In conclusion, AQP11 disruption will initially lead to early endosome dysfunction and the intracellular vacuole develops in organs where active solute transports are conducted.

**Importance of Cysteine 227 on Water Permeability and Multimerization of AQP11 in Transfected Mammalian Cells** Kanako Muta, Sayaka Oshikawa, Masahiro Ikeda. *Veterinary Pharmacology, University of Miyazaki, Miyazaki, Japan.*

The aquaporins (AQPs) are a family of membrane channel protein and thirteen members (AQP0 - AQP12) have been identified in mammals. The AQPs exist as a multi-subunit oligomer and this structure is suggested to be important for their function. Among the AQPs, it has been reported that AQP11 is expressed at the proximal tubules in the kidney and the knockdown of the protein causes polycystic kidney disease in mice. Recently, an amino acid substitution (Cys227Ser) of AQP11 was reported to be responsible for renal cystic phenotype in mice, suggesting the importance of Cys227 in AQP11 function. However, roles of Cys227 in AQP11 water permeability and multimerization have yet to be elucidated. Although AQP11 is originally thought to be an intracellular AQP, a significant amount of AQP11 has been shown to be expressed at the plasma membrane, allowing us to measure the water permeability through AQP11 by a conventional cell swelling assay. In this study, we investigated the effect of Cys to Ser substitution at position 227 in AQP11 on its water permeability and multimerization in transfected CHO cells. When we measured the osmotic water permeability of the cell using swelling assay, the cells expressing AQP11-Cys227Ser had significantly increased osmotic water permeability (Pf = 9.9 +/- 0.8 cm/s x $10^{-4}$, n = 15, P < 0.05) compared with the cells expressing wild-type AQP11 (Pf = 7.1 +/- 0.6 cm/s x $10^{-4}$, n = 15). We also performed biotinylation assay and the results showed that the plasma membrane expression level of AQP11-Cys227Ser was lower than that of the wild-type protein. A chemical cross-linking experiment with paraformaldehyde revealed less multimer formation by AQP11-Cys227Ser, compared with the wild-type form. Collectively, these results indicate that Cys227 had an important role in 3D- structure of AQP11 molecule in association with its normal water transport function. Furthermore, this study suggests that both loss- and gain-of-function mutations of AQP11 appear to cause polycystic kidney disease.

**Chronic Use of Chloroquine Disrupts the Urine Concentration Mechanism by Lowering cAMP Levels in the Inner Medulla** Mitsi A. Blount, Tobias N. Von Bergen, Janet D. Klein, Jeff M. Sands. *Department of Medicine - Renal Division, Emory University School of Medicine, Atlanta, GA.*

Chloroquine, a widely used anti-malaria drug, has gained popularity for the treatment of rheumatoid arthritis, SLE, and HIV. Unfortunately, chloroquine may also negatively impact renal function for patients whose fluid and electrolyte homeostasis is already compromised by diseases such as chronic kidney disease (CKD). Chronic administration of chloroquine also results in polyuria which may be explained by suppression of the antidiuretic response of vasopressin. Several of the transporters responsible for concentrating urine are vasopressin-sensitive including the urea transporters UT-A1 and UT-A3, the water channel aquaporin-2 (AQP2), and the Na+-K+-2Cl- cotransporter (NKCC2). To examine the effect of chloroquine on these transporters Sprague-Dawley rats received daily subcutaneous injections of 80 mg/kg/day of chloroquine for 4 days. Twenty-four hour urine output was 2-fold higher and urine osmolality was decreased by 2-fold in chloroquine-treated rats compared to controls. Urine analysis of treated rats detected the presence chloroquine as well as decreased urine urea and cAMP levels compared to control rats. Western blot analysis showed a down regulation of AQP2 and NKCC2 transporters, however UT-A1 and UT-A3 abundances were unaffected by chloroquine treatment. Immunohistochemistry showed a marked reduction of phosphorylated UT-A1 and total AQP2 in the apical membrane in IMCDs of chloroquine-treated rats. Furthermore, activated CREB, a transcription factor for AQP2 and NKCC2 but not for the urea transporters, is decreased. RT-PCR analysis confirms a decrease of AQP2 and NKCC2 mRNA, while UT-A1 and UT-A3 mRNA levels remained unchanged. In conclusion, chloroquine-induced polyuria likely occurs as a result of lowered cAMP production. Acutely, low cAMP levels cause improper membrane association of UT-A1 and AQP2. Chronically, AQP2 and NKCC2 expression is downregulated on a transcriptional level. These findings suggest that chronic chloroquine treatment would exacerbate the already compromised fluid homeostasis observed in diseases like CKD.

**Renal Phenotype of Transgenic Mice Over-Expressing hCD39/NTPDase1** Yue Zhang,[1] Keiichi Enjyoji,[2] Kaiya L. Morris,[1] Shannon K. Sparrow,[1] Karen M. Dwyer,[3] Simon C. Robson,[2] Bellamkonda K. Kishore.[1] *[1]Medicine, VA Med Ctr & Univ. of Utah, Salt Lake City, UT; [2]Medicine, BIDMC, Harvard Med School, Boston, MA; [3]Nephrology, St. Vincent's Hospital & Univ. of Melbourne, Melbourne, Victoria, Australia.*

Extracellular nucleotides regulate urinary concentration in a type-2 purinergic receptor (P2-R)-dependent manner. Ectonucleoside triphosphate diphosphohydrolase-1 (NTPDase1/CD39) hydrolyzes ATP and ADP to AMP, and thus regulates the availability of ligands for P2-Rs. CD39 and related ectonucleotidases are expressed by the vasculature and other structures in kidney (Kishore et al, *AJP Renal* 288:F1032, 2005). Here we evaluated the urinary concentration/dilution capability of transgenic mice (TG) globally over-expressing hCD39 (Dwyer et al, *JCI* 113:1440, 2004). When allowed *ad libitum* access to solid chow and drinking water, the TG mice tend to drink more water and void quantitatively more and dilute urine as compared to wild type (WT) control mice, without significant differences in urinary excretion of vasopressin (AVP). Under stable and basal hydrated conditions (feeding gelled diet for 7 days), TG mice concentrated urine to a significantly lesser degree, despite lack of significant alterations in water intake, urine output and AVP, and protein abundance of AVP-regulated AQP2 in the kidney relative to WT mice. TG mice could dispose of an acute water load more rapidly, albeit total amounts excreted were not significantly different from the WT mice. When subjected to water restriction for 3 days, the TG mice could not concentrate urine to the level noted in WT mice, and had significantly lesser urinary AVP levels (TG 229 vs. WT 555 pg/mg creatinine, N = 5, $P < 0.02$). However, the increases in urinary osmolalities in response to sub-acute or chronic dDAVP treatment were similar or somewhat higher, respectively, in TG mice. Our observations suggest that although hCD39 over-expressing TG mice fail to concentrate urine as efficiently as the WT mice in response to water restriction, collecting ducts are responsive to dDAVP. Heightened nucleotide scavenging by the over expression of CD39 likely alter the release of endogenous AVP in response to water restriction.

**Mice with Disrupted COX-2 Expression Display Impaired Urine Concentration Ability** Rikke Norregaard,[1] Kirsten Madsen,[2] Pernille B. Hansen,[2] Peter Bie,[2] Jorgen Frokiaer,[1] Boye Jensen.[2] *[1]Institute of Clinical Medicine, University of Aarhus, Aarhus, Denmark; [2]Cardiovascular and Renal Research, University of Southern Denmark, Odense, Denmark.*

Recent data showed that hypothalamic $PGE_2$-EP1 receptor interaction promotes urine concentrating ability through stimulation of vasopressin (AVP) release. We hypothesized that hypothalamic COX-2 activity promotes urine concentrating ability through stimulation of AVP release. To address this we measured water turnover, AVP expression, AVP plasma concentration and renal transport proteins in normohydrated and water deprived (WD) COX-2 deficient ($^{-/-}$) and wildtype (WT) littermate controls. Basal urine output and water intake was enhanced and urine osmolality was lower in male COX-$2^{-/-}$ mice on a pure C57/bl6 background. Water deprivation (WD) resulted in lower urine concentration ability with a higher plasma osmolality and $Na^+$ concentration in COX-$2^{-/-}$ mice with no gender difference. Hypothalamic COX-2 expression was not altered by WD. Cerebral tissue $PGE_2$ concentration was enhanced in COX-$2^{-/-}$. Hypothalamic AVP mRNA was enhanced by WD in both genotypes. Total AVP peptide content was higher in COX-$2^{-/-}$ compared to WT at baseline and not changed by WD. Plasma AVP concentration in conscious catheterized WD mice did not differ between genotypes. WD increased inner medulla COX-2 protein abundance and $PGE_2$ urine excretion in WT. This was abolished in COX-$2^{-/-}$. Baseline medullary interstitial osmolality was higher in COX-$2^{-/-}$ and increased similar to WT in response to WD. The protein abundance of AVP V2 receptor in inner medulla (IM) and cAMP urine excretion was lower in COX-$2^{-/-}$ after WD. Baseline abundance and apical targeting of total aquaporin-2 (AQP2) was not different after WD in IM whereas pAQP2 was stimulated similarly in WT and COX-$2^{-/-}$. In summary, COX-$2^{-/-}$ mice exhibit chronically increased AVP stores but insufficient plasma levels to attain urine concentrating ability similar to WT despite elevated interstitial medullary osmolality and enhanced AQP levels. We speculate that increased flow in fewer nephrons and/or impaired local, COX-2 mediated, cAMP-dependent effects in the IM cause the observed attenuation in urine concentration.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2127**

**Mice with Disrupted Acyl-CoA Binding Protein Gene Display Impaired Urine Concentrating Ability** Stine Langaa,[1] Maria Bloksgaard,[2] Signe Bek,[2] Ditte Neess Pedersen,[2] Pernille B. Hansen,[1] Susanne Mandrup,[2] Boye Jensen.[1] *[1]Cardiovascular and Renal Research, University of Southern Denmark, Odense, Denmark; [2]Biochemistry and Molecular Biology, University of Southern Denmark, Odense, Denmark.*

Acyl-CoA binding protein (ACBP) is a lipid-binding protein expressed in most eukaryotic cells. To elucidate the role of ACBP in the intact organism, the ACBP gene was disrupted in mice. ACBP knock-out mice (ACBP$^{-/-}$) were grossly normal but displayed a skin/fur phenotype and increased water turnover.

It was hypothesized that transepithelial transport of water in the kidney is supported by ACBP.

Mice were placed in metabolic cages for quantitative studies of NaCl balance and urine concentrating ability. Blood was sampled by orbital- and cardiac puncture. Organs were rapidly removed and frozen for molecular analyses.

Under baseline conditions, adult ACBP$^{-/-}$ did not differ from wild type mice (WT) with respect to food intake. Water intake and diuresis were significantly higher in ACBP$^{-/-}$ whereas urine osmolality was lower. Renal excretion of $Na^+$ and $K^+$ did not differ between genotypes. After water deprivation for 20 hours, ACBP$^{-/-}$ exhibited higher diuresis, lower urine osmolality, elevated hematocrit and higher relative weight loss compared to WT. Kidney and adrenal weight compared to body weight did not differ between genotypes. $Na^+$ and $K^+$-excretion in urine were similar in the two groups. Renal papillary interstitial fluid osmolality, $Na^+$, $K^+$ and urea concentrations did not differ significantly between genotypes. ACBP$^{-/-}$ did not differ from WT with respect to kidney mRNA levels of aquaporin 1 (AQP1) and the $Na^+$-$K^+$-2 $Cl^-$ co-transporter. AQP2 mRNA and protein abundances and the intracellular localization of AQP2 were not different between the two groups. Adrenal mRNA level of cholesterol side-chain cleavage enzyme and plasma corticosterone concentration did not differ between genotypes. Adrenal aldosterone synthase mRNA was significantly elevated in ACBP$^{-/-}$ compared to WT whereas plasma renin and aldosterone levels were similar in the two groups.

We conclude that ACBP is necessary for an intact urine concentrating ability most likely through effects on collecting duct water transport.

**SA-PO2128**

**Transporters and Urine Concentration in Low-Protein Fed Mice with P2Y2 Receptor Knock-Out** Janet D. Klein,[1] Jeff M. Sands,[1] Christopher F. Martin,[1] Yue Zhang,[2] Bellamkonda K. Kishore.[2] *[1]Dept. of Medicine, Renal Div., Emory University, Atlanta, GA; [2]Dept. of Medicine, VA Medical Center and Univ. of Utah, Salt Lake City, UT.*

Transport of urea and movement of water to produce concentrated urine must respond to changes in protein load. Previous work in rats showed that low protein diet (LPD) causes UT-A1 to increase in inner medullary base and decrease in inner medullary tip (Kim, AJP Renal 296: F66, 2009). The contribution of UT-A in the LPD-induced polyuria is, therefore, unclear. AQP2 in LPD-fed rats is markedly reduced (Sands, JCI 97:2807, 1996). We examined the possible role of the P2Y2 receptor in the response of transporters involved in urine concentration by comparing P2Y2 knock-out (KO) mice with wild type (WT) controls fed normal protein (23%) vs low protein (8%) diet for 2 weeks. Water intake increased 63% in WT but not KO mice (n=5/grp). Urine output increased in both WT (133%) and KO (81%) mice after LPD, with a commensurate decrease in urine osmolalities of both WT (2115 pre vs 1583 mosmol/kg $H_2O$ post LPD) and KO (2493 pre vs 1966 mOsmol/kg $H_2O$ post LPD) mice. UT-A1 protein was increased 65% in IM of LPD-fed P2Y2 KO mice (n=9, $p<0.05$) but was unchanged in the WT mice. AQP2 tended toward decrease in the LPD WT mice, but the change was not statistically different. The P2Y2 KO mice showed no decrease in AQP2 upon LPD feeding. Similarly, AQP1 was decreased by 36% ($p<0.05$, n=5) in the LPD-fed WT mice but showed no decrease in the LPD-fed P2Y2 KO mice (n=5, p=n.s.). These results suggest that the relatively milder polyuria in the LPD-fed P2Y2 KO mice may reflect a combination of lower AQP2 impairment and increased compensatory action from the upregulated urea transporters. Conversely, this may suggest that the P2Y2 receptor could exacerbate the effect of LPD on the normal kidney's ability to concentrate urine.

**Disrupting Interactions of Protein Kinase A (PKA) and A-Kinase Anchoring Proteins (AKAP) with Small Molecules as a Novel Strategy for the Treatment of SIADH** Vedrana Tabor,[1] Kerstin Zuehlke,[1] Sabine Friedl,[1] Solveig Grossmann,[1] Jelena Milic,[2] Nico Kotzur,[1] Aline Kirschner,[2] Anita Neumann,[1] Beate Eisermann,[1] Andrea Geehlhaar,[1] Walter Rosenthal,[2,3] Enno Klussmann.[1] *[1]Signal Transduction, Leibniz Institute for Molecular Pharmacology, Berlin, Germany; [2]Max Delbrueck Center for Molecular Medicine, Berlin, Germany; [3]Molecular Pharmacology and Cell Biology, Charité University Medicine Berlin, Berlin, Germany.*

Increased secretion of arginine vasopressin (AVP or ADH) leads to the development of the syndrome of inappropriate ADH secretion (SIADH), which is the most frequent cause of hyponatremia in humans. This syndrome is associated with a three-fold increased mortality. Elevated AVP levels are also common in patients suffering from chronic heart failure. AVP binds to vasopressin V2 receptors (V2R) and increases water reabsorption in renal collecting duct principal cells via activation of adenylyl cyclase (AC) and the consequent increase in cAMP levels. cAMP activates PKA and induces PKA-driven AQP2 phosphorylation of serine 256 (AQP2 Ser256). This elicits AQP2s insertion into the plasma membrane thereby facilitating water reabsorption from primary urine. This redistribution of AQP2 depends on the interaction of PKA with A-kinase anchoring proteins (AKAPs), which position PKA at defined sites within cells and thereby coordinate PKA signalling temporally and spatially. The objective of our study was to develop new strategies for targeting the excessive water retention caused by inappropriate AVP secretion.

According to our in vitro, as well as in vivo studies in mice, a novel drug-like small molecule, FMP-API-3, inhibits AKAP-PKA interactions. The compound blocked the AVP-induced AQP2 translocation in primary renal principal cells of rats and mice in vivo. This inhibition is a consequence of reduced PKA-dependant phosphorylation of AQP2-Ser256. In addition, Na+ blood serum levels, water uptake and urine excretion in the SIADH model normalised upon the long-term FMP-API-3 treatment. Thus disruption of AKAP-PKA interaction might lead to a new concept for the treatment of SIADH and diseases associated with AVP-dependent water retention (such as chronic heart failure).

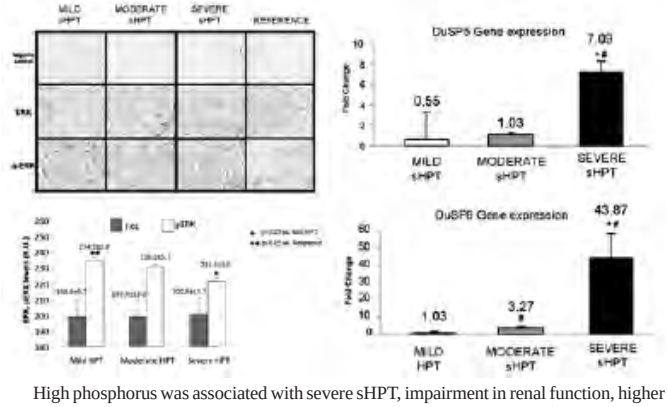
**Phosphorus Load and Severe Secondary Hyperparathyroidism Are Associated with Widespread Gene Expression Downregulation but Upregulation of Antiproliferative Pathway** Pablo Roman-Garcia, Natalia Carrillo-Lopez, Ana Rodriguez-Rebollar, Jose L. Fernandez-Martin, Manuel Naves-Diaz, Jorge B. Cannata-Andia. *Servicio de Metabolismo Óseo y Mineral, Hospital Universitario Central de Asturias, Oviedo, Asturias, Spain.*

Secondary hyperparathyroidism (sHPT) is a common complication of CKD that can be worsened by phosphate load. FGF23 is a phosphaturic hormone that also inhibits PTH secretion through MAPK pathway activation. The aim of this study was to study the molecular mechanisms involved in severe FGF23-resistant sHPT in CKD.

Rats were nephrectomized (7/8) and subsequently divided in two groups: normal P diet (0.6% P) and high P diet (0.9% P). In addition, a group of animals with a normal P diet without nephrectomy was used as reference group. Rats were sacrificed at 4, 8, 12, 16 and 20 weeks. Blood samples were collected, and parathyroid glands extracted and pooled according to PTH levels into three groups: no sHPT, mild sHPT and severe sHPT (Mean PTH: 60±63, 583±545 and 2238±851 pg/mL, respectively). Biochemical parameters, differential PTGs gene expression (microarrays and qPCR) and ERK and pERK levels were assessed.

Severe sHPT was associated with PTGs, higher serum PTH, FGF23, P levels and higher mortality. It was also associated with low serum Ca levels, severe impairment of renal function, together with a marked widespread gene expression down-regulation. Interestingly, Dual Specificity Phosphatases (Dusps) 5 and 6, involved in the de-phosphorilation of pERK (inhibition of PTGs growth pathway) were highly and significantly over-expressed.



High phosphorus was associated with severe sHPT, impairment in renal function, higher mortality, severe gene expression downregulation. And overexpression of Dusp 5 and 6. The latter, together with the likely inactivation of MAPK pathway reflects the mechanism triggered to counteract the progression of sHPT .

**Acute Decrease of Serum Parathyroid Hormone after Iron Dextran Administration in Experimental Rat Model of Chronic Renal Failure with Secondary Hyperparathyroidism** Sylvie Sulkova,[1] Jitka Kuncova,[2] Renata Slavickova,[1] Jitka Sviglerova,[2] Ondrej Viklicky,[1] Milan Stengl,[2] Martin Matejovic.[3] *[1]Dept Nephrol, IKEM, Prague, Czech Republic; [2]Dept Physiol, Charles Univ Med Faculty, Pilsen, Czech Republic; [3]Dept Medicine, Charles Univ Med Faculty, Pilsen, Czech Republic.*

**Background**: Calcium-sensing receptor in parathyroid tissue (PT) is sensitive also to other methals, including iron (Fe). We tested the hypothesis that Fe administration may decrease parathyroid hormone secretion.

**Methods:** Secondary hyperparathyroidism was induced by high-phosphate (1,29%) diet in 5/6 nephrectomy rat model of chronic renal failure (CRF). Basal and time-course (30, 60, 90 and 120 min) serum PTH after bolus administration of Fe-dextran (100 ug/kg) was measured in 4 experimental groups /sham-operated rats with normal diet (SH-N) and with high-P diet (SH-P); CRF with normal diet (CRF-N) and with high-P diet (CRF-P)/. PT tissue was weighted at the end of experiment. At least 5 animals in each group completed experiment. Statistics was tested by ANOVA followed by post-hoc Sheffe´s test or by repeated measures ANOVA (STATISTICA Cz, version 7, StatSoft, CZ).

**Results:** Controls animals (SH-N) had significantly lower PT weight as well as basal serum PTH. The highest PT weight was found in CRF-P. Iron administration induced marked acute decrease in serum PTH in all subgroups with basal high PTH (CRF-P, CRF-N, SH-P). This decrease of PTH started as early as in 1st hour after Fe administration.

Weight of PT nodule and PTH levels in subgroups

| | Weight of PT nodule (mg) | PTH (pg/nodule) | Baseline serum PTH (pg/ml) | Serum PTH 60 min after Fe administration (pg/ml) |
|---|---|---|---|---|
| SH-N | 0.6 ± 0.08 | 32.7 ± 7.2 | 319 ± 38 | 364 ± 73 |
| SH-P | 2.4 ± 0.48 | 88.4 ± 19.2 | 1157 ± 110 | 691 ± 96 |
| CRF-N | 1.9 ± 0.28 | 82.5 ± 16.6 | 397 ± 27 | 309 ± 19 |
| CRF-P | 3.7 ± 0.26 | 146.15 ± 30.5 | 501 ± 66 | 373 ± 53 |

a: $p<0.05$ vs SH-N; b: $p<0.05$ vs SH-H; c: $p<0.05$ vs CRF-N; d: $p<0.05$ vs CRF-P; e: $p<0.05$ vs respective baseline value

**Conclusion:** Parenteral iron administration induced acute decrease of serum PTH. These findings should be further explored in clinical practice.

**Comparative Gene Expression in Parathyroid Oxyphil and Chief Cells** Cynthia S. Ritter,[1] Bruce H. Haughey,[2] Brent W. Miller,[1] Alex J. Brown.[1] *[1]Renal Division, Washington University School of Medicine, St. Louis, MO; [2]Department of Otolaryngology, Barnes Jewish Hospital, St. Louis, MO.*

The parathyroid glands (PTGs) of young adults are composed almost entirely of chief cells, but with age and stress another cell type appears, the oxyphil cell. These cells are thought to be derived by transdifferentiation of chief cells, but how and why they form, as well as their function, is totally unknown. Oxyphil cell number increases in PTGs of patients with chronic kidney disease (CKD) and increases further after treatment of hyperparathyroidism with calcitriol and cinacalcet (Lomonte, CJASN 2008). Here, we compared the gene expression in oxyphil and chief cells of PTGs of CKD patients by immunostaining for PTH, PTHrP, CaR, VDR and 25-hydroxyvitamin D-1a-hydroxylase (1aOHase or CYP27B1). Oxyphil cells, found in defined nodules or as diffuse, undefined "islands," were identified by H&E staining. The most impressive differential expression was seen with the 1aOHase, which was very highly expressed in oxyphil islands, to a lesser degree in oxyphil nodules, with virtually none in chief cells. PTHrP was also highly expressed in oxyphil islands, compared to trace amounts in oxyphil nodules and chief cells. Both oxyphil islands and nodules expressed PTH at a level equal to or greater than chief cells. Both the CaR and VDR were expressed in oxyphil cells, but like the chief cells, expression was variable in diffuse and nodular areas. The hypothesis that CaR activation by cinacalcet or calcitriol (indirect via Ca) leads to an increase in oxyphil cells is supported by our observation that incubation of normal rat parathyroid glands in high Ca medium led to the formation of oxyphilic cells. Studies are underway to further characterize the gene expression profile and secretome of parathyroid oxyphil cells, and to determine the role of these cells (positive or negative) in the morbidity and mortality of CKD patients.

**The Effects of Cyclooxygenase 2 Downstream mPGES1-PGE2-EP2 on the Hyperplasia of Parathyroid Gland in Uremic Patients** Chuan-Ming Hao. *Huashan Hospital, Fudan University.*

**Objective**

To explore the potential role of COX2 downstream pathway mPGES1-PGE2-EP2 in hyperplasia of uremic parathyroid gland.

**Methods**

mPGES1 and EP2 were detected by immunohistochemistry and immunoblot. Freshly excised PTG tissues were incubated for 24 hours: normal phosphate 1mM(NP), high phosphate 4mM (HP), HP with COX2 inhibitor NS398, HP with mPGES1 inhibitor MK886, and HP with EP2 antagonist AH6809. The dose-dependent effects of PGE2 and EP2 agonist butaprost ($10^{-7}$M-$10^{-5}$M) were also observed. The PTH levels were determined by DPC IMMULITE. preproPTH and PCNA of cultured tissues were assessed by realtime PCR and immunoblot.

**Results**

mPGES1 and EP2 were located in cytoplasmic, especially in the perinuclear region of PTG cells. They were expressed much more in nodular hyperplasia than those in diffuse hyperplasia glands. Immunoblot analysis supported the expression of mPGES1 and EP2 in the hyperplastic PTGs. High-phosphate treatment further increased the production of PTH compared to normal phosphate treated group (NP1.00±0.49, HP4.54±2.11, $p<0.05$). COX2 inhibitor NS398, mPGES1 inhibitor MK886 and EP2 antagonist AH6809 significantly inhibited this effect, respectively (2.00±1.24 1.88±0.58 0.80±0.76, $p<0.05$). The changes of preproPTH mRNA levels of PTGs showed the similar trend. HP treatment also induced an elevated expression of PCNA in PTGs (1.68±0.13) compared to NP treatment (1.06±0.02 $p<0.05$). Such stimulation was significantly blocked by either NS398(0.72±0.42), MK886(1.13±0.12) or AH6809(0.89±0.30). PGE2 directly induced a dose-dependent over-production of PTH and high expression of PCNA in cultured PTG tissues. Butaprost ($10^{-6}$M) produced similar changes of high PTH synthesis and PCNA expression in PTGs.

**Conclusion**

Increased expression of mPGES1-EP2 was detected in PTGs of uremic patients. Inhibition this pathway reduced the secretion of PTH and PTG cell proliferation, while PGE2 and EP2 agonist directly stimulated such reactions. These data suggest that this pathway plays an important role in the pathogenesis of secondary hyperparathyrodism.

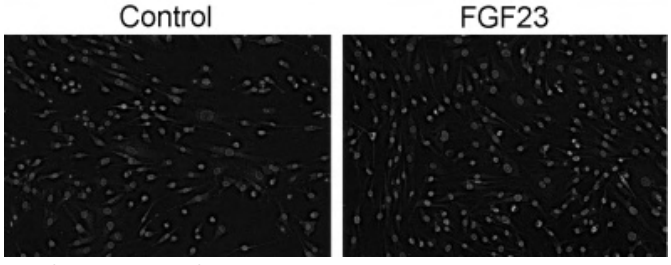
**FGF23 Modulate Osteocytes Life Span** R. C. Pereira, Harald Jueppner, Isidro B. Salusky, Katherine Wesseling-Perry. *Pediatrics Nephrology, David Geffen School of Medicine, Los Angeles, CA.*

Impaired osteoblast/osteocyte viability contributes to bone loss in pts. with osteoporosis and in kidney transplant recipients. ROD contributes to increased fracture rates, and osteocyte function is altered in CKD pts, as evidenced by increased FGF-23 and DMP1 expression in osteocytes. However, rates of osteocyte apoptosis and factors that regulate this process in CKD are unknown. We exame apoptosis in BBX from 14 pediatric pts. with CKD stages 3-5. Biochemical values were: Ca 9.1±0.2 mg/dl, P 5.1±0.4 mg/dl, Alk P'tase 364±70 IU/l, PTH (1st IMA, Immutopics$^{R}$) 357±100pg/ml, C-term FGF-23 (2nd generation Immutopics$^{R}$) 1106±295 RU/ml. Bone histology was OF (n=1), mixed disease (n=4), adynamic (n=4) and osteomalacia (n=2) and normal (n=3). Apoptosis in bone sections was assessed via *in situ* nick-end labeling (TUNEL) Klenow T-deoxynucleotidyl transferase per manufacturer's instructions (Oncogene Products). Sections incubated with vehicle alone served as negative controls; control bone samples were obtained from individuals with normal kidney function. Apoptotic osteoblasts and osteocytes were not detected in bone from CKD pts. whereas 10-20% of osteocytes were apoptotic in normal controls. To assess potential mechanisms underlying this decreased apoptotic rate in CKD bone, the mouse osteocyte cell line MLOY-4 was cultured in serum-free medium in the presence of FGF-23 (10, 50 and 100 ng/ml) or PTH (10 nM) for 24 and 48 hours. Cell death was assessed by acridine orange/ethidium bromide staining (orange death /green alive cells).



After 24 and 48 hrs of FGF23 treatment, osteocyte viability was increased by 50% at all concentrations. PTH failed to affect osteocyte viability. Thus FGF-23, which is increased in CDK pts, may prevent osteocyte cell death. Further studies are warranted to determine the mechanism by which FGF-23 mediates this affect in the context of CKD.

**PTH-Dependent Regulation of Npt2a and Npt2c Expression Appears To Involve Predominantly cAMP/PKA-Dependent Mechanisms** Hiroko Segawa,[1, 2] Akira Maeda,[1] Thomas J. Gardella,[1] Ken-Ichi Miyamoto,[2] Harald Jueppner.[1] *[1]Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA; [2]Department of Molecular Nutrition, Institution of Health Bioscience, the University of Tokushima Graduate School, Tokushima, Japan.*

Parathyroid hormone (PTH), a major regulator of renal ionic phosphate (Pi) reabsorption, regulates brush border membrane (BBM) expression of three distinct Na/Pi transporters, Npt2a, 2c, and PiT-2. It activates several signaling pathways down-stream of the PTH/PTHrP receptor (PTHR), including phospholipase C (PLC)/protein kinase C (PKC), which has been suggested to be prominently involved in the control of renal Pi transport. However, patients with pseudohypoparathyroidism (PHP), a disorder caused by maternally inherited GNAS mutations that inactivate the stimulatory G protein (Gαs), present with hyperphosphatemia due to impaired PTH-stimulated Pi excretion, thus implicating cAMP/PKA-dependent mechanisms in renal regulation of Pi homeostasis. To examine which signaling pathways down-stream of PTHR are involved in regulating Npt2a and Npt2c expression, we compared the phosphaturic actions of M-PTH(1-34) (M: Ala 1,12,Aib3,Gln10,homoArg11,Trp14,Arg19), a long-acting analog which stimulates both cAMP and IP3 formation, to those of Trp1-M-PTH(1-34), a PLC-defective variant. When injected into WT or Npt2c-null mice, each analog induced similar reductions in plasma Pi levels, as well as similar reductions in Npt2a expression. When injected into Npt2a-null mice, each analog again induced similar decreases in plasma Pi and Npt2c expression levels. Effects of each analog on Npt2a expression were rapid, whereas those on Npt2c expression were gradual. The two analogs also showed similar reductions in plasma Pi levels in mice expressing a mutant PTHR (DSEL) that signals via cAMP/PKA but not PLC/PKC. The data thus suggest that the cAMP/PKA pathway is importantly involved in the acute PTHR-dependent regulation of Npt2a and Npt2c expression, which is consistent with findings in PHP patients.

**FGF Receptors 3 and 4 Mediate Regulation of 1,25 Vitamin D Metabolism by FGF23** Jyothsna Gattineni,[1] Regina Goetz,[2] Moosa Mohammadi,[2] Michel G. Baum.[1] *[1]Pediatric Nephrology, UT Southwestern Medical Center, Dallas, TX; [2]Pharmacology, NYU Medical Center, New York, NY.*

Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone implicated in many hypophosphatemic disorders. FGF23 causes phosphaturia and decreased serum 1,25 Vitamin D levels. We have shown that FGF receptor 1 (FGFR1) is the predominant receptor for the hypophosphatemic actions of FGF23 by decreasing renal NaPi-2a and 2c expression. Studies in individual FGFR null mice have not identified the FGFR(s) mediating the regulation of vitamin D metabolism by FGF23. We have studied FGFR3FGFR4 double mutant mice (DKO) as these mice have shortened life span and are growth retarded similar to *fgf*23 null mice. The effect of FGF23 (12 mcg/mouse/BID for 4 days intraperitoneally) was examined on serum levels of phosphate, PTH, 1,25 Vitamin D, renal BBMV NaPi-2a expression and phosphate transport:

Effect of Pharmocological doses of FGF23 on Control and DKO mice

| | Control Vehicle | Control FGF23 | DKO Vehicle | DKO FGF23 |
|---|---|---|---|---|
| Serum Phosphate (mg/dl) | 8.3±0.4 (n=12) | 5.6±0.2* | 6.9±0.3 (n=9)† | 11.6±0.5* |
| Serum 1,25 Vitamin D (pmol/L) | 77.4±13.1 (n=11) | 19.2±3.7* | 173.4±32.7 (n=11)† | 216.9±47.6 |
| Serum PTH (pg/ml) | 86.8±16.2 (n=9) | 88.3±9.5 | 126.8±25.6 (n=9) | 21.3±5.1* |
| BBMV phosphate transport pmol/mg/10 secs | 176.7±10.0 (n=7) | 129.2±8.4* | 167±6.5 (n=9) | 192.7±4.2* |
| Renal BBMV NaPi-2a-ßactin expression | 0.9±0.04 | 0.7±0.06* | 0.5±0.04 | 0.8±0.05* |

* Vehicle vs FGF23 <0.05; †control vehicle vs DKO vehicle <0.05

FGF23 administration to DKO mice increased serum phosphate levels, increased renal BBMV NaPi-2a expression and renal BBMV phosphate transport, unlike control mice. Basal 1,25 Vitamin D levels were higher in DKO mice relative to control mice and did not decrease in response to FGF23. PTH levels decreased in response to FGF23 in the DKO mice while they were unchanged in the control mice. We conclude that hyperphosphatemia in DKO mice in response to FGF23 was due to decreased PTH levels and unchanged 1,25 Vitamin D levels. These data indicate that FGFR3&4 are the receptors that mediate the regulation of 1,25 Vitamin D metabolism by FGF23.

## SA-PO2137

**Fibroblast Growth Factor 23 (FGF23) and Left Ventricular Hypertrophy (LVH) in Children on Dialysis** Wacharee Seeherunvong,[1] Carolyn L. Abitbol,[1] Jayanthi Chandar,[1] Paolo Rusconi,[2] Gaston E. Zilleruelo,[1] Michael Freundlich.[1] *[1]Pediatric Nephrology, University of Miami, Miami, FL; [2]Pediatric Cardiology, University of Miami, Miami, FL.*

Cardiac death in children on dialysis is 700-fold higher than normal children and accounts for 40% of pediatric dialysis deaths. Vitamin D (D) abnormalities and ↑FGF23 levels associate with ↑ mortality risk and LVH in CKD adults. Comparable studies in children are lacking. Children and adolescents (n=36), age 15.7 ± 5.0 yr on maintenance dialysis (7 peritoneal; 29 hemo) underwent echocardiography with LV mass index (LVMI= mass/height in m $^{2.7}$) calculation (LVH defined as height-age adjusted LVMI >95%tile). All required phosphate (P) binders and 31 (86%) calcitriol or paricalcitol treatment. D insufficiency (25-OHD < 30 ng/ml) was detected in 58% (< 20 ng/ml in 29%). Serum Ca was normal (9.42 ± 0.7 mg/dl) and most had ↑serum P (6.6 ±1.2 mg/dl). Parathyroid hormone (PTH) was adequately controlled in most (384 ± 418 pg/ml). Median FGF23 concentration (n=17) was 21,450 RU/ml (normal <230 for age < 17 yr), mean log FGF23 was 4.29 ± 0.46. Plasma Pro brain-natriuretic peptide (BNP) was ↑ in all (7179 ± 14952 pg/ml, normal 0-125). Average LVMI was 49.6 ± 27.4 g/m $^{2.7}$ with LVH in 49% of patients. In univariate analyses, age, time on dialysis, and serum levels of P, PTH, 25(OH)D or $1,25(OH)_2D_3$ did not associate significantly with LVMI. However, systolic and diastolic BP centiles (p=0.03), Pro BNP (<0.001) and logFGF23 (p=0.03) correlated with LVMI. Multiple regression analysis for cardiac risk variables significantly (p<0.05) associated with LVMI in univariate analysis revealed that the log FGF23 provided the highest contribution to LVMI (p=0.07). Each standard deviation ↑ in log FGF23 resulted in a 7.4 g/m $^{2.7}$ LVMI increase. Thus, ↑LVMI and LVH in children and adolescents on maintenance dialysis correlate strongly with the biomarker Pro BNP. Our preliminary observations indicate that ↑FGF23 levels are strongly associated with LVMI in young dialysis patients. Larger studies are needed to detect more robust associations between FGF23 and LVMI and its use as a predictive marker of cardiovascular outcomes.[/bold]

## SA-PO2138

**Elevation of Phosphate but Not Circulating FGF23 Increases Mortality in the Jck Model of CKD-MBD** Shiguang Liu, Joseph H. Boulanger, Wenping Song, Yves Sabbagh, Susan Schiavi. *Endocrine and Renal Sciences, Genzyme Corp, Framingham, MA.*

A biphasic increase in serum FGF23 is observed during chronic kidney disease (CKD) progression. Small increases (2-3X) are associated with stage 2-3 suggesting that FGF23 induction may be an adaptation to initial renal damage that promotes increased fractional phosphate (Pi) excretion. In late stages of CKD, FGF23 levels become overwhelming elevated by tens of thousand fold and significantly correlate with mortality. This association is independent of serum Pi levels despite the known role of Pi on mortality. To first confirm the influence of Pi on mortality of jck mice, a genetic model of polycystic kidney disease that mimics the progression of CKD-Mineral and Bone Disorder, animals were maintained on diets containing either normal (0.4%) or high (1.0%) Pi. Although increased dietary Pi content had no apparent influence on renal function, it significantly increased serum Pi, PTH, $1,25(OH)_2D_3$ and FGF23. Importantly, the life span of Jck mice was significantly decreased from an average of 25 to 20 weeks ($p < 0.05$). As a means of further assessing the role of FGF23 and Pi on mortality, we utilized high pressure tail vein (HPTV) injection to induce a more rapid and severe induction of supra-physiological FGF23 levels in the Jck mouse fed either normal or high Pi diets. HPTV injection of FGF23 plasmid increased serum FGF23 levels from ~100 to 100,000 pg/ml at 8 weeks of age that was sustained for at least 8 weeks post HPTV injection. FGF23 over-expression slightly lowered serum Pi levels in the early stages of CKD (from 8 to 13 weeks of ages) with both diets, however, the serum Pi levels of the FGF23 group on high-Pi diet was not lower than the vector group on normal Pi diet. In addition, overexpressing FGF23 did not prevent the hyperphosphatemia accompanying declining kidney function. Importantly, the supra-physiological FGF23 induction by HPTV early in CKD did not significantly increase renal dysfunction or mortality regardless of Pi levels. These results suggest that Pi rather than FGF23 contributes largely to mortality in the setting of CKD and underscores the importance of managing Pi early in CKD.

**Effects of 1, 25 Dihydroxyvitamin D3 on Calcium and Phosphorus Homeostasis in the Mouse** David J. Berlove, Alexander Brezzani, Kelly Keefe, Robert Sacchiero, Zhonglin Zhao. *Preclinical Pharmacology, Genzyme, Waltham, MA.*

Maintenance of calcium and phosphorus balance is critical for a wide range of physiologic functions. In the presence of renal disease, dysregulation of these essential minerals is common and a variety of pathological sequelae ensue, including vascular calcification, bone disorders and acceleration of kidney damage.

One consequence of renal damage is a loss of 1, 25 dihydroxyvitamin D3 (D3) which is essential for mineral balance and other functions. Renal failure patients are typically supplemented with D3 which may have unintended consequences in hyperphosphatemic patients. We have chosen to explore some of the effects of D3 administration on phosphate and calcium-related parameters in adult C57/Bl6 mouse.

Our initial study surveyed the effects of a single injection of D3 (IP, dose range 0-5000ng/kg) in mouse. Ileum, jejunum and kidney were collected at 6 hours. Treatment had no effect on mRNA expression of the renal phosphorus transporter, NaPi-2a. The renal phosphorus transporter, NaPi-2c, which was expressed at lower basal levels, increased around 50% at all doses from 300ng/kg. The intestinal phosphorus transporter NaPi-2b was up-regulated in jejunum 4-5X at doses from 600-5000ng/kg. There was a pronounced dose-dependent increase in the D3 metabolizing enzyme, cyp24a1, in both kidney and jejunum. D3 receptor expression was not affected in any tissue. Urinary phosphorus excretion was elevated for the 6 hours after D3 administration with a strong trend towards increased Ca excretion.

A follow-up study exploring the time-course of changes (0-24 hours) demonstrated that the massive increase in Cyp24a1 mRNA peaked at 3-6 hours and then rapidly subsided. Expression of NaPi-2b mRNA was more complex with significant elevations at 3 and 6 hours followed by a subsequent decrease, below basal expression at 24 hours. Serum phosphorus was increased while PTH levels were reduced. We conclude that pharmacologic treatment with D3 significantly alters expression of phosphate transporters in the intestine and urinary excretion of phosphate. However the effects over longer periods of treatment may be different than those observed very acutely.

**Analysis of the Parathyroid Glands in Hemodialysis Patients with Secondary Hyperparathyroidism Refractory to Cinacalcet Hydrochloride** Keiichi Sumida, Yoshifumi Ubara, Junichi Hoshino, Rikako Hiramatsu. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Cinacalcet hydrochloride (cinacalcet) increases sensitivity of calcium sensing receptors (CaSR) to activation by extracellular calcium, and thus suppresses parathyroid hormone (PTH) release, while controlling calcium-phosphate balance. There have been few studies of histopathological alterations in hyperplastic parathyroid glands in secondary hyperparathyroidism (SHPT) after cinacalcet administration.

Hemodialysis patients with severe SHPT were divided into those treated with and without cinacalcet (cinacalcet group and conventional group, respectively; both *n*=12). Total maximal parathyroid gland weight and maximal to minimal parathyroid gland weight ratio were significantly higher in the cinacalcet group compared with the conventional group (1798.7±1658.3 mg *vs.* 764.2±471.1 mg, *P*=0.018, 15.8±13.9 *vs.* 6.6±4.2, *P*=0.047, respectively).

Significant increases were observed in oxyphil cell area (61.7%±17.1% *vs.* 36.7%±15.6%, *P*=0.001), hemosiderosis score (1.50±1.24 *vs.* 0.42±0.51, *P*=0.029), and CaSR expression (1.67±0.75 *vs.* 0.75±0.75, *P*=0.025) in the former than the latter group. These findings indicated that cinacalcet induced specific qualitative alterations of hyperplastic parathyroid glands in patients with severe SHPT.

Our results suggest new effects of cinacalcet on hyperplastic parathyroid glands, although further analyses are needed to confirm the physiopathological mechanisms responsible for these alterations.

**Combination Therapy with Cinacalcet for Patients with Secondary Hyperparathyroidism (SHPT) during Intravenous Vitamin D Treatment – A Randomized Controlled Trial Comparing Dose Escalation of Vitamin D Pharmaceutical Infusion and Dose Escalation of Calcium Carbonate** Shigeo Negi,[1] Takashi Shigematsu.[2] *[1]Division of Nephrology and Blood Purification Medicine, Wakayama Medical University, Wakayama City, Kimiidera, Japan; [2]Division of Nephrology and Blood Purification Medicine, Wakayama Medical University, Wakayama City, Kimiidera, Japan.*

[Aims] (1) To investigate (1) the efficacy of combined administration of Cinacalcet for patients with SHPT during Maxacalcitol (OCT) treatment. (2) To compare dose escalation of OCT and dose escalation of calcium (Ca) preparation for hypocalcemia associated with Cinacalcet administration in a prospective, multicenter, randomized controlled trial.

[Methods] Cinacalcet was concurrently administered to patients undergoing treatment with OCT and having an intact-PTH ≥ 180pg/ml, adjusted Ca ≥ 9.0mg/dl, and serum phosphorus concentration ≥ 3.5mg/dl. The patients were randomly divided into either the OCT dose-escalation group or Ca preparation dose-escalation group, followed for 48 weeks, and analyzed for achievement rate according to the Clinical Practice Guideline for the Management of Secondary Hyperparathyroidism in Chronic Dialysis Patients from the Japanese Society for Dialysis Therapy (JSDT).

[Results] (1) The combination therapy with Cinacalcet was effective in all 94 patients with SHPT. (2) Of 52 patients, 25 were divided into the OCT dose-escalation group, and of 42 patients, 19 were divided into the Ca preparation dose-escalation group. There was no significant difference in the achievement rate for each factor of Ca, P, and PTH between the two groups. The achievement rate for the two factors of Ca and P was significantly higher in the OCT dose-escalation group ($p < 0.05$) and that for the three factors of Ca, P, and PTH tended to be higher in the OCT dose-escalation group ($p = 0.058$).

[Conclusions]

(1) The combination therapy of OCT and Cinacalcet was effective for patients with SHPT showing resistance to OCT. (2) Dose escalation of OCT was more effective than that of Ca preparation for hypocalcemia induced by Cinacalcet.

**Cinacalcet for Secondary Hyperparathyroidism Lowers FGF23 Levels in Patients Receiving Hemodialysis** Masahiro Koizumi,[1] Hirotaka Komaba,[1] Hisae Tanaka,[1] Shohei Nakanishi,[2] Akira Fujimori,[3] Masafumi Fukagawa.[1] *[1]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [2]Chibune Kidney and Dialysis Clinic, Osaka, Japan; [3]Division of Blood Purification and Kidney Center, Konan Hospital, Kobe, Japan.*

**Background.** Fibroblast growth factor 23 (FGF23) is a bone-derived hormone that plays an important role in the regulation of phosphate and vitamin D homeostasis. Serum levels of FGF23 are markedly elevated in patients with end-stage renal disease and associated with resistance to active vitamin D therapy for secondary hyperparathyroidism (SHPT). However, little is known whether cinacalcet therapy modulates FGF23 secretion and whether FGF23 levels predict response to this therapy.

**Methods.** This was a post hoc analysis of data from a 52-week, multicenter, open-label, single-arm trial that examined the effect of cinacalcet on SHPT in patients undergoing hemodialysis. Alteration of vitamin D dosage was permitted only on the grounds of patient safety. Full-length intact FGF23 was measured at baseline and study weeks 12, 24, and 52, using serum samples of subjects who completed the study (N = 55).

**Results.** Treatment with cinacalcet resulted in a significant decline in log-transformed FGF23 levels by 9% and this response was sustained over 52 weeks. Changes in log FGF23 levels were significantly and positively associated with changes in serum phosphate ($r = 0.332$, $P = 0.013$) and calcium ($r = 0.590$, $P < 0.001$) independently of changes in parathyroid hormone levels and active vitamin D dose. Logistic-regression analysis showed that baseline FGF23 levels did not predict the likelihood of achieving an intact PTH <180 pg/ml at the study end (odds ratio, 0.134; 95% CI, 0.901 to 2.177).

**Conclusions.** Cinacalcet lowers serum FGF23 levels in patients with SHPT, even in the setting of sustained active vitamin D therapy which should increase FGF23 secretion from the bone. Further studies are needed to elucidate the precise mechanism of FGF23 reduction by cinacalcet and whether this results in improved patient survival.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2143**

**Cinacalcet HCl Influences Frequency of Parathyroidectomy for Advanced Secondary Hyperparathyroidism** Yoshihiro Tominaga. *Transplant & Endocrine Surgery, Nagoya Second Red Cross Hospital, Nagoya, Aichi, Japan.*

Requirement of parathyroidectomy (PTx) for secondary hyperparathyroidism (SHPT) due to chronic kidney disease (CKD) may be influenced by the medical treatment, guideline of the treatment and medical insurance system ect in each country. Recent induction of Cinacalcet HCL (cinacalcet) may significantly reduce the frequency of PTx for SHPT. However, the influence by cinacalcet has not been clarified.

We established the Japanese Association of Parathyroid Surgeons. The aims of the association are (1) to establish registration system to evaluate the annual number of PTx, the surgical indications, procedure and outcomes (2) to propose surgical indications for advanced SHPT to physicians on surgeons view point (3) to distribute adequate surgical technique and network system (4) to perform clinical studies concerning advanced SHPT and PTx in multi-centers.

We picked up the institutes in which PTx for SHPT was routinely performed base on questionnaires to 4036 hemodialysis (HD) centers in Japan.Out of 340 institutes 109 agreed to participate in the association. Based on DOPPS and Japanese Society of Dialysis Therapy (JSDT) studies, more than 90% of PTx for SHPT could be recruited in our association.

At first we evaluated the annual number of initial PTx and re-operation for SHPT in each institute by questionnaires. Total annual number of initial PTx for SHPT from 2004 to 2009 were 1137, 1154,1375,1749,1042,490 operations respectively. In Japan the number of PTx increased from 2004 to 2007. In 2006 JSDT established the guideline of treatment for SHPT in HD patients and the guideline proposed that the PTx should be performed at relatively early stage of SHPT to acquire good patient's survival. And the number of PTx significantly decreased from 2008 to 2009. Cinacalcet has been available from the beginning of 2008 in Japan.

In conclusion in Japan the frequency of PTx for SHPT significantly decreased after the induction of cinacalcet. Surgical indications and outcomes in era cinacalcet should be evaluated and the adequate treatment including PTx for advanced SHPT should be established.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2144**

**Residual Renal Function Is an Independent Determinant of Serum FGF-23 Levels in Prevalent Hemodialysis Patients** Liesbeth Viaene,[1] Bjorn K. I. Meijers,[1] Bert Bammens,[1] Vanrenterghem Yves,[1] Dirk Vanderschueren,[2] Pieter Evenepoel.[1] *[1]Nephrology, University Hospital, Leuven, Belgium; [2]Endocrinology, University Hospital, Leuven, Belgium.*

Introduction: Poor residual renal function (RRF) and high FGF-23 levels are associated with arterial stiffness, left ventricular hypertrophy and increased (cardiovascular) mortality. Therapy with active vitamin D, dietary phosphate loading and high serum phosphate and calcium levels have been associated with high serum FGF-23 levels. The present study aimed to investigate the impact of RRF on FGF-23 levels in hemodialysis (HD) patients. Methods: We performed a cross-sectional observational study in 68 prevalent HD patients (36 male, age 71 ± 12 yrs, dialysis vintage 31 ± 33 months). Mid-week predialysis blood samples were collected and analyzed for parameters of mineral metabolism including calcidiol,calcitriol, biointact PTH, and FGF-23 (Kainos). Weekly total phosphate clearances as well as mass removals were calculated from urine and dialysate collections. Residual glomerular filtration rate (rGFR), determined as the arithmetic mean of renal urea nitrogen and creatinine clearance, below 1 ml/min/1.73m² and/or a 24-h urine output < 100 ml was defined as anuria. Results: In multivariate regression analysis, rGFR was found to be inversely associated with serum FGF-23 levels, independent of dialysis vintage, total phosphate clearance, estimates of dietary phosphate intake (i.e. nPNA and total phosphate mass removal), active vitamin D therapy and serum phosphate and calcium levels. rGFR, serum phosphate and calcium levels and active vitamin D therapy explain 66 % of the variation in FGF-23 ($p<0.0001$). The 38 anuric patients had borderline higher FGF-23 levels (2219 vs. 1129 ng/L, median, $p = 0.09$) but similar serum phosphate (4.6 vs. 4.4 mg/dL, mean) and calcium levels (9.4 vs. 9.5 mg/dL, mean). Conclusion: Our data indicate that RRF is an important determinant of FGF-23 and favour the hypothesis that the ailing kidney directly contributes to raising FGF-23 levels, e.g. by a decreased expression of an inhibitor or by less clearance. Whether FGF-23 is associated with poor outcomes independent of RRF, or vice versa, remains to be clarified.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2145**

**Hepcidin and Disordered Mineral Metabolism in CKD** Cristiane Carvalho,[1] Tamara Isakova,[1] Gordana Olbina,[2] Myles S. Wolf,[1] Mark E. Westerman,[2] Orlando M. Gutierrez.[1] *[1]University of Miami; [2]Intrinsic Life Sciences.*

**Intro:** Hepcidin regulates iron homeostasis. Elevated hepcidin levels block iron absorption in the gut and iron release from macrophages and hepatocytes, restricting iron availability for erythropoiesis. Because hepcidin secretion is induced by inflammation, increased hepcidin levels are thought to play a key role in anemia of chronic inflammatory conditions, such as chronic kidney disease (CKD). Disorders of mineral metabolism are common in CKD and have been implicated in the pathogenesis of inflammation. Few studies examined the association between hepcidin and markers of mineral metabolism in CKD.

**Methods**: We examined the associations between hepcidin, iron, and markers of mineral metabolism in 125 patients with pre-dialysis CKD. Hepcidin was measured by competitive ELISA.

**Results:** Hepcidin levels were inversely correlated with eGFR ($r=-0.3$, $P<0.001$), and linearly correlated with TSAT ($r=0.2$, $P=0.01$) and ferritin ($r=0.7$, $P<0.001$). In univariate analyses, higher phosphate and parathyroid hormone (PTH) levels and lower calcitriol levels were associated with higher hepcidin levels ($P<0.001$ for all). In addition, there was a trend towards an inverse association between fibroblast growth factor 23 (FGF23) and hepcidin ($P=0.05$). In multivariable-adjusted analyses, log FGF23, log calcitriol, phosphate, and log PTH levels were independently associated with log hepcidin levels, whereas the association between eGFR and hepcidin was no longer significant (Table).

**Conclusion:** Abnormalities in phosphate and vitamin D metabolism were associated with increased hepcidin levels in patients with pre-dialysis CKD, and attenuated an inverse association between eGFR and hepcidin. These results suggest that disorders of mineral metabolism contribute to increased hepcidin secretion in CKD. Whether inflammation mediates this link requires further study.

**Stanniocalcin-1 (STC1) Is Upregulated in the Tunica Media of Calcifying Aortas of Uremic Rats** Luis F. Michea, Peter Murphy, Magdalena Gonzalez. *ICBM, Facultad de Medicina, Universidad de Chile, Santiago, Chile.*

Medial vascular calcification (VC) of large arteries is frequent in end-stage renal disease and correlates with hyperphosphatemia. Is now recognized that VC involves phenotypic trans-differentiation of vascular smooth muscle/mesenchymal cells into osteogene-expressing, sharing many features with embryonic bone formation. STC1 is a homodimeric glycoprotein, acting as an autocrine/paracrine factor that promotes osteochondrogenic differentiation in developing bone of mammals. We hypothesized that the expression of STC1 would be increased in VC observed in chronic renal failure (CRF). Male SD rats were nephrectomized (5/6 kidney ablation) and separated into the following groups: standard diet, high phosphate diet (HP), vitamin D plus HP. These groups were compared to sham operated rats under standard or HP diet. Physiological parameters were determined. After 5 weeks animals were killed to obtain blood, urine and aorta samples for biochemical and histological studies. We observed an increase in blood pressure and creatinine in all NPX groups (n=6,P<0,05). HP diet caused increased plasma phosphate levels in all NPX groups (n=6,P<0,05). NPX increased the expression of STC1 in rat aorta (1,6 fold,P<0.05). HP diet increased STC1 expression in aorta of NPX rats (2,3 fold compared to normal,P<0.05) and in aorta from NPXVD+HP. STC1 protein abundance increased 3.0±0.4 fold in NPX-HP and 4.5±0.9 fold in NPXHP+VD, as compared to SHAM aorta (P<0.05). Aortic sections from NPX rats showed the presence of STC1 in tunica media. HP and HP+VD caused a further increase in STC1 immunodetection, consistent with western blot studies. To evaluate the potential role of phosphate and VD as upregulators of STC1 expression in aorta, aortic explants were incubated in medium supplemented with HP (2.5 mM), VD (100nM), VD+HP or vehicle during 48 hours. As compared to vehicle treated control explants, HP, VD and HP+VD increased STC1 mRNA abundance (25,8±10,3;15,3±9,9;48,2±6,1 fold;n=4;P<0.05). Our data demonstrate increased expression of STC1 in calcifying aorta of NPX, which can be induced by HP and VD. Supported by FONDECYT 1090223, NMII P07/088F, Fondecyt-FONDAP 15010006.

### SA-PO2147

**Regulation of Calcitriol and Urinary Phosphate Excretion in the Immediate Post Transplantation Period: A Role for FGF-23** Katherine Wesseling-Perry,[1] Justine Bacchetta,[3] Eileen W. Tsai,[1] Robert B. Ettenger,[1] Harald Jueppner,[2] Isidro B. Salusky.[1] *[1]Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Endocrine Unit, Mass General Hospital, Boston, MA; [3]Hospices Civils de Leon, Leon, France.*

Levels of FGF-23 have been implicated in hypophosphatemia and suppressed calcitriol levels in the first year post transplantation. FGF-23 levels are elevated in dialysis pts. and profound changes in mineral metabolism occur immediately post-transplantation; however, the role of pre-transplant FGF-23 levels in these alterations is unknown. Biochemical values were obtained in 44 pediatric renal transplant pts. age 16.3 ± 2.9 yrs at baseline, daily for the first 5 days post-transplant, and at 3 and 6 mos. FGF-23 correlated with serum creatinine (r=0.37, p<0.05) and 1,25$(OH)_2$D (r= -0.32,p<0.05), and PTH (r= -0.31,p<0.05) at baseline. Subjects were divided into two subgroups: high (above the median) v. low (below the median) baseline FGF-23. Data are expressed as median (IQ range).

| | Baseline FGF-23<759 RU/ml ("low FGF") | | Baseline FGF-23>759 RU/ml ("high FGF") | |
|---|---|---|---|---|
| | Baseline | Day 5 | Baseline | Day 5 |
| S-Cr (mg/dl) | 5.9 (2.7, 8.6) | 1.7 (1, 2.6)* | 8 (5.5, 10) | 1.2 (0.8, 2.1)* |
| S-P (mg/dl) | 4.6 (4.1, 5.2) | 5.4 (2.6, 3.9)* | 4.8 (4.3, 6.1) | 5.5 (2.1, 4.5)* |
| 1$^{st}$ PTH (pg/ml) | 288 (193, 410) | 95 (58, 158)* | 152 (82, 290) | 68 (52, 126)* |
| 1,25$(OH)_2$ vitamin D (pg/ml) | 23.8 (10.7, 57.2) | 44.4 (28.4, 62.9)* | 15.1 (2, 21.4) † | 15.4 (5.8, 35.5) † |

| $FE_{PO4}$ (%) | 49 (42, 73) | 24 (12, 37)* | 50 (39, 64) | 36 (18, 59)* † |
| U-FGF-23/Cr (RU/mg) | 1.68 (0.48, 5.96) | 0.36 (0.22, 0.90)* | 12.4 (1.4, 183) † | 0.35 (0.18, 1.07)* |

*p≤0.05 from baseline
†p≤0.05 between groups

The effect of baseline FGF-23 level on 1,25$(OH)_2$D, phosphate, and $FE_{PO4}$ after kidney transplant was evaluated using a mixed model. Baseline 1,25$(OH)_2$D levels did not differ between groups. 1,25$(OH)_2$D were higher in pts with low baseline FGF-23 levels than in pts. with high FGF-23 during the first five days; no differences were observed by 3 and 6 mos. Baseline FGF-23 was not associated with S-P following kidney transplant; however, $FE_{PO4}$ was significantly higher in pts with high baseline FGF-23 in the first 5 days. Thus, pre-transplant FGF-23 values have significant impact on calcitriol levels and phosphate excretion in the early transplant period; the effect of pre-transplant FGF-23 levels are attenuated by 3 months post-op.

**Serum Phosphate and FGF-23 Levels Increase in Incident Peritoneal Dialysis Patients along the Decline of Residual Renal Function** Liesbeth Viaene,[1] Bert Bammens,[1] Vanrenterghem Yves,[1] Dirk Vanderschueren,[2] Pieter Evenepoel.[1] *[1]Nephrology, University Hospital, Leuven, Belgium; [2]Endocrinology, University Hospital, Leuven, Belgium.*

Introduction: Poor residual renal function (RRF) and a disordered mineral metabolism are associated with increased mortality in peritoneal dialysis (PD) patients. Information about the impact of RRF on mineral metabolism is scanty. Methods: A prospective observational cohort study with data collection 2, 6, 12 and 24 months after start of PD was performed in 35 patients (19 male, age 55 ± 17 year). Mid-day blood samples were collected and analyzed for parameters of mineral metabolism including calcidiol, calcitriol, biointact PTH and FGF-23 (Kainos). Residual glomerular filtration rate (rGFR) was determined as the arithmetic mean of renal urea nitrogen and creatinine clearance. Differences between time points were analyzed by Wilcoxon signed-rank test (month 2 vs 24) and linear mixed models (LMM). Results: rGFR significantly declined over time (LMM p<0.0001). Peritoneal clearances tended to increase but did not compensate for the declining renal clearances. Dietary protein intake, as estimated by nPNA, and phosphate binder therapy did not change, however serum phosphate and FGF-23 levels significantly increased over time (LMM). Similar results were obtained in 18 patients free of active vitamin D therapy during the study period. Conclusion: Serum phosphate and FGF-23 levels increase in incident PD patients along the loss of RRF. Whether the increasing FGF-23 levels are a direct consequence of the ailing kidney (e.g. less expression of an inhibitor, less clearance) and/or secondary to the increased phosphate levels remains to be investigated.

### SA-PO2149

**Effect of Different Ergocalciferol Dosing on Mineral Metabolism and Anemia Management in End Stage Kidney Disease** Neenoo Khosla, Junine Darby Degraf, Hongyan Du, Jaime N. Sua, Derek Larson, L. Tammy Ho, Stuart M. Sprague. *Nephrology, Northshore University Healthsystem, Evanston, IL.*

There is increasing interest in the impact of 25-hydroxyvitamin D (25D) repletion in patients with end stage kidney disease (ESKD). It is not known what dose of 25D should be given or what clinical effect repletion of 25D will achieve. To explore these questions Ergocalciferol (Ergo) was administered to hemodialysis (HD) patients at two dosing strategies. In 2 HD units (Group 1), patients with 25D levels <30 ng/ml were prescribed 50,000 units of Ergo weekly, while patients with levels>30 ng/ml were given 50,000 units monthly. In the third unit, all patients were given 50,000 units weekly (Group 2) for 25D <50 ng/mL. Patients were followed prospectively with baseline and quarterly labs for 6 months. Change from month 0 to 6 was calculated from difference of values with assigned rank test to assess significance. Spearman's correlation coefficient and a Wilcoxon two sample test was used to assess the difference between the two groups.

Baseline 25D median values for Group 1 was 19.5 versus Group 2 at 22.7 ng/mL (p=.135). Additional baseline lab values were similar except Group 1 had a higher baseline alkaline phosphatase value (82 vs 62.5 I.U.).

Mean 25D levels increased to 33.4 and 44 ng/ml for Groups 1 and 2 respectively, with a significantly greater increase in those with the more aggressive treatment. There was no effect on parameters of mineral metabolism in either group. There was a significant decline in Epo dosing with no change in Hgb for both Group 1 and 2. Although there was no change in iron dosing or % iron saturation in either group, those who received the higher dose of Ergo had a significant decrease in ferritin.

In conclusion, weekly dosing of Ergo for 25D <50 raises 25D levels to a greater extent compared to dosing based on 25D<30 and this was associated with a lower ferritin and decreased requirement for Epo. These data suggest that increasing the 25 D level may result in a decreased inflammatory state. Further studies are needed to explore these findings.

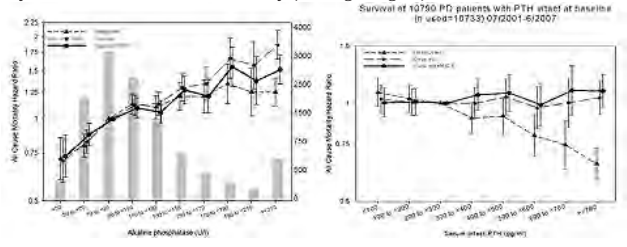
**SA-PO2150**

**Association of Mortality with Serum Alkaline Phosphatase (AlkPhos) and Parathyroid Hormone (PTH) in Chronic Peritoneal Dialysis (CPD) Patients** Kamyar Kalantar-Zadeh,[1] Uyen Duong,[1] Csaba P. Kovesdy,[3] Allen R. Nissenson,[4] Keith C. Norris,[5] Rajnish Mehrotra.[2] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Salem VA Medical Center, Salem, VA; [4]Davita, Lakewood, CO; [5]King-Drew School of Medicine, Lynwood, CA.*

**Background:** Serum AlkPhos may be a better mortality predictor than PTH in dialysis patients (pts). We examined this hypothesis in CPD pts, since the spectrum of bone disease may vary by dialysis modality.**Methods:** We examined cohort of all CPD pts from July 2001 through June 2007. **Results:** We identified 12,422 CPD pts who had baseline AlkPhos and PTH measures. They were 54±16 years old, 47% women and 23% African Americans. Serum AlkPhos was divided into 10 preselected groups by increments of 20 U/L. Higher AlkPhos was associated with increased death risk including adjustment for case-mix and malnutrition-inflammation complex syndrome. Death hazard ratios (HR) and 95% CIs for AlkPhos groups >130 U/L were 1.3(1.1-1.4), 1.2(1.1-1.4), 1.6(1.3-1.8), 1.4(1.1-1.7), and 1.5(1.3-1.7) respectively. We also found that lower AlkPhos levels were independently associated with better survival: Death HRs (95% CI) for AlkPhos in 50-<70 and ≤50 U/L were 0.7(0.6-0.9), 0.8(0.7-0.9), respectively (see Left Figure). By contrast, eight a preselected groups of PTH <100 pg/ml to ≥ 700pg/ml and 6 groups of 100 pg/ml increments in-between did not show any notable association with mortality (see Right Figure).



**Conclusions:** In this CPD cohort, increase in AlkPhos (≥130U/L) was associated with increase in all-cause mortality and decrease in Alkphos (≤70U/L) with greater survival, whereas PTH did not exhibit death association. Additional studies to examine utility of AlkPhos for clinical decision making in CPD patients are indicated.

**Evaluation of 16 Months of Clinical Use of Cinacalcet in Haemodialysis and Peritoneal Dialysis Patients: An Observational Study in Belgium (ECHO-B)** Frederic D. Debelle,[1] Gert Meeus,[2] Michel Dhaene,[1] Georges F. M. Cornet,[3] Xavier Warling,[4] Sofie Jamar,[5] Evemie Schutyser,[6] Michel Y. Jadoul.[7] *[1]RHMS, Baudour; [2]AZ Groeninge, Kortrijk; [3]CH Peltzer-La Tourelle, Verviers; [4]CHR de la Citadelle, Liège; [5]Imelda, Bonheiden; [6]Amgen Belgium; [7]UCL St-Luc, Brussels.*

In this Belgian observational study we investigated the effectiveness and treatment patterns of cinacalcet in dialysis patients with secondary hyperparathyroidism (SHPT). Data from 81 SHPT patients from 20 centers were collected from 6 months before to 16 months after cinacalcet initiation. Results are presented as means±SD, unless indicated otherwise. Follow-up time after cinacalcet initiation was 15.4±2.7 months. Patients were 48% male, aged 58±16 (SD) years and on dialysis for 5.2±5.7 years. They had markedly elevated intact parathyroid hormone (iPTH) levels (860±526 pg/ml) and elevated phosphorus (P) levels (5.7±1.5 mg/dL) whereas albumin-corrected calcium (Ca) concentration was 9.4±0.9 mg/dL at baseline (cinacalcet initiation).

At baseline, the proportion achieving the NKF-K/DOQI™ targets was: PTH (1%), P (40%), Ca (54%), and CaxP (48%). These values were 25%, 47%, 48% & 81% at 6 months, and 42%, 52%, 34% & 80% at 16 months after cinacalcet initiation, respectively. The proportion of patients reaching both the iPTH and CaxP targets was 21% at 6 months and 33% at 16 months *versus* 2% at baseline. Maximum reductions of Ca (-7.5%), P (-11.9%) and CaxP (-17.6%) were seen at 4 months, whereas iPTH levels were even further reduced by 36% at 4 months and 51% at 16 months. The primary endpoint (achievement of an iPTH level between 150 and 300 pg/ml and/or a reduction of 30% or more within 4 months of cinacalcet start) was achieved in 80% of patients.

Mean and median Cinacalcet doses were 48 and 30 mg in the 6th month, and 52 and 51 mg in the 16th month, respectively. Sevelamer use decreased upon cinacalcet initiation, while doses of Ca-containing P binders slightly increased. The data from this observational study are in line with published randomized controlled trials and larger observational studies, and further support the use of cinacalcet for the treatment of SHPT in dialysis patients.

**SA-PO2152**

**Effect of Intravenous Iron Therapy on Serum FGF23 Levels and Mineral Metabolism in ESRD Patient Undergoing Hemodialysis** Yoko Takeda,[1] Hirotaka Komaba,[2] Shunsuke Goto,[1] Keiji Kono,[1] Kentaro Nakai,[1] Hideki Fujii,[1] Shinichi Nishi,[1] Masafumi Fukagawa.[2] *[1]Division of Nephrology and Kidney Center, Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan; [2]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Kanagawa, Japan.*

**INTRODUCTION AND AIMS:** Fibroblast growth factor 23 (FGF23) induces urinary phosphate excretion, suppresses 1,25-dihydroxyvitamin D synthesis, and inhibits parathyroid hormone (PTH) secretion. Recent data suggest that FGF23 plays a role in the development of iron-induced hypophosphatemia in subjects with normal kidney function. The aim of this study was to examine the effect of intravenous iron therapy on serum FGF23 levels and mineral metabolism in patients undergoing hemodialysis.

**METHODS:** This prospective study enrolled 27 patients who were receiving hemodialysis for more than three months and had iron-deficiency anemia defined by a hemoglobin concentration less than 10.5 g/dl and serum ferritin less than 100 ng/ml. Intravenous saccharated ferric oxide(SFO) at a dose of 40 mg was administered thrice weekly over three weeks. Serum FGF23, intact PTH and other parameters were prospectively monitored for five weeks.

**RESULTS:** Intravenous iron therapy resulted in a significant increase in hemoglobin and ferritin levels at wk 3 (10.0 ± 0.5 g/dl to 10.6 ± 0.5 g/dl; P < 0.001, 30.1 ± 22.7 to 153.83 ± 83 ng/ml; P <0.001, respectively). Serum FGF23 increased from 4906 ± 6201 pg/ml at baseline to 8824 ± 11041 pg/ml at wk 3 (P = 0.031), whereas intact PTH decreased from 146 ± 109 pg/ml to 109 ± 77 pg/ml (P <0.001). TRACP-5b decreased from 477 ± 295 mU/dL to 412 ± 254 mU/dL (P <0.001) at wk 3. These levels gradually returned to baseline by wk 5. There were no significant changes in serum calcium and phosphorus during the study period.

**CONCLUSIONS:** Intravenous iron therapy results in further increase in FGF23 levels in hemodialysis patients. This increase does not induce hypophosphatemia in the absence of functioning kidney, but may result in transient PTH suppression and its related decreased bone resorption.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2153**

**Racial Differences in Vitamin D, Parathyroid Hormone and Fibroblast Growth Factor-23 Levels in Patients with Severe Chronic Kidney Disease** Anna Jeanette Jovanovich,[1] Michel B. Chonchol,[1] Alfred K. Cheung,[2,4] James S. Kaufman,[3] Tom H. Greene,[4] William L. Roberts,[4] Gerard John Smits,[1] Jessica B. Kendrick.[1] *[1]University of Colorado Denver Health Sciences Center, Denver, CO; [2]VASLCHCS, Salt Lake City, UT; [3]VA Boston Healthcare System, Boston, MA; [4]University of Utah, Salt Lake City, UT.*

Purpose: Abnormalities of mineral metabolism have not been described across races in patients with severe CKD.

Methods: Study was conducted among patients with severe CKD, but not on dialysis, who participated in the Homocysteine in Kidney and End Stage Renal Disease study. 25-hydroxyvitamin D (25(OH)D), calcitriol (1,25(OH)2D), intact parathyroid hormone (iPTH), and fibroblast growth factor (FGF-23) levels were measured in plasma samples. Multivariable regression analyses were performed to examine the association between race and vitamin D, iPTH, and FGF-23 levels.

Results: There were a total of 1099 patients with an eGFR of 18 ± 6.5 mL/min/1.73m2. 57% of the cohort was non-Hispanic white (NHW), 26% was non-Hispanic black (NHB) and 17% were categorized as other races. NHB had the lowest 25(OH) D levels when compared to NHW and others (15.8±9.0 vs. 22±10 vs. 24±10 ng/mL respectively; p<0.0001). However, there was no significant difference in 1,25(OH)2D levels among races. NHB had higher iPTH levels than NHW and others (248±208 vs. 167±131 vs. 210±156 pg/mL respectively; p<0.0001). The median [IQR] FGF-23 levels among NHB, NHW and others were 324 [181-655], 431 [232-1026], and 364 [219-895] RU/mL, respectively (p=0.0001). After adjustment for demographics, cardiovascular risk factors and eGFR, NHB was independently associated with lower 25(OH)D (β= -0.25; p<0.0001) and higher iPTH (β=0.22; p<0.0001) levels than non-Blacks. NHB was independently associated with increased iPTH when further adjusted for calcium, phosphorus, 25(OH)D, 1,25(OH)2D and FGF-23 suggesting that other mechanism play a role in elevated iPTH levels in NHB. There were no racial differences in multivariable-adjusted 1,25(OH)2D and FGF-23 levels.

Conclusions: Low 25(OH)D and elevated iPTH levels are more severe in NHB when compared to non-blacks with severe CKD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2154**

**Preliminary Validation of Three Commercially Available Assays for Measurement of Human Plasma FGF23** Sandra M. Malakauskas,[1] Jun Ling Lu,[2] Ali Iranmanesh,[1,3] Csaba P. Kovesdy.[1,3] *[1]Salem VA Medical Center, Salem, VA; [2]Salem Research Institute, Salem, VA; [3]University of Virginia, Charlottesville, VA.*

FGF23 is a bone-derived peptide hormone that is emerging as an integral regulator of phosphorus balance and vitamin D hydroxylation, yet its clinical significance in CKD and ESRD is poorly understood. The purpose of this study is to perform preliminary validation of 3 commercially available assays for measurement of FGF23 in human plasma

and to examine the influence of sample handling on assay performance. 30 patients were enrolled from a single center and included those with normal GFR, CKD (eGFR < 60 mL/min/1.73m$^2$), and ESRD on HD. Blood was collected, and plasma FGF23 levels were determined according to the manufacturers' instructions using assays from Millipore (intact, MiFGF) and Immutopics (C-terminal, IcFGF; intact, IiFGF).

Intra-assay coefficients of variation (CV) were calculated. To examine matrix influence, plasma was spiked with known concentrations of standard FGF23 at the low and high end of the detectable range and % recovery was calculated. To assess for FGF23 degradation with delayed processing, measured FGF23 concentrations were compared between samples immediately processed ($t_0$) with those incubated at room temperature (RT) for 30-465 minutes (RT- $t_0$/ $t_0$*100).

The CV for intra-assay sample replication ranged from 3.1-36% for MiFGF and was greatest at the lower FGF23 levels observed in controls. For the IcFGF and IiFGF assays, the CV ranged 3.7-10% and 2.3-7.5% respectively. % recovery ranged 87-140% (median 110%) and 91-245% (108%) for IcFGF and IiFGF, respectively (MiFGF pending). Within each patient group, the overestimation of recoverable FGF23 was greatest at the higher concentration. RT incubation trended toward overestimation for all assays and all patient groups: -4.3-91% (median 13%) for MiFGF, -8.2-36% (15%) for IcFGF, and -5.0-11% (3.3%) for IiFGF.

Our preliminary validation confirms the previously published adequacy of IcFGF, suggests inferiority of IiFGF based on % recovery analysis, supports near-equivalence of MiFGF, and suggests that FGF23 is sufficiently stable to allow routine sample processing by clinical labs.

**The Association of Steroid Use and 25(OH)D Deficiency: Results from the National Health and Nutrition Examination Survey (NHANES) 2001-2006**

Amy L. Skversky,[1] Juhi Kumar,[2] Frederick J. Kaskel,[1] Michal L. Melamed.[1]
*[1]Pediatric/Medicine Nephrology, Albert Einstein College of Medicine, Bronx, NY; [2]Pediatric Nephrology, Cornell University, NY, NY.*

**Background**: In many kidney disorders requiring glucocorticoid therapy, there is a substantial decrease in bone mineral density. The etiology of glucocorticoid-induced osteoporosis is multifactorial and may involve 25(OH)D deficiency. The association between steroid use and 25(OH)D deficiency is theoretical and has not been confirmed in large population based studies. Recommendations for vitamin D supplementation are 400 IU/day. There are no specific recommendations for steroid users.

**Methods**: Cross-sectional analysis using children, adolescents and adults from NHANES 2001-2006 (n= 24,235), representative of 251 million US residents. We evaluated the association of serum 25(OH)D deficiency (defined as 25(OH)D <10ng/mL) with oral or IV steroid use within the past 30 days.

**Results**: 1% of the population used steroids within the past 30 days. These participants were more likely to be older, black, obese, and have eGFR <60. 5% of the population had 25(OH)D levels <10ng/ml. Among those with 25(OH)D deficiency, 10% reported steroid use. The odds of having 25(OH)D deficiency were two-fold higher in those who reported steroid use as compared to those without steroid use (OR 2.1, 95% CI 1.1, 4.0). This remained after multivariate adjustment (OR 2.1, 95% CI 1.0, 4.5). Consistent with recent studies, females (OR 1.7, 95% CI 1.5, 2.0), those >21y (OR 1.5, 95% CI 1.3, 1.7), black (OR 11.4, 95% CI 9.2, 14.2), Hispanic (OR 2.7, 95% CI 1.9, 3.8), obese (OR 1.9, 95% CI 1.6, 2.2), and those who drank milk less than once per week (OR 3.2, 95% CI 2.6, 4.1) were more likely to be 25(OH)D deficient. Those who used either 200 IU or 400 IU vitamin D supplementation per day were less likely to be 25(OH)D deficient (OR 0.2, 95% CI 0.1, 0.4, and OR 0.3, 95% CI 0.2, 0.5, respectively). When defining 25(OH)D deficiency as levels <15ng/mL, the OR for steroid users was 1.4 (95% CI 0.99, 1.94).

**Conclusion**: Steroid use is independently associated with 25(OH)D deficiency suggesting the need for screening and repletion in patients with kidney disease on chronic steroids.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2156

**Repletion of Vitamin D Deficiency by Cholecalciferol Is Blunted in Chronic Kidney Disease (CKD)**

Amay Parikh,[1] Herbert S. Chase,[2] Linda Vernocchi,[1] Leonard Stern.[1] *[1]Nephrology, Columbia University, New York, NY; [2]Biomedical Informatics, Columbia University.*

**BACKGROUND:** Previous studies have shown that ergocalciferol in pts with CKD stage 3+4 is not effective with less than 33% of pts achieving a 25-Vitamin D (VitD) target of >30 ng/ml and only pts with CKD 3 demonstrating a partial reduction in PTH. The aim of this study was to test the response to cholecalciferol (presumably more potent than ergocalciferol) in CKD. We attempted to replete VitD to a target level of 40-60 ng/ml using PTH suppression as an outcome measure.

**METHODS:** Demographics, creatinine and VitD were extracted from the Columbia CKD Program database. The MDRD eGFR was calculated. Pts with initial VitD ≥40 were labeled REPLETE. Pts were treated with cholecalciferol 10,000 IU weekly. Doses were titrated to a maximum of 50,000 IU weekly for levels <40. Pts achieving a VitD of ≥40 were labeled RESPONDER. Suboptimal response was labeled INTERMEDIATE. No change or a decrease in VitD was labeled NON-RESPONDER.

**RESULTS:** 389 pts (345 CKD, 44 transplant) were included with a mean follow up of 2.4 years. 48 (11.2%) were REPLETE, 100 (23%) were RESPONDER, 205 (47.8%) were INTERMEDIATE, 76 (17.7%) were NON-RESPONDER. The initial VitD in the NON-RESPONDER (27) and RESPONDER (24) were similar (p=NS). The initial eGFR in the RESPONDER (44) was significantly higher than the NON-RESPONDER (29)(p<0.001). The final eGFR in the REPLETE and RESPONDER were significantly higher than the INTERMEDIATE and NON-RESPONDER (46 and 41 vs. 32 and 25 respectively, p<0.001). This finding was similar in the transplant population (p<0.02). The post-treatment PTH in the RESPONDER decreased (121 to 87 pg/ml, p<0.05); in the NON-RESPONDER, PTH increased (148 to 216 pg/ml, p=0.002). Initial VitD and final eGFR predicted response to treatment by multivariate logistic regression (p=0.03 and p=0.005).

**CONCLUSION:** Despite aggressive repletion, only 23% of pts achieved a clinically significant increase in VitD levels. Lower initial VitD and lower final eGFR were associated with a blunted response to treatment. Treatment resistance to cholecalciferol is similar to ergocalciferol; the mechanisms for both remain unclear.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2157

**Association of Markers of Mineral Metabolism with Arterial Stiffness in Community-Living Elders: The Health ABC Study**

Magdalena Madero,[1] Christina Wassel,[2] Carmen A. Peralta,[3] Samer Najjar,[8] Kim Sutton-Tyrrell,[4] Linda F. Fried,[4] Ian H. de Boer,[5] Michael Shlipak,[3] Anne B. Newman,[4] Dorothy B. Hausman,[7] Mark J. Sarnak,[6] Stephen B. Kritchevsky,[9] Joachim H. Ix.[2] *[1]Instituto Nacional de Cardiologia; [2]U San Diego; [3]U San Francisco; [4]U Pittsburgh; [5]U Washington; [6]Tufts; [7]U Georgia; [8]Wash Hosp Ctr; [9]Wake Forest.*

Disorders of mineral metabolism are associated with greater risk for cardiovascular disease (CVD) events in the general population, even in persons without kidney disease. This risk may be mediated through arterial stiffness.The aim of the study was to evaluate the association of mineral metabolism markers with arterial pulse wave velocity (aPWV), in 2,229 older adults from the Health ABC study.Mean age was 72 years, 52% were woman, 39% were black, and 17% had chronic kidney disease (CKD). In unadjusted analyses, lower 25-hydroxyvitamin D, lower phosphorus and higher iPTH were associated with greater aPWV.

Association of Serum Markers of Mineral Metabolism with Pulse Wave Velocity

| | 25-OH-Vitamin D * | PTH * | Phosphorus * | Calcium * |
|---|---|---|---|---|
| | Δ aPWV (m/sec) (95% CI) | | | |
| Model 1 (unadjusted) | -2.86 (-4.38, -1.31) | 3.04, (1.42, 4.68) | -2.37(-3.90, -0.81) | 0.52 (-1.01, 2.08) |
| Model 2 ** | -0.59 (-2.20, 1.05) | 1.01(-0.60, 2.65) | -1.67 (-3.25, -0.07) | -0.83 (-2.34, 0.71) |

** Adjusted for age, sex, race, field, season, eGFR, BMI, smoking, physical act, DM, LDL, HDL, tryg, lipid med, SBP. DBP, BP meds

Except for phosphorus, these associations were attenuated and no longer significant after adjustment for demographic variables, site, season, kidney function and CVD risk factors.Contrary to our hypothesis, higher phosphorus was associated with lower aPWV. There was no association between serum calcium and aPWV in unadjusted or adjusted models. Results were similar by sex and the presence of CKD.We found no evidence that abnormal mineral metabolism is associated with greater aPWV in community-living elders. This study suggests that pathways other than vascular stiffness may mediate the relationship between disordered mineral metabolism and CVD events in older adults.

**1, 25 Dihydroxyvitamin D3 Promotes Medial Vascular Calcification in Uremic Rat**

Zhonglin Zhao,[1] Alexander Brezzani,[1] Lucy A. Phillips,[2] Martin Hanus,[1] Robert Sacchiero,[1] David J. Berlove.[1] *[1]Preclinical Pharmacology, Genzyme Corporation, Waltham, MA; [2]Histopathology, Genzyme Corporation, Framingham, MA.*

1, 25 dihydroxyvitamin D3 (D3) is a hormone with multiple essential functions including regulation of mineral balance. Levels fall sharply in advanced renal disease and replacement therapy is widely practiced. Our study was designed to study the effects of D3 treatment on vascular calcification in a severe rat uremia model.

We first conducted a dose-ranging study in rats with uremia, testing 5 different doses of D3 (0-100ng/kg IP, twice weekly) for 8 days. Serum calcium and phosphorus began trending higher at 60mg/kg and were significantly higher at 100ng/kg. We selected the highest non-calcemic dose, 40ng/kg, for our treatment study.

We then began a four week study using our previously reported uremia induction (1% adenine for 1 week followed by 0.35% for 3 weeks). This model recapitulates many changes associated with human disease including changes in serum creatinine, BUN, phosphorus, and calcium and inflammatory state.

Following a week of uremia induction, half of the animals began 3 weeks of treatment with D3, 40ng/kg IP, 3 times weekly. Uremic groups had mean serum creatinine of 0.85mg/dL. At study termination, aorta was collected for mineral quantitation and histopathological analysis.

Serum - Week 4

| Group | Calcium | Pi | BUN | Creatinine | PTH | FGF-23 |
|---|---|---|---|---|---|---|
| Non-uremic | 12.6 | 12.0 | 19.6 | 0.4 | 1052 | 771 |
| Non-uremic/D | 12.4 | 10.9 | 20.4 | 0.4 | 1125 | 4563 |
| Uremic | 10.8 | 14.7 | 99.6 | 2.0 | 3626 | 5761 |
| Uremic/D | 12.0 | 15.6 | 99.9 | 1.9 | 2383 | 305416 |

There was no significant change in aortic mineral content except for uremic rats treated with D3 which had a 66X elevation in calcium, with 8-9X increases in Pi and Mg.

Aortic medial calcification was observed by Von Kossa staining only in uremic rats supplemented with D3. This was true even though serum calcium levels were normal (compared to non-uremic) and PTH was not suppressed below normal. This suggests that D3 can be a potent stimulator for calcification even at doses with no apparent hypercalcemia. The massive increase in FGF-23 in D3-treated uremic rat may play a role in this process.

**Comparison of Fetuin A, 25-Hydroxyvitamin D, Erythrocyte Fatty Acid Contents and Vascular Calcification on Plain Radiographs According to Dialysis Modality** Won Suk An, Young Ki Son, Seong Eun Kim, Ki Hyun Kim. *Internal Medicine, Dong-A University, Busan, Republic of Korea.*

Low fetuin-A, vitamin D insufficiency and vascular calcification (VC) on plain radiographs are related to mortality in hemodialysis (HD) patients. However there are few reports about differences of fetuin-A level, vitamin D status, erythrocyte fatty acid (FA) contents and VC on plain radiographic films according to dialysis modality. The present study was designed to demonstrate associations and any difference of fetuin-A level, vitamin D status, erythrocyte FA contents and VC on plain radiographic films according to dialysis modality. We recruited 31 HD patients and 30 peritoneal dialysis (PD) patients from a single dialysis center. We checked the plain radiographic films of the feet, hands, pelvis and lateral lumbar spine and defined significant VC as any one finding among the abdominal aortic calcifications scores >5, VC scores of the pelvis and hands >3 or arterial media calcifications of the feet on plain radiographs. Erythrocyte membrane FA contents were measured by gas chromatography. The mean age, dialysis duration, the prevalence of VC on plain radiographs (60.0 *vs* 61.3 %) were not significantly different in PD patients compared to HD patients. But Fetuin-A levels (408.1±79.0 *vs* 297.8±71.1), body mass index, total cholesterol, LDL cholesterol, monounsaturated FA, oleic acid were significantly higher in PD patients compared to HD paitients. Serum albumin and 25-hydroxyvitamin D (8.6±5.7 *vs* 21.7.±6.0) was significantly lower in PD patients compared to HD paitients. Patients who showed significant VC on plain radiographs had longer dialysis vintage, higher prevalence of coronary artery disease and higher monounsaturated FA than patients without significant VC in HD patients. Patients who showed significant VC on plain radiographs had lower Fetuin-A and higher CRP than patients without significant VC in PD patients. Fetuin-A was independent risk factor related with VC on plain radiographs in PD patients. Fetuin A, 25-hydroxyvitamin D and monounsaturated FA were significantly different, although the prevalence of VC on plain radiographs was not different according to dialysis modality.

**Detection of Vascular Calcification Patients with Stage 3, 4, and 5 Chronic Kidney Disease Who Are Not on Dialysis. OSERCE II Study** Jose L. Gorriz,[1] Javier Nieto,[2] Alberto M. Martinez-Castelao,[3] Celestino Pinera,[5] Guillermina Barril.[4] *[1]Servicio de Nefrologia, Hospital Universitario Dr Peset, Valencia, Spain; [2]Servicio de Nefrologia, Hospital General de Ciudad Real, Ciudad Real, Spain; [3]Servicio de Nefrologia, Hospital de Bellvitge, Barcelona, Spain; [4]Servicio de Nefrologia, Hospital de la Princesa, Madrid, Spain; [5]Servicio de Nefrologia, Hospital M. Valdecilla, Santander, Spain; [6]Servicio de Nefrologia, Fundació Puigvert, Barcelona.*

**OBJECTIVE:** To analyze the presence of vascular calcifications through plain X-rays of hands, hip, and abdomen in patients included in the OSERCE II study, and to assess the factors associated with the calcifications.

**METHODS:** OSERCE II is an observational study conducted in 39 sites in 3, 4, and 5 CKD patients not on dialysis. K/DOQI stage (39.6%, 46.3%, and 14.1% in 3, 4, and 5 not on dialysis stages). 37% were diabetic.

Vascular calcifications were detected using the Adragao index (plain pelvis and hand X-rays) and the Kauppila index (spinal X-ray). The films were forwarded to a hospital for centralized reading by two radiologists. Complete data were available for 572 and 568 patients (Adragao and Kauppila indices, respectively).

**RESULTS:** Significant calcifications (Adragao ≥ 3 or Kauppila > 6) were present in 30.3% and 31% respectively.

Multivariate analysis: Adragao index ≥3 was associated with male gender (OR:0.67-[0.41-1.08]), diabetes mellitus (OR:3.27-[1.86-5.77]), cerebrovascular disease (OR:2.47-[0.94-6.52]), pathological ankle-brachial index (OR:1.81-[1.11-1.2.93]), higher levels of phosphorus (OR:1.55-[1.15-2.08]), and age (OR:1.10-[1.08-1.12]).

Multivariate analysis: Kauppila index >6 was associated with peripheral vascular disease (OR:2.07-[1.22-3.51]), elevated phosphorus levels (OR:1.90-[1.44-2.50]), diabetes mellitus (OR:1.49-[0.95-2.30]), pathological ankle/brachial index (OR:1.48-[0.95-2.30]), and age (OR:1.07-[1.05-1.10]).

**CONCLUSIONS:** Stage 3, 4, and 5 CKD patients not on dialysis have a high prevalence of vascular calcifications detected with the Adragao and Kauppila indices. The prognostic significance for cardiovascular morbidity and mortality of these patients is yet to be established.

**SA-PO2161**

**Lack of Association of Klotho Gene Variants with Valvular and Vascular Calcification in Caucasians: A Candidate Gene Study of the Framingham Offspring Cohort** Navdeep Tangri, Ahsan Alam, Eric C. Wooten, Gordon S. Huggins. *Division of Nephrology, Tufts Medical Center, Boston, MA.*

Background: Valvular and vascular calcification are important early aging phenotypes and represent risk factors for cardiovascular morbidity and mortality. Klotho is a gene primarily expressed in the kidney that has an important role in calcium phosphate homeostasis. The functional KL-VS variant of Klotho has been associated with aging and cardiovascular disease in human studies, but its role in valvular and vascular calcification remains unknown. We performed a candidate gene study in the Framingham Offspring cohort to evaluate the effect of KL-VS variant of the Klotho gene on valvular calcification.

Methods: We analyzed the Klotho KL-VS genotype (rs9536314) from the Affymetrix 550K genome-wide dataset, distributed by dbGAP, on 1389 cases and 2139 controls from the Framingham Heart Study Offspring Cohort. Allele and genotype frequencies were compared between cases and controls. Valvular calcification was defined as presence of calcification on the mitral annulus or the aortic valve as determined by echocardiography. A sensitivity analysis of coronary artery calcification by EBCT was performed on 1363 patients.

Results: The frequency of the TT vs the TG allele was not different between the cases and the controls (39 % vs 41 %). The KL-VS variant of Klotho was not associated with valvular or vascular calcification, despite adequate power to detect association (86% for OR 1.2 or greater). In sensitivity analyses, no association (p>0.001) between other common variants of Klotho, beta klotho or FGF23 and the endpoints of valvular or vascular calcification was observed.

Conclusions: In our adequately powered candidate gene study, we did not observe an association with the functional KL-VS variant of Klotho and presence of valvular or vascular calcification. Future studies aimed at combining cohorts with echocardiographic phenotypes need to be conducted to identify genetic variants associated with valvular calcification.

**SA-PO2162**

**Value of Plain Bone X-Ray and Blood Chemistry for Detection of Vascular Calcification (VC) of Patients on Different Dialysis Modalities** Moon-Jae Kim, Seoung Woo Lee, Woo Chul Joo, Joon Ho Song. *Kidney Center, Inha University Hospital, Incheon City, Korea.*

**Purpose:** To evaluate detection for vascular calcification (VC) of patients between hemodialysis(HD) and peritoneal dialysis(PD) with plain radilologic bone series and blood chemistry.

**Methods**: VC was assessed using plain X-ray on L-spine, pelvis and hand in 51 HD and 74 PD patients who used calcium-based phsophate binder more than 5 years. Calcification scoring proposed by Kauppila and Adragao were used to evaluate the presence of VC in abdominal aorta, iliac and femoral, radial and digital arteries. We analyzed the difference in VC according to dialysis modality.

**Results:** One hundred and twenty five patients were included. Mean age were 57±13, 54±13 years in HD and PD groups respectively. Dialysis duration was 6.4±3.4 years in HD, 5.6±2.3 years in PD. Diabetics (DM) were 29(56.9%) in HD and 25(33.3%) in PD. Calcification scores of lumbar was correlated with scores of pelvis(r=0.561, p<0.001) and of hand(r=0.236, p=0.008). In HD patients, lumber score was correlated with age (r=0.378, p=0.006) and albumin(r= -0.284, p=0.046). In PD patients, lumbar score was correlated with age. However, HD showed more VC of digital bone(37.3 vs. 17.6%, p=0.013) and had higher scores than PD ( 0.9+1.3 vs. 0.5+1.0, p=0.054). Diabetics and male were also high scores of VC on abdominal arteries in both groups. Daily calcium load of phasphate binder and presence of residual renal function were similar between two modailties. But serum creatinine, HDL-cholesterol and iPTH levels were significantly lower in patients with low scores of VC in radial and digital arteries in both groups.

**Conclusion:** There seems to be significant difference in the location and degree of VC according to dialysis modality. HD showed more VC of digital bone and higher scores than PD on long-term use of calcium-based phosphate binders. Routine bone X-ray and blood chemistry had some value for detection for VC of patients on dialysis.

**SA-PO2163**

**Intact PTH Overestimates Parathyroid Function in Patients under Cinacalcet Hydrochloride Treatment** Ryo Koda, Junichiro J. Kazama, Minako Wakasugi, Ichiei Narita. *Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

The stimulation of calcium sensing receptor in parathyroid cells increases the relative amount of 7-84PTH secretion to 1-84PTH secretion besides it decreases absolute amount of PTH secretion. Intact PTH detects both 1-84PTH and 7-84PTH, while whole PTH does only 1-84PTH. Therefore the ratio of whole PTH level / intact PTH level (w/i) was expected to decrease in patients under cinacalcet hydrochloride (CH) treatment. However, this expectation was not fully confirmed by clinical observations, because CH therapy also decreases extracellular Ca level, which is the major regulator of 1-84PTH/7-84PTH in parathyroid cells. Forty CKD5D patients who were going to receive CH treatment due to secondary hyperparathyroidism (M27:F13, 63.3±14.2yo, hemodialysis vintage 11.8±8.2 year, intact PTH 480.2±267.6 pg/ml, Ca10.0±0.7 mg/dl) were included for the analysis as the treatment group. CH was administrated to them for 24 weeks. Eighty seven of those without need of CH therapy (M56:F31, 64.5±13.1yo, hemodialysis vintage 12.0±7.7 year, intact PTH 203.3±128.7 pg/ml (p<.001 vs the treatment group), Ca9.1±0.9 mg/dl (p<.001

vs the treatment group)) were registered as control group. The serum Ca and intact PTH levels in the treatment group decreased along with CH treatment, and the levels became comparable with those of the control group at the 8, 12, 16 and 24 weeks. The w/i ratio was significantly greater in the control group than that of the treatment group at those time points (.532±.112 vs .456±.067, .448±.081, .447±.077, .453±.066, p<.0001 respectively). No significant difference was found in w/i levels in the treatment group before and during the CH therapy. Since CH therapy decreases Ca levels, it is difficult to detect the direct effect of CH on w/i in the data obtained from same patients before and during the therapy. We could successfully demonstrate it by comparing the treatment group and control group that share comparable serum Ca levels. Thus, intact PTH assay overestimates parathyroid function in patients under CH therapy, which possibly leads to the risk of the over treatment.

## SA-PO2164

**Discrete Effect of Cinacalcet with Maxacalcitol on the Parathyroid Growth and PTH Secretion in Patients with Secondary Hyperparathyroidism** Tatsuo Tsukamoto. *Division of Nephrology and Dialysis, The Tazuke Kofukai Medical Research Institute, Kitano Hospital, Osaka, Japan.*

Cinacalcet has decreased PTH secretion through the activation of calcium-sensing receptor in the hyperplastic parathyroid grand of dialysis patients. In addition, cinacalcet has a suppressive effect on the parathyroid growth not only in experimental animals but also patients with severe hyperparathyroidism. Thus, we established a prospective clinical study to prove this regressive effect of cinacalcet combined with intravenous maxacalcitol, a vitamin D derivative, on hyperplastic parathyroid gland in moderate to severe SHPT (iPTH 300-1000pg/ml) (UMIN 000001793), of which interim report was demonstrated in the last meeting [JASN 20, F-PO1894, 2009]. The starting dose of cinacalcet was 25mg daily, which was increased by 25mg every 2-4 weeks, until intolerance. Ca and phosphorus were adequately controlled by increase of maxacalcitol and calcium carbonate along the Japanese guideline. 53 patients with 157 of enlarged parathyroid glands were enrolled, and followed for 1 year. The gland size was measured every 6 months by a high-resolution color Doppler sonography. The average dose of cinacalcet and maxacalcitol were 39mg daily and 14μg per week at the end of the study, respectively. PTH decreased significantly from 565.5±32.0pg/ml to 164.3±20.1pg/ml after the protocol treatment. Although the averaged annual volume expansion rate was 7.5% increase in all of the parathyroid glands, 54% of the glands showed significant volume reduction after the one-year treatment. In addition, 10.2% of the glands displayed cystic degeneration during the treatment, which was determined by loss of Doppler echo. Patients with larger glands (>500mm3) responded to the treatment similar to those with smaller glands (<500mm3) in the population of moderate to severe hyperparathyroidism. Taken together, the final result of this clinical study reveals a discrete effect of cinacalcet with maxacalcitol on parathyroid growth and PTH secretion in patients with secondary hyperparathyroidism. The biological mechanism should be clarified to understand this therapeutic evidence.

## SA-PO2165

**Inadequate Strategy for Treating Very Low PTH Levels in Haemodialysis Patients Leads to Poor Survival Rates: Results from the French ARNOS Cohort** Guillaume Jean,[1] X. Moreau-Gaudry,[2] Denis Fouque.[3] *[1]Hémodialyse, Centre de Rein Artificiel, Tassin, France; [2]Hémodialyse, AGDUC, Montélimar, France; [3]Néphrologie Hémodialyse, Hôpital Edouard Herriot, Lyon, France.*

**Introduction**: A very low parathyroid hormone (PTH) level (VLPL) is associated with an increased risk of vascular calcification, and mortality in haemodialysis (HD) patients. The aim of the study was to assess the frequency, the associated factors, and the prognosis of non-surgical VLPL in a cohort of prevalent HD patients.

**Methods**: In July 2005, a cross-sectional study was performed on the French ARNOS cohort in 1348 prevalent HD patients from 24 dialysis centres in the Rhône-Alpes area. Patients with a baseline PTH level < 50 pg/ml (VLPL, Group 1) and ≥ 50 pg/ml (Group 2) were compared and a 42-month survival analysis was performed. Patients with prevalent or incident parathyroidectomy (PTX) were excluded.

**Results**: We studied 1138 prevalent HD patients. As compared to patients of Group 2 (n = 1019), patients with VLPL (Group 1, n = 119) had lower serum albumin levels (34.5 ± 5 vs. 36.4 ± 5 g/L, p < 0.0001), less protein intake (nPCR 0.99 ± 0.28 vs. 1.1 ± 0.28 g/kg/d, *P* = 0.01), higher calcaemia (2.30 ± 0.2 vs. 2.26 ± 0.2 mmol/l, *P* = 0.01) and were more frequently treated with calcium carbonate (67% vs. 54%, p< 0.001). Patients with VLPL had a higher mortality rate (HR: 1.4 (1.07–1.8), *P* = 0.006) after adjustments for age, gender, diabetes, and dialysis vintage. The odds ratios of mortality for patients with VLPL remained higher in all calcaemia and serum albumin quartiles. Only 3/119 patients in Group 1 did not receive any PTH-lowering therapies (i.e. calcium carbonate (67%), alfacalcidol (38%), cinacalcet (10.1%), and dialysate calcium ≥ 1.5 mmol/l (94%)).

**Conclusion**: In this observational French cohort, VLPL was observed in 10% of prevalent HD patients and was associated with poor survival rates. The real consequences of this iatrogenic adynamic bone disease remain hypothetical, but it may be related to the risk of developing vascular calcification. It is hypothesized that a more adequate strategy, using fewer PTH-lowering therapies in cases of VLPL, may help in improving the poor prognosis.

Disclosure of Financial Relationships: Employer: my wife works for Merk laboratory; Consultancy: fresenius medical care, genzyme; Ownership: noneResearch Funding: Amgen; Honoraria: Shire, Amgen, Fresenius, Genzyme; Patent: none; Scientific Advisor: Fresenius medical care, Amgen, Genzyme; Other Relationship: none.

## SA-PO2166

**Secretion of FGF23 Is Regulated by PTH** Ignacio Lopez,[1] Maria Encarnacion Rodriguez Ortiz,[2] Yolanda Almaden Peña,[2] Addy Rosa Montes de Oca Gonzalez,[1] Carmen Pineda,[1] Victoria Shalhoub,[3] Mariano Rodriguez,[2] Escolastico Aguilera-Tejero.[1] *[1]Medicina y Cirugía Animal, Universidad of Cordoba, Spain; [2]Research Unit, Neprology Department, Hospital Universitario Reina Sofia, Cordoba, Spain; [3]Amgen Inc, Thousand Oaks, CA.*

The secretion of FGF23 is stimulated by phosphate and calcitriol. FGF23 increases urinary phosphorus excretion and decreases calcitriol production by kidneys. In addition to the kidney, the parathyroid glands also respond to FGF23 by decreasing PTH secretion. As a consequence of reduced PTH levels, calcium and calcitriol concentrations tend to decrease and, phosphorus levels tend to increase. It remain to be explored if PTH may directly affect FGF23 secretion. We hypothesized that, in addition to phosphorus and calcitriol, FGF23 secretion is also regulated by PTH.

Wistar rats were parathyroidectomized (PTX) and randomly allocated to 4 groups of 8 rats each. Sham: underwent a sham surgery and were not implanted pumps for PTH infusion; PTX: received constant infusion of vehicle using miniosmotic Alzet Pump; PTX1: received a physiological dose of PTH, and PTX3 received three times the physiological dose of PTH through the miniosmotic pump. Blood was collected on days 10, 20 and 28 day for measurements of: plasma ionized calcium (iCa), phosphorus (P), and FGF23. Urine was also obtained at the time of sacrifice for measurement of fractional excretion of calcium (FECa) phosphorus (FEP).

table1

| | Ca2+ (mM) | P (mM) | FGF23 (pg/ml) | EFCa (%) | EFP (%) |
|---|---|---|---|---|---|
| Sham | 1.23±0.05b | 2.04±0.2b | 241.4±61.6b | 0.80±0.17 | 19.3±4.0 |
| PTX | 0.59±0.07a | 3.75±1.09a | 115.7±35.3a | 1.14±0.19 | 13.3±1.4 |
| PTX1 | 1.18±0.09b | 1.71±0.29b | 238.0±41.3b | 1.02±0.17 | 29.3±2.5b |
| PTX3 | 1.46±0.18ab | 1.19±0.57b | 363.5±66.3ab | 1.13±0.15 | 50.2±8.0ab |

Mean±SE, a p<0.05 vs Sham, b p<0.05 vs PTX

The results show that PTH is necessary to maintain normal circulating FGF23 levels. In PTX rats, which are markedly hyperphosphatemic, plasma FGF23 concentration declines. Moreover, PTH supplementation increases FGF23 concentrations in a dose-dependent manner despite the concomitant decrease in serum P.

## SA-PO2167

**Calcineurin (CN) Activation Promotes Apoptosis of Glomerular Podocytes Both In Vitro and In Vivo** Liming Wang,[1] Jae-Hyung Chang,[1] Seung-Yeol Paik,[2] Yuping Tang,[1] Robert F. Spurney.[1] *[1]Medicine, Duke Medical Center, Durham, NC; [2]Medical School, Chung-ang University, Seoul, Korea.*

A reduction in glomerular podocytes is a characteristic feature of several glomerular disease processes in humans. While the etiology of podocyte loss is likely multifactorial, apoptosis is an important mechanism of podocyte depletion in glomerular diseases. Both angiotensin II (ANGII) and endothelin-1 (ET-1) cause podocyte apoptosis by activation of G protein coupled receptors (GPCRs). To investigate the signaling pathways activated by these GPCRs that cause apoptosis, we treated a podocyte cell line with ANGII or ET-1 in the presence or absence of the CN inhibitor FK506. Podocyte apoptosis induced by either ANGII or ET-1 was prevented by FK506. Because ANGII and ET-1 activate Gq coupled GPCRs, we used protein transduction to introduce a constitutively active Gq α-subunit (GqQ>L) into podocytes by tagging Gq>L with the TAT HIV protein sequence [Gq(+)]. We found that treatment with Gq(+) enhanced podocyte apoptosis in a CN dependent fashion. In support of a role for CN in this apoptotic effect, podocyte apoptosis was similarly induced by a constitutively active CN protein tagged with the TAT protein sequence [CN(+)]. Induction of apoptosis required NFAT (nuclear factor of activated T cells) induced gene transcription because apoptosis caused by either Gq(+) or CN(+) was blocked by a cell permeable peptide inhibitor (VIVIT) that blocks NFAT activation without affecting CN phosphatase activity. To determine if CN inhibition attenuated podocyte apoptosis in vivo, we treated a mouse model of type 1 diabetes mellitus (Akita mice) with FK506 or vehicle for 1 week. In 4-week old mice, apoptosis was significantly increased in Akita mice compared to wild type controls and treatment with FK506 significantly reduced podocyte apoptosis in the Akita animals. These data suggest that Gq signaling stimulates CN and, in turn, CN activity promotes podocyte apoptosis both in vitro and in vivo by mechanisms that require NFAT dependent gene transcription. A component of the beneficial effects of CN inhibitors in glomerular diseases may be mediated by inhibiting podocyte apoptosis.

## SA-PO2168

**The Role of Smooth Muscle Protein SM22α in Podocyte Injury** Caroline B. Marshall,[1] Ron D. Krofft,[1] Mary Blonski,[1] Jeffrey W. Pippin,[1] Charles E. Alpers,[2] Stuart J. Shankland.[1] *[1]Dept. of Medicine, Division of Nephrology, University of Washington, Seattle, WA; [2]Dept. of Pathology, University of Washington, Seattle, WA.*

Podocytes are considered terminally differentiated cells in the mature kidney under basal conditions. Upon injury, podocytes may proceed along several pathways, including de-differentiation and proliferation, persistent cell cycle arrest, hypertrophy, apoptosis, and necrosis. There is mounting evidence that transdifferentiation into a dysregulated phenotype may also be a potential cell fate. Previously, we reported that the transcript of actin-binding protein SM22α, an early marker of smooth muscle differentiation, is upregulated nearly 70-fold in glomeruli of rats with passive Heymann nephritis (PHN). In

contrast, the SM22α transcript is absent in normal adult rat glomeruli. This study's purpose was to define SM22α's expression during kidney development and its role in glomerular diseases characterized by podocyte injury and proteinuria. During glomerulogenesis and podocyte differentiation, SM22α was expressed in glomeruli. This expression disappeared with glomerular maturation. Along with SM22α induction in PHN, confirmed at both mRNA and protein levels, SM22α was also induced across a broad range of proteinuric diseases, including experimental animal models (PAN, ADR nephropathy, passive nephrotoxic nephritis, diet-induced obesity) and human diseases (collapsing glomerulopathy, diabetic nephropathy, FSGS, IgA nephropathy, minimal-change disease, membranous nephropathy, MPGN). Crescentic glomerulonephritis (CGN) was induced in SM22α +/+ and SM22α -/- mice by IP injection of sheep anti-rabbit glomeruli antibody 12.5 mg/20 g b.w. x 2 doses (n=12-15/group), with mice sacrificed at 7d and 14d. Compared to SM22α -/- mice, SM22α +/+ mice had worse histopathologic disease. In addition, there was greater apoptosis (cleaved caspase-3 immunostaining) and fewer podocytes (WT-1 immunostaining) in diseased SM22α +/+ mice. Furthermore, there was decreased activation of Erk1/2 in diseased SM22α +/+ mice. We conclude that the *de novo* expression of smooth muscle protein SM22α is maladaptive in the podocyte response in CGN.

**Angiotensin (Ang) II Promotes Podocyte Autophagy: Role of Oxidative Stress** Madhuri Adabala, Anju Yadav, Shitij Arora, Divya Salhan, Swapna Sayeneni, Ashwani Malhotra, Pravin C. Singhal. *Feinstein Institute for Medical Research, North Shore LIJ Health System, Great Neck, NY.*

Podocyte injury plays a critical role in the development of glomerulosclerosis both in human and animal models of renal diseases. Since, podocytes are terminally differentiated, they are not capable of utilizing ongoing protein synthesis into their cell cycle progression. Thus, they have to have an efficient system to handle damaged organelles and oxidized proteins. We have previously demonstrated that Ang II promotes podocyte apoptosis both *in vivo* and *in vitro* (Am J Physiol 28:F173-180, 2002). In the present study, we evaluated the effect of Ang II on the induction of autophagy and apoptosis in conditionally immortalized mouse podocytes (CIMPs).

To evaluate the effect of Ang II on podocytes, CIMPs were incubated in media containing either buffer or Ang II ($10^{-8}$ to $10^{-6}$M) for 36 hours followed by morphologic evaluation for autophagy (electron microscopy, and monodansylcadaverine staining) and apoptosis (TUNEL assay). Cells treated under identical conditions were also probed for LC-3-2 and beclin-1 expression by immunoblotting . To evaluate the role of autophagy in the promotion of Ang II-induced apoptosis, Ang II treated cells were evaluated in the presence or absence of 3-mehyl adenine (3MA, an inhibitor of autophagy, 1 mM)/rapamycin (a promoter of autophagy, 100ng/ml) followed by apoptotic evaluation.

Ang II promoted both autophagy and apoptosis in CIMPs. Ang II promoted mitochondrial reactive oxygen species (ROS) generation; whereas, antioxidants partially inhibited Ang II-induced podocyte apoptosis and autophagy. Interestingly, 3MA facilitated Ang II-induced podocyte apoptosis; on the other hand, rapamycin, inhibited Ang II-induced podocyte apoptosis. Ang II also enhanced podocyte LC3-2 and beclin-1 expression in a dose and time dependent manner. Hydrogen peroxide ($H_2O_2$) at lower concentrations, enhanced both LC3-2 and beclin-1 expression in CIMPs.

These findings indicate that severity of oxidative stress determines occurrence of autophagy vs. apoptosis. It appears that Ang II may be invoking autophagy to provide protection against its proapoptotic effect.

**TGF-beta Effect on Bioenergetics and Reactive Oxygen Species Generation in Mouse Podocytes** Yoshifusa Abe,[1, 2] Toru Sakairi,[1] Craig Cano Beeson,[3] Jeffrey B. Kopp.[1] *[1]NIDDK, NIH, Bethesda, MD; [2]Pediatrics, Showa University School of Medicine, Tokyo, Japan; [3]Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

TGF-beta contributes to progressive glomerulosclerosis, including diabetic nephropathy and focal segmental glomerulosclerosis (FSGS). TGF-beta over-expression in transgenic mice induces podocyte apoptosis and FSGS. To determine whether TGF-beta alters podocyte bioenergetics, we studied transformed mouse podocytes, using a label-free assay system, Seahorse XF24, which measures oxygen consumption rate (OCR) and extracellular acidification rates (ECAR). In the presence of glucose, pyruvate and glutamine as substrates, TGF-beta (3 ng/mL) increased basal OCR 147~174% and oxidative capacity 107~196% relative to control after 24, 48, and 72 hours. After 48 hours exposure of TGF-beta, glycolytic capacity was higher than control. ATP content was 119% (P<0.01) and 130% (P<0.01) relative to control after 48 and 72 hours exposure, respectively. We investigated the effect of TGF-beta on fatty oxidation under conditions of maximal mitochondrial function (using the mitochondrial uncoupler FCCP) and found that palmitate-driven OCR was 168% (P<0.001) relative to control. These data indicate that TGF-beta increases mitochondrial oxygen consumption and ATP generation in the presence of diverse energy substrates. These effects of TGF-beta were not due to increased cell number (as shown by cell counts and calcein AM stain). Reactive oxygen species (ROS) were increased 150% by TGF-beta treatment for 48 hours (P<0.0001). Active caspase 3/7, a pro-apoptotic enzyme, was increased after TGF-beta treatment, 139% (P<0.05), 215% (P<0.001), and 143% (P<0.001), after 24, 48, and 72 hours. With regard to basal OCR, glycolytic capacity, and ROS generation, primary mouse podocyte showed similar in direction and magnitude. We propose that TGF-beta alters bioenergetics in mouse podocytes, and these changes are associated with increased ROS and a pro-apoptotic state.

**TGF-β1 Induces Podocyte Injury Via the Src Kinase Fyn-Dependent Upregulation of the Phosphorylated Ion Channel TRPC6** Jianming Ye,[1] Qiuxia Lin,[2] Lixia Yu,[1] Hua Liao,[3] Xiaohong Dong,[1] Jianhua Feng.[1] *[1]Department of Nephrology, First People's Hospital of Kunshan, Kunshan, Jiangsu, China; [2]Department of Tissue Engineering, Institute of Basic Medical Sciences and Tissue Engineering Research Center, Academy of Military Medical Sciences, Beijing, China; [3]Department of Anatomy, Southern Medical University, Guangzhou, China.*

Purpose

We explored the potential role of TRPC6 on TGF-β1-induced podocyte apoptosis and the underlying proximal signaling to further elucidate the mechanism by which TGF-β promotes podocyte injury and the development of glomerulosclerosis.

Methods and Results

1) Flow cytometry showed that podocyte apoptosis increased significantly following 5ng/ml of TGF-β1 stimulation for 24h. Immunofluorescence staining displayed that TGF-β1 induced obvious alterations of F-actin.

2) In TGF-β1-stimulated podocyte, the cytosolic free Ca2+ upregulated markedly, which was evidently inhibited by the specific TRPC6 knockdown. TRPC6 knockdown alleviated TGF-β1-induced podocyte apoptosis.

3) TGF-β1 caused significant increment of TRPC6 protein, especially the phosphorylated form. The Src kinase Fyn increased obviously in TGF-β1-stimulated podocyte, displaying the increment of active form pY418 and the reduction of the inactive form pY530.

4) Immunoprecipitation assay revealed that Fyn interacts with TRPC6 in podocyte. Notably, the specific knockdown of Fyn markedly blocked the phosphorylation of TRPC6 and the increment of cytosolic free Ca2+ following TGF-β1 stimulation.

5) Western blot showed that TGF-β1 induced significant activation of p-smad3, p-ERK and RelA/p65. Importantly, Western blot and immunofluorescence staining revealed the obvious translocation of RelA/p65 to nuclei in TGF-β1-stimulated podocyte, which was reduced by the treatment of ERK inhibitor U0126. Both U0126 and NF-kb inhibitor PDTC obviously inhibited the increment of TRPC6 protein and the flux of cytosolic Ca2+ induced by TGF-β1.

Conclusion

We provide evidences: 1) Fyn interacts with TRPC6 in podocyte; 2) TGF-β1 induces TRPC6 increment via the activation of smad3-ERK-NF-kB pathway; 3) Fyn-dependent upregulation of the phosphorylated TRPC6 might be responsible for TGF-β1-induced podocyte injury.β

**Regulation of Podocyte Survival and Endoplasmatic Reticulum Stress by Fatty Acids** Jonas Sieber,[1] Maja Lindenmeyer,[3] Kapil Dev Kampe,[1] Kirk N. Campbell,[5] Clemens D. Cohen,[3,4] Peter H. Mundel,[5] Andreas Werner Jehle.[1,2] *[1]Department of Biomedicine, University Hospital, Basel, Switzerland; [2]Internal Medicine, Kantonsspital Bruderholz, Basel, Switzerland; [3]Institute of Physiology, University of Zurich, Zurich, Switzerland; [4]Division of Nephrology, University of Zurich, Zurich, Switzerland; [5]Department of Medicine, University of Miami, Miller School, Miami.*

**Introduction/Objectives:** Type 2 diabetes mellitus is associated with elevated free fatty acids (FFAs). The objectives of this study were to elucidate the role of palmitic acid, palmitoleic acid, and oleic acid in the regulation of podocyte cell death and endoplasmic reticulum (ER) stress.

**Methods:** Conditionally immortalized murine podocytes were differentiated for at least 11 days and FFA were complexed to BSA. Apoptosis and necrosis were quantified by staining with Annexin V and propidium iodide. BiP, CHOP and activated Caspase 3 levels were assessed by immunoblotting. CHOP knockdown was applied by shRNA using a lentiviral system.

**Results:** We show that palmitic acid increases apoptosis and necrosis of podocytes in a dose- and time-dependent fashion. Palmitic acid induces podocyte ER stress leading to an unfolded protein response (UPR) as reflected by the induction of the ER chaperone BiP and proapoptotic transcription factor CHOP. Of note, the monounsaturated palmitoleic and oleic acid can attenuate the palmitic acid-induced upregulation of CHOP, thereby preventing cell death. Similarly, gene silencing of CHOP protects against palmitic acid induced podocyte apoptosis. The clinical relevance of our results is underscored by the observation that the gene expression of BiP is significantly upregulated in microdissected glomeruli from patients with diabetic nephropathy.

**Summary/Conclusion:** Our results unveil the antagonistic effects of palmitic acid versus monounsaturated FFAs on podocyte survival, ER-stress and UPR. They support an important role of CHOP in the regulation of podocyte cell death by FFAs.

**Erythropoietin Receptor Agonist Protects Podocytes Against Apoptosis and Modulates Podocyte-Endothelial Cell Crosstalk** Keizo Matsushita, Lijun Ma, Haichun Yang, Agnes B. Fogo. *Pathology, Vanderbilt University Medical Center, Nashville, TN.*

Background: Enhanced survival of podocytes not only has direct benefit on maintaining the capillary wall barrier but also indirectly affects glomerular endothelial cells (GEN) by secreted angiogenesis factors. We assessed effects of long lasting EPO-R agonist, darbepoetin, on TGF-β-induced podocyte injury and on podocyte-GEN interaction.

Methods: Primary cultured mouse podocytes were pretreated with darbepoetin (100μg/ml) for 3 hr before injury with TGF-β (5 ng/ml) for 24 hrs. VEGF secreted in podocyte supernatant was measured by ELISA. Markers of podocyte differentiation (synaptopodin) and apoptosis (Bax) were examined by Western blot. The migration of GEN in response to conditioned medium from intact or injured podocytes with or without darbepoetin was estimated with wound-healing assay.

Results: TGF-β significantly increased expression of Bax and decreased expression of synaptopodin in podocytes. Treatment with darbepoetin restored expression of Bax and synaptopodin. Further, TGF-β significantly increased phosphorylation of Akt, and darbepoetin partially prevented p-Akt activation.

We assessed angiogenesis factors secreted in medium of podocytes. TGF-β significantly increased secretion of VEGF. darbepoetin had no effect on this TGF-β-induced VEGF secretion.

GEN migration was induced by media from TGF-β injured podocytes ($p<0.05$). Media from podocytes protected from TGF-β injury with darbepoetin induced less migration than that without darbepoetin ($p<0.05$).

Conclusion: Our data confirm a protective role of darbepoetin in TGF-β-induced podocyte injury, and suggest that darbepoetin also affects podocyte-GEN crosstalk by mechanisms other than VEGF secretion.

**tPA Activates Mitogenic Signaling Involving LDL Receptor-Related Protein 1-Mediated p90RSK and GSK3β Pathway** Ling Lin, William Brian Reeves, Kebin Hu. *Department of Medicine, Penn State University College of Medicine, Hershey, PA.*

The numbers of interstitial fibroblasts closely correlate with the extent of kidney damage. In renal fibrosis, interstitial fibroblasts have an increased proliferative phenotype, leading to expansion of the interstitium. However, the underlying mechanisms remain largely unknown. Here we define the intracellular signaling events by which tissue plasminogen activator (tPA) promotes interstitial fibroblast proliferation. tPA promoted the proliferation of renal interstitial fibroblasts independent of its protease activity. The mitogenic effect of tPA required $Tyr^{4507}$ phosphorylation of the cytoplasmic tail of its receptor LDL receptor-related protein 1 (LRP-1). tPA triggered sequential proliferative signaling events involving Erk1/2, p90RSK, GSK3β phosphorylation, and cyclin D1 induction. Blockade of Erk1/2 activation or knockdown of p90RSK suppressed tPA-induced GSK3β phosphorylation, cyclin D1 expression, and fibroblast proliferation. In contrast, expression of constitutively active Mek1 mimicked tPA in inducing GSK3β phosphorylation and cyclin D1 expression. Ectopic over-expression of an uninhibitable GSK3β mutant eliminated tPA-induced cyclin D1 expression. In the murine obstructive injury model, tPA deficiency reduced renal GSK3β phosphorylation after 7 and 14 days of obstruction. These findings show that tPA induces $Tyr^{4507}$ phosphorylation of LRP-1, which in turn leads to the downstream phosphorylation of Erk1/2, p90RSK, and GSK3β, followed by the induction of cyclin D1 in murine interstitial fibroblasts. This study implicates tPA as a mitogen that promotes interstitial fibroblast proliferation, leading to expansion of these cells.

**INK4a Knockout Mice Exhibit Increased Fibrosis under Normal Conditions and in Response to Unilateral Ureteral Obstruction** David H. Lee, Jesse M. Wolstein, Jennine Michaud, Vanessa C. Buot, Matthew D. Plotkin. *Nephrology, New York Medical College, Valhalla, NY.*

The two proteins encoded by the INK4a locus, $p16^{INK4a}$ and $p19^{ARF}$, have been shown to contribute to cell cycle arrest and senescence. However, the role of these proteins in controlling cell proliferation in normal kidney and kidney repair and the fibrotic response to injury is unknown. We performed unilateral ureteral obstruction (UUO) to induce fibrosis in 2-3 month old WT C57/B6 and INK4a knockout mice. By quantitative RT PCR, $p16^{INK4a}$ levels were increased 6-fold in WT mice 7 days after UUO and $p19^{ARF}$ remained undetectable. Kidney sections were examined to determine levels and localization of $p16^{INK4a}$, apoptosis, fibrosis, and senescent cells. INK4a knockout mice displayed mesangial cell proliferation, increased matrix deposition and medullary myofibroblast differentiation under normal conditions. Following UUO, INK4a knockout mice displayed 10-fold increased tubular and interstitial cell proliferation, 75% decreased collecting duct apoptosis by TUNEL staining, 2-fold greater collagen and fibronectin deposition, and no cell senescence by SA-ß-galactosidase staining compared to WT mice. Both INK4a knockout mesangial cells grown *in vitro* and kidney lysates from knockout mice following injury showed elevated levels of IL-6 by ELISA compared to WT samples. In addition, INK4a knockout proximal tubule cell cultures displayed increased mesenchymal cell markers compared to WT cells when exposed to TGF-ß. These results confirm that $p16^{INK4a}$ controls mesenchymal cell proliferation and matrix production and mitigates fibrosis in response to injury and suggest that the mechanism involves a role in limiting inflammation and cell proliferation.

**SA-PO2176**

***Grem1* Deletion Alters Cell Proliferation *In Vitro* and *In Vivo* in a UUO Model of Fibrosis** Simon P. Curran,[1,2] Alan J. Watson,[1] Derek P. Brazil.[3] *[1]Nephrology Dept., St. Vincent's University Hospital, Dublin, Ireland; [2]Diabetes Research Centre, University College Dublin, Ireland; [3]Centre for Vision and Vascular Science, Queen's University Belfast, United Kingdom.*

Gremlin1 is a Bone Morphogenetic Protein antagonist that displays increased expression in models of renal fibrosis. It has been shown that allelic deletion of *grem1* attenuates Diabetic Nephropathy in mice. Previous reports have suggested that Gremlin1 can drive cell proliferation and promote apoptosis. We explored the role of this protein in cell proliferation to shed light on it's role in renal fibrosis.

Mouse embryonic fibroblasts (MEFs), wild type (+/+), *grem1*+/- and *grem1*-/-, were used to study *in vitro* markers of proliferation. An MTT assay found that *in vitro* there was increased proliferation in *grem1*-/- MEFs. A scratch wound assay indicated a trend for greater wound closure after serum stimulation in *grem1*-/- MEFs.

Unilateral ureteric obstruction was performed on +/+ and *grem1*+/- mice and kidney sections were examined for markers of renal damage and cell proliferation. An increase in kidney weight was seen in the contralateral kidney in both the sham and UUO mice at day 3 which reached statistical significance in the +/+ but not the *grem1*+/- animal. Histological staining for Ki-67 detected an increased number of proliferating cells in +/+ versus *grem1*+/- at baseline. The total number of proliferating cells increased in both +/+ and *grem1*+/- and this response was greater in +/+ mice.

These results suggest that Gremlin1 has a definite role in proliferation in both fibroblasts and kidney cells in vivo. The observed differences *in vitro* and *in vivo* may reflect cell specific effects of Gremlin1 deletion in embryonic fibroblasts compared to kidney epithelial cells. These data suggest that future efforts to modify Gremlin1 activity in areas of cellular injury may provide benefit to the fibrotic kidney.

**Interactions between Dead and Viable Proximal Tubular Cells (PTC) Influence Cell Survival, Growth, and Proliferation: Implications for Recovery after Acute Kidney Injury (AKI)** Vimal Patel,[1] Lanfei Feng,[1] Donald Massenburg,[1] Angelika Antoni,[3] Joyce Rauch,[4] Wilfred Lieberthal,[2] Jerrold S. Levine.[1] *[1]Medicine, University of Illinois, Chicago, IL; [2]Medicine, SUNY at Stony Brook, Stony Brook, NY; [3]Medicine, Kutztown University, Kutztown, PA; [4]Medicine, McGill University, Montreal, Canada.*

During AKI, PTC sustain sublethal injury or die by apoptosis or necrosis. Recovery depends on survival of injured cells and regeneration, which in turn requires cell growth (increased cell mass) and cell proliferation. We used BU.MPT cells, a conditionally immortalized PTC line, to examine the effects of receptor-mediated interaction between dead and viable BU.MPT cells. We show that apoptotic and necrotic PTC targets have profound, directionally opposite effects on survival, growth, and proliferation of viable PTC responders.

(1) Survival: Apoptotic PTC targets inhibited Akt activity in viable BU.MPT responders and induced apoptotic death of ~80% responders by 48 hrs. A constitutively active Akt construct blocked apoptosis of BU.MPT cells by only ~50%, implying that apoptotic PTC targets induce death via both Akt-dependent and -independent pathways. In contrast, necrotic PTC activated Akt and promoted BU.MPT cell survival.

(2) Proliferation: Apoptotic PTC targets inhibited ERK1/2 activity and markedly slowed cell cycle progression of actively proliferating BU.MPT cells. In contrast, necrotic targets activated ERK1/2 and stimulated cell cycle progression of quiescent BU.MPT cells.

(3) Growth: Apoptotic PTC decreased activity of mTOR and its downstream target p70S6K, inhibiting growth of viable BU.MPT cells. Inhibition of mTOR seemed to occur via at least two apoptotic target-dependent pathways, inhibition of Akt and activation of AMPK.

All effects on cell fate occurred in a dose-dependent manner, and required physical contact between dead and viable PTC. Effects were independent of engulfment, requiring only receptor-mediated recognition. Our data show that signaling events, induced by recognition of apoptotic and necrotic PTC, have distinct effects on survival, proliferation, and growth of viable PTC, events that are important to recovery from AKI.

Disclosure of Financial Relationships: nothing to disclose

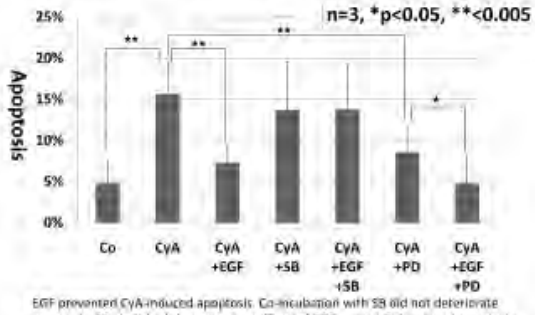
**SA-PO2178**

**Crosstalk between Smads and p38MAP Kinase and ERK and Its Modulation by Epidermal Growth Factor Regulate Apoptosis in Cyclosporine A-Induced Renal Tubular Injury** Hideyuki Iwayama,[1] Norishi Ueda.[2] *[1]Neonatology and Pediatrics, Nagoya City University, Nagoya, Aichi, Japan; [2]Nagoya University, Nagoya, Aichi, Jordan.*

We examined whether there is a crosstalk between Smads and MAPK kinases (MAPKs) and its modulation by epidermal growth factor (EGF) in cyclosporine A (CyA)-induced renal tubular cell (RTC) injury. HK-2 cells, human renal proximal tubular cells, were exposed to CyA (0.42-42μM) for 0-24 hrs in a serum-free condition. Apoptosis, measured by Hoechst 33258 staining, ocurred at 24 hrs after exposure to CyA. CyA induced apoptosis

in a time- and dose-dependent manner. Nuclear translocation (NT) of phospho(p)-Smad2/3, determined by immunofluorescence staining and Western blotting, occurred at 3 hrs after exposure to CyA (42μM), preceding apoptosis, increasing up to 24 hrs. CyA increased expression of p-p38MAPK, determined by Western blotting, at 1 hr and returned to control level at 12 hrs. CyA increased expression of p-ERK at 1 hr, increasing up to 24 hrs compared to control. EGF (20 ng/ml) activated both p-p38MAPK and p-ERK in control cells. EGF prevented CyA-induced NT of p-Smad2/3 and apoptosis. Co-incubation of HK-2 cells with a specific inhibitor of p38MAPK, SB202190 (SB:20μM), deteriorated CyA-induced NT of p-Sma2/3 but not apoptosis. SB202190 abolished the protective effects of EGF against CyA-induced NT of p-Smad2/3 and apoptosis. An inhibitor of ERK, PD98059 (20μM) did not affect the effect of CyA-induced NT of p-Smad2/3, but enhanced the protective effect of EGF on CyA-induced NT of Smad2/3 and apoptosis. Our data demonstrate a crosstalk between Smad2/3 and p38MAPK and ERK and that EGF inhibits Smad2/3 signaling and apoptosis through activation of p38MAPK and ERK in CyA-induced RTC injury.

**Figure1. Effect of EGF on CyA-Induced apoptosis and its modulation by an inhibition of ERK or p38MAPK**



EGF prevented CyA-induced apoptosis. Co-incubation with SB did not deteriorate apoptosis. SB abolished the protective effects of EGF against CyA-induced apoptosis. PD enhanced the protective effect of EGF on CyA-induced apoptosis.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2179**

**Pharmacological Activation of Epac1 Protects Against Cisplatin-Induced Nephrotoxic Injury in Renal Tubular Epithelial Cells** Geurt Stokman,[1] Yu Qin,[1] Ingeborg M. Bajema,[2] Bob Water,[1] Leo Price.[1] *[1]Toxicology, LACDR, Leiden University, Leiden, Netherlands; [2]Pathology, LUMC, Leiden University, Leiden, Netherlands.*

Nephrotoxicity is the primary reason for discontinuation of cisplatin administration in cancer treatment. Toxicity is associated with disruption of adhesion of proximal tubular epithelial cells and apoptosis. Activation of the small GTPase Rap1 by Exchange Protein directly Activated by cAMP 1 (Epac1) promotes cell adhesion and supports adhesion-mediated cell survival signaling. Here we demonstrate the anti-apoptotic effect of Epac-Rap signaling pathway activation on in vitro cisplatin-induced cell death.

Proximal tubular epithelial cells were exposed to cisplatin, in combination with the Epac1 selective cAMP analogue 8-pCPT-2'-O-Me-cAMP (007). Activation of Rap1 was detected using Ral-GDS-RBD-pull down analysis. Cell death was measured by caspase 3 activity and cell cycle analysis. Cell-cell adhesion was quantified based on expression patterns of beta-catenin and zona occludens-1. Epac1 and Rap1 knockdown was performed by siRNA transfection. A panel of lung and breast cancer cell lines were tested for their responsiveness to 007 in cisplatin-induced cell death.

A 24 hour incubation of a proximal tubular epithelial cell line with cisplatin induced severe cellular apoptosis. This was accompanied by extensive disassembly of adherens and tight junctions. 007 treatment reduced cisplatin-induced apoptosis and cell junction disassembly – an effect that was dependent on expression of Epac1 and Rap1. In contrast, cell lines derived from lung and breast cancer tumors did not express Epac1 and were not protected against cisplatin-induced cell death by 007.

Activation of Epac-Rap signalling and stabilisation of tubular epithelial cell adhesions offers a potential strategy to reduce cisplatin-induced nephrotoxicity and widen the therapeutic window for cisplatin treatment without impairing efficacy towards cancer cells.

**Consideration of Protein Expression Changing with Pitavastatin Therapy in Chronic Puromaycin Aminonucreoside Nephropaty** Tokushi Nakajima, Koichi Kanozawa, Hajime Hasegawa. *Departement of Renal and Hypertension, Kasagoe, Saitama, Japan.*

< Back ground >

In puromaycin aminonucreoside nephrosis rats which is one of human nephritic syndrome model. In hyperlipidemia, statins have many evidences to protect from cardiovascular disease and renal failure. In nephritic syndrome, hyperlipidemia is one of main symptom. Excessive oxidants play roles in the pathogenesis of glomerular injury. Several studies have demonstrated protective effects of pitavastain against renal injury. To clarify the protective effects of pitavastatin, we investigated changes in chemical markers of lipid peroxidation and renal histology, and protein array in rats with chronic puromycin aminonucleoside nephrosis (C-PAN).

< Methods >

C-PAN was induced by intraperitoneal injections of PAN (130 mg/kg on day 1 and 60 mg/kg on day 14). Rats administered normal saline served as controls (n=5). C- PAN rats were divided into two groups (each group: n=4). Blood and urinary samples were collected every week. Animals were sacrificed at the end of experiment for histological and protein array analysis.

< Results >

In C-PAN+Pit rats, urinary excretion of albumin and 8-isoPGF2 were significantly decreased compared with that in C-PAN rats ($p<0.01$), whereas levels of urinary thiobarbituric acid-reactive substances (TBARS) did not differ between the two groups. On histological examination, the scores for glomerular injury and area positive for 4-HNE were significantly lower in C-PAN+Pit than in C-PAN rats ($p<0.01$). Infiltration of macrophages was also suppressed in C-PAN+Pit rats. By protein microarray analysis, mammalian target of rapamaycin (mTOR) protein is significantly upregulated (1500 field).

< Conclusion >

Pitavastatin treatment of C-PAN was able to decrease albuminuria and to ameliorate glomerular injury. Levels of several markers related to oxidative stress and lipid peroxidation were reduced after treatment, accompanied by reduction of macrophage infiltration and decrease in apoptotic cells in the glomeruli. These findings indicate that pitavastatin has protective effects against the glomerular injury observed in C-PAN nephrosis, and the effect is strongly connect with mTOR protein activity.

**Akt Regulates Albumin Uptake Via Dab2 Phosphorylation** Elif Erkan,[1] Kenneth R. Hallows,[2] Jeffrey Lee,[2] Kelly Koral.[1] *[1]Pediatrics, University of Pittsburgh; [2]Internal Medicine, University of Pittsburgh.*

Proteins involved in endocytosis have the potential to initiate signaling events. In addition to its role in clathrin assembly and sorting, Disabled 2 (Dab2) is implicated in cell positioning, adhesion and differentiation. Albumin endocytosis in proximal tubule epithelial cells occur via receptor mediated endocytosis with the involvement of clathrin, clathrin associated sorting proteins (CLASPs) and transmembrane receptor megalin. We examined whether there is a link between endocytosis and a kinase implicated in cell survival, protein kinase B (Akt). The proline rich domain (residues 600-730) of Dab2 and protein kinase B (Akt) co- immunoprecipitate and co-precipitate in GST pull-down experiments. The physiological relevance of this interaction was examined in albumin uptake studies. Overexpression of Akt in human kidney proximal tubule cells (HKC-8) with plasmids encoding wild type and constitutively active (CA) Akt increased internalization of albumin. Expression of dominant negative of Akt (Akt-T308A/S473A) or pretreatment of cells with the specific Akt inhibitor, API-2, caused a significant decrease in albumin uptake. Furthermore, inhibition of Dab2 by silencing RNA decreased albumin uptake in HKC-8 cell transfected with CA-Akt ,validating the role of Dab2-Akt interaction in regulation of albumin uptake and suggesting that Akt operates upstream from Dab2. *In vitro* phosphorylation experiments demonstrated that Akt phosphorylates the M15 portion (residues 335-610) of Dab2. In summary, we have demonstrated an interaction between Dab2 and Akt, that modulates albumin uptake in a proximal tubular cell line. We believe Akt is a new member of the endocytic machinery and may be involved in trafficking and sorting events by interacting and phosphorylating CLASPs in proximal tubule cells. Delineation of protein-protein interactions surrounding activation of Akt and identifying network of proteins involved in albumin uptake will enable us to understand the physiology of proximal tubule function and develop strategies to halt proteinuria induced progression by targeting key proteins of the endocytic pathway

**SA-PO2182**

**Regulation of the Ste20-Like Kinase SLK by Phosphorylation** Artem Luhovy, Andrey V. Cybulsky. *Medicine, McGill University, Montreal, QC, Canada.*

Expression and activation of SLK is increased during kidney development and recovery from ischemic acute kidney injury, which recapitulates aspects of kidney development. SLK promotes apoptosis and may, therefore, regulate cell growth during development, injury or healing. We propose that activation of SLK may be due to upregulation of expression, which may then favor homodimerization and autophosphorylation. The aim of this study was to determine the role of phosphorylation in the regulation of kinase activity. We mutated serine and threonine residues in the putative activation segment of the SLK catalytic domain, and expressed wild type (WT) and mutant proteins in COS-1 or glomerular epithelial cells. Compared with SLK WT, the S189A mutant and the T183A/S189A double mutant showed trivial in vitro kinase activity, while kinase activity was reduced significantly by the T183A mutation. Expression of SLK WT increased activation-specific phosphorylation of c-Jun N-terminal kinase (JNK) and p38 kinase, reflecting enhanced signaling via stress kinase pathways. In contrast, activation of JNK and p38 by SLK T183A, S189A, and T183A/S189A was impaired. Similarly, expression of SLK WT stimulated activator protein-1 (AP1) reporter activity, but activation of AP1 by the three SLK mutants was ineffective. To test if homodimerization of SLK affects phosphorylation, the cDNA encoding the SLK catalytic domain (amino acids 1-373) was fused with a cDNA for a modified FK506 binding protein, Fv (SLK-Fv). After transfection, addition of AP20187 (an FK506 analog) induced regulated dimerization of SLK-Fv. AP20187-stimulated dimerization enhanced the kinase activity of SLK-Fv WT. In contrast, kinase activities of SLK-Fv T183A/S189A and another activation site mutant, T193A, were weak, and were not enhanced after dimerization. Surprisingly,

phosphomimetic mutants of SLK-Fv, including T183D, T183E, S189D, and S189E showed weak kinase activity, which was unaffected by dimerization. Finally, apoptosis and necrosis were increased after expression of SLK-Fv WT, but not T183A/S189A. Thus, phosphorylation of T183, S189 and T193 plays a key role in the activation and signaling of SLK, and could represent a target for novel therapeutic approaches to renal injury.

**IL-17A Induces Granulocyte Colony-Stimulating Factor Via ERK1/2 but Not p38 and JNK in Human Renal Proximal Tubular Epithelial Cells** Yuki Hirai, Masayuki Iyoda, Takanori Shibata, Yoshihiro Kuno, Tadao Akizawa. *Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan.*

Introduction: We investigated the potential role of interleukin (IL)-17A in the induction of granulocyte colony-stimulating factor (G-CSF), a critical granulopoietic growth factor, in renal proximal tubular epithelial cells. Methods: We used human renal proximal tubular cells (HK-2). The expression of G-CSF was evaluated by enzyme-linked immunosorbent assay (ELISA) and real-time RT-PCR. Activation of mitogen-activated protein kinase (MAPK) was assessed by immunoblotting. Results: We found that IL-17A stimulation of the cells led to a dose-dependent (27.54±0.69 vs. 41.86±1.39, pg/ml, IL-17A (10 ng/ml) vs. IL-17A (100 ng/ml)) and time-dependent (4.10±0.48 vs. 41.86±1.39, pg/ml, 6h vs. 24h stimulation with IL-17A (100 ng/ml)) increase in G-CSF release. This effect was dependent on mRNA transcription and protein translation (51.21±1.47 vs. 5.88±0.29 vs. 8.01±0.26, pg/ml, IL-17A (100 ng/ml) vs. IL-17A (100 ng/ml) + actinomycin D (1 μg/ml) vs. IL-17A (100 ng/ml) + cycloheximide (10 μg/ml)). Real-time RT-PCR demonstrated that G-CSF mRNA expression reached a maximum level 6 h following IL-17A stimulation. IL-17A also enhanced TNF-α or IL-1β-mediated G-CSF release in the cells (3.50±0.41 vs. 26.19±1.21 vs. 335.90±7.41, pg/ml, TNF-α (1 ng/ml) vs. IL-17A (100 ng/ml) vs. TNF-α (1 ng/ml) + IL-17A (100 ng/ml)). Additionally, we observed that IL-17A induced MAPK (ERK1/2 but not p38 MAPK or JNK) activation (Western blotting analysis showed the phosphrylation of ERK1/2 started at 5 min returned to baseline levels from 120 min in IL-17A-stimulated proximal tubular cells), and that pharmacological inhibitors of MEK1/2 (U0126) but not p38 MAPK (SB203580) or JNK (SP600125), significantly blocked the IL-17A-mediated G-CSF release (32.05±0.77 vs. 17.56±1.44, pg/ml, IL-17A (100 ng/ml) + DMSO vs. IL-17A (100 ng/ml) + U0126 (10μM)). Conclusion: We demonstrate the previously unappreciated ability of IL-17A in the induction of G-CSF in renal proximal tubular cells. It is proposed that IL-17A may play an important role in neutrophil recruitment via stimulating G-CSF in tubular injury.

**High Glucose Degradation Products PD-Fluids Overcome the Protective Effect of Apoptosis Inhibitors on Inflammation Induced Cell Death** Alberto Benito Martin, Beatriz Santamaria Pérez, Alvaro C. Ucero, Jesus Egido, Alberto Ortiz. *Experimental Nephrology Department, Fundacion Jimenez Diaz, Madrid, Spain.*

***Background*:** Peritoneal dialysis is complicated by peritonitis episodes that cause loss of mesothelium. Proinflammatory cytokines increase mesothelial cell apoptosis. However, there is scarce information about the influence of the cytokine-peritoneal dialysis solution interplay on mesothelial cell death.

***Methodology***: Human mesothelial cells were cultured from effluents of stable peritoneal dialysis patients and from omentum of non-dialysis patients. The cytokine combination of tumor necrosis factor alpha and interferon gamma increased the rate of mesothelial cell apoptosis and a polymeric nanoconjugate Apaf-1 inhibitor protected from apoptosis. Culture in the presence of high glucose, high glucose degradation product (GDP) containing PD solutions increased cell death induced by this cytokine combination. This increment was not observed when high glucose, low GDP PD solutions were added. Addition of high glucose, high GDP PD solutions resulted in an increased Bax/BclxL ratio. A BH4 peptide that behaves like BclxL protected from spontaneous or staurosporin-induced mesothelial cell apoptosis but did not protect from apoptosis induced by the cytokine combination in the presence of high glucose, high GDP PD solutions. Furthermore, the polymeric nanoconjugate Apaf-1 inhibitor also protected from high glucose, high GDP PD solution-induced apoptosis, but was unable to prevent apoptosis induced by the cytokine combination in the presence of high glucose, high GDP PD solutions.

***Conclusion*:** Cooperation between tumor necrosis factor alpha and interferon gamma contributes to mesothelial injury. The lethal effect is exacerbated by high glucose, high GDP PD solutions. Lowering the GDP content of PD solutions, but not the use of drugs targeting the apoptotic machinery, reverses cytokine induced apoptosis in the presence of inflammation.

**AATF/Che-1 in DNA-Damage Response and Its Function in Carcinogenesis of Epithelial Cells in the Kidney** Katja Hoepker, Henning Hagmann, Safiya Khurshid, Bernhard Schermer, Thomas Benzing. *Department of Nephrology, University Hospital Cologne, Cologne, Germany.*

In every eukaryotic cell genomic integrity is continuously being challenged by DNA damage. An increased rate of DNA damage and mutations has been implicated as key causal events in the process of carcinogenesis. In response to genotoxic stress eukaryotic cells activate DNA damage checkpoint pathways to protect genomic integrity. Damaged cells with alarmed checkpoints can be eliminated by apoptosis, silenced by cellular senescence or can survive and resume cell cycle progression upon DNA repair and checkpoint termination.

We and other groups have identified AATF/Che-1, a transcriptional regulator and RNA polymerase II binding protein, as a key protein involved in DNA damage response pathways.

Here we show that under normal conditions AATF/Che-1 resides in the cytoplasm where it interacts with Myosin Regulatory Light Chain 3 (MRLC3). This interaction is regulated through the basophilic MAPKAP kinase 2 (MK2). DNA damage caused by genotoxic stress results in the activation of MK2 via the p38 pathway and phosphorylation of AATF/Che-1. This abrogates the interaction with MRLC3 and releases AATF/Che-1 from its cytoplasmic pool, allowing it to travel to the nucleus where it promotes transcription of target genes. We further show that AATF/Che-1 plays a critical role in resistance to apoptosis after DNA-damage. Suppression of AATF/Che-1 by siRNA increases the rate of apoptotic cells after genotoxic stimuli. Whereas RNAi knock down of MRLC3 leads to decreased apoptotic response. This "apoptosis antagonizing effect" of AATF/Che-1 was found to be largely p53 dependent.

Perspective: Renal cell carcinoma is a notoriously difficult to treat entity and largely resistant to conventional chemotherapy. Here we show that AATF/Che-1 is a key player in DNA-damage response regulated by the MK2 pathway. After genotoxic stress AATF/Che-1 delicately modulates the balance of p53 and other genes involved in DNA damage response preventing the cell from undergoing apoptosis. Being a part of the pharmacologically targetable MK2-pathway AATF/Che-1 may have implications in chemo-sensitizing therapy of renal cell carcinoma.

**Armcx2 Is Expressed in Late Stages of Nephrogenesis and Is Lost in Renal Cell Carcinoma** Stephan Grouls,[1] Ellen Krautkrämer,[1] Luis Eduardo Becker,[1] Jochen Reiser,[2] Martin G. Zeier.[1] *[1]Nephrology, University of Heidelberg, Heidelberg, Germany; [2]Nephrology and Hypertension, University of Miami, Miami.*

Background:

ARMCX2 is a member of the armadillo repeat protein family. Proteins containing arm repeat motifs, i.e. beta-catenin, are involved in fundamental processes such as proliferation, migration, and differentiation. Those processes play a key role not only during development but also in tumorigenesis. Therefore we wanted to investigate the potential role of ARMCX2 expression during nephrogenesis and in renal cell carcinoma.

Methods:

We analyzed the expression pattern of ARMCX2 in human renal cell lines, primary renal epithelial cells and renal cell carcinoma cell lines. Furthermore, we performed immunohistochemistry for the detection of ARMCX2 in sections of normal human kidney and renal cell carcinoma.

Results:

In normal human kidneys ARMCX2 was expressed exclusively in epithelial cells of the kidney including podocytes. These in vivo data were in consistence with our in vitro data which revealed strong ARMCX2 expression in primary tubular epithelial kidney cells and podocytes. During nephrogenesis ARMCX2 was earliest detectable in late stages. While there was no ARMCX2 expression in the s-shaped body stage strong expression was present in glomerular and tubular epithelial cells in the maturing glomeruli stage. However, ARMCX2 expression was downregulated in renal cell carcinoma cell lines and in biopsies of renal cell carcinoma. ARMCX2 was mainly localized in the perinuclear region and in filament-like structures in the periphery where it was colocalized with focal adhesions.

Conclusion:

We conclude that ARMCX2 is expressed in epithelial cells of the adult kidney and late during nephrogenesis. These findings indicate a role of ARMCX2 in the differentiation of kidney epithelial cells. The association with focal adhesions underlines the assumption that ARMCX2 plays a role in the final process of cell differentiation of renal epithelial cells. Furthermore, our results demonstrate that ARMCX2 is downregulated in renal cell carcinoma cell lines indicating a role as possible tumorsuppressor.

**SA-PO2187**

**SC35-Dependent Sequestration of Phospho-BADser112 in Nuclear Speckles Is a Novel Cell Survival Mechanism** Kirk N. Campbell,[1] Ritu Gupta,[1] Katsuhiko Asanuma,[2] Peter H. Mundel.[3] *[1]Nephrology and Hypertension, University of Miami Miller School of Medicine, Miami, FL; [2]Nephrology, Juntendo University School of Medicine, Tokyo, Japan; [3]Molecular Medicine, University of Miami Miller School of Medicine, Miami, FL.*

Speckles are nuclear organelles enriched in small nuclear ribonucleoproteins (snRNP) and numerous other splicing and transcription related proteins and kinases. SC35 is a non-snRNP serine/arginine-rich RNA binding protein important in splicing and spliceosome assembly that is constitutively expressed in speckles. A role for SC35 has also been identified in regulating cell cycle progression and genomic stability. We previously identified dendrin as a glomerular slit diaphragm component that relocates to the nucleus under disease conditions to promote podocyte apoptosis. Here we show that the binding of Yes-associated protein 2 (YAP2) to dendrin increases the steady-state protein expression of SC35 by inhibiting its degradation via the nuclear ubiquitin-proteasome system. We also show that phospho-BADser112 accumulates and co-localizes with SC35 in nuclear speckles induced by binding of YAP2 to dendrin. Gene silencing of SC35 abrogates the accumulation of phospho-BADser112 in speckles and enhances staurosporine-induced apoptosis in HEK293 cells cotransfected with YAP2 and dendrin.

In summary, we have identified a novel pro-survival mechanism where the binding of YAP2 to dendrin increases steady-state protein expression of SC35 culminating in the sequestration of phospho-BADser112 in nuclear speckles.

**Nucleosphosmin: An Apoptosis Promoting Co-Factor for Bax in ATP Depleted Renal Epithelial Cells** Zhiyong Wang, Jonathan M. Gall, Andrea Havasi, John H. Schwartz, Steven C. Borkan. *Renal Section, Boston Medical Center, Boston, MA.*

Nucelosphomin (NPM), a nuclear co-factor that regulates ribosomal protein synthesis, has recently been shown to complex with Bax, a key cause of stress-induced mitochondrial injury and cell death. We hypothesized that NPM acts as a co-factor that promotes Bax toxicity and apoptosis. To test this hypothesis, human renal proximal tubule cells were subjected to ATP depletion sufficient to induce apoptosis. At baseline, NPM localized almost exclusively to the nucleus. ATP depletion caused marked cytosolic NPM accumulation before mitochondrial injury or apoptosis occurred and without altering total cell NPM content. Injury induced Bax activation, evidenced by exposure of the 6A7 epitope and also increased the interaction between NPM and active Bax. Expression of either flag-tagged wild type NPM or a mutant lacking the nuclear localizing sequence (NPMΔNLS) increased both cytosolic NPM accumulation and stress-induced cell death. In contrast, over-expression of a NPM mutant lacking the nuclear export sequence (NPMΔNES) neither increased its cytosolic accumulation or promoted cell death after stress. Prior exposure of cells to leptomycin B, a nuclear pore inhibitor, decreased stress-induced cytosolic NPM accumulation in a dose-dependent manner. Furthermore, RNAi-mediated Bax knockdown completely prevented the toxic effects of NPMΔNLS expression during stress. These results show that with ATP depletion, NPM undergoes regulated nuclear export to the cytosol, interacts with active Bax and promotes Bax-mediated apoptosis. Thus NPM is a functional Bax co-factor that promotes apoptosis during renal epithelial cell stress.

**Inactivation of Mxi1 Decreases Insulin-Like Growth Factor Binding Protein-3 in Polycystic Kidney** Jong Hoon Park, Je Yeong Ko, Kyung Hyun Yoo. *Department of Biological Science, Sookmyung Women's University, Seoul, Korea.*

The Mxi1, an antagonist of c-Myc, is a member of Mad family that participate in cell proliferation and differentiation. According to the reports that have been published, overexpression of c-Myc is related to molecular mechanism of autosomal dominant polycystic kidney disease (ADPKD). Previously, multiple tubular cysts were observed in kidney of Mxi1-deficient mice aged 6 months or more. From these backgrounds, microarray analysis of Mxi1+/+ and Mxi1-/- MEFs was performed to identify the mechanism of cyst formation. We obtained some genes associated with cyst formation and selected insulin-like growth factor binding protein-3 (IGFBP-3), which has role for growth suppressor. Because increase of cell proliferation is necessary for early stage of cyst formation, we selected IGFBP-3 as a candidate gene. In our results, expression of IGFBP-3 was decreased in Mxi1-/- MEFs and level of this gene was regulated by Mxi1 expression in Mxi1 MEFs. Also, IGFBP-3 was reduced in not only Mxi1-/- MEFs but also Mxi1-/- mice and proliferation pathways related to IGFBP-3 were regulated in kidney of Mxi1-/- mice compared to controls. To determine whether inactivation of Mxi1 induces cell proliferation, we performed proliferation assay in both Mxi1 MEFs and Mxi1 mice. The cell viability was regulated by Mxi1 in Mxi1 MEFs and number of PCNA-positive cells was increased in Mxi1-/- mice when compared with Mxi1+/+ mice. Moreover, we found that IGFBP-3 level was significantly decreased in surrounding of cyst in Mxi1-/- mice. In conclusion, these findings suggest that inactivation of Mxi1 has a positive effect on cyst formation via down-regulation of IGFBP-3, so this mechanism is the potential target for polycystic kidney disease.

**Activation of a Nuclear Factor of Activated T-Lymphocyte-3 (NFAT3) by Oxidative Stress in Carboplatin-Mediated Renal Apoptosis** Heng Lin,[2] Shu-Hui Juan,[1] Wei-Shiung Lian,[3] Hsiao-Fen Li.[3] *[1]Physiology, Taipei Medical University, Taipei, Taiwan; [2]Institute of Pharmacology and Toxicology, Tzu Chi University, Hualien, Taiwan; [3]Academia Sinica, Institute of Biomedical Sciences, Taipei, Taiwan.*

Although carboplatin is currently used as a therapeutic drug for ovarian, breast, and non-small cell lung cancers, it has serious side effects including renal and cardiac toxicity that results in cell death. Herein, we examined the effect of carboplatin on murine renal tubular cell (RTC) apoptosis both *in vivo* and *in vitro* and its underlying molecular mechanisms associated with activation of the nuclear factor of activated T-lymphocytes-3 (NFAT3; a nuclear transcription factor). We demonstrated that carboplatin initiated an intrinsic apoptotic pathway of activating caspase-3 and -9, accompanied by a decrease in the ratio of Bcl-XL/Bax and a significant increase in Bcl-XS. Carboplatin increased NFAT activation in NFAT-luciferase reporter transgenic mice, RTCs, and in cells exogenously overexpressing NFAT3 that exacerbated cell death. Furthermore, the addition of either N-acetylcysteine (NAC, an antioxidant) or NFAT inhibitors, including FK-506 (tacrolimus), cyclosporin A (CsA, a calcineurin inhibitor), and BAPTA-AM (a calcium chelator) and successfully reversed the cell apoptosis induced by carboplatin, which was further confirmed using siNFAT3. Additionally, NAC blocked NFAT3 activation by inhibition of NADPH oxidase activation, and ERK/JNK and PKC pathways, resulting in the decrease in cell apoptosis, and the therapeutic effect of NAC was verified in vivo.The results presented herein show that carboplatin-mediated ROS might signal calcineurin and NFAT3 activation in RTCs, whereas NAC and NFAT inhibitors reversed carboplatin-mediated RTC apoptosis, suggesting that oxidative stress-mediated NFAT3 activation is essential for carboplatin-mediated RTC apoptosis.

**Ouabain Protects Renal Tubular Cell from Shiga Toxin Induced Apoptosis** Xiao Liu,[1] Evgeniya Burlaka,[1] Rachel Vieux,[1] Diana Karpman,[2] Anita Aperia.[1] *[1]Department of Woman and Child Health, Karolinska Institutet, Stockholm, Sweden; [2]Department of Pediatrics, Clinical Sciences Lund, Lund University, Stockholm, Sweden.*

Ouabain can protect renal tubule cells from apoptosis by triggering a Na, K-ATPase (NKA) / inositol 1,4,5-triphosphate receptor (IP3R) interaction and activating transcription factor NF-kB signaling pathway (Juan, JASN 2006). As shiga toxin (Stx) can cause apoptosis of human and murine renal tubular cells, we aimed to examine if ouabain protects from Stx-induced apoptosis. The study were performed in rat proximal tubule cells (RPTC) primary culture treated for 24h with Stx in the presence of ouabain or vehicle. Apoptotic degree was estimated by TUNEL assay, genomic DNA fragmentation, and flow cytometry detecting Annexin V. Immunoprecipitation, immunostaining and NF-kB TransAM assays were used to determine the signal pathway of the ouabain/NKA.

The experiment data indicated that 24h treatment with 5 nM ouabain, which has no effect on intracellular sodium (Juan, JASN 2006), almost completely rescued the RPTC from apoptosis provoked by Stx. Furthermore, NKA/IP3R immunoprecipitation, NF-kB nuclear translocation and NF-kB activity quantification measurement, as well as specific anti-apoptotic Bcl-xL protein detection showed that ouabain's protective effect in RPTC was mediated through the ouabain/NKA/IP3R signaling cascade which directly transduce the downstream activation of NF-kB into the increase of anti-apoptotic protein Bcl-xL expression. Taken together, our results provide an important research model and suggest that ouabain might be a novel therapeutic option to reduce toxic tubular injury in the development of renal disease.

**HIV-Associated Nephropathy (HIVAN): Role of Autophagy** Divya Salhan, Shitij Arora, Anju Yadav, Dileep Kumar, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Long Island Jewish Medical Center, New Hyde Park, NY.*

Autophagy is a highly regulated process to provide protection against oxidative stress-mediated cell injury. Oxidative stress-induced damaged organelles and proteins are usually degraded by the induction of autophagy. Inefficient or loss of autophagic process may allow accumulation of oxidized proteins and damaged organelles intracelluraly, which may be detrimental for cell survival. In *in vitro* studies, oxidative stress has been reported to contribute HIV-1-induced podocyte injury by the induction of podocyte apoptosis. We studied the role of oxidative stress and ongoing autophagy in a mouse model of HIVAN.

Age and sex matched control and Tg26 mice (8 weeks old) in groups of six were evaluated for ongoing oxidative stress by immunolabeling of frozen renal cortical sections with redox sensitive probe dihydroethidium (DHE). In addition, electron microscopic studies were carried out to study number of autophagosomes in renal cortical sections of control and Tg26 mice. Renal cortical sections were immunolabeled for expression of LC3-2, a gene associated with autophagosome formation. To establish a cause and effect relationship between autophagy and development of HIVAN, four weeks old Tg26 mice in groups of six were treated with either buffer or rapamycin (5 mg/kg/every other day), a stimulator of autophagy for two weeks, followed by evaluation of renal histology.

Tg26 mice showed enhanced generation of ROS both by glomerular and tubular cells. However, renal cortical section of Tg26 mice showed lower number of autophagosomes when compared with control mice. HIVAN mice showed higher number of both glomerular and tubular apoptotic cells. Interestingly, rapamycin, an autophagy promoter attenuated renal lesions in Tg26 mice.

We conclude that development of HIVAN is associated with the generation of oxidative stress but at the same time an attenuated response of autophagosome formation. The later may contribute to ongoing apoptosis of tubular and glomerular cells and progressive renal injury. Our hypothesis was further supported with the findings that the stimulation of autophagy by rapamycin slowed down the development of HIVAN.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2193**

**HIV-1 Compromises Redox Activity Induced Stress Response Program in Tubular Cells** Divya Salhan, Dileep Kumar, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Long Island Jewish Medical Center, New Hyde Park, NY.*

HIV-associated nephropathy is associated with microcystic dilatation of tubules and tubular cell apoptosis. HIV-1 has been demonstrated to induce apoptosis in tubular cells by multiple mechanisms. Since HIV-1 has been reported to induce oxidative stress in a variety of cells, we evaluated the role of redox activity and associated stress response program in HIV-1-induced tubular cell apoptosis.

For *in vitro* models of HIV-1 infection, we have used mouse proximal tubular cells (MPTECs)-transduced with NL4-3 HIV (NL4-3/MPTEC, NL4-3 is an HIV-1 construct containing all the genes except *gag* and *pol*) and primary human proximal tubular cells pulsed with HIV-1 (HIV/HRPTEC). Both NL4-3/MPTEC and HIV/HRPTECs were evaluated for occurrence of apoptosis by morphologic assays. ROS generation as well ROS kinetics was studied in NL4-3/MPTECs and HIV/HRPTECs. In addition, proteins were extracted from NL4-3/MPTECs and HIV/HRPTECs, Western blots were prepared and probed for phospho-p66ShcA, Akt, Foxo3A, MnSOD and catalase.

Both NL4-3/MPTECs and HIV/HRPTECs showed enhanced apoptosis when compared with control cells. Both NL4-3/MPTEC and HIV/HRPTEs showed enhanced ROS generation. Both antioxidants and free radical scavengers inhibited apoptosis in both NL4-3/MPTECs and HIV/HRPTECs. Interestingly, NL4-3/MPTEC showed only mild increase in mRNA expression of MnSOD and catalase; whereas, HIV/HRPTECs showed only moderate increase in MnSOD and no increase in catalase. Both NL4-3/MPTECs and HIV/HRPTECs not only showed enhanced phosphorylation of p66 (ShcA) but also of Akt. However, both NL4-3/MPTEC and HIV/HRPTECs did not show any decrease in phospho-Foxo3A.

HIV-1 infected tubular cell apoptosis is mediated through ROS generation. Since there was no significant alteration in phosphorylation of Foxo3A despite ongoing oxidative stress and only modest increase in antioxidant molecules such as MnSOD and catalase, it appears that HIV-1-induced tubular cell apoptosis may be a consequence of the compromised redox activity-induced stress response program.

**SA-PO2194**

**Id1 Protects Mesangial Cells from Apoptosis Induced by TGFβ by Inhibiting USF2 Activity** Alex Yuri Sato,[1,2] Eliane Antonioli,[1] Alexandre Holthausen Campos.[1] *[1]IIEP-Albert Einstein Hospital, Sao Paulo, Brazil; [2]Dept. of Physiology, ICB-USP, Brazil.*

The late phase of diabetic glomerulopathy is characterized by death of mesangial cells (MC) and fibrosis. The identification of novel elements involved in cell death in MC would facilitate the comprehension of the pathophysiology of glomerular diseases. The Inhibitor of DNA Binding genes (Id) have been implicated in cell survival control and are expressed in MC. This study aims to investigate the role of Id1 in MC apoptosis.

Human MC were treated with TGF-β1(2ng/ml), BMP4(1ng/ml), BMP7(5ng/ml) or vehicle for different periods of time, and total RNA was extracted. To identify Id1/DNA interactions, we performed chromatin immunoprecipitation (ChIP). DNA fragments obtained were sequenced, and analyzed with bioinformatics tools. For apoptosis and gene reporter assays, Id1 overexpression in MC was followed by chromatin morphology analysis, caspase-3 and luciferase activity assays. qPCR was performed to measure mRNA expression levels of potentially regulated genes. BMP4 and 7 rapidly and potently up-regulated Id1 in MC (21 and 9 fold-change respectively, N=4, $p<0.01$). ChIP assay showed that Id1 interacts with conserved binding sites of the transcription factor USF2, with high specificity (dissimilarity ≤ 0.52%; hit by chance ≤ 0.001). Gene reporter assays showed that both BMP4 and Id1 reduce (-50% and -30%, N=6, $p<0.01$, respectively), whereas TGFβ1 increases USF2 activity (+40%, N=6, $p<0.01$). qPCR demonstrated that TGFβ-1 treatment increased USF2 expression (2.5 fold-change, N=4, $p<0.05$). Bioinformatics analysis disclosed USF2 binding sites in the promoter region of BAX, a pro-apoptotic gene. In fact, TGFβ-1 and USF2 stimulated BAX expression (1.8 and 1.5 fold-change, respectively, N=4, $p<0.05$), while Bcl2 levels remained unaffected. In addition, TGF-β1 increased whereas BMP-7 and Id1 decreased apoptosis in hMC (+25%, -35%, and -68% N=6, $p<0.01$ respectively).

In this study we demonstrated that Id1 is upregulated by BMPs and antagonizes TGFβ1-induced death by inhibiting USF2 activity in human MC. Our results point to a potentially novel molecular path involved in the pathogenesis of glomerular diseases.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2195**

**The LIM Protein Hic-5 Mediates Extracellular Matrix Dependent Changes in Mesangial Cell Phenotype Independent of TGF-β** Nick Hornigold,[1] Andrew F. Mooney.[2] *[1]CRUK Clinical Research Centre, St James's University Hospital, Leeds, West Yorkshire, United Kingdom; [2]Renal Unit, St James's University Hospital, Leeds, West Yorkshire, United Kingdom.*

Glomerular scarring is the final common pathway by which all glomerular diseases lead to renal failure, during which the mesangial cell assumes the phenotype of an activated myofibroblast.

Recently, we have reported the role of Hic-5 in glomerular scarring. Hic-5 is upregulated in mesangial cells following attachment to collagen I, and this is associated with increased susceptibility to apoptosis and increased synthesis of collagen I precursors.

Due to the established role of TGF-β in glomerulosclerosis, and because TGF- β has been shown to induce Hic-5 epxression in other cell types, we examined whether this growth factor mediated the pro-sclerotic phenotype of mesangial cells following collagen I attachment and Hic-5 upregulation.

Using a rat mesangial cell line, Hic-5 protein levels can be greatly reduced either by using siRNA, or by cell attachment to collagen IV rather than collagen I. In both cases Hic-5 downregulation leads to a large reduction in collagen I mRNA expression at 16 hours. Treatment of cells with exogenous TGF- β had no effect on collagen I expression in Hic-5 positive cells, but led to a slight upregulation of collagen I in Hic-5 negative cells, after 48 hours. Mesangial cells may express TGF- β, and it may also be present in growth media. Therefore we examined the effects of blocking TGF- β signalling, either with a blocking antibody or using the SMAD3 inhibitor SIS3. TGF- β blockade by either means did not affect collagen I or Hic-5 levels, either in Hic-5 positive or negative cells. Addition of exogenous TGF- β increased mesangial cell apoptosis in a dose-dependent manner, but this effect was attenuated in Hic-5 negative cells.

Taken together, these data show that mesangial cell attachment to collagen I leads to a Hic-5 dependent pro-sclerotic phenotype independent of TGF- β. The demonstration of a TGF- β independent mechanism of pro-sclerotic mesangial cell phenotype regulation has important implications for the understanding of glomerulosclerosis

This work was supported by KRUK and the Yorkshire Kidney Research Fund.

**SA-PO2196**

**Role of Glutamine Transport and Metabolism in the Development of Renal Hypertrophy** Hassane Amlal. *Internal Medicine, University of Cincinnati, Cincinnati, OH.*

Renal hypertrophy develops in several conditions associated with increased ammoniagenesis including $NH_4Cl$ loading-induced metabolic acidosis and hypokalemia. However, the role of glutamine transport and its metabolism through glucosamine vs. ammoniagenesis pathways in renal hypertrophy is poorly understood. To address this issue, we examined renal mass in rat models with and without increased ammoniagenesis. Experiment #1, rats were treated for 2 days, 2 and 5 weeks with normal diet (controls), $K^+$-free diet (KD), 280 mM $NH_4Cl$ loading (acidosis) and KD + acidosis. Experiment #2, ovariectomized (OVX) rats treated with vehicle or 17b-estradiol (E2) for 3 and 6 days. Our results indicate that as early as 2 days of treatment, $NH_4^+$ excretion increased from an average of (in mM/day) 0.32 in control to 0.74 ($P<0.01$) in KD, 1.77 ($P<0.001$) in acidosis and 2.48 ($P<0.0001$) in KD + acidosis. After 2 weeks, renal mass (kidney wt/BW) increased slightly by 4% in KD and 12% in acidosis, and was sharply increased by 62% ($P<0.01$) in KD + acidosis compared to controls. After 5 weeks renal mass was also significantly increased in KD alone and acidosis alone vs. controls ($P<0.05$). Interestingly, while $NH_4^+$ excretion did not increase in E2- vs. vehicle-treated OVX rats at 3 or 6 days, renal mass significantly increased by 37% after 6 days in E2 vs. vehicle rats ($P<0.001$). The proximal tubule glutamine transporter (SN1 or SNAT3) expression was upregulated after 2 days by 51% in KD, 156% in acidosis and 195% in KD + acidosis vs. controls. Interestingly, SN1 expression also increased by 60% ($P<0.02$) and 121% ($P<0.001$) after 3 and 6 days of E2 vs. vehicle treatment, respectively. Lastly, the increased renal mass correlated with the upregulation of cyclin-dependent kinase (CDK) inhibitors $p21^{Cip1}$ but not $p27^{KiP1}$ in 2 weeks KD + acidosis rats (4-fold) and 6 days of E2-treated rats (+ 51%, $P<0.01$ vs. vehicle). In conclusion, we propose that the upregulation of glutamine transporter SN1 and the

metabolism of glutamine through ammoniagenesis (KD, acidosis and KD + acidosis) or glucosamine pathway (E2) is likely responsible for renal hypertrophy in these conditions via the upregulation and activation of CDK inhibitor $p21^{Cip1}$.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2197**

**Heme Oxygenase (HO) Activity Modulates Subpressor Angiotensin II (SP-AngII)-Induced Hypertension (HTN) and Renal Injury** Kiran B. Chandrashekar,[1] Arnaldo F. Lopez-Ruiz,[1] Ramiro Juncos,[1] David E. Stec,[1] Karl A. Nath,[2] Ruisheng Liu,[1] Luis A. Juncos.[1] *[1]Nephrology/Physiology, Univ of Mississippi Medical Center, Jackson, MS; [2]Nephrology, Mayo Clinic, Rochester, MN.*

AngII causes HTN and promotes renal injury,but concurrently induces adaptive enzymes like HO.We examined the role of HO in modulating SP-AngII-induced renal inflammation and injury.Male SD rats were infused with either SP-AngII(200ng/kg/min) or vehicle for 14 days.We asked,whether,

1) Preventing SP-AngII-induced HO,by chronically inhibiting HO(SnPP;30mol/kg,i.p every 3rd day) exacerbate SP-AngII-induced renal injury?

2) Reversing SP-AngII-induced HO, by late HO inhibition(SnPP;50mol/kg,i.p on day 12) worsen this injury?

3) Further inducing HO chronically(CoPP;30mol/kg,i.p every 3rd day) prevent this injury?

4) Late HO induction(CoPP;50mol/kg,i.p on day 12) ameliorate this injury?

| | SBP mmHg | Renal TNFα-pg/ml | Renal IL6 pg/mg | Plasma Creatinine mg/dl | NGAL Ul/mg creat | HO activity nmol/mg/hr |

| SP-AngII + Late CoPP | 154 ± 10 | 12.0 ± 2.9* | 23.1 ± 2.5* | 0.8 ± 0.04 | 5 ± 0.8* | 3 ± 0.21*# |

Data: Mean ± SEM, * P < 0.05 vs. CT, # P< 0.05 vs. SP-AngII (n=5 or 6 per group)

Both chronic and late HO inhibition exacerbated SP-AngII-induced renal injury without increasing BP.Chronic HO induction prevented SP-AngII-induced HTN,while blunting the injury.Late HO induction ameliorated these parameters.We conclude that SP-AngII-induced HO dampens renal inflammation and injury independent of its blood pressure effects. Likewise, further induction of HO prevents SP-AngII's hypertensive effects and ameliorates renal dysfunction.

**Syndrome of Rapid Onset End-Stage Renal Disease (SORO-ESRD): A New Unrecognized Pattern of CKD Progression to ESRD** Macaulay A. Onuigbo,[1] Macaulay A. Onuigbo.[2] *[1]College of Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology, Midelfort Clinic, Mayo Health System, Eau Claire, WI.*

Background

By most estimates, we have an increasing worldwide ESRD epidemic. This is despite at least two decades of intensified reno-protection strategies including extensive applications of RAAS blockade. The current consensus is that CKD-ESRD progression is a continuous, progressive and predictable loss of eGFR in CKD patients, inexorably leading to ESRD.

Objective

Our recent experience in a Mayo Health System Hypertension Clinic, and new reports associating CKD-ESRD progression following AKI, led us to hypothesize that CKD-ESRD progression may be unpredictable, after all.

Methods

In June 2009, we completed an 82-month prospective patient-level data analysis of CKD-ESRD progression in 100 high-risk CKD patients.

Results

All Caucasians. M:F = 52/48, age 71.5 (25-92) years. Enrollment CKD stages - II (1), III (25), IV (57) and V (16). 17 patients progressed to ESRD. CKD-ESRD progression was unpredictable by age nor by eGFR. ESRD was superseded by AKI in 15/17 (88%) patients. AKI was secondary to hypotension/shock (7), sepsis (2), following cardio-thoracic surgery (2), and following lymphoma, contrast nephropathy, urinary obstruction and dementia/failure to thrive, in 1 each. We have coined a new term, syndrome of rapid onset end-stage renal disease (SORO-ESRD) to represent this unrecognized syndrome of abrupt onset, unanticipated and precipitous but irreversible renal failure in CKD patients following medical and surgical events that precipitated AKI, with subsequent accelerated loss of GFR and finally irreversible ESRD.

Conclusion

The current popular theory of CKD-ESRD progression was debunked by our study. The majority of ESRD progression from CKD observed in our cohort was triggered unpredictably by AKI. Ishani et al recently demonstrated that 25.2% of patients who developed ESRD in a Medicare "Seniors" cohort similarly had experienced prior AKI. Larger studies are warranted. If confirmed, this finding will demand major paradigm shifts in current concepts of reno-protection and related "A-V Fistula first" programs.

**Urine Podocin:Uromodullin mRNA Ratio Is a Candidate of Biomarker in Patients with Glomerulonephrits** Yuji Sato,[1] Shouichi Fujimoto.[2] *[1]Div. of Circulatory and Body Fluid Regulation, Dept of Int Med, University of Miyazaki, Miyazaki, Japan; [2]Div. of Dialysis, University of Miyazaki Hosp., Miyazaki, Japan.*

If we could monitor the disease activity of glomerulonephritis (GN) by analyzing non-invasive methods (eg. urine biomarker), it would be clinically useful. We previously demonstrated urine podocyte mRNAs marked progression of glomerular disease using human diphtheria toxin receptor transgenic rat (JASN 20:1041, 2009), and podocyte-specific mRNAs (NPHS1 and NPHS2) were excreted in the urine of healthy controls and of patients with GN (JASN 20:309A, 2009). However, urine aquaporine2 (Aqp2) mRNA was not suitable as a candidate of kidney-specific reference gene to correct urine podocyte-specific mRNAs in human different from rats.

In this study, we examine whether the quantitative measurement of urine podocyte-specific mRNAs can distinguish between healthy controls and patients with GN, and is useful for the evaluation of the disease activity.

Human urine was centrifuged and pellet was collected. RNA was extracted using RNeasyMiniKit protocol and reverse transcribed to cDNAs. Real-time PCR was performed using TaqMan probes (for NPHS1, NPHS2, Aqp2 and uromodullin(UMOD)). Human kidney RNA transcribes was used as standard cDNAs. The %crescent formation was calculated at least 10 glomeruli on the PAS stained section of patients with IgA nephropathy.

Urine NPHS2:UMOD mRNA ratio can distinguish between healthy controls and patients with GN (membranous nephropathy, IgA nephropathy and diffuse crescentic glomerulonephritis). This mRNA ratio also showed significant positive correlation with %crescent formation (r=0.87) but not correlated with %segmental sclerosis (r= -0.15) on kidney biopsy specimens of patients with IgA nephropathy. Urine NPHS2:Aqp2 ratio and urine protein:creatinine ratio did not correlate with this %crescent formation (r=0.37).

We propose urine UMOD mRNA is a good kidney-specific reference gene in a setting of evaluation of urine podocyte-specific mRNAs. Increased urine NPHS2:UMOD mRNA ratio can reflect active glomerular lesion of IgA nephropathy and the change of this ratio may be a useful biomarker for the evaluation of the disease activity.

**FT011, a New Anti-Fibrotic Drug, Attenuates Progressive Renal Injury in 5/6 Renal Ablation Model** Yuan Zhang,[1] Robyn S. Kelly,[1] Alison Joy Cox,[1] Sih Min Tan,[1] Steven C. Zammit,[2] Spencer J. Williams,[2] Henry Krum,[3] Richard E. Gilbert,[4] Darren J. Kelly.[1,5] *[1]University of Melbourne, Australia; [2]Bio-21, University of Melbourne, Australia; [3]Monash University, Australia; [4]University of Toronto, Canada; [5]Fibrotech Therapeutics, Australia.*

To test the hypothesis that treatment with FT011 will attenuate the functional and structural manifestations of progressive kidney disease.

Progressive kidney disease is associated with glomerulosclerosis and tubulointerstitial fibrosis and obliteration of the microvasculature, that all correlate with declining renal function and development of proteinuria. FT011 (Fibrotech Therapeutics Pty Ltd, Australia) is an anti-fibrotic drug in preclinical development for diabetic nephropathy.

Subtotal nephrectomized (STNx) rats were randomly assigned to receive either FT011 (100mg/kg bid gavage) or vehicle for 12 weeks (n=10). Sham-operated rats were used as controls. In addition to renal function and histopathology examination, immunohistochemistry staining for ED-1 and RECA-1 were used to evaluate interstitial macrophage accumulation and the glomerular and peri-tubular capillary endothelial cell density, respectively. Changes of mRNA expression of VEGF and collagen IV were quantitated in situ hybridisation. STNx rats treated with FT011 were associated with less proteinuria (366±42 Vs 180±38 mg/day), glomerulosclerosis (1.38±0.18 Vs 0.69±0.07), tubulointerstitial fibrosis (9.53±2 Vs 5.34±1.25 %/area), macrophage infiltration (28±3.6 Vs 17±3 number/filed) and collagen IV mRNA expression (87±25 Vs 48±9 density/AU) along with improved GFR (0.38±0.14 Vs 1.19±0.14 ml/minute) when compared with vehicle treated STNx rats. In addition, treatment with FT011 was associated with a reduction in the loss of glomerular and peri-tubular capillary endothelial cells (RECA-1 1.24±0.27 Vs 6.34±0.87 %/gcs; and 0.08±0.04 Vs 0.23±0.04 %/interstitial area), and increased in VEGF mRNA expression (84.46±5.1 Vs 126.4±8.5 density/AU).

Treatment with FT011 attenuates structural and functional manifestations of experimental progressive kidney disease. While the precise mode of action is still uncertain, FT011 represents a new treatment for chronic kidney disease.

**SA-PO2201**

**NRK-49F Cells as a Model for Studying the Pro-Fibrotic Effects of All-*trans* Retinoic Acid: Roles for Retinoid Nuclear Receptors and Carrier Proteins** Alexandra C. Rankin, Bruce M. Hendry, Qihe Xu. *Department of Renal Medicine, King's College London, London, United Kingdom.*

Purpose: All-*trans* retinoic acid (tRA) is reported to have both anti- and pro-fibrotic effects in animal models of renal disease, the mechanisms of which are poorly understood. We have established a dose-dependent pro-fibrotic effect of tRA in a normal rat kidney fibroblast cell line (NRK-49F). Here we explore the effects of tRA on fibrosis-related genes, and the roles of the retinoid nuclear receptors and carrier proteins in the pro-fibrotic effects of tRA in NRK-49F cells.

Methods: NRK-49F cells were treated with tRA +/- TGF-β1 for 48 h. Picro-Sirius red (PSR) stain was used to quantify total collagen deposition. A PCR array and standard RT-qPCR were used to determine changes in expression of fibrosis-related genes, retinoid receptors and carrier proteins in cells treated with tRA +/- TGF-β1. Matrix metalloproteinase (MMP) activity was assessed using an activity assay. Roles of the receptors in the fibrogenic response to tRA were explored using retinoid receptor agonists and antagonists.

Results: tRA dose-dependently increased PSR staining that was further increased by TGF-β1. Despite this net pro-fibrotic effect, there was down-regulation of some fibrogenic markers, while some matrix degradation enzymes were also down-regulated. Furthermore, MMP activity was reduced following tRA or TGF-β1 treatment, however no additive effect was seen with dual treatment. All 7 retinoid receptors and 2 carrier proteins were expressed in NRK-49F cells and their levels changed following treatment with tRA and TGF-β1. Pan-RAR/RXR agonists increased PSR staining in the presence of TGF-β1, but pan-RAR/ RXR antagonists did not prevent the increase in PSR staining seen with tRA+TGF-β1.

Conclusions: tRA has both anti- and pro-fibrotic effects in NRK-49F cells at the molecular level. Its net pro-fibrotic effect may partly be due to reduced matrix degradation. Although activation of either RARs or RXRs was sufficient to induce a pro-fibrotic response, RAR and RXR pathways may not be necessary for the pro-fibrotic effect.

**Up-Regulation of SL CO4C1 Uremic Toxin Transporter Expression and Function by Statins for Therapeutics of Chronic Kidney Disease** Takehiro Suzuki,[1] Takafumi Toyohara,[1] Yasutoshi Akiyama,[1] Yoichi Takeuchi,[1] Eikan Mishima,[1] Masayuki Tanemoto,[1] Hiroshi Sato,[2] Masaaki Nakayama,[1] Sadayoshi Ito,[1] Tomoyoshi Soga,[3] Takaaki Abe.[1] *[1]Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan; [3]Institute for Advanced Biosciences, Keio University, Tsuruoka, Japan.*

[Purpose] Chronic kidney disease (CKD) is strongly associated with cardiovascular events and prognosis. The reduction of accumulated uremic toxins protects against the development of hypertension and renal damage in patients with CKD, but there is no established treatment. We have revealed that 1) human kidney-specific organic anion transporter SLCO4C1 is a responsive molecule for excreting uremic toxins (PNAS 2004), 2) the overexpression of human SLCO4C1 in rat kidney promotes renal excretion of uremic toxins and reduced hypertension, cardiomegaly and inflammation in renal failure (JASN 2009). Our purpose is to develop the new therapeutic strategy for CKD based on the uremic toxin excretion by the transporter.

[Methods] Analyzing the transcriptional regulation of human SLCO4C1 and exploring the drugs to enhance the expression and the function of SLCO4C1 in vivo.

[Results] Human SLCO4C1 transcription is regulated by xenobiotic responsive element (XRE)-like motifs. Various statins act as nuclear aryl hydrocarbon receptor (AhR) ligands and up-regulate SLCO4C1 transcription by AhR nuclear translocation and binding XRE. Statin promoted SLCO4C1 expression and SLCO4C1 substrate uptake in kidney derived ACHN cells. Luciferase reporter assay of SLCO4C1 promoter by statins revealed transcriptional enhancement in a dose-responsive manner. In addition, co-administration of statins and corticosteroids exerted additive effects on SLCO4C1 expression. Finally administration of statin to 5/6-nephrectomized renal failure rats exerted increased renal uremic toxin excretion.

[Conclusions] These data suggest that SLCO4C1 up-regulation by statins might provide a novel transporter-based therapeutic strategy for CKD patients to reduce major life-threatening events. Statins could be effective drugs for CKD remedy (JASN 20: 2546-2555, 2009).

**Increases in Intrarenal Prorenin and Renin Are Mediated by Angiotensin II in Chronic Anti-Thymocyte Serum (ATS) Nephritis Rats on High Salt Intake (HSI)** Yanjie Huang,[1] Tatsuo Yamamoto,[3] Hiroyuki Suzuki,[1] Akashi Togawa,[1] Hideo Yasuda,[1] Yoshihide Fujigaki,[1] Akihiko Kato,[2] Akira Nishiyama,[4] Naoki Ikegaya,[5] Akira Hishida.[1] *[1]First Dpt. Med., Hamamatsu Univ. Sch. Med., Hamamatsu, Shizuoka, Japan; [2]Div. Blood Purification, Hamamatsu Univ. Sch. Med., Hamamatsu, Shizuoka, Japan; [3]Dpt. Health & Nutritional Sciences, Hamamatsu Univ., Hamamatsu, Shizuoka, Japan; [4]Dpt. Pharm., Kagawa Med., Kagawa, Japan; [5]Med. Care Center, Shizuoka Univ., Shizuoka, Japan.*

Previously we reported that HSI increased intrarenal prorenin and renin in chronic ATS nephritis despite significant suppression of circulating RAS activity. To elucidate whether increased intrarenal prorenin and renin on HSI were mediated through the action of angiotensin II, we investigated the circulating and intrarenal RAS activities in 1) rats with chronic ATS nephritis induced by uninephrectomy and two consecutive injections of ATS fed on HSI (0.5% NaCl solution as drinking water; UAH), 2) UAH rats treated with olmesartan medoxomil (10 mg/kg/day; UAH+O), and 3) UAH rats treated with hydralazine hydrochloride (5 mg/kg/day; UAH+H). Increased blood pressure was noted only in UAH on day 21. Increases in urinary protein excretion, intrarenal TGF-b1 expression, and kidney fibrosis were observed in UAH and UAH+H, however, their levels were significantly less in UAH+O. Immunoreactivity for total renin and non-proteolytically activated prorenin was observed mainly in distal tubules and some proximal tubules in UAH and UAH+H despite significant suppression of their expression in the juxtaglomerular apparatus, and was markedly less in UAH+O. Membrane-bound (pro)renin receptor ((P)RR) was increased in UAH and UAH+H, and was decreased by olmesartan. No significant changes were noted in the levels of intrarenal AT1-receptor among each group. These data suggest that the increase in membrane-bound (P)RR, which was regulated, at least partly, through the action of angiotensin II, was involved in the augmentation of intrarenal binding of prorenin and renin, resulting in progression of kidney fibrosis in chronic ATS nephritis on HSI.

**Serologic Profiles of Fvb.ROP Os/+ Mice with Reduced Nephron Number, Glomerular Hypertension, and Renal Failure** N. Stanley Nahman,[1,4] Robert Faulhaber-Walter,[2] Kathleen O. Heilig,[3, 4] Youli Wang,[3] Dilip K. Deb,[3] Jurgen B. Schnermann,[2] Victor Lopez De Mendoza,[4] Charles W. Heilig.[3, 4] *[1]Medicine, Charlie Norwood VA Medical Center & Medical College of Georgia, Augusta, GA; [2]Kidney Disease Branch, NIDDK, NIH, Bethesda, MD; [3]Medicine, University of Chicago, Chicago, IL; [4]Medicine, University of Florida COM Jacksonville, Jacksonville, FL.*

We have reported that Fvb.ROP Os/+ mice (Os) are a new & susceptible model of reduced nephron number (RNN) with rapid onset and progression of glomerulosclerosis (GS) and renal failure (Lab Invest 90:83, 2010). RNN was associated with glomerular hypertension and hyperfiltration (FASEB J 21:595.28, 2007). Herein, we assessed the serologic profiles of 4-5 week old Os mice and a control, fvb.ROP +/+ (WT). Compared to WT at this early time point, Os had a significant increase in serum BUN and creatinine (BUN: 93±9 mg/dl vs 29±4 for Os vs WT, respectively, and creatinine: 0.42±0.04 mg/dl vs 0.23±0.03 for Os vs WT, respectively, $p < 0.05$ for both). Os exhibited a decrease in total protein and albumin (total protein: 2.8±0.07 g/dl vs 3.3±0.03 for Os vs WT, respectively, and albumin: 1.8±0.04 g/dl vs 2.0±0.03 for Os vs WT, respectively, $p < 0.05$ for both). Plasma oncotic pressure (vapor pressure osmometry) was significantly decreased in Os (7.2±0.21 vs 8.9±0.12 for Os vs WT, respectively, $p < 0.05$). There were no differences in glucose, Na+, K+, Cl-, Ca++, phosphorus or uric acid at this time point. These data are consistent with the histologic demonstration of severe GS in Os when compared to WT (Lab Invest). Os also demonstrated increased expression of the glucose transporter GLUT1, and the prosclerotic cytokine VEGF. Thus, Os mice with the Fvb background, marked albuminuria & rapidly progressive GS exhibit early and rapid onset of azotemia, hypoproteinemia, hypoalbuminemia and decreased plasma oncotic pressure. These changes correlate with proteinuria and renal failure in these mice, providing clinical confirmation of the effects of the severe glomerulopathy in this new model. These changes may be used to monitor the progression of the disease in subsequent studies.

## SA-PO2205

**Effect of Caloric Restriction and a Ketogenic Diet on Proteinuria in Münich-Wistar-Frömter Rats** Astrid Klooster, Lianne Messchendorp, Henri G. D. Leuvenink, Harry Van Goor, Reinold O. B. Gans, Gerjan Navis, Stephan J. L. Bakker. *Kidney Center, University Medical Center Groningen, Groningen, Netherlands.*

Caloric restriction (CR) induced at young age delays onset of age-related proteinuria. This might act through stimulation of ketogenesis. Ketogenesis increases the number of mitochondria and thereby increases metabolic efficiency. It is unknown whether CR and/ or ketogenesis reduce established proteinuria. We studied CR and a ketogenic diet in an animal model of established proteinuria.

Münich-Wistar-Frömter (MWF) rats (n=56) and Wistar rats (n=14) were nephrectomised at 22 wks of age. At 26-wks, MWF rats were divided in 4 groups: control diet ad libitum (CON), control diet CR (CCR) (caloric intake 60% of CON), ketogenic diet ad libitum (KAL) and ketogenic diet CR (KCR) (caloric intake 60% of KAL). Differences between groups were tested with ANOVA and post-hoc Tukey.

At baseline weight (mean±SD) was significantly higher in Wistar rats than in MWF rats (453±34 vs. 372±26 g, $p<0.001$). Urinary protein excretion (UPE) was lower in Wistar than in MWF rats (median [IQR]: 5[4-10] vs. 57[42-78] mg/24 h, $p<0.001$). The same was true for plasma creatinine (38±4 vs. 42±5 mol/L, $p=0.004$) and mean arterial pressure (MAP) (115±14 vs. 131±9 mmHg, $p<0.001$). At baseline, there were no differences between the MWF groups.

After 14 wks of diet weight and UPE were significantly lower in CR than in ad libitum fed MWF groups (table 1). Plasma creatinine was lower in CCR, KAL and KCR compared to CON. There was no significant difference between the CR groups. Blood pressure was elevated in KAL compared to CON. This was reversed by CR.

In conclusion, CR reverses established proteinuria in MWF rats. It also prevented the rise in plasma creatinine and increase in blood pressure. These beneficial effects can not be attributed to stimulation of ketogenesis.

Table 1. Characteristics after 14 weeks of diet

| | CON | CCR | KAL | KCR |
|---|---|---|---|---|
| Weight (g) | 443±44 | 303±11 a,b | 468±32 | 320±12 a,b |
| UPE (mg/24 h) | 132[96-155] | 32[25-45] a,b | 144[109-167] | 38[19-52] a,b |
| Kreatinine (μmol/L) | 69±13 | 46±5 a | 54±13 a | 41±9 a,b |
| MAP (mmHg) | 152±18 | 135±15 a,b | 167±16 a | 135±8 a,b |

a = $p<0.05$ compared to CON; b = $p<0.05$ compared to KAL

**SA-PO2206**

**Fibrosis in Wild Type and CTGF-Transgenic Mice with Aristolochic Acid Nephropathy Is Associated with Tubular Epithelial Cells and Not with Interstitial Myofibroblasts** Maria Fragiadaki, Abi S. Witherden, Charles D. Pusey, George Bou-Gharios, Roger M. Mason. *Renal Medicine, Imperial College London, London, United Kingdom.*

Aristolochic acid (AA) causes progressive renal interstitial fibrosis in humans and has been used successfully to induce fibrosis in rodents. Murine AA nephropathy (AAN) can serve as a model to study the involvement of specific cells and candidate genes in the development of interstitial fibrosis. We induced AAN (5mg/kg AAdaily, 5days) in either male wild-type (WT) or transgenic mice that overexpress connective tissue growth factor (CTGF) under the control of the *Col1a2* promoter (TG-mice). AA-treated WT and CTGF TG-mice developed the same degree of tubular damage and interstitial extracellular matrix and collagen deposition, as detected by Masson's trichrome and picrosirius–red staining. CTGF expression in cortex was measured by qPCR and western blot and was significantly increased in AA TG mice compared with AA control mice. CTGF was expressed predominantly in tubular epithelial cells. .Increased expression of CTGF in TG-mice was associated with increased kidney vascularisation, detected by staining for α-smooth muscle actin (α-SMA), a marker for vascular smooth muscle cells and myofibroblasts. Interestingly, α-SMA expression was confined to renal blood vessels and was not detected in the interstitium in either AAN or control animals. However, HSP-47, a collagen chaperone and intracellular marker for fibrillar collagen synthesis, was expressed in many tubular epithelial cells in both WT and TG-mice treated with AA, but was not expressed in control mice. Injured tubular epithelial cells continued to express E-cadherin, a marker of epithelial phenotype, in AAN. Conclusions: (1) Injured tubular epithelial cells show no evidence of giving rise to interstitial myofibroblasts by epithelial mesenchymal transition but adopt some mesenchymal phenotype characteristics *in situ* (HSP-47 expression, *Col1a2* promoter activation) and appear to be responsible for synthesising and depositing interstitial collagen. (2) Overexpression of CTGF in murine AAN does not enhance fibrosis.

**Increased Lipolysis in Visceral and Subcutaneous White Adipose Tissue in 5/6 Nephrectomized Rats** Qiugen Zhou, Lili Hu, Fan Fan Hou. *Nephrology, Nanfang Hospital, Guangzhou, Guangzhou, Guangdong, China.*

Protein energy wasting, a state of decreased stores of body protein and fat, is a risk factor for mortality in advanced chronic kidney disease (CKD). Little is known about the mechanism underlying loss of fat in CKD. In the present study, we tested whether abnormality in lipolysis which is a process of fat catabolism occurs in a rat model of chronic renal failure. Our data showed that lipolysis in both visceral and subcutaneous white adipose tissue (WAT) were increased in 5/6 nephrectomized rats compared with control rat as revealed by increased release of glycerol in ex vivo fat pads and cultured primary adipocytes. In addition, increased phosphorylation of hormone sensitive lipase (HSL) and binding of adipose triglyceride lipase (ATGL) with comparative gene identification-58 (CGI-58) protein were observed in WAT from model rats, suggesting the activity of HSL and ATGL, two key lipases in lipolysis, enhanced in fat in the chronic renal failure rats. Moreover, phosphorylation of protein kinase A and mitogen-activated protein kinase, which is linked to activation of HSL and ATGL, were increased in WAT. While the differentiation capacity of preadipocytes isolated from WAT was comparable in the model and control rats as revealed by intracellular accumulation of triacylglycerol. Collectively, our results showed that increased lipolysis occurred in 5/6 nephrectomized rats, which was associated with increased activity of HSL and ATGL. This information may provide new light for better understanding the protein energy wasting and ectopic lipid accumulation in chronic renal failure.

**SA-PO2208**

**Serum Proteomics for Biomarkers of FSGS Recurrence Post-Transplant** Megan M. Lo, Prasad Devarajan, Michael R. Bennett. *Cincinnati Children's Hospital, OH.*

Introduction: Focal Segmental Glomerulosclerosis (FSGS) recurrence after transplant causes significant morbidity and shortens graft life. Currently, there are no predictors of recurrence, hindering prevention and treatment. As recurrence often occurs immediately after transplant, persistent circulating factors have been implicated. We hypothesized that FSGS recurrence patients (Group R) have these factors, while non-FSGS patients, FSGS non-recurrent patients, and FSGS patients in remission (Group C) do not. Our goal was to use serum proteomics to identify such factors.

Methods: Serum was collected from patients with FSGS and those receiving an allograft for other causes. Samples were analyzed by surface enhanced laser-desorption ionization time-of-flight mass spectrometry (SELDI). Protein peaks with a signal-to-noise ratio over 5 in at least 20% of spectra were analyzed. Peaks were compared between Groups R and C by Mann-Whitney rank sum test.

Results: There were 6 FSGS recurrence, 6 FSGS non-recurrence, and 8 non-FSGS patients, ages 8 to 19 years, with 7 females. 7 peaks were significantly different ($p<0.05$) with intensity ratios >3 in Group R (see Table 1). The most promising peaks are at 11.5kDa (22-fold change), 3.8kDa (6 to 35-fold change), and 4.1kDa (highest ROC at 0.93). These peaks were present both pre- and post-transplant.

Table 1

| M/Z (Da) | Chip Type | Group R | Group C | p-value | ROC | R:C ratio |
|---|---|---|---|---|---|---|
| 4097 | Q10 | 50.77 | 12.54 | 0.001 | 0.93 | 4.05 |
| 4383 | Q10 | 34.33 | 9.45 | 0.04 | 0.75 | 3.63 |
| 7140 | H50 | 109.22 | 22.66 | 0.002 | 0.89 | 4.82 |
| 11,482 | H50 | 41.05 | 1.83 | 0.01 | 0.82 | 22.41 |
| 3809 | CM10 | 207.71 | 5.99 | 0.002 | 0.83 | 34.70 |
| 3810 | IMAC | 103.52 | 16.28 | 0.01 | 0.83 | 6.36 |

M/Z: mass to charge ratio. ROC: receiver-operator characteristics. R:C: ratio Group R to Group C intensity ratios.

Conclusion: We have identified a proteomic signature in the serum of patients with FSGS who recur post-transplant, consisting primarily of peaks at 11.5, 4.1, and 3.8 kDa. Using these biomarkers prior to transplant may help predict recurrence and develop strategies to prevent recurrence.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2209**

**Possible Involvement of Proteinuria-Elicited ADMA Accumulation in Accelerated Atherosclerosis in Chronic Kidney Disease** Yusuke Kaida, Seiji Ueda, Yosuke Nakayama, Ryotaro Ando, Kei Fukami, Seiya Okuda. *Division of Nephrology, Department of Medicine, Kurume University, Kurume, Fukuoka, Japan.*

***Background.*** Albuminuria is widely recognized as a strong indicator of cardiovascular disease (CVD). There is an increasing body of evidence that endothelial dysfunction due to impaired NO generation is linked to albuminuria. In addition, it has been recently reported that there is a close relationship between proteinuria and ADMA in patients with chronic kidney disease (CKD). These observations led us to speculate that ADMA could link albuminuria to CVD in CKD patients. However, the underlying mechanisms for the possible association between ADMA and albuminuria remain to be elucidated.

***Methods.*** We investigated the relationship between ADMA levels and proteinuria in adriamycin (ADR)-treated rats, an animal model of nephritic syndrome. We also examined the expression levels and activity of DDAH and PRMT in the kidney of this animal. Further, we examined the effects of albumin on ADMA-DDAH axis in cultured human renal proximal tubular epithelial cells (RPTEC).

***Results.*** A positive correlation between ADMA and proteinuria was observed in the ADR-treated rats ($n=28$, $r^2=0.46$, $p<0.01$). Although the expression levels of DDAH were not changed 14 days after the treatment of ADR, the enzymatic activity of DDAH was significantly decreased in the kidney of ADR-treated rats. The expressin levels of PRMT significantly increased in the kidney of ADR-treated rats. In vitro, albumin time- and dose-dependently increased ADMA accumulation in cultured media of RPTEC. Albumin also decreased DDAH activity and increased the expression levels of PRMT in RPTEC. Albumin-elicited dysregulation of DDAH and PRMT was completely abolished by pretreatment of an anti-oxidant, N-acetyl cystein.

***Conclusion.*** These results suggest that albuminuria could increase ADMA accumulation via suppression of renal DDAH activity and PRMT overexpression, partly explaining a link between albuminuria and CVD.

**Selective Estrogen Receptor Modulator Attenuates Albumin-Induced Apoptosis in Renal Proximal Tubules through Inhibition of Mitochondrial Stress** Yuko Nishi, Minoru Satoh, Naruya Tomita, Tamaki Sasaki, Naoki Kashihara. *Division of Nephrology and Hypertension, Department of Internal Medicine, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

[Background] Females are less susceptible than males to developing chronic kidney disease. However, the mechanisms responsible for the reduction have not yet been clarified. Recent studies have shown that mitochondrial oxidative stress is involved in proteinuria-induced apoptosis of proximal tubular cells. Estrogen has been shown to affect mitochondrial function by reducing oxidative stress. Therefore, we investigated whether the stimulation of estrogen receptor using estradiol or a selective estrogen receptor modulator, raloxifene, could attenuate albumin-induced tubular injury through reducing mitochondrial oxidative stress.

[Methods and Results] In vitro study, human renal proximal epithelial cells (hPTECs) were cultured with human fatty acid-bearing albumin (0, 5, 10, 20 mg/ml). This resulted in a dose- and duration-dependent cell viability loss, as determined by lactate dehydrogenase release and mitochondrial viability, mitochondrial membrane potential loss, and induction of apoptosis, as revealed by externalization of plasma membrane phosphatidylserine. Prestimulation of estrogen receptor with 1mM raloxifene successfully attenuated albumin-induced apoptosis in hPTECs. The effect was blocked by co-incubation with an estrogen receptor antagonist (ICI 182,780). In the in vivo study, ICR-derived glomerulonephritis (ICGN) mice underwent ovariectomy, and were treated with raloxifene (50μg/kg/day) for 6 weeks. Ovariectomy induced the apoptotic cell death in renal proximal cells (terminal deoxynucleotidyl transferase dUTP nick-end labeling staining) and decreased cytochrome-c oxidase activity in mitochondria. Electron microscopy of the ovariectomized ICGN mice revealed morphologically abnormal mitochondria, and these changes were suppressed following treatment with raloxifene with upregulation of the mitochondrial thioredoxin system.

[Conclusion] Stimulation of estrogen receptor attenuated programmed cell death in renal proximal tubules induced by albumin-overload as a result of amelioration of mitochondrial dysfunction.

**Protective Effects of Shichimotsukokato on Anti-Thy-1-Induced Irreversible Nephritis in Rats** Takahiko Ono,[1] Kohei Kamikado,[2] Tatsuya Morimoto.[2] *[1]Department of Nephrology, Shimada Municipal Hospital, Shimada, Japan; [2]Division of Molecular Medicine, University of Shizuoka, Shizuoka, Japan.*

Purpose: Oxidative stress is involved in the progression of chronic kidney disease (CKD). Shichimotsukokato (SKT), an herbal prescription in Japan, possesses an anti-oxidative activity and protective effects against hypertension in experimental studies. We investigated the mechanisms of the effects by long-term administration of SKT on irreversible nephritis induced by the anti-thymocyte antibody.

Methods: Six-week-old male Wistar rats were subjected to uninephrectomy, and to injection of rabbit anti-rat thymocyte serum to generate irreversible nephritis. These rats were then randomly assigned to a sham operation group (n = 6), a control vehicle (n = 5), and SKT (TJ-46) group (500 mg/kg, nearly 5 times of clinical dose) (n = 5). Drinking water with SKT was continued to give for 15 weeks.

Results: Blood pressure in the SKT group (127 ± 1 mmHg, $p < 0.05$ vs. vehicle) was significantly lower as well as sham group, comparing with the vehicle (138 ± 2 mmHg). Although SKT slightly reduced urinary protein, SKT markedly ameliorated renal function evaluated with urea nitrogen clearance (vehicle, 0.50 ± 0.06 ml/min; SKT, 0.74 ± 0.06 ml/min, $p < 0.05$). Compared with vehicle, SKT treatment lowered the glomerular enlargement and total glomerular cells number both by 80% ($p < 0.05$, respectively), and lowered extracellular matrix area by 75% ($p < 0.05$). SKT treatment also suppressed tubular injury score (vehicle, 3.0 ± 0.2; SKT, 2.1 ± 0.1, $p < 0.05$), and maintained CD31-positive peritubular capillary networks (vehicle, 3.7 ± 0.3 / 10 tubules, n = 5; SKT, 5.5 ± 0.5, $p < 0.05$). Furthermore, SKT recovered the superoxide dismutase (SOD) activity, a marker of anti-oxidative system, to the levels of sham group (vehicle, 272 ± 6 U/mg protein; SKT, 337 ± 21, $p < 0.05$).

Conclusion: These results suggest that SKT may be useful for the treatment of CKD during the progress to nephrosclerosis, through the mechanisms of anti-oxidative activity and maintenance of perivascular capillary networks.

**Comparative Research of Serum Cystatin C and Other Endogenous Markers in Glomerular Filtration Rate Measurement in Chronic Kidney Disease Patients with Mild to Moderate Impairment of Kidney Function** Xiaoying Du,[1] Qiang He,[1] Yu Chen,[2] Linfa Li,[3] Jianyong Wu,[1] Jianghua Chen.[1] *[1]Kidney Disease Center, the First Affiliated Hospital, College of Medicine,, Zhejiang University, Hangzhou, Zhejiang, China; [2]Clinical Laboratory, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China; [3]Nuclear Medicine,The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

To evaluate the diagnostic value of serum Cys C in GFR measurement in comparison with other endogenous markers in CKD patients with mild to moderate impairment of GFR.107 patients (64 males and 43 females, aged 23-87 years) with chronic kidney disease stages 2-3 (GFR 30-89 ml/min/1.73m2) were enrolled. On the day when the patients had performed 99mTc-DTPA clearance, the patients' blood had been withdrawn before breakfast and the serum samples been stored below -80°. One year later, all the frozen samples were thawed out and Cys C,β2-MG),RBP,creatinine were determined on the same day. The correlation coefficients,sensitivities and diagnostic accuracy between the different markers and $GFR_{DTPA}$ were determined. The correlation coefficients between $GFR_{DTPA}$ and serum concentrations were -0.811 for Cys C , -0.699 forβ2-MG , -0.69 for creatinine , -0.419 for RBP . ROC analysis indicated that the accuracy of Cys C was similar to that of creatinine andβ2-MG, while the diagnostic accuracy of RBP was significantly lower than that of Cys C. Sensitivity analysis showed that Cys C (98.1%) and β2-MG (98.1%) were better than creatinine (86.9%), while the sensitivity of RBP was very low (56.5%). We made the conclusion that:1. Retinol-binding protein is not an adequate marker of glomerular filtrateion rate. 2. The sensitivity of cystatin C and β2-microglobulin was better than that of creatinine, indicating that serum cystatin C and β2-microglobulin can reflect the decrease of GFR much earlier and more rapidly than serum creatinine in patients with mild to moderate kidney dysfunction.

