Selective deletion of *Pkd1* in the osteoblasts using either *Osteocalcin*-Cre or *Dmp1*-Cre results in osteopenia and in kidney using *Ksp*-Cre causes polycystic kidneys. *Pkd1* is also expressed in undifferentiated mesencyme. To broadly examine the function of Pkd1, we respectively used *Col1a1*(3.6)-Cre and *Co1a1*(2.3)-Cre mice to achieve selective inactivation of *Pkd1* at E14.5 and E18.5 in mesenchymal precursors. Bone and kidney samples were analyzed from newborn and 6 week-old control *Pkd1*$^{flox/+}$ and condtional *Col1a1(3.6 or 2.3)*-Cre;*Pkd1*$^{flox/flox}$, *Col1a1(3.6 or 2.3)*-Cre;*Pkd1*$^{flox/null}$ mice, which differed in the timing and magnitude of Pkd1 ablation. Transgenic *Col1a(3.6 or 2.3)*-Cre;*Pkd1*$^{flox/flox}$ and *Col1a(3.6 or 2.3)*-Cre; *Pkd1*$^{flox/null}$ mice displayed osteopenia at 6 weeks-of-age. Histological analyses found that cysts were absent in kidneys and pancreas from newborn of *Col1a1(3.6)*-Cre;*Pkd1*$^{flox/flox}$ mice, but cysts developed in these organs by 6 weeks-of-age. In contrast, *Col1a1(3.6)*-Cre;*Pkd1*$^{flox/null}$ mice had major cyst formation at birth that was associated with increased mortality. Neither transgenic *Col1a(2.3)*-Cre;*Pkd1*$^{flox/flox}$ or *Col1a(2.3)*-Cre; *Pkd1*$^{flox/null}$ mice developed cystic disease. Thus, ablation of Pkd1 in the mesenchymal precursors giving rise to the osteoblast lineage results in osteopenia that is porportionate to the magnitude of Pkd1 reduction rather than the timining of Cre expression. In contrast, the earlier onset and more severe cystic phenotypes in *Col1a1(3.6)*-Cre;*Pkd1*$^{flox/null}$ compared to *Col1a1(3.6 or 2.3)*-Cre;*Pkd1*$^{flox/flox}$ or *Col1a(2.3)*-Cre; *Pkd1*$^{flox/null}$ mice indicates that both gene dose and timing of Pkd1 ablation during embryogenesis influences the severity of cyst formation. The selective deletion of *Pkd1* from mesenchymal lineage results in both defective bone formation and polycystic kidney disease, indicating that *Pkd1* has essential function in mesenchymal precursors to regulate both skeletal and renal development. The long-term survival of *Col1a1(3.6)*-Cre;*Pkd1*$^{flox/flox}$ mice establishes a potential model to study postnatal interventions to retard cyst formation.

**Vangl2, a Gene Encoding a Planar Cell Polarity (PCP) Protein, Is Required for Branching Morphogenesis and Glomerulogenesis in the Mammalian Kidney** Jenny Papakrivopoulou,[1] Laura Yates,[2] David A. Long,[3] John Connolly,[1] Adrian S. Woolf,[4] Charlotte Dean.[2] *[1]UCL Centre for Nephrology, Royal Free Hospital, London, United Kingdom; [2]Mammalian Genetics Unit, Medical Research Council Harwell, Oxford, United Kingdom; [3]Nephro-Urology Unit, Institute of Child Health, University College London, London, United Kingdom; [4]Biomedical Research Centre, University of Manchester, Manchester, United Kingdom.*

Previous studies have highlighted a role for the PCP pathway in maintaining kidney tubule differentiation, with mutations associated with cystogenesis. However, whether the pathway has other roles in kidney development is unclear. The loop-tail (*Lp*) allele results in absence of functional Vang-like protein 2 (*Vangl2*), a core PCP protein. Here we show that homozygous fetuses had neither duplex nor hydronephrotic kidneys. The *Lp/Lp* ureteric bud penetrated adjacent renal mesenchyme normally but the first rounds of *Lp/Lp* ureteric bud/collecting duct branching were reduced *in vivo*. The observed ureteric bud dysmorphology occurred after just-formed metanephroi were explanted and maintained in organ culture for 2 days. In late gestation, the homozygous mutant kidney had a hypoplastic medulla and contained glomerular tufts which were smaller than normal, with less prominent capillary loops. Proliferation rates were reduced in *Lp/Lp* glomeruli but expression of podocyte proteins nephrin and synaptopodin was unchanged. *Lp/Lp* metanephroi contained occasional distorted tubules but an overt polycystic phenotype was not observed. Non viability of homozygous mice due to severe neural tube defects precluded analysis after birth. *Lp*/+ metanephroi displayed a glomerular phenotype midway between wild-types and homozygous mutants and postnatally, after nephrogenesis was complete, heterozygous kidneys had modest reductions in glomerular numbers. *Vangl2* was expressed in podocytes as were other PCP genes including Scribble and Celsr1, themselves also expressed in S-shaped bodies. The data show for the first time that *Vangl2*, and by implication the PCP pathway, is required for early morphogenesis of collecting ducts and complete differentiation of glomeruli.

**Construction of Lentiviral Vector Encoding HIF-1α and HIF-1α Expression in Human Adipose-Derived Stem Cells** Weiwei Wang, Jinyuan Zhang. *Nephrology Division, Jimin Hospital of Shanghai, Shanghai, China.*

**Objective** Adult stem cells derived from adipose tissue is an attractive cell source. Because adipose tissue is obtained as lipospirate from the patient in a less invasive manner and provides a large quantity of autologous cells, the use of adipose-derived stem cells (ADSCs)is an alternative way of providing seed cells. Hypoxia-inducible transcription factor-1α (HIF-1α) is known as a key regulator in protective role of renal damage by induction of downstream protective genes. Proteins coded by protective genes are sufficient to induce renoprotection. We transfected human adipose-derived stem cells(hADSCs) using lentiviral vector encoding hypoxia inducible factor-1α (HIF-1α) to study its expression level in vitro and to get a stable cell line expressing HIF-1α.

**Methods** The multi-directional differentiation of hADSCs was assessed by alizarin red staining and oil red O staining. HIF-1α gene was sub-cloned into the lentiviral transfer vector. The recombinant lentiviral supernatant were packaged by 293T cells through three plasmids transient co-transfection method using standard lipofectamine reagent. The viral titer was tested by the transfection efficiency of 293T cells. Lentiviral vector carrying HIF-1α transduced to hADSCs in different multiplicity of infection (MOI=1,5,10,15,20). Transfection efficiency was tested by fluorescence-activated cell sorting. HIF-1α gene expression level and protein secretion level of hADSCs were tested by real-time PCR and western blot methods after transfection.

**Results** The alizarin red staining and oil red O staining showed hADSCs could be induced to osteogenic and adipogenic lineages. The viral titer was $3.5\times10^{8}$TU/ml. Transfection efficiency was over 90% under MOI=20 at 7$^{th}$ day after infection. The expression of HIF-1α in transfected hADSCs was increased obviously detected by real-time PCR and western blot compared with vector group. The morphology and viability of transfected hADSCs had no marked change. **Conclusions** We successfully use lentiviral vectors encoding HIF-1α to transfected human adipose-derived stem cells and got a stable human adipose-derived stem cells lines sustained over-expressing HIF-1α.

**Generation of Inducible Pluripotent Stem Cells from Patients with Autosomal Dominant Polycystic Kidney Disease** Albert Q. Lam, Joseph V. Bonventre. *Department of Medicine, Renal Division, Brigham and Women's Hospital, Boston, MA.*

Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common inherited diseases, affecting 1 in 600-1000 individuals. Patients with ADPKD typically present in the 4th and 5th decades of life with bilateral renal cysts, hypertension, and progressive loss of renal function. Mutations in the PKD1 and PKD2 genes encoding polycystin-1 and polycystin-2, respectively, are responsible for nearly 100% of cases of ADPKD. We demonstrate for the first time that inducible pluripotent stem (iPS) cells can be generated from patients with ADPKD by reprogramming their skin fibroblasts with four transcription factors (OCT4, SOX2, KLF4, C-MYC). We have derived, expanded, and characterized six iPS cell lines from fibroblast cell lines of three adult patients with ADPKD. ADPKD-specific iPS cells form compact colonies with embryonic stem (ES) cell-like morphology when co-cultured on a feeder layer of mouse embryonic fibroblasts. ADPKD iPS cells express the hallmarks of pluripotency, as demonstrated by positive alkaline phosphatase staining and positive immunocytochemistry for OCT4, NANOG, Tra-1-60, SSEA-3, and SSEA-4. The expression of pluripotency-promoting genes in ADPKD iPS cells as quantified by RT-PCR is similar to that of human ES cells and human iPS cells from normal controls and elevated compared to the parent fibroblast cell lines. All ADPKD iPS cell lines are capable of differentiating into cell types of all three germ layers in vitro and form teratomas when injected into SCID mice. ADPKD iPS cells remain karyotypically normal after multiple passages. The establishment of pluripotent ADPKD iPS cell lines represents the first step in the process of using human iPS cells for patient-specific ADPKD disease modeling and potential therapeutic testing.

**Expression of Prox1 in the Renal Cortex during Mouse Development** Yumi Kim, Wan-Young Kim, Eun-Young Park, Jin Kim. *Anatomy and MRC for Cell Death Disease Research Center, The Catholic University of Korea, Seoul, Republic of Korea.*

Prospero-related homeobox1 transcription factor (Prox1), is known to be expressed in various internal organs and is related to their embryogenesis. It is also expressed in lymphatic endothelial cells and plays an essential role in embryonic lymphangiogenesis. However, little is known about Prox1 expression in the development of the lymphatic vasculature of the kidney. This study is intended to examine the expression of Prox1 in the developing mouse kidney with particular emphasis on the lymphatic system of the renal cortex**.** The expression and localization of Prox1 in developing kidneys from 14-, 15-, 16- and 18-day-old fetuses (E14 to E18), 1-, 4-, 7-, 14-, and 21-day-old pups (P1 to P21), and adult C57BL/6 mice were examined using immunohistochemical technique. In the renal cortex, Prox1 was localization in the cell nucleus, and initially expressed on E14 in the LYVE-1$^{+}$ lymphatic endothelial cells. Prox1 was expressed in these cells during the embryonic and postnatal lymphatic development and through to adulthood. However Prox1 was not expressed in a subset of LYVE-1$^{+}$ endothelial cells in glomerular capillaries or arcuate veins. We have reportd previously that LYVE-1 is also expressed transiently in a F4/80$^{+}$/CD11b$^{-}$ macrophages but Prox1 was not coexpressed in these cells. During lymphatic vessel development, LYVE-1$^{+}$/F4/80$^{+}$/CD11b$^{-}$ macrophages may be involved indirectly in active branching process of lymphangiogenesis. These findings suggest that Prox1 plays a major role in lymphangiogenesis in the developing mouse kidney and is required to maintain the lymphatic vasculature during later stages of development and in adulthood.

**GLI3 Repressor Controls Nephrogenesis and Ureteropelvic Junction Development** Norman D. Rosenblum,[1,2,4] Marian Vicky Staite,[1,2] Brian J. Nieman,[3] Jason Cain.[1] *[1]Prog Dev & Stem Cell Biol, Hosp Sick Child; [2]Dept Physiology, U Toronto; [3]Toronto Centre for Phenogenomics; [4]Div Neph, Dept Peds, U Toronto, Toronto, Canada.*

Hedgehog (HH) signaling controls renal development by increasing GLI transcriptional activators (GLIA) and inhibiting formation of GLI3 transcriptional repressor (GLI3R) (Hu et al, Development, 2006; Cain et al, PLoS ONE, 2009). HH ligands are bound by PTC1, a cell surface protein, that constitutively inhibits GLI signaling in the unbound state. Mutations in *PTC1* cause tissue malformation and cancer in nonrenal tissues. We tested our hypothesis that constitutive active HH signaling is deleterious to renal development in mice with *PTC1* deficiency targeted to the metanephric mesenchyme (MM) (*Rarb2-Cre;Ptc1$^{loxP/-}$*, termed *Ptc1* mutants). Increased HH signaling in MM was confirmed by quantitiative *Ptc1* PCR and expression of the *Ptc1-lacZ* HH signaling reporter. Mutant mice died immediately after birth with a thin renal cortex and massive hydropelvis. Ureteropelvic junction (UPJ) obstruction was demonstrated by intrapelvic dye injection and MRI, the latter demonstrating a 9-fold increase in pelvic volume. As early as E13.5, a cluster of cells marked by ectopic expression of *Raldh2* and *Ptc2* and increased expression of *Bmp4* accumulated at the presumptive UPJ. Reduced cortical volume was associated with decreased formation of NCAM-positive nephrogenic precursors (2.6-fold decrease, p=0.01, n=3) at E13.5 and WT1-positive glomeruli (1.4-fold decrease, p=0.02, n=3) at E18.5, normal *Gdnf, Ret* and *Wnt11* expression and ureteric branching but increased cortical expression of *Foxd1*. The relative contribution of GLIA and GLI3R to the mutant phenotype was defined in mutant mice with deficiency of *Gli2*, the major GLIA, or expression of a single allele of *Gli3$^{\Delta 699}$*, which encodes GLI3R, respectively. Heterozygous *Gli2* deficiency in *Ptc1* mutant mice did not rescue the mutant phenotype. In contrast, expression of *Gli3$^{\Delta 699}$* in *Ptc1* mutant mice increased nephron number to levels observed in WT mice (n=3, p=0.03) and decreased pelvic volume 2.4-fold (n=3, p=0.004) compared to *Ptc1* mutant mice. We conclude that GLI3R is required for nephrogenesis and patterning of the UPJ.

**TH-PO356**

**Organ-Specific Defects in IGF Signaling and Asymetric Organ Growth in Mice with Intrauterine Growth Retardation** Tatiana Novitskaya, Mark P. De Caestecker. *Nephrology Division, Vanderbilt University, Nashville, TN.*

Intrauterine growth retardation (IUGR) resulting from placental insufficiency affects embryonic patterning of the kidney and gives rise to a decrease in the number of functioning nephrons. However the fetal mechanisms regulating abnormal renal growth in IUGR are unknown. There are currently no established mouse models of placental insufficiency with IUGR that would enable genetic manipulation of the signaling pathways regulating this fetal response. To address this, we have developed a mouse model in which loss of placental Cited1 expression gives rise to late gestational placental insufficiency. These mice have classical asymmetric IUGR with decreased kidney, liver and lung size along with preservation of fetal brain weight. Since IGF signaling plays a critical role in regulating fetal organ growth, we interrogated in IGF signaling pathway in these mice. IGF1 protein levels are reduced in kidney and livers from E18.5 embryos with IUGR compared with wild type littermates, while IGF2 protein expression is selectively decreased in the lung. In contrast IGF1 and IGF2 are increased in brains from embryos with IUGR. Decreased IGF1 in the kidney and liver is associated with reduced activating $Y^{1135/1136}$ phosphorylation of the IGF-1 receptor, while reduced IGF2 expression in the lung is associated with decreased activating $Y^{1135/1136}$ phosphorylation of the insulin receptor (IR). Since IR signals downstream of IGF2 but not IGF1 in the embryo, this suggests that decreased IGF2 in the lungs of embryos with IUGR is functionally significant. In contrast there is no change in IGF1 or IR receptor phosphorylation in the brains of embryos with IUGR. Thus organ-specific loss of IGF1 and IR receptor signaling correlates with asymmetric organ growth retardation and could play a direct role in promoting abnormal kidney, liver and lung growth in IUGR.

**TH-PO357**

**β1 Integrin Is Required for Ureterovesicular Junction Development** Paul R. Brakeman,[1] Denise K. Marciano,[2] Natalie Spivak,[1] Chao-Zong Lee,[2] Louis Reichardt,[4] Keith Mostov.[3] *[1]Pediatrics, University of California, San Francisco, CA; [2]Medicine, University of California, San Francisco, CA; [3]Anatomy, University of California, San Francisco, CA; [4]Physiology & Biochem/ Biophysics, University of California, San Francisco, CA.*

Integrins are transmembrane receptors that mediate interactions between cells and extra-cellular matrix and are present in signaling complexes at sites of adhesion called focal adhesions (FAs). ß1-containing integrins are known to be critical for renal development. The structure and dynamics of FAs have been well described in 2-dimensional cell culture; however, little is known about FAs in 3-dimensional (3-D) epithelial structures. We have now visualized FAs in 3-D MDCK cultures and in developing renal epithelia *in vivo*. We find that loss of ß1 integrin via shRNA knockdown in MDCK cells in 3-D culture disrupts FA complexes and cellular motility in response to hepatocyte growth factor. In order to study the role of ß1 integrin and FAs *in vivo* during urogenital development, we generated tissue specific knockout mice with disruption of ß1 integrin in the collecting system, the ureteric bud and nephric duct. As recently shown by Zhang et al (2009), we confirm that loss of ß1 integrins in the renal collecting system results in severely hypoplastic kidneys. Further, we observe the novel phenotype that mutant mice develop severe hydroureter owing to a failure of the distal ureter to fuse with and penetrate through the bladder wall, resulting in a markedly abnormal ureterovesicular junction. Together, our results demonstrate that it is possible to study focal adhesion complexes in 3-D epithelial structures and that ß1 integrins are essential for ureterovesicular junction development.

**TH-PO358**

**Characterization of Renal Injury in Megabladder Mouse, a Unique Animal Model of Congenital Obstructive Nephropathy** Susan E. Ingraham,[1] Kirk M. McHugh.[2] *[1]Pediatric Nephrology, Nationwide Children's Hospital, Columbus, OH; [2]Center for Molecular and Human Genetics, The Research Institute at Nationwide CHildrne's Hospital, Columbus, OH.*

Congenital obstructive nephropathy is the most common cause of chronic renal failure in children, often progressing to end stage renal disease. The transgenic mutant megabladder (mgb) mouse exhibits signs of lower urinary tract obstruction in utero, resulting in the development of congenital hydroureteronephrosis and progressive renal failure following birth. This study examines the development and progression of renal injury in homozygotic mgb mice (mgb-/-). Renal ultrasound was utilized to stratify the disease state of individual mgb-/- mice, while surgical rescue of the phenotype was investigated using cutaneous vesicostomy. The progression of renal injury in these animals was characterized histopathologically using a series of markers that included α-smooth muscle isoactin, TGF-β1, CTGF, WT-1, and Pax2. This analysis indicated that mgb-/- mice are born with pathologic changes in kidney development that progressively worsen in correlation with the severity of hydronephrosis. The initiation and pattern of fibrotic changes observed in mgb-/- kidneys appeared distinctive compared to prior animal models of obstruction, and shared similarities with the development of congenital obstructive nephropathy in humans. These observations suggest that the mgb mouse represents a unique small animal model for the study of congenital obstructive nephropathy.

**TH-PO359**

**MicroRNA Regulation of Gene Expression during the Ureteric Bud Outgrowth from the Wolffian Duct** James B. Tee. *Dept of Paediatrics, University of Calgary, Calgary, AB, Canada.*

Embryonic kidney development begins with the outgrowth of the ureteric bud (UB) from the Wolffian duct (WD). Disruptions to this process can lead to renal malformations that are a major contributor to ESRD in children. While recent studies have focused on the gene regulation of this process, little is known about the potential role of governing miRNAs which can serve to silence the expression of target mRNAs. To evaluate this possibility, WDs were extracted with their attaching mesonephros from embryonic day 11 CD-1 mice. UB outgrowth along the duct was induced by the in-vitro administration of glial cell line-derived neurotrophic factor. Biological replicate samples for each condition were concurrently evaluated by whole-transcript gene expression microarray analysis and miRNA array profiling. Comparing the budded with the unbudded WD conditions by T-Test unpaired Benjamini-Hochberg multiple testing correction revealed 16 miRNAs that exhibited a minimum 2-fold increase in expression, ranging from let-7c (2.2-fold change) to miR-29a (16.6-fold change). Utilizing an established miRanda-based algorithm, a generated list of predicted target mRNAs ($p < 0.05$) was cross-referenced with the 5,632 significantly downregulated genes uncovered by the whole-transcript array. This resulted in 1,083 unique gene targets for this set of miRNA that were downregulated in the budded WD, of which the most well-predicted targets are presented. Two downregulated miRNA gene targets had GO terminology referencing either the kidney or ureter: Agtr1b and Pkhd1. Conversely, 7 miRNAs exhibited a 2-fold decrease in expression in the budded WD (ranging from miR-669c (2.2-fold change) to miR-292 (4.5-fold change). Cross-referencing the predicted targets of this subset of miRNAs with the 4,861 significantly upregulated genes on the whole-transcript array revealed 1,022 unique gene targets in the budded WD, of which three referenced similar GO terminology: Nog, Eya1, and Jmjd6. The presented results suggest that microRNAs may be involved in the regulation of gene expression governing the UB outgrowth from the Wolffian duct, and sets the stage for the validation of the most highly-predicted targets in this process.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO360**

**WNT-$Ca^{2+}$ Pathway Activity Peaks during Kidney Development and Restricts Mesenchymal Cell Motility *In Vitro*** Michelle Miller,[1] Paul R. Goodyer,[1] Diana Iglesias.[2] *[1]Human Genetics, McGill University, Montreal, QC, Canada; [2]Pediatrics, McGill University Health Center, Montreal, QC, Canada.*

The non-canonical, calcium-dependent WNT signalling pathway is poorly understood in the context of renal development. In this study, we characterize WNT-$Ca^{2+}$ signalling during normal kidney development using transgenic mice bearing a luciferase reporter driven by the transcription factor NFAT, the major effector of calcineurin activation.

In NFAT-luciferase reporter mice, WNT-$Ca^{2+}$ pathway activity is extremely high in the embryonic kidneys. Reporter activity peaks from E13-E16 and drops significantly by P15 after which WNT-$Ca^{2+}$ signalling as well as nephrogenesis comes to an end. These data suggest that the WNT-$Ca^{2+}$ pathway plays an important role in kidney development.

To understand the function of the pathway, we developed systems *in vitro* and *ex vivo* to specifically manipulate the WNT-$Ca^{2+}$ pathway and used renal mesenchymal cell lines to determine pathway effects on cell migration. When the MK3 cell line (derived from early metanephric mesenchyme) was co-cultured with fibroblasts secreting the classic non-canonical WNT5A, we found that WNT-$Ca^{2+}$ activity was stimulated 2-fold. This increase in pathway activity could be abolished by adding cyclosporine A (CsA), a specific inhibitor of calcineurin, to the co-culture media. E14 kidney explants were also co-cultured with WNT5A-secreting fibroblasts and a 2.5-fold increase in pathway activity was seen, which was again abolished by the addition of CsA. Taken together, these observations indicate that the calcineurin/NFAT pathway is stimulated by WNT5A in the metanephric mesenchyme.

To ascertain whether the NFAT pathway affects cell movement, we performed scratch assays with MK3 cells treated with WNT5A in the presence or absence of CsA. Cell movement was significantly reduced after WNT5A treatment; this inhibitory effect was abolished in the presence of CsA.

We hypothesize that the WNT-$Ca^{2+}$ pathway is stimulated by a non-canonical WNT signal during nephrogenesis and is required for a process that restricts cell movement.

**TH-PO361**

**Prematurity Leads to Reduced Nephron Number and Hypertension** Ashraf El-Meanawy. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Reduced nephron number (oligonephronia) is a risk factor for hypertension and chronic kidney disease (CKD). The etiology of oligonephronia and how it leads to hypertension and CKD are poorly understood. Prematurity is a risk factor development of hypertension, metabolic syndrome, and kidney disease later in life. In the USA, one of every 8 children is born prematurely, and incidence in blacks of non-Hispanic origin is twice the incidence in white population. Worldwide, there are 12.5 million premature births annually. The consequences of prematurity are dependent on gestational age as well as other factors including genetic, environmental, and socioeconomic variable. Animal models provide an invaluable resource to study the effect of prematurity on kidney development and the health consequences later in life as it lacks the confounding variable which makes these studies in humans near impossible.

In this report we describe the development of a mouse model for prematurity with evidence of renal developmental abnormality. Adult mice born one or two days early have 20-25% reduction of nephron number compared to full term controls. The premature mice have statistically significant lower Glomerular filtration rate, as measured by real-time inulin clearance. Premature mice also have higher serum creatinine and abnormal urinary protein excretion. The premature mice were found to have a base line statistically significant higher blood pressure.

The renal consequences of prematurity in human has been attributed to the either the etiological factors of prematurity (IGUR and placental aging), or to the insults sustained in the post-natal period in the form of sepsis or exposure to toxic medications. The animal model developed in this study will provide a very useful resource to study effect of prematurity on kidney development and its reflection on hypertension and renal disease in the adult individual. We concluded that loss of placental support prematurely leads to arrest and/or abnormal programming of the developing kidney which leads to reduced nephron number and hypertension in adult animals.

## TH-PO362

**Deletion of NuRD Component Mta2 Results in Renal Hypoplasia and Abnormal Papillary Development** Darcy R. Denner,[1] Kelly M. Stumpff,[1] Michael I. Rauchman.[1, 2] *[1]Biochemistry and Molecular Biology, St. Louis University, St. Louis, MO; [2]St. Louis VA Medical Center.*

Sall1 is a Zn-finger transcription factor essential for kidney development and when mutated leads to the human developmental disorder Townes-Brocks Syndrome. Our lab discovered that Sall1 recruits the Nucleosome Remodeling and Deacetylase (NuRD) complex via a conserved peptide motif to repress gene expression. Through in vitro binding assays, we have determined that Sall1 associates with NuRD by direct interaction with the metastasis tumor-associated protein 2 (Mta2). We detected all NuRD components by western blotting of E13 embryonic kidney lysates and found that they co-elute with Sall1 by size-exclusion chromatography at an expected size of 1.2 MDa. Like Sall1, Mta2 is highly expressed in the metanephric mesenchyme of the peripheral nephrogenic zone of the developing kidney by in situ hybridization and immunofluorescence. Deletion of *Mta2* in cap mesenchyme using Cre recombinase under control of the *Six2* promoter resulted hypoplastic kidneys in *Six2Cre$^{Tg+}$Mta2$^{flox/flox}$* mutants. This phenotype is similar to that exhibited by specific deletion of *Sall1* in the cap mesenchyme. Mta2 expression is also detected in the maturing renal tubules, collecting duct epithelium and medullary stroma. To determine if *Mta2* plays a role in these regions we deleted Mta2 ubiquitously using the tamoxifen-inducible β-*actinCreER* mouse strain. β-*actinCre$^{Tg+}$Mta2$^{flox/flox}$* mutants (8/11) exhibited renal hypoplasia at E14.5-17.5 similar to that observed in *Six2Cre$^{Tg+}$Mta2$^{flox/flox}$*. However, in contrast to mesenchymal deletion of *Mta2* these mutants also exhibited reduced papillary development. These results suggest multiple roles for the NuRD component Mta2 in developing kidney.

## TH-PO363

**Hedgehog Controls Ureteric Bud Branching Morphogenesis and Contribute to Reduced Nephron Number in a Mouse Model of Oligomeganephronia** Ashraf El-Meanawy, Cary T. Stelloh. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Developmental reduction of nephron number is an acknowledged risk factor for renal disease and hypertension. Nephrogenesis proceed through complex process involving myriad of genes and pathways and is dependent on spatiotemporal and quantitative expression of controlling genes. A number of genes and pathways have been shown to control nephron number. In this report we identify Hedgehog signaling as a newly identified regulator of nephron number. The hedgehog regulation of nephron number is exerted through regulation of ureteric bud branching morphogenesis. We exploited the Oligosyndactyly mouse model of oligomeganephronia to identify the genes which can control nephron number. We identified the hedgehog modulating morphogen; hedgehog interacting protein (Hhip), to be a critical gene in controlling nephrogenesis. Hhip is dysregulated in the Os mouse, it is overexpressed early on at embryonic day 14 in the Os embryonic kidneys compared to wild type litter mates. This leads to localized suppression of hedgehog signaling. As a consequence there is suppression of ureteric bud branching morphogenesis. To validate the hypothesis, we used wild type metanephric culture system. Incubating E12.5 cultured kidney explants with recombinant mouse Hhip protein led to significant reduction in ureteric bud branching morphogenesis. We were also able to reproduce these results by transfecting E11.5-E12 embryonic kidney with plasmid expressing Hhip cDNA under control of CMV promotor. Moreover, globally inhibiting the Hedgehog signaling using cyclopamine or the blocking antibody 5E1 produced a similar ureteric bud branching defect. The block of the Hedgehog signal led to the suppressed expression of the mesenchyme specific zinc finger protein Sall1. We conclude that Hhip gene product is an important morphogen which critically regulate local hedgehog signaling in the developing kidney. This leads to regulation of final nephron number by altering ureteric bid branching morphogenesis. The clinical relevance of this finding could be extrapolated from the link of functional defects of other branching organs with SNPS in HHIP gene in human GWAS.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO364

**Pursuing the Human Renal Stem Cells – Isolation and Characterization of Human Fetal Kidney Stem Cell** Sally Metsuyanim,[1,3] Orit Harari-Steinberg,[1] Oren Pleniceanu,[1,2] Tzahi Noiman,[3] Ronald S. Goldstein,[3] Benjamin Dekel.[1,2] *[1]Sheba Center of Regenerative Medicine, Sheba Medical Center, Tel Hashomer, Israel; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]The Mina & Everard Goodman Faculty of Life Sciences, Bar-Ilan University, Ramat Gan, Israel.*

The ability to isolate human fetal kidney (hFK) stem cells is essential to explore their role in kidney development, regeneration and disease. *In vitro* hFK limiting dilution and colony-forming assays were used to quantitatively measure hFK stem/progenitor cell enrichment and self-renewal. Cell surface markers were screened for their ability to positively or negatively enrich for cells with enhanced growth potential in these assays. Sorted subpopulations were analyzed for tissue regeneration capabilities after grafting in the chick embryo.

Clones developed from single hFK cells at a variable rate (0.5-4%) and could be serially propagated to high-passages (P15) indicative of self-renewal. Nevertheless, these cell clones rapidly adopt a mesenchymal appearance and express a combination of renal progenitor markers (Six2/Osr1 but not Pax2/Wt1) and mesenchymal stem cell markers (CD73, CD105, CD90) and therefore do not resemble epithelial nephron progenitors. FACS sorting of hFK cells demonstrate that specific cell surface markers such as NCAM, PSA-NCAM and aldehyde dehydrogenase (ALDH) that localize to the MM and its early nephron derivatives can be used to highly enrich for expression of the entire battery of renal progenitor genes (Six2/Osr1/Sall1/Pax2/Wt1) as well as for clonogenic capacities, especially NCAM+EpCAM- cells. These cells can be serially passaged in serum-free defined media and when grafted ($10^5 – 0.5X10^6$ cells) in the chick can robustly differentiate to produce multiple nephron tubule structures in contrast with the negative fraction which fails to do so.

In sum, human fetal nephron stem/progenitor cells can be isolated by using this antigenic profile. These cell types are strong candidates for cell therapy; tissue engineering and genetic manipulation.

**The Effect of Intrauterine Hypoxia on the Development of the Kidney** Lorine J. Wilkinson,[1] Han Sheng Chiu,[1] Adler (Ali) Leigh Ju,[2] Bree Rumballe,[1] Karen M. Moritz,[2] Melissa H. Little.[1] *[1]Institute for Molecular Bioscience, Brisbane, QLD, Australia; [2]School of Biomedical Sciences, University of QLD, Brisbane, QLD, Australia.*

Perturbations to the intrauterine environment of the fetus are widely accepted as a key factor in the aetiology of adult onset diseases such as hypertension and chronic kidney disease. Intrauterine hypoxia is one of the more common insults to the developing fetus and is known to result in low birth weight. Very little research to date has focused on the effect of fetal hypoxia on kidney development, however a correlation between low birth weight and reduced nephron endowment is well established in both animal models and in humans. In turn, reduced nephron number in the human correlates with hypertension, and renal disease. It is likely that fetal hypoxia will also result in reduced nephron endowment and thereby contribute towards adult onset renal disease. We have begun to examine the affect of hypoxia on the development of the mouse kidney using ex-vivo organ culture as a model. Kidneys were dissected from embryos at 12 dpc and grown in culture for 30 hours in normoxic conditions or with the addition of the hypoxia mimic, cobalt chloride. Cobalt chloride activates the HIFα hypoxia response pathway. Cultured kidneys in normoxic conditions continued to develop and undergo branching morphogenesis and nephrogenesis. In contrast, explants grown in hypoxic conditions failed to develop any nephron structures. Growth and branching of the UB continued, although to a lesser degree than in normoxic cultures. In situ analysis of genes specific for cap mesenchyme, stroma, and UB indicated that these compartments developed normally. However, an early marker of MET, Wnt4, was in most cases completely absent, while the epithelial marker, E-cadherin was confined to UB only. Taken together the results suggest that the major effect of hypoxia on the explants is a block in the mesenchyme to epithelial transition required for nephron formation. This may be due to ER stress associated degradation of key signaling molecules . We are currently investigating whether a similar block in MET occurs in vivo in response to hypoxia.

## TH-PO366

**Lithium Impairs Kidney Development and Inhibits Glycogen Synthase Kinase-3β in Collecting Duct Principal Cells** Gitte Kjaersgaard,[1] Kirsten Madsen,[1] Niels Marcussen,[2] Boye Jensen.[1] *[1]Cadiovascular and Renal Research, University of Southern Denmark, Odense, Denmark; [2]Clinical Pathology, Odense University Hospital, Odense, Denmark.*

The postnatal rat kidney is highly susceptible to Lithium ($Li^+$), which leads to significant tissue injury. We hypothesized that $Li^+$ impairs development of the kidney through entry into epithelial cells of the distal nephron, inhibition of Glycogen Synthase Kinase-3β (GSK-3β) through phosphorylation on serine9 (pGSK-3β)and subsequent epithelial to mesenchymal dedifferentiation (EMT). GSK-3β immunoreactive protein was associated with collecting ducts in developing and adult human and rat kidney. Total GSK-3β protein abundance was stable in medulla while it decreased in cortex in the postnatal period in rat kidney. In contrast pGSK-3β protein abundance decreased significantly with development

in cortex and medulla. Food pellets containing $Li^+$ were given to female Wistar rats with litters through postnatal (P) days 7-29. At P29, plasma $Li^+$ in offspring was 0.99 mmol/L and quantitative stereological analysis showed reduced total kidney volume and reduced cortex and outer medulla volumes compared to control. At P70, 5 weeks after $Li^+$ withdrawal, stereological analysis showed a persisting reduction of outer medulla volume compared to control kidneys. $Li^+$ treatment (P7-P29) increased pGSK-3β protein level significantly whereas total GSK-3β abundance was unaltered. $Li^+$ treatment increased α-Smooth Muscle Actin (α-SMA) protein level significantly whereas E-cadherin expression was unaltered. In summary, $Li^+$ treatment impairs postnatal development of the kidney cortex and outer medulla and increases pGSK-3β abundance in collecting duct. The data are compatible with the notion that increased GSK-3β activity in the postnatal kidney medulla is necessary for kidney development.

**The Oxidative Stress Role in Renal Injury Induced in Rats by Losartan Exposition during Lactation** Evelyn Cristina Santana Marin, Cleonice G. Da Silva, Terezila Machado Coimbra. *Physiology, Faculty of Medicine of Ribeirão Preto, Ribeirão Preto, Sao Paulo, Brazil.*

The nephrogenesis of rats is completed between 10 and 15 days after birth. Rats exposed to angiotensin II antagonists during lactation present disturbances in renal function and structure. This study investigates the role of the oxidative stress in rats exposed to losartan during lactation. Male Wistar rats were divided in three groups: control (C), pups of dams that received 2% sucrose, n=15; losartan (LO), pups of dams that received losartan (100 mg/kg/day) diluted in 2% sucrose, n=26; losartan plus tempol, an antioxidant (LOT), pups of dams that received losartan (100 mg/kg/day) diluted in 2% sucrose plus tempol (0.34 g/L), n=22. Losartan and/or tempol were administered in drinking water during lactation. At 21 days after birth blood and urine samples were collected to evaluate the renal function and the animals were killed. The kidneys were removed for histological and immunohistochemical studies. No difference in creatinine serum was observed between the groups. Urinary albumina/creatinine ratio was higher in LO group [0.15 (0.10; 0.55)] compared to C group [0.03 (0.01; 0.07)]. LO group presented higher fractional sodium (3.28%±0.67) and potassium (83.57%±17.31) excretions compared to C group (0.34%±0.08; 37.81%±5.99, respectively). Fractional sodium and potassium excretions were lower in LOT group (1.68% ±0.44 and 57.93%±10.79, respectively) compared to the LO group. Higher number of ED1-positive cells (macrophages/ monocytes) was found in the immunohistochemical studies in LO compared to the C group (23.91±3.15 vs 5.13±0.60 per area of 0.245 $mm^2$). Treatment with tempol attenuated this ED1-positive cells increase in the tubulointerstitial area from renal cortex induced by losartan (10.62±1.21 per area of 0.245 $mm^2$). In conclusion, the use of the antioxidant tempol attenuated the increase of fractional sodium and potassium excretions and the infiltration of macrophages and monocytes in the tubulointerstitial area from renal cortex, showing the role of oxidative stress in renal injury in rats exposed to losartan during lactation. **TH-PO368**

**Functional Analysis of the *RET Y791F* Mutation in Renal Hypodyspasia** Cecile Jeanpierre,[1] Lamisse Mansour,[1] Marta Truffi,[1] Sophie Saunier,[1] Corinne Antignac,[1,2] Remi Salomon.[1,3] *[1]Inserm U983, Necker Hospital, Paris, France; [2]Department of Genetics, Necker Hospital, Paris, France; [3]Department of Pediatric Nephrology and MARHEA Reference Center, Necker Hospital, Paris, France.*

The RET receptor tyrosine kinase and its ligand GDNF (glial cell line-derived neurotrophic factor) play pivotal roles during early nephrogenesis and enteric nervous system development. *RET* is the most frequently mutated gene in patients with Hirschsprung (HSCR) disease. It is also a proto-oncogene involved in predisposition to medullary thyroid carcinoma (MTC). While HSCR and MTC are associated with inactivating and activating *RET* mutations respectively, some mutations may have concomitant gain and loss of function, as demonstrated for the C620R mutation associated with both HSCR and MTC.

Although *RET* or *GDNF* deficiency cause renal hypodysplasia (RHD) in mouse models, whether and how these genes play a role in human RHD is still poorly characterized. In a cohort of 99 children with RHD from 12 European countries, we have previously identified a heterozygous *RET* Y791F mutation in 6 patients. This mutation is usually reported in MTC and leads to signaling activation. To investigate if the *RET* Y791F mutation could be deleterious for nephrogenesis, we developed a 3D-culture assay in MDCK cells. We demonstrated that this mutation inhibits branching, suggesting that, similarly to the C620R mutation, it could have activating and inactivating effects on different biological processes.

Interestingly, in one family with branchio-oto-renal syndrome, the Y791F *RET* mutation segregated with two other heterozygous mutations affecting *GNDF* (Y197H) and *EYA1* (G427_V428insG). The sole child with RHD presented with the three mutations, suggesting that the *RET* mutated allele is not sufficient to cause RHD. To characterize the epistatic effect of these mutations, we are currently analysing the effect of the mutated form of GDNF, in combination with the *RET* mutation, on branching induction, as well as the consequence of the *EYA1* mutation on transcriptional regulation of *GNDF*.

**Iron Is Required for Development of Proximal Tubules** Melanie Viltard, Andong Qiu, Rosemary V. Sampogna, Jonathan M. Barasch. *Medicine/ Nephrology, Columbia Presbyterian, New York, NY.*

Iron deficiency is the most common nutritional disorder in the world. It has been reported that during pregnancy, iron deficiency is associated with a higher risk of low birth weight and an increased morbidity and mortality. It is well known that iron is crucial for the growth of any cell, however, the specific steps of development which are controlled by iron are not clear, and embryonic anemia is a confounder. Moreover, because specific defects in vivo have not been determined, in vitro models alone are not directly useful, particularly because the selection and concentration of iron donors for in vitro work is unfounded. The aim of this study was to determine the effects of severe maternal iron deficiency on kidney development. 8 weeks-old C57Bl/6 female mice were fed iron-deficient (2-6ppm) or control diet (220ppm) for 3 weeks before mating up till embryo harvest at E15.5. Iron deficiency was assessed by measuring maternal hematocrit, which fell to 18.5±4.1% compared to 30±3.7%. Fe-deficient embryonic kidneys decreased in size by approximately 40% and embryonic lethality was found. Iron regulatory genes were upregulated in the liver of survivors, evidence of sensing global iron deficiency. However microarray analysis of E15.5 kidneys revealed a surprisingly specific set of down-regulated genes in the kidney; 72% of the downregulated genes were specifically expressed or highly associated with the proximal tubule, and by immunostaining we found that tubules expressing proximal tubule genes megalin, aqp1 and aminopeptidase were markedly decreased in Fe-deficiency compared to control mice. Genes regulating vitamin D production were particularly affected. A 3-D analysis of ureteric bud branching showed that while there were defects in later generations as well as in the formation of the renal pelvis, the general branching program seemed to be maintained. These results suggest that the establishment of the mature proximal tubule required higher levels of iron which result either from higher iron demand or alternatively from poor iron avidity. Hence, iron controls kidney development in a segment specific manner, which is replicated in a parallel set of experiments in vitro.

**Grainyhead-Like 2 (Grhl2) Targets Cldn8 Expression in Mouse Inner Medullary Collecting Duct (mIMCD-3) Cells** Annekatrin Aue,[1,2] Katharina Walentin,[1,2] Friedrich C. Luft,[1,2] Kai M. Schmidt-Ott.[1,2] *[1]Max-Delbrueck Center for Molecular Medicine, Berlin, Germany; [2]Experimental and Clinical Research Center, Charité-Universitaetsmedizin Berlin, Campus Buch, Berlin, Germany.*

In the nephron, the segment-specific molecular composition of the apical junctional complex determines transport characteristics and paracellular permeability. Proteins of the claudin family are central components of the apical junctional complex by determining structural properties of tight junctions. We have previously identified grainyhead-like 2 (Grhl2), a transcription factor of the CP2 family, as a distal nephron-specific regulator of epithelial gene expression. To assess target genes of Grhl2, we used inner medullary collecting duct cells (mIMCD-3) as an in vitro model of the distal nephron. We used transient lentiviral gene transfer of shRNAs targeting Grhl2 to explore the response of target gene expression to knock-down of Grhl2. Using microarrays, we identified on a genome-wide scale transcripts that are - directly or indirectly - regulated by Grhl2. We combined this approach with chromatin immunoprecipitation using a Grhl2 antibody followed by massively parallel sequencing to identify genome-wide Grhl2-DNA association in mIMCD-3 cells. While we had previously reported and confirm here regulation of E-cadherin via an intronic enhancer, we now report binding of Grhl2 to the core promoter of distal nephron-specific claudin Cldn8. While E-cadherin is only moderately down-regulated following Grhl2 knockdown, Cldn8 is down-regulated more markedly. Our data provide additional evidence that Grhl2 regulates molecular components of the epithelial apical junctional complex by directly targeting their expression. Via the control of Cldn8 expression, Grhl2 may participate in the regulation of distal nephron-specific epithelial properties. Moreover, our data provide evidence that Grhl2 binding at the core promoter exhibits stronger effects on gene expression compared with more distant enhancers, which may constitute one potential mechanism of how genome organization and transcription factor expression contribute to nephron segment-specific gene expression.

**Lineage Tracing in Adult Human Kidney: Clonal Analysis of Patches Containing Diverse Epithelial Phenotypes** Sagrario Canadillas,[1,2] Nadine T. Gaisa,[1,3] Rosemary Jeffery,[1] Jan U. Becker,[4] Malcolm R. Alison,[1,5] Nicholas A. Wright,[1,6] Richard Poulsom.[1] *[1]Histopathology Lab., London Research Institute - Cancer Research UK, London, United Kingdom; [2]Research Unit (Renal Section), Reina Sofía Hospital – Cordoba University, Cordoba, Spain; [3]Institute of Pathology, RWTH Aachen University, Aachen, Germany; [4]Institut für Pathologie, Medizinische Hochschule Hannover, Hannover, Germany; [5]Diabetes, BICMS - Queen Mary University of London, London, United Kingdom; [6]Digestive Diseases, BICMS - Queen Mary University of London, London, United Kingdom.*

Epithelial cells within adult nephrons are considered by many to self-renew only by division of differentiated cells, although recent evidence supports a common origin of parietal/podocyte and proximal tubule lineages. We aimed to test whether phenotypically

distinct epithelia have a clonal origin. We identified cell fates by lectin histochemistry and this was combined with detection of patches of cells in which mitochondrial cytochrome c oxidase (CCO1) had become suppressed, putatively by mutation or methylation, and thereby had a common origin. Patches of CCO loss existed in tubular epithelium, and were readily detected in formalin fixed paraffin embedded tissues: they were increasingly common in tissue from more elderly persons, consistent with the age-related accumulation of mitochondrial DNA mutations reported in other organs. Mitochondrial genome sequencing will allow the lineage relationship of cells following different fates to be established in sections of frozen tissue, provided there was no influence of methylation. 3D-reconstruction revealed phenotypic boundaries within CCO-null patches, suggesting that a common adult progenitor provides for maintenance of different epithelial cell types, and that the progeny do not migrate far in tubules. Diverse fates within patches could not occur if division of differentiated cells always produced identical daughters. Each daughter cell may respond to neighbouring cells and stromal cues. Our data so far does not exclude or support the hypothesis that nephron regeneration could be assisted by insertion and expansion of progenitors arriving via the interstitium.

**The Distal Nephron Transcription Factor Grhl2 Regulates Composition of the Apical Junctional Complex In Vivo** Katharina Walentin,[1,2] Annekatrin Aue,[1,2] Michael Bader,[1] Jonathan M. Barasch,[3] Friedrich C. Luft,[1,2] Kai M. Schmidt-Ott.[1,2] *[1]Max-Delbrueck Center for Molecular Medicine, Berlin, Germany; [2]Experimental and Clinical Research Center, Charité-Universitaetsmedizin Berlin, Campus Buch, Berlin, Germany; [3]Department of Medicine, Columbia University College of Physicians and Surgeons, New York.*

Differentiation of epithelial cells and morphogenesis of epithelial tubes or layers is closely linked with the establishment and remodeling of the apical junctional complex, which includes adherens junctions and tight junctions. We show that the distal nephron transcription factor grainyhead-like 2 (Grhl2), an epithelium-specific mammalian homolog of Drosophila grainyhead, is essential for adequate expression of the adherens junction gene E-cadherin and the tight junction gene claudin 4 (Cldn4) in several types of epithelia including gut endoderm, surface ectoderm and otic epithelium. We generate Grhl2 mutant mice carrying an inactivated Grhl2 allele as a result of gene trapping to demonstrate perturbed epithelial differentiation in these compartments of homozygous Grhl2 mutant mice coinciding with the occurrence of anterior and posterior neural tube defects and embryonic lethality between E10.5 and E11.5, which is due to a placental defect. While an analysis of metanephric development in these mice is precluded by embryonic lethality, chorioallantoic branching and labyrinthal development is severely impaired in Grhl2 mutant placentas indicating defective epithelial morphogenesis. On the molecular level, we show that Grhl2 specifically associates with a unique conserved cis-regulatory element localized in intron 2 of the E-cadherin gene. Loss of Grhl2 leads to a specific decrease of histone acetylation at the E-cadherin promoter. Together, our data indicate that Grhl2 is directly involved in epithelium-specific gene expression and, thereby, controls epithelial differentiation and epithelial morphogenesis.

**Calcineurin Regulates the Transcription and Functions of the Urinary Tract Smooth Muscle Cells** Qiusha Guo,[1] Matthew J. Coussens,[2] Feng Chen.[1] *[1]Department of Internal Medicine, Renal Division, Washington University in St Louis, Saint Louis, MO; [2]Sigma-Aldrich, Saint Louis, MO.*

Calcineurin is a $Ca^{2+}$-dependent serine/threonine phosphatase and we have previously shown that the inactivation of Calcineurin in the metanephric and ureteric mesenchyme (progenitors of the ureteral smooth muscle cells) leads to defective pyeloureteral peristalsis and obstructive nephropathy. In this study, we have established immortalized cell lines from the developing ureteral smooth muscle cells from control and mutant mice that have calcineurin deficiency in the ureteral smooth muscles. We have shown that the smooth muscle cells with calcineurin deficiency have higher contractile tension. Such abnormal constractile property may interfere with the highly regulated pyeloureteral peristalsis necessary for effective transfer of urine from the kidney to the bladder. By transcription profiling, we have further identified significant expression alterations in a set of genes caused by Calcineurin deficiency in the mutant cells, including some genes that are closely linked to the development of the urinary system or the functions of smooth muscle cells. Furthermore, we have found that calcineurin deficiency also affected the transcriptional responses to Bmp4 signaling in the ureteral smooth muscle cells. These results suggest that Calcineurin regulates the transcription programs in the ureteral smooth muscle cells. Interruption of such regulation may cause alteration in the contractile property of the smooth muscle cells, contributing to ureteral dysfunction.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO374

**Scribble Is Required for Normal Mouse Kidney and Ureter Development** Sung Tae Kim, Jeffrey H. Miner. *Renal Division, Washington University, St. Louis, MO.*

Scribble (Scrib) is a large, multidomain scaffold protein containing 16 leucine-rich repeats and 4 PDZ domains. Scrib acts together with discs-large (Dlg) and lethal giant larvae (Lgl) at cell-cell junctions to regulate epithelial cell polarity and proliferation. Scrib "Circletail" mutant mice carry a single base insertion (c.3182-3183insC) that causes a frame shift, leading to truncation of the Scrib protein. Homozygous Scrib mutants survive to at least E18.5 and exhibit a severe open neural tube defect and failure of abdominal wall closure. Here we studied the urinary system in Scrib mutant embryos. Scrib is broadly expressed in the epithelial cells of embryonic kidney and ureter. Scrib mutant embryos exhibited abnormally shaped kidneys and very short ureters. Although insertion of the distal ureter into the bladder appeared superficially normal, the tip of the distal ureter showed an abnormal, thinned morphology. Both proximal ureters and proximal tubules were dilated at E18.5, though not at earlier stages. Glomerular development, podocyte architecture, and the expression of E-cadherin, beta-catenin, integrins, and laminins were normal, but PKC-zeta and Pals1 expression were decreased in the collecting ducts of Scrib mutant kidneys. Claudin1 protein level was decreased in both kidney and ureter, while ZO2 localization was abnormal in the mutant ureter. Moreover, Dlg1 localization was abnormal in Scrb mutant kidney and ureter, consistent with a direct interaction between the two proteins in normal tissue. Finally, in the mutant kidney cortex there was an increase in the number of Ki-67-positive cells. Taken together, these results suggest that Scribble plays a role in the development of kidney and ureter by regulating cell polarization, migration, and proliferation and in the organization of cell-cell junctions.

### TH-PO375

**Over-Expression of GTP Cyclohydrolase-I Retards Development of Albuminuria and Ameliorates Renal Injuries in Diabetes** Kengo Kidokoro, Minoru Satoh, Naruya Tomita, Tamaki Sasaki, Naoki Kashihara. *Division of Nephrology and Hypertension, Department of Internal Medicine, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background

Growing evidence indicates that endothelial dysfunction underlies and precedes the developments of diabetic vascular complications, including nephropathy. Increased oxidative stress has been demonstrated to be involved in endothelial nitric oxide (NO) synthase (eNOS) uncoupling via oxidation of tetrahydrobiopterin (BH4), a cofactor required for NO production. We have reported that NAD(P)H oxidase and uncoupled eNOS were major mechanisms of oxidative stress and impaired bioavailability of NO in rat models of diabetes. We hypothesized that transgenic overexpression of GTP cyclohydrolase-1 (GCH1), the rate-limiting enzyme in BH4 biosynthesis, could induce re-coupling of eNOS and ameliorate the development and progression of diabetic renal complications through improvement of NO availability and suppression of oxidative stress as well.

Method and Result

Male diabetic Akita mice were crossed with endothelium-specific GCH1 transgenic mice (GCHtg/AKITA mice) and were bred for 20 weeks. Akita mice developed albuminuria by the age of 12 weeks, whereas urinary excretion of albumin was significantly suppressed in GCHtg/AKITA mice. Productions of reactive oxygen species (ROS) and NO were evaluated by 2',7'-dichlorofluorescein diacetate (ROS marker) and diaminorhodamine-4M (NO marker) with L-arginine using confocal laser microscopy in the kidney tissue. Exacerbated ROS production and diminished bioavailable NO were noted in the glomeruli of Akita mice. Renal mRNA and protein expression of NADPH oxidase components were significantly increased in Akita mice compared to GCHtg/AKITA mice. Biochemical analysis revealed eNOS were uncoupled in Akita mice. On the other hand, in GCHtg/AKITA mice, serum levels of BH4 were preserved and glomerular eNOS were re-coupled.

Conclusion

These data indicate that development of albuminuria in diabetic mice is associated with glomerular endothelial dysfunction caused by reduced BH4 and eNOS uncoupling. Increased endothelial BH4 biosynthesis by transgenic GCH1 overexpression corrects eNOS uncoupling and reduces albuminuria.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO376

**Involvement of Post-Transcriptional Regulation of Tsc-22 by Ybx1, a miR-216a Target, and the E-box Activator Tfe3 in TGF-β Induced Collagen Expression in Mesangial Cells** Mitsuo Kato, Sumanth Putta, Mei Wang, Guangdong Sun, Linda L. Lanting, Rama Natarajan. *Diabetes, Beckman Research Institute of City of Hope, Duarte, CA.*

Transforming growth factor-beta1 (TGF-b) induces extracellular matrix proteins and fibrotic events in kidney cells such as glomerular mesangial cells (MC) and plays a role in the pathogenesis of Diabetic Nephropathy (DN). Although the post-transcriptional regulation of key genes has been implicated in these events, details are not fully understood. Here we show that TGF-b downregulates Ybx1, a target of microRNA-216a (miR-216a) and an RNA binding protein regulating RNA stability and translation. Conversely, miR-216a levels were increased in glomeruli of diabetic mice and in TGF-b-treated mouse MC (MMC). miR-216a inhibited the expression of Ybx1 through its 3'UTR, suggesting that Ybx1 is a direct target of miR-216a. Phosphorylation of Ybx1 by Akt, a key mechanism of inhibition of the translational repressor activity of Ybx1, was also observed in MMC treated with TGF-b. Ybx1 was colocalized with processing bodies (P-bodies) in MMC and formed a ribonucleoprotein complex with its target *Tsc-22* mRNA. Ybx1-Tsc-22 mRNA interaction was reduced by TGF-b, as well as by miR-216a or Ybx1 shRNA, but increased by miR-216a inhibitor. Tsc-22 protein levels were enhanced by TGF-b due to reduction in Ybx1 levels. Chromatin immunoprecipitation (ChIP) assays revealed increased occupancies of Tsc-22 and Tfe3, an E-box activator, on far-upstream enhancer E-boxes of collagen type I alpha-2 (Col1a2) by TGF-b treatment. Co-IP assays confirmed, for the first time, the physical interaction of Tsc-22 and Tfe3 in TGF-b-treated MMC. Since both Tsc-22 and Tfe3 have typical leucine zipper (LZ) structures, these two proteins may interact with each

other through these LZ and enhance Col1a2 expression through far-upstream enhancer E-boxes. These results demonstrate that post-transcriptional regulation of Tsc-22 mediated through Ybx1, a target of miR-216a, along with Tsc-22 interactions with the E-box activator Tfe3 at enhancer E-boxes, constitute a key novel mechanism of TGF-b-induced Col1a2 expression in MMC related to the pathogenesis of DN.

**Acceleration of Diabetic Glomerulopathy in db/db Mice in Chronic Hypoxia** Naoki Takahashi,[1] Hideki Kimura,[1] Kazuko Kamiyama,[1] Tomomi Kurose,[2] Hidehiro Sugimoto,[2] Toshio Imura,[2] Daisuke Mikami,[1] Kenji Kasuno,[1] Haruyoshi Yoshida.[1] *[1]Division of Nephrology, Fukui University, Fukui, Japan; [2]Division of Clinical Laboratories, Fukui University Hospital, Fukui, Japan.*

Background: Although hypoxia in the tubulointerstitial area has been considered one of the key mediators of disease progression, the role of hypoxia for diabetic glomerulopathy has not been elucidated.

Purpose: We examine whether chronic hypoxia induces the characteristic severe diabetic glomerulosclerosis (including nodular formation and microaneurysms) in db/db mice.

Methods: 8 w.o. male db/db mice were bred in a normobaric hypoxic chamber (12%$O_2$). The hypoxic group (H-group) was kept in this chamber for 16 weeks (n=4), the hypo-normoxic group (HN-group) was kept in this chamber for 12 weeks prior to 4-week normoxia (n=3) and the control group (N-group) was bred in room air (n=3). Mice were sacrificed at 24 w.o. for histological analysis.

Results: The antecedent experiments on blood and urine chemistry with 8-10 mice in each group have shown that chronic hypoxia induced prominent erythrocytosis and accelerated increase of albuminuria. However, hypertension and increases of serum Cr and UN were not observed. In N-group the moderate diffuse mesangial sclerosis was observed. In H-group hypertrophic glomeruli with microaneurysms were observed and the tuft area significantly increased in comparison to N-group (108700±6400 vs. 87700±2600 pixels, $p<0.01$). In HN-group the nodular formation was observed. Immunohistologically, the percentage of CD34 positive area in glomeruli was significantly decreased in H-group in comparison to N-group (9.4±2.7 vs. 17.0±2.2%, $p<0.01$). The number of WT-1 positive cells were also significantly decreased in H-group in comparison to N-group (1.0±0.1 vs. 1.5±0.1, $P<0.01$). The number of podocyte had negative correlations to the degree of microaneurysms ($r=-0.26$), nodular formation ($r=-0.35$), respectively ($p<0.01$).

Conclusion: These results suggest that chronic hypoxia may cause podocyte loss and microaneurysms due to endothelial dysfunction, and that hyperglycemia with preconditioned endothelial injury by hypoxia may induce the nodular formation in db/db mice.

**The Succinate Receptor GPR91 Controls Cell and Mitochondrial Metabolism and Signaling of Diabetic Nephropathy** James L. Burford, Jahoon Koo, Janos Peti-Peterdi. *Dept. of Physiology, University of Southern California, Los Angeles, CA.*

The succinate receptor GPR91 is a newly established direct link between hypoxia/hyperglycemia and the activation of the renin-angiotensin system (RAS). In contrast to the proximal tubule (PT), cells of the distal nephron, connecting segment (CNT) and collecting duct (CD) have a high rate of glycolysis and mitochondrial ROS production. Also, the CNT-CD is the major source of (pro)renin in diabetes. Since renal GPR91 expression is the highest in the CNT-CD, we hypothesized that GPR91 signaling may be an important determinant of cell and mitochondrial metabolism and consequently a trigger of diabetes pathology. Using multiphoton microscopy we directly visualized mitochondrial membrane potential ($\Psi$)in vivo using MitoTracker-Red in distal (D) and proximal (P) tubules in control (C) and STZ-diabetic (DM) wild type (WT) and GPR91-/- mice (n=4). The D/P ratio of MitoTracker-Red fluorescence intensity was 2.3±0.2 in C WT, 1.7±0.1 in C GPR91-/-, 2.6±0.2 in DM WT, and 1.6±0.1 in DM GPR91-/- mice indicating significantly higher $\Psi$ in D versus P nephron segments, which is further increased in DM and is dependent on GPR91. Consistent with these findings, immunoblot analysis of whole kidney homogenates showed a 25% reduction in GLUT-1 and GAPDH expression in both C and DM GPR91-/- versus WT kidneys. Immunofluorescence staining of a-SMA, a marker of epithelial-mesenchymal transformation, VEGF, and MCP-1 were most intense in the CNT-CD and their expression was entirely GPR91-dependent in DM. Immunoblot analysis confirmed significantly elevated levels of TGF-beta, the key mediator of tissue fibrosis in DM (2.1±0.2) compared to C (normalized to 1), which was almost completely abolished in DM GPR91-/- mice (1.3±0.2). In conclusion, GPR91 signaling is a novel feedback mechanism between mitochondrial and cell metabolism and may explain the high glycolytic and mitochondrial activity in D versus P nephron segments. In DM, the increased glucose uptake and glycolysis via succinate accumulation may overactivate GPR91 and trigger pathological signaling particularly in cells of the distal nephron-CD that ultimately results in diabetic nephropathy.

**TH-PO379**

**Glomerular Mitochondrial Dysfunction and Oxidative mtDNA Damage Are Hallmarks of Susceptibility for Podocyte Depletion and Diabetic Nephropathy** Gabriella Casalena, Ilse S. Daehn, Haiying Qi, Erwin P. Bottinger. *Nephrology/Medicine, Mount Sinai School of Medicine, New York, NY.*

Susceptibility to diabetic nephropathy (DN) is in part determined by genetic factors. Oxidative stress and mitochondrial dysfunction are key factors promoting DN. Our previous transcriptomic analysis suggested that podocyte depletion, a hallmark of progressive DN, may be associated with oxidative phosphorylation and mitochondrial dysfunction in diabetic DBA/2J (D2) inbred mice with susceptibility to DN, but not in DN-resistant C57BL/6J (B6) inbred mice [ASN 2009, abstract: 554886].

HYPOTHESIS: Genetic susceptibility to podocyte depletion and DN in mice correlates with mitochondrial dysfunction and oxidative stress.

PURPOSE: To examine mitochondrial function and mitochondrial DNA (mtDNA) oxidation in diabetic and non-diabetic DN-resistant B6 and DN-susceptible D2 inbred mouse strains.

METHODS: Type I diabetes was induced in D2 and B6 mice with multiple, low-dose streptozotocin(STZ) injections. Glomerular and tubular fractions were collected from diabetic and non-diabetic control animals at days 1, 8 and 24 after the onset of hyperglycemia.

RESULTS: Blood glucose levels were comparable (> 400 mg/dl) between diabetic B6 and D2 mice. Uncoupled (FCCP-stimulated) oxygen consumption was significantly reduced at day 8 of hyperglycemica in glomeruli from STZ-D2 mice, but not in STZ-B6 mice, when compared to control mice. Oxidative DNA damage was quantitated by QPCR in mtDNA and nuclear DNA (nDNA). mtDNA lesions were significantly increased in day 1 STZ-D2, and further increased by 10-fold in day 24 STZ-D2 mice, compared to STZ-B6 mice, whilst oxidation of nDNA was not detected in either strain. Increased mtDNA damage accumulation, observed specifically in STZ-D2 mice, was confirmed by increased 8-oxoguanine in STZ-D2 mice compared to STZ-B6 mice.

CONCLUSIONS: Functional in vivo studies demonstrate that mitochondrial dysfunction and oxidative mtDNA damage are detectable in early-onset T1D specifically in inbred DN-susceptible D2 mice with diabetes-induced podoycte depletion, but not in DN-resistant B6 mice without podocyte depletion.

**Altered Endothelial-Podocyte Crosstalk Mediates Albuminuria in Diabetic eNOS$^{-/-}$ Mice** Darren A. Yuen,[1] Yanling Zhang,[1] Kathryn E. White,[2] Kim Connelly,[1] Darren J. Kelly,[3] Takamune Takahashi,[4] Raymond C. Harris,[4] Andrew Advani.[1] *[1]Department of Medicine, St. Michael's Hospital, Toronto, ON, Canada; [2]EM Research Services, Newcastle University, Newcastle upon Tyne, United Kingdom; [3]Department of Medicine, St. Vincent's Hospital, Melbourne, Australia; [4]Department of Medicine, Vanderbilt University School of Medicine, Nashville, TN.*

Endothelial dysfunction may predispose to albuminuria in diabetic nephropathy through direct effects on glomerular endothelial cells or crosstalk with neighbouring podocytes. In experimental diabetes, anti-angiogenic therapy may improve renal function despite clinical experience to the contrary. The present study sought to unravel the relationship between endothelial dysfunction, podocyte injury and albuminuria in diabetic eNOS$^{-/-}$ mice, a model characterized by abnormal angiogenesis. Fluorescent microangiography demonstrated glomerular capillary volume was increased 2-fold in streptozotocin (STZ)-diabetic eNOS$^{-/-}$ mice in comparison to wildtype (cap. vol. [x10$^4$µm$^3$], control 5.0±0.5, STZ-eNOS$^{-/-}$ 11.4±1.9 [$p<0.01$]). Treatment with the VEGFR-2 inhibitor, vatalanib caused an increase in BP and AER in wildtype, while STZ-eNOS$^{-/-}$ mice had heavy albuminuria that was unaffected by vatalanib (AER [µg/24h], vehicle 923±225, vatalanib 891±252), even though VEGFR-2 inhibition normalized capillary volume (cap. vol. [x10$^4$µm$^3$], 5.4±0.9 [$p<0.01$]). Increased albumin excretion occurred in STZ-eNOS$^{-/-}$ mice as early as 2 weeks after diabetes induction (AER [µg/24h], eNOS$^{-/-}$ 87±12, STZ-eNOS$^{-/-}$ 566±57 [$p<0.001$]), when endothelial morphology was preserved. At this timepoint, there was significant podocyte injury including vacuoles and electron dense deposits with areas of foot process fusion and effacement. Similar early podocytopathy was observed in db/dbeNOS$^{-/-}$ mice. These observations indicate that a) the primary cause of albuminuria in diabetic eNOS$^{-/-}$ mice is a podocytopathy that occurs with the onset of hyperglycemia and b) normalization of glomerular capillary growth in diabetes does not restore permselectivity. Altered endothelial-podocyte crosstalk is likely to be a major mechanism by which endothelial injury causes albuminuria in diabetes.

**Lipid Phosphatase SHIP2 Downregulates Insulin Signaling and Promotes Apoptosis in Podocytes** Mervi E. Hyvonen,[1,2] Pauliina H. Saurus,[1] Anita A. Wasik,[1] Eija Heikkila,[1] Marika Havana,[1] Moin Saleem,[3] Harry B. Holthofer,[1,4] Sanna H. Lehtonen.[1] *[1]Haartman Institute, University of Helsinki, Finland; [2]Hospital for Children and Adolescents, University of Helsinki, Finland; [3]Southmead Hospital, University of Bristol, United Kingdom; [4]Dublin City University, Ireland.*

Podocyte injury plays an important role in the development of diabetic nephropathy. Podocytes are insulin responsive cells and develop insulin resistance, but the mechanisms are not known. Considering the finding that insulin resistance associates with proteinuria in diabetic patients, we hypothesize that disturbances in insulin response can affect podocyte function and aimed to investigate the regulation of insulin signaling in podocytes. We found by yeast-two-hybrid screening of a rat glomerular library that CD2AP, an adaptor protein essential for the glomerular filtration barrier, binds to SH2-domain-containing inositol polyphosphate 5-phosphatase 2 (SHIP2), a negative regulator of insulin signaling and a molecule associated with metabolic syndrome. The in vivo interaction of CD2AP and SHIP2 was confirmed by co-immunoprecipitation showing that CD2AP binds to the non-tyrosine phosphorylated form of SHIP2. By pull-down assay we found that the strongest interaction with SHIP2 is mediated by the 3rd SH3 domain of CD2AP. In order to investigate the role of SHIP2 in the regulation of insulin signaling in podocytes, we overexpressed SHIP2 in cultured human podocytes and analyzed Akt activation in response to insulin. In SHIP2 overexpressing podocytes Akt was not activated in response to insulin stimulation, and also, SHIP2 overexpression induced apoptosis in differentiated podocytes. We found that SHIP2 localizes in podocytes, and is upregulated in glomeruli of obese Zucker rats and diabetic db/db mice, animal models of insulin resistance and type 2 diabetes. These results indicate that SHIP2 downregulates insulin signaling in podocytes and promotes podocyte apoptosis. The upregulation of SHIP2 in Zucker rat glomeruli prior to the onset of proteinuria shows that it is not a secondary effect to the podocyte injury but rather might contribute to the development of the disease.

**TH-PO382**

**TNF-α Affects Podocyte Expression of Collagen IV and Integrin α3: Role of PI3K and MCP-1** Jingyi Fan,[1] Choon Hee Chung,[2] Eun-Young Lee,[3] Petr Pyagay,[1] Amy Wang,[1] Sheldon C. Chen.[1] *[1]Medicine/Nephrology, Northwestern University, Chicago, IL; [2]Internal Medicine, Yonsei University, Wonju, Korea; [3]Internal Medicine, Soon Chun Hyang University, Cheonan, Korea.*

The inflammatory cytokine, tumor necrosis factor-α (TNF-α), is believed to play a role in diabetic kidney disease, but specific effects of TNF-α regarding nephropathy-relevant parameters have not been studied in the podocyte. Cultured mouse podocytes treated with recombinant TNF-α showed a surprisingly robust increase (~900%) in the secretion of monocyte chemoattractant protein-1 (MCP-1), induced in a dose- and time-dependent manner. The signaling mechanism partly relies on the phosphatidylinositol 3-kinase (PI3K) pathway but does not involve the ERK or p38 mitogen-activated protein kinase (MAPK) pathways. The NF-κB transcription factor may be involved, based on the successful prevention of TNF-α-induced MCP-1 with the specific inhibitors MG132 and CAPE, but the p65 subunit of NF-κB did not appear to be involved, because shRNA knockdown of p65 failed to suppress the stimulation of MCP-1. Other TNF-α effects on podocyte biology included an increase in collagen IV production and a decrease in integrin α3 expression. The collagen IV increase was preventable by an inhibitor of the MCP-1 receptor, CCR2, demonstrating that the MCP-1/CCR2 axis plays an intermediary role between TNF-α and collagen IV, but not for integrin α3. Furthermore, TNF-α and MCP-1 were assayed in the *db/db* mouse model of type 2 diabetic nephropathy. Though TNF-α and MCP-1 levels in the plasma or kidney parenchyma were unchanged vs. control after eight weeks of diabetes, the urinary excretions of TNF-α and MCP-1 were both significantly elevated in the *db/db* mice. Both urinary measures were highly correlated with the severity of diabetic albuminuria.

We posit that podocytes, exposed to elevated TNF-α concentrations in the urinary space, increase collagen IV and decrease integrin α3 expression, potential contributors to glomerular basement membrane thickening and podocyte detachment. Collagen IV production is stimulated by TNF-α-induced MCP-1 acting on its CCR2 receptor, while MCP-1 itself is partially signaled by the PI3K pathway.

**Glucose-Changed Bioenergetic Profiles in Podocytes** Nicole Stieger,[1] Kirstin Worthmann,[1] Stefan Engeli,[2] Hermann G. Haller,[1] Mario Schiffer.[1] *[1]Division of Nephrology, Medical School Hannover, Hannover, Germany; [2]Institute of Clinical Pharmacology, Medical School Hannover, Hannover, Germany.*

Background:Diabetic nephropathy is the most common cause of chronic renal failure in the industrialized countries. Depletion of podocytes plays an important role in progression of diabetic glomerulopathy.Various factors in the diabetic milieu lead to serious podocyte stress driving the cells towards cell cycle arrest, hypertrophy,detachment and apoptosis. Mitochondria are responsible for glucose metabolism and energy supply in podocytes. Recent studies indicate that mitochondrial dysfunction is a key factor in diabetic nephropathy.In the present study we investigated the glucose metabolism of podocytes under diabetic conditions.

Methods:The oxygen consumption rates(OCR) of murine podocytes were measured using the Seahorse Bioscience XF24 Extracellular Flux Analyzer. Mitochondrial function was characterized by addition of respiratory chain inhibitors. In additional experiments either Glucose or Insulin or both compounds were injected to measure the acute effect on podocyte metabolism. Cells were cultured either permanently under high glucose conditions or exposed to high glucose for 48 h.

Results:We compared the bioenergetic profiles of podocytes under normal, high glucose or mannitol conditions. 48 h high glucose exposure shows no effect on the OCR rates in comparison to the mannitol control. In contrast, cells cultured permanently in high glucose showed significantly increased baseline rates compared to the mannitol controls and dependent on this fact there was major decrease after the injection of oligomycin. Interestingly, the cells under high glucose condition showed an increase in OCR rates after FCCP injection corresponding to a higher mitochondrial oxidative capacity. Rotenone reduced both OCR rates to the same level indicating no changes in non-mitochondrial respiration. Normalisation of the hyperglycaemic milieu back to normal medium for 48 h did not cause any changes in OCR in comparison to the corresponding chronic profile.

Conclusion:In summary, we provide evidence that the diabetic milieu changes glucose metabolism and mitochondrial function in podocytes.

**TH-PO384**

**TRB3 Is Stimulated in Diabetic Kidneys, Regulated by the ER Stress Marker CHOP and Is a Suppressor of Podocyte MCP-1** Robyn A. Cunard,[1,2,3] Elizabeth Morse,[2] Jana Schroth,[3] Donald Pizzo,[3] Shinichi Okada,[3] Satish P. Ramachandrarao,[3] Volker Vallon,[1,2,3] Kumar Sharma.[1,2,3] *[1]Research and Nephrology-Hypertension, Veterans Affairs San Diego Healthcare System, San Diego, CA; [2]Veterans Medical Research Foundation, San Diego, CA; [3]Medicine, University of California, San Diego, La Jolla, CA.*

Diabetic Nephropathy is the leading cause of renal failure in the United States, and it is associated with podocyte loss and defective podocyte function. TRB3 is a kinase-like protein, that modulates cellular signaling pathways and transcriptional events. Our studies demonstrate that TRB3 expression is increased in the kidneys of Type 1 and Type 2 diabetic mice. TRB3 is expressed in conditionally immortalized podocytes, and its expression is enhanced by reactive oxygen species (ROS) such as H2O2 and superoxide anion (via the xanthine/xanthine oxidase reaction), as well as the free fatty acid (FFA), palmitate. C/EBP homologous protein (CHOP) is a transcription factor that is associated with the Endoplasmic Reticulum (ER) Stress Response and we provide further evidence that CHOP expression increases in diabetic mouse kidneys. CHOP expression is also enhanced in podocytes treated with ROS and FFA and chromatin immunoprecipitation studies reveal that ROS augment recruitment of CHOP to the proximal TRB3 promoter. MCP-1/CCL2 is a chemokine that contributes to the inflammatory injury associated with diabetic nephropathy and we demonstrate that TRB3 can inhibit basal and stimulated podocyte production of MCP-1. In summary, enhanced ROS and/or FFA associated with the diabetic milieu induce podocyte CHOP and TRB3 expression. Because TRB3 inhibits MCP-1, manipulation of TRB3 expression could provide a novel therapeutic approach in diabetic kidney disease.

**TH-PO385**

**Nicorandil Ameliorates Glomerular and Tubulointerstitial Injury in an Advanced Diabetic Nephropathy Mouse Model** Katsuyuki Tanabe, Wataru Kitagawa, Christopher J. Rivard, Richard J. Johnson, Takahiko Nakagawa. *Division of Renal Diseases and Hypertension, University of Colorado Denver, Aurora, CO.*

Diabetic nephropathy is one of the major complications in patients with diabetes and associated with end-stage renal diseases as well as cardiovascular diseases. Recently, we have reported that diabetic endothelial nitric oxide synthase (eNOS) knockout mice showed severe renal lesions which resemble human diabetic nephropathy, suggesting endothelial nitric oxide deficiency might be a key factor to cause the progression of advanced diabetic nephropathy. Nicorandil is well-known anti-anginal drug. This agent not only releases NO but also open ATP-dependent K channel, leading to the improvement of endothelial dysfunction. Here, we examined if nicorandil slows the progression of advanced diabetic nephropathy in our mouse model. Eight week-old male eNOS-KO mice received intraperitoneal injections of 50mg/kg of streptozotocin for 5 consecutive days to induce diabetes. Nicorandil was administered at the dosage of 30mg/kg for 8 weeks. Urinary nitrate+nitrite and cyclic GMP excretion were significantly increased by nicorandil administration. While it did not lower blood pressure, nicorandil significantly ameliorated microalbuminuria (0.57±0.12 vs 0.17±0.10, μg/mgCre) and urinary 8-OHdG excretion (7.9±1.0 vs. 6.3±1.0 μg/mgCre). Likewise, mesangiolysis and glomerulosclerosis were significantly inhibited by nicorandil treatment. Immunohistochemistry demonstrated that mesangial deposition of type IV collagen, interstitial accumulation of type III collagen, and glomerular/tubulointerstitial F4/80-positive monocyte/macrophage infiltration were significantly prevented by nicorandil treatment. These results indicate that nicorandil can be a novel therapeutic option against advanced diabetic nephropathy in the presence of severe endothelial dysfunction.

**Purinergic $P2X_7$ Receptors Are Implicated in the Macrophage Recruitment and TGF-β Secretion of Diabetic Nephropathy in Mice** Maurilo Leite, Marfiza Meirelles, Claudio Bernardazzi, Husten Da Silva Carvalho, Andre Barreira, Christina Maeda Takiya. *Universidade Federal do Rio de Janeiro, Brazil.*

Purinergic $P2X_7$ receptors ($P2X_7R$) are involved in the pathogenesis of several kidney diseases. In the present study we attempted to investigate the role of $P2X_7$ activation on the pathogenesis of diabetic nephropathy in streptozotocin (STZ)-treated mice. Four groups of mice included wild type (WT) C57/Bl6 (group 1), $P2X_7$ knockout (-/-) (group 2), both treated with STZ 60 mg/kg/day (5 days); Groups 3 and 4, WT and $P2X_7$(-/-), respectively, were treated with vehicle for STZ (citrate buffer). The STZ-treated mice were kept with serum glucose between 300-600 mg/dl. The mice were sacrificed after 20 weeks of STZ induction or vehicle, the urine collected for albumin/creatinine (alb/cr), and the kidneys prepared for histology, immunostaining for macrophages (F4/80) and TGF-β, PCR and Western blot analyzes for $P2X_7R$ and interleukin-1β (IL-1β). Results: There was no statistical difference of alb/cr (mg/mg) between groups 1 and 2, but both were higher than groups 3 and 4 (14.4±4.7; 13.6±4.4 vs 0.8±0.7 and 0.7±0.6, respectively, P<0.05). The mean glomerular volume ($\mu m^3 x 10^{-3}$) was higher in group 1 compared to 2 (145.4±21.8 vs 128.7±17.4, P<0.001). Interstitial macrophages count (cells/field) was higher in group 1 compared to 2 (16.5±9.3 vs 6.7±4.6, respectively, P<0.05), whereas groups 3 and 4 were lower than groups 1 and 2 (0.2±0.4 and 0.6±0.8, P<0.001). The surface density of TGF-β staining (% of total surface) was higher in group 1 compared to 2 (37.2±5.1 vs 12.4±3.6, P<0.001), both higher than 3 and 4 (0.7±0.1 and 0.6±0.1, P<0.001, relative to 1 and 2). PCR and Western blot analyzes for $P2X_7R$ and IL-1β revealed mRNA for IL-1β only in group 1. Conclusion: $P2X_7R$(-/-) mice showed less glomerular lesion, less interstitial macrophages and lower expression of TGF-β in renal tissue. Neither the expression of $P2X_7R$, nor its mRNA, could be detected at this time. However, IL-1β mRNA, but not the protein, was detected only in wild type mice. These results constitute evidence that $P2X_7R$ activation and downstream IL-1β signaling are partly involved in the pathogenesis of diabetic nephropathy.

Disclosure of Financial Relationships: nothing to disclose

**R3h-Domain Containing Like Protein Is a Novel Regulator of Glomerular Basement Membrane** Takahiro Ishikawa,[1] Minoru Takemoto,[2] Yoshihiro Akimoto,[3] Kunimasa Yan,[4] Karl Tryggvason,[5] Christer Betsholtz,[5] Koutaro Yokote.[1,2] *[1]Department of Clinical Cell Biology and Medicine, Chiba University Graduate School of Medicine, Chiba, Japan; [2]Division of Diabetes, Metabolism and Endocrinology, Chiba University Hospital, Chiba, Japan; [3]Department of Anatomy, Kyorin University School of Medicine, Tokyo, Japan; [4]Department of Pediatrics, Kyorin University School of Medicine, Tokyo, Japan; [5]Department of Medical Biochemistry and Biophysics, Division of Matrix Biology, Karolinska Institutet, Stockholm, Sweden.*

We have identified R3h-domain containing like (R3hdml) as a podocytes specific gene. This study aimed to elucidate the function of the R3hdml protein in the glomeruli. In order to investigate the function of the R3hdml protein in vivo, we created R3hdml null mice. In addition, we used cultured podocytes to investigate the functions of R3hdml. Light microscopic analysis revealed that the R3hdml null mice had no observable glomerular developmental defects. However, an electron microscopic study revealed thickening of the glomerular basement membrane (GBM) and effacement of the podocyte foot processes. We examined the alteration of the GBM components and found that the expression of fibronectin mRNA in the glomeruli of the R3hdml null mice was significantly higher than that in the glomeruli of the controls. Because the fibronectin gene is one of the target genes of the transforming growth factor-ß (TGF-ß), we examined the effect of TGF-ß on fibronectin expression in the presence and absence of R3hdml in the cultured podocytes. When the expression of R3hdml was knocked down by siRNA in cultured podocytes, the expression of fibronectin, which was induced by TGF-ß, was significantly increased compared to the controls. The expression of R3hdml was also regulated by TGF-ß. To conclude, we identified R3hdml as a novel podocyte-specific protein that might play a role in the regulation of GBM possibly through the modulation of TGF-ß signaling.

**TH-PO388**

**EP1 Receptor Deletion in Mice; Implications for Diabetic Nephropathy** Jean Francois Thibodeau,[1,2] Chris R. Kennedy.[1,2] *[1]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]Cellular & Molecular Medicine, University of Ottawa, Ottawa, ON, Canada.*

Prostaglandin (PG) levels and expression of their receptors is enhanced in various clinical and experimental kidney diseases, including diabetic nephropathy (DN). $PGE_2$, the most abundant renal PG signals via its E-Prostanoid (EP)1-4 receptors, activating G-protein coupled signaling pathways. However, the functional relevance of EP receptors in kidney disease remains unclear. To this end, we employed gene-targeted EP1 receptor knockout male mice ($EP1^{-/-}$) on a FVB/N background and induced DN using either the low-dose streptozotocin (STZ) model of type 1 diabetes (5 day i.p., 50 mg/kg bw; Na-citrate as vehicle) or by breeding $EP1^{-/-}$ mice with transgenic OVE26 type 1 diabetic mice with β-cell calmodulin overexpression. Mice were followed for 16 weeks. Although induction of STZ-diabetes was without effect on systolic blood pressure, both STZ-wt and STZ-$EP1^{-/-}$ mice became equivalently hyperglycaemic (>35 mmol/L) and were hyperfiltering to similar levels at 16 weeks post-STZ, as measured by FITC-inulin clearance (STZ-wt, 26.1 ± 3.5 vs wt, 10.3 ± 2.1 $\mu l.min^{-1}.g.bw^{-1}$ , p<0.01; STZ-$EP1^{-/-}$, 28.6 ± 3.9 vs $EP1^{-/-}$, 11.1 ± 2.5 $\mu l.min^{-1}.g.bw^{-1}$, p<0.01). However, consistent with our previously reported urine concentrating defect in $EP1^{-/-}$ mice, STZ-$EP1^{-/-}$ mice produced a significantly more dilute urine than STZ-wt mice (STZ-wt, 1506 ± 96 vs STZ-$EP1^{-/-}$, 1170 ± 117 mOsm/kg.H20, p<0.01) that was accompanied by greater polyuria (STZ-wt, 24 ± 2 vs STZ-$EP1^{-/-}$, 32 ± 2 ml/24h, p<0.01). Importantly, a diabetes-induced glomerular filtration barrier defect was more prominent in STZ-$EP1^{-/-}$ mice (STZ-wt, 164 ± 9 vs wt, 33 ± 9; STZ-$EP1^{-/-}$: 341 ± 183 vs $EP1^{-/-}$, 32 ± 7 µg albumin/mg creatinine). Albuminuria was likewise exacerbated in $EP1^{-/-}$ OVE26 mice (OVE26: 443±139 vs OVE26 $EP1^{-/-}$3301±1119 µg albumin/mg creatinine; p<0.05). Lastly, DN-induced renal hypertrophy was more severe in STZ-$EP1^{-/-}$ mice as compared to STZ-wt (STZ-wt, 20.5 ± 0.9 vs STZ-$EP1^{-/-}$, 23.1 ± 0.6 mg/kg bw p<0.05). Taken together, these data suggest a protective role for the PGE2 EP1 receptor in the context of early DN progression.

**New Mouse Model for Diabetic Kidney Disease Expressing Human CD36 in Tubular Epithelial Cells** Seon-Ho Ahn,[1,2] Katalin Susztak.[1] *[1]Nephrology/ Internal Medicine, Albert Einstein College of Medicine, Bronx, NY; [2]Nephrology/ Internal Medicine, Wonkwang University College of Medicine & Hospital, Iksan, Jeonbuk, Korea.*

Diabetic nephropathy (DN) is one of the major causes of end-stage renal disease. It has been proposed that CD36, which is a scavenger receptor and fatty acid transporter, plays an important role in development of diabetic complications. Hyperglycemia regulates translation efficiency of CD36 in human macrophages and atherosclerotic vascular lesions, stimulating enhanced fatty acid uptake. We previously reported decreased CD36 expression in diabetic mouse kidneys, while its expression is increased in patients with diabetic nephropathy. Mechanistic studies showed that CD36 mediates tubule cell apoptosis and damage in diabetic kidneys. We hypothesized that such species specific differences could be responsible for the resistance of mice to diabetic tubular damage and progressive diabetic kidney disease. To test this concept, we developed a new mouse with tubule specific inducible expression of CD36. We generated mice where CD36 expression is under the control of the 'Tet'O operator. We crossed these animals with the Pax8 rtTA mouse, expressing the tetracycline transactivator in the renal tubules, and animals were placed on food containing doxycycline at 4 weeks of age. Out of the four founder lines, we found increased CD36 mRNA expression in 3 lines and increased protein expression in 2 transgenic lines. Gene expression studies indicated key differences in levels of lipid and glucose metabolic enzymes. We found a two-fold decrease in fatty acid metabolizing enzyme, medium-chain acyl CoA dehydrogenase, while the expression of key transcriptional regulator, PPAR gamma was increased four-fold in animals with increased expression of CD36.

In conclusion, it is expected that inducible transgenic humanized CD36 expression model will help to understand the role of CD36 and lipid metabolism in diabetic kidney disease.

**SOD1, but Not SOD3, Deficiency Causes Diabetic Nephropathy through Reduction of Glomerular Endothelial Nitric Oxide in C57BL/6-*Ins2$^{Akita}$* Mice** Hiroki Fujita,[1,2] Hiromi Fujishima,[1] Keiko Takahashi,[2] Matthew D. Breyer,[2] Raymond C. Harris,[2] Yuichiro Yamada,[1] Takamune Takahashi.[2] *[1]Division of Endocrinology and Metabolism, Akita University Graduate School of Medicine, Akita, Japan; [2]Division of Nephrology, Vanderbilt University Medical Center, Nashville, TN.*

Superoxide dismutase (SOD) is a major defender against superoxide. We have reported that renal SOD1 (cytosolic CuZn-SOD) and SOD3 (extracellular CuZn-SOD) isoenzymes are remarkably down-regulated in KK/Ta-*Ins2$^{Akita}$* diabetic mice, which exhibit progressive diabetic nephropathy (DN), but not in DN-resistant C57BL/6- *Ins2$^{Akita}$* (B6-Akita) diabetic mice (JASN 20: 1303, 2009). To determine the role of SOD1 and SOD3 in DN, we generated SOD1, SOD3, and SOD1/3 double knockout B6-Akita mice and investigated their renal phenotype up to the age of 20 weeks. Increased glomerular superoxide levels were observed in $SOD1^{-/-}$ $SOD3^{+/+}$ and $SOD1^{-/-}$ $SOD3^{-/-}$ B6-Akita mice but not in $SOD1^{+/+}$ $SOD3^{-/-}$ B6-Akita mice. In parallel with glomerular superoxide excess, $SOD1^{-/-}$ $SOD3^{+/+}$ and $SOD1^{-/-}$ $SOD3^{-/-}$ B6-Akita mice exhibited increased urinary albumin levels and histopathologically progressive mesangial expansion, yet the severity of DN did not differ in these two groups. Significant differences were not observed in blood glucose, blood pressure, body weight, kidney weight or GFR among $SOD1^{+/+}$ $SOD3^{+/+}$, $SOD1^{-/-}$ $SOD3^{+/+}$, $SOD1^{+/+}$ $SOD3^{-/-}$, and $SOD1^{-/-}$ $SOD3^{-/-}$ B6-Akita mice. Interestingly, glomerular endothelial nitric oxide (NO) levels were markedly reduced in $SOD1^{-/-}$ $SOD3^{+/+}$ and $SOD1^{-/-}$ $SOD3^{-/-}$ B6-Akita mice, indicating that excessive superoxide scavenged NO. In conclusion, the present study demonstrates that deficiency of SOD1 rather than SOD3 predominantly reduces renal defense capacity against superoxide and accelerates diabetic renal injury, possibly via endothelial dysfunction in DN-resistant mice.

**TH-PO391**

**(Pro)renin Receptor – COX-2 Interaction in Diabetes Induced Podocyte Injury** Huifang Cheng,[1] Xiaofeng Fan,[1] Gilbert W. Moeckel,[2] Raymond C. Harris.[1] *[1]Nephrology/Medicine, Vanderbilt University Medical School, Nashville, TN; [2]Pathology, Yale University Medical School, New Haven, CT.*

Our animal studies suggested that increased COX-2 expression in podocytes promotes diabetic glomerular injury, but the underlying mechanisms remain undetermined. To investigate the impact of high glucose on podocytes, we incubated differentiated wild type (POD $_{WT}$) or COX-2 over-expressing podocytes (POD $_{COX-2}$) with normal glucose (5.5 mM), high mannitol (30 mM) or high glucose (30 mM, HG) for 48 hours. HG selectively induced further COX-2 up-regulation in POD $_{COX-2}$ (3.2±0.2 fold of wild type control), along with cytoskeleton disorganization and down-regulation of α-actinin 4. HG also induced increased apoptosis in POD $_{COX-2}$.

Since previous studies have demonstrated that most RAS components exist in differentiated podocytes, we further investigated their role in HG-induced podocyte injury. In response to high glucose incubation, intracellular and medium renin activity in POD $_{COX-2}$ increased from 1.3±0.1 to 2.5±0.2 ng Ang I/mg protein and from 1.1±0.1 to 1.8 ±0.2 fold, respectively (n=4, P<0.05). HG also induced ERK and P38 phosphorylation significantly in POD $_{COX-2}$. HG increased (Pro)renin mRNA in POD $_{COX-2}$ to 4.4±0.2 fold POD $_{WT}$ (n=4, P<0.05), and COX-2 inhibition decreased HG-stimulated (Pro)renin mRNA expression in POD $_{COX-2}$, as well as inhibiting HG-induced ERK and P38 activation, apoptosis and cytoskeleton disorganization. Similarly, SiRNA down-regulation of (Pro)renin in POD $_{COX-2}$ inhibited HG-induced ERK and P38 phosphorylation and partially prevented the apoptosis and cytoskeleton alterations induced by HG. AT1 receptor blockade also inhibited HG-induced phospho-ERK and phospho-p38 expression, and reduced apoptosis. In transgenic mice selectively over-expressing COX-2 in podocytes, streptozotocin-induced diabetes up-regulated glomerular (Pro)renin receptor expression, which was inhibited by the administration of the COX-2 specific inhibitor, SC58236. These results indicate a possible role for the (Pro)renin receptor in mediation of diabetic podocyte injury.

**TH-PO392**

**Targeting Intracellular Angiotensin II To Block High Glucose Effects on Mesangial Matrix** Rekha Singh, Bilquis Basith, David J. Leehey. *Hines VA Medical Center, Hines, IL.*

High glucose has been shown to increase both extracellular and intracellular Ang II levels, which are accompanied by increased TGF-b1 and matrix proteins in mesangial cells. Our recent work with human mesangial cells (HMC) showed that angiotensin converting enzyme inhibitors failed to block high glucose-induced increase in intracellular Ang II (int-Ang II), TGF-b1 and matrix proteins. These findings led us to hypothesize that int-Ang II may play an important role in mediating the stimulatory effect of high glucose on TGF-b1 and matrix proteins. To test this, we investigated whether blockade of int-Ang II by Ang II type 1 (AT1) receptor antagonists could normalize TGF-b1 and matrix under high glucose conditions. Cultured HMC (ScienCell, CA) were incubated with 5 mM (NG) or 25 mM (HG) glucose for 5 days. Since candesartan binds to cell membrane AT1 receptors (extracellular) and losartan can bind to both extracellular and intracellular AT1 receptors, cells were co-incubated with HG and $10^{-4}$M candesartan alone or in combination with losartan. HG significantly increased TGF-b1, collagen IV and fibronectin, and these effects were partially blocked by candesartan. In contrast, the combined treatment of candesartan and losartan completely normalized TGF-b1 and matrix proteins. In further studies, HMC were pretreated with $10^{-4}$M candesartan to block extracellular AT1 receptors and transfected with Ang II ($10^{-6}$M) to increase int-Ang II levels. In some experiments, losartan ($10^{-4}$M) was added to the transfection mixture to deliver losartan intracellulary. Transfection of cells with Ang II increased int-Ang II in a time- and dose- dependent manner and significantly increased TGF-b1, collagen IV and fibronectin. Candesartan did not block int-Ang II effects on TGF-b1 or matrix proteins whereas intracellular delivery of losartan attenuated int-Ang II-induced increase in TGF-b1, collagen IV and fibronectin. These results suggest that int-Ang II has a role in HG-induced stimulation of TGF-b1 and matrix and that targeting int-Ang II action may be necessary to completely block high glucose effects on TGF-b1 and mesangial matrix.

**RAS Blockade Normalizes Angiotensin Converting Enzyme-2 Expression and Prevents Hypertension, Tubulointerstitial Fibrosis and Tubular Apoptosis in Akita Angiotensinogen-Transgenic Mice** John S. D. Chan,[1] Fang Liu,[1] Nicolas Godin,[1] Shiao-Ying Chang,[1] Chao-Sheng Lo,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang.[1] *[1]Res. Ctr., CHUM-Hotel Dieu Hosp., Montreal, QC, Canada; [2]Res. Ctr., Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [3]Pediatr Nephrol Unit, Mass Gen Hosp., Boston, MA.*

We investigated the impact of renin-angiotensin system (RAS) blockade on angiotensin converting enzyme-2 (ACE2) expression and prevents hypertension, tubulointerstitital fibrosis and renal proximal tubular cell (RPTC) apoptosis in Akita (a model of type 1 diabetes) angiotensinogen (Agt)-transgenic (Tg) mice. Akita Agt-Tg mice were created by cross-breeding Akita mice with our Agt-Tg mice, which specifically overexpress Agt in their RPTCs (Kidney Int, 2006). Non-Akita littermates served as controls. Blood glucose, systolic blood pressure (SBP) and albuminuria were monitored weekly from 7 until 16 weeks of age. Kidneys were processed for histology and apoptosis studies. Renal proximal tubular ACE2, pro-fibrotic and pro-apoptotic gene and protein expression were quantified by respective real time-qPCR and Western blotting. Akita Agt-Tg mice developed hyperglycemia and significantly higher SBPs, kidney/body weight ratios and albuminuria, compared to non-Akita littermates. Kidneys from Akita Agt-Tg mice displayed progressive hydronephrosis, renal hypertrophy, tubulointerstitial fibrosis and tubular apoptosis as compared to non-Akita littermates. Down-regulation of ACE2 expression and increased expression of transforming growth factor-beta1 receptor II, collagen type IV, plasminogen activator inhibitor-1 and active caspase-3 were evident in RPTCs of Akita Agt-Tg mice. Finally, treatment with RAS blockers (perindopril and losartan) normalized ACE2 expression, prevented hypertension and albuminuria and attenuated kidney abnormalities, pro-fibrotic and pro-apoptotic gene expression in Akita-Agt Tg mice. These results demonstrate that RAS blockade effectively prevents hypertension, albuminuria, tubulointerstitial fibrosis and tubular apoptosis in diabetes via inhibition of intrarenal RAS activation and normalization of ACE2 expression in the kidney.

**Role of Blood Pressure and Renin-Angiotensin System (RAS) in Development of Diabetic Nephropathy (DN) in eNOS-/- db/db Mice** Suwan Wang,[1] Haichun Yang,[2] Xiaofeng Fan,[1] Takamune Takahashi,[1] Raymond C. Harris,[1] Mingzhi Zhang.[1] *[1]Medicine, Vanderbilt University, Nashville, TN; [2]Pathology, Vanderbilt University, Nashville, TN; [3]Nashville, TN.*

We previously reported that deletion of eNOS in db/db mice (eNOS-/- db/db) leads to significant and early onset albuminuria, arteriolar hyalinosis, mesangiolysis and focal segmental and nodular glomerulosclerosis, similar to human diabetic nephropathy. Blood pressure was higher in eNOS-/- db/db mice than db/db mice (146 ± 6 vs. 120 ± 3 mmHg). eNOS-/- db/db mice (8 wks old, albuminuria 837 ± 79 µg/mg Alb/Cr) were randomly divided into 3 groups: vehicle, treatment with the ACEI, captopril or "triple therapy" (hydralazine, resperine, HCTZ), and the animals were sacrificed after treatment for 12 wks. Captopril treatment led to significant decreases in blood pressure (102 ±5 mmHg), albuminuria (432 ± 101 vs. 2574 ± 974 µg/mg Alb/Cr of vehicle), and glomerulosclerosis index (0.37 ± 0.03 vs. 1.26 ± 0.29 of vehicle), along with less macrophage infiltration and decreased expression of nitrotyrosylated proteins (a marker of oxidative stress), Kim-1 (a marker of renal injury) and CTGF. Triple therapy reduced blood pressure to similar levels in captopril-treated mice (106 ± 4 mmHg). However, triple therapy was less effective in reducing albuminuria (1204 ± 180 µg/mg Alb/Cr) and glomerulosclerosis index (0.58 ± 0.07, P<0.01 vs. captopril group), along with less reduction of macrophage infiltration, nitrotyrosylated proteins, Kim-1 and CTGF. In vehicle treated eNOS-/- db/db, there was increased expression of $p22^{phox}$, a component of NADPH oxidase. Captopril significantly reduced $p22^{phox}$ expression, but triple therapy did not. Therefore, ACEI is more effective than triple therapy in reducing the progression of DN in eNOS-/- db/db mice, indicating an additional role for RAS inhibition in addition to blood pressure control.

**Activation of Local Renin Angiotensin System in Glomerular Endothelial Cells by High Glucose** Hui Peng, Yan-Fang Xing, Cheng Wang, Zengchun Ye, Hua Tang, Yan-Ru Chen, Canming Li, Tan-Qi Lou. *Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, GD, China.*

Objective: To explore the effect of high glucose on local renin angiotensin system (RAS) in glomerular endothelial cells (GEnCs) and its probable mechanism in diabetic kidney disease.

Methods: Rat GEnCs were cultured and then exposed for 12h, 24h, 48h and 72h to culture medium containing: control group (5mM, NG), high glucose group ( 30mM, HG), captopril group ( HG+ captopril 1mM), chymostatin group (HG+chymostatin 50uM) . NG+mannitol (25mM), NG+captoril(1mM) and NG+chymostatin(50uM) were control groups. Captopril and chymostatin were pre-incubated for 1h. Then culture medium and cell lysate were collected. ELISA, Real-time PCR, Western blot and immunofluorescence were employed to examine AngII concentration in cell lysate and culture medium, mRNA and protein expression of RAS components and localization of RAS components.

Results: (1) Compared with control group, exposure to HG for 12h increased AngII in cell supernatant (P<0.001). However, there was no difference in intracellular AngII generation between these two groups (P=0.94). Exposure to HG for 72h, AngII levels significantly increased both in culture medium and cell lysate compared with control cells(P<0.001). However, it did not increased when exposure for 24h or 48h (P>0.05). Captopril and chymostatin respectively inhibited HG induced AngII both in culture medium and cell lysate (P<0.05). (2) Both angiotensinogen and renin mRNA were significantly increased when cells were exposed to HG for 72h (P<0.001), while ACE mRNA were unchanged (P>0.05). (3) Angiotensinogen protein in GEnCs was significantly increased when exposed to high glucose for 72h (P<0.001), while AT1R protein expression was significantly down-regulated (P<0.05). AT2R and renin protein were unchanged. Interestingly, redistribution of AT2R from cell nucleus to cytoplasm was observed by immofluorescence.

Conclusion: we suggest that high glucose can activate the local RAS by upregulating angiotensinogen expression in glomerular endothelial cells. It may through ACE and non-ACE pathways.

Disclosure of Financial Relationships: nothing to disclose

**Dose Dependent Anti-Inflammatory Effect of Irbesartan Determined by Antibody Microarray in Patients with Chronic Kidney Disease** Jie Ni, Linli Lv, Bi-Cheng Liu. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China.*

**Objective:** The non-hemodynamic effect of angiotensin II type 1 receptor antagonist in delay the progression of chronic kidney disease (CKD) has still been unclear. In this study, we investigated the influence of irbesartan on the urinary excretion of cytokines in hypertensive patients with CKD determined by a novel antibody microarray.

**Methods:** Sixteen patients were randomly divided into 2 groups (A and B group). After 8 weeks wash-out, irbesartan was given (300 mg·d$^{-1}$ in group A and 150 mg·d$^{-1}$ in group B) for 8 weeks. After 8 weeks, the dosage in group A and B has been changed to 150 mg·d$^{-1}$ and 300 mg·d$^{-1}$ respectively. Blood pressure (BP) and 24 hour proteinuria were examined before and after the treatment. Urinary excretion of cytokines was determined by human inflammation antibody aarry (Raybio®). A two-fold changes in spot intensity was considered significant change.

**Results:** It was shown that irbesartan (150 mg·d$^{-1}$) treatment induced the urinary excretion of GCSF, GM-CSF, IFN-γ, IL-1α, IL-11, IL-12p40, MCP-2, MIP-1α two to nine folds decrease, while increasing the dosage of irbesartan to 300mg·d$^{-1}$, the excretion of GCSF, GM-CSF, IL-12p40, MCP-2, MIP-1α further decreased in group A. In group B, only MIP-1α was found a decreasing in urinary cytokine excretion, and there is no significant difference when the dose changed to 150 mg·d$^{-1}$ for another 8 weeks. After treatment, the levels of EOTAXIN, EOTAXIN-2, GCSF, GM-CSF, ICAM-1, IFN-γ, IL-1β, IL-2, IL-3, IL-4, IL-6, IL-8, IL-10, IL-11, IL-12p40,IL-12p70, IL-15, IL-16, MCP-2, M-CSF, MIG, MIP-1α, MIP-1β, MIP-1δ, RANTES, TGF-β1 and TNF-α in group B were significantly increased compared to group A, while there is no cytokine decreasing in group B compared to group A. The level of BP and 24 hour urine protein in both groups dropped similarly.

**Conclusion:** This study firstly demonstrates the dose dependent renoprotective effects of irbesartan on patients with CKD via the inhibition of urinary excretion of cytokines.

**TH-PO397**

**ACE/ACE2 Expression in Kidney from NOD (Non-Obese) Diabetic Mice with Early Diabetic Kidney Disease** Marta Riera,[1] Julio Pascual,[1] Judit Rigol,[1] Eva Marquez,[1] Daniel Batlle,[2] Maria Jose Soler.[1] *[1]Nephrology, Hospital del Mar. Parc de Salut Mar. Fundació IMIM, Barcelona, Spain; [2]Northwestern University Feinberg School of Medicine., Chicago.*

It has been previously shown that renin angiotensin system(RAS) is altered in diabetic kidney disease. RAS has not been studied in non-obese diabetic(NOD)mice, a model that develops autoimmune diabetes that mimics human type 1 diabetes. We studied kidney histology as well as angiotensin converting enzyme(ACE)-2 and ACE expression in kidney from NOD mice at 21 days after diabetes development and compared with the respective non-obese resistant(NOR) mice controls.

Blood glucose(BG) and urinary albumin excretion(UAE) at the end of the study was significantly increased in NOD(n=7) as compared to NOR mice(n=6)(BG:571.1±20.3 vs 112±4.9 mg/dL;UAE:91.4±27 vs 8.6±3μgalbumin/mg creatinine,p<0.05). Glomerular size was increased in NOD as compared to NOR mice (8.324±271 vs 6.238±226um2,p<0.05). We did not observe differences in podocyte number/glomerulus and optical microscopy lesions. ACE2 and ACE activity were increased in plasma from NOD as compared from NOR mice(ACE2:31.2±4.78 vs 11.6±2.3RFU/μL/h; ACE:335.2±10.8 vs 262.3±4.8RFU/μg S/μL;p<0.05). In tubules from NOD, ACE2 protein was determined by Western Blot(WB) and activity expression was increased as compared to NOR mice(WB:0.93±0.05 vs 0.78±0.04 ACE2/βactin; activity: 63.2±14.5 vs 29.8±5.5 RFU/μgprot/h,p<0.05). By immunostaining, the glomerular expression of ACE2 and ACE were significantly increased in NOD as compared with NOR mice (ACE2: 38.5 ± 6.2% vs 16.8 ± 2.6; ACE: 24.6±6.02% vs 6.4±2.26; p<0.05). We conclude that in NOD mice after 21days of new-onset diabetes, UAE and glomerular size are increased. However, we did not observe podocyte loss or other diabetic kidney lesions. In this early model of diabetic kidney disease, ACE2 and ACE expression are increased in plasma, tubules and glomeruli. In conclusion, the NOD mice develops albuminuria and glomerular hypertrophy as the earliest manifestation of kidney disease and at this stage ACE2 in plasma and kidney expression are increased likely as a mechanism to counterbalance increased ACE expression within the kidney.

**Urinary Excretion of ACE2 – A Biomarker of Diabetic Kidney Disease?** Jan A. Wysocki,[1] Karla Evora,[1] Minghao Ye,[1] Maria Jose Soler,[2] Anastasia Z. Kalea,[1] Daniel Batlle.[1] *[1]Division of Nephrology & Hypertension, Northwestern University, Chicago, IL; [2]Hospital del Mar, Barcelona, Spain.*

ACE2, an Ang II-dissipating enzyme, is abundantly present on apical membrane of renal cortical tubules but also in renal vasculature and glomeruli. We have previously shown that kidney cortex ACE2 activity is increased in diabetic mice whereas glomerular ACE2 expression is decreased by immunostaining. The aim of this study was to examine urinary ACE2 activity in two diabetic models: the *db/db* and STZ-treated mice with established kidney lesions and increased urinary albumin excretion.

Enzymatic ACE2 activity was measured in urine using Mca-APK-Dnp as a substrate. Urine ACE2 activity was not measurable in *Ace2* KO, whereas in WT controls it was about 10-fold higher than in serum. Female mice carrying only one functional allele of the *ace2* gene (*ace2*$^{+/-}$) exhibited a reduced urinary ACE2 activity as compared to WT mice (30-40% of the WT).

In diabetic *db/db* mice, urine ACE2 activity was markedly higher than in *db/m* (137±26 vs. 17±4 RFU/ug creat/hr, respectively, *p<0.001*). Urinary ACE2 excretion was also strikingly increased in diabetic STZ-mice as compared to non-diabetic controls (99±11 vs. 8.6±0.7 RFU/ug creat/hr, respectively, p<0.001). Serum and kidney ACE2 activity were significantly elevated in both, the *db/db* [1.7-fold (p<0.005) and 3.3-fold (p<0.05) higher than in *db/m*, respectively] and STZ mice [2-fold (p<0.01) and 1.7-fold (p<0.005) higher than in control, respectively]. The differences in serum and kidney, however, were small as compared to the large differences in the urine. To examine whether the increase in urinary ACE2 excretion stems from an increase in renal or serum ACE2, recombinant (r)ACE2 was administered via osmotic minipumps. rACE2 administration resulted in amplification of serum but not urinary ACE2 activity suggesting that kidney but not serum ACE2 is the primary source of ACE2 found in the urine.

We conclude that in diabetic mice, there is a marked increase in urinary ACE2 activity and suggest a possibility that this enzyme may be a biomarker of diabetic kidney disease.