**Lipoxin $A_4$ and Benzo-Lipoxin $A_4$ Protects Against Renal Fibrosis** Emma Borgeson,[1] Eoin P. Brennan,[1] Karen Nolan,[1] Aidan Ryan,[1] Debra F. Higgins,[1] Patrick Guiry,[2] Neil G. Docherty,[3] Catherine Godson.[1] *[1]Diabetic Research Centre, Conway Institute, UCD, Dublin, Ireland; [2]Centre for Synthesis and Chemical Biology, UCD, Dublin, Ireland; [3]Department of Physiology, Trinity College Dublin, Dublin, Ireland.*

Tubulo-interstitial fibrosis and inflammation are hallmarks of renal pathology and chronic kidney disease (CKD). Lipoxin $A_4$ ($LXA_4$) is an endogenously produced eicosanoid and there is growing evidence that $LXA_4$ promotes resolution of inflammatory responses and may be antifibrotic. We have explored the potential of $LXA_4$ and a synthetic benzo-$LXA_4$ to regulate renal fibrosis using *in vivo* and *in vitro* models. Using a rat renal fibroblast cell line (NRK49F) we found that $LXA_4$ (1 nM, 30') pretreatment modulated TGFβ1 (10 ng/ml) induced proliferation and fibroblast activation (α-smooth muscle actin, thrombospondin and CTGF expression). Interestingly, we also find that $LXA_4$ (1 nM, 30') protects human kidney epithelial cell line from mesenchymal transition (EMT) in response to TGFβ1, attenuating TGFβ1-induced Jagged-1 and N-cadherin expression. These responses were associated with upregulation of a specific cohort of miRNAs. The effect of $LXA_4$ on fibroblast activation and EMT suggested antifibrotic potential in renal disease. We have investigated the effect of pretreatment with vehicle, $LXA_4$ (15μg/250g, 30' prior ligation) or benzo-$LXA_4$ (45 μg/250g, 30' prior ligation) on the UUO model of renal fibrosis in the male Wistar rat. Three days post ligation animals were sacrificed and ligation significantly increased hydronephrosis in all obstructed kidneys relative to controls. Upregulation of collagen-1α2, CTGF, Jagged-1, MCP-1 and TNF-α gene expression was seen in the ligated verses contralateral kidneys. $LXA_4$ and benzo-$LXA_4$ significantly ($p<0.05$) attenuated collagen-1α2, Jagged-1, MCP-1 and TNF-α expression. Ligation also caused a significant increase in renal collagen deposition [+2.5 fold], as analysed by sirius red staining, and benzo-$LXA_4$ pretreatment caused a marked decrease of collagen deposition in obstructed kidneys relative to contralateral ($p<0.05$). In conclusion we propose that $LXA_4$ and synthetic analogs of $LXA_4$ represent a novel class of antifibrotic agents.

**Suppression of Podocyte Albumin Transcytosis by a NADPH Oxidase Inhibitor** Satoshi Kinugasa, Akihiro Tojo, Toshiro Fujita. *Department of Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan.*

Background: We investigated whether NADPH oxidase inhibitor suppresses albumin endocytosis by podocytes and reduces glomerular albumin filtration in nephrotic syndrome rats.

Methods: We used male sprague-Dawley rats as controls (n=19), and administered puromycin aminonucleoside (PAN) to rats to serve as a nephrotic syndrome model (n=24). Some rats were treated with apocynin (16mg/kg/day orally, n=8). Production of reactive oxygen species was detected by cerium chloride (CeCl3) histochemistry, and urinary H2O2 was measured, along with immunohistochemistry (IHC) for p47phox. Following intravenous injection of Evans blue-labeled human serum albumin (EB-HSA), a clearance study and immunogold scanning electron microscopy (immunogold SEM) for HSA were performed to detect glomerular albumin filtration.

Results: CeCl3 histochemistry showed enhanced production of reactive oxygen species (ROS) in the podocyte of PAN rats, which was much reduced in apocynin-treated rats. IHC stained positive for p47phox in the podocyte cytoplasm of PAN rats, providing evidence that the ROS was produced by NADPH oxidase. In PAN nephrotic rats, glomerular filtration of EB-HSA excretion showed a132-fold increase compared to control rats ($p<0.01$ vs. control), which was significantly decreased in the apocynin-treated group (41.0±4.6 vs. 12.8 ± 5.8 mg/day, $P<0.01$ vs. PAN). With immunogold SEM, many more gold particles were observed inside podocyte vesicles compared to controls (0.3±0.2 vs.33.3±6.0 vs. control), suggestive of enhanced albumin endocytosis. With apocynin treatment, the number of gold particles in the podocyte vesicles was significantly decreased (6.6±2.3 particles/cell, $p<0.01$ vs. PAN). Similarly, particles observed on the podocyte apical membrane was greatly increased in PAN rats (5.2±0.8 vs. 113.8±21.3 particles/image, $p<0.01$ vs. control), which may represent albumin exocytosis, and significantly decreased in apocynin-treated rats (26.2±3.4 particles/image, $p<0.01$ vs. PAN).

Conclusion: The NADPH oxidase inhibitor apocynin suppressed podocyte albumin endocytosis and ameliorated glomerular albumin filtration in nephrotic syndrome rats, which may lead to a novel strategy for nephrotic syndrome.

**Spironolactone Reverses Experimental Uremic Cardiomyopathy** George Budny, Steven T. Haller, Jiang Tian, Sankaridrug Periyasamy, Deepak K. Malhotra, Joseph I. Shapiro. *Medicine, University of Toledo Medical Center, Toledo, OH.*

Spironolactone has been noted to attenuate the development of cardiac fibrosis and diastolic dysfunction seen with experimental renal failure. We have also established that spironolactone and its major metabolite, canrenone, in addition to their well established roles as mineralocorticoid receptor antagonists also serve as competitive inhibitors of the binding of cardiotonic steroids to the plasmalemmal Na/K-ATPase. We performed the following studies to determine whether spironolactone might actually reverse established experimental uremic cardiomyopathy. Male Sprague Dawley rats weighing between 250-300g were used for these studies. Rats we subjected to partial nephrectomy (PNx) as we have previously described. This maneuver produces sustained hypertension by 2 weeks. Four weeks after surgery when we have previously determined the cardiac fibrosis is well established, the rats were divided into 4 groups. The first, second and third groups received spironolactone (in doses 5mg/kg; 20 mg/kg; 80mg/kg respectively) orally through gavage tube daily for one week. In the fourth group, the exact volume of vehicle was administered. After one week of treatment animals were sacrificed and their organs harvested. The PNx animals showed an increased systolic BP and cardiac fibrosis as previously reported. We found that spironolactone (in doses 20 mg/kg/day and 80 mg/kg/day, but not 5 mg/kg/day) decreased systolic blood pressure and attenuated the diastolic dysfunction as assessed by analysis of ventricular pressure-volume loops. Spironolactone decreased the cardiac fibrosis compared to PNx as assessed by quantitative morphology determined with Sirius red staining and collagen expression measured with Western blot in a dose dependent fashion. Our results suggest that not only does spironolactone therapy ameliorate the development of experimental uremic cardiomyopathy but that spironolactone therapy can reverse cardiac fibrosis which has already been established. If these data are confirmed clinically, spironolactone may have potential utility in the treatment of patients with uremic cardiomyopathy.

**Phosphate Handling in Experimental Chronic Kidney Disease** Bonnie W. Y. Shum,[1] Kristin M. McCabe,[1] Navid Shobeiri,[1] David P. Beseau,[1] Michael A. Adams,[1] Rachel M. Holden.[2] *[1]Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada; [2]Division of Nephrology, Queen's University, Kingston, ON, Canada.*

In chronic kidney disease (CKD), altered phosphate disposition (e.g. hyperphosphatemia) is considered to be important in the initiation of vascular calcification; the latter, is a key risk factor for the high cardiovascular mortality seen in this patient population. In the present study, we sought to develop a quantitative assessment of systemic phosphate handling in a rat CKD model. Sprague-Dawley rats (275-300g) were given a diet containing 0.25% adenine (CKD; n=10) or no adenine (control; n=6) for 3 weeks. Pulse pressure, tissue calcium, the phosphate regulating hormone fibroblast growth factor-23 (FGF-23), and serum phosphate were measured with the latter assessed before (t=0min) and after (0-60min) an intravenous infusion of sodium phosphate (100mM in saline, 4mL/kg, over 1-2min). In addition, to determine the impact of renal phosphate clearance, the procedure was repeated after the kidneys were removed in some animals. Kidney function, assessed by serum creatinine, was significantly compromised in the CKD group (114.26±37.61μmol/L) compared to controls (38.26±5.18μmol/L, $p<0.01$). There was a significant correlation between serum phosphate and creatinine levels ($r^2=0.67$, $p<0.001$). The rate of phosphate clearance was not altered by nephrectomy, but was greater in rats with CKD (-0.18±0.087mM/min) than in controls (-0.10±0.03mM/min). Furthermore, the phosphate clearance rate also correlated significantly with both serum creatinine ($r^2=0.64$, $p<0.01$) and FGF-23 ($r^2=0.92$, $p<0.0001$). These novel findings indicate that short-term handling of phosphate occurs independently of the kidneys, and the rate of phosphate clearance increases with severity of CKD. The strong correlation with elevated FGF-23 suggests a mechanistic link with enhanced phosphate uptake into extracellular compartments in CKD is possible.

**Suramin Is a Potent Anti-Fibrotic Agent in Obstructive Nephropathy** Shougang Zhuang. *Department of Medicine, Rhode Island Hospital and Warren Alpert Medical School of Brown University, Providence, RI.*

Suramin, a compound that inhibits multiple cytokines/growth factors binding to their receptors, has been used to treat some tumors in patients and prevent skeletal muscle fibrosis in experimental animals. In this study, we examined the effect of suramin on progression of renal fibrosis induced by unilateral ureteral obstruction (UUO). UUO or sham-operated mice were randomly assigned to suramin or vehicle and were killed on day 7 after UUO or sham operation. Suramin at a single dose after surgery significantly attenuated renal interstitial fibrosis as demonstrated by reduced collagen deposition and repressed protein expression of fibronectin and type I collagen. Suramin also inhibited the injury-induced expression of alpha-smooth muscle actin and proliferating cell nuclear antigen (PCNA) as well as accumulation of renal interstitial fibroblasts. Furthermore, suramin reduced infiltration of leukocytes and gene expression of multiple cytokines including transforming growth factor-beta-1 (TGF-beta1) and TGF-β receptor Type II. *In vitro*, treatment with suramin inhibited activation and proliferation of cultured renal interstitial fibroblasts, as evidenced by dose and time -dependent blockade of expression of alpha-smooth muscle actin, fibronectin and PCNA and reduction of cell numbers. Finally, we observed that suramin inhibits activation of STAT3, a critical transcription factor implicated in renal fibrosis both *in vivo* and *in vitro*. Collectively, these findings demonstrate that suramin is a potent anti-fibrotic agent and suggest its therapeutic potential in the treatment of kidney fibrotic diseases.

**SA-PO2218**

**Impaired Glomerular and Tubular Antioxidative Defense Mechanisms in Nephrotic Syndrome** Anna Granqvist, Ulf A. Nilsson, Kerstin Ebefors, Borje Haraldsson, Jenny C. Nystrom. *Medicine, University of Gothenburg, Molecular and Clinical Medicine, Gothenburg, Sweden.*

**Background:** The molecular mechanisms behind acquired nephrotic syndrome (NS) are still largely unknown. One possible explanation to the development of proteinuria is oxidative damage to the glomerular cells. Our hypothesis was that the oxidative defense is weakened in NS and we focused on measurements of the oxidative – antioxidative status in the glomerular and tubular parts of the nephron.

**Method:** Gene expression was analyzed in renal biopsies from patients with NS and healthy controls (n=8). In addition, to compare the acute and chronic phases of the disease, we studied puromycin-treated nephrotic rats (n=8). Gene data was combined with measurements on urine and plasma for several different markers of oxidative stress.

**Result:** In the biopsy material the expression of enzymes involved in the antioxidative defense was higher in the tubulointerstitial compartment than in the glomerular cells (both in control and NS). Real-time PCR analysis revealed a decreased glomerular expression in nephrotic kidneys for the antioxidant enzymes catalase (by 42%) ), glutathione peroxidase-3 (by 62%) and -4 (by 40%). The tubular gene expression was down-regulated for catalase (by 27%), glutathione peroxidase -3 (by 29%), thioredoxin reductases -1 and -2 (by 48% and 18% respectively). The altered gene expression seen in NS was accompanied by an increase in lipid peroxidation, a major indicator for oxidative stress, in the urine ($p\leq 0.001$).

In rats, serum concentrations of ascorbyl free radicals, measured with electron spin resonance (ESR), were elevated in the acute phase of the disease, suggesting increased oxidative stress in the circulation ($p\leq0.01$). In addition we saw an increase in the plasma antioxidant capacity ($p\leq0.05$) combined with a decreased oxidation of proteins in sera ($p\leq0.001$) from nephrotic rats, but not from humans.

**Conclusion:** In conclusion, there is a marked down-regulation of several antioxidative enzymes in nephrotic kidneys, especially in glomerular structures. Our data suggest that oxidative damage to glomerular cells may contribute significantly to the course and prognosis of nephrotic syndrome.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2219**

**Dietary Salt Restriction May Ameliorate the Increased Renal Expression of α-Smooth Muscle Actin and Fibronectin in Adriamycin Nephrosis** Joon-Sung Park, Chor Ho Jo, Sua Kim, Chang Hwa Lee, Gheun-Ho Kim. *Department of Internal Medicine, Hanyang University, Seoul, Republic of Korea.*

**Purpose:** Adriamycin (ADR) induces severe glomerular proteinuria in rats, and proteinuria is a major factor leading to renal fibrosis probably via epithelial mesenchymal transition (EMT). This study was undertaken to test the hypothesis that renal fibrosis may be modulated by dietary salt restriction in a rat model of ADR nephrosis.

**Methods:** Male Sragues-Dawley rats were randomly divided into normal-salt controls (n=4), normal-salt ADR (NS-ADR, n=5), and low-salt ADR (LS-ADR, n=5). ADR was intravenously given into the femoral vein as a single bolus (7.5 mg/kg). Five weeks later, kidneys were harvested for histopathologic studies, immunohistochemistry and western immunoblot analysis.

**Results:** At the end of the animal experiment, remarkable proteinuria was induced in both NS-ADR (234 ± 37 mg/d/100 g BW) and LS-ADR (210 ± 27 mg/d/100 g BW) groups in contrast to controls (2 ± 0 mg/d/100 g BW). Renal histopathology revealed that tubulointerstitial injury was remarkable in both NS-ADR (cortex, 3.7 ± 0.3; medulla, 3.7 ± 0.2) and LS-ADR (cortex, 2.8 ± 0.9; medulla, 2.6 ± 0.7) rats compared with controls (cortex, 0.1 ± 0.1; medulla, 0.1 ± 0.1). Compared with controls, the expression of α-smooth muscle actin (αSMA) in NS-ADR rats was increased in both cortex (5.5 ± 1.3 *vs.* 0.6 ± 0.1 %area, $P<0.05$) and medulla (7.8 ± 2.9 *vs.* 0.2 ± 0.0 %area, $P<0.05$). The abundance of fibronectin was also increased in NS-ADR rats in both cortex (6.71 ± 1.32 *vs.* 1.01 ± 0.36, $P<0.05$) and medulla (2.52 ± 0.23 *vs.* 1.01 ± 0.10, $P<0.05$). Compared with NS-ADR, the expression of medullary α-SMA (2.3 ± 1.4 %area, $P<0.05$) and fibronectin (1.59 ± 0.22, $P<0.05$) was significantly ameliorated in LS-ADR rats. Notably, both expression levels of α-SMA (cortex, $r^2=0.46$, $P<0.01$; medulla, $r^2=0.43$, $P<0.05$) and fibronectin (cortex, $r^2=0.76$, $P<0.01$; medulla, $r^2=0.63$, $P<0.01$) were correlated with proteinuria.

**Conclusions:** In rats with ADR nephrosis, the process of EMT and interstitial fibrosis appears to be associated with proteinuria. Dietary salt restriction may ameliorate renal expression of α-SMA and fibronectin in ADR nephrosis.

**SA-PO2220**

**Definition of the Pericyte Transcriptome during Kidney Fibrosis by Polysome Immunoaffinity Purification from Whole Kidney** Ivica Grgic, Matthew A. Lalli, Jeremy S. Duffield, Benjamin D. Humphreys. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Renal fibrosis, an abnormal repair process in the kidney leading to progressive renal failure, is the main cause for end stage renal disease and remains a major unresolved problem in clinical medicine. We have shown using genetic fate mapping that pericytes and perivascular fibroblasts are the progenitor population for myofibroblasts which represent the main effector cells in the pathogenesis of tubulointerstitial fibrosis responsible for increased synthesis and deposition of extracellular matrix. Currently, our knowledge about kidney pericytes in health and disease remains very limited. This can be attributed to the challenge of studying single cell populations in highly complex tissues such as the kidney. To better understand the biological properties of renal pericytes and to dissect their role in states of disease we have applied *Translating Ribosome Affinity Purification* (TRAP) to isolate RNA from a genetically defined cell population *in vivo*. We generated a transgenic mouse line that expresses a GFP-tagged ribosomal fusion protein (eGFP-L10a) under the control of the collagen 1α1 promoter. Expression of eGFP-L10a was present in kidney medulla, strictly confined to cells in the tubulointerstitium staining positive for pericyte markers. These cells underwent dramatic expansion during the unilateral ureteral obstruction (UUO) fibrosis model and acquired αSMA expression, consistent with differentiation into myofibroblasts. Using the TRAP approach, we affinity purified GFP-tagged polysomes from healthy and fibrotic kidneys with anti-GFP antibodies, resulting in pericyte-specific mRNA isolation from whole kidney in a one-step procedure. We have used this RNA to generate the pericyte transcriptome by gene microarray during differentiation into myofibroblasts in kidney fibrosis. Polysome affinity purification represents a novel, powerful tool to isolate cell-specific RNA from genetically defined kidney cell populations *in vivo* and our dataset will inform our understanding of these critical cells during fibrotic kidney disease.

**SA-PO2221**

**Chronic Metabolic Acidosis Increases Renal Oxygen Consumption Rates** Daniel F. Balkovetz,[1,2] Cynthia Miracle,[3,4] Phillip H. Chumley.[1] *[1]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Medicine, Birmingham VA Medical Center, Birmingham, AL; [3]Medicine, University of California San Diego, San Diego, CA; [4]Medicine, Veterans Affairs San Diego Healhcare System, San Diego, CA.*

A major factor in the progression of chronic kidney disease (CKD) is chronic metabolic acidosis (CMA). In rodents, CMA is associated with worsening of renal function and normalization of acid-base parameters with bicarbonate attenuated this renal disease. Correction of CMA in humans also slows the rate of CKD progression. The mechanism by which CMA accelerates CKD progression is not known. We have reported that CMA decreases levels of claudin-2 in proximal tubule. Claudin-2 mediates passive paracellular reabsorption Na+ selectively in the proximal tubule. Decreased claudin-2 expression would result in increased delivery of Na+ to the distal nephron to be reabsorbed by transcellular, active, transport mechanisms. This increase in active renal transport mechanisms in the kidney during CMA would also increase renal oxygen consumption rates. Increased renal oxygen consumption is critical for progression of CKD. To test this hypothesis, we measured renal oxygen consumption rates in whole kidney and in mitochondria isolated from the kidney of control and acidotic rats. CMA was induced in the rats using the protocol of NH4Cl (280 mM) added to the drinking water. In whole kidney, oxygen consumption rates normalized to GFR were significantly greater in the acidotic rats compared to control animals. Oxygen consumption rates in mitochondria isolated from control and CMA kidneys were greater in the mitochondria isolated from acidotic kidneys. These data are consistent with the hypothesis that CMA accelerates of CKD progression, in part, by increasing renal oxygen consumption rates. Future work will focus on the role of renal claudin-2 expression on the relative shift from passive paracellular to active transcellular transport in the renal tubule on the increased oxygen consumption rates. This work will help define the mechanism by which CMA increases renal oxygen consumption and CKD progression rates.

**SA-PO2222**

**Random Urinalysis Proteinuria Predicts Renal Function Change, a Pilot Study** Steven J. Rosansky,[1, 2] James W. Hardin,[2] Martin W. Durkin,[1] Kathlyn Sue Haddock.[1] *[1]Dorn Research Institute, WJBD VA Hospital, Columbia, SC; [2]School of Public Health, USC, Columbia, SC.*

**Purpose:** Examine the association of serum creatinine level (C) , the presence of proteinuria and renal function change over time, measured by change in C, in patients with CKD Class 2/3.

**Methods**: Male subjects from a VA Hospital data sample with at least: one (C) of ≥1.3 mg/dl; 2 creatinine values ≥ year apart; ≥ one reported urinalysis(UA) ; entry interval,1989 to 2003.Followup data obtained through 12-31-2008.The same serum creatinine methodology was used throughout the study (modified Jaffe). We investigated whether UA proteinuria influenced growth curve analysis (average creatinine changes per month) for a sample of 5558 patients with last names beginning A, B or C. We defined 3 groups of patients based on initial C: group 1 (n=4,014) ≥1.3mg/dl, group 2 (n=1040) 1.3 to 1.7 mg/dl and group 3 (n=504) > 1.7 mg/dl. Initial MDRD eGFR was calculated using the 4 variable model. We defined a binary variable for proteinuria, present if any random UA protein ≥30mg/dl. Growth curve analysis included creatinine group, proteinuria and their interaction.

**Results:** Mean values : age 62; follow-up 8.4 years; C's 21.1; UAs 7.9. For the 3 groups initial C (mg/dl) /MDRD (eGFR ml/min/1.73m$^2$) were:1.14/74.6, 1.47/51.83, 2.59/33.7. Creatinine group, proteinuria, and their interaction were all significant ($p < .001$); no statistical difference between group 2 and group 1. Group 3 maintained significantly higher creatinine level changes (average difference over the study interval of 0.35, $p<0.001$). For the total population, there was a tendency for creatinine levels to decline (average monthly decline 0.004, $p<0.001$), but proteinuric patients across all groups showed a tendency for creatinine levels to increase (average monthly growth 0.010, $p<0.001$). There were no significant associations over time of C with age or race.

**Conclusion**: In these CKD Class 2/3 patients over an average 8 year follow-up C's for non-proteinuric patients remain stable, while for proteinuric patients (any UA with ≥30 mg/dl protein) creatinine levels increase by 0.12 mg/dl per year, or an average of 1 mg/dl over the 8.4 year follow-up.

**Association of Chronic Kidney Disease with Skeletal Muscle Mitochondrial Dysfunction** Puya G. Yazdi, Jia-Ying John Yang, Pavan Gollapudi, Nosratola D. Vaziri. *Medicine, University of California, Irvine, Irvine, CA.*

Advanced chronic kidney disease (CKD) is associated with impaired exercise capacity, skeletal muscle dysfunction, and oxidative stress. Mitochondria are the primary source of production of energy and generation of reactive oxygen species (ROS). The present study was designed to test the hypothesis that skeletal muscle dysfunction and oxidative stress in CKD are, in part, due to impaired energy production and heightened ROS generation by mitochondria. Mitochondrial state 3 respiration (measured as the maximal rate of ADP conversion to ATP, using pyruvate and malate as substrates) and mitochondrial complex enzyme activities were determined in the gastrocnemius muscle of male SD rats 12 weeks after 5/6 nephrectomy (CKD) or sham-operation (control). The CKD group exhibited proteinuria, hypertension, azotemia, and reduced weight gain. This was associated with significant reduction (-39%, $p<0.05$) of state 3 mitochondrial respiration and a significant increase in the mitochondrial complex I plus III enzyme activity (18% , $p<0.05$). The latter is the first step in oxidative phosphorylation by catalyzing oxidation of reduced nicotinamide adenine dinucleotide (NADH→NAD+), a process which is linked to production of ROS. We further found a mild reduction in Complex IV activity (-13%) that was accompanied by a decrease in abundance of Complex IV subunit IV (-15%) in the CKD rats. Finally we found a mild reduction of Porin abundance (-8%), which points to diminished mitochondrial abundance in the skeletal muscle of CKD rats compared with the controls. Thus, the study demonstrated the deleterious effects of uremia on the skeletal muscle mitochondrial abundance and activity which can, in part, account for the CKD-induced reduction of exercise capacity.

**High Dose ARB Promotes Survival and Parietal Epithelial Cell to Podocyte Transition in 5/6 Nephrectomy Rats** Dan Gao,[1, 2] Vittorio Albertazzi,[1] Li-Jun Ma,[1] Haichun Yang,[1] Kang-Hsien Fan,[3] Yu Shyr,[3] Agnes B. Fogo.[1] *[1]Department of Pathology, Vanderbilt University; [2]Department of Nephrology, First Affiliated Hospital of ZhengZhou University, ZhengZhou, China; [3]Cancer Biostatistic Center, Vanderbilt-Ingram Cancer Center.*

Angiotensin receptor blocker (ARB) can regress existing sclerosis induced by 5/6 nephrectomy (Nx) if given short term from 8 to 12 wks. We now further investigated 1) long term effects on regression and survival and 2) potential parietal epithelial cell (PECs)-podocyte transition in regression.

Adult male Sprague Dawley rats underwent 5/6 Nx. Glomerulosclerosis (0-4 scale) was assessed by renal biopsy (Bx) at 8 weeks. Rats were then divided into two groups with equal average systolic blood pressure (SBP), 24-h urinary protein (Uprot) and sclerosis index (SI), and treated with high dose ARB (n=21, losartan, 200 mg/L/DW) or no treatment (CONT, n=21) till 30 wks after Nx.

ARB lowered SBP and proteinuria vs CONT, increased survival rate (median survival time 27.1 wks vs 19.7 wks, log-rank test, p=0.013). Protective effects of ARB on survival rate were greater in those animals with Bx SI>1.1 (as assessed by original data and 5000 bootstrap re-sampling analysis, median survival time: ARB 22.4 wks vs CONT 17.3 wks, log-rank test, p=0.018) compared to those with Bx SI≤1.1 (median survival time: ARB >30 wks vs CONT 20.6 wks, log-rank test, p=0.068). ARB significantly maintained WT1-positive podocyte numbers at sacrifice compared to CONT (2.4±0.3 vs 1.7±0.2, $p<0.05$). Interestingly, claudin 1 staining (PEC marker) was increased in capillary loop area at sacrifice (0-4 scale, ARB 1.1±0.1 vs CONT 0.6±0.1, $p<0.05$), indicating parietal-like cells were in anatomical location of podocytes.

We conclude that high dose ARB improves survival in this CKD model, and the beneficial effect is further potentiated when the intervention occurred at moderate stages of glomerulosclerosis. We postulate that the beneficial effects of ARB on survival are in part linked to maintained podocyte numbers contributed to by parietal epithelial cell to podocyte transition.

**Protein Restriction Plus Ketoacids Reduces the Severity of Renal Disease in 5/6 Nephrectomized Rats: An Association with KLF15 Levels** Xiang Gao, Changlin Mei. *Kidney Institute of PLA, Department of Medicine, Kidney Institute of PLA, Department of Medicine, Changzheng Hospital, Second Military Medical University, Shanghai, China.*

**Objective**: To investigate the efficacy and mechanism of kruppel-like factor 15 (KLF15) on renal fibrosis in chronic kidney disease (CKD).

**Methods**: 5/6 nephrectomy SD rats were randomly divided into three groups, respectively fed with normal protein (NPD), low protein (LPD) or low protein plus ketoacids (LPD+KA). The functional and morphological alterations of the remnant kidneys, oxidative stress and inflammatory level were measured. Then we examined the levels of KLF15 in remnant kidney. In vitro we observed the effect of TGF-β, oxidative stress and inflammatory on KLF15 in rat mesangial cells (RMCs) and explored the underlying mechanism. For further study RMCs and HEK293 cells were transfected with a KLF15 cDNA expression vector and the level of extracellular matrix was measured.

**Results**: Progressive injury was found in the remnant kidneys of NPD group. Protein restriction ameliorated above changes, and the role was more obvious in LPD+KA group after 5/6 nephrectomy. Oxidative products as well as chronic inflammation were significantly increased in LPD group compared with LPD+KA group. KLF15 was expressed in both glomeruli and interstitium. The levels drastically decreased in remnant kidney of 5/6 nephrectomized rats, while restriction of protein intake partially restored the levels of KLF15, and LPD+KA increased more effectively than LPD. In vitro we found that levels of KLF15 in RMCs were decreased by TGF-b1, TNF-a, as well as $H_2O_2$, and overexpression of KLF15 in RNCs and HEK293 significantly decreased extracellular matrix expression.

**Conclusion**: LPD+KA plays a more renal protective role than LPD in CKD rats. The effect may be mediated by ketoacids ameliorating oxidative stress and inflammation injury in remnant kidney tissue. The expression of KLF15 can be affected by oxidative stress and inflammation, and it may also have a role in extracellular matrix regulation in renal fibrosis in CKD. The improvement of renal disease by dietary treatment was associated with a partial restoration of KLF15 expression in remnant kidney.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2226**

**Very Advanced Chronic Kidney Disease (CKD) Can Still Be Arrested by Combined Losartan (L) and Hydrochlorothiazide (H) Treatment** Simone R. Costa, Carla P. Valente, Claudia R. Sena, Camilla Fanelli, Bianca H. Ventura, Denise M. Malheiros, Roberto Zatz, Clarice K. Fujihara. *Univ of Sao Paulo, Brazil.*

We showed earlier (AJP 292:F1810) that LH treatment started 1 month after 5/6 renal ablation (Nx) arrests renal injury for at least 7 months. However, such early intervention is unrealistic. We investigated if LH would still afford renoprotection when started 4 months after Nx, when renal injury is comparable to that seen in very advanced human CKD. Adult male Munich-Wistar rats underwent Nx, remaining untreated until 4 months after Nx, when tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/d), plasma triglycerides (TG, mg/dL), serum creatinine (Scr, mg/dL), % glomerulosclerosis (%GS), % cortical interstitium (%INT) and tubulointerstitial (TI) proliferating cell nuclear antigen (PCNA+, cells/mm$^2$) were measured in 14 pretreatment controls (**$Nx_{pre}$**). The remaining 53 rats were distributed among **Nx** (untreated); **$Nx_L$** (L, 50 mg/kg/d) and **$Nx_{LH}$** (L+H, 6 mg/Kg/d). Results 3 months later (Mean±SE, $^a$p<0.05 vs. $Nx_{pre}$, $^b$p<0.05 vs. Nx; $^c$p<0.05 vs. $Nx_L$):

| | TCP | ALB | %GS | %INT | TI PCNA+ | $S_{Cr}$ | TG |
|---|---|---|---|---|---|---|---|
| $Nx_{pre}$ | 208±3 | 147±17 | 28±4 | 4.1±0.5 | 194±34 | 1.4±0.1 | 79±2 |
| Nx | 216±5 | 256±47$^a$ | 55±4$^a$ | 6.8±0.7$^a$ | 264±43 | 2.4±0.2$^a$ | 91±6 |
| $Nx_L$ | 209±3 | 174±24$^b$ | 46±5$^a$ | 6.2±0.4 | 191±24 | 2.0±0.3$^a$ | 91±12 |
| $Nx_{LH}$ | 163±4$^{abc}$ | 43±5$^{abc}$ | 25±4$^{bc}$ | 4.0±0.7$^b$ | 78±8$^{abc}$ | 1.4±0.1$^{bc}$ | 66±6$^{abc}$ |

At baseline (Group $Nx_{pre}$), severe renal injury and renal insufficiency (with $S_{Cr}$ almost threefold higher than normal) were evident. Untreated Nx rats mimicked severe human CKD, with high mortality (75%), marked hypertension and fast increase of ALB, $S_{Cr}$, GS, %INT and TI hyperplasia. Unlike L, LH arrested or reversed all abnormalities and reduced mortality (27%). Conclusions: 1) very advanced CKD can still be arrested; 2) as with early treatment, very late L may require a diuretic for best renoprotection; 3) at odds with established concepts: a) H can still be effective in very advanced CKD; b) H does not necessarily worsen, and may even ameliorate, dyslipidemia in CKD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2227**

**Amniotic Fluid Stem Cells and CKD** Laura Perin,[1,3] Sargis Sedrakyan,[1,3] Stefano Da Sacco,[1,3] Liron Shiri,[1,3] Astgik Petrosyan,[1,3] Kevin V. Lemley,[2,4] Roger E. De Filippo.[1,3] *[1]Urology, Childrens Hospital Los Angeles, Los Angeles, CA; [2]Nephrology, Childrens Hospital Los Angeles, Los Angeles, CA; [3]Laboratory for Organ Regenerative Research and Cell Therapeutics, Institute of Urology, Keck School of Medicine, University of Southern California, Los Angeles, CA; [4]Clinical Pediatrics, Keck School of Medicine, University of Southern California, Los Angeles, CA.*

Alport Syndrome is characterized by a hereditary form of glomerulonephritis, wherein an abnormal level of glomerular basement membrane (GBM) is produced, gradually leading to interstitial fibrosis and eventual loss of renal function. At present, there is no definitive therapy to delay progression to ESRD for patients with Alport Syndrome. Stem-cell based therapies may provide alternative therapeutic opportunities. Amniotic fluid stem cells (AFSCs) are well established to have pluripotential capabilities and represent a possible alternative approach to current therapies for CKD. Systemic injection of the cells provides beneficial effects; we found decreased levels of albuminuria, creatinine and BUN as well as significant increase in the life-span of the treated mice as compared to their untreated controls. Additionally, treated mice present lower number of macrophage infiltration, lower myofibrostast trasformation in the kidney interstitial space, accompanied with downregulated expression of chemokines such as MPC-1, IP-10 and cytokines such as IL-1, TNFα and TGFβ. Data from AFSC treated mice also show altered expression of other molecules/proteins associated with ECM turnover and fibrosis. In this study we demonstrate that AFSCs are capable of slowing down the progression of Alport disease by incurring structural and functional benefits to the kidney. These cells may present an alternative approach to treat various medical conditions where currently therapeutic options are either limited or inadequate.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2228**

**Molecular Characterization of a Murine Model of Nephrolithiasis and Kidney Failure Using Untargeted Plasma Metabolite Profiling** Qun Chen,[1] Hyeong-Cheon Park,[2] Michael S. Goligorsky,[3] Steven S. Gross.[1] *[1]Weill Cornell Medical College, NY, NY; [2]College of Medicine, Seoul, Korea; [3]New York Medical College, Valhalla, NY.*

We found that Xanthine oxidoreductase (XOR) nullizygous mice develop severe renal dysfunction and early death, in association with the accumulation of crystalline purine deposits in the renal tubules and parenchyma. Despite knowledge of XOR's substrates (xanthine and hypoxanthine) and ultimate product (urate), purine-independent actions of XOR on intermediary metabolism have been inferred and indirect consequences of XOR inactivation are likely. Metabolomic technologies offer the potential to broadly survey changes in the expression levels of thousands of structurally diverse metabolites in complex biological mixtures. The present study employed untargeted plasma metabolite profiling in attempt to discover systemic changes that result from XOR deletion or inhibition. Using untargeted LC-MS in conjunction with a chemoinformatic platform for data acquisition, filtering and statistical analysis, we surveyed >3700 metabolites (50 – 1000 Da) for differential expression in plasma of wild-type vs. xor-nullizygous mice. Notably, of 150 plasma metabolites that were significantly altered by > 2-fold in xor-null mice (up or down), 110 changes were recapitulated in wild-type mice after treatment with allopurinol, a pharmacological inhibitor of XOR. We discovered that XOR inhibition results in 6-fold reduction in circulating levels of the XOR cofactor molybdopterin as well as profound changes in circulating phospholipid profiles. The lower level of molybdopterin suggests that XOR may regulate the expression of its cognate cofactor and altered phospholipid levels may be explained by a prior report showing that XOR-knockout results in a developmental defect in adipogenesis. Anatomical and functional studies confirmed the plasma metabolite evidence of renal dysfunction in XOR-null mice. These studies suggest unrecognized XOR activities and demonstrate the power of untargeted plasma metabolite profiling for systemic discovery of both direct and indirect consequences of gene mutations and drug treatments.

**Anti-Angiogenic Proteins as Premonitory Diagnostic Markers of Chronic Allograft Dysfunction** Eliza Moskowitz-Kassai,[1] Lina Mackelaite,[1] Jun Chen,[1] Darshana M. Dadhania,[2] Steven S. Gross,[2] Praveen Chander,[1] Veronica Delaney,[1] Manikam Suthanthiran,[2] Michael S. Goligorsky.[1] *[1]New York Medical College, Valhalla, NY; [2]Weill Cornell Medical College, NY, NY.*

Our previous "shotgun" mass spectroscopy studies demonstrated the de novo appearance in the urine of CAD patients of 180 proteins/peptides, of which 39 were not detectable in the urine from patients with stable graft function and 21 were unique for CAD grades 1-3. We have recently documented the appearance of one anti-angiogenic peptides, endorepellin, in the urine of patients occurred at the expense of the parent molecule, perlecan. Here, we analyzed three additional anti-angiogenic peptides previously detected in the urine of CAD patients, endostatin, pigment epithelium-derived factor (PEDF) and Kruppel-like factor-2 (KLF-2). In healthy subjects and patients with CAD 0, endostatin excretion was confined to the level of detection. In contrast, Tukey's Multiple Comparison Test (MCT) indicated that there were significant differences ($p<0.05$) between the subgroups of patients with CAD 3 and CAD 0, CAD 1, and healthy patient controls. PEDF excretion in healthy controls and CAD0 patients was at the lower level of detection. MCT indicated that there were significant differences ($p<0.05$) between the subgroups of patients with CAD 3 and CAD 0, CAD 2, and healthy controls. KLF-2 urinary excretion by healthy controls and CAD0 patients was also at the lower level of detection. MCT showed that there were significant differences ($p<0.05$) between the subgroups of patients with CAD 3 and CAD 2 and healthy controls. ROC curve analyses demonstrated a highly discriminative profile for all three biomarkers offered 83% sensitivity and 90% specificity in distinguishing patients with CAD-0 from groups CAD-1-3. PEDF and KLF-2 levels in the urine were elevated in patients with CyA nephrotoxicity detected by biopsy. In conclusion, these findings indicate the diagnostic potential of urinary detection of endostatin, PEDF and KLF-2 and are suggestive of the mechanistic role played by anti-angiogenic substances in the developing vasculopathy and vascular rarefaction in patients with CAD.

**Effect of Chronic Kidney Disease on the Expression of Thiamin and Folic Acid Transporters** Farhan J. Bukhari,[2] Hamid Moradi,[1] Hyun Ju Kim,[1] Nosratola D. Vaziri,[1] Hamid M. Said.[2] *[1]Medicine/Nephrology, University of California, Irvine, Irvine, CA; [2]Medicine, Long Beach VA Medical Center, Long Beach, CA.*

**Objectives:** Chronic kidney disease (CKD) is associated with significant cardiovascular, neurological and metabolic complications. Thiamin and folate are essential for growth, development and normal cellular function, and their uptake is mediated by regulated transport systems. While plasma folate and thiamin levels are generally normal in patients with CKD, they commonly exhibit features resembling vitamin deficiency states. Earlier studies have documented impaired intestinal absorption of several B vitamins in experimental CKD. In this study we explored the effect of CKD on expression of folate and thiamin transporters in the key organs and tissues.

**Method:** Sprague-Dawley rats were randomized to undergo 5/6 nephrectomy or sham-operation and observed for 12 weeks. Plasma folate and thiamin concentrations and gene expression of folate (RFC, PCFT) and thiamin transporters (THTR-1 and THTR-2) were determined in the liver, brain, heart and intestinal tissues using real-time PCR.

**Results:** Plasma folate and thiamine levels were comparable among the CKD control groups. However expressions of both folate (RFC and PCFT) and thiamin (THTR-1, THTR-2) transporters were markedly reduced in the small intestine, heart, liver and brain of the CKD animals. Similarly, expression of the mitochondrial folate (MFT) and thiamin pyrophosphate transporters (MTPP) was significantly reduced in the CKD animals.

**Conclusion:** CKD results in marked down-regulation in the expression of folate and thiamin transporters in the intestine, heart, liver and brain. These events can lead to reduced intestinal absorption and impaired cellular homeostasis of these essential micronutrients despite their normal plasma levels.

**Table:** Thiamin and Folate transporters percent difference in CRF compared to sham-operated animals.

| | RFC | PCFT | THTR-1 | THTR-2 | MFT | MTPP |
|---|---|---|---|---|---|---|
| INTESTINE | -47%** | -74%* | -47% | -64%** | | |
| LIVER | -48%* | -67%** | -57%* | -68%* | -55%** | -43%** |

## SA-PO2231

**Ezetimibe Alone or in Combination with Pitavastatin Prevents Kidney Dysfunction in 5/6 Nephrectomized Rats Fed High-Cholesterol** Yusaku Mori, Tsutomu Hirano. *Diabetes, Metabolism, and Endocrinology, Showa university school of medicine, Shinagawa, Tokyo, Japan.*

Purpose: We investigated the renoprotective effect of ezetimibe, an inhibitor of cholesterol absorption, in 5/6 nephrectomized rats and compared with a statin.

Methods: The nephrectomized rats or sham-operated rats were fed either 1% cholesterol or normal chow containing ezetimibe or pitavastatin for 12 weeks.

Results: The nephrectomized rats exhibited kidney dysfunction (creatinine clearance (CCr, ml/min/kg) 7.5±0.8 vs. control 2.7±0.8; urine protein excretion (UPE, mg/dl/creatinine) 24.7±0.9 vs. control 1.4±0.2), hypercholesterolemia, and pathological changes (glomerulosclerosis and interstitial fibrosis). Pitavastatin failed to improve hypercholesterolemia in the nephrectomized rats but it significantly ameliorated renal dysfunction (CCr 3.4±0.3; UPE 11.5±3.3) and pathological changes. Ezetimibe conferred no effect on either cholesterol or kidney damage. The high-cholesterol diet increased serum cholesterol even further and worsened the kidney damage (CCr 1.5±1.1 vs. control 6.8±0.7; UPE 36.4±11.4 vs. control 5.3±2.6). Ezetimibe attenuated the hypercholesterolemia and significantly ameliorated the kidney dysfunction (CCr 2.4±0.6; UPE 30.1±6.1) and pathological changes, while pitavastatin failed to improve the kidney damage (CCr 2.1±1.0; UPE 34.6±13.8). The combination of ezetimibe and pitavastatin additively ameliorated the kidney damage (CCr 3.0±0.4; UPE 24.4±9.8). Macrophage infiltration area on glomeruli which was caused by high cholesterol diet was ameliorated by ezetimibe (5.8±2.9 vs. without ezetimibe 11.2±1.8%), and that area was closely associated with serum cholesterol levels. The kidney dysfunction and morphological changes were significantly associated with serum cholesterol levels and the gene expression of connective tissue growth factor in the remnant kidney.

Conclusion: These results suggest that ezetimibe and pitavastatin confer their renoprotective effects in different ways, the former by cholesterol reduction via inhibition of cholesterol absorption, and the latter by a pleiotropic effect independent of the cholesterol reduction.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2232

**Effect of Indoxyl Sulfate on Apoptosis, Reactive Oxygen Species Production in Neutrophils and Synthesis of MCP-1 and Monocytes** Edgar Ferreira Cruz, Silman Manfredi, Gori Mouro, Marie Beata Redublo Quinto, Caren Cristina Grabulosa, Marcelo Costa Batista, Miguel Cendoroglo, Maria Dalboni. *Medicine/Nephrology, Universidade Federal de São Paulo, Sao Paulo, Brazil.*

Introduction: Indoxyl sulfate is a uremic toxin that accelerates the progression of chronic kidney disease (CKD). Serum levels of indoxyl sulfate are increased in dialysis patients.

Aim: The aim of this study was to evaluate the effect of the uremic compound indoxyl sulfate (IS) on apoptosis, reactive oxygen species production (ROS) and synthesis of MCP-1 in polymorphonuclear cells and mononuclear cells.

Methods: We selected 35 healthy subjects (20 men and 15 women. Neutrophils (PMN) and monocytes (PBMC) were incubated in the absence and presence of IS. Apoptosis was evaluated by annexin V- FITC and the expression of CD95-FITC. To measure ROS production we used DCFH-DA and DAF. Apoptosis, CD95 expression and ROS was analysed mean intensity of fluorescence (MIF) by flow cytometry. MCP-1 was measured by immunoassay (ELISA).

Results: We observed that the viability of PMN was lower after incubation with indoxyl sulfate (18 ± 11 vs 33 ± 14, p <0.001). Moreover, apoptosis (47 ± 20 vs. 36 ± 11, p <0.001), expression of CD95 (110 ± 29 vs 48 ± 20, p <0.001) and hydrogen peroxide (43,234 ± 31,488 vs. 8,663 ± 5,138; p <0.001) and nitric oxide (27,077 ± 9,688 vs 2,278 ± 2,965, p <0.001) were higher in PMN incubated in the presence of indoxyl sulfate compared with PMN incubated in the absence of toxin. The expression of MCP-1 was lower in monocytes incubated with indoxyl sulfate (1,105 ± 663 vs. 1,673 ± 1,233, p <0.01).

Conclusions: Thus, in accordance with our results, we suggest that IS is a uremic toxin that increases the generation of hydrogen peroxide and nitric oxide, substances that are potentially inducing or contributing to injury in vascular endothelium. Indeed, this toxin might be associated with atherosclerosis. Additionally, the IS induces apoptosis of PMN and decreased synthesis of MCP-1, suggesting that this toxin may also contribute to low response to challenge infectious and consequently susceptibility to infections observed in the CKD patients.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2233

**Can Podocytes Undergo Epithelial-to-Mesenchymal Transition?** Tet-Kin Yeo, Charbel C. Khoury, Sheldon C. Chen. *Medicine/Nephrology & Hypertension, Northwestern University, Chicago, IL.*

Transforming Growth Factor-beta (TGF-β) is a major cytokine known to induce podocyte dysfunction leading to glomerulosclerosis and albuminuria. TGF-β is also a strong inducer of epithelial-to-mesenchymal transition (EMT). While EMT has been suggested to be a mechanism of podocyte disease, this remains controversial. To obtain a more comprehensive understanding, we determined the mRNA and protein expression profiles of cultured podocytes when treated with TGF-β.

Expression profile of podocyte culture in the presence of TGF-β

| Category | Increased Expression | Decreased Expression | Unchanged Expression |
|---|---|---|---|
| Cell Surface Proteins | Integrins α5, β1, B3 | Integrin α3 | Integrin αv |
| | | Nephrin | |
| | | P-Cadherin | |
| Cytoskeletal Proteins | Vimentin | | FSP1 |
| | α-SMA | | |
| Matrix Proteins | Fibronectin | | |
| | Collagens 1α2, 3α1, 5α2 | | |
| Polarity Proteins | | Crumbs 3 | |
| | | PALS1 | |
| | | PATJ | |
| | | Protein Kinase C, iota | |
| Transcription Factors | Zeb2 | | Zeb1 |
| | Snail | | |
| Matrix Metalloproteases | Mmp 2, 9 | | |
| Protease Inhibitors | PAI-1 | | |
| | Timp | | |

Exposure of the podocytes to TGF-β (2 ng/mL) for 24 or 48 hr resulted in a decrease of slit diaphragm proteins as well as an increase in phosphorylation of Nephrin. Also notable was a marked decrease in the Crumbs apical cell polarity complex. These changes correlated with alterations in functional characteristics including the loss of cellular arborization and actin stress fibers, as well as increased cell motility. However TGF-β-treated cells failed to upregulate FSP-1. Nonetheless, the sum of these changes, along with the increased expression of other known mesenchymal markers, suggests that the podocyte undergoes EMT. The phenotypic changes of podocyte EMT might be attributable to an increase of the transcription factor Zeb2, an E-box repressor known to participate in EMT. Zeb2 itself might be increased because of loss of inhibition by members of the microRNA-200 family. This marks the first time that Zeb2 has been correlated with components of podocyte EMT.

We provide a more complete profile of EMT, including the repression of Crumbs polarity complex, and identify Zeb2 and others as novel signaling pathways involved in the podocytopathy that contributes to TGF-β-related kidney diseases, ranging from obstruction to diabetic nephropathy to nephritis.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2234

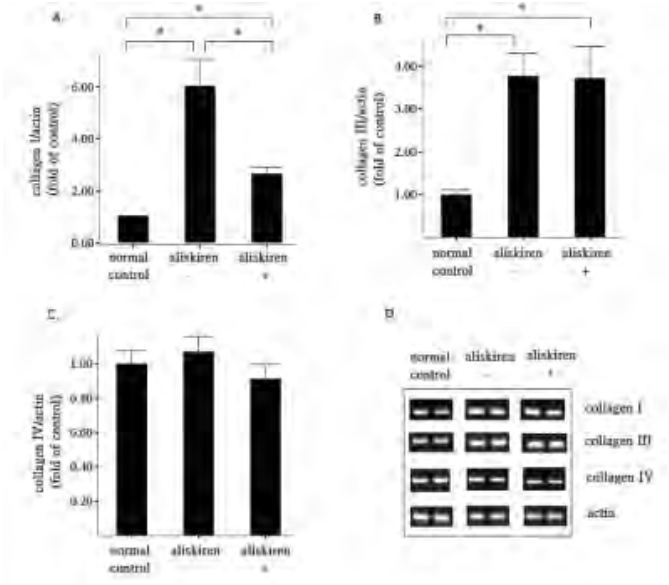
**Revisiting Renin-Angiotensin System in Chronic Renal Ischemia/ Renovascular Hypertension with Direct Rennin Inhibitor – A Study from a 2K1C Mice Model** Chiao-Yin Sun. *Nephrology, Chang Gung Memorial Hospital, Keelung, Taiwan.*

Chronic renal ischemia (CRI)leads to renal fibrosis. The aim of this study is to define the renal RAAS alteration and the effect of direct renin inhibition by aliskiren in kidney with CRI. A two kidney-one clip model was used in this study.Aliskiren significantly lowered the blood pressure in mice with renal artery constriction (92.1 ± 1.1 vs. 81.0 ± 1.8 mmHg, P< 0.05). Renal renin (0.20 ± 0.10 vs. 1.00 ± 0.06, P<0.05) and AT2 receptor (0.46 ± 0.24 vs. 1.00 ± 0.00, P<0.05) expression decreased after CRI. Renin (0.35 ± 0.06 vs. 1.00 ± 0.06, P<0.05) expression decreased and angiotensinogen (3.46 ± 1.08 vs. 1.00 ± 0.14, P<0.05) expression increased in un-clipped kidney. (Pro)renin receptor was decreased by direct renin inhibition (clipped kidney: 0.52 ± 0.06 vs.0.95 ± 0.05, P< 0.05; un-clipped kidney: 0.59 ± 0.03 vs. 0.91 ± 0.14, P<0.05).

Summary of RAAS profile changes in study animal.

| | Ischemic kidney (vs. normal control) | Compensatory kidney (vs. normal control) |
|---|---|---|
| Renin | ↓ | ↓ |
| (pro)renin receptor | — | — |
| Angiotensinogen | — | ↑ |
| AT1 receptor | — | — |
| AT2 receptor | ↓ | — |
| | Ischemic kidney (aliskiren+ vs. aliskiren-) | Compensatory kidney (aliskiren+ vs. aliskiren-) |
| Renin | ↑ | ↑ |
| (pro)renin receptor | ↓ | ↓ |
| Angiotensinogen | — | — |
| AT1 receptor | — | ↓ |
| AT2 receptor | ↑ | — |

CRI dcreased klotho expression, increased Bax, caspase-3, TGF-β1, and CTGF expression significantly, which can be all reversed by direct renin inhibition with aliskiren. The relative changes of collagen expression were showed in Figure 1.



Histology exam revealed that aliskiren significantly decreased renal fibrosis induced by CRI. In our study, we demonstrated that aliskiren significantly reversed renal fibrosis, apoptosis, and *klotho* expression after CRI possibly via angiotensin II dependent and independent pathways.

## SA-PO2235

**Discovery and Validation of A1BG as a Differential Urinary Biomarker in Pediatric Nephrotic Syndrome** Nuntawan Piyaphanee, Michael R. Bennett, Kimberly Czech, Mark Mitsnefes, Prasad Devarajan. *Nephrology, Cincinnati Children's Hospital, Cincinnati, OH.*

We set out to discover a non-invasive biomarker that could distinguish steroid resistant nephrotic syndrome (SRNS) vs steroid sensitive nephrotic syndrome (SSNS).

Methods: Urine and clinical data were collected from patients with idiopathic nephrotic syndrome and healthy controls. Using surface enhanced laser desorption ionization time of flight (SELDI-TOF) mass spectrometry, we identified a strongly upregulated 13.8 kDa fragment of α-1B-glycoprotein (A1BG fr) in urine in SRSS and/or FSGS. To validate our findings, A1BG was detected by western blot. Creatinine was measured and transformed to GFR by the new Schwartz formula and classified to CKD stage. P-values were determined by unpaired t-test and Mann-Whitney Rank Sum analysis.

Results: By western blot, the 13.8 kDa A1BG was present in 7 of 13 patients with FSGS; the fragment was absent in SSNS (n=15) and controls (n=10). The A1BG fr+ patients had higher serum creatinine and lower GFR than the A1BG fr- patients. CKD stage was also higher, but not statistically significant (table1).

Table1 Clinical data and renal function of A1BG fr+ and A1BG fr- patients

| Variable | A1BG fr+ (n=7) | A1BG fr- (n=21) | P-value |
|---|---|---|---|
| Age (years; mean±SD) | 13.1±2.9 | 7.9±4.9 | 0.003 |
| Sex Male:Female | 2.5:1 | 1.6:1 | NS |
| Race(%)African American/Caucasian | 50.0/50.0 | 42.9/42.9 | NS |
| Cr (mg/dl; median [IQR]) | 1.4 (0.68-3.23) | 0.5 (0.40-0.60) | 0.006 |
| GFR (ml/min/1.73m2; mean±SD) | 54.66±36.31 | 102.43±40.47 | 0.011 |
| CKD stage (median [IQR]) | 3 (1.25-3.75) | 1 (1.0-2.0) | 0.069 |

Conclusions: The A1BG fragment was absent in patients with SSNS or normal subjects, and therefore is potentially useful as a non-invasive biomarker for prediction of FSGS with unfavorable renal function.

**Enalapril Reduces Albuminuria Via Inhibiting Multiple Disease Pathways but Not Apoptosis in a Rat Model of Crescentic Glomerulonephritis** Mandy M. Smith, Eric C. Roux, Steven R. Ledbetter, Hong Ling. *Cardiovascular Metabolic Renal Science, Genzyme Corp, Framingham, MA.*

Crescent glomerulonephritis (CGN), a debilitating kidney disease, could lead to renal failure within weeks or months. Several disease pathways may be implicated, including TGF-β expression, infiltration of macrophages, and podocyte derangement. However, the potential therapeutic role along with the modulation of these pathogenic events by ACEi is not fully elucidated. The aim of this study was to examine the effects of enalapril in a rat model of anti-GBM CGN. The model was induced by one bolus injection of sheep anti-rat GBM serum, followed with enalapril (200 mg/L in drinking water) for 6 weeks. Following the dosing of anti-serum, rats developed albuminuria, glomerular crescents, sclerosis and tubulointerstitial damage. Enalapril significantly reduced albuminuria, with almost normalized renal function and histological appearance. Consistent to these observations, TGF-β gene expression was remarkably attenuated, along with reduction of PAI-1, collagen III genes, suggesting an inhibition of fibrogenesis in this model. Molecules involved in macrophage recruitment and proliferation, osteopontin and c-fms, were upregulated (2-20 fold), in untreated rats. Treatment with enalapril partially abrogated the up-regulation of OPN and c-fms mRNA, which was associated with a significant reduction of serum MCP-1 level and inhibition of macrophage accumulation within the kidney. Moreover, distressed podocytes, a key element for the integrity of glomerular filtration barrier, was rescued by enalapril, as evidenced by restored expression of nephrin and podocin, accompanied with reduced urinary nephrin excretion (344 vs.102 ug/mg Cr). Apoptosis related proteins, Bcl-xl, Apaf-1 and c-caspase 3, however were not altered nor affected by enalapril. Our results indicate an activation of multiple disease pathways which contributed to disease progression was retarded by enalapril. The study sheds light on the mechanisms of action of ACEi and set a model system for discovery of novel therapeutics to CGN and other chronic kidney diseases.

## SA-PO2237

**Is Decreased Renal ACE2 Expression Specific for Diabetic Nephropathy?** Sonoo Mizuiri,[1] Hiromichi Hemmi,[2] Moriatsu Miyagi,[1] Michitsune Arita,[2] Atsuhiko Mutou,[1] Yoshinari Hattori,[1] Yasunori Suzuki,[1] Yoshihide Tanaka,[1] Yasushi Ohashi,[1] Ken Sakai,[1] Kazutoshi Shibuya,[3] Atsushi Aikawa.[1] *[1]Nephrology, Toho University School of Medicine, Tokyo, Japan; [2]Molecular Biology, Toho University School of Medicine, Tokyo, Japan; [3]Surgical Pathology, Toho University School of Medicine, Tokyo, Japan.*

Angiotensin-converting enzyme 2 (ACE2) generates angiotensin 1-7, which may protect the kidney by attenuating the effects of angiotensin II. Decreased renal ACE2 expression in diabetic nephropathy is reported. This is possible that this may occur other renal diseases. Renal ACE and ACE2 expression was assessed in 13 patients with primary membranous nephropathy (MN), 17 patients with minimal change nephrotic syndrome (MCNS) and 20 healthy kidney transplant donors (controls) by immunohistochemistry and in situ hybridization. The percentage and intensity of labeled area were evaluated using a computer-based image analyzer. Blood pressure, proteinuira, serum albumin, eGFR at biopsy was also evaluated. There were no significant differences in blood pressure and eGFR across groups. Proteinuira (g/day) was higher in MCNS [6.2 (4.8-10.9)] than MN [3.7 (2.8-7.1)], but the difference was not significant. There were no differences in renal ACE and ACE2 protein expression in MCNS compared with controls. There were significantly decreased tubulointerstitial ACE2 protein [ 28.7 (22.5-32.1) vs. 47.5 (41.5-53.6), P<0.001] and glomerular ACE2 protein [0.9 (0.2-2.0) VS. 6.9 (1.8-12.0), P<0.01] and increased tubulointerstitial ACE protein [36.8 (31.9-43.9) vs. 21.2 (14.6-31.7), p<0.05] expression (density/pixel ) in MN compared with controls but no difference in glomerular ACE protein expression. The differences in ACE and ACE2 mRNA expression were not statistically significant across the 3 groups. None of clinical parameters significantly correlated with renal ACE, ACE2 expression in all subjects (n=50). However, significant correlation between tubulointerstitial ACE2 protein and eGFR (r=0.7, p<0.05) was observed in MN.

**Conclusion:** Membranous nephropathy is associated with decreased renal ACE2 expression and decreased renal ACE2 expression may be a common feature in progressive kidney disease.

## SA-PO2238

**Non-Diabetic Renal Disease in Diabetic Patients: A Learning Experience from over 3,500 Renal Biopsies with Diabetic Glomerulosclerosis** LaTonya J. Hickson,[1] Ziad El-Zoghby,[1] Sanjeev Sethi,[2] Mary E. Fidler,[2] Samih H. Nasr,[2] Lynn D. Cornell.[2] *[1]Nephrology & Hypertension, Mayo Clinic, Rochester, MN; [2]Anatomic Pathology, Mayo Clinic, Rochester, MN.*

The frequency of renal diseases other than diabetic nephropathy has been estimated to be 12-81% in diabetics based on limited data or small sample size.

Aim: To determine the prevalence of non-diabetic (non-DM) renal disease in biopsies with diabetic changes

Methods: Our renal biopsy database was queried for "diabetic glomerulosclerosis" (DGS) from July 1994 to February 2010. Each report was reviewed for non-DM renal disease and DM findings. Arteriosclerosis/arteriolar hyalinosis, secondary FSGS, and interstitial fibrosis/tubular atrophy were considered part of DM.

Results: Of ~57,400 native biopsies, 3575 (6.2%) had DGS. Among these, 92.3% had diffuse and/or nodular DGS while 7.7% had early, mild changes. Non-DM renal disease was present in 972 biopsies (**27.2% of total**). Tubulointerstitial was more common than glomerular disease (**18.7% vs 8%**). Tubulointerstitial findings consisted of acute tubular necrosis (60%), interstitial nephritis (36%), and other diseases (2.7%) including light chain cast nephropathy (0.7%) and pyelonephritis (0.6%). 18 cases (0.5%) had atheroembolic disease. Non-DM glomerular disease was present in 286 (**8% of total**) including: IgA (21.7%), pauci-immune crescentic glomerulonephritis (16.8%), membranous (16.4%), post-infectious (16.4%), membranoproliferative (7.7%), thrombotic microangiopathy (4.5%) and other diseases (16.4%). The "other" 49 cases were other immune complex(11), primary FSGS with collapse(7), fibrillary(6), lupus(6), amyloid(5), anti-GBM(5), minimal change(5), light chain deposition(2), type III collagen(1), and dense deposit disease(1). One-fourth (24.5%) of glomerular diseases had concurrent tubulointerstitial disease. The majority of non-DM glomerular diseases were found in those with advanced DGS compared to earlier diabetic changes (87% vs 13%).

Conclusion: Non-DM renal disease is not infrequent in biopsies with DGS. Even in advanced diabetic nephropathy, kidney biopsy is an important diagnostic tool which allows for appropriate intervention.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2239**

**Cytochrome P450 Polymorphisms Do Not Affect Response of Lupus Nephritis (LN) to Cyclophosphamide (CTX) Therapy** Brad H. Rovin, Johan Winoto, Haikady Nagaraja, Huijuan Song. *Ohio State University, Columbus, OH.*

The addition of CTX to corticosteroids significantly improves the prognosis of severe kidney involvement in systemic lupus erythematosus (SLE). However, not all patients respond to CTX. It has been suggested that genetic variations that reduce the metabolism of CTX reduce its effectiveness. CTX is metabolized and activated by the cytochrome P450 (CYP) system and in particular the CYP enzymes 2B6 and 2C19. Both CYP2B6 and CYP2C19 have variant alleles (designated CYP2B6*5 and CYP2C19*2) that attenuate or eliminate enzymatic activity. This investigation was done to determine the impact of CYP2B6*5 and CYP2C19*2 on the renal response in LN patients treated with CTX.

Patients with SLE (n=197), unclassified autoimmune disease (n=40), and healthy controls (n=202) were genotyped for the poor metabolizer alleles CYP2B6*5 and CYP2C19*2. The associations between these alleles and achievement of complete or partial response, development of end-stage renal disease, and time to remission were determined.

The frequencies of the variant alleles CYP2B6*5 and CYP2C19*2 were 6.9 % and 14.2% respectively. CYP2C19*2 genotypes were more frequent among African Americans than European Americans (33 vs 22%, P=0.018), and CYP2B6*5 genotypes were more frequent among European American SLE patients than healthy controls (20 vs 9%, P=0.043). Among LN patients treated with CTX (n=36), there were no differences between those with or without these genotypes in regard to the frequency of complete or partial remissions or the time to remission. Partial responders with a variant CYP allele used a higher cumulative CTX dose than wild-type patients (P=0.032), but unexpectedly variant complete responders tended to have a lower cumulative CTX dose than wild-type patients (P=0.067).

**Conclusion**: This single center retrospective analysis failed to show an association between the common variant alleles CYP2B6*5 and CYP2C19*2 and treatment outcomes in LN. This suggests that genotyping for these CYP450 variants will not be useful in individualizing treatment for severe LN. However, CYP2B6*5 may predispose to the development of SLE.

**Chronicity Index as a Prognostic Factor in the Outcome of Severe Lupus Nephritis** Elerson Costalonga, Lectícia Jorge, Victor Sato, Rui Toledo Barros, Viktoria Woronik. *Nephrology, Hospital das Clinicas, School of Medicine, University of Sao Paulo, Sao Paulo, Brazil.*

**Introduction:** Factors which predict renal outcomes in patients with severe lupus nephritis (LN) are poorly understood, as these patients are often excluded from treatment trials. **Aim:** To access clinical and kidney biopsy features which predict renal outcome in LN patients with eGFR < 30ml\min\1.73 m²(estimated by MDRD simplified formula) at biopsy time. **Methods:** Analyses of 311 patients with systemic lupus erithematosus submitted to kidney biopsy at our center from 1999 to 2007 were carried out. Eighty four patients with eGFR < 30ml\min\1.73 m² were selected. All patients were treated with intravenous cyclophosphamide and prednisone for at least 3 months. Multivariate logistic regression analyses were performed to access variables which were associated with an eGFR > 30ml\min\1.73 m² at one year follow up. **Results:** Baseline clinical and histological features are showed in table 1.

Baseline Features

| | |
|---|---|
| Age(yr) | 29(23-39) |
| Female | 83% |
| eGFR(ml\min\1.73 m²) | 17(11-23) |
| Proteinuria(g\day) | 3,7(1,8-6) |
| Hematuria | 78% |
| Hemoglobin(g\dL) | 8,5(7,5-10) |
| C3 (mg\dl) | 60(40-80) |
| Histological Features | |
| WHO LN Classes | |
| LN II | 5% |
| LN III+IV | 75% |
| LN V | 13% |
| LN VI | 7% |
| Crescents | 61% |
| Diffuse Interstitial Fibrosis | 33% |
| Activity Index | 4(3-6) |
| Chronicity Index | 5(2,8-7) |

Results expressed as median and IQR

At one year follow up, eGFR increased in an average rate of 12ml\min (CI 6.6 – 17.7ml\min) and 43% of subjects reached an eGFR < 15ml\min. Chronicity index (OR:0.62, CI 0.43-0.9; p<0.01) was independently associated to renal outcome after adjustment for initial eGFR(p=0.08), diffuse interstitial fibrosis(p=0.27) and proliferative LN(p=0.7). Based on the ROC curve (AUC 0.83, CI 0.73-0.91), the best chronicity index cutoff value to identify patients who improved renal function was 3 (sensibility 62%; specificity 90%; predictive positive value of 80%). **Conclusion:** Chronicity index can predict renal outcomes in patients with severe lupus nephritis and can be used as a tool to guide therapeutic decision in this group of patients.

**Elevated Double Stranded DNA Antibodies Are Associated with Future Diagnosis of Proliferative Lupus Nephritis** Jessica J. Lee, Kevin C. Abbott, Stephen W. Olson. *Department of Nephrology, Walter Reed Army Medical Center, Washington, DC.*

Arbuckle et al (*NEJM* 2003) found that 55% of systemic lupus erythematosus (SLE) cases had elevated double stranded DNA antibodies (dsDNA-Ab) prior to diagnosis. There have been no subsequent studies to further delineate a potential subpopulation of SLE that has a stronger association with elevated dsDNA-Ab. Elevated dsDNA-Ab are associated with lupus nephritis (LN) at diagnosis but are not present in all cases. We hypothesize that proliferative lupus nephritis (PLN) cases have elevated and rising dsDNA-Ab prior to diagnosis.

**Methods:** Twenty-three cases of biopsy proven PLN were identified using the Walter Reed Army Medical Center renal biopsy database. The Department of Defense Serum Repository (DoDSR) identified an age, sex, race, and age of serum matched SLE disease control for each study subject. Up to three chronologic serum samples for each study and disease control subject from prior to the date of biopsy diagnosis were sent from the DoDSR to Quest diagnostics® for measurement of plasma dsDNA-Ab levels. The Fisher's exact test was used for data analysis.

**Results:** A greater percentage of LN cases had elevated dsDNA-Ab levels (>10 IU/ml) prior to diagnosis compared to matched diseased (SLE) controls (78% vs. 5%; p<0.0001). dsDNA-Ab levels greater than 40 IU/ml were 100% specific for future LN (70% vs. 0%; p<0.0001). Subgroup comparisons of disease versus disease controls at less than 1 year (82% vs. 8%; p=0.0001), 1-4 years (53% vs. 0%; p=0.0008), and >4 years (33% vs. 0%; p=0.04) prior to biopsy diagnosis remained significant. Increasing dsDNA-Ab >1 IU/ml per year was 100% specific for future diagnosis of proliferative LN (70% vs. 0%; p<0.0001).

**Conclusion:** Elevated and rising dsDNA-Ab are strongly associated with the future diagnosis of PLN, but not the diagnosis of SLE without nephritis. PLN has the highest risk for end stage renal disease. Our novel data could provide a diagnostic and prognostic tool to identify SLE patients at high risk for PLN. This information could allow for more tailored follow up plans and potential earlier intervention for maximal preservation of renal function.

**SA-PO2242**

**Anti-C1q IgG Levels Are Unreliable as Biomarkers of Lupus Nephritis Flare** Joshua E. Bitter, Haikady Nagaraja, Udayan Y. Bhatt, Chack-Yung Yu, Brad H. Rovin, Lee A. Hebert, Daniel J. Birmingham. *Ohio State University College of Medicine, Columbus, OH.*

The recognition of biomarkers that reliably identify, or more importantly forecast, a lupus nephritis (LN) flare would greatly improve LN management. The presence of anti-C1q is strongly associated with active LN, which has led to the belief that circulating anti-C1q IgG levels can also serve as a valid LN flare biomarker. This study tested this premise. Anti-C1q IgG levels were measured by standardized ELISAs in 112 SLE patients (72 with LN) enrolled in the Ohio SLE Study (OSS), a longitudinal study of active SLE patients tested at regular bimonthly visits (mean of 44 months), and 40 age/race matched unrelated controls. The OSS samples selected were at the patients' first LN flare (N=37), or at baseline if they never experienced a LN flare. Patients who were anti-C1q-positive and who experienced LN flares with available plasma samples at 8, 6, 4, and 2 months before (-8, -6, -4, -2) and at the time of LN flare (together termed a flare interval) were further tested at these times. For the cross-sectional analysis, anti-C1q IgG was present in 51% of the OSS patients vs. 5% of the controls (P < 0.001), in 62% of the LN patients vs. 30% of the nonrenal SLE patients (P = 0.002), and in 73% of the LN patients with at least 1 LN flare vs. 51% of LN patients with no LN flare during the entire OSS period (P = 0.088). For the longitudinal analysis, 24 LN flare intervals were identified from the anti-C1q positive LN patients. Though there was a trend for an increase in mean levels at -2 and at flare (compared to -8, -6, and -4), it did not reach significance (P = 0.159 by repeated measures ANOVA of least squares means). Furthermore, analysis of each of the 24 individual flare intervals revealed that anti-C1q IgG levels increased in only 6/24 at -2, and only 9/24 at flare. In conclusion, these data show a significant association between the presence of anti-C1q IgG and SLE, and specifically with LN, in agreement with previous reports. However, changes in anti-C1q levels over time in a given patient are neither reliable forecasters nor markers of LN flare.

**SA-PO2243**

**Rituximab for Severe Lupus Nephritis: A Systematic Review and Meta-Analysis** Kiran Pokhrel, Gautham Viswanathan, Smita Padala. *Nephrology Division, Tufts Medical Centre, Boston, MA.*

Current treatment options for severe lupus nephritis (LN) are limited by high failure rates and adverse effects. Rituximab, an anti-CD20 monoclonal antibody has recently been used in patients with LN. Although the LUNAR trial evaluating Rituximab as an initial induction agent in LN did not show any benefit, evidence regarding the role of Rituximab in refractory LN (persistence of active LN despite immunosuppressive therapy) is lacking. We systematically reviewed the available evidence of Rituximab in refractory LN and performed a meta-analysis.

**Methods** MEDLINE, Pubmed and Cochrane library were searched for studies analyzing the efficacy of Rituximab in LN. Data on renal response was extracted. Results were expressed as weighted mean difference (WMD) for continuous outcomes and as

proportions for categorical outcomes with 95% confidence intervals (CI) using random effects model.

**Results** Nine studies reported the effect of Rituximab in 189 patients with LN, 41 of whom had refractory LN. The mean age of patients with refractory LN was 28yrs and median duration of LN was 3yrs. Mean cumulative cyclophosphamide dose before Rituximab therapy was 6.8g and 80% had class IV LN. Mean reduction in proteinuria was 2.02 g/24h (95% CI 2.96-1.08). The table shows the different renal responses to Rituximab. Serious adverse events including infection occurred in 8 patients including 3 deaths.

**Conclusion** Although there was a significant reduction in proteinuria and an overall renal response of 57% in refractory LN, the analysis was limited by observational studies with few patients. Randomized trials are needed to better evaluate the efficacy of Rituximab in refractory LN.

Renal response to Rituximab in refractory LN

| | Proportion | 95% CI |
|---|---|---|
| Complete Response (CR) | 0.27 | 0.16, 0.43 |
| Partial Response (PR) | 0.30 | 0.18, 0.46 |
| Overall Response (CR+PR) | 0.57 | 0.41, 0.70 |
| | WMD | 95% CI |
| Decrease in proteinuria (g/24h) | 2.02 | 1.08, 2.96 |
| Increase in GFR (ml/min/1.73 $m^2$) | 2.46 | 0.93, 3.99 |

CR: Normal serum creatinine and albumin, inactive urinary sediment and 24h urinary protein <0.5g PR: >50% improvement in all renal parameters GFR: Glomerular filtration rate

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2244

**Efficacy of Low-Dose Tacrolimus (TAC) in Induction Therapy of Lupus Nephritis (LN)** Satoshi Takahashi, Keiju Hiromura, Hiroko Hamatani, Noriyuki Sakurai, Hidekazu Ikeuchi, Akito Maeshima, Takashi Kuroiwa, Yoshihisa Nojima. *Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan.*

A previous pilot study showed that TAC was an effective option for induction treatment of diffuse proliferative lupus nephritis (Mok-C, Kidney Int 68:813, 2005). Recently, a placebo-controlled double-blind study demonstrated that TAC was effective in patients with LN who had moderate and persistent disease activity despite of steroid therapy (Miyasaka-N, Mod Rheumatol 19:606, 2009). Based on this study, TAC was approved for LN in Japan. However, the approved maximal dose is 3 mg/day that is almost half of the dose used in the Mok's study. In the current study, we retrospectively evaluated the efficacy of low-dose TAC for induction therapy of active LN. Thirteen adult patients (2 male and 11 female) who were treated with TAC for induction therapy in our department since Mar-07 to Mar-09 were examined. Eight patients were treated for a flare-up of LN and 6 of them had a history of receiving other immunosuppressants. Mean serum creatinine level and urinary protein/creatinine ratio before treatment was 0.7±0.2 mg/dl and 2.5±2.1 g/gCr, respectively. Twelve patients received or had received renal biopsy: 8 with class IV, 2 with class III+V, 1 with class IV+V and 1 with class V, according to ISN/RPS classification. The mean initial dose of prednisone and TAC was 34.6±14.5 and 2.7±0.6 mg/day (0.69±0.32 and 0.05±0.01 mg/kg/day), respectively. All patients reached complete remission (CR) (mean intervals, 7.1±7.1 months), except for 2 patients who discontinued TAC (1 for hypertension and 1 for worsening SLE). Two patients experienced a flare-up after achieving CR. The mean TAC blood concentration which was measured 12 hrs after the last administration was lower in patients with a flare-up compared to those with sustained CR (1.5±1.5 vs 5.1±1.5 ng/ml, p=0.041). These data showed that low-dose TAC was also effective in induction therapy of active LN, although lower TAC blood concentration may be associated with a poor outcome.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2245

**The Association of Disease Activity and Metabolic Syndrome in Lupus Nephritis** Masako Kochi,[#1] Kentaro Kohagura,[#1] Yusuke Ohya,[#1] Kunitoshi Iseki.[#2] *[1]Cardiovascular Medicine and Nephrology and Neurology, University of the Ryukyus, Nishihara-cho, Okinawa, Japan; [2]Dialysis Unit, University of the Ryukyus, Nishihara-cho, Okinawa, Japan.*

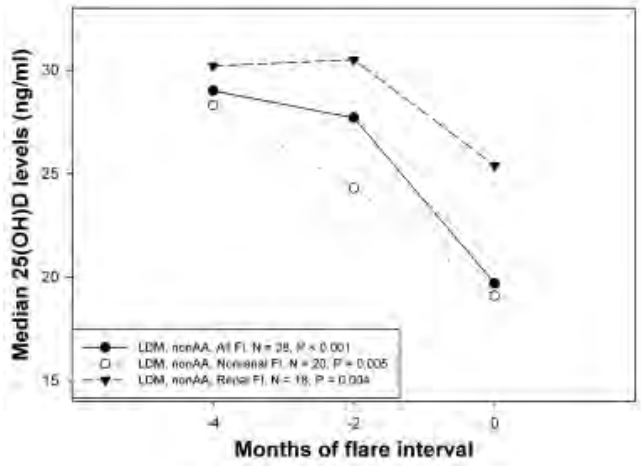
Patients with lupus have been reported to have higher prevalence of metabolic syndrome (Mets). Components of Mets such as hyper triglyceridemia (TG) were shown to be associated with the disease activity of lupus. However, it has not been clear whether Mets is associated with the activity and proteinuria in lupus nephritis. We examined 23 patients with lupus nephritis (91% female) and analyzed the association of Mets and parameter of disease activity of lupus such as anti-double-stranded DNA antibody (anti-dsDNA Ab) and urine protein (UP). The diagnosis of Mets was based on the Japanese definition including waist circumference. The mean (SD) was: age 36.3 (14.3) years, UP 3.2 g/gCr (range 0.1-9.6), and eGFR 79.7 (37) ml/min/1.73$m^2$. There were six patients (26%) with Mets. UP and anti-dsDNA Ab were significantly higher in the Mets group than those in non Mets group. We found the significant positive relationship between the number of components of Mets and UP ($\rho$=0.502, $P$=0.012) as well as between the parameter of disease activity of lupus such as anti-dsDNA Ab and UP. Moreover, there was significant positive correlation between the number of Mets and anti-dsDNA Ab. Finally, multiple logistic analysis adjusted for age and the dose of steroid used showed that the presence of Mets was significantly associated with higher risk for the presence of higher UP (above the highest quartile): the adjusted odds ratios (95% CI) were 176.9 (1.2 to 26557.2). In conclusion, the presence of Mets was associated with both anti-dsDNA Ab and UP. The intervention for Mets might be effective to prevent CKD progression of Lupus nephritis.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2246

**Evidence That Abnormally Large Seasonal Declines in Vitamin D Status Can Trigger SLE Flare in Non-African Americans** Daniel J. Birmingham,[1] Lee A. Hebert,[1] Huijuan Song,[1] Haikady Nagaraja,[1] William T. Noonan,[2] Brad H. Rovin,[1] Chack-Yung Yu.[1] *[1]Ohio State University College of Medicine, Columbus, OH; [2]Abbott Laboratories, Abbott Park, IL.*

Cross-sectional studies have suggested a role for vitamin D levels in SLE flare. However this has not been tested through serial vitamin D measurements leading up to flare. This study did so by measuring serum 25-OH vitamin D (25(OH)D) levels at 4 and 2 months before and at flare (-4, -2, 0: a flare interval) in 46 SLE patients (35 with nephritis) experiencing 82 flares (31 renal). The patients were from the Ohio SLE Study, a longitudinal study of SLE patients tested bimonthly. Our results showed no serial differences in 25(OH)D levels when considering all flare intervals. However, when analyzing only the flares that occurred during the 6 lowest daylight months (LDM, Oct-Mar), significant decreases in 25(OH)D were found, but only in non-African Americans (nonAA, 21 European Caucasians, 3 Asians) (38 flares, P < 0.001, Fig). This decrease (mean 17% from -4 to 0, P < 0.001) occurred in both renal (19%, N = 18, P = 0.004) and nonrenal (15%, N = 20, P = 0.005) flares.



To account for independent seasonal effects of LDM, 25(OH)D levels were measured in samples from 15 of these 24 patients who had a 4-month no-flare interval occurring in the same months as their flare interval and within 2 years of the flare. The mean decrease in 25(OH)D levels during the no-flare interval (11%) was not quite significant (P = 0.056), and was less than the mean decrease that occurred in the matching flare intervals (25%, P = 0.018 by paired t test). In conclusion, our data suggest that greater than usual seasonal decreases in 25(OH)D can trigger SLE flare in nonAA. AA typically have chronically low 25(OH)D levels with less seasonal variation. Thus, the effects of vitamin D on SLE flare may be muted in AA.

**A Combinatorial Urine Biomarker That Identifies Renal Interstitial Inflammation (INF) in Patients with Lupus Nephritis (LN)** Brad H. Rovin, Xiaolan Zhang, Huijuan Song, Haikady Nagaraja, Tibor Nadasdy. *Ohio State University, Columbus, OH.*

Kidney pathology is important for choosing therapy and monitoring disease progress in LN. Because it is not practical to biopsy an SLE patient at every renal flare, a non-invasive test that accurately reflects renal pathology is highly desirable. The objective of this study was to identify urine biomarkers that can be used as surrogates for specific pathologic kidney lesions. Here we report the results of biomarker discovery for INF in LN.

INF was semi-quantitatively graded as not present (0), mild (1, occupying less than 25% of the interstitium), or moderate-severe (2) in 45 diagnostic LN kidney biopsies. Three proteins known or postulated to be relevant to interstitial kidney injury were measured by ELISA in urine samples collected at biopsy and correlated to the level of INF. These proteins were MCP-1, L-FABP, and hepcidin. The ability of these markers to discriminate between levels of INF was tested by receiver operating characteristic (ROC) analysis.

Regression analysis demonstrated significantly increased expression of uMCP-1 (P<0.0004, $r^2$=0.26), uL-FABP (P=0.004, $r^2$=0.17), and uHepcidin (P=0.004, $r^2$=0.17) with severity of INF, however correlation coefficients were low. While all three markers were significantly higher in grade 2 INF than grade 0, only uMCP-1 was higher in grade 1 compared to grade 0. ROC curves were generated for each protein to determine if they could predict the level of INF. The area under the ROC curve (AUC) for uMCP-1 was 0.79, uL-FABP was 0.81, and uHepcidin was 0.78. As predictors these proteins misclassified INF in 47-62% of the biopsies. Using discriminant analysis, a linear equation combining all three proteins was derived that gave a combinatorial biomarker score. This score was used to plot an ROC curve to discriminate between grade [0+1] and grade 2 INF. It showed an AUC of 0.91, sensitivity of 90%, specificity of 80%, and misclassification rate of only 20%.

Conclusion: Combining several weak urine biomarkers can yield a more robust biomarker that can discriminate between different levels of severity of INF in LN without a biopsy.

**Biomarkers for Global and Renal Disease Activity in Juvenile Systemic Lupus Erythematosus (jSLE)** Michael R. Bennett, Rina Mina, Joshua David Pendl, Hermine Brunner, Prasad Devarajan. *Cincinnati Children's Hospital.*

Background: Preliminary data show that the Lupus Nephritis Renal Panel (LNRP), composed of transferring (Tf), ceruloplasmin(CP), acid-1-glycoprotein (AAG), neutrophil gelatinase-associated lipocalin (NGAL), prostaglandin-D synthethase (L-PDGS) and monocyte chemotactic protein 1 (MCP1), is associated with worsening lupus nephritis in jSLE. Cell-bound complement activated products (CB-CAP) which consist of erythrocyte, reticulocyte and platelet-bound complement components (E-C4d, E-C3d E-fBb, E-CR1, R-C4d, R-C3d, R-fBb and P-C4d) have been shown to reflect ongoing global disease activity in studies limited to adults with SLE.

Objectives: Evaluate the association of the LNRP and CB-CAP with global and renal disease activity in jSLE.

Methods: Clinical, laboratory and biomarker data were collected from 12 jSLE patients during initial and follow-up visits. Levels of LNRP standardized to urine creatinine and CB-CAP were measured by enzyme-linked immunosorbent assay and flow cytometry respectively. Physician-rated change in patient's disease course between visits (global/renal disease worsening: yes/no) served as the criterion standard.

Results: Using Wilcoxon Rank Sum Test and Spearman's correlation, statistically significant association was seen between levels of all urine biomarkers and the renal domains of 1-3 disease activity indices each (Renal SLAM, SLEDAI and BILAG), and the criterion standard. Levels of Tf, CP, L-PGDS and AAG were seen to be elevated three months prior to renal worsening with the change in the biomarker level associated with the change in the renal disease activity scores. No significant correlation between extra-renal disease activity and urine biomarkers was seen. Of the CB-CAP, only the E-CR1 and R-C4d were associated with current global/extra-renal disease activity. Traditional biomarkers for global and renal worsening correlated poorly with disease course or activity.

Conclusions: LNRP and CB-CAP are associated with renal and extra-renal disease activity in jSLE, respectively. The LNRP is predictive of worsening jSLE renal disease. Further studies assessing the predictive properties of combining these biomarkers are in progress.

**Clinical Impact of Serial Renal Biopsies in Patients with Lupus Nephritis** Smaragdi Marinaki,[1] Chrysanthi Skalioti,[1] Irene Synodinou,[1] Argyrios Georgalis,[1] Lydia Nakopoulou,[2] Charalambos Moutsopoulos,[3] John Boletis.[1] *[1]Nephrology and Transplantation Unit, Laiko Hospital, Athens, Greece; [2]Pathology Department, Medical School of Athens, Athens, Greece; [3]Pathophysiology Department, Medical School of Athens, Athens, Greece.*

OBJECTIVE:To evaluate the role of serial renal biopsies in the monitoring and therapeutic guiding in patients with lupus nephritis.

METHODS:We retrospectively analyzed the clinical course and the histological findings in patients with lupus nephritis, who underwent repeat renal biopsies between 2000 and 2009. Seventeen patients (16 women,1man) with a mean age of 24.8±5.4 years were evaluated. The mean SLE duration before renal involvement was 34±42 months.

Twenty eight repeat indication biopsies were performed in 17 patients with: relapse (n:10), ongoing activity/partial remission (n:11), aggravation (n:7).

Proliferative lupus nephritis (class III and IV-ISN/RPS2003) was the first diagnosis in 13/17(76.4%) patients. Eleven patients underwent 2 kidney biopsies (median time between 1st and 2nd biopsy 21 months), four patients had 3 biopsies (median time between the 2nd and the 3rd biopsy, 31 months); one patient had 4 and another one 5 renal biopsies.

There was no difference in patients' clinical characteristics at the time of the repeat biopsies. There was no difference in the mean activity scores whereas the mean chronicity score increased significantly (2.1±1.9and4±2.6) between 2nd and 3rd biopsy. Conversion to another class of nephritis occurred in 9/17(53%), and 2/4 patients(50%) between 1st to 2nd and 2nd to 3rd biopsy, respectively. Among these patients, 7/9(77%), and 1/2(50%) had conversion to a higher class.

In all the cases but one, therapy was intensified after biopsy, either by increasing the dose and/or the duration of therapy (8/27,29.6%) or by switching to other immunosuppressives (20/27,74%).

At the end of follow-up, 7/17 patients (25%) were in complete remission, 9/17 (32%) in partial remission and one patient was on haemodialysis.

In conclusion, given the poor clinicohistological correlation in lupus nephritis and the need for long term toxic immunosuppression, serial renal biopsies may have a central role in guiding therapeutic decisions..

**Evaluation of MMF as Induction Agent in Pediatric SLE Subjects: An Indian Experience** Sandip K. Bhattacharya, Saubhik Sural. *Department of Nephrology, Peerless Hospital & B.K.Roy Research Centre, Kolkata, West Bengal, India.*

**Purpose :** MMF has been proved to be as good as Cyclophosphamide (Cyc) in adult population with lupus nephritis but very few studies have been conducted in pediatric patients. The purpose of this study is to evaluate the outcome of pediatric lupus patients treated with Enteric Coated Mycophenolate Sodium (ECMPS) as induction agent.

**Method :** It is a single centre retrospective cohort study. Cohorts were evaluated at presentation (including Renal Biopsy). They were followed up at 6 months, 12 months and 24 months with urine, renal function , serology and complement.

**Results :** The population consisted of 20 patients, mean age 12.8 ± 3.2 years . All were female of Indian origin. 14 patients had class IV and 6 patients had class III lesion. Mean albuminuria was 2.6± 1.2 gm/day and mean GFR was 48.3 ± 18.4 ml/min at presentation. All the patients received ECMPS 30 mg/kg/day in 2 divided dosages for 1 year followed by 1.5 mg/kg/day of Azathioprine (Aza) along with prednisolone 1 mg/kg to start with and slowly tapered to 5 mg/day and maintained thereafter.

17 patients reached complete remission (CR) by 8 months and 3 patients achieved partial remission (PR). Two patients from PR group and 1 patient from CR group had proteinuric relapse on Aza and did not respond to reinstitution of ECMPS. Pulse Cyc also failed in these patients.

Three patients had diarrhea and managed with dose reduction of ECMPS. Two patients with ECMPS and 1 patient with Aza had leucopenia. None required discontinuation of therapy. Serious infective episode was not observed in any individual. 17 patients are still in remission after 28 months from initiation of therapy.

**Conclusion :** MMF is a good therapeutic option as induction agent in pediatric SLE patients with minimal adverse reaction. Aza is effective as maintenance drug after MMF induction for 1 year. Long term follow up is required to prove its efficacy in preventing ESRD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2251**

**The Low-Dose Cyclosporine A Treatment Improves SLE Disease Activity of Japanese Patients with Diffuse Proliferative Lupus Nephritis** Yuji Kamijo, Makoto Higuchi. *Department of Nephrology Internal Medicine, Shinshu University School of Medicine, Matsumoto, Nagano, Japan.*

Cyclosporine A (CyA), a representative calcineurin inhibitor, would be a useful medicine for the treatment of lupus nephritis accompanied with severe proteinuria. In contrast to its strong effects against proteinuria, the beneficial effects of CyA against SLE disease activity had been obscure. To elucidate it, we investigated the effects of low-dose CyA treatment (2.5 mg/kg/day) in 11 Japanese patients (Male 1, Female 10), which having uncontrolled diffuse proliferative lupus nephritis (WHO type IV) with relatively high SLE disease activity. The high level of serum makers of SLE disease activity and disease activity index in all patients were significantly improved within 1 month, as well as amelioration of their proteinuric state. The required amounts of corticosteroid were decreased in these patients. These favourable effects were continued for 2 years without serious adverse effects. Kidney function was not changed in the patients having enough kidney function prior to CyA therapy (serum creatinin level < 1.1 mg/dl, and eGFR > 45 ml/min/1.73m$^2$), while two of three patients having obvious kidney impairment with chronic tubulointerstitial changes exhibited aggravation of kidney dysfunction. The current study suggests that low-dose CyA treatment could ameliorate the high SLE disease activity as well as improvement of proteinuria in Japanese patients. This treatment would be safe and useful for the SLE patients having enough kidney function.

**SA-PO2252**

**Treatment of Class IV Lupus Nephritis with Rituximab & Mycophenolate Mofetil (MMF) with No Oral Steroids Is Effective and Safe** Marie B. Condon, Megan Griffith, H. Terence Cook, Jeremy B. Levy, Liz Lightstone, Tom Cairns. *Imperial College Kidney and Transplant Institute.*

**Purpose:** To assess whether treatment with Rituximab & MMF without oral steroids is effective in severe (class IV) lupus nephritis.

**Methods:** Patients presenting with biopsy-proven lupus nephritis ISN class IV were treated with 2 doses of Rituximab (1g) + methyl prednisolone (500mg) 2 wks apart, & maintenance MMF (to MPA trough levels 1.2-2.4mg/l). They received NO oral steroids. Pts with cerebritis, requiring dialysis, and those already on oral steroids were excluded.

Complete remission (CR) was defined as stable creatinine, normal albumin and urine PCR <50mg/mmol OR histological resolution on repeat biopsy (= no active lesions on LM & no new deposits on EM).

Partial remission (PR) as stable creatinine, albumin 30g/l, nephrotic to non nephrotic proteinuria OR >50% fall of urine PCR if baseline non-nephrotic

**Results:**

21 patients (5 male, mean age 35+/-13.8 yrs) were treated with mean follow up of 35+/-13.8 months. Mean albumin was 22+/-6g/L, mean creatinine was 129+/-52umol/L.

16/21 (76%) have achieved CR, (15 clinical, 1 histological). Mean time to CR 11.8+/-9.3 months. A further 2 (9.5%) are in PR, mean time to PR 6+/-4.24 months, 1 of whom has received further rituximab, the other is poorly compliant with treatment.

3 patients (14.2%) have not achieved remission, 2 have been switched to cyclophosphamide, 1 has so far achieved remission.

1 patient relapsed at 36 months.

The treatment was generally well tolerated. 4 patients required hospital admission: 1 coronary stents, 1 cellulitis, 1 patient 3 admissions (2 with peripheral oedema and 1 with diarrhea). One had multiple admissions with peripheral vascular disease and died post surgery. In 1 patient (in CR) MMF was changed to tacrolimus due to leucopenia.

**Conclusions:** Exclusion of steroids from maintenance therapy by using rituximab and methylprednisolone induction followed by MMF alone in class IV lupus nephritis, leads to high rates of sustained complete remission and low toxicity.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2253

**Enteric-Coated Mycophenolate Sodium (EC-MPS) for the Treatment of Lupus Nephritis – MyLupus Study** David R. W. Jayne, Margit Zeher. *For MyLupus Study Group.*

**Purpose of the study**: The MyLupus study was designed to compare the non-inferior efficacy and safety of EC-MPS using two different oral prednisolone regimens (standard SD or reduced dose RD) for the induction of remission of a lupus nephritis (LN) flare.

**Methods**: A 24-week (W) exploratory, multi-center, open-label study was conducted in patients with a LN flare (ISN/RPS Class III or IV documented by renal biopsy within 24 months of study entry). All patients received EC-MPS 1440 mg/day for the first 2W, followed by 2160 mg/day for the remaining 22W, and methylprednisolone iv. (0.5 g/day) for the first 3 days. Patients were randomized to either SD or RD (starting dose of 1.0 mg/kg/day and 0.5 mg/kg/day for 2W, respectively, followed by pre-specified dose reduction). Primary end-point was the proportion of patients with complete response (urine protein/creatinine [P/C] ratio <0.5, urine sediment normalized, and serum creatinine <10% normal value) of LN after 24W. Partial response was defined as urine P/C ratio reduced by at least 50% from baseline and serum creatinine stable (<10% of baseline value) or improved.

**Results**: 81 patients were enrolled, 42 in SD and 39 in RD group. Baseline characteristics were comparable between groups. After 24 W, a similar proportion of patients achieved complete response in both groups (19% SD vs. 18% RD), although non-inferiority was not demonstrated. A higher proportion of patients achieved partial response in SD (48% SD vs. 33% RD). Index scores decreased in both groups from 4 to 24W (British Isles Lupus Assessment Group [BILAG] index: mean change from baseline -8.6 SD vs. -9.4 RD, Systemic Lupus Erythematosus Disease Activity Index [SLEDAI]: -10.4 SD vs. -9.4 RD). There was greater improvement in glomerular filtration rate (mL/min/1.73m$^2$) in RD (mean change from baseline 9.0 SD vs. 15.2 RD). There were 2 deaths, both in SD group. The incidence of serious adverse events was 16.7% (SD) vs. 10.3% (RD).

**Conclusions**: This exploratory study suggests that EC-MPS in combination with steroids is a viable therapy for LN. The overall clinical results indicate that RD of CS may offer benefits in terms of tolerability compared to SD of CS while maintaining efficacy.

## SA-PO2254

**Corticosteroid Therapy beyond 6 Months Does Not Decrease Relapses in ANCA Disease** JulieAnne G. McGregor, Susan L. Hogan, Yichun Hu, Caroline E. Jennette, Ronald J. Falk, Patrick H. Nachman. *Division of Nephrology and Hypertension, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Purpose: To assess the impact on patient outcomes and complications of corticosteroid therapy beyond 6 months (mo.) in an inception cohort of patients with biopsy-proven with Antineutrophil Cytoplasmic Antibody (ANCA) disease.

Methods: 147 patients were selected if diagnosed between 1/2000- 1/2009 and received induction therapy with corticosteroids and cyclophosphamide. Patients who presented with end stage kidney disease (ESKD), died within 6 mo., or had no response to treatment were excluded.

Patients were divided into 3 groups based on whether they were on 0, 5 or >5mg/day of prednisone at 6 mo. after therapy induction. Groups were analyzed for disease relapse, death, ESKD, new onset diabetes mellitus (DM) and infection. Comparisons between groups were done by Kruska-Wallis, Wilcoxon or Fisher Exact tests. Time to relapse was evaluated by Kaplan-Meier analysis with a log-rank test to compare groups.

Results: There were no statistically significant differences between the 3 groups in age, sex, ANCA specificity, disease category, frequency of risk factors of relapse, serum creatinine, length of therapy with cyclophosphamide (mean 8.7 mo.±5.9) or any maintenance immunosuppressant (mean 15.3 ± 23.1 mo.). The mean dose of prednisone in the >5mg group was 21.8±15.7mg/d.

Outcomes in ANCA Vasculitis by Corticosteroid Treatment Groups

| Steroid Dose at 6 months | 0 mg.(n= 69) | 5 mg/d.(n=17) | >5mg/d.(n=61) | P values |
|---|---|---|---|---|
| Relapse | 31(44.9%) | 4(23.5%) | 26(42.6%) | 0.269 |
| DM | 13(18.8%) | 6(35.3%) | 19(31.2%) | 0.165 |
| DM | 13(18.8%) | 25(32.1%)* | | 0.089 |
| Absolute Number of Infections | 2.20±1.49 | 1.94±1.09 | 2.43±1.55 | 0.533 |

*Prednisone 5mg. and >5mg. groups combined

Relapse-free survival, ESKD and death were not different between the 3 groups. The odds ratio of DM in patients receiving corticosteroids of any dose beyond 6 mo. was 2.03 (95%CI 0.94-4.38).

Conclusion: Corticosteroid therapy beyond 6 mo. does not improve outcomes or the frequency of relapse in patients with ANCA disease but is associated with a trend towards an increased risk of DM.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2255

**Microparticle Tissue Factor Activity Is Increased in PR3-ANCA Vasculitis Patients with Active Disease** Madelyn Burkart,[1] Sam L. Glover,[2] JulieAnne G. McGregor,[1] Elisabeth Berg,[1] Yichun Hu,[1] Susan L. Hogan,[1] Raj Kasthuri,[2] Ronald J. Falk,[1] Donna O. Bunch.[1] *[1]UNC Kidney Center, University of North Carolina; [2]McAllister Heart Institute, University of North Carolina, Chapel Hill, NC.*

Microparticles are small, membrane-bound vesicles shed into circulation in response to cellular activation or apoptosis. Microparticles can participate in many biological processes including inflammation and vascular reactivity and are known to contain tissue factor activity and participate in thrombosis. We studied the role of microparticles as a biomarker of disease activity in patients with ANtineutrophil Cytoplasmic Autoantibodies (ANCA) disease. Platelet free plasma was obtained from whole blood of 25 healthy controls and 84 ANCA disease patients (36 MPO and 48 PR3) during active disease (BVAS >1) and remission (BVAS ≤1). Microparticles were isolated and analyzed by flow cytometry according to methods established in 2009 by the Vascular Biology Scientific Subcommittee of the International Society on Thrombosis and Haemostasis. To capture microparticles not identified by Annexin V only, staining for HLA CI, a protein on all nucleated cells, was done. Cell of origin was determined with antibodies to endothelial, platelet, neutrophil, and red blood cell antigens. Trucount tube beads were utilized to enumerate microparticles. In our patient cohort, we detected no differences in the number of total, endothelial-derived, platelet-derived, red blood cell-derived, or neutrophil-derived microparticles of any subclass between patients classified as active or in remission. However, microparticles from PR3-ANCA patients with active disease had statistically higher tissue factor activity (0.097 ± 0.113 pg/ml) compared to healthy controls (0.008 ± 0.018 pg/ml; P=0.001). Thrombotic and bleeding events are common in PR3-ANCA patients with active disease. It will be important to correlate tissue factor activity temporally with clotting and bleeding events and the presence of anti-plasminogen antibodies. Microparticle tissue factor activity is a new marker of disease activity and may be more useful than microparticle number as a measure of disease activity in patients with ANCA vasculitis.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2256

**Protocolised Versus Non-Protocolised Rituximab Treatment for Refractory ANCA-Associated Vasculitis** Rachel B. Jones, Rona M. Smith, Mary-Jane C. Guerry, Fausta Catapano, Afzal N. Chaudhry, David R. W. Jayne. *Vasculitis and Lupus Clinic, Addenbrookes Hospital, Cambridge, United Kingdom.*

Rituximab is effective new therapy for refractory ANCA-associated vasculitis (AAV). However, the majority of patients relapse after rituximab, needing further treatment courses. Relapses occur from six months onwards and are associated with organ damage and high corticosteroid exposure. Relapse avoidance is desirable; however biomarkers that accurately predict relapse are not available.

We performed a single centre cohort study comparing six monthly, protocolised rituximab re-treatment and non-protocolised rituximab re-treatment according to clinical need for refractory AAV.

72 patients received a protocolised rituximab regimen; 1g x2 followed by 1g x1 every 6 months for 2 years (5g total) with early immunosuppression and corticosteroid withdrawal. 34 received non-protcolised rituximab; either 1g x2 or 375mg/m$^2$ x4 only repeated if relapse occurred.

Overall 75% patients had Wegener's granulomatosis. At first rituximab median disease duration was 55 months; prior cyclophosphamide exposure was 14g. Rituximab indication was relapsing disease in 82% of protocol and 83% of non-protocol patients; the remainder had grumbling disease whilst receiving continuous high dose corticosteroids or immunosuppression.

Median follow-up was 31 (4-56) months, protocol patients vs 22 (6-84) months, non-protocol patients. Response to rituximab occurred in 70/72 (97%) protocol patients (93% full remission, 4% partial), and 33/34 (97%) non-protocol patients (82% full remission, 15% partial). In protocol patients only 4/72 (6%) were still receiving immunosuppression at 6 months and by 24 months 26% had withdrawn from prednisolone (4.75mg/day median). At 2 years relapse had occurred in 16/72 (22%) protocol patients vs 24/34 (71%) non-protocol patients and by the end of follow-up 21/72 (29%) protocol patients, 26/34 (76%) non-protocol patients (p<0.01). Serious infections occurred in 10/72 (31%) protocol patients and 6/34 (26%) non-protocol patients.

Six monthly protocolised rituximab re-treatment is effective for relapse prevention, allows immunosuppression withdrawal and appears safe in refractory AAV.

## SA-PO2257

**Renal Survival in PR-3 ANCA and MPO-ANCA Associated Systemic Vasculitis during Long-Term Follow Up** Anoek A. E. de Joode, Johannes S. Sanders, Coen A. Stegeman. *Nephrology, UMCG, Groningen, Netherlands.*

**Purpose**: We evaluated renal survival in a large cohort of patients with PR3- ANCA- and MPO-ANCA-associated vascilitis (AAV).

**Methods**: All patients diagnosed with AAV in our hospital from january 1990 until december 2009 were evaluated from first contact until last visit or death. Primary end-point was ESRD defined as in need for renal replacement therapy (RRT), renal transplantation or death due to renal failure.

**Results**: We evaluated 235 patients: 178 were PR3-ANCA and 57 MPO-ANCA positive. They were all treated with cyclophosphamide and prednisolone, from 1996 onwards patients were switched to azathioprine after induction of remission. Mean follow-up was

7,5 years in the PR3- and 7 years in the MPO-group. Renal involvement at diagnosis was present in 137 of 178 (77%) patients in the PR3-group and in 48 of 57 (84%) patients in the MPO-group.In the PR3-group 25 (14%) patients needed RRT at diagnosis. Of these 25 patients, 5 (20%) died within 3 months and 5 (20%) had to continue RRT. Renal function recovered within three months in 15 (60%) patients, in 4 of these 15 RRT had to be restarted later. Additionally 8 other patients developed ESRD, all but one related to renal relapses of disease activity. Overall, 17 (10%) patients with PR3-AAV developed ESRD during long-term follow up. At 5 and 10 years after diagnosis, 91% and 89% of surviving patients were independent of RRT. In the MPO-group, 16 (28%) patients needed RRT at diagnosis (p=0,043 vs PR3-group). Of these 16 patients, 6 (38%) died, and 5 (31%) had to continue RRT. Renal function recovered in 5 (31%) patients (p=0.11 vs PR-3 group), in 1 of these RRT had to be restarted later. Another 2 patients developed ESRD, without relation to renal relapse. Overall 8 (14%) patients with MPO-AAV reached ESRD during long-term follow-up. At 5 and 10 years after diagnosis 86% of surviving patients were independent of RRT.

**Conclusion**: In this single center retrospective study we found that patients with MPO-AAV were significantly more often in need of RRT than patients with PR3-AAV at diagnosis and were less likely to recover renal function. Patients who did not need RRT at diagnosis did rarely develop ESRD during follow-up.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2258

**Alveolar Haemorrhage in ANCA Associated Vasculitis: A Retrospective Analysis from the European Vasculitis Study Group** Alina L. Casian,[1] Annelies Evaline Berden,[2] David R. W. Jayne.[1] *[1]Addenbrooke's Hospital; [2]Leiden Medical Centre.*

Alveolar haemorrhage (AH) is a pauci-immune capillaritis and potential life-threatening feature of ANCA associated vasculitis (AAV): previous studies report 50% mortality in severe presentations.

**Aims:** To characterise the prevalence and outcomes (end-stage renal failure and mortality) of AH further. We undertook a retrospective analysis in 387 patients with AAV from 3 RCTs of the European Vasculitis Study Group: NORAM (non-renal vasculitis), CYCAZAREM (creatinine < 500 micromol/l) and MEPEX (creatinine >500 micromol/l).

**Methods:** Data was retrieved from the EUVAS database and analysed by SPSS and Access. AH was defined as haemoptysis and/or pulmonary infiltrates scored by the Birmingham Vasculitis Activity Score. No patients with severe, ventilator dependent AH were included in these trials.

Re**sults:** 93/387 (24%) AAV patients had AH at presentation. Haemoptysis was present in 16%, whilst the remainder had isolated pulmonary infiltrates. AH developed subsequently in a further 4%. Renal involvement accompanied 78/93 (84%) of those presenting with AH and 160/294 (54%) of those without AH (p=0.0001). Mean presenting creatinine in those with and without AH was 385 micromol/l and 387 micromol/l respectively (p>0.005). 19/93 (20%) patients presenting with AH developed ESRF vs 49/294 (17%) who did not present with AH (p=0.44).

Of 161 with PR3-ANCA, 52 (32%) had AH vs 41/131 with MPO-ANCA and AH (31%) (p=0.9); 4/22 (18%) ANCA negative patients had AH (p=0.6).

Mortality at 1 year was 15% in the AH group vs 11% in patients without AH (p=0.27). 12 of the 24 (50%) MEPEX AH patients who died were treated with plasma exchange and 12 (50%) with methylprednisolone. Causes of death were sepsis in 53% and respiratory failure in 27%.

**Conclusions:** Alveolar haemorrhage was present in 24% of AAV patients at presentation and developed subsequently in a further 4%. The frequency of AH was not influenced by ANCA subtype. AH was associated with the presence but not the severity of renal vasculitis, consistent with the 2 manifestations having a common pathogenesis. AH was not associated with a higher mortality at 1 year, which may reflect the exclusion of severe AH.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2259

**Low Cyclophosphamide (CYC) Dose and Plasma Exchange (PLEX) a Less Toxic Induction Treatment of ANCA Associated Vasculitis (AAV)** Wladimir M. Szpirt, Elizabeth Krarup, Martin Egfjord. *Nephrology P, Rigshospitalet, Copenhagen, Denmark.*

The AAV treatment related adverse events are the greatest threat influencing the induction treatment outcome more than active vasculitis. The use of PLEX in AAV is not commonly accepted in patients (pts.) with plasma creatinine below 500 µmol/L (<500) despite growing evidence of the involvement of ANCA in the pathogenesis of vasculitis. We combined low dose of CYC and PLEX in order to minimize the infection/sepsis rate mostly due to over-immunosuppression. A prospective cohort study of all AAV pts. referred to our centre between 2000 and 2010 was performed. All pts. had AAV based on positive ANCA titre and a compatible clinical syndrome, whereas PLEX use was determined on active lesions on renal biopsy and ANCA titres. Standard therapy for all pts. consisted of prednisolone 1 mg/kg/day and a low dose of oral CYC (100 mg/day in pts. <65 years and 50 mg/day in pts. >65). All pts. received PCP prophylaxis. Azathioprine or Mycophenolate Mofetil was given for maintenance of remission after 4 months. 128 pts. were admitted and 116 followed for a mean of 3 years (range 0.5-9,0; 391 patient years). 58% were male, 76% were PR3-ANCA and 24% were MPO-ANCA positive. 44% had an initial creatinine >500. 39% were aged >65 and 61% <65 years. 103 pts. received PLEX (mean 7 (range 5-11)). Only 3 pts (2,4%) died during CYC treatment 1 sepsis, 1 AMI, 1 lung haemorrhage, all on HD. Totally 9 pts. (7,0%) died initially within 12 months of active vasculitis (5 pts. from >500) and 9 more pts. died within 7 years without signs of active vasculitis. (Total mortality of 14%). 17 pts (13%) had infection within the first 4 months, 8 (47%) being leucopenic; 5>500. UTI (27%), pneumonia (18%) predo-minated, whereas 1 died of septicaemia - 2 (9%). 36 relapses occurred during the 9 years of follow up, 12 during the first year after induction, 14 (11%) developed ESRD. Pts. aged <65, <500 had significantly better dialysis free survival. Thus, the use of induction therapy with low dose CYC and PLEX resulted in a high remission rate with good preservation of renal function and low rate of complications providing evidence of possible sparing effect of PLEX.

Disclosure of Financial Relationships: nothing to disclose

**Severe Lymphopenia Is Frequent and Predictive of Infectious Complications in ANCA Vasculitis** Remi Goupil,[1] Annie-Claire Nadeau-Fredette,[1] Stephan Troyanov,[1] Soumeya Brachemi.[2] *[1]Medicine, Hôpital du Sacré-Coeur de Montréal, Montréal, QC, Canada; [2]Medicine, CHUM, Montréal, QC, Canada.*

Infections can be severe and life-threatening consequences of immunosuppressive therapy of ANCA-associated vasculitis (AAV). Few tools help clinicians manage the intensity of treatment to minimize these events. We sought to determine risk factors of infectious complications.

We identified AAV vasculitis patients by reviewing all ELISA ANCA measurements since February 2004. Demographics, clinical and laboratory assessment at diagnosis and during follow-up, treatment and infectious complications were collected from medical records.

Of the 39 AAV patients identified, 36 received immunosuppressive therapy. The mean age was 56 ± 15 years, 44% were females. Twenty-one and 15 patients were c and p-ANCA positive, respectively, 3 displaying both antibodies. The Birmingham vasculitis activity score at onset (BVAS) was 7.1 ± 3.1 with an initial eGFR of 35 ± 31 mL/min/1.73m2. A third required dialysis. All patients received corticosteroids (24 with pulse methylprednisolone), 29 cyclophosphamide, 2 methotrexate and a third plasmapheresis. The median follow-up duration was 37 months. During that time, 25% (9) of patients died, 53% (19) had an infectious complication of which 11 were hospitalized and 5 died as a consequence. Sixteen percent experienced neutropenia, 80.6% lymphopenia (< 1,0x10(9)/L) and 36% severe lymphopenia (<0.3x10(9)/L). Predictors of infections were the need for dialysis, lymphopenia and severe lymphopenia. Predictors of infections leading to death correlated with the severity of the disease and included the need for dialysis, BVAS score at onset, pulmonary haemorrhage and use of plasmapheresis. Severe lymphopenia was also associated with death from infectious complications with an odds ratio of 9.8 (95% CI 1.0-99.9, p=0.05). Neutropenia was not predictive of this outcome.

In conclusion, lymphopenia, particularly severe lymphopenia, is strongly associated with infectious complications during the treatment of AAV. Monitoring therapy to minimize lymphopenia may reduce infectious side effects of these potent therapies.

### SA-PO2261

**A Multi-Centre Survey of Plasma Exchange Practices in ANCA Associated Vasculitis** Alina L. Casian,[1] Michael W. Walsh,[2] David R. W. Jayne.[1] *[1]Vasculitis, Addenbrooke's Hospital, Cambridge, United Kingdom; [2]Epidemiology and Biostatistics, McMaster University, Hamilton, Canada; [3]Dr.Walsh & Dr.Casian are joint first authors, .*

Background: The optimal prescription of plasma exchange (PLEX) for the treatment of ANCA associated vasculitis (AAV) is uncertain. We performed a multi-centre, international survey to assess practice patterns in the use of plasma exchange for AAV.

Methods: We assessed the provision of PLEX in 48 hospitals from Europe, North America, and Australia/New Zealand using an internet based survey. Centres were selected by contacting locally identified experts in AAV and PLEX. The survey assessed practice patterns in terms of PLEX modality, frequency, and replacement fluid use. We conducted a survey of indications for use of PLEX in a subgroup of 34 centres.

Results: All 34 centres surveyed for PLEX indications reported using PLEX routinely for AAV with nephritis: 6 centres (18%) would consider PLEX in patients with creatinine >200 micromol/l, 15 (44%) would PLEX if creatinine >250 micromol/l and 13 (38%) centres use PLEX for rapidly rising creatinine. 26/34 (76%) reported using PLEX routinely for alveolar hemorrhage.

25 of 48 (52%) centres used only centrifugation, 10 (21%) used used filtration only, 10 (21%) used a combination and 3(6%) did not comment. 5 (10%) of centres aim to provide <7 PLEX sessions, 19 (40%) 7 sessions, and 8 (17%) >7 sessions for AAV. 11 (23%) of centres modified the number of PLEX treatments according to disease activity but no centres modified PLEX according to ANCA levels; the remaining 5 (10%) centres did not comment. The volume of exchanges was fixed in 27 of 48 (56%) centres (most commonly 1 plasma volume) while 15 of 48 (31%) used body weight to guide volume. The commonest replacement fluid was albumin alone (36 centres; 75%) in patients not at risk of bleeding. In patients at risk of bleeding, 56% of centres used a combination of plasma and albumin, while in patients with active bleeding 48% of centres used plasma only.

Conclusions: The way in which patients with AAV receive PLEX varies significantly between centres. Further research is required to determine whether the method of PLEX prescription influences its efficacy.

**SA-PO2262**

**PEXIVAS: Design of a Randomised Controlled Trial of Plasma Exchange and Glucocorticoid Dosing in Severe ANCA Associated Vasculitis** Alina L. Casian,[1] Michael W. Walsh,[2] Peter A. Merkel,[3] David R. W. Jayne.[1] *[1]Vasculitis, Addenbrooke's; [2]Biostatistics, McMaster University; [3]Vasculitis, Boston University.*

The outcomes of ANCA associated vasculitis(AAV) are frequently poor for patients presenting with severe renal disease or lung hemorrhage and drug-related toxicity contributes to mortality and morbidity. Plasma exchange(PLEX) removes potentially pathogenic ANCA and was shown by a meta-analysis of all PLEX trials in vasculitis to improve renal recovery in severe renal vasculitis. However it is unclear whether this benefit is sustained and PLEX reduces mortality or is effective in lung hemorrhage. The expense and potential complications of PLEX demand stronger evidence before recommending its routine use. Current glucocorticoid(GC) dosing contributes to adverse events, especially in those with uremia or respiratory failure. Recent optimisation of other immunosuppressives in AAV has re-focused attention on whether GC can be reduced without compromising efficacy.

**Primary Objectives: 1)** The effect of PLEX (in addition to immunosuppressives and GC) on death and end-stage renal disease (ESRD)**, 2)** To determine whether a reduced GC regimen is non-inferior to standard GC with respect to death and ESRD, and superior with respect to adverse events (especially infections)**.**

**Secondary Objectives:** the effects of the 2 interventions on disease activity, quality of life, cost-effectiveness, disease-related damage, vasculitis biomarkers.

**Design:** 500 Patients with new or relapsing severe AAV (recent eGFR< 50 mls/min or/ and pulmonary haemorrhage), >=15 years of age, from 97 centres in 15 countries will be recruited over 5 years and followed-up for a maximum of 7, minimum 2 years. PEXIVAS is an open RCT; randomisation is centralized into 4 groups with 125 in each: 1) PLEX + standard GC 2) PLEX+ reduced GC 3) no PLEX + standard GC 4) no PLEX + reduced GC. All patients will receive induction therapy with cyclophosphamide or rituximab and maintenance azathioprine.

**Conclusions:** PEXIVAS aims to clarify the role of PLEX in severe AAV and whether GC dosing can be safely reduced. The multi-national collaboration will promote best practice in vasculitis management

**SA-PO2263**

**Outcomes of ANCA Associated Vasculitis (AAV) in Multidisciplinary Vasculitis Clinic & General Nephrology Clinics in North-West England** Nina Brown,[1] Ajay Prabhakar Dhaygude,[2] Donal J. O'Donoghue,[3] Philip A. Kalra,[3] Michael Venning,[1] Laurence Richard Solomon,[2] Paul Brenchley.[1] *[1]MRI; [2]Preston Hospital; [3]Hope Hospital.*

**Introduction and Aims:** The impact of specialist versus generalist care on outcomes of patients with AAV is uncertain. Evidence suggests improved outcomes for patients treated by a specialist. EULAR recommendations state "*patients with primary small and medium vessel vasculitis be managed in collaboration with, or at centres of expertise"*. In Northwest England AAV patient care is in general nephrology clinics (Neph OP, centres A, B) or in a dedicated multidisciplinary vasculitis clinic (Vasc OP, centre C) with input from nephrologist, rheumatologist, immunologist and neurologist. We compare outcomes (infection and relapse rates) in these clinics.

**Methods:** A retrospective study of immunosuppression, rate of relapse and infections for 133 patients attending vasculitis clinic in the year 2007- 2008 at centres A, B and C (infection defined as requiring hospital admission/IV antibiotics or herpes zoster; relapse defined as disease activity in a patient in remission requiring increased immunosuppression). We recruited >95% patients from centres A and C but 30% patients from centre B -missing AAV cohorts from some centre B-based Neph OPs

**Results:** (Cyp= cyclophosphamide).

| Centre | Pt nos. | F/U pt months | Mean cum Cyp dose (grams) | Median cum Cyp dose (grams) | Relapse/ 100 pt months | Infections/ 100 pt months | Malignancies |
|---|---|---|---|---|---|---|---|
| A | 59 | 2891 | 5.45 | 3.5 | 0.86 | 0.55 | 3 |
| B | 31 | 1581 | 6.6 | 4.0 | 1.01 | 0.44 | 0 |
| C | 43 | 3612 | 26.19 | 11.3 | 0.44 | 0.28 | 2 |

**Conclusions:** Patients treated in Vasc OP had higher cumulative dose of Cyp, lower relapse rates and fewer infective complications.

**Discussion:** Patients in Vasc OP had longer follow-up and higher median dose of Cyp, but a lower rate of adverse events in terms of infection rates and cancer. Despite lower ascertainment from the various Neph OP in Centre B, the outcome data are comparable to centre A. Within the limitations of retrospective study, we believe these are the first data to suggest better outcomes for patients attending Vasc OP compared with Neph OP.

**SA-PO2264**

**ANCA-Associated Glomerulonephritis in the Very Elderly** Andrew S. Bomback, Gerald B. Appel, Jai Radhakrishnan, Shayan Shirazian, Leal C. Herlitz, Michael B. Stokes, Vivette D. D'Agati, Glen S. Markowitz. *Columbia University College of Physicians & Surgeons.*

**BACKGROUND:** Antineutrophil cytoplasmic autoantibody (ANCA)-associated pauci-immune glomerulonephritis (GN) is the most common renal biopsy finding in very elderly patients biopsied for acute kidney injury, with a biopsy incidence of 33%. Appropriate treatment strategies in this age group currently are undefined because it is unclear whether the benefits of immunosuppression exceed the risks.

**METHODS:** This retrospective cohort study evaluated all cases of pauci-immune GN in individuals aged ≥ 80 years, diagnosed by kidney biopsy from 2001-2008. We obtained available patient data from time of diagnosis until death or last clinical encounter and used logistic regression and Cox proportional hazards models to evaluate outcomes of end stage renal disease (ESRD) and death.

**RESULTS:** Seventy-eight cases were identified, with a mean age of 83.3 years. p-ANCA and c-ANCA positivity were seen in 71.8% and 19.7% of patients, respectively. Follow-up data were available for 69 of 78 patients (88.5%), ranging from 1 week to 67 months. Patients treated with immunosuppression had a significantly lower incidence of ESRD 1 year after biopsy (36.2%) compared with untreated patients (72.7%; p=0.03). Only peak serum creatinine before biopsy and use of immunosuppressive therapy influenced progression to ESRD. Although differences in 1-year mortality rates between these groups were not statistically significant (46.9% vs. 63.6%; p=0.3), in multivariate models extending out to >2 years of follow-up, immunosuppressive therapy was associated with a lower risk for death (HR 0.33, 95% CI 0.11-0.97) and death or ESRD (HR 0.16, 95% CI 0.06-0.42). ROC curves suggested that this benefit could be most expected in patients presenting with a creatinine ≤4.5 mg/dl.

**CONCLUSION:** In very elderly patients with ANCA-associated pauci-immune GN, the benefit of immunosuppressive therapy is experienced early (within the first 6 months) in the form of reduced risk for ESRD and later (after 1 year) in the form of prolonged survival and, in particular, prolonged dialysis-free survival.

**Podocalyxin Positive Glomerular Epithelial Cells in the Urine Correlate with a Positive Outcome in Glomerular Diseases** Janina Müller-Deile, Philipp Kümpers, Hermann G. Haller, Mario Schiffer. *Nephrology, Hannover Medical School, Hannover, Germany.*

**Background:** Parietal epithelial cells (PECs) and podocytes are the two epithelial cell types in the glomerulus. In contrast to podocytes, PECs have the ability to proliferate lifelong and they have the ability to transdifferentiate into other cell types. We previously published that excretion of podocalyxin-positive PECs in the urine correlates with disease activity in different glomerular diseases. Here we investigated whether urinary excretion of podocalyxin-positive cells might be a prognostic marker for proteinuria development and kidney function. **Methods:** We analyzed the excretion of podocalyxin-positive cells in the urine of patients with FSGS, MGN and MPGN. Follow up serum creatinine and total urine protein of these patients was analyzed ~ 3 years after urinary cell count. Differences in serum creatinine and urine protein between the two visits were expressed as delta-values. **Results:** FSGS- and MPGN-patients with excretion of podocalyxin-positive cells in the urine had a negative delta serum creatinine three years later (FSGS: ∅ -18µmol/l; MPGN: ∅ -18µmol/l). In contrast to that FSGS- and MPGN-patients without cell excretion showed a positive delta serum creatinine three years later (FSGS: ∅ +53µmol/l; MPGN: ∅ +63µmol/l). Interestingly in patients with MGN we detected a positive delta serum creatinine regardless of cell excretion. All patients with excretion of podocalyxin-positive cells in the urine had negative delta total urine protein three years later, reflecting a reduction in protein excretion between the two visits. FSGS and MPGN-patients showed a negative correlation between of podocalyxin-positive cells in the urine and delta serum creatinine. (Corr.-coefficient: FSGS: -0,4 ; MPGN:-0,5). Moreover all patient groups with podocalyxin-positive cells had lower delta total urine protein compared to patients with the same renal disease but no significant cell excretion. **Conclusion:** Our data indicate that patients excreting high amounts of podocalyxin-positive cells in their urine have a better outcome regarding kidney function compared to patients without excretion of podocalyxin-positive cells.

**SA-PO2266**

**Risk Factors for Hepatitis B Virus Associated Nephropathy** Jianfang Cai, Hang Li, Xuemei Li, Xue-Wang Li. *Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Science, Beijing, China.*

**Objective** To retrospectively evaluate the potential risk factors for hepatitis B virus associated nephropathy (HBV-AN) and its pathological types.

**Methods** 86 cases of HBV-AN and 160 controls with renal biopsy obtained during 2001 to 2009 were enrolled in this retrospective case-control study. HBV-AN was diagnosed as biopsy-proven glomerulonephropathy in chronic HBV carriers with other secondary glomerulonephropathy excluded and glomerular deposition of HBsAg or HBcAg. Chronic HBV carriers without glomerular deposition of HBsAg or HBcAg were recruited as controls. In pathology, HBV-AN was presented as membranous nephropathy (HBV-MN, 50cases), membranoproliferative glomerulonephrtitis (HBV-MPGN, 18 cases) and IgA nephropathy (HBV-IgAN, 18 cases). Upper limit of normal (ULN) of alanine amiotransferase (ALT) was defined as 19U/L in women and 30U/L in men. Step forward multivariate logistic regression was used.

**Results** In chronic HBV carriers, HBV-AN was associated with male (OR 1.85; 95% CI 0.96-3.56; p=0.065), liver cirrhosis(OR 2.59; 95% CI 0.92-7.28; p=0.072), HBV-DNA ≥$10^5$copies/µl (OR 2.17; 95% CI 1.10-4.28; p=0.025) and ALT ≥1.5*ULN (OR 1.91; 95% CI 1.07-3.42; p=0.030). When the patients with MN and MPGN, in whom glomerular HBeAg deposition is common, were excluded from the controls, the associations were strengthened and listed as follows, male (OR 2.78; 95% CI 1.16-4.49; p=0.017), liver cirrhosis(OR 4.23; 95% CI 1.20-14.95; p=0.025), HBV-DNA ≥$10^5$copies/µl (OR 2.74; 95% CI 1.14-5.55; p=0.005) and ALT ≥1.5*ULN (OR 2.14; 95% CI 1.14-4.03; p=0.018). In patients with

HBV-AN, compared with those with HBV-IgAN, HBV-MN was associated with male (OR 5.92; 95% CI 1.65-21.12; P=0.006), ALT ≥1.5*ULN (OR 3.18; 95% CI 0.90-11.25; P=0.073) and HBV-DNA ≥$10^5$copies/μl (OR 4.38; 95% CI 1.19-16.10; P=0.026), while HBV-MPGN was associated with male (OR 7.12; 95% CI 1.16-43.80; P=0.034) and HBV DNA ≥$10^5$ copies/μl (OR 10.71; 95% CI 1.09-105.50; P=0.042).

**Conclusions** In chronic HBV carriers, Male, liver cirrhosis, HBV-DNA ≥$10^5$ copies/μl and elevated ALTcopies/μl are associated with HBV-AN. In patients with HBV-AN, male and HBV-DNA ≥$10^5$ copies/μl are related with HBV-MN and HBV-MPGN.

## SA-PO2267

**Both Obesity and Low Glomerular Number in Biopsy Are Independent Risk Factors for the Development of Glomerular Hypertrophy** Nobuo Tsuboi, Yasunori Utsunomiya, Tetsuya Kawamura, Tatsuo Hosoya. *Division of Kidney and Hypertension, The Jikei University School of Medicine, Tokyo, Japan.*

Studies have suggested that glomerular hypertrophy represents one of the structural components of glomerular hyperfiltration, which is an established risk factor for the development of glomerulosclerosis and the loss of renal function. We have recently reported that a low glomerular density (GD, number of non-sclerotic glomeruli per renal cortical area) in renal biopsy is associated with an increased glomerular volume (Gv) and also a progression of IgA nephropathy (IgAN) (NDT2009, CJASN2010). To date, however, it has not been fully elucidated regarding by which factors the $G_v$ is defined, because clinically and/or histopathologically relevant factors associated with $G_v$ are multi-factorial and are often overlapping within each individual. To examine the essential determinants of $G_v$, the present study analyzed the relationship between the clinicopathological factors and the $G_v$ in biopsy specimens. We included proteinuric patients (n=64) without a histological diagnosis of primary or secondary immunological nephropathies, diabetic nephropathy, nephrotic syndrome and acute kidney injury. The Gv in biopsy specimens was calculated by measuring the glomerular area with a computed imaging analyzer. In univariate analyses, the $G_v$ correlated with mean arterial pressure (MAP, r=0.31) and body mass index (BMI, r=0.46), and inversely correlated with GD (r=-0.46). On the other hand, the $G_v$ did not show any correlation with age, eGFR or the degree of global glomerulosclerosis. In a multivariate analysis, only BMI (t=3.44) and GD (t=-3.14) were still independent factors that associated with Gv. Furthermore, almost the same results were obtained by analyzing a patient cohort of IgAN (n=124).

Conclusion: Our results suggest that both obesity and low GD independently contribute to the development of glomerular hypertrophy. Also, these results indicate that a mismatch between obesity-related increased metabolic demands and reduced nephron number, either acquired or later in life, may be an important determinant for the development of glomerular hypertrophy.

## SA-PO2268

**Renal Involvement in Monoclonal Gammopathies** Ana Carina Ferreira, Fernanda Carvalho, Dulce Carvalho, Maria Joao Galvao, Helena Viana, Manuel A. Ferreira, Fernando Nolasco. *Nephrology, H Curry Cabral, Lx, Portugal.*

Monoclonal gammopathies (MG) are frequently associated with organ dysfunction. The aim of this retrospective study was to evaluate the histological findings of kidney biopsies (KB) and clinical data in patients (pts) with MG, with or without multiple myeloma (MM).

In the last 30 years, 181 KB were performed: 54.7% females, 95.8% caucasian, mean age 64.5±10 years. At the time of the KB, MG was known in 49%, and a history of MM was present in 24.5%. The MG were: IgG in 17 pts, IgA in 8, IgM in 3, IgD in 2, λ in 60%, k in 30%.

KB was performed for nephrotic syndrome (35.4%), acute kidney injury (22.7)%, rapidly progressive renal failure (15.5%), chronic kidney disease (9.9)%, sub nephrotic proteinuria (8.8%), nephritic syndrome (2.8%), and hematoproteinuria (1.1%).

The predominant lesions were AL amyloidosis (40.3%), myeloma kidney (38.1%), and light chain deposition disease (LCDD - 11%). Other histological features found: heavy chain deposition disease, chronic interstitial nephrities, IgA nephropathy, acute tubular necrosis, segmental and focal glomeruloesclerosis, chronic glomerulopathy, crescentic glomerulonephrities, AA amyloidosis, membranoproliferative glomerulonephritis, post infectious glomerulopathy, minimal change disease, diabetic nephropathy, malignant hypertension.

Clinical findings

| | AL amyloidosis (n=73) | Myeloma Kidney (n=69) | LCDD (n=20) |
|---|---|---|---|
| Scr (mg/dl) | 1.9±1.5 | 6.5±3.5 | 5.8±6.1 |
| Proteinuria (g/day) | 7.3±5.8 | 2.4±4.4 | 5.2±3.2 |
| Haemodialysis (%) | 6.3 | 90 | 56 |
| Known MM (%) | 12.3 | 39 | 25 |
| Known MG (%) | 27.4 | 62.3 | 40 |
| Presence of Myeloma kidney (%) | 5.5 | 100 | 50 |
| Main light chain (%) | λ in 79.5 | No predominance | No predominance |

In conclusion, MG are associated with a variety of renal disorders, not all related to monoclonal chain. The majority of pts submitted to KB didn't have MG previously identified and the majority of pts with myeloma kidney didn't have previous MM diagnosis. MG related renal disorders may be coupled. MGUS seems to be linked with renal disorders. Light chain is the most frequent chain related to these renal diseases. KB is the gold standard to establish diagnosis and ascertain therapeutic in pts with MG and renal involvement.

## SA-PO2269

**HIV-Associated Nephropathy in the Twenty First Century: Presentation, Outcome and Prognosis Factors** Naïke Bigé,[1] Fanny Lanternier,[2] Prochore Kamgang,[3] Eric Daugas,[4] Kaoutar Jidar,[5] Marie Noelle Peraldi,[6] Olivier Lortholary,[2] Laure-Helene Noel,[7] Guillaume Bollee.[1] *[1]Nephrology, Necker Hospital, APHP, Paris, France; [2]Infectious Diseases, Necker Hospital, APHP, Paris, France; [3]Nephrology, La Pitie Hospital, APHP, Paris, France; [4]Nephrology, Bichat Hospital, APHP, Paris, France; [5]Nephrology, Saint Louis Hospital, APHP, Paris, France; [6]Infectious Diseases, Bichat Hospital, APHP, Paris, France; [7]Pathology, Necker Hospital, APHP, Paris, France.*

HIV associated nephropathy (HIVAN) is the first cause of end stage renal disease (ESRD) among HIV-infected patients. The purpose of our study was to describe the presentation and outcome of HIVAN and to identify factors associated with progression to ESRD in the era of highly active antiretroviral therapy.

**Methods:**

We retrospectively studied 57 patients with biopsy-proven HIVAN diagnosed between 2000 and 2009 in four teaching hospitals in Paris, France. Clinical features at diagnosis and over follow-up were analyzed.

**Results:**

African ancestry (86.8%), severe renal dysfunction (median eGFR 20 ml/min/1.73m²), high grade proteinuria (median 4.1g/L), highly replicative HIV infection (median viral load 4.5 log) and severe immunodeficiency (median CD4 count 127/mm3) were typically present. Nevertheless, about quarter of patients displayed less typical presentation. Data on follow-up were available in 51 patients, of whom 30 (58.8%) 21 reached ESRD (median renal survival 40 months). Time from diagnosis of HIV infection to those of HIVAN <1 year ($p<0.05$) and percentage of sclerotic glomeruli at diagnosis ($p<0.05$) were significantly associated with progression to ESRD. Forty-eight patients (96.1%) received HAART during follow-up. Viral suppression was associated with better outcome, as the proportion of patients reaching ERSRD was 53.3% in those with undetectable viral load at last follow up compared to 90.5% in others ($p<0.05$).

**Conclusion**

HIVAN remains a severe complication of HIV infection, leading to ESRD in more than half of patients. Our study demonstrates the favourable impact of viral suppression on the course of HIVAN and highlights the crucial importance of early diagnosis.

## SA-PO2270

**Henoch-Schönlein Purpura in Adults: A Single Centre Review** Arvind Ponnusamy, Jyothi Kondlapudi, Krish S. Raman, Philip A. Kalra. *Renal, Salford Royal NHS Trust Foundation, Salford, United Kingdom.*

**Introduction:** Henoch-Schönlein purpura (HSP) is a leukocytoclastic small-vessel vasculitis involving small vessels with the deposition of immune complexes containing immunoglobulin A and neutrophil and eosinophilic infiltration. It is a multisystem characterized by the association of skin, joint, and gastrointestinal manifestations

**Method:** A retrospective analysis of 31 patients was undertaken between 2000 till 2008. We reviewed clinical symptoms, laboratory data, renal pathology and immunological data (Ig A/C3 ratio) at the time of presentation. These parameters were correlated to outcome (End Stage Renal Disease, Chronic Kidney disease Stage 3-5). We divided the group into progressers and non-progressers. Progressers were those with chronic kidney disease (Stage 3 – 5)at the last follow up.

**Results:** Average age onset [Mean±SD] was 50.6±22 and the median follow up period was 21 (range 1 to 91) months. Males represented 66% of the cohort. Clinical presentation included purpura (100%), proteinuria (>3gm) (26%) and acute kidney injury (AKI). One patient who presented with AKI requiring dialysis subsequently recovered their renal function. Baseline proteinuria was [Mean± SD] 3.1 gm±3.4 and the follow up proteinuria was 0.97±2.1. Mean creatinine at presentation was 1.3gm/dl±0.9. Crescents were found in 45% of patients that were biopsied. 8.6% died during the follow up. Mean Ig A levels were 3.98± 1.4. The mean Ig A /C3 ratio was 2.8±1.15.

| Mean | Progressers | Non-Progressers | p-value |
|---|---|---|---|
| Creatinine | 1.9+1.3mg/dl | 0.9+0.2mg/dl | 0.005* |
| Proteinuria | 3.8+ 4.9 | 2.7+ 2.9 | 0.270 |
| IgA C3 ratio | 2.76+1.3 | 2.8+1.2 | 0.82 |

**Baseline characteristics of HSP patients separated according to renal functional outcome category**

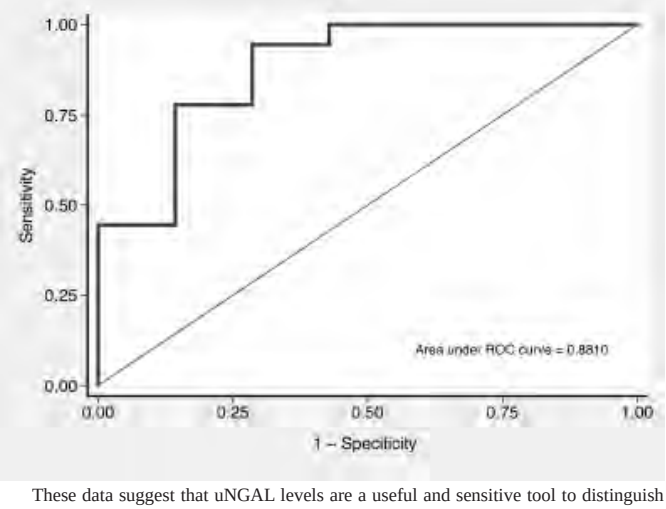
CONCLUSION: The presence of higher creatinine at presentation is an indicator of progression in HSP patients. Mean proteinuria in the progressers group was higher than the non-progresses although this was not statistically significant. None of our patients reached end stage renal disease however there was mortality rate of 8%. Mean IgA/C3 ratio does not appear to be a marker of progression.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2271**

**Urinary NGAL Is a Useful Clinical Biomarker of HIV-Associated Nephropathy** Sumit Mohan,[1] David Sola-Del Valle,[2] Jen-Tse Cheng,[1] Neal A. Paragas,[2] Meghan E. Sise,[2] Vivette D. D'Agati,[3] Jonathan M. Barasch.[2] *[1]Dept of Medicine, Columbia University & Harlem Hospital; [2]Dept of Medicine, Columbia University; [3]Dept of Pathology, Columbia University, New York, NY.*

HIV-associated nephropathy (HIVAN) is a progressive form of chronic kidney disease (CKD) characterized by collapsing focal segmental glomerulosclerosis and microcytic tubular dilatation that often leads to ESRD. Urinary Neutrophil Gelatinase Associated Lipocalin (uNGAL) is known to be expressed in AKI, but has also been observed in some progressive forms of CKD. We have previously reported upregulation of uNGAL and abundant NGAL mRNA expression in the microcystic tubules of HIVAN (JASN 20: 1687,2009). Here we examine the utility of uNGAL levels as a noninvasive biomarker for HIVAN by performing a comparative study of HIV-positive patients with diverse proteinuric glomerulopathies. Among 25 HIV-positive patients,, 18 (72%) had a diagnosis of HIVAN and 7 had other glomerulopathies (4 MPGN, 1 MGN, 1 amyloid and 1 malarial GN). The HIVAN and non-HIVAN glomerulopathy patients did not differ with respect to age (43.5 vs 44.8 yrs, p=0.6), ethnicity (100 vs 94% black, p=0.65), serum creatinine (sCr: 4.2 vs 2.8 mg/dL, p=0.11), estimated GFR (31.5 vs 46.6 mL/min, p=0.86), degree of proteinuria (9.4 vs 7.9 g/day, p=0.34) or prevalence of hypocomplementemia (6 vs 29%, p=0.18) while patients with HIVAN were less likely to have HCV coinfection (11 vs 57%, p=0.03). The HIVAN patients had higher uNGAL than the HIV patients with other glomerulopathies (387±338 vs. 94±101 µg/g uCr, p=0.02). A cutpoint of 121.5 µg uNGAL/g uCr demonstrated 94.4% sensitivity and 71.3% specificity for the diagnosis of HIVAN, with an area under the ROC curve of 0.88 (see figure).



These data suggest that uNGAL levels are a useful and sensitive tool to distinguish HIVAN from other proteinuric glomerulopathies in HIV-infected patients.

**A Prospective Study of HIV-Associated Albuminuria: Interim Report** Karmini Sampath,[1] Colleen Hadigan,[2] Leon L. Lai,[3] Jeffrey B. Kopp.[1] *[1]NIDDK, National Institutes of Health, Bethesda, MD; [2]NIAID, National Institutes of Health, Bethesda, MD; [3]Washington Hospital Center, Washington, DC.*

HIV-associated microalbuminuria may be due to incipient HIV-associated nephropathy, metabolic syndrome and medication-associated tubular dysfunction. We are carrying out a prospective study to define the period prevalence of HIV-associated albuminuria, enrolling 250 subjects at the NIH Clinical Center and Washington Hospital Center. Inclusion criteria include HIV infection and age >18 years. Exclusion criteria include diabetes, serum creatinine >1.4 g/dL, urine protein/creatinine (P/C) >0.5 g/g, pregnancy and recent cancer or active opportunistic infection. In the baseline phase, we measured random urine albumin/creatinine (A/C) ratio 3 times over 6-9 months. Microalbuminuria was defined as a geometric mean A/C ratio of 25-355 mg/g in females and 17-250 mg/g in males. Macroproteinuria was defined as P/C >0.5 g/g. Tubular proteinuria was defined as the presence of 2 of the following: glycosuria, phosphaturia, or uricosuria. In the extension phase involving subjects with microalbuminuria, urine A/C was measured at 12, 18, 24 and 36 months after entry. 142 subjects have completed the baseline phase. Mean age was 44 years, with a range of 23 to 67; racial background included 69 European descent (17 Hispanic), 68 African descent, and 5 Asian descent. 18/146 (9%) had microalbuminuria; no subject had incident macroproteinuria. Of those with microalbuminuria, 7 had glomerular albuminuria, 6 had tubular albuminuria (3 on tenofovir) and 5 were not categorized. Among those with microalbuminuria, the mean urine A/C was 47 mg/g and the range was 17 to 146 mg/g. Among the 128 subjects without microalbuminuria, 113 (89%) had all three A/C values below the microalbuminuria threshold. Among the 18 subjects with microalbuminuria, 12 (69%) had all 3 values within the microalbuminuria range; for the remaining 5 subjects, 4 had 1 normal value and 2 had 2 normal values. We conclude that 1) microalbuminuria is more common in HIV disease compared to the general population and 2) a single determination of albuminuria is reasonably predictive of albuminuria status.

**SA-PO2273**

**Urinary Angiotensinogen Originates from Kidney and Reflects Kidney Injury Regardless of the Extent of Proteinuria** Junseok Jeon, Ajin Cho, Hye Ryoun Jang, Jung Eun Lee, Wooseong Huh, Dae Joong Kim, Ha Young Oh, Yoon-Goo Kim. *Nephrology Division, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

The origin and clinical significance of urinary angiotensinogen (AGT) excretion are not known in patients with nephrotic syndrome. We studied the main source and clinical significance of urinary AGT in patients with various degrees of proteinuria.

A total of 119 GN and diabetic nephropathy (DN) patients [minimal change disease (MCD) in 22, focal segmental glomerulosclerosis (FSGS) in 18, membranous nephropathy (MN) in 30, IgA nephropathy (IgAN) in 27, DN in 22 patients] with proteinuria were included and 9 thin basement membrane disease (TBM) patients were used as control. Urinary and plasma AGT was measured using sandwich ELISA and intrarenal AGT expression was measured using western blotting.

The mean age of patients (M:F=72:47) was 44.5 years. Sixty patients had nephrotic syndrome. Urinary AGT excretion was markedly increased in GN and DN patients [Ln (urine AGT/Cr): mean±SD, 1.04±1.40 in TBM, 2.86±2.00 in MCD, 4.76±2.02 in FSGS, 4.74±1.35 in MN, 3.45±1.47 in IgAN, 5.08±1.79 in DN]. Although estimated urinary AGT/Cr (ug/g) calculated using fractional excretion of albumin was higher in nephrotic syndrome, it was less than 0.3% of measured urinary AGT/Cr in all patients (% of estimated among measured urinary AGT/Cr, mean±SE, 0.04±0.01% in non-nephrotic proteinuria, 0.20±0.07% in nephrotic proteinuria, P=0.04). Urinary AGT/Cr was positively correlated with AGT/β-actin in patients with non-nephrotic proteinuria ($P = 0.007$, $r = 0.385$). Urinary AGT excretion was positively correlated with proteinuria ($P < 0.001$, $r = 0.452$) and negatively correlated with eGFR ($P < 0.001$, $r = -0.438$) in all patients but there was no correlation between plasma AGT and proteinuria or eGFR.

Regardless of the extent of proteinuria, more than 99.5% of urinary AGT originates from the kidney, suggesting that urinary AGT consistently reflects the activity of intrarenal RAS. In GN and DN patients, urinary AGT excretion was enhanced and seems to reflect the degree of renal injury independent of systemic RAS.

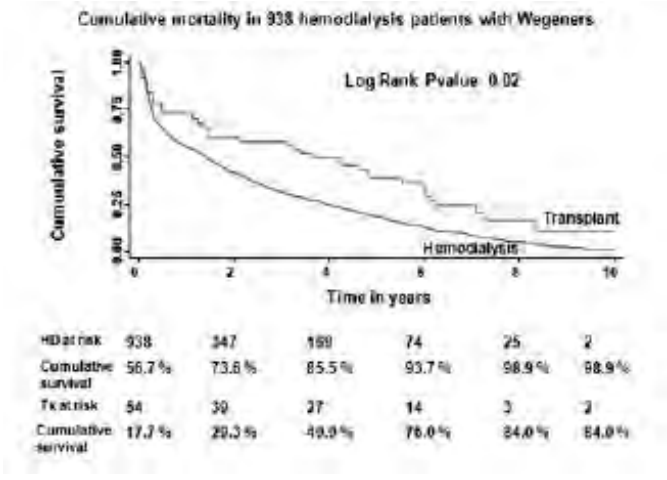
**Wegener's Granulomatosis: Survival on Dialysis and Transplant** Duvuru Geetha,[1] Pooja C. Oberai,[1] Rulan S. Parekh.[2] *[1]Johns Hopkins University; [2]Hospital for Sick Children.*

Renal morbidity is common in Wegener's granulomatosis (WG) and end stage renal disease occurs in up to 30% of patients with kidney transplantation as an important therapeutic option. Using data from the United States Renal Data System from 1996 to 2005, we performed a non concurrent cohort study of dialysis patients with WG compared to those with a primary glomerulonephritis (GN) and studied time to wait list for kidney transplant, and survival on dialysis, waitlisted and post transplant.Using the WG study population, we randomly selected primary GN patients in a 2:1 ratio matched by age and year of dialysis initiation. Logistic regression analysis was used to model the time listing for renal transplantation, censored for death and transplantation adjusting for gender, race and comorbidities. The study population consisted of 938 WG and 1715 GN patients. The WG patients had a mean age of 66 years, 43 % were female and 93% were White. Median time to wait list for renal transplant was 1.2 (95% CI: 1.1, 1.3) years for patients with Wegener's granulomatosis and 1.5 (95% CI: 1.4, 1.6) years for those with primary GN. The risk of death was 59% lower when ESRD patients with WG were transplanted. In multivariate analysis, lower age and absence of cardiac failure were protective of risk of death. These results indicate that time to wait list for kidney transplant is comparable for patients with WG and primary GN. Long term survival in WG patients with ESRD is better for those that undergo transplantation compared to those that are on dialysis.



Patients with WG and ESRD should therefore be offered pre-emptive renal transplantation or be wait listed sooner.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2275

**Profile and Prognosis of Rapidly Progressive Glomerulonephritis in a Tertiary Care Hospital in Queensland** Dwarakanathan Ranganathan,[1] Dev Krish Jegatheesan,[1] Thaminda Liyanage,[1] Leo P. Francis,[1] Sree Krishna Venuthurupalli.[2] *[1]Renal Medicine, Royal Brisbane & Women's Hospitals, Herston, QLD, Australia; [2]Renal Medicine, Rockhompton Base Hospital, Rockhompton, QLD, Australia.*

BACKGROUND: Rapidly progressive glomerulonephritis (RPGN) is an important cause of end-stage renal failure. RPGN can be grouped according to immunofluorescence patterns as linear type I (anti-glomerular basement membrane); pauci-immune type II (anti-neutrophil cytoplasmic antibody) and granular type III (immune complex disease). This retrospective study looked at the profile and prognosis of RPGN patients seen in a tertiary care setting over the last ten years. METHODS: Electronic records and case notes of all patients diagnosed with biopsy-proven (crescentic) RPGN between January 2000 to November 2009 at the Royal Brisbane and Women's Hospital were reviewed. Patient demographics, laboratory parameters, patient survival and the need for immunosuppressive and or renal replacement therapy were noted. Type I disease patients were excluded from analysis. RESULTS: 34 patients were diagnosed with type II disease, with a mean age of 57.7 years and mean haemoglobin at presentation of 96.0 ± 18.2 g/L. Those who required long-term dialysis presented with significantly higher mean serum creatinine levels (764.0 ± 454.9 VS 231.4 ± 138.7 µmol/L; p<0.05), but this was not the case for patients who eventually died (606.0 ± 385.2 VS 566.8 ± 478.0 µmol/L; p=0.83). 17 patients were diagnosed with type III disease, with a mean age of 38.1 years; mean haemoglobin of 106.8 ± 21.2 g/L. Those who required long-term dialysis presented with significantly higher mean serum creatinine levels (283.7 ± 81.2 VS 91.8 ± 44.6 µmol/L; p<0.05) but this was not the case for patients who eventually died (141.7 ± 140.1 VS 163.4 ± 109.3 µmol/L; p=0.769). CONCLUSIONS: This study suggests that early referral would most likely reduce the need for long-term dialysis and may improve renal and patient survival.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2276

**Acute Post-Infectious Glomerulonephritis in the Elderly** Samih H. Nasr,[1] Mary E. Fidler,[1] Anthony M. Valeri,[2] Lynn D. Cornell,[1] Sanjeev Sethi,[1] Michael B. Stokes,[2] Glen S. Markowitz,[2] Vivette D. D'Agati.[2] *[1]Pathology, Mayo Clinic, Rochester, MN; [2]Pathology and Nephrology, Columbia University, New York, NY.*

Acute post-infectious glomerulonephritis (APIGN) is primarily a childhood disease that occurs after upper respiratory tract infection or impetigo. There have been no clinicopathologic studies addressing APIGN in the elderly. We report 109 cases of APIGN in the elderly (≥65 years of age) diagnosed by renal biopsy at 2 large North American referral centers between 1995-2010. The M:F ratio was 2.8:1. Sixty-one percent (61%) of patients had immunocompromised background, most commonly diabetes (49%) and malignancy (14%). The most common site of infection was skin (28%), followed by pneumonia (16%) and urinary tract infection (13%). Staphylococcus was by far the most common causative agent found in 46% of patients followed by streptococcus (16%) and unusual gram negative organisms. Hypocomplementemia was present in 72% of patients. The mean peak creatinine was 5.1 mg/dl; 67% of patients had a peak creatinine >4.0 mg/dl and 46% required acute dialysis. Twenty-six percent (26%) of patients developed new onset congestive heart failure at presentation. The most common light microscopic patterns were diffuse (53%), focal (28%), and mesangial (13%) proliferative glomerulonephritis. IgA-dominant APIGN was seen in 17% of patients. Of the 72 patients with ≥3 months of follow up (mean 29 months), 22% achieved complete recovery, 44% had persistent renal dysfunction, and 33% progressed to ESRD. Outcomes were worse than in adult counterparts 16-64 years of age. Correlates of reaching ESRD were presence of diabetes, higher creatinine at biopsy, dialysis at presentation, presence of diabetic glomerulosclerosis, and greater tubular atrophy and interstitial fibrosis.

In conclusion, the epidemiology of APIGN is shifting as the population ages. Elderly males, diabetics, and patients with malignancy are particularly at risk. Skin, lung and urinary tract are more common sites of infection than upper respiratory tract, and staphylococcus is 3-fold more frequent than streptococcus. Prognosis is guarded with less than a quarter of patients fully recovering renal function.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2277

**The Validation Study of Oxford Classification: The Significance of Crescent** Ritsuko Katafuchi,[1] Toshiharu Ninomiya,[2] Koji Mitsuiki,[3] Masaharu Nagata,[2] Hideki N. Hirakata.[3] *[1]Kidney Unit, National Fukuoka-Higashi Medical Center, Koga, Fukuoka, Japan; [2]Department of Medicine and Clinical Science Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [3]Kidney Unit, Fukuoka Red Cross Hospital, Fukuoka, Japan.*

**BACKGROUND**: An international IgA nephropathy (IgAN) group has proposed an Oxford classification, consisting mesangial hypercellularity score(M), and the presence or absence of segmental glomerulosclerosis(S), endocapillary hypercellularity(E), and tubular atrophy/interstitial fibrosis(T).

**AIM**: To clarify the prognostic significance of crescent as well as M, E, S, T in our cohort study.

**MATERIALS**: 702 patients with IgAN with 12 months or more follow-up were included.

**METHODS**: The prognostic significance of M, E, S, T and crescent was investigated by the Cox's proportional hazards model. Endpoint was the development of end-stage renal failure (ESRF) defined as initiation of renal replacement therapy.

**RESULTS**: Median age was 30 years old. The mean value of estimated glomerular filtration rate (eGFR) was 82 ml/min/1.73m$^2$. During the median 62-month follow-up, 85 patients developed ESRF. M, S and E did not show any significant influence on kidney survival. The risk of ESRF increased gradually with higher grade of T (hazard ratio [HR] 2.63, p=0.009 in grade 2 and HR 8.06, p<0.001 in grade 3). Patients with crescent had a significantly greater risk for ESRF than those without (HR 2.07, p=0.01). When the effect of crescent on kidney survival was examined in two group divided according to inclusion criteria in the study of Oxford classification (i.e. eGFR of more than 30 ml/min per 1.73m$^2$ and urinary protein: creatinine ratio of more than 0.5), the presence of crescent was associated with increased risk of the development of ESRF in 286 patients who did not meet the Oxford criteria (HR 4.10, p=0.004), but not in 416 patients who met it (HR 1.23, p=0.529).

**CONCLUSION**: The prognostic significance of crescent was evident in our cohort study. The reason why the prognostic value of crescent was not evident in Oxford classification is likely that the patients with eGFR of less than 30 ml/min per 1.73m$^2$ were excluded in their study as they suggested.

### SA-PO2278

**Cigarette Smoking Abrogates a Renoprotective Effect of Renin-Angiotensin-Aldosterone System (RAAS) Blockade in Patients with IgA Nephropathy** Ryohei Yamamoto,[1] Yasuyuki Nagasawa,[1] Tatsuya Shoji,[2] Noritaka Kawada,[1] Masaru Horio,[1] Toshiki Moriyama,[1] Atsushi Yamauchi,[3] Yoshiharu Tsubakihara,[2] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Department of Geriatric Medicine and Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Department of Kidney Disease and Hypertension, Osaka General Medical Center, Osaka, Japan; [3]Department of Nephrology, Osaka Rosai Hospital, Sakai, Osaka, Japan.*

**Aim**: To evaluate predictive power for renoprotective effect of RAAS blockade in patients with IgA nephropathy (IgAN).

**Design and Setting**: Multicenter retrospective cohort study in three major nephrology centers in Osaka, Japan.

**Patients**: 726 IgAN patients aged at least 20 yr.

**Covariates**: Baseline characteristics at kidney biopsy and therapeutic interventions initiated within 1 year of kidney biopsy (RAAS blockers and corticosteroid).

**Outcome**: Slope of eGFR (ΔeGFR, mL/min/1.73m$^2$/yr)

**Statistics**: Effect modifications between RAAS blockade and potential predictors of effectiveness of RAAS blockade were assessed incorporating their interaction terms into multivariate linear regression models to evaluate their predictive powers for renoprotective effect of RAAS blockers.

**Results**: Clinical characteristics were as follows; age 37 ±13 yr, male 42.7%, systolic/diastolic blood pressure 122 ±17/75 ±13 mmHg, eGFR 79 ±24 mL/min/1.73m$^2$, urinary protein 0.8 ±1.0 g/day, current smokers 24.9%, RAAS blockade 48.8%, corticosteroid 30.0%, and observational period 7.6 ±4.4 yr. Multivariate linear regression model revealed that urinary protein (per g/day, β -1.40 [95%CI -2.07 to -0.72, P=0.013) and current smokers(β -1.07 [-1.79 to -0.35], P=0.024) were significantly associated with ΔeGFR. Interestingly, smoking status was identified as significant predictors of effectiveness of RAAS blockers (P=0.027 for interaction), along with urinary protein (P=0.007 for interaction). Effectiveness of RAAS blockers were blunted in current smokers and the patients at lower level of urinary protein, especially, less than 1g/day.

**Conclusion**: Smoking status was identified as the predictor of renoprotective effect of RAAS blockers in IgAN, along with urinary protein.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2279**

**Reduced eGFR in IgAN Predicts Poor Response to Corticosteroid Treatment**
Pietro A. Canetta, Ana Huerta, Andrew S. Bomback, Jai Radhakrishnan, Gerald B. Appel. *Division of Nephrology, Columbia University College of Physicians & Surgeons, New York, NY.*

**INTRODUCTION:**
A number of studies suggest that 6 months of corticosteroids can reduce proteinuria and prevent a decline in renal function in IgAN, especially in patients who do not achieve disease control with RAAS inhibition alone. However, defining which patients will benefit from treatment remains a challenge. We studied a series of patients with IgAN treated with steroids to evaluate factors predicting progression of disease despite treatment.

**METHODS:**
We reviewed clinical, histopathologic, and laboratory data in 20 patients with IgAN treated with corticosteroids at the Center for Glomerular Diseases at Columbia University. Inclusion criteria were biopsy-proven IgAN (scored according to the Oxford-MEST classification) and proteinuria >1 g/day despite RAAS inhibition. Patients were treated with a course of every other day prednisone, starting at 2 mg/kg for 1 month then tapering off over 5-6 months. Response was defined as a >50% decrease in proteinuria to <1 g/day, with <25% increase in serum creatinine from baseline to 12 months of follow-up. Logistic regression was performed to evaluate factors predicting failure to respond.

**RESULTS:**
Of 20 patients, 9 had progression of disease despite corticosteroid treatment. There was no significant difference between responders and non-responders with respect to age, race, gender, time since diagnosis, proteinuria, or serum albumin. Non-responders had significantly lower eGFR than responders (33 vs. 68 ml/min/1.73m$^2$, p = 0.002), higher tubular atrophy/interstitial fibrosis score and higher percentage of globally sclerotic glomeruli. On multivariate logistic regression, the only factor that predicted failure to respond to treatment was an eGFR <45 ml/min/1.73m$^2$ (p = 0.003).

**CONCLUSION:**
In this uncontrolled series of patients with IgAN treated with every other day corticosteroids, the key predictor of failure to respond to treatment was an eGFR <45 ml/min/1.73m$^2$. IgAN patients with significant reductions in GFR may not benefit from 6 months of corticosteroids.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2280**

**Urinary KIM-1 and NGAL Excretion in Immunoglobulin A Nephropathy**
Hilde P. Peters,[1] Femke Waanders,[2] Esther Meijer,[2] Jan A. J. G. van den Brand,[1] Harry Van Goor,[2] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [2]Kidney Center, University Medical Center Groningen, Groningen, Netherlands.*

The variable course in patients with Immunoglobulin A nephropathy (IgAN) warrants accurate tools for prediction of progression. Urinary kidney injury molecule-1 (KIM-1) and neutrophil gelatinase-associated lipocalin (NGAL) are solid markers for the detection of active tubulointerstitial damage in various renal diseases.

We evaluated the prognostic value of KIM-1 and NGAL in patients with IgAN.

**Methods**
We included patients (n=65, 72% male, age 39 (range 17-70) yrs) with IgAN who were evaluated for severe proteinuria between 1995-2007. Healthy controls were matched for age and gender. KIM-1 and NGAL were measured in urine by ELISA. Univariate and multivariate cox regression analysis was used to assess predictors of ESRD.

**Results**
Median plasma creatinine was 142 (range 70-362) mol/L, and proteinuria 2.2 (0.4-24.2) g/day. During follow-up (median 75 (3-146) months), 23 patients (35%) developed ESRD. In patients with IgAN median urinary KIM-1 excretion was 1.7 [interquartile range 0.8-3.2] ng/min and NGAL excretion was 47 [21.7-104.0] ng/min, both significantly higher than in healthy controls (KIM-1 excretion 0.6 [0.4-0.9] ng/min and NGAL excretion 15.7 [10.5-20.1] ng/min).

KIM-1 and NGAL correlated with proteinuria (r=0.40 and 0.35 respectively, p<0.01) and with each other (r=0.53, p<0.01) but not with serum creatinine or GFR. By univariate analysis excretion of KIM-1, NGAL and IgG, proteinuria and serum creatinine were significantly associated with ESRD. Multivariate analysis showed that serum creatinine and KIM-1 excretion were the only significant independent predictors of ESRD. The hazard ratio for KIM-1 excretion was 1.2 corresponding to a 20% increase in the risk of developing ESRD for each ng/min increase in urinary KIM-1 excretion.

**Conclusion**
Urinary KIM-1 and NGAL excretion is increased in patients with IgAN and correlates with proteinuria but not with GFR. Serum creatinine and KIM-1 excretion, but not proteinuria, are independent predictors of ESRD in patients with IgAN.

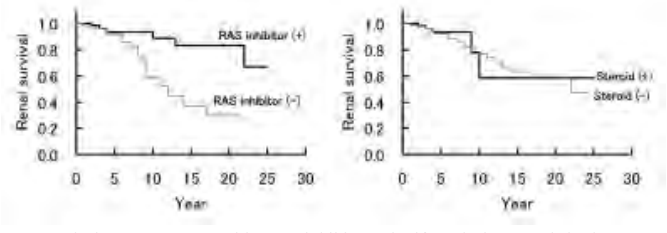
**SA-PO2281**

**Renin-Angiotensin System Blockade Improves the Long-Term Renal Survival Better Than Steroid Therapy in IgA Nephropathy**
Kensuke Asaba, Akihiro Tojo, Satoshi Kinugasa, Kikuno Hanamura, Toshiro Fujita. *Division of Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan.*

Purpose: Patients with IgA nephropathy may gradually progress to end-stage renal disease (ESRD), and the long-term randomized controlled trial using dialysis induction as an outcome is difficult. We used the start of dialysis as the end point and examined the long-term renal survival in IgA nephropathy.

Methods: We evaluated retrospectively the effects of renin-angiotensin system (RAS) inhibitors and steroid therapy on the renal survival rate by Kaplan-Meier method in 159 patients with biopsy-proven IgA nephropathy diagnosed in the last 25 years.

Results: By multivariate analysis, lower eGFR and higher score of glomerulosclerosis index at renal biopsy and treatment without RAS inhibitors were independent risk factors for ESRD. Eight (9%) of 93 patients treated with RAS inhibitors and 16 (24%) of 66 patients treated without RAS inhibitors developed ESRD, respectively. Kaplan-Meier renal survival curve was significantly better in the former than in the latter (P = 0.002). Five (8%) of 60 patients treated with prednisolone and 19 (19%) of 99 patients treated without prednisolone developed ESRD, respectively, and the renal survival was not different significantly between these two groups (P = 0.673). To investigate the additional effects of steroid therapy to the RAS blockade, we compared 47 patients treated with both RAS inhibitors and prednisolone and 46 patients treated with RAS inhibitors but without prednisolone, and found no difference in the renal survival (P = 0.420).



Conclusions: Treatment with RAS inhibitors significantly improved the long-term renal survival better than steroid therapy in IgA nephropathy.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2282**

**Impact of Body Mass Index on the Clinical Course of IgA Nephropathy**
Christos Bantis,[1,2] Peter J. Heering,[1] Maria Stangou,[2] Magdalena Siekierka-Harreis,[1] Sendogan Aker,[1] Dimitrios Memmos,[2] Lars C. Rump,[1] Katrin Ivens.[1] *[1]Department of Nephrology, Heinrich-Heine University, Düsseldorf, Germany; [2]Department of Nephrology, Aristotle University, Thessaloniki, Greece.*

In the present study we evaluated the influence of body mass index (BMI) on clinical and histological parameters of IgA nephropathy.

We studied n=178 patients with biopsy proven primary IgA nephropathy, followed up for a mean of 5.9 ± 6.0. The rate of deterioration of renal function was estimated by the slope of the curve of reciprocal serum creatinine against time. According to the BMI at the time of renal biopsy, patients were divided into the following groups: normal BMI (<25, n=104), overweight (25-29.99, n=54) and obese (≥30, n=20).

Age, initial renal function, proteinuria, blood pressure under treatment and the number of antihypertensive agents taken at the time of renal biopsy were similar among normal, overweight and obese patients (ns). The rate of progression however differed significantly between patients with normal BMI (-0.092 ± 0.116), overweight (-0.188 ± 0.366) and obese patients (-0.211 ± 0346 dl*mg$^{-1}$*year$^{-1}$, p=0.020). Similarly, BMI as a continuous variable correlated with the rate of deterioration of renal function (r=0.232, p=0.002).

An increased BMI is associated with a faster decline of renal function in patients with IgA nephropathy.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2283**

**Elevated Serum Uric Acid Is Associated with Reduced Renal Function and Severity of Histological Injury in IgA Nephropathy**
Jingyuan Xie,[1,2] Krzysztof Kiryluk,[2] Zhaohui Wang,[1] Hong Ren,[1] Xiaoxia Pan,[1] Weiming Wang,[1] Yifu Li,[2] Ali G. Gharavi,[2] Nan Chen.[1] *[1]Nephrology Department, Ruijin Hospital, Shanghai Jiaotong University, Shanghai, China; [2]Medicine, Div. Nephrology, Columbia University, New York, NY.*

Our objective was to determine the role of serum uric acid (UA) in the pathogenesis and progression of IgA nephrolophy (IgAN). For this purpose, we analyzed a cohort of 1,360 biopsy-diagnosed primary IgAN cases and 1,093 healthy controls; a subgroup of 458 cases was followed for an average of 2.7 years (1mo-20 yrs). All participants were recruited in Shanghai, east China. Hyperuricemia was defined by gender-specific criteria of serum UA >450 umol/L in males and >340 umol/L in females. Statistical analyses were performed in SPSS v18.0.

Hyperuricemia was 3x more common in cases compared to controls (38% *vs.* 11%, p=5.7x10$^{-50}$). After age, gender, and disease status adjustments, higher serum UA levels were strongly associated with reduced eGFR; beta= -8.0 (8 mL/min/1.73m2 decline in

eGFR per 1 mg/dL increase in UA, $p=3.9x10^{-124}$). This association remained significant after additional adjustments for serum triglycerides, cholesterol, hemoglobin, and albumin levels (beta=-7.0, $p=3.9x10^{-50}$). When case and control groups were analyzed separately, the age and gender-adjusted association was strongest within the case group; beta=-9.3 ($p=1.6x10^{-87}$) in cases vs. beta=-2.6 ($p=2.9x10^{-11}$) in controls. Among cases, increased UA levels were also independently associated with a greater degree of histological injury by HAAS criteria after adjustment for age, gender, blood pressure, serum albumin, hematuria, proteinuria, and eGFR (p=0.007). In the fully adjusted Cox proportional hazards model, eGFR at the time of biopsy, hypertension, and age were the most important predictors of progression to ESRD. Age-and gender- adjusted UA level was associated with disease progression (p=0.001), but this effect lost significance after accounting for eGFR in the model.

In summary, our data indicate that elevated serum UA level is independently associated with decreased renal function and severity of histological injury in IgA nephropathy.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2284

**Relocation of Dendrin to the Podocyte Nucleus in Kidney Biopsy Specimens and Urine Samples in Patients with IgA Nephropathy** Fumiko Kodama, Katsuhiko Asanuma, Rin Asao, Miyuki Takagi, Yasuhiko Tomino. *Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Bunkyo-ku, Tokyo, Japan.*

An often insidious progression to end-stage kidney disease includes development of glomerulosclerosis that is associated with podocytopenia. It has been reported that podocytopenia occures with increasing disease severity in patients with IgA nephropathy (IgAN). Dendrin, proline-rich protein, is localized at the slit diaphragm (SD) insertion site in podocytes. We showed that dendrin relocates to the nucleus of injured podocytes in experimental nephritis and nuclear dendrin promotes podocyte apoptosis. It is not known whether dendrin translocates from the SD to the podocyte nucleus in human IgAN. We investigated the presence of nuclear dendrin in human kidney biopsy specimens with IgAN and the association of relocated dendrin to podocyte nucleus with disease progression. Fourteen adult patients with IgAN, diagnosed by renal biopsy, were enrolled. The patients were divided into four groups by the Japanese predicted prognosis classification system . The pathological parameters of Shigematsu et al. were analyzed. Immunostaining of kidney sections and urinary sediments from IgAN patients and three minimal change nephrotic syndrome (MCNS) patients was performed for dendrin, podocaryxin, annexin V and DAPI. Dendrin relocated dendrin to the podocyte nucleus was detected in glomeruli of kidney specimens with IgAN. A positive correlation was detected between acute extracapillary change and the number of dendrin positive nuclei. Nuclear dendrin was observed in urinary podocytes from IgAN patients. Moreover, the number of dendrin positive nuclei per urinary podocyte from IgAN patients was significantly higher than that from MCNS patients. Urinary annexin V positive podocytes were also detected in IgAN. **(Conclusion)** An increasing number of dendrin positive nuclei suggests the acute phase of glomerular inflammation in patients with IgAN. The apoptotic podocytes were shed into the urine in IgAN patients. It is suggested that dendrin relocated to podocyte nuclei enhances podocyte apoptosis for acute inflammation in IgAN and leads to podocytopenia.

**A Randomized Multicenter Trial of Valsaratan in Normotensive IgA Nephropathy with Mild Proteinuria** Young-Il Jo,[1] Ju-Young Moon,[2] Sang-Ho Lee,[2] Sang-Woong Han,[3] Dongho Yang,[4] Sug Kyun Shin.[5] *[1]Nephrology, Konkuk University Hospital, Seoul, Republic of Korea; [2]Kyung-Hee Univ EWN Medical Center, Seoul, Republic of Korea; [3]Hanyang University Guri Hospital, Guri, Republic of Korea; [4]Bungdang CHA Hospital, Sungnam, Republic of Korea; [5]NHIC Ilsan Hospital, Goyang, Republic of Korea.*

1. Background; Proteinuria, even though it is mild, causes renal damage that accelerates the progression of IgA nephropathy (IgAN) towards ESRD and decreased by ACE inhibition. However, prospective controlled studies of the clinical benefit of angiotensin II receptor blocker (ARB) in the treatment of normotensive IgAN with mild proteinuria are lacking.

2. Purpose; This study was designed to investigate the antiproteinuric effects of a ARB, valsartan, in normontensive IgAN patients with mild proteinuria.

3. Methods; Sixty-one IgAN patients (M:F 22:39, age 41.0±12.7) were recruited from 5 centers in this randomized, prospective, multicenter study. Inclusion criteria were persistent proteinuria with spot urine protein-to-Cr ratio (UPCR) of 0.3-1.5 (mg/mg), BP <140/80mmHg without antihypertensive medication, and eGFR-MDRD >60 mL/min/1.73m$^2$. Eligible subjects were randomized assigned to administration of valsartan 40 mg/day or 80 mg/day.

4. Results; There were no significant differences in baseline parameters including UPCR, eGFR, serum K, and BP between two groups. Proteinuria gradually and significantly decreased from 4 weeks after administration of valsartan 80mg, but partially ameliorated by valsartan 40mg (see Figure). BP, eGFR, and serum K levels did not significantly change during 12 weeks in both groups. There were no serious adverse events that caused withdrawal of treatment.

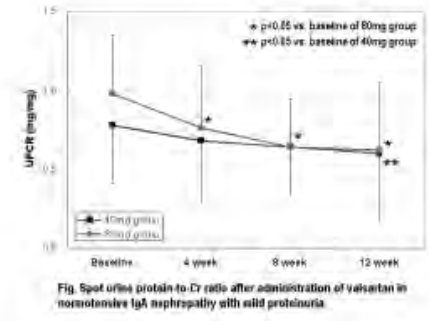

Fig. Spot urine protein-to-Cr ratio after administration of valsartan in normotensive IgA nephropathy with mild proteinuria

5. Conclusion; These results suggest that valsartan (40 or 80mg) could significantly decrease proteinuria without any serious adverse events in normotensive IgAN patients with mild proteinuria.

**Evaluation with Oxford Classification: Correlations between Pathological Features and Clinical Features in Patients of IgA Nephropathy with Crescents** Jiong Tian, Rong Lv, Huiping Wang, Jianghua Chen. *Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Oxford classification for IgA nephropathy (IgAN) was presented in Kidney International 2009 by International IgA nephropathy Network. However the predict value of the novel classification for the renal prognosis needs more validation in different cohorts. Besides, the significance of crescent is not included in Oxford classification and remains to be clarified.A total of 83 patients (age 34.7±13 years, 54% male vs 46% female) diagnosed primary IgAN during Jan, 2005-Dec, 2006 were included in the present study. Blindly and randomly 10 glomeruli per slide were selected for re-observation by renal pathologist according to the four pathological variables: mesangial hypercellularity, segmental glomerulosclerosis, endocapillary hypercellularity and tubular atrophy/interstitial fibrosis. Patients were divided into various groups based on the semi-quantitative scores. Rapid renal function decline was defined by slope > 1.6ml/min/ per 1.73m$^2$ per year calculated by eGFR. At the time of biopsy the daily protein was 3.0±2.8g and declined to 1.3±1.5 g after a follow-up for a median of 36 months. 5 patients progressed into ESRD or doubling of serum creatinine within the time of follow-up. Both endothelial proliferation and tubular atrophy were associated with rapid renal function decline significantly whereas mesangial hypercellularity or segmental glomerulosclerosis was not. The proteinuria in patients with endothelial hypercellularity was more than that in patients without the pathological feature (2.7±1.3 vs 1.5±1.5 p=0.001). Differences of proteinuria in three groups divided according to percentage of crescent (<10%,10-20%,>20%) were significant (1.37±1.1 vs 2.8±1.1 vs 3.6±2.3, p<0.05 ). The percentage of crescent was not related to renal outcome either using rapid renal function decline parameter or creatinine increase >25% of baseline. Crescent formation was related to proteinuria in IgAN patients but not to the renal prognosis in the present cohort. Larger cohorts and longer follow-up are needed to evaluate the Oxford classification in Asian patients.

## SA-PO2287

**Clinical Remission of IGA Nephropathy (IGAN)** David K. Packham. *Melbourne Renal Research Group, Melbourne, Victoria, Australia.*

Aim

To establish the frequency of clinical remission of IGAN in adult patients and the significance of associated vasculitic rash (VR).

Introduction

Reported cases of spontaneous remission in IgAN vary between 0-33%. This discrepancy may reflect differences in the definition of remission and particularly resolution of significant haematuria.

We report the incidence of clinical remission in an adult cohort of patients followed for a minimum of 24 months post-biopsy. The significance of VR is discussed.

Methods

Retrospective analysis of 99 adult patients with biopsy proven IgAN and a minimum follow up (FU) of 24 months. Biopsied between 1991-2005.

Patient demographics, the presence of recent history of VR, creatinine (Cr), protein excretion (24 hr UPr) and glomerular red blood cell counts (grbcc), were recorded at biopsy and at six monthly intervals thereafter. Grbcc <18x103/ml were regarded as normal. Resolution of glomerular haematuria was defined as at least three sequential normal grbcc over a minimum of eighteen months without subsequent abnormal grbcc. Remission of IgAN was only diagnosed in patients with resolution of glomerular haematuria in the absence of renal impairment (Cr > 120mmol/L) or significant proteinuria (>0.15g/24 hrs).

Results

Median follow up was 72 months (24-162). 20% had resolution of haematuria. However, 63% of these had either renal impairment, significant proteinuria or both. Thus, only 7 patients (7%) fulfilled our definition of clinical remission (remitters). 7 (7%) of patients in the whole cohort reported VR but 4 of these (57%) were subsequently remitters. Thus if VR was absent, only 3% of patients went into clinical remission.

Conclusions

1 Clinical remission of IgAN occurred in 7% of patients followed for a median of 72 months.

2 If patients presenting with a history of VR are excluded, clinical remission rate was 3%.

3 Patients with VR are over-represented amongst remitters. They may represent adult Henoch Schönlein purpura and have a different natural history.

**SA-PO2288**

**Urinary Kidney Injury Molecule-1 and Neutrophil Gelatinase-Associated Lipocalin Correlate with Clinical and Pathologic Findings in IgA Nephropathy** Se-Bin Song, Dongyoung Lee, Ju-Young Moon, Kyung-Hwan Jeong, Tae Won Lee, Chun-Gyoo Ihm. *Department of Nephrology, Kyung Hee University, School of Medicine, Seoul, Republic of Korea.*

Introduction: Urinary neutrophil gelatinase-associated lipocalin (uNGAL) and Kidney injury molecule-1 (uKIM-1) have been known as a predictor of kidney injury but there was a lack of study on its roles in chronic glomerulonephritis. This study was performed to exam the levels of uNGAL and uKIM-1 and to assess whether they had an association with a pathologic finding and clinical activity in patients with IgA nephropathy.

Method: uNGAL and uKIM-1 were measured using commercial human ELISA kits on 40 patients with IgA nephropathy (15 males (37.5%) with a mean age of 36.2±12.9 years) and 10 healthy volunteers (5 males (50%) with a mean age of 37.3±9.6 years).

Results: The patients with IgA nephropathy had higher uNGAL (26.9±35.4 ng/mgCr vs. 9.1±7.8 ng/mgCr, p=0.006) and uKIM-1 (1.17±1.51 ng/mgCr vs. 0.29±0.20 ng/mgCr, p=0.001) compared with those of healthy volunteers. On univariate regression analysis, uNGAL was correlated with serum creatinine (r=0.652), eGFR (r=-0.393), and albumin (r=-0.423) and uKIM-1 was correlated with pathologic grading (H.S Lee grading) (r=0.335), tubulointerstitial inflammation (r=0.353), and hemoglobin (r=-486). In a model of multivariate regression analysis, uNGAL had an association with serum creatinine (p=0.006) and eGFR (p=0.005) and uKIM-1 did with H.S. Lee grading (p=0.004) and tubulointerstitial inflammation (p=0.011).

Conclusion: uNGAL was associated with residual renal function and uKIM-1 had high correlation with pathologic severity such as tubulointerstitial inflammation.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2289**

**Normoalbuminemia May Predict IgA Nephropathy in Primary Glomerulopathy with Nephrotic-Range of Proteinuria in Chinese Patients** Fude Zhou, Min Chen, Ming Hui Zhao, Hai Yan Wang. *Renal Division, Peking University First Hospital, Beijing, China.*

**[Purpose]** Massive proteinuria is often associated with hypoalbuminemia in glomerulopathy. However, patients may have normal level of serum albumin in spite of heavy proteinuria in many circumstances. The current study aimed to investigate factors affecting serum level of albumin in primary glomerulopathy patients with nephrotic-range of proteinuria with special attention paid to different pathological types.

**[Methods]** The renal histopathology data of adult patients (age ≥18 year-old) with primary glomerulpathy and nephrotic-range of proteinuria, who received native renal biopsies in Peking University First Hospital from 1998 to 2007, were retrospectively analyzed. Demographic data, interval between the onset of disease and renal biopsy, blood pressure, 24 h proteinuria, serum albumin level, serum lipid profile, serum creatinine concentration, eGFR, histological diagnosis were collected and analysed. The receiver operating characteristic (ROC) curve analysis was employed to determine the specificity and senstivity for predicting certain type of glomerulopathy.

**[Results]** There were totally 780 patients with primary glomerulopathy and nephrotic-range of proteinuria recruited for further analysis in this retrospective study. Compared with patients with hypoalbuminemia (serum albumin lower than 30g/L), patients without hypoalbuminemia were significantly younger (36.8±11.6 vs. 41.0±15.8 years old, P=0.000), and had significantly lower level of proteinuria (5.34±2.06 vs. 8.63±4.26g/24hr, P=0.000). Patients without hypoalbuminemia had significantly higher proportion of IgA nephropathy (66.0% vs. 17.2%, P=0.000). The independent predictors of hypoalbuminemia in nephrotic-range of proteinuria patients included age, gender, interval between onset of the disease and renal biopsy, proteinuria level and pathological type of glomerulopathy. A serum level of albumin ≥ 35g/L could predict IgA nephropathy with the specificity of 95.8%, and the specificity increased with age.

**[Conclusion]** Among patients with primary glomerulopathy and nephrotic-range of proteinuria, normoalbuminemia is a useful predictor for the diagnosis of IgA nephropathy.

**Hyperuricemia as a Marker for Progression of IgA Nephropathy** Su-Ji Kim, Junghoon Kim, Sujin Seok, Hyo-Wook Gil, Jong-Oh Yang, Eun-Young Lee, Sae-Yong Hong. *Internal Medicine, Soonchunghyang University, Cheonan, Korea.*

Because of variable clinical and histopathological manifestation of immunoglobulin A nephropathy (IgAN), it is very difficult to predict the disease progression. In recent studies, hyperuricemia which is common in hypertension and vascular disease has also been thought to contribute to the renal dysfunction and the histological changes, including renal arterioleosclerosis, tubular atrophy and interstitial fibrosis. In the present study, we investigated the clinical significance of uric acid level at the time of biopsy as a marker for the progression of IgAN.

**Methods:** A total 193 patients (men 103, women 90, 14 to 71 years) with biopsy-proven IgAN were studied. Mean follow up duration after renal biopsy were 5.8 years. Progression of renal disease defined as an elevation of serum creatinine above 1.2 mg/dL or over 20% elevation from baseline. Hyperuricemia defined as a level of serum uric acid ≥ 7.3 mg/dL in men or ≥ 5.3 mg/dL in women according to the consensus from our hospital, upper level of one standard deviation of normal control group. The control group consisted of 6245 participants, who were clinically well and without hypertension, diabetes, hematuria or proteinuria at Soonchunhyang health promotion center.

**Results:** The hyperuricemia group (*n*=50) showed higher systolic blood pressure, body mass index, serum creatinine, total cholesterol, triglyceride, a greater amount of proteinuria and lower glomerular filtration rate than normal hyperuricemia group (*n*=143). Hyperuricemia increased risk for progression of IgAN (OR 4.53, 95% CI 1.31-15.66) after adjusted for age, gender, body mass index, hypertriglyceridemia, hypercholesterolemia and proteinuria. The disease progression group (*n*=26) had a greater frequency of hyperuricemia, hypertension, proteinuria and the nephrotic range of proteinuria than non progression group (*n*=119). The survival curves for renal function in relation to hyperuriceima showed that the hyperuricemia group had a higher rate of disease progression in IgAN.

**Conclusion:** We conclude that hyperuricemia at the time of diagnosis might be an important marker for progression of IgAN.

**Relationship between Urinary Podocalyxin Level and Histological Activity in Patients with IgA Nephropathy** Rin Asao,[1] Katsuhiko Asanuma,[1] Fumiko Kodama,[1] Miyuki Takagi,[1] Yukihiko Takeda,[1] Isao Ohsawa,[1] Yoshiaki Hirayama,[2] Satoshi Horikoshi,[1] Masanori Hara,[3] Yasuhiko Tomino.[1] *[1]Nephrology, Juntendo University, Tokyo, Japan; [2]Reagents Development, Denka Seiken Co., Ltd, Niigata, Japan; [3]Pediatrics, Yoshida Hospital, Niigata, Japan.*

[Introduction)

Podocalyxin is present on apical cell membrane of podocytes and is shed into urine from injured podocytes. Urinary podocalyxin is associated with severity of active glomerular injury in children with glomerular diseases. In the present study, we examined the relationship between level of urinary podocalyxin and glomerular injury in adult patients with IgA nephropathy.

[Materials and Methods)

Urine samples voided in the morning were obtained from 42 patients with IgAN (13 males and 29 females; mean age 32.9 yr) during the period from October 2007 to July 2009. Patients with corticosteroid treatment and/or tonsillectomy were excluded from this study. All renal biopsy specimens were analyzed histologically. The pathologic parameters of IgAN were analyzed according to Shigematsu's classification (Pathol Int. 1997 Apr;47(4):194-202) and the Oxford classification of IgAN. Levels of urinary podocalyxin (PCX) were measured by sandwich ELISA.

[Results)

In the histological analysis based on Shigematsu's clasiffication, there was a significant correlation between levels of urinary PCX and severity of acute extracapillary changes (r=0.6006 p<0.01), but levels of urinary podocalyxin were not related to severity of chronic glomerular and interstitial changes. There was a significant correlation between levels of urinary protein and severity of chronic endocapillary and extracapillary changes (r=0.5677 p<0.01, r=0.4752 p<0.01, respectively). There was no statistically significant correlation with levels of urinary protein and severity of acute glomerular changes. In the histological analysis based on the Oxford classification, there was no correlation between levels of urinary PCX and histological renal findings.

[Conclusion)

It appears that urinary podocalyxin is a useful marker for predicting the histological activity in patients with IgA nephropathy.

**Combination of Tonsillectomy and Corticosteroid Suppressed Recurrence of Urinary Protein and Occult Blood in Patients with IgA Nephropathy, Compared with Corticosteroid Alone** Atsushi Takahashi,[1] Ryohei Yamamoto,[1] Yasuyuki Nagasawa,[1] Hirotsugu Iwatani,[1] Kenichiro Iio,[1] Maki Shinzawa,[1] Arata Horii,[2] Atsushi Yamauchi,[3] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Otolaryngology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [3]Nephrology, Osaka Rosai Hospital, Sakai, Osaka, Japan.*

*Background:* Although several recent studies suggest that tonsillectomy with corticosteroid (TLX+CS) may have a renoprotective effect on immunogloblin A nephropathy (IgAN), it remains to be elucidated whether TLX+CS is more effective than corticosteroid therapy alone (CS). *Methods:* We retrospectively reviewed 59 IgAN patients who received TLX+CS and 37 patients who did CS between 2000 and 2007 in two nephrology centers. Outcomes were time from initiation of TLX+CS or CS to disappearance (- or ± by dipstick) and recurrence of urinary protein (UP) or occult blood (UOB). Cumulative incidence rate of outcomes in TLX+CS and CS were estimated and compared using Kaplan-Meier method and Log-rank test. Cox proportional hazard (CPH) analysis was used to determine the factors associated with remission and recurrence of urinary abnormalities. *Results*: No significant

difference between TLX+CS and CS groups was observed in baseline characteristics before treatment, including age, gender, urinary protein/creatinine ratio (0.64 (0.39-1.38) vs. 0.78 (0.48-1.45), p=0.58), eGFR (77(58-88) vs. 72 (56-86) ml/min/1.73m$^2$, p=0.83), and systolic blood pressure (116 (105-130) vs. 114 (107-123) mmHg, p=0.37). Cumulative remission rate of UP and UOB were not significantly different between TLX+CS and CS (UP; p=0.73 for Log-rank test and UOB; p=0.08). On the contrary, cumulative recurrence rate of UP and UOB were significantly higher in CS, compared with TLX+CS (UP; p = 0.007 for Log-rank test and UOB; p=0.002). Univariate CPH analysis identified CS (vs. TLX+CS) as significant predictors of recurrence of UP and UOB (UP: hazard ratio 4.17 [95% confident interval 1.49-14.3] and UOB (12.5 [2.33-100]). *Conclusion*: Tonsillectomy with corticosteroid was more effective than corticosteroid alone in preventing recurrence of IgAN.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2293

**Serial Measurement of Galactose-Deficient IgA1 (Gd-IgA1) in Children** Margaret Colleen Hastings,[1] John T. Sanders,[1] Zina Moldoveanu,[2] Jan Novak,[2] Bruce A. Julian,[2] Robert J. Wyatt.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of Alabama-Birmingham, Birmingham, AL.*

Gd-IgA1 is a key factor in the pathogenesis of IgA nephropathy (IgAN). Serum Gd-IgA1 levels are elevated in adult IgAN patients. However, serum Gd-IgA1 levels and their stability over time in pediatric IgAN patients, healthy children, and children with other glomerular diseases have not been assessed. To address this issue, serial serum samples from 15 children with biopsy-proven IgAN, 33 healthy controls, and 12 non-IgAN disease controls were analyzed for Gd-IgA1. Children with Henoch-Schonlein purpura were excluded. Serum samples from children (2-19 years) were obtained at the time of study entry and then at 6-month intervals, with 54 children sampled at 6 months and 38 children at 12 months. Serum Gd-IgA1 levels were determined by lectin ELISA using an *N*-acetylgalactosamine-specific lectin from *Helix aspersa*. Mixed linear modeling was used to determine statistical significance. At study entry, mean age (in years) of the healthy controls, disease controls, and patients with IgAN were 12.9±2.8, 11.2±3.5, and 11.2±3.5, respectively, with male:female ratios 1.5, 0.7, and 0.7. African Americans comprised 67% of healthy controls, 67% of disease controls, and 27% of patients with IgAN. Median (range) serum Gd-IgA1 levels (units/ml) at entry, 6 months, and 12 months for healthy controls were 284 (117-1009), 238 (129-910), and 215 (96-427); for disease controls 316 (176-716), 218 (116-987), and 280 (115-769); and for patients with IgAN 635 (315-1517), 684 (180-1516), and 647 (543-1342). When serum Gd-IgA1 levels from subsequent visits were compared with the levels at the initial visit within each group, no statistically significant difference was identified. Serum Gd-IgA1 levels were elevated in the patients with IgAN group compared with those for healthy children and disease controls ($p<0.0001$), adjusting for age, gender, and ethnicity. In summary, in this small pediatric cohort, serum Gd-IgA1 levels were elevated in patients with IgAN and appear to be stable over 12 months of follow-up in all cohorts, including children with IgAN or non-IgAN glomerular disease and healthy children.

**Increased Urinary KIM-1 and Tubular KIM-1 Expression in IgA Nephroapathy** Soon Hyo Kwon, Moo Yong Park, Jin Seok Jeon, Jin Kook Kim, Dong-Cheol Han, Seung D. Hwang. *Internal Medicine, Soon Chun Hyang University, Korea.*

**Background:** Tubulo-interstitial fibrosis is one of the important prognostic factors in IgA nephropathy (IgAN). Kidney injury molecule-1 (KIM-1) is a specific marker of the proximal tubular injury. This molecule is increased in various renal diseases. It suggests KIM-1 could represent degree of tubular injury in IgAN.

**Method:** To investigate the role of KIM-1 in predicting the kidney injury of IgAN. We prospectively enrolled 50 patients with IgAN and 27 normal controls (NC). Spot urine KIM-1 standardized by urine creatinine were measured by ELISA and tubular KIM-1 was stained by immunohistochemistry. We classified pathologic classification of IgAN with Oxford classification. Quantification of tubular KIM-1 expression was defined as the count of the stained tubules.

**Results:** The concentration of urinary KIM/Cr of IgAN was significantly higher than that of normal control.($p<0.0001$)(1.32±0.18 vs 0.56±0.19) There was no significant difference of urinary KIM-1 level in the extent of severity of tubular lesion. (p=0.37)[T0= 1.7±1.7(n=26): T1=1.1±1.0(n=27): T2=0.6±0.4(n=7)] There was significant increase of tubular KIM-1 expression in T1, T2 lesions.($p<0.0001$)(2.2±2.0 vs 7.9±3.8; 6.5±0.7) Urinary KIM-1 was not correlated with proteinuria and tubular KIM expression.

**Conclusion:** KIM-1 is upregulated in IgAN. Tubular KIM-1 more predictable to estimate tubular injury than urinary KIM-1. There is a need for a study about clinical implication of high level of urinary KIM-1 in T0 lesion.

## SA-PO2295

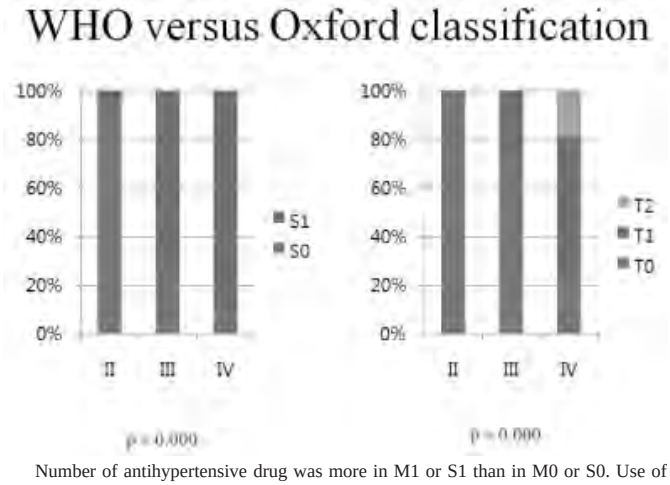
**Comparision between Oxford Classification and WHO Classification of IgA Nephropathy** Seokhui Kang,[1] Cheol Whee Park,[1] Young Soo Kim,[1] Chul Woo Yang,[1] Bumsoon Choi,[1] Young Jin Choi,[3] Byung Ha Chung.[1] *[1]Division of Nephrology, Department of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea; [2]Department of Pathology, Seoul St. Mary's Hospital, Seoul, Korea.*

IgA nephropathy is most common cause of glomerulonephritis. Prognostic factors of IgA nephropathy are pathologic finding, serum creatinine, hypertension, proteinuria. Althought pathologic classification of IgA nephropathy is important, most classifications for IgA nephropathy are complicated, difficult. Oxford classification for IgA nephropathy was reported in 2009. We compared clinical outcmes of different pathologic classification (Oxford, WHO classification). A retrospective study comprised of 103 patients of IgA nephropathy who underwent renal biopsy between 2000 and 2006.

Baseline characteristics

| | Mean ± SD |
|---|---|
| Total number of patients | 103 |
| Age (years) | 34 ± 11 |
| BMI (kg/m2) | 22 ± 3 |
| Taking antihypertensive drug | 28 (26%) |
| Proteinuria (g/day) | 2.69 ± 2.87 |
| Creatinine (mg/dl) | 1.06 ± 0.43 |
| MDRD GFR (ml/min/1.73m2) | 80 ± 25 |

WHO classification showed class I as 1%, II as 16.5%, III as 50.5%, IV as 32%. Oxford classification showed M1 as 96.2%, S1 as 67.3%. E1 as 15.4%, T1 as 32.7% and T2 as 5.8%. The higher class of WHO classification, S and T class of Oxford classification was higher.



Number of antihypertensive drug was more in M1 or S1 than in M0 or S0. Use of immunosuppressants was more patients with T1 or T2 than T0. Patients with E1 had more decline of proteinuria. In CKD stage 2 and 3, patients with E1 had less decline of GFR than E0. In CKD stage 2, patients with T1 and T2 had more decline of GFR than than T0. Oxford classification is well correlated with other classification regarding IgA nephropathy.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2296

**Oxford Classification of IgA Nephropathy: Is It Prognostic in Different Cohort of Patients?** Katia Lopez-Revuelta,[1] Dolores Martin-Rios,[2] Elena Corchete,[1] Mrenee Gomez,[1] M. Carmen Guerrero.[3] *[1]Nephrology Unit, Hospital Universitario Fundacion Alcorcon, Alcorcon, Madrid, Spain; [2]Preventive Medicine; [3]Pathology Unit, .*

Oxford classification of IgA nephropathy needs to be validated in different cohorts of patients.

Purpose: To study the clinico-pathological associations of Oxford IgA classification at biopsy and follow-up in a non-selected cohort of patients.

Methods: Retrospective cohort study of all IgA nephropathy biopsies (≥8 glomeruli) in one adult center between 05/1998-05/2009 reclassified using Oxford classification. Demographic, clinical and laboratory data at biopsy, yearly and at the end of follow-up were recorded. Primary endpoint was progression of renal disease (PRD): ESRD and/or 50% drop in eGFR. Follow-up period: months from biopsy until endpoint, dead or last follow-up. Statistical analysis included Kaplan Meier, Cox regression and linear regression models to assess predictive role of pathological data on renal function loss.

Results: 62 patients (86% male), median (SD) age 50(17)yr were included, 20% liver disease, 20% Schönlein-Henoch, 56% AKI. Clinical data are shown in Table 1.

Table 1. Clinical characteristics at biopsy and follow-up

| | At time of biopsy | At follow-up |
|---|---|---|
| Median (IQR) s Cr(mg/dl) | 1.66(1.97) | 1.66(1.59) |
| Median(IQR) eGFR (ml/min/1.73m2) | 43 (52) | 47(37) |
| %Stage 1-2,3,4,5 | 32,31,24,13 | 26,43,10,21 |
| %HTA | 68 | 99 |
| Median(IQR)uProt/cr (mg/mg) | 1.54(1.66) | 0.51(1.83) |

Median (IQR) follow-up (mo): 33(62)

Twenty two % reached study endpoint, and 10% died. Main histological data were: 97% M1, 48% E1, 40%S1, T1-2 40-3%, 11% had >25% crescents. Independent predictors of PRD: sCr at biopsy p<0.40, uPCR at last follow-up p<0.001, HR (95% CI) T1-2/0 5.69(1.36-23.78) p<0.01, E1/0 4.88 (1.02-23.34) p<0.05, liver disease 6.68 (1.35-33.22) p<0.20. Independent predictors of yearly sCr increment were E (p< 0.032) and sCr at biopsy (p<0.006).

Conclusion: New Oxford IgA classification helps to stablish risk of renal disease progression in patients with severe renal failure at the time of biopsy. Endocapillary hypercellularity (E) and interstitial fibrosis are independent predictors of renal outcome. Confirmation of these observations need larger studies.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2297

**IgA Nephropathy Associated with End-Stage Liver Disease Has Features of Membranoproliferative Glomerulonephritis and May Not Improve after Liver Transplantation** Donna S. Sanders,[1] Mohamed Mokhtar Desouki,[3] Stephen Osaguona,[1] Wayne R. Fitzgibbon,[1] Juan Carlos Q. Velez.[1] *[1]Medicine, MUSC, Charleston, SC; [2]Lifeline Vascular Center, Wichita, KS; [3]Pathology, MUSC, Charleston, SC.*

IgA nephropathy (IgAN) presents as primary or secondary glomerulonephritis. The most common cause of secondary IgAN is end-stage liver disease (ESLD). Because of the bleeding risks intrinsic to ESLD, subjects with IgAN secondary to ESLD (ESLD-IgAN) are rarely biopsied. Thus, the histopathological features of this entity, compared to primary IgAN, are poorly recognized. Moreover, the prognosis after liver transplantation (OLT) is not well known. Therefore, we reviewed non-transplant kidney biopsy of all IgAN cases diagnosed at our institution from 1994 to 2009 (n=57), in order to compare the histology of ESLD-IgAN with primary IgAN. We found 8 cases (14%) of ESLD-IgAN. In comparison to primary IgAN (n=49), we observed a significant increase in membranoproliferative (MPGN) changes [glomerular basement membrane (GBM) double contour] in ESLD-IgAN (p<0.001). Similarly, we found an increase in C1q by immunofluorescence (p<0.005) as well as in reduplication of the GBM and subendothelial and mesangial deposits by electron microscopy (p<0.01). Subjects with ESLD-IgAN were all male, older (52 ± 8 vs. 36 ± 9) and had a higher serum creatinine at the time of the biopsy (4.7 ± 2.6 vs. 2.3 ± 0.5 mg/dl). Positive Hepatitis C viral (HCV) serology did not account for the MPGN features [3 of 5 HCV (-) cases had MPGN features vs. 1 of 3 HCV (+) cases]. Three patients with ESLD-IgAN underwent OLT. At 6 months post-transplant, none of the patients had resolution of hematuria or proteinuria or improvement in kidney function. One patient had a biopsy 4 months post-OLT showing persistence and worsening of the IgAN findings. In conclusion, ESLD-IgAN commonly has histological features of MPGN that are not accounted by positive HCV serology. Liver transplantation does not uniformly result in reversal of ESLD-IgAN as has been previously reported. Prospective studies are needed to improve our understanding of this entity and design outcome-oriented strategies.

**Tumor Necrosis Factor-α Gene (TNFA) G-308A Polymorphism Is Not Associated with IgA Nephropathy (IgAN): A Meta-Analysis** Ioannis Stefanidis,[1] Theodoros Eleftheriadis,[1] Christos Bantis,[4] Peter R. Mertens,[2] Vassilios Liakopoulos.[3] *[1]Nephrology, University Thessaly, School of Medicine, Larissa, Thessaly, Greece; [2]Nephrology, Otto von Guericke University Magdeburg, School of Medicine, Magdeburg, Germany; [3]Nephrology Ahepa Hospital, School of Medicine, Aristoteleion University, Thessaloniki, Greece; [4]Nephrology, Hippokrateion Hospital, School of Medicine, Aristoteleion University, Thessaloniki, Greece.*

Tumor necrosis factor α (TNF-α) is an inflammatory cytokine, pathogenetically involved in IgAN. A polymorphism in the promoter region, at position -308 (G/A) of TNFA is associated with increased TNF-α production. However, previous association studies of this polymorphism and IgAN rendered contradictory findings. Therefore, a meta-analysis of these association studies was conducted.

Five studies involving 723 cases of IgAN and 910 healthy controls were analyzed. Three included European and two east Asian populations. The meta-analysis examined the association of allele A with IgAN or with progressive IgAN relative to allele G. Associations were indicated as odds ratios (OR) with the corresponding 95% confidence interval (ci). Heterogeneity between studies was tested using the Q-statistic.

Meta-analysis suggested large heterogeneity between studies (p=0.024, $I^2$=64%) and no significant association between G-308A transition and the risk of developing IgAN: random effects OR=0.78[95%ci(0.54, 1.13)]. Sensitivity analysis (exclusion of one European study with controls not in HWE) showed no heterogeneity (p=0.15, $I^2$=44%) and no significant association: fixed effects OR=0.93[95%ci(0.72, 1.20)] and random effects OR=0.90[95%ci(0.64, 1.27)]. Both, subgroup analysis for the Asian and the European population, and sensitivity analysis in the Caucasian population, produced no significant association. For studies investigating the role of the polymorphism in IgAN progression, no significant association overall and in subgroups was detected.

There was no significant association between TNFA G-308A polymorphism and the development or progression of IgAN. Analysis is based on a relatively small number of studies and participants and any inferences have to be cautious.

## SA-PO2299

**Skin-Autofluorescence Is Associated with Amount of Proteinuria and Tubulointerstitial Damage in Patients with IgA Nephropathy** Kenichi Tanaka, Yoshihiro Tani, Jun Asai, Yuki Kusano, Hodaka Suzuki, Yoshimitsu Hayashi, Koichi Asahi, Tsuyoshi Watanabe. *Nephrology and Hypertension, Fukushima Medical Univerity, Fukushima City, Japan.*

**Background.** Tissue accumulation of advanced glycation end-products (AGE) is thought to be a contributing factor to the progression of vascular complications in renal disease. Our recent study showed that skin AGE accumulation is related to renal function and cardiovascular disease in chronic kidney disease (CKD) patients (*Nephrol Dial Transpl; in press, 2010*). The present study aimed to evaluate relationships of skin AGE accumulation to clinical parameters such as proteinuria and histopathological damage in IgA nephropathy (IgAN) patients in early stage of CKD.

**Methods.** Subjects in this cross-sectional analysis comprised 50 untreated biopsy-proven IgAN patients (median age, 54.0 years; median eGFR, 66.3 ml/min/1.73 $m^2$; CKD stage 1, n=12; stage 2, n=16; stage 3, n=22). Patients with diabetes or CKD stage over 4 were excluded. AGE accumulation in skin was assessed by skin-autofluorescence (AF) using an AF reader at the time of renal biopsy. Histopathological changes were classified into four glomerular grades and three tubulointerstitial grades. Relationships between skin-AF, clinical parameters, and histopathological grade were evaluated.

**Results.** Skin-AF significantly correlated with age (r=0.45, *P*<0.01), systolic blood pressure (r=0.36, *P*<0.01), diastolic blood pressure (r=0.45, *P*<0.01), amount of proteinuria (r=0.35, *P*=0.01), duration of proteinuria (r=0.39, *P*<0.01), eGFR (r=-0.60, *P*<0.01), glomerular grade (r=0.43, *P*<0.01), and tubulointerstitial grade (r=0.43, *P*<0.01). Multiple regression analysis revealed significant correlations of skin-AF with age (β=0.46, *P*<0.01), amount of proteinuria (β=0.26, *P*=0.02), and tubulointerstitial grade (β=0.30, *P*=0.01) ($R^2$=0.54).

**Conclusions.** Tissue AGE accumulation measured as skin-AF was independently related to amount of proteinuria and tubulointerstitial damage in IgAN patients in early stage of CKD. Non-invasive AF readers may provide useful additional markers for clinical risk assessment in daily practice, reflecting renal histopathological change in these patients.

## SA-PO2300

**Medium Dose of Cyclosporine Combined with Methlprednisolone in IgA Nephropathy: Prospective Randomized Controlled Trial** Hong Liu, Xiaoqiang Ding, Yi Fang, Xialian Xu, Xiaoyan Zhang, Yihong Zhong. *Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

**Background.** IgA nephropathy (IgAN) is the most common form glomerulonephritis in worldwide. Approximately 30% of patients will progress to end-stage renal disease (ESRD) after 10-20 years. High dose cyclosporine A (CsA) can reduce proteinuria but have no renal protective effect. In this study, we aim to evaluate the effects of a combined therapy with medium dose of CsA and methprednisolone on clinic outcomes.

**Methods.** It is a prospective randomized controlled trial.43 IgAN patients aged 18-70 years with proteinuria >1g/24hours and eGFR≥30ml/min.1.73$m^2$ . Patients were divided into two groups: (1)full-dose steroid treatment group (methlprednisolone 0.8mg/kg for 8 weeks gradually reduced to maintenance doses 4mg/d), and (2)combined therapy group (methprednisolone 0.6mg/kg and CsA 3mg/kg/d as the initial dosage, then maintained with 4mg/d and 25-50mg/d, respectively. ) The primary end point was reduction of proteinuria by 50% or more. Secondary end point was a 50% increase of serum creatinine level or 25% decrease in eGFR.

**Results:** After 12 months treatment, 24 hr urinary protein excretion declined from 3.23±3.31g to 0.37±0.23g (*P*=0.002) in combined therapy group. Patients in steroid group also experienced a significantly remission on proteinuria (0.38±0.27g/24h vs 2.87±2.20 g/24, P=0.0001). The complete remission rate was 52.63% and 47.37% in combiened group and steroid group respectively. Patients undertook combined therapy achieved significantly improvement on eGFR after 9 months (91.0±32.02 vs 78.75±23.12ml/min.1.73$m^2$, P=0.02)while the steroid group patients achieved significantly increased of eGFR after 3 months(100.10±28.10 to 86.46±26.12 ml/min.1.73$m^2$ (P=0.011). The incidence of a transient drop of eGFR (<25%) was 27.27% in combined therapy group and 4.76% in steroid group .

**Conclusion:** Full dose of steroid treatment and the combined therapy with medium dose of CsA and steroid both can remarkably reduce proteinuria and ameliorate renal function in patients with IgAN without sever adverse events, however, the combined trerapy didn't show any additional benefit on outcomes.

**Prognostic Factors in Childhood IgA Nephropathy with Focal Mesangial Proliferation Treated with Angiotensin Converting Enzyme Inhibitors**
Yuko Shima,[1] Koichi Nakanishi,[1] Hiroko Togawa,[1] Hironobu Mukaiyama,[1] Taketsugu Hama,[1] Kandai Nozu,[2] Ryojiro Tanaka,[3] Kazumoto Iijima,[2] Norishige Yoshikawa.[1] *[1]Pediatrics, Wakayama Medical University, Wakayama City, Wakayama, Japan; [2]Pediatrics, Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan; [3]Pediatric Nephrology, Hyogo Prefectural Kobe Children's Hospital, Kobe, Hyogo, Japan.*

Objective: It is generally considered that the prognosis of childhood IgA nephropathy (IgAN) is unpredictable. In Japan since the beginning of the 1990s, generally in pediatric area, angiotensin converting enzyme inhibitors (ACEIs) have been used for children with IgAN showing focal mesangial proliferation (FMP). Details of the effectiveness and prognostic factors of them remain unclear. The purpose of this study is to clarify them in childhood IgAN with FMP treated with ACEIs.

Methods: We analyzed retrospectively consecutive 65 children with newly diagnosed childhood IgAN with FMP treated with ACEIs from August 1987 to October 2007 and observed for more than 2yrs after the start of ACEIs treatments.

Results: Mean observation period was 4.1±1.9 years. Among 65 children, 28 children (43.1%) showed proteinuria remission after 2yrs of ACEIs treatments. There was no significant difference in clinical findings (onset mode, blood pressure, urinary protein excretion, and serum IgA level) and in pathological findings (scleroses, crescents, adhesions, and mesangial proliferation) depending on proteinuria remission after 2 yrs of ACEIs treatments.

The prognostic factor related to proteinuria remission after 2 yrs of ACEIs treatments was the ratio of glomeruli showing crescents at diagnosis in multivariate analyses (OR 0.66, 95%CI 0.41-0.88, p=0.02). The cut off point of the ratio in ROC curve was 8.8%.

Conclusions: The proteinuria remission rate in childhood IgAN with FMP after 2 yrs of ACEIs treatments was 43.1%. If the patients show the ratio of glomeruli showing crescents of over 8.8%, we may have to consider another treatment option, because such patients are likely to be refractory to ACEIs treatments.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2302**

**Urinary Angiotensinogen Reflects Clinico-Pathological Findings in IgA Nephropathy**
Chun-Gyoo Ihm, Se-Bin Song, Dongyoung Lee, Ju-Young Moon, Kyung-Hwan Jeong, Tae Won Lee. *Division of Nephrology, Kyung Hee University, School of Medicine, Seoul, Republic of Korea.*

**Introduction**: Urinary angiotensinogen (uAGT) provides a specific index of intrarenal renin-angiotensin system (RAS). However, its role is not evident in IgA nephropathy (IgAN). This study was performed to exam the levels of uAGT in patients with IgAN and to find the relation of uAGT to clinicopathologic findings and mRNAs of renin, angiotensin converting enzyme (ACE) and ACE2 from renal biopsy tissue.

**Methods**: Forty patients with IgAN and 15 healthy volunteers were included. Samples of serum and random morning urine were obtained. The AGT concentration was measured with commercial human ELISA kits.

**Result**: The patients with IgAN had higher uAGT (113.1 ng/mgCr vs 9.5 ng/mgCr) and lower GFR (82.6 mL/min/1.73m$^2$ vs 116.6 mL/min/1.73m$^2$) compared with those of healthy volunteers. When patients were grouped by their uAGT levels of above (Group A) and below 100 ng/mgCr (Group B), group A showed significantly lower eGFR (65 vs 87 mL/min/1.73 m$^2$) and higher urine protein/creatinine ratio (PCR) (2.91 vs 0.78 g/gCr) and higher degree of hematuria (3.5 vs 2.8 grade) compared to group B. uAGT levels correlated with serum AGT levels (r=0.33), amount of proteinuria (r=0.45), diastolic blood pressure (r=0.32), tubulointerstitial inflammation (r=0.52) and tubular atrophy (r=0.52) in pathologic findings. Also uAGT correlated negatively with Δurine PCR at 0-3mo (r=0.41) regardless of treatment. However, it had no correlation with renin, ACE and ACE2 mRNAs from renal biopsy tissue.

**Conclusion**: uAGT can be considered a good index of clinic-pathological activity in IgAN.

**SA-PO2303**

**IgA-Dominant Postinfectious Glomerulonephritis**
Tai Yeon Koo,[1] Jung-Sik Park,[1] Gheun-Ho Kim,[2] Moon Hyang Park.[3] *[1]Department of Internal Medicine/Division of Nephrology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; [2]Department of Internal Medicine/Division of Nephrology, Hanyang University College of Medicine, Seoul, Korea; [3]Department of Pathology, Hanyang University College of Medicine, Seoul, Korea.*

**Background:** Pathologic findings in postinfectious glomerulonephritis (PIGN) are various, and the subtypes may have different clinical significances. IgA-dominant PIGN was recently reported as a unique subtype of PIGN, but its clinicopathologic features were not clearly characterized. We present demographic, clinical and renal biopsy findings from 7 patients with IgA-dominant PIGN.**Methods:** All renal biopsy specimens (n=1119) processed from 2005 to 2009 by the Department of Pathology in Hanyang University Hospital, Seoul, Korea were reviewed. Seven patients with IgA-dominant PIGN were identified, and their clinical data were analyzed. **Results:** The patient age ranged from 31 to 84 years, and males were 6 out of 7. All glomeruli showed diffuse endocapillary proliferation, infiltration of neutrophils, granular IgA and C3 deposits along the peripheral capillary walls and in the mesangium, and subepithelial 'humps' with intramembranous and mesangial electron dense deposits. All patients had renal insufficiency (mean serum creatinine ± SD,3.1±1.0 mg/dL), hematuria and heavy proteinuria. End-stage renal disease was developed in 2 patients, chronic renal failure was stationary in 2, and azotemia was improved in 3. Two patients had recent methicillin-resistant *Staphylococcus aureus* infection, and one recent Rickettsial infection. Only one was diabetic, and none of our patients had any underlying renal disease. **Conclusions:** We demonstrate that IgA-dominant PIGN is various in its causes of preceding infection, demographic profiles, course and prognosis. It is often associated with overt staphylococcal infections, and the underlying infection may be subclinical or rickettsial. Both non-diabetic and diabetic patients can be subject to this form of PIGN. The prognosis could be despaired in some cases with PIGN, and other bad prognostic factors than underlying diabetic nephropathy and renal insufficiency should be identified

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2304**

**The Oxford IgA Nephropathy Classification Predicting 1-Year Renal Outcome**
Youngki Lee,[1] Seung Min Lee,[1] Soo Jin Kim,[1] Sung Gyun Kim,[1] Jong-Woo Yoon,[1] Ja-Ryong Koo,[1] Jung-Woo Noh,[1] Mi Kyung Shin,[2] Eun Suk Nam,[2] Ji Eun Oh.[1] *[1]Department of Internal Medicine, Hallym Kidney Research Institute, Hallym University, Seoul, Republic of Korea; [2]Department of Pathology, Hallym Kidney Research Institute, Hallym University, Seoul, Republic of Korea.*

**Background:** There had been no international consensus for pathological classification for IgA nephropathy until Oxford classification was presented in 2009. Oxford classification was reported to predict the average rate of renal function decline. But it did not show the association of renal outcome with the pathologic lesions at specific time-point. The present study tested whether Oxford classification is useful to predict renal outcome of patients with IgA nephropathy at 1-year after biopsy.

**Methods**: The diagnosis of IgA nephropathy was made between 2006 and 2009 on 181 adult patients. We retrospectively re-analyzed the cohort according to Oxford classification system for IgA nephropathy and collected clinical parameters within 1 months of date of biopsy and during 1-year follow-up. We also included the global sclerosis for clinical relevance in the patients.

**Results:** The subjects consisted of 90 males and 91 females. At the time of renal biopsy, the median age was 37 years (18-77 years). There were a median number of 17 glomeruli per biopsy. By Oxford classification, 52.5% and 48.7% of patients had mesangial hypercellularity or segmental glomerulosclerosis. Tubular atrophy/interstitial fibrosis was seen in 63 cases (34.8%). Severe pathologic lesions by Oxford classification were correlated with high grade WHO classification. Mesangial score, segmental glomerulosclerosis, tubular atrophy/interstitial fibrosis, and global sclerosis were strongly associated with eGFR at the time of biopsy. By multivariate analysis, the rate of renal function decline at 1-year was significantly associated only with tubular atrophy/interstitial fibrosis.

**Conclusions:** The study demonstrates tubular atrophy/interstitial fibrosis has an independent value in predicting 1-year renal outcome of patients. Other pathologic lesions of Oxford classification and global sclerosis were correlated with renal function at the time of biopsy but not at 1-year.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2305**

**Graft-Versus-Host Disease and Membranous Nephropathy in Patients of Post-Allogeneic Haematopoietic Stem Cell Transplantation**
Xiang-Hua Huang,[1] Wei-Song Qin,[1] Ming-Chao Zhang,[1] Chun-Xia Zheng,[1] Cai-Hong Zeng,[1] David J. Salant,[2] Zhi-Hong Liu.[1] *[1]Research Insitute of Nephrology, Jinling Hospital, Nanjing, Nanjing, Jiangsu, China; [2]Boston University School of Medicine, Boston, MA.*

We studied the clinical and pathological features and pathogenesis of the patients with post-allogeneic haematopoietic stem cell transplantation (Allo-HSCT) membranous nephropathy (MN) and investigated the relationship between the Allo-HSCT MN and graft-versus-host disease (GVHD). Five patients with Allo-HSCT MN which proved by renal biopsy were involved in this study. The clinical manifestations, laboratory data, and morphology, immunefluorescence and electron microscopy of the renal pathology of those patients were analyzed. Moreover, the IgG subclasses in glomerular deposits and the co-deposition of nephrin and IgG4 were studied. Finally, We detected the Anti-PLA2R(M-type phospholipase A2 receptor) autoantibodies in serum samples from patients with Allo-HSCT MN. The following items are the clinical and pathological features of the 5 patients: (1) All of the 5 patients have no history of kidney disease. (2) All patients were combined with the syndrome of chronic GVHD at the time of proteinuria presence, and 4 patients had a history of acute GVHD, after an effective anti-GVHD treatment, the patients' proteinuria all remissioned. (3) The autoantibodies for some of the patients were positive and were accompanied by the deposition of C4 and C1q in kidney, suggesting the existence of autoimmune phenomenon. (4) The IgG subclasses showed that all patients were positive for IgG1 and IgG4, and negative for IgG3. The staining intensity of IgG1 and IgG4 were the same in two cases, but in three cases the dominant subclass of IgG deposition was IgG4. Moreover, the distribution of IgG4 was as same as nephrin.(5) The Anti-PLA2R autoantibodies were negative other than one case with positive result.

Our data suggest that the MN of Allo-HSCT patients is a form of cGVHD. It is characterized by coincidence of proteinuria and cGVHD, remission of proteinuria after anti GVHD immunosuppressant therapy, and the Anti-PLA2R autoantibodies were negative in most of the patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2306**

**Efficacy, Durability, and Immunological Analyses Following Rituximab Therapy in Idiopathic Membranous Nephropathy: A 2-Year Study**
Fernando C. Fervenza,[1] Roshini Abraham,[1] Stephen B. Erickson,[1] Maria V. Irazabal-Mira,[1] Alfonso Eirin,[1] Ulrich Specks,[1] Patrick H. Nachman,[2] Eric J. Bergstralh,[1] Nelson Leung,[1] Fernando G. Cosio,[1] Marie C. Hogan,[1] John J. Dillon,[1] LaTonya J. Hickson,[1] Daniel C. Cattran.[3] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Division of Nephrology and Hypertension, UNC, Chapel Hill, NC; [3]Division of Nephrology, University of Toronto, Toronto, ON, Canada.*

**Introduction:** Pharmacokinetic (PK) analysis in patients with Membranous Nephropathy (MN), treated with Rituximab (RTX) dosed at 1g x 2 showed that RTX levels were 50% lower compared to non-proteinuric patients. This study tested the hypothesis that weekly doses of RTX would result in more effective B cell depletion, a higher remission rate while maintaining the same safety profile.

**Methods:** Twenty patients (11 failed prior therapy) with MN and proteinuria (P) >5g/24h received RTX (375mg/m$^2$ x 4), with retreatment at 6 mo regardless of P response. Analysis of B and T cell subsets were performed to clarify the role of RTX on lymphocyte subpopulations. A detailed PK analysis was also repeated.

**Results:** Baseline P=11.9±4.9g/24h decreased to 4.2±3.8g/24h and 2.0±1.7g/24h at 12 and 24 months, respectively (p<0.001) while creatinine clearance increased from 72.4±33 at baseline to 90.2 ±32 ml/min/1.73m$^2$ at 24 months (p=0.02). Of 18 patients who completed 24-mos follow up, 4 are in complete remission, 12 are in partial remission, 1 has a limited response (>50% drop in P but >3.5g/24h) and 1 relapsed. Serum RTX levels were similar to those obtained with 2 doses of RTX.

**Conclusion:** Four weekly course of RTX is effective in reducing P in a significant number of patients with MN, however, P reduction was similar to RTX 1g x 2. B cell depletion was more profound and persisted longer when compared to our previous study. We found no baseline B cell abnormalities nor any quantitative abnormalities in B cell subsets that helped predict response to RTX therapy.

**PLA2R Specific Autoantibodies in Patients with Membranous Glomerulonephritis (MN) – The Effect of Rituximab**
Elion Hoxha,[1] Kai Fechner,[2] Sigrid Harendza,[1] Rolf A. Stahl.[1] *[1]Department of Internal Medicine III, University Hospital Eppendorf, Hamburg, Germany; [2]Institute of Experimental Immunology, EUROIMMUN AG, Lübeck, Germany.*

Background

Idiopathic membranous glomerulonephritis (IMN) is a leading cause of the nephrotic syndrome in adults. Autoantibodies (AAb) against M-type phospholipase A2 receptors (PLA2R) might be involved in disease induction. PLA2R in the kidney are exclusively expressed on glomerular podocytes. Detection and titration of AAb in patients with IMN may help to guide therapy and the monitoring of therapeutic effectiveness.

Methods

In 12 patients with biopsy proven MN, PLA2R-specific AAb titers were measured in serum by indirect immunofluorescence using HEK293 cells which were transiently transfected with full-length PLA2R isoform 1 cDNA. In addition to supportive therapy (ACE-i, ARB, diuretics, statins, anti-coagulation) or immunosuppressive therapy (3 patients with glucocorticoids, 2 with glucocorticoids + MMF, 1 with glucocorticoids + CNI) all patients were treated with 375 mg/m² rituximab (RTX). 10 patients had at least 1 immunosuppressive therapy before RTX therapy.

Results

PLA2R-specific AAb were detected in 7 of 12 patients tested. Following RTX therapy, anti-PLA2R-AAb levels decreased in 4 patients within 1 week (w), 2 of these patients had no detectable AAb after 3 and 6 months (m), respectively. 1 patient had a decrease in AAb levels after 3m, 2 had constant levels over 3m.

In 3 patients anti-PLA2R-AAb levels increased 3m to 6m after RTX therapy. In 1 of these patients, anti-PLA2R-AAb levels never decreased after RTX. In the other 2 patients anti-PLA2R-AAb levels decreased after RTX therapy and increased again after 3m and 6m.

Proteinuria decreased in all patients with decrease in AAb titers. Patients with an increase in AAb titers had a paralleled increase in proteinuria.

Conclusions

58.3% of our patients with biopsy proven MN had anti-PLA2R AAb in serum. Changes in AAb titer upon RTX therapy were paralleled by changes in proteinuria.

These results indicate that anti-PLA2R AAb may help to guide and monitor the follow-up of patients with IMN following RTX. A prospective study in a large cohort, however, is necessary to validate these preliminary findings.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2308**

**Glycan Analysis of Serum IGG4 in Idiopathic Membranous Nephropathy Using Lectin Microarray**
Aki Kuroki,[1] Yoshiki Narimatsu,[2] Hiromi Itoh,[2] Hisashi Narimatsu,[2] Tadao Akizawa.[1] *[1]Division of Nephrology, Department of Medicine, Showa University, Tokyo, Japan; [2]Research Center for Medical Glycoscience, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan.*

IgG4, the major IgG subclass in glomerular deposits and of anti-phospholipase A2 receptor (PLA2R) antibody (Ab) in idiopathic membranous nephropathy (IMN), is incapable of activating the classical complement pathway. However, experimental and clinical investigations indicate that complement dependent mechanism may play roles in podocytes damage. These suggest the possibility that the alternative or mannan binding lectin pathways may be involved in the pathogenesis of the disease. In this study, we analyzed serum IgG4 glycan profiles using lectin microarray to examine whether IgG4 in IMN have unique glycan structure, which is responsible for activating the complement pathway.

Serum samples were obtained from 6 patients with IMN, 4 patients with benign nephrosclerosis (BNS), 2 patients with minimal change disease (MCD), and 6 healthy individuals (normal control, NC). From each sample, IgG4 was enriched by immunoprecipitation with anti-IgG4 Ab. For glycan analysis, IgG4 were labeled with Cy3 and were subjected to lectin microarray in serial dilutions. The glycan profiles were analyzed using the dilution, which showed the comparable concentration of IgG4. Signal intensity was standardized using the lectin, which showed a good linearity in the dose-response curve in all of the samples.

From 10µl of sera, 0.5-1.0µg of IgG4 were obtained without contamination of IgG1or IgM. Compared to the NC group, the IMN group showed slightly higher signals for core fucose (Fucα1-6GlcNac) binders (e.g. PSA and LCA) and α2-6 Sialic acid binder (e.g. SNA and SSA). However, those IgG4 glycan profiles found in IMN were also found in the BNS and the MCD group.

In summary, although serum IgG4 in IMN patients showed a particular glycan structure compared to the NC group, this structure was also found in other proteinuric diseases. Further studies, analyses of glycan profiles of IgG4 anti-PLA2R Ab, or IgG4 eluted from the kidneys of IMN are required to understand the role of mannan binding lectin pathway in IMN.

**Efficacy and Safety of Mycophenolate Mofetil for Patients with Idiopathic Membranous Nephropathy: A Systematic Review**
Yan Song, Jianyong Wu, Jianghua Chen. *Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.*

Mycophenolate mofetil (MMF), an immunosuppressive drug acting by impairing *de novo* purine synthesis in T and B lymphocytes, was recently off-label used for treating idiopathic membranous nephropathy (IMN). We searched PubMed database to perform a systematic review of relevant English-language articles until September 2009. Articles accessing the efficacy and safety of MMF for treating IMN were included in this review. Sixteen articles including 153 patients, composed of 3 randomized controlled trials (RCTs), 1 clinical controlled trial, 5 observational studies, 5 case series, and 1 case report, were included in this review. Results were described qualitatively instead of being pooled because of heterogeneity of the included studies. Most patients were steroisds/immunosuppressants-resistant. Two RCTs showed that MMF therapy (concomitant with steroids) was as effective as the comparative immunosuppressants to reduce proteinuria. However, one RCT showed that MMF monotherapy had no benefit to proteinuria comparing with conservative treatment. Most observational studies without controls and case series/reports showed MMF was efficient in decreasing proteinuria. Adverse effects were not well described in most studies. MMF can effectively reduce proteinuria and improve/stabilize renal function in most reported studies. However, the evidence did not show that the drug is superior to conventional immunosuppressants. Adverse effects of MMF for treating IMN were not well described in most studies. Double blind RCTs with larger number of patients and longer term follow-up are required to evaluate the efficacy and safety of MMF monotherapy in IMN patients.

Disclosure of Financial Relationships: nothing to disclose

**Tacrolimus Monotherapy for Idiopathic Membranous Nephropathy: Long Term Outcomes**
Marie B. Condon, Nicholas R. Thomas, Neill D. Duncan, Tom Cairns, Megan Griffith. *Imperial College Kidney and Transplant Institute.*

Nephrotic syndrome secondary to idiopathic membranous nephropathy (IMN) is associated with poor renal out come. We have previously reported effective induction of remission with tacrolimus (Tac) monotherapy. We now report the long term outcomes of Tac monotherapy.

Longterm data was available on 29 nephrotic patients (20 male, 49+/-15.1yrs) with biopsy proven IMN commenced on tacrolimus monotherapy. 5 patients were converted from CyA and 3 from oral pred. In addition all received standard treatment with ace inhibitors/ARB. Complete remission (CR) was defined as a normal serum albumin with proteinuria <0.5g/day, partial remission (PR) as normalisation of serum albumin (>33g/l) with residual proteinuria,

Mean follow up was 45.3+/-20.28 months. Mean serum albumin at presentation was 21.3+/-6.4g/L. Remission was achieved in 24 patients (82.7%) at an average of 18.3+/-13.2 months: 18 (75%) achieved CR and 6 (25%) achieved PR.

3/24 patients achieving remission on Tac relapsed whilst on Tac at 34+/-22.7 months post remission, they have been switched to alternative treatment regimes.

5/24 in CR had Tac withdrawn. Time on Tac 49.6+/-17.6mths. Pre withdrawal biopsies were done on 2 patients, both showed resolving lesions with no new deposits. 3/5 have relapsed at 5+/-1.73 months post Tac withdrawal, including those biopsied. 2 of the 5 patients remain in remission off Tac at 7 and 18 months respectively.

16/24 remain on Tac (mean duration 44.8+/-20.8 months) their mean current creat is 124.7+/-48.0umol/L, which is not a significant difference from their baseline mean creat of 108.3+/-41.2umol/L (p=0.047 paired t-test).

5 patients did not achieve remission; 2/5 have also failed to achieve remission with alternative immunosuppressive regimes, suggesting resistant disease, 1/5 achieved PR with the addition of Mycophenolate mofetil.

Tac is an effective treatment of IMN, but longterm treatment is often required, and patients relapse both on and off treatment. Additional work on predictors of relapse including biopsy features is required. Additional agents may be needed to prevent relapse, and this is currently being investigated (Clinical trials.gov ref no. NCT00843856)

**ACTH Treatment of Nephrotic Patients with Membranous Nephropathy – Long Time Follow Up** Anna-Lena Berg. *Department of Nephrology, University Hospital, Lund, Sweden.*

**Background**

In 1994, we published the novel finding that ACTH at pharmacological dosage has a considerable lipid-lowering effect in healthy subjects. Short-term treatment with ACTH decreased ApoB-containing lipoproteins also in patient groups with various lipid disorders. In one of the follow-up studies of the ACTH-specific lipid-lowering effect I also found an ACTH-specific antiproteinuric effect in patients with membranous nephropathy. Synthetic adrenocorticotrophic hormone (ACTH 1-24) has been given to nephrotic patients with membranous nephropathy in about 15 years at the department of nephrology, university hospital in Lund, Sweden.

**Methods**

ACTH was given subcutaneous first 1 mg weekly during four weeks then increased to 0.75 mg and later in some patients to 1 mg twice a week. The treatment continued at this dose until two months after clinical remission and then it was lessened during three months. The patients were individually treated during about 9 to 15 months. 30 of the treated patients have been observed in this follow up study.

**Result**

The results in 30 patients after 8 (3-13) years are presented (medians). Before treatment albumin in urine was 7.92 (3.71-16.32) g/L, in serum 19 (10-27) g/L and serum creatinine was120 (46-310) micromol/L and at the end of the follow-up period the values were 0.19 (0-1.30) g/L, 38 (32-48) g/L and 128 (42-388) micromol/L respectively. Five of the 30 patients had relapsed during the follow up period and were treated again with ACTH. One patient developed end stage kidney disease and received a kidney transplant.. The side effects during ACTH treatment were mild and reversible.

**Conclusion**

Most of the patients seem to have a lasting decrease of albumin in the urine and a lasting increase in the serum after treatment. Serum creatinine was unchanged after the follow up period.

Speculations

Glucocorticosteroids has unproven effect on membranous nephropathy. ACTHs effect in membranous nephropathy might be mediated by melanocortinreceptors, (MCR 1-5). MCR 1 and 3 are known to be located in white blood cells and MCR 1 in the kidney. MCR 2 acts in the adrenals for production of cortisol.

## SA-PO2312

**Anti-PLA2R-Antibodies in a Patient Recurrent Membranous Nephropathy after Renal Transplantation** Elion Hoxha,[1] Kai Fechner,[2] Rolf A. Stahl.[1] *[1]Department of Internal Medicine III, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Institute for Experimental Immunology, EUROIMMUN AG, Lübeck, Germany.*

Introduction

Up to one third of patients with membranous nephropathy (MN) develop end stage renal disease (ESRD). Following renal transplantation MN recurs in up to 40% of patients. Recurrence of disease is often seen at a very early stage, even days after transplantation. The recently discovered autoantibodies (AAb) against M-type phospholipase A2 receptor (PLA2R) which may be responsible for the induction of idiopathic MN, could play a major role in recurrent MN after renal transplantation.

Methods

In three patients with biopsy proven MN, PLA2R-specific AAb titers were measured from serum collected before and after renal transplantation. AAb titers were measured by indirect immunofluorescence (IIF). HEK293 cells were transiently transfected with full-length PLA2R isoform 1 cDNA and used as substrates for IIF.

Results

Anti-PLA2R-AAb could be detected in serum from one patient before renal transplantation. Three days after transplantation the patient developed proteinuria, which increased to 9 g/24h. After renal biopsy showed recurrent MN, the patient was treated with 375 mg/m² rituximab in addition to the standard immunosuppressive therapy with mycophenolate mofetil, cyclosporine and corticosteroids. Following rituximab, anti-PLA2R-AAb levels fell from 1:100 to 1:10 at 3 months and remained at 1:10 after 5 months. Proteinuria decreased from 9.0 g/24h to 3.1 mg/24h after 5 months.

The remaining two patients had no detectable anti-PLA2R-AAb in serum before transplantation or during the follow-up time, 3 months and 1 year respectively. In this time, both these patients showed no proteinuria and no recurrence of disease.

Conclusions

Anti-PLA2R-AAb can be persistent in patients with endstage renal disease due to membranous nephropathy. These AAb could be responsible for the recurrence of MN in the renal transplant. Measurement of anti-PLA2R-AAb titers of patients with MN on dialysis prior to renal transplantation may discover a potential risk for recurrence of disease in the transplant and may modify immunosuppressive therapy for these patients.

## SA-PO2313

**Successful Remission Induction of Nephrotic Syndrome in a Patient with M-Type Phospholipase A2 Receptor (PLA2R) Autoantibodies with Immunoadsorption Therapy Followed by Rituximab** Mario Schiffer, Jan T. Kielstein, Bernhard M. W. Schmidt, Hermann G. Haller, Marion Haubitz. *Nephrology, Hannover Medical School, Hannover, Germany.*

**Background:** Recently a close association of idiopathic membranous nephropathy and autoantibodies against the M-type phospholipase A2 receptor (PLA2R) was described. However, even though 70-80% of patients are positive for anti-PLA2R-antibodies a real causative relationship has not been conclusively demonstrated. Here we describe a case where the Ponticelli-Scheme was not successful for remission induction, however immunoadsorption therapy and rituximab treatment led to remission induction which correlated with the reduction of anti-PLA2R-antibody levels.

**Case report:** A 37 year old patient was diagnosed with idiopathic membranous nephropathy (II-IV) in October 2005 after the patient had developed a pulmonary embolism. Proteinuria was 22 g/day and renal function was normal. Treatment with prednisolon and cyclosporin led only to a transient and insufficient reduction in proteinuria (13g/d) and renal function detoriated. Cyclosporin A was stopped and steroids and oral cyclophosphamide (in monthly alteration, according to the Ponticelli-Schema) was initiated. Renal function was stabilized but only a partial and transient improvement was seen (proteinuria 6g/d). In January 2010 the patient presented with a proteinuria of 17g/d MDRD-clearance was 80 ml/min at that time. The patient was diagnosed to be highly positive for anti-PLA2R-antibodies and was treated with 5 cycles of immunoadsorption therapy with a Globaffin®adsorber (Fresenius Medical Care, Germany) which contains synthetic peptide-GAM® as ligand known to be very effective in binding of IgG4 and in addition he received 4 cycles of rituximab (375mg/m2). Proteinuria 2 months after treatment was 8.3g/d and further decreased to 5g/d 3months after treatment (at the time of abstract submission). **Conclusion:** This case indicates a good correlation with anti-PLA2R-antibodies and proteinuria and demonstrates a successful partial remission induction by removal of anti-PLA2R-antibodies using immunoadsorption and rituximab.

## SA-PO2314

**Maintenance of Hemoglobin Levels with Once-Monthly C.E.R.A. in Patients with Chronic Kidney Disease Not on Dialysis: The PRADO Study** Jean-Philippe Ryckelynck,[1] Vincent L. M. Esnault,[2] Bertrand Knebelmann,[3] Maurice Laville,[4] Christophe Pompon,[5] Bernard Richalet.[6] *[1]Nephrology, CHU Clemenceau, Caen, France; [2]Nephrology, CHU Pasteur, Nice, France; [3]Nephrology, CHU Necker, Paris, France; [4]Nephrology, CHU E. Herriot, Lyon, France; [5]Roche, Neuilly-sur-Seine, France; [6]Nephrology, CH Memorial France Etats-Unis, Saint-Lo, France.*

**Objective:** Methoxy polyethylene glycol-epoetin beta is a Continuous Erythropoietin Receptor Activator (C.E.R.A.) approved for once-monthly treatment of renal anemia in chronic kidney disease patients. This prospective, single-arm, open-label, multicentre study investigates direct switch from shorter acting Erythropoiesis Stimulating Agents (ESA) to once-monthly C.E.R.A. in a real-life setting.

**Material and Methods:** Predialysis patients with stable ESA treatment and adequate iron status were directly converted from SC epoetin β or darbepoetin α to SC C.E.R.A. once-monthly for a periode of 48 weeks (16 for dose ajustment, 8 for evaluation and 24 for follow-up). We here report on the primary endpoint: Hb stability between 10 and 12g/dL during evaluation (weeks 16-24).

**Results:** 127 patients were included in the present analysis. 58% female, age 71±11 years, 36% diabetics, baseline eGFR 24±8 ml/mn/1.73m². ESA treatments at inclusion were: epoetin β in 62% and darbepoetin α in 38% of patients, with median weekly doses of 3000 IU and 17.5 µg respectively. Baseline ferritin was 226±157 µg/L and TSAT was 24±10%. The Hb level was 11.2±0.5 g/dL during the run-in period (week -4, -2 and D0) and 11.7±0.8g/dL during the evaluation period (week 16, 20 and 24). 50% of the patients were in the target between 10 and 12g/dL during the evaluation period. 10 patients (9%) with at least one missing Hb during evaluation were not considered as in the target. 87% were between 10 and 13g/dL The monthly dose of C.E.R.A. was 125±20µg at D0 and 103±60µg at week 20. The safety profile was comparable to published data. No serious adverse event has been considered as related to C.E.R.A.

**Conclusion:** These preliminary results in a real-life setting show that Hb stability can be achieved with once-monthly SC C.E.R.A. in predialysis patients directly converted from shorter acting ESA.

**SA-PO2315**

**Is Aliskiren Combined with ARBs or ACEIs in Type 2 Diabetes and CKD Stages 3 and 4 Renoprotective?** Hiromichi Suzuki, Tsutomu Inoue, Yusuke Watanabe, Tsuneo Takenaka, Hirokazu Okada. *Nephrology, Saitama Medical University, Irumagun, Saitama, Japan.*

**Background**: Although the renoprotective effects of Aliskiren have been clearly demonstrated in CKD stage 2 patients with hypertension, type 2 diabetes, and nephropathy treated with losartan, questions still remain whether these effects are also applicable to CKD patients in stages 3 and 4.

**Purpose:** The aim of this preliminary study was to evaluate the renoprotective effects of Aliskiren in CKD patients in stages 3 and 4 with hypertension and type 2 diabetes.

**Subjects and Methods:** Thirty two patients (female/male: 10/22; 62±7 years old) were enrolled. All were diabetic patients who were on an angiotensin receptor blocker (ARB) therapy alone or in combination with an angiotensin converting enzyme inhibitor (ACE), had more than 1 g daily proteinuria (1.8 ± 0.6 g/gcr daily), and estimated GFR less than 60 ml/min/1.73 m2 (28.3 ± 5.7 ml/min/1.73 m$^2$). Patients received Aliskiren 150 mg daily for 3 months. If proteinuria was not reduced to less than 1 g daily**,** or not decreased from baseline to 50%, dosage was increased up to 300 mg. A reduction of estimated GFR (eGFR) and increase in serum potassium level were evaluated during 6 months, as well as a reduction in the ratio of protein to creatinine, as measured in an early morning urine sample every month.

**Results**: Thirteen patients were withdrawn from the study, because of increases in potassium levels greater than 5.5 mEq/L in 3, of decreases in eGFR more than 30% in 2, and of both in 8 patients. In 9 patients, daily proteinuria was reduced to less than 1 g and/or 50% without increases in potassium levels and reduction of eGFR was observed. In 10 patients, daily proteinuria was decreased from baseline ranging from 30% to 42% with mild reduction of eGFR and increases in potassium levels. Both systolic and diastolic blood pressures of all patients were significantly reduced (144/80 ± 11/8 to 126/72 ± 12/9 mmHg) ($p<0.01$).

**Conclusion:** Add-on therapy with Aliskiren to ARBs or ACEIs should be cautiously used in diabetic CKD patients in stages 3 and 4.

**SA-PO2316**

**Trends in Health-Related Quality of Life in Children with Mild to Moderate CKD** Susan R. Mendley,[1] Arlene C. Gerson,[2] Stephen R. Hooper,[3] Alison G. Abraham,[2] Matthew Matheson,[2] Debbie S. Gipson,[4] Marc Lande,[5] Bruce Z. Morgenstern,[6] Shlomo Shinnar,[7] Bradley A. Warady,[8] Susan L. Furth.[9] *[1]Univ of MD; [2]Johns Hopkins Univ; [3]Univ of NC; [4]Univ of MI; [5]Univ of Rochester; [6]Phoenix Children's Hosp; [7]Montefiore Med Ctr; [8]Children's Mercy Hosp; [9]Children's Hosp of PA.*

We and others have shown that children with CKD have inferior health-related quality of life (HRQoL) when compared to normals and that this deficit is most pronounced in children on dialysis. However, data on the natural history of changes in HRQoL are lacking and questions as to which children are at greatest risk and which specific domains are most sensitive to declining GFR remain unanswered.

Methods: We evaluated annual change in HRQoL as assessed by Quality of Life Core Scales 4.0 (PedsQL) in 485 participants in the NIH-sponsored CKiD cohort study over a median follow-up of 2.9 years. Annual HRQoL change was stratified by baseline iohexol GFR category (>50, 41-50, 31-40, ≤30 ml/min/1.73 m$^2$) and the proportions experiencing change greater than 5 points were compared between GFR groups.

Results: Subjects had a median age of 11 yr and median iGFR of 45. Overall parent and child-reported HRQoL was 78, compared to published norms of 81 (parent) and 83 (child). While median Physical Function scores in CKiD (84, parent and child) were not different from norms of 83 (parent) and 87 (child), pairwise comparison of the highest and lowest GFR strata showed a significantly larger proportion of children with GFR ≤30 experienced a decline in the Physical Function subscale of at least 5 points ($p<.05$ parent and child). There were no substantial differences in changes in the PedsQL subscales of Emotional, Social and School Function across the GFR strata.

In summary, parent and child-reported declines in Physical Function are significant in those with the most advanced CKD, while other domains appear stable over the duration of observation.

**SA-PO2317**

**Diabetes Impairs the *In Vitro* and *In Vivo* Activity of Progenitor Cells in CKD: Implications for Autologous Cell Therapy** Darren A. Yuen, Yanling Zhang, Andrew Advani, Kim Connelly, Karim Ladak, David Kepecs, Suzanne Advani, Kerri Thai, Richard E. Gilbert. *St. Michael's Hospital, Toronto, Canada.*

**Background:** Diabetic nephropathy, the leading cause of CKD, is characterized by microvascular loss. While several studies have shown that bone marrow derived progenitor cells can ameliorate kidney damage in a range of disease models, donor cells from healthy animals have almost invariably been administered. However, in the human context, autologous cells derived from an unhealthy donor would instead be used. As such, we sought to compare the *in vivo* and *in vitro* efficacy of endothelial progenitor cells (EPCs) derived from diabetic and healthy donors. **Methods:** We cultured EPCs derived from streptozotocin-diabetic and non-diabetic F344 rats, examining the angiogenic effects of their secretory products using a capillary tube formation assay. The renoprotective effects of EPCs were then assessed by the tail vein administration of: saline, 1 x $10^6$ EPCs derived from diabetic donors, or 1 x $10^6$ EPCs derived from healthy donors, into subtotally nephrectomized (SNX) F344 rats, 4 wks post-SNX. Urine protein and glomerular capillary density were analyzed 4 wks later. **Results:** Conditioned medium from non-diabetic EPCs induced robust endothelial tube formation, while that from diabetic EPCs was substantially reduced ($p < 0.05$). In contrast to the renoprotective effect of non-diabetic EPCs, those derived from diabetic animals were ineffective, leading to worsening proteinuria (Table 1) and capillary rarefaction in SNX rats (non-diabetic EPCs vs diabetic EPCs: 0.55 ± 0.02 vs 0.38 ± 0.06 AU, $p < 0.05$). **Conclusions:** Diabetic EPCs display reduced angiogenic activity *in vitro*, in association with impaired renoprotective capacity *in vivo*. Since the human context would require autologous EPCs to be administered in order to avoid immunosuppression, *ex vivo* strategies to restore diabetic EPC angiogenicity need to be explored.

| | SNX - saline | SNX - Healthy EPC | SNX - Diabetic EPC |
|---|---|---|---|
| Urinary protein (mg/day) | 111 ± 23 | 35 ± 8*† | 118 ± 27 |

**Anemia Treatment among Patients with Chronic Kidney Disease Not on Dialysis (CKD-NOD) and Moderately Severe Anemia** H. Lester Kirchner,[1] Ze Cong,[4] Robert M. Perkins,[1] James E. Hartle,[2] Ion D. Bucaloiu,[2] Jeffrey Petersen.[4] *[1]Center for Health Research, Danville, PA; [2]Nephrology/Geisinger, Danville, PA; [3]Amgen, Inc, Thousand Oaks, CA.*

**Background:** Iron and Erythropoiesis-Stimulating Agent (ESA) use among patients with CKD-NOD and moderately severe anemia has not been well characterized. **Methods:** Patients with prevalent CKD-NOD and anemia (new-onset hemoglobin (hgb) < 10 g/dl) and receiving ESA, IV and/or oral iron, PRBC transfusion, or who had a confirmatory hgb < 10 g/dl within 6 months were identified (2004-2009) from the database of a tertiary medical center. Summary statistics of demographics, baseline labs, and iron and ESA use were analyzed. **Results:** From 18688 CKD-NOD patients, we identified 1546 with anemia [8.3%, mean (SD) age 74 (12.0), 97% white, 40% male, mean (SD) follow up of 3.4 (1.5) years].

Iron and ESA use among patients with CKD-NOD and anemia

| | Iron Mono Therapy | | Iron Dual Therapy | | No iron Therapy |
|---|---|---|---|---|---|
| | IV only (n=93) | Oral only (n=381) | IV First (n=29) | Oral First (n=60) | (n = 983) |
| Baseline eGFR, ml/min/1.73m$^2$, mean (SD) | 38.5 (15.8) | 42.2 (12.5) | 36.8 (13.4) | 34.7 (13.2) | 40.9 (14.2) |
| Baseline HGB, g/dl, mean (SD) | 9.1 (0.9) | 9.1 (0.9) | 9.2 (0.6) | 9.2 (0.8) | 9.2 (1.1) |
| Baseline TSAT, %, mean (SD) | 16.6 (15.5) | 22.2 (12.5) | 14.2 (4.0) | 18.4 (10.7) | 24.5 (15.6) |
| ESA during follow up, n (%) | 45 (48.4) | 115 (30.2) | 19 (65.5) | 37 (61.7) | 230 (23.4) |

Almost 50% of patients received no treatment, 15% ESA alone, 22% iron alone, and 14% both. Baseline TSAT was higher among iron users than non-users (mono vs. none: $p<0.01$, dual vs. none, $p<0.01$). ESA use was more common among iron users than non-users (mono vs. none, OR 1.67, 95% CI 1.31-2.21; dual vs. none, OR 5.56, 95% CI 3.53-8.75, $p < 0.001$ for both). **Conclusions:** A significant proportion of patients with CKD-NOD and new onset moderately severe anemia are not treated with iron or ESA. Of those treated, nearly half received iron therapy alone with oral iron usage more common. The optimal modality and timing of iron and ESA treatment require further investigation.

**SA-PO2319**

**Treatment of Osteoporosis by RANKL Inhibition with Denosumab in Women at High Cardiovascular Risk and with Renal Impairment Does Not Accelerate Vascular Calcification** Ogo I. Egbuna,[1] A. M. Cheung,[2] S. Siddhanti,[1] A. Wang,[1] N. Daizadeh,[1] M. Anthony,[1] L. Grazette,[1] Paul D. Miller.[3] *[1]Amgen Inc., Thousand Oaks, CA; [2]University Health Network and University of Toronto, Toronto, Canada; [3]Colorado Center for Bone Research, Lakewood, CO.*

The relationship between OPG/RANK/RANKL and vascular calcification is unclear. We report the effects of denosumab (DMAb), a mAb that inhibits RANKL, on abdominal aortic calcification in women from the FREEDOM trial at high risk of cardiovascular (CV) events. These effects were also examined by renal function status as patients with renal impairment are at increased risk for vascular calcification.

Postmenopausal women with osteoporosis (N=7868) were randomized to receive placebo (Pbo) or DMAb for 3 years. Women at high risk for CV events (N=2363) were identified using modified RUTH criteria at baseline and categorized by level of renal function (< or ≥45 mL/min using Cockcroft-Gault [CG] and MDRD equations). Abdominal aortic calcification was scored for L1-L4 anterior and posterior segments on lumbar spine x-rays and total score was the sum of these 8 measures. Change in total score from baseline to 3 years was calculated for women with complete data (N=1045) and categorized as no change or increased score (worsening). Proportion of DMAb and Pbo women with a change score >0 overall and by renal function was compared between groups with logistic regression.

Baseline demographics and CV risk factors were similar between groups. Proportion of women with an increase in calcification score was not different between Pbo and DMAb groups, regardless of renal function level or method of renal function estimation (CG [Table] or MDRD [not shown]).

Treatment of osteoporosis with DMAb in women at high CV risk did not increase the likelihood of more extensive vascular calcification compared with Pbo after 3 years, regardless of renal function.

**Table: Odds of Increased Total Aortic Calcification Severity Score in DMAb vs Pbo Groups From Baseline to Year 3 by Baseline Estimated Creatinine Clearance (CrCl) Level**

| | Subjects With Change >0 | Odds Ratio* | |
|---|---|---|---|
| | n (%) | Est (95% CI) | P value |
| **All subjects** | | | |
| Pbo (N=501) | 109 (21.8) | | |
| DMAb (N=544) | 118 (21.7) | 1.02 (0.76, 1.36) | 0.92 |
| **Baseline CrCl <45 mL/min** | | | |
| Pbo (N=64) | 16 (25.0) | | |
| DMAb (N=69) | 17 (24.6) | 0.97 (0.44, 2.15) | 0.94 |
| **Baseline CrCl ≥45 mL/min** | | | |
| Pbo (N=437) | 93 (21.3) | | |
| DMAb (N=475) | 101 (21.3) | 1.02 (0.74, 1.40) | 0.90 |
| Baseline CrCl by treatment group interaction† | | | 0.91 |

N = Number of randomized women who received ≥ 1 dose of investigational product, belonged to the cardiovascular high risk subset, and had observed data at all 8 abdominal aortic segments at baseline and at the time point of interest. n = Number of women with an increase in aortic calcification from baseline (score change >0). *Based on a logistic regression model adjusting for baseline total aortic calcification severity score; an odds ratio > 1 represents higher risk for increased aortic calcification in DMAb-treated women when comparing between treatment groups. †Adding baseline CrCl level variable and treatment-by-baseline CrCl level interaction to the logistic regression model.

## SA-PO2320

**Effect of Atorvastatin on NGAL and Cystatin C in Chronic Kidney Disease: A Post-Hoc Analysis of the LORD Trial** Robert G. Fassett,[1] Iain Robertson,[2] Helen G. Healy,[1] Dominic P. Geraghty,[2] Madeline J. Ball,[2] John William Cardinal,[4] Jeff Coombes.[3] *[1]Renal Medicine, Royal Brisbane and Women's Hospital and The University of Queensland, Brisbane, Queensland, Australia; [2]Human Life Sciences, University of Tasmania, Launceston, Tasmania, Australia; [3]Human Movement Studies, The University of Queensland, Brisbane, Queensland, Australia; [4]Pathology Queensland, Queensland Health, Brisbane, Queensland, Australia.*

Aims The effect of atorvastatin on serum neutrophil gelatinase-associated lipocalin (NGAL) and cystatin C and their relationships to kidney function were assessed in patients with stages 2-4 CKD.

Methods We conducted a post-hoc analysis using stored blood samples of 88 patients from the LORD Trial, a randomised, double-blind, placebo-controlled trial that assessed the effects of atorvastatin on kidney function. Patients received either atorvastatin 10 mg/day (48) or placebo (40) and were followed for a mean of 2.9 years. The primary aims were to determine the effects of atorvastatin on NGAL and cystatin C and relationships between MDRD eGFR and serum NGAL and cystatin C. Analysis was based on intention to treat and included all patients with at least one follow-up sample. Serum NGAL was measured at baseline and study conclusion using an immunoturbidometric method, cystatin C using a competitive immunoassay.

Results There was a strong negative association between initial NGAL levels and initial MDRD eGFR (P<0.001), but no association between initial NGAL level and subsequent MDRD eGFR (P=0.88). The rate of change of MDRD eGFR was not associated with initial NGAL or cystatin C levels. The rate of change of NGAL increased in the placebo group (mean 4.6 ng/mL/year; SD 56.6) but decreased in the atorvastatin group (mean -7.4 ng/mL/year (SD 128.4))(P=0.047). There was a strong association between incident cystatin C level and incident MDRD eGFR (P<0.001)

Conclusions This study reveals NGAL is a biomarker of existing CKD but baseline NGAL did not predict CKD progression. Atorvastatin reduced serum NGAL but the significance and mechanism require further investigation. Atorvastatin had no significant effects on cystatin C. Registration: http://www.anzctr.org.au ACRN012605000693628.

## SA-PO2321

**Sevelamer Treatment in Stage III-IV Pre-Dialysis Patients with Secondary iperPTH and Chronic Inflammatoy Status: Impact on Clinical Features and Biochemical Pattern** Luca Di Lullo, Fulvio Floccari, Pasquale Polito. *Department of Nephrology and Dialysis, San Giovanni Evangelista Hospital, Tivoli, Roma, Italy.*

INTRODUCTION AND AIMS: CV involvement, chronic inflammatory status and secondary hyperPTH are complications emerging on first stages of CKD. Fibroblast growth factor (FGF23) is a new sensitive biomarker being increasingly used to monitor the efficacy of treatments aimed to prevent calcium/phosphorus dismetabolism. We studied the clinical efficacy of sevelamer chlorohydrate on echocardiographic and serum parameters in stage III and IV of CKD patients with signs and symptoms of secondary hyperPTH and CV comorbidities.

METHODS: 200 CKD patients (120M/80F, mean age 50.7 +/- 4.3 years, 100/170 [58.8%] with anemia at the baseline visit) were studied. All patients with CKD related anemia were divided into two subgroups and treated with darbepoietin or alpha-epopoietin for 12 months before entering the study. Efficacy of 12-month daily 1600 mg oral dose of sevelamer has been evaluated by laboratory tests (FGF23, PCR, phosphoremia, calcemia), echocardiography(e.g.: EF, LVEDV and Wilkins Score on mitral calcifications) at 0, 6 and 12 months of therapy.

RESULTS: After 12 months of treatment, a mean reduction of 27.2% of serum phosphate (mg/dl), 33.1% of FGF23 (pg/ml) and 43.6% of PCR (mg/dl) and a dramatic improvement of cardiovascular tissue deposition (79.3% mean reduction of Wilkins score) were observed in all patients. By contrast, hemodynamic exams improved slightly (EF 4.1%, LVEDV -2.4%). The degree of improvement of serum phosphorus, FGF23, PCR, EF and Wilkins score after 12 months of sevelamer therapy was comparable among anemic and not anemic subgroups.

CONCLUSIONS:treatment for hyperPTH in stage III-IV of CKD patients has typically focused on the use of oral calcium-based phosphate binders. Sevelamer,non-calcium and aluminium-free agent has accumulated consistent body of evidence on the effects on all-cause of cardiovascular mortality. Our study confirms published data on serum mineral levels control efficacy of this phosphate binder drug, and draws the attention on its role in reducing chronic inflammation markers (FGF23, PCR) and the sclerotic process of cardiovascular apparatus (Wilkins score).

**Effect of the Vitamin D Receptor Agonist Paricalcitol on Biomarkers of Vascular Reactivity in CKD 3 and 4** Amy B. Pai,[1] Darren W. Grabe,[1] George Eisele.[2] *[1]Albany College of Health of Health Sciences, Albany, NY; [2]Albany Medical College, Albany, NY.*

Non-classical effects of vitamin D receptor agonists (VDRA) may explain, in part, mortality benefits in observational analyses. Reduced expression of cell adhesion molecules has been observed with VDRAs *in vitro*. This study investigates the effect of the VDRA, paricalcitol (PCT) on soluble cell adhesion molecules in patients with CKD 3 and 4.

This is a preliminary analysis of an 8 week, randomized, single-blind, controlled trial of PCT versus placebo(NCT00915876). Eligible patients are randomized to 1 mcg of PCT or placebo daily. Study visits are at Baseline, Week 4 and Week 8. Soluble intracellular adhesion molecule (sICAM ) and vascular adhesion molecule (sVCAM) were assayed simultaneously in serum using customized human cytokine multiplex suspension panels. Serum sICAM and sVCAM are reported as median (range), all other data are reported as mean ± SD. The proportion of patients achieving a >20% reduction from baseline was determined by Fishers exact test.

Demographic characteristics of the 18 patients (9 PCT and 9 placebo) were well matched. Baseline eGFR (ml/min/1.73m2) for PCT and placebo groups at baseline were 29.8 ± 7.4 and 35.8 ± 11.3, respectively. Serum sICAM concentrations (ng/mL) at baseline were 1275.9 (654.8-2377.7) in PCT treated patients vs. 271.9 (249.6-1276.2) in patients receiving placebo. There were no significant changes in sICAM at Week 4 in either group, however at Week 8, sICAM was reduced from baseline in the PCT group 278.3 (225.1-1715.3) vs. placebo 254.2 (223.8-1204.3). Similarly, there was a greater proportional reduction in sVCAM concentrations (ng/mL) from baseline to Week 8 in the PCT group [1605.7 (400.2-2622.8) to 495.1 (456.4-2316.2)] vs. placebo treated patients [842.7 (362.9-1879) to 648.5 (308.6-2327)]. More patients receiving PCT (55% vs. 12.5%) had a ≥ 20% reduction in sICAM and sVCAM after 8 weeks of treatment (p=0.061).

This is the first clinical investigation of the effects of a VDRA on biomarkers of vascular reactivity. These preliminary data suggest that treatment with the VDRA paricalcitol may reduce principal mediators of vascular monocyte adhesion.

**Enzyme Replacement Therapy Improves Serum Asymmetric Dimethylarginine Levels and Coronary Microvascular Dysfunction in Fabry Disease** Hideki Fujii,[1] Keiji Kono,[1] Shinichi Nishi,[1] Masafumi Fukagawa.[1, 2] *[1]Division of Nephrology and Kidney Center, Kobe University Graduate School of Medicine, Kobe, Japan; [2]Division of Nephrology and Metabolism, Tokai University School of Medicine, Isehara, Japan.*

B**ACKGROUND**

Fabry disease (FD) is a rare disease and one of the causes of progressive renal and cardiac dysfunction. FD results from an X-linked recessive lysosomal storage disorder caused by a defect in the gene encoding lysosomal α-galactosidase A. Though the accumulation of globotriaosylcelamide (GL-3) leads to renal and cardiac manifestation, the detailed mechanisms remain unclear. Coronary endothelial dysfunction seems to be one of the causes of cardiac complications in FD. The aim of our study was to access coronary flow reserve (CFR) and the effect of enzyme replacement therapy (ERT) on coronary microvascular dysfunction.

**METHODS**

Recently, we performed a screening test of FD for more than 1,000 subjects and found seven FD patients. Present study included three FD patients (two male and one female patient) among them, who have never received ERT. We measured serum asymmetric dymethylarginine (ADMA) levels as a marker of endothelial dysfunction and performed ehocardiography and measurement of CFR by adenosine-triphosphate stress transthoracic Doppler echocardiography for all the study patients before starting ERT, and 3, 6, 12 months after starting ERT.

**RESULTS**

All the study patients could receive ERT without any side effects. At baseline, two of them had impaired CFR, increased left ventricular mass index (LVMI) and elevated serum ADMA levels. Twelve months after starting ERT, CFR was increased in all the patients and LVMI and serum ADMA levels were decreased in two patients. In one patient who

showed most greatly improved CFR, serum brain natriuretic peptide level also decreased remarkably. Furthermore, serum ADMA levels were significantly correlated with CFR ($r = -0.698$, $p < 0.05$).

**CONCLUSIONS**

The results of our study suggest that ERT prevents the progression of cardiac abnormalities possibly by improving coronary microvascular dysfunction and ADMA may be a useful surrogate marker in FD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2324**

**Sodium Bicarbonate Supplementation in Chronic Kidney Disease: Evaluation of Dose-Response and Changes in Muscle Strength** Matthew K. Abramowitz, Michal L. Melamed, Amanda C. Raff, Carolyn A. Bauer, Thomas H. Hostetter. *Albert Einstein College of Medicine, Bronx, NY.*

Background: Metabolic acidosis is associated with protein-energy wasting in patients with chronic kidney disease (CKD). In severe acidosis, sodium bicarbonate ($NaHCO_3$) supplementation is prescribed routinely. However, the role of alkali treatment of mild acidosis remains unclear. In CKD patients with mild acidosis, we evaluated the change in serum bicarbonate at specific doses of $NaHCO_3$ and the effect on muscle strength of alkali supplementation.

Methods: Sixteen adult subjects with estimated GFR 16 – 45 ml/min/1.73 $m^2$ and serum bicarbonate 20 – 24 mEq/L were treated during successive 2 week periods with placebo followed by escalating doses of oral $NaHCO_3$ (0.3, 0.6, and 1.0 mEq/kg/day, based on ideal body weight). Subjects were blinded to treatment status. At each visit handgrip strength was tested using a hydraulic hand dynamometer and the time required to complete 10 repetitions of a sit-to-stand (STS) test was measured. Random-effects models were created to examine the association of $NaHCO_3$ dose with outcomes at each 2 week interval.

Results: The mean age was 64 years, 10 were women, 5 were Hispanic, 11 were non-Hispanic black, mean BMI was 30.7 kg/$m^2$, 15 had hypertension, 13 had diabetes mellitus, and 2 had congestive heart failure. Mean (± SD) eGFR was 34.8 ± 8.9 ml/min/1.73 $m^2$ and mean serum bicarbonate was 22.9 ± 2.5 mEq/L at baseline. After 2 weeks of placebo, or $NaHCO_3$ 0.3, 0.6, or 1.0 mEq/kg/day, serum bicarbonate was 22.9 ± 2.3, 23.9 ± 2.5, 24.7 ± 2.2, and 25.6 ± 2.5 mEq/L, respectively ($p<0.001$ for trend). Each 0.1 mEq/kg/day increase in $NaHCO_3$ dose was associated with a 0.3 mEq/L (95% confidence interval, 0.2 – 0.4 mEq/L) higher serum bicarbonate. The time required for the STS test decreased after 6 weeks of $NaHCO_3$ supplementation (24.3 ± 1.8 vs. 25.7 ± 1.6 seconds, $p=0.02$). No change was seen in handgrip strength ($p=0.18$). Higher $NaHCO_3$ doses were not associated with increased systolic or diastolic blood pressure or edema.

Conclusions: $NaHCO_3$ supplementation produces a dose-dependent increase in serum bicarbonate and may improve muscle strength in patients with CKD and mild acidosis.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2325**

**Sodium Bicarbonate Supplementation Decreases Electronegative LDL in Patients with Chronic Kidney Disease under Conservative Management** Felipe Rizzetto Santos,[1] Deise Monteiro Carvalho,[2] Denise Mafra,[3] Dulcinéia Saes Parra Abdalla,[4] Maurilo Leite.[1] *[1]Universidade Federal do Rio de Janeiro, Brazil; [2]Hospital Federal de Bonsucesso; [3]Universidade Federal Fluminense; [4]Universidade de Sao Paulo.*

The mortality of patients with chronic kidney disease (CKD) is mostly related to cardiovascular disease and associated with diverse factors, including metabolic acidosis (MA). Serum concentrations of electronegative LDL (LDL(-)), a minimally oxidized LDL, in CKD patients on dialysis, are higher than healthy individuals. This modified LDL is related to acute coronary syndrome. In this study we measured serum levels of LDL(-) in CKD patients stage 4, and further addressed the effect of oral sodium bicarbonate supplementation ($NaHCO_3$, 1mEq/kg/day), on LDL(-) in this population. Methods: Twenty pre-dialysis patients ($Cl_{Cr}$: 20.0±6.0 ml/min, age 46.1±11 years; 10 men), from Hospital Federal de Bonsucesso, were studied and compared with 21 healthy individuals (age 50.7±15.7 years; 9 men). Thereafter, CKD patients were randomly divided into 2 groups: group 1 received daily doses of $NaHCO_3$, while group 2 received placebo, all for a period of 20 weeks. Blood samples were collected before and after this period for creatinine and urea. Serum LDL(-) was measured by ELISA. Results: The concentrations of LDL(-) (µg/l) were higher in CKD patients as compared to healthy individuals (0.30±0.15 vs 0.12±0.09, respectively, $P<0.001$), and was positively correlated with serum levels of creatinine ($r=0.58$, $P<001$) and urea ($r=0.5$, $P<004$). Levels of LDL(-), before and after oral $NaHCO_3$, decreased in group 1 (0.40±0.16 and 0.27±0.15, respectively, $P<0.01$), whereas in group 2 there was no significant change (0.36±0.13 and 0.38±0.15, respectively). Conclusion: CKD patients under conservative management have high levels of LDL(-), which seem to increase as renal function decreases. Oral bicarbonate supplementation for 20 weeks decreased LDL(-) levels in these patients. These results suggest that oral alkali supplementation in CKD patients stage 4 may be beneficial to decrease LDL modification, which attenuates the development of cardiovascular disease.

**SA-PO2326**

**Effect of Homocysteine Lowering on Benefits and Harms in People with Kidney Disease: A Systematic Review** Meg J. Jardine,[1] Amy Kang,[1] Sagar U. Nigwekar,[2] Sophia Zoungas,[1] Toshiharu Ninomiya,[1] Sankar D. Navaneethan,[3] Martin P. Gallagher,[1] Giovanni F. M. Strippoli,[4] Alan Cass,[1] Vlado Perkovic.[1] *[1]The George Institute for International Health; [2]Rochester General Hospital; [3]Glickman Urological and Kidney Institute, Cleveland; [4]Consorzio Mario Negri Sud.*

**Aim:** To systematically review all randomized trial data examining the effect of homocysteine lowering on cardiovascular events in people with kidney disease.

**Background:** High homocysteine levels are associated with an increased risk of cardiovascular events. Trials of homocysteine lowering in the general population have not shown a reduction in the risk of cardiovascular events, but people with kidney disease have higher homocysteine levels, higher rates of cardiovascular disease and potentially different mechanisms of cardiovascular disease.

**Methods:** MEDLINE, EMASE, the Cochrane Library from 1950 to December 2009, conference proceedings and trials websites were searched without language restriction. Studies of homocysteine lowering therapy with a minimum of 100 patient years of follow-up, reporting outcomes for people with kidney disease including end stage kidney disease (ESKD), functioning kidney transplant (KT) and chronic kidney disease (CKD), were included. The primary outcome was cardiovascular mortality. Analyses were conducted using a random effects model. Heterogeneity was assessed using the Cochran Q test and the $I^2$ test.

**Results:** Data was extracted from ten trials (9113 participants) conducted in populations with CKD (2 trials), CKD or ESKD (2 trials), ESKD (5 trials) and KT (1 trial). Homocysteine lowering had no effect on cardiovascular mortality (relative risk 1.00, 95% confidence interval (CI) 0.81-1.25), all-cause mortality (RR 0.98, 95%CI 0.89-1.08), myocardial infarction (RR 0.94, 95%CI 0.80-1.12), stroke (0.91, 95%CI 0.69-1.20) access thrombosis (RR 0.97, 95%CI 0.84-1.11) or adverse events (RR 0.99, 95%CI 0.91-1.08). There was no evidence of heterogeneity across trials for any endpoint (all p for heterogeneity ≥0.2).

**Conclusions:** Homocysteine lowering does not prevent cardiovascular mortality, myocardial infarction, stroke or access thrombosis in people with chronic kidney disease.

**SA-PO2327**

**Effects of Cinacalcet with Low Dose Vitamin D Sterols in Hemodialysis Patients with Secondary Hyperparathyroidism; Results from the ADVANCE Study** Carmel M. Hawley,[1] Pablo A. Urena,[2] William G. Goodman,[3] Frank Petavy,[4] Bastian Dehmel,[5] Jurgen Floege.[6] *[1]Univ. of Queensland, Princess Alexandra Hospital, Australia; [2]Clinique du Landy, Saint Ouen, France; [3]Amgen Inc.; [4]Amgen Europe GmbH, Switzerland; [5]Amgen Europe GmbH, Switzerland; [6]RWTH University, Aachen, Germany.*

The ADVANCE study (NCT00379899) investigated the progression of vascular and cardiac valve calcification in 360 prevalent hemodialysis patients with sHPT randomized to either cinacalcet plus vitamin D (VitD) sterols or flexible doses of vitD sterols alone for 52 weeks. As per protocol, patients in the cinacalcet arm were to receive low dose vitD (≤6µg paricalcitol equivalent/week) but *actually received* a mean dose of 8-11µg/week after initiation of treatment.

Progression of calcification and laboratory parameters were analysed in a subset of patients in the cinacalcet arm treated per protocol at week2 ("per protocol" group). Week2 was chosen as the cut-off for this analysis assuming that the investigators needed this time to adapt their patients' vitD regimen.

Overall, 70/115(61%) cinacalcet patients were treated per protocol at week2. The mean(SD) doses for vitD at week2 in the per protocol and control groups were 4.7(1.9) and 12.8(10.2)µg/week, respectively.

Baseline patient characteristics were similar between the two groups. Differences in calcification (Agatston) scores are reported in the Table.

Reductions in iPTH(pg/mL), Ca(mg/dL) & P(mg/dL) were significantly greater in the per protocol group vs. control: $p=0.033$;$p<0.001$;$p=0.024$ respectively.

Table 1

| Median % change (Q1, Q3) in calcification | Per protocol | Control | P value* |
|---|---|---|---|
| Coronary Artery | n=70 | n=119 | p=0.017 |
| | 17.8(-1.8, 54.7) | 31.3(7.6, 81.1) | |
| Aorta | n=54 | n=102 | p=0.166 |
| | 23.8(2.2, 39.8) | 33.1(3.8, 69.4) | |
| Aortic valve | n=37 | n=51 | p=0.017 |
| | 6.0(-16.8, 34.4) | 51.5(-9.9, 123.4) | |
| Mitral valve | n=33 | n=64 | p=0.087 |
| | 6.7(-22.0, 117.5) | 54.4(-3.9, 177.7) | |

*Generalised Cochran-Mantel-Haenszel

Cinacalcet plus low doses of vitD improves laboratory control and may attenuate the progression of calcification compared to the control group as shown in a sub-analysis of ADVANCE study patients.

Disclosure of Financial Relationships: Research Funding: I have received travel and research grants from Amgen.

**SA-PO2328**

**Anemia Knowledge Is Limited among Patients with Kidney Disease Receiving ESA Therapy** Kerri L. Cavanaugh,[1] Neil S. Sanghani,[1] Kenneth A. Wallston,[1] Mae Thamer,[2] Dennis J. Cotter,[2] Russell Rothman,[1] T. Alp Ikizler.[1] *[1]Vanderbilt University; [2]MTPPI.*

FDA has put forth safety warnings regarding use of erythropoietin-stimulating agents (ESA) to treat anemia associated with kidney disease. Little is known about risks for low anemia management knowledge in patients receiving therapy.

From January until May 2010, chronic kidney disease (CKD) or Hemodialysis (HD) patients receiving ESAs were enrolled from one center. We measured anemia knowledge with the newly developed Patient Anemia Knowledge in Kidney Disease (PAKKD) survey (Score:0-100%). We also measured health literacy and risk numeracy. ESA use and clinical variables were abstracted from the medical record. Associations with anemia knowledge were examined with Spearman's correlations and regression analyses.

In 99 patients (50% CKD/50% HD), mean(SD) age was 56(16) years, 43% male, 47% black, 50% had a diagnosis of diabetes, 23% had limited health literacy, 65% had poor risk numeracy skill. Median hemoglobin was 11 mg/dl, in both CKD and HD subjects. Duration of ESA therapy was longer in HD patients (42 mo) compared to CKD (19 mo). Anemia knowledge score was a mean(SD) 58%(21%), however <10% of subjects could describe how therapy may be harmful, and <50% correctly answered multiple choice items regarding potential harm. When asked if there may be *serious* risks to ESA therapy, 68% were not sure, and 11% disagreed. Lower anemia knowledge was associated with older age (rho (r):-0.28, p<0.01), fewer years of education (r:0.26; p=0.01), limited health literacy (r:0.23, p=0.02), and lower risk numeracy score (r:0.34, p<0.01). In adjusted analyses only lower risk numeracy (p<0.01) remained significantly associated with anemia knowledge. No association was found with type of ESA or duration of use. The most common source of information about anemia management for patients was their physician (43%), but 33% reported receiving no information about ESAs.

Even patients with long-standing kidney disease receiving ESA therapy may not understand the rationale or the risks related to this important element of their care. Improving patient education about ESA risks, while addressing limited health literacy and numeracy, is needed.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2329**

**Conversion to Methoxy Polyethylene Glycol-Epoetin-b (C.E.R.A.) with Administration of Iron Carboxymaltose in Anemia Associated with K/DOQI Stage 3B and 4 Chronic Kidney Disease** Jose L. Gorriz,[1] Monica Climente-Marti,[2] Veronica Escudero,[1] Amelia Garcia-Hervas,[1] Victor Jiménez-Torres,[2] Luis M. Pallardo.[1] *[1]Servicio de Nefrologia, Hospital Unuiversitario Dr Peset, Valencia, Spain; [2]Servicio de Farmacia, Hospital Unuiversitario Dr Peset, Valencia, Spain.*

**Aim:** To evaluate the effectiveness of the treatment with methoxy-polyethylene glycol-epoietin-βb (CERA) in the correction of renal anaemia after treatment start or change with epoietin-beta or darbepoietin-alpha and to estimate the conversion factor to CERA from epo-β and darbe-α.

**Methods:** Prospective study. 21 patients CKD stages 3b and 4. In 4 CERA was initiated; in 10 (48%), there was a change from darbepoietin-a, and, in 7 patients, from epoietin-β (33%) with previous optimal response during the last 3 months and stable doses.

Patients with darbepoetin doses: 40, 60, 80, 100 µg/month were converted to 30, 60, 80 and 100 µg/month, respectively, of C.E.R.A.. Patients with epoetin-β doses: 8000-11000, 12000-15000, 16000-18000, 20000 IU/month were converted to 30, 50, 60 and 75 µg/month, respectively. All patients received iron carboxymaltose to achieve optimum ferritin levels (300-500 ng/mL or TSAT > 20). A C.E.R.A. dose reduction of 52.0±13.9% (45.1–59.0) was applied versus Summary of Product Characteristics (SPC) recommendations, and of 33.0±13.2% (26.5–39.6) versus over the expert ones. Mean initial C.E.R.A. dose was: 66.9±2.9 (95% CI 54.2–79.6) µg/month.

**Results:** Initial and final values of Hb (g/dL) were 11.2±1.0 and 11.1±1.4 (Median-diference: 0.03, 95% CI -0.58–0.64, p=0.924); ferritin 213.8±111.1 and 601.9±388.3, p=0.001); and TSI 27.7±19.6 and 30.0±14.8 (p=0.58). The conversion factors in our study were: 1 µg C.E.R.A.= 1.17 µg darbepoetin-a (1.1-1.25); 1 µg C.E.R.A.: 293±36.5 IU epoetin-β (248.0–338.7).

**Conclusions:** Conversion from darbepoetin-a and epoetin-β to C.E.R.A. with adequate replenishment of iron stores achieves a 52% reduction in CERA dose over the dose recommended in the SPC and a 33% reduction over other recommended dose schedules without significant changes in hemoglobin.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2330**

**Effects of Modality Change and Transplant on Health-Related Quality of Life in Dialysis Patients** Patricia Lynn Painter,[1] Lynda A. Frassetto,[2] Joanne Krasnoff,[3] Kirsten L. Johansen.[3] *[1]School of Nursing, University of Minnesota, Minneapolis, MN; [2]Dept of Medicine, University of Miami, Miami, FL; [3]Dept of Medicine, Univerisity of Califormia-San Francisco, San Francisco, CA.*

There are reports of improved health-related quality of life (HRQOL) with increased frequency of hemodialysis (HD) and with transplant (TX). It is unclear whether there is a relationship between changes in exercise capacity ($VO_{2peak}$) and HRQOL with changing treatment modality in ESRD. Three groups of patients with ESRD were studied in a pre-post design 6 months apart. Groups were patients treated with conventional hemodialysis (CHD) who stayed on CHD (n=13; age 45.6± 12.8; 11m/ 2 f); changed to daily HD (n=10; age 43.9±12.7; 9m /1f); changed to living donor TX (n=20; age 42.5 ± 13.4; 17m/ 3f). Healthy controls (n=34; age 47.7 ± 8.5; 28m / 6f) were tested once for comparison. HRQOL was assessed using the SF-36 questionnaire and $VO_{2peak}$ was measured using a symptom-limited exercise test. Analysis of co-variance was used to determine differences among the groups at baseline, at 6 months and in changes on the HRQOL scale scores from baseline to 6 month follow-up. The CHD group was the patient reference group. At baseline, all patient groups were lower in 3 of 4 physical scales and the physical composite scale (PCS) of the SF-36 than the controls (p<.05), whereas at 6 months, HRQOL scales for the TX were similar to controls but the CHD and SDD groups remained lower in 3 of 4 physical scales and the PCS. There were no changes in the physical scales in either CHD or SDD, whereas change in TX was significant compared to CHD on 3 of 4 physical scores, the vitality score and the PCS. $VO_{2peak}$ increased only in the TX group (p=.02). Significant correlations were observed between change in $VO_{2peak}$ and change in physical function scale (r=0.51;p<.001, and in the change on the vitality scale (r=0.39;p=0.01). TX but not changing to SDD improves HRQOL and $VO_{2peak}$ in ESRD.

**SA-PO2331**

**Desensitisation in Patients with Chronic Kidney Disease (CKD) and Allergy to Allopurinol** Antonio Di Felice, Emiliana Ferramosca, Antonio Santoro. *Division of Nephrology Dialysis and Hypertension, St. Orsola-Malpighi University Hospital, Bologna, Italy.*

Hyperuricemia is frequent in patients with CKD and it is on the one hand a severe risk-factor for gout or nephrolithiasis, on the other it presents a potential toxicity on the vascular endothelium and therefore can accelerate the progression of the nephropathy. Allopurinol is a low-cost widely-prescribed urate-lowering agent and is the only one available for oral administration; to date uricosuric drugs are not available in commerce and i.v. urate-lowering drugs are very expensive and not indicated for routinary employment. However, allopurinol hypersensitivity syndrome, a form of cutaneous adverse reaction with high risk of mortality and morbidity, is frequent in this population and precludes further administration.

In this study we report our experience with desensitisation using a schedule of titrated dosages in a group of patients with hyperuricemia and renal impairment who interrupted their therapy because of various cutaneous eruptions due to hypersensitivity to allopurinol.

*Methods*. We considered 11 patients, 7 male and 4 females, 52-77 years old, serum creatinine range 1,3-3.2 mg/dl , GFR range 23-67 ml/min; 3 of them suffered from gout. All of them showed pruritic micro and macropapular rash during treatment with allopurinol at standard dose of 150-300 mg/day, that was then withdrawn. After regression of cutaneous lesions, a treatment was started with oral suspension of allopurinol at increasing dosage, starting from 50 micrograms/day, increasing every 3 days until 100 mg/day within 30 days.

*Results*. Basal uric acid levels were 10.75 ± 1.75 mg/dl (range 9,4-11,7); after 3-6 months treatment urate levels were 6.73±0.72 (range 5.8-7.6) (p=<0.05). No patient showed recurrence of cutaneous reactions. Renal function was unmodified.

In *conclusion*, our data suggest a good efficacy and safety of slow oral desensitisation with low-increasing dosage in patients with allergy to allopurinol and renal disease, who cannot be treated with uricosurics or i.v. urate-lowering drugs. Lowering uric acid levels is important in renal patients not only for gout or nephrolythiasis risk, but also for the progression of renal damage.

**SA-PO2332**

**Effect of 25 Hydroxy Vitamin D on Endothelial Function in Predialysis CKD** Nihil Chitalia,[1] Elanor W. Au,[1] Anatoli Kiotsekoglou,[2] Juan Carlos Kaski,[2] Debasish Banerjee.[1] *[1]Renal Medicine, St. George's Hospital, London, United Kingdom; [2]CV Sciences, St. George's University of London, London, United Kingdom.*

**Introduction**

Non traditional CV risk factors such as vitamin D deficiency have been implicated for the heightened CV risk in CKD patients. In large observational studies, hypovitaminosis D relates to CVD in CKD patients. However the relationship of vitamin D levels with early markers of CVD are unknown in pre-dialysis CKD. This study investigated the relationship of vitamin D with endothelial function and carotid Intima Media Thickness (IMT), independent of traditional risk factors, in predialysis CKD patients.

**Methods and Results**

44 non-diabetic, pre-dialysis CKD patients were investigated: age 56±11 years, hypertension 84%, males 59%, current smokers 11%, BMI 25±4 kg/m$^2$, total cholesterol 4.9±1.2mmol/L, eGFR 37±16 ml/min/1.73m$^2$. Serum 25(OH)D levels were 54±34 nmol/L. Brachial artery Flow Mediated Vasodilatation (FMD) was measured in the vascular laboratory under standardized conditions. IMT of the common carotid artery was measured bilaterally 2 cm proximal to the carotid bulb. Serum 25 hydroxy vitamin D [25(OH)D] levels were assessed by electrochemiluminescence immunoassay. All data were analysed using SPSS v.17.

FMD correlated with serum 25 (OH) D (r=0.44,p<0.005) (figure 1) and hsCRP (r=-0.46,p<0.05). IMT also correlated with hsCRP (r=0.503, p<0.01), but did not correlate with 25 (OH)D levels (r=0.189,p=0.26). Adjusted for traditional risk factors (age, male gender, blood pressure, BMI, cholesterol and smoking), 25 (OH) D was directly related to FMD (Ad.β=0.48, 95%CI 0.13-0.61,p<0.005) on multiple regression analyses.

**Conclusion**

This study demonstrates for the first time a relationship between 25(OH)D levels and endothelial function in predialysis CKD. This suggests vitamin D deficiency as a possible risk factor for CV complications in CKD.

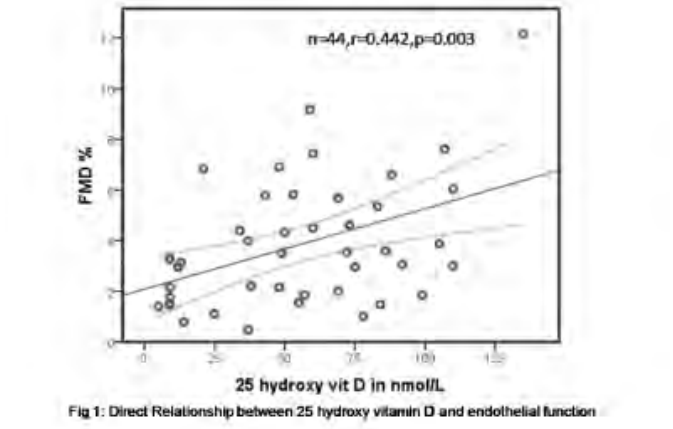

Fig 1: Direct Relationship between 25 hydroxy vitamin D and endothelial function

**The Long-Term Effects of Melatonin on Sleep and Quality of Life in Hemodialysis Patients** Marije Russcher,[1] Birgit Koch,[1] Ernst C. Hagen,[1] Carlo A. Gaillard,[1,2] Elsbeth Nagtegaal,[1] Pieter M. Ter Wee.[2] *[1]Clinical Pharmacy, Internal Medicine, Meander Medical Center, Amersfoort, Netherlands; [2]Nephrology, VU Medical Center, Amsterdam, Netherlands.*

Purpose

The pineal hormone melatonin plays a major role in circadian sleep-wake rhythm. Previously, we reported that the nocturnal endogenous melatonin rise is absent in hemodialysis (HD) patients and that short-term daily use of exogenous melatonin improves sleep onset latency (SOL), actual sleep time (AST) and sleep efficiency (SE) in HD-patients. The aim of the present study was to investigate long-term effects of exogenous melatonin on sleep and quality of life (QoL) in HD-patients.

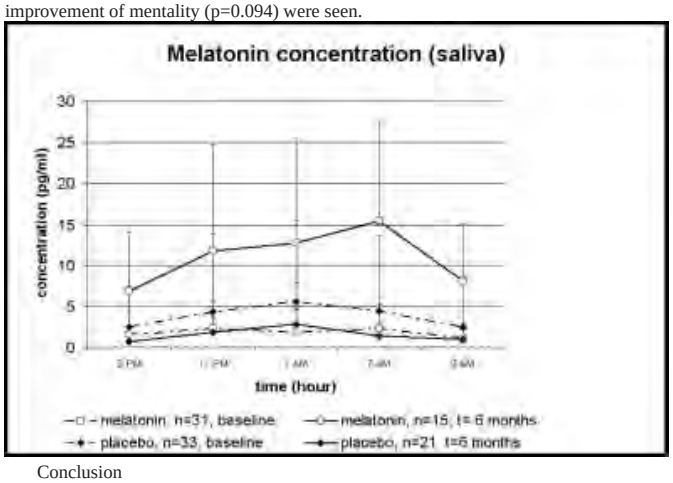
Methods

We conducted a 1 year randomized double-blind placebo-controlled trial with melatonin 3 mg in 70 HD-patients (ClinicalTrials.gov: NCT00388661). Objective sleep measurements were taken at 0, 3, 6, 9 and 12 months by means of actigraphy. QoL parameters were measured by the Medical Outcomes Study Short Form-36 questionnaire. Melatonin concentration curves were sampled in saliva at 0 and 6 months. Statistical analysis was performed by generalized estimating equation.

Results

Administration of exogenous melatonin resulted in higher endogenous melatonin levels (figure).

At 3 months, the previously shown beneficial effect of the short-term use of exogenous melatonin on SOL was confirmed (p=0.023). A trend in improvement of SE (p=0.105), AST (p=0.057) and actual awake time (AAT) (p=0.150) was observed. In contrast, at 12 months none of the measured sleep parameters differed significantly from placebo. At the end of the study period a positive effect on social functioning (p=0.032) and a trend in improvement of mentality (p=0.094) were seen.



Conclusion

In this study the short term beneficial effects of melatonin on sleep were confirmed. However, there is no indication that these beneficial effects persist in long-term usage of melatonin.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2334

**Contribution of Common Medications and Comorbidities to Physical Activity and Exercise Capacity in Chronic Kidney Disease** Erin Howden, William G. Petchey, Nicole M. Isbel, Jeff Coombes. *CCRE – Cardiovascular and Metabolic Health, University of Queensland, Australia.*

Chronic kidney disease (CKD) is associated with inactivity and reduced exercise capacity. We sought to determine whether common medications and co-morbities contribute to physical activity and exercise capacity.

**Methods** Cross sectional analysis of 101 pts with stages 3/4 CKD (eGFR 25-60ml/min) was performed. Physical activity (PA) was assessed using a standard questionnaire and classified as sedentary (<600 MET mins per week, SG) or active (>600, AG). Exercise capacity and endurance were assessed by graded treadmill test ($VO_2$peak) and six minute walk test (6MW).

**Results** Pts were 59.2±9.9 yrs (eGFR 39±9.3ml/min, 60% male). Compared to the AG (n=34), the SG (n= 67) had lower exercise capacity (22.1±4.8 vs. 25.5±9.0ml/kg/min), 6MW distance (445±106 vs. 493±110m) and peak systolic blood pressure (177±23 vs. 188±23mmHg; p<0.05 for all). The SG were taking less antihypertensive medications (2.33 vs. 2.68/pt), diuretics (0.4 vs 0.5/pt), statins (0.6 vs 0.8/pt) and allopurinol (0.14 vs. 0.24/pt), had less hypertension (93% vs. 97%), hyperlipidemia (66% vs. 74%), previous cardiac events (40% vs. 47%), peripheral vascular disease (16% vs. 18%) and more diabetes (50% vs. 44%). Multivariate regression analysis identifed predictors of exercise capacity in all patients (table1).

**Conclusion** Antihypertensive medications (including heart rate limiting) do not have an association with the level of PA or exercise capacity of CKD patients. Common comorbidities such as obesity, diabetes and hyperlipidemia are independent predictors of exercise capacity.

Table 1.Associations and regression analysis of VO2peak

| Variable | Univariate | | Multivariate (VO2) (n=93, adjusted $R^2$ 0.421) | |
|---|---|---|---|---|
| | r | p | β | p |
| BMI | -0.403 | <0.001 | | |
| Waist (cm) | -0.402 | <0.001 | -0.365 | <0.001 |
| Hip (cm) | -0.354 | <0.001 | | |
| Hyperlipidemia | | <0.001 | -0.237 | 0.009 |

## SA-PO2335

**Cross-Sectional, Observational Study To Evaluate the Effectiveness and Safety of Mircera® for Treatment of Anemia in Patients with Chronic Kidney Disease Stage III/V with or without Dialysis in Conversion or Correction, in Routine Clinical Practice** J. M. Portolés,[1] N. J. Vega,[2] G. Fernández-Fresnedo,[3] R. Romero,[4] S. Bea,[5] M. J. Camba.[6] *[1]Hospital Fundación Alcorcón, Spain; [2]Hospital Dr. Negrín, Gran Canaria, Spain; [3]Hospital Marqués de Valdecilla, Santander, Spain; [4]Policlínica Souto Boo, Santiago de Compostela, Spain; [5]Centro de HD Gamapal, Valencia, Spain; [6]CH Ourense, Spain.*

**Background:** In randomised controlled trials (RCTs), Mircera® once-monthly dosing, has shown non-inferiority in efficacy and safety to others ESAs. However, clinical practice differs from RCTs.

**Methods:** A cross-sectional observational study performed in 12 nephrology centers from patients who completed 6 months of Mircera® for correction or maintenance. We present preliminary analysis.

**Results:** A total of 171 patients were evaluated. Mean age: 66.5(14.5) years, 63.7% male. At baseline, the percentage of patients with CKD stages III, IV and V was 6.4%, 25.7% and 67.8%, respectively. 61.4% on hemodialysis. Etiologies: vascular (24%), DM (21.1%), interstitial (7%), polycystic (5.8%), unknown (15.2%) and others (27%). Mean Charlson index 4.64(2.06), weight 72.7(15.09)kg and BMI 26.6. 96% of patients previously received another ESA: 21.4% epoetin alfa (mean weekly dose 11,612.90IU, once or more per week in 100%), 57.2% epoetina beta (5,798 IU/week, once a week in 73.8%) and 19.3% darbepoetina alfa (34 IU/week, once a week in 85%). At time of conversion to Mircera®, mean Hb level was 11.7(0.6)g/dL, and the proportion of patients with Hb values <11g/dL was 31%. Mean initial dose was 123.2(70.14)µg/month. At month 6, mean Hb was 11.8(0.6)g/dL and only 24% of patients had Hb values <11g/dL. In subgroup who initiated Mircera® as first treatment, mean Hb levels increased significantly for 10.4(0.88)g/dL to 11.6(1.34)g/dL (p<0.005). There were 17 minor adverse events not related to study drug. No discontinuation or dose reduction due to adverse drug reaction were identified. No patient died during the study.

**Conclusion:** Mircera® is a safe and effective option regardless the previous type of ESA or dosing schedule and simplifies anemia treatment secondary to CKD in routine clinical practice.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2336**

**Once-Monthly C.E.R.A. Maintains Stable Hemoglobin Levels in Patients with Chronic Kidney Disease Not on Dialysis (CKD NOD) Previously Treated with Darbepoetin alfa: An Italian Multicenter Experience** Bruno Cianciaruso. *Nephrology Division, University Federico II, Naples, Italy.*

Purpose: Once-monthly (QM) continuous erythropoietin receptor activator (C.E.R.A.) is approved for the maintenance of hemoglobin (Hb) levels in patients (pts) with CKD NOD. This Phase IIIb multicenter, single-arm, open-label study investigates direct switching from darbepoetin alfa (DA) to C.E.R.A. QM in pts NOD in a real-life clinical setting.

**Methods:** Adult pts with CKD NOD receiving a range of DA schedules as maintenance therapy were switched to subcutaneous C.E.R.A. QM over a 16-week titration period, followed by a 12-week evaluation period. Three Hb stability criteria (A, B and C) were applied through the study: (A) maintaining mean Hb levels within target range (10.0-12.0 g/dL); (B) maintaining mean Hb within ±1 g/dL of baseline Hb. The proportion of patients with (A) and (B) was defined as a challenging end point; (A) or (B) was defined as overall stability; (C) was defined as fulfilling overall stability without Hb ≥0.5 g/dL outside of 10.0-12.0 g/dL. The study also examined safety.

**Results:** Pts (n=87) had a mean age of 68.2 (36-87) years, with 55% having hypertension and 32% having diabetes at baseline; most pts were pre-treated with DA either once weekly (56%), once every 2 weeks (33%) or QM (5%). During titration and evaluation, respectively, mean (SD) Hb levels were 11.8 (0.9) and 11.5 (0.7) g/dL. Stable Hb was maintained in 60% of pts who fulfilled the more challenging end point (A+B), while 84% of pts maintained the more clinically relevant overall stability criterion (A or B), and 82% of pts achieved criterion C during evaluation. Mean Hb fluctuation was 0.46 g/dL during titration and 0.38 g/dL during evaluation. There was a mean of 2.0 dose changes per pt in 28 weeks of treatment; 59% of all dose changes were dose decreases with a median C.E.R.A. dose of 90 μg during the evaluation period.

**Conclusion:** These preliminary results show that C.E.R.A. QM is able to maintain stable Hb levels in pts with CKD NOD previously treated with DA (Q2W-QM), and indicate that lower than recommended C.E.R.A. doses may be effective in maintaining Hb stability in this pt population.

**Low-Protein Diet Supplemented with α-Ketoacids Delays Progression of Diabetic Nephropathy by Anti-Oxidative Stress in a KKAy Mice Model** Dongmei Liu, Xiang Gao, Changlin Mei. *Kidney Institute of PLA, Division of Nephrology, Chang Zheng Hospital, Second Military Medical University, Shanghai, China.*

There are controversies over whether low-protein diet (LPD) could delay the progression of chronic kidney disease (CKD) and reduce mortality. The aim of the present study was to see whether low-protein diet supplemented with ketoacids could slow down the progression of DN by observing progression of DN in a mice model of early diabetic kidney fed with different diets. The possible mechanisms were also discussed.

8-week-old male KK-Ay mice were selected as the type 2 diabetes model, and randomly divided into 3 groups: normal protein diet (NPD) group, low protein diet (LPD) group, and low protein diet supplemented with ketoacids (LPD+ KA) group. C57BL/6J mice were used as the control group.

The mice were fed with the NPD for the first 4 weeks, and then with the designated food for additional 12 weeks. Blood and urine samples were collected at 12,16, 20 and 24 weeks and 24-h urine for calculation of the urine protein/creatinine ratio.

Compared with the control group, significant pathological changes of DN, a visible increase in mesangial matrix, and significant thickening of glomerular basement membrane were observed in 24-week-old mice of NPD group. The changes in LPD and LPD + KA groups were not so severe as those in NPD group, and the mildest in LPD + KA mice. Lower body weight, lower serum albumin level, and increased urine protein/creatinine ratio were observed in LPD group, as compared with those of LPD + KA group.

SOD, MDA, oxybolt and nitrotyrosine in the renal tissue homogenate were detected. Compared with the control group, MDA, nitrotyrosine and oxybolt increased and SOD decreased significantly in KKAy mice ($P < 0.05$). Related parameters of LPD + KA group were significantly better than those of NPD and LPD groups.

In conclusion, compared with simple low-protein diet, low-protein diet supplemented with ketoacids delayed kidney damage in KKAy mice through reducing renal oxidative stress state. Low-protein diet supplemented with ketoacids may therefore prove to be a suitable diet for diabetic patients.

**SA-PO2338**

**Iron-Deficit Correction after the Administration of a Single Dose of Ferric Carboxymaltose (FCM) in Patients with Chronic Renal Disease (CKD) in Stages 3B and 4 K/DOQI in Treatment with Erythropoiesis-Stimulating Agents** Jose L. Gorriz,[1] Monica Climente-Marti,[2] Amelia Garcia-Hervas,[1] Veronica Escudero,[1] Victor Jiménez-Torres,[2] Luis M. Pallardo.[1] *[1]Servicio de Nefrologia, Hospital Universitario Dr Peset; [2]Servicio de Farmacia, Hospital Universitario Dr Peset.*

**Objective:** To evaluate the effectiveness and the safety of the administration of a single dose FCM in the correction of iron deficiency in patients with CKD stages 3b and 4 K/DOQI.

**Methods:** Longitudinal, prospective study including 21 patients CKD 3b and 4, who were treated with C.E.R.A and show suboptimal iron stores: ferritin < 300ng/mL and/or transferrin saturation (TSAT) < 20%. One dose of FCM was administrated. If ferritin < 300: 1000 mg; if ferritin 300-500: 500 mg.

The main ferritin values and TSAT were compared at the beginning and at the end (2 months after administrating FCM). 90.5% of the patients (19/21) were given 1000mg of FCM, whereas 2 patients were given 500mg. The median CERA dose was 66.9±27.9 (IC95% 54.2-79.6) mcg/month.

**Results:** Two months after treatment with one FCM dose, the proportion of patients with optimal ferritin values incremented from 14.3% (3/21) (IC95% -0.7-29.3) to 90.5% (19/21) (IC95% 77.9-103.0) with an RR 6.33 (IC95% 2.20-18.22) and for TSAT from 58.8% (10/17) (IC95% 35.4-82.2) to 83.3% % (15/18) (IC95% 66.1-100.6) with an RR 1.42 (IC95% 0.90-2.22). Complete response (optimal Ferritin and TSAT): 61.9% of patients (13/21). Partial response (optimal ferritin or TSAT): 38.1% (8/21). Patients with ferritin >500ng/mL: 38.1% (8/21) (IC95%17.3-58.9%). IST higher than 50%: 5.6% (1/18) (IC95% -5.0-16.1). Patients with Hb >11g/dL: 61.9% (13/21) at the beginning and 42.9% (9/21) at the end. Two patients (9.5%) reached Hb levels above 13.0g/dL by the end of the trial.

**Conclusions:** The administration of a single dose of FCM increases the proportion of patients with optimal ferritin and TS values; after 2 months, 61.9% of patients showed a complete response in the correction of iron deficiency. 38.1% of patients reached higher-than-optimal ferritin levels in the same period. The proportion of patients with optimal Hb levels did not change significantly.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2339**

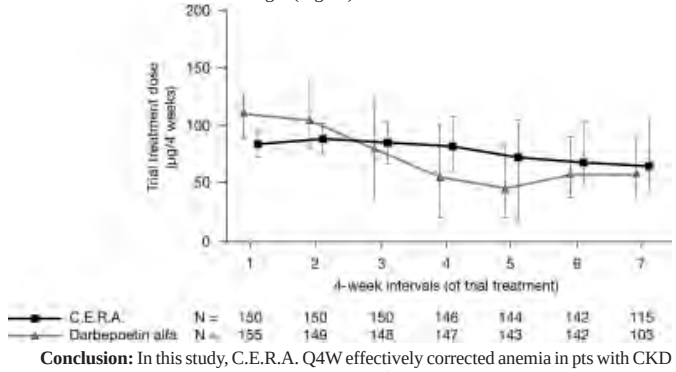
**Fewer Dose Changes and Hemoglobin (Hb) Values above the Target Range Following Once-Monthly (Q4W) C.E.R.A. Treatment in Anemic Patients (pts) with Chronic Kidney Disease (CKD)** Francesco Locatelli. *Alessandro Manzoni Hospital, Via dell'Eremo, Lecco, Italy.*

**Purpose:** The Phase III CORDATUS trial showed that once-monthly (Q4W) continuous erythropoietin receptor activator (C.E.R.A.) effectively corrects anemia in pts with CKD not on dialysis. These data were analyzed with respect to the relationship between dose and Hb values above the target range.

**Methods:** Adult pts with stage 3/4 CKD received either subcutaneous C.E.R.A. Q4W (starting dose of 1.2 μg/kg) or darbepoetin alfa (DA) either weekly or once every 2 weeks according to local labeling. After response (a single Hb value ≥10.0 g/dL and an increase from baseline ≥1.0 g/dL), Hb was to be maintained within the range of ±1.0 g/dL of the response level and between 10.0-12.0 g/dL.

**Results:** Of the randomized pts, 150 received C.E.R.A. and 155 DA. High response rates were achieved with both C.E.R.A. (94.1%) and DA (93.5%). Median times to Hb response were 43 days (C.E.R.A.) and 29 days (DA); fewer C.E.R.A.-treated pts than DA-treated pts had Hb values >12.0 g/dL in the first 8 weeks (25.8% and 47.7% respectively; $p<0.0001$). DA-treated pts required more dose adjustments to achieve and maintain Hb: 21% of the DA pts required ≥5 adjustments, compared with 11% of the C.E.R.A. pts.

Median C.E.R.A. doses changed little from baseline to evaluation period (6.6%) compared with a 35.6% decrease with DA, indicating a need for more modification of DA dose in order to maintain Hb in target (Figure).



**Conclusion:** In this study, C.E.R.A. Q4W effectively corrected anemia in pts with CKD not on dialysis. A more gradual increase in Hb and fewer Hb values above the target range were observed with C.E.R.A. than with DA. The results also indicate that a lower rate of Hb increase than proposed in current guidelines (1-2 g/dL per month) can correct anemia and significantly lower the number of Hb values exceeding the upper target.

**Evolution of Calciphylaxis before and after Introduction of Bisphosphonates. Our Experience** Ana Ramos, Jose-Vicente Torregrosa, Aleix Cases, Marta Arias, Josep Campistol. *ICNU, Hospital Clinic, Barcelona, Spain.*

Calciphylaxis is a rare and serious disease, with a very high morbi-mortality. It is a vascular pathology affecting almost exclusively patients with end stage renal failure (ESRF) either on hemodialysis (HD) or renal transplanted (RT) (prevalence of 1-4%). There are few

effective treatments. Bisphosphonates experimentally have showed interesting effects on vascular calcifications thorough an inhibition of cytokines and proinflammatory mediators, so they could be usefulness in this setting.

We describe our experience comparing the last 7 patients presenting with calciphylaxis before introduction of bisphosphonates (Group I) and our first 7 patients with calciphylaxis treated with bisphosphonates (Group II).

METHODS: Group I (before 2002): 7 patients (3 on HD / 4 RT) mean age: 50±13 years. 4 men/3women, mean time on HD: 4.8±1.5 years. 4 with history of PTH>800 pg/ml, steroids in 4. Group II (after 2002): 7 patients (5 on HD / 2 RT) mean age: 61±7 years, 3 men/4women, mean time on HD: 6.7±5.9 years. 5 with history of PTH>800 pg/ml, steroids in 5. All of them (14) showed an important cutaneous involvement in the inner part of both thighs diagnosed of calciphylaxis (cutaneous biopsy in 12 of them). Group I: in all patients on HD the frequency was increased, 3 patients (1 TR) were parathyroidectomized (PTx). Group II: all of them received bisphosphonates: Alendronate 70 mg/weekly in one case, Risendronate 35 mg/weekly in four cases and Ibandronate 3 mg/ev + Ibandronate 150 mg/ monthly in two cases. No negative effects were observed.

RESULTS: Group I =5 cases required an amputation of the leg, 1 case died and in 1 case the lesion improved and resolved (RT patient with high PTH that was PTx). Group II =all of them showed a progressive improvement of the cutaneous lesions with complete resolution after 6 months. There were no significant changes in blood levels of Ca and P in patients receiving bisphosphonates. Renal function remained stable.

CONCLUSIONS: Bisphosphonates could constitute a new and attractive alternative as a treatment of calciphylaxis.

## SA-PO2341

**Toward a Rational Basis for Phosphate Binder Prescribing: Estimating the Binding Capacity of Available Binders** Raymond D. Pratt,[1] Michael D. L. Smyth.[2] *[1]Shire Pharmaceuticals, Wayne, PA; [2]Shire Pharmaceuticals, Basingstoke, United Kingdom.*

**Purpose:** Self-adjustment of phosphate binder (PB) dose to suit meal phosphate content has recently been shown to improve the management of hyperphosphatemia in CKD patients. We calculated the binding capacity of available PBs to provide information that may help to tailor dosage to the patient's needs. **Methods:** We examined dietary phosphate absorption in hemodialysis patients and healthy individuals, and calculated the binding capacities of PBs based on data from a metabolic study of lanthanum carbonate and sevelamer carbonate and the published results of other trials in healthy volunteers; these studies directly measured phosphate binding in the gastrointestinal tract. Results were compared with estimates based on urinary phosphate excretion. **Results:** A metabolic study in hemodialysis patients showed that absorption of ingested phosphate ranged from 60–86% depending upon vitamin D status. In healthy controls, 80% of phosphate was absorbed. This was consistent with the results of the lanthanum/sevelamer study in volunteers (N = 18), in whom 76% of phosphate was absorbed. Therefore, published data from healthy volunteers were used to calculate the binding capacities of PBs (Table).

| | Phosphate bound, mg (Dose [mg] per meal, N) | | |
|---|---|---|---|
| Binder | Metabolic Study | Urinary Excretion | Phosphate bound per tablet, mg |
| Lanthanum carbonate | 135 (1000[a], 18) | 79–156[b] (1000[a], 6–48) | 135 vs 79–156 |
| Calcium acetate | 177 (1000[a], 10) | 132 (1000[a], 6) | 30 vs 22[c] |
| Calcium carbonate | 116 (1000[a], 10) | 31 (1000[a], 6) | 46 vs 12[d] |
| Sevelamer | 63 (2400, 18) | 36 (1000, 6) | 21 vs 29[e] |

[a]Elemental La or Ca. Calculations are vs controls or [b]change from baseline. [c]Based on PhosLo®. [d]Based on ultra strength TUMS®. [e]Sevelamer carbonate vs sevelamer hydrochloride, respectively.

**Conclusions:** Data from direct phosphate binding studies in healthy volunteers generally gave similar results to calculations of binding capacity using urinary phosphate excretion. These data may be useful to begin tailoring PB dosage to the patient's dietary phosphate intake.

**Medication Regimen Complexity among Patients with Chronic Kidney Disease Stages 3-5D** Katie E. Cardone, Magdalene M. Assimon, Darius Mason, Amy B. Pai, Darren W. Grabe. *ANephRx, Albany College of Pharmacy and Health Sciences, Albany, NY.*

Background: Medication regimen complexity should be evaluated in patients with chronic kidney disease (CKD). The Medication Regimen Complexity Index (MRCI) is a tool that has been validated in patients with respiratory disease, and accounts for dosage forms, administration frequency, and special instructions that may complicate a medication regimen and lead to poor adherence or medication-related problems (MRPs). The typical patient with ESRD takes approximately 12 medications, putting them at high risk for MRPs. MRCI may have utility in assessing regimens of those with CKD. The objective of this study was to evaluate the MRCI for typical medication regimens in patients with CKD 3-5D.

Methods: This is a cross-sectional study in which patients with CKD 3, 4, & 5D (on hemodialysis), at least 18 y.o. & seen at least twice at the study clinic were included. Home medication regimens were determined for each patient at enrollment. Number of medications (NM), pill burden (PB) and MRCI were calculated for each regimen. Student's t test was used to compare means between groups. Pearson's correlation was used to identify relationships between MRCI and number of comorbid conditions (NCC), PB, & NM. A 5% significance level was used.

Results:

| | CKD 3-4 (n=31) | HD (n=40) |
|---|---|---|
| DEMOGRAPHIC | | |
| Age (yr) | 65.8±14.7 | 64.4±15.6 |
| Male (%) | 43.3 | 52.5 |
| GFR (ml/min/1.73 m2) | 32.5±14.0 | |
| HD vintage (yr) | | 3.4±2.8 |
| NCC* | 8.6±3.1 | 12.3±3.2 |
| MEDICATION REGIMEN | | |
| NM | 12.9±3.7 | 14.3±5.0 |
| PB* | 16.7±5.2 | 22.4±10.8 |
| MRCI* | 25.6±11.4 | 33.8±13.5 |

Mean±SD; *p<0.05

MRCI positively correlated with NM (r = 0.82) and PB (r = 0.86) in the CKD group and positively correlated with NM (r = 0.90), PB (r = 0.76) and NCC (r = 0.73) in the HD group, $p < 0.05$ for all correlations.

Conclusion: MRCIs are higher in patients receiving HD compared to those with CKD 3-4. This finding is associated with more comorbid disease states and accordingly, a greater number of medications and pill burden, well-established risk factors for MRPs. These data indicate the importance of evaluating the predictive value of MRCI on costly outcomes such as adverse drug events and hospitalizations.

## SA-PO2343

**Adding Dietary Fruits and Vegetables Reduces Kidney Injury in Subjects with Moderately Reduced GFR** Nimirit Goraya,[1, 2] Jan Simoni,[3] Kristine Broglio,[4] Donald E. Wesson.[1, 2] *[1]Internal Medicine, Texas A&M College of Medicine, Temple, TX; [2]Internal Medicine, Scott and White Healthcare, Temple, TX; [3]Surgery, Texas Tech University Health Sciences, Lubbock, TX; [4]Statistics, CenterTexas A&M University, College Station, TX.*

Subjects with hypertensive nephropathy (HN) have progressive GFR decline despite blood pressure reduction and ACE inhibition (Arch Int Med 2008). Dietary alkali ameliorates kidney injury and GFR decline in HN with severely reduced (Kid Int 2010) and moderately reduced (Kid Int 2010) eGFR. Because diets in industrialized societies are largely acid-inducing, we explored if dietary addition of base-inducing fruits + vegetables reduces kidney injury in HN with moderately reduced eGFR (CKD stage 2 = 60-90 ml/min). Subjects with macroalbuminuric HN and eGFR 60-90 ml/min (n=40) and those with eGFR > 90 ml/min (n=26) had blood pressue reduction with regimens including ACE inhibition. eGFR 60-90 compared to eGFR > 90 had baseline potential renal acid load (PRAL), a measure of dietary acid intake (60.4 ± 19.4 vs. 62.8 ± 14.5 mmol/day, respectively, $p = 0.582$) and baseline 8 hour urine net acid excretion (8h NAE) (24.6 ± 5.0 vs. 24.7 ± 2.9 meq, respectively, $p = 0.924$) that were not different. Thirty days of fruits + vegetables added in an amount calculated to reduce PRAL by 50% in eGFR 60-90 subjects reduced 8h NAE to 16.5 ± 5.1 meq, $p < 0.0001$. This dietary intervention in eGFR 60-90 subjects also reduced urine excretion of albumin (422 ± 152 to 388 ± 122 mg/g creatinine [cr], $p < 0.0001$), N-acetyl-β-D-glucosaminidase (2.68 ± 0.73 to 2.60 ± 0.70 U/g cr, $p < 0.0001$) and transforming growth factor β (63.8 ± 14.5 to 57.3 ± 13.7 ng/g cr, $p < 0.0001$), consistent with reduced kidney injury. Time control eGFR subjects (n=40) showed no change in any of the 3 kidney injury parameters. The data show that adding fruits + vegetables to diets of subjects with macroalbuminuric hypetensive nephropathy and CKD stage 2 eGFR improves urine parameters of kidney injury and support exploring this dietary intervention as an adjunctive kidney protective strategy to blood pressure reduction and ACE inhibition.

## SA-PO2344

**Efficacy and Safety of Long-Term Intravenous (I.V.) Ferric Carboxymaltose (FCM) in the Treatment of Iron Deficiency Anemia in Non-Dialysis Dependent Chronic Kidney Disease (ND-CKD) Patients** Joseph Benjamin. *Dept of Nephrology, Temple University, Philadelphia, PA.*

**Introduction:** The purpose of this study was to evaluate the safety and efficacy of I.V. ferric carboxymaltose (FCM) when used as long-term therapy of iron deficiency anemia (IDA) in ND-CKD patients.

**Methods:** This was an open-label, uncontrolled, extension (up to 44 wks) of a previously conducted study comparing I.V. FCM to oral iron in anemic ND-CKD patients. FCM was administered as 15mg iron/kg bodyweight I.V. over 15 minutes to a maximum of 1000mg iron in subjects with TSAT <25% and ferritin <300ng/ml (dose was reduced to 500mg iron if TSAT <30% & ferritin < 500ng/ml). Hb and iron parameters were measured every 4 wks. Clinical & laboratory findings, and adverse events (AEs) were monitored. Efficacy (clinical success) was defined as % of subjects with Hb >11.0g/dL, TSAT 30-50%, and ferritin 100-800ng/ml at any single visit. In addition, the mean change from baseline to the highest value for Hb, TSAT and ferritin were summarized.

**Results:** A total of 28 sites enrolled 145 subjects (104 subjects [71.7%] completed the study;140 were included for efficacy analysis; 127 for safety). The mean baseline values were: Hb 10.36g/dL, TSAT 17.2% and ferritin 115ng/ml. Clinical success was achieved in 51.4% (72/140) of subjects. Similar proportions of subjects receiving FCM (52.3%) or oral iron (50.0%) in the previous trial achieved clincial success in the present study. The mean change from baseline to highest Hb was 1.89g/dL, baseline to highest TSAT was 20.4%, & baseline to highest ferritin was 745ng/ml. During the study, at least one AE was experienced by 66.1% (84/127) of subjects. Most of these were classified as mild to moderate in severity. At least one serious AE was reported in 18.1% (23/127) of subjects, including

2 deaths (intestine perforation due to diverticulitis 98 days after last dose of FCM, upper GI bleed following exploratory laparotomy 46 days after last dose). No serious AEs were determined to be related to FCM.

**Conclusion:** In this study of ND-CKD patients, ferric carboxymaltose was shown to be effective & well tolerated for the long-term treatment of IDA regardless of previous treatment.

### SA-PO2345

**Insulin Resistance in ESRD** Sara Kazempour,[1] Maytham Omran,[4] Jeremy J. Turner,[3] Frederick W. K. Tam,[2] Gary S. Frpst,[1] Anne Dornhorst,[1] Andrew H. Frankel.[2] *[1]Imperial College; [2]Imperial College; [3]Norfolk & Norwich University Hospital; [4]Imperial College.*

Insulin resistance (IR) is known as a contributing factor to cardiovascular disease (CVD), and CVD is the main cause of high morbidity and mortality rates in the end-stage renal disease (ESRD) population. Although it is likely that multiple factors contribute to CVD risk, understanding changes in IR is likely to be of importance in preventing adverse outcomes. Inflammation and adiponectin are also known to influence both insulin sensitivity and CVD, and may therefore be important regulating factors in prevention against CVD.

**Aims.** To examine changes in IR, inflammation and adiponectin levels in chronic kidney disease (CKD) stages 3, 4, 5 and maintenance haemodialysis (MHD) and to establish whether these changes are predictors of cardiovascular events (CVE) and mortality.

**Methods.** Assessment of IR (HOMA-IR model), inflammation status assessed by high-sensitivity CRP (hs-CRP) and adiponectin levels were available for 55 patients with CKD (stages 3-5) and 51 patients on MHD together with 40-month CVE and mortality data.

**Results.** The mean IR as measured by HOMA-IR increased through the CKD stages 3-5 before significantly falling in the MHD group (1.78±1.30 in CKD 3, 2.73±2.52 in CKD 4, 3.57±2.33 in CKD 5 and 1.50±1.46 in the MHD group, p=0.001). The mean adiponectin and hs-CRP were similar among the CKD and MHD groups.

Regression analysis for CVE risk revealed that hs-CRP was significantly associated with increased CVE in the CKD group with a hazard ratio (HR) of 1.092 (CI: 1.024, 1.165; p=0.002). Calculations for risk of mortality showed that high adiponectin and hs-CRP levels were both predictive of mortality in the MHD group (HR: 1.029, CI: 1.005, 1.054; p=0.020 and HR: 1.018, CI: 1.000, 1.038; p=0.05 respectively).

**Conclusions.** Our study clearly shows that IR increases as renal function deteriorates but is significantly improved with haemodialysis. In this cohort changes in IR were not predictive of CVE or mortality. However, an increased hs-CRP was predictive of CVE in the CKD group while increased adiponectin and hs-CRP levels were both predictive of mortality among the MHD group.

### SA-PO2346

**A Cost Analysis of Effecting Whole Population Improvement in Blood Pressure Control in CKD** Hannah Kilbride, Jean Irving, Paul E. Stevens, Kushan Karunaratne, Helen Hobbs, Richard W. C. Kingston, Christopher K. T. Farmer. *Kent Kidney Care Centre, East Kent Hospitals, Canterbury, Kent, United Kingdom.*

Introduction

Inclusion of renal indicators in primary care incentive payments, the Quality and Outcomes Framework (QOF), has led to a significant improvement in blood pressure (BP) control.

Aim

To undertake a cost analysis of the improvement in BP control following implementation of renal indicators in the QOF.

Methods

7474 of 36519 individuals with serum creatinine estimations 2 y pre- and 2 y post-QOF had stage 3-5 CKD and comprised the study cohort. Demographic, GFR, BP and anti-hypertensive prescription data were recorded. Hypertension was defined as a mean BP >140/85 or on antihypertensive drugs pre-QOF. The annual cost of antihypertensives was calculated based on primary care prescription data. Generic prescribing costs were also calculated.

Results

5871/7474 (79%) were hypertensive pre-QOF. BP control improved from 147/79 ± 14/8 to 140/76 ± 22/12 mmHg post-QOF (p<0.001). The table details annual prescription data, actual costs and generic costs pre- and post- introduction of renal indicators in the QOF.

| | | Pre-QOF | | | Post-QOF | |
|---|---|---|---|---|---|---|
| Prescription item | N | Actual cost, $ | Generic cost, $ | N | Actual cost, $ | Generic cost, $ |
| Diuretic | 624 | 39,051 | 8,828 | 1,780 | 56,408 | 24,929 |
| Beta-blocker | 390 | 15,880 | 5,859 | 1,166 | 53,167 | 17,244 |
| Alpha-blocker | 213 | 12,052 | 11,013 | 430 | 24,666 | 22,129 |
| Ca channel blocker | 407 | 66,571 | 8,815 | 1,080 | 179,884 | 23,132 |
| ACEI | 2,904 | 124,853 | 75,578 | 2,186 | 86,742 | 56,318 |
| ARB | 1,166 | 278,028 | 278,028 | 1,451 | 342,532 | 342,532 |
| Other | 30 | 4,301 | 8,733 | 45 | 8,187 | 13,100 |
| Total prescription costs | | 540,735 | 449,774 | | 751,585 | 565,854 |

Conclusion

Improved BP control was effected through increased antihypertensive prescribing, a 40% increase in prescribing costs. Incentive payments to primary care will have further increased costs but a significant proportion of these could be offset by generic prescribing. The increased cost is approximately $36.4/patient treated/y which, given the reduction in BP achieved, is well within the cost effective threshold of $30K per quality adjusted life year (QALY) outlined in UK NICE guidance.

Disclosure of Financial Relationships: nothing to disclose

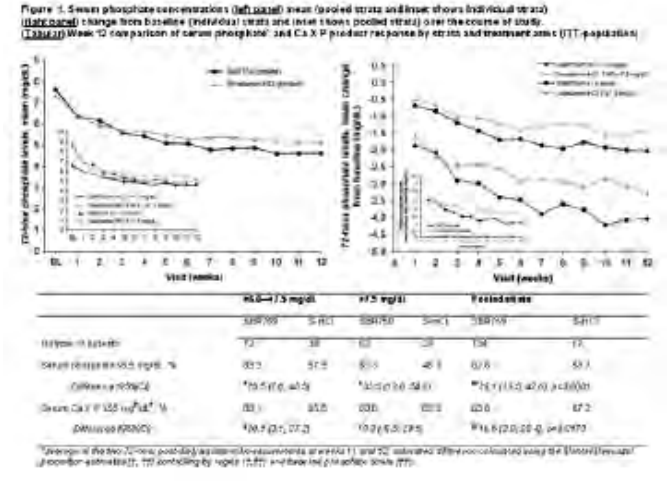
### SA-PO2347

**SBR759 Is More Effective Than Sevelamer Hydrochloride in Sustaining Serum Phosphate Reduction in Hemodialysis Patients** J. B. Chen, S. S. Chiang, H. C. Chen, S. Obayashi, M. Nagasawa, M. Hexham, A. Balfour, N. Cretin, Takashi Akiba, Masafumi Fukagawa. *For Study A2202.*

**Purpose**: SBR759, a novel calcium-free, polymeric, iron(III)-based oral phosphate binder (OPB) for the treatment of hyperphosphatemia was compared with sevelamer-HCl (S-HCl).

**Methods**: This was a 12 week, open-label, dose-titration study in Asian hemodialysis (HD) patients with hyperphosphatemia. Patients (N=203) were stratified (baseline P< or ≥7.5mg/dL) and randomized to starting doses of 3.0 or 4.5g SBR759 (N=135) or 2.4 or 4.8g S-HCl (N=68). Daily doses were up-titrated every 2 weeks to reach target serum P levels ≤5.5mg/dL at 72-h post-dialysis. Primary end point was the proportion of patients with mean target P at week 12.

**Results**: Age, dialysis conditions, and baseline P levels were comparable between SBR759 and S-HCl groups. A significantly higher proportion of SBR759 patients achieved target P levels at week 12 compared to S-HCl (83% vs 54%, p<0.0001; pooled). P levels in pooled strata were numerically lower from week 3 to 12 with SBR759 than with S-HCl and better in both strata at week 12. Greater reductions in P levels throughout the study with SBR759 were clinically meaningful and statistically significant vs S-HCl at week 12 (-0.95 vs -0.71mg/dL, p=0.0024) (Fig.1).



Calcium (Ca) levels did not change from baseline and CaXP was ≤55mg$^2$/dL$^2$ in a significantly higher proportion of patients on SBR759 (p=0.0173). Similar incidences of (serious)/adverse event (S/AE) were seen with SBR759 and S-HCl (5.2/90.3% vs 4.4/94.1%), but overall discontinuation rates were lower with SBR759 (11.9% vs 20.6%). Diarrhea reported as AE was more frequent with SBR759 whereas constipation and abdominal distension affected more patients on S-HCl. No SAE was drug-related.

**Conclusion**: SBR759 was superior to standard of care OPB S-HCl in achieving target serum P levels in HD patients and was well-tolerated.

### SA-PO2348

**SBR759 Is Well-Tolerated with Good Gastrointestinal Tolerability Profile Compared to Sevelamer Hydrochloride** Takashi Akiba,[1] J. B. Chen,[2] H. C. Chen,[2] S. Obayashi,[2] M. Nagasawa,[2] M. Hexham,[2] A. Balfour,[2] N. Cretin,[2] Masafumi Fukagawa,[2] S. S. Chiang.[2] *[1]Tokyo Women's Medical University, Japan; [2]For Study A2202.*

**Purpose**: SBR759 is a novel, calcium-free, polymeric, iron (III)-based oral phosphate binder for the treatment of hyperphosphatemia. 12wk safety results from a phase II, open-label, dose-titration study in Japanese and Taiwanese hemodialysis patients are reported here.

**Methods**: Patients (N=203) with elevated phosphate (P) levels were stratified according to baseline P levels (< or ≥7.5mg/dL) and randomized 2:1 to starting doses of 3.0 or 4.5g SBR759 (N=135) or 2.4 or 4.8g sevelamer hydrochloride (S-HCl) (N=68). Daily doses were up-titrated every 2 wk to reach target serum P level ≤5.5mg/dL at 72h post-dialysis. Safety was evaluated on the basis of adverse events (AE), serious AE (SAE) and changes in laboratory values. Efficacy was assessed by number of patients achieving target serum P at wk 12.

**Results:** Efficacy of SBR759 was superior to S-HCl in achieving target serum P at wk 12 (83% vs 54%; p<0.0001). Similar incidences of SAE/AE were seen with SBR759 and S-HCl (5.2/90.3% vs 4.4/94.1%); no SAE was drug-related. Overall discontinuation rates were lower with SBR759 (11.9% vs 20.6%) as well as discontinuation due to AE (3.7%

vs 13.2%). Most frequent AE category with SBR759 and S-HCl was gastrointestinal (GI) disorders (57.5% vs 64.7%). GI AE intensity was mostly mild with SBR759 (mild 45.5%, moderate 11.2%; severe 0.7%) whereas with S-HCl more moderate and severe AEs were reported (mild 30.9%; moderate 27.9%; severe 5.9%). Diarrhea AEs were more frequent with SBR759 (19.4% vs 10.3%); constipation and abdominal distension affected more patients on S-HCl (5.2% and 25.0% vs 3.0% and 25.0%, respectively). Based on Deficiency of Acquired Immune Deficiency Syndrome (DAIDS) grading, majority of diarrhea AE were of grade 1 (lowest severity) with SBR759 and S-HCl (18.7% vs 10.3%).

**Conclusion:** SBR759 is well-tolerated with good GI tolerability profile compared to S-HCl.

## SA-PO2349

**One Dose Iron Repletion with Iron Isomaltoside 1000 (Monofer®) in Pre-Dialysis CKD Patients** Philip A. Kalra,[1] Sunil Bhandari,[2] Lars L. Thomsen.[3] *[1]Renal Medicine, Salford Royal Hospital, Salford, United Kingdom; [2]Renal Medicine, East Yorkshire Hospitals, East Yorkshire, United Kingdom; [3]Clinical R&D, Pharmacosmos A/S, Holbaek, Denmark.*

Purpose: Patients with chronic kidney disease (CKD) often need treatment with intravenous iron preparations. The present study analysed the use of high single dose infusion of iron isomaltoside 1000 to treat anemia in a pre-dialysis subgroup of patients recruited in a previously presented open-label, multicentre safety study (1).

Methods: 21 pre-dialysis patients with CKD and anemia (mean age 69y; range 43-83y; 8 F , 13 M, mean (SD): serum creatinine 325µmol/L (131), Hb 102g/L (8), TSAT 16.9% (11.5), Ferritin 191ug/L (134)) were included in the 8 week study. 19 patients were not currently treated with parenteral iron and 2 patients switched from an existing parenteral iron treatment. 7 patients were on ESA therapy which was maintained without dose change during the study. Iron isomaltoside 1000 was administered as a Total Dose Infusion (mean dose: 953.5mg (range 650-1550mg)) diluted in 100-500 ml 0.9 % saline and infused over 30-60min at baseline. No initial test dose was given.

Results: One solitary possible treatment related adverse reaction was observed. This was an anginal episode in an 80 year old male patient with a known medical history of angina pectoris. The reaction was classified as serious and possibly related to the trial medication by the investigator. However, it occurred 10 days after the patient had received 1400 mg iron isomaltoside 1000. No acute anaphylactoid/anaphylactic or delayed allergic reactions were observed. There were no clinically significant changes in routine clinical laboratory tests or vital signs. The mean maximal change from baseline in Hb was 8.5 g/L (SD: 8.8: p=0.0003). The mean maximal change from baseline in serum ferritin was 500 µg/L (SD: 208::p < 0.0001).

Conclusion: One dose iron repletion with Iron isomaltoside 1000 administered intravenously to pre-dialysis CKD patients in this study was safe and well tolerated and improved markers of iron deficiency anemia.

1) Poster No. M560, World Congress of Nephrology, May 22-26 2009, Milan, Italy.

## SA-PO2350

**The Effect of Once-Monthly C.E.R.A. Administration on Iron Status and Hemoglobin Concentrations in Dialysis Patients with Chronic Kidney Disease** Kostas C. Siamopoulos. *(on Behalf of the ML20952 Study Group) Department of Nephrology, University Hospital of Ioannina, Ioannina, Greece.*

**INTRODUCTION AND AIMS:** Continuous erythropoietin receptor activator (CERA) is a novel agent with unique receptor activity, allowing once-monthly (Q4W) administration for effective maintenance of stable hemoglobin (Hb) in patients (pts) with chronic kidney disease (CKD). We examined the effect of Q4W CERA on iron status, assessed by ferritin/transferrin saturation (TSAT), and on Hb concentrations.

**METHODS:** This prospective, multicentre, single arm, open label study assessed the efficacy, safety and tolerability of Q4W CERA for the maintenance of Hb levels in dialysis patients with CKD. Pts (n=188) in Greece (≥18y) receiving adequate dialysis and IV epoetin or darbepoetin with stable baseline (bl) Hb (10.5-12.5g/dL) entered a 16-week (wk) CERA dose titration phase (DTP) followed by an 8wk efficacy evaluation period (EEP). At DTP (wk16) and EEP (wk24) efficacy parameters and exposure were analyzed by bl tertiles of ferritin and TSAT. The iron administration protocol remained unchanged during the whole course of the study.

**RESULTS:** The table below shows that CERA Q4W was effective in maintaining Hb levels, irrespective of ferritin/TSAT bl levels (ANOVA test).

| | Bl mean (SD) Hb (g/dL) | Wk 16 mean (SD) Hb (g/dL) | Wk 24 mean (SD) Hb (g/dL) |
|---|---|---|---|
| Ferritin µg/L | | | |
| ≤295 | 11.6 (0.56) | 11.9 (0.87) | 11.6 (1.01) |
| >295-≤529 | 11.6 (0.54) | 11.8 (1.02) | 11.7 (1.15) |
| >529 | 11.6 (0.60) | 11.7 (1.06) | 11.4 (1.20) |
| TSAT % | | | |
| ≤25.5 | 11.6 (0.57) | 11.8 (0.87) | 11.7 (1.19) |
| >25.5-≤35.5 | 11.6 (0.54) | 11.8 (1.09) | 11.5 (1.08) |
| >35.5 | 11.6 (0.60) | 11.7 (0.99) | 11.5 (1.11) |

Mean TSAT at wk16 was 40(SD=18.8)% and wk24 43(30.0)% were significantly higher (*p<0.05;* sign ranked test*)* compared to bl 35(16.1)%. This could be correlated with the trend of decreasing CERA doses over time, especially in the low TSAT subpopulation.

**CONCLUSIONS:** Irrespective of baseline ferritin and TSAT levels, Q4W CERA administration in dialysis pts provided stable Hb maintenance. Interestingly, the analysis showed that during the 24wks of the study the mean TSAT levels significantly increased compared to baseline.

## SA-PO2351

**Effect of Iron Repletion on Platelet Counts (PLT) in Iron Deficient (ID) Non-Dialysis-CKD Patients** Anatole Besarab, Jerry Yee, Stan Frinak. *Nephrology & Hypertension, Henry Ford Health System.*

ID produces "relative" thrombocytosis that may contribute to thrombotic complications noted in erythropoietin treated patients. A database analysis of 40,000 hemodialysis (HD) pts found PLT to be inversely related to severity of ID. Post-hoc analysis of the DRIVE Study showed a reduction in PLT after administration of 1000 mg of ferric gluconate over 8 dialysis sessions to HD patients.

We dosed non-dialysis CKD outpatients with 500 or 1000 mg of low molecular weight iron dextran over 2-4 hr to correct ID, [TSAT < 20%, ferritin <100 ng/mL] and analyzed hematologic responses of Hb, iron indices, and PLT in 132 subjects without intercurrent events who were receiving once-monthly darbepoetin (DA) and 32 pts "unresponsive to oral iron therapy" not on DA (table1).

Results are presented as mean (sem). Age and eGFR of the DA treated (+) and DA-naive (-) subjects were 69.9 yr and 68.3 yr and 34.4 (1.4) and 36.5 (1.7) mL/min/1.73 $m^2$ respectively, both p >0.05.

| parameter | Dose status/Time | - 1 mo | 0 (basal) | + 1 mo | +2 mo |
|---|---|---|---|---|---|
| Hb (g/dL) | DA+ | 10.2 (0.1) | 10.3 (0.2) | 11.4 (0.2) | 11.5 (0.2) |
| Hb (g/dL) | DA- | 10.1 (0.2) | 10.0 (0.2) | 10.7 (0.2) | 10.9 (0.2) |
| PLTS (x 1000) | DA+ | 295 (12) | 296 (9) | 268 (12) | 255 (7) |
| PLTS (x 1000) | DA- | 289 (19) | 308 (18) | 281 (17) | 264 (13) |
| TSAT (%) | DA+ | 16.3 (1.0) | 13.2 (0.6) | 24.4 (1.2) | 25.3 (1.3) |
| TSAT (%) | DA- | 15.5 (1.1) | 14.0 (1.0) | 24.5 (1.9) | 25.6 (2.0) |
| Ferritin (ng/mL) | DA+ | 56 (5) | 39 (5) | 167 (16) | 155 (15) |
| Ferritin (ng/mL) | DA- | 66 (8) | 53 (7) | 237 (21) | 203 (18) |
| DA dose (mcg/mo) | DA+ | 116 (10) | 170 (11) | 157 (12) | 115 (11) |
| DA dose (mcg/mo) | DA- | 0 | 0 | 0 | 0 |

MANOVA : iron dose in DA + pts determined magnitude of change from baseline in PLT, DA dose, Hb and ferritin (all p<0.05). PLT decrease was greatest in those with basal counts >300 K, varied inversely with initial basal PLT (R=0.70,, p<0.05)) and was independent of basal ferritin, TSAT or DA dose.

In summary, correction of ID lowers PLTS and improves erythropoiesis. The PLT effect is independent of DA. Clinical significance of PLT reduction to other outcomes requires additional study.

## SA-PO2352

**The Impact of Intravenous Ferric Carboxymaltose on Renal Function: An Analysis of the FAIR-HF Study** Piotr Ponikowski,[2] Iain C. Macdougall,[1] Stefan D. Anker.[3] *[1]Kings College Hospital, London, United Kingdom; [2]4th Military Hospital, Wroclaw, Poland; [3]Charité, Campus Virchow-Klinikum, Berlin, Germany.*

Background: Renal dysfunction commonly complicates the natural course of chronic heart failure (CHF) and predicts poor outcome. Currently applied CHF therapies have either no effect on, or even worsen renal function. The FAIR-HF study demonstrated that treatment with intravenous ferric carboxymaltose (FCM) in iron deficient CHF patients is well tolerated and improves symptoms and quality of life. Here we report the effects of FCM on renal function in FAIR-HF. Methods: We enrolled 459 CHF patients (NYHA class II/III, LVEF 32%) with iron deficiency (ferritin <100 µg/L, or between 100-300 µg/L if transferrin saturation <20%); 304 patients were randomly assigned to FCM and 155 to placebo; treatment was continued for 24 weeks. Renal function was assessed at baseline and at Week 4, 12 and 24 visits as estimated glomerular filtration rate (eGFR) using the MDRD formula. Results: At baseline, renal function did not differ between groups (63.8±21.2 vs 64.8±25.3 mL/min/1.73$m^2$, FCM vs placebo). FCM significantly improved NHYA class and self-assessed patient global assessment from week 4 (P<0.001) and the effect was independent of baseline eGFR and anemia status (P>0.42). Treatment with FCM was associated with improved renal function across all patients (table; P>0.2 for interaction with baseline renal function, age, sex, CHF severity, underlying CHF aetiology, anemia status). More patients in the FCM group demonstrated an eGFR improvement of at least 5mL/min/1.73$m^2$ (week 4: 38% vs 34%, week 12: 33% vs 26%, week 24: 35% vs 25%, FCM vs placebo respectively).

Effect of FCM on renal function

| | eGFR change (mL/min/1.73m$^2$) | | | |
|---|---|---|---|---|
| | FCM | Placebo | eGFR difference (ml/min/1.73m$^2$)* | P for treatment |
| Week 4 | 3.7±0.9 | 0.9±1.2 | 2.8±1.5 | 0.054 |
| Week 12 | 2.3±0.9 | -0.7±1.1 | 3.0±1.5 | 0.049 |
| Week 24 | 3.2±0.7 | -0.6±1.4 | 4.0±1.7 | 0.017 |

*difference between FCM and placebo (LSM mean±SE)

Conclusions: Intravenous FCM improved CHF symptoms and quality of life regardless of baseline renal function. Iron treatment was also associated with improved renal function.

Disclosure of Financial Relationships: Consultancy: Vifor PharmaResearch Funding: Vifor Pharma; Honoraria: Vifor Pharma; Scientific Advisor: Vifor Pharma.

## SA-PO2353

**Early Improvement in Blood Pressure and Renal Cytokines after Bariatric Surgery** Sukhpreet Singh Dubb,[1] Marco Bueter,[1] Abhijit Singh Gill,[1] Lia Joannou,[2] Ahmed Ahmed,[3] Andrew H. Frankel,[4] Frederick W. K. Tam,[4] Carel W. Le Roux.[1] *[1]Department of Investigative Medicine, Imperial College, London, United Kingdom; [2]Department of Chemical Pathology, Imperial College, London, United Kingdom; [3]Department of Academic Surgery, Imperial College, London, United Kingdom; [4]Imperial Kidney and Transplant Institute, Imperial College, London, United Kingdom.*

**Introduction:** We hypothesised that metabolic related inflammatory cytokines monocyte chemotactic protein 1 (MCP-1), macrophage migration inhibitory factor (MIF) and chemokine (C-C motif) ligand 18 (CCL-18) are associated with obesity related glomerulopathy (ORG) and measured changes in these cytokines in patients with weight-loss following bariatric surgery.

**Methods:** Blood pressure (BP) measurements, urine and blood samples were collected from 34 morbidly obese patients prior to and 4 weeks after bariatric surgery. Serum biochemistry, urine albumin and creatinine were measured. Glomerular filtration rate (GFR) was assessed by serum cystatin C. Urinary and serum levels of MCP-1, MIF, CCL-18 and hemofiltrate CC chemokine 15 (CCL-15, a non-metabolic control cytokine) were measured using ELISA.

**Results:** Weight loss averaged 9.3 ±0.8 kg 4 weeks after surgery. Systolic BP decreased from 142.9 ±3.2 to 128.1 ±2.1 mmHg (p<0.001), and diastolic BP decreased from 87.1 ±1.5 to 79.2 ±1.1 mmHg (p<0.001). Serum creatinine decreased from 73.6 ±2.0 to 68.1 ±1.7 umol/L postoperatively (p<0.05), however there were no significant differences in urinary albumin/creatinine ratio (p=0.47) or serum cystatin C (p=0.47). Bariatric surgery significantly improved the inflammatory status of patients with a reduction of serum CRP (25.2 ±4.4 to 8.1 ±1.1 mg/L, p<0.001). Furthermore there were reduced levels of urinary MIF (203.1 ±26.6 to 90.4±12.1 ng/mmol Cr, p<0.001), urinary MCP-1 (26.1±2.6 to 16.7±2.3 ng/mmol, p<0.001), urinary CCL-18 (96.8±29.2 to 22.0±7.5 ng/mmol Cr, p<0.05) and serum CCL-18 (423.1 ±106.5 to 96.1 ±23.7 ng/ml, p<0.001). Urinary CCL-15, serum MIF, MCP-1 and CCL-15 changes were not statistically significant.

**Conclusion:** This study demonstrates the early effects of surgically induced weight loss upon BP and urinary cytokines.

**The Effect of a Multidisciplinary Care Clinic on Outcomes in Pediatric Chronic Kidney Disease** Salma A. Ajarmeh,[1] Lee Er,[2] Ognjenka Djurdjev,[2] Janis M. Dionne.[1] *[1]Pediatric Nephrology, BC Children's Hospital, University of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada.*

**Objectives**: To describe the effect of multidisciplinary care (MDC) on the clinical outcomes of children with chronic kidney disease (CKD) in British Columbia.

**Methods**: The MDC clinic started at BC Children's Hospital in 2006. In this cross-sectional retrospective study, we analyzed the data of all patients seen in 2003 (n=73) and in 2009 (n=125). Patient demographics and laboratory results were analyzed.

**Results**: Patient demographics were similar though CKD stage is significantly lower in 2009 (P=0.02). Hemoglobin level was significantly higher in 2009 (130 g/L vs. 122 g/L, P=0.002) and varied by both cohort and CKD stage. For bone mineral metabolism, 78% of the patients reached KDOQI calcium target for age in 2009 compared to 55% in 2003 (P=0.001). Calcium level varied by cohort and CKD stage (P<0.01). Phosphate and PTH varied only by CKD stage. Albumin level was significantly higher in 2009 (44 g/L vs. 40 g/L, p=0.0001) and varied by CKD stage and cohort. Blood pressure control was better in 2009 with 17% hypertensive on evaluation compared to 30% in 2003 (P= 0.045). There were no significant differences in physical growth or renal disease progression between groups. Patients were significantly more likely to see a social worker or pharmacist in 2009 and a dietician if they had CKD stages 3-5 (P<0.05). Allied health support was essential as the median number of medications per patient in 2009 was 4.0 (max 10) and 30% were receiving caloric supplements. Hospitalization events were comparable but the total length of stay in 2009 was shorter than in 2003 (median 0.2 vs 3.0 days, P=0.012).

**Conclusions:** The multidisciplinary care clinic improved the outcome of children with CKD especially in anemia, bone metabolism and blood pressure control.

**Irbesartan Prevented the High Glucose Induced Endothelial Mesenchymal Transition** Rining Tang, Hou-Yong Dai, Jie Ni, Kun Ling Ma, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China.*

**Background---:** Substantial evidence suggests that high glucose causes endothelial cells damage, while the potential mechanism remains to be clarified. The aim of this study was to investigate the influence of high glucose on endothelial to mesenchymal transition (EndMT) and it's relevance with the activation of renin angiotensin system.

**Methods:** Primary human aortic endothelial cells (HAEC) were divided into three groups: normal glucose group (NG), high glucose group (HG) and the Irbesartan (1μM) treated group (HG+Irb). The concentration of angiotensin II in the supernatant was detected by radioimmunoassay. The pathological changes were investigated by fluorescence microscope, electron microscope. Immunofluorescence staining was performed to detect the co-expression of CD31 and markers of fibroblasts such as fibroblast specific protein1 (FSP1). Expression of FSP1 and α-SMA were detected by RT-PCR and Western Blot.

**Results:** Treatment of HAEC to HG led to a significant increasing expression of FSP1 protein and angiotensin II in dose and time dependent manner. Incubation of HAEC with HG resulted in a fibroblast-like phenotype and an increasing microfilament and rough endoplasmic reticulumin in the cytoplasm. And the expression of FSP1, α-SMA was significantly increased in the HG group. These changes were inhibited by treatment with Irbesartan ($P$<0.05). Double staining of HAEC showed co-localization of CD31 and FSP1, and some cells acquisition of a spindle-shaped morphology and loss of CD31 staining. Irbesartan, however, attenuated the expression of EndMT ($P$<0.05).

**Conclusions:** These findings suggested a novel mechanism that angiotensin II might mediate the HG induced endothelial damage through EndMT, which provided a new insight about the early application of ARB to protect the blood vessels and finally to prevent the organ failure in diabetes.

**Hemodialysis Does Not Reverse Cognitive Dysfunction and Cerebral Metabolic Changes in Patients with Chronic Renal Insufficiency** Anita Blanka Tryc,[1,5] Güldan Alwan,[1] Martin A. Bokemeyer,[2] Annemarie Goldbecker,[1,5] Hartmut Hecker,[3] Karin Weissenborn,[1] Marion Haubitz.[4] *[1]Clinic for Neurology, Hannover Medical School, Hannover, Germany; [2]Institute for Neuroradiology, Hannover Medical School, Hannover, Germany; [3]Institute for Biometry, Hannover Medical School, Hannover, Germany; [4]Centre for Internal Medicine, Clinic for Nephrology, Hannover Medical School, Hannover, Germany; [5]Centre for Integrated Research and Treatment in Transplantation Medicine, Hannover Medical School, Hannover, Germany.*

**Background:** The diagnosis of uremic encephalopathy is normally considered if patients with end-stage renal disease present with neuropsychiatric symptoms. However, cognitive deficits may occur in patients with chronic renal insufficiency (CRI) long before any overt neurological symptoms can be observed. We hypothesized that cognitive dysfunction in patients with CRI both, treated and untreated by hemodialysis, may correspond to metabolic changes in distinct brain regions. **Methods:** Magnetic resonance spectroscopy ($^1$H-MRS) of the parieto-occipital white matter, the occipital gray matter, the basal ganglia and the pons, conventional magnetic resonance imaging of the brain and a comprehensive neuropsychological assessment was performed in 38 patients with CRI compared to 63 healthy controls, adjusted for age and education. Fifteen patients were on hemodialysis, twenty-three suffered CRI stage 4 to 5. **Results:** MRS alterations were predominantly found in the white matter. Concentrations of creatine containing compounds (Cr) were decreased in dialyzed and non-dialyzed patients. Choline concentration (Cho) and combined N-acetylaspartate and N-acetylaspartylglutamate concentration (NAx) were reduced only in dialyzed patients. Disturbance in memory and learning ability as well as attention deficits were observed in both patient groups. Of note, attention deficits were more severe in dialyzed patients. MRS results correlated with attention deficits in dialyzed patients. **Conclusions:** Hemodialysis does not warrant cognitive capability in patients with chronic renal insufficiency. Instead a negative impact of hemodialysis on cognitive function must be considered.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2357

**A Randomized, Crossover, Multicenter Study of Once-Biweekly Administration of Epoetin-α Compared with Darbepoetin-α in CKD Patients Not Receiving Dialysis** Young-Il Jo,[1] Dongho Yang,[2] Sug Kyun Shin.[3] *[1]Nephrology, Konkuk University Hospital, Seoul, Republic of Korea; [2]Bundang CHA Hospital, Sungnam, Republic of Korea; [3]NHIC Ilsan Hospital, Goyang, Republic of Korea.*

1. Background: There is now increasing evidence that epoetin-α (EPO), despite its relatively short serum half-life, can be administrated at extended dosing intervals. However, there is no randomized, cross-over trial concerning comparison of once-biweekly (Q2W) EPO with darbepoetin-α (DA) in CKD patients not receiving dialysis.

2. Introduction: We designed this study to investigate whether Q2W EPO is as effective as Q2W equal dose of DA in correcting of anemia in CKD patients not receiving dialysis.

3. Methods: Seventy-four pre-ESRD subjects with renal anemia (M:F 31:43, age 60.6±12.2, eGFR-MDRD 22.9±9.9 mL/min/1.73m$^2$, DM 58.1%) were equally randomized to EPO or DA group and treated with Q2W subcutaneous EPO or DA for 2 months. After 4 or 8 weeks of washout period, subjects of EPO or DA group switched to another regimen for 2 months.

4. Results: No significant differences were observed in baseline parameters before DA or EPO therapy, including Hb levels, serum ferritin, and transferrin saturation. Hb levels of post-erythropoiesis stimulating agents (ESA) therapy significantly increased compared with those of pre-ESA therapy (DA, 9.5±0.9 *vs.* 10.7±1.2 g/dL, *p<0.001*; EPO, 9.6±0.9 *vs.* 10.3±1.2 g/dL, *p=0.002*). Percent increase of Hb levels of DA therapy was significantly higher than that of EPO therapy (112.6±13.5 *vs.* 107.3±9.8%, *p=0.018*) although there was no significant difference in Hb levels of post-ESA therapy between two groups. During washout period, Hb levels were slightly decreased both two groups, but there was no significant difference in % decrease of Hb levels between two groups. Erythropoietin resistance index did not show significant difference between two groups (DA *vs.* EPO, 7.9±1.7 *vs.* 8.1±1.9 IU/kg weight/g Hb, *p=0.683*). There were no any serious adverse effects that led to permanent withdrawal.

5. Conclusion: These findings of our study indicate that Q2W high dose of EPO therapy may be effective as Q2W DA therapy in the management of renal anemia in CKD patients who are not on dialysis.

Disclosure of Financial Relationships: nothing to disclose

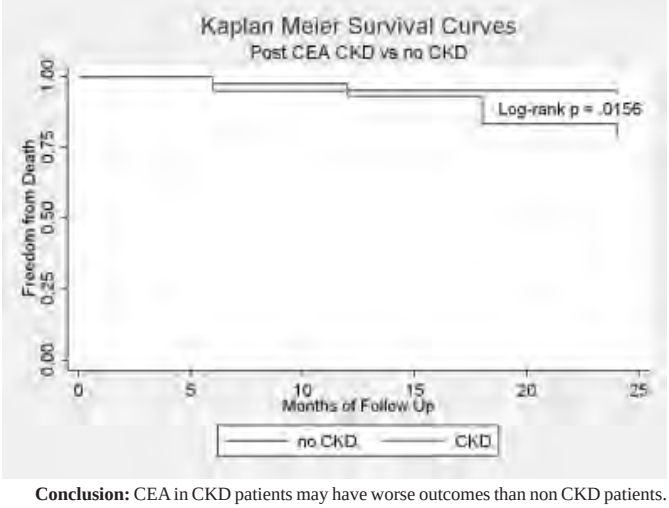
## SA-PO2358

**Chronic Kidney Disease Negatively Impacts Survival in Patients Having Carotid Endarterectomy Surgery** Laura Hesemann,[1] Sri Divya Muppala,[1] Gautam M. Phadke,[1] Georges Saab,[2] Kunal Chaudhary.[1,3] *[1]Department of Medicine, University of Missouri, Columbia, MO; [2]Division of Nephrology, Washington University, St Louis, MO; [3]Nephrology Division, Harry S Truman VA Hospital, Columbia, MO.*

**Introduction** : There are multiple etiologies for Cardiovascular accidents(CVA) , and among them extracranial carotid artery disease accounts for approximately 25% of ischemic strokes. It has been shown that carotid revascularization by carotid endarterectomy(CEA) can decrease the risk of CVA in appropriately selected population with carotid artery disease. Carotid revascularization has been shown to be safe and clinically effective in many large multicentered randomized clinical trials. However, most of these large trials have predominately excluded the patients with kidney failure. The aim of the study was to find out whether underlying Chronic Kidney Disease(CKD) influences outcomes in patients undergoing CEA.

**Methods:** We retrospectively analyzed data of one hundred sixty-eight patients who had undergone CEA at the University of Missouri and Harry S Truman Veterans Hospital between years 2002 and 2008.

**Results:** After adjusting for age, race, body mass index, coronary artery disease, statin use, ACE inhibitor/ARB use , beta blocker use and Diabetes mellitus, each 10ml/min/1.73 m$^2$ increase in GFR was associated with a 49% (95% CI;23%-66%, p =0.001) lower risk of death after CEA. At 24 months of follow up patient survival was greater in non CKD patients as compared to CKD patients (95% vs 80% ; log rank p= 0.016).



**Conclusion:** CEA in CKD patients may have worse outcomes than non CKD patients. Providers should take this in account when making decisions regarding this surgery. Larger clinical studies will be needed to verify this conclusion with certainty.

Disclosure of Financial Relationships: nothing to disclose

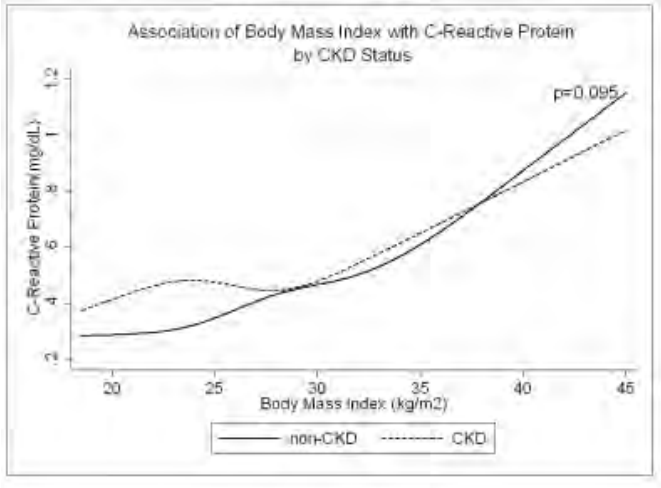
## SA-PO2359

**Does Chronic Kidney Disease Modify the Association between Body Mass Index and Cardiovascular Disease Risk Factors?** Nisha Bansal, Eric Vittinghoff, Laura C. Plantinga, Chi-Yuan Hsu. *Medicine, University of California, San Francisco, San Francisco, CA.*

Background: Several studies have shown that excess weight is "paradoxically" associated with better cardiovascular (CVD) outcomes and mortality in chronic kidney disease (CKD). One potential explanation for this "inverse" relationship is that the usual positive correlation between severity of CVD risk factors -- such as worse lipid levels, inflammation, blood pressure and fasting glucose levels -- and higher body mass index (BMI) is reversed among those with CKD. To test this hypothesis, we determined the relationship between BMI and CVD risk factors in patients with and without CKD.

Methods: This was a cross-sectional study of NHANES 1999-2006. Subjects with BMI <18.5 kg/m$^2$ were excluded. CKD was defined as glomerular filtration rate < 60 ml/min/1.73 m$^2$. Covariates were: age, race, gender and use of relevant prescription medications. Outcome variables were: total cholesterol, LDL cholesterol, HDL cholesterol, triglycerides (TG), C-reactive protein (CRP), systolic blood pressure (SBP), diastolic blood pressure (DBP), and fasting glucose (FG).

Results: There were 1,895 and 32,431 patients with and without CKD, respectively. Those with CKD were older, more likely to be female or white, and had higher BMI. The shapes of the association between BMI and total cholesterol, LDL cholesterol, HDL cholesterol, TG, CRP, SBP, and FG were similar in those with or without CKD. The figure below illustrates the association between BMI and CRP. In a sensitivity analysis excluding patients taking relevant prescription medications, our results did not differ substantially.



Conclusions: CKD did not modify the relationship between higher BMI and CVD risk factors. Thus, inverse associations between BMI and CVD risk factors cannot explain why CKD patients with higher BMI have better outcomes.

## SA-PO2360

**Chronic Kidney Disease Impairs the Hematopoietic Stem Cell Compartment** Matthieu Monge,[1,2] Melissa van Pel,[3] Michiel Siebelt,[4] Marina M. Aleksinskaya,[1] Hetty C. de Boer,[1] Jacques Duijs,[1] Coen van Solingen,[1] Ziad Massy,[2] Ton J. Rabelink,[1] Anton Jan Van Zonneveld.[1] *[1]Nephrology and Einthoven Laboratory for Vascular Experimental Medicine, LUMC, Leiden, Netherlands; [2]INSERM ERI12, Amiens University, Amiens, France; [3]Department of Immunohematology and Bloodtransfusion, LUMC, Leiden, Netherlands; [4]Orthopaedic Research Laboratory, ErasmusMC, Rotterdam, Netherlands.*

Chronic kidney disease (CKD) is marked by sustained parathyroid hormone (PTH) increase. This results in specific bone disorders (CKD-MBD), mainly due to increased osteoblast activity. Osteoblasts are key regulators of the hematopoietic stem cell (HSC) niche. We investigated the effect of increased osteoblast activity on HSC homeostasis.

Ten C57Bl/6 mice underwent surgically-induced CKD (thermocauterisation-nephrectomy), and were compared to sham operated controls. 12 weeks after CKD-induction, bone structure was analyzed by micro-CT scan to confirm CKD-MBD and bone marrow cells (BMC) were harvested. HSC and hematopoietic progenitor cells (HPC) (long- and short-term repopulating cells respectively) were analyzed phenotypically by flowcytometry and functionally by cobblestone area forming cell (CAFC) assay.

Throughout the study urea levels were increased in the CKD group compared to controls (30.5mM±2.8 vs 10.2mM±1.3 , p<0.01). Bone analysis showed increased trabecular bone volume (BV, 515µ$^3$±64 vs 400µ$^3$±89, p<0.001), decreased span incurvation (1.9AU±0.1 vs 2.1AU±0.1, p<0.01), and decreased cortical thickness (150µ±9 vs 158µ±9, p<0.05 ), compatible with a chronic exposure to high levels of PTH.

In CKD mice, long-term repopulating Lin$^{neg}$Sca1$^{pos}$cKit$^{pos}$ (LSK) CD135$^{neg}$CD34$^{neg}$ HSC were significantly decreased compared to controls (0.0028%±0.001 vs 0.0049%±0.001, p<0.05), whereas HPC (LSK CD135$^{neg}$CD34$^{pos}$) remained unaltered. However, CAFC analysis showed a decrease (0.5±0.1 vs 1.4±0.7 per 10$^5$ BMC, p<0.05) in both HSC and

HPC frequencies, indicating a functional defect in their repopulating capacities. Also, total LSK cells number correlated positively to BV.

Our data show that CKD is associated with functional changes in the hematopoietic compartment, due to increased osteoblasts activity, as indicated by the bone changes.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2361**

**Evolution of Left Ventricular Geometry from CKD through ESRD: Results from the CRIC Study** Nisha Bansal, Martin Keane, Dawei Xie, Kelvin Tao, Crystal A. Gadegbeku, Alan S. Go, Akinlolu O. Ojo, Mahboob Rahman, Jackson T. Wright, Patrice Delafontaine, L. Lee Hamm, John W. Kusek, Leigh Rosen, Chi-Yuan Hsu. *Chronic Renal Insufficiency Cohort.*

Background: Left ventricular (LV) hypertrophy is a powerful and independent predictor of mortality in incident end-stage renal disease (ESRD) patients. However, little is known about the longitudinal change in LV geometry as patients transition from chronic kidney disease (CKD) to ESRD, which will identify opportunities for intervention during the natural history of disease. To our knowledge, no prior study performed research echocardiograms among advanced CKD patients who subsequently transitioned to ESRD.

Methods: We examined participants enrolled in the Chronic Renal Insufficiency Cohort (CRIC). In pair-wise analyses we compared protocol echocardiograms performed at advanced CKD and incident ESRD.

Results: One hundred sixty two participants (age 55.2 ± 12.1 years, 46% female and 62% African-American) had echocardiograms performed at advanced CKD and again at incident ESRD. Mean estimated GFR at advanced CKD was 17 ± 4 ml/min/1.73 $m^2$. The mean time between the two echocardiograms was 23 ± 11 months. There was no change in LV geometry between advanced CKD and incident ESRD [Table 1]. However, ejection fraction (EF) decreased. The prevalence of myocardial infarction increased from 24% to 35% (p=0.02) and congestive heart failure from 14% to 24% (p=0.02).

Conclusions: There was further decrement in EF accompanied by an increase in clinical cardiac events during the transition from advanced CKD to ESRD. However, much of the cardiac structural disease observed among incident ESRD patients was already present during advanced CKD. Interventions to prevent and treat cardiovascular disease must start at earlier stages of CKD.

Table 1

| Echocardiographic Measurement | Advanced CKD | Incident ESRD | P-Value |
|---|---|---|---|
| LV mass index (g/m^2.7) | 76 ± 28 | 75 ± 24 | 0.8 |
| LV EF (%) | 53 ± 8 | 50 ± 9 | 0.006 |
| EF < 35% (%) | 1 | 7 | 0.007 |
| LV geometry | | | 0.8 |
| Normal (%) | 7 | 5 | |
| Concentric remodeling (%) | 5 | 7 | |
| Eccentric hypertrophy (%) | 20 | 25 | |
| Concentric hypertrophy (%) | 68 | 63 | |

Disclosure of Financial Relationships: nothing to disclose

**Association of Impaired Endothelium-Dependent and Nitroglycerin-Induced Vasodilation with Risk of Chronic Kidney Disease (CKD)** Jing Chen,[1] L. Lee Hamm,[1] Fred E. Husserl,[3] Emile Mohler,[2] Robin Arora,[1] Islam Enver Khan,[1] Arnold B. Alper,[1] Myra A. Kleinpeter,[1] Rajesh G. Shenava,[1] Eric E. Simon,[1] Jiang He.[1] *[1]Medicine, Tulane University, New Orleans, LA; [2]Medicine, University of Pennsylvania, Philadelphia, PA; [3]Medicine, Ochsner Health System, New Orleans, LA.*

Previous clinical studies reported that impaired endothelium-dependent vasodilation was common in patients with end stage renal disease. We studied endothelium-dependent and nitroglycerin-induced vasodilation in 171 patients with CKD and 183 controls without CKD from community. CKD was defined as estimated glomerular filtration rate (eGFR) <60 ml/min/1.73$m^2$ or presence of albuminuria. Brachial artery endothelium-dependent vasodilation [flow mediated dilation (FMD)] to reactive hyperemia following 5 min of forearm ischemia and the response to sublingual nitroglycerin (NTG) were measured in the subjects using a standard protocol. Compared to those without CKD, patients with CKD were older (56 vs. 53 yrs), more likely to be male (57% vs. 45%), less likely to have graduated from high school (59% vs. 81%), or consume alcohol (29% vs. 58.2%). Race and cigarette smoking were comparable between CKD patients and controls. Mean systolic blood pressure (132 vs. 122 mmHg), body mass index (32 vs. 29 kg/$m^2$), fasting glucose (120 vs. 102 mg/dL), and triglyceride (144 vs. 106 mg/dL) were higher while HDL (50 vs. 58 mg/dL) and LDL cholesterol (102 vs. 118 mg/dL) were lower in CKD patients than in controls. After adjustment for these risk factors, multivariable-adjusted median (inter-quartile range) of FMD was 5.4% (2.6%, 8.7%) in CKD patients and 8.8% (5.8%, 11.9%) in controls (p<0.0001 for group difference). In addition, multivariable-adjusted median (inter-quartile range) of nitroglycerin-induced vasodilation was 14.2% (9.4%, 19.5%) in CKD patients and 20.9% (14.6%, 26.5%) in controls (p=0.005 for group difference). These data indicated that impaired endothelium-dependent and nitroglycerin-induced vasodilation were associated with CKD.

**SA-PO2363**

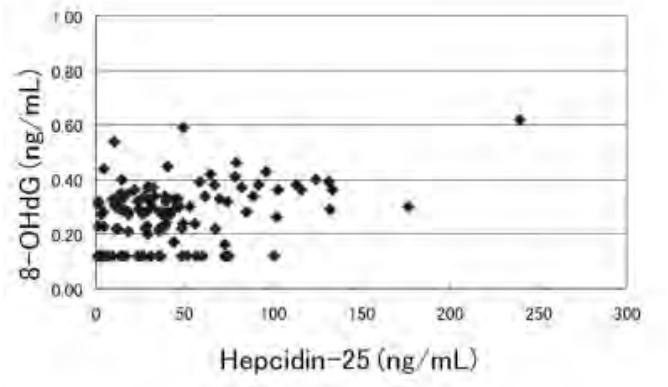
**Association between Hepcidin and Oxidative Stress in Chronic Kidney Disease** Yukio Maruyama,[1] Keitaro Yokoyama,[1] Hiroyasu Yamamoto,[1] Masaaki Nakayama,[1] Tatsuo Hosoya.[1] *[1]Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Reseach Division of Dialysis and Chronic Kidney Disease, Tohoku University Graduate School of Medicine, Sendai, Japan.*

INTRODUCTION AND AIMS. Among patients with chronic kidney disease (CKD), both increased oxidative stress and higher serum ferritin levels are risk factors for CVD, and correlate with one another. Hepcidin controls circulating iron levels by regulating the absorption from the intestine as well as the release from macrophages. Although it is clear that hepcidin is a key mediator of anemia of chronic disorders, associations between hepcidin and oxidative stress in CKD are still unknown.

METHODS. One hundred seventeen CKD patients not receiving renal replacement therapy (62±15 years and 85 males) participated in this cross-sectional study. The concentration of serum hepcidin were measured using surface-enhanced laser desorption ionization time of flight mass spectrometry (SELDI-TOF MS), and serum 8-hydroxy-2'-deoxyguanosine (8-OHdG), a marker of DNA oxidative injury, were measured using competitive ELISA kit.

RESULTS. The serum hepcidin and serum 8-OHdG levels were 32.8 (0.7 to 240) ng/mL and 0.27±0.11 ng/mL, respectively. There were strong positive associations between serum hepcidin and serum ferritin levels (rho=0.68, P<0.01). Interestingly, serum hepcidin levels were positively associated with serum 8-OHdG levels (rho= 0.34, P<0.01). The serum 8-OHdG level was independently associated with serum hepcidin level in a multiple regression model.

CONCLUSIONS. It is the first report to show a positive association between increased oxidative stress and serum hepcidin levels among CKD patients. It is suggested that increased oxidative stress induces defective iron utilization and increased body iron storage through hepcidin synthesis.



Disclosure of Financial Relationships: nothing to disclose

**Aortic Valve Calcification in Patients with Stage 5D Chronic Kidney Disease** Tatsuhiro Yaginuma, Ichiro Ohkido, Hiroyasu Yamamoto, Keitaro Yokoyama, Yasunori Utsunomiya, Tatsuo Hosoya. *Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University, School of Medicine, Minato, Tokyo, Japan.*

Background: There are many cases of recurrent calcification in patients with chronic kidney disease (CKD) and hemodialysis (HD) at an early time point after aortic valve replacement (AVR). While atherosclerotic plaque is thought to be one of the main factors of aortic valve calcification, mineral metabolism (calcium and phosphate) might contribute to aortic valve calcification. However, additional mechanisms of plaque formation remain uncertain. Therefore, we performed histopathological analysis to determine whether mineral metabolism had been associated with the development of aortic valve calcification in CKD patients with HD.

Methods: We performed histopathological analysis in CKD patients due to non diabetic mellitus (DM) with HD who underwent AVR for aortic stenosis (AS) (N=4) and normal kidney function patients without DM who underwent AVR (N=6) in the hospital from 2006 through 2009.

Results: We found the same expression of markers related to calcification such as Sodium/Phosphate co-transporter type-III (Pit-1), Cbfa1/Runx2 and Osteopontin (OPN) in CKD patients with hemodialysis as compared with normal kidney function patients. In addition, we found robust CD34 expression on calcified valves within both groups.

Conclusions: These findings collectively suggest that mineral metabolism might not contribute to the mechanism of aortic valve calcification in CKD patients with hemodialysis.

**SA-PO2365**

**Right Ventricular Diastolic Function in Dialysis Patients Could Be Affected by Vascular Access** Luca Di Lullo, Fulvio Floccari, Pasquale Polito. *Department of Nephrology and Dialysis, San Giovanni Evangelista Hospital, Tivoli, Roma, Italy.*

BACKGROUND. Tricuspidal annulus plane excursion (TAPSE) measurement is a prognostic index for stratification of cardiac mortality risk in CRF patients with heart failure. It can be easily measured in all patients irrespective of heart rate and rhythm; its usefulness can therefore be extended to those patients in whom tachycardia or atrial fibrillation limits findings from mithral valve Doppler velocity curve. It has been demonstrated adding significant prognostic information to NYHA clinical classification.

AIM. Aim of the study was to examine effects of acute pre-load reduction by hemodialysis (HD) on TAPSE, with focus on the effects of vascular access typology

PATIENTS AND METHODS. Thirty chronically uremic patients (age 51 +/- 10 years, dialytic age 24 +/- 8 months), without overt heart disease, underwent conventional 2D and Doppler ECHO immediately before starting and 15 minutes after ending a mid week hemodialysis session. Twenty patients had distal radio-cephalic artero-venous fistula (AVF), whether ten of them had permanent CVC. Fluid volume removed by HD was 2706 +/- 1047 g/session.

RESULTS. Hemodialysis led to reduction in TAPSE, LVEDV, LVESV, RVEDV, RVESV, peak early (E wave) transmitral flow velocity and ratio of early to late Doppler velocities of diastolic mitral flow.

AVF patients showed significantly greater RV diameters versus CVC patients, whether TAPSE appeared higher in second ones. Only AVF patients group showed TAPSE values below 15 mm.

CONCLUSIONS. Right ventricle diastolic function plays a crucial role in determining clinical outcome in patients with CHF; reduction in TAPSE means reduction in ventricular diastolic distensibility, leading to diastolic dysfunction.

Our data confirm effects of terminal uremia on right ventricle function (chamber dilation, impaired diastolic function), showing that these abnormalities are more frequent in AVF patients versus CVC patients. It is reasonable to explain these clinical features as the effect of pre – load increase operated by AVF.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2366**

**Cardiovascular Autonomic Tone and Vascular Stiffness in Chronic Kidney Disease Stage 5 Patients** Manpreet Kaur,[1] Charanjit Lal,[2] Ashok Kumar Jaryal,[1] Dipankar M. Bhowmik,[2] Dinu Chandran,[1] Kishore Kumar Deepak.[1] *[1]Physiology, All India Institute of Medical Sciences, New Delhi, Delhi, India; [2]Nephrology, All India Institute of Medical Sciences, New Delhi, Delhi, India.*

Arterial baroreflex sensitivity (BRS) is markedly reduced in Chronic Kidney Disease stage 5 (CKD-5) patients. It could be due to vascular stiffening and/or autonomic neuropathy. We investigated baroreflex function and its relation to arterial stiffness and autonomic tone (Heart rate variability, HRV; and blood pressure variability ,BPV)in CKD-5 patients. 15 CKD-5 patients (Age - 40.9 +/- 11 years) and 15 age matched healthy controls were studied. Simultaneous and continuous lead II ECG recordings for HRV and non- invasive beat to beat blood pressure recordings for BPV were done using short term recording protocol. HRV was assessed using time and frequency domain analysis and BRS by sequence method using HRV and BPV data. Vascular stiffness was measured by carotid femoral pulse wave velocity (PWV) and Augmentation index (AI) using applanation tonometry. There were significant differences in BRS, PWV, AI and HRV in CKD-5 patients as compared to controls. BRS was markedly reduced in CKD-5 patients (8.36 +/- 2.1 vs. 17.89 +/- 1.35 ms/mmHg ; p=0.001). Patients showed significantly increased vascular stiffness indices : PWV (9.27 +/- 0.81 vs 7.8 +/- 0.4 m/s; p=0.003) and AI (23.87 +/- 5.26 vs. 16.2 +/- 2.15 % ; p=0.001). PWV and AI were not found to be correlated with BRS. HRV indices in both time and frequency domain were reduced in patients (p=0.001) and directly correlated with BRS (r = 0.479 p=0.03). Values are expressed as Mean +/- SEM. In summary, CKD-5 patients have a decreased BRS, reduced HRV and increased vascular stiffness indices. Our results suggest that, probably increase in arterial stiffness is not primarily responsible for the reduced BRS in CKD-5 patients.

**Effect of Exercise (EXE) on Renal and Cardiac Functions in Animals with Nx5/6 Nephrectomy** Rafael Da Silva Luiz,[1] Kleiton Silva,[1] Rodolfo Rampaso,[1] Luciana Teixeira,[1] Ednei Antônio,[2] Jairo Montemor,[2] Danilo Bocalini,[2] Luiz Moura,[1] Leonardo dos Santos,[2] Paulo Tucci,[2] Nayda P. Abreu,[1] Nestor Schor.[1] *[1]Nephrology Division, UNIFESP, São Paulo, São Paulo, Brazil; [2]Cardio-Physiology and Pathophysiology Laboratory, UNIFESP, São Paulo, São Paulo, Brazil.*

The aim was to evaluate the effects of chronic aerobic EXE on renal and cardiac functions. Adult Wistar rats were studied as control(C,n=8), control+EXE(E,n=8), Nx5/6sedentary(NxS,n=8) and Nx5/6+EXE(NxE,n=8). EXE sessions were performed by swimming with overload of 70% of the maximum load reached for 30min, applied 5days/week/5weeks. Creatinine clearance (CrCl), 24h proteinuria and sclerosis index, cardiac function through echodopplercardiography(ECHO), hemodynamic and muscle papillary contractility (in vitro) were evaluated. CrCl were lower for NxS and NxE vs C and E(0.90±0.11, 1.10±0.09 vs 2.01±0.15, 1.57±0.13mL/min,p<0.05), respectively. Proteinuria was lower in NxE than for NxS (51.4±9.9 vs 96.9±9.9 mg/24h p<0.05). From 100 glomeruli evaluated, NxS presented higher index of alterations vs NxE (16% vs 2%,p<0.05). ECHO disclosed that the weight LV of NxS increased vs C,E and NxE(1.15±0.06 vs 0.98±0.03, 0.91±0.02 and 1.08±0.04 $cm^2$,p≤0.05), respectively. The systolic pressure in the LV was higher in NxS vs C(134 vs 112mmHg,p≤0.05). The maximum strength of contraction developed isometrically at Lmáx was lower in NxS vs NxE, E and C(2.56±0.12 vs 4.56±0.58 , 5.00±0.28, 5.29±0.37g/$mm^2$, p<0.05). Cardiac weight was higher in NxS and NxE vs E and C (4.0±0.1, 3.6±0.3 vs 3.0±0.1, 2.8±0.1mg, respectively, p<0.05) and the weight of LV of NxS was greater than the NxE, E and C (3.2±0.1 vs, 2.8±0.2, 2.3±0.1, 2.1±0.1 mg,respectively,p<0.05). It is suggested that despite the mild effect of EXE on CrCl (~20%:NxE>NxS), there was a significant reduction on proteinuria (~50%) and an important reduction of glomeruli sclerosis in NxE. Also the EXE attenuates the cardiac dysfunction in rats in this model. Thus, it is suggested that these animals would have a diminished progression of renal disease and lower cardiovascular impact of Nx5/6, which indicates that this EXE, could contribute to a better evolution in renal and cardiac functions.

**SA-PO2368**

**Abdominal Obesity Is a Relevant Risk Factor of Subclinical Cardiac Damage in a Cohort of Patients Affected by Chronic Kidney Disease** Carlo Maria Alfieri,[1] Simone Vettoretti,[1] Riccardo Floreani,[1] Cosimo Cafforio,[1] Carla Bonanomi,[2] Gian Battista Danzi,[2] Piergiorgio Messa.[1] *[1]U.O. Nephrology and Dialysis, Fondazione IRCCS CA' GRANDA Ospedale Maggiore Policlinico, Milan, Italy; [2]U.O. Cardiology, FONDAZIONE IRCCS CA'GRANDA Ospedale Maggiore Policlinico, Milan, Italy.*

**Background**: We evaluated whether the coexistence of chronic kidney disease (CKD) and metabolic syndrome (MS) may influence the presence of subclinical cardiac damage.

**Methods**: we evaluated 168 patients with CKD and free from previous cardiovascular (CV) events. Albuminuria (A/C) was determined on the first voiding on three different days and on 24h collection.We used echocardiography to determine left ventricular mass index (LVMI, $g/m^{2.7}$) and midwall Fractional Shortening (mFS) as a precocious index of systolic dysfunction. Left ventricular hypertrophy (LVH) was defined as LVMI>51 $g/m^{2.7}$ and MS according to ATPIII criteria.

**Results**: age 62±15 yrs; males 64%; MS+ 56%; type 2 diabetes 51%; SBP 140±22 mmHg; DBP 80±13 mmHg; waist circumference 100±13 cm; eGFR 60±32 ml/min; logA/C 1,25±0,86. Patients were equally distributed between CKD stages (stage 1=25%;2=25%;3=25%;4=25%). MS+ subjects had a higher prevalence of type 2 diabetes (DM+ 68% in MS+ vs 34% in MS- ;p<0,0001), higher SBP (MS+143±18 mmHg; MS-130±24 mmHg, p=0,0002) while eGFR and logA/C did not differ between two groups. MS+ had higher LVMI (MS+ 57,4±14,5 and MS- 42,5±12,5 $g/m^{2.7}$; p<0,0001) and lower mFS (MS+ 12,2±4% and MS- 16,7±5,3%; p<0,0001). LVMI and mFS correlated with: age, eGFR, logA/C and with all the variables that define MS. In a logistic regression, LVH correlated only with waist circumference (WC), SBP and HDL (RR 1,59 p< 0,0001; RR 1,138 p=0,038 and RR 1,28 p=0,002 for 5 cm increase of WC, 5 mmHg increase of SBP and 5 mg/dl decrease of HDL), while eGFR and logA/C did not.

**Conclusions**: although patients affected by CKD are generally considered to have a high CV risk, the coexistence of MS may increase the risk of subclinical cardiac damage beyond the severity of renal impairment and other relevant risk factors. Moreover, in this population waist circumference was the most important risk factor correlated with subclinical cardiac damage.

Disclosure of Financial Relationships: nothing to disclose

**Skin Autofluoresence Is Associated with Important Cardiovascular Risk Factors in Patients with CKD Stage 3** Natasha J. Mcintyre, Richard J. Fluck, Chris W. McIntyre, Maarten W. Taal. *The Department of Renal Medicine, The Royal Derby Hospital, Derby, Derbyshire, United Kingdom.*

**INTRODUCTION**: Tissue advanced glycation end products (AGE) accumulation is a measure of cumulative metabolic stress. Assessment of tissue AGE by skin autofluoresence (AF) correlates well with cardiovascular (CV) outcomes in diabetic, transplant and dialysis patients and may be a useful marker of CV risk in earlier stages of CKD.

**METHODS**: 1741 patients with estimated GFR 59-30ml/min/1.73$m^2$ were recruited from Primary Care Practices for the Renal Risk In Derby ($R^2$ID) Study. Detailed medical history was obtained and each participant underwent clinical assessment as well as urine and serum biochemistry tests. Skin AF was assessed (mean of 3 readings) as a measure of skin AGE deposition using a cutaneous AF device (AGE Reader®, DiagnOptics, Groningen, The Netherlands).

**RESULTS**: Univariate analysis revealed significant correlations between AF readings and several potential risk factors for CV disease including age, eGFR, cholesterol, haemoglobin, albumin, glucose, diastolic BP, pulse wave velocity, waist to hip ratio, uric acid and deprivation score.

Skin AF readings were also significantly higher among males, diabetics, patients with microalbuminuria, a history of smoking or evidence of self reported cardiovascular disease and also those with CKD Stage 3b.

Multivariable linear regression analysis identified independent determinants of higher skin AF (Table 1; $R^2$=0.16 for equation).

Table 1. Independant determinants of higher skin AF

| | β | p value |
|---|---|---|
| Age (yrs) | 0.153 | <0.0001 |
| Diabetes | 0.137 | <0.0001 |
| Haemoglobin (g/dL) | -0.138 | <0.0001 |
| eGFR (ml/min/1.73m²) | -0.102 | <0.0001 |
| Ever smoked | 0.119 | <0.0001 |
| Previous CVD | 0.085 | <0.0001 |
| Microalbuminuria | 0.072 | 0.002 |
| IMD score (Deprivation) | 0.066 | 0.004 |

**CONCLUSION**: Increased skin AF is independently associated with multiple CV risk markers in CKD 3. Long-term follow up will be conducted to assess the value of skin AF as a predictor of cardiovascular risk in this population.

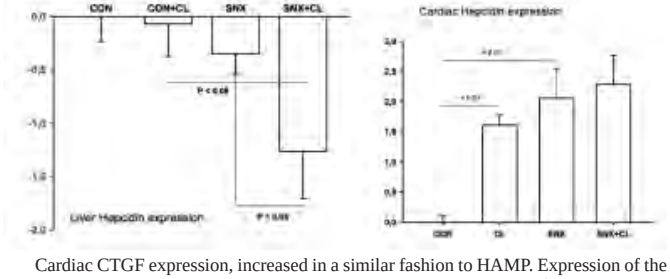
**Myocardial Hepcidin Expression Is Associated with Cardiac Injury in Experimental Cardiorenal Failure** Lennart G. Bongartz,[1] Jaap A. Joles,[1] Marianne Christina Verhaar,[1] Maarten Jan M. Cramer,[2] Roel Goldschmeding,[3] Pieter Doevendans,[2] Branko Braam,[4] Carlo A. Gaillard.[5] *[1]Nephrology, UMC Utrecht, Netherlands; [2]Cardiology, UMC Utrecht, Netherlands; [3]Pathology, UMC Utrecht, Netherlands; [4]Nephrology, Univ. of Alberta, Canada; [5]Nephrology, VUMC, Amsterdam, Netherlands.*

In response to increased iron stores and inflammation hepcidin leads to degradation of ferroportin, the iron efflux channel. Hepcidin is expressed in hearts of rats exposed to hypoxia or inflammation. We hypothesized that cardiac expression of hepcidin in experimental combined heart and kidney failure is also increased. We subjected male Lewis rats to subtotal nephrectomy (SNX) or sham (CON). In wk 9, we performed coronary ligation (CL) or sham-surgery into 4 groups (n=10/grp): CON, SNX, CON+CL, and SNX+CL. Myocardial and hepatic expression of hepcidin (HAMP), CTGF, a marker of fibrosis and the erythropoietin receptor (EPOR) was measured by q-RT-PCR. Biochemical and hemodynamic parameters and cardiac and renal function confirmed the existence of cardiorenal failure. At 15 weeks hepatic expression of HAMP was unchanged or decreased as compared to CON whereas cardiac HAMP expression was increased in CL, SNX and SNX+CL.



Cardiac CTGF expression, increased in a similar fashion to HAMP. Expression of the EPOR did not change. Interestingly, tempol and molsidomine treatment further increased cardiac HAMP expression. In contrast to liver, cardiac HAMP expression is increased by cardiac (local) and renal (remote) injury, which is not associated with modulated EPOR expression. Since destruction of cardiomyocytes may change iron distribution, we speculate that hepcidin expressed in (surviving) cardiomyocytes regulates distribution of iron and iron homeostasis in damaged hearts. The increase in cardiac HAMP upon tempol and molsodomine suggests that ROS does not cause increased HAMP in SNX±CL.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2371

**Beneficial Effects on Arterial Stiffness and Pulse-Wave Reflection of Combined Enalapril and Candesartan in Chronic Kidney Disease** Marie Frimodt-Møller,[1] Anne-Lise Kamper,[2] Svend Strandgaard,[1] Svend Kreiner,[3] Arne Høj Nielsen.[1] *[1]Department of Nephrology, Herlev University Hospital, Herlev, Denmark; [2]Department of Nephrology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [3]Department of Biostatistics, University of Copenhagen, Copenhagen, Denmark.*

Cardio-vascular disease (CVD) is highly prevalent in patients with chronic kidney disease (CKD). Inhibition of the renin-angiotensinsystem (RAS) in hypertension causes differential effects on central and brachial blood pressure (BP), which has been translated into improved cardio-vascular (CV) outcome. *Objective*: To examine if a more complete inhibition of RAS by combining an angiotensin converting enzyme inhibitor (ACEI) and an angiotensin receptor antagonist (ARB) compared to monotherapy has an additive effect on central BP and pulse-wave velocity (PWV), which are known markers of CVD. *Methods:* 67 CKD patients (mean GFR 30, range 13-59 ml/min/1.73m²) participated in an open randomized study of 16 weeks of monotherapy with either enalapril or candesartan followed by 8 weeks of dual blockade aiming at a total dose of 16 mg candesartan and 20 mg enalapril o.d. Pulse-wave measurements were performed at week 0, 8, 16 and 24 by the SphygmoCor device. *Results:* Significant additive BP-independent reductions were found after dual blockade in aortic PWV (-0.3 m/s, P<0.05) and in augmentation index (-2 %, P<0.01) compared to monotherapy. Furthermore PP-amplification was improved (P<0.05) and central systolic BP reduced (-6 mmHg, P<0.01). *Conclusions*: Dual blockade of the RAS resulted in an additive BP-independent reduction in pulse-wave reflection and arterial stiffness compared to monotherapy in CKD patients.

## SA-PO2372

**Carotid Intima Media Thickness (cIMT) in Children with Chronic Kidney Disease (CKD): Results from the Chronic Kidney Disease in Children (CKiD) Cohort Study** Tammy M. Brady,[1] Michael F. Schneider,[2] Joseph T. Flynn,[2] Christopher Cox,[2] Thomas R. Kimball,[2] Mark Mentser,[2] Colin T. White,[2] Susan L. Furth,[2] Bradley A. Warady,[2] Mark Mitsnefes.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]CKiD Study Group.*

OBJECTIVE: To determine the association between selected cardiovascular and demographic exposures and cIMT in children with stage 2-4 CKD.

METHODS: Carotid artery ultrasound (u/s) was obtained 1 year after enrollment in 96 children enrolled in the CKiD study. Standardized protocol imaging was done locally by B-mode u/s and read centrally. Since cIMT was normally distributed, a multivariate linear regression analysis was conducted to quantify the relationship each exposure had with cIMT.

RESULTS: The median age was 12.4 y; median GFR 42.9 ml/min/1.73m2 (IQR: 29.0 to 53.8); median cIMT 0.43 mm (IQR: 0.38 to 0.48). Multivariate analysis which included age, sex, race, pubertal status, birth weight (BWT), CKD etiology, GFR, Ca x P, BMI percentile, LDL-c, baseline and concurrent SBP index (SBPi = SBP/95th %ile BP), and use of antihypertensive medications revealed that each 0.1 unit increase in a child's SBPi at baseline (approximately 1 year prior to cIMT measurement) was associated with a 0.02 mm increase in cIMT (95% CI: -0.001 to 0.03; p=0.07). cIMT in children taking antihypertensive medications was 0.04 mm thicker (95% CI: 0.004 to 0.07, p=0.03) than those not receiving antihypertensive agents, and was 0.05mm smaller in children with a BWT < 2.5kg (-0.09 to -0.007, p=0.02) compared to those with BWT≥2.5kg. All other exposures, including concurrent SBPi, were not associated with cIMT.

CONCLUSION: Children with CKD have impaired carotid artery structure. SBP 1 year prior to cIMT measurement, use of BP medications and higher BWT is associated with increased cIMT. This suggests that despite treatment, hypertensive children with CKD may continue to be at risk for increased cIMT. Further studies are needed to better understand the mechanisms of increased cIMT in this population, and to further explore the relationship between BWT and cIMT.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2373

**The Accuracy of Myocardial Perfusion Imaging in Patients with CKD** Hilana H. Hatoum,[1] Aileen May Arguelles,[1] Kavitha Kesari,[1] Ali K. Owda,[1] Fadi S. Rzouq.[2] *[1]Michigan State University/MRMC; [2]University of Washington.*

Background: Myocardial perfusion imaging (MPI) using sestamibi has gained considerable importance in the evaluation of coronary artery disease (CAD). Nonetheless, little is known about the accuracy of MPI in patients with chronic kidney disease (CKD). We sought to evaluate the accuracy of MPI in patients with CKD with coronary angiography (CA) as the gold standard.

Method: Patients who were admitted to our hospital with suspected acute coronary syndrome were involved in the study. Those who had a sestamibi-MPI followed by CA were the final study group. Characteristics of the patients and their MPS and angiography results were collected and concordance between the two studies were analyzed (we identified the lesions reported in the CA and reviewed the MPS to see if they detected the exact lesions). Then, we identified the true positive (TP), false positive (FP), and the false negative (FN) results on MPS (keeping in mind that a single MPS can have a combination of the TP,FP, and FN results based on the number of lesions in detected in CA). Next, we compared the proportions of TP, TN, and FN between the patients who had a normal kidney function (GFR >60ml/min) Vs those with CKD(GFR <60ml/min).

Results: 150 patients had complete data that was analyzed. 103 had normal kidney function (group A) and 47 had CKD (group B). TP results were reported in 56% Vs 73% in patients in group A Vs B (z value of 1.8, P 0.08), FP results were reported in 27% Vs 15% in patients with group A Vs B (z value of -1.65, P 0.049), and FN results were reported 33% Vs 42% in patients with group A vs B (z value 1.13, P 0.13).

Conclusion: Our analysis showed that MPI is as accurate in patients with CKD as in normal patients. While the TP and FN results were not statistically significant between the 2 groups, patients with CKD had statistically significant lower percentage of FP results (15% Vs 27% and thus a better specificity of the study (79% Vs 71%)), making MPI an even more accurate and dependable study in patients with CKD. These findings need to be confirmed by larger studies but we think that the use of MPI to evaluate for CAD is very reasonable in patients with CKD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2374**

**Retinal Arterioles and Venules Narrow with Progressive Renal Failure** Qi-Lun Ooi,[1] Foong Kien Newk-Fon Hey Tow,[1] Rajeev Deva,[1] Mohd Afzal Alias,[1] Ryo Kawasaki,[2] Tien Y. Wong,[2,3] Deb J. Colville,[1] Anastasia F. Hutchinson,[1] Judith A. Savige.[1] *[1]Medicine (Northern Health), The University of Melbourne, Melbourne, VIC, Australia; [2]Centre for Eye Research Australia, The University of Melbourne, Royal Victorian Eye and Ear Hospital, Melbourne, VIC, Australia; [3]Singapore Eye Research Institute, Singapore National Eye Centre, Singapore.*

**Background and Objectives:** Retinal microvascular narrowing reflects systemic small vessel disease such as stroke and possibly diastolic dysfunction. This study examined the effects of chronic kidney disease (CKD) on retinal vascular caliber, and the role of traditional risk factors in these changes.

**Design, setting, participants and measurements:** This was a cross-sectional study of 126 patients with CKD 3-5 (eGFR< 60 ml/min/1.73 $m^2$) and 126 hospital patients with CKD 1-2. Retinal vessel diameters were measured from digital fundus images (Canon CR5-45NM non-mydriatic camera) by a trained grader using a computer-assisted grading method (University of Wisconsin, Maddison, WI, USA) and Knudtson's formula. These were summarized as the central retinal arteriolar equivalent (CRAE) and central retinal venular equivalent (CRVE).

**Results:** Patients with CKD 3-5 had a smaller mean CRAE (139.4 ± 17.8 um versus 148.5 ± 16.0 um, p<0.001) and CRVE (205.0 ± 30.7 um versus 217.4 ± 25.8 um, p = 0.001) than patients with CKD1-2. CRAE and CRVE decreased progressively as renal function deteriorated from CKD stage 3 to stage 5 (p for trend = 0.075 and 0.044 respectively). Hypertension (OR 3.94, CI 1.52 - 10.2, p = 0.005) and CKD (OR 2.84, CI 1.25 - 6.46, p = 0.013) were independent determinants of arteriolar narrowing but only CKD was an independent risk factor for venular narrowing (OR 3.59, 1.46 - 8.85, p = 0.005) after adjusting for age, gender, diabetes, dyslipidemia and smoking history. Patients with CKD5 and diabetes had a larger mean CRAE (141.4 ± 14.9 um versus 132.9 ± 14.2 um, p=0.05) and CRVE (211.1 ± 34.4 um versus 194.8 ± 23.8 um, p=0.05) than non-diabetics with CKD5.

**Conclusions:** Retinal small vessel narrowing in CKD 3-5 depends on the severity of renal impairment. Studies of retinal vessel caliber must control for impaired renal function.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2375**

**Low 1,25-Dihydroxyvitamin D Is Associated with Vascular Calcification, but Not Vascular Structure or Function in Chronic Kidney Disease** William G. Petchey, Trevor Watkins, Erin Howden, Carmel M. Hawley, Nicole M. Isbel. *CCRE-Cardiovascular Disease and Metabolic Disorders, Brisbane, Australia.*

**Background:** Vascular calcification (VC) and function (VF) may be modulated by vitamin D. In pre-dialysis chronic kidney disease (CKD) circulating 1,25-dihydroxyvitamin D (1,25-OHD) concentrations are still homeostatically maintained and it is not clear whether substrate (25-hydroxyvitamin D, 25-OHD) or active 1,25-OHD is more important, and whether either is associated with either VC or VF.

**Aim:** To examine the relationship between 25- and 1,25-OHD with VC and VF in CKD.

**Methods:** Patients with stage 3-4 CKD (eGFR 25-60ml/min/1.73$m^2$) were recruited. Vascular parameters were assessed by; abdominal aortic calcification score (AAC) on lateral lumbar radiograph (n=41); carotid-femoral pulse wave velocity (PWV; arterial stiffness); ultrasound measured flow-mediated brachial artery reactivity (FMD; endothelial function), and common carotid imtima-media thickness (cIMT; atheroma burden).

**Results:** Study characteristics of participants (n=104); Age 59±10 years, eGFR 39±9ml/min/1.73$m^2$, 60% male, 44% diabetic, 25-OHD 82±32 nmol/L, 1,25-OHD 87±33 pmol/L. 1,25-OHD was lower in patients with aortic calcification (107 vs 83 pmol/L, p=0.03), but concentrations did not correlate with PWV (rho=-0.06, p=0.6). Moreover, 25-OHD did not correlate with either VC or PWV, and neither 25- or 1,25-OHD correlated with FMD or cIMT. Adjusting for age and systolic BP, the risk of vascular calcification was reduced by 7% for every 1pmol/L increase in serum 1,25-OHD (OR 0.93, 95% CI: 0.87-1.0 p=0.05). No relationship with calcium, phosphate or PTH was observed.

**Conclusion:** The presence of vascular calcification was associated with lower levels of 1,25-OHD, but not 25-OHD, independent of age and systolic blood pressure in patients with pre-dialysis CKD. Neither vitamin D moiety was related to vascular stiffness, atheroma burden or endothelial function at the concentrations observed. Whether 1,25-OHD may be protective against development of vascular calcification *de novo* in CKD needs prospective study.

**Left Ventricular Mass Is Greater in Stage 2-4 Chronic Kidney Disease Patients Than in Controls** Laima Siddiqi,[1,2] Peter J. Blankestijn.[1,2] *[1]Nephrology and Hypertension, University Medical center, Utrecht, Netherlands; [2]On Behalf of Smart Heart Study Group, University Medical Center, Utrecht, Netherlands.*

Cardiovascular (CV) mortality and morbidity are major problems in patients with chronic kidney disease (CKD). Almost all CKD patients are hypertensive. Hypertension is considered an important CV risk factor.LVM is an accepted surrogate endpoint for assessing CV risk. MRI is considered the gold standard. Aim: Compare LVM assessed by MRI in CKD patients and age matched controls and to identify factors associated with LVmass. Hypothesis: CKD patients have higher LVM than age matched controls. Further, for any given blood pressure CKD patients have higher LVmass than healthy controls.

Methods: 228 CKD (stage 2-4) patients and 30 healthy volunteers received cardiac MRI to assess LV variables. Blood pressure was the mean of office blood pressures. Patients were recruited from the outdoor clinics for cardiovascular diseases.

Results: In CKD patients arterial blood pressure was 148/85 ± 18/10 mmHg, eGFR 62 ± 15 ml/min, Hb 8.7 ± 0.8 mmol/l (14.5 ± 0.7 g/dL), BMI 26 ± 3.8 kg / $m^2$. LVM index in controls and CKD patients were 38.5 ± 8.2 and 52 ± 12 g/ $m^2$ respectively (P < 0.01), after adjusting for blood pressure and haemoglobin. Healthy volunteers had an arterial blood pressure 126/76±13/9 mmHg, normal kidney function, BMI 23 ± 3 kg / $m^2$.

Univariate analysis showed that LVM is significantly correlated only to systolic blood pressure and haemoglobin level (P < 0.005). In CKD patients the mean LVM were 98 ± 26 and in healthy volunteers 76 ± 9.6 g (P < 0.01); Further analysis showed that for any given blood pressure patients have a higher LVMindex than healthy volunteers.

Conclusion: CKD patients have a greater LVM than healthy volunteers, independent of the level of blood pressure and haemoglobin. Moreover, for any given blood pressure CKD patients have a higher LVM than healthy volunteers. This suggests that there are kidney specific risk factors such as sympathetic nerve activity that play a role in CV damage in this population.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2377**

**Risk Factors for Vascular Events in CKD Patients Not on Dialysis Receiving Once-Monthly (Q4W) C.E.R.A. or Once-Weekly (QW) or Once Every 2 Weeks (Q2W) Darbepoetin Alfa: Post Hoc Analysis of the CORDATUS Study** Simon D. Roger. *Department of Renal Medicine, Gosford Hospital, Gosford, NSW, Australia.*

**Purpose:** CORDATUS was a large randomized study demonstrating non-inferiority of Q4W methoxy polyethylene glycol-epoetin beta (a continuous erythropoietin receptor activator [C.E.R.A.]) to QW or Q2W darbepoetin alfa for anemia correction in CKD patients not on dialysis. This post hoc analysis has been conducted to investigate the effect of vascular risk factors on correction of anemia.

**Methods:** CKD patients not on dialysis (n=307) were randomized to Q4W C.E.R.A. or darbepoetin alfa QW or Q2W for a 20-week correction period, followed by an 8-week evaluation period. The primary efficacy analyses (Hb response defined as an increase in Hb ≥1 g/dL from baseline and a concentration ≥10.5 g/dL; non-inferiority [NI] test for Hb change from baseline in group comparison) were repeated in subgroups defined by presence of vascular disease (ischemic heart disease [IHD], peripheral vascular disease [PVD], cerebrovascular disease [CVD]) or vascular risk factors (hypertension [HTN], hyperlipidemia [HLP], diabetes [DM]).

**Results:** Hb response rates were similar for Q4W C.E.R.A. vs QW/Q2W darbepoetin alfa, irrespective of the presence of vascular disease or risk factors. Similarly, NI test for Hb change from baseline was significant for each category analyzed, with the exception of 'absence of HTN', in which there were only 10 patients.

| | Hb response rate (%) | | NI for the difference between groups in Hb change from baseline to evaluation | |
|---|---|---|---|---|
| **Risk factor** | **C.E.R.A.** | **Darbepoetin alfa** | **Difference in mean Hb (g/dL)** | **p value** |
| HTN | 94.0 | 93.9 | -0.015 | <0.0001 |
| No HTN | 100.0 | 85.7 | -0.941 | 0.8033 |
| HLP | 94.3 | 93.5 | -0.015 | <0.0001 |
| No HLP | 93.6 | 93.6 | -0.941 | 0.0026 |
| DM | 94.2 | 95.1 | 0.010 | <0.0001 |
| No DM | 94.0 | 91.8 | -0.078 | <0.0001 |
| IHD | 86.0 | 91.7 | -0.046 | 0.0014 |
| No IHD | 97.3 | 94.3 | 0.001 | <0.0001 |
| PVD | 89.5 | 91.3 | 0.285 | 0.0001 |
| No PVD | 94.8 | 93.9 | -0.088 | <0.0001 |
| CVD | 85.7 | 100.0 | 0.414 | 0.0148 |
| No CVD | 94.5 | 92.8 | -0.031 | <0.0001 |
| HLP, DM, IHD, PVD or CVD | 93.8 | 93.3 | -0.044 | <0.0001 |
| No HLP, DM, IHD, PVD or CVD | 95.7 | 94.7 | 0.122 | 0.0050 |

**Conclusion:** Q4W C.E.R.A. is as effective as QW/Q2W darbepoetin alfa in correcting Hb levels in CKD patients not on dialysis, regardless of existing vascular disease and risk factors.

**A Renal Arterial Resistive Index Superior to 0.65 Is Associated with Interstitial Fibrosis and Arteriolosclerosis and Is Predictive of Renal Function Decline** Naïke Bigé,[1] Pierre Levy,[2] Patrice Callard,[4] Jean-Manuel Faintuch,[3] Pierre M. Ronco,[1] Jean-Jacques Boffa.[1] *[1]Nephrology, Tenon Hospital, APHP, Paris, France; [2]Biostatistics, Tenon Hospital, APHP, Paris, France; [3]Radiology, Tenon Hospital, APHP, Paris, France; [4]Pathology, Tenon Hospital, APHP, Paris, France.*

The clinical interest of arterial resistive index (RI) in the management of chronic kidney disease (CKD) is questionable. Our purpose was to analyze parameters associated with RI in order to emphasize its predictive value.

Patients and Methods

RI was measured before renal biopsy in 58 patients between 2006 and 2007. Data were collected prospectively. On renal biopsy, we determined the percentage of interstitial fibrosis and sclerotic glomeruli and the presence of arteriolosclerosis. Standardized ultrasonographic exam included measurement of maximal kidney length, diastolic and systolic velocities on three points and calculation of mean RI according to the Pourcelot formula. MDRD eGFR at 12 and 18 months was retrospectively collected for 42 and 34 patients.

Results

Median values for age, eGFR, percentage of interstitial fibrosis and sclerotic glomeruli and RI were respectively: 46 years (21-87), eGFR 59mL/min/1,73m² (5-130), fibrosis 10% (0-90), 13% (0-96), 0.63 (0.31-1.00). Forty-seven patients (82%) had glomerulonephritis, 5 (5.1%) tubulointerstitial nephropathy and 2 (3.4%) vascular nephropathy. In a univariate analysis, RI was positively correlated with age ($p<0.001$), pulse pressure ($p<0.05$), and negatively with renal length ($p<0.05$) and eGFR ($p<0.005$). RI was higher in patients with intima/media ratio ≥ 1 ($p<0.05$). In a multivariate analysis, only age ($p<0.01$) and eGFR ($p<0.05$) were correlated with RI. Patients with baseline RI >0.65 were older, had lower baseline eGFR, more interstitial fibrosis ($p<0.05$) and arteriolosclerosis ($p<0.005$) and more renal function decline at 12 and 18 months than those with baseline RI<0.65 ($p<0.05$).

Conclusion

RI is a non invasive marker of interstitial fibrosis and arteriolosclerosis and is predictive of renal function decline. Its measurement could help to identify patients with high risk of CKD progression to improve their nephroprotective treatment.

**Cardiomyopathy in Patients with Chronic Renal Failure Is Accompanied by Thickening of Intramyocardial Arterioles** Kerstin Benz,[2] Solveig Knauth,[1] Kerstin U. Amann.[1] *[1]Pathology, University of Erlangen-Nürnberg, Erlangen, Germany; [2]Pediatrics, University of Erlangen-Nürnberg, Germany.*

Background:

In patients with chronic renal failure (CRF), cardiovascular morbidity and mortality are major clinical problems with cardiac death as the main cause of death. In animal and human studies specific uremic cardiovascular alterations were identified, i.e. coronary artery sclerosis and reduced myocardial capillarisation. Since myocardial ischemia in CRF patients is also seen in the absence of stenosis of epicardial vessels, changes of intramyocardial arterioles are under discussion.

Patients:

Using morphometry and immunohistochemistry we investigated the heart (both ventricles, septum) and different sites of the vascular bed (aorta asc. and desc., a. carotis communis, int.,ext., a. mesenterica int., a. iliaca communis, int., ext. in 36 autopsy cases (mean age: 62 years) . Cases were divided in 17 CRF and 19 age-matched non-renal control patients.

Results:

In CRF patients, relative heart weight, right and left ventricular wall thickness were significantly increased compared to controls. Interestingly, significantly higher wall thickness of intramyocardial arterioles (8.57±3.61 vs. 4.97±1.53 $_{\mu}$m), wall-lumen-ratio (0.59±0.21 vs. 0.36±0.16) and myocardial fibrosis was seen in CRF patients compared to controls. Detailed analysis of various vascular beds showed intima thickening and in several vessels also higher plaque areas, increased intima calcification and plaque neovascularisation in patients with CRF compared to controls. Atherosclerosis was significantly advanced in aorta, iliacal and mesenterial arteries whereas media calcification was more pronounced in the aorta of CRF patients compared to controls.

Conclusion:

We found thickening of intramyocardial arterioles in both ventricles in CRF patients confirming studies in experimental renal failure. This microarteriopathy could play an important role for cardiac blood and oxygen supply and may account for the higher rate of cardiac death in CRF patients. Our findings in extracardiac vessels point to different regulation of vascular thickening and vessel calcification at various sites of the vascular bed.

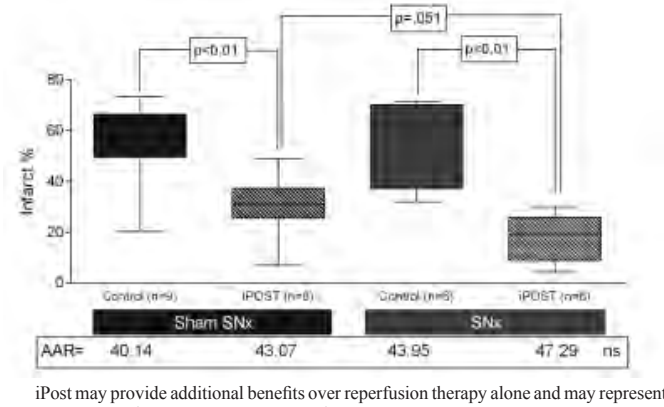
**Experimental Uremia Is Not a Barrier to Myocardial Protection by Post-Conditioning** Conor Byrne, Kieran Mccafferty, Julius Edward Kieswich, Martin J. Raftery, Magdi Yaqoob. *WHRI, Queen Mary, University of London, London, United Kingdom.*

CKD is associated with both increased incidence of acute myocardial infarction (AMI) and an increased post AMI mortality. Moreover, reperfusion therapy does not appear to improve outcomes for patients with advanced CKD. Adjuvant myocardial protective strategies may further limit infarct size and thus improve outcome for patients with CKD.

We have previously demonstrated that ischemic preconditioning reduces myocardial infarct size in subtotally nephrectomised rats (SNx) (see F-PO1228, 2009). However, preconditioning strategies are only applicable to predictable events such as elective surgery or percutaneous coronary intervention (PCI). In non-uremic animals infarct size can be reduced by interrupting reperfusion with brief episodes of ischemia, termed Post-conditioning (iPost). We investigated whether iPost would be efficacious in the context of uremia.

Male Wistar rats underwent a 2 stage SNx or a sham procedure. 4 weeks later we induced AMI by ligating the LAD for 25 mins. we allowed reperfusion for 10 secs before reoccluding the LAD for 10 secs, this was repeated 5 times. After 2 hours reperfusion the animals were sacrificed and infarct size determined.

iPost was associated with a relative reduction in infarct size of 50% in non-uremic animals ($p=0.008$) and 70% in uremic animals ($p=0.002$)(Fig.1). The area at risk was similar for all groups. iPost appeared more beneficial in uremic animals, this was of borderline statistical significance ($p=0.051$) Median serum creatinine for the four groups was; 32.9, 29.0, 128, and 125 (in same order as shown in Fig.1). Hematocrit was significantly lower in the SNx groups versus the shams (40,43 32 and 23%, same order as above).



iPost may provide additional benefits over reperfusion therapy alone and may represent our best chance of reducing the high rate of post AMI mortality in CKD.

Disclosure of Financial Relationships: nothing to disclose

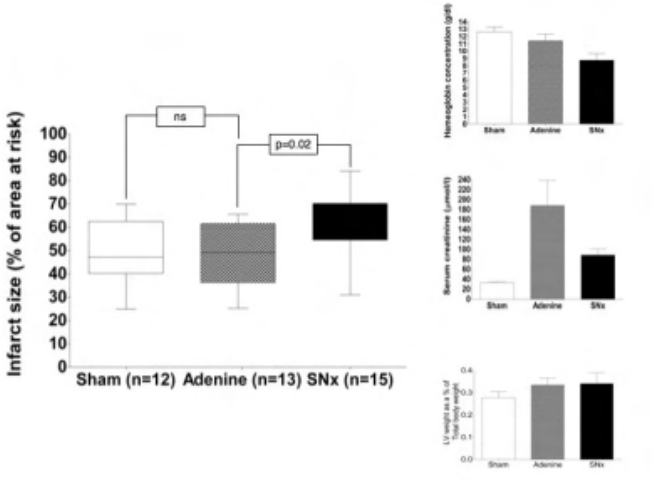
## SA-PO2381

**Myocardial Infarct Size in Two Different Rodent Models of Chronic Uremia** Conor Byrne, Kieran Mccafferty, Julius Edward Kieswich, Martin J. Raftery, Magdi Yaqoob. *WHRI, Queen Mary, University of London, London, United Kingdom.*

Cardiovascular disease is the leading cause of death in patients with CKD. It has previously been suggested that this is due to a reduced ischemia tolerance in the uremic heart. Reversible left anterior descending artery (LAD) ligation was performed in 2 rat models of chronic uremia; sub-total nephrectomy (SNx) and adenine induced uremia (Ad).

Male Wistar rats were fed a diet containing 0.75% adenine for 4 weeks or underwent a 2 stage sub-total nephrectomy or a sham procedure. The animals were allowed 4 weeks to develop a uremic phenotype. Myocardial infarction was induced by occluding the left anterior descending artery for 25 min followed by 2 hrs reperfusion at the end of which the animals were sacrificed and infarct size determined.

Serum creatinine was significantly higher in the animals with adenine induced renal failure (median 145 v 86 v 34.7 µmol/l; p=0.0001). Despite this there was no difference in infarct size between rats with adenine induced uraemia or sham animals fed control diet (52.2% +/- 11.8 v 50.0% +/- 8.8).However, there was a significant increase in infarct size in the rats that underwent SNx (61.2% +/-12.8; p=<0.05). The SNx rats had significantly higher mean arterial blood pressures (MAP) compared with the other groups (141 +/- 17 v 150 +/- 12.4 v 143 +/- 19.7 mmHg), they also had the lowest mean haemoglobin of the 3 groups (11.4 +/- 1.84 v 13.8 +/- 1.85 v 8.7 +/- 1.68 g/dl).



In these animal models of chronic kidney disease, the degree of uremia per se does not appear to have a significant impact on myocardial infarct size. Hypertension and degree of anaemia may well play a more significant role in determining infarct size. Further work is required to identify the factors contributing to larger infarct size in the SNx model.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2382

**Ischemic Preconditioning Protects the Heart in the Adenine Model of Severe Chronic Uremia** Kieran Mccafferty, Conor Byrne, Julius Edward Kieswich, Martin J. Raftery, Magdi Yaqoob. *William Harvery Research Institute, Queen Mary university London, London, United Kingdom.*

Ischemic preconditioning (IPC) is a process by which brief episodes of ischemia and reperfusion to an organ render that tissue resistant to subsequent ischemic injury. Comorbidities such as diabetes and senescence attenuate the effects of IPC. We have previously shown that the uremic heart can be preconditioned (ASN 2009 PO1228). However, the sub-total nephrectomy model(SNx) is a model of mild-moderate CKD. It is still unknown whether severe CKD limits the effects of IPC.

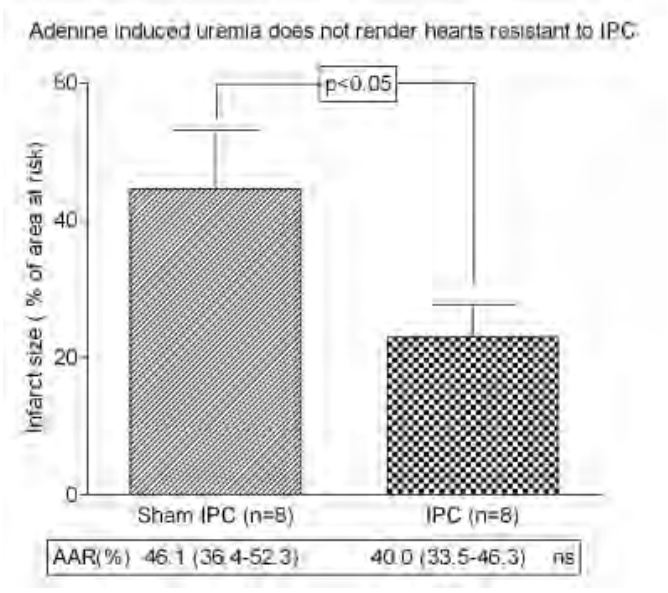
Male Wistar rats were given 4 weeks of 0.75% Adenine diet to induce severe uremia. Animals then underwent either an IPC protocol of 3cycles of 5 minutes ischaemia/reperfusion to the left anterior descending artery (LAD), or sham IPC protocol before undergoing an acute myocardial infarction (AMI) of 25 minutes LAD ligation and 2 hours reperfusion.

Results

| | Control | Adenine | SNx | p |
|---|---|---|---|---|
| Weight (g) | 419 (35) | 223 (20) | 389 (29) | 0.0001 |
| Creatinine (umol/l) | 32.1 (4.8) | 252.6 (52.4) | 133.5 (79.7) | 0.0001 |
| Hematocrit (%) | 41.6 (3.1) | 29.8 (7.3) | 28 (5.7) | 0.0001 |

Values shown as Mean (SD) and analyzed using ANOVA

Adenine animals are anemic, growth restricted, have twice the plasma creatinine of the SNx model, and 7 times the creatinine of a non uremic control group. (Data shown from previous work)



Despite severe renal dysfunction IPC animals had a 33% reduction in infarct size following IPC compared to Sham IPC animals.

Conclusions

These data in conjunction with our past work in the SNx model, suggests preconditioning affords protection across the spectrum of CKD.

CKD patients have poor outcomes following AMI and have been routinely excluded from trials in IPC. Our work suggests CKD patients should not be excluded from trials and have much to gain from future work in preconditioning.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2383

**1,25-Dihydroxyvitamin D Is Associated with Cardiac Structure but Not Function in Patients with CKD** William G. Petchey, Brian A. Haluska, Erin Howden, Rodel Leano, David W. Johnson, Nicole M. Isbel. *CCRE - Cardiovascular Disease and Metabolic Disorders, Brisbane, Australia.*

**Background** Patients with Chronic Kidney Disease (CKD) experience a greatly increased risk of cardiovascular events. Vitamin D status is inversely related to cardiovascular morbidity, both in the general and CKD populations. Animal models suggest this risk may be related to cardiac hypertrophy and dysfunction in states of hypovitaminosis D. CKD patients are at increased risk of hypovitaminosis D, due to an impaired ability to generate active 1,25-dihydroxyvitamin D (1,25-OHD), irrespective of substrate availability (25-hydroxyvitamin D, 25-OHD).

**Hypothesis** 1,25-OHD but not 25-OHD is negatively associated with cardiac mass and early diastolic dysfunction in patients with CKD.

**Methods** Patients with stages 3-4 CKD were recruited. Cardiac structure was assessed echocardiographically by: left ventricular (LV) mass (indexed to height$^{2.7}$, LVMI); septal and posterior wall thickness (SWT and PWT respectively). Diastolic dysfunction was defined as; mitral inflow deceleration time <150msec or >250msec, E/E' >15, or >10 with left atrial enlargement (>20cm$^2$).

**Results** Population characteristics (n=104); age 59±10 years, 60% male, eGFR 39±9ml/min, BP 135±14/77±7mmHg. Whilst there was no association between cardiac structure and 25-OHD, 1,25-OHD correlated negatively with SWT (r=-0.22, p=0.032), PWT (r=-0.22, p=0.029), and LVMI (r=-0.26, p=0.011), and the effect was independent of eGFR. Diastolic dysfunction was present in 60 subjects (58%), but did not correlate significantly with either 25-OHD or 1,25-OHD concentrations. In multivariate analysis, higher LVMI was independently associated with a history of coronary artery disease, LV preload (end diastolic volume), BMI, systolic BP and inversely with 1,25-OHD (adjusted $R^2$=0.40, p<0.0001). In this model, every 6.7pmol/L increase in serum 1,25-OHD predicted an average decrease in LV mass of 1g/m$^{2.7}$ (p=0.004).

**Conclusion** LV mass is negatively correlated with 1,25-OHD in patients with CKD, however there is no association with LV diastolic function. Whether 1,25-OHD supplementation can regress LV mass in pre-dialysis CKD patients should be the subject of future work.

**SA-PO2384**

**Activation of Innate Immunity by LPS Is Associated with Systemic Inflammation and Endothelial Dysfunction in Patients with Chronic Kidney Disease** Andréa Marques Stinghen,[2] Aline Borsato Hauser,[1] Simone Cristina Mikosz Goncalves,[1] Bettina Gruber,[2] Roberto Pecoits-Filho.[1] *[1]Center for Health and Biological Sciences, Pontificia Universidade Católica do Paraná, Curitiba, Paraná, Brazil; [2]Basic Pathology Department, Universidade Federal do Paraná, Curitiba, Paraná, Brazil.*

Patients with CKD have high levels of systemic inflammatory markers and increased cardiovascular risk. Circulating levels of LPS may represent a trigger for the inflammatory response. The protein CD14 is an essential part of the innate immune response through TLR4, which is a molecule in the cellular signaling of the innate response to LPS. The biomarker of this phenomenon is soluble CD14 (CD14s). In this study we investigated the associations between plasma levels of CD14s, systemic inflammation and endothelial dysfunction in patients with CKD. Plasma were collected from patients at different stages of CKD evaluated according to the average of the clearances of urea and creatinine. The systemic inflammation and endothelial dysfunction was assessed by fibrinogen and sICAM-1 levels, respectively. CD14s (evaluated using ELISA), was used as a biomarker of LPS-mediated innate immunity response. The population consisted of 73 pre-dialysis patients (57±1.4 years old, 51% males) with GFR of 34±21mL/min. Plasma levels of sICAM-1 and CD14s were respectively 80±1.7 ng/mL and 2.6±0.1 µg/mL. There was a negative correlation between GFR with fibrinogen (ρ=-0.48, P<0.0001) and CD14s (ρ=-0.26, P<0.05). When patients were evaluated according to the median of their GFR, we observed higher levels of CD14s (2.9±0.1 µg/mL) in patients with GFR below 34±21mL/min, compared to patients with higher GFR (34-107±21 mL/min; P<0.05). We also observed a positive correlation between CD14s with systemic inflammation (fibrinogen)(ρ=0.32, P<0.005) and with endothelial dysfunction (sICAM-1)(ρ=0.33, P<0.005). Finally there was a positive correlation between fibrinogen and sICAM-1 (ρ= 0.32, P<0.001). Based on the analysis of associations between biomarkers in this pre-dialysis patients, systemic inflammation in CKD may be partially induced by activation from LPS through TLR4 and may additionally be associated with endothelial dysfunction.

**Relationships of Skin-Autofluorescence to Renal Function and Cardiovascular Disease in Patients with Diabetes and Chronic Kidney Disease** Yoshihiro Tani, Kenichi Tanaka, Jun Asai, Yuki Kusano, Hodaka Suzuki, Yoshimitsu Hayashi, Koichi Asahi, Tsuyoshi Watanabe. *Nephrology and Hypertention, Fukushima Medical University, Fukushima, Japan.*

Background

The accumulation of advanced glycation endproduct (AGE) is thought to play a role in the pathogenesis of chronic complications such as atherosclerosis and cardiovascular disease (CVD) in patients with diabetes and renal failure. An Autofluorescence (AF) reader non-invasively assesses AGE accumulation using skin-AF. We recently reported that skin-AF had an independent relationship to CVD in Japanese patients with ESRD (*Ther Apher Dial* 14;2010). The present study aimed to evaluate relationships of skin-AF to clinical parameters and CVD in pre-dialysis patients.

Methods

Subjects in this cross-sectional analysis comprised 379 patients with CKD and/or diabetes who visited Fukushima University Hospital between December 2008 and December 2009 (median age, 60.6 years; median eGFR, 61.2 ml/min/1.73m$^2$). Of the 379 patients, 154 (40.6%) had diabetes, 306 (80.7%) had CKD, 81 (21.3%) had both diabetes and CKD. AGE accumulation in skin was assessed by skin-AF using an AF reader.

Result

Skin-AF was increased as CKD stage advanced in patients with diabetes and/or CKD. Twenty percent of the variance in skin-AF among diabetic patients could be explained by the independent effects of eGFR (β=-0.27, *P*<0.01), serum albumin (β=-0.27, *P*<0.01). Twenty-seven of the variance in skin-AF among CKD patients could be explained by the independent effect of diabetes (β=0.17, *P*<0.01), age (β=0.23, *P*<0.01), eGFR (β=-0.24, *P*<0.01), serum albumin (β=-0.12, *P*=0.01). Gender, smoking, age, skin-AF, eGFR, hemoglobin, high-density lipoprotein cholesterol were significantly correlated with CVD history, and age (odds ratio 1.05, 95%CI 1.009-1.105, *P*<0.05), skin-AF (odds ratio 2.23, 95%CI 1.01-4.91, *P*<0.05), eGFR (odds ratio 0.97, 95%CI 0.94-0.99, *P*<0.05) were independently related to CVD history in the multiple logistic regression analysis.

Conclusions

Skin-AF was independently related to renal function and CVD history in Japanese CKD and diabetes patients. Non-invasive AF reader may provide potential marker for clinical risk assessment in these patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2386**

**Endothelial Dysfunction and Left Ventricular Diastolic Dysfunction Are Markers of Cardio-Renal Syndrome in the Early Stages of Chronic Kidney Disease** Masashi Kitagawa, Hitoshi Sugiyama, Hiroshi Morinaga, Tatsuyuki Inoue, Keiichi Takiue, Shinji Kitamura, Yohei Maeshima, Hirofumi Makino. *Medical and Clinical Science, Okayama University Graduate School, Okayama, Japan.*

[Purpose] Cardiovascular disease (CVD) is the major cause of mortality in patients with moderate to advanced chronic kidney disease (CKD). Endothelial dysfunction has been shown to be prevalent in mild to moderate CKD. A higher left ventricular (LV) mass and worse diastolic dysfunction in CKD patients is reported.

[Methods] This study observed 62 Japanese patients with different stages of non-diabetic CKD (mean age 54 ± 16 years old, 46.8% male). The relationships between the brachial artery flow-mediated dilation (FMD), the brachial-ankle pulse wave velocity (baPWV), intima-media thickness (IMT) of the common carotid artery, echocardiography, and albuminuria were all evaluated. Echo measurements included the left ventricular mass index (LVMI), ejection fraction (EF), peak early (E) and late (A) diastolic mitral filling velocity (E/A) ratio, peak early diastolic mitral annular velocity (e'), and E/e' ratio.

[Results] The level of FMD was found to significantly correlate with the estimated GFR ($r^2$=0.2711, p<0.0001). The level of FMD in CKD stage 2 significantly decreased in comparison to CKD stage 1. The e' and E/A ratio showed a positive correlation with the level of FMD, and LVMI negatively correlated with the level of FMD, however, EF did not. The estimated GFR demonstrated a significant positive correlation with the e' ($r^2$=0.3461, p<0.0001) and E/A ratio, it negatively correlated with LVMI. The e' demonstrated a significant negative correlation with baPWV and max IMT. The e' and E/A ratio in CKD stage 3 significantly decreased in comparison to CKD stage 1. In a multiple regression analysis, age, albuminuria and hypertension were independently associated with the e'.