**Diferuloylmethane (Curcumin) Augments Renoprotective Effects of Angiotensin Blockade in Diabetic Nephropathy by Ameliorating Mitochondrial Oxidative Stress** Sharma S. Prabhakar, Kevin Wyatt McMahon, Shobha Pandey. *Medicine, Texas Tech University Health Sciences Center, Lubbock, TX.*

The treatment of diabetic nephropathy (DN) remains suboptimal since the pathogenesis remains incompletely understood. We recently demonstrated that curcumin slows renal disease in obese ZSF rats, a model of type II diabetes by inhibiting VEGF and TGF-β in the kidney (Pandey, 2009). It is currently unclear if these effects are additive to the renoprotection with angiotensin blockade, an established treatment to slow DN. To examine our hypothesis, we studied ZSF rats (8th to 26th week) given either plain water (control) or curcumin (1mg/ml) or losartan (25 mg/L) or losartan plus curcumin in drinking water. Body weights and daily water intake was monitored weekly. Endogenous creatinine clearance and urinary protein excretion rates were measured at the beginning and end of the study. Expression of TGF-β and VEGF in kidneys harvested at euthanesia and urinary levels of 8-isoprostane, and 8-OHdG (8-hydroxy deoxyguanosine), markers of lipid peroxidation and mitochondrial oxidative stress respectively were measured at the end of the study.

Characteristics of ZSF rats at 26 weeks

| Group | BW (gms) | Ccr (L/Kg BW/d) | Uprot (mg/G cr) | 8 isoprostane (pg/G creat) | 8-OHdG (ng/Kg BW |
|---|---|---|---|---|---|
| Control | 716±32 | 3.7±0.31 | 1254± 211 | 65±13 | 5423±459 |
| curcumin | 702±37 | 4.4±0.32* | 623±154* | 53±11† | 2325±271* |
| losartan | 695±34 | 4.1±0.28† | 836±198† | 46±9* | 3875±366 † |
| losartan+curcumin | 678±29 | 4.6±0.27** | 516±138** | 47 ±11* | 2176±298** |

*P<0.01 vs. control, ** P<0.001 vs. control, †P<0.05 vs.control

Results: Rats tolerated curcumin, losartan and the combination well as evidenced by weight gains and water intake. There was a greater reduction in proteinuria and preservation of renal function with the combination than either agent alone along with a consistent inhibition of renal VEGF and TGF-β. Curcumin more significantly inhibited 8-OHdG than losartan and augmented the renal protection from losartan. We conclude that the additional renoprotective effects of curcumin derive from effective inhibition of mitochondrial oxidative stress, a better indicator of total body oxidative stress than lipid peroxidation.

Disclosure of Financial Relationships: nothing to disclose

**BMP4/Smad1 Signaling Is a Critical Therapeutic Target for Diabetic Nephropathy** Takeshi Matsubara,[1] Hideharu Abe,[2] Otoya Ueda,[3] Tatsuya Tominaga,[2] Akira Mima,[2] Kojiro Nagai,[2] Kazuo Torikoshi,[1] Makoto Araki,[1] Chisato Goto,[3] Masahiko Kinosaki,[3] Kou-Ichi Jishage,[3] Naoshi Fukushima,[3] Noriyuki Iehara,[1] Atsushi Fukatsu,[1] Hidenori Arai,[4] Toshio Doi.[2] *[1]Department of Nephrology, Kyoto University, Kyoto, Japan; [2]Department of Nephrology, University of Tokushima, Tokushima, Japan; [3]Chugai Pharmaceutical Co., Ltd, Shizuoka, Japan; [4]Department of Human Health Sciences, kyoto University, Kyoto, Japan.*

Accumulation of α1/α2 type IV collagen (Col4) in mesangium is the hallmark of diabetic nephropathy. We have shown that Smad1 transcriptionally regulates Col4 and α smooth muscle actin (αSMA) *in vitro*, and that overexpression of Smad1 accelerates matrix expansion in diabetic mice . Our study, however, demonstrated that overexpression of Smad1 by itself did not exacerbate nephropathy, but induction of diabetes resulted in marked matrix expansion along with prominent Smad1 phosphorylation. Trying to identify a regulatory factor of Smad1, we found that bone morphogenetic protein 4 (BMP4) was increased under diabetic condition *in vitro*. Therefore, the aim of this study was to examine the role of BMP4/Smad1 for diabetic nephropathy. Glomerular expressions of BMP4 and its receptor, quantified by qPCR from isolated glomeruli, were increased along with phospho-Smad1 in streptozotocin (STZ)-induced diabetic mice at 36 weeks. Immunohistochemistry showed that BMP4 was increased in podocytes, whereas its receptor, ALK3 was localized mainly in mesangium. Next, STZ-mice (Wild type and Smad1-Tg) were treated with either a neutralizing antibody against BMP4 (αB) or control IgG from 20 to 36 weeks. As a result, diabetic mice treated with αB showed less Smad1 phosphorylation, mesangial expansion, and Col4 accumulation than those with control IgG. In mesangial cells, overexpression

of constitutive active Smad1 increased transcriptional activity of αSMA, whereas no activation was found in cells overexpressing an inactive mutant of Smad1. BMP4 increased the expression of αSMA, which was blocked by Dorsomorphin, an inhibitor of Smad1. In conclusion, phosphorylation of Smad1 by BMP4 is crucial and blocking this signal could be a critical therapeutic strategy for diabetic nephropathy.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO401**

**Biglycan Deficiency Attenuates Diabetic Nephropathy** Patricia Wilson,[1] Joel Thompson,[1] Liliana Schaefer,[2] Shuxia Wang,[1] Lisa R. Tannock.[1] *[1]Internal Medicine, University of Kentucky, Lexington, KY; [2]Allgemeine Pharmakologie und Toxikologie, Goethe University Frankfurt, Frankfurt am Main, Germany.*

Hyperlipidemia and renal lipid accumulation has been shown to exacerbate diabetic nephropathy, although the mechanism by which renal lipid accumulates is unknown. Glomerulosclerosis is characterized by increased deposition of mesangial matrix including proteoglycans as well as increased renal deposition of apolipoproteinB and/or E. We recently reported that there is a striking co-localization between glomerular biglycan and apolipoproteinB, and regression analyses demonstrated a correlation between renal biglycan and apolipoproteinB content, suggesting that renal biglycan content influences renal apolipoproteinB accumulation. The goal of this study was to determine if renal biglycan mediates renal lipid accumulation. Biglycan deficient or biglycan wildtype mice on a hyperlipidemic background (LDL receptor deficient) were made diabetic with streptozotocin then fed a diet containing 0.12% g/kg cholesterol for 26 weeks. Biglycan deficiency had no effect on survival, body weight, renal weight, blood pressure, or glycated hemoglobin levels. Biglycan deficient mice had no difference in plasma triglyceride or cholesterol levels compared to biglycan wildtype mice, but biglycan deficient mice had significantly less glomerular lipid accumulation. Although diabetic biglycan deficient mice had elevated TGF-beta levels compared to diabetic biglycan wildtype mice (13.0±3.4 vs 4.9±2.3 ng/ml, p=0.02), the diabetic biglycan deficient mice had less matrix expansion than diabetic littermate controls and did not develop renal hypertrophy. Furthermore, diabetic biglycan deficient mice had significantly less elevation in urinary albumin excretion compared to diabetic biglycan wildtype mice (204±17 vs 410±12 mg/g creatinine, p<0.001). Thus, biglycan deficiency attenuates renal lipid accumulation and appears to be protective against development of diabetic nephropathy, despite the elevated TGF-beta levels.

**SREBP-1 Activation by Glucose Mediates TGFβ Upregulation in Mesangial Cells** Lalita Uttarwar, Bo Gao, Alistair J. Ingram, Joan C. Krepinsky. *Medicine/Nephrology, McMaster University, Hamilton, ON, Canada.*

Glomerular matrix accumulation is a hallmark of diabetic nephropathy. Recent studies have shown that overexpression of the transcription factor SREBP-1 induces pathology reminiscent of diabetic nephropathy, and SREBP-1 upregulation has been seen in diabetic kidneys. We thus studied whether SREBP-1 is activated by high glucose (HG) and mediates its profibrogenic responses.

In primary rat MC, HG (30mM) activated SREBP-1 by 30min, as shown by the appearance of the cleaved active form of SREBP-1 (nSREBP-1) in the nucleus, and by EMSA. This was confirmed by HG-induced activation of an SREBP-1 response element (SRE)-driven GFP construct. Activation was dose-dependent, and not induced by an osmotic control. Cleavage by proteases S1P and S2P were required for activation, since their inhibition by AEBSF prevented SREBP-1 activation. SCAP, the ER-associated chaperone for SREBP-1, was also necessary since its inhibition by fatostatin also blocked SREBP-1 activation. Signaling through the EGFR/PI3K pathway, which we have previously shown to mediate HG-induced TGFβ1 upregulation, was upstream of SREBP-1 activation. Inhibitors of EGFR (AG1478) and PI3K (LY294002, wortmannin) all blocked HG-induced SREBP-1 activation. By northern analysis, we next showed that both fatostatin and AEBSF prevented HG-induced TGFβ1 upregulation. Using a TGFβ1 promoter-luciferase construct, we showed that HG-induced promoter activation was inhibited by both fatostatin as well as a dominant negative SREBP-1a. By ChIP analysis, we confirmed that HG-induced activation of SREBP-1 led to its binding to a putative SREBP-1 binding site (SRE) in the TGFβ1 promoter (within -200bp of the start site).

Thus, HG-induced TGFβ1 activation by SREBP-1 in MC is mediated through EGFR/PI3K activation and processing of SREBP-1 through SCAP-mediated transport to the Golgi for proteolytic cleavage. SREBP-1 activation mediates TGFβ1 upregulation through its binding to its response element in the promoter. SREBP-1 thus provides a potential novel therapeutic target for the treatment of diabetic nephropathy, which will be evaluted in further studies.

**High Glucose-Stimulated UBF-1 Activation Increases Ribosome Biogenesis for Enhanced Protein Synthesis in Glomerular Epithelial Cells** Meenalakshmi M. Mariappan,[1,2] Kristin D'Silva,[1] Myung-Ja Lee,[1] Kavithalakshmi Sataranatarajan,[1,2] Goutam Ghosh-Choudhury,[1,2] B. S. Kasinath.[1,2] *[1]University of Texas Health Science Center, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX.*

We have reported that high glucose increases efficiency of mRNA translation in renal epithelial cells that leads to increase in matrix laminin synthesis. We tested the hypothesis that high glucose expands the capacity for protein synthesis by inducing ribosomal biogenesis as indicated by rDNA transcription in glomerular epithelial cells (GECs). High glucose (30mM), but not equimolar mannitol, significantly increased global protein synthesis and laminin gamma1 and fibronectin expression. This was associated with induction of rDNA transcription as indicated by increase in luciferase activity of a construct consisting of an rDNA promoter-driven IRES-luciferase that was expressed in GEC. High glucose induced Ser388 phosphorylation of upstream binding factor1 (UBF1, a rDNA transcription factor) along with increased phosphorylation of Erk and p70S6kinase. Inactivation of Erk, p70S6kinase or mTOR by inhibitors or by dominant negative enzyme expression blocked high glucose-induced UBF1 phosphorylation. In resting state, nuclear p19ARF combines with UBF1 and prevents it from binding to rDNA promoter and RNA polymerase I (Pol I). High glucose reduced nuclear content of p19ARF, promoted dissociation of UBF1-p19ARF complex and association of UBF1 with RPA194, a subunit of Pol I. Inhibition of Erk, p70S6kinase, mTOR and UBF1 by dominant negatives abolished high glucose induction of laminin gamma1 synthesis, protein synthesis, and, rDNA transcription. In contrast, expression of active S388D mutant of UBF1 in 5mM glucose mimicked the effect of high glucose on protein synthesis. Renal cortex from rodents with type 1 and type 2 diabetes showed increased phosphorylation of UBF1, Erk, p70S6kinase and mTOR, coinciding with renal hypertrophy and matrix accumulation. We conclude that high glucose promotes ribosomal biogenesis by promoting Erk/mTOR/p70S6kinase-UBF1-Pol I axis in GECs. This was confirmed by activation of UBF1 in kidneys of rodents with type 1 or type 2 diabetes.

**TH-PO404**

**Rap1b GTPase Ameliorates Glucose-Induced Mitochondrial Dysfunction Via Regulating Mitochondiral Biogenesis, Intra-Mitochondrial Dynamics and Antioxidant Gene Expression** Xuejing Zhu,[#1] Fu-You Liu,[#1] Guanghui Ling,[#1] Li Xiao,[#1] Hong Liu,[#1] Yinghong Liu,[#1] Youming Peng,[#1] Yashpal S. Kanwar,[#2] Lin Sun.[#1,2] *[1]Department of Nephrology, Second Xiangya Hospital of Central South University, Changsha, Hunan, China; [2]Department of Pathology and Medicine, Northwestern University Medical School, Chicago.*

Our previous studies have demonstrated that the GTPase Ras-proximate-1 (Rap1b) ameliorates glucose-induced mitochondrial dysfunction in renal tubular cells (JASN 2008). In the present study, we observed that Rap1 expression was decreased in renal proximal tubular cells of patients with diabetic nephropathy (DN), which was associated with the tubular atrophy and decreased tubular functions. This indicated that abnormal expression of Rap1b was related to tubular cell damage in DN. In this study, we investigated whether Rap1b is relevant to tubular cell survival in DN. To address this question, subcellular localization of the Rap1 and its role in mitochondrial biogenesis and mitochondrial gene expression in renal tubular cells was investigated under high glucose (HG) ambience was evaluated. Rap1b was localized to mitochondrial cristae by Immunoelectronmicroscopy. Compared to control (5 mM), 30 mM D-gluocse (HG) induced mitochondrial dysfunction, including altered mitochondrial morphology and membrane potential, as measured by TMRE staining. ATP levels were also decreased. However, over- expression of Rap1b partially reversed such abnormalities. In addition, HG increases overproduction of mitochondrial superoxide, as analyzed by Mito Sox staining with confocal microscopy. Furthermore, HG decreased the expression of mitochondrial fusion gene (MFN) and antioxidant enzymes. Whereas, increased expression of mitochondrial fission gene, DMN, apoptosis related genes, and protein expression of caspase-3 and caspase-9 were observed. These effects were partially reduced by transfection with Rap1b as assayed by QPCR, Western blotting and immunofluorescence microscopy. These data indicate that Rap1b ameliorates glucose-induced mitochondrial dysfunction by maintaining a balance in the favor of biogenesis genes and antioxidant enzymes in the mitochondria of renal tubular cells.

**Free Symmetrical Dimethylarginine Increases Collagen IV by Altering the AT2-VEGF Signaling Axis. Potential Role in Diabetic Nephropathy** Denis Feliers, Yves Gorin, B. S. Kasinath. *UTHSCSA, San Antonio, TX.*

Circulating symmetric dimethylarginine (sDMA) is increased and intrarenal renin-angiotensin system is activated in diabetes. We studied whether sDMA interferes with AngII in regulation of collagen IValpha5 (col4A5) expression in glomerular endothelial cells (GEndos) and diabetic kidneys. In GEndos, use of losartan and PD123319, AT1 And AT2 antagonists, showed that AngII induced increase in col4A5 by was mediated by AT1 and inhibited by AT2. AngII stimulation of VEGF and VEGFR2 activation was mediated by AT2 only. AT2 repression of col4A5 was prevented by sFlt1, a specific VEGF inhibitor. AngII stimulation of eNOS activation and NO production (a known anti-fibrotic factor) was blocked by inhibition of either AT2 or VEGF. This suggests that activation of an

AT2-VEGF axis represses col4A5 through eNOS activation. sDMA suppressed col4A5 repression, but not increased VEGF and VEGFR2 signaling induced by AT2 activation. It also suppressed VEGF-induced eNOS activation and NO production, but not VEGFR2 signaling leading to eNOS activation. sDMA caused eNOS uncoupling and superoxide anion production in response to VEGF. All these effects were blocked by preventing cellular uptake of sDMA with excess arginine. This shows that sDMA interferes with NO production by uncoupling eNOS and leads to oxidative stress in response to activation of the AT2-VEGF axis. In normal mice administration of losartan and PD123319 showed that AT2 but not AT1 repressed col4A5 expression in the kidney. In OVE26 mice with type 1 diabetes, however, both receptors contributed to increase of col4A5. In nondiabetic mice, VEGF expression as well as VEGF-R2 and eNOS activation were mediated by AT2 alone, demonstrating the existence of a AT2-VEGF axis that could repress col4A5. In diabetic kidneys, the AT2-VEGF axis contributed to col4A5 increment in spite of VEGF-R2 and eNOS activation, reminiscent of data from GEndos in culture. This suggests that alteration of eNOS activation and NO production by free sDMA could contribute to increased col4A5 in diabetic kidneys. By altering signaling by the AT2-VEGF axis, circulating sDMA could contribute to matrix expansion in diabetic nephropathy.

**Farnesoid X Receptor Deficiency Accelerates Diabetic Nephropathy in FVB/N Mice** Tao Jiang, Cydney Lynn Urbanek, Nathaniel L. Solis, Hannah Danielle Santamaria, Moshe Levi, Xiaoxin X. Wang. *Medicine, University of Colorado Denver.*

The pathogenesis of diabetic nephropathy remains poorly defined, and animal models that represent the human disease have been lacking. We have demonstrated recently that farnesoid X receptor (FXR) agonist has renal protective role in db/db mice of type 2 diabetes model and that FXR deficiency potentiates diabetic nephropathy in nephropathy-resistant C57BL/6 mice. In this study we are further testing the effect of FXR deficiency in FVB/N mice, a strain known to be susceptible to diabetic nephropathy. The diabetes was caused with Akita mice. We kept male mice on chow diet until 20 wk old. Although the severity of hyperglycemia in diabetic FXR KO mice was similar to diabetic wild-type mice, the diabetic FXR KO mice on FVB background developed kidney injury including increased proteinuria (15 fold vs non-diabetic FXR KO mice; 3 fold vs diabetic wild-type mice), massive glomerulosclerosis, severe tubule atrophy and fibrosis, and increased extracellular matrix protein deposition. Furthermore diabetic FXR KO mice have increased oil red o positive lipid deposits in both the glomeruli and tubular epithelial cells. We have also determined that diabetic FXR KO mice have increased macrophage infiltration. In summary, diabetic FXR KO mice in the FVB background provide a novel model of diabetic nephropathy and support a role for FXR deficiency in modulating diabetic nephropathy.

**High Glucose Induces Human Glomerular Endothelial-to-Mesenchymal Transition through TGF-β1 Pathway in Diabetes Mellitus** Hui Peng, Canming Li, Yan-Ru Chen, Cheng Wang, Zengchun Ye, Bo Peng, Tan-Qi Lou. *Devision of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, Guangdong, China.*

Background: Emerging evidence suggests that endothelial-to-mesenchymal transition (EndMT) contributes to kidney fibrosis. Our aim is to explore if EndMT exists in human diabetic nephropathy (DN), and also to investigate if high glucose induces EndMT in glomerular endothelial cells (GEnCs) and the mechanisms in DN. Methods: Primary human GEnCs were exposed for 24 hours to culture medium containing: (1) no additions (control), (2) high glucose (HG, 30mM), (3) high glucose with TGF-β1 receptor kinase inhibitor LY-364947 (1mM), (4) TGF-β1 (10ng/ml), (5) mannital control. Immunofluorescent staining was performed to detect the expression of CD31, fibroblast specific protein-1 (FSP-1), and α -smooth muscle actin (α-SMA) in GEnCs, five human diabetic kidney sections and three normal renal controls (from renal carcinoma patients). Phenotypic changes of GEnCs were observed using phase contrast microscope. Protein and mRNA expression of FSP-1, α-SMA, TGF-β1 was measured by Western blotting and real-time PCR respectively. Total TGF-β1 in cell supernatant and cell lysate were detected by ELISA. Results: Double staining of FSP-1 with CD31 as well as α-SMA with CD31 revealed EndMT also existed in the glomerulis of human diabetic kidney. In vitro study showed GEnCs changed their phenotype from cobble-like to fibroblast-like cells in HG, which did not happen in mannitol groups. It also showed that α-SMA with CD31 double positive percentage was significantly increased in HG and TGF-β1 group when comparing with control($P<0.05$). Real-time PCR and Western blotting results indicated FSP-1 and α-SMA mRNA and protein significantly increased in HG and TGF-β1 groups compared with control($P<0.05$). TGF-β1 both in cell supernatant and cell lysate were significantly increased in HG compared with control($P<0.01$). When pre-incubated with LY-364947, EndMT induced by HG was partly decreased ($P<0.05$). Conclusions: Our results indicate that EndMT exists in the glomerulis of human diabetic kidney. High glucose may contribute to the EndMT of GEnCs through TGF-β1 signaling pathway.

### TH-PO408

**High-Glucose Induces CTGF Which Leads to Activation of TrkA and Subsequent Renal Cell Migration** Maria Fragiadaki,[1] Aleksandra Wright,[1] Yoshifumi Itoh,[2] Nadia Wahab,[1] Roger M. Mason.[1] *[1]Renal Medicine, Imperial College London, London, United Kingdom; [2]Kennedy Institute of Rheumatology, Imperial College London, United Kingdom.*

High-glucose plays an important role in the development of diabetic nephropathy (DN) through a variety of molecular mechanisms. These include activation of connective tissue growth factor (CTGF), a profibrotic cytokine, which is upregulated in glomeruli in DN and in mesangial cells exposed to high glucose *in vitro*. We previously identified TrkA as a CTGF receptor and showed that CTGF binding to TrkA activates downstream cell signalling. To investigate whether this induces a biological response in mesangial and tubular epithelial cells we investigated whether stimulation with high-glucose promotes cell migration via this pathway. Migration was measured using a transwell migration assay and a scratch wound assay with live cell imaging. We show that glucose-stimulated migration is dependent on induction of CTGF and CTGF-mediated activation of TrkA. Knockdown of CTGF with siRNA or neutralising anti-CTGF antibodies, abolished both the activation of TrkA and cell migration in high glucose conditions, as did siRNA knockdown of TrkA. Moreover, pharmacological inhibition of TrkA (K252a, or GW441756) had similar effects. The N-terminal half of CTGF was responsible for CTGF-TrkA mediated cell migration. We also studied the expression and activation of TrkA in kidney biopsies from patients with DN and in control kidneys from patients with thin basement membrane disease. TrkA is not expressed in the control kidney but is strongly expressed and activated in tubular epithelial cells in DN patients. Overall these results indicate that glucose-induced CTGF expression in DN may activate TrkA receptor signalling and downstream cellular responses during disease development.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO409

**Urinary Connective Tissue Growth Factor Is Associated with Tubular Dysfunction in Diabetic Nephropathy** Jan Willem Leeuwis,[1] Karin G. Gerritsen,[1] Tri Q. Nguyen,[1] Maarten P. Koeners,[2] Jaap A. Joles,[2] Stephan J. L. Bakker,[4] Roel Goldschmeding,[1] Robbert J. Kok.[3] *[1]Pathology, University Medical Center, Utrecht, Netherlands; [2]Nephrology, University Medical Center, Utrecht, Netherlands; [3]Pharmaceutical Sciences, Utrecht University, Utrecht, Netherlands; [4]Nephrology, University Medical Center, Groningen, Netherlands.*

Connective tissue growth factor (CTGF) plays a key role in the development of diabetic nephropathy (DN). Urinary CTGF (uCTGF) is elevated in DN and relates to markers of disease severity. It is unknown which processes contribute to elevated uCTGF. We investigated how tubular dysfunction affects uCTGF in type 1 DN.

We examined uCTGF and tubular reabsorption marker $\beta_2$-microglobulin ($\beta_2$M) in patients with type 1 DN, and studied renal handling of endogenous CTGF (eCTGF) and recombinant CTGF (rCTGF) in mice with streptozotocin-induced DN. rCTGF and FITC-inulin were infused by minipumps. Fractional excretion (FE) of rCTGF was used as a measurement for tubular reabsorption of CTGF.

In patients, uCTGF was independently associated with $\beta_2$M ($\beta=0.41$, $P<0.001$), and not with glomerular damage marker IgG1.

Diabetic mice had increased urinary eCTGF and FE of rCTGF ($P<0.001$), which correlated tightly ($r=0.95$, $P<0.001$). Approximately 40% of uCTGF could be accounted for by decreased reabsorption of filtered plasma eCTGF, indicating that the remaining uCTGF had a direct renal source. *In situ* hybridization showed that CTGF was mainly located in glomeruli and medullary tubuli. While medullary CTGF mRNA in DN did not correlate with directly kidney-derived uCTGF, both glomerular CTGF mRNA and FE of rCTGF showed a strong correlation with directly kidney-derived uCTGF ($r=0.86$ and $0.91$, $P<0.001$). However, it should be kept in mind that glomeruli-derived CTGF will undergo tubular reabsorption and tubular dysfunction will result in a major increase in uCTGF from this source.

Our data indicate that in DN, uCTGF is strongly dependent on reduced tubular reabsorption of both filtered plasma CTGF and glomeruli-derived CTGF. This should be taken into account when using uCTGF as a biomarker and in research addressing its pathogenic role.

*(JWL and KGG contributed equally)*

### TH-PO410

**Transcriptional Regulation of MicroRNAs-192 and -194 by TGF-β1. Implications for the Pathogenesis of Diabetic Nephropathy** Robert H. Jenkins, John Martin, Aled O. Phillips, Timothy Bowen, Donald Fraser. *Institute of Nephrology, School of Medicine, Cardiff University, Cardiff, Wales, United Kingdom.*

Tubulointerstitial fibrosis is a key determinant of progressive chronic kidney disease (CKD). Epithelial-to-mesenchymal transition of proximal tubular epithelial cells (PTC) primarily due to the cytokine transforming growth factor-β1 (TGF-β1) is integral to this process. Several recent studies show that microRNA-192 (miR-192) has functionally important targets in the kidney, and implicate alterations in miR-192 expression downstream of TGF-β1 in the pathological changes in diabetic nephropathy. The data is complex, however, with evidence for both induction and suppression of miR-192 by TGF-β1 in

renal cells in vivo and in vitro under differing contexts. The aim of the current study was to define the mechanisms by which miR-192 expression is regulated. Initial screening demonstrated that miR-192 is found in a restricted subset of human tissues, including kidney, as part of a family of miRs sharing a similar expression pattern, which also includes miR-194. miR-192 and miR-194 are processed from the same primary transcript (pri-192/194). miR quantification in primary human cells showed expression in proximal tubular cells (PTC), mesangial cells and podocytes, with predominant expression in PTC. Incubation of PTC with TGF-β1 suppressed pri-192/194 expression for time points from 12 to 96h, suggesting transcriptional regulation by TGF-β1. A series of luciferase reporter gene constructs incorporating a nested set of pri-192/194 promoter fragments identified a TGF-β1 responsive element in the pri-192/194 promoter, and in silico analysis suggested the presence of a Hepatocyte Nuclear Factor binding site. Electrophoretic mobility shift assay demonstrated HNF binding to this sequence. Screening of human tissues showed strong correlation between HNF family member expression and miR-192/194 expression. Taken together, these data identify transcriptional regulation of miRs -192 and -194 by TGF-β1, and implicate Hepatocyte Nuclear Binding Factors in this process.

**Post-Transcriptional Regulation of Transforming Growth Factor-β1 by microRNA** John Martin, Robert H. Jenkins, Aled O. Phillips, Timothy Bowen, Donald Fraser. *Institute of Nephrology, School of Medicine, Cardiff University, Cardiff, United Kingdom.*

TGF-β1 is an important mediator of progressive renal tubulointerstitial fibrosis in diabetic nephropathy. There is substantial evidence for post-transcriptional regulation of TGF-β1 synthesis in various in vitro and in vivo contexts. We have shown previously that in proximal tubular cells, TGF-β1 synthesis is controlled independently at the level of translation by stimuli of relevance to the pathogenesis of diabetic nephropathy (glucose, insulin and PDGF). The mechanisms underlying this remain incompletely defined. The purpose of this work was to investigate the potential role for microRNA, recently identified post-transcriptional regulators of gene expression, in regulation of TGF-β1. In vitro experiments were performed with primary proximal tubular cells (PTC) and with the cell line, HK-2.

MicroRNA exert their regulatory action via binding to sites in the 3'Untranslated Region (3'UTR) of target genes. The TGF-β1 3'UTR is reported as 543 nucleotides, but an alternative polyadenylation site leading to a significantly shorter transcript has also been reported. Absolute quantification using reference standards showed that, while both UTR lengths are detectable in a broad range of tissues, the short form of the TGF-β1 3'UTR predominates in the kidney and elsewhere. Incorporation of the short UTR into a luciferase reporter gene significantly reduced reporter protein synthesis without major effect on RNA, suggesting post-transcriptional inhibition. In silico approaches identified two microRNAs with multiple potential binding sites within the TGF-β1 UTR. miR transfection inhibited endogenous PTC TGF-β1 synthesis, and in separate experiments, decreased TGF-β1 3'UTR reporter activity, confirming direct targeting of TGF-β1. This work identifies important post-transcriptional regulation of TGF-β1 by its 3'UTR, and identifies microRNAs that regulate synthesis of this key pro-fibrotic cytokine in the kidney.

**Toll-Like Receptor 4 Mediates High Glucose Induced Tubular Inflammation in Diabetic Nephropathy** Miao Lin,[1] Wo-Shing Au,[1] Loretta Y. Y. Chan,[1] Joseph C. K. Leung,[1] Kwok Wah Chan,[2] Hao-Jia Wu,[1] Gary Chan,[1] Kar Neng Lai,[1] Sydney C. W. Tang.[1] *[1]Department of Medicine, The University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [2]Department of Pathology, The University of Hong Kong, Queen Mary Hospital, Hong Kong, China.*

Tubulointerstitial inflammation is a hallmark of diabetic nephropathy, and governs overall renal prognosis. We recently showed that high glucose (HG) stimulated tubular proinflammatory signals via MAPK and PKC signaling (*Nephrol Dial Transplant* 2009). Here, we studied whether Toll-like receptor 4 (TLR4), a key mediator of immune responses and inflammatory signaling, is involved in tubular inflammation of diabetic nephropathy. Immunohistochemical analyses of human renal biopsies revealed that TLR4 were expressed in proximal and distal tubules, with more intense staining in kidneys with histologically proven diabetic nephropathy (n=8) compared with normal controls (n=10). In vitro, we showed that HG induced TLR4 overexpression in cultured human proximal tubular epithelial cells (PTEC) in a time- and dose- dependent manner, resulting in upregulation of IL-6, CCL-2 mRNA expression and protein secretion via IκB phosphorylation and NF-κB p65 nuclear translocation. Knocking down TLR4 expression with TLR4-specific siRNA in PTEC resulted in a significant decrease in HG-induced IκB/NF-κB activation (76-80%, $p<0.01$) compared with the scrambled control. The associated downstream proinflammatory cytokine IL-6, chemokine CCL-2 mRNA level and protein synthesis were also substantially attenuated by transfection with TLR4 siRNA (68%-74%, all $p<0.01$). In conclusion, our findings suggest a novel TLR4-mediated pathway through which hyperglycemia may contribute to tubular inflammation in the diabetic kidney.

**Diabetes Attenuates the Blood Pressure Responses to Nitric Oxide (NO) Synthesis Inhibition: Potential Mechanisms and Relationship to Nephropathy Susceptibility** Karen A. Griffin,[1] Aaron Polichnowski,[1] Hector Licea-Vargas,[1] Jianrui Long,[2] Geoffrey A. Williamson,[2] Anil K. Bidani.[1] *[1]Medicine, Loyola Univ and Hines VA Hosp, Maywood, IL; [2]Electrical and Computer Engineering, Illinois Institute of Technology, Chicago, IL.*

We and others have shown that the Sprague-Dawley (SD) rats from Charles River (CR), exhibit reduced BP responses to L-NAME as compared to the SD rats from Harlan (H). Given the postulated importance of NO in the pathogenesis of DN, BP radiotelemetry was used to examine the effects of ~2 weeks of streptozotocin (STZ) diabetes *per se* on the dose response relationship of BP to L-NAME in control (CR, n=7; H, n=10) and diabetic rats (CR, n=8; H, n=9). Results mean ± SEM.

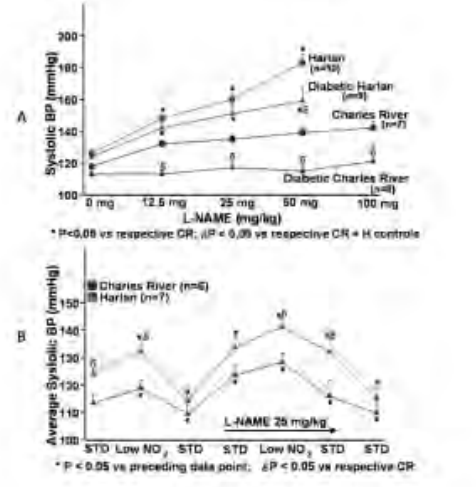

Fig. 1A shows that diabetes blunts the BP responses in both CR and H rats suggesting an increase in NO availability in early diabetes, with the effects being particularly prominent in CR rats (each L-NAME dose was given for 1 wk). Evidence that vascular nitrite ($NO_2$) may be an additional NO source in diabetes is provided by the significant and reversible increases in BP produced by the substitution of a low $NO_2$ for a standard (STD) diet for 72 hrs in diabetic (CR, n=6; H, n=7) (Fig. 1B), but not control rats (data not shown). Similar BP effects of a low $NO_2$ diet were seen during concurrent L-NAME administration (Fig. 1B). After 4 months of partially insulin-treated STZ diabetes (blood glucose 300-400 mg/dl), average systolic BP was also modestly but significantly lower in diabetic CR (n=6) vs. H (n=8) rats (112±2 vs 122±2 mmHg). However, much larger differences were seen between CR vs. H rats for proteinuria (23±4 vs. 77±13 mg/24hr; $p<0.001$) and percent glomerulosclerosis (1±0.2 vs. 9±3; $p<0.01$). The strong correlation between the BP response to L-NAME phenotype and the severity of DN suggest its potential utility as a predictor of DN susceptibility.

**TH-PO414**

**Generation of a Conditional eNOS Allele for the Assessment of Cell Specific eNOS Function** Rosie T. Jiang,[1] Suwan Wang,[1] Keiko Takahashi,[1] Hiroki Fujita,[2] Matthew D. Breyer,[1] Raymond C. Harris,[1] Takamune Takahashi.[1] *[1]Nephrology, Vanderbilt University Medical Center, Nashville, TN; [2]Endocrinology and Metabolism, Akita University Graduate School of Medicine, Akita, Akita, Japan.*

Nitric oxide (NO) generated by eNOS enzyme plays a major role in vascular homeostasis. Further, recent studies of eNOS knockout mice have shown that abnormalities in eNOS expression and activity play a central role in the pathogenesis of diabetic nephropathy (DN). However, there remain uncertainties about the precise role of eNOS in DN. First, eNOS is present in a variety of non-endothelial cell types, including hematopoietic cells, cardiac cells, and renal tubular cells. Second, eNOS knockout mouse have been shown to exhibit congenital vascular and renal anomalies with high frequency, including septal defects, abnormal aortic valve development, and focal renal scars. Thus, a conditional knockout approach to target endothelial eNOS in adult diabetic mice is required to determine the role of endothelial eNOS in DN. To this end, we designed and generated a conditional allele (flox allele) in which the exons 9-12, encoding the sites essential to eNOS function, are excised by Cre-loxP recombination. Correct targeting events were confirmed by a series of Southern blot analysis and genomic PCR. Mice homozygous for floxed eNOS allele (flox/flox mouse) are healthy with morphologically normal kidneys, and their blood pressure and tissue eNOS protein levels do not differ from those in wild-type littermates. To evaluate the exons-deleted eNOS allele (lox allele), we also generated mice homozygous for lox allele (lox/lox mouse) by crossing with Sox2-Cre mice. Compared with wild-type littermates, the lox/lox mice showed higher blood pressure levels that are comparable to eNOS -/- mice, and Western blot analysis showed deletion of the targeted eNOS protein sequences in tissues. Taken together, these findings demonstrate that conditional targeting of eNOS gene can be achieved in our floxed eNOS mouse. This model should provide a

useful reagent for elucidating cell or tissue-specific eNOS function. Endothelial specific eNOS targeting study is currently underway.

**Elevated Tissue Factor Expression Contributes to Exacerbated Diabetic Nephropathy in Mice Lacking eNOS Fed a High Fat Diet** Nobuyuki Takahashi, Feng None Li, Chih-Hong Wang, Nobuyo Maeda. *Pathology, University of North Carolina at CH, Chapel Hill, NC.*

Human endothelial nitric oxide synthase (eNOS) polymorphisms that lower its expression are associated with advanced diabetic nephropathy (DN), and the lack of eNOS accelerates kidney damage in diabetic mice. Diabetes is associated with fibrin deposition. Lack of nitric oxide and fatty acids stimulate the NF-kB pathway, which increases tissue factor (TF). To test the hypothesis that TF contributes to the severity of DN in the diabetic eNOS-/- mice fed a high fat (HF) diet. We made eNOS-/- and wild type mice diabetic with streptozotocin. Half of them were placed on a HF diet. Blood glucose levels were not affected by either the diet or eNOS genotype. The lack of eNOS in the diabetic mice increased urinary albumin excretion, glomerulosclerosis, interstitial fibrosis, and glomerular basement membrane thickness. HF by itself did not affect DN in the wild type mice, but significantly enhanced DN in the eNOS-/- mice. More than half of diabetic eNOS-/- mice on HF died prematurely with signs of thrombotic complications. Diabetic kidneys contained fibrin and TF, and their levels were increased by the lack of eNOS and by HF in an additive fashion. The HF diet increased the kidney expression of inflammatory genes, including cell adhesion molecules, interleukin-1b, and interleukin-6. The increase in TF preceded the development of DN, and administration of an anti-mouse TF neutralizing antibody to diabetic mice reduced the increase in the expression of inflammatory genes. Together, these data indicate a causal link between TF and the exacerbation of DN in the eNOS-/- mice. The condition is significantly worsened by enhanced inflammatory responses to a HF diet via TF.

### TH-PO416

**Amelioration of Diabetes-Induced Renal Injury by Sodium Nitroprusside Is Associated with Glycogen Synthase Kinase 3 beta Activation** Meenalakshmi M. Mariappan,[1,2] Kavithalakshmi Sataranatarajan,[1,2] Goutam Ghosh-Choudhury,[1,2] B. S. Kasinath.[1,2] *[1]University of Texas Health Science Center, San Antonio, TX; [2]South Texas Veterans Health Care System, San Antonio, TX.*

We have previously shown that unphosphorylated glycogen synthase kinase 3beta (GSK 3beta) inhibits protein synthesis by phosphorylating eIF2Bepsilon (eIF2Be), a regulator of mRNA translation; high glucose-induced matrix protein synthesis in renal cells is mediated by Ser9 phosphorylation and inactivation of GSK 3beta (JBC, 2008). We hypothesized that activation of GSK 3beta by sodium nitroprusside (SNP) mitigates renal injury in diabetes. Male mice were divided into: Control (Con), Con+SNP (200ug/kg/day,IPx 3wks), Diab (induced by STZ), Diab+SNP. SNP did not affect blood glucose, body wt and blood pressure in non-diabetic or diabetic mice. Renal hypertrophy (45% increase in kidney/body wt ratio, $p<0.001$) seen in diabetes was reduced by 30% by SNP ($p<0.01$). Urinary albumin excretion, increased by 5-fold in diabetes ($p<0.001$), was reduced by 40% by SNP ($p<0.01$). Renal cortical matrix proteins fibronectin, laminin beta1 and laminin gamma1, increased by 2-fold in diabetes ($p<0.05$), were reduced by SNP ($p<0.05$). Diabetes increased inactivating Ser9 phosphorylation of renal cortex GSK 3beta by 4-fold ($p<0.01$) that was robustly decreased by SNP ($p<0.001$) indicating activation of the kinase. Neither diabetes nor SNP affected phosphorylation of GSK3 alpha isoform, indicating specificity for beta isoform. Diabetes promoted dephosphorylation of eIF2Be and SNP treatment fully restored it indicating its inhibition. Diabetes increased phosphorylation of Akt and Erk, upstream regulators of GSK 3beta; this was also reduced by SNP. SNP did not induce significant changes in above paremeters in control mice. Our study shows: 1. Diabetes-induced hypertrophy and matrix protein accumulation are associated with decrease in GSK 3beta phosphorylation and inactivation. 2. SNP ameliorates diabetes-induced renal hypertrophy, albuminuria and matrix protein increment. 3. SNP inhibits diabetes-activated Akt and Erk, resulting in activation of GSK 3 beta and inactivation of eIF2Be to inhibit protein synthesis in the kidney.

**When Should We Stop CRRT in AKI? Analysis of an International ICU Cohort** Dinna N. Cruz,[1] Roberto Fumagalli,[2] Manuel E. Herrera-Gutiérrez,[3] Paola Inguaggiato,[4] Detlef Kindgen-Milles,[5] Aníbal Defensor Marinho,[6] Rene Robert,[7] Claudio Ronco.[1] *[1]S Bortolo Hosp, Vicenza, Italy; [2]Milano Bicocca Univ, Monza, Italy; [3]Carlos Haya Hosp, Malaga, Spain; [4]S. Croce e Carle Hosp, Cuneo, Italy; [5]Univ Hosp, Dusseldorf, Germany; [6]Santo Antonio General Hosp, Porto, Portugal; [7]Univ Hosp, Poiters, France.*

**Introduction**

There is no consensus on timing of RRT initiation and discontinuation (DC) for acute kidney injury (AKI) in the ICU. Our aim was to identify predictors of successful DC.

**Methods**

We studied ICU patients started on CRRT in the DoReMi study. We excluded patients who died or were discharged from ICU while on RRT. Among those who stopped RRT, we classified them as "failed DC" (F) if they required repeat RRT or died ≤7 days after RRT was first stopped; "successful DC" (S) if they remained RRT-free for >7 days. We compared the 2 groups by uni- and multivariate analysis to identify independent predictors of "S".

**Results**

Of 294 patients who stopped first RRT cycle, 186 were classified as "S" while 108 as "F". At RRT-DC, S patients had lower SOFA, higher platelets, $PaO_2$, MAP and urine output. Serum Cr at RRT-DC was same in both groups. The S group had lower hospital mortality (25.9% vs 77.2% $p<0.01$). On multivariate analysis, urine output >400 ml/d was the strongest predictor for successful "weaning".

Table 1: Analysis for successful weaning from Acute RRT

| | Univariate | | Multivariate | |
|---|---|---|---|---|
| | OR(95%CI) | p | OR(95%CI) | p |
| **pH>7.35 at start RRT** | 0.43(0.26-0.70) | <0.001 | 0.46(0.27-0.79) | 0.005 |
| **$PaO_2$ at RRT-DC** | 1.01(1.00-1.02) | 0.075 | 1.01(1.00-1.02) | 0.002 |
| **Urine Output>400 ml/d at RRT-DC** | 2.77(1.36-4.68) | <0.001 | 2.69(1.52-4.77) | <0.001 |
| **MAP at RRT-DC(mmHg)** | 1.03(1.01-1.04) | <0.001 | 1.03(1.01-1.04) | 0.002 |
| **CRRT first cycle(days)** | 1.08(1.02-1.14) | 0.006 | 1.09(1.02-1.15) | 0.006 |

**Conclusion**

Over 60% of CRRT patients can be successfully weaned from RRT for >7 days. Adequate urine output was the strongest predictor for successful discontinuation.

### TH-PO418

**Early Start of Renal Replacement Therapy in Critically Ill Patients May Improve Renal Outcome but Not Survival** Matthias Klingele, Anne Lerner-Gräber, Danilo Fliser, Timo Speer. *Department of Internal Medicine, Nephrology, Saarland University Medical Centre, Homburg / Saar, Germany.*

**Methods**

Observational study of all patients requiring RRT in 2 internal medicine and 4 surgical intensive care units of our tertiary medical centre between 03/2007 and 08/2009. Patients being on chronic RRT before admission to the hospital were excluded from analysis. Serum creatinine and urea levels at the start of RRT, mortality and recovery of kidney function were assessed during hospitalization and in a follow-up period of 511 ± 249 days after discharge.

**Results**

In total, 583 patients and 5,694 RRTs were included for analysis. The in-hospital mortality was 68.4% (n=399), whereas the mortality rate in survivors after discharge who were not lost to follow-up was 25.7% (n=140). There was no statistically significant difference in serum creatinine and urea levels at initiation of RRT between those patients who died and those who survived. After discharge, in 20 survivors no recovery of renal function after AKI could be observed and they required RRT due to persistent renal insufficiency. In these patients serum creatinine (261 ± 151 vs. 475 ± 282 µmol/L; $p=0.000$) as well as serum urea (20.8 ± 11 vs. 30.8 ± 16.5 mmol/L; $p=0.007$) levels were significantly higher at initiation of RRT compared to those in whom renal function recovered after discharge.

**Conclusion**

In critically ill patients with AKI requiring RRT on the intensive care unit, lower serum creatinine and urea levels at the initiation of RRT indicate better renal outcome after hospital discharge, while mortality is not affected. This observation supports the notion that an earlier start of RRT in critically ill patients with AKI may preserve kidney function.

**Behavior of the Middle and Large Solutes during SLED and SLED-*f*** Pei-Chen Wu,[1] Vincent Wu,[1] Hung-Bin Tsai,[2] Pi-Ru Tsai,[3] Wen-Je Ko,[3] Kwan-Dun Wu.[1] *[1]Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [2]Internal Medicine, Buddhist Tzu Chi General Hospital, Chiayi, Taiwan; [3]Surgery, National Taiwan University Hospital, Taipei, Taiwan.*

**Introduction:** It remains challenging for nephrologists to evaluate the dose of renal replacement therapy (RRT) in critically ill patients with AKI. Since SLED and SLED-*f* have gained increasing popularity in the ICUs while few studies have focused on their dialysis efficiency, we examine the dialysis dose by these modalities.

**Methods:** We prospectively enrolled 7 patients with AKI and with MRSA infection receiving vancomycin treatment. These patients were randomly assigned to either SLED or SLED-*f*, and exchanged their RRT on the following day. The extent of solute (urea, vancomycin, and β2-microglobulin) removal was measured from direct dialysate quantification (DDQ). We examined the behavior of solutes in the perfused compartment during dialysis by the EKR and double-pool kinetic model.

**Results:** These patients (mean age 63.7±11.5; 4 of them female) had ultrafiltration 2.4±1.0 kg during SLED and 1.7±1.2 kg during SLED-*f*. The solute clearance, calculated by EKR and double-pool kinetic model separately, showed good correlation with DDQ.

Solute Behavior Predicted by EKR and Double-Pool Kinetic Model During SLED-f and SLED

| Mode | SLED-f (urea) | SLED (urea) | SLED-f (vancomycin) | SLED (vancomycin) | SLED-f (B2M) | SLED (B2M) |
|---|---|---|---|---|---|---|
| Patient Number | 7 | 7 | 3 | 3 | 5 | 3 |
| Post-Dialysis Weight (kg) | 66.4±14.1 | 65.8±13.2 | 70.4±15.7 | 69.0±13.9 | 68.9±16.0 | 61.8±13.5 |
| Ultrafiltration (kg) | 1.7±1.2 | 2.4±1.0 | 2.7±0.8 | 2.9±0.9 | 2.0±1.3 | 2.0±0.7 |
| EKR (ml/min) | 132.5±32.3 | 131.4±30.5 | 95.3±24.9 | 84.5±19.4 | 36.6±4.6 | 26.6±3.3 |
| R | 0.990 | 0.980 | 0.948 | 0.945 | 0.917 | 0.902 |
| dpK (ml/min) | 106.3±26.2 | 94.0±24.7 | - | - | 24.1±2.1 | 18.6±3.2 |
| R | 0.981 | 0.966 | - | - | 0.891 | 0.880 |

**Conclusion:** The EKR and double-pool kinetic model could specifically predict the behavior of urea, a small molecular weight solute, as well as middle and large molecules such as vancomycin and β2-microglobulin during SLED and SLED-*f*. Not surprisingly, SLED-*f* offers higher solute clearance than SLED does.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO420

**High Cut-Off (HCO) Renal Replacement Therapy for Removal of Myoglobin in Severe Rhabdomyolysis and Acute Kidney Injury** Nils Heyne,[1] Martina Guthoff,[1] Katja C. Weisel,[2] Hans-Ulrich Haering.[1] *[1]Department of Endocronology and Diabetology, Angiology, Nephrology and Clinical Chemistry, University of Tübingen, Tübingen, Germany; [2]Department of Hematology, Oncology and Immunology, Unversity of Tübingen, Tübingen, Germany.*

Rationale: Rhabdomyolysis is associated with the release of myoglobin into the circulation, promoting acute kidney injury (AKI) by cellular toxicity, altered renal hemodynamics and heme pigment tubular obstruction. In rhabdomyolysis patients, dialysis-dependent AKI doubles mortality. Myoglobin removal by standard blood purification techniques has limited efficacy and prognostic impact. We describe the use of high cut-off (HCO) protein permeable filters for rapid extracorporeal elimination of myoglobin in severe rhabdomyolysis.

Methods: With an in vivo molecular cut-off at 45 kD, HCO filters (Gambro HCO1100, Theralite) are effective in removing 17.8 kD myoglobin. Elimination kinetics (n = 118) across standard and HCO filters were intraindividually assessed in 9 patients with severe rhabdomyolysis and AKI using continuous and intermittent renal replacement therapy (CVVHD, batch hemodialysis (SLEDD), hemodialysis (HD)). Clearances rates were normalized per m² of membrane surface area.

Results: Median myoglobin clearance on CVVHD was 1.1 [interquartile range 0.8 - 1.2] ml/min. Standard high-flux hemodialysis resulted in a median myoglobin clearance of 2.2 [1.7 - 3.9] ml/min. Up to 20-fold higher clearances were obtained using HCO filters in both continuous (SLEDD: 20.2 [17.9 - 24.3] ml/min) and intermittent (HD: 40.2 [37.5 - 42.7] ml/min) dialysis techniques. Using full size (2.1 m²) HCO filters, median absolute myoglobin clearances in excess of 70 ml/min (HD) were achieved, resulting in rapid and highly effective reduction of plasma myoglobin concentration. Albumin losses across HCO filters require substitution over time.

In conclusion, HCO renal replacement therapy for the fist time allows the safe and highly efficient elimination of myoglobin in severe rhabdomyolysis and acute kidney injury. Limiting exposure of the kidneys to myoglobin may improve renal recovery and patient prognosis.

**The "Gap" between Prescribed and Delivered CRRT Dose: Analysis of an International ICU Cohort** Dinna N. Cruz,[1] Roberto Fumagalli,[2] Manuel E. Herrera-Gutiérrez,[3] Paola Inguaggiato,[4] Detlef Kindgen-Milles,[5] Aníbal Defensor Marinho,[6] Rene Robert,[7] Claudio Ronco.[1] *[1]S Bortolo Hosp, Vicenza, Italy; [2]Milano Bicocca Univ, Monza, Italy; [3]Carlos Haya Hosp, Malaga, Spain; [4]S. Croce e Carle Hosp, Cuneo, Italy; [5]Univ Hosp, Dusseldorf, Germany; [6]Santo Antonio General Hosp, Porto, Portugal; [7]Univ Hosp, Poiters, France.*

**Introduction**

CRRT dose is a modifiable factor in the ICU management of acute kidney injury (AKI). In the DoReMi study, the median prescribed CRRT dose (RxD) was 34.3 while delivered (DD) was 27.1ml/kg/hr. Other studies also show that DD is lower than RxD. Our aim was to identify factors contributing to the "gap" between RxD and DD.

**Methods**

We studied 338 patients treated with CRRT in the DoReMi study. We calculated "%dose gap" as 100*((RxD-DD)/RxD). We grouped patients into "low gap" (≤15%, n=108) and "high gap" (>15%, n=220). We performed uni- and multivariate analysis to identify independent predictors of high CRRT dose gap.

**Results**

The "high gap" group was younger, had lower pH, higher WBC & platelet counts. They had longer "downtime" (no. of hours/day in which CRRT is interrupted), more likely to have femoral access, and used higher % of pre-dilution replacement fluid. On multivariate analysis, %pre-dilution and CRRT downtime were significant independent predictors of a high dose gap.

Table 1: Predictors of "high" CRRT dose gap

| | Univariate | | Multivariate | |
|---|---|---|---|---|
| | OR(95%CI) | p | OR(95%CI) | p |
| Age(yrs) | 0.98(0.97-0.99) | 0.008 | 0.98(0.97-1.00) | 0.053 |
| CVVH or HVHF modality | 0.62(0.40-0.98) | 0.042 | 1.82 (0.93-3.56) | 0.080 |
| pH<7.2 | 1.57(0.98-2.51) | 0.059 | 2.86(1.23-6.67) | 0.015 |
| Downtime(hrs) | 2.07(1.62-2.65) | <0.001 | 1.92(1.50-2.46) | <0.001 |
| Pre-dilution>67% | 3.29(2.05- 5.29) | <0.001 | 4.20(2.14-8.28) | <0.001 |

**Conclusions**

Other than CRRT downtime, the use of high %pre-dilution for replacement fluid may be a significant, and previously unrecognized, contributing factor to the CRRT dose gap. Physicians should take this into consideration when prescribing CRRT.

Disclosure of Financial Relationships: Honoraria: Speaker Honoraria for Biosite/ Inverness Medical.

## TH-PO422

**Effect of Type of Anticoagulation on Delivered Dialysis Dose of CRRT** Rolando Claure-Del Granado,[1] Etienne Macedo,[1] Sharon Soroko,[1] Glenn M. Chertow,[2] Jonathan Himmelfarb,[3] T. Alp Ikizler,[4] Emil P. Paganini,[5] Ravindra L. Mehta.[1] *[1]University of California, San Diego; [2]Stanford University School of Medicine; [3]Kidney Research Institute, University of Washington; [4]Vanderbilt University Medical Center; [5]Cleveland Clinic Foundation.*

***Background:*** Efficiency of CRRT depends on circuit longevity which is influenced by anticoagulation and the operational characteristics of the modality. Effluent volume is a surrogate for dose delivered, however comparisons across modalities are scant. We evaluated the effect of anticoagulation (AC) on the efficacy of 3 CRRT modalities on delivered dose. We hypothesized that the choice of AC and modality affect delivered dose of dialysis. ***Methods:*** We analyzed data from 1,730 sessions of 24 hrs in 244 critically ill pts from 5 centers included in the PICARD study, with at least 48 hours on CRRT (CVVH, CVVHD or CVVHDF). Citrate (TSC), heparin (Hep) or no anticoagulant (No-AC) was used to prevent filter clotting. Delivered dose was calculated by using stdKt/V adjusted for each type of therapy (Artif Organs 30:178-185;2006). ***Results:*** Among modalities CVVHDF had the highest delivered dose when citrate was used as AC. Filter longevity is significantly lower with heparin and non AC circuits and resulted in the use of a higher number of filters to achieve the same delivered dose(Table 1).

Comparisons of delivered stdKt/V with use of heparin, citrate or no anticoagulation among different types of CRRT

| **Type of anticoagulant** | | | | |
|---|---|---|---|---|
| | Mean filter life [hrs] (# of filters) | CVVH * | CVVHD * | CVVHDF * |
| **Citrate** | 54.5 (173) | 1.7 (0.59-2.9) | - | 8.2(5.9-10.4) |
| **Heparin** | 21.1 (824) | 2.85(1.8-4.1) | 5.6(4.6-7.4) | 8.3(5.8-10.8) |
| **No anticoagulant** | 23.1 (403) | 7.3(5.3-9.0) | 5.9(4.5-7.3) | 8.5(6.3-11.2) |
| **p value** | < 0.001 | < 0.001 | 0.584 | 0.062 |

*Median (IQR) stdKt/V

***Conclusions:*** Computation of stdKt/V allows comparison of delivered dose across modalities. Choice of AC influences the dose delivered with citrate AC providing the highest dose per filter used. Dose studies should consider AC type as a factor influencing delivered dose.

**Hemodiafiltration with High Flux Polyphenylene Membrane (Phylther®). A Much Cheaper Alternative to HCO Dialysis for Kappa Light Chain Cast Nephropathy** Simon Desmeules, Mohsen Agharazii. *Medicine, CHUQ, Quebec, QC, Canada.*

Introduction : Addition of extended High Cut-Off (HCO) dialysis to uninterrupted chemotherapy might improve renal recovery in patients with cast nephropathy (CN). Reported Free Light Chain (FLC) reduction ratios average 65-71%. Unfortunately, HCO dialysers costs are prohibitive. We report the reduction ratios (RR) of FLC and clinical outcome of 6 patients with renal failure due to multiple myeloma (MM), using hemodiafiltration (HDF) with various types of dialysers.

Methods: Retrospective and prospective data collection among patients with acute renal failure due to MM needing dialysis. Only one filter per session were used. HDF was performed with either online fluid generation (predilution ol-HDF(34-49L)) or a biofiltration system using Hemosol B0 5L bags as an post filter infusion fluid (9-14L). FLC were measured by nephelometry (FREELITETM, The Binding Site, San Diego, USA) before and at the end of the each hemodiafiltration session using the slow flow/stop pump technique. Results: A total of 116 HDF sessions were evaluated. 5/6 patients had kappa FLC elevation among which, 4 had biopsy proven cast nephropathy (creatinine 5.6-13.8 mg/dL). One patient had lambda CN. Table summarizes FLC and beta2-microglobuline RR. Our results demonstrate that ol-HDF with Phylther®HF22SD achieves kappa FLC RR comparable to HCO dialysis/HDF. All 4 patients with biopsy proven kappa FLC CN recovered dialysis-independent renal function within 5-100 d (creatinine 0.76-2.9 mg/dL). Regarding lambda FLC clearance, HCO HDF with Theralite offers better clearances.

| | | reduction ratio | | | reduction ratio | |
|---|---|---|---|---|---|---|
| | n | kappa | beta2 | n | lambda | Beta2 |
| HCO 1100 | 14 | 70.2% | na | | | |
| TheraLite | | | | 34 | 63.0% | 69.6% |
| HF22SD | | | | | | |
| olHDF | 21 | 79.6% | 67.1% | 4 | 35.0% | 56.2% |
| bagHDF | 20 | 50.2% | 50.1% | | | |
| Nephral500 | 7 | 45.3% | na | | | |
| Polyflux 210H | 16 | 25.8% | na | | | |

Conclusion: Our experience suggests that in patient with dialysis dependant kappa FLC cast nephropathy, HDF with high flux Phylther® HF22SD resulted in a similar degree of kappa FLC RR as compared to HCO, and in addition to early chemotherapy resulted in renal function recovery.

**TH-PO424**

**Factors Affecting the Adequacy of Hemodialysis in Acute Setting – A Follow-Up Study** Jasmeet Kaur, Manjusha Rajamohanty, Manpreet Singh, Kaushik Manthani, Mersema Abate, Nand K. Wadhwa. *Division of Nephrology, SUNY, Stony Brook, NY.*

Urea reduction ratio (URR) of ≥ 65% is considered optimal hemodialysis (HD) treatment in chronic setting. Prescribed HD treatment, more often may not be adequate and may also not be delivered as prescribed in the acute setting. We previously reported that 34% of acute HD treatments had URR < 65% due to inadequate HD prescription and delivery (Am J Kid Dis 51: B28, 2008). We initiated a protocol where parameters were set to provide an adequate HD treatment. The patients with AVF/AVG should be prescribed a BFR of 450 ml/min and with catheters a BFR of 350 ml/min. URR was measured each HD treatment. We collected data on 389 HD sessions in 67 patients from March 2008 to November 2009. Three hundred thirty six (86%) HD sessions had URR ≥65% while 53 (14%) sessions had URR < 65%. One hundred sixty four (42%) HD sessions were done using AVF/AVG and 225 (58%) done using catheters. Mean BFR of ≥300ml/min was delivered in 350 (90%) of HD sessions.

Patient Characteristics and URR

| Variable | URR ≥ 65% | URR < 65% | P value |
|---|---|---|---|
| Age (years) | 61 ± 15 | 57 ± 17 | NS |
| Weight (Kg) | 75.1 ± 20.7 | 87.6 ± 24.8 | < 0.001 |
| AVF-AVG/Catheter | 148/190 | 19/32 | NS |
| HD duration prescribed (hours) | 3.9 ± 0.2 | 3.7 ± 0.5 | NS |
| HD duration delivered (hours) | 3.9 ± 0.3 | 3.6 ± 0.5 | NS |
| BFR prescribed (ml/min) | 393.0 ± 54.1 | 361.6 ± 66.1 | < 0.05 |
| BFR delivered (ml/min) | 365.9 ± 54.6 | 328.5 ± 68.0 | NS |
| UF prescribed (liters) | 3.0 ± 9.7 | 2.5 ± 0.9 | NS |
| UF delivered (liters) | 2.3 ± 0.8 | 2.6 ± 1.2 | < 0.05 |

Patients with URR <65% had significantly higher body weight. Prescribed and delivered BFR were significantly lower in HD using catheters compared to AVF/AVG. Prescribed and delivered BFR were significantly lower in the group with URR < 65% compared to the group with URR ≥ 65%. In both groups, delivered BFR was significantly lower than the prescribed rate. Sub optimal HD (URR < 65%) decreased to 14% of the HD sessions compared to 34% in our previous study. In conclusion, we as prescribers not only prescribe adequate dialysis but also need to ensure proper delivery in order to improve dialysis treatment in acute setting.

**Optimal Timing of CRRT and Clinical Outcomes in Critically Ill Patients with AKI** Yong Chul Kim, Kwon Wook Joo, Yon Su Kim, Curie Ahn, Jin Suk Han, Suhnggwon Kim, Dong Ki Kim. *Internal Medicine, Seoul National University College of Medicine, Seoul, Korea.*

**Introduction** We evaluated retrospectively the optimal timing of CRRT stratified by various clinical and laboratory parameters and its association with clinical outcomes in patients with rapidly progressive AKI.

**Methods** A retrospective study was performed on the data of 658 AKI patients received CRRT in intensive care unit (ICU) of Seoul National University Hospital from October 2007 to January 2010. Rapidly progressive AKI was defined as >2-fold increase of serum creatinine or >50% reduction of hourly urine output during 24h prior to initiation of CRRT. Data included RIFLE criteria, SOFA score, APACHE II score, and number of organ failures. Timing of CRRT was stratified into 'early' and 'late' by median value of BUN and creatinine levels at the start of CRRT, and also by median urine output during 6h, 12h, and 24h before the initiation of CRRT. The clinical outcomes assessed included duration of RRT, ICU stay, hospital stay and 90 day-mortality.

**Results** There were no significant differences in outcomes of patients between early and late group stratified by median value of creatinine at the start of CRRT. However, in terms of BUN, 90 day mortality rate was significantly higher for late group (BUN 54 > mg/dL) in univariate analysis (P=0.013), but not in multivariate analysis. When the patients were stratified by urine output before CRRT, patients with lower urine output during 6h (early >110ml) and 12h (early >260ml) before CRRT had significant higher multivariate-adjusted, 90 day-mortality. (6h: OR 1.45, 95% CI 0.99-2.15, P=0.005, 12h: OR 1.69, 95% CI 1.14-2.39, P=0.008). Finally, when CRRT was started at 'Failure' stage of RIFLE criteria compared with 'Injury' stage, the multivariate adjusted OR for death was 1.74 (95% CI 1.15-2.64). Duration of RRT, ICU stay and hospital stay had no significant differences between 'early' and 'late' group.

**Conclusion** Our data suggest that early CRRT may have survival benefit in critically ill patients with rapidly progressive AKI, and urine output is the most important parameter for the decision to start CRRT.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO426**

**Influence of DECAP and DECAP+CVVH Treatment on Hemodinamics and Respiratory Pressures** Anthi Panagiotou,[1,3] Gramaticopolo Silvia,[2] Dinna N. Cruz,[1,3] Nicola Marchionna,[1,3] Matteo Floris,[1,3] Alessandra Brendolan,[1] Federico Nalesso,[1,3] Monica Zanella,[1] Francesco Garzotto,[1,3] Pasquale Piccinni,[2] Claudio Ronco.[1,3] *[1]Nephrology, S Bortolo Hosp, Vicenza, Italy; [2]Intensive Care Unite, S Bortolo Hosp, Vicenza, Italy; [3]IRRIV, Vicenza, Italy.*

Introduction: In Acute Lung Injury (ALI) it is important to limit alveolar pressure and shear stress by applying low tidal volumes (TV) at the cost of increased arterial blood $CO_2$ and respiratory acidosis. Extracorporeal CO2 removal (DECAP) is a method to achieve ultra-low TV in mechanically ventilated (MV) patients with severe respiratory failure avoiding respiratory acidosis. The extracorporeal CO2 removal cartridge can be combined with a hemofilter for renal replacement therapy (RRT). This coupled system has been used in AKI + ALI, MV patients, reducing ventilatory pressures expressed as Peak Inspiratory Pressure (PIP), ameliorating hemodinamics and respiratory acidosis.

Methods: Four patients (3 F, 1 M) admitted to the ICU for septic multiorgan failure were treated with DECAP and DECAP+CVVH. Duration of DECAP treatment ranged from 24 to 48 hours while for DECAP+CRRT was 12hours. Blood gas analysis, respiratory and hemodinamics parameters were recorded at time 0, 1st hour and after 6 hours.

Results: During DECAP treatment alone and CVVH+DECAP treatment it was possible to reduce the PIP, normalize pH with an improvement in hemodinamics without adverse events.

DECAP AND DECAP+CVVH DATA

| DECAP DATA | | | | | | | |
|---|---|---|---|---|---|---|---|
| | t0 | 1st hr | 6th hr | | | | |
| Max PIP (cmH2O) | 32 | 29 | 29 | | | | |
| pH | 7,22 | 7,39 | 7,35 | | | | |
| Medium BP (mmHg) | 82 | 89 | 87 | | | | |
| pCO2 (mmHg) | 121 | 77 | 80 | | | | |
| | | | | | | | |
| DECAP+CVVH DATA | | | | | | | |
| pH | t0 | 1st hr | 6th hr | pCO2 (mmHg) | t0 | 1st hr | 6th hr |
| A | 7,31 | 7,4 | - | A | 92 | 67 | - |
| B | 7,33 | 7,36 | 7,36 | B | 47,2 | 45,1 | 54 |
| C | 7,22 | 7,23 | 7,39 | C | 74,1 | 65 | 43,9 |
| | | | | | | | |
| PIP (cmH2O) | t0 | 1st hr | 6th hr | Medium BP (mmHg) | t0 | 1st hr | 6th hr |
| A | 30 | 28 | - | A | 53 | 84 | 73 |
| B | 33 | 29 | 27 | B | 58 | 88 | 80 |
| C | 39 | 37 | 29 | C | 108 | 92 | 89 |

Conclusions: DECAP system combines CO2 removal and protective ventilation, protecting the lung by a further reduction in TV, managing acidosis with a minimally invasive system and side effects. In AKI patients the same system can be used in combination with a hemofilter using a single venous access to perform standard CRRT.

Disclosure of Financial Relationships: nothing to disclose

**24-Hour Sustained Low Efficiency Dialysis (SLED) with Near-Automated Regional Citrate Anticoagulation (RCA) Incorporating Online Ionic Dialysance (OLC) and Optical Hematocrit Monitoring: The First 1000 Hours Experience** Balazs Szamosfalvi, Stan Frinak, Lenar T. Yessayan, Jerry Yee. *Division of Nephrology and Hypertension, Henry Ford Health System, Detroit, MI.*

**Purpose:** Evaluation of a 24-h SLED-RCA protocol with OLC that provides highly effective anticoagulation with a calcium infusion (QCa) prediction algorithm which maintains normal systemic ionized Ca (iCa) in all patients.

**Methods:** 8 critically ill patients, 5 with severe liver dysfunction were treated with 24-h SLED-RCA for total >1000 treatment hours. The system includes a 1.5 $m^2$ high-flux hemodialyzer; zero calcium, 140 Na and 32 bicarbonate dialysate with optional phosphate supplement 3.2 mg/dL; a dialysis machine with OLC measurement and an optical hematocrit (Hct) sensor. Flow rates were QB=60 mL/min; QD=400 mL/min; Qcitrate=150 mL/h of Acid Citrate Dextrose-A; and net ultrafiltration as indicated. The QCa was infused into the venous limb of the circuit and adjusted hourly as a function of online Hct and a <24 h-old albumin level. Systemic iCa was sampled every 6 h.

**Results:** The high Qcitrate to QB ratio completely abrogated circuit clotting without adverse electrolyte or acid-base effects. The algorithm QCa accurately adjusted systemic iCa between 0.9 and 1.3 for all patients. Sodium and bicarbonate approximated normal values during treatment. OLC was feasible and stable in the range of 40-57 mL/min. Optical hematocrit correlated well with laboratory values. Ultrafiltration was well tolerated and effective over several days. Access recirculation was noted in one patient but did not affect QCa dosing. Systemic citrate accumulation did not occur even after days of SLED-RCA as evidenced by systemic total calcium to iCa ratio. Nurse satisfaction with the modality was very high.

**Summary:** The >95% citrate extraction on the dialyzer prevented systemic citrate accumulation even in shock liver patients. Predictive QCa dosing based on albumin and Hct resulted in normal systemic iCa and a very simple to perform RCA protocol. We conclude that 24-h SLED-RCA is a safe alternative to traditional CRRT and holds great promise to expand the use of 24-hour renal support in the ICU without an increase in costs.

Disclosure of Financial Relationships: Consultancy: Baxter, Inc.Research Funding: Fresenius; Honoraria: Renal Research Institute; Patent: Automated system for the delivery of regional citrate anticoagulation (patent application).

**TH-PO428**

**Liver Dysfunction Predicts Development of Citrate Toxicity in Patients on Continuous Renal Replacement Therapy** Scott E. Liebman,[1] Joseph J. Guido,[2] Rebeca D. Monk.[1] *[1]Medicine, University of Rochester, Rochester, NY; [2]Preventitive Medicine, University of Rochester, Rochester, NY.*

**Background-** Citrate use during continuous renal replacement therapy (CRRT) may lead to toxicity if citrate entering the systemic circulation is not sufficiently metabolized. Liver failure is considered a risk factor for citrate toxicity, but supporting data are scant. We hypothesized that patients who develop citrate toxicity have more severe liver dysfunction compared with patients who do not.

**Methods-** This is a retrospective study of 372 patients receiving CRRT (typically continuous venovenous hemodiafiltration, starting with predilutional citrate-containing replacement fluid at one liter per hour, and dialysate at one liter per hour) at the University of Rochester between 1/1/2006 and 7/24/2009. Citrate toxicity was defined as one or two occurrences of a total to ionized calcium ratio of ≥2.5 (T/I ratio). Relevant pre-CRRT laboratory values were compared between toxic and non-toxic patients.

**Results-** Of 372 patients, 116 had one elevated T/I ratio (31%) and 59 had at least two (16%). Patients developing citrate toxicity by both definitions had a significantly higher AST, INR, albumin, lactate and total bilirubin compared with those who did not. Ammonia was also higher in patients with two elevated T/I ratios.

Demographic factors predicting the development of citrate toxicity on univariate analysis included female gender. Toxic patients were more likely to be younger (by two T/I ratios) and African American (by one T/I ratio).

Albumin, INR, lactate and total bilirubin remain significant in the multivariate stepwise logistic regression model.

**Conclusions-** Pre-CRRT laboratory values indicative of more severe liver dysfunction are associated with the development of citrate toxicity on CRRT. Female gender, age, and African American race may also be predictive.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO429**

**In Vitro Evaluation of Teicoplanin Adsorption Kinetics onto Polysulfone Membrane** Marco Sartori,[1] Dinna N. Cruz,[1] Giuliano Dall'olio,[1] Francesco Garzotto,[1] Mirella Zancato,[2] Claudio Ronco.[1] *[1]S Bortolo Hosp; [2]University of Padua.*

Teicoplanin is an alternative drug for sepsis due to Gram(+) Vancomycin-resistant infection. Septic patients can develop severe acute kidney injury requiring Renal Replacement Therapy. Therefore it is important to understand drug removal by RRT to help guide dosing.

METHODS

Mock hemopefusion (HP) was performed for 120 min using 5L of Teicoplanin solution (71.0 µg/ml). After 5 min of priming, this solution was circulated in a closed circuit simulating HP (Qb 300mL/min) using a 1.5m2 polysulfone membrane. Drug levels were measured at 15,30,60,120 min from arterial(Cpin)and venous(Cpout)ports. After 120 min of HP, mock zero-balance hemofiltration (HF) was then performed (Qb 300mL/min,Quf 60mL/min) with 0.9%NS as replacement fluid. Samples were taken from arterial, venous and ultrafiltrate(Cpuf)ports at same intervals. Teicoplanin levels were measured using fluorescence polarization immunoassay. Teicoplanin removal kinetics,adsorption,sieving coefficient(SC) were calculated.

FINDINGS

At end of HP, Teicoplanin level (Cpout) was 38.9µg/mL. Ratio of Cpout/Cpin rose rapidly during priming and first 30 min of HP, then plateaued (Fig 1), likely due to drug adsorption in the first 30 min. Furthermore, SC was stable at 1.09, 1.03, 1.01 and 1.01 after 15, 30, 60 and 120 min of HF, supporting this presumption. On mass balance analysis, the sum total amount of Teicoplanin retrieved from the system at the end of HP (M-outflow 221.8 mg)was notably less than that introduced into the system (494.9 mg), suggesting that 273.1 mg (55%) were adsorbed onto the polysulfone membrane (Fig 2).

CONCLUSION

In this in-vitro study,the estimated adsorption was more than half the dose. This should be considered when Teicoplanin is used in patients on RRT. A supplemental dose at RRT initiation may be needed to avoid potential underdosing.

**Is It True That Fluid Overload Is Independent Risk Factor of Mortality in Critically Ill Patients Regardless of Disease Severity?** Ihm Soo Kwak, Sang Heon Song, Jung Sub Kim, Harin Rhee, Eun Young Seong, Soo Bong Lee, Il Young Kim, Jungmin Son. *Department of Internal Medicine, Pusan National University School of Medicine, Busan, Korea.*

**Purpose**: Recent studies suggested that fluid accumulation is associated with adverse outcome in critically ill patients. **Method**: From January 2007 to December 2008, a total of 146 patients who underwent CRRT in ICU were evaluated. Percent fluid overload(%FO) was defined as total fluid input minus output (3days before CRRT start(%FO1) and from CRRT initiation to ICU discharge(%FO2)) divided by body weight. Also, we calculated APACHIE IV score from clinical data. **Results**: Mean renal replacement time was 74±77.8 hours and 64patients survived(43.8%). Mean %FO1 and total %FO were significantly lower in survivors than non-survivors(2.8% vs. 5.4%, p=0.001 and 4.9% vs. 9.4%, p=0.004, respectively). Patients' characteristics stratified by fluid overload status are summarized in Table 1. For the low APACHIE IV(below 89)group, %FO1 was higher in non-survivors than survivors(2.2±3.5 vs. 5.0±5.4, p=0.013). But for the high APACHIE IV group(above 89), total %FO was higher in non-survivors than survivors (4.9±8.8 vs. 9.4±9.4, p=0.047). **Conclusion**: Our study shows fluid overload was associated with mortality, but it was not an independent risk factor. According to the results of subgroup analysis, we suggest that high APACHIE IV group has much more difficulties in correcting fluid overload during CRRT.

Table 1. Patients' characteristics based on fluid status

| Baseline Characteristics | Non fluid overload(n=74) | Fluid overload(n=72) | P |
|---|---|---|---|
| MAP (mmHg) | 80.8 (17.4) | 74.8 (14.8) | 0.025 |
| Urine output (ml/day) | 1242.0 (1220.3) | 653.6 (854.1) | 0.001 |
| Tachycardia | 29 (39.2%) | 44 (61.1%) | 0.008 |
| Peak Cr (mg/dl) | 5.0 (3.0) | 3.9 (1.7) | 0.007 |
| CRP (mg/dl) | 12.2 (12.4) | 16.7 (12.6) | 0.034 |
| AST (IU) | 328.1 (810.7) | 729.4 (1309.8) | 0.028 |
| ALT (IU) | 171.2 (371.4) | 367.9 (688.0) | 0.035 |
| APACHE IV | 83.6 (25.5) | 93.5 (24.1) | 0.017 |
| Cardiovascular failure | 51 (68.9%) | 64 (88.9%) | 0.003 |
| Ventilator use | 45 (60.8%) | 56 (77.8%) | 0.026 |

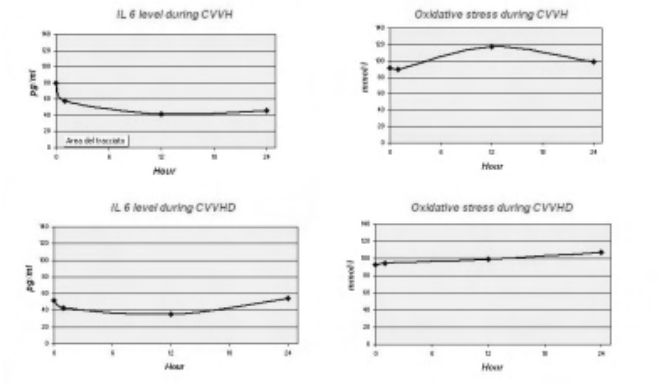
**IL-6 Decrese and Oxidative Stress Evaluation during Continuous Renal Replacement Therapy with a New High Polysulfone-Based Hemofilter (CUREFLO®)** Matteo Floris,[1,3] Nicola Marchionna,[1,3] Alessandra Brendolan,[1] Federico Nalesso,[1,3] Monica Zanella,[1] Pasquale Piccinni,[2] Massimo De Cal,[1,3,4] Grazia Maria Virzì,[1,3] Dinna N. Cruz,[1,3] Claudio Ronco.[1,3] *[1]Nephrology, S Bortolo Hosp, Vicenza, Italy; [2]ICU, S Bortolo Hosp, Vicenza, Italy; [3]IRRIV, Italy; [4]University of Padua.*

BACKGROUND: The Oxidative Stress (OS) and the balance between pro- and anti- inflammatory cytokines may contribute to unfavourable outcomes in ICU patients; death is even higher when associated with Acute Kidney Injury (AKI). Continuous Renal Replacement Therapy (CRRT) can reduce the inflammatory status. We reported the variation of an inflammatory biomarker, the Interleukine 6 (IL6) and oxidative stress with advanced oxidation protein products (AOPP)in a patient requiring CRRT admitted in ICU for AKI.

METHODS: we performed 11 treatments, 6 Continuous Veno Venous Hemofiltration (CVVH) and 5 Continuous Veno Venous Hemodialysis (CVVHD) using ACF-130W hollow-fiber dialyzer (1.3 sqm, Asahi Kasei Kuraray Medical co.Ltd. Patients were treated by CRRT using the Multifiltrate Fresenius machine. The treatment conditions were: CVVH (Qb 200 ml/min; Qr 1500 ml/h in postdiluition; Qf -100 ml/h) or CVVHD (Qb 200 ml/min; Qd 2500 ml/h; Qf -100 ml/h). Samples were collected before the sessions and after 1, 12 and 24h from the beginning. We measured the decrease in IL-6 and oxidative stress after every session.

RESULTS: As shown, the CVVH treatment is related with a major reduction of IL 6 level.



Furthermore AOPP increase during both treatments, especially in CVVHD mode.

CONCLUSION: Our data suggest that this filter is able to remove Il-6 by convection but not by diffusion and adsorption. The study of oxidative stress demonstrated that during all treatments AOPP increased more in CVVHD than in CVVH as it can be explained by the IL-6 (and other cytokines) removal by convection only.

**Hypophosphatemia – Major but Relatively Unrecognized Complication during CRRT** Norio Hanafusa,[1] Kousuke Negishi,[1] Kent Doi,[1] Naoki Yahagi,[2] Eisei Noiri,[1] Toshiro Fujita.[1] *[1]Department of Hemodialysis and Apheresis, The University of Tokyo Hospital, Tokyo, Japan; [2]Department of Emergency and Critical Care Medicine, The University of Tokyo Hospital, Tokyo, Japan.*

**Introduction:** Several investigations have shown that hypophosphatemia frequently occurs during CRRT especially in higher dose of CRRT [NEJM 361: 1627, 2009]. In Japan we often deliver the reduced dose of CRRT. Therefore we investigate the incidence of hypophosphatemia during CRRT, the causative factors and its relation with mortality.

**Settings:** The study was conducted in a retrospective observational manner. We investigated all patients who underwent CRRT in the ICU at our tertiary teaching hospital during 2007. We collected data from medical charts for CRRT therapy and laboratory data including serum phosphate concentration.

**Results:** During the study period, 106 CRRT courses were identified. Among them, the serum phosphate of only 57 patients was measured. Most who were measured experienced hypophosphatemia (median 2.0 mg/dl) during the course, though they were received reduced dose of CRRT; effluent flow rate was 19.7±8.86ml/kg/hr. The time up to the measurement was inversely related with the lowest value of phosphate. In the multivariate analysis, the lowest value of phosphate predicted 30 days mortality (OR 0.38 95%CI 0.08-0.98 $p$=0.045) after adjustment of age, SOFA score, ESRD or not, and initial creatinine value.

**Discussion:** The incidence of hypophosphatemia was high also in this population, though the reduced dose of CRRT. The serum phosphate level was not determined in many cases, which indicates that hypophosphatemia during CRRT might seem not so familiar to physicians in the ICU. Moreover the reason remains unclear but hypophosphatemia itself was related with the survival. These factors might affect the non-superiority of higher dose of CRRT. Because appropriate supplementation of phosphate can avoid hypophosphatemia, nephrologists should take efforts to make ICU physicians aware of the significance of hypophosphatemia during CRRT.

**Conclusion:** Results of this study reconfirmed the high incidence of hypophosphatemia. Nephrologists might have to raise awareness of hypophosphatemia during CRRT.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO433**

**Clinical Characteristics and Prognostic Predictors in Acute Kidney Injury Treated by Continuous Renal Replacement Therapy, Retrospective Study** Jong Woo Seo, Hyun-Jung Kim, Dong Jun Park, Dong Won Lee, Hyeon Jeong Lee, Se-Ho Chang. *Internal Medicine, Gyeoungsang National University Hospital, Jinju, Republic of Korea.*

Continuous renal replacement therapy (CRRT) has been used widely for treating critically ill patients with AKI because of the hemodynamic tolerance. We performed this study to identify clinical characteristics and prognostic predictors of mortality in critically ill patients with AKI treated by CRRT at intensive care units in our hospital.

We analyzed the data of 181 patients who were treated by CRRT from Jan, 2007 to Feb, 2010. We excluded patients treated by CRRT within 24 hrs.

Of the 181 cases who treated by CRRT, 117 were males. The average age was 61.4 years. Type 2 diabetes mellitus was the most frequent comorbid illness (49%), followed by hypertension (38%), chronic kidney disease (CKD) (31%), liver cirrhosis (21%), heart failure (12%) and malignancy (19%). Causes of AKI included sepsis in 100 (55.2%), surgery in 34 (18.8%), cardiogenic shock in 13 (7.2%), rhadomyolysis in 11 (61%), drug intoxication in 4 (2.2%), trauma in 3 (1.7%), and hepatorenal syndrome in 2 (1.1%) patients. The overall mortality was 68%. The average APACHE II score was 49.27±11.11. Univariate analyses suggested APACHE II scores, comorbid illness of CKD, heart failure and sepsis, serum bicarbonate started CRRT after 48hours were significantly lower in survivors. Multivariate analysis revealed that APACHE II scores (Odd ratio : 1.12; 95% Cl 1.05-1.19; p = 0.01), prothrombin time (Odd ratio : 1.52; 95% Cl 1.22-1.88; p = 0.01), predialysis oliguria (Odd ratio : 13.32; 95% Cl 1.19-148.46; p = 0.03), presence of sepsis (Odd ratio : 4.04; 95% Cl 1.11-14.61; p = 0.03), and serum bicarbonate started CRRT after 48hrs (Odd ratio : 0.05; 95% Cl 0.37-0.68; p = 0.01) were independent predictors for the prediction of mortality.

This study showed that independent prognostic predictors for mortality in AKI patients treated with CRRT were APACHE II scores, prothrombin time, predialysis oliguria, presence of sepsis and serum bicarbonate after 48hrs started CRRT. Using these prognostic predictors in critically ill patients will be made for the appropriate circumstances.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO434**

**Evaluation of Filter Patency, Acid-Base and Electrolyte Balance of a Prismaflex-Based Regional Citrate Anticoagulation Protocol for Continuous Renal Replacement Therapy** Dmytro Khadzhynov, Ina Lieker, Torsten Slowinski, Hans-Hellmut Neumayer, Harm Peters. *Department of Nephrology, Charite Campus Mitte, Charite Universitaetsmedizin, Berlin, Germany.*

**Purpose:** Regional citrate anticoagulation has been shown to be an excellent alternative to heparin anticoagulation for patients requiring CRRT. Here, we evaluate a new commercially available citrate protocol involving the actual PrismaFlex dialysis device and an isotonic citrate solution (Prismocitrate) (Gambro GmbH, Germany).

**Methods:** According to the manufacture´s information, this citrate protocol was based on a PrismaFlex ST100 set (AN69®ST membrane) mounted on the Prismaflex dialysis device, a blood flow 120 ml/min, 1.8 l/h Prismocitrate (10 mmol/l citrate) in pre-dilution mode and a 0.8 l/h dialysate flow employing Prism0Cal. Separate i.v. infusions of potassium, calcium and magnesium were initiated according to the manufacture´s protocol. Blood pH, bicarbonate, base excess and ionized calcium levels were measured before and at least every 6 h after start of CRRT, magnesium levels before and every 24 h, respectively. Scheduled hemofilter run time was 72 h.

**Results:** A series of 25 CCRT treatments in 16 patients was included. Of the 25 hemofilters started, only 5 reached the scheduled run time (20%). 20 treatments stopped prematurely (9 because of filter clotting, 10 because of Prismaflex hardware or software problems). Mean filter running time achieved was 33.2±24.4 h (46% of the scheduled time). During CCRT, 70% of the blood bicarbonate levels were lower than normal range (21-28 mmol/L), 65.7% of ionized calcium measurements were outside the normal range (1.1-1.3 mmol/L) and 56.4% of the magnesium readings were above the normal range (0.75-1.06 mmol/l). In addition, mean bicarbonate decreased from 23 to 20 mmol/l and mean base excess from -1.5 to -4 mmol/L, resp.. Substitution of bicarbonate was necessary in 6 treatments.

**Conclusion:** The present study shows that the evaluated Prismaflex/Prismocitrate-based regional citrate anticoagulation protocol yields not satisfying filter running times. Furthermore, the control of blood acid base status, calcium and magnesium homeostasis is of poor quality.

**Prophylactic Hemodiafiltration after Coronary Angiography** Maria Joao Carvalho Azevedo Rocha, António Cabrita. *Nephrology, Hospital de Santo António - Centro Hospitalar do Porto, Porto, Portugal.*

Contrast induced nephropathy (CIN) is a form of acute kidney injury (AKI) that can be prevented.Small elevations of plasma creatinine have a negative impact in patient outcome bringing a lot of attention to prophylactic strategies.Convective or diffusive

techniques for contrast elimination have been proposed as a possible form of prophylaxis in patients with chronic kidney disease (CKD).Our purpose was to evaluate the impact of prophylactic hemodiafiltration(PHDF) on incidence and severity of AKI in patients submitted to coronary angiography (CA).We performed an observational case control study. We performed 1 4 hour session of PHDF (auto-flux,postdilution mode,0 ultrafiltration) in 19 patients immediately after CA.The control group 19 patients submitted to CA with no PHDF.Isotonic saline (1mL/Kg/h in the 12 h previous and after CA) and N-acetylcistein (1200mg before and after CA) were administered to all patients.Fifteen patients required a central venous catheter (CVC),4 had an arteriovenous fistula.There was no statistically significant difference between case and control groups with respect to prevalence of diabetes(89% vs74%:p=0,2),incidence of moderate to severe cardiac dysfunction (63% vs 52%; p=0,7),admission plasma creatinine(Pcr)(2.08±0.58 mg/dL vs 2.23±0.49 mg/dL;p=0,8), dose of contrast evaluated by need of angioplasty 84%vs73%;p=0,43).Mean age was higher in the control group (72 ± 9.24 vs 65±10 years; p=0.01)

PCr was analyzed post-procedure days 3 to 5.AKI was defined according to Acute Kidney Injury Network criteria.The incidence of AKI was higher in the case group but did not have statistical significance (47% vs 68%; p=0,2).Average Pcr elevation was higher in the control group (0.36±0.3mg/dL vs 1.58±1.72 mg/dL; p=0.006).No patient in the case group needed further dialysis, 3 patients in the control group did, 1 needed 14 sessions and 2 needed 2.There were no complications related to the CVC.PHDF did not reduce the incidence of AKI,however the smaller elevations of Pcr and absence of need for further dialysis,suggest less severe forms of AKI. Since our patients had only moderate renal dysfunction on admission we cannot exclude benefit in more severe CKD.

**Predictors of Post-Hospital Discharge Outcomes in Patients with Acute Renal Failure** Lawand A. Saadulla, Christin M. Spatz, Nasrollah Ghahramani. *Hershey, Penn State University/Hershey Med Center, Hershey, PA.*

**Introduction:** Predictors of post-hospital discharge outcome among patients with acute renal failure (ARF) requiring renal replacement therapy (RRT) are not well known. We investigated potential predicting variables among a group of patients at our institution.

**Methods:** Between January 2004 and December 2005, 898 adult patients were diagnosed with ARF, of whom 278 required RRT. Post-hospital discharge follow-up data (for at least one year; average: 50.5 ± 17.4 months) was available on 35 patients. Twenty-one had been on continuous renal replacement therapy (CRRT) and 14 on hemodialysis (HD). Six of the CRRT group and 9 of the HD group were dialysis dependent at time of discharge (DC). One patient in each group died in follow-up. Ten of the CRRT group and 11 of the HD group progressed to chronic kidney disease (CKD). Among this group, 5 from the CRRT group and 6 from the HD group developed end stage renal disease (ESRD). Multivariate regression analysis was used to examine the association between outcomes (CKD, ESRD, death, complete recovery of renal function) and independent variables: age, treatment group, sepsis, acidosis, Sequential Organ Failure Assessment (SOFA) score, dialysis-dependence at DC, and creatinine at DC.

**Results:** Progression to CKD and to ESRD were both associated with dialysis dependence at time of discharge (r= 0.354; p= 0.037 and r=0.53; p= 0.001, respectively). Post-discharge mortality was associated with sepsis at time of ARF (r=0.603; p=0.0001), while complete recovery of renal function was negatively associated with age (r=-0.32; p=0.008) and SOFA score (r= -0.4; p=0.005).

**Conclusions**: Among patients with ARF, dialysis-dependence at time of discharge is a strong predictor of progression to CKD and ESRD. Younger patients with ARF and those with lower SOFA scores are more likely to have complete recovery of renal function in follow-up.

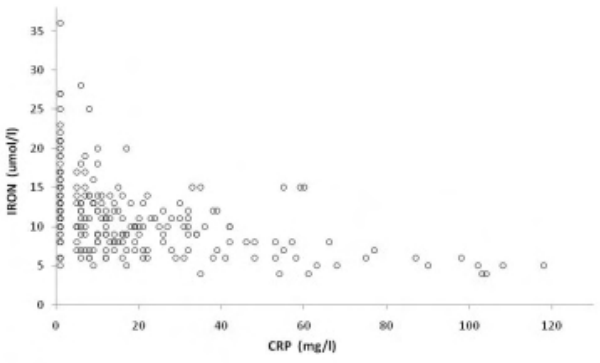
### TH-PO437

**Determinants of Circulating Iron in Haemodialysis Patients** Damien Ashby,[1] Georgina Henrietta Aldous,[1] Mark Busbridge,[2] Kevin G. Murphy,[2] Stephen R. Bloom,[2] David Taube,[1] Tom Cairns,[1] Neill D. Duncan,[1] Frederick W. K. Tam,[1] Peter Choi.[1] [1]*Imperial College Kidney and Transplant Institute, Hammersmith Hospital, London, United Kingdom;* [2]*Investigative Medicine, Imperial College, London, United Kingdom.*

Erythropoiesis is dependent on efficient transport of iron to the bone marrow, and low levels of circulating iron are associated with anaemia in renal patients. The hepatic peptide hepcidin limits iron transport, and elevated levels in renal failure are thought to restrict iron availability.

Plasma iron and related parameters were measured in a stable group of haemodialysis patients. Hepcidin was measured by radioimmunoassay.

In 100 haemodialysis patients (66 male, aged 25-87) mean+/-sd plasma iron was 11.4+/-4.6umol/l, and correlated negatively with haemoglobin (R=0.272, p<0.001). By multiple linear regression, plasma iron was independently predicted by TIBC (beta=0.405, p<0.001), CRP (beta=-0.367, p<0.001, figure 1), reticulocytes (beta=-0.293, p<0.001), ferritin (beta=0.254, p<0.001) and hepcidin (beta=-0.132, p=0.03).



Only baseline hepcidin was predictive of the change in plasma iron over the next month (R=-0.151, p=0.05)

Plasma iron levels are influenced by multiple factors, including iron stores, bone marrow activity and inflammatory state. High hepcidin levels are associated with subsequent deterioration in iron availability, suggesting a role in the pathogenesis of anaemia and erythropoietin resistance in haemodialysis patients.

Disclosure of Financial Relationships: nothing to disclose

**Comparison of Therapeutic Efficacy of Epoetin alfa vs. Epoetin beta in Haemodialysis Patients** Alice Loughnan, Galil Rahman Ali, Sumith C. Abeygunasekara. *Nephrology Department, Broomfield Hospital, Broomfield, United Kingdom.*

PURPOSE: Evaluate the therapeutic efficacy of epoetin alfa compared to epoetin beta in maintenance haemodialysis patients.

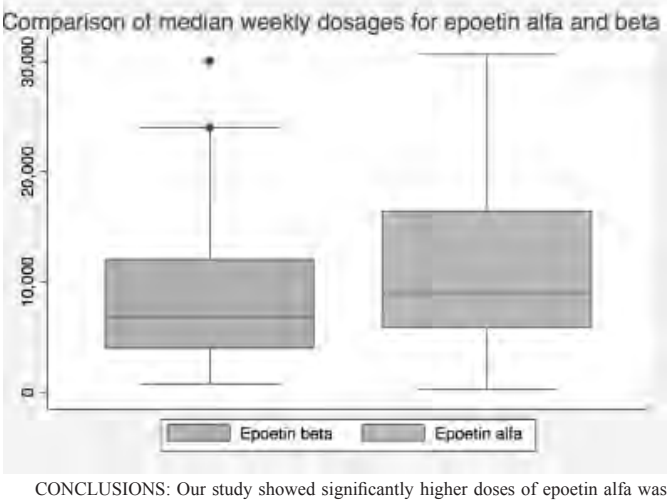
METHOD: In May 2009, the epoetin product for all dialysis patients in our unit changed from epoetin beta to epoetin alfa. Current evidence suggests equal efficacy at the same dose. We compared epoetin dosage required to maintain target haemoglobin in the same group of patients.

Patients selected for the study were all those who had their haemoglobin maintained at 11-12.5g/dl by haemodialysis and epoetin. Iron levels were monitored and ferritin kept within range of 200-500 g/l. In all patients, we examined haemoglobin concentration, mean dose of epoetin per week and EPO index (weekly epoetin dose/ mean monthly HCT).

Data excluded was; conversion month, and if within the study period patients developed signs of infection, bleeding, required blood transfusion, under dialysis or required hospital admission.

Values are stated as mean (standard deviation) or median (inter quartile range) where appropriate. The data for each patient before and after regimen change was compared using paired t-test or Wilcoxons signed rank sum test as appropriate (Stata corp).

RESULTS: Out of 128 patients, 79 were eligible. The mean (SD) for haematocrit concentration achieved before and after epoetin change was 0.343 (0.312) % and 0.348(0.241) % respectively (paired T test p=0.1504). Weekly epoetin doses increased from 6733.333 (4000- 12000) IU/wk to 9000(5833.333- 16375) IU/wk (p=0.0001). EPO index similarly increased from 20465.19 (12549.12- 33389.63) IU/wk/% to 27073 (15086.55-46875)IU/wk/% for epoetin beta and epoetin alfa respectively (p=0.0003).



CONCLUSIONS: Our study showed significantly higher doses of epoetin alfa was needed to maintain target haemoglobin. We recommend a prospective randomised control trial to compare the two products.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO439**

**Comparison of Efficacy and Safety for Anemia Management between Darbepoetin alpha and Epoetin beta for Chronic Hemodialysis Patients**
Tadashi Kuji,[1] Gen Yasuda.[2] *[1]Yokodai Central Clinic; [2]2nd Internal Medicine, Yokohama City University, Yokohama, Kanagawa, Japan.*

**Introduction and Aims**: Erythropoiesis-stimulating agents (ESAs) are effective in the management for anemia of chronic kidney disease. Darbepoetin alpha is a longer half-life and unique biological activity ESA that can be administered to patients less frequently. The European equimoler conversion factor recommended 1 μg darbepoetin alpha corresponded to 200 IU epoetin beta. We performed a comparison of the efficacy of 1 μg darbepoetin alpha corresponded to 300 IU epoetin beta for chronic hemodialysis patients.

**Methods**: A total of 281 patients of intermittent hemodialysis were enrolled. One hundred twenty-five patients were for darbepoetin alpha and one hundred fifty-six were for epoetin beta. Hematcrit levels were checked once a week on Monday or Tuesday. When hematocrit levels were below 32%, ESAs were administered intravenously at the end of hemodialysis (On/Off method). One group was administered 30 μg of darbepoetin alpha once a week. Another were administered 3000 IU of epoetin beta in every hemodialysis, three times a week. CBC and blood chemistry were checked every other week for 44 weeks totally. Variabilities of hematocrit level weekly were calculated. **Results**: The weekly ratio of ESAs was 1 μg darbepoetin alpha corresponded to 289 IU epoetin beta. There are no differences from baseline CBC, blood chemistry and adequacy of hemodialysis between two groups. Hematocrit levels were well managed with ESAs. No patients need transfusion during this study. Hematocrit levels were 32.1±2.7% and 32.9±3.1% (p=NS) in darbepoetin alpha group and in epoetin beta group, respectively. There are no differences of variabilities of hematocrit level weekly (p=NS) and ESAs administrative weeks (p=NS) in both groups. **Conclusion**: In this study, 1 μg darbepoetin alpha could keep hematocrit level corresponded to 300 IU epoetin beta and no variability differences of weekly hematocrit in both agents. Darbepoetin alpha have benefits for treatment costs and nursing times by reducing frequency of administration for management of anemia for chronic hemodialysis patients.

**TH-PO440**

**Effects of the Difference in the Timing of Darbepoetin Alfa (DA) Administration on Cardiac Function and Endothelial Progenitor Cells in Hemodialysis (HD) Patients**
Shuzo Kobayashi,[1] Hidekazu Moriya,[1] Takayasu Ohtake,[1] Sumi Hidaka,[1] Eisei Noiri,[2] Yuko Shibuya.[3] *[1]Nephrology, Immnology, and Vascular Medicine, Shonan Kamakura General Hospital, Kamakura, Kanagawa, Japan; [2]Nephrology, Tokyo University, Tokyo, Japan; [3]Nephrology, NTT Nippon Kanto Teishin Hospital, Tokyo, Japan.*

**BACKGROUND** DA can treat anemia by once-weekly (QW) administration, while little is known about the differential effects of the timing of DA administration on cardiac function between the first and the last in a week. Endothelial progenitor cell cells (EPC) in circulating peripheral blood (CPB) which are mobilized by erythropoietin stimulating agent (ESA) are known to be related with cardiovascular events.

**METHODS** We conducted prospective, randomized, open-label, multicenter trial for 48 weeks including 61 maintenance HD patients. Patients with well controlled Hb levels by rHuEPO were switched to DA administration once-weekly, and the timing was divided into two groups: DA was administered on the first dialysis day in a week, Group A (n=34) or on the last dialysis day, Group B (n=27). CD34-positive cells, a population that includes EPC in CPB were analyzed by flowcytometry.

**RESULTS** There was no significant difference in the patients' demographic characteristics including pre-HD BPs, Hb levels, and dosage of DA throughout 48 weeks. At 24 weeks, the changes in LVMI before and after DA administration showed statistically significant difference between two groups (+8.84 vs. -11.59 g/m$^2$ in Group A and Group B, respectively:P<0.05). EF (%) was also significantly increased from 63±8.8 to 66±10 (P<0.05) in Group B, while it was not significantly changed in Group A. At 48 weeks, there was a significant difference in the changes of EF compared with values before and after DA treatment (-4.03 vs. +1.65 % in Group A and Group B, respectively: P<0.005). The number of CD34$^+$ cells at 48 weeks after DA was higher in Group B than that in Group A (Median: 0.495/μl vs. 0.890/μl).

**CONCLUSIONS** Administering DA on the last dialysis day in a week significantly improved LVMI and %EF, compared with those on the first dialysis day. The underlying mechanisms may suggest the difference of EPC-mobilizing effects of ESA.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO441**

**Switch of ESA Therapy from CERA to Darbepoetin-alpha in Chronic Hemodialysis Patients: A Multicenter Experience**
Pascal Meier. *Nephrology, CHCVs, Sion, Switzerland.*

CERA, a continuous erythropoietin receptor activator and darbepoetin-alpha (DA), are approved for the treatment of anemia in patients with end-stage renal disease (ESRD). The molecular differences of both erythropoiesis-stimulating agents (ESAs) may enable a reduced dosing frequency as well as different treatment dosage. We aimed to assess the impact of a switch from CERA to DA in unselected chronic hemodialysis (HD) patients on change in hemoglobin (Hb), the proportion of patients reaching target guideline levels and on the monthly requirement of medication. Twenty-one HD patients from three dialysis centers were eligible and were switched from CERA iv (QM) to DA iv (QW, Q2W or QM). As no data were published on the equimolar conversion from one to the other ESA, intra-individual evaluation was compared 12 weeks before with 12 weeks after the switch. The dose of the ESA and the Hb levels were analyzed for the whole period. During treatment with CERA, 66.7% of the 21 patients achieved an Hb level ≥ 110 g/L. After switching to DA, the mean Hb level increased significantly from 114±12.2 g/L to 119.5±15.9 g/L (p = 0.007) and the percentage of patients with Hb levels ≥ 110 g/L was 71.4% at 12 weeks. Furthermore, the weekly median required ESA doses was 38.5 mcg [10-100] for CERA and 30 mcg [10-130] for DA. This corresponded to a 28% increase of CERA to reach a median Hb level of 116 g/L. The overall cost decreased by 22% [17-29] after switching from CERA to DA (p = 0.02). After the switch from CERA to DA using an equimolar conversion rate, more patients reached an Hb level of ≥ 110 g/L despite a dose decrease of 22%. Previous data showed that after the reverse switch from DA to CERA according to the manufacturers guidance a significant drop in Hb level and an increased requirement for transfusions were observed. Thus the conversion rate for a switch from CERA to DA seems to be lower than the equimolar dose, and might be in the range of 1 mcg CERA to 0.7-0.9 mcg DA. The results of this pilot evaluation should be further substantiated by a larger data pool in order to be able to provide stronger dosing guidance for such a drug switch.

Disclosure of Financial Relationships: nothing to disclose

**Cost Savings after Implementation of an Anemia Management Protocol in a Hemodialysis Unit**
Emily Charlesworth,[1,2] Robert M. Richardson,[1,2] Marisa Battistella.[1,2] *[1]Nephrology, University Health Network, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada.*

**Background:** National guidelines recommend the use of anemia management protocols to guide treatment and promote consistency. **Objectives**: We aimed to determine if an anemia management protocol would improve the proportion of hemodialysis patients within the target hemoglobin range and to determine whether within-patient hemoglobin (Hgb) variability would be reduced. Secondary objectives included whether the protocol would reduce the amount and cost of darbepoetin alfa (DBO) and intravenous iron (iv iron) used. **Methods:** An anemia management protocol was created and implemented in the hemodialysis unit at the Toronto General Hospital in December 2009. A retrospective observational review in 174 patients was conducted in two six-month blocks- one before and one after implementation of the anemia protocol. Data collection included baseline characteristics, DBO and iv iron doses and relevant lab parameters including hemoglobin, transferrin saturation and ferritin. Differences between means and proportions were analyzed using the two-sided paired t-test and the chi-square test respectively and were reported by the Fisher's exact test for significance. **Results:** The number of Hgb measurements in the target range of 110-125g/L increased from 44.3% to 46.0% (p=0.48) after protocol implementation. Hemoglobin variability decreased from 33% to 28% (p=0.29) after protocol implementation. The mean weekly dose of DBO was reduced from 34.56 ± 31.12mcg to 31.11 ± 28.64mcg post-protocol implementation (p=0.011), which translated to a cost savings of $41,649 over six months. The mean monthly iv iron dose also decreased from 139.56 ± 98.83mg pre-protocol to 97.65 ± 79.05mg post-protocol (p<0.005), a cost savings of $18,594 over the same time period. The percentage of patients with target ferritin and Tsat (200-500ug/L ; 20-50%) remained the same during the study period. **Conclusions:** Anemia management protocols may increase the number of patients in target and decrease variability in hemodialysis patients. These protocols do significantly reduce costs of anemia therapy in the hemodialysis population.

**Effect of Rapamycin on Peritoneal Dialysis Related Peritoneal Membrane Changes**
Vega Goedecke, Joon-Keun Park, Jan Menne, Marcus Hiss, Hermann G. Haller. *Nephrology and Hypertension, Medical School Hannover, Hannover, Germany.*

Peritoneal dialysis is a well established renal replacement therapy. One of its major limitations are the negative long-term effects of dialysis on the peritoneal membrane, which may subsequently even lead to technique failure. Dialysis-associated peritoneal changes are characterized by cell proliferation, inflammation and fibrosis. Since rapamycin is an immunosuppressive agent with antiproliferative properties, we tested its effect on peritoneal membrane changes during dialysis in an animal model.

We used C57BL/6J mice (n=12) and performed daily peritoneal dialysis for 4 weeks using twice daily intraperitoneal injections of a sterile pre-warmed dialysis solutions (Physioneal, 3,86%, Baxter). We used 75 ml/kg body weight, on average 1,5 ml, of dialysis fluid for each injection. A treatment group received rapamycin at a concentration of 1,5 mg/kg body weight mixed with the peritoneal dialysis fluid on every single day of treatment. Control groups received the equivalent amount of normal saline (0,9%), rapamycin only or no treatment, respectively. Peritoneal membrane thickness was significantly reduced with rapamycin mixed with dialysate fluid.

In the group treated with dialysate and rapamycin, CTGF expression was markedly reduced compared to dialysate alone. Rapamycin seems to ameliorate dialysis fluid related effects on the peritoneal membrane, such as thickening of the mesothelial layer, expression of CTGF and expression of α-smooth muscle actin in the mesothelial zone.

Rapamycin itself shows no negative effects on the peritoneal membrane.

These results demonstrate that rapamycin prevents the deleterious changes of peritoneal dialysis and suggests a potential therapeutic use of rapamycin for the prevention of dialysis related changes of the peritoneal membrane.

**Relation of N-Terminal pro-B-Type Natriuretic Peptide (NT-proBNP) and Left Atrial Volume Index to Left Ventricular Function in Chronic Hemodialysis (HD) Patients** Tetsuya Ogawa, Kosaku Nitta. *Department of Medicine, Kidney Center, Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan.*

**Aim:** The left atrium volume (LAV) is associated with adverse cardiovascular (CV) outcomes in general population. The aim of the present study was to investigate the relation of N-terminal pro-B-type natriuretic peptide (NT-proBNP) and LAV to left ventricular (LV) function in chronic HD patients.

**Methods:** A total of 117 patients (74 men and 43 women) were enrolled as subjects. Echocardiography was performed to evaluate the LAV index (LAVi) and left ventricular mass index (LVMI). Diastolic left ventricular function was estimated as E/E' by tissue doppler imaging with cardiac ultrasonography. Serum NT-proBNP was measured at the time of echocardiographic measurements.