[Conclusion] These data suggest that renal impairment in CKD patients is closely associated with either endothelial dysfunction, atherosclerosis, or LV diastolic dysfunction. Moreover, both endothelial dysfunction and LV diastolic dysfunction appear even in the early stages of CKD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2387**

**Elevated Angiopoietin-2 Independently Correlated with Arterial Stiffness in Chronic Kidney Disease** Fan-Chi Chang, Chih-Kang Chiang, Shuei-Liong Lin. *Renal Division, Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.*

Purpose

Accelerated arterial stiffness is recognized detrimental to cardiovascular outcome in chronic kidney disease (CKD). Given arterial remodeling taking place during CKD progression, we hypothesize that CKD causes arterial stiffness through disturbed angiotrophic growth factors vascular endothelial growth factor (VEGF) and angiopoietin (Ang).

Methods

We investigated 416 patients with CKD stages 3 to 5. Arterial stiffness was measured by noninvasive pulse wave velocity (PWV).

Results

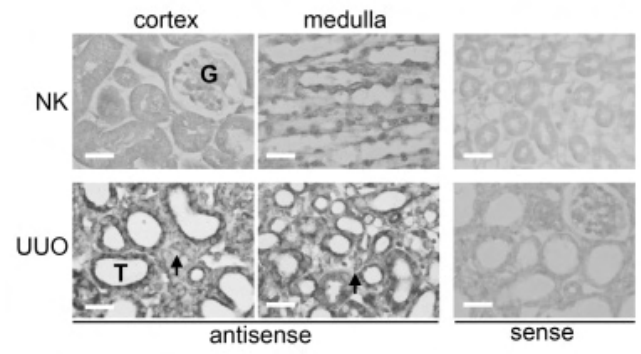
Plasma levels of Ang-2 and VEGF increased as estimated glomerular filtration rate (eGFR) declined (correlation coefficient -0.373, P < 0.0001 for Ang-2 and -0.148, P = 0.002 for VEGF). Plasma Ang-1 did not show significant change (P =0.207). The endogenous Ang antagonist, soluble Tie-2, decreased as eGFR declined (P <0.0001). Only Ang-2 was independently correlated with PWV by multivariate analysis.

Multivariate-adjusted regression analyses of plasma Ang-2 and PWV

| | Regression Coefficient (x10-5) | P | 95% CI (x10-5) |
|---|---|---|---|
| Univariate | | | |
| Ang-2 | 1.65 | <0.001 | 0.87–2.4 |
| Multivariate | | | |
| Model 1 | 1.25 | 0.001 | 0.54–1.96 |
| Model 2 | 0.96 | 0.008 | 0.25–1.67 |
| Model 3 | 0.86 | 0.023 | 0.12–1.61 |

Model 1, Ang-2+age; Model 2, Model 1+traditional risk; Model 3: Model 2+CaXP, medication including ACE inhibitor, ARB, statin, calcium channel blocker, β-blocker).

We further demonstrated increased Ang-2 expression in fibrotic kidneys following unilateral ureteral obstruction, principally in the injured tubular epithelial cells and interstitial fibroblasts.



Conclusions

Increased circulating Ang-2 was associated with arterial stiffness in CKD patients. The progressively fibrotic kidneys might increase circulating Ang-2 at least in part through Ang-2 upregulation in kidneys.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2388**

**Fibroblast Growth Factor-23 (FGF-23) Concentrations Predict Coronary and Aortic Calcification in Stage 3-5 CKD Patients** David C. Wheeler,[1] Ben Caplin,[1] Joanne Marks,[1] Nicholas A. Faure Walker,[1] Michael B. Rubens,[7] Leon J. Schurgers,[2] Willi Jahnen-Dechent,[5] Edward R. Smith,[3] W. Charles O'Neill,[4] Helen Colhoun,[6] John Cunningham,[1] Todd A. Dewees.[6] *[1]UCL Medical School, United Kingdom; [2]Univ of Maastricht, Netherlands; [3]Royal Sussex County Hospital, United Kingdom; [4]Emory Univ, Atlanta; [5]RWTH Aachen Univ, Germany; [6]Univ of Aberdeen, United Kingdom; [7]Royal Brompton Hospital, London, United Kingdom.*

The London Arterial Calcification, Kidney and Bone Outcomes (LACKABO) study set out to determine the association between cardiovascular (CV) risk factors, soluble biomarkers and arterial calcification in 289 patients with stages 2-5 CKD (eGFR <86 ml/min/1.73m2, range 8.3-85.5), of whom 21.11% had a prior diagnosis of CV disease. Coronary artery calcification (CAC) was quantified using electron beam CT scanning (Agatston protocol). A left censored (TOBIT) regression model was used. eGFR was weakly associated with CAC score adjusted for age and sex with 4% higher CAC score for every ml/min/1.73m² lower eGFR (p=0.023). FGF-23 levels did not significantly differ between those with or without prior CV disease. In cross sectional analysis adjusted for age and sex, higher FGF-23 levels were positively associated with urea, urate, phosphate, NT-proBNP, parathyroid hormone and osteoprotegerin and inversely associated with matrix GLA protein and eGFR (all p<0.05). However only eGFR was independently associated with FGF-23 such that for every unit decrease in eGFR, FGF-23 increased by 2% (p<0.0001) with a borderline relationship with urate. Overall the strongest independent relationships with logCAC score were seen with age (ß=0.20, p<0.0001), BMI (ß=0.14, p=0.004), and logFGF-23 (ß=1.02, p=0.007) with lower CAC score in women than men (ß for female vs. male = -1.38, p=0.045). A similar pattern of relationships was seen in patients without prior CV disease. Modelling for aortic calcification showed the same patterns, although the relationship with eGFR was stronger (p=0.0068). FGF-23 and urate maintained significance (p=0.0045 and 0.0983, respectively). **Conclusion:** In stages 2-5 CKD, FGF-23 is an independent biomarker of arterial calcification.

**SA-PO2389**

**Evaluation of Arterial Stiffness in Chronic Kidney Disease (CKD) Stage 2-5 by Pulse Wave Measurements and Ambulatory Arterial Stiffness Index (AASI)** Lene Boesby,[1] Thomas Elung-Jensen,[2] Svend Strandgaard,[1] Anne-Lise Kamper.[2] *[1]Department of Nephrology, Herlev Hospital, Herlev, Copenhagen, Denmark; [2]Department of Nephrology, Rigshospitalet, Copenhagen, Denmark.*

**Purpose:** To study arterial stiffness in CKD stage 2-5 by AASI as compared to Augmentation Index (AIx) and aortic pulse wave velocity (aPWV) obtained by applanation tonometry. The intra-patient reproducibility of AASI was also studied.

**Methods:** Patients were studied 2 days within 2 weeks. Double recordings of the radial pressure wave form and aPWV and 24-h ambulatory blood pressure measurements were done. Examination conditions were standardized and all measurements made by the same observer. AASI was calculated as 1 minus the regression slope of diastolic over systolic blood pressure. CKD stage was determined by estimated glomerular filtration rate (eGFR) using the MDRD7-formula. Spearman's correlation coefficient (SCC) was used for evaluating correlations. Day-to-day reproducibility was evaluated by the intra-class correlation coefficient (ICC).

**Results:** 68 patients (M50:F18), median age 63 years (range 30-79), with CKD stage 2 (n=17), stage 3 (n=22), stage 4 (n=20) and stage 5 (n=9) were studied. Thirteen had diabetes. Mean (±SD) AASI was 0.44±0.15, mean AIx was 28.2%±10.4 % and mean aPWV was 9.4 m/s ±1.0 m/s with no significant differences among the stages. The SCC between AASI and AIx was 0.320 (P=0.01), between AASI and aPWV it was 0.643 (P<0.0001) and between AIX and aPWV it was 0.346 (P=0.006). $ICC_{AASI}$ was 0.755 (95% CI: 0.630-0.841) with even greater reproducibility in CKD stages 4-5 (ICC>0.860).

**Conclusions:** The observed values of AASI in CKD patients were similar to those previously reported for the background population, while AIx and aPWV were higher. Despite good correlations between these parameters, the normal values of AASI found in the present study preclude its use as an index of vascular stiffness in CKD. However, intra-patient reproducibility of AASI in CKD stage 2-5 was high.

**Cardiovascular-Renal Interaction in Japanese Patients with Essential Hypertension** Junichi Yatabe,[1,2] Midori Sasaki Yatabe,[2,3] Tsuyoshi Watanabe,[2] Pedro A. Jose,[4] Hironobu Sanada.[1] *[1]Div. of Health Science Research, Fukushima Welfare Federation of Agricultural Cooperatives, Fukushima, Japan; [2]Dept. of Nephrology, Hypertension, Diabetology, Endocrinology and Metabolism, Fukushima Med. Univ., Fukushima, Japan; [3]Dept. of Pharmacology, Fukushima Med. Univ., Fukushima, Japan; [4]Center for Molecular Physiology Research, Children's National Medical Center, Washington, DC.*

Background: Long-term prognosis of hypertensive patients depends greatly on the presence of CKD and/or cardiovascular damage. The current study examined relations among indices of renal function and atherosclerosis to determine clinical manifestations of cardiovasucular-renal interaction in Japanese.

Methods: The study examined 368 essential hypertensive patients (164 male and 204 female, age 32-85). CKD group was defined by estimated GFR (eGFR) below 60 ml/min/1.73 m², calculated using the Japanese equation.

Results: Body weight was significantly less in CKD (n=80) than non-CKD (n=268) (non-CKD vs. CKD; 59.1±12.3 vs 55.9±10.8 kg, p<0.05). CKD group showed similar systolic blood pressure (BP) (143.6±17.1 vs 144.5±16.6 mmHg) with lower diastolic BP (85.0±12.6 vs 80.2±10.9 mmHg, p<0.01), resulting in greater pulse pressure (58.7±13.8 vs 64.3±13.8 mmHg, p<0.01). Augmentation index (AI) was significantly higher (84.0±14.1 vs 87.5±11.7 %, p<0.05) in CKD. Pulse wave velocity (PWV) was accelerated (1274±382 vs 1500±409 cm/s, p<0.05), and ankle-brachial index was slightly but significantly lower in CKD group (1.13±0.07 vs 1.11±0.08, p<0.05). Multiple linear regression analysis showed that eGFR independently correlated with diastolic BP, pulse pressure, AI and PWV. Human heart-type cytoplasmic fatty acid-binding protein (H-FABP) was significantly higher in CKD group (3.0±1.2 vs 3.8±1.3 ng/ml, p<0.05). However, cystatine C did not have significant correlation with H-FABP.

Conclusion: In Japanese hypertensive patients, those with low eGFR were associated with significantly worse indices of atherosclerosis. This may reflect the presence of cardiovascular-renal interaction in these patients. The results reinforce the importance of careful management in hypertensive patients with CKD.

**Physical Function and Subclinical Brain Disease in Stage 3-4 CKD** Stephen L. Seliger,[1] Joshua Francis Betz,[2] Gregory Steinbrenner,[1] Shari R. Waldstein,[3] Leslie I. Katzel.[1] *[1]Medicine, U Maryland Sch Med, Baltimore, MD; [2]Radiology, U Maryland Sch Med, Baltimore; [3]Psych, U MD Balt Co, Baltimore.*

**Purpose**: To determine the severity of physical functional impairment in older adults with CKD, and examine the association of subclinical vascular brain disease with functional impairment.

**Methods:** We performed cranial magnetic resonance imaging (MRI) and measured physical performance in 46 community-dwelling adults with stage 3-4 CKD (mean age = 71 yrs; 91% male; 39% Black) without dementia or stroke. Physical performance tests included the 6-minute walk (6MW) and timed get up and go (TGUAG) tests, grip strength, peak expiratory flow, and (among 28 subjects) peak aerobic capacity ($V0_2$peak) on graded treadmill. From MRI, we derived the white matter (WM) lesion burden and ventricle:brain ratio (subcortical atrophy). Observed performance was compared to expected performance based on normative data, and to performance in healthy older controls. Among CKD patients, age-adjusted correlations between functional and neuroanatomical measures were estimated.

**Results:** Mean eGFR was 36.5 mL/min/1.73m², body mass index 29.7 kg/m². 24% had >500mg/g proteinuria, and 67% were diabetic. Compared to normative (expected) performance and older controls, CKD patients had markedly reduced $V0_2$peak and performance on the 6MW and TGUAG tests (Table). Among CKD subjects, greater subcortical atrophy correlated with poorer performance on the 6MWT (r=0.6; p<.001) and TGUAG tests (r=0.5; p<.001), and greater WM lesion burden correlated with poorer performance on the 6MWT (r=0.35; p<.05), after adjusting for age.

| Test | Function Tested | CKD | Normative | Controls |
|---|---|---|---|---|
| Peak V02 (mL/kg/min)* | Aerobic capacity | 14.1 (4.0)* | >25.0 | 23.0 (6.6) |
| "Get Up and Go" (secs.) | Strength, balance | 11.3 (3.5)* | <10.0 | 6.0 (1.0) |
| 6-Min. walk (ft) | Submaximal Gait | 1,286 (344)* | 1,683 (194) | 1,986 (387) |
| Peak Expiratory Flow (L/min) | Respiratory Function | 373 (146) | 499 (44.7) | 441 (121) |
| Grip (kg) | Strength | 35.3 (9.5) | 35.1 (7.5) | 36,4 (11.7) |

* p<.05 vs older controls

**Conclusion:** Physical performance is markedly impaired in older adults with stage 3-4 CKD, and is associated with greater burden of subclinial brain disease.

**The Relationship between Age, Blood Pressure, Kidney Function and Outcomes among a National Cohort of Veterans** Michael J. Fischer,[1] Jessica W. Weiss,[3] Adam J. Batten,[2] Dan Bertenthal,[4] Indra Gupta,[2] Jeffrey Todd-Stenberg,[2] Ann M. O'Hare.[2] *[1]Jesse Brown and Hines VA; [2]VA Puget Sound; [3]Oregon Health & Science U.; [4]San Francisco VA.*

Hypertension and chronic kidney disease (CKD) are both common in the elderly. How the relationship between blood pressure (BP), estimated glomerular filtration rate (eGFR), and health outcomes varies across age groups is not known.

We identified all Veterans with at least one outpatient serum creatinine (SCr) within the Department of Veterans Affairs (VA) between 10/1/2000 - 9/30/2001 and at least one BP measurement up to one year before and 1 month after that SCr. We examined the cross-sectional association between eGFR (ml/min/m$^2$) and BP (mmHg) as a function of age (yrs) and the longitudinal association between BP and incident end-stage kidney disease (ESKD) and death as a function of both age and eGFR.

Among 1,875,516 Veterans, the prevalence of systolic hypertension (SBP > 140) ranged from 19% to 40%, diastolic hypertension (DBP > 90) from 6% to 3%, and eGFR < 60 from 3% to 38% in adults < 45 yrs compared with those ≥ 75 yrs. In logistic regression analysis, while there was a greater likelihood of both systolic and diastolic hypertension at progressively lower levels of eGFR for adults < 45 yrs ($p < 0.05$), this relationship was progressively attenuated at older ages and no longer present in adults ≥ 75 yrs ($p>0.05$). In Cox proportional hazard analyses across all age and eGFR strata, progressively higher levels of SBP but not DBP were significantly associated with a greater risk of ESKD ($p<0.05$). For all age and eGFR groups, there was a U-shaped relationship between SBP and death. However, the level of SBP associated with the lowest risk of death ranged from 120-139 mmHg in those aged 45-59 yrs to 150-159 mmHg in those aged ≥ 75 yrs. DBP was inconsistently associated with risk of death in all age groups.

In older compared with younger adults, the prevalence of systolic hypertension is higher but varies less as a function of eGFR. While SBP is strongly and linearly associated with risk of ESKD at all levels of eGFR regardless of age, its association with death was non-linear and varied substantially by age.

**Complete Recovery of Renal Function after Acute Kidney Injury Is Associated with Long-Term All-Cause Mortality in a Large Managed Care Organization** Jennifer A. DeGraauw,[1] John R. Holmen,[2] Jason Jones,[2] Sidney N. Thornton,[2] Michel B. Chonchol.[1] *[1]University of Colorado Denver Health Sciences Center, Aurora, CO; [2]Intermountain Health Care, Salt Lake City, UT.*

Purpose: Risk of long-term mortality among patients with complete recovery of renal function after acute kidney injury (AKI) has been poorly studied. This study aimed to determine the risk of death in hospitalized patients who had an episode of AKI with complete recovery of renal function.

Methods: We conducted a population-based cohort study of adult patients with no history of chronic kidney disease (CKD) and who developed AKI requiring hospitalization with complete recovery of renal function between January 1 1999 and December 31 2009. AKI was defined by the RIFLE classification, which requires at least a 50% increase in serum creatinine. Complete renal recovery was defined if the serum creatinine returned to a level less than 50% above baseline serum creatinine within 7 days after discharge. The primary outcome of interest was all-cause mortality occurring after hospital discharge. Patients were tracked for outcomes beginning at discharge and followed until March 31 2010. All subjects were required to have a minimum of 12 months follow-up data. These patients were matched for demographics and risk factors associated with death with individuals without AKI or CKD.

Results: We identified 1411 individuals with complete recovery of renal function after AKI and 1411 matched controls with no AKI during the index hospitalization. The median age of the enrolled participants was 65 years, 45% were women. Approximately 56% and 19% had a history of diabetes and myocardial infarction, respectively. After a median follow-up of 2.8 years, the deaths were 27% and 18% among those with and without AKI, respectively, corresponding to a unadjusted HR of 1.60 (95% CI, 1.38-1.86). After adjusting for potential confounders, the HR decreased to1.26 (95% CI, 1.07-1.48).

Conclusion: Subjects with an episode of AKI during hospitalization that have complete recovery of renal function appear to have an increased risk of all-cause mortality. Further studies are needed to confirm these findings.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2394**

**Survival of Patients on Dialysis by Incident Intake Volume in Hemodialysis and Peritoneal Dialysis Units** Lilyanna Trpeski,[1] Charmaine E. Lok,[2] Stanley S. Fenton.[2] *[1]Ontario Renal Network, Cancer Care Ontario, Toronto, ON, Canada; [2]Nephrology Department, University Health Network, Toronto, ON, Canada.*

Introduction: Survival on dialysis is dependent on patient, provider and other external factors. The effect of the volume of patients initiated onto dialysis in a facility may impact survival and has not been well studied.

Objective: To examine whether the intake volume of patients into a dialysis program influences overall patient survival on dialysis

Methodology: The study population consisted of patients who initiated dialysis between 1998 and 2005 in Ontario, Canada from The Renal Disease Registry (TRDR). 1,290 peritoneal dialysis (PD) and 5,587 hemodialysis (HD) patients were analyzed by Cox regression and adjusted for the variables in Table 1. Patients were censored on December 31 2009 (end of study), and when they were transferred to a non-TRDR site or received a transplant.

Results: Overall 6,877 patients received HD in 12 centers and PD in 10 centers. Facilities that had an average of 75 new patients/year (>643 total/8yrs) had better 3 year survival (65.4%) than those with an average of 40 new patients/year (52.4% ). Even when adjusted for patient demographics and comorbidities, dialyzing in a facility with a high volume of incident patients was associated with improved survival. The volume of incident patients did not affect survival in PD patients.

Table 1. Adjusted survival on dialysis by volume of incident patients, TRDR, Ontario, Canada

| Factors in Peritoneal Dialysis Patients | Hazard Ratio PD | Upper CI | Lower CI | Factors in Hemodialysis Patients | Hazard Ratio HD | Upper CI | Lower CI |
|---|---|---|---|---|---|---|---|
| Age 45-64 yrs | 2.093 | 2.48 | | Age 45-64 yrs | 1.815 | 1.98 | 1.66 |
| >65 years | 3.499 | 4.14 | 2.96 | >65 yrs | 2.857 | 2.9 | 2.43 |
| Ethnicity: Black | 0.634 | 0.82 | 0.49 | Ethnicity: Black | 0.498 | 0.59 | 0.43 |
| Indigenous | 1.701 | 3.82 | 0.76 | Indigenous | 0.762 | 1.14 | 0.51 |
| Other | 0.648 | 0.78 | 0.55 | Other | 0.823 | 0.88 | 0.57 |
| 120-160 incident patients | 1.041 | 1.39 | 0.78 | 300-534 incident patients | 0.961 | 1.06 | 0.87 |
| 160-247 incident patients | 1.042 | 1.37 | 0.79 | 534-643 incident patient | 1.048 | 1.15 | 0.95 |
| >247incident patients | 1.217 | 1.62 | 0.92 | >643 incident patients | 0.83 | 0.92 | 0.75 |
| Sex: female | 1.031 | 1.18 | 0.9 | Sex: female | 0.901 | 0.97 | 0.84 |
| diabetes | 1.818 | 2.09 | 1.58 | diabetes | 1.406 | 1.51 | 1.31 |
| coronary artery disease | 1.549 | 1.77 | 1.36 | coronary artery disease | 1.34 | 1.44 | 1.25 |

HD-Hemodialysis PD-Peritoneal Dialysis CI-confidence interval

Conclusion: Facilities with high volumes of patient dialysis initiation per year are associated with improved patient survival. The data suggests that the experience of larger patient volumes may be associated with processes that promote improved care and patient survival.

Disclosure of Financial Relationships: nothing to disclose

**In Dialysis Patients the Spatial QRS-T Angle Is a Significant Predictor of All-Cause and Cardiovascular Mortality** Arien Gaasbeek,[1] Mihaly K. De Bie,[1] Marion G. Koopman,[2] Pascal F. Van Dessel,[2] Cees A. Swenne,[1] Arthur A. Wilde,[2] Martin J. Schalij,[1] Ton J. Rabelink,[1] J. Wouter Jukema.[1] *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Academic Medical Center, Amsterdam, Netherlands.*

**Introduction**

Cardiovascular disease largely contributes to mortality in dialysis patients. Assessing the predictive value of CV parameters is therefore warrented, but has proven difficult. In several non-dialysis patient groups, the spatial vectorcardiogram QRS-T angle, has shown to have predictive value for CV and all-cause mortality. The aim of this study was to assess the predictive value of an abnormal spatial QRS-T angle in dialysis patients.

**Methods**

All patients who initiated dialysis therapy between 2002 and 2009 in the hospitals of Leiden (LUMC) and Amsterdam (AMC) at least 3 months on dialysis with a routine ECG available were included. The vectorcardiogram was approximated from the standard 12-lead ECG and the spatial QRS-T angle was calculated. Finally its predictive value for all-cause and cardiovascular mortality was assessed. An abnormal QRS-T angle was defined as > 130 in men and > 116 in women.

**Results**

A total of 273 patients (170 male, avg. age 56 ± 17) were included. During an avg. follow-up of 891 ± 601 days 88 (32%) patients died (19 due to cardiovascular causes). In patients with an abnormal spatial QRS-T angle both mortality and cardiovascular mortality were significantly higher in patients with an abnormal spatial QRS-T angle (fig1). Adjusted for all univariate predictors, an abnormal QRS-T angle was associated with a higher risk of death from all causes (HR 2.45, 95% CI 1.57 – 3.83) and also with a higher risk of cardiovascular mortality (HR 7.10, 95% CI 2.28 – 22.05)

**Conclusions**

In a population of chronic dialysis patients the spatial QRS-T angle is a significant and independent predictor of all-cause and cardiovascular mortality.

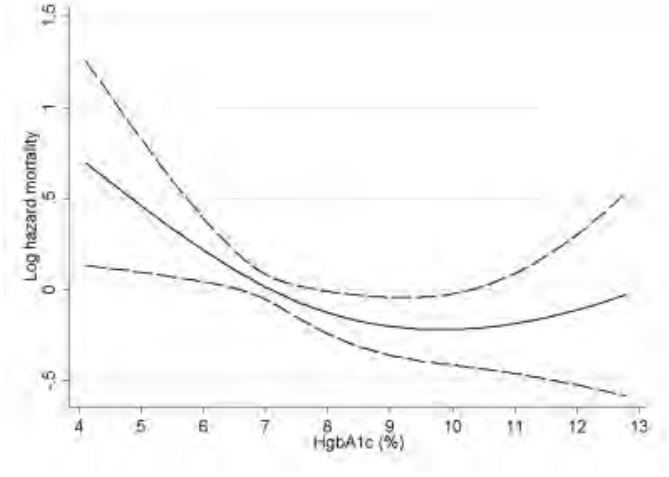
**Association of HgbA1c with Outcomes in Non-Dialysis Dependent CKD: Effect Modification by Hypoglycemia** Fregenet A. Alemu,[1] Jun Ling Lu,[2] Sandra M. Malakauskas,[1] Rasheed A. Balogun,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1,3] *[1]Salem VA Medical Center, Salem, VA; [2]Salem Research Institute, Salem, VA; [3]University of Virginia, Charlottesville, VA; [4]Harbor-UCLA, Torrance, CA.*

The impact of glycemic control and the role of hypoglycemic episodes on clinical outcomes in diabetic patients with non-dialysis dependent CKD (NDD-CKD) is unclear.

We examined the association of hemoglobin A1c (HgbA1c) with all-cause mortality, ESRD and slopes of eGFR in 660 diabetics with NDD-CKD. Associations were examined in Cox models, competing risk regression models and mixed effects models, with separate analyses in patients with and without documented severe hypoglycemia (blood sugar <50 mg/dl).

HgbA1c showed non-linear association with mortality, with an increase in mortality at HgbA1c levels <9% (Figure).



The higher mortality associated with lower HgbA1c was more accentuated in patients with hypoglycemia: adjusted hazard ratio of mortality associated with a 1% lower HgbA1c below 9% was 1.33 (95%CI: 1.06-1.67), p=0.015 vs. 1.19 (0.93-1.52), p=0.18 in patients with and without hypoglycemia, respectively. Higher HgbA1c was associated linearly with higher ESRD incidence in unadjusted analyses (unadjusted HR for 1% higher HgbA1c: 1.15 (1.07-1.23), p=0.006), with attenuation after adjustments (1.08 (0.97-1.20), p=0.17). Similar attenuation was observed for associations with slopes of eGFR (unadjusted and adjusted changes in eGFR/year associated with 1% higher HgbA1c: -0.36 (-0.57, -0.14), p=0.001 vs. -0.11 (-0.31, 0.08), p=0.26). The association of HgbA1c with ESRD and slopes of eGFR was independent of hypoglycemia.

Lower HgbA1c is associated with higher mortality at levels <9% in CKD patients who experience severe hypoglycemia, but may also be associated with attenuated progression of CKD. Glucose control may be beneficial in NDD-CKD if hypoglycemic episodes are avoided.

**SA-PO2397**

**Advanced Age Does Not Modify the Relationship between Low GFR and the Metabolic Complications of CKD** Paul E. Drawz,[1] Denise C. Babineau,[2] Mahboob Rahman.[1] *[1]Nephrology and Hypertension, Case Western Reserve University, Cleveland, OH; [2]Center for Clinical Investigation, Case Western Reserve University, Cleveland, OH.*

Background: Significant controversy exists as to clinical significance of a low glomerular filtration rate (GFR) in the elderly.

Purpose: To evaluate whether age modifies the relationship between low GFR and the metabolic complications of chronic kidney disease (CKD).

Methods: We performed a retrospective cross-sectional study within Veterans Integrated Service Network 10 of patients over 65 years of age with an outpatient GFR between 15 and 45 mL/min per 1.73m$^2$ in 2008 with at least one outpatient GFR less than 60 between 90 and 365 days prior to the index GFR. Anemia was defined as a hemoglobin <10 g/dL, hyperkalemia as a potassium >5.5 mEq/L, acidosis as a serum bicarbonate level <21 mEq/L, and hyperphosphatemia as a phosphorus level >4.6 mg/dL. Multivariable logistic regression was used to evaluate the association between age, GFR, hypertension, diabetes, cancer, medications and anemia, hyperkalemia, acidosis, and hyperphosphatemia. To evaluate whether age modifies the effect of low GFR on metabolic complications, an interaction term including age and GFR was included in each model.

Results: There were 6998 veterans included in the study. The average (SD) age was 80 (6.3), the average GFR was 37.4 (6.8), 4.9% had anemia, 3.7% hyperkalemia, 3.8% acidosis, and 6.3% had hyperphosphatemia. There was no significant interaction between age and GFR in the models including only age and GFR or in multivariable models (*P* value for interaction term in multivariate models: 0.70 for anemia, 0.20 for hyperkalemia, 0.24 for acidosis, and 0.23 for hyperphosphatemia). The adjusted odds ratio (95% CI) per 5 mL/min per 1.73m$^2$ decrease in GFR for anemia was 1.17 (1.08, 1.27), for hyperkalemia was 1.22 (1.12, 1.33), for acidosis was 1.52 (1.40, 1.64), and for hyperphosphatemia was 1.62 (1.45, 1.82) ($P < 0.001$ for all).

Conclusions: This study demonstrates that age does not modify the relationship between low GFR and anemia, hyperkalemia, acidosis, or hyperphosphatemia. Elderly patients with CKD should be monitored for metabolic complications.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2398**

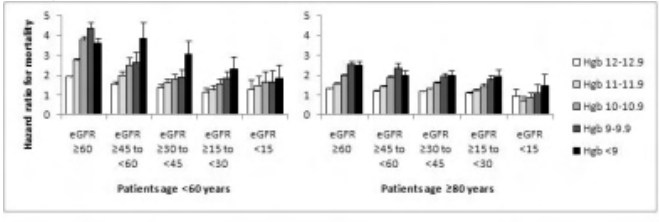
**Anemia in Chronic Kidney Disease (CKD): Differential Prevalence and Outcomes among Older Versus Younger Patients Stratified by GFR** Jessica W. Weiss,[1] Thy Do,[2] Indra Gupta,[2] Jeffrey Todd-Stenberg,[2] Adam J. Batten,[2] Dan Bertenthal,[3] Ann M. O'Hare.[2] *[1]Division of Nephrology, Oregon Health and Science University, Portland, OR; [2]Division of Nephrology, University of Washington, VA Puget Sound Healthcare, Seattle, WA; [3]Medicine, VA Medical Center, San Francisco, San Francisco, CA.*

Prior studies have described an association between anemia and death among patients with CKD but have not examined whether or how this relationship varies with age.

We conducted a retrospective analysis among national VA patients (1,751,819) ages 18-100; at least one outpatient serum creatinine between 10/1/2000 - 9/30/2001 and at least one outpatient hemoglobin (Hgb) within one year before or one month after that creatinine measurement were required. Within this cohort we examined the association of Hgb with time to death after stratification by age and eGFR.

The prevalence of anemia (Hgb <13 g/dL) increased with age and eGFR. In adjusted logistic regression analyses, a lower eGFR was associated with increased odds of anemia in all age groups, but the magnitude of this association was attenuated with increasing age. In Cox proportional hazards analysis, even mild decreases in Hgb were associated with an increased risk of death at most ages and most levels of eGFR. However, the strength of this association was attenuated with both increasing age and decreasing eGFR (p<0.001 for both eGFR and age interactions). The relative risk of death associated with a given level of Hgb was attenuated at lower levels of eGFR in all age groups, and varied more as a function of eGFR in younger versus older patients (Figure 1).

Our study suggests that the prognostic significance of a given Hgb level varies with both age and eGFR.



Adjusted hazard ratios for mortality in patients age <60 and >80. Hgb >13 g/dL is the reference group.

Disclosure of Financial Relationships: nothing to disclose

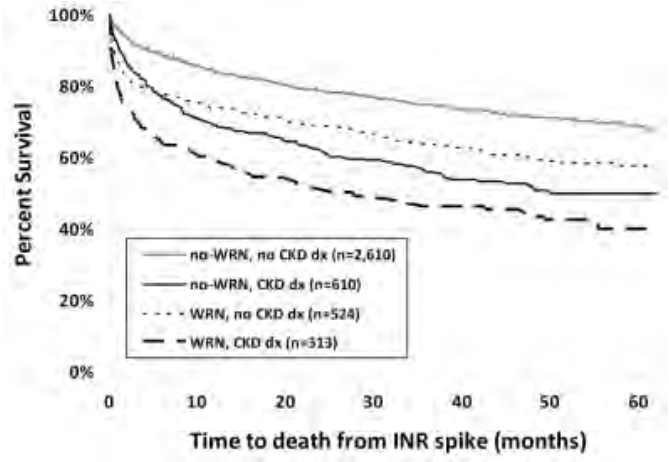
**Warfarin Related Nephropathy (WRN) Is a Risk Factor for Increased Mortality in Chronic Kidney Disease (CKD) and Non-CKD Patients** Sergey V. Brodsky, Brad H. Rovin, Tibor Nadasdy, Amy M. Lehman, Gyongyi Nadasdy, Anjali A. Satoskar, Udayan Y. Bhatt, Jon R. Von Visger, Lee A. Hebert. *The Ohio State University, Columbus, OH.*

Recently we demonstrated that warfarin therapy that results in an INR>3.0 can result in acute kidney injury (AKI). The mechanism involves glomerular hemorrhage and renal tubular obstruction by red blood cell (RBC) casts and perhaps other mechanisms. This study involves the 15,258 patients who had at least one order for warfarin therapy at our institution during 2005-2009. Of these, 6019 had at least 1 episode of INR>3.0. Of these, 4059 had serial serum creatinine (SC) measures in relation to the INR>3.0. Of these, 838 (21%) experienced an increase in SC>0.3 mg/dl within 1 week after INR>3.0 (WRN group). The remaining 3221 patients (79%) were designated no-WRN. The WRN group had a 5-year mortality rate of 42±3%, as compared to 27±2% for the no-WRN group (p<.001). The highest risk of death in the WRN cohort occurred within the 1st month after INR>3.0 (hazard ratio =2.15). For both WRN and no-WRN groups, the 5-year mortality rate was consistently higher in those with CKD compared to those with no-CKD (50.8±5.5% vs. 37.0±4.1% for the WRN cohort; 39.7±3.9% vs. 24.5±1.7% for the no-WRN cohort; p<.0001).



Compared to no-WRN patients, WRN patients tended to be older (63.7±14.7 years vs. 61.7±15.6 years, p=.025), diabetic (47% vs 37%, p<.0001), hypertensive (82% vs 72%, p<.001) and had a history of heart failure (62% vs 42%, p<.001). Preliminary models indicate that WRN still is a significant predictor of death even after adjusting for these factors.

We conclude that WRN is associated with increased mortality rate in the elderly, the diabetic, and those with CKD and cardiovascular diseases. However, the mechanisms of the association are not clear. Further study is needed to elucidate the pathogenesis and prevention of WRN.

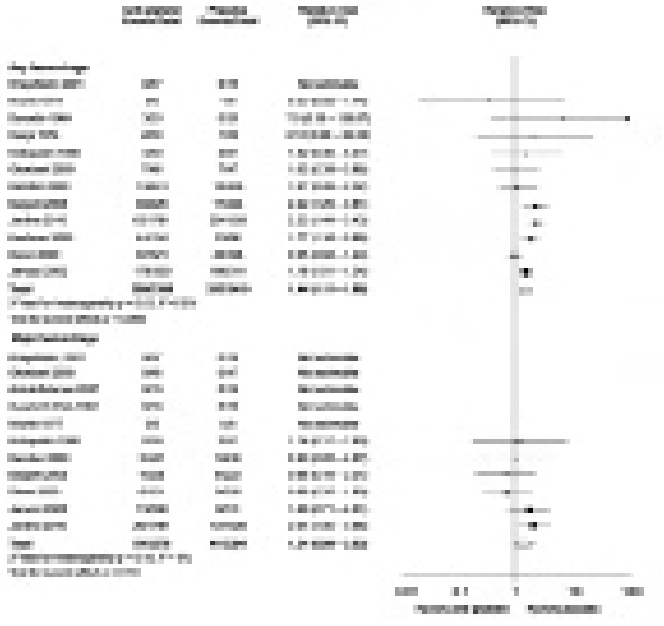
**Benefits and Harms of Anti-Platelet Therapy in Chronic Kidney Disease: A Systematic Review** Suetonia Palmer,[1] Lucia Di Micco,[2] Vlado Perkovic,[3] Meg J. Jardine,[3] Jonathan C. Craig,[4] Giovanni F. M. Strippoli,[4,5,6] Mona Razavian.[3] *[1]University of Otago Christchurch; [2]University of Naples; [3]George Institute for International Health; [4]University of Sydney; [5]Consorzio Mario Negri Sud; [6]Diaverum Medical Scientific Office, .*

Anti-platelet agents are widely used for prevention and treatment of cardiovascular disease in high-risk populations. We are conducting a systematic review of randomized trials to determine benefits and harms of anti-platelet treatment in people with chronic kidney disease.

Effects of anti-platelet agents in people with chronic kidney disease (GFR<60ml/min/1.73 $m^2$ or urine abnormalities), receiving dialysis, or with a kidney transplant were summarized as relative risks (RR) with 95% CI and pooled using random-effects models.

25 trials were identified (9486 patients). 22 placebo-controlled trials evaluated aspirin, dipyridamole, clopidogrel, sulphinpyrazone, picotamide, ticlopidine, tirofiban, or aspirin and dipyridamole combined. Anti-platelet agents did not reduce the risk of all-cause/cardiovascular death, or vascular access thrombosis. Compared with placebo, anti-platelet therapy reduced the risk of myocardial infarction (142 events; 2 trials, 5628 patients; RR 0.62, 95% CI 0.45-0.87), but not stroke (146 events; 4 trials, 7154 patients; RR 0.86, 95% CI 0.62-1.18). Anti-platelet agents increased the risk of bleeding, but risks of major hemorrhage were not significantly different.



The level of renal impairment was not an effect-modifier of risks of clinical outcomes.

In conclusion, anti-platelet agents reduce the risk of myocardial infarction in people with chronic kidney disease, while increasing risks of hemorrhage. Beneficial effects of anti-platelet therapy on mortality, cardiovascular death, and vascular access thrombosis in this population at high risk for cardiovascular disease are not proven.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2401**

**Risk Factors for Vascular Calcifications Preventing the Eligibility for a Kidney Transplant** Samira Sadowski,[1] Marie-Josee Hebert,[1] Francois Madore,[2] Agnes Rakel.[1] *[1]Research Center, Centre Hospitalier de l'Université de Montréal, Montreal, QC, Canada; [2]Nephrology Division, Hôpital Sacré-Coeur de Montréal, Montreal, QC, Canada.*

Vascular calcifications (VCs) are observed in about 50 to 65% of patients with end-stage renal disease (ESRD) and are thought to increase the risk of cardiovascular disease and mortality in this population. Patients with severe pre-transplant calcifications may be denied access to transplantation because of cardiovascular risk or technical contraindications to surgery. Several factors have been associated with VCs including hyperphosphatemia, high calcium phosphorus product and secondary hyperparathyroidism. However, the importance of these factors in the development of VCs severe enough to deny access to renal transplantation has not been clearly delineated.

The purpose of this study was to evaluate the association between the phosphocalcic product and the risk of severe VCs preventing the eligibility to kidney transplantation.

We conducted a case control study in a single-centered cohort of 1574 adults from our computerized transplant database, which included data on all patients evaluated for a renal transplant from January 1995 to June 2009. Cases were defined as patients who were refused for a kidney transplant because of severe VCs and controls were defined as patients who were accepted for a kidney transplant. The evaluation date for transplant eligibility was the case index date.

The study included 83 cases and 80 controls. The phosphocalcic product was above 4 $mmol^2/L^2$ in 44% of the cases and in 22% of the controls (crude OR: 2.77; 95% CI: 1.4–5.5). After adjusting for age, dialysis duration, history of smoking, diabetes as cause of ESRD and history of coronary artery disease, the phosphocalcic product above 4 $mmol^2/L^2$ remained a significant risk factor for transplant non eligibility (adjusted OR: 3.3; 95% CI: 1.1–9.8).

A high phosphocalcic product significantly increases the risk of non eligibility for a kidney transplant among adults with ESRD. Since the phosphocalcic product is a modifiable risk factor, nephrologists should be attentive to its level, in order to prevent long-term consequences of severe VCs and its impact on transplantation.

Disclosure of Financial Relationships: nothing to disclose

**Mortality Associated with Hepatitis C and Chronic Kidney Disease among Community-Dwelling Adults: NHANES 1988-1994** Rajiv J. Gandhi, Robert N. Foley. *Department of Medicine, Division of Renal Diseases and Hypertension, University of Minnesota, Minneapolis, MN.*

Purpose: Chronic hepatitis C virus (HCV) infection and chronic kidney disease (CKD) are both individually associated with increased mortality. The interaction of HCV and CKD on mortality, however, in non-referred, community-dwelling adults is unknown.

Methods: We compared blood pressure levels, estimated glomerular filtration rate (eGFR) (with the 4-variable MDRD and CKD-EPI equations), and urinary albumin-creatinine ratio (ACR) among adult participants age 20 years in the National Health and Nutrition Examination Survey (1988 to 1994, N = 15,540). Participants in the NHANES linked mortality files were then compared on mortality categorized by HCV and CKD status. All population estimates and statistical comparisons were weighted for the survey design employed.

Results: 2.3% of US adults were HCV-positive. Although HCV-positive and HCV-negative subjects had similar blood pressures and ACR, mean age (40.8 Vs. 44.9) was lower ($P < 0.05$) in subjects with HCV. Mean MDRD eGFR (101.6 Vs. 92.5) and CKD-EPI eGFR (106.4 Vs. 98.8) were higher ($P < 0.05$) in subjects with HCV. HCV-positivity showed a non-significant trend toward increased percentage of dead participants (22.2 Vs. 17.2). The unadjusted hazard ratios for all-cause mortality were 6.5 for CKD alone ($P < 0.01$; 95% CI 5.7, 7.6) compared with 1.5 for HCV-positivity alone ($P < 0.01$; 1.0, 2.6), and 6.9 when both conditions were present ($P < 0.01$; 3.4, 14.0). After adjusting for age, sex, and race, the corresponding hazard ratios for all-cause mortality were 2.5 ($P = 0.8$; 2.1, 2.8), 3.9 ($P < 0.05$; 2.3, 6.7), and 4.3 ($P = 0.1$; 1.8, 10.2).

Conclusion: The risk for mortality attributable to HCV alone is higher than that for CKD alone. When both conditions are present, the risk increases slightly, suggesting that the addition of CKD does not significantly increase mortality beyond the risk associated with HCV alone. This may have implications regarding the utility of screening for CKD among HCV-positive individuals in the community.

**Exploring the Relationship between Temporal Trends in PTH, P and Ca in HD Patients** Ryan D. Kilpatrick,[1] Karminder S. Gill,[2] Geoffrey A. Block.[3] *[1]Biostatistics and Epidemiology, Amgen, Inc, Thousand Oaks, CA; [2]Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Denver Nephrologists PC, Denver, CO.*

Objective: The pathogenesis of CKD-MBD is multi-factorial and there are important temporal interactions among biochemical parameters including PTH, Ca and P. Although the KDIGO guidelines recommend using dynamic trends in PTH to inform therapeutic decisions, most studies to date have focused only on static measures of biochemical indices. Methods: We conducted a retrospective cohort study using data from a large dialysis provider in 54,641 HD patients in 2007. PTH, Ca and P were provided as the last value of each month. The first monthly PTH in the dataset and the P and Ca measurement from the same month were considered baseline values. Follow-up values were those occurring 12 +/- 2 mos after baseline. PTH at both points was categorized into three groups: < 150, 150-600, and > 600 pg/dl, corresponding to 2 and 9 times the upper limit of normal stated in KDIGO. Results: Whether mediated by disease progression or changes in treatment, large changes in PTH over 12 mos were seen in many patients. Approx. 6% of patients shifted from <150 to >600 and 13% moved from 150-600 to > 600 cat. Changes in PTH category were associated with changes in P but not in Ca. Those showing an upward shift in PTH had higher P levels at 12 mos., those remaining in same PTH category had similar avg. P values at baseline and 12 mos, and those with a downward change in PTH had lower P values at 12 mos compared with baseline. Only minor changes in Ca suggest the relationship between PTH and P over time is unlikely related to change in vitamin D use. Conclusion: Large changes in PTH occur often in HD patients over 12 mos. and temporal changes in PTH are associated with changes in P but not Ca.

**Past Smoking Determines Development of Chronic Kidney Disease after Lung Transplantation** Merel E. Hellemons, Stephan J. L. Bakker, Gerjan Navis. *Internal Medicine, University Medical Center of Groningen, Groningen, Netherlands.*

Smoking is risk factor for chronic kidney disease (CKD) and for pulmonary disease. CKD is a main complication after lung transplantation (LTx). We investigated whether past smoking was a risk factor for CKD and mortality after LTx in the patients that underwent LTx in our centre (1990-2008). Smoking cessation > 1 year was required to be eligible for LTx. Glomerular filtration rate (GFR; $^{125}$I-Iothalamate) was measured before LTx and regularly during follow-up. Of 326 patients (age 45 ± 12 yrs, 51 % male; GFR 99 ± 24ml/min/1.73m2) 134 were never smokers and 192 were former smokers with a median [IQR] of 17.5 [10-30] packyears (PCKY). Incidences of CKD stage III, IV and death at 5 yrs after LTx were 73, 21 and 35 %, respectively. Former smokers had a higher risk for CKD (stage III: HR [95% Confidence Interval (CI)] = 1.71 [1.25 – 2.33]); stage IV (HR 1.85 [1.04- 3.33]) but not mortality (HR 0.99 [0.71 – 1.38]) compared to never smokers. A dose-dependent association existed between PCKY and CKD stage III (HR per 10 PCKY 1.20 [1.03 – 1.37]) and IV (HR 1.47 [1.10 – 1.89]). Figure 1 shows that the increased risk persists on long term follow-up. Interaction analysis showed a higher risk for CKD per PCKY in subjects older at LTx. Thus, smoking prior to LTx is dose-dependently associated with a persisting higher risk for CKD after LTx, in spite of smoking cessation, in particular in older patients.

**Carotid Plaque, Carotid Intima Media Thickness, and Coronary Calcification Are Comparable Predictors of Prevalent Cardiovascular Disease: Report from the Chronic Renal Insufficiency Cohort (CRIC) Study** Gbemisola Adeseun, Dawei Xie, Xin Wang, Marshall M. Joffe, Emile Mohler, Raymond R. Townsend, Sylvia E. Rosas. *University of Pennsylvania, Philadelphia, PA.*

Despite the significant morbidity and mortality attributable to cardiovascular disease (CVD), risk stratification remains an important challenge in the chronic kidney disease population. We compared the relationship of non-invasive measures of atherosclerosis, including carotid intima-media thickness (IMT), carotid plaque, coronary artery calcification (CAC) and ascending and descending thoracic aorta calcification to prevalent self-reported CVD. Participants were enrolled in the carotid IMT ancillary study of the Chronic Renal Insufficiency Cohort Study who also had all of the above measures within an 18 month period. CVD, defined as history of myocardial infarction/revascularization, stroke, and peripheral vascular disease, was present in 20% of participants. C-statistics were used to ascertain the discriminatory power of each measure of atherosclerosis. The study population (n=155) was 60.5% male; 50% black and 46% white; with 22%, 40%, 26.5%, and 11.6% of individuals in eGFR strata <60, 45-60, 30-44, and <30ml/min/1.73m², respectively. In multivariate analyses, CAC (C-statistic 0.74, 95% CI: 0.64-0.83), carotid plaque (C-statistic 0.68, 95% CI: 0.60-0.76) and carotid IMT (C-statistic 0.64, CI: 0.55-0.72) were the best predictors of CVD when compared to ascending and descending thoracic aorta calcification (table 1); however, only the difference between CAC and measures of thoracic aorta calcification achieved statistical significance. CAC, carotid plaque, and carotid IMT were comparable predictors of prevalent CVD, but only CAC outperformed aortic calcification as a non-invasive measure of atherosclerosis.

The association between measures of atherosclerosis and prevalent CVD

| Measurement | C-statistic§ | CI |
|---|---|---|
| CAC | 0.74 | 0.64-0.83 |
| Plaque | 0.68 | 0.60-0.76 |
| Carotid IMT | 0.64 | 0.55-0.72 |
| Ascending aorta calcification | 0.62 | 0.54-0.71 |
| Descending aorta calcification | 0.60 | 0.52-0.68 |

**Rates of Progression to Death or Renal Replacement Therapy after Reaching CKD Stage 5 in 1,971 Patients at 7 UK Renal Centers** Daniel Ford,[1,3] Dirk J. Van Schalkwyk,[1] David Ansell,[1] Charles Tomson,[1,2] Yoav Ben-Shlomo,[3] Damian G. Fogarty.[1,4] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Southmead Hospital, Bristol, United Kingdom; [3]University of Bristol, United Kingdom; [4]City Hospital, Belfast, United Kingdom.*

**Introduction** We have shown elsewhere that there are demographic differences between patients reaching CKD stage 5 (not on RRT) and patients commencing RRT. It is hypothesized that one reason for these differences could be differing rates of progression to RRT or death.

**Methods** All adult patients reaching CKD stage 5 (two eGFR results <15ml/min/1.73m², >90 days apart with no intervening eGFR results ≥15) during 2006-7 at 7 UK renal centers were included. Baseline demographic and clinical data were extracted direct from the centers' IT systems. Patients were followed up until December 2008. Rate of progression to RRT (censored for death) and to death (uncensored) were calculated using the Kaplan-Meier method. Groups were compared using a log-rank test for survivor function.

**Results** 1,971 patients reached CKD5 during 2006-7. 1,020 commenced RRT before the end of the study period. Significant differences in rate of progression to RRT were found by gender (males progressing faster, figure 1), age (younger patients progressing faster, figure 2) and primary renal disease (GN progressing fastest). Differences in rates of death were found by age (younger patients having better survival) and primary renal disease (GN & PKD having better survival) (all log-rank tests p<0.001). These differences persisted after adjustment for age, gender, ethnicity, center and primary renal disease.

**Conclusions** These differences in the rate of progression to RRT or death explain at least some of the differences in demographic make-up between CKD stage 5 and incident RRT patients.

**Both Hypokalemia and Hyperkalemia Predict Cardiovascular Risk during Blood Pressure Lowering Therapy in Patients with Diabetes and Nephropathy** Hiddo Jan Lambers Heerspink,[1] Gozewijn Dirk Laverman,[1] Julia Lewis,[2] Hans-Henrik Parving,[3] Dick De Zeeuw.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Vanderbilt University, Naishville; [3]University Hospital Copenhagen, Copenhagen, Denmark.*

Both hypokalemia and hyperkalemia increase cardiovascular risk. Treatment with angiotensin receptor blockers (ARBs) increase serum potassium levels, while some report that treatment with calcium channel blocker (CCB) lower serum potassium. We examined the association between the on-treatment serum potassium and subsequent cardiovascular risk.

A post-hoc analysis in the merged RENAAL and IDNT trials was performed. Patients with diabetes and nephropathy were randomized to ARB treatment (losartan or irbesartan), CCB treatment (amlodipine in the IDNT trial), or placebo. The impact of the month 3 serum potassium level on CV outcomes was assessed by multivariate Cox analysis. Hypo-, and hyperkalemia were defined as a serum potassium concentration < 3.5 mmol/L and ≥ 5.5 mmol/L, respectively. The CV endpoint was the composite of myocardial infarction, stroke, hospitalization for heart failure, revascularization procedures, or CV death.

At month 3 hyperkalemia had developed in 131 (10.9%) patients on ARB treatment, 13 (2.7%) on CCB treatment and 47 (4.0%) on placebo (p<0.001 vs. ARB), Hypokalemia developed in 11 (0.9%) patients on ARB treatment, 13 (2.7%) on CCB treatment, and 12 (1.0 %) on placebo (p<0.008 vs. CCB). Both hypo- and hyperkalemia were independently associated with increased overall cardiovascular risk (table). Similar associations were observed for the myocardial infarction and stroke component of the CV endpoint.

ARB treatment is associated with increased likelihood of hyperkalemia while CCB treatment is associated with an increased likelihood of hypokalemia. Both hypo- and hyperkalemia are in turn associated with increased CV risk and may limit the CV protective efficacy of these drugs.

| Month 3 serum potassium concentration (mmol/L) | Hazard ratio CV endpoints (95%CI) | p-value |
|---|---|---|
| <3.5 | 1.79 (1.06 – 3.01) | 0.029 |
| 3.5 - 5.0 | reference | - |
| 5.0 - 5.5 | 1.17 (0.96 – 1.43) | 0.129 |
| ≥ 5.5 | 1.34 (1.01 – 1.77) | 0.039 |

**Comparison of Cardiovascular Prognosis by Three Serum Cystatin C Methods** Michael Shlipak,[1] Yongmei Li,[1] Joachim H. Ix,[2] Lars-Olof Hansson,[3] Anders Larsson,[3] Mary Whooley.[1] *[1]San Francisco VA Medical Center; University of California, San Francisco, San Francisco, CA; [2]University of California, San Diego, San Diego, CA; [3]University Hospital, Uppsala, Sweden.*

Cystatin C (cysC) is a promising new measure of glomerular filtration that has been proven superior to creatinine-based estimated GFR (eGFR-MDRD) in forecasting clinical outcomes. However, Siemens' cystatin C assay (cysC-S), used in many longitudinal studies, has had limited applicability because it requires a Siemens nephelometer. Two other companies, Gentian and Roche, have developed cystatin C assays (cysC-G and cysC-R) that can be measured using most clinical auto-analyzers. We compared the agreement of cysC-G and cysC-R with cysC-S in 948 participants from The Heart and Soul Study, a longitudinal study of persons with established coronary artery disease who were followed for an average of 8 years. We then compared associations of all 3 measures and eGFR-MDRD with clinical outcomes. The cysC-S had higher correlations with cysC-G (0.96) than cysC-R (0.93); agreement (K) across cysC-S quartiles was 0.73 for cysC-G and 0.64 for cysC-R quartiles. These differences in agreement had minimal impact on associations with clinical outcomes; the Table presents hazard ratios for the high vs. low quartile of each measure with mortality, cardiovascular events (CVD), and heart failure (CHF), adjusted for age, sex, race, BMI, diabetes, hypertension, smoking, HDL, and CRP. All cysC measures had stronger and more linear associations than eGFR-MDRD. In summary, 3 methods for cystatin C measurement had similar utility as predictors of clinical outcomes. For widespread clinical use as a GFR marker, however, the optimal cystatin C assay will need to demonstrate consistent accuracy and calibration against a reference standard.

Adjusted Hazard Ratios for Clinical Outcomes of High versus Low Quartiles using 3 Cystatin C Measures and eGFR-MDRD

| | Mortality | | CVD | | CHF | |
|---|---|---|---|---|---|---|
| | HR | 95% CI | HR | 95% CI | HR | 95% CI |
| CysC-S | 3.2 | 2.1-4.8 | 2.6 | 1.6-4.2 | 5.3 | 2.4-12.1 |
| CysC-G | 3.1 | 2.1-4.7 | 2.6 | 1.6-4.2 | 5.2 | 2.4-11.3 |
| CysC-R | 3.1 | 2.1-4.7 | 2.4 | 1.5-3.9 | 4.6 | 2.0-10.3 |
| eGFR-MDRD | 1.6 | 1.1-2.3 | 1.9 | 1.2-2.9 | 3.2 | 1.6-6.6 |

**Acute Renal Failure May Not Affect Mortality in Patients with Extreme APACHE II Scores** Jean-Sebastien Rachoin, Lawrence S. Weisberg, David R. Gerber, Christa Schorr, Daniel Fabius, Jean-Pierre El-Khoury. *Medicine, UMDNJ-RWJ Medical School, Cooper University Hospital, Camden, NJ.*

Acute renal failure (ARF) is associated with increased mortality in large cohorts of critically-ill patients. Indeed, mortality reduction is used to define success of interventions in patients with ARF. It is unclear, however, whether the impact of ARF on mortality is uniform across the range of severity of illness. We performed a retrospective observational study of all patients admitted to a medical/surgical ICU from 2003 through 2009. Patients were categorized by severity of illness using the admission APACHE II score. We defined ARF as that requiring renal replacement therapy (RRT). We analyzed mortality by APACHE II strata. 9441 patients were initially considered for inclusion, of whom 7202 had complete data available. The median [IQR] APACHE II score was 15[11-20]. 256 patients (3.6%) had ARF requiring RRT. 1268 of 7202 patients (17.6%) died in hospital. Using recursive partitioning analysis we found that APACHE II score cutoff points of 13 and 22 improved group homogeneity for mortality. In these three APACHE groups (<13, 13-22 and >22), mortality increased progressively: 3.9%, 16.2% and 52.5%, respectively (P<0.001). Among patients with ARF, 111patients (43.4%) died. ARF was significantly associated with increased mortality in all patients (OR 3.8 [3-4.9], P<0.001), and in patients with intermediate APACHE score (2.8 [1.9-4.2], P<0.001), but not in patients with low (P=0.112) or high (p=0.570) scores. After adjusting for other confounding variables (age, gender, diabetes, hypertension, CKD, CHF) the associations were unchanged. Thus, ARF appears to increase the risk of death in patients with intermediate severity of illness, but not in patients with low or high severity scores. Future clinical trials should take into account this finding.

**Pulse Wave Velocity (PWV) and Heart Rate Variability (HRV) Predict Cardiovascular (CV) Outcomes in Chronic Kidney Disease (CKD)** Preeti Chandra,[1] Robin L. Sands,[1] Brenda W. Gillespie,[1] Nathan W. Levin,[2] Peter Kotanko,[2] Margaret A. Kiser,[3] Fredric O. Finkelstein,[4] Alan L. Hinderliter,[3] David Sengstock,[5] Sanjay Rajagopalan,[6] Rajiv Saran.[1] *[1]Univ of MI, Ann Arbor, MI; [2]Renal Research Inst., NYC, NY; [3]Univ of NC, Chapel Hill, NC; [4]St. Raphael Yale Univ, New Haven, CT; [5]Oakwood Healthcare System, Dearborn, MI; [6]Ohio State Univ, Columbus, OH.*

The relationship between arterial stiffness, autonomic dysfunction and CV events has not been evaluated in CKD. We postulated that low HRV (a measure of autonomic dysfunction) would be associated with increased arterial stiffness (PWV) and that both would independently predict CV events in CKD.

The RRI-CKD Study is a 4-center prospective cohort study of CKD stages 3-5 (n=834). A subset underwent both HRV testing using 24-hour Holter monitoring and carotid-femoral PWV (n=240). Cox regression was used to test HRV parameters (time and frequency domain) and PWV as predictors of CV events, adjusted for history (h/o) of CV, age, gender, phosphorus, and albumin (i.e., CV base model). Selection of the CV base model was obtained by method of best subsets with the $R^2$ selection criterion.

Mean age was 60 ± 15, 50% were male, 78% white, 31% diabetic (DM), 89% hypertensive and 37% with h/o of CV events. 47 patients had at least one CV event (including 5 cardiac deaths). Several HRV measures (LF, VLF, TP, ASDNN) were negatively correlated with PWV, with or without adjustment for age, systolic blood pressure, DM, and BMI ($p < 0.05$). HRV measures were more strongly predictive of CV events than PWV in separate models, and when in the same model. Lower HRV and higher PWV were both associated with adverse CV events (Table).

Both HRV and PWV predict CV events in CKD independent of traditional risk factors. Their role as intermediate outcomes for clinical trials needs further evaluation in this high risk population.

| | | HRV | | PWV | |
|---|---|---|---|---|---|
| | Generalized Model $R^2$ | Hazard Ratio | p-value | Hazard Ratio | p-value |
| CV base model (includes hlo CV, age, gender, albumin, and phosphorus) | 0.13 | – | – | – | – |
| + Pulse Wave Velocity (PWV) | 0.15 | – | – | 1.15 | 0.0541 |
| + Low frequency* (LF) | 0.18 | 0.57 | 0.0009 | – | – |
| + LF + PWV | 0.19 | 0.62 | 0.0017 | 1.10 | 0.1287 |
| + Very low frequency* (VLF) | 0.16 | 0.61 | 0.0072 | – | – |
| + VLF + PWV | 0.18 | 0.66 | 0.0300 | 1.08 | 0.1928 |
| + Low to High Frequency ratio* (LF/HF) | 0.15 | 0.61 | 0.0222 | – | – |
| + LF/HF + PWV | 0.18 | 0.60 | 0.0163 | 1.15 | 0.0425 |
| + Total power* (TP) | 0.16 | 0.55 | 0.0092 | – | – |
| + TP + PWV | 0.17 | 0.58 | 0.0170 | 1.10 | 0.1273 |
| + Average of all 5-minute standard deviation of NN over 24 hours (ASDNN) | 0.16 | 0.32 | 0.0112 | – | – |
| + ASDNN + PWV | 0.17 | 0.36 | 0.0188 | 1.10 | 0.1111 |

**SA-PO2411**

**Nationwide Frequency and Outcomes of Atrial Fibrillation in Patients with Chronic Kidney Disease in an Inpatient Population** Ankit Sakhuja, Abhishek Deshmukh, Nilay Kumar, Rahul S. Nanchal, Aaron T. Dall, Gagan Kumar. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

**Background**

Literature suggests inflammation may play a role in the pathogenesis of atrial fibrillation (AF). In a few smaller studies, the prevalence of AF has been shown to be greater in patients with chronic kidney disease (CKD) which is known to be a chronic inflammatory state. The clinical outcomes in patients with AF who have CKD are largely unknown. We sought to examine the frequency of AF in CKD and outcomes of patients with CKD who developed AF.

**Methods**

Using the Nationwide Inpatient Sample 2007, patients aged ≥18 years discharged with a diagnosis of AF and stage 1-5 CKD were identified through appropriate ICD-9, clinical modification codes. Patients with end stage renal disease were excluded. Outcome variables included in-hospital mortality, LOS and disposition on discharge. Multivariate regression analysis was used to adjust for age, sex, demographics and other clinically relevant co-morbid conditions.

**Results**

There were an estimated 32,759,253 adult discharges in 2007; out of which 3,324,689 had AF. The frequency of AF in patients with CKD and normal renal function was 455,047(25.3%) and 2,727,138(9.1%) respectively. After adjusting for the above mentioned variables, the odds for developing AF in CKD patients was 1.2 (95%CI 1.18-1.22) times higher than those with normal kidney function.

In-hospital mortality in patients admitted with the primary diagnosis of AF was 0.88% in patients with normal kidney function and 2.1% in CKD patients (adjusted OR 1.33, 95%CI 1.04-1.69). AF patients with CKD had significantly longer LOS (1.1 days longer, 95%CI 0.91-1.17days) and were more likely to be discharged to a nursing home compared to those with AF who did not have CKD (OR 1.45; 95%CI 1.31-1.60).

**Conclusion**This observational study showed that the frequency of AF is greater in patients with CKD. Presence of CKD was predictive of worse outcomes in terms of mortality and lengths of stay in patients discharged with the primary diagnosis of AF. Further prospective studies are needed to investigate causal relationships.

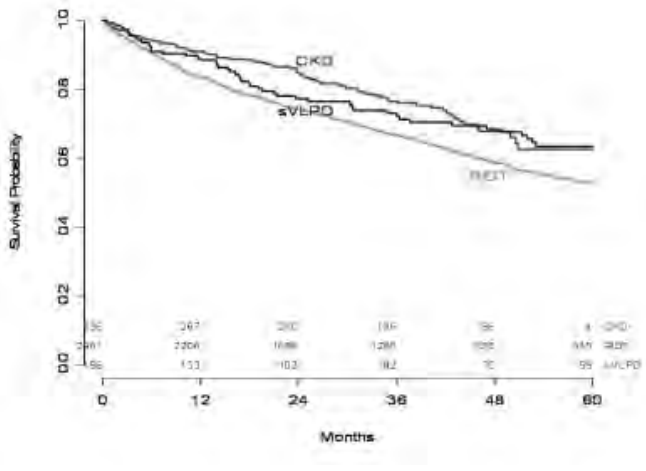
**SA-PO2412**

**Very Low-Protein Diet Plus Ketoanalogs (sVLPD) during CKD and Survival during Renal Replacement Therapy (RRT): A Controlled, Cohort Study** Vincenzo Bellizzi,[1] Paolo Chiodini,[2] Adamasco Cupisti,[3] Mauro Pezzotta,[4] Battista Fabio Viola,[4] Luca De Nicola,[2] Roberto Minutolo,[2] Giuliano Barsotti,[3] Giorgina B. Piccoli.[5] *[1]Salerno; [2]Napoli; [3]Pisa; [4]Brescia; [5]Torino, Italy.*

In CKD low protein-diets allow better control of metabolic disorders and delay dialysis start, but it has been suggested sVLPD may worsen survival after starting RRT. We evaluated whether prolonged sVLPD during CKD affects mortality during RRT by comparing time to all-cause death during RRT in patients previously followed in renal clinics either treated (sVLPD, n=158) or not (CKD, n=335) with sVLPD. As controls, we selected 2.961 coeval patients from Italian dialysis & transplantation registry (RIDT). Age (67±18, 66±14, 67±14 yrs) and CV disease (39, 31, 31%) did not differ in sVLPD, CKD and RIDT. Females were 54, 55 and 60% (p=0.037) in the three groups while diabetes was similar in CKD and RIDT (31 *vs.* 22%), but lower in sVLPD (13%; p<0.001). The median follow-up time in RRT (37 [18-103], 30 [15-43], 30 [12-55] mts [IQR]) did not differ. A better survival was detected in sVLPD and CKD [log-rank, 20.62; p<0.001].



These results persisted in the Cox model adjusted for age, gender, diabetes, CV disease; as compared with controls, the HRs [95% CI] for death were 0.74 [0.56-0.96] (p=0.024) and 0.68 [0.54-0.85] (p=0.001) for sVLPD and CKD. Due to the age interaction with survival in sVLPD (p=0.024), we re-evaluated survival after patients stratification in older (≥70 y) and younger (<70 y). In the latter, HRs for death reduced to 0.34 [0.16-0.73] and 0.58 [0.37-0.92] for both sVLPD and CKD while HRs resulted unchanged, 0.89 [0.67-0.18] and 0.72 [0.55-0.94], for elderly sVLPD or CKD. Thus, prescription of sVLPD during CKD improved survival after starting RRT. This survival advantage held particularly true in younger patients.

**Renal Function Is Associated with Arterial Stiffness among African Caribbean Families of Tobago** Alan L. Patrick,[1,2] Hu Li,[2] Lewis Kuller,[2] Candace M. Kammerer,[2] Joseph M. Zmuda,[2] Iva Miljkovic,[2] Victor W. Wheeler,[1,2] Clareann H. Bunker.[2] *[1]Tobago Health Studies Office, Scarborough, Tobago, Trinidad and Tobago; [2]Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA; [3]Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA; [4]Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA; [5]Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA; [6]Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA; [7]Tobago Health Studies Office, Scarborough, Tobago, Trinidad and Tobago.*

Purpose of study: To test the hypothesis that an increased serum creatinine concentration and a decreased eGFR may be related to increased arterial stiffness as measured by pulse wave velocity at the level of the peripheral arteries in this community-based sample of African ancestry population.

**Methods:** Serum creatinine and brachial ankle pulse wave velocity (baPWV) were measured using standard protocols on 7 large, multi-generation pedigrees (average family size: 50; range: 19 to 96; nearly 3500 relative pairs) a total of 402 participants, aged 18 to 103 years (male: 42.1 ± 16.9 (SD) years, female: 42.6 ± 17.3 (SD) years). eGFR was calculated using the four-variable MDRD equation for standardized serum creatinine. A multivariate regression model was built for males and females separately to assess significant predictors of baPWV.

**Results:** The average baPWV was 1438.2 ± 319.7 (cm/s) in men and 1412.9 ± 404.1(cm/s) in women. BaPWV increased across age groups. Among Tobago men, serum creatinine and eGFR were found to be independently associated with baPWV along with age, systolic blood pressure and triglyceride (β=-0.18, 0.2 and p=0.04, 0.006 respectively). Such significant association was stronger among Tobago women, after adjusting for age, systolic blood pressure (β= 0.05, -0.13 and p <0.0001, 0.003 respectively).

Conclusion: our data suggest that reduced kidney function, indicated by either increased serum creatinine level or decreased eGFR was an independent predictor for arterial stiffness in this Afro-Caribbean population in each gender.

## SA-PO2414

**High Non-Steroidal Anti-Inflammatory Drug Use among Persons with Chronic Kidney Disease in the U.S.** Laura C. Plantinga,[1] Vanessa Grubbs,[1] Chi-Yuan Hsu,[1] Elizabeth Hedgeman,[2] Bruce M. Robinson,[2] Nilka Rios Burrows,[3] Mark Eberhardt,[4] Neil R. Powe.[1] *[1]University of California, San Francisco, CA; [2]University of Michigan, Ann Arbor, MI; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]National Center for Health Statistics, Hyattsville, MD.*

Use of non-steroidal anti-inflammatory drugs (NSAIDs) has been associated with greater difficulty in controlling hypertension, hyperkalemia, and acute renal failure among persons with CKD. We characterized patterns of NSAID use among persons with CKD in the U.S. In the 1999-2004 National Health and Nutrition Examination Survey, 12,755 adult participants (≥20 years) were surveyed regarding their use of over-the-counter (OTC) and prescription NSAIDs (excluding aspirin and acetaminophen). CKD was defined as a urinary albumin:creatinine ratio of ≥30 mg/g (stages 1/2) or estimated GFR of 15-59 ml/min/1.73 $m^2$ (stages 3/4). All estimates were calculated using appropriate population-based weighting. Chronic use (*i.e.*, nearly every day for ≥30 days) of any NSAID was reported by 8.5%, 8.0%, and 8.1% of the U.S. population with no CKD, CKD stages 1/2, and CKD stages 3/4, respectively. Nearly all (>99%) of the chronically used NSAIDs were available OTC: ibuprofen (77.8%) and naproxen (24.6%) were used most often. Among those with CKD stages 3/4, almost 10% had a current NSAID prescription and, among chronic users, 63% had used NSAIDs for ≥1 year. Many of those with CKD who had prescriptions for NSAIDs also had prescriptions for ACEIs/ARBs (18%) or loop diuretics (18%); joint use of either with NSAIDs lessens their therapeutic actions and increases the risk of acute renal failure. After adjustment for demographics and comorbid conditions, including arthritis, chronic NSAID use was not significantly different between those with CKD and those without CKD (6.1% vs. 7.3%, *P*=0.143). Persons with CKD, were, however, less likely to report current NSAID prescriptions (5.1% vs. 6.9%, *P*=0.003). This study found high usage rates of NSAIDs among those with CKD in the U.S., reinforcing the benefits of assessing NSAID use and informing those with CKD about appropriate NSAID use.

**Renal Impairment in Patients with Type 2 Diabetes Mellitus and Associated Antihyperglycemic Medication Adjustment: Evidence from an Electronic Medical Records Database** Kathleen Lang,[1] Juliana Meyers,[2] Sean D. Candrilli,[2] Birgit Kovacs.[1] *[1]BIPI, Ridgefield, CT; [2]RTI Health Solutions, Research Triangle Park, NC.*

**Objective:** This study evaluated the presence of renal impairment (RI) in patients (pts) with type 2 diabetes mellitus (T2DM) and the dose adjustment of oral antidiabetic drugs (OAD) for which a dose reduction is indicated in RI.

**Methods:** This retrospective analysis used the GE Centricity outpatient electronic medical record database. Subjects ≥18 years were included if they had evidence of T2DM (ICD-9-CM codes 250.X0, 250.X2) between 1/1/00 and 6/30/09 and had ≥12 months of data following identification. Renal function was evaluated using the MDRD formula-derived eGFR value, with pts classified as having moderate RI (eGFR 30-59 ml/min/1.73$m^2$), severe RI (eGFR 15-29ml/min/1.73$m^2$), or ESRD (eGFR <15ml/min/1.73$m^2$) based on the first observed serum creatinine (SC) result. Days between eGFR and physician diagnosis were calculated when a diagnosis was recorded. Dose adjustment after development of RI was reported for metformin and sitagliptin. The relationship between presence of RI and progression to ESRD was explored in a multivariate logistic regression.

**Results:** Of 344,770 pts identified with T2DM, 121,395 (35.2%) had evidence of RI. Of those, only 20% also had a physician diagnosis (ranging from 16% to 66% among those with moderate RI and ESRD). Physician diagnosis was recorded an average (SD) of 253.4 (584.5) and 86.9 (417.7) days after a confirmatory SC result among patients with moderate and severe RI, respectively. Among pts with moderate or severe RI, a corresponding clinical diagnosis was associated with significantly lower odds of progressing to ESRD (OR: 0.200; 95% CI: 0.188 to 0.213). Following the SC, 15.1% and 0.1% of pts treated with sitagliptin and metformin were receiving an appropriately adjusted dose for their level of RI.

**Conclusions:** RI is common but often undetected in pts with T2DM. Pts with accurate RI diagnosis have lower odds of progression to ESRD. Many RI pts are on inappropriate doses of OADs. Further analyses to understand the clinical and economic consequences of these findings are needed.

## SA-PO2416

**The Association of Cognitive Function with Albuminuria and Kidney Function in the General Population** Hanneke Joosten,[1,2] Gerbrand J. Izaks,[2] Joris Slaets,[2] Henk Bilo,[3] Paul E. de Jong,[1] Ron T. Gansevoort.[1] *[1]Department of Internal Medicine, Division of Nephrology, University Medical Center Groningen, Groningen, Netherlands; [2]Department of Internal Medicine, Division of Geriatrics, University Medical Center Groningen, Groningen, Netherlands; [3]Department of Internal Medicine, Diabetes Center, Isala Clinics, Zwolle, Netherlands.*

Recent studies found various associations between a decreased glomerular filtration rate (GFR) or albuminuria with cognitive function. These studies were limited to elderly and vascular high-risk populations and did not take both CKD associated variables into account. We therefore aimed to analyze the association of estimated GFR (eGFR) as well as albuminuria with cognitive function in community-dwelling persons with a wide age range (35-82 year).

This study comprised 4095 subjects participating in the third survey of the PREVEND study (52% male, mean (SD) age 55 (12) year). Cognitive function was measured with the Ruff Figural Fluency test (RFFT) (scores 0-175) Mean (SD) RFFT score was 69 (26). Mean (SD) eGFR was 79 (15) ml/min/1.73$m^2$ (range 21-150). The prevalence of elevated albuminuria (≥30mg/24h) was 15%. Unadjusted, cognitive function was associated with both eGFR and albuminuria. After adjustment for age, sex and education level, no significant association was found between eGFR and RFFT (p=0.57). As an interaction of albuminuria was noted with age, adjusted analysis were performed per age group. This showed a significant association for albuminuria in the youngest tertile (35-48 years) (*p*=0.028), but not in older tertiles. Moreover, participants with normal albuminuria at baseline (1997-1998), who developed elevated albuminuria at the third survey (2003-2006) had a significantly lower mean RFFT score (SD) compared to participants with stable, normal albuminuria. Again, this was only significant in the youngest tertile (RFFT score 76 (22) versus 84 (22), respectively, *p*=0.04). In conclusion, elevated albuminuria was associated with worse cognitive function in this community-based cohort, being most explicit in the young. Thus, elevated albuminuria not only reflects renal damage, but also impaired cognitive functioning, especially at young age.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2417**

**Albuminuria as a Risk Factor for Peripheral Arterial Disease in a General Japanese Population: The Hisayama Study** Tomoko Usui,[1,2] Toshiharu Ninomiya,[2] Masaharu Nagata,[1,2] Yasufumi Doi,[2] Masayo Fukuhara,[1] Yutaka Kiyohara.[1] *[1]Department of Environmental Medicine, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

**Background:**
Albuminuria has been acknowledged to be a risk factor for cardiovascular disease and death. However, there are limited studies investigating the influence of albuminuria on the risk of peripheral arterial disease (PAD). The aims of this study are to elucidate the relationship between albuminuria and the prevalence of PAD, and to assess the effect of albuminuria on the accuracy of the risk assessment of PAD in a general Japanese population.
**Methods:**
In a total of 3,061 community-dwelling subjects aged ≥40 years, we investigated the association of urinary albumin-creatinine ratio (UACR) levels with the prevalence of PAD. PAD was defined as ankle-brachial index <0.9. The odds ratio for the presence of PAD was estimated by using the logistic regression model. To compare the accuracy of the risk assessment for the presence of PAD between the models adjusted for potential risk factors with and without UACR levels, the receiver operating characteristic (ROC) curves were plotted.
**Results:**
Overall, 1.47% of the study participants had PAD. The age- and sex-adjusted prevalence of PAD increased linearly for UACR levels of <5.6, 5.6-10.8, 10.9-29.9, 30.0-299.9 and ≥300.0 mg/g, being 0.34, 0.80, 2.02, 2.50 and 2.53%, respectively (p for trend <0.001). The multivariate-adjusted odds ratio for the presence of PAD was 1.89 (95% confidence interval 1.14-3.12) for every 10-fold increment in UACR. The area under the ROC curve significantly increased when UACR levels was incorporated into a model with potential risk factors for PAD (0.80 vs. 0.76, p =0.02).
**Conclusion:**
Our findings suggest that greater UACR levels are associated linearly with higher prevalence of PAD, even within normoalbuminuric range, in the general Japanese population, and the information of UACR levels substantially improves the accuracy of the risk assessment of PAD beyond a model based on potential risk factors.

**SA-PO2418**

**Electrocardiogram Abnormalities and Cardiovascular Mortality in Patients with Chronic Kidney Disease** Mirela A. Dobre,[1] Andrei Brateanu,[1] Arash Rashidi,[2] Mahboob Rahman.[3] *[1]Huron Hospital, A Cleveland Clinic Hospital; [2]Nephrology, Fairview Hospital A Cleveland Clinic Hospital; [3]Nephrology and Hypertension, Case Western Reserve University.*

**Background**: The objective of the study was to evaluate whether electrocardiogram (EKG) abnormalities are predictors of cardiovascular mortality in patients with chronic kidney disease (CKD).
**Methods:** We used the Cardiovascular Health Study limited database from 1989 – 2005 to identify a cohort of patients with CKD at baseline (eGFR<60 mL/min/1.73m$^2$). The study population was categorized as having major, minor or no EKG abnormalities. Major EKG abnormalities included ventricular conduction delay, left ventricular hypertrophy, major Q-QS abnormalities, ST-T changes, atrial fibrillation and first degree atrio-ventricular block. Minor EKG abnormalities were defined as minor Q, QS waves, high R waves, minor isolated ST-T abnormalities, ST elevation, incomplete right bundle branch block, long QT, short PR interval, right axis deviation, or left axis deviation. The rates of cardiovascular events and mortality were compared between the three groups using proportional hazards regression analysis.
**Results:** 1192 patients had CKD at baseline. Of these, 452 (38.8%) had major, 346 (29.7%) had minor and 367 (31.5%) had no EKG changes. Patients with eGFR<60 were more likely to have EKG changes at baseline (adjusted risk ratio 1.23; 95% confidence interval [CI], 1.06-1.43) than those with higher eGFRs. 814 (68.3%) patients died during the mean (SD) follow-up of 10.3 (3.8) years. A cardiovascular cause of death was found in 184 (54.4%) patients with major EKG changes, 95 (28.1%) patients with minor EKG changes, and 59 (17.5%) patients with no EKG changes. The group of patients with major EKG changes had the highest risk for cardiovascular events and mortality, hazard ratio (HR), 2.0; 95% CI, 1.6-2.7, and 2.2; 95% CI, 1.6-3.0, respectively. In patients with minor EKG changes HR was 1.3; 95% CI, 1.0-1.7 and 1.5; 95% CI, 1.1-2.1, respectively.
**Conclusion:** In patients with CKD (eGFR<60 mL/min/1.73m$^2$), major EKG abnormalities are frequently present and predict a significantly higher risk of mortality and adverse cardiovascular outcomes.
Disclosure of Financial Relationships: nothing to disclose

**SA-PO2419**

**Alcohol, Tobacco and Illicit Drug Use and Progression of Chronic Kidney Disease (CKD)** Lydia Bazzano, Manjunath Balaram, Janet Cohan, Jeffrey C. Fink, Kenneth A. Jamerson, James P. Lash, Gail K. Makos, Nancy Robinson, Susan P. Steigerwalt, Kelvin Tao, Jacqueline R. Theurer, Dawei Xie, Chi-Yuan Hsu. *For the CRIC Study Investigators.*

Lifestyle factors associated with progression of CKD are of increasing interest. Most studies have not found strong associations between alcohol and tobacco use and progression of CKD. Less is known about illicit drug use. We obtained self-reported use of alcohol, tobacco (usual consumption) and illicit drugs (lifetime use) among 3,939 persons in the Chronic Renal Insufficiency Cohort (CRIC). Cox proportional hazards models adjusted for age, sex, race/ethnicity, education, diabetes, hypertension, BMI, systolic blood pressure, clinical site, eGFR and proteinuria at baseline were used to examine time to 50% reduction in eGFR from baseline and/or the development of ESRD by category of alcohol, tobacco and illicit drug use. Reference categories for alcohol, tobacco and illicit drug use were <once/year, not currently smoking, and never using illicit drugs. Alcohol, tobacco or lifetime use of illicit drugs did not increase the risk of CKD progression [Table]. However, few participants reported active use of illicit drugs in the last 30 days (marijuana n=152, methamphetamine n=2, inhaled cocaine n=28, injected cocaine n=0, heroin n=0). Alcohol and tobacco do not appear to be important factors in CKD progression. The impact of illicit drugs is less clear.

| *Variable* | *N* | *Frequency of use* | *Hazard Ratio (95% CI)* | *P-value* |
|---|---|---|---|---|
| Alcohol | 980 | <once/month | 1.00 (0.80, 1.25) | 0.99 |
| | 269 | once/month | 0.71 (0.47, 1.06) | 0.09 |
| | 432 | 2-4 times/month | 1.04 (0.76, 1.42) | 0.83 |
| | 355 | 1-2 times/week | 0.84 (0.58, 1.22) | 0.36 |
| | 438 | >2 times/week | 1.12 (0.79, 1.58) | 0.51 |
| Tobacco | 517 | current smoking | 1.26 (0.99, 1.60) | 0.06 |
| Marijuana | 1,293 | ever used | 1.04 (0.85, 1.26) | 0.74 |
| Methamphetamine | 146 | ever used | 1.01 (0.65, 1.57) | 0.96 |
| Cocaine (inhaled) | 424 | ever used | 0.96 (0.72, 1.27) | 0.76 |
| Cocaine (injected) | 45 | ever used | 0.99 (0.48, 2.02) | 0.98 |
| Heroin | 58 | ever used | 1.23 (0.72, 2.10) | 0.45 |

**SA-PO2420**

**Impact of Chronic Kidney Disease on Risk of Incident Atrial Fibrillation (AF) and Subsequent Survival in Medicare Patients** Charles A. Herzog, Shuling Li. *CVSSC, USRDS, Minneapolis, MN.*

**Introduction:** Atrial Fibrillation (AF) is common in elderly pts and its prevalence increased in pts with chronic kidney disease (CKD). Few studies have examined CKD as a risk factor for incident AF in elderly pts.
**Methods:** We identified 1,092,649 pts (age 66+) prevalent on 12/31/06 in the 5% General Medicare database (prior AF and ESRD excluded) and followed through 12/31/08. CKD stage was identified from ICD-9 codes 585.1-585.5, 585.9. The risk of developing AF was assessed in a Cox model adjusting for demographics, and comorbidity. Unadjusted survival after incident AF was estimated by Kaplan-Meier method.
**Results:** The prevalent 2006 cohort was 41% male, 88% white, 23% age 66-69, 25% age 70-74, 21% age 75-79, 16% age 80-84, and 14% age 85+. By CKD stage: 94.9% no CKD, 0.5% stage I-II, 1.8% stage III-V, 2.9% stage unknown. By CKD stage incident AF occurred in 7.0% no CKD, 11.1% stage I-II, 12.4% stage III-V, 11.6% stage unknown. The Table shows predictors of AF (age 66-69, male, white, no CKD, no comorbid conditions is reference) with hazard ratio (HR) and survival of AF pts.
**Conclusion:** CKD stage is a predictor of incident AF and subsequent risk of death in elderly pts. Medicare pts with CKD and AF have a high (>30%) one year mortality.
Predictors of AF

| Variable | HR (95%CI) | P | | |
|---|---|---|---|---|
| CKD Stage I-II | 0.99 (0.91, 1.08) | 0.8992 | | |
| CKD Stage III-V | 1.12 (1.07, 1.16) | <.0001 | | |
| CKD (Stage unknown) | 0.97 (0.94, 1.01) | 0.1062 | | |
| Age 70-74 | 1.42 (1.38, 1.46) | <.0001 | | |
| Age 75-79 | 1.99 (1.94, 2.05) | <.0001 | | |
| Age 80-84 | 2.61 (2.55, 2.68) | <.0001 | | |
| Age 85+ | 3.56 (3.47, 3.65) | <.0001 | | |
| Female | 0.77 (0.76, 0.78) | <.0001 | | |
| Black | 0.64 (0.62, 0.66) | <.0001 | | |

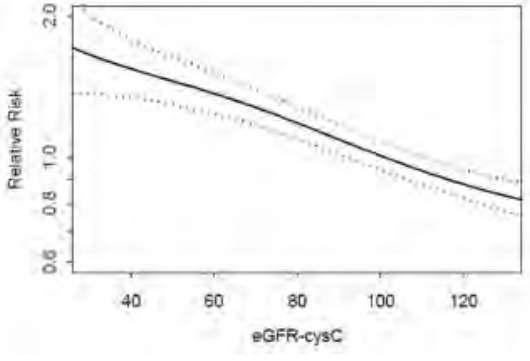
**Infectious Hospitalization among Older Patients with Chronic Kidney Disease** Lorien S. Dalrymple,[1] Ronit Katz,[2] Linda F. Fried,[3,4] Ian H. de Boer,[5] Bryan R. Kestenbaum,[5] Mark J. Sarnak,[6] Michael Shlipak.[7,8] *[1]Medicine, UC Davis, CA; [2]Biostatistics, University of Washington, WA; [3]Medicine and Epidemiology, University of Pittsburgh, PA; [4]VA Pittsburgh Health Care System, PA; [5]Medicine, University of Washington, WA; [6]Medicine, Tufts Medical Center, MA; [7]Medicine, VAMC San Francisco, CA; [8]Medicine, UC San Francisco, CA.*

**Purpose:** Moderate chronic kidney disease (CKD) may independently predispose patients to serious infectious complications. We characterized the association of kidney function with infectious hospitalizations in the Cardiovascular Health Study (CHS).

**Methods:** CHS participants with baseline serum cystatin C measures (n=5,157) were included, and kidney function was estimated by the CKD-EPI cystatin C equation (eGFR-cysC). Outcomes included hospitalizations with infection as the primary cause. We evaluated specific (pulmonary, genitourinary) and all-cause infectious hospitalization. Poisson regression was used to estimate rate ratios, adjusted for age, gender, race, BMI, diabetes, coronary artery disease, stroke, heart failure, cancer, chronic obstructive pulmonary disease, and serum albumin.

**Results:** The age-adjusted rate of infectious hospitalization (per 100 person-years) was 5.6, 4.2, 2.8 and 2.1 for eGFR-cysC < 45, 45-< 60, 60-< 90, and ≥ 90, respectively. Baseline level of kidney function was linearly and inversely associated with overall risk of infection.

Figure 1. Age-Adjusted Risk of Infectious Hospitalization by eGFR-cysC



The strength of association, however, differed by the type of infection: in multivariable models, each 10 ml/min/1.73 m² lower level of eGFR-cysC was associated with a 9% (95% CI: 6-12%) increased risk of hospitalization for all-cause infection, 9% (4–14%) increased risk of pulmonary infection and 16% (6-27%) increased risk of genitourinary infection.

**Conclusion**: Reduced kidney function is independently associated with risk of infectious hospitalization.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2422**

**Proteinuria Is Superior to eGFR as a Predictor of Cardiovascular Death in Patients with CKD Attending a Hypertension Clinic** Shona Methven,[1] Bruce Mackinnon,[2] Billy Sloan,[3] Lilian Murray,[1] Adel A. Alharf,[1] Matthew Walters,[1] Gordon T. Mcinnes,[1] Alan G. Jardine.[1] *[1]Dept of Medicine, Univeristy of Glasgow, United Kingdom; [2]Renal Unit, Glasgow Royal Infirmary, United Kingdom; [3]Dept of Public Health, University of Glasgow, United Kingdom.*

Proteinuria and reduced eGFR independently predict the development of end stage kidney disease. It is unclear which is the superior predictor of death in patients with hypertension and chronic kidney disease (CKD).

We studied 9981 attendees at a hospital hypertension clinic with a baseline measurement of kidney function. Those <18 years (n=39), eGFR <15ml/min/1.73m² (n=45) and not screened for proteinuria (n=1420) were excluded. A Cox Proportional Hazards model was constructed. Outcomes were cardiovascular (CV) and all cause mortality. Model covariates were eGFR (4 variable MDRD formula), dipstick measure of proteinuria, age, sex, blood pressure, vascular disease, smoking and diabetes.

Of 8477 patients, 23% had an eGFR of <60ml/min/1.73m² and 22% had proteinuria. Mean age was 50(±13) years, blood pressure 169/100(±29/15) mmHg, 52% male and 7% diabetic. During follow-up, 49% of those with eGFR<60ml/min/1.73m² died, 76% of whom died of CV disease.

Adjusted hazard ratios (aHR) for CV and all-cause mortality, divided according to CKD stage

| | CKD 1/2 | CKD 3A | | CKD 3B | | CKD 4 | |
|---|---|---|---|---|---|---|---|
| | p+ | p- | p+ | p- | p+ | p- | p+ |
| All-cause mortality | 1.19 (1.05-1.35) | 1.10 (0.99-1.22) | 1.40 (1.15-1.71) | 1.54 (1.31-1.82) | 1.80 (1.45-2.23) | 2.45 (1.69-3.54) | 4.65 (3.49-6.20) |
| CV Mortality | 1.22 (1.05-1.41) | 1.13 (1.00-1.28) | 1.52 (1.22-1.90) | 1.67 (1.39-2.02) | 1.95 (1.53-2.49) | 2.51 (1.64-3.84) | 4.89 (3.55-6.75) |

p+; proteinuria, p-; none, ref group; eGFR>60ml/min/1.73m2, p-

Proteinuria and eGFR entered as dichotomous variables (co-variates as before); proteinuria is a stronger predictor of both CV and all-cause mortality, aHR 1.38(1.24-1.54) vs 1.27(1.16-1.40) and 1.36(1.23-1.49) vs 1.22(1.13-1.33) respectively (though confidence intervals overlap).

In conclusion, proteinuria is a powerful predictor of CV and all cause mortality in patients with hypertension, and is essential in addition to eGFR for risk stratification in this population.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2423**

**Incidence of Symptomatic Stroke and Cancer in Chronic Kidney Disease Patients Treated with Epoetins** Enyu Imai,[1] Ryohei Yamamoto,[2] Hiromichi Suzuki,[3] Tsuyoshi Watanabe.[4] *[1]Nephrology, Nagoya University, Nagoya, Japan; [2]Osaka University; [3]Saitama Medical University; [4]Fukushima Medical University.*

Use of erythropoiesis-stimulating agents (ESA) was reported to increase cardiovascular diseases. TREAT study showed increasing stroke and cancer by use of darbepoetin in diabetic patients. Surveillance of epoetin adverse events of stroke and cancer was urgently conducted by the Japanese Society of Nephrology. The patients aged at least 18 years with CKD stage 4 and 5, eGFR < 30 mL/min/1.73m², who visited the outpatient department of the participating facilities between December 2009 and January 2010 with at least six month of prior medical treatment in the participating facilities, were eligible. Among 7415 patients with CKD stage 4 and 5, 3653 (49.3%), 879 (11.9%), and 2883 (38.9%) patients received no epoetin, Epoetin for less than 6 months, and epoetin for at least 6 months, respectively. In patients with no use of epoetin, use of epoetin for less than 6 months, and use of epoetin for at least 6 months, the numbers of patients with stroke were 38 (1.0%), 8 (0.9%), and 27 (0.9%), respectively, and those with newly diagnosed or exacerbation of malignancy were 88 (2.4%), 30 (3.4%), and 71 (2.5%), respectively, demonstrating insignificant associations between outcomes and duration of treatment with epoetin (P for trend = 0.666 in stroke and 0.836 in malignancy). Regarding stroke, age (per 10 years, odds ratio 1.40 [1.15 - 1.71], P = 0.001), male gender (2.17 [1.26 - 3.72], P = 0.005), and diabetes (2.02 [1.26 - 3.25], P = 0.004), not use of epoetin (0.89 [0.55 - 1.43], P = 0.621), were associated with stroke after adjusting for random effect of the facility. Their associations remained significant even after adjustment for the multiple covariates (age per 10 years, 1.43 [1.15 - 1.77], P = 0.001; male gender 2.00 [1.15 - 3.47], P = 0.014; diabetes 1.85 [1.14 - 3.00], P = 0.013), whereas not use of epoetin (0.74 [0.42 - 1.31], P = 0.301) . In conclusion, no significant increase in risk of symptomatic stroke and cancer development was observed by use of epoetin in a present clinical practice in Japan.

**SA-PO2424**

**Serum Phosphorus, Parathyroid Hormone and Calcium Levels and Risks of Death and Cardiovascular Disease in Chronic Kidney Disease: Systematic Review** Suetonia Palmer,[1] Andrew Hayen,[2] Petra Macaskill,[2] Fabio Pellegrini,[3] Grahame J. Elder,[4] Jonathan C. Craig,[2] Giovanni F. M. Strippoli.[2,3,5] *[1]University of Otago Christchurch; [2]University of Sydney; [3]Consorzio Mario Negri Sud; [4]Garvan Institute of Medical Research, Sydney; [5]Diaverum Medical Scientific Office.*

Clinical practice guidelines for care of individuals with chronic kidney disease recommend low targets for serum phosphorus, parathyroid hormone (PTH), and calcium.

We evaluated the association between serum phosphorus, PTH, and calcium levels and risks of death and cardiovascular disease in cohort studies of people with chronic kidney disease. 23 studies (218791 patients) contributed to meta-analyses. 19 (213238 patients) were conducted in dialysis, 3 (4845 patients) in chronic kidney disease not requiring dialysis, and one (708 patients) in transplant. 3 (3643 patients) evaluated incident patients commencing dialysis and 8 (204655 patients) were from registry data.

Six adequately adjusted studies reported risks of mortality by variable levels of serum phosphorus. We could not fit a summary model to describe the relationship between serum phosphorus and mortality as there was strong non-linearity in a single study. Visual inspection of studies with adequate adjustment for confounding suggested a J-shaped association between serum phosphorus and mortality. The risk of cardiovascular death associated with serum phosphorus (risk per 1 mg/dl increase, relative to 3.5 mg/dl, 1.13; 95% CI, 1.12-1.14) relied on a single adequately adjusted study. No relationships between all-cause or cardiovascular mortality and serum PTH or all-cause mortality and calcium were evident. The risk between serum calcium and cardiovascular mortality was reported in one adequately adjusted study (risk per 1 mg/dl increase, relative to 5 mg/dl, 1.02; 95% CI, 1.01-1.03).

Serum PTH levels are not associated with increased risks of cardiovascular and all-cause mortality in chronic kidney disease in adequately adjusted cohort studies. Associations between higher serum phosphorus and risks of all-cause mortality and both serum phosphorus and calcium with cardiovascular mortality require evaluation in randomized trials.

**Proteinuria and Kidney Function Independently Predict Cardiovascular Outcomes: Pooled Analysis of 7 Cohort Studies (EPOCH-JAPAN)** Masaharu Nagata,[1] Toshiharu Ninomiya,[1] Yutaka Kiyohara,[1] Yoshitaka Murakami,[2] Fujiko Irie,[3] Toshimi Sairenchi,[4] Tomonori Okamura,[5] Katsuyuki Miura,[6] Hirotsugu Ueshima,[6] EPOCH-JAPAN Group. *[1]Department of Environmental Medicine, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [2]Department of Medical Statistics, Shiga University of Medical Science, Otsu, Japan; [3]Department of Health and Welfare, Ibaraki Prefectural Office, Mito, Japan; [4]Department of Public Health, Dokkyo Medical University School of Medicine, Mibu, Japan; [5]Department of Preventive Cardiology, National Cardiovascular Center, Suita, Japan; [6]Department of Health Science, Shiga University of Medical Science, Otsu, Japan.*

**Background:** Proteinuria and reduced kidney function are risk factors for cardiovascular (CV) disease. It is unclear whether these risk factors are mutually independent or synergistic.

**Methods:** Using individual pooled data of 7 prospective cohort studies in Japan, we assessed the effect of proteinuria (defined as dipstick 1+ or over) and estimated glomerular filtration rate (eGFR) on the risk of CV death in 39,406 participants aged 40 to 89 years without kidney failure at baseline. The hazard ratios were estimated by Cox proportional hazards model.

**Results:** During an average of 10-year follow-up, 1,928 subjects died from CV disease. Participants with proteinuria had a significantly higher age- and sex-adjusted CV mortality rate than those without it (10.8 vs. 4.4 per 1000 person-years). The age- and sex-adjusted CV mortality rate increased linearly for eGFR of ≥90, 60-89, 45-59 and <45 mL/min/1.73m$^2$, being 2.4, 5.4, 7.9 and 14.7 per 1000 person-years, respectively. After adjusting for the potential confounding factors, proteinuria and eGFR<45 mL/min/1.73 m$^2$ were associated with significant 1.7 and 2.3-fold higher risk of CV death, respectively, and the combination with a 4.0-fold higher risk of CV death, as compared to participants without these factors. There was no evidence of interaction between proteinuria and reduced eGFR (p for interaction=0.40).

**Conclusions:** Proteinuria and reduced eGFR are significant and independent risk factors for CV death in the Japanese population.

**SA-PO2426**

**Erythropoietin Resistance Predicts Mortality in Hemodialysis Patients from the Japan Dialysis Outcomes and Practice Patterns Study** Tetsuya Fujikawa,[1] Yumiko Ikeda,[2] Shunichi Fukuhara,[3] Takashi Akiba,[4] Tadao Akizawa,[5] Akira Saito.[6] *[1]Department of Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan; [2]Yokohama Minami Kyousai Hospital, Yokohama, Kanagawa, Japan; [3]Department of Epidemiology and Healthcare Research, Kyoto University Graduate School of Medicine, Kyoto, Japan; [4]Department of Blood Purification and Internal Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan; [5]Division of Nephrology, Showa University School of Medicine, Tokyo, Japan; [6]Department of Internal Medicine and Institute of Medical Science, Tokai University School of Medicine, Kanagawa, Japan.*

Our aim in this study is to investigate the availability of EPO resistance as an independent lethal predictor in hemodialysis patients. This study investigated 2105 Japanese hemodialysis patients participating in the Dialysis Outcomes and Practice Patterns Study III . Erythropoietin resistance index (ERI) was defined as the weekly weight-adjusted dose of EPO divided by the hemoglobin concentration. ERI in females was significantly higher than in males (9.73 ± 5.89 vs. 6.98 ± 5.31 IU/week/g per 100 ml, p<0.001). Of all patients, the number of all lethal events were 227 (10.8%), which included 113 events (5.4%) of cardiovascular disease (CVD), 48 (2.3%) of infection, 23 (1.1%) of cancer, and 5 (0.2%) of gastrointestinal bleeding. In multivariate analysis, ERI was independently significantly related to the all-cause mortality after adjusting the related factors (HR 1.04, 95% CI(1.02-1.07), p<0.001). In addition to ERI, this analysis identified age, sex, cause of chronic kidney disease, serum albumin, and congestive heart failure as independent significant factors related to all-cause mortality. In analysis for CVD mortality, ERI was an independent factor related to CVD related mortality (HR 1.05, 95% CI (1.02-1.08), p=0.002). This investigation concluded that ERI is an independent risk factor for all cause and CVD mortality in hemodialysis patients. Further study is needed to investigate the underlying mechanism of the relation between ERI and mortality.

Disclosure of Financial Relationships: nothing to disclose

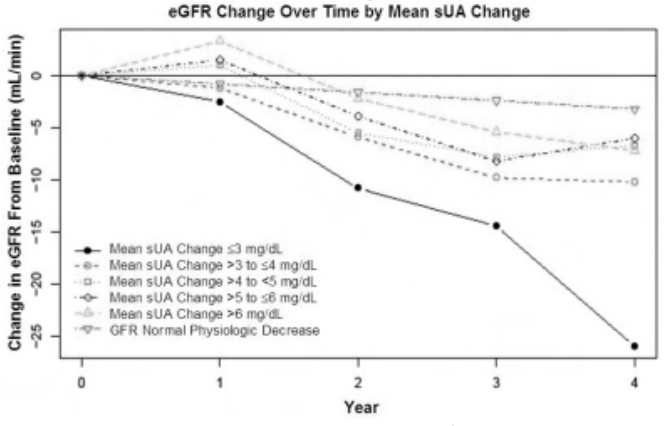
**Long-Term Impact of Urate-Lowering Therapy on Renal Function in Hyperuricemic Gout Subjects** Andrew Whelton,[1] Patricia MacDonald,[2] Lhanoo Gunawardhana,[2] Barbara J. Hunt.[2] *[1]UCRC, Inc., and The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Takeda Global Research & Development Center, Inc., Deerfield, IL.*

**Objective:** To evaluate the effect of urate-lowering therapy (ULT) on renal function (estimated glomerular filtration rate [eGFR]) in hyperuricemic gout subjects treated daily with febuxostat (80 or 120 mg) or allopurinol (300 mg).

**Methods:** Subjects (1086) completing 2 phase 3 trials (FACT and APEX) were enrolled in the long-term EXCEL study and received ULT for ≤4 years. eGFR was calculated using the Modification of Diet in Renal Disease (MDRD) equation. A repeated-measures linear model was used to assess the relationship between eGFR change and sUA change, with factors for year of treatment and baseline (BL) renal function (eGFR <60 vs ≥60 mL/min).

**Results:** Most subjects were male (96%) and Caucasian (79%); BMI was ≥30 kg/m$^2$ (63%) and mean age 51 yrs; 7% had BL eGFR <60. Greater sustained sUA decreases were associated with less renal function deterioration (p<0.001; Figure).



The model projects that every 1 mg/dL sUA reduction from BL will yield 1.25 mL/min less of a decrease in eGFR compared with no sUA reduction. Based on available data, the model is relevant for treatment duration up to 4 years and sUA change up to 10 mg/dL. BL renal impairment was also significant (p<0.05): given the same treatment duration and sUA change, subjects with renal impairment (BL eGFR <60 mL/min) had 4.7 mL/min less of an eGFR decrease compared to those with BL eGFR >60 mL/min.

**Conclusion:** In treated gout subjects, the magnitude of persistent sUA decrease significantly influences, in an inverse fashion, progression of renal impairment. These findings are consistent with our previously reported results from a 5-year (n=116) trial wherein greater sustained sUA decreases from BL were associated with less renal function deterioration.

**SA-PO2428**

**Ischemia Reperfusion Injury as a Risk Factor for Native Kidney Dysfunction after Liver Transplantation** Bernd Krüger,[1,2] Anja Richter,[1] Vinay Nair,[3] Sridhar Reddy Allam,[1] Bernhard K. Krämer,[2] Barbara T. Murphy,[1,3] Bernd Schroppel.[1,3] *[1]Mount Sinai School of Medicine, Division of Nephrology, New York; [2]V. Medizinische Klinik, Universitätsklinikum Mannheim, Mannheim, Germany; [3]Mount Sinai School of Medicine, The Transplantation Institute, New York.*

Kidney dysfunction after liver transplantation (LT) is common and has detrimental impact on mortality and morbidity. The pathophysiology of acute and chronic kidney injury associated with LT is poorly understood. Here, we tested the hypothesis that recipients or livers with severe IR injury are at higher risk to develop long-term kidney dysfunction.

577 adult patients underwent LT between January 2000 and December 2004. After exclusion of retransplants and living donor transplants we included 316 decreased donor LT with available kidney function data. We established 3 groups of IR injury based on liver enzymes ((AST+ALT)/2) on day 2: immediate LT function: <25th percentile (<285 U/l), average LT function: 25th-75th percentile (285-986 U/l), and delayed LT function: >75th percentile (>986 U/l). Immunosuppressive maintenance therapy consisted of tacrolimus and/or mycophenolate.

At baseline chronic renal failure, i.e. eGFR ≤30 ml/min as suggested by Ojo et al., was not different between the 3 groups (p=0.06). Compared to pre-transplant kidney function, Δ eGFR post-transplant was gradually increased post LT in groups 1 to 3. This effect was maintained throughout 12 months follow-up, and remained significant after adjusting for HCV-status, donor and recipient age and race (p=0.01).

| | Δ eGFR from pretransplant [ml/min] | | | |
|---|---|---|---|---|
| | immediate LT function | average LT function | delayed LT function | p-value |
| 1 month | 3.6 ± 43.1 | -13.8 ± 39.8 | -20.7 ± 39.9 | 0.001 |
| 3 months | -8.7 ± 38.9 | -17.0 ± 37.0 | -26.8 ± 37.7 | 0.013 |
| 6 months | -12.2 ±35.8 | -18.8 ± 38.0 | -29.4 ± 38.8 | 0.023 |
| 12 months | -12.9 ± 38.3 | -18.4 ± 35.7 | -29.9 ± 36.9 | 0.026 |

Our results show that recipients of liver transplants that are subjected to severe IR injury develop kidney dysfunction post LT. Strategies to prevent acute liver injury at the time of transplantation can preserve native kidney function after LT.

Disclosure of Financial Relationships: nothing to disclose

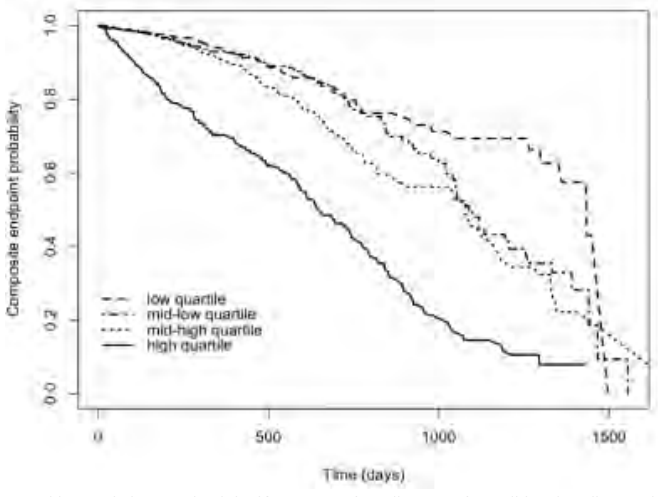
**SA-PO2429**

**Chronic Kidney Disease Progression and Mortality in Mild to Moderate Kidney Dysfunction According to Serum Phosphorous Levels** Antonio Bellasi, Marcora Mandreoli, Antonio Santoro. *On Behalf of the PIRP Study Group, Nephrology Unit-Policlinico S.Orsola-Malpighi, Bologna, Italy.*

The impact of serum phosphate abnormalities on Chronic Kidney Disease (CKD) progression and mortality among patients with mild to moderate kidney failure is still far from being established.

We determined the association of baseline phosphatemia with the composite endpoint of dialysis inception or all-cause mortality. We utilized the patient's records from the "Prevenzione Insufficienza Renale Progressiva" (PIRP) database, a large project sponsored by the Emilia-Romagna Institute of Health aimed at optimizing CKD patients care.

We identified all patients who underwent a glomerular filtration rate (GFR) and serum phosphorous assessment between 2004 and 2007. The patients were followed up to 4 years. Survival analyses estimated the relationship between serum phosphorous at baseline and outcomes. A total of 1716 female and male subjects with CKD stage 3-5 were identified. Elevated serum phosphorous was significantly associated with diabetes mellitus, but inversely associated with GFR, age and male sex (all p-trend<0.001). A graded increase in the risk of starting dialysis or dying was noted across quartiles of serum phosphorous (log-rank test p<0.001).



This association remained significant even after adjustment for traditional cardiovascular risk factors and CKD stage.Indeed, patients in the highest serum phosphorous quartile (>4.3 mg/dl) experienced a 117% increase in the risk of the occurrence of the composite endpoint when compared to patients with serum levels of phosphorous of 3.3-3.8 mg/dl (HR 2.17; 95%; CI 1.62-2.93; p<0.001).

These analyses lend support to the hypothesis that serum phosphorous levels at baseline might accelerate residual renal function deterioration and increase the risk of death in patients with mild to moderate renal function impairment.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2430**

**CanPREDDICT: Canadian Study for Predicting Dialysis, Death and Cardiovascular (CVD) Risk in CKD** Adeera Levin,[1] Francois Madore,[2] Claudio Rigatto,[3] Brendan J. Barrett,[4] Norman Muirhead,[5] Daniel T. Holmes,[1] Ognjenka Djurdjev.[1] *[1]UBC; [2]CHUM; [3]UM, Canada; [4]MU; [5]LHSC.*

CanPREDDICT is a prospective observational cohort study of 2500 pts known to nephrologists at 25 Canadian centers. Primary objectives are to describe the levels and temporal evolution of 5 known biomarkers (BM) for inflammation (CRP, IL-6), cardiac injury (Troponin I), heart failure ( ProBNP), and vascular health (ADMA); and establish whether these BM , can accurately discriminate pts at high or low risk of renal or CVD outcomes.

2542 CKD pts ( eGFR 15-45 ml/min) were enrolled: mean age is 68yrs, median eGFR is 28ml/min, 62% are male, 90% are Caucasian; 48% have DM; 34% have IHD and 27% have CHF. Table 1 presents BM associated with comorbidities at baseline:

Biomarkers associated with comorbidities at baseline

| Variables | Diabetes OR (95% C.I.) | Ischemic HD OR (95% C.I.) | Congestive HF OR (95% C.I.) |
|---|---|---|---|
| Age (5 yrs) | 1.02 (0.97-1.06) | 1.22 (1.17-1.29)* | 1.19 (1.11-1.28)* |
| Sex (Male vs. Female) | 1.25 (1.01-1.57)* | 1.69 (1.36-2.09)* | 0.86 (0.63-1.18) |
| Race (Other vs. Caucasian) | 1.26 (0.90-1.76) | 0.90 (0.63-1.27) | 0.71 (0.44-1.14) |
| DM | n/a | 1.94 (1.58-2.38)* | 1.18 (0.88-1.60) |
| eGFR (5mL/min) | 1.10 (1.01-1.17)* | 1.04 (0.98-1.11) | 1.17 (1.07-1.28)* |
| Po4 (0.1 mmol/L) | 1.11 (1.06-1.16)* | ns | ns |
| iPTH (log pmol/L) | ns | ns | 1.22 (1.01-1.47)* |
| Alb (g/L) | 0.96 (0.94-0.99)* | ns | ns |
| Hb (5g/L) | 0.94 (0.90-0.97)* | ns | ns |
| IL6 (>LLD - 6pg/mL vs. <LLD) | 1.56 (1.20-2.03)* | 1.35 (1.04-1.75)* | ns |
| IL6 (>6.0 pg/mL vs. <LLD) | 2.17 (1.66-2.83)* | 1.42 (1.09-1.84)* | ns |
| Troponin (>LLD vs. <LLD) | 1.61 (1.28-2.02)* | 1.79 (1.44-2.23)* | 2.36 (1.70-3.28)* |
| ProBNP (1000 pg/mL) | ns | 1.08 (1.04-1.12)* | 1.18 (1.10-1.26)* |

The addition of BM to multivariate models with traditional variables increased the AUC for DM (63% to 67%), IHD (69% to 73%) and CHF (67% to 75%) models.

The ability to identify pts who will progress wrt CVD or CKD is important in planning interventional trials. Use of BM to discriminate and identify high risk pts appears to be possible.

Disclosure of Financial Relationships: nothing to disclose

**Coronary Artery Calcification and Kidney Function: *Association or Causation*** Sejoong Kim, Jae Hyun Chang, Jiyoon Sung, Sun Young Na, Ji Yong Jung, Hyun Hee Lee, Wookyung Chung. *Internal Medicine, Gachon University of Medicine and Science.*

*Introduction:* Cardiovascular disease (CVD) is the most common cause of morbidity and mortality in patients with chronic kidney disease (CKD). Coronary artery calcification (CAC) is a phenomenon described in individuals with CKD, and its presence is associated with an increased risk of cardiovascular death. The aims of this study were to evaluate the association of renal function with CAC and whether CAC may predict the rate of change in renal function over time.

*Methods:* We retrospectively enrolled 918 Korean outpatients who had undergone multislice computed tomographic coronary angiography in Gachon University Gil Hospital from January 2008 to December 2009. Of these, 237 patients underwent followe-up more than 3 months. Decrease of renal function was defined as > 8% decrease per year in estimated glomerular filtration rate (eGFR)

*Results:* The mean age was 57±12 years, and the mean eGFR 82.5 ± 15.4 mL/min/1.73 $m^2$. Compared with CAC score (CACS) >100 group (n=136), CACS <100 group (n=782) were more likely to have younger age, and higher levels of eGFR, albumin, hemoglobin, and HDL-cholesterol. Hypertension and DM were less frequent among CACS<100 group compared with CACS >100 group. After the adjustment for age, gender, smoking, hypertension, diabetes, albumin, hemoglobin, calcium-phosphorus product, total cholesterol, and body mass index, eGFR was negatively associated with CACS >100 (odds ratio[OR], 0.983; 95% confidence interval[CI], 0.968-0.999; *P*=0.031). The mean follow-up duration of 237 followed-up patients was 9.6±4.9 months, and 62 (26.2%) patients had decrease of renal function. After the adjustment for the same confounding variables, CACS >100 was independently associated with decrease of renal function (OR, 2.351; 95% CI, 1.133-4.88; *P*=0.022).

*Conclusion:* This study suggests that CACS may be inversely related to baseline renal function and can also predict the aggravation of renal function.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2432**

**Physical Functioning in Chronic Kidney Disease: Contribution of Uremia** Eva Segura-Ortí,[2] Patricia L. Gordon,[1] Julie W. Doyle,[1] Kirsten L. Johansen.[1] *[1]UCSF; [2]Universidad CEU Cardenal Herrera, Valencia, Spain.*

The aim of the study was to determine the extent to which poor physical functioning and muscle atrophy among patients on dialysis is evident in the pre-dialysis phase of chronic kidney disease (CKD) and to explore the contributions of uremia to functioning in this cohort.

57 subjects completed the study (19 control, 53.2 ± 8.0 years; 22 CKD, 62.5 ± 10.1 years; 16 dialysis patients, 54.7 ± 7.2 years). Measures included: Cross-sectional area (CSA) of the quadriceps muscle contractile tissue by MRI; maximum voluntary contraction (MVC) and isokinetic peak torque during knee extension by dynamometer; physical activity (PA) using three-dimensional accelerometers; 6-min walk test; and SF-36. Characteristics were compared across groups using ANOVA. Univariate and multivariate linear regression was performed.

By ANOVA, muscle area was smaller and MVC was lower in dialysis patients than controls, but CKD patients were not different from controls. On the other hand, daily PA and 6-min walk were significantly lower than controls in both CKD and dialysis subjects. In univariate regression, eGFR was positively correlated with daily PA (r=0.54), muscle CSA (r=0.54), isometric MVC (r=0.47), and 6-min walk distance (r=0.32). Multivariable models showed association of eGFR, PA and subjects' age and BMI with muscle area (r2 = 0.63).

Multivariable correlates of physical function

| Dependent variable | eGFR | Age | BMI | PA |
|---|---|---|---|---|
| Muscle area | 0.26 | -0.34 | 0.46 | 0.38 |
| Isometric MVC | 0.34 | -0.34 | 0.34 | - |
| Isokinetic peak torque, 90° | 0.29 | -0.33 | - | - |
| 6-min walk | 0.37 | - | - | - |
| SF-36 PF | 0.32 | - | - | - |

All coefficients and models statistically significant.

For most variables related to functioning, eGFR was either more strongly associated than PA (e.g., MVC, 6-min walk, SF-36 PF) or independently associated after considering PA (e.g., muscle area). This study demonstrated that CKD patients' were less active than sedentary controls, with PA levels similar to those of dialysis patients. Decreased kidney function was associated with muscular atrophy and functional impairments in CKD patients even after controlling for low PA.

Disclosure of Financial Relationships: nothing to disclose

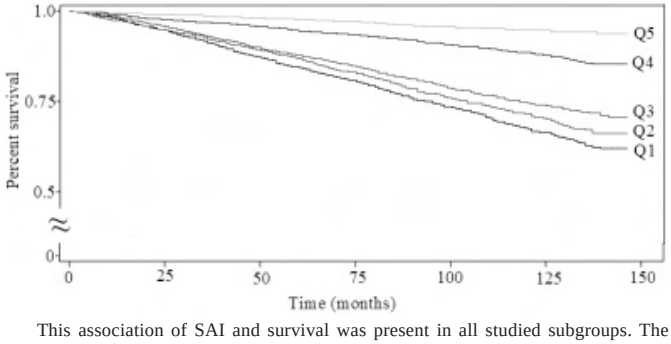
## SA-PO2433

**Social Adaptability Index Predicts Survival of Patients with Chronic Kidney Disease** Alexander S. Goldfarb-Rumyantzev,[1] Gurprataap Singh Sandhu,[1] Hongying Tang,[2] Preeti Rout,[1] Mark E. Williams,[1] Anna Barenbaum.[3] *[1]Division of Nephrology, Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA; [2]Transplant Institute, Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA; [3]Tel Aviv University, Tel Aviv, Israel.*

Background. While individual socioeconomic factors have been associated with clinical outcome, a composite index has not been developed. In this project we tested the hypothesis that Social Adaptability Index (SAI) based on employment, education, income, marital status and substance abuse is associated with survival in chronic kidney disease (CKD) patients.

Methods. This is a retrospective cohort study of patients (18 years or older) from NHANES -3 with CKD stage 2 or greater. Our primary variable of interest is SAI. Each component of SAI (employment status, education, marital status, income, and substance abuse) has been graded on the scale of 0 to 3. Age, sex, race, diabetes, co morbidity index, BMI, geographic location, hemoglobin, serum creatinine, serum albumin, serum cholesterol, and Hba1c were used as covariates. The outcome of the study is patient's mortality (time between the first interview by NHANES and death).

Results. We analyzed 13,400 subjects with mean age of 50.6 ± 20; 53.6% males; 44.4 % white; 29.7 % African American. Lower SAI is associated with greater stage of CKD. Higher SAI was associated with decreased mortality (HR 0.88, p <0.001, 95% CI 0.86-0.89). There was "dose dependent" association between SAI quintiles and survival.



This association of SAI and survival was present in all studied subgroups. The limitations of the study include retrospective design, potential misreporting and misclassification, reverse causality.

Conclusions. We demonstrated that Social Adaptability Index has a strong and clinically significant association with mortality in CKD patients.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2434

**Family Socioeconomic Status (SES) and Disease Severity in Children with CKD: Results from the Chronic Kidney Disease in Children (CKiD) Cohort Study** Guillermo Hidalgo,[1] Susan L. Furth,[2] Derek Ng,[3] Colin T. White.[4] *[1]Pediatrics, University of Illinois, Chicago, IL; [2]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA; [3]Bloomberg School of Public Health, John Hopkins, Baltimore, MD; [4]Pediatrics, BC Children's Hospital, Vancouver, BC, Canada.*

**Introduction:** The role of SES on disease severity in children with CKD is not well established. To examine this relationship, we described and compared subjects by SES strata at time of enrollment in the CKiD cohort using co-morbid conditions as a proxy for disease severity. Our hypothesis was that household (HH) income and level of maternal education are associated with uncontrolled hypertension, hyperphosphatemia, elevated Ca X P, increased iPTH and growth failure.**Methods:** Cross-sectional analysis used descriptive statistics to examine trends and Poisson regression to calculate prevalence ratios (PrR) for univariate and adjusted analyses. Adjusted models included age, race, type of CKD and GFR.

**Results:** There were 586 subjects at enrollment of which 572 had complete data for HH income and maternal education. The cohort consisted of 62% males and 23% AA. Their mean age was 11 y. ± 5 SD and mean iohexol GFR of 47.1 ± 19.0 mL/min/1.73m². Glomerular CKD diagnosis was found in 22% of subjects. In univariate analyses, higher income groups had a lower prevalence of all specified co-morbidities, when compared to lower income groups.

Table 1

| Co-morbid Condition | Income < $ 30K n=240 (42%) | Income $30 to $75K n=174 (30%) | Income >$75K n=158 (28%) | Test for trend p-value |
|---|---|---|---|---|
| SBP or DBP> 95th %tile | 24% | 23% | 17% | 0.43 |
| Hyperphosphatemia | 17% | 18% | 11% | 0.21 |
| Elevated Ca X P | 12% | 6% | 7% | 0.01 |
| Growth failure | 18% | 13% | 12% | 0.04 |
| > 3 co-morbidities | 11% | 6% | 5% | 0.01 |

These trends persisted in the adjusted analysis. Similar results were observed among strata of maternal education (<HS, HS to college, >college). **Conclusion:** The results show a relationship between lower SES and higher disease severity, as measured by prevalent comorbidities among the CKiD population. This high risk group warrants clinical attention when treating pediatric CKD.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2435

**Effect of Zinc Supplementation and Dietary Counseling on Nutritional and Antioxidant Status as Well as Quality of Life of the Patients with CKD** Nancy Sahni,[1] Rajindra Prasad,[2] Satya V. Rana,[3] A. K. Bhalla,[4] Vinay Sakhuja,[5] Krishan L. Gupta.[5] *[1]Deptts of Dietetics,; [2]Biochemistry; [3]Gastro-enterology; [4]Pediactrics; [5]Nephrology, PGIMER, Chandigarh, India.*

This study **aimed** at assessing the influence of Zinc (Z) supplementation/dietary counseling on the antioxidant and nutritional status and quality of life of patients with Chronic kidney disease (CKD). **Methods:** A total of 95 patients with CKD (mean age = 42.88±11.48yrs) and 40 apparently healthy adults as controls (mean age=42.42±2.23 yrs) were included. The patients were divided into moderate (s creat<5 mg/dl) and severe (s creat>5 mg/dl) CRF groups. In group I (n=45) dietary counseling alone was given to 25 moderate and 20 severe CRF patients whereas in group II (n=50) dietary counseling along with zinc supplementation was given to 30 moderate and 20 severe CRF patients. Statistical significance was calculated using student's t-test and paired t-test between two groups as well as before and after interventions respectively. All the patients were followed weekly for compliance for a period of one month. **Results:** All CKD patients showed ↓mean nutritional intake($p \leq 0.001$) [in terms of macronutrients such as energy, carbohydrates, fats and proteins as well as micronutrients such as vitamin A , vitamin C & zinc and essential amino acids such as cystiene and methionine], as compared to the control group. After one month of individualized diet counseling, both group-1 and group-2 patients showed significant ↑ in nutritional status evaluated anthropometrically (weight and BMI). Antioxidant enzymes viz. SOD and catalase as well as Serum GSH were significantly higher in group-2 patients ($p \leq 0.001$) as compared to group-1 patients ($p \leq 0.05$). Serum zinc levels did not change significantly after diet counseling alone (group-1), while there was a significant ↑ ($p \leq 0.001$) in group-2 patients on Zn supplementation. Quality of life of all CRF patients showed significant improvement. **Conclusion:** The role of diet counseling in removing the myths, taboos and food misconceptions along with zinc supplementation resulted in improving the nutritional and antioxidant status and quality of life of CRF patients.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2436

**Clinical Features and Prognosis of Extrapulmonary Tuberculosis in Patients with Chronic Kidney Disease** Jung Sub Kim, Ihm Soo Kwak, Soo Bong Lee, Sang Heon Song, Eun Young Seong, Jungmin Son, Il Young Kim, Harin Rhee. *Department of Internal Medicine, Pusan National University School of Medicine, Busan, Korea.*

There is an increased risk of tuberculosis (TB) owing to impaired cellular immunity in patients with chronic kidney disease. Extrapulmonary TB is more common in patients with chronic kidney disease with percentages varying from 38% up to more than 80%. We explored the clinical features of the extrapulmonary TB according to the renal function.

This study was performed retrospectively through the review of medical records of the patients at Pusan national university hospital. From January 2003 to December 2007, 342 patients aged ≥18 years were diagnosed with extrapulmonary TB. We classifed patients into two groups according to estimated glomerular filtration rate (eGFR) by MDRD formula as follows; eGFR< 60 ml/min/1.73m² (group I) vs.eGFR ≥ 60 ml/min/1.73m² (group II). Their clinical features, treatment outcomes, and mortality related to extrapulmonary TB about them were evaluated.

eGFR of Group I (N=30) and Group II (N=312) was 34±19ml/min/1.73m² and 102±26ml/min/1.73m². The pleura was the most frequent site in both groups (Group I, 30.0% vs. Group II, 28.2%, p=0.379). There was no treatment failure and recurrence in both groups. The mortality in Group I is higher than that of Group II (22.2% vs. 2.8%, p<0.01). In multivariate analysis, the eGFR<60 ml/min/1.73m² was an independent risk factor for mortality (HR=11.51 CI 2.512-52.741, p=0.002).

The mortality related with extrapulmonary TB is higher in patients with impaired renal function and the kidney function is an independent predictor. However, there is no difference in treatment failure and recurrence according to renal function. Therefore, if early diagnosis and prompt initiation of treatment is done, the mortality rate related to tuberculosis will decrease.

Disclosure of Financial Relationships: nothing to disclose

**Predictors of Outcome in the Elderly Patients with Chronic Kidney Disease (CKD)** Maria Marin,[1] Rafi T. Ishaq,[3] Anacleto Baizas Diaz,[2] Joel Topf.[1] *[1]Department of Nephrology, St John Hospital and Medical Center, Detroit, MI; [2]Department of Internal Medicine, St John Hospital and Medical Center, Detroit, MI; [3]Department of Internal Medicine, Providence Hospital, Southfield, MI.*

CKD occurs in 49% of the elderly and increases the risk of cardiovascular disease, end-stage renal disease (ESRD) and death. Elderly patients represent the fastest growing group initiating dialysis. The aim of our study is to examine the determinants of outcome in an elderly population followed in a CKD clinic.

We retrospectively examined the charts of patients older than 65, with eGFR 15-45 mL/min at inclusion. CKD was defined as a persistent decrease in eGFR to < 60 mL/min over 3 months.

A total of 198 patients were included: 117 females and 81 males, average age 75.6 (range 65-96). There were 149 Caucasian and 48 African American subjects. The average GFR was 30 mL/min.

At a mean follow-up of 39.9 (± 24) months, 18 patients died and 19 progressed to ESRD. The GFR at baseline was lower in patients who progressed to ESRD (22.1 mL/min) than in those who died (28.2 mL/min) or those without an endpoint (31.2 mL/min) ($p<0.0001$). Men were more likely to die than women (14.8% vs 5.1%, $p=0.05$) and females were more likely to progress to ESRD (11.1% vs 7.4%, $p=0.05$). Patients who progressed to ESRD had a lower calcium and higher phosphorus, PTH and urinary protein levels at baseline. Patients with CKD due to diabetes mellitus had a faster loss of GFR and were more likely to progress to ESRD ($p=0.003$) than patients with other causes of CKD. In multivariable logistic regression, female patients ($p=0.006$) and those treated with erythropoietin ($p=0.01$) were more likely to progress to ESRD and patients with a history of peripheral vascular disease ($p=0.002$) or treated with erythropoietin ($p=0.052$) were more likely to die.

This study shows a higher rate of dialysis than previously reported. We show equal rates of death versus dialysis. Female gender and lower GFR at baseline were predictive of dialysis while male gender and history of peripheral vascular disease were predictors of death. This information will be helpful for practitioners to guide CKD care.

**Complement Factor H Related 5 (CFHR5) Nephropathy: An Endemic Cause of Renal Disease in Cyprus** Daniel P. Gale,[1] Elena Goicoechea de Jorge,[2] H. Terence Cook,[3] Rubén Martínez-Barricarte,[4] Andreas Hadjisavvas,[5] Adam Mclean,[1] Charles D. Pusey,[1] Alkis Mikis Pierides,[6] Konstantinos Voskarides,[7] Constantinos Deltas,[7] Andrew B. D. Palmer,[1] Santiago Rodriguez de Cordoba,[4] Matthew C. Pickering,[2] Patrick Maxwell.[8] *[1]Imperial College Kidney and Transplant Institute, Imperial College, London, United Kingdom; [2]Rheumatology Section, Imeprial College, London, United Kingdom; [3]Histopathology Department, Imperial College, London, United Kingdom; [4]Centro de Investigaciones Biológicas, Instituto Reina Sofía de Investigaciones Nefrológicas, Madrid, Spain; [5]Department of Electron Microscopy and Pathology, Institute of Neurology and Genetics, Nicosia, Cyprus; [6]Nephrology Department, Hippocrateon Hopsital, Nicosia, Cyprus; [7]Department of Biological Science, University of Cyprus, Nicosia, Cyprus; [8]Division of Medicine, University College, London, United Kingdom.*

We report an autosomal dominant disease in which microscopic and synpharyngitic macroscopic hematuria cosegregates with C3 glomerulonephritis (C3GN: membranoproliferative GN with C3 but not immunoglobulins deposited in the glomerulus).

There was genome-wide linkage in two unrelated families from Cyprus to the Complement Factor H/Complement Factor H Related (CFHR) 1-5 gene cluster, LOD 3.4. A duplication of exons 2 and 3 of *CFHR5* cosegregated with the disease and was present in one out of 1015 Cypriot controls. It was subsequently identified in over 100 Cypriot individuals with familial hematuria, C3GN or renal failure of unknown cause. Haplotype analysis confirmed a common ancestor in all 19 of the families studied, most likely c90 generations (2500 years) ago.

The mutant CFHR5 protein was detectable in the circulation and demonstrated reduced affinity for heparin and complement-lysed erythrocytes. Recombinant mutant CFHR5 exhibited reduced affinity for heparin and glomerular C3 when compared with the recombinant wild type protein.

This disease, designated 'CFHR5 Nephropathy,' accounts for a significant proportion of renal disease in Cyprus and implicates CFHR5 as an important regulator of complement within the kidney, suggesting that it may have therapeutic potential in diseases associated with complement deposition.

**Mutation Analysis of 18 Nephronophthisis-Related Ciliopathy Genes Using a DNA Pooling and Massively Parallel Resequencing Strategy** Gokul Ramaswami,[1] Edgar Otto,[1] Sabine Janssen,[1] Moumita Chaki,[1] Susan J. Allen,[1] Weibin Zhou,[1] Rannar Airik,[1] Toby W. Hurd,[1] Amiya K. Ghosh,[1] Corinne Antignac,[2, 3] Sophie Saunier,[3] Colin A. Johnson,[4] Friedhelm Hildebrandt.[1, 5] *[1]Departments of Pediatrics and of Human Genetics, University of Michigan, Ann Arbor, MI; [2]Department of Genetics, Hôpital Necker-Enfants Malades, Assistance Publique–Hopitaux de Paris, Paris, France; [3]INSERM U-983, Hôpital Necker-Enfants Malades, Université Paris Descartes, Paris, France; [4]Division of Molecular & Translational Medicine, Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom; [5]Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI.*

Nephronophthisis-related ciliopathies (NPHP-RC) comprise a group of autosomal recessive cystic kidney diseases that includes nephronophthisis (NPHP), Senior-Loken syndrome (SLSN), Joubert syndrome (JBTS), and Meckel-Gruber syndrome (MKS). To date, mutations in 18 different genes have been described to cause NPHP-RC, rendering mutation analysis tedious and expensive. To perform mutation screening in NPHP-RC we devised a strategy of DNA pooling with consecutive massively parallel resequencing (MPR) in order to overcome the genetic locus heterogeneity. Genomic DNA of 120 patients with a severe NPHP-RC phenotype was divided into 5 pools (24 patients each) and used as templates to amplify all 376 exons of 18 NPHP-RC genes by PCR. PCR products were then subjected to MPR on an Illumina Genome Analyzer II platform. Identified mutations were subsequently assigned to their respective mutation carrier via CEL I endonuclease based heteroduplex screening and confirmed by Sanger sequencing. Using this technique led to the molecular diagnosis in 30/120 individuals (25%). A total of 43 different mutations were identified in the genes *NPHP4* (4), *IQCB1* (1), *CEP290* (11), *RPGRIP1L* (2), *TMEM67* (13), *AHI1* (1), *CC2D2A* (6), and *TTC21B* (5), 28 of which were novel findings. The combined approach of DNA pooling followed by MPR strongly facilitates mutation analysis in heterogeneous single-gene disorders. The lack of identified mutations in 75% of patients in our cohort indicates further genetic heterogeneity in NPHP-RC.

***INF2* Is a Major Gene of Autosomal Dominant Focal and Segmental Glomerulosclerosis** Olivia Boyer,[1] Genevieve Benoit,[1] Olivier Gribouval,[1] M. J. Tete,[1] Jacques Dantal,[2] Brigitte Gilbert-Dussardier,[3] Guy Touchard,[4] Alexandre Karras,[5] Claire Presne,[6] Christophe M. Legendre,[7] Jean-Pierre Grunfeld,[7] Dominique Joly,[7] Nabil Mohsin,[8] Thierry P. Hannedouche,[9] Philippe Rieu,[10] Marie-Claire Gubler,[1] Isabelle Broutin,[11] Geraldine Mollet,[1] Corinne Antignac.[1] *[1]Inserm U983, Hopital Necker, Paris, France; [2]Nephrology Department, CHU Hotel Dieu, Nantes, France; [3]Genetic Department, CHU La Miletrie, Poitiers, France; [4]Nephrology Department, CHU La Miletrie, Poitiers, France; [5]Nephrology Department, HEGP, Paris, France; [6]Nephrology Department, CHU, Amiens, France; [7]Nephrology Department, Necker Hospital, Paris, France; [8]Nephrology Department, Royal Hospital, Muscat, Oman; [9]Nephrology Department, CHU, Starsbourg, France; [10]Nephrology Department, CHU, Klemlin Bicetre, France; [11]Cristallography Lab, CNRS UMR 8015, Paris, France.*

Mutations in the *INF2* gene, encoding a member of the formin family of actin-regulating proteins, have recently been identified in familial focal and segmental glomerulosclerosis (FSGS) cases, thereby emphasizing the importance of an intact actin cytoskeleton in podocyte function. In order to better determine the prevalence of *INF2* mutations in autosomal dominant FSGS, we screened 54 families (78 patients) and detected mutations in 17% of them. All were missense variants localized in the N-terminal diaphanous inhibitory domain (DID) of the protein, a region which interacts with the C-terminal diaphanous autoregulatory domain (DAD), thereby competing for actin monomer binding and inhibiting depolymerization. Interestingly, six out of the seven altered different residues identified were localized in the corresponding INF2 region of a mDia1 DID subdomain reported to co-immunoprecipitate with IQGAP1. Ninety sporadic cases were also evaluated and no mutation was detected. In conclusion, *INF2* is a major gene of autosomal dominant FSGS. As IQGAP1 is known to interact with crucial podocyte proteins (nephrin, PLCε1), the identification of mutations which may alter the putative INF2-IQGAP1 interaction provides additional insights into the pathophysiological mechanisms linking formin proteins to podocyte dysfunction and FSGS.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2441**

**Total Exome Capture and NextGen Sequencing Reveal Mutation of *Cubilin* as a Single-Gene Cause of Proteinuria** Virginia Vega-Warner,[1] Bugsu Ovunc,[1] Edgar Otto,[1] Pawaree Saisawat,[1] Shazia Ashraf,[1] Hanan Fathy,[3] Gil Chernin,[1] Friedhelm Hildebrandt.[1,2] *[1]Department of Pediatrics and of Human Genetics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI; [3]Pediatric Nephrology Unit, El Shatty Children's Hospital, Alexandria, Egypt.*

Childhood nephrotic syndrome (NS) is a genetically heterogeneous disorder with prominent protenuria.

**Hypothesis.** The likely existence of dozens of rare recessive NS genes necessitates the ability to identify new NS-causing genes in single families.

**Methods.** We therefore performed homozygosity mapping (Affymetrix™ SNP 6.0 Array) with consecutive total human exome capture (THEC) (NimbleGen™ Sequence Capture Human Exome 2.1M Array) and NextGen sequencing (Illumina™) in two siblings (A2410) with intermittent nephrotic-range proteinuria.

**Results.** Total genome homozygosity mapping yielded 7 segments of homozygosity by descent that covered a cumulative physical distance of 130 Mb. THEC revealed 309 homozygous non-synonymous exonic (or splice) variants from normal reference sequence throughout the entire genome. 21 of the exonic variants occurred within the mapped homozygous candidate regions. One of those variants was a homozygous truncating mutation in exon 53 of the *CUBN* gene (c.8355delA; p.S2785fsX19), which was present in both affected siblings and absent from 180 normal control individuals (1000 Genome project). We thereby identified mutation of *CUBN* as the cause of proteinuria in this sibship. Recessive *CUBN* mutations are known to cause Imerslund-Gräsbeck syndrome, a hereditary from of megaloblastic anemia secondary to vitamin $B_{12}$ deficiency. Proteinuria occurs in 50% of cases in addition to anemia due to the dual role of cubulin as coreceptor for both, i) the intestinal vitamin $B_{12}$-intrinsic factor complex and, ii) the receptor complex that mediates tubular reabsorption of protein from primary urine in the proximal tubule.

**Conclusion.** Homozygosity mapping with consecutive THEC and NextGen sequencing allows identification of very rare single-gene causes of NS. In our case an unexpected tubular rather than glomerular pathogenesis was revealed.

**SA-PO2442**

**Identification of 34 Novel Mutations in 12 Known Bardet-Biedl Syndrome (BBS) Genes by DNA Pooling and Massively Parallel Resequencing in 90 Individuals** Sabine Janssen,[1] Gokul Ramaswami,[1] Jennifer M. Kasanuki,[1] Rannar Airik,[1] Toby W. Hurd,[1] Erica E. Davis,[3] Nicholas Katsanis,[3] Elise Héon,[4] Lauren A. Van der Kraak,[4] Susan J. Allen,[1] Edgar Otto,[1] Friedhelm Hildebrandt.[1] *[1]Departments of Pediatrics and of Human Genetics, University of Michigan, Ann Arbor, MI; [2]Molecular Medicine Unit, UCL Institute of Child Health, London, United Kingdom; [3]Center for Human Disease Modeling, Duke University Medical Center, Durham, NC; [4]Department of Genetics and Genome Biology, The Hospital for Sick Children, Toronto, ON, Canada.*

Bardet-Biedl syndrome (BBS) is a rare autosomal-recessive ciliopathy. The phenotype of this pleiotropic disease includes cone-rod dystrophy, postaxial polydactyly, truncal obesity, learning disabilities, hypogonadism and renal abnormalities, among others. To date, 12 genes *(BBS1-12)* have been described to cause BBS. Mutations in these genes can be identified in approximately 75% of individuals with BBS. The broad genetic locus heterogeneity renders mutational screening time-consuming and expensive. We screened individuals from 90 families with BBS for mutations in known *BBS* genes by DNA pooling and subsequent massively parallel resequencing (MPR). DNA of 90 individuals with BBS was pooled in 4 pools (3x24 individuals + 1x18 individuals). All 133 coding exons of 12 known *BBS* genes (*BBS1-12*) were amplified by conventional PCR. Subsequent MPR was performed on an Illumina Genome Analyzer II platform. Following mutation identification, the mutation carrier was assigned by CEL I endonuclease-based heteroduplex screening and confirmed by Sanger sequencing. In 27 out of 90 individuals (30.0%) 56 mutations in 11 different *BBS* genes were found, 26 of which were novel. In 13 out of 90 (14.4%) individuals 15 single heterozygous mutations were found, 8 of which were novel. Thus, DNA pooling combined with MPR offers a valuable strategy for mutation analysis of large patient cohorts, especially in genetically heterogeneous diseases such as BBS.

**SA-PO2443**

**Detection of CAKUT-Causing Genes Using Next Generation Exon Resequencing of 30 Candidate Genes in 45 Patients with Unilateral Renal Agenesis** Pawaree Saisawat,[1] Velibor Tasic,[2] Elijah O. Kehinde,[3] Virginia Vega-Warner,[1] Edgar Otto,[1] Friedhelm Hildebrandt.[1] *[1]Department of Pediatrics and of Human Genetics and Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI; [2]Department of Pediatric Nephrology, University Children's Hospital, Skopje, Macedonia, The Former Yugoslav Republic of; [3]Department of Surgery, Kuwait University, Safat, Kuwait.*

**Background.** Congenital abnormalities of the kidney and urinary tract (CAKUT) account for ~50% of all chronic kidney disease in children. Although many forms of CAKUT are likely caused by single-gene defects, only few causative genes have been identified. The broad genetic heterogeneity of CAKUT necessitates analysis of many candidate genes. We therefore applied a newly developed approach of next generation exon resequencing to 45 patients with unilateral renal agenesis from 43 different families.

**Methods.** We pooled genomic DNA of 20 individuals each and performed exon PCR in 30 CAKUT candidate genes (402 exons) simultaneously using next generation resequencing. We repeated pooling 3 times to cover 45 renal agenesis patients. Candidates were genes implicated in renal agenesis in humans or mice. Sequencing was performed using Illumina Genome Analyzer II.

**Result.** We detected 7 heterozygous missense mutations in 4 new CAKUT genes not previously implicated in non-syndromic CAKUT in humans: 1 each in *EMX2, FREM2* and *SPRY1* and 4 in *FRAS1*. All mutations were absent from 96 healthy controls and had a polyphen score of >2.0, except 2 *FRAS1* mutations with a score of 1.69. Whereas recessive *truncating* mutations in *FRAS1* and *FREM2* cause Fraser syndrome in human and mice, we detected heterozygous *missense* mutations in both genes in non-syndromic CAKUT. Likewise, homozygous *EMX2* mutations cause CAKUT in mice, and heterozygous *truncating* mutations cause human schizencephaly. However, we found heterozygous *missense* mutations as causing non-syndromic CAKUT. While *Spry1*-null mice develop CAKUT, no human phenotype of *SRPY1* mutation is known.

**Conclusions.** We thus generate evidence that heterozygous missense mutations in *FRAS1, FREM2, EMX2* or *SPRY1* may be a new cause of non-syndromic CAKUT in humans.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2444**

**Total Exome Capture and Next Generation Sequencing Reveals Mutations of *NAT10, ANGEL1* and *TOP1MT* in Patients with CAKUT** Pawaree Saisawat,[1] Elijah O. Kehinde,[2] Velibor Tasic,[3] Rannar Airik,[1] Virginia Vega-Warner,[1] Edgar Otto,[1] Friedhelm Hildebrandt.[1] *[1]Departments of Pediatrics and of Human Genetics and Howard Hughes Medical Institute, University of Michigan, Ann Arbor, MI; [2]Department of Surgery, Kuwait University, Safat, Kuwait; [3]Department of Pediatric Nephrology, University Children's Hospital, Skopje, Macedonia, The Former Yugoslav Republic of.*

**Introduction:** Congenital abnormalities of the kidney and urinary tract (CAKUT) account for 50% of all chronic kidney disease in children. Although non-syndromic CAKUT does not frequently cluster in families, there is strong evidence from mouse models that recessive monogenic causes of non-syndromic CAKUT exist. By total genome homozygosity mapping we demonstrated the presence of homozygosity peaks in patients with non-syndromic CAKUT. To identify new recessive CAKUT-causing genes we established a new method of total human exome capture (THEC) of 180,000 exons with consecutive next generation exon sequencing.

**Method:** We performed in solution total exome capture using NimbleGen's SeqCaP EZ Exome™ protocol in 3 patients with unilateral renal agenesis from 3 different families who showed homozygous candidate regions by homozygosity mapping. Sequencing was performed using Illumina Genome Analyzer II.

**Result:** We detected 1 homozygous truncating mutation p.K1020KfsX17 in the *NAT10* gene (family A1077) and 1 homozygous missense mutation each in *ANGEL1* (p.R398C) (family A796) and *TOP1MT* (p.D319H) (family A899). Mutations in *ANGEL1* and *TOP1MT* had a maximum polyphen-2 score of 1 and were absent from 120 multi-ethnic healthy controls. NAT10 protein was reported to regulate cytokinesis, and *NAT10* depletion leads to cell cycle arrest.

**Discussion:** Mutations in *NAT10, TOP1MT* or *ANGEL1* may represent new causes of non-syndromic CAKUT in humans. We are currently studying loss of function phenotypes for these genes. THEC can be an efficient tool to detect new CAKUT-causing genes.

**SA-PO2445**

**Clinical and Immunohistochemical Analyses of Japanese Families with Genetically-Defined Autosomal-Recessive Alport Syndrome** Kazumoto Iijima,[1] Masafumi Oka,[1,2] Yuya Hashimura,[1] Ohtsuka Yasufumi,[2] Hiroshi Kaito,[1] Yoshikazu Sado,[3] Kunimasa Yan,[4] Koichi Nakanishi,[5] Norishige Yoshikawa,[5] Hironobu Nagasako,[6] Kandai Nozu,[1] Masafumi Matsuo.[1] *[1]Pediatrics, Kobe Univ., Kobe, Japan; [2]Pediatrics, Saga Medical Sch., Saga, Japan; [3]Shigei Medical Research Institute, Okayama, Japan; [4]Pediatrics, Kyorin Univ., Mitaka, Japan; [5]Pediatrics, Wakayama Medical Univ., Wakayama, Japan; [6]Department of Pediatrics, Kagoshima Univ., Kagoshima, Japan.*

**Background.** Autosomal recessive Alport syndrome (ARAS) is caused by *COL4A3* or *COL4A4* mutations. Clinical and immunohistochemical characteristics of ARAS are still unclear because the mutation detection rates were low in previous studies.

**Methods.** To improve the detection rates of *COL4A3* and *COL4A4* mutations, we utilized combined several molecular techniques: 1) Direct sequencing of genomic DNA, 2) semi-quantitative PCR amplification using capillary electrophoresis of genomic DNA, and 3) RT-PCR and direct sequencing analysis of RNA. Thus, we examined clinical and immunohistochemical characteristics in Japanese families with genetically-defined ARAS.

**Results.** We examined *COL4A3* and/or *COL4A4* mutations in 14 patients (3 -25 years old) in 12 families with possible ARAS. We detected homozygous or compound heterozygous mutations in *COL4A3* or *COL4A4* in all the patients. We found 19 mutations, and 17 were novel. The median age of ESRD was 19 years (25 years in X-linked Alport syndrome (XLAS) male patients in the previous study). Six patients over 15 years of age showed no expression of type IV collagen alpha 3-5 chains ((IV) α3-5) in GBM. Four of them developed ESRD, 2 had heavy proteinuria, and 4 of 6 patients had hearing loss.

However, 2 patients over 15 years of age showed the weaker but definite expression of ((IV) α3-5) in GBM, mild urinary abnormalities with normal renal function and no hearing loss although they had no distinct characteristics of mutations in *COL4A3* or *COL4A4.*

**Conclusions.** The renal prognosis of ARAS patients is worse than that of XLAS male patients. And, the expression pattern of ((IV) α3-5) in GBM may be correlated with the prognosis of ARAS

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2446

**Novel Dominant Renin Gene Mutations Associated with Hyperuricemia, Anemia and Chronic Renal Failure** Vincent Moriniere,[1] Fabien Nevo,[2] Olivier Gribouval,[2] Chantal Loirat,[3] Guillaume Bollee,[4] Patrick Niaudet,[4] Marie-Claire Gubler,[2] Corinne Antignac.[2, 5] *[1]MARHEA, Necker Hospital, Paris, France; [2]Inserm U983, Necker Hospital, Paris, France; [3]Nephrology Department, Robert Debre Hospital, Paris, France; [4]Nephrology Department, Necker Hospital, Paris, France; [5]Genetic Department, Necker Hospital, Paris, France.*

Recently, two different heterozygous mutations in the first exon of the *REN* gene encoding renin have been described in patients with autosomal dominant chronic tubulointerstitial nephritis (CTIN), hyperuricemia and anemia responding to EPO in childhood (Zivná M et al, 2009). The mutations resulted in the deletion (p.Leu16del) or the amino acid exchange (p.Leu16Arg) of a single leucine residue in the peptide signal sequence.

Given the phenotypic similarities with familial hyperuricemic nephropathy due to UMOD mutations, we screened *REN* exon 1, encoding the pepdide signal of preprorenin in 141 unrelated individuals with CTIN without UMOD mutations. Autosomal dominant inheritance and hyperuricemia and/or gout were present in 97 and 90 cases respectively. In 3 cases, we identified 3 novel missense mutations involving the signal sequence, not found in ~100 controls and segregating with the phenotype in the families. All these mutations (p.Leu16Pro, p.Trp17Arg et p.Cys20Arg) are predicted to be probably damaging (Polyphen scores 2.2, 3.7 et 3.6 respectively) and to drastically decrease the hydrophobicity of the peptide signal.

As previously described, the 3 patients present with CTIN (discovered at 9, 26 and 29 years), hyperuricemia (and gout at 26 years in a female patient) and anemia in childhood in two cases, the anemia being present before the development of renal failure. All had a family history of CTIN and gout.

Altogether, these data prove that *REN* mutations can be responsible for a small percentage of familial cases of CTIN and screening of *REN* exon 1 should be undertaken in these families, especially when a history of anemia in childhood is clearly documented. It remains to be understood the exact mechanism leading to chronic renal failure in these patients and whether mutations in other parts of the gene might also be responsible for the same renal disease.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2447

**Heterozygous Deletions in the SLC12A3 Gene as a Cause of Gitelman Syndrome: Analysis of a Large Cohort** Rosa Vargas-Poussou,[1] Diana Kahila,[1] Annabelle Venisse,[1] Pascal Houillier,[2] Anne Blanchard,[3] Olivier Devuyst,[4] Xavier Jeunemaitre.[1] *[1]Genetics, APHP Hôpital Européen Georges Pompidou, Paris, France; [2]Physiology, APHP Hôpital Européen Georges Pompidou, Paris, France; [3]Centre d'Investigations Cliniques, APHP Hôpital Européen Georges Pompidou, Paris, France; [4]Nephrology, Université Catholique de Louvain, Bruxelles, Belgium.*

Gitelman Syndrome (GS) is an autosomal recessive salt losing tubulopathy caused in the vast majority of cases by mutations in the SLC12A3 gene, encoding the thiazide-sensitive NaCl cotransporter. Between 18 to 40% of patients with clinical GS are found to carry only one mutant allele after SLC12A3 screening. It has been suggested that large genomic rearrangements could account for these unidentified alleles. We screened by direct sequencing a large cohort of 451 GS that allowed the detection of two mutations in 321 patients (71%), but only one or none in 80 (18%) and 50 (11%) patients, respectively. We then performed a search for large rearrangements by multiplex ligation dependent probe amplification (MLPA) in a subset of patients either simple heterozygous (n=53) or with no punctual mutation (n=25). Nine different deletions (E1_E7del, E2_E3del, E4_E5del, E19_E23del and E24_E25del) and two duplications (E1_E3dup and E1_E4dup) were found in 24 out of the 53 heterozygous patients (45%) but none in the non-mutated group. Each copy number variation was confirmed by a second technique (QMPSF, gap-PCR and direct sequencing or micro arrays in one case). Large rearrangements accounted for at least 6% of all mutations detected in our cohort. The breakpoints of 6 deletions were characterized, showing that non-allelic homologous recombination by Alu sequences as well as non-homologous end-joining are most likely responsible for intragenic deletions. In 5.5 % of our GS patients we have excluded mutations and large rearrangements in SLC12A3 gene, even after the analysis of the CLCNKB gene, which raises the question of the diagnosis of GS and/or of the possible genetic heterogeneity of this tubulopathy.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2448

**Characterization of the Genetic Complexity of Meckel Syndrome (MKS) Using Targeted Exon-Enriched Next-Generation Sequencing** Katharina Hopp,[1] Christina M. Heyer,[2] Susan A. Henke,[3] Jamie L. Sundsbak,[2] Vicente E. Torres,[2] Sandro Rossetti,[2] Peter C. Harris.[2] *[1]BMB, Mayo Clinic; [2]Nephrology Research, Mayo Clinic; [3]Genome Center, Mayo Clinic, Rochester, MN.*

Meckel Syndrome (MKS) is an embryonic lethal, apparent autosomal recessive disorder characterized by polycystic kidney disease, central nervous system defects, polydactyly and liver fibrosis; phenotypic parameters that place it in the group of ciliopathies. Up to now five genes have been clearly implicated, highlighting a high level of genetic heterogeneity. Mutation screening of these genes (*MKS1, MKS3, CEP290, CC2D2A,* and *RPGRIP1L*), revealed two mutated alleles in only 52% of our MKS cohort (46 families) while a further 12 families had one potential mutation in MKS or one other ciliopathy gene. To explore the full genetic complexity and to re-sequence all implicated MKS genes, we have performed targeted exon-enrichment on pedigrees with unclear etiology. Using *RainDance* droplet-PCR, DNA samples were enriched for the coding region of 31 ciliopathy associated genes and sequenced on the *IlluminaGAII*. We found a likely pathogenic *MKS3* change (G250R) that was missed by Sanger sequencing in a pedigree that had already one known *MKS3* change (R549C). Segregation analysis shows appropriate inheritance of both changes, categorizing this pedigree as a *MKS3* family. In accordance with possible complex inheritance we found a pathogenic splicing change in a novel MKS gene, *B9D1*. The fetus inherited the IVS4+2T>C change and a possible pathogenic *CEP290* change (R2210C). *B9D1* cDNA analysis of fetal cells shows skipping of exon 4 causing a frameshift and no WT product, suggesting a second deleted allele. *B9D1* is one of three proteins containing a B9 domain, others being *MKS1* and *B9D2*. The protein has been proposed to be important in cilia development of *C. elegans* but has not been found mutated in any ciliopathy prior this case. To identify other possible disease genes, we are widening the screen to 707 ciliome genes using the *SureSelect* technology. Both studies will not only provide comparative information of two novel exon-enrichment technologies, but will reveal a much clearer view of the complex inheritance of MKS.

**Genetics of Renal Hypodysplasia in the Chronic Kidney Disease in Children Cohort Study (CKiD)** Rosemary Thomas,[1] Simone Sanna-Cherchi,[2] Patricia L. Weng,[2] Bradley A. Warady,[3] Susan L. Furth,[4] Frederick J. Kaskel,[1] Ali G. Gharavi.[2] *[1]Ped Nephrol, Children's Hospital at Montefiore, Bronx, NY; [2]Nephrol, Columbia University, New York, NY; [3]Ped Nephrol, Children's Mercy Hospital, Kansas City, MO; [4]Ped Nephrol, Children's Hospital of Philadelphia, Philadelphia, PA.*

**Introduction:** Malformations of the kidney and lower urinary tract are the most common cause of End Stage Renal Disease in children. *TCF2* and *PAX2* are transcription factors with crucial roles in kidney development.

**Objective:**

1) Determine the prevalence of mutations in *TCF2* and *PAX2* genes in the North American CKiD population with RHD.

2) In patients with no mutations in *TCF2* or *PAX2* genes, explore the contribution of rare copy number variations using high-density single nucleotide polymorphism arrays.

**Methods:** Genomic DNA was obtained from the NIH biorepository. We performed direct sequencing of *TCF2* and *PAX2* exons and intron boundaries. We then performed simultaneous amplification of multiple short exonic fragments (MLPA) to assess the prevalence of *TCF2* whole/partial gene deletions, as these are not found by sequencing alone. Findings on MLPA were then verified by QPCR.

**Results:** We received 73 DNA samples of children with RHD. By sequencing, we confirmed 6 likely pathogenic variants.Three in *TCF2*: a premature termination signal (p.R181X), a missense mutation (p.S148L), and a frameshift (Y352fsX352); the first two were noted previously to be pathogenic . Three in *PAX2:* one splice site mutation (IVS4-1G>T), one missense mutation (p.G24E), and one frameshift mutation (G24fsX28); the last one was previously reported to be pathogenic. Using MLPA, we found one child with a whole gene deletion in *TCF2*. All the cases were Caucasian. 10% of total cohort (14% of the Caucasians) were noted to have mutations.

**Conclusions:** A proportion of patients with non-syndromic RHD carry mutations in either *TCF2* or *PAX2* genes. These patients should be evaluated for complications (e.g. diabetes for TCF2 mutations, colobomas for *PAX2*) and referred for genetic counseling.

A genome-wide screen for novel pathogenic structural variants in patients without mutations in *TCF2* or *PAX2* genes is ongoing.

**Familial Interstitial Nephritis Is Linked to Chromosome 1q21-23** Peter J. Lavin,[1] Rasheed A. Gbadegesin,[1] Jason J. Eckel,[1] Gentzon Hall,[1] Guanghong Wu,[1] Alison Byrd,[1] Alison Homstad,[1] Peter J. Conlon,[2] Michelle P. Winn.[1] *[1]Duke University Medical Center, NC; [2]Beaumont Hospital, Ireland.*

Chronic tubulo-interstitial nephritis (TIN) leads to progressive decline in renal function, involving patho-physiological processes that are implicated in the progression of most types of renal disease. Here, we present six kindreds with familial interstitial nephritis (FIN) and report a locus for the disease on chromosome 1q21-23 in one kindred.

Affected individuals were initially identified by the Department of Nephrology,

Beaumont Hospital, Ireland. Affected families had two or more members with biopsy-proven primary TIN in the absence of renal cysts or hyperuricemia. All family members were offered screening to determine their affection status by measurement of serum creatinine, serum uric acid levels and qualitative urinalysis. Genomic DNA was isolated from blood using a standardized salting out procedure. The maximal attainable logarithm of the odds (LOD) scores for each pedigree, using full pedigree and affected-only models, was calculated via computer simulation with the SIMLINK 4.1 program. Genome-wide linkage scan was performed with the Illumina Infinium II HumanLinkage-12 genotyping beadchip. Two-point and parametric multipoint LOD scores were calculated by using the VITESSE and MERLIN statistical programs. Microsatellite markers were genotyped in areas suggestive of linkage on the genome-wide screen. The largest kindred, with 12 affected individuals spanning 3 generations, had a maximal predicted LOD score of 4.5 when calculated with SIMLINK. Genome-wide linkage analysis yielded a two-point LOD score of 2.62 at chromosome 1q23.1 and significant multipoint LOD score of 3.38 at D1S2721, D1S394 and D1S2635. Recombination events among affected individuals, as detected by haplotype analysis, established an 18-centiMorgan minimal candidate region flanked by markers D1SPJL and D1S2844. These data support a gene locus for FIN at chromosome 1q21-23. Fine mapping to further refine the minimal candidate region is underway. Identification of the mutated gene at this locus may provide further insight into the disease mechanisms of interstitial nephritis.

**Identification of a Novel Disease Gene in Dominantly Transmitted Glomerulocystic Kidney Disease** Monica C. Tucci,[1] Xiang-Yang Lou,[2] Lisa M. Guay-Woodford.[1] *[1]Pediatric Nephrology / Genetics, University of Alabama Birmingham, Birmingham, AL; [2]Biostatistics, University of Alabama Birmingham, Birmingham, AL.*

Glomerulocystic kidney disease (GCKD) is a relatively rare form of PKD with both sporadic and familial occurrence. In previous studies, we have identified a large, four-generation African-American family with autosomal dominant GCKD. Using a set of directed linkage studies, we determined that this GCKD phenotype results from mutation in a novel locus distinct from the ADPKD genes, *PKD1* and *PKD2*, as well *BICC1*, the human orthologue of the gene disrupted in the mouse *jcpk* model. The current study was designed to expand our initial phenotypic characterization of this family and perform a genome-wide linkage study to localize and identify the novel disease-susceptibility gene.

**Methods/Results:** We characterized all available individuals who were 14 years or older by evaluating blood pressure and renal function, and we assessed renal structure using sonography. Of the 19 family members evaluated, 13 were classified as affected based on renal ultrasound, renal biopsy, or progression to ESRD. Using the Illumina Cyto-SNP12 assay (294,655 SNPs), we genotyped each of the 19 individuals and performed a genome wide association study (GWAS) using the statistical software PLINK to identify SNPs strongly associated with disease transmission. The significance was set at a p-value threshold greater than $-\log_{10}(p)=3.5$. Analyses to date do not support linkage to *UMOD* on chromosome 16 but have identified potential candidate intervals on chromosomes 4,6,9,11,18.

**Conclusions/Ongoing Studies:** We have characterized a large, four-generation African-American family with autosomal dominant GCKD. Using a GWAS-based strategy, we have identified several candidate genomic intervals for this novel GCKD locus. Current efforts are directed towards building haplotype blocks within these intervals and using linkage analysis to identify and delimit a single candidate interval. We propose that identification of this novel GCKD gene will add to the current knowledge of renal cystic disease genetics and provide new insights into pathogenic pathways.

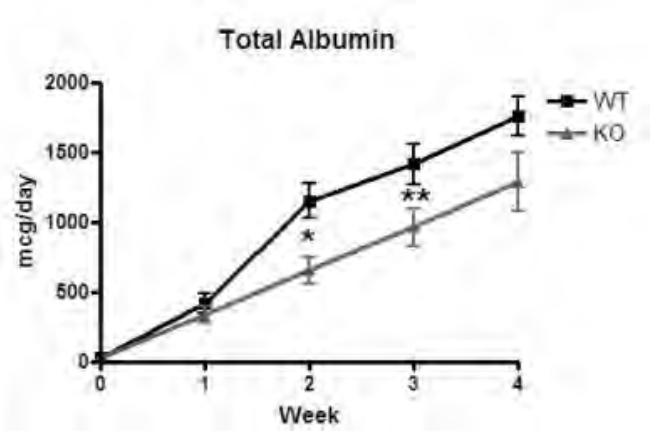
**SA-PO2452**

**A Role for TRPC6 in Angiotensin II-Induced Albuminuria in Mice** Jason J. Eckel,[1] Peter J. Lavin,[1] Rasheed A. Gbadegesin,[1] Laura M. C. Barisoni,[2] Matthew A. Sparks,[1] Michelle P. Winn.[1] *[1]Medicine, Duke University Medical Center, Durham, NC; [2]Nephrology, New York University, New York, NY.*

Mutations in the canonical transient receptor potential cation channel 6 (*TRPC6*) are responsible for familial forms of adult onset focal segmental glomerulosclerosis (FSGS). However, speculation exists at to the precise mechanism whereby *TRCP6* mutations cause kidney disease. We used a TRPC6-deficient mouse line to examine the role of TRPC6 in the kidney. We found no difference in baseline blood pressures, measured by radiotelemetry, between TRPC6-deficient and wild type mice. Additionally, there was no difference in urinary albumin excretion between these two groups at baseline. Mice were then infused with angiotensin II for 28 days to determine whether the absence of TRPC6 would alter susceptibility to hypertension and renal injury. TRPC6-deficient mice had significantly less albuminuria especially during the early phase of the infusion despite similar increases in blood pressure.



Cell membrane currents were analyzed by whole-cell patch-clamping in primary cultures of podocytes from wild type and TRPC6-deficient mice. There was an augmented response to angiotensin II in podocytes from wild type mice, and these currents were abolished in podocytes lacking TRPC6. Our findings suggest that TRPC6 promotes albuminuria, perhaps by promoting angiotensin II-dependent calcium transients. The absence of TRPC6 protects against angiotensin II-dependent albuminuria without affecting blood pressure suggesting that specific blockade of *TRPC6* may be beneficial in proteinuric kidney disease.

**Identification of PAR6γ as a New Interaction Partner of PLCε1, the Protein Mutated in Nephrotic Syndrome Type 3** Shazia Ashraf,[1] Toby W. Hurd,[1] Virginia Vega-Warner,[1] Friedhelm Hildebrandt.[1,2] *[1]Departments of Pediatrics and of Human Genetics, University of Michigan, Ann Arbor, MI; [2]Howard Hughes Medical Institute, .*

**Objectives:** Steroid resistant nephrotic syndrome (NS) is a malfunction of the kidney glomerular filter that leads to proteinuria, hypoalbuminemia, edema, and renal failure. Using positional cloning, we have identified recessive mutations in the *phospholipase C epsilon 1* (*PLCE1*) gene as causing early onset NS with end stage kidney disease (1). We also demonstrated the interaction of the PLCε1 protein with IQGAP1 (1), BRAF (2), β-arrestin 2 and ERK1/2. We hypothesized that identifying novel interaction partners of PLCε1 would help clarify the mechanism by which *PLCE1* mutations cause NS.

**Methods:** To search for additional members of the PLCε1-associated protein complex, we performed GST pull down assay in rat glomerular lysates with purified GST-PLCε1 fusion protein, represented by exons 4-6. Proteins thus obtained were subsequently analysed with two-dimensional gel electrophoresis and compared to proteins from a GST-only negative control. Proteins differentially pulled down by GST-PLCε1 were identified by liquid chromatography/mass spectroscopy (LC-MS) analysis.

**Results:** One of the proteins showed identity with PAR6-gamma (PAR6γ), an adaptor protein that engages in many protein-protein interactions that are spatiotemporally regulated to control cell polarity. We then confirmed by *in vivo* analysis that overexpressed myc-tagged PAR6γ coimmunoprecipitates with overexpressed flag-tagged PLCε1 in HEK293T cells demonstrating that PAR6γ can form a protein complex with PLCε1. We examined and confirmed the interaction both ways endogenously by coimmunoprecipitation in rat glomerular lysates, the most relevant tissue source for glomerular expression. We also mapped the interaction of PAR6γ to exons 4-6 of PLCε1, encoding the RAS-GEF domain.

**Conclusion:** We identified PAR6γ as a novel interaction partner of PLCε1 in glomeruli, strongly suggesting a functional role of PLCε1 in the regulation of cell polarity.

**Characterisation of a Novel Mouse Model of Joubert Syndrome** Ann Marie Hynes, Lorraine Eley, Roslyn Jane Simms, Colin Miles, John A. Sayer. *Institute of Human Genetics, Newcastle University, Newcastle upon Tyne, United Kingdom.*

Joubert syndrome (JBTS) is an inherited ciliopathy leading to a cerebellum-retinal-renal syndrome. Recent genetic advances have allowed positional cloning and identification of several JBTS genes. *CEP290 (alias NPHP6)* encodes nephrocystin-6, a centrosomal protein. Mutations in *CEP290* account for 7% of patients with JBTS5. Here we create and characterise a novel murine model of JBTS, carrying a truncating mutation in the *Cep290* gene.

A murine ES cell line containing a *Cep290* "gene trap" was identified. Re-sequencing confirmed this cell line harboured a β-galactosidase reporter gene (β-*geo*) inserted into the endogenous *Cep290* locus leading to a truncating mutation. ES cells were cultured before injecting into murine blastocysts to create chimaeric mice. Chimeras were bred to produce

viable, healthy heterozygous mutant mice. The β-*geo* reporter gene, being placed under transcriptional control of the *Cep290* regulatory elements, allowed determination of the spatiotemporal expression pattern of *Cep290* in heterozygous mutant mice, using X-gal staining of tissue in adult and embryos. Heterozygotes were bred to give rise to homozygote *Cep290*$^{-/-}$ animals which were viable for up to 9 months of age. Histological examination of retinal and renal tissues was performed, alongside immunofluorescent antibody staining and fluorescent microscopy.

In *Cep290*$^{+/-}$ animals, specific X-gal staining representative of *Cep290* expression was observed in a range of tissues (including the kidney, eyes and cerebellum) at various embryological time points. Interestingly, in renal tissues *Cep290* expression was noted at the corticomedullary junction. Homozygous mice developed corticomedullary cysts, in contrast to wild type and heterozygous littermates. Retinal degeneration and hydrocephalus was also observed in the homozygous mice over the first month of life.

The development of *Cep290-/-* mouse has provided a novel model of JBTS with a cerebro-retinal-renal phenotype, consistent with the human disease phenotype. We aim to use this mouse to dissect out disease mechanisms and test novel therapeutic agents in this disease.

### SA-PO2455

**Uromodulin Controls Centrosome Integrity in Cells of the Thick Ascending Limb of the Loop of Henle** Lorenzo Battini, Kim Lee, Carles Martinez-Romero, Lin Geng, G. Luca Gusella. *Medicine, Division of Nephrology, Mount Sinai School of Medicine, New York, NY.*

Mutations of the uromodulin gene, UMOD, are responsible for familial juvenile hyperuricemic nephropathy (FJHN) and medullary cystic kidney disease type 2 (MCKD2). Both diseases are autosomal dominant tubulointerstitial nephropathies, characterized by hyperuricemia, gout, hypertension, cysts formation, and end-stage renal disease. The biological function of uromodulin in cystogenesis is not completely understood, partly for the lack of suitable in vitro models. We generated a novel cell line, TIRE131, by infecting normal human primary epithelial cells with a lentiviral vector expressing the human telomerase. TIRE131 showed no expression of alkaline phosphatase, low levels of aquaporin-2, and high expression of uromodulin. TIRE131 cells formed monolayers with weak transepithelial resistance, but showed resistance to hyperosmolar culture conditions comparable to that of (IMCD3) cells. These morphological and functional properties are consistent with the origin of TIRE131 cell line from the thick ascending limb of the loop of Henle (TAL). To investigate the role of uromodulin in the cystogenic process, we used lentiviral-mediated expression of specific siRNAs to knockdown the gene. Inhibition of uromodulin expression in TIRE131 cells rapidly induced centrosome amplification and genomic instability, similarly to what observed after PKD1 knockdown in IMCD3 and MDCK, suggesting overlapping mechanisms in the cystogenic process triggered by the two genes.However, despite the constitutive expression of polycystin-1 in TIRE131 cells, PKD1 knockdown had no effects on the centrosome integrity or cell growth profiles. IMCD3 and MDCK cells were equally unaffected by UMOD knockdown. Overall, these data show that another cystic gene, uromodulin, is involved in the control of centrosome integrity. Furthermore, these results indicate a variable susceptibility of different renal cell types to cystic genes, supporting the observed prevalence of cyst formation along different tracts of the nephron or collecting ducts, and suggest that adult renal cytoarchitecture is controlled by different genes in different cell types.

### SA-PO2456

**Diabetes Accelerates Cystogenesis in the Adult Conditional *ift88* Knockout Mouse** Kelli Margot Sas, May Y. Amria, P. Darwin Bell. *Medicine, Medical University of South Carolina, Charleston, SC.*

Recently we have found that deletion of cilia in the adult mouse exacerbates renal hypertrophy and accelerates cystogenesis in response to unilateral nephrectomy. In this model, hypertrophic signaling in the absence of cilia may initiate cyst formation, at least in part through inappropriate activation of the mTOR pathway. Diabetes, the leading cause of end stage renal disease, also results in structural and functional hypertrophy in the kidney. The goal of this study was to determine if the presence of diabetes would modify the time course of cyst formation in the adult mouse with deletion of cilia. To examine the role of cilia in diabetes, we utilized a conditional floxed allele for the *ift88/Tg737* gene to produce cilia (+) or cilia (-) adult mice. Mice were administered streptozotocin at 50 mg/kg for 5 days to induce diabetes. Blood glucose concentrations ranged from 250 mg/dl to 600 mg/dl and were not different between mice that had cilia and mice in which cilia had been removed. After 7 weeks, mice underwent MRI to determine kidney volume and cystic burden and kidneys were removed for histological analysis. MRI and histological analyses identified accelerated cystogenesis mainly in the collecting ducts of diabetic cilia (-) mice, as well as exaggerated structural hypertrophy. Cilia (-) mice without diabetes had little to no cystogenesis or structural hypertrophy at the 7 wk time point. In diabetic cilia (-) mice, there was a marked increase in cellular proliferation, especially in collecting ducts/distal tubules as well as in glomeruli. There was also enhanced mTOR activity in kidneys from the diabetic cilia (-) versus cilia (+) mice. Thus diabetes may be a significant risk factor for accelerated cyst formation and renal failure in PKD.

### SA-PO2457

**Novel *UMOD* Mutations Result in Decreased Ciliary Uromodulin Expression *In Vitro*** Matthias Tilmann Florian Wolf,[1,2] John A. Sayer,[3] Luca Rampoldi,[4] Bernd Hoppe,[1] Friedhelm Hildebrandt,[5] Frank Zaucke.[6] *[1]Department of Pediatrics, University Hospital Cologne, Cologne, Germany; [2]Department of Pediatrics, University of Texas, Southwestern Medical Center, Dallas, TX; [3]Institute of Human Genetics, Newcastle University, Newcastle upon Tyne, United Kingdom; [4]Dulbecco Telethon Institute, DIBIT, San Raffaele Scientific Institute, Milan, Italy; [5]Departments of Pediatrics and Human Genetics, University of Michigan, Ann Arbor, MI; [6]Center for Biochemistry, Medical Faculty, University of Cologne, Cologne, Germany.*

Mutations in *Uromodulin* (*UMOD*) have been described in: 1. medullary cystic kidney disease type 2, 2. familial juvenile hyperuricemic nephropathy, and 3. glomerulocystic kidney disease. Previously, we have demonstrated Uromodulin expression in renal primary cilia. We were interested if *UMOD* mutations would result in a decreased ciliary Uromodulin expression in cell culture. We also compared in patients from the 3 disease groups whether presence or absence of *UMOD* mutations are associated with different clinical features.

We performed mutation analysis in *UMOD* for 33 kindreds and identified 13 (10 novel and 3 previously published) *UMOD* mutations. In IMCD3 cells we show that the mutant constructs C150S and T225K do no traffick to cilia in contrast to wildtype UMOD. Between 17 individuals from 13 kindreds with *UMOD* mutations and 20 individuals without *UMOD* mutations there was no significant difference in age of onset (25.3 vs. 19.1 years) or GFR (49.9 vs. 61 ml/min/1.73m$^2$). When comparing the group with *UMOD* mutations vs. the group without there was more frequently a positive family history (88% vs. 50%; p=0.01) and hyperuricemia (47% vs. 16.7%; p=0.04). Presenting symptoms in the patients with *UMOD* mutation were mostly hypertension (65%) and anemia (23.5%), whereas the non *UMOD* group presented initially with polyuria (29.1%).

We show that *UMOD* mutations may impair the UMOD ciliary expression. We identified 10 novel mutations. Patients with *UMOD* mutations have more frequently a positive family history and hyperuricemia and present initially more frequently with hypertension.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2458

**Expression of Mutant Uromodulin Leads to Progressive Tubulo-Interstitial Damage and Renal Function Defects in Transgenic Mice** Ilenia Bernascone,[1] Sylvie Janas,[2] Masami Ikehata,[3] Matteo Trudu,[1] Alessandro Corbelli,[3] Celine Schaeffer,[1] Antonio Amoroso,[4] Gian Marco Ghiggeri,[5] Francesco Scolari,[6] Maria Pia Rastaldi,[3] Olivier Devuyst,[2] Luca Rampoldi.[1] *[1]Dulbecco Telethon Institute c/o San Raffaele Scientific Institute, Milan, Italy; [2]Université Catholique de Louvain, Brussels, Belgium; [3]Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, Italy; [4]University of Turin, Turin, Italy; [5]G. Gaslini Institute, Genoa, Italy; [6]Montichiari Hospital, Montichiari, Italy.*

Uromodulin-associated kidney diseases (UAKD) are autosomal dominant tubulo-interstitial disorders caused by mutations in UMOD, the gene encoding uromodulin. We recently reported on the generation and characterisation of the first UAKD mouse model. Transgenic mice expressing the C147W mutant uromodulin develop a tubulo-interstitial disease very similar to the human condition characterised by extensive fibrosis, inflammatory cell infiltration and tubular dilation. Interestingly, we observed specific cellular damage of the thick ascending limb of Henle's loop. These features are accompanied by urinary concentrating defect of renal origin and mild renal failure. As in UAKD patients, urinary excretion of uromodulin is markedly reduced and the protein accumulates in the ER of expressing cells.

All these features are clearly present in 24 weeks-old mice. To gain insight into the disease progression, we extended our analyses at earlier time points. Interestingly, a mild urine-concentrating defect, enhanced after furosemide treatment, could be seen at 9 weeks of age when the interstitial damage and infiltration are very moderate. ER enrichment of mutant protein is already present even in younger (6 weeks) pre-symptomatic animals and is likely the primary event in the disease pathogenesis. Notably, preliminary data on the molecular mechanisms of ER retention showed that mutant protein interacts with the ER-resident chaperone GRP78/BiP, a main player in the ER quality control process that has a pivotal role in the ER stress responses following accumulation of misfolded protein.

These data demonstrate a gain-of-toxic function of uromodulin mutations and provide insights into the pathogenesis of UAKD.

### SA-PO2459

**Albumin Induced Production of Proinflammatory Substances in Cystinotic Proximal Tubular Cells** Martijn J. Wilmer,[1,4] Leo A. H. Monnens,[3] Lambertus V. Heuvel,[1,4] Elena N. Levtchenko.[2,4] *[1]Laboratory of Pediatrics and Neurology, Radboud University Medical Center, Nijmegen, Netherlands; [2]Department of Pediatric Nephrology, University Hospitals Leuven, Leuven, Belgium; [3]Department of Physiology, Radboud University Medical Center, Nijmegen, Netherlands; [4]Laboratory of Pediatrics, KULeuven, Leuven, Belgium.*

**Objectives:** Lysosomal cystine accumulation is the hallmark of the autosomal recessive disorder cystinosis, caused by mutations in the *CTNS* gene. Patients with cystinosis usually develop renal Fanconi syndrome in the first year of life leading to progressive renal failure.

Whether tubular chemokine and cytokine production is involved in the pathogenesis of renal disease in cystinosis is investigated.

**Methods:** Conditionally immortalized proximal tubular cell lines (ciPTEC) of controls (n=4) and cystinotic patients (n=8) were developed by transfection with SV40T and hTERT. Production of IL-8, MCP-1 and TGF-1 were measured after incubation with bovine serum albumin (BSA; range 20-500g/ml) using ELISA and corrected for intracellular protein. Urinary levels of IL-8, MCP-1 and RANTES were measured and corrected for creatinine in cystinotic patients (n=11) and controls (n=6). Data are presented as pg/mol creatinine.

**Results:** In control and cystinotic ciPTEC, BSA dependent IL-8, MCP-1 and TGF-1 production was demonstrated. No differences between the two groups were observed at basal or stimulated conditions. IL-8 (control 1.5 versus cystinosis 7.5), MCP-1 (10.2 versus 107.9) and RANTES (0.7 versus 4.0) were increased in cystinotic urine ($p<0.05$).

**Conclusions:** Cystinotic ciPTEC are susceptible to albumin induced production of proinflammatory substances comparable to control cells. Because our previous studies in cystinosis patients showed, next to tubular proteinuria, glomerular protein loss, treatment targeting RAAS inhibition is indicated.

**SA-PO2460**

**A Novel Rat Model with >75% of Offspring Exhibiting Spontaneous Unilateral Renal Agenesis** Nicholas D. Kampa,[1] Leah C. Solberg Woods,[2] Kevin R. Regner,[1] Cary T. Stelloh,[1] Michael R. Garrett.[1] *[1]Department of Medicine- Nephrology, Medical College of Wisconsin, Milwaukee, WI; [2]Department of Pediatrics, Medical College of Wisconsin, Milwaukee, WI.*

Unilateral renal agenesis (URA) is a relatively common developmental defect that occurs in 1:500-1000 births. Children born with URA are often asymptomatic but may exhibit defects in the urinary tract or extra renal organs. The long-term prognosis of URA is poorly understood due to lack of long-term follow-up data. However, some patients with URA develop proteinuria, hypertension, and chronic kidney disease. Current animal models of URA utilize either invasive methods (i.e. nephrectomy or renal abalation) or genetic knockout of known developmental genes. There are no spontaneous models of URA that are feasible for use in large scale studies of this disorder. We recently screened NIH heterogeneous stock (HS) rats for variation in renal phenotypes and identified an animal exhibiting URA. Subsequent selection has established several breeding lines that consistently demonstrate URA ranging from 50-80%. In this model, URA most often affects the right kidney (80%) and is associated with other urogenital abnormalities including the absence of the ipsilateral adrenal, ureter, seminal vesicles or uterine horn and ovaries. URA rats exhibit significant renal hypertrophy (20-50% depending on age) with increased glomerular area (7092±627 $\mu m^2$), while having lower nephron numbers (18955±1126) compared to two-kidney littermates (5768±418 $\mu m^2$ and 24789±1126, respectively). Some male one-kidney animals do exhibit increased proteinuria (compared to normal two-kidney littermates) with concomitant histological injury characterized by glomerulosclerosis and tubulointerstitial damage later in life (week 32-40). In summary, this model exhibits a high incidence of spontaneous URA and demonstrates clinical features similar to the human disorder. The model will overcome the limitations of current URA models and will allow for long-term study of cardiovascular and renal implications of URA, provide insight into renal development, and serve as a unique genetic resource to better understand gene modifiers involved in renal agenesis.

**SA-PO2461**

**Functional Loss of Cystin in the *cpk* Mouse Causes Necdin-Mediated *cmyc* Over-Expression: A Mechanism for Pathogenesis** Chaozhe Yang, Maoqing Wu, Binli Tao, Lisa M. Guay-Woodford. *Genetics, UAB, Birmingham, AL.*

Over-expression of *cmyc* has been proposed as a key modulator of renal cystogenesis in the *cpk* mouse model of ARPKD (JASN 1:1048, 1991). In previous studies, we have shown: 1) cystin, the cilia-associated protein disrupted in the *cpk* mouse, interacts with the anti-apoptotic protein, necdin; 2) the cystin C-terminal 25 AA harbors the necdin-binding site; 3) in luciferase reporter assays, necdin enhances *cmyc* P1 promoter (P1) activity by binding to the P1 GN box and full-length cystin, but not a C-25 deletion construct (cystin C-25), antagonizes this effect; 4) in ChIP assays, necdin, cystin, and cystin C-25 can be immunoprecipitated with the *cmyc* P1 GN box. In the current study, we sought to further characterize the mechanism through which cystin and necdin modulate *cmyc* expression. **Methods/Results**: To confirm previously published observations, we used quantitative immunoblotting to demonstrate that c-myc was highly expressed in kidneys from 14 day old *cpk* mice when compared to wild-type controls. We then generated a doubly transfected stable mIMCD3 cell line expressing cystin::GFP and necdin::RFP and observed that cystin co-localizes with necdin in the nucleus. Previous studies by our group demonstrated that cystin contains a functional nuclear localization signal (JASN 20:2570, 2009). In electrophoretic mobility shift assays (EMSA) using a biotin-labeled GN box and mIMCD3 cells transfected with pCMV-cystin-HA, pCMV-necdin-myc, pCMV-HA (empty vector) constructs, DNA-protein complexes were observed in the nuclear extracts of cystin- and necdin-transfected mIMCD3 cells, but not empty vector-transfected cells. **Conclusions**: Our data demonstrate: 1) both cystin and necdin interact with the *cmyc* P1 GN box; 2) cystin-DNA binding is independent of the cystin-necdin interaction; and 3) cystin antagonizes the stimulatory effect of necdin on the *cmyc* P1 promoter and down-regulates gene expression. We are testing whether this antagonistic action involves direct cystin-necdin binding. We propose that functional loss of cystin causes renal cystogenesis in this mouse ARPKD model by *cmyc* over-expression and dysregulation of *cmyc* downstream targets.

**SA-PO2462**

**Progressive Renal Failure in Infancy – A Manifestation of a New Mitochondrial Cytopathy** Ruth Belostotsky, Efrat Ben Shalom, Rachel Becker-Cohen, Sofia Feinstein, Choni Rinat, Yaacov Frishberg. *Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel.*

Mitochondrial cytopathy (MC) in childhood usually manifests as tubulopathy, the most common being Fanconi syndrome, or the nephrotic syndrome due to FSGS. Two infants born prematurely to an inbred kindred of Arab descent presented with a fatal multi-system disease manifesting as poor feeding, developmental delay, primary pulmonary hypertension and elevated serum lactate concentrations associated with metabolic alkalosis. Diabetes mellitus developed in one. Their renal manifestations included marked azotemia disproportionate to serum creatinine levels, persistent hyperuricemia, salt wasting, hypomagnesemia and progression to ESRD in the first year of life. Muscle biopsy obtained from one patient revealed extremely reduced activity of all respiratory complexes but complex II. The latter, which was relatively preserved, is the only complex encoded solely by the nuclear genome. Analysis of the consanguineous pedigree suggested that this would be an autosomal recessive disorder, associated with compromised energy production, and led to the assumption that this is likely a defect in nuclear DNA. Nuclear-encoded genes are central to a number of processes pertinent to the synthesis of mtDNA-encoded proteins (transcription, translation and replication machinery). Homozygosity mapping (Affymetrix 250K Array SNP) was implemented searching for homozygous identity-by-descent-regions, shared by both infants. KinSNP analysis of the data demonstrated 2 shared homozygous chromosomal fragments: on chromosome 19 - 5 Mbp, and on chromosome 4 - 2 Mbp. These loci contained 221 and 144 SNPs, respectively. A priority list of proteins located within these loci was constructed and analysis of candidate genes is underway. This is a new multi-organ MC with devastating renal involvement in infancy.

**Targeting Cytostatic vs. Cytotoxic Effects on TSC Angiomyolipoma Cell Viability** Brian J. Siroky, Lu Lu, Anna R. Hellmann, John J. Bissler. *Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Tuberous sclerosis complex (TSC), an inherited tumor predisposition syndrome associated with mutations in *TSC1* or *TSC2*, affects approximately 1 in 6000 individuals. 80% of TSC patients develop renal angiomyolipomata, and renal involvement in TSC is a major contributor to patient morbidity and mortality. Recent work has shown that mammalian target of rapamycin complex 1 (mTORC1) inhibition with rapamycin caused angiomyolipoma shrinkage. However, angiomyolipomas trended toward baseline size when the drug was discontinued, indicating a greater cytostatic rather than cytotoxic effect. We sought to identify potential cytotoxic therapies. Endoplasmic reticulum (ER) stress can develop in TSC angiomyolipomas due to increased protein translation stemming from constitutive mTORC1 activity. We hypothesized that renal angiomyolipoma cells experience ER stress that can be leveraged to result in targeted cytotoxicity. We used a human angiomyolipoma cell line immortalized with HPV E6/7 and telomerase that was stably transfected with empty vector, or the *TSC2* gene (encoding tuberin). By western blot, we found that angiomyolipoma cells lacked tuberin and greatly over-expressed phospho-S6 ribosomal protein compared to tuberin-rescued cells. In cell viability assays, we found that everolimus (20 nM), an mTORC1 inhibitor, had no effect at 24 hours, but after 72 hours significantly suppressed proliferation of angiomyolipoma cells, while tuberin-rescued cells were not affected, supporting a cytostatic effect. Similar studies were performed with the proteasome inhibitor MG-132 (500 nM), which has been shown to induce ER stress. Western blot analyses showed induction of C/EBP-homologous protein (CHOP), a marker of ER stress, by MG-132 in both cell lines. Poly (ADP-ribose) polymerase (PARP) cleavage, which indicates apoptosis, was observed in MG-132 treated angiomyolipoma cells but not tuberin-rescued cells. By 8 hours of MG-132 treatment, viability was substantially reduced in angiomyolipoma cells, but not tuberin-rescued cells. These results suggest that human angiomyolipoma cells may be uniquely susceptible to therapies that exacerbate ER stress.

**IQCB1/NPHP5 Mutations Are Involved in Senior-Løken Syndrome with Very Late Onset of Renal Failure** Isabelle Perrault,[1] Remi Salomon,[2,3] Kallman Tory,[4] Vincent Moriniere,[2] Eduardo Silva,[5] Helene Dollfus,[6] Christian Hamel,[7] Albert Bensman,[8] Josseline Kaplan,[1] Corinne Antignac,[2] Jean-Michel Rozet,[1] Sophie Saunier.[2] *[1]Inserm U781, Necker Hospital, Paris, France; [2]Inserm U983, Necker Hospital, Paris, France; [3]Pediatric Nephrology Department, Necker Hospital, Paris, France; [4]Ist Department of Pediatrics, Semmelweis University, Budapest, Hungary; [5]Ophtalmology Department, University Hospital, Coimbra, Portugal; [6]Genetics Department, Faculté de médecine, Starsbourg, France; [7]Inserm U583, INM, Montpellier, France; [8]Nephrology Department, Trousseau Hospital, Paris, France.*

Senior-Løken syndrome (SLSN) is an autosomal recessive disorder with the main features of nephronophthisis (NPHP) leading to ESRD at a mean age of 12 years (12y), and retinal degeneration with variable visual impairment from mild to Leber congenital amaurosis (LCA). Mutations in five SLSN genes have been reported to account for SLSN including NPHP1, CEP290/NPHP6 and IQCB1/NPHP5. We aimed to evaluate the

occurrence of IQCB1 mutations in SLSN and to define the clinical course of renal disease in these patients. We considered 41 SLSN patients with no mutations in either NPHP1 or CEP290 and extended our study to 240 isolated LCA patients without obvious renal alterations. Probands' DNAs were screened for mutations in the 13 IQCB1 coding exons. A total of 42 IQCB1 disease alleles were identified in 15/41 SLSN families with LCA and 7/240 LCA families (26 patients; 14 different nonsense or splice mutations). Renal investigation revealed NPHP symptoms in 3/7 LCA families. The remaining LCA patients (range 5-12y, mean=10y, n=6) are still under investigation. A total of 20 patients from 18 families presented with NPHP symptoms of early to very late onset: 10 patients with ESRD from 7-55y (mean= 41y), 9 patients with chronic renal failure from 3-16y (mean=12y) and 1 patient (7y) with a urinary concentrating defect. Altogether, IQCB1 mutations lead to SLSN with LCA and very variable onset of renal failure even within families, ranging from early childhood to very late adulthood. Therefore, we recommend that renal function should be closely monitored in LCA patients with IQCB1 mutations, regardless of age.

### SA-PO2465

**Clinical Characterization of an Italian Group of Patients Suffering from Bardet-Biedl Syndrome** Miriam Zacchia,[1] Valentina Di Iorio,[3] Francesco Trepiccione,[1] Francesca Simonelli,[3] Elio Marciano,[2] Giovambattista Capasso.[1] *[1]Internal Medicine, SUN, Naples, Italy; [2]Neuroscience, Federico II, Naples, Italy; [3]Oftalmology, SUN, Naples, Italy.*

Bardet Biedl syndrome (BBS) is a rare genetic disorder characterized by multiple organ dysfunctions including the kidney. This study has been designed to elucidate renal and extra-renal phenotype in a group of Italian BBS patients.

22 patients with a clinical diagnosis of BBS have been enrolled; so far 10 patients aged 17-38 years have been screened. Study design: biochemical evaluation, ultrasound imaging, water deprivation test plus ddAVP (desmopessin 4 µg), electroretinal studies, audiometry and otoacustic emission (OAE) testing have been performed.

*eGlomerular filtration rate (eGFR) by CKD-EPI:* 8/10 patients showed normal eGFR (mean±SD, 111±28 ml/min/1.73 $m^2$); 2 adolescent patients were in ESRD.

*Tubular functions*: These studies were performed in patients with eGFR higher than 60 mL/min. No signs of proximal tubule dysfunction were found; plasma and urinary levels of electrolytes (Na, K, Ca, Mg) and acid-base status were normal (mean pH 7.42±0.03, $HCO_3^-$25.38±0.61 mEq/L, $pCO_2$ 39.85±2.50). The majority of patients (6/8) showed a defect in urinary concentration ability, with urine osmolality below 400 mOsm/Kg 12 hrs after water deprivation and lower than 500 mOsm/kg up to 2 hrs after ddAVP administration. Only one patient was frankly poliuric.

*Renal ultrasound imaging:* fetal lobulations were found in 8 patients, renal dysplasia, renal cysts and calyceal diverticula in 2, 6 and 3 patients, respectively.

*Extrarenal phenotype*: retinal degeneration and a story of obesity were found in all patients; 2 patients manifested severe hearing loss, while in 8 it was confined to high frequencies (4 to 8 kHz); polydactyly and cognitive impairment were found in 9 and 4 patients respectively; a patient with normal eGFR was hypertensive.

In conclusion, urinary concentration defect is the most common renal dysfunction, while CKD is rare and not age-dependent. All patients showed renal malformations. In addition to retinal degeneration, a high prevalence of hearing loss limited to high frequences has been revealed, a finding never described in literature.

### SA-PO2466

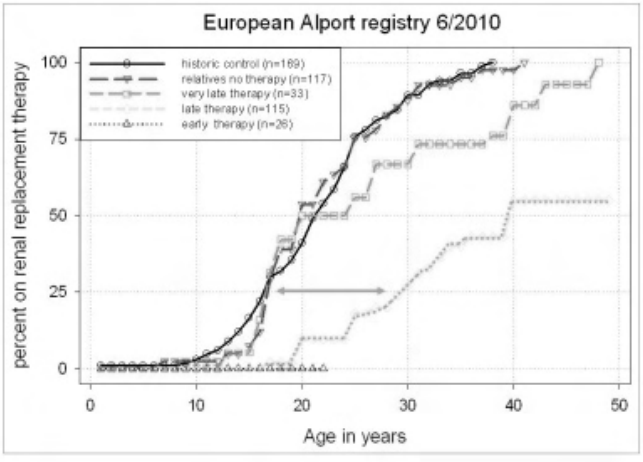
**Primary Endpoints of the European Alport Registry and Its Implications for Future Trials: Early Diagnosis and Therapy Delays Renal Failure** Oliver Gross, Gerhard A. Mueller. *Nephrology & Rheumatology, University Medicine Center Goettingen, Goettingen, Germany.*

Alport syndrome inevitably leads to end stage renal failure (ESRF) in adolescents and young adults. In Alport mice, ACE-inhibition delays renal failure. In humans, however, no efficient therapy can be offered - despite early diagnosis. For that reason, the European Alport registry evaluates the outcome of ACE-inhibition therapy in children and young adults.

552 individuals (237 carriers and 315 patients) have been included into the registry.

A total of 286 individuals (112 carriers and 174 patients) were treated with ACE-inhibition. No SAEs were reported. AEs that lead to discontinuation of therapy included symptomatic hypotension in 2.0% and hyperkalemia (less than 5.5mmol/l) in 1.7% of patients. All AEs were classified as minor and did not cause hospital admission. Treated patients were divided into: (1) early therapy (n=33, proteinuria less than 0.3g/day or hematuria only); (2) late therapy (n=115, proteinuria >= 0.3g/day); (3) very late therapy (n=26, Crea-Clearance<60 ml/min).

Untreated controls (black circles) reach ESRF at the same time point as untreated uncles or brothers (red triangles) with the same genetic defect as treated patients.



In contrast, very late therapy (green squares, p=0.014) and late therapy (yellow diamonds, p<0.0001) significantly delay ESRF. No patient on early therapy (blue triangles) did yet reach renal failure, therefore, effectiveness of early therapy can not (yet) be calculated.

For the first time in humans, our registry data show that Alport syndrome is a treatable disease and ESRF can be delayed by ACE-inhibition. Early start of therapy may be more effective than late therapy. Our data strongly support the need for early diagnosis and therapy in children with Alport syndrome. Hereby, the registry created the essential base for future prospective international trials.

### SA-PO2467

**Progression of Nephropathic Cystinosis in Adults: The Impact of Cysteamine Therapy** Albane Brodin-Sartorius,[1] Patrick Niaudet,[2] Corinne Antignac,[3] Christophe M. Legendre,[4] Philippe H. Lesavre,[1] Aude Servais.[1] *[1]Nephrology, Necker Hospital, Paris, France; [2]Paediatric Nephrology, Necker Hospital, Paris, France; [3]Genetics, Necker Hospital, Paris, France; [4]Transplantation, Necker Hospital, Paris, France.*

Nephropathic cystinosis is a multisystem autosomal recessive disease caused by cystine accumulation. The effect of long term oral cysteamine therapy has to be examined.

Eighty-six adult patients (mean age 26.7±7.1 years) diagnosed with nephropathic cystinosis between 1961 and 1995 were studied. Data were collected on diagnosis, genetics, socio-professional outcome and mortality; time of initiation and duration of cysteamine; and abnormalities of thyroid, pancreas and neuromuscular function.

Cysteamine was administered in 89% of patients, initiated at a mean age of 9.9±10.3 years. By last follow-up, 91% of the patients had end-stage renal disease (mean age 11.1±4.0 years), 72% had hypothyroidism (13.4±6.2 years), 56% diabetes (17.1±7.2 years), and 37% neuromuscular disorder (23.3±6.3 years). Twenty-four patients died. Life expectancy was significantly higher in cysteamine-treated patients versus untreated patients (mean 29.4±7.9 versus 21.6±4.6 years, respectively). Survival curves showed that cysteamine treatment from >5 years significantly delayed the onset of end-stage renal disease, hypothyroidism, diabetes and neuromuscular disorder. Initiating cysteamine before the age of 5 years also significantly delayed the occurrence of those complications.

Cysteamine treatment increases the life expectancy of cystinotic patients. This series indicated that cysteamine treatment for more than 5 years delays the onset of complications, particularly if it is initiated before the age of 5 years.

### SA-PO2468

**Serum Uric Acid Is the Predictor for Progression of Renal Dysfunction Since the Appearance of Overt Nephropathy in Type 2 Diabetes** Kentaro Tanaka,[#1,2,4] Shigeko Hara,[#2,3] Akifumi Kushiyama,[#2] Yoko Yoshida,[#2] Yoshifumi Ubara,[#3] Sonoo Mizuiri,[#4] Atsushi Aikawa,[#4] Shouji Kawazu.[#2] *[1]Depatment of Nephrology, Saiseikai Kanagawa-ken Hospital, Yokohama, Japan; [2]Divison of Diabetes and Metabolism, The Institute for Adult Diseases, Asahi Life Foundation, Tokyo, Japan; [3]Kidney Center and Okinaka Memorial Institute for Medical Research, Toranomon Hospital, Tokyo, Japan; [4]Depatment of Nephrology, Toho University School of Medicine, Tokyo, Japan.*

**Purpose** In diabetic microalbuminuric stage, control of hypertension and hyperglycemia bring in reversible effect. Even though intensive therapy, some groups progress to the renal dysfunction since overt nephropathy. This study is retrospective cohort investigation to reveal the predictor for progression of renal dysfunction since the appearance of overt nephropathy in type 2 diabetic individuals.

**Methods** 290 patients (231men, 59women, age61.9yr, follow-up period5.9yr) were investigated at baseline(retinopathy with UACR ≥300mg/gCr and/or urinary dipstick≥+). We examined the progression of renal dysfunction by Cr doubling. Cr doubling and no

doubling group were compared in clinical findings. The risk factor of Cr doubling was assessed by Cox models.

**Results** 85 of 290 patients developed Cr doubling.In two groups,Cr doubling group showed significantly, early onset of overt nephropathy,higher smoking rates, higher levels of LDL-C, $HbA_{1C}$,serum uric acid(SUA).

In univariate analysis, risk factors of Cr doubling were women, diabetes duration,LDL-C,smoking,$HbA_{1C}$ and SUA. In multivariate analysis, smoking(1.76;1.08-2.91,p=0.02),HbA1c(1.26;1.10-1.44,p=0.0006) and SUA(1.36;1.14-1.62,p=0.0005) remained significant.The highest tertile(≥6.2mg/dl for men, ≥5.1 for women) of SUA levels showed higher rate of Cr doubling than the lower two tertiles (5.1-6.2, ≤5.1 for men, 4.1-5.1, ≤4.1 for women) by the Kaplan-Meier method(log-rank test, p=0.0007).

**Conclusions** Independent predictors for progression of renal dysfunction since the appearance of overt nephropathy in type 2 diabetes are smoking, $HbA_{1C}$ and SUA levels. SUA levels at the overt nephropathy is the strongest predictor for progression of renal dysfunction.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2469

### Entity of CKD Stage 4 over 75 Years Old Is Different from That of Less Than 75 Years of Age

Hiromichi Suzuki, Tsutomu Inoue, Yusuke Watanabe, Tsuneo Takenaka, Hirokazu Okada. *Nephrology, Saitama Medical University, Iruma gun, Saitama, Japan.*

**Background**: Although dependent on the age factor, estimated glomerular filtration rate (eGFR) is commonly used for evaluation of kidney function. Recently, a population based study demonstrated that the eGFR-based criteria for evaluation of CKD were not reliable in patients over 75 years of age. However, whether the assessment of CKD stage 4 patients older than 75 years is better suited for their management and prognosis has not been clearly established.

**Aim:** To compare the characteristics of patients with CKD stage 4 older than 75 years (elderly group) with those between 74 and 65 years (younger group).

**Subjects and Methods**: A single center, retrospective cohort study was performed which included 183 patients (female/male: 66/117**;** 79.2 ± 2.6 years old) with CKD stage 4 (eGFR 19.3 ± 1.7 ml/min/1.73 $m^2$) and 312 patients (female/male: 129/183**;** 70.8 ± 2.0years old) (eGFR 21.5 ± 1.9 ml/min/1.73 $m^2$) from 2004 to 2009. Electronic databases were used to examine the characteristics and mortalities.

**Results**: The ratios of females and males were significantly different between the two groups (p<0.01). The underlying diseases of the elderly group: 146 (79.8%) were due to hypertension, 22(12.0%) were diabetic and others. In the younger group, 118 (37.8%) were diabetic, 96 (30.7%) had glomerulonephritis and others. These were also significant differences (p<0.01). The causes of death were: 9 of 31 (29.0%) in the elderly and 24/47 (51.0%) in the younger group were due to cardiovascular diseases (p<0.01). Progression of eGFR were 0.5 ± 0.2 ml/min/1.73 $m^2$ /year in the elderly group and 1.4 ± 2 ml/min/1.73 $m^2$/year in the younger group (p<0.01). During 6 years, 27 (14.7%) in the elderly group and 140 (44.8%) in the younger group were introduced into dialysis therapy.

**Conclusions**: First, CKD stage 4 patients older than 75 years of age are a different entity from the same stage of the younger group. Second, application of eGFR in CKD stage 4 patients older than 75 years needs to be reconsidered, and other markers such as cystatin C should be explored

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2470

### Glomerular Structure Predicts Diabetic Nephropathy (DN) in Normoalbuminuric (NA) Type 1 Diabetic (T1D) Patients (pts)

Alicia Parks, Michael Mauer, Maria Luiza A. Caramori. *University of Minnesota.*

Over half of the new end-stage renal disease (ESRD) cases in the US are due to diabetes (D). Early identification of pts at increased DN risk would allow preventative strategies to be targeted at this population. We determined whether renal biopsy findings in NA T1D pts predict progression to a composite endpoint of overt proteinuria, ESRD, or cardiovascular (CV) death. Kidney research biopsies and function tests were performed on 106 NA pts [D duration ≥5 years (yrs)]. Albumin excretion rate (AER) was measured by immunoassay (3 samples). Retinopathy was assessed by fundoscopy. Mesangial fractional volume [Vv(Mes/glom)], glomerular basement membrane (GBM) width, and surface density of peripheral GBM per glomerulus [Sv(PGBM/glom)] were estimated by electron microscopic morphometry. *T*-test and Fisher's exact test were used to compare pts remaining NA (non-progressors; NP) to those reaching the endpoint (progressors; P). After 12.4±6.6 (mean±SD) yrs of follow-up, 61 pts were NP, 13 were P, 4 were microalbuminuric, 12 died of non-CV causes, and no follow-up was available in 16. Baseline characteristics, with the exception of hemoglobin $A_{1c}$ ($A_{1c}$) (8.4±1.6 *vs.* 9.4±2.1%; p=0.038) and AER (7.3±4.6 *vs.* 10.1±5.4 µg/min; p=0.033), were not different between pts studied and not studied, respectively. Sex (4M/9F *vs.* 26M/35F), D duration (16.4±8.2 *vs.* 20.1±10.1 yrs), AER (7.2±5.0 *vs.*7.5±4.8 µg/min), mean blood pressure (88.9±10.6 *vs.* 85.6±8.6 mmHg), hypertension (38 *vs.* 25%), retinopathy (55% *vs.* 31%), and duration of follow-up were not different between P (12.1±8.5) and NP (12.9±5.8 yrs), respectively. P were younger at D onset (10.9±6.0 *vs.* 15.3±9.4 yrs; p=0.04) and at kidney biopsy (27.3±8.2 *vs.* 35.4±9.5 yrs; p=0.006), had higher $A_{1c}$ (10.1±2.5 *vs.* 8.0±1.2%; p=0.016) and greater GBM width (584.9±118.3 *vs.* 452.3±79.0 nm; p<0.00001) than NP, respectively. No other variables were different between P and NP. GBM width, $A_{1c}$ and age at D onset were independent predictors of progression. This study found that, despite the absence of clinically apparent renal disease, NA T1D pts with younger onset of D, higher $A_{1c}$ and greater GBM width are at increased risk of progression.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2471

### Safety and Efficacy of Acthar Gel (ACTH) on Albuminuria and Progression of Diabetic Nephropathy in Patients with Nephrotic Range Proteinuria: A Randomized Prospective Study

James A. Tumlin. *Southeast Renal Research Institute, University of Tennessee College Medicine, Chattanooga, TN.*

Tight blood glucose control and ACE/ARB therapy can reduce proteinuria in diabetic nephropathy. Diabetics with nephrotic range proteinuria despite ACE/ARB therapy are more likely to develop ESRD. Treatment of membranous glomerulonephritis with ACTH can reduce proteinuria through activation of endothelial and podocyte melanocortin-1 (MCP-1) receptors. To determine whether ACTH reduces proteinuria in diabetic nephropathy, we conducted a randomized, prospective trial of Acthar Gel (ACTH) in patients with nephrotic range proteinuria.

| Demographics | No. Pts | Age (yrs) | DM (yrs) | % ACE | %ARB | % Biopsy |
|---|---|---|---|---|---|---|
| No./% Pts | 18 | 53±3 | 15±2 | 46% | 60% | 53% |
| Table-1 | | | | | | |
| Proteinuria | Baseline | Month-1 | Month-3 | Month-6 | Complete | Partial |
| Total Pop. | 7.4±0.8 | 4.5±0.8 | 3.90.8 | 2.30.4 | 7.6% | 61.5% |
| 16 units | 7.6±1.4 | 4.4±1.1 | 2.4±0.6 | 2.3±0.6 | 14% | 57% |
| 32 units | 7.3±0.9 | 4.5±1.2 | 5.1±1.1 | 2.4±0.5 | 0.0% | 66.0% |

Methods: Patients with type I or II diabetes and > 3000 mg proteinuria/24 hrs on ACE alone or > 2000 mg/24 hrs on combination ACE/ARB or other protein lowering agent were enrolled. All patients had GFRs ≥ 20 mls/min by Cockcroft-Gault and HgBA1c ≤ 9.0%. Patients were randomized to SQ ACTHar Gel (16 or 32 units) daily for 6 months. Primary endpoint was the percent patients achieving complete (<300mg/24hr) or partial response (> 50% reduction) proteinuria. Secondary endpoints included changes in serum Cr and HgBA1c after 6 months therapy.

As shown in Table-1, mean proteinuria reduced from 7.8±0.8 to 2.3±0.4 gms/24 hrs after 6 months ACTH therapy (P=0.018). Despite advanced diabetic nephropathy (mean GFR-42.0 ml/min), serum Cr remained stable over six months (2.8±0.4 to 2.6±0.5 mg/dl). There was no difference in protein reduction between patients randomized to 16 or 32 units ACTHarGel. Two patients required reduction in ACTH dose secondary to hyperglycemia. We find that SQ ACTH significantly reduces proteinuria in advanced diabetic nephropathy and stabilizes renal function over 6 months. The use of ACTH and other MCR agonists may represent a novel pathway for treatment of diabetic nephropathy.

### Microalbuminuria and Silent Cerebral Infarction Independently Predict Renal Outcomes in Type 2 Diabetes

Takashi Uzu,[1] Shin-Ichi Araki,[1] Shinji Kume,[1] Kousuke Yamahara,[1] Toshiro Sugimoto,[1] Keiji Isshiki,[1] Masami Kanasaki,[1] Masakazu Haneda,[2] Daisuke Koya,[3] Hiroshi Maegawa.[1] *[1]Department of Medicine, Shiga University of Medical Science, Otsu, Shiga, Japan; [2]Department of Medicine, Kanazawa Medical University, Kahoku-gun, Ishikawa, Japan; [3]Second Department of Medicine, Asahikawa Medical College, Asahikawa, Hokkaido, Japan.*

Recently, we reported that silent cerebral infarction was an independent risk factor for renal failure in type 2 diabetes. This study indicates that the presence of vascular diseases is a predictor of the decline in renal function in patients with type 2 diabetes. On the other hand, albuminuria has been well established as a marker strongly predictive of renal and cardiovascular prognosis. However, there are few data regarding whether albuminuria and the presence of vascular diseases are separate and independent risk factors for cardiovascular and renal events among individuals with type 2 diabetes. In the present study, we studied the effects of microalbuminuria (MA) and SCI on the risk for renal events in 608 type 2 diabetic patients without overt proteinuria (513 with normoalbuminuria and 95 with microalbuminuria) by a post hoc analysis of our results (Uzu T, et al. JASN 2010). The patients underwent cerebral magnetic resonance imaging at baseline, and 177 of 608 patients had SCI. Over the average 7.5-year follow-up period, 58 patients reached the primary composite end point of end stage renal disease (ESRD) or death. In addition, 99 patients reached the secondary renal end point of any dialysis and doubling of the serum Cr concentration. Multivariate analysis using the Cox proportional hazards model found that both SCI and MA were independent prognostic factors for the primary composite outcome. In addition, SCI and MA were also found as independent prognostic factors for the secondary renal outcome. Patients with both MA and SCI at baseline had a 4.2-fold higher risk for primary events and a 6.4-fold higher risk for secondary renal events, compared with patients with neither of these risk factors. In conclusion, SCI and MA are independent risk factors for renal events among type 2 diabetic patients.

**SA-PO2473**

**Relation between Echocardiography and Coronary Artery Disease in Asymptomatic Type 2 Diabetic Patients with Elevated Urinary Albumin Excretion Rate** Henrik Reinhard,[1] Peter R. Hansen,[2] Niels Wiinberg,[3] Claus Leth Petersen,[3] Hans-Henrik Parving,[4] Peter Rossing,[1] Peter Karl Jacobsen.[1] *[1]Steno Diabetes Center; [2]Gentofte Hospital; [3]Frederiksberg Hospital; [4]Rigshospitalet.*

Left ventricular (LV) hypertrophy and systolic/diastolic abnormalities are common in type 2 diabetic patients with elevated urinary albumin excretion rate (UAER) but relation to coronary artery disease (CAD) is unclear. This study examined echocardiographic parameters, including LV mass index, LV systolic and diastolic function, and their relation to previously undiagnosed CAD in type 2 diabetic patients with UAER >30mg/24h.

We included 200 type 2 diabetic patients without prior CAD. Patients with P-NT-proBNP >45.2 ng/L and/or coronary calcium score (CCS) >400 were stratified as high risk patients for CAD (n=133), and all other patients as low risk (n=67). High risk patients were examined by myocardial perfusion imaging (MPI; n=109) and/or coronary angiography (CAG; n=86). LV systolic and/or diastolic dysfunctions were evaluated in all patients by conventional echocardiography and tissue Doppler**.** Moderate-severe LV hypertrophy was defined by LV mass index >131 g/m$^2$ in men and >108 g/m$^2$ in women.

Results: Patients received mulitifactorial intervention. LV mass index was 87 (21) g/m$^2$ and 4% of patients had moderate-severe LV hypertrophy. LV systolic function was impaired (<50%) in only 5% of patients. LV diastolic dysfunction (LVDD) was found in 54.5% of patients. In 70 high risk patients, significant CAD was demonstrated by MPI and/or CAG. Adjusted odd ratio (OR [95% CI]) for having significant CAD was 2.91 (1.41-6.00) in patients with LV mass index above the median. LVDD was not associated with LV mass index or significant CAD but was associated with poor metabolic control with adjusted OR 1.46 (1.14-1.87) per 1% increase of $HbA_{1c}$ (p=0.003).

Conclusions: In our study of asymptomatic diabetic patients with elevated UAER that received multifactorial intervention, the prevalence of abnormal LV mass and function was surprisingly low. However, even within normal range, LV mass index was an independent predictor of significant CAD. LVDD was common but not associated with significant CAD

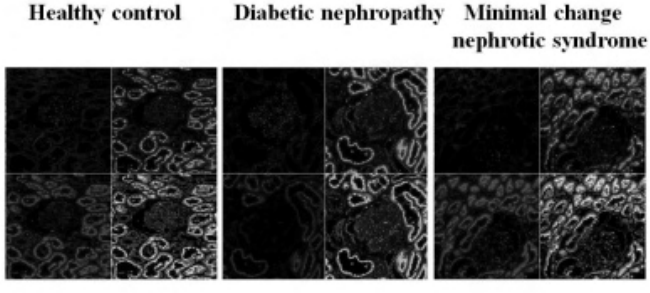
**SA-PO2474**

**ACE/ACE2-Angiotensin (1-7)-MAS Receptor Expression in Diabetic Nephropathy** Sonoo Mizuiri,[1] Makoto Hamanoue,[2] Hiromichi Hemmi,[3] Michitsune Arita,[1] Toshiyuki Aoki,[1] Yasushi Ohashi,[1] Ken Sakai,[1] Minoru Shinozaki,[4] Kazutoshi Shibuya,[4] Atsushi Aikawa.[1] *[1]Nephrology, Toho University of School of Medicine, Tokyo, Japan; [2]Physiology, Toho University of School of Medicine, Tokyo, Japan; [3]Molecular Biology, Toho University of School of Medicine, Tokyo, Japan; [4]Surgical Pathology, Toho University of School of Medicine, Tokyo, Japan.*

ACE2-Ang (17)-Mas receptor (MAS) axis is possibly acting as a counter-regulatory system against the ACE-Ang II-AT1 Axis. The detail of the ACE2-Ang (1-7)-MAS axis was uncertain in human diabetic nephropathy. We studied renal ACE/ACE2-Ang (1-7)-MAS expression by double immunofluorescence staining using confocal microscopy and DAB staining. Percentage and intensity of the labeled area in the DAB staining were evaluated by a computerized imaging analysis. Subjects were 17 patients with diabetic nephropathy (DN), 11 patients with minimal change nephrotic syndrome (MCNS) and 17 healthy kidney donors (controls). Median value of serum creatinine was 1.1 mg/dl, 0.8 mg/dl and 0.8 mg/dl in DN, MCNS and controls. Median value of proteinuria was 3.7 g/day and 6.8 g/day in DN and MCNS. ACE2 was mainly stained in proximal tubules but also in glomeruli, and co-localized with ACE, Ang (1-7) and MAS. In diabetic kidneys, increased ACE and decreased ACE2 expression was observed compared with other specimens.



**Double immunofluorescence staining of ACE (green) and ACE2 (red) with nuclear staining with DAPI (blue). Merged images (right lower panels, yellow or green) show co-localization of ACE and ACE2.**

Tubular Ang (1-7) expression (density/pixel) was significantly (p<0.05) downregulated in DN [12.6. (5.7-18.7)] compared with controls [31.3 (25.9-36.4) ] and MCNS [19.0 (16.7-28.3)]. Tubular MAS expression was also downregulated in DN compared with controls (p<0.001) but similar to MCNS. There were no significant changes in glomerular Ang (1-7) and MAS expression across groups.

**Tubular ACE2-Ang (1-7)-MAS axis is downregulated in patients with diabetic nephropathy and this may exacerbate renal injury.**

**Cardiovascular Risk Factors in Type 2 Diabetic Patients with and without Renal Impairment – The Swedish National Diabetes Register (NDR)** Henrik Hadimeri,[1] Hanri Afghahi,[1] Bjorn Eliasson,[2] Jan Cederholm,[3] Maria Svensson.[2] *[1]Dept of Nephrology, Kärnsjukhuset, Skövde, Sweden; [2]Inst of Medicine, University of Gothenburg, Gothenburg, Sweden; [3]Public Health and Caring Sciences,Family Medicin and Clinincal Epidemiology, Uppsala University, Uppsala, Sweden.*

**Aim of study:** To assess differences in cardiovascular risk factors in type 2 diabetic patients with and without renal impairment in a cross-sectional study using data from a nation-wide population-based diabetes register.

**Patients and method:** 62661 patients with T2D (18-80 years) with complete datasets on albumin excretion, renal function and clinical characteristics reported to the Swedish National Diabetes Register (NDR) in 2008. Albuminuria was defined as urinary albumin excretion rate > 20 µg/min and renal impairment as estimated glomerular filtration rate; eGFR< 60 ml/min/1.73 m2 according to MDRD. **Results**: 15% of all patients had renal impairment (n=9308). 58% of these patients were non-albuminuric. Patients with renal impairment were older (71.2±6.7 vs. 64.0 ±9.3 years), had a longer diabetes duration (11.1±7.7 vs. 7.8±6.4 years), more often women (50 vs. 40%), had lower total cholesterol (4.6±1.0 vs. 4.7±1.0 mmol/L), higher triglycerides (2.0±1.2 vs. 1.8±1.1 mmol/L), higher HbA1c (7.1±1.1 vs. 7.0± 1.1 % (DCCT)), higher BMI (30.2±5.3 vs. 29.7±5.2 kg/m$^2$), higher systolic blood pressure (138±18 vs. 137±16 mmHg) and a smaller proportion were smokers (10 vs. 15%) (all p-values <0.001) compared to patients without renal impairment. When patients with and without renal impairment were compared at GLM regression adjusting for all other variables similar relationships were found except for HbA1c and systolic blood pressure where adjusted values were lower in patient with renal impairment.

**Conclusions:** The majority of patients with type 2 diabetes and renal impairment have non-albuminuric renal disease. Several differences in cardiovascular risk factor pattern were found between type 2 diabetic patients with and without renal impairment. The cause-effect relationship and potential treatment effects could not be assessed in this cross-sectional study and thus prospective studies are warranted.

**Determinants of Diabetic Nephropathy (DN) in Patients (pts) with Type 1 Diabetes (T1DM)** Maria Luiza A. Caramori, Youngki Kim, York Marahrens, Michael Mauer. *University of Minnesota.*

Stochastic and environmental factors may cause persistent epigenetic changes that alter phenotype. Genes susceptible to such variations have been shown to derive their epigenetic properties from nearby transposable elements, which make up 45% of the human genome. We studied the relationships between Alu and LINE-1 transposable element concentrations and microarray (Affymetrix HG-U133A) gene expression levels in skin fibroblasts (SF) of T1DM pts with ("fast-track") and without ("slow-track") DN. The mRNA expression value of each gene in each of the 18 "fast-track" pts (proteinuric and very rapid development of glomerular lesions) was compared to the averaged normalized SF expression value of each gene in the 20 "slow-track" pts [normoalbuminuric and very slow development of lesions]. Genes that are up- or down-regulated (≥2.4-fold) between healthy controls are typically flanked by lower Alu and higher LINE-1 concentrations than genes with lesser differences, this defining the four components of the "typical Alu/LINE-1 pattern". Eleven "fast-track" pts had the typical Alu/LINE-1 pattern and 7 were atypical, 1 with downregulated genes displaying robustly lower rather than higher concentrations of LINE-1 sequence in their flanking regions. The other 6 deviated in one or more components of the typical pattern without weakened typical patterns in the others. $HbA_{1c}$ was higher ($P$=0.001) in the atypical (10.6±1.7%) *vs*. typical (8.9±1.0) Alu/LINE-1 pattern DN "fast-track" pts. These two "fast-track" groups also showed distinctly different Affymetrix microarray directional pathway gene expression differences when compared with the "slow-track" group. OxPhos ($P$<0.001), pentose phosphate ($P$=0.013) and citrate ($P$=0.046) pathways were up-regulated in the typical Alu/LINE-1 pattern "fast-track" group, while the differences in the atypical Alu/LINE-1 pattern "fast-" *vs*. "slow-track" T1DM pts were in ribosome ($P$<0.001), aminoacyl-tRNA ($P$<0.01) and ubiquitin mediated proteolysis ($P$<0.05) pathways, these overlapping with the ones we previously observed in T1DM pts *per se vs.* normal controls (unpublished data). These studies support the concept that "fast-track" T1DM DN pts are not a homogeneous group.

**Obstructive Sleep Apnea Contributes to Renal Dysfunction in Type 2 Diabetes Mellitus** Ashish Tikotekar,[1] Anthony Sica,[2] Jean Fleischman,[1] Chinmay Patel,[1] Harigopal Reddy,[1] Erik Perez,[1] Sharon Merdian,[1] Harly Greenberg.[2] *[1]Queens Hospital Center; [2]Long Island Jewish Medical Center.*

Introduction:

Obstructive sleep apnea (OSA) & type 2 diabetes mellitus (DMII) are frequent co-morbid conditions in patients with chronic kidney disease (CKD). While microvascular renal injury is related to DMII, the contribution of OSA to renal dysfunction is unclear.

We evaluated the association of metrics describing OSA severity with markers of renal function in patients with DMII.

Method:

221 patients, age >18 yrs with DMII & symptoms of OSA who underwent polysomnography were evaluated. Pregnancy, connective tissue disorders & CKD stage 4 or 5 were exclusionary criteria. Variables assessed included measures of OSA severity [apnea hypopnea index (AHI) & % sleep time with SaO2 <90% (T90] measures of renal function [serum creatinine (SrCr), creatinine clearance (CrCl), spot urine albumin (SPA)], systolic & diastolic blood pressure [SBP & DBP], hemoglobin A1c [HbA1c] & use of ACE I or ARB.

Results:

Subjects were 58±11 yrs old, 92 m & 129 f, BMI=38±11 kg/m2, SrCr=1.04 ±0.5mg/dl, CrCl 105.6±50.9ml/min & HbA1C=7.2±1.3%. Mean AHI was in the moderate range 28.0±28.6/hr of sleep with T90%=14.1±22.5%. The percent of subjects by quartile of AHI was: Normal: 0-5=19.5%; Mild: 5-14=23.7%; Moderate:15-29=22.8%; Severe:> 30=34%.

Median (IQR) SrCr & SPA were higher in subjects with AHI>15 than in those with AHI<15 (SrCr: 1.0 (0.8 – 1.2) vs. 0.9 (0.8 – 1.0), p<0.035; SPA: 20.8 (5.0 – 28.0) vs.10 (5.0 – 52.8) µg/mg, p<0.05). Kruskal–Wallis one-way analysis of variance demonstrated a significant effect of AHI group on SrCr, p=0.04.

A multiple linear regression using a combination of predictor variables provided by best subsets analysis showed that SrCr is predicted by a highly significant (p<0.0001) combination of: age (p=0.001); AHI (p=0.027); SBP (p=0.03); HbA1C% (p=0.005); & female gender(p=0.001); R2adjusted=21.4%. Use of an ACEI or ARB was not a significant contributor to the regression.

Conclusion:

OSA severity, as assessed by the AHI, significantly contributes to renal dysfunction in DMII. Future studies should assess the impact of OSA treatment on progression of renal dysfunction in DMII.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2478

**Association of Urinary MCP-1, Serum Aldosterone, Renal Function and Microalbuminuria in Recently Diagnosed Type 2 Diabetes Mellitus Patients** Carlos Kornhauser. *Ciencias Medicas, University of Guanajuato, Leon, Mexico.*

INTRODUCTION AND AIM: The exact mechanisms of diabetic renal disease and progression remain unclear and require further investigation. MCP-1 is a highly chemotactic citokine associated with kidney disease development and progression. Our main objective was to evaluate the association of urinary MCP-1 (uMCP-1), serum aldosterone, microalbuminuria and kidney disease in recently diagnosed type 2 diabetes mellitus (DM2) patients with and without metabolic control.

MATERIAL AND METHODS: Serum glucose, creatinine, uric acid, HbA1, FGF-23, and C reactive protein, were assessed, as well as serum and uMCP-1, EGF, aldosterone, and microalbuminuria in 100 DM2 patients diagnosed in the last 14 months. Glomerular filtration rate (GFR) was estimated with the MDRD formula.

RESULTS: 15 patients out of the controlled metabolic group were in stage 1 or 2 of chronic kidney disease (CKD), 18 patients in the uncontrolled metabolic group were in stage 1 or 2 of CKD.

Microalbuminuria showed a positive association with serum uric acid (r=0.31; p<0.05) and with uMCP-1, (r=0.20; p<0.05). uMCP-1 also shows an independent positive association with serum aldosterone (r=0.20; p<0.05).

Urinary EGF showed an independent positive association with urinary aldosterone (0.22, p<0.05).

Serum uric acid as well as microalbumiuria showed a negative association with GFR (r=-0.54, p<0.05; and -0.26, p<0.05) respectively.

CONCLUSIONS: The association between urinary aldosterone and EGF may be due to EGFR activation by aldosterone stimulation in mesangial cells. Urinary MCP-1 association with microalbuminuria and kidney disease in DM2 patients shows that it may be used as an early predictor of kidney disease in these patients.

## SA-PO2479

**Nephrinuria Is a Potential Biomarker for a Loss of Renal Function in Singaporean Chinese Patients with Type 2 Diabetes Mellitus Even in the Absence of Albuminuria** Daniel P. K. Ng,[1] Mervi Ristola,[2] Bee-Choo Tai,[1] Elaine Tan,[3] Helen Soh Sum Leong,[3] Kee Seng Chia,[1,4] Chia Siong Wong,[4] Wei-Yen Lim,[4] Harry B. Holthofer.[2] *[1]Epidemiology and Public Health, National University of Singapore, Singapore, Singapore; [2]The Haartman Institute, University of Helsinki, Helsinki, Finland; [3]Clinical Services, National Healthcare Group Polyclinics, Singapore, Singapore; [4]Centre for Molecular Epidemiology, National University of Singapore, Singapore, Singapore.*

The involvement of nephrin in controlling renal function is unclear with the literature only emphasizing its role in albuminuria. We therefore investigated the potential association between nephrinuria as evidenced by the appearance of urinary immuno-positive nephrin fragments, with renal function in 381 Chinese type 2 diabetic patients. Western blot analysis of the urine samples using an antibody against human nephrin revealed the presence of up to four distinct protein bands. Each fragment was associated with a decline in estimated glomerular filtration rate (eGFR; largest P=0.003). lnACR was not a significant independent predictor of eGFR and even with the deliberate retention of lnACR in the statistical model, the 25, 50 and 60 kDa fragments remained associated with eGFR reduction (P<0.05). The 25 kDa fragment was the strongest predictor of eGFR decline, being associated with eGFR reduction of 6.55 ml/min/1.73 $m^2$ (95%CI: 0.07-13.03). Stratifying the patients according to the presence of the 25 kDa fragment did not reveal any significant differences in clinical characteristics apart from eGFR. Aside from the 75 kDa fragment, nephrinuria was significantly associated with a loss of eGFR in patients with normoalbuminuria (ACR <=30mg/g). Particularly, the presence of the 25 kDa fragment was associated with a loss in eGFR of 17.29 (95%CI: 6.56-28.01) ml/min/1.73 $m^2$ (P = 0.002). Nephrinuria may therefore provide new clinical insights into renal biology in diabetes even in normoalbuminuric patients who have traditionally been perceived as having a low risk of chronic kidney disease.

**Treatment with Synthetic ACTH in Patients with Idiopathic Membranous Nephropathy and High Risk for Renal Failure** Julia M. Hofstra,[1] Hans S. Brink,[2] Jos J. Van de Kerkhof,[3] Jack F. Wetzels.[1] *[1]Nephrology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [2]Internal Medicine, Medisch Spectrum Twente, Enschede, Netherlands; [3]Internal Medicine, Bernhoven Hospital, Veghel, Netherlands.*

BACKGROUND: Therapy in idiopathic membranous nephropathy remains debated. New therapeutic agents are warranted. Previous studies with synthetic ACTH, in which nephrotic patients with iMN at both low and high risk for renal failure were included, showed remission rates up to 85% and no significant side effects. We conducted a prospective study in patients with iMN and a high risk for renal failure (NCT00694863).

METHODS: Patients with a biopsy proven iMN, a nephrotic syndrome, normal renal function (eGFR > 60 ml/min) and a high risk for progression (based on elevated urinary β2m and IgG levels) were treated with intramuscular injections of synthetic ACTH during 9 months. Maximal treatment dose was 1 mg tetracosactide-hexacetate (Synacthen Depot®) twice a week.

RESULTS: Preliminary results of 14 patients (M/F 11/3, age 52 ±16 yrs, sCr 102 ±20 umol/l, sAlb 23 ±6 g/L, proteinuria 11.7 ±5.5 g/day) who have completed the study so far are presented here. Twelve patients completed treatment; in 1 patient treatment was changed because of progressive renal failure, in another patient ACTH was stopped because of side effects. During follow-up renal function was stable in all but 1 patient. Proteinuria decreased with median 84% (range 29-96%), with 7 patients (50%) reaching proteinuria <2 g/day. No patient reached a complete remission. At the end of follow up (median 13 months, range 10-21) 3 out of 4 patients with a remission and follow-up >3 months after end of treatment had experienced a relapse.

CONCLUSION: Treatment with synthetic ACTH induced significant reduction of proteinuria in high risk patients with iMN. However, sustained remission was induced in only a minority of patients. These preliminary data suggest that synthetical ACTH has limited value in the treatment of high risk patients with iMN.

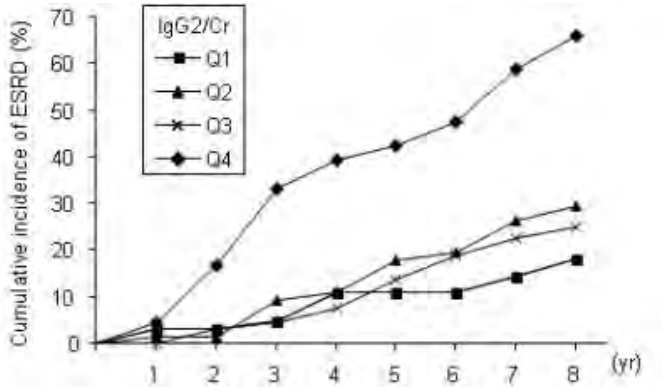
## SA-PO2481

**Urinary Excretion of Immunoglobulin Classes and Progression to End-Stage Renal Disease (ESRD) in Patients with Type 1 Diabetes (T1D) and Proteinuria (PT)** Tomohito Gohda, William Walker, Jan Skupien, James Warram, Andrzej S. Krolewski, Monika A. Niewczas. *Research Division, Joslin Diabetes Center, Boston, MA.*

Elevated urinary albumin excretion is a hallmark of diabetic nephropathy (DN). Some data suggest that albumin does not display a toxic effect on tubular cells. Therefore the aim of this study was to evaluate whether urinary excretion of proteins different in size and charge, classes of immunoglobulins, may predict ESRD in patients with T1D and PT. Urinary concentrations of total protein, albumin and immunoglobulins (IgG1-4, IgA, IgM), were measured at baseline using nephelometry and Luminex based-immunoassay, respectively. Total of 312 patients with T1D and PT at baseline were followed for median 5.8 yr. At entry median proteinuria was 1567 mg/g creatinine and median eGFR was 62 ml/min/1.73m². During follow-up 126 patients (40%) reached ESRD. Baseline concentrations of all immunoglobulins, albumin and total protein were significantly higher in patients who progressed to ESRD compared to those who still had functioning kidneys. In Cox analysis controlled for clinical covariates, including eGFR and AER, high concentrations of IgG2 (quartile 4 vs quartile 1-3) remained significant predictors of ESRD (hazard ratio, 95% CI, 2.3,1.5-3.8).



Spearman correlations among all proteins at baseline were statistically significant. Interestingly, all proteins also correlated strongly with urinary markers of inflammation (IL8, MCP1, IP10, IL6) and MMPs. In conclusion, increase in urinary excretion of immunoglobulins predicts progression to ESRD in subjects with T1D and proteinuria. The effect of IgG2 on this outcome was independent from AER and GFR. Our data suggest that impairment of filtration barrier as well as inflammatory processes, distinct for different proteins, might contribute to the progression of DN. This research was supported by JDRF.

## SA-PO2482

**Increased Platelet-Leukocyte Aggregation in Diabetic Patients with Chronic Kidney Disease (CKD) Stages 3-4** Tora C. Almquist,[1,2] Stefan H. Jacobson,[2] Per-Eric Lins,[3] Paul Hjemdahl.[1] *[1]Dept of Medicine, Clinical Pharmacology Unit, Karolinska University Hospital (Solna), Stockholm, Sweden; [2]Dept of Nephrology, Danderyd Hospital, Stockholm, Sweden; [3]Dept of Medicine, Diabetology Unit, Danderyd Hospital, Stockholm, Sweden.*

Diabetes mellitus (DM) is associated with hyperreactive platelets and increased platelet-leukocyte cross-talk, but the impact of concomitant renal dysfunction, i.e. diabetic nephropathy, has been much less studied. Platelets interact with coagulation, endothelial function and inflammation, and have a central role in the pathophysiology of atherosclerosis and thrombosis. Platelet- and leukocyte activation may contribute to the high risk of suffering atherosclerotic cardiovascular disease in patients with DM and chronic kidney disease (CKD).

Platelet- and leukocyte function, and platelet-leukocyte aggregation was evaluated in 18 DM patients with CKD stages 3-4 (estimated glomerular filtration rate (eGFR) 15-59 ml/min x1.73 m² (mean 41±14 ml/min) and in 21 DM patients with eGFR >75 ml/min x 1.73 m² (mean 87±11 ml/min), using whole blood flow cytometry.

Platelet-leukocyte aggregation (PLA) was significantly higher in patients with CKD 3-4 both in resting samples (4.9±2.2% vs. 3.4±1.7%; p=0.02) and in samples stimulated with a Collagen-Related Peptide (CRP) (53.4±5.1% vs. 46.4±11.0%; p=0.02). There was no significant difference in platelet activity between the two groups, measured as platelet P-selectin expression in unstimulated samples, or adenosine diphosphate (ADP), thrombin or CRP- induced platelet P-selectin expression or as basal or stimulated PAC-1 binding (activated fibrinogen receptor). Leukocyte activation, assessed as expression of leukocyte CD11b, tended to be higher on monocytes in unstimulated samples, in patients with CKD 3-4 (MFI 2.0 ±0.3 vs.1.8±0.4; p<0.1).

We conclude that patients with DM and CKD stages 3-4 have signs of increased platelet-leukocyte aggregation compared to DM patients with eGFR>75 ml/min. This may contribute to an increased cardiovascular risk.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2483

**Excess Urinary Excretion of Protein Glycation Adducts Predict Subsequent Early GFR Loss in Type 1 Diabetes** Bruce A. Perkins,[1] Naila Rabbani,[2] Andrew J. Weston,[2] Adaikalakoteswari Antonysunil,[2] Linda Hanna Ficociello,[3] Monika A. Niewczas,[3] James Warram,[3] Andrzej S. Krolewski,[3] Paul Thornalley.[2] *[1]University of Toronto; [2]University of Essex; [3]Joslin Diabetes Center.*

Although protein glycation is implicated in onset of microalbuminuria (MA) in type 1 diabetes, its role in the etiology of *'early GFR loss'* is unknown. Among 86 patients with normal GFR and new onset MA followed for 12 years in the First Joslin Kidney Study, we selected 22 cases of early GFR loss, defined by change in $GFR_{CYSTATIN\ C}$ exceeding -3.3 percent per year and 33 stable GFR controls. For comparison, we selected 30 contemporaneous controls with normoalbuminuria (NA) and stable GFR. Quantification of eight glycation free adducts was made by liquid chromatography-tandem mass spectrometry in baseline urine and plasma ultrafiltrate. The 55 subjects with new onset MA had similar characteristics and baseline GFR regardless of subsequent stable GFR or early GFR loss. The levels of most (7 of 8) adducts were incrementally the same or lower in the NA, MA-stable GFR, and MA-early GFR loss groups, respectively. However, urinary fractional excretion was highest in early GFR loss for the majority (5 of the 8) adducts.

Fractional Excretion (median Values) of Glycation Adducts

| | NA (n=30) | MA-Stable GFR (n=33) | MA-Early GFR Loss (n-22) | P Multi-Variate* |
|---|---|---|---|---|
| N-frutosyl-lysine | 1.00 | 1.00 | 2.04 | 0.04 |
| N-carboxymethyl-lysine | 0.30 | 0.32 | 0.52 | 0.01 |
| N-Carboxyethyl-lysine | 0.26 | 0.23 | 0.42 | 0.007 |
| Pentosidine | 0.087 | 0.72 | 1.09 | <0.001 |
| Glyoxal-Derived | 0.31 | 0.097 | 0.18 | NS |
| Methyldlyoxal-derived | 1.14 | 0.82 | 1.82 | NS |
| 3-deoxyglucosone-derived | 0.15 | 0.13 | 0.20 | NS |
| N-carboxymethylarginine | 0.043 | 0.18 | 0.32 | <0.0001 |

* adjusted for albumin excretion rate and A1c

Increased fractional excretion - not circulating levels - of glycation free adducts were independently associated with subsequent risk of early GFR loss. This "superexcretion" phenotype may be etiologically related to and serve as a biomarker for early GFR loss.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2484

**Proteinuria in Type 2 Diabetic Patients with Renal Impairment: The Changing Face of Diabetic Nephropathy** David K. Packham, Sara Ivory, Anne T. Reutens, Rory Wolfe, Richard D. Rohde, Hiddo Jan Lambers Heerspink, Jamie P. Dwyer, Robert C. Atkins, Julia Lewis. *Collaborative Study Group.*

Aim

To investigate whether traditional clinical paradigm of type 2 diabetic nephropathy (type 2 DN) has been influenced by widespread use of angiotensin converting enzyme inhibitors (ACEi) or angiotensin receptor blockers (ARBs) and to establish whether patients with lower initial PCR have a better short term renal prognosis.

Background

Type 2 DN patients who progress to end stage renal disease (ESRD) traditionally develop significant proteinuria prior to the development of renal impairment. The effect of the widespread use of ACEi or ARBs on this clinical paradigm has not been established.

Methods

2303 patients enrolled in the Sulodexide Overt Nephropathy Study (OVERT) were analysed. Incidence of renal impairment with and without significant proteinuria was established and comparison made between groups. Follow up data on randomized patients for those with urinary protein creatinine ratio (PCR) <1000mg/g at screening was compared with those with PCR ≥1000 mg/g.

Results

Twenty two percent had significant renal impairment with a PCR at screening of <500mg/g. Therapy with ACEi and/or ARBs at the time of screening was recorded in 94%, where prior medication data was available. Randomised patients who had screening PCR < 1000mg/g had an annualized incidence rate of ESRD 0.5%, less than one tenth of those with screening PCR > 1000mg/g (5.4%).

Conclusions

In patients with type 2 DN and moderately severe renal impairment, low levels of proteinuria are found in over one fifth of patients. This suggests an effect of the widespread usage of ACEi or ARBs on the traditional clinical paradigm of type 2 DN.

Patients with an initial screening PCR <1000mg/g appear to have a better long-term prognosis than those with PCR ≥1000mg/g.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2485

**Progression of Diabetic Kidney Disease in Type 1 and Type 2 Diabetic Patients** Nobue Tanaka, Tetsuya Babazono, Yasuhiko Iwamoto. *Diabetes Center, Tokyo Women's Medical University, Tokyo, Japan.*

The impact of type of diabetes (type 1 or type 2) on the progression of diabetic kidney disease is not well known. We therefore conducted this observational cohort study to evaluate the differences in the decline in glomerular filtration rate (GFR) and progression of albuminuria between type 1 and type 2 diabetic patients.

A total of 3,856 adult patients with diabetes were recruited into this study between 2003 and 2005, including 693 patients with type 1 (mean [± SD]; 38 ± 12 years) and 3,163 patients with type 2 diabetes (60 ± 12 years). Albuminuria was assessed based on albumin-to-creatinine ratio (ACR), and classified into normoalbuminuria (n=2,664), microalbuminuria (n=824), and macroalbuminuria (n=368). The rate of change in estimated GFR (eGFR) was determined by regression analysis with eGFR as a function of time, and was compared by means of analysis of covariance, adjusting for age, sex, blood pressure, duration of diabetes, eGFR at baseline, ACR, hemoglobin, HbA1c and total cholesterol. Cumulative incidence of transition from any stage to a more advanced stage of albuminuria was estimated using the Kaplan-Meier method.

eGFRs (mL/min/1.73 m²) at baseline were 88.0 ± 20.2 for type 1 and 74.8 ± 20.8 for type 2 diabetic patients (p<0.001). Patients were followed-up for 4.5 ± 0.8 years. The mean rates of change in eGFR (%/year), after adjustment for clinical parameters, were -0.97 ± 0.16 for type 1 and -1.09 ± 0.08 for type 2 in normoalbuminuric patients ($p$=0.53, ANCOVA), -2.56 ± 0.55 and -2.82 ± 0.16 in microalbuminuric patients ($p$=0.66), and -9.36 ± 1.78 and -9.94 ±0.50 in macroalbuminuric patients ($p$=0.76), respectively. In Kaplan-Meier method, the incidence of microalbuminuria was significantly higher in type 2 than type 1 diabetic patients (log-rank test p<0.001). There was no difference, however, in the progression to macroalbuminuria from microalbuminuria (log-rank; p=0.419).

In conclusion, this longitudinal study suggests that, while the decline in kidney function is similar in type 1 and type 2 diabetic patients in each stage of albuminuria, the incidence of microalbuminuria is likely to be higher in type 2 diabetic patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2486**

**Which Level of $HbA_{1c}$ Is Appropriate for Prevention of ESRD in Diabetes?**
Sewon Oh,[1] Ho Seok Koo,[2] Kook-Hwan Oh,[2] Ki Young Na,[1] Kwon Wook Joo,[2] Chun-Soo Lim,[2] Yon Su Kim,[2] Dong Wan Chae,[1] Curie Ahn,[2] Jin Suk Han,[2] Suhnggwon Kim,[2] Ho Jun Chin.[1] *[1]Department of Internal Medicine, Seoul National University Bundang Hospital, Kyeong-Kido, Democratic Peoples Republic of Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Democratic Peoples Republic of Korea.*

**Background** : Diabetes mellitus (DM) is a common cause of end stage renal disease (ESRD). The KDOQI guidelines recommend glycated hemoglobin ($HbA_{1c}$) should be lower than 7.0% to reduce the rate of decrease in glomerular filtration rate (GFR). However, it is controversial whether tighter glycemic control is associated with better clinical outcomes. We assessed the relationship between ESRD and the $HbA_{1c}$ and the association between all cause mortality and $HbA_{1c}$ in patients with DM.

**Methods:** A cohort of patients aged 25 years and older who had treated for DM were generated from Seoul National University Bundang Hospital (SNUBH) database from January 2004 to December 2004. We identified 4494 patients and classified patients into four groups by the first measured $HbA_{1c}$ in 2004 ($HbA_{1c}$ <6.5%, 6.5-7.5%, 7.6-8.5% and >8.5%). We obtained data from SNUBH electronic resources to search for medical history by International Classification of Disease (ICD)-10 code and medication history in 2004 by Anatomical Therapeutic Chemical Cassificatio System (ATC) code. Age, sex, cholesterol, blood pressure, GFR, medication history, cardiovascular disease, cancer and the duration of DM were identified as confounding factors, and cox survival models were adjusted for these factors.

**Results:** Ninety one patients developed ESRD during 63 months of mean follow up period. The observed event rates were 1.3%, 1.8%, 2.4% and 3.1% in $HbA_{1c}$ <6.5%, 6.5-7.5%, 7.6-8.5%, and >8.5% group, respectively. The cumulative renal survival benefit was observed in the lowest $HbA_{1c}$ group. Compared with the lowest $HbA_{1c}$ group with the lowest hazard, the adjusted hazard ratio of ESRD in $HbA_{1c}$ 6.5-7.5 % group was 2.93, $HbA_{1c}$ 7.6-8.5 % group was 4.44 and $HbA_{1c}$>8.5 % group was 4.51. All cause mortality was not associated with $HbA_{1c}$.

**Conclusions:** Lowered $HbA_{1c}$ value to 6.5% was associated with reduced development of ESRD.

**Vitamin D Levels and Asymptomatic Coronary Artery Disease in Type 2 Diabetic Patients with Elevated Urinary Albumin Excretion Rate**
Christel Joergensen,[1] Henrik Reinhard,[1] Anne Schmedes,[2] Peter R. Hansen,[3] Niels Wiinberg,[4] Claus Leth Petersen,[4] Kaj Winther,[8] Hans-Henrik Parving,[5] Peter Karl Jacobsen,[7] Peter Rossing.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Dept. of Clinical Biochemistry, Lillebaelt Hospital, Vejle, Denmark; [3]Dept. of Cardiology, Gentofte University Hospital, Denmark; [4]Dept. of Clinical Physiology and Nuclear Medicine, Frederiksberg University Hospital, Denmark; [5]Dept. of Medical Endocrinology, Copenhagen University Hospital, Rigshospitalet, Denmark; [6]The Heart Centre, Copenhagen University Hospital, Rigshospitalet, Denmark; [7]Dept. of Clinical Biochemistry, Frederiksberg University Hospital, Denmark.*

***Aims*** Severe vitamin D deficiency has been shown to predict cardiovascular mortality in type 2 diabetic patients. We investigated the association between severe vitamin D deficiency and asymptomatic Coronary artery disease (CAD) as well as coronary calcium score (CCS) in type 2 diabetic patients with urinary albumin excretion rate (UAER) > 30mg/24h.

***Methods*** A cross sectional study including 200 type 2 diabetic patients without clinical signs of CAD. Severe vitamin D deficiency was defined as p-25OHD < 12.5nmol/l. Patients with p-NT-proBNP > 45.2ng/L and/or CCS > 400 were stratified as high risk patients of CAD (n=133). High risk patients were examined by myocardial perfusion imaging (MPI; n=109), and/or CT-angiography (CTA; n=20), and/or coronary angiography (CAG; n=86).

***Results*** Median (range) vitamin D level was 36.9 (3.8-118.6)nmol/l. The prevalence of severe vitamin D deficiency was 9.5% (19/200). In 70 (35%) patients, significant CAD was demonstrated by MPI and/or CAG.

Severe vitamin D deficiency was associated with asymptomatic CAD, odds ratio (OR) [95% CI] 2.2 [0.9-5.8]. After adjusting for additional risk factors, OR was 5.0 [1.3-19.5]. The prevalence of CCS > 400 was 34% (68/200). Severe vitamin D deficiency was associated with CCS>400, OR 4.3 [1.5-12.1]. The association persisted after adjusting for additional risk factors, OR 4.0 [1.2-13.1].

***Conclusion*** In high risk type 2 diabetic patients with elevated UAER, low levels of vitamin D are strongly and independently associated with asymptomatic CAD.

**Urine Metabalomic Profile of Diabetic Nephropathy**
Anna V. Mathew,[1] Satish P. Ramachandrarao,[1] Joachim H. Ix,[2] Ronghui Xu,[3] Bruce A. Barshop,[4] Robert K. Naviaux,[4] Kumar Sharma.[1] *[1]Center for Renal Translational Medicine, University of California San Diego; [2]Department of Nephrology, University of California San Diego; [3]Department of Mathematics, University of California San Diego; [4]Mitochondrial and Metabolic Disease Center, University of Califonia San Diego, La Jolla, CA.*

We studied the urine metabolite profile of diabetic patients with kidney disease to help identify organic acid derangements that can serve as biomarkers.

**Methods:** Our study included 14 patients with diabetic kidney disease (eGFR 31.79±7.329)**(DN)**. This population was compared to a control of 23 healthy volunteers with no diabetes or kidney disease. The control group contained 6 (26%) and the DN group contained 5 (35%) females. 24 hour urine was collected from both groups. A composite quantitative urine organic acid estimation was done using the Agilent 5973 GC/MS. 76 different organic acids were looked at per sample and the results were standardized per mmol of creatinine. We compared the 2 groups for each of the 76 metabolites and found 11 significant metabolites using the unpaired t-test. We chose a cut off of P <0.00846 to have an estimated false discovery rate <0.05. Glomerular filtration rate (GFR), albumin creatinine ratio (ACR) of the DN group were then correlated to the 11 significant metabolites using linear regression analysis**.**

**Results:** We found that glycolic acid, 3OH isobutyric acid, 3OH isovaleric acid, aconitic acid, homovanillic acid, succinic acid, citric acid, uracil and glutaric acid were significantly decreased in the DN group. 5OH hexanoic acid was significantly increased in the DN group when compared to the controls. Of these metabolites, only citric acid ($r^2$=0.4755) negatively correlated and 3OH isovaleric acid levels ($r^2$=0.4755) positively correlated to ACR but not to GFR.

**Conclusion:** We found that the organic acid profile of urine from DN patients to be significantly decreased in metabolites related to the mitochondrial intermediary metabolism. This finding will be validated in a larger patient population and hopefully will lead to identification of biomarker profiles that provide more information than GFR in these patients.

**Greater Frequency of End Stage Renal Disease Than Cardiovascular Mortality in Proteinuric Type 2 Diabetic Nephropathy: Results from the DIAMETRIC Database**
David K. Packham, Tahira P. Alves, Jamie P. Dwyer, Robert C. Atkins, Dick De Zeeuw, Shahnaz Shahinfar, Julia Lewis, Hiddo Jan Lambers Heerspink. *Clinical Pharmacology, University Medical Centre, Groningen, Netherlands.*

Aim

To investigate comparative incidence of cardiovascular death (CVD) versus progression to end stage renal disease (ESRD) in a cohort of proteinuric type 2 diabetic patients with renal impairment.

Background

Previous studies have demonstrated that patients with chronic kidney disease (including diabetic nephropathy) are more likely to die from cardiovascular disease than ESRD. This study was conducted to determine whether ESRD is a more common primary outcome than CVD in patients with established proteinuric type 2 diabetic nephropathy (type 2 DN) and renal impairment.

Methods

Data on 3228 adult patients with type 2 DN from the IDNT and RENAAL trials were combined to establish the Diabetes Mellitus Treatment for Renal Insufficiency Consortium (DIAMETRIC) database. The incidence rate of ESRD was compared with CVD and all cause mortality (ACM) in the overall population and in subgroup analysis.

Results

Mean follow up was 2.8 years. A total of 19.5% of patients developed ESRD, roughly five times the incidence of CVD and three times the incidence of ACM. ESRD was more common than CVD in all subgroups analysed with the exception of subjects with low levels of albuminuria and well preserved levels of renal function at baseline.

Conclusions

Patients with type 2 DN, characterized by renal impairment and significant proteinuria, are more likely to reach ESRD than die. Given the rapidly increasing number of cases of type 2 diabetes worldwide, this has implications for predicting the future renal replacement therapy (RRT) requirements.

Disclosure of Financial Relationships: nothing to disclose

**Effect of Oral Cholecalciferol (Vitamin $D_3$) on Proteinuria and Cytokines in Type 2 Diabetic Patients with Chronic Kidney Disease (CKD)**
Min Jeong Kim,[1] Andrew H. Frankel,[1] Mandy Donaldson,[2] Sarah J. Darch,[2] Charles D. Pusey,[1] Frederick W. K. Tam.[1] *[1]Kidney and Transplant Institute, Hammersmith Hospital, Imperial College London; [2]Clinical Biochemistry, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: Anti-inflammatory effects of active vitamin D have been demonstrated *in vitro* as well as *in vivo*. Growing evidence indicates that active vitamin D analogues may have anti-proteinuric and renoprotective effects in CKD patients. However, it remains

unclear, if treatment with inactive vitamin D can achieve similar effects. In a prospective study, the effect of cholecalciferol on proteinuria and urinary cytokines were investigated in type 2 diabetic patients.

Methods: Type 2 diabetic patients with CKD stage 2-4 attending the Hammersmith Hospital renal outpatient clinic were enrolled in a prospective study. Patients taking vitamin D analogues were not eligible. Serum 25(OH)D and $1,25(OH)_2D$, and urinary albumin-creatinine ratio (ACR), monocyte chemoattractant protein-1 (MCP-1) and transforming growth factor-β1 (TGF-β1) were measured. Patients with insufficient levels of 25(OH)D (< 80 nmol/L) were treated with cholecalciferol according to the hospital standard management guidelines and monitored at 2 and 4 months.

Results: From 67 enrolled patients, 54 patients with insufficient 25(OH)D were treated and 45 patients were monitored at 2-month follow-up. Serum 25(OH)D and $1,25(OH)_2D$ increased from 38.5 nmol/L (median; interquartile range 22-47.5) to 95 (85 – 123) and 20.2 pg/mL (13.6 – 32.5) to 48.9 (38.1 – 66.4) ($p < 0.0001$) respectively. ACR decreased from 13 mg/mmol (4.1 – 89.3) to 10.7 (2.7 – 53.8) ($p= 0.0042$). All patients except 3 were on RAS inhibition at the enrolment. Blood pressure and eGFR were stable. No significant changes of urinary MCP-1/creatinine ratio (10.6 ng/mmol (7.1 – 22.2) to 11.7 (6.9 – 19.7)) and TGF-β1/creatinine ratio (34.1 (16.9 – 56.2) to 17.9 (9.3 – 47.4)) were observed. No adverse effect was observed.

Conclusions: This is the first report showing a potential anti-proteinuric effect of cholecalciferol in type 2 diabetic patients. There was a trend of reduction in urinary TGFβ1. The ongoing follow-up data will clarify the results.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2491

**Impaired Renal Function Modifies the Risk of Severe Hypoglycemia among Users of Insulin but Not Glyburide: A Nested Case-Control Study** Matthew A. Weir,[1] Tara Gomes,[2] Muhammad Mamdani,[2,3,4] David N. Juurlink,[2,3] Daniel G. Hackam,[5,6] Arsh Jain,[1] Amit X. Garg.[1,2,6] *[1]Medicine, Division of Nephrology, University of Western Ontario, London, ON, Canada; [2]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; [3]Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada; [4]Applied Health Research Center, Li Ka Shing Knowledge Institute, Toronto, ON, Canada; [5]Clinical Pharmacology, University of Western Ontario, London, ON, Canada; [6]Epidemiology and Biostatistics, University of Western Ontario, London, ON, Canada.*

Background: Little evidence justifies the avoidance of glyburide in patients with impaired renal function. We aimed to determine if renal function modifies the risk of hypoglycemia among patients using glyburide.

Methods: We conducted a nested case-control study using administrative records and laboratory data from Ontario, Canada. We included outpatients 66 years of age and older with diabetes mellitus and prescriptions for glyburide, insulin or metformin. We ascertained hypoglycemic events using administrative records and we estimated glomerular filtration rates (eGFR) using serum creatinine concentrations.

Results: From a cohort of 19,620 patients, we identified 204 cases whose eGFR was ≥ 60 ml/min/1.73m2 (normal renal function) and 354 cases whose eGFR was < 60 ml/min/1.73m2 (impaired renal function). Compared to metformin, glyburide associated with a greater risk of hypoglycemia in patients with both normal (adjusted OR 9.0, 95% CI 4.9 to 16.4) and impaired renal function (adjusted OR 6.0, 95% CI 3.8 to 9.5). We observed a similar relationship when comparing insulin to metformin; the risk was greater in patients with normal renal function (adjusted OR 18.7, 95% CI 10.5 to 33.5) compared to those with impaired renal function (adjusted OR 7.9, 95% CI 5.0 to 12.4). Tests of interaction showed that among glyburide users renal function did not significantly modify the risk of hypoglycemia, but among insulin users, impaired renal function associated with a lower risk.

Conclusions: In this population-based study, impaired renal function did not augment the risk of hypoglycemia associated with glyburide use.

Disclosure of Financial Relationships: nothing to disclose

**Gene Expression Profiles in Human Proximal Tubular Cells (PTC) Exposed to Urines from Patients with Type 1 Diabetes (T1D) and Early GFR Loss** Bozena Krolewski,[1] Krzysztof Wanic,[1,2] Monika A. Niewczas,[1,3,4] William Walker,[1] James Warram,[1] Andrzej S. Krolewski.[1,3] *[1]Research Division, Joslin Diabetes Center, Boston, MA; [2]Metabolic Research Unit, Department of Endocrinology, St. James's Hosital, Trinity College, Dublin, Ireland; [3]Department of Medicine, Harvard Medical School, Boston, MA; [4]Department of Immunology, Transplantology and Internal Diseases, Medical University of Warsaw, Poland.*

The goal of our study was to identify novel genes possibly involved in the development of early GFR loss in patients with T1D and microalbuminuria. We hypothesize that development of an early GFR loss may be initiated by toxic protein(s) and/or growth factors present in urines of these patients possibly inducing proximal tubular cell damage.

In our in vitro experiments, human immortalized PTC (HK-2) cells were exposed to pooled concentrated (2x), endotoxin-free urines collected from two groups of T1D patients with microalbuminuria who were followed for 4-8 years and during that follow-up had either early GFR loss or stable renal function. At baseline, when urine specimens were collected, all patients had normal GFR and similar elevated urinary albumin excretion.

Following 6 hrs exposure to the pooled urines, RNA was extracted from cells and genome-wide expression profiles were examined using Ilumina Sentrix Beadchip Array (Human-8V2) in two experiments and a pattern of expression of specific genes was confirmed in the third experiment by qPCR. In each experiment urines from different sets of patients were used. In the analysis, we used the fold change criterion <0.77or > 1.3. Interestingly in all three experiments, we found that urines obtained from patients who were at high risk of early GFR loss induced significant changes in expression of four distinctive inflammatory genes: *IL8, CSF2, MAPK6* (all up-regulated) and *LRRF1PI* (down-regulated) (False Discovery Rate < 0.0001).

All these genes (members of inflammatory pathways) are mechanistically closely related, most likely causing damage to PTC cells. These preliminary data could possibly help to identify and characterize novel therapeutic target(s) for intervention to prevent the early GFR loss in T1D patients.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2493

**Serum Fructosamine (SF), but Not Glycosylated Hemoglobin (A1c), Predicts Survival in Diabetic Hemodialysis (HD) Patients (pts)** Neal Mittman, Brinda Desiraju, Hitesh Kapupara, Jyotiprakas Chattopadhyay, Morrell M. Avram. *Avram Division of Nephrology, Long Island College Hospital, Brooklyn, NY.*

Diabetes is the most common cause of end-stage renal disease and an important risk factor for morbidity and mortality in dialysis patients. We and others have suggested that glycosylated hemoglobin (A1c) may not be a reliable measure of glycemic control in dialysis patients, and therefore have explored the use of serum fructosamine (SF) as an alternative marker. We recently reported that albumin-corrected fructosamine (AlbF), but not HbA1c, is associated with morbidity (hospitalizations and infections) in diabetic HD pts. The objective of this study was to investigate the prognostic importance of enrollment SF on survival. We enrolled 100 diabetic HD pts and followed them prospectively for up to 5 1/2 years. Demographics, clinical, biochemical and outcome data were recorded. The mean age was 63 years. Fifty percent were women and the majority were African-Americans (72%). SF values were corrected for the variations in the concentration of serum albumin (AlbF) (method of Lamb et al., 1993). Mean values for SF and AlbF were 373 µmol/l (range: 243-618 µmol/l) and 973 µmol/g (range: 607–1994 µmol/g), respectively. During the study period, 44 pts (44%) expired. Pts who died during the study had significantly higher AlbF (1025 vs. 911, p=0.033) compared to those who survived. Using Cox's multivariate regression analysis, adjusting for age, race, gender and months on dialysis at enrollment, AlbF was a significant independent predictor of mortality (Relative Risk=1.002, p=0.011) in these diabetic HD pts. In contrast, A1c did not predict mortality (p=0.15) in this population.

Predictors of Mortality in HD: Cox's Multivariate analysis

| Variable | Relative Risk | p |
|---|---|---|
| Age (years) | 1.033 | 0.066 |
| Gender (Male vs. Female) | 1.166 | 0.85 |
| Race (AA vs. others) | 0.62 | 0.16 |
| AlbF (µmol/g) | 1.001 | 0.031 |

AA= African American

In conclusion, AlbF, but not A1c, the most commonly utilized measure of glycemic control, predicts long-term survival as well as morbidity in diabetic HD pts.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2494

**Residual Proteinuria and eGFR Predict Progression of Renal Impairment within 2 Years in Type 2 Diabetic Patients with Established Proteinuria and Renal Impairment Who Have Received Irbesartan for a Minimum of 3 Months** David K. Packham, Sara Ivory, Rory Wolfe, Anne T. Reutens, Richard D. Rohde, Julia Lewis, Robert C. Atkins. *Collaborative Study Group, Chicago, IL.*

Aim

To investigate whether residual urinary proteinuria (UPr) and estimated glomerular filtration rate (egfr) predict incidence of significant progression of renal impairment in patients with established type 2 diabetic nephropathy (type 2 dn) already receiving full dose angiotensin receptor blocker (ARB) therapy.

Background

Both UPr and egfr are established predictors of progression in type 2 dn patients with established proteinuric renal impairment and ARBs have been shown to significantly improve their renal prognosis. The relative significance and interaction between UPr and egfr in patients already receiving a maximal dose of ARB before measurement of these predictors is yet to be established.

Methods

1,278 patients with type 2 diabetic nephropathy and moderate proteinuric renal impairment were analysed retrospectively, 413 from the Irbesartan Diabetic Nephropathy Trial and 885 from the Sulodexide Overt Nephropathy Study. Patients had received irbesartan 300mg daily, or a maximum tolerated dose, for at least 3 months. A significant renal event was defined as end stage renal failure, a doubling of baseline creatinine or a creatinine > 6 mg/l. Survival analysis was used to provide estimates of 24 month absolute risk for nine categories in a 3x3 matrix for levels of UPr and eGFR.

Results

UPR and egfr were strongly related to risk of significant progression of renal failure. The interaction between eGFR category and proteinuria category was not statistically significant.

eGFR PCR
<1000 1000-<2000 2000+
45 - <60 0.00% 3.1% 10.7%
30 - <45 6.7% 4.0% 21.4%
15 - <30 7.0% 12.9% 45.2%

Conclusions

Patients with type 2 dn and moderately severe proteinuric renal impairment already stabilized on ARB, have increased risk of renal events with increasing proteinuria and decreasing eGFR over the medium term. Awareness of the wide variation in incidence among subgroups is of value in clinical management and the design of clinical trials.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2495**

**Lack of Racial/Ethnic Differences in the Progression of Nephropathy in a Hypertensive Diabetic Population** Raymond Estacio,[1,2] Brenda Beaty,[2] Rebecca Hanratty,[1,2] Michel B. Chonchol.[2] *[1]General Internal Medicine, Denver Health, Denver, CO; [2]University of Colorado Denver, Denver, CO.*

Purpose: We examined the relationship of race and ethnicity, glycemic and blood pressure control on the occurrence or progression of diabetic nephropathy.

Methods: A retrospective cohort study of diabetic patients with hypertension in a safety-net community health system in Denver, Colorado. A total of 923 type 2 diabetic patients with concurrent measures of systolic blood pressure (SBP), hemoglobin A1c (HbA1c), and urinary albumin/creatinine ratio (ACR) were included. We evaluated the relationship of selected sociodemographic and clinical factors on the change in $\log_{10}$ (ACR). Mixed effects longitudinal models to partition between and within patient effects of SBP and HbA1c on log (ACR) over time were utilized

Results: The mean follow-up period was 47.3 ± 23.9 months. Analyses were adjusted for age, gender, race/ethnicity, insurance status, history of vascular disease, time between diabetes diagnosis and ACR measurement, and baseline estimated glomerular filtration rate. Higher baseline HbA1c and SBP were associated with higher baseline $\log_{10}$(ACR) values in the whole population ($p<0.001$ for both). No differences in the $\log_{10}$(ACR) were seen when comparing African Americans and Hispanics with non-Hispanic whites. Analyses with SBP and HbA1c as time-varying covariates and complete partitioning of between and within patient effects demonstrated that a decline in SBP and in HbA1c were independently associated with a decline in $\log_{10}$(ACR) ($p<0.0001$ for both), after adjusting for patients' overall SBP and HbA1c levels and level of albuminuria.

Conclusion: In a population of hypertensive diabetic patients, race and ethnicity was not associated with the progression of diabetic nephropathy. The current findings suggest that any improvement of BP and glycemic control no matter the overall level of control or albuminuria is independently associated with improvement of diabetic nephropathy.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2496**

**Glycated Albumin as an Indicator of Glycemic Control in Predialysis Diabetic Nephropathy Patients** Hyeong Cheon Park,[1] Sung Jin Moon,[1] Jung Eun Lee,[2] Sung Chang Bae,[1] Sung-Kyu Ha.[1] *[1]Internal Medicine, Gangnam Severance Hospital, Seoul, Korea; [2]Internal Medicine, Yongin Severance Hospital, Yongin, Korea.*

Glycated albumin (GA) has been proposed to better reflect glycemic control in diabetic hemodialysis patients. We assessed the usefulness of GA as a parameter of glycemic control in predialysis diabetic nephropathy patients.

A total of 499 diabetic patients (296 men, mean age 61.6 ± 12.5 years) were enrolled in this cross-sectional study. Parameters of glycemic control (mean glucose, HbA1C, and GA) were investigated along with other biochemical and clinical parameters.

The patient distribution according to CKD stages from 1 to 5 were 51, 116, 115, 35, and 182, respectively. When CKD 5 was compared to CKD 1, the mean glucose level was significantly higher (179±60 vs. 158±43 mg/dL, $p<0.02$) whereas HbA1c was much lower (7.3±1.3% vs. 8.4±1.8%, $p<0.001$) in CKD 5. The slope of the regression line between mean glucose and HbA1C was more shallow (CKD 1: beta=0.027 vs. CKD 5: beta= 0.007, $p<0.001$), and the GA/HbA1C ratio was significantly increased (CKD 1: 2.58 vs CKD 5: 3.84, $p<0.001$) in CKD 5 patients. However, no significant differences in the relationship between GA and mean glucose were observed between CKD 1 and 5. HbA1C in CKD 5 was negatively associated with weekly erythropoietin dose. In CKD 3 and 4 patients, the GA/HbA1C ratio also showed significant increase compared to CKD 1 (2.9±0.6 and 3.0±0.6, $p<0.001$) and the slopes of the regression lines between mean glucose and HbA1C in CKD 3 and 4 were significantly more shallow compared with CKD 1 (beta: CKD1=0.027, CKD2= 0.020, CKD3= 0.016, CKD4= 0.016, $p<0.05$). However, slopes of the regression lines between mean glucose and GA were comparable among the 4 groups. Multiple linear regression analysis showed that CKD stage 3, 4 status significantly impacted HbA1C, without significant effect on GA. In conclusion, our results suggest that HbA1C underestimate the status of glycemic control even in predialysis diabetic nephropathy patients as well as diabetic hemodialysis patient. The GA, however, may more accurately reflect glycemic control in these predialysis diabetic patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2497**

**Pentoxifylline for Renoprotection in Diabetic Nephropathy: The PREDIAN Study** Juan F. Navarro,[1,2] Carmen Mora,[2] Mercedes Muros,[3] Antonio Rivero,[1] Nieves Del Castillo,[1] Javier García.[1] *[1]Nephrology Service, University Hospital Nuestra Señora de Candelaria (HUNSC); [2]Research Unit, HUNSC; [3]Clinical Biochemistry, HUNSC, Santa Cruz de Tenerife, Spain.*

Diabetic nephropathy (DN) is the main cause of end-stage renal disease (ESRD). Despite renin-angiotensin system (RAS) blockade, a significant proportion of patients progress to ESRD. Pentoxifylline (PTF) posses antiproteinuric and anti-inflammatory effects, suggesting potential renoprotective efficacy. The aim of the Pentoxifylline for Renoprotection in Diabetic Nephropathy (PREDIAN) study is to test the efficacy of PTF addition to RAS blockade on the progression of DN. Here we report the study design and the baseline patient characteristics.

The PREDIAN study is 2-year, investigator-initiated, single-center, prospective, randomized, controlled, clinical trial funded by the Spanish Ministry of Science and Innovation. One-hundred and sixty nine type 2 diabetic patients with chronic kidney disease (CKD) stages 3 and 4 were randomized to a control group (N=87) or an active group (N=82). All patients received angiotensin-convering enzyme inhibitor (ACEI) or angiotensin II receptor blockers (ARB) at the maximal recommended dosage for more that 6 months. Patients in the active group were treated with PTF (1200 mg/day) on top of ACEI or ARB, whereas control subjects continued with RAS blockers. The primary outcome measure was the difference in estimated glomerular filtration rate (eGFR) between the groups at the end of the study. Baseline characteristics of the subjects are: 116 patients (68.6%) stage 3 and 53 (31.3%) stage 4 CKD, age 69±9 years, duration of diabetes 15±3 years, eGFR 37±12 ml/min/1.73m$^2$, albuminuria 1.39±1.16 g/day, blood pressure 142±8/86±8 mmHg. Serum concentrations of inflammatory cytokines (tumor necrosis factor-alpha (TNFa), interleukin-6 (IL-6) and interleukin-10 (IL-10)) and polymorphisms of the coding genes for these molecules (TNFa, –174 G/C; IL-6, –308 G/A; and IL-10, –1082 G/A), and the relationships among these variables with albuminuria and eGFR are studied. In conclusion, the PREDIAN study will provide evidence on the renoprotective benefit of PTF in addition to RAS blockade in DN.

**SA-PO2498**

**Pulse Pressure Predicts All-Cause and Cardiovascular Mortality, Cardiovascular Events and Progression to End Stage Renal Failure in Type 1 Diabetic Patients** Simone Theilade,[1] Maria Lajer,[1] Anders Jorsal,[1] Lise Tarnow,[1] Hans-Henrik Parving,[2] Peter Rossing.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Dept. of Medical Endocrinology, Copenhagen University Hospital, Rigshospitalet, Denmark.*

***Background and Aim***

Patients with diabetes have an elevated risk of early death due to cardiovascular disease (CVD) and development of end stage renal disease (ESRD). The aim of this analysis is to evaluate whether office pulse pressure (PP) (as an estimate of arterial stiffness) predicts mortality, cardiovascular events and progression to ESRD in patients with type 1 diabetes.

***Materials and Methods***

A prospective observational follow-up study including 900 patients with type 1 diabetes (512 men; age 44±11 years (mean±SD) ; duration of diabetes 28±11 years). Of these patients, 458 had diabetic nephropathy (glomerular filtration rate (GFR) 76±34ml/min/1.73 m$^2$) and 442 had persistent normoalbuminuria. The patients were followed for 8(0-13) years (median(range)).

***Results***

During follow-up 178(20%) patients died, of which 109(12%) where CVD deaths and 75 patients (16% of patients with diabetic nephropathy) developed ESRD. Patients with elevated PP had significantly higher all-cause mortality (adjusted HR (per 10 mmHg increase) 1.2(1.1-1.4); $p<0.001$), CVD mortality (adjusted HR 1.3(1.2-1.5); $p<0.001$), non fatal CVD events (adjusted HR 1.2(1.0-1.3); $p=0.01$) and combined fatal and non-fatal CVD (adjusted HR 1.2(1.1-1.3); $p<0.001$), (adjusted for sex, age, duration of diabetes, smoking, diastolic blood pressure, $HbA_{1c}$, cholesterol, UAER, history of CVD and nephropathy status).

In patients with diabetic nephropathy elevated PP was associated with progression to ESRD (adjusted HR (per 10 mmHg increase) 1.2(1.0-1.4); $p=0.048$), (adjusted for sex, age, duration of diabetes, diastolic blood pressure, $HbA_{1c}$, cholesterol and UAER).

***Conclusion/interpretation***

Elevated office PP predicts all-cause and CVD mortality, CVD events and progression to ESRD in patients with type 1 diabetes.

Disclosure of Financial Relationships: nothing to disclose

**Serum Levels of Cleaved and Intact Forms of Tumor Necrosis Factor Receptor 1 (TNFR1) and Early Progressive Renal Function Loss in Patients with Diabetes** William Walker, Monika A. Niewczas, Souphatta Sasorith, Andrzej S. Krolewski. *Joslin Diabetes Center, Boston, MA.*

In diabetes, progressive renal function decline can begin early when patients have microalbuminuria and normal renal function. Recently we have shown that the serum concentration of the soluble TNFR1 protein is an extremely good predictor of this early GFR loss, and subsequent development of ESRD. Also, it has been shown that sTNFR1

exists in two forms in serum: a cleaved 28-kDa form and an intact, full length 55-kDa form. Thus, the goal of this study was to determine which form of the protein is associated with early GFR loss in patients with Type 1 Diabetes.

We chose 79 individuals from the *Second Joslin Kidney Study on the Natural History of Microalbuminuria*. All subjects had microalbuminuria at baseline examination and were followed for 4-6 years to obtain serial measurements of serum cystatin C for tracing the trajectory of GFR loss. Changes over time were summarized as percent change in GFRcystatin per year using a mixed effects model. All patients had GFRcystatin >60 ml/min at entry. During follow-up, the annual percent change in GFRcystatin varied among patients from -32.3 to + 3.7 (median -2.53). Baseline specimens were analyzed using western blots to quantitatively determine the presence of both forms of the protein. These results, combined with ELISA measurements, allowed for calculation of the concentration of each form of the receptor. Simple linear regression analysis of the percent change in GFRcystatin in comparison with six important clinical characteristics (intact and cleaved TNFR1 concentration, HbA1C, AER, baseline GFR, and age) revealed that the only significant predictor of renal function loss is the intact TNFR1 concentration ($p = .0034$). This form of the receptor remains as the only significant contributor when including all six of the covariates in a multiple regression model. More specifically, as the intact TNFR1 concentration increases by quartile, the GFRcystatin decreases at an accelerated rate of 1.41% per year ($p = .02$). In conclusion, these results support the hypothesis that the differing forms of sTNFR1 have distinct effects on renal function loss in patients with T1D.

**Epidemiology of Diabetic Nephropathy in African American Children with Type 2 Diabetes Mellitus** Josefina Sharma, Shirley Shwu-Shiow Chang. *Pediatrics Division of Nephrology, SUNY Downstate Medical Ctr, Brooklyn, NY.*

We conducted a retrospective longitudinal study on the natural course of diabetic nephropathy in African American Children with type 2 diabetes mellitus (T2DM) followed at SUNY Downstate and Kings County Hospital Center from 1999 to 2010. Inclusion criteria consist at least 2 spot urine albumin to Cr (UAC) ratios, at least 6 months of diabetes duration, and childhood onset T2DM. There were 31 subjects (68% F, 32% M; 84% AA, 10% Hispanics, 6% Asians), with diabetes duration 5.0 ± 5.7 years (mean ± 2SD), age of T2DM onset at 13 ± 5 years, initial urinary albumin excretion (UAE) status (74% were normoalbuminuric, 26% microalbuminuric). Clinical characteristics are as follows: BMI 33.3 (20.9-50.9) kg/m$^2$ [median (range)], mean BP 88 (80-107) mmHg, HbA1c 9.3 ± 6.5%, serum Cr 0.75 ± 0.29 mg/dL with eGFR by Schwartz 137 ± 39 mL/min/1.73m$^2$, spot UAC 5.6 (0.01-190.9) mg/gram, cholesterol 169 ± 73 mg/dL, triglycerides 113 ± 91 mg/dl, HDL 45 (34-88) mg/dL, LDL 100 ± 70 mg/dL. After follow-up of 3.6 ± 5.8 years, 87 % of all subjects with initial UAC in the normoalbuminuric range remained normoalbuminuric, 8.7 % developed microalbuminuria, and 4.3% progressed to macroalbuminuria. Of those subjects with initial UAC in the microalbuminuric range, 37.5% reverted back to normoalbuminuria, 50% remained microalbuminuric, and 12.5% progressed to macroalbuminuria. UAE is positively correlated with diabetes duration (r=0.526, p=0.02), and to LDL (r=0.408, p=0.025). Glycemic control is positively correlated to UAE (r=0.498, p=0.04), and cholesterol levels (r=0.435, p=0.016). With regards to UAE status at the end of the follow-up period, glycemic control and cholesterol level as well as LDL were different (p=0.05, 0.026, 0.04 respectively) among the normoalbuminuric, microalbuminuric, and macroalbuminuric groups. In this study, glycemic control is a predictor of UAE ($R^2$=0.246, p=0.003). Further prospective, larger, and longer studies are needed in elucidating the protective and/or progressive risk factors for diabetic nephropathy in minority children with T2DM.

**Relationship of Visceral and Subcutaneous Adiposity with Renal Function in People with Type 2 Diabetes Mellitus** Biro Kim,[1] Yongkyun Kim,[2] Jihee Lim,[3] Minyoung Kim,[3] Cheolwhee Park,[3] Ho-Cheol Song,[2] Yongsoo Kim,[3] Euy-Jin Choi,[2] Yoonsik Chang,[1] Bumsoon Choi.[3] *[1]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea, Yeouido, St. Mary's Hospital, Republic of Korea; [2]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea, Bucheon, St. Mary's Hospital, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, The Catholic University of Korea, Seoul, St.Mary's Hospital, Republic of Korea.*

**Background.** Obesity and diabetes mellitus (DM) are established risk factors for the development of chronic kidney disease. The visceral adiposity (VAT) and subcutaneous adiposity (SAT) may be associated with the differential metabolic risk. Our study was performed to determine whether VAT or SAT was associated with the deterioration of renal function in people with type 2 DM.

**Methods.** Nine hundred twenty-nine people with type 2 DM (488 women and 441 men) and who had undergone abdominal computed tomography assessment of the SAT and VAT areas were included. The estimated glomerular filtration rate (eGFR) was calculated using the Modification of Diet in Renal Disease four-variable equation at the time of the assessment of the SAT and VAT areas.

**Results**. The mean visceral fat area was 118 ± 56 Cm$^2$ in women and 126 ± 65 Cm$^2$ in men. The mean subcutaneous fat area was 192 ± 79 Cm$^2$ in women and 124 ± 66 Cm$^2$ in men. The visceral fat area was independently associated with the eGFR after adjustment for age, gender, the duration of diabetes, the systolic blood pressure, the diastolic blood pressure, the serum triglyceride, the homeostasis model for insulin resistance score, uric acid and urinary albumin excretion (β-coefficient = -0.075. $p = 0.034$), while the body mass index, total fat area and subcutaneous fat area were not significantly associated with the eGFR.

**Conclusion.** Our data suggest that VAT might be an additional prognostic factor for the deterioration of renal function in people with type 2 DM.

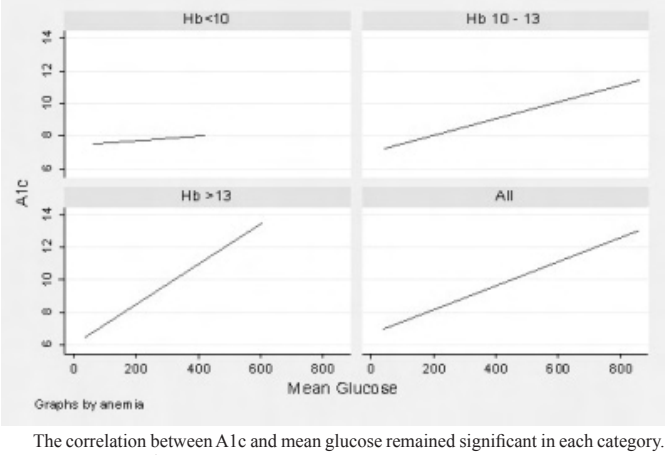
**Impact of Anemia on Hemoglobin A1c and Average Glucose Correlations in Diabetic Chronic Kidney Disease** Salman Waheed,[1] Mark E. Williams.[2] *[1]Medicine, University of Massachusetts Medical School, Worcester, MA; [2]Renal Unit, Joslin Diabetes Center, Boston, MA.*

The optimal target for glycemic control in diabetic CKD has not been established, and the validity of hemoglobin A1c, its standard metric, is being called into question, due to both pathophysiologic and methodologic factors related to CKD. We evaluated the association of A1c with average glucose levels, and the effect of anemia on this association using a database of 3707 patients at a large diabetes referral center. The cohort consisted of patients with diabetic CKD (eGFR<60 and not on dialysis). Average A1c was positively correlated with average glucose levels with a Pearson correlation coefficient of 0.292 ($p<.0001$). We then categorized subjects into 3 groups: hemoglobin (Hb) <10, Hb10-13 and Hb>13, and correlated average A1c with average glucose levels in each category. We noted that there was no statistically significant difference among the three groups in terms of their mean eGFR (P=0.1) or age (P=0.4). However, the groups differed from one another in their mean glucose values (P<0.0001), A1c (P<0.001), calcium (<0.0001), vitamin D (P=0.04) and albumin/creatinine ratio (ACR) (0.001).



The correlation between A1c and mean glucose remained significant in each category. However, the level of correlation decreased at lower Hb values. In a regression model using A1c as dependent variable and mean glucose as the predictor variable, the correlation between A1c and mean glucose decreased with worsening anemia even after controlling for age, eGFR, calcium, vitamin D and ACR values.

Hemoglobin A1c may be less valid as a glycemia metric in CKD patients as anemia advances. Further evaluation with prospective data is needed to further support this finding.

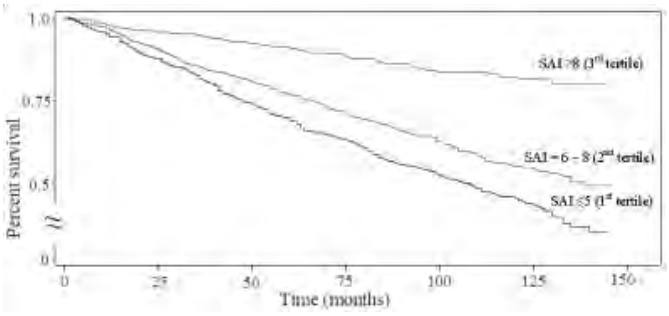
## SA-PO2503

**Social Adaptability Is Associated with Mortality in Patients with Diabetes** Alexander S. Goldfarb-Rumyantzev,[1] Preeti Rout,[1] Gurprataap Singh Sandhu,[1] Hongying Tang,[2] Anna Barenbaum,[3] Mark E. Williams.[1] *[1]Division of Nephrology, Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA; [2]Transplant Institute, Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA; [3]Tel Aviv University, Tel Aviv, Israel.*

Objective. A quantifiable assessment of socio-economic status and its bearing on clinical outcome in patients with diabetes is lacking. The social adaptability index (SAI) has previously been validated in the general population and in patients with chronic kidney disease. We hypothesize that SAI could be used in diabetes practice to identify disadvantaged population at risk for inferior outcome.

Research Design and Methods. The association of the SAI (calculated as linear combination of education status, employment, income, marital status and substance abuse) with patient survival was examined using a Cox model in NHANES-3 population.

Results. We identified 1,634 subjects with diabetes with mean age 61.9±15.3 years; 40.9% males; 38.5% White, 27.7% African American, and 31.3% Mexican American. The highest SAI was in Whites (6.9±2.5), followed by Mexican Americans (6.5±2.3), and then African Americans (6.1±2.6) (ANOVA, $p<0.001$). SAI was higher in subjects living in metropolitan areas (6.8±2.6) compared to the rural population (6.3±2.4) (T-test, $p<0.001$). Finally SAI was greater in males (7.1±2.4) than in females (6.1±2.4) (T-test, $p<0.001$). SAI had association with survival (HR 0.9, $p<0.001$) in the entire study population and in most of the subgroups (divided by race, sex, and urban/rural location). Similarly, SAI divided into tertiles (≤5, 6 to 8, >8) demonstrated a significant and "dose-dependent" association with survival.



Conclusions. Social adaptability index is associated with mortality in the diabetic population and is useful in identifying individuals who are at risk for inferior outcome.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2504**

**Sweet Pee: A Novel Mouse Model of SGLT2 Dysfunction for Studying Diabetes** Joseph Ly,[1] Tuncer Onay,[1] Colin Mckerlie,[4] Lucy Osborne,[5] Ann Flenniken,[1] Susan E. Quaggin.[1] *[1]Samuel Lunenfeld Research Institute, Toronto, ON, Canada; [2]Deparrtment of Medicine II, University Hospital Aachen, Aachen, Germany; [3]Hospital for Sick Children, Toronto, ON, Canada; [4]Toronto Center for Phenogenomics, Toronto, ON, Canada; [5]Department of Medicine, University of Toronto, Toronto, ON, Canada.*

The targeting of renal tubular SGLT2, a sodium glucose cotransporter, has become a new alternative to the management of Diabetes II. Dapagliflozin, among other SGLT inhibitors are being studied in clinical trials. Although early trial observed an increase in genitourinary infections, adverse effects have not been systematically studied. In this study, we describe a new mouse model of SGLT2 mutation, Sweet Pee, and report a significant mortality secondary to dehydration and urosepsis when these mice were treated with streptozotocin (STZ). We hypothesize that chronic tubular glucose exposure due to SGLT2 dysfunction will exert untoward effects on the health of these animals. Sweet Pee mutants were generated with ENU. We mapped the mutation to mouse chromosome 7 (LOD >4) within a critical region between 127-140 MB. Sequencing of Sweet Pee led to the discovery of a frameshift mutation in SLC5A2 (encodes SGLT2)from a single thymine insertion in exon 4 that resulted in a truncated neopepitide. Glucose tolerance test revealed a trend towards lower glucose levels. A total of 44 homozygous, 16 heterozygous and 7 wild type male mice were treated with low-dose STZ to induce diabetes and were followed for 16 weeks for survival. 26(60%) homozygotes, 13(81%) heterozygotes, and 7(100%) wild type demonstrated random serum glucose greater than 20 mmol/L. Of these, 8(31%) homozygotes, 5(38%) heterozygotes, and 7(100%) wild type survived. The sick mice exhibited severe dehydration and some developed urine infection. Histology of selected kidneys demonstrated dense white blood cells infiltration and parenchymal necrosis. We conclude that our diabetic Sweet Pee mutants had a significantly higher mortality compared to wild type. This data may suggest a heightened surveillance for urosepsis in patients treated with SGLT inhibitors.

Disclosure of Financial Relationships: nothing to disclose

**Is the MDRD Formula Valid during Renin Inhibition in Diabetic Kidney Disease?** Frederik I. Persson,[1] Hans-Henrik Parving,[2] Peter Rossing.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Medical Endocrinology, Rigshospitalet, Copenhagen, Denmark.*

It has been suggested that chronic RAS blockade with ACE inhibition in patients with diabetic kidney disease increases organic ion clearance e.g. creatinine. Consequently, it is possible that the benefit attributed to this therapy may be related to improved tubular secretion of creatinine, as this lowers serum creatinine. We therefore studied the effect of RAS blockade during renin inhibition on GFR (51Cr-EDTA plasma clearance) and estimated GFR. This was a pooled analysis from two studies of 43 patients with type 2 diabetes, hypertension and albuminuria, all having GFR measured after a 2 month placebo period (n=43) as well as after a 2 month treatment period with aliskiren 300 mg daily (n=43). We calculated eGFR using the MDRD formula and compared with the results of the GFR measurements.

After the placebo period mean GFR was 85 (27) and eGFR was 77 (27) ml/min/1.73m$^2$, mean difference 8.7 ml/min/1.73m$^2$ (95% CI 4.5, 12.9), p<0.001.

After 2 months treatment with 300 mg aliskiren once daily mean GFR was 81 (27) and eGFR was 73 (26) ml/min/1.73m$^2$, mean difference 7.0 ml/min/1.73m$^2$ (95% CI 3.2, 10.8), p=0.001 . There was no significant difference in decline in renal function from placebo to aliskiren evaluated by GFR: 4.7 (9) ml/min/1.73m$^2$or by eGFR: 3.0 (10) ml/min/1.73m$^2$, mean difference 1.7 ml/min/1.73m$^2$ (95% CI -1.0, 4.4)..

In conclusion the use of the MDRD formula is valid during renin inhibition in patients with type 2 diabetes, hypertension and albuminuria.

**Quantitative Magentic Resonance Imaging of Diabetic Nephropathy** Christopher A. Flask,[1] John R. Sedor,[1,2] Lan Lu,[1] Katherine M. Dell.[1,2] *[1]Departments of Radiology, Biomedical Engineering, Medicine and Pediatrics, Case Western Reserve University, Cleveland, OH; [2]CWRU Center for the Study of Kidney Disease and Biology, MetroHealth System Campus, Case Western Reserve University, Cleveland, OH.*

Diabetic nephropathy (DN) is the leading cause of end-stage kidney disease in the US. However, there are currently no established non-invasive assessments that can reliably detect early-stage DN, the point at which targeted interventions are most likely to impact disease progression. Changes in estimated glomerular filtration rate (eGFR) may not be seen until significant damage has occurred; microalbuminuria may indicate early damage but regresses in a significant proportion of patients. The goal of this study was to examine changes in diffusion tensor imaging (DTI) parameters as a potential biomarker for DN in a well-characterized cohort of patients with diabetes and a range of eGFRs.

DTI images were obtained on 8 diabetic subjects with a range of kidney function (eGFR = 32-108 mL/min/1.73m$^2$) currently participating in the Renal Disease Progression Genes and Environmental Impact on Diabetic Nephropathy Study. eGFR was based on the CKD-EPI equation. Five normal subjects were scanned for comparison. Image maps of Fractional Anisotropy (FA) and Apparent Diffusion Coefficient (ADC) were computed, and 16 medullary and cortical regions of interest (ROIs) for left and right kidneys of each subject were selected for analysis.

Medullary FA strongly correlated with eGFR ($R^2$ = 0.78) for all subjects, while neither cortical nor medullary ADC values correlated with eGFR ($R^2$ = 0.19 and 0.16, respectively). Cortical FA values were also unchanged among all subjects. Mean FA values for all diabetic subjects were also significantly lower than controls (0.23 vs. 0.30, $p < 0.05$). Mean ADC and FA values for normal subjects were comparable to published reports.

These data suggest that medullary diffusion FA may be a sensitive assessment for DN progression. These data further suggest that quantitative MRI modalities may serve as biomarkers for early disease in other chronic kidney diseases.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2507**

**Noninvasive 7tesla MRI Determination of Intramyocellular Lipid Concentrations in Chronic Kidney Disease** Devasmita Choudhury, Manisha Shah, Maram Museitif, Lynne M. Roetzer. *Medicine, Dallas VA Medical Center/ UT Southwestern Medical Center, Dallas, TX.*

Insulin resistance (IR) is prevalent in chronic kidney disease (CKD). It is widely-accepted that, among patients with normal renal function, elevated intramyocellular lipids (IMCLs) correlate with fatty acid metabolites that cause IR. Although hypertriglyceridemia is common among patients with CKD, little is known about the impact of CKD on IMCL. Magnetic resonance spectroscopy offers noninvasive monitoring of IMCLs. At high fields (7T) detection of IMCL is improved compared to standard clinical systems. This study investigated the utility of noninvasive 7 Tesla MRS in IMCL accumulation in CKD(1-5, MDRD eGFR) patients with and without diabetes (DM) and compared intramyocellular lipid (IMCL) concentration (mmol/kg/ wet weight muscle) to aged matched healthy controls (HC). Calf muscle NMR spectroscopic data from of 14 male CKD and 8 male healthy subjects was analyzed to calculate [IMCL] based on the amplitude of the triglyceride methyl signal compared to creatine. Results: Of 14CKD patients (mean age 57±11, BMI 32±6), 6 patients, all with CKD 3-5 had high extramyocellular (EMCL) lipid signal that overwhelmed the IMCL signal. When this subgroup was compared to those with CKD 3-5, with detectable IMCL, 5/6 in high EMCL group were nonwhite compared to 3/8 in the IMCL detectable group. Further non-white IMCL detectable patients had less severe CKD stage. IMCL concentration of 8 CKD 1-5 (mean age 56±15, BMI 30±7) was 5.0 (2.1-6.6) mmol/kg wet weight, compared to 8 HC (52±10, BMI 29±4), with IMCL 3.7 (.005-10), p =n.s. In those with measurable IMCL, stage of ckd 1-2 vs 3-5, level of serum cholesterol, TGL, HBA1c or presence or absence of DM were not different as compared to HC. Early data indicates nearly 42% advanced CKD have marked increase in EMCL concentrations rendering IMCL measurements undectable even by high resolution 7tesla imaging, particularly in patients of nonwhite origin. Race may be important in intramuscular lipid distribution. Further exploration of IMCL to EMCL distribution using non-invasive 7Tesla MRI imaging may elucidate risks for early insulin resistance in non-white patient population.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2508**

**An Acute Fall in Glomerular Filtration Rate (GFR) during Treatment with an Angiotensin Receptor Blocker (ARB) Is Associated with Renoprotection: A Post-Hoc Analysis in RENAAL** Frank Holtkamp,[1] Hiddo Jan Lambers Heerspink,[1] Pieter de Graeff,[1] Mark E. Cooper,[2] Dick De Zeeuw.[1] *[1]Dep Clin Pharmacology, UMCG, Groningen, Netherlands; [2]Baker IDI Heart & Diabetes Institute, Melbourne, Victoria, Australia.*

**Introduction:** ARB treatment confers renoprotection. However, during therapy initiation, ARB treatment may induce an acute fall in GFR, which opposes renal protection. We hypothesize that this initial fall in GFR upon ARB treatment reflects a renal hemodynamic effect that is associated with long-term structural renal protection.

**Methods:** A post-hoc analysis in the RENAAL trial was conducted. The acute fall in estimated (e)GFR (MDRD formula) from baseline to month 3 and its relationship with long term eGFR slope (and hard renal endpoints) were determined.

**Results:** Patients assigned to losartan had a 0.73 ml/min greater acute fall in eGFR during the first 3 months (p=0.031) compared to patients assigned to placebo, but a 0.8 ml/min/year slower mean eGFR decline thereafter (-4.2 (95%CI -3.9, 4.6) versus -5.0 (-4.7, 5.4) ml/min/1.73m$^2$/year; p<0.001). A large inter-individual difference in acute eGFR change was noticed. When all subjects were divided in tertiles of initial eGFR change, subjects within the losartan group with a large fall in eGFR had a significant less steep slope in long-term eGFR compared to those with a moderate fall or rise in eGFR (table). In addition, a larger fall in acute eGFR upon ARB treatment was associated with a larger treatment effect on renal endpoints (table).

| Tertiles of acute eGFR change (ml/min/1.73m2) | Long term eGFR in losartan treated patients (ml/min/1.73m2/year) | Treatment effect vs placebo | | |
|---|---|---|---|---|
| mean (sd) | mean (95%CI) | HR | 95% CI | p value |
| -8.5 (4.0) | -3.65 (-4.20 to -3.10) | 0.71 | 0.54-0.93 | 0.014 |
| -2.1 (1.3) | -3.85 (-4.40 to -3.30) | 0.77 | 0.56-1.05 | 0.093 |
| +4.5 (2.9) | -4.43 (-4.97 to -3.90)* | 0.92 | 0.62-1.36 | 0.661 |

* p=0.045 vs tertile 1

**Conclusion:** An initial fall in eGFR during ARB treatment is independently associated with a slower rate of renal function loss during follow-up suggesting that an initial fall in eGFR can be interpreted as a marker of therapeutic effectiveness.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2509

**Early Renal Function Decline in Type 2 Diabetes** Meda E. Pavkov,[1] William Knowler,[2] Clinton C. Mason,[2] Kevin V. Lemley,[3] Bryan D. Myers,[4] Robert G. Nelson.[2] *[1]CDC, GA; [2]NIDDK, AZ; [3]USC, CA; [4]Stanford University, CA.*

Early renal function decline (ERFD), a decline in glomerular filtration rate (GFR) in excess of normal aging, is described in type 1 diabetic persons with normo- or microalbuminuria but not in type 2 diabetes. We measured GFR (iothalamate clearance) and urinary albumin/creatinine (ACR) at least 5 times during a median follow-up of 8.8 years (range=2.5-10.0 years) in 189 Pima Indians with type 2 diabetes. At baseline, 93 subjects had normal albuminuria (ACR <30 mg/g) and 96 had microalbuminuria (30≤ACR<300 mg/g). ERFD was defined by an average decline in GFR of ≥3.3%/year during this initial follow-up period, a threshold corresponding to the upper 2.5 percentile of the distribution of the decline in creatinine clearance in nondiabetic normotensive Caucasians in the Baltimore Longitudinal Study on Aging--the same definition that has been used in type 1 diabetes. Subsequently, subjects were followed for up to 17.5 years to the onset of end-stage renal disease, death, or December 31, 2009. At baseline, median GFR was 158 ml/min (range 49-296 ml/min), and the prevalence of ERFD was higher in subjects with baseline microalbuminuria (47%) than in those with normoalbuminuria (24%). The prevalence of ERFD was lowest at the end of the initial follow-up period in subjects who remained or regressed to normal ACR (13%), intermediate in those who remained or progressed to microalbuminuria (35%), and highest in those who progressed to macroalbuminuria (64%; ACR ≥300 mg/g). The cumulative incidence of end-stage renal disease 9 years after the initial follow-up period, when 75% of the observations were censored, is shown in the table according to albuminuria level at the end of the initial period.

Cumulative incidence of kidney failure

| | Remaining or regressing to normoalbuminuria | Remaining or progressing to microalbuminuria | Progressing to macroalbuminuria |
|---|---|---|---|
| ERFD - | 7.1% (1 event) | 0 | 14.9% (2 events) |
| ERFD + | 0 | 0 | 60.4% (13 events) |

In type 2 diabetes, progressive loss of GFR begins before the onset of macroalbuminuria, but a decline in excess of that expected by normal aging (ERFD) is strongly dependent on progression to macroalbuminuria.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2510

**Body Mass Index Is a Predictor of Angiotensin Receptor Blocker (ARB) Induced Albuminuria Reduction** Frank Holtkamp,[1] Hiddo Jan Lambers Heerspink,[1] Gozewijn Dirk Laverman,[1] Gerjan Navis,[1] Hans-Henrik Parving,[2] Julia Lewis,[3] Dick De Zeeuw.[1] *[1]University Medical Center, Groningen, Netherlands; [2]University Hospital, Copenhagen, Denmark; [3]Vanderbilt University School of Medicine, Nashville, TN.*

**Introduction** The effect of ARB-induced reduction in albuminuria varies between individuals. Sodium intake and concomitant diuretic use increase plasma RAAS activity and enhance the albuminuria response. Higher body mass index (BMI) has also been associated with increased tissue RAAS activity and an increased renal vascular response to RAAS blockade in healthy subjects and type 2 diabetes. We assessed whether a higher BMI was associated with a larger reduction in albuminuria during ARB therapy in patients with type 2 diabetes and nephropathy.

**Method** Available data for change in albuminuria in ARB and placebo treated patients in the combined RENAAL and IDNT trials were used (n=2661). Short term response in albuminuria was defined as change from baseline to month 6. Univariate and multivariate regression analyses was applied to determine whether baseline BMI predicted changes in 24h urinary albumin excretion, corrected for multiple response determinants including albuminuria, eGFR, blood pressure, diuretic use.

**Results** Albuminuria was reduced with 29.7% (95% range: -86.9% to +178.9%) during ARB therapy versus a decrease of 5.7% (95% range: -80.4 % to +280.4%) during placebo. A higher BMI was significantly associated with a larger albuminuria reduction (table). This was independent of other baseline parameters (multivariate (β=0.009 per kg/m$^2$; p=0.007). Interestingly, higher BMI was positively associated with the DD ACE-genotype polymorphism.

| BMI quartiles (kg/m2) | 25.8 < | > 25.8 and < 29.3 | > 29.3 and <33.6 | > 33.6 |
|---|---|---|---|---|
| Albuminuria response (%, month6 - baseline) (median, IQR) | -12.9 (-42, +30) | -16.5 (-48, +30) | -15.0 (-49, +27) | -21.8 (-53, +18)* |
| DD genotype (%) | 24.5 | 27.1 | 28.7 | 31.9* |

*p<0.05 vs lowest quartile

**Conclusion** A higher BMI was associated with a larger albuminuria response in patients with diabetes and nephropathy. These data suggest that a (genetically determined) intrinsic activity of the RAAS is an important determinant for ARB treatment response.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2511

**In Vivo Delivery of Megsin siRNA Plasmid Reveals Therapeutic Potential Against Diabetic Nephropathy by Down-Regulating P27$^{kip1}$ Level** Ying Li, Maodong Liu, Yanling Zhang, Yanqing Chi. *Nephrology, 3rd Hospital of Hebei Medical University, Shijiazhuang, Hebei, China.*

**Aims:** A mesangium-predominant gene,Megsin, has emerged as a participant in mesangial cell proliferation and/or mesangial matrix expansion. We hypothesize that Megsin may serve as a therapeutic target in the management of diabetic nephropathy and a series of in vivo or in vitro experiments were designed.**Methods:** We have constructed a Megsin siRNA plasmid and have examined the effect of Megsin inhibition on the progression of diabetic nephropathy in a mouse model. CD-1 mice underwent uninephrectomy and STZ treatment prior to receiving weekly tail-vein rein injections of the plasmid. Animals were sacrificed at week-1, week-2 and week-12. At each time point, urine and blood samples were collected, and kidney tissues were harvested. The level of serum glucose in every group's mice was measured in vena caudalis by the blood sugar analyzer. Furthermore, serum creatine ( Scr) and urine protein( UP) in 24 hours were estimated by the automatic biochemistry analyzer. In vitro Mouse mesangial cells (MCs) were transfected with pBAsi mU6 Neo megsin siRNA plasmid or pBAsi mU6 Neo plasmid using lipofectamine 2000 reagent . After 24 hours, cells were further cultured in DMEM containing high glucose (HG; 25mM) or normal glucose ( NG; 2.8mM). Cells in 6-well culture plates were collected for protein extraction and culture medium was collected for Collagen IV radioimmunoassay at hour-12, 24 and 48. The levels of megsin, MMP-2, TIMP-2 and P27$^{kip1}$ were measured by Immunohistochemistry or western blotting.**Results:** Inhibition of Megsin alleviated proteinuria and glomerular collagen IV accumulation 12 weeks after the STZ injection and inhibited renal cell proliferation. Furthermore, in vitro experiments showed that, after the transfection of Megsin siRNA plasmid, the mouse mesangial cellular abnormalities induced by high glucose, such as increased cell proliferation and collagen IV production were reversed. Significantly, the level of P27kip1 was down-regulated in transfected mesangial cells.**Conclusion:** the inhibition of Megsin might exert beneficial effects on the diabetic kidney partly through down-regulation of P27$^{kip1}$ level.

Disclosure of Financial Relationships: nothing to disclose

**Dual Inhibition of Classical PKC-α and PKC-β Isoforms in a Pharmacological and Double Knock-Out Mouse Approach Leads to Protection Against Experimental Murine Diabetic Nephropathy** Jan Menne, Joon-Keun Park, Nelli Shushakova, Hermann G. Haller. *Nephrology and Hypertension, Medical School Hannover, Hannover, Germany.*

**INTRODUCTION AND AIMS:**

Both classical PKC isoforms, PKC-α and -β, have been implicated in the pathogenesis of diabetic microvascular diseases. We previously elucidated the specific role of these individual isoforms and revealed that activation of the PKC-β-isoform contributes to high-glucose-induced renal fibrosis whereas perlecan as well as nephrin and VEGF expression are regulated by a PKC-α-isoform-dependent signaling pathway leading to diabetic albuminuria.

**METHODS:**

We now tested the hypothesis if deletion of both classical PKC isoforms is able to completely abolish the development of diabetic nephropathy in the streptozotocin-induced diabetic mouse model. We therefore studied distinct pharmacological approaches while inhibiting both classical PKC isoforms and validated the phenotype of nondiabetic and streptozotocin-induced diabetic homozygeous PKC-α/β double knock-out mice (PKC-α/β$^{-/-}$) compared to appropriate 129/SV wild type mice.

**RESULTS:**

After 8 weeks of diabetes mellitus the high-glucose-induced renal and glomerular hypertrophy as well as the increased expression of extracellular matrix proteins such as collagen and fibronectin was abolished in the PKC-α/β$^{-/-}$ mice compared to WT controls. Furthermore, the high-glucose-induced expression of the profibrotic cytokine TGF-$\beta_1$ was significantly diminished in the PKC-α/β$^{-/-}$ mice in comparison to diabetic WT mice. The loss of the basal membrane proteoglycan perlecan and the podocyte protein nephrin is prevented in the diabetic state in the PKC-α/β$^{-/-}$ mice. Furthermore, we were able to demonstrate, that a PKC-α/β inhibitor had a similar effect.

**CONCLUSIONS:**

In summary, blockade of the two prominent PKC isoforms prevent early diabetic nephropathy while inhibiting prosclerotic glomerular and tubulo-interstitial changes as well as the development of albuminuria. These results demonstrate that downregulation of the dual PKC-isoform activation in the diabetic state *in vivo* is a suitable therapeutic target in the prevention of diabetic microvascular complications such as diabetic nephropathy.

**Reduction of Glomerulosclerosis and Prevention of Interstitial Inflammation in Diabetic CD-1 Mice by Pentosan Polysulfate and Pyridoxamine** Fabrizio Grosjean,[1] Vittoria Esposito,[1] Maya Ramdas,[1] Massimo Torreggiani,[2] Helen Vlassara,[1] Feng Zheng,[1] Gary E. Striker.[1] *[1]Geriatrics and Palliative Medicine, Mount Sinai School of Medicine, New York, NY; [2]Unit of Nephrology, IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy.*

The levels of both systemic and kidney inflammation markers are increased in diabetic nephropathy (DN). We showed that the levels of inflammation in diabetic patients directly correlate with those of advanced glycation endproducts (AGEs), that reducing AGEs lowers circulating and cellular markers of inflammation, and that AGE inhibitors reduce DN. Since inflammation is partly due to elevated AGEs, we studied a combination of two drugs, one that reduces inflammation (PPS) and one that reduces AGE levels (PYR) using STZ-induced diabetic CD1 mice, a model of rapidly progressive DN. After 4 weeks of hyperglycemia mice were randomized to EN (enalapril, 10 mg/kg/day), EN+PYR (PYR 200 mg/kg/day), EN+PPS (PPS 25 mg/kg/day), EN+PYR+PPS, or tap water. After 24 weeks, untreated diabetic mice (DB) had prominent glomerulosclerosis with thickened basement membranes, tubular atrophy, and diffuse interstitial inflammation. The percent glomerulosclerosis in DB mice (17.5±6) was reduced by EN (14.1±3), EN+PYR (13.7±3), and EN+PYR+PPS (10.5±3). While interstitial inflammation was also reduced in all treatment groups, it was nearly completely ablated in the PPS groups (DB+EN+PYR+PPS; 0.2±0.5 vs. DB: 2.3±0.7; $p<0.05$). All DB mice had an increased kidney weight/body weight ratio and hyperglycemia, which were not influenced by treatment. In conclusion, treatment of DN by the combined use of an inhibitor of inflammation (PPS) and an inhibitor of AGEs (PY) substantially reduces kidney lesions typical of DN in CD-1 mice. Since both drugs are FDA-approved and have few side-effects, this may represent an additive approach in the clinical management of DN.

**The Effect of GW610742, PPAR-δ Agonist, on Diabetic Nephropathy and Albuminuria** Eun-Young Lee,[1] Geun Tae Kim,[1] Su-Ji Kim,[1] Sujin Seok,[1] Ran Choi,[2] Mi Young Lee,[2] Choon Hee Chung.[2] *[1]Internal Medicine, Soon Chun Hyang University, Cheonan, Korea; [2]Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea.*

Peroxisome proliferator–activated receptor (PPAR)-δ, a member of the ligand-activated nuclear receptor superfamily, plays an important role in lipid and glucose homeostasis and inflammation. However, the role of PPAR- δ in the pathogenesis of diabetic nephropathy has not been determined. We investigated the effect of PPAR-δ on kidney pathology and albuminuria in spontaneously developed diabetic rats. Otsuka-Long-Evans-Tokushima-Fatty rats, an animal model for type 2 diabetes, were randomized into a non-treated and a GW610742 (10 mg/kg, a highly specific ligand for PPAR-δ)-treated group. Long-Evans Tokushima Otsuka rats were used as a non-diabetic control. In diabetic rats, albuminuria, glomerular hypertrophy and glomerular sclerosis were more severe than in non-diabetic rats. GW610742 did not affect hyperglycemia, kidney weight and glomerular hypertrophy in diabetes. However, GW610742 did significantly ameliorate diabetic albuminuria. Diabetic glomerular basement membrane thickening was significantly prevented in GW610742-treated diabetic rats. Decreased density of slit pores between podocyte foot processes in diabetic rats was significantly recovered toward normal by GW610742. Nephrin protein was decreased in the diabetic rats but was significantly restored by GW610742. Taken together, PPAR-δ activation by GW610742 ameliorated albuminuria with corresponding change in podocyte-related structures, such as nephrin, glomerular basement membrane thickening and slit pore density. In conclusion, this is the first report that PPAR-δ activation by GW610742, PPAR-δ agonist, has a renoprotective effect via recovery of urinary filtration barrier integrity in diabetes.

**Tubulointerstitial Injury Is Exacerbated in Streptozotocin-Induced Diabetic Matrix Metalloproteinase-2 Knockout Mice** Ryotaro Ando, Kei Fukami, Seiya Okuda. *Division of Nephrology Department of Medicine, Kurume University School of Medicine, Fukuoka, Japan.*

Background and aims:Matrix metalloproteinnase2 (MMP-2) is one of the potent metalloproteinases which can degrade various types of extracellular matrix (ECM) . It has been suggested that diabetes-induced accumulation of ECM are, at least in part, by down-regulation of MMP-2. However there is no data whether MMP-2 activity and expression affect diabetes-induced renal damage in vivo. Therefore, we investigated the effects of MMP-2 deficiency on tubulointerstitial injury in diabetic animals.

Materials and methods: Diabetes was induced by streptozotocin (STZ)(50mg/kg) in male MMP-2 knockout mice (MMP-2 KO) and C57BL/6J mice (Ctrl). After 16 weeks,cortical MMP-2 expression and activity were measured by zymography and real-timePCR, respectively. Urinary albumin excretion (UAE) and N-acetyl β-D-glucosaminidase were measured by enzyme-linked immunosorbent assay. Alfa-smooth muscle actin (α-SMA) was evaluated by western blots and immnohistochemistry.Tubutointerstitial injury and fibrosis were evatuated by hematoxylin and eosin staining and Masson-trichrome staining.

Results: Plasma levels of glucose and HbA1c were increased by about 2-3-folds in 16-week diabetic mice compared with non-diabetic Ctrl mice (plasma glucose; 490.3±7.5mg/dl, HbA1c; 9.91±0.22 %). MMP-2 expression and activity in the total kidney cortex of diabetic mice were increased in zymography and RT-PCR analysis. Serum levels of BUN, creatinine (Cr) and UAE were significantly increased in MMP-2 KO DM mice compared with Ctrl DM mice (BUN; 23.2±1.7 vs 39.8±6.0 mg/dl,$p<0.01$, Cr; 0.07±0.01 vs 0.17±0.04 mg/dl, $p<0.01$, UAE; 0.08±0.01 vs 0.16±0.03 mg/mgCr, $p<0.05$). Further, tubulointerstitial injury and cortical α-SMA expression were enhanced in DM mice, which were further increased in MMP-2 KO DM mice.

Conclusions: We demonstrate for the first time that tubulointerstitial injury and fibrosis were exacerbated in diabetic MMP-2 knockout mice, even though MMP-2 levels were increased in diabetic mice. The present study suggests that the decrease in other matrix-degrading enzymes may be involved in the tubulointerstitial injury and fibrosis in diabetic nephropathy.

## SA-PO2516

**Tissue Inhibitors of Metalloproteinases-1 (TIMP-1), Is a Urinary Marker for Proximal Tubular Cell Damage in Diabetic OVE26 Mice** Shirong Zheng,[1,2] Yun Huang,[1] Paul N. Epstein.[1] *[1]Juvenile Diabetes Research, Department of Pediatrics, University of Louisville, Louisville, KY; [2]Institute for Cellular Therapeutics, Department of Surgery, University of Louisville, Louisville, KY.*

Tissue inhibitor of metalloproteinases-1 (TIMP-1) is a major and specific inhibitor of matrix metalloproteinase, which regulate diverse processes including remodeling of extracellular matrix. TIMP-1 remains low in normal kidney and increases significantly in many kidney diseases with renal fibrosis. In this study, we investigated the expression of TIMP-1 in a mouse model of diabetic nephropathy. Diabetic OVE26 and control FVB mice were used and uninephrectomy and sham surgery was performed at two month of age to accelerate albuminuria and fibrosis. At four months of age, kidney TIMP-1 mRNA expression increased more than 4 fold in diabetic mice and almost 75 fold in uninephrectomized diabetic mice ($p<0.05$). Increased TIMP-1 gene expression correlated with the elevation of albuminuria and degree of fibrosis in diabetic mice. Immunohistochemistry revealed that most TIMP-1 was localized to tubular cells, especially tubules with atrophy or severe dilation. TIMP-1 staining was also evident on isolated cells in the interstitial space. TIMP-1 staining in tubular cells overlapped with staining for albumin, complement C3 and caspase 3. Double staining with megalin confined these proteins to proximal tubular cells. By Elisa analysis we detected TIMP-1 protein in the urine, which was positively correlated with urine albuminuria and renal fibrosis in diabetic mice. Since TIMP-1 expression in proximal tubular cells is strongly associated with albumin and complement accumulation, tubular cell atrophy and dilation and tubulointerstital fibrosis, these results indicate that urine TIMP-1 provides an indicator of proximal tubular cell damage and progression of diabetic nephropathy.

## SA-PO2517

**Long-Term Administration of Resveratrol Reduces Metabolic Disturbances and Renal Injury in db/db Mice** Ji Eun Lee,[1] Hyunwook Kim,[1] Young Youl Hyun,[2] Jinjoo Cha,[2] Kum Hyun Han,[3] Sang Youb Han,[3] Hyoung-Kyu Kim,[2] Young Sun Kang,[2] Dae R. Cha.[2] *[1]Department of Internal Medicine, Wonkwang University Sanbon Hospital, Gunpo-si, Gyeonggi-do, Korea; [2]Department of Internal Medicine, Korea University Ansan Hospital, Ansan-si, Gyeonggi-do, Korea; [3]Department of Internal Medicine, Inje University Ilsan Baek Hospital, Goyang-si, Gyeonggi-do, Korea.*

Resveratrol, a polyphenolic SIRT1 activator, has been found to possess beneficial properties against metabolic diseases such as obesity and type 2 diabetes. In this study, we investigated the effects of chronic daily administration of resveratrol on metabolic disturbances and renal injury in db/db mice.

Experimental animals at 8 weeks of age were given resveratrol (20 mg/kg/d) and vehicle for 3 months. After resveratrol treatment, there were no significant changes in the levels of fasting blood glucose, HbA1c and blood pressure. However, plasma insulin level, HOMA-IR, plasma lipid levels, and insulin resistance measured by insulin tolerace test were significantly improved. After 2 month-treatment, resveratrol-fed diabetic mice showed reduced urinary albumin compared with vehicle-fed diabetic mice. This effect was much more apparent after 3 month-resveratrol treatment. Resveratrol treatment decreased plasma isoprostane level and increased renal adiponectin receptor and AMPK mRNA expressions compared with vehicles. Furthermore, resveratrol treatment suppressed mesangial expansion and decreased the synthesis of pro-fibrotic molecules including TGF-β, PAI-1 and type IV collagen. In summary, long-term administration of resveratrol improves insulin resistance, dyslipidemia, and renal injury in db/db mice. Our results suggest that these effects may be associated with decreased oxidative stress and regulation of renal adiponectin receptor-AMPK pathway.

**SA-PO2518**

**Intermittent Administration of ONO-1301, a Sustained-Release Prostacyclin Analog, Ameliorates Renal Alterations in Obese Type 2 Diabetes Mice** Hiroko Yamasaki, Yohei Maeshima, Tatsuyo Nasu, Daisuke Saito, Katsuyuki Tanabe, Hitoshi Sugiyama, Hirofumi Makino. *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan.*

Diabetic nephropathy is the most common pathological disorder predisposing end-stage renal disease, and novel therapeutic approaches are required. ONO-1301 is a novel sustained-release prostacyclin analog possessing thromboxane A2 synthase inhibitory activity, with potent therapeutic efficacies on experimental pulmonary hypertension, pulmonary fibrosis and myocardial ischemia. We recently observed the therapeutic efficacies of slow-release ONO-1301 (SR-ONO) in experimental type 1 diabetic nephropathy, an unilateral ureteral obstruction, and a rat progressive Thy-1 nephritis model. Here, we examined the therapeutic efficacy of intermittent administration of SR-ONO on renal alterations in the obese type 2 diabetes mouse. Db/db mice, a model of obese type 2 diabetes at 8 weeks of age exhibiting hyperglycemia, received subcutaneous injections of either SR-ONO (3mg/kg) or vehicle buffer every 3 weeks. Animals were sacrificed at 16 weeks of age. Cultured mouse mesangial cells (Mes13) were stimulated with high ambient glucose (HG; 25mM) in the presence of ONO-1301(1-100nM) for 24 hrs. Clinical parameters (albuminuria, creatinine clearance), kidney weight, glomerular volume and mesangial matrix index were examined, and immunohistochemistry and immunoblot was performed. SR-ONO treatment did not affect obesity or hyperglycemia, but significantly ameliorated albuminuria, glomerular hypertrophy, the increase of mesangial matrix index, glomerular accumulation of type IV collagen, F4/80+ monocyte/macrophage, TGF-beta1, alpha-smooth muscle actin (SMA) and MCP-1 in db/db mice compared with vehicle treatment. In Mes13 cells, ONO-1301 dose-dependently suppressed the increase of TGF-beta, type IV collagen and alpha-SMA induced by HG (immunoblot). Taken together, these results suggest the potential therapeutic efficacy of intermittent administration of SR-ONO on renal alterations in type 2 diabetes mediated via anti-fibrotic and anti-inflammatory effects, partially through its direct effects on mesangial cells.

**Amelioration of Microalbuminiuria in ROCK1 Knockout Mice with STZ-Induced Diabetic Kidney Disease** Li Zhou,[1] Fei Liu,[1] Hui Y. Lan,[2] Ping Fu.[1] *[1]Department of Medicine-Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan Province, China; [2]Department of Medicine and Therapeutic and Li Ka Shing Institute of Health Sciences, Chinese University of Hong Kong, Hong Kong, China.*

**Background.** It has been shown that blockade of Rho kinase with pharmacologic inhibitors ameliorates renal fibrosis and diabetic kidney disease (DKD). But the underlined mechanisms are still not clear. We hypothesize that Rho kinase is a key mediator regulating the expression of megalin/cubilin and tubular function of reabsorption for albumin in the early stage of DKD.

**Methods.** This study examined the role of Rho kinase in the early stage of STZ-induced DKD model of mice that do not express ROCK1 gene, a critical downstream mediator of Rho GTPase, in the aspect of effect on tubular function of reabsorption for albumin and the expression of megalin/cubilin, an endocytosis receptors complex. In vitro experiment on NRK52E, a normal rat tubular epithelial cell line with high glucose stimulating was introduced.

**Results.** Results showed that *microalbuminuria was attenuated in ROCK1 KO mice treated with STZ which was consistent to the attenuation of reduced megalin/cubilin expression in renal cortex at 8 week. In vitro* study with ROCK inhibitor Y-27632 further confirmed the protective role of ROCK inhibitor on the decrease of megalin expression and the reduced endocytosis of renal tubular epithelial cells induced by high glucose.

**Conclusions.** This study further confirmed the pathogenic role of ROCK1 in DKD and it indicated potential downstream pathway on an endocytosis receptors complex - *megalin/cubilin which was related to the pathogenesis of microalbuminuria in the early stage of DKD.*

**SA-PO2520**

**Natural History of Albuminuria in Akita Diabetic Mice – Potential Role of USF1** Amber P. Sanchez, Young H. You, Shinichi Okada, Anne-Emilie Decleves, Kumar Sharma. *Department of Medicine, Division of Nephrology, University of California San Diego, La Jolla, CA.*

The clinical hallmark of diabetic nephropathy (DN) is mesangial matrix expansion, largely driven by TGF-β, and albuminuria. We have previously identified that the USF1 transcription factor mediates glucose-induced TGF-β1 stimulation in mesangial cells, however its role in regulating albuminuria is unknown. We investigated the natural history of albuminuria in male Akita mice (Ins2/Akita), a genetic model of type 1 diabetes, and determined the role of USF1 in the development of albuminuria by intercrossing USF1 knockout (KO) with Akita mice. Mice were evaluated at 6, 12, 20, and 28 weeks by 24h urine collection and compared to wild type control (WT) (n=6-8 each group). We observed a time-dependent fluctuation of albuminuria in Akita mice. As early as 6 weeks, Akita mice had significantly higher urinary albumin excretion (UAE) than WT (mean 267.8 vs 19.6μg/24h, P<0.0001). However, at 12 weeks albuminuria was reduced and not significantly different than WT (mean 52.5 vs 31μg/24h). Albuminuria peaked at 20 weeks (1113 vs 13.6 μg/24h, P<0.05) and returned to values similar to the 6 week time point by 28 weeks of age (275 vs 15.7μg/24h, P<0.001). Diabetic mice heterozygous for USF1 followed the same pattern of UAE as Akita mice. However, diabetic USF1 KO mice had no significant difference in UAE than WT mice at any of the time points (mean UAE <108μg/24h, all time points, P=NS). Kidney cortex was evaluated by quantitative real time PCR and immunostaining from mice sacrificed after 28 weeks. Akita mice had significantly higher TGF-β1 mRNA (p<0.05) whereas diabetic USF1 KO mice had no significant difference from WT. On immunostaining, Akita mice stained strongly for TGF-β in the glomeruli and tubules, whereas in diabetic USF1 KO mice TGF-β staining was substantially reduced. In conclusion, Akita mice exhibit a fluctuating pattern of albuminuria that is time-dependent. In mice lacking the USF1 transcription factor there is no significant increase in albuminuria or glomerular TGF-β staining in the setting of diabetes.

**Nitric Oxide Negatively Regulates HB-EGF Expression in Vascular Endothelial Cells in eNOS Knockout Diabetic Mice** Fenghua Zeng, Suwan Wang, Xiaofeng Fan, Hongling Jiang, Huifang Cheng, Raymond C. Harris. *Medicine, Vanderbilt University, Nashville, TN.*

Diabetes mellitus (DM) is a heterogeneous disorder that initiates a diverse spectrum of effects on the vasculature and causes vasculopathy, such as macroangiopathy-related major cardiovascular events and end-stage renal disease caused by microangiopathy-related diabetic nephropathy (DN). A hallmark of diabetic vasculopathy is endothelial cell (EC) dysfunction, where the loss of nitric oxide (NO) and the consequent impairment of endothelium-dependent vasorelaxation play a major role. Studies have suggested that HB-EGF may serve as a mediator of EC dysfunction in diabetes. In the current studies, we investigated 1) whether HB-EGF expression is increased in the EC of the DN model; and 2) whether the loss of NO contributes to the augmentation of HB-EGF expression. As endothelial nitric oxide synthase (eNOS) is the main source of NO in EC, the well established eNOS knockout diabetic mouse model (*eNOSKO db/db*) was used. We found that HB-EGF was highly expressed in the glomeruli, EC of the small blood vessels and smooth muscle cells of the medium blood vessels in the DN kidney of *eNOSKO db/db* mice. HB-EGF expression levels in the kidney cortex were higher in both eNOSKO db/db and *eNOSKO* non-diabetic mice than either db/db or non-diabetic mice, with *eNOSKO db/db mice having* the highest HB-EGF level. HB-EGF expression correlated with the extent of renal injury, with increases noted by 12 weeks of age when DN begins to develop, and with further elevations paralleling the progressive glomerulopathy. Those results suggested that loss of NO may be a main contributor of HB-EGF expression. In a cultured glomerular endothelial cell line, administration of the eNOS inhibitors L-NAME or L-NIO increased HB-EGF expression in a dose- and time length-dependent manner. In conclusion, our results suggest that under normal conditions, NO may negatively regulate HB-EGF expression in the EC of the blood vessel, but that with endothelial dysfunction, decreased NO production may allow increased HB-EGF expression, which may be an important mediator of the vascular damage in the DN development and progression in *eNOSKO db/db* mice.

**SA-PO2522**

**Epidermal Growth Factor Receptor (EGFR) Inhibitor Ameliorates Apoptosis in Experimental Diabetic Glomeruli** Shin-Wook Kang, Jung Tak Park, Bo Young Nam, Tae-Hyun Yoo. *Brain Korea 21 Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Kidney size is increased in diabetes due to glomerular and tubular hypertrophy. In addition to hypertrophy, apoptosis has been documented in the course of diabetic nephropathy (DN). Cell death by apoptosis is surmised to be involved in mesangial cell loss in the late stage of DN and podocyte loss, contributing to the development of albuminuria. In spite of numerous studies on hypertrophy and apoptosis in DN, little is known on the interrelationship between hypertrophy and apoptosis in diabetic glomeruli. To clarify the consequence of inhibiting hypertrophy on apoptosis in diabetic glomeruli, we examined the changes in glomerular expression of apoptosis-related molecules in experimental diabetic rats treated with a selective epidermal growth factor (EGF) receptor tyrosine kinase inhibitor, known to abrogate hypertrophy in diabetic glomeruli. Rats were injected either with diluent (n=16, C) or STZ IP (n=16, DM). After confirming diabetes, 8 rats from each group were treated with 100 mg/kg/day of PKI 166 (PKI), a selective EGF receptor inhibitor. Urinary albumin excretion were significantly higher in DM compared to C rats (p<0.05), and PKI treatment significantly reduced albuminuria in DM rats (p<0.05). The mean glomerular volume in DM was 60.6% larger than in C rats, and PKI treatment for 3 months significantly prevented glomerular hypertrophy in DM rats (p<0.05). The ratio of Bax/Bcl-2 protein expression and active caspase-3 protein expression were significantly increased in DM compared to C glomeruli (p<0.01, p<0.05, respectively), and these changes in DM glomeruli were significantly abrogated by the administration of PKI (p<0.05). PKI treatment also significantly inhibited the increase in TUNEL-positive apoptotic cells within DM glomeruli (p<0.05). Compared to C rats, the number of total glomerular cells was significantly decreased in DM, and this decrement in DM rats was significantly ameliorated by PKI treatment (p<0.05). PKI treatment attenuated apoptosis in DM glomeruli, suggesting that the inhibition of glomerular hypertrophy could inhibit glomerular cells apoptosis under DM conditions.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2523**

**Bradykinin Receptor 1 Deficiency Aggravates Albuminuria in Diabetic Mice** Nelly Blaes,[1] Lucie Libert,[1] Christianne Pecher,[1] Francoise Praddaude,[1&2] Acil Jaffar,[1&2] Julien Allard,[1] Ivan A. Tack,[1&2] Jean-Pierre Girolami.[1] *[1]U858, INSERM, Toulouse, France; [2]Physiology Medical School, University Paul Sabatier, Toulouse, France.*

Bradykinin receptor 1 (B1R) is induced during diabetes in several organs including the kidneys. We investigated the role of B1R during the onset of diabetic nephropathy using streptozotocin-induced diabetes in B1R knock out (B1KO) and wild-type (WT) mice. Early renal alterations, including albuminuria, cortical gene and protein expressions, and structural and ultrastructural changes, were monitored up to 4 weeks of diabetes. Diabetes, both incidence and hyperglycemia, was less severe in B1KO. However albuminuria was aggravated in B1KO. Electron micrographs from WT diabetic mice revealed irregularly thickened glomerular basement membrane, extensive podocyte foot effacement process and noticeable interstitial fibrosis. Surprisingly, podocytes lesions were not aggravated in diabetic B1KO. Glomerular hypertrophy and mesangial matrix expansion were unchanged in diabetic B1KO. Similar increase in cortical nephrin expression was observed during diabetes in both strains. Endothelial proteins (VE-cadherin , CD31, ESAM (Endothelial Specific Adhesion Molecule)) expression were higher in control B1KO. Diabetes induced similar alterations of these proteins in both strains. In contrast, diabetic B1KO showed a blunted increase in eNOS expression. The tight junction ZO1 protein was over expressed in control B1KO, but showed a lower increase during diabetes than diabetic WT. The data show that deletion of B1R results in diabetes-induced aggravated albuminuria. This early renal diabetic impact was associated with a marked alteration of cortical eNOS whereas podocytes lesions were similar in both strains. This suggests that B1R deficiency may aggravate diabetic nephropathy through at least impaired endothelial function. Therefore the physiopathological significance of B1R overexpression in diabetes has to be addressed.

**SA-PO2524**

**Resveratrol Improves Oxidative Stress and Protects Against Diabetic Nephropathy through Normalization of Mn-SOD Dysfunction** Munehiro Kitada,[1] Keizo Kanasaki,[1] Shinji Kume,[2] Daisuke Koya.[1] *[1]Diabetes & Endocrinology, Kanazawa Medical University, Kahoku-gun, Ishikawa, Japan; [2]Diabetes & Nephrology & Neurology, Shiga University of Medical Science, Otsu, Shiga, Japan.*

**Purpose:** Despite the beneficial effects of resveratrol (RSV) on renal diseases including type 1 diabetic nephropathy, its effects on type 2 diabetic nephropathy remains elusive. This study examined the renoprotective effect of RSV in db/db mice, a model of type 2 diabetes.

**Methods:** Db/db mice were treated with RSV (0.3% mixed in chow) for 8 weeks. We measured urinary albumin excretion (UAE), histological changes including mesangial expansion, fibronectin accumulation and macrophage infiltration, oxidative stress markers (urinary 8-hydroxy-2'-deoxyguanosine (8-OHdG) excretion, nitrotyrosine expression, 8-OHdG content and D-17 deletion in mitochondrial DNA), and manganese-superoxide dismutase (Mn-SOD) activity together with its tyrosine-nitrated modification in the kidney. Mitochondrial biogenesis was assessed by measuring mRNA expression levels of peroxisome proliferative activated receptor γ coactivator-1α (PGC-1 α), nuclear respiratory factors-1(NRF-1), mitochondrial DNA content and mitochondrial number counted under electron microscopy. Blood glucose, HbA1c and plasma lipid profiles were also measured.

**Results:** RSV significantly reduced UAE and attenuated renal histological changes in db/db mice. Oxidative stress and mitochondrial biogenesis were enhanced in db/db mice; however, Mn-SOD activity was reduced by its increased tyrosine-nitrated modification. RSV ameliorated systemic and renal mitochondrial oxidative stress, Mn-SOD activity, mitochondrial biogenesis, and partially improved blood glucose, HbA1c and abnormal lipid profiles in db/db mice.

**Conclusions:** RSV ameliorates renal injury and enhanced mitochondrial biogenesis with Mn-SOD dysfunction in the kidney of db/db mice, through improvement in oxidative stress via normalization of Mn-SOD function and glucose-lipid metabolism.

**Involvement of Fibrocytes in the Progression of Diabetic Nephropathy Via MCP-1/CCR2 Signaling** Akinori Hara,[1] Kiyoki Kitagawa,[1] Kengo Furuichi,[1] Takashi Wada.[2] *[1]Department of Disease Control and Homeostasis, Kanazawa University, Kanazawa, Ishikawa, Japan; [2]Department of Laboratory Medicine, Kanazawa University, Kanazawa, Ishikawa, Japan.*

**Purpose**: The migration and activation of a circulating mesenchymal progenitor cell, fibrocyte, by the action of the chemokine/chemokine receptor system has been implicated in the pathologic fibrogenesis including kidney fibrosis. In the present study, the involvement of fibrocytes via CC chemokine receptor 2 (CCR2), a cognate receptor of monocyte chemoattractant protein (MCP)-1/CCL2, was examined in the progression of diabetic nephropathy.

**Methods**: Human fibrocytes were isolated and incubated with high concentrations of D-glucose and/or MCP-1. Diabetic kidney injury was induced by the administration of streptozotocin in CCR2 knockout mice and mice treated with propagermanium (PG), a CCR2 inhibitor.

**Results**: *In vitro* examination revealed that stimulation of fibrocytes with high glucose increased the mRNA levels of transforming growth factor (TGF)-$\beta_1$ and pro $\alpha$1 chain of type I collagen (COL1A1) and MCP-1, and this effect was mediated in part by increased osmolality. In *in vivo* studies, fibrocytes, dual-positive for CD45 and type I collagen, infiltrated the diseased kidneys, especially the interstitium, and the number was reduced both in CCR2 knockout and PG-treated mice. Importantly, the blockade of CCR2 signaling reduced glomerulosclerosis and interstitial fibrosis. Concomitantly, transcripts of TGF-$\beta_1$, COL1A1, and MCP-1 in diseased kidney were decreased both in CCR2 knockout and PG-treated mice.

**Conclusion**: These findings suggest that fibrocytes infiltrate the kidney via MCP-1/CCR2 signaling and play a role in the progression of diabetic nephropathy.

**Simvastatin Alleviates Diabetes-Induced VEGF-Mediated Nephropathy Via the Modulation of Tight Junction Protein Occludin** Hui Peng,[1] Yan-Ru Chen,[1] Wenfang Chen,[2] Cheng Wang,[1] Farhad R. Danesh,[3] Tan-Qi Lou.[1] *[1]Division of Internal Medicine, Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; [2]Department of Pathology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China; [3]Department of Internal Medicine, Baylor College of Medicine, Houston, TX.*

Previous studies showed VEGF could increase glomerular endothelial cell permeability by disrupting tight junction protein occludin and ZO-1. We hypothesis occludin in glomerulis of diabetic nephropathy is disrupted, and simvastatin could ameliorate the disruption of occludin induced by VEGF in diabetic nephropathy. By using immunofluorescence, we assessed occludin expression in the renal biopsy sections of five diabetic nephropathy patients and three normal controls from renal carcinoma patients after nephrectomy. It showed the immunostaining of occludin was significantly decreased and discontinued in the glomerulis of diabetic nephropathy comparing normal renal control. Diabetic db/db mice received simvastatin (40 mg. kg. day p.o.) for 16 weeks, untreated db/db and db/m mice served as control. Occludin was detected by immuofluorescence and immunoblot, which was conducted with glomerulis extracted from mice kidneys. Urinary microalbumin concentrations were measured by ELISA. Simvastatin-treated mice exhibited significant reduction in albuminuria as well as significant recovery in occludin expression in the glomerulis compared with untreated db/db mice (n=3, $P<0.05$). We cultured glomerular endothelial cells, with or without simvastatin (1μM) pretreatment, in 50ng/ml VEGF. Simvastatin clearly attenuated the hyperpermeability promoted by VEGF when detected by trans-endothelial electrical resistance (TEER). Simvastatin also reversed VEGF induced occludin translocation from para-membrance to cytoplasm and reduced occludin tyrosine phosphorylation caused by VEGF. Based on these data, we propose that occludin is disrupted in glomerulis of diabetic nephropathy, which may be caused by elevated VEGF. It also suggests simvastatin may alleviates diabetes-induced VEGF-mediated endothelial via modulation of occludin.

**Paricalcitol, Vitamin D Analogue, Ameliorated Renal Injury through an Improvement of Lipid Metabolism and an Anti-Oxidative Effect in Diabetic Nephropathy** Young Sun Kang,[1] Young Youl Hyun,[1] Jinjoo Cha,[1] Ji Eun Lee,[2] Hyunwook Kim,[2] Kum Hyun Han,[3] Hyoung-Kyu Kim,[1] Dae R. Cha.[1] *[1]Nephrology, Korea University Ansan Hospital, Ansan, Republic of Korea; [2]Nephrology, Wonkwang University, Republic of Korea; [3]Nephrology, Inje University, Republic of Korea.*

Vitamin D deficiency is related to the cardiovascular and chronic kidney disease. Vitamin D improves albuminuria and the progression of renal injury. However, the mechanism in diabetic nephropathy remain unclear, independent of the classical action of vitamin D. We investigated the mechanism for the effect of vitamin D on type 2 diabetic nephropathy and lipid metabolism.Type 2 diabetic db/db mice were injected subcutaneously with 0.5ug/kg paricalcitol for 3 months. There were no differences in body weights, FPG, HbA1c, glucose/insulin tolerance test, serum creatinine level, systolic/diastolic blood pressure of the basal characteristic parameters. Organ weights such as kidney, heart, fat and liver were decreased in paricalcitol-treated diabetic mice. Paricalcitol improved cardiac LVMI and urinary albumin excretion. Paricalcitol-treated diabetic mice also showed improved plasma lipid profiles of total cholesterol, triglyceride and LDL.More interestingly, cholesterol and triglyceride contents in kidney tissue were dramatically decreased by paricalcitol, which showed the similar result in fat and liver. In addition, plasma and urinary 8-isoprostane levels were inhibited markedly by paricalcitol treatment. Tissue LPO in kidney, fat and liver was significantly improved. Paricalcitol suppressed the gene expressions and protein synthesis of TGF-b1, PAI-1 and type IV collagen. It also improved glomerulosclerosis, hepatic steatosis and adipose phenotypic change. These results were in accordance with *in vitro* experiment of cultured VDR siRNA mesangial cells that revealed the inhibitory changes in gene expression and protein synthesis of TGF-b1, PAI-1, type IV collagen and the enzymes related with lipid metabolism of FAS, HMG-CoA and SREBP1c. Collectively, paricalcitol might have the protective effect on diabetic nephropathy via an improvement of systemic and tissue lipid metabolism and an anti-oxidative effect.

**Hydrogen Sulfide Activates AMPK and Inhibits High Glucose Induction of Protein and Matrix Laminin Synthesis in Glomerular Endothelial Cells**
Hak Joo Lee,[1] Denis Feliers,[1] Meenalakshmi M. Mariappan,[1,2] Kavithalakshmi Sataranatarajan,[1,2] Goutam Ghosh-Choudhury,[1,2] B. S. Kasinath.[1,2] *[1]University of Texas Health Science Center, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX.*

Hydrogen sulfide (H2S) is a signaling gas that regulates vasculature; its role in diabetic nephropathy is not known. We hypothesized that H2S regulates high glucose effects on glomerular endothelial cells (GEndo). High glucose (30mM glucose), but not equimolar mannitol, significantly promoted global protein synthesis at 8 and 16 hrs and laminin (a1b1g1) synthesis at 1 hr; these events were inhibited by 250 uM NaHS, a H2S donor. Role of AMPK, an inhibitor of protein synthesis, was examined. NaHS stimulated activating Thr172 phosphorylation of AMPK peaking at 250 uM. High glucose reduced AMPK phosphorylation that was fully restored by NaHS at both 5 min and 8 hrs. H2S regulation of calcium-calmodulin kinase kinase beta (CamKKb) as an upstream kinase for AMPK was explored. STO-169 (10uM), an inhibitor of CamKKb, modestly but significantly inhibited NaHS stimulation of AMPK. Downstream of AMPK, high glucose induction of p70S6kinase (S6k) phosphorylation was inhibited by NaHS. High glucose induction of elongation phase events in mRNA translation that are controlled by S6k such as Ser366 phosphorylation of eEF2 kinase and Thr56 dephosphorylation of eEF2 were also inhibited by NaHS. Renal cortical content of cystathionine beta synthase (CBS), a H2S generating enzyme, was significantly reduced in OVE26 mice with type 1 diabetes and in db/db mice with type 2 diabetes compared to that in nondiabetic mice. These data suggest the following: 1. H2S stimulates AMPK phosphorylation in GEndos. 2. H2S inhibits high glucose induction of global and matrix laminin synthesis, probably by stimulating AMPK activity and inhibiting S6k and elongation phase of mRNA translation. 3. H2S induction of AMPK partly involves activation of CamKKbeta. 4. Reduction in CBS in renal cortex of diabetic mice suggests that H2S production in the kidney may be reduced in diabetes. Our data suggest that diabetes-induced reduction in H2S may contribute to renal hypertrophy and matrix accumulation.

**The Post-Ischemia Inflammatory Syndrome of Diabetic Nephropathy**
Katherine J. Kelly,[1] Jesus H. Dominguez.[1,2] *[1]Medicine/Nephrology, Indiana University School of Medicine, Indianapolis, IN; [2]Medicine/Nephrology, Roudebush VAMC, Indianapolis, IN.*

Diabetes mellitus and its complications are a public health problem of epidemic proportions. Both diabetes and chronic kidney disease (CKD) increase the risk of acute kidney injury. In spontaneously obese-diabetic rats (ZS rats) we have demonstrated accelerated progression of nephropathy, with progressive increases in serum creatinine and proteinuria following a single episode of acute renal ischemia. Severe renal inflammation was closely linked to renal dysfunction in this novel model of "acute-on-chronic" renal failure. We termed this entity the post-ischemic inflammatory syndrome (PIIS). Currently, there is no specific therapy for this syndrome. We now demonstrate that renal function continues to deteriorate in rats over months after an acute injury and multiple inflammatory markers are significantly activated in the diabetic kidneys, including interleukin-6, cytokine induced neutrophil chemoattractant, macrophage migration inhibitory factor and transforming growth factor receptor. We further characterized the inflammatory phenotype in cultured tubular cells and found that tumor necrosis factor a and angiotensin II increased expression of both intercellular adhesion molecule-1 (ICAM-1) and the receptor for oxidized LDL, LOX-1, in NRK52E tubule cells. This proinflammatory response was abrogated by GW0742, a selective agonist of peroxisome proliferator activator receptor (PPAR) δ. Hence PPAR δ activation exerts powerful anti-inflammatory action on renal tubular cells. We speculate that PPARδ agonists could improve the postischemia inflammatory syndrome.

**Osteopontin-to-Creatinine Ratio as a Biomarker of Type 2 Diabetic Nephropathy**
Susanne B. Nicholas,[1, 2] John M. Basgen.[2] *[1]Medicine, David Gefen School of Medicine at UCLA, Los Angeles, CA; [2]Research, Charles Drew University of Medicine and Science, Lynwood, CA.*

Osteopontin (OPN) is a secreted, multi-functional, matrix glycoprotein present in low levels in kidneys, but is significantly upregulated in tissue injury. Increased OPN plays an important role in several animal models of chronic kidney disease, wound healing and coronary artery calcification and is a potential biomarker of coronary artery disease. We have demonstrated that OPN is critical in angiotensin II-induced tubulointerstitial fibrosis, and glomerulosclerosis of type 1 and type 2 diabetic nephropathy (DN). Here we show that increased urinary osteopontin-to-creatinine ratio (OCR) in the *db/db* mouse, a well characterized genetic model of human type 2 DN, correlates well with several structural parameters characteristic of human DN.

Non-diabetic *db/m* and diabetic *db/db* mice (n=5-7) were followed from the start of diabetes (age 8 weeks) to age 20 weeks. Plasma glucose and tail-cuff blood pressures were measured and animals were placed in metabolic cages for 24h urine and determination of OCR and albumin-to-creatinine ratio (ACR; by ELISA). At age 20 weeks, the right kidney was harvested for paraffin-embedded sections for Periodic Acid Schiff (PAS) staining and the left kidney was perfused-fixed and processed for light and electron microscopy.

As expected, plasma glucose significantly increased after 12 weeks of diabetes. In addition, there was a 1.6-fold, $p<0.05$ increase in % mesangial area, a 1.1-fold, $p<0.05$ increase in glomerular basement membrane thickening, 1.3-fold, $p<0.001$ increase in fractional volume of mesangium, and 1.6-fold, $p<0.005$ increase in glomerular volume. OCR and ACR were significantly increased between *db/m* and *db/db* mice, 15-fold and 24-fold, $p<0.05$ respectively. Urinary OCR in *db/db* mice showed a consistent increase up to 64.8-fold, $p<0.005$. However, ACR peaked at 16 weeks (6.4-fold, $p<0.05$) and then declined.

The data indicate that OCR is an acceptable indicator of the structural glomerular progression of DN and that OCR may be a better determinant of DN compared to ACR in the *db/db* mouse. The data also suggests that OCR may be a biomarker of DN in humans.

**Advanced Glycation End-Products (AGEs) Inhibit Focal Adhesion Kinase and Rac-1 Activition Via Suppression of Neuropilin-1 (NRP1) Expression**
Gunter B. Wolf. *KLinik für Innere Medizin III, University of Jena, Jena, Germany.*

Aim: We have recently demonstrated that glycated-BSA (AGE-BSA) inhibits podocytes migration in a NRP1 dependent manner. The purpose of this study was to analyze the contribution of AGEs and NRP1 in regulation of focal adhesion kinase (FAK) activity and small RhoA GTPases in differentiated podocytes.

Methods: Murine differentiated podocytes were treated with 5 mg/ml AGE-BSA or the same amount of a control-BSA(Co-BSA), for 24 h. After that the cells were left untreated or stimulated with 10-7M (Phorbol 12-myristate 13-acetate, PMA), a well-known FAK activator for 10 min and lysates were analyzed via western blot. NRP1 expression was down-regulated via SIRNA technology. Influence of NRP1 on FAK activation was also tested through forced overexpression of NRP1. The activity of Rac-1 and RhoA was analyzed in pull-down assays.

Results: Our data revealed that pFAK activation was significantly reduced in cells treated with AGE-BSA compared to Co-BSA. Similarly, podocytes depleted of NRP1 via transfection of Nrp1 SiRNA inhibited PMA dependent FAK activation, In contrast, forced overexpression of full length mouse NRP1 in podocytes induced stronger FAK Tyr 576 phosphorylation in PMA treated cells then the empty vector transfection. As migration is also related to the activation of the small RhoA GTPases we addressed the influence of AGE-BSA and NRP1. Our data demonstrate that treatment of podocytes with PMA induced an accumulation of the Rac-1 GTP, active state, in Co-BSA incubated cells, while AGE-BSA remarkably inhibited Rac-1 activation. Down-regulation of NRP1 suppressed PMA induced Rac-1 activity. In fact, there was not a detectable signal for Rac-1 in the western blots from the pull-down assays. Nevertheless, no inhibitory effect of the co siRNA was detected. Opposite, NRP1 overexpression increased the accumulation of Rac-1 GTP in PMA stimulated podocytes above the empty vector transfected cells treated with PMA. Conclusions: AGE-BSA treatment inhibits FAK activity in podocytes stimulated with PMA compared with Co-BSA. This effect was NRP1 dependent These mechanisms may contribute to diabetic nephropathy.

**Advanced Glycation End Products (AGEs) Increase Human Mesangial Foam Cell Formation by Increasing SCAP Golgi Modification**
Xiong Z. Ruan,[3] Yang Yuan,[1,3] Lei Zhao,[2] John F. Moorhead,[3] Zachariah Varghese.[3] *[1]Endocrinology, Zhongda Hospital Southeast University, Nanjing, China; [2]Centre for Lipid Research, Chongqing Medical University, Chongqing, China; [3]Centre for Nephrology, University College London Medical School, London, United Kingdom.*

Diabetic nephropathy caused by advanced glycation end products (AGEs) is associated with lipid accumulation in glomeruli. This study was designed to investigate whether $N^{\varepsilon}$-(carboxymethyl) lysine (CML) (one of AGEs family) increase lipid accumulation in human mesangial cells (HMCs) via LDL receptor pathway by increasing SREBP cleavage-activating protein (SCAP) transcription and its posttranslational modification in Golgi.

HMCs were treated with CML. Intracellular cholesterol content was assessed by Oil Red O staining and cholesterol enzymatic assay. Expression of mRNA and protein of molecules controlling cholesterol homeostasis in the treated cells was examined by real-time quantitative PCR and western blotting, respectively. Golgi enzymes activity was determined using enzyme-based method. SCAP translocation was detected by confocal microscopy.

CML increased cholesterol accumulation in HMCs. Exposure to CML increased expression and abnormal translocation of SCAP from ER to Golgi even in the presence of a high concentration of LDL. The increased SCAP translocation carried more transcription factor SREBP2 to the Golgi for activation by cleavage which enhanced gene transcription of LDL receptor and HMGCoA reductase. Furthermore, CML enhanced SCAP glycolyzation by upregulating Golgi mannosidase activity. This prolonged the half-life and enhanced recycling of SCAP between the ER and the Golgi. The effects of CML were blocked by inhibitors of Golgi mannosidases.

*Conclusions:* AGEs (CML) increased lipid synthesis and uptake, thereby causing foam cell formation via increasing transcription and protein glycolyzation of SCAP by Golgi enzymes in HMCs. These data imply that Golgi enzymes inhibitors might have a potential renal protective role in prevention of mesangial foam cell formation.

**Attenuation of Diabetic Nephropathy Via RAGE Deletion in Type 1 Diabetic Transgenic Mice Expressing Human Aldose Reductase** Anjali Ganda, Radha Ananthakrishnan, Rosa Rosario, Vivette D. D'Agati, Ravichandran Ramasamy, Ann Marie Schmidt. *Medicine, Surgery, Pathology, Columbia University College of Physicians & Surgeons, New York, NY.*

Substrate flux via aldose reductase (AR), the rate limiting enzyme in the polyol pathway, mediates the generation of pre-advanced glycation end-products (pre-AGEs) from glucose. AR-inhibitors suppress albuminuria, mesangial expansion, and glomerular basement membrane (GBM) thickening in animal models, and reduce microalbuminuria in human type 1 diabetics. AR gene polymorphism is present in patients with diabetic nephropathy. We tested the hypothesis that Receptor for Advanced Glycation End-Products (RAGE) gene deletion in Type 1 diabetic transgenic mice expressing human levels/activity of AR (TghAR+) will exert protection against indices of diabetic nephropathy (DN).

TghAR+ mice (C57BL/6) were bred into the RAGE-expressing(+) or RAGE-null background and rendered Type 1 diabetic with streptozotocin at age 6 wks. Mice were sacrificed at age 15 and 26 wks. Kidneys were stained with periodic-acid Schiff (PAS). A semi-quantitative mesangial sclerosis score was calculated by averaging findings in >100 glomeruli/mouse (scale 0-3+; 0=absent, 1=mild, 2=moderate, 3=severe). GBM thickness and foot process (FP) effacement were determined by ultrastructural analysis (≥ 8 glomeruli/mouse studied).

TghAR+RAGE+ mice sacrificed at 15 wks of age (n=2) had mean 0.5 mesangial sclerosis, GBM diameter 156.76±22.96 nm, and 5% FP effacement. TghAR+RAGE+ mice sacrificed at 26 wks of age (n=2) demonstrated progression of all indices of DN with mean 2.5 mesangial sclerosis, GBM diameter 268.22±117.25 nm, and 21% FP effacement. TghAR+RAGE-null mice sacrificed at age 26 wks (n=2) displayed sizable, although not complete, protection in all indices of DN with mean 1.5 mesangial sclerosis, GBM diameter 200.11±41.13 nm, and 12% FP effacement.

RAGE deletion is known to protect against indices of DN in animal models. One major previously unexplored mechanism may be its effect on inhibiting the downstream effects of toxic products generated by AR. Drugs targeting both AR and RAGE may exert additive/synergistic benefit in preventing progression of DN.

**SA-PO2534**

**Kidney Handling of Glycated and Advanced-Glycated End Product Albumin Using Two-Photon Microscopy** Monika D. Gandhi, Mark C. Wagner, George Rhodes, Exing Wang, Ruben M. Sandoval, Silvia B. Campos-Bilderback, Bruce A. Molitoris. *Nephrology, Indiana University, Indianapolis, IN.*

Glycated and Advanced Glycation End Products (AGE) are different stages of glucosylated proteins commonly shown as strong markers of Diabetic complications. In particular, glucosylated proteins derived from the Glucose and Dicarbonyl α-oxaldehyde Methylglyoxal (MGO) incubations are closely associated with hyperglycemia and increased susceptibility to Diabetic Nephropathy. The, *Kidney* is the major site for glucosylated protein excretion with selective excretion of glucosylated albumin, known as the "editing" phenomenon - however, little is known about the *process of* editing.

Therefore, our study tests the hypothesis that glucosylated-modified albumin is filtered through the glomerular barrier at similar rates, but it is handled differently by the proximal tubule cells. This was evaluated by infusion of Texas Red conjugated, un-glycated, glucose-modified, and MGO-modified albumin into *Munich Wistar Fromter* rats. Two-photon microscopy was used to directly quantify *in vivo* albumin filtration and proximal tubule handling.

MGO-modified albumin showed a significant reduction in plasma fluorescence at 24 hrs compared to both un-glycated (P 0.006) and glucose-modified albumins (P 0.031) with percent plasma fluorescent at 24hrs/2hrs for Un-glycated of 19.41+/-3.33%, Glucose-modified of 20.17+/-5.91% and MGO-modified of 7.43+/-0.31%. We measured similar glomerular permeability (Glomerular Sieving Coefficient - GSC) between Glucosylated albumin (GSC for MGO-albumin of 0.0113+/-0.0081 and Glycated-albumin of 0.0099+/-0.0051) and un-glycated albumin (GSC of 0.0109+/-0.0047). These differences indicate that it is not the glomerular handling, but possible protein handling and trafficking by the renal proximal tubule of the AGE-modified proteins that is affected. However, the reversible mid-phase glucosylated proteins made by glucose-modification of the albumin is not handled differently as the end-phase Amadori products of AGEs. This is consistent with the pathogenic role of AGEs and early proximal tubule functional changes seen leading to hypertrophy and nephropathy in diabetes.

**SA-PO2535**

**Advanced Glycation End-Products (AGEs) Differentially Regulate Morg1 Expression in Renal Cells** Gunter B. Wolf. *Internal Medicine II, University of Jena, Jena, Germany.*

Aim: The mitogen-activated protein kinase organizer 1 (Morg1) was recently identified as a novel protein that covalently binds to PHD3. The purpose of this study was to analyze the influence of AGEs on Morg1 expression in different kidney cell lines. Methods: MMC (mouse mesangial cells) and MTC (mouse tubular cells) . Differentiated murine podocytes were also studied. Cells were serum deprived for 24 h, followed by treatment with 5 mg/ml Co-BSA (not glycated BSA) or AGE-BSA (glycated - BSA) for 24 h. Morg1 expression was analyzed by real-time PCR and western blot. HIF-1alpha promoter activity was tested in a reporter-gene assay system. PHD3 activity was measured using hydroxylation-coupled decarboxylation of (1-14C)-2-oxoglutarate followed by liquid scintillation counting of the formed 14CO2. Results: All three kidney cell lines expressed Morg1, but podocytes somewhat less then MMC and MTC cells. Our data revealed that AGE-BSA increased Morg1 expression in MMCs and podocytes, whereas its expression in MTCs was significantly reduced. Western blot analysis confirmed the real time PCR findings. In addition we checked the HIF-1α and HIF-2α expression on a protein level but did not detect significant changes. Therefore, we analyzed HIF-1alpha expression using a gene–reporter assay, which is more sensitive method to test gene expression and regulation. We observed that HIF-1α promoter activity in MMC and MTC exposed to AGE-BSA was induced correspondingly 1.66±0.16 fold and 1.82±0.12 fold relative to Co-BSA treated cells. In contrast HIF-1α promoter activity demonstrated significant reduction in luciferase activity in differentiated podocytes incubated with AGE-BSA (0.7±0.1 fold vs. Co-BSA). We found that AGE-BSA treatment increased PHD3 activity in MMC and podocytes, but inhibited PHD3 activation in MTCs. Conclusion: The relationship between Morg1 expression, PHD3 activity and HiF1α activation is complex and cell specific. Although AGE-BSA-mediated suppression of PHD3 activity increased HiF1α expression, Morg1 appears to be concomitantly regulated with PHD3. Our finding may provide a novel link between AGEs and hypoxia in diabetic nephropathy.

**SA-PO2536**

**Additive Renoprotective Effects of B2-Kinin Receptor Blocker and PPAR-γ Agonist in Uninephrectomized *db/db* Mice** Sydney C. W. Tang,[1] Loretta Y. Y. Chan,[1] Joseph C. K. Leung,[1] Hui Y. Lan,[2] Kar Neng Lai.[1] *[1]Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [2]Department of Medicine and Therapeutics, Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong.*

We recently showed that the bradykinin B2 receptor (B2R) blocker icatibant and the perioxisome proliferator-activated receptor-γ agonist rosiglitazone (Ros) exerted anti-inflammatory effects in renal tubular cells exposed to a diabetic milieu. This study aims to explore whether these effects can be translated to an experimental model of type 2 diabetic nephropathy. *db/db* mice and their nondiabetic *db/m* littermates underwent sham operation or uninephrectomy (Unx) at 10 weeks and received vehicle, metformin, icatibant, Ros, or icatibant plus Ros for 8 weeks before sacrifice. Among the *db/db* group, mice that received icatibant or Ros had significantly lower serum creatinine and albuminuria, which was further reduced when icatibant and Ros were given in combination. These beneficial effects were not observed in the metformin group that achieved similar glycemic control as Ros-treated animals. Likewise, the severity of glomerulosclerosis, interstitial injury, cortical F4/80 and a-smooth muscle actin immunostaining, and CCL-2, ICAM-1, and TGF-β overexpression were all attenuated by icatibant and Ros, and these effects were enhanced when both agents were combined. At the signaling level, icatibant and Ros reduced ERK1/2 and STAT1 activation, respectively. Our results suggest a deleterious role of the kallikrein-kinin system in murine accelerated diabetic nephropathy, which can be ameliorated by the B2R blocker icatibant and enhanced by the addition of Ros. This may open a novel therapeutic approach for further evaluation.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2537**

**Kidney Injury Molecule-1 (Kim-1) Mediates Tubular Epithelial Cell Injury in Diabetic Nephropathy** Takaharu Ichimura, Huiping Zhao, Suetonia Palmer, Shan Mou, Davide Pietro Cina, Heung-Myong Woo, Joseph V. Bonventre. *Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Diabetes mellitus is the leading cause of end-stage renal failure. Although diabetic nephropathy (DN) is characterized by glomerulopathy and albuminuria, disease progression best correlates with tubular degeneration and interstitial fibrosis. Kim-1, a scavenger receptor highly expressed by injured proximal tubule cells, is present in the urine of patients with DN.

To study the effects of Kim-1 on disease progression, we developed a murine model of DN combining streptozotocin injection, unilateral nephrectomy, and high fat diet. Mice developed albuminuria and progressive kidney injury; Kim-1 was expressed by proximal tubule cells. *In vitro* high glucose levels enhanced cultured epithelial cell Kim-1 expression, via a process that was reactive oxygen species dependent. *In vivo* and *in vitro*, Kim-1 augmented tubule cell uptake of advanced glycation end products (AGE) and oxidized lipids, two components of the proximal tubular fluid in patients with diabetes mellitus. In mouse DN kidneys *in vivo*, tubules that expressed Kim-1 had augmented AGE uptake, brush border loss, and were surrounded by F4/80 positive macrophages. In these kidneys, proximal tubules showed accelerated tubule cell senescence and increased interstitial myofibroblast expansion. Ingestion of oxidized lipids or AGE by primary tubule cells that express Kim-1 in culture markedly enhanced caspase 3 activity and apoptosis, reflecting tubule cell toxicity. Uptake of oxidized lipids by tubule cells also enhanced subsequent TNFα release by co-cultured macrophages.

In conclusion, Kim-1 expression in DN is induced by hyperglycemia and associated oxidant stress. Kim-1 enhances tubule cell uptake of AGE and oxidized lipids, and potentiates a pro-inflammatory tubular injury that ultimately contributes to tubule degeneration and fibrosis, and progressive kidney disease.

Disclosure of Financial Relationships: Patent: Kim-1 patents licensed by Partners Healthcare to Johnson and Johnson, BiogenIdec and Genzyme.

**Inhibition of Inflammation by Oral Pentosan Polysulfate Prevents Diabetic Nephropathy in Aging C57B6 Mice** Jin Wu, Fabrizio Grosjean, Helen Vlassara, Gary E. Striker, Feng Zheng. *Geriatrics and Palliative Medicine, Mount Sinai School of Medicine, New York, NY.*

Since inflammation plays a key role in the development and progression of diabetic nephropathy, we asked whether a drug that reduces inflammation would reduce diabetic nephropathy in mice. We previously found that PPS reduces interstitial inflammation and prevents glomerulosclerosis in 5/6th nephrectomy rats (JASN 12:2080-87, 2001). In addition, we recently found that, whereas young diabetic C57B6 mice develop only mild lesions, old diabetic C57Bl6 mice develop severe DN involving glomeruli, tubules, blood vessels and the tubulointerstitium (AmJPath 176:2163-76, 2010). Since PPS reduces interstitial inflammation, we examined old diabetic C57B6 mice to determine if PPS treatment affected DN. We examined fresh renal tissue and renal cells in culture to determine the mechanisms by which PPS affects proinflammatory responses in diabetes. C57B6 mice (18 months old) were treated with streptozotocin to induce diabetes in aging C57B6 mice. One month after the induction of stable diabetes, mice were randomized to receive either oral PPS (25 mg/kg/day) or tap water for 4 months. PPS treatment preserved renal function (Scr 0.109±.03 vs. 0.138±.02 mg/dl, $p<0.05$) and significantly reduced the progression of albuminuria (710 vs. 48 µg/mgCr, $p<0.01$) in aging diabetic mice, and decreased the severity of renal lesions, especially the tubulointerstitial inflammation (<1+ vs. 3+) and 70% reduction in apoptosis. The upregulation of TNFa and proinflammatory genes (MCP-1, RANTES, CXCl-1, MIP-2, and ICAM-1) in aging diabetic kidneys was reduced by >50% with PPS treatment. In cultured renal cells, PPS suppressed NF-kB and decreased the proinflammatory action of TNFa by >2-fold. PPS also decreased TNFa, high glucose, and advanced glycation end product-stimulated MCP-1 production. Finally, PPS decreased TNFa-induced increase in albumin permeability in podocytes in culture. Thus, 1) PPS treatment decreases inflammatory lesions of aging diabetic nephropathy and largely prevents disease progression, 2) PPS may be a useful adjunct in the management of DN in aging patients.

**Therapeutic Augmentation of Tubular Regeneration Following Acute Kidney Injury** Takuto Chiba,[2] Raymond C. Harris,[1] Neil A. Hukriede,[3] Mark P. De Caestecker.[1, 2] *[1]Nephrology Division, Vanderbilt University, Nashville, TN; [2]Cell and Developmental Biology, Vanderbilt University, Nashville, TN; [3]Microbiology and Molecular Genetics, University of Pittsburgh, Pittsburgh, PA.*

As part of a screen to identify compounds that promote expansion of renal progenitor cells, we identified a novel histone deacetylase (HDAC) inhibitor, methyl-4-(phenylthio) butanoate (M4PTB). M4PTB promotes expansion of renal progenitor cells in zebrafish embryos, and enhances renal tubular recovery in a zebrafish model of acute kidney injury (AKI). Other HDAC inhibitors such as phenylbutanoic acid and trichostatin A likewise promote expansion of the renal progenitor cells in zebrafish embryos. In comparison to M4PTB, these compounds induce generalized defects in embryonic patterning at equivalent effective doses indicating greater toxicity. To determine whether M4PTB augments renal tubular regeneration following AKI in mice, we first evaluated the effect of systemic administration of M4PTB on renal histone acetylation in mice. A single dose of m4PTB induced a marked increase in H3 K9 acetylation for 24 hours after treatment. Having established the effective dose of M4PTB, we developed a mouse model of AKI in which selective proximal tubular injury is induced by administration of diphtheria toxin (DT) to transgenic mice expressing the diphtheria toxin receptor under the control of gamma-GT promoter (γ-GT-hHB-EGF mice). M4PTB was administered subcutaneously 24 hours after DT injection in γ-GT-hHB-EGF mice and then daily thereafter. At four days post-injury there was a reduction in blood urea nitrogen (BUN) levels, and tubulointerstitial injury scores are decreased in M4PTB-treated vs. vehicle-treated mice after 10 days. Moreover, M4PTB treatment is associated with increased proximal tubular cell and decreased interstitial cell proliferation during recovery. These data indicate that treatment with M4PTB increases the rate of renal recovery, reduces post-injury tubulointerstitial fibrosis and suggest that these effects result from selective enhancement of renal tubular regeneration and inhibition of interstitial fibrosis.

**SA-PO2540**

**Variability in PTEN Expression Regulates Glomerular Endothelial Cell Permeability** Zhaoyong Hu,[1] Wenjian Wang,[2] William E. Mitch.[1] *[1]Internal Medicine, Baylor College of Medicine, Houston, TX; [2]Internal Medicine, Guangdong General Hospital, Guangzhou, Guangdong, China.*

Growth factors have been implicated in modulating kidney functions because they can promote cell growth and mobility plus cytoskeletal rearrangement. Many growth factor-initiated signaling pathways include stimulation of phosphatidylinositol 3-kinase (PI3K) activity, producing the 2nd messanger, PIP3. PIP3 is also regulated by PTEN, a phsphatase converting PIP3 to the inactive product, PIP2. In db/db mice with diabetic nephropathy, PTEN expression was shown to be reduced in glomeruli leading to the conclusion that a decrease in PTEN causes measangial expansion as a prelude to diabetic nephropathy. In normal mouse kidney, we found that PTEN is expressed in glomerular endothelial cells,podocytes and tubular cells. In kidneys of db/db mice, we found PTEN expression decreassed in glomerular endothelial cells and podocytes. We then evaluated whether changes in PTEN expression could affect kidney function by measuring albumin permeability through a monolayer of glomerular endothelial cells. First, we knocked down PTEN in glomerular endothelial cells and found a 1.5-fold increase in albumin permeability compared to cells treated with a scrambled control siRNA. Second, we over expressed PTEN in glomerular endothelial cells: albumin permeability was unchanged from control, but permeability stimulated by VEGF or PDGF were blocked. Because changes in the actin cytoskeleton can regulate cell permeability in glomerular endothelial cells, we evaluated how varying PTEN expression would influence actin cytoskeleton rearrangement. PTEN over-expression inhibited the rearrangment of actin filaments induced by VEGF; Knokdown of PTEN increased F-actin formation, consistent with the increase in albumin permeability. We also studied the BpV inhibitor of PTEN, when we added BpV (Hopic) to glomerular endothelial cells, albumin permeability was increased.We concluded that changes in PTEN expression regulate the permeability of glomerular endothelial cells. Manipulation of PTEN could provide a target for preventing albuminuria associated with diabetic nephropathy and potenitally, other chronic kidney diseases.

**Mannose-Binding Lectin (MBL) and High-Sensitive C-Reactive Protein (hsCRP) Concentrations Predicts Cardiovascular Events and Kidney Function among Patients with Type 1 Diabetes and Diabetic Nephropathy** Maria Lajer,[1] Anders Jorsal,[1] Troels Krarup Hansen,[3] Lise Tarnow,[1] Steffen Thiel,[3] Hans-Henrik Parving,[2] Allan Flyvbjerg,[3] Peter Rossing.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Dep. of Medical Endocrinology, Rigshospitalet, Copenhagen University Hospital, Denmark; [3]Medical Department M and Medical Research Laboratories, Aarhus University Hospital, Denmark; [4]Medical Microbiology and Immunology, Aarhus University.*

Mannose-binding lectin (MBL) and high-sensitive C-reactive protein (hsCRP) are markers of complement activation and inflammation suggested to be involved in diabetic vascular damage.

This prospective observational follow-up study included 198 type 1 diabetic patients with overt diabetic nephropathy (121 men; age 40.9±9.5 years (mean±SD); $^{51}$Cr-EDTA-GFR 74±33ml/min/1.73m$^2$) and 175 longstanding type 1 diabetic patients with persistent normoalbuminuria (103 men; age 42.6±9.5 years; duration of diabetes 27.6±8.2 years). Patients were followed for 12.6(0.0-12.9) years (median (range)).

Among patients with diabetic nephropathy, 78 patients died and 84 suffered fatal or non-fatal cardiovascular event. Those with both serum MBL and hsCRP levels above the median had an increased risk of all-cause mortality and fatal or non-fatal cardiovascular disease, compared to patients with both levels below the median ($p<0.008$). After adjusting for covariates (sex, age, smoking, SysBP, $HbA_{1c}$, cholesterol, and GFR), hazard ratio (95% CI) were 1.9(1.0-3.9) and 2.0(1.0-3.8), respectively.

Regarding kidney function, the decline in GFR was faster among patients with higher MBL and hsCRP levels (-4.7±5.8) ml/min/year) vs. lower (-3.2±2.5) ml/min/year), ($p=0.042$). However, MBL and hsCRP levels did not predict development of end-stage renal disease (n=40), ($p=0.71$). Among the normoalbuminuric patients, MBL above vs. below the median did not predict either all-cause mortality or fatal and non-fatal cardiovascular disease 1.4(0.6-3.6) and 0.7(0.3-1.6), respectively.

In conclusion, combined higher levels of MBL and hsCRP are predictive of cardiovascular disease and loss of kidney function among type 1 diabetic patients with diabetic nephropathy.

**Discovery of Novel Biomarkers for Diagnostics of Diabetic Nephropathy** Ulrika Lundin,[1] Angel Argiles,[2] Harald Mischak,[3] Klaus M. Weinberger.[1] *[1]BIOCRATES Life Sciences AG, Innsbruck, Austria; [2]RD Néphrologie, Montpellier, France; [3]Mosaiques Diagnostics & Therapeutics AG, Hannover, Germany.*

Diabetic nephropathy is one of the most severe complications from type II diabetes and often leads to end stage renal disease. The epidemiological increase of type II diabetes and the fact that conventional diagnostic markers like creatinine and albumin are insensitive and unable to detect renal damage at initial stages of pathogenesis emphasizes the need of novel and more sensitive markers.

In this study, samples from six cohorts, diabetics and non diabetics at different stages of nephropathy, were collected. Targeted metabolomics was used to quantitate about 460 metabolites in plasma and 270 in urine including the classes amino acids, biogenic amines, polyamines, acylcarnitines, phosphatidylcholines, reducing mono- and oligosaccharides, sphingomyelins, eicosanoids, bile acids and energy metabolism intermediates. The analytical methodology of choice was flow injection analysis (FIA) or HPLC-ESI-MS/MS in highly selective multiple reaction monitoring mode performed on an AB Sciex API 4000 QTRAP® instrument (AB Sciex). Additionally, 160 fatty acids were quantitated in plasma by GC-MS/MS.

The datasets were analyzed using principal components- and discriminant analysis and several advanced statistical tests to assess the most significant metabolites. By first looking at the different metabolic pathways and then grouping the significantly altered metabolites thereafter, we found compounds involved in dimethylarginine metabolism, in urea cycle / NO synthase, TCA cycle, certain low abundant acylcarnitines, and oxidative stress related compounds to be associated with progression of renal damage. These results both confirmed old findings, such as symmetric dimethylarginine (SDMA), already an established marker for renal damage, but also presented potential novel biomarkers like

the acylcarnitines glutarylcarnitine and pelargonylcarnitine, which both show an increase with progression of renal damage. With metabolomics, not only new markers can be found but by covering the main pathways of intermediary metabolism a deeper understanding of the cause of the disease can also be obtained.

### SA-PO2543

**A Novel Model of Metabolic Syndrome and Insulin Resistance (IR) in Uremic Rodents and Effect of Inhibition of the Enzyme 11 beta Hydroxy-Steroid Dehydrogenase Type 1 (11HSD1)** Ananda Chapagain, Paul W. Caton, Julius Edward Kieswich, Nanda K. Nayuni, Steven Michael Harwood, Martin J. Raftery, Magdi Yaqoob. *Translational Medicine and Therapeutics, QMUL, London, United Kingdom.*

We have shown that IR in uremia can be partly explained by excessive gluconeogenesis due to increased hepatic glucocorticoid (GC)activity through 11HSD1 in 5/6 nephrectomized rats. Here, we present further data in a different animal model. Eight week old Wistar rats were subjected to a diet consisting of 0.75% adenine or standard chow for a total of 4 weeks.At 2 weeks carbenoxolone (CX; 50 mg/kg) was gavaged to half of the rats to give 4 groups (1) adenine-induced uremia (2) adenine-induced uremia plus CX (3) standard chow (4) standard chow plus CX.After 4 weeks,the rats were fasted, anaesthetized and plasma samples obtained. Rats were then subjected to glucose and insulin tolerance tests.The animals were sacrificed,and plasma and tissue samples obtained.To assess gluconeogenesis, phosphoenolpyruvate carboxykinase (PCK1) and Glucose-6 phosphatase (G6Pase) was assayed using western blot, along with protein levels of 11HSD1, PCK1 transcription factors p-CREB and FOXO1,PGC-1a (PPAR-gamma coactivator 1 alpha)and TORC2(PGC1a coactivator).Insulin and levels of inflammatory cytokines IL-1b and TNF-a,known up-regulators of HSD1,were measured using specific ELISA.Statistical comparisons were determined by ANOVA.Plasma urea (8.8 fold; $p<0.01$) and creatinine (6.2 fold; $p<0.01$) levels were raised in uremia,as well as higher fasting plasma Insulin levels(2.1 fold, 503±16 pg/ml, $p<0.05$), abnormal glucose and insulin tolerance tests, elevated circulating levels of IL-1b (1.9 fold, 66 ±12 pg/ml, $p<0.05$) and increased 11HSD1, p-CREB, TORC2, PGCa, PCK1 and G6Pase protein compared to sham animals.These changes reversed with CX treatment,with 11HSD1 and PCK1 protein reduced by 1.6± 0.4fold ($p<0.05$) and 1.4± 0.1 fold ($p<0.01$) respectively and similar reduction in associated proteins.

These results confirm that IR in uremia occurs through abnormally elevated GC-directed gluconeogenesis as a result of increased 11HSD1. Furthermore, we also demonstrate a novel and easily reproducible model of IR in uremia.

### SA-PO2544

**Mouse Model of Diabetic Cardiorenal Syndrome** Jae-Hyung Chang,[1] Seung-Yeol Paik,[2] Lan Mao,[1] Susan B. Gurley,[1] Phillip Ruiz,[3] Robert F. Spurney.[1] *[1]Duke University, Durham, NC; [2]Chung-ang University, Seoul, Korea; [3]University of Miami, Miami, FL.*

A significant subset of patients with diabetes mellitus develop cardiovascular disease and diabetic nephropathy (DN) which may result from a constellation of coexistent risk factors including hypertension, left ventricular hypertrophy (LVH), hyperglycemia and albuminuria. In developed countries, diabetic cardiorenal syndrome is a significant healthcare burden because the incidence of diabetes mellitus has reached epidemic proportions. Akita mice are a genetic model of type 1 diabetes caused by a mutation (*Ins2*$^{+/C96Y}$) that results in selective pancreatic β-cell failure as a result of proteotoxicity due to misfolding of insulin 2. The phenotypic effect of these abnormalities is, however, significantly influenced by genetic background. In the present studies, we determined if Akita mice on the FVB/NJ background have features of human diabetic cardiorenal syndrome including hypertension and durable hyperglycemia as well as histopathologic, functional and molecular characteristics of DN and LVH in humans. We found that male FVB/NJ Akita mice developed sustained hyperglycemia as well as polyuria by 4 weeks of age, which was associated with increased rates of podocyte apoptosis. These abnormalities were associated with a significant increase in systolic blood pressure in 10-week old Akita mice. At this time point, heart weight was significantly increased and was associated with echocardiographic evidence of LV systolic dysfunction as well as enhanced expression of molecular markers of cardiac hypertrophy including mRNA for β-myosin heavy chain as well as atrial natriuretic peptide. Pathological examination revealed interstitial fibrosis and inflammatory infiltrates in hearts of 10-week old Akita mice. By 20 weeks of age, Akita mice developed features of human DN including renal hypertrophy, a 10-fold increase in albuminuria, glomerular hypertrophy and a decrease in the number of podocytes. While additional studies are required to fully validate the FVB/NJ Akita model, these data suggest that Akita mice on the FVB/NJ background may be a useful platform for studying the mechanisms of diabetic cardiorenal injury in humans.

### SA-PO2545

**Self-Assemble Peptide Nanofibers Serve as an Acellular Develivery Platform for the Secretome from Human Embryonic Stem Cells: Implications for Diabetic Nephropathy** Yin Wang, Wenjian Wang, Farhad R. Danesh. *Medicine/Nephrology, Baylor College of Medicine, Houston, TX.*

Recent studies have suggested that paracrine/endocrine factors secreted from stem cells account for many of the beneficial effects of stem cells in the kidney recovery following acute kidney injury. However, the contribution of secretome from stem cells on chronic kidney diseases such as diabetic nephropathy (DN) is unknown. In this regards, human embryonic stem cells (hES) represent a powerful tool for cell therapy in the kidney due to their extensive profile of cytokines/chemokines and growth factors. In the current study, we developed a self-assembled peptide nanofiber preparation as an acellular platform for delivery of secreted paracine/endocrine factors released from human embryonic stem cells (hES). To prepare preconditioned nanofibers, nanofibers were exposed to secretome from hES for 24hrs using a two-compartment transwell system, in which nanofibers were placed in the upper compartment, and hES cells were seeded in the lower compartment. To assess the effect of preconditioned nanofibers on high glucose-induced endothelial cell permeability, preconditioned nanofibers were transferred to the lower compartment of a new transwell system, whereas kidney microvascular endothelial cells were seeded on the upper compartment. After 24 hours of coculture in the presence of high glucose, $^{125}$I-BSA was added into the upper compartment, and the permeability of $^{125}$I-BSA across confluent endothelial cell monolayer was determined. We observed that preconditioned nanofibers significantly decreased high glucose (25mM)-induced endothelial cell permeability ($4.7x10^{-2}$ul/min *vs*.$3.5x10^{-2}$ul/min, $P<0.05$). Preconditioned nanofibers also reversed high glucose-induced apoptosis in podocytes (25mM x 24hrs, 20% *vs*. 8%, $P<0.01$) through inhibition of caspase-3 activity. Our findings indicate that the use of preconditioned nanofibers can potentially address many concerns associated with the use of hES cells in vivo, and provide a novel scientific rationale for the use of preconditioned nanofibers in vivo in animal models of diabetes.

### SA-PO2546

**Renal Co-Regulation of Carnosine Synthase and Carnosinase in Developing Diabetic Nephropathy** Ana Zutinic, Antien Mooyaart, Jan A. Bruijn, Emile De Heer, Hans J. Baelde. *Department of Pathology, Leiden University Medical Centre, Leiden, Netherlands.*

L-carnosine is known for its antioxidant effects, degradation of advanced glycation end products, inhibition of ACE and reduction of TGF-β induced synthesis of extracellular matrix. These properties make it potentially protective against microvascular complications in a diabetic environment. Its rapid degradation by carnosinase (CNDP1) is therefore considered disadvantageous for diabetes patients. It has been shown that patients with more leucine repeats in CNDP1 show higher circulating carnosinase levels, and are more susceptible for diabetic nephropathy than patients with a low number of leucine repeats in CNDP1. Carnosine synthase (CARNS1) could compensate for this carnosine deficiency by increasing carnosine synthesis. We investigated whether carnosine synthase is expressed by the kidney and whether this is related to the transcription level of CNDP1 in diabetic nephropathy versus control samples.

Carnosine synthase mRNA expression level was measured in 41 kidney biopsies by Q-PCR. This included 28 diabetic samples and 13 healthy controls. Additionally, protein expression of carnosine synthase was determined by immunohistochemistry in the kidney using the antibodies described by Margolis et al, journal name, publication name.

CARNS1 mRNA expression was found both in microdissected glomeruli and tubulo-interstitial compartment (3.3 times higher in glomeruli than in the latter). There was no difference in mRNA levels in diabetic samples compared to controls. There was a strong correlation of the mRNA expression between CNDP1 and CARNS1 in diabetic samples as well as in healthy controls. Additionally, immunostaining of tubular epithelial cells was found with monoclonal antibodies against carnosine synthase, showing that CARNS1 is expressed in both tubuli and podocytes.

We have shown that both CARNS1 and CNDP1 are expressed in the kidney. The relation between CARNS1 and CNDP1 provides evidence for a simultaneous co-regulation of these two genes, and a coordinated regulation of carnosine metabolism in the kidney. The importance of this local carnosinase metabolism in diabetic nephropathy remains to be investigated.

### SA-PO2547

**Role of Previous Physical Training in the Renal Function and Autonomic System in Experimental Diabetes** Kleiton Silva,[1;2] Rafael Da Silva Luiz,[1] Nayda P. Abreu,[1] Maria Claudia Irigoyen,[2] Nestor Schor.[1] *[1]Department of Nephrology, Federal University of São Paulo, Brazil; [2]Heart of Institution, São Paulo of University, Brazil.*

The impact of previous physical training (PPT) in diabetes (DM) is largely unexplored. In this study the effect of PPT in the renal function and autonomic system in streptozotocin (STZ)-induced DM was evaluated. Wistar rats were induced to DM weighing 300 – 320g and were divided into 4 groups: control (C), diabetic (D), diabetic trained (DT), and pre-trained diabetic (4 weeks before STZ +10 post STZ, PTD). Physical capacity was evaluated by maximal speed test. Renal function was assessed by proteinuria, creatinine clearance and serum creatinine. Blood pressure was recorded to evaluate hemodynamic and autonomic parameters. We studied tachycardic (TR) and bradycardic (BR) responses.

The Systolic BP (SBP) was lower in group D (15%) and DT (12%) while no changing in PTD in comparison with C.

| Variable (final)/Groups | C | D | DT | PTD |
|---|---|---|---|---|
| Glycemia (mg/dl) | 89±2.8 | 509±23* | 372±28*# | 379±33*# |
| Physical capacity (km/h) | 1.3±0.09$ | 0.9±0.05$ | 1.6±0.1$ | 2.1±0.04$ |
| Proteinuria (mg/dl) | 21.82±1.2 | 100±14.2$ | 25.95±4 | 24.02± 8.5 |
| Creatinine clearance (ml/kg/min) | 1.4± 0.1 | 0.1± 0.01$ | 1.84± 0.3 | 2± 0.3 |
| Serum creatinine (mg/dl) | 0.3±0.04 | 1.2±0.05* | 0.9±0.02* | 0.6±0.04# |
| Tachycardic responses (bpm/mmHg) | 3.44±0.3 | 1.7±0.09* | 2.26±0.09* | 3.66±0.2#+ |
| Bradycardic responses (bpm/mmHg) | -2.24±0.1 | -1.2±0.2* | -1.52±0.2* | 2.49±0.2#+ |

*p<0.05 vs C; #p<0.05 vs D; +p<0.05 vs DT; $p<0.05 vs all groups.

The pulse interval (PIV) increased in group D, DT and PTD when compared to C group. The sympathetic (LF) as well as the parasympathetic (HF) cardiac autonomic modulation decreased in group D when compared to C. The DT and PTD groups presented similar values for the LF and HF components of PIV. These results suggest that PPT is effective to attenuate the renal and autonomic impaired function induced by experimental diabetes.

Suport: FAPESP, CAPES and CNPq.

## SA-PO2548

**Inhibition of Uncoupling Protein 2 by Genipin Ameliorates Diabetic Nephropathy** Wenjing Qiu, Ruoyun Tan, Junwei Yang. *Center of Kidney Disease, the 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Increasing evidence indicates that mitochondrial uncoupling protein 2 (UCP2) is associated with pathogenesis of diabetes. UCP2-mediated proton leak can be inhibited by genipin, which is extracted from the traditional Chinese herb gardenia fruit that has been used to relieve the symptoms of diabetes in clinical settings. However, the effect of genipin on diabetic nephropathy remains unknown. In this study, we examined the therapeutic potential of genipin on diabetic nephropathy induced by low–dose streptozotocin. One week after diabetes onset, half of diabetic mice were given genipin orally at a dose of 50mg/kg body weight once a day for 12 weeks. In vehicle treated diabetic mice, we identified positive correlation between the enhanced expression of UCP2 and the increased expression of a-smooth muscle actin (a-SMA), desmin, and fibronectin, as well as the decreased expression of slit diaphragm-associated protein nephrin, podocin, CD2-associated protein (CD2AP), and Wilms Tumor 1 (WT-1). However, genipin largely blunted UCP2 expression and the glomeruli injury in the diabetic mice. Our results were also confirmed with indirect immunohisto-chemical staining, immunofluorescence and electron microscope. *In vitro*, we cultured mouse podocyte cells in high glucose with and without genipin. We found that genipin effectively suppressed the expression of UCP2 at a dose of 50 μM. In high glucose environment, the expression of podocin and WT-1 was decreased, while a-SMA and desmin was increased in a time dependent manner. However, genipin almost completely suppressed these changes induced by high glucose. Furthermore, knock down of UCP2 with small interfering RNA yielded similar results as what we found with genipin. In conclusion, the expression of UCP2 was significantly upregulated in diabetic nephropathy, and genipin could mitigate the progression of diabetic nephropathy by effectively inhibiting UCP2.

## SA-PO2549

**Dual Bile Acid Receptors Agonist INT-767 Prevents Diabetic Nephropathy through Multiple Mechanisms** Xiaoxin X. Wang, Cydney Lynn Urbanek, Nathaniel L. Solis, Hannah Danielle Santamaria, Moshe Levi, Tao Jiang. *Medicine, University of Colorado Denver.*

Bile acids have recently emerged as versatile signaling molecules endowed with systemic endocrine functions. Bile acids are ligands for nuclear hormone receptor farnesoid X receptor (FXR) and G-protein-coupled receptors such as TGR5. To determine the functional consequences of bile-acid activated signaling in the pathogenesis of diabetic nephropathy, we induced type 1 diabetes in western diet fed DBA/2J mice using multiple low-dose streptozotocin injection and treated mice for 12-wk after diabetes with FXR/TGR5 dual agonist INT-767. The studies have shown the renal protective role of bile acid receptors activation on proteinuria, podocyte damage, accumulation of extracellular matrix proteins, and glomerulosclerosis through its coordinated effects on modulation of renal lipid metabolism, oxidative stress, inflammation, and profibrotic growth factors. Analysis of gene profiling further reveals that INT-767 acts on a) intrarenal renin-angiotensin-system and b) glucose transporters. INT-767 treatment dramatically decreased the renal expression of renin, renin receptor, angiotensinogen and angiotensin-converting enzyme. In addition, INT-767 treatment markedly decreased multiple renal glucose transporters such as GLUT1 and GLUT4. These results therefore indicate a new and important role for FXR and TGR5 in the kidney and provide new therapeutic avenues for the treatment of diabetic nephropathy.

## SA-PO2550

**Effect of Mutual Epididymal Fat Transplantation between db/db Mice and db/m Mice on Urinary Albumin Excretion Level** Hyunwook Kim,[1] Ji Eun Lee,[1] Young Youl Hyun,[2] Kum Hyun Han,[3] Young Sun Kang,[2] Dae R. Cha.[2] *[1]Department of Internal Medicine, Wonkwang University College of Medicine Sanbon Hospital, Gunpo, Kyunggi, Korea; [2]Department of Internal Medicine, Korea University College of Medicine Ansan Hospital, Ansan, Kyunggi, Korea; [3]Department of Internal Medicine, Inje University College of Medicine Ilsan Baik Hospital, Goyang, Kyunggi, Korea.*

The adipose tissue is now accepted as a major regulatory organ that plays a key role in diabetic milieu, but the metabolic effects associated with diabetic db/db mouse versus non-diabetic db/m mouse visceral fat on kidney have not been fully explored. Therefore, in this study, we performed the mutual transplantation of the same amount epididymal fat from diabetic db/db mice and non-diabetic db/m mice into the subcutaneous back of db/m mice and db/db mice, respectively, and investigated the effects on renal parameters as well as changes in insulin resistance and diabetic conditions compared with non-transplanted db/m and db/db mice, respectively. At 3 months after transplantation, although there were no significant differences in fasting blood glucose, HbA1c, adipokine levels, creatinine clearance, and blood pressure, db/db mouse epididymal fat-transplanted db/m mice showed significantly increased urinary albumin excretion (25.54 ± 8.86 μg/day vs. 3.21 ± 0.99 μg/day, $P = 0.014$) along with the trend towards aggravation of insulin resistance assessed by fasting plasma insulin and homeostasis model assessment of insulin resistance (HOMA-IR) as well as more weight gain compared with non-transplanted db/m mice. In case of db/m mouse epididymal fat-transplanted db/db mice, we also found no differences in adipokine level, creatinine clearance, and blood pressure. However, there was a definite trend towards decreased urinary albumin excretion (206.09 ± 83.37 μg/day vs. 697.99 ± 139.12 μg/day, $P = 0.066$) along with significant improvement of insulin resistance represented by insulin tolerance test, fasting blood sugar, blood cholesterol, and HbA1c levels compared with non-transplanted db/db mice. Collectively, this study suggests that adipose tissue plays a central role in albumin excretion level, likely by modulating insulin resistance status.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2551

**Effect of Gastric Bypass Surgery on Renal Glucose Handling** Havovi Chichger,[1] Joanne Marks,[1] Marco Bueter,[2] Carel W. Le Roux,[2] Edward S. Debnam,[1] Robert J. Unwin.[1] *[1]Neuroscience, Physiology & Pharmacology, University College London; [2]Investigative Medicine, Imperial College London.*

The epidemic of obesity that has developed in the last 20 years is thought to be largely diet-related, and it is strongly associated with a range of clinical disorders, including hypertension and type II diabetes. One method of treatment for severe obesity is gastric bypass surgery, Roux-en-Y (RYGB), which has been shown to rapidly correct hyperglycaemia in type II diabetes.

Hyperglycaemia in type I diabetic rats induces expression of the facilitative glucose transporter, GLUT2, at the proximal tubule (PT) brush border membrane (BBM); moreover, GLUT2 correlates positively with expression of PKC-βI (Goestemeyer, 2007). In models of insulin-resistance and obesity, such as Goto-Kakizaki type II diabetes, junk-food induced obesity, and a high-fat fed rat model (unpublished data), we have shown that GLUT2 expression also occurs at the PT BBM and correlates with PKC-βI expression. In the present study we have investigated the expression of GLUT2 and PKC-βI at the PT BBM in response to RYGB gastric bypass surgery in a rat model.

RYGB surgery was performed in male Wistar rats, with sham surgery as control (Bueter, 2010). After 16 weeks, kidneys were removed and the cortex dissected for BBM vesicle preparation and western blotting, or RNA extraction and real-time PCR.

Despite no diiferences in fasting plasma glucose levels between sham and RYGB animals (8.5 ± 0.2 mM vs 8.5 ± 0.8 mM), RYGB rats exhibited a significant decrease in renal GLUT2 mRNA (80% $p<0.001$) and PT BBM protein expression (55% $p<0.05$), with an accompanying decrease in PKC-βI protein expression (30.8% $p<0.05$).

This study shows that in RYGB animals there is a reduction in renal BBM GLUT2 expression and its upstream signal PKC-βI, which suggests an important relationship between intestinal glucose absorption, improved glucose homeostasis and renal glucose handling post-RYGB. It also highlights the potential value of this animal model in investigating altered renal transport mechanisms following gastric bypass surgery, and it confirms the close signalling relationship between renal PKC-βI activity and PT BBM GLUT2 expression *in vivo*.

**SA-PO2552**

**Insulin Resistance, Visceral Obesity, Fasting Hyperglycemia, and Dyslipidemia in Mice with Homozygous Mutation of the Gene Encoding Canonical Transient Receptor Potential 1 (TRPC1) Channel: A Mouse Model of Metabolic Syndrome**

Leonidas Tsiokas,[2] Bonnie Eby,[1] Alexander Lau,[1] Erin Johnston,[1] Jan L. Guz,[2] Joel Abramowitz,[3] Lutz Birnbaumer,[3] Kai Lau.[1] *[1]Medicine, University of Oklahoma, Oklahoma City, OK; [2]Cell Biology, University of Oklahoma, Oklahoma City, OK; [3]Intramural Research, NIEHS, Research Triangle Park, NC.*

TRPC superfamily includes various channels involved in signal transduction & metabolism. Some members have been implicated in obesity, triglyceridemia, diabetes & hypertension, features of Metabolic Syndrome (MS). TRPC1 expression was reduced in diabetes. But the relationship was unclear despite being the 1st TRP channel cloned & identified in beta cells. We tested the hypothesis that TRPC1 knockout impairs glucose tolerance due to blunted insulin release or sensitivity. No abnormalities were found till 9th mon, when non-fasted plasma glucose in TRPC1 -/- males was 35% higher than age- & sex-matched +/+ mice (135 vs. 100 mg/dl, p<0.01). At 10 mon, they were 10% heavier & fasting glucose was 50% higher (109 vs. 72 mg/dl, p<0.01). By 1yr, they were 20% heavier. Hyperglycemia persisted. Glucose tolerance test with 2 mg/kg IP after 13 h fast revealed significant & sustained hyperglycemia in -/- mice, ~ 2 fold higher the 1st 3 h & 65% higher at 6th h. Plasma insulin was ~ 2.5 fold higher throughout. Fasting insulin (23 vs. 7 µunits/ml, p<0.01) & glucose (6.9 vs. 3.7 mM, p<0.01) were both elevated. Insulin resistance (IR) by homeostatic model assessment (HOMA) was greatly increased (7.9 vs. 1.1, p<0.01), with normal HOMA beta cell function (90 vs. 99 %). At 13 mon, HOMA IR (4.6 vs. 1.1, p<0.05) remained elevated, with unchanged beta cell function (84 vs. 105 %). In -/- mice, fasting plasma total cholesterol (153 vs. 118 mg/dl, p<0.01) was elevated by 39% & LDL cholesterol (94 vs. 59 mg/dl, p<0.01) by 60%. Liver echogenicity was elevated by 50% at 7 mon & by 75% at 1y, suggesting hepatic steatosis. Hypertension was absent. Our data support the hypothesis that TRPC1 deficiency produces insulin resistance, visceral obesity, hyperglycemia & dyslipidemia. TRPC1 null mice represent an excellent model of MS without hypertension.

**Dietary Energy and Carbohydrate Decrease on Non-Dialysis Treatment Days in Female Maintenance Hemodialysis (MHD) Patients**

Natalie Corso,[1] Rachelle Bross,[1] Deborah A. Benner,[2] Csaba P. Kovesdy,[3] Joel D. Kopple,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA, Torrance, CA; [2]DaVita, El Sugundo, CA; [3]Renal, Salem VA, Salem, VA.*

**Background:** Protein energy wasting (PEW) is commons in MHD patients and associated with adverse outcomes. Inadequate dietary intake may engender or aggravate PEW. Previous studies indicated lower energy intake on dialysis days when compared to non-dialysis days. **Methods**: We evaluated differences between dietary energy (DEI), protein (DPI), fat (DFI), and carbohydrate (DCI) intake in MHD patients on dialysis days (D) and non–dialysis treatment days (ND1=1 day after dialysis; ND2=2 days after dialysis) in 136 adults [59 female (F), 77 male (M)] enrolled in the "Nutrition and Inflammation Evaluation in Dialysis Patients" (NIED) Study using interview assisted 3-day food records. **Results:** In males, DEI, DPI, DFI, and DCI did not differ between treatment days. However, DEI tended to be lower on ND1 and ND2 compared with D in female patients [p= 0.08 and 0.11], as did DCI [p= 0.01 and 0.06]. The drop in DCI from D to ND1 and ND2 was greater in females vs. males [p=0.02, 0.07]. DPI was lower on all treatment days in females vs. males (p=0.04). DFI was not different between males and females.

Table: Dietary intake in 136 MHD patients (mean [95% CI])

| | DEI (kcal) | DEI (kcal) | DPI (g) | DPI (g) | DFI (g) | DFI (g) |
|---|---|---|---|---|---|---|
| Day | Woman | Man | Woman | Man | Woman | Man |
| D (dialysis day) | 1600 [1408,1792] | 1756 [1588,1923] | 61.2* [52.4,69.9] | 73.4 [65.8,81.0] | 59.9 [50.6,69.1] | 68.0 [60.0,76.1] |
| ND-1 | 1440* [1247,1632] | 1767 [1599,1934] | 57.5* [48.7,66.2] | 75.8 [68.2,83.5] | 57.9 [48.7,67.2] | 65.0 [56.9,73.1] ] 65.0 [56.9,73.1] |
| ND-2 | 1455* [1263,1647] | 1749 [1582,1917] | 59.1* [50.4,67.9] | 72.2 [64.6,79.8] | 55.3 [46.0,64.5] | 64.5 [56.4,72.6] |

*Female vs. Male p<0.05

**Conclusion:** Contrary to previous studies, the DEI tended to be lower on ND days in female MHD patients, which may be at least in part due to lower DCI, whereas in male MHD patients DEI and DPI were not different on D and ND days. Attention to different dietary status on different weekdays in MHD patients may correct PEW.

**Postprandial Metabolic Response to a Fat- and Carbohydrate-Rich Meal in Patients with Chronic Kidney Disease**

Tetsu Miyamoto, Abdul Rashid Tony Qureshi, Tae Yamamoto, Ayumu Nakashima, Bengt Lindholm, Peter Stenvinkel, Anders Alvestrand, Jonas Axelsson. *Divisions of Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

**Background**: While chronic kidney disease (CKD) is associated with dysmetabolism including a marked insulin resistance, the postprandial response has not comprehensively been studied in CKD patients.

**Methods**: We conducted an interventional study comparing fasting and postprandial circulating biomarkers of glucose and lipid homeostasis, incretins, anabolic hormones, inflammation, oxidative stress and pulse wave analysis (PWA) in nine prevalent non-diabetic hemodialysis (HD) patients and ten matched controls assessed after a standardized meal consisting of 75 g of milk fat, 80 g of carbohydrates and 6 g of proteins/m$^2$.

**Results**: Glucose and triglyceride increased in a similar manner following the meal, while insulin, glucose-dependent insulinotropic polypeptide and especially C-peptide ($\Delta AUC_{\text{C-peptide 240min}}$ 1550 ±190 ng.min/L in patients vs 740 ± 80 ng.min/L in controls; P=0.001) increased more in HD-patients. HDL and LDL cholesterol decreased slightly with no significant difference between the groups. The elevated baseline growth hormone in patients dropped, resulting in comparable levels in both groups 240 min after the meal ($\Delta AUC_{GH240min}$ -1220 ± 490 ng.min/mL in patients vs. -410 ± 160 ng.min/mL in controls; p<0.05); however, there was no change in IGF-1 levels. No marked changes of IL-6 and TNF-α were observed in either group. A marked increase in the DNA oxidative product 8-hydoxydeoxyguanosine (8-OHdG) was observed in HD-patients ($\Delta 8\text{-}OHdG_{240min}$ 0.05 ± 0.02 ng/mL vs. 0.001 ± 0.008 ng/mL; p<0.05). Postprandial increase in heart rates as well as pulse pressures, and the drop in subendocardial viability ratio (SEVR) calculated by PWA, were smaller in HD-patients ($\Delta AUC_{SEVR180min}$ - 27.8 ± 5.2 %.hr in patients vs. – 66.0 ± 11.2 %.hr in controls; p<0.05)

**Conclusions**: The postprandial state in CKD is characterized by impaired insulin sensitivity with an increased incretin levels, along with GH/IGF-1 axis uncoupling, a marked rise in an oxidative stress marker and a blunted hemodynamic response.

Disclosure of Financial Relationships: nothing to disclose

**Association of the Malnutrition-Inflammation Score (MIS) with First 90-Day Mortality in Incident Hemodialysis (HD) Patients**

Deborah A. Benner,[1] Kamyar Kalantar-Zadeh,[2] Lilia R. Lukowsky,[2] Steven M. Wilson,[1] Kathy Lahr,[1] Karen M. Spach,[1] Mahesh Krishnan.[1] *[1]DaVita Inc., Denver, CO; [2]Division of Nephrology & Hypertension, Harbor-UCLA, Los Angeles, CA.*

Protein-energy wasting (PEW) is associated with increased mortality in HD patients but its association with first 90-day death in incident HD patients is not clear. The MIS, an evaluator-friendly composite score ranging from 0 (well-nourished) to 30 (severely malnourished), includes 10 components (each with a score between 0 to 3) across nutritional history (5 components), nutritional physical exam (2 components), BMI and 2 laboratory values (albumin and transferrin). We hypothesized that worsening nutritional status detected by MIS is associated with increased first 90-day mortality in incident HD patients.

Methods: During the first calendar quarter of 2009 the MIS was recorded by over 1100 dietitians in 9,441 incident (vintage <30 days) and 19,174 prevalent HD patients. MIS scores were divided into 4 worsening quartiles. Incident patient mortality was defined as death occurring within 90 days of the first treatment at the facility per 100 patient years. Crude and relative mortality across quartiles were calculated including after adjustment for age, gender, diabetes, race/ethnicity and vintage.

Results: Incident HD patients were 64.6±14.6 years old and included 43.9% women, 34.2% African Americans and 69.1% diabetics. Incident HD patients had worse nutritional status (MIS=7.8 ± 4.4) than prevalent patients (MIS= 6.4 ± 4.5, p<0.001). The standardized first 90 day mortality was the lowest in the quartile with the best nutritional status, whereas it was 8.6 times higher in the worse nutritional quartile (see Table):

| MIS | 0, 1, 2 and 3 | 4 and 5 | 6, 7 and 8 | 9 and higher |
|---|---|---|---|---|
| Incident Patient N | 7,151 | 5,840 | 6,919 | 8,708 |
| Deaths per 100 Patient Years | 4.9 | 9.1 | 15.3 | 41.6 |
| Relative Mortality | 1.0 (ref) | 1.9 (1.7-2.7) | 3.1 (2.4-3.9) | 8.6 (6.7-10.9) |

Conclusions: In incident HD patients, worse nutritional status detected by MIS is a strong predictor of short-term death. Improving nutritional status in incident HD patients may improve survival, which needs to be tested in controlled trials.

**Protein-Energy Wasting Modifies the Association of Endogenous Ghrelin with Mortality in Hemodialysis Patients**

Juan J. Carrero, Ayumu Nakashima, Abdul Rashid Tony Qureshi, Bengt Lindholm, Olof Heimburger, Peter F. Barany, Peter Stenvinkel. *Divisions of Renal Medicine and Baxter Novum, CLINTEC, Karolinska Institutet, Sweden.*

**Introduction:** Ghrelin abnormalities may contribute to anorexia, inflammation and cardiovascular risk in hemodialysis patients, leading to worse outcome. Conflicting results of circulating ghrelin levels in patients with chronic kidney disease have been reported, and multiple confounding factors may contribute to these seemingly contradicting findings. One of such factors may be the individual's nutritional status. We hypothesized that the consequences of ghrelin in hemodialysis patients are context-sensitive and dependent on the presence of protein-energy wasting (PEW).

**Methods:** This is a cross-sectional study of hemodialysis patients (n = 217; 125 men; average +/- SD age: 66 +/- 14 y) followed for 31 (25$^{th}$-75$^{th}$ percentile 20-38) months where ghrelin, leptin, PEW (subjective global assessment) and CRP were assessed.

**Results:** Patients with low ghrelin (low third) were older, with higher BMI and leptin, presenting an increased mortality risk that persisted after adjustment for age, sex and dialysis vintage ((HR 1.55 95% CI [0.99-2.40]) but was lost after correction for comorbidities. Four categories were created according to ghrelin groups and the presence of PEW. Patients with PEW and low ghrelin values showed abnormally high levels of CRP and leptin (MANOVA interaction, p<0.05), while also presenting the highest all-cause (adjusted HR 3.34 [1.74-6.41]) and cardiovascular-related (adjusted HR 3.54 [1.40-8.91] mortality risk.

**Conclusions:** The consequences of low ghrelin concentration may depend on pre-existent PEW. Low ghrelin values in wasted hemodialysis patients were linked to a markedly increased (cardiovascular) mortality risk. As these patients exhibited a more anorectic phenotype (increased CRP and leptin), our results provide a clinical scenario where ghrelin therapies may be particularly useful.

### SA-PO2557

**Oral Nutritional Supplementation (ONS) as Part of Disease Management (DM) Improves Clinical Outcomes in the End Stage Renal Disease (ESRD) Population** Christine Cheu,[1] Sylvia Paz B. Ramirez,[1] Jeffrey Pearson,[1] Claudia Dahlerus,[1] Peter F. Sauer,[2] Robert E. Farrell,[2] Stephen D. McMurray,[2] Tania Chowdhury.[1] *[1]Arbor Research; [2]Fresenius Medical Care Health Plan.*

Serum albumin (ALB) is a predictor of morbidity and mortality, however, there have been limited changes in the nutritional management of ESRD patients (pts). As part of DM, Fresenius Medical Health Care Plan (FMCHP) provided ONS to enrollees at ALB<3.8 g/dL. This study evaluates the impact of FMCHP's ONS program on ALB, hospitalization, and mortality. FMCHP placed pts with a 3 mo mean ALB <3.8g/dL on ONS, revising to a 2 mo mean ALB<3.8g/dL within 6 mos of program initiation. ONS was discontinued when the 3 mo mean ALB exceeded 3.8 g/dL. The United States Dialysis Outcomes Practice Patterns Study (DOPPS) was the comparison group; only baseline ONS use was available. Logistic regression was used to evaluate associations between ONS and ALB. Cox models were used to calculate hospitalization and mortality percentages. Adjustments were age, sex, race, Hispanic ethnicity, ESRD vintage, comorbidity, new Medicare enrollee status. Among 1,377 pts, 712 (52%) received ONS. Pts were on continuous ONS use for a mean of 3.4 (±4.0) mos. Pts who received ONS the previous month were more likely to have an increase in ALB (OR=1.08, p=0.01). FMCHP pts on ONS had lower hospitalization percentages compared to non ONS pts. U.S. DOPPS pts on ONS had higher hospitalization percentages at one year compared to non-ONS users. ONS use in FMCHP was associated with a lower mortality percentage at one year regardless of achievement of target ALB. Similar protective effects of ONS on mortality were seen in U.S. DOPPS among pts with an ALB<3.8 g/dL. Findings show that FMCHP's ONS program as part of DM was associated with increased ALB, and reduced hospitalization and mortality.

| | FMCHP | | U.S. DOPPS | |
|---|---|---|---|---|
| **Hospitalization** | **No ONS (95% CI)** | **ONS (95% CI)** | **No ONS (95% CI)** | **ONS (95% CI)** |
| Achieved ALB >/= 3.8 g/dL | 68.4% (64.3, 72.0) | 18.1% (11.9, 23.9) | 33.6% (29.4, 37.5) | 39.7% (27.6, 49.7) |
| Always < 3.8 g/dL | 90.3% (83.4, 94.4) | 62.7% (35.8, 78.3) | 57.4% (48.6, 64.6) | 78.7% (62.3, 88.0) |
| **Mortality** | **No ONS (95% CI)** | **ONS (95% CI)** | **No ONS (95% CI)** | **ONS (95% CI)** |
| Achieved ALB >/= 3.8 g/dL | 10.0% (6.7, 13.2) | 5.5% (3.6, 7.4) | 9.2% (7.0, 11.4) | 12.9% (6.6, 18.0) |
| Always < 3.8 g/dL | 56.3% (32.9%, 71.5) | 26.0% (15.0, 35.6) | 24.9% (9.2, 17.7) | 19.2% (7.2, 29.6) |

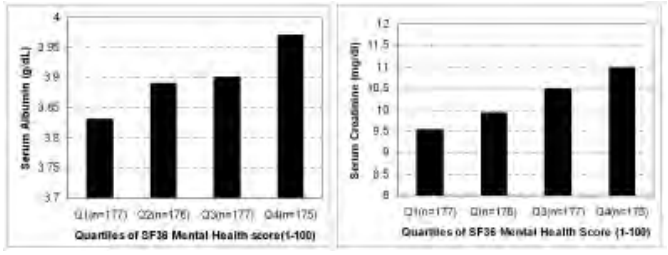
### SA-PO2558

**Association of Nutritional Status and Health-Related Quality of Life SF-36 Score in Maintenance Hemodialysis Patients** Usama Feroze,[1] Gangadarshni Chandramohan,[1] Ramanath B. Dukkipati,[1] Nazanin Noori,[1] Deborah A. Benner,[2] Csaba P. Kovesdy,[3] Joel D. Kopple,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]DaVita, Lakewood, CO; [3]Salem VA, Salem, VA.*

**Background:** Maintenance hemodialysis (MHD) patients usually report an unfavorable health-related quality of life (HR-QOL). Many MHD patients also suffer from protein-energy wasting (PEW), as indicated by low serum albumin and/or creatinine levels. We hypothesized that better nutritional status is related to a better self-perceived HR-QOL

**Methods:** Out of 893 MHD patients who were followed from 2001 to 2007 in the NIED Study, SF-36 mental health score was obtained from 705 patients. Patients were ranked according to SF-36 mental health score and then divided into 4 quartiles(<37, 37-<51, 51-<69, and >=69).

**Results:** MHD patients across the above 4 SF36 mental health score quartiles were 55.2±13.2, 53.6±14.4, 52.51±15.1 and 52.7±16 years old (mean±SD) and included 56%, 49%, 45% and 38% women; 64%, 58%, 54% and 47% diabetics; and 37%, 26%, 33% and 31% African Americans, respectively. Both serum albumin and creatinine levels showed incrementally higher values for the better (higher) score groups across the SF-36 quartiles (see Figure).



**Conclusions:** Better nutritional status as reflected by higher serum albumin and creatinine concentrations are associated with better self-reported HR-QoL score in MHD patients. Interventional studies to improve nutritional statues and to examine its impact on improving outcomes including HR-QOL are indicated.

### SA-PO2559

**Comparison of Body Composition Determined by Multifrequency Bioelectrical Impedance and Dual Energy X-Ray Absorptiometry in Stable Peritoneal Dialysis Outpatients** Antje Fürstenberg,[1] Andrew Davenport.[2] *[1]Centre for Nephrology, Royal Free Hospital, London, United Kingdom; [2]Centre for Nephrology, University College London, Medical School, Royal Free Campus, London, United Kingdom.*

Introduction

Malnutrition is common in peritoneal dialysis patients and associated with poor outcome. Therefore, simple, reliable and easily available methods to determe nutritional status and to recognise short-term changes in body composition are desirable. The accuracy of multifrequency bioelectrical impedance analysis (MF-BIA) as a tool to assess body composition is unknown in this population.

Methods

We compared whole body and segmental composition determined by MF-BIA with that obtained using dual energy x-ray absorptiometry (DEXA) in 104 outpatient adult peritoneal dialysis patients.

Results

Assessment of whole body composition showed that lean body mass (LBM) measured by the two techniques was highly correlated with good method agreement (Figure 1) using DEXA as the reference test (r=0.95, p<0.0001; BIAS -0.88kg; 95% CI -1.53 to 0.23kg). Similarly, high correlation and good method agreement were found for fat mass (FM) (r=0.93, p<0.0001; bias 0.69kg; 95% CI 0.03kg to 1.6kg). Segmental analysis of the lean body mass revealed strong correlations between lean body mass of trunk, left and right arms and legs (r= 0.90, 0.86 0.84, 0.89 and 0.90 respectively, p<0.0001). Bone mineral content (BMC) derived by MF-BIA overestimated that measured by DEXA (bias 0.740 kg; 95% CI 0.66 to 0.82kg).

Conclusion

MF-BIA appears to be a robust tool for measuring and monitoring body composition in peritoneal dialysis patients.

**Long Term Changes of Body Composition in HD Patients** Peter Wabel,[1] Ulrich Moissl,[1] Sebastian Wieskotten,[1] Volker Wizemann.[2] *[1]Fresenius Medical Care D GmbH; [2]PHV - Dialysis Centre Giessen.*

*Background*

Body composition in haemodialysis (HD) patients is prone to long term changes. The aim of this work was to highlight changes in lean (LTM) and adipose tissue mass (ATM) in prevalent HD patients over a period of 7 years and to compare this data to reference ranges in age and gender matched healthy subjects.

*Subjects and Methods*

In 124 HD patients (72 male, 52 female, 16 male and 14 female diabetics) bioimpedance measurements (BCM – Body Composition Monitor, Fresenius Medical Care) were performed over 2-7 years. The BCM calculated LTM, Lean Tissue Index LTI (= LTM / Height²), ATM and Fat Tissue Index FTI (= ATM / Height²) according to the model of Chamney (AJCN 2007). For each patient LTI and FTI data over time was fitted by

a regression line and the mean slope of LTI and FTI was calculated. Additionally this information was compared with existing data of 2071 healthy subjects with gender- and age-dependent ranges of body composition (JASNsuppl2009).

*Results*

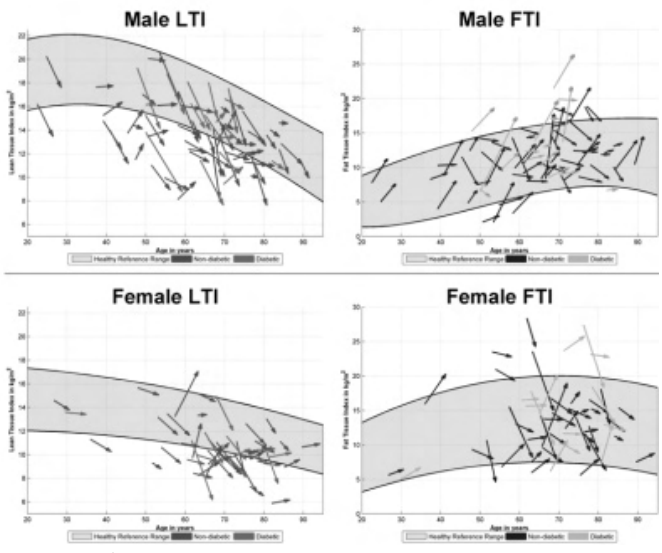
The differences between the slopes are tested by a Kruskal-Wallis test.

Mean changes of body composition in HD patients over 7 years

| Unit (kg/m²/year) | Male | Female |
|---|---|---|
| BMI | 0.037 | -0.284 # |
| BMI subgroup diabetics | 0.145 | -0.139 |
| subgroup diabetics | -0.363 # | -0.133 # |
| LTI subgroup diabetics | -0.493 # | -0.291 # |
| Adipose tissue (FTI) | -0.332 # | -0.251 #,* |
| FTI subgroup diabetics | 0.536 | 0.035 |

# significantly different to a mean change of 0 kg / m²/year ($p < 0,05$)

Male patients exhibited a significant loss of LTI and significant accumulation of FTI. Female patients showed a significant decrease in BMI, LTI and FTI. In contrast to male patients females decreased their FTI. There were no significant differences between diabetic and non-diabetic HD patients. The comparison of the individual patients with the reference population is shown in figure 1.



Disclosure of Financial Relationships: Employer: Fresenius Medical Care.

## SA-PO2561

**Ghrelin and Obestatin in Pediatric Patients with Chronic Renal Insufficiency and Following Renal Transplantation: Possible Insights into Appetite Dysregulation** Rainer Buescher, Anja K. Büscher, Peter F. Hoyer. *University of Duisburg-Essen, Pediatrics 2, Pediatric Nephrology, Essen, Germany.*

**Background:** Cachexia and growth retardation are common problems in pediatric patients with chronic renal insufficiency. Disturbances of appetite-regulating hormones are discussed to be causative factors. Acyl ghrelin is a potent orexigenic hormone, whereas desacyl ghrelin and obestatin, an alternative splicing product of the ghrelin gene, exert opposite functions. The understanding of the regulation of acyl ghrelin and its anorexigenic opponents and its role for the development of cachexia in renal insufficiency remains unclear.

**Methods:** We measured plasma total ghrelin, acylated ghrelin, obestatin, serum leptin and adiponectin in children with chronic kidney disease (CKD, n=29), children undergoing hemodialysis (HD) or peritoneal dialysis (PD, n=29), children following renal transplantation (RTx, n=91) and healthy controls (n=27), and analyzed the data in relation to the auxological parameters BMI and height.

**Results:** Patients with renal insufficiency showed lower BMI SDS and height SDS compared to healthy controls and children undergoing RTx. Total ghrelin was elevated in CKD and PD patients compared to controls or transplant recipients ($P<0.001$). As acyl ghrelin showed no difference between groups, the acyl ghrelin/total ghrelin ratio was reduced in uremic patients ($P<0.05$). Obestatin plasma levels were increased in uremic children compared to controls and RTx patients ($P<0.05$).

**Conclusions:** Uremia leads to an accumulation of the anorexigenic hormones desacyl ghrelin and obestatin, whereas orexigens like acyl ghrelin are not elevated. An imbalance between anorexigenic and orexigenic hormones may have an impact on cachexia development in pediatric patients with chronic renal insufficiency.

## SA-PO2562

**Novel Equations To Estimate Lean Body Mass in Maintenance Hemodialysis Patients** Nazanin Noori,[1] Csaba P. Kovesdy,[2] Rachelle Bross,[1] Antigone Oreopoulos,[3] Deborah A. Benner,[4] Rajnish Mehrotra,[1] Joel D. Kopple,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA, Torrance, CA; [2]Nephrology, Salem VA, Salem, VA; [3]Univ. of Alberta, Edmonton, AB, Canada; [4]DaVita, Lakewood, CO.*

**Background:** Lean body mass (LBM) represents muscle mass, somatic protein storage and an important nutritional measure in maintenance hemodialysis (MHD) patients. We developed and tested equations to estimate LBM in MHD patients using simple measures. **Methods**: In 118 MHD patients, who underwent dual energy X-ray absorptiometry (DEXA) to assess their LBM. The validity of equations were tested against the near-infrared (NIR) measured LBM in 612 additional MHD patients. **Results:** DEXA measured LBM correlated with serum creatinine, mid-arm muscle circumference (MAMC), hand grip strength (HGS). MAMC in men and serum creatinine and HGS in women were the best surrogates of LBM. Three equations to estimate LBM were developed based on these 3 surrogates and gender, height, weight, ageand urea reduction ratio (for the serum creatinine).

Equations to estimate LBM in MHD patients

| | |
|---|---|
| Equation #1 | LBMSCr = 0.34*SCr (mg/dL) + 5.58*gender + 0.30*weight (kg) + 0.67*height (inch) - 0.23*URR - 5.75 |
| Equation #2 | LBMHGS = 9.09*HGS (unit) + 5.15*gender + 0.33*weight (kg) + 0.74*height (inch) - 29.06 |
| Equation #3 | LBMMAMC = 0.28*MAMC (cm) + 5.52*gender + 0.28*weight (kg) + 0.82*height (inch) - 35.30 |

The first and third equation estimates correlated well with NIR measured LBM ($R^2 \geq 0.88$) in the NIR cohort, although difference (Bland-Altman) plot showed that in higher LBM ranges they tended to underestimate it. **Conclusions:** Comparing to DEXA and NIR measured LBM, our developed equations using serum creatinine, MAMC, or HGS and demographic variables can relatively accurately estimate LBM in long-term MHD patients.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2563

**Characteristics of Body Composition and Nutritional Status in Patients Receiving Hemodialysis Therapy for More Than 30 Years** Shigeru Otsubo,[1] Miwa Ishihara,[1] Naoki Kimata,[2] Takashi Akiba,[2] Kosaku Nitta.[3] *[1]Department of Blood Purification, Sangenjaya Hospital, Tokyo, Japan; [2]Department of Blood Purification, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan; [3]Department of Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

***Backgroud***

The number of long-term survivors of chronic kidney disease (CKD) receiving hemodialysis has been increasing. On the other hand, patients with advanced CKD, especially those on long-term dialysis, often suffer from muscle wasting. In the present study, we investigated the body composition and nutritional status of extremely long-term hemodialysis patients.

***Methods***

Eighty outpatients receiving maintenance hemodialysis (including 18 for more than 30 years) were enrolled. The biochemical parameters were measured before the start of the hemodialysis session. The muscle mass was assessed by measuring the mid-upper arm muscle area (AMA). We classified the patients according to the duration of hemodialysis therapy (less than 10 years, 10 - 20 years, 20 - 30 years, or over 30 years) and compared the laboratory and anthropometric data between the groups. AMA and body mass index (BMI) were corrected using the following formula.

Corrected AMA (BMI) = measured AMA (BMI) / mean AMA (BMI) for same age and same sex, as obtained from the Japanese Anthropometric Reference Data 2001.

***Results***

No significant differences in age or the total protein, albumin, total cholesterol, triglyceride or CRP levels were observed among 4 groups. The corrected BMI was significantly lower in the more than 30 years group than in the less than 10 years group ($0.88 \pm 0.11$ versus $0.98 \pm 0.19$, $p=0.0417$). The corrected AMA was significantly lower in the more than 30 years group ($0.79 \pm 0.13$) than in the other groups ($P=0.0003$ compared with less than 10 years group ($1.01 \pm 0.22$), $P=0.0002$ compared with 10 - 20 years group ($1.04 \pm 0.17$), and $P=0.0046$ compared with 20 - 30 years group ($1.04 \pm 0.29$)).