**Results:** By univariate analysis, LAVi was positively associated with serum NT-proBNP levels (r=0.418, p<0.0001) and echocardiographic parameters including LVDd (r=0.489, p<0.0001), LVDs (r=0.375, p<0.0001), LVMI (r=0.538, p<0.0001), and E/E' (r=0.494, p<0.0001). Multiple regression analysis showed that LAVi (F=24.372, p<0.0001) and E/E' (F=23.473, p<0.0116) were significant predictors for serum NT-proBNP levels, and LVMI (F=46.807, p<0.0001) was a best predictor for LAVi among associated factors.

**Conclusion:** These findings suggest that both serum NT-proBNP and LAVi is a good biomarker for predicting the LV remodeling in chronic HD patients.

Disclosure of Financial Relationships: nothing to disclose

**Plasma Gelsolin Is Associated with Inflammatory Biomarkers in Chronic Hemodialysis Patients** Georges Ouellet,[1, 2] Laura Rosales,[1] Viktoriya Kuntsevich,[2] Boris Medvedovsky,[2] Stephan Thijssen,[1, 2] Peter Kotanko,[1, 2] Nathan W. Levin.[1, 2] *[1]Renal Research Institute; [2]Beth Israel Medical Center, New York.*

Plasma gelsolin (pGSN) is an extracellular protein mainly secreted by striated muscle cells, which binds actin and buffers inflammatory mediators. pGSN depletion in acute injury is associated with a poorer prognosis. However, data are limited in situations of chronic inflammation. We aimed to characterize levels of pGSN in prevalent hemodialysis (HD) patients, and to test the hypothesis that pGSN level is associated with inflammatory biomarkers in this population.

Stable maintenance HD patients were recruited. Pre-HD pGSN was measured with the 2C4 Plasma Gelsolin ELISA kit (Critical Biologics, Cambridge, MA). C-reactive protein (CRP) and neutrophil-to-lymphocyte ratio (NLR) were obtained by routine laboratory techniques and interleukin-6 (IL-6) was measured with the Quantikine ELISA kit (R&D, Mpls, MN) at Spectra Clinical Research (Rockleigh, NJ). Univariate and multivariate linear regression analysis was performed with pGSN as the dependent variable.

We studied 153 patients (mean age 61±15 years; median dialysis vintage 2.3 (range 0.2-20.0) years; 52% male; 42% Blacks, 52% diabetic). pGSN distribution was skewed (median 6353 mU/mL, IQR 5244-7640). In univariate analysis, pGSN correlated inversely with CRP, IL-6 and NLR and positively with serum albumin (table 1). Age and CRP were significant predictors of pGSN in multivariate regression analysis with age, gender, race, access type, IL-6, CRP, serum albumin and NLR as independent variables.

Table 1. Pearson (r) and Spearman ($r_s$) correlations for pGSN and inflammatory markers

| | Log CRP | IL-6 | Serum albumin | Log NLR |
|---|---|---|---|---|
| pGSN | r=-0.316 P<0.001 | $r_s$=-0.317 P<0.001 | $r_s$=0.247 P=0.001 | r=-0.228 P=0.014 |

In stable prevalent HD patients, pGSN is inversely associated with CRP, IL-6 and NLR, and directly associated with serum albumin. Our data suggest that markers of inflammation influence pGSN and are thus consistent with current knowledge in situations of acute inflammation. Whether lower pGSN is a predictor of mortality in prevalent HD patients remains to be determined.

**TH-PO446**

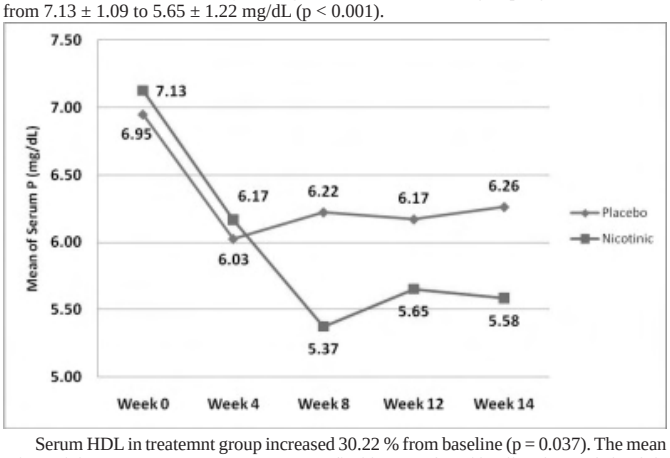
**Effectiveness and Safety of Extended-Release Nicotinic Acid for the Reduction of Serum Phosphorus Level in Maintenance Hemodialysis Patients** Ouppatham Supasyndh,[1] Rachanon Srisawadwong,[2] Pornanong Aramwit.[2] *[1]Nephrology, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand; [2]Pharmacy Practice, Chulalongkorn University, Bangkok, Thailand.*

**Background:** Inadequate control of serum phosphorus (P) in dialysis patient leads to elevation of the calcium-phosphate product. This plays a pivotal role in vascular calcification, cardiovascular disease and death. Experimental and clinical studies found that nicotinic acid and its metabolite nicotinamide decrease P level in dialysis patients by inhibition of the Na-Pi-2b sodium-dependent phosphate co-transporter in the GI tract.

**Objective:** To evaluate the effectiveness and safety of extended-release (ER) nicotinic acid for the reduction of serum phosphorus level in dialysis patients.

**Method:** A randomized placebo- controlled trial was conducted for 18 weeks. The 28 hemodialysis patients with serum P > 5.5 mg/dL after 4 weeks of diet control period were randomized to receive once daily ER nicotinic acid at bedtime for 12 weeks. The initial daily dose of ER nicotinic acid was 375 mg and titrated once weekly to 500, 750 and 1,000 mg, as tolerated. Control group was received placebo in the same manner. All patients still received standard P binder. Blood chemistries were tested every 4 weeks. Data was analyzed using the intention-to-treat principle.

**Result:** At the end of study, average serum P of treatment group significant reduced from 7.13 ± 1.09 to 5.65 ± 1.22 mg/dL (p < 0.001).



Serum HDL in treatemnt group increased 30.22 % from baseline (p = 0.037). The mean tolerated dose was 723.21 ± 302.95 mg. Hot flushing was found in all patients of nicotinic acid group. Common GI adverse effects and dizziness were found in both groups.

**Conclusion:** We can conclude that extended-release nicotinic acid is effective and safe in reducing serum phosphorus as add-on standard therapy in hemodialysis patients.

**Effect of Glucocorticoid on Phenotypic Transition of Human Peritoneal Mesothelial Cells and Fibroblasts** Yang Hee Jang, Eun Sun Ryu, Mina Yu, Dong-Ryeol Ryu, Seung-Jung Kim, Kyu Bok Choi, Duk-Hee Kang. *Nephrology, Ewha Womans University, School of Medicine, Seoul, Korea.*

There were several reports demonstrating that glucocorticoid restored the deterioration of peritoneal water transport and protected the peritoneum from the development of encapsulating peritoneal sclerosis in animal model of PD. On the other hand, glucocorticoid was known to activate TGF-β and other profibrotic proteins in hepatocytes. In this study, we investigated the effects of glucocorticoid on TGF-β-induced EMT in HPMCs. EMT was evaluated by morphological changes and the expressions of E-cadherin and α-SMA after stimulation of TGF-β with or without pretreatment of dexamethasone (1-10 μM) or hydrocortisone (1-10 μM). To examine the effect of steroid on TGF-β-induced cell signaling pathway, phosphorylation of ERK1/2 and p38 MAPK were also assessed. We also examined the effect of glucocorticoid on mesenchymal-to-epithelial transition (MET) of human peritoneal fibroblast and TGF-β-treated HPMCs. TGF-β (>1 ng/ml) induced a morphological transformation from cuboidal and cobble stone appearance to spindle shaped scattered fibroblast-like cells at 48hrs, which was inhibited by pre-treatment of dexamethasone (5 μM) and hydrocortisone (10 μM). TGF-β down-regulated E-cadherin and up-regulated α-SMA expression at 48 hrs, which were significantly attenuated by pre-treatment with dexamethasone (5 μM) or hydrocortisone (10 μM). Furthermore, TGF-β-induced morphological changes and the expression of E-cadherin/α-SMA were reversible with a removal of TGF-β and subsequent exposure to dexamethasone or hydrocortisone, suggesting the reversal of TGF-β-induced EMT by glucocortocoid even after the development of morphologic changes. TGF-β significantly increased phosphorylation ERK1/2 and p38 MAPK in HPMCs from 5 minutes of stimulation, which was also blocked by dexamethasone or hydrocortisone. Neither dexamethasone nor hydrocortisone induced MET of human peritoneal fibroblasts.

In conclusion, glucocorticoid prevented or reversed TGF-β induced EMT in HPMCs. These results suggest glucocorticoid may be one of the possible therapeutic strategies to prevent peritoneal fibrosis in PD patients.

**Continuous Glucose Monitoring in Insulin Treated Type 2-Diabetic Hemodialysis Patients** Katsushige Abe,[1,2] Rie Abe,[1,2] Nobuyuki Abe,[2] Kenichi Saruwatari.[1] *[1]Renal Medicine, Jinikai Hospital, Oita, Japan; [2]Internal Medicine, Abe Diabetic Clinic, Oita, Japan.*

**Background:** Diabetes mellitus is the most common cause of end-stage renal disease (ESRD) in Japan. The diabetic patient with ESRD exhibits greater fluctuations in glucose due to decreased kidney function and to dialytic therapies and has greater cardiovascular problems. The aim of this study was to analyze, with the use of 4 day continuous glucose monitoring system (CGMS), the influence of dialysis therapy on daily glucose profile in insulin treated diabetic patients with hemodialysis therapy.

**Methods:** Twenty insulin treated type 2 diabetic patients undergoing maintenance hemodialysis were evaluated. CGMS was performed to examine the difference in glycemic variability during the dialysis in 2 days with and 2 days without dialysis.

**Results:** The average insulin requirement was 13±7 IU/day in the day with dialysis and 15±7 IU/day in the day without dialysis. 24-h mean glucose values and their SDs were significantly higher during the day with dialysis than without dialysis. During the dialysis, glucose concentration decreased and return to 100-150mg/dl at the end of dialysis. The incidence of hypoglycemia (<70 mg/dl) and hyperglycemia (>180mg/dl) were significantly higher in the day with dialysis.

**Conclusion:** Glucose values were significantly higher and more glucose variability was observed on dialysis days in insulin treated dialysis patients. CGM could be a useful tool to evaluate glycemic control in dialysis patients and it should be used for medication adjustments around dialysis days to optimize glycemic control and avoid hypoglycemia.

**Effect of Hemodialysis on microRNA Expression in Serum of Uremia** Hong Ye, Ping Wen, Huiqin Zhong, Lei Jiang, Junwei Yang. *Center for Kidney Disease, the 2nd Affiliated Hospital of Nanjing Medical University, Nanjing, Jiangsu, China.*

**Purpose:** Hemodialysis is the main theray strategy of ESRD patients, which has many complications, such as cardiovascular diseases and metabolic bone disease. However, the mechanisms of these complications are not completely elucidated. During the hemodialysis, with the eliminating of toxins, internal environment of the patients may change. The effects of hemodialysis on the patients' metabolisms have not been evaluated. Recently, the development of Systematic Biology provide us a new approach to explore new molecules. MicroRNA is a class of endogenous ~22nt small non-coding RNA, which are important regulators of cell differentiation, proliferation, mobility, and apoptosis. It has been shown that microRNA play important roles in many diseases such as tumor. Since it can not be cleared by hemodialysis, this study aims to observe the expression microRNA before and after hemodialysis.

**Method:** Twenty patients undergoing routine hemodilysis therapy are choosen for objects. Blood samples before and after hemodialysis are collected for microarry analysis.

**Results:** The microRNA spectrum of ESRD patients are significantly different in plasma and blood cell. After hemodialysis therapy, unique peak of some microRNA was observed and some microRNAs can not be detected.

**Conclusions:** MicroRNA expression can be affected by hemodialysis, the new microRNAs secreted after hemodialysis may relate to the metabolisms change in ESRD patients.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO450

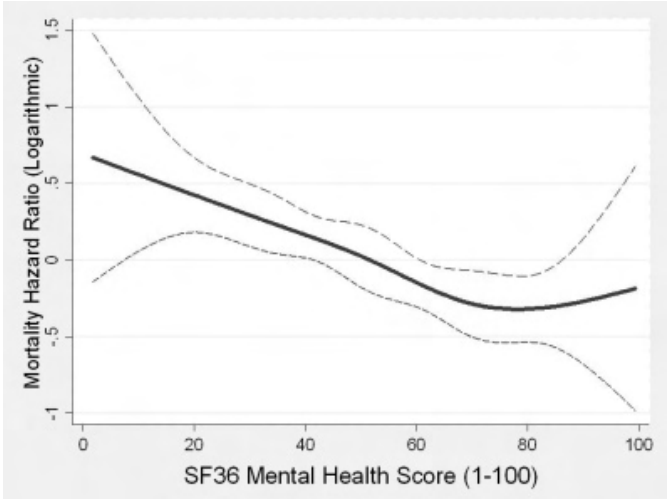
**Mental Health Score of SF-36 Quality of Life and 5-Year Mortality in Maintenance Hemodialysis Patients** Usama Feroze,[1] Ramanath B. Dukkipati,[1] Deborah A. Benner,[2] Allen R. Nissenson,[2] Csaba P. Kovesdy,[3] Joel D. Kopple,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]DaVita, Lakewood, CO; [3]Salem VA Medical Center, Salem, VA.*

Hemodialysis (HD) patients (pts) have a high mortality and often suffer from mental health (MH) derangements. The We hypothesized that MH is a predictor of survival in HD pts. Mortality predictability of MH, assessed via SF36 questionnaires quality of life was examined in 705 HD pts over 2001-07 period using Cox models and cubic splines. HD patients age across the above 4 increasing (improving) MH score quartiles were 55.2±13.2, 53.6 ±14.4, 52.5 ±15.1, 52.7 ±16 yrs old. Fully adjusted death hazard ratio (HR) (and 95%CI) for the lowest (worse) compared to the highest (best) MH quartile showed 67% higher death risk: HR 1.67(1.14-2.41). Cubic spline graph confirmed the almost linear association:

Death HR of quartiles of SF36 MH score in 705 HD pts

| Mental Health Quartiles | T1 (n=177) HR(%CI) | T2 (n=176) HR(%CI) | T3 (n=177) HR(%CI) | Trend p |
|---|---|---|---|---|
| Unadjusted | 1.8(1.2-2.5) P=0.001 | 1.6(1.1-2.3) P=0.008 | 1.1(0.79-1.63) P=0.5 | 0.000 |
| Case-mix* | 1.5(1.06-2.1) P=0.02 | 1.5(1.05-2.12) P=0.02 | 1.08(0.75-1.56)P=0.68 | 0.005 |
| Previous + MICS# | 1.63(1.13-2.3) P=0.009 | 1.52(1.05-2.2) P=0.026 | 0.97(0.64-1.4)P=0.87 | 0.001 |
| Previous + inflammation†(full mode) | 1.62(1.12-2.34) P=0.01 | 1.66(1.14-2.4) P=0.008 | 0.99(0.66-1.5)P=0.95 | 0.001 |

Reference group: 4th (best) MH score quartile



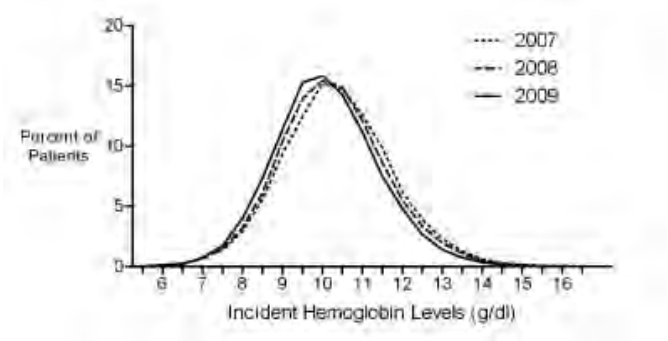
Hence, better MH appears associated with greater survival in HD pts.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO451

**The Effect of Pre-ESRD Care on Incident Patient Outcomes** Joe Weldon, Karen M. Spach, Mahesh Krishnan. *DaVita, Denver, CO.*

Starting in 2007, significant changes to ESA product labeling and new data have decreased ESA use in the pre-dialysis setting. However, this has had an unintended effect on outcomes for incident ESRD patients. MEDCAC recently discussed lower Hb targets in CKD.We sought to understand how anemia management in pre-ESRD has changed and to quantitate the impact that such potential revisions in payment policy may have on ESRD outcomes. Patients receiving ≥12 ICHD treatments and no other modality treatments in the 1st 30 days of dialysis were identified in a large US dialysis provider's database. We performed an analysis using Hb results in both the first 30 and next 30 days (n=29,969). Initial Hb levels were grouped into 0.5g/dL increments and charted over time, and a matched analysis for Hb increment to first month's ESA dose was completed. Initial Hb levels and ESA requirements were compared by Chi square test. The % of patients entering dialysis with Hb levels of <10 g/dL has increased in the past 3 years; 32.6% in 2007, 36.1% in 2008 and 40.8% in 2009, p<0.0001 between each set of years (Figure).



ESA requirements in the 1st month (ranging from a median 30 day ESA dose of 0 U to 176,000 U) correlated with incident Hb (from <6.5 mg/dL to 16 mg/dL). The dose prescribed to those patients has also declined year over year for the same incident Hb increment. The changes to pre ESRD-related ESA use in the last 3 years have had a predictable decline in incident Hb outcomes for patients new to dialysis. This downward trend in progressively lower Hb is likely to continue given the current controversies in ESA use. The amount of ESA required in the 1st month of dialysis was proportional to initial Hb on dialysis with lower Hbs requiring higher doses. Over time both first hemoglobin on dialysis and 1st month ESA dose have decreased. Significant changes in pre-ESRD ESA coverage may have an effect on anemia outcomes for new ESRD patients.

Disclosure of Financial Relationships: Employer: DaVita Inc.

## TH-PO452

**Long-Term Tolerance and Efficacy of Cinacalcet for the Treatment of Secondary Hyperparathyroidism (SHPT) in Peritoneal Dialysis Patients** Jesus Montenegro, José Ignacio Cornago, Maria Isabel Gallardo, Paula García, Ainhoa Hernando, Isabel Martínez, Rosa Muñoz. *Hospital de Galdakao-Usansolo, Galdakao, Spain.*

Purpose: SHPT is relatively uncommon in PD patients, generally because of positive peritoneal Ca balances and the fact that most patients are controlled with regular measures: phosphorous-chelating agents and vitamin D. A small number of patients, however, due to inefficacy of or intolerance to classic treatment, have to resort to cinacalcet treatment.

Methods: We describe our experience with cinacalcet in PD patients with SHPT.

Results: Since it was approved, of the 129 patients treated with CAPD in the last few years, 12 received Cinacalcet for 12 months to maintain PTH at over 300 pg/ml; all of them were resistant to or did not tolerate standard treatment. CKD etiology was normal and time in CAPD was 24 months, with a mean age of 60 years and 40% women. The Ca of the bath was 7 mg/dl. Before starting cinacalcet and after 1, 3, 6, 9 and 12 months, we collected: PTH, Calcium, Ca++, P, alkaline phosphatase, GOT, GPT and albumin. PCR-n, Kt/V of urea, residual renal function and peritoneal Ca and P balances were calculated.

| | 0 months | 1 month | 6 months | 12 months |
|---|---|---|---|---|
| PTH pg/ml | 509±158 | 287±164* | 174±108* | 199±91* |
| Total Ca mg/dl | 9.66±0.41 | 9.06±0.67* | 9.48±0.73* | 9.30±0.52* |
| Ca++ mg/dl | 4.98±0.33 | 4.64±0.29* | 4.89±0.38 | 4.65±0.25* |
| P mg/dl | 5.63±1.62 | 5.37±1.25 | 4.86±1.03* | 5.40±1.28 |
| Mimpara mg/d | 0 | 30 | 30 (15-90) | 25 (15-60) |
| *=p<0.05 | | | | |

Most of them took calcitriol 0.25 mcg/d and a few were taking oral paricalcitol 1 mg/d. The most common P-chelating agent was Ca salts. Peritoneal Ca balances were usually positive, depending on the degree of ultrafiltration.

Conclusions: It can be concluded that cinacalcet is efficient in maintained reduction of PTH. Cinacalcet was well tolerated in the long term by most of the patients. There were no hypocalcemia episodes, possibly because of the positive Ca balances. Gastrointestinal symptoms were few and mild, related to the dose. Since cinacalcet became available, no patient resistant to classic SHPT treated has needed a parathyroidectomy.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO453

**Clinical Advantages of Acetate Free Dialysate Containing Citrate** Takahiro Kuragano, Takeshi Nakanishi. *Hyogo College of Medicine, Department of Internal Medicine, Division of Kidney and Dialysis, Nishinomiya, Hyogo, Japan.*

Background: Dialysate for hemodialysis (HD) treatment had inevitably contained acetate as a buffer. We evaluated clinical advantages of acetate free dialyzate containing citrate (AFCD) over acetate containing dialysate (AD) on acid-base balance, anemia, nutritional condition, and mineral and bone disease in HD patients. Method: 29 HD patients were treated with AD for 4 month (first AD) switched AFCD for 4 month (AFCD), and returned to AD for next 4 month (second AD). Result: HCO3- levels did not changed in the patients with normal HCO3- (≥ 20mEq/L). While in the patients with low HCO3-, it was significantly increased in AFCD. In the patients with target hemoglobin (Hb) (≥10g/dL), Hb were maintained, even if dose of ESA decreased in AFCD. In the patients with low Hb, it was significantly increased in AFCD without increasing ESA and iron doses. In the patients with normal albumin (≥3.8g/dL), it did not change. While in the patients with lower albumin, it was significantly increased in AFCD. In the patients with normal parathyroid function (≥60pg/mL), intact-parathyroid hormone (int-PTH) did not changed. While in the patients with hypoparathyroidism, int-PTH were significantly increased in AFCD. These improvements of acidosis, anemia, nutrition, and bone turnover indexes in AFCD totally dissipated in the second AD.

table 1

| | First AD period | AFCD period | Second AD period |
|---|---|---|---|
| HCO3- (≥20mEq/L) | 22.4±2.4 | 23.2±1.8 | 20±1.2 |
| HCO3- (<20mEq/L) | 18.4±2 | 22.1±2.8* | 18.1±1.8 |
| Hb (≥10g/dL) | 10.8±0.4 | 10.7±0.3 | 10.9±0.4 |
| Hb (10<g/dL) | 9.2±0.2 | 10.4±0.3* | 10.1±0.2 |
| Albumin (≥3.8g/dL) | 4.0±0.2 | 3.9±0.3 | 3.8±0.2 |
| Albumin (<3.8g/dL) | 3.6±0.2 | 3.9±0.3* | 3.6±0.2 |
| Int-PTH (≥60pg/mL) | 132±22 | 151±18 | 136±22 |
| Int-PTH (<60pg/mL) | 38±3 | 58±3* | 40±2 |

*P<0.05: Compared with first AD period.

Conclusion: HD treatment with AFCD may improve the patients with intractable metabolic acidosis, hyporesponsiveness of ESA, malnutritional condition, and low turnover bone disease, which had not been normalized in the condition of HD using AD.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO454

**Phosphorus (PO4) Clearances Based on Blood (BFR) and Dialysate Flow Rates (DFR) during Thrice Weekly In-Center 8-Hour Hemodialysis (3x8HD)** Laura K. Troidle, Fredric O. Finkelstein. *Renal Research Institute, Metabolism Associates, New Haven, CT.*

PO4 levels are strong predictors of mortality in HD patients. Recently, we showed that PO4 is steadily removed during a 3x8HD (Troidle et al, HDI 13:487, 2009) using 400 mL/min BFR and 600 ml/min DFR. More traditionally, blood flows during 3x8HD are run at 200 to 250 cc/min. Thus, we wondered if the 400 BFR results in higher PO4 clearances than a 200 BFR. Patients in our 3x8HD who had a fistula/graft were invited to participate. All were dialyzed with the Fresenius180NR Optiflux dialyzer. Serum PO4 and creatinine samples were taken at treatment start and at 1,2,4,6, 8 hours, and, 30 minutes post treatment. Dialysate samples were obtained at 1,2,4,6 and 8 hours. The study was performed on each patient for two consecutive treatments using a 400 BFR at the first treatment and a 200 BFR at the second. PO4 clearances were obtained by using D/P x DFR where D/P is the dialysate to plasma PO4 ratio. 6 patients participated; 4 patients were male.

(A) Serum PO4 Levels (mg/dL) (B) PO4 Clearances (cc/min)

| **(A)** | PRE | 1H | 2H | 4H | 6H | 8H | POST |
|---|---|---|---|---|---|---|---|
| 400 BFR | 4.6 +/- 1.8 | 3.1 +/- 1.3 | 2.6 +/- 1.1 | 2.4 +/- 0.7 | 2.1 +/- 0.7 | 1.9 +/- 0.6 | 2.4 +/- 0.7 |
| 200 BFR | 4.4 +/- 2.4 | 3.3 +/- 1.9 | 3.5 +/- 1.9 | 3.2 +/- 1.3 | 2.9 +/- 1.2 | 2.8 +/- 1.3 | 3.1 +/- 1.5 |
| P VALUE | 0.55 | 0.79 | 0.07 | 0.09 | 0.05 | 0.02 | 0.10 |
| **(B)** 400 BFR | | 133 +/- 27 | 136 +/- 23 | 122 +/- 25 | 105 +/- 28 | 103 +/- 31 | |
| 200 BFR | | 96 +/- 31 | 99 +/- 31 | 101 +/- 35 | 90 +/- 33 | 88 +/- 40 | |
| P VALUE | | 0.03 | 0.002 | 0.04 | 0.13 | 0.16 | |

H=Hour

Table 1 shows serum PO4 levels and PO4 clearances at each time point. The data indicates significantly higher PO4 clearances using a 400 BFR during the first 4 hours; clearances remain higher at 6 and 8 hours, but are not statistically significant. Serum PO4 levels are lower after the 1st hour with the higher BFR but the reduction is not statistically significantly until 6 hours. Thus, it is important to maximize BFR during 3x8HD, particularly for the initial few hours of treatment to optimize PO4 removal.

**Does Sevelamer Hydrochloride Affect Trace Element Levels in Chronic Kidney Disease Patients Treated by Regular Haemodialysis?** Kristin Vibeke Veighey, John William Booth, Andrew Davenport. *UCL Centre for Nephrology, Royal Free Hospital, London, United Kingdom.*

Introduction

Zinc, copper and selenium are essential micronutrients, incorporated into many metallo-enzymes and proteins involved in cell metabolism, production of neurotransmitters and regulatory enzymes controlling oxidative stress.

Previous reports have suggested that ion exchange resins can bind trace elements, and sevelamer in particular binds both copper and zinc, particularly at acid pH.

We decided to audit trace elements in our haemodialysis cohort, to determine whether those patients prescribed sevelamer hydrochloride had lower plasma levels of zinc and copper.

Methods

Trace elements were measured prior to the midweek haemodialysis session in 210 stable adult outpatients attending a University Hospital haemodialysis centre.

Results

Patient characteristics in those prescribed sevelamer hydrochloride vs not. (Patients taking oral zinc/intravenous trace element supplements excluded)

| | No sevelamer group | Sevelamer group |
|---|---|---|
| Number | 138 | 44 |
| Age years | 58.6 +/-1.6 | 58.9 +/-2.5 |
| % male | 53.6 | 52.3 |
| % diabetic | 35.5 | 43.2 |
| % caucasoid | 62.2* | 40.9 |
| vintage months | 28 (12-57) | 45.5 (20-82) |
| urine volume ml/day | 150 (0-915)* | 0 (0-197) |
| zinc umol/l | 11.6 +/-0.2 | 12.0 +/-0.03 |
| copper umol/l | 16.8 +/-0.4 | 16.7 +/-0.7 |
| selenium umol/l | 0.82 +/-0.02 | 0.91 +/-0.03 |
| bicarbonate mmol/l | 23.7 +/-0.3 | 23.2 +/-0.3 |
| chloride mmol/l | 100.2 +/-0.3 | 100.7 +/-0.2 |
| calcium mmol/l | 2.25 +/-0.02 | 2.26 +/-0.03 |
| magnesium mmol/l | 0.96 +/-0.01 | 0.98 +/-0.02 |

* p <0.05, ** p<0.01 vs Sevalemer group.

Conclusions

Although in-vitro studies have suggested that ion exchange resins, including sevelamer hydrochloride could bind trace elements and micronutrients, we found no difference in copper or zinc levels. Indeed rather than have micronutrient deficiency, the sevelamer group had significantly greater selenium values.

## TH-PO456

**Pulverized Lanthanum Carbonate Hydrate Pulverized Administration: A Comparison of Serum Phosphorous Levels before and after Administration in Tube Feeding and Oral Feeding Hemodialysis Patients** Sato Megumi, Yuzuru Sato. *Nephrology, Satojunnkannkikanaika, Matsuyama City, Ehime, Japan.*

[Objectives]

Lanthanum carbonate hydrate(LC), a therapeutic agent for hyperphosphatemia, is basically chewed before swallowing. In this study, pulverized LC was administered to tube feeding patients and dental prosthesis patients who can't chew it. We investigated the effects on serum phosphate levels before and after administration.

[Methods]

Subjects were 7 oral feeding patients and 4 tube feeding hemodialysis patients with hyperphosphatemia in whom the dietary intake and drug intake could be confirmed. Pulverized LC was stirred into a small amount of water and administered either oral ingestion or by infusion immediately after food. We investigated the serum phosphate level, adjusted calcium level, sevelamer hydrochloride(SH) dose and calcium carbonate(CC) dose before administration, and three months and six months after administration.

[Results]

The LC dose was 750 mg/day in each person. The enteral nutrient of tube feeding subjects consisted of 1200 kcal/day of energy content and 600 mg/day of phosphorous content. In oral feeding patients, the energy intake was 1900 kcal/day and the phosphorus content was no more than 900 mg/day. The serum phosphate level decreased significantly

from an average of 6.5 ±1.3 mg/dl immediately before LC administration to an average of 5.1 ±0.4 mg/dl three months after administration (P<0.05). After six months, the serum phosphate level decreased significantly from 6.5 ±1.3 mg/dl before administration to an average of 5.1 ±0.4 (P<0.05). The adjusted calcium level wasn't affected before and after administration. The SH dose decreased from an average of 750 mg/day before LC administration to 273 mg/day three months after administration, and 136 mg/day six months after administration, and the CC dose was an average of 193 mg/day before LC administration, and zero after administration.

[Conclusion]

Among hemodialysis patients with hyperphosphatemia, we concluded that in tube feeding patients and in patients not able to chew due to dental prosthesis etc., serum phosphate control was made easier by the pulverized administration of LC.

## TH-PO457

**Free Triiodothyronine Levels and Inflammation in US Chronic Hemodialysis Patients** Georges Ouellet,[1,2] Laura Rosales,[1] Stephan Thijssen,[1,2] Peter Kotanko,[1,2] Nathan W. Levin.[1,2] *[1]Renal Research Institute; [2]Beth Israel Medical Center, New York.*

A relationship between free triiodothyronine (fT3) and inflammation has been shown in Caucasian hemodialysis (HD) patients. We aimed to investigate this relationship further in an ethnically diverse US HD population.

Stable maintenance HD patients with no history of thyroid disease were recruited. fT3 was measured pre-HD by direct chemiluminescence (ADVIA Centaur, Deerfield, IL). C-reactive protein (CRP) and complete blood count were obtained by routine laboratory techniques; interleukin-6 (IL-6) was measured with the Quantikine ELISA kit (R&D, Mpls, MN). Univariate and multivariate linear regression models with fT3 as the dependent variable were constructed.

We studied 141 patients (age 61±15 years; median vintage 2.4 years (range 0.2-20.0); 55% male; 43% Blacks, 52% diabetic). fT3 levels were not normally distributed (median 2.4 pg/mL, range 1.7-3.5). fT3 decreased with age (r=-0.327, p<0.001). In univariate analysis, fT3 was negatively associated with CRP, neutrophil-lymphocyte ratio (NLR), epoetin resistance index (ERI) and directly associated with serum albumin. There was no relation to pre-HD body temperature. A negative correlation between fT3 and IL-6 was observed only in non-black patients ($r_s$=-0.221, P=0.042). Multivariate analysis including age, race, gender, CRP, NLR, IL-6, ERI and serum albumin, identified a set of independent predictors of fT3 (Table 1).

Table 1. Independent predictors of fT3 ($R^2$= 0.264; P<0.001)

| Variable | Coefficient | Standard error | Std. coefficient | P value |
|---|---|---|---|---|
| Age | -0.006 | 0.002 | -0.259 | 0.001 |
| Black race | -0.175 | 0.053 | -0.256 | 0.001 |
| NLR | -0.027 | 0.012 | -0.194 | 0.019 |
| IL-6 | -0.006 | 0.003 | -0.160 | 0.045 |
| Albumin | 0.163 | 0.071 | 0.177 | 0.023 |

In stable maintenance HD patients, we observed that low fT3 was associated with inflammatory markers, age and black race. Low fT3 has been reported to be associated with inflammation in Caucasian HD patients. Our results corroborate these findings in an ethnically diverse cohort of US HD patients.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO458

**Serum Lactate Amendment (SLC) in Hemodialysis Patients (HD) and Its Relationship with Intrahemodialysis Hypotension (HDHypo)** Emilio E. Gonzalez-Parra,[1] Pablo Justo Avila,[1] Beatriz Fernández,[1] Catalina Martin Cleary,[1] Secundino Cigarran,[2] Jesus Egido.[1] *[1]Nephrology, Fundacion Jimenez Diaz, Madrid, Spain; [2]Nephrology, Hospital de Burela, Lugo, Spain.*

sLC is an anaerobic oxidation carbohydrates intermediate. It has been associated with non oclusive mesenteric ischemia (NOMI) in HD. The incidence of NOMI is 1.04% of patients/yr and with high mortality. There have been no changes in the sLC in HD high-flow. HDHypo correlate with high rate of NOMI.

OBJECTIVES

1 .- Determine sLC baseline and its modification by HD, in the first HD of the week.

2 .- Observe the changes of the SLC at the beginning of HD in the intervening day.

3 .- Check if symptomatic hypotension arising fromsLc and increase that impact.

MATERIALS AND METHODS

18 patients (10 f., 8 m), age of 71.8 ± 14.55 (42 to 87 yrs), and hypotension usual events. We measured sLc (normal 5.7-22 mg / dl) and blood gas test before and after a HD, and before next HD. 12 patients had HDHypo, and 6 no. All with a conventional high flux HD. None of the patients had abdominal pain.

RESULTS

Hypotension intraHD was 1.05 (0-2), with a UF rate over the weight of 3.11 ± 0.9%. Basal sLc was higher than normal and it decreased with HD (20.94 vs 13.11), and increased before next HD (16.00). The CO3H HD increased (22.54 vs 28.71 mEq/L) with decreasing values in next HD (22.64 mEq/L). 4 cases sLC rose and 14 fell. No relationship between the number of HDHypo number and the UF rate with increased sLC. Basal sLC in first group was increased, and levels above baseline are manteined 48 hours later, whereas second group did not reach baseline values. Patients with sLC increases had HDHypo. The systolic blood pressure was higher in non sLc increased group (p<.0001). No correlation with vascular calcification.

CONCLUSIONS

1 .- The sLc values HD patients are hight before HD with a significant decrease after HD, which increases again before the next HD.

2 .- sLC increased in 4 of the 12 cases with symptomatic hypotension (33.33%), which do not regain baseline values at the beginning of the next HD, yet maintain acidosis.

3 .- 100% of patients with increase the sLC without abdominal pain had HDHypo, and correlate with postHD systolic blood pressure.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO459

**Sodium Thiosulfate Therapy for Calciphylaxis in Hemodialysis Patients** Debra Meade, Eduardo K. Lacson, Weiling Wang, Cindy A. Premo, Melanie Cousins, J. Michael Lazarus, Jeffrey L. Hymes. *Fresenius Medical Care, North America, Waltham, MA.*

We previously reported a case series of 16 HD patients diagnosed with calciphylaxis and treated with intravenous sodium thiosulfate (IV-ST) in Fresenius Medical Care North America (FMCNA) facilities in 2008. We extend the report to 53 patients initiating therapy by 6/30/09.

Calciphylaxis was diagnosed clinically, with 25 of 53 cases (47%) supported by skin biopsy. Most (70%) had lesions in the lower extremities and commonly affected areas included abdomen, buttocks, and hands. Initial therapy was increased phosphate binder dose in 62% (with 45% using non-calcium binders and/or lowering dialysate calcium), along with starting cincacalcet (58%), wound debridement (48%), stopping Vitamin D (34%) and parathyroidectomy (17%). At the start of IV-ST, mean age was 51.6±12.3 years, 72% female, 62% white, 60% with diabetes, and mean vintage 4.4±4.7 years. The median dose was 25g (100 ml) per treatment, given for 50±51 treatments (range: 2-201) over 176±200 days (range: 3-954). Eight patients (15%) reported initial nausea and vomiting but only 1 patient stopped therapy after 2 doses. One patient reported temporary bad taste/periorbital tingling and another questionable decreased hearing. In 39 of 53 patients (74%) skin lesions improved (10 with marked improvement and 13 had complete resolution). Ten (19%) remained on therapy as of 12/31/09 so mean values for 43 patients who completed therapy are shown:

| IV-ST Treatment | Sodium (mEq/L) | IDWG (kg) | Post-Wt (kg) | Calcium (mg/dL) | Phosphorus (mg/dL) | iPTH (pg/ml) | Anion Gap (mEq/L) | Bicarbonate (mEq/L) |
|---|---|---|---|---|---|---|---|---|
| Baseline | 138.9 | 3.1 | 95.8 | 8.7 | 6.1 | 512.9 | 18.0 | 22.8 |
| During | 139.2 | 3.1 | 94.2 | 8.6 | 5.7 | 515.8 | 21.2 | 22.2 |
| Stopped | 138.4 | 3.2 | 93.5 | 8.3* | 5.9 | 650.6 | 16.7** | 23.0 |

* p=0.002 compared to baseline and p=0.01 vs. during; ** p=0.005 compared to during – all else not significant; IDWG = Inter-dialytic Weight Gain, iPTH = Intact Parathyroid Hormone

Anion gap increased during IV-ST then declined after stopping (along with calcium).

Updated information from FMCNA physicians who volunteered clinical data on a larger cohort confirmed that therapy with IV-ST is well tolerated and effective for most HD patients with calciphylaxis. Although encouraging, findings are subject to reporting bias due to incomplete (33.5% of treated patients) data capture.

## TH-PO460

**Isotopic Detection To Study Muscle Wasting in ESRD** Biruh Workeneh, William E. Mitch. *Nephrology Division, Baylor College of Medicine, Houston, TX.*

Clinically significant muscle wasting affects up to 70% of the millions of patients with advanced CKD and the process accelerates in patients with ESRD. Muscle wasting results in significant weakness, dependency and decreased quality of life. Unfortunately, muscle wasting is difficult to study in CKD patients because significant interstitial edema is often present making interpretation of traditional modalities (CT, DXA, MRI) difficult. This problem can be overcome by measuring radioactive isotopes naturally present in the body, namely potassium and nitrogen, which reflect body cell mass and muscle stores, respectively. Reconstruction of body composition from the elemental level is reliable because it minimizes assumptions related to tissue density, hydration and other factors compared with traditionally employed modalities. Methods: We conducted an observational study involving 5 adult subjects (3 men; 2 women) using 3 imaging modalities: 1) DXA scan; 2) TBK (total body potassium); and 3) TBN (total body nitrogen). Subjects were studied post-dialysis and studies were repeated again 6 months later. Results: The characteristics of these subjects including weight (73±13kg), BMI (26±4) or albumin (3.8±.3g/dL) provided no evidence that a significant loss of lean body mass was present. At baseline, 1 subject showed to have sufficiently excess body fat to be considered obese, which was identified by both DXA and TBK/TBN. In contrast, 2 subjects had significant depletion of muscle mass (-1.8 standard deviations from age/gender matched controls) identified by the TBK/TBN measurements that DXA analysis did not capture. Three out of the 4 subjects who underwent repeat testing showed significant losses in lean mass, which corresponded with significant reductions in total body potassium and nitrogen. Conclusions: Our findings are consistent with previous reports that show patients with ESRD suffer from accelerated loss is muscle mass. The degree of lost protein stores varies considerably among patients and high resolution techniques, like TBK/TBN, can be extremely useful in the study of muscle wasting and can complement other methods to assess in-vivo responses to potential interventions.

**TH-PO461**

**Does Inflammation Independently Contribute to Malnutrition in Chronic HD Patients? A Longitudinal Study** Ilia Beberashvili,[1] Inna Sinuani,[1] Ada Azar,[2] Leonid Feldman,[1] Zhan Averbukh,[1] Joshua Weissgarten.[1] *[1]Nephrology, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Nutrition Department, Assaf Harofeh Medical Center, Zerifin, Israel.*

The present report describes a prospective longitudinal study of interleulin-6 (IL-6) levels and nutritional parameters to determine whether high IL-6 levels play a decreasing role in the nutritional status in a cohort of prevalent clinically stable hemodialysis patients.

IL-6, dietary energy and protein intake, biochemical markers of nutrition and body composition (anthropometry and bioimpedance analysis) were measured at baseline and at 6, 12, 18 and 24 months following enrollment, in 96 prevalent hemodialysis patients. Observation of this cohort was continued over 2 additional years. In total, the study period extended 35±17 months. Changes in repeated measures were evaluated, with adjustment for baseline differences in age, sex, diabetes status, dialysis vintage and history of cardiovascular disease.

At baseline, no statistically significant differences in dietary protein or energy intake, laboratory nutritional markers and body composition parameters (anthropometry and BIA derived) between groups according to tertiles of baseline IL-6 were observed. Significant reductions of fat mass index (linear estimate: -0.1460±0.06 kg/m$^2$; p=0.017), fat free mass index (linear estimate: -0.1974±0.04 kg/m$^2$; p=0.0001) and phase angle (linear estimate: -0.1061±0.03$^0$; p=0.0001) with time were observed. A longitudinal decrease in body composition parameters was not influenced by IL-6 (IL-6-by-time interactions were not significant). Finally, cumulative incidences of survival were affected by the baseline serum IL-6 levels (p=0.006 by log-rank test).

Our results suggest that while IL-6 is a robust predictor of death, inflammation alone does not independently contribute to uremic anorexia or modify nutritional status in chronic HD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO462**

**Hormonal Regulation of Energy Homeostasis in Hemodialysis Patients: An Anorexigenic Profile That May Predispose to Adverse Cardiovascular Outcomes** Manish Suneja, John B. Stokes, Victoria S. Lim. *Department of Medicine, university of Iowa Hospital and Clinics, Iowa City, IA.*

To assess hormonal control of energy homeostasis in uremia, we profiled peptides around the circadian clock with a built-in perturbation of a 40-hr fast in 10 hemodialysis patients [HD] with no co-morbid illnesses and 8 normal controls (C). We measured energy and protein balance,quantitated appetite and body composition. Baseline leptin (ng/ml) showed a higher nocturnal peak in HD {15±4 (C) and 36±9 (HD), p=0.08}. Fasting led to rapid decline in both groups with similar disappearance rate constants, suggesting similar metabolic rates in both groups. On re-feeding, leptin tended to have a higher peak in HD patients. These results suggest that leptin in HD is higher because of greater secretion. Poly-peptide Y (PYY), a gut hormone, showed higher levels in the HD during the entire time of the study and showed little circadian variation. Acylated-ghrelin (AG), a orexigenic gut hormone, was only mildly lower in HD at baseline, but the differences became more prominent before lunch and supper after fasting as the HD patient lost the pre-meal spike. Alpha-MSH levels were not different between the two groups. Neuropeptide Y (NPY), showed higher levels in HD at baseline and stayed elevated at all times during the study. Nor-epinephrine (NE, pg/ml) levels tended to be higher in HD at all time points. NPY and PYY showed some removal by hemodialysis. Energy and protein balance as well as lean and fat mass were not different in the two groups. High leptin and PYY combined with a low ghrelin indicate an anorexigenic profile, yet HD patients had good appetite. These data demonstrate that HD patients with no co-morbid illnesses have good appetite and nutrition status. We hypothesize that impaired para-sympathetic function in HD patients could explain both the high PYY and the absence of anorexia. The hormone profile of high leptin, elevated PYY, and NPY may enhance vasoconstriction, the low ghrelin may impair vasodilation. The increased NPY and NE may reflect heightened sympathetic activity. All these abnormalities can potentially, predispose HD patients to adverse cardiovascular events.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO463**

**Thyroid Function in Japanese Patients with End-Stage Renal Disease Undergoing Hemodialysis** Toru Sanai,[1] Ken Okamura,[2] Hiroki Miyazaki,[1] Tomoya Kishi,[1] Motoaki Miyazono,[1] Koichi Node.[1] *[1]The Department of Cardiovascular and Renal Medicine, Faculty of Medicine, Saga University, Saga, Japan; [2]The Department of Medicine and Clinical Science, Kyushu University, Fukuoka, Japan.*

**Background/Methods.** Thyroid function was evaluated in 145 Japanese end-stage renal disease (ESRD) patients on hemodialysis comparing with the data of 158 control in different age group such as young (13-39 years), old (40-69) and very old (over 70). **Results.** Although free thyroxine ($fT_4$) was stable, age-dependent slight increase in thyroid-stimulating hormone (TSH) and decrease in free triiodothyronine ($fT_3$) were observed both in control and ESRD, especially in very old patients aged 70 or more. In each age group, fT4 and fT3 were lower and TSH was higher in ESRD with minimal change in $fT_3/fT_4$. Excluding the data of very old group and those with apparently abnormal TSH (undetectable or over 4.5 U/ml), reference values for ESRD (n=91) compared with control (n=143) were as follows; fT4 1.0 +/- 0.2 vs 1.2 +/- 0.2 ng/dl (P<0.05), fT3 2.3 +/- 0.4 vs 3.2 +/- 0.7 pg/ml (P<0.05), TSH 1.73 (0.55-5.45) vs 1.12 (0.31-4.65) mU/l (P<0.05), and fT3/fT4 2.4 +/- 0.6 vs 2.7 +/- 0.7 (not significant). Compared with these reference values, apparent thyroid dysfunction among 145 ESRD patients was suggested as follows; thyrotoxicosis in 2 (1.4%), latent hypothyroidism in 17 (11.6%), overt hypothyroidism 8 (5.6%) and low $T_3$ syndrome in 23 (15.9%) of the patients. **Conclusion.** Slight but significant abnormality in thyroid function was confirmed in ESRD patients. Decrease in both serum $fT_4$ and $fT_3$ levels with slight increase in serum TSH level was the characteristic abnormality in ESRD, which was quite different from typical non-thyroidal illness pattern or low $T_3$ syndrome.

**TH-PO464**

**Hemodialyzer Design May Affect Iron and Anemia Parameters in Long-Term Hemodialysis Patients** Hiba Hamdan, Andrew I. Chin, Thomas A. Depner. *Internal Medicine, Division of Nephrology, University of California at Davis, Sacramento, CA.*

**Background**: We made a change in hemodialyzers within our community-based dialysis units. Improved rinse back with the new filters was noted by the clinical staff. We speculated that less blood was being lost and that anemia parameters may be improved. **Purpose**: To evaluate whether or not anemia parameters were improved upon switch to a new hemodialysis filter. **Methods**: A retrospective cohort review of anemia parameters in our dialysis clinic patients, comparing transferrin saturation (TSat%), ferritin, hemoglobin (Hgb), platelets, spKt/V, total dose of erythropoietin (EPO), and total dose of IV iron administered, between 4-month intervals before and after the switch in high-flux, re-use dialyzers. Paired t-test was used to compare 4 month average values, before and after the switch. **Results**: We evaluated 207 chronic hemodialysis patients, mean age was 57.7 years, 55% male. There was a statistically significant improvement in iron parameters (TSat & ferritin), pre-dialysis Hgb, and spKt/V after the switch.

Laboratory data before and after dialyzer change

| | Before dialyzer change | After dialyzer change | p value |
|---|---|---|---|
| TSat% | 22.9 ± 7.6 | 25.0 ± 9.5 | .009 |
| Ferritin | 691 ± 327 | 798 ± 358 | <0.001 |
| Hgb | 11.6 ± 0.8 | 11.7 ± 0.7 | 0.02 |
| Albumin | 3.8 ± 0.4 | 3.8 ± 0.4 | 0.3 |
| spKt/V | 1.52 ± 0.27 | 1.61 ± 0.23 | <0.001 |

There was no significant difference in EPO dose (units/kg/HD treatment), total administered IV iron, or heparin dose between the 2 time periods. Serum albumin also remained unchanged before and after the dialyzer change, suggesting that patients remained clinically stable between the time periods. **Conclusion**: Maintaining adequate iron stores is a key aspect of anemia management in the care of hemodialysis patients. We noted that a switch to a different hemodialyzer improved anemia parameters. Therefore, dialyzer design may have a significant impact on iron loss. Whether these noted differences are simply due to improved rinse back and hence lower blood loss, or if they are partially due to improved bio-compatibility of the new dialyzer, remains to be seen.

**TH-PO465**

**Hemoglobin Variability in Peritoneal Dialysis Patients; a Comparison of Epoetin Beta and CERA** Sally Ann Fonseca, Maarten W. Taal, Richard J. Fluck, Georgina Chandler, Nicholas M. Selby. *Department of Renal Medicine, Royal Derby Hospital, Derby, United Kingdom.*

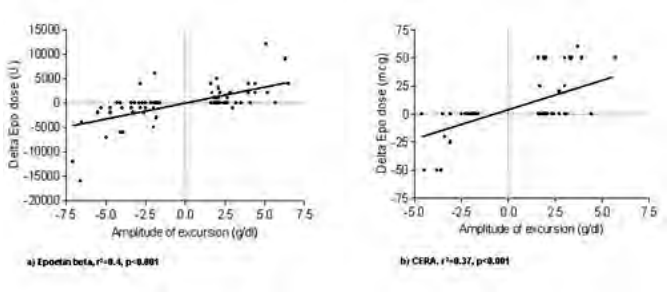
The extent to which hemoglobin (Hb) cycling occurs in peritoneal dialysis patients is unclear. It is also uncertain whether the half-life of erythropoietin stimulating agents (ESA) impacts on this. We therefore performed a retrospective cohort study of our peritoneal dialysis population before and after the entire programme was changed from epoetin beta (Neorecomon®) to CERA (Mircera®).

All patients treated with an ESA and peritoneal dialysis were screened for inclusion. Hb concentrations were measured monthly, each study period was 12mths. A significant Hb excursion was defined as a change in serum Hb of >1.5g/dl sustained for more than four weeks. Each complete Hb cycle consisted of two consecutive excursions in opposite directions.

A total of 79 patients were included (41 period one, 38 period two, 15 patients in both groups). There was a trend to fewer patients on CERA experiencing Hb excursions (26 patients, 68.4%) compared to those on epoetin beta (36 patients, 87.8%, p=0.054). There were also signficantly fewer dose changes in the CERA group (0.8 ± 0.7 per patient) as compared to epoetin beta (2.0 ± 1.7 per patient, p=0.0007). However there was no difference between the frequency of those with complete cycles.

Factors associated with Hb excursions were the number of dose changes, ESA dose, hospital admission and infection. There was a positive correlation between delta ESA dose and amplitude of Hb excursion, suggesting that the dose changes were causal, rather than reactive (see figure).

In conclusion, Hb cycling occurs in peritoneal dialysis patients and seems largely due to current practice in ESA dosing plus the effects of intercurrent illness. The longer half-life of CERA may offer a slight advantage in reducing Hb variability, possibly because of fewer dose changes per patient.

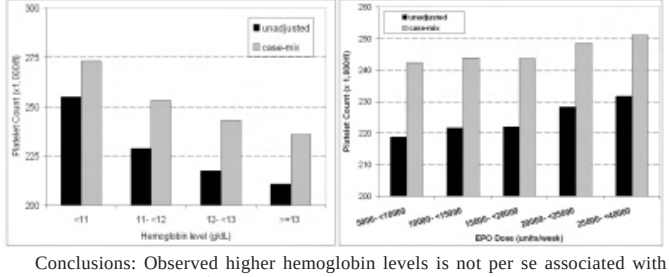


Disclosure of Financial Relationships: nothing to disclose

### TH-PO466

**Dissociation of Relative Thrombocytosis Associated with Higher ESA Dose vs. Hemoglobin Levels in Hemodialysis Patients** Elani Streja,[1] Csaba P. Kovesdy,[3] Lilia R. Lukowsky,[1] Ramanath B. Dukkipati,[1] Allen R. Nissenson,[2] Keith C. Norris,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]DaVita, Lakewood, CO; [3]Salem VA MC, Salem, VA; [4]Charles Drew University, Los Angeles, CA.*

Background: Recent randomized controlled trials indicated increased thromboembolic events and mortality upon targeting higher hemoglobin levels using higher doses of erythropoietin stimulating agents (ESA). It is not clear whether the high mortality is as a result of high ESA per se or high hemoglobin level. We, hence, examined the association of the latter 2 factors with relative thrombocytosis (increased platelet count), which is a predictor of increased thromboembolic events and death. Methods: Using linear regression models, we separately examined the associations between ESA dose and hemoglobin levels with13-week week (calendar quarter) averaged platelet count during July to Dec 2001 in a cohort of 40,697 maintenance hemodialysis (MHD) patients from in all DaVita clinics. Models were adjusted for case-mix. Results: MHD patients were 47%women; 46% diabetics; 34% African Americans, respectively. The 13-week averaged platelet count was 229 x103/µl. In unadjusted, and case-mix adjusted models, incrementally higher hemoglobin levels were associated with lower platelet count, whereas incrementally higher ESA doses were associated with higher platelet count (see Figures).



Conclusions: Observed higher hemoglobin levels is not per se associated with thrombocytosis, but only if associated with higher ESA dose or conditions that require higher ESA dose.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO467

**Conversion to Mircera in a UK Haemodialysis Unit: Effects on Haemoglobin Targets and Staff Time** Riaz Bavakunji,[1] Belinda Dring,[1] Amanda Pulfer,[2] Sheila Cooper,[2] Mark A. J. Devonald,[1] Simon Roe.[1] *[1]Nottingham University Hospital; [2]pH Associates.*

**Aims:** To study effects of converting IV epoetin alfa (Eprex) to IV Methoxy polyethylene glycol-epoetin beta (Mircera) with respect to achieving target haemoglobin (Hb), stability of Hb and nursing time required for drug administration in a UK satellite haemodialysis unit.

**Methods:** 60 patients receiving haemodialysis at a satellite unit were converted from Eprex to Mircera using a computerised decision support conversion algorithm and monitored for 12 months. Hb was measured monthly and percentage of patients within target (10.5-12.5 g/dL) recorded, along with mean Hb and Mircera dose. Mean times required for administration of Eprex and Mircera were calculated.

| Variables | Month -1 | Month 1 | Month 12 |
|---|---|---|---|
| Mean (+SD)Hb(g/dL) | 11.47(1.59) | 11.35(1.63) | 11.69(1.10) |
| Mean (95% CI) change in Hb(g/dL), from baseline | - | 0.15(-0.13-0.43) | 0.52(0.18-0.86) |
| Patients within target range, percent(n) | 81(35/43) | 71(41/60) | 86(25/29) |
| Mean ferritin( g/L) | 655 | 642 | 609 |
| Mean Mircera dose( g/month) | - | 150 | 200 |

**Results :** For those with complete data, 71%(41/60), and 86%(25/29) achieved target Hb of 10.5-12.5g/dL at 1 and 12 months respectively (Table 1). At 12 months 14% had Hb of <10.5g/dL and 28% >12.5g/dL. The initial drop in Hb recovered by 3 months (55-71% achieved Hb between 10.5-12.5g/dL from month 2 onwards. Mean dose of Mircera increased over 12 months from 150 to 200g/month. In any month post-conversion, an average of 69% patients (range 58-80%) did not require a change in dose of Mircera.

Mean nursing time required per patient for administration of Eprex was 3 min 14 sec(38min 48sec/patient/month based on a most common administration Eprex schedule of 4000 IU x3/week) compared with 3min 56sec/patient/month for Mircera. Seven patients attributed new, non-specific symptoms to the conversion and were changed back to Eprex.

**Conclusions:** Conversion to Mircera resulted in an initial dip in Hb followed by increase and stabilization with 86% of patients within target at 12 months. Nurse time saving of 34min 52sec/patient/month was calculated. 7/60 patients attributed non-specific symptoms to Mircera.

**Determining Maximum Clinically Effective Dose of Epoetin Alfa in ESRD Anemia Management** Adam Gaweda,[1] George R. Aronoff,[1] Alfred A. Jacobs,[1] Michael Brier.[2] *[1]Department of Medicine, University of Louisville, Louisville, KY; [2]Department of Veterans Affairs.*

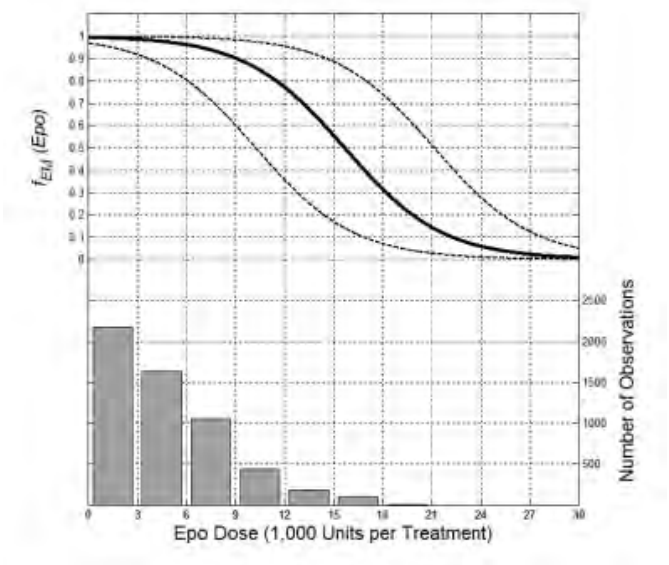
Secondary analysis of the CHOIR study indicates that increasing Hemoglobin (Hb) with excessive ESA doses may be harmful. Furthermore, the new Medicare reimbursement system provides an incentive to reduce the ESA dose. We performed a retrospective cohort study to answer the question: What is the maximum clinically effective ESA dose?

We studied a population of 209 ESRD patients treated at the Kidney Disease Program, University of Louisville, Louisville, KY, between 1996 and 2001, who received Epoetin alfa (Epo). We collected their monthly Hb and weekly Epo and estimated their erythropoietic sensitivity using the following model:

$\Delta Hb(k) = \Sigma^{N}_{i=1} \beta_i f_{EM}(Epo(k-i)) \Delta Epo(k-i)$

This model relates monthly change in Hb, $\Delta Hb(k)$, to past monthly changes in Epo dose, $\Delta Epo(k-i)$. $\beta_i$ represents erythropoietic sensitivity, $f_{EM}(Epo(k-i))$ represents the change in erythropoietic sensitivity with respect to the Epo dose per treatment received at month k-i. The inflection point of $f_{EM}$ represents 50% of the maximum erythropoietic sensitivity. We estimated this model using mixed effect nonlinear regression in MATLAB®.

Statistically, the best model incorporates three past Epo dose changes (N=3). The $\beta$ coefficients for this model are $\beta_1 = 0.28$, $\beta_2 = 0.13$, $\beta_3 = 0.09$ (all, $p < 0.001$). The mean inflection point for $f_{EM}$ is 15.7 ($p < 0.001$).



Top: Mean $f_{EM}$ (thick line) and its 95% Confidence Interval (dotted lines). Bottom: Data histogram.

The mean erythropoietic sensitivity decreases by 10% at 9,000, by 50% at 16,000, and by 90% at 22,000 Units Epo per treatment. The results of this study can be used by the physician to determine the stopping point for dose escalation when no clinically significant effect is expected.

### TH-PO469

**Evaluating the Impact of Change in Pre-Dialysis Weight on a Change in Measured Hemoglobin (Hb)** Joe Weldon, Tracy Jack Mayne, Steven M. Wilson, Mahesh Krishnan. *DaVita Inc., Denver, CO.*

The literature has shown an association between low Hb, higher ESA doses and increased morbidity and mortality in dialysis patients, but many have questioned the role of confounding factors. Interdialytic weight gain is associated with increased morbidity and mortality. Increased volume status could produce spuriously low Hb measures via simple dilution, triggering ESA dose increases and confounding associations between both variables and outcomes. We examined the association between interdialytic weight gain, measured

Hb, and ESA dose. **Methods:** Retrospective analysis of 164866 hemodialysis patients dialyzed between January 1 and December 31 of 2009 at a large dialysis organization. Sequentially paired Hb values were created within a 30 day period. For each treatment corresponding to those dates, change in ESA and Hb were recorded and categorized by change in pre dialysis wt. Multiple observations per patient were used. **Results:** Prior mean Hb ranged from 11.2 to 11.7 g/dL and prior mean weekly ESA dose from 20k to 26k Units. Table 1 shows change in Hb and ESA dose by interdialytic weight gain category. To control for multiple measurements on many patients, the weighted Pearson product moment correlation was calculated on mean scores. The correlation was r = -0.17 between change in pre-dialytic weight and change in Hb, and r = 0.03 between change in pre-dialytic weight and change in ESA dose.

| Change in Pre-Dialytic Weight | Matched Hb Draws | Change in Hb (g/dl) Mean±SD | Change in Weekly ESA U from Prior Draw |
|---|---|---|---|
| >2.0 to 10.0 kg | 422,528 | -0.29±0.86 | 6.8% |
| 0.5 to ≤2.0 kg | 1,467,172 | -0.09±0.73 | 1.0% |
| >-0.5 to >0.5 kg | 1,544,905 | +0.07±0.70 | -1.3% |
| -0.5 to ≤-2.0 kg | 1,473,124 | +0.23±0.74 | -2.5% |
| <2.0 to -10.0 kg | 478,550 | +0.39±0.91 | 0.4% |

**Conclusions:** Changes in pre-dialysis weight were associated with reciprocal changes in both Hb and, in sequence, ESA dose. Given the magnitude of these effects, changes in pre-dialysis weight may be a clinically meaningful confounder of the relationship between Hb, ESA dose and morbidity & mortality in dialysis patients.

### The Influence of CMV and EBV Serostatus on Haemoglobin (Hb) and Erythropoietin Stimulating Agent (ESA) Responsiveness in Patients with CKD Stage 5

Cherrise Baldeo,[2] Wael F. Hussein,[1] Mark D. Denton.[1] *[1]Renal Unit, Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons Ireland, Dublin, Ireland.*

**Background.** CMV seropositivity has been reported to be a major determinant of ESA resistance in patients with CKD. We wished to examine whether CMV or EBV serostatus influenced Hb and / or ESA dose in our population of CKD stage 5 patients.

**Methods** We collected data on CMV and EBV serology, age, sex and Hb on 1417 patients presenting for a renal transplant at our institution between 2000 to 2009. We examined whether CMV and EBV serostatus influenced Hb values pre transplantation. We next examined 117 patients on the transplant waiting list. CMV and EBV serostatus, Hb, ESA dose, iron studies, B12/folate, albumin, PTH, diabetes, vascular access type, and dialysis adequacy were collected. Multivariate analysis was performed to determine factors associated with increased ESA dosage.

**Results:** We found no effect of CMV or EBV serostatus on Hb or ESA dosage. Firstly, analysis of 1417 patients showed no difference in mean Hb between the various CMV / EBV serostatus groups. Analysis of variance showed that only increasing age and female sex were associated with lower haemoglobin values. Secondly, analysis of patients currently on the transplant pool also showed that there was no difference in mean Hb between the CMV or EBV groups. There was a trend for increased ESA dose in patients who were CMV seropositive but this was not significant. Analysis of a subpopulation of patients not on ESA also showed no difference in mean Hb between CMV / EBV groups. Analysis of haemodialysis patients alone, CMV positivity was associated with a higher mean Hb and a lower mean ESA dose. On multivariate analysis only low serum iron was associated with ESA resistance.

**Conclusion:** Our results contrast with those of a recent report linking ESA resistance to CMV seropositivity. Our study benefitted from a large population size and completeness of data collection. We found no association between CMV or EBV serostatus on Hb or ESA dosage. These conflicting results may be due to 1) differences in patient demographics (younger, and fewer diabetic patients) and 2) differences in target Hb and mean ESA dosage.

## TH-PO471

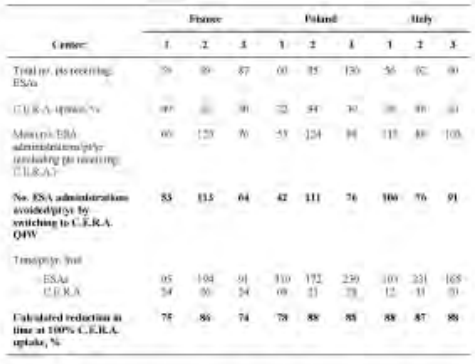
### Time Savings Associated with Once-Monthly (Q4w) C.E.R.A.: A Time and Motion Study Conducted in Dialysis Centers in France, Poland, and Italy

Wieslaw Klatko,[1] Giuseppe Villa,[2] Jean-Claude Glachant,[3] Erwin De Cock.[4] *[1]Nephrology Department, Specjalistyczny Szpital Wojewódzki, Ciechanów, Poland; [2]Fondazione Salvatore Maugeri, Pavia, Italy; [3]Service Néphrologie – Hémodialyse, Bourg en Bresse, France; [4]United Biosource Corporation.*

**Purpose:** Anemia management in CKD is time consuming for healthcare professionals and patients. The challenge for hemodialysis centers is to improve efficiency while maintaining high standards of quality of care. Simplifying anemia management may reduce resource usage, allowing healthcare staff to devote more time to other important CKD care needs. We report results from a multinational, multicenter time and motion study that documents healthcare personnel time savings for anemia management after the introduction of Q4W maintenance therapy with a continuous erythropoiesis receptor activator (C.E.R.A.) in hemodialysis centers in France, Poland, and Italy.

**Methods:** The time spent on frequent anemia management tasks (preparation and distribution, injection, and record-keeping) was timed by trained observers and recorded on case report forms. The time per patient per session was used to calculate the annual time per patient and per center.

**Results:** Key parameters that determined time for anemia management with traditional ESAs and C.E.R.A., and that impacted on time reductions with 100% C.E.R.A. uptake, are shown below.



| Center: | France 1 | France 2 | France 3 | Poland 1 | Poland 2 | Poland 3 | Italy 1 | Italy 2 | Italy 3 |
|---|---|---|---|---|---|---|---|---|---|
| Total nr. pts receiving ESAs | 79 | 89 | 87 | 60 | 85 | 130 | 56 | 82 | 90 |
| C.E.R.A. uptake, % | 97 | 96 | 90 | 92 | 94 | 93 | 98 | 98 | 94 |
| Mean ESA administrations/pt/yr (excluding pts receiving C.E.R.A.) | 60 | 120 | 90 | 53 | 124 | 94 | 115 | 89 | 108 |
| **No. ESA administrations avoided/pt/yr by switching to C.E.R.A. Q4W** | **55** | **115** | **64** | **42** | **111** | **76** | **106** | **76** | **91** |
| Time/pt/yr, hrs | | | | | | | | | |
| ESAs | 95 | 198 | 91 | 310 | 372 | 230 | 169 | 231 | 165 |
| C.E.R.A. | 24 | 50 | 24 | 98 | 93 | 58 | 42 | 58 | 41 |
| **Calculated reduction in time at 100% C.E.R.A. uptake, %** | **75** | **86** | **74** | **78** | **88** | **85** | **88** | **87** | **88** |

**Conclusion:** Modeled 100% uptake of C.E.R.A. Q4W maintenance therapy was shown to offer substantial annual time savings on frequent tasks related to anemia management of 74-86% in France, 78-88% in Poland and 87-88% in Italy, allowing healthcare resources to be reallocated to other important CKD therapy needs and improving overall patient care. This confirms findings from a previous study using time and motion methodology.[1]

### Normalisation of CRP and LDL-C Levels Is Related to Reduction of Cardiovascular Morbidity and Mortality in Haemodialysis Patients on Rosuvastatin Treatment – A *Post Hoc* Analysis of the AURORA Trial

Bengt C. Fellstrom,[1] Hallvard Holdaas,[2] Alan G. Jardine,[4] Roland E. Schmieder,[3] Ingar Holme,[5] Faiez Zannad.[6] *[1]Nephrology, Uppsala; [2]Nephrology, Oslo; [3]Nephrology, Erlangen; [4]Cardiovasc Res Center, Glasgow; [5]Preventive Cardiology, Oslo; [6]Inserm, Nancy.*

**Purpose:** C-reactive protein (CRP) is an important marker for cardiovascular (CV) events in patients on dialysis.We analysed CRP and LDL-C levels in haemodialysis patients randomised to rosuvastatin 10 mg or placebo in the AURORA trial. to determine if there was a treatment effect related to reduction in LDL-C or CRP.

**Methods** : Levels of CRP and LDL-cholestrol at 3 or 12 months post-randomization were analysed in both treatment groups, and split points of CRP = 2 mg/ l and LDL-C = 1.8 mmol/l were used..

**Results** : Of 2776 patients randomised in AURORA, 813 had CRP <2 mg/L on treatment, 1418 had LDL-C <1.8 mmol/L, and 509 had both CRP <2 mg/L and LDL-C <1.8 mmol/L.In the subgroup of 813 patients in whom CRP was < 2 mg/liter after 3 or 12 months of statin/placebo therapy, LDL-C emerged as a significant risk factor for CV events (HR 1.53 , P= 0.014 ). In this subgroup, rosuvastatin treatment lead to reduced risk of major CV events compared to placebo (HR= 0.71, P= 0.018). Subgroups based on CRP or LDL-cholesterol levels at baseline were not predictive of treatment effects by rosuvastatin upon any of the endpoints. However, in patients who had post-randomisation CRP < 2 mg/l and LDL< 1,8 mmol/l ( 509 / 2516 patients (20%) ), rosuvastatin treatment was associated with a significant lower risk of major cardiovascular events (HR= 0.53 , P=0.0005), of cardiovascular death (HR = 0.54, p= 0.0012) of combined endpoint of major CV event or patient death (HR= 0.64, p = 0,0035) and of all cause mortality (HR = 0.71 , p= 0.014). Non-CV death did not differ in the rosuvastatin low post randomization CRP (HR= 0,88, P = 0,61). **Conclusion** : CRP is an important marker for CV events and death and LDL-C is a risk factor for major CV events in haemodialysis patients with CRP <2 mg/L on treatment. A significant risk reduction was observed in patients in whom CRP and LDL-C levels were normalised with rosuvastatin.

## TH-PO473

### Cardiovascular Events Following an Infectious Hospitalization in Patients on Dialysis

Lorien S. Dalrymple,[1] Sandra Mohammed,[1] Yi Mu,[1] Kirsten L. Johansen,[2,3] Glenn M. Chertow,[4] Barbara A. Grimes,[3] George A. Kaysen,[1,5] Danh V. Nguyen.[1] *[1]UC Davis; [2]San Francisco and N. California VAMC; [3]UC San Francisco; [4]Stanford University; [5]VA Mather.*

**Purpose:** To examine whether an infectious hospitalization increases the subsequent risk of a cardiovascular (CV) event in older patients on dialysis.

**Methods:** The source population was assembled from the United States Renal Data System and included patients aged 65 to 100 years newly starting dialysis between 1/1/00 and 12/31/02. Patients were followed until transplant, death or study end 12/31/04. All discharge diagnoses were examined to determine whether an infection occurred during hospitalization. Only principal discharge diagnoses were examined to ascertain CV events (unstable angina, myocardial infarction, transient ischemic attack or stroke). We used the

case series method to estimate the relative incidence of a CV event within 90 days following an infectious hospitalization compared to periods without infection.

**Results:** The source population included 138,665 patients, of whom 16,874 had at least one CV event and were included in the analysis. The risk of a CV event was increased by 25% in the first 30 days following an infection, and decreased over the first 90 days. Each type of infection examined (septicemia, pulmonary, and genitourinary) was associated with an increased risk of CV events.

Table 1. Age-Adjusted Relative Incidence (RI) of a CV Event Following Infectious Hospitalization

| Risk Period | All Infections | Septicemia | Pulmonary | Genitourinary |
|---|---|---|---|---|
| Days | RI (95% CI) | RI (95% CI) | RI (95% CI) | RI (95% CI) |
| 1-30 | 1.25 (1.18,1.33) | 1.15 (1.02,1.28) | 1.20 (1.08,1.34) | 1.20 (1.08,1.34) |
| 31-60 | 1.17 (1.09,1.26) | 1.18 (1.04,1.34) | 1.10 (0.98,1.25) | 1.10 (0.97,1.25) |
| 61-90 | 1.08 (1.00,1.17) | 1.21 (1.06,1.39) | 1.10 (0.96,1.25) | 1.01 (0.88,1.16) |
| 1-90 (combined) | 1.18 (1.13,1.24) | 1.17 (1.09,1.27) | 1.14 (1.06,1.23) | 1.12 (1.04,1.21) |

**Conclusions:** The first 30 days following an infection is a high risk period for CV events and may represent an opportunity for risk reduction in older patients on dialysis.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO474

**Carotid Intima-Media Thickness Is Associated with the Severity of Coronary Artery Disease and Cardiovascular Prognosis in Hemodialysis Patients** Shinji Tanaka, Naobumi Mise, Tokuichiro Sugimoto. *Nephrology, Mitsui Memorial Hospital, Chiyoda-ku, Tokyo, Japan.*

**Purpose:** This study aimed to investigate the association between carotid intima-media thickness (IMT) and the angiographic severity of coronary artery disease (CAD), and to clarify prognostic factors for cardiovascular mortality in chronic hemodialysis (HD) patients.

**Methods:** This retrospective cohort study comprised 64 consecutive HD patients (44 male, mean age 65 ± 8 years, 34 (53.1%) diabetics, mean dialysis vintage 98 ± 90 months) who underwent elective coronary angiography for suspected CAD between July 2002 and March 2004. IMT was measured by ultrasonography within a month before the angiography. All patients were followed until the end of 2009, and the study endpoint was death from cardiovascular disease.

**Results:** Coronary angiography revealed no significant stenosis in 24 (37.5%) patients, single-vessel disease in 14 (21.9%), and multi-vessel disease in 26 (40.6%). There was a consistent incremental increase in mean IMT with increasing severity of CAD: 0.71 ± 0.16 mm in zero-vessel, 0.84 ± 0.17 mm in single-vessel, and 1.05 ± 0.30 mm in multi-vessel disease patients (zero vs. single: p=0.016, single vs. multi: p=0.023).

There were 29 cardiovascular deaths (45.3%) during the follow-up period of 50 ± 30 months. In univariate analysis using Cox proportional hazard model, IMT (p<0.01), the severity of CAD (p=0.068), and age (p<0.01) influenced cardiovascular mortality (p<0.1). Multivariate analysis including these 3 variables demonstrated that IMT (hazard ratio per 0.1 mm increase: 1.19, 95% confidence interval 1.04-1.35, p=0.014) and age (hazard ratio per 1 year increase: 1.06, 95% confidence interval 1.01-1.12, p=0.037) were significant predictors of cardiovascular mortality.

**Conclusions:** IMT was associated with the angiographic severity of CAD in HD patients. In addition, IMT was more strongly related to cardiovascular prognosis than was CAD severity in this population.

## TH-PO475

**Repeat Coronary Revascularization of Dialysis Patients in the US after Surgical Versus Percutaneous Coronary Intervention** Charles A. Herzog, David T. Gilbertson, Craig Solid. *CVSSC, USRDS, Minneapolis, MN.*

**Introduction:** There are few published data on the comparative risk of repeat coronary revascularization of dialysis pts following surgical versus percutaneous coronary .intervention (PCI).

We searched the records of the United States Renal Data System database to identify 12,792 dialysis pts having coronary artery bypass surgery (CAB), drug eluting stents (DES), or bare metal stents (BMS) in 2004-2006. Event-free survival for repeat coronary revascularization (PCI or CAB) and the combined event of repeat revascularization or death was estimated by Kaplan-Meier method and independent predictors were examined in a comorbidity-adjusted Cox model.

**Results:** There were 3,455 CAB pts, 7,486 DES pts, and 1,851 BMS pts. The tables show event-free survival and predictors for repeat revascularization and the combined endpoint of revascularization/death (age < 65, male, white, hemodialysis, time on dialysis < 2 years, no comorbidity, CAB is reference) with hazard ratio (HR). The risk of repeat revascularization is markedly lower in CAB patients, while DES and BMS patients have similar rates of repeat coronary revascularization. The combined event of repeat coronary revascularization or death is least likely to occur in CAB pts.

**Conclusion:** Our data indicate that dialysis pts receiving CAB (vs PCI) have a lower rate of repeat coronary revascularization. DES and BMS pts have comparable rates of repeat coronary revascularization.

Event-Free Survival(%)

| | Repeat Revascularization | | | Repeat Revascularization/Death | | |
|---|---|---|---|---|---|---|
| Months | CAB | DES | BMS | CAB | DES | BMS |
| 1 | 98.3 | 94.3 | 94.4 | 86.4 | 88.5 | 85.2 |
| 6 | 95.1 | 85.5 | 84.2 | 71.5 | 69.6 | 62.9 |

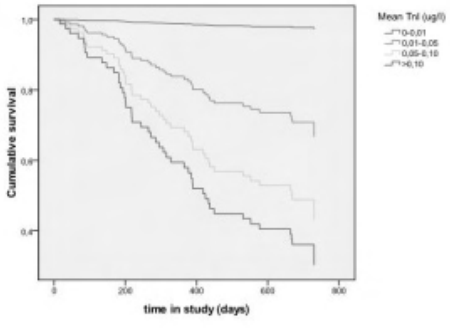
## TH-PO476

**Troponin I as a Cardiac Biomarker for Cardiovascular Mortality in Patients on Chronic Haemodialysis** Stefanie Vogels,[1] Volkher Scharnhorst,[1] Daniel A. Geerse,[1] Constantijn Konings,[1] Frank Van der Sande,[2] Jeroen Kooman,[2] Karel M. Leunissen.[2] *[1]Internal Medicine, Catharina Hospital, Eindhoven, Netherlands; [2]Nephrology, University Hospital, Maastricht, Netherlands.*

***Background:*** The high prevalence of cardiovascular mortality in patients on chronic haemodialysis is well established. Biomarkers like BNP and Troponin T are correlated with cardiovascular (CV) mortality, but this relationship is much less clear for troponin I (TnI). With a more sensitive test for TnI we found a strong correlation between TnI and cardiovascular mortality.

***Materials and methods:*** Plasma TnI levels of 206 chronic haemodialysis patients in our centre were measured every 3 months for a period of 24 months. We used a TnI-ultra assay on an Advia Centaur analyzer. Cardiovascular morbidity and mortality were assessed over a period of 30 months.

***Results:*** 206 patients were divided in 4 groups by their mean TnI according to the reference values of TnI used in our hospital. Group 1 (n=59) had a TnI level <0.01µg/l; group 2 (n=94) had TnI levels of 0.01-0.05µg/l; group 3 (n=29) 0.05-0.10µg/l and group 4 (n=24) had a TnI level ≥0.10µg/l. Forty-nine patients (23.8%) died; 31 (63.3%) due to CV disease. In group 1 one patient (1.7%) died of a CV cause. Group 2 had 21 deaths (22.3%); 11 (52.4%) of a CV cause. In group 3 13 patients (44.8%) died; 8 (61.5%) due to CV causes. Fourteen patients (58.3%) in group 4 died. Eleven of them (78.6%) died of a CV event. Twenty patients had a heart attack; per subgroup: n=2 (3.4%), n=9 (9.6%), n=3 (10.3%) and n=6 (25.0%) respectively. In a univariate analysis a high TnI was related with a significant higher risk for myocardial infarction (p=0.007) and cardiovascular death (p=0.001).



In a multivariate analysis TnI remained a strong independent risk factor.

***Conclusion:*** TnI can be a prognostic biomarker for (cardiovascular) mortality in patients on chronic haemodialysis.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO477**

**Accelerated Progression of Vascular Calcification in Paediatric CKD and Dialysis Patients Is Associated with Baseline Vessel Calcification** Rukshana C. Shroff,[1] Ambrose M. Gullett,[1] Melanie Hiorns,[2] John Deanfield,[3] Lesley Rees,[1] Catherine M. Shanahan,[4] Kimberly Rita Hassen.[1] *[1]Nephrology Unit, Great Ormond Street Hospital, London, United Kingdom; [2]Radiology Unit, Great Ormond Street Hospital; [3]Vascular Physiology Unit, Institute of Child Health; [4]Cardiovascular Division, King's College London.*

Vascular calcification is thought to begin early in CKD and progress rapidly on dialysis, but there are few studies demonstrating this. We compared vascular changes as seen on imaging with a quantitative and histological assessment of the vessel calcium [Ca] load on arterial biopsy to study progression of vascular changes.

39 children (13 pre-dialysis CKD 4-5; 26 dialysis) had carotid intima-media thickness [cIMT], pulse wave velocity [PWV] and coronary artery calcification [CAC] scoring on CT and an arterial biopsy at the time of renal transplantation or PD catheter insertion. The Ca load in the vessel wall was quantified and vessel histology performed. 32 children (19 dialysis, 13 transplants) had repeat imaging after 10.8±6.6 months. Changes in vascular measures and their correlation with baseline arterial biopsy was noted.

At initial measurement cIMT was increased in 85% of dialysis patients and showed a positive correlation with increased vessel Ca load ($p<0.003$). Only 2 of 13 pre-dialysis patients had an increased cIMT despite an increased vessel Ca load in all ($p=0.7$). On follow-up dialysis patients had an increase in cIMT (0.54±0.07 to 0.68±0.04mm; $p=0.02$), PWV (6.4±0.2 to 7.3±0.8 m/sec; $p=0.005$) and CAC increased in 2 children with baseline CAC and was found in 3 others. cIMT progression correlated with baseline vessel Ca load ($p=0.004$, $r=0.58$), vascular smooth muscle cell number and apoptosis. Only 4 dialysis patients with the highest vessel Ca loads showed an increase in PWV and CAC. No correlation was seen between vessel alkaline phosphatase or osteogenic marker runx2 and imaging studies. Pre-dialysis patients had a deterioration in PWV (6.1±0.3 to 7.0±0.2 m/sec), but cIMT and CAC were unchanged and did not correlate with vessel Ca load.

Calcification is rapidly progressive on dialysis and strongly correlates with baseline vessel wall changes.

**Increased Circulating PIVKA-II (Protein Induced by Vitamin K Absence II) Levels in Dialysis Patients and Its Relation to Calcification, Outcome and Vitamin K2 Administration** Georg Schlieper,[1] Leon J. Schurgers,[2] Ralf Westenfeld,[3] Cees Vermeer,[2] Jurgen Floege,[1] Thilo Krueger.[1] *[1]Nephrology, RWTH University Hospital, Aachen, Germany; [2]CARIM, Maastricht University, Mastricht, Netherlands; [3]Cardiology, Heinrich-Heine University, Duesseldorf, Germany.*

End-stage renal disease patients exhibit a clinical vitamin K deficiency as indicated by increased serum levels of uncarboxylated osteocalcin and - as recently shown - by increased PIVKA-II (protein induced by vitamin K absence II) levels. Recent experimental and clinical data suggest that vitamin K antagonism by warfarin use is associated with increased cardiovascular calcifications.

In this study we addressed the question whether PIVKA-II levels were associated with cardiovascular calcifications (Adragao and extended score) and mortality in 188 hemodialysis (HD) patients (59 ± 11 years). In addition, we tested whether vitamin K2 (MK-7) administration over 6 weeks was able to lower PIVKA-II levels in 50 HD patients. Patients on warfarin were excluded because of its vitamin K-antagonising effect.

PIVKA-II levels were increased (> 2 ng/mL) in 121 (64%) of the HD patients (median 2.98; range 0.45 – 318 ng/mL), indicating hepatic vitamin K deficiency. PIVKA-II levels correlated well with those of desphosphorylated uncarboxylated matrix gla protein (MGP; $r = 0.62$; $p < 0.0001$) and to a lesser extent with desphosphorylated carboxylated MGP ($r = 0.19$; $p = 0.01$). In contrast to MGP levels PIVKA-II levels did not show an association with cardiovascular calcifications. High PIVKA-II levels (> 2 ng/mL) were not associated with an increased mortality risk (log-rank test: $p = 0.67$; Cox regression: HR 1.00, CI 0.53 – 1.89, $p = 1.00$). Daily vitamin K2 administration (45, 135 or 360 µg/d) in HD patients lowered PIVKA-II levels by 32%, 39% and 50%, respectively (all $p<0.01$).

HD patients display a profound vitamin K deficiency. Elevated PIVKA-II levels likely reflect hepatic vitamin K deficiency whereas MGP levels seem to serve as more robust marker for vascular vitamin K deficiency. Whether vitamin K treatment can improve survival needs to be tested in future studies.

**Predictors of Survival in Dialysis Patients with Acute Myocardial Infarction: Findings from the USRDS AMI Special Study** Samy M. Riad,[1] Sally K. Gustafson,[2] Xinyue Wang,[2] David T. Gilbertson,[2] Charles A. Herzog.[1,2] *[1]Dept of Nephrology, U of MN, Minneapolis, MN; [2]USRDS, Minneapolis, MN.*

**Background:** Acute myocardial infarction (AMI) in dialysis pts is associated with poor survival. This study aims to identify predictors of survival in dialysis pts prior to AMI and to examine the association between survival and different revascularization techniques.

**Methods and Results:** 3049 US prevalent dialysis pts hospitalized for AMI 4/1/1998-6/30/2000 were identified by cross-matching United States Renal Data System (USRDS) database and the Third National Registry of Myocardial Infarction (NRMI 3). Of the 3011 data abstraction forms sent to the 18 renal networks, 1696 were sufficiently complete for analysis. Average age was 66.4 years old and average years on dialysis 2.7 years. 69% were white and 47% were females. Diabetes (DM) and dysrhythmia were prevalent in 72.5% and 65.5% respectively. At 1 yr post-AMI, 62% of the cohort had died. The impact of independent predictors on survival was examined in a Cox Proportional Hazards model. Beta Blocker (BB) use was associated with a favorable 1-yr all-cause mortality (hazard ratio (HR) of 0.8, $p=0.003$). As compared to pts who dialyzed via catheter, fistula use was associated with favorable outcome (HR=0.76, $p=0.008$), as was graft use (HR=0.82, $p= 0.016$). Compared to pre-dialysis systolic blood pressure (PDSBP) between 120-179 mmHg, PDSBP < 120 mmHg was more hazardous (HR=1.46, $p\leq 0.0001$) while PDSBP ≥ 180 mmHg (HR=0.7, $p=0.004$) had better survival. Coronary artery bypass graft surgery (CABG) and percutaneous coronary intervention (PCI) within 30 days of AMI were examined in time-independent and time-dependent Cox models. In the time-independent model, PCI and CABG were similarly associated with favorable outcome. However, in all time-dependent models, CABG lost its significance (HR = 0.86, P = 0.35), while PCI maintained its protective association (HR=0.67, $p=0.0005$).

**Conclusion:** BB use prior to AMI, and PCI within 30 days of AMI are associated with favorable one year survival in dialysis patients. Validation of these observational findings by randomized clinical trials is needed.

**Study of the Autonomic Response in Hemodialysis Patients at Different Levels of Fluid Overload** Manuela Ferrario,[1] Ulrich Moissl,[2] Francesco Garzotto,[3] Maria Gabriella Signorini,[1] Dinna N. Cruz,[3] Flavio Basso,[3] Alessandra Brendolan,[3] Federico Nalesso,[3] Ciro Tetta,[2] Sergio Cerutti,[1] Claudio Ronco.[3] *[1]Department of Bioengineering, Politecnico di Milano, Milano, Italy; [2]Fresenius Medical Care GmbH, Bad Homburg, Germany; [3]Nephrology, San Bortolo Hospital, Vienza, Italy.*

**Background**

This work aims at studying the autonomic nervous system (ANS) response to hemodialysis (HD) treatments in a population of end stage renal disease (ESRD) patients which are characterized by different conditions in terms of blood pressure (BP) and fluid overload (FO).

**Methods**

80 patients were recruited from the dialysis unit of San Bortolo Hospital, Vicenza. Whole body bioimpedance spectroscopy measurements were performed for each patient before HD and 24 hr ECG Holter were recorded starting from the period immediately before HD. Patients were classified according to the FO values and the systolic blood pressure (SBP) measured before HD [Wabel et al., NDT, 2008]. Time and frequency domain indices for heart rate variability (HRV) were determined for the first 30 minutes and last 30 minutes of HD, the first hour after HD, and night (12.00 p.m.-4 a.m.) [Task Force, Circulation, 1996].

**Results**

Significant differences were obtained in fluid overloaded but normotensive patients (Group IV) with respect to fluid overloaded and hypertensive patients (Group I) and normohydrated and normotensive patients (Group N+Dx), see Figure 1. In particular, SDNN, RMSSD, SDSD, pNN50%, indices were significantly higher in Group IV with respect to the other groups.

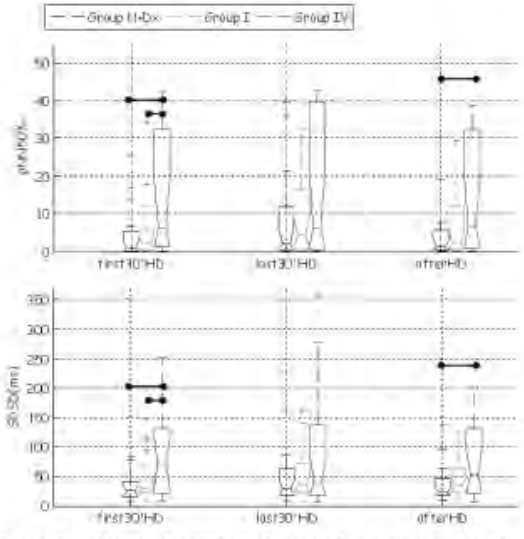

Figure 1. Upper Panel: Boxplot of the pNN50% values. Lower panel: Boxplot of the SDSD values for the 3 groups. The lines mark the significant differences between the groups (ANOVA p-value<0.05 and Bonferroni multicomparisons test p-value<0.05).

**Conclusion**

Overhydrated patients with hypertension (Group I) could be affected by a blunted parasympathetic activity, which may contribute to hypertension.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO481

**Secular Trends in Cardiovascular Mortality Rates of Patients Receiving Dialysis Compared to the General Population** Matthew A. Roberts,[1] Kevan R. Polkinghorne,[2] Stephen P. McDonald,[3] Francesco L. Ierino.[1] *[1]Nephrology, Austin Health, Victoria, Australia; [2]Nephrology, Monash Medical Centre, Victoria, Australia; [3]Nephrology, The Queen Elizabeth Hospital, South Australia, Australia.*

We analysed cardiovascular mortality rates (CVMR) of dialysis patients over time and compared these to the general population.

CVMR were calculated from ANZDATA Registry data for Australian patients receiving dialysis from 1992-2005, and from Australian Bureau of Statistics data for the comparable general population. Patients were included if dialysis was the first renal replacement therapy, and censored at transplantation or three years from commencing dialysis. Age-stratified CVMR were reported per hundred person-years and Relative Risks (RR) calculated relative to the Australian population rates. Secular changes in CVMR were analysed with negative binomial regression.

The analysis included 24,352 patients with 68,407 person-years of follow up and 5,134 cardiovascular deaths. CVMR declined over time in the general population (not shown). Age-stratified CVMR declined in patients on dialysis aged 55-74 years but the corresponding RR increased over this time (Table). The RR of dialysis patients increased markedly with younger age, a trend which did not alter over time. The risk associated with dialysis compared to the general population increased over time (p=0.044 for interaction). CVMR in Australia were comparable to those in the United States and Europe.

Although cardiovascular mortality rates are falling, the excess cardiovascular risk in dialysis patients compared to the general population is increasing over time.

Age-stratified CVMR and RR (95% CI) in 1992-1994 and 2004-2005

| Era: | CVMR per 100 person-years | | RR | |
|---|---|---|---|---|
| Age | 1992-1994 | 2004-2005 | 1992-1994 | 2004-2005 |
| 35-44 | 2.5 (1.4-4.4) | 3.3 (2.3-4.9) | 122 (69.1-214) | 192 (130-284) |
| 45-54 | 3.5 (2.4-5.3) | 3.2 (2.4-4.4) | 46.9 (31.4-70.0) | 69.0 (51.0-93.4) |
| 55-64 | 7.3 (5.8-9.1) | 6.0 (5.0-7.3) | 26.3 (20.9-33.1) | 49.2 (40.6-59.5) |
| 65-74 | 9.4 (7.7-11.4) | 6.6 (5.6-7.8) | 10.5 (8.6-12.7) | 16.6 (14.1-19.5) |
| 75-84 | 14.2 (9.8-20.6) | 10.2 (8.8-11.8) | 4.8 (3.3-6.9) | 6.4 (5.5-7.4) |

## TH-PO482

**Long-Term Survival of Dialysis Patients in the US after Surgical Versus Percutaneous Coronary Revascularization** Charles A. Herzog, David T. Gilbertson, Craig Solid. *CVSSC, USRDS, Minneapolis, MN.*

**Introduction:** There are few published data on the comparative long-term survival of dialysis patients undergoing surgical versus percutaneous coronary revascularization in the era of drug-eluting stents (DES).

We searched the records of the United States Renal Data System database to identify 10,941 dialysis pts having coronary artery bypass surgery (CAB) or DES in 2004-2006. Long-term survival was estimated by Kaplan-Meier method and independent predictors of death were examined in a comorbidity-adjusted Cox model.

**Results:** There were 3,455 CAB pts and 7,486 DES patients. The tables show survival and predictors of death, (age < 65, male, white, hemodialysis, time on dialysis < 2 years, no comorbidity, CAB is reference) with hazard ratio (HR), as well as estimated survival within CAB patients related to utilization of internal mammary grafts [IMG(+) or IMG (-)]. DES patients have better survival at 12 months, but after 18 months CAB patients have better outcome. CAB patients receiving internal mammary grafts (68% of CAB pts, n=2356) do significantly better than those without (Log-Rank p-value = 0.0005); the risk of death is 14% lower in IMG(+) CAB vs IMG(-) CAB pts (HR 0.86, (95%CI 0.78, 0.95)).

**Conclusion:** Our data suggest that drug-eluting stents provide the best first year survival, but unadjusted long-term survival is best in CAB patients receiving internal mammary grafts.

| | Survival (%) | | Survival (%) for CAB | |
|---|---|---|---|---|
| Months | CAB | DES | IMG (+) | IMG (-) |
| 1 | 88.0 | 93.8 | 88.6 | 86.8 |
| 6 | 75.5 | 81.6 | 77.4 | 71.4 |
| 12 | 68.0 | 70.3 | 70.3 | 63.0 |
| 24 | 55.0 | 52.3 | 57.1 | 50.5 |
| 36 | 43.9 | 39.6 | 45.8 | 39.9 |
| 48 | 34.6 | 30.6 | 35.8 | 31.9 |
| Predictors of Death | | | | |
| | Death | | | |
| Variable | HR (95% CI) | | | |
| Age 65-74 | 1.24 (1.16, 1.32) | | | |
| Age 75+ | 1.66 (1.55, 1.77) | | | |

## TH-PO483

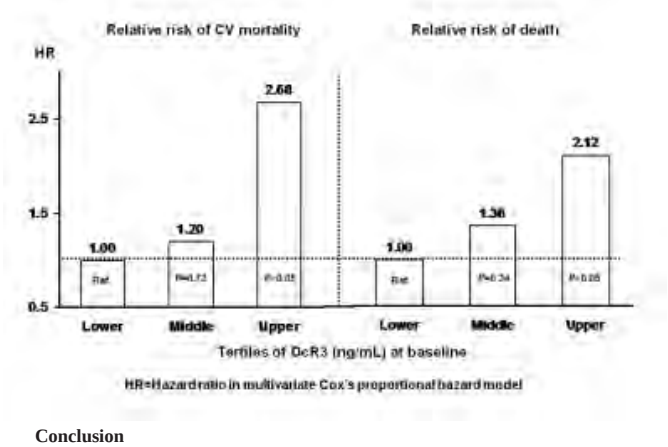
**Serum Decoy Receptor 3 (DcR3) Predicts Cardiovascular and All-Cause Mortality among Chronic Hemodialysis (HD) Patients** Ta-Wei Hsu,[1] Der-Cherng Tarng.[2,3] *[1]Division of Nephrology, Department of Internal Medicine, National Yang-Ming University Hospital, Yilan, Taiwan; [2]Division of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan; [3]Department and Institute of Physiology, National Yang-Ming University, Taipei, Taiwan.*

**Aim**

Cardiovascular disease (CVD) is the leading cause of morbidity and mortality in HD patients. Novel but not traditional risk factors are far more prevalent in this population and contribute significantly to atherosclerosis and CVD. DcR3, belonging to the tumor necrosis factor receptor superfamily, is a soluble receptor considered to play a role in immune modulation. Increased serum DcR3 levels have been reported in patients with renal failure. However, whether serum DcR3 is a biomarker for predicting outcome in HD patients has not been elucidated.

**Methods and Results**

Three-hundred and sixteen patients (155 men and 161 women; mean age 59 ± 13 years) undergoing maintenance HD (vintage 84 ± 63 months) were studied. The baseline serum DcR3 level was 2.29 ± 2.20 ng/mL. Serum DcR3 was significantly correlated with albumin (r= -0.321, P<0.001), hs-CRP (r= 0.223, P<0.001), hemoglobin (r= -0.128, P=0.033), and ferritin (r= 0.129, P=0.032). All patients were further stratified into the tertiles of serum DcR3 at baseline. The follow-up duration of this study was 54 months. Kaplan-Meier survival curves showed that patients with DcR3 upper tertile had worse outcome for CV mortality (P=0.003) and all-cause death (P<0.001). A multivariate Cox regression analysis demonstrated that DcR3 upper tertile independently had higher risks toward CV death with a hazard ratio of 2.68 (P <0.05) and overall death with a hazard ratio of 2.12 (P <0.05), respectively.



**Conclusion**

Serum DcR3 level is a surrogate biomarker of malnutrition-inflammation complex and independently predicts the CV and all-cause mortality among chronic HD patients.

Disclosure of Financial Relationships: nothing to disclose

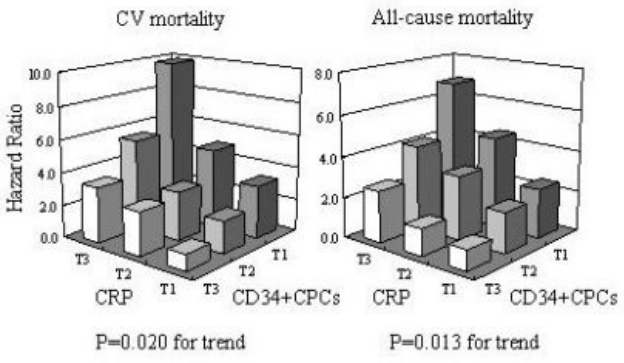
## TH-PO484

**Association of CD34+ Circulating Progenitor Cells and C-Reactive Protein with Cardiovascular and All-Cause Mortality in Hemodialysis Patients** Shoichi Maruyama,[1] Takenori Ozaki,[1] Waichi Sato,[1] Naotake Tsuboi,[1] Masashi Mizuno,[1] Hiroshi Takahashi,[2] Hirotake Kasuga,[2] Enyu Imai,[1] Yasuhiko Ito,[1] Seiichi Matsuo.[1] *[1]Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Department of Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan.*

Background: Circulating progenitor cells (CPCs) are believed to act to maintain the endothelial function. C-reactive protein (CRP) has also been reported to predict cardiovascular (CV) events. We investigated the association between CD34+ CPCs and CRP and their role with prediction of mortality in hemodialysis (HD) patients.

Methods: The number of CD34+ CPCs was determined in 216 HD patients. The patients were divided into tertiles according to CD34+ levels and serum CRP levels. Follow-up period was 5 years.

Results: CRP levels were 6.1±9.4 mg/l, 3.1±4.1 mg/L and 2.1±2.0 mg/L in T1, T2 and T3 of CD34+ CPCs levels (p=0.0010), and were negatively correlated with CD34+ CPCs levels (r=0.31, p<0.0001). Adjusted hazard ratio (HR) of reduced CD34+ CPCs was 3.38 (95%CI 1.24-9.25, p=0.016 for T1 vs. T3) for CV mortality and 2.71 (95%CI 1.20-6.13, p=0.017 for T1 vs. T3) for all-cause mortality. Among tertiles of CRP, adjusted HR of elevated CRP levels was 4.46 (95%CI 1.46-9.57, p=0.021 for T3 vs. T1) for CV mortality and 3.69 (95%CI 1.56-8.72, p=0.0064 for T3 vs. T1) for all-cause mortality. In the joint setting of CD34+ CPCs and CRP, the risk of CV and all-cause mortality was 9.8 (p=0.020) and 6.9 (p=0.013) in the T1 of CD34+ CPCs with T3 of CRP compared with the T3 of CD34+ CPCs with T1 of CRP even after adjustment, respectively.



Conclusions: Reduced number of CD34+ CPCs and elevated CRP levels may interactively increase mortality risk in HD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO485**

**Risk Factors for Non-Peridialytic Sudden Cardiac Death in Hemodialysis Patients** Patrick H. Pun, Ruediger W. Lehrich, John Paul Middleton. *Medicine, Nephrology, Duke University, Durham, NC.*

We have previously found that dialysis-specific factors such as exposure to low potassium dialysate and low pre-dialysis blood pressure are potent risk factors for sudden cardiac death (SCD) occurring within dialysis facilities, but whether or not these factors are also predictive of the majority of SCD events that occur outside of dialysis facilities is unclear. We sought to examine the role of dialysis-specific factors in determining the risk of out-of-clinic SCD in a large cohort of hemodialysis patients.

We examined a cohort of hemodialysis patients (N=1632) from among 43,200 US Davita hemodialysis patients who did not experience adverse events in the outpatient dialysis clinic during the observation period 2002-2005. Using standardized medicare death reporting forms, we determined that 172 subjects experienced SCD outside the dialysis clinic during the observation period. We examined the clinical and dialytic characteristics of patients over a 90-day period among those who experienced SCD compared to those that died from other causes or were alive at the end of the observation period.

Patients who suffered a SCD were older (69 vs 64 years), and more likely to carry a diagnosis of coronary artery disease (44% vs 29%), congestive heart failure (38% vs 31%), and peripheral vascular disease (29% vs 18%). After accounting for differences in baseline comorbidities and patient demographics, mean 90-day dialysate potassium concentration (OR 1.4 per 1 meq/L decrease, 95% CI 1.1-2.0), pre-dialysis mean arterial blood pressure (OR 1.2 per 10 mmHg decrease, 95% CI 1.01-1.33), mean serum creatinine (OR 1.09 per 1 mg/dl decrease, 95% CI 1.01-1.17) and exposure to aspirin (OR 1.6, 95% 1.1-2.3) and statin medications (OR 0.6, 95% CI 0.4-0.8) were independently predictive of SCD.

This analysis suggests that potentially modifiable risk factors for SCA in dialysis clinics such as exposure to low potassium dialysate and low pre-dialysis blood pressure are also consistent predictors of SCD occurring outside of dialysis clinics. These and other identified risk factors may be helpful in targeting patients at highest risk for SCD for preventive strategies.

**TH-PO486**

**Echocardiography at Dialysis Initiation: Use and Association with Mortality among Medicare Beneficiaries in the United States** Rajiv Saran,[1] Brett Lantz,[2] Dori Bilik,[2] Bruce M. Robinson,[2] Richard Hirth,[1] Jeffrey Pearson,[2] J. M. Messana.[1] *[1]Kidney Epidemiology and Cost Center, University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Current guidelines recommend performing an echocardiogram (echo) in all patients (pts) at dialysis initiation (KDOQI 2005). We examined echo use in incident pts to evaluate whether the practice was associated with lower first-year mortality. Medicare pts age≥65 years initiating dialysis in 2004-08 were included (N=190902) and linked to facilities using the CMS-2728. Echo use was determined from inpatient, outpatient, skilled nursing facility, and carrier claims. Pts were found to meet the guideline if an echo was performed within 90 days before/after starting dialysis. Pts were "converted" if an echo was not performed in the 90 days prior to initiation (N=121538) but was performed ≤ 90 days after. By these criteria, 49% (N=93329) of pts met the guideline and 20% (N=23965) of pts were converted. The percent of pts meeting the guideline rose from 46% to 50% from 2004 to 2008 (p<.001); similarly, the conversion rate rose from 18% to 20% (p<.001). Echo practice patterns also varied by facility (N=4393). The median facility had 50% meeting guidelines (top quintile > 62%; bottom quintile < 38%) and a 20% conversion rate (top quintile > 30%; bottom quintile < 11%). First-year mortality was somewhat elevated among pts meeting the guideline (HR=1.05, p<.001) and among converted pts (HR=1.07, p<.001) even after adjustment for demographics and comorbidities. After limiting to 2005-07 (N=3924), facilities in the top quintile of meeting the guideline had higher adjusted first-year mortality versus the lowest quintile (RR=1.08, p<.001) as did the top quintile for conversions (RR=1.06, p<.001). Despite the 2005 KDOQI guideline, echo use at dialysis start became only slightly more common from 2004-08. Although echo use was associated with elevated first-year mortality, this finding may be due to treatment-by-indication bias or sub-optimal use of echo data to guide treatment decisions. Further research is necessary to evaluate the effectiveness of routine echocardiography in new dialysis pts.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO487**

**Obesity Is a Risk Factor for Mortality, Especially among Younger Dialysis Patients** Ellen K. Hoogeveen,[1] Nynke Halbesma,[2] Friedo W. Dekker,[2] Elisabeth W. Boeschoten.[3] *[1]Internal Medicine, Jeroen Bosch Hospital, Den Bosch, Netherlands; [2]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands; [3]Clinical Epidemiology, Hans Mak Institute, Naarden, Netherlands.*

Obesity is an important risk factor for cardiovascular disease and mortality in dialysis patients. However, differences in mortality between young and elderly dialysis patients have not been well addressed. Therefore, our aim was to investigate whether the association of BMI and mortality differs between younger (<65 y) and older (≥65 y) dialysis patients.

In a prospective multi-centre cohort study, all dialysis patients (>18 y) starting with their first dialysis treatment were included and followed until death, transplantation or a maximum of 7 years (NECOSAD). We divided patients into eight categories based on their baseline BMI and age: <20 (7.5%), 20 to 25 (47%), 25 to 30 (34.5%) and ≥30 (11%) kg/m$^2$. Cox regression analysis was performed to calculate hazard ratios (HR) associated with BMI groups, using a normal BMI (20-25 kg/m$^2$) in the younger patients as the reference category. Analyses were adjusted for age, sex, treatment modality and smoking.

In total, 1749 patients were included (age (mean (SD)) younger patients: 49 y (11), older patients: 73 y (5) years, BMI: 25 (4) kg/m$^2$, 62% male, 62% HD). Overall, the 7-years mortality was 67%. Compared to a normal BMI and <65 y at baseline, the adjusted HRs (95%-CI) by BMI category were for the younger patients: 2.16 (1.37-3.40), 1 (reference), 0.89 (0.65-1.23), 1.60 (1.11-2.30), and for the elderly 1.64 (1.03-2.63), 1.18 (0.84-1.66), 1.18 (0.84-1.65), 1.06 (0.71-1.59).

We conclude that both young and elderly dialysis patients with underweight have an about 2-fold increased risk factor for mortality, although this maybe due to reverse causality. However, obesity is about 1.5-fold stronger risk factor for mortality in young compared to elderly dialysis patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO488**

**Outcomes of Elderly Diabetic Patients Starting on Hemodialysis** Gero D. von Gersdorff,[1] Mathias Schaller,[1] Thomas Benzing,[1] Claudia Barth.[2] *[1]Nephrology, Cologne University Medical Center, Cologne, Germany; [2]KfH - Curatorium for Dialysis and Kidney Transplantation, Neu-Isenburg, Germany.*

**Introduction**: We sought to identify factors associated with survival in elderly diabetic patients (DM) starting on hemodialysis. **Methods:** Incident patients who survived at least 90 days were eligible and were divided into age groups ≤ 55 years, 56 – 75 years, and > 75 years. Survival was calculated for each age group using the Kaplan-Meier method. Cox regression models, which included interaction terms for age and diabetes, were constructed to determine hazard ratios of survival. All calculations were two-sided with significance at p < 0,05. **Results**: There were 12290 incident patients and 27% of <55y, 55% of 56-75 y, and 52% of >75y were diabetic. 34%, 34%, and 49%, respectively, were women. Unadjusted mortality difference was marked between DM and n-DM patients ≤55y, but was no longer present >75y (p= 0,24). Cox regression models with multiple adjustments confirmed that there was a significant interaction of age with diabetes, and that diabetes was not a risk factor anymore in elderly incident dialysis patients (p=0,07). 1899 DM and 1770 n-DM patients >75y were therefore analyzed further (mean age 80,5y vs. 81,1y; 54% vs. 43% female; weight 73 vs. 67 kg; all p<0,001). There were more comorbidities among DM patients. Laboratory parameters at baseline were similar. Mortality was not different between groups of DM based on HbA1c of < 5,5%, 5,5 – 7%, and > 7% (p=0,969). However, a small number of patients (N=581) showed large SD >1 of HbA1c and a significantly increased mortality, suggesting that wide swings in HbA1c measurements may be associated with worse prognosis. **Conclusions**: In patients who started hemodialysis over age 75 years, there was no difference in survival between diabetic and non-diabetic subjects. No association was found between mean or median HbA1c and mortality. Wide swings in HbA1c, however, were associated with worse prognosis. This may reflect sicker patients in whom there is increased erythrocyte- and hemoglobin turnover, or frequent periods of hypo- or hyperglycemia. In elderly patients HbA1c is to be used cautiously for management of diabetes on dialysis.

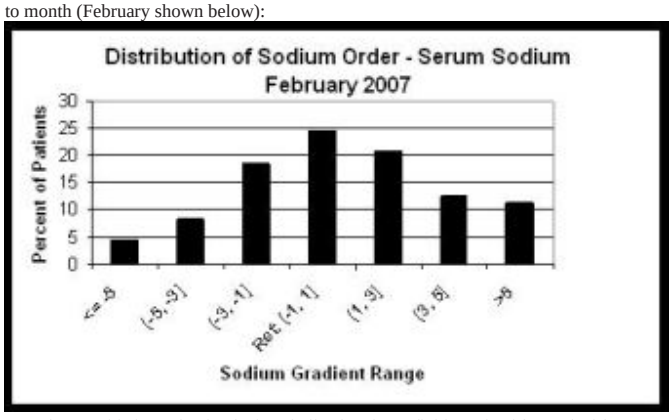
**Sodium Gradient & Hospitalization for Fluid Overload in Hemodialysis Patients** Eduardo K. Lacson, Weiling Wang, J. Michael Lazarus, Raymond M. Hakim. *Fresenius Medical Care, North America, Waltham, MA.*

**Introduction:** Sodium load is associated with fluid retention in hemodialysis patients. We hypothesized that the sodium gradient (between serum vs. dialysate) may impact salt/fluid retention and hospitalization risk for fluid overload.

**Methods**: All chronic HD patients treated from January 1 to March 31, 2007 at legacy Fresenius Medical Care North America facilities with serum sodium data (~89%) were included. The weighted mean of the prescribed dialysate sodium was computed monthly

and the gradient determined. Interdialytic weight gain (IDWG) was recorded. Case-mix (age, gender, race, DM, BSA, and vintage) and vascular access were identified as of 1/1/07 and hospitalizations (≥1 day) primarily due to fluid overload (including heart failure and acute pulmonary edema) were tracked. Cox models were constructed based on the sodium gradient for each of the three study months.

**Results**: Mean age (N=71,767) was 61.3±14.9 years, with 54.3% males, 49.9% white, 41.3% black and 52.5% diabetic, with vintage of 3.6±3.7 years and 44% had fistulas, with 28% grafts, and 28% catheters. The distribution of sodium gradient was similar from month to month (February shown below):



The monthly hazard ratios for hospitalization due to fluid overload for Jan/Feb/Mar was consistently high at 1.54/2.17/1.92 for gradient >5 meq/L and after case-mix adjustment were 1.48/2.08/1.86, respectively (all p<0.003). A gradient >5 meq/L was also associated with +0.4 kg higher IDWG each month (p<0.0001).

**Conclusion**: A positive sodium gradient >5 meq/L, seen in 11%-14% of patients, was consistently associated with greater IDWG and a 50-100% increased hazard rate for hospitalization due to fluid overload. Physicians need to pay more attention to the sodium component of dialysate prescriptions. Minimizing the sodium gradient could potentially decrease hospitalizations for fluid overload.

Disclosure of Financial Relationships: Employer: I am an employee of Fresenius Medical Care, North America.

### Use of High Magnesium Dialysate Does Not Abrogate Intradialytic Haemodynamic Instability or Haemodialysis-Induced Myocardial Stunning

Helen J. Jefferies,[1] Chris W. McIntyre.[1,2] *[1]Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; [2]School of Graduate Entry Medicine and Health, University of Nottingham, Derby, United Kingdom.*

Haemodialysis (HD) induced ischaemic cardiac injury (myocardial stunning) is common, associated with adverse cardiovascular (CV) outcomes, mortality, and appears important in development of HD-related heart failure. Intradialytic hypotension is a critical modifiable determinant of myocardial stunning. Magnesium (Mg) is reportedly important in maintaining intradialytic blood pressure, with cardiovascular effects which could protect against demand myocardial ischaemia. This study aimed to compare the effects of high vs low dialysate Mg on intradialytic haemodynamics and myocardial stunning.

20 stable prevalent HD patients entered a randomised cross-over trial of low vs high (0.5 vs 1.0 mmol/L) dialysate Mg. Patients were studied after 2 weeks of standard HD at each Mg concentration. Dialysate composition differed only by Mg; other HD parameters were unchanged. Serial echocardiography (pre-HD, peak stress and post-HD) assessed myocardial stunning, measured by left ventricular regional wall motion abnormalities (RWMAs). Noninvasive haemodynamics and biochemistry were assessed.

Pre-dialysis serum Mg was higher with high dialysate Mg (1.42±0.20 vs 1.05±0.13mmol/L, p<0.0001). Low Mg dialysate was associated with intradialytic fall in serum Mg (-0.19±0.09 mmol/L); intradialytic serum Mg rose (+0.02±0.13 mmol/L) with high Mg dialysate (p<0.0001). There was no difference in mean number of peak stress RWMA per patient (3.4±1.9 vs 3.7±1.9, p=0.5). UF volume, a critical determinant of stunning, did not differ between high and low dialysate Mg studies (1.5±0.9 vs 1.5±0.7 litres, p=0.6). There was no advantage from high Mg dialysate with respect to intradialytic blood pressure stability or CV performance.

Serum Mg does not appear to critically modulate the propensity to haemodialysis-induced myocardial ischaemia. This study provides no evidence for use of high Mg dialysate to treat haemodynamic instability during HD, and suggests commonly-used lower dialysate Mg concentrations remain useful to optimise serum Mg without significant adverse haemodynamic effects.

### Plasma Level of Fibroblast Growth Factor-23 and Intracranial Artery Calcification in Hemodialysis Patients

Yuko Iwasa,[1] Shigeru Otsubo,[2] Aiji Yajima,[1] Naoki Kimata,[3] Kosaku Nitta,[2] Takashi Akiba.[3] *[1]Nephrology, Towa Hospital, Tokyo, Japan; [2]Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan; [3]Blood Purification, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

***Objective*** Intracranial artery calcification has been reported to be an independent risk factor for ischemic stroke. Fibroblast growth factor (FGF) 23 is involved in the regulation of mineral metabolism, which may in turn affect vascular calcification. We investigated the relationship between FGF-23 and intracranial artery calcification in hemodialysis patients.

***Materials and Methods*** Brain computed tomographic examinations were performed in 107 patients received maintenance hemodialysis therapy. For comparison, 43 general population were also studied. FGF-23 levels were determined using an enzyme-linked immunosorbent assay.

***Results*** Intracranial artery calcification was found in 94 of the 107 patients. The plasma FGF-23 levels tended to be higher among the hemodialysis patients with intracranial artery calcification(5868.3±9441.2pg/mL) than among those without calcification(4211.6±8273.8pg/mL). Intracranial calcifications were more frequently found among the 58 hemodialysis patients who were under the age of 70 years(60.9±6.5years, 87.9%) than among the 43 age and gender-matched control subjects(61.0±6.2years, 53.5%, p=0.0003). The prevalence of calcification were as follows in the hemodialysis patients under 70 years of age and the 43 general population, respectively: vertebral artery(65.5% vs. 25.6%, p=0.0002), internal carotid artery(62.1% vs. 18.6%, p<0.0001), basilar artery(34.5% vs. 34.9%, ns), anterior cerebral artery(0% vs. 2.3%, ns), middle cerebral artery(24.1% vs. 20.9%, p=0.0203), and posterior cerebral artery(5.2% vs. 4.7%, ns).

***Conclusion*** The results showed a much higher rate of intracranial artery calcification among hemodialysis patients than among the general population and the more frequently involved sites of calcification were internal carotid artery and vertebral artery, which are relatively large intracranial arteries. FGF-23 level tended to be higher among hemodialysis patients with intracranial artery calcification than among those without calcification.

### High Serum Prolactin (PRL) Predicts Mortality in Male Hemodialysis (HD) Patients

John Kyriazis,[1] Kostas Stylianou,[2] Ioannis P. Tzanakis,[3] Eleftheria A. Vardaki,[2] Antonia N. Papadaki,[3] Eugene Daphnis.[2] *[1]Nephrology, General Hospital of Chios, Chios, Greece; [2]Nephrology, University Hospital of Heraklion, Heraklion, Crete, Greece; [3]Nephrology, General Hospital of Chania, Chania, Crete, Greece.*

Introduction. In the general population, hyperprolactinemia has been associated with an adverse cardiovascular risk profile. Elevated PRL levels are usually found in 25 to 75 % of HD patients, due to both increased production and decreased metabolic clearance. The current study was undertaken on male HD patients to examine a) the possible associations between PRL levels and cardiovascular markers, including arterial stiffness (AS), and b) the relationship between hyperprolactinemia and subsequent mortality due to all causes and cardiovascular disease (CVD).

Methods. One hundred and eleven HD men were assessed at baseline and were followed-up until a maximum of 51 months after the start of the study (median follow-up time 37 months).

Results. The median PRL value in our patient cohort was 16.3 ng/ml (interquartile ranges 8.4 - 32.9). PRL levels were inversely related to serum albumin, hemoglobin and smoking habits and were positively related to serum phosphorus, C-reactive protein (CRP), body mass index (MBI), prevalence of diabetes mellitus and pulse wave velocity (r=0.250; p<0.01), a reliable index of AS. During follow up, 49 deaths occurred, 28 (57%) of which were caused by CVD. As compared to those below the median value, patients with PRL levels above the median had an greater risk of CVD and all-cause mortality (crude hazard ratio: 2.24 [95% CI, 1.02 to 4.88] and 2.02 [95% CI, 1.13 to 3.61], respectively), even after adjustment for age, MBI, serum albumin and phosphorus, CRP, clinical history of CVD at baseline, presence of diabetes and smoking habits. The association of PRL levels with CVD mortality, but not with all-cause mortality, lost its significance after adjusting for pulse wave velocity

Conclusions. Our results indicate that PRL levels are inversely associated with all-cause and CVD mortality in HD men and that AS might be a potential mechanism underlying this association.

### Risk Factors and Course of Peripheral Arterial Disease (PAD) in Incident Chronic Dialysis Patients (CDP)

Thomas Weinreich. *Nephrologisches Zentrum, Villingen-Schwenningen, Germany.*

*Background*: PAD is a major risk factor of morbidity and mortality in CDP. The impact of conventional and uremia associated risk factors for PAD in CDP is not well defined.

*Aim*: To assess course of PAD in incident CDP and the role of potential risk factors.

*Method*: Prospective multicenter observational study over 24 month including all patients entering a chronic dialysis program. PAD was defined by ankle / brachial index (ABI) ≤ 0.9 and/or clinical signs. Primary endpoints were death, newly developed PAD

stage IV or therapeutic intervention for PAD; sec. endpoints: non lethal CV – complications, progression of preexisting PAD (ABI). Data are given as mean±SD; the impact of various risk factors was analysed by Cox proportional hazards survival analysis. Significance level p<0.05.

*Results*: 233 patients from 5 centres (m=64%; age 68.2±12.2; 10.5% PD) were included, 53.3% diabetics; 18.1% current smoker. Preexisting coronary artery disease was found in 39.5%. At start of dialysis 37.6 % had PAD. Mean ABI was 1.1±0.4 and did not change over 24 mo. The percentage of CDP with ABI <0.9 increased from 20 to 25%, ABI 0.9-1.1 decreased from 51.6 to 46.2% of pts. Primary endpoints were observed in 56.8%, sec. endpoints in 43.2% of pts. Fifty-five pts. died, 7 developed stage IV PAD, 21 had therapeutic interventions for PAD. Progression of PAD occurred in 57 pts., non-lethal CV-events in 6. Incidence of primary and sec. endpoints was higher throughout the first 12 months of study. Primary endpoints were associated with older age and neg. with S-Alb., a trend was shown for diabetes and blood pressure (n.s.). Fifty % of CDP not taking CaPB died compared to 25.3% on CaPB. Sec. endpoints did not correlate with any of the covariates tested, including S-chol., triglyceride, CRP, fibrinogen, t-homocystein, Ca, $PO_4$, iPTH, the use of CSEI or platelet inhibitors.

*Conclusions*: PAD in incident CDP was more frequent then reported previously. Primary endpoints developed in more than 50% of the patients, predominantly during the first year after start of dialysis. Only age, and S-Alb. and the intake of Ca-$PO_4$ binders were associated with primary endpoints.

### TH-PO494

**Short and Long Term Blood Pressure Measurements and Cardiovascular Mortality in Hemodialysis Patients** Robert Ekart,[1] Radovan Hojs,[2] Sebastjan Bevc,[1] Vojko Kanic,[3] Karl Pecovnik.[1] *[1]Department of Dialysis, University Clinical Centre Maribor, Maribor, Slovenia; [2]Department of Nephrology, University Clinical Centre Maribor, Maribor, Slovenia; [3]Department of Cardiology, University Clinical Centre Maribor, Maribor, Slovenia.*

**Purpose of study**: Arterial hypertension (AH) is common and contributes to the high cardiovascular (CV) mortality in hemodialysis (HD) patients. The best method and timing for measuring blood pressure (BP) is still uncertain. It is unknown which BP measurement better defines the influence on CV mortality. The purpose of study was to analyze association between single BP measurements on HD day and ambulatory BP measurements (ABPM) and CV mortality in HD patients.

**Methods:** In our prospective study 73 HD patients (44 males and 29 females; mean age 54.2 years; 19-78 years;SD±13.3) were included. Thirty-two (43.8%) patients were habitual smokers and 11 (15.1%) patients were diabetics. BP was measured with a standard mercury sphygmomanometer before and after the HD session. 48-hour ambulatory BP measurements (ABPM) were performed after the end of HD session using a non-invasive ABPM monitor (Spacelabs 90207, USA). Using echocardiography (ATL HDI 3000) left ventricular mass (LVM) was measured and LVM index (LVMI) was calculated. Using B-mode ultrasonography (ATL HDI 3000), carotid intima-media thickness (IMT) was measured.

**Results:** The mean predialysis systolic/diastolic BP was 147/84 mmHg, mean postdialysis systolic/diastolic BP was 138/81 mmHg and the mean 48-hour systolic/diastolic ABPM was 135/80 mmHg. The mean LVMI was 148.9 g/m$^2$ (69-308;SD±49,44) and carotid IMT 0,78 mm (0,4-1.3;SD±0.2). During a follow-up period (mean 1795 days; 23-3664 days; SD±1063.5) 28 patients (38.3%) died, 16 (57%) of them of CV causes. In a Cox regression model that included age, gender, smoking, diabetes, sensitive CRP, albumin, haemoglobin, troponin T, LDL cholesterol, HDL cholesterol, triglycerides, Ca, P, carotid IMT and LVMI only 48-hour systolic ABPM (P=0.037) and 48-hour diastolic ABPM (P=0.006) turned out to be independent predictors of CV death.

**Conclusion**: Only 48-hour ABPM and not single BP measurements before or after HD were associated with CV mortality in HD patients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO495

**Relation between Intradialytic Changes in Systolic Blood Pressure and Sodium Gradient in Chronic Hemodialysis Patients** E. Lars Penne,[1,2] Len A. Usvyat,[1] Samer Rateb Abbas,[1,2] Olga Sergeyeva,[1] Jochen G. Raimann,[1,2] Stephan Thijssen,[1,2] Nathan W. Levin,[1,2] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York; [2]Beth Israel Medical Center, New York.*

Intradialytic hypertension has been associated with increased hospitalization and mortality rates in chronic hemodialysis (HD) patients. Intradialytic sodium loading has been proposed as a contributor of intradialytic hypertension. The aim of the present analysis was to evaluate the relation between intradialytic blood pressure changes and sodium gradient ($grNa^+$), defined as the difference between the dialysate sodium and the serum sodium concentration ($grNa^+ = dNa^+ - sNa^+$).

Chronic HD patients from nine Renal Research Institute clinics that did not use dialysate sodium profiling between Sep 1 2009 and Dec 31 2009 were included. The relation between the average $grNa^+$ and intradialytic changes in SBP (ΔSBP) during this period were analyzed with linear regression models, adjusting for patient characteristics (sex, age, race, diabetes, dialysis vintage) and ultrafiltration rate (UFR). In addition, odds ratios (OR) for an increase in SBP (ΔSBP > 0 mmHg) during treatment were estimated.

We studied 560 patients (age 61±15 [±SD] yr, 53% males and 49% blacks). Mean pre- and post-dialysis blood pressures were 149±19/77±12 and 139±18/72±10 mmHg, respectively. The mean $grNa^+$ was -2.2±2.7 mEq/L ($grNa^+$ > 0mEq/L in 19% of the patients). The adjusted $grNa^+$ was positively related to ΔSBP (B=0.5; 95% CI 0.1 to 1.0, P=0.02). Dialysis vintage (P=0.02), diabetes (P=0.004) and UFR (P=0.001) were inversely related to ΔSBP. SBP increased in 126 patients (23%). Increases in SBP were more often observed in patients with a positive gradient (OR = 2.1; 95% CI 1.3 to 3.3).

These data identify a positive sodium gradient as a contributing and potentially modifiable factor for intradialytic hypertension, which can probably be explained by intradialytic sodium loading. Whether intradialytic hypertension can be treated by lowering the dialysate sodium concentration in these patients needs further study.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO496

**Uremic Cardiomyopathy Is Associated with Reduced Cardiac High Energy Phosphate Metabolism: A Phosphorus Magnetic Resonance Spectroscopy Study** Rajan Kantilal Patel,[1] Patrick Barry Mark,[1] Kathryn K. Stevens,[1] Emily P. Mcquarrie,[1] Alan G. Jardine.[1] *[1]Renal Research Group, BHFGCRC, University of Glasgow, Glasgow, United Kingdom; [2]Department of Cardiology, Western Infirmary, Glasgow, United Kingdom.*

**Purpose:** Premature cardiovascular (usually sudden) death is the commonest cause of death in end stage renal disease (ESRD) patients and associated with uremic cardiomyopathy (comprising left ventricular hypertrophy (LVH), systolic dysfunction (LVSD) and LV dilation). High energy phosphate (HEP) metabolism, quantified using $^{31}$P magnetic resonance spectroscopy, is reduced in diabetic and heart failure patients. Phosphocreatine: β ATP ratio (PCr: β ATP) relates to cardiac metabolic activity. **Aim**: To compare resting HEP metabolism in ESRD patients and hypertensive LVH patients with normal renal function and assess associations with abnormalities of uremic cardiomyopathy. **Methods:** 53 ESRD and 30 hypertensive patients with LVH and normal renal function (LVH only) underwent cardiac MRI and $^{31}$P magnetic resonance spectroscopy of their LVs. Left ventricular dimensions were measured. PCr: β ATP ratios were calculated from $^{31}$P-MR spectra obtained from the LV. No spectra were obtained from areas of reduced/absent LV motion.**Results:** There were no significant differences in LV mass, chamber sizes and ejection fraction between patient groups. PCr:β ATP was significantly higher in LVH patients compared to ESRD patients (1.6±0.4 vs. 1.3 ±0.5 respectively; p=0.007). PCr: β ATP was significantly lower in ESRD patients with LV systolic dysfunction (n=10; no LVSD 2.0±0.5vs LVSD 1.2±0.2; p=0.05) and LV dilation (n=16; no LV Dilation 1.79±0.4 vs LV Dilation 0.98±0.8; p=0.01). LVH was not associated with significant difference in PCr: β ATP. **Conclusion:** Despite similar myocardial mass, ESRD patients have lower HEP metabolism compared to LVH patients. Lower PCr: βATP ratio is associated with features of uremic cardiomyopathy and may contribute to higher risk of sudden cardiac death.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO497

**Effect Modification by C-Reactive Protein and Interleukin-6 on the Relationship between Asymmetric Dimethyl-Arginine (ADMA), Death and Cardiovascular Events in End Stage Renal Diseases (ESRD) Patients** Giovanni Tripepi, Patrizia Pizzini, Sebastiano Cutrupi, Carmine Zoccali, Francesca Mallamaci. *CNR-IBIM, Clin. Epid. and Physiopath. of Renal Dis. and Hypertension, Reggio Calabria, Italy.*

Asymmetric dimethyl-arginine (ADMA) and inflammation have been implicated in atherosclerotic complications, death and cardiovascular (CV) events in patients with end stage renal diseases (ESRD). Inflammation amplifies the effect of ADMA on the severity of atherosclerosis in ESRD (*JASN 13: 490-496, 2002*) but it remains unclear whether inflammation and ADMA interact in the high risk of death and CV events in this population. In a cohort of 225 hemodialysis patients we investigated the interaction of CRP and IL-6 with ADMA as predictors of death and CV events (average follow-up: 42 months). The effect modification of CRP and IL-6 on the relationship between ADMA and study outcomes (additive model) was analysed by dividing the study population according to the corresponding median values of these biomarkers.

Circulating levels of ADMA (median: 2.4 μMol/L, inter-quartile range: 1.6-3.8 μMol/L), CRP (7.4 mg/L, 3.4-16.4 mg/L) and IL-6 (5.0 pg/mL, 2.7-9.2 pg/mL) were significantly inter-related (r ranging from 0.13 to 0.33, P<0.05). During the follow-up, 112 patients died and 104 had fatal and non fatal CV events. Both on unadjusted and adjusted Cox regression analyses, a biological interaction was found between inflammation biomarkers and ADMA for predicting death and fatal and non fatal CV events in ESRD patients. Indeed, the adjusted hazard ratios (HR) for death (HR: 2.08, 95% CI: 1.16-3.73) and CV outcomes (HR: 2.11, 95% CI: 1.17-3.83) of patients with increased CRP and ADMA were higher than those expected in the absence of interaction under the additive model (HR: 1.05 and HR: 1.79, respectively) and this was also true when the same analysis was carried out by stratifying according to IL-6.

These data support the hypothesis that inflammation amplifies the ADMA associated risk of death and CV events in ESRD patients. These analyses further emphasize the need of interventional studies to clarify the nature (causal/non causal) of these relationships.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO498**

**Impact of Arterial Stiffness on Adverse Cardiovascular Outcome and Mortality in Peritoneal Dialysis Patients** Murat H. Sipahioglu,[1] Hamit Kucuk,[1] Fatih Oguz,[2] Aydin Unal,[1] Bulent Tokgoz,[1] Oktay Oymak,[1] Cengiz Utas.[1] *[1]Nephrology, Erciyes University Medical Faculty, Kayseri, Turkey; [2]Cardiology, Erciyes University Medical Faculty, Kayseri, Turkey.*

Our aim was to determine whether arterial stiffness is an independent risk predictor of mortality and adverse cardiovascular (CV) outcomes in peritoneal dialysis (PD) patients.

Methods

This is a prospective, observational cohort study with 2 years of follow-up. A cohort of 156 PD patients was studied with mean follow-up of 19.2 (± 6.4) months. Aortic stiffness index β (ASI β) (as surrogate marker of arterial stiffness) were calculated using transthoracic echocardiography from the formulae: β=ln (Systolic BP/Diastolic BP)/[(SystolicDiameter-DiastolicDiameter)/DiastolicDiameter].

Results

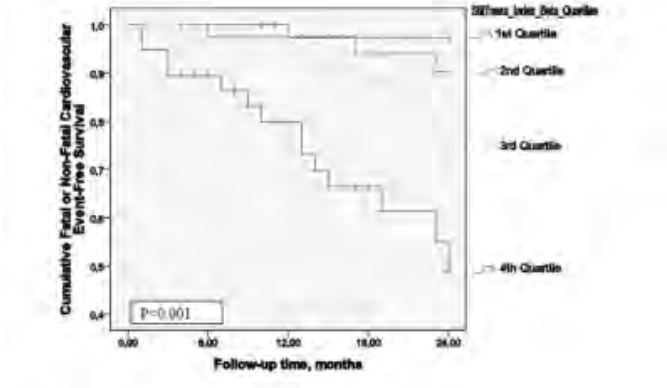
Baseline demographic, clinical and echocardiographic parameters were shown in Table 1.

Baseline Clinical and Biochemical Characteristics

| | |
|---|---|
| Age (years) | 48.2 ±13.7 |
| Sex (M:F) | 76:80 |
| Duration of dialysis (months) | 41.2 ±33.5 |
| Comorbid DM | 31 (20%) |
| Hb (g/dL) | 11.2 ±1.8 |
| Alb (g/dL) | 3.2 ±0.4 |
| LDL (mg/dL) | 123 ±39.9 |
| Total Kt/V | 2.48 ±0.78 |
| Residual GFR (ml/min1.73 m2 | 5.8 ±3.9 |
| D/P Creatinine | 0.70 ±0.11 |

DM:Diabetes mellitus

Twenty-five (16.0%) patients had died, 10 deaths were CV causes. Fifteen patients had non-fatal CV events. In the fully adjusted multivariable Cox regression analysis (age, gender, alb, hb, DM, comorbid CVD, LVMI, residual GFR, D/P creatinine, LDL were covariates) ASI β independently predicted fatal and non-fatal CV event and CV mortality [HR:1.244 (95 %CI 1.107-1.399)], [HR:1.298 (1.048-1.609)], but not all-cause mortality. Cumulative fatal or nonfatal CV event-free survival for ASI β-quartiles was shown.



Conclusion

To our knowledge, these results provide the first direct evidence that arterial stiffness is an independent risk predictor of adverse CV outcome and CV mortality in PD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO499**

**Pre-Dialysis Dietitian Care and Survival during the First Year on Dialysis** Yelena Slinin,[1] Haifeng Guo,[2] David T. Gilbertson,[2] Kristine E. Ensrud,[1] Allan J. Collins,[2] Areef Ishani.[1,2] *[1]Minneapolis VA Medical Center, Minneapolis, MN; [2]Chronic Disease Research Group, Hennepin County Medical Center, Minneapolis, MN.*

The National Kidney Foundation recommends management by a registered dietitian for patients with chronic kidney disease.

We aimed to determine whether dietitian care prior to ESRD is associated with normoalbuminemia at dialysis onset and lower 1 year mortality among incident hemodialysis patients.

Patients ≥20 years of age who initiated hemodialysis between 6/2005, and 6/2007 in the US and had pre-dialysis dietitian care reported on the Medical Evidence Form were included (N=156,440). Multivariate regression analyses were performed to identify associations with serum albumin (SA) ≥ 4gm/dL at dialysis initiation and to compare time to death on dialysis.

Dietician care was present for: none, 0-12 and > 12 months for 88%, 9%, and 3% of patients respectively and was tightly linked to pre-dialysis nephrology care. Adjusted odds ratios (95% CI) of having SA≥ 4gm/dL at the time of dialysis initiation was 1.11(1.07-1.16) and 1.15(1.08-1.23) for patients who had pre-dialysis dietitian care for 0-12 months and >12 months, respectively, compared to patients without dietitian care. The association between pre-dialysis dietitian care and survival during the first year on dialysis was explained by the difference in pre-dialysis nephrology care in the total cohort, but significant in the cohort limited to patients with nephrology care.

Table. Pre-dialysis Dietitian Care and Risk of Death during the First Year

| | Multivariable Model | | |
|---|---|---|---|
| | Not Including Nephrology Care | Including Nephrology | Limited to Patients with Nephrology Care |
| Variables | HR (95% CI) | | |
| Dietitian care | | | |
| None | 1 | 1 | 1 |
| 0-12 months | 0.95 (0.91-0.98) | 0.99 (0.95-1.03) | 1.02 (0.98-1.06) |
| > 12 months | 0.85 (0.79-0.91) | 0.97 (0.90-1.04) | 0.91(0.85-0.98) |

Pre-dialysis dietitian care is independently associated with SA≥ 4gm/dL at initiation. Pre-dialysis dietitian care for > 12 months is associated with lower mortality during the first year on dialysis in patients with pre-dialysis nephrology follow-up.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO500**

**The Effect of Sevelamer Hydrochloride (SE) on Arterial Stiffness and Left Ventricular Function. A Prospective Cohort Study** Yusuke Tsukamoto,[1] Soichiro Iimori,[2] Sei Sasaki.[1] *[1]Department of Nephrology, Shuwa General Hospital, Kasukabe-shi, Saitama-ken, Japan; [2]Department of Nephrology, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan.*

[Background] We previously reported that dialysis patients on SE resulted a reduced incidence of cardiovascular (CV) death [ASN09#TH-PO284]. This study analyzed the same cohort to demonstrate the etiology of lower CV death in SE by studying a change of arterial stiffness and left ventricular (LV) function. [Methods] Hemodialyzed patients (n=484) were enrolled between April/2005 and March/2008. CKD-MBD was treated according to the K/DOQI Bone and Mineral CPG. SE was the first choice of P-binder, unless GI side effect prevented. Since there was a significant difference of demographics between SE and Non-SE group at the end, these two groups were matched by propensity score (adjusted by age, vintage, gender and diabetes). In SE group, SE alone was 34 patients and 138 patients also with calcium carbonate. Cinacalcet was not used. Oral or IV vitamin D was given to 71% in SE (n=172) and 53% in non-SE (n=172) (p<0.001). Brachial-ankle pulse wave velocity (PWV) and echocardiography were recorded annually at same interval. [Results] (1) HDL cholesterol increased from 46±15 to 48.8±15.0 mg/dL in SE (p<0.01), but did not change in Non-SE (43.4±12.8 vs 45±13). LDL cholesterol increased from 83±24 to 92±31 mg/dL in Non-SE (p<0.001) but not in SE. LDL cholesterol level inversely correlated with SE dose. (2) In SE, mean arterial pressure did not change (112 vs 112 mmHg), but changed from 109 to 115 mmHg in Non-SE (p<0.0001). (3) PWV did not change (1750±453 vs 1799±497 cm/s) in SE, but changed from 1734±635 to 1829±677 cm/s in Non-SE (p<0.05). (4) LV mass index did not change either in SE or Non-SE. (5) Abnormal LV wall motion was recorded in 45.6% of SE and 54.4% of Non-SE at the beginning (p<0.05). There was a significant improvement in SE than in Non-SE (Mann-Whitney, Z=2.15, p<0.05). [Conclusion] There was an improvement of lipid abnormality, arterial mean pressure, arterial stiffness and LV wall motion in SE group when compared with Non-SE. That may explain the reason of reduced incidence of CVD death in hemodialyzed patients on SE.

**Heart Failure Symptoms Are Not Reliable in Diagnosing Low Ejection Fraction in Incident Hemodialysis Patients: The Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) Study** Tariq Shafi,[1] Bernard G. Jaar,[1] Stephen M. Sozio,[1] Julia J. Scialla,[1] Pooja C. Oberai,[1] Zarqa Tariq,[1] Lucy A. Meoni,[1] Wen Hong Linda Kao,[1] Rulan S. Parekh.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]University of Toronto, Toronto, ON.*

Congestive heart failure (CHF) in hemodialysis patients is an independent predictor of mortality and treatment of CHF with beta-blockers improves survival. Guidelines recommend echocardiograms (echo) after dialysis initiation and re-evaluation with an echo if "symptoms of CHF" occur. However, the validity of CHF symptoms in predicting low left ventricular ejection fraction (EF) among dialysis patients is not known. Our objective was to determine if symptoms of CHF in dialysis patients are associated with low EF measured on echo. The PACE study is an ongoing prospective cohort study of incident in-center hemodialysis patients in the Baltimore area. We administered Kansas City Cardiomyopathy Questionnaire (KCCQ), a valid and reliable health status measure of CHF in non-dialysis patients, to PACE participants. Higher KCCQ scores (range 0-100) indicate worsening symptoms. EF was measured by an echo performed on the interdialytic day. Low EF was defined as EF ≤40%. We used linear and logistic regression to assess the association between symptoms of CHF and EF. Information on EF and KCCQ was available for 111 PACE participants. Mean age was 54 yrs, 58% male and 64% African American. Mean EF was 61%; 6.3% had EF <40%. Among those with a self-reported history of CHF (n=17) compared to those without, there was no difference in EF (60% vs. 62%; p=0.6) or score on the symptoms domain of KCCQ (61±15 and 60±19; p=0.8). For each 20 higher symptom score, EF decreased by 3% but did not reach statistical significance (p=0.06). Symptom score was also not associated with low EF (odds ratio per 20 higher score, 1.47; p=0.5). Clinical symptoms of CHF in dialysis patients may not be a reliable indicator of EF. Sole reliance on symptoms to identify development of low EF may result in under-diagnosis, under-treatment and potentially, increased mortality. Routine echo should be considered as a part of dialysis care and monitored as a clinical performance improvement target.

**Left Ventricular Dyssynchrony: A Potential Contributor to Left Ventricular Dysfunction in Chronic Kidney Disease?** Shirley Yumi Hayashi,[1,2] Marcelo M. Nascimento,[1] Astrid Seeberger,[1] Britta Lind,[2] Miguel C. Riella,[3] Britta Lind,[2] Lars-Åke Brodin,[2] Bengt Lindholm.[1] *[1]Baxter Novum & Renal Medicine Karolinska Institute, Stockholm, Sweden; [2]School of Technology and Health KTH, Royal Institute of Technology, Stockholm, Sweden; [3]Nephrology, Pontifícia Universidade Católica do Paraná, Curitiba, Brazil.*

Sudden death is common in chronic kidney disease (CKD) and could be associated with abnormalities in cardiac synchronicity. The aim of this study was to analyze cardiac synchronicity in patients with different CKD stages. Tissue doppler echocardiography (TDE) was used to evaluate LV synchronicity in 147 patients; 44 HD (29 men, 56.3±13.8 yr), 50 PD (28 men, 59.2±16.3yr) and 54 CKD stages 3-4 patients (34 men, 60.5±11.3yr) Left ventricular dyssynchrony (LVD) was defined as a regional difference in time to peak systolic myocardial velocity (PSv) or peak longitudinal strain (PSLS), between different LV walls > 105 ms in at least 2 of the following techniques; manual and automatic measurements of time to PSv using TDE and tissue synchronization imaging (TSI), respectively, and time to PSLS using speckle tracking imaging (STI). Twelve LV segments, six basal and six midventricular were evaluated. Abnormal LV synchronicity was present in 55 % of tho whole cohort with no difference in the prevalence between HD (52%), PD (53%) and CKD3-4(60%)($p>0.05$). Patients with LVD presented with significantly higher left atrium diameter (43.5±6.6 vs. 40.8±5.5, $p<0.05$), LV end diastolic diameter (50.4±7.8 vs. 47.5±6.9, $p<0.05$) and LV mass (245.7±81.0 vs. 206.2±70.9, $p<0.01$) compared to patients without LVD. LVD patients also showed significantly lower LV isovolumetric contraction velocities (2.5±1.6 vs. 3.4±1.6, $p<0.001$), PSv (4.3±1.4 vs. 5.4±1.6, $p<0.0001$), early diastolic myocardial velocities (4.4±1.8vs. 5.3±2.3, $p<0.01$), increased LV end diastolic pressure (22.3±14.4 vs. 15.7±10.5, $p<0.0001$) and a higher prevalence of pulmonary hypertension (30% vs. 9%, $p<0.05$). In conclusion, LV dyssynchrony was highly prevalent in CKD patients regardless to CKD stage showing a possible role in the mechanism of LV dysfunction in CKD patients.

**The Analysis of Competing Events like Cause-Specific Mortality – Beware of the Kaplan-Meier Method** Marion Verduijn,[1] Diana C. Grootendorst,[1] Friedo W. Dekker,[1] Kitty J. Jager,[2] Saskia le Cessie.[1] *[1]Leiden University Medical Center, Amsterdam, Netherlands; [2]Academic Medical Center, Amsterdam, Netherlands.*

**Introduction**

Kaplan-Meier analysis is a popular method used for analyzing time-to-event data, but profoundly overestimates the cumulative mortality probabilities in case of competing endpoints such as cardiovascular (CV) and non-CV mortality. This study compares application of 1) Kaplan-Meier analysis and 2) competing risk analysis for estimation of cumulative probabilities of CV and non-CV mortality in dialysis patients.

**Methods**

Data were used of 617 elderly incident dialysis patients from the Dutch NECOSAD cohort (>70 years). CV mortality was defined as death due to myocardial infarction or ischemia, hyper- or hypokalaemia, haemorrhagic pericarditis, hypertensive cardiac failure, other causes of cardiac failure, cardiac arrest, fluid overload, cerebro-vascular accident, haemorrhage from ruptured vascular aneurysm or mesenteric infarction, uncertain or unknown cause of death. All other causes of death were considered non-CV mortality. Follow-up was maximized at 5 years.

**Results**

Within 5 years of follow-up, 202 patients (32.7%) died due to CV causes (14.7 per 100 person-years), and 201 (32.6%) patients due to non-CV causes (14.5 per 100 person-years). The 5-year cumulative all-cause mortality probability estimated by Kaplan-Meier analysis was 78.3%. The 5-year cumulative mortality probability estimated using Kaplan-Meier analysis was 51.8% for CV causes and 55.1% for non-CV causes, suggesti ng that total (all-cause) mortality was 106.9%. In contrast, the 5-year cumulative probability for CV mortality estimated by competing risk analysis was 38.8% and for non-CV mortality 39.5%. The sum of CV and non-CV mortality from this model was 78.3%, equal to the cumulative 5-year all-cause mortality as obtained from Kaplan-Meier analysis.

**Conclusion**

This study demonstrates that, in contrast to the Kaplan-Meier method, application of competing risk analysis yields unbiased estimates of the cumulative probabilities for cause-specific mortality. Therefore, mortality from competing endpoints should not be reported from Kaplan-Meier based methods, but from competing risk analysis.

**Regression of Left Ventricular Mass Following Conversion from Conventional Hemodialysis to In-Centre Nocturnal Hemodialysis** Ron Wald, Andrew T. Yan, Jeffrey Perl, Howard Leong-Poi, Marc B. Goldstein. *Department of Medicine and the Keenan Research Centre in the Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada.*

Background: Left ventricular mass (LVM) is closely associated with adverse outcomes in patients receiving chronic hemodialysis. Conversion from conventional hemodialysis (CHD, 3x/week, 4 hrs/session) to home nocturnal hemodialysis (5-6x/week, 7-8 hrs/session) may reduce LVM. However, a minority of patients with ESRD are eligible for home hemodialysis. For other individuals, intensification of dialysis with in-centre nocturnal hemodialysis (INHD, 3x /week, 7-8 hrs/session in the dialysis unit) may confer a similar cardiovascular benefit.

Methods: We evaluated changes in LVM following INHD conversion in individuals who received INHD for at least 6 months. In our primary analysis, LVM on the first echocardiogram performed at least 6 months post-conversion was compared to LVM on the study that most closely preceded conversion. In a secondary analysis, we restricted the cohort to patients with post-conversion echocardiograms > 12 months since starting INHD. To determine the effect of conversion to INHD on LVM over time, we performed a longitudinal analysis using a mixed model that incorporated all LVM data on patients who had at least two evaluable echocardiograms (n=41).

Results: 61 patients converted to INHD, of whom 37 were eligible for the primary analysis. Mean age at conversion was 49±12 yrs, median time on CHD was 4.0 (IQR 1.4-8.3) yrs and 30% were women. Principal causes of ESRD were glomerulonephritis (35%) and diabetes mellitus (32%). Mean pre-conversion LVM was 219±66 gm and following conversion, LVM declined by 32±58 gm ($p=0.002$). Among patients whose follow-up echocardiogram occurred at least 12 months following conversion (n=31), LVM declined by 40±56 gm ($p=0.0004$). The rate of change of LVM decreased significantly from 1 gm/yr before conversion, to -13 gm/yr in the post-conversion period (difference -12 gm/yr, $p<0.0001$).

Conclusion: Conversion to INHD from CHD is associated with a regression in LVM, which may portend a more favourable cardiovascular outcome.

**Effects of Sodium Thiosulfate on Vascular Calcification in ESRD: A Pilot Study** James A. Delmez,[1] Eduardo Slatopolsky,[1] Anton Cabellon,[1] Lisa de las Fuentes,[1] Andrew J. Bierhals,[2] Prashanth Podaralla,[1] Santhosh Mathews,[1] Victor G. Davila-Roman.[1] *[1]Medicine, Washington University School of Medicine, Saint Louis, MO; [2]Mallinckrodt Institute of Radiology, Washington University School of Medicine, Saint Louis, MO.*

**Purpose:** Vascular calcification (VC) in ESRD patients is usually progressive and associated with increased mortality. Sodium thiosulfate (TS), an antioxidant that increases the solubility of Ca, may affect VC. The purpose of the study was to assess the effects of IV TS on VC of the coronary, carotid, and thoracic aorta and on L1-L2 vertebrae bone density. **Methods:** ESRD patients with initial Agatston scores >50 were imaged by 64-slice MDCT of the neck, chest, and lumbar spine at baseline and after 5 months of intravenous TS (12.5-18.75 gm given after each HD). Images were analyzed by 2 independent blinded observers. Annualized rate of change was calculated as the difference between the square roots of the follow-up and baseline calcium volumes; by definition, Progressors had annualized change ≥2.5 $mm^3$. Variables are mean ± SD. **Results:** Subjects completing the entire protocol (N=22) were 86% black, 59±10 years old, 41% diabetic, with a HD vintage of 67±52 months. Mean annualized change of the coronary, carotid, and thoracic aorta and L1-L2 vertebrae were not significant in the entire cohort. In subgroup analyses, Progressors (N=14; annualized change 12.3±7.1%) and Non-progressors (N=8; annualized change -3.2±3.7%) had similar baseline coronary artery scores (1813±1700 and 1622±1114, respectively; P=NS). There was no correlation between annualized change of the coronary arteries and anion gap (reflecting TS levels), fetuin, phosphorus, or CRP levels during treatment. The annualized change of the coronary arteries correlated with that of the thoracic aorta Ca (r=0.61, p=0.003) but not the carotid arteries or L1-L2. Although nausea was common, there were no serious adverse events related to TS treatment. **Conclusion:** TS treatment may safely decrease the rate of progression of VC in ESRD patients without effecting L1-L2 calcium. A large randomized, controlled study to further assess the safety and efficacy of this treatment should be performed.

**TH-PO506**

**Acute Coronary Disease and VDR Activation in Hemodialysis Patients** Luca Emilio Bernardi, Paola Padovese, Claudio Minoretti. *Nephrology and Dialysis, Sant'Anna Hospital, Como, CO, Italy.*

BACKGROUND

25-OH Hydroxyvitamin D levels inversely associate with the risk of developing coronary artery calcification (De Boer, JASN 2009), while active serum vitamin D levels show inverse correlation with coronary calcifications (Watson, Circulation 1997).

AIM

To study VDR activators potential to prevent coronary artery disease (CAD) in hemodialysis (HD) patients.

MATERIAL AND METHODS

We studied 578 patients who underwent dialysis treatment since 1/1/2002 until 31/12/2009 in our Center. 81/578 patients (14,01%) underwent coronary angioplasty during follow up time.

Table 1

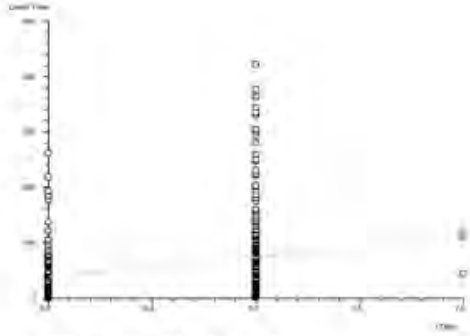
| | | |
|---|---|---|
| Patients Number 578 | Male 350 (60.55%) | Female 228 (39.45%) |
| | Coronary Angioplasty 81 | No Angioplasty 497 |
| | Dead at follow up 346 | Alive at follow up 232 |
| HD starting age (months±standard error) 66.12±0.58 | Median 69 | Range 16-91 |
| Death time since starting HD (months±standard error) 62.76±3.83 | Median 41 | Range 1-422 |

RESULTS

Cross tabulation with VDR activators as first classifier and coronary angioplasty as second classifier showed a significant statistical difference between groups (p=0.0077).

The relationship between mortality and VDR activators showed a correlation coefficient significantly different from zero (P<0.0001).

Figure 1



Legend: **mortality and VDR activators**
First column = No VDR activator therapy
Second column: oral or endovenous calcitriol therapy
Third column: calcitriol plus paricalcitol

Oral calcitriol was inversely related with coronary artery disease (two sided p = 0.0011), while multiple linear regression model showed a reduction in mortality rate using oral and endovenous calcitriol and paricalcitol (p=0,0374, p=0.0881 and p<0.0001 respectively).

DISCUSSION

VDR activation seems to protect dialysis patient from both overall mortality and coronary artery disease. Paricalcitol seems to be more effective in our population in reducing overall mortality, while the lack in reducing coronary artery disease as calcitriol should be related to the relatively recent introduction of paracalcitol in our center, reducing a potential effect in early population.

## TH-PO507

**LDL Size Reduction as a Possible Risk Factor for the Prevalence of Coronary Artery Diseases in Hemodialysis Patients** Hideki Kimura,[1] Ryoichi Miyazaki,[2] Shinya Masunaga,[3] Akihiro Shimada,[3] Toshio Imura,[3] Daisuke Mikami,[1] Kenji Kasuno,[1] Naoki Takahashi,[1] Tsutomu Hirano,[4] Haruyoshi Yoshida.[1] *[1]Div of Nephrol, Sch of Med, Univ of Fukui, Fukui, Japan; [2]Dept. of Internal Med., Fujita Memorial Hosp, Fukui, Japan; [3]Dept of Clin Lab, Univ of Fukui Hosp, Fukui, Japan; [4]Division of Diabetes and Metabolism, Showa Univ Sch of Med, Tokyo, Japan.*

Smaller LDL size has recently been reported as a non-traditional lipid risk factor for coronary artery disease (CAD). Cholesteryl ester transfer protein (CETP) and the hepatic lipase (HL) C/T mutation may promote LDL size reduction via the CETP-mediated exchange of CE for TG and subsequent HL-mediated TG hydrolysis in LDL. However, little is known about LDL size status and its relationship with CAD prevalence in hemodialysis (HD) patients who are at high risk for atherosclerosis.

We determined CETP levels, HL genotype, and LDL size in a total of 236 HD patients aged over 30 years and investigated the determinants of LDL size and its association with CAD prevalence.

The HD patients had a significant negative correlation between LDL size and serum TG levels, and a similar LDL size to the healthy subjects. In the HD group, HDL-C was an independent positive determinant of LDL size, while log10 (TG) was an independent negative determinant in the high (≥2.1 μg/ml) but not low (<2.1 μg/ml) CETP group. In the patients with hypertriglyceridemia, the high CETP group had a significantly smaller LDL size than the low CETP group (256.9 ± 3.7 Å vs. 264.7± 6.6 Å). Among the patients with above-median TG levels, the CC genotype and CETP were independent negative determinants of LDL size, as these factors enhanced the negative slope of the regression line relating serum TG levels and LDL size. In the whole group and the high CETP group, the patients with CAD had a significantly smaller LDL size than those without CAD (259.2 Å vs. 262.0 Å and 258.3 Å vs. 261.5 Å). Finally, multivariate stepwise logistic regression analyses showed that DM and LDL size reduction were identified as independent risks factor for CAD prevalence.

These suggest that LDL size reduction mediated by TG, CETP, and HL genotype may serve as a risk factor for CAD in HD patients.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO508

**Impact of Circulating Soluble Receptor for Advanced Glycation End Product (sRAGE) and the Pro-Inflammatory RAGE Ligand (EN-RAGE, S100A12) on Mortality in Hemodialysis Patients** Ayumu Nakashima, Juan J. Carrero, Abdul Rashid Tony Qureshi, Tetsu Miyamoto, Björn Anderstam, Peter F. Barany, Olof Heimburger, Peter Stenvinkel, Bengt Lindholm. *Divisions of Renal Medicine and Baxter Novum, Department of Clinical Science, Karolinska Institutet, Stockholm, Sweden.*

**Background:** The soluble receptor of advanced glycation end products (sRAGE) may exert anti-inflammatory protective roles on the vasculature. In contrast, the RAGE ligand S100A12 (also known as EN-RAGE) contributes to inflammation and the development of atherosclerosis in animal models. Whether alterations at this level contribute to the increased mortality observed in dialysis patients is currently unknown.

**Methods:** This prospective study included 184 prevalent hemodialysis (HD) patients and 50 healthy controls matched for age and gender. Plasma concentrations of S100A12 and sRAGE were studied in relation to risk profile and mortality after a median follow-up period of 41 months.

**Results:** S100A12 and sRAGE levels were significantly elevated in HD patients compared to controls. S100A12 had a strong positive correlation with CRP and IL-6, whereas sRAGE negatively associated with CRP. S100A12, but not sRAGE, was independently and positively associated with clinical cardiovascular disease (CVD). During follow-up, 85 (33 CVD-related) deaths occurred. Whereas sRAGE did not predict mortality, S100A12 was associated with both all-cause (per log10 ng/ml hazard ratio [HR] 1.93, 95% confidence interval [CI] 1.18 to 3.15) and CVD-related (HR 3.23, 95% CI 1.48 to 7.01) mortality, even after adjustment for age, sex, vintage, and co-morbidity. Further adjustment for inflammation made the prognostic value of S100A12 disappear for all-cause mortality, while it still persisted for CVD-related mortality.

**Conclusions:** Circulating S100A12 and sRAGE are both elevated in HD patients. However, only S100A12 associates with mortality, which only partly is explained by its links with inflammation.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO509

**Prognostic Values of C-Reactive Protein Levels on Clinical Outcome after Endovascular Therapy in Hemodialysis Patients with Peripheral Artery Disease** Hirotake Kasuga,[1] Tetsuya Yamada,[2] Nobumasa Nakamura,[1] Ryo Takahashi,[1] Keiko Kimura,[1] Takanobu Toriyama,[1] Seiichi Matsuo,[3] Hirohisa Kawahara.[1] *[1]Internal Medicine, Division of Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; [2]Seto Kyoritsu Clinic, Seto, Japan; [3]Nephrology, Nagoya University Hospital, Nagoya, Japan.*

**Background:** Endovascular therapy (EVT) has become the common therapeutic standard for peripheral artery disease (PAD). However, the high restenosis rate after EVT remains a major problem in patients on HD. Recent studies suggest that C-reactive protein (CRP) reflects vascular wall inflammation and can predict adverse cardiovascular events. We evaluated the possible prognostic values of CRP on clinical outcomes after EVT in HD patients.

**Methods**: A total of 234 HD patients successfully undergoing EVT for PAD were enrolled and were followed-up for up to 5 years. Serum CRP levels were measured prior to EVT. They were divided into tertiles according to serum CRP levels; tertile 1 (T1): < 1.4 mg/l, T2: 1.4 – 6.0 mg/l, and T3: ≥ 6.0 mg/l). We analyzed the incidence of major adverse cardiovascular events (MACE) as a composite endpoint including all-cause death, target lesion revascularization (TLR) after EVT, and amputation.

**Results:** During follow-up period (33±21months), 76 TLR (32%) and 35 amputations (15%) were performed, and 53 patients died (23%). The event-free survival rate from MACE for 5 years was 60.2%, 50.0%, and 25.1% in the T1, T2 and T3, respectively (p<0.0001). In addition, freedom rate from TLR was 72.5%, 64.1% and 44.5% (p=0.0014), and all-cause survival rate was 81.5%, 65.2% and 59.3% in the T1, T2 and T3, respectively (p=0.0078). The difference of limb salvage rate was not significant (88.7%, 77.3% and 74.8% in T1, T2 and T3, respectively, p=0.15). Even after adjustment for other risk factors, pre-procedural CRP levels were a significant predictor for MACE after EVT (HR 1.93, 95%CI 1.07-3.49 for T2 vs. T1 and HR 3.08, 95%CI 1.75-5.41 for T3 vs. T1, p=0.0004 for trend). Elevated CRP levels were also independently associated with TLR and mortality after EVT, respectively.
**Conclusions:** Elevated pre-procedural serum CRP levels could strongly predict MACE after EVT in HD patients with PAD.

Disclosure of Financial Relationships: nothing to disclose

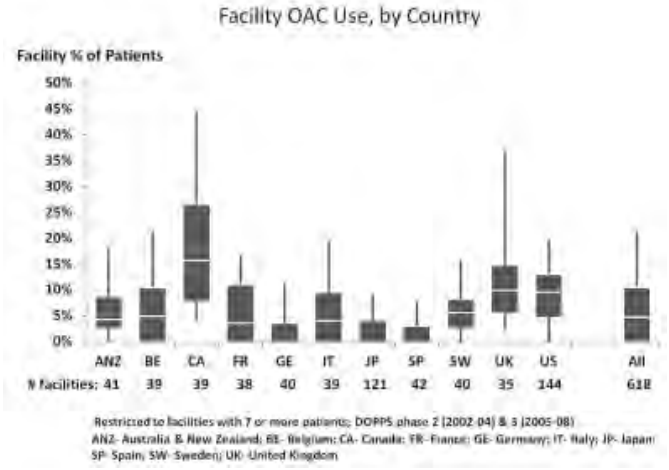
## TH-PO510

**Oral Anticoagulants (OAC): Prescription Patterns and Outcomes in the Dialysis Outcomes and Practice Patterns Study (DOPPS)** Manish M. Sood,[1] Jyothi R. Thumma,[2] Francesca Tentori,[2] Brenda W. Gillespie,[3] Shunichi Fukuhara,[6] David C. Mendelssohn,[4] Kevin Chan,[5] Bruce M. Robinson.[2,3] *[1]St. Boniface Gen. Hosp., Winnipeg, MB, Canada; [2]Arbor Research, Ann Arbor, MI; [3]Univ. of Michigan, Ann Arbor, MI; [4]Humber River Regional Hosp., ON, Canada; [5]FMC North America, MA; [6]Kyoto Univ., Japan.*

Indications for OAC use in hemodialysis (HD) remain controversial. We report OAC prescription and clinical events in the international DOPPS cohort.

The study sample comprised 37,863 HD patients (pts) with no mechanical heart valves from 925 facilities in the US, Canada (CA), Japan (JP), Europe + Australia and New Zealand [Eur/ANZ] in 1996-2008. Associations between baseline OAC prescription and bleeding events, stroke, and mortality were assessed in fully adjusted Cox models.

OAC prescription was 18% in CA, 10% in the US, 5% in Eur/ANZ, and 3% in JP. OACs were more commonly used in pts with atrial fibrillation (40% in CA, 34% in the US, 20% in Eur/ANZ and 13% in JP); OAC use in pts using a catheter was more common in CA (22%) vs. the US ( 8%) and Eur/ANZ (6%). Among patients on OACs, low dose warfarin (<10.5 mg/week) was prescribed to a minority of pts (31% in CA; 29% in JP; 17% in Eur/ANZ and the US). The % of facility pts on OACs varied in each country.



Older age, low serum albumin, cardiovascular and lung disease were associated with OAC use. Compared those not on OAC, OAC patients had a higher risk of bleeding events (hazard ratio: 1.19 [95% confidence interval: 1.04-1.37]; p=0.01), all-cause (1.16 [1. 08-1.25]; p<.0001) and cardiovascular mortality (1.13 [1.01-1.26]; p=0.03) and stroke (1.13 [0.92-1.38]; p=0.25).

OAC use varies internationally and is associated with poor clinical outcomes, despite extensive case-mix adjustment. Health care providers should consider the potential harms of OAC therapy in HD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO511**

**Contrasts between Risk Factors for Stroke and Other Cardiovascular (CV) Events in Hemodialysis (HD) Patients: Data from the DOPPS** Christian Combe,[1] Jyothi R. Thumma,[2] Jonathan W. Bazeley,[3] Brenda W. Gillespie,[3] Hiroyasu Yamamoto,[5] Werner Kleophas,[4] Martin P. Gallagher,[6] Friedrich K. Port,[2] Bruce M. Robinson,[2,3] Patricia De Sequera.[7] *[1]CHU de Bordeaux, France; [2]Arbor Research; [3]Univ. of Michigan; [4]Dialysezentrum Karlstrasse, Germany; [5]Jikei Univ. School of Medicine, Japan; [6]Concord Repatriation & Gen. Hosp., Australia; [7]Hosp. Infanta Leonor, Spain.*

CV morbidity and mortality rates are high in HD patients (pts). Studies of therapeutic interventions in clinical trials for composite CV endpoints have led to conflicting results, which may be due to non-homogeneous associations of risk factors (RF) with different types of CV events.

Data were from 41,208 HD pts followed for a median of 1.5 years in the DOPPS, an international prospective cohort study. Cox regression was used to evaluate associations of different types of events with traditional and non-traditional RF (listed in table).

The number of events ranged from 1,202 (Amp) to 9,863 (ACM). Associations between RF and events are reported in Table.

| Calcium (per 1 mg/dl) | 1.10[A] | 1.12[A] | 1.11[A] | 1.16[A] | 1.02 | 1.03 | 1.06 |
| PTH (per 200 pg/ml) | 1.03[A] | 1.04[A] | 1.03[A] | 1.03[A] | 1 | 1.01 | 0.99 |
| Hgb (per 1 g/dl) | 0.95[A] | 0.97[A] | 0.95[A] | 0.99 | 0.97 | 0.95[A] | 0.93[A] |

Elevated risk | Reduced risk | Weak or no association (p≥0.05)

[A] p<0.001; [B] p=0.001 - <0.05

-Models adjusted for above RF, 13 summary comorbidities, years on dialysis, ferritin, WBC, potassium, creatinine, catheter; stratified by phase, country and accounted for facility clustering.
-ACM=all-cause mortality; CVM=CV mortality; SD=sudden death; Amp=amputation; MI, Stroke, HF = death or hospitalization from myocardial infarction, stroke, or heart failure, respectively.
-CVM includes death from MI, stroke, HF, and sudden death
[C] Reference: Previous smoker (>1 yr since quit) or non-smoker

Key findings include: male sex associated with lower risk of stroke, but higher risk of other CV events. Black race associated with lower risk for MI than other events. Smoking associated with higher risk of ACM and HF. Higher WBC associated with higher risk of all events except stroke. Higher SBP associated with lower risk for all events except stroke. Treated categorically, SBP <130 associated with elevated mortality for all events except stroke (HR 0.87, p=0.045) and SBP ≥160 associated with elevated mortality for stroke (HR 1.28, p=<.0001) and HF (HR 1.14, p=0.002), but not other CV events.

In HD pts, different types of CV events are associated with specific RF patterns: Stroke is associated with a specific RF pattern, with higher risk in females and with high SBP, in contrast to other CV events.

**Lowering Dailysate Calcium Concentration from 3.0 mEq/L to 2.5 mEq/L Attenuates the Progression of Abdominal Aortic Calcification in Patients on Chronic Hemodialysis** Kazuhiro Yamada, Shouichi Fujimoto, Yuji Sato, Kazuo Kitamura. *Department of Internal Medicine, Circulatory and Body Fluid Regulation, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan.*

Background: Vascular calcification is an independent determinant of cardiovascular events in patients on chronic hemodialysis (HD). However, the relation between dialysate Ca concentration and vascular calcification has not been clarified. This study was planned to clarify the effect of lowering dailysate Ca concentration from 3.0 mEq/L to 2.5 mEq/L on the progression of abdominal aortic calcification in HD patients.

Methods: We enrolled 44 HD patients with dialysate containing 3.0 mEq/L of Ca, and randomly 26 HD patients (lowering group) lowered the their dialysate Ca concentration from 3.0 mEq/L to 2.5 mEq/L after about three years. Eighteen patients (control group) continued HD with dialysate containing 3.0 mEq/L of Ca. All patients underwent abdominal computed tomography (CT) three times at an interval of approximately three years. The aortic calcification index (ACI) was quantified morphometrically using abdominal CT films (range of ACI, 0–240). The progression rate of aortic calcification was calculated as ΔACI/year.

Results: The first ACI and ΔACI/year was no significant difference in lowering and control group (first ACI: 42.7 ± 42.8 vs 57.4 ± 38.1, first ΔACI/year: 6.7 ± 6.4 vs 8.5 ± 6.4). In lowering group, the second ΔACI/year, after lowering dialysate Ca concentration, was significantly decreased compared with the first ΔACI/year (6.7 ± 4.3 vs 4.9 ± 5.1, p < 0.0263, Wilcoxon signed rank test). On the other hand, in control group the second ΔACI/year was significantly increased compared with the first ΔACI/year (8.5 ± 6.4 vs 12.1 ± 7.2, p < 0.0249). In stepwise multivariate analysis the progression of ACI after lowering dailysate Ca concentration was negatively and independently associated with lowering dailysate Ca concentration, age and serum Ca concentration just after HD, and positively associated with serum phosphate.

Conclusion: Lowering dailysate Ca concentration from 3.0 mEq/L to 2.5 mEq/L attenuated the progression of abdominal aortic calcification in HD patients.

**TH-PO513**

**Higher Plasma Fibroblast Growth Factor-23 Level Is Associated with Lower Body Mass Index and Dyslipidemia in Dialysis Patients** Jessica B. Kendrick,[1] Alfred K. Cheung,[2,4] James S. Kaufman,[3] Tom H. Greene,[4] William L. Roberts,[4] Gerard John Smits,[1] Michel B. Chonchol.[1] *[1]University of Colorado Denver Health Sciences Center, Denver, CO; [2]VASLCHCS, Salt Lake City, UT; [3]VA Boston Healthcare System, Boston, MA; [4]University of Utah, Salt Lake City, UT.*

Purpose: Fibroblast growth factor-23 (FGF-23) has recently been associated with death in dialysis patients. Since FGF-23 shares structural features with the FGF-19-subfamily members (FGF-19, FGF-21) that exert hormonal control of fat mass and glucose metabolism, we hypothesized that FGF-23 would be associated with metabolic factors that predispose to increased cardiovascular risk.

Methods: Study was conducted among 654 patients receiving dialysis who participated in the Homocysteine in Kidney and End Stage Renal Disease study. FGF-23 levels were measured in stored plasma samples. Linear regression was used to examine the cross-sectional associations of plasma FGF-23 with body mass index (BMI), total cholesterol (TC), low density lipoprotein-cholesterol (LDL-C), high density lipoprotein-cholesterol (HDL-C) and total triglycerides (TG).

Results: Participants had a mean age of 60±11 years and median dialysis vintage of 1.4 years. Mean (SD) serum phosphorus and the median [IQR] FGF-23 levels were 5.6±1.8 mg/dL and 4212 [1411-13816] RU/mL, respectively. The mean (SD) BMI, TC, LDL-C, HDL-C and TG were 27±6 kg/m2, 156±39 mg/dL, 84±32 mg/dL, 41±14 mg/dL and 160±107 mg/dL. An increase in log10 FGF-23 was associated with lower BMI (β= -1.11 95% CI -1.91, -0.31; p=0.008), total cholesterol (β= -6.46 95% CI -11.96, -0.96; p=0.02), LDL-C (β= -4.73 95% CI -9.23, -0.1; p=0.04) and HDL-C (β= -2.14 95% CI -4.08, -0.20; p=0.03), after adjusting for age, gender, race, serum albumin, calcium, phosphorus, 25-hydroxyvitamin D, calcitriol, and parathyroid hormone levels. No significant relationship was observed between FGF-23 and TG (p=0.80).

Conclusions: Higher FGF-23 levels are associated with lower BMI and dyslipidemia in dialysis patients. These findings suggest the relationship between FGF-23 and death in dialysis patients may be mediated through risk factors unrelated to mineral metabolism.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO514**

**FGF-23 Is Associated with Cardiac Troponin, Osteocalcin and Mortality in Prevalent Hemodialysis Patients** Rachel M. Holden,[1] David P. Beseau,[2] Michael A. Adams,[2] Jocelyn S. Garland,[1] Alexander R. Morton,[1] Robert N. Foley.[3] *[1]Medicine, Queen's University, Kingston, ON, Canada; [2]Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada; [3]Chronic Disease Research Group, Minneapolis, MN.*

FGF-23 is elevated in patients with ESKD and is linked with adverse patient outcomes including mortality and left ventricular hypertrophy. We determined the correlates of FGF-23 (including cardiac troponin T (cTNT) and osteocalcin (OC)) and determined its association with mortality over 3.5 years of follow-up in 103 prevalent hemodialysis patients. Linear regression was used to examine the association between FGF-23 and age, gender, dialysis vintage, albumin, calcium, phosphate, hemoglobin, Kt/V, PTH, cholesterol, triglycerides, cTNT and total and uncarboxylated OC. Unadjusted comparisons by tertile of FGF-23 were also performed and adjusted odds ratios were calculated for being in the highest tertile of FGF-23. Cox proportional hazards models were used to examine the effect of FGF-23 (per 1000 RU/ml) as well as patient characteristics and laboratory variables on mortality. The mean age was 61.2(15.5), 33% were female and the mean dialysis vintage was 4.19 (4.6) years. The mean FGF-23 level was 2732±4506 RU/ml and the median [IQR] was 1259 (491,2885) RU/mL. In multivariable analysis including adjustment for age and phosphorus, independent predictors of FGF-23 concentrations included dialysis vintage, total OC, uncarboxylated OC and cTNT. The phosphate and age-adjusted odds ratio (CI) of being in the highest tertile of FGF-23 included total OC (1.02(1.0,1.04). There were 57 deaths in 103 patients over 3.5 years of follow-up. In the fully-adjusted model, the significant predictors of mortality included FGF-23 (HR 1.09 per 1000 units increase: 1.01, 1.17, p=0.02), age and albumin. FGF-23 is an independent biomarker that predicts mortality in ESKD. The independent association between FGF-23 and cTNT is a novel finding that may relate to hypertrophic changes of left ventricular geometry that have been associated with these biomarkers. The association between higher levels of OC and FGF-23, both products of the osteoblast, is a novel finding and requires further study.

**TH-PO515**

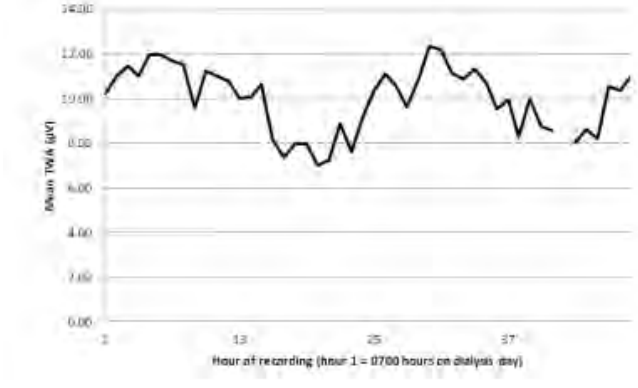
**Diurnal Variation of Ventricular Repolarization in Dialysis Patients** Darren Green,[1] Velislav N. Batchvarov,[2] Ganepola Arachhige Chandrkumara Wijesekara,[1] David I. New,[1] Philip A. Kalra.[1] *[1]Department of Renal Medicine, Salford Royal Hospital, Salford, United Kingdom; [2]Division of Cardiac and Vascular Sciences, St. George's Hospital, London, United Kingdom.*

Sudden cardiac death (SCD) is a major cause of death in dialysis patients, with a peak incidence on dialysis days. T wave alternans (TWA) measures beat to beat variation in t wave amplitude on ECG and is associated with risk of ventricular arrhythmia. It is recognized to be useful in risk stratification for SCD in other patient groups but not yet dialysis patients. Modified Moving Average (MMA) TWA is recorded via ambulatory ECG to give continual TWA. This may show change in risk relative to timing of dialysis.

We recorded 48 hour, 12 lead Holter ECG on 19 chronic haemodialysis patients from the onset of dialysis. This is the first patient group to have undergone MMA TWA testing. We previously reported an increase in TWA during dialysis with a return to baseline 2 hours after dialysis. Here we describe further analysis from this cohort.

For this analysis, the hourly group mean of TWA was sorted by time of day rather than by time from onset of recording. Figure 1 shows the hourly group mean TWA over a 48 hour period from 0700 hours on the dialysis day. One aberrant peak has been removed (mean TWA = 12.90 µV at 0100 hours on day 2, caused by a prolonged rise in a single patient). Figure 1 shows a peak TWA at approximately 1200 hours with a trough in measurement 12 hours later, on both days.

Figure 1



This is the first evidence of diurnal variation in TWA in any patient group. Its occurrence in dialysis patients may indicate instability of ventricular repolarisation specific to this group, though similar analysis in other at-risk populations is necessary for validation. This may provide some support for the high incidence of SCD in these patients as abnormal repolarisation is a potential trigger for ventricular arrhythmia.

**TH-PO516**

**Differentiated Role for Novel Biomarkers in Cardiovascular Calcification in ESRD** Theresa Gross,[1] Markus Ketteler,[2] Jurgen Floege,[1] Leon J. Schurgers,[3] Thilo Krueger,[1] Georg Schlieper,[1] Vincent Brandenburg.[4] *[1]Nephrology, RWTH University Hospital Aachen, Aachen, Germany; [2]Nephrology, Klinikum Coburg, Coburg, Germany; [3]CARIM, University of Maastricht, Maastricht, Netherlands; [4]Cardiology, RWTH University Hospital Aachen, Aachen, Germany.*

**INTRODUCTION AND AIMS:** Cardiovascular calcification is associated with high mortality in ESRD patients. Novel serum/plasma biomarkers may help establishing the diagnosis and estimating severity of the disease.

**METHODS:** We investigated 66 chronic HD patients (52% female) with MSCT scans for coronary artery calcification (CAC) and aortic valve calcification (AVC). We analyzed various potential serum / plasma biomarkers regarding their association with CAC and AVC, respectively: adiponektin, fetuin-A, osteoprotegerin (OPG), uncarboxylated matrix-gla protein (ucMGP), osteocalcin, CRP, PTH, alk. phos., sclerostin, and YKL-40.

**RESULTS:** CAC defined as Agatston score > 100 was present in 65%, any degree of AVC in 38% of pts. We stratified pts according to CAC (> 100 vs < 100 Agatston score) and AVC (present vs absent), respectively, into two groups each. There was no strong association between CAC and AVC: pts with CAC > 100 had no AVC in 50% of cases; on the contrary pts without AVC had a median CAC of 169 (range 0 - 1542). Regarding biomarkers, intergroup comparison for CAC revealed significant ($p<0.05$) higher OPG (5.8 +/- 2.6 vs 4.1 +/- 2.6 pmol/L) and YKL-40 levels (288 +/-91 vs 230 +/- 98 ng/mL) for pts with CAC>100 vs pts with CAC <100. In pts with AVC vs pts without AVC, serum sclerostin was elevated: 1.83 +/- 0.84 vs 1.35 +/- 0.72 ng/mL ($p<0.05$). Regression analyses revealed a sign. positive association between AVC and sclerostin serum levels.

**CONCLUSIONS:** Cardiovascular calcification is highly prevalent in chronic HD patients. The occurrence of ACV and CAC do not correlate in our HD pts. Concerning the association to cardiovascular calcification, the biomarkers applied show a different behaviour regarding their association to CAC and AVC. Of the novel biomarkers, high YKL-40 and OPG were associated with the presence of CAC, while sclerostin was associated with the presence and the severity of AVC in HD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO517**

**Prevalence, Period Trends and Survival of Dialysis Patients with Peripheral Arterial Disease in the United States: 1995-2004** Austin G. Stack,[1] Kieran Hannan,[2] Catherine A. Wall.[3] *[1]Regional Kidney Centre, Letterkenny General Hospital, Letterkenny, Donegal; [2]Cavan General Hospital, Cavan; [3]Nephrology Department, Adeliade and Meath Hospitals, Tallaght, Dublin, Ireland.*

Peripheral Arterial Disease (PAD) is a major risk factor for death in dialysis patients. The principal aim was to assess trends in prevalence and associated mortality in the U.S. dialysis population.

Methods: Data on all new dialysis patients (N=1,003,305) between 1995-2004 were obtained from the US Renal Data System, a national registry of the U.S. End Stage Kidney Disease population. Data on patient characteristics recorded at dialysis onset was linked with mortality data from the CMS Death Notification files. Patients were followed until 4/10/2006. Annual Mortality was calculated for those with and without PAD by year of incidence from 1995-2004. Multivariable Cox regression was used to estimate 2- year mortality hazard (RR) ratios for each calendar year (with 2000 as referent) in sequentially adjusted models. The final multivariable model was adjusted for demographic, socioeconomic, and comorbid factors (n=21). Analyses were conducted using SAS V 9.12.

Results: The prevalence of PAD has remained relatively stable between 14-15 % from 1995-2004. Over 50% of patients were dead within 2 years of dialysis initiation. The adjusted mortality risk has decreased at most by 14% since 1998 and 7% since 2000.

| Year | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 |
|---|---|---|---|---|---|---|---|---|---|---|
| PAD (%) | 13.8 | 14.4 | 15 | 15 | 14.6 | 14.5 | 14.5 | 14.1 | 14.3 | 14 |
| Annual Mortality | | | | | | | | | | |
| With PAD (%) | 55.4 | 55.4 | 56.6 | 57.5 | 56.1 | 56.2 | 55.7 | 55.7 | 54.9 | 52.5 |
| Without PAD (%) | 36.5 | 37.2 | 38.2 | 38.4 | 38.5 | 38.6 | 38.3 | 38.7 | 38.3 | 36.3 |
| RR Death | | | | | | | | | | |
| Unadjusted | 0.97 | 0.97 | 1.01 | 1.04 | 1 | 1.00 (ref) | 0.99 | 0.99 | 0.97* | 0.94** |
| Adjusted | 1.04* | 1.03* | 1.03 | 1.07** | 1.03 | 1.00 (ref) | 0.97 | 0.97 | 0.97 | 0.93** |

Conclusions: Although peripheral arterial disease remains a common diagnosis at dialysis initiation, mortality rates in these patients remain exceedingly high. Nevertheless, an encouraging trend of improved survival is observed in recent cohorts.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO518

**Increased Hospital Admissions on Mondays and Tuesdays in Hemodialysis Patients** Eduardo K. Lacson, Shu-Fang Lin, J. Michael Lazarus, Raymond M. Hakim. *Fresenius Medical Care, North America, Waltham, MA.*

**Introduction:** Sudden deaths in hemodialysis (HD) patients occur more frequently on Mondays and Tuesdays, after the longest interdialytic period on a thrice weekly treatment schedule (3Tx/Wk). We hypothesized that hospitalization for all causes and more specifically for conditions due to fluid overload occur in a similar pattern.

**Methods:** All 70,374 chronic in-center 3Tx/Wk HD patients who were active in all Fresenius Medical Care, North America legacy facilities and survived during the entire quarter from January 1 to March 31, 2009 were included. All hospitalizations were tracked, tagging those primarily due to fluid overload, including congestive heart failure and pulmonary edema. Events were mapped to the day of the week of occurrence.

**Results**: More patients (60% vs. 40%) dialyzed on the MWF than TThS schedule. There were 18,381 patients (26%) with 26,602 hospitalization events during the quarter, proportionately distributed between the MWF and TThS HD schedule. 5,509 of 15,489 MWF events (36%) occurred on Mondays while 4,129 of 11,098 TThS events (37%) occurred on Tuesdays – more than the (proportionate) 14% expected. Furthermore, 44% of hospitalizations due to fluid overload occurred either on Mondays (for MWF) or Tuesdays (for TThS). Cumulative fluid overload hospitalizations during the longest interdialytic period (i.e. including the weekend events), percentages increased further to 49% and 52%, respectively. Almost 1 in 5 patients with hospitalization for fluid overload had a similar event in the prior quarter.

**Conclusions**: Disproportionately more hospitalization events occur on Mondays or Tuesdays after the 2-day interdialytic period of a thrice weekly HD schedule. The proportion of hospitalizations primarily due to fluid overload is even higher. Additional HD treatment during the long interdialytic period may help prevent hospitalization for fluid overload in patients with recurrent events.

### TH-PO519

**Use and Costs of ACEIs, ARBs and Renin Inhibitors in U.S. Adult Dialysis Patients with Medicare Part D in 2007** Wendy L. St. Peter,[2,3] Christopher Powers,[1] Eric D. Weinhandl,[2] Benjamin L. Howell,[1] James P. Ebben,[2] Diane L. Frankenfield.[1] *[1]ORDI, CMS, Baltimore, MD; [2]USRDS Coordinating Center, MMRF, Minneapolis, MN; [3]College of Pharmacy, University of MN, Minneapolis, MN.*

**Background:** Angiotensin-converting enzyme inhibitors (ACEIs) and angiontensin receptor blockers (ARBs) use have been associated with improved survival in dialysis patients (pts) in several small clinical trials. However, current prevalence of use is largely unknown, as relevant studies predate implementation of the Medicare Part D drug benefit. **Methods:** Use and costs of ACEIs, ARBs, and renin inhibitors (RIs) in prevalent dialysis pts in the U.S. in 2007 were assessed using Part D data in Medicare's Chronic Condition Warehouse linked to administrative data from the United States Renal Data System. All adult pts alive on December 31, 2007 with Part D coverage during all of 2007 were included (n=169,443). **Results:** ACEIs were the most commonly used agents (38%), followed by ARBs (21%), and RIs (0.2%). The use of ACEIs was slightly higher in pts with diabetes as a comorbidity (41%) or hypertension as primary ESRD cause (39%). ACEI use was greater in younger (<65 yr), Black, American Indian/Alaska Native, and Hispanic pts. ARB use was greater in female, Asian/Pacific Islander, and Hispanic pts, as well as in those with shorter dialysis duration. Pts in independent facilities were less likely to use ACEIs and more likely to use ARBs than pts receiving care in large dialysis organizations. There was considerable variation in use across ESRD Networks, ranging from 32 to 44% for ACEIs and 15 to 27% for ARBs. During 2007, the total cost per person per year was about $157, $494, and $232 for ACEIs, ARBs, and RIs, respectively. The average out-of-pocket cost per prescription was $3.07, $10.40, and $8.16 for ACEIs, ARBs, and RIs, respectively. **Conclusions:** Disparities in use existed for some patient groups, by some facility characteristics and by geographic region. ARBs were more than three times the cost of ACEIs and were used extensively. Further research is necessary to determine whether step therapy was applied in patients receiving ARBs.

**Decline in Glomerular Filtration Rate during Predialysis Phase and Survival on Chronic Renal Replacement Therapy** Mikko Haapio,[1] Jaakko Helve,[2] Carola Gronhagen-Riska,[1] Patrik Finne.[2] *[1]Division of Nephrology, Helsinki University Central Hospital, Helsinki, Finland; [2]Finnish Registry for Kidney Diseases, Helsinki, Finland.*

INTRODUCTION

Estimated glomerular filtration rate (GFR) at RRT start has been shown to correlate with mortality on RRT, with lower values paradoxically associating with better survival. Knowledge is very limited, however, on the impact of GFR decline pattern during the predialysis phase on consequent survival on RRT. We aimed at exploring the effect of GFR slope on survival of patients on chronic RRT.

METHODS

Using the database of the Finnish Registry for Kidney Diseases, we conducted a cohort study of all incident patients 20 years or older entering chronic RRT in Finland in 1998, with follow-up until 31 December 2008. Of these 457 patients, we included those (n=365) with 2 or more serum creatinine measurements (at approximately 12 and 3 months, and 1–2 weeks prior to RRT start), and calculated their slopes of estimated GFR with Modification of Diet in Renal Disease formula. According to GFR slopes (in ml/min/1.73m$^2$ per year), patients were divided into tertiles: most rapid decline (over 9.1, n=121), intermediate group (3.7–9.1, n=122), and slowest decline (3.6 or less, n=122). Survival probabilities were calculated with the Kaplan-Meier method, with death as the event, and Cox proportional hazards regression was used to perform multivariable modelling of survival probabilities.

RESULTS

Median survival time of the 365 patients was 5.5 (95%CI 4.3–6.6) years. Compared to the patient group with the slowest GFR decline, the age and sex-adjusted relative risk of death was 1.22 (95% CI 0.89–1.67, P=0.221) and 1.64 (1.20–2.24, P=0.002) in patients with a GFR slope from 3.7 to 9.1, and over 9.1 ml/min/1.73m$^2$ per year. When including only patients with all 3 creatinine measurements (n=324) available, and after adjustment for age and sex, the patients with the steepest decline had 1.98-fold risk (95% CI 1.40–2.81, P<0.001) of death compared the patients with the slowest GFR decline (P<0.001).

CONCLUSIONS

Rapid decline in GFR before entering chronic RRT is associated with increased mortality on RRT.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO521

**Survival Analysis in Incident Dialysis Patients: A National Cohort Study in Taiwan** Chih-Chiang Chien. *Nephrology, Chi-Mei Medical Center, Tainan, Taiwan.*

**Background:** The incidence and prevalence of ESRD in Taiwan ranked first in the world. However, most reports for mortality in dialysis patients were from Western countries. The study is aim to investigate the impact on survival in dialysis patients based on the Taiwan's National Health Insurance (NHI) claim data.

**Patients and methods:** We selected all ESRD patients who initiated dialysis treatment in 1999. Patients had to be more than 20 years. Follow-up began at the first reported data of renal replacement therapy to the date of death or at the end of database (December 31, 2003). A total of 5302 incident HD and 341 incident PD patients were enrolled. The Cox proportional hazards model was applied to identify factors that predict survival.

**Results:** The PD group had a better survival status than did the HD group (66.57% vs. 55.88%, $p = 0.01$). In non-diabetic patients, survival rate did not differ significantly between HD and PD. However, all-cause mortality rate was significantly higher for diabetic PD patients than for diabetic HD patients [PD vs HD; HR 1.65, 95% CI: 1.29-2.10]. The interaction of PD patients and diabetes mellitus (DM) was significantly associated with all-cause mortality.

Mortality risk increased with age. In HD group, comparing with young-age (20-44 years), the hazard ratio of all-cause mortality were 2.54 for middle-age (45-64 years) and 5.38 for old-age (≥65 years) ( $p < 0.01$). In PD group, the trend was much more apparent; comparing with young-age, the hazard ratio of all-cause mortality were 4.13 for middle-age and 14.30 for old-age ($p < 0.01$).

DM was the only significant predictor of mortality in young-age patients. However, DM, congestive heart failure and cerebrovascular accident were significant predictor of mortality in middle- and old-age patients.

**Conclusion:** This is the first study to use Taiwan's NHI claim data to investigate the

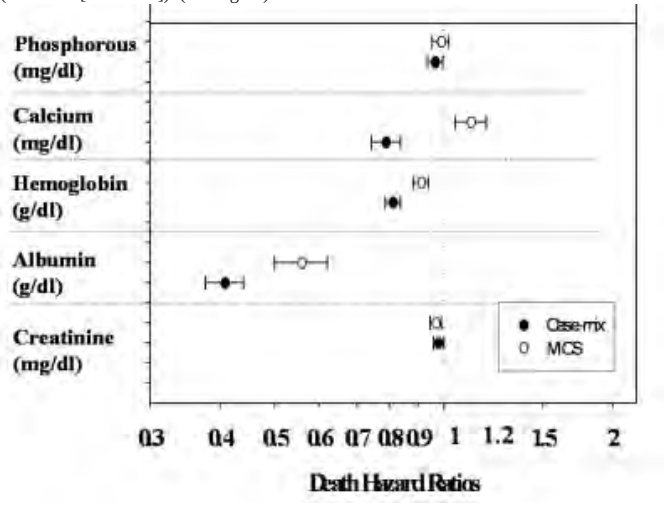
impact on survival in dialysis patients. Age and DM were significantly associated with all-cause mortality. Mortality risk increased with age in both HD and PD patients. In non-diabetic patients, survival rate did not differ significantly between HD and PD patients; however, HD provided a better survival rate than PD in diabetic patients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO522

**Laboratory Measures as Predictors of the First 3-Month Mortality in Incident Hemodialysis Patients** Lilia R. Lukowsky,[1,2] Leeka I. Kheifets,[2] Onyebuchi A. Arah,[2] Allen R. Nissenson,[3] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]Epidemiology, UCLA, Los Angeles, CA; [3]DaVita, Lakewood, CO; [4]Salem VA MC, Salem, VA.*

**Background:** All-cause mortality is among maintenance hemodialysis (MHD) patients is much higher during the first 3 months of initiation of MHD treatment. We examined the association of first 90-day mortality with several laboratory measures in the first 3 months of treatment. **Methods:** Using data on 20,348 incident MHD patients, who started MHD treatment between 7/2001 and 6/2006, we calculated the hazard ratio (HR) for death (and 95% confidence intervals) given selected laboratory measures in the first 3 months using Cox proportional models adjusted for case-mix and predictors of malnutrition-inflammation complex syndrome (MICS). **Results:** There were 2,058 deaths (10.1% of the entire population) during the first 90 days. The mean age for all MHD patients in cohort (vs. those who died) was 62±17 years (vs.71±13 years). Women comprised 45% (vs. 46% who died), African Americans 23% (vs. 18%), and Hispanics 13% (vs. 10%) of the sample. Among laboratory markers, each 1.0 g/dl higher levels for serum albumin was associated with 37% greater survival (death HR 0.63 [0.52-0.75]) and for hemoglobin with 8% greater survival (HR=0.92 [0.87-0.97]). (see Figure)



**Conclusions:** Among MHD patients, higher serum albumin and higher blood hemoglobin levels were the strongest predictors of the greatesr first 3-month survival. Serum phosphorus and creatinine did not appear to play a major role whereas serum calcium showed inconsistent association with mortality during this early period.

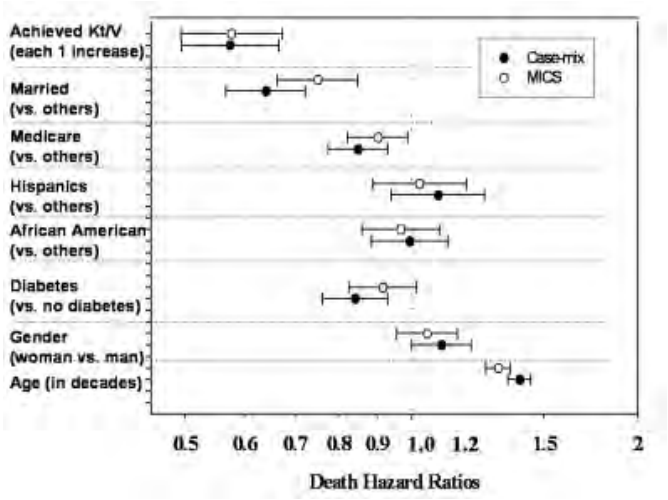
### TH-PO523

**Comparing Demographic Factors as Predictors of the First 90-Day Mortality in Incident Hemodialysis Patients** Lilia R. Lukowsky,[1,2] Leeka I. Kheifets,[2] Onyebuchi A. Arah,[2] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]Epidemiology, UCLA, Los Angeles, CA; [3]DaVita, Lakewood, CO.*

**Background:** Mortality among dialysis patients in the United States is exceptionally high (~20% per year). It is even higher during the first year, in especially in the first 90 days of initiation of maintenance hemodialysis (MHD) treatment. We examined the associations between the first 90-day mortality and several patient demographics and compared and achieved dialysis dose in the first 90 days. **Methods:** Using data on 20,348 incident MHD patients, who started MHD treatment between 7/2001 and 6/2006, we calculated the hazard ratio (HR) of death (and 95% confidence intervals) in the first 90 days using Cox proportional models adjusted for case-mix and predictors of malnutrition-inflammation complex syndrome (MICS). **Results:** There were 2,058 deaths (10.1% of the entire population) during the first 90 days. The mean age for all MHD patients in cohort (vs. those who died) was 62±17 years (vs. 71±13 years), Women comprised 45% (vs. 46% who died), African Americans 23% (vs. 18%), Hispanics 13% (vs. 10%). Death HR during the first 90 days was <1.0 for higher achieved Kt/V, married status and diabetes mellitus, whereas it was >1.0 for older age (see Figure).



**Conclusions:** Risk factors of the first-90-day mortality among incident MHD patients include lower achieved dialysis dose, a surrogate catheter (vs. arteriovenous fistula or graft), non-married status, no diabetes mellitus, and older age. Race, ethnicity and gender do not appear to have substantial associations with the first-90-day mortality.

### TH-PO524

**Discriminators of Death and Survival in the First Year of Hemodialysis: Threshold Values and Hierarchical Importance – The United States Renal Data System (USRDS)** Robert N. Foley,[1,2] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

High first year mortality is an ongoing public health issue in the US. In this regard, knowing optimally discriminating threshold values of suspected risk factors, high-yield subgroups and hierarchical importance could help gauge the appropriateness of renal replacement therapy and identify interventions. Using data at initiation of dialysis from the USRDS Medical Evidence Form, we identified thresholds with maximum sensitivity and specificity ($Max_{Sn+Sp}$) predictions for death in the first year in 156,924 adults who began hemodialysis in 2005 and 2006, and then applied classification tree methodology to define subgroups, interactions, and hierarchical rank. For the overall population, age > 66 years was the best discriminator between death and survival (sensitivity 0.63/specificity 0.66), followed by congestive heart failure (0.45/0.72), GFR ≤ 10 mL/min/1.73m$^2$ (0.55/0.60), access with a catheter (0.70/0.43), immobility (0.21/0.91) and albumin ≤ 3.2 g/dL. In a classification tree with nodes defined by $Max_{Sn+Sp}$, the first two iterations produced four age bands, ≤ 53, 54-66, 67-76 and > 76 years; within these age bands, the best discriminators between death and survival were catheter use (0.68/0.47), serum albumin ≤ 3.1 g/dL (0.61/0.53), catheter use (0.68/0.47) and catheter use (0.71/0.45), respectively. After four iterations, best discriminators included older age (applicable to subgroups totaling 100% of the study population), catheter use (applicable to 100%), congestive heart failure (applicable to 55.3%), low serum albumin levels (applicable to 53.2%), immobility (applicable to 29.0%), diabetes (applicable to 5.1%) and white race (applicable to 4.8%). Initiation of dialysis with a catheter appears to be the most important modifiable discriminator of mortality within the first year of hemodialysis therapy.

### TH-PO525

**Potentially Modifiable Patient Characteristics and First-Year Hemodialysis (HD) Mortality: Results from the DOPPS** Bruce M. Robinson,[1,2] Jinyao Zhang,[1] Yun Li,[2] Hal Morgenstern,[2] Ronald L. Pisoni,[1] Brian D. Bradbury,[3] Masafumi Fukagawa,[4] Peter G. Kerr,[5] Leslie Ng,[3] Hugh C. Rayner,[6] Friedrich K. Port,[1,2] Rajiv Saran.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Univeristy of Michigan; [3]Amgen, Thousand Oaks, CA; [4]Tokai University, Japan; [5]Monash Medical Centre, Australia; [6]Birmingham Heartlands Hospital, United Kingdom.*

Hemodialysis (HD) patients have especially high mortality risk in the early dialysis period. This study aims to identify the most important potentially modifiable patient characteristics in the first year of dialysis.

We analyzed 5,942 incident HD patients (enrolling within 30 days of first dialysis) in the DOPPS, a prospective cohort study (1996-2004) in 12 countries. Multivariable logistic regression was used to model the odds ratio of first-year mortality by patient characteristics at study enrollment. For categorical exposures, cut-points used were clinically accepted values and/or best fitting functional forms. Attributable fractions (AFs) were calculated from patient-specific predicted risks to estimate the proportion of first-year deaths attributable to each exposure in this population. The AF estimates can be interpreted as the maximum potential impact of eliminating each exposure.

Elevated first-year mortality was associated with older age (p<0.001), non-black race (p =0.04), higher BMI (p =0.05) and 7 of 13 comorbidities (p <0.05). Findings for potentially modifiable patient characteristics are in Table.

| Lab Value or Other Patient Characteristic [1] | Exposure (Reference) | Exposure Prevalence (%) | Odds Ratio (p value) for 1st Year Mortality | Attributable Fraction for 1st Year Mortality (%) |
|---|---|---|---|---|
| Creatinine [2] | < (vs. ≥) 6 mg/dL | 38.8 | 1.47 (<0.0001) | 9.6 |
| Albumin | < (vs. ≥) 3.5 g/dL | 52.6 | 1.38 (0.0007) | 8.2 |
| White blood cells | > (vs. ≤) 10k | 21.3 | 1.61 (<0.0001) | 6.2 |
| Phosphate | >5.5 (vs. 3.5-5.5) mg/dL | 44.2 | 1.28 (0.01) | 4.6 |
| Phosphate | <3.5 (vs. 3.5-5.5) mg/dL | 10.4 | 1.37 (0.01) | 2.0 |
| Ferritin | > (vs. ≤) 500 ng/mL | 15.7 | 1.35 (0.02) | 1.9 |
| Catheter | yes (vs. no) | 56.5 | 1.49 (<0.0001) | 15.6 |
| Systolic blood pressure | < 130 (vs. ≥130) mm Hg | 23.1 | 1.55 (<0.0001) | 7.0 |
| Pre-ESRD nephrology care | no or ≤1month (vs. >1 month) care | 24.4 | 1.41 (0.0001) | 5.4 |
| Residual kidney function (RKF) [3] | no (vs. yes) | 18.0 | 1.47 (0.0002) | 4.5 |

Logistic regression model accounted for facility clustering and adjusted for all variables listed plus age, sex, race, BMI, 13 comorbidities, other labs (below), country, and study phase.
Comparable estimates were found in a Cox model including censored patients.

[1] Potentially modifiable variables with p ≥0.05 for association with 1st year mortality (not shown above) were: hemoglobin, PTH, calcium, and TSAT.

[2] Creatinine (Cr) after starting dialysis; correlation (r) with RKF=0.01

[3] RKF estimated by urine output > 200 mL/day

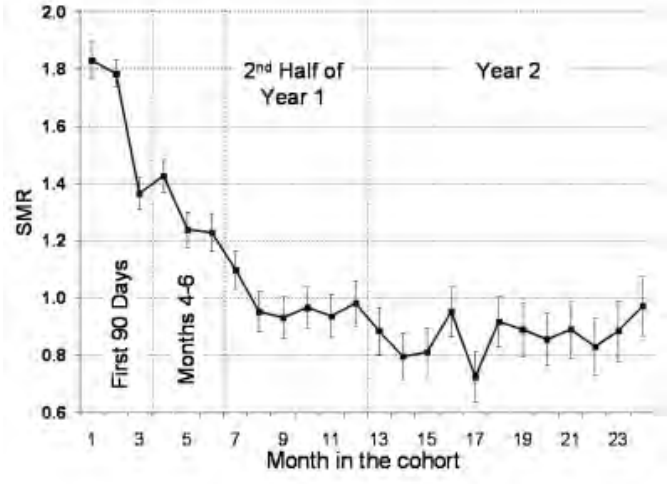
These results indicate that a substantial proportion of the first-year mortality among HD patients could potentially be reduced by addressing modifiable factors. Highest priority targets should include decreasing catheter use and avoiding or treating malnutrition/ inflammation, when possible.

Disclosure of Financial Relationships: Research Funding: The DOPPS is administered by Arbor Research Collaborative for Health and is supported by scientific research grants from Amgen (since 1996), Kyowa Hakko Kirin (since 1999, in Japan), Genzyme (since 2009), and Abbott (since 2009), without restrictions on publications.

## TH-PO526

**Relative Mortality Trends in the First 2 Years among Incident Hemodialysis Patients** Lilia R. Lukowsky,[1,2] Leeka I. Kheifets,[2] Onyebuchi A. Arah,[2] Allen R. Nissenson,[3] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1,2] *[1]Harold Simmons Center, Harbor-UCLA, Torrance, CA; [2]Epidemiology, UCLA, Los Angeles, CA; [3]DaVita, Lakewood, CO; [4]Salem VA MC, Salem, VA.*

**Background:** All-cause mortality among maintenance hemodialysis (MHD) patients is much higher during the first year of initiation of MHD treatment then in subsequent years. We examined the mortality trends during the first 24-months among a group of incident MHD patients. **Methods:** Using data from 524 DaVita clinics (prior to Gambro acquisition) on 21,772 incident MHD patients from who started MHD treatment between 7/2001 and 6/2006 in a DaVita clinic, we calculated the standardized mortality ratio (SMR) [and 95% confidence intervals] using the entire DaVita MHD cohort over the same period (~140,000 MHD patients) as the reference group. We standardized to age, gender, race (whites vs. non-whites), and diabetes status. **Results:** The incident MHD patients had a mean age of 62.5±15.9 years and included 45% women, 24% African Americans and 14% Hispanics. The SMR were the highest during the first several months but decreased after 6 to 8 months and remained relatively stale during year 2. The highest SMR was in the first month [1.82 (1.74 -1.91)], followed by Months 2, 3 and 4 with SMRs of 1.77 (1.69 -1.86), 1.36 (1.27-1.44), and 1.42 (1.37-1.51) respectively. The SMRs for months 12 and 24 were similar and close to unity, i.e., 0.98 (0.89-1.06) and 0.97 (0.88-1.05), respectively.



**Conclusions:** Among incident MHD patients, mortality is up to 80% higher in the first few months, but it declines over the subsequent 6 to 8 months to reaches a relatively steady state by the end of first year. Interventions to improve outcomes during the first 3 to 4 months need to be examined.

Disclosure of Financial Relationships: nothing to disclose

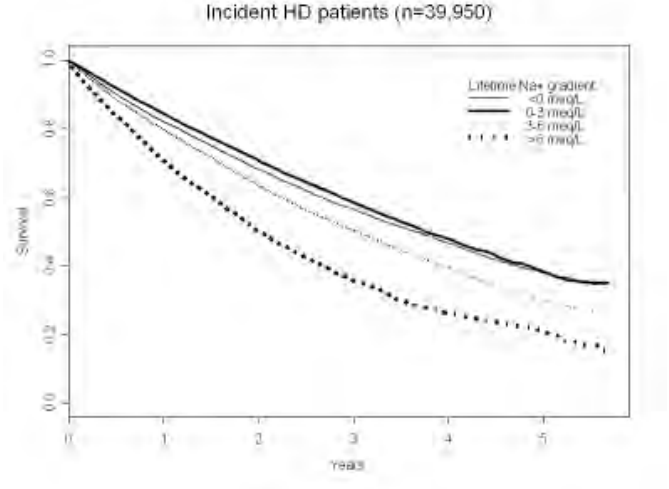
## TH-PO527

**The Relationship of Na+ Gradient and Mortality in Incident Hemodialysis Patients** John Rogus,[1,2] Eduardo K. Lacson,[2] Peter Kotanko,[1] Nathan W. Levin.[1] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care North America, Waltham, MA.*

Objective: To evaluate the impact of Na+ flux during hemodialysis, we examined the relationship of the Na+ gradient (dialysate concentration minus plasma concentration) and mortality. We hypothesized that mortality would be positively correlated with Na+ gradient.

Methods: All 39,950 adult (age >18 years) black/white incident in-center chronic HD patients with Na+ data at Fresenius Medical Care, North America facilities admitted during 2001 — 2004 were included. Deaths and censoring events (i.e., transplant or transfer out of FMCNA) were followed up to December 31, 2006.

Results: Compared to patients with a negative Na+ gradient, those with gradients from 0-3, 3-6, and >6 had hazard rate ratios (HRR) of 0.94 (95%CI: 0.90-0.97), 1.20 (95%CI: 1.15-1.25) and 1.77 (95%CI: 1.68-1.88), respectively (all p<0.001). Similar results were obtained after adjusting for case-mix variables (i.e., age, race, gender, and diabetes status) and after adjusting for case-mix variables plus nutritional status (i.e., baseline albumin).



Conclusion: Our findings are consistent with a hypothesis that higher Na+ gradients may increase mortality, presumably due to outcomes related to fluid overload. However, causality cannot be proven from this observational study and prospective studies are required to test this hypothesis.

**TH-PO528**

**Association between Dependency and Depressive Symptoms with Mortality in Hemodialysis Patients** Joaquin Manrique, Carolina Purroy, Maria Jesus Sorbet, Juan Jose Unzue, Jesus Arteaga. *Nephrology, Hospital de Navarra, Pamplona, Navarra, Spain.*

The presence of depressive symptoms is high in patients on hemodialysis (HD). According to the population ages, their limitations in performing daily activities affect the their well-being as well as increase the burden on caregivers and the use of health services. There are some scales useful to detect depressive symptoms and to define physical dependency useful in HD.

In this prospective study, we measured the proportion of patients undergoing chronic outpatient HD who presented any degree of dependency and/or depressive symptoms and identified the clinical characteristics of this population at most risk. Their dependence were measured by the Barthel scale (BS) performed by nursing HD staff. We assessed it association with presence of depressive symptoms (by Beck Depression score, BDs), and mortality after one year follow-up (Kaplan-Meier survival)

A cohort of 115 patients has been studied and 97 were followed for 12 months. The 44.1% of patients had depressive symptoms assessed by BDs (BDs>or=8). We observed a significant association between BS and BDs ($r=-0.5$; $p<0.001$). Patients with greater disability (Bs<90) had worse depressive score ($p<0.001$). We observed worse nutritional status assessed by albumin and phosphorus in depressive patients compared to non depressive, and lower weight gain ($p<0.05$). Female, diabetic and patients not on waiting list showed higher BDI ($p<0.05$)

After 12 months of follow-up, survival rates were 80.5% for BDs≥8 and 94.3% for BDs < 8 ($p=0.036$), and 71.4% for dependent and 95.5% for no dependent patients ($p<0.001$). Other studies variables, including age, gender, and time on dialysis, were not significantly associated with mortality.

Our study shows that the disability in self-care and the presence of depressive symptoms are common among patients on haemodialysis. Both of them may act as independent risks factors for mortality. Strategies could be helpful to routinely identify those dialysis patients at risk of functional impairment and depression to limit their disabilities. Self-report scales and those performed by nursing staff could improve the integral treatment of those patients

Disclosure of Financial Relationships: nothing to disclose

**TH-PO529**

**The Association of Baseline, New-Onset, and Persistent Depressive Symptoms with Mortality in ESRD Patients** Tessa O. Van den Beukel,[1,2] Marion Verduijn,[1] Elisabeth W. Boeschoten,[3] Raymond T. Krediet,[4] Friedo W. Dekker,[1] Sandra Van Dijk.[5] *[1]Dept. of Clinical Epidemiology, Leiden University Medical Center, Leiden; [2]Dept. of Nephrology, Sint Lucas Andreas Hospital, Amsterdam; [3]Hans Mak Institute, Naarden; [4]Dept. of Nephrology, Academic Medical Center, Amsterdam; [5]Dept. of Medical Psychology, Leiden University Medical Center, Leiden, Netherlands.*

*Introduction*

Among dialysis patients it is suggested that depressed patients have decreased survival compared to those who are non-depressed. The aim of this study is to examine the survival of dialysis patients with depressive symptoms (DS) at baseline only, new-onset DS, and persistent DS compared to patients without DS.

*Methods*

1078 patients participating in the NECOSAD study, a prospective multicenter cohort study of hemodialysis and peritoneal dialysis patients in the Netherlands, completed the SF-36 mental health scale, which was used as a measure of DS, 3 and 12 months after starting dialysis. Cox regression analyses were used to examine survival.

*Results*

After an average of 3.8 years of follow-up 40 percent of the patients had died. Patients with persistent DS had the highest mortality risk, both unadjusted and adjusted for sociodemographic and clinical characteristics (Table 1).

Hazard ratios (HR) for mortality for dialysis patients with depressive symptoms (DS) at baseline only (n=96), new-onset DS (n=98), and persistent DS (n=117) compared to dialysis patients without DS (n=767).

| | Unadjusted | | Adjusted [1] | |
|---|---|---|---|---|
| | HR | 95% CI | HR | 95% CI |
| DS baseline only | 1.47 | 1.07 – 2.03 | 1.37 | 0.97 – 1.93 |
| DS new onset | 1.77 | 1.31 – 2.39 | 1.39 | 1.02 – 1.89 |
| DS persistent | 2.45 | 1.87 – 3.20 | 1.83 | 1.36 – 2.45 |

[1] Adjusted for age, sex, education, marital status, Davies comobidity index, primary kidney disease, dialysis modality, serum albumin, and hemoglobin.

*Discussion*

Among dialysis patients persistent DS are related to an increased mortality risk. In the dialysis population DS may be masked by physical symptoms, because symptoms can be attributed to the renal disease or treatment instead of depression it selves. This may have implications for recognition and treatment of depression.

Disclosure of Financial Relationships: nothing to disclose

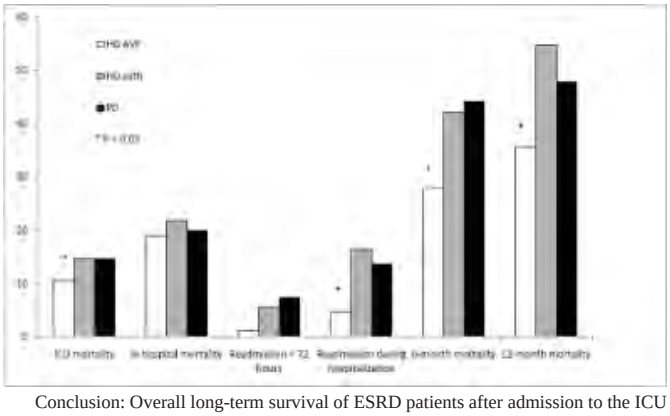
**TH-PO530**

**Long-Term Outcomes of End Stage Renal Disease Patients Admitted to the ICU** Manish M. Sood,[1] Lisa M. Miller,[1] Paul Komenda,[1] Martina Reslerova,[1] Claudio Rigatto.[1] *[1]Nephrology, University of Manitoba, Winnipeg, MB, Canada; [2]Critical Care, University of Manitoba, Winnipeg, MB, Canada.*

Introduction: End stage renal disease (ESRD) patients admitted to the ICU have poor survival and high rates of readmission however little evidence exists on long-term outcomes. We set out to investigate the long-term (6 month and 12 month) survival of ESRD patients admitted to the ICU and whether differential survival could be explained by dialysis modality and vascular access.

Methods: We compared the admission characteristics, outcomes and readmission rates of 619 ESRD (95 peritoneal dialysis (PD), 334 hemodialysis with a catheter (HD CVC), 190 hemodialysis with an AV fistula (HD AVF)) patients admitted to 11 ICU's in Winnipeg, Manitoba, Canada. Parametric and non-parametric tests were used as appropriate to determine differences in baseline characteristics. Multivariable logistic regression was used to assess outcomes between the groups.

Results: The 6 and 12-month crude survival was 62 and 52% respectively. Modality and vascular access were associated with an increased odds ratio of death (6 month: PD OR 2.05, HD CVC OR 1.87, 12-month: PD OR 2.22, HD CVC OR 2.12) compared to patients on HD with an AVF. In 3 different, multivariate adjusted models, this association persisted with odds ratio for death of 2.09-2.62 for PD and 1.83-2.37 for HD CVC.