***Conclusion***

In extremely long-term hemodialysis outpatients (for more than 30 years), the BMI and AMA were reduced, whereas nutritional markers such as the total protein, albumin, total cholesterol and triglyceride levels were relatively preserved.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2564**

**Relationship between Total Ghrelin and Inflammation in Hemodialysis Patients** Denise Mafra,[1] Najla Elias Farage,[2] Julie Lobo,[2] Milena Barcza Stockler-Pinto,[2] Viviane Oliveira Leal,[1] Luciana Catunda Brito,[4] Denis Fouque,[3] Maurilo Leite.[2] *[1]Clinical Nutrition, Federal University Fluminense, Niterói, Rio de Janeiro, Brazil; [2]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [3]University Claude Bernard Hopital Edouard Herriot, Lyon, France; [4]Federal University of Sergipe.*

**Introduction:** Ghrelin is a peptide involved in appetite and food intake. Previous studies show that plasma ghrelin is increased in hemodialysis (HD) patients, without particular impact on body composition, suggesting that there may be resistance to the ghrelin action in these patients. On the other hand, some studies have speculated that the high levels of ghrelin might be related to systemic inflammation in renal patients. The present study addressed this issue. **Materials and Methods:** Fifty HD patients from RenalCor Clinic at Rio de Janeiro, Brazil (19 women, 11 diabetics, mean age 54.3 ± 12.6 yr; BMI 24.4 ± 4.1 kg/m$^2$; % body fat 29.4 ± 7.4%), were studied. Blood samples were collected during fasting, before a regular HD session. Serum total ghrelin levels were measured using the enzyme immunometric assay (EIA) method and compared to 21 healthy subjects (12 women, 50.7 ± 15.7yr and BMI 25.6 ± 4.0 kg/m$^2$; % body fat 30.0 ± 5.7%). The body composition was evaluated by dual energy X-ray absortiometry (DEXA). Energy and protein intake were evaluated using a 2-day food record.

**Results:** Patients showed elevated plasma ghrelin levels when compared to healthy subjects (1.21 ± 1.0 ng/mL *vs* 0.42 ± 0.2; P<0.001). There was a positive correlation between ghrelin levels and TNF-a (r=0.25; P<0.01), IL-6 (r=0.42; P<0.05), and a negative correlation between TNF-a and protein intake (r=-0.28; P<0.05) and energy intake (r=-0.34; P<0.01). No correlation was observed with any aspect of body composition. **Conclusion:** Plasma ghrelin levels are elevated in HD patients and associated with the state of systemic inflammation. We suggest that inflammation may impact on plasma ghrelin bioactivity and metabolism in hemodialysis patients. *Supported by CNPq and FAPERJ.*

**Comparisons on Control of Mineral Metabolism and Prescription Patterns by Dialysis Modality in ESRD Patients: Cross-Sectional Study of Clinical Research Center for End Stage Renal Disease in Korea** Young-Deuk Yoon,[1,2] Ja-Yong Park,[1,2] Eun-Joo Song,[1,2] Ji-Young Choi,[1,2] Se-Hee Yoon,[1,2] Sun-Hee Park,[1,2] Chan-Duck Kim,[1,2] Sung-Ho Kim,[1] Jun-Young Do,[1] Seong Eun Kim,[1] Sang Heon Song,[1] Yeong Hoon Kim,[1] Yon Su Kim,[1] Shin-Wook Kang,[1] Chul Woo Yang,[1] Nam Ho Kim,[1] Yong-Lim Kim.[1,2] *[1]Kyungpook National University School of Medicine; [2]Clinical Research Center for End Stage Renal Disease, Korea.*

To examine the abnormality of mineral metabolism and prescription pattern by dialysis modality in ESRD patients. Using the data from1,141 ESRD patients in CRC for ESRD in Korea between April 2009 and March 2010, we investigated albumin corrected-serum calcium, serum phosphate, serum parathyroid hormone(**iPTH**), prescription pattern of vit D-related drug (Calcitriol, Alfacalcidol, Paricalcitol) and phosphate-binders. Of 1141 patients (HD:PD 794:347, mean age of 56.2±13.6 years), men were 59.3%, mean dialysis duration was 43.8±52.8 months. There were no differences in dialysis duration, gender ratio, percentage of incident patients between HD and PD patients. Mean age was higher in HD group, whereas body mass index was higher in PD group (p=0.001). Patients with diabetes as a co-morbidity is higher in HD group (48.7% vs 40.3%, p=0.009). Many patients did not reach the recommended K/DOQI guideline in terms of serum phosphorus (16% of patients below lower target range, 30% of patients above upper target range), corrected calcium (27% below, 23% above), calcium-phosphorus product (20% above), and iPTH (47% below, 26% above). There were no differences in phosphorus, Calcium, Calcium×phosphorus product control between HD and PD patients, but iPTH is higher in PD group (323.8 vs 207.2 pg/ml, p<0.001). Only 10% of patients are satisfied with recommended target range. Higher prescription of vit D-related drug was noted in PD group (21.0 vs 14.2%, p=0.003), whereas higher prescription of phosphate binder in HD group (68.5 vs 59.9%, p=0.004). In cross-sectional analysis of dialysis patients, there are no significant differences in the control of mineral metabolism between HD and PD patients except iPTH. In addition, the prescription of vit D-related drug was higher in PD group.

**Inflammatory Marker (IL-6 -174 G/C) Gene Polymorphism in Malnourished Patients with End Stage Renal Disease** Raj K. Sharma, Richa Sharma, Anita Saxena, Suraksha Agarwal. *Nephrology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, UP, India.*

End Stage Renal Disease (ESRD) is an inflammed state and mediators of inflammation are activated. Retention of uremic toxins in the body, contact with foreign membrane (Dialysis) and kidney failure induces various immunological and metabolic imbalances in body. Patients develop inflammation, malnutrition, atherosclerosis, anemia etc. Strong associations between malnutrition, inflammation and atherosclerosis in the patient population suggest the presence of syndrome of Malnutrition, Inflammation, and Atherosclerosis (MIA), which when associated with various co-morbidities results in exceptionally high mortality rate. Therefore, based upon above hypothesis we studied the interleukin-6 (IL-6 -174G/C) gene polymorphism with malnutrition in maintenance hemodialysis patients. A total of 40 patients on MHD were enrolled in the study, 4mL venous blood was collected in EDTA vial. To assess the nutritional status, Subjective Global Assessment (SGA), body composition (BMI and waist circumference), bioelectrical impedance analysis (BIA) were used. Carotid atherosclerosis was investigated by ultrasonographically by carotid intimal-media thickness (cIMT). IL6 -174G/C gene polymorphism was done using standard PCR-RFLP method. Serum albumin for the patients was 3.6±0.67g% and was found to be below normal for 13 patients. Serum protein was found to be 6.33±0.93g% with severe hypoalbuminuria in 37% of patients, PTH was 158.2±200pg/ml, CRP levels were 4.02±12.9pg/ml and 12 patients (30%) had elevated CRP levels. 14, 5 and 20 patients had normal, mild and moderate SGA score respectively. Out of 40 patients 3 patients showed increased carotid intimal thickness (CIT) on carotid doppler more than normal limits. We observed significant increase in the genotype frequency of the IL-6-174 G/C (p=<0.05) in malnourished patients on MHD. The C allele of IL-6 -G174C were significantly different in ESRD when compared to controls (p=<0.05). Our results suggest that IL-6 -174G/C gene polymorphism may be a risk factor for patients of MIA for development of malnutrition in ESRD patient on MHD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2567**

**Dietary Intake in Incident Hemodialysis Patients: The Predictors of Arrhythmic and Cardiovascular Risk in End Stage Renal Disease (PACE) Study** Julia J. Scialla,[1] Cheryl A. Anderson,[1] Stephen M. Sozio,[1] Bobbie Henry,[1] Bernard G. Jaar,[1] Tariq Shafi,[1] Wen Hong Linda Kao,[1] Rulan S. Parekh.[2] *[1]Johns Hopkins University; [2]University of Toronto.*

Biomarkers of malnutrition are risk factors for death in ESRD patients, but directly measured dietary intakes have not been well described. We recruited 176 incident hemodialysis patients from the Baltimore area between 10/08 and 4/10. Diet was assessed by a registered dietician using a 24 hour dietary recall interview in 115 participants. From the 2005-2006 National Health and Nutrition Examination Survey (NHANES), a survey of the non-institutionalized US population, we created a matched comparison population among those with 24 hour dietary recall interviews performed and estimated GFR of ≥ 30 mL/min/1.73 m$^2$. We matched 4:1 on categories of age, sex and race to the PACE population. Intakes were compared between the populations using linear regression. Mean age of the PACE study population was 53y (range 20 to 90 y); 43% were female; 68% black; 47% had diabetes. Energy intake was lower (p<0.001) in PACE, but macronutrient composition was similar.

| Nutrient † | PACE (n=115) | Matched NHANES population (n=460) | p-value |
|---|---|---|---|
| Energy (kcal/d) | 1522 (1065, 2140) | 1996 (1433, 2693) | <0.001 |
| % kcal from protein | 16.5 (13.1, 20.7) | 15.3 (12.3, 18.0) | 0.08 |
| % kcal from fat | 32.9 (26.2, 40.2) | 33.6 (28.1, 39.8) | 0.8 |
| % kcal from saturated fat | 10.6 (8.1, 13.1) | 10.5 (8.3, 13.3) | 0.8 |
| % kcal from carbohydrate | 48.6 (41.1, 56.8) | 48.8 (39.8, 56.8) | 0.7 |
| Sodium* | 1763 (1348, 2139) | 1570 (1260, 1876) | <0.001 |
| Potassium* | 966 (755, 1252) | 1209 (915, 1511) | <0.001 |
| Phosphorus* | 519 (457, 633) | 577 (464, 692) | 0.04 |

†Median (IQR); *mg/1000 kcal

After adjustment for diabetes, energy (p<0.001), potassium (p<0.001) and phosphorus (p=0.002) intake remained lower and sodium intake higher (p=0.01) in PACE compared with the matched NHANES population. Our results suggest that decreased energy intake, as opposed to a selective decrease in protein intake, is present early in the course of ESRD. Greater attention to energy intake in dialysis patients is needed.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2568**

**Prevalence of Metabolic Syndrome in PD Patients and the Correlation with Vascular Calcification** Hye Won Kim, Ha Na Yang, Won-Yong Cho, Hyoung-Kyu Kim, Sang-Kyung Jo. *Department of Internal Medicine, Korea University Anam Hospital, Seoul, Republic of Korea.*

**Background**: Although metabolic syndrome is known to be closely related to increased cardiovascular morbidity and mortality in general population, its prognostic value in patients with peritoneal dialysis (PD) is largely unknown. This study was planned to evaluate the prevalence of metabolic syndrome and its correlation with other cardiovascular risk factors in stable PD patients.

**Methods**: One hundred eleven patients who have been treated by peritoneal dialysis for more than 1 year were enrolled. Metabolic syndrome is defined as the presence of three or more components using the modified National Cholesterol Education Program (Adult Treatment Panel III) guidelines. Patients were also divided as the number of corresponding components and the correlation between the number of components of metabolic syndrome with various parameters including simple vascular calcification score (SVCS), brachial-ankle pulse wave velocity (ba-PWV), plasma inflammatory cytokines and other clinical parameters was performed.

**Results**: The prevalence of metabolic syndrome was 81.7%. Two patients (1.8%) had none of the component, 13 patients (11.9%) had two components, 41 patients (37.6%) had three components, 39 patients (35.8%) had four components and 8 patients (7.3%) corresponded all of five criteria. Patients with metabolic syndrome were significantly older, had higher CRP, WBC count, percentage of neutrophil and SVCS. With multiple regression analysis, as the number of satisfied components increased, WBC counts, CRP and SVCS were increased after adjustment by age. However, there were no significant correlation between ba-PWV or plasma inflammatory cytokines and number of metabolic syndrome components.

**Conclusion**: PD patients showed higher prevalence of metabolic syndrome than general population. Our observation that there is positive correlation between the number of corresponding components of metabolic syndrome and CRP, WBC counts, medial vascular calcification might suggest that metabolic syndrome in PD patients might also be served as a strong predictor of cardiovascular morbidity and mortality.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2569

**Estimation of Average Plasma Glucose Levels by Glycated Albumin and Optimal Target Value of Glycated Albumin in Patients with Diabetic ESRD** Jwa-Kyung Kim, Jung Tak Park, Bo Young Nam, Hye-Young Kang, Shin-Wook Kang, Tae-Hyun Yoo. *Brain Korea 21 Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Compared to glycated hemoglobin (HbA1c), serum glycated albumin (GA) level reflects recent glycemic control more accurately in DM ESRD patients. However, no definite relationship between serum GA and mean plasma glucose (MPG) level is determined and the optimal reference value of serum GA is not set up. A total of 117 ESRD patients, including 99 subjects with type 2 DM and 18 non-DM subjects were included in this study (76 on HD, 41 on PD). Patients were asked to perform four–point daily self-monitoring blood glucose (BG) at least 3 continuous days per week for 4 weeks. Mean BG level was determined using area-under-the-curve analysis and MPG was estimated by adding 11% of mean BG to mean BG level. Serum GA and other biochemical parameters were obtained at the end of one month and HbA1c level was checked at 8-10 weeks after BG monitoring. Approximately, 41 BG values were checked by each subject. MPG, GA and HbA1c levels were 163.2±44.2mg/dl, 19.6±6.9% and 6.45±1.4%, respectively. GA level of DM patients was 21.2±6.4% and 11.1±1.5% in non-DM patients, but there was no significant difference between dialysis modalities (HD 20.8±7.3%, PD 17.3±5.5%; p=0.13). GA showed a positive correlation with dialysis duration (r=0.42, p<0.001), but there was a significant negative correlation between GA and serum albumin level (r=-0.32, p<0.001). Among individual time points, postprandial glucose level showed higher correlation with GA than fasting glucose level (r=0.51, p=0.01 vs. r=0.20, p=0.06). Linear regression analysis between MPG and GA or HbA1c provided a close relationship of MPG (mg/dl)=5.95 X GA% + 47.52 (r= 0.74, p<0.001) and MPG (mg/dl)=27.7 X HbA1c% - 38.91 (r=0.60, p<0.001). Considering that the recommended average MPG level is 155 mg/dl, which is equivalent to 7% of HbA1c in the general population, the optimal target range of GA% is thought to be 17-18% in diabetic ESRD patients. Compared to HbA1c, GA levels had better correlation with MPG, and average MPG levels of the preceding 4 weeks could be estimated using the GA values.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2570

**Changes of Serum Adipokine Concentration after Start of Peritoneal Dialysis** Chul Ho Chung, Jung Hwan Park, Eun Jung Kim, Moo Yong Park, Soo Jeong Choi, Jin Kuk Kim, Seung D. Hwang. *Division of Nephrology, Soonchunhyang University Bucheon Hospital, Bucheon-si, Gyeonggi-do, Korea.*

**Background -** Fat tissue is complex organ that secretes several cytokines. In the PD patients, continous glucose absorption from dialysate lead to weight gain and fat mass increase. In this study, we prospectively investigated the effect of initiating PD on fat mass and the relation of adipokine changes.

**Methods -** Adipokines(leptin, adiponectin, TNF-α, IL-6), abdominal fat CT, several nutritional parameters, peritoneal equilibration teats(PET) were measured 7days, 6 months and 12 months after the initiation of PD.

**Results -** 36 patients were enrolled. At baseline, woman was higher than man in leptin(383.3±116.6 vs. 95.1±29.6, p=0.029) and adiponectin levels(330.9±40.9 vs.193.9±37.3, p=0.018). Body weight and total cholesterol increased continuously for 12 months. There was no significant change in visceral and subcutaneous fat mass. Subcutaneous fat was correlated positively with leptin(r=0.804, p<0.01), and negatively with adiponectin(r=-0.593, p<0.01). Adiponectin was negatively correlated with leptin(r=-0.556, p<0.01). Nutritional parameter and PET result was no significant changes. There was no significant changes in leptin, adiponectin and IL-6. TNF-α decreased at 6months, but increased at 12months(p=0.011).

Serial changes

| | Baseline | 6 months | 12 months | p-value |
|---|---|---|---|---|
| Weight(Kg) | 60.1±9.6 | 61.8±10.2 | 62.9±11.2 | **0.022** |
| Cholesterol(mg/dL) | 149.3±46.0 | 172.1±59.7 | 173.9±38.2 | **0.009** |
| Visceral fat mass(cm2) | 83.5±63.6 | 103.2±71.9 | 74.1±29.9 | 0.981 |
| Subcutaneous fat mass(cm2) | 95.8±58.5 | 125.9±64.7 | 112.4±51.0 | 0.172 |
| Leptin(ng/mL) | 247.2±66.9 | 383.5±103.3 | 418.8±147.2 | 0.159 |
| Adiponectin(ug/mL) | 266.2±29.8 | 256.1±29.2 | 203.5±23.0 | 0.138 |
| IL-6(pg/mL) | 11.3±1.7 | 7.7±3.2 | 10.4±2.3 | 0.948 |
| TNF-a(pg/mL) | 9.4±1.4 | 6.6±0.8 | 8.0±0.9 | **0.011** |

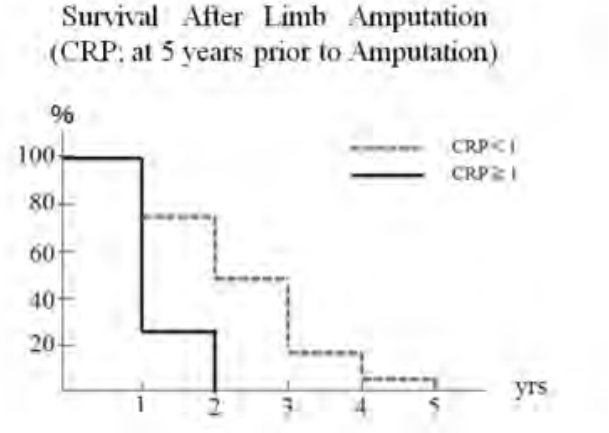
**Conclusion -** Baseline subcutaneous fat was correlated positively with leptin, and negatively with adiponectin. Body weight increased consistently for 12 months. There was no change in leptin, adiponectin and IL-6 levels, but TNF-α decreased at 6 months, and increased at 12 months.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2571

**Continuous Inflammation Is a Strong Indicator of Patient Survival Following Limb Amputation in Hemodialysis (HD) Patients** Masao Aoyagi,[1] Miwa Shirahama,[1] Satoshi Funakoshi,[1] Yoshiaki Lee,[1] Takashi Harada,[1] Mineaki Kitamura,[2] Akira Furusu,[2] Shigeru Kohno.[2] *[1]Sakuramachi Clinic, Nagasaki, Japan; [2]Nagasaki University School of Medicine, Nagasaki, Japan.*

Background: Limb-threatening ischemia due to arteriosclerosis obliterans is becoming more common in HD patients along with an increase in diabetic nephropathy in elderly ESRD. Purpose: The survival rate of HD patients who had undergone limb amputation was analyzed to determine common factors affecting patient survival. Methods: From 1999 to 2009, there were 36 HD patients (26 DM, 10 non-DM) who had undergone limb amputation at our facility. Various parameters including average Hb, serum albumin, and CRP, were determined 5 years prior to each amputation, when no symptoms had yet been documented in their limbs. Results: There was no significant change in average Hb, albumin during the period of 5 years. As shown in Figure 1, patients with a CRP level of < 1.0 mg/dL 5 years prior to amputation (11 DM / 6 non-DM) had a 3.1 +2.2 year survival rate following limb amputation.



On the other hand, no patients with a CRP level of > 1.0 mg/dL (6 DM / 3 non-DM) survived for more than 2 years. Interestingly the presence of DM or nutritional status was not observed to be a critical factor for patient survival. Conclusions: Our data suggest that continuous systemic inflammation may have a stronger impact than nutrition status for the prognosis of HD patients with potential arteriosclerosis obliterans.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2572

**Leptin: Adiponectin Ratio Is an Independent Predictor of Mortality in Non Diabetic Peritoneal Dialysis Patients** Jung Tak Park, Jwa-Kyung Kim, Bo Young Nam, Hye-Young Kang, Tae-Hyun Yoo, Shin-Wook Kang. *Brain Korea 21 Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Leptin/Adiponectin (L:A) ratio has been suggested as an atherosclerotic index in diabetic patients and as a useful parameter for insulin resistance in patients with and without diabetes. Although peritoneal dialysis patients are well characterized for alterations in adipocytokine metabolism, the corresponding effects of L:A ratio in this particular population have not been clearly defined. In this study, we prospectively investigated the effect of L:A ratio on outcome in non-diabetic peritoneal dialysis (PD) patients.

Methods: The study subjects included 131 stable non-diabetic PD patients who had been on PD for more than 3 months. Baseline serum leptin and adiponectin levels were measured. Mortality was evaluated during the follow-up period.

Resluts: During the follow-up period (mean follow-up duration: 49.2 ± 24.6 months), 17 patients died (12.9 %), 9 (52.9 %) as a result of cardiovascular disease. L:A ratio showed a significant positive correlation with body mass index ($r = 0.69$, $P < 0.001$), HOMA-IR ($r = 0.44$, $P < 0.001$), hsCRP($r = 0.31$, $P < 0.001$). However a significant negative correlation was found with lean body mass index ($r = -0.26$, $P = 0.003$). There was no significant correlation with normalized protein catabolic rate ($r = -0.29$, $P = 0.74$) or serum albumin levels ($r = 0.05$, $P = 0.61$). Cox proportional hazards analysis revealed that log L:A ratio [RR (95% CI): 1.67 (1.09-2.55)] (P = 0.02), log leptin levels [RR (95% CI): 2.02 (1.08-3.79)] (P = 0.03), and lower adiponectin levels [RR (95% CI): 0.91 (0.84-0.99)] (P = 0.03) were independent predictors for mortality. The area under the curve of the L:A ratio (0.73) in receiver operator characteristic analysis for mortality was greater than that of log leptin (0.68) or adiponectin (0.33) indicating that log L:A ratio better predicts death than leptin or adiponectin alone.

Conclusion: L:A ratio, which correlates with metabolic and inflammatory parameters, could be a better predictor for mortality than each single adipocytokine in non diabetic patients undergoing peritoneal dialysis.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2573**

**Correlates of Plasma Gelsolin Levels in Prevalent Hemodialysis (HD) Patients** Laura Rosales,[1] Georges Ouellet,[1-2] Viktoriya Kuntsevich,[2] Boris Medvedovsky,[2] Mary Carter,[1] Peter Kotanko,[1-2] Nathan W. Levin,[1-2] Stephan Thijssen.[1-2] *[1]Renal Research Institute; [2]Beth Israel Medical Center, New York.*

Plasma gelsolin (pGSN) is an actin binding protein and muscle tissue is its major source. The association between pGSN levels and co-morbidities, anthropometric, demographic and routine laboratory parameters has not been studied

Methods:

pGSN levels were determined with the 2C4 pGSN ELISA kit (Critical Biologics, Cambridge, MA) in maintenance HD patients from 3 HD centers; demographics (age, HD vintage, race, gender, BMI), co-morbidities (diabetes (DM), atherosclerotic cardiovascular disease (CVD)), were recorded. Univariate associations with pGSN were assessed with Pearson (r) or Spearman (rho) correlations and groups comparison by t test. Multiple linear regression with backward parameter elimination determined independent predictors of pGSN.

Results

We studied 153 patients (mean age 61±15 years; median HD vintage 2.3 (range 0.2-20.0) years; 52% male; 42% Blacks, 52% DM). In univariate analysis, pGSN positively associated with pre-HD creatinine (r=0.38, P<0.001), BMI (rho=0.2, P=0.01), and pre-HD body weight (rho=0.2, P=0.01), and inversely correlated with age (r=-0.294, P<0.001). pGSN levels were lower in non-blacks vs. blacks (P=0.047), DM vs. non-DM (P=0.023), and patients with CVD vs. without CVD (P=0.053). After backward stepwise regression, BMI, pre-HD serum creatinine concentration and CVD status remained as independent predictors of pGSN level in the final model, which yielded an adjusted R2 of 0.16 and an overall significance of P<0.001. (Table 1).

Table 1. Parameter estimates and significance levels of pGSN

| Predictors | B | SE | P |
|---|---|---|---|
| BMI | 48.7 | 20.6 | 0.02 |
| Creatinine | 216 | 52 | <0.001 |
| Cardiovascular disease | -471 | 280 | 0.094 |

Conclusion:

Our study shows that serum creatinine, BMI, and atherosclerotic CVD status(borderline) are independent predictors of pGSN levels in chronic HD patients. The significant association between pGSN and surrogates of muscle mass is in line with muscle being its primary source. The relationship with CVD may be linked to microinflammation and warrants further investigation.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2574**

**Are Circulating Zinc α2-Glycoprotein (ZAG) Levels Increased in Hemodialysis Patients?** Viviane Oliveira Leal,[1] Milena Barcza Stockler-Pinto,[2] Najla Elias Farage,[2] Julie Lobo,[2] Maurilo Leite,[2] Denis Fouque,[3] Denise Mafra.[1] *[1]Federal University Fluminense, Niteroi, Brazil; [2]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [3]University Claude Bernard Hopital Edouard Herriot, Lyon, France.*

Zinc α2-glycoprotein (ZAG), a soluble glycoprotein secreted from the liver and adipose tissue, acts a lipid-mobilizing factor involved in regulating lipid metabolism and adiposity. The role of ZAG is also connected with its ability to directly influence expression of uncoupling proteins which are implicated in the regulation of energy balance. In cancer cachexia, current data point to ZAG as a potential candidate for mediating lipid catabolism. Cachexia also occurs in chronic kidney disease. Nevertheless, to date, there is no information about ZAG levels in hemodialysis (HD) patients.

**Objective**: The purpose of this study was to describe plasma ZAG levels in HD patients.

**Methods**: Twenty-nine HD patients (18 men, 7 diabetics, aged 53.5 ± 12.1 yr, 36 (8-144) months on HD, Kt/V of 1.40 ± 0.25, body mass index (BMI) of 24.3 ± 4.4 kg/m$^2$) from RenalCor Clinic at Rio de Janeiro, Brazil, were studied. Blood samples were collected during fasting, before a regular HD session. ZAG was determined by ELISA (Biovendor®) and compared to 10 healthy subjects (6 men, 53.8 ± 14.2 yr old, BMI of 25.7 ± 2.3kg/m$^2$). The SPSS for Windows (version 11.0) was used as statistical program.

**Results**: Plasma ZAG levels were approximately 3-fold higher in HD patients (171.6 ± 41.6mg/L) when compared to healthy subjects (62.5 ± 21.7mg/L) (p<0.0001). ZAG levels were not correlated with age, time on HD, BMI and % body fat.

**Conclusions**: The circulating ZAG levels are increased in HD patients. Therefore, the role of ZAG on lipid metabolism and energy balance in this population deserves further investigation. *Supported by CNPq and FAPERJ*

**Insulin-Resistance and End Stage Renal Disease: The Role of Retinol Binding Protein 4** Elisa Gabanti, Giovanni Piotti, Valeria Corradetti, Teresa Valsania, Camillo Carrara, Eleonora Pattonieri, Pasquale Esposito, Teresa Rampino, Antonio Dal Canton. *Unit of Nephrology Dilaysis and Tranplantation, IRCCS Fondazione Policlinico San Matteo and University of Pavia, Pavia, Italy.*

INTRODUCTION

Insulin resistance (IR) affects patients with end stage renal disease (ESRD). Studies on animals and humans demonstrated the adipose tissue of glucose transporter protein 4 (GLUT4) decrease results in serum RBP4 increase that in turn induces IR. Since its renal excrection, we investigated whether RBP4 plays a role in inducing IR in ESRD.

METHODS

We enrolled 16 controls (C) and 16 patients on hemodialysis (HD), 18-72, free from diabetes, matched for sex, age and BMI. We obtained history, blood pressure, BMI, biochemical exams and we measured serum RBP4 levels by ELISA. Moreover we collected subcutaneous fat samples, from 6 HD at the time of renal transplantation and 6 paired C undergone hernia correction, to evaluate rbp4 and glut4 expression on adipose tissue by RT-PCR.

RESULTS

Serum glucose was similar in C and HD. Serum RBP4 was four times higher in HD than C (HD: 176,8+/-63,2 mg/dl; C: 39,2+/-17,4 mg/dl; p=0,0001). As expected HD insulin levels and HOMA index were significantly higher than C (insulin, HD: 15,8+/-12,2 µIU/ml; C: 6,7+/-4,3 µIU/ml, p=0,005; HOMA index, HD: 3,2+/-2,6, C: 1,4+/-1,0, p=0,008). Serum RBP4 in HD was significantly correlated with fasting serum glucose (p=0,04), total serum cholesterol (p=0,04), triglyceride (p=0,0004) and serum protein (p=0,005).

Serum RBP4 levels were lower in HD patients with a residual diuresis greater than 5000 ml/24 hours (D) compared to anuric patients (A) (D: 141,3+/-12,1 mg/dl, A: 193,4+/-16,1 mg/dl, p=0,02).

HD glut4 mRNA expression on adipose tissue was lower than C; it was inversely correlated with age, BMI in HD and age, BMI and urea in C (p=0,05). HD rbp4 mRNA expression too was lower than C, it was significantly correlated with age and renal function in C and with age and insulin levels in HD (p=0,05).

CONCLUSIONS

Our results demonstrate IR may be mediated by reduced adipose glut4 expression and high serum RBP4 levels in ESRD. The decrease of RBP4 renal clearance may be responsible for high levels of serum RBP4 in ESRD.

Disclosure of Financial Relationships: nothing to disclose

**The Short-Term Influence of Hepatitis C Virus Activity on Malnutrition-Inflammation Complex Syndrome in Maintenance Hemodialysis Patients** Hung-Bin Tsai.[1,2] *[1]Department of Internal Medicine, Buddhist Dalin Tzu Chi General Hospital, Chiayi, Taiwan; [2]School of Medicine, Tzu Chi University, Hualian, Taiwan.*

**Background.** Patients with maintenance hemodialysis (MHD) have a significantly higher prevalence of hepatitis C virus (HCV) infection and malnutrition-inflammation complex syndrome (MICS). This study was conducted to find clinical characteristics and influence of HCV infection on MICS using a nutritional-inflammatory scoring system known as the Malnutrition-inflammation Score (MIS) in Taiwanese MHD patients. **Methods.** This was a prospective, longitudinal study performed at a single hemodialysis center in Taiwan from September 2007 through March 2008. The study had 58 (37.9%) subjects in the active HCV group and 95 (62.1%) subjects in the non-HCV group, whose two or three weekly hemodialysis sessions were reviewed over a seven-month period. An additional 18 patients were included, and their inactive HCV status indicated previous HCV eradication spontaneously or after successful antiviral therapy. The malnutrition-inflammation score (MIS) was assessed using 10 components, combining the 7 components of the conventional Subjective Global Assessment (SGA) of Nutrition with 3 new elements (body mass index, serum albumin, and total iron binding capacity). **Results.** Hemodialysis duration and total MIS score increased with active HCV risk. The active HCV group had lower predialysis mean blood pressure, postdialysis weight, serum albumin, total cholesterol, and triglycerides levels but higher MIS scores compared to the non-HCV group. The MIS 5 score, indicative of major comorbid conditions, was significantly higher in the active HCV group than the non-HCV group throughout the trial. **Conclusion.** HCV infection incidence remains significant in MHD patients. The HCV-infected MHD patients have a greater MICS-associated metabolic and physiological disease.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2577**

**Differences in Muscle Action Potential in Patients with ESRD Compared to Age-Matched Sedentary Control Subjects** Cynthia Delgado,[1] Julie W. Doyle,[1] Kirsten L. Johansen.[1,2] *[1]Nephrology, UCSF, San Francisco, CA; [2]Nephrology, SFVAMC, San Francisco, Ca.*

Introduction: Compound motor action potentials (CMAPs) represent the summated electrical activity of individual nerve fibers activated by stimulation. CMAPs are known to be an accurate measure of activated muscle fibers, with reduction in amplitude suggestive of denervation injury. Evaluation of CMAPs has been applied in the clinical assessment of person with ALS in addition to other neuromuscular disorders. ESRD patients have

muscle weakness and sarcopenia compared to age matched controls. The purpose of the study was to determine whether differences in muscle function among patients with CKD are associated with EMG signs of denervation/reinnervation injury.

Methods: Eighty patients on hemodialysis > 3 months were included in the study if there was evidence of malnutrition or poor quality of life assessed by questionnaire. 20 age matched control subjects who were not on dialysis were studied for comparison. Participants underwent EMG action potential evaluation of the anterior tibialis muscle using surface electrodes. Cross-sectional area of the contractile tissue of the anterior tibialis muscle was measured by MRI.

Results: 48 patients had EMG and muscle CSA data available. The majority of subjects were male (64%) with mean age 55 (±13 yrs). 54% of participants were African American, 12% Caucasian and 25% Asian. ESRD patients had smaller muscle CMAP amplitude (P<0.005) than control subjects. In multivariate analysis, ESRD patients had lower CMAP amplitude than control subjects even after adjustment for muscle area, age and sex (coef -.0031, p<0.01).

Conclusion: ESRD patients have decreased CMAP potentials beyond what is expected based on their muscle atrophy. This is suggestive of axonal damage and loss, possibly as a result of denervation reinnervation injury or uremic toxins despite adequate dialysis by modern standards.

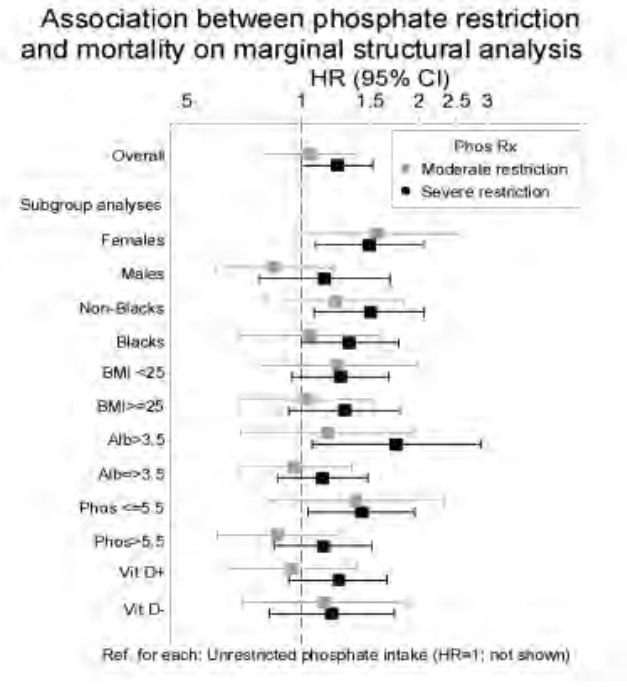
**Prescribed Dietary Phosphate Restriction and Mortality in Hemodialysis (HD)** Katherine E. Lynch,[1] Rebecca Lynch,[2] Gary C. Curhan,[2] Steven M. Brunelli.[2] *[1]Beth Israel Deaconess Medical Center; [2]Brigham and Women's Hospital.*

**Purpose:** To evaluate the association between prescribed dietary phosphate restriction and mortality among HD patients.

**Methods:** We conducted a post-hoc analysis of data from the Hemodialysis Study. Dietary phosphate prescription (considered as *unrestricted*, *moderately restricted* (1-2 g/day), and *severely restricted* (≤1 g/day)) was assessed at baseline and yearly thereafter. Covariates (also updated annually) included pertinent demographics, comorbidities, procedural data, laboratories, and dietary protein/caloric intake. Marginal structural models were fit in order to estimate the adjusted association between dietary phosphate restriction and mortality in the setting of time-dependent confounding.

**Results:** The cohort consisted of 1780 subjects; mean age was 58+/-14 years; 57% were female; 62% were black; total at-risk time was 5025 pt-years; 838 deaths were observed. At baseline dietary phosphate was unrestricted, moderately restricted and severely restricted in 525(29.5%), 304(17.1%), and 951(53.4%), respectively. Compared to *unrestricted* dietary phosphate, *severe* restriction was associated with greater mortality: adjusted HR (95% CI) 1.24 (1.00-1.53). *Moderate* phosphate restriction bore an intermediate association with mortality, which did not achieve statistical significance: HR (95% CI) 1.05 (0.80-1.39). The association between *severe* phosphate restriction and mortality was accentuated among women, non-blacks, subjects with hypoalbuminemia and those without hyperphosphatemia (Figure).



**Conclusions:** This study suggests that prescribed dietary phosphate restriction is not associated with improved survival among prevalent hemodialysis patients, and severe restriction may be associated with greater mortality particularly in some subgroups. Further work is needed to confirm and generalize these findings.

Disclosure of Financial Relationships: nothing to disclose

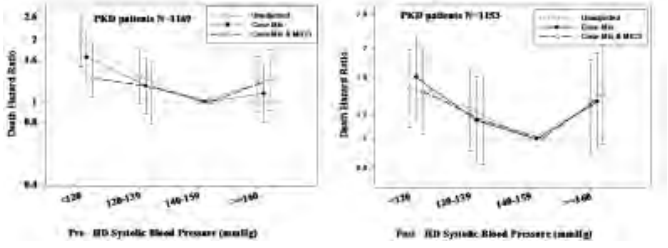
## SA-PO2579

**Blood Pressure and Survival in Long-Term Hemodialysis Patients with and without Polycystic Kidney Disease** Miklos Z. Molnar,[1] Lilia R. Lukowsky,[1] Ramanath B. Dukkipati,[1] Jennie Jing,[1] Allen R. Nissenson,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]DaVita Inc, Lakewood, CO; [3]Division of Nephrology, Salem VA Medical Center, Salem, VA.*

**Background:** In maintenance dialysis patients, low blood pressure (BP) is associated with higher death rates when compared to normal to moderately high values. This "hypertension paradox" may be related to comorbid conditions. Dialysis patients with polycystic kidney disease (PKD) usually have a lower comorbidity burden and greater survival. We hypothesized that in PKD dialysis patients, a representative of a healthier dialysis patient population, high BP is associated with higher mortality.

**Methods:** Time-dependent survival models including after multivariate adjustment were examined to assess the association between pre- and post-hemodialysis BP and all-cause mortality in a 5-year cohort of 67,085 non-PKD and 1,579 PKD hemodialysis patients.

**Results:** In PKD patients low pre- and post-hemodialysis systolic BPs were associated with increased mortality, whereas high pre-hemodialysis diastolic BP was associated with greater survival. Fully adjusted death hazard ratios (and 95% confidence levels) for pre- and post-hemodialysis BP of <120 (reference: 140-<160 mmHg) were 1.30 (1.06-1.92) (Figure 1) and 1.45 (1.04-2.02) (Figure 2), respectively, and for pre-hemodialysis diastolic BP of >=80 (reference: 70-<80 mmHg) was 0.68 (0.49-0.93, all p-values <0.05). Similar associations were observed in non-PKD patients. In pooled analyses, within each commensurate BP stratum, PKD patients exhibited superior survival to non-PKD patients.



**Conclusions:** Among hemodialysis patients, those with PKD display a similar BP paradox as without PKD, even though within each BP category PKD patients maintain superior survival.

## SA-PO2580

**Zinc May Regulate Serum Leptin Concentrations in Hemodialysis Patients** Denise Mafra,[1] Luciana Nicolau Aranha,[1] Julie Lobo,[2] Milena Barcza Stockler-Pinto,[2] Viviane Oliveira Leal,[1] Najla Elias Farage,[2] Denis Fouque.[3] *[1]Nutrition, Federal University Fluminense, Niteroi, Rio de Janeiro, Brazil; [2]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [3]Nephrology, University Claude Bernard Hopital Edouard Herriot, Lyon, France.*

Anorexia is a common complication in hemodialysis (HD) and is associated with development of malnutrition and consequently with increased risk of mortality. Recent evidences suggests that zinc can be a mediator of leptin production indicating a possible relationship between zinc deficiency and leptin levels in the pathogenesis of anorexia in HD.

**Aim:** The purpose of this study was to evaluate the relationship between zinc levels and plasma leptin in hemodialysis patients.

**Methods:** Forty eight HD patients (mean age 54.4 ± 12.8 yr, 62.5% men) from RenalCor Clinic at Rio de Janeiro, Brazil, were studied and compared to 21 healthy individuals, aged 50.7 ± 15.7 yr. Blood samples were collected at fasting, before a regular HD session. Serum zinc concentration was measured by atomic absorption spectrometry and plasma leptin levels were determined using Multiplex kits (R&D System) on a Luminex. Anthropometry was used to evaluate the nutritional status.

**Results:** Leptin levels were significantly higher in patients than in healthy individuals (22.3 ± 48.5 *vs.* 7.6 ± 8.6 µg/mL; p = 0.04), whereas serum zinc levels were significantly lower (54.5 ±16.3 *vs.* 78.4 ±9.4 µg/dL; p= 0.0001). Plasma leptin was negatively correlated with plasma zinc (r=-0.34; p=0.006) and positively correlated with BMI (r=0.38; p=0.008) and % body fat (r=0.48; p=0.002). Plasma zinc was negatively associated with TNF-α (r=- 0.37; p=0.002).

**Conclusion:** In conclusion, this study showed that plasma zinc is possibly involved in leptin regulation. Further studies are required to investigate the regulatory pathways by which zinc and leptin regulate energy intake and body composition in hemodialysis patients. *Supported by Faperj, CNPq.*

**SA-PO2581**

**Impact of the Route of Erythropoietin Administration on Hemoglobin Variability in Hemodialysis Patients** Youngki Lee, Ja-Ryong Koo, Seung Min Lee, Soo Jin Kim, Sung Gyun Kim, Ji Eun Oh, Jung-Woo Noh. *Department of Internal Medicine, Hallym Kidney Research Institute, Hallym University, Seoul, Republic of Korea.*

**Background:** Hemoglobin variability is a commonly occurring problem in hemodialysis patients receiving erythropoietin (EPO), and may portend poor outcomes. Drug-related factors such as difference in pharmacokinetics among EPO and different route of administration may affect hemoglobin variability. We reported that the risk of vascular access failure may be greater with subcutaneous (SC) compared to intravenous (IV) administration of EPO previously (Am J Kidney Dis 53:815-822, 2009). The present study was undertaken to analyze the impact of the different route of EPO administration on hemoglobin variability in hemodialysis patients.

**Methods**: 78 Korean hemodialysis patients were randomized to receive either IV (n=40) or SC (n=38) EPO therapy. EPO was administered during dialysis and the dose titrated to maintain hemoglobin level between 9 to 12 g/dL. We calculated the number of hemoglobin measurements out of the target range during all visits. Study duration was 4-77 months.

**Results:** The number of hemoglobin values out of the target range in patients receiving SC administration of EPO was higher than that of IV group (0.36±0.19 vs. 0.27±0.12/visit, P=0.03). There were no significant differences in the probability of the CVD-free rate between the groups. However, increased number of hemoglobin values out of the target range was associated with high probability of cardiovascular events regardless the route of EPO administration (p=0.018). And it was independently associated with increased CVD (HR: 2.85, 95% CI: 1.02, 7.94, P=0.04) after adjustment for age, previous CVD, dialysis vintage, and diabetes mellitus. There were no significant differences in either hemoglobin concentration or EPO doses between the two groups during the study period.

**Conclusions:** This study suggests that the risk of hemoglobin variability is greater with SC compared to IV administration of EPO in hemodialysis patients. Number of hemoglobin values out of the target range may be associated with increased risk of CVD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2582**

**Cost-Savings Associated with Reduction in Lower Limit Hemoglobin Target in EPO-Treated Hemodialysis Patients** Timothy V. Nguyen,[1] David S. Goldfarb.[2] *[1]Pharmacy Practice and Administration, Arnold & Marie Schwartz College of Pharmacy, Long Island University and The Mount Sinai Medical Center, New York, NY; [2]Medicine and Nephrology, NYU School of Medicine and NY Harbor VA Medical Center, New York, NY.*

**Purpose**: ESAs are widely used in dialysis patients. Patients treated with ESAs to Hb level >12 g/dL experience multiple complications including death. The FDA issued black box warnings and recommended not to treat to Hb level >12 g/dL. The NKF-KDOQI guidelines recommend target Hb levels in the range of 11-12 g/dL not to exceed 13 g/dL. We hypothesized that reducing target Hb in ESA-treated patients would prevent Hb levels rising above 12 g/dL and lead to significant cost savings.

**Methods**: In response to complications associated with ESA therapy (CHOIR, CREATE, TREAT), our target Hb levels were reduced to 9-11 g/dL from 11-12 g/dL. Thirty five chronic adult HD patients received EPO and IV iron from January to December 2009. Retrospective data analysis include: Hb levels, EPO dose, TSAT and ferritin levels. EPO was administered via subcutaneous injection weekly or twice weekly. IV iron ferric gluconate was administered to maintain TSAT >20% and ferritin >200 ng/mL.

**Results**: The mean monthly Hb levels changed from 11.2 g/dL in Jan to 10.6 g/dL in Dec. The percentage (%) of patients with mean monthly Hb(g/dL) >10, >12 and >13 were 82±6.5, 10±5.6 and 1.8±1.9 respectively. The mean weekly EPO doses decreased from 9,500 to 5,600 units. The reduction was approximately 40% per dose per patient, which translated to a 40% reduction in costs of treatment. The savings exceeded $60,000 for 35 patients. More than 80% of patients had TSAT>20% and ferritin level >200 ng/mL throughout the entire period.

**Conclusions**: Lowering target Hb level to 9-11 g/dL in HD patients treated with EPO achieved quality anemia management and resulted in significant cost savings. The literature suggests that this cost savings would be associated with minimal reduction in quality of life and no change in cardiovascular morbidity or mortality.

**SA-PO2583**

**The MIRACEL Study – Dosing and Dose Modifications Following the Direct Switch from Shorter-Acting ESA to Once Monthly C.E.R.A.** Danilo Fliser.[1] *[1]Klinik für Innere Medizin IV, Univeritätsklinikum des Saarlandes, Homburg/Saar, Germany; [2]Dialysezentrum Karlstrasse, Düsseldorf, Germany; [3]Medizinische Klinik III, Klinikum Fulda, Fulda, Germany.*

**INTRODUCTION AND AIMS:** The MIRACEL study was the first post-approval study with CERA to investigate hemoglobin (Hb) levels in CKD stage V pts receiving hemodialysis. We present additional in-depth data on dosing patterns and dose modification throughout the trial.

**METHODS:** In this prospective, single-arm national trial, 424 pts were converted from epoetin (Epo) α, β, δ, or Darbepoetin α (Dα) to CERA trt, of those 416 (98.1%) formed the ITT population. After a screening phase (2 months), pts were directly switched to once monthly CERA iv, regardless of their previous ESA, route of administration or dosing interval. Starting doses were 125µg or 200µg/months, depending on the pre-switch ESA-dose, followed by individual adaptation. After a titration phase (5 months), an evaluation phase (3 months) followed.

**RESULTS:** 311 (73.3%) pts started with 125µg/m, 106 (25.0%) pts initially received 200µg/months. During titration, dose was adjusted in 310 (73.1%) pts, and during evaluation in 171 (40.3%) pts. 260 (62.5%) pts needed only one dose modification during titration, to achieve target Hb levels. 120 (28.3%) pts required >1 dose modification during titration, while during evaluation, a second modification became necessary in only 41 (9.7%) pts. Overall, 1.19 ± 0.93 and 0.57 ± 0.68 dose modifications were needed in titration and evaluation phase, respectively. Mean CERA dose was 142 ± 48 µg/months throughout the study. When comparing the initial two pre-defined doses of 125 µg/months resp. 200 µg/months – with the last dose, the 125-µg-group was treated a mean of 129.6 ± 60.9 µg/months and the 200-µg-cohort arrived at a mean dose of 203.4 ± 58.5 µg/months.

**CONCLUSION:** Data from this large multi-center study emphasizes the clinical ease of switching hemodialysis pts from shorter acting ESAs at different dosing intervals to once monthly CERA. Starting from the recommended dosing, the majority of pts needed only one dose modification, with a robust starting-to-end-correlation of employed doses.

**$^{14}$C-Peginesatide Clearance, Metabolism, and Excretion in Monkeys Following IV Administration** Kathryn W. Woodburn,[1] Yuu Moriya,[2] Yoshihiko Tagawa,[2] Christopher P. Holmes.[1] *[1]Affymax Inc, Palo Alto, CA; [2]Takeda Pharmaceutical Company, Ltd, Yodogawa-ku, Osaka, Japan.*

**Background:** Hematide™/peginesatide is a PEGylated, investigational, peptide-based erythropoiesis-stimulating agent that was designed and engineered to stimulate specifically the erythropoietin receptor dimer that governs erythropoiesis. This study was conducted to evaluate the pharmacokinetics and excretion of $^{14}$C-peginesatide in monkeys. **Methods:** Four male Cynomolgus monkeys were given a single IV dose of 5 mg/kg $^{14}$C-peginesatide. Blood samples for pharmacokinetic analysis were obtained at 0.25, 1, 6, 24, 48, 72, 96, 120, 144, 168, 240, and 336 h postdose. Urine and fecal samples were obtained at 24 h intervals up to 336 h. Samples were measured for radioactivity and plasma, urine, and fecal metabolite profiles were assessed by high performance liquid chromatography. **Results:** Radioactivity in the plasma exhibited a $t_{1/2\,\alpha}$ of 35.7 h and a $t_{1/2\,\beta}$ of 80.0 h. The mean $AUC_{0\text{-}336\,h}$ in the plasma was 10756 µg equiv.·h/mL. By 24 h, the mean recovery from the urine and feces was 12.4% and 0.2% of the dose, respectively. At 336 h, the recovery into the urine and feces was 59.7% and 7.0% of the dose, respectively. The sum of the excretion ratios was 66.7% of the dose. Peginesatide was identified as the predominant compound in the plasma, urine, and fecal samples. **Conclusions:** Elimination of peginesatide derived radioactivity from the plasma was prolonged after intravenous administration. Negligible metabolites of $^{14}$C-peginesatide were detected in plasma, urine, and feces.

**Clearance, Metabolism, and Excretion of $^{14}$C-Peginesatide in Rats Following IV Administration** Kathryn W. Woodburn,[1] Yuu Moriya,[2] Yoshihiko Tagawa,[2] Christopher P. Holmes.[1] *[1]Affymax Inc, Palo Alto, CA; [2]Takeda Pharmaceutical Company, Ltd, Yodogawa-ku, Osaka, Japan.*

**Background:** Hematide™/peginesatide is a PEGylated, investigational, peptide-based erythropoiesis-stimulating agent that was designed and engineered to stimulate specifically the erythropoietin receptor dimer that governs erythropoiesis. This study was conducted to characterize the clearance and major routes of elimination of peginesatide. **Methods:** Mass balance and pharmacokinetic evaluation was performed in male Sprague-Dawley rats following IV administration of 5 mg/kg $^{14}$C-peginesatide. Blood samples were collected at 0.25, 1, 6, 24, 48, 72, 120, 168, 240, and 336 h, the expired air was collected up to 24 hours, and urine and feces were collected at 24 h intervals up to 336 h postdose. Samples were measured for radioactivity and metabolite characterization was determined by HPLC. **Results:** Plasma half-life values of the radioactivity, $t_{1/2\,\alpha}$ and $t_{1/2\,\beta}$ were 27.8 and 109.7 hours, respectively with an $AUC_{0\text{-}336h}$ of 6198 µg equiv.•h/mL. No radioactivity was measured in expired air. At the end of the study (336 h), the radioactivity recovered in urine, feces, and carcass was 41.3%, 11.8%, and 49.9%, respectively. Metabolite profiling from collected samples demonstrated that $^{14}$C-peginesatide was the main radioactive component in plasma, feces, and urine. **Conclusions:** Clearance of $^{14}$C-peginesatide derived radioactivity was prolonged, with urinary excretion being a predominant elimination route. Negligible metabolites of $^{14}$C-peginesatide were detected in plasma, urine, and feces.

Disclosure of Financial Relationships: Employer: Affymax Inc; Ownership: Affymax Inc.

**SA-PO2586**

**Hematide™/Peginesatide Is Metabolically Stable and Does Not Induce or Inhibit Human Cytochrome P450 Enzymes** Sue Im,[1] Kei-Lai Fong,[2] Mitsuhiro Nishihara,[3] Jyunzo Takahashi,[3] Yoshihiko Tagawa,[3] Christopher P. Holmes,[1] Kathryn W. Woodburn.[1] *[1]Affymax Inc, Palo Alto, CA; [2]Accellient Partners LLC, Berkeley, CA; [3]Takeda Pharmaceutical Company Ltd, Osaka, Japan.*

**Background:** Peginesatide is a PEGylated, investigational, peptide-based erythropoiesis-stimulating agent that was designed and engineered to stimulate specifically the erythropoietin receptor dimer that governs erythropoiesis. Patients receiving peginesatide treatment for chronic kidney disease may be taking other medications concomitantly; therefore, drug-drug interactions resulting from the alteration of drug metabolizing enzymes may affect safety or efficacy responses. Peginesatide and its non-pegylated dimer and monomer were evaluated for their potential to induce or inhibit human cytochrome P450 enzymes (CYPs). In vitro metabolism of peginesatide was also assessed. **Methods**: To assess induction of CYP activities, cultured human hepatocytes were treated for 72 h with peginesatide (≤500 µg/mL), dimer or monomer (≤10 µg/mL). To assess inhibition, peginesatide, dimer or monomer (same concentrations) were incubated (37°C) with human liver microsomes or microsomes expressing human CYP in the presence of an NADPH generating system and marker substrates for CYP activities. In both evaluations, negative and positive controls were included and the percent change in enzyme activity determined. Separately, radiolabeled peginesatide was incubated (37°C) with liver and renal microsomes and S9 fractions from rats, monkeys and humans in the presence of an NADPH generating system. Metabolite formation was monitored by HPLC. **Results**: Peginesatide and its dimer and monomer did not cause either inhibition or induction of human CYP enzymes. In vitro, peginesatide was the main component following incubation with microsomes from all 3 species. **Conclusions**: Peginesatide, its dimer, or monomer did not cause inhibition or induction of human CYP enzymes. Peginesatide was metabolically stable in vitro. These in vitro results suggest that administration of peginesatide is not likely to result in CYP-mediated drug-drug interactions; however, the clinical significance of these results is unknown.

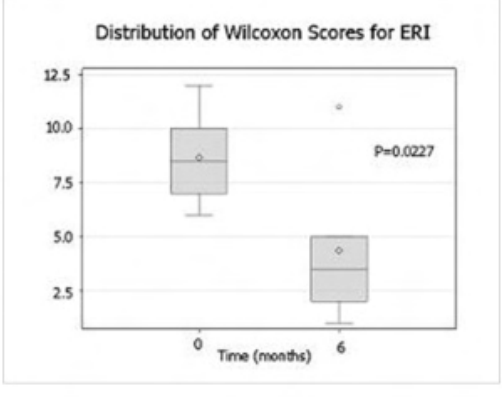
**N-Acetylcysteine (NAC) May Improve Erythropoietin Resistant Anemia (ERA) in Hemodialysis Patients** Nancy A. Finnigan,[1] Michael M. Chernick,[3] Robert L. Benz.[1,2] *[1]Nephrology, Lankenau Hospital, Wynnewood, PA; [2]Lankenau Institute for Medical Research, Wynnewood, PA; [3]Biostatistics, Lankenau Institute for Medical Research, Wynnewood, PA.*

PURPOSE: We studied the effect of N-acetylcysteine on hemodialysis patients with EPO resistance of undetermined etiology, presuming oxidative stress as the cause.

METHODS: All chronic hemodialysis patients from a single center were screened for eligibility. Inclusion criteria were age > 18, on hemodialysis > 3 months, and an ERI of >10 (Erythropoietin-Resistance Index, defined as weekly EPO dose / weight Kg / Hgb) for 2 months. Exclusion criteria included recent hospitalization, bleeding, infection, major surgery, active malignancy, iron deficiency, Kt/V<1.2, prior renal transplantation, and severe hyperparathyroidism. Subjects were administered oral N-acetylcysteine 600mg twice daily for 6 months. Hemoglobin was monitored monthly, and EPO dose adjusted per dialysis unit protocol.

RESULTS: Of 12 subjects enrolled, 2 discontinued due to GI side effects, 6 have completed the protocol, and 4 are actively receiving NAC. Of subjects completing the protocol, all had reduction of ERI from baseline with one exception, whose increase in ERI was attributed to a dental infection requiring dental extractions. Average ERI reduction was 19.9 to 9.3 (53%).



Wilcoxon Rank Sum Test on 6 subjects with complete data sets shows an ERI reduction from baseline (p=0.0227). Two month follow-up data is available on 5 patients, 4 of which are uninfected and show an ERI increase of 56% after NAC discontinuation.

CONCLUSIONS: The preliminary results of this small pilot study demonstrate an improvement in ERI with the administration of N-acetylcysteine to hemodialysis patients with EPO resistance presumed due to oxidative stress. Recruitment of subjects is ongoing to confirm these results.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2588**

**Erythropoietin Utilization in Hemodialysis Patients Receiving Paricalcitol vs. Doxercalciferol for Secondary Hyperparathyroidism** Samina Khan, Steven E. Marx, Beverly A. Johns, Utpaul Audhya. *Abbott, Abbott Park, IL.*

OBJECTIVE: To assess the impact of erythropoietin utilization among hemodialysis patients previously receiving erythropoietin who began paricalcitol or doxercalciferol.

METHODS: A retrospective cohort analysis from 2004 thru 2009 was conducted using database from a large dialysis organization of hemodialysis patients receiving erythropoietin. Patients were assigned to either paricalcitol or doxercalciferol treatment cohorts based on patients receiving a minimum of 10-doses of the respective drug. Inclusion criteria: erythropoietin use prior to index date, age >17year, minimum 90 days of data availability pre-index date, survival first 90 days after index date, & presence of consistent records. The index date was defined as the date of first dose of paricalcitol or doxercalciferol. A multivariate analysis of 14,043 patients adjusting for (1) age, gender, race, diabetes status, duration of dialysis, hemoglobin; (2) plus ferritin, and (3) plus study entry period was conducted. Additionally, 2,270 propensity matched patients using age, gender, race, and baseline hemoglobin were assessed as above. Sub-analyses were performed replacing ferritin with iron saturation & adding baseline iPTH to propensity match.

RESULTS: Multivariate analyses demonstrated statistically significant lower erythropoietin utilization for all three adjustments models comparing paricalcitol vs. doxercalciferol: (1) n=12,908 vs. 1,135, -0.05, p<0.05, (2) n=12,747 vs. 1,116, -0.05, p<0.05, and (3) n=12,747 vs. 1,116, -0.06, p<0.05. Similarly propensity matched analysis showed a trend towards lower erythropoietin use comparing paricalcitol vs. doxercalciferol for the first two, while statistically significant for the third adjustment analysis: (1) n=1,135 vs. 1,135, -0.05, p=0.10; (2) n=1,126 vs. 1,126, -0.05, p=0.09; (3) n=1,126 vs. 1,126, -0.08, p<0.05. Sub-analyses demonstrated similar results.

CONCLUSION: Hemodialysis patients with secondary hyperparathyroidism at this provider who received paricalcitol appear to have less erythropoietin dose requirements than those receiving doxercalciferol. Further prospective studies are required to confirm these results.

**Prevalence of Atrial Fibrillation and Anticoagulation for Stroke Prophylaxis in Patients with Atrial Fibrillation: A Cross-Sectional Study of Patients on Hemodialysis** Juan Guzman,[1] Andrew Edward Gibson,[1] Amindeep S. Sandhu,[1] Trevor J. Wilkieson,[1] Nischal Ranganath,[1] Deborah Lynn Zimmerman,[2] Catherine M. Clase.[1] *[1]Department of Medicine - Division Nephrology, McMaster University, Hamilton, ON, Canada; [2]Department of Medicine - Division Nephrology, University of Ottawa, Ottawa, ON, Canada.*

**BACKGROUND:** Atrial fibrillation (AF) appears more frequent in haemodialysis (HD) patients. Previous studies have reported prevalences between 11 and 27% in previous studies.

**OBJECTIVE:** To determine the prevalence of AF and the prevalence of anticoagulation in those with AF in HD patients at St Joseph's Healthcare Hamilton (SJHH) dialysis unit.

**METHODOLOGY:** We performed a cross-sectional chart review of all 415 patients on HD attending to the SJHH. We collected data using an electronic-based survey linked to an electronic network database. We recorded demographic data, past medical history, anticoagulation data, risk of major bleeding (HEMORR2HAGES score), AF clinical information and AF embolic stroke risk score (CHADS2) in all the participants. The McMaster University research ethics board reviewed and approved the protocol. Data collection and analysis was completed from December 2009 to May 2010. Alpha level was set at 0.05. Data was analyzed with SPSS Version 18.0 (Chicago, IL, USA).

**RESULTS:** From 415 total study population, 32 (7%) patients were excluded. A total of 81 patients were identified as having either current AF or history of AF (prevalence: 22%; 95% CI 18 to 26%). Of the 81 patients, 28 (34.6%) were anticoagulated with Warfarin and 53 (65.4%) were not. There was no statistically significant difference in the mean total CHADS2 score [3.2 (1.4) vs. 3.4 (1.6)] or the mean total HEMORR2HAGES score [3.96 (1.6) vs. 4.6 (1.4)] between the Warfarin and no Warfarin groups respectively.

**CONCLUSION**: Warfarin use for stroke prevention in HD patients with AF is not prevalent and the variation in the use of Warfarin does not seem to be explained by risk of stroke or risk of bleeding. We hypothesize that the practice variation might be related to equipoise or uncertainty in the community, because of lack of direct evidence of benefit in this group of patients

**SA-PO2590**

**Cardiovascular Risk Factors Correlate with Cardiac Anatomy in Pediatric Dialysis Patients** Douglas M. Silverstein. *Pediatric Nephrology, Children's National Medical Center, Washington, DC.*

Cardiovascular disease (CVD) is a major cause of mortality in children with end-stage renal disease (ESRD). We assessed the prevalence of 12 CVD risk factors in 28 pediatric ESRD patients: 12 on hemodialysis (HD) and 16 on peritoneal dialysis (PD), age 14.8±0.8 years, dialysis vintage 26.9±5.1 months. Pre-treatment systolic blood pressure index (SBPI) values were those recorded over 1 month. Values for homocysteine and 25 hydroxy vitamin D represent one value; all other lab values were those averaged over 3 months. 39% of patients had elevated left ventricular mass index (LVMI). 25 OH Vitamin D and hemoglobin levels, and BMI percentile were significantly more abnormal in patients with high LVMI. There were 4.1±0.3 CVD risk factors/patient. 50% of patients with normal LVMI had <4 CVD risk factors compared to 17% of those with high LVMI.

CVD RISK FACTORS: IMPACT ON LVMI

| RISK FACTOR | % OF PATIENTS WITH RISK FACTOR | NORMAL LVMI | HIGH LVMI | p VALUE |
|---|---|---|---|---|
| Pre-Treatment Systolic BP Index | 50% | 0.99±0.01 | 1.02±0.03 | 0.5 |
| Serum Albumin (g/dl) | 4% | 4.1±0.2 | 4.1±0.1 | 0.9 |
| Serum homocysteine (mmol/L) | 71% | 15.5±2.8 | 18.3±2.5 | 0.5 |
| HDL (mg/dl) | 18% | 117.7±22.3 | 115.5±28.1 | 0.9 |
| LDL (mg/dl) | 21% | 44.3±2.1 | 45.3±4.2 | 0.8 |

**The Effect of Hemodialysis Modality on Insulin Resistance** Sung Jin Moon,[1] Jwa-Kyung Kim,[2] Jung Eun Lee,[3] Hyeong Cheon Park,[1] Tae-Hyun Yoo,[2] Shin-Wook Kang,[2] Ho Yung Lee,[2] Sung-Kyu Ha.[1] *[1]Internal Medicine, Gangnam Severance Hospital, Seoul, Korea; [2]Internal Medicine, Severance Hospital, Seoul, Korea; [3]Internal Medicine, Yongin Severance Hospital, Yongin, Korea.*

Introduction: Cardiovascular disease (CVD) is the leading cause of mortality in patients with end-stage renal disease (ESRD). Insulin resistance (IR) is associated with development of the CVD. We examined the factors containing hemodialysis modalities, associated with insulin resistance in hemodialysis patients.

Methods: In a cross-sectional study, 82 non-diabetic HD patients (47 men, mean age 59.2±14.4 years) were enrolled and divided into two groups by median homeostasis model assessment index (HOMA-IR). Other clinical and bio-chemical data associated with IR were collected.

Results: Higher HOMA-IR group had higher BMI (23.0 ± 3.1 vs. 20.9 ± 2.3 kg/m$^2$, p=0.001) and lower HDL cholesterol (42.4 ± 11.0 vs. 47.5 ± 10.4 mg/dL, p=0.038) levels. In addition, lower HOMA-IR group had more β-2 microglobulin reduction rate (39.1 ± 25.1 vs. 16.0 ± 22.8 %, p=0.001) and more proportion of hemodiafiltration (HDF) modality (p=0.002). HOMA-IR was significantly correlated with β-2 microglobulin reduction rate (r=-0.318, p=0.004). On multivariate logistic regression analysis adjusted by age, sex, BMI, hemodialysis modality, HDL cholesterol, and medication of statins and beta blockers, BMI and HDF modality were significant factors associated with HOMA-IR.

Conclusion: Lower HOMA-IR was significantly associated with HDF modality. It suggests that HDF therapy, enhancing removal of middle-molecular-weight substances by convection may reduce insulin resistance in hemodialysis patients.

**Coronary Artery Calcification and Cardiovascular Events in Incident Patients on Haemodialysis** Trevor J. Wilkieson, Mohammed Omair Rahman, Maurice D. Voss, Alistair J. Ingram, Nischal Ranganath, Charlie H. Goldsmith, Cathy Z. Kotsamanes, Azim S. Gangji, Mark A. Crowther, Christian G. Rabbat, Catherine M. Clase. *Medicine, McMaster University, Hamilton, ON, Canada.*

**Background.** Coronary artery calcification (CAC) is prevalent in patients with end stage renal disease. CAC is progressive and is a risk factor for many adverse outcomes including cardiovascular events and death.

**Methods.** We conducted a prospective cohort study of consenting adult incident patients on haemodialysis (HD) at St Joseph's Healthcare Hamilton (SJHH), recruiting from October 2004 to October 2007. Patients were characterized in terms of age, sex, presence of diabetes, serum calcium, phosphorus, type of phosphate binder used, warfarin use, active vitamin D compounds, and baseline cardiovascular disease. CAC was measured by spiral CT and scored using the Agatston-Janowitz (AJ-130) method. Patients were followed until May 2008 for the primary outcome composite: all cause death, first myocardial infarction (MI) or stroke.

**Results.** The longitudinal cohort study recruited 164 patients at SJHH. 51 patients consented to spiral CT. There were 16 primary outcomes. The hazard ratio for CAC above the median was 2.5 (95% confidence interval [CI] 0.87, 7.3) (Figure 1). In the analysis adjusted for age, the hazard ratio for CAC above the median was 1.7 (95% CI 0.55, 5.4).

**Conclusion.** The primary limitation of this study is that few events occurred; which precluded a more comprehensive multivariate analysis. Accepting this limitation, in these data, CAC is associated with all cause death, first MI or stroke in incident patients on HD. However, the relationship is confounded by age.

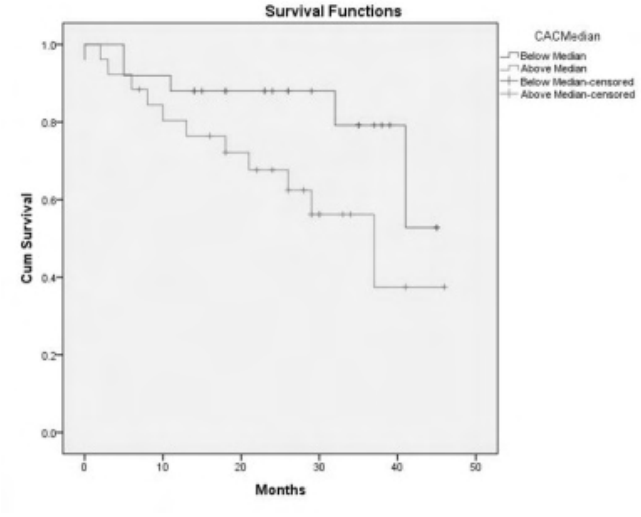

Figure 1. Relationship between CAC and all cause death, first MI or stroke; CAC divided at the median.

**Apo E2 Polymorphism Is Associated with Higher Levels of HDL2 Subfraction in Dialysis Patients** Fasika M. Tedla, Olusegun L. Amao, Moro O. Salifu, Clinton D. Brown. *Department of Medicine, Division of Nephrology, SUNY Downstate Medical Center, Brooklyn, NY.*

Background: Apo E gene polymorphisms have been associated with dyslipidemia in the general as well as dialysis population but the impact of these polymorphisms on lipoprotein subfractions has not been studied in dialysis patients.

Methods: We measured total cholesterol (TC), LDL cholesterol (LDL-C), HDL cholesterol (HDL-C), triglycerides (TG), apolipoprotein B (apo B), lipoprotein a (Lpa), C-reactive protein (CRP) levels; apo E genotype; and percentages of HDL2b and small dense LDL in 67 hemodialysis patients using assays available at an independent laboratory (Berkeley HeartLab, Alameda, CA). Patients were classified into three Apo E genotypes: E2 (e2/e2, e2/e3), E3 (e3/e3, e2/e4) or E4 (e4/e4, e3/e4). Genotypes were compared using analysis of variance or $\chi 2$ for continuous or categorical variables, respectively. Genotype frequencies were tested for Hardy-Weinberg equilibrium using exact probability test. Statistical significance was determined if $\alpha < 0.05$.

Results: The genotype frequencies were found to be in Hardy-Weinberg proportion. Apo E2, E3, and E4 genotypes represented 15%, 53.7% and 31.3%, of the study subjects respectively, and had no significant difference in gender, mean age (57.3±7., 57±5, 60.1±8.2 years), TC (139.2±20.1, 146±13.6, 144.3±17.4 mg/dL), LDL-C (67±13.8, 78±11.2, 78±14.6 mg/dL), HDL-C (55±10.8, 46±5, 52±20.5 mg/dL), TG (84±28.4, 107±23, 107±32.7 mg/dL), apo B (60±11.5, 73±9.2, 73±10.2 mg/dL), Lpa (54±29, 64±18, 72±24 mg/dL), CRP (13.3±14, 10±3.2, 10.5±6.5 mg/L), or small dense LDL % (13±3.8, 19±2.5, 19±5). The genotype groups, however, had significantly different HDL2b % (37.8±7.8, 24.5±7.5, 24.4±5.3, p<0.01). Significant inverse correlation was noted between HDL2b concentration and percentage of small dense LDL for Apo E2 (r=-0.74, p=0.02)and Apo E4 (r=0.68, p=0.01) polymorphisms, but not the wild genotype (Apo E3).

Conclusion: Dialysis patients with Apo E2 polymorphism have higher percentage of the cardio-protective HDL2b subfraction compared to dialysis patients with Apo E3 and Apo E4 polymorphisms.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2594**

**Effects of HFR Aequilibrium Therapy on Cardiovascular Stability: A European Multicentric Study** Francesco Locatelli,[1] Sergio Stefoni,[2] Thierry Petitclerc.[3] *[1]Manzoni, Lecco; [2]S. Orsola Malpighi, Bologna; [3]AURA, Paris.*

HFR Aequilibrium (HFR Aeq) is a dialysis technique based on the combination of HFR treatment with dialysate $Na^+$ and UF profiles elaborated automatically by a mathematical kinetic model and supported by the Natrium sensor measure of the patient's blood $Na^+$ concentration. The objective is to stabilize intradialytic BV taking into account the BW decrease and $Na^+$ balance of the session. Aim of the study was to evaluate the efficacy of HFR Aeq vs HFR.

An international study was carried out in 50 patients. After 1 month of wash out treatment, they were dialyzed with HFR or HFR Aeq (2 months)and then crossed. The study was carried out evaluating: intradialytic SBP, DBP and HR (time 0, every 30' and at 240'). Other intradialytic symptoms, operative and medical interventions were registered.

More than 900 sessions were performed for each period (Wash out, standard HFR, HFR Aeq). Intradialytic SBP and DBP significantly increased on HFR Aeq vs HFR respectively from 60' and 120' from start through session end. Intradialytic HR was more stable with HFR Aeq. Symptomatic hypotension episodes resulted significantly lower on HFR Aeq vs HFR (23±20% vs 31±28% of sessions respectively, $p<0.05$), as lower was the % of operative and medical interventions (17±20% of sessions with almost 1 intervention on HFR Aeq vs 22±24% on HFR; $p<0.01$). HFR Aeq resulted more effective on more unstable patients (35±15% of sessions with hypotension on HFR Aeq vs 60±28% on HFR; $p<0,01$). No clinical or biochemical signs of $Na^+$ - water overload appeared during the periods of treatment with HFR Aeq.

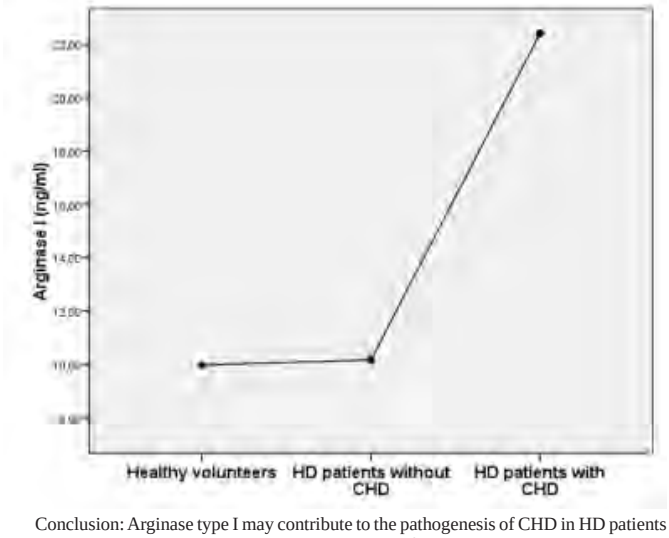
**SA-PO2595**

**Arginase Type I as a Marker of Coronary Heart Disease in Hemodialysis Patients** Theodoros Eleftheriadis, Vassilios Liakopoulos, Georgia Antoniadi, Ioannis Stefanidis. *Department of Nephrology, University of Thessaly, Larissa, Greece.*

Background: Cardiovascular disease, and mainly coronary heart disease (CHD), is the leading cause of death in hemodialysis (HD) patients. Non-traditional risk factors may play an important role in this population. Arginase is known to contribute directly in atherosclerosis progression and to counteract the beneficial effects of nitric oxide. HD could be considered as an inflammatory condition. Inflammation contributes to atherosclerosis progression and influences both arginase and nitric oxide synthase expression. In the present study serum arginase type I was evaluated as a marker of CHD in HD patients. The markers of inflammation nterleukin-6 (IL-6) and tumor necrosis factor-α (TNF-α) were also assessed.

Patients and methods: 68 HD patients and 24 healthy volunteers were enrolled into the study. 20 HD patients suffered from CHD confirmed with coronary angiography, while the rest 48 HD patients were asymptomatic. The asymptomatic HD patients were followed up for a period of 24 months after the blood collection and none of them developed symptoms of CHD. Serum arginase type I, IL-6 and TNF-α were measured with ELISA.

Results: IL-6 and TNF-α levels were increased in HD patients, but did not differ between HD patients with or without CHD. On the contrary, arginase levels did not differ between healthy subjects and HD patients, but were twice higher in HD patients with CHD than in HD patients without CHD (22.41±15.47 ng/ml vs. 10.16±8.13 ng/ml).



Conclusion: Arginase type I may contribute to the pathogenesis of CHD in HD patients and its levels in the serum could be used as a marker of CHD in this population.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2596**

**Impact of Functional Genetic Polymorphisms of the Renin-Angiotensin-Aldosterone System on Coronary Artery Disease, Cardiovascular Complications and Mortality in Dialysis Patients** Sendogan Aker, Christos Bantis, Philip Reis, Peter J. Heering, Christina Schwandt, Lars C. Rump, Katrin Ivens. *Department of Nephrology, Heinrich-Heine University, Düsseldorf, Germany.*

We investigated the impact of angiotensin converting enzyme (ACE) I/D and aldosterone synthase gene C-344T polymorphisms on coronary artery disease (CAD) in chronic dialysis patients.

We studied n=462 patients on chronic dialysis with angiographically confirmed (n=217) or excluded (n=245) CAD followed up for 5.4±4.0 years. Cardiovascular complications and the need for intervention (coronary angioplasty or coronary artery bypass grafting) were monitored. The polymorphisms were determined by PCR. Serum aldosterone and ACE activity were determined by ELISA and RIA in 57 and 91 CKD patients respectively.

Aldosterone synthase C-344T and ACE-I/D polymorphisms influenced the serum aldosterone levels (CC/CT: 106.8±70.4, TT: 243.2±323 pg/ml, $p=0.013$) and ACE serum activity (DD/DT: 98.7±21, II: 65.6±18 U/L, $p<0.001$). Patients with CAD were comparable to those without CAD regarding age at coronary angiography, time on dialysis, LDL cholesterol and prevalence of arterial hypertension (ns). Among patients with CAD there were significantly more men (73.9 vs. 61.2%, $p<0.01$), diabetics (29.8 vs. 17.6%, $p<0.01$) and smokers (42.8 vs. 34.3%, $p<0.05$). Patients with CAD had also higher CRP (1.15±1.17 vs. 0.94±1.15mg/dl, $p<0.05$) and fibrinogen levels (453±134 vs. 417±109 mg/dl, $p<0.05$). There was no difference in the genotype distribution in patients with CAD (ACE I/D: DD=26.3%, DI=48.8%, II=24.9%; C-344T: CC=14.9%, CT=52.6%, TT=32.6%) and without CAD (ACE I/D: DD=25.4%, DI=51.2%, II=23.4%; C-344T: CC=20.4%, CT=47.8%, TT=31.8%, ns). Furthermore, no impact of the investigated polymorphisms was detected in the Kaplan-Meier analysis of intervention-free or myocardial-infarction-free survival as well in the general patient survival (ns).

The functional ACE-I/D and aldosterone synthase gene C-344T polymorphisms are not risk factors for the development of coronary artery disease in dialysis patients. Furthermore, they do not influence the incidence of myocardial infarction, need for intervention and mortality in this patients.

**SA-PO2597**

**Chronic Ambulatory Ultrafiltration Therapy for Heart Failure: Lack of Impact on Established Predictors of Mortality** Amir Kazory,[1] Matthias Goldstein,[2] Ardalan Enkeshafi,[3] Jerald Insel.[2] *[1]Division of Nephrology, Hypertension, University of Florida, Gainesville, FL; [2]Division of Cardiology, Good Samaritan Hospital, Baltimore, MD; [3]Department of Medicine, Western Maryland Health System, Cumberland, MD.*

**Background**: Although several studies have demonstrated the efficacy of ultrafiltration therapy in patients with heart failure (HF), there is currently no data on the impact of this therapy on long-term outcomes. Blood urea nitrogen (BUN) and serum sodium levels are the two "modifiable" laboratory parameters that have consistently been shown to predict outcomes in this population both at short- and long-term. We sought to explore the impact of chronic ultrafiltration on these established predictors of mortality.

**Methods:** All ambulatory patients with HF who were referred to the "aquapheresis clinic" for extracorporeal therapy were included. The clinic provided chronic ultrafiltration therapy to patients with refractory HF. Patients with less than 3 sessions of therapy were excluded. For each ultrafiltration session, relevant clinical and laboratory data at various time points (e.g. prior to initiation of therapy, one week, and four weeks) were recorded and compared.

**Results:** Between March 2006 and December 2008, 16 patients underwent a total of 279 sessions of ultrafiltration. The mean ejection fraction was 38% , with a baseline eGFR of 52.2 ml/min. The patients who completed a minimum of 4 weeks of ultrafiltration (9) had a mean baseline BUN of 38.5 mg/dl and serum sodium of 137.4 mEq/l; two of them were hyponatremic (serum sodium level ≤ 135 mEq/l) with a mean serum sodium concentration of 134 mEq/l. After 4 weeks of ultrafiltration therapy, BUN levels increased to 43.6 mg/dl and there was no significant change in the serum sodium level of the overall population (138.1 mEq/l) or the hyponatremic subgroup (135 mEq/l).

**Conclusion**: This study suggest that chronic ultrafiltration therapy does not portend a beneficial impact on certain predictors of mortality (BUN and serum sodium) in patients with HF. Whether this translates into a lack of effect on long-term outcomes needs to be addressed by future studies.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2598**

**Impact of Predialysis Care by Nephrologists on Selection of Dialysis Modality for Therapy and Prognosis of Stages 4 and 5 CKD Patients Older Than 75 Years of Age** Hiromichi Suzuki, Tsutomu Inoue, Yusuke Watanabe, Tsuneo Takenaka, Hirokazu Okada. *Nephrology, Saitama Medical University, Iruma gun, Saitama, Japan.*

**Background:** Overwhelming increases in numbers of the elderly population undergoing dialysis have become a serious problem in many countries with respect to medical as well as economic aspects. Early referral to nephrologists is recommended in patients with CKD. Moreover, it is well known that predialysis care is important for delaying introduction to renal replacement therapy (RRT). However, no conclusive data are available on whether predialysis care affects the selection of dialysis modality in the therapy and prognosis of elderly patients.

**Aim**: To examine the influence of predialysis care by nephrologists on the selection of dialysis modality and to evaluate the prognosis of elderly patients.

**Methods and Subjects**: A single center, retrospective cohort study was performed that included 210 patients (female/male**:** 52/158**;** 78 ± 9 years old) with stages 4 and 5 CKD (estimated GFR (eGFR) 8.7 ± 1.3 ml/min/1.73 $m^2$) referred to the kidney disease center from 2004 to 2009. Electronic databases were used to obtain information on selection of RRT and mortality.

**Results**: Only 60 (28%) patients were referred to the center 6 months prior to the introduction of RRT. Of the 60 patients, 42 selected continuous ambulatory peritoneal dialysis (CAPD), while 18 selected hemodialysis (HD) therapy. Of the other patients, 139

selected HD, 9 patients did CAPD and 2 refused RRT. More than 50% (32) of patients receiving predialysis care survived more than 29 months after introduction of RRT. In contrast, less than 10% (12) of late referral patients survived more than 30 months ($p<0.01$). There were significant differences in the levels of eGFR, albumin, hemoglobin, potassium, calcium, and phosphate between the two groups at the start of RRT, but no difference was seen for age.

**Conclusion**: Predialysis care by nephrologists is important for selection of RRT modality, and for improvement of prognosis after introduction of RRT in stages 4 and 5 CKD patients older than 75 years of age.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2599

**Beta Blockers for Prevention of Sudden Cardiac Death in Patients on Hemodialysis: A Propensity Score Analysis of the HEMO Study** Navdeep Tangri, Shani Shastri, Hocine Tighiouart, Gerald J. Beck, Alfred K. Cheung, Gary Eknoyan, Mark J. Sarnak. *Division of Nephrology, Tufts Medical Center, Boston, MA.*

Hemodialysis (HD) patients are at high risk for sudden cardiac death (SCD). Although beta blockers have been proven beneficial for prevention of SCD in the general population, little evidence exists for their efficacy in HD. The purpose of this analysis was to evaluate the potential benefit of beta blockers in a post-hoc analysis of the HEMO study.

The HEMO study was a randomized trial that enrolled 1,846 HD patients. Medications were ascertained from the dialysis chart, and SCD was a secondary outcome of interest. We used Cox regression models, as well as propensity score methods to study the effect of beta blockers on SCD.

1,747 patients were included in this analysis, and 521 were on beta blockers at baseline. Mean age was 58 years with 57 % females. 39% had ischemic heart disease (IHD) and 12% had severe heart failure (HF). 181 patients died from SCD during a mean follow-up of 31 months. Beta blocker use was not associated with a lower risk of SCD in univariate, multivariable or propensity-based analysis(Table). There was a significant interaction ($p=0.03$) between beta blocker use and IHD (HR 0.65(0.42,1.01) for patients with IHD and 1.61(0.92,2.80) for those without IHD), but not with HF ($p>0.05$). There was no association between beta blockers and other cardiac or all-cause mortality.

In HD patients without preexisting IHD, beta blocker use is not associated with a lower risk of SCD. These findings suggest that clinical equipoise may exist for a randomized controlled trial of beta blockers in HD patients without IHD.

Table: Effect of beta blockers on sudden cardiac death using different statistical methods

| Method | HR (95 % CI) |
|---|---|
| Survival Analysis | |
| Univariate | 0.89 (0.64 – 1.24) |
| Multivariable* | 0.87 (0.62 – 1.22) |
| Propensity Score (PS) Analysis | |
| PS Matching | 0.86 (0.58 – 1.28) |
| PS Stratification | 0.92 (0.43 – 1.95) |
| PS Adjustment | 0.87 (0.62 – 1.22) |

*Adjusted for age, sex, race, dialysis access, albumin, BMI, presence of diabetes, ischemic heart disease, HF, arrhythmia and cerebrovascular disease at baseline

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2600

**Increasing PD Reduces Medicaid Spending** Eric Berger, Kelly Yori, Renee Jg Arnold, John E. Moran. *DaVita Inc., Denver, CO.*

To meet 2011 budget shortfalls, states are enacting Medicaid budget cuts, including proposals to reduce dialysis reimbursement. In dual-eligible (Medicaid/Medicare) dialysis patients, Medicaid covers the 1st 3 months of tx until Medicare becomes effective. If a dual-eligible patient initiates training for PD, Medicare coverage becomes effective immediately. We examined the potential Medicaid savings associated with increasing PD among incident dialysis patients. This is a cost minimization model, taking a California Medicaid (MediCal) perspective, with a 1-year time horizon. We assumed 10% of ESRD incident patients who start dialysis without previous nephrologic care ("crash") and 25% of non-"crash" ESRD incident patients will choose PD.

| Assumptions | N* | Target PD Population | Model PD | Annual Savings |
|---|---|---|---|---|
| Incident Patients | | | | |
| Dual eligible | 1358 | | 217 | $6.1M |
| -"Crash" | 815 | 10% | 82 | |
| -Non-"Crash" | 543 | 25% | 135 | |
| Non-Medicare | 1280 | | 205 | $3.6M |
| -"Crash" | 768 | 10% | 77 | |
| -Non-"Crash" | 572 | 25% | 128 | |
| | Medicare Costs 12-month * | Medicare Costs 1st 3 months | MediCal Costs 1st 3 months | MediCal Savings 12-month |
| Per Dual-Eligible Patient | | | | |
| HD | $73,000 | $35,300 | $31,808 | N/A |
| PD | $53,500 | $25,900 | $5,174 | $28,101 |
| Difference | $19,500 | | $26,634 | |
| -with 10% Medicare discount | $17,600 | | | |

* 2009 MediCal actual ** 2008 USRDS

The model assumes an increase in incident PD from 5.8% (actual) to 7% in the dual-eligible patients and from 7.6% (actual) to 10.3% for MediCal-only patients. The model calculated the 3-month savings associated with changing coverage from MediCal to Medicare in dual-eligibles, and the annual savings for lower PD reimbursement (relative to HD) for non-Medicare eligible patients.The cumulative savings of treating 217 additional dually-eligible incident patients with PD vs HD was $6.1M over 1 year and treating 205 more non-Medicare eligible incident patients with PD was $3.6M yielding California an annual savings of $9.7M.Increasing the number of incident patients treated with PD instead of HD could save MediCal $5 to $10 million per year, likely the latter. This is a viable alternative for state officials seeking options to decrease Medicaid spending without compromising patient outcomes.

## SA-PO2601

**Predictors of Mismatch between Chosen and Actual Dialysis Modality** Scott E. Liebman,[1] Steven P. Lamontagne,[1] Nancy Caswell.[2] *[1]Medicine, University of Rochester, Rochester, NY; [2]National Kidney Foundation of Upstate New York, Rochester, NY.*

**Background:** Although dialysis modality education (DME) is associated with higher rates of peritoneal dialysis (PD) use, some patients start hemodialysis (HD) despite an initially selecting PD as their modality of choice. This study tests the hypothesis that patients choosing and subsequently starting PD are educated earlier than those who choose PD, but start HD.

**Methods**: We performed a retrospective analysis of all patients who 1) Received DME at the University of Rochester between January 2004 and September 2009, 2) chose PD, and 3) subsequently started dialysis. Patients with contraindications to PD and those receiving education within two weeks of starting dialysis were excluded.

**Results:** Of the 112 patients receiving DME and choosing PD, 52 started dialysis with PD, 60 with HD. The primary hypothesis was negative. There was no difference in time between education and dialysis start between the two initial modalities ($41.4 \pm 42.9$ weeks for those starting PD vs. $46 \pm 49.9$ weeks for those starting HD, $p= 0.5$). Those starting PD had fewer comorbidities (2.1 vs.2.7) and were more likely to be under 75 years of age (94% vs. 78%) and working (24% vs. 6%) compared to those starting HD. In addition to the factors above, glomerular disease as ESRD cause was predictive of being on PD at day 90 of dialysis (26% of PD patients vs. 10% of HD patients), irrespective of initial modality.

Patients starting on HD were significantly more likely to have an unplanned dialysis start compared to those starting PD (57% vs. 2%).

Of the 54 patients who started HD and completed 90 days of dialysis, only six had transferred to PD by day 90.

Glomerular filtration rate (GFR) at DME, race, gender, ethnicity, BMI, education level, smoking , marital or insurance status and time of or GFR at initial nephrology encounter were not associated with initial modality.

**Conclusion:** Our data suggest that many people who initially select PD do not start with this modality, and few variables predict this discrepancy. Once on HD, most patients do not change modality. Further investigation using a qualitative approach may help explain the mismatch.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2602

**Predialysis Education and Care for Peritoneal Dialysis Catheters: A Need for Improvement** Leslie P. Wong,[1,2] Kalani T. Yamamoto,[2] Hien Pham.[2] *[1]Northwest Kidney Centers, Seattle, WA; [2]Nephrology, University of Washington Medical Center, Seattle, WA.*

**Background:** Peritoneal dialysis (PD) catheter-related complications are an important cause of morbidity and technique failure. Although guidelines outlining predialysis PD catheter- and exit-site care have been published by the International Society for Peritoneal Dialysis (ISPD), it is not known if these recommendations are followed in clinical practice. We are conducting a population-based study at a large U.S. PD program to examine this question.

**Methods:** We have enrolled 90 patients to date. Subjects answered a questionnaire about the care and instructions they received before and after PD catheter placement. Questions were derived directly from ISPD guidelines. Patient characteristics were recorded

**Results:** Fifty seven percent of participants were female. Mean age was 56 (±16) years. Most subjects were White (52%) and 69% had attended college or graduate school. The majority (99%) of patients had their PD catheters placed by surgeons. Before surgery, 46% of patients were checked for a hernia. Only 60% were asked if they could visualize their planned exit site. Instructions to shower with soap (52%) or perform bowel cleansing (20%) were not always given before surgery. Following PD catheter placement, most patients were told to call their surgeon (47%) or PD nurse (32%) for problems, not their nephrologist (5%). Only 44% of patients were instructed to leave their catheter dressing undisturbed after surgery. Thirty two percent of patients were not counseled about signs of PD catheter infection and 23% were not instructed on avoiding constipation. Many (42%) patients reported having a suture at their exit site. Only 58% of patients had their catheter examined by their nephrologist prior to starting PD.

**Conclusions:** Our preliminary results suggest that recommended predialysis PD catheter- and exit-site practices are not followed consistently. Improved education and implementation of current guidelines is needed.

**Superior Survival Rate in Long-Duration PD Patients with Peritoneal Dialysis Fluids (PDFs) with Neutral pH and Low Glucose Degradation Product (GDP)** Hoon Young Choi, Yong Kyu Lee, Beom Seok Kim, Hyeong Cheon Park, Ho Yung Lee. *Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Long-term peritoneal dialysis has shown that peritoneal membrane performance and anatomy deteriorates with time of exposure to PDFs.

We carried out the retrospective cohort study comparing the long-term clinical impact of peritoneal dialysis (PD) treatment with either conventional PDFs or low GDP PDFs. On Dec. 31th 2009, the database included 1,257 individual PD patients' records. According to TR (treatment received) classification, PD patients were grouped either conventional PDFs (C-PDF group) or low GDP PDFs (L-GDP PDF group) in Korea single center. We investigated the demographic data, patient and technical survivals.

A total of 1,257 patients were included in this study (TR classification; C-PDF group= 573, L-GDP PDF group= 684). Age, sex, DM distribution were not significantly different between the two groups. L-GDP PDF group has longer PD duration than in C-PDF group (65.0 ± 56.4* vs. 58.1 ± 51.3 months, p<0.05).

The technical survival by Kaplan-Meir analysis was not different between the two groups. (Log rank; p=0.071). Patient-survival rate were significant higher in L-GDP PDF group than in C-PDF group (log rank; p=0.000).

Our data showed that the long-duration PD patients with low GDP PDFs treatment showed better patient-survival in Korea single center.

**Impact of Icodextrin on Residual Renal Function during 3 Years in Incident CAPD Patients** Jun-Young Do, Sun Young Jung, Kyu-Hyang Cho, Jong-Won Park, Kyung-Woo Yoon. *Internal Medicine, Yeungnam University Hospital, Daegu, Korea.*

Objectives: This study was designed to verify the impact of icodextrin solution on preservation of residual renal function in incident CAPD patients.

Methods: Among 301 incident CAPD patients during Apr. 2001 to Dec. 2006, 99 incident CAPD patients completed 36months protocol, prospectively. Residual renal function (RRF: mean of CCr and Curea), daily UFV, dialysate(D)-CA125, adequacy, 4.25% modified PET and clinical indices were measured at 1st, 6th,12th, 18th, 24th, 30th and 36th months. There used one solution among 4 PD solutions (2 low GDP: Physioneal and Balance, 2 high GDP:Dianeal and stay safe) through the 36 months and patients who changed PD solution were excluded. Icodextrin solution was used in 32 patients for volume control or improvement of quality of life. Sex, age, percent of diabetes were not significantly different between icodextrin and non-icodextrin groups. Pearson chi square analysis and independent T test were used to analyze the data.

Results: There were no significant differences of RRF, D/P4Cr and D/P1Na between icodextrin and non-icodextrin groups at the 1 month (5.08±6.68 vs. 4.03±2.27 ml/min, 0.70±0.16 vs. 0.69±0.09 and 0.87±0.16 vs. 0.88±0.11, p>0.05, respectively). At the 36 month, icodextrin group showed higher RRF (2.98±5.09 vs. 1.60±1.67 ml/mim, p<0.05) and higher D/P1Na (0.90±0.03 vs. 0.88±0.03, p<0.01) than non-icodextrin group but daily ultrafiltration volume was not significantly different.

In conclusion, Icodextrin group showed beneficial effect on preservation of RRF but not on preservation of aquaporin function.

**SA-PO2605**

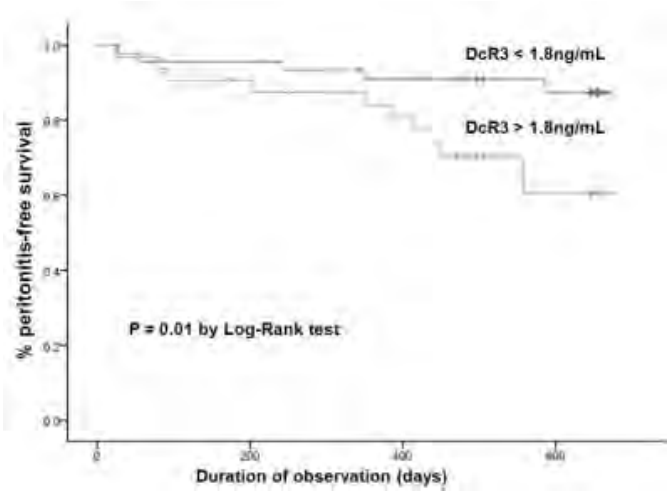
**Risk Factors of Peritoneal Dialysis (PD)-Related Peritonitis: A Novel Maker of Serum Decoy Receptor 3 (DcR3)** Yi-Sheng Lin,[1,2] Szu-Chun Hung,[3] Der-Cherng Tarng.[1,4] *[1]Department and Institute of Physiology, National Yang-Ming University; [2]Division of Nephrology, Taipei City Hospital; [3]Division of Nephrology, Buddhist Tzu Chi General Hospital; [4]Division of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.*

**Aim**

Peritonitis is a major complication in PD, which is associated with technique failure and mortality. Till now, the risk factors of PD-related peritonitis are inconsistent. DcR3 is a member of tumor necrosis factor receptor family with immunomodulatory effects. Elevated serum DcR3 was found in several chronic inflammation status such as malignancy and could be served as a predictor for survival. However, the role of DcR3 in predicting PD-related peritonitis remains unknown.

**Methods and Results**

Seventy-seven patients (38 male and 39 female; mean age 58 ± 13 years) undergoing PD (vintage 24.5 months) were recruited for this observational study. Serum DcR3 and C-reactive protein (hs-CRP) levels were measured at the beginning of the study. Forty-six (60 %) patients were diabetic. The mean follow-up duration was 499 ± 17 days. The peritonitis incidence rate was 0.17 episodes/patient-year. The baseline serum DcR3 level was 1.94 ± 1.23 ng/mL. We observed that age (>55 years), gender, diabetes mellitus, baseline serum albumin (>3.5 g/dL), and hs-CRP (>0.5 mg/dL) were not associated with PD-related peritonitis (all $p$> 0.05). Only patients with serum DcR3 level >1.8 ng/mL had higher peritonitis rate as compared to those with serum DcR3 level <1.8 ng/mL ($p$< 0.05). Kaplan-Meier survival analysis showed PD patients with serum DcR3 level >1.8 ng/mL had higher risk for peritonitis ($p$=0.01).



**Conclusion**

Serum DcR3 level is a potential predictor of peritonitis in chronic PD patients. DcR3 has been shown a surrogate of malnutrition-inflammatory complex in our previous studies. Its role in modulating immune competency in PD patients is highly speculative.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2606**

**Impact of Peritonitis on Ex-Vivo Phenotype of Human Peritoneal Mesothelial Cells (HPMCs) during 3 Years in Incident CAPD Patients** Jun-Young Do, Sun Young Jung, Kyu-Hyang Cho, Jong-Won Park, Kyung-Woo Yoon. *Internal Medicine, Yeungnam University Hospital, Daegu, Korea.*

Objectives: This study was designed to verify the impact of peritonitis on ex vivo phenotype of HPMC and the associating factors with higher epithelial to mesenchymal transition (EMT) in CAPD patients.

Methods: Among 301 incident CAPD patients during Apr. 2001 to Dec. 2006, 99 incident CAPD patients completed 36months protocol, prospectively. Effluent cell cultures, dialysate(D)-CA125, adequacy, 4.25% modified PET and clinical indices were measured at 1st, 6th,12th, 18th, 24th, 30th and 36th months. One solution among 4 PD solutions (2 low GDP: Physioneal and Balance, 2 high GDP:Dianeal and stay safe) was used through the 36 months and patients who changed PD solution were excluded. D-CA125 and HPMCs from overnight effluent were completely isolated and cultured on the T25 flask at 1st and every 6 months. Cell score was blindly measured by the same person at near confluence (score 1: cobble-stone shaped HPMCs, score 2: mixed, score 3: fibroblastoid cell). Incidence of peritonitis and levels of D-CA125 during 36 months were compared between Score 1(n=32) and score 3(n=22) groups at the 36 months. Pearson chi square analysis and independent T test were used to analyze the data.

Results: There were no significant differences of D/P 4Cr, D/P 1hr Na, ultrafiltration volume during PET, sex, age, diabetes between cell score 1 and score 3 groups. Cell score 1 (less EMT) group at the 36th month showed significantly higher D-CA125 level than cell score 3 group (32.16±29.77 vs. 15.65±9.51, 37.62±31.91 vs. 13.74±6.02, 36.48±24.84 vs. 13.87±8.29, 35.19±17.65 vs. 11.98±6.84, 36.00±25.69 vs. 14.30±11.21 and 34.02±26.57 vs. 11.89±7.43, p=0.009, p=0.000, p=0.029, p=0.000, p=0.029 and p=0.000 at 6th , 12th , 18th , 24th , 30th and 36th months). Incidence of peritonitis was not significantly different between cell score 1 and score 3 groups during 36 months (0.32±0.41/year vs. 0.38±0.45/year, p=n.s.).

In conclusion, Dialysate CA125 showed significant association with ex vivo phenotype of HPMC but usual incidence of peritonitis didn't show significant impact on EMT during 3 years.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2607**

**Dialysis Vintage and Number of Previous Episodes Are Risk Factors of Peritonitis – A Single Center Study** Mira Varagunam, Ananda Chapagain, Magdi Yaqoob, Stanley Fan. *Department of Translational Medicine and Therapeutics, William Harvey Research Institute, London, United Kingdom.*

Despite the technical improvements in PD (peritoneal dialysis ) systems peritonitis remains a major problem leading to catheter loss, technique failure , sepsis and mortality. Understanding risk factors of peritonitis which are modifiable as well as those factors which are not modifiable is an important aspect of clinical management.We investigated the risk factors associated with peritonitis in patients who initiated PD between 2003 and 2007 in our renal unit. Our primary outcome was to quantify the risk of peritonitis with time on dialysis using random effects Poisson regression with Lexis expansion which allows the rates to be determined in specific time periods after initiating dialysis . Secondary outcome was to identify other putative risk factors associated with peritonitis . Out of the 367 patients 208 (57%) had peritonitis episodes. 159 (43.3%) patients had 0 episodes, 138(37.6%) had 1 episode, 49 (13.4%) had 2 episodes 19 (5.2%) had 3 episodes and 2 (0.5%) had 4 episodes. The median(min, max) follow up time was 1.5(0.01,5.7) years. Table 1 shows the rate ratio comparing different time periods after inception with the base line of 0-2 years.

| Time bands | Absolute rate (episodes/ person year) | *RR(95% CI) | p value |
|---|---|---|---|
| 0-2 years (Reference) | 0.45 | 1 | |
| 2-4 years | 0.83 | 1.85 (1.29,2.67) | 0.001 |
| 4-6 years | 1.85 | 4.11 (1.72,9.8) | 0.001 |

* rate ratio

Age at start of dialysis, sex, diabetes as cause of end stage renal disease, race, season, starting modality (APD vs PD) ,adjusted for dialysis vintage did not show a significant association with peritonitis rate . An increase in episode of peritonitis (after adjusting for dialysis vintage) was associated with peritonitis rate in a linear manner, with an increase in peritonitis episode associated with a rate ratio (95%CI) 2.1 (1.77,2.52) p<0.001.

Both time on dialysis and number of previous episodes are significantly associated with peritonits rate, and this may have to be taken into account when making a clinical descion to switch to haemodialysis.

**SA-PO2608**

**Anuric Patients and Peritoneal Patients** Ricardo Vizinho, Patricia Quadros Branco, Maria Augusta Cabrita Silva Gaspar, Jose Diogo Barata. *Nephrology, Hospital Santa Cruz, Centro Hospitalar Lisboa Ocidental, Carnaxide, Lisboa, Portugal.*

Introduction: Anuric patients do not have the advantage of renal funtion preservation associated to Peritoneal Dialysis (PD) technique and so they do not benefit form its favorable impact on quality of life and survival.

Objective: To compare outcomes of baseline anuric Vs non-anuric PD patients, based on the experience of our center.

Methods: Retrospective analysis of data regarding 122 PD patients followed in our center, between 2002 and 2009, 48 of them under active treatment at the moment of data collection. Statistical analysis was done using SPSS version 16.0 and a p value < 0,5 was considered significant.

Results: The studied population had an average age of 59 years, 58% females, an average Body Mass Index (BMI) of 24.5, a mean Glomerular Filtration Rate (GFR) of 4.69ml/min, with 24% of anuric patients at baseline and 19% diabetic patients. Seventeen patients were on PD because they had no other option of dialysis (vascular access failure for hemodialysis).

There was no statistical significant difference between anuric and non-anuric patients regarding daily fluid-removal, type of transporters, kt/v, number of peritonitis or of in-stays for any cause, or time on DP.

When evaluating global mortality, adjusting for age, anury, peritonitis, in-stays and fluid-removal, diabetes was a positive predictor factor of mortality (HR=15, p=0.04).

In multivariate analysis, when adjusted for age, diabetes and time on DP and dialysis efficacy, anury was the only predictor of change to other dialysis modality (RR=2.6, p=0,035).

Conclusions: Based on our experience, although anury predicts transfer to hemodialysis, we found no difference regarding other major outcomes.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2609**

**How Renal Transplantation Induces Bias in Peritoneal Dialysis Survival Analysis** Jean-Baptiste Beuscart,[1,2] Dominique C. Pagniez,[2] Luc Frimat,[3] David Evans,[4] Celia Lessore,[2] Christian Verger,[4] Alain Duhamel.[1] *[1]Biostatisctics, EA2694, UDSL, Lille, France; [2]Nephrology, CHU Lille, France; [3]Nephrology, EA 4003, Nancy-Université, France; [4]RDPLF, Pontoise, France.*

Background: Survival analyses on dialysis usually do not exclude patients for whom renal transplantation (RT) is planned. Only these patients can access to RT, which may occur before death during PD is observed. This competition between death and RT can lead to biased estimations in the total population.

Patients and methods: (i) Single center cohort of 293 incident PD patients (1992-2007) (ii) Analysis verified on a cohort of 6650 PD patients from the Registre de Dialyse Peritoneale de Langue Francaise (RDPLF). We estimated cumulative incidences for death and RT, according to whether RT was planned or not. We explored risk factors for death and RT using the Cox proportional hazard model.

Results: (i) RT was planned for 114 (39%) patients, none of whom died. At 6 years, their estimated probability of RT was 69%. They were younger and had fewer comorbidities.

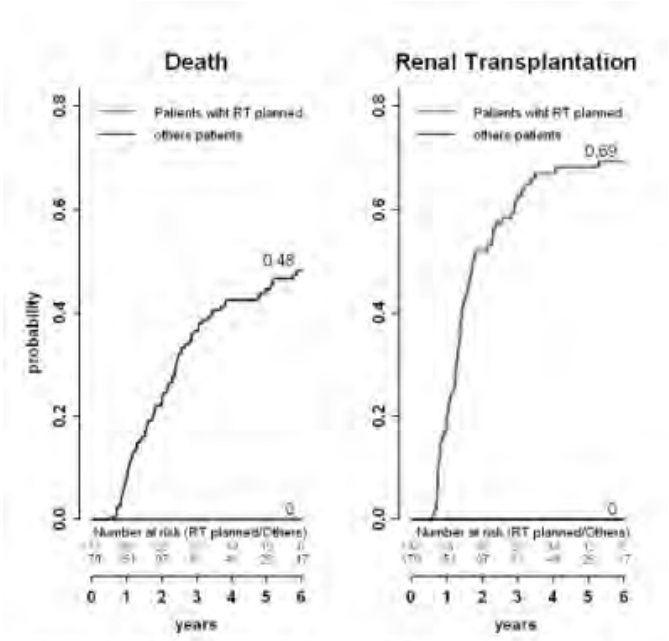

**Figure 1:** Cumulative incidences of death and renal transplantation (RT) during PD, according to whether RT was planned or not.

In the total population, older age, diabetes, low albumin, low residual renal function, and high CRP were significant risk factors for death and significant protective factors for RT. Therefore, the death hazard ratio could not be estimated independently of RT. (ii) The RDPLF data confirmed these results. RT was planned for 2205 (33%) patients. Their probability of death was estimated at 5% at four years, against 57% for the 4422 (67%) other patients. Age and diabetes were inversely related to death and RT.

Conclusion: Patients for whom RT is planned are much more likely to undergo renal transplantation than to die on PD. This competition between death and RT means that relative risks for death cannot be estimated independently of RT in the total population. PD survival analyzes should be stratified on inscription on RT waiting list.

**SA-PO2610**

**Characteristics of the CKD Patients Preferentially Directed to Pre-Emptive Renal Transplantation (Pre-RT) in the PREPARE Study** Bertrand Dussol,[1] Malik Touam,[2] Eric Daugas,[3] Paul Stroumza,[4] Yvon Berland,[1] Patrick Henri,[5] Georges J. Mourad.[6] *[1]Nephrology, Aix Marseille University, Marseille, France; [2]AURA, Cedh, Paris, France; [3]Nephrology, Hopital Bichat, Paris, France; [4]Diaverium, Clinique du Parc, Marseille, France; [5]Nephrology, Caen CHU, Caen, France; [6]Nephrology, Montpellier Medical School, Montpellier, France.*

The characteristics of the CKD patients preferentially directed by the nephrologists to pre-RT are not known. The aim of the PREPARE study was to describe the characteristics of stage 3 and 4 CKD patients, and the nephrologist's intention concerning type of ESRD treatment in case of evolution to stage 5. 1382 patients seen by their nephrologists during the first week of November 2009 were included in the study: a pre-RT was considered for 105 (7.5%), dialysis followed by RT (D-RT) for 317 (23%) and dialysis only (D) for 863 (62.5%). We compared the characteristics of pre-RT, D-RT, and D groups.

Table 1

| | pre-RT | D-RT | D | p |
|---|---|---|---|---|
| Age (years) | 50±13 | 50±13 | 74±10* | < 0.001 |
| Sex (male/female) % | 63/37 | 61/39 | 61/39 | ns |
| Nephrologic follow up (years) | 7.5±8 | 6.4±8 | 4.5±6 | ns |
| eGFR (ml/min) | 33±13 | 27±15* | 29±13* | <0.01 |
| HTA (%) | 80 | 88* | 87* | <0.05 |
| Diabetes mellitus (%) | 19 | 31* | 42* | <0.0001 |
| Other cardiovascular risk factors (%) | 12 | 13 | 19* | <0.05 |
| Cardiovascular complications (%) | 11 | 23* | 47* | <0.001 |
| Charlson score | 3.3±1 | 4.1±2* | 6.5±2* | <0.0001 |

*significantly different of pre-RT

This study showed that nephrologists in France envisaged pre-RT in a very small percentage of stage 3 and 4 CKD patients.This result explained that only 2.3% of the renal transplantations performed in France in 2008 were pre-emptive (Agence de la Biomedecine registry). Pre-RT patients were significantly younger, had higher eGFR, and had less cardiovascular risk factors and complications. French nephrologists are probably reluctant to give access to renal transplantation waiting list to some old and/or diabetic and/or patients with comorbidities, while it is known that pre-RT provides the best results and that duration of dialysis negatively impacts results of RT.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2611**

**Quality of Life (QoL) in the Oldest Dialysis Patients – Important Differences' between Hemodialysis (HD) and Peritoneal Dialysis (PD)?** Inger Laegreid,[1,2] Knut Aasarod,[1,2] Marit Jordhoy.[3] *[1]Department of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway; [2]Department of Nephrology, St. Olavs University Hospital, Trondheim, Norway; [3]Regional Center of Excellence in Palliative Care, Oslo University Hospital, Oslo, Norway.*

The elderly dialysis population is increasing, little is known about their QoL, and very few choose PD. **Aims**: was to describe and compare the QoL of the older Norwegian HD and PD population, and to explore whether the starting point of PD and HD differ(early vs late start).

**Method:** All patients > 75 years (n = 320) who according to the Norwegian Renal Registry (NRR) were in dialyses by 01.01.2009 and alive by Sept 2009 were asked to participate and mailed the QoL questionnaire SF 36. Medical data were collected from the NNR.

**Results**. In total, 230 pts (72%) responded, 152(66%) men and 78 (34%) women, 189 pts (82%) were in HD, 41 pts (18%) in PD. Mean age HD: 80.5 years, PD: 80.0 years. At start of dialysis, there was no significant difference in the distribution of comorbidities (diabetes mellitus type II, coronary and cerebrovascular diseases and malignancies), estimated glomerular filtration rate (eGFR, ml/min) (HD: 8.7; PD: 8.1) or the proportion of early start (eGFR > 10 ml/min), 27% in both groups. Preplanned start was more frequent among PD pts (86% vs73%) and duration of treatment was shorter (27 vs 38 months).

PD pts had lower blood pressure (mean 131/72 mm/Hg vs 143/71, annual report NNR 2008). Se-Albumin g/l (HD: 38.1, PD: 36.2) and BMI (kg/m²) (HD: 24.0, PD: 25.9) were comparable.

Table.1 SF 36 scores

| mean | HD | PD |
|---|---|---|
| Physical function | 42.0 | 38.3* |
| Role physical | 19.1 | 11.4* |
| Bodily pain | 56.7 | 60.6* |
| General health | 46.2 | 44.7* |
| Vitality | 40.2 | 35.4* |
| Social function | 61.4 | 69.7* |
| Role emotional | 43.5 | 39.0* |
| Mental health | 73.9 | 72.2* |

*p > 0.05 (Mann-Whitney U test)

Overall, the QoL scores were low, and there was no statistical or clinically significant difference between the two groups. In conclusion there are little differences between HD and PD pts in terms of QoL scores and basic characteristic. The findings may encourage a higher PD proportion in the elderly dialysis population.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2612**

**The Comparison of Incidence of Tuberculosis in Patients on Hemodialysis and Peritoneal Dialysis** Rumeyza Kazancioglu, Meltem Gursu, Savas Ozturk, Zeki Aydin, Sami Uzun, Serhat Karadag, Emel Tatli. *Nephrology, Haseki Training and Research Hospital, Istanbul, Turkey.*

**INTRODUCTION:** The increased incidence of tuberculosis in dialysis population has been shown by many studies. Tuberculosis has different clinical presentation, laboratory findings and drug side effects in this population. We aimed to compare tuberculosis incidence in hemodialysis(HD) and peritoneal dialysis(PD) patients.

**METHODS:** Patients who were on HD or PD treatment in our city for more than 3 months were included. Among the screened population; those who had tuberculosis during the dialysis period have been selected and divided into 2 groups according to dialysis modality: HD group and PD group. Their demographic and clinical data were recorded. Data were analyzed using SPSS ver 13.0.

**RESULTS:** 935 HD patients from 7 centers and 322 PD patients from 5 centers were screened. Thirty one patient in the HD group (3.35%); and 4 patients in the PD group (%1.24) were found to have diagnosis of tuberculosis during their dialysis treatment. The incidence of tuberculosis was statistically significantly higher in HD group [risk ratio:1.63; confidence interval: 95% (1.23-2.16)]. Patients in HD group were older (52.3±13.5 versus 26.7±5.9 years, p=0.001). Male/female ratio in HD and PD groups were 18/13 and 3/1, respectively. The time periods between the start of dialysis and the diagnosis of tuberculosis in HD and PD groups were 21.7±25.7 and 10.2±8.1 months, respectively (p=0.67). Extra pulmonary involvement in the groups was similar (48% in HD and 50% in PD group). One patient died due to tuberculosis in each group. But 12 patients in HD group and 1 patient in PD group were continuing their treatment at the time of analysis.

**DISCUSSION:** Tuberculosis was more frequent in HD group in the population we screened. This may be related with the fact that patients who prefer PD in our country are younger, have higher socioeconomic level and less co-morbidities in our country. Another factor may be related with less change in immunity against tuberculosis in PD population. These findings favor PD in terms of risk of tuberculosis.

**SA-PO2613**

**Evaluation of the Utility of beta2-Microglobulin Adsorbent Column (Lixelle) for Dialyasis-Related Amyloidosis** Yuichiro Yamamoto,[1] Gen Yasuda,[1] Nobuhito Hirawa,[1] Satoshi Umemura.[2] *[1]Kidney Internal Medicine, Yokohama City University Medical Center, Yokohama, Kanagawa, Japan; [2]Kidney / Hypertensive Internal Medicine, Yokohama City University Hospital, Yokohama, Kanagawa, Japan.*

***Background.*** Dialysis-related amyloidosis (DRA) is one of major complication often seen in long-term dialysis patients,and is a factor decrease quality of life(QOL). Beta2-microglobulin (β2-m) is considered a major pathogenic factor in DRA . Lixelle column has been developed to absorb circulating β2-m ,and that various type of capacity column has been developed . Using minimum capacity of β2-m absorbing column :Lixelle Type S-15, we evaluated the utility and safety of column for patients of DRA. ***Methods.*** Seventeen hemodialysis patients with DRA were treated with Lixelle column for 1 year. Lixelle S-15 were used every haemodialysis . During the study period, pinch strength, visual analog scale , and activities of daily living were evaluated every three months,and collected blood sample every six months. ***Results.*** After 1-year treatment with Lixelle column, the β2-m level decreased 29.3 ± 9.6mg/L to 24.7 ± 5.1mg/L ($P < 0.05$),and the high sensitive c-reactive protein (hs-CRP) level decreased from 2996 ± 4380ng/ml to 1292 ± 1774ng/ml . After 1 year of Lixelle column use, the pinch strength increased from 5.9 ± 3.0 pounds to 7.2 ± 3.2 pounds ($P < 0.05$),and the visual analog scale and the activities of daily living score was also significantly improved. ***Conclusion.*** Long term use of Lixelle S-15 is effective for improvement of quality of life on dialysis patients with DRA , and is possible to improve the prognosis of them by suppressing chronic inflammation.

**SA-PO2614**

**Impact of Changes in Predictors of Mortality during the First Year of Peritoneal Dialysis on Long-Term Patient Survival** Sung Hee Chung,[1,2] Jin Seok Jeon,[1] Soon Hyo Kwon,[1] Bengt Lindholm,[2] Dong-Cheol Han.[1] *[1]Hyonam Kidney Laboratory, Soon Chung Hyang University, Seoul, Korea; [2]Baxter Novum and Renal Medicine, Karolinska Institutet, Stockholm, Sweden.*

**Background**: We hypothesized that factors influencing patient survival and thus the predictive power of risk factors may change during the course of treatment with peritoneal dialysis (PD).

**Aim:** To evaluate impact of changes in predictors of mortality during the first year of PD on long-term patient survival after the first year, 148 PD patients (85 males, mean age 55±13 years) who underwent two assessments of nutritional status, residual renal function (RRF), dialysis adequacy, and peritoneal transport characteristics at a mean of 0.3 months and 11.5 months were included. After the second assessment patients were followed for 37 ± 25 months (range 7 - 115 months).

**Results**: At start of PD, patients who died during the follow-up period (Group D, n=43) were older and had higher prevalence of cardiovascular disease (CVD) and protein-energy wasting (PEW), higher fasting blood glucose (FBS), and lower serum creatinine (SCr) compared to patients who survived. At reassessment, Group D had higher prevalence of PEW, higher FBS, and lower serum albumin (SAlb), normalized protein equivalent of total nitrogen appearance, and RRF. During the first year of PD, SAlb and RRF decreased significantly and SCr increased significantly in Group D. On Cox proportional hazards multivariate analysis, independent predictors of mortality were based on initial assessment age (RR =1.06), CVD (RR =2.68), PEW (RR=2.16), and FBS (RR=1.04) and based on 1-year assessment age (RR =1.06), CVD (RR =2.93), SAlb (RR=0.26), and RRF (RR=0.79). Initial FBS correlated with initial SAlb (rho=-0.21), 1-year SAlb (rho=-0.16), and change in dialysate to plasma creatinine concentration ratio (rho=0.19).

**Conclusions.** This study demonstrates that in a selected group of PD patients who had been on PD more than 7 months, the predictive power of risk factors of mortality is changed during the initial treatment period, underlying the importance of repeating the analysis of risk factors during the course of treatment on PD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2615**

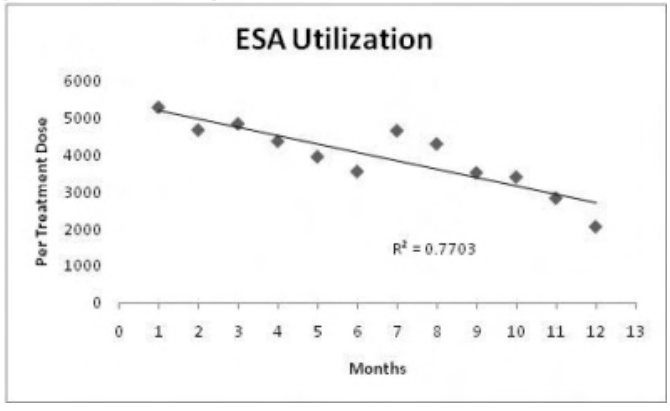
**A Nocturnal In-Center Hemodialysis Pilot Program – Logistic Issues and Improved Clinical Outcomes** Sheila Doss, Brigitte Schiller, Donna Lemus. *Satellite Healthcare, Mountain View, CA.*

A pilot in-center nocturnal hemodialysis (HD) program to evaluate the logistics and feasibility for alternative extended hour therapy was started in Jan 2009. A total of 21 patients were enrolled, providing 247 patient months of experience. Two patients died (1 withdrawal, 1 cardiac) and one transferred to home HD. Thrice weekly 8 hour overnight HD was offered to patients on conventional HD. Recruitment was easily achieved via meetings explaining to interested patients and families the purpose of the pilot. Reasons to switch to nocturnal were not doing well on current therapy (12/21), physician initiated (2/21), excess fluid gains (1/21), benefits of longer dialysis (4/21), employment (1/21), and 1 transfer from another nocturnal program.

The major operational issue was recruiting and retaining the RN staff for nocturnal schedule.

Clinical outcome measures improved during 12 months of nocturnal HD with 97% albumin ≥ 3.5 g/dL compared to 86% in the previous 12 months. 62% of phosphate values ≤ 5.5 mg/dL were reached on nocturnal compared to 46% prior on conventional HD. Mean

std Kt/V during the 12 months prior to starting nocturnal was 2.5 ± 0.4 and increased to 2.8 ± 0.3 on nocturnal HD. While maintaining Hb levels (pre-nocturnal 11.8 ± 1.2; nocturnal 12.3 ± 1.5g/dL) ESA utilization decreased over time reaching a 62% lower epogen dose per treatment by month 12 (p = 0.0002).



Quality of life assessment by KDQOL-SF36 at six months compared to baseline (n = 14) showed improvements in energy/fatigue (p = 0.04), effect of kidney disease (p = 0.05) and patient satisfaction with delivery of ESRD care (n = 0.009).

Patients on in-center nocturnal HD experience significant improvement in QOL. Challenges in implementation of nocturnal programs as part of routine ESRD care are outweighed by improved outcomes including decreased drug utilization.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2616

**Revalidation of the Kidney Disease Quality of Life Questionnaire (KDQOL)** Tracy Jack Mayne,[1] Duane V. Dunn,[1] Gilbert Marlowe,[1] Dorian R. Schatell.[2] *[1]DaVita Inc., Denver, CO; [2]MEI, Madison, WI.*

**Background** The Medicare Conditions of Coverage mandate the annual administration of the Kidney Disease Quality of Life questionnaire (KDQOL). The KDQOL was validated on 165 patients in 1997 and requires revalidation in a larger, more contemporary sample.

**Method** 19,337 KDQOLs were administered to dialysis patients between 1/08 and 12/09. We ran a confirmatory factor analyses and internal reliability on each subscale (SF-12; Kidney Disease Burden; Kidney Disease Symptoms; and Kidney Disease Effects).

**Results** *Burden* items produced a single factor explaining 69% of the variance, with good internal consistency, but floor & ceiling effects. *Symptoms* items produced two factors, but the second factor included only itchy/dry skin items, and the drop of in Eigen values occurred after the first factor. The parsimonious interpretation is a single factor explaining 27% of the variance, with good internal consistency, but ceiling effects. *Effect* items produced a single factor explaining 48% of the variance, with good internal consistency, but ceiling effects. A forced 2-factor solution of the SF-12 produced the expected *Physical* and *Mental Component* factors, explaining 28% and 25% of the variance respectively, with no floor/ceiling effects. However, internal consistency was low, and Cronbach's alfa improved appreciably with the removal of items.

| | SF-12 | | Kidney Disease | | |
|---|---|---|---|---|---|
| | Factor 1 Physical | Factor 2 Mental | Factor 1 Burden | Factor 1 Symptoms | Factor 1 Effect |
| Number of items | 12 | 12 | 4 | 12 | 8 |
| Eigen value | 4.93 | 1.41 | 2.77 | 4.11 | 3.81 |
| Variance explained | 28% | 25% | 69% | 27% | 48% |
| Cronbach's alpha | 0.60 | 0.57 | 0.85 | 0.82 | 0.84 |
| Item-total correlation range | -0.21 to 0.59 | -0.21 to 0.55 | 0.57 to 0.74 | 0.30 to 0.60 | 0.44 to 0.67 |
| Floor/Ceiling effects | No | No | F&C | C | C |

**Conclusion** The KDQOL, now mandated for annual collection by CMS, will become the *de facto* measure for tracking dialysis patient QOL in the US. Pre/post bundle comparisons are inevitable. The KDQOL does not adequately assess patients with very high dialysis Symptoms, Burdens & Effects, and thus may not detect if these measures worsen over time.

Disclosure of Financial Relationships: Employer: DaVita, Inc.; Honoraria: Sanofi-Aventis.

## SA-PO2617

**Subgroup Norms for the Kidney Disease Quality of Life Questionnaire in US Dialysis Patients** Duane V. Dunn,[1] Gilbert Marlowe,[1] Dorian R. Schatell,[2] Tracy Jack Mayne.[1] *[1]DaVita Inc., Denver, CO; [2]MEI, Madison, WI.*

**Background** CMS mandates annual administration of the KDQOL to US dialysis patients. Measuring norms before & after implementation of the new bundled payment system will allow us to assess its impact on patients.

**Method** 19,337 dialysis patients completed KDQOLs from 1/08 to 12/09. ANOVAs tested differences between groups by Gender; Race/Ethnicity; Age; Dialysis Vintage.

**Results**

| | SF-12 M±SD | | Kidney Disease M±SD | | |
|---|---|---|---|---|---|
| | *Physical* | *Mental* | *Burden* | *Symptoms* | *Effect* |
| GENDER | | | | | |

| >20 years (1604) | 37.3±10.5 | 48.9±10.4 | 49.9±28.6 | 75.9±16.1 | 68.0±21.7 |
| Missing (2861) | 36.3±10.2 | 49.0±11.0 | 47.9±29.3 | 75.2±16.2 | 67.1±22.6 |

**Conclusion** There were statistically significant, but few clinically meaningful differences across groups. These norms establish the pre-bundling baseline on dialysis patient QOL.

Disclosure of Financial Relationships: Employer: DaVita, Inc.

## SA-PO2618

**Clinical Guidelines and Quality of Life in Hemodialysis Patients: A Wake-Up Call** Albert H. Mazairac,[1] G. Ardine De Wit,[2] E. Lars Penne,[1,3] Neelke C. Van Der Weerd,[1,3] Claire H. Den Hoedt,[1,4] Muriel Grooteman,[3] Marinus A. Van Den Dorpel,[4] Pieter M. Ter Wee,[3] Michiel Bots,[2] Peter J. Blankestijn.[1] *[1]UMCU, Utrecht, Netherlands; [2]JULIUS, Utrecht, Netherlands; [3]VUmc, Amsterdam, Netherlands; [4]Maasstad Hospital, Rotterdam.*

**Background:** The quality of life (QOL) of hemodialysis patients is poor. The development of clinical practice guidelines in dialysis care is based on various outcomes. However, it is unclear if achievement of treatment goals is related to an improved QOL.

**Aim:** To assess the relation between recommended treatment goals and QOL in hemodialysis patients.

**Methods:** We analyzed the baseline data of 697 hemodialysis patients (mean age 64 ±14 years [±SD], 63% male) of the ongoing CONvective TRAnsport Study (CONTRAST). Five clinical target levels as recommended by the Kidney Disease Quality Outcomes Initiative (KDOQI) were evaluated: spKtV (≥1.2), hemoglobin (11 to 13 g/dL), vascular access (AV fistula), phosphate (2.3 to 4.5 mg/dL) and blood pressure (<130/80 mm Hg). QOL was measured with the KDQOL-SF, a questionnaire that provides a physical (PCS) and mental (MCS) composite score as well as 12 kidney disease-specific QOL domains. We applied linear or logistic regression models and adjusted for confounders that caused ≥5% change to the crude relation.

**Results:** After adjustments for confounding, none of the target levels achieved related with the PCS or MCS. With regard to disease-specific QOL: patients with optimal phosphate levels reported a preferable effect of their kidney disease on daily life (OR: 1.50; 95% CI 1.07 - 2.10; $p<0.05$) and an enhanced quality of social interaction (OR: 1.53; 1.09 - 2.14; $p<0.05$). The domain burden of kidney disease was improved when hemoglobin target levels were met (OR: 1.36; 1.00 - 1.86, $p<0.05$). Patient satisfaction was better if blood pressure was as recommended (OR: 1.64; 1.08 - 2.47; $p<0.05$).

**Conclusion:** Overall, the achievement of the assessed clinical guidelines, which are generally based on level B/C evidence, only show a limited relation with the quality of life of hemodialysis patients. An effort should be made to provide evidence for further incorporation of perceived health status in guidelines.

## SA-PO2619

**Factors Correlated with Time Taken To Recover from a Hemodialysis (HD) Session** Usama T. Hussein, Kwabena T. Awuah, Radu R. Raducu, Fredric O. Finkelstein. *Nephrology Department, Saint Raphael Hospital, New Haven, CT.*

**INTRODUCTION**: Patients with end stage renal disease (ESRD) on HD have impairment of health related quality of life (HRQOL). This impairment is associated with various symptoms after HD treatments that impair patients' ability to resume normal activities after each session. Patients on short daily (SD) or long nocturnal dialysis (ND) have a shorter time to recovery (TTR) than those maintained on conventional hemodialysis (CHD). This shortened TTR is associated with improved HRQOL measures. The present study was undertaken to assess the TTR and clinical factors related to it in a large cohort of HD patients.

**METHODS:** All patients on CHD and ND in our 4 HD units were invited to participate. Patients were asked how long it took them to recover from their previous session for 3 consecutive treatments; data on age, gender, duration on renal replacement therapy(RRT), co-morbidities, BP during hemodialysis, time spent on HD and amount of ultra filtration(UF) were assessed from corresponding records. The mean value of the three sessions was used for analysis. 12 patients on ND and 263 on CHD participated.

**RESULTS:** The mean age was 66.7(+/- 15.69) for CHD group and 42.1(+/- 14.42) for the ND group. Mean number of co-morbidities for the two groups were 1.4(+/- 0.88) for CHD and 0.67(+/- 0.65) for ND. The mean duration on RRT was 40.2(+/- 37.78) and 49.67(+/- 35.28) months for CHD and ND respectively.A multivariate regression analysis including age, gender, number of co-morbidities, duration on RRT, occurrence of hypotension during dialysis, amount of UF and time spent on HD per session revealed that none of these covariates was significantly associated with TTR from HD. Importantly, there was no correlation between TTR and UF volume There was a difference in the TTR between ND (100 +/-162minutes) and CHD group (246+/-450minutes) p=0.0464.

**CONCLUSION:** In this cohort of HD patients, there was no correlation between TTR after HD session and studied covariates . This information is important as we assess the impact of new HD treatments on TTR and HRQOL. The difference in TTR between ND and CHD groups noted by earlier studies was confirmed.

## SA-PO2620

**Associations of Fluid and Dietary Restrictions with Mental Components of Quality of Life and Sociodemographic Characteristics in Patients on Maintenance Hemodialysis** Antonio Alberto Lopes,[1,2] Luciana Ferreira Silva,[1] Lidiane Dias Ribeiro,[1] Lívia Santana Oliveira,[1] Gildete Barreto Lopes.[1] *[1]Faculdade de Medicina da Universidade Federal da Bahia (UFBA); [2]Núcleo de Epidemiologia Clínica do Hospital Universitário Professor Edgard Santos, UFBA, Salvador, BA, Brazil.*

Purpose. We investigated whether the degree that maintenance hemodialysis (MHD) patients reported being bothered by fluid or dietary restriction was associated with mental components of health-related quality of life (HRQOL) and sociodemographic factors.

Methods. Cross-section of data of 1107 patients from PROHEMO Study developed in Salvador, Brazil. Patients were asked about the extent that they were bothered by fluid and dietary restrictions. SF-36 was used to assess HRQOL components: general health, vitality, social functioning, emotional well-being and role emotional. Logistic regression was used to identify characteristics associated with the bother of fluid or dietary restrictions. The assessed characteristics were age, gender, education, race and living status. Linear regression was used for assessing associations of HRQOL with being bothered by fluid and by dietary restrictions. The models were adjusted for sociodemographics, vintage, dialysis by catheter, albumin, creatinine, hemoglobin, Kt/V, diabetes, heart failure, cerebrovascular and peripheral vascular disease.

Results. Significantly (P<0.05) higher adjusted odds of being moderately to extremely bothered by fluid restriction were observed for women (adjusted odds ratio(AOR)=1.40) and those not living with family(AOR=1.72). Compared to patients aged ≥60 yr, those aged 18-39 yr showed higher odds of being bothered by fluid(AOR=2.18) and dietary restrictions(AOR=1.91). Patients moderately to extremely bothered by fluid or dietary restriction had significantly(P<0.001) lower adjusted scores for all assessed mental HRQOL scales, with differences >7 points.

Conclusion. The results are consistent with an important role of the burden of fluid and dietary restrictions in reducing the mental HRQOL of MHD patients. The burden related to these restrictions is apparently greater for younger patients, women and those not living with family.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2621

**The Influence of Sleep Quality, Depression and the Bother of Dry Skin on the Association between Pruritus Severity and the Burden of Chronic Hemodialysis Treatment** Gildete Barreto Lopes,[1] Gabriel Schnitman,[1] Lidiane Dias Ribeiro,[1] Dandara Reis Silva,[1] Antonio Alberto Lopes.[1,2] *[1]Núcleo de Epidemiologia Clínica do Hospital Universitário Professor Edgard Santos, Universidade Federal da Bahia (UFBA); [2]Faculdade de Medicina, UFBA, Salvador, BA, Brazil.*

Purpose: The main objective of the study was to assess whether severe pruritus is associated with greater perceived burden of kidney disease in maintenance hemodialysis patients without and with adjustments for sleep quality, depression symptoms and the bother of dry skin.

Methods: Cross section of baseline data of 980 patients enrolled in the Prospective Study of the Prognosis of Chronic Hemodialysis Patients (PROHEMO), a prospective study developed at dialysis units in Salvador, Brazil. The Kidney Disease Quality of Life Short Form was used to determine scores (range: 0 to 100) of the burden of kidney disease and sleep quality with higher scores indicating less burden of kidney disease and better sleep quality, respectively. The Center for Epidemiological Studies Depression Index was used to determine scores of depression symptoms (range: 0 to 60) with higher scores indicating higher depression symptoms.

Results: Mean age of the patients was 48.8±14.2 years; 58.7% were represented by men. The prevalence of severe pruritus (very much or extreme) was 19.4%. Lower score of the burden of kidney disease was observed for patients with severe pruritus than for those with no or mild pruritus (difference=11.44, P<0.001). Severe pruritus was also significantly associated with lower sleep score, higher odds of reporting being bothered by dry skin and higher score of depression symptoms. The difference in the burden of kidney disease by degree of pruritus was virtually unchanged after adjustments for demographics and comorbidities. By contrast, the differences was almost totally eliminated after adjustment for sleep score, depression score and the bother of dry skin (difference=0.89, P=0.719).

Conclusions: The results indicate that the higher burden of chronic hemodialysis treatment in patients with severe pruritus is almost entirely explained by poorer sleep quality, higher level of depression symptoms and the bother of dry skin.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2622

**Prevalence and Correlates of Depression Symptoms in Haemodialysis Patients: A Multinational Cross-Sectional Study** Valeria Maria Saglimbene,[1] Giorgia De Berardis,[1] Fabio Pellegrini,[1] David W. Johnson,[2] Jonathan C. Craig,[3] Jorgen B. A. Hegbrant,[4] Giovanni F. M. Strippoli.[1,3,4] *[1]Mario Negri Sud Consortium; [2]University of Queensland; [3]University of Sydney; [4]Diaverum Medical Scientific Office.*

Depression is common but underrecognized in people on hemodialysis. Existing studies found variable prevalence and conflicting data on correlates/predictors. In this multinational cross-sectional study, we enrolled people receiving hemodialysis in 27 outpatient clinics selected randomly from a collaborative dialysis network. Depressive symptoms were evaluated with the Center for Epidemiological Studies Depression (CES-D) Scale. Depression was considered a CES-D score>=18. Multivariable logistic regression was used to determine correlates of depression adjusting for clinical and sociodemographic characteristics.

Of 2920 haemodialysis patients in the participating clinics, 2180 (75%) completed the CES-D questionnaire. Overall, 1092 (50%) respondents reported depressive symptoms. Depressive symptoms were correlated with female gender (AOR 1.55, 95% CI 1.28 to 1.88), alcohol abuse (AOR 2.82, 95% CI 1.32 to 6.03), previous cardiovascular events (AOR 1.32, 95% CI 1.07 to 1.64) and sexual dysfunction (AOR 2.11, 95% CI 1.36 to 2.12). Education >5 years and daily physical activity were protective factors for depression (AOR 0.38, 95% CI 0.24 to 0.62 and AOR 0.58, 95% CI 0.44 to 0.76 respectively). Managing physicians had diagnosed depression in only 109 (10%) patients compared with 1092 (50%) actually reporting CES-D scores ≥18. Only 89 (8%) received treatment for their depressive symptoms.

In conclusion, we found depressive symptoms in 50% of the study population. Potentially modifiable risk factors include physical activity, identification and treatment of sexual dysfunction. We contend that assessment of depressive symptoms should be incorporated in clinical practice and intervention studies for this condition should be designed and conducted.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2623

**Musculoskeletal Disease Severity and Outcome in the HEMO Study** Heather L. Bujnicki, Jennifer M. Harness, Thomas I. Phelps, Phillip R. Rozak, Jane S. Tschang, Raymond J. Vergona, Mark L. Unruh. *University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Both hemodialysis and musculoskeletal (MSC) disorders significantly affect quality of life. Chronic hemodialysis is associated with decreased bone density and muscle mass which may predispose to more MSC. The relationship between severity of MSC disease and outcomes among patients on dialysis is uncertain.

Methods: We undertook a secondary data analysis of the HEMO study, a randomized clinical trial in which 1846 patients underwent thrice-weekly dialysis. The data collected from this study was analyzed and correlations between MSC scores and demographic, socioeconomic, clinical, and laboratory variables were identified. MSC scores in the HEMO study were separated into four classes; no musculoskeletal or connective disease diagnosis (0), disease diagnosis with mild distress (1), moderate disease progression requiring medication (2), and severe, incapacitating, uncontrolled pain (3). For data analysis, moderate (2) and severe (3) classes were combined.

Results: Of the 1,846 study participants, 1,037 (56%) had a musculoskeletal score of 0 (none), and 430 (23%) had a score of 1 (mild), while 379 (21%) had a score of 2(moderate-severe). Age (OR = 1.02, 95% CI = 1.01-1.03), increasing duration of dialysis (OR = 1.13, 95% CI = 1.10-1.15), and diabetes (OR = 1.44, 95% CI = 1.18-1.76) were independently associated with increasing severity of musculoskeletal scores after accounting for key demographic and clinical covariates. Increasing severity of musculoskeletal scores were found to be associated with several quality of life measures including physical function ($p < 0.0001$), bodily pain ($p < 0.0001$), and physical component score ($p < 0.0001$). Increasing severity of MSC scores were not found to be significantly associated with survival.

Conclusion: Although musculoskeletal disease severity was not significantly associated with survival, increased severity of disease was associated with key quality of life measures. Further investigations could focus on the association between musculoskeletal functioning such as ambulation and falls on quality of life and survival.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2624**

**Self-Reported Physical Functioning in Maintenance Hemodialysis Patients Is Unrelated to Cognitive Performance** Brian T. Agganis,[1] Daniel E. Weiner,[1] Lena M. Giang,[1] Hocine Tighiouart,[2] Tammy Scott,[3] Mark J. Sarnak.[1] *[1]Nephrology, Tufts Medical Center, Boston, MA; [2]Biostatistics Research Center, Tufts Medical Center, Boston, MA; [3]Psychiatry, Tufts Medical Center, Boston, MA.*

Prior research highlights physical activity as a possible moderator of cognitive decline in the general population. As part of the ongoing Cognition and Dialysis Study, we evaluated the association between physical functioning and cognitive performance in maintenance hemodialysis patients.

The Short Form Health Survey (SF-36) is a self-reported health questionnaire commonly used to evaluate disease burden in individuals and across populations. The SF-36's Physical Component Score (PCS) provides a global measure of physical functioning derived from questions related to general health, bodily pain, daily activities, and physical performance. Study participants with SF-36 questionnaires administered as part of their routine care within 3 months of cognitive testing were included in this analysis. Linear regression was used to evaluate the association between PCS and cognitive test performance in unadjusted and adjusted analyses.

195 participants met the inclusion criteria. Mean age was 65 years, 49% were female, 22% African American, 52% had diabetes, and 35% had coronary disease. The mean (SD) PCS score was 37 (10). In univariate analysis, individuals with higher PCS performed better on Digit Symbol Coding although this finding was not consistent across other measures of executive function and did not remain significant after multivariable analysis (Table). PCS was unrelated to cognitive performance in all other tests of cognitive function.

We found no significant or consistent relationship between self-reported physical functioning and cognitive performance in hemodialysis patients.

| Cognitive Test | Function Tested | Unadjusted Estimate per 1 SD increase in PCS , p-value | Adjusted Estimate per 1 SD increase in PCS, p-value |
|---|---|---|---|
| Mini Mental State Exam | Screen | 0.11, 0.398 | 0.16, 0.413 |
| Verbal Intelligence | Intelligence | -1.67, 0.053 | -1.08, 0.181 |
| WMS-III Short Delay | Primary Cortical (Memory) | 0.19, 0.397 | 0.13, 0.523 |
| WMS-III Delayed Recall | | 0.17, 0.407 | 0.04, 0.841 |
| WMS-III Retention | | 2.89, 0.165 | 1.25, 0.384 |
| WAIS-III Recognition | | 0.32, 0.156 | 0.21, 0.314 |
| WAIS-III Block Design | Primarily Subcortical (Executive function and processing speed) | 0.35, 0.642 | 0.35, 0.611 |
| WAIS-III Digit Symbol Coding | | 4.15, 0.001 | 2.02, 0.056 |
| Trails A | | -3.27, 0.239 | 0.95, 0.731 |
| Trails B* | | -14.10, 0.073 | -0.85, 0.900 |

All tests represent scores/tasks completed except Trails A and B which are time required to complete a task. Positive values correspond with better test performance for all tasks except Trails A and B. Multivariable adjustments included age, sex, race, and education. *Trails B analyses were performed using Tobit regression to account for failure to complete the task within 5 minutes.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2625**

**Association of Frailty with Muscle Size among Dialysis Patients and Sedentary Control Subjects** Cynthia Delgado,[1] Julie W. Doyle,[1] Kirsten L. Johansen.[1,2] *[1]Nephrology, UCSF, San Francisco, CA; [2]Nephrology, SFVAMC, San Francisco, CA.*

Frailty is a physiological syndrome characterized by decreased reserve and diminished resistance to stressors. Frailty has been independently linked to decreased survival in several large cohort studies, including studies of patients with chronic kidney disease (CKD). The prevalence of frailty in the CKD population is quite high – estimated to be 21% based on NHANES data. The purpose of the study was to determine the extent to which frailty is linked to measured muscle size and function in patients with ESRD and controls using baseline data from patients enrolled in an interventional study.

Methods: Eighty patients undergoing hemodialysis for > 3 months were included in the study if there was evidence of malnutrition or poor quality of life assessed by questionnaire. 20 age matched control subjects were not on dialysis. Electromyography action potentials of the anterior tibialis muscle were recorded using a surface electrode. Cross-sectional area of the contractile tissue of the muscle was measured using MRI . Frailty was defined based on questionnaire measures of physical functioning, exhaustion, and physical activity as has been previously described. These included SF-36 physical function score < 75 (2 points), SF-36 Vitality score < 55 (1 point), and the lowest quartile of weekly kcal energy expenditure on leisure activity calculated from the Physical Activity Scale for the Elderly (PASE) questionnaire. A frailty score of ≥ 3 was defined as frail.

Results: 48 subjects had EMG and muscle CSA data available for analysis. The majority of subjects were male (64%) with mean age 55 (± 13 yrs). 54% of participants were African American, 12% were Caucasian and 25% Asian. 14% of control subjects met frailty criteria compared to 61% of those on dialysis (p<0.0001). In multivariate analysis, frailty was associated with decreased muscle area even after adjustment for age and sex (coef -0.64, p<0.03)

Conclusion: Frailty as defined by the Woods criteria is associated with muscle atrophy, providing important validation of the syndrome as reflective of sarcopenia.

**Blood Pressure and Cognitive Function in Dialysis Patients** Lena M. Giang, Daniel E. Weiner, Hocine Tighiouart, Brian T. Agganis, Tammy Scott, Mark J. Sarnak. *Nephrology, Tufts Medical Center, Boston, MA.*

There are few data on the relationship of blood pressure and cognitive function in chronic dialysis patients.

The Cognition and Dialysis Study is an ongoing investigation of cognitive function and its risk factors in 5 Boston area DCI units. In this analysis we evaluated the relationship of different domains of cognitive function to systolic and diastolic blood pressure as well as pulse pressure in univariate and multivariable linear regression models adjusted for age, sex, race and education.

Among 273 participants with complete data, mean age was 63 years; 47% were female, 22% African American and 48% had diabetes. Mean (SD) of pulse pressure, systolic blood pressure and diastolic blood pressure were 69 (14) and 143 (21), and 73 (12) mm Hg, respectively. In univariate analyses, the performance on cognitive tests assessing memory, executive function and processing speeds was worse among participants with higher pulse pressure and higher diastolic blood pressure (data not shown).

| Cognitive Test | Function Tested | Unadjusted Estimate Per 1 SD increase in Pulse Pressure, p-value | Adjusted Estimate Per 1 SD increase in Pulse Pressure, p-value |
|---|---|---|---|
| Mini Mental State Exam | Screen | -0.30, 0.089 | -0.11, 0.518 |
| Verbal Intelligence | Intelligence | 0.36, 0.621 | -0.34, 0.624 |
| WMS-III Short Delay | Primary Cortical (Memory) | -0.46, 0.009 | -0.13, 0.295 |
| WMS-III Delay Recall | | -0.23, 0.058 | -0.07, 0.687 |
| WMS-III Retention | | -1.35, 0.425 | 0.57, 0.744 |
| WMS-III Recognition | | -0.43, 0.018 | -0.19, 0.279 |
| WAIS-III Block Design | Primarily Subcortical (Executive function and processing speed) | -1.38, 0.035 | -0.04, 0.941 |
| WAIS-III Symbol Coding | | -3.16, 0.004 | -0.58, 0.521 |
| Trails A | | 5.14, 0.029 | 1.08, 0.639 |
| Trails B* | | 15.73, 0.025 | 0.62, 0.229 |

All tests represent scores/tasks completed except Trails A and B which are time required to complete a task. Positive estimates are consistent with improved performance except for Trials A and B.
*Trails B analyses were performed using Tobit regression to account for failure to complete the task within 5 minutes.

These relationships however were not significant after multivariable adjustment. There was no association between cognitive function and systolic blood pressure in either univariate or multivariable analysis.

We found no association between blood pressure and cognitive function in this cross sectional analysis. These results need to be reproduced in longitudinal studies.

Disclosure of Financial Relationships: nothing to disclose

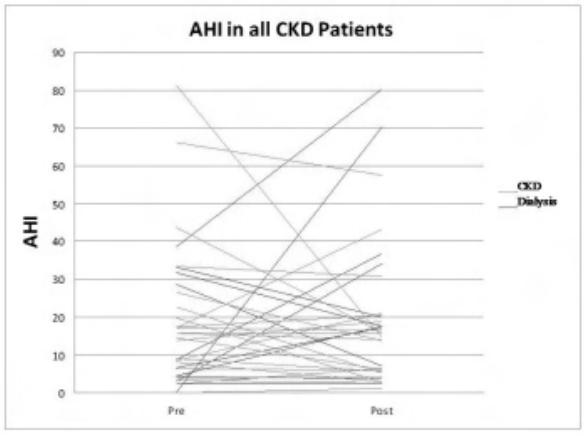
**SA-PO2627**

**Influence of Dialysis on Severity of Sleep Apnea in Advance Chronic Kidney Disease** Dionne C. Okafor, Sheena Ann Dohar, Mark L. Unruh. *University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Objective: While sleep apnea has been strongly linked to ESRD, very little is known regarding the prevalence of sleep apnea in advanced CKD. It is also unknown if the initiation of dialysis would change the severity of sleep apnea. Therefore, we initiatived a prospective study to describe longitudinal changes in sleep apnea severity among patients with advanced CKD and to assess whether sleep apnea improves with the initiation of dialysis.

Methods: We recruited 61 patients. Of these patients, 32 participants completed two unattended home polysyomnographies (PSG). The first PSG study completed at time of enrollment into the study, the next performed either 3 months following the start of dialysis or 1 year after initiating the study (post).

Results: The study sample was an average of 53 years old, predominantly men (66.6%), and white (71.8%), with a mean BMI of 30.51 kg/m2. The overall average eGFR was 21.51; CKD patients had an eGFR of 23.84 vs. 17.49 in the dialysis group. There was no signficant increase in Apnea-hypopnea index (AHI) from pre to post (18.56 vs. 19.30; P=0.86). However, those who remained off dialysis at follow-up had a decrease in AHI (20.566 vs. 14.78) while those who started dialysis demonstrated an increase in AHI (14.76 vs. 27.94) (P=0.03). The vast majority of apneic events were obstructive in both groups. There was no significant difference in nocturnal hypoxemia as measured by the amount of time with oxygen saturation less than 90% while sleeping (pre 6.03 vs. post 6.67; p=0.16)



Conclusions: Sleep apnea is prevalent in the CKD population and significantly worsens with the initiation of dialysis. However, there still needs to be more exploration into this field to understand the factors connecting CKD to obstructive sleep apnea.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2628**

**Significance of Circadian Chronotype on Sleep in HD Patients** Tushar Sharma,[1] Daniel Hahn,[1] Kelly Glazer Baron,[2] James J. Paparello,[1] Vincent L. Yang,[1] Shyam J. Uttamchandani,[1] William A. Schlueter,[1] Lisa Wolfe,[1] Shubha Ahya.[1] *[1]Medicine, Northwestern University, Chicago, IL; [2]Neurology, Northwestern University, Chicago, IL.*

PURPOSE: 1-evaluate the prevalence of sleep disturbances in an outpatient HD population. 2-identify a relationship between circadian chronotype (morning type vs evening type) and dialysis adherence.

METHODS: 72 patients from 6 dialysis shifts (12 per shift) completed 8 surveys to assess for circadian preference (Horne Ostberg), sleep quality (PSQI), daytime sleepiness (ESS), restless legs syndrome, depression, sleep apnea syndrome (OSA STOP), barriers to care, and affect of sleep on daytime functioning (modified FOSQ). Adherence was measured by a quantitative and qualitative assessment of missed dialysis treatment sessions in each dialysis shift over the past 1 year.

RESULTS: RLS symptoms were noted in 47.2%. The mean score on the PSQI was 7.68 and 61% of the patients had a score of >5, indicating poor sleep quality. Excessive daytime sleepiness was found in 45% of the patients. Patients were identified as morning type (43%) or neither type (54%). Only 2 patients were evening type. Neither types had shorter sleep duration (p=0.013), longer sleep latency (p=0.000), greater daytime dysfunction (p=0.006), overall higher scores on the PSQI (p=0.002), and more barriers to treatment (p=0.013). There was a trend for higher rates of nonadherence with neither types vs morning types (p=0.091). When biochemical parameters were analyzed, only PTH was found to be higher in the neither types vs morning types (672 vs 297, p=0.048). Morning types were older (63 vs 55, p=0.03) and had less years on dialysis (3.1 vs 5.6 years, p=0.01). When regression analysis was performed, Horne Ostberg scores were significant predictors of barriers to care (p=0.001) and sleep quality (p=0.002). Dialysis nonadherence correlated with transportation barriers (r= .29 p.024), barriers total(r=.29 p=.023), more time on HD (r=-.27 p=.024) and PTH (r=-.28, p=.023).

CONCLUSION: Morning types have better sleep quality,overall functioning and are on dialysis for a shorter time. Dialysis vintage and transportation may be reasons for dialysis nonadherence.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2629**

**Difficulties in Sexual Arousal, Enjoyment and Perceived Sex Life among New Dialysis Patients: A National Study** Austin G. Stack,[1] Catherine A. Wall,[2] Kieran Hannan.[3] *[1]Regional Kidney Centre, Letterkenny General Hospital, Letterkenny, Donegal, Ireland; [2]Department of Nephrology, Adelaide and Meath Hospitals, Dublin, Ireland; [3]Department of Nephrology, Cavan General Hospital, Cavan, Ireland.*

Sexual dysfunction is thought to be common in patients with advanced chronic kidney disease. The aim of this study was to describe and measure the impact of factors associated with sexual arousal, enjoyment and overall sex life in a national cohort.

Methods: Data were obtained on a subset of patients (n=2,480; 62 %) from the Dialysis Morbidity and Mortality Study Wave 2, an incident dialysis cohort study. A validated quality of life instrument (KDQOL-SF) was used to assess patient's attitudes to kidney disease at the start of dialysis and its impact on quality of life. Multivariable logistic regression was used to determine associations (Odds Ratio (OR)) of demographic, clinical and laboratory factors with difficulty in sexual arousement and sexual enjoyment.

Results: Overall, 39% of new dialysis patients reported moderate to severe impact on their sex life; 44% reported moderate to severe difficulties in becomming sexually aroused and enjoying sex. The likelihood of reporting moderate-severe difficulties in relaxing & enjoying sex were significantly greater for younger patients (Age18-50, OR=1.60; Age 50-70, OR=1.62; Age > 70, OR=1.00), males (OR=2.71), married couples (OR=2.59), those reporting negative affect (OR=2.40), receiving prescribed antidepressants (OR=1.27), and treated with PD (OR=1.21). Conversely, the likelihood of reporting difficulties were significantly lower for patients who exhibited positive affect (OR=0.53), exercised regularly (OR=0.64), were in full or part-time employment (OR=0.80 and 0.79), and who were dialyzing with a permanent vascular access (OR=0.79). Surprisingly, none of the co-existing cardiovascular or non-cardiovascular comorbidities recorded at dialysis initiation were significant.

Conclusions: Difficulties in relaxing and enjoying sex are common among new dialysis patients and negatively impact on sex life. Further studies should address in-depth the barriers to sexual enjoyment in this patient population in order to improve overall quality of life.

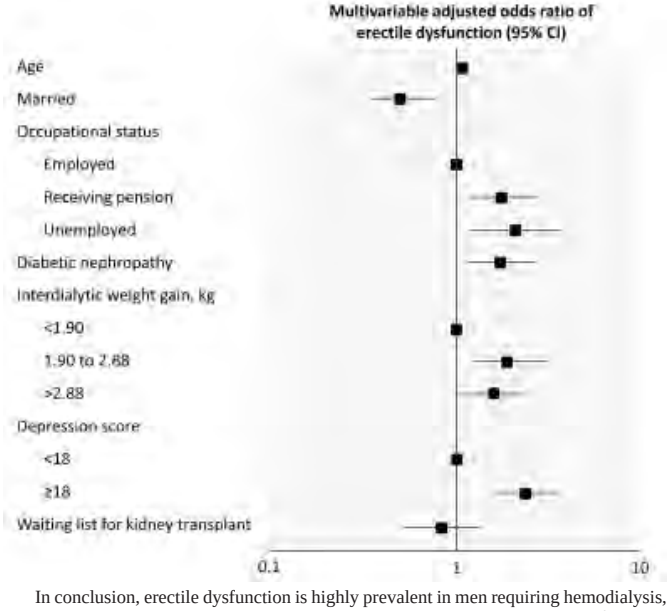
Disclosure of Financial Relationships: nothing to disclose

**SA-PO2630**

**The Prevalence and Correlates of Erectile Dysfunction in 946 Men Receiving Hemodialysis: A Multi-Center Cross-Sectional Study** Mariacristina Vecchio,[1] Suetonia Palmer,[2] Giorgia De Berardis,[1] Fabio Pellegrini,[1] David W. Johnson,[3] Jonathan C. Craig,[4] Giovanni F. M. Strippoli.[1,4,5] *[1]Consorzio Mario Negri Sud; [2]University of Otago Christchurch; [3]University of Queensland; [4]University of Sydney; [5]Diaverum Medical Scientific Office.*

Existing studies suggest erectile dysfunction is common in men receiving hemodialysis but have limited by study size and methods problems. In this multinational cross-sectional study, we enrolled men receiving hemodialysis in 27 outpatient clinics selected randomly from a collaborative dialysis network. Erectile function was assessed anonymously by the International Index of Erectile Function (IIEF) questionnaire. Depressive symptoms were evaluated with the Center for Epidemiological Studies Depression (CES-D) Scale. Multivariable logistic regression was used to determine correlates of erectile dysfunction adjusting for clinical and sociodemographic characteristics.

Overall, 946 (59%) of 1611 eligible men responded. Of these, 781 (83%) men reported erectile dysfunction and 445 (57%) reported severe erectile dysfunction. Only 33 (4%) men with erectile dysfunction reported receiving specific treatment. Depression (CES-D score ≥18) was the strongest correlate of erectile dysfunction whereas being married reduced the risk. Erectile dysfunction was also independently correlated with age, unemployment, diabetic nephropathy and interdialytic weight gain (**Figure**). Diabetic nephropathy nearly trebled the risk of severe erectile dysfunction (adjusted odds ratio (AOR) 2.54, CI 1.61-4.02)).



In conclusion, erectile dysfunction is highly prevalent in men requiring hemodialysis, and is rarely treated. Depression and unemployment are important correlates of erectile dysfunction in this population.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2631**

**The Seasonal Variations of Uremic Pruritus Prevalence in Patients with Hemodialysis** Jwa-Kyung Kim,[1] Sung Jin Moon,[2] Hyeong Cheon Park,[2] Sung-Kyu Ha,[2] Tae-Hyun Yoo,[1] Shin-Wook Kang,[1] Ho Yung Lee,[1] Sang Choel Lee,[3] Soo Young Yoon,[3] Jung Eun Lee,[4] Hyung-Jong Kim,[5] Dongho Yang.[5] *[1]Severance Hospital; [2]Gangnam Severance Hospital; [3]Kwandong University; [4]Yongin Severance Hospital; [5]Bundang CHA Hospital.*

Uremic pruritus is one of the most common and potentially disabling symptoms in patients with ESRD. Although uremia is regarded as the main cause of pruritus, the precise diagnostic methods of the condition and its treatment remains unknown. Moreover, the seasonal variation of uremic pruritus is not evaluated in patient with hemodialysis. A self-

administered questionnaire was constructed for the evaluation of uremic pruritus. Patients receiving maintenance hemodialysis therapy in 5 centers completed this survey with an interval of 6 months (at February 2009, August 2009). To assess the intensity of pruritus, each subject was asked to check a Visual Analogue Scale (VAS) and the score was graded from 0 to 5; 0 (none), 1,2,3,4 and 5 (very severe). The number of uremic patients who agreed to the questionnaire-based survey during the winter (February 2009) and summer (August 2009) was 297 and 336, respectively and 230 responders completed both of the questionnaires. The mean age of the 230 patients was 59.0±12.5 years and mean dialysis duration was 35±8.5 months. The prevalence rate of uremic pruritus in winter was 65.6% (n=150) and 48.3% (n=110) in summer. Although the prevalence rate showed decreasing tendency in summer, however, there was no significant seasonal variation in uremic pruritus (p=0.13). Whereas, the prevalence rate ranged from 16.7 to 83.3% among the five centers and this inter-hospital difference was statistically significant (p=0.03). Among the 80 patients who did not have pruritus in the winter, 27.6% of the patients (n=22) developed new itching sensation during the summer. Conversely, in the 34.4% of the patients who experienced pruritus in the winter (n=51), the pruritic symptom was disappeared during the summer season. This data suggest that there's no seasonal variation of uremic pruritus in maintenance hemodialyis patients. Approximately 30% of patients showed seasonal difference in pruritic symptom.

### SA-PO2632

**Levels of Indican and Restless Legs Syndrome in Hemodialysis Patients: The Retained Organic Solutes and Clinical Outcomes in Hemodialyis (ROSCO) Study** Laura C. Plantinga,[1] Michal L. Melamed,[2] Thomas H. Hostetter,[2] Timothy W. Meyer,[3] Tariq Shafi,[4] Nancy E. Fink,[4] Neil R. Powe.[1] *[1]University of California, San Francisco, CA; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Stanford University, Palo Alto, CA; [4]Johns Hopkins University, Baltimore, MD.*

Restless legs syndrome (RLS) is a common symptom among hemodialysis (HD) patients. Indoxyl sulfate (indican), which accumulates in ESRD patients and is not removed entirely by HD, can influence central nervous system function and has been proposed to contribute to RLS. We examined the association of self-reported RLS in a U.S. cohort of 459 incident HD patients (enrolled 1995-1998) with indican levels measured by high-performance liquid chromatography in frozen plasma samples collected ~6 months after dialysis initiation. RLS was defined as patient report of being very to extremely bothered by RLS at baseline (BL) and/or 1 year. Logistic and GEE regression were used to calculate odds ratios for RLS at BL and longitudinally. At baseline, 14.4% of those with indican levels less than the median (1.6 mg/dl) and 17.8% of those with levels above the median (P=0.316) reported having RLS. With adjustment for age, sex, race, body mass index, and creatinine, those with indican levels above the median were more likely to report RLS [OR=1.53 (1.07-2.21)]. Stratified analyses revealed no significant interaction by diabetes, gastrointestinal (GI) disease, or albumin or creatinine level, although the positive associations seen in subgroups with diabetes and with no GI disease were statistically significant. Results were similar but less significant among the 358 patients with information on RLS at 1 year; change in RLS from BL to 1 year was associated with indican level [OR=1.35 (0.84-2.15)] but not statistically significantly. Severe RLS symptoms may be associated with high levels of indican, an organic solute that is retained in HD.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2633

**The Prevalence of Uremic Neuropathy in a Contemporary Hemodialysis Cohort** Meg J. Jardine,[1 2] Arun V. Krishnan,[3] Martin P. Gallagher,[1 2] Paul Snelling,[1] Ria Arnold,[3] Carmel M. Hawley,[4] Bruce A. Pussell,[5] Vlado Perkovic,[2] Michael G. Suranyi,[1] Matthew C. Kiernan,[3] Josette M. Eris.[1] *[1]Sydney South West Area Health Service; [2]The George Institute for International Health; [3]Institute of Neurological Sciences, University of New South Wales; [4]Princess Alexandra Hospital; [5]Prince of Wales Hospital.*

**Aim:** To establish the prevalence of neuropathy in a contemporary hemodialysis population enrolled in the FINESSE trial.

**Introduction:** People with End Stage Kidney Disease (ESKD) experience greater weakness, less muscle mass, diminished physical activity and lower physical quality of life scores than controls. They are susceptible to neuropathies, including uremic and diabetic neuropathies, causing symptoms of paresthesia, pain, weakness and muscle wasting. The FINESSE trial (Filtration In the Neuropathy of End Stage kidney disease Symptom Evolution) is a randomized controlled trial evaluating the effect of hemodiafiltration compared with standard hemodialysis.

**Methods:** The presence of neuropathy was assessed in a cohort of stable maintenance hemodialysis patients. A standardized neuropathy instrument, the Total Neuropathy Score combining symptoms, signs and nerve conduction components, was measured prior to randomization.

**Results:** Baseline assessment was completed by 58 participants. Comorbidities included diabetes (38%), ischaemic heart disease (27%), and any vascular disease (35%). Overall evidence of neuropathy was found in 81% of participants, including symptomatic neuropathy in 35%. Neuropathy was present in 95% of the participants with diabetes, and in 71% of participants without diabetes.

**Conclusions:** UN remains highly prevalent among contemporary hemodialysis patients. The neuropathy burden may increase with the greater prevalence of diabetes and longer durations spent on dialysis associated with lengthening transplant waiting periods. FINESSE will provide important information on UN and will contribute substantially to high level evidence on the benefits and harms of HDF therapy. (Trial Registration: ACTRN12609000615280)

### SA-PO2634

**Pain Is Underrecognized and Undertreated in Hemodialysis Patients** Monica C. Beaulieu,[1,2] Marianna S. Leung,[1] Lee Er,[2] Fong Hue Huynh,[1] Clifford Chan Yan,[1] Ronald Werb,[1] Beverly Jung,[1] Mercedeh Kiaii.[1] *[1]Division of Nephrology, UBC, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada.*

Effective pain management improves patient's quality of life and is an integral component of patient care. Pain is commonly experienced by hemodialysis (HD) patients but is often underrecognized and undertreated.

The aim of this study was to (1) describe the prevalence, severity, and management of pain in HD patients (2) determine if there are factors that differentiate those with and without pain.

We performed a prospective cohort study, surveying patients at an in-centre urban dialysis unit. All patients in the HD unit were approached to participate. Patients who reported pain were interviewed using Short-Form Brief Pain Inventory (SF-BPI) and Short Form McGill Pain Questionnaire (SF-MPQ)

161/233 patients participated in the study (63% male, 40% caucasian, 29% asain). 34% (57/161) of patients reported pain. Patients with pain had slightly longer HD duration (40.6 vs 27.2 mos; p=0.14) and more cardiovascular disease (57% vs 41%; p=0.02).

Of the 54 patients with pain on the SF-BPI, 46.3% rated their pain at it's worse as severe (pain score ≥ 7). The most common descriptors of pain were aching and tiring-exhausting.

30% of patients had no treatment presecribed for their pain. Of the 70% (38/54) who were treated, 82% received pharmacologic treatment, 18% non-pharmacologic. Of treated patients, 33% reported that their pain was not relieved effectively.

In conclusion, in a cohort of HD patients, 34% reported pain. Of patients with pain, 30% are untreated and a large number of treated patients still report pain. Practitioners caring for HD patients should have a systematic program for pain assessment and management in their units.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2635

**Regimen Complexity, Burden of Therapy and Prescription Adherence in Dialysis** Luca Neri,[1, 2] Maurizio Gallieni,[4] Alma Martini,[4] Lisa Allegra Rocca Rey,[5] Diego Brancaccio.[3] *[1]Dipartimento di Medicine del Lavoro e Biostatistica, Universita' di Milano, Milano, Italy; [2]Center for Outcomes Research, Saint Louis University, St. Louis, MO; [3]Fondazione Italiana del Rene [Italian Kidney Foundation], Milano, Italy; [4]U.O. Nefrologia, Ospedale San Carlo Borromeo, Milano, Italy; [5]U.O. Nefrologia, Multimedica Holding, Castellanza - Varese, Italy.*

**Background and Aims.** Poor prescription adherence is common in dialysis patients and may cause sub-optimal outcomes and increased health care costs. We evaluated the association between regimen complexity, perceived burden of therapy and prescription adherence in hemodiaysis (HD).

**Methods.** We enrolled 1238 HD patients in 54 Italian centers. We collected data on patients' socio-demographic characteristics, perceived burden of therapy (BOT), quality of life, health care satisfaction, social support and prescription adherence with a self-administered questionnaire. Data on medication regimen, comorbidities, hospitalizations, transplant listing status were provided by the nursing staff. We estimated the adjusted association of regimen complexity, BOT and prescription adherence with logistic regression.

**Results.** Sample characteristics are described in table 1. Mean daily burden was 9.7 tablets and 48% of patients were adherent to medication prescriptions. Every tablet added to the medication regimen was associated to a 10% decrease in adherence likelihood after adjustment for possible confounders. Perceived burden of therapy moderated the association between tablet count and self-reported adherence (Interaction term, OR: 1.04, p<0.01; figure 1).

**Conclusion.** Poor adherence was very common in our sample. Reducing tablet burden might help patients be adherent. However our results suggest that modulating regimen complexity might be ineffective if patients' negative attitudes toward medications are not addressed concurrently.

| Characteristics | N (%) or mean (SD) | Characteristics | N (%) or mean (SD) |
|---|---|---|---|
| SRH | 5.9 (1.8) | Dialysis Vintage | |
| IIRS | 35.5 (14.3) | <1 years | 259 (20.7) |
| BOT | 2.3 (0.5) | 1-5 years | 541 (43.8) |
| Women | 449 (36.3) | >5 years | 446 (35.6) |
| Mean Age | 64.4 (16.8) | Hypertension | 736 (69.6) |
| > High School | 367 (29.9) | Hypotension | 128 (10.3) |
| E/P ratio | 147 (34.3) | CVD | 638 (51.5) |
| Disabled | 1052 (85.0) | Diabetes | 262 (21.2) |

Table 1. Subjects characteristic of the MgilorDialds sample. Legend: BOT, perceived Burden of Oral Therapy; E/P ratio: ratio between employed patients and working age individuals (legal retirement age is 60 years in Italy); CVD: cardiovascular disease. Hypotension refers to history of recurrent episodes of post-dialysis hypotension.

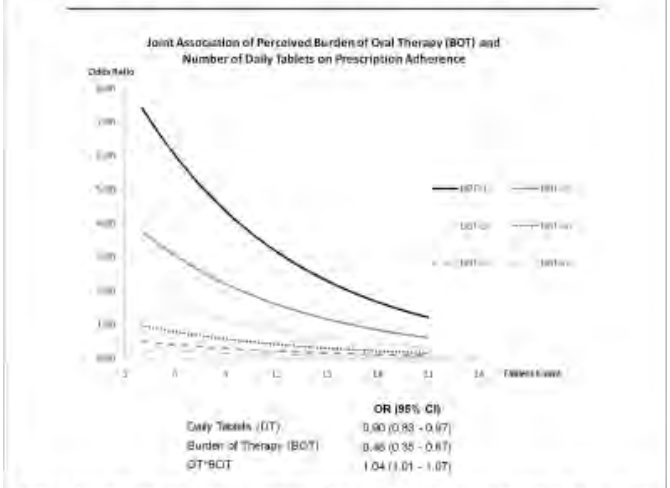

**Figure 1. Association of oral regimen characteristics and self reported adherence.** Multivariable logistic regression analysis evaluating correlates of regimen adherence among hemodialysis patients. Burden of therapy refers to self reported interference of oral therapy in daily life (6 items; ratings occurred along a 5-point Likert scale). Odds ratios refer to the marginal conditional likelihood associated to 1 unit increase in the independent variable. Analysis also adjusted for number of hospitalizations in the 12 months prior to enrollment, number of comorbidities, disability status, dialysis vintage, age, gender, employment status, education, support from health care providers, illness intrusiveness rating scale, sleep quality scale, transplant listing status, region of residence, living arrangement (living alone/nursing home vs. living with family members)

**SA-PO2636**

**Hemodialysis Patients May Overestimate Their Ability To Manage Complex Medical Regimens** James B. Post, Kel G. Morin, Ann M. Spungen. *Research & Development, James J. Peters VAMC, Bronx, NY.*

Despite a high prevalence of cerebrovascular disease in hemodialysis (HD) patients, they are expected to adhere to complex treatment regimens in order to avoid adverse complications. Very little is known about the HD patient's perceived functional ability and whether or not it correlates with actual functional performance. The purpose of our study was to compare subjective and observed measures of independent activities of daily living (IADLs) in HD patients with no clinical evidence of dementia to appropriate controls matched for age, BMI, diabetes, hypertension, and hyperlipidemia. In 27 HD and 16 controls, the MMSE, Lawton IADL test (subjective), and Hopkins Medication Schedule (HMS) test (observed) were performed to compare the relationship between subjective and observed measures of IADLs in each group. Lawton-HMS differential scores were calculated by subtracting HMS scores from Lawton scores. Group comparisons were made using t-tests and chi-squared tests as appropriate. There were no significant differences between HD and controls in age 61±10 vs. 65±11 y, years of education, ethnicity, BMI, hypertension, diabetes, hyperlipidemia, or MMSE (29±1 vs. 29±1). HD patients scored significantly lower on IADL assessments vs. controls: Lawton 15±2 vs. 16±1 (p=.02), HMS 9±3 vs. 11±1 (p=.002). HD patients scored higher than controls, trending toward significance, on the Lawton-HMS differential score 6±3 vs. 4±1 (p=.07), suggesting that there may be a larger discrepancy between perceived and actual functional abilities in patients on HD. HD patients with no clinical or objective evidence of dementia demonstrate that they may overestimate their ability to adhere to and understand the complex medical regimens required of HD patients.

Disclosure of Financial Relationships: nothing to disclose

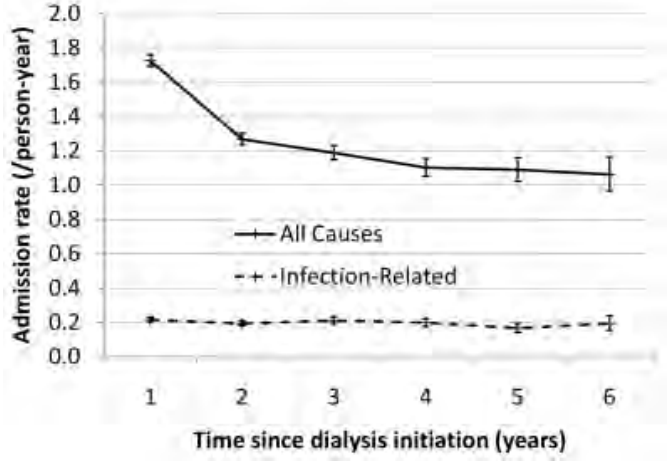
**SA-PO2637**

**Overall and Infection-Related Hospitalization Rate Trends in Dialysis Accounting for Dialysis Vintage** Jean-Philippe Lafrance,[1] Elham Rahme,[2] Sameena Z. Iqbal,[2] Michel Vallee.[1] *[1]Centre de recherche Hopital Maisonneuve-Rosemont, QC, Canada; [2]McGill University, QC, Canada.*

Chronic dialysis is associated with a high burden of morbidity requiring frequent hospital admissions. Trends of all cause and infection-related admissions have not been evaluated in newly dialyzed patients. We aimed at describing population-based incidence rate trends of all cause and infection-related hospitalizations in dialysis patients.

Using administrative databases from the universal health care system in Quebec, Canada (Regie de l'assurance maladie du Quebec), we built a retrospective cohort of all adults initiating chronic dialysis between 2001 and 2007. Patients with a prior history of kidney transplant or with <90d of follow-up were excluded. Hospitalizations during which a dialysis was initiated were not counted. Only patients in their 1st year of dialysis were included in the estimation of incidence rates per calendar years.

6567 patients (mean age=64.4±14.5 y, and 40% females) were included in the cohort. The mean follow-up was 2.38±1.7 y. In total 21,846 hospitalizations occurred and 86% of patients had ≥1 admission. All cause and infection-related hospitalizations remained stable between 2001 and 2006, (respectively: 1.81 vs.1.66 /p-y, P=0.11; and 0.23 to 0.21, P=0.55). Rates of all cause hospitalizations were higher in the 1st year following dialysis initiation (1.73 vs. 1.06, P<0.001), possibly explained by a survivor effect. However, infection-related rates remained stable over the follow-up period (0.22 to 0.19, P=0.09).



Overall hospitalization rates declined with dialysis vintage, which should be accounted for when estimating trends over calendar years in prevalent dialysis populations (if proportions of incident patients vary with time). Since the infection-related rates did not decline, the proportion of admissions due to infections increased with time on dialysis.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2638**

**P-Cresol Sulfate Level and Infection-Related Hospitalizations in Hemodialysis Patients: The Retained Organic Solutes and Clinical Outcomes in Hemodialyis (ROSCO) Study** Neil R. Powe,[1] Laura C. Plantinga,[1] Thomas H. Hostetter,[2] Michal L. Melamed,[2] Bernard G. Jaar,[3] Tariq Shafi,[3] Nancy E. Fink,[3] Timothy W. Meyer.[4] *[1]University of California, San Francisco, CA; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Johns Hopkins University, Baltimore, MD; [4]Stanford University, Palo Alto, CA.*

P-cresol sulfate (PCS), an organic solute formed by the action of colonic bacteria on the amino acids tyrosine and phenylalanine, accumulates in uremic patients and is poorly removed by conventional dialysis. Recent studies have identified relations between increased levels of PCS and adverse clinical outcomes in hemodialysis (HD) patients and between PCS and decreased leukocyte transendothelial migration *in vitro*. We examined the association of PCS with infection-related hospitalizations (IH) in a U.S. cohort of 518 incident HD patients enrolled in 1995-1998 and followed for an average of 3.4 years. PCS levels were measured by high-performance liquid chromatography in frozen plasma samples collected ~6 months after dialysis initiation. We linked USRDS Medicare billing records to ascertain IH over follow-up. We used Poisson regression to calculate incidence rate ratios (IRRs) for IH. The incidence of IHs per 1000 patient-years was 180.7 in the lowest tertile, 277.9 in the middle tertile and 256.2 in the highest tertile of PCS level. After adjustment for age, sex, race, body mass index, comorbid disease, albumin and creatinine, compared to patients with PCS levels in the lowest tertile, those with levels in the middle and highest tertiles had a 40-60% higher risk of IH [IRR=1.42 (1.09-1.86) and 1.60 (1.21-2.12), respectively. Stratified analyses suggested an interaction by presence of GI disease, with the relation only being present in those without any GI disease. Higher levels of PCS, an organic solute that is retained in patients undergoing HD, are independently associated with infection-related hospitalizations. Methods for removal of PCS and the effect on outcomes should be investigated further.

**SA-PO2639**

**Prevalence of Nephrogenic Systemic Fibrosis in Dialysis Patients: The Pro-FINEST Study** Sabine Amet,[1] Vincent Launay-Vacher,[1] Benedicte Stengel,[2] Anne Castot,[3] Camille Frances,[4] Nicolas Grenier,[5] Jean-Yves Gauvrit,[6] Genevieve M. Reinhardt,[7] Olivier Clement,[8] Nicolas Janus,[1] Carmen Kreft-Jais,[3] Gabriel Choukroun,[9] Maurice Laville,[10] Gilbert Deray.[1] *[1]Service ICAR, Nephrology, Pitie-Salpetriere Hospital, Paris, France; [2]Paul Brousse Hospital, Villejuif, France; [3]Afssaps, Saint-Denis, France; [4]Tenon Hospital, Paris, France; [5]Pellegrin Hospital, Bordeaux, France; [6]Pontchaillou Hospital, Rennes, France; [7]Haguenau Hospital, Haguenau, France; [8]HEGP Hospital, Paris, France; [9]South Hospital, Amiens, France; [10]Edouard Herriot Hospital, Lyon, France.*

NSF is a cutaneous and systemic disorder characterized by widespread tissue fibrosis. It has been suggested that gadolinium-based contrast agents (GBCA) may be responsible for NSF, especially in dialysis patients. The Pro-FINEST study is a national prospective study endorsed by the French Drug Agency (Afssaps), and the French Societies of Nephrology, Dermatology, and Radiology. It aims at determining the prevalence of NSF after a Magnetic Resonance Imaging (MRI) examination, +/- GBCA, in dialysis patients.

The study is based on a 3-section patient form. Section 1: demographics and dialysis; Section 2: MRI examination; Section 3: any dermatological event (DE). Further investigations are planned in case of DE. When a NSF diagnosis is confirmed, an ancillary study is to be performed, with random selection of 4 patients (same gender, dialysis technique, centre, and without any DE after MRI with the same GBCA, if injected).

Since 01/2009, 297 patients have been included (247 centres): mean age 64.1 years, 60.3% men 55.5% of the patients received GBCA; 87.7% Gadoterate. 5 patients reported DE although no NSF (1 hemodialysis-related prurit, 1 localized skin reaction to a trinitrine patch, 1 thoracic zona, 1 hardening feet skin linked to vascular lesions and no clear dermatological diagnosis in the fifth case but no evidence of NSF.

So far thus, no case of NSF has been reported in 195 dialysis patients among whom the majority received a GBCA. Most patients received a macrocyclic gadolinium chelate for which no case of NSF has been observed worldwide (Gadoterate).

**Characteristics of and Outcomes for Patients Recovering from ESRD** Michael Heung, Flannery Campbell, John Kalbfleisch, T. H. Shearon, V. B. Ashby, Rajiv Saran. *Univ of Michigan.*

By definition, ESRD certification implies an "irreversible and permanent" state, yet many patients recover each year. The ability to identify such patients and to understand their prognosis following recovery is of major clinical significance.

ESRD recovery events were identified by a specific code in the Centers for Medicare and Medicaid Services (CMS) ESRD database (2002-2008). Multivariate logistic regression identified patient characteristics associated with renal recovery and Cox regression was used to assess survival up to 5 years following the recovery event compared to non-recovering ESRD and transplant patients.

During the study period, 37,482 patients recovered from ESRD among 744,143 patients starting ESRD. The incidence of recovery in the first year after starting dialysis rose throughout the study period, from 3.9% in 2002 to 5.6% in 2007 ($p<0.001$). Recovery occurred within 3 months in 56% of patients, and within 1 year for 90%. African-Americans were less likely to recover than Caucasians (OR 0.53, $p<0.05$). Patients with ATN and scleroderma as the primary cause of ESRD were more likely to recover than patients with a primary diagnosis of DM (OR 15.4 and 4.7 respectively, $p<0.05$ for both). Most (73%) patients remained recovered at 1 year, and 25% were still dialysis-independent after 5 years. Compared to patients recovering renal function, patients remaining on dialysis had worse long-term mortality (HR 2.15, $p<0.001$) while transplanted patients had a lower mortality (HR 0.30, $p<0.001$).

An increasing percentage of patients recover from ESRD each year. We identified characteristics that may be predictive of renal recovery, and these factors may aid in the counseling of patients starting dialysis. Interestingly, even causes that are considered irreversible (such as DM) showed evidence of recovery, highlighting superimposed acute kidney injury as a likely unrecognized factor in CKD progression. A majority of recovering patients remained dialysis-independent at 1 year following recovery, but these patients need to be followed closely as ~10% return to dialysis each year. Recovery of renal function is associated with a significantly better survival than remaining on dialysis.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2641**

**A Randomized Controlled Trial To Compare the Safety and Efficacy of Oral Paricalcitol with Calcitriol in Dialysis Patients with Secondary Hyperparathyroidism** L. M. Ong, N. Punitha, H. K. Goh, A. B. Manocha, Ghazali T. V. Ahmad, M. Sukeri, B. L. Goh, S. Shahnaz, M. R. Seman, V. Indralingam. *MOH, Malaysia.*

There have been no studies comparing oral paricalcitol (OP) with oral calcitriol (OC) in treatment of secondary hyperparathyroidism (SH) in dialysis patients (DP).

**Aim**

To compare the efficacy and safety of OP with OC in DP with SH.

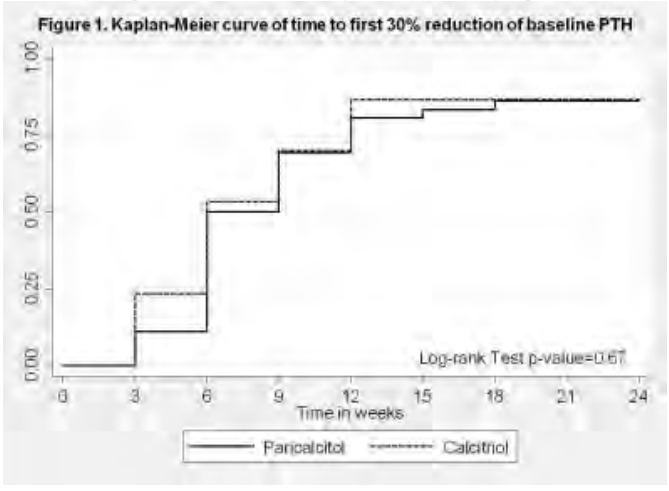
**Method**

We conducted a multicentre, open-labeled, parallel group RCT over 24 weeks. The initial thrice weekly dose of OP (PTH/120µg) and OC (PTH/360µg) was titrated 3-weekly to serum intact parathyroid hormone (PTH), calcium (Ca) & calcium-phosphate product (CaP). The primary end-point was time to ≥30% reduction from baseline PTH.

**Results**

36 patients were randomized to OP and 30 to OC. Baseline characteristics were similar between groups.

Primary end-point (PEP) did not differ significantly between groups.



86.1% (OP) vs 86.7% (OC) achieved PEP by 24 weeks. The mean time (weeks) to first event was 7.7 (OP) vs 6.9 (OC) p=0.4. The mean time (weeks) to maximal reduction in PTH (MRP) was 16.1 (OP) vs 15.5 (OC) p=0.7.The mean % of MRP from baseline was 68.7% (OP) vs 72.4% (OC) p=0.3. There were no significant differences in bone mineral parameters except for phosphate (P) & CaP at week 12.

Table 1. Mean change from baseline

| | Week | OP | OC |
|---|---|---|---|
| PTH (%) | 12 | -42.1 | -52.7 |
| | 24 | -44.2 | -40.7 |
| Ca (mg/dl) | 12 | 0.69 | 0.87 |
| | 24 | 0.78 | 0.77 |
| P (mg/dl) | 12 | -0.38 | 0.46* |
| | 24 | -0.04 | 0.8 |
| CaP (mg2/dl2) | 12 | -0.22 | 9.22* |
| | 24 | 3.94 | 11.9 |
| ALP (U/l) | 12 | -36.1 | -50.1 |
| | 24 | -51.1 | -89.5 |

*$p<0.05$

Drug compliance was comparable. 23 episodes of hypercalcemia were seen in 6 patients (17%) in OP & 16 episodes in 6 patients (20%) in OC group p=0.7. Other adverse events were similar in both groups.

**Conclusion**

OP has similar efficacy and safety compared with OC in dialysis patients with SH. There was no difference in the incidence of hypercalcemia.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2642**

**Exposure to Ionizing Radiation in End Stage Kidney Disease (ESKD)** Sinead Kinsella,[1] Joe P. Coyle,[2] Siobhan McCarthy,[3] Sebastian R. McWilliams,[3] Michael Clarkson,[1] Michael M. Maher,[2] Joseph A. Eustace.[1] *[1]Renal Medicine, Cork University Hospital, Cork, Ireland; [2]Radiology, Cork University Hospital, Cork, Ireland; [3]University College Cork, Cork, Ireland.*

Introduction: Exposure to ionizing radiation is associated with an increased risk of malignancy, as is ESKD.

Methods: We conducted a retrospective study of 394 patients (244 on maintenance haemodialysis (HD) and 150 with a functioning renal transplant) to quantify and compare ionizing radiation exposure from medical procedures in these populations. Patient demographics and comorbidities were obtained from medical record review. The number and type of radiological procedures were obtained from a computerised radiology database. Cumulative effective radiation dose (CED) expressed in milliSieverts (mSv) was calculated using published reference effective doses for diagnostic imaging studies.

Results: Patients were followed for a median (Intraquartile Range [IQR]) of 4 (1.7 to 6) years, data from 1513 patient years was included. Mean (sd) age at study entry was 52.7 (16.8) years. During the study period a total of 7311 radiological procedures were performed exposing the study population to an estimated total of 10548mSv of ionizing radiation. Computed tomography accounted for 61% of total CED while accounting for only 9% of the total number of radiological procedures performed. The median (IQR) CED per patient was 9.2 (1 to 33) mSv and was significantly higher in HD patients compared to the transplant group (15.1 Vs 2.9 mSv, $p<0.001$). On univariate logistic regression analysis HD patients had a significantly increased Odds Ratio (OR) (95% CI) of exposure to >50mSv of ionizing radiation compared to the transplant group (OR 3.5 (1.8-6.8)). Following simultaneous adjustment for age, duration of follow-up, cause of ESKD, and recorded comorbidities, HD remained significantly and independently associated with radiation exposure >50mSv.(OR 9.5, (95% CI 3.8-22.6)).

Conclusion: Patients with ESKD undergo repeated and frequent radiological procedures exposing them to substantial cumulative doses of radiation. HD patients in particular are at increased risk of exposure to high doses of ionizing radiation from medical procedures.

### SA-PO2643

**Risk Factors and Prevalence of Calciphylaxis in Japanese Hemodialysis Population; a Case-Control Study by Japanese Calciphylaxis Study Group** Matsuhiko Hayashi, Yoshihiko Kanno, Tadashi Yoshida. *Apheresis and Dialysis Center, University of Keio, School of Medicine, Shinjuku-ku, Tokyo, Japan.*

Calciphylaxis, also called calcific uremic arteriolopathy, is a rare and often fatal complication of end-stage renal disease, characterized by cutaneous ischemia and ulcer with medial calcification and intimal proliferation of small arteries. Previous studies reported its incidence ranging from 1 to 5 % of the patients on chronic hemodialysis. To reveal the characteristics of calciphylaxis in Japanese dialysis population, we conducted a nationwide surveillance and a case-control study. Firstly, we sent a questionnaire to 3760 hemodialysis centers in Japan, asking whether calciphylaxis cases were encountered in the past decade, and then the detailed clinical data with skin biopsy specimens were collected. Furthermore, two control dialysis patients matched to age and duration of hemodialysis were identified from the participated centers for each calciphylaxis case. The results of surveillance showed that there were 151 cases in the past 10 years and suggested that prevalence rate is lower than 2/10000 hemodialysis patients per year. Sixty-seven detailed clinical data were collected and 28 cases were diagnosed as definite cases by clinical characteristics and skin biopsy findings. In comparison with 56 matched controls, a logistic regression model identified that warfarin administration (odds ratio [OR] 10.8, 95% confidence interval [CI] 2.90 to 40.5, p<0.001), each 1 g/dl decrease in serum albumin (OR 19.7, 95% CI 4.36 to 89.5, p<0.05), and each 1 mg/dl increase in adjusted serum calcium level (OR 3.21, 95% CI 1.63 to 6.30, p<0.05) at the time of diagnosis were associated with calciphylaxis, while association of female gender, vitamin D analogue, serum phosphate level, adjusted calcium-phosphate products, and serum alkaline-phosphatase were not significant. We conclude that prevalence of calciphylaxis is much lower in Japan than in previous reports, suggesting that incidence of calciphylaxis may be different by races and geographic factors, and that warfarin therapy, lower serum albumin, and higher serum calcium level are risk factors for the development of calciphylaxis.

### SA-PO2644

**Employment in Inner City Hemodialysis Patients: A Study of the Interplay of Socio-Demographic and Health Related Factors** Adeyinka A. Adegoroye, Ikechukwu O. Nwobu, Ayoola Adekile, Moro O. Salifu. *Depatment of Medicine, SUNY Downstate Medical Center, Brooklyn, NY.*

Introduction:

Employment status of hemodialysis (HD) patients is an index of a rehabilitated patient with a chronic illness. Many factors including co-morbidities, physical deconditioning, emotional/psychological problems, quality of life, educational status, occupational history and US legal resident status may impact the employment status of HD patients.

Methods:

Cross sectional study of patients aged 50 and below in two outpatient dialysis centers. Data was collected using a self-administered questionnaire which included the Beck depression inventory-ll (BD-II), a depression screening tool and the Short form 36 health survey (SF-36), a quality of life evaluation tool.

Results:

65 HD patients participated in the study, of whom 37 (57%) were males. 60 (92.3%) were African or African American, 4 (6.2%) were Hispanic and 1 (1.5%) Asian American. 35 (53.8%) were employed. There was no difference between the employed and unemployed groups in Age, Gender, US residency status (Permanent resident/US citizen, Undocumented alien), Education level (Primary, High school and College), Pre-Hemodialysis employment status, duration of Hemodialysis therapy, Hemoglobin, Serum Albumin, Urea reduction ratio (URR) and BD-II. The two groups however significantly differed in the SF-36 score (72±16 vs. 62±20, p=0.037) and Diabetes Mellitus (p= 0.032). Using logistic regression analysis, only the SF-36 score predicted employment in this population. We did not identify any predictors of the SF 36 score.

Conclusion:

Employed HD patients tend to have a higher SF-36 score than unemployed HD patients. These results need verification in prospective studies.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2645

**Pulmonary Hypertension in Hemodialysis Patients: Insights from Hemodynamic Measurements** Chirag B. Patel,[1] James Gossage,[2] John White.[1] *[1]Medicine, Nephrology, Medical College of Georgia, Augusta, GA; [2]Medicine, Pulmonary Critical Care, Medical College of Georgia, Augusta, GA; [3]Augusta, GA.*

Pulmonary hypertension (PH) is common in hemodialysis (HD) patients and is associated with adverse outcomes. Potential etiologies include high flow states from AV grafts or fistulae, the high prevalence of sleep apnea, and chronic volume overload. Previous studies estimated pulmonary artery systolic pressure (ePASP) by 2D echocardiography (echo), the reliability of which has not been adequately assessed in HD. The purpose of this study is to determine the accuracy of echo in this population for diagnosing PH as compared to right heart catheterization (RHC) and to determine the role of volume status.

We conducted a retrospective review of 17 HD pts referred for suspected PH. Demographic data, dialysis access, lab, echo data, and RHC data were collected. ePASP >= 35 mmHg was used to diagnose PH by echo. Mean pulmonary artery pressure (mPAP) >= 25 mmHg was considered diagnostic by RHC. Pulmonary vascular resistance (PVR) > 200 dynes/sec/cm-5 and pulmonary capillary wedge pressure (PCWP) >= 15 mmHg were considered elevated. In patients with elevated PCWP, the trans-pulmonary gradient (TPG) was calculated. TPG < 15 suggests heart failure as cause of PH while TPG > 15 suggests mixed disease. The relation between mPAP, PCWP, and other important clinical factors were assessed.

87% (n = 15) pts were confirmed to have PH by RHC. PCWP was elevated in 13 pts. TPG was < 15 in 2 pts and > 15 in 11 pts. In patients with elevated PCWP, PVR was elevated in 54% (n = 7). mPAP was strongly related to PVR (0.719) but moderately related to PCWP (0.521) and PASP (0.483). Despite only 7 measurements, there was a strong relation between BNP and RAP (0.935), PASP (0.868), and mPAP (0.74).

In conclusion, in this study 2D echo reasonably predicts PH in HD patients. The majority had elevated PCWPs, but also TPGs and PVRs suggesting mixed processes. The relation between PCWP and mPAP is relatively weak confirming the need for further investigation of the chronic effects of fluctuating volume status and high flow dialysis shunts on the pulmonary vasculature.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2646

**Hepatitis B Virus (HBV) e Seromarkers in Prevalence Hemodialysis (HD) Patients** Alicja E. Grzegorzewska,[1] Jerzy Uzar.[2] *[1]Department of Nephrology, University of Medical Sciences, Poznan; [2]B.Braun Avitum, Legnica, Poland.*

HBV e antigen (HBeAg) serves a marker of active HBV replication. Antibodies to HBeAg (HBeAb) appear once HBeAg has been cleared and persist for 5-6 years. Total antibodies to core HBV antigen (HBcAb) appear before HBeAg disappearance and last for the entire life, possibly with HBV minichromosome in liver cells of both HBV surface antigen (HBsAg) carriers and non-carriers. Our aim was an evaluation of epidemiological status of HD population by examination of HBsAg negative patients for presence of HBV e seromarkers in relation to results of total HBcAb testing. Among prevalence HD patients, known as HBsAg negative according to at least every 6-month HBsAg monitoring, positive HBcAb/negative HBV DNA (n = 89) and negative HBcAb (n = 112) patients were blindly selected. Interval between seroconversion and detection of HBcAb positivity remained unknown. HBeAg and HBeAb were determined in HBcAb positive group; results of HBeAb testing were related to demographic, clinical and laboratory data. HBeAg and HBcAb (for control) were simultaneously determined in HBcAb negative group. Early non-HBsAg carrier stage (HBeAb positive) was shown in 46 (51.7%), whereas late non-HBsAg carrier stage (HBeAb negative) – in 43 (48.3%) of all HBcAb positive patients. As compared to HBeAb negative patients, HBeAb positive subjects were younger (53.6 ± 15.6 vs 64.0 ± 13.5 years), had shorter interval between first detection of HBcAb and current HBeAb determination (16.5 ± 15.5 months vs 22.1 ± 19.3 months) and showed lower prevalence of positive antibodies to hepatitis C virus (HCVAb) (28.3% vs 41.9%). None HBcAb positive patient was HBeAg positive. HBcAb negativity was confirmed in all 112 patients. In this group, one patient (0.89%) was HBeAg positive, what indicated an early stage of HBV infection (confirmed by positive HBsAg testing immediately performed). Testing of HD patients for HBV e seromarkers shows that prevalence of HBeAb positivity in HBcAb positive non-HBsAg carriers is present in approximetwly 50% of cases and is related to younger age and lower prevalence of HCVAb positivity. Testing of HBsAg negative patients for HBeAg can occasionally detect HBV replication.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2647

**Increased Local Expression of Connective Tissue Growth Factor (CTGF) Is an Earlier Event Than Peritoneal Thickening in Peritoneal Dialysis Patients** Alferso C. Abrahams,[1] Amelie Dendooven,[2] Tri Q. Nguyen,[2] Roel Goldschmeding.[2] *[1]Nephrology, UMC, Utrecht, Netherlands; [2]Pathology, UMC, Utrecht, Netherlands.*

**Introduction**

Chronic treatment with peritoneal dialysis (PD) is complicated by peritoneal fibrosis and thickening, which leads to loss of ultrafiltration capacity. It has been suggested that transforming growth factor-β1 (TGF-β1) plays a central role in this process. CTGF is a downstream mediator of profibrotic TGF-β1 activity and plays a key role in the pathogenesis of multiple fibrotic disorders. We hypothesized that increased CTGF precedes PD-associated peritoneal thickening.

**Methods and Results**

A biopsy of the parietal peritoneum was obtained during kidney transplantation procedure in 17 PD patients and 17 non-PD patients, i.e. ESRD patients treated by either hemodialysis or during a pre-emptive kidney transplantation. Mean PD duration in the PD group was 31±18 months, and none of the PD-patients had signs of ultrafiltration failure. The thickness of the submesothelial compact zone was independently and blindly assessed by two examiners on H&E-stained formalin-fixed tissue using image analysis software. TGF-β1 and CTGF mRNA expression were assessed by quantitative real-time PCR.

Although average peritoneal thickness was not different between the PD patients and non-PD patients (111±86 μm vs. 101±42 μm), peritoneal expression of CTGF mRNA was significantly increased in PD patients compared to non-PD patients (fold change 2.4±0.8 vs. 1.0±0.6, p < 0.05). There was no correlation between peritoneal CTGF mRNA expression and peritoneal thickness. Gene expression of TGF-β1 in peritoneum was not significantly

different (fold change 1.8±0.9 in PD patients vs. 1.0±0.8 in non-PD patients, p = 0.19), but there was a correlation between TGF-β1 and CTGF ($r^2 = 0.21$, $p < 0.006$).

**Conclusions**

In PD patients, increased peritoneal CTGF expression appears to precede peritoneal thickening and loss of PD efficiency. This temporal relation suggests that CTGF might play an important role in fibrotic events leading to peritoneal thickening and ultrafiltration failure. Almost 80% of the peritoneal CTGF expression is explained by other factors than TGF-β1.

## SA-PO2648

**Survival of Neonates, Infants and Toddlers Commencing Renal Replacement Therapy** R. Todd Alexander,[1] Bethany J. Foster,[2] Marcello Tonelli,[1] Andrea Soo,[3] Alberto Nettel-Aguirre,[3] Brenda Hemmelgarn,[3] Susan M. Samuel.[3] *[1]University of Alberta; [2]McGill University; [3]University of Calgary.*

BACKGROUND: It is known that children younger than 4 years old experience increased morbidity and mortality with ESRD, however, there is a paucity of detailed long-term follow-up data.

METHODS: We utilized a population-based retrospective cohort design employing data from a national organ failure registry and administrative data from Canada's universal health care system. We included 87 children (ages 0-2) who initiated renal replacement therapy (RRT) during the period 1992 to 2007 and followed them until death or date of last contact (median follow-up 4.67 years [interquartile range 1.37-9.83]). We assessed overall survival and impact of age at onset of RRT on survival.

RESULTS: Patients were mostly male (69.0%) and the etiology of ESRD was due to renal malformations in 54%. Peritoneal dialysis was the most common initial renal replacement modality (83.9%) and 57 (65.5%) children received a renal transplant. During 490 person-years of follow-up, there were 23 (26.4%) deaths; 22 of these occurred in patients who never received a transplant. Average age at renal transplantation was 2.82 years (SD: 1.14). Average weight at transplantation was 12.78 kg (SD: 3.07). Overall 5 and 10 year unadjusted survival from initiation of RRT were 74.9% (95% CI: 66.1% - 84.8%) and 72.9% (95% CI: 63.7% - 83.4%). In unadjusted analysis, children who initiated RRT between 0-3 months had decreased survival compared to those initiating RRT between 1-2 years (Fig. 1, log rank p = 0.04).

CONCLUSION: Children initiating RRT before 3 months of age have significantly increased mortality compared with those initiating RRT at an older age. Among those children receiving a transplant the overall survival was good.

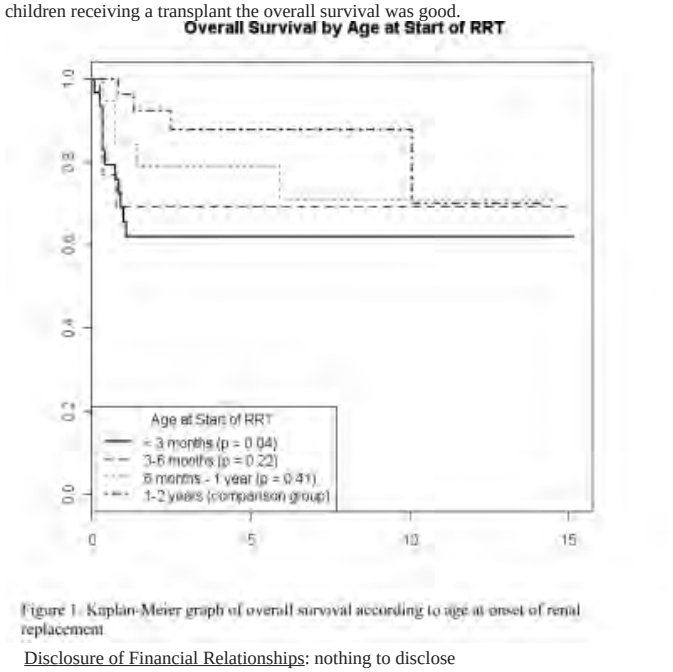

Figure 1. Kaplan-Meier graph of overall survival according to age at onset of renal replacement

**Death, Dialysis and Renal Transplantation among Aboriginal Children with Kidney Failure in Canada** Susan M. Samuel,[1] Marcello Tonelli,[2] Bethany J. Foster,[3] Alberto Nettel-Aguirre,[1] R. Todd Alexander,[2] Andrea Soo,[1] Brenda Hemmelgarn.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada; [3]McGill University, Montreal, QC, Canada.*

**Background:** Ethnicity is a risk factor for adverse outcomes among patients with end-stage renal disease. We evaluated differences in overall survival, time spent on dialysis and kidney transplantation rates among Aboriginal and Caucasian children in Canada. **Methods:** We used a population-based retrospective cohort design utilizing data from a national organ failure registry and administrative data of a universal healthcare system. Patients (ages 0-18) who were Aboriginal or Caucasian starting renal replacement therapy (RRT) in Canada between years 1992 and 2007 were followed until death, last contact or study end (Dec 31, 2007). **Results:** Among 843 paediatric patients who initiated RRT during study period, 104(12.3%) were Aboriginal and 521(62.5%) were Caucasian. During study period, 65(12.5%) Caucasians and 15(14.4%) Aboriginals died. Overall 5 and 10 yr survival from start of RRT for Aboriginal patients were 91.3%(95% CI: 85.6% - 97.3%) and 84.8%(95% CI: 76.4% - 94.3%), and among Caucasians were 92.2%(95% CI: 89.8% - 94.7%) and 85.8%(95% CI: 82.2% - 89.6%) respectively. There was no evidence of a difference in overall survival between the two groups (log rank p=0.29) Aboriginal children spent longer on dialysis before first kidney transplant: 1.75 years(IQR 0.69-2.81); compared to Caucasians: 0.75 year(IQR 0.08-1.75); p < 0.001. Unadjusted kidney transplantation rates per 100 person years were 10.8(95% CI 8.5-13.6) for Aboriginals and 12.3(95% CI 11.2-13.4) for Caucasians (Rate ratio: 1.14(95% CI: 0.89-1.45), p = 0.30). Among Aboriginals, 67.1% of first kidney transplants were from deceased donors and in Caucasians, 42.9% first kidney transplants were from deceased donors(p <0.001).**Conclusions:** There was no evidence of a difference in unadjusted survival between Canadian Aboriginal and Caucasian children starting RRT. Aboriginal children spent longer on dialysis prior to receiving a transplant. Evaluation is needed to examine barriers to receiving a kidney transplant among Aboriginal children.

## SA-PO2650

**Benfotiamine Protects Human Peritoneal Mesothelial Cells Against AGE Mediated Damage in PD** Sandra Muller-Krebs, Lars Kihm, Laura Mertes, Martin G. Zeier, Vedat Schwenger. *Nephrology, University of Heidelberg, Heidelberg, Germany.*

Introduction

High glucose and advanced glycation end-products (AGE) were suggested as contributing factors for local peritoneal damage. Previous studies demonstrated the ability of the lipid-soluble thiamine derivative benfotiamine (BF) to decrease high glucose induced tissue damage by an activation of transketolase (TK).

Methods

Human peritoneal mesothelial cells (HMPC) were isolated from omenta and incubated with low (1.5%) and high (3.9%) glucose containing PD fluids (PDF) either ± BF substitution for 48 h.

Expression of TK was assessed using immunofluorescence (IF). AGE mediated damage was analyzed by IF and western blot regarding the expression of the receptor for AGE (RAGE), epithelial to mesenchymal transition (EMT), and the cytoskeletal organization. For quantitation a semiquantitative score was used. The inflammatory status was analyzed by ELISA technique. Data are shown as mean ± SD.

Results

After incubation with PDF, HPMC revealed a decreased level of TK, higher expression of RAGE and vimentin as a marker of EMT. Moreover there was a higher percentage of HPMC exhibiting a reorganized actin cytoskeleton.

When cells were incubated with BF and PDF, TK expression was higher in the low glucose group in comparison to low glucose PDF without BF incubation (PDF1.5: 1.30±0.15 vs. PDF1.5+BF: 1.61±0.22, p<0.05).

RAGE expression was significantly lower when incubated with BF (PDF1.5: 1.65±0.11 vs. PDF1.5+BF: 1.37±0.14, p<0.001; PDF3.9: 1.71±0.16 vs. PDF3.9+BF: 1.49±0.14, p<0.001), EMT, shown by vimentin expression, was reduced (PDF1.5: 1.78±0.37 vs. PDF1.5+BF: 1.60±0.40, p<0.05; PDF3.9: 2.15±0.57 vs. PDF3.9+BF: 1.69±0.64, p<0.05). The actin cytoskeleton was reorganized in less % of when incubated with BF (PDF1.5: 26.3±13.1 vs. PDF1.5+BF: 17.5±7.54, p<0.01; PDF 3.9: 28.5±9.75 vs. PDF3.9+BF: 24.8±11.8). Interleukin-6 release was reduced by incubation with BF (PDF3.9 [ng/ml]: 6.14±2.91 vs. PDF3.9+BF [ng/ml]: 3.57±2.19).

Conclusions

Our findings suggest that BF mediates activation of TK and thereby provides specific protective effects to HMPC that affect RAGE, EMT, cytoskeletal organization, and inflammation during AGE mediated damage in PD.

**Protective Effects of Non Glucose-Based Peritoneal Dialysis Fluid (PDF) Against PD-Induced Hypoxic Peritoneum** Wasin Manuprasert,[1] Sirigul Kanchanabuch,[1] Somchai Eiam-Ong,[2] Talerngsak Kanjanabuch.[1,2] *[1]Kidney&Metabolic Disorder Research Center, Chulalongkorn University, Thailand; [2]Medicine, Chulalongkorn University, Thailand.*

Long-term exposure of the peritoneal membrane to unphysiologic PDF results in an injury of peritoneum. The roles of polyglucose against PDF-induced hypoxic peritoneum were investigated in both *in vitro* & *in vivo*.

**Methods:** 20 Male Sprague-Dawley rats, divided into 3 groups were subjected to twice daily injections with 1) 0.9%NSS, 2) 3.86%G PDF, 3) 7.5%polyglucose solution. After 4- & 12-weeks injections, morphologies of peritoneal membrane, HIF-1α, and VEGF were investigated. To confirm hypoxic condition, pimodazol (hypoxyprobe) was immediately injected to animals prior to sacrifice and was assessed. In *in-vitro* study, omental-derived primary human mesothelial cells (HPMC) were exposure for 15 hours to either of 1.36%G PDF, 7.5%polyglucose solution, or 0.1%FCS in normoxic condition (5%CO2, 95%Air) and hypoxic condition (1%O2, 5%CO2, 94%Air). The mesothelium injury & death were assessed by morphological changes, %LDH release, and TUNEL staining.

**Results:** Rat submesothelial thickness & fibrosis in the omental & parietal peritoneum were increased significantly and corresponded to up-regulation of HIF-1α and VEGF expressions. Both changes were significantly ameliorated compared to injection with

7.5%polyglucose. HPMC cultured with glucose-based PDF for up to 15 hours showed time-dependent morphological changes, which was accompanied by cell death and loss of mesothelial markers, in both normoxic and hypoxic conditions. Using polyglucose significantly ameliorated HPMC injury, loss of mesothelial markers, and apoptosis in response to PDF in both conditions. Beneficial effects of non glucose-based PDF on peritoneal hypoxia were further confirmed using hypoxyprobe. PDF activated VEGF in a dose-dependent manner with attenuation by polyglucose which was consistent both *in-vivo* and *in-vitro* studies.

**Conclusions:** PDF-induced peritoneal hypoxia may act in parallel or synergistically with bio-incompatible properties of PDF to develop long-term peritoneal damages. Using of non glucose-based PDF can prevent PD-induced hypoxic peritoneum.

**Nebivolol (NV) Prevents Peritoneal Membrane (PM) Failure Induced by Peritoneal Dialysis (PD) Fluids** Anna Rita Aguirre,[1] Guadalupe González-Mateo,[3] Hugo Abensur,[1] Patricia Albar-Vizcaino,[2] Mª Luisa Perez-Lozano,[2] Rafael Selgas,[3] Manuel Lopez-Cabrera,[2] Abelardo I. Aguilera.[2] *[1]Nephrology Department, University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Servicio de Nefrología, Hospital Universitario de la Princesa, Madrid, Spain; [3]Servicio de Nefrología, Hospital Universitario La Paz, Madrid, Spain.*

In PD patients, β-blockers have been considered deleterious to PM by their association with loss of ultrafiltration (UF) capacity due to splanchnic vasoconstriction and fibrosis. NV is a new β-blocker with novel characteristics mediated by nitric oxide release. Herein, we analyzed the effects of NV on human peritoneal mesothelial cells (HPMC), on a mice PD model and on 16 PD patients receiving oral NV after suffering an acute myocardial infarction.