Conclusion: Overall long-term survival of ESRD patients after admission to the ICU is poor. Being on peritoneal dialysis or being dialyzed with a catheter was independently associated with an increased mortality.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO531**

**All-Cause Mortality in a French Cohort of Incident Hemodialysis Patients from 2007 to 2010: KDOQI vs KDIGO** Denis Fouque,[1] Hubert Roth,[2] Gerard M. London,[3] Thierry P. Hannedouche,[4] Guillaume Jean,[5] Jean-Louis Bouchet,[6] Tilman B. Drueke.[7] *[1]Nephrology, Herriot, Lyon, France; [2]univ Fourier, Grenoble, France; [3]H. Manhes, Fleury Merogis, France; [4]H. Civils, Strasbourg, France; [5]CRAT, Tassin, France; [6]cl. St Augustin, Bordeaux, France; [7]inserm, Amiens, France.*

PhotoGraph is a prospective observational French cohort in CKD-5D patients. We report data from 4018 incident pts followed from July 1 2007 to January 1 2010 using a Cox model, aged 67.3±15.1 yr, sex ratio 1.56 (m/f), 31% diabetic.

Predictors of all-cause mortality

| K/DOQI | HR | 95% CI | p |
|---|---|---|---|
| Phosphorus>5.5 mg/dl | 1.07 | 0.84-1.37 | 0.59 |
| Phosphorus<3.5 mg/dl | 1.24 | 0.95-1.62 | 0.11 |
| PTH>300 pg/ml | 0.75 | 0.58-0.97 | 0.032 |
| PTH<150 pg/ml | 1.09 | 0.85-1.39 | 0.49 |
| Calcium>9.5 mg/dl* | 1.45 | 1.15-1.82 | 0.001 |
| Calcium<8.4 mg/dl* | 1.19 | 0.84-1.67 | 0.32 |
| KDIGO | | | |
| Phosphorus>4.3 mg/dl | 1.06 | 0.84-1.33 | 0.65 |
| Phosphorus<2.8 mg/dl | 1.59 | 1.11-2.28 | 0.012 |
| PTH>585 pg/ml | 1.00 | 0.68-1.47 | 0.99 |
| PTH<130 pg/ml | 1.12 | 0.89-1.42 | 0.33 |
| Calcium>10.2 mg/dl | 1.31 | 0.67-2.57 | 0.42 |
| Calcium<8.6 mg/dl | 0.80 | 0.65-0.996 | 0.046 |
| | | | |
| Phosphate binder (Y/N) | 0.58 | 0.47-0.71 | <0.001 |

models adjusted for age, gender, BMI, diabetes, CVD history, albumin and hemoglobin; *albumin-corrected calcemia

Basal hypercalcemia (KDOQI>9.5 mg/dl) and hypophosphatemia (KDIGO<2.8 mg/dl) were associated with increased mortality, elevated iPTH (KDOQI>300 pg/ml) and hypocalcemia (KDIGO<8.6 mg/dl) with better survival. The different prognosis of calcemia may be explained by correcting (KDOQI) or not (KDIGO) total calcium by albumin. There is a strong independent association between the use of phosphate binders (69% pts received a calcium-based and/or non calcium-based binder) and improved survival. Nutrition, inflammation and anemia were also predictors of mortality. These results from

an up to date cohort highlight the role of modifiable factors with the potential to improve patient outcome, namely optimal management of nutritional status and early start of phosphate binder treatment.

### TH-PO532

**Mortality Patterns and Day of the Week – The United States Renal Data System (USRDS)** Robert N. Foley,[1,2] Allan J. Collins.[1,2] *[1]USRDS Coordinating Center, MMRF, Minneapolis, MN; [2]Medicine, University of MN, Minneapolis, MN.*

Hemodialysis in many countries is delivered on a thrice weekly basis, with intervals of 2 (Monday-Wednesday or Tuesday-Thursday), 2 (Wednesday-Friday or Thursday-Saturday) and 3 (Friday-Monday or Saturday-Tuesday) days between sessions. All things being equal, including configuration of renal replacement therapy (RRT) services, one would expect that deaths in RRT would be equally spaced, with one seventh (14.3%) of all deaths occurring on each day of the week. We hypothesized that asymmetrical spacing of dialysis treatments may have unintended mortality consequences. To address this hypothesis, we examined annual trends from 1980 to 2007 in the proportions of deaths that occurred in RRT patients on different days of the week (1.35 million deaths). Relative deviation from expected proportional mortality for each day of the week was calculated as 100 x (observed percentage of deaths - 14.3)/14.3. In 1980, ranks of relative deviations from expected proportional mortality were as follows +21.1% on Mondays, +4.7% on Fridays, -0.8% on Sundays, -1.4% on Tuesdays, -2.9% on Thursdays -9% on Wednesdays, and -11.5% on Saturdays. Corresponding arrays in 1990, 2000 and 2007 were as follows: 1990 - +9.7% on Wednesdays, +8.3% on Mondays, +1.8% on Tuesdays, +0.2% on Fridays, -3.5% on Saturdays, -5.9% on Thursdays and -10.8% on Sundays; 2000 - +10.5% on Mondays, +3.9% on Tuesdays, -0.7% on Thursdays, -0.8% on Fridays, -1.3% on Wednesdays, - 5.4% on Saturdays and -6.4% on Sundays; 2007 - +7.9% on Mondays, + 3.4% on Tuesdays, + 1.4% on Fridays, +1.0% on Wednesdays, -3.2% on Thursdays, -4.2% on Saturdays and -6.4% on Sundays. The pattern of meaningfully higher mortality on Mondays and Tuesdays and meaningfully lower mortality on Sundays appears to have become established from 1996: mortality was highest on Mondays in every year between 1996 and 2007, second highest on Tuesdays in every year except 1997 (replaced by Fridays), and lowest on Sunday in every year except 1999 (replaced by Thursdays). Day-to-day mortality appears to differ substantially in RRT patients in the US, compatible with the hypothesis that long interdialytic intervals may have adverse consequences.

### TH-PO533

**The Survival of Asian Americans Is Superior to Other Race Groups Receiving Haemodialysis and Peritoneal Dialysis Treatment in the United States: A Trend Analysis from 1995-2006** Austin G. Stack,[1] Catherine A. Wall,[2] Hoang Thanh Nguyen.[3] *[1]Regional Kidney Centre, Letterkenny General Hospital, Letterkenny, Ireland; [2]Renal Department, Adelaide and Meath Hospitals, Tallaght, Dublin, Ireland; [3]University of Texas MD Anderson Cancer Center, Houston, TX.*

Prior studies have demonstrated superior survival of Asian Americans over Whites and African Americans. Whether this survival advantage is present in both peritoneal dialysis (PD) and haemodialysis (HD) and the extent to which these survival differences have changed over time has not been fully explored.

Methods: We compared mortality differences among Asians, Blacks and Whites using data from the US Renal Data System. National incidence data were available on all new patients (N=823,753) between May 1995 and December 2004 and all patients were followed until Oct 2006. Mortality rates over 2 years were compared among race groups (White=referent) across 3 calendar periods (1995-1998, 1999-2001, and 2002-2004) and separately for PD and HD subgroups with the generation of adjusted hazard ratios[1] (HR) 95% Confidence intervals) using multivariable Cox regression analysis. Additional models examined mortality trends for the entire Asian population over 3 calendar periods.

Results: Mortality risks for Asians were significantly lower than Blacks and Whites across 3 calendar periods as shown in table below. Recent cohorts experienced better survival compared with earlier cohorts.

| | Calendar Period | 1995-1998 | 1999-2001 | 2002-2004 |
|---|---|---|---|---|
| | Number | (N=256,575) | (N=278,906) | (N=289,384) |
| | Race Group | | | |

Conclusions: The survival of Asian-Americans who reach end-stage kidney disease and receive dialysis is superior to other race groups and demonstrates a trend of continued improvement. The factors (internal and external) that confer this survival advantage require further exploration.

Disclosure of Financial Relationships: nothing to disclose

**The Influence of Ethnicity on Survival of Incident Dialysis Patients in the Netherlands** Tessa O. Van den Beukel,[1,2] Marion Verduijn,[1] Carl E. H. Siegert,[2] Adriaan Honig,[3] Elisabeth W. Boeschoten,[4] Raymond T. Krediet,[5] Friedo W. Dekker.[1] *[1]Dept. of Clinical Epidemiology, Leiden University Medical Center, Leiden; [2]Dept. of Nephrology, Sint Lucas Andreas Hospital, Amsterdam; [3]Dept. of Psychiatry, Sint Lucas Andreas Hospital, Amsterdam; [4]Hans Mak Institue, Naarden; [5]Dept. of Nephrology, Academic Medical Center, Amsterdam, Netherlands.*

*Introduction*

Ethnic minority patients on dialysis have better survival rates compared to whites. The reasons for this finding are not exactly understood and European studies are limited. This study examined whether ethnic survival differences could be explained by different patient characteristics, and in particular by psychosocial factors.

*Methods*

We analyzed data of the NECOSAD study, an observational prospective cohort study of incident hemodialysis and peritoneal dialysis patients in the Netherlands. Ethnicity was classified as white, black, and Asian according to patients' country of origin. Other data collected at baseline included demographic, clinical, and laboratory characteristics, as well as quality of life (QoL) and depressive symptoms (DS), both determined using the SF-36 questionnaire.

*Results*

1775 patients were white, 45 black, and 108 Asian. Characteristics that were significantly different between the ethnic groups were age, marital status, rGFR, diabetes mellitus, erythropoietin use, hemoglobin, calcium, and the presence of DS. No ethnic differences were found in QoL. Hazard ratios for mortality (HR) for whites compared to blacks and Asians were 3.0 (95 % CI 1.5–5.7) and 1.2 (95% CI 1.0–1.6 ), respectively. After adjustment for a range of potential explanatory variables, including QoL and DS, the HRs were 2.9 (95 % CI 1.4–6.0) and 1.1 (95% CI 0.8–1.6), respectively.

*Conclusions*

This study demonstrates increased survival for black compared to white dialysis patients, and slightly increased survival for Asian compared to white dialysis patients in the Netherlands. Adjustment for demographic, clinical, laboratory, and psychosocial characteristics did not materially influence ethnic survival differences, despite significant differences in baseline characteristics between ethnic groups.

**Racial Disparities in ESRD Outcomes for African Americans with Diabetes Mellitus: USRDS Data** Mark E. Williams,[1] Gurprataap Singh Sandhu,[2] Alexander S. Goldfarb-Rumyantzev.[2] *[1]Renal Unit, Joslin Diabetes Center, Boston, MA; [2]Renal Division, Beth Israel Deaconess Medical Center, Boston, MA.*

Eliminating racial health disparities is a national health objective for 2010. Racial disparities in the prevalence of kidney disease are well-known, and African American (AA) with diabetes (DM) have a 4X excess burden of ESRD in the U.S. AA maintenance hemodialysis patients have greater survival compared to other races, and unadjusted USRDS data indicate that AA survival advantage with diabetes as primary cause of ESRD increases with time on dialysis. We analyzed USRDS data for all incident and prevalent dialysis (HD and PD) patients with the diagnosis of DM from 1990 to 2007 using a classic Cox model analysis adjusted for age, comorbidities, duration of nephrology care, ESRD cause, access type, education level, serum albumin, hemoglobin, dialysis type, and BMI. Data were also analyzed without and with HgbA1c as a variable. Parameters affecting the mortality hazard

ratios included age, Charlson comobidity index, dialysis type, serum albumin and creatinine, education index, and race. The mortality hazard ratio for AA was .73 compared to whites (W). Statistics for major cause of death by race (Cardiac: AA 51%, W 54%; Infection: 18% AA, W 14.5%; Cerebrovascular: AA 6%, W 5%; Malignancy AA 4%, W 3%) differed by chi-square analysis (<.001). AA with DM and ESRD have reduced mortality on dialysis, and the disparity appears to equal or exceed that of the general USRDS dialysis population. Longitudinal data are needed to further analyze this finding.

Disclosure of Financial Relationships: nothing to disclose

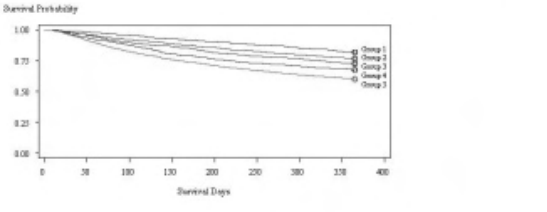
### TH-PO536

**Incident Arteriovenous Fistula (AVF) and Associated Mortality: A Comparison of Medicare Claims and CMS-2728 Data** Eiichiro Kanda,[1] T. Christopher Bond,[1] Jenna O. Krisher,[2] William M. McClellan.[1] *[1]Epidemiology, Rollins School of Public Health, Emory University, Atlanta, GA; [2]ESRD Network 6, Raleigh, NC.*

**Background and Objectives:** The Centers for Medicare & Medicaid Services (CMS) 2728 are used to develop quality improvement interventions. We compared the predictive validity for mortality of an incident AVF on the CMS-2728 (2728-AVF) or from Medicare claim (Med-AVF).

**Methods:** Data was collected for patients beginning hemodialysis between June 1, 2006 and May 31, 2007 in North Carolina, South Carolina and Georgia (ESRD Network 6); 10,401 patients (aged 66 years and older). Patients were followed for one year after beginning hemodialysis. Incident AVF was categorized as: Group 1, yes 2728-AVF and yes Med-AVF (881, 8.5%); Group 2, either 2728-AVF or maturing AVF and no Med-AVF (1138, 10.9%); Group 3, maturing 2728-AVF and Med-AVF (837, 8.1%); Group 4, no 2728-AVF or maturing 2728-AVF and yes Med-AVF (1163, 11.2%); Group 5, no 2728-AVF and no Med-AVF (6382, 61.4%). Mortality was evaluated by adjusted Cox Proportional Hazard Model (PHM). Race was included in analyses as a variables that predict health care quality and outcomes, such as access to care and differential treatment. **Results:** The mean age was 76.0; 41.2% diabetes; 52.0% male; 67.5%, black; a history of myocardial infarction 30.7%; and cerebrovascular disease 13.9%. Mortality was 34.5% (18.2% (Group 1) to 40.0% (Group 5)). Higher survival was noted for Groups 1, 2 and 3 who had a 2728-AVF or maturing AVF (p<0.0001).

Figure 1 Survival Probability Associated with Incident AVF Placement Persons diagnosed as ESRD in Network 6 area (6/1/06-5/31/07)



| Group | AVF Status per 2728 (2728-AVF) | AVF Status per Medicare Billing (Med-AVF) |
|---|---|---|
| 1 | Yes-in place | Yes-in place |
| 2 | Yes-in place or maturing | No |
| 3 | Yes-maturing | Yes-in place |
| 4 | No | Yes-in place |
| 5 | No | No |

The hazard ratio (HR) (95% confidential interval [CI]) for groups 1 to 4 compared to Group 5 were: 0.59 (0.48-0.71); 0.60 (0.53-0.69); 0.80 (0.69-0.92); 0.92 (0.82-1.0). **Conclusion:** The association between mortality may be stronger for incident access measured by 2728-AVF than for Med-AVF and supports use of 2728 data for quality assurance activities by the Networks.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO537

**Circulting Cell Free DNA (CFD) in Hemodialysis (HD) Patients Is Associated with Risk Factors and Mortality** David Tovbin,[1] Moshe Zlotnik,[1] Amir Abd Elkadir,[3] Jony Sheynin,[3] Amos Douvdevani.[2] *[1]Nephrology, Soroka Medical Center; [2]Nephrology Lab, Soroka Medical Center; [3]Biomedical Engineering, Ben-Guriun University of the Negev, Beer-Sheva, Israel.*

Circulating cell-free DNA (CFD) is present in healthy individuals and increases in hemodialysis (HD) and in various disorders including inflammation and diabetes (DM), which are important risk factors in HD patients. We hypothesized that CFD is an integrative marker of damage and thus has prognostic value. Therefore, we assessed CFD in HD patients and its relation to clinical/laboratory parameters and prognosis. In a prospective study, 31 chronic HD patients with no acute disease were evaluated for serum CFD levels before and after HD, using the reported rapid non-cumbersome inexpensive fluorometric assay developed in our laboratory. Follow-up CFD levels were assessed at 18 months in 20 patients. Pre-HD-CFD levels were higher than in healthy subjects (582±305 Vs 431± 221 ng/ml, p<0.05) and increased after HD (832±296 ng/ml, p<0.01). Post-HD CFD were high (>850 ng/ml) in 35% of patients and at 18 months in 80%, with 47% increase in levels (p<0.0001). Post-HD-CFD was higher in the DM subgroup (1004±278 Vs 737±268 ng/ml in non-DM, p<0.05), correlated positively to post-HD interleukin-6 (IL-6) levels (p<0.05, r=0.51) and negatively to creatinine (p<0.01,r=-0.54). No correlation was found with serum albumin, urea, glucose, hemoglobin, leukocyte count and dialysis-related parameters. Pre-HD-CFD levels correlated with neutrophil number (p<0.05, r=0.36), but showed less prominent correlation then post-HD-CFD for other parameters. Post-HD-CFD was positively correlated with death at one year (p<0.01, r=0.46) and 5/6 patients who died within one year had elevated CFD levels. Conclusions: CFD in HD patients is associated with diabetes, inflammation, low muscle mass reflected by serum creatinine and mortality. The increase after HD and the stronger associations with post–HD levels suggest combined effect of patients' state and the dialysis process. We suggest that CFD is an integrative marker of pathologic processes and a correlate of outcome. Its' detection is a cheap applicable tool for identifying patients at risk and follow up.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO538

**N-Terminal Pro-B-Type Natriuretic Peptide and Interleukin-6 Associate Synergistically in Increasing the Risk of Mortality in Maintenance Hemodialysis Patients** Hirokazu Honda,[1] Keiko Takahashi,[2] Tetsuo Michihata,[3] Hiroaki Ogata,[4] Fumihiko Koiwa,[5] Eriko Kinugasa,[4] Kanji Shishido,[2] Tadao Akizawa.[1] *[1]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; [2]Kawasaki Clinic, Kawasaki, Japan; [3]Ebara Clinic, Tokyo, Japan; [4]Department of Internal Medicine, Showa University Northern Yokohama Hospital, Yokohama, Japan; [5]Division of Nephrology, Department of Medicine, Showa University Fujigaoka Hospital, Yokohama, Japan.*

INTRODUCTION AND AIMS: N-terminal pro-B-type natriuretic (NT-proBNP) and interleukin (IL)-6 are risk factors for cardiovascular disease (CVD), protein-energy wasting (PEW) and mortality in prevalent hemodialysis (HD) patients. Aim of the study was to estimate the predictive ability of NT-proBNP and interleukin-6 for CVD, PEW and mortality in those patients.

METHODS: Blood samples were obtained from 383 prevalent HD patients (mean age 65 year, men 63%, diabetes mellitus state (DM) 32%) measuring high-sensitive (hs) CRP, IL-6 and NT-proBNP for this prospective cohort study. PEW was defined by subjective global assessment (SGA). Clinical CVD was ascertained from hospital record. After baseline estimation, patients were followed for 36 months.

RESULTS: NT-proBNP was correlated with BMI (rho -0.27, p<0.0001), hsCRP (rho 0.18, p=0.0005), IL-6 (rho 0.26, p<0.0001). Receiver operative characteristics curves showed that predictive values of NT-proBNP and IL-6 for CVD were similar, however, NT-proBNP was fair and more accurate predictor for PEW than IL-6. In four combined NT-proBNP and IL-6 groups classified according to the median values, prevalence of CVD and PEW was higher in the group with high NT-proBNP and high IL6 than in other groups. Kaplan-Meier analysis demonstrated that patients with high NT-proBNP and high IL6 exhibited a higher all-cause mortality (Long-rank $\chi 2$=18.1, p=0.0004). This finding was also confirmed by Cox hazard model adjusted for confounders (HR: 2.28, 95% confidence interval: 1.00 to 5.91, p<0.05).

CONCLUSIONS: High NT-proBNP together with high IL-6 compared to elevated NT-proBNP or IL-6 alone might be strong predictor for mortality in prevalent HD patients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO539

**Red Blood Cell Macrocytosis: A Novel Marker of Survival in Stable Hemodialysis Patients** Karthik K. Tennankore, Steven D. Soroka, Bryce A. Kiberd. *Department of Medicine, Division of Nephrology, Dalhousie, Halifax, NS, Canada.*

BACKGROUND: Red blood cell macrocytosis is a common finding in chronic hemodialysis (CHD) patients; however its significance is unknown. We analyzed the prevalence, distribution, associations and impact on survival of macrocytosis in stable CHD patients.

METHODS: We studied 150 CHD patients at our center. Patients were excluded if they received a blood transfusion within two months or were inpatients at the time of study. Macrocytosis was defined as a mean cellular volume (MCV) > 97 fl averaged over 3 months. All patients were on folate supplementation.

RESULTS: The mean MCV was 99.1+/- 6.3 fl, (range 66-120 fl). MCV was normally distributed. 92 (61%) patients had an MCV > 97 fl, 70 (47%) > 99 fl, 45 (30%) > 102 fl and 24 (16%) > 105 fl. Patients were not B12 or folate deficient. Five patients were on antiepileptic medication.

In a logistic regression analysis, both MCV >102 and >105 fl were associated with older age, antiepileptic use and higher ratios of darbepoeitin alpha dose/(kgBW*hemoglobin). There were 18 deaths at six months in the study. Both mean MCV >102 fl and >105 fl were associated with a statistically significant increase in all cause mortality (log rank p=0.002 and <0.001, respectively).

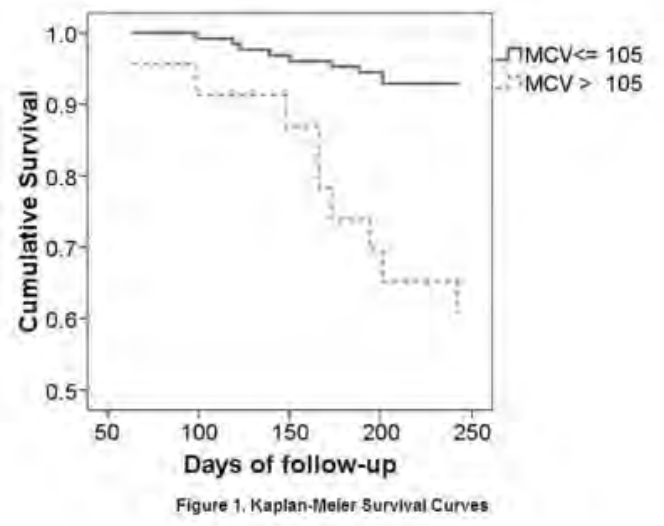


Figure 1. Kaplan-Meier Survival Curves

There was a trend for increased mortality in patients with an MCV > 99 fl (log rank p = 0.067). Adjusting for age, duration of HD, gender, comorbid conditions (diabetes, coronary artery disease, stroke, peripheral vascular disease), HD access, urea reduction ratio, darbepoeitin alpha dose, mean hemoglobin, albumin and ferritin, an MCV > 105 fl was associated with increased mortality (HR 6.13, 95% CI 2.10-17.89 p = 0.01).

CONCLUSION: Macrocytosis may be a novel independent predictor of mortality in stable CHD patients. A longer duration of follow-up will be necessary to confirm this association.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO540

**Neutrophil-to-Lymphocyte Ratio: A Novel Predictor of Survival in Chronic Hemodialysis Patients?** Georges Ouellet,[1,2] E. Lars Penne,[1,2] Len A. Usvyat,[1] Stephan Thijssen,[1,2] Nathan W. Levin,[1,2] Peter Kotanko.[1,2] *[1]Renal Research Institute; [2]Beth Israel Medical Center, New York.*

Neutrophil-to-lymphocyte ratio (NLR), defined as the neutrophil count divided by lymphocyte count, is increasingly recognized as a marker of systemic inflammation and as a prognostic factor for survival in the cardiologic and oncologic literature. Its prognostic value in chronic hemodialysis (CHD) patients is unknown. We aimed to study NLR as a predictor of survival in this population.

Incident CHD patients at RRI clinics between 1/1/2001 and 7/31/2008 were studied. Causes of death were classified as cardiovascular (CV), infection-related (INF), or other. NLR was measured 90 days after dialysis initiation. Patients were stratified in NLR tertiles (T1 to T3). Cox regression analysis was performed with age, gender, race, diabetic status, serum albumin, epoetin resistance index (ERI), NLR and vascular access type as covariates.

We analyzed data from 3707 patients (mean age 61±15 years, 55% male, 48% Black, 52% diabetics, 52% fistulas, 22% grafts, 27% catheters). Median NLR was 3.1 (IQR 2.1 to 4.5). NLR > 3.9 was a significant predictor of mortality in 3 adjusted models (Table 1). Patients in the highest NLR tertile (≥3.9) were at increased risk of death for CV (HR=1.40; 95% CI: 1.14-1.71; P=0.001) and INF (HR=1.70; 95% CI: 1.15-2.50; P=0.008) causes.

Table 1. Cox regression models of NLR and overall mortality

| | NLR tertile | HR | 95% CI | | P value |
|---|---|---|---|---|---|
| Model 1: Adjusted for age, sex, race and diabetic status | T2 | 1.24 | 1.06 | 1.46 | 0.009 |
| | T3 | 1.71 | 1.45 | 2.00 | <0.001 |
| Model 2: Model 1 + serum albumin | T2 | 1.20 | 1.02 | 1.40 | 0.03 |
| | T3 | 1.47 | 1.25 | 1.73 | <0.001 |
| Model 3: Model 2 + ERI and vascular access | T2 | 1.15 | 0.98 | 1.35 | 0.1 |
| | T3 | 1.40 | 1.20 | 1.65 | <0.001 |

T1: NLR< 2.42; T2: 2.42≤NLR<3.90; T3: NLR≥3.90; reference group: T1

This study identifies NLR as a novel and robust predictor of all-cause mortality in incident CHD patients. A NLR greater than 3.9 is associated with an increased risk for CV and INF causes. NLR is an inexpensive and readily available marker that may help to identify incident CHD patients with increased risk of death.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO541

**Relationship of Body Size and Blood Pressure: Impact on Survival in Incident Hemodialysis Patients** Olga Sergeyeva, Len A. Usvyat, Nathan W. Levin, Peter Kotanko. *RRI, NY, NY.*

**Background:**

In hemodialysis(HD) patients (pts) survival improves with body size. Here we explore the relationship between survival, weight and blood pressure (BP).

**Methods:**

All RRI in-center HD patients (pts) who started HD btw Jan 1, 2000 and Jan 2009 with at least 13 txts were studied. Pts' pre-HD systolic (preSBP) and diastolic (preDBP) BP were recorded per txt in the 1st year of HD. preSBP, post-HD weight (postWt) and pulse pressure as % of preSBP (prePPP = 100%*[preSBP - preDBP]/ preSBP) were averaged over the first 30 days; the individual linear slope of preSBP change ($preSBP_{slope}$) was computed over the first year.

Pts were stratified in quartiles (Qt) of postWt: Qt 1 (<63kg), 2 (63-74kg), 3 (74-88kg), 4 (>74kg) and by $preSBP_{slope}$: increased>1mmHg/month; decreased>1mmHg/month; stable: change ± 1mmHg/month.

**Results:**

7077 pts were included (56% male, 53% white, 39% black, 53% diabetic, age [SD]: 62.2 [15.8] years). Pts in postWt Qt 1 had the lowest preSBP and highest prePPP; no significant differences btw $preSBP_{slope}$ were observed although the slope was more positive in higher postWt Qt. Low preSBP, declining preSBP and high prePPP were associated with poorer survival.

Cox proportional hazards models with PreSBP, prePPP, SBP slope, and PostWt Qt adjusted for age, gender, race, and DM status were constructed. PostWt Qt remained a significant predictor of survival (HR [95%CI]: Qt 1: 1.34 [1.08-1.70], Qt 2: ref. group, Qt 3:0.74 [0.57-0.96], Qt 4:0.63 [0.47-0.84].

| Post Wt Qt | Avg preSBP [mmHg] | Avg prePPP [%] | Avg preSBP Slope [mmHg/yr] |
|---|---|---|---|
| 1 | 145.7 | 48.2 | 0.856 |
| 2 | 147.6 | 47.8 | 0.335 |
| 3 | 146.8 | 47.6 | 2.856 |
| 4 | 148.6 | 47.3 | 2.68 |

| significant differences observed | 1 & 2; 1 & 4 | 1 & 3; 1 & 4 | none |
|---|---|---|---|

| | preSBP<120 | | preSBP>150 | |
|---|---|---|---|---|
| Post Wt Qt | HR | p-value | HR | p-value |
| 1 | 1.26 | 0.41 | 1.57 | 0.02 |
| 2 | ref | 1 | ref | 1 |
| 3 | 0.96 | 0.82 | 0.59 | 0.04 |
| 4 | 1.03 | 0.94 | 0.60 | 0.12 |

In pts with preSBP<120 mmHg survival did not differ between PostWt Qt. However, in pts with preSBP>150 mmHg, survival was less in smaller compared to larger pts.

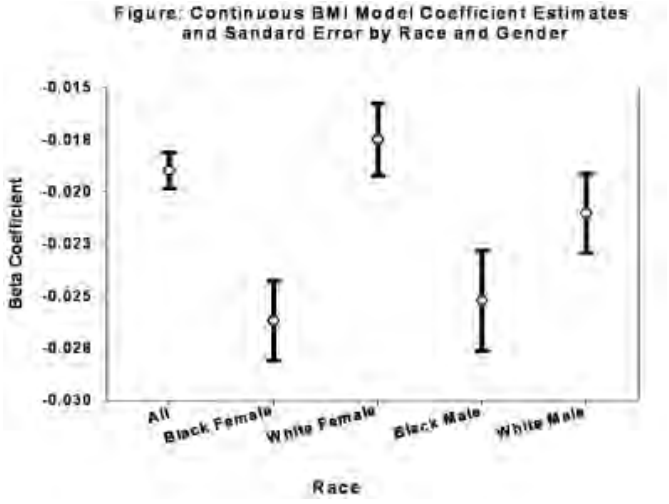
**Conclusion:** The overall beneficial effect of larger size on survival disappears in pts. with systolic BP<120mmHg. In pts with SBP>150 mmHg the benefit of larger body size was still evident. Body size remains a critical determinant of survival.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO542

**Racial and Gender Differences of the Survival Advantage of Obesity in Maintenance Hemodialysis Patients** Joni L. Ricks,[1] Csaba P. Kovesdy,[2] Joel D. Kopple,[1] Keith C. Norris,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor -UCLA, Torrance, CA; [2]Salem VA MC, Salem, VA; [3]King-Drew School of Medicine, Los Angeles, CA.*

**Background:** High body mass index (BMI) is associated with lower death risk in maintenance hemodialysis (MHD) patients, among whom African-Americans (AA) have superior survival. It is not known whether the survival advantage of high BMI differ across race and gender. **Methods:** In the cohort of 122,869 MHD patients including 39,090 AAs and 53,098 Whites from all DaVita dialysis clinics between 7/2001 to 6/2006 with survival follow-up till 6/2007 Cox survival regression models were examined across race and gender strata including after adjustment for case-mix and malnutrition-inflammation complex syndrome (MICS). **Results:** Among AA and White men and women, the mean BMI values were 26.6, 28.1, 26.4 and 27.1 kg/m$^2$, age (mean±SD) was 55.8±4.6, 59.8±15.1, 65.2±15.2, and 65.8±14.9yrs old and 39%, 49%, 41%, and 45% diabetic, respectively. Across all 4 groups, higher BMI was associated with better survival rates. Overall, for each 1 kg/m$^2$ rise in BMI there was approximately 1.9% improvement in mortality. Within race and gender strata, the survival advantage of 1 kg/m$^2$ higher BMI was the largest among AA women (2.6%) and AA men (2.5%), whereas lower survival benefit was observed in white men (2.1%) and white women (1.7%) (See Figure).



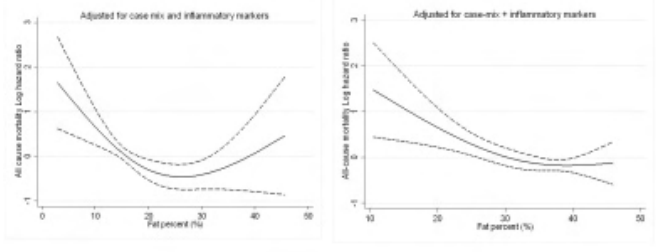
**Conclusions:** Survival advantage of obesity is most prominent among AA men and women and the weakest among White women. The racial and gender differences of obesity paradox deserve further investigations.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO543

**Gender Differences in the Survival-Predictability of Lean vs. Fat Mass in Maintenance Hemodialysis Patients** Nazanin Noori,[1] Ramanath B. Dukkipati,[1] Rachelle Bross,[1] Antigone Oreopoulos,[2] Deborah A. Benner,[3] Joel D. Kopple,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]Univ . Alberta, Edmonton, AB, Canada; [3]DaVita, Lakewood, CO.*

**Background:** Larger body size is associated with greater survival in maintenance hemodialysis (MHD) patients. However, it is not clear whether lean body mass (LBM) or fat mass (FM) are equal predictors of survival in men and women. **Methods**: In 732 MHD patients we categorized men (n=391) and women (n=341) separately into four quartiles of Near-infrared (NIR) measured LBM and FM. Cox proportional models were used to estimate death hazard ratios (HR) [and 95% confidence intervals (95%CI)] after adjustment for case-mix over 5 years (2001-06). **Results:** In women the highest quartiles of FM, FM% and LBM were all associated with greater survival: HR=0.38 (0.20-0.71), 0.57 (0.32-1.03) and 0.34 (0.17-0.67), respectively. In men the highest quartiles of FM and FM%, but not LBM, were associated with lower mortality: HR=0.56 (0.27-0.96), 0.45 (0.23-0.88) and 1.17 (0.60-2.27), respectively. Figure compares cubic spline survival models in men and women.



**Conclusions:** In MHD patients higher fat mass in both genders and higher lean mass in women appear protective. The gender differences of body composition and their impact on survival warrant additional studies.

### TH-PO544

**Association of Malnutrition and Mortality in Hemodialysis Patients: 5-Year Prospective Cohort Study** Yoshihiko Kanno,[1] Tsuneo Takenaka,[2] Tadashi Yoshida,[1] Matsuhiko Hayashi,[1] Hiromichi Suzuki.[2] *[1]Apheresis and Dialysis Center, Keio University, School of Medicine, Tokyo, Japan; [2]Department of Nephrology, Saitama Medical University, School of Medicine, Iruma, Saitama, Japan.*

346 Japanese patients receiving hemodialysis were followed up for 5 years according to their status on dietary intake. Their mean age at registration was 62 ± 11, mean age of history on hemodialysis was 10 ± 6 years, and 32.9% of them had diabetes mellitus. The status of dietary intake was assessed using self-administered diet history questionnaire (DHQ) with dietician interview. At the end of 5-year observation, 313 of 346 patients were completed the study protocol. Total survival was 78.2% (male 76.0%, female 81.4). The patients were divided into 3 groups according to the event during the study period; Death by any reason [D], Admission by any reason [A], No event [N]).

Dietary intake at the start of the study.

| | | Energy (kcal/kg) | Protein (g/kg) | Salt (g) | Phosphate (mg) |

| | Male | 24.4±7.9 | 0.78±0.26 | 5.0±2.7 | 666±243 |
| | Female | 27.0±10.1 | 0.99±0.47 | 5.9±3.0 | 726±352 |
| Total | Total | 27.3±8.8 | 0.91±0.34 | 5.8±2.9 | 738±272 |
| | Male | 26.5±8.5 | 0.87±0.31 | 5.9±3.0 | 743±268 |
| | Female | 28.4±9.1 | 0.99±0.37 | 5.8±2.7 | 731±280 |

As shown in table. Dietary intake of energy, protein and salt were significantly lower in D group compared with A and N groups. As food material, intake of meat and animal fat were also significantly lower in D group than other two groups. It is suggested that shortage of calorie and protein intake may result in malnutrition and can be a predictor of prognosis of dialysis patients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO545

**Impact of Seropositivity for Hepatitis C Virus Core Antigen on Long-Term Mortality in Patients on Maintenance Hemodialysis** Akihiko Kato,[1] Hideo Yasuda,[2] Hiroyuki Suzuki,[2] Yoshihide Fujigaki,[2] Tatsuo Yamamoto,[3] Akira Hishida.[2] *[1]Division of Blood Purification, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; [2]First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; [3]Faculty of Health Promotional Sciences, Department of Health and Nutritional Sciences, Hamamatsu University, Hamamatsu, Shizuoka, Japan.*

Serological status positive for anti-HCV antibodies (HCV-Ab) is independently associated with poor prognosis in hemodialysis (HD) patients. However, HCV-Ab cannot distinguish between patients with active infection and those who have recovered from infection. Although measurement of HCV core antigen (HCVcAg) is shown useful to detect active HCV infection, there was no study to assess the impact of HCVcAg seropositivity on clinical outcomes in HD patients. In this study, we measured serum HCVcAg using an immunoradiometric assay (IRMA) in 405 HD patients (age: 63±13 years, time on HD: 126±104 months), and examined whether HCVcAg seropositivity is associated with mortality during the 93-month follow-up. There were 82 (20.2%) patients who had been positive for HCV-Ab, and 57 (69.5%) of them had been positive for HCVcAg. A significant increase was found in serum ALT (21±10 vs. 10±6 IU/L, p<0.01) and AST (19±9 vs. 13±8 IU/L, p<0.01), while there was a significantly lower level of platelet count (14.8±4.7 vs. 19.5±6.7 x$10^4$/μL, p<0.01) in patients positive for HCVcAg when compared with those for negative. During the follow-up, 113 (39.1%) out of the 289 patients who had been younger than 75 years old had expired, 57 out of them were due to non-cardiovascular (non-CV) causes. Univariate Cox hazards analysis revealed that HCVcAg seropositivity was associated with total (hazards ratio (HR): 1.67 [1.07-2.59], p<0.03) and non-CVD death (HR: 2.24 [1.24-4.02], p<0.01). After adjusting for co-morbid parameters, HCVcAg was also associated with total (HR: 1.81 [1.08-3.03], p<0.03) and non-CV mortality (HR: 2.12 [1.11-4.06], p<0.03). It follows from these findings that HCVcAg seropositivity is more sensitive to identify persistent HCV infection, and associated with long-term mortality in HD patients.

Disclosure of Financial Relationships: nothing to disclose

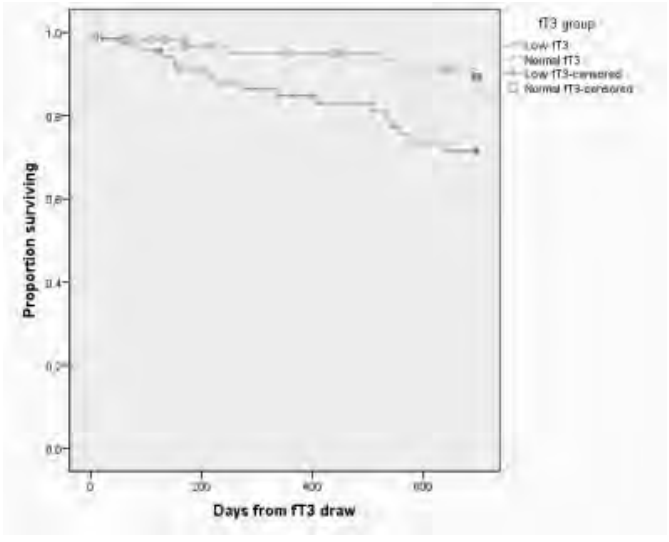
### TH-PO546

**Free and Total Triiodothyronine Levels and 2-Year Survival in Chronic Hemodialysis (HD) Patients** Rebecca Apruzzese,[1] Sudhi Tyagi,[1] Anja Kruse,[1,3] Georges Ouellet,[1,2] Laura Rosales,[1] Len A. Usvyat,[1] Mary Carter,[1] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]RRI, NYC; [2]Beth Israel Medical Center, NYC; [3]Bern University Hospital, Bern.*

Background: Low levels of total (T3) and free (fT3) triiodothyronine are independent predictors of mortality in White chronic HD patients (pts) (Zoccali, 2006; Carrero, 2007). This study aimed to examine the relationship between survival, T3 and fT3 in Black and Non-Black US HD pts.

Methods: Cross-sectional T3 and fT3 samples were obtained pre-HD from pts in 1 NYC RRI clinic, June 2008. 1.5 yr followup fT3 sampling was done on a subset of original cohort and compared by paired T-Test. T3 and fT3 were measured by direct chemiluminescence (T3:ADVIA T3 Lite Reagent and Solid Phase; fT3: ADVIA Centaur assay). Pts were stratified by levels of fT3 (low > 2.3; normal - 2.3-4.2pg/ml). T3 was analyzed as a continuous variable because 98.7% of the data were in the normal range. Survival was analyzed with the Kaplan-Meier method and Cox proportional hazard model adjusted for race, gender, diabetes, age, and vintage.

Results: We studied 155 pts (age 61±15 yrs (mean±SD); HD mean vintage 3.76±3.8; 52% male; 39% diabetics; 62% black. 1.5 yr follow-up fT3 data for 33 pts did not differ significantly from baseline. Kaplan-Meier analysis showed reduced 2 yr survival in pts with low fT3 (P=0.015; log-rank test). In multivariate Cox analysis normal levels of fT3 predicted improved survival (HR 0.38 [95% CI 0.15 to 0.96], P= 0.042). T3 showed borderline significant associations with survival (HR 0.21 [95% CI 0.04 to 1.05], P=0.057). No differences between Blacks and Non-Blacks were observed.



Conclusion: Results show low fT3 levels are associated with poor survival in a diverse cohort of US HD pts corroborating findings obtained in Whites. fT3 levels did not significantly change over 1.5 yrs, rendering it a valuable predictor of survival.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO547

**Increased Rate of Hospitalization in Adult Patients with ESRD Secondary to Systemic Lupus Erythematosus (SLE)** Sangeeta D. Sule,[1] Barbara A. Fivush,[1] Alicia M. Neu,[1] Susan L. Furth.[2] *[1]Pediatrics, Johns Hopkins Univ, Baltimore, MD; [2]Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA.*

**Background:** To assess whether the risk of hospitalization is higher in patients with ESRD secondary to SLE compared to patients with ESRD secondary to other causes.

**Methods:** Data from the United States Renal Data Systems (USRDS) 2004 Hospitalization File were used to compare hospitalization rates among pediatric (age < 19 yrs) and adult patients who initiated dialysis between Jan 1, 2000 through Dec 31, 2004. Patients were censored at transplant or the end of follow-up. Hospitalization rate ratios were compared by Poisson regression.

**Results:** 9935 patients were included in the analysis. There was an increased prevalence of female and Black race patients in those with SLE (Table 1). Pediatric patients with SLE had a trend toward higher rate of hospitalization, although it did not reach statistical significance (IRR: 1.2, 95% CI: 0.9-1.5). Despite being much younger (mean age 40 vs 58 yrs (p<0.001), adult patients with SLE were hospitalized more frequently than adults with other causes of ESRD (IRR: 1.3, 95% CI: 1.2-1.4). The most frequent reason for hospitalization for adult patients with SLE was cardiovascular disease (myocardial disease) and malignant hypertension.

Table 1

| | SLE causing ESRD | | Other Causes of ESRD | |
|---|---|---|---|---|
| | Peds N=64 | Adults N=134 | Peds N=948 | Adults N=8189 |
| Mean Age (years [SD]) | 16 [2.5] | 40 [14.8] | 13.6[4.9] | 58 [15.6] |
| % Black Race | 66 | 55 | 35 | 38 |
| % Female | 79 | 83 | 44 | 47 |
| Hospitalization Rate Ratio | 1.2 | 1.3 | -- | -- |

**Conclusions:** Although pediatric patients with SLE do not have a significantly increased risk of hospitalization, this data supports that adult patients with SLE do. It will be important to understand the impact of cardiovascular disease in both the pediatric and adult population with SLE and its impact on morbidity and hospitalization risk.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO548

**Risks of All Malignancies, Liver, Kidney, and Urinary Tract Cancers before and after Dialysis in ESRD Patients – Data from Taiwan National Health Insurance** Shang-Jyh Hwang,[1,2] Ming-Yen Lin,[1] Li-Tzong Chen,[3] H. C. Chen.[1,2] *[1]Division of Nephrology, Kaohsiung Medical University Hospital, Taiwan; [2]Faculty of Renal Care, College of Medicine, Kaohsiung Medical University, Taiwan; [3]National Health Research Institute, Taiwan.*

**Background:** We aimed to estimate the risks of malignancies for dialysis patients in period before and after dialysis.

**Method:** Patients initiating dialysis over 90 days in 1997-2004 from National Health Insurance is considered as dialysis group (DG) and matching Control group (CG), was from general populations, by birth year and sex. Time was backward and forward calculated from the dialysis date to the first date of malignancies diagnosed or first of 1997 and Sept. 30 of 2004. Cox regression model was used and two sides p value less than 0.05 was considered as significant.

**Results:** The risks of all malignancies, liver cancer, renal cancer, transitional cell carcinoma, upper urinary tract cancer, and bladder cancer were higher in DG group than in CG group,in periods before and after dialysis.

Table 1. Hazard ratios of various malignancies in dialysis group compared to control group before and after dialysis

| Sites (ICD9 code) | Before dialysis | | After dialysis | |
|---|---|---|---|---|
| | Hazard Ratio (95% CI) | p-value | Hazard Ratio (95% CI) | p-value |
| All malignancy (140-208) | 2.25 (2.09, 2.43) | <0.001 | 1.66 (1.57-1.75) | <0.001 |
| Liver cancer (155) | 2.06 (1.61, 2.62) | <0.001 | 1.78 (1.54-2.07) | <0.001 |
| Renal cancer ( 189 or 189.0) | 11.91 (5.54, 25.61) | <0.001 | 9.65 (6.22-14.99) | <0.001 |
| Transitional cell carcinoma (188 or 189.1, 189.2) | 5.73 (4.72, 7.96) | <0.001 | 7.74 (6.04-9.92) | <0.001 |
| Upper urinary tract cancer (189.1 or 189.2 ) | 15.79 (6.44-38.71) | <0.001 | 10.78 (6.35-18.28) | <0.001 |
| Bladder cancer (188) | 4.47 (3.13-6.40) | <0.001 | 7.16 (5.41-9.47) | <0.001 |

Full Model adjusted by age, sex, dialysis year, and geographic.

**Conclusions:** The study demonstrates that dialysis ESRD patients had higher risks of malignancies than the general populations even before dialysis.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO549

**Factors That Determine Survival in Patients with Multiple Myeloma Who Receive Dialysis** Rebecca Jane Roberts,[1] Dominic Summers,[2] Murugan Sivalingam,[1] Ken Farrington.[1] *[1]Nephrology, Lister Hospital, United Kingdom; [2]Department of Surgery, Addenbrooke's Hospital, United Kingdom.*

Registry data indicate that patients with end stage renal failure and multiple myeloma have a median survival of approximately 11 months. However some patients exceed survival expectations and may live several years. Early recognition of factors that are associated with better prognosis would inform clinical decisions and enhance care. The aim of this study was to investigate factors that predict survival advantage in patients with multiple myeloma who require dialysis.

Methods: The case notes of 91 patients who presented between 1991 and 2009 with myeloma (diagnosed according to International Myeloma Working Group criteria) who received dialysis were reviewed. The influence on survival of: presentation blood parameters (haemoglobin, white cell count, serum calcium, creatinine and albumin); patient age (median, 68, range 37-88) and gender (58:33 M:F ratio); era of diagnosis (before or after 2000); and renal recovery was assessed using Cox regression methods.

Results: The unadjusted factors that were associated with improved survival were renal recovery, haemoglobin (Hb) and albumin of 25-35g/L. On performing adjusted cox regression analysis, only renal recovery and Hb were independent predictors of improved survival. The association between renal recovery and survival was striking; the hazard ratio (HR) for death in those requiring dialysis versus those whose renal function recovered was 4.9 (95% CI 2.4-10.1, p=<0.001). An Hb of <10g/dl at presentation was linked to poorer prognosis (adjusted HR 1.64 (CI 1-2.70) p= 0.05).

Conclusion: Reversal of renal failure offers a key survival advantage to patients with a diagnosis of multiple myeloma who require dialysis. While this association may simply reflect a subgroup of patients with less severe myeloma and a reversible precipitant (such as hypercalcaemia or infection), it raises the question of whether aggressive therapies to improve renal function, such as chemotherapy and removal of nephrotoxic immunoglobulin, would improve survival.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO550

**Survival on Dialysis in the Systemic Amyloidoses** Jennifer H. Pinney,[1,2] Helen J. Lachmann,[1] Prayman Sattianayagam,[1] Simon Gibbs,[1] Carol J. Whelan,[1] Ashutosh D. Wechalekar,[1] Philip Hawkins,[1] Julian D. Gillmore.[1] *[1]National Amyloidosis Centre, Division of Medicine, UCL Medical School, London, United Kingdom; [2]Centre for Nephrology, Division of Medicine, UCL Medical School, London, United Kingdom.*

Systemic amyloidosis frequently involves the kidneys and may lead to end stage renal disease (ESRD). The prognosis on dialysis depends on the amyloid type but is reportedly poor in both AA and AL amyloidosis. We report outcome among all dialysis-dependent patients with systemic amyloidosis evaluated at the UK National Amyloidosis Centre (NAC) between 1983 and 2010. Survival was estimated by Kaplan-Meier plots, and patients were censored at renal transplantation.

Two hundred and forty nine of 1094 (23%) patients with renal AL amyloidosis, 158 of 425 (37%) patients with AA amyloidosis, 50 of 89 (56%) with fibrinogen Aa-chain amyloidosis (AFib), 11 of 58 (19%) with apolipoprotein AI amyloidosis (AApoAI), and 3 of 17 (18%) with lysozyme amyloidosis (ALys) reached ESRD. Median age at start of dialysis in AL, AA, AFib, AApoAI and ALys was 62, 47, 60, 50 and 62 years respectively. Median time from diagnosis of amyloidosis to ESRD in AL, AA, AFib, AApoAI and ALys was 1.0, 3.8, 4.5, 6.6 and 8 years respectively. Median survival on dialysis in AA amyloidosis was 45.5 months; 1 year mortality was 14% with an annual mortality of 10%. Median survival on dialysis in AL amyloidosis was 38.9 months and was heavily influenced by presence of cardiac amyloid deposits (P<0.0001). Median survival on dialysis in AFib was 116 months and 1 and 5 year mortality was 5% and 20% respectively. A single patient with AApoAI died after 67 months of dialysis and the remainder received renal transplants a median of 32 months after starting dialysis. Two patients with ALys were on dialysis for 7 and 30 months respectively and the third received a renal transplant after 3 months of dialysis which was functioning at censor.

Survival on dialysis is substantially better in AA and AL amyloidosis than previously reported and is better still among patients with hereditary renal amyloidosis who reach ESRD. These findings highlight the importance of correctly diagnosing the amyloid fibril type in patients with renal amyloidosis.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO551**

**Novel Measures of LDL and HDL Subfractions and Mortality in Maintenance Hemodialysis Patients** Nazanin Noori,[1] Michael Caulfield,[2] Allen R. Nissenson,[3] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]Quest Diagnostics, Irvine, CA; [3]DaVita, Lakewood, CO; [4]Salem VA, Salem, VA.*

Measuring subfractions of lipoproteins via novel ion mobility method may better risk-stratify maintenance hemodialysis (MHD) patients (pts). We examined mortality predictability of LDL and HDL subfractions in 235 MHD pts over 6 yrs (2001-07). HDL subfractions did not correlate with mortality. Cox regression was adjusted for case-mix (including vintage, Charlson score & Kt/V), malnutrition-inflammation complex (albumin, creatinine, phos, calcium, ferritin, hemoglobin, nPCR, & BMI) and inflammatory markers (CRP, IL-6, & TNFα). The highest quartiles of VERY SMALL and LARGE particles of LDL were associated with highest and lowest death risk, respectively (see Table):

Death hazard ratios according to quartiles of LDL subfractions concentration

| Very Small LDL quartiles | Q2(n=60) | Q3(n=59) | Q4(n=58) | p for trend |
|---|---|---|---|---|
| concentration (nmol/L) | 57-87 | 88-121 | >121 | |
| Unadjusted | 0.84(0.42-1.70) | 0.93(0.45-1.91) | 1.54(0.82-2.89) | 0.13 |
| Case-mix | 0.79(0.39-1.61) | 0.97(0.47-2.03) | 1.75(0.95-3.33) | 0.05 |
| | | | | |
| + MICS | 0.65(0.29-1.46) | 0.89(0.40-1.99) | 2.15(1.02-4.56)* | 0.02 |
| + inflammation | 0.65(0.29-1.49) | 0.84(0.37-1.94) | 2.14(1.00-4.62)* | 0.02 |
| Large LDL quartiles | Q2(n=54) | Q3(n=58) | Q4(n=58) | p for trend |
| concentration (nmol/L) | 44-76 | 77-105 | >105 | |
| Unadjusted | 0.70(0.37-1.34) | 0.88(0.47-1.62) | 0.45(0.22-0.92)* | 0.05 |
| Case-mix | 0.76(0.38-1.52) | 0.96(0.51-1.84) | 0.53(0.25-1.12) | 0.18 |
| | | | | |
| + MICS | 0.45(0.21-0.98) | 1.07(0.52-2.21) | 0.49(0.21-0.98)* | 0.36 |
| + inflammation | 0.45(0.21-0.98) | 1.14(0.55-2.37) | 0.47(0.20-0.99)* | 0.37 |

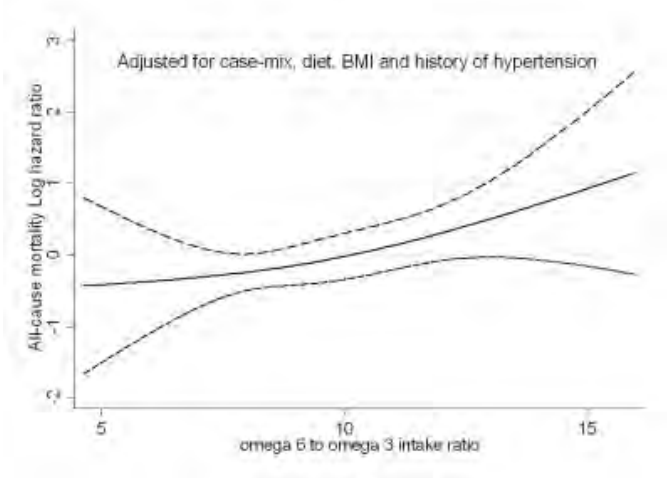
Hence, lower concentrations of VERY SMALL LDL and higher concentrations of LARGE LDL appear associated with greater survival, which needs to be verified in additional prospective studies.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO552**

**Dietary Omega-3 Fatty Acid, Ratio of Omega-6 to Omega-3 Intake and Survival in Long-Term Hemodialysis Patients** Nazanin Noori,[1] Sameer B. Murali,[1] Ramanath B. Dukkipati,[1] John J. Sim,[2] Usama Feroze,[1] Rachelle Bross,[1] Deborah A. Benner,[3] Joel D. Kopple,[1] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Hrabor-UCLA Medical Center, Torrance, CA; [2]Kaiser Permanente, Los Angeles, CA; [3]DaVita, Lakewood, CO; [4]Salem VA, Salem, VA.*

**Background:** Human beings evolved on a diet with an equal proportion of omega-6 to omega-3 poly-unsaturated fatty acid (PUFA). In Western diets this ratio has dramatically increased up to 15 times higher. Given the evidence that half of all CKD deaths are attributed to cardiovascular disease, the anti-inflammatory and cardioprotective benefits of omega-3 PUFA may play an important role in modulating these processes to reduce mortality. **Methods:** Using 3-day diet record, we examine the survival predictability of dietary omega-3 PUFA and the ratio of omega-6 to omega-3 PUFA at the start of the cohort of 145 hemodialysis patients who were followed for up to 6 years (2001-07). **Results:** There was no correlation between omega-3 PUFA intake and mortality. However, the lowest (vs. highest) quartile of dietary omega-6 to omega-3 ratio was associated with decreased mortality hazard ratio (95% CI) in the analyses adjusted for age and gender [0.54 (0.21-1.38), p trend=0.14], case-mix plus diet [0.37 (0.14-1.08), p trend=0.04] and case-mix plus diet plus BMI plus history of hypertension (HTN) [0.39 (0.14-1.18),p trend=0.06]. Spline survival models confirmed the associations (Figure).



**Conclusions:** Higher omega-6 to omega-3 PUFA intake ratios are associated with increased death risk in hemodialysis patients, even after adjustments for energy, saturated fatty acids, trans fat, cholesterol and fiber intakes. These findings, if verified in additional, prospective studies, suggest that the low dietary ratios of omega 6 to omega 3 PUFA should be recommended to MHD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO553**

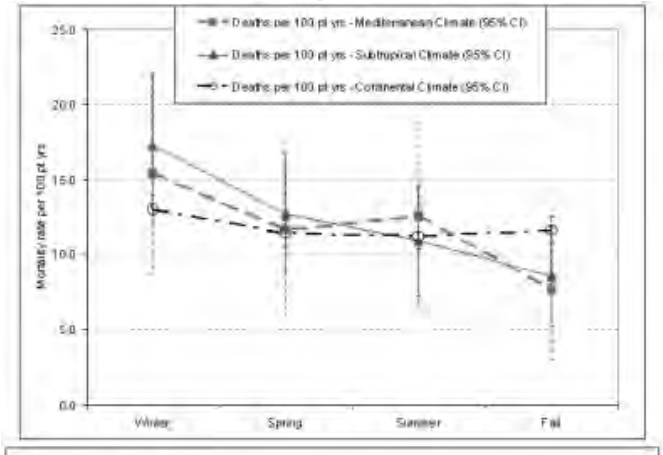
**Seasonal Variability in Mortality of Chronic Hemodialysis Patients** Len A. Usvyat,[1] Frank Van der Sande,[2] Jeroen Kooman,[2] Nathan W. Levin,[1] Peter Kotanko.[1] *[1]Renal Research Institute, NY, NY; [2]Maastricht University Medical Centre, Maastricht, Netherlands.*

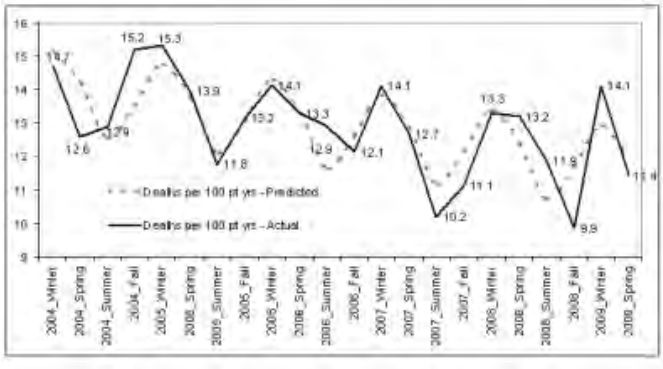
In the general population, mortality varies seasonally, but it is unknown whether this phenomenon is present in hemodialysis (HD) patients (pts). The aim of the present study was to assess seasonal variations in mortality across diverse climatic US regions.

We reviewed records of HD pts treated in RRI clinics b/n Apr 1, 2004 and Mar 31, 2009. 15,056 pts were studied (55% male, 45% black, 45% white, 48% diabetic). Seasons were defined on a calendar basis. All cause mortality was noted per season and expressed as deaths [95% confidence interval] per 100 pt yrs (D100PY).

Cosinor analysis was conducted to test for seasonality in mortality. Given that RRI clinics are located in 6 states, they were grouped in distinct climate groups: continental (14,015 pts in NY, CT, MI, and IL), mediterranean (316 pts in CA), and subtropical (737 pts in NC).

Irrespective of climatic zone all cause mortality was highest in winter (14.2 [13.3 to 15.1] D100PY), followed by spring (13.1 [12.2 to 14.0] D100PY), fall (12.3 [11.4 to 13.2] D100PY), and summer (11.9 [11.1 to 12.7] D100PY). The results were further confirmed by comparing seasonal variations across climates with highest mortality in winter ($p<0.05$ for all geographies); mortality was lowest in summer in the continental climate ($p<0.05$) and in fall in the mediterranean and subtropical climates (NS).





Cosinor analysis over a 5 yr period demonstrated a seasonal component of mortality: highest in winter and lowest in summer. Overall decline in mortality over a 5 yr period was observed.

This study demonstrates a significant seasonal influence on mortality in chronic hemodialysis pts with highest mortality in the winter and lowest mortality in the summer. Seasonal effects of mortality should be considered in the design and analysis of clinical trials.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO554**

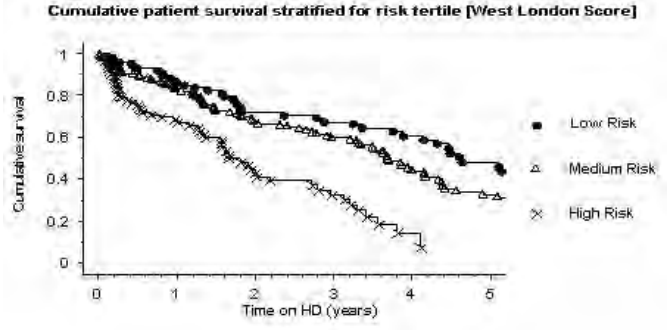
**Prognosis of Elderly Patients on Haemodialysis – A Novel Comorbidity Score** Albert J. Power, Kakit Chan, Seema Singh, David Taube, Neill D. Duncan. *Imperial College Kidney & Transplant Institute, West London Renal & Transplant Centre, Hammersmith Hospital, London, United Kingdom.*

Although a number of scoring systems have been developed and validated in patients with ESRD to predict survival they are complex and address all age groups. The purpose of this study was to develop a simple scoring system to predict prognosis in elderly hemodialysis [HD] patients.

All incident patients >75 yrs on HD alone Jan 2000-Dec 2009 were examined. The Charlson Comorbidity Index [CCI] and its adapted form for ESRD [Hemmelgarn, 2003] was calculated using standardised definitions and cardiac failure defined as LV ejection fraction <35% and/or NYHA Class III/IV. Weibull and logistic regression models were used to test associations and 2yr predictive power.

Mean CCI was 4.5±2.0, adapted CCI 3.7±3 [n=410, mean age 80.0±3.5 yrs, 64% male, mean MDRD eGFR 8.4±3.3ml/min]. Cumulative survival [inc. first 90d] was 80%, 63%, 56% & 32% at 1, 2, 3 & 5 yrs; mean survival 3.5 yrs [2.3 yrs, USRDS 2005, 8.5 yrs in age-matched UK population].

Four factors associated with worse survival: cardiac failure [HR 1.70, 95%CI 1.09-2.64, p<0.001], age per yr [HR 1.06, 95%CI 1.00-1.12, p=0.01], male [HR 1.56, 95%CI 1.00-2.45, p=0.05] and metastatic malignancy [HR 3.66, 95% CI 1.14-11.7, p<0.05] and predicted 2yr survival [AUC=0.69]. Ethnicity, diabetes, eGFR and other coded comorbidities had no effect on survival. Higher CCI & adapted CCI also associated with worse survival [p=0.03 & p<0.001].



This succinct prognostic model in the elderly on HD is unique in the literature to our knowledge. Cardiac function appears to be the prime determinant of survival and needs accurate definition at an ideal dry weight. Other factors known to affect survival in other age groups do not appear to be significant. The favourable performance of our model requires larger studies for comprehensive validation.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO555**

**Assessment of 5-Year Survival on Hemodialysis (HD) in Brazil: A Cohort of 3,149 Incident Patients** Jorge Strogoff-de-Matos,[1] Frederico Ruzany,[3] Adrian Marcos Guinsburg,[2] Ana Beatriz Barra,[3] Marcos Sandro Fernandes de Vasconcelos,[3] Eufronio D'Almeida,[3] Marcos Hoette,[3] Jocemir R. Lugon.[1] *[1]Medicine / Nephrology, Universidade Federal Fluminense, Rio de Janeiro, RJ, Brazil; [2]Fresenius Medical Care, Buenos Aires, BA, Argentina; [3]Fresenius Medical Care, Rio de Janeiro, RJ, Brazil.*

Brazil has the third largest contingent of patients on maintenance HD worldwide. However, little is known regarding survival rate and predictors of mortality risk in that population, which are the objectives of this study.

Incident patients on HD from 01/01/2000 to 06/30/2004 from 26 dialysis facilities distributed among 7 out of 26 states of Brazil were followed up until 06/30/2009. Data were extracted from Latin America FCM Registry. Primary outcome was all cause mortality. Data were censored at 5 years of followed-up. Survival was calculated by Kaplan-Meier method; curves were compared by Log-Rank test. Cox proportional model was used to assess associations of demographic, clinical and laboratory variables with the risk of death.

A total of 3,159 patients were included in this analysis. Patients were 52 ± 16 years old, 57.8% males, 20.1% diabetics, 4.2% HCV+, 1.3% HBV+, and 0.5% HIV+. Out of those, 2101 patients dropped out before completing the 5-year follow-up (47% death, 31% change of center, 16% kidney transplant, 3% migration to peritoneal dialysis, 3% recovery of renal function, and 1% abandonment of treatment). The global 5-year survival rate was 58.5%. Age (HR= 1.04 per year, P <0.0001), and diabetes (HR= 1.61, P <0.0001) were associated with increased risk of death, whereas serum albumin (HR= 0.70 per g/dL, P <0.0001) and body mass index (HR= 0.98 per Kg/m2, P= 0.018) were protective.

The mortality rate on HD in this Brazilian cohort was found to be relatively low, but the population is younger and has a lower prevalence of diabetes than the ones reported for developed countries.

Williams,[1] Alexander S. Goldfarb-Rumyantzev.[1] *[1]Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA; [2]Tel Aviv University, Tel Aviv, Israel; [3]University of Utah, Salt Lake City, UT.*

Background. Patient groups associated with disparities in health care are usually defined on the basis of race, gender or geographic location. Social Adaptability Index (SAI) calculated based on education, marital status, income, employment and substance abuse has been strongly associated with clinical outcome in other patient populations.

Methods. We used data from trhe USRDS to evaluate the role of SAI in survival of patients on dialysis in Cox model. We also studied subgroups based on age, race, sex, comorbidites and diabetic status.

Results. We analyzed 3,396 patients (age of ESRD onset 56.9±16.1 years, 54.2% males, 64.2% White, 30.3% African American). Mean SAI was 7.1±2.5 (range 0 to 12 points). SAI was higher in Whites (7.4±2.4) than African Americans (6.5±2.5) [ANOVA, p<0.001] and greater in men (7.4±2.4) than in women (6.7±2.5) [T-test, p<0.001]. In Cox model adjusted for potential confounders SAI was associated with decreased mortality (HR of 0.97, [95% CI 0.95-0.99], p=0.005). Subgroup analysis demonstrated association of SAI with survival in most of the subgroups.

The SAI association with mortality in the entire population and study subgroups by proportional hazards model

| | Hazard ratio (95% CI) | p |
|---|---|---|
| SAI in the entire study population | 0.97 (0.95-0.99) | 0.005 |
| SAI in males | 0.95 (0.93-0.97) | <0.001 |
| SAI in females | 0.97 (0.94-0.99) | 0.027 |
| SAI in patients 18-40 years old | 0.87 (0.80-0.94) | 0.002 |
| SAI in patients 40-65 years old | 0.95 (0.92-0.98) | 0.003 |
| SAI in patients >65 years old | 0.98 (0.95-1.01) | 0.216 |

Potential limitations of the study include reverse causality, possible misclassification, deficient psychometric data and retrospective design.

Conclusion. SAI is significantly associated with mortality in dialysis patients. SAI could be used to identify individuals at risk for inferior clinical outcomes.

**Survival of Patients on Renal Replacement Therapy (RRT) after Intensive Care Unit (ICU) Admission** Bhadran Bose,[1] Roy Cherian,[1] Michael Steele,[2] Thomas T. Titus.[1] *[1]Department of Nephrology, Gold Coast Hospital, Southport, Queensland, Australia; [2]Faculty of Health Science & Medicine, Bond University, Gold Coast, Queensland, Australia.*

**Aim:** To report the survival rates of patients on renal replacement therapy admitted to ICU and its relationship to their co-morbidities (Charlson Co-morbidity index), SAPS-2, APACHE II, APACHE III and APACHE III risk scores on admission.

**Background:** Survival of patients on RRT after an ICU admission is believed to be poor given the high co-morbidity in these patients. We hypothesised that survival in these patients was related to their co-morbid status and the severity of their illness at the time of admission to the ICU rather than the presence of End Stage Renal Disease (ESRD).

**Methods:** A retrospective cohort study was undertaken evaluating the hospital charts of 53 ESRD patients who were admitted to Gold Coast Hospital ICU from July 2003 – June 2008.

**Results:** Out of 4825 admissions to ICU, there were 65 admissions with ESRD (1.3%) with 53 patients. The major causes of ICU admission was post- surgery (32.3%), pulmonary oedema (15.4%) and sepsis (13.8%). 89.2% of admissions were discharged from the ICU to the ward and 75.4% were discharged alive from the hospital. SAPS-2, APACHE II, APACHE III, APACHE III risk scores showed statistically significant differences between survivors and non survivors at the time of discharge from ICU and from hospital. Charlson co morbidity score did not show any statistically significant difference between survivors and non-survivors at the time of ICU and hospital discharge.

From the initial admission to ICU, 54% of patients were alive at one year. APACHE III and APACHE III risk scores at the first ICU admission were predictive of survival at one year using logistical regression analysis**.**

**Conclusions:** Survival of ESRD patients after ICU admission appears to be related to the severity of illness necessitating ICU admission as measured by the acute physiological scores. APACHE III and APACHE III risk scores correlated with survival at one year. Charlson co-morbidity scores did not differentiate survivors from non-survivors.

**Urinary Biomarkers Predict Renal Recovery in Critically Ill Patients with Renal Support: Result from BioMaRK Study** Nattachai Srisawat,[1] Xiao Yan Wen,[1] Minjae Lee,[1,2] Lan Kong,[1,2] Mark L. Unruh,[1,3] Kevin W. Finkel,[4] Anitha Vijayan,[5] Emil P. Paganini,[6] Mohan Ramkumar,[3,7] Paul M. Palevsky,[1,3,7] John A. Kellum.[1,3] *[1]CRISMA Center, Critical Care Medicine, University of Pittsburgh, Pittsburgh, PA; [2]Dpt Biostatistics, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; [3]Dpt Medicine, University of Pittsburgh, Pittsburgh, PA; [4]University of Texas Medical School at Houston, TX; [5]Washington University in St. Louis, MO; [6]Cleveland Clinic Foundation, Cleveland, OH; [7]VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Introduction: Predicting renal recovery after acute kidney injury (AKI) is challenging and there are no clinical methods available. The discovery of biomarkers to predict recovery could represent an important new prognostic tool for management of AKI.

Methods: We conducted the Biological Markers of Recovery for the Kidney (BioMaRK) study as an ancillary to the VA/NIH Acute Renal Failure Trial Network (ATN) study, a prospective, multicenter randomized trial comparing two intensities of renal support. We collected urine on days 1, 7, and 14 from 76 patients who developed AKI and received renal replacement therapy. We explored whether urinary NGAL (uNGAL), HGF (uHGF), Cystatin C (uCystatin C), IL-18 (uIL-18), or NGAL/MMP-9 (uNGAL/MMP-9) could predict renal recovery. We defined recovery as alive and free of dialysis by day 60.

Results: Patients who had higher uCystatin C on day 1 (7.27 [6.50-8.33] vs 6.60 [4.97-7.58] ng, P=0.02), lower uHGF on days 7 and 14 (2.97 [2.24-3.63] vs 3.48 [3.04-4.44], P=0.01, 2.24 [1.35-2.95] vs 3.40 [2.87-4.79] ng, P=0.04, respectively), all per mg creatinine, and decreasing uNGAL and uHGF in the first fourteen days had greater odds of renal recovery, (P = 0.01 and P = 0.003, respectively). A prediction model combining urinary biomarkers with clinical markers resulted in an area under the receiver operator characteristics curve of 0.94 for predicting renal recovery at day 60.

Conclusion: This study demonstrates that biomarkers may be useful for predicting renal recovery after AKI especially together with clinical data.

**Successful Detection of Venous Needle Dislodgement Using Extracted Heart Pulses Obtained from Venous Pressure Monitoring** Marten Segelmark,[1] Lena Mattsson,[2] Sarok Said,[2] Bo Olde,[3] Kristian Solem.[3] *[1]Division of Nephrology, Department of Clinical Sciences, Faculty of Medicine, Lund University, Lund, Sweden; [2]Department of Nephrology, University Hospital, Lund, Sweden; [3]Research Department, Gambro Lundia AB, Lund, Sweden.*

Accidental venous needle dislodgement (VND) during dialysis is a rare, but serious clinical event. Modern dialysis machines rely on pressure monitoring to detect VND. However, better venous needle monitoring (VNM) is needed because in practice it may be difficult to set alarm limits adequately to assure safety. We have developed a new VNM method, which is based on detection of heart pressure pulses passing from the patient via the blood access to pressure transducers in the blood line. The pressure signal contains the heart pulses but is dominated by pressure variations from the blood pump. Our algorithm eliminates the blood pump variations and extracts the heart pulses. Disappearance of the heart pulses from the venous pressure indicates VND. Ten treatments with intact access connection and 3 treatments with controlled VND were clinically evaluated. The venous needle was deliberately disconnected from the access during 30 s while the arterial needle was still connected and the blood pump was still running. Pressure data from the extracorporeal circuit was acquired and a pulse oximeter was used as reference for the heart pulses. The method was capable of detecting the heart pressure pulse in all treatments despite varying heart rate (53-112 bpm), blood flow (320-500 ml/min) and relative amplitude of pulse to pump (1/250-1/3). All VND events were successfully detected within 20 s after the needle was disconnected. Variations in the venous pressure signal, the extracted heart pulses, and the reference of the heart pulses are illustrated in the figure, before and after a VND.

**Are Differences in Incident Fistula Use across Dialysis Facilities Explained by Casemix and Community Characteristics?** Janet R. Lynch, Michael P. Lilly, William M. McClellan. *Fistula First Breakthrough Initiative Data Committee, Mid-Atlantic Renal Coalition, Midlothian, VA.*

**Purpose.** K/DOQI Guidelines recommend incident AVF use ≥ 50%, yet US facilities vary and most fall short. We aimed to see if patient risk and community factors explain differences. **Methods.** US patient-level Medical Evidence Report and county-level Area Resource File data were used. We sorted facilities into quartiles based on 2008-2009 facility incident AVF use and examined patient risk (per published risk of maturation failure formula) across quartiles using Cochran-Armitage for linear trends. Kruskal-Wallis was used to compare facility community characteristics. **Results.** 4,587 facilities received ≥ 12 new start adult HD patients. Quartile facility AVF use range, facility and patient counts: Q1 (0-7.3%, 1247, 48000); Q2 (7.3-13.2%, 1150, 52891); Q3 (13.2-19.5%, 1146, 50459); Q4 (19.5-66.7%, 1144; 46103). Percent prior nephrology care, high and very high risk increased with increasing quartiles. The median number of office-based physicians varied from 203.1 to 206.1 (p=.007) but did not follow a trend. Total general surgeons per 100,000 population increased from 11.6 - 12.2 (p=.003) and percent poverty in surrounding county decreased from 15.0 - 13.3 (p<.0001) as quartiles increased. **Conclusion.** We found no evidence that case complexity, per risk formula, explains low incident AVF use rates. Higher use facilities have a more complex casemix and higher percent patients with prior care, reinforcing the importance of nephrologist referral and evaluation of all patients for AVF placement. External factors are also related.

Patient Characteristics by Facility Incident AVF Use Quartile

| | Q1 | Q2 | Q3 | Q4 | p-value |
|---|---|---|---|---|---|
| Prior Nephrology Care | | | | | |
| % Any | 39.5 | 52.1 | 59.0 | 67.7 | <.0001 |
| % ≥ 6 Months | 29.7 | 40.6 | 45.8 | 55.4 | <.0001 |
| Risk | | | | | |
| Low | 22.4 | 21.4 | 21.5 | 21.9 | ns |

**TH-PO561**

**Stenosis Length Predicts Percutaneous Transluminal Angioplasty (PTA) Failure after First Radiologic Salvage** Alexandra Romann,[1] Pascal Rheaume,[2] Mercedeh Kiaii,[3] Ravi Sidhu,[2] Monica C. Beaulieu.[1,3] *[1]BC Provincial Renal Agency, Vancouver, BC, Canada; [2]Divison of Vascular Surgery, UBC, Vancouver, BC, Canada; [3]Divison of Nephrology, UBC, Vancouver, BC, Canada.*

The most common AV fistula (AVF) complication is stenosis. Percutaneous transluminal angioplasty (PTA) has generally replaced surgical procedures to treat AVF stenosis. There is little data examining post-intervention patency after PTA, and even less data identifying the factors that predict success of this endovascular approach.

The aim of this study was to (1) assess patency after PTA of dysfunctional AVFs and (2) identify factors predictive of PTA failure after first radiological salvage.

A retrolective analysis was conducted in patients with an AVF creation between Jan 2005 – Jan 2008 and at least one PTA to maintain or re-establish patency. Follow-up data

was collected until Jan 31, 2009. Demographic data and information about fistula creation, use, interventions and failure were extracted. Characteristics of the stenosis and success of the intervention were re-assessed by one investigator (PR) blinded to the initial report.

161 of 375 (43%) AVFs created during the study required at least one angioplasty. The post-intervention primary patency was 31%, 21% and 21% at 1, 2, and 3 yrs. Post-intervention secondary patency was 76%, 66% and 64%.

Multivariate Cox Proportional Hazards analysis of post-intervention primary patency, adjusted for age and gender, identified the following predictors of requiring a 2nd PTA: outflow vein lesion (HR=2.268, p=0.0343), multiple lesions (HR=1.660, p=0.0379) and stenosis > 2 cm (HR=2.024, p=0.0020).

Adjusted multivariate competing risks analysis, (age, gender), recognized stenosis > 2 cm to be a good predictor of requiring a 2nd PTA (HR=1.814, p=0.0089) after further addressing the competing risk of AVF failure, study end date or death.

In summary, length, number, and location of stenotic lesions predict poor outcomes. Repeated angioplasties may not be effective for these lesions. Future studies are needed to determine the optimal approach to treating these lesions, especially once they require several repeated PTAs.

**Venography or Ultrasound: Which Mapping Technique Is Superior?** Deuzimar Kulawik,[1] Kelly M. Mayo,[3] Jifeng Ma,[4] Jeffrey J. Sands,[2] Arif Asif.[5] *[1]FMQAI: The Florida ESRD Network, Tampa, FL; [2]FMC, Celebration, FL; [3]FMQAI, Tampa, FL; [4]FMQAI, Tampa, FL; [5]Intervention Nephrology, University of Miami Miller School of Medicine, Miami, FL.*

**Objective**: Both venography and vascular ultrasound based mapping techniques provide objective assessment of the vasculature prior to the creation of an arteriovenous fistula (AVF). While these vessel mapping (VM) techniques have been known to increase AVF rates, whether one technique is superior to the other has not been systematically studied. In this retrospective analysis we investigated the role of venography and ultrasound on AVF rates separately and in combination.

**Methods:** Incident Medicare end stage renal disease patient claims from the State of Florida (1/1/2006 to 12/31/2009) were used to identify VMs. The type of vascular access that was used for the first outpatient dialysis was determined by the CMS form 2728. VMs were identified by CPT codes used for venography and ultrasound mapping techniques: G0365 '93930', '93931', '93970', '93971', '36005','75822','75820'. Chi-square test and logistic regression were used to ascertain the association of types of vessel mapping and AVF rates.

**Results:** After controlling for age, body mass index, gender and race, venography resulted in significant higher AVF rates (51.30%) compared to ultrasound (33.97%). A combination of the two mapping techniques did not increase AVF rates above and beyond what was achieved by venography alone.

**Conclusion:** The results suggest that venography results in higher AVF rates compared to ultrasound. This result may not be causal and possibly related to the small number of surgeons or differences in the reasons for use of the two techniques.

Impact of Type of VM on AVF Rates.

| | Venography VM | Both Types of VM | VM Ultrasound |
|---|---|---|---|
| Denominator | 154 | 262 | 4846 |
| AVF rate | 51.30% | 49.24% | 33.97% |
| Odds Ratio | Reference | 0.939 | 0.507 |
| 95% CI of Odds Ratio | Reference | 0.627-1.404 | 0.367-0.703 |
| P-Value | | 0.07 | < .0001 |

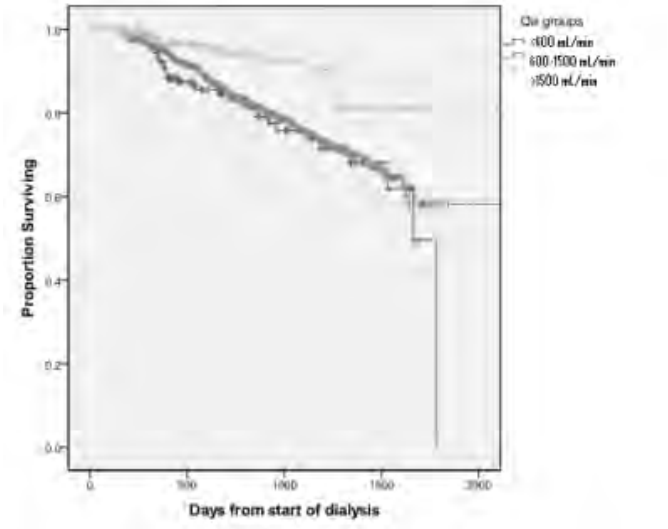
## TH-PO563

**Relationship between Survival and Access Flow in Hemodialysis Patients** Laura Rosales,[1] Len A. Usvyat,[1] Mary Carter,[1] Nathan W. Levin,[1, 2] Peter Kotanko,[1, 2] Stephan Thijssen.[1, 2] *[1]Renal Research Institute; [2]Beth Israel Medical Center, New York.*

Sufficient access blood flow (Qa) is vital in hemodialysis (HD). Complications derived from low and high Qa relate to morbidity and mortality. We investigated the association of Qa and survival in incident HD patients (pts).

We reviewed retrospectively records in all RRI in-center pts who started HD between Jan 2001 and Dec 2009 and survived the first 6 months. Only pts with arterio-venous fistula (AVF) or graft (AVG) who had 3 Qa measurements by online clearance were included. Pts were followed until death or censoring. Mean Qa for the first 6 months was computed and pts stratified into 3 groups: Qa<600mL/min, Qa 600-1500 mL/min, and Qa >1500 mL/min.

Data on 1006 pts (64% males, age (SD): 62.6 (14.6) years, 52% diabetic; 42% Black; 51% White) were analyzed. Number of pts: Qa <600 mL/min 149 (15%); 600-1500 mL/min 687 (68%) and Qa >1500 mL/min 170 (17%). In Kaplan-Meier analysis, mean survival time was 1410 days (95% CI: 1299-1521) in pts with Qa<600 mL/min, 1689 days (95% CI: 1607-1770) for Qa 600-1500 mL/min, and 1875 days (95% CI: 1758-1993) for Qa>1500 mL/min. In the highest Qa group, survival was significantly better compared to the other groups (Figure 1).



In Cox proportional hazards analysis, adjusted for age, gender, diabetic status, race, and access type, pts with Qa>1500 had a HR of 0.49 (95% CI:0.25-0.95) compared to the Qa 600-1500 group; again, survival in pts with low Qa did not differ from those in the Qa 600-1500 group.

In this large population of HD pts using AVF or AVG as vascular access, pts with Qa>1500 mL/min had a significantly lower risk of death compared to those with Qa of 600 to 1500 mL/min or <600 mL/min. Qa <600 mL/min was not associated with higher death rates than those between 600 and 1500 mL/min.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO564

**Clinical Significance of Early Post-Operative Venography of Vascular Access before First Needling in Hemodialysis Patients** Jayoung Lee,[1] Hyun Gyung Kim,[2] Hye Eun Yoon,[3] Yong-Soo Kim,[1] Chul Woo Yang,[1] Young Soo Kim,[2] Young Ok Kim.[2] *[1]Nephrology, Seoul St' Mary Hospital, Seoul, Republic of Korea; [2]Nephrology, Uijeongbu St. Mary's Hospital, Uijeongbu, Republic of Korea; [3]Nephrology, Incheon St' Mary Hospital, Incheon, Republic of Korea.*

Introduction: Venography has been a standard method to detect vascular access dysfunction (VAD) under maintenance hemodialysis (HD). However, there has been few data about the venography verifing VAD before 1st needling. This study was performed to define clinical significance of early post-operative venography of vascular access before 1st needling in HD patients.

Methods: From August, 2004 to April, 2010, 300 patients received vascular access operation in an academic tertiary care center. The type and location of vascular access was decided by surgeon's physical examination. Venography was performed 4~6 weeks after the operation and before 1st needling for HD. In patients with severe stenosis with more than 50% of luminal diameter, percutaneous angioplasty (PTA) or re-operation was done. In patients with no or mild stenosis, vascular access was used for HD. VAD was evaluated 1 year after the operation.

Results: Mean age of the patients was 56±13year. Male and female were 148 and 152, respectively. Vascular access composed 237 AVFs (192 radio-cephalic, 25 braciho-cephalic, and 20 brachio-basilic) and 63 AVGs. Venography revealed 31.3% (n=94) of severe stenosis, 28% (n=84) of mild stenosis and 40.7% (n=122) of good patency. For 31.4% (n=94) with severe stenosis, PTA and re-operation were performed in 70.2% (n=66) and 17% (n=16), respectively. All patients who received PTA showed immediate success. Although AVG group (n=63) showed higher incidence of severe stenosis than AVF group (237), there was no statistical difference (41.2% vs. 28.9%, p=0.06). Out of 86 patients with mild stenosis, 65 patients were followed for 1 year. VAD occurred in 13 patients (20%) and 11 patients received successful PTA. Out of 122 patients with normal venography, 102 patients were followed for 1 year and no one had VAD in 1 year.

Conclusion: Early post-operative venography before first needling is helpful to detect and treat early VAD in HD patients.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO565

**Does the Risk of Maturation Failure Explain Arteriovenous Fistula (AVF) Use in Incident Hemodialysis (HD) Patients?** Michael P. Lilly, Janet R. Lynch, William M. McClellan. *Fistula First Breakthrough Initiative Data Committee, Mid-Atlantic Renal Coalition, Midlothian, VA.*

**Background.** The US falls short of the Fistula First goal for 50% incident AVF use. Some suggest certain patient characteristics predict difficult AVF construction and poor maturation. **Methods.** We examined AVF use with logistic regression and CMS Medical Evidence Report data for all US new start adult HD patients between July 1, 2005 and December 31, 2009 with ≥ 6 months nephrologist care. Risk was assessed using a validated prediction rule for maturation failure (Lok et al, JASN 2006: Risk Score = 3 + 2*(Age≥65)

+ 3*PVD + 2.5*CAD - 3*White; Score: <2.0, low risk, 2.0-3.0, moderate, 3.1-7.9, high, >8, very high) alone and with other risk factors. **Results.** Of 196,936 patients, 43.8% had a placed AVF (23.3% in use) and 63.6% were low or moderate risk. Placed AVF varied (41.6%, very high risk to 46.2%, low risk, F=46.4, p<.0001) with differences among risk classes for placed/unused (F=9.3, p<.0001) and in-use (F=91.3, p<.0001). Logistic regression revealed lower odds of AVF use for moderate, OR (95% CI) = 0.903 (0.876, 0.930); high, OR (95% CI) = 0.871 (0.841, 0.901); very high, OR (95% CI) = 0.779 (0.742, 0.861) risk patients vs. low. Odds were lower for women, Hispanics, co-morbid CHF and diabetes, cardiac disease, CVA/TIA, low BMI. Odds were higher for diabetes or hypertension as ESRD etiology, co-morbid hypertension, high BMI, and Medicare coverage. Despite associations, c statistic was 0.603 and pseudo $R^2$ = 0.034. **Conclusion.** Risk factors have limited ability to predict incident AVF use. Even patients judged at highest risk can have successful AVF construction and initiate dialysis via a functioning AVF.

Frequency (%) of AVFs at Incident HD By Risk Category, Adults with Nephrologist Care ≥ 6 Mos, 7/1/2005 – 12/31/2009

| | Low (n) | Moderate (n) | High (n) | Very High (n) |
|---|---|---|---|---|
| Placed AVF | 46.2 (18,087) | 43.8 (37,649) | 42.6 (28,234) | 41.6 (2,251) |
| Placed But Unused | 20.6 (8,053) | 20.1 (17,309) | 20.9 (13,838) | 22.6 (1,225) |

## TH-PO566

**Choice of Vascular Access among Incident Hemodialysis Patients: A Decision and Cost-Utility Analysis** Hui Xue,[1] Eduardo K. Lacson,[2] Weiling Wang,[2] Gary C. Curhan,[1] Steven M. Brunelli.[1] *[1]Department of Medicine, Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Fresenius Medical Care, North America, Waltham, MA.*

Introduction: Arteriovenous fistula (AVF) are the preferred hemodialysis (HD) vascular access type. However, supporting data have not considered morbidity and mortality resulting from bridge catheter exposure during failed/prolonged maturation. These analyses compare predicted outcomes and costs among incident HD assigned to receive AVF or arteriovenous grafts (AVG).

Methods: Analogous Markov models were created, one each for AVF and AVG. Patients entered consideration at time of first access creation simultaneous with dialysis initiation.

Subsequent outcomes were determined probabilistically; transition probabilities, utilities and costs were gathered from published sources; the timing and likelihood of access maturation were measured in a contemporary cohort of incident HD patients.

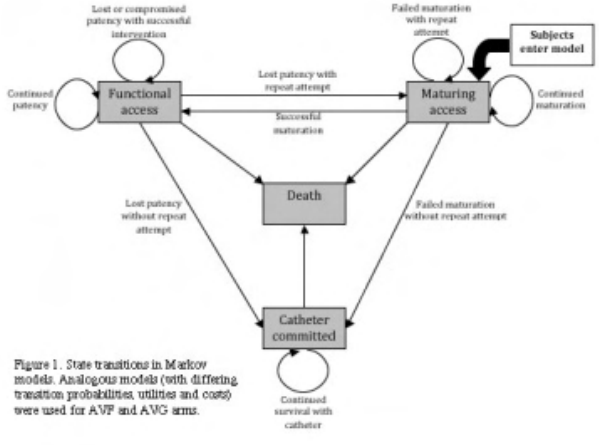

Figure 1. State transitions in Markov models. Analogous models (with differing transition probabilities, utilities and costs) were used for AVF and AVG arms.

Results: Mean survival was 39.2+/-0.8 and 36.7+/-1.0 months for AVF and AVG, respectively: difference 2.6 months (p<0.001). Quality-adjusted survival was 36.1+/-0.8 and 32.5+/-0.9 QALMs for AVF and AVG, respectively: difference 3.6 QALMs (p<0.001). One-way sensitivity analysis indicated that AVG was the preferred strategy among patients in whom the probability of AVF maturation was <41% of that for the overall AVF cohort (i.e., patients at high risk for maturation failure). The incremental cost effectiveness ratio (95% CI) for AVF relative to AVG was $446 (166, 720) per quality-adjusted life year saved.

Conclusion: AVF is associated with greater overall and quality-adjusted survival than AVG at an acceptable cost. Observed differences were much less pronounced than might be expected from prior literature, suggesting that individualized planning for patients at high risk for AVF maturational failure might improve outcomes.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO567

**Fistula First Initiative (FFBI) Improves Fistula (AVF) Use, Reduces Catheter Use and Does Not Cause Increased Immature AVF** Vo D. Nguyen. *Nephrology, Memorial Nephrology Associates, Olympia, WA.*

FFBI has led to 54.8% prevalent AVF use in February 2010. There is concern that creating AVF in HD patients with high co-morbidities leads to increased immature AVF and catheter (CVC). We used FFBI data from 2003 to 2010 to determine if increasing AVF rates leads to increased immature AVF and CVC use. **Methods**. Monthly census of vascular access was collected by all dialysis centers (4234 centers). Percent immature AVF is defined as maturing AVF (difference between AVF placed -AVF used) divided by total AVF used.

| Date | #AVF in use | #AVF placed | #Maturing AVF | %Maturing/in use AVF | % Total catheter | %Graft |
|---|---|---|---|---|---|---|
| July 2003 | 49 786 | 59 370 | 9584 | 19.25% | 26.9% | 40.1% |
| July 2004 | 99 823 | 118 006 | 18 183 | 18.2% | 27% | 35.6% |
| July 2005 | 114 429 | 136 926 | 22 497 | 19.7% | 28% | 31.8% |
| July 2006 | 130 476 | 156 514 | 26 038 | 19.95% | 28.5% | 27.8% |
| July 2007 | 149 694 | 177 537 | 27 843 | 18.6% | 27.7% | 24.6% |
| July 2008 | 168 075 | 193 957 | 25 882 | 15.4% | 26.3% | 22.7% |
| July 2009 | 186 306 | 214 430 | 28 124 | 15.1% | 25.5% | 21.2% |
| Feb 2010 | 195 462 | 223 519 | 28 057 | 14.4% | 24.4% | 20.6% |

**Conclusion:** FFBI has improved vascular access outcome: AVF in use increased dramatically, while percent immature AVF, graft and catheter decreased.

## TH-PO568

**Low Rate of Incident Fistulas in a Veterans Administration Healthcare System Are Due to Poor Processes of Care** Timmy C. Lee,[1,2] Elisha I. Lancaster,[1] Prabir Roy-Chaudhury,[1,2] Charuhas V. Thakar.[1,2] *[1]Internal Medicine, University of Cincinnati, Cincinnati, OH; [2]Veterans Administration Medical Center, Cincinnati, OH.*

According to the 2009 USRDS the AVF incident rate is only 15%. The K/DOQI guidelines for vascular access targets greater than 50% incident AVFs. The purpose of this study was to determine the proportion of patients meeting specific benchmarks (initial nephrology referral, pre-operative vessel mapping, surgical referral, and access placement) necessary in pre-dialysis vascular access care and associated GFR when these benchmarks were reached. We performed a retrospective study at the Cincinnati Veterans Administration (VA) using a database of identified patients with a GFR ≤30 from 2006 to 2007 seen in our CKD clinics and performed a 2-year follow-up. We identified 344 patients who met the above criteria. 98% were male, 76% white, 58% diabetics, and 37% had peripheral vascular disease. 83% (n=285) had an initial nephrology consult from a primary care physician. Median GFR at the time of initial nephrology clinic referral was 28. 29% (n= 99) of patients had referral for pre-operative access mapping during the follow-up period. Median GFR at the time of vein mapping referral was 15 with only 2.0% of patients having a GFR ≥25 at the time of vein mapping referral. 20% (n=69) of patients had referral to a surgeon for vascular access surgery, and 79.7% (n=55) of patients referred for surgery had documented permanent access placement. Among those patients with vascular access surgery, median GFR at the time of vascular access placement was 11. Only 13% of the patients with vascular access placement had GFR ≥ 20 at the time of vascular access placement. Among the 344 patients 24% (n=84) initiated hemodialysis during the follow-up period. The patient distribution of access type at the initiation of dialysis was 26% AVFs, 1% AVGs, and 73% catheters. Even in a VA health care system, we see delayed referral for pre-operative vascular mapping and surgical evaluation, placement of AVF at low GFRs, and low rates of AVFs at dialysis initiation. Focusing on improving these processes of care measures may increase incident AVF use.

## TH-PO569

**Vascular Access Blood Flow Measurement: Variability Is Real** Janet Lynn Graham, Swapnil Hiremath, Peter Magner. *Division of Nephrology, Kidney Research Centre, The Ottawa Hospital, Ottawa, ON, Canada.*

Background: The gold standard for diagnosing AV fistula stenosis is conventional angiography (fistulogram). The best known non-invasive predictor of stenosis and risk of occlusion is the measurement of fistula blood flow. The recommendation is to intervene if access flow decreases by >20% . The standard measurement of fistula blood flow is calculated using an ultrasound dilution technique with a Transonic access monitor (Transonic Corp) utilizing the Krivitski formula. An alternative method of access flow measurement uses changes in dialysate conductivity. This is an option available on standard Fresenius haemodialysis machines.

Objectives: To assess the reproducibility of access flow measurements with both Fresenius and Transonic measurements in individual patients over multiple measures.

Methods: A cohort of dialysis patients with AV fistula had paired measures with the Fresenius machine and the Transonic machine. The repeated measures with both Fresenius and Transonic machines were performed at 20 consecutive, routinely scheduled dialysis treatments to assess intra-individual variability of access flow and factors that influence this. Results: A total of 40 patients had repeated access blood flow measurements using the Transonics and Fresenius measurement device. 9/40 patients had Fresenius flows >2000 mL/min and were excluded from the analysis of variability. 60/517 (11.2%) pairs of consecutive readings with the Transonic method showing a 20% drop compared with 100/528 (18.9%) using the Fresenius method (p <0.001). 77/577 (13.8%) readings with the Transonic varied >20% from the average reading compared to 131/542 (24.2%) with Fresenius (p <0.001). 6/31 (19.4%) of patients had more than 20% of the values that were >20% different from the average value using the Transonic method when compared to 18/31 (58.1%) with Fresenius (p <0.001).

Conclusion: Both methods of access blood flow measurement demonstrate high variability but the Fresenius method demonstrates a significantly greater variability which may result in excessive interventions.

Disclosure of Financial Relationships: nothing to disclose

**Pressure Gradients in Hemodialysis Fistulae: A New Non Invasive Method**

David H. King,[1] Graeme Taylor,[2] Mo Al-Qaisi,[1] Sumith C. Abeygunasekara,[1] Yiannis Panayiotopoulos,[3] Galil Rahman Ali.[1] *[1]Renal Unit, Broomfield Hospital, Chelmsford, Essex, United Kingdom; [2]Department of Physics, Guy's and St Thomas Hospital Trust, London, United Kingdom; [3]Department of Surgery, Broomfield Hospital, Chelmsford, Essex, United Kingdom.*

Introduction: BP gradients in hemodialysis fistulae can identify venous or arterial stenoses *(Sullivan et al 1993)*. Gradients can be obtained non invasively.

Method: An algorithm[3] combining arm BP with Doppler U/S spectral data has been tested against direct pressure measurement in an in vivo animal model *(slope = 0.93 ,zero intercept +0.12mmHg, r =.94, range 34 to 82mmHg).*

A prototype instrument[4] computes a pressure gradient plot by sampling at multiple locations.

Aim: Demonstrate the clinical utility of the instrument on a-v fistulae.

Results: 39 sets of measurements were made on 33 native fistulae. Doppler data was recorded from the mid brachial artery and the basilic or cephalic vein in the upper arm. In several cases multiple sites were sampled.

Table 1 shows mean, SD and SD % for MAP, computed arterial pressure Pa/MAP, computed venous pressure Pv/MAP and brachial artery flow Q ml/min (Duplex measurement).

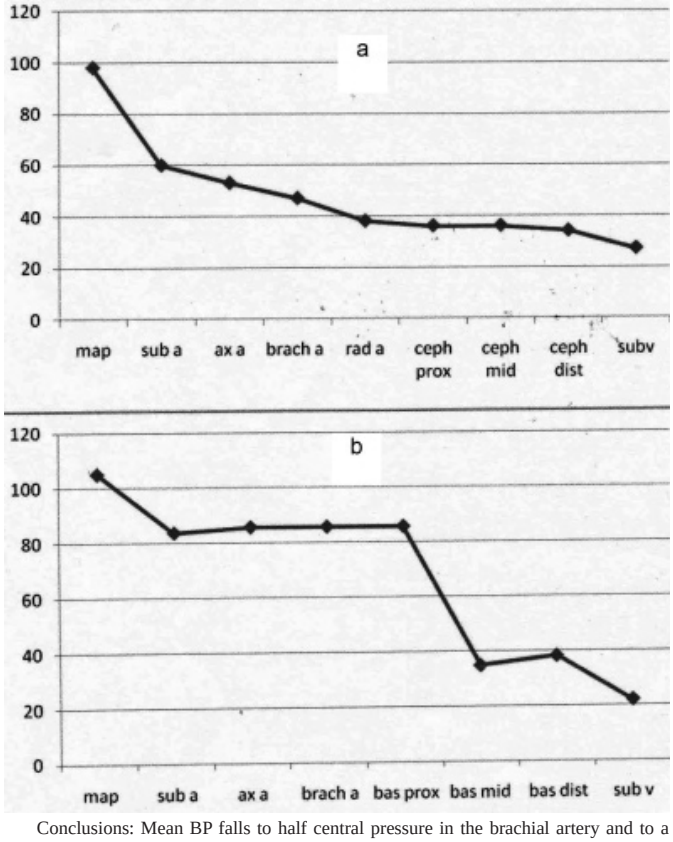
Table 1

| | MAP mmHg | Pa/MAP | Pv/MAP | Q ml/min |
|---|---|---|---|---|
| Mean | 97.1 | .48 | .34 | 1099 |
| SD | 16.0 | .08 | .08 | 467 |
| SD% | 16 | 17 | 24 | 42 |
| N | 39 | 39 | 39 | 31 |

Fig 1a shows the BP gradient recorded in a normal functioning fistula

Fig 1b shows the BP gradient in a failing fistula with a 70% stenosis

**Figure 1**



Conclusions: Mean BP falls to half central pressure in the brachial artery and to a third in the vein.Noninvasively obtained mean BP gradients may provide a clinically useful monitoring method.

[3]DK and MA are joint holders of the provisional international patent P45995GB-PCT.

[4]DK and GT are co developers of the prototype instrument.

**TH-PO571**

**The Impact of Vascular Access (VA) Practices on Dialysis Facility Costs and Clinical Outcomes**

Richard Hirth,[1] Marc Turenne,[2] K. Sleeman,[1] Wei Zhang,[1] Robin L. Sands,[1] J. M. Messana.[1] *[1]KECC, U Mich, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

The Fistula First initiative brought greater focus on the desirability of increased use of arteriovenous fistulae (AVF) for hemodialysis VA. Dialysis Facility Reports (DFR) show that AVF use rose from 35% in 2004 to 50% in 2008. Increased AVF use may improve outcomes and lower costs of providing dialysis through reductions in complications and missed treatments.

Using data from DFRs, Medicare Cost Reports, and Medicare claims, we estimated cross-sectional and time series models of the relationship between VA and septicemia rates, standardized mortality ratios (SMRs), and costs per dialysis session. Cross-sectional models controlled for year fixed effects, patient characteristics (age, sex, race, body size, insurer, comorbid conditions) and facility characteristics (size, chain/ hospital status, rural location). Time series models used year-to-year changes within facilities to estimate the relationship between VA and outcomes. An advantage of the time series approach is that it eliminates non-time varying, unobserved confounders. Both sets of models showed generally statistically significant associations between %AVF and the outcome measures and yielded similar results. The table shows the effect sizes scaled to a 15% increase in AVF (magnitude of increase observed in the sample period) along with p-values.

| Outcome Measure | Cross-Section Model | Time Series Model |
|---|---|---|
| Composite Rate (CR) Dialysis Costs | - $1.22 (.06) | - $0.96 (.13) |
| Separately Billable (SB) Drugs and Labs | - $1.06 (.003) | - $1.05 (.001) |
| Total Costs (CR + SB) | - $2.16 (.004) | - $2.09 (.01) |
| SMR | - .062 (<.0001) | - .054 (<.0001) |
| % of Patients with Septicemia | - .78% (<.0001) | - .84% (<.0001) |

Increased AVF use between 2004 and 2008 was associated with modest decreases in cost per treatment. The clinical effects are quite meaningful, with SMRs falling more than 5%, and occurrences of septicemia in the current or previous three months falling by about 8% (.8% reduction relative to a 10.1% occurrence rate).

**TH-PO572**

**Better Agreement between Incident Arteriovenous Fistula Status on the Centers for Medicare & Medicaid CMS-2728 Form and Medicare Claims Identifies Facilities with Better Quality of Pre-Dialysis Care**

Eiichiro Kanda,[1] Jenna O. Krisher,[2] William M. McClellan,[1] T. Christopher Bond.[1] *[1]Epidemiology, Emory University, Rollins School of Public Health, Atlanta, GA; [2]ESRD Network 6, Raleigh, NC.*

**Background and Objectives:** This study investigates the agreement between CMS-2728 and Medicare claims data for pre-ESRD AVF placement.

**Methods:** CMS-2728 forms were linked to Medicare in- and out-patient claims for 10,401 incident ESRD patients aged 65 years or older at the onset of hemodialysis between June 1, 2006 and May 31, 2007 in North Carolina, South Carolina and Georgia (ESRD Network6). Records were matched to the first Medicare claim for AVF placement during the year prior to beginning dialysis. CMS-2728 AVF and Medicare claims were classified (Yes, No). We assessed percent agreement between CMS-2728 data and Medicare claims by Cohen's kappa coefficient for 375 facilities. The association between agreement and pre-ESRD care (nephrologist referral, degree to which albumin, hemoglobin and erythropoietin met clinical guidelines) was evaluated with regression models adjusted for facility mean age, race, and gender. Race was included in models as a variable that predict health care quality and outcomes (access to care, insurance status, and differential treatment).

**Results:** Facility rate of agreement between CMS-2728 and Medicare billing was 77.8%, median 80.0%, 25th to 75th range (70.0% to 86.7%); mean kappa statistic was 0.45 (modest agreement); median 0.46 (range 0.27 to 0.63). As CMS-2728 and Medicare claims became more congruent, the proportion of incident patients with AVF and nephrologist referral increased.

Table 1 Relationship between the Degree of Agreement between 2728Data and Medicare Billing Data and Incident AVF Rate in Network 6 Area (6/1/06-5/31/07)

| 2728/claims agree Kappa group | All | No agreement | Slight 0-0.2 | Modest 0.2-0.4 | Moderate 0.4-0.6 | Strong >0.6 | ANOVA P-value |
|---|---|---|---|---|---|---|---|
| Facilities (n) | 375 | 31 | 39 | 75 | 108 | 122 | - |
| Patients/center | 16.2 | 13.3 | 15.9 | 16.4 | 18.0 | 15.3 | 0.002 |
| Average value of % agreement | 77.8% | 59.6% | 61.5% | 72.0% | 79.4% | 89.9% | <0.0001 |
| Neph referral | 61.0% | 59.3% | 54.1% | 64.1% | 60.3% | 62.4% | 0.174 |
| Incident AVF | 13.7% | 9.1% | 10.9% | 13.4% | 14.2% | 15.4% | 0.01 |

**Conclusion:** Agreement between AVF placement by CMS-2728 and Medicare claims varies among facilities. Higher AVF placement and nephrologist referral rates tended to predict better congruence between the two data sources.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO573**

**Effective Bedside Screening for Fistula (AVF) Stenosis Should Be Taylored to the Site of Arteriovenous Anastomosis** Nicola Tessitore,[1] Valeria Bedogna,[1] Giovanni Lipari,[2] Giancarlo Mansueto,[3] Antonio Lupo,[1] Albino Poli.[4] *[1]Hemodialysis Unit Ospedale Policlinico, Nephrology Div.; [2]Surgical Science Dpt.; [3]Radiology Inst.; [4]Public Health Dpt., University of Verona, Verona, Italy.*

Given different sites of stenosis and access blood flow rates (Qa), diagnostic tools and criteria for AVF stenosis might conceivably vary according to the anastomosis site.

To test this hypothesis, we assessed the performance of several bedside tests (physical examination(PE), blood pump flow/arterial pressure(Qb/AP), venous pressure at Qb 200 ml/min(VP200) and Qb 300 ml/min(VP300), derived static venous pressure(VAPR), and Qa measurement) in diagnosing angiographically-proven >50% stenosis in an unselected population of 114 hemodialysis patients (82 m, 32 f, aged 63±16 y) with mature AVFs (41 at the wrist [dAVF],73 more proximally at the mid-forearm or the elbow region [pAVF]).

The prevalence of inflow stenosis(upstream from the venous needle)(STin) was uninfluenced by the anastomosis site (41% in dAVF vs 38% in pAVF), while that of outflow stenosis(downstream from the venous needle)(STout) was higher in pAVF (20% vs 2%,p=0.01).

In dAVF, the best test for STin was Qa<650 ml/min (90%[76-97] accuracy, 82%[57-96] sensitivity, 96%[79-100] specificity). In pAVF, the best test for STin was the combination of positive PE and Qa<900 ml/m (85%[73-91] accuracy, 71%[51-87] sensitivity, 91%[79-97] specificity), which significantly improved specificity in comparison with PE (76%[60-87]) and Qa<900 ml/min (73%[58-85])(p=0.02) without unduly reducing sensitivity. A positive PE and VAPR>0.5 were both equally highly diagnostic for STout (86%[76-93] and 85%[75-92] accuracy, 80%[52-95] and 87%[59-98] sensitivity, 88%[77-95] and 84%[73-93] specificity). Combining PE and VAPR>0.5 afforded a non-significant improvement in specificity.

Our study shows that an effective screening program for detecting and locating stenosis with an accuracy of 85% or more can be implemented during dialysis by tailoring the choice of the screening procedures to the site of the arteriovenous anastomosis, Qa being the best choice for wrist AVF, and PE followed by Qa or VAPR measurement for more proximally-located accesses.

**Single Centre Experience of Routine Post-Operative Doppler of Vascular Access for Dialysis** Krish S. Raman,[1] Anuradha Jayanti,[1] Arvind Ponnusamy,[1] Lourinti Fletchman,[1] Zulfikar Ali Pondor,[1] Babatunde Adeniyi Campbell,[2] Afshin Tavakoli,[2] Alistair G. Cowie,[1] Rosemary L. Donne.[1] *[1]Renal Medicine, Salford Royal Hospital, Salford, United Kingdom; [2]Surgery, Manchester Royal Infirmary, Manchester, United Kingdom.*

**Introduction**

The UK Vascular Access Joint Working party report recommends that at least 70% of incident haemodialysis patients should start dialysis via an AV fistula and that an early post-operative review of fistula function is performed. In our unit a single radiologist performs a post-operative doppler ultrasound at 8-12 weeks.

**Aim**

To assess whether our current practice is effective in ensuring a functioning fistula at dialysis start.

**Methods**

Prospective data collection on incident haemodialysis patients identified those who had fistula surgery prior to dialysis start. These patients were analysed retrospectively recording details of surgery, doppler results and further action taken.

**Results**

64 patients who had prior AV fistula surgery commenced haemodialysis during the 12 months before 1st May 2010. 56 patients had a Doppler of the fistula. 51 of these were within 8-12 weeks and the remainder occurred later because of cancellations or non-attendance. 90% of the patients who attended for a Doppler started dialysis via an AV fistula.

27/56 patients had a normal scan and 26 of these commenced dialysis with an AV fistula. 29/56 patients (52%) had an abnormal scan. Of these, 32% had a further scan but no intervention, 15% had radiological intervention and 63% required further surgery. 86% of these 29 patients commenced dialysis via an AV fistula. The remaining 14% commenced dialysis via a line, which in the majority occurred within 8 weeks of fistula creation. Of 96 patients starting maintenance haemodialysis during this period, 64 patients (66.6%) started dialysis through AV fistula and none on grafts.

**Conclusion**

Post-operative doppler successfully identified problems with fistula maturation allowing action to be taken to minimise dialysis catheter use. In the most challenging patients, with difficult vessels or low GFR, catheter use may have been avoided by a post-operative doppler within 2 weeks followed by urgent intervention.

**TH-PO575**

**The Pragmatic Association of Vessel Mapping Timing and AVF Placement** Deuzimar Kulawik,[1] Jeffrey J. Sands,[2] Kelly M. Mayo,[3] Jifeng Ma,[4] Arif Asif.[5] *[1]FMQAI, Tampa, FL; [2]FMC, Celebration, FL; [3]FMQAI, Tampa, FL; [4]FMQAI, Tampa, FL; [5]Univ of Miami, Miami, FL.*

**Objective**: The primary purpose of vessel mapping (VM) is to identify vessels suitable for AVF placement. While the role of vessel mapping on AVF rates has been well studied, the impact of the timing of VM prior to the initiation of hemodialysis on AVF rates has not been systematically studied.

**Methods:** Incident Medicare end stage renal disease patient claims from the State of Florida (1/1/2006 to 12/31/2009) were used to identify VMs. The type of vascular access that was used for the first outpatient dialysis was determined by the CMS form 2728. VMs were identified by CPT codes: G0365 for overall vessel mapping; '93930', '93931', '93970', '93971' for ultrasound VM; '36005','75822','75820' for venography VM. Chi-square test and logistic regression were used to ascertain the association of timeliness of vessel mapping and AVF rates.

**Results:** Consistent with previous studies, VM increased AVF rates (VM=35.17% versus no VM=27.10%, p<0.0001). The length of time interval from VM to the initiation of hemodialysis had a significant impact on AVF rates. Vessel mapping performed 2 months to a year prior to the initiation of hemodialysis had the highest impact on increasing AVF rates (Table 1). Patients with VM within 30 days of the initiation of hemodialysis had similar AVF rate than the patients who did not have VM at all.

**Conclusion:** The results suggest that VM has the greatest impact on improving AVF rates when performed within 2 months to a year prior to the initiation of hemodialysis.

Impact of Timing of VM on AVF Rates

| | No VM | VM within 0-30 days | VM within 31-60 days | VM within 61-90 days | VM within 91-180 days | VM within 181-365 days | VM >365 days |
|---|---|---|---|---|---|---|---|

**TH-PO576**

**The Viability of Arteriovenous Access for Hemodialysis in Elderly Versus Middle-Aged Patients** Samir Parikh, Chadwick E. Barnes, Anil K. Agarwal. *Nephrology, The Ohio State University, Columbus, OH.*

Purpose: Arteriovenous fistula (AVF) is considered the most preferable vascular access (VA) for hemodialysis (HD), followed by arteriovenous graft (AVG). Catheters are the least desirable VA. Recently, the success and appropriateness of AVF and AVG in older patients has been debated due to the limited life span of the patient and the VA as well as the efforts required to develop and maintain these VA. The purpose of this study is to compare the success rates of AV accesses in older and younger cohorts of HD patients.

Methods: We are retrospectively reviewing the AV accesses placed between 1998 and 2008 (N=1200) at our center for rates of primary and cumulative patency, numbers of interventions required to establish and maintain patency, time before first intervention, time from access creation to first use and several patient demographics. Findings in patients ≥70 years of age and a group of patients aged 30 to 55 years are being compared.

Results: We have analyzed data from 2007 and 2008 thus far. Of a total of 235 AV accesses placed during this period, 32 were in elderly patients, and 4 were lost to follow up. We randomly selected 35 patients, ages 30-55 years, as controls.

| DEMOGRAPHICS | Average Age(yrs) | Sex(%male) | Race (%Black) | Access (%fistulas) | Diabetes (%) | Tobacco (%) | |
|---|---|---|---|---|---|---|---|
| Elderly (n=28) | 76.9 | 60.7 | 17.9 | 78.6 | 53.6 | 39.3 | |
| Control (n=35) | 45.5 | 68.6 | 68.6 | 65.7 | 54.3 | 42.9 | |
| | | | | | | | |
| RESULTS | Cumulative patency(%) | Interventions prior 1st use (avg) | Total Inter-ventions (avg) | Time to 1st intervention (mos) | Time to 1st use (mos) | Deceased (%) | Primary failure (%) |
| Elderly (n=28) | 67.9 | 1.29 | 4.17 | 7.05 | 4.18 | 32.1 | 21.5 |
| Control (n=35) | 80 | 1.26 | 3.03 | 3.67 | 4.3 | 23 | 20 |

Conclusions: Our preliminary analysis demonstrates that AV accesses in patients ≥70 years of age have a high cumulative patency rate similar to younger patients. The primary failure rate, number of interventions prior to first access, and total number of interventions are also similar. Our preliminary data suggest that permanent VA is a viable form of HD access for advanced age patients. A complete analysis from 1998 to 2008 is in progress to be presented at the meeting.

**TH-PO577**

**Superficialization of the Radial Artery – The Novel Option of the Vascular Access Creation on the Forearm** Waclaw Weyde, Tomasz Golebiowski, Mariusz Kusztal, Jozef Penar, Madziarska Katarzyna, Magdalena Krajewska, Krzysztof Letachowicz, Miroslaw Banasik, Beata Strempska, Marian Klinger. *Nephrology and Transplantation Medicine, Wroclaw Medical University, Wroclaw, Poland.*

The standard approach in patients (pts) with clotted forearm arteriovenous fistula (AVF) is the creation of the next vascular access on upper arm using own patient vessels or prosthetic graft. We have elaborated the new procedure based on the superficialization of the radial artery which diameter extends during fistula maturation from 1.5–2.5 mm up to 5-6 mm. This enlargement remains even after clotting of AVF.

Material and methods

The procedure of radial artery superficialization was undertaken in 6 chronic HD pts (age 68±16 y, 2 F, 4 M) dialyzed by forearm AVF for 27±26 months. In 4 pts the forearm veins were completely obstructed, in 2 pts the central outflow stenosis required AVF closure. In these persons the procedure was performed after arm edema subsidence. Preoperatively the diameter and patency of radial and ulnar arteries were evaluated by Doppler ultrasound. In local anesthesia, 10cm long skin incision above radial artery was made. All collaterals were ligated to allow the artery mobilization, and finally it was placed in subcutaneous pocket. At the end the vessel bed and the skin was sutured. The attempt was successful in 5 pts, complicated by transient hematoma in one case. In 1 female patient the procedure was abandoned due to small radial artery diameter (4mm) detected intraoperatively. The superficialized radial artery is punctured uneventfully during HD sessions in 5 pts by period from 4 up to 9 months without pain complains. The plethysmography examination (PVL device; Biomedix, USA) did not reveal any signs of hand's ischemia.

Conclusions:1.The described superficialization of the radial artery is the new procedure enabling the maintenance of the forearm HD access in patients with irreversible clotted wrist AVF and/or with untreatable central outflow stenosis. 2.The procedure is particularly suitable for patients with compromised cardiac function.

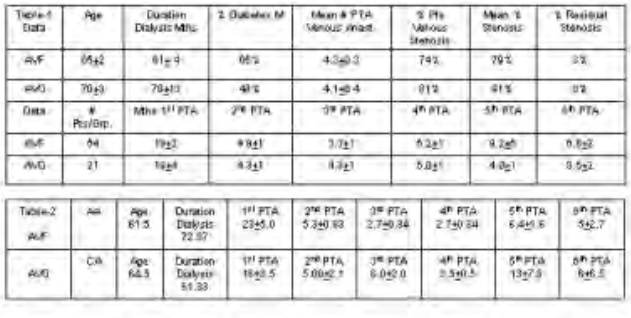
**TH-PO578**

**Serial PTA of Dialysis Access: Comparative Responsiveness of AVF and AVG Venous Outflow Tracts to Repeated Angioplasty** James A. Tumlin. *Division Nephrology, University Tennessee College Medicine Chattanooga, Southeast Renal Research Institute, Chattanooga, TN.*

The failure of dialysis accesses remains a leading cause of morbidity and cost among ESRD populations. The onset of intimal hyperplasia and smooth muscle cell infiltration leads to progressive narrowing of the lumen, impaired blood flow and ultimately thrombosis of both AVF and AVGs. Percutaneous angioplasty (PTA) can restore blood flow, but is limited by elastic recoil and recurrent stenosis. Few studies have investigated the efficacy of or time between serial PTA of individual lesions within venous outflow tracts. To investigate this, we have prospectively studied 75 ESRD patients with stenotic dialysis accesses (54 AVF:21 AVG) undergoing serial PTA of venous outflow tracts. The primary endpoint is the time between serial PTAs and percent recoil of lesions within the venous outflow tract.



As in Table-1, 74% of patients with AVF and 81% with AVG developed a stenosis in the venous outflow. There was no difference in age, duration of dialysis or percentage of diabetics between AVF or AVG. The mean time from insertion to 1st PTA was 19±2 and 19±4 months for AVF and AVG respectively (P=NS). There was no difference in the mean number of angioplasties to venous outflow tracts for AVF 4.3±0.3 and AVG 4.1±0.4 respectively (p=NS). There was no difference in time between the 1st and 6th PTA; averaging 5.8 and 5.2 months for AVF and AVG respectively (P=NS). Moreover, the percent dilation in response to PTAs did not diminish over time. Lastly, there was no difference between African Americans and Caucasians or diabetic and non-diabetic patients in the number or frequency of serial PTA (table-2). In summary, we find that serial PTAs of AVF and AVG remains effective through the 6th PTA without significant elastic recoil. The current data suggests that serial PTA to the venous outflow is safe and effective.

**Clinical Predictors of Arteriovenous Fistula (AVF) Patency** Carrie Grafft, James T. McCarthy, John J. Dillon, Robert C. Albright, Bernice (Bonnie) M. Jenson, Karl A. Nath. *Nephrology, Mayo Clinic, Rochester, MN.*

The AVF is the optimal access for hemodialysis (HD). Unfortunately, the rate of primary failure is high and complications associated with placement are rarely reported. We analyzed the outcomes of AVF placement and predictors of patency with a retrospective cohort study of AVFs placed at Mayo Clinic Rochester from January 2006 through December 2008. We examined the primary and secondary failure rate, plus hospitalizations and complications associated with AVF placement. The complications included infection, bleeding, steal syndrome, aneurysm, nerve injury, seroma, and subclavian stenosis. Primary failure was defined as AVF abandonment prior to use for HD; secondary failure was abandonment after use for HD. Primary patency was the interval from AVF placement to intervention or abandonment, and secondary patency was the interval from placement to abandonment. The first AVF for each patient was used for this analysis. Primary patency and secondary patency were determined using Kaplan-Meier survival curves, and Cox-proportional hazard models were used to determine predictors of patency.

During the studied time period, 293 patients had AVF created. The primary failure rate was 37.1% after exclusions (patients never requiring HD; died before use; transplanted prior to AVF use, or lost to follow up). Of the AVF that were suitable for dialysis, 11.4% failed during the median follow-up time of 379 days. A complication occurred in 21.2% of patients and a hospitalization was associated with fistula creation in 12.3% of the patients. Artery size was the only predictor of both primary and secondary patency in our cohort, and diabetes predicted primary patency only.

The decision to create AVF for HD will need to be individualized for each patient, but should be the primary HD vascular access if possible. Age, sex, gender, BMI, diabetes, cardiovascular disease, or time on HD (vintage) should not preclude AVF placement. More stringent criteria for artery size may need be considered prior to AVF creation to improve patency rates.

**Use of Low Dose Aspirin Does Not Prolong Post Dialysis Needle Site Holding Time for Hemostasis** Sorour Rahgoshay,[1] Alejandro Solano Bayardo,[1] Saadia Sherazi,[1] Geetha Koushik,[1] Anum Choudhry,[2] Michael Disalle,[1] Wajid M. Choudhry.[3] *[1]Internal Medicine, Unity Health System, Rochester, NY; [2]MHS, Rochester, NY; [3]Department of Nephrology, Unity Health System/University of Rochester, Rochester, NY.*

**Background**

Aspirin is underutilized in dialysis patients. There is generally a fear of excessive bleeding from AVG/AVF in dialysis patients who are treated with aspirin. We studied the effect of low dose aspirin (81mg) on post dialysis needle site holding time (NSHT).

**Method**

A longitudinal cross over study of patients receiving outpatient dialysis using AVF/AVG at Unity Health System Rochester NY from Dec. 2009 to May 2010. Patients were divided into two arms. "On Aspirin" and "Off Aspirin". At the end of dialysis treatment needles were removed and needle sites were held under pressure to record time to hemostasis.(NSHT). The dose of heparin used during individual dialysis treatment remained unchanged as these patients served their own controls. Patients were studied for 2 weeks on aspirin followed by 1 week of wash out period. They were then studied for another 2 weeks as off aspirin arm. Patients were excluded if they required aspirin for secondary prevention or had any contraindication to aspirin use.

**Results**

There were 38 patients who completed the study, no side effects were noted. Data was analyzed by using paired T test. Average NSHT for venous site was 11.07±3.8 minutes in on aspirin arm compared with 11.24 ±3.9 minutes in off aspirin (p 0.74)

Average NSHT for arterial site was 10.8±3 min in on aspirin arm compared with 11.7± 4.7 min in off aspirin (p 0.07) as shown.

Post Dialysis Needle site Holding time (NSHT) in ptients "On-Aspirin" and "Off- Aspirin"

| | No. of NSHT observed | Venous site Holding Time (Minutes) | Arterial site Holding Time (Minutes) |
|---|---|---|---|
| On Aspirin | 228 | 11.07 ± 3.8 | 10.8 ± 3.0 |
| Off Aspirin | 228 | 11.24 ± 3.9 | 11.7 ± 4.7 |
| Statistical Significance | | NS | NS |

NS= Not statistically significant NSHT=Needle site holding time

**Conclusion**

In our study population we did not find any difference in NSHT in patients receiving low dose aspirin compared when they were off aspirin.

**Patient Attitudes towards the Arteriovenous Fistula: A Qualitative Study on Vascular Access Decision Making** Wang Xi,[1] Lori E. Harwood,[1] Michael Diamant,[1] Kerri Gallo,[1] Jessica M. Sontrop,[2] Jennifer J. Macnab,[2] Louise M. Moist.[1] *[1]Nephrology, London Health Sciences Center, University of Western Ontario, London, ON, Canada; [2]Epidemiology and Biostatistics, University of Western Ontario, London, ON, Canada.*

The incident and prevalent use of arteriovenous fistula (AVF) in Canadian hemodialysis patients is declining and up to 30% of eligible patients refuse the creation or cannulation of an AVF. The objective of this qualitative study was to understand patient attitudes, beliefs, preferences and values around vascular access (VA). We conducted semi-structured interviews with 13 patients, 6 of whom had previously used an AVF and 7 who continued to dialyze with a catheter. Transcribed interviews were reviewed by 3 persons with agreement on the following 3 main themes that impacted decision making around VA: (1) impact of previous personal or vicarious experiences with the fistula. Patients suggested cannulation, bleeding, time commitment, and appearance to be important deterrents against obtaining an AVF; (2) knowledge transfer and informed decision making. Patients identified knowledge transfer from other patients to be as important as knowledge transfer from health care workers, that information on VA was presented but not understood, and that timing of information was crucial with information overload at the start of dialysis; and (3) maintenance of status quo and outlook on life. This was an important determinant of VA as patients' stated they live day to day and maintain the status quo without being influenced by the mortality risks with a catheter. They expressed being overwhelmed with decision making and change preferring to maintain their current state. These themes allow us to understand the reasoning process behind patient AVF refusal and to identify opportunities in timing and formatting of information transfer, assisting in decision making, and ensuring a patient-centered approach to use of the fistula.

**The Creation of Native Fistula as First Vascular Access in Elderly Patients: An Italian Experience** Chiara Venturelli,[1] Giovanni Cancarini,[2] Giuliano Brunori.[1] *[1]Division of Nephrology, "S.Chiara" Hospital, Trento, Italy; [2]Division and Institution of Nephrology, University of Brescia Spedali Civili, Brescia, Italy.*

Background: In the last decade, the number of elderly patients (≥65 years) who started hemodialysis increased. These patients have an elevated incidence of comorbidities that can make difficult to create a vascular access using native vessels. The type of vascular access (fistula, graft, catheter) plays an important role in the results of dialysis treatment. The ideal vascular access remains the arterovenus fistula (AVF). Graft (AVG) and catheter (CVC) should be considered as 'second choice' for a higher incidence of complications.

Methods: we analyzed the patients who started hemodialysis in 2 tertiary care centres of northern Italy between 1st January 2006 to 31th December 2008 (Trento and Brescia). Dialysis population is 600 patients in an area of 1.100.000 people. Patients were divided in two group: patients ≥65 years (E) and <65 years (Y). The analysis between the two group was performed using demographic characteristic (age, gender, risk factors), access function, type of vascular access. As vascular access we considered AVF, AVG, CVC. We assay the survival rate of patient and vascular access.

Results: In a 3-year period 336 patients started HD: 208 E and 128 Y. As first vascular access for HD in the total population we have 191 (57%) wrist AVF, in 80 (24%) elbow AVF, 15 (4%) AVG, 50 (15%) CVC.

Type of access in E vs Y

| | E | Y |
|---|---|---|
| AVF | 157 (75.5%) | 114 (89%) |
| AVG | 9 (4.3%) | 6 (4.7%) |
| CVC | 42 (20.2%) | 8 (6.3%) |

The primary patency of AVF was similar in Y and E, for AVG patency was 100% in Y and 44.4% in E (p=0.018).Using Cox analysis for vascular access survival, we did not observe any statistically significant difference in E vs Y for all the risk factors tested. Analyzing patients survival rate with Cox analysis we find a grater mortality rate in patients that had used CVC as first vascular access (p<0.0001).

Conclusions: According to NFK DOQI Clinical Practice Guidelines, we suggest that AVF can be considered the preferred types of access because of the low incidence of complications and better survival. AVF can be created also in elderly patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO583**

**Increased Hemoglobin Variability as a Risk Factor for Vascular Access Dysfunction in Chronic Hemodialysis Patients** Tsutomu Koike,[1] Fumihiro Tomoda,[1] Taizo Nakagawa,[1] Hidenori Yamazaki,[1] Hexing Liu,[1] Satoshi Kagitani,[1] Hiroshi Inoue,[1] Hitoshi Hirata,[2] Masanari Kageyama.[2] *[1]The Second Department of Internal Medicine, University of Toyama, Toyama, Japan; [2]Jonan Naika Clinic, Toyama, Japan.*

Objective: Increased Hb level leads to the occurrences of vascular access thrombosis in hemodialysis (HD) patients. Recently, increased variability of hemoglobin (Hb) has been highlighted as a risk of mortality of HD patients. However, the influences of Hb variability (HbV) on vascular access have not yet been explored. In the present study, therefore, the associations of HbV with occurrences of vascular access dysfunction (VAD) were evaluated in HD patients. Design and Methods: In 70 chronic HD patients, HbV was estimated at the prospective follow-up of 1 year by 4 parameters including standard deviation (SD) of Hb, residual SD (RSD) of Hb, and numbers of Hb cycling defined by cycles which amplitude > 1.5 g/dL and duration > 8 weeks, and numbers of excursion defined by half of one cycle. The parameters of HbV and the other factors affecting VAD were compared between 29 patients complicated with VAD defined by venous stenosis or thrombosis (D group) and the remainders without VAD (N group). Results: SD and RSD of Hb were significantly elevated in D group compared with N group (0.86±0.09 g/dL, 0.70±0.06 g/dL vs 0.67±0.03, 0.54±0.01). The numbers of Hb cycling and excursion were also increased in D group than in N group (0.74±0.20 per patient/year, 1.84±0.21 per patient/year vs 0.31±0.02, 1.31±0.14). However, averaged levels of Hb, weekly erythropoiesis stimulating agent (ESA) doses and responsiveness to ESA defined by the weekly ESA doses divided by Hb, did not differ between the two groups. There was no difference in calcium × phosphate product, C-reactive protein, interdialytic weight gain and blood pressure during HD between both groups. In multiple logistic regression analysis, SD of Hb and weekly ESA doses were independent determinant factors for VAD, as shown by odds ratio of 12.01 (95% CI 1.38-209.49) and 0.997 (95% CI 0.993-0.999), respectively. Conclusions: In chronic HD patients, the occurrences of VAD might be associated with HbV in addition to the used dosage of ESA.

**Costs and Outcomes of Endovascular Treatment of Thrombosed Arteriovenous Fistulas** Luis Coentrao,[1] Pedro Bizarro,[1] Carlos Alexandre Ribeiro,[2] Ricardo Neto,[1] Manuel Pestana.[1] *[1]Nephrology R&D Unit, Hospital S. João, Faculty of Medicine, Porto, Portugal; [2]Financial Managment Unit of Medicine, Hospital S. João, Porto, Portugal.*

**Background:** Previous studies that have examined the procedure of choice for arteriovenous fistula (AVF) thrombectomy have focused exclusively on clinical outcomes and, in the absence of costing data, current guidelines do not take into consideration economic issues. In the present study, we determined the costs and outcomes of endovascular treatment of thrombosed AVF in a single centre.

**Methods:** Retrospective cohort of 44 consecutive hemodialysis patients who underwent percutaneous declotting of a completely thrombosed AVF by manual catheter-directed thromboaspiration over a period of 1 year (January 1 to December 31, 2008). Patients were followed-up for a period of 1 year. Success, complications and secondary interventions were recorded according to consensus definitions. A comprehensive measure of total vascular access costs was obtained. Costs are reported in US 2009 Dollars.

**Results:** The mean patient age was 66 years, 66% were male and 35% had diabetes. The average time on dialysis was 4.9 years and the mean fistula age was 4.5 years. Fifty five percent of the patients had forearm AVF. Technical success was achieved in 42/44 following percutaneous thromboaspiration. The primary and secondary patency rates were 63% and 78% at 1 year, respectively. Primary patency rate at 12 months was significantly better for forearm AVF (70% *vs.* 43%; $P = 0.047$). The mean cost of all vascular access care during year 1 was $3459 (median $2115; IQR $2115 to $19505). The mean cost for maintaining a forearm and an upper arm AVF was $2595 (median $2115; IQR $2115 to $4653) and $4580 (median $2724; IQR $2115 to $19035) per patient-year at risk, respectively ($P = 0.015$).

**Conclusion:** Endovascular treatment of thrombosed AVF is a cost-effective procedure for the maintenance of vascular access in hemodialysis patients. Percutaneous thrombectomy efficiency is superior in forearm AVF.

**Design of the Hemodialysis Fistula Maturation (HFM) Study** Gerald J. Beck,[1] Alfred K. Cheung,[2] Laura M. Dember,[3] Harold I. Feldman,[4] Jonathan Himmelfarb,[5] Thomas S. Huber,[6] John W. Kusek,[7] Prabir Roy-Chaudhury,[8] Miguel A. Vazquez,[9] Charles E. Alpers,[5] Michelle Robbin,[10] Joseph Vita,[3] The HFM Study Group.[7] *[1]Cleveland Clinic; [2]U Utah; [3]Boston U; [4]U Penn; [5]U Wash; [6]U Florida; [7]NIDDK; [8]U Cincinnati; [9]U Texas SW; [10]UAB.*

The DAC Fistula Study found that only 40% of new arteriovenous fistulas (AVFs) matured adequately for use (*JAMA* 2008). Consequently, the NIDDK-sponsored HFM Study was initiated to identify predictors and causes of AVF maturation failure. The goal is to enroll 600 patients undergoing AVF creation. Detailed data on demographics, surgery, clinical factors, vascular anatomy and histology, and vascular biology and physiology are collected pre-operatively, intra-operatively and/or post-operatively, and patients are followed under routine clinical care until AVF maturation or abandonment. Participating sites include 6 clinical centers (Boston U, U Cincinnati, U Florida, U Texas SW, U Utah, U Wash), the Data Coordinating Center (Cleveland Clinic), and the Ultrasound (U Alabama), Vascular Function (Boston U) and Histology (U Wash) cores.

Unique features of the study protocol include 1) pre-operative physiological examination of the vasculature with measurements of arterial flow-mediated dilation, arterial pulse wave velocity, and venous capacitance in the planned surgical arm; 2) detailed documentation of attributes of the surgical personnel and surgical procedures at the time of AVF creation; and 3) serial post-operative ultrasounds, including one within 2 days, to define the course of development of the AVF and changes in adjacent blood vessels. These and other factors will be correlated with each other and with the careful, uniform characterization of subsequent AVF function. Additionally, samples of serum, plasma, DNA and vein used for AVF creation are being stored for future biomarker and mechanistic studies. We anticipate that

this multifaceted assessment will identify clinically useful early predictors of AVF outcome as well as potential targets for interventions to improve maturation. The enrollment period began in May 2010 and the study is expected to be completed in 2013.

**TH-PO586**

**Mathematical Model of Arteriovenous Fistula (AVF): A Powerful Method To Improve Understanding of the Hemodynamics of AVF Failure** William D. Paulson,[1] Arif Asif,[2] Loay H. Salman,[2] Steven A. Jones.[3] *[1]Medicine, Charlie Norwood VA Med. Center, Augusta, GA; [2]Medicine, U. of Miami Miller School of Med., Miami, FL; [3]Biomedical Engineering, Louisiana Tech U., Ruston, LA.*

Failure of AVFs is an important cause of morbidity in dialysis patients. Analysis of the hemodynamics of AVF failure should improve understanding of the mechanisms, diagnosis, and treatment of this problem. In this study, we developed mathematical models of radiocephalic (see figure) and brachiocephalic AVFs that extend a previous model of the synthetic graft (Jones SA: J Biomech Eng 2005). The AVF model includes the cephalic V. anastomosed end to side to either the brachial or radial A., the ulnar A., palmar arch, and a vein that drains the hand and forms a Y connection to the cephalic V. We set mean arterial pressure = 93 mmHg, central venous pressure = 5 mmHg, Hct = 36%. Luminal diameters were based on data from angiographic evaluation of AVFs. Stenosis was placed at the arteriovenous anastomosis of the AVF. Equations from the engineering literature were used to predict circuit blood flows and pressure drops. The equations defined whether flow is laminar entry-flow, laminar, or turbulent, as indicated by the previous in vitro model. Turbulent flow was applied when the Reynolds No. was ≥1500. Equations for turbulent flow and stenosis were modified to reflect the effect of upstream events on downstream segments. The model defines relations between stenosis, flow, intra-access pressures, and luminal diameters. The radiocephalic case predicts reversal of radial A. flow with possible steal that resolves as stenosis progresses at the anastomosis. We conclude that the model provides a powerful method to improve understanding of the hemodynamics of AVF failure by allowing control of circuit conditions while changing values of selected variables at will.

**TH-PO587**

**Predictors of Fistula Maturation in the Dialysis Access Consortium (DAC) Fistula Trial** Laura M. Dember,[1] Michael Allon,[2] Bradley S. Dixon,[3] Bo Hu,[4] Milena Radeva,[4] Tom H. Greene,[5] Gerald J. Beck,[4] John W. Kusek,[6] Harold I. Feldman,[7] The DAC Study Group.[6] *[1]Boston Univ.; [2]Univ. Alabama Birmingham; [3]Univ. Iowa; [4]Cleveland Clinic; [5]Univ. Utah; [6]NIDDK; [7]Univ. Pennsylvania.*

**Background:** A high proportion of new fistulas fail to mature adequately for use. Identifying risk factors for maturation failure should facilitate development of interventions to improve fistula outcomes.

**Methods:** We performed a secondary analysis of the DAC Fistula Trial in which 877 subjects from 9 centers were randomized to clopidogrel or placebo for 6 weeks after fistula creation and followed to ascertain use of the fistula for dialysis. Demographic, clinical, and surgical predictors of fistula usability were identified using forward stepwise regression with adjustment for randomized treatment group and surgical center.

**Results:** Older age, female sex, forearm fistula site and aspirin use at baseline were associated with fistula usability failure (see Table). The relationship between aspirin and usability failure was not attenuated by including cardiovascular disease in the model and may reflect either aspirin use before surgery or the protocol-required discontinuation of aspirin for 6 weeks after surgery. Surgical center was also an independent predictor of usability (adjusted OR 2.94, P=0.02).

**Conclusion:** Among DAC Fistula Trial participants, age, sex, aspirin use, fistula location and surgical center were independent predictors of fistula usability. Further exploration of the relationships between fistula outcome and both aspirin use and modifiable surgical factors is warranted.

Predictors of Fistula Usability Failure

| Predictor | Adjusted Odds Ratio for Failure | 95% CI | P Value |
|---|---|---|---|
| Age (per year)* | 1.02 | 1.00-1.03 | 0.01 |
| Female sex* | 3.58 | 2.51-5.12 | <.0001 |
| Black race | 1.32 | 0.92-1.89 | 0.13 |
| Absence of diabetes mellitus | 1.27 | 0.90-1.78 | 0.17 |
| Forearm fistula* | 2.40 | 1.72-3.35 | <.0001 |
| Aspirin use* | 1.55 | 1.01-2.36 | 0.04 |
| Cardiovascular Disease | 0.97 | 0.66-1.43 | 0.87 |

**Long Term Results of Percutaneous Transluminal Angioplasty (PTA) for Artero-Venous Fistula (AVF) Stenosis Treatment: A Single Centre 5 Years Experience** Emanuele Mambelli,[1] Elena Mancini,[1] Alberto Bazzocchi,[2] Marco Veronesi,[1] Maria Grazia Facchini,[1] Francesco Losinno,[2] Antonio Santoro.[1] *[1]Nephrology, Dialysis, Hypertension, S. Orsola-Malpighi, Bologna, Italy; [2]Radiological Sciences Department, S. Orsola-Malpighi, Bologna, Italy.*

Percutaneous Transluminal Angioplasty is a standard care for AVF stenosis in hemodialysis (HD) patients. However some concern remains over frequency and severity of re-stenosis. The aim of this work was to evaluate the long term results of PTA for the treatment of AVF stenosis in the HD population of our Centre.

We retrospectively analyzed the case records of 531 HD patients considering: type of AVF; use of cutting balloon (CB); incidence of procedure-related complications; number, site and time of restenosis after PTA. Primary patency was the time interval between PTA and the day of access failure or reintervention or end follow-up. Secondary patency included all further PTA procedures until the day of access failure. Death or renal transplant were considered end of follow-up.

Sixty-eight patients (12.8%; 49 M; 69±12 yrs) were treated with 115 PTA performed with a high pressure balloon; CB was used in case of not satisfactory results. Stent placement was avoided. Seventeen patients (25%) showed recurrence of stenosis and were submitted to 64 PTA procedures (7 using CB). Primary treated stenosis were distributed as follows: 2 arterial, 24 juxta-anastomosis vein, 8 draining vein, 3 central vein. The corresponding re-stenosis rate per region was: 17/24 (70.8%), 5/8 (60.3%), 2/3 (66.7%), respectively. On a patient-based analysis, primary stenosis incurred after 205±160 days, restenosis (or new stenosis) after 205±246 (p=NS), 154±116 and 245±243 days, respectively for proximal and distal AVF (p=NS). Only two out of 7 stenosis tretated with CB had restenosis (p=0.05 vs PTA without CB). The only treatment complication was a venous cleft with hematoma. PTA is confirmed as an effective treatment to extend life-time of AVFs. Time of restenosis after PTA is higly variable but generally shorter for proximal AVF. The introduction of CB seems to be a promising event, suggesting that its shrewd use might improve the long-term results of some PTA procedures.

**The Factors Related with Arteriovenous Fistula Patency According to the Hemodialysis Duration** Ju-Young Moon,[1] Young-Il Jo,[2] Sang-Woong Han,[3] Tae Won Lee,[5] Kyung-Hwan Jeong,[5] Sug Kyun Shin,[4] Chun-Gyoo Ihm.[5] *[1]Internal Medicine, Kyung-Hee Univ EWN Medical Center, Seoul, Korea; [2]Internal Medicine, Konkuk University Hospital, Seoul, Korea; [3]Internal Medicine, Hanyang University Guri Hospital, Guri, Korea; [4]Internal Medicine, NHIC Ilsan Hospital, Ilsan, Korea; [5]Internal Medicine, Kyung Hee University Medical Center, Seoul, Korea.*

The patency of arteriovenous access is important for stable and effective hemodialysis (HD), and long-term technical survival is best achieved with a native arteriovenous fistula (AVF). However, maintaining the AVF patency remains a challenging problem. This study was designed to determine the independent prognostic factor for AVF patency according to the HD duration.

We enrolled patients with end-stage renal disease (ESRD) who were treated on maintenance HD in 2010 at several hospitals with available complete medical records. The primary study end point was unassisted patency of the AVF, which was defined as the time from the first fistula surgery to the first AVF failure. An AVF failure was defined as an event that required percutaneous intervention or surgery to revise or replace the fistula, which occurred at least 2 months after fistula formation.

We enrolled 526 patients, mean age was 54±3.4 and the mean duration of dialysis was 40±23 months. Total 111 cases (21.1%) of AVF failure events occurred. The factors related with AVF patency ware different according to the HD duration. Using Cox-adjusted model, we observed a significant correlation between the incidence of AVF failure and surgeon and diabetes in the first half of patients. The last half of patients with AVF failure was related with hyperphosphatemia (mean serum phosphorus >5.5 mg/dL during HD).

The different factor was associated with the development of AVF failure according to the HD duration, and a preventive role of hyperphosphatemia control will be examined more precisely.

**TH-PO590**

**Angiography after Surgical Thrombectomy of Dialysis Grafts: Findings, Procedures and Outcomes** Luis Resende,[1] Artur P. Mendes,[2] Carlos Lucas,[2] Celia Gil,[2] Jose Diogo Barata.[2] *[1]Nephrology, Hospital Central do Funchal, Funchal, Portugal; [2]Nephrology, Hospital de Santa Cruz, Carnaxide, Lisboa, Portugal.*

**Introduction:** Thrombosis is a common complication of vascular access for haemodialysis. Surgical thrombectomy alone fails to identify the underlying vascular lesion. Percutaneous balloon angioplasty as an adjunctive therapy is associated with better graft outcome.

**Methods:** From 1st January 2007 to 31st December 2009, 883 angiographies were performed; 93 (10,5%) were done after dialysis graft surgical thrombectomy. Demographic and clinical data of patients, angiography findings, procedures and outcomes were reviewed.

**Objectives:** Evaluate the angiography findings after surgical thrombectomy of dialysis grafts and determine the factors that influence graft rethrombosis and primary patency.

**Results:** A total of 93 procedures were performed in 78 patients (52,7% males, 67.7±14.3 years, 93.5% caucasians, 34,4% diabetics, 64.2±39.4 months on dialysis, 89.2% upper arm grafts, 18.9±17.5 months graft age).

Vascular stenosis was present in 77 procedures (82.8%) (central - 29%; axillary - 14%; venous anastomosis - 52.7%; intra-graft - 21.5%; multiple - 32.2%). Percutaneous balloon angioplasty was performed in 68,8%. Residual stenosis after angioplasty remained in 24.7% and clinical graft pulsatility in 12.9%.

On univariate analysis, higher graft age (p=0.004), previous graft thrombosis (p<0.001) and axillary stenosis (p=0.015) were significant predictors for graft rethrombosis.

Graft primary patency after angiography was 61.3% and 45% at 3- and 6 months, respectively. According to Kaplan-Meyer survival curve analysis, graft primary patency was lower in black race (p=0.033), diabetics younger than 60 years (p=0.038), episodes of previous thrombosis (p=0.001), axillary stenosis on angiography (p=0.004) and clinical pulsatility after angioplasty (p=0.035). Patients submitted to baloon angioplasty presented a better graft survival (p=0.033).

**Conclusions:** Elevated number of vascular access stenosis, mainly venous anastomosis stenosis. Axillary stenosis were associated with a greater risk of graft rethrombosis. Grafts submitted to balloon angioplasty had a better primary patency rate.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO591**

**Impact of Ultrasonographic Mapping in Construction and Patency of Arteriovenous Fistula in End-Stage Kidney Disease Patients** Maria Joao Carvalho Azevedo Rocha, António Cabrita. *Nephrology, Hospital de Santo António - Centro Hospitalar do Porto, Porto, Portugal.*

Ultrasonographic mapping (UM) of vessels prior to construction of AVF increases the number of distal arteriovenous fistulas formed and improves overall patency rates.

Our purpose is to evaluate the impact in site of fistula and patency rates in our patients after the introduction of our UM programme in 2008.

We retrospectively evaluated demographic and clinical data of 343 patients who attended our clinic for programming a vascular access for dialysis. All patients had a thorough physical examination. In 180 patients (52.5%) UM of arm and forearm was performed by a trained nephrologist. Inner diameter of veins and arteries was evaluated as well as distensibility of veins. The minimum diameter considered adequate was 2 mm for both arteries and veins.

Site of AVF was then proposed and construction was carried out by a team of vascular surgeons. Patency and adequate development were evaluated at 48h and 1 month after construction.

There was no significant difference in mean age (62,96±15,27y vs 64,54±15,75 y; p=0,34), sex distribuition (42% vs 58% female patients; p=0,44) or prevalence of diabetes (51% vs 38%; p=0,24) between the two groups (UM and no-UM).

The AVF sites didn't differ significantly among both groups with the exception of humero-basilic (HB) AVF proposed and constructed in 11.1% of patients with UM and 3,7% of patients with no UM (p=0,013). The other sites were the following (UM vs no UM): wrist radiocephalic AVF (25% vs 22,7%; p=0,70), forearm radiocephalic AVF (5,6% vs 10,4%; p=0,10), elbow braquiocephalic AVF (58,3% vs 63,2%; p=0,38).

The rate of primary failure was significantly different between both groups, 23,3% failure in the UM group and 36,2% in the non UM group (p=0,013).

Ultrasonographic vascular mapping improved primary patency rates of AVF constructed at our center. Its introduction caused an increased number of HB fistulas allowing for more AVF construction in patients otherwise not considered for this type of vascular access.

**Factors Influencing Failure To Create Vascular Access in Municipal Hospital Incident Hemodialysis Patients** Lada Beara Lasic,[1,2] Trina D. Banerjee,[1] Nathan Thompson,[1] Frank Modersitzki,[2] David S. Goldfarb.[1,2] *[1]Nephrology, NYU Medical Center, New York, NY; [2]Nephrology Section, New York Harbor VAMC, New York, NY.*

**BACKGROUND**. A high percentage of municipal hospital (MH) end stage renal disease (ESRD) patients who start hemodialysis (HD) are racial/ethnic minorities with low socio-economic status; a significant proportion is uninsured with poor English language skills. These factors are associated with decreased access to pre-dialysis care, which leads to higher percentage of central venous catheter (CVC) use, rather than arterio-venous fistula (AVF) or graft (AVG) at first HD. We sought to determine factors associated with failure to create vascular access in a MH incident dialysis population.

**METHODS**. Retrospective chart reviews were done of incident HD patients from 2005-2007. Hospitalizations and deaths were recorded in the first 90 days after hemodialysis was started. Results were compared to 2007 USRDS population incident dialysis patients.

**RESULTS.** Compared to USRDS, MH patients are younger (51.6 vs. 64.4 y), have higher percentage of racial/ethnic minority (26% vs. 4.6% of Asian, 42.9 vs. 13.56% Hispanic, 24 vs. 21% African American), have higher % of glomerulonephritis as cause of ESRD (23% vs. 6.8%), start dialysis with lower hemoglobin (9.5 vs. 10.2 g/dl) and lower estimated glomerular filtration rate (7.9 vs. 10.9 ml/min/1.73m$^2$). Higher % of MH patients start dialysis with no insurance (18.6 vs. 7.7%) or with Medicaid (42.8 vs. 24.8%) and with CVC (97.3% vs. 80.6%). Primary cause of failure to create vascular access was patient/disease related in 65% and physician/hospital related in 35%. 51% of patients were hospitalized in the first 90 days, 30% hospitalizations were related to CVCs.

**CONCLUSIONS.** Municipal hospital patients differ from USRDS population but their care is inferior. Timely nephrology and vascular surgery referral and shorter time to access creation is needed. 21% of patients were 19-39 years old, consistent with 2007 USRDS data showing increasing ESRD incidence rates for racial/ethnic minorities age 30-39 y. Better care of the growing, young minority ESRD patients is warranted.

**Utility of Access Flow Monitoring in Predicting Access Thrombosis in ESRD Patients** David B. DaRocha-Afodu, Jennifer J. Tan, Rajesh Agarwala, Sumit Mohan, Herman L. Anderson, Velvie A. Pogue, Jen-Tse Cheng. *Medicine, Harlem Hospital Center/Columbia University, New York, NY.*

Malfunction of vascular access is a challenge in ESRD patients on chronic hemodialysis. Recently CMS started reimbursement for access flow (Qa) surveillance with transonic hemodialysis monitoring systems to evaluate vascular access dysfunction. There is a paucity of data on the optimal value of Qa that best predicts thrombosis of native AV fistulas (AVF) and AV grafts (AVG). We have a monthly vascular monitoring protocol using the transonic ultrasound dilution HD-02 monitor. We reviewed Qa measurements for 101 hemodialysis patients with either an AVF or AVG at our dialysis center retrospectively for the past 30 months to assess the utility of Qa in predicting access thrombosis. Our cohort was 71.3% male, 26.7% diabetic, mean age 54±15.8 yrs. 75 patients (74.3%) had AVF and 26 patients (25.7%) had AVG. A total of 25 patients (27.7%) had a first thrombotic event: 8 events occurring with AVF and 17 with AVG. Our study suggests a significantly lower incidence of access thrombosis among patients with AVF (65.4 vs. 10.7%, p<0.001). There was no difference between the lowest Qa in accesses that did and did not have a thrombosis- among patients with AVF (1028±780 vs 731±331 mL/min, *p=ns*) and AVG (649±509 vs 778±435 mL/min, *p=ns*). In addition, neither diabetes nor location of the access influenced flow rates or outcomes. Our findings suggest that the use of Qa transonic monitoring systems does not improve the diagnostic yield in predicting thrombosis in both AVF and AVG. Larger multicenter studies need to be done to formulate specific guidelines regarding vascular access surveillance.

Incidence of first thrombotic events: AVF vs AVG

| Access | Clotted | Patent | Total | % clotted |
|---|---|---|---|---|
| AVF | 8 | 67 | 75 | 10.7 |
| AVG | 17 | 9 | 26 | 65.4 |
| Total | 25 | 76 | 101 | 24.8 |

chi-square ($\chi 2$ ) test p <0.001

**Interrupted Time Series Analysis of an End Stage Renal Disease (ESRD) Network-Initiated Intervention To Improve the Prevalent Arteriovenous Fistula Rate in a Group of Facilities** Janet R. Lynch,[1] Nancy Gregory,[1] Nancy Armistead,[1] Stephen L. Seliger.[2] *[1]Mid-Atlantic Renal Coalition, Midlothian, VA; [2]Department of Nephrology, University of Maryland School of Medicine, Baltimore, MD.*

**Purpose.** ESRD Network 5 aimed to improve prevalent arteriovenous fistula (AVF) rates in a small dialysis organization (SDO) serving about 1,000 patients through 9 and 7 facilities in each of regions 1 and 2, respectively. **Methods.** Technical assistance in the Fistula First (FF) Change Concepts (CC) was used to stimulate improvement. Monthly vascular access data were tracked and pre- and post-intervention rates compared. Interrupted time series (ITS) regression corrected for autocorrelation and using maximum likelihood estimation used 15 months pre and 14 months post QI project initiation data. **Results.** There was no difference in pre (October 2007, 31.3%) and post (December 2008, 34.6%) region 1 AVF rates (p-value=.235). Region 2 improved significantly in the same time period (35.3% to 43.5%, p-value=.008). ITS revealed the AVF rate for region 2 was increasing prior to the intervention (0.38/month, p-value<0.0001) but increased more rapidly afterward (an incremental 0.13/month, p-value=.03 for a total 0.51/month average increase), $R^2$=.98. **Conclusions.** Barriers remain to improving AVF rates. Unlike region 2, region 1 staff reported problems identifying accessible surgeons willing to place AVFs (CC #4). Region 2 facilities made changes (e.g. added vascular access managers - CC #1) and the nurse leader was actively involved in improvements. Network initiated QI interventions, in partnership with natural groupings of facilities, where leadership is actively involved and change concepts are successfully employed, can result in improved quality.

Interrupted Time-Series Regression of Prevalent AVF Rates, Adjusted for Autocorrelation

| | Coefficient | Standard Error | t-statistic | p-value |
|---|---|---|---|---|
| Intercept | 31.1 | 0.33 | 93.5 | <.0001 |
| Baseline trend | 0.38 | 0.03 | 11.95 | <.0001 |
| Trend after intervention | 0.13 | 0.06 | 2.34 | 0.03 |

### TH-PO595

**Prospective Evaluation of Primary Patency of Hemodialysis Vascular Access after Angiography and Angioplasty** Marco Mendes,[1,2] Vasco Baptista Fernandes,[2] Ines Aires,[1,2] Fernanda Gomes,[1] Nilza Gonçalves,[3] Manuel A. Ferreira,[1,2] Fernando Nolasco.[2] *[1]Hemodial, Vila Franca de Xira, Portugal; [2]Hospital Curry Cabral, Lisbon, Portugal; [3]KeyPoint, Lisbon, Portugal.*

Efforts have been done to prevent and solve hemodialysis (HD) vascular access (VA) dysfunction.

During 36 months (m) we prospectively evaluated indications for angiography and the primary patency (PP) (median time to new intervention or thrombosis) of VA, in all our patients (pts) (mean population: 166 HD pts)

The PP was evaluated by Kaplan-Meier method, covariates were adjusted by Cox Regression and results expressed by Hazard Ratio (HR) (SPSS-15.0.).

We conducted monthly determinations of VA flow (Qa) using the BTM-Blood Temperature Monitor-Fresenius Medical Care.

Predefined indications for angiography were: A-V fistula (AVF)Qa < 200 ml/min; PTFE graft < 600 ml/min or a Qa drop > 50% in 2 consecutive months (65.2% pts); significant high venous pressure (VP) and/or edema of VA limb (25.8% pts) and thrombosis of the VA (9.1% pts).

According to these criteria 67 pts were submitted to angiography (mean age 66.7 years; 46.3% male). Hypertension (58%) and diabetes (44%) were the two major co-morbidities. In 51% of cases, VA was an AVF and in 49% a PTFE graft. Antiplatelet drugs were used in 52.2% of pts.

The most frequent angiographic findings included: graft-vein anastomosis stenosis (49.2%), AVF stenosis (14.4%) and central vein stenosis (12.3%.) Angiography was normal in 18.5% of cases.

A successful angioplasty was performed in 66.1% of the pts; 13.8% were referred to surgery.

After angioplasty, thrombosis occurred in 47.0% of cases, mainly in PTFE VA (60.6% vs 33.3%) (p=0.026).

The median PP of VA was 18 m (9.6-26.4 m) for AVF, 12 m (6.9-17.0 m) for PTFE graft and 18 m (13.1-23.0 m) for VA of pts under antiplatelet therapy. PTFE grafts were associated with worse PP results (HR=2.1, IC95% [1.1; 4.4]).According to these results, surveillance programmes of VA disfunction (specially Qa analysis by BTM) and angiographic intervention contribute to a longer survival of VA. The use of antiplatelet agents appears to be protective and prolong VA patency in grafts. Larger cost-benefit analysis are needed to confirm these results.

### TH-PO596

**Improving AVF Rates in Obese Patients: The Role of Vessel Mapping** Deuzimar Kulawik,[1] Jifeng Ma,[2] Jeffrey J. Sands,[3] Kelly M. Mayo,[4] Arif Asif.[5] *[1]FMQAI, Tampa, FL; [2]FMQAI, Tampa, FL; [3]FMC, Celebration, FL; [4]FMQAI, Tampa, FL; [5]Univ Miami, Miami, FL.*

**Background:** The rising prevalence of obesity has been concomitant with the increasing prevalence of CKD population. Due to poor visibility of the veins, traditionally obese patients have not been considered good candidates for an AVF. We investigated the role of vessel mapping (VM) on AVF rates by using BMI.

**Methods:** Incident Medicare ESRD claims from 18,020 Florida patients (1/1/2006 to 12/31/2009) were used to identify CKD patients with and without VMs. BMI was used to categorize patients into underweight (<18.5), normal (18.5-24.9), overweight (25 -29.9) and obese (≥30) categories. The type of VM that was used for the first outpatient dialysis was determined by the CMS form 2728. VMs were identified by CPT codes: G0365, '93930', '93931', '93970', '93971','36005','75822','75820'. Chi-square test and logistic regression were used to ascertain the association of VM, BMI and AVF rates.

**Results:** Significantly increased AVFs rates were observed across all ranges of BMI when preoperative VM was performed. When VM was performed, the AVF rates for underweight, normal, overweight and obese patients were 28.4%, 35.4%, 36.0%, 35.1%, respectively. These differences were not statistically significant. However these values were significantly higher for patients with similar BMI with no VM. The adjusted odds ratio for AVF is 1.46 (95% CI 1.36, 1.56) in favor of VM.

**Conclusion:** The study demonstrates significantly higher AVF in each BMI category with VM and demonstrates that patients with increased BMI have the same likelihood of receiving AVF as patients with normal BMI.

Association BMI / AVF Rates

| | | Under weight | Normal Weight (BMI=18.5-24.9) | Overweight (BMI=25 -29.9) | Obesity (BMI>30) |
|---|---|---|---|---|---|
| No VM | Denominator | 507 | 4203 | 3678 | 4370 |
| No VM | AVF rate | 18.7% | 25.4% | 27.1% | 29.7% |
| VM | Denominator | 176 | 1650 | 1505 | 1931 |
| VM | AVF rate | 28.4% | 35.4% | 36.0% | 35.1% |
| Odds ratio (95% CI) | | 1.72 (1.16, 2.59) | 1.61 (1.42, 1.82) | 1.51 (1.33, 1.72) | 1.28 (1.15, 1.44) |

### TH-PO597

**Defective Membrane Expression of Na-HCO3 Cotransporter NBCe1 Is Associated with Migraine** Masashi Suzuki,[1] George Seki,[1] Shoko Horita,[1] Hideomi Yamada,[1] Takashi Igarashi,[2] Toshiro Fujita.[1] *[1]Internal Medicine, Tokyo University, Tokyo, Japan; [2]Pediatrics, Tokyo University, Tokyo, Japan.*

The $Na^+$-$HCO_3^-$ cotransporter, encoded by SLC4A4, has three splice variants: NBCe1A, NBCe1B, and NBCe1C, mediating distinct physiological roles in the systemic and/or local pH regulation. Homozygous mutations in SLC4A4 cause proximal renal tubular acidosis (pRTA) and ocular abnormalities. In this study, we found two sisters with pRTA, ocular abnormalities, and hemiplegic migraine. Genetic analysis ruled out pathological mutations in the known genes for familial hemiplegic migraine, but identified a novel homozygous 65-base-pair deletion (Δ65bp) in the C-terminus of NBCe1, corresponding to a codon change S982NfsX4 for NBCe1A. Several heterozygous members of this family also presented glaucoma and migraine with or without aura. Despite the normal electrogenic activity in Xenopus oocytes, the Δ65bp mutant showed almost no transport activity due to a predominant cytosolic retention in mammalian cells. Furthermore, the co-expression experiments mimicking the heterozygous status uncovered a dominant negative effect of the mutant through the formation of hetero-oligomer complexes with wild-type NBCe1, which could potentially explain the occurrence of migraine and glaucoma in the heterozygous members. Among other pRTA pedigrees with distinct NBCe1 mutations, we identified 4 additional homozygous patients with migraine: hemiplegic migraine with episodic ataxia in L522P, migraine with aura in Δ2311A, and migraine without aura in R510H and R881C. Evaluation of the corresponding NBCe1B mutants revealed a remarkable coincidence between the lack of plasma membrane expression and the occurrence of migraine, which could not be attributed to a chance coincidence. Furthermore, functional analysis in HEK293 cells confirmed that NBCe1B mutants that lack plasma membrane expression had almost no transport activities, while the other mutants reaching the plasma membrane had reduced transport activities corresponding 30-40% of the wild-type activity. These results demonstrate that the near total loss of NBCe1B activity in astrocytes can potentially cause migraine through dysregulation of synaptic pH.

**Functional Analysis of SNP Mutations Leading to Single Amino Acid Substitution in NBCe1** Osamu Yamazaki, Hideomi Yamada, Masashi Suzuki, Shoko Horita, Ayumi Shirai, George Seki, Toshiro Fujita. *Internal Medicine, Tokyo University, Tokyo, Japan.*

Homozygous mutations in SLC4A4 encoding the electrogenic Na-HCO3 cotransporter cause proximal renal tubular acidosis associated with ocular abnormalities. Although up to 11 SLC4A4 mutations have been identified, the mechanism of NBCe1 inactivation due to the individual mutations has not been completely clarified. Recently, rare mutations in renal sodium transporters such as NCCT and NKCC2 have been shown to affect the level

of blood pressure in general population. In the present study we investigated the impact of SNP (Single Nucleotide Polymorphism) mutations on NBCe1 function. We identified 4 SNP mutations in NBCe1A, resulting in the single amino acid substitution E122G, S356Y, K558R, and N640I. Among them, the frequency of rare allele was reported only for N640I (2.6%). Functional analysis in Xenopus oocytes with two-electrode voltage clamp method revealed that E122G, S356Y, N640I had the activity comparable to that of wild-type NBCe1A. However, K558R had a significantly reduced activity corresponding to 47% of that of wild-type ($p<0.01$). Functional analysis in HEK293 cells with the pH-sensitive dye BCECF also revealed the reduction in transport activity of K558R (45% of wild-type, $p<0.01$), but the activities of other mutants were comparable to the wild-type NBCe1A activity. Immunohistological analysis with confocal microscopy revealed that these SNP mutants were predominantly expressed in the plasma membrane of HEK293 cells. In addition, these SNP mutants were predominantly expressed in the basolateral membrane in the polarized MDCK cells. Biotynylation Western blotting in HEK293 cells confirmed that the surface expression of these SNP mutants was comparable to that of wild-type. These results indicate that, K558R, the only one SNP in the transmembrane domains, inactivates the NBCe1 function without changing the membrane expression in polarized and non-polarized epithelia. Because NBCe1 plays a major role in renal proximal sodium and bicarbonate reabsorption, K558R SNP may be associated with disturbance in systemic acid-base balance or changes in blood pressure.

## TH-PO599

**The C-Terminal Tails of the NBCe1-A Dimer Are Structured: Relevance to CAII Binding** Quansheng Zhu, Liyo Kao, Debra Newman, Ira Kurtz. *Division of Nephrology, UCLA, Los Angeles, CA.*

NBCe1-A mediates basolateral $Na^+$-coupled $HCO_3^-$ efflux in the proximal tubule. The C-terminal tail of NBCe1-A contains a $D^{986}NDD^{989}$ motif that was predicted to interact with intracellular carbonic anhydrase II (CAII) to form a metabolon thereby enhancing $HCO_3^-$ transport. Previous *in vitro* studies have either supported or refuted the existence of the interaction. In order to study this question, we examined the structural properties of the NBCe1-A C-terminal tail *in vivo*. Wild-type NBCe1-A expressed in HEK cells appeared as both monomers and dimers when separated on SDS-PAGE. Surprisingly, the dimerization was eliminated when the cells were pre-treated with NEM (a cysteine reactive regent) indicating that none of the native NBCe1-A cysteines mediates dimerization. Surprisingly, the dimers on SDS-PAGE were found to be due to the spontaneous cross-linking of endogenous cytoplasmic Cys992 in the detergent. Further studies revealed that the residues neighboring Cys992 (10 on each side) could not be cross-linked. Therefore, the two C-terminal monomer tails in the NBCe1-A dimer must be located in close proximity (2 Angstrom) at Cys992 *in vivo*. Importantly, the predicted CAII binding site is near Cys992, raising the question as to how CAII (28 kDa) can bind to this spatially confined region. Asn987 an uncharged residue within the predicted CAII binding site was substituted with cysteine and its accessibility to BM labeling was tested in the absence and presence of over-expressed CAII. In these experiments, no differences in the level of BM labeling were observed. In conclusion, our data demonstrate that the C-terminal tail of the NBCe1-A dimer is highly structured and may sterically prevent CAII binding.

## TH-PO600

**C-Terminal Transmembrane Region of NBCe1-A: Structural Properties and Functional Role** Quansheng Zhu, Rustam Azimov, Liyo Kao, Debra Newman, Ira Kurtz. *Division of Nephrology, University of California, Los Angeles, Los Angeles, CA.*

NBCe1-A and AE1 belong to the SLC4 transport family of membrane proteins that mediate $HCO_3^-$ transport. The C-terminal transmembrane region of AE1 is implicated in anion translocation, and has a unique topology with two re-entrant loops. Although NBCe1-A and AE1 share 40% sequence homology in the C-terminal transmembrane region, we recently showed that their topology differs. To clearly determine the *in vivo* folding of this potential functional important region of NBCe1-A, we performed substituted cysteine scanning mutagenesis of NBCe1-A expressed in HEK cells covering the entire C-terminal transmembrane region (Ala-800 to Lys-967). The topologic location of the introduced cysteine residues was determined by whole cell labeling with the membrane permeant biotin maleimide (BM) and a membrane impermeant MTS-TAMRA cysteine reactive reagent. The results show that regions M813-G828 and D960-K967 are only accessible to BM labeling, indicating their intracellular location. M858 is accessible to both BM and TAMRA and S925-A929 only to TAMRA labeling, indicating their extracellular location. Surprisingly, the P888-R905 region is inaccessible to BM whole cell labeling but partially accessible to TAMRA labeling in isolated plasma membranes, suggesting its cryptic cytosolic location. Substitution of NBCe1-A P868-L967 residues (a functionally important region in AE1) had only a minimal affect on transport function. In summary, our data demonstrate that the C-terminal transmembrane region of NBCe1-A is tightly folded and significantly differs from AE1. This region of NBCe1-A has several interesting features including: 1) highly exposed and cryptic cytosolic loops; and 2) sharp turn between transmembrane segment (TM) 11 and 12, and a cryptic extracellular facing loop between TM 13 and 14. In comparison to AE1, the average size of NBCe1-A C-terminal TMs is greater. Unlike AE1, the C-terminal region is not functionally involved in ion translocation.

## TH-PO601

**Measurement of Oligomerization State of NBCe1-A in Kidney Tissue Via Spatial Fluorescence Intensity Fluctuation Analysis** Mikhail Sergeev,[1] Antoine Guillaume Godin,[1] Paul W. Wiseman,[1] Liyo Kao,[2] Natalia Abuladze,[2] Ira Kurtz.[2] *[1]Department of Physics, McGill University, Montreal, QC, Canada; [2]UCLA School of Medicine for Health Sciences, UCLA, Los Angeles, CA.*

The electrogenic sodium bicarbonate cotransporter NBCe1-A plays an important role in absorbing sodium bicarbonate across the basolateral membrane of the proximal tubule. In the present study, we developed an in situ measurement methodology to determine the oligomeric state of NBCe1-A without requiring tissue disruption using biochemical methods. We first used fluorescent moment image analysis and spatial intensity distribution analysis (SpIDA) to study the oligomeric state of NBCe1-A in cultured mammalian cells expressing NBCe1-A. Both methods allow for unbiased quantitative measurement of fluorescent particle densities and oligomerization states within individual images acquired with confocal laser scanning microscopy. We used cells expressing GPI-anchored monomeric eGFP to quantify the quantal brightness of eGFP. We then examined the basal membrane of cells expressing eGFP-tagged NBCe1-A. Utilizing the recovered values of the eGFP monomeric quantal brightness, we show that NBCe1-A exists on the cell membrane predominantly as a monomer and negligibly as higher order oligomers. As an alternative approach, we performed spatial fluctuation analysis on Alexa488 dye immobilized on cover slips. We then used an Alexa488-α-bungarotoxin conjugate to label cells expressing an NBCe1A-bungarotoxin binding peptide construct. Spatial fluctuation analysis revealed a similar distribution of aggregates as shown for the eGFP data. We then performed SpIDA and moment analysis on immunolabeled NBCe1-A in rat kidney tissue. As a control, we expressed wild type NBCe1-A in HEK293 cells and immunolabeled the cotransporter with the same primary and secondary antibodies used for kidney tissue staining. In rat kidney, SpIDA and moment analysis show that NBCe1-A is present on the proximal tubule basolateral membrane in predominantly dimeric and rarely higher order oligomeric states. Our results demonstrate for the first time that proteins can have a different oligomeric state in native tissue and in heterologous expression systems.

## TH-PO602

**Bicarbonate Translocation of the Sodium/Bicarbonate Transporter SLC4A4 (NBCe1)** Soojung Lee, Inyeong Choi. *Physiology, Emory University School of Medicine, Atlanta, GA.*

NBCe1 plays an essential role in the basolateral $HCO_3^-$ reabsorption in the proximal tubules. We previously demonstrated that the conserved substitution of $Asp^{555}$ in transmembrane domain (TM) 5 with a Glu (D555E) causes the transporter to carry $Cl^-$ in the absence of $HCO_3^-$. To further examine the anion selectivity of this residue, we replaced TM5 of NBCe1 with the corresponding TM of NBCn1, which contains a Glu instead of Asp. Measured by two-electrode voltage clamp, the chimeric transporter in *Xenopus* oocytes produced electrogenic $HCO_3^-$ currents ($I_{HCO3}$). However, the chimeric transporter did not produce $Cl^-$ currents ($I_{Cl}$). Sequence comparison showed that the residues downstream of $Asp^{555}$ (i.e., 558-562) are weakly conserved between NBCe1 and NBCn1. NBCe1 has KKMIK at this region, while NBCn1 has EKLFD (745-749) at the corresponding region. To test whether the lack of $I_{Cl}$ in the above chimeric transporter is associated with these residues, we replaced EKLFD in the chimeric transporter to **K**KLFD, EKLF**K** and **K**KLF**K**. We found that mutants **K**KLFD and **K**KLFK produced $I_{Cl}$, whereas the mutant EKLFK did not. Thus, $Glu^{745}$ in EKLFD of NBCn1 (or $Lys^{558}$ in KKMIK of NBCe1) contributes to anion selectivity. In other experiments, we examined the effect of $Na^+$ depletion on D555E-mediated $I_{Cl}$ and $I_{HCO3}$. D555E induced $I_{Cl}$ in the absence of $CO_2/HCO_3^-$ but $I_{HCO3}$ in the presence of $CO_2/HCO_3^-$. Interestingly, $Na^+$ depletion from the bath solution caused D555E to produce $I_{Cl}$ in the presence of $CO_2/HCO_3^-$, implying that D555E does not select $HCO_3^-$ if $Na^+$ is absent. $Na^+$ is likely bind to the protein before $HCO_3^-$ binds. Our study is significant for providing direct structural and molecular insights into the mechanism for electrogenic $Na/HCO_3$ cotransport of NBCe1 that plays an essential role in renal $HCO_3^-$ reabsorption.

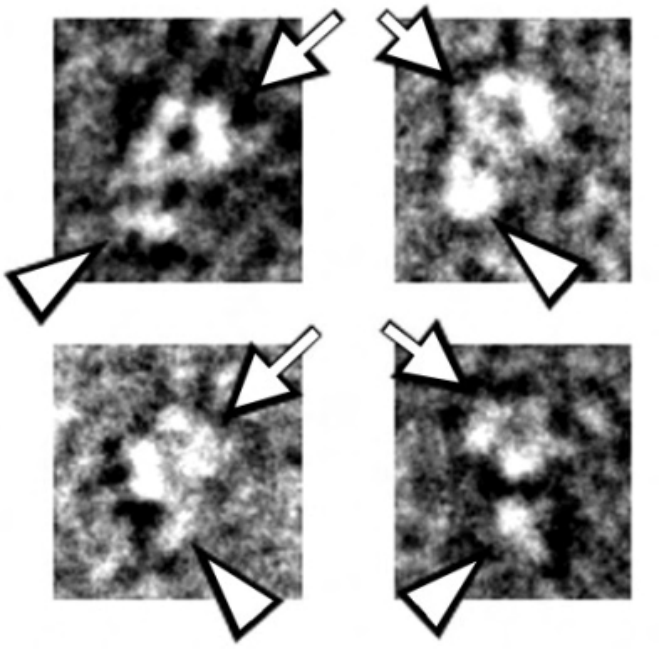
## TH-PO603

**Three-Dimensional (3D) Model of Erythrocyte Full-Length Band 3 (Anion Exchanger 1, AE1)** Alexander Pushkin,[1] Ivo Atanasov,[2] Kirill Tsirulnikov,[1] Peng Ge,[2] Nathaniel Magilnick,[1] Z. Hong Zhou,[2] Ira Kurtz.[1] *[1]Medicine/Nephrology, D. Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Microbiology, Immunology and Molecular Genetics, D. Geffen School of Medicine at UCLA, Los Angeles, CA.*

AE1 plays an essential role in transporting $HCO_3^-$ in erythrocytes and in the renal collecting duct. In erythrocytes AE1 mediates $Cl^-/HCO_3^-$ exchange and thereby contributes to the systemic transport of $HCO_3^-$ derived from metabolically produced $CO_2$. AE1 also is involved in the structural integrity of erythrocytes. In kidney alpha intercalated cells, an N-terminal splice variant of AE1 mediates transcellular $HCO_3^-$ transport, and mutations in AE1 result in distal renal tubular acidosis. The structure of AE1 is currently unknown. In this study, the low-resolution three-dimensional (3D) structure of AE1 was generated using electron tomography of negatively stained AE1 dimers. Selected electron micrographs of AE1 dimers are shown in the figure 1.



The dimers were purified under non-denaturing conditions from bovine erythrocyte ghosts. Two major components are seen in AE1 dimers: 1) doughnut-like (arrows); and 2) asymmetric shapes (arrowheads). We hypothesize that the doughnut-like and asymmetric components are membrane and cytoplasmic domains respectively. The membrane domain has a central pore that may be involved in ion transport. This is the first 3D model of full-length native AE1 protein. This model will help to generate a high resolution 3D structure of AE1 using cryoelectron microscopy.

**TH-PO604**

**The Receptor Protein Tyrosine Phosphatase Gamma (RPTPγ) Is Located at the Basal (but Not Lateral) Membrane of Proximal Tubules** Lara A. Skelton, Walter F. Boron. *Department of Physiology and Biophysics, Case Western Reserve University, Cleveland, OH.*

RPTPγ is a receptor protein tyrosine phosphatase that possesses an N-terminal, extracellular carbonic anhydrase like domain (CALD) that shares between 35-40% homology with α-type carbonic anhydrases. Yuehan Zhou, who perfused single proximal tubules (PTs), has shown that RPTPγ-null mice are unable to alter their rate of $HCO_3$ reabsorption in response to isolated increases in basolateral [$CO_2$] or [$HCO_3$]. In this work we determined the immunolocalization pattern of RPTPγ along the nephron of mouse kidney by developing a rabbit polyclonal antibody (pAb) to the CALD. The chosen epitope is a 17-amino acid peptide sequence unique to the CALD of RPTPγ. The affinity-purified pAb recognizes a 180-kDa band by western blot of whole-kidney lysates from WT but not RPTPγ-null mice, consistent with the predicted molecular weight of the RPTPγ monomer plus N-linked glycosylation. Next, we used a PLP-based fixative to perfuse wild type and RPTPγ-null mice and harvested the kidneys for cryosectioning. The 5 μM sections were co-labeled with a monoclonal antibody to the α-subunit of the Na-K ATPase as a basolateral marker, and the RPTPγ pAb followed by alexa-dye conjugated secondary antibodies and imaged on an Olympus Fluoview confocal microscope. For PTs of WT kidneys, immunostaining with the RPTPγ pAb revealed a punctate pattern along the basal membrane of most PT cells. However, RPTPγ was completely absent from the lateral infoldings of the basolateral membrane, as well as from the apical membrane. RPTPγ-null kidneys yielded only a diffuse background immunostaining pattern. Thus RPTPγ appears to be trafficked to a highly specialized region of the basal side of the cell. In thick ascending limb and collecting ducts, we observed RPTPγ immunostaining at the basal membrane, as in the PT, but also a more vesicular pattern between the nucleus and the basal membrane. We hypothesize that along the PT, the basal localization of RPTPγ allows the CALD to the sense acid-base status of the interstitial fluid in contact with the blood rather than the interstitial fluid in contact with the lateral infoldings of the PT cells.

**Receptor Signaling Mechanisms Involved in Inhibition of $HCO_3^-$ Absorption by Lipopolysaccharide (LPS) in Medullary Thick Ascending Limb (MTAL)** David W. Good, Thampi George, Bruns A. Watts III. *Medicine, Univ TX Medical Branch, Galveston, TX.*

Recently we demonstrated that LPS inhibits $HCO_3^-$ absorption in the MTAL through distinct TLR4-dependent signaling pathways in the basolateral and apical membranes. These studies established that bacterial molecules act directly through Toll-like receptors to impair the transport function of renal tubules. Here we examined molecular mechanisms involved in the inhibition of $HCO_3^-$ absorption by basolateral LPS. Addition of LPS to the bath decreased $HCO_3^-$ absorption by 35% in isolated, perfused mouse and rat MTALs. The inhibition by bath LPS was eliminated by the MEK/ERK inhibitors U0126 and PD98095. LPS induced a 1.8-fold increase in ERK phosphorylation, as assessed in microdissected MTALs by confocal immunofluorescence using antiphospho-ERK1/2 antibody. LPS had no effect on ERK phosphorylation or $HCO_3^-$ absorption in MTALs from $TLR4^{-/-}$ mice. Analysis of TLR4 adapter proteins showed that LPS-induced ERK activation was eliminated in MTALs from $MyD88^{-/-}$ mice but preserved in tubules from $Trif^{-/-}$ mice. Surprisingly, inhibition of $HCO_3^-$ absorption by bath LPS, but not inhibition by lumen LPS, was eliminated in MTALs from $TLR2^{-/-}$ mice, despite normal expression of TLR4 in $TLR2^{-/-}$ MTALs. LPS also did not activate ERK in $TLR2^{-/-}$ MTALs. Immunoprecipitation of TLR2 from inner stripe of outer medulla resulted in coprecipitation of TLR4, as shown by immunoblot analysis using two different TLR4 antibodies. The extent of the association between TLR2 and TLR4 was increased by stimulation with LPS. We conclude that basolateral LPS inhibits $HCO_3^-$ absorption in the MTAL through activation of a TLR4/MyD88/ERK-dependent signaling pathway that depends on a novel interaction of TLR4 with TLR2. In previous studies, we found that activation of basolateral TLR2 by bacterial lipoproteins inhibits $HCO_3^-$ absorption through a signaling pathway distinct from that activated by LPS. Thus, basolateral TLR2 functions in a dual capacity to inhibit $HCO_3^-$ absorption in the MTAL, both through interaction with TLR4 to mediate ERK signaling by Gram-negative LPS and through an independent signaling pathway activated by Gram-positive bacterial lipoproteins.

**Mutations That 'Restore' Enzymatic Activity to the Carbonic Anhydrase-Like Domain (CALD) of Receptor Protein Tyrosine Phosphatase Gamma (RPTPγ): Importance of the Shuttle His and $CO_2$ Binding Site** Lara A. Skelton,[1] Raif Musa-Aziz,[1,2] Xue Qin,[1] Walter F. Boron.[1] *[1]Physiol & Biophys, Case Western Reserve Univ, Cleveland, OH; [2]Physiol & Biophys, Univ of Sao Paulo, Sao Paulo, SP, Brazil.*

In an accompanying abstract we demonstrate that the putative $CO_2$/$HCO_3$ sensor RPTPγ is present in the basal membrane of the proximal tubule. RPTPγ is a single-pass membrane protein with a 730-aa extracellular N terminus that includes a 250-aa carbonic anhydrase-like domain (CALD) that is 30-40% identical to canonical α-type carbonic anhydrases (CAs) and a 680-aa intracellular C terminus that has phosphatase activity. Although it retains the overall fold of catalytically active CAs, CALD lacks CA activity. Previously we reported the 'restoration' of some CA activity to CALD after returning: (1) the 2 missing His residues (E149H and Q175H, analogous to CAIV's H115 and H140) that, along with H151, are required for $Zn^{++}$ coordination, and (2) the $H^+$-shuttle His (K122H, analogous to CAIV's H88). Here, we expressed mutated RPTPγ in *Xenopus* oocytes and pushed a pH-sensitive microelectrode against the oocyte surface ($pH_S$). We exposed cells to $CO_2$/$HCO_3$ and monitored the rising $pH_S$ spike caused by $CO_2$ influx ($H^+ + HCO_3 \rightarrow CO_2 + H_2O$), taking the RPTPγ-dependent $\Delta pH_S$ as a proxy for CA activity. Restoring two CALD residues to improve $CO_2$ access (F177V and F178H) greatly increased $\Delta pH_S$. However, on this 5x-mutant background, reverting either E149H or Q175H to wt eliminates CA activity, presumably because of impaired $Zn^{++}$ co-ordination. On the 5x-mutant background, reverting K112H to wt reduces CA activity but only slightly, suggesting that the shuttle His is not so important. Reverting F178H to wt slight enhances CA activity probably by improving the native local structure. In the wt CALD, F177 is positioned at the mouth of the $CO_2$ binding cavity, where canonical CAs would have the smaller Val residue. The Phe may reduce CA activity by hindering $CO_2$ access to the hydrophobic $CO_2$ binding site or causing other local structural changes.

**Effect of Chronic Metabolic Acidosis on the Proteome of the Brush Border Membrane of the Proximal Convoluted Tubule (PCT)** Scott J. Walmsley, Norman P. Curthoys. *Biochemistry and Molecular Biology, Colorado State Univ, Fort Collins, CO.*

During chronic metabolic acidosis (CMA), increased catabolism of glutamine within the PCT results in increased production of $NH_4^+$ and $HCO_3^-$ ions that aid in restoration of blood pH. In humans and rats, the residual carbons from glutamine are largely converted to glucose. The latter process is mediated, in part, by increased expression of the enzymes unique to gluconeogenesis. Previous proteomic analyses of brush border membrane vesicles isolated from purified rat renal PCTs ($BBMV_{PCT}$) versus vesicles from cortex ($BBMV_{CTX}$) was performed using an ion trap (LTQ) mass spectrometer and spectral counting. This comparison indicated that $BBMV_{PCT}$ are enriched for 11 enzymes of glycolysis and gluconeogenesis. Of these, fructose-1,6-bisphosphatase-1 (FBP1), was previously localized to the apical membrane. The current study used a QTOF mass spectrometer (Agilent 6520) with a C18-HPLC-chip to perform a global analysis of the effect of CMA on protein expression in $BBMV_{PCT}$. Vesicles were isolated from normal and 7-d acidotic rats (n=4/group), solubilized with 7 M urea/1M thiourea, and digested with trypsin. The samples were analyzed using two approaches. $MS^2$ spectra were identified using SEQUEST and changes were quantified by comparing the sum of the total ion current (TIC) for all of the spectra per identified protein (Total proteins: 128 normal, 140 acidotic). Using the retention time and mass, aligned peptide arrays were quantified by comparing the mean peak intensities ($I_M$) of the ion chromatogram of the identified peptide. The two approaches produced very similar results. The NaPi2 transporter decreased 3.2 fold by TIC ($p=0.04$) and 6.3 fold by $I_M$ ($p=0.004$) in response to CMA. By contrast, γ-glutamyltranspeptidase increased 2.8 fold by $I_M$ and 2.4 fold ($p=0.016$) by TIC. This response was validated (2.9 fold) by enzyme assay ($p<0.001$). Surprisingly, enolase1 ($I_M$: 4.0, TIC: 4.3) and FBP1 ($I_M$: 4.0, TIC: 4.6)

were both significantly decreased during CMA. The latter results suggest that enzymes of gluconeogenesis are normally sequestered in the apical region of the cell and translocated to the cytoplasm and activated in response to CMA.

**High Sodium Intake Increases *In Vivo* $HCO_3^-$ Absorption in the Loop of Henle (LOH) through Activation of Basolateral $Na^+/H^+$ Exchanger (NHE1)** Oriana Petrazzuolo, Roberto Scanni, Sara Damiano, Francesco Trepiccione, Miriam Zacchia, Giovambattista Capasso. *Internal Medicine, SUN, Naples, Italy.*

It has been reported that sodium intake may affect renal tubular acidification. Previous data have also demonstrated that most of the bicarbonate transport along the loop of Henle (LOH) is localised in the medullary thick ascending limb (mTAL) and it is mainly driven by luminal $Na^+$-$H^+$ exchanger (NHE3) and partially by $H^+$-ATPase. In the present study we have investigated the effect of high sodium diet (HSD)(0.28 M NaCl for 14 days in the drinking water) on: 1. bicarbonate transport along the LOH; 2. mRNAs and proteins abundance of acid-base transporters expressed along the mTALs. Rats fed HSD became hypertensive and showed a reduction in GFR as measured by inuline clearances (0.72±0.04 vs 0.95±0.01 ml.min$^{-1}$ 100g b.w.)($p<0.01$). To measure LOH net bicarbonate reabsorption ($JHCO_3$), superficial loops were perfused at 40 nl.min$^{-1}$ from late proximal to early distal tubules by in vivo micropuncture. Perfusate was an end-like proximal solution containing $^3$H-methoxy-inulin. Total [$CO_2$] in the collected fluid was measured by microcalorimetry. In the presence of similar LOH perfusion rate (39.1±0.9 vs 38.7±0.9 nl/min), and with 13 mM bicarbonate in the perfusate, $JHCO_3$ was 160±5 pmol.min$^{-1}$ (n=20) (mean±ES) in control animals and 192±5 pmol.min$^{-1}$ (n=22) ( $p<0.05$) in rats fed HSD. Increased $JHCO_3$ was found in HSD animals also when the luminal bicarbonate was raised to 24 and 38 mM, thus demostrating a load dependence of $JHCO_3$ . For the molecular biology experiments, total RNA and proteins were extracted from mTALs, identified and microdissected from collagenase treated kidneys. mRNAs and proteins abundance were measured by real rime PCR and immunoblotting, respectively. NHE3 and NHERF1 were unchanged both at mRNA and protein levels; the same holds for B1- and A4 subunits of $H^+$-ATPase. At variance NHE1/β- actin protein abundance was significantly enhanced in mTALs isolated from HSD (0.84±0.02 o.d.) as compared to control animals (0.65±0.01 o.d.) ($p<0.001$). Thus, a high salt intake enhances LOH bicarbonate transport by increasing the expression and abundance of NHE1.

**Sepsis Impairs $HCO_3^-$ Absorption in the Medullary Thick Ascending Limb (MTAL) through a Two Hit Mechanism** Bruns A. Watts III, Thampi George, Edward R. Sherwood, David W. Good. *Univ TX Medical Branch, Galveston, TX.*

Sepsis is associated with renal tubule dysfunction and dysregulation of systemic electrolyte balance but the underlying mechanisms are incompletely understood. Recently we demonstrated that $HCO_3^-$ absorption by the MTAL is inhibited by LPS through activation of TLR4, indicating that bacterial molecules act directly through innate immune receptors to impair the transport function of renal tubules. In the present study, we used a cecal ligation and puncture (CLP) model of polymicrobial sepsis to examine the effects of sepsis on MTAL $HCO_3^-$ absorption. MTALs from sham-operated and CLP mice were dissected and perfused in vitro at 18 h after surgery. The basal rate of $HCO_3^-$ absorption was reduced 30% in MTALs from CLP mice compared with sham controls ($p<0.05$). The reduced $HCO_3^-$ absorption rate was associated with a 2-fold increase in ERK phosphorylation in the CLP MTALs. Activation of ERK decreases $HCO_3^-$ absorption in the MTAL through inhibition of NHE1. To test the role of basolateral $Na^+/H^+$ exchange in mediating inhibition by CLP, we examined the effects of bath amiloride, which inhibits $HCO_3^-$ absorption in the MTAL through inhibition of NHE1. Addition of 10 μM amiloride to the bath decreased $HCO_3^-$ absorption by 26% in MTALs from sham controls but had no effect in MTALs from CLP mice. These findings suggest that CLP reduces basal $HCO_3^-$ absorption by increasing ERK activity and inhibiting NHE1. Adding LPS to the bath decreased $HCO_3^-$ absorption by 48% in MTALs from CLP mice compared with a decrease of only 28% in tubules from sham controls ($p<0.05$). The inhibition by bath LPS was eliminated by the MEK/ERK inhibitor U0126 in MTALs from both sham and CLP mice. These results indicate that CLP sepsis impairs $HCO_3^-$ absorption in the MTAL through a two hit mechanism involving a decrease in basal $HCO_3^-$ absorption rate and potentiation of inhibition by LPS. These effects would impair the correction of metabolic acidosis that contributes to sepsis pathogenesis. The ERK signaling pathway appears to play a role in both inhibitory effects and thus represents a potential therapeutic target to treat and prevent sepsis-induced renal tubule dysfunction.

**Multiple Molecular Determinants in the Carboxyl-Terminus Regulate ER Exit and Cell-Surface Expression of NKCC2** Nancy Zaarour,[1, 2, 3] Sylvie Demaretz,[1, 2, 3] Nadia Defontaine,[1, 2, 3] Kamel Laghmani.[1, 2, 3] *[1]INSERM, UMRS 872 - Equipe 3- ERL7226; [2]Universite Paris-Descartes; [3]Universite Paris-VI, Paris, France.*

Mutations in the apical Na-K-2Cl co-transporter, NKCC2, cause type I Bartter syndrome (BS1), a life-threatening kidney disease. Yet the mechanisms underlying the regulation of NKCC2 mutants in renal cells are scarcely known. We previously showed that BS1 mutations denying NKCC2 of its distal C-terminal tail and/or interfering with the highly conserved LLV motif, located at positions 1081-1083, result in ER exit defect of the co-transporter. The aim of the present study was to investigate whether there are carboxyl-terminal residues, other than LLV, that are essential for NKCC2 trafficking. Sequence analysis revealed that the distal C-terminal region of NKCC2 is enriched in di-leucine like motifs. These adjacent hydrophobic residues have been reported to function as ER export signals. Consequently, we mutated these residues to alanines and expressed the mutant proteins in OKP and HEK cells. Using cell surface biotinylation, we show that $^{1050}$VL$^{1051}$, $^{1064}$LL$^{1065}$ and $^{1072}$IL$^{1073}$ motifs had no effect on NKCC2 expression. In contrast, double mutations of $^{1037}$LL$^{1038}$ or $^{1048}$LI$^{1049}$ disrupted glycosylation and cell surface expression of NKCC2. Using microscopic confocal imaging, we further demonstrate that $^{1037}$LL$^{1038}$ and $^{1048}$LI$^{1049}$ mutants were not expressed at the cell surface and were localized to the ER as indicated by co-localization with the ER marker calnexin. To determine if the ER localization of NKCC2 mutants reflected a defect in maturation, we analyzed the biosynthetic processing of NKCC2 by pulse-chase analysis. In contrast to WT NKCC2, the conversion to the mature form was not detectable during the chase period indicating failure in ER exit of the mutated proteins. Altogether, these data are consistent with a model whereby multiple molecular determinants in the carboxyl-terminus regulate ER exit and cell-surface expression of NKCC2. The exact characterization and identification of the molecular mechanisms of the motif-facilitated ER export is essential for the development of therapeutic strategies targeting NKCC2 transport from the ER to the cell surface.

**Identification of a Candidate Functional Partner for Vacuolar $H^+$-ATPase: SLC26A11 (KBAT = Kidney Brain Anion Transporter) Co-Localizes with $H^+$-ATPase in the Kidney Collecting Duct and Mediates Electrogenic Transport of Chloride** Jie Xu,[1, 3] Sharon L. Barone,[1, 2] Hong C. Li,[1, 3] Kamyar A. Zahedi,[1, 2] Manoocher Soleimani.[1, 2, 3] *[1]Medicine, University of Cincinnati, Cincinnati, OH; [2]Center on Genetics of Transport, University of Cincinnati, Cincinnati, OH; [3]Research Services, Veterans Administration, Cincinnati, OH.*

Chloride plays an important role in regulating vacuolar $H^+$-ATPase activity across specialized cellular and intracellular membranes. Here we report the identification of a transporter which mediates electrogenic transport of chloride, and demonstrates co-localization, co-regulation and co-trafficking with V $H^+$-ATPase in the kidney collecting duct. Immunoblotting identified Slc26a11 as a ~72 kDa band in kidney membrane proteins and immunofluorescent labeling detected its expression in a subset of cells in the collecting duct. Double immunofluorescent labeling with AQP2 indicated that Slc26a11 is expressed in cells distinct from principal cells in the collecting duct. Double immunofluorescence labeling with $H^+$-ATPase demonstrated remarkably identical co-localization of Slc26a11 with $H^+$-ATPase along the length of the collecting duct: Slc26a11 and $H^+$-ATPase co-localized on the apical membrane of A-intercalated and basolateral membrane of B intercalated cells. Mouse Slc26a11 has two distinct variants, a 593 aa or long, and a 421 aa or short variant; the long variant is predominantly expressed in the kidney and other epithelial tissues whereas the short variant is predominantly expressed in the brain. Functional studies in transfected COS7 cells demonstrated that KBAT can mediate the electrogenic transport of $^{36}$chloride. Immunofluorescent studies indicated co-trafficking of KBAT and $H^+$-ATPase from subapical to the apical membrane of A-intercalated cells in potassium depletion and metabolic acidosis. We propose that KBAT facilitates $H^+$-ATPase-mediated acid secretion in the collecting duct through direct stimulation and/or by dissipating the membrane potential resulting from $H^+$ secretion with electrogenic chloride transport.

**Regulation of Vacuolar $H^+$-ATPase Localization and Activity by PKA and AMPK Phosphorylation of the A Subunit in Kidney Cells** Nuria M. Pastor-Soler,[1] Rodrigo Alzamora,[1] Fan Gong,[1] Ramon Fabio Thali,[2] Christy Smolak,[1] Hui Li,[1] Yolanda Joho-Auchli,[3] Rene A. Brunisholz,[3] Dietbert Neumann,[2] Kenneth R. Hallows.[1] *[1]Renal-Electrolyte Division, Department of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Department of Biology, Institute of Cell Biology, ETH Zurich, Zurich, Switzerland; [3]Functional Genomics Center Zurich (FGCZ), University of Zurich, Zurich, Switzerland.*

Vacuolar $H^+$-ATPases (V-ATPases) are protein complexes that are highly expressed at the apical membrane in kidney type A intercalated cells where they contribute to luminal collecting duct acidification. We have shown that acute apical V-ATPase accumulation in intercalated cells depends on active soluble adenylyl cyclase. We also recently showed that the metabolic sensor AMP-activated protein kinase (AMPK) prevents PKA-mediated V-ATPase apical accumulation in kidney intercalated cells. Moreover, we showed that both

kinases phosphorylate the V-ATPase A subunit (ATP6V1A) in vitro and in a kidney cell line and that PKA-dependent phosphorylation at residue Ser-175 of the A subunit contributes to V-ATPase apical accumulation and activity in kidney cells. We hypothesized that direct phosphorylation of the A subunit by AMPK prevents apical V-ATPase accumulation and thus reduces pump activity in kidney intercalated cells. Indeed, we have identified a novel AMPK phosphorylation site on the V-ATPase A subunit by mass spectrometry. Mutation of this phosphorylation site significantly reduced A subunit phosphorylation by AMPK both in vitro and in kidney cells. V-ATPase apical membrane accumulation in a cell line of intercalated cell characteristics (Clone C) was enhanced by a phosphorylation-deficient A-subunit mutant at this novel AMPK site. These results suggest that PKA and AMPK phosphorylation sites on the A subunit may be involved in the inter-regulation of V-ATPase activity and subcellular localization by acid-base stimuli via PKA and by metabolic stress via AMPK. (Supported by NIH, ASN, and AHA).

## TH-PO613

**Expression Profile and Regulation of an H/K-ATPase α2 (*Atp12a*) Gene-Reporter Transgene in Mice** Zhiyuan Yu,[1] Pedro E. Cruz,[2] Qun Kong,[1] Brian Poindexter,[1] Bruce C. Kone.[1] *[1]Medicine, University of Texas-Houston Medical School, Houston, TX; [2]Medicine, University of Florida College of Medicine, Gainesville, FL.*

The *Atp12a* gene helps maintain K and acid-base balance. Atp12a is basally expressed at high levels in distal colon surface epithelium, and at lower levels in collecting duct principal cells. With dietary K deprivation, Atp12a expression increases in collecting duct, but not distal colon. Previously, we developed transgenic mice carrying an insertional *Atp12a* promoter-reporter gene. These mice exhibited transgene expression in principal cells, but surprisingly not in distal colon (Am J Physiol 286: F1171, 2004). This result suggested that sequences outside the promoter region direct distal colon-specific expression. Accordingly, we sought to develop a model system with which to test the molecular basis for differential regulation of the *Atp12a* gene in these tissues. The recombineering system was used to introduce a humanized *Renilla reniformis* GFP (hrGFP) cassette in-frame with the *Atp12a* coding region just before the *Atp12a* stop codon contained within a 188 kb BAC clone. The construct placed hrGFP under control of the entire natural genomic sequence context for the 23.6 kb *Atp12a* gene. The *Atp12a*-hrGFP BAC recombination and genotyping were confirmed by restriction enzyme, PCR, and Southern analysis. Patterns of *Atp12a*-hrGFP transgene expression were examined by qRT-PCR and deconvolution fluorescence microscopy. Of 10 major organs examined, *Atp12a*-hrGFP transgene mRNA was abundant in distal colon and kidney, with low levels in lung. In kidney, hrGFP fluorescence colocalized with aquaporin-2 immunoreactivity, consistent with expression in principal cells. hrGFP fluorescence also localized to the surface epithelium of distal colon. Dietary K restriction comparably induced endogenous Atp12a and *Atp12a*-hrGFP mRNAs in kidney medulla, but did not alter the abundance in distal colon. Thus, these *Atp12a*-hrGFP BAC transgenic mice faithfully mimic the differential expression and regulation of the endogenous *Atp12a*2 gene in kidney and distal colon and provide a critical model to dissect the cell- and stimulus-specific regulation of this gene.

## TH-PO614

**Modulatory Role of Renal Complex Sulfatides in the Control of Acid-Base Balance by the Kidney** Paula Stettner,[1] Soline Bourgeois,[2] Christian Marsching,[3] Milena Traykova-Brauch,[1] Tjeerd Petrus Sijmonsma,[1] Roger Sandhoff,[1,3] Carsten A. Wagner,[2] Richard Jennemann,[1] Elisabeth Groene,[1] Hermann-Josef Groene.[1] *[1]Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany; [2]Institute of Physiology, University of Zuerich, Zuerich, Switzerland; [3]Instrumental Analytics and Bioanalytics, Mannheim University of Applied Sciences, Mannheim, Germany.*

Glycosphingolipids (GSL) are amphipathic molecules localized in the outer layer of the plasma membrane of all eukaryotic cells. GSL mediate several cellular functions, including cellular growth, differentiation, and cell-cell interactions. The mouse kidney expresses mainly uncharged neutral GSL and sulfated GSL (sulfatides). The function of renal sulfatides has not been defined. We postulated an influence on ionic transport in tubular epithelia. Mouse models with renal tubular epithelium specific (Pax8) deletion of genes encoding the key enzymes involved in synthesis of glucosylceramide based GSL (Ugcg, UDP-glucose:ceramide glucosyltransferase), sulfatides (Cst, cerebroside sulfotransferase), and combination of both, were generated.

Mice with renal Ugcg, - Cst, and - Ugcg//Cst deletion displayed a normal life span and morphology of the kidney. However, metabolic experiments revealed a significantly lower urinary pH. HCl loading (9d) induced a more severe and persistent hyperchloremic acidosis in Ugcg//Cst double deleted mice (blood pH controls: 7.2+/- 0.1 vs. mutants: 7.0 +/-0.1; n=7-8, p<0.05). The increase of urinary ammonium was significantly less in Ugcg//Cst deficient animals. Enzymes involved in ammoniagenesis were not differentially expressed and NHE3 activity was not altered as compared to control mice.

The pH phenotype could be referred to the absence of the complex sulfatides SM3 and SB1a as these are the only GSL which are lost in all 3 mutant mice. MALDI-tissue-MS demonstrated SM3 to be localized in cortical collecting ducts (CCDs). In vitro microperfused CCDs of HCl challenged GSL-deficient mice showed a reduced NH3 permeability. With this findings, we propose a modulatory function for SM3, and possibly SB1a, in the control of systemic acid-base balance by generating a plasma membrane permeable for NH3 in CCDs.

## TH-PO615

**Mechanisms of Type 4 (Hyperkalemic) Renal Tubular Acidosis** Kahori Hori,[1] Takanori Nagai,[1] Yuichiro Izumi,[2] Yushi Nakayama,[3] Yukiko Hasuike,[1] Masayoshi Nanami,[1] Yukiko Yasuoka,[4] Yoshinaga Otaki,[1] Akito Tanoue,[5] Katsumasa Kawahara,[4] Takeshi Nakanishi,[1] Hiroshi Nonoguchi.[1] *[1]Division of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; [2]LKEM, NHLBI, National Institutes of Health, Bethesda, MD; [3]Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [4]Physiology, Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan; [5]Pharmacology, National Research Institute for Child Health, Tokyo, Japan.*

The main role of kidney is to maintain water/sodium and acid-base balance. We found that vasopresin V1a receptor knockout (KO) mice shows hyporeninemic hypoaldosteronism, reduced renal function, metabolic acidosis with resiratory compensation, and hyperkalemia, showing the characteristics of type 4 (hyperkalemic) renal tubular acidosis (RTA). We examined the mehcanisms of type 4 RTA in V1aR KO mice. Although urine pH was slightly lower in V1aR KO than wild type (WT) mice (6.29±.03 and 6.45±.03, respectively, ns), urinary excretion of ammonium was significantly lower in V1aR KO than WT mice (0.13±.01 and 0.16±.01 μEq/μg.Cr, respectively, p<0.05). The administration of fludrocortisone to V1aR KO mice ameliorated metabolic acidosis by increasing urinary ammonium excretion (0.39±.04 μEq/μg.Cr,) while decreasing titratable acid excretion. Fludrocortisone slightly increased urinary ammonium excretion in WT mice (0.24±.04 μEq/μg.Cr,). Urine pH was closely related with urinary amonium excretion both in KO and WT mice. In V1aR KO mice, HK-ATPase and Rhcg exressions were decreased but H-ATPase expression was increased. Fludrocortisone decreased H-ATPase and increased HK-ATPase and Rhcg expressions in the kidney. These data show that 1)decreased response to aldosterone in type 4 RTA is caused by reduced function of V1aR 2) low urine pH in V1aR KO mice is caused by upregulation of H-ATPase 3) decreased Rhcg and HK-ATPase expression causes low urinary ammonium excretion 4)Urine pH is not a determinant of urinary ammonium excretion but is related with the amount of urinary ammonium excretion 5) vasopressin and aldosterone has major role for urinary ammonium excretion.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO616

**Impaired Cellular Response to Acid Challenge in Proton Sensor Null Mice** Xuming Sun,[1,2] Lisa M. Stephens,[1] Raymond B. Penn,[3] Thomas D. DuBose,[4] Snezana Petrovic.[1,2] *[1]Medicine, University of Cincinnati, Cincinnati, OH; [2]Research Service, Veterans' Affairs Medical Center, Cincinnati, OH; [3]Medicine, University of Maryland Baltimore, Baltimore, MD; [4]Medicine, Wake Forest University, Winston Salem, NC.*

Deletion of proton receptor GPR4 results in metabolic acidosis and impairs net acid secretion. To define cellular mechanisms of this phenotype, we examined expression of acid-base transporters by real-time RT-PCR in kidneys of GPR4-/- and GPR4+/+ before/after acid loading with $NH_4Cl$, and identified the numbers of intercalated (ICs) and principal cells (PCs) in collecting ducts (PCs as AQP2-positive, ICs as $H^+$-ATPase-positive, A-ICs as AE1-positive, B-ICs as pendrin-positive/Rhbg-negative, and nonA-nonB ICs as pendrin/Rhbg-positive). We analyzed 10 (100x100μm) fields/section and expressed results as avg# cells/field. We examined corresponding nephron segments in kidney sections from 3 GPR+/+ and 3 GPR-/- before/after acid loading. mRNA expression of AQP2, ATP6V0A4, AE1, SLC26A7 and pendrin was similar at baseline. AE1 mRNA nearly doubled in acid loaded GPR4+/+, but not in acid loaded GPR4-/-. Table 1 shows that acidosis increased A-IC numbers and decreased B-IC and nonA-nonB IC numbers in GPR4+/+. GPR4-/- lacked this response, likely because the mice are partially adapted to chronic acidosis. Baseline GPR4-/- show IC-profile akin to acid loaded GPR4+/+. (ICs/PCs in GPR4+/+ and -/- were similar.)

| TABLE 1 | ICs | A-ICs | B-ICs | nonA-nonB ICs |
|---|---|---|---|---|
| Baseline GPR4+/+ | 26.5±0.6 | 15.3±1.4 | 6.4±0.25 | 4.8±0.26 |

| p value | 0.02 | 0.2 | 0.6 | 0.2 |
| Baseline GPR4-/- | 27.1±1 | 20.2±1.6 | 5.1±0.35 | 1.7±0.4 |
| Acid loaded GPR4+/+ | 30.3±0.9 | 23.7±2.3 | 3.9±0.4 | 2.6±0.21 |
| p value | 0.07 | 0.2 | 0.09 | 0.2 |

While acidosis in GPR4-/- may be caused by defective transporter activity/trafficking, our data also suggest a cellular response that may alleviate the severity of acidosis in GPR4-/-. Expression of other proton receptors OGR1 and TDAG8 was equal in GPR4+/+ vs. -/-. It is possible that other sensory pathways compensate for GPR4 loss, and/or additional $H^+$ transporters like $H^+$-$K^+$ATPase take part in alternative signaling pathways.

Disclosure of Financial Relationships: nothing to disclose

**Induced but Constrained Expression of GPR4 Mediates Acid-Induced HK$\alpha_2$ Expression** Juan Codina,[1] Snezana Petrovic,[2] Raymond B. Penn,[3] Thomas D. DuBose.[1] *[1]Internal Medicina/Nephrology, Wake Forest University School of Medicine, Winston-Salem, NC; [2]Division of Nephrology, University of Cincinnati, Cincinnati, OH; [3]Department of Medicine, University of Maryland School of Medicine, Baltimore, MD.*

Preliminary experiments from our laboratory demonstrate that PKA activity (measured as phosphorylation of Ser157 of the vasodilator-stimulated phosphoprotein, VASP) is increased by transfection of HEK293 cells with rat or human GPR4. PKA activity is potentiated when the cells are treated with acute acidosis (3-30 minutes). Moreover, chronic acidosis induced up-regulation of HK$\alpha_2$ protein in cells stably transfected with HK$\alpha_2$/NK$\beta_1$ and transiently transfected with GPR4. However, these effects required modest levels of GPR4 expression, because typical transfection methods (1 µg pCDNA3GPR4/3.5 cm dish) promoted expression of poorly glycosylated (assessed by sensitivity to glycosidase F and Endo H), non-functional GPR4 that accumulated in intracellular compartments (revealed by ICC and immunoprecipitation with antibodies using CHAPS solubilized proteins). Transfecting HEK293 cells with a low concentration of plasmid (<100 ng pCDNA3GPR4/3.5 cm dish) enabled plasma membrane GPR4 expression, increased basal VASP phosphorylation, acid-induced (media pH ~ 6.8) VASP phosphorylation, and increased expression of HK$\alpha_2$ by chronic acidosis (via reduction of media [$HCO_3^-$] for 16-24 hours). Additional findings suggest assembly of GPR4 with $\beta_2$-arrestin-GFP that correlates with the level of expression. These results support the view that acid pH (protons) activates GPR4 to increases PKA activity and regulate the expression of a proton transporter important in the control of acid-base balance.

**Acid Retention Mediates Augmented Kidney Endothelin and Aldosterone Production in Subjects with Moderately Reduced GFR** Donald E. Wesson,[1,2] Jan Simoni,[3] Kristine Broglio.[4] *[1]Internal Medicine, Texas A&M College of Medicine, Temple, TX; [2]Internal Medicine, Scott and White Healthcare, Temple, TX; [3]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX; [4]Statistics, Texas A&M University, College Station, TX.*

Oral $NaHCO_3$ but not NaCl slows GFR decline in subjects with moderately reduced eGFR (CKD stage 2 = 60-90 ml/min) without metabolic acidosis (Kid Int, 2010). Animals with 2/3 nephrectomy have no metabolic acidiosis but have acid retention with GFR decline (Kid Int 2009). Because kidney endothelin-1 (ET) and aldosterone (aldo) mediate GFR decline in animals with partial nephrectomy, we tested if subjects with eGFR 60-90 ml/min (n=40) compared to normal eGFR (> 90 ml/min) (N=40), each without metabolic acidosis, have acid retention that increases kidney ET and aldo measured by urine ET (UET) and aldo (Ualdo) excretion. eGFR 60-90 subjects had higher UET (5.5 ± 1.2 vs. 3.5 ± 1.7 ng/g creatinine [cr], $p < 0.0001$) and Ualdo (36.7 ± 8.7 vs.13.1 ± 2.8 µg/g cr, $p < 0.0001$). UET (4.9 ± 1.2 ng/g cr, $p = 0.028$) and Ualdo (25.7 ± 5.9 µg/g cr, $p < 0.0001$) were each lower in separate eGFR 60-90 subjects (n=40) after 30 days of oral $NaHCO_3$. By contrast, separate eGFR 60-90 subjects after 30 days of oral NaCl (n=40) had lower Ualdo (32.7 ± 8.2 µg/g cr, $p = 0.038$) but not lower UET. Ualdo was lower in $NaHCO_3$-ingesting than NaCl-ingesting eGFR 60-90 ($p < 0.0001$). Baseline urine net acid excretion (NAE) was not different among groups. Acid retention was assessed by measuring urine NAE after an acute oral $NaHCO_3$ bolus. We assumed that greater acid retention would manifest as greater acid tritration of the ingested $NaHCO_3$ bolus, yielding lower urine $HCO_3$ excretion and less urine NAE reduction. $NaHCO_3$ bolus reduced urine NAE less (i.e., post bolus NAE was higher, $p < 0.0001$) in eGFR 60-90 than > 90 subjects, supporting greater acid retention in eGFR 60-90. The data show that UET and Ualdo excretion are increased in CKD stage 2 eGFR and that daily $NaHCO_3$, but not NaCl, reduces each. The data suggest that GFR decline in CKD stage 2 eGFR is mediated by increased kidney ET and aldo production induced by acid retention.

**TH-PO619**

**Renal Adaptation to Metabolic Acidosis Is Impaired in a Rat Model of Autosomal Dominant Polycystic Kidney Disease (ADPKD)** Remy Buerki,[1] Nilufar Mohebbi,[1,2] Andreas L. Serra,[2] Carsten A. Wagner.[1] *[1]Institute of Physiology, University of Zurich, Zurich, Switzerland; [2]Division of Nephrology, University Hospital Zurich, Zurich, Switzerland.*

ADPKD is associated with renal tubular acidosis. Here, we used an animal model for ADPKD (Han:SPRD rat (Cy/+)) and investigated regulation of key proteins in renal acid-base handling. Wild type rats served as controls. All animals were treated at baseline with standard diet and consecutively challenged with HCl diet for 2 days to induce metabolic acidosis. Under baseline conditions, both groups showed similar arterial blood pH but lower $HCO_3^-$ and $pCO_2$ in ADPKD rats. After 2 days HCl diet, ADPKD animals showed a much more severe metabolic acidosis when compared to controls. At baseline, urinary pH was significantly lower in Cy/+ rats. However, after an acid load with HCl, control and ADPKD rats acidified their urine to the same pH indicating preserved ability to acidify urine. Urinary ammonium excretion was much lower in Cy/+ rats compared to controls. Using realtime RT-qPCR, the kidney specific phosphate transporters NaPi-IIa and NaPi-IIc were significantly down-regulated whereas Pit-2 was up-regulated in Cy/+ rats. Also, relative mRNA abundance of the $Na^+/H^+$ exchanger NHE3 and the $Cl^-/HCO_3^-$ exchanger AE1, as well as the glutamine transporter SNAT3 were reduced. Immunoblotting for NaPi-IIa, NaPi-IIc, NHE3 and AE1 showed down-regulation in Cy/+ rats. In conclusion, cyst formation in Han:SPRD rat model causes renal acidosis and results in more severe metabolic acidosis upon acid-loading. Cy/+ rats showed normal urinary acidification but reduced expression of key transport proteins involved in ammoniagenesis and bicarbonate regeneration.