***In vitro,*** HPMC were co-treated with NV and TGF-β, to induce epithelial-to-mesenchymal transition (EMT). NV decreased fibronectin and pre-collagen-I production, increased tPA but did not affect the EMT, VEGF, neither vessel-formation (matrix-gel).

***In vivo***, 21 C57BL/6 mice were divided in 3 groups. Control group (CG) carried a PD catheter without PD fluid infusion. Study group (SG) received 2 ml of intraperitoneal dextrose (D) 4.24%/ day and oral NV during 30 days. Positive control (PC) group received 2 mL/ day of intraperitoneal D for 30 days. SG showed lower PM thickness, lower counts of submesothelial vessels (Tie1+), less mesothelial cells suffering EMT (cytokeratin + and α-SMA +) and less AGEs than PC group. The lymphatic vessel counts were similar in all groups. In PD effluent, SG also showed a tendency of decreased IL-6 production. Functionally, NV protected the UF capacity and small solute peritoneal transport (SPT).

***The PD patients*** who received NV showed a lower frequency of high SPT rate than a CG matched by age, gender and PD events during a 2 year follow-up.

***Conclusion:*** NV showed an anti- fibrotic, anti- EMT and pro- fibrinolytic effect on PM exposed to bio - incompatible PD fluids, functionally protecting from UF failure.

## SA-PO2653

**Exposure of Peritoneum to Polymer Catheters for 1-7 Days Results in Acute Inflammation in Rats** Michael F. Flessner,[1] Xiaorong Li,[1] Elise Peery Gomez-Sanchez,[1] Zhi He.[2] *[1]Medicine, University of Mississippi Medical Center, Jackson, MS; [2]Pathology, University of Mississippi Medical Center, Jackson, MS.*

To test the hypothesis that measurable changes in the peritoneum occur rapidly after catheter exposure, polyethylene rings were placed in the peritoneal cavity of 18 Sprague-Dawley rats (E); controls (C, n=18) underwent sham laparotomy without catheters. After 1, 3, 7 days, peritoneal lavage was carried out, the rings recovered and cells adhering to the catheters separated using ultrasound; the cells, catheter, and abdominal swab were cultured for 96 hours to insure sterility. Data from 4 E rats and 3 C rats were discarded due to bacterial contamination. Abdominal wall tissues were collected after sacrifice and processed for CD31, Trichrome, and cytokine immunohistochemistry (IHC). Initial cell densities on the catheter material (#cells/cm$^2$, mean±SE) were: day 1, 976±298; day 3, 18371±2291; day 7, 27313±3343. CD31 staining and peritoneal thickness were significantly greater than controls by day 1; overall means respectively were: E 29.4±3.6 vs C 3.8±3.1 vessels/mm peritoneum; E 46.4±4.6 vs C 25.1±4.1 microns. IHC for VEGF, TGF, and αSMA of E animals was significantly elevated at day 1 and remained elevated through day 7. Real time RT-PCR was done on lavage cells for TNFα, TGFβ, IL-1, CD68, and mineralocorticoid receptor (MR). As expected, inflammation increased after the injury of surgery and was reflected by an increase in inflammatory markers in both groups over the 7 days. However cells recovered from the peritoneal lavage of E rats expressed significantly ($p<0.05$) less mRNA for CD68 and TNFα than C rats. MR expression in peritoneal lavage cells in E rats was more than 10-fold greater than in C rats. Our hypothesis was upheld: innate immune responses likely begin immediately with the introduction into the cavity of the foreign body resulting in measurable structural change in the peritoneum within 24 hours. Sequestration of macrophages may explain the decrease in CD68 and TNFα expressing cells in the E groups. MR, which is also associated with inflammatory events in cardiovascular and renal damage, appears to be involved in the process.

## SA-PO2654

**Chronic HCV Infection Is Associated with Low Serum C-Reactive Protein (CRP) in Hemodialysis (HD)** Philip Goldwasser,[1] Maria Ajaimy.[2] *[1]VA NY Harbor Healthcare System, Brooklyn, NY; [2]SUNY Downstate Medical Ctr, Bkln, NY.*

CRP level is a sensitive indicator of inflammation and mortality risk. CRP has been reported to be lower in HCV patients (pts), but only a borderline effect of HCV on CRP has been reported in HD (Nascimento et al, 2005). In a prevalent cohort of 69 HD pts, we examined the relationship of high sensitivity-CRP to HCV, adjusting for markers of inflammation derived from routine monthly bloodwork, and other potential confounders. After excluding 16 pts who, in the prior month, were diagnosed with an inflammatory condition or hospitalized, 53 pts remained. Samples with CRP below the detectable limit (<0.01 mg/dL) were assigned a value of 0.01 mg/dL (n=4). HCV was present in 26% of the cohort (14/53). HCV pts tended to be younger than non-HCV pts and more often HIV+ (both $p<0.01$), but the groups were similar in diabetes, race, serum albumin, ferritin, white count (WBC), and HD access. CRP ranged from 0.01 to 9.22 mg/dL (median = 0.50 mg/dL). Median CRP was lower in pts with HCV (0.09 mg/dL *vs*. 0.55 mg/dL; $p<0.01$ by Mann-Whitney U-test). When CRP was divided into quartiles, the frequency of HCV was very high (62%) in the lowest quartile (≤0.12 mg/dL), but lower (15%, 7%, and 23%, respectively) in the other quartiles ($p<0.01$ for quartile × HCV status). The 4 pts with undetectable CRP all had HCV, and their mean albumin was 4.1±0.4[sd], suggesting adequate hepatic synthetic status. Log (CRP) correlated with albumin ($r = -0.39$, $p<0.005$), log (ferritin) ($r=0.36$, $P=0.01$), and WBC ($r=0.31$, $P<0.03$). In a multivariate model, log (CRP) continued to be associated with HCV ($P<0.04$), adjusting for albumin ($p<0.06$), WBC ($p<0.08$), log (ferritin) ($P<0.21$), and age ($p=0.3$). When HIV+ pts were excluded, HCV remained the strongest predictor ($p<0.05$), adjusted for the same covariates. **In summary**, among prevalent HD pts, HCV was associated with a lower CRP in both univariate and multivariate analyses. A high proportion of HCV pts had very low CRP. Possible explanations include reduced synthesis, increased clearance, assay interference, and survivor bias. This association may affect the clinical and epidemiologic utility of CRP.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2655

**Hepatitis C Virus Infected Chronic Hemodialysis Patients Have Increased Cardiovascular Risk** Nageswara Reddy Pamidi. *Nephrology, Kasturba Medical College, Manipal, Karnataka, India.*

**BACKGROUND:** Cardiovascular disease (CVD)is the leading cause of mortality in hemodialysis subjects.This study is done to assess effect of HCV infection on oxidative stress markers and its correlation to arterial stiffness in HD.

**METHODS:** A prospective study done with IEC approval and informed consent. Serum levels of malondialdehyde as thiobarbituric acid reactive substance (TBARS), protein carbonyl content (oxidant stress), protein sulfohydryl groups as antioxidant marker are measured and were correlated with Carotid-Femoral pulse wave velocity (cfPWV) and Aortic augmentation(Aix) done by SphygmoCor.®

**RESULTS:** Demographics comparable among all groups ($p>0.05$). As the duration of HD is significantly higher in HCV positive subjects they were divided into 2 sub groups to nullify the effect of HD duration. HD is associated with raise in serum TBARS and protein carbonyl content and a decrease in protein sulfhydryl levels. HCV infection augments the adverse effects of HD on serum markers of oxidative stress as shown in Table1.

Table 1

| PARAMETER | CONTROL(a) | HCV NEGATIVE(b) | HCV POSITIVE < 2 YRS(c) | HCV POSITIVE ≥ 2 YRS(d) |
|---|---|---|---|---|
| Serum TBARS (nmol/L) | 3.54±0.32 | 8.82±2.21 | 12.59±3.68* | 11.01±2.75* |
| Protein carbonyl (nmol/L) | 0.66±0.21 | 1.23±0.38 | 1.77±0.89* | 2.00±0.76* |
| Protein sulfhydryl (µmol/mL) | 588.3±29.03 | 302.3± 99.54 | 234.8±77.9* | 233.1±77.8* |
| Serum NO (µmol/L) | 33.67±5.78 | 8.18±4.12 | 9.13±3.51 | 10.29±7.84 |
| cf PWV (m/s) | 7.4±1.19 | 11.0±1.45 | 11.91±0.76* | 13.0±1.35* |
| AIx (%) | 8.7±0.63 | 28.7±4.64 | 31.0±6.41 | 37.5±5.27* |

* p=<0.001 betqween (b) & (d)

The increased oxidative stress in HCV positive patients is probably not due to increased duration on HD as there is no significant difference between these among group **c** compared with those of group **d**. The markers of arterial stiffness viz. PWV and AiX are higher in HCV positive compared to those without HCV again after nullifying the effect of duration on HD.

**CONCLUSION:** As there is increased oxidative stress and arterial stiffness in HCV infected hemodialysis patients they can have increased cardiovascular mortality and morbidity. Long term follow up studies are recommended.

## SA-PO2656

**Effect of Gadolinium Contrast on Iron Metabolism Pathways and Inhibition by Iron Chelator** Sundararaman Swaminathan,[1] Chhanda X. Bose,[1] Sudhir V. Shah,[1] Kim M. Hiatt.[2] *[1]Nephrology, University of Arkansas for Medical Sciences, Little Rock, AR; [2]Dermatopathology, University of Arkansas for Medical Sciences, Little Rock, AR.*

**Background**: Nephrogenic Systemic Fibrosis (NSF) is characterized by fibrosis and infiltration of fibrocytic cells. We have recently demonstrated iron mobilization and tissue accumulation of iron in NSF. Cellular pathways that participate in iron dysmetabolism of NSF are unknown. CD163- Heme Oxygenase (HO-1) – Ferroportin pathway is well known to be a pivotal regulator of iron metabolism in the body.

**Methods:** We first evaluated the *in vitro* effects of Omniscan on cultured human peripheral blood mononuclear cells (PBMC). Unsorted PBMC were cultured with various concentrations of Omniscan (0.1 to 2.5 mmol/Kg BW) in DMEM medium. Between Day 5-8, adherent cells were isolated and evaluated with flow cytometry and immunofluorescence for phenotype and protein expression confirmed with western blot. We performed additional *in vitro* studies with oral iron chelator- deferiprone to evaluate its effect on Omniscan-induced changes. We also performed immunohistochemistry on NSF biopsy specimen for a panel of cellular markers.

**Results:** Omniscan treatment induced increased number of adherent spindle cells which morphology similar to fibrocytes. Omniscan-treated cells strongly expressed markers of Iron metabolism such as CD163, HO-1, H-Ferritin and *Iron export protein*- Ferroportin and inhibited Hepcidin. Iron chelator significantly decreased the development of $CD163^+$ adherent spindle cells. Spindle cells in NSF skin biopsies showed strong expression of CD163 and Ferroportin.

**Conclusion:** Omniscan induces development of $CD163^+$ spindle cells *in vitro* and $CD163^+$/ Ferroportin-$1^+$ cells accumulate in human NSF lesions. Strong activation of CD163-HO-1-H-Ferritin-Ferroportin pathway and inhibition of Hepcidin *in vitro* by Omniscan taken along with inhibition of $CD163^+$ spindle cell development by deferiprone suggests a potent role of CD163 scavenger pathway and iron export in NSF pathogenesis.

## SA-PO2657

**Neutrophil Gelatinase-Associated Lipocalin (NGAL) in Hemodialysis (HD) Patients Correlates with Iron Status, Increases by Intravenous Iron Administration (IVIR) and May Modulate Its' Complications** David Tovbin,[1] Shani Kesari,[3] David Sola-Del Valle,[6] Jonathan M. Barasch,[6] Amos Douvdevani,[2] Moshe Zlotnik,[1] Amir Abd Elkadir,[4] Shimon Storch.[5] *[1]Nephrology, Soroka Medical Center; [2]Nephrology Laboratory, Soroka Medical Center; [3]Joyce and Irving Goldman Medical School; [4]Biomedical Engineering, Ben-Gurion University of the Negev; [5]Nephrology, Bnai-Zion Medical Center, Haifa, Israel; [6]Nephrology, Columbia Medical Center, New York, NY.*

Neutrophil gelatinase-associated lipocalin (NGAL) binds the bacterial iron carrier siderophore protecting against infection, and increases in infection, inflammation and oxidative stress. These disturbances are present in hemodialysis (HD) patients, augmented by intravenous iron (IVIR) and associated with impaired iron homeostasis, anemia and atherosclerosis. We hypothesized that NGAL in HD patients is affected by iron status and IVIR and modulates their complications. Thus, we assessed the relation of serum NGAL levels and their changes by IVIR to iron, inflammation and oxidative stress related parameters. In a prospective study, 20 chronic HD patients in 2 hospitals received 100 mg /week iron-sucrose in midweek HD for 4 weeks after 4 weeks without IVIR. Serum NGAL levels and iron, inflammation and oxidative stress (AOPP-advanced oxidation protein products) related parameters were evaluated at mid week sessions in HD without IVIR and with the 1st and 4th IVIR. Comparing the 1st center 14 patients to the 2nd center 6 patients, pre-1st IVIR serum ferritin (116 ± 235 ng/ml Vs 417 ± 574 ng/ml, p<0.01) and iron (45 ± 24 Vs 71 ± 37 µg/100 ml, p<0.05) levels were lower, and were associated with lower NGAL levels (69 ± 46 Vs 227 ± 141 ng/ml, p<0.05). In 1st center, IVIR increased serum NGAL to pre-4th IVIR levels of 188 ± 47 ng/ml (P<0.001)), parallel to increase in ferritin (to 236 ± 290 ng/ml, p<0.0001). Pre-1st IVIR NGAL levels were negatively associated with 1st IVIR % CRP change (r=-0.45, p<0.05) and AOPP change (r=-0.54, p<0.054, NS). Conclusions: Serum NGAL in HD patients correlates with iron status and in depleted patients increases with IVIR. NGAL may modulate IVIR related complications.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2658

**The Effect of Different Types and Doses of Iron on Inflammaton and Oxidative Stress in Hemodialysis Patients** Rumeyza Kazancioglu,[1] Savas Ozturk,[1] Meltem Gursu,[1] Cagdas Kaya,[2] A. Baki Kumbasar,[2] Abdulkadir Ergen,[2] Zeki Aydin,[1] Sami Uzun,[1] Serhat Karadag.[1] *[1]Nephrology, Haseki Training and Research Hospital, Istanbul, Turkey; [2]Internal Medicine, Haseki Training and Research Hospital, Istanbul, Turkey.*

**INTRODUCTION:** There are many studies about inflammatory and atherogenic effects of intravenous iron(IVI). Moreover, monthly total dose iron application has not been compared with standard intermittent therapies. Herein, different doses and types of IVI were examined for late effects on inflammatory-oxidative stress indices.

**METHODS:** Stable chronic hemodialysis(HD) patients with hemoglobin levels more than 8gr/dl were included if they did not have history of recent bleeding, transfusion, oral or parenteral iron use within the last 15 days and active infection. Patients were grouped as those not receiving IVI(Group 1, n=29, 100mg/week), those having intermittent iron sucrose(Group 2, n=25, 100mg/week), those receiving intermittent iron dextran(Group 3, n=24, 100mg/week) and those having monthly total dose iron dextran(Group 4, n=23, 400mg/week). Samples for MDA(malone dialdehyde), AOPP(advanced oxidation protein product), CRP(C-reactive protein) and TNF-α were taken at days-0, 2, 7 and 30 within the first 10 minutes of dialysis. Statistical analysis was carried on by SPSS for Windows with p values less than 0.05 being accepted as significant.

**RESULTS:** 101 patients with a male/female ratio of 48/53 were included. The mean age of the patients was 47.6±13.9 years. Groups were similar in terms of age, gender, hemoglobin, iron indices and total monthly amount of IVI. When all patients were considered together; MDA levels at days-7 and 30; AOPP levels at days-0 and 30, CRP levels at day-30 and TNF-α levels at day-7 were significantly higher than other days. But, there were not any significant differences within and between groups in multi-and bilateral group analysis. IVI injections were well tolerated in all groups without significant side effects.

**CONCLUSION:** Although IVI has potential oxidant effects; the different types and doses of IVI treatments are well tolerated without negative effects on lipid and protein oxidation and inflammatory indices in chronic HD patients.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2659

**Effects of Intravenous (IV) Iron Sucrose (IS) Preparations on Oxidative/ Nitrosative Stress and Inflammatory Markers in Rat Brain** Jorge E. Toblli, G. Cao, J. Giani, M. Munoz, L. Oliveri, F. Dominici. *Hospital Aleman, University of Buenos Aires.*

**Purpose:**IV iron is effective in treating iron deficiency, but iron may be associated with oxidative stress and inflammation. Clinical experience with the original IS Venofer® is based on >240 million doses used up to 2010, but subtle differences in IS similar (ISS) products affect iron release. This study explores potential differences on oxidative and nitrosative stress and inflammatory response in the brain of normal rats. **Methods:**5 groups of Sprague-Dawley rats were studied: G1(IS); G2(ISS Portugal); G3(ISS Colombia); G4(ISS Argentina), G5(controls). G1,G2,G3&G4 received IV iron weekly (40mg iron/kg), and G5 normal saline solution, on days 0, 7, 14, 21 and 28. TBARS and GSH/GSSH ratio were evaluated in brain homogenates. Nitrotyrosine, IL-6, TNF-alpha, heat shock protein-70 (HSP70) and caspase-3 were detected by immunohistochemistry.

Results after 5 weekly injections of 40mg iron/kg

*p<0.01 vs all groups **p<0.01 vs G2, G3 & G4

**Conclusions:**The tested ISSs cause substantially more oxidative and nitrosative stress, increased inflammatory response and apoptosis in the brain of normal rats than the original IS. It is possible that, in contrast to the originator IS, significant amounts of weakly-bound iron are liberated from these ISS due to lower stability of the iron complex.

Disclosure of Financial Relationships: Research Funding: Vifor (International) AG, a company of Vifor Pharma group.

## SA-PO2660

**Comparison of Iron Sucrose and Iron Sucrose Similar Substances on Oxidative Stress and Inflammatory Parameters in the Rat** Jorge E. Toblli, G. Cao, L. Oliveri, M. Angerosa. *Hospital Aleman, University of Buenos Aires.*

**Purpose:** Subtle differences in the structure of intravenous (IV) iron carbohydrate complexes like iron sucrose (IS) may affect iron release, which can result in oxidative stress and inflammation. This abstract summarizes 5 nonclinical studies evaluating IS similar (ISS) preparations vs the original IV IS (Venofer®) using identical methodologies. **Methods:** 11 groups of Sprague-Dawley rats (n=8) received IV iron preparations weekly (40mg/kg body weight on days 0, 7, 14, 21 & 28): $ISS_1$ Feriv, Spain; $ISS_2$ Hematin, Colombia; $ISS_3$ Generis, Portugal; $ISS_4$ Energavit, Argentina; $ISS_5$ Fe-lib, Taiwan; $ISS_6$ Ferplex SS, Pakistan; $ISS_7$ Encifer, India; $ISS_8$ Fesin, Japan; $ISS_9$ Anerrum, South-Korea; IS Venofer; controls (C) received normal saline. At the end of the 4-week studies, oxidative stress parameters (TBARS) were evaluated in liver homogenates. TNF-a was evaluated by immunohistochemistry. **Results:** IS and ISS groups differed in terms of iron markers, markers of oxidative stress and inflammation, and functional parameters (p<0.01).

**Effects of α-Lipoic Acid on Oxidative Stress in ESRD Patients Receiving IV Iron** Arif Showkat,[1] Joanna Q. Hudson.[1,2] *[1]Medicine, University of Tennessee, Memphis, TN; [2]Clinical Pharmacy, University of Tennessee, Memphis, TN.*

Oxidative stress is associated with increased risk of cardiovascular disease in ESRD patients (pts). IV iron has been shown to increase oxidative stress in this population. The purpose of the study was to evaluate changes in oxidative stress markers following administration of IV sodium ferric gluconate (SFG) to hemodialysis pts with and without prior administration of the antioxidant α-lipoic acid.

ESRD pts who met inclusion criteria were enrolled in this open-label, crossover study. During a control (C) and intervention (I) visit 125 mg IV SFG was administered over 10 minutes. During the I visit 600 mg of α-lipoic acid was given orally 30 minutes prior to IV SFG. Pts received both treatments in random order. Blood samples were collected at 0, 15, 30, 60, 90, 120, 150, and 180 minutes post-infusion for measurement of malondialdehyde (MDA), F2-isoprostane (FIP), lipid hydroperoxide (LHP), and iron indices. The change in oxidative stress markers over time and differences in the percent change at each time point between C and I were evaluated.

Ten African-American ESRD pts were enrolled; 5 males; mean age 45±9 yrs; mean Hb13±1 g/dL; ferritin 571±241 ng/mL; TSat 27±4%. MDA, FIP, and LHP increased significantly for both C and I visits after administration of IV SFG with a greater increase observed in the I group.

Percentage Change of Oxidative Markers Over Time

| Time (min) | 30 | 60 | 90 | 120 | 180 |
|---|---|---|---|---|---|
| MDA-C | 12.6±8.9 | 21.7±26.5 | 19.4±30.5 | 22.3±38.7 | 19.6±39 |
| MDA-I | 25±22 | 72.1±96.3* | 66.7±70.6* | 60.6±60** | 65.9±69.3** |
| FIP-C | 20.7±8.9 | 13.8±20.7 | 19.5±17.5 | 7.7±21.1 | 10.8±15.9 |
| FIP-I | 30.3±18.7 | 56.8±32.4** | 37.6±28.7 | 38.9±40.4** | 19.9±34 |
| LHP-C | 28.2±18.3 | 23.5±13.2 | 16.2±10 | 9.4±10.4 | 5.1±6.1 |
| LHP-I | 36.1±15.8 | 37.4±18** | 28.7±15.3** | 23.1±13.2** | 14.8±8.4** |

Values expressed as mean ± SD. MDA & LHP in μmol/L, FIP in pg/mL. *P≤0.01, **0.01>P ≤0.05 compared to C group.

Administration of IV SFG is associated with an acute rise in oxidative stress . In contrast to previous studies, administration of an antioxidant was associated with a greater increase in oxidative stress.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2662**

**Prolyl Hydroxylase Inhibitors Reduce Hepcidin Levels and Affect Multiple Iron-Modulating Proteins** Richard A. Brigandi,[1] Mangatt Biju,[2] Jennifer L. Ariazi,[2] Sanjay Kumar,[1] Kevin James Duffy,[2] Connie L. Erickson-Miller.[1] *[1]GlaxoSmithKline, King of Prussia, PA; [2]GlaxoSmithKline, Collegeville, PA.*

Hepcidin and other iron-modulating proteins are responsible for the regulated release and transport of iron to the marrow to optimize erythropoiesis. The role of prolyl hydroxylase inhibitors (PHI) on these proteins was investigated using several small molecule α-ketoglutarate mimetic compounds. Hep3B cells were treated for 6 h with 25 ng/mL BMP-6 to stimulate an up-regulation of hepcidin. Following 16 h treatment with 3-50 uM PHI, quantitative RT-PCR (qRT-PCR) was performed to assess mRNA levels. PHI compounds stabilized HIF-1 and HIF-2 protein expression in Hep3B cells and induced EPO production. Results from qRT-PCR demonstrated that BMP-6 enhanced the level of hepcidin mRNA 12-15-fold, while the amount of hemajuvelin mRNA increased very slightly. However, following PHI treatment there was a consistent 3-fold decrease in hepcidin and 3-6-fold decrease in hemajuvelin mRNA. TMPRSS6 mRNA was not induced by BMP-6, but increased ~2-fold in response to PHI. These data suggest that PHI compounds can regulate an expanded set of iron modulating proteins rather than just the BMP-induced hepcidin. This is most likely a direct effect of the PHI as evidenced by data in which treatment with EPO (10-1000 mIU/mL) did not reduce the level of hepcidin mRNA in BMP-6 stimulated Hep3B cells. To determine the effects of PHI on iron-regulation in vivo, rats were treated with a single oral dose of vehicle or PHI (30 mg/kg) and livers collected at 0, 2, 4, 6, 8, 10, 12, 14, 16 and 24 h. The levels of mRNA were determined by qRT-PCR. There was a statistically significant increase in mRNA expression of EPO as early as 2 h and of ferroportin over 5 timepoints. There was a 15-fold decrease in hemojuvelin and hepcidin mRNA in the liver. Thus, inhibition of prolyl hydroxylases by small molecule compounds affects multiple iron-modulating genes in both in vitro and in vivo systems. The changes in this set of iron utilization proteins suggest that the PHI compounds can directly modulate the release and transport of iron to ensure adequate availability for more efficient erythropoiesis.

**The Prolyl Hydroxylase Inhibitor, GSK1278863A, Induced EPO *In Vitro* and Efficient Erythropoiesis Leading to Increased Hemoglobin *In Vivo*** Richard A. Brigandi,[1] Jennifer L. Ariazi,[2] Kevin James Duffy,[2] Lusong Luo,[2] David F. Adams,[1] Connie L. Erickson-Miller.[1] *[1]GlaxoSmithKline, King of Prussia, PA; [2]GlaxoSmithKline, Collegeville, PA.*

GSK1278863A is a highly selective orally bioavailable small molecule prolyl hydroxylase inhibitor that demonstrated *in vitro* and *in vivo* responses predictive of erythroid responses in humans. In biochemical assays, GSK1278863A inhibited EGLN 1(PHD2) and EGLN3(PHD3) with an IC50 of 22 and 5.5 nM, respectively. Treatment of the liver carcinoma Hep3B cell line for 6 hours with 25 and 50 μM GSK1278863A resulted in the accumulation of both HIF1α and HIF2α protein. Erythropoietin (EPO) mRNA was induced 7-fold relative to vehicle at 16 hrs following treatment of Hep3B cells and a 4-fold increase in EPO protein was detected in Hep3B conditioned medium at 24 hrs. These *in vitro* responses were predictive of the production of EPO and elevation of hemoglobin observed in mice, rats and dogs. A single 60 mg/kg oral dose of GSK1278863A in normal mice increased EPO mRNA by 450- and 60-fold in the liver and kidney, respectively at 6-8 hours post treatment. An 8-fold increase in plasma EPO protein levels was also observed at 8 hrs. Daily oral GSK1278863A gavage of normal mice for 8 days resulted in significant changes in all red blood cell parameters. Increases in hemoglobin of up to 2.8 g/dL relative to vehicle were observed after dosing with 3-30 mg/kg GSK1278863A. Increases in hematocrit and RBC were also observed. Daily oral GSK1278863A gavage in normal rats resulted in statistically significant 9-22% increases in hemoglobin, hematocrit and RBCs at 3 and 10 mg/kg/day following 14 and 21 days treatment. Progressive increases in red blood cell parameters, preceded by reticulocytosis, were also observed over the course of a one month study in dogs receiving daily oral doses of 3 mg/kg/day. Thus, stabilization of HIFa subunits and the production of EPO mRNA and protein by GSK1278863A predicted the *in vivo* responses in mice, rats and dogs of increased plasma EPO protein, and increased hemoglobin and other red blood cell parameters. Increased plasma EPO was also observed in healthy subjects treated with a single dose of GSK1278863A.

**SA-PO2664**

**Ezetimibe Improves Dyslipidemia and Oxidative Stress Conditions in Hemodialysis Patients** Yoshifumi Hamasaki, Kent Doi, Eisei Noiri, Toshiro Fujita. *Nephrology and Endocrinology / Hemodialysis and Apheresis, The University of Tokyo, Tokyo, Japan.*

[Background] Dyslipidemia and oxidative stress are the traditional and non-traditional cardiovascular risk factors for hemodialysis (HD) patients. Ezetimibe (EZT) is a new cholesterol-lowering agent that inhibits cholesterol absorption at small intestine. Little is known whether administration of EZT to HD patients is safe and effective to improve dyslipidemia and oxidative stress.

[Method] Twenty hyperlipidemic ESRD patients receiving maintenance HD were treated by EZT (10mg/day) for 6 months. Lipid profile and oxidative stress conditions were compared with control HD patients who had untreated dyslipidemia. Oxidative stress condition was evaluated by Reactive Oxygen Metabolites test (d-ROMs test) and Biological Anti-oxidant Potential test (BAP test) that have been developed to quantify oxidative stress and anti-oxidant capacity in blood easily.

[Results] After administration of EZT for 6 months, three patients were discontinued EZT. LDL cholesterol level and non-HDL cholesterol level were significantly reduced in the EZT group (n=17) compared with the control group (n=16) [-25.7% versus 4.0%, $p<0.05$ and -24.7% versus 2.4%, $p<0.05$, respectively]. MDA-LDL level was also reduced in the EZT group (-36.6% versus -13.8%, $p<0.05$). EZT significantly reduced value of d-ROMs test in the patients with low inflammation [$\log_{10}$(hs-CRP) <3.5] and high HDL cholesterol level (HDL-C >45 mg/dl) at 0 month compared with the control patients of the same profile [-10.0% in the EZT subgroup (n=11) versus 13.2% in the control subgroup (n=9), $p<0.05$]. In the patients with low serum albumin (<4.0 g/dl) at 0 month, value of BAP test (anti-oxidative stress) were maintained at 6 month in the EZT group [the change rate is 0.6% in the EZT subgroup (n=5) versus -12.9% in the control subgroup(n=9), $p<0.05$].

[Conclusion] EZT in HD patients improve lipid profile effectively and safely. EZT showed potential beneficial effect to reduce oxidative stress in HD patients with low inflammation and high HDL cholesterol, and to maintain anti-oxidant capacity in patients with low serum albumin level.

**SA-PO2665**

**Effect of Brazilian Nut Supplementation on Selenium and Glutathione Peroxidase in Hemodialysis Patients: A 12-Month Follow-Up** Milena Barcza Stockler-Pinto,[1] Denise Mafra,[2] Najla Elias Farage,[1] Viviane Oliveira Leal,[2] Julie Lobo,[1] Carolina Souza Sulis,[2] Gilson Teles Boaventura,[2] Olaf Malm,[1] Denis Fouque,[4] Silvia Maria Franciscato Cozzolino.[3] *[1]Federal University of Rio de Janeiro, Brazil; [2]Federal Fluminense University, Brazil; [3]University of São Paulo, Brazil; [4]University Claude Bernard Hopital Edouard, France.*

In hemodialysis (HD) patients large amounts of reactive oxygen species (ROS) are produced and, at higher concentrations, ROS are thought to be involved in the pathogenesis of cardiovascular disease. Selenium (Se) may exert an anti-atherogenic influence by reducing oxidative stress. The richest known food source of selenium is the Brazil nut (*Bertholletia excelsa*) found in the Amazon region. **Objective**: To evaluate the effect of Brazil nut supplementation on plasma Se and glutathione peroxidase (GSH-Px) activity in HD patients and verify if the effects could be sustained after 12 months.

**Methods**: 81 HD patients (52.0 ± 15.2 yr, dialysis vintage 82.3 ± 91.4 mo, BMI of 24.9 ± 4.4 kg/m$^2$) were studied. 21 patients were followed 12 months without supplementation. All patients received 1 nut, average of 58.1 μg Se/g, a day for three months. Se concentration in nuts and in plasma was determined by atomic absorption spectrophotometry with hydride generation and the levels of GSH-Px were measured by using commercial kits.**Results**: Plasma Se (17.3 ± 19.9 μg/L) was below normal (60 - 120μg/L) before nut supplementation. After 3 months of supplementation, plasma Se increased to 106.8 ± 50.3 μg/L ($p< 0.0001$), and after 12 months it decreased to 31.9 ± 14.8 μg/L ($p< 0.0001$). The activity of GSH-Px also increased after supplementation from 46.6 ± 14.9 to 55.9 ± 23.6 U/gHb ($p<0.0001$). Before supplementation, 11% of patients had GSH-Px activity below normal range (27.5

– 73.6 U/gHb) and after supplementation, all patients showed GSH-Px activity within the normal range.**Conclusion**: HD patients were Se deficient and consumption of only one brazilian nut per day (5 g) during 3 months was effective to increase Se and GSH-Px parameters. Selenium levels 12 months after the supplementation period were not as low as pre-supplementation levels but yet significantly lower.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2666**

**Impact of Intradialytic Low-to Moderate Intensity Exercise Training on Cellular Inflammation** Christof Ulrich,[1] Henning Theissinger,[1] Roman Fiedler,[1] Sylvia Hanika,[1] Axel Schlitt,[2] Eric Seibert,[1] Matthias Girndt.[1] *[1]Internal Medicine II, Martin-Luther University Halle-Wittenberg, Halle (Saale), Germany; [2]Internal Medicine III, Martin-Luther University Halle-Wittenberg, Halle (Saale), Germany.*

Exercise training strengthens the performance of haemodialysis patients and appears to lower their high cardiovascular risk burden. We speculated that improvement of cardiovascular outcome by exercise training may partially be attributed to a reduction of cellular inflammation to which the inflammatory CD16+ monocyte subset is linked.

21 pts were enrolled in a low-to-moderate intradialytic exercise program, 14 of whom (49.8±8.0 years) were willing to take part in cycling exercises (EX) thrice a week. 7 pts served as controls (CO: 54.0±10.5 years). Serum parameters were analysed at baseline (t0), 4 (t4), 8 (t8) and 12 (t12) weeks. Monocyte subsets, CD14++CD16- (Mo1), CD14++CD16+ (Mo2), CD14(+)CD16+ (Mo3) were determined by flow cytometry at t0, t8 and t12. Analysis was performed using Repeated Measures ANOVA.

The mean cycling time exceeded 30 min (t4:38.8±9.4; t8:41.3±13.9; t12:41.1±15.8). The average cycling power capacity increased over time (t4:18.7±6.9; t8:21.0±10.5; t12:27.0±13.0 (watt), $p<0.01$ (t4 vs. t12). CRP was not different in both groups. Phosphate and potassium serum levels did not change; calcium levels significantly increased in EX (t0:2.2±0.2; t8:2.3±0.2; t12:2.4±0.1, $p<0.001$, t0 vs. t12]. Mean blood pressure slightly decreased in EX (t0:90.8±15.3; t4:89.9±12.5; t8:86.5±11.0; t12:87.4±13.0, $p=0.06$), and remained unchanged in CO (t0:96.2±11.6; t4:96.7±10.3; t8:94.1±8.8; t12:94.8±8.3, $p=0.33$). Although Mo3 values tended to be lower in CO (%Mo3; t0:17.1±7.4; t8:12.0±8.3; t12:12.7±9.2; $p=0.24$), the frequency of inflammatory Mo3 only significantly declined over time in EX (%Mo3; t0:23.1±11.2; t8:16.0±4.6; t12:12.5±6.9; $p<0.001$, t0 vs. t12).

Our data indicate a trend in blood pressure lowering and therefore improvement of the cardiovascular risk profile by exercise training. We observe a trend for reduction of cellular inflammation, however, a potential decrease of CD16+ monocytes remains to be confirmed after longer exercise training.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2667**

**Ethylene-Vinyl Alcohol Copolymer Dialyzer Membrane Reduces Protein Oxidation in Hemodialysis Patients** Yoshihiro Matsumoto,[1] Hiromachi Kumagai.[2] *[1]Nephrology, Shizuoka City Hospital, Shizuoka, Japan; [2]University of Shizuoka, Shizuoka, Japan.*

*Background:* Oxidative stress has been implicated in the cardiovascular complications that affect hemodialysis (HD) patients. Ethylene-vinyl alcohol copolymer (EVAL) dialyzer membrane induces less production of reactive oxygen species compared to conventional dialyzers. We evaluated the impact of EVAL membrane on plasma protein oxidation in HD patients.

*Methods:* HD patients treated with cellulose triacetate (CTA) dialyzers were selected. In the first study performed in a 2-month crossover design alternating between CTA and EVAL, nonmercaptalbumin (HNA) and advanced oxidation protein products (AOPP) levels were measured in the predialysis blood from 10 subjects. In the second study, predialysis plasma myeloperoxidase (MPO) levels were measured before and after a 2-week EVAL treatment on 12 patients.

*Results:* Plasma AOPP levels were significantly reduced after a 2-month EVAL treatment and increased again after CTA treatment, although the HNA proportions were not affected significantly by the change in dialyzer membranes. The following study, a 2-week EVAL treatment, showed the decrease in MPO levels immediately before HD.

*Discussion:* The frequent use of EVAL dialyzers has been shown to reduce protein oxidation, possibly through the suppression of circulating phagocytes. This novel biocompatible dialyzer is expected to protect cardiovascular mortality in HD patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2668**

**Increasing Continuous Renal Replacement Therapy Intensity in Septic Patients with Acute Kidney Injury: A Single-Center Randonmized Clinical Trial** Ping Zhang, Lina Shao, Jing Yuan, Jianghua Chen. *The Kidney Disease Center, The First Affiliated Hospital, Medical College, Zhejiang University, Hangzhou, Zhejiang, China.*

Acute renal injury (AKI) is an important complication in septic patients and is an independent predictor of mortality. However the optimal renal replacement therapy intensity and timing in septic patients with AKI is still unclear. We randomly assigned septic patients with AKI to continuous replacement therapy (CRRT) with high volume hemofiltration (50ml per kilogram per hour ,HVHF group) or extra high volume hemofiltration (85ml per kilogram per hour , extra high volume group, EHVHF group).*The primary study outcome was death from any cause within 28 day, 60 days and 90days after randomization.* Of the 280 patients enrolled patients, 141 was assigned to the EHVHF group and 139 to the HVHF group. Data were available for 230 patients, 114 patients in EHVHF group and 116 in HVHF group. The two groups had similar baseline characteristics and received the study treatment for average of 10.9 and 10.8 days respectively ($p=0.95$). At 28 days after randomization, 59 patients (51.75%) died in the EHVHF group and 57 (49.13%) in the HVHF group. At 9o days after randomization, 64 patients died in the EHVHF group (56.14%) and in the HVHF group (55.17%) respectively The probability of death in 90days was also similar between the two groups by Kaplan –Merier method ($p=0.942$). No differences were found of renal outcome in survivors to 90d after randomization between the two groups ($p=0.374$). Inotropic support of norepinephrine, time in hospital more than 7 days, Blood platelet count less than 8*10E9/L, APACHE II score >25 and total bilirubin >170 umol/L before randomization were the independent risk in 90d survival after renal replacement for sepsis and AKI patients. In septic patients with AKI, increasing intensity of CRRT didn't improve the survival at 28 days and 90 days.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2669**

**Evolution of Endothelial Injury on Dialysis and after Kidney Transplantation** Keren Mandelzweig,[1] Claudio Rigatto,[2] Lisa M. Miller,[2] Manish M. Sood,[2] Paul Komenda,[2] David N. Rush,[2] Joe A. Bueti.[2] *[1]Department of Internal Medicine, University of Manitoba, Winnipeg, MB, Canada; [2]Section of Nephrology, Department of Internal Medicine, University of Manitoba, Winnipeg, MB, Canada.*

Cardiovascular disease progresses on dialysis and improves after renal transplantation. Endothelial injury (EI) may play a role, but changes in EI over time on dialysis and post-transplantation are poorly characterized. We measured soluble Vascular Cell Adhesion Molecule-1 (VCAM), a validated measure of EI, in a retrospective cohort of kidney transplant patients between Jan. 1, 2000 and Dec. 31, 2005 (n=186). Patients with a minimum of 2 serum samples drawn at least 6 months apart in both the pre and post transplant periods were analyzed (n=172). Data abstraction was by chart review. VCAM was measured by ELISA. Mixed linear modeling was used to analyze changes in VCAM as a function of time and transplantation, adjusted for age, gender and several time dependent variables (co-morbidities, dialysis modality, medications and heparin induced antibodies (HIA)).

VCAM levels increased progressively on dialysis (49 ng/mL per year, $p<0.0001$). Transplantation was associated with a large decrease in VCAM (-664 ng/mL, $p<0.0001$ within one month). VCAM levels continued to decline in the 24 months post transplantation (143 ng/mL per year, $p<.0001$). Adjustment for all confounders did not alter these relationships. Medications and HIA levels were not associated with VCAM. Age and heart failure were associated with higher VCAM levels; however, these variables did not predict change in VCAM slope before or after transplant (i.e. all variable*time interactions=NS). VCAM pre transplant was a predictor of death ($p=.04$) and the composite outcome of death and vascular events ($p=.03$). In conclusion, EI worsens over time on dialysis and significantly improves post renal transplantation. These longitudinal repeated measures data confirm less rigorous cross-sectional observations, and may partly explain the elevated CVD rate in dialysis and the salutary effect of transplantation. We speculate that components of dialysis not measured in our analysis drive EI in ESRD.

Disclosure of Financial Relationships: nothing to disclose

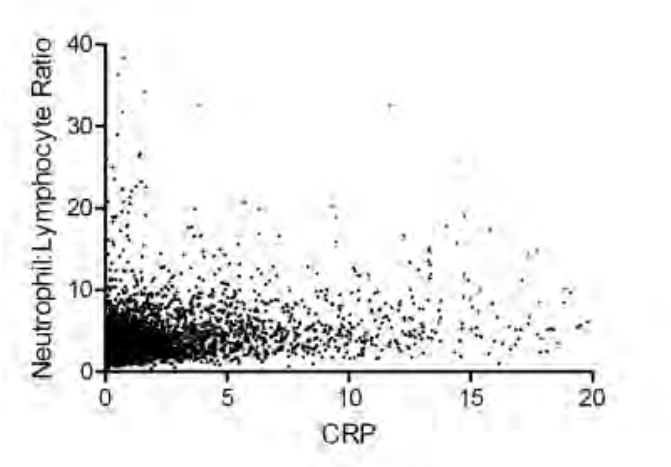
**SA-PO2670**

**Neutrophil to Lymphocyte Ratio, White Blood Cell Count, and Ferritin Are Not Validated Surrogates for Inflammation in End-Stage Renal Disease Patient** Mahesh Krishnan, Carey Colson, Steven M. Wilson, Robert Provenzano. *DaVita Inc., Denver, CO.*

Background: Despite the fact that patients on dialysis have significant amounts of inflammation, the gold standard test, C reactive protein (CRP) is not routinely monitored. As a result, epidemiologic studies have attempted to use surrogates such as Neutrophil to Lymphocye ratio (NLR), white blood cell count (WBC) and ferritin. To date, these surrogates have not been validated but continue to be widely used in analyses. Using a large US dialysis provider's database, we sought to complete this validation.

Methods: CRP values from 4,565 dialysis patient samples collected between 2007 and 2009 were correlated with same day NLR , absolute WBC count and ferritin. Correlation coefficient was determined by Pearson's for each value

Results: CRP values did not correlate with NL ratio ($r2 = 0.07$; see Figure), WBC ($r2 = 0.10$) or ferritin ($r2 = 0.02$).



Conclusions: NLR, WBC and ferritin were not validated as surrogates for inflammation (through CRP values) in a large number of ESRD patient samples. These values should not be used to adjust for inflammation in prospective or retrospective studies in dialysis patients. Further work should be done to find better surrogates for inflammation in ESRD patients until CRP or similar testing is more routinely used.

Disclosure of Financial Relationships: Employer: DaVita Inc; Other Relationship: Previous Employer Amgen Inc. (until July 2009).

**SA-PO2671**

**Pentraxin 3 Is a Useful Marker of the Microinflammatory Response during a Single Hemodialysis Session** Tae Yamamoto,[1] Marcelo M. Nascimento,[1,3] Shirley Yumi Hayashi,[1,2,3] Abdul Rashid Tony Qureshi,[1] Jacek Waniewski,[1] Björn Anderstam,[1] Astrid Seeberger,[1] Britta Lind,[2] Bengt Lindholm.[1] *[1]Renal Medicine and Baxter Novum, Karolinska Institute, Stockholm, Sweden; [2]Medical Engineering, Royal Institute of Technology, Stockholm, Sweden; [3]PUCP, Curitiba, Brazil.*

The acute impact of the hemodialysis (HD) procedure on cardiovascular disease (CVD) risk markers such as circulating cytokines and proteins involved in vascular calcification is not fully known. Therefore we studied changes in circulating CVD risk markers during a single HD session, and examined putative associations with carotid intima-media thickness (IMT).

We enrolled 44 clinically stable patients (median age 56 years; 64% males) who were treated by conventional HD with cellulose acetate membrane, three times a week (3.5-4 hours per session) and measured circulating markers of *inflammation* (CRP, IL-6, TNF-alpha and PTX3), *vascular calcification* (FGF23, OPG and fetuin-A) and *oxidative stress* (8-OHdG) before and after a single session of HD. Protein concentrations were corrected for ultrafiltration during HD. IMT was measured by ultrasonography.

Whereas small molecules decline during HD (e.g., 8-OHdG from 0.26 to 0.16 ng/ml; $p<0.001$), the pattern of changes of larger not dialyzable substances differs markedly: Markers related to *vascular calcification* did not change (fetuin-A) or decreased (OPG and FGF23), and among *inflammation markers*, hsCRP was unchanged and TNF-alpha decreased. In contrast, the median IL-6 increased by 16 % from 4.9 to 5.6 pg/ml ($p<0.05$) and the median PTX 3 increased by 45 % from 4.5 to 7.1 ng/ml ($p<0.001$). Changes in PTX3 and IL-6 were observed in patients with normal IMT, while in patients with abnormal IMT who had already high values of PTX3 and IL-6, the concentrations did not change significantly during HD. Among the measured risk markers, OPG, IL-6 and hsCRP levels were associated with IMT.

We conclude that a single HD session resulted in increased levels of IL-6 and PTX3 whereas CRP did not change. IL-6 and especially PTX3 could be valid markers to monitor the intradialytic inflammatory response during HD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2672**

**Decrease in Frataxin (FRX) Is Linked to Oxidative Stress in Patients on Maintenance Hemodialysis (MHD)** Yukiko Hasuike, Hiroshi Nonoguchi, Yoshinaga Otaki, Takanori Nagai, Masayoshi Nanami, Takahiro Kuragano, Takeshi Nakanishi. *Internal Medicine, Division of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.*

**Introduction**. The mitochondrial (Mito) protein, FRX, regulates iron metabolism in Mito and attenuates iron-mediated oxidative damage. FRX is reduced in neuro- and cardio-degenerative disease, Friedreich's ataxia. We have already reported the dysregulation of iron metabolism in polymorphonuclear leukocytes (PMNLs), from MHD patients. To clarify whether FRX is affected and linked to oxidative stress in MHD, the association of FRX and several parameters related to uremic status were investigated. **Methods**. 17 MHD patients and 15 healthy controls were recruited in the study. Relative quantitative polymerase chain reaction was used to measure frataxin messenger RNA (mRNA) in PMNLs and FRX content was semiquantified by means of Western blot analysis. Serum albumin (Alb) and several parameters of iron metabolism, inflammation, (interleukin-6 [IL-6], tumor necrosis factor-α [TNF-α], high sensitivity-C reactive protein [hCRP]), malondialdehyde (MDA) as a marker of oxidative stress and dose of erythropoietin were determined. **Results**. FRX mRNA levels in PMNLs from MHD patients were significantly lower compared with those in healthy subjects (54.5%). Western blot analysis confirmed that content of the corresponding protein paralleled that of the mRNAs (65.0%). Serum MDA levels as well as markers of inflammation were significantly elevated in MHD. FRX mRNA levels were significantly associated with serum iron, TNF-α, IL-6, hCRP, MDA and Alb. In stepwise multiple regression analyses, MDA was only selected as an independent predictor of FRX in PMNLs ($R^2=0.661$, $p<0.0001$). **Discussion**. Decrease in FRX content could cause the acceleration of oxidative stress in MHD patients, which might be related to the dysregulation of iron metabolism in Mito.

**SA-PO2673**

**Growth Arrest Specific Gene 6 (Gas6) Levels Are Elevated in Chronic Hemodialysis Patients** Iris J. Lee,[1] Gautam S. Choure,[1] Brijesh S. Bodiwala,[1] Brendan A. Hilliard,[2] Jesse M. Goldman,[1] Jean Lee,[1] Philip L. Cohen.[2] *[1]Section of Nephrology, Temple University, Philadelphia, PA; [2]Section of Rheumatology, Temple University, Philadelphia, PA.*

Purpose: Gas6 is a vitamin-K dependent protein with diverse biologic functions. Animal and in vitro studies demonstrate a role for Gas6 in mediating endothelial and vascular smooth muscle cell function, atherosclerosis and vascular calcification. Gas6 also has multiple functions in leukocyte biology and inflammation. Little is still known about the role of Gas6 in humans, and no data exists on Gas6 levels in hemodialysis patients. Given the increased prevalence of vascular disease and chronic inflammation in the ESRD population, we investigated whether Gas6 plasma levels are altered in patients on chronic hemodialysis.

Methods: Blood samples were obtained from 23 normal subjects and 53 chronic hemodialysis patients from a university affiliated dialysis center. Patients with known malignancy, coagulation disorders, or on warfarin therapy were excluded. Pre-dialysis blood was collected and Gas6 quantified in plasma by ELISA.

Results: Plasma samples from 52 chronic dialysis patients were compared to 23 healthy normal subjects. The mean Gas6 level in normal subjects was 36.23ng/ml +/- 18.33 and the mean Gas6 level in dialysis patients was on average 3 fold higher 102.8 +/- 35.19, ($p<.0001$). The dose of intravenous iron was directly associated with higher Gas6 levels. ($r=.33$; $p=.0138$) Conversely, albumin levels were inversely associated with Gas6 levels. ($r=-.34$; $p=.0121$) In a multivariate analysis, albumin and iron dose were found to be independently associated with Gas6. There was no significant correlation found between Gas6 levels and hemoglobin, Epogen™ dose, ferritin, PTH, Ca, Phos, Kt/V, presence of DM, HTN and CAD.

Conclusions: This is the first report of Gas6 levels in hemodialysis patients. Gas6 may be increased in dialysis patients secondary to chronic inflammation. Low albumin and higher IV iron administration was associated with higher Gas6 levels, suggesting a possible connection between inflammation, oxidative stress mediated by iron and development of vascular disease in dialysis patients.

**Serum Calprotectin Increases with Time in Haemodialysis Patients: An Important New Factor in the Modulation of Response to Inflammatory Stress** Laura E. A. Harrison,[1] Ruth J. Pepper,[2] James O. Burton,[1] Alan D. Salama,[2] Chris W. McIntyre.[3] *[1]Department of Renal Medicine, Royal Derby Hospital, United Kingdom; [2]Renal Section, Imperial College London, United Kingdom; [3]School of Graduate Entry Medicine and Health, University of Nottingham, United Kingdom.*

Haemodialysis (HD) patients suffer a complex of metabolic stress, systemic inflammation and dialysis induced end-organ ischaemia resulting in elevated cardiovascular mortality. Interactions within this pathophysiology are still poorly characterised. Calprotectin (MRP8/14), a protein expressed in neutrophils, is implicated in modulation of the inflammatory response. Previous study has identified elevated calprotectin levels in prevalent HD patients. We aimed to study prospective changes in calprotectin levels and the associated cardiovascular risk 'phenotype' in HD patients.

50 established HD patients were studied at baseline and 12 months later. Dialysis details and blood samples were taken pre-HD. Serum calprotectin (sCAL) was quantified with ELISA and endotoxin (ET) (resulting from presumed gut translocation and indicative of non-infective pro-inflammatory stress) by LAL assay.

At study inclusion, pre-HD sCAL level was 2961[IQR 2383-6206]ng/ml, with 34% of patients having undetectable levels. Only 28% had sCAL levels >3500ng/ml (clinically relevant cutoff cf healthy controls). There were no significant differences in sCAL levels between patients with or without diabetes or cardiovascular comorbidities and no significant correlations with systemic inflammation as measured by serum hsCRP or IL6.

A year later, median sCAL levels had significantly increased to 6874 [IQR 3693-11097] ng/ml ($p<0.05$), no patients had undetectable levels, and the proportion of patients with levels >3500ng/ml increased from 28% to 78%. Serum ET from presumed gut translocation (in the absence of clinically apparent infection) demonstrated a degree of significant correlation with sCAL in survivors.

Calprotectin levels increase with time in HD patients and appear in part to be associated with non-infective dialysis induced inflammatory stress. The role of regulation of pro-inflammatory neutrophils and macrophages in these processes awaits further elucidation.

**SA-PO2675**

**Osteopontin Levels Are Elevated and Related to Bone, Vascular and Inflammatory Markers in Pediatric Dialysis Patients** Douglas M. Silverstein,[1] Poyyapakkam Srivaths,[2] Stuart Goldstein.[3] *[1]Pediatric Nephrology, Children's National Medical Center, Washington, DC; [2]Pediatric Nephrology, Baylor College of Medicine, Houston, TX; [3]Pediatric Nephrology, Cincinnati Children's Hospital Medical Center, Cncinnati, OH.*

Osteopontin (OPN) is an extracellular matrix cell adhesion protein that is expressed the bone, kidney and vasculature. OPN plays a role in bone turnover, immunity, and vascular modeling. We assessed serum OPN levels in 16 children (16.6±3.3 years) receiving maintenance hemodialysis (HD). The mean OPN level was 1099.0±331.8 (range 116.5-4603) ng/ml. Only two patients exhibited OPN levels <200 ng/ml while seven had levels >500 ng/ml. OPN levels were unrelated to either spKt/V (r= -0.01; p=0.9) or dialysis vintage (r=0.15, p=0.5). Serum intact parathyroid hormone (iPTH) and vascular cell adhesion molecule-1 (sVCAM-1) levels were significantly higher in patients with OPN levels >420 ng/ml. OPN levels were positively associated with markers of bone turnover (iPTH: r=0.77; p=0.0005), vascular disease (sVCAM-1: r= 0.65; p=0.006 and sE-Selectin: r= 0.76; p=0.0006) and inflammation (TNF-alpha: r= 0.52; p=0.04).

| PARAMETERS | CORRELATION (r) | p VALUE |
|---|---|---|
| Intact PTH | 0.77 | 0.0005 |
| Serum Calcium | 0.25 | 0.3 |
| Serum Phosphorous | 0.39 | 0.1 |
| sVCAM-1 | 0.65 | 0.006 |
| sE-Selectin | 0.76 | 0.0006 |
| sICAM-1 | -0.12 | 0.7 |
| TNF-alpha | 0.52 | 0.04 |

We conclude that serum OPN levels are elevated in pediatric ESRD patients and correlate with markers of bone turnover, vascular disease and inflammation. OPN therefore seems to be another important link in the bone-vascular-inflammation disease axis in ESRD.

Disclosure of Financial Relationships: nothing to disclose

**Serum Zinc Concentrations Is Negatively Correlated with Electronegative LDL in Hemodialysis Patients** Julie Lobo,[1] Milena Barcza Stockler-Pinto,[1] Luciana Nicolau Aranha,[2] Najla Elias Farage,[1] Viviane Oliveira Leal,[2] Dulcinéia Saes Parra Abdalla,[3] João Paulo Torres,[1] Denis Fouque,[4] Denise Mafra.[2] *[1]Federal Univ of Rio de Janeiro, Rio de Janeiro, Brazil; [2]Federal Univ Fluminense, Niterói, Brazil; [3]Univ of São Paulo, São Paulo, Brazil; [4]University Claude Bernard Hopital Edouard Herriot, France.*

Oxidative modification of low-density lipoprotein (LDL) plays a key role in the pathogenesis of atherosclerosis. The generation of minimally oxidized LDL, also called electronegative LDL [LDL(-)], is present in plasma at higher concentrations in diseases with high cardiovascular risk, such as chronic kidney disease (CKD). Zinc is an essential micronutrient that can function as an antiinflammatory and antioxidative agent, and as such, it may have atheroprotective properties. However, patients with CKD often exhibit zinc deficiency.Our aim was to investigate the relationship between LDL(-) levels and plasma zinc levels in hemodialysis (HD) patients. **Methods:** The levels of LDL(-), zinc and Tumos necrosis factor-alpha (TNF-α) were measured in 50 patients undergoing HD (31M/19F) from RenalCor Clinic, Rio de Janeiro, Brazil [age 54.3 ± 12.6yr, on dialysis for the mean period of 49.7 ± 46.5 months and Body mass index (BMI) 24.4 ± 4.1 Kg/m2)] and compared to 21 healthy subjects (HS) (9M/12F) (age 50.7 ± 15.7yr, BMI *25.5 ± 4* Kg/m$^2$). LDL(-) was measured by ELISA, zinc by atomic absorption spectrophotometry and TNF-α by a multiplex assay kit. **Results:** HD patients presented higher LDL(-) levels (0.18 ± 0.12 U/L) when compared to HS (0.11 ± 0.92 U/L) (p=0.02) and TNF-α was also higher in patients (5.9 ± 2.1 pg/ml) than in HS (2.49 ± 1.1 pg/ml) (p=0.0001). While zinc levels were significantly lower in HD patients (54.5 ± 16.3 µg/dL) than in HS (78.4 ± 9.4 µg/dL) (p=0.0001), 80% of the patients had zinc levels below normal values. We found a negative correlation between LDL(-) and zinc levels in the patients (r=0.43; p=0.0001). **Conclusion:** In the present study, HD patients showed significantly increased levels of LDL(-) and TNF-α, and decreased levels of zinc than HS. Zinc deficiency can contribute to the development of atherosclerotic cardiovascular disease in these patients.

**Vascular Endothelial Growth Factor Increase Differentially Regulates Cytokines in End Stage Renal Disease** Vinod K. Bansal,[1] Debra Hoppensteadt,[2] Evangelos Litinas,[2] Indermohan Thethi,[2] Jawed Fareed.[2] *[1]Department of Nephrology, Loyola University Medical Center, Maywood, IL; [2]Department of Pathology, Loyola University Medical Center, Maywood, IL.*

Vascular endothelial growth factor (VEGF) mediates nitric oxide dependent angiogenic effects contribute to the inflammatory responses. VEGF is upregulated in ESRD and contributes to the cardiovascular dysfunction in ESRD. VEGF is also upregulated by erythropoietin which is commonly used in the management of ESRD patients. With the availability of BioChip Array Technology , a multiparametric screening of inflammatory mediators/cytokines can be measured and the relevance of VEGF can be established. Utilizing the Randox Biochip technology, we profiled the plasma levels from 53 ESRD patients to determine their relevance to VEGF levels. Pre-dialysis samples from 53 male and female ESRD patients on maintenance hemodialysis were analyzed using a cytokine biochip for VEGF, IL2, IL4, IL6, IL8, IL10, IFNG1, TNF, IL1, IL1, MCP-1 and EGF were analyzed. In addition, NO and asymmetric dimethyl arginine (ADMA) levels were also measured. A group of 50 normal healthy males and females constituted the control group. The circulating levels of VEGF and mediators were compared with the normals. In addition, VEGF levels were compared with the other mediators. In comparison to the normals, ESRD patients exhibited decreased levels of IL4, IL8, TNF and EGF which ranged from 20-210%. Increased levels of IL2, IL6, IL10, IFNG1, IL1 and MCP-1 were noted (20-350%). NO levels were also increased, however ADMA remained unchanged. VEGF levels showed wide variation, however on a cumulative basis a 30-210% increase in VEGF was noted. Except for the MCP-1, the correlation of VEGF with other inflammatory markers was relatively poor (r2=<0.25). These results show that ESRD patients can be profiled for various inflammatory mediators, VEGF levels were markedly increased, however only MCP-1 levels correlated well with the increase in VEGF levels. Additional studies are warranted to clarify the regulatory role of VEGF on inflammatory cytokines in ESRD.αβ®ααα

**SA-PO2678**

**Vascular Endothelial Growth Factor Receptor 2 (VEGF-R2) Is Responsible for the Downstream Signaling Effects Attributed to the beta-Common Receptor (βC-R)** Jennafer Hochmuth, Laura Sautina, Mark S. Segal. *Department of Medicine, University of Florida, Gainesville, FL.*

We have previously demonstrated that the heterodimeric erythropoietin (EPO) receptor and the beta-common receptor (βC-R) are required for EPO-mediated endothelial progenitor cell migration via a nitric oxide (NO) dependent mechanism. Investigation into the mechanism revealed a novel interaction between the βC-R and VEGF-R2 and demonstrated that the stimulation of NO is not dependent on VEGF but is instead dependent on VEGF-R2. Examination of the literature demonstrates that many of the downstream activities of the βC-R and VEGF-R2, such as differentiation, proliferation, and inflammation, are identical. We tested the hypothesis that all of the downstream activities putatively mediated by the βC-R require and are mediated via VEGF-R2. To test this hypothesis we knocked-down expression of the βC-R or VEGF-R2 in HCAECs and studied the effect on tubulogenesis, migration, NO production, proliferation, and inflammation in response to EPO or VEGF stimulation.

We have found a significant increase in inflammatory cytokines in endothelial cells stimulated with high EPO doses (50 mU/mL), however we hypothesize that this is due to EPO-R's interaction with VEGF-R2. Since the km of the homodimeric EPO receptor is 10-fold less than the heterodimeric EPO-R/βC-R, 5 mU/mL versus 50 mU/mL respectively, we examined the downstream effects of low (10 mU/mL) and high (75 mU/mL) EPO doses.

An increasing number of clinical trials have shown that when higher doses of erythropoietin are used in chronic kidney disease patients there is an increase in the number of cardiovascular complications. In addition, high doses of EPO given to breast cancer patients lead to an increased mortality. Interaction and cross-stimulation of EPO-R, βC-R, and VEGF-R2 could explain these adverse outcomes. We believe that understanding each receptor's role will be helpful in correcting and ultimately avoiding adverse side effects and complications attributed to EPO therapy.

**SA-PO2679**

**Association of the Metabolic Syndrome with Periodontal Disease in Hemodialysis Patients** Li-Ping Chen,[1] Chih-Kang Chiang,[2,3] Kuan-Yu Hung.[3] *[1]Department of Dentistry, Chang Gung Memorial Hospital, Taipei, Taiwan; [2]Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan; [3]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.*

Metabolic syndrome and periodontitis both have an increasing prevalence worldwide; however, limited information is available on their association.

Objective: The objective of the study was to assess the association between periodontitis and the metabolic syndrome in a hemodialysis outcome cohort.

Design, Setting, and Participants: Data analysis from the Manutrition and Inflammation Cachexia Syndrome Survey on 253 hemodialysis patients who received periodontal examination was studied.

Main Outcome Measures: Association of diagnosis and extent of microbial dental plaque burdern and periodontitis (gingival bleeding and probing pocket depths by Plaque Index, Gingivial Inedx and Periodontal Disease Index) with the metabolic syndrome and its individual component conditions (central obesity, hypertriglyceridemia, low high-density lipoprotein-cholesterol, hypertension, and insulin resistance) were measured. Adjustment for age, sex, social economical status, general conditions, and smoking were considered.

Results: The prevalence of the metabolic syndrome was 46.2%, and 65.1% among individuals with no-mild and moderate-severe periodontitis, respectively. After adjusting for confounders, hemodialysis patients suffering from moderate to severe periodontitis were 2.03 times (95% CI 1.20–3.448) more likely to have the metabolic syndrome than unaffected and mild periodontitis individuals. Diagnosis of metabolic syndrome increased by 1.56 times (95% CI 1.12–2.16) in increasing severity of gingival inflammation and 1.72 times (95% CI 1.13–12.61) in increasing microbial dental plaque on tooth surface.

Conclusions: Moderate to severe periodontitis is associated with metabolic syndrome in hemodialysis patients. Further studies are required to test whether improvements in oral health lead to reductions in cardiometabolic traits and the risk of metabolic syndrome.

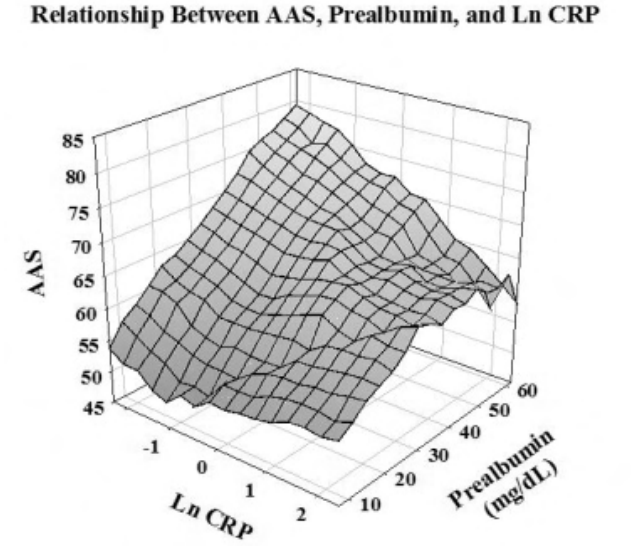
**Association of Self Reported Physical Activity with Laboratory Markers of Nutrition and Inflammation: The Comprehensive Dialysis Study** Shuchi Anand,[1] George A. Kaysen,[2] Kirsten L. Johansen,[3] Barbara A. Grimes,[3] Manjula Kurella Tamura,[1] Glenn M. Chertow.[1] *[1]Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Nephrology, University of California, Davis, Davis, CA; [3]Nephrology, University of California, San Francisco, San Francisco, CA.*

Persons on dialysis maintain extremely low levels of physical activity. Prior studies have demonstrated a direct correlation between nutrition and physical activity but provide conflicting data on the link between inflammation and physical activity. Using a cohort of patients new to dialysis from the Comprehensive Dialysis Study, we examined the correlations among laboratory markers of nutrition and inflammation and physical activity. Baseline laboratory measures--albumin, prealbumin, C reactive protein (CRP) and alpha-1-glycoprotein (AAG)--were collected in a subset of participants who also provided estimates of physical activity using the Human Activity Profile. We present univariate correlation and multivariable analyses adjusting for age, sex, race/ethnicity, diabetes and center. The mean age (n=201) was 61 years. The adjusted activity scores (AAS) and maximal activity scores (MAS) were below the 10th percentile in comparison to healthy 60 year-old volunteers. Both activity scores were directly correlated with albumin (r2=0.3) and prealbumin (r2=0.3), and inversely correlated with CRP (r2=-0.2) and AAG (r2=-0.1). In multivariable analyses activity scores showed a significant direct correlation with prealbumin, and an inverse correlation with CRP.



The magnitude of correlation was modest; prealbumin higher by 0.3 mg/dL or CRP lower by 40% corresponded to a 1 point higher activity score. Our analyses suggest that dialysis patients with evidence of malnutrition or inflammation are likely to report lower levels of physical activity.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2681**

**Association of Dietary Omega-6 to Omega-3 Ratio and Inflammation in Maintenance Hemodialysis Patients** Nazanin Noori,[1] Sameer B. Murali,[1] John J. Sim,[4] Rachelle Bross,[1] Deborah A. Benner,[2] Allen R. Nissenson,[2] Joel D. Kopple,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]DaVita, Lakewood, CO; [3]Salem VA, Salem, VA; [4]Nephrology, Kaiser Permanente, Los Angeles, CA.*

**Background :** Chronic inflammation, as shown by higher levels of C-reactive protein (CRP) is present in maintenance hemodialysis (MHD) patients with protein-energy wasting (PEW). It is not known whether diet has a bearing on inflammation. Many MHD patients eat fast food, which is known to have an unfavorably high ratio of omega-6 to omega-3 poly-unsaturated fatty acids (PUFA) and which may activate pro-inflammatory cascades. **Methods:** Using 3-day dietary record supplemented with dietary interview we examined the correlation of serum CRP changes during the first year and the estimated dietary omega-6 to omega-3 PUFA ratio at the start of the cohort of 145 MHD patients. **Results:** Higher omega-3 intake per se was associated with a non-significant trend towards decreased serum CRP. However, a higher omega-6 to omega-3 PUFA ratio was associated with a significant increase in serum CRP over 12 months, after adjustment for case-mix (age and gender), diet (energy, saturated fatty acids, trans fat, cholesterol and fiber intakes), body mass index, and history of hypertension (HTN) (r=0.20, p=0.03) (see Table).

| | Correlation (r) | p-value |
|---|---|---|
| Age and gender adjusted | 0.16 | 0.09 |
| Case-mix + diet adjusted | 0.19 | 0.04 |
| Previous + BMI + HTN adjusted | 0.20 | 0.03 |

Cubic spline analysis confirmed that higher omega-6 to omega-3 PUFA ratio was associated with likelihood of increase in CRP by at least 5 mg/L. **Conclusions:** Higher omega-6 to omega-3 PUFA intake ratios are associated with worsening inflammation in MHD patients, even after adjustments for other dietary components. These findings support the conclusion that dietary modulation of inflammation is possible in dialysis patients, a hypothesis which requires a randomized controlled trial to confirm.

Disclosure of Financial Relationships: nothing to disclose

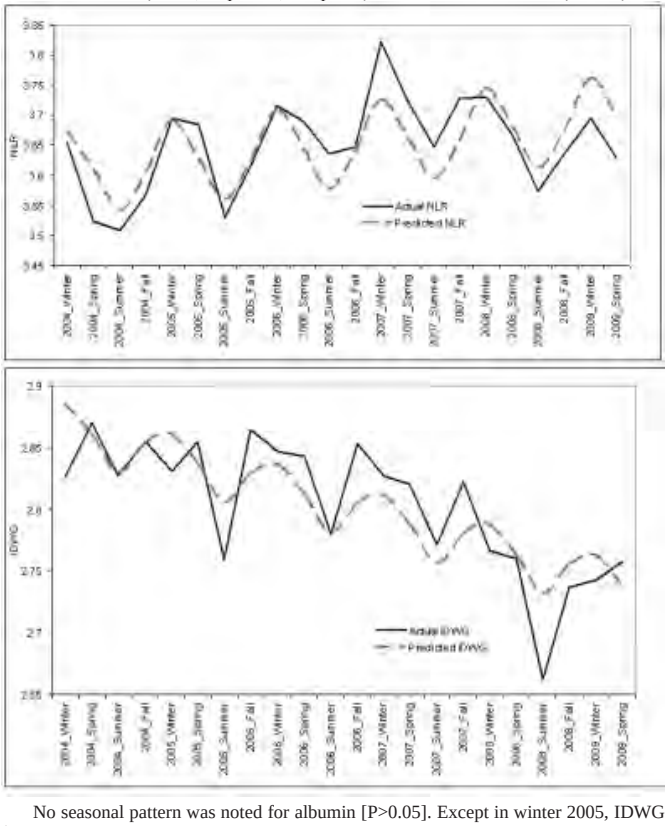
**SA-PO2682**

**Seasonal Variability in Inflammation and Interdialytic Weight Gain in Chronic Hemodialysis Patients** Len A. Usvyat,[1] Jeroen Kooman,[2] Frank Van der Sande,[2] Georges Ouellet,[1] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Renal Research Institute, NY, NY; [2]Maastricht University Medical Centre, Maastricht, Netherlands.*

In the hemodialysis (HD) population, blood pressure and body temperature follows circannual rhythm. However, it is unknown whether inflammatory parameters and intradialytic weight gains (IDWG) also follow a seasonal pattern.

We reviewed records of HD patients (pts) treated in RRI clinics between Apr 1, 2004 and Mar 31, 2009. Only pts with at least one treatment in each of the four seasons were included. Seasons were defined on a calendar basis: winter as Dec through Feb, spring as Mar through May, summer as June through Aug, fall as Sep through Nov. Neutrophil-to-lymphocyte ratio (NLR), albumin, and IDWG were recorded as averages per pt per month and per season. Cosinor analysis was conducted to test for seasonality in NLR, albumin, and IDWG.

In total 10,303 patients were studied (55% male, 49% black, 41% white, 49% diabetic, avg age [stdev]: 60.5 [15.5] years). Cosinor analysis over a five year period demonstrated a seasonal component of NLR with highest NLR in winter and nadir in summer. Coefficients of seasonal factors (mesor, amplitude, acrophase) were different from zero (P<0.05).



No seasonal pattern was noted for albumin [P>0.05]. Except in winter 2005, IDWG followed a cyclical pattern with highest IDWG in winter and lowest in summer [cyclical coefficients p-values<0.10]. IDWG declined over the 5-year period on average by 0.024 kg per year, suggesting improved fluid control in RRI pts.

This study in chronic HD patients demonstrates a significant influence of seasons on NLR with highest inflammation in the winter and lowest in the summer. Albumin did not change over seasons potentially suggesting more food intake in the winter months; this interpretation is corroborated by analysis of IDWG.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2683**

**Hemodialysis Patients with Low and Moderate Level of Inflammation Show a Comparable Immune Response to Influenza Vaccine** Jaromir Eiselt,[1] Terezie Sedlackova,[2] Lukas Kielberger,[1] Jaroslav Racek,[2] Lada Malanova,[3] Petr Pazdiora.[4] *[1]Internal Dept. 1, Charles Univ., Plzen, Czech Republic; [2]Dept. of Biochemistry, Charles Univ., Czech Republic; [3]Dialysis Unit, B.Braun Avitum, Czech Republic; [4]Dept. of Epidemiology, Charles Univ., Czech Republic.*

Hemodialysis patients (HD) suffer from a defective host defense and show a reduced response to vaccines. The immune response to vaccinations in HD can be negatively influenced by inflammatory state.

Our multi-center study was designed to compare the antibody response to the influenza vaccine (Influvac 2009/10) in 35 controls without renal disease and with normal C-reactive protein (CRP) ≤3 mg/L (Controls), 64 HD with CRP ≤3 mg/L (HD LowCRP) and 58 HD with CRP ≥4 and <30 mg/L (HD HighCRP). All participants were in stable condition and had no clinical signs of infection. In addition to CRP, we examined markers of inflammation interleukin-6 (Il-6) and hepcidin. Immune reactivity was evaluated according to an anti-hemaglutinine titer (anti-HA) at baseline and 4 weeks after the vaccination. Seroconversion was defined as at least a 4fold rise in anti-HA. Results are summarized in the table.

Inflammation and response to influenza vaccine

| | Controls (n=35) | HD LowCRP (n=64) | HD HighCRP (n=58) |
|---|---|---|---|
| Interleukin-6 (pg/mL) | 0.89 (0.70-1.60)[a] | 4.08 (2.59-5.34)[b] | 7.09 (4.43-9.38) |
| Hepcidin (ng/mL) | 10 (8-19)[a] | 21 (10-34) | 23 (10-38) |
| A H1N1 seroconversion (%) | 74[c] | 36 | 52 |
| A H3N2 seroconversion (%) | 57 | 39 | 47 |
| B seroconversion (%) | 66[c] | 27[d] | 47 |

Data is median (interquartile range) or % of positive results; Mann-Whitney, Fisher and $\chi^2$ tests; [a]p<0.01 vs. HD LowCRP and HD HighCRP, [b]p<0.001 vs. HD HighCRP, [c]p<0.001 vs. HD LowCRP, [d]p<0.05 vs. HD HighCRP

Normal CRP in HD patient does not exclude substantial elevation of other markers of inflammation, as documented by high Il-6 and hepcidin in HD LowCRP group. The entire HD population displayed diminished immune reactivity to vaccine strains A H1N1 and B when compared to the controls. However, patients with low level of inflammation and those with elevation of markers of inflammation showed comparable immune response to influenza vaccine and both groups should be vaccinated.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2684**

**Catheter Use Associates with Reduced Inflammation and Erythropoetin Resistance in Maintenance Hemodialysis** Albert J. Power, Seema Singh, Kakit Chan, Peter Hill, David Taube, Neill D. Duncan. *Imperial College Kidney & Transplant Institute, West London Renal & Transplant Centre, Hammersmith Hospital, London, United Kingdom.*

Erythropoetin resistance [EPO-R] in hemodialysis associates with greater systemic inflammation. Central venous catheter [CVC] use without superadded infection has been associated with greater inflammation and EPO-R and recent data suggest higher EPO dosing may be harmful. We studied the effect of vascular access type on inflammation and EPO-R.

This retrospective cohort study examined 1163 patients established [>90d] on hemodialysis [HD] Sept 2009-Mar 2010 [7077 observations spanning 8077 patient months, AVF n=213, mean age 63.8±14.4yrs, spKt/V 1.92±0.36, Hb 12.2±1.2g/dL, EPO dose 0.63±0.51mcg/kg/wk]. Dialysis adequacy was targeted monthly to spKt/V≥1.6, weekly IV darbepoetin targeted to hemoglobin [Hb] 10.5-12.5g/dL. A measure of EPO-R, erythropoesis resistance index [ERI] was calculated: weekly dose/postdialysis weight/Hb. Data in the presence of active infection was excluded.

Median CRP was 0.7mg/dL [IQR 0.3-1.5mg/dL] and levels did not differ by vascular access type [p=0.3]. Higher CRP associated with peripheral vascular disease on univariate & multivariate analysis [p<0.001] but not with age, diabetes and other comorbidities, spKt/V or HD vintage.

Older age, female gender, lower CRP [p<0.001] & CVC use [p=0.01] associated with lower ERI on univariate as well as multivariate regression [all p<0.01]. ERI was not significantly associated with spKt/V, ethnicity, HD vintage and major comorbidities.

This large representative study demonstrates that age, gender and low levels of systemic inflammation influence EPO-R. CVC do not associate with higher inflammation and appear associated with lower EPO-R which may relate to low access-related infection rates. This important but apparently counterintuitive finding warrants further prospective study.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2685**

**Activation of Caspase-3 in the Skeletal Muscle during Hemodialysis** Parham Eftekhari, Dominic S. Raj. *Renal Disease and Hypertension, George Washington University, Washington, DC.*

Background: Muscle atrophy in end-stage renal disease (ESRD) may be due to the activation of apoptotic and proteolytic pathways.

Objective: We hypothesized that activation of caspase-3 in the skeletal muscle mediates apoptosis and proteolysis during hemodialysis (HD).

Materials and Methods: Eight ESRD patients were studied before (pre-HD) and during HD and the findings were compared with those from six healthy volunteers. Protein kinetics was determined by primed constant infusion of L-(ring 13C6) Phenylalanine.

Results: Caspase-3 activity in the skeletal muscle was higher in ESRD patients pre-HD than in controls (24966.0±4023.9 vs. 15293.3±2120.0 units, p<0.01) and increased further during HD (end-HD) (37666.6±4208.3 units) (p<0.001). 14 kDa actin fragments generated by caspase-3 mediated cleavage of actomyosin was higher in the skeletal muscle pre-HD (68%) and during HD (164%) compared to controls. The abundance of ubiquitinized carboxy-terminal actin fragment was also significantly increased during HD. Skeletal muscle biopsies obtained at the end of HD exhibited augmented apoptosis, which was higher than that observed in pre-HD and control samples (p<0.001). IL-6 content in the soluble fraction of the muscle skeletal muscle was increased significantly during HD. Protein kinetic studies showed that catabolism was higher in ESRD patients during HD compared to pre-HD and control subjects. Muscle protein catabolism was positively associated with caspase-3 activity and skeletal muscle IL-6 content.

Conclusion: Muscle atrophy in ESRD may be due to IL-6 induced activation of caspase-3 resulting in apoptosis as well as muscle proteolysis during HD.

Disclosure of Financial Relationships: nothing to disclose

**Oxidized LDL Promotes Tregs Apoptosis through GSK-3b Activity in Uremic Patients** Pascal Meier. *Nephrology, CHCVs, Sion, Switzerland.*

Several lines of evidence support the idea that oxidative stress may play a major role in uremic T cell dysfunction. Patients with end-stage kidney disease (ESKD) have increased plasma levels of oxidized low-density lipoproteins (oxLDL). We have demonstrated that oxLDL induce regulatory $CD4^+/FOXP3^+$ T cells (Tregs) cell cycle arrest and apoptosis affecting their suppression capacity and finally promote a constant micro-inflammatory state in patients with ESKD. The present study used human Tregs to test the hypothesis that a physiologically relevant level of oxLDL influences Tregs apoptosis through the reduced expression of the canonical Wnt signaling and the increase expression of glycogen synthase kinase 3 beta (GSK-3b) both responsible for the increase phosphorylation of b-catenin, which affects Bcl-$X_L$ expression. The immunoprofile of peripheral Tregs was examined with protein quantification assays, flow cytometry and quantitative RT-PCR. Tregs from five healthy subjects were cultured in 10% uremic serum or in presence of increasing concentrations (50 to 200 mg/mL) of either native LDL or oxLDL for 72 hours. Uremic serum and oxLDL (200 mg/mL) but not native LDL led to the reduced Wnt signaling and the high expression of phosphorylated GSK-3b in cultured Tregs. The same results were obtained with Tregs from five uremic patients. The down-regulation of the Wnt cascade resulted in cytoplasmic and nuclear phosphorylated b-catenin accumulation. Consecutively, the nuclear expression of Bcl-$X_L$ was reduced and Tregs apoptosis was confirmed (DNA fragmentation). Tregs suppressive capacity was significantly reduced when cultured in 10% uremic serum or with 200 mg/mL oxLDL. In contrast, *in vitro* assays done in the presence of the GSK-3b inhibitor lithium led to dramatically prolonged Tregs survival and improved suppressive capacity *via* nuclear factor of activated T cells (NFAT) that remained in the nucleus. Together, these data demonstrate, in uremic patients, that oxLDL promotes Tregs apoptosis *via* GSK-3b activity, which negatively regulates Tregs physiological response and may contribute to immune dysfunction in patients with ESKD.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2687**

**Altered Function of IL-17 Producing $FOXP3^+$ Regulatory T Cells in Patients with End-Stage Kidney Disease** Pascal Meier. *Nephrology, CHCVs, Sion, Switzerland.*

The IL-17-producing $CD4^+$ T helper cell (Th17) differentiation is induced by a combination of IL-6 and TGF-β and is augmented by induction of IL-21. Signaling induced by these cytokines results in expression of the orphan nuclear receptor RORγt, transcription factors that are required for induction of IL-17 expression. Furthermore, human Th17 memory cells selectively express high levels of CCR6. We report that human peripheral blood from chronic HD patients (n = 10), chronic PD patients (n = 10) and patients with chronic kidney disease (CKD) (n = 10) show a significantly lower number of $CD4^+FOXP3^+$ T cells compared with healthy subjects with normal kidney function (Controls, n = 10) ($p < 0.01$). In HD patients, these cells express significantly less CCR6 and lose the capacity to produce IL-17 upon activation (PMA/iono for 24 h), ($p < 0.02$). $CD4^+FOXP3^+$ T cells from HD patients do not coexpress FOXP3 and RORγt transcription factors. Whereas, the $CD4^+FOXP3^+CCR6^+$ IL-17-producing cells strongly inhibit the proliferation of $CD4^+$ responder T cells in CKD patients and Controls, these cells do not present any regulation in chronic HD and PD patients. $CD4^+FOXP3^+CCR6^-$ regulatory T cells from Controls differentiate into IL-17 producer cells (Th17) upon T-cell receptor (TCR) stimulation in the presence of IL-1β, IL-2, IL-21, IL-23, and human serum. However, this differentiation is excessively marked when cells from Controls are cultured in presence of 10% uremic serum (HD patients). The same results are found with cells from HD patients. This suggests first that in human, the $IL\text{-}17^+FOXP3^+$ Treg cells are found in the periphery. Second, IL-17-producing Treg cells may play critical roles in controlling inflammation. Third, HD patients present a low number of IL-17-producing Tregs, which show an altered function *ex vivo* and *in vitro* with a parallel high number of Th17 with a normal high function. Although the biological significance of T cells that display the function of Tregs and the opposing function of Th17 remains unclear. This may be one mechanistic explanation of the T cell immune dysfunction in uremic patients, and may have important implications in clinics.

**Uremic HDL Disrupts Macrophage Lipid Homeostasis and Potentiates Inflammation** Suguru Yamamoto,[1] Patricia G. Yancey,[2] T. Alp Ikizler,[3] W. Gray Jerome,[4] Valentina Kon.[1] *[1]Vanderbilt University, Pediatrics, Nashville, TN; [2]Vanderbilt University, Medicine, Nashville, TN; [3]Vanderbilt University, Nephrology, Nashville, TN; [4]Vanderbilt University, Pathology, Nashville, TN.*

**Background** Although chronic renal disease (CKD) increases atherosclerotic cardiovascular disease (CVD) the underlying mechanisms are unknown, not explained by traditional risks, and resist conventional lipid lowering therapies. Since macrophage foam cell is the hallmark of atherogenic lesions, we examined if normal lipid homeostasis and inflammatory functions of macrophages are perturbed by lipoproteins from CKD patients on dialysis.

**Methods** Cell cholesterol content, efflux and inflammatory response were assessed in human macrophage-like THP-1 cells and peritoneal macrophages of apolipoprotein E-deficient mice (apoE-/-). Cells were exposed to high density lipoprotein (HDL) fraction isolated from hemodialysis patients (n=10) and matched normal controls (n=10). Sequential density ultracentrifugation was used to isolate HDL fractions. Gas liquid chromatography measured cellular lipid content which determined cholesterol efflux. mRNA expression assessed inflammatory markers.

**Results** Compared with controls, HDL fraction of uremics was less effective in facilitating cholesterol efflux from cholesterol-loaded THP-1 cells (5.3±1.8 vs 16.4±4.8%) or apoE-/- cells (18.6±3.8 vs 22.5±3.3%). Further, HDL of uremics heightened expression of inflammatory cytokines in THP-1 cells (relative mRNA expression for TNF-a: 4.1±0.6 vs 2.0±0.4, IL-6: 13.0±0.8 vs 2.0±0.8, IL-1b: 7.7±0.8 vs 2.0±0.1, $p<0.05$) and apoE-/- cells (relative mRNA expression for TNF-a: 13.0±1.9 vs 5.1±1.4, IL-6: 32.3±6.0 vs 8.4±3.7, and IL-1b: 33.3±4.0 vs 12.6±5.8, $p<0.05$).

**Conclusion** Thus, compared with individuals with intact kidney function, HDL of dialysis patients is revealed to have impaired cholesterol acceptor functions that reduce cholesterol efflux together with heightened inflammatory modulators. These findings predict increased foam cell formation and CVD that may explain dissociation of CVD with plasma lipid levels and resistance to standard lipid lowering therapies in patients with advanced CKD.

**Soluble Epoxide Hydrolase Inhibitor (sEHI) Attenuates Release of Monocyte Chemotactic Protein-1 (MCP-1) from Human Monocytes** William G. Sanders,[1] Christi M. Terry,[2] Yuxia He,[2] Bruce D. Hammock,[3] Alfred K. Cheung.[2,4] *[1]Pharmaceutics, University of Utah, Salt Lake City, UT; [2]Medicine, University of Utah, Salt Lake City, UT; [3]Entymology, UC-Davis, Davis, CA; [4]Medical Service, VAMC, Salt Lake City, UT.*

In synthetic hemodialysis arteriovenous (AV) grafts, monocytes and T-cells appear early at the vein-graft anastomosis following placement and may participate in stenosis formation. Cellular epoxyeicosatrienoic acids (EETs) possess anti-inflammatory properties via down-regulation of NF-kB, a transcription factor important in cytokine expression. Soluble epoxide hydrolase (sEH) catabolizes EETs, thus sEH inhibitors (sEHI) may be effective as anti-inflammatory agents. Previously we showed increased sEH protein and activity in our pig model of AV graft stenosis. Here we investigated the expression of sEH in cultured monocytes and T cells and the effect of sEHI on cytokine release from these cells to determine if they could be targets for the anti-inflammatory actions of sEHI.

sEH expression in cultured human blood monocytes and T-cells was assessed by immunocytochemistry (ICC) and immunoblotting. The effect of pretreatment with a specific pharmacological sEHI (5 mM), with or without EETs (0.1 mM), on release of the proinflammatory cytokines monocyte chemotactic protein (MCP-1), macrophage inflammatory protein-1a (MIP-1a) and IL-6, from these cells exposed to LPS (10 ng/ml) for 24h was tested by ELISA. MCP-1 expression in explanted pig AV graft tissue was examined by immunohistochemistry (IHC).

Cultured monocytes and T-cells expressed sEH protein. sEHI inhibited MCP-1 release by ~50% ($p<0.05$), but not MIP-1α or IL-6, from monocytes and no further inhibition was observed with addition of EETs. No inhibitory effect of sEHI was observed on the release of any cytokine from T-cells. Thus the inhibitory effects of sEHI appear to be cytokine- and cell-specific. At 3 weeks post-placement, MCP-1 expression in the graft anastomosis was elevated compared to control vein. As monocytes are a primary source of MCP-1, which is vital in leukocyte recruitment and activation, sEHI may decrease inflammatory response and therefore stenosis in AV grafts.

**Increased Generation of Superoxide Anion (SA) and Decreased SA Scavenging in a Rat Arteriovenous Fistula (AVF) Model** Mykola V. Tsapenko, Anthony J. Croatt, Livius V. d'Uscio, Melissa C. Hernandez, Allan W. Ackerman, Joseph P. Grande, Zvonimir S. Katusic, Karl A. Nath. *Mayo Clinic, Rochester, MN.*

We have recently described a rat femoral AVF model (Am J Pathol 176:2530, 2010) characterized by neointimal hyperplasia and thrombogenesis at 4 weeks, and upregulation of vasculopathic genes and eNOS at 1 week. Since increased SA production can contribute to neointimal hyperplasia, the current study examined SA generation in the venous segment of this AVF model at 1 week. SA production, measured by HPLC, increased significantly in the venous limb of the AVF as compared to the control vein (3.41±0.71 vs. 9.59±2.04 μmol/mg protein, P<0.02). To determine the basis for such generation, we examined potential mechanisms including content of tetrahydrobiopterin (BH4, reduced form, the co-factor for eNOS) and 7,8-dihydrobiopterin (BH2, oxidized form) in the AVF: BH4 and BH2 were both significantly increased in the AVF, BH2 disproportionately so, thereby leading to a lower BH4/BH2 ratio in the venous segment of the AVF as compared with control veins (56±12 vs. 16±3, P<0.005). Such reduction in the BH4/BH2 ratio can cause uncoupling of eNOS, and thus the generation of SA rather than NO by eNOS. Other sources of SA, including NADPH oxidase (NOX1, NOX2, NOX4, subunits p47phox and p67phox), and COX (COX1 and COX2) isoforms, determined by Western analysis, were not significantly different between the groups. We also examined superoxide dismutase activity (SOD), the main SA scavenger. In the venous limb of the AVF as compared to control veins, activities of total SOD (17.2±1.4 vs. 11.5±0.9 U/mg protein, P<0.005) and Cu/Zn-SOD (14.6±1.3 vs. 9.7±0.9 U/mg protein, P<0.01) were both significantly diminished. In summary, SA is generated in increased amounts in the venous limb of the AVF because of a reduced BH4/BH2 ratio and an attendant uncoupling of eNOS, and because of reduced SA scavenging due to diminished SOD activity. We suggest that such increased generation of SA may contribute to venous neointimal hyperplasia that occurs in this AVF model.

**SA-PO2692**

**Investigation of the Association between TCF7L2 and Kidney Function in the Multi-Ethnic Study of Atherosclerosis (MESA)** Jamison W. Chang,[1] Michele Sale,[2] Stephen Rich,[2] Carmen A. Peralta,[3] Nehal N. Mehta.[4] *[1]Division of Nephrology and CIIR, University of Virginia, Charlottesville, VA; [2]Center for Public Genomics, University of Virginia, Charlottesville, VA; [3]Divsion of Nephrology, UCSF, San Francisco, CA; [4]Cardiology, University of Penn, Phildelphia, PA.*

The transcription factor 7-like 2 gene (TCF7L2), coding for a high-mobility box-containing transcription factor is an important effector in the canonical Wnt pathway. To date, variants of TCF7L2 show the strongest associations with type 2 diabetes among the common type 2 diabetes genes. In 2008, Kottgen et al demonstrated an association between TCF7L2 variants and progression of chronic kidney disease and eGFR both in diabetics and non-diabetics. These results suggested that variants in TCF7L2 may confer a risk of kidney disease independent of their influence on type 2 diabetes risk.

To further explore the relationship between variants in TCF7L2 and kidney disease, we examined the effects of 64 SNPs in TCF7L2 on kidney function in a large, diverse cohort, the Multi-Ethnic Study of Atherosclerosis (MESA) candidate gene study (n=2800). Using multivariable linear regression and adjusting for age, gender, race, and center of ascertainment, two SNPs in TCF7L2, rs11196199 and rs11196203 were found to be associated with mean eGFR in cross-sectional analysis of MESA (p value= 0.0004 and 0.0003 respectively). These SNPs were not associated with type 2 diabetes (P>0.9). Finally, adding in diabetic status and serum glucose to the model above, rs11196199 and rs11196203 remained significantly associated with eGFR (p value 0.0004 and 0.0003). None of the 64 variants in TCF7L2 were associated with urine albuminuria or progression of CKD in longitudinal analysis.

Taken together, the results suggest that variants in TCF7L2 may influence kidney function independently of their effect on type 2 diabetes risk. Planned analyses will determine whether these results replicate in the remainder of the MESA cohort (n=3500). The mechanism by which these variants influence kidney function is unclear at this time but will be studied further if this association is replicated.

**Accounting for Risk Variants in *MYH9* Reveals *FRMD3* Association with Diabetic ESRD in African Americans** Barry I. Freedman,[1] Carl D. Langefeld,[2] Lingyi Lu,[2] Jasmin Divers,[2] Mary E. Comeau,[2] Jeffrey B. Kopp,[4] Cheryl Winkler,[5] George W. Nelson,[5] Nicholette D. Allred,[3] Pamela J. Hicks,[3] Meredith A. Bostrom,[3] Jessica N. Cooke,[3] Caitrin W. Mcdonough,[3] Donald W. Bowden.[3] *[1]Internal Medicine, Wake Forest Univ Sch Med; [2]Biostatistical Sciences/Center for Public Health Genomics, Wake Forest Univ Sch Med; [3]Biochemistry/Center for Diabetes Research, Wake Forest Univ Sch Med, Winston-Salem, NC; [4]Kidney DIsease Section, NIDDK, Bethesda, MD; [5]Laboratory of Genomic Diversity, SAIC-Frederick, National Cancer Institute, Frederick, MD.*

Variants in *MYH9* are strongly associated with end-stage renal disease (ESRD) in African Americans (AA) and may mask identification of variants in other genes. The Affymetrix SNP Array 6.0 was genotyped in 966 AA with type 2 diabetes-(T2D) associated ESRD and 1032 non-diabetic, non-nephropathy (NDNN) controls. A T2D-ESRD case-only logistic regression analysis tested for gene-gene interactions with the *MYH9* E1 haplotype; and *MYH9* E1-stratified analyses tested for additional gene associations. Seven *FRMD3* SNPs exhibited significant interaction with E1 in an initial T2D-ESRD case-only analysis (*e.g.*, rs942280 p-value $1.48 \times 10^{-4}$ additive; OR=0.67, 95% CI 0.54-0.82). Analyses were repeated in another 640 AA with T2D-ESRD, 683 NDNN controls and 513 AA with T2D lacking nephropathy. *FRMD3-MYH9* interactions were observed in the replication analysis with 640 T2D-ESRD cases (rs942280 $p=1.37 \times 10^{-3}$) and combined 1,592 T2D-ESRD cases

(p=9.28 x $10^{-7}$ additive; OR=0.67). In non-*MYH9* E1 homozygotes, this *FRMD3* SNP was associated with T2D-ESRD (OR=1.28; heterozygosity p-value vs. E1 homozygotes 4.3 x $10^{-4}$) and 5 *FRMD3* SNPS were significantly associated with ESRD when contrasting T2D-ESRD cases with T2D non-nephropathy controls. Significant *FRMD3* associations with T2D-ESRD were detectable only after accounting for the effect of *MYH9*. *MYH9-FRMD3* statistical interactions likely result from *MYH9* identifying diabetic cases with non-diabetic ESRD. These analyses support the role of *FRMD3* in T2D-ESRD and suggest that identifying diabetic nephropathy genes in AA benefits from accounting for variation in *MYH9*.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2694**

**A Genome Wide Association Study for Diabetic Nephropathy Genes in African Americans** Caitrin W. Mcdonough,[1] Nicholette D. Allred,[2] Pamela J. Hicks,[2] Meredith A. Bostrom,[2] Lingyi Lu,[3] Maggie Ng,[4] Jasmin Divers,[3] Carl D. Langefeld,[3] Barry I. Freedman,[5] Donald W. Bowden.[2,5] *[1]Program in Molecular Medicine and Translational Science, Wake Forest University School of Medicine; [2]Biochemistry, Wake Forest University School of Medicine; [3]Biostatistical Sciences, Wake Forest University School of Medicine; [4]Pediatrics, Wake Forest University School of Medicine; [5]Internal Medicine, Wake Forest University School of Medicine, Winston-Salem, NC.*

African Americans (AA) have increased risk of developing ESRD compared to Caucasian Americans and many studies reveal that a genetic component contributes. We performed a genome-wide association study (GWAS) in 965 AA type 2 diabetic (T2D)-ESRD cases and 1,029 AA non-T2D non-nephropathy controls on the Affy6.0 platform. The top 754 SNPs were genotyped in a replication sample of 709 AA T2D-ESRD cases and 690 AA non-T2D non-nephropathy controls. To discriminate between T2D, T2D-ESRD, and/or all-cause ESRD, SNPs that replicated were then genotyped in 1,216 AA non-T2D ESRD cases and 1,246 AA T2D non- nephropathy controls. Analyses were adjusted for admixture. We detected 25 SNPs associated with T2D-ESRD in 19 regions ($P_{ADD} \leq$ 2E-04 in the combined analysis (GWAS+Replication), associated in T2D-ESRD vs T2D comparison, and with no/nominal association with T2D vs non T2D controls). Although genome wide significance for T2D-ESRD was not observed with any SNP, several genes, including *RPS12*, *LIMK2*, and *SFI1* are strong nephropathy candidates. *RPS12*, ribosomal protein S12, SNPs rs9493454 and rs7769051 showed combined P-values of 1.7x$10^{-5}$ and 2.2x$10^{-6}$, and odds ratios (OR) and 95% confidence intervals (95% CI) of 1.24(1.13-1.37) and 1.28(1.16-1.42), respectively. Two SNPs, rs2106294 and rs4820043 in *LIMK2*, LIM domain kinase 2, had combined P-values of 4.1x$10^{-6}$ and 5.1x$10^{-6}$, and OR (95% CI) of 0.57(0.45-0.72) and 0.57(0.45-0.73), respectively. A combined analysis of all 2,890 ESRD cases (1,674 T2D-ESRD; 1,216 non-T2D ESRD) revealed SNPs in *LIMK2* and *SFI1* with P-values 3.3x$10^{-8}$ to 6.5x$10^{-11}$ suggesting that they may contribute to all-cause ESRD. These results suggest that multiple loci underlie nephropathy susceptibility in AA with T2D.

**Association of Adrenomedullin 2 Gene I/D Polymorphism with Cerebral and Renal Damage in a Japanese General Population: The Ohasama Study** Kazuhito Totsune,[1,2] Takuo Hirose,[1] Hirohito Metoki,[1,3] Kei Asayama,[1] Masahiro Kikuya,[1] Takayoshi Ohkubo,[1,4] Kazuhiro Takahashi,[5] Yutaka Imai.[1] *[1]Planning for Drug Development and Clinical Evaluation, Tohoku Univ Grad Sch of Pharm Sci and Med, Sendai, Japan; [2]Faculty of Synthetic Welfare, Tohoku Fukushi Univ, Sendai; [3]Obstetrics and Gynecology, Tohoku Univ Grad Sch of Med, Sendai; [4]Department of Health Science, Shiga Univ of Med Sci, Otsu; [5]Endocrinology and Applied Med Sci, Tohoku Univ Grad Sch of Med, Sendai, Japan.*

Adrenomedullin 2 (AM2), also called intermedin, is a possible reno-protective peptide with various effects on the cardiovascular system and the kidney function. An exonic insertion/deletion (I/D) polymorphism (rs3840963) likely influences generation of AM2-53, due to its location within the N-terminal sequence. We previously reported the association of this polymorphism with blood pressure in a Japanese population (Renal Week 2008). In the present study, we examined the association of the polymorphism with renal function and the risk of silent cerebrovascular lesions (lacunar infarction and white matter hyperintensity). We recorded the estimated glomerular filtration rate (eGFR) and proteinurea of 1073 individuals over 40 years of age. Silent cerebrovascular lesions were recorded in 794 individuals over 55 years of age. Chronic kidney disease was diagnosed when an individual had proteinuria and/or decreased eGFR less than 60 ml/min/1.73$m^2$. DD carriers, compared to II and ID carriers, displayed significantly lower eGFR (75.4 vs. 82.6 and 82.9 mL/min/1.73$m^2$, respectively, P=0.04). DD carriers also had a significantly higher odds ratio (OR) for prevalence of chronic kidney disease (OR: 2.7, P=0.003), presence of lacunar infarction (OR:2.4, P=0.01), and white matter hyperintensity (OR:2.7, P=0.003), compared with II carriers. AM2 I/D polymorphism had no significant association with any other clinical manifestation tested, such as cardiac infarction and symptomatic strokes. Thus, the AM2 I/D polymorphism is associated with renal dysfunction and asymptomatic cerebrovascular diseases in the Japanese general population. These results suggest that AM2 has a certain role against the renal and cerebrovascular damages.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2696**

**Sequencing of α-Actinin-4 To Identify Variants Associated with Non-Diabetic End-Stage Renal Disease (ESRD) in African Americans** Meredith A. Bostrom,[1,5] Pamela J. Hicks,[1,5] Lingyi Lu,[2] Maggie Ng,[4,5] Carl D. Langefeld,[2] Barry I. Freedman,[3] Donald W. Bowden.[1,5] *[1]Biochemistry, Wake Forest University School of Medicine; [2]Biostatistical Sciences, Wake Forest University School of Medicine; [3]Internal Medicine, Wake Forest University School of Medicine; [4]Pediatrics, Wake Forest University School of Medicine; [5]Centers for Human Genomics and Diabetes Research, Winston-Salem, NC.*

African Americans (AA) disproportionately develop non-diabetic (non-DM) forms of ESRD and studies reveal a genetic component. *ACTN4* (α-actinin-4) is an actin binding protein expressed in podocytes; rare mutations have been implicated in familial focal segmental glomerulosclerosis. Nineteen exons and 2800 bases of the promoter of *ACTN4* were sequenced in 96 AA non-DM ESRD cases and 96 non-nephropathy controls. Sixty-seven SNPs were identified (49 were novel), including 33 intronic, 21 promoter, 12 exonic, and 1 3' of the gene. Sixty-one SNPs were genotyped in 278 AA non-DM ESRD cases and 327 AA non-nephropathy controls. One promoter SNP, rs10404257, was associated with non-DM ESRD (p=0.004, odds ratio (OR)=0.60, confidence interval (CI) 0.43-0.85; dominant model). Forty SNPs had minor allele frequencies less than 5%. These SNPs were collapsed into a single marker, designated by the presence (n=251) or absence (n=404) of any rare allele. There was no association with having a rare allele at any of these SNPs in non-DM ESRD. SNPs were tested for interaction with *MYH9*, previously associated with non-DM ESRD in AA, and no interaction was detected with single SNPs or collapsed rare alleles. 21 of the most associated SNPs were genotyped in an independent set of 525 AA non-DM ESRD cases and 267 controls. Although rs10404257 was not associated in the replication sample (p=0.768, OR=1.05, CI=0.75-1.48; dominant), it remained modestly associated when all samples were combined (p=0.033, OR=0.78, CI 0.62-0.98; dominant). We have sequenced the promoter and coding regions in the *ACTN4* gene and detected limited evidence of association with non-DM ESRD in AA. This negative finding for nephropathy suggests that common to moderately uncommon *ACTN4* variants impacting gene function may affect survival.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2697**

**Association of (Pro)renin Receptor Gene Polymorphism with Cardiac Hypertrophy, Asymptomatic Cerebrovascular Lesions and Chronic Kidney Disease in Japanese: The Ohasama Study** Kazuhito Totsune,[1,2] Takuo Hirose,[1] Hirohito Metoki,[1,3] Kei Asayama,[1] Masahiro Kikuya,[1] Takayoshi Ohkubo,[1,4] Kazuhiro Takahashi,[5] Yutaka Imai.[1] *[1]Planning for Drug Development and Clinical Evaluation, Tohoku Univ Grad Sch of Pharm Sci and Med, Sendai; [2]Faculty of Synthetic Welfare, Tohoku Fukushi Univ, Sendai; [3]Obstetrics and Gynecology, Tohoku Univ Grad Sch of Med, Sendai; [4]Department of Health Science, Shiga Univ of Med Sci, Otsu; [5]Endocrinology and Applied Med Sci, Tohoku Univ Grad Sch of Med, Sendai, Japan.*

(Pro)rennin receptor (PRR) is a new member of renin-angiotensin system. We previously reported the association of intervening sequence (IVS)5+169C>T (rs5918007) polymorphism of PRR with blood pressure in Japanese men (Am J Hypertens, 2009). In the present study, we investigated the association of PRR gene polymorphisms with left ventricular hypertrophy (LVH), silent cerebrovascular lesions (lacunar infarction and white matter hyperintensity (WMH)) and chronic kidney disease (CKD). For association study, we selected three polymorphisms: -782A>G (rs2968915), IVS5+169C>T, and +1513A>G (rs6609080). A total of 779 subjects were recruited. We defined LVH by ECG records and lacunar infarction and/or WMH by MRI. Since PRR gene is located on the X chromosome, men and women were analyzed separately. In women, the prevalence of LVH and lacunar infarction was significantly higher in subjects with the +1513GG genotype than in those with the AA or AG genotype (*P*=0.003 and *P*=0.01, respectively), but not WMH (*P*=0.07) nor CKD. Multiple logistic regression analysis adjusted for confounding factors demonstrated that +1513A>G polymorphism was significantly and independently associated with the risk of LVH (trend *P*=0.007) and lacunar infarction (trend *P*=0.04). Plasma renin activity (PRA) levels in women with the GG genotype were significantly lower than those in women with the AA or AG genotypes (*P*=0.01). In men, no significant association was observed with LVH, lacunar infarction, WMH and CKD. Thus, PRR gene polymorphism +1513A>G is associated with LVH and lacunar infarction in Japanese women. These results suggest that PRR has a role in organ damage in humans.

**Investigation of Genetic Mutations That Influence Telomerase Length for Association with End Stage Renal Disease** A. J. McKnight, Alexander P. Maxwell. *Nephrology Research Group, Queen's University of Belfast, Belfast, Northern Ireland, United Kingdom.*

Renal dysfunction is associated with reduced telomere length. Genetic mutations influencing telomerase (an enzyme that maintains telomere length) are an important disease mechanism that may have crucial implications for patients with end stage renal disease (ESRD).

A recent genome-wide association study (Nat Genet 42(3):197, 2010) reported two robustly replicated SNPs that were strongly associated with telomere length; rs12696304, *P*=$10^{-14}$, rs16847897, *P*=$10^{-12}$, $r^2$=0.49, SNPs across the 87 kb interval were also significantly

associated with reduced telomere length. These SNPs are located in a prioritised genomic region for renal disease (3q26) and are near the telomerase RNA component (TERC) gene.

To investigate the influence of these SNPs on ESRD, we conducted a case-control study in a White, European population. Individuals recruited to the case group had received a kidney transplant (n=574) and were compared to individuals in the control group that comprised kidney donors (n=517). SNPs were genotyped using commercial TaqMan kits with a genotype success rate greater than 99%. Genotype and allele frequencies were compared between cases and controls using SPSS. Statistically significant association was not observed in our collection, despite 1,091 individuals providing approximately 80% power to identify a risk allele ($p<0.05$) with an odds ratio of 1.3 for a minor allele frequency of 30%.

These SNPs are not major risk factors for ESRD within our population, however we suggest that studies evaluating age-related telomere length for renal phenotypes should also consider the influence of genetic contributions on observed telomere length.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2699

**Exome Sequencing of Type 1 Diabetes (T1D) Survivors and T1D End-Stage Renal Disease (ESRD) Cases Identifies Coding SNPs Implicated in the Pathogenesis of Diabetic Nephropathy** Marcus G. Pezzolesi,[1] Hillary A. Keenan,[1] Gabriel David Poznik,[1] Stephen Rich,[3] James Warram,[1] George L. King,[1] Andrzej S. Krolewski,[1] Jonathon Dunn,[1] Josyf Mychaleckyj.[3] *[1]Research Division, Joslin Diabetes Center, Boston, MA; [2]Center for Public Health Genomics, University of Virginia School of Medicine, Charlottesville, VA.*

Objective

Diabetic nephropathy (DN) affects 30% of all patients with T1D. Only 5% of patients with T1D survive without this complication for 50 or more years following the onset of disease. To identify genetic variants that contribute to protection or risk of DN in T1D, we performed exome sequencing in individuals who either remained free of renal complications despite a long duration of T1D or developed ERSD after a short duration of disease.

Research Design

Targeted resequencing of approximately 180,000 exons for 18,673 protein-coding genes was performed on 3 long-duration 'survivors' with normoalbuminuria and 3 short-duration 'ESRD cases'.

Results

We identified 6,193 previously reported nsSNPs, including 6,144 missense and 49 nonsense variants, per exome. These nsSNPs map to 6,004 distinct genes. Six-hundred eighteen genes contained nsSNPs that were exclusively observed in survivors. Ten genes contained nsSNPs present only among all 3 survivors. Similarly, we identified 537 genes that contained nsSNPs exclusively observed in ESRD cases, including 15 that contained nsSNPs present in all case subjects. We also identified 4,669 novel coding SNPs not annotated in dbSNP or present in data available from the 1000 Genomes Project. Of these, novel coding SNPs mapping to 4 genes were present only among survivors, while 6 genes contained novel coding SNPs found only in ESRD cases.

Conclusions

Exome sequencing using an extreme-trait study design identified multiple genes containing coding SNPs exclusive to either T1D survivors or ESRD cases. While further characterization of these SNPs in a larger collection of survivors and ESRD cases is necessary to determine their contribution to disease, our data demonstrate the utility of this approach in identifying potentially important functional changes associated with this complication.

**Meta-Analysis of Genome-Wide Association Studies for Nephropathy in Type 1 Diabetes** A. J. McKnight,[1] Rany M. Salem,[2] Niina Sandholm,[3] Eoin P. Brennan,[4] On Behalf of the GENIE Consortium.[5] *[1]Queen's University of Belfast, Belfast, United Kingdom; [2]Broad Institute, Cambridge; [3]Folkhalsan Research Center, Helsinki, Finland; [4]University College Dublin, Dublin, Ireland; [5]GENIE Consortium, International.*

We have performed novel, independent genome-wide association studies (GWAS) and meta-analyses to advance understanding of the genetic contribution to diabetic nephropathy.

As part of the GENIE (GEnetics of Nephropathy, an International Effort) consortium we have assembled a large collection of individuals with type 1 diabetes (T1D, n=6,462). Recruited individuals include cases with overt diabetic nephropathy compared to normoalbuminuric controls that had T1D for at least 15 years with no evidence of renal disease. The All Ireland-Warren 3-UK GoKinD collection (823 cases, 903 controls) was genotyped on the Illumina Omni1-quad while FinnDiane (1,411 cases, 1,708 controls) was genotyped using the Illumina 610-quad. Publicly available data from US GoKinD (782 cases, 835 controls), genotyped on the Affymetrix 5.0 array, was obtained from dbGAP. Following standardised quality control, genotypes were imputed using MACH with the HapMap2 CEU panel. Association was investigated for approximately 2.4 million SNPs using PLINK with principal components of ancestry, age at recruitment, duration of diabetes, gender and study site as covariates; meta-analysis was performed using METAL.

A total of 15 SNPs achieved a p value of less than $10^{-6}$ in the combined analysis for diabetic nephropathy. Several of these SNPs mapped to 3q13, 4q34 and 20q11 with multiple SNPs mapping to a biologically plausible gene at 2q34. Further analyses have been conducted for secondary phenotypes and genetic outcomes are being examined in relation to our microarray and RNA Seq data. The best evidence for association was observed for ESRD where several SNPs in close vicinity achieved genome-wide significance at 2q11.2-q12. The top SNPs are undergoing replication in additional, independent collections.

By combining genetic and expression data we provide further novel insights into the pathogenesis of diabetic nephropathy.

Disclosure of Financial Relationships: nothing to disclose

**Genetic Variants Identified by GWAS Suggest Intracellular Calcium, Vascular Remodeling, and Cardiac Repolarization Pathways Impact Dialytic Survival in African Americans with Diabetes** Mariana Murea,[1] Lingyi Lu,[2] Pamela J. Hicks,[3] Donald W. Bowden,[1,3] Jasmin Divers,[2] Carl D. Langefeld,[2] Barry I. Freedman.[1] *[1]Internal Medicine/Nephrology, Wake Forest University School of Medicine; [2]Department of Biostatistical Sciences, Wake Forest University School of Medicine; [3]Department of Biochemistry, Wake Forest University School of Medicine, Winston-Salem, NC.*

Relative to Caucasians, African Americans (AA) have a nearly 40% lower risk of death on dialysis. As genetic factors may play a role, we performed a genome-wide association study (GWAS) in 610 AA patients with end-stage renal disease (ESRD) attributed to type 2 diabetes using the Affymetrix 6.0 platform (868,155 single nucleotide polymorphisms; SNPs). Time to all-cause mortality was assessed by a Cox proportional hazard model with adjustment for ancestry, age at ESRD, gender, BMI, and incident year. Cases were censored at kidney transplant or if alive at the final observation (n= 160); 430 deaths were observed after mean follow-up of 5.4 years. Primary inference is the additive genetic model unless significant departure from additivity ($P<0.05$), then minimum of dominant, additive or recessive model was reported. Five SNPs were associated with time to death at $p<1x10-7$: rs2681019 near KLHL29 (Hazard Ratio [HR]=2.58, PREC=8x10-8), rs815815 on CALM2 (HR=1.51, PADD=6x10-7), rs926392 (HR=2.37, PREC= 4x10-7) and rs926391 (HR=2.30, PREC= 7x10-7) near DHX35, and rs11128347 on PDZRN3 (HR=0.57, PADD=6x10-7). Ten SNPs in 8 other genes were associated at $P<1x10-6$: GAS2, LOC729980, PTPRM, ABCA4, PCSK2, NRG1 with high HR; and SVIP, SH3BP4 with low HR for time to death. Several intergenic SNPs located near ADAMTS3, ADAMTS5, HAS2, SLC24S4, IRX3, and IRX5 were also associated at $P<1x10-6$. Genetic variation was predominantly located within or in close proximity to genes playing critical roles in intracellular calcium trafficking, extracellular matrix turnover and mineralization, vascular remodeling under mechanical stretch, and cardiac ventricular repolarization. These results warrant additional investigation and replication to detect genes that contribute to survival on dialysis.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2702

**Genetic Associations for Diabetic Nephropathy: A Meta-Analysis** Antien Mooyaart,[1] Lisette Valk,[1] Jan A. Bruijn,[1] Emile De Heer,[1] Olaf Dekkers,[2] Hans J. Baelde.[1] *[1]Pathology, LUMC, Leiden, Netherlands; [2]Clinical Epidemiology, LUMC, Leiden, Netherlands.*

*Background* Many genetic association studies for diabetic nephropathy have been performed. The aim of our meta-analysis study was to assess the pooled effect of genetic variants reproducibly associated with diabetic nephropathy.

*Methods* PubMed, EMBASE, and Web of Science were searched for genes associated with diabetic nephropathy. All genetic variants associated with diabetic nephropathy, which are reproduced in at least two independent studies were selected. The association between these variants and diabetic nephropathy (macroalbuminuria/ proteinuria or ESRD) was calculated at the allele level and expressed as odds ratios. Pre-specified subgroup analyses were performed, stratifying type 1/type 2 diabetes, proteinuria/ESRD, different ethnic groups. The main measure of effect was the pooled odds ratio in a random effects model.

*Results* Our initial literature search yielded 3455 citations of which 610 were genetic association studies investigating diabetic nephropathy. A number of 33 reproduced genetic variants was found, of which 21 remained significantly associated with diabetic nephropathy in a random-effects meta-analysis. These variants were in or near the following genes: *ACE, ALR2* (2 variants), *APOC1, APOe, ELMO1, EPO, HSPG2, IL-1B, VEGF, FRMD3* (2 variants), *CARS* (2 variants), *UNC13B, CPVL/CHN2, GREM1*, four variants were not near genes. The odds ratios of these genetic variants ranged between 0.48 and 1.70. Additional variants were found from the subgroup analyses: *CCR5* (subgroup: Asians), *CNDP1* (subgroup: type 2 diabetes).

*Conclusion* In conclusion, this meta-analysis shows that several genetic variants are associated with the risk of diabetic nephropathy. The road ahead is to investigate the role of these variants in the pathogenesis of diabetic nephropathy.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2703**

**Polymorphisms in *MYH9* Are Associated with Diabetic Nephropathy in European Americans** Jessica N. Cooke,[1,2] Meredith A. Bostrom,[1,2] Pamela J. Hicks,[1,2] Maggie Ng,[1,2,3] Mary E. Comeau,[4] Jasmin Divers,[4] Carl D. Langefeld,[4] Barry I. Freedman,[5] Donald W. Bowden.[1,2,5] *[1]Biochemistry, Wake Forest University School of Medicine; [2]Center for Genomics and Personalized Medicine Research and Center for Diabetes Research, Wake Forest University School of Medicine; [3]Pediatrics--Medical Genetics, Wake Forest University School of Medicine; [4]Public Health Sciences, Wake Forest University School of Medicine; [5]Internal Medicine, Wake Forest University School of Medicine, Winston-Salem, NC.*

Diabetes is the leading cause of end-stage renal disease (ESRD) in the U.S., accounting for 44% of incident cases each year. Polymorphisms in the non-muscle myosin IIA gene (*MYH9*) are strongly associated with focal segmental glomerulosclerosis (FSGS) and non-diabetic ESRD in African Americans (AA) and with FSGS in European Americans (EA), less strongly with type 2 diabetic (T2D)-ESRD in AA. We tested for association of single nucleotide polymorphisms (SNPs) in *MYH9* with T2D-ESRD in EA. Fifteen *MYH9* SNPs were genotyped in 1948 EA; 540 cases with T2D-ESRD and 1408 non-nephropathy controls (461 with T2D and 947 without diabetes). Comparing T2D-ESRD cases with the 461 T2D non-nephropathy controls, single SNP associations were detected with *MYH9* SNPs rs4821480, rs2032487 and rs4281481, comprising part of the major E1 risk haplotype (p-values 0.014-0.041 recessive, odds ratio [OR] 4.31-8.66). Comparing T2D-ESRD cases to all 1408 non-nephropathy controls confirmed association with these three SNPs as well as the fourth SNP in the E1 haplotype (rs3752462; p-values 0.004-0.026, OR 1.42-3.77). Haplotype analysis contrasting T2D-ESRD cases to all 1408 non-nephropathy controls suggested that the partial *MYH9* E1 risk haplotype was associated with nephropathy risk (GCC haplotype two-sided p-value 0.039 additive [one-sided p-value 0.020], OR 1.54: haplotype frequency 7.1% in T2D-ESRD cases vs. 4.8% in non-nephropathy controls). These analyses indicate that *MYH9* E1 haplotype SNPs are associated with T2D-ESRD susceptibility in European Americans and that three of the four E1 risk haplotype SNPs that are associated with FSGS in African Americans appear to confer risk.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2704**

**Genome-Wide Association Study (GWAS) Identifies Five New Susceptibility Loci for IgA Nephropathy (IgAN)** Ali G. Gharavi,[1] Krzysztof Kiryluk,[1] Murim Choi,[2] Yifu Li,[1] Jingyuan Xie,[5] Ping Hou,[4] Simone Sanna-Cherchi,[1] Jan Novak,[3] Robert J. Wyatt,[9] Bruce A. Julian,[3] Silvana Savoldi,[7] Landino Allegri,[12] Gian Marco Ghiggeri,[10] Riccardo Magistroni,[8] Maurizio Salvadori,[11] Giuliano Boscutti,[6] Antonio Amoroso,[7] Francesco Scolari,[6] Nan Chen,[5] Hong Zhang,[4] Richard P. Lifton.[2] *[1]Columbia Univ.; [2]Yale Univ.; [3]Univ. of Alabama; [4]Peking Univ.; [5]Shanghai Ruijin Hospital; [6]Univ. of Brescia; [7]Univ. of Torino; [8]Univ. of Modena; [9]Univ. of Tennessee; [10]Gaslini Hospital; [11]Univ. of Florence; [12]Univ. of Parma.*

Objective: IgAN is a common cause of kidney failure. We performed a GWAS to identify common genetic variants underlying susceptibility to IgAN.

Methods: We performed a GWAS and replication in 5966 subjects. We genotyped 1194 cases and 902 controls from China on Illumina 610K SNP chips. Potentially significant SNPs were studied in 2 follow-up cohorts: Chinese (712 cases and 748 controls) and Caucasian (1,238 cases and 1,172 controls). SNPs with $p \leq 5 \times 10\text{-}8$ across all cohorts were considered significant. We formulated a genetic risk score model based on the discovered loci, and we applied it to diverse populations across 4 continents.

Findings: Our top association signal resides in the MHC-II on Chr. 6 and conveys a strong protective effect against IgAN (odds ratio = 0.59, $p = 3.1 \times 10\text{-}27$). This association is strongest with the DQB1*602-DQA1*102-DRB1*1501 haplotype, which has previously been shown to confer risk to or protection from other immune disorders. In addition, we discovered four other independent loci with genome-wide significance. Disease risk varies 10-fold between the highest and lowest risk score groups and these loci explain 7% of the variation in disease risk. Interestingly, mean risk scores are significantly different among populations, and are highest in Chinese, intermediate in Europeans, and lowest in Africans, which parallels disease frequency among these groups.

Conclusions: We have discovered five new disease susceptibility loci for IgAN which provide new insight into the biology and geographic variability in the prevalence of IgAN.

Disclosure of Financial Relationships: nothing to disclose

**Distinguishing Familial IgA Nephropathy from COL4A Associated Nephropathy** Yifu Li,[1] Simone Sanna-Cherchi,[1] Hussein H. Karnib,[2] Gianluca Caridi,[3] Krzysztof Kiryluk,[1] Gian Marco Ghiggeri,[3] Ali G. Gharavi.[1] *[1]Medicine, Div. of Nephrology, Columbia University, New York, NY; [2]Medicine, American University of Beirut, Beirut, Lebanon; [3]Pediatric Nephrology, G. Gaslini, Genoa, Italy.*

**Introduction.** Familial IgA Nephropathy (IgAN), thin basement membrane nephropathy (TBMN) and Alport syndrome (AS) are primary glomerular disorders which all present with micro- or macroscopic hematuria, proteinuria and variable progression to ESRD. Distinguishing between these entities can be complicated if there is concomitant IgA deposition on kidney biopsy. This distinction is further complicated because a locus for familial IgA nephropathy was mapped to the COL4A3/A4 locus on Chr. 2q36.

**Methods.** We evaluated the possibility of familial IgA nephropathy in 4 multigenerational kindreds ascertained via an index case with renal failure, mesangial sclerosis and IgA deposition on kidney biopsy; each kindred featured multiple individuals with dominant transmission of hematuria/proteinuria with/without chronic renal failure, and absence of hearing or ocular defects. We performed linkage analysis and mutational screening of all exons of the COL4A3, COL4A4 and COL4A5 genes.

**Results.** Linkage analysis demonstrated linkage to the COL4A3/A4 or the COL4A5 loci in three families (LOD = 2.1 and 2.2 at 2q35-37, and LOD = 3.6 at Xq22-25). Mutational screening revealed a single segregating mutation in three families (COL4A3 G291E, COL4A4 G852A, and COL4A5 G174C). These mutations affected conserved glycine residues, segregated in all affected individuals and were not present in at least 200 ethnically-matched controls, thus establishing the diagnosis of COL4A-associated diseases. In the fourth family, we found no linkage to, nor mutations in the collagen loci, suggesting it was a true case of familial IgAN.

**Conclusions.** In familial hematuric disease, linkage analysis and mutational screening of COL4A genes can help distinguish between familial IgAN and COL4A-associated diseases, resolving confounders such as the presence of renal failure and coincidental mesangial IgA deposition.

**SA-PO2706**

**Genome-Wide Linkage Scan for Familial IgA Nephropathy among Southeast Asian Chinese: Identification of a Novel Susceptibility Locus on Chromosome 8p22-23** Yuxin Niu,[1] Sonia Davila,[2] M. F. Lam,[3] Sydney C. W. Tang,[3] Kar Neng Lai,[3] Stephen I.-Hong Hsu.[1] *[1]Division of Nephrology, Hypertension and Renal Transplantation, College of Medicine, University of Florida, Gainesville, FL; [2]Department of Population Genetics, Genome Institute of Singapore, Singapore; [3]Department of Medicine, Queen Mary Hospital, The University of Hong Kong, Hong Kong.*

IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide with a particularly high incidence reported by Asian/Southeast Asian biopsy registries. Over the past decade, three independent genome-wide scans for linkage to familial IgAN among Caucasians have identified two susceptibility loci on chromosomes 6q22-23 (*IGAN1*) and 2q36, as well as a locus suggestive for linkage on 4q26-31. We now report the results of a genome-wide scan based on a large 4-generation Singaporean Chinese family (F66) as well as 23 smaller Chinese IgAN kindreds from Hong Kong (HK23). Linkage analysis of F66 was first performed at 10 cM resolution using microsatellite markers. By parametric analysis (assuming autosomal dominant inheritance, allele frequency of 0.001, phenocopy rate of 0.01 and penetrance of 75%), a region of suggestive linkage with a maximum multipoint LOD score of 2.23 was identified on chromosome 8p23. By non-parametric (NPL) analysis, a significant linkage to 8p23 (maximum multipoint LOD score 3.89, *p*-value 0.004) was confirmed. Genotyping of 4 additional microsatellite markers in this region in F66 and HK23 yielded a maximum heterogeneous LOD (HLOD) score of 3.26 ($\alpha$=0.5) with *D8S552* located near the boundary of 8p22 and 8p23. The LOD-1 support interval is flanked by markers that define a physical distance of ~4.5 Mb. Affected-only analysis yielded a maximum HLOD score of approximately 2.37 with the marker *D8S552*. We are genotyping 11 additional markers to conduct fine resolution mapping of the 8p22-23 locus, expected to increase the HLOD score and narrow the critical region. Our results indicate that a novel locus on chromosome 8p22-23 contributes a large genetic effect in 50% of IgAN kindreds in our study, representative of large populations of Southeast Asian Chinese among whom familial IgAN is not uncommon.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2707**

**Genetic Evidence for Involvement of Adaptive Immunity in the Development of IgA Nephropathy: Several Alleles of MHC Class II Are Protective in a Caucasian Population** Mai Tuyet Vuong,[1,3,4] Sigrid Lundberg,[2] Iva Gunnarsson,[1] Lars Wramner,[7] Emeli Lundstrom,[1] Anders Fernstrom,[6] Lars Alfredsson,[5] Stefan H. Jacobson,[3] Leonid Padyukov.[1] *[1]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden; [2]Nephrology Unit, Department of Medicine, Karolinska University Hospital, Stockholm, Sweden; [3]Department of Nephrology, Danderyd Hospital, Karolinska Institutet, Stockholm, Sweden; [4]Department of Internal Medicine, Hanoi Medical University, Hanoi, Viet Nam; [5]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; [6]Department of Nephrology, Linköping University Hospital, Linköping, Sweden; [7]Transplantation Center, Sahlgrenska University Hospital, Göteborg, Sweden.*

Background: There is evidence suggesting that IgA nephropathy (IgAN) is an immunological disease and genetic findings contributing to disease development have been demonstrated. The role of Human Leukocyte Antigen (HLA) class II DR beta 1 (DRB1) has previously not been well studied. The aim of our study was to investigate the association of HLA-DRB1 alleles with IgAN in a Swedish Caucasian cohort.

Patients and Methods: The 1782 individuals included in our study consisted of 213 patients with biopsy proven IgAN, all of self-reported Caucasian ancestry. As a control cohort, 1569 healthy subjects from the same population in Sweden were included. HLA-DRB1 low resolution genotyping was performed and odds ratios adjusted for age and gender were calculated to assess the risk.

Results: In a simple allelic model the HLA-DRB1 *01, *04, *10 and *14 alleles represented an increased risk for IgAN with a cumulative odds ratio reaching 1.85 (95%CI 1.3-2.6). In opposite, the HLA-DRB1*03, *07, and *15 indicated a protective effect for IgAN, with cumulative OR=0.49 (95%CI 0.35-0.69). When the influence of risk alleles was adjusted for protective alleles and vice versa, only the protection from HLA-DRB1 remained significant.

Conclusion: The variants of HLA-DRB1 were associated with IgAN of which the HLA-DRB1 *03, and *15 revealed strong protective effect for IgAN. Our data suggest that involvement of adaptive immunity may be of importance in the development of the disease.

## SA-PO2708

### Polymorphisms in the Nonmuscle Myosin Heavy Chain 9 Gene (MYH9) Are Associated with the Progression of IgA Nephropathy in Chinese

Wenrong Cheng,[123] Li Zhu,[123] Sufang Shi,[123] Xujie Zhou,[123] Jicheng Lv,[123] Lijun Liu,[123] Hong Zhang.[123] *[1]Renal Division, Peking University First Hospital; [2]Peking University Institute of Nephrology; [3]Key Laboratory of Renal Disease, Ministry of Health of China.*

**Background** IgA nephropathy (IgAN) is the leading cause of end-stage renal disease (ESRD) in China considering different composition of ESRD causes in different ethnicities. Recent genome-wide association study(GWAS)indicated MYH9 gene was significantly associated with nondiabetic ESRD in African Americans, and also influenced kidney function in Europeans. Thus, in the present study, we aim to clarify whether MYH9 confers a shared mechanism among different causes of ESRD, and to seek a possibly further insight into our understanding of IgAN by applying GWAS data from ESRD to IgAN.

**Methods** 1116 Chinese, including 527 patients with renal biopsy-proved IgAN and 589 healthy controls, were enrolled in the present study. 3 SNPs (rs3752462, rs4821480, rs11089788) reported to be associated with ESRD with the most significance were genotyped by TaqMan assay and for further case control study.

**Results** None of the three SNPs was associated with the susceptibility to IgAN or clinical characters(systolic and diastolic blood pressure, serum creatinine, eGFR and urinary protein excretion)at the time of renal biopsy. However, eGFR decline rate was associated with rs11089788 in dominant model (p=0.028). Cox regression showed that rs11089788 (hazard ratio, 4.16; 95% confidence interval,1.58 to 11.00; $P=4.0\times10^{-3}$) was an independent predictive factor for renal survival besides time average proteinuria and serum creatinine.

**Conclusion** Based on a large Chinese IgAN cohort, we found an association between rs11089788 and prognosis of IgAN, mounting evidence of MYH9 as an important gene in IgAN to ESRD.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2709

### Genetic Variants in *Arhgef11* Linked to Proteinuria, Renal Hemodynamic Parameters and GFR in the Dahl Salt-Sensitive Rat

Jan Michael Williams,[2] Cary T. Stelloh,[1] Robert P. Ryan,[2] Kevin R. Regner,[1] Richard J. Roman,[2] Michael R. Garrett.[1] *[1]Dept of Medicine-Nephrology, Medical College of Wisconsin, Milwaukee, WI; [2]Dept of Physiology, Medical College of Wisconsin, Milwaukee, WI.*

The Dahl salt-sensitive (S) rat is a widely studied model of salt-sensitive hypertension which develops significant renal injury. Previously, a genetic analysis using the S and spontaneous hypertensive rat (SHR) identified a locus on chromosome 2 that strongly influences the development of renal injury. Temporal study (weeks 8-20) of blood pressure (BP) and renal parameters were compared between the S and a small congenic strain (which narrowed the locus to <1Mb). No significant difference in BP was detected from week 8-20 between strains (week 20, 202±6.4 and 194±2.1 mmHg, respectively). The congenic strain did exhibit significantly reduced proteinuria and improved renal function over the entire period of study. At week 20, proteinuria was 40% lower in the congenic and creatinine clearance was significantly higher (0.60±0.08 ml/min/gkw) compared to the S (0.40±0.02). Renal hemodynamic parameters were evaluated including: RBF, GFR and glomerular permeability ($P_{alb}$) at week 12. RBF was significantly higher in the congenic (4.4±0.33 ml/min/gkw) compared to S (3.0±0.19) as was FITC-inulin measured GFR (1033±101 and 564±63 µl/min/gkw, respectively). No significant difference was observed in $P_{alb}$ or nephron number between strains. Lastly, the congenic lived significantly longer compared to the S (median survival = 345 vs. 176 days). Using genetic and genomic methods we identified a small number of likely genetic variants linked to renal injury. The current evidence [promoter and coding sequence variants, gene expression differences, and a strong biological role] suggests that *Arhgef11* is a strong candidate underlying the locus. ARHGEF11 protein levels (in the S rat) are associated with up-regulation of the Rho/ROCK signaling pathway whereas this pathway is down-regulated in the congenic. In summary, this work provides evidence that renal injury and decline in renal function exhibited in the S rat may be linked to Rho/ROCK signaling and influenced by allelic variants in *Arhgef11*.

Disclosure of Financial Relationships: nothing to disclose

### Survival and Renal Damage during Development Salt-Sensitive Hypertension Can Be Regulated by Genes in Rat Chromosome 2

Andrey Sorokin, Victoriya Rufanova. *Medicine (Nephrology), Medical College of Wisconsin, Milwaukee, WI.*

The existence of genes associated with salt-sensitive hypertension on rat chromosome 2 has been confirmed previously using different congenic strains. It is plausible that the chromosome 2 congenic can attenuate renal damage primarily through an altered fibrotic response. However, long-term studies of survival and renal sclerosis had not been conducted. We used a chromosome 2 substitution strain (SS-2(BN)) in which one chromosome was transferred from the Brown Norway (BN) rat onto the Dahl salt-sensitive (SS) genetic background. At the weaning SS (n=8) and SS-2(BN) (n=8) males had been placed on 1% salt diet for seven months. By the end of this period 75% of SS and none of SS-2(BN) rat died. Heart weight and histological evaluation did not reveal any differences between rat strains. Kidney weight was significantly increased in SS compared to SS-2(BN) strain (1.98±0.11 vs. 1.68±0.02 g). Daily urine volume was elevated in SS compared to SS-2(BN) strain (36.9±9.0 vs. 10.9±1.7 ml/day). These effects were accompanied by sever glomerulosclerosis, protein deposition and tubular degradation. Expression of several proteins, involved into pro-fibrotic signaling was analyzed in kidney cortex and medulla using Western blotting. BCAR3 expression in cortex was increased and C3G expression in medulla was decreased in SS-2(BN) compared to SS strain. Immunohistochemistry evaluation of C3G localization uncovered strong positive signal in glomerular and abnormal tubular cells. In conclusion, these observations indicate that BN rat chromosome 2 harbor genes that contribute to survival and renal damage during development of salt-sensitive hypertension.

### Polymorphisms in the Protein C Pathway Increase Mortality in Dialysis Patients

Gurbey Ocak,[1] Marion Verduijn,[1] Hans L. Vos,[2] Carla Y. Vossen,[1] Frits R. Rosendaal,[1-3] Pieter H. Reitsma,[2-3] Raymond T. Krediet,[4] Elisabeth W. Boeschoten,[5] Friedo W. Dekker.[1] *[1]Clinical Epidemiology, LUMC; [2]Einthoven Laboratory for Experimental Vascular Medicine, LUMC; [3]Thrombosis and Haemostasis, LUMC; [4]Nephrology, AMC; [5]HMI, Naarden, Netherlands.*

**Objectives:** The protein C pathway plays an important role in the protection of endothelial barriers and in inflammatory and anticoagulant processes, which are fundamental in patients treated with dialysis. The aim of this study was to investigate the mortality risk of known SNPs in the protein C pathway.

**Methods:** 1070 incident dialysis patients were genotyped for rs6025 (Factor V Leiden), rs1042580 (THromBomoDulin), rs1799808 and rs1799809 (PROtein C), and rs867186 and rs2069952 (Endothelial Protein C Receptor). Hazard ratios (HRs) with 95% confidence intervals (95% CIs) were calculated for 1.5-year (short-term) and 5-year (long-term) all-cause and cause-specific mortality risk for homozygotes and heterozygotes combined for the minor allele (mutant genotype) as compared to homozygotes for the major allele (wild-type).

**Results:** Factor V Leiden was associated with an increased short-term all-cause mortality risk (HR 2.05; 95% CI 1.13-3.72) (Figure 1) and cardiovascular mortality risk (HR 2.34; 95% CI 1.00-5.47). *PROC* rs1799809 was associated with an increased short-term mortality risk due to other causes than infections and cardiovascular diseases (HR 1.95; 95% CI 1.05-3.60), especially due to treatment cessation. Furthermore, these two SNPs combined with *THBD* rs1042580 showed an increased short-term term all-cause mortality risk (HR 3.32; 95% CI 1.09-10.16). None of the SNPs was associated with long-term mortality risk conditional on survival of 1.5 years.

**Conclusion:** Our data study suggests that Factor V Leiden, *PROC* rs1799809, and *THBD* rs1042580 contributes to an increased short-term mortality risk in dialysis patients.

**SA-PO2712**

**Variation in the VDR Gene and Neuroantibody Markers in Dialysis Patients** Darius Mason,[1] Magdalene M. Assimon,[1] Michael H. Akroush,[2] Jeffrey R. Bishop,[2] Hassan El-Fawal.[1] *[1]Albany College of Pharmacy & Health Sciences, Albany, NY; [2]University of Illinois at Chicago, Chicago, NY.*

Cognitive deficits associated with reduced survival are prevalent in hemodialysis (HD) patients. Vitamin D receptor (VDR) SNPs have been linked to neuroprotection and neurodegeneration (ND). Chemokines and autoantibodies (Ab) to myelin basic protein (MBP), glial fibrillary acidic protein (GFAP), and neurofilament (NF) triplet proteins have been reported in ND studies. These Ab arise secondary to nervous system (NS) damage providing a means to assess NS injury in HD patients. Characterization of Ab biomarkers of neuropathy in HD patients and their association with VDR SNPs was studied.

Biomarkers in HD subjects receiving ergocalciferol (ergo) were compared to non-users. Subjects were genotyped for VDR BsmI [rs154410]. IL-6, TNF-α, and IgG titers against NF (NF-68, NF-160, and NF-200), GFAP and MBP were measured by immunoassay. BsmI genotypes and ND biomarkers relationships were assessed.

Subjects (age 63.3±16.1 years, 66% male) genotype frequencies (Bsm1;CC/CT/TT: 41.4%/49.5%/9.1%) did not deviate from Hardy-Weinberg equilibrium(p=0.34). Ergo users with the C allele had lower anti-NF160 and anti-MBP titers compared to non-users ($p<0.05$).

| | Ergo: n=40 | No Ergo: n=71 |
|---|---|---|
| Log IL-6 (pg/mL) | 0.60±0.40 | 0.52±0.43 |
| TNF-α (pg/mL) | 11.56±5.6± | 12.97±7.0 |
| anti-NF68 | 1.71±0.34 | 1.69±0.27 |
| anti-NF160 | 1.48±0.31* | 1.63±0.31 |
| anti-NF200 | 1.66±0.33 | 1.71±0.26 |
| anti-GFAP | 1.69±0.34 | 1.78±0.41 |
| anti-MBP | 1.63±0.25* | 1.76±0.28 |

* $p<0.05$; Values: mean±SD; Ab values=absorbance at 405nm

IgG against NS proteins in HD patients suggests neuronal and glial insult. Anti-NF presence, particularly anti-NF160 in patients with the C allele, is consistent with studies showing reduced expression of these proteins in vitamin D deficiency. Loss of these structural proteins, indicated by serum IgG, contributes to ND. Vitamin D deficiency may also contribute to demyelination, indicated by anti-MBP, which was ameliorated by ergo therapy. This preliminary study suggests Ab detection may be useful in monitoring ND changes and the efficacy of ergo in HD patients.

**KCNMB1 Variants Contribute to Glonmerular Filtration Rate and Progression of Chronic Kidney Disease** Jia Han, Yuqing Chen, Yu Liang, Ying Liu, Hong Zhang, Haiyan Wang. *Renal Division, Peking University First Hospital, Beijing, China.*

Background: Glomerular filtration rate (GFR) is a heritable trait, suggesting roles for genes in its regulation and decline. Mesangial and vascular smooth muscle cells control GFR by contraction dependent on voltage-gated Ca2+ influx. After membrane depolarization in these excitable cells, activation of large-conductance heteromeric K+ ("BK") channels repolarizes the plasma membrane, terminating Ca2+ influx in negative-feedback fashion. The regulatory beta1-subunit (KCNMB1) of BK, expressed in smooth muscle and mesangial cells, regulates the negative-feedback mechanism and determines contraction as well as basal tone. KCNMB1 variants were reported to be associated with hypertension as well as other disease. Here we asked whether the KCNMB1 variant influences GFR, in the basal state or during progressive renal decline.

Methods: We explored 3 KCNMB1 variants of rs11739136 (Glu65Lys), rs2301149 (Val110Leu), rs827778 (5'UTR) effects on GFR in three populations. A community-based population of Chinese Han (CH); individuals with IgA nephropathy with more than 24 months follow-up (IGAF) and end stage renal disease (ESRD) accepted dialysis. eGFR from serum creatinine, was calculated by CKD-EPI.

Results: The Glu65Lys variant predicted eGFR in CH population, and 65Lys carriers exhibited higher GFR (by ~1%, p=0.020, n=1176). In IGAF population with progressive renal disease as a result of IgA nephropathy, Val110Leu was associated with GFR decline. 110Leu carriers displayed faster chronic GFR decline slope (by ~1.7%, p=0.020, n=256), and 110L were more significantly frequent in ESRD persons (Chi-square=23.48, $p<0.001$, ESRD n=136 Vs control n=730).

Conclusions: Common KCNMB1 variants influence GFR. The results suggest that KCNMB1 is one of the candidate genes that influence GFR and affect the progression of chronic kidney disease.

**Association of Common Variants in Mendelian Disorder Genes with Renal Function: The CKDGen Consortium** Afshin Parsa,[1] Christian Fuchsberger,[2] Anna Kottgen,[6] Carsten A. Böger,[5] Conall M. O'Seaghdha,[8] Tennille S. Leak,[4] David Siscovick,[3] Wen Hong Linda Kao,[7] Caroline S. Fox.[8] *[1]University of Maryland; [2]University of Michigan; [3]University of Washington; [4]University of Pittsburgh; [5]Regensburg University, Germany; [6]Freiburg University, Germany; [7]Johns Hopkins University; [8]NHLBI's Framingham Heart Study, on Behalf of the CKDgen Consortium.*

INTRODUCTION: Results from population-based genome-wide association studies (GWAS) have uncovered new associations between common genetic variants and a variety of traits. Many of these associations map to genes previously linked to rare Mendelian disorders. Thus, we hypothesized that common variations in genes that harbor rare mutations causing Mendelian diseases with a renal phenotype would be associated with renal function in the general population.

METHODS: Using the keyword "kidney", we queried ~4000 listings within the OMIM public database. From this list, we curated 227 disease entries with described renal phenotypes and one or more identified putative autosomal gene. Our final candidate gene list included 283 unique entries. The renal phenotypes associated with these diseases are quite diverse and include renal dysplasia, tubular dysfunction, cysts and vesico-ureteric reflux. We then looked for association between common variants (minor allele frequency>5%) in these genes with eGFRcrea in 67,093 Caucasian participants of the CKDGen Consortium.

RESULTS: We identified a total of 6 novel associated candidate genes at $p < 10\text{-}5$ and identified another 11 moderately associated candidates ($p<10\text{-}4$). These findings include variants within the LRP2, NSD1, TSC1 and GSS genes. Replication efforts for our candidate loci are underway.

CONCLUSION: By exploring an extensive list of Mendelian genes known to be associated with renal pathology, we have identified numerous potentially novel common genetic variants that are associated with renal function in the general population. While preliminary, these findings suggest that database mining of common complex diseases may be feasible using a targeted Mendelian candidate gene approach.

**SA-PO2715**

**High Resolution Mapping of a CAKUT Locus on Mouse Chromosome 2** Francesca Lugani,[1,2] Zongyu Zheng,[1] Ali G. Gharavi.[1] *[1]Department of Medicine, Division of Nephrology, Columbia University, New York, NY; [2]Laboratory on Pathophysiology of Uremia, G. Gaslini Insitute, Genoa, Italy.*

**Objective**: Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) are the most common causes of end stage renal disease in children. We studied a spontaneous mouse mutant model of CAKUT, the Danforth's short tail mouse (*Sd*) . The heterozygous *Sd* mutants display a short tail with 100% penetrance and CAKUT (especially agenesis/hypodysplasia) with 80% penetrance. The homozygous mutants die shortly after birth due to severe multiorgan malformations, including bilateral renal agenesis, anorectal malformation, intestinal dysganglionosis and major defect of the axial cytoskeleton.

**Methods**: The *Sd* locus had previously been localized to Chr 2A3. To refine this locus, we produced 147 F2 segregants between Rsv/LeJ $^{Sd/+}$ mice and C57BL/6J mice and genotyped 10 informative markers (5 microsatellites and 5 SNPs) across the Sd locus. Multipoint lod scores were calculated using the R/QTL package, utilizing the discrete trait analytic model.

**Results**: Analysis of linkage yielded a peak lod score of 39 ($p=6x10^{-41}$) at rs33491214. Analysis of critical recombinants refined the Sd locus to a 1.3 cM region delimited by rs27129240 and rs29504224, which contains 15 transcriptional units. Of these positional candidates, 4 are known to be expressed in the developing urinary tract. Critically none of the positional candidates have been implicated in human malformation syndromes.

**Conclusions:** Identification of the *Sd* mutation and downstream pathways will provide significant insight into pathways underlying urogenital development and may clarify pathogenesis of human CAKUT and related malformation syndromes.

**SA-PO2716**

**Familial Focal Segmental Glomerulosclerosis Is Linked to a Locus on Chromosome 6q16~22** Nan Chen, Jun Ma, Jingyuan Xie, Zhaohui Wang, Weiming Wang, Hong Ren, Wen Zhang. *Department of Nephrology, Ruijin Hospital, Shanghai JiaoTong University, School of Medicine, Shanghai, China.*

**Objective** Recently, mutations in several genes including ACTN4, TRPC6, PLCE1 and INF2 were found to cause familial focal segmental glomerulosclerosis( FSGS) by linkage analysis . But most of the pathogenic genes were identified in Caucasian pedigrees. So we performed linkage analysis to map the disease gene in a large Chinese FSGS family.

**Methods :** A Chinese FSGS family was investigated. 78 members in this family were screened. Peripheral blood sample were taken and genomic DNA was extracted. Polymerase chain reaction(PCR) and sequence-direct were used to exclude already known genes. Affymetrix 10k SNPs chip were selected as markers for the whole genome-wide scan in some family members. Merlin and SimWalk2 software were taken for linkage analysis.

**Results** The family comprised four-generation, 103 members which is the largest FSGS kindred reported in China. It was a late-onset, autosomal dominant inherited FSGS family with eleven affected members. There was no mutation found in the NPHS2,

ACTN4 and TRPC6 gene. Linkage analysis of single nucleotide polymorphism (SNP) data identified consistently positive log of the odds (LOD) scores across chromosome 6q (maximal LOD score of 3.795 at rs1431213). Recombination narrowed the conserved haplotype to 5 Mb at 6q16~22(flanking markers rs2001102 and rs722366), which were not reported previously.

**Conclusions** The family is the largest late-onset, autosomal dominant inherited Chinese FSGS kindred. Pathogenic gene for this family may linked to a new locus on chromosome 6q16~22.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2717

**The Uridine Diphosphate Glucuronosyltransferase (UGT) 2B7 C802T Single Nucleotide Polymorphism (SNP) and Small Vessel Vasculitis** Melanie S. Joy,[1] Yichun Hu,[2] Susan L. Hogan,[2] Philip C. Smith,[3] Ronald J. Falk.[2] *[1]Schools of Medicine and Pharmacy, University of North Carolina, Chapel Hill, NC; [2]School of Medicine, Kidney Center, University of North Carolina, Chapel Hill, NC; [3]School of Pharmacy, University of North Carolina, Chapel Hill, NC.*

The uridine diphosphate glucuronosyltransferases (UGTs) are Phase II metabolism enzymes that conjugate glucuronic acid to functional groups including carboxylic acids (e.g. mycophenolic acid), alcohols, amines, and thiols. Numerous xenobiotics associated with drug-induced vasculitis are also substrates for UGTs. The *C802T* variant allele in *UGT2B7* is associated with decreased metabolic activity. The current study evaluated the susceptibility of small vessel vasculitis (SVV), lupus nephritis, and rheumatoid arthritis in patients who carried the *UGT2B7 C802T* allelic variant.

Genotyping for the *UGT2B7 C802T* single nucleotide polymorphism was conducted on DNA from disease and control populations. Allelic and genotype frequencies were reported by disease cohort and Hardy Weinberg Equilibrium was assessed. The odds of disease were calculated by the Logistic Model and controlled for race.

A total of 320 DNA samples were genotyped; 170 SVV, 53 lupus nephritis, 26 rheumatoid arthritis, and 71 healthy controls. The SVV patient demographics showed: 84F/86M and 98% Caucasian. The odds ratio between *UGT2B7* genotype groups, using healthy controls as a reference group are shown in the Table. The analyses controlled for race.

| Subject Group | OR (95% CI) | p value |
|---|---|---|
| Small Vessel Vasculitis | 3.46 (1.883, 6.345) | <0.0001 |
| Lupus Nephritis | 1.43 (0.620, 3.320) | 0.3998 |
| Rheumatoid Arthritis | 0.89 (0.348, 2.265) | 0.8025 |

The association between SVV and a polymorphism in the gene of a phase II metabolizing enzyme is intriguing given numerous publications that suggest exposure to various xenobiotics may be one etiology of SVV. A review of implicated drugs demonstrate that propylthiouracil, isotretinoin, diuretics, and NSAIDs are substrates for UGT2B7. These data could have implications for SVV risk secondary to potential environmental toxins that are also UGT2B7 substrates.

## SA-PO2718

**Denys-Drash Syndrome Associated with a Novel Exon 6 *WT1* Gene Mutation in a 18-Year-Old Girl** Pietro Claudio Dattolo,[1] Stefano Michelassi,[1] Giuseppe Ferro,[1] Alma Mehmetaj,[1] Paraskevas Iatropoulos,[2] Francesco Pizzarelli.[1] *[1]Nephrology and Dialysis Unit, S. M. Annunziata Hospital, Florence, Italy; [2]Genetic Department, Mario Negri Institute, Bergamo, Italy.*

Wilms tumor suppressor gene WT1 maps on chromosome 11p13 and is involved in several syndromes characterized by genital and kidney abnormalities. Classically, WT1 mutations occurring in exons 8 or 9 have been associated with Denys-Drash syndrome (DDS), characterized by early-onset and progressive nephropathy with progression to uraemia within the first four years of age, pseudoermaphroditism and Wilms tumor. Intron 9 splice donor site mutations have been associated with Frasier syndrome (FS), characterized by pseudoermaphroditism, slow progressive nephropathy and gonadoblastoma. The full-blown clinical picture only occurs in XY subjects as XX patients usually show normal genital development.

We describe a 18-year-old female patient with a past history of uninephrectomy in childhood for Wilms tumor and presenting to our unit because of end-stage renal disease secondary to chronic proteinuric nephropathy discovered two years before. The girl had a normal genital development except for evidence of right ovarian hypertrophy on ultrasound investigation. Genetic analysis showed XX karyotype and a WT1 exon 6 non-synonimous mutation due to aminoacid substitution (c.1012A>T) at nucleotide position 338 (R338X). Such a mutation has never been reported in literature and it was found neither in her parents nor in 178 chromosome controls. This case reinforces the hypothesis that WT1 mutations can be more numerous than the ones just reported in literature and cause a spectrum of different nephropathy-associated syndromes, with DDS and FS representing only the most known ones. WT1-related nephropathies may be less rare than we commonly believe and they should be kept in mind in every not immunologically mediated primary proteinuric nephropathy.

**Genetic Polymorphism of Proinflammatory Cytokines and Albuminuria in Japanese General Population: The Takahata Study** Ami Ikeda, Tsuneo Konta, Kazuko Suzuki, Yusuke Mashima, Kazunobu Ichikawa, Satoshi Takasaki, Isao Kubota. *Department of Cardiology, Pulmonology, and Nephrology, Yamagata University School of Medicine, Yamagata, Japan.*

**Background:** A cluster of proinflammatory cytokines play an important role in the development of various renal diseases and the expression of these cytokines is genetically modified. To examine the relation between genetic polymorphism of proinflammatory cytokines and albuminuria, we conducted a cross-sectional study in general population.

**Methods:** We genotyped the SNPs of six proinflammatory cytokines including IL-1beta, IL-6, IL-8 TNF-alpha, CCL1 and MCP-1 in 2927 Japanese subjects. Urine albumin-creatinine ratio (UACR) was obtained from morning spot urine.

**Results:** Albuminuria (UACR $\geq$ 30 mg/g) was observed in 19.2% of total subjects and was significantly related with the A/A+A/G genotypes of rs2069852 in IL-6 ($P$ = 0.010) and the A/A genotype of rs2282691 in CCL1 ($P$ = 0.002), as compared with the remaining genotypes. The multivariate analysis adjusted with traditional risk factors showed that these genotypes independently predicted albuminuria (Odds ratio [OR] 1.782, 95% confidence interval [CI] 1.171-2.712, $P$ = 0.007 for the A/A+A/G genotypes of rs2069852 in IL-6, and OR 1.432, 95%CI 1.128-1.770, $P$ = 0.003 for the A/A genotype of rs2282691 in CCL1, respectively). Along with the increase in the number of risk genotypes, the prevalence of albuminuria and UACR levels were increased.

**Conclusion:** This study revealed that the genotypes of IL-6 and CCL1 were related with albuminuria and the combination of these genotypes showed an additive effect on the prevalence and severity of albuminuria. This indicates that genetic background of inflammatory response might affect the development of renal injury in Japanese general population.

## SA-PO2720

**Transcriptional Complexity of the PKD1 Gene** Robert L. Bacallao,[1] Almira Kurbegovic,[2] Jeanette N. Mcclintick,[3] Marie Trudel.[2] *[1]Medicine, Richard Roudebush VAMC and Indiana University, Indianapolis, IN; [2]Molecular Genetics and Development, Institut de Recherches Cliniques de Montreal,Universite de Montreal, Montreal, QC, Canada; [3]Biochemistry and Molecular Biology, Indiana University, Indianapolis, IN.*

The PKD1 gene is comprised of 45 introns and exons encoding a 450 kDa protein. Mutations in this gene are associated with autosomal dominant polycystic kidney disease, the most common monogenetic cause of renal failure. While the gene locus is known to produce a 14 kb mRNA, recent evidence in the ACEView database suggests that the PKD1 locus may produce up to 14 different transcripts. To evaluate the degree of transcriptional complexity, we isolated RNA from mouse embryonic fibroblasts derived from 3 mouse lines; a PKD1 transgenic mouse ($PKD1^{++/++}$), a wild type ($PKD1^{+/+}$) mouse and a PKD1 knockout mouse ($PKD1^{-/-}$). The $PKD1^{-/-}$ mouse was generated by a knockout of exon 3 in the pKD1 locus. Transcript expression was analyzed using the GeneChip® Mouse Exon 1.0 ST Array (Affymetrix, Santa Clara, CA). The Mouse Exon 1.0 ST array has at least four probes per exon. Intra-sample variability in the RNA was less than 5 %. Comparing the intensity values from the exon probes between the $PKD1^{++/++}$ RNA and $PKD1^{+/+}$ RNA revealed that virtually all the PKD1 exons were expressed at two times the level observed in the $PKD1^{+/+}$ mouse save exons 18 and 30. Exons 18 and 30 were expressed six fold more in the $PKD1^{++/++}$ mouse. Strikingly evaluation of the RNA from the PKD1-/- mouse line showed significant signals from exons 1,5, 6,8,10,11, 14, 15, 18, 22-23, 25-27, 29, 34, 36, 38, 39-43. Also one exon 45 probe also showed significant level of expression. This data suggests that multiple transcripts arise from the PKD1 locus and their expression pattern has not been fully elucidated.

## SA-PO2721

**PC1 Regulates ER $Ca^{2+}$ Release through Activation of the PI3K/Akt Pathway To Modulate PC2-$IP_3$R-STIM1 Interaction** Netty Santoso, William B. Guggino. *Physiology, Johns Hopkins School of Medicine, Baltimore, MD.*

Mutations of Polycystin-1 (PC1) and Polycystin-2 (PC2) are the main cause for development of the genetic disease Polycystic Kidney disease (ADPKD). However, the molecular mechanism underlying how these mutations cause ADPKD is still unclear. PC2, a member of the TRP channel family, has been suggested to function as a $Ca^{2+}$ channel in the Endoplasmic reticulum (ER) and on the cell surface. Meanwhile, PC1 was shown to interact with PC2 to facilitate the trafficking and function of PC2 as a $Ca^{2+}$ channel on the cell surface. Although PC1 is thought not to have channel properties, misregulation of intracellular $Ca^{2+}$ homeostasis has been implicated in both PC1 and PC2 mutations. Here, we try to investigate whether PC1 is involved in the regulation of $Ca^{2+}$ homeostasis. We utilized a MDCK cell line that has stable expression of full-length PC1 to analyze intracellular $Ca^{2+}$ release from the ER. Expression of full-length PC1 in these cells caused inhibition of the $Ca^{2+}$ release compared to the control cells. We then correlated the $Ca^{2+}$ release inhibition with the reduction of endogenous PC2-$IP_3$R interaction in the PC1-expressing cells. Normally, PC2 interacts with the $IP_3$R, and this interaction is known to enhance $Ca^{2+}$ release. We also found that endogenous STIM1 interacted with the $IP_3$R, and this interaction was enhanced with PC1 expression. This interaction appeared competitive to the PC2-$IP_3$R interaction to inhibit ER $Ca^{2+}$ release. Finally, we show that the PI3K/Akt signaling pathway was involved in regulating the STIM1-$IP_3$R-PC2 interaction to modulate ER $Ca^{2+}$ release. Previously, it

was shown that PC1 expression in MDCK cells induces activation of the PI3K/Akt signaling pathway to suppress cell apoptosis. Here, we confirm the increased activation of the PI3K/Akt pathway in the PC1 cells, and we found that activation of the pathway inhibited the PC2-$IP_3R$ interaction, and ER $Ca^{2+}$ release, while increasing the STIM1-$IP_3R$ interaction. We propose that PC1 expression suppresses cell apoptosis through activation of the PI3K/Akt pathway by reducing the intracellular $Ca^{2+}$ release.

**Mechanisms of Plasticity of CD133+ Renal Progenitor Cells** Benedetta Bussolati, Cristina Grange, Aldo Moggio, Federica Collino, Giulia Aghemo, Giovanni Camussi. *Internal Medicine, University of Torino, Torino, Italy.*

The tubular compartment of the nephron displays a high regenerative ability. $CD133^+$ renal cells have been isolated in the tubular compartment and display characteristics of progenitor cells. However, the possible contribution of this resident population to repair is unknown. The purpose of this study was to evaluate whether hypoxia modulates stemness of $CD133^+$ progenitor cells. Methods: We isolated and cultured in normal and hypoxic ($1\%O_2$) conditions CD133+ renal progenitors. Expression of stem transcription factors was evaluated by Western Blot analysis and quantitative RT-PCR. Activation of Oct4 promoter was evaluated after cell lentiviral infection with an Oct4 GFP-reporter system. In vivo differentiation was evaluated after cell injection within Matrigel under the renal capsule of immuno-compromised mice.Results: CD133+ cells showed an expression of Oct4A, Oct4B and Oct4B1. Klf4 and c-Myc mRNA and protein were expressed, at low level, in renal CD133+ progenitors, whereas Sox2 expression was inconsistent. Hypoxia by increasing HIF-1alpha up-regulated Oct-4 isoforms in CD133+ cells via regulation of the Oct4 promoter. In parallel, hypoxia increased proliferation, clonogenicity and CD133 expression in the renal progenitors. When injected in vivo, CD133+ hypoxic progenitors showed an increase in their differentiative ability. In particular, the injected cells differentiated in structures resembling the different segments of the nephron, and expressed aminpeptidase, Tamm-horsfall protein and aquaporin-2 and 3 markers. In conclusion, these results suggest that hypoxia may direct $CD133^+$ progenitors toward a more stem phenotype, via Oct4A activation, inducing an increased proliferation, clonogenicity and differentiative potency. The plasticity of renal CD133+ cells could be implied in renal regeneration after hypoxic conditions.

**SA-PO2723**

**Phenotypic Dispersion in a Rodent Model of Hypercalciuria Is Linked to Sex and to Genes for Spliceosome Formation, RNA Manipulation, Metal Ion Binding and Energy Metabolism** Guy M. L. Perry,[1] Keith Nehrke,[2] David A. Bushinsky,[2] Steven J. Scheinman.[1] *[1]Medicine, SUNY Upstate Medical University, Syracuse, NY; [2]Medicine, University of Rochester, Rochester, NY.*

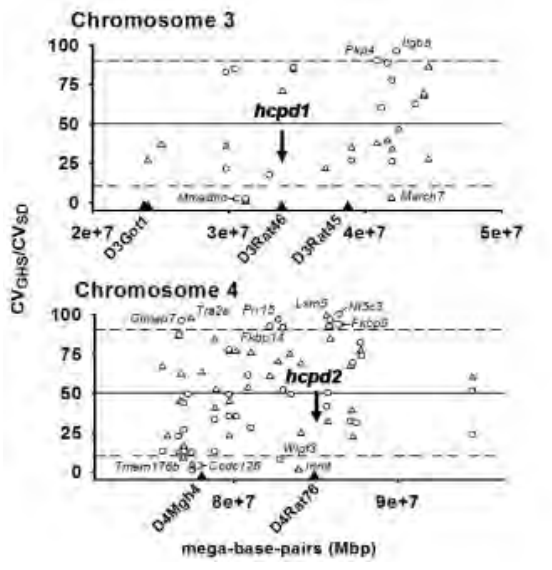
Empirical evidence from several animal models indicates that residual phenotypic variance is under genetic control and may be affected by sex; urinary physiology is also notable for high residual variability. We mapped two quantitative trait loci (QTL) for phenotypic dispersion (*PD*) in urinary calcium (*hcpd1, hcpd2*) in F2 intercrosses of Genetic Hypercalciuric Stone-forming (GHS) rats - Wistar-Kyoto (WKY) controls. In female F2s, *hcpd1* was significantly associated with PD ($P_{Bon}$<0.05) and *hcpd2* and two other microsatellite markers were suggestively ($P_{FDR}$<0.05) associated with *PD.*

Table1: QTL for PD in F2 GHS-WKY rats

| Locus (QTL) | n | $\sigma^2(CV)_{WKY}$ | $\sigma^2(CV)_{Het}$ | $\sigma^2(CV)_{GHS}$ | *P* |
|---|---|---|---|---|---|
| *D3Rat46* (*hcpd1*) | 125 | 3.76 (66.4) | 1.23 (45.8) | 1.58 (53.7) | 0.0002 |
| *D4Rat76* (*hcpd2*) | 126 | 0.972 (43.8) | 2.15 (62.2) | 2.41 (49.4) | 0.0024 |
| *D9Mgh2* | 105 | 1.15 (42.4) | 2.72 (68.5) | 2.61 (52.9) | 0.0009 |
| *D12Rat25* | 101 | 3.49 (64.5) | 1.49 (55.0) | 0.983 (45.6) | 0.0007 |

No locus was associated with PD in males (*P*>0.2). Relative variability in gene expression in GHS rats was compared to that in unselected Sprague-Dawley controls using coefficient of variance (CV) ratios; 31% of genes with extreme expression ratios nearby (10 MB) *PD* QTLs had methylation, RNA transcription or spliceosome functions, 20% were involved with energy metabolism and 19% with metal ions.

Figure 1: Expression CV ratios for genes linked to *hcpd1* and *hcpd2*



Sexual patterns in urinary PD were also detected in congenic rat lines. Our results indicate the existence of genes causing residual variance in urinary calcium excretion, expressed primarily in females and via RNA-modifying genes, a finding of enormous potential importance to nephrological genetics.

**SA-PO2724**

**Sleep Disordered Breathing Does Not Improve with Alternate Nightly Nocturnal Home Hemodialysis** Carolyn L. Van Eps,[1] Brett Duce,[2] Carmel M. Hawley,[1] Craig Hukins.[2] *[1]Department of Nephrology, Princess Alexandra Hospital, Brisbane, Queensland, Australia; [2]Department of Respiratory Medicine, Princess Alexandra Hospital, Brisbane, Queensland, Australia.*

Sleep disordered breathing (SDB) is common in ESKD and linked to adverse cardiovascular and quality of life outcomes. Daily dialysis regimens have been shown to improve SBD. We hypothesize that alternate nightly nocturnal home hemodialysis (NHD) may improve SDB.

47 patients converted from conventional home hemodialysis to NHD (6-9hours for 3.5-5sessions weekly). 32 patients(Age 55±11years, 88% Male, BMI 28.8±7.2kg/$m^2$, Diabetes 25%) at baseline and 25 patients at 3 months consented to sleep assessment using polysomnography with esophageal pressure assessment; ventilatory response to hypoxia and hypercapnia using rebreathing techniques; Epworth Sleepiness Score (ESS).

97% of patients had SDB which was predominantly obstructive(>98% of events). Most patients had moderately severe (Total Apnea Hypopnea Index(AHI) 95% CI 17.8-29.8/sleep hour),and 21% severe obstructive sleep apnea (OSA). There was no significant sleep hypoxia. 56% of patients had >15 leg movements/hour. There were no significant changes in sleep architecture, AHI, Arousal Index or ESS (6.9±3.1 vs7.0±4.1, p=0.20). Non-REM sleep mean partial pressure of oxygen improved but other measures of oxygenation did not. Benzodiazepine use increased(6-28%). There was a decrease in the intercept of the carbon dioxide-minute ventilation relationship but no change in its slope. The slope of the minute ventilation-oxygen saturation relationship during hypoxic challenge did not change. Interdialytic weight gains trended to increase.

Prevalence of OSA, periodic leg movements and the relationship between ventilatory drive and arterial carbon dioxide concentration did not improve with conversion to NHD. Central apneic events were unusual suggesting that control of uremic toxins and acidemia is of minimal importance in SDB in ESKD. Our failure to show improvement in OSA may result from persistently high interdialytic fluid gains with pharyngeal narrowing and obstruction when excess fluid redistributes as patients are recumbent. Increased benzodiazepine use may contribute.

Disclosure of Financial Relationships: Other Relationship: Sponsorship for conference travel from Amgen and Fresenius Medical Care.

**SA-PO2725**

**Gentamicin Pharmacokinetics during Short-Daily Hemodialysis** Brian S. Decker,[1] Sharon M. Moe,[1] Kevin Sowinski.[1,2] *[1]Department of Medicine, Division of Nephrology, Indiana University School of Medicine, Indianapolis, IN; [2]Department of Pharmacy Practice, School of Pharmacy and Pharmaceutical Sciences, Purdue University, West Lafayette, IN.*

**Introduction**

Short-daily hemodialysis (SDHD) is emerging as an alternative to conventional, thrice-weekly hemodialysis due to its putative physiological benefits. However, there is a paucity of data regarding the appropriate dosing of medications in patients receiving SDHD.

**Purpose**

The purpose of this study was to investigate the effect of SDHD on the pharmacokinetics (PK) and intradialytic removal of gentamicin.

**Methods**

Six non-infected anuric adults treated with SDHD were studied and received four dialysis sessions over 4 days. Following the completion of a subject's first SDHD, gentamicin IV 2 mg/kg was administered. Blood samples were obtained over the ensuing 3 days during each subsequent inter and intradialytic period. During that time, subjects received three additional SDHD sessions. Gentamicin concentrations were determined by EMIT. Candidate pharmacokinetic models were fit to the concentration-time data using ADAPT 5 and PK parameters were determined by standard methods. Data are presented as median (range).

**Results**

5 men and 1 women [Age: 53.5 (28-59 yrs); Weight: 91 (59-110 Kg)] were studied. All subjects received SDHD with a new CT dialyzer (Exeltra 150, Baxter Healthcare, Inc.). SDHD dialysis operating characteristics were: dialysis time: 2.5 (2-2.5 hours) and Qb: 500 (450-500) mL/min. Pharmacokinetic parameter estimates and other relevant data are shown in Table 1. A two compartment open model best fit the pharmacokinetic data.

Gentamicin Pharmacokinetic Data

| CLs (mL/min) | CLdial (mL/min) | Vc (L) | Vss (L) |
|---|---|---|---|
| 3.1 (2.7-11.1) | 128 (77.9-252) | 13.1 (3.85-32.9) | 24.6 (14.5-46.0) |

**Conclusions**

The pharmacokinetic data for gentamicin in our SDHD patients is similar to the pharmacokinetic data for gentamicin administered to thrice-weekly HD patients. This suggests that the dosing recommendations for gentamicin in thrice-weekly HD can be used for patients receiving SDHD.

**Continuos Ultrafiltration Can Improve Blood Pressure Control and the Efficiency of Hemodialysis** James P. Jones,[1] Edward F. Leonard,[2] Antony A. Farias,[1] Nathan W. Levin,[3] Maria E. Tarallo,[3] Stanley Cortell.[1] *[1]Medicine, St. Luke's Roosevelt Hospital Center, New York, NY; [2]Chemical and Biomedical Engineering, Columbia University, New York, NY; [3]Renal Research Institute, New York, NY.*

The high prevalence of hypertension (80%) is a major factor in the high mortality rate in ESRD patients. Fluid removal is essential for volume and blood pressure control. We have designed an ambulatory, ultrafiltration (UF) device based on microfluidic flow paths and ultrathin silicon-based nanopore filters. The device has a very small blood contact area ~50 $cm^2$ and an active transport volume of less than 0.5 ml. It operates at an ultrafiltration rate of 1 ml/min (equivalent to 10 kg/wk), and if worn continuously would maintain a nearly invariant, dry weight. As a simulation of the device, we have tested the hypothesis that hemodialysis patients maintained near their dry weight would have better controlled blood pressure and the efficiency of improved urea clearance. We studied 12 stable hemodialysis patients who received UF 4 days/week (M,W,Th,S) and twice weekly dialysis with UF (Tu,F). The pre-dialysis blood pressures and Kt/V of the 12 patients were compared in each patient with 4 weeks of standard 3 times per week hemodialysis and UF. MAP decreased from 110 to 95 ($P < 0.001$). Dialysis time decreased from 10.74 to 8.24 hours per week. UF per dialysis treatment decreased from 3.25 L to 1.82 L. Weekly Kt/V decreased from 4.19 to 3.75. Weekly Kt/V per minute showed an improvement of 16.65 %. This study supports the premise that an ambulatory UF device providing continuous UF would not only improve blood pressure control, but could also support a new regimen of continuous daily UF and in-center dialysis in two rather than three sessions/week. However this would require long term studies.

| | Pre Trial | | | | | | Daily Phase | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Patient | Sys. | Dia. | MAP | HD Time (hours/wk) | weekly kT/V | HD UF Volume (L/wk) | Sys. | Dia. | MAP | HD Time (hours/wk) | weekly kT/V | HD UF Volume (L/wk) |

**Nocturnal Hemodialysis in Pregnancy; the Mounting Toronto Experience** Tom Cornelis,[1] Johannes Keunen,[2] Moumita Barua,[1] Andreas Pierratos,[3] Marc B. Goldstein,[4] Christopher T. Chan,[1,5] Michelle A. Hladunewich.[1,2,5] *[1]Division of Nephrology, University Health Network, Toronto, ON, Canada; [2]Department of Obstetrics and Gynecology, Mount Sinai Hospital, Toronto, ON, Canada; [3]Division of Nephrology, Humber River Regional Hospital, Toronto, ON, Canada; [4]Division of Nephrology, St Michael's Hospital, Toronto, ON, Canada; [5]Equal Contribution.*

*Background*: Nocturnal hemodialysis (NHD) may improve fertility and lower pregnancy complications in women with chronic kidney disease (CKD). Here we expand our experience in NHD during pregnancy.

*Methods*: Cohort study of pregnant CKD patients on NHD from 2001 through 2010 in Toronto. Primary objective was to describe maternal-fetal outcomes and biochemical indices through pregnancy. Obstetrical follow-up included nuchal translucency ultrasound (US) (11-14 wk), quad test (16 wk), placental US (22 wk), and serial biophysical profile (BPP) scores and biometry US (from 26 wk).

*Results*: 11 patients (median age 34 y) had 14 pregnancies. At time of conception, 8 patients were on NHD (11 pregnancies), 1 patient was on conventional HD and 2 were not on dialysis. In NHD patients, the dialysis dose was increased to a weekly minimum of 42 hours and in non-NHD patients, NHD was started after conception. Median predialysis urea and blood pressure were maintained within physiological levels. Serial US revealed the estimated fetal weight averaged along the 50$^{th}$ percentile. BPP scores and placenta studies were by in large normal. Only 1 patient had transient polyhydramnios. Median gestational age and birth weight were 36 wk 5 days and 2020 g respectively. Complications were more common in patients not yet on NHD at time of conception and included placental insufficiency (n=1), low birth weight (below 10$^{th}$ percentile) (n=3), as well as preterm delivery (before 34 weeks) (n=4) secondary to cervical incompetence in 3 patients and leading to neonatal death in 1 patient.

*Conclusions*: NHD in pregnancy is feasible and may reduce maternal-fetal complications in ESRD patients. Pregnancy counselling in ESRD patients should include education on NHD as the best available dialysis modality. Strict combined obstetrical-renal follow-up is crucial.

## SA-PO2728

**A Single Centre Study Comparing Vascular Access Related Infection Rates in Nocturnal Versus Conventional Home Haemodialysis Patients Using Rope Ladder Needling Technique** Amy A. Crosthwaite, Rosemary Masterson. *Department of Nephrology, Royal Melbourne Hospital, Melbourne Health, Melbourne, Victoria, Australia.*

Background:

Extended hours nocturnal home haemodialysis (NHD) confers many advantages but there is concern about increased infection related morbidity and mortality in this cohort. In addition, it is unclear whether vascular access needling technique (buttonhole vs rope ladder) confers additional infection risk. We compared septic access event rates between cohorts of conventional (CHD) and nocturnal home haemodialysis patients to ascertain whether extended hours dialysis was associated with increased infection risk.

Methods:

A retrospective observational single centre cohort study comparing rates of infection and associated complications between NHD (n=78) and CHD (n=30) home dialysis patients between 2005 and 2010. All patients were followed for at least 12 months after commencing home dialysis.

Results:

Between May 2005- May 2010 261.60 (NHD 154.06, CHD 107.61) patient years of home haemodialysis were analysed. The average patient age was 47±19 years and 80% were male. Rope ladder needling technique was universally used. 19.5% of all patients experienced at least 1 septic access event. 67% events occured in the NHD patient cohort and 9 patients had ≥1 event. There was no significant difference in the rate of events between the 2 cohorts (NHD=0.14 events/patient year, CHD = 0.1 events/patient year, p=ns). Similar proportions of each group developed infections (NHD 27%, CHD 28%). The event rates in AVF and AVG were 0.08 and 0.03/patient year respectively. MSSA was the commonest pathogen identified. Complications of infected access included blood stream (NHD 66%, CHD 54.5%) and metastatic infection (NHD 19%, CHD 18%). There was no infection related deaths. Five patients discontinued home dialysis due to septic access events.

Conclusion:

This data confirms the significant morbidity associated with septic access events in the home dialysis population. In this cohort, the increased risk of infection was not associated with longer dialysis hours. Compared with other observational data. rope ladder needling technique appears to be associated with a lower rate of access infection.

**SA-PO2729**

**Impact of Urgent In-Hospital Chronic Kidney Disease Education among Patients with Unplanned Dialysis Start** Jean-Philippe Rioux, Harpaul Cheema, Diane M. Watson, Joanne M. Bargman, Christopher T. Chan. *Department of Medicine, Division of Nephrology, University Health Network, Toronto, ON, Canada.*

**Background:** The impact of urgent in-hospital educational interventions on the adoption of home dialysis (peritoneal dialysis (PD) and home hemodialysis (HHD)) after unplanned renal replacement therapy (RRT) start is unknown.

**Methods:** Clinical demographics of consecutive patients initiating RRT acutely from January 2005 to December 2009 were abstracted using our institutional electronic records. All patients received multimedia chronic kidney disease and modality education by the same consulting nurse practioner prior to discharge from the hospital. Clinical characteristics of patients choosing home dialysis or staying on in-center hemodialysis were compared.

**Results:** Between 2005 and 2009, 203 patients started hemodialysis acutely at our center. Seventy one patients adopted home dialysis (49 patients to PD and 22 to HHD) and 132 remained on in-center HD. Patients adopting home dialysis were similar to in-center HD patients in term of age and gender but had a different distribution of co-morbidities and etiology of end-stage renal disease. Patients known by a nephrologist before initiating RRT represent 39% of acute starters.

**Conclusion:** Home dialysis is feasible after unplanned renal replacement therapy start. Educational interventions are beneficial and should be promoted among inpatients initiating dialysis acutely. Prospective evaluation of clinical outcomes of this vulnerable population warrants further investigation.

Characteristics of patients adopting home or in-center dialysis

| | Home dialysis | In-center HD | p-value |
|---|---|---|---|
| | (n=71) | (n=132) | |
| | | | |
| Age, yrs | 55 ± 18 | 59 ± 16 | 0.09 |
| Gender, male, % | 49 | 52 | 0.2 |
| Etiology of ESRD | | | |
| Glomerulonephritis, % | 14 | 6 | 0.07 |

**Nocturnal Hemodialysis Is Associated with Improved Angiogenicity of Endothelial Progenitor Cells Compared with Conventional Hemodialysis** Darren A. Yuen,[1] Michael Kuliszewski,[1] Christine Liao,[1] Dimitry Rudenko,[1] Suzanne Advani,[1] Kerri Thai,[1] Howard Leong-Poi,[1] Christopher T. Chan.[2] *[1]St. Michael's Hospital, Toronto, Canada; [2]Toronto General Hospital, Toronto, Canada.*

**Background**: CKD is associated with an increased risk of peripheral vascular disease (PVD). Endothelial progenitor cells (EPCs) play important roles in maintaining vascular health. While EPCs from healthy individuals exert angiogenic effects in PVD models, uremia impairs EPC function *in vitro*. Nocturnal hemodialysis (NHD) increases uremic clearance and improves vascular function when compared with conventional hemodialysis (CHD). Whether NHD affects *in vivo* EPC angiogenic activity in the setting of ischemic limb disease is unknown. **Methods**: Peripheral blood-derived EPCs from healthy controls (n = 5) and age- and gender-matched CHD (12 hrs/wk, n = 10) and NHD (30 - 50 hrs/wk, n = 8) patients were cultured. 5 x $10^5$ EPCs or saline were injected at 5 sites in the ischemic hindlimb muscle of athymic nude rats 1 day post-left common iliac artery ligation. Hindlimb perfusion was assessed on day 28 via contrast bubble perfusion. Capillary density was assessed via lectin staining and expression of the angiogenic cytokines VEGF and SDF-1α via qPCR. **Results**: NHD was associated with increased clearance (CHD vs NHD PRU: 70 ± 6 vs 80 ± 3%, $p < 0.05$). While CHD EPC injection had no effect vs. saline, NHD EPC injection significantly improved ischemic hindlimb perfusion and capillary density to levels similar to that achieved with healthy control EPCs (Table 1). Levels of cytokines activated early in the angiogenic response (VEGF, SDF-1α) were not different 28 days post-ligation across all 4 treatment groups. **Conclusions**: NHD is associated with a significantly improved ability of EPCs to restore perfusion in a model of PVD, providing a possible explanation for the improved vascular outcomes seen with NHD.

| | Saline | Healthy Control | CHD | NHD | p value |
|---|---|---|---|---|---|
| Hindlimb perfusion ratio (ischemic:nonischemic limb) | 0.46 ± 0.05 | 0.80 ± 0.11 | 0.61 ± 0.06 | 0.85 ± 0.04 | < 0.05 |
| Ischemic hindlimb capillary density (capillaries/hpf) | 49 ± 6 | 75 ± 11 | 46 ± 7 | 86 ± 5 | < 0.05 |

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2731**

**Every-Other Night Home Hemodialysis with NxStage System One: A Crossover Pilot Study** Brigitte Schiller, Sheila Doss, John E. Moran. *Satellite Healthcare, Mountain View, CA.*

The standard practice for home hemodialysis (HD) with the NxStage System One is for the patient to dialyze 5-6 times weekly. We hypothesized that equally good outcomes could be achieved with higher doses of dialysis every second day, thereby potentially reducing burn-out with daily therapy.

We performed a crossover pilot study in prevalent patients following an A-B-$A^+$ design, with Phase A 4 weeks on current therapy, Phase B 8 weeks of high volume every-other night therapy (EON), and Phase $A^+$ 4 weeks of original therapy. Clinically stable patients undergoing weekly 5-6 times short daily home HD (SDHD) or nocturnal home HD (NHHD) with the NxStage System One took part. SDHD averaged 20 ± 3 hours with 151 ± 32 L dialysate, NHHD 47 ± 3 hours with 151 ± 23 L. Therapy for EON was prescribed with 50 or 60 L over a minimum of eight hours resulting in a mean of 31 ± 3 hours dialysis per week using 200 ± 17 L dialysate. Thus far 13 patients aged 52 ± 11 years have been enrolled, including 11 males, 5 diabetics; 7 have completed the study with 3 patients stopping prior to completion, and 3 still in study.

Results (mean ± SD) are shown from 27 patient months on EON, including follow-up.

| | Phase A | Phase B | Phase A+ | Follow-up |
|---|---|---|---|---|
| std Kt/V | 2.7 ± 1 | 3.4 ± 0.2 | 2.8 ± 0.8 | 3.0 ± 0.4 |
| Hgb | 10.6 ± 0.2 | 11.2 ± 0.7 | 11.2 ± 0.5 | 11.2 ± 0.4 |
| PO4 | 5.4 ± 1.5 | 5 ± 1.6 | 4.8 ± 1.3 | 4.6 ± 0.6 |
| Albumin | 4 ± 0.2 | 4.2 ± 0.2 | 4.2 ± 0.1 | 4.1 ± 0.1 |
| nPNA | 0.9 ± 0.02 | 0.9 ± 0.02 | 0.8 ± 0.02 | 0.9 ± 0.01 |

No change in antihypertensives or phosphate binders was observed. ESA usage was not evaluable due to conversion from a long-acting to a short-acting ESA during the study. All 7 completed study patients continued on EON. Only 1/13 patient stopped due to medical issues, 2/13 were unable to adhere to study timeline due to surgery.

These preliminary data suggest that EON with increased dialysate volume and longer times provides an alternative to daily HD in this stable patient group. EON is an attractive regimen, aligning solute and fluid removal with a less burdensome dialysis schedule. Long-term follow up is in progress.

**SA-PO2732**

**Simulating Hemodialysis Modalities Using an Individualized Bayesian Urea Kinetic Modeling (IBKM)** Liping Zhang,[1] Adriana Hung,[2] Marc Pfister.[1] *[1]Dept. of Laboratory Medicine, University of California San Francisco, San Francisco, CA; [2]Dept. of Medicine, Vanderbilt University, Nashville, TN.*

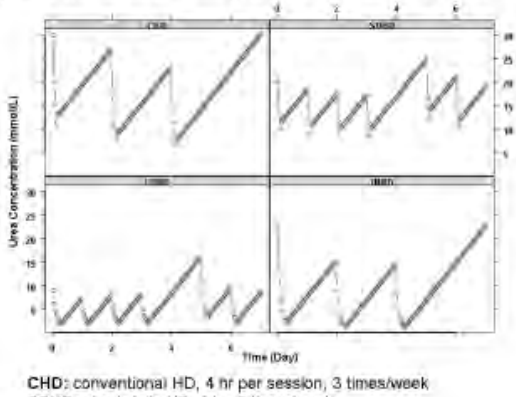
**Background:** Non-conventional hemodialysis (NCHD) modalities such as short daily HD are promising and increasingly used in practice as alternatives to "conventional HD (CHD)" of 3 treatments per week. Lacking of good standards to measure and methods to forecast their performance, the prescription of NCHD is often done empirically.

**Objective:** To simulate urea kinetic profiles under different HD modalities using individualized Bayesian urea kinetic model (IBKM) and to assess IBKM as a potential tool for forecasting NCHD prescription.

**Methods:** Based on a Bayesian framework, IBKM is a double-pool kinetic model developed with adult data on CHD to forecast and guide individual HD prescription. IBKM is applied to simulate urea kinetic weekly profiles in a single patient (i) at steady state under CHD and 3 NCHD modalities, and (ii) when HD prescription is switched from CHD to a NCHD modality.

**Results:** For a study patient with body weight of 75 kg, the IBKM-simulated urea kinetic profiles are shown in Figure 1.

Figure 1. IBKM-simulated urea kinetic profiles at steady state for various HD modalities



**CHD:** conventional HD, 4 hr per session, 3 times/week
**SDHD:** short-daily HD, 1 hr, 6 times/week
**LDHD:** long daily HD; 6 hr, 6 times/week
**INHD:** in-center nocturnal HD; 6 hr, 3 times/week

Average urea concentrations and area under concentration curves (AUC) above a hypothetical threshold of 15 mmol/L are calculated to illustrate how IBKM may be used to forecast and quantify HD performance.

**Conclusion:** IBKM is able to simulate individual urea kinetic profiles for various HD modalities, can be applied to other solutes, and is a promising tool for forecasting and guiding NCHD prescription.

**Next-Generation Access for Peritoneal Dialysis without the Catheter Exit Site** Yudo Tanno,[1] Hiroyasu Yamamoto,[1] Keitaro Yokoyama,[1] Masami Uechi,[2] Tatsuo Hosoya.[1] *[1]Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Laboratory of Veterinary Internal Medicine, Department of Veterinary Medicine, College of Bioresource Sciences, Nihon University, Kanagawa, Japan.*

Peritoneal dialysis (PD) is currently performed with a portion of the catheter exposed and consequently may cause catheter-related complications (catheter breakage, catheter exit-site infections, tunnel infection, peritonitis due to touch contamination, etc.). On the other hand, patients may refuse to undergo PD especially for cosmetic reasons as a part of the catheter is seen protruding from the abdominal wall. To address these issues, we have developed "Fully Embedded Subcutaneous Access for Peritoneal Dialysis" (FESTA for PD). While the PD catheter is placed into the peritoneal cavity, percutaneous access is gained via vascular graft (GRASIL®, Terumo, Japan), which has good elasticity and a high self-sealing capability, on the opposite side. The percutaneous access device is then embedded subcutaneously so that peritoneal access can be gained by subcutaneous puncture for changing the replacement/dialysate fluid bags.

The FESTA for PD was tested for durability and subcutaneous fluid leakage while the volume of dialysate instilled and drained was measured in pigs. Consequently, the estimated volume of subcutaneous fluid leakage per puncture in FESTA for PD was 2 g or less while it had an estimated life of 10 years. The volume of dialysate instilled and drained was almost equal to that in the conventional PD technique. In a 10-day study of FESTA for PD in beagle dogs, neither puncture-site infection nor peritonitis was observed.

These findings suggest that FESTA for PD, which is next generation peritoneal access system without the catheter exit site, will make a positive impact on the renal replacement therapy.

**Impact of Catheter Style on Pediatric Peritoneal Dialysis Complications** Susan E. Ingraham, Hiren P. Patel. *Pediatric Nephrology, Nationwide Children's Hospital, Columbus, OH.*

Infection and catheter malfunction are common complications of chronic peritoneal dialysis (PD). Some studies have suggested that infection rate may be reduced by a caudally-oriented exit site, which is facilitated by use of a swan-neck catheter with a preformed bend in the extraperitoneal segment. In 2007, our pediatric renal dialysis unit began routine use of swan-neck catheters instead of straight catheters for chronic PD patients. We performed a retrospective chart review of all chronic PD patients treated in the Renal Dialysis Unit at Nationwide Children's Hospital from January 2004 through October 2009. We compared outcomes of swan-neck catheters to straight catheters with laterally-directed exit sites. Specific practice-based questions were: 1. Has use of swan-neck PD catheters reduced the incidence of catheter-related infections?; 2. Has use of swan-neck PD catheters altered the incidence of catheter malfunction?; 3. What factors are associated with increased risk of PD catheter malfunction?

A total of 31 straight and 37 swan-neck catheters were used during the study period, with 363 and 364 patient-months of use respectively. The overall incidence of catheter-related infection did not differ significantly, but rate of catheter removal due to infection decreased with use of swan-neck catheters (7/31 vs 1/37, p=0.014). Rate of catheter removal due to malfunction was higher with swan-neck catheters compared to straight catheters (14/37 vs 3/31, p=0.007). Patients with Prune Belly Syndrome demonstrated the highest rate of PD catheter malfunction, with a trend toward more frequent malfunction with swan-neck catheters (p=0.06). There was also a trend toward an increased rate of catheter malfunction with swan-neck catheters (56%) compared to straight catheters (11%) when placed by surgeons who insert PD catheters infrequently.

In conclusion, reduction in PD catheter-related infections by use of the swan-neck catheter style may be partially offset by an increased incidence of catheter malfunction. Placement by an unpracticed surgeon or diagnosis of Prune Belly Syndrome may lead to higher malfunction rates with swan-neck catheters compared to straight catheters in the pediatric population.

**Infection, Technique Failure and Mortality in First Nations Peoples on Peritoneal Dialysis** Manish M. Sood, Paul Komenda, Mauro Verrelli, Martina Reslerova, Claudio Rigatto. *Nephrology, University of Manitoba, Winnipeg, MB, Canada.*

Background: The Canadian First Nations population suffers from high rates of end stage renal disease and the need for dialytic therapies. The objective of this study was to examine mortality, technique failure and peritonitis in First Nations patients on peritoneal dialysis and to explore whether differences may be accounted for by location of residence.

Methods: All adult peritoneal dialysis patients (N=727) from 1997-2007 residing in Manitoba, Canada were included. Data was extracted from a local administrative database, Canadian Organ Replacement Registry (CORR) and Peritonitis Organism Exit sites Tunnel infections (POET) databases. Cox and logistic regression models were used to determine the relationship between outcomes and First Nations status. Kaplan Meyer analyses were performed to examine the relationship between urban First Nations (<50 km from city) and rural First Nations (>50 km) status and outcomes.

Results: 161 First Nations and 566 Non-First nations were included in the analyses. Adjusted mortality (HR 1.476, CI 1.073-2.030), and adjusted time to peritonitis (HR 1.785, CI 1.352-2.357) were significantly higher in First Nations compared to Non-First Nations. There was no statistically significant difference in mortality, technique failure or peritonitis between urban or rural residing First Nations.

Conclusions: First Nations peoples on peritoneal dialysis suffer from higher mortality and faster time to peritonitis independent of co-morbidities and demographic characteristics. This effect is not influenced by place of residence, whether rural or urban. Efforts to improve the care of First Nations peoples on peritoneal dialysis should be targeted.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2736

**Peritonitis and Exit Site Infections in First Nations Patients on Peritoneal Dialysis** Manish M. Sood, Paul Komenda, Lisa M. Miller, Mauro Verrelli, Martina Reslerova, Claudio Rigatto. *Nephrology, University of Manitoba, Winnipeg, MB, Canada.*

Background: First Nations (FN) patients on peritoneal dialysis experience poor outcomes. Whether discrepancies exist regarding the microbiology, rate of infections and outcomes between FN and Non-FN peoples remains unknown.

Methods: All adult peritoneal dialysis patients (N=727) from 1997-2007 residing in Manitoba, Canada were included. Parametric and nonparametric tests were used as necessary. Negative binomial regression was used to determine the relationship of rates of exit site infections (ESI) and peritonitis between FN and Non-FN peoples.

Results: 161 FN and 566 Non-FN were included in the analyses. The unadjusted relative rates of peritonitis and ESI in FN were 132.7/100 pt yrs and 86.0/100-pt yrs compared to 87.8 and 78.2/100-pt yrs in non-FN populations. FN were more likely to have culture negative peritonitis (36.5 vs. 20.8%, p<0.0001) and *staphylococcus* ESI (54.1 vs. 32.9%, p<0.0001). The crude and adjusted rates of peritonitis were higher in FN for total episodes, culture negative and gram negative peritonitis. Catheter removal due to peritonitis was similar in both groups (42.9 FN vs. 38.1% non-FN, p=0.261).

Conclusions: FN patients experience higher rates of peritonitis and similar rates of ESI compared to non-FN. Interventions to improve outcomes and prevent infections should specifically be targeted to the First Nations population.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2737

**Peritoneal Dialysis in an Ageing Population: A 10-Year Single Centre Experience** Andrew Smyth, Evonne McCann, Lynn Redahan, Barbara Lambert, George J. Mellotte, Catherine A. Wall. *Department of Nephrology, Adelaide & Meath Hospital, Tallaght, Dublin, Ireland.*

*Background*

Chronic kidney disease (CKD) is becoming increasingly prevalent and there are increasing numbers of older patients with advanced CKD. Peritoneal dialysis (PD) is a potential treatment modality. Studies report older age to be a contra-indication for PD but others report co-morbidities to be more important. This study aims to assess PD outcomes in an elderly population in the largest PD centre in the Republic of Ireland over a ten-year period.

*Methods*

We retrospectively identified all adult patients, over the age of 50 years, who commenced PD for the first time between 1 January 1998 and 31 December 2008 at our institution. Primary outcome was survival with secondary outcomes of technique failure, peritonitis-free survival and transplantation.

*Results*

A total of 148 patients with a mean age of 63.17 years were included, who were stratified into three groups, 50-59 years (n=61), 60-69 years (n=46) and over 70 years (n=41). Twenty-two patients were on assisted peritoneal dialysis. Mean Charlson Co-Morbidity Index (CCMI) was higher in older patients (p<0.001), but modified Charlson Co-Morbidity Index (m-CCMI) was similar in all groups (p=0.737). Assisted PD was not associated with an increase in early complications (p=0.097) or technique failure (p=0.933) but death rates were higher (p=0.002). There were no significant differences by age group in early complication rates (p=0.222), number of hospitalizations (p=0.580), number of inpatient days (p=0.077), inpatient days during last year of life (p=0.135), peritonitis-free survival (p=0.794) and survival (p=0.905). CCMI was associated with mortality (p=0.002) as was

the m-CCMI (p=0.018) Renal transplantation occurred predominantly in younger patients (p=0.001) with a lower CCMI (p<0.001) who performed PD independently (p=0.004).

*Conclusion*

This study shows PD to be a safe option for renal replacement therapy in elderly patients with no differences in survival, technique survival or complication rates. Co-morbidities appear to play a stronger role in predicting survival than age alone. Assisted PD is a viable option in those unable to undergo PD independently.

**A Low-Site Tenckhoff Catheter Implantation Operation with Improved Peritoneal Dialysis Catheter Tip Migration** Jia Liu, Changying Xing. *Dept of Nephrology, First Affiliated Hospital of Nanjing Medical Univeristy, Nanjing, Jiangsu, China.*

Objective To report a low-site catheter implantation method with better catheter survival. Methods 180 ESRD patients starting PD from 2001 to 2009 in our center were screened. The operation procedure with the low-site catheter implantation method was different from the conventional method in three key steps. First, 3.5~4.5cm above the pubic symphysis was used as the body marker in this method other than 2 to 3cm under navel. Second, 1~2cm catheter tip was cut off with scissors so that the length could suit the shorter distance from the incision to the pouch of Douglas. Third, the catheter went through the rectus abdominis on the uppermost point of the incision, which meant the catheter went upward for about 2cm after it was fixed in the peritoneum incision. Results During the follow-up period, 3 patients (1.66%) experienced catheter tip migration. 4 patients (2.22%) experienced mechanical catheter obstruction caused by greater omentum. The incidence of the catheter tip migration and omentum obstruction is lower than that reported with conventional method by others. Conclusions Low-site catheter implantation method is an easy, safe, economic and effective technique for PD surgical procedure with lower morbidity of catheter tip migration and greater omentum obstruction.

**Peritoneal Dialysis as First Treatment Option in Late Referral (LR) Chronic Kidney Disease (CKD) Patients** Ewa Suchowierska,[1] Michal Mysliwiec,[1] Edyta Golembiewska,[2] Kazimierz Ciechanowski,[2] Jozef Penar,[3] Marian Klinger,[3] Jacek Lange,[4] Danuta Deckert.[4] *[1]Nephrology, Transplantation, Medical Univ., Bialystok, Poland; [2]Nephrology, Transplantology and Internal Medicine, Pomeranian Medical Univ., Szczecin, Poland; [3]Nephrology and Transplantation, Medical Univ., Wroclaw, Poland; [4]Baxter HealthCare.*

Introduction

One third of the patients are referred late to nephrology or dialysis units and are typically started on hemodialysis. It is known that unplanned hemodialysis initiation with central venous catheters (CVC) is independently associated with increased mortality and greater hospitalization rates, particularly vascular access–related and infections related hospitalizations. It is possible that starting with peritoneal dialysis as a first option may improve clinical outcomes. Education on dialysis treatment options in LR CKD patients may encourage patients to choose PD as first RRT option but is a challenge in this difficult patient group.

Results: From January to May, 2010 nine LR patients have participated in the educational program. At the start of the education program, 6 patients were requiring urgent HD via a CVC, and 2/6 chose PD, catheters were inserted and PD commenced after healing with no complications observed. Three patients were referred late but urgent HD was not required and after education they commenced PD first with rapid catheter insertion and PD starting before healing of the exit site (1-7 days after insertion). Within the first 30 days of PD, 2/3 of these patients had transient problems (peritonitis, scrotal hernia) but remained on PD but 1/3 had intractable fluid overload related to high peritoneal permeability and was transferred to HD. Patient reported outcomes (anxiety, depression and social isolation) were low in all 9 late referred patients commencing PD.

Summary This pilot study suggests that a specific educational program in LR CKD patients can allow patients to choose PD as a first long term option. Systems for rapid catheter insertion and starting of PD are possible but there is a risk of early complications in these patients. Further data gathering is essential to examine long term clinical outcomes in late referred patients.

**Symptom Burden in Older Dialysis Patients: Data from the BOLDE Study** Lina Johansson,[1] Ken Farrington,[2] Hugh Gallagher,[3] Edwina A. Brown.[1] *[1]Imperial College Kidney and Transplant Institute, Hammersmith Hospital, London, United Kingdom; [2]Lister Hospital, Stevenage, United Kingdom; [3]St Helier Hospital, Carshalton, United Kingdom.*

Data from BOLDE (Broadening Options for Long-Term Dialysis in the Elderly) shows that symptom burden is an independent predictor for quality of life, as determined by depression (Hospital Anxiety and Depression Scale), illness intrusion and physical and mental component scores on SF-12. Little is known, however, about the symptomatology of dialysis patients ≥65 years old.

A one-off questionnaire with 16 symptoms (graded none, mild, moderate or severe) was completed 70 pairs of patients on HD and PD matched for age [73.3±5.3 years], time on dialysis [30.9±27.3 months], gender [70% male], ethnicity [93% White European] and Index of Deprivation. The 6 most prevalent symptoms were: lack of energy (85%), pain in joints (73.6%), cold hands and feet (72.9%), cramps in legs (72.1%), weakness of limbs (68.6%) and sleep problems (68.6%).

Logistic regression modelling for each symptom identified which variables (age, length of time on dialysis, gender, dialysis modality, comorbidity score, depression score and nutritional status by Subjective Global Assessment) were associated with symptom severity (none/mild compared to moderate/severe). Increasing comorbidities and depression scores, female gender, malnutrition and being on HD were associated with greater symptom severity. The analyses also identified which individual symptoms were significantly associated with each of the 7 variables; an example is shown below.

Symptoms where greater severity is associated with dialysis modality

| Symptom | Odds ratio HD compared to PD | P value |
|---|---|---|
| Headaches | 5.952 | 0.039 |
| Dry mouth | 4.001 | 0.001 |
| Cramps in legs (comparable comorbidity scores) | 2.179 | 0.017 |
| Taste changes (comparable depression scores) | 1.447 | 0.035 |

In conclusion, older dialysis patients have a high symptom burden. Some symptoms were found to be associated with modality HD. Identifying the symptoms associated with specific variables will improve symptom understanding and management and therefore lead to improvements in quality of life.

**Use of Population (pop) Pharmacokinetic (PK) Modeling and Monte Carlo Simulation (MCS) To Determine Optimal Daptomycin (D) Dosing in Patients on Continuous Ambulatory Peritoneal Dialysis (CAPD)** Katie E. Cardone,[1,2] Thomas P. Lodise,[1,3] Nimish Patel,[1] Harold J. Manley,[4] Christopher D. Hoy,[5] Shari A. Meola,[5] George L. Drusano,[3] Darren W. Grabe.[1,2] *[1]Dept of Pharmacy Practice, Albany College of Pharmacy and Health Sciences, Albany, NY; [2]Albany Nephrology Pharmacy Group (ANephRx), ACPHS, Albany, NY; [3]Ordway Research Inst, Albany, NY; [4]Village Health Disease Management, Glenmont, NY; [5]Hortense & Louis Rubin Dialysis Center, Clifton Park, NY.*

Background: There is a dearth of data on optimal D dosing for pts on PD. Pop PK modeling & MCS were used to identify a D PD dosing scheme that yielded an exposure profile comparable to that obtained from a MCS using the D pop PK model derived from pts in the D vs. vancomycin S. aureus bacteremia infective endocarditis (SAB-IE) study (non-dialysis referent exposure).

Methods: Inclusion criteria: 18 yrs; non-infected; on PD (1 month); Hb 11mg/dL; non-pregnant; no peritonitis within 4 wks. Pts received a standardized CAPD prescription for 1 wk prior to study. Pts (n=8) received D 6mg/kg IV over 30 min. Dialysate and blood were collected over 12hrs & assayed with LC/MS/MS. Plasma conc-time profiles were modeled as a 3-compartment model with zero-order infusion & 1st order elimination & transfer (BigNPAG). A MCS (ADAPT II) using the D PD pop PK model simulated Cmax, Cmin48h, AUC0-24h & AUC0-48h for 6 mg/kg of D as a single dose. Exposure values were compared to those generated from a MCS using the D pop PK model derived from the SAB-IE study. For the SAB-IE MCS, D was given 6 mg/kg Q24H for 2 doses.

Results: Mean(SD) age:59(15) yrs, weight: 89(17) kg. Mean(SD) PK parameters: Vc:6.3 (1.2) L, CL:0.31 (0.17) L/h, k12:1.12 (1.20) h-1, k21:2.55 (2.97) h-1, k13:0.0077 (0.0025) h-1, k31:0.12 (0.11) h-1, Vpd:2.64 (1.27) L.

Conc-time profiles from MCS for PD & SAB-IE PK models (6 mg/kg)

| | CAPD | SAB-IE |
|---|---|---|
| Cmax | 55.4±23 | 44.9±31 |
| Cmin48h | 14±9 | 8.8±8 |
| AUC0-24h | 904±371 | 416±251 |
| AUC0-48h | 1358±585 | 927±542 |

Conclusions: Administration of D 6 mg/kg Q48H during CAPD yielded isometric exposure profiles relative to daptomycin 6 mg/IV Q24H from the SAB-IE (non-dialysis referent exposure) model.

**Increased Concentration of beta-1,3-D-Glucan in Dialysate from Peritoneal Dialysis Patients with Fungal Peritonitis** Masatoshi Kuratsune,[1] Kensuke Sasaki,[1] Akira Hirabayashi,[1] Yasuhiko Fukuda,[2] Noriaki Yorioka.[3] *[1]Nephrology, JA Hiroshima General Hospital, Hatsukaichi, Hiroshima, Japan; [2]Surgery, JA Hiroshima General Hospital, Hatsukaichi, Hiroshima, Japan; [3]Nephrology, Hiroshima University Graduate School of Medical Science, Hiroshima, Hiroshima, Japan.*

Background and aim : Since fungal peritonitis is a rare but very serious complication in peritoneal dialysis (PD) patients, its earliest diagnosis is desirable. The diagnosis usually requires identification of fungus by gram stain and positive culture. In this study, we measured the concentration of beta-1,3-D-glucan (BD), which is a component of the fungal cell wall, in dialysate and serum from patients with peritonitis.

Methods and patients : Between July 2007 and June 2010, a total of 54 incidences of peritonitis occurred in 28 PD patients at our hospital and BD was measured in 53 incidences. Peritonitis was defined according to the guideline by ISPD. At the immediate hospital visit with peritonitis symptoms, BD was measured by Beta-glucan Test Wako (Wako Pure Chemical Industries, Tokyo) in the dialysate (pBD) and serum (sBD) as well

as smear and culture sampling of dialysate. This test requires only 100 minutes to measure BD concentration and costs about 40 US dollars. Intergroup comparison was made by Mann-Whitney's U test.

Results : The causative organisms were identified by positive culture in 3 cases as fungus (Candida) (Group A) and 36 as bacteria (Gram negative 5, Gram positive 31)(Group B). As the other 14 were both culture and smear negative cases, we excluded them from further analysis. The average concentrations of pBD in Group A and B were 116.8±117.8 and 2.8±0.4 ng/mL, respectively ($p<0.001$). The average concentrations of sBD in Group A and B were 36.6±29.7 and 5.3±4.0 ng/mL, respectively ($p=0.32$). The calculated ratios of sBD to pBD in Group A and B were 0.33±0.26 and 1.93±1.36, respectively ($p<0.001$).

Conclusion : These results indicate that the measurement of BD in both dialysate and serum could be a quick method to differentiate fungal from bacterial peritonitis at early stage of peritonitis in PD patients.

**Connexin Hemichannels Mediate Low Calcium-Elicited Activation of cAMP Signaling Pathway and Elevation of Renin Production in Juxtaglomerular Cells** Tao Huang, Shotaro Nakajima, Masanori Kitamura, Jian Yao. *Department of Molecular Signaling, University of Yamanashi, Chuo, Yamanashi, Japan.*

Gap junctions, formed by the specific proteins called connexin (Cx), play an important role in the regulation of renin secretion in juxtaglomerular cells. Mice lacking Cx40 or Cx45 develop renin-dependent hypertension. Besides forming intercellular channels, connexins also form nonjunctional hemichannels. Once activated, hemichannels permit the rapid exchange of ions ($Ca^{2+}$, $Na^{+}$) and small molecules ($PGE_2$, ATP, $IP_3$, etc.) between the cytoplasm and the extracellular space. Given that hemichannels are activated by lowering extracellular calcium, a well-known stimulator of renin production, we speculated that hemichannels might be involved in the regulation of renin. Using a renin-secreting cell line As4.1 and primarily cultured mouse juxtaglomerular cells, we tested this hypothesis. Results: 1) As4.1 cells were characterized to express Cx43 and Cx45, and have the functional gap junctional intercellular communication, as evaluated by immunofluorescent staining, Western blot analysis, and diffusion of lucifer yellow (LY) after single cell injection. 2) Lowering extracellular calcium activated connexin hemichannels in As4.1 cells, as evidenced by the influx of LY and efflux of ATP. Hemichannel opening was associated with activation of cAMP signaling pathway, as revealed by increased levels of phosphorylated VASP (a PKA substrate) and CREB, as well as elevation of renin protein levels, as detected by Western blot analysis and renin activity assay. 3) Inhibition of hemichannels with heptanol or downregulation of Cx proteins with the specific siRNA for Cx40, Cx43 and Cx45 almost completely abolished the effects of calcium depletion on cAMP signals and renin production. 4) The similar results were achieved in primarily cultured mouse juxtaglomerular cells. Taken togethehr, our study indicates that Cx hemichannels mediates low calcium-elicited activation of cAMP signaling pathway and elevation of renin production in juxtaglomerular cells. Cx hemichannels could be a presently unrecognized mechansim involved in the control of renin synthesis and secretion.

**Prorenin Is a Determinant of Angiotensin Receptor Blockade Response in Microalbuminuric Patients with Diabetes** Merel E. Hellemons,[1] Hiddo Jan Lambers Heerspink,[1] Stephan J. L. Bakker,[1] Hans-Henrik Parving,[2] Dick De Zeeuw,[1] Peter Rossing.[3] *[1]University Medical Center of Groningen, The Netherlands; [2]Rigshospitalet, Denmark; [3]Steno Medical Center, Denmark.*

The response in albumin-creatinine ratio (ACR) and systolic blood pressure (SBP) to Angiotensin Receptor Blockade (ARB) varies between individuals. Renin Angiotensin System (RAS) activity is an established determinant of the response to ARB-treatment. To date, however, no relation has been observed between ARB-induced changes in traditional RAS activity indicators (prorenin, renin and angiotensin II (ATII)) and individual ACR or BP response. We aimed to determine whether changes in these parameters correlated to the response in ACR and SBP during ARB-treatment in microalbuminuric patients with diabetes.

Data from the IRMA-2 trial comparing Irbesartan (150 and 300mg) versus placebo was used. Prorenin, renin and ATII concentrations were measured in a random sample (n=125 out of 590). Multivariate linear regression analysis was used.

Low baseline prorenin, but not renin or ATII, independently predicted larger reduction in ACR ($\beta$= 0.30; p=0.02). A dose-dependent (placebo-150-300mg) increase in concentrations of prorenin (88-110-204%), renin (71-189-412%), and ATII (43-131-215%) was observed during treatment. The rise in prorenin, but not of renin or AngII, was independently associated with each log unit reduction in ACR ($\beta$= -0.36; P=0.01) and each mmHg reduction in SBP ($\beta$= -0.23; P=0.04). Interestingly, the largest increases in prorenin were observed in patients with both ACR and SBP reduction and the lowest increase in patients with neither reduction in ACR nor SBP, whereas a reduction in either parameter was associated with an intermediate increase in prorenin (figure 1). The degree of increase in prorenin reflects the therapeutic efficacy in lowering ACR and SBP in irbesartan treatment.

**Ang-(1-7) Ameliorates p38-Related Renal Vasoreactivity in ApolipoproteinE Deficient Mice through Reduction of Reactive Oxygen Species** Sebastian A. Potthoff,[1] Tilman Clasen,[1] Michael Fähling,[2] Henning Hoch,[1] Eva Koenigshausen,[1] Magdalena Woznowski,[1] Lorenz Sellin,[1] Ivo Quack,[1] Oliver Vonend,[1] Andreas Patzak,[2] Lars C. Rump,[1] Johannes Stegbauer.[1] *[1]University of Duesseldorf, Germany; [2]Medical University of Berlin, Germany.*

Increased vascular reactivity to angiotensin (Ang)II in atherosclerotic vessels may contribute to the development of hypertension. Recent studies suggest that the p38-kinase is involved in regulating vascular reactivity. p38-kinase is activated by reactive oxygen species (ROS) which contributes to sustained smooth-muscle contraction by MLC(20) phosphorylation.

In apoE deficient (apoE-/-) and wild type (WT) mice we investigate if increased renal vasoreactivity to AngII is caused by ROS-related p38 activation and if Ang-(1-7) treatment influences renal vasoreactivity.

12 week old apoE-/- and WT mice on western diet were treated via minipumps either with saline or Ang-(1-7) (82µg/kg/hr) for 6 weeks. Vascular reactivity was tested in the isolated perfused kidney.

AngII induced renal pressor response was significantly increased in apoE-/- compared to WT mice. Ang-(1-7) treatment attenuates pressor response to AngII in apoE-/- mice. Accordingly, MLC(20) phosphorylation is increased in apoE-/- mice and reduced after Ang-(1-7) treatment. p38 inhibition (SB203580-5µmol/L) attenuates pressor response to AngII in apoE-/- but not in WT mice. Protein analysis of cortex and pre-glomerular vessel showed a two-fold increase in phosphor-p38 in apoE-/- compared to WT mice. Ang-(1-7) treatment decreased renal phosphor-p38 levels to WT baseline. In apoE-/- mice, expression of the NADPH-oxidase-subunit p47phox is 1.5-fold increased and restored by Ang-(1-7) treatment compared to WT mice. Concordantly, isoprostane-8 excretion in 24h-urine samples was significantly reduced in Ang-(1-7) treated apoE-/- mice.

Therefore, ROS-dependent p38-activation contributes to the increased renal vasoreactivity in apoE-/- mice. Ang-(1-7) treatment ameliorates vascular function at least partially through decreasing NADPH-oxidase overexpression and p38-activation. These data provide new insights in vascular function in atherosclerosis and beneficial mechanisms of Ang-(1-7).

**Combined Treatment with Irbesartan and Vitamin D Retards Renal Injury in Salt-Loaded Uni-Nephrectomized Stroke-Prone Spontaneously Hypertensive Rats** Tsuneo Takenaka,[1] Tsutomu Inoue,[1] Hirokazu Okada,[1] Yoichi Ohno,[1] Takashi Miyazaki,[1] Akira Nishiyama,[2] Naohito Ishii,[3] Hiromichi Suzuki.[1] *[1]Saitama Medical University, Iruma, Saitama, Japan; [2]Kagawa University, Kagawa, Japan; [3]Kitasato University, Kanagawa, Japan.*

Vitamin D diminishes renin expression. We previously reported that vitamin D increased renal expression of klotho in rats with normal kidney function. In the present study, effects of vitamin D on renal injury was assessed in 4 groups of rats (n=6-8 for each group); uni-nephrectomized stroke-prone spontaneously hypertensive rats fed high salt (6%) diet as a control (C), those treated with irbesartan (100 mg/kg/day, I), rats treated with calcitriol (30 ng/kg/day, V), and rats treated with both irbesartan and calcitriol (I+V). Six weeks later, right kidney was harvested for analysis. Systolic blood pressure (SBP) in C was higher than I and I+V groups. While renal angiotensin II (AngII) concentration was lower in I and I+V groups than C, plasma AngII levels of I and V groups are higher and lower than C, respectively. In addition, urine albumin/creatinine ratio (Alb/Cr) was lower in I and I+V group than C, and 8-epi-prostaglandin F2$\alpha$ (PGF2$\alpha$) excretion was reduced in V and I+V groups. Immunoblot analysis revealed that compared to C, renal klotho expression was preserved in V and I+V group. Creatinine clearance (Ccr) was elevated in I+V group than C. The present data indicate that irbesartan effectively decreases blood pressure with reductions

in renal AngII and albuminuria. Our findings demonstrate that vitamin D enhances klotho expression, suppressing oxidative stress and albuminuria without substantial changes in renal AngII. The current results may provide evidence that renal renin-angiotensin system is regulated independently of circulating one.

| variables | unit | C | I | V | I+V |
|---|---|---|---|---|---|
| SBP | mmHg | 215±6 | 162±4* | 210±5 | 157±4* |

**Loss of Collectrin Results in Paradoxical Response to L-NAME** Sylvia Cechova,[1] Qing Zeng,[1] Rosa Chan,[1] Sandra M. Malakauskas,[2] Thu H. Le.[1] *[1]Medicine, University of Virginia, Charlottesville, VA; [2]Medicine, Salem Veterans Administration, Salem, VA.*

Collectrin is a protein with 40% homology to ACE2 but lacks any catalytic domain. It was first discovered in a search for genes that are upregulated during the hypertrophic phase after sub-total nephrectomy. We reported that collectrin-deficient mice (KO) display severe urinary amino acid wasting due to impaired trafficking of amino acid transporters in proximal tubular plasma membrane. On a mixed background, compared to wild-type mice (WT), KO mice have normal blood pressures (BP) at baseline, but have significantly elevated BPs after uni-nephrectomy (UNx). Here, to determine the mechanism(s) causing worse hypertension in the KO mice UNx, we compared renal plasma membrane expression of various salt transporters pre and post UNx, using Western blot analysis. Before UNx, there was no difference in expression in NHE3, NKCC, Na-K-ATPase, aENaC and NaPi2 channels between WT and KO mice. After UNx, there was a significant reduction in expression of aENaC and NaPi2 channels in KO mice (30% and 50%, respectively, by densitometry, $p < 0.006$). The reduced expressions of aENaC and NaPi2 channels are likely a compensatory response to elevated BPs. We posited that collectrin KO mice might have alteration in nitric oxide (NO) synthetic pathway that could play a role in elevated BP after UNx. We administered L-NAME in drinking water (20 mg/kg/day) for two weeks to adult mice at 3 months of age, without nephrectomy, and measured BP response using tail cuff manometer. Compared to baseline BPs, WT mice (n = 12) exhibited an average increase in systolic BP by + 14.7 ± 2.1 mm Hg after L-NAME (range + 4 to + 31 mm Hg). Surprisingly, collectrin KO mice (n = 18) exhibited no response to L-NAME, with average change in systolic BP of –2.1 ± 3.5 mm Hg (range – 27 to +16 mm Hg). The difference in change in BP in response to L-NAME was statistically significant, $p = 0.0004$. Our data suggest that collectrin KO mice have abnormalities in the NO synthetic pathway that may be exaggerated after loss of nephron mass. We speculate that arginine amino acid transport in endothelial cells is impaired in collectrin KO mice.

**SA-PO2748**

**Oxidative Stress Is Increased in ACE2 Deficiency and Restored Partially by Recombinant ACE2 Infusion** Jan A. Wysocki,[1] Karla Evora,[1] Minghao Ye,[1] Mirza S. Khan,[1] Susan B. Gurley,[2] Daniel Batlle.[1] *[1]Division of Nephrology & Hypertension, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Duke University Medical Center, Durham, NC.*

We have recently shown that human rACE2 effectively metabolizes circulating Angiotensin II and prevents Angiotensin II dependent hypertension in mice. Here, we examine kidney oxidative stress and the effect of rACE2 in male mice with genetic ACE2 deficiency and wild-type controls.

In ACE2 KO male mice, kidney H2O2 was increased as compared to wild type at 14 weeks of age (WT: 37.9 ± 1.4 μM/mg; ACE2 KO: 50.9 ± 3.1 μM/mg, $p < 0.001$). Likewise, at 40 weeks of age, H2O2 was also increased (KO: 58.1 ± 3.3; WT: 32.1 ± 3.0 μM/mg, $p < 0.001$). These changes in H2O2 were associated with corresponding increases in kidney NAD(P)H oxidase activity in both age groups.

The levels of kidney Angiotensin II were significantly higher in male ACE2 KO as compared to the wild-type (KO: 23.0 ± 4.8; WT: 10.7 ± 2.3 fmol/mg, $p < 0.05$), probably reflecting reduced Ang II degradation in the ACE2 KO. After three days of rACE2 administration, the ACE2 KO experienced a significant reduction in H2O2 (KO: 50.9 ± 3.1 μM/mg, KO/rACE2: 34.2 ± 8.3 μM/mg, $p < 0.05$). In ACE2 KO infused with Ang II, there was also a significant reduction in H2O2 when rACE2 was administered concurrently (ACE2 KO/AngII: 53.5 ± 1.8, ACE2 KO/AngII/rACE2: 42.7 ± 4.8 μM/mg, $p < 0.05$), but this level was still greater than that of the wild-type (WT: 32.1 ± 3.0 μM/mg, $p = 0.075$).

In conclusion, ACE2 deficiency leads to increased H2O2 production at the kidney level in association with increased kidney Ang II levels. The administration of human rACE2 attenuates H2O2 levels likely by increasing Ang II degradation, and thereby suggests a novel approach to reduce oxidative stress within the kidney.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2749**

**Chronic Antagonism of Mineralocorticoid Recepter Prevents Hypertension Progression and End Organ Damage in a Rodent Model of Salt-Sensitive Hypertension** Xiaoyan Zhou,[1] Martin Crook,[1] Wanda Sharif-Rodriguez,[1] Yonghua Zhu,[1] Zadok Ruben,[2] Gail M. Forrest,[1] Daphne Szeto,[1] Huawei Zhao,[1] Michael J. Forrest.[1] *[1]Cardiovascular Diseases, Merck & Co., Rahway, NJ; [2]Patoximed Consultants, Westfield, NJ.*

Excessive or inappropriate mineralocorticoid receptor (MR) activation not only enhances sodium and water retention and elevates blood pressure (BP), but may also promote deleterious effects on target organs via both hemodynamic and non-hemodynamic mechanisms. The aim of the present study is to investigate the effects of chronic MR antagonism with eplerenone on the development and progression of hypertension and target organ function in a rodent model of salt-sensitive hypertension, namely Dahl Salt Sensitive (Dahl SS) rats. Adult Dahl SS rats were administered eplerenone (100 $mg \cdot kg^{-1} \cdot d^{-1}$ for 8 weeks) mixed either in low salt (0.3% NaCl) or high salt (4% NaCl) rodent chow. BP was recorded daily by radiotelemetry and renal function was assessed weekly. Histopathological analyses of kidneys and hearts were performed at the end of the study. Low salt fed Dahl SS rats developed a slow progression of hypertension (systolic BP increased by 18±3 mmHg over 8 weeks), which was completely blocked by eplerenone. High salt fed Dahl SS rats developed severe hypertension, cardiac and renal hypertrophy, massive proteniura, glomerulosclerosis, perivascular fibrosis, tubular dilation, and renal interstitial injury. Eplerenone significantly attenuated the progressive rise in systolic BP (204±3 vs.179±3 mmHg, $p<0.05$), reduced proteinuria (605.5±29.6 vs. 479.7±26.1 mg/24h, $p<0.05$), improved injury scores of glomeruli (2.2±0.3 vs. 1.0±0.2, $p<0.05$), tubules (2.9±0.2 vs. 2.4±0.1, $p<0.05$), renal interstitium (2.2±0.1 vs.1.7±0.1, $p<0.05$), and vasculature (2.3±0.3 vs. 0.9±0.3, $p<0.05$). Cardiac collagen content score was not significantly changed by eplerernone (2.0±0.2 vs.1.8±0.2, $p>0.05$). These results demonstrate that MR antagonism provides target organ protection and attenuates the development of elevated BP in a model of salt-sensitive hypertension. Importantly, these data further support the promise of MR antagonists for the treatment of hypertension.

**Amelioration of AngiotensinII (AII)-Induced Salt-Sensitive Hypertension (SSHT) in Liver-Type Fatty Acid-Binding Protein (L-FABP) Transgenic Mice (Tg)** Ken Osaki,[1] Yusuke Suzuki,[1] Takeshi Sugaya,[2] Satoshi Horikoshi,[1] Yasuhiko Tomino.[1] *[1]Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]CMIC Co Ltd., Tokyo, Japan.*

Background: Recent findings indicated that inappropriate activation of the intrarenal renin-angiotensin system (RAS) induces reactive oxygen species production and tubulointerstitial inflammation, which may contribute to SSHT. It is well known that AII infusion induces enhancement of intrarenal RAS activation and subsequent experimental SSHT in mice.

On the other hand, L-FABP is expressed in proximal tubules in humans, but not rodents. L-FABP binds long-chain fatty acid oxidation products, and thus may play an endogenous antioxidative role in the human kidney.

Aim: The objective of the present study is to examine the antioxidative effect of L-FABP on AII-induced SSHT with Tg in which human L-FABP is overexpressed in proximal tubules.

Methods: Female Tg and their wild-type mice (WT) were subjected to the AII-infusion at doses of 500 ng/kg/day for 4 weeks, and then a high-sodium diet (HSD: 6% NaCl) was started from 5 to10 week.

Results: During AII infusion, a progressive increase of mean blood pressure (MBP) peaking at the week 4 (132.0±12.9 mmHg) was observed in WT, while a progressive increase of MBP was detected until week 2 in Tg. After AII infusion, both strains showed normal MBP (WT: 81.0±5.1, Tg: 85.6±7.1 mmHg) at week 5. MBP in WT gradually increased after week 6, although that SSHT was not observed in Tg until week 10. Renal renin mRNA expression at week 10 in Tg was significantly lower than that in WT ($P<0.05$). In addition, the protein level of angiotensinogen in Tg was also lower than that in WT. Urinary 8-OHdG concentration ($P<0.05$), renal 4-HNE protein expression and numbers of tubulointerstitial T lymphocytes were also attenuated in Tg.

Conclusion: The present findings showed that Tg with AII-induced SSHT were protected by attenuation of intrarenal RAS activation, oxidative stress and tubulointerstitial inflammation. Therefore, it appears that antioxidative action of L-FABP in proximal tubules may be important in this protection.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2751**

**ARB Protects Podocytes of HIV-1 Nephropathy Independently of Podocyte AT1** Akihiro Shimizu,[1] Taiji Matsusaka,[2] Jianyong Zhong,[3] Yoichi Miyazaki,[1] Tatsuo Hosoya,[1] Iekuni Ichikawa.[4] *[1]The Jikei University School of Medicine; [2]Tokai University; [3]Huashan Hospital; [4]Vanderbilt University School of Medicine.*

It is now well established that angiotensin (Ang) II via the Ang II type 1 receptor (AT1) plays important roles in the progression of glomerulosclerosis. It has been shown that podocytes express functional AT1 and transgenic rats overexpessing AT1 on podocytes develop glomerulosclerosis. In the present study, we investigated the mechanism of AII

action on podocytes in a mouse model of HIV-1 nephropathy. HIV-1 mice with sclerosis-prone FVB/N genetic background were treated with an ARB, losartan (30 mg/kg BW/day, s.c.) (n=7), or left untreated (n=7). At 4 weeks of age, HIV-1 mice with ARB showed significantly attenuated urinary protein/creatinine ratio (23.2+-9.8 vs. 55.3+-6.0 mg/mg) and glomerulosclerosis index (0.41+-0.21 vs. 1.34+- 0.27, on 0 to 4 scale) compared with control HIV mice.

We, then, studied the effect of podocyte-specific deletion of AT1 in HIV-1 mice on nephropathy-resistant C57BL/6 genetic background. At 8 months of age, mice carrying both HIV-1 gene and podocyte-selectively nullified AT1 gene (AT1KO/HIV-1) (n=13) and control/HIV-1(n=15) mice were statistically indistinguishable with respect to urinary albumin/creatinine ratio (2.5+-1.0 vs. 9.1+-4.8 mg/mg), glomerulosclerosis (0.61+-0.11 vs. 0.67+-0.17) and downregulation of nephrin (6.65+-0.28 vs. 6.71+-0.36 on 0 to 8 scale). These indicate that the injurious effect on podocytes and pro-sclerogenic effect of Ang II in HIV nephropathy are channeled through its receptors on cells other than podocytes, which include efferent arteriolar smooth muscle cells.

## SA-PO2752

**Absence of AT1A Angiotensin Receptors from Vascular Smooth Muscle Cells (VSMCs) Does Not Attenuate Vascular Remodeling in Hypertension** Matthew A. Sparks,[1] Eric W. Raasch,[1] Susan B. Gurley,[1] Johannes Stegbauer,[1] Anuradha Vivekanandan-Giri,[2] Subramaniam Pennathur,[2] Thu H. Le,[3] Thomas M. Coffman.[1] *[1]Division of Nephrology, Duke University; [2]Division of Nephrology, University of Michigan; [3]Division of Nephrology, University of Virginia.*

Vascular injury and remodeling are common pathological sequelae of hypertension. Previous studies have suggested that angiotensin II (ang II) acting through the AT1 receptor promotes vascular pathology in hypertension. To study the contribution of direct actions of AT1 receptors in this process, we generated mice with cell-specific deletion of the major murine AT1 receptor isoform (AT1A) from VSMCs using Cre/Loxp technology. To this end, we crossed a transgenic mouse line expressing Cre recombinase in smooth muscle (SM22α-Cre ) with a mouse line bearing a conditional allele of the Agtr1a gene, encoding the AT1A receptor. In SM22α-Cre+Agtr1a flox/flox (SMKO) mice, there was virtually complete elimination of AT1A receptor expression from VSMCs in the aorta, but not from small resistance vessels such as pre-glomerular arterioles. Thus, acute vasoconstrictor responses to angiotensin II were preserved in SMKOs. To induce hypertensive vascular remodeling, mice were continuously infused with ang II for 4 weeks. During infusion of ang II, mean arterial pressure measured by radiotelemetry increased significantly and to a similar extent in SMKOs (157±1 mm Hg) and controls (154±2 mm Hg). In the control mice, there was evidence of vascular oxidative stress indicated by enhanced hydrogen peroxide generation and nitrated tyrosine residues in segments of aorta; this was significantly attenuated in the SMKOs by 44% ($p<0.005$) and 74 % ($p<0.005$), respectively. With ang II infusion, the area of the aortic media increased by ~45% in both groups ($p<0.005$ vs. baseline) and despite the marked differences in free radical generation, the extent of medial expansion following the ang II infusion was not significantly different between the groups (50.5± 2.4 μ m in controls vs. 47± 4.6 μm in SMKOs). Thus, vascular AT1A receptors promote oxidative stress in the aortic wall but are not required for remodeling in angiotensin II-dependent hypertension.

## SA-PO2753

**Angiotensin II Infusion in Pregnant Rats as a Model of Preeclampsia** Steven Wagner,[1] Iasmina Craici,[1] Joseph P. Grande,[2] Karl A. Nath,[1] Vesna D. Garovic.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Department of Pathology, Mayo Clinic, Rochester, MN.*

Preeclampsia is a pregnancy specific disorder characterized by hypertension and proteinuria manifested after 20 weeks gestation. The renin-angiotensin system is implicated in the pathophysiology of preeclampsia. Previous studies have shown that angiotensin II infusion in non-pregnant rats produces hypertension and proteinuria. We hypothesize that angiotensin II (Ang II) infusion in pregnant rats may provide a model of preeclampsia.

Pregnant Sprague-Dawley rats (n=15) were infused with either Ang II at 0.96 mg/kg/day (n=7) or normal saline (n=8) delivered via osmotic minipumps implanted at gestational day 5 (n=9) or day 9 (n=6). All Ang II-treated animals displayed hypertension one day after pump implantation (SBP 163 mmHg vs 125 mmHg in controls, $p=0.0045$). Systolic hypertension became more pronounced 5 days after implantation (181 mmHg vs 115 mmHg in controls, $p<0.0001$). At gestational day 17, 24-hour urinary protein was 3.1 mg in angiotensin II treated animals compared to 0.75 mg in saline controls ($p=0.049$). Average fetal mass was significantly decreased in Ang II-treated rats (3.64 vs. 4.16 grams, $p=0.032$), as was maternal weight (283 vs. 318 grams, $p=0.0004$).

Renal histology revealed arteriolar fibrinoid necrosis in three Ang II-treated rats; endotheliosis was not observed. Placental infarction was noted in one Ang II-treated rat, and decidual edema was consistently noted.

At sacrifice on gestational day 19, plasma levels of uric acid (0.67 vs 0.45 mg/dL, $p=0.007$) and BUN (25 vs 19 mg/dL, $p=0.008$) were increased in Ang II-treated rats. After correction for body weight, plasma creatinine was elevated in Ang II-treated rats (1.12 mg/dL/kg vs. 0.946 mg/dL/kg, $p=0.02$).

Our data demonstrate that Ang II infusion induces in pregnant rats features of preeclampsia, including systemic hypertension, proteinuria, and decreased GFR. We suggest that such chronic administration of Ang II in pregnant rats provides a model for preeclampsia.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2754

**The SKCa Ca-Activated K Channel Is a Target of Aldosterone in the Endothelium** Frederic Jaisser,[1] Violaine Charhbili,[1] Smail Messaoudi,[1] Aurelie Nguyen,[1] Ana-Maria Gomez.[2] *[1]INSERM U872 Team1, Paris, France; [2]INSERM U-637, Montpellier, France.*

To specifically address the role of the mineralocorticoid receptor (MR) in the endothelium in vivo, we have previously generated a mouse model with conditional overexpression of the MR in endothelial cells only (MR-EC mice). MR-EC mice presented with an altered myoendothelial crosstalk (Nguyen et al., FASEB J, 2010) leading to altered vasoreactivity. In the present study, we tested whether MR activation modulates the expression and activity of Ca-activated K channels (SKCa and IKCa) also known as Endothelium Derived Hyperpolarizing Factors involved in myoendothelial crosstalk. SKCa expression was induced by 10-8 M aldosterone in human and mouse endothelial cells, an effect prevented by 10-6 M spironolactone, a pharmacological MR antagonist. The expression of SKCa was also increased in the aorta of MR-EC mice. Pharmacological inhibition of the endothelial Ca2+-activated K+ channels with apamin and Tram-34 revealed an impaired relaxation response in MR-EC mice, indicating that the activity of endothelial Ca2+-activated K+ channels is increased upon long-term overexpression of the MR in the endothelium. Agonist-evoked Ca homeostasis was analyzed by confocal imaging in endothelial cells of intact aorta pre-incubated ex vivo with Fluo4-AM upon stimulation by Acetylcholine (Ach) in the presence or not of apamin and Tram34. Intracellular Ca transients were strongly increased upon Ach stimulation in the endothelium of aorta from aldosterone-treated wild-type mice or MR-EC mice as compared to control mice. This increased response was prevented upon inhibition of the endothelial Ca2+-activated K+ channels with apamin and Tram-34. Our results demonstrate for the first time that the SKCa Ca-activated K channel is a target of aldosterone in the endothelium and is involved in the altered vasoactive response and agonist-evoked Ca homeostasis modulated by endothelial MR activation

## SA-PO2755

**Role of Hydrogen Sulfide and KCNQ Channels in Periadventitial Vasoregulation** Maik Gollasch,[1] Johanna Schleifenbaum,[1] Olga Zavaritskaya,[2] Rudolf Schubert,[2] Friedrich C. Luft,[3] Carolin Koehn,[4] Nadezda Voblova.[5] *[1]Nephrology/ECRC, Charité, Berlin, Germany; [2]Physiology, University Heidelberg, Germany; [3]Charite, Franz Volhard Clinic; [4]ECRC Berlin Buch, Charité Berlin, Germany; [5]Rostock University, Rostock.*

**Background:** Perivascular adipose tissue secretes an adipocyte-derived relaxing factor (ADRF) that opens voltage-dependent $K^+$ ($K_v$) channels in peripheral arteries. We studied the role of KCNQ-type $K_v$ channels and tested the hypothesis that hydrogen sulfide ($H_2S$) could be an ADRF in periadventitial vasoregulation. **Methods:** We performed isometric contraction studies on systemic arteries of rats and mice. **Results:** In mesenteric arteries and aortas without perivascular adipose tissue, the KCNQ channel openers retigabine, VRX0530727, VRX0621238, and VRX0621688 produced concentration-dependent vasorelaxation; VRX0621688 was the most potent vasodilator. The KCNQ inhibitor XE991 (30 μM) blocked the effects of both the drugs and ADRF. Inhibitors of cystathionine gamma lyase (CSE) ß-cyano-L-alanine (BCA, 5 mM) and 4-propargyl glycine (PPG, 10 mM) also blocked the relaxations. Cystathionine gamma lyase is expressed in perivascular adipose tissue and endogenously generates $H_2S$. The $H_2S$ donor NaHS produced concentration-dependent vasorelaxation, which was also blocked by XE991. The vasodilatory capacities of retigabine, VRX0530727, VRX0621238, and VRX0621688 were preserved following inhibition of $H_2S$ generation in perivascular fat. **Conclusions:** We suggest that KCNQ channel opening is a powerful mechanism to produce vasorelaxation of visceral arteries in rats and mice. Furthermore, KCNQ channels play a major role in the paracrine control of vascular tone by perivascular adipose tissue, which is at least in part mediated or modulated by $H_2S$. KCNQ channel opening is novel approach to improve impaired periadventitial vasoregulation, increased peripheral resistance and associated hypertension.

## SA-PO2756

**Cardiovascular Dysfunctions in Mice with Homozygous Mutation of the Gene Encoding Canonical Transient Receptor Potential 1 (TRPC1) Channel: Evidence for Hypoplastic Heart and Arterial Stiffness** Kai Lau,[1 & 4] Leonidas Tsiokas,[2] Becky Pennington,[1] Bonnie Eby,[1] Joel Abramowitz,[3] Lutz Birnbaumer,[3] Pedro Lozano.[1 & 4] *[1]Medicine, University of Oklahoma, Oklahoma City, OK; [2]Cell Biology, University of Oklahoma, Oklahoma City, OK; [3]Intramural Research, NIEHS, Research Triangle Park, NC; [4]Medicine, VA Hospital, Oklahoma City, OK.*

Previously we demonstrated the critical role of TRPC1 gene in the hypertrophic response to thoracic aorta constriction. But the impact of diploid deficiency of TRPC1 on the development & function of the circulatory system in the native state has not been defined. To test the hypothesis that TRPC1 null mice develop cardiovascular phenotypes in the absence of imposed stimuli, we measured left ventricular (LV) functions by echocardiographic studies and systemic arterial blood pressure (BP) by tail cuffs method using the computerized system of Visitech in 7-month-old TRPC1 -/- male mice and age- and sex matched wild type controls.Compared to TRPC +/+ controls, LV end-diastolic (ED) diameter (3.02 vs. 3.78 mm, $p<0.001$) and end-systolic (ES) diameter (1.38 vs. 2.09 mm, $p<0.001$) were both reduced, resulting in markedly reduced ED LV volume (29 vs. 56 μl, $p<0.001$), ES LV

volume (3 vs. 11 µl, p<0.01), and 42 % decrease in stroke volume (26 vs. 45 µl, p<0.001). Stroke index (SI) was thus reduced by 44 % in the null mice [0.8 vs. 1.4 µl/g body weight (BW), p<0.001] and cardiac output (CO) (14 vs. 21 ml/min, p<0.01) was reduced by 33 %. Systolic BP (113 vs. 121 torr, p<0.01), diastolic BP (77 vs.86 torr, p<0.01) and mean arterial (MA) BP (89 vs. 98 torr, p<0.001) were all reduced in the null mice. Systemic arterial resistance (SAR), calculated as MABP/CO, was markedly elevated (7.2 vs. 5 torr/ml/min, p<0.05). Pulse pressure was similar (36 vs. 33 torr). Arterial stiffness, calculated as pulse pressure / stroke index, was increased to 2 fold of wild type mice (51 vs. 25 torr/µl/min/g BW, p<0.001). Conversely, arterial compliance, the reciprocal of stiffness (22 vs. 43 µl/min/g BW/torr, p<0.001) was reduced by 49%. These data support our hypothesis of cardiovascular phenotypes in TRPC1 null mice.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2757

**Molecular Mechanisms of Ouabain-Induced Hypertension in Rats** Syed J. Khundmiri,[1] Sarah A. Salyer,[1] Nina W. Lesousky,[1] Eleanor D. Lederer.[1,2] *[1]Medicine/Kidney Disease Program, University of Louisville, Louisville, KY; [2]Medicine, Robley Rex VAMC, Louisville, KY.*

Increased levels of endogenous cardiac glycosides have been implicated in hypertension in patients with chronic kidney disease.We have recently demonstrated that low molar concentrations of ouabain increase phosphorylation, expression, and association of the α subunit of Na-K ATPase (NaK) with NHE-1 in rat kidney basolateral membranes and in human kidney proximal tubule cells. The ouabain-stimulated increase in NaK expression was accompanied by an increase in blood pressure in Sprague Dawley rats. We hypothesize that ouabain raises blood pressure through an NHE-1 dependent increase in renal Na-K activity. To address this hypothesis we treated Sprague Dawley rats with vehicle or ouabain (1mg/kg body weight/day) for 9 days in the presence or absence of an antibody to cardiac glycosides (Digibind) or an NHE-1 inhibitor (Zoniporide). Blood pressure was measured in anesthetized animals carotid artery catheter. NaK activity and expression was measured in basolateral membranes prepared from the above rats. Ouabain, but not vehicle, increased mean arterial pressure from 87.4±5.32 to 102.93±3.26 (p<0.01). Treatment with zoniporide prevented the increase in MAP (92.33±3.72, p=ns). Zoniporide alone did not alter the MAP (95.23±1.36, p=ns). Treatment with Digibind significantly decreased MAP given alone or in the presence of ouabain (66.17±9.64, p<.01 and 70.63±7.87, p<.01, respectively). Both zoniporide and digibind prevented ouabain induced Na-K activity and expression in kidney basolateral membranes. To confirm the NHE-1 dependence of ouabain induced increase in NaK, we compared ouabain-stimulated rubidium (Rb) uptake in proximal tubules isolated from wild type and NHE-1 knock-out mice. Ouabain increased Rb uptake in PT from WT mice (2.13±0.28 vs 4.87±0.73) but not in PT isolated from NHE-1-/- mice (2.21±0.32 vs 1.76±0.059). These data suggest that ouabain increases blood pressure through NHE-1 dependent activation of renal NaK.

## SA-PO2758

**Involvement of the Signaling Na/K-ATPase in Blood Pressure Regulation** Yiliang Chen,[1] Jiang Tian,[1] Changxuan Liu,[1] Joseph I. Shapiro,[2] Zi-Jian Xie.[1] *[1]Department of Physiology and Pharmacology, University of Toledo, Toledo, OH; [2]Department of Medicine, University of Toledo, Toledo, OH.*

Purpose of study:

To reveal the physiological role of the signaling function of the Na/K-ATPase

Major methods used:

Endosomal fractionation isolation; 22Na+ transcellular transport assay; mice blood pressure measurement by tail-cuff system.

Results:

The Na/K-ATPase (NKA), conventionally known as an ion transporter, also functions as a signal transducer. However, the physiological role of this newly discovered signaling function is not well understood. In this report, we demonstrate that the signaling NKA coordinates membrane trafficking and expression of NKA and sodium hydrogen exchanger isoform 3 (NHE3) in the renal epithelial cells. Activation of NKA signaling leads to endocytosis of both NKA and NHE3, which causes a reduction of transcellular Na+ transport in LLC-PK1 cells. Expression of the N-terminus of NKA α1 subunit (NT), which behaves as a dominant negative mutant, specifically blocks the NKA signaling and prevents ouabain-induced inhibition of transcellular Na+ transport. These *in vitro* experiments suggest that the signaling NKA be involved in renal sodium handling and therefore, may play a role in blood pressure regulation. To study the signaling NKA *in vivo*, we generated three lines of NT-YFP transgenic mice (NT mice). Then we fed the mice with either normal salt diet (0.5% NaCl) or high salt diet (4.0%) and measured blood pressure. As expected, the high salt diet produced hypertension (from 110 mmHg to 160 mmHg) in NT mice, but not in littermates. Moreover, the extent of blood pressure increase is correlated with NT-YFP renal expression level. Finally, renal functional curves show that expression of the NT produced salt-sensitive hypertension in NT mice.

Conclusion:

The signaling function of the NKA is involved in blood pressure regulation.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2759

**Sympathetic-Activity Induced Salt-Sensitive Hypertension Involved of WNKs** Shengyu Mu,[1] Tatsuo Shimosawa,[2] Fumiko Kawakami Mori,[1] Toshiro Fujita.[1] *[1]Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan; [2]Clinical Laboratory, University of Tokyo, Tokyo, Japan.*

(Background) Recent studies have showed that WNK kinases play important roles in the regulation of sodium transport in the distal nephron, therefore regulate the blood pressure. In this experiment we show the regulation of WNKs in sympathetic nerve activity-induced salt-sensitive hypertension.(Method) We used norepinephrine(NE) treated C57/B6 mice and DOCA-HS rats to show that sympathetic activation could decrease WNK4 expression, therefore increase sodium re-absorption and results in salt-sensitive hypertension. Then we used beta-1/2 knockout mice and mice distal nephrone cells (mDCTs) to show the mechanism of WNK4 regulation under high sympathetic activity. WNKs mRNA expression were measured by realtime-RT-PCR. The expressions of ion channels in the distal nephron were detected by western blot and immunostaining. Animal direct blood pressure was measured by catheter.(Result) After two weeks treatment either by NE or DOCA-salt, WNK4 expression was significantly lower than control groups (-50% in NE injected and -30% in DOCA-salt). Also sodium channels expression and activity were up-regulated in high sympathetic activity groups. NE treatment of beta1 but not 2 KO mice reduced WNK4 and salt sensitive hypertension. PKA inhibitor reversed effect of isoproterenol in reducing WNK4 expression.(Conclusion) In this study we found that sympathetic-activity inhibits WNK4, therefore increase the sodium re-absorption and finally induced to salt-sensitive hypertension. We suggest that regulation of WNK4 could be a new target for salt sensitive-hypertension.

## SA-PO2760

**Cyclosporine-Induced FHHt-Like Syndrome Is Associated with a Rise in WNK4; a Study in Rats and mDCT Cells** Haim Mayan,[1,2] Semyon Melnikov,[4] Shinichi Uchida,[3] Eliezer J. Holtzman,[2,5] Zvi Farfel.[1,2,4] *[1]Department of Medicine E, Sheba Medical Center, Israel; [2]Sackler School of Medicine, Tel Aviv University, Israel; [3]Tokyo Medical and Dental University, Tokyo, Japan; [4]Laboratory of Biochemical Pharmacology, Sheba Medical Center, Israel; [5]Laboratory of Molecular Nephrology, Sheba Medical Center, Israel.*

**Background**: Cyclosporine A is used for treatment of transplanted patients and for immune mediated diseases. Cyclosporine is known to cause a combination of metabolic side effects including hypertension, hyperkalemia , hypercalciuria and hypomagnesemia. These side effects except for hypomagnesemia are the cardinal features of familial hyperkalemia and hypertension (FHHt), also called pseudohypoaldosteronism type II (PHA II). FHHt is caused by mutations in the kinases WNK1 and WNK4 resulting in an increase in renal Na-Cl Cotransporter (NCC) apical distribution and function. Therefore we studied whether cyclosporine's metabolic side effects are mediated by WNK4 and NCC.

**Methods**: Sprague-Dawley (SD) rats were treated by cyclosporine 25 mg/Kg subcutaneously for 14 days. Blood pressure, blood chemistry values and kidney WNK4 protein were determined. In addition, mDCT cells were exposed to cyclosporine, and their WNK4 mRNA and protein content and their Na-Cl cotransporter (NCC) protein content were determined.

**Results**: The rats developed an FHHt-like syndrome including hypertension, hyperkalemia and salt sensitive hypercalciuria. These rats developed a significant increase in their kidney WNK4 protein content (0.13±0.01 vs 0.67±0.16 WNK4/GAPDH in controls, p=0.0183). In mDCT cells cyclosporine caused a rise in WNK4 mRNA levels and also a three fold rise in WNK4 protein content. This rise was followed by a rise in NCC protein content.**Conclusions**: Cyclosporine treatment causes an increase in WNK4 abundance in rats and in mDCT cells. This may be in part, the mechanism of cyclosporine- induced hypertension, hyperkalemia and hypercalciuria.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2761

**Apical NKCC2 Is Activated in Hypertensive Rats Contributing to Maintenance of Salt-Sensitive Hypertension** Monica Carmosino,[1] Patrizia Ferrari,[2] Lucia Torielli,[2] Mara Ferrandi,[2] Federica Rizzo,[1] Francesca Romano,[1] Giuseppe Bianchi,[3] Maria Svelto,[1] Giovanna Valenti.[1] *[1]General and Environmental Physiology, University of Bari, Bari, Italy; [2]Prassis Research Institute, Sigma Tau, Milan, Italy; [3]Università Vita Salute, S. Raffaele Hospital, Milan, Italy.*

The Milan hypertensive strain of rats (MHS) develops hypertension as consequence of the increased expression and activity of the tubular Na-K-ATPase. Regarding the other tubular sodium transporters no change in NKCC2 expression in the TAL was observed in this strain of rats (Capasso et al. 2008), despite NKCC2-dependent salt transport constitutes one of the major pathways for transepithelial salt reabsorption in the kidney. Since the activity of the renal-specific NKCC2 is regulated by changes in phosphorylation state, in this work we have analyzed the phosphorylation state of NKCC2 in Milan rats to verify whether the cotransporter activation is involved in the maintenance of hypertension in MHS rats.

Western blotting analysis using a specific antibody against the regulatory phospho-threonines in the NKCC2 N-terminus (R5 antibody) revealed that the renal expression of the phosphorylated-NKCC2 (p-NKCC2) increased by about 50% in hypertensive MHS rats compared to age-matched MNS control rats. Immunofluorescence analysis using the same antibody also showed that compared to age-matched controls, both the fluorescence

intensity of single tubules and the number of stained tubules significantly increased in MHS rats compared to MNS rats. On the other hand, western blotting analysis using T4 antibody, against both unphosphorylated and phosphorylated NKCC2, confirmed that the total expression of NKCC2 is unchanged in both strains of rats. Moreover, a six weeks oral administration of 20 mg/kg/day of furosemide prevented the insurgence of hypertension in treated MHS rats. In conclusion, we demonstrated that an increase in the activity of NKCC2 along the TAL might significantly contribute to sodium retention resulting in increase in systemic blood pressure in hypertensive MHS rats, placing NKCC2 as a key element in the pathogenesis of salt-sensitive hypertension.

Disclosure of Financial Relationships: nothing to disclose

n=4, means±SD

The diets did not change plasma [Na] or [K]. Compared to 1K2Na, 4K2Na lowered MAP, increased UV, UNa and UK. Aldosterone was elevated with 4%KCl diets but lower in 4K2Na than in 4K1Na. Renal Na transporters, analyzed by microscopy and density gradient fractionation revealed: proximal NHE3 was retracted out of the microvilli but DCT NCC distribution was unaltered. Skeletal muscle sodium pump abundance was elevated by both 4%KCl diets. This set of results suggests that doubling SHR chow [KCl]: 1) provokes diuretic and natriuretic responses, perhaps emanating with lower PT NHE3 activity, that could drive flow sensitive K secretion in the distal nephron, 2) reduces MAP, more with 4K2Na, perhaps secondary to greater diuresis and lower [aldosterone], 3) increases muscle Na,K-ATPase expression, perhaps to buffer increased dietary K load, 4) has beneficial effects even with 2% NaCl, suggesting that further efforts should be directed toward increasing dietary K.

Disclosure of Financial Relationships: Employer: USC Keck School of Medicine; Honoraria: APS, AM Physiol Society; Patent: Chemicon Royalties for Sodium Pump Antibodies; Scientific Advisor: AM Physiol Society.

**γ-Adducin Functions as a Novel Regulator of the Thiazide-Sensitive NaCl-Cotransporter** Henrik Dimke,[1] Pedro San Cristobal,[1] Mark J. J. De Graaf,[1] Jacob (Jaap) Deinum,[2] Jacques W. M. Lenders,[3] Joost G. Hoenderop,[1] Rene J. Bindels.[1] *[1]Physiology, Radboud University, Nijmegen Medical Center, Nijmegen, Netherlands; [2]Department of Internal Medicine, Section of Vascular Medicine, Radboud University, Nijmegen Medical Center, Nijmegen, Netherlands; [3]Department of Medicine, Carl Gustav Carus University Medical Center, Dresden, Germany.*

Hypertension is projected to affect more than 1 billion individuals worldwide. The National Vital Statistics Report lists heart disease as the primary cause of death, affecting more than 20 million people in the United States alone. Primary hypertension remains a major risk factor for the development of cardiovascular and chronic kidney diseases. The thiazide-sensitive NaCl cotransporter (NCC) plays a key role in renal salt reabsorption and thereby the maintenance of systemic blood pressure. This study was designed to further elucidate the molecular mechanisms governing the regulation of NCC. Pull down experiments coupled to mass spectrometry identified γ-adducin as a novel interactor of the transporter. γ-Adducin co-localized with NCC to the distal convoluted tubule. $^{22}Na^+$ uptake experiments in the Xenopus laevis oocyte showed that γ-adducin stimulated NCC activity in a dose-dependent manner. The stimulatory effect of γ-adducin occurs upstream from the With-No-Lysine Kinase 4. The binding site of γ-adducin mapped to the N-terminus of NCC encompassing three previously reported phosphorylation sites. Furthermore, competition with the N-terminal domain of NCC abolished the stimulatory effect of γ-adducin on the transporter. γ-Adducin was unable to increase NCC activity when these phosphorylation sites were made constitutively inactive or active. In addition, γ-adducin bound only to the dephosphorylated N-terminal of NCC. Taken together, our observations suggest that γ-adducin functions as a dynamic regulator of NCC, likely by amending the phosphorylation state of the transporter and consequently its activity. These observations suggest a novel mechanism by which γ-adducin influences renal NaCl transport and hence blood pressure maintenance.

**Functional Analysis of Novel Thiazide-Sensitive NaCl-Cotransporter Sequence Variants in a New Cohort of Patients with Gitelman Syndrome** Pedro San Cristobal,[1] Bob Glaudemans,[1] Joost G. Hoenderop,[1] Rene J. Bindels,[1] Nine V. Knoers.[2] *[1]Physiology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [2]Human Genetics, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.*

Gitelman syndrome (GS) is an autosomal recessive disorder characterized by low blood pressure, hyponatremia, hypokalemia and metabolic alkalosis in conjunction with significant hypomagnesemia and hypocalciuria. Periods of muscle weakness and tetany are commonly observed in patients with GS. The underlying cause for the GS phenotype is genetic aberrations in the solute carrier family 12, member 3 (SLC12A3) gene that encodes the thiazide-sensitive NaCl cotransporter (NCC). NCC localizes to the luminal membrane of the distal convoluted tubule (DCT), where it facilitates the cotransport of $Na^+$ and $Cl^-$ from the pro-urine into the cell. Here, we analyzed DNA samples of 263 patients with clinical phenotype compatible with GS by direct sequencing of all 26 exons of the SLC12A3 gene. In total 114 different mutations were identified, 50 of which have not been reported in literature before. These novel variants include 7 deletions, 30 missense-, 9 splice site- and 4 nonsense mutations. 7 missense mutations were selected (Glu121Asp, Thr392Ile, Asn442Ser, Ser475Cys, Tyr489His, Pro751Leu, Gln1030Arg) to investigate their effect on NCC activity and plasma membrane localization using the Xenopus laevis oocyte expression system, by $^{22}Na^+$ tracer uptake and confocal microscopy. Our results demonstrated that the Thr392Ile mutant was retained in the endoplasmic reticulum (ER) (class 2 mutation), while the Asn442Ser and Gln1030Arg NCC mutants showed decreased plasma membrane localization and consequently function, likely due to impaired trafficking (class 3 mutation). Even though the NaCl uptake was hampered for NCC mutants Glu121Asp, Pro751Leu, Ser475Cys and Tyr489His, the transporters reached the plasma membrane (class 4 mutation), suggesting an effect on NCC regulation or ion affinity. The present study identifies and characterizes new mutations in NCC, thereby providing insight into the molecular mechanisms underlying GS.

**Antagonists of Prostaglandin $E_2$ Receptors for the Treatment of Hypertension** Jason Duane Downey,[1] Richard M. Breyer.[2] *[1]Pharmacology, Vanderbilt University, Nashville, TN; [2]Medicine, Vanderbilt University, Nashville, TN.*

In contrast to blockade of all prostanoid production with NSAIDs, pharmacological blockade of $PGE_2$ pressor receptors EP1 and EP3 may decrease systemic blood pressure and protect from hypertensive renal damage. To test this hypothesis, EP1 and EP3 small molecule antagonists were synthesized and their pharmacology, pharmacokinetics, and physiologic effects on mean arterial pressure (MAP) were assessed. Two lead compounds, DG-041 and JD-200, were synthesized as subtype-selective antagonists of the pressor EP receptors. DG-041 binds the mEP3γ receptor with a $K_i$ of 449 ± 130.0 pM and potently blocks mEP3γ signaling with an $IC_{50}$ of 420.0 pM in an LVIP2.0zc cell-based CRE reporter assay. JD-200 blocked signaling through mEP1 with an $IC_{50}$ of 18.8 ± 11.5 nM in a fluorescent calcium flux cell-based assay. In vivo mouse pharmacokinetic experiments demonstrated that DG-041 is orally bioavailable with an elimination half-life of 1.2 h. JD-200 had an elimination half-life of 28 min. Preliminary studies demonstrate that while acute infusion of the EP1/EP3 agonist sulprostone caused a transient increase in MAP (+33.3 mmHg) in the EP1-/- mouse, pretreatment with DG-041 blocked the pressor effect of acute sulprostone infusion (+4.60 mmHg); the vasopressor effect of acute infusion of an unrelated pressor, α-adrenergic agonist phenylephrine, was not different (vehicle +42.0 mmHg, DG-041 +39.0 mmHg). Taken together these results suggest that these EP1 and EP3 receptor antagonists will be suitable for use in mouse models of hypertension.

## SA-PO2766

**EP1 Receptors Exacerbate Mortality in a Mouse Model of Hypertension** Christina E. Swan,[1] Kelli L. Boyd,[2] Roy Zent,[1] Richard M. Breyer.[1] *[1]Medicine, Vanderbilt University, Nashville, TN; [2]Pathology, Vanderbilt University, Nashville, TN.*

The role of the E-Prostanoid 1 (EP1) Prostaglandin E2 receptor in hypertensive end-organ damage was evaluated. Mice with a disrupted EP1 allele (EP1-/-; n = 25) or wild type controls (EP1+/+; n= 47) were subjected to a recently described model of hypertension and renal damage. Mice were uninephrectomized, and after two weeks recovery, a 50 mg deoxycorticosterone acetate pellet was implanted and 1 % NaCl was supplied in the drinking water. After a further week, angiotensin II (Ang II) was administered via Alzet minipumps (1.5 ng/min/g) implanted s.c. Blood pressure was measured by tail cuff plethysmography and proteinuria was assessed in spot urine collections on a weekly basis throughout the study. At the end of the study, mice were euthanized and histopathology was performed to assess renal damage. EP1+/+ mice in this model suffered from previously unreported high rates of mortality (56%), while EP1-/- mice had significantly lower mortality (23% P = 0.018). Systolic blood pressure was elevated in both groups post Ang II administration (EP1+/+ 179.8 ± 8.9 mmHg , EP1-/- 200.3 ± 8.0 mmHg P = 0.648). No differences were observed in levels of proteinuria between genotypes as determined by albumin to creatinine ratio (ACR) P = 0.216. Histopathological analysis revealed moderate hypertensive renal damage including glomerulosclerosis and mesangial expansion; but no differences were observed between the two groups. Taken together these data suggest that this deoxycorticosterone

acetate/Ang II model induces robust hypertension and modest renal damage in both EP1+/+ mice and EP1-/- mice. While the EP1 -/- mice are protected in this model, the lower mortality observed does not appear to be associated with either decrease in blood pressure or protection from renal damage.

**Changes in Extracellular Matriz (ECM) Composition Regulate COX-2 Expression in Human Mesangial Cells (HMC) Via FAK/PI3K/AKT/CREB Signaling Pathway** Laura Calleros,[1] Matilde Alique,[1] Alicia Luengo,[1] Mercedes Griera,[1] Diego Rodriguez-Puyol,[1, 2] Manuel Rodriguez-Puyol.[1] *[1]Department of Physiology, Universidad de Alcalá, Alcalá de Henares, Madrid, Spain; [2]Nephrology Section and Research Unit, Hospital Universitario "Príncipe de Asturias", IRSIN, Alcalá de Henares, Madrid, Spain.*

Renal fibrosis is the common final outcome of many clinical conditions, both inflammatory and non-inflammatory, that lead to chronic renal failure. It is characterized by a progressive substitution of cellular elements by extracellular matrix (ECM) proteins, as well as the loss of the normal equilibrium between the synthesis and degradation of ECM. In normal conditions, collagen IV seems to be the most relevant glomerular collagen but in pathological conditions, such as hypertension or diabetes, characterized by an augmented profibrotic cytokines at the local level, an increased ECM protein synthesis with a progressive accumulation of interstitial collagen I takes place at glomerular level. ECM proteins, through the interaction with transmembrane proteins, may induce significant changes in cell phenotype. Interestingly, evidence obtained in the past decade indicates that progression to advanced renal fibrosis requires the participation of inflammatory events such as COX-2 up-regulation. Moreover it is known that AKT may act through different transcription factors in the regulation of the COX-2 promoter. Present results show that progressive accumulation of collagen I in the extracellular medium induces a significant increase of COX-2 expression in human mesangial cells and an enhancement in PGE2 production. This COX-2 overexpression is due to increased COX-2 mRNA levels. The analysis of the mechanism implicated in COX-2 up-regulation by collagen I showed FAK activation. Furthermore, we observed that the activation of the PI3K/AKT pathway by collagen I, and collagen I-induced COX-2 over expression was abolished by PI3K and AKT inhibitors, or abrogation of AKT expression. Additionally, we showed that the CRE transcription factor is implicated. In summary, our results provide evidence that collagen type I increases COX-2 expression via the FAK/PI3K/AKT/CREB signaling pathway.

**Pro-Fibrotic Effects of Aldosterone on Normal Heart and Aorta: Processes Attenuated by Endogenous Glucocorticoids and Their 11-Dehydro Metabolites** Andrew S. Brem,[1] David Morris,[2] Rujun Gong.[1] *[1]Division of Kidney Diseases and Hypertension; [2]Department of Pathology, Rhode Island Hospital, Brown Medical School, Providence, RI.*

Aldosterone (ALDO) is known to be a pro-fibrotic factor in both cardiovascular and renal tissues. The effects of ALDO on fibrosis have largely been studied in animal models of pre-existing hypertension and/or systemic disease. This study tests the hypothesis that prolonged ALDO exposure is able to directly induce fibrotic changes normal mice in the absence of hypertension or systemic disease. Experiments were conducted with intact or adrenalectomized (ADX) mice. Mice were divided into 8 groups (n=4/group) and treated for 1 week: CONTROLS; mice treated with ALDO (8 µg/kg/day via mini-pump); ADX-CONTROLS; ADX plus corticosterone (CORT 800 µg/kg/day); ADX-ALDO; ADX-ALDO plus the mineralocorticoid receptor (MR) antagonist RU-318 (800 µg/kg/day); ADX -ALDO plus CORT (800 µg/kg/day); and ADX-ALDO plus 11-dehydro-CORT (800 µg/kg/day). Four variables were measured: aortic smooth muscle to collagen ratio, aortic intimal thickness (µm), heart/body weight ratio (mg/gm), and left ventricular collagen volume (%). Mice in all 8 groups exhibited normal blood pressures at 1 week prior to sacrifice. CORT alone had no effect on any of the variables examined. However, ALDO exposure was associated with fibrotic changes in intact mice but the changes were significantly more pronounced in the ADX-ALDO mice. The fibrotic changes were distributed in a peri-vascular pattern, closely associated with micro-vessels. The ALDO induced effects were attenuated in the ADX-ALDO-RU-318 mice and in the ADX-ALDO-11-deydro-CORT treated mice. ADX-ALDO-CORT mice also showed a decrease in fibrotic changes but the findings were not as reproducible. Thus, extended low-level ALDO exposure induces fibrotic changes in heart and aorta from normal mice in the absence of hypertension or systemic disease. MR antagonists and the 11-dehydro-metabolite of vascular 11β-HSD (dehydrogenase) attenuate these fibrogenic effects. Vascular 11β-HSD isoforms may provide locally synthesized agents, which directly limit ALDO induced fibrotic activity in normal heart and aorta.

**SA-PO2769**

**Age-Dependent Impairment of Renal Vascular Function in Mature Ciliary Neurotrophic Factor Deficient Mice** Sebastian A. Potthoff, Yuriko Mori, Henning Hoch, Eva Koenigshausen, Magdalena Woznowski, Lorenz Sellin, Oliver Vonend, Johannes Stegbauer, Lars C. Rump, Ivo Quack. *Deparment of Nephrology, Heinrich-Heine University, Duesseldorf, Germany.*

Ciliary neurotrophic factor (CNTF), an interleukin-6-like cytokine with distinct impact on neuronal cell survival, mediates anti-inflammatory effects and reduces apoptosis by activating the JAK2-STAT3-signaling cascade and MAP kinases. CNTF is highly expressed in vessels and the kidney. To investigate a potential role of CNTF on renal vascular function, vasoreactivity to Ang II was tested in isolated perfused kidneys of CNTF-KO and WT mice. Furthermore, we investigated whether Ang II induced pressor responses were dependent on JAK2-STAT3 signalling pathway or MAP-kinase signal transduction. Therefore, dose-response-curves to Ang II were performend in the presence or absence of AG490 (JAK2-Inhibitor, 5µM), SB203580 (p38-inhibition, 5µM) and PD98059 (MEK1-inhibition, 5µm).

CNTF-KO vs. WT-mice at the age of 14 +/- 3 weeks (n=8) showed no significant difference in Ang II pressor response. However, at 31 +/- 7 weeks (n=12), CNTF-KO mice showed a significant decrease in Ang II pressor response with a minimum of 59.8% of WT-response at EC50. Neither in young nor old mice, acute inhibition of p38, MEK1 and JAK2 significantly altered Ang II dependent pressor responses.

Interestingly, pressor response to potassium chloride (1M) showed a trend to be reduced in old CNTF-KO vs. WT mice (KO vs. WT: 124+/-53 vs. 161+/-59 mmHg; p=0.16), whereas young CNTF-KO vs. WT mice mice had an equal pressor response to KCl (KO vs. WT: 152+/-24 mmHg vs. 159+/-33 mmHg; p=0.51).

In our study, we demonstrate that neither JAK2-STAT3 signaling pathway nor the MAP-kinases signal transduction have any impact on renal pressor response to Ang II in non-pathological conditions. However, CNTF deficiency causes an age-dependent impairment of renal vasoreactivity to Ang II. Thus, our data suggest that CNTF is nessecary to preserve maximal renal vascular function. Whether this observed age-dependant difference in pressor response is limited only to Ang II induced vasoconstriction or to general impairment of vasoreactivity is subject of ongoing research.

**SIRT1 Activation Protects the Endothelial Dysfunction To Promote Atherogenesis through LKB1/ AMP-Activated Protein Kinase Activation** Hideyuki Negoro.[1] *[1]Medicine, Harvard Medical School, Boston, MA; [2]Japanese Red Cross Medical Center Hospital, Tokyo, Japan.*

SIRT1 is a conserved NAD(+)-dependent deacetylase and possesses beneficial effects against aging-related diseases, but little information is available on a putative role of SIRT1 in endothelial and vascular homeostasis. Endothelial senescence causes endothelial dysfunction to promote atherosclerotic change and contribute to age-related vascular diseases. In the present study, we evaluate the protective effects of SIRT1 on the endothelial dysfunction and elucidate the underlying mechanisms. We established an in vitro senescence model by prolonged culture of primary endothelial cells isolated from bovine aorta. The freshly isolated young endothelial cells gradually underwent senescence during 1 month of repetitive passages. It was observed that protein expressions of SIRT1 were decreased time dependently in the senescent endothelial cells. In contrast, the protein levels of LKB1, a serine/threonine kinase, the phosphorylation of its downstream target AMP-activated protein kinase (AMPK) and plasminogen activator inhibitor (PAI)-1generation were dramatically increased in the senescent cells. On the other hand, resveratrol activated SIRT1 in the endothelial cells. SIRT1 activation with resveratrol inhibited the increase of LKB1, AMPK. At the same time, SIRT1 activation with resveratrol reduced PAI-1 generation in the endothelial cells significantly. We knocked down SIRT1 and the protein levels of LKB1, phosphorylated AMPK and PAI-1 elevated in the knocked down cells. The protein levels of LKB1, phosphorylated AMPK and PAI-1generation did not changed in the SIRT1 knocked down cells even if they were stimulated with resveratrol.

These findings indicate that activation of SIRT1 provides beneficial effects against the endothelial dysfunction to promote atherogenesis through LKB1/ AMPK pathways.

**SA-PO2771**

**Renal Hyperfiltration in Swine Obesity Is Associated with Increased Intra-Renal Microvascular Density** John R. Woollard, Michael James Korsmo, Kyra L. Jordan, Hui Tang, James Krier, Xiang-Yang Zhu, Lilach O. Lerman. *Nephrology & Hypertension, Mayo Clinic, Rochester, MN.*

**Objective:** Obesity is an important predictor of chronic kidney disease, and also associated with an early increase in glomerular filtration rate (GFR) and renal blood flow (RBF), which might contribute to progression of renal injury, but the mechanisms remain unclear. This study tested the hypothesis that obesity-induced hyperfiltration is associated with remodeling and dysfunction of the renal microvasculature. **METHODS:** Ossabaw littermate pigs (a model prone to obesity induced by an atherogenic diet and sedentary life style) were fed either a standard (lean, n=7) or atherogenic (obese, n=7) diet for 10 weeks. Visceral fat volume and renal hemodynamics and function were then studied in vivo using multi-detector CT before/after infusion of acetylcholine (Ach). Intra-renal microvascular density was then studied in vitro using micro CT.

**Results:** Obese were ~50% heavier than lean pigs (p=0.004) due to elevated visceral fat volume, and had increased serum cholesterol and oxidized-LDL (675±142 vs. 382±75

ng/mL, p<0.05) levels, while blood pressure was not different. Basal RBF and GFR were elevated in obese. RBF increased in response to Ach in both groups, but response was attenuated in obese compared to lean pigs (+17±6 vs +59±14%, p=0.007), as was GFR response to Ach (-10±5 vs +11±5%, p=0.004). Fractional vascular volume and spatial density of microvessels (20-200μm in diameter) were higher in the cortex of obese pigs.

**Conclusion:** Obesity leads to proliferation of dysfunctional intra-renal microvessels, and in turn an increase in RBF and GFR, likely secondary to inflammation and oxidative stress. The associated hyperfiltration and endothelial dysfunction may partly account for progression of renal injury in obesity.

## SA-PO2772

**Endothelial-to-Mesenchymal Transition (Endo-MT) in Human Vascular Endothelial Cells as a Novel Mechanism of Uric Acid-Induced Endothelial Dysfunction** Yang Hee Jang, Eun Sun Ryu, Mina Yu, Dong-Ryeol Ryu, Seung-Jung Kim, Kyu Bok Choi, Duk-Hee Kang. *Nephrology, Ewha Womans University, School of Medicine, Seoul, Republic of Korea.*

Recent data from experimental and clinical studies suggested a causative role of uric acid in the development and/or aggravation of cardiovascular, renal and metabolic diseases. Endothelial dysfunction, which is characterized by a decrease in nitric oxide (NO) production, an induction of oxidative stress and cell senescence, is regarded as one of the key mechanisms of uric acid-induced vascular and metabolic diseases. Endothelial-to-Mesenchymal transition (endo-MT) is an early and reversible process of endothelial dysfunction, and is known to play a role in cardiac fibrosis and interstitial fibrosis of diabetic nephropathy. We investigated whether uric acid per se induced endo-MT in cultured human vascular endothelial cells in order to define the early therapeutic target of uric acid-induced vascular, renal and metabolic disease. HUVECs were isolated from umbical cord, and stimulated with uric acid (3, 6, 9, 12 mg/dl). Endo-MT was evaluated by a comparison of the expression of the endothelial markers, CD31 or VE-cadherin and the mesenchymal marker, alpha smooth muscle actin (α-SMA) by western blot analysis and immunocytochemistry. Uric acid (3-12 mg/dl) induced the morphologic changes of HUVEC from 96 hours of stimulation with a loss of cell contact and elongation. From 48 hours of stimulation before the development of morphologic changes, uric acid down-regulated the expression of CD31 and VE-cadherin and up-regulated α-SMA expression in a dose-dependent and time-dependent manner, which were significantly attenuate by pre-treatment of organic anion transporter inhibitor, probenecid (1 mM). Fluorescence microscopy of uric acid-stimulated HUVEC also demonstrated that uric acid altered the expression of CD31 and α-SMA, Interestingly, uric acid-induced endo-MT in HUVEC was associated with a senescence of endothelial cells and a decrease in NO production. These findings suggested uric acid per se induced a phenotypic transition of endothelial cells, endo-MT, which could be one of the mechanisms of uric acid-induced endothelial dysfunction.

## SA-PO2773

**Indoxyl Sulfate, a Uremic Toxin, Promotes Cell Senescence in Aorta of Hypertensive Rats** Toshimitsu Niwa,[1] Ayinuer Adijiang,[1] Yuusuke Higuchi,[2] Fuyuhiko Nishijima,[2] Hidehisa Shimizu.[1] *[1]Department of Advanced Medicine for Uremia, Nagoya University School of Medicine, Nagoya, Japan; [2]Biomedical Research Laboratories, Kureha Co., Tokyo, Japan.*

We demonstrated that administration of indoxyl sulfate, a uremic toxin, promotes aortic calcification in hypertensive rats. This study aimed to clarify if indoxyl sulfate could contribute to cell senescence in the aorta of hypertensive rats.

The rat groups consisted of 1) Dahl salt-resistant normotensive rats (DN), 2) Dahl salt-resistant normotensive indoxyl sulfate-administered rats (DN+IS), 3) Dahl salt-sensitive hypertensive rats (DH), and 4) Dahl salt-sensitive hypertensive indoxyl sulfate-administered rats (DH+IS). After 32 weeks, their arcuate aortas were excised for histological and immunohistochemical analysis. Cell senescence was evaluated by immunohistochemistry of senescence-associated beta-galactosidase (SA-beta-gal), and senescence-related proteins such as $p16^{INK4a}$, $p21^{WAF1/CIP1}$, p53 and retinoblastoma protein (Rb).

Both DH and DH+IS rats showed significantly increased systolic blood pressure as compared with DN and DN+IS rats, respectively. Serum indoxyl sulfate levels were significantly increased in DN+IS and DH+IS rats as compared with DN and DH rats, respectively. DH+IS rats showed significantly increased serum creatinine and decreased creatinine clearance as compared with DH rats. In aorta, DH rats showed significantly increased aortic calcification and wall thickness, and increased expression of SA-beta-gal, $p16^{INK4a}$, $p21^{WAF1/CIP1}$, p53 and Rb in the calcification area of arcuate aorta as compared with DN rats. More notably, DH+IS rats showed significantly increased aortic calcification and wall thickness, and significantly increased expression of SA-beta-gal, $p16^{INK4a}$, $p21^{WAF1/CIP1}$, p53 and Rb in the cells embedded in the calcification area as compared with DH rats.

In conclusion, indoxyl sulfate promotes cell senescence with aortic calcification and expression of senescence-related proteins in hypertensive rats.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2774

**Mechanical Stretch Prevents Calcification and Regulates Calcium-Sensing Receptor Expression, Function in Long-Term Cultures of Human Aortic Smooth Muscle Cells** Daniel Zehnder,[1] Guerman Molostvov,[1] Rosemary Bland.[2] *[1]Clinical Siences Research Institute, University of Warwick, Coventry, United Kingdom; [2]BioMedical Research Institute, University of Warwick, Coventry, United Kingdom.*

Vascular smooth muscle cells (VSMC) play a crucial role in the development of arterial calcification, which is responsible for premature cardiovascular mortality in chronic kidney disease patients. This study investigates the role of calcium-sensing receptor (CaSR) and mechanical strain on VSMC phenotype and calcification.

Human aortic SMC (HAoSMC) were cultured under static or cyclic strain conditions using Flexcell apparatus for up to 2 weeks. HAoSMC phenotype and calcification were quantified by Western blot, alizarin red staining, alkaline phosphatase (ALP) and osteocalcin (OC) activity assays. For statistical analysis one-way ANOVA followed by Tukey's test was used.

Culture under cyclic strain resulted in up-regulation of α-actin expression by days 7 and 10 (23%, p<0.05) and a 45% increase in CaSR expression (p<0.05) compared to static cultures.

To assess the role of CaSR, cells were treated with CaSR agonists: 2 and 5mM $Ca^{2+}$ or 50μM $Gd^{3+}$ alone or in combination. Treatment of static HAoSMC with $Ca^{2+}$, $Gd^{3+}$ or both for 7 days induced a marked down-regulation (p<0.01) of CaSR expression and up-regulation (p<0.01) of HAoSMC calcification. ALP and OC levels were markedly increased in cells treated with both CaSR agonists (p<0.05). In HAoSMC cultured under cyclic strain, $Ca^{2+}$ and $Gd^{3+}$-induced down-regulation of CaSR expression and increased calcification were significantly attenuated (p<0.05 to p<0.001). In addition, cyclic strain induced a significant down-regulation of ALP and OC production in control and CaSR agonist-treated cells (p<0.01).

CaSR knockdown with a CaSR siRNA resulted in a further increase in calcification in $Ca^{2+}$ and $Gd^{3+}$-treated cells when compared to untransfected cells (p<0.05). In addition, there was a pronounced up-regulation of ALP and OC production in control and agonist-treated CaSR knockdown cells (p<0.01).

In conclusion, our findings indicate that a functional CaSR may serve to prevent a shift towards calcifying SMC phenotype and, therefore, protect against calcification.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2775

**Gene Therapy with Human Hepatocyte Growth Factor Prevents the Development of Hypertension and Suppresses Vascular MCP-1 and IL-6 mRNA Expression in Fructose-Fed Rats** Freddy J. Romero,[1] Maribel Ch. Chavez,[2] Jose L. Arcaya,[2] Jose D. Herrera,[2] Richard J. Johnson,[3] Bernardo Rodriguez-Iturbe.[1] *[1]IVIC-Zulia, Maracaibo, Venezuela; [2]Universidad del Zulia, Maracaibo, Venezuela; [3]University of Colorado, Denver.*

**Background**: Although previous studies have shown that increased serum concentration of hepatocyte growth factor (HGF) are present in association with the metabolic syndrome, the relationship of HGF abundance with hypertension and vascular inflammation remain largely unknown. The purpose of this study was to investigate the effect of gene therapy with human HGF on the development of these features in the fructose-induced model of metabolic syndrome. **Methods**: Six-weeks-old male Sprague Dawley rats were randomly divided into four groups (n=6 each):1)control group fed normal chow and water; 2)FFR group fed normal chow and given water containing 10% (w/v) fructose during 6 weeks; 3)FFR-pCMV-HGF group, fructose-fed rats that received hydrodynamic injection of HGF gene via naked plasmid vector (1 mg/Kg) and 4)FFR-pcDNA3.1 group, fructose-fed rats that received empty vector. Systolic blood pressure (SBP) and fasted plasma parameters were measured every week. The aorta was extracted to evaluate pro-inflammatory cytokines mRNA expression by real time PCR.

**Results**: As predicted, 6 weeks of fructose consumption in the drinking water resulted in mildly elevated SBP(mmHg) (control= 116 ± 2.01 vs. FFR= 140 ± 3.02) hypertriglyceridemia (mM) (FFR= 0.71 ± 0.04 vs. Control= 0.33 ± 0.05) and vascular inflammation compared with the controls rats. HGF gene therapy reduced SBP in FFR-pCMV-HGF vs. FFR-pcDNA3.1 (121.0 ± 2.76 vs. 139 ± 3.0, p<0.01) without modifying triglyceride blood levels. In addition, HGF therapy suppressed aorta mRNA expression of MCP-1 (0.98 ± 0.29 vs. 2.99 ± 0.96, p<0.05) and IL-6 (1.28 ± 0.42 vs. 3.53 ± 0.48, p<0.05) for FFR-pCMV-HGF vs. FFR-pcDNA3.1.

**Conclusions**: These results indicate that gene therapy with human HGF reduce vascular inflammatory cytokines and lowers blood pressure in fructose-induced metabolic syndrome without modifying hyperlipidemia. Elevated HGF levels in the metabolic syndrome may be an adaptive response to suppress vascular inflammation

### SA-PO2776

**Bone Marrow-Derived Fibroblast Precursors Mediate Angiotensin II Induced Cardiac Fibrosis – Role of CCR2** Jing Xu, Song-Chang Lin, George E. Taffet, Mark L. Entman, William E. Mitch, Yanlin Wang. *Department of Medicine, Baylor College of Medicine, Houston, TX.*

Cardiovascular disease is a major cause of morbidity and mortality in patients with chronic kidney disease. Angiotensin II (Ang II) plays an important role of the development of cardiac hypertrophy and fibrosis, but the underlying cellular and molecular mechanisms are not completely understood. Recent studies have shown that bone marrow-derived fibroblast precursors are involved in the pathogenesis of tissue fibrosis. Since bone marrow-derived fibroblast precursors express chemokine receptor - CCR2, we tested the hypothesis that CCR2 can regulate the recruitment of bone marrow-derived fibroblast precursors into the heart, mediating Ang II-induced cardiac fibrosis. Wild-type (WT) and CCR2-deficient (CCR2-KO) mice underwent unilateral nephrectomy and were treated with angiotensin II (Ang II) via subcutaneous osmotic minipumps at 1500 ng/kg/min. Ang II treatment resulted in elevation of blood pressure and cardiac hypertrophy that was not significantly different between WT and CCR2-KO mice. Ang II treatment of WT mice caused cardiac fibrosis as measured by picrosirius red stain. There also was accumulation of bone marrow-derived fibroblast precursors expressing hematopoietic markers-CD34 and CD45, mesenchymal marker-collagen type I, and myofibroblast marker-α-smooth muscle actin (α-SMA) as determined by flow cytometry. Ang II-induced cardiac fibrosis and recruitment of bone marrow-derived fibroblast precursors in the heart were attenuated in CCR2-KO mice. Furthermore, Ang II treatment of WT mice increased collagen type I, fibronectin, and α-SMA expression in the heart as revealed by real time RT-PCR, immunohistochemistry, and Western blot analyses. These changes were abrogated in the CCR2-KO mice. Functional studies with cardiac ECHO showed that the reduction of cardiac fibrosis led to an impairment of cardiac systolic function and subsequent left ventricular dilatation in Ang II–treated CCR2-KO mice. Our results suggest that CCR2 play a pivotal role in the development of Ang II–induced cardiac fibrosis through regulation of bone marrow-derived fibroblast precursors.

**CCR5 Deficiency Does Not Reduce Renal Endorgan Damage in Hypertensive Mice** Christian Krebs, Christoph Fraune, Jan-Eric Turner, Ulf Panzer, Rolf A. Stahl, Ulrich O. Wenzel. *III. Med. Klinik - Nephrology, University Hospital Hamburg-Eppendorf, Hamburg, Germany.*

The chemokine-receptor CCR5 has been linked to pathology in hypertension; i.e. CCR5 antagonists influence hypertension and CCR5 is expressed on infiltrating T cells in hypertensive mice.

By combining DOCA salt and Ang II we have recently established a model of hypertension in C57Bl/6 mice with massive renal endorgan damage (Kidney Int 73:643-50, 2008). To evaluate the role of CCR5 in hypertension we compared wildtype (WT) and CCR5 deficient mice in this model.

DOCA + Ang II induced hypertension in WT and CCR5 $^{-/-}$ mice and blood pressure and renal function did not differ between hypertensive WT and CCR5 $^{-/-}$. DOCA + Ang II induced massive albuminuria and glomerular injury as assessed by scoring and renal PAI-1 expression but no difference was found. In addition, no difference was found for renal inflammation as measured by infiltrating cells (T cells and macrophages) and CCL-2 expression. The renal expression of CCR5 ligands CCL4 and CCL5 were increased in hypertensive mice with no difference between the two groups. CCL3 was increased in CCR5 $^{-/-}$ as compared to hypertensive WT (rel. exp. 1.8 vs. 2.8; p<0.05).

In conclusion, CCR5 deficiency does not influence hypertensive renal endorgan damage. Since infiltrating T cells have a high expression of CCR5, these cells are either not pathogenic or CCR5 positive T cells immigrate via a different chemokine receptor. Beneficial effects of CCR5 antagonists in hypertension are most likely due to unspecific effect of the antagonists. Other chemokine receptors in concert with CCR5 must be important for hypertensive injury.

**Mizoribine Ameliorates Hypertension and Renal Injury Caused by Aldosterone-Salt Treatment** Toshiki Doi,[1] Kouichirou Kawaoka,[1] Noriaki Yorioka.[2] *[1]Department of Molecular and Internal Medicine, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan; [2]Department of Advanced Nephrology, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan.*

Purpose. We investigated whether mizoribine, an effective immunosuppressant, could ameliorate hypertension and renal injury in a rat model of aldosterone-salt treatment.

Methods. Six-week-old male Sprague-Dawley rats underwent right nephrectomy under anesthesia. After 10 days for recovery from surgery, the rats were given 1% NaCl as drinking water. The animals were divided into 3 groups (n=7 each): vehicle infusion, 0.75 μg/hour aldosterone infusion, or aldosterone infusion and 3 mg/kg/day of oral mizoribine. Systolic blood pressure was measured by the tail cuff method every other week. Two days before killing, 24-hour urine was collected for measurement of protein. Six weeks after the start of treatment, all of the rats were sacrificed. Renal sections were assessed for glomerulosclerosis, interstitial fibrosis, and T lymphocyte and macrophage infiltration. Expression of interferon-gamma (INF-gamma), tumor necrosis factor-alpha (TNF-alpha), transforming growth factor-beta1 (TGF-beta1), monocyte chemotactic protein-1 (MCP-1), and endothelin-1 (ET-1) was measured by real-time PCR.

Results. Rats with aldosterone infusion exhibited hypertension and renal injury characterized by proteinuria, glomerulosclerosis, interstitial fibrosis, and interstitial infiltration of T lymphocytes and macrophages. Renal cortical mRNA expression of INF-gamma, TNF-alpha, TGF-beta1, MCP-1, and ET-1 were increased by aldosterone infusion. Treatment with mizoribine improved both hypertension and renal injury. Expression of INF-gamma, TNF-alpha, TGF-beta1, MCP-1, and ET-1 showed a decrease with mizoribine treatment.

Conclusion. Infiltration of immune cells was associated with hypertension and renal injury in rats infused with aldosterone.

**The Glucocorticoid Receptor in the Vascular Endothelium Is a Critical Mediator of Nitric Oxide Release in LPS-Induced Sepsis** Julie Goodwin,[1] Yan Feng,[1] William C. Sessa.[2] *[1]Pediatrics, Yale University School of Medicine, New Haven, CT; [2]Pharmacology, Yale University School of Medicine, New Haven, CT; [3].*

Introduction: Glucocorticoids are commonly used as therapy for septic shock, yet there is continued debate as to whether they provide benefit and which of their many effects are relevant. Study of the glucocorticoid receptor in the vascular endothelium may provide insight into the mechanism of action of glucocorticoids in this setting.

Methods: Using an in vitro model of tissue-specific glucocorticoid receptor (GR) knockout in the endothelium through targeted siRNA in HUVECs we exposed control and knockout (KO) cells to LPS treatment with and without dexamethasone pre-treatment. Nitric oxide (NO) levels in the conditioned media were assessed by chemiluminescent NO analyzer. In vivo, mice with tissue-specific GR KO in the endothelium were treated with LPS with and without dexamethasone and iNOS expression was assessed in aortic lysates by Western blotting.

Results: Knockdown of GR in HUVECs by siRNA was >95% efficient. At baseline, loss of GR in HUVEC resulted in a 16% increase in total NO levels (p<.001). After treatment with LPS, KO cells showed an increase of 33% in NO levels compared to WT cells (p<.001). When pretreated with dexamethasone, KO cells had 70% higher NO levels compared to control cells that were similarly treated (p<.001). KO animals treated with 12.5 mg/kg LPS had both increased and earlier temporal expression of iNOS compared to control animals. When control animals were pre-treated with dexamethasone 2 mg/kg 2 hours prior to LPS, iNOS expression was significantly decreased as well as delayed. Similar treatment in KO animals resulted in no such improvement.

Conclusions: These studies suggest that:

(1) loss of GR in HUVECs increases basal expression of NO as well as NO expression after LPS alone and with dexamethasone pre-treatment

(2) loss of GR in the endothelium in vivo results in increased iNOS expression in response to LPS

(3) the glucocorticoid receptor in the vascular endothelium is likely a critical mediator of NO release in sepsis

### SA-PO2780

**High-Fat Diet-Induced Renal Lipotoxicity in Spontaneously Hypertensive Rat Via PPARα-PI3K/Akt/FoxO3a-Oxidative Stress** Hyun Wha Chung, Ji Hee Lim, Min Young Kim, Seok Joon Shin, Bumsoon Choi, Cheol Whee Park. *Division of Nephrology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea.*

Phosphatidylinositol-3 kinase (PI3K)/protein kinase B (AKT)/forkhead box-containing protein O (FoxO) signaling regulates cell metabolism, cell cycle arrest, oxidative stress, and apoptosis. Therefore, we investigated which PI3K/AKT-FoxOs pathways would be involved in high-fat diet-induced intra-renal lipotoxity in Spontaneously Hypertensive Rat (SHR).

SHR and Wistar-Kyoto rat (WKY) at 8 weeks age were treated with either a normal diet (SHR-NF or WKY-NF group) or a high-fat diet (SHR-HF or WKY-HF group) with or

without fenofibrate and tempol for 12 weeks. After the end of 12 week, a high-fat diet in SHR gained more body weight and systolic blood pressure, elevated plasma insulin and triglycerides levels, and induced glucose intolerance. The high-fat diet resulted in increases in intra-renal free fatty acid and triglycerides accumulation related to a decrease in PPAR-α expression in the kidney as well as albuminuria, the expansion of mesangial areas, and inflammation in the kidney. The high-fat diet also significantly down-regulated PI3K-Ser473 pAKT-Ser253 pFoxO3a signaling, resulted in a decrease in MnSOD and an increase in Bim expression leading to the oxidative stress and apoptosis respectively. On the contrary, no such appreciable differences were observed between WKY and WKY-HF. Administration of fenofibrate or tempol in the high-fat diet-induced SHR reversed the elevation of the systolic blood pressure, insulin resistance, and intra-renal lipotoxicity via the induction of intra-renal PPARa and the activation of PI3K-Ser473 pAKT-Ser253 pFoxO3a signaling, which led to decreases in oxidative stress and apoptosis.

Our results suggest that PPAR-α agonists or antioxidants can ameliorate high-fat diet-induced renal lipotoxicity and hypertension by the up-regulation of the PI3K-pAkt-pFoxO3a signaling.

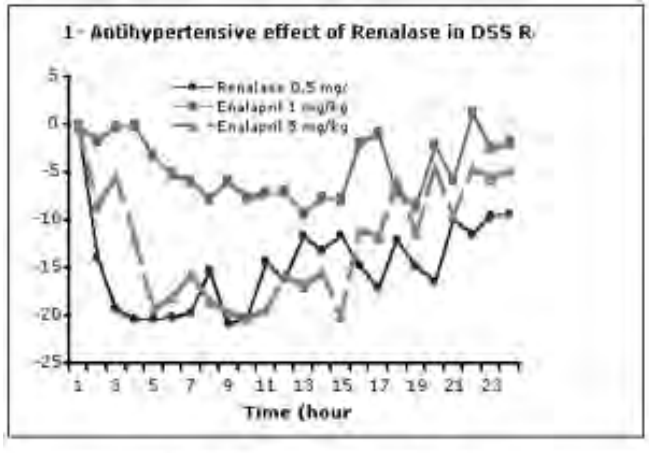
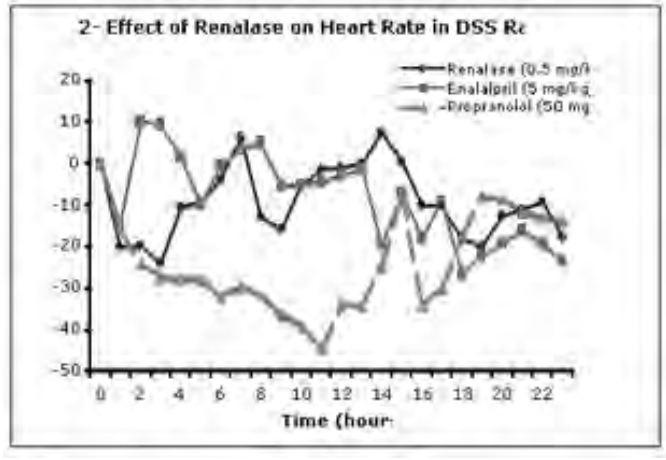
### SA-PO2781

**Antihypertensive Effect of Recombinant Renalase in Dahl Salt Sensitive (DSS) Rats** Gary V. Desir,[1,2] Lieqi Tang,[1,2] Peili Wang,[1,2] Guoyong Li,[1,2] Heino Velazquez.[1,2] *[1]Medicine, Yale School Med, New Haven, CT; [2]Medicine, VACHS, West Haven, CT.*

Renalase is a FAD containing protein that is expressed in kidney, heart, skeletal muscle, and small intestine, and is secreted into blood. Its levels are decreased in CKD, and vitro data indicate it specifically degrades catecholamines. Renalase deficiency in a mouse knockout model causes hypertension in the absence of changes in cardiac and renal function, and plasma aldosterone, suggesting that renalase directly modulates blood pressure. It is not known if recombinant renalase administration modulates ambulatory blood pressure.

Therefore, the effect of recombinant renalase on ambulatory blood pressure was assessed in DSS rats. Radio transmitters were surgically implanted into DSS rats (200 to 300 g body wt) maintained on a low salt diet, and blood pressure values were recorded continuously for the duration of the experiment. The animals were allowed to recover for 1 week until the diurnal variation in blood pressure returned to normal, and then switched to a high salt diet for the remainder of the study period. Test compounds were administered once the animals developed salt dependent hypertension. A single dose of recombinant renalase (0.5 mg/kg subcu) significantly decreased systolic and diastolic pressure for up to 12 hours (n=9, p<0.001).





Renalase lowered blood pressure significantly more than enalapril at a dose of 1 mg/kg (n=9, p<0.002), and comparably to enalapril (5 mg/kg) (n=9), (Fig 1) and propranolol (50 mg/kg) (n=9) (Not shown). Heart rate was reduced to a significantly greater degree by propranolol (n=9, p<0.001), than by either renalase or enalapril (Fig 2).

These data indicate that recombinant renalase has a potent and prolonged anti hypertensive effect in a rat model of salt sensitive hypertension.

**The Effect of Changes in Salt Intake on the Circadian Rhythm of Blood Pressure and Heart Rate in Diabetic Akita Mice** Yan Qin,[1,3] Yuning George Huang,[1] Josephine P. Briggs,[2] Jurgen B. Schnermann.[1] *[1]NIDDK, National Institutes of Health, Bethesda, MD; [2]NCCAM, National Institutes of Health, Bethesda, MD; [3]Nephrology Division, Peking Union Medical College Hospital, Beijing, China.*

Mice heterozygous for an Ins2 mutation (Akita mice) develop severe insulin-dependent diabetes mellitus and represent a useful mouse model to study diabetic nephropathy. We determined long-term blood pressure and heart rate levels, their circadian variability, and their regulation by changes in salt intake. Circadian cardiovascular characteristics of mean blood pressure (MAP), systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR), pulse pressure (PP) and locomotor activity were measured in conscious and unrestrained 12-week old Ins2+/- mice (C57BL/6J background) and age-matched C57BL/6J mice by the telemetry. After baseline studies, the mice were placed on diets with either a high (8.0%) or low (0.04%) NaCl content in a random order.

Akita mice demonstrated robust circadian rhythms of MAP, SBP, DBP, PP, HR and locomotor activity without significant differences in the mesor, amplitude, and acrophase of the rhythms compared with C57BL/6J mice respectively. However, 24-h mean HR was significant lower in Akita mice compared with C57BL/6J mice (527 ± 10 vs 581± 14 bpm, p=0.008), especially in the dark period. Both Akita and C57BL/6J mice adapted to the low NaCl diet without significant changes of the rhythm and the mean values of MAP, DBP, PP, and locomotor activity although blood pressure tended to be lower in Akita reaching significance for SBP. On the high NaCl diet, Akita mice showed a striking further reduction in HR in both light and dark phases (489 ± 12 vs 571 ± 10 bpm, p=0.001), and the appearance of a second heart rate and blood pressure minimum at 2 AM. We conclude that circadian patterns of blood pressure, heart rate and locomotor activity are not dramatically altered in 12-week old Akita mice with established diabetes mellitus. However, reduced heart rates in response to a high salt diet and reduced blood pressures during low NaCl diet suggest an impairment of autonomic regulation and baroreflex function in type 1 diabetes.

**Dissecting the Genetics of Kidney Disease Using *Rf*-3 and *Rf*-4 Congenic Models** Caitlin C. O'Meara, Jozef Lazar, Howard J. Jacob. *Physiology, Medical College of Wisconsin, Milwaukee, WI.*

It is well known that genetic components play a role in the onset and progression of chronic kidney disease (CKD). As CKD is a complex disease, there are multiple genes, as well as gene-gene interactions that contribute to the development of the disease. These genes can cause changes in glomerular capillary pressure, glomerular barrier permeability, or impaired tubular function, all of which can lead to kidney damage. The focus of the present study was to identify the role of two separate renal failure quantitative trait loci (QTL), *Rf*-3 and *Rf*-4, in the development of kidney disease in the FHH rat, and to identify the gene(s) causing the phenotype in these regions using positional cloning and next generation sequencing approaches.

Five renal failure QTL (*Rf*-1 to *Rf*-5) have been identified in a cross between the CKD susceptible FHH, and the CKD resistant ACI rat strains. *Rf*-1 has been shown to synergistically interact with *Rf*-3 and *Rf*-4, so to examine the contribution of the *Rf*-3 and *Rf*-4 QTLs to the development of CKD, we have generated single (*Rf*-1), double (*Rf*-1+4), and triple (*Rf*-1+3+4) congenic strains by introgressing the FHH genome onto the resistant ACI genetic background. Using these models, we have been able to determine that gene(s) in the *Rf*-4 region cause increased glomerular permeability to albumin leading to modest proteinuria at 13 weeks of age. We found *Rf*-3 also results in glomerular permeability to albumin, and these animals present with tubular protein casting as well as mild increases in blood pressure and severe proteinuria at just 9 weeks of age.

From these congenic lines, we have subsequently generated minimal congenic lines targeting the *Rf*-3 and *Rf*-4 regions in order to narrow the number of positional candidate genes. Generating these minimal congenic lines has allowed us to narrow both the *Rf*-3 and *Rf*-4 candidate region to just a few megabases (Mb), and a handful of known and predicted genes. Next generation sequencing technology has allowed us to elucidate gene polymorphisms within the minimal congenic regions that could potentially cause the observed CKD phenotype.

**Sex Differences in Cardiac Pro-Hypertrophic Signaling in Cardiorenal Interaction Depend on Estrogen Receptor-beta and Determine Adaptive and Maladaptive Phenotypes** Bjoern Hegner,[1] Dennis B. Guergen,[1] Rusan Catar,[1] Lyubov Chaykovska,[1] Angelika Kusch,[1] Friedrich C. Luft,[2] Duska Dragun.[1] *[1]Nephrology and Intensive Care Medicine; [2]ECRC, Charité University Hospital, Berlin, Germany.*

In renal diseases, pre-menopausal women are protected from cardiac pathologies which has been attributed to less severe hypertension. In the deoxycorticosterone acetate (DOCA)/salt model for cardiorenal interaction we found worse myocardial hypertrophy (MH) in normotensive male mice dependent on calcineurin signaling. We hypothesized the contribution of estrogenreceptor beta (ERβ) to observed sex differences.

Blood pressure independent MH was induced in wild type (WT) and ERβ-/- uninephrectomized female and male mice by 6-weeks release DOCA-pellet, 1% NaCl and 250 mg/L hydralazine in drinking water. Telemetric recordings excluded blood pressure differences in all groups. In ERβ-/- animals, increases in heart weight/body weight ratios (HW/BW) upon DOCA/salt were opposite to WT littermates (male: WT 16%, ERβ-/- 10%; female: WT 7%, ERβ-/- 23%). Echocardiography revealed decompensated dilative MH in female ERβ-/- mice whereas male WT mice had concentric MH. This was reflected by different levels of a-type and b-type natriuretic peptide (ANP, BNP) transcripts. Elevation of TGFβ and collagen I characteristic for maladaptive MH was observed in DOCA treated WT males and ERβ-/- females. Signal transduction analyses demonstrated an inversion of protective Akt phosphorylation in ERβ-/- mice with lowest levels in male WT and female ERβ-/- mice. In addition, in ERβ-/- mice Akt activation was not followed by phosphorylation of the downstream target p70S6K which may be crucial for an adaptive response. Expression of Calcineurin Aβ and its positive regulator MCIP-1 was greatly reduced in DOCA treated ERβ-/- compared to WT males and increased in DOCA treated female ERβ-/- mice indicating divergent effects on maladaptive calcineurin signalling in ERβ-/- animals.

ERβ influences MH in the cardiorenal syndrome by modulating protective Akt and maladaptive calcineurin signalling. Our findings may provide a rationale for sex-specific therapeutic strategies to prevent MH in chronic renal diseases.

**Serum Protein and Nephrin Expression Changes in Living Mouse Glomeruli under the Acute Hypertensive Condition** Zilong Li, Juan Wang, Fengxia Yu, Jun Wang, Hua Zhou, Lining Wang. *Department of Nephrology, First Affiliated Hospital of China Medical University, Shenyang, Liaoning Province, China.*

**ntroduction:** To visualize topographical serum proteins and nephrin changes in living mouse glomerular capillary loops under various hemodynamic conditions by novel "in vivo cryotechnique"[1, 2].

**Materials and Methods: "In vivo cryotechnique" group:** The "in vivo cryotechnique" was performed on left kidneys of anesthetized C57BL/6 mice, as reported before[3]. **Control group:** the kidney tissues were fixed with the conventional immersion and perfusion methods. Their serial sections were stained and observed by light, confocal laser scanning microscopy[4] and immunoelectron microscopy. The animals were evaluated for renal nephrin mRNA and protein expression.

**Results:** By the "in vivo cryotechnique", the distribution of serum proteins: albumin and immunoglobulinG light chain kappa (KL) was disorder, which immunolocalized in apical areas of the foot processes and urinary space, not slit-diaphragm, and the immunoreactivity of them markedly increased, but the nephrin expression seriously decreased under the acute hypertensive condition. The abnormal distribution of serum proteins and nephrin was also found in control group under the normotensive condition, similar to that under the acute hypertensive condition by "in vivo cryotechnique".

**Conclusion:** The redistribution of serum proteins and nephrin was the important factor about proteinuria under the acute hypertensive condition. The "in vivo cryotechnique" should be a reliable tool to observed serum or renal proteins in situ and capture transient images of functioning glomeruli in living mice.

**Peripheral Pulse Pressure as a Surrogate Marker of Central Arterial Stiffness in Patients with Predialysis CKD and Post Kidney Transplantation** Nina Ashraf Kashani, Jennifer R. Joslin, Nihil Chitalia, Debasish Banerjee. *Renal, St Georges Hospital, London, United Kingdom.*

**Introduction**

Measurement of central arterial stiffness, namely pulse wave velocity (PWV), has been proposed to be a better predictor of adverse outcomes than brachial blood pressure (BP). The central BP is proposed to be better related to measures of central artery stiffness- PWV and augmentation index (AI), than brachial BP in patients with essential hypertension. Such relationships have not been examined in predialysis (CKD) and post kidney transplantation.

**Methods and Results**

This study investigated the relationship of brachial Pulse Pressure (PP) with carotid-femoral PWV, radial AI, and central BP in predialysis CKD, post kidney transplantation and normotensive controls; using the SphygmoCor Pulse Wave Velocity system, *AtCor Medical Inc*. Informed consent was obtained from all participants. Data were anonymised and analysed using SPSS V17.

74 CKD patients (42 predialysis CKD, 32 transplant) and 18 healthy normotensive controls participated in the study; mean age = 55 ± 17 yrs. The PWV in the controls lower ($6.9 \pm 1.2$ m/sec$^2$ vs $8.6 \pm 2.3$ m/sec$^2$; $p<0.001$) compared to patients with CKD. However the controls were younger and had lower brachial systolic BP. The central SBP and PP were lower in controls but the AI was not different. Predialysis and transplant patients had no difference in age, eGFR, brachial BPs, central BPs, PWV or AI.

In CKD patients (predialysis and post transplant) brachial PP correlated well with central PP ($r=0.96$ ,$p= <0.001$) The PWV was related to both brachial and central PP ($r=0.35$, $p=0.002$ and $r=0.30$, $p=0.01$). Similarly AI correlated well both brachial and peripheral PP ($r=0.45$, $p<0.001$ and $r=0.63$, $p<0.001$). In controls the PWV and AI did not correlate with brachial PP.

**Conclusion**

In patients with predialysis CKD and post kidney transplantation the measurements of central arterial stiffness correlates well with brachial PP. Such correlations do not exist in normotensive controls. We propose that peripheral PP could be used as a surrogate for measurements of central arterial stiffness for follow up trials in patients with CKD.

**SA-PO2787**

**Effect of Tamsulosin on Bladder Microcirculation in a Rat Ischemia-Reperfusion Model, Evaluated by Pencil Lens Charge-Coupled Device Microscopy System** Hideki Mizuno, Tokunori Yamamoto, Naoto Sassa, Norihisa Matsukawa, Masashi Katoh, Yasushi Yoshino, Kazuo Mizutani, Ryohei Hattori, Momokazu Gotoh. *Urology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.*

**Aim:** To investigate the effect of tamsulosin hydrochloride on bladder microcirculation in a rat ischemia-reperfusion model using a pencil lens charge-coupled device microscopy system (PLCMS).

**Methods:** Changes in blood flow through a submucosal capillary of the rat bladder were measured during bladder filling using the PLCMS. One week after starting infusion of either physiological saline or tamsulosin, blood flow in the bladder was halted by bladder overdistension via an infusion of physiological saline. The bladder was then emptied to be reperfused with blood. Changes in blood flow through a submucosal capillary of the bladder during ischemia and reperfusion were measured using a PLCMS, and the data obtained for the control group and tamsulosin group were compared.

**Results:** As the bladder was distended, the velocity of red blood cell flow in a submucosal capillary of the bladder slowed, and stopped altogether when the bladder became overdistended. In the control group, capillary blood flow improved over time after release from overdistension, but failed to return to the baseline level, demonstrating that reperfusion injury to bladder micro-circulation was caused by bladder overdistension and emptying. In the tamsulosin group, capillary blood flow rapidly returned to baseline after release from overdistension.

**Conclusions:** Using a PLCMS, bladder micro-circulation was able to be visualized and quantitatively assessed by measuring the velocity of blood flow in a submucosal capillary of the bladder. Findings from the present study suggest that tamsulosin hydrochloride exerts a protective effect on blood flow in ischemia-reperfusion injury of the bladder.

**NLRP3 Inflammasome Activation in the Kidney: Implications for Glomerular Diseases** Julia Lichtnekert, Khader Valli Rupanagudi, Mi Ryu, Onkar Kulkarni, Hans J. Anders. *Medizinische Poliklinik, LMU, Munich, Germany.*

Inflammasomes are cytoplasmic multiprotein complexes that mediate the maturation of the proinflammatory cytokines interleukin-1β (IL-1β), IL-18 and IL-33. The NLRP3 inflammasome is the most extensively studied inflammasome and has large number of stimuli, such as various inflammatory crystals, bacterial toxins, ATP and several endogenous molecules. A few studies reported the role of caspase 1 and IL-1β in kidney injury and fibrosis. Here we studied the role of NLRP3 inflammasome in immune complex glomerulonephritis. In mouse models of lupus nephritis and nephrotoxic serum nephritis we detected elevated levels of IL-1β, NLRP3 and caspase 1 in the kidney. These data support the role of NLRP3 inflammasome in renal inflammatory diseases. The kidney is composed of several intrinsic renal and immune cells, however the source of IL-1β production in glomerulonephritis is obscure. Whether renal cells contain the NLRP3 inflammasome machinery is also still unknown. Here we investigated the functional role of NLRP3 inflammasome in intrinsic renal cells such as mesangial cells, podocytes, glomerular endothelial cells, tubular epithelial cells and tubular fibroblasts. We found that various NLRP3 stimuli did not lead to caspase 1 activation and production of IL-1β in these cells. However, in renal dendritic cells (CD11c+) these stimuli induced caspase 1 activation and production of IL-1β, emphasizing the important role of renal dendritic cells in innate immune response in the kidney. Together, these findings provide functional data for NLRP3 inflammasome in renal cells and draw attention to the presumable role of NLRP3 inflammasome activation in renal inflammatory diseases.

**SA-PO2789**

**Antigens in Glomerular Mesangium Recruit Activated T Cells and Induce Glomerulonephritis** Yogesh M. Scindia. *CIIR-Div of Nephrology, Dept of Medicine, University of Virginia, Charlottesville, VA.*

Purpose: We have previously described anti-a8 integrin immunoliposomes (a8ILs) for targeted delivery specifically to the glomerular mesangium. Here, we have used the a8ILs to establish an antigen specific model of glomerulonephritis (GN). This model will be used to investigate the pathogenic role of antigen-specific T cells in GN.

Methods: A rabbit polyclonal antibody to a8 integrin was conjugated to the surface of liposomes to generate a8ILs. The a8ILs were loaded with ovalbumin (ova-IL) and injected i.v. into C57BL/6 mice. This was followed by injection of activated ovalbumin-reactive CD4+ T cells obtained from OT2 mice. OT2 mice express a transgenic T cell receptor specific to ovalbumin. The recipient mice were sacrificed 3, 8 and 14 days later. Trafficking of OT2 T cells into the renal lymph nodes and kidney was studied by flow cytometry. Kidneys were evaluated for pathology, and infiltrating cells studied by immunostaining.

Results: Ovalbumin was rapidly deposited in the mesangium after ova-IL injection. Activated CD4+OT2 T cells accumulated preferentially in the renal lymph nodes on day 3 after cell transfer. By day 8, OT2 cells were detected in the kidney progressively increasing to day 14. Significantly, this was associated with an increase of non-OT2 CD4+ T (endogenous) cells. Infiltration of T cells, macrophages and dendritic cells was seen in and around glomeruli.

Conclusions: We have established an antigen-specific model of GN using ovalbumin as a surrogate mesangial antigen. Our study shows that CD4+ T cells reactive to mesangial antigens traffic to the kidney and induce intra- and peri-glomerular inflammation. These antigen-specific T cells recruit macrophages, dendritic cells and other T cells to induce GN. In lupus nephritis, immune complex deposition leading to macrophage infiltration into the renal interstitium has been identified as the critical indicator of progressive renal inflammation. Our studies suggest that this macrophage recruitment may be driven by glomerular antigen-specific T cell infiltration

**Activin Receptor-Like Kinase Inhibitor, SB431542, Attenuates Experimental Mesangial Proliferative Glomerulonephritis** Yu-Hsiang Chou, Yung-Ming Chen, Shuei-Liong Lin, Wen-Chih Chiang, Tun-Jun Tsai. *National Taiwan University Hospital, Renal Division, Department of Internal Medicine, Taipei, Taiwan.*

Transforming growth factor-b (TGF-b) isoforms are considered the most important regulators in renal fibrogenesis. Here in this study, we investigated an inhibitor of type I activin receptor-like kinase (ALK) receptors , SB431542, for its therapeutic efficacy in rat mesangial cells (MC) in culture and anti-Thy1 glomerulonephritis *in vivo*. Our results showed that SB431542 dose-dependently inhibited TGF-b1-induced Smad2 activation, and target gene expression *in vitro*. It did not exert any effect on platelet-derived growth factor-stimulated mitogenesis or TGF-b1-induced extracellular signal-regulated kinase activation. In our anti-Thy1 model where glomerular mRNAs for TGF-b1, TGF-b3 and activin A were maximally upregulated on day 3, SB431542 (20 mg/kg/day) given intraperitoneally reduced the mRNA induction of these genes. Further, treatment with SB431542 (20 mg/kg/day) for 5 days reduced glomerular Smad2 activation in association with reduction of proteinuria, glomerular sclerosis, activated MC and macrophages, and glomerular mRNA and protein expression of PAI-1 and collagen I(a1). SB431542 did not affect the expression of Smad7, nor activate the NF-kB pathway in the nephritc animals. In sum, our data indicate that downregulation of Smad2 activation by selective inhibition of TGF-b/activin signaling attenuates anti-Thy1 disease and may have a therapeutic value in acute phase or relapses of mesangial proliferative glomerulonephritis.

**Tamm-Horsfall Protein Acts as a Cofactor for Factor I-Mediated Complement C3b Degradation** Diana Rhodes. *Division of Anatomy, Pacific Northwest University of Health Sciences, Yakima, WA.*

Tamm-Horsfall protein (THP), an abundant urinary protein of renal origin, previously was shown to bind C1q of the classical complement pathway and to inhibit activation of this pathway. THP also binds complement factor H (CFH) of the alternate complement pathway. The initial purpose of the present study was to determine if THP's binding to CFH altered the normal ability of CFH to act as a cofactor in complement factor I (CFI)-mediated complement C3b degradation, C3b being a key molecule at the cross-roads of all three complement pathways. *In vitro* C3b degradation assays were performed with purified C3b, CFI, CFH, and THP. Degradation of the alpha chain of C3b into its two fragments was monitored using silver-stained 8% SDS-PAGE gels. Control experiments in these assays suggested that THP, without added CFH, could act as a cofactor in C3b degradation. Having detected this unexpected result, the study purpose shifted to exploring further the potential cofactor activity of THP. The cofactor activity of THP did not appear to be due to contamination of the THP with CFH since CFH was not detected in THP samples using Western blots evaluated by a sensitive infrared imaging system. Furthermore, while cofactor activity was significantly decreased in CFH that was heated to 56°C or 100°C prior to the assays, cofactor activity in THP samples was unaffected by this heating. The ability of THP to act as a cofactor in CFI-mediated degradation of C3b appears to be an inherent property of THP since 10 different THP samples, from a wide range of individuals, all possessed similar cofactor activities. This activity most likely resides in the protein portion of THP since the cofactor activity was present in THP from which most of the carbohydrate moieties had been removed. In conclusion, THP appears to participate directly in complement regulation by its ability to act as a cofactor for CFI-mediated C3b degradation.

**Characterization of the Glomerular Endothelial Binding Sites for Full-Length Complement Factor H (FH) and for Domains FH19-20 and FH5-7** Angelique Rops,[1] Markus J. Lehtinen,[2] Mohamed R. Daha,[3] Marinka Bakker,[1] Karita Haapasalo,[2] Richard J. Smith,[4] Jo H. M. Berden,[1] T. Sakari Jokiranta,[2] Johan Van der Vlag.[1] *[1]Dept. of Nephrology, Radboud University Nijmegen Medical Centre, Netherlands; [2]Dept. of Bacteriology and Immunology, University of Helsinki, Finland; [3]Dept. of Nephrology, Leiden University Medical Centre, Netherlands; [4]Dept. of Internal Medicine and Otolaryngology, University of Iowa.*

Complement factor H (FH) is the major regulator of the alternative complement pathway and binds via its domains FH19-20 to endothelial cells. Abnormalities in FH are associated with the renal diseases membranoproliferative glomerulonephritis type II (Dense Deposit Disease) and atypical hemolytic uremic syndrome. Furthermore, the Y402H polymorphism within domain 7 of FH is associated with age-related macular degeneration and DDD. Domains 7, 8-15 and 19-20 in FH can bind glycosaminoglycans/heparin. FH displays anti-inflammatory activities and endothelial heparan sulfate (HS) plays a crucial role during inflammation. Here, we evaluated the role of glomerular endothelial HS in binding of full-length FH and FH domains.

Binding of full-length FH and the domains FH19-20, FH5-7(402)Y, FH5-7(402)H to (activated) mouse glomerular endothelial cells (mGEnC-1) was evaluated by enzyme-linked immunosorbent assay (ELISA) and flow cytometry. To determine the involvement of HS in this binding, HS on mGEnC-1 was removed by treating with heparinase I/II/III, or competition ELISAs were performed with heparin(oids) or HS.

Full-length FH and the FH domains exhibited a dose-dependent binding to mGEnC-1. Activation of mGEnC-1 with TNF-$\alpha$ resulted in a significant increased binding of FH and FH domains. Heparin and HS inhibited dose-dependently the binding of FH, FH19-20 and FH5-7(402)Y/H to mGEnC-1, whereas N-, 2-O-, and 6-O-desulfated heparin showed differential inhibitory effects. Pre-incubation of mGEnC-1 with heparinase I/II/III inhibited the binding of FH and FH5-7(402)Y/H 2-fold, while the binding of FH19-20 was inhibited only 1.2-fold.

Conclusion: Binding of FH and domains FH19-20 and FH5-7 to (activated) glomerular endothelial cells is differentially mediated by HS.

**SA-PO2793**

**Protective Role of Mast Cells in Autoimmune Anti-Myeloperoxidase Induced Glomerulonephritis** Poh-Yi Gan, Shaun Andrew Summers, A. Richard Kitching, Stephen R. Holdsworth. *Centre for Inflammatory Diseases, Department of Medicine, Monash Medical Centre, Monash University, Melbourne, Victoria, Australia.*

Mast cells (MC) are traditionally viewed as barrier defense sentinels and first responders required in innate immunity, especially in the context of asthma and allergy. It is now clear that MC are able to produce and release a variety of inflammatory mediators that are important in the activation of both effector and regulatory cells. However little is known about the role of MC in immune tolerance and autoimmunity. To study the role of MC in nephritogenic autoimmunity, we compared the outcomes of an experimental model of myeloperoxidase (MPO)ANCA associated and segmental necrotizing GN between MC deficient Kitwsh/Kitwsh (Wsh) and WT mice.

MC deficient and WT mice were immunized with murine MPO in Complete Freund's adjuvant and GN was triggered by glomerular neutrophil recruitment and MPO deposition initiated by low dose anti-GBM antibody. Four days later, Wsh mice had developed enhanced T cell autoimmunity to MPO. Lymphocytes isolated from the lymph node (LN) draining the MPO immunization site in Wsh mice showed enhanced MPO recall proliferation (9773±2342counts/min vs 4767±386counts/min, p=0.02) and IFN-$\gamma$ production (31.7±6.0 vs 6.9±2.1ng/ml p=0.05). Dermal MPO induced DTH was also enhanced in Wsh mice (0.2±0.1 vs 0.4±0.1$\Delta$mm, p=0.04). MC accumulation in WT draining LNs was quantified after 6 days (non-immunized 5.0±1.0 vs immunized 24.6±4.8c/LN). By immunostaining prominent interaction between MC and T regs was apparent. In Wsh mice the number of LN CD4+FoxP3+ T regs was reduced (17.1 0.3% vs 15.9 0.4%, p=0.02). Increased MPO autoimmunity in Wsh mice was associated with increased severity of GN demonstrated by proteinuria (7.41 1.9 vs 2.5 0.6mg/24hr, p=0.01) and increased glomerular fibrinoid necrosis (27 vs 16%, p=0.02). Glomerular leukocyte effectors were also increased; T cells (0.6 0.1 vs 0.2 0.1c/gcs, p=0.01) and macrophages (1.7 0.2 vs 0.8 0.2c/gcs, p=0.01).

This study demonstrates that MC play a protective role in the development of autoimmunity to MPO and suggests that MC interact with T regs to facilitate peripheral tolerance.

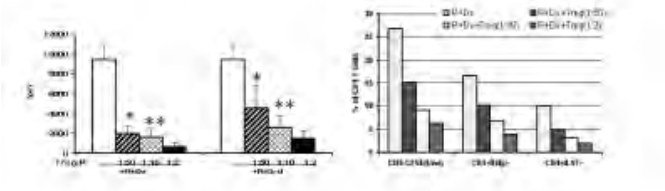
**MTOR Inhibitors Generated Human Tregs Have Suppressive Activity, but Their Generation Is Impaired by Inflammatory Cytokines** Lorenzo G. Gallon,[1] Anton I. Skaro,[2] Giovanna La Monica,[1] Joseph Ross Leventhal,[1] Luting Xu.[1] *[1]Medicine/Nephrology, Northwestern University Medical School, Chicago; [2]Transplant, Northwestern University Medical School.*

Regulatory T cells (Tregs) play a major role in facilitating regulatory immune-mechanisms for the development of a pro-tolerant state towards the transplant. MTOR inhibitors (Sirolimus, SRL) can facilitate the expansion of Tregs. Little is known, in human, about the functionality of SRL-induced Tregs on allospecific T-cell subset responses. Methods: Alloreactive CD4+ T cells were first generated in MLR culture with responding CD4+CD45RA+ naive T cells and allogeneic CD14+ monocytes. Alloreactive CD4+ T cells, from the primary MLR, were enriched and re-stimulated by co-culturing with autologous CD14+ monocytes in the presence of antigenic stimulation of anti-CD3 and SRL to increase the frequency of Treg cells. SRL-induced Tregs were then tested for their capacity to suppress T cell responses by adding Tregs at increasing doses (1:50, 1:10, 1:2) in a MLR. Thymidine incorporation and CFSE dilution technique were used as a read out methodologies. Results: FOXP3 expression (Treg) was markedly increased when SRL was added to the culture. When inflammatory cytokines (IL-6, IL-1 β) were added with SRL to the cell culture, there was a marked decrease of the generation of SRL-induced Tregs (data not shown). SRL-derived Tregs showed alloantigen specific suppression of alloreactive CD4+CD25- T cells and of subpopulation of Th1 and Th17 measured, respectively, by thymidine incorporation and CFSE labeling.



SRL-derived CD4+CD25high Tregs showed alloantigen-specific suppression of proliferation of allo-reactive CD4+CD25- T cells and the subpopulations of Th1 and Th17

Conclusions: MTOR inhibitor can expands human Tregs and these cells have suppressive capacity on Th1 and Th17 alloresponses. Inflammatory conditions can block the generation SRL-induced Tregs. These findings have important clinical implications for patients receiving MTOR inibitors as part of their main immunosuppressive regimen.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2795**

**The Class II Phosphatidylinositol 3 Kinase C2 Beta Is Required for the Activation of the K+ Channel KCa3.1 and CD4 T Cells** Shekhar Srivastava,[1] Lie Di,[1] Olga Zhdanova,[1] Jon Backer,[3] Heike Wulff,[2] Edward Y. Skolnik.[1] *[1]Skirball Institute, Department of Internal Medicine, New York University Langone Medical Center, New York, NY; [2]Department of Pharmacology, University of California, Davis, Davis, CA; [3]Department of Molecular Pharmacology, Albert Einstein College of Medicine, New York, NY.*

The Ca2+-activated K+ channel KCa3.1 is required for Ca2+ influx and the subsequent activation of T cells. We previously showed that Nucleoside Diphosphate Kinase Beta (NDPK-B), a mammalian histidine kinase, directly phosphorylates and activates KCa3.1 and is required for the activation of human CD4 T lymphocytes. We now show that the class II phosphatidylinositol 3 kinase-C2beta (PI3K-C2β) is activated by the T cell receptor (TCR) and functions upstream of NDPK-B to activate KCa3.1 channel activity. Decreased expression of PI3K-C2β by siRNA in human CD4 T cells resulted in inhibition of KCa3.1 channel activity. The inhibition was due to decreased PI(3)P because dialyzing PI3K-C2β siRNA treated T cells with PI(3)P rescued KCa3.1 channel activity. Moreover, overexpression of PI3K-C2β in KCa3.1-transfected Jurkat T cells led to increased TCR-stimulated activation of KCa3.1 and Ca2+ influx, whereas silencing of PI3K-C2β inhibited both responses. Using total internal reflection fluorescence microscopy (TIRF) and planar lipid bilayers, we found that PI3K-C2β co-localized with Zap70 and the TCR in peripheral microclusters in the immunological synapse. This is the first demonstration that a class II PI3K plays a critical role in T cell activation.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2796**

**The K+ Channels KCa3.1 and Kv1.3 as Therapeutic Targets To Treat Autoimmune Diseases** Lie Di,[1] Shekhar Srivastava,[1] Olga Zhdanova,[1] Heike Wulff,[2] Edward Y. Skolnik.[1] *[1]Internal Medicine, Skirball Institute, New York University Langone Medical Center, New York, NY; [2]Department of Pharmacology, University of California, Davis, Davis, CA.*

The calcium activated K+ channel KCa3.1, and the voltage activated K+ channel, Kv1.3 play critical roles in T lymphocyte Ca2+ signaling by helping to maintain a negative membrane potential which provides an electrochemical gradient to drive Ca2+ influx. To assess the role of KCa3.1 channels in lymphocyte activation in vivo, we studied T cell function in KCa3.1-/- mice. CD4 T helper (Th0) cells isolated from KCa3.1-/- mice lacked KCa3.1 channel activity, which resulted in decreased TCR-stimulated Ca2+ influx and interleukin 2 (IL-2) production. While loss of KCa3.1 did not interfere with CD4 T cell differentiation, both Ca2+ influx and cytokine production were markedly impaired in KCa3.1-/- Th1 and Th2 CD4 T cells, while T-regulatory and Th17 function were normal. In contrast, Th17 activation was dependent upon Kv1.3 for activation. We found that KCa3.1-/- mice were protected from developing severe colitis in two mouse models of inflammatory bowel disease (IBD) that are dependent upon CD4 Th1 cells, which were induced by (i) the adoptive transfer of mouse naïve CD4 T cells into rag2-/- recipients and (ii) trinitobencene sulfonic acid (TNBS). Thus, these findings suggest that KCa3.1 may be a novel therapeutic target to treat autoimmune diseases mediated by Th1 cells, while Kv1.3 may provide a novel therapeutic target to treat Th17-mediated autoimmune disease. Pharmacologic inhibitors of KCa3.1 and Kv1.3 have already been shown to be safe in humans. Thus, extending these observations to various forms of experimental glomerulonephritis may identify new opportunities to treat kidney disease.

**SA-PO2797**

**Attenuation of Experimental Crescentic Glomerulonephritis in IL-17 Deficient and STAT3β-Deficient Mice** Seung Hee Yang,[1] Un Sil Jeon,[1, 2] Jung Pyo Lee,[3] Ran-Hui Cha,[1, 3] Yon Su Kim.[1, 3] *[1]Seoul National University Kidney Research Institute, Seoul, Republic of Korea; [2]Internal Medicine, Korea University Guro Hospital, Seoul, Republic of Korea; [3]Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

T cells play a major role in the pathogenesis of crescent glomerulonephritis (GN) which is the most severe form of GN and progresses to end-stage renal disease unless treated adequately. Th17 cells have been reported to contribute to renal injury in crescentic GN. In the present study, we examined whether modulation of Th17 response could reduce the renal injury in experimental cresentic GN. IL-17 deficient and STAT3β deficient mice were used because IL-17 is the major cytokine of Th17 cells and STAT3 is the essential transcriptional factor of Th17 cell differentiation.

Experimental crescentic GN was induced by injection of anti-glomerular basement membrane (GBM) antibodies in Balb/c, C57BL/6, IL-17 deficient Balb/c, and STAT3β deficient C57BL/6 mice. After 7 days of disease induction, elevation of BUN and urine protein/creatinine ratio reduced significantly in IL-17 deficient (BUN 55 ± 22.7 vs 154 ± 17.5mg/dl, $p<0.01$; U prot/cr 114 ± 10. 6 vs 143 ± 16.6 mg/mg, $p<0.05$) and STAT3β deficient mice (BUN 116 ± 25.0 vs 156 ± 8.0 mg/dl, $p<0.05$; U prot/cr 53 ± 6.8 vs 99 ± 6.8, $p<0.05$) compared to those of wild type mice. In addition, glomerular injury and crescent formation by anti-GBM antibody reduced in IL-17 deficient and STAT3β deficient mice compared to those of wild type mice. Renal mRNA expression of IL-1β, TGF-β, MCP-1, IL-12p19 and STAT3 increased in wild type mice, but these changes were attenuated in IL-17 and STAT3β deficient mice. Treatment of CD3 in co-cultured mesanigal cells and NKT cells induced mRNA expression of IL-17 receptor and secretion of IL-17 and IL-12p70 as well as inflammatory cytokines like IL-2, TNFa and IL-6. Blocking of IL-17 receptor reduced these inflammatory reactions.

All together, the data suggest that Th17 cells play an important role in the pathogenesis of experimental cresecentic GN. IL-17 and STAT3 might be a feasible target in protecting renal injury in the disease.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2798**

**C4d Deposition in Thrombotic Microangiopathy Following Allogeneic Stem Cell Transplantation: Evidence for Humoral Graft Versus Host Disease?** Jamie S. Chua,[1] Danielle Cohen,[1] Khadro Jama,[1] Stefan P. Berger,[2] Johan W. De Fijter,[3] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden University Medical Center, Leiden, Netherlands; [2]Nephrology, Haga Teaching Hospital, The Hague, Netherlands; [3]Nephrology, Leiden University Medical Center, Leiden, Netherlands.*

Thrombotic microangiopathy (TMA) is one of the most severe complications of allogeneic stem cell transplantation. Mortality is high, around 50% and the pathogenesis is poorly understood. We hypothesize that TMA in this clinical setting could be the result of humoral activity in graft versus host disease (GVHD), causing classical complement activation, endothelial damage and finally, thrombosis.

Deposition patterns of C4d in renal tissue of 5 patients who died of TMA following allogeneic stem cell transplantation were investigated by staining with a polyclonal anti-C4d antibody. A properdin stain was used to determine presence of alternative pathway activity. Five patients who died of rapidly progressive TMA of various causes served as controls. All patients had end stage renal disease at time of death.

All patients with TMA following allogeneic stem cell transplantation had extensive glomerular and arteriolar deposition of C4d. Arteriolar positivity was associated with presence of arteriolar microthrombi in all 5 cases. In control patients C4d staining was negative. Properdin staining was negative in all cases.

Glomerular and arteriolar C4d deposition was present in all patients with TMA following allogeneic stem cell transplantation, and this pattern was not observed in any of the control patients. Presence of C4d may be a witness of an antibody mediated component of GVHD, causing severe endothelial damage which leads to TMA. As a diagnostical tool, C4d staining on a renal biopsy in patients with TMA associated with stem cell transplantation,

may be helpful in distinguishing those patients with a humoral component of GVHD. Additionally, this finding may have therapeutic implications in view of possible treatment with anti-CD20 or anti-C5 therapy.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2799**

**Mesenchymal Stromal Cells Suppress Primary T-Helper 17 (Th17) Differentiation as Well as Re-Activation of Th17 Cells from Injured Kidney**
Michelle M. Duffy,[1] Jana Pindjakova,[1] Shirley Hanley,[1] Cathal Mccarthy,[2] Orina Belton,[2] Rhodri Ceredig,[1] Matthew D. Griffin.[1] *[1]Regenerative Medicine Institute, College of Medicine, National University of Ireland, Galway, Ireland; [2]School of Biomolecular & Biomedical Science, Conway Institute, University College Dublin, Dublin, Ireland.*

**Background and Aims:** Interleukin 17-producing T-helper cells (Th17 cells) are implicated in AKI, glomerulonephritis and transplant rejection. Mesenchymal stromal cells (MSC) are immunosuppressive with potential to treat inflammatory and immune-mediated disease. The effects of MSC on Th17 differentiation and activation *in vitro* and in mouse unilateral ureteral obstruction (UUO) were studied. **Methods:** Th17 differentiation was induced by activation of CD4+ T-cells in the presence of IL-6, TGFβ1, anti-IFNγ and anti-IL-4. Bone marrow-derived MSC were added in varying ratios. MSC/Th17 co-cultures were analyzed by ELISA and multi-color flow cytometry. UUO was carried out in adult mice for 72 hours. Cell suspensions were prepared from obstructed and control kidneys, enriched for CD45+ cells by magnetic separation then stimulated *in vitro* with anti-CD3 followed by IL-17 ELISA of culture supernatants. **Results:** MSC inhibited primary Th17 induction in a dose-dependent manner as evidenced by reduced IL-17 intra-cellular staining and decreased IL-17 secretion upon re-stimulation in the absence of MSC. Conditioned medium from MSC/Th17 co-cultures strongly inhibited fresh Th17 cultures - an effect that was reversed by indomethacin or a selective COX-II inhibitor and reproduced by addition of PGE2. T-cell/MSC contact under Th17 skewing conditions was associated with production by MSC of high concentrations of PGE2. MSC suppressed anti-CD3-induced IL-17 secretion by effector-memory Th17 cells from acutely obstructed kidneys. MSC inhibition of intra-renal Th17 cells was also reversed by COX inhibition. **Conclusions:** MSC potently suppress primary differentiation of Th17 cells as well as the reactivation of Th17 cells from obstructed kidney. The effect is mediated by contact-dependent production by MSC of a prostanoid (likely PGE2) and has potential therapeutic applications for renal diseases involving Th17 activation.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2800**

**Cross-Species Transcriptional Network Analysis Defines Shared Inflammatory Responses in Murine and Human Lupus Nephritis**
Celine C. Berthier,[1] Tania C. Gonzalez-Rivera,[1] Viji Nair,[1] Ramalingam Bethunaickan,[2] Anne Davidson,[2] Matthias Kretzler.[1] *[1]Internal Medicine, Nephrology and Rheumatology, University of Michigan, Ann Arbor, MI; [2]Autoimmunity Center, Feinstein Institute for Medical Research, Manhasset, NY.*

Lupus nephritis (LN) is a significant cause of morbidity and mortality in lupus. Several immunomodulators effective in murine LN models failed human trials, raising concerns about the relevance of these models in human LN. We used a transcriptional network comparison to define similarities and differences between LN murine models and human LN.

Affymetrix based expression profiles from 3 LN mouse models (NZB/W, NZM2410, NZW/BXSB; n=40) and human renal biopsies (n=47) were analyzed with Bibliosphere software. Transcriptional networks were compared using the *T*ool for *A*pproximate *L*arg*E* graph matching (TALE) to define cross-species conserved functional interactions. Pathway analysis of 17 nodes shared by human and 3 murine models highlighted macrophage activation pathways ($p<0.01$).

To confirm that the signatures were derived from resident or infiltrating cells, gene expression profiles of macrophages isolated from NZB/W kidneys were compared with murine and human LN kidney profiles. 406 transcripts were concordantly regulated between NZB/W kidney isolated macrophages and whole kidneys. Of those, 132 transcripts were regulated in the human LN kidneys, consistent with an mRNA macrophage-derived expression. Network analysis of the shared murine-human renal macrophage signature defined Anxa2 as one of the major hubs. MESH filter "macrophage activation" on the network highlighted Lyn and CD44.

Treatment response of tissue resident macrophages was assessed in NZB/W mice in which complete remission was induced with cyclophosphamide/CTLA4Ig/anti-CD154. Lyn, Anxa2, and CD44 mRNA levels were significantly repressed in kidney resident macrophages by triple therapy.

Our transcriptional analysis of renal tissue and kidney derived macrophages defined key regulators of inflammation shared between murine and human LN. Key nodes in the murine macrophage inflammatory response were affected by triple therapy, representing potential therapeutic targets in humans.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2801**

**Intrinsic APRIL and BLyS Production in Human Lupus Nephritis (LN)**
Matthias A. Neusser,[1] Maja Lindenmeyer,[1] Ilka Edenhofer,[1] Stefanie Gaiser,[1] Matthias Kretzler,[2] Stephan Segerer,[1] Clemens D. Cohen.[1] *[1]Nephrology, University of Zurich, Zurich, Switzerland; [2]Nephrology, University of Michigan, Ann Arbor.*

Introduction: APRIL and BLyS, two B cell survival factors, play an important role in B cell maturation and activation. Large clinical trials for systemic lupus erythematosus are underway investigating interference with B cell function by targeting these molecules. However, the local expression of APRIL and BLyS has not been studied in detail in kidneys with LN.

Methods: We analyzed the mRNA expression of APRIL, BLyS and the corresponding receptors BCMA, TACI and BAFF-R in microdissected human biopsies with proliferative LN (n=25) and compared it with pretransplant biopsies of living donors (n=9). To identify the cells expressing the respective proteins in the kidney, APRIL, BLyS and BAFF-R were also studied by immunohistochemistry in renal biopsies with proliferative (n=21) or membranous (n=8) LN.

Results: APRIL and BLyS mRNA levels were increased in glomeruli of patients with proliferative LN (12 ± 22- [$p<0.05$] and 30 ± 47-fold [$p<0.01$], respectively). Tubulointerstitial expression of APRIL, BLyS, BCMA, and TACI was also elevated (13 ± 25- [$p<0.01$], 58 ± 94-[$p<0.01$], 136 ± 332-[$p<0.01$], and 109 ± 305–fold [$p<0.05$], respectively) and BAFF-R showed low basal expression. APRIL stained prominently in glomeruli with proliferative, but not membranous LN and the pattern was consistent with mesangial cells. An accumulation of CD68 positive cells was present in glomeruli in association with APRIL expression. APRIL, BLyS and BAFF-R could also be localized to interstitial inflammatory cells.

Conclusion: This is the first study to provide detailed data on local expression of APRIL and BLyS in glomeruli and tubulointerstitium of human proliferative LN. Future studies should aim to clarify intrarenal effects of APRIL and BLyS inhibition.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2802**

**Treatment with Anti-IgA Fc Receptor (FcαRI) Antibody Prevents Progression of Lupus Nephritis in Pristane Mice**
Chunbei Liu,[1] Yutaka Kanamaru,[1] Tomonari Watanabe,[1] Nobuhiro Tada,[2] Yusuke Suzuki,[1] Satoshi Horikoshi,[1] Yasuhiko Tomino.[1] *[1]Division of Nephrology, Department of Internal Medicine, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Research Institute for Diseases of Old Age, Juntendo University Faculty of Medicine, Tokyo, Japan.*

The Fc receptor for IgA (FcαRI), with an inhibitory immunoreceptor tyrosine-based activatory motif (iITAM) in the cytoplasmic domain, down-regulates humoral immune responses and modulates the risk of autoimmunity in animal models. The model of progressive lupus nephritis in autoimmune disease mice induced by pristane was used to evaluate whether FcαRI targeting late in the disease course can affect progression to renal failure. FcαRI/FcRγ transgenic mice (Tg) were treated with intraperitoneal (IP) injections of either vehicle or MIP-8a, anti-FcαRI Fab, three times a week from week 8 to 36 of age. MIP-8a improved proteinuria levels, markers of glomerular injury, deposition of immunoglobulins, and serum cytokine levels, and reduced the amount of F4/80 macrophages, CD3 lymphocytes in the interstitium and glomeruli. MIP-8a affected serum anti-nuclear antibody (ANA) in the pristane mice. This was associated with reduced serum titers of immunoglobulin IgG2a but not IgG1, IgG2b, and IgG3. Furthermore, MIP-8a reduced the extent of interstitial fibrosis as evaluated by interstitial masson-trichrome staining and type I collagen deposits. This is the first evidence that, in advanced lupus nephritis, FcαRI targeting through iITAM can halt disease progression and improve renal function by selective inhibition of leukocyte recruitment and renal inflammation.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2803**

**Th17 Responses in the Experimental Lupus Nephritis**
Un Sil Jeon,[1,2] Seung Hee Yang,[2] Ran-Hui Cha,[2,3] Jung Pyo Lee,[2,3] Yon Su Kim.[2,3] *[1]Internal Medicine, Korea University Guro Hospital, Seoul, Republic of Korea; [2]Seoul National University Kidney Research Institute, Seoul, Republic of Korea; [3]Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Th17 cells, secreting potent proinflammatory cytokine IL-17, are emerging as a major player in several autoimmune diseases like multiple sclerosis, previously known as a Th1 mediated disease. It has been suggested that Th17 cells are also involved in the pathogenesis of lupus nephritis (LN). In the present study, we examined the Th17 response in the experimental LN mice.

The experimental LN was induced by injection of lymphocytes from (C57BL/6xDBA/2J) F1 hybrids into wild C57BL/6 mice. The transferred donor lymphocytes were observed in the recipient glomeruli. Induction of LN was confirmed by increased BUN and serum creatinine levels, the development of proteinuria, and renal pathology (mesangial proliferation and glomerular crescents formation accompanied with CD3 cell infiltration in mice kidney). CD69, activated T cell marker, and intracellular IL-17 expression increased in the spleen of LN mice. Inflammatory cytokine/chemokine MCP-1, IL-6, INF-γ mRNA increased in LN mice spleen. Th17 related cytokines, IL-17, IL-23 and IL-27 mRNA levels also increased in the spleen. In the LN kidney, IL-17 receptor (IL-17R), IL-27 and STAT3

mRNA all increased. The expression of intracellular IL-17 protein also increased in the LN mice kidney. In addition, immunohistochemical study showed that IL-17 and STAT3, the essential transcriptional factor of Th17 cell differentiation, were observed only in the disease-induced mice kidney. Treatment of CD3 in co-cultured mesanigal cells and NKT cells induced the secretion of inflammatory cytokines like IL-2, TNFα and IL-6. The expression of IL-17R mRNA and secretion of IL-17 and IL-12p70 also increased in the co-cultured cells. Blocking of IL-17R reduced these inflammatory reactions.

Taken all together, Th17 response was activated in the experimental LN. Th17 related molecules like IL-17, IL-17R, STAT3 might be the novel therapeutic target of LN.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2804**

**Comparison of Mycophenolate Mofetil and Rapamycin on Inflammatory and Fibrotic Mediators in NZB/W Mice with Active Nephritis** Daniel Tak Mao Chan, Chen Zhu Zhang, Mel Chau, Susan Yung. *Department of Medicine, The University of Hong Kong, Hong Kong.*

Rapamycin might have a role in the treatment of lupus nephritis because of its immunosuppressive and anti-proliferative effect. This study compared the effect of rapamycin and mycophenolate mofetil (MMF) on inflammatory and fibrotic mediators in a murine lupus nephritis model.

Female NZB/W mice with established nephritis and proteinuria >3g/L were randomized to receive treatment with vehicle alone (control), MMF (100mg/kg/d), or rapamycin (3mg/kg/d) for 2, 6 and 12 weeks (n=6 for all time points in each group), and clinical parameters and renal histology assessed.

Albumin-to-creatinine ratio and circulating anti-DNA antibodies increased progressively in control mice, and these abnormalities were ameliorated in both MMF and rapamycin treated groups ($P$<0.01 for both compared to control mice after 12 weeks). Mice treated with MMF or rapamycin demonstrated reduced glomerular expansion (glomerular tuft area: 4252.15±324.15, 2645.76±564.21 and 2648.21±468.32μm$^2$ for control, MMF and rapamycin respectively, $P$<0.01 for control vs MMF or rapamycin after 12 weeks treatment), and decreased interstitial fibrosis as well as tubular atrophy compared to control mice. Both MMF and rapamycin significantly reduced glomerular IgG and C3 deposition and this was associated with the abrogation of intra-glomerular expression of CD4, CD8, CD19 and MAC-1. Renal expression of IL-6, TGF-β1, fibronectin and collagen type I was reduced to near normal levels in MMF treated mice, whilst tubular expression of the aforementioned fibrotic markers was still significant in mice treated with rapamycin for 12 weeks.

These results suggest that while both MMF and rapamycin ameliorate disease manifestations in lupus nephritis, rapamycin might be less effective in suppressing tubulointerstitial expression of fibrosis markers compared with MMF.

**SA-PO2805**

**Effect of Anti-IL6 Monoclonal Antibody Therapy in the Treatment of Established Experimental Autoimmune Glomerulonephritis in the CD1 Mouse** John Reynolds,[1] Jill Wechsler,[1] Diane Marshall,[2] Stevan G. Shaw,[2] Richard E. Gelinas,[3] H. Terence Cook,[1] Charles D. Pusey.[1] *[1]Renal Section, Division of Medicine, Imperial College London, United Kingdom; [2]UCB Celltech, Slough, United Kingdom; [3]Battelle Seattle Research Center, Seattle.*

Experimental autoimmune glomerulonephritis (EAG) can be induced in CD1 mice by immunization with the recombinant NC1 domain of the alpha 3 chain of type IV collagen (α3(IV)NC1). In this murine model of EAG, CD1 mice develop circulating and deposited anti-glomerular basement membrane (GBM) antibodies, and focal necrotizing glomerulonephritis with crescent formation by week 12 after immunization. Previous unpublished studies from our group have demonstrated that anti-IL6 monoclonal antibody (mAb) is effective in the prevention of EAG in the CD1 mouse. The aim of this study was therefore to examine the role of anti-IL6 mAb therapy in the treatment of established disease. Groups of CD1 mice with EAG (n=10) were given a weekly subcutaneous injection of anti-IL6 mAb (54E07), or an irrelevant mAb (101.4, positive control) at a dose of 30mg/kg, starting at week 6 after immunization, when disease was established. Animals given the anti-IL6 mAb showed a significant reduction in the urinary albumin/creatinine ratio (control 6.9mg/mmol vs anti-IL6 mAb 4.1mg/mmol, p<0.04), glomerular abnormalities (control 54% vs anti-IL6 mAb 33%, p<0.006) and glomerular T cells (control 3.9/glomerulus vs anti-IL6 mAb 2.2/glomerulus, p<0.0003) by week 12, when compared to positive controls. No significant reduction was observed in the levels of circulating antibodies directed towards α3(IV)NC1, or in the intensity of deposits of IgG on the GBM, suggesting an effect on cell-mediated immunity. The results from this study demonstrate that anti-IL6 mAb therapy is effective in the treatment of established EAG. This confirms the importance of IL-6 in the development of glomerulonephritis, and implies that IL-6 may represent a valid therapeutic target in the treatment of human glomerulonephritis.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2806**

**MHC-DRB1 Alleles in PR3-ANCA Disease: A Highly Immunogenic Role for the HLA DRB1*15 Allele** Yali Cao,[1] Jia Jin Yang,[1] John Schmitz,[2] Susan L. Hogan,[1] Donna O. Bunch,[1] Yichun Hu,[1] Caroline E. Jennette,[1] Elisabeth Berg,[1] Frank C. Arnett,[3] J. Charles Jennette,[2,1] Ronald J. Falk,[1,2] Gloria A. Preston.[1,2] *[1]UNC Kidney Center, UNC-CH; [2]Dept of Pathology, UNC-CH, Chapel Hill, NC; [3]Dept of Internal Medicine, UT Health Science Center, Huston, TX.*

MHC class II molecules present a range of peptides for recognition by T cell receptors of CD4+T helper cells and in presenting self antigens stimulating the maturation of autoantibody expressing B cells and autoimmune disease. The objective here was to genotype Caucasian and African American patients to establish whether PR3-ANCA and/or MPO-ANCA are HLA-linked disorders.

By RPE analysis, strikingly, the allele linked with the greatest risk for PR3-ANCA disease in African Americans was *DRB1*15*($p=5.52x10^{-11}$). In the Caucasian patient group *DRB1*15* was linked also with PR3-ANCA serology (p=0.0001). RPE analysis of alleles associated with MPO-ANCA serology in African Americans showed a significant correlation with *DRB1*16* (DR2 serologic group). In the Caucasian group, no *DRB1* allele was significantly associated with MPO-ANCA serology.

The odds ratio that *DRB1*15* is a risk factor for African Americans to develop PR3-ANCA disease is 73.3 ($p=2.3x10^{-9}$). *DRB1*15* is also a risk factor in Caucasians with an odds ratio of 2.2 (p=0.008), as is *DRB1*14*, with an odds ratio of 5.9 (p=0.007). A disproportionate number of African American patients carried the *DRB1*1501* allele of Caucasian descent (50% versus 13%), rather than the *DRB1*1503* allele of African descent. All Caucasians were of the *DRB1*1501* genotype.

Functionally, DRB1*1501 protein bound specific sense-PR3 peptides and specific complementary-PR3 peptides in an *in vitro* assay, in agreement with *in silico* predictions. Peripheral neutrophils/monocytes from patients homozygous for *DRB1*1501*, expressed surface DRB1 proteins, after TNF-alpha exposure, that similarly bound the same specific peptides, while cells from a patient carrying the *DRB1*04*14* alleles bound complementary-PR3 but not the sense-PR3 peptides. The data support that *HLA-DRB1*15* is a risk factor for PR3-ANCA disease, especially impacting African American patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2807**

**Anti-Plasminogen Antibodies in Patients with ANCA-Associated Vasculitis Compromise Fibrinolysis and Are Related to Hallmark Histopathological Renal Lesions** Annelies Evaline Berden,[1] Sarah Nolan,[2] Hannah L. Morris,[2] Rogier M. Bertina,[3] Nico H. Van Tilburg,[3] Dianhdra Dyane Erasmus,[1] Ernst C. Hagen,[4] Donal P. Hayes,[5] Jan A. Bruijn,[1] Caroline O. S. Savage,[2] Ingeborg M. Bajema,[1] Peter Hewins.[2] *[1]Pathology, Leiden University Medical Center, Leiden, Netherlands; [2]Renal Immunobiology, Medical School, University of Birmingham, Birmingham, United Kingdom; [3]Thrombosis and Hemostasis, Leiden University Medical Center, Leiden, Netherlands; [4]Internal Medicine, Meander Medical Center, Amersfoort, Netherlands; [5]Pathology, Meander Medical Center, Amersfoort, Netherlands.*

Antibodies recognizing plasminogen were correlated with venous thrombotic events in PR3-ANCA vasculitis. We investigated the prevalence and functionality of these antibodies in UK and Dutch AAV patients.

AAV-IgG and healthy control IgG was screened by ELISA. Eighteen of 74 (24.3%) UK and 10/38 (26.3%) Dutch AAV-IgG were anti-plasminogen antibody (anti-PLG) positive compared to 0/50 and 1/61 (2%) controls ($P$ < 0.001). Anti-PLG antibodies were detected in PR3- and MPO-ANCA positive patients. Furthermore anti-tissue plasminogen activator (tPA) antibodies were demonstrated in 13/74 (17.6%) patients. Anti-tPA antibodies associated with anti-PLG antibodies: 7/18 (39%) anti-PLG antibody positive patients were also anti-tPA antibody positive versus 6/56 (11%) anti-PLG antibody negative patients ($P$ = 0.011). Eighteen of 74 AAV-IgG but no control IgG retarded in vitro fibrinolysis ($P$ <0.001) and this associated with anti-PLG and/or anti-tPA antibody positivity. Only 4/18 AAV-IgG retarding fibrinolysis harbored no such antibodies. Dual positive samples retarded fibrinolysis to the greatest extent. Patients with anti-PLG antibodies had higher percentages of glomeruli with fibrinoid necrosis ($P$ < 0.05) and cellular crescents ($P$<0.001) than patients without and had more severely reduced renal function.

Concluding, anti-PLG and anti-tPA antibodies occur in AAV and are associated with functional inhibition of in vitro fibrinolysis. Seropositivity for anti-PLG antibodies correlates with renal lesions and renal function. Conceivably, fibrinolysis-enhancing therapies might benefit a subset of AAV patients.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2808**

**Tolerance to Myeloperoxidase and Resistance to Autoimmune Anti-MPO Nephritis Is Maintained by Thymic Deletion and Peripheral Regulatory T Cells** Diana S. Tan, Kim O'Sullivan, A. Richard Kitching, Stephen R. Holdsworth. *Centre for Inflammatory Diseases, Department of Medicine, Monash Medical Centre, Monash Univeristy, Victoria, Australia.*

The role of thymic deletion and peripheral regulatory T cells (Tregs) in developing and maintaining tolerance to myeloperoxidase (MPO) was assessed in C57BL/6 mice. Immunohistogical colocalisation confirmed that MPO was expressed in an AIRE independent manner by medullary thymic epithelial cells in mouse and human thymi but was absent in MPO-/- mice. Immunisation of MPO+/+ mice with MPO in CFA induced

autoreactive anti-MPO T cells in draining lymph nodes (LN). The number of responder LN cells was higher in MPO-/- mice (ELISPOT IFNγ: 202±45 vs 526±26/$10^6$ LN cells; IL-17A: 136±42 vs 333±43/$10^6$ LN cells; both p<0.001). ANCA titres were also higher in MPO-/- mice confirming the role of thymic deletion of autoreactive anti-MPO T cells in repertoire generation. To assess peripheral tolerance in normal mice, PC61 mAb was used to deplete CD4+CD25+ Tregs in normal mice that were then immunised with MPO in CFA. Depletion of Tregs resulted in elevated anti-MPO ANCA titres (control IgG: 0.8±0.1 vs PC61: 1.2±0.4 $OD_{450nm}$; p<0.001) and MPO-specific T cell responses (IFNγ 41±49 vs 207±67/$10^6$ and IL-17A 28±20 vs 104±52/$10^6$ LN cells; both p<0.001). Fewer Tregs (CD4+Foxp3+) were seen in the draining LN of PC61-depleted mice (9.7±0.5% vs 6.1±0.8 LN cells; p<0.001). Glomerulonephritis (GN) was triggered by low dose anti-GBM antibody to induce glomerular neutrophil degranulation and MPO deposition. Proteinuria was enhanced in Treg-depleted mice (2.1±0.3 vs 6.7±4.2mg/24hrs; p<0.01) as was glomerular injury (0.8±2.1 vs 29±22% segmental necrosis; p<0.001). Glomerular leukocyte recruitment was also increased in Treg-depleted mice, with increased glomerular CD4+ T cells (0.8±0.4 vs 1.5±0.5 cells per glomerular cross-section (c/gcs)), macrophages (0.9±0.3 vs 1.6±0.4 c/gcs), and neutrophils (1.5±0.7 vs 2.5±0.7 c/gcs; all p<0.01). Thus both central tolerance through thymic deletion and peripheral tolerance maintained by Tregs are important in the induction and maintenance of tolerance to MPO. They also confer resistance to the development of autoimmune anti-MPO GN.

### SA-PO2809

**IgA1 Antibodies Specific for Galactose-Deficient IgA1 (Gd-IgA1) Are Elevated in Sera from Patients with IgA Nephropathy (IgAN)** Koshi Yamada,[1,2] Hitoshi Suzuki,[1,2] Stacy D. Hall,[1] Zina Moldoveanu,[1] Bruce A. Julian,[1] Yasuhiko Tomino,[2] Jiri F. Mestecky,[1] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Juntendo University Faculty of Medicine, Tokyo, Japan.*

Patients with IgAN have elevated serum levels of Gd-IgA1 that is recognized by naturally occurring anti-glycan antibodies, leading to formation of immune complexes that deposit in the glomeruli to induce renal injury. We have shown previously that anti-glycan IgG antibodies that recognize Gd-IgA1 are elevated in serum of patients with IgAN. However, a possible role of IgA1 antibodies in binding Gd-IgA1 has not been studied. To assess the presence and levels of IgA1 antibodies specific for Gd-IgA1, we have developed a novel dot-blot assay using Fab fragment of Gd-IgA1 (Ste) myeloma protein that contained a portion of the hinge region with the attached *O*-glycans. We also prepared a variant of the Fab fragment, by adsorption on immobilized lectin from *Helix aspersa* (HAA), that had predominantly fully galactosylated *O*-glycans. Following application of samples with normalized concentration of IgA, the detection of IgA1 binding to Fab of IgA1 was achieved by Fc-specific anti-IgA antibody and was evaluated densitometrically. Using this assay, we measured IgA1 anti-Gd-IgA1 antibody levels in sera from 24 patients with biopsy-proven IgAN, 24 disease controls (patients with non-IgAN renal diseases), and 10 healthy controls. Our results showed that sera from IgAN patients had higher levels of IgA1 antibodies binding to the Fab fragment of Gd-IgA1 (Ste) compared to those from healthy controls and disease controls (p<0.05 and p<0.0001, respectively). Binding of IgA1 from IgAN patients but not that from healthy controls was glycan-specific, as evidenced by the reduced binding to the Fab fragment with predominantly fully galactosylated *O*-glycans (p<0.01). Furthermore, we have identified Gd-IgA1-specific IgA1 in supernatants of Epstein-Barr virus-immortalized cell lines from patients with IgAN. These results prove the feasibility to further characterize these IgA1 antibodies at the molecular level and assess the roles of anti-glycan IgG and IgA1 isotypes in IgAN.

**Excessive Premature Ageing of Circulating T Cells in Endstage Renal Disease Patients** Michiel G. H. Betjes, Elly L. E. A. De Wit, Nicolle H. R. Litjens. *Nephrology, Erasmus Medical Center, Rotterdam, Netherlands.*

**Background:** Progressive loss of renal function is associated with clinical signs of decreased T cell immunity. Changes in the number and differentiation of circulating T cells are probably contributing significantly to the ESRD-related immune deficiency. In this study we have tested the hypothesis that ESRD-related changes of the T cell compartment are in fact compatible with the concept of premature ageing.

**Patients and Methods:** The differentiation profile of circulating T cells of young (18-40 years) and old (60-80 years) ESRD patients (n=120) were compared to age-matched healthy controls. Expression of CD45RO combined with CCR7 (differentiation markers), and CD28 and CD57 (ageing markers) were used to characterize T cell subsets within the CD4pos and CD8pos T cell compartment. In addition, the naïve T cell compartment was analyzed in more detail for the presence of recent thymic emigrants (CD31pos cells), homeostatic proliferation and susceptibility for apoptosis.

**Results:** In the young age group the absolute number of CD4+ and CD8+ naive T cells from ESRD patients were on average decreased by 60%, compared to their age-matched healthy controls. T cells from ESRD patients showed an age-dependent decrease in naive T cells and recent thymic emigrants which exceeded normal age-related changes by at least 2-3 fold. This was accompanied by a significantly increased percentage of dividing naive T cells in ESRD patients (0.6% vs 0.3 %, p<0.05), indicating increased homeostatic proliferation. This increased proliferation was specifically observed in the CD31neg naive T cell population. The memory T cell compartment of both CD4pos and CD8pos T cells showed a dramatic shift towards terminal T cell differentiation with loss of CD28 expression and increased expression of CD57. Activation-induced apoptosis, but not apoptosis of resting T cells, was significantly increased in all T cell subsets of ESRD patients.

**Conclusions:** A remarkable premature ageing of T cells is present in ESRD patients which may underlie their immunedeficiency. Increased activation-induced T cell apoptosis could be a cause or consequence of premature ageing.

### SA-PO2811

**Biological Activities of IgA1-Containing Immune Complexes from Pediatric Patients with IgA Nephropathy (IgAN)** Jan Novak,[1] Leona Raskova-Kafkova,[1,4] Hitoshi Suzuki,[1,3] Milan Tomana,[1] Karel Matousovic,[1,5] Rhubell T. Brown,[1] Stacy D. Hall,[1] John T. Sanders,[2] Theodore Matthew Eison,[2] Zina Moldoveanu,[1] Lea Novak,[1] Zdenek Novak,[1] Richard Mayne,[1] Bruce A. Julian,[1] Jiri F. Mestecky,[1] Robert J. Wyatt.[2] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Tennessee Health Sciences Center, Memphis, TN; [3]Juntendo University Faculty of Medicine, Tokyo, Japan; [4]Palacky University, Olomouc, Czech Republic; [5]Charles University, Prague and Plzen, Czech Republic.*

Sera of patients with IgAN contain immune complexes (IC) composed of galactose-deficient IgA1 (Gd-IgA1) bound by anti-glycan antibodies. We isolated from sera of pediatric IgAN patients IC of different size and determined their effect on cultured human mesangial cells. Our results showed that IC with molecular mass >800 kDa containing Gd-IgA1 stimulated cellular proliferation, while smaller IC were inhibitory. Addition of stimulatory and inhibitory IC to cultures of human mesangial cells differentially altered phosphorylation patterns of three major tyrosine-phosphorylated proteins of molecular mass 37, 60, and 115 kDa. The stimulatory IC transiently increased tyrosine-phosphorylation of the 37-kDa protein and decreased phosphorylation of the other two proteins, whereas the inhibitory IC increased phosphorylation of all three proteins. Furthermore, we investigated the influence of IgA1-containing IC from sera of children with IgAN with clinically active or inactive disease on the expression of IL-6 and IL-8 genes by mesangial cells. Our RealTime RT-PCR results showed that the IC from patient with active disease stimulated mesangial cells to express the two cytokine genes at higher levels than did the IC from patient with inactive disease. Moreover, stimulatory IC increased production of the extracellular matrix protein laminin. These data indicate that sera of pediatric IgAN patients contain biologically active IC with Gd-IgA1 and that their level and/or biological activity may reflect clinical activity of the disease.

### SA-PO2812

**Dual Non-HLA Antibodies Simultaneously Targeting Endothelial AT1- and ETA Receptors Induce Vascular Proliferation and Coagulation** Melanie Naether,[1] Aurélie Philippe,[1] Rusan Catar,[1] Andreas Eisenreich,[2] Gabriela Riemekasten,[3] Ursula Rauch-Kröhnert,[2] Duska Dragun.[1] *[1]Nephrology and Intensive Care Medicine, Charité Campus Virchow; [2]Cardiology and Pulmology, Charité Campus Benjamin-Franklin; [3]Rheumatology, Charité Campus Mitte, Berlin, Germany.*

Transplant recipients and patients with vascular autoimmune pathologies harbouring non-HLA-antibodies directed against Angiotensin II type 1 (AT1R-Abs) and Endothelin-1 type A receptors (ETAR-Abs) are at increased risk for early onset of microvasculopathy. We hypothesized that these non-HLA antibodies may actively contribute to vascular obliteration by induction of complement-independent mechanisms and sought to investigate mechanisms responsible for intravascular coagulation and proliferation responses.

AT1R-Ab and ETAR-Ab positive IgG fraction isolated from patients with obliterative vasculopathy or control IgG served for signal transduction and transcription factor activation studies, as well as for coagulation and proliferation assays in human microvascular endothelial cells.

Both autoantibodies were biologically active as they induced stress-kinase ERK1/2 phosphorylation which could be blocked by respective receptor inhibitors. AT1R- and ETAR-Abs specifically triggered activation of transcription factor Ets-1 down-stream from ERK1/2, as confirmed by phosphorylation, chromatin immunoprecipitation and electromobility shift assays followed by cell proliferation. Pharmacological inhibition of the upstream kinases of ERK1/2 established a direct link between ERK1/2, Ets-1 and endothelial proliferation.

We also detected increased tissue factor expression, a gene target of Ets-1. AT1R- and ETAR-Abs also enhanced tissue factor procoagulatory activity of endothelium determined in coagulation assay.

Anti- AT1- and ETA receptor autoantibodies may directly contribute to the key mechanisms involved in pathogenesis of obliterative vasculopathy and represent a link between the increased vascular responsiveness, intravascular coagulation and proliferation responses. Dual receptor pharmacologic targeting should add to current immunosuppressive regimens in patients harbouring non-HLA antibodies directed against vascular receptors.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2813**

**Altered Gene Silencing in Leukocytes of Lupus Nephritis Patients** Elizabeth R. Blyth, Jia Jin Yang, Dominic J. Ciavatta, Susan L. Hogan, Yichun Hu, Gloria A. Preston, J. Charles Jennette, Ronald J. Falk, Keisha L. Gibson. *UNC Kidney Center, UNC, Chapel Hill, NC.*

ANCA disease patients aberrantly express neutrophil granule genes PR3 and MPO due to depleted histone H3K27me3 modifications and loss of normal gene silencing. A subset of patients with lupus nephritis also exhibit aberrant leukocyte PR3 and MPO gene expression. The objective here is to determine the underlying factors attributable to changes in gene expression in lupus; specifically, can expression be linked to positive ANCA titers? Is necrosis in the renal biopsy a factor? Is aberrant transcription in lupus nephritis initiated by epigenetic changes similar to those observed in ANCA disease?

Increased PR3 and/or MPO mRNA expression (2 SD above mean of healthy controls) was present in patients with lupus nephritis (27/68), but not RA (n=46) or IBD (n=40). All lupus patients were negative for ANCA titers. There was no difference in PR3 or MPO expression between lupus patients with histological evidence of necrosis (n=44) versus those with no necrosis (p=0.56). Expression did not differ based on race, age or SLEDAI score.

Patients with lupus nephritis had significantly lower levels of PR3 compared to patients with ANCA disease (p=0.009) but comparable levels of MPO (p=0.95). Statistical analysis of MPO to PR3 ratios comparing all disease groups was significant (p<0.0001, F-test), with a higher ratio in lupus nephritis than ANCA.

Epigenetic studies (ChIP) of four lupus patients determined that H3K27me3 was depleted at the MPO gene and reduced at PR3 compared to MYO-D, which is transcriptionally silent in neutrophils; however, there was slight enrichment at the PR3 gene compared to mock immunoprecipitated samples. These data suggest that MPO is not epigenetically silenced in lupus, while PR3 may be silenced in a fraction of neutrophils. Thus, regulation of MPO and PR3 is altered in individuals with lupus nephritis, but the stimuli for this modulation of gene silencing deviates from ANCA disease.

**SA-PO2814**

**TLR4 and TLR9 Enhance Experimental Lupus Induced by Pristane** Shaun Andrew Summers, Oliver M. Steinmetz, A. Richard Kitching, Stephen R. Holdsworth. *Centre for Inflammatory Diseases, Monash University, Melbourne, Victoria, Australia.*

**Aim:** To define the role of Toll-like receptor (TLR) 4 and TLR9 in experimental systemic lupus erythematosus (SLE), induced by pristane.

**Methods:** To determine TLR4 and TLR9 function in experimental SLE we administered pristane to C57BL/6 wild-type (WT), TLR4-/- and TLR9-/- mice (both on BL/6 backgrounds). Systemic cellular immune responses and serum auto-antibodies, including total immunoglobulin (IgG), anti-dsDNA and anti-RNP IgG were assessed after 8 months. Functional renal injury, albuminuria, glomerular injury and proliferative glomerulonephritis were studied. Glomerular IgG and complement, deposition were assessed by direct immunoflourescence.

**Results:** Analysing systemic immune responses demonstrated decreased IFNγ splenocyte production in TLR4-/- and TLR9-/- mice (WT 236±59, TLR4-/- 39±39, TLR9-/- 50±25pg/ml, p<0.05). In TLR4-/- mice IL-17A (49±11 vs. 16±4pg/ml, p<0.05) and IL-6 (489±114 vs. 36±8pg/ml, p<0.05) production was also decreased compared to WT mice. Total serum immunoglobulin (IgG) levels were decreased in TLR4-/- and TLR9-/- mice. Compared to WT mice, TLR4-/- mice demonstrated decreased titres of anti-dsDNA IgG (0.22±0.06 vs. 0.13±0.04 $OD_{450}$ p<0.05) and anti-RNP IgG autoantibody levels (0.61±0.08 vs. 0.18±0.03 $OD_{450}$ p<0.05). TLR9-/- mice demonstrated a selective decrease in anti-RNP IgG titres (0.08±0.01 $OD_{450}$ p<0.01 vs. WT).

All mice developed progressive renal injury. After 8 months albuminuria was decreased in TLR4-/- and TLR9-/- mice (WT 432±97, TLR4-/- 150±30, TLR9-/- 117±61µg/24 hours, p<0.05). Proliferative glomerulonephritis and histological injury was attenuated in TLR4-/- and TLR9-/- mice. Using a semi-quantative scoring system direct immunoflourescence demonstrated decreased glomerular IgG (WT 1.4±0.1, TLR4-/- 0.9±0.1, TLR9-/- 0.9±0.1, p<0.001) and complement deposition (WT 1.8±0.1, TLR4-/- 1.3±0.1, TLR9-/- 1.3±0.1, p<0.001) in TLR4-/- and TLR9-/- mice.

**Conclusion:** Both TLR4 and TLR9 enhance the development of lupus autoimmunity and lupus nephritis. While TLR9 deficiency results in a selective decrease in Th1 associated cytokines and anti-RNP IgG, TLR4 deficiency results in a generalised decrease in immune responses.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2815**

**Anti-dsDNA Antibodies from Patients with Lupus Nephritis Bind to Annexin II on Human Mesangial Cells** Susan Yung, Kwok Fan Cheung, Qing Zhang, Daniel Tak Mao Chan. *Department of Medicine, The University of Hong Kong, Hong Kong.*

Lupus nephritis is characterized by the production of anti-dsDNA antibodies and proliferative glomerulonephritis. The mechanism through which anti-dsDNA antibodies interact with resident renal cells remains to be elucidated. We and others have previously demonstrated that human anti-dsDNA antibodies can bind to human mesangial cells (HMC) without the need of bridging chromatin material. In this study, we characterized the cross-reactive antigen(s) on HMC that mediate the binding.

Human polyclonal anti-dsDNA antibodies were isolated from patients with lupus nephritis using Protein A-Sepharose followed by DNA-cellulose affinity chromatography. The binding of anti-dsDNA antibodies to HMC was assessed by flow cytometry and cellular ELISA. HMC plasma membrane fractions were subjected to Western blotting, probed with purified anti-dsDNA antibodies, and analyzed with MALDI-TOF spectrometry to identify 'cross-reactive' membrane proteins. Renal biopsies were examined with immunohistochemistry.

Limited trypsin but not DNase treatment of HMC significantly reduced anti-dsDNA antibody binding ($P$<0.05). Anti-dsDNA antibodies predominantly bound to a cell surface antigen with molecular weight of ~36kDa. This band was identified as annexin II by MALDI-TOF spectrometry. The binding activity between anti-dsDNA antibodies and annexin II correlated with disease activity. Glomerular annexin II expression was significantly increased in active lupus nephritis compared with controls and non-lupus kidney diseases ($P$<0.05), and co-localized with IgG and C3 deposition.

Our data demonstrate that annexin II on the plasma membrane of HMC mediates anti-dsDNA antibody binding.

**SA-PO2816**

**Defects in B Cell Tolerance in BWF1 Mice with Severe Lupus Nephritis** Qihua Fan,[1,2] Amy G. Clark,[1,2] Melissa L. Weston,[1,2] Mary H. Foster.[1,2] *[1]Medicine, Duke University Medical Center, Durham, NC; [2]Medicine, VAMC, Durham, NC.*

Understanding the basis of lupus genetic susceptibility will provide new insight into disease mechanisms and a basis for novel therapies. Because autoantibody (autoAb) mediated nephritis is a major cause of morbidity in lupus, we examined genetic control of B cell tolerance. Through successive backcrossing, we established a single lupus autoAb transgene (Tg) on multiple lupus-prone strains, each of which carries a unique constellation of susceptibility loci that predispose to disease resembling human SLE with severe glomerulonephritis. Previously we showed that in healthy B6 mice and MRL lupus mice, B cells expressing the Tg, which encodes a dominant anti-laminin Ig heavy chain, are tightly regulated by clonal deletion, receptor editing, and anergy. Tolerance was also maintained in Tg BXSB lupus mice despite increased B cell numbers, whereas detection of serum Tg autoAb in Tg NZB lupus mice suggested partial loss of tolerance. Herein we report the fate of Tg B cells in (NZBxNZW)F1, or BWF1, mice with aggressive lupus (values refer to splenic B cells, Tg vs non-Tg littermates). 79% of cells express surface Tg vs 3% background in non-Tg mice. Mean spleen B cell count is 3.2-fold lower in Tg mice (7.1±4.1 vs 23.0±10.6, millions±SD, p<0.001), consistent with substantial deletion. Nonetheless, B cell depletion is less striking than the 8.3-, 6.8-, and 5.1-fold difference previously observed in B6, MRL, and BXSB Tg mice, respectively. Receptor editing as gauged by increased %lambda expression on spleen B cells is not detected (4.2±2.3% vs 5.8±2.7%, p=NS). Evidence of anergy in Tg cells is limited: in vivo B cell %BrdU+ is higher in Tg mice after 30 days (48.6±4.0% vs 35.7±4.1%, p<0.05); however, there is no difference in ex vivo proliferation in response to Ig crosslinking or LPS, and minimal difference in surface activation marker expression. Serum Tg autoAb levels are low but detectable (0.050±0.03 vs 0.010±0.04, p=0.004, mean OD±SD). We conclude that clonal deletion is intact in BWF1 lupus mice, but that at least a subset of surviving autoreactive B cells are functional and express autoreactivity.

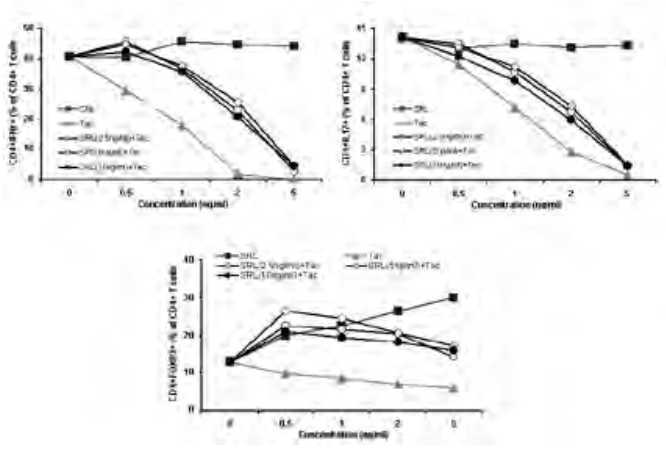
**Human Allospecific Th1, Th17 and Treg Are Differentially Affected by Calcineurin and mTOR Inhibitors** Lorenzo G. Gallon,[1] Nader Najafian,[2] Anton I. Skaro,[1] Giovanna La Monica,[1] Joseph Ross Leventhal,[1] Luting Xu.[1] *[1]Nephrology, Northwestern University; [2]Harvard Medical School.*

Subpopulation of T helper cells (Th1, Th17, and Treg) play a major role in promoting rejection or can facilitate regulatory immune-mechanisms for the development of a pro-tolerant state towards the transplant. Little is known about the impact of immunosuppressive (IS) drugs on allospecific T cell subpopulations. Methods: Alloreactve CD4+ T cells were first generated in MLR culture with responding CD4+CD45RA+ nave T cells and allogeneic CD14+ monocytes. Alloreactive CD4+ T cells, from the primary MLR, were enriched and re-stimulated by co-culturing with autologous CD14+ monocytes in the presence of antigenic stimulation of anti-CD3 to increase the frequency of Th1,Th17 and Treg cells. Two different IS agents, Tacrolimus (Tac) and Sirolimus (SRL) were added to the second culture alone or in combination at different concentrations. The effects on the generation of Th1, Th17, Treg cells from alloreactive memory T cells (CD4+CD45RO+) were then determined by intracellular cytokine staining. Results: Tac at low doses, significantly blocked the productions of IFN- (Th1) and IL-17 (Th17), while SRL even at high concentration (10ng/ml or 20ng/ml) had minimal effect on IFN- and IL-17 production (see top panels of figure). FOXP3 expression (Treg) was markedly increased in SRL compared to Tac (see bottom panel). When Tac and SRL were used in combination and at different concentrations, we found that Tac at 2-5 ng/ml with SRL at 2.5-10ng/ml achieved the maximal effect in inhibiting the production of IFN- and IL-17 while maintaining a high level of FOXP3 expression.



Conclusions: Tac and SRL have differential effects on subpopulation of T helper cells. These findings can help to guide the clinical use of IS drugs to promote Treg expansion while controlling Th1 and Th17 responses.

### SA-PO2818

**A Role for the ChemR23/Chemerin Axis in the Recruitment of Plasmacytoid Dendritic Cells in Lupus Nephritis** G. Castellano, Giuseppe De Palma, A. Loverre, G. Grandaliano, Francesco Paolo Schena. *Renal Unit, University of Bari, Bari, Italy.*

Plasmacytoid dendritic cells (pDC) play a pivotal role in driving the autoimmune response in SLE. Recent data showed that pDC infiltrate the kidney of patients with lupus nephritis (LN), but the factors regulating the pDC recruitment at renal level are unknown. Chemerin is the recently identified natural ligand of ChemR23, a receptor expressed by pDC. The aim of this study was to investigate the possible role of the ChemR23/Chemerin axis in the recruitment of pDC in LN.

The presence of ChemR23 and Chemerin were determined by immunohistochemical and immunofluorescence analysis of kidney sections from 10 patients with LN. Chemerin transcript levels were quantified using Real-time RT-PCR and Chemerin protein production was assessed by ELISA in human renal proximal tubular epithelial cells (RPTEC). Chemerin-dependent trans-endothelial migration of pDC was examined in transwell systems.

Quantification of percentage of ChemR23+ staining area revealed a significative increase of ChemR23+ pDC in class III-IV patients (4.4±1.1%) compared to class I-II patients (1.1±2.1%). ChemR23+ pDC clearly surrounded tubular epithelial cells and frequently localized around the glomeruli, but rarely within them. In addition, we found ChemR23+ pDC associated with renal vessels. In accordance, we identified Chemerin associated to tubular epithelial cells. The intensity of Chemerin staining was significantly higher in class IV LN, indicating an increased production in patients with worse kidney involvement. Chemerin was also associated to Podoplanin+ lymphatic endothelial cells. RPTEC express specific Chemerin mRNA, and produced Chemerin in vitro (25 ng/ml). in additioni, Chemerin was significantly down-regulated by TNF-α and IFN-γ after 48h of activation (reduction of 80% and 58% respectively). Interestingly, only TNF-α was capable to induce the functionally active form of renal Chemerin, resulting in an efficient recruitment of pDC.

Therefore, we hypothesize that the Chemerin/ChemR23 axis may play a pivotal role in the recruitment of pDC within the kidney in patients affected by LN.

### SA-PO2819

**Interleukin-1 Receptor-Associated Kinase-M Prevents Lupus Nephritis by Suppressing Toll-Like Receptor-7 Signaling** Maciej Lech, Claudia Kantner, Hans J. Anders. *Medizinische Poliklinik, University of Munich, Munich, Germany.*

SLE is a heterogenous autoimmune syndrome deriving from multiple gene polymorphisms of immunoregulatory genes. Loss of function muations in genes that regulate Toll-like receptor-7 signaling have been shown to affect SLE and lupus nephritis. The interleukin-1 receptor-associated kinase (IRAK)-M suppresses innate immune activation in bacterial sepsis, hence, we hypothesized a similar role for IRAK-M in lupus nephritis.

*Irak-m*-deficiency converted the mild autoimmune phenotype of C57BL/6-lpr/lpr mice into a massive lymphoproliferative syndrome with severe lupus nephritis. *Irak-m*-deficiency induced a number of interferon-related genes, cytokines and plasma cell survival factors in spleen dendritic cells of these mice. *Irak-m*-deficient C57BL/6-lpr/lpr mice revealed expansion of autoreactive T cells, dysfunctional regulatory T cells, and plasma cells which was associated with increased lupus autoantibody production and immune complex disease. TLR7 antagonism completely abrogated this phenotype in-vivo consistent with IRAK-M-mediated suppression of TLR7 signaling in-vitro. In addition, distinct haplotype polymorphisms of the human IRAK-M gene were associated with systemic lupus in a cohort of 840 lupus patients and 1218 controls.

These data identify a previously unknown function of IRAK-M, i.e. suppression of autoimmunity, and vice versa, mutant IRAK-M as a genetic risk for SLE and lupus nephritis.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2820

**Role of TH9 Cells in Nephrotixic Serum Nephritis** Kathrin Eller, Philipp Eller, Gert J. Mayer, Alexander R. Rosenkranz. *Internal Medicine IV, Innsbruck Medical University, Austria.*

Very recently, TH9 cells have been described as a new subpopulation of T helper (TH) cells, which have the capacity to act either pro- or anti-inflammatory when activated. Their marker cytokine interleukin (IL)-9 promotes on the one hand the development of TH17 cells and on the other hand the activity of regulatory T cells.

To evaluate the impact of TH9 cells on nephrotoxic serum nephritis (NTS), NTS was induced in either IL-9 knock-out (ko) or wild-type (wt) controls. Mice were followed for 7 or 14 days and evaluated for albuminuria, histologic changes, immune cell infiltration in the kidney, cytokine profiles of the kidney and lymph node.

IL-9 ko mice displayed significantly decreased disease indices such as albuminuria and histologic changes compared to wt controls 7 and 14 days after induction of NTS. Furthermore, significantly decreased numbers of infiltrating CD4 T cells and F4/80+ cells as well as CD68+ macrophages were detected in IL-9 ko mice, whereas no difference in the infiltration of CD8+ T cells was found 14 days after NTS induction. Kidney infiltration of neutrophils was significantly decreased in kidneys of IL-9 ko mice 7 days after induction of NTS. Cytokine profiling in the kidneys revealed significantly decreased amounts of IFN-gamma, IL-10 and IL-17 in the kidneys of IL-9 ko mice as compared to wt controls 14 days after induction of NTS. In the regional draining lymph nodes the cytokines IL-6, IFN-gamma, IL-10 and IL-17 were significantly decreased in IL-9 ko mice, whereas the regulatory T cell marker FoxP3 was increased. Mast cells, as detected by mast cell tryptase, were slightly diminished in lymph nodes of IL-9 ko mice 7 days after NTS induction.

Thus, the TH9 cell population is crucial in the pathogenesis of NTS. They have the potential to tip the immune balance towards a TH1 and TH17 response, whereas Treg activity was blocked.

### SA-PO2821

**Circulating Endothelial Biomarkers and the Activity of ANCA Associated Vasulitis (AAV)** Wei-Xin Hu, Ying-Hua Chen, Zheng-Zhao Liu, Hai-Tao Zhang, Zhi-Hong Liu. *Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu, China.*

During vascular inflammation, activated endothelial cells express various membrane molecules, which facilitate the binding of circulating leukocytes. Damaged endothelial cells may detach from the endothelium to form circulating endothelial cells (CECs). Therefore, CECs and the plasma concentration of soluble molecules are supposed to reflect the degree of AAV activity, which has not been widely studied. This study investigates CECs, soluble endothelial biomarkers (vWF, thrombomodulin, VCAM-1 and E-selectin) in patients with active and remission stage. We aim to document the relationship between various endothelial markers and the activity of AAV. 51 patients with AAV in active phase (M:20, F:31, mean age 47.8+17.4y, BVAS score 13.0+2.9), 31 in remission phase (M:12, F:19, mean age 48.2+16.9, BVAS score 1.0+1.7), 20 healthy controls were studied. Endothelial cells were isolated from peripheral blood by use of Dynabeads coated with antibodies against CD146. Plasma vWF, thrombomodulin(TM), VCAM-1 and E-selectin were detected with ELISA. Results showed that CECs, vWF, E-selectin and TM levels, except VCAM-1 were much higher in the active phase of AAV than controls ($P<0.01$). No significant differences of endothelial markers were found among AAV patients in remission and controls. CECs and plasma TM levels were significantly higher in patients with active AAV than patients in remission ($P<0.01$), yet plasma vWF and E-selectin levels showed no significant differences between patients in active phase and patients in remission.

| | AAV in active(n=51) | AAV in remission(n=31) | Control(n=20) |
|---|---|---|---|
| CECs(cell/ml) | 30± 12## | 17±6** | 15± 2 |
| TM(ng/ml) | 9.4± 7.0## | 5.9± 3.2** | 4.9± 1.3 |
| vWF% | 200.8± 28.4## | 177.4± 54.8 | 155.5±25.7 |
| E-selectin(ng/ml) | 88.6± 45.4## | 76.4± 36.6 | 51.1± 14.9 |
| VCAM-1(ng/ml) | 1800.5± 1147.5 | 1496.9± 744.9 | 1420.4± 372.4 |

AAV in active or in remission *vs* control, ##: $P$ <0.01; AAV in remission *vs* AAV in active, ** : $P$<0.01

In conclusion, Circulating endothelial cells and plasma thrombomodulin level are potential biomarkers in evaluating the activity of ANCA associated vasulitis.

Disclosure of Financial Relationships: nothing to disclose

### SA-PO2822

**ANCA Stimulated Neutrophils Release BLyS and Promote B Cell Survival *In Vitro*** Neil J. Holden,[1] Julie M. Williams,[2] Lorraine Harper,[1] John Gordon,[1] Caroline O. S. Savage.[1] *[1]School of Immunity and Infection, University of Birmingham, United Kingdom; [2]Wellcome Trust Clinical Research Facility, Queen Elizabeth Hospital Birmingham, United Kingdom.*

The presence of B cell infiltrates within the kidney has been reported in a number of inflammatory renal diseases, including the ANCA-associated vasculitides. These cells are likely to promote continued inflammation and may represent a niche for auto-antibody production. We sought to determine a role for ANCA activated neutrophils in promoting B cell survival, through the release of BLyS (B Lymphocyte Stimulator). Neutrophils

isolated from healthy donors were assessed for BLyS expression by flow cytometry and release by capture ELISA. Both non primed neutrophils treated with TNF-α (10ng/ml) or fMLP (1μM) and TNF-α (2ng/ml) primed cells treated with ANCA (200μg/ml) exhibited a significant increase in BLyS surface expression, within 30 minutes, which returned to basal levels following 2 hours culture. BLyS was also detected in cell supernatants supporting the notion that BLyS can be shed from the neutrophil surface. To determine whether ANCA activated neutrophils support B cell survival *in vitro*, supernatants collected from ANCA treated neutrophils (2 hours) were added to the B cell lymphoma cell line L3055 (10%): L3055 cells were cultured for 48 hours with low serum (2.5%) to induce apoptosis and cell death was measured by measuring annexin V binding expression. Supernatants from ANCA IgG but not normal IgG treated neutrophils significantly increased B cell survival, equivalent to a BLyS at 10ng/ml. Using CFSE to label actively dividing B cells, we were also able to demonstrate that neutrophil supernatants added to L3055 cell culture were able to significantly increase cell proliferation over 72 hours. In summary, we have shown that ANCA specifically causes the release of BLyS from activated neutrophils and that supernatants from activated neutrophils can support B cell survival *in vitro*. The work highlights BLyS as a potential therapeutic target to inhibit ANCA induced inflammation and may be particularly relevant in light of proposed uses of novel anti-BLyS monoclonal antibody therapies to treat a number of autoimmune diseases.

## SA-PO2823

**Identification of Structural Isomers of IgA1 Hinge-Region *O*-Glycopeptides: Implications for Pathogenesis of IgA Nephropathy (IgAN)** Kazuo Takahashi,[1,3] Hitoshi Suzuki,[1,4] Archer D. Smith,[1] Knud Poulsen,[2] Mogens Kilian,[2] Yukio Yuzawa,[3] Yoshiyuki Hiki,[3] Bruce A. Julian,[1] Jiri F. Mestecky,[1] Matthew B. Renfrow,[1] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Aarhus University, Aarhus, Denmark; [3]Fujita Health University, Toyoake, Japan; [4]Juntendo University Faculty of Medicine, Tokyo, Japan.*

IgA1 with galactose (Gal)-deficient hinge-region (HR) *O*-glycans plays a pivotal role in the pathogenesis of IgAN. To characterize the pathogenic forms of IgA1, *O*-glycan microheterogeneity and attachment sites should be analyzed, as each HR has 9 potential *O*-glycosylation sites. We have developed mass spectrometric protocol using 3 bacterial IgA-specific proteases and trypsin combined with electron capture dissociation (ECD) to localize all *O*-glycosylation sites in IgA1. Using IgA1 (Mce1) myeloma protein as a model Gal-deficient IgA1 protein, we prepared HR glycopeptides and fractionated them by on-line liquid chromatography (LC) and analyzed them by Fourier transform ion cyclotron resonance (FT-ICR) mass spectrometry (MS) and tandem MS (MS/MS). Some of the HR glycopeptides exhibited multimodal-peak distribution in LC, indicating possible structural isomers. Off-line LC was used to separate the structural isomers of HR glycopeptides, and the sites of glycan attachment and glycan compositions were determined by activated-ion (AI)-ECD MS/MS. The attachment of an *O*-glycan alternatively to T233 or T236 produced structural isomers, including those with Gal-deficient glycans. Further analyses indicated that similar isomeric glycoforms exist in normal human serum IgA1. Furthermore, LC-extracted ion chromatogram indicated the presence of isomeric structures of Gal-deficient GalNAc in IgA1 HR from serum IgA1 and IgA1 secreted by IgA1-producing cells from patients with IgAN. These findings represent the first definitive identification of structural isomeric IgA1 *O*-glycoforms, including two unique Gal-deficient forms. Future studies will determine whether distinct Gal-deficient structural isomers are differentially recognized by anti-glycan antibodies and, thus, are relevant to IgAN pathogenesis.

## SA-PO2824

**Melatonin Ameliorates Experimental Murine Membranous Nephropathy: Immunomodulatory, Anti-Oxidative, and Anti-Apoptotic Effects** Chia-Chao Wu,[1] Jin-Shuen Chen,[1] Shih-Hua P. Lin,[1] Yuh-Feng Lin,[2] Pauling Chu.[1] *[1]Division of Nephrology, Department of Internal Medicine, Tri-Service General Hospital, Taipei, Taiwan; [2]Division of Nephrology, Department of Internal Medicine, Shuang-Ho Hospital, Taipei, Taiwan.*

Therapeutic agents for membranous nephropathy (MN) remain ill-defined. Melatonin is the major secretory product of the pineal gland and displays multifunctional properties including the regulation of circadian and seasonal rhythms, antioxidation reactions and immune modulation. Based on the immunosuppressive properties of melatonin, we we assessed the efficacy of malatonin therapy for MN. MN mice were induced with intravenous injections of cationic bovine serum albumin. Three groups of mice were administered low dose melatonin (2mg/kg/bw), high dose melatonin (20mg/kg/bw), or phosphate-buffered saline via subcutaneously injection daily. Disease severity, cytokine profiles, immunoglobulin production, oxidative stress and apoptosis were determined. Mice treated with high dose melatonin displayed a significant reduction in proteinuria and a marked amelioration of glomerular lesions, accompanied by attenuated complement activation. The subpopulation of immune cells, especially proportion of CD19+ B cells and CD25+ T cells, were significantly modulated compared with those of mice in the other two groups. Oxidative stresses in the serum and kidneys, as well as apoptosis, were also significantly reduced in high dose melatonin -treated mice. Cytokine mRNA expression in the kidney indicated that melatonin not only decreased the expression of proinflammatory cytokines, but also increased the expression of anti-inflammatory cytokines. Melatonin therapy may ameliorate experimental MN via multiple pathways, including immunomodulatory, anti-oxidative, and anti-apoptotic effects. Melatonin should be considered a potential therapeutic intervention in MN in the future.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2825

**Cancer Associated Membranous Nephropathy: Analysis of Anti-$PLA_2R$ Autoantibodies and Glomerular IgG Subclass Deposits** Shi-Jun Li,[1] Wei-Song Qin,[1] Ming-Chao Zhang,[1] Chun-Xia Zheng,[1] Ke Zuo,[1] Hui-Ping Chen,[1] Yan Wu,[1] Laurence H. Beck,[2] David J. Salant,[2] Zhi-Hong Liu.[1] *[1]Research Insitute of Nephrology, Jinling Hospital, Nanjing University of Medcine, Nanjing, Jiangsu, China; [2]Boston University School of Medicine, Boston, MA.*

Membranous nephropathy (MN) might be associated with cancer in adult patients, but the characteristics of cancer associated MN are unknown. We studied the clinical pathologic features of MN patients associated with cancer and the relationship between MN and cancer.

MN patients who developed cancer at the time of renal biopsy or within a year were involved in this study. The clinical and pathologic data of those patients were analyzed. Anti-$PLA_2R$ (M-type phospholipase $A_2$ receptor) autoantibodies in serum and the glomerular IgG subclass deposits were examined.

Ten patients developed solid tumors of various types, including carcinomas of lung (5 cases), stomach (2 cases), colon (1 case), larynx (1 case), and tongue (1 case). All of the patients presented proteinuria and edema; 8 patients showed nephrotic syndrome. Anti-$PLA_2R$ autoantibodies were detected in the serum of 3 patients; IgG1 (IgG4 negative) was the dominant IgG in the glomerular deposits of 8 patients. However, the glomerular IF intensities of IgG4 deposits were the same as IgG1 in 2 patients with Anti-$PLA_2R$ autoantibodies. During follow-up, in 7 patients without Anti-$PLA_2R$ autoantibodies, complete remission of the proteinuria was seen in 2 patients associated with tumor remission; three patients died of cancer; the remaining 2 patients had persistent proteinuria without tumor resection. 3 patients with Anti-$PLA_2R$ autoantibodies had persistent or relapse of proteinuria after resection of the tumor.

In conclusion, the clinical and pathologic features of cancer-associated MN are not significantly different from those of idiopathic MN. Most of patients have no Anti-$PLA_2R$ autoantibodies in the sera and have glomerular IgG1 deposits, which indicates that the pathogenesis of cancer-associated MN differs from that of idiopathic MN. The patients with Anti-$PLA_2R$ autoantibodies in the sera and glomerular IgG4 deposits may suggest the coincidence of cancer and idiopathic MN.

Disclosure of Financial Relationships: nothing to disclose

## SA-PO2826

**Anti-Phospholipase A2 Receptor Antibody in Chinese Membranous Nephropathy Patients** Wei-Song Qin,[1] Laurence H. Beck,[2] David J. Salant,[2] Cai-Hong Zeng,[1] Zhao-Hong Chen,[1] Zhi-Hong Liu.[1] *[1]Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, Jiangsu, China; [2]Boston University School of Medicine, Boston, MA.*

Membranous nephropathy (MN) is a common cause of idiopathic nephrotic syndrome in Chinese patients. The M-type phospholipase A2 receptor (PLA2R) is the first autoantigen identified in adult idiopathic membranous nephropathy. In this research, the prevalence of autoantibody against PLA2R was explored in Chinese patients with primary and secondary MN.

Idiopathic MN (n=60), lupus MN (n=20), HBV associated MN (n=16), mercury-induced MN (n=10) and tumor associated MN (n=10) were diagnosed by kidney biopsy in Nanjing. Anti-PLA2R antibody in serum was detected by Western blotting under non-reducing conditions using protein extracts from normal human glomeruli and was checked with recombinant PLA2R. Sheep anti-human IgG4 was used as primary antibody and HRP-donkey anti-sheep IgG as secondary antibody.

Among 60 Chinese patients with idiopathic MN, 49 of them were detected of Anti-PLA2R autoantibody. The reactive serum specimens recognized PLA2R in extracts of human glomeruli and in extracts of HEK cells expressing recombinant PLA2R. Anti-PLA2R autoantibodies in serum samples from patients with membranous nephropathy were mainly IgG4, the predominant immunoglobulin subclass in glomerular deposits.

Anti-PLA2R antibody was detected in one MN patient with lupus, one MN patient with HBV and two MN patients that had been exposed to mercury. Anti-PLA2R antibody was also detected in three MN patients with cancer of lung, larynx and stomach respectively.

Anti-PLA2R antibody in Chinese membranous nephropathy

| MN | n | Anti-PLA2R | % |
|---|---|---|---|
| Idiopathic MN | 60 | 49 | 81.7% |
| Lupus MN | 20 | 1 | 5.0% |
| HBV-MN | 16 | 1 | 6.3% |
| Mercury induced MN | 10 | 2 | 20% |
| Tumor associated MN | 10 | 3 | 30% |

Anti-PLA2R autoantibody was positive in a majority of Chinese patients with idiopathic MN, which indicates that PLA2R is a major target antigen in primary MN Chinese patients. Although anti-PLA2R was also detected in a small number of patients with apparent secondary MN, we cannot rule out the possibility that this is a coincidental occurrence.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2827**

**Endotoxin-Tolerance Monocyte Profile in Minimal Change Nephritic Syndrome (MCNS): Role in Increased Susceptibility to Bacterial Infections**
Chang Yien Chan,[1] Wee Song Yeo,[1] Jinmiao Chen,[2] Tarun K. Maheshwari,[1] Subhra K. Biswas,[2] Henry Yang,[2] Hui Kim Yap.[1] *[1]Pediatrics, National University of Singapore, Singapore; [2]SIgN, BMSI (A*Star), Singapore.*

MCNS is often complicated by bacterial infections, contributing significantly to the morbidity of this benign disease. The pathogenic mechanisms responsible for the increased susceptibility to bacterial infections are not well understood. We have previously shown that lymphocyte interleukin (IL)-13 gene expression was upregulated during relapses in children with MCNS. This was associated with downregulation of proinflammatory cytokines, IL-8 and tumor necrosis factor (TNF)-a, in lipopolysaccharide (LPS)-stimulated monocytes, as well as decreased expression CD14, suggestive of an anti-inflammatory effect of IL-13. This study aimed to identify the 'gene signature' in monocytes isolated from MCNS patients, in both remission and relapse. Monocytes were isolated from the patients using MACS-monocyte Isolation Kit II and cultured for 4 hours with and without LPS. Monocyte RNA from 5 patients in relapse and remission were converted to cRNA and hybridized into Illumina Human Ref 8 chips. Gene ontology (GO) and pathway analysis were carried out using MetaCore™. The transcription profile of unstimulated monocytes from patients with MCNS in relapse revealed >2-fold change in expression in 734 genes. GO analysis showed genes involved in inflammatory response (*IL-1R1, IL-6, LTA, TNF*) were greatly upregulated, including interferon-inducible genes (*IRF4, IRF7, IFI6, IFI27, IFI35, IFI44, SERPING1, Mx1, OAS1, OAS2, OAS3, OASL, CXCL9, CXCL10*), antiviral genes (*DDX58*) and genes involved in STAT1 pathway. However, following LPS stimulation, genes that were usually responsive to LPS (*CD86, IL-1, IL-6, TNF*) were downregulated, exhibiting a refractory state of monocytes. In conclusion, our results demonstrated the bipolar nature of monocytes in MCNS patients following infection-triggered relapse, with the presence of an inflammatory profile *in-vivo*, but which appeared refractory to LPS stimulation suggesting an anti-inflammatory or endotoxin-tolerance profile. This could explain the increased susceptibility to infections during MCNS relapses.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2828**

**Activation of Toll-Like Receptor 3 Induces Proteinuria and Glomerular CD80, and Increases Urinary CD80 in Mice**
Takuji Ishimoto,[1] Michiko Shimada,[1] Miguel A. Lanaspa,[1] Christopher J. Rivard,[1] Pui Lee,[3] Eduardo H. Garin,[2] Richard J. Johnson.[1] *[1]Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO; [2]Division of Pediatric Nephrology, University of Florida, Gainesville, FL; [3]Division of Renal Diseases and Hypertension, University of Florida, Gainesville, FL.*

We have reported that children with biopsy-proven minimal change disease express CD80 in their podocytes and excrete high levels of CD80 (also known as B7.1) in their urine during active nephrotic syndrome. We also reported that polyIC, a Toll-like receptor 3 (TLR3) ligand, increases CD80 mRNA and protein in cultured human podocytes dose-dependently, with actin re-organization and a reduction in synaptopodin expression.

To determine the effect of polyIC in the kidney, C57BL6/J mice (male, 6 weeks-old) underwent systemic injection of polyIC or PBS. Urine, blood and kidney tissue were collected at 6 h, 24 h, 1 week and 2 weeks. Mice injected with polyIC developed significant proteinuria compared to PBS injected controls with a peak at 6 h. CD80 production in the kidney was measured by ELISA, and was significantly increased in mice injected with polyIC at 6 and 24 h (2.9 fold increase vs. PBS), with increased CD80 mRNA expression peaking at 6 h (16 fold increase vs. PBS). Urinary CD80 concentration was significantly increased in mice with polyIC. In pathological examination, glomeruli from mice injected with polyIC were normal (PAS staining). To examine the effect of systemically injected polyIC in the glomeruli, we isolated the glomeruli from mice injected with polyIC or PBS at 6 h, and examined the mRNA expression of CD80, CTLA-4, IL-10 and synaptopodin by QPCR. In the glomeruli, CD80 and IL-10 were significantly increased (CD80, 2.9 Fold vs. PBS) with a mild increase of CTLA-4. Synaptopodin in the glomeruli was decreased significantly.

Our study demonstrates that systemically administered polyIC can induce transient proteinuria and urinary CD80 excretion with increased glomerular CD80 and reduced synaptopodin expression as in cultured human podocyte. These findings may be relevant to the pathogenesis of minimal change disease.

Disclosure of Financial Relationships: nothing to disclose

**SA-PO2829**

**Mice with Higher Angiotensinogen (Agt) Copies Show Exacerbation of *In Situ* HIV-Associated Nephropathy (HIVAN)**
Dileep Kumar,[1] Sandeep Magoon,[1] Deepti D. Torri,[1] Hersh Goel,[1] Swapna Sayeneni,[1] Ashwani Malhotra,[1] Praveen N. Chander,[2] Pravin C. Singhal.[1] *[1]Medicine, Long Island Jewish Medical Center, New Hyde Park, NY; [2]Pathology, New York Medical College, Valhalla, NY.*

Incidence of AIDS-associated complications has reportedly declined since the advent and utilization of highly active anti-retroviral therapy (HAART). Moreover, HIV-infected patients treated with HAART show higher longevity and a normal life style. It has been expected that in post-HAART era, the spectrum of HIV-related diseases will also change. We hypothesized that after an HIV-1-induced initial injury, adverse environment such as elevated levels of Ang II may exacerbate *clinically occult* (minimal or submicroscopic) HIV renal lesions incurred during the period of significant viral loads may progress into an overt HIVAN phenotype despite use of HAART in the later period. We further hypothesized that not only timing of the institution of HAART but also the host factors may determine the development of an overt HIVAN phenotype.

Vpr mice (a kind gift From Prof. Jeffery Kopp, NIH) were bred with FVB/N mice with four angiotensinogen (Agt) copies to generate Vpr mice with 2, 3, and 4 Agt copies. By three weeks, doxycycline (doxy)-fed Vpr mice (2 Agt copies) display either minimal or no microscopic renal lesions, whereas, six weeks of doxy-treatment is required to develop an overt HIVAN phenotype. Eight weeks old Vpr mice (five mice per group) with variable copies of angiotensinogen (Vpr-Agt 2, Vpr-Agt 3 and Vpr-Agt 4) were fed drinking water containing doxy for three weeks. After three weeks, doxy was withheld from the drinking water. These mice were sacrificed at the end of 6 wks; kidneys were isolated and evaluated for renal histology.

Vpr-Agt-2 mice revealed no glomerular lesions and only mild tubular dilatation without any microcyst formation. Vpr-Agt-3 mice showed mild mesangial expansion and minimal tubular dilatation; whereas, Vpr-Agt-4 mice showed glomerular sclerosis albeit, mild and moderate tubular dilatation.

These findings indicate that higher Ang II levels allow the progression of *clinically occult* renal lesions into an overt HIVAN phenotype.

Disclosure of Financial Relationships: nothing to disclose

**Background:** CD39 is a dominant ectoenzyme that degrades ATP to AMP and is highly expressed on *Foxp3*+ regulatory T cells (Tregs) in both mice and humans. Human CD39 transgenic mice on the BALB/c background have been generated. **Aims:** The aim of the study was to evaluate a key Treg molecule CD39 *in vivo* in Adriamycin Nephropathy (AN) then to define where CD39 exerted its effect. **Methods:** Human-CD39 transgenic mice (CD39Tg) and wild type mice (WT) were treated with ADR. Then mixed chimeric mice were generated and AN was induced in four groups of mice as donors→ recipients (WT→Tg, WT→WT, Tg→WT, Tg→Tg). Finally adoptive transfer of CD25+ and CD25- T cells isolated from both CD39Tg and WT in AN was performed. **Results:** CD39Tg mice were protected from renal injury. Urinary protein and serum creatinine were significantly reduced, and there was significantly less glomerulosclerosis, tubular damage, and less fibrosis in, compared with WT ($P<0.05$ and $p<0.01$). Mixed chimeras showed that tissue and circulating CD39 was most effective in protecting against renal injury; though local and circulating expression alone also provided protection compared to WT to WT mice. Expression of hCD39 on CD25- cells was protective as were WT CD25 Tregs and hCD39 CD25+ Tregs. **Conclusions:** CD39 protects against AN. Tissue expression of CD39 and circulating CD39 including that on Tregs contributes to this protection. This supports a role of purines as mediators of injury and the key role of enzymes involved in purine metabolism.

**Cytoskeleton Proteins Promote HIV Accumulation by Expressing DC-Specific ICAM-3-Grabbing Nonintegrin (DC-SIGN) Expression by Human Podocytes**
Dileep Kumar, Divya Salhan, Shabina Rehman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Long Island Jewish Medical Center, New Hyde Park, NY.*

The occurrence of the collapsing variant of glomerulosclerosis in HIVAN (HIV-associated nephropathy) patients highlighted the role of HIV-1 in the development of characteristic podocyte phenotype. However, the involved mechanism of HIV-1 entry is far from clear. Recently, we demonstrated that DC-SIGN facilitated HIV-1 entry into conditionally immortalized human podocytes (CIHPs) (J Am Soc Nephrol 2009). Similarly, DEC-205 acted as a receptor for HIV-1 entry into human tubular cells (J Am Soc. Nephrol. 18:780-787, 2007). In the present study we examined the role of cytoskeleton proteins in podocyte viral accumulation.

CIHPs were incubated with R5 and X4 HIV-1 primary strains for two hours, followed by trypsiniztion and repeated washings. Subsequently, intracellular viral presence was assayed by p24 ELISA, RT-PCR, and electron microscopic studies at different time periods. CIHPs rapidly internalized R5 and X4 HIV-1 primary strains via endocytosis, without establishing a productive infection. Electron microscopic studies confirmed the presence of HIV-1 in podocytes. Pre-treatment with anti-DC-SIGN antibody inhibited HIV-1 entry into podocytes. Similarly, CIHPs transfected with siRNA/DC-SIGN showed attenuated HIV-1 entry into podocytes.Pretreatment of CIHPs with both colchicine and cytochalasin B increased podocyte HIV-1 accumulation and thus, showed the role of actin and microtubules in the podocyte viral trafficking. Since Brefeldin A (an inhibitor of the Golgi-ER pathway) also enhanced podocyte HIV-1 accumulation, it seemed that Golgi-ER pathway might be linked to podocyte viral sorting. To determine the involved mechanism of cytoskeleton protein-

mediated enhanced podocyte viral accumulation, we evaluated the effect of colchicine, cytochalasin B and Brefedin A on podocyte expression of DC-SIGN. Interestingly, CIHPs treated with colchicine, cytochalasin B, and Brefedin A showed a two-fold increase in DC-SIGN expression. We conclude that cytoskeleton proteins promote podocyte HIV-1 accumulation by enhancing podocyte expression of DC-SIGN.

**B7-1 Mediated Danger Signalling in Podocyte Injury in IL-13 Overexpression Rat Model of Minimal Change-Like Nephropathy (MCN)** Chang Yien Chan,[1] Tarun K. Maheshwari,[1] Jinmiao Chen,[2] Caroline G. L. Lee,[1] Subhra K. Biswas,[2] Henry Yang,[2] Hui Kim Yap.[1] *[1]Pediatrics, National University of Singapore, Singapore; [2]SIgN, BMSI (A*Star), Singapore.*

We have previously shown that *interleukin-13 (IL-13)* overexpression in rats can result in MCN accompanied by podocyte injury with downregulation of slit diaphragm proteins. This was associated with increase in glomerular expression of IL-13 receptor subunits and B7-1 at both gene and protein level. This study examined the *in-vitro* effect of IL-13 on podocyte B7-1 expression, and subsequently profiled the differentially regulated molecules in the glomerular B7-1 danger signaling pathways that resulted in podocyte effacement in the *IL-13* overexpression rat model of MCN. RNA isolated from conditionally immortalized murine podocyte cell line (H-2Kb-tsA58), unstimulated and stimulated with mouse recombinant IL-13, were used for real-time PCR analysis. RNA from the glomeruli of 6 control and 6 *IL-13* transfected rats with MCN were reverse transcribed and hybridized into Illumina Rat Ref12 microarray chips. Gene ontology and pathway analysis were carried out using MetaCore™. *In-vitro* experiments on IL-13-stimulated podocytes showed significant upregulation of *IL-13Rα2* and *B7-1* (0.00056±0.00015 and 1.05±0.49 respectively), compared to controls (0.000077±0.000015 and 0.59±0.36 respectively) ($p<0.001$). Microarray analysis of the glomeruli showed 1120 differentially expressed genes with >1.5-fold change in expression. Genes involved in *B7-1* transcription, *JAK3*, *PIK3cd*, and *Rel*, and podocyte cytoskeleton remodeling were upregulated in the glomeruli of nephrotic rats. This was associated with downregulation of podocyte slit diaphragm molecules, *NEPH2*, *nephrin*, *podocin*, *JAM4*, *cadherin-1*, *cadherin-11*, and *cadherin-16*, actin cytoskeleton molecules *ZO-1*, *Nck2*, *Synpo*, *MAGI-2*, *α-catenin* and *α-actinin-4*, podocyte basal and apical membrane domain protein complex molecules, *dystroglycan*, *α3β1 integrin*, *GLEPP1* and linkage molecule *Ezrin*. In conclusion, our results suggest that IL-13 can act directly on podocytes by activating the B7-1 danger signaling pathway which then acts on cytoskeleton and slit diaphragm molecules causing podocyte effacement.

**Human Proximal Tubule Epithelial Cells Modulate Autologous Immunity** Kerry (Kathrein) E. Roper, Xiangju Wang, Helen G. Healy, Ray Wilkinson. *Renal Laboratory, Dept. of Renal Medicine, Royal Brisbane and Women's Hospital/Queensland Health, Brisbane, Queensland, Australia.*

**Background:** The role of proximal tubular epithelial cells (PTECs) in the immunology of renal disease has largely been deduced through animal models and transformed cell lines. We aimed to understand if PTECs mediate human autologous immunity in renal pathology by similar pathways.

**Methods:** Primary PTECs and peripheral blood mononuclear cells (PBMC) were collected from patients undergoing nephrectomies at RBWH. PBMC and purified T and B lymphocytes were cultured with activated autologous PTECs in conditions mimicking immunological signaling ie specific Ag (TT, KLH), cross-linking Ab (CD3/CD28, IgM) and mitogen (PHA, PWM). Responses were monitored by proliferation, cytokine production and surface Ag expression.

**Results:** PTECs activated by IFNγ expressed 5-10 fold more PD-L1 and up to 5 fold more HLA-DR then resting PTECs. Our findings indicate that these activated autologous PTECs significantly suppress the proliferation response of PBMC, CD4+, CD8+ T cell and B cell populations to PHA and/or cross-linking Abs and that this was partially reversed with the addition of blocking antibodies to PD-L1. CD4+ proliferative responses to both naïve and recall Ags were also decreased. Interestingly, maturation/activation markers, particularly CD69 and CD38, were increased in the presence of PTECs. Cytokine profiles were also modulated by autologous PTECs, with decreased expression of IFNγ, IL-2, IL-10 and TNF and an increased expression of IL-4 in most cell populations. There was no significant effect on the levels of Treg cells in any of our cultures.

**Discussion:** We have shown that the inhibitory effect of activated PTECs on both T and B cell proliferation occurs in response to cross-linking Ab and specific Ag, as well as polyclonal activation through mitogen stimulation. Together our results suggest that PTECs act to modulate human autologous immunity via complex interactions with immune cells and this is partially mediated by PD-L1. Further dissection of the mechanism of PTECs modulation of autologous immune responses may prove beneficial for clinical intervention or monitoring in renal medicine.

**Renoprotective Effects of Kv1.3 Blocker in Rats with Anti-Glomerular Basement Membrane Glomerulonephritis** Toshitake Hyodo,[1] Takashi Oda,[1] Keishi Higashi,[1] Kojiro Yamamoto,[1] Taketoshi Kushiyama,[1] Naoki Oshima,[1] Soichiro Miura,[2] Hiroo Kumagai.[1] *[1]Department of Nephrology, National Defense Medical College, Tokorozawa, Saitama, Japan; [2]Department of Internal Medicine, National Defense Medical College, Tokorozawa, Saitama, Japan.*

We previously reported that the blocker (Psora-4) against a voltage-gated K channel, Kv1.3, could reduce the level of proteinuria and the ratio of crescentic glomeruli in the model of rats with anti-glomerular basement membrane (GBM) glomerulonephritis (GN). In the present study, we investigated the mechanisms for this renoprotective effect of Psora-4 by analyzing phenotypes of renal infiltrating cells. Flow cytometric analysis of kidney cells of anti-GBM GN rats revealed that most of the $CD4^+$ T cells showed the effector memory Tcell ($T_{[sup]EM[/sup]}$) phenotype ($CD45RC^-CD62L^-$). Furthermore, flow cytometric analysis of T cells isolated by magnetic cell sorting from peripheral blood (PB) and from kidney samples of anti-GBM GN revealed that T cells from the kidney samples were mostly $CD62L^-$ cells while those from PB included numerous $CD62L^+$ cells. A higher intensity of Kv1.3 expression was observed on the $CD62L^-$ T cells (corresponding to $T_{[sup]EM[/sup]}$) than on the $CD62L^+$ T cells (corresponding to naive or central memory T cells). We also confirmed the expression of Kv1.3 channels on isolated T cells from kidney samples of anti-GBM GN by double immunofluorescence staining. These results suggest that Kv1.3 channels expressed on $T_{[sup]EM[/sup]}$ play a critical role in the pathogenesis of rat crescentic GN, and therefore, Psora-4 might be more specific and efficient treatment for patients with rapidly progressive GN.

**Renal-Associated NLRP3 Mediates Renal Dysfunction Following Ischemia/Reperfusion Injury** Pieter J. Bakker,[1] Ingrid Stroo,[1] Loes Butter,[1] Richard A. Flavell,[2] Sandrine Florquin,[1] Jaklien Leemans.[1] *[1]Pathology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [2]Immunobiology, Yale University School of Medicine, New Haven, CT.*

Renal ischemia/reperfusion injury (IRI) can be characterized as a sterile inflammation where danger-associated molecular patterns are released that subsequently activate Toll-like receptors and Nod-like receptors. It has previously been established that the NLRP3-dependent inflammasome contributes to renal inflammation in IRI. NLRP3 -/- mice have decreased mortality in case of lethal IRI. NLRP3 is expressed on inflammatory cells and also on renal tubular epithelial cells. To date, it is not yet known what the role is of renal- or leukocyte-associated cells NLRP3 in IRI.

A bone marrow transplantation was carried out. C57Bl/6J wild-type (wt) or NLRP3 -/- mice were subjected to 2 doses of sub-lethal irradiation followed by an i.v. injection of splenocytes and bone marrow cells, either derived from wt or NLRP3 -/- mice. Six weeks after bone marrow transplantation, IRI was induced by clamping renal arteries and mice were sacrificed the following day. Blood was collected via heart puncture. Kidneys were formalin fixed and paraffin-embedded. Kidney sections were used for immunohistochemistry.

Apoptosis (Caspase-3+) and proliferation (Ki67+) of tubular epithelium was similar in all groups. In concordance, tubular necrosis (PAS-D scores) was also equal in all groups. Despite equal damage, influx of leukocytes differed between groups. Nalp3-/- bone marrow, Nalp3-/- parenchyma (ko→ko) mice had a significant lower influx of granulocytes (Ly6+) and macrophages (F4/80+) compared to wt-bone marrow, wt-parenchyma (wt→wt) mice. Both chimeras (wt→ko and ko→wt) showed a tendency of lower granulocyte and macrophage influx. Finally, creatine levels were significantly lower in ko→ko mice and wt→ko compared to wt→wt mice.

In conclusion, renal-associated NLRP3 deficiency limits renal dysfunction but not leukocyte-associated NLRP3 deficiency following IRI. Moreover, a NLRP3 deficiency-related reduction of macrophage and granulocyte influx is observed.

**SA-PO2836**

**Investigating Lymphocyte Function during Tubulointerstitial Injury in the Native Kidney** Victoria J. Ingham, Neil S. Sheerin. *Institute of Cellular Medicine, Newcastle University, Newcastle-upon-Tyne, United Kingdom.*

Tubulointerstitial (TI) inflammation and fibrosis is seen in progressive renal failure irrespective of aetiology. If infiltrating T lymphocytes demonstrated clonal proliferation within injured kidney, this would suggest a break in self tolerance and evidence for the role of TI lymphocytes in non-immunologically mediated renal injury.

Methods

The unilateral ureteric obstruction (UUO) model was used. There are 22 T Cell Receptor (TCR) Variable genes on the β chain (TRVβ) however only one is expressed by any T cell. Real time PCR with primers specific to the 22 TRVβ genes was used to assess restriction of TRVβ gene usage in kidney compared to spleen. Over expressed TRVβ gene PCR products were sequenced. Lymphocytes were extracted from digested UUO kidney and sorted by FACS into CD4+ and CD8+ populations and sequenced.

Results

T cells expressing TRVβ3 were over represented in the UUO kidney compared to the spleen. This was not seen in normal animals. In each day 7 and 14 UUO kidney 20-30% of TCR sequences expressing TRVβ3 were identical. Such a clonal population was not seen in UUO spleen. In normal kidney there were also identical T cells accounting for around 1/3rd of all lymphocytes expressing TRVβ3, again not seen in normal spleen.

Multiple identical TCR sequences were demonstrated in the sorted CD8+ population from UUO kidney.

Short, identical amino acid sequences in the CDR3 region were found in the clonal T cell population of both UUO and normal kidneys.

Conclusions

In day 7 and 14 UUO kidneys a large clonal population of T cells were seen, suggesting loss of tolerance to self and possibly renal autoantigen. This was less evident at day 28 and may be due to epitope spreading or chemokine mediated recruitment of polyclonal T cells. The clonal population of T cells within normal kidney may represent an anergic or regulatory population of T cells.

The T cell clone from both UUO and normal kidneys had an identical amino acid motif within the CDR3 region, suggesting T cells in normal kidney may proliferate in response to injury. Understanding the role of lymphocytes in non-immunologically mediated renal injury may guide therapeutic strategies in chronic kidney disease.

**SA-PO2837**

**Regulatory Renal Dendritic Cells Provide Innate Cytoprotection to Podocytes in Endotoxemia** Bettina Burnworth,[1] Nicole Kahoud,[1] Leslie A. Bruggeman,[2] Kelly D. Smith,[1] Peter J. Nelson.[1] *[1]University of Washington, Seattle, WA; [2]MetroHealth Medical Center, Cleveland, OH.*

Mechanisms of peripheral tolerance in the kidney that protect podocytes from injury during auto-inflammatory insults are poorly understood; however, within other non-lymphoid tissues, surveying conventional dendritic cells present at steady-state (ssDCs) perform this role, producing regulatory cytokines that maintain local tissue homeostasis during the innate phases of peripheral tolerance. Thus, we asked whether ssDCs ameliorate podocyte injury and albuminuria during endotoxemia, a model system to decipher inflammatory *versus* regulatory innate responses. Specific pathogen free (SPF) mice exhibited a dose-dependent threshold to albuminuria from LPS. In contrast, SPF mice depleted of renal ssDCs developed significant albuminuria with focal podocyte foot process effacement from normally sub-proteinuric LPS. Parallel examination of intra-renal IL-10 showed that normal kidneys, but not kidneys minus renal ssDCs, significantly up-regulated IL-10 from sub-proteinuric LPS. Opposite the cytokine response by inflammatory GM-CSF-derived DCs, renal ssDCs challenged with LPS *ex vivo* secreted high IL-10-to-TNF-α ratios, confirming renal ssDCs as a key regulatory source of intra-renal IL-10. Because heme oxygenase- 1 (HO-1) is a mediator of innate cytoprotection by IL-10, we investigated this candidate mechanistic pathway for podocytes *ex vivo*. Quiescent podocytes expressed IL-10 receptor and responded to soluble IL-10 by inducing HO-1, abrogating activation of NF-κB in podocytes by LPS. Together, these results suggest that renal ssDCs are regulatory and provide innate cytoprotection to podocytes, setting an important threshold to proteinuria during auto-inflammatory insults. Research is ongoing to determine whether the IL-10-HO-1 axis or additional pathways are responsible for setting this threshold.

**SA-PO2838**

**Analysis of Aberrant *O*-Glycosylation of IgA1 in Patients with IgA Nephropathy (IgAN): Bacterial IgA-Specific Proteases and High-Resolution Mass Spectrometry (MS)** Hitoshi Suzuki,[1,2] Kazuo Takahashi,[1] Zina Moldoveanu,[1] Bruce A. Julian,[1] Mogens Kilian,[3] Knud Poulsen,[3] Yasuhiko Tomino,[2] Jiri F. Mestecky,[1] Matthew B. Renfrow,[1] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Juntendo University Faculty of Medicine, Tokyo, Japan; [3]Aarhus University, Aarhus, Denmark.*

IgA1 in the circulation of patients with IgAN is aberrantly glycosylated; some of the multiple *O*-glycans in the hinge region (HR) are galactose (Gal)-deficient. These aberrant glycans are recognized by anti-glycan antibodies, resulting in formation of pathogenic immune complexes. *O*-glycans on IgA1 secreted by IgA1-producing cells from patients with IgAN (IgAN cells), but not from controls, is Gal-deficient with sialylated or terminal GalNAc, due to decreased β1,3-galactosyltransferase and elevated α2,6-GalNAc-sialyltransferase II enzyme activities in IgAN cells. It is not known whether the Gal deficiency occurs randomly or preferentially at specific sites and which sites are recognized by anti-glycan antibodies. To address this question, we analyzed glycosylation and IgG binding of IgA1 produced by IgA1-secreting cell lines from IgAN patients and healthy controls. *O*-glycosylation of these proteins was analyzed by lectin- and antibody-western blotting after digestion with a panel of bacterial IgA-specific proteases that cleave different sites in the HR. In IgA1 from IgAN patients, Gal-deficient glycans, predominantly in the middle part of the HR with a fraction also in the C-terminal part, bound IgG antibody. For high-resolution MS analysis, IgA1 proteins were digested with an IgA-specific protease followed by trypsin. Three to six *O*-glycans per HR with up to three Gal-deficient sites were detected. Relative abundance of glycopeptides was independently calculated by area under the curve from extracted ion chromatogram. Sialylated glycopeptides with Gal-deficient GalNAc were elevated in IgA1 from IgAN patients. In summary, Gal-deficient glycans are localized at specific sites of the HR and are recognized by anti-glycan antibodies. These sites can be localized by western blotting after digestion with a panel of bacterial IgA proteases and by high-resolution MS analysis.

Disclosure of Financial Relationships: nothing to disclose