Disclosure of Financial Relationships: nothing to disclose

**Regulation of AE4 Expression in β-ICs by Acid/Base Status** Jeffrey M. Purkerson, Aya Nakamori, George J. Schwartz, Eric V. Heintz. *Pediatrics, University of Rochester Medical Center, Rochester, NY.*

Adaptation of the rabbit CCD to acidosis is characterized by a reduction in bicarbonate secretion by β-intercalated cells (β-ICs) and increased proton secretion by α-ICs. To identify mechanisms that underlie changes in $H^+/HCO_3$ flux in the CCD, we examined IC phenotypes in normal (urine pH: 8.1±0.1, $HCO_3$:27± 1 mM), 3 day acid (urine pH:4.7±0.2, $HCO_3$:16±1), and rabbits immediately transitioned from 3 day acid to alkali loading for 16-18 h (recovery: urine pH: 7.8±0.1, $HCO_3$:29±1). Recent studies have identified decreased size and intensity of apical pendrin (PND) caps and increased basolateral distribution of AE1 that may reflect increased endocytosis and exocytosis of the respective anion transporter, as well as decreased expression of PND mRNA and protein expression as mechanisms for adaptation of ICs to metabolic acidosis. In β–ICs a reversible redistribution was observed for B1-V-ATPase, as the percentage of cells exhibiting a predominantly apical B1 distribution increased from 33% in normal rabbit kidney sections to 80% in acidotic animals and returned to 29% upon recovery. We have initiated a study of other anion exchangers that may contribute to $HCO_3$ transport in these cells. Confocal microscopy of microdissected CCDs revealed that AE4 expression in β-ICs occurs subapically in a ring-like pattern. Staining of kidney sections failed to demonstrate co-expression of AE4 and AE1. Consistent with expression of AE4 in β-ICs, the relative abundance of AE4 and pendrin mRNA was cortex>outer medulla>>inner medulla. Regulation of AE4 mRNA abundance mirrored PND expression. Specifically, PND and AE4 mRNA levels decreased 2-3 fold after 3 day acidosis; 14- and 5-fold, respectively, following 7 day acidosis. Examination of AE4 localization in kidney sections revealed a predominant lateral distribution of AE4 in normal and acidotic rabbits, whereas upon recovery from acidosis there was an apparent shift toward apical expression. Conclusion: AE4 is expressed in the CCD and may act in conjunction with pendrin to regulate $HCO_3$ secretion in β-ICs during alkali-loading.

Disclosure of Financial Relationships: nothing to disclose

**Effect of Sodium-Free Diet on Renal Ammonia Metabolism and the Role the Ammonia Transporter Family Member, Rh C Glycoprotein** Hyun-Wook Lee,[1] Jill W. Verlander,[1] Jesse M. Bishop,[1] Mary E. Handlogten,[1] David Weiner.[1,2] *[1]Division of Nephrology, Hypertension and Transplantation, University of Florida, College of Medicine, Gainesville, FL; [2]Nephrology and Hypertension Section, NF/SGVHS, Gainesville, FL.*

Sodium depletion commonly leads to metabolic alkalosis, but the mechanisms are incompletely understood. The current studies were designed to address the mechanism and to determine the role of the ammonia transporter, Rhcg, in this response in the mouse. A $Na^+$-free diet for 7 days increased urinary ammonia excretion from 115 ± 14 to 336 ± 58 µmol/d (n= 8; $p<0.03$). Urine pH did not change significantly (pre, 6.02 ± 0.04; post, 6.16 ± 0.06, p=NS). In contrast to metabolic acidosis, where increased PEPCK and PDG expression contribute to increased renal ammonia metabolism, a $Na^+$-free diet did not increase expression of either PEPCK or PDG. However, glutamine synthetase expression decreased significantly in the cortex, suggesting that decreased proximal tubule glutamine synthetase-mediated ammonia degradation might contribute to increased net renal ammonia production. Also in contrast to metabolic acidosis, $Na^+$-free diet did not alter significantly renal expression of either of the ammonia transporter family members, Rh B Glycoprotein (Rhbg) or Rh C Glycoprotein (Rhcg). To confirm the lack of role of Rhcg in the increased renal ammonia excretion, we examined the effect of collecting duct-specific Rhcg deletion on the response to a $Na^+$-free diet. Rhcg deletion did not alter changes in either urinary ammonia or urine pH. We conclude: 1) a $Na^+$-free diet increases urinary ammonia excretion, which likely contributes to the metabolic alkalosis commonly observed with $Na^+$ depletion; 2) altered glutamine synthetase expression may contribute to increased renal ammonia excretion in response to a $Na^+$-free diet; and, 3) the mechanisms of increased ammonia excretion in response to a $Na^+$-free diet fundamentally differ from those observed in response to metabolic acidosis.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO622**

**Angiotensin II-Stimulated Ammonia Production by Proximal Tubules from Acidotic Mice Is Modulated by Increased Expression of AT2 Receptors**
Glenn T. Nagami, Alexandria K. Plumer, Jennifer S. Rashidi, Evelyn M. Warech. *Nephrology Section, VA Greater Los Angeles HCS and UCLA Sch of Med, Los Angeles, CA.*

AT1 receptor (AT1R) activation by angiotensin II (Ang II) increases ammonia ($tNH_3$) production (AP) rates by isolated perfused S2 proximal tubules (S2 PTs). As shown previously, Ang II increased AP more in S2 PTs from short-term (18-h) acid-loaded mice than in those from non-acid- loaded controls and this was associated with increased AT1R and reduced AT2 receptor (AT2R) protein levels in brush border membranes (BBMs). In this study, we examined the effects of Ang II and the AT2R blocker PD123319 on AP by S2 PTs and the expression of AT1R and AT2R proteins in BBMs from long-term (7-d) acid-loaded or control mice. Mice (N=5 per group) were given 0.3 M $NH_4Cl$ in 2% sucrose drinking water or sucrose water alone for 7 d. The acid-loaded mice had lower plasma total $CO_2$ and pH levels (acidosis) and excreted higher urinary $tNH_3$ levels than control mice. As shown before, S2 PTs from acidotic mice displayed higher AP rates than controls. Ang II added to the lumen increased AP rates in S2 PTs from acidotic and control mice by comparable amounts (Increase in AP: 9.8±1.0 pmol/min/mm (Control) vs 10.3±1.1 (Acidotic) (mean±SEM)) and was not accentuated as previously observed in S2 PTs from 18-h acid-loaded mice. When PD123319 was added with Ang II, AP rates increased in S2 PTs from acidotic (+Ang II no PD 50.2±1.2; +Ang II +PD 61.2±1.4, $p<0.01$) and control (+Ang II no PD 29.6±1.5; +Ang II +PD 36.2±1.2; $p<0.05$) mice. Western blot analysis demonstrated that both AT1R and AT2R protein levels were higher in BBMs from acidotic mice compared to controls (AT1R: 2.2±0.3-fold increase vs control, $p<0.05$; AT2R: 1.9±0.1-fold increase, $p<0.05$). Thus, the comparable stimulatory effects of Ang II on AP in S2 PTs from acidotic and control mice despite increased AT1R protein levels in BBMs may have resulted from the concurrent increase in AT2R BBM levels with the 7-d acid load. We conclude that AT2Rs attenuate the AT1R-mediated stimulatory effect of Ang II on AP in S2 PTs from acidotic and control mice while reduced AT2R levels with short-term acid loading accentuate this AT1R-mediated effect.

**Both Luminal and Basolateral $NH_3$ Permeabilities Are Decreased in Rhcg-Null Mice**
Soline Bourgeois,[1] Lisa Bounoure,[1] Erik I. Christensen,[3] Suresh Krishna Ramakrishnan,[4] Pascal Houillier,[4,6] Isabelle Mouro-Chanteloup,[5,7] Yves Colin,[5,7] Olivier Devuyst,[2] Carsten A. Wagner.[1] *[1]Institute of Physiology, University of Zürich, Zürich, Switzerland; [2]Université Catholique de Louvain, Brussels, Belgium; [3]Department of Anatomy, University of Aarhus, Aarhus, Denmark; [4]INSERM U 872, Paris, France; [5]INSERM U 655, Paris, France; [6]University Paris Descartes, Paris, France; [7]University Paris Diderot, Paris, France.*

We previously showed that disruption of the rhesus protein Rhcg in mouse leads to defective renal handling of ammonia and incomplete dominant renal tubular acidosis. Here we investigated the role of Rhcg in $NH_3$ and $NH_4^+$ handling by the apical and basolateral membranes of cells lining the collecting duct (CD).

Rhcg related staining was detected at the light microscopy level in mouse kidneys both at the luminal and basolateral sides of principal and intercalated cells. Immunogold electron microscopy further demonstrated the presence of Rhcg in the luminal membrane and in the membrane lining the basolateral interdigitations of type A intercalated cells. We assessed total transepithelial, luminal, and basolateral ammonia membrane permeabilities (MP) on microperfused CD after an acute 2 day HCl load. Transepithelial $NH_3$ MP was reduced by 80% and 40% respectively in CDs from Rhcg-/- and +/- mice compared to control. Luminal $NH_3$ MP was drastically reduced both in CDs from Rhcg-/- and +/- mice but only CDs from Rhcg+/- mice exhibited also a decrease in apical $NH_4^+$ MP. Finally, in the presence of ouabain and furosemide and in the absence of extracellular potassium (to block NKCC1 and Na,K-ATPase mediated $NH_4^+$ fluxes), basolateral $NH_3$ MP was also decreased in CDs from Rhcg-/- mice.

In conclusion, we demonstrate for the first time that $NH_3$ permeates the basolateral membrane by non-ionic diffusion and that this process is in part dependent on the presence of Rhcg. We also show that haplo-insufficiency in Rhcg is associated with impaired $NH_3$ transport in the CD. These data further enlighten the functional role of Rhcg in $NH_3$ transport across the epithelium of the collecting duct.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO624**

**$NH_3$ Permeability of Human RhAG, RhBG, and RhCG**
R. Ryan Geyer,[2] Ashley Mark Toye,[3] Mark D. Parker,[2] Walter F. Boron,[2] Raif Musa-Aziz.[1,2] *[1]Physiol & Biophys, Univ of Sao Paulo, Sao Paulo, Brazil; [2]Physiol & Biophys, Case Western Reserve Univ, Cleveland; [3]Biochem, Univ of Bristol, United Kingdom.*

Mammalian Rhesus (Rh) proteins include the erythroid RhAG, RhCE, and RhD, as well as the non-erythroid RhBG and RhCG, which are mainly expressed in kidney and liver. In human erythrocytes, the Rh proteins are highly abundant membrane proteins forming the Rh complex, which probably consists of a trimer of 2 molecules of RhAG plus RhCE and/or RhD, plus further accessory proteins of unknown function [e.g., CD47, LW, glycophorin B (GPB)]. RhAG, RhBG, and RhCG can function as gas channels, mediating the movement of $NH_3$ and, at least in the case of RhAG, $CO_2$. This study explored the $NH_3$ permeability of mammalian Rh proteins expressed in *Xenopus* oocytes and began to determine the contributions of the proteins within the erythroid Rh complex. We used microelectrodes to monitor surface-pH ($pH_S$), intracellular-pH ($pH_i$), and membrane potential ($V_m$) as we added 0.5mM $NH_4Cl$ ($pH_o$=7.5) to the extracellular fluid (ECF). An ultra-fine micromanipulator positioned the flat tip (20mm diameter) of the $pH_S$ electrode until it just touched the oocyte surface, and then further advanced the tip ~40mm. Periodically we retracted this electrode for calibration in the bulk ECF. Adding 0.5mM $NH_4Cl$ caused no $pH_i$ changes, only small depolarizations, and a rapid fall in $pH_S$ ($\Delta pH_S$) that was followed by a slow recovery. The magnitude of $\Delta pH_S$ is a semiquantitative index of maximal $NH_3$ influx, uncorrected for protein expression at the membrane. The $\Delta pH_S$ with $NH_3$ addition was 0.096±0.015 (n=4) in RhAG oocytes, 5 times the value of $H_2O$-injected control oocytes (0.020±0.001, n=4). The $\Delta pH_S$ values were 0.063±0.004 (n=6) for RhBG and 0.085±0.001 (n=9) for RhCG, but only 0.030±0.005 (n=6) for RhCE. The combinations RhAG+RhCE and RhAG+GPB were no different from RhAG alone. Furthermore, the combination RhCE+GPB was no different from RhCE alone, GPB alone or $H_2O$. Thus, we have no evidence that RhCE enhances the $NH_3$ permeability of RhAG, nor that RhCE has $NH_3$ permeability alone or in combination with GPB. However, using the $pH_S$ approach, we can confirm that RhAG, RhBG, and RhCG all have significant $NH_3$ permeability.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO625**

**Rh B Glycoprotein (Rhbg) Is Necessary for Increased Renal Ammonia Excretion during Hypokalemia in the Mouse**
Jesse M. Bishop,[1,2] Jill W. Verlander,[1] Hyun-Wook Lee,[1] Mary E. Handlogten,[1] David Weiner.[1,2] *[1]Renal Division, University of Florida, Gainesville, FL; [2]Nephrology Section, NF/SGVHS, Gainesville, FL.*

Rhbg is an $NH_3$-specific transporter and Rhbg-mediated $NH_3$ transport contributes to increased renal ammonia excretion during metabolic acidosis. Hypokalemia increases renal ammonia excretion and urine pH, suggesting increased collecting duct $NH_3$ secretion. We reported previously that the ammonia transporter, Rh C Glycoprotein (Rhcg), does not contribute to the increased urinary ammonia excretion induced by hypokalemia in the mouse, suggesting other mechanisms are involved. Thus we examined the role of renal Rhbg in ammonia excretion during hypokalemia by quantifying Rhbg protein expression and urinary ammonia excretion in control mice (C) and mice with intercalated cell-specific Rhbg deletion (IC-Rhbg-KO) generated using Cre-loxP techniques. We induced hypokalemia by feeding mice a $K^+$ free diet for 3 days. In C mice, dietary $K^+$-restriction increased urinary ammonia excretion and urine pH within 24 hrs. After 3 days, Rhbg protein expression increased in the renal cortex and outer medulla. IC-Rhbg-KO did not alter basal rates of urinary ammonia excretion, or urine pH on either diet. Potassium deficiency increased urinary ammonia excretion in IC-Rhbg-KO on each day, but the increase was significantly less in IC-Rhbg-KO than C mice (day 1; C, 291±25 vs IC-Rhbg-KO, 186±17 μmol $d^{-1}$, $P\leq0.05$; day 2; C, 333±33 vs IC-Rhbg-KO, 231±29 μmol $d^{-1}$, $P<0.05$;day 3; C, 374±28 vs IC-Rhbg-KO, 249±33 μmol $d^{-1}$, $P<0.05$ ; n=8 each group). Unlike C mice, IC-Rhbg-KO mice did not increase urine ammonia concentration during $K^+$-restriction; the increase in urinary ammonia excretion was produced by increased urine volume. We conclude: 1) hypokalemia increases renal ammonia excretion at least in part by increasing intercalated cell Rhbg-mediated $NH_3$ transport; 2) intercalated cell Rhbg is necessary for the normal increase in ammonia excretion response during hypokalemia; and 3) because Rhbg has a specific role in ammonia excretion in the mouse in hypokalemia, whereas Rhcg does not, these two ammonia transporters serve distinct roles in renal ammonia excretion.

**Regulation of Frizzled-Dependent Planar Cell Polarity and Wnt Signaling by the (Pro)renin Receptor**
Matias Simons,[1,2] Deniz Saltukoglu,[1,2] Julian Gruenewald,[1,2] Tobias Franz Hermle.[1,2] *[1]Center for Systems Biology, University of Freiburg, Freiburg, Germany; [2]Renal Division, University Hospital Freiburg, Freiburg, Germany.*

Frizzled (Fz) is a seven-pass transmembrane receptor that acts in both Wnt/β-catenin and Wnt/planar cell polarity (PCP) pathways. Both pathways are essential for numerous developmental processes and are deregulated in many human diseases. A prerequisite for PCP signaling is the asymmetric subcellular distribution of Fz in epithelial cells. However, the regulation of Fz asymmetry is currently not well understood. Here, we describe that the transmembrane protein CG8444 (here termed VhaPRR) is needed for PCP signaling in Drosophila melanogaster. VhaPRR is an accessory subunit of the vacuolar (V)-ATPase proton pump. It also functions as a receptor for (pro)renin (PRR) in mammals and has recently gained importance as a potential target in anti-hypertensive therapy. We show that VhaPRR function is tightly linked with Fz but not other PCP core proteins. Fz fails to localize asymmetrically at the plasma membrane and accumulates in cytoplasmic vesicels in the absence of VhaPRR. This is accompanied by prehair mispositioning and mispolarization in pupal wing cells. In addition, VhaPRR forms a protein complex with Fz receptors and interacts genetically with Fz in the Drosophila eye. VhaPRR also acts as a modulator of canonical Wnt signaling in larval and adult wing tissue. Its loss leads to an expansion of the Wnt/Wingless (Wg) morphogen gradient and reduction of Wg target gene expression. The requirement for additional V-ATPase subunits suggests that proton fluxes contribute to normal Fz receptor function and signaling. Our findings have broad implications on the relationship between membrane trafficking and signaling events, and may also suggest that novel PRR-targeting drugs may need to be critically assessed to avoid serious side effects.

**TH-PO627**

**Mineralocorticoid Receptor Degradation Is Promoted by Hsp90 Inhibition and the Ubiquitin-Protein Ligase CHIP** Olivier Staub, Nourdine Faresse. *Department of Pharmacology & Toxicology, University of Lausanne, Lausanne, Switzerland.*

The mineralocorticoid receptor (MR) plays a crucial role in the regulation of Na+ balance and blood pressure, as evidenced by gain of function mutations in the MR of hypertensive families. In the kidney, aldosterone binds to the MR, induces its nuclear translocation, and promotes a transcriptional program leading to increased transepithelial Na+ transport via the epithelial Na+ channel ENaC. In the unliganded state, MR is localized in the cytosol and part of a multiprotein complex, including Hsp90, which keeps it ligand binding competent. 17-AAG is a benzoquinone ansamycin antibiotic that binds to Hsp90 and alters its function. We investigated whether 17-AAG affects the stability and transcriptional activity of MR and consequently Na+ reabsorption by renal cells. 17-AAG treatment lead to reduction of MR protein level in epithelial cells in vitro and in vivo, thereby interfering with aldosterone-dependant transcription. Moreover, 17-AAG inhibited aldosterone-induced Na+ transport, possibly by interfering with MR availability for the ligand. Finally, we identified the ubiquitin-protein ligase CHIP as a novel partner of the cytosolic MR, which is responsible for its polyubiquitylation and proteasomal degradation in presence of 17-AAG. In conclusion, 17-AAG may represent a novel pharmacological tool to interfere with Na+ reabsorption and hypertension.

**Impaired Aldosterone Responsiveness in Corticosteroid Binding Globulin (CBG) Deficient Mice** Jens G. Leipziger,[1] Helle A. Praetorius,[1] Anders Nykjaer,[3] Mads Vaarby Sorensen.[1] *[1]Physiology and Biophysics, Aarhus University, Aarhus, Denmark; [2]Medical Biochemistry, Aarhus University, Aarhus, Denmark.*

Corticosteroid Binding Globulin (CBG) is the relevant plasma carrier protein for corticosterone. CBG is assumed to keep the steroids inactive and to define the amount of free hormone acting on target tissues. Previous findings have shown that the delivery of corticosterone to peripheral tissues is insufficient in $CBG^{-/-}$ mice despite elevated free plasma corticosterone. In the large intestine glucocorticoids synergistically enhance the pro-absorptive effects of aldosterone (aldo). In addition, CBG is also known to carry about 20% of the total plasma aldo. We therefore hypothesized that $CBG^{-/-}$ mice show altered responsiveness to aldo. Methods: We used $CBG^{-/-}$ and $CBG^{+/+}$ mice to test aldo-up-regulated, ENaC-mediated $Na^+$ absorption. An Ussing chamber was used to quantify amiloride-sensitive $Na^+$ transport in distal colonic mucosa. The amiloride-sensitive short circuit current ($\Delta$Isc(amil)) was used to quantify the physiological aldo action. Total and free plasma aldo levels were measured by RIA. A low sodium diet (3 weeks) was used to augment endogenous aldo. Q-PCR was used to quantify aldo target gene expression. Results: No functional differences were observed in $\Delta$Isc(amil) or aldo levels in animals on control diet. When $Na^+$ restricted, both genotypes up-regulated the $\Delta$Isc(amil). In $CBG^{+/+}$ up-regulation was 25-fold, contrasting to a much smaller degree (13-fold) in $CBG^{-/-}$ tissue. Interestingly, in $CBG^{+/+}$ mice the associated increase of aldo was only 2-fold (both free and total), whereas the $CBG^{-/-}$ mice showed a 4-fold increase in aldo. In $CBG^{-/-}$ the transcription of $\gamma$-ENaC was blunted. Summary: Despite a dramatic increase of aldo in $CBG^{-/-}$ mice on low $Na^+$ diet, the functional response in the aldo-sensitive distal colon remains markedly insufficient. Our data indicate that CBG is a necessary factor for intact aldo-responsiveness in mouse distal colon.

**TH-PO629**

**microRNAs Expression Pattern and Regulation by Aldosterone in the Distal Nephron** Juliette Hadchouel,[1,2] Emilie Elvira-Matelot,[1,2] Christelle Soukaseum,[1,2] Celine Latouche,[2,3] Dewi Vernerey,[1,2] Nicolette E. Farman,[2,3] Frederic Jaisser,[2,3] Xavier Jeunemaitre.[1,2] *[1]Paris Cardiovascular Research Center, INSERM UMR 970, Paris, France; [2]University Paris-Descartes, Paris, France; [3]Cordeliers Research Center, INSERM UMR872, Paris, France.*

We previously showed that expression of WNK1, an important regulator of Na+ and K+ transport in the distal nephron, is controlled by miR-192, a microRNA whose expression is inhibited by aldosterone (Elvira-Matelot et al.,JASN,2010). miRs could thus participate in the regulation of renal ion transport by aldosterone.

In order to identify such miRs, we first established the pattern of expression of miRs in the nephron. Mouse Proximal Tubules (PCT/PR), Distal Convoluted Tubules (DCT), Connecting Tubules and Cortical Collecting Ducts (CNT/CCD) were microdissected and the level of expression of 518 murine miRs in each segment was quantified using TaqMan® Rodent microRNA Plates (Applied Biosystems). 357 miRs were expressed in at least one segment. Unsupervised hierarchical clustering analysis nicely separates PCT/PR from the DCT and CNT/CCD. Statistical analysis then showed that 4, 3 and 7 miRs were specifically expressed in the PCT/PR, DCT and CNT/CCD, respectively, while 16 miRs are expressed only in the distal nephron (DCT+CNT/CCD). In addition, 15 and 36 miRs were preferentially expressed in the proximal or distal nephron, respectively.

In a second step, the expression of the same miRs was quantified in the kidney of mice submitted to Na+ depletion, Na+ load or chronic aldosterone infusion. Expression of 50 miRs was modified by either one of these challenges; among those, 4 exhibited a tubular-specific expression pattern. The modification of miR expression observed was either a down-regulation, an up-regulation or a complete inhibition of an expressed miR or an induction of a non-expressed miR.

In conclusion, the proximal nephron differs from the distal nephron in terms of miR expression and miR expression is regulated by sodium intake. Computational identification of potential targets of selected miRs and in vitro validation of the miR-target interaction in mDCT cells would help unravel the roles played by miRs in the regulation of renal ion transport.

**Aldosterone Inhibits Repressive Histone Lysine Methyltransferases (KMT) and Recruits the Permissive Lysine-Specific Demethylase-1 (LSD1) To Activate $\alpha$-ENaC Transcription in mIMCD3 Cells** Zhiyuan Yu, Qun Kong, Bruce C. Kone. *Medicine, University of Texas-Houston Medical School, Houston, TX.*

Aldosterone increases renal tubular $Na^+$ reabsorption in large part by enhancing $\alpha$-ENaC transcription. We recently reported that a complex containing the histone H3K79 methyltransferase Dot1 and the histone deacetylase Sirt1 associates with and represses the $\alpha$-ENaC promoter in mIMCD3 cells, effects that are reversed by aldosterone (J Biol Chem 284:20917-26, 2009). In other cell types, Sirt1 promotes establishment of the repressive chromatin mark H3K9me3 through its interaction and stimulation of the KMT Suv39H1. We hypothesized that, in addition to augmenting Dot1-mediated hypermethylation of H3K79, Sirt1 facilitates repressive chromatin formation through Suv39H1-mediated hypermethylation of H3K9me3 at the $\alpha$-ENaC promoter under basal conditions. We further hypothesized that aldosterone promotes de-repression of $\alpha$-ENaC transcription by suppressing the actions of Dot1, Sirt1, and Suv39H1, and by recruiting LSD1 to mark active chromatin with H3K9me1. We performed ChIP/qPCR assays for Suv39H1 occupancy and the three H3K9 methylation states at specific subregions of the $\alpha$-ENaC promoter in mIMCD3 cells treated with vehicle or aldosterone for 2h. Under basal conditions, Suv39H1 and H3K9me3 were present in chromatin associated with the same promoter subregions as Dot1a and Sirt1. Aldosterone induced loss of Suv39H1 and H3K9me3 from chromatin at these subregions, as we had shown for Dot1 and Sirt1. Aldosterone also induced LSD1 occupation and a shift to the active chromatin mark H3K9me1 at the $\alpha$-ENaC promoter in mIMCD3 cells. Knockdown or pharmacologic inhibition of LSD1 impaired aldosterone induction of endogenous $\alpha$-ENaC mRNA expression. We conclude that basal repression of $\alpha$-ENaC transcription in mIMCD3 cells involves not only Dot1 and Sirt1 but also Suv39h1-mediated H3K9 trimethylation at the $\alpha$-ENaC promoter. Aldosterone de-represses $\alpha$-ENaC transcription by suppressing Suv39H1, Dot1, and Sirt1, and by recruiting LSD1 to demethylate H3K9 to the $\alpha$-ENaC promoter. These results identify aldosterone as the most versatile epigenetic modifier of any nuclear hormone.

**Disruption of Putative Transcriptional Regulator AF17 Impairs Na+ Retention and Lowers Blood Pressure in Mice** Wenzheng Zhang,[1,2] Hongyu Wu,[1] Le Huang,[2,] Hejab Ayub.[1] *[1]Internal Medicine, University of Texas Medical School at Houston, Houston, TX; [2]Graduate School of Biomedical Sciences, University of Texas Health Science Center at Houston, Houston, TX; [3]Department of Biochemistry and Molecular Biology, University of Texas Medical School at Houston, Houston, TX; [4]Department of Internal Medicine, Xiangya Hospital, Changsha, Hunan, China.*

We recently reported that AF17 competes with AF9 to bind the same domain of Dot1a and promotes Dot1a nuclear export, leading to H3 K79 hypomethylation, transcriptional activation of several aldosterone regulated genes including $\alpha$, $\beta$, $\gamma$ENaC and their key regulators, and elevated ENaC activity in 293T cells. To solidify and extend these observations to in vivo, we have generated and characterized the first AF17-deficient mice (AF17-/-). On a normal Na+ diet, AF17-/- mice displayed an increased H3 K79 methylation at the $\alpha$ENaC promoter, reduced mRNA and protein expression of ENaC and Sgk1 genes. Functionally, we found that these mice showed an elevated urine volume, urinary Na+ and K+ excretion, serum aldosterone and decreased serum [Na+] coupled with a lower blood pressure than those of wild type mice. These findings suggest that the elevated serum aldosterone level under normal Na+ diet is not high enough to compensate for the AF17 loss to relieve Dot1a-mediated repression of ENaC and Sgk1 gene expression. In contrast, the AF17-/--mediated renal dysfunction and decreased blood pressure were largely attenuated by three means to increase serum aldosterone levels remarkably: a low Na+ diet, a high K+ diet, or aldosterone perfusion. In conclusion, we have provided the first in vivo genetic evidence showing that AF17 functions as a positive regulator of ENaC transcription and Na+ retention through its modulation of Dot1a-catalyzed, aldosterone-sensitive H3 K79 methylation in mouse kidney.

**Flow Regulation of Endothelin-1 Production in the Collecting Duct** Donald E. Kohan, Brianna Lyon-Roberts, Kevin A. Strait. *Division of Nephrology, University of Utah, Salt Lake City, UT.*

Collecting duct (CD) endothelin-1 (ET-1) is an important autocrine inhibitor of CD Na reabsorption. Salt loading increases CD ET-1 production, however the mechanisms transducing this effect are poorly understood. Tubule fluid flow increases in response to Na loading, hence we studied flow modulation of CD ET-1 production. Three days of a high salt diet in mice increased acutely isolated inner medullary CD ET-1 mRNA expression.

Primary cultures of mouse IMCD detached in response to flow using a closed perfusion chamber, consequently a CD cell line (mpkCCDcl4) was examined. Flow increased ET-1 mRNA in mpkCCD cells at shear stress rates exceeding 1 dyne/cm$^2$, with the maximal effect seen between 2-10 dyne/cm$^2$. Induction of ET-1 mRNA was first evident after 1 hr of flow. Inhibition of calmodulin or dihydropyridine-sensitive calcium channels did not alter the flow response, however chelation of intracellular calcium with BAPTA largely prevented flow-stimulated ET-1 mRNA accumulation. Notably, flow increased intracellular calcium concentration as assessed by Fluo-4 fluorescence. Downregulation of PKC using overnight exposure to PMA, or PKC inhibition with calphostin C, markedly reduced flow-stimulated ET-1 mRNA levels. Flow-stimulated ET-1 synthesis was partially dependent upon sodium delivery since hypertonic NaCl perfusate increased, while absence of perfusate Na (replacing NaCl with choline Cl) decreased, flow-stimulated ET-1 mRNA. Furthermore, amiloride partially reduced the ET-1 response to flow. Initial studies do not support a role for cilia in mediating the flow response since treatment with chloral hydrate for 1 day, a procedure designed to eliminate primary cilia, did not alter flow-stimulated ET-1 synthesis. However, further studies on the role of cilia and related proteins are necessary. In summary, apical flow increases CD ET-1 biosynthesis. This effect is dependent upon intracellular calcium and PKC, and partly relates to changes in apical Na channel Na transport. These studies suggest a novel pathway for coupling alterations in extracellular fluid volume to CD ET-1 production and ultimately control of CD Na reabsorption.

**Epithelial Na Channel Domains That Modulate the Response to Laminar Shear Stress** Tania Abi Antoun, Lindsey Tolino, Thomas R. Kleyman, Marcelo D. Carattino. *Medicine/Renal-Electrolyte, University of Pittsburgh, Pittsburgh, PA.*

The epithelial Na channel (ENaC) mediates the rate-limiting step in Na reabsorption in the distal nephron and plays a key role in volume homeostasis. Na reabsorption and K secretion in this segment of the nephron are modulated by the rate of luminal flow. Four different ENaC subunits have been identified in humans, α, β, γ, and δ. Channels composed of α, β and γ subunits respond to laminar shear stress (LSS) with an increase in open probability. Given that the δ subunit is functionally related to the α subunit while sharing only 37% of sequence identity, we investigated the response of αβδ channels to flow. Both the time course and magnitude of activation of αβδ channels by LLS were remarkably different than those of αβγ channels. ENaC subunits have similar topology with an extracellular domain (ECL) connected by two transmembrane domains (TM1 and TM2) with intracellular N- and C- termini. To identify the specific domains that are responsible for the differential response to flow, we generated a series of α-δ chimeras and studied the parameters of activation by LSS. We found that the region encompassing the TM2 and C-terminus was responsible for the differences in the magnitude and time course of channel activation by LSS.

**Base of the Thumb Region of Epithelial Sodium Channel Modulates the Channel's Response to Shear Stress** Shujie Shi, Marcelo D. Carattino, Thomas R. Kleyman. *Renal-Electrolyte Division, Department of Medicine, University of Pittsburgh, Pittsburgh, PA.*

The epithelial sodium channel (ENaC) has a key role in the regulation of extracellular fluid volume and blood pressure, primarily by mediating $Na^+$ uptake at the apical membrane of principal cells in the distal nephron. Studies in our laboratory and by others suggest that laminar shear stress (LSS) activates ENaC by increasing channel open probability (Po). Based on the recently resolved crystal structure of ASIC1, a member of the ENaC/degenerin family, we hypothesized that the large extracellular region is involved in the regulation of ENaC by mechanical forces. Current studies investigated whether a Tyr residue at the base of the thumb domain of all three ENaC subunits, at a location homologous to a key Trp residue in ASIC1, affects LSS-mediated ENaC gating. Three *alpha* Y418 mutations (Ala, Cys and Trp) significantly enhanced ENaC's response to LSS. Channel activation by LSS was not affected by *beta* Y356 mutations. When the Tyr in *gamma* subunit was substituted with Ala or Cys, the response to LSS was similar to the wild type channel, whereas the *gamma* Y375W mutant exhibited enhanced channel activation. Residues adjacent to Y418 in the *alpha* subunit (L414 to D420) were substituted with Trp, and LSS-mediated channel activation was examined. Each mutant (L414W, G415W, G416W, N417W, G419W and D420W) enhanced the channel's response to LSS. Taken together, our data suggest that the base of the thumb has a role in modulating channel gating in response to external mechanical forces. Our results are consistent with the hypothesis that shear stress induces movement within the periphery of the extracellular regions of ENaC subunits that are transmitted, via the base of the thumb, to the channel's gate residing in the membrane spanning domains.

### TH-PO635

**TMPRSS4 Activates the Epithelial $Na^+$ Channel by Cleaving the γ Subunit in the Vicinity of the Prostasin-Dependent Cleavage Site** Christopher J. Passero, Gunhild M. Mueller, Mike M. Myerburg, Rebecca P. Hughey, Thomas R. Kleyman. *Department of Medicine, University of Pittsburgh, Pittsburgh, PA.*

The epithelial sodium channel (ENaC) facilitates sodium and fluid transport in the epithelia of the lung and kidney. Proteases modulate ENaC activity by cleaving and releasing inhibitory tracts from the α and γ subunits. Furin, a proprotein convertase residing in the trans-Golgi apparatus, cleaves the α subunit at sites flanking a 26 residue inhibitory tract, but furin only cleaves the γ subunit once. Prostasin, a GPI-anchored serine protease, activates mouse ENaC by cleaving at γRKRK186, releasing a 43 residue inhibitory tract. Prostasin cleavage and activation can be abolished by mutation of the polybasic tract γRKRK186QQQQ. TMPRSS4, a type II transmembrane serine protease, is known to activate ENaC and has previously been shown to cleave the channel at the furin-dependent site of the γ subunit. The question we addressed was whether cleavage distal to the furin site was required to activate the channel. We expressed mouse ENaC with either wild type or mutant (γRKRK186QQQQ) γ subunits in *Xenopus* oocytes with and without co-expression of TMPRSS4. Co-expression of TMPRSS4 increased ENaC currents measured by two-electrode voltage clamping by 1.9 fold. Detection of the surface pool of ENaC containing γ subunits with C-terminal V5 epitope tags identified the generation of a new 70kDa fragment similar to the previously described prostasin-induced cleavage fragment. The mutation γRKRK186QQQQ largely abolished functional activation as well as gamma subunit cleavage by TMPRSS4. The mutation γD172-182RKRK186QQQQ lacks three basic residues (K173, K175, and R177) in addition to the mutations within the polybasic prostasin cleavage site, and completely abolished functional activation by TMPRSS4. Our results show that TMPRSS4 activates furin processed mouse ENaC by cleaving the γ subunit at and/or near the prostasin-dependent cleavage site to release an inhibitory tract. As TMPRSS4 has previously been shown to cleave at the furin-dependent site, it may activate near silent channels by cleaving at sites flanking the inhibitory region.

**Regulation of Epithelial Na Channels by Tissue Kallikrein** Ankit B. Patel,[1,2] Lawrence G. Palmer.[1] *[1]Department of Physiology and Biophysics, Weill Cornell Medical College, New York, NY; [2]Tri-Institutional MD-PhD Program, Weill Cornell/Rockefeller University/Sloan-Kettering Institute, New York, NY.*

Epithelial Na Channels (ENaC) are heterotrimeric proteins formed from three different subunits; αENaC, βENaC, and γENaC. The functional heterotrimer is responsible for the apical entry of Na+ in a number of different epithelia including the renal connecting tubule and cortical collecting duct. Proteolytic cleavage of αENaC and γENaC has been shown to increase channel activity by increasing the open probability (Po) of channels with low Po. A number of different serine proteases including trypsin, furin, elastase, and prostasin are implicated in activating ENaC by cleaving a part of the extracellular domain of γENaC . We tested whether tissue kallikrein, a serine protease secreted by the connecting tubule of the nephron, can also cleave ENaC leading to its activation. When Xenopus oocytes co-expressing the three rat ENaC subunits were exposed to kallikrein from porcine pancreas, there was a 3 fold increase in amiloride sensitive Na+ current within 10 minutes measured by two-electrode voltage clamp (TEVC) that was not further increased by the addition of trypsin. However, this activation was sensitive to soybean trypsin inhibitor (SBTI), suggesting serine proteases other than tissue kallikrein were responsible for ENaC activation. Subsequently, tissue kallikrein purified from rat salivary glands was found to increase ENaC mediated currents 3 fold both in the presence and absence of SBTI. In addition, biotinylation of cell surface γENaC followed by western blot showed oocytes pretreated with rat tissue kallikrein displayed an additional cleaved band of γENaC at the cell surface. Using a specific substrate to measure tissue kallikrein activity, we found the kallikrein activity in the urine of rats fed a high K+ or low Na+ diet was comparable to the kallikrein activity found to activate ENaC in vitro. This suggests tissue kallikrein may act as a physiological regulator of ENaC activity in the kidney.

### TH-PO637

**Molecular Determinants of Ligand Recognition Specificity of the Novel Plasminogen Receptor, Plg-$R_{KT}$** Caitlin M. Parmer,[1] Nagyung Baik,[2] Lindsey A. Miles,[2] Robert J. Parmer.[3,4] *[1]Yale University, New Haven, CT; [2]The Scripps Research Institute, La Jolla, CA; [3]University of California, San Diego; [4]VA San Diego Healthcare System, La Jolla, CA.*

Activation of plasminogen (Plg) to plasmin by plasminogen activators is markedly promoted when Plg is bound to cells. Recent results suggest that proteolytic processing of ENaC by plasmin plays a key role in ENaC activation in nephrotic syndrome, in which increased Plg levels are present in urine. We recently identified a novel transmembrane Plg receptor, Plg-$R_{KT}$, and have observed prominent expression of Plg-$R_{KT}$ in renal tubular epithelial cells. Here, we investigated the ligand recognition specificity of Plg-$R_{KT}$ for Plg. The Plg-$R_{KT}$ peptide, E139-K147, corresponding to the 9 C-terminal amino acids, was coupled to BSA via addition of an amino terminal cysteine and coated onto microtiter wells. Human Plg was biotinylated and then incubated with the immobilized peptide and detected with streptavidin-HRP. Plg bound to the peptide in a concentration-dependent manner. In specificity controls, biotinylated-Plg binding was competed by unlabeled Plg and no biotinylated-Plg binding to the reverse peptide was detected. Plg binding was inhibited in a dose-dependent manner by the E139-K147 soluble peptide ($IC_{50}$=2 μM), but not by

a mutated peptide E139-K147A. A peptide with the proximal upstream R replaced with K (R142K) was a more effective inhibitor of biotinylated-Plg binding than the wild type peptide. Human Plg also recognized the C-termini of murine, rat, and bovine Plg-$R_{KT}$'s that contain the R142K substitution. Plg domains containing the disulfide-bonded kringle (Kr) structures (Plg has 5 Kr structures that mediate the interaction of Plg with cells) inhibited Plg binding with the following order of effectiveness: Plg>Kr1-3>Kr5>Kr4. In conclusion, the binding of Plg-$R_{KT}$ to Plg requires the presence of a C-terminal lysine and can be modulated by a proximal upstream basic residue. Furthermore, kringle domains of Plg interact with the C-terminus of Plg-$R_{KT}$. Plg-$R_{KT}$ is a structurally unique plasminogen receptor that represents a novel control point for regulating cell surface proteolysis.

**Regulation of ENaC Function by Oxygen** Russell F. Husted,[1] John B. Stokes.[1,2] *[1]Internal Medicine, University of Iowa, Iowa City, IA; [2]Internal Medicine, VA Medical Center, Iowa City, IA.*

The $PO_2$ of the renal interstitium changes dramatically from the surface of the cortex to the tip of the papilla and regional $PO_2$ can change under several physiological conditions. Using mpkCCDc14 cells as a model we tested the effect of changes in $PO_2$ on ENaC mediated Na transport (JNa). Incubating monolayers in 40% $O_2$ for 24 h produced a 50% increase in JNa; a 95% $O_2$ medium produced no further effect. Reducing $O_2$ to 8% reduced JNa by ~40%. The effect of $O_2$ was not evident for several hours; acute changes in $PO_2$ of the medium had no effect on JNa. Lactate production and medium pH varied inversely with $PO_2$, but changes in medium pH to mimic that produced by changes in $O_2$ produced no change in JNa. In contrast to our hypothesis, changes in $PO_2$ did not change the abundance in hypoxia inducible factors (HIF1a and HIF2a), nor did it change activation of AMP kinase. Supporting the lack of a role of these mechanisms in the oxygen effect, we found that pharmacological inhibition of HIF degradation or activation of AMP kinase did not prevent the oxygen effect on JNa. We also found that oxygen regulation was independent of corticosteroid stimulation of JNa. The effects of steroids were additive to that of oxygen and the gene expression pattern produced by steroids was different from that of oxygen. Notably, steroids increased expression of SGK1, USP2-45, and GILZ but oxygen did not; Slc2a1 (Glut1) and HO-1 were modulated by oxygen but not by steroids. Oxygen modulated the expression of the beta-ENaC subunit but not alpha- or gamma-ENaC. Surface expression of gamma-ENaC was increased by high $PO_2$ and the cleaved form was increased to an even greater extent. Incubation with aprotinin did not provide evidence that the oxygen effect was produced by an increased production of a protease. These results indicate that oxygen can have a potent role in regulating ENaC activity. The majority of its effect appears to be related to altered surface expression of ENaC. The time course of its effect suggests a mechanism involving changes in transcription.

**Role of the Cortical Actin and Cortactin in Regulation of ENaC Activity** Daria Ilatovskaya,[1,3] Alexey Karpushev,[1] Tengis S. Pavlov,[1] Vladislav Levchenko,[1] Yuri A. Negulyaev,[3] Alexander Staruschenko.[1,2] *[1]Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Kidney Disease Center, Medical College of Wisconsin, Milwaukee, WI; [3]Institute of Cytology RAS, St. Petersburg, Russian Federation.*

Sodium reabsorption via the epithelial $Na^+$ channel (ENaC) in the ASDN plays a central role in body fluid volume regulation. Coordinated regulation of ENaC activity by changes in actin cytoskeleton dynamics has been shown in several studies. However, how ENaC interacts with the actin cytoskeleton is essentially unknown. First we confirmed that destroying of the actin cytoskeleton with cytochalasin D rapidly increased ENaC activity in freshly isolated rat cortical collecting duct (CCD) and polarized mpkCCD$_{c14}$ principal cells. Furthermore, this is the first report we are aware of describing a mechanism of ENaC regulation by cortical actin-associated protein cortactin. We demonstrated that cortactin is highly expressed in kidney cortex, polarized epithelial mpkCCD$_{c14}$, M-1 and MDCK cells, and is localized to the CCD in Sprague-Dawley rat kidneys. As measured in patch-clamp experiments, co-expression of cortactin with ENaC in CHO cells decreased ENaC activity. Co-immunoprecipitation analysis revealed direct interactions between cortactin and α-ENaC in overexpressed CHO and native mpkCCD$_{c14}$ cells. Similar, fluorescence imaging and quantification techniques showed that cortactin is associated with all three ENaC subunits. Biotinylation experiments and single channel analysis revealed that cortactin decreased ENaC activity via affecting channel open probability ($P_o$). To address the question of what mechanism underlies the action of cortactin on ENaC activity, we assayed the effects of various mutants of cortactin. Only a cortactin mutant unable to bind Arp2/3 complex did not influence ENaC activity. Moreover, novel inhibitor of the Arp2/3 complex CK-0944666 precluded the effect of cortactin. Thus, these results indicate that cortical actin and cortactin are essential for ENaC activity and that Arp2/3 complex is involved in cortactin-mediated decrease of ENaC activity.

**Effects of CYP P450 Metabolites of Arachidonic Acid on the Epithelial Sodium Channel (ENaC)** Tengis S. Pavlov,[1] Daria Ilatovskaya,[1,2] Richard J. Roman,[3] Alexander Staruschenko.[1] *[1]Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Institute of Cytology RAS, St. Petersburg, Russian Federation; [3]Pharmacology and Toxicology, University of Mississippi Medical Center, Jackson, MS.*

Sodium reabsorption via ENaC in the ASDN plays a central role in body fluid volume regulation. Previous studies have indicated that arachidonic acid (AA) inhibits $Na^+$ transport in the collecting duct (CD), and that 11,12-EET inhibits ENaC activity. However the mechanism of action of EETs remains to be determined. The goal of this study was to investigate the endogenous metabolism of AA in cultured mpkCCD$_{c14}$ principal cells and the effects of each of these metabolites on ENaC activity. In addition we examined the effects of EETs and co-expression of Cyp2c8 and Cyp4a10 in CHO cells to more specifically study the mechanism of action and discriminate between actions on the channel number and channel open probability (Po). LC/MS/MS analysis in the mpkCCD$_{c14}$ cells identified the presence of 8,9-EET, 11,12-EET, 14,15-EET, 5-HETE, 12/8-HETE, and 15-HETE but not 20-HETE. Single channel analysis revealed that EETs but not HETEs acutely decrease ENaC Po in the mpkCCD$_{c14}$ cells. Interestingly that 8,9-EET and 14,15-EET similar to 11,12-EET modulate channel's activity. Neither 20-HETE nor 5-HETE, 12/8-HETE and 15-HETE had effect on ENaC activity. Co-expression of Cyp2c8 but not Cyp4a10 with all three ENaC subunits in CHO cells significantly decreased ENaC activity in whole-cell experiments. Downregulaion of ENaC activity was PKA-dependent and prevented by myristilated PKI treatment. Furthermore, biotinylation experiments and single channel analysis revealed that the long-term (4hrs) treatment with 11,12-EET decreased the number of channel in the membrane. We conclude that 11,12-EET, 8,9-EET and 14,15-EET are important for maintaining transepithelial $Na^+$ transport and ENaC activity. We hypothesize that EETs have biphasic effect on ENaC activity. Chronic treatment with 11,12-EET inhibits ENaC by decreasing the number of channels through PKA pathway, but acute treatment affect Po.

**Novel Role of Rac1/WAVE Signaling Mechanism in Regulation of the Epithelial $Na^+$ Channel (ENaC)** Alexander Staruschenko,[1,2] Alexey Karpushev,[1] Vladislav Levchenko,[1] Tengis S. Pavlov.[1] *[1]Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Kidney Disease Center, Medical College of Wisconsin, Milwaukee, WI.*

The epithelial $Na^+$ channel (ENaC) is an essential channel responsible for $Na^+$ reabsorption in the ASDN. Consequently, ENaC is a major effector impacting systemic blood volume and pressure. We have shown recently that small GTPase Rac1 increases ENaC activity, whereas Cdc42 fails to change channel activity. Here we tested whether Rac1 signaling plays a physiologic role in modulating ENaC in native tissue and polarized epithelial cells. We have found that Rac1 inhibitor NSC23766 markedly decreased ENaC activity in freshly isolated collecting ducts. Knockdown of Rac1 in native principal cells decreased ENaC-mediated sodium reabsorption and the number of channels at the apical plasma membrane. Members of the Wiskott-Aldrich syndrome protein (WASP) family play central roles in control of the actin cytoskeleton. N-WASP binds Arp2/3 in response to Cdc42, whereas WAVE proteins are effectors of Rac1 activity. N-WASP and all three isoforms of WAVE significantly increased ENaC activity when co-expressed in CHO cells. However, wiskostatin, an inhibitor of N-WASP had no effect on ENaC activity over-expressed in CHO cells and $Na^+$ reabsorption across mpkCCD$_{c14}$ monolayers. Immunoblotting demonstrated the presence of WAVE1 and WAVE2 and absence of N-WASP and WAVE3 in mpkCCD$_{c14}$ and M-1 principal cells. Immunohistochemistry analysis also revealed localization of WAVE1 but not N-WASP in the cortical collecting duct in Sprague-Dawley rat kidneys. Moreover patch clamp analysis revealed that Rac1 and WAVE1/2 are parts of the same signaling with respect to activation of ENaC. Thus, our findings suggest that Rac1 is essential for ENaC activity and regulates the channel via WAVE proteins.

**TH-PO642**

**A Major Role for Minor Site Phosphorylation in 14-3-3-Mediated Regulation of Nedd4-2 and ENaC** Sindhu Chandran,[1] Rodrigo Alzamora,[2] Kenneth R. Hallows,[2] Vivek Bhalla.[1] *[1]Nephrology, Stanford University, Stanford, CA; [2]Renal-Electrolyte Division, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

The E3 ubiquitin ligase Nedd4-2 inhibits sodium transport through decreased cell surface expression of the epithelial sodium channel (ENaC) in the collecting duct. Several hormonally regulated kinases activate ENaC by phosphorylating Nedd4-2, thereby inducing an inhibitory interaction with 14-3-3 dimers. However, the mechanisms of 14-3-3-mediated Nedd4-2 inhibition are unclear. Our previous work suggests that phosphorylation at Nedd4-2 Ser444 (*Xenopus* numbering), the major 14-3-3 interaction site, is necessary but not sufficient for inhibition of Nedd4-2, and that phosphorylation at minor 14-3-3 interaction sites, Ser338 and Thr363, may play more important roles than previously recognized. By co-immunoprecipitation Nedd4-2 phosphorylation-deficient minor site mutants (S338A,

T363A, and S338A/T363A) bind significantly less 14-3-3e than does wild-type (WT) Nedd4-2 (by 12 ± 2%, 35 ± 17%, and 51 ± 11%, respectively). These mutations did not affect ubiquitin ligase activity by an auto-ubiquitin assay, but inhibited ENaC expression in a cell surface biotinylation assay less well than WT (by 59 ± 8%, 72 ± 5%, and 70 ± 14%, respectively). By pulse-chase analysis, we observed that S444A has a shorter half-life (1.3 h) than WT (2.7 h) or S338A (2.9 h). P446A Nedd4-2, with decreased 14-3-3 binding but comparable Ser444 phosphorylation, also has a shorter half-life than WT (2.0 h). Moreover, we found that dimerization-deficient 14-3-3ε binds Nedd4-2 and inhibits Nedd4-2 function less than WT 14-3-3ε. Although phosphorylation at the "major" site, Ser444, is important for interaction with 14-3-3 dimers, "minor" site phosphorylation at Ser338 or Thr363 by hormonally regulated kinases such as SGK1 or PKA may be the relevant molecular switch that stabilizes Nedd4-2 interaction with 14-3-3 dimers and promotes ENaC cell surface expression. We also propose that enhanced binding to 14-3-3 dimers conferred by phosphorylation at Ser444 promotes Nedd4-2 protein stability in cells, which represents a novel role for 14-3-3 proteins in ENaC regulation.

**Rosiglitazone Increases Epithelial Sodium Channel Activity Via the SGK1/Nedd4-2 Pathway** Ahmed Chraibi, Stephane Renauld, Karine Tremblay, Hugo Garneau, Siham Aitbenichou. *Department of Physiology and Biophysics, Faculty of Medicine and Health Sciences, University of Sherbrooke, Sherbrooke, QC, Canada.*

Thiazolidinediones (TZDs) are peroxisome proliferator-activated receptor gamma (PPARγ) agonists used to treat type II diabetes. Recent studies have shown that TZDs can cause fluid retention and oedema by increasing sodium reabsorption in the renal collecting duct. Those side effects may be caused by the up-regulation of the epithelial Na+ channel (ENaC) and Na+/K+-ATPase. However, the mechanisms involved are not clearly understood. Our goal is to study the effects and the mechanisms involved in rosiglitazone action on the expression and function of ENaC. To do so, we performed two electrode voltage clamp studies (TEVC) in *Xenopus laevis* oocytes expressing PPARγ receptor, wild type (wt) and mutant ENaC channels. We have shown that a 48h treatment with 10 µM RGZ produced a 2-fold increase of ENaC activity and this activation is blocked by GW9662, a PPARγ antagonist. We have also generated a mutation in a potential SGK1 (serum- and glucocorticoid-regulated kinase) binding site in the αENaC subunit and expressed the mutant channel together with the PPARγ receptor in *Xenopus* oocytes. RGZ-induced activation was similar in both wt and mutant channels, suggesting that direct phosphorylation of ENaC by SGK1 is not involved in this regulation. SGK1 is also known to inhibit ENaC internalization through Nedd4-2 phosphorylation and subsequent inactivation. ENaC lacking Nedd4-2 binding motifs (Liddle's mutation) are not stimulated by RGZ. Those results suggest RGZ treatment have increased ENaC expression and activity through Nedd4-2 inhibition mediated by SGK1. In accordance with these results, RGZ increase the activity of ENaC by enhancing its cell surface expression, most probably indirectly, through the increase of SGK1 expression. Western blot analysis and confocal microscopy experiments have confirmed that the RGZ-induced ENaC activity and expression via the SGK1/Nedd4-2 pathway in our model.

**Renal Phosphodiesterase-5 Inhibtion Promotes Natriuresis in Both Virgin and Pregnant Female Rats** Jennifer M. Sasser,[1] Michael H. Humphreys,[2] Christine Baylis.[1] *[1]Physiology and Functional Genomics, University of Florida, Gainesville, FL; [2]Division of Nephrology, University of California San Francisco, San Francisco, CA.*

Pregnancy is characterized by plasma volume expansion and sodium retention due to increased medullary PDE5. Here, we determined if PDE5 inhibition would induce a natriuretic response in virgin and pregnant rats. Anesthetized 16-day pregnant and virgin rats were studied at baseline and during intrarenal (IR) infusion of the PDE5 inhibitor sildenafil (SILD, 0.5 µg/min). The right kidney served as a control. IR SILD increased urine flow rate (UV) and decreased mean arterial pressure (MAP) and renal plasma flow (RPF) in virgin rats (Table), but had no effect on these parameters in pregnant rats. SILD stimulated sodium excretion (UNaV) and fractional excretion of sodium (FENa) in virgin and pregnant rats. We further investigated the regulation of renal PDE5 during pregnancy by isolating kidneys from virgin, postpartum, and pregnant rats on days 6, 12, 16, and 20 of pregnancy. No changes in PDE5 protein abundance (Western blot) were observed in the renal cortex or outer medulla at any point. On day 16, inner medullary PDE5 protein abundance was increased compared to virgin levels (2.2±0.3 vs 1.0±0.1 relative densitometric units, p=0.04). No significant increase in inner medullary PDE5 was observed during early pregnancy, and PDE5 abundance returned to virgin levels by day 20 of pregnancy and postpartum. We conclude that intrarenal PDE5 has a functional role in the regulation of sodium transport in the renal tubule in the female rat and likely plays an important role in permitting the sodium retention and plasma volume expansion required for optimal pregnancy. The role of PDE5 in tubular sodium transport in the non-pregnant state merits further investigation.

Percent change from baseline values during Sildenafil infusion

| | MAP (% of baseline) | UV (% of baseline) | GFR (% of baseline) | RPF (% of baseline) | UNaV (% of baseline) | FENa (% of baseline) |
|---|---|---|---|---|---|---|
| Virgin (n=11) | 91±1* | 153±16* | 104±11 | 86±5* | 331±55* | 327±58* |
| Pregnant (n=9) | 95±1 | 108±8 | 106±9 | 100±13 | 221±25* | 221±28* |

**TBC1D4 (AS160) Is an Aldosterone-Stabilized Protein That Increases ENaC Cell Surface Abundance** Nikolay Gresko,[1] Olivier Staub,[2] Johannes Loffing.[1] *[1]Institute of Anatomy, University of Zurich, Zurich, Switzerland; [2]Pharmacology and Toxicology, University of Lausanne, Lausanne, Vaude, Switzerland.*

Aldosterone stimulates sodium transport in the aldosterone-sensitive distal nephron (ASDN) by increasing the cell surface abundance of the epithelial sodium channel (ENaC). Small Rab-GTPases control the cell surface targeting of ENaC. Here we studied the role of the Rab-GTPase activating protein TBC1D4 (AS160) for aldosterone-dependent ENaC regulation. Immunoblotting and immmunohistochemistry revealed that TBC1D4 is highly abundant in ENaC-positive ASDN cells of mouse kidneys and in a mouse cortical collecting duct (mCCD1) cell line. In mice, dietary sodium restriction (elevating plasma aldosterone) profoundly increased renal TBC1D4 protein, but not mRNA abundances. Consistent, in mCCD cells, aldosterone (1-300 nM for 24h) stimulated the expression of TBC1D4 protein, but not mRNA in a dose-dependent manner. Pre-treatment of the mCCD cells with the translational inhibitor cycloheximide did not block the aldosterone-induced increase of TBC1D4 protein expression, while pre-treatment with proteasomal (MG132) and lysosomal (chloroquine) inhibitors diminished any difference in expression of TBC1D4 protein between control and aldosterone-treated cells. Lentiviral-based, RNAi-mediated "knock-down" of TBC1D4 in mCCD cells profoundly reduced both baseline and aldosterone-stimulated ENaC cell surface activity and abundance as evidenced by amiloride-sensitive short-circuit current measurements and cell surface biotinylation experiments, respectively. Over-expression of wild-type and mutant TBC1D4 forms in ENaC-expressing HEK293 cells confirmed that TBC1D4 increases the cell surface localization of ENaC, which likely depends on an intact TBC1D4 Rab-GTPase domain. Taken together our data suggest that TBC1D4 is an aldosterone-stabilized protein that controls cell surface activity and abundance of ENaC and hence likely contributes to the aldosterone-dependent regulation of sodium reabsorption in the ASDN.

### TH-PO646

**Inhibition of ENaC by Local Purinergic Signaling as a Mechanism for Aldosterone-Escape** Elena V. Mironova,[1] Vladislav V. Bugay,[1] Timo M. Rieg,[2] Paul Insel,[2] Volker Vallon,[2] Janos Peti-Peterdi,[3] Oleh Pochynyuk,[1] James D. Stockand.[1] *[1]Physiology, UTHSCSA, San Antonio, TX; [2]Pharmacology, UCSD, La Jolla, CA; [3]Physiology, USC, Los Angeles, CA.*

We tested whether the control of ENaC by purinergic tone intrinsic to the distal nephron is involved in aldosterone-escape: the excretion of sodium during high sodium intake despite elevated mineralocorticoids. Urinary ATP concentration increases with dietary sodium intake. Physiological concentrations of ATP decrease ENaC activity in a dose-dependent manner. Increasing sodium intake increases fractional $Na^+$ excretion ($Fe_{Na}$) significantly more in wild-type than in $P2Y_2$ -/- mice, demonstrating impaired renal sodium handling in the latter. To determine the contribution of mineralocorticoid and purinergic regulation of ENaC to salt-sensitive changes in $Fe_{Na}$, we normalized ENaC activity on a high sodium diet to that on a sodium free diet. This gauges how responsive changes in ENaC activity are to changes in sodium intake. Normally, ENaC is responsive because of feedback regulation. Exogenous DOCA or deletion of the $P2Y_2$ receptor each modestly increases the resistance of the channel to changes in sodium intake; together, they markedly increase resistance. ENaC under these latter conditions cannot respond to changes in sodium intake. Due to aldosterone-escape, $Fe_{Na}$ in wild-type mice with high sodium intake is similarly elevated in either the absence or presence of high DOCA. This is not the case in $P2Y_2$ -/- mice, which have lower $Fe_{Na}$ in these conditions. Thus, control of ENaC by purinergic signaling is necessary for complete aldosterone-escape, consistent with a loss of aldosterone-escape in $P2Y_2$ -/- mice contributing to hypertension relative to normal mice in the presence of DOCA and high salt intake.

### TH-PO647

**Diminished Paracrine Regulation of ENaC by Purinergic Signaling in Mice Lacking Connexin 30** Vladislav V. Bugay,[1] Janos Peti-Peterdi,[2] Elena V. Mironova,[1] James D. Stockand.[1] *[1]Physiology, UTHSCSA, San Antonio, TX; [2]Physiology and Biophysics, University of Southern California, Los Angeles, CA.*

We tested if ATP release through Connexin 30 (Cx30) is part of a local purinergic regulatory system intrinsic to the aldosterone-sensitive distal nephron (ASDN) important for proper control of sodium excretion; if changes in sodium intake influence ATP release via Cx30, and if this allows a normal ENaC response to changes in systemic sodium levels. In addition, we define the consequences of disrupting ATP regulation of ENaC in Cx30 -/- mice. Urinary ATP levels in wild-type mice increase with sodium intake, being lower and less dependent on sodium intake in Cx30 -/- mice. Loss of inhibitory ATP regulation causes ENaC activity to be greater in Cx30 -/- vs. wild-type mice, particularly with high sodium intake. These results from compromised ATP release rather than end-organ resistance: ENaC in Cx30 -/- mice responds to exogenous ATP. Thus, loss of paracrine ATP feedback regulation of ENaC in Cx30 -/- mice disrupts normal responses to changes in sodium intake. Consequently, ENaC is hyperactive in Cx30 -/- mice inappropriately lowering sodium excretion particularly during increases in sodium intake. Clamping mineralocorticoids high in Cx30 -/- mice fed a high sodium diet causes a marked decline

in renal sodium excretion. This is not the case in wild-type mice, which are capable of undergoing aldosterone-escape. It is the loss of the ability of ENaC to respond to changes in sodium levels that causes salt-sensitive hypertension in Cx30 -/- mice.

**TH-PO648**

**The Complex Nature of P2 Receptor-Mediated Regulation of ENaC: Dependence on Na Concentration, Nucleotide Concentration and Exposure Time, and Tubular pH** Scott S. P. Wildman,[1] Sean G. Brown.[2] *[1]Royal Veterinary College, London, United Kingdom; [2]University of Abertay, Dundee, United Kingdom.*

ENaC controls Na reabsorption along the CD and helps determine systemic BP. We have shown that ENaC activity is inhibited by the activation of luminal $P2Y_{2\ and/or\ 4}$ receptors and $P2X_{4\ and/or\ 4/6}$ receptors when luminal concentrations of $Na^+$ are high (145 mM), and that the $P2X_{4\ and/or\ 6}$ receptors switch to being potentiators of ENaC activity when concentrations of $Na^+$ are lowered (to 50 mM) [1]. Here we address whether other luminal factors can affect P2 receptor-mediated regulation of ENaC.

Sprague Dawley rats (~200 g) were maintained on a low $Na^+$ diet (0.01% NaCl) to increase ENaC expression. Kidneys were removed, microdissected and CCD split-open to expose the apical membrane of cells for whole-cell patch clamp experiments (50 mM $[Na^+]_{ext}$).

When concentrations of P2 receptor agonists (10 µM, applied for 30 s) were high, UTP-evoked currents (i.e. $P2Y_{2\ and/or\ 4}$-mediated) reduced, and 2meSATP-evoked currents (i.e. $P2X_{4\ and/or\ 4/6}$-mediated) increased, the amplitude of subsequent ENaC-mediated currents. Lowering pH from 7.4 to 6.5 did not alter these effects. Further acidification to pH 5.5 increased the degree of inhibition by UTP and abolished the stimulatory effects of 2meSATP-evoked currents. Lowering the concentration of P2 receptor agonists (to 300 nM, applied for 30 s, pH 7.4 and 6.5) caused the inhibitory effect of UTP to be abolished. Interestingly, preincubation with UTP (300 nM, for 5 min, at pH 7.4 and 6.5) led to a significant decrease in ENaC-mediated current amplitude.

These data suggest that P2X receptor-mediated increases in ENaC activity are optimal when luminal $Na^+$ and nucleotide levels are low, and tubular fluid pH is ≥6.5. In contrast, P2Y receptor-mediated decreases in ENaC activity are optimal when luminal nucleotide levels are high and prolonged, and tubular fluid pH is 5.5. Clearly apical P2 receptor and ENaC interactions in the CCD are complex, with an interplay between P2X and P2Y receptors dependent on luminal Na concentration, the concentration of nucleotides, duration of nucleotide exposure and tubular pH.

**TH-PO649**

**Renal Sodium Retention in Cholestatic Mice Is Independent of ENaC in CCD** David Mordasini,[1] Johannes Loffing,[2] Edith Hummler,[3] Marc P. Maillard,[1] Michel Burnier,[1] Bruno Vogt.[1] *[1]Service de Néphrologie et Hypertension, CHUV, Lausanne, Vaud, Switzerland; [2]Institute of Anatomy, University of Zurich, Zurich, Switzerland; [3]Département de Pharmacologie et de Toxicologie, University of Lausanne, Lausanne, Vaud, Switzerland.*

The renal site of sodium retention in cirrhosis as well as the transporters involved and the way they are activated, although extensively studied in rats and dogs, is still a matter of debate. Our previous study using the cholestatic mouse model revealed an aldosterone independent stimulation of the basolateral Na+,K+ATPase activity exclusively in the cortical collecting duct (CCD). In order to explore the role of the apical amiloride sensitive sodium channel (ENaC) in the CCD we took advantage of existing CCD specific αENaC KO (Hoxb7 cre; scnn1aloxlox).

Control (CTL) and CCD specific αENaC KO (KO) mice underwent bile duct ligation (BDL) or sham operation. Urinary sodium and potassium excretion was measured every 3 days in metabolic studies over 3-hours period and αENaC expression analyzed by immunofluorescence.

Two to three weeks after BDL, 30% (CTL and KO) mice displayed ascites (~20 ml, BDL(+)) whether the remaining ones did not (BDL(-)). Six groups were distinguished subsequently for analysis: CTL and KO; with sham operation, BDL without ascites (BDL(-)) and BDL with ascites (BDL(+)). At the time of evident ascites the urinary Na/K ratio (mean±SEM) was as follow: CTL-sham 0.9±0.2 (n=6), CTL-BDL(-) 0.8±0.3 (n=7; ns vs CTL-sham), CTL-BDL(+) 0.1±0.1 (n=4; $p<0.05$ vs CTL-sham) and KO-sham 1.3±0.2 (n=6), KO-BDL(-) 1.2±0.3 (n=7; ns vs KO-sham), KO-BDL(+) 0.2±0.1 (n=5; $p<0.01$ vs KO-sham). The differences observed between CTL and KO groups were not significant. Macroscopically kidneys of non ascitic mice are more affected by the disease. Immunofluorescence confirmed cre-mediated deletion of αENaC in the collecting duct of floxed mice. Aside from altered ENaC abundance in CD, no other obvious changes were seen by immunofluorescence between CTL and KO mice.

In conclusion, ENaC activity in the CCD is not required for renal sodium retention in cholestatic mice. The urinary Na/K ratio reflects that aldosterone can be involved in the development of Na+ retention.

**Chronic Blockade of the Epithelial Sodium Channel (ENaC) Reduces Blood Pressure and Induces Fetal Growth Restriction in the Late Pregnant (LP) Rat** Shyama Masilamani. *Nephrology, VCU / MCV, Richmond, VA.*

A healthy pregnancy requires avid sodium retention and plasma volume expansion (PVE). However, the mechanisms of sodium retention in pregnancy are unknown. We have previously found that in vivo ENaC activity is increased in late pregnancy through a MR mediated mechanism. Further, that the increased ENaC activity maintains PV status. To access the importance of this channel in pregnancy we have chronically blocked ENaC with daily benzamil (0.7 mg/kg, increased to 1.05 mg/kg to account for plasma volume expansion in LP) SC injections from day 12-20 of pregnancy. Compared to normal LP rats, pregnant animals under chronic ENaC blockade have lower gestational body weights (LP = 403 ± 11, LP ChBz = 316 ± 22g, $p<0.05$) and growth restricted pups (LP = 5.08 ± 0.14, LP ChBz = 2.99 ± 0.76g, $p<0.05$). In addition, LP BP is reduced in rats receiving chronic benzamil compared to either virgin rats with chronic ENaC blockade (8 days) or LP animals receiving vehicle (day 12-20) (V ChBz = 102 ± 4, LP = 96 ± 3, LP ChBz = 85 ± 2 mmHg, $p<0.05$), however, heart rate is unchanged (LP = 401 ± 9, LP ChBz = 401 ± 5 BPM). Chronic ENaC blockade in LP animals retain less sodium versus normal LP rats (V = 0.10 ± 0.08, LP = 1.08 ± 0.18, LP ChBz = -0.13 ± 0.48 mmol/day, $p<0.05$). These data indicate ENaC is important for sodium retention, blood pressure regulation, and progression of a healthy pregnancy. (Support: NIH K22 award and CHRB award)

**TH-PO651**

**Notch3 Deficiency Is Responsible for Increased Natriuresis and Polyuria** Claire Trivin, Dominique Guerrot, Pierre M. Ronco, Nada Boulos, Christos Chatziantoniou, Jean-Claude Dussaule. *Unité 702, INSERM, Paris, France.*

INTRODUCTION: Notch3 is a transmembrane receptor predominantly expressed by vascular smooth muscle cells in mammals. We have recently shown that Notch3 is implicated in the regulation of renal vascular resistance. The mechanisms whereby the kidney regulates natriuresis and urine concentration remain incompletely understood, in spite of important clinical implications. The purpose of this study was to analyze the functional consequences of Notch3 deficiency on water and Na excretion.

METHODS: Notch3 KO mice and control WT littermates were analyzed in metabolic cages. Plasma osmolality, body weight, urine volume, osmolality and Na excretion were measured in basal, water deprivation (WD) and salt restriction conditions. An additional WD test was performed after injection of desmopressin.

RESULTS: In basal conditions, Notch3-deficiency was associated with polyuria (2.4±0.9mL/24h vs 1.4±0.5mL/24h in WT ; $p<0.01$) and reduced urine osmolality (742±185mOsm/kg vs 953±148mOsm/kg ; $p<0.01$). In WD conditions, Notch3 KO mice presented persistent increased diuresis (0.5±0.2mL/9h vs 0.2±0.1mL/9h ; $p<0.01$), reduced urine osmolality (1150±431mOsm/kg vs 1656±499mOsm/kg ; $p<0.01$), increased plasma osmolality (369±9mOsm/kg vs 358±8mOsm/kg ; $p<0.05$) and more important weight loss (-12.1±1.8% vs -10.0±2.0% ; $p<0.01$), consistent with an impaired concentration ability. Differences between KO and WT mice remained after desmopressin-WD test. Na excretion was twofold higher in Notch3 KO mice at baseline. Importantly, increased natriuresis remained during sodium-restriction regimen, with excessive weight loss, indicating primitive renal Na waste.

CONCLUSION: We demonstrate that Notch3-deficient mice present increased Na excretion associated with polyuria. These original results suggest that Notch3 may be an important actor in the regulation of natriuresis and urine concentration. Owing to the importance of these processes in renal and cardiovascular physiology, our data prompt further investigations to uncover the vascular and/or tubular mechanisms whereby Notch3 contributes to the regulation of renal excretion of Na and water.

**TH-PO652**

**Renal Tubular Salt Reabsorption Is GPR91-Dependent** Anush Gevorgyan, Agnes Prokai, Arnold Sipos, Jahoon Koo, Janos Peti-Peterdi. *Physiology and Biophysics, University of Southern California, Los Angeles, CA.*

The newly identified succinate receptor GPR91 is a detector of local tissue metabolism and is highly expressed in the hypoxic distal nephron and collecting duct. GPR91 signaling involves changes in cytosolic calcium, and activation of mitogen-activated protein kinases ERK1/2 and p38. Succinate via GPR91 causes renin release, activation of the renin-angiotensin system (RAS), and elevations in blood pressure. Since the RAS and the distal nephron are important regulatory mechanisms/sites of body fluid and electrolyte homeostasis, we hypothesized that GPR91 may regulate the expression of salt reabsorbing ion transporters/channels in the nephron. GPR91 wild type (WT) and knockout (GPR91-/-) mice were fed normal or high salt (8%)-containing chow (n=3 each) for two weeks. Immunoblotting of NHE3, NCC, and alpha-ENaC was performed using whole kidney or cortical homogenates. M1 cells, a model of the mouse collecting duct were treated with 1mM succinate for 24h twice a day to assess the direct effects of succinate/GPR91 signaling. Cells treated with 5mM glucose served as controls. The expression of all three proteins, NHE3, NCC, and a-ENaC were significantly decreased in GPR91-/- mice (1.0, 9.8, 0.2, respectively, densitometry values normalized to b-actin) compared to WT (1.3, 15.5, 0.4, respectively). High salt diet significantly reduced the expression of these proteins in all groups with similar differences in WT versus GPR91-/- mice. M1 cells showed a 4-fold increase in a-ENaC levels in response to succinate compared to controls. Consistent with these data, GPR91-/- mice had lower mean arterial blood pressure (94.2±6.7 mmHg)

compared to WT (112.7±9.7 mmHg). These results suggest that GPR91 either directly or via the RAS regulates renal tubular salt reabsorption in the entire nephron and it participates in blood pressure control. GPR91-control of renal salt reabsorption may be important in diabetic and ischemic kidney disease which are associated with increased local tissue succinate levels.

**TH-PO653**

**GLP1 Receptor Activation by Exendin-4, but Not the Endogenous GLP1 Receptor Tone or DPP-4 Inhibition, Induces Natriuresis and Diuresis in Awake Mice** Volker Vallon,[1] Maria Gerasimova,[1] Daniel J. Drucker,[2] Timo M. Rieg.[1] *[1]Dept of Medicine, UC San Diego and VA San Diego Healthcare System, San Diego, CA; [2]Samuel Lunenfeld Research Institute, University of Toronto, Toronto, Canada.*

The serine protease dipeptidyl peptidase-4 (DPP-4) is an ecto-enzyme that degrades glucagon-like peptide-1 (GLP1), an incretin hormone that stimulates glucose-dependent insulin release. DPP-4 inhibitors (like alogliptin; AGT) and GLP1 receptor (GLP1-R) agonists (like exendin-4, EX4) are novel antidiabetic drugs. The DPP-4/GLP1-R system is also expressed in proximal tubular brush border and may regulate $Na^+$ reabsorption. Here we assessed the role and endogenous tone of the DPP-4/GLP1-R system in renal $Na^+$ handling in awake mice. After emptying the bladder, mice were loaded by oral gavage with isotonic saline (30µl/g; ~30% of daily NaCl intake) and placed in metabolic cages for quantitative urine collection over 3h. First, the responses in urinary fluid, $Na^+$, $K^+$ and $Cl^-$ excretion were not different between wild-type (WT) and littermate gene-targeted mice lacking the GLP1-R (0.23±0.01 vs 0.21±0.01 µl/(min x g); 15±2 vs 14±2, 9±1 vs 9±1, and 23±2 vs 25±2 nmol/(min x g); n=6; NS). Second, application of AGT (10mg/kg in gavage) to WT mice did not significantly change renal excretion of fluid, $Na^+$, $K^+$ or $Cl^-$ vs vehicle (0.23±0.03 vs 0.23±0.04 µl/(min x g); 13±2 vs 15±2, 8±1 vs 9±1, and 22±3 vs 23±2 nmol/(min x g); n=6; NS). Third, application of EX4 (10µg/kg i.p.) to WT mice increased urinary excretion of fluid and $Na^+$, whereas $K^+$ was unchanged vs vehicle (0.33±0.02 vs 0.23±0.02 µl/(min x g); $P<0.001$; 20±1 vs 12±2 nmol/(min x g); $P<0.005$; 8±1 vs 7±2 nmol/(min x g); NS; n=6). This effect on fluid and $Na^+$ excretion was absent in mice lacking GLP1-R (0.16±0.03 vs 0.17±0.03 µl/(min x g); 9±1 vs 11±2 nmol/(min x g); NS; n=5). In summary, GLP1-R knockout or DPP-4 inhibition does not affect the natriuretic and diuretic response in mice being acutely gavaged with isotonic saline, indicating a negligible contribution of the endogenous DPP-4/GLP1 receptor system under these conditions. However, direct activation of the GLP1 receptor by exendin-4 induces diuresis and natriuresis without kaliuresis.

**The Role of EP4 Receptors/MKP-1/P38MAPK Signaling in the Regulation of Renal Tubular Electrolytes Transport** Noritaka Kawada,[1] Toshiki Moriyama,[1] Harumi Kitamura,[1] Yoshitsugu Takabatake,[1] Carolyn M. Ecelbarger,[2] Enyu Imai,[3] William J. Welch,[4] Christopher S. Wilcox,[4] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Division of Nephrology, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; [2]Division of Endocrinology and Metabolism, Georgetown University, Washington, DC; [3]Division of Nephrology, Nagoya University, Aichi, Japan; [4]Center for Hypertension and Kidney, Diabetic and Vascular Diseases and Division of Nephrology and Hypertension, Georgetown University, Washington, DC.*

Background. cAMP has been shown to activate Amirolide sensitive epithelial sodium channel (ENaC) and Na/K-ATPase by promoting the trafficking of these proteins to the cell membrane. In contrast to the prediction that cAMP enhances the sodium absorption, the inhibition of cAMP production by EP4 blockade increases salt absorption in vivo. Therefore, we tested the role of EP4 activation on the renal tubular electrolyte transports. Results. The administration of EP4 agonist (ONO-AE1-329: EP4AG, $6x10^{-10}$mol/gram Body weight in every one hour) in rats had no effects on FENa (Vehicle, 0.036±0.008%; EP4AG, 0.029±0.008%; n=5 each; $p<0.05$), but increased urine/serum creatinine ratio (Veh, 251±22; EP4AG, 594±36; n=5 each; $p<0.05$) and reduced urinary volume (Veh, 840±170µl/2hr; EP4AG, 190±40µl/hr; n=5 each; $p<0.05$), FEK (Veh, 10.1±0.8%; EP4AG, 2.8±0.7%; n=5 each; $p<0.05$) and TTKG (Veh, 7.8±0.5; EP4AG, 3.1±1.0; n=5 each; $p<0.05$). This was accompanied by the induction of MAP kinase phosphatase1 (MKP1) mRNA in distal nephron segments. Both EP4AG ($10^{-6}$M) and adenyalte cyclase activator (Forscolin: $10^{-5}$M) in cultured mice collecting duct (M-1) cells increased the expression of MKP1 protein and mRNA and reduced the phosphorylation of p38, Akt and Sgk1 proteins. M-1 cells exposed to p38 inhibitor (BIRB796: $10^{-5}$M) reduced the expression of phosphorylated Akt and Sgk-1 protein. Conclusions. EP4AG increases water absorption, blunts aldosterone signaling, reduces pottasium excretion, and does not increase sodium absorption in renal tubular cells. Induction of MKP1 in distal nephron segments may play important roles in the renal tubular electrolyte transports.

**TRPV4 Mediates Shear Stress-Induced Nitric Oxide Production in Thick Ascending Limbs** Pablo D. Cabral, Jeffrey L. Garvin. *Hypertension and Vascular Research Division, Department of Internal Medicine, Henry Ford Hospital, Detroit, MI.*

NO inhibits sodium chloride transport in thick ascending limbs (TALs). We have shown that luminal flow stimulates nitric oxide (NO) production in this segment. Transient receptor potential vanilloid (TRPV) 4 is a Ca2+ permeable cation channel expressed in both luminal and basolateral membranes in TALs. TRPV4 is activated by mechanical stimulation such as flow and cell swelling. In endothelial cells, shear stress-induced NO production is mediated by TRPV4. We hypothesized that the shear stress component of luminal flow induces NO production in TALs and this effect is mediated by TRPV4 activation. We measured NO production in isolated, perfused rat TALs using the fluorescent dye DAF FM. The dye was excited at 488 nm and emitted fluorescence intensities were measured between 495-510 nm. The rate of increase in DAF FM fluorescence reflects NO accumulation. Increasing luminal flow from 0 to 20 nL/min stimulated NO from 21 ± 7 to 58 ± 12 arbitrary units (AU)/min ($p < 0.02$; n=7). Eliminating shear stress by pinching the distal ends of tubules closed prevented the increase in NO (2±8 vs. 8±8 AU/min (n=6). To test the role of TRPV4 we used two different inhibitors. In the presence of the TRPV antagonist ruthenium red (15 uM) increasing luminal flow did not increase NO production (from 18 ± 5 to 16 ± 9 AU/min; n = 4). When luminal flow was increased in the presence of the selective TRPV4 antagonist RN 1734 (10 uM), NO levels did not change significantly (11 ± 7 to 9 ± 2; n = 4) . We concluded that TRPV4 mediates flow-induced NO production in thick ascending limbs.

**Proximal Tubule Uptake Is Not Involved in the Generation of Urinary Albumin Fragments** Kathrin Weyer, Rikke Nielsen, Pierre J. Verroust, Erik I. Christensen, Henrik Birn. *Department of Anatomy, Aarhus University, Aarhus, Denmark.*

Urinary albumin excretion is an important diagnostic and prognostic marker of renal function. Recent data have shown that animal and human urine contains both immunoreactive albumin and additional immuno-unreactive albumin fragments. Identification of the site of formation of these albumin fragments is of importance for the understanding of their physiological significance and potential use as disease markers. The receptors megalin and cubilin play an important role in normal proximal tubule endocytic recovery of filtered albumin. It has therefore been speculated that the megalin and cubilin mediated endocytic uptake of albumin is crucial to proximal tubule degradation of albumin and that disruption of these receptors will lead to a change in the excretion of albumin fragments. Using targeted, kidney specific knockout mice of megalin and cubilin, we have examined the kidney uptake and urinary excretion of intact albumin as well as albumin fragments by size-exclusion chromatography of urine following injection of $^{125}$I-labeled mouse albumin. Consistent with previous observations, we found that most label in the urine of wildtype mice eluted as small fragments with no detectable intact, labeled albumin. Megalin and cubilin knockout mice exhibited a decreased uptake and degradation of albumin in the kidney as well as an increased excretion of intact albumin, however, no decrease in the excretion of albumin fragments was observed. This demonstrates that the generation of albumin fragments is independent of megalin and cubilin mediated endocytic uptake of albumin in the kidney proximal tubule. Although no degradation of albumin was observed by incubation with plasma or urine, small amounts of labeled albumin fragments were identified in the plasma of injected mice, suggesting that at least a fraction of the labelled albumin fragments found in the urine may result from glomerular filtration.

**Impaired Proximal Tubular and Kidney Glucose Reabsorption in Gene-Targeted Mice Lacking SGLT1** Volker Vallon,[1] Timo M. Rieg,[1] Robyn A. Cunard,[1] Hermann Koepsell.[2] *[1]Medicine, UC San Diego, San Diego, CA; [2]Institute for Anatomy and Cell Biology, University of Wuerzburg, Wuerzburg, Germany.*

The high-affinity/low-capacity sodium glucose cotransporter SGLT1 (Slc5a1) has been localized in distal parts of the proximal tubule but direct experimental in vivo evidence on its tubular site of action and quantitative contribution is lacking. Here we characterized SGLT1-deficient mice generated by gene targeting. Control wild type (WT) and *Sglt1*-/- mice were fed a glucose-free diet to prevent diarrhea in the latter. Real-time PCR confirmed knockout of *Sglt1* in the kidney of *Sglt1*-/- mice, while the renal mRNA expression of *Sglt2*, *Glut1*, *Glut2*, and *Glut5* were not significantly different compared with WT; similar SGLT2 expression was confirmed at the protein level. Body weight and hematocrit were not different between *Sglt1*-/- and WT mice independent of gender. Spontaneous urine collection in awake adult *Sglt1*-/- mice demonstrated greater urinary glucose concentrations in absolute terms and related to creatinine compared with WT (female: 18.5±1.1 vs. 1.1±0.1 mM and 11.7±0.7 vs. 0.51±0.04 mmol/mmol creatinine; male: 15.2±1.4 vs. 1.0±0.1 mM and 9.3±0.8 vs. 0.44±0.06 mmol/mmol creatinine; n=8-10; all $P<0.001$), in the absence of differences in blood glucose levels. GFR determined by FITC-inulin kinetics in awake mice was similar in *Sglt1*-/- and WT mice (11.1±0.9 vs. 11.6±0.6 µl/(min x g bw); n=9; NS). Renal clearance and free-flow micropuncture experiments under anesthesia revealed similar mean arterial blood pressure and heart rate in *Sglt1*-/- vs. WT mice (79±4 vs. 84±4 mmHg; 470±12 vs. 518±11 $min^{-1}$; n=6-7 mice; *NS*). Absolute and fractional renal excretion

of glucose were greater in *Sglt1*-/- compared to WT mice (1.63±0.31 vs. 0.18±0.04 nmol/(min x g bw) and 3.06±0.25 vs. 0.24±0.03 %; both P<0.001). Moreover, the absolute and fractional delivery of glucose to the last surface loop of proximal convoluted tubules was increased in *Sglt1*-/- compared with WT (3.8±0.4 vs. 1.8±0.3 pmol/min and 5.5±0.6 vs. 2.7±0.5 %; both P<0.001). The results demonstrate a minor but significant contribution of SGLT1 to renal glucose reabsorption in the proximal tubule and the whole kidney.

**Expression of SGLT3a in the Kidneys of Zucker Diabetic Fatty (ZDF) Rats** Niloofar Tabatabai,[1] Rajendra Kishore Kothinti,[2] Amy Blodgett.[2] *[1]Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Chemistry and Biochemistry, University of Wisconsin-Milwaukee, Milwaukee, WI.*

Diabetes may alter normal expression of sodium-dependent glucose transporters, SGLT1 and SGLT2, in the kidney; however, effect of diabetes on expression of SGLT3 has not previously been investigated. At the amino acid sequence level, human(h) SGLT3 is most homologous to hSGLT1; however, hSGLT3 may function as a glucose stimulated sodium channel. While human has one gene encoding SGLT3, mouse(m) and rat(r) each has two genes encoding SGLT3a and SGLT3b. We previously showed that SGLT3a mRNA is expressed in mouse kidney. Here, we investigated whether SGLT3a protein is expressed in the kidneys of mouse and rat, and if its expression is modulated in diabetes. BLAST analysis showed that the amino acid sequence of rSGLT3a is 80% and 92% identical to hSGLT3 and mSGLT3a, respectively. Mouse and rat SGLT3a sequences were aligned, a common sequence was selected to synthesize peptide, which was used as antigen to raise antibody in rabbit. SGLT3a expression was examined by Western blot on kidney proteins from C57BL/6 mouse and Zucker Diabetic Fatty (ZDF) rat, *Lepr*$^{fa}$/Crl, a model of type 2 diabetes. Actin expression was used for normalization. To examine the effect of diabetes, five *fa/fa* rats at each 5, 8, 12, 15, and 19 weeks of age were used. Glucose was measured in overnight urine samples from fasted animals, and expression of SGLT3 in their kidneys was examined. Western blot analysis showed that our SGLT3a antibody reacted with single ~72 kDa protein from mouse and rat kidneys. In ZDF rats, glucose excretion was only 0.02 g/day at 5 weeks of age, but it sharply increased to 9, 16, and 20 g/day in 8, 12, and 15 weeks old diabetic rats, respectively. SGLT3a was expressed in the kidneys of ZDF rats at all ages; however, its relative expression increased by 40% from 5 to 8 weeks of age and remained elevated until 19 weeks of age. Here, we showed for the first time that SGLT3a protein is expressed in the kidneys of mouse and rat, and that its expression level was elevated in glucosuric ZDF rats. Above suggest that SGLT3a expression in the kidney may be enhanced by hyperglycemia.

**Calcium and Other Polyvalent Cations Inhibit Paracellular Sodium Conductance through the Proximal Tubule Tight Junction Protein, Claudin-2** Alan S. L. Yu,[1] Mary H. Cheng,[2] Rob D. Coalson.[2] *[1]Division of Nephrology, University of Southern California Keck School of Medicine, Los Angeles, CA; [2]Dept. of Chemistry, University of Pittsburgh, Pittsburgh, PA.*

Claudin-2 is a tight junction integral membrane protein that forms cation-selective paracellular pores in the proximal tubule epithelium. Depletion of extracellular Ca (≤ 0.1 mM) is known to cause dissociation of intercellular junctions, endocytosis of tight junction membrane proteins, and profound loss of transepithelial resistance. Here, we tested the effect of moderate changes in extracellular Ca that might be observed in vivo under physiological and pathological conditions. MDCK I cells expressing wild-type claudin-2 under a Tet-responsive inducible promoter were mounted in Ussing chambers for measurement of transepithelial conductance. Moderate increases in Ca (up to 5 mM) caused a rapid ($\tau$ ~10 s), graded and fully reversible inhibition of claudin-2 conductance, while decreases in Ca (down to 0.25 mM) similarly increased conductance. Half-maximal inhibition occurred at 5.5 mM Ca in the presence of 100 mM Na, but at 3.5 mM Ca in the presence of 50 mM Na, suggesting that the two cations interact. Indeed, Brownian dynamics simulations showed that Ca and Na compete for occupancy within the claudin pore. Mutation of D65, which we previously showed to be an intrapore Na-binding site, to asparagine, reduced calcium inhibition by half, indicating that the calcium effect is in part mediated by cation competition for occupancy at this site. Interestingly, other polyvalent cations also inhibited claudin-2 ($La^{3+}$ >> $Ba^{2+}$ = $Ca^{2+}$ > $Mg^{2+}$) suggesting that they may be useful reagents to probe claudin function. It is well known that hypercalcemia induces a profound natriuresis, presumably as a mechanism to prevent calcium nephrolithiasis, and that this occurs in part through inhibition of proximal tubule Na reabsorption (DiBona, G. F. , 1971 Am J Physiol 220, 49-53). Our findings suggest that high luminal Ca would inhibit paracellular Na reabsorption in the proximal tubule, thus providing a potential mechanism to explain this phenomenon.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO660**

**Claudins Are Differentially Controlled in the Kidney by Variations in Sodium and Water Balance** Miguel A. Lanaspa, Ana Andres-Hernando, Carlos Alberto Roncal-Jimenez, Nanxing Li, Christina Cicerchi, Weidong Wang, Tomas Berl. *University of Colorado Denver.*

Claudins are an integrative family of proteins located in the tight junctions of epithelial cells where they regulate paracellular flux of water and ions while maintaining transepithelial resistance. Claudin-2, which renders the membrane permeable to sodium, is highly expressed at isotonic conditions and markedly decreased (by 95%, p<0.01) when tonicity is increased to 550 mOsm/kg$H_2O$ by addition of NaCl to the medium. This decrease is paralleled by a robust increase in claudin-4 which renders the membrane impermeable to sodium (by 3.5-fold, p<0.01). Overexpression of claudin-4 at isotonic conditions leads to degradation of claudin-2 by the lysosome. Conversely, silencing claudin-4 maintains claudin-2 expression in hypertonic conditions reflecting that these claudins are differentially regulated by their expression in the cell during changes in either sodium or tonicity. To discriminate between the effects of high tonicity versus high sodium in claudin-4 expression, we pair-fed rats with 26 g of low sodium (LS) or high sodium (HS, 8 % NaCl) diets. Rats receiving high sodium diets were either restricted or allowed ad libitum access to water. Results: (mean ± SD)

claudin-4 expression and urinary parameters in rats fed with LS and HS diets

| | LS n=4 | HS n=4 | HS n=3 |
|---|---|---|---|
| claudin-4 fold expression | 1 | 5 ± 0.8 | 2 ± 1 |
| Water intake (ml/day) | 40 | 40 | ad libitum, > 70 |
| Urinary osmolality (mOsm/kg) | 1056 ± 150 | 2100 ± 123 | 1275 ± 185 |
| Urinary sodium concentration (meq/L) | < 40 | 415 ± 85 | 259 ± 110 |
| Total sodium excretion (mg/day) | < 10.2 | 81.1 ± 20 | 70.5 ± 20.5 |

We interpret these data to suggest that the regulation of the "tight" claudin-4 is primarily mediated by the concentration of sodium independent in changes of tonicity. This regulation may play a critical role in the control of sodium excretion by determining the sodium permeability at the terminal of collecting duct.

**The miR-21 Regulates Renal Tubular Epithelial to Mesenchymal Transition in Obstructed Nephropathy** Mingxia Xiong, Yi Fang, Yang Zhou, Ruoyun Tan, Junwei Yang. *Center of Kidney Disease, the 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, Jiangsu, China.*

Chronic kidney disease (CKD) has emerged as a huge threat to public health worldwide. Regardless of the diverse disease process, renal interstitial fibrosis is considered to be a common and irreversible pathway that eventually leads to the end stage renal diseases. Epithelial-mesenchymal transition (EMT) is a major contributor to the pathogenesis of renal fibrosis. Despite a great deal of intense study, comprehensive understanding of the pathogenesis of renal scar formation after injury remains a daunting task that poses a major obstacle toward designing effective therapeutic strategies. microRNAs (miRNAs) are a family of short non-coding RNAs, and have become one of the most fascinating topics in the studies of embryonic development, tumor metastasis, and organ fibrosis in recent years. miRNAs have the potential to play central roles in pathogenesis of kidney diseases. Here, we performed expression profiling of miRNAs in murine interstitial fibrotic kidneys induced by unilateral ureteral obstruction (UUO) and its sham-operated tissue. We found that miR-21 was up-regulated significantly in a time-dependent manner. *In vitro*, treatment of NRK-52E with TGF-β1 increased miR-21 expression. Over expression of miR-21 had similar effects as TGF- β1, whereas, miR-21 inhibitors blocked TGF-β1 induced EMT. Manipulation of the miR-21 level could influence PTEN expression. miR-21 inhibitors blocked TGF-β1 induced phosphoryltion of Akt and chemical blockade of Akt activation could completely block the phenotypic conversion of tubular epithelial cells treated with miR-21 mimic. In summary, we have discovered a mechanism for TGF-β1-mediated EMT that involves cross-talk between miR-21 and PTEN/Akt.

**MicroRNA-21 Regulates Renal Fibrosis in a Mouse Model of Unilateral Ureteral Obstruction** Abolfazl Zarjou, Anupam Agarwal, Gang Liu. *Medicine, University of Alabama at Birmingham, Birmingham, AL.*

MicroRNAs (miRNAs) are a class of non-coding small RNAs, 22 nt. in length, which bind to the 3' UTR of target genes and thereby repress translation of target genes and/or induces degradation of target gene mRNA. miRNAs play essential roles in numerous cellular and developmental processes. Aberrant expression of miRNAs is closely associated with initiation and progression of pathophysiologic processes including diabetes, cancer, and cardiovascular disease. Whereas evidence suggests that miR-21 plays a central role in cardiac and lung fibrosis, it's role in regulation of renal fibrosis is currently unknown. In this study, we found that the expression of miR-21 is significantly enhanced in the kidneys of mice undergoing unilateral ureteral obstrtruction (UUO) along with E-cadherin and α-SMA. miR-21 increased rapidly after UUO (as early as 6h) and the increase was enhanced at later time points (3 and 7 days after UUO). The enhanced expression of miR-21 was localized in proximal and distal tubule epithelial cells in UUO kidneys by in situ hybridization**.** We found that LNA modified anti-miR-21 probes effectively sequestered endogenous miR-21. Furthermore, the enhanced expression of TGF-β and α-SMA was decreased in UUO kidneys from mice that were given anti-miR-21 probes. The extent of fibrosis was also

significantly decreased with anti-miR-21 treatment. These data suggested that miR-21 plays a role in kidney fibrogenesis after UUO. These results provide novel mechanistic insights and validate miR-21 as a potential therapeutic target in renal fibrosis.

**MicroRNA-155 Functions as a Suppressor of Endothelial to Mesenchymal Transition** Roel Bijkerk,[1] Coen van Solingen,[1] Jacques Duijs,[1] Eric P. Van der Veer,[1] Peter Dijke,[2] Hetty C. de Boer,[1] Ton J. Rabelink,[1] Marie-Jose Goumans,[2] Anton Jan Van Zonneveld.[1] *[1]Dept. of Nephrology and Einthoven Laboratory for Experimental Vascular Medicine, LUMC, Leiden, Netherlands; [2]Dept. of Molecular Cell Biology, LUMC, Leiden, Netherlands.*

Background: Endothelial to mesenchymal transition (EndoMT) is an essential process in embryonic development of the heart valves and involves dedifferentiation of endothelial cells (EC) towards a mesenchymal, pro-fibrotic phenotype. Evidence is accumulating that in renal failure, EndoMT can also occur in the adult and contribute to the loss of microvascular capillaries and the progression of renal fibrosis. MicroRNAs (miRNAs) could serve as a target to prevent EndoMT or reverse this process, as they have been shown to play a key role in cell differentiation.

Methods: We studied immortalized mouse embryonic endothelial cells (MEEC) that undergo EndoMT when stimulated with transforming growth factor-β (TGF-β). To identify differentially expressed miRNAs in EndoMT, we profiled the miRNAs in this model and confirmed differential miRNA-expression by qPCR.

Results: Upon TGF-β stimulation MEECs showed a characteristic morphological alteration towards a mesenchymal phenotype, upregulation of alpha-smooth muscle actin (α-SMA) and down regulation of EC-markers CD31 and MECA32. Using qPCR we also showed decreased expression of the EC-markers eNOS and CD31. In addition TGF-β induced the formation of stress fibers and increased extracellular matrix deposition. Furthermore, hypoxia markedly augmented TGF-β induced EndoMT.

TGF-β upregulated miR-155, which was even more elevated under hypoxic conditions. Blocking miR-155 with antagomir-155 resulted in increased mRNA-expression of its target RhoA and elevated ROS levels, indicating an EndoMT suppressive role for miR-155. Overexpression of miR-155 with synthetic miR-155 precursors resulted in full suppression of EndoMT as evidenced by a lack of change in morphology, decreased upregulation of α-SMA expression and preservation of CD31 expression.

Conclusion: Our data demonstrate a RhoA dependent protective role for miR-155 in EndoMT.

Disclosure of Financial Relationships: nothing to disclose

**Basigin/CD147 Promotes Renal Fibrosis after Unilateral Ureteral Obstruction** Noritoshi Kato,[1] Tomoki Kosugi,[2] Waichi Sato,[2] Takuji Ishimoto,[2] Shoichi Maruyama,[2] Yukio Yuzawa,[3] Kenji Kadomatsu,[4] Seiichi Matsuo.[2] *[1]Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; [2]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Nephrology, Fujita Health University School of Medicine, Toyoake, Japan; [4]Biochemistry, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

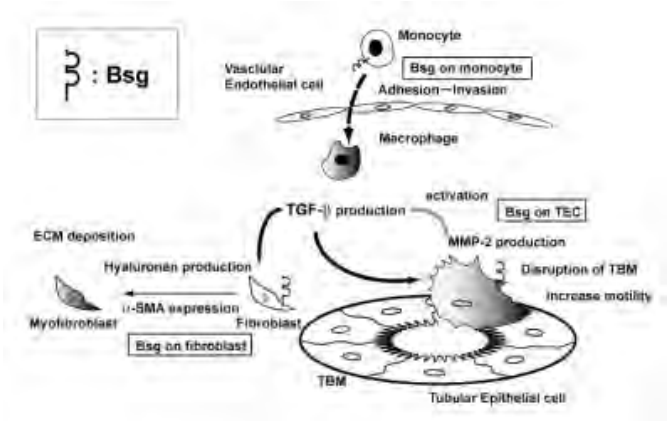
**Background**: Basigin/CD147 is a plasma membrane protein that belongs to the immunoglobulin superfamily. It is said to be a multifunctional molecule. For example, it induces matrix metalloproteinases and hyaluronan, and has a roll in inflammatory cells trafficking. Recently it was revealed that Basigin contributed to induce α-smooth muscle actin in fibroblasts. However, the relationship between Basigin and organ fibrosis has been poorly studied. Here, we investigated Basigin's roll in renal fibrosis using a unilateral ureteral obstruction model.

**Purpose**: To investigate Basigin's roll in renal fibrosis.

**Methods**: Subject Basigin wild and knockout mice to unilateral ureteral obstruction surgery.

**Results**: Basigin-deficient (*Bsg*$^{-/-}$) mice demonstrated significantly less fibrosis after surgery than *Bsg*$^{+/+}$ mice. Fewer macrophages had infiltrated in *Bsg*$^{-/-}$ kidneys. Consistent with these *in vivo* data, primary cultured tubular epithelial cells from *Bsg*$^{-/-}$ mice produced less matrix metalloproteinase and exhibited less motility upon stimulation with TGF-β. Furthermore, *Bsg*$^{-/-}$ embryonic fibroblasts produced less hyaluronan and α-smooth muscle actin after TGF-β stimulation.

**Conclusion**: Basigin has multiple rolls in renal fibrosis. We focused on Basigin's function in different cell types, monocytes, tubular epithelial cells, and fibroblasts respectively. This is the first report which demonstrates that Basigin is a key regulator of renal fibrosis. Basigin could be a candidate target molecule for the prevention of organ fibrosis.



Disclosure of Financial Relationships: nothing to disclose

**TH-PO665**

**Inhibition of Chemokine Receptor Cxcr4 Slows down Renal Tubulointerstitial Fibrosis in a Mouse Model of Unilateral Ureteral Obstruction (UUO)** Amy Yuan,[2] Yashang Lee,[1] Joseph Ueland,[1] Kevin Tang,[2] Erik Shapiro,[2] Gilbert W. Moeckel,[3] Anil K. Karihaloo.[1] *[1]Internal Medicine, Section of Nephrology, Yale University School of Medicine, New Haven, CT; [2]Biomedical Engineering, Yale University, New Haven, CT; [3]Pathology, Yale University School of Medicine, New Haven, CT.*

Renal fibrosis is the consequence of virtually every kidney disease and is characterized by the activation of myofibroblasts and matrix deposition. Multiple studies implicate macrophages, fibrocytes, pericytes and altered tubular epithelial and endothelial cell biology (via EMT) in the process of fibrosis. All these cell types express chemokine receptor Cxcr4. Presence of hypoxia during fibrosis activates Hif1α & Hif2α. Both Cxcr4 and its ligand Sdf-1 are Hif-1 targets. We thus hypothesized increased Cxcr4 and Sdf-1 expression during renal fibrosis. Increased Cxcr4 is associated with enhanced motility and EMT. Since all the cell types listed above express Cxcr4, it could potentially be a target for intervention.

We used mouse UUO model of fibrosis and a known Cxcr4 inhibitor AMD3100 (AMD). Mice underwent UUO ± AMD treatment. Fibrosis was assessed 3, 6 or 12 days post-UUO. RESULTS: UUO led to > 3-fold increase in kidney Sdf1 and Cxcr4 expression by day 3. Saline treated UUO mice developed significant fibrosis by day 6 that worsened by day 12 with major loss of parenchyma, tubular atrophy and matrix deposition. QPCR from UUO kidneys showed upregulation of TGF-β, TNF-α, CTGF, α-SMA, Fsp1, Col-I, pro-apoptotic Bax. Enhacned STAT-3 activation was detected in UUO kidneys. In contrast, AMD treated mice had 40% less fibrosis; significantly less TNF-α, α-SMA, Fsp1, and Col-I with no significant change in TGF-β. Further, reduced Bax (pro-apoptotic) and increased Bcl2 (anti-apoptotic) expression and reduced tubular atrophy, and STAT3 activation, were observed in AMD treated group. FACS and in-vivo MRI imaging, revelaed a 50% decrease in F4/80/Cxcr4+ macrophages and a 60% fewer Cxcr4/CD45/Col-I+ fibrocytes in the UUO kidneys of AMD treated mice. CONCLUSION: These results demonstrate that Cxcr4 inhibitor can slow down fibrosis and may potentially provide novel therapeutic option.

**Time Sequence of Protease Profile after the Release of Unilateral Ureteral Obstruction in Mice** Muneharu Yamada,[1] Takashi Oda,[1] Taketoshi Kushiyama,[1] Keishi Higashi,[1] Kojiro Yamamoto,[1] Toshitake Hyodo,[1] Naoki Oshima,[1] Yutaka Sakurai,[2] Soichiro Miura,[3] Hiroo Kumagai.[1] *[1]Department of Nephrology, National Defense Medical College; [2]Department of Preventive Medicine and Public Health, National Defense Medical College; [3]Department of Internal Medicine, National Defense Medical College, Tokorozawa, Saitama, Japan.*

The role of proteases, such as plasminogen activator (PA)/plasmin cascade and matrix metalloproteases (MMPs), in the repair of renal fibrosis has yet to be elucidated. In this study we investigated the change in the profile of proteases after the release of unilateral ureteral obstruction (UUO), in order to clarify their role in the process of renal fibrosis repair. UUO was performed on the left kidney with the use of a vascular clamp and the obstruction was released by removing the clamp on day 10 after UUO. Mice were killed and kidney tissues were harvested on days 0, 3, 7, and 21 after release. The expression levels of mRNA of various molecules related with protease activity were analyzed by real time RT-PCR, and the net activities of proteases were assessed by polyacrylamide gel zymography. The mRNA expressions for u-PA, t-PA and plasminogen activator inhibitor-1 were decreased rapidly and constantly over time. On the other hand, mRNA expressions for MMP-2 and MMP-9 were significantly increased gradually from day 0 to day 7 after UUO-release, but were decreased at 21 days after release (MMP-9 mRNA: 0day 1.00 ± 0.39, 3day 1.75 ± 0.35, 7day 2.11 ± 0.44, 21day 0.35 ± 0.14). Similar to the trend of u-PA and t-PA, plasmin activity assessed by casein gel zymography was decreased rapidly and constantly over time after UUO-release (0day 1.00 ± 0.35, 3day 0.41 ± 0.15, 7day 0.29 ± 0.18, 21day 0.23 ± 0.11). On the contrary, MMP-9 activity assessed by gelatin gel zymography showed the sustained activity till day 7 after the UUO-release, and was significantly decreased at 21

days after release (0day 1.00 ± 0.22, 3day 0.91 ± 0.22, 7day 0.94 ± 0.22, 21 day 0.14 ± 0.15). These results suggested that activities of MMPs are up-regulated in the early phase of UUO-release and may contribute to the repair of renal fibrosis by degrading extracellular matrix proteins.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO667**

**MMP-2 Contribute to the Development of Interstitial Fibrosis in Rat UUO Model** Xuanyi Du,[1,2] Yukinari Masuda,[1] Shinya Nagasaka,[1] Emiko Fujita,[1] Akira Shimizu.[1] *[1]Nippon Medical School, Pathology, Bunkyo-ku, Tokyo, Japan; [2]Nephroly, Harbin Medical School, Harbin, China.*

A gelatinase matrix, known as metalloproteinase-2 (MMP-2,) can degrade a broad range of extracellular matrix components like type IV collagen . We investigated the role of MMP-2 on the development of renal interstitial fibrosis. MMP-2 knockout (KO) mice ureter was experimentally obstructed by tying ligature unilaterally and made UUO (unilateral ureteral obstruction) .Wild type (WT) and minocycline treatment (Mino) mice were also made in similar way. Minocycline, an inhibitor of MMPs, was administered at a dose of 30 mg/kg (low dose) and 150 mg/kg (high dose) twice daily intraperitoneally from the day of UUO surgery. All the mice were sacrificed at day 5 and 14 respectively after UUO. Routine pathological staining was carried out to examine the interstitial fibrosis and tubular injury and the expression of MMPs and TIMPs (Tissue inhibitor of metalloproteinase-1) in kidneys were examined. Gelatin zymography and in situ zymography were used to detect the proteolytic activity and location of MMPs and TIMPs. The expression of fibroblast phenotypes and collagen were examined by immunostaining. In WT mice at day 14 after UUO, the renal interstitial fibrosis and tubular injury score developed along with tubular epithelial cell (TEC) expressing fibroblast phenotypes, and more significantly in WT mice than in KO and Mino mice. Zymogrophy results showed both activities of MMP-2 and -9 increased in WT at day 14, without significant differences of activity of MMP-9 between WT and KO mice at day 14. In sizu zymography indicated the gelatin-degrading activity mainly localized at tubular epithelial cells in WT mice. As epithelial-to-mesenchymal transition (EMT) markers, a-SMA, heat shock proteins (HSP-47), vimentin, S100 calcium binding protein A4 (S100A4) significantly expressed in tubular epithelial cells at day 14 after UUO in WT mice than other two groups. In conclusions, MMP-2 accelerated renal fibrosis in the model of UUO possibly through enhanced the promotion of EMT. Our results shows that Inhibition of MMP-2 pathway may provide a novel therapeutic intervention aimed at attenuating progressive renal diseases.

**The Effects of Apelin on Obstructive Nephropathy** Masashi Nishida, Yasuko Okumura, Kenji Hamaoka. *Department of Pediatric Cardiology and Nephrology, Kyoto Prefectural University of Medicine Graduate School of Medical Science, Kyoto, Japan.*

Background. Apelin is a vasoactive peptide isolated as a selective endogenous ligand of APJ receptor, which was genetically identified to have closest identity to the angiotensin II type 1 receptor. The effects of apelin/APJ system on the evolution of renal fibrinogenesis remain unclear.

Methods. The mRNA expressions for apelin and APJ receptor in the kidneys were assessed in a mouse model of unilateral ureteral obstruction (UUO). Mice were treated with either apelin or apelin + L-NAME during the early stage (day 0 to 7) after UUO, and the obstructed kidneys were assessed at day 7.

Results. Both apelin and APJ receptor mRNAs are upregulated in the UUO kidney within 7 days following ureteral ligation, with APJ receptor mRNA being increased in a time-dependent manner. Treatment with apelin resulted in an increased endothelial nitric oxide synthase (eNOS) expression, a decreased tubular apoptosis, a decreased myofibroblast accumulation as well as an attenuated renal interstitial fibrosis at day 7 after UUO, although no significant change was observed in the degree of interstitial macrophage infiltration. When mice were treated with a nitric oxide synthase (NOS) inhibitor, L-NAME, concomitantly with apelin, these effects of apelin on the obstructed kidney were all absent, and the degrees of tubular apoptosis, myofibroblast accumulation, renal fibrosis, and interstitial macrophage infiltration were all rather increased compared with the control mice.

Conclusions. Exogenous infusion of apelin ameliorates pathological changes related to renal fibrinogenesis in an early stage of mouse obstructive nephropathy, at least in part, through the NO-dependent mechanism.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO669**

**TRPV4 in Urinary Tract Obstruction** Michael J. Hiatt,[1,2] Larissa Ivanova,[1,2] Douglas G. Matsell.[1,2] *[1]Paediatrics, University of British Columbia, Vancouver, BC, Canada; [2]Child and Family Research Institute, Vancouver, BC, Canada.*

While many of the histopathological features of obstructive nephropathy have been identified using the surgically induced mouse unilateral ureteric obstruction model (UUO), the impact of obstruction on the mechanisms of collecting duct (CD) epithelial injury and repair are poorly understood. The well studied ion channel TRPV4 can be activated by physical stimuli including cellular stretch and is expressed throughout the epithelium of the distal nephron. We hypothesize that TRPV4 modulates the sensing of injury by CD epithelium and its subsequent epithelial repair.

Kidneys from mice sacrificed at 3, 6 or 9 days after surgical ligation or sham manipulation were analyzed via laser capture microdissection, qPCR, western blot, and immunohistochemistry, in vitro cell culture.

Following UUO, CD cells lose their expression of proteins integral to 1) their differentiated phenotypes (vATPase and Aquaporin-2), and 2) maintenance of epithelial integrity (E-Cadherin and beta-Catenin), in parallel with a dramatic increase of alpha-smooth muscle actin positive cells in the surrounding interstitium. In vitro, TRPV4 can be detected at the intercellular membranes of IMCD3 cells cultured on transwell supports. In vivo, TRPV4 is expressed diffusely in CDs of control and sham kidneys, but is more distinctly associated with the basolateral membrane following 3 and 6 days of obstruction. Following 9 days obstruction, expression of TRPV4 is more diffusely expressed in the cytoplasm of epithelial cells, particularly in the outer medulla. qPCR analyses indicate that while inner medullary TRPV4 expression is decreased by >2-fold over the course of the obstruction, expression in the outer medulla is increased by 2 fold at 6 days obstruction and declines toward control levels by 9 days. TRPV4 protein expression is similarly increased at 6 days.

This work identifies the expression and epithelial localization of TRPV4 in obstructive nephropathy. TRPV4 is up-regulated in the early phases of obstruction, but decreases with more prolonged obstruction and injury. These studies implicate TRPV4 in the sensing of CD epithelial injury and in the mechanisms of epithelial repair following obstruction.

**CXCL16 Mediates Recruitment of Bone Marrow-Derived Fibroblast Precursors in Renal Fibrosis** Gang Chen, Song-Chang Lin, Feixia Dong, Jie Du, William E. Mitch, Yanlin Wang. *Department of Medicine-Nephrology, Baylor College of Medicine, Houston, TX.*

Renal fibrosis is a prominent pathological feature of chronic kidney disease (CKD). Although myofibroblasts are responsible for the production and deposition of the extracellular matrix which define interstitial fibrosis in CKD, the origin of fibroblasts mediating renal fibrosis has been controversial. Recent reports have shown that circulating $CD45^+$ collagen $I^+$ fibroblast precursors termed fibrocytes are involved in the pathogenesis of renal fibrosis. However, the signaling mechanisms accounting for the recruitment of bone marrow-derived fibroblast precursors into the kidney are poorly understood. Using RT-PCR and immunohistochemistry, we found that the expression of the chemokine, CXCL16, is upregulated in the murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO). CXCL16 is a small cytokine belonging to the CXC chemokine family, which exists in two forms. The soluble form generated by its cleavage at the cell surface functions as a chemoattractant to recruit cells. The transmembrane form has a transmembrane structure which functions as an adhesion molecule for CXCR6 expressing cells. Therefore, we examined if CXCL16 could regulate the recruitment of bone marrow-derived fibroblast precursors into the kidney. To test this hypothesis, wild-type (WT) and CXCL16-deficient (CXCL16-KO) mice were subjected to UUO. Flow cytometric analysis revealed that a significant number of bone marrow-derived fibroblast precursors that are dual positive for CD45 or collagen I or CD34 and collagen I accumulated in obstructed kidneys of WT mice, reaching a peak on day 5. The number of infiltrating bone marrow-derived fibroblast precursors was significantly reduced in obstructed kidneys of CXCL16-KO mice. Using real time RT-PCR, immunohistochemistry, and Western blot analysis, we found the expression of collagen type I, fibronectin, and α-SMA was upregulated in obstructed kidneys of WT mice, which was abrogated in obstructed kidneys of CXCL16-KO mice. We conclude that CXCL16 can play a pivotal role in the development of renal fibrosis by recruiting bone marrow-derived fibroblast precursors.

**Effect of Mast Cell Mediators on Fibroblast Activation: Role in Renal Fibrosis** Randi B. Silver, Arul Veerappan, Albert S. Jung, Rob Janssen, Diane Felsen, Jie Chen, Daniel Phillip Rhoades. *Physiology and Biophysics, Weill Cornell Medical College, NY, NY.*

Evidence suggests an intra-renal RAS plays a role in fibrosis. ANG II-induced TGF-β expression plays a critical role with fibroblasts (FB) the main effector cells but this mechanism has yet to be elucidated. We observe mast cells (MCs) in close proximity to FB in fibrotic regions in UUO kidneys. It is hypothesized that MC mediators (renin-ANG II and histamine) are involved in receptor-mediated FB activation. Freshly isolated rat FB were screened for ANG II AT1R and histamine H1R expression. FB were exposed to exogenous ANG II(100 nM) and histamine (1μM). Cell lysates and supernatants were assayed for TGF-β, prolyl-4-hydroxylase(P4H) and collagen. Exposure to ANG II or histamine caused significant proliferation (ANG II:2480±260 cells/mm3 and Histamine:3571±456; vs Control: 998±118, $p<0.05$) and was inhibited by the ANG II AT1R blocker, EXP3174 and pyrilamine, a H1R blocker (ANG II+EXP3174: 1554±244 cells/mm3, Histamine+pyrilamine:1414±218 $p<0.05$) respectively. Similarly, ANG II and histamine increased supernatant TGF-β (ANG II: 169.1±8.2 pg/μg, Histamine: 147.6±4.5; vs Control: 110.7±3.9, $p<0.01$), and increased P4H immunoexpression and abundance by Western blot two fold. Collagen secretion was enhanced by ANG II or histamine (22.4±0.3 and 29.2±0.9 vs. control 14.7±0.7, $p<0.001$) (ANG II+EXP3174: 15.1±1.4, Histamine+pyrilamine: 18.2±1.5). Our hypothesis was explored in MC-deficient WBB6F1-W/Wv mice(MCD) and their congenic controls WBB6F1-+/+(CC). The FB population/mm2 tissue was elevated in UUO kidneys from MCD (23.8±4.0 UUO MCD, n=3 vs 3.2±0.1 sham-operated, n=3) and CC mice (11.8±0.7 UUO CC, n=3; vs 2.0±0.1 sham-operated, n=3). Unlike the CC mice renal fibrosis was not observed in MCD mice. To determine whether MCD UUO FB were less activated than those from CC mice, UUO kidney FB were immunoscreened for H1R, AT1R, P4H

and α-SMA expression. The receptors were present in MCD and CC FB. P4H and α-SMA were more abundant in CC than MCD kidney FB. Our results show that MC mediators lead to FB proliferation and activation suggesting MCs are coupled to FB and play a role in renal fibrosis.

**Lack of Collagen XVIII/Endostatin Exacerbates Interstitial Fibrosis in a Mouse Model of Aristolochic Acid Nephropathy** Ryota Shirai,[1] Takahiro Aoki,[1] Yuki Tokui,[1] Ryota Kimura,[1] Yuki Udagawa,[1] Shiro Ueda,[1] Yoshihiko Ueda,[2] Osamu Yokosuka,[3] Makoto Ogawa,[4] Raghu Kalluri,[5] Yuki Hamano.[4] *[1]Graduate School of Pharmaceutical Sciences, Chiba University, Japan; [2]Dokkyo Medical University Koshigaya Hospital, Japan; [3]Graduate School of Medicine, Chiba University, Japan; [4]Chiba University Hospital, Japan; [5]Beth Israel Deaconess Medical Center and Harvard Medical School.*

**Objective:** Collagen XVIII (Col18) is a component of highly specialized extracellular matrix associated with basement membranes (BM) of epithelia and endothelia. Proteolytic cleavage within its C-terminal domain releases a fragment, endostatin, which has anti-angiogenesis effects. Aristolochic acid nephropathy (AAN) is a rapidly progressive tubulointerstitial nephritis that results in interstitial fibrosis and end-stage renal disease. To investigate the role of Col18/endostatin in the development of interstitial fibrosis, a mouse model of AAN was induced in Col18α1-null (KO) and wild-type (WT) mice.

**Methods:** AA sodium salt was administered into KO and WT mice from C57BL/6J background by intraperitoneal injection. On days 42 and 84, mice were sacrificed for the histological assessment.

**Results:** Upon induction of AAN in WT mice, Col18/endostatin expression was clearly upregulated within the tubular and vascular BM and interstitium. In KO mice with AAN (KO-AA) compared with WT mice with AAN (WT-AA), tubular atrophy and interstitial fibrosis were observed on day 42 and further progressed along with accumulation of collagen IV and perlecan in the interstitium on day 84. KO-AA demonstrated rupture of the tubular and vascular BM. The apoptosis and caspase-3 activation of tubular cells and interstitial endothelial cells (EC) were more observed in KO-AA on day 84. In addition, the expression of CTGF, but not TGF-β1, was upregulated exclusively in caspase-3-positive EC via activation of Smad3 and JNK signaling pathway in KO-AA compared with WT-AA on day 84.

**Conclusion:** Col18/endostatin plays an important role in preserving the integrity of tubular and vascular BM and has a protective effect against tubular damage, loss of peritubular capillaries and interstitial fibrosis in AAN.

### TH-PO673

**Inhibition of Epithelial-Mesenchymal Transition (EMT) during Renal Fibrosis by an N-Type Calcium Channel Blocker, Cilnidipine** Keiichiro Mishima, Akito Maeshima, Masaaki Miya, Noriyuki Sakurai, Hidekazu Ikeuchi, Takashi Kuroiwa, Keiju Hiromura, Yoshihisa Nojima. *Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan.*

By in vivo BrdU labeling, we have recently identified label-retaining cells (LRCs) with renal progenitor-like property in renal tubules of normal rat kidney. We also observed that LRCs migrated into the interstitium and transdifferentiated into myofibroblasts in a rat unilateral ureteral obstruction (UUO) model (JASN 16: 2044-51, 2005). It is known that cilnidipine, an N-type calcium channel blocker (CCB), reduces the renin activity by suppressing the peripheral sympathetic nerve activity, suggesting its renotropic actions similar to angiotensin II receptor blockers (ARBs). In this study, we examined whether cilnidipine has any effects on renal fibrosis.

After BrdU labeling for 1 week and 2 week chase periods, UUO was induced in male Wistar rats. After UUO operation, either cilnidipine or amlodipine was given orally into these rats (3 mg/kg/day each). One or two weeks later, the kidneys were removed for histological analysis. BrdU-positive cells were assessed as LRCs.

Both cilnidipine and amlodipine did not affect mean blood pressure at the dose tested. Consistent with previous study, tubular LRCs migrated into the interstitum of the UUO kidneys. The number of interstitial LRCs was significantly decreased in cilnidipine-treated group but not in amlodipine-treated group compared to that in the untreated group ($4.6 \pm 0.4$ vs. $6.2 \pm 0.7$, cilnidipine vs. none, $p<0.05$). In cilnidipine-treated group, the number of interstitial CD68-positive macrophages was significantly lower than that in amlodipine-treated or untreated group ($7.4 \pm 0.7$ vs. $13.2 \pm 0.9$, cilnidipine vs. none, $p<0.01$). In both cilnidipine-treated and amlodipine-treated groups, fibrotic area (Masson-trichrome staining), the expression of alpha-SMA, the number of interstitial PCNA-positive cells were significantly reduced compared to those in the untreated group.

These data suggest that cilnidipine has a potential to inhibit EMT. Like with ARBs, CCBs might have renoprotective effects on renal fibrosis via multiple mechanisms.

### TH-PO674

**The Interaction of $\alpha_L\beta_2$ Integrin on Leukocytes and ICAM-1 on Renal Epithelial Cells Accelerates TGF-β Induced Renal Epithelial-Mesanchymal Transition by Activating ERK 1/2 Signaling Pathway** Yoshiyuki Morishita, Eiko Nakazawa, Eiji Kusano. *Nephrology, Jichi Medical University, Shimotuke, Tochigi, Japan.*

The epithelial-mesanchymal transition (EMT) induced by TGF-β has pivotal roles in the development of tubulointerstitial fibrosis. Although infiltration of leukocytes has been detected during tubulointerstitial fibrosis, their physiological roles to EMT remind to clarify. $\alpha_L\beta_2$ integrin is the predominant integrin on leukocytes and plays important roles not only adhesion and migration but also signal transduction by binding its ligands such as ICAM-1. In this study, we investigated the effect of interaction of $\alpha_L\beta_2$ integrin on peripheral blood mononuclear cells(PBMCs) and ICAM-1 on cultured human renal epithelial cells (HK-2 cells and RPTECs) to TGF-β induced EMT. Flow cytometry showed highly expressed ICAM-1 in both HK-2 cells and RPTECs. After TGF-β stimulation (0.1-10ng/ml), chemokines that activate $\alpha_L\beta_2$ integrin such as CXCL12 and CCL20 increased in both HK-2 cells and RPTECs. Then, HK-2 cells or RPTECs after stimulation with TGF-β (0.1ng/m) were co-cultured with PBMCs purified from healthy volunteers. After 24hrs co-culture, flow cytometry using anti-$\alpha_L\beta_2$ integrin mAb (TS1/22) and anti-active form $\alpha_L\beta_2$ integrin mAb (AL-57) showed active form $\alpha_L\beta_2$ integrin on PBMCs increased; however, total $\alpha_L\beta_2$ integrin did not change. Real time PCR and western blotting showed that down-regulation of E-cadherin and vimentin and up-regulation of α-smooth muscle actin and fibronectin by TGF-β stimulation in HK-2 cells and PRTECs were accelerated by co-cultured with PBMCs. These changes of EMT markers were blocked by TS 1/22 and ab20. Western blotting showed that phosphorylation of ERK 1/2 but not smad2, 3 and p38 MAP kinase increased in both HK-2 cells and RPTECs by co-cultured with PBMCs. This increased phosphorylation of ERK 1/2 was blocked by TS1/22 and ab20. In conclusion, the interaction of $\alpha_L\beta_2$ integrin on PBMCs and ICAM-1 on renal epithelial cells accelerated TGF-β induced EMT of renal epithelial cells by activating ERK 1/2 signaling pathway. These results suggested drugs that can block the interaction of $\alpha_L\beta_2$ integrin and ICAM-1 would be a potential option to treat renal fibrosis.

### TH-PO675

**Claudin-2 Expression Alters Cellular Morphogenesis and Cilia Formation** Amar B. Singh,[1] Fnu Bhawana,[1] Raymond C. Harris,[2] Punita Dhawan.[1] *[1]Surgery, Vanderbilt University Medical Center, Nashville, TN; [2]Medicine, Vanderbilt University Medical Center, Nashville, TN.*

Among claudin family members, claudin-2 is unique as its expression in polarized epithelial cells leads to a decrease in transepithelial resistance (TER). Notably, emerging studies suggest that experimental manipulations that lead to junctional remodeling also modulate claudin-2 expression. However, a causal role of claudin-2 expression in the regulation of epithelial morphogenesis remains uninvestigated. In our study, we stably knocked down claudin-2 expression in MDCK II cells (MDCKcl2KD cells) using canine claudin-2 specific shRNA. As predicted, TER in MDCKcl2KD cells increased 3-fold compared to the control cells. However, no obvious differences were observed in the morphology of confluent MDCKcl2KD cells. In contrast, MDCKcl2KD cells showed significant changes compared to the control cells when plated as single cells. In MDCKcl2KD cells, formation of focal complexes, including lamellipodia and filopodia, was markedly decreased during cell spreading ($19\pm2.2$ vs. $47\pm3.4$). This decrease in focal complexes was associated with marked decreases in the tyrosine phosphorylation of FAK and paxillin, proteins important in the regulation of cell spreading. Furthermore, cell migration and cell attachment were decreased by 60% and 40% in MDCKcl2KD cells compared to control cells. Cell scattering in response to HGF, which requires both cell spreading and migration, was significantly inhibited in claudin-2KD cells. Importantly, further investigations showed marked decreases in cilia formation in post-confluent MDCKcl2KD cells compared to the control cells. On the other hand, stable expression of claudin-2 in CHO cells, a fibroblast cell line deficient in claudin expression, resulted in cuboidal epithelial morphology, redistribution of actin along the cortical bundles and marked decreases in Rho and Rac-GTPase activity, suggesting an important role for claudin-2 expression in the regulation of the actin cytoskeleton. In summary, our data suggest an important role for claudin-2 in the regulation of actin cytoskeletal organization and possibly in the establishment of tight junctions.

### TH-PO676

**Activation of the Epac-Rap Signaling Pathway Reduces Cell Detachment and Renal Failure in Ischemia-Reperfusion Injury** Geurt Stokman,[1] Yu Qin,[1] Emile De Heer,[2] Ingeborg M. Bajema,[2] Bob Water,[1] Leo Price.[1] *[1]Toxicology, LACDR, Leiden University, Leiden, Netherlands; [2]Pathology, LUMC, Leiden University, Leiden, Netherlands.*

Tubular epithelial cell detachment is an early feature of renal ischemia-reperfusion (IR) injury involving loss of cell junction and matrix adhesion. The Epac-Rap pathway is involved in the activation of cell adhesion by promoting integrin activation and formation of cell-cell contacts. Epac1 is expressed by the tubular epithelium. We investigated if selective activation of Epac using the cAMP analogue 8-pCPT-2'-O-Me-cAMP (007) could prevent ischemic renal injury using in vitro and in vivo models. Mouse proximal tubular epithelial cells were used for all in vitro experiments. Activation of Epac-Rap1 by 007 was detected using Rap1-specific pull down analysis. Hypoxia was induced by

mineral oil submersion. Cellular injury and cytoskeletal rearrangement were imaged and quantified using digital image analysis. Immunostainings for Epac1, β-catenin, ZO-1 and paxillin were performed. Knockdown for Epac1 was performed using siRNA. C57BL6 mice were subjected to bilateral ischemia for 25 minutes, 007 or saline were administered intrarenally and animals were sacrificed the next day. Plasma urea levels were determined and tissue sections were stained for β-catenin and clusterin-α.

Stimulation of cells to 007 led to Rap1 activation. Epac activation reduced monolayer disruption and loss of junction and matrix adhesion during hypoxia. Knockdown of Epac1 prevented 007-mediated cell junction stabilization. Intrarenal administration of 007 in mice increased Rap activation. Mice treated with 007 had less renal failure (plasma urea 29.09mM ± 3.014 and 20.39mM ± 1.778 for saline and 007 treated animals respectively, *P=0.02). Treatment with 007 reduced irregular β-catenin and clusterin-α expression during IR injury compared to controls demonstrating that Epac activation prevents cell junction disassembly and reduces cell stress. Our study indicates that protection of tubular epithelial cell adhesion by activation of Epac1 is a novel therapeutic strategy to prevent kidney failure following ischemia or after transplantation.

## TH-PO677

**Interdependence of HIF-1α and TGF-β Signaling in Normoxic and Hypoxic Renal Epithelial Cell Collagen Expression** Susan C. Hubchak,[1] Rajit K. Basu,[2] Paul T. Schumacker,[1] H. William Schnaper.[1] *[1]Department of Pediatrics, Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Department of Critical Care, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

The transforming growth factor (TGF)-β pathway, acting through the Smad signaling proteins, has been shown to interact with hypoxia-inducible factor (HIF)-1α in models of hypoxic kidney injury. Previously, we showed that TGF-β1 increased HIF-1α transcriptional activity and protein expression in a human proximal tubule cell (HKC) line under normoxia (21% $O_2$) and hypoxia (1.5% $O_2$). Blockade of the Smad3 signaling pathway by TβRI kinase inhibition or transfection with the dominant-negative Smad3A construct reduced TGF-β1-stimulated HIF-1α expression but had no effect on induction of HIF-1α protein by the hypoxia mimetic, desferoxamine mesylate. Here, we describe the effect of HIF-1α on TGF-β1-Smad3 transcriptional activity and collagen expression. Transfection of HKC with a dominant-negative (DN) HIF-1α construct reduces basal Smad3 transcriptional activity 44% and TGF-β1-stimulated activity by 33% over that of empty vector so that TGF-β-stimulated activity in the presence of DN-HIF-1α was only slightly higher than control, basal activity. Similarly, DN-HIF-1α reduces basal COL1A2 reporter activity by about half and TGF-β1-stimulated activity to approximately that of basal control activity. Conversely, overexpressing HIF-1α in normoxic HKC through transfection of a non-degradable mutant increases basal COL1A2 reporter activity 5-fold and TGF-β1-stimulated activity 16-fold over that of empty vector control, significantly increasing fold induction from 2.3 to 3.0x. Finally, pretreatment of HKC with a HIF-1α transcriptional inhibitor, CAY10585, reduces both basal and TGF-β1-stimulated α1(I) collagen mRNA expression. Together, our data suggest that TGF-β1 stimulates cooperation between Smad3 and HIF-1α to promote collagen I expression.

## TH-PO678

**Prostacyclin Analog ONO-1301 Ameliorates Tubulointerstitial Alterations through Induction of HGF** Tatsuyo Nasu,[1] Yohei Maeshima,[1] Daisuke Saito,[1] Hiroko Yamasaki,[1] Katsuyuki Tanabe,[1] Masaru Kinomura,[1] Hitoshi Sugiyama,[3] Hirofumi Makino.[1] *[1]Medicine and Clinical Science, Okayama Univ., Okayama, Japan; [2]Center for Chronic Kidney Disease and Peritoneal Dialysis, Okayama Univ., Okayama, Japan.*

<Background>

Tubulointerstitial injuries are involved in the progression of CKD and predict deterioration of renal function. ONO-1301 is a novel sustained-release prostacyclin analog, possessing thromboxane A2 synthase inhibitory activity. ONO-1301 also up-regulates the production of hepatocyte growth factor (HGF) from fibroblasts. We previously observed the inhibitory effects of slow release ONO-1301 (SR-ONO) on tubulointerstitial injuries in the unilateral ureteral obstruction (UUO) model.

<Purpose>

We aimed to evaluate the potential involvement of HGF in the therapeutic efficacies of SR-ONO to ameliorate tubulointerstitial injuries in the UUO model.

<Method> Female C57/BL6J mice received a single subcutaneous injection of SR-ONO (10 mg/kg) after inducing UUO, and received intraperitoneal injections of rabbit anti-HGF antibody or normal control IgG on Day 1, 3 and 5, and were sacrificed on Day 7.

<Results>

Single injection of SR-ONO could maintain serum concentrations of ONO within therapeutic range for 7 days. SR-ONO treatment suppressed interstitial fibrosis, accumulation of type I and III collagen, monocyte/macrophage infiltration, increase in the levels of TGF-β1, phosphorylation of Smad2/3 and the number of fibroblast specific protein (FSP)1+ fibroblasts in the obstructed kidneys (OBK). The renal levels of HGF were mildly elevated in the control OBK, and SR-ONO further enhanced HGF levels. In vitro, ONO-1301 maintained the expression of E-cadherin and ZO-1 and suppressed the induction of FSP1 and α-SMA in mouse proximal tubular epithelial cells (mProx24) stimulated by TGF-β1. Injections of anti-HGF antibody reversed inhibitory effects of SR-ONO on interstitial fibrosis, accumulation of type I and III collagen and the increase of FSP1+ fibroblasts.

<Conclusion>

These results implicate the therapeutic efficacies of ONO-1301 in ameliorating tubulointerstitial injuries via inducting HGF, which may play a role in counteracting the pro-fibrotic effect of TGF-β1 and suppressing EMT.

## TH-PO679

**Rat Mesenchymal Stem Cells (RMSCs) Replace Damaged for New Matrix during Remodeling Process: A 6D (Dimensional) Live Cell Model** Jiamin Teng, Elba A. Turbat-Herrera, Guillermo A. Herrera. *Pathology, Nephrocor, Tempe, AZ.*

**Background:** How mesangial matrix is renewed after injury remains poorly understood. The injured matrix is eventually replaced by new matrix with not well defined characteristics as or yet. An in-vitro platform using a 6D live cell model allows to monitor the sequential steps that must take place for mesangial repair to occur.

**Materials and methods:** Rat mesangial cells (RMCs) were cultured on Matrigel loaded glass bottomed multi-wells plates with 10% FBS/RPMI 1640 until confluence. RMCs were then made quiescent by incubating them with 0.5% FBS/RPMI for 48 hours and afterwards incubated with glomerulopathic light chains (GLCs) (10 ug/ml, 48 hours x 2) purified from the urine of renal biopsy-proven light chain deposition disease (LCDD) and AL (light chain-associated) amyloidosis added to the wells every other day. RMSCs were marked with PKH-2 fluorescence dye (green) or with Lysotracker linked to Texas Red (red) and placed later into the wells of GLCs-treated RMCs for up to 2 weeks. MCs were maintained alive and monitored with sequential photos. Fifteen different locations were monitored simultaneously and documented every 15 minutes resulting in a complete appreciation of how the injured mesangium developed and subsequent repair process with emphasis on the characteristics of the new matrix being laid down.

**Results:** The repair process followed a similar sequence of events at all monitored sites but the changes did not necessarily occurred with the same speed. Once RMSCs had cleared the damaged RMCs and affected matrix, they acquired more cytoplasm endowed with organelles normally present in MCs such as bundles of myofilaments and a large number of rough endoplasmic reticulum cisternae, while attachement plaques developed at their surface. The extracellular material that was laid down by these transformed RMSCs showed characteristics typical of the normal mesangium.

**Results:** The RMSCs repopulated the damaged mesangium and laid down mesangial matrix re-establishing mesangial homeostasis. The new matrix recapitulated normal mesangial matrix in composition and overall appearance.

## TH-PO680

**Transglutaminase Inhibition Reduces Glomerulosclerosis by a Hic-5 Dependent Mechanism in Experimental Diabetic Nephropathy** Nick Hornigold,[1] Timothy Scott Johnson,[2] Andrew F. Mooney.[3] *[1]CRUK Clinical Research Centre, St James's University Hospital, Leeds, West Yorkshire, United Kingdom; [2]Sheffield Kidney Institute, University of Sheffield, Sheffield, South Yorkshire, United Kingdom; [3]Renal Unit, St James's University Hospital, Leeds, West Yorkshire, United Kingdom.*

It has recently been shown that the LIM protein, Hic-5, plays a central role in experimentally induced glomerulosclerosis (KI 2010). In vitro, Hic-5 is upregulated in mesangial cells following attachment to collagen I, and leads to increased susceptibility to apoptosis and adoption of a pro-sclerotic phenotype, including further expression of collagen I. We posited that this same feedback loop exists in vivo.

Streptozotocin-induced diabetic rats underwent unilateral nephrectomy. Some rats were also treated with the transglutaminase (TG-2) inhibitor, NTU281. Rats were sacrificed at days 30, 120 and 240. Serial measurements of proteinuria and serum creatinine were undertaken prior to sacrifice. Tissue sections were immunostained for collagen I, Hic-5 and α-smooth muscle actin (α-SMA). Glomerular expression was semi-quantitatively scored on a 0-5 scale by a blinded observer. Total glomerular cell count and number of apoptotic cells in glomeruli were counted on PAS stained sections.

Results showed that TG-2 inhibition was associated with a significant down-regulation of collagen I expression. This coincided with reduced Hic-5 expression and reduced α-SMA expression, reduced numbers of apoptotic cells and reduced proteinuria and serum creatinine. Hic-5 knock down in mesangial cells in vitro leads to reduced α-SMA expression (by Western blotting) and reduced collagen I precursor transcription (by real time PCR).

These data show that there is, in vivo, a positive feedback loop between collagen I and Hic-5. This leads to a pro-sclerotic phenotype, including increased α-SMA expression, increased collagen I precursor transcription and increased susceptibility to apoptosis. Interrupting this feedback, by NTU281treatment, leads to a major reduction in sclerotic damage to glomeruli. This has important implications for strategies to reduce progressive glomerulosclerosis.

**Full-Length Galectin-3 Mediates Polymerization of Hensin That Is Secreted by Clone C Intercalated Cells (ICs): Its Carbohydrate Recognition Domain (CRD) Is Necessary but Not Sufficient** Hu Peng, Soundarapandian Vijayakumar, George J. Schwartz. *Pediatrics, University of Rochester Medical Center, Rochester, NY.*

Hensin is a multifunctional, multidomain protein that is implicated in the regulation of epithelial differentiation and adaptation of the collecting duct to metabolic acidosis. Hensin is secreted as a monomer and then polymerized and deposited in the extracellular matrix (ECM) where it serves to differentiate ICs. To investigate the mechanism of hensin polymerization, we first examined the expression level of galectin-3 in conditioned media from clone C plated at low density (LD, 2 x $10^4$ cells/ml) versus that from cells plated at high density (HD, 5 x $10^5$ ). Galectin-3 was significantly more abundant in HD medium compared to LD medium, suggesting that galectin-3 is responsible for hensin polymerization. Opti-prep density gradient size fractionation demonstrated that LD medium only contained monomeric hensin, whereas HD medium contained oligo- and polymeric hensin. NTA-bound full-length recombinant galectin-3 (1-242 aa) pulled down hensin, and this interaction could be completely blocked by lactose (100 mM) but not by sucrose or mannitose. Incubation of LD medium with recombinant galectin-3 caused polymerization of hensin, similar to that observed in HD medium. Such galectin-3 induced polyermerization could be blocked by lactose (100 mM). The CRD (aa 110-242) alone was unable to polymerize hensin from LD medium. These data suggest that full-length galectin-3 is able to polymerize hensin in vitro. Presumably, the CRD interacts with hensin and the N-terminal domain of galectin-3 induces galectin-3 oligomerization; the oligomerization of galectin-3 brings multiple hensin monomers together, resulting in hensin polymerization.

**TH-PO682**

**Role of Thioredoxin-Interacting Protein (Txnip) as a Mediator of Tubulointerstitial Fibrosis in Experimental Diabetic Nephropathy** Christina Yan Ru Tan,[1] Weier Qi,[1] Yuan Zhang,[1] Robyn G. Langham,[1,2] Darren J. Kelly.[1] *[1]Medicine, St. Vincent's Hospital, The University of Melbourne, Fitzroy, VIC, Australia; [2]Nephrology, St. Vincent's Hospital, Fitzroy, VIC, Australia.*

**Aim** To examine a potential therapeutic role for targeted Txnip inhibition in experimental diabetic nephropathy (DN) using a Txnip DNAzyme.

**Background** Txnip, an endogenous inhibitor of antioxidant thioredoxin, has been shown to be greatly upregulated by high glucose in microarray studies. It is thought to be a mediator of progressive fibrosis in DN, possibly through increased oxidative stress.

**Methods** Ren-2 rats with streptozotocin-induced diabetes were randomly assigned to receive Txnip DNAzyme or control scrambled DNAzyme delivered by osmotic minipump. Renal injury was assessed by biochemical measures of renal function and histological changes. Renal gene expression of Txnip, Collagen IV, TGFβ and Nitrotyrosine were assessed by RT-PCR, and peptide expression and localization measured by semi-quantitative immunohistochemistry.

**Results** Elevated cortical Txnip mRNA and protein expression in DN rats were shown to be significantly attenuated by Txnip DNAzyme (treated DN 1.24±0.28-fold(mRNA)/3.08 ±0.23%(protein) vs non-treated DN 2.40±0.49-fold(mRNA)/6.21±0.48%(protein), n=8-10, p<0.05). Tubulointerstitial fibrosis and oxidative stress were markedly attenuated in the tubulointerstitium of Txnip DNAzyme treated rats by 1.80- and 1.44-fold, respectively, compared to non-treated DN (n=8-10, p<0.05). Furthermore, collagen IV and TGFβ levels in Txnip DNAzyme-treated rats were significantly reduced by 2.42- and 2.03-fold respectively (n=8-10, p<0.01). The effects of Txnip inhibition were limited to the tubulo-interstitial compartment. No change was observed in the upregulation of glomerular Txnip expression in Txnip DNAzyme treated rats. Similarly, increased glomerulosclerosis, indicated by glomerulosclerotic index, noted in DN rats was not altered by Txnip DNAzyme (treated DN 1.59±0.09 vs non-treated DN 1.63±0.09, n=8-10, p>0.05).

**Conclusions** This study supports the role of Txnip as an important mediator of progressive tubulointerstitial fibrosis in DN, further highlighting Txnip as a potential new therapeutic target for DN.

**α2β1 Integrin-Mediated Signaling Induces Expression of Intercellular Adhesion Molecule-1 Expression on Human Mesangial Cells and Leukocyte Adhesion** Masahito Tamura, Narutoshi Kabashima, Ryota Serino, Tatsuya Shibata, Tetsu Miyamoto, Yumi Furuno, Junichi Nakamata, Yoko Fujimoto, Emi Hasegawa, Yutaka Otsuji. *Kidney Center, University of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan.*

Integrins are major adhesion receptors that regulate cytoskeletal organization, and trigger a variety of signal transduction pathways and specific gene expression. We investigated the effects of extracellular matrix (ECM) accumulation on the expression of cell adhesion molecules involved in the progression of renal diseases. Quiescent cultured human mesangial cells (MCs) abundantly expressed cell surface molecules such as α2-5 and β1 integrins, CD44, and weakly α6, αv, and β3 integrins, intercellular adhesion molecule (ICAM)-1, and Fas. Stimulation of β1 integrin using a specific monoclonal antibody induced time-dependent expression of ICAM-1 on MCs. Cell adhesion to ECM proteins, e.g., type I and III collagens with affinity for α2β1 integrin, effectively enhanced ICAM-1 expression, while type IV collagen, fibronectin, or laminin without affinity for α2β1 integrin had no effect on ICAM-1 expression. Furthermore, pretreatment of cells with anti-α2 integrin inhibitory antibody completely inhibited β1 integrin- or type I or III collagen-induced expression of ICAM-1. β1 integrin increased phosphorylation of mitogen-activated protein or extracellular signal-related kinase (MEK) 1/2 and protein kinase C (PKC), and pretreatment of cells with a MEK1/2 inhibitor, PD98059, tyrosin kinase inhibitor, genistein, or PKC inhibitor, calphostin C, suppressed levels of β1 integrin-induced ICAM-1 expression. Up-regulation of ICAM-1 expression was accompanied by increased cell adhesions between mesangial cells and leukocytes, which was completely suppressed by anti-ICAM-1 antibody pretreatment. These results indicate that stimulation of α2β1 integrin induces ICAM-1 expression through MEK1/2 and PKC, and suggest that accumulation of pathological ECM components such as type I and III collagens might play a role in the progression of glomerular diseases by enhancing ICAM-1 expression and leukocyte adhesion to mesangial cells.

**Interleukin 17 – A New Actor in Acute and Chronic Kidney Injury** Tanja Loof, Stephanie Kraemer, Hans-Hellmut Neumayer, Harm Peters. *Nephrology, Charité Universitätsmedizin Berlin, Berlin, Germany.*

**Purpose**

Overexpression of pro-fibrotic and pro-inflammatory cytokines, such as TGF-ß and IL-6, and extracellular matrix accumulation are hallmarks of acute and chronic glomerular injury. A functional interaction between TGF-ß signaling and the inflammatory cytokine IL-17 has recently been proposed. This study analyzed the expression patterns of TGF-ß and IL-17 in rat models of acute anti-Thy1 glomerulonephritis (aGN), in streptozotozin-induced diabetic nephropathy (STZ), hypertensive nephropathy (HN) and chronic anti-Thy1 glomerulosclerosis (cGs).

**Methods**

Materials were harvested at the following points: d0.5/d1 (injury), d5/d10 (matrix expansion) and d15/d20 (resolution) for aGN (induced by OX-7-injection in Wistar rats) and week 12 for STZ (i.p. streptozotocin-injected male spontaneously hypertensive-stroke-prone rats), HN (uninephrectomy, followed by a 2/3 nephectomy 2 weeks later, Wistar rats) and cGs (uninephrectomy and i.v. OX-7-injection in Wistar rats), respectively.

**Results**

Induction of aGN was characterized by marked proteinuria (d5 113±12 mg/d; 3.9-fold vs. con; p<0.001) and histological glomerular matrix accumulation (d5 +3-fold vs. con; p<0.001), in parallel with highest glomerular TGF-ß1 and IL-17 mRNA-expression (+2.25-fold; +6.50-fold vs. con; p<0.05). STZ, HN, cGs showed significantly increased proteinuria at week 12 (STZ 4.5-fold; HN; 26.0-fold; cGs 17.4-fold vs. con; all p<0.01). In the kidneys, glomerular TGF-ß1 and IL-17 protein expressions were highly up-regulated in diseased rats compared to controls (STZ: TGF-ß1 7.3-fold; IL-17 4.7-fold; HN: TGF-ß1 7.9-fold; IL-17 25.0-fold, cGs: TGF-ß1 2.5-fold; IL-17 14.2-fold; all p<0.001).

**Conclusion**

This study documents a marked up-regulation of the new pro-inflammatory cytokine IL-17 in acute anti-Thy1 glomerulonephritis. IL-17 is constitutively expressed in glomerular cells and highly induced under inflammatory conditions. In STZ, HN and cGs rats, IL-17 and TGF-ß are co-expressed by glomerular cells.The results points an new regulatory pathway between inflammation and fibrosis in the pathogenesis of acute and chronic kidney diseases.

**Inhibitors of Mitochondrial Respiration Inhibit TGF-Induced Upregulation of PAI-1 and Fibronectin Expression in Renal Cells through Upregulation of SMAD7 and TGIF** Jens Gaedeke, Hans-Hellmut Neumayer, Harm Peters. *Nephrology, Charité, Campus Mitte, Berlin, Germany.*

The anti-diabetic drugs metformin and phenformin have been shown to inhibit PAI-1 secretion in liver cells. Inhibition of mitochondrial respiratory chain and upregulation of AMP-activated kinase (AMPK) activity has been shown as one of the cellular target of these drugs. Here we analyzed the effect of established inhibitors of mitochondrial oxidative phosphorylation (OxPhos) (rotenone, oligomycin, D942) and of ciglitazone and troglitazone, also haracterized as inhibitors of mitochondrial function, on cellular signaling pathways and TGF effects in renal fibroblasts and tubular epithelial cells. Rat renal fibroblasts (NRK49F) and tubular epithelial cells (NRK52E) were treated with various inhibitors at non-toxic doses and TGF effects were analyzed by western blotting of FN and PAI-1. Signaling pathways were analyzed by western blotting. SMAD7 was analyzed by RT-PCR, TGIF expression by western blotting. D942 and oligomycin, but not rotenone activated AMPK and blocked TGF Induced PAI-1 and FN. Blockade of TGF effects was associated with an upregulation of SMAD7 mRNA in both tubular cells and renal fibroblasts and an upregulation of the transcriptional repressor TGIF protein in tubular cells. Blockade of intracellular calcium with BAPTA-AM abolished these effects.

Treatment of cells with ciglitazone and troglitazone similarly activated AMPK and blocked TGF effects, eventhough no PPARgamma was detected. Exchange of glucose in the medium for galactose (which forces the cell to use only mitochondrial OxPhos to generate ATP) leads to increased baseline AMPK activation, reduced TGF effects and increased toxicity of both ciglotazone and troglitazone, whereas high glucose had opposite effects.

Our data show that mild inhibition of mitochondrial function followed by activation of AMP-kinase leads to inhibition of TGF effects. This is associated with increased expression of the TGF-beta antagonists SMAD7 and TGIF in a calcium-dependent pathway.

Our data suggest that the functional status of mitochondria is involved in regulating TGF signalling in renal cells though modulation of SMAD7 and TGIF.

**Combining Renin Receptor Inhibition and Angiotensin II Blockade Results in Enhanced Antifibrotic Effect in Experimental Glomerulonephritis** Jiandong Zhang,[1,2] Wayne Border,[1] Nancy Noble,[1] Yufeng Huang.[1] *[1]Fibrosis Research Laboratory, University of Utah, Salt Lake City, UT; [2]Institute of Nephrology, Southeast University, Nanjing, Jiangsu, China.*

Recent evidence suggesting a receptor-mediated profibrotic action of renin independent of angiotensin generation and action led us to hypothesize that combining renin receptor inhibition and Ang II blockade would enhance antifibrotic effect. Using the anti-Thy-1 model of glomerulonephritis,the maximally effective dose of enalaprilate was determined and compared with the effect of silencing renin receptor. Then, both treatments at maximal doses were combined. After disease induction with OX-7, intact glomeruli from normal and nephritic rats were isolated at d4 and put in culture at 5000 gloms/2ml medium with 2.5% FBS for 48h. The supernatant was harvested for TGFß1 and FN ELISA assay and glomeruli were harvested for mRNA analysis by real time RT/PCR. Enalaprilate dose-dependently reduced markers of fibrosis, with 10-4M showing maximal effects, reducing mRNA of FN 65%, PAI-1 56% and TGFß1 49%, and production of proteins fibronectin 60%, and TGFß1 49%,. Glomerular renin mRNA and activities and Ang II levels were increased in untreated nephritic glomeruli 2-,4-and 6.8-fold, respectively vs. normal glomeruli. Administration of 10-4M enalaprilate reduced Ang II generation 65% and resulted in 2- and 10-fold further increases in diseased glomerular renin mRNA expression and activity, respectively but had no effect on glomerular renin receptor expression. Depressing the renin receptor with siRNA by 80% in cultured nephritic glomeruli reduced fibrotic markers comparably to enalapril alone but had no effect on glomerular renin expression. However, combination therapy led to a further reduction in disease markers. Notably, elevated TGFß1 and FN production were reduced 73% and 84%, respectively. These results support our hypothesis that adding renin receptor inhibition to Ang II blockade in patients may have therapeutic potential. These results also indicate that the limited effectiveness of Ang II blockade may be due, at least in part, to the elevated renin levels they induce and the receptor-mediated, profibrotic action of renin.

**Oncostatin M Inhibits Basal and TGF-β1-Induced Expression of Matricellular Proteins in Human Kidney-2 Cells** Rita Sarkozi, Christine M. Hauser, Susie-Jane Noppert, Michael Rudnicki, Andreas Kronbichler, Markus Pirklbauer, Gert J. Mayer, Herbert Schramek. *Department of Internal Medicine IV, Nephrology and Hypertension, Innsbruck Medical University, Innsbruck, Austria.*

Matricellular proteins (MP) are non-structural proteins that are secreted and sequestered in the extracellular matrix. They modulate cell function by interacting with cytokines, growth factors, receptors and extracellular matrix proteins. Microarray analysis revealed an inhibitory effect of oncostatin M (OSM) on the expression of four MP in proximal tubular human kidney-2 (HK-2) cells. As MP expression is increased in renal tubulointerstitial fibrosis, we decided to study it in HK-2 cells stimulated with the pro-fibrotic cytokine transforming growth factor-ß1 (TGF-ß1) when compared with the multifunctional cytokine OSM.

Real-time PCR analysis of HK-2 cells stimulated with 10 ng/ml TGF-ß1 revealed a time-dependent induction of connective tissue growth factor (CTGF), thrombospondin-1 (TSP1), tenascin-C (TNC), and SPARC (secreted protein, acidic and rich in cystein). In contrast, 10 ng/ml OSM did not only inhibit basal mRNA expression of all four MP after 12 h and 24 h of incubation but also almost abolished TGF-ß1-induced MP mRNA expression. This inhibitory OSM effect did not depend on the sequence of ligand administration. Simultaneous addition of TGF-ß1 and OSM blocked TGF-ß1-mediated induction of all four MP after 24 h. Identical results were obtained when OSM was added 5 min and 1 h prior or past TGF-ß1 administration. For the CTGF gene these results were verified by Western blot analysis. 24 h incubation with an inhibitor of DNA methyltransferases, 5-aza-2'-deoxycytidine (2.5 µM), increased basal and TGF-ß1-stimulated CTGF mRNA expression but hardly attenuated OSM's inhibitory effect on CTGF expression.

We conclude that TGF-ß1 is a potent stimulator of CTGF, TSP1, TNC and SPARC in HK-2 cells, while OSM inhibits basal and TGF-ß1-induced mRNA expression of these MP. Inhibition of DNA methylation further stimulates CTGF mRNA expression without major effects on the inhibitory action of OSM. Hence OSM may fulfill an anti-fibrotic function by blocking MP expression in human proximal tubular cells.

**Lymphangiogenesis Develops during Tubulo-Interstitial Fibrosis Via the TGF-β–VEGF-C Pathway in Rat Unilateral Ureteral Obstruction** Yasuhiro Suzuki,[1] Yasuhiko Ito,[1] Masashi Mizuno,[1] Akiho Sawai,[1] Hiroshi Kinashi,[1] Waichi Sato,[1] Shoichi Maruyama,[1] Enyu Imai,[1] Yoshifumi Takei,[2] Seiichi Matsuo.[1] *[1]Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Department of Biochemistry, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

**Backgroud and Purpose** We recently reported that lymphangiogenesis was observed in tubulo-interstitial lesions and was correlated with fibrosis. However, endogenous TGF-β was reported to inhibit lymphangiogenesis. In order to clarify the mechanisms of lymphangiogenesis in renal fibrosis, we studied the interaction between lymphangiogenesis and fibrosis in rat unilateral ureteral obstruction (UUO) model and in cultured cells. **Methods** We analyzed inflammation (ED1 positive macrophage), fibrosis (α-SMA, typeIII collagen), lymphangiogenesis (LYVE-1, podoplanin) and growth factors (TGF-β and VEGF-C) in UUO model by RT-PCR and immunohistochemistry. In addition, we investigated interaction between TGF-β1 and VEGF-C in cultured proximal tubular epithelial cells (HK-2), collecting tubules (M-1), macrophages (RAW264.7) and fibroblasts (NRK49F). **Results** In UUO, a strong infiltration of macrophages preceded an increase of α-SMA, typeIII collagen expression, and growth of lymphatics. VEGF-C, detected in tubules and mononuclear cells, gradually increased and peaked at Day 14. The kinetics and localization of VEGF-C were similar to those of TGF-β and the expression of these growth factors and lymphangiogenesis were linked with fibrosis rather than inflammation. Ten min after the administration of 3% Evansblue into the extended ureter, dye was excreted into the hilar lymphatics of the obstructed kidney. In vitro, VEGF-C expression was upregulated by TGF-β1 in HK-2, M-1 and RAW264.7, but not in NRK49F. Upregulation of VEGF-C was completely suppressed by TGF-β typeI receptor inhibitor. **Discussion** VEGF-C induction by TGF-β might be a key pathway that leads to lymphangiogenesis in fibrosis. Lymphatics might contribute to drain the urine from the dilated pelvis. **Conclusion** In tubulo-interstitial fibrosis of UUO, lymphangiogenesis develops in the tubulo-inerstitial fibrosis through TGF-β-VEGF-C pathway.

**Protein Kinase C Delta Inhibitor, Rottlerin, Blocks TGFβ-Stimulated Epithelial-Mesenchymal Transition in Renal Tubular Epithelial Cells** Xiaoying Liu, Constance Runyan, H. William Schnaper. *Division of Kidney Diseases, Department of Pediatrics, Feinberg School of Medicine, Northwestern University, Chicago, IL.*

TGFβ signaling plays an important and complex role in renal fibrogenesis. Our laboratory has studied how non-canonical signaling pathways interact with and modulate classical Smad signaling. Previously, we defined a role for protein kinase C delta (PKCδ) modulation of Smad3 signaling in TGFβ1-induced, human mesangial cell collagen expression. Here, we investigated a role for PKCδ in renal epithelial cell fibrogenesis, examining its effect on TGFβ-stimulated phenotypic changes associated with epithelial-mesenchymal transition (EMT). We characterized EMT in our cells by increased collagen I and smooth muscle α-actin expression, and decreased E-cadherin expression. Treatment of a human kidney proximal tubular cell line (HKC) with rottlerin, a PKCδ-specific inhibitor, blocked the ability of TGFβ to induce these changes at both the RNA and protein level. Previous work from our lab has demonstrated an antagonism of EMT by Smad anchor for receptor activation (SARA), and determined that TGFβ-induced reduction in SARA expression is an important contributor to EMT progression. Here, we found that rottlerin inhibited the TGFβ-mediated decrease in SARA. However, rottlerin did not inhibit phosphorylation of Smad2 or Smad3 by TGFβ. Thus, rottlerin does not affect EMT-like changes by an effect on receptor-mediated Smad phosphorylation. Instead, our data suggest that PKCδ may play a role in TGFβ-stimulated EMT by regulating SARA expression.

**TH-PO690**

**SMAD3 Knockout Mice Are Protected Against Renal Damage in a 2-Kidney, 1-Clip Model of Renovascular Hypertension** Joseph P. Grande,[1,2] Gina M. Warner,[1] Bruce Knudsen,[1] Jingfei Cheng,[1] Justin E. Juskewitch,[1] Catherine Gray,[1] Lilach O. Lerman,[2] Stephen C. Textor,[2] Karl A. Nath,[2] Karen R. Lien.[1] *[1]Laboratory Medicine & Pathology, Mayo Clinic, Rochester, MN; [2]Nephrology, Mayo Clinic, Rochester, MN.*

The two-kidney, one-clip model of renovascular hypertension is associated with interstitial fibrosis and tubular atrophy (IF/TA) in the clipped kidney and compensatory hyperplasia in the contralateral kidney. We have previously demonstrated that the development of IF/TA in the clipped kidney is associated with a marked and persistent induction of TGF-β (Cheng J, et al. Am J Physiol Renal Physiol 2009; 297(4):F1055). Based on reports that TGF-β neutralizing antibodies reduce blood pressure in salt-sensitive rats (Dahly AJ, et al. Am J Physiol Regul Integr Comp Physiol 2002; 283(3):R757), we sought to test the hypothesis that abrogation of the TGF-β signaling pathway would prevent fibrosis/atrophy in the clipped kidney. Unilateral renal artery stenosis (RAS) was induced in mice with homozygous deletion of Smad3 (KO), a critical intermediate in TGF-β signaling, and colony-matched wild type (WT) controls with a fixed 0.2 mm (I.D.) polytetrafluoroethylene tubing. In WT mice, 8 of 11 developed IF/TA >10%. In KO mice, only 4 of 20 developed IF/TA. Mean external renal artery diameter in KO mice was greater (0.256 mm) than in WT

mice (0.247 mm; p=0.0013), indicating that the protective effect of the KO genotype was not due to a smaller renal artery diameter. All 11 WT mice developed hypertension (HTN, systolic blood pressure [BP] increase >20%); 10 of 20 KO mice developed HTN. Mean maximum postoperative BP was 140±4 in WT and 117±3 mmHg in KO mice; baseline BP 93±2 in WT and 96±2 mmHg in KO mice. In both WT and KO mice, the heart:body weight ratio was increased in RAS mice compared to sham/controls (WT RAS 6.71±0.13; WT sham/control 5.34±0.24; KO RAS 9.30±0.54, KO sham/control 6.42±0.58, p=0.0002). In WT, but not KO mice, heart:body weight ratio correlated with % atrophy (Pearson $R^2$=0.5206; p=0.0076). We conclude that KO mice are protected from the development of IF/TA through a mechanism only in part related to reduction in BP.

**Direct Targeting of TGF-β1 Preserves Peritoneal Membrane from Dialysis Fluid-Induced Damage** Abelardo I. Aguilera,[1] Jesus Loureiro,[1] Rafael Selgas,[4] Jose-Antonio Sanchez-Tomero,[2] Pilar Sandoval-Correa,[1] Patricia Albar-Vizcaino,[1] Mª Luisa Perez-Lozano,[1] Javier Dotor,[3] Francisco Borras-Cuesta,[3] Manuel Lopez-Cabrera.[1] *[1]Unidad de Biología Molecular, Hospital Universitario de la Princesa, Madrid, Spain; [2]Nephrology, Hospital Universitario de la Princesa, Madrid, Spain; [3]DIGNA Biotech, DIGNA Biotech, Madrid, Spain; [4]Nephrology, Hospital Universitario de la Paz, Madrid, Spain.*

Exposure to non-physiological solutions during peritoneal dialysis (PD) induces an epithelial-to-mesenchymal transition (EMT) of mesothelial cells (MCs), and this process is associated with peritoneal membrane (PM) damage. Transforming growth factor (TGF)-β1 is a well-characterized inducer of EMT and has been proposed, but not demonstrated, to be a master molecule in PD fluid-induced (PM) deterioration. Hence, we evaluated the efficacy of two TGF-β1 blocking peptides (P17 and P144) in modulating PD fluid-induced EMT of MCs and in ameliorating PM damage in a mouse PD model. Exposure of omentum-derived mesothelial cells to standard PD fluid induced a mesenchymal-like conversion of these cells, and treatment with P17 blocked the EMT process. Exposure of the mouse peritoneum to PD fluid induced fibrosis, angiogenesis, and functional impairment of the PM. PD fluid treatment also resulted in the loss of MCs monolayer and in the accumulation of trans-differentiated MCs in the compact zone (cytokeratin$^+$ cells), some of which also co-expressed "fibroblast specific protein-1" (FSP-1). Interestingly, PD fluid treatment provoked the appearance of CD31$^+$/FSP1$^+$ and CD45$^+$/FSP1$^+$ cells, indicating that activated fibroblasts may also originate from endothelial cells by endothelial to mesenchymal transition (EndMT) and from cells recruited from the bone marrow (fibrocytes). The administration of peptides P17 and P144 preserved the MCs monolayer, reduced fibrosis and angiogenesis, and improved peritoneal function. In addition, the blocking peptides markedly decreased the number of activated fibroblasts (FSP1$^+$ cells) in the compact zone, being most evident the reduction of fibroblasts derived from MCs via EMT (Cyt$^+$/FSP1$^+$). TGF-β has a central role in PD fluid-induced PM structural and functional alteration.

## TH-PO692

**Secreted Klotho Protein Counteracts Renal Fibrosis through Inhibiting TGF-b1 Signaling** Shigehiro Doi,[1,2] Noriaki Yorioka,[3] Makoto Kuroo.[2] *[1]Neprology, Hiroshima-nishi Medical Center, Ohtake, Japan; [2]Pathology, University of Texas Southwestern Medical Center, Dallas, TX; [3]Advenced Nephrology, Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan.*

The *klotho* was identified as an "aging-suppressor" in mice. Therefore, we hypothesize that Klotho may function as a renoprotective factor. To test this hypothesis, we asked if recombinant secreted Klotho protein (rKL) might mitigate renal fibrosis induced in 129S1/SvImJ mice by unilateral ureteral obstruction (UUO). These mice were treated with rKL (0.01 or 0.02 mg/kg, every other day) or vehicle by intraperitoneal injection. On Day 3 and 7, the mice were subjected to magnetic resonance imaging (MRI) and then sacrificed to harvest kidneys for histological, mRNA, and protein analysis. Results were as follows: 1) UUO induced significant down-regulation of endogenous Klotho expression. 2) MRI and histological analysis confirmed that rKL treatment alleviated renal fibrosis induced by UUO. 3) rKL treatment suppressed expression of fibrosis markers (α-Smooth muscle actin (SMA), Vimentin, Collagen-1, Metalloproteases) and TGF-b1 target genes (Snail, Twist) in a dose dependent manner. 4) However, rKL treatment did not reduce TGF-b1 expression in UUO kidney. These observations indicate that A) decrease in endogenous Klotho expression contributes to pathogenesis of renal fibrosis and that B) rKL may not reduce TGF-b1 production but inhibit TGF-b1 signaling. In fact, we confirmed that rKL inhibited TGF-b1-induced phosphorylation of Smad2 and production of SMA and Vimentin in a rat tubular epithelial cell line (NRK52E) *in vitro*. This is a newly identified function of Klotho. Considering that injection of a neutralizing TGF-b1 antibody (1D11) alleviated renal fibrosis induced by UUO, the anti-fibrosis property of rKL may stem from its ability to inhibit TGF-b1 signaling. In fact, we confirmed that the effect of combination therapy (1D11 and rKL) on renal fibrosis was comparable to that of individual therapy (1D11 alone or rKL alone), suggesting that 1D11 and rKL acted through the same mechanism. In conclusion, rKL prevents renal fibrosis primarily through inhibiting TGF-b1 signaling.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO693

**Effect of Statin on Klotho, Anti-Aging Gene, Expression in Cyclosporine A-Treated Mice Kidney: The Possible Mechanism of Anti-Aging Effect of Statin** Ji-Hyun Song,[1] Jungyeon Ghee,[1] ShangGuo Piao,[1] Sol Kim,[2] Chul Woo Yang.[1] *[1]Transplant Research Center, The Catholic University of Korea, Seoul, Republic of Korea; [2]Department of Bioengineering, University of Pennsylvania, Philadelphia.*

**Background:** We reported that statin has a protective effect against chronic cyclosporine A (CsA)-induced nephropathy, but its effect on aging process is still undermined in kidney. This study was performed to investigate the influence of statin on aging process using KLOTHO, angi-aging, expression in experimental model of chronic CsA nephropathy.

**Methods:** Two separate studies were conducted with rats. First, dose-dependent effect of pravastatin (PRVT) on Klotho expression was evaluated (5, 10, 20 and 40 mg/kg). Second, the effect of PRVT on KLOTHO expression was evaluated with an experimental model of chronic CsA nephropathy. Mouse were put on a low-salt diet (0.01% sodium) and categorized into four groups—vehicle (olive oil; 1 ml/kg sc), CsA (30 mg/kg sc), PRVT (10 or 20mg/kg in the drinking water), and a combination of CsA and pravastatin. The drugs were injected daily for one week or four weeks. Development of nephrotoxicity caused by CsA was evaluated with renal function and tubulointerstitial fibrosis. The expression of Klotho protein and mRNA were also compared among different treatment groups. Anti-inflammatory effects of PRVT were studied by evaluating the concentrations of C-reactive protein.

**Results:** PRVT treatment increased Klotho mRNA and protein in normal mouse kidney in a dose-dependent manner. In the second study, mouse receiving PRVT treatment displayed significantly improved renal function and histopathology than those treated with CsA. CsA treatment (26.7±3.3%) significantly decreased the expression of renal Klotho protein and mRNA compared to VH (100±1.6%) or those that solely received PRVT (110.4±1.9%) treatment. However, concurrent treatment of CsA with PRVT (36.6±3.9%) reversed the increase in Klotho expression with histological improvement. This finding was more marked in long-term high dosage than short-term low dosage. **Conclusions:** Statin treatment may inhibit the acceleration of aging process by upregulating KLOTHO expression in chronic CsA nephropathy.

## TH-PO694

**Regulation of Podocyte Function by B7-1** Chih-Chuan Yu,[1] Teruo Hidaka,[1] Dony Maiguel,[2] Hafeez Faridi,[2] Vineet Gupta,[2] Peter H. Mundel.[1] *[1]Division of Molecular Medicine, University of Miami, Miami, FL; [2]Division of Nephrology, University of Miami, Miami, FL.*

B7-1 (CD80), is a transmembrane protein of B cells and other antigen presenting cells, originally identified as a regulator of T cell activation and tolerance through binding to CD28 or CTLA-4 on T cells. We previously reported that under pathologic conditions characterized by FP effacement and proteinuria, podocytes express B7-1. The clinical significance of these results was underscored by the observation that podocyte B7-1 expression correlates with the severity of human lupus nephritis. These findings unveiled an unanticipated role for B7-1 in kidney podocytes as an inducible modifier of glomerular permselectivity, but the precise mechanisms for the regulation of B7-1 remain unknown.

Here we show that B7-1 can bind to integrin beta1 via cytoplasmic tail-tail interaction. This interaction is physiologically relevant because it suppresses beta1 activation and signaling by blocking the binding of talin to the cytoplasmic domain of beta1. Overexpression of B7-1 in wild type podocytes is sufficient to increase cell motility. Moreover, in vivo overexpression of B7-1 in mice is sufficient to suppress beta1 activation in kidney podocytes, thereby causing proteinuria. These results uncover a mechanism for the regulation of integrin activation by B7-1. This novel function of B7-1 is distinct from its role in T cell signaling: B7-1 does not act through CD28 or CTLA-4, but instead regulates cell matrix receptor function in a cell-autonomous fashion. Inhibition of B7-1 function in podocytes may be a new anti-proteinuric treatment option.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO695

**Collagen Receptor Signaling in Podocytes of COL4A3 -/- Mice with Renal Fibrosis** Diana Rubel, Gerhard A. Mueller, Oliver Gross. *Nephrology & Rheumatology, University Medical Center Goettingen, Goettingen, Germany.*

Introduction: Podocytes are the major source of the α3/4/5 (IV) chains in the glomerular basement membrane (GBM). COL4A3 -/- mice develop renal fibrosis due to the missing α3/4/5 type IV collagen chains. For that reason, we investigate the interaction between the GBM and podocytes via their collagen receptors DDR1 (discoidin domain receptor 1) and ITGA2 (Integrin α2) by comparing podocytes of wildtype mice to COL4A3-, DDR1- and ITGA2-knockout mice.

Methods: Glomeruli were isolated via perfusion with magnetic beads. TGF-β and TGF-β receptor expression was determined by quantification of PCR products in relation to housekeeping genes.

Results: After magnetic separation, cultured podocytes of the precipitated glomeruli showed a different TGF-β- and TGF-β receptor expression compared to tubular cells in the cultured supernatant . Expression of TGF-β and its receptor correlated to each other. After type I collagen stimulation, mimicking abnormal GBM composition, podocytes of wildtype and ITGA2 -/- mice did not respond with a clear rise of TGF-β production.

Further, TGF-β production was even decreased in podocytes of DDR1 -/- mice after type I collagen stimulation. In contrast, type I collagen stimulation of the tubular cells in the cultured supernatant lead to a major increase of TGF-β production.

Conclusions: Podocytes sense an incorrect GBM-composition via both collagen receptors, ITGA2 and DDR1, but do not respond on this by TGF-β overexpression. Further studies will focus on the intracellular downstream pathways in podocytes of COL4A3 -/- mice with their modified collagen receptor signal transduction.

**The Uremic Retention Solute p-Cresol/p-Cresyl-Sulfate Induce Insulin Resistance in C2C12 Muscle Cells and in Mice** Laetitia Koppe,[1,2] Denis Fouque.[1,2] *[1]Service de Néphrologie, Hôpital E Herriot, Lyon, France; [2]U870 INSERM/INSA-Lyon, Régulations Métaboliques Nutrition et Diabètes, Villeurbanne, France.*

Introduction: Uremic toxins retained in uremia might contribute to increased cardiovascular risk in chronic kidney disease (CKD). CKD results in multiple metabolic disturbance (dyslipidemia, insulin resistance). Over the last years, p-cresol has been identified as one of the main uremic toxins involved in the pathogenesis of accelerated atherosclerosis in CKD. Free concentrations of p-cresol and its main metabolite p-cresyl sulfate, are independent predictors of mortality. The purpose of this study was to evaluate the putative role of p-cresol/p-cresyl sulfate in insulin resistance and metabolic complications associated with CKD.

Methods:Mouse C2C12 myotubes were stimulated with insulin in the presence or absence of p-cresol or p-cresyl sulfate (40 µg/ml) for 30 min. The glucose uptake was measured by the technique of tritiated 2-deoxy-glucose. The phosphorylation of key proteins from the insulin signaling pathway (PKB/AKT and IRS-1) was studied by Western blot. Mice were treated for 3 weeks with p-cresol (10 mg/kg intra peritoneal, twice daily) or vehicle. The insulin sensitivity was estimated by intra-peritoneal insulin tolerance test. The different compartments of white adipose tissue were dissected out, weighed and cellularity was analyzed by Coulter Counter.

Results: The p-cresol/p-cresyl sulfate inhibited insulin-stimulated glucose uptake ($p < 0.005$) and impaired serin phosphorylation of PKB/Akt ($p < 0.05$) and tyrosin phosphorylation of IRS-1, ($p<0.05$). The mice p-cresol showed a marked decrease in insulin sensitivity and exhibited a significant decrease in white adipose tissue accretion (-51%, $p< 0.05$) associated with hypercholesterolemia (27%, $p< 0.05$) and increased muscle (+46,9 % , $p <0,05$) and liver (+21%, $P <0.05$) lipid contents compared to controls.

Discussion: These results suggest that p-cresol/p-cresyl sulfate could contribute to the metabolic disturbances observed in CKD and interfere with insulin signaling pathways. The decrease in white adipose tissue accretion, high cholesterol and the ectopic lipid deposits suggest a possible role of lipotoxicity.

**Differential Proteoglycan and Growth Factor Profiles in Experimental Chronic Renal Transplant Dysfunction** Kirankumar Katta,[1] Miriam Boersema,[2] Heleen Rienstra,[3] Johanna Wam Celie,[5] Gerjan Navis,[1] Jan-Luuk Hillebrands,[4] Jacob Van den Born.[1] *[1]Nephrology, UMCG; [2]Medical Biology, UMCG; [3]Cell Biology, UMCG; [4]Pathology, University Medical Center Groningen (UMCG), Netherlands; [5]Pathology, Academic Med Center, Amsterdam, Netherlands.*

Chronic transplant dysfunction (CTD) results from multifactorial progressive tissue remodelling. Proteoglycans (PG) play a role in tissue remodelling by binding and presenting adhesion molecules, chemokines and growth factors. In this study, we investigated spatial mRNA and protein expression levels of various PG and heparin-binding growth factors in tubulointerstitium (TI), glomeruli, and neointimas (NI) in rat renal allografts with CTD.

Kidneys of Dark Agouti (DA) to Wistar Furth allografts with CTD (n=5), of DA to DA isografts (n=5) and of non-transplanted DA (n=5) were used for immunohistochemistry. Glomeruli, TI and NI were isolated by laser dissection microscopy. mRNA expressions were analyzed by low density qPCR array. Proliferation assays were done with rat mesangial and human renal epithelial cells (HK2).

The following observations were done in the allografts compared to isografts and control kidneys. i) In glomeruli, TI and NI we observed uniform upregulation of *CCL2*, *TGF*-β and *Coll IV*, and downregulation of *BMP7*. ii) Matrix PG perlecan was significantly upregulated both on mRNA and protein level in glomeruli and NI, whereas syndecan-1, a cell membrane PG was upregulated in the TI and NI. iii) In glomeruli and NI, FGF2 was abundantly present on protein level, probably secondary to platelet degranulation, evidenced by CD61 (integrin beta3) positivity. HB-EGF was prominently expressed at the basal side of tubular cells. Functional significances of these findings were shown *in vitro* where we showed the FGF2-induced proliferative response of rat mesangial cells to be fully dependent on intact PG. Moreover knock-down of syndecan-1 in HK2 cells downregulates their proliferation.

These data indicate that in CTD differential PG and growth factor expression profiles contribute to tissue remodelling in different intrarenal compartments. Our results pave the way to the use of heparin-like glycomimetica to limit CTD.

## TH-PO698

**Alpha1 Antitrypsin Polymers Prime Neutrophils and Are Proinflammatory** Hannah L. Morris,[1] Alice Wood,[1] Matthew David Morgan,[1] Stuart W. Smith,[1] Elena Miranda,[2] Ugo I. Ekeowa,[3] Anne Bevins,[1] Alexander J. Howie,[5] Julie M. Williams,[1] Robert A. Stockley,[4] David Lomas,[3] Caroline O. S. Savage,[1] Lorraine Harper.[1] *[1]University of Birmingham; [2]Universita' "La Sapienza"; [3]University of Cambridge; [4]University Hospitals Birmingham; [5]University College London.*

Alpha1 anti-trypsin (A1AT) is an inhibitor of serine proteases which are inflammatory mediators in ANCA vasculitis (AAV). The A1AT gene Z allele produces a protein that forms intra-hepatic and circulating polymers. It is reported to increase the risk and severity of AAV. We investigated the prevalence of Z alleles in patients with AAV and whether A1AT polymers are pro-inflammatory by priming ANCA induced neutrophil responses.

A cohort of 919 AAV patients and 1141 disease controls were screened for A1AT SNPs. Serum polymer concentrations were measured by ELISA. Neutrophils (PMN) were primed with either A1AT polymer or monomer (0.2mg/ml) and activated with either normal or ANCA containing IgG. Degranulation (MPO assay), CD62L shedding (flow cytometry) and superoxide release assays assessed activation. Immunohistochemistry (IHC) staining for polymers in the renal biopsy of a patient carrying the Z allele was performed.

Patients were more likely to have the Z but not the S allele than controls, table1. AAV patients with 1 or more Z allele had higher serum concentrations of A1AT polymer (0, 1 or 2 Z alleles 0.2, 1.3 and 7.4 mcg/ml respectively $p<0.001$). Compared to unprimed neutrophils A1AT polymer (but not monomer) priming caused CD62L shedding (MFI 132 vs 109 $p=0.046$). A1AT polymer (but not monomer) primed PMN for ANCA stimulated superoxide production (1.1 vs 3.7 nmol $SO/10^5$ PMN $p=0.013$) but not PMN degranulation. A1AT polymers were detected in glomeruli by IHC.

Table 1

| | CONTROL | PATIENT | TOTAL |
|---|---|---|---|
| M | 2149 | 1707 | 4856 |
| S | 80 | 73 | 153 |
| Z | 53 | 78 | 131 |
| TOTAL | 2282 | 1838 | 4140 |

$X=12.46$ 2 Degrees Freedom $P=0.002$

Carriage of the Z allele is increased in AAV. A1AT polymers have a direct pro-inflammatory effect in AAV by priming PMN for subsequent ANCA activation and are present at sites of inflammation.

## TH-PO699

**Adenosine 2a Receptor (A2aR) Regulates Dendritic Cell (DC)-Natural Killer T Cell (NKT) Immunological Synapse: A Cell-Based Strategy To Protect Kidneys from Ischemia-Reperfusion Injury (IRI)** Li Li, Liping Huang, Hong Ye, Mark D. Okusa. *Division of Nephrology, Department of Medicine, University of Virginia, Charlottesville, VA.*

Kidney resident DCs activate CD1d-restricted NKT cells to mediate damage in kidney IRI. Endogenous adenosine accumulates in the kidney following IRI and terminates an overactive immune response through A2aRs expressed on bone marrow-derived cells.We hypothesize that A2aR agonists (ATL313) protect kidneys from IRI by suppressing NKT cell activation by regulating the expression of co-stimulatory molecule on DCs and/or the production of cytokines by DCs. Both kidney pedicles were clamped in B6 mice for 28 min or 24 min (mild ischemia) and then released for 24 hrs. FACS, ELISA and plasma creatinine (PCr) measurement were performed. In vivo ATL313 (1ng/kg/min) significantly decreased migration of $Gr\text{-}1^+IFN\text{-}g^+$ neutrophils and NKT cells to the inflamed kidney compared with vehicle control IRI mice ($P<0.05$). Adoptive transfer of a-galactosylceramide loaded BMDCs (DC-aGalCer, 0.1ng/mL) significantly increased kidney mild IRI with higher PCr, more neutrophil infiltration and kidney IFN-g production compared with vehicle-loaded BMDC control ($P<0.01$); DC-aGalCer-promoted injury in WT mice was not apparent in NKT cell-deficient (CD1dKO and Ja18KO) and IFN-gKO mice ($P>0.05$). Furthermore, prior to adoptive transfer, ex vivo treatment of WT but not A2aRKO DC-aGalCer with ATL313 (1nM) (ATL313-DC-aGalCer) protected kidney from IRI and lowered PCr ($P<0.01$), neutrophil migration and plasma IFN-g secretion ($P<0.01$). In vitro studies demonstrated that prior treatment with ATL313 attenuated WT but not A2aR KO DC-aGalCer activation of NKT cells ($P<0.05$). Attenuation of NKT activation by ATL313-DC-aGalCer was not due to blocking CD1d/glycolipid trafficking. However, ATL313 significantly suppressed LPS (0.01ng/mL)-mediated DC IA, CD40 and CD86 expression, IL-6, IL-1b and IL-12p40 secretion and increased negative co-stimulatory molecules B7-H1 and B7-DC expression ($P<0.05$). We conclude that specific targeting of DC function ex vivo by A2aR activation is a unique and potent cell-based strategy to attenuate IRI by blocking DC-NKT cell immunological synapse.

**B Cell Subsets Contribute to Both Renal Injury and Renal Protection after Ischemia/Reperfusion** Joshua M. Thurman,[1] Brandon Renner,[1] Derek Strassheim,[1] Liudmila Kulik,[1] Danica Ljubanovic,[3] Magdalena Glogowska,[1] Kazue Takahashi,[2] V. Michael Holers.[1] *[1]Medicine, University of Colorado School of Medicine, Aurora, CO; [2]Developmental Immunology, Massachusetts General Hospital, Boston, MA; [3]Pathology, University Hospital Dubrava, Zagreb, Croatia.*

Ischemia/reperfusion (I/R) triggers a robust inflammatory response within the kidney. We sought to identify whether natural antibodies bind to the post-ischemic kidney and activate the complement system after I/R. We depleted peritoneal B cells in 8-10 week-old mice by hypotonic shock. Then, peritoneal B cell depleted mice or control (PBS injected) mice were subjected to 24 minutes of bilateral renal ischemia. Depletion of the B cells prevented the deposition of IgM within the glomeruli after renal I/R, although the level of circulating IgM as measured by ELISA was unaffected by this treatment. Peritoneal B cell depletion also attenuated renal injury after I/R (BUN 116 +/-13 mg/dL versus 146 +/- 4 in control mice, n=5, $P < 0.05$). We found that glomerular IgM activates the classical pathway of complement but does not cause substantial deposition of C3 within the kidney. We also subjected mice deficient in all mature B cells (μMT mice) to renal I/R and found that they sustained worse renal injury than wild-type controls (BUN 135 +/- 18 versus 80 +/- 11 in control mice, $n = 12$, $P < 0.05$). A subpopulation of splenic B cells (sometimes referred to as B regs) has been demonstrated to limit injury in autoimmune disease through the production of IL-10. Therefore, we measured the level if IL-10 in the B cell deficient and wild-type mice. The serum IL-10 level was 81 +/- 37 in wild-type mice after I/R, but was undetectable in the μMT mice ($n = 7$-8 mice per group, $P < 0.05$). Regarded together, these results indicate that natural antibody produced by peritoneal B cells binds within the glomerulus after renal I/R and contributes to functional renal injury. However, non-peritoneal B cells attenuate renal injury after I/R, possibly through the production of IL-10. Given the increasing use of B cell depleting therapies in patients with renal disease, a full understanding of the role of B cells in disease is critical.

**Deoxycorticosterone-Salt Induces Th17 Differentiation and Downregulation of FoxP3 in the Kidney** Juan Pedro Peña Mendez, Cristian A. Amador, Magdalena Gonzalez, Fabiola Venegas, Luis F. Michea. *ICBM, Facultad de Medicina, Universidad de Chile, Santiago, Chile.*

Aldosteronism causes hypertension and an inflammatory phenotype in heart and kidney. Recent findings have implicated the Interleukin-17 (IL-17) pathway as a pathogenic mechanism in cardiovascular disease. Studies of autoimmune disease have demonstrated that regulatory T cells express the transcription factor Forkhead Box P3 (FoxP3) and antagonize Th17 differentiation. Recently, we showed the ability of aldosterone to promote autoimmune damage by enhancing Th17-mediated immunity. We hypothesized that aldosteronism-dependent hypertension induces activation of Th17 and downregulation of FoxP3. Three groups of uninephrectomized rats were studied (n=4, 8 and 16 days): Vehicle, DOCA-salt (0.5mg/0.1kg + 0.9% NaCl/0.3% KCl in drinking water), and DOCA-salt+spironolactone (50 mg/kg/d, SPIRO). The DOCA-salt treatment increased systolic blood pressure, starting at day 4 (152mmHg vs. vehicle 116 ± 7.1mmHg, $p<0.05$). Changes in blood pressure were prevented by SPIRO. The kidney of DOCA-salt rats presented increased abundance of TGF-β1 mRNA, a Th17 differentiation cytokine, at day 8; mRNA transcripts of cytokines secreted by Th17 cells (IL-17, p19 subunit of IL-23, and IL-1β) increased after 16 days of treatment (IL-17; 20 fold vs. control, IL-23; 3 fold vs. control and IL-1β; 3 fold vs. control, n=4; $p<0.05$). Protein expression of IL-17 was increased in kidney at day 16. Kidney sections showed glomerular infiltration of T CD4+ and Th17 lymphocytes (8 and 16 days). Contrasting with IL-17, the expression of FoxP3 decreased in the DOCA-salt group. All the above-mentioned changes caused by DOCA-salt were prevented by SPIRO. The analysis of peripheral blood mononuclear cells showed Th17 induction at 8 days. The upregulation of IL-17 in PBMC was also prevented by the treatment with SPIRO. Interestingly, after 16 days, we did not observe activation of IL-17 in PBMC. These results suggest that the inflammatory renal phenotype caused by DOCA-salt also implicates the downregulation of FoxP3. **Bardoxolone Methyl (BARD) Activates the Antioxidant Keap1-Nrf2 Pathway and Increases Glutathione Levels in Cultured Cells** Ron Bumeister, Greg Miller, Rhesa D. Stidham, Pritam Kambuj, Deborah A. Ferguson, Christian Wigley. *Reata Pharmaceuticals, Inc., Irving, TX.*

Stimulation of pro-inflammatory signaling pathways by hyperglycemia and activation of the renin-angiotensin system (RAS) induces renal oxidative stress, leading to the development and progression of chronic kidney disease (CKD), which frequently progresses to end-stage renal disease. Bardoxolone methyl (BARD), the lead molecule from the Antioxidant Inflammation Modulator (AIM) drug class, is a highly potent inducer of Nrf2, a transcription factor that positively regulates a battery of antioxidant and detoxification genes. Importantly, BARD exhibits significant tissue protective effects in several models of renal damage *in vivo*. Upon activation, Nrf2 promotes transcription of a series of enzymes and transporters important for the production and maintenance of appropriate levels of glutathione, a sulfhydryl buffer that plays a central role in detoxification of various proinflammatory reactive oxygen species (ROS). To ascertain whether BARD treatment results in enhanced cellular antioxidant capacity, cell lines derived from various tissues including renal proximal tubule epithelial (NRK-52E and OK), podocyte (AB8/13), mesangial (RMC, MES13, and nHMC), and glomerular endothelial (ciGENc) cells were treated with BARD and evaluated for induction of Nrf2 and total glutathione levels. Relative transcription levels of Nrf2 target genes (including *NQO1, TXNRD1, and HO-1*) were monitored by qPCR, and total cellular glutathione was measured by chemiluminescence. In all cell lines tested, BARD induced the expression of Nrf2 target genes at concentrations as low as 10 nM. Consistent with a critical role for Nrf2 in regulating glutathione antioxidant capacity, treatment with BARD increased glutathione levels in a time- and dose-dependent manner. Significant elevations in glutathione were observed at concentrations as low as 25 nM. The results of this study strongly support the use of BARD in renal indications where oxidative stress and inflammation play a central role in the progression of the disease. A 12-month placebo-controlled, pivotal Phase 2b clinical trial in CKD patients with type 2 diabetes is underway.

**TH-PO703**

**Combination Therapy with CCR2 Antagonist and Angiotensin II Type 1 Receptor Blocker Markedly Ameliorates Crescentic Glomerulonephritis** Maki Urushihara, Naro Ohashi, Kayoko Miyata, Masumi Kamiyama, Ryousuke Satou, Hiroyuki Kobori. *Department of Physiology, Tulane University Health Sciences Center, New Orleans, LA.*

Monocyte chemoattractant protein-1 (MCP-1) plays a critical role in the development of anti-glomerular basement membrane (GBM) nephritis, and inhibition of the MCP-1/CC chemokine receptor 2 (CCR2) pathway is currently used for treatment of anti-GBM nephritis. We recently showed that angiotensin (Ang) II infusion in rats activated MCP-1 and transforming growth factor-β1 (TGF-β1), which in turn induced macrophage infiltration of renal tissues. Here we examined whether combination therapy with a CCR2 antagonist (CA, RS102895) and an AngII type 1 receptor (AT1) blocker (ARB, olmesartan) ameliorated renal injury in the anti-GBM nephritis model via suppression of TGF-β1 activation by ARB, leading to more effective CCR2 inhibition. Anti-GBM nephritis rat model was introduced by single injection of anti-GBM antibody and developed progressive proteinuria and glomerular crescent formation, accompanied by increased macrophage infiltration and glomerular expression of MCP-1, angiotensinogen, AngII, AT1, TGF-β1 and type 1 collagen. Treatment with CA or ARB alone moderately ameliorated renal injury; however, combined treatment with CA and ARB dramatically prevented proteinuria and markedly reduced glomerular crescent. The combination treatment suppressed the induction of macrophage infiltration, angiotensinogen, AngII, AT1 and TGF-β1, and reversed the fibrotic change in the glomeruli. Primary cultured glomerular mesangial cells stimulated by AngII showed significant increases of MCP-1 and TGF-β1 expression. Furthermore, co-cultured model consisting glomerular mesangial cells, parietal epithelial cells, and monocyte-derived macrophage showed an increase in AngII-induced cell proliferation and soluble collagen secretion. By the treatment with ARB, these augmentations were attenuated. These data suggest that AngII enhances glomerular crescent formation of anti-GBM nephritis. Moreover, our results demonstrate that inhibition of MCP-1/CCR2 pathway with combination of ARB effectively prevents renal injury in anti-GBM nephritis.

**TH-PO704**

**Suppression of Adiponectin Secretion by Aberrantly Glycosylated IgA1 in Glomerular Mesangial and Endothelial Cells: A Possible Mechanism of Anti-Inflammation in IgA Nephropathy** Hitoshi Sugiyama, Tatsuyuki Inoue, Masashi Kitagawa, Hiroshi Morinaga, Keiichi Takiue, Shinji Kitamura, Yohei Maeshima, Hirofumi Makino. *Department of Medicine and Clinical Science, Okayama Univ. Grad. Sch. of Med., Okayama, Japan.*

The pathogenesis of IgA nephropathy (IgAN) is thought to be the mesangial deposition of aberrantly glycosylated IgA1 with reduced galactose and/or sialic acid. The effect of desialylated and degalactosylated (deSial/deGal) IgA1 on human mesangial cells (HMC) and human glomerular endothelial cells (hGEC) is largely unknown. We generated deSial/deGal IgA1 and investigated its effect on HMC and hGEC. DeSial/deGal IgA1 was produced by treatment to human IgA with neuraminidase and β-galactosidase. The state of deglycosylation was confirmed by the lectin bindings to *Herix aspersa* and Sambucus Nigra Agglutinin. Cultured HMC or hGEC were stimulated with native IgA or deSial/deGal IgA1 (50 μg/ml) for 48 hr and then culture supernatant was analyzed using cytokine array to detect expression levels of 507 proteins. The protein and mRNA levels were examined by ELISA and real-time PCR, respectively. Stimulation with native IgA increased the intensity of spots corresponding to adiponectin which was significantly suppressed by stimulation with deSial/deGal IgA1 in cultured HMC and hGEC. Concentration of total and high molecular weight adiponectin in culture supernatant significantly elevated after stimulation with native IgA in dose- and time-dependent manners. However, there was no significant increase in either total or high molecular weight adiponectin after incubation with deSial/deGal IgA1 up to 48 hr. Adiponectin mRNA levels were similar in HMC and hGEC after stimulation with native and deSial/deGal IgA1. The HMC and hGEC expressed mRNA of adiponectin receptor type 1 but not type 2. Our results demonstrate that adiponectin is synthesized by cultured

HMC and hGEC, and deSial/deGal IgA1 suppresses the secretion of adiponectin. The data suggest that the local suppression of the adipokine by aberrantly glycosylated IgA1 could be involved in the regulation of glomerular inflammation and sclerosis.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO705

**MMP9 Deficiency Ameliorates Nephrotoxic Serum Nephritis by Impairing Macrophage Migration** Malte A. Kluger, Gunther Zahner, Melanie Schaper, Hans-Joachim Paust, Ulf Panzer, Rolf A. Stahl. *III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

**Background:** Matrix metalloproteinase 9 (MMP9) is involved in physiologic extracellular matrix turnover and tissue homeostasis, but has also been associated with a number of inflammatory and autoimmune diseases. In this study, we assessed its functional role in a T cell-dependent model of glomerulonephritis using MMP9 deficient mice ($MMP9^{-/-}$). **Methods:** $MMP9^{-/-}$ mice were backcrossed on a C57BL/6 background (microsatellite analysis). Nephrotoxic serum nephritis (NTN) was induced in 10-12 wk-old male wildtype (WT) and $MMP9^{-/-}$ mice. Controls received nonspecific sheep IgG. Urine and blood were collected for determination of albuminuria (ELISA) and BUN at day 10. Kidneys were prepared for immunohistochemistry, RT-PCR or flow cytometry. Migratory capacity of peritonitis-elicited macrophages was assessed in a FACS-analyzed transwell chemotactic-assay. **Results:** In WT mice, induction of NTN caused a pronounced renal infiltration by monocytes and T cells followed by intense tissue injury, albuminuria and loss of renal function. These findings were attenuated in nephritic $MMP9^{-/-}$ mice. Kidney function was preserved and albuminuria was determined at significantly lower values. Histological damage was only mild. The numbers of infiltrating monocytes and T cells were dramatically reduced, though less extensive for the latter.

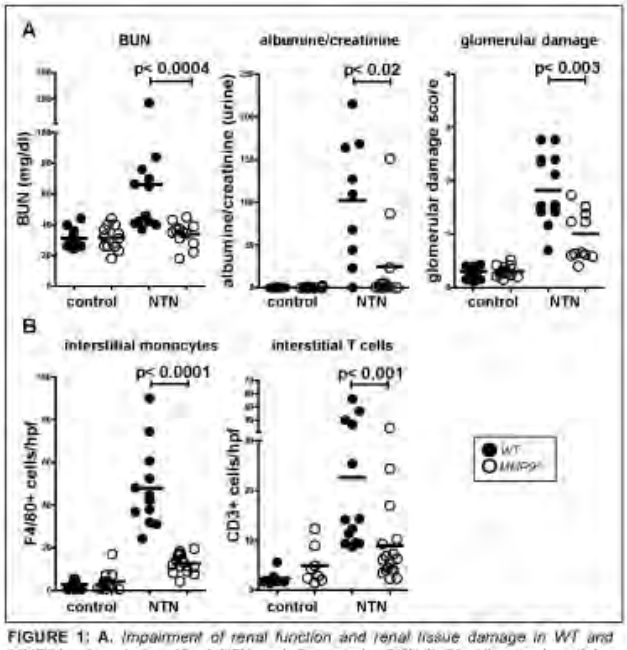

**FIGURE 1:** *A. Impairment of renal function and renal tissue damage in WT and $MMP9^{-/-}$ mice at day 10 of NTN or IgG controls. BUN* **(left)**, *albumine/creatinine* **(middle)** *and scoring of affected glomeruli in PAS-stained kidney sections* **(right)**. **B.** *Renal T cell and monocyte recruitment in WT and $MMP9^{-/-}$ mice at day 10 of NTN or IgG controls. F 4/80+ interstitial monocytes* **(left)** *and CD3+ interstitial T cells* **(right)**. *Symbols indicate individual data points, horizontal lines indicate mean values. Statistical analysis was performed using Mann-Whitney test*

These observations could be specified by flow cytometry, revealing a diminished influx of $CD45^+/F4/80^+/CD11b^+/CD11c^-$ cells into nephritic $MMP9^{-/-}$ kidneys. In a chemotactic assay, migratory capacity of $MMP9^{-/-}$ derived peritoneal macrophages, but not $T_H$ lymphocytes, was derogated when compared to WT. **Conclusions:** MMP9 deficiency ameliorates renal impairment during nephrotoxic nephritis in C57BL/6 mice by attenuating macrophage chemotaxis.

### TH-PO706

**Syk Blockade Inhibits Acute Platelet and Neutrophil Mediated Glomerular Injury** Jessica Ryan,[1,2] Frank Yuanfang Ma,[1,2] John Kanellis,[1,2] Kate Blease,[3] David J. Nikolic-Paterson.[1,2] *[1]Nephrology, Monash Medical Centre, Clayton, Victoria, Australia; [2]Medicine, Monash University, Clayton, Victoria, Australia; [3]Celgene, San Diego, CA.*

Glomerular antibody deposition can induce acute renal injury via Fcγ-receptor dependent activation of platelets and neutrophils. Fcγ-receptor signalling induces cytoskeletal reorganisation and pro-inflammatory responses via the spleen tyrosine kinase (Syk). Syk inhibitors can suppress macrophage-mediated renal injury, but whether Syk is also involved in platelet/neutrophil dependent glomerular injury is unknown. This study evaluated the ability of a selective Syk inhibitor (SYKi) to inhibit the acute neutrophil-dependent phase of glomerular injury in rat anti-GBM disease. SD rats were immunized with sheep IgG and 5 days later given sheep anti-rat GBM serum. Rats were treated with SYKi (10mg/kg/qid) or vehicle (Veh) from 1hr before anti-GBM serum until being killed 3 or 24hr later. At 24hr, heterologous phase glomerular injury was evident in Veh treated disease as shown by heavy proteinuria (227±79 vs 5±1mg/day normal; P<0.001), glomerular thrombosis evident on PAS sections, prominent capillary P-selectin staining of platelets, a macrophage and T cell infiltrate, and up-regulation of glomerular mRNA levels for the pro-inflammatory markers TNF-α, iNOS and MMP-12. In contrast, SYKi treatment at 24hr prevented proteinuria (19±20mg/day; P<0.001 vs Veh), prevented glomerular thrombosis, largely abrogated glomerular P-selectin staining, reduced glomerular macrophage and T cell infiltration (by 40% and 90%, respectively), and significantly reduced the up-regulation of mRNA levels of pro-inflammatory molecules. Furthermore, immunostaining of Veh treated rats at 3hr showed Syk phosphorylation which co-localised with the transient glomerular neutrophil influx seen at this time. SYKi largely prevented this transient neutrophil influx and abrogated p-Syk staining. In conclusion, Syk signalling is required for acute antibody and neutrophil-dependent glomerular injury. These findings support the therapeutic potential for Syk inhibitors in antibody-dependent forms of kidney disease.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO707

**Inflammation and Cytokines in Polycystic Kidney Disease** Kameswaran Ravichandran, Iram Zafar, Sarah Faubel, Zhibin He, Chris Altmann, Charles L. Edelstein. *Univ of Colorado.*

Inflammation may contribute to the progression of PKD. The aims of the study were to quantify the inflammation, measure cytokines in early and late stages of PKD. 8 wk old Han: SPRD rats (Cy/+) with early PKD, 1 yr old Cy/+ rats and 4wk old cpk mice with advanced PKD were studied. Inflammation was quantified as 0=absence of infiltrates; 1= focal, mild; 2=focal moderate; 3= diffuse mild; 4=diffuse moderate or severe. Cy/+ rats were treated with rapamycin (0.2 mg/kg/weekday) from 3-52 weeks of age. Cytokines were measured using 2-bead based multiplex cytokine kits with flow-based protein detection. Inflammation score was 0.7 in ++, 2.3 in 8wk old Cy/+ (P<0.05); 1.4 in ++ , 2.8 in 1yr old Cy/+ (P<0.05) and 2.6 in Cy/+R; 1.6 in +/+ and 2.2 in cpk (NS). Furthermore, kidney myeloperoxidase (MPO) activity an indicator of polymorphonuclear leucocyte infiltration was assessed . MPO activity was 0.032 in ++, 0.11 in Cy/+(P<0.05) and 0.033 in Cy/+R(P<0.05).Cytokines are shown in the table. In 4 wk old cpk mice the following cytokines were not changed; IFN-γ, RANTES, MIP-1, IL-6, IL-12, IL-9, IL-5, IL-2, TNF-α, IL-1, IL-10. In 8 wk old Cy/+ none of the cytokines were increased. In summary, inflammation and proinflammatory cytokines are increased in the later stages of PKD. Cytokine profiles differed between cpk mice and Cy/+ rats with advanced PKD. Impressive increases in MCP-1, G-CSF and KC in cpk mice and IL-1, IL-1and IL-6 in rats were seen. Rapamycin therapy reduced IL-1, IL-1, IL-6 and decreased MPO activity in 1yr old Cy/+ rats. In conclusion, cytokine inhibition e.g IL-1Ra (Anakiren) in PKD merits further study.

Cytokines profile in PKD kidneys

**PGE2 Promotes Cellular Recovery from Nephrotoxic Serum Nephritis (NTN) in Mice by a Direct Effect on Glomerular Cells** Nino Kvirkvelia, Maggie McMenamin, Kapil Chaudhary, Michael P. Madaio. *Medicine, Medical College of Georgia, Augusta, GA.*

Although many strategies have been shown to prevent immune-mediated nephritis, promoting recovery of established disease has been more difficult. We postulated that PGE2, a bioactive eicosanoid which exhibits multiple, tissue dependent regulatory functions to control immune-mediated inflammation, tissue repair and fibrosis, has the potential to improve the course of ongoing nephritis. To evaluate this hypothesis, the therapeutic potential and protective effect of exogenous PGE2 on established NTN in mice was evaluated along with its' cytoprotective effect on murine endothelial cells (GEC) and podocytes (POD). Initially, mice were injected with nephrotoxic serum (NTS), followed by PGE2 administration 5μg/g/d, started either on day 1, 2 or 3 after NTS dosing. Mice injected with PGE2 normalized BUN, Upr and histology. Benefit was optimal with dosing at day 1, although later treatment was effective. To determine whether the benefit was at least, in part, due to a protective effect of PGE2 on glomerular cells, the capacity of PGE2

to limit injury of cultured cells was evaluated. Thus, murine POD and GEC were pretreated with PGE2, 1-5µl/ml for 2-4h, and afterwards, NTS 5-10% was added for additional 7-12 h. The number of phosphatidyl serine and propidium iodide positive cells were assessed by FACS. PGE2 reduced NTS induced apoptosis of cultured POD and GEC up to 30%. Furthermore, when POD and GEC were subjected to NTS, and then treated with PGE2 (1-5µg/ml), cell numbers were increased (25-55%), indicating that PGE2 promoted cell regeneration after NTS induced injury. PGE2 also limited NTS induced GEC upregulation of CD47, an integrin associated protein; its' ligation in many cases leads to inhibition of cell proliferation and cell death. Altogether, the results indicate that PGE2 is candidate to further investigate its therapeutic potential to improve cellular recovery and improved function during the course of glomerulonephritis.

**Darbepoetin-α Suppresses TNF-α-Induced Endothelin-1 Production through Antioxidant Effect: Role of Sialic Acid Residues** Wonseok Yang, Su-Kil Park. *Internal Medicine, Asan Medical Center, College of Medicine, University of Ulsan, Seoul, Korea.*

Endothelin-1(ET-1) is implicated in the pathogenesis of atherosclerosis. We have previously demonstrated that, in cultured human aortic endothelial cells(HAECs), TNF-α stimulates ET-1 production through reactive oxygen species(ROS)-dependent c-Jun $NH_2$-terminal kinase(JNK) and ROS independent P38 mitogen-activated protein kinase that regulates activation of both AP-1 and NF-κB. This study was conducted to evaluate the effect of darbepoetin-α, a hypersialylated analogues of r-HuEPO, on TNF-α-induced ET-1 production in HAECs.

Darbepoetin-α (5,10, 50, 250ng/ml) attenuated TNF-a-induced ET-1 at mRNA and protein levels in ELISA and RT-PCR. This was accompanied by inhibition of TNF-a-induced DNA-binding activities of both NF-kB and AP-1 in electrophoretic mobility shift assay. Darbepoetin-α (250ng/ml) inhibited TNF-a-induced reactive oxygen species(ROS) generation which was visualized with confocal microscopy and activation of JNK, but not p38 MAPK in western blot. As with N-acetylcysteine and SP600125 (JNK inhibitor), darbepoetin-α did not inhibit either IkBa degradation or p65 nuclear translocation, but attenuated p65 phosphorylation at serine 276 in western blot. TNF-a increased phosphorylation of mitogen- and stress-activated protein kinase 1, the enzyme responsible for serine 276 phosphorylation of p65, while darbepoetin-α attenuated those response like N-acetylcysteine and SP600125. Desialation of darbepoetin-α by sialidase (5mU/ml, recombinant, *Arthrobacter ureafaciens* α2-3,6,8,9-neuraminidase expressed in *E. coli*) completely abolished its inhibitory effect on TNF-a-induced ROS generation and ET-1 mRNA expression. However, desialated darbepoetin-α still increased STAT5 in endothelial cells.

In conclusion, darbepoetin-α modulates TNF-a-induced intracellular signaling by its antioxidant effect. It suppressed TNF-a-induced ET-1 production through inhibition of ROS-dependent JNK activation. The high content of sialic acid in darbepoetin-α seems to be essential for its antioxidant effect by scavenging ROS. These results might suggest that darbepoetin-α could ameliorate the progression of atherosclerosis where ET-1 has a major role.

**Regulation of RAGE Via Paracrine Estrogens** Brooke E. Harcourt, Melinda T. Coughlan, Anna Gasser, Karly C. Sourris, Mark E. Cooper, Josephine M. Forbes. *Glycation and Diabetes Complications, BakerIDI Heart and Diabetes Research Institute, Melbourne, Victoria, Australia.*

Obesity is a major contributor to type 2 diabetic nephropathy. Additional risk factors are male gender and post-menopausal status in females. This suggests that the balance between estrone (E1) secreted from white adipose tissue and 17-ß-estradiol (E2), may be an important determinant of this disease. Previous studies have shown that the protection against cardiovascular disease afforded by higher levels of E2 in menstrual women is abrogated by obesity and that decreases in E2 levels are often associated with declining renal function in diabetes.

We examined the effects of peri-renal adipose tissue deposition on renal function in a mouse model of obesity; high fat feeding (HFF) for 16 weeks. We also studied mice with a genetic deficiency in RAGE (RAGE-/-). We identified that although all HFF mice had increases in central adiposity, obese RAGE-/- mice did not have an increase in their peri-renal fat depots compared to WT HFF mice. We also showed that in peri-renal adipose deposits RAGE-/- mice have a decreased E2/E1 ratio compared with control. Furthermore, WT HFF mice had a concomitant decline in kidney function that was not evident in obese RAGE-/- mice. Since renal cortical membrane RAGE expression was increased with HFF, we then examined modulatory factors using chromatin immuno-precipitation in renal corticies, which revealed that estrogen receptor ß (ER-ß) interacts with the RAGE promoter at binding sites for both NF-κB and Sp-1.

This study demonstrated protection against renal injury by the amelioration of local adipose tissue deposition, in this case, the peri-renal depot in HFF RAGE-/- mice, despite a lack of beneficial effects on either central obesity or glycaemic control. Importantly, it was evident that excesses of locally rather than systemically derived E1 via ligation to ER-ß, activated known pathways implicated in renal injury. Therefore, we suggest that the local paracrine environment may be of greater pathological relevance than systemic events in the development obesity related renal injury.

**Lipoxin A4 and a Related Synthetic Analog Suppress the Activation of Primary Dendritic Cells from Kidney and Spleen** Michelle Holland,[1] Shirley Hanley,[1] Jana Pindjakova,[1] Patrick Guiry,[3] Rhodri Ceredig,[1] Catherine Godson,[2] Matthew D. Griffin.[1] *[1]Regenerative Medicine Institute, College of Medicine, National University of Ireland Galway, Galway, Ireland; [2]Diabetes Research Centre, Conway Institute, University College Dublin, Dublin, Ireland; [3]School of Chemistry and Chemical Biology, University College Dublin, Dublin, Ireland.*

**Background and Aims:** Dendritic cells (DC) are abundant in the renal interstitium and modulate inflammatory responses to acute injury. Lipoxins (LX) are eicosanoids which aid resolution of inflammation via inhibition of neutrophils and monocyte/macrophages. LX effects on DC have been less well examined. In this study LX regulation of renal, splenic and bone marrow-derived DC was investigated. **Methods:** Primary DCs were prepared by anti-CD11c magnetic separation from collagenase-digested mouse spleen and kidney. BMDCs were prepared by 5-8 day culture of bone marrow cells with GM-CSF and IL-4. LXA4 and a synthetic LX analog (LX-analog) were added to DC cultures at final concentrations of 0.1-1000ng/ml. DC activation was induced by ligands for TLR4 (LPS), TLR2 (LTA) and CD40. DC responses and were measured by ELISA, multi-color flow cytometry and mixed lymphocyte reaction (MLR). **Results:** Pre-incubation of kidney and spleen DC with LXA4 for 6-12 hr resulted in blunting of IL-6 production in response to TLR ligands and reduced numbers of highly mature (CD80/CD86hi) DCs with maximal effect at 100ng/ml (~300nmol). LX-pre-treated splenic DC exhibited reduced T-cell stimulatory capacity in mixed lymphocyte cultures. Similar effects were observed for LX-analog at 10ng/ml. Culture of DC with LX-analog 5-10ng/ml for 6 hr was associated with strikingly increased apoptosis by AnnexinV/PI staining. Maturation of BMDCs in response to TLR ligands or CD40 ligation, assessed by surface expression of CD80, CD86, CD40 and CD54 and by IL-6 release was also potently inhibited by LX-analogue. **Conclusion:** LX and related synthetic analogs directly suppress DC innate and cognate immune functions and mediate pro-apoptotic effects at supra-physiological but therapeutically relevant concentrations *in vitro*. Inhibitory effects were observed for DC purified directly from kidney.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO712**

**Temporal and Spatial Expression of AT1 and AT2 Receptors in Pre- and Post-Natal Periods Determines Development of HIVAN in Mice with Variable Angiotensinogen (Agt) Copies** Ankita Sagar,[1] Divya Salhan,[1] Madhuri Adabala,[1] Ashwani Malhotra,[1] Praveen N. Chander,[2] Pravin C. Singhal.[1] *[1]Medicine, Long Island Jewish Medical Center, New Hyde Park, NY; [2]Pathology, New York Medical College, Valhalla, NY.*

Angiotensin (Ang) II has been demonstrated to play a role in the progression of HIVAN. In the present study, we evaluated the role of variable angiotensinogen (Agt) copies in the progression of renal lesions in Tg26 mice, a mouse model of HIVAN.

Tg26 mice with various copies of Agt (*Agt*-2, *Agt*-3, and *Agt*-4) were evaluated for expression of AT1 and AT2 receptors during embryogenesis (E13, E15, and E18) and after birth, on days 1 and 10 by immunohistochemical and *in situ* hybridization techniques, and confocal microscopy. In addition, mice were evaluated for severity of proteinuria, BUN, renal lesions, collagen deposition, blood pressure, arteriosclerosis, and renal tissue mRNA for PAI-1 at 4, 9, 12 and 16 weeks (n=5).

During embryogenesis and on days 1 and 10, renal cells showed greater expression of AT2 receptors when compared to AT1 receptors. Both tubular cells and podocytes showed temporal and spatial relationship between AT1 and AT2 receptors. Mice with 4 *Agt* copies showed lower blood pressure (BP, mean 110/80 mm Hg) at 4 and 8 wks vs. mice with two Agt copies (BP, mean 140/90 mm Hg). Four wks old mice with 4 *Agt* copies displayed attenuated expression of PAI-1 when compared to age-matched mice with 2 *Agt* copies; whereas, 16 wks old mice with 4 *Agt* copies showed 3-fold greater PAI-1 expression than mice with age-matched mice with 2 *Agt* copies ($P<0.01$). Nine weeks old *Agt*-2 mice developed renal lesions that were more severe than those seen in age-matched *Agt*-3 and *Agt*-4 mice. However, 16 wks old *Agt*-4 mice, displayed more advanced renal lesions when compared to *Agt*-2 mice.

We conclude that higher *Agt* copies in transgenic mice induce reno-protective effect during initiation of HIVAN; an effect that may be mediated through the temopro-spatial expression of AT1 and AT2 receptors during embryogenesis and post natal period. This protective effect however, dissipates at more advanced age possibly related to predominance of AT1 receptors.

Disclosure of Financial Relationships: nothing to disclose

**Role of PD-L1 and PD-1 Interaction in Tubular Cell-Cell HIV-1 Dynamism** Hersh Goel, Divya Salhan, Dileep Kumar, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Long Island Jewish Medical Center, New Hyde Park, NY.*

In renal biopsy studies of HIV-associated nephropathy (HIVAN), renal tubular cells have been reported to be infected by HIV-1. In addition, it has been suggested that tubular cells may be serving as a reservoir for HIV-1 infection. We previously reported that tubular cells had potential to transmit HIV-1 to T cells and facilitated replication of the transmitted HIV-1 in T cells (J. Am Soc. Nephrol. 18:780-787, 2007). In the present study, we examined whether interaction of PD-L1 (expressed by tubular cells) with its specific receptor PD-1

(expressed by normal as well as HIV-1 infected T cells) had potential to induce apoptosis/necrosis of infected T cells and thus, providing release of HIV-1 proteins and RNAs for ednocytosis by tubular cells.

Human tubular cells (HK2) were pulsed with HIV-1 (X4 HIV-$1_{92HT599}$) for two hours, followed by rescue of virus by tubular cells. One week later, HIV-1 infected or non- infected CD4+ ive T cells were incubated either with HK2 cells or 293T cells (negative for CD4 and PDL-1) for 48 hours. Subsequently, CD4+ ive T cells were assayed for proliferation and apoptosis by FACS analysis. In addition, HIV-1 proteins and RNAs were assayed in incubation media. Tubular cells probed for HIV-1 mRNA and protein expression.

The population of CD4+ ive T cells dropped significantly after interaction with HK-2 cells, and the effect was more pronounced in HIV-1-infected CD4+ ive T cells. Also, there was increased apoptosis in CD4+ ive T cells on interaction with HK2 indicating that the mechanism of depletion is via apoptosis, and is more significant in HIV-1 infected CD4+T cells. HIV-1 infected CD4+ ive T cells express higher level of PD-1, suggesting involvement of PD-1: PD-L1 pathway. Pretreatment of HK-2 cells with anti-PD-L1 antibody significantly reduced apoptosis on CD4 T cells. HK2 incubated with infected CD4 +ve cells also showed expression of HIV-1 proteins. Altogether, our results indicate that tubular cells may preferentially deplete CD4+ ive T cells especially those infected with HIV-1. Moreover, there may be bidirectional traffic of HIV-1 during interaction of tubular cells and CD4+ ive T cells.

## TH-PO714

**Discrete Regulation of VEGF-A and -C in Human Proximal Renal Tubular Cells under Hypoxic and/or Inflammatory Conditions – Inhibitory Effects of Glucocorticoids on Basal and Inducible VEGF Expression** Hideki Kimura,[1] Hidehiro Sugimoto,[2] Kazuko Kamiyama,[1] Daisuke Mikami,[1] Kenji Kasuno,[1] Naoki Takahashi,[1] Haruyoshi Yoshida.[1] *[1]Div of Nephrol, Dept of General Med, Fukui Univ, Fukui, Japan; [2]Dept of Clin Lab, Fukui Univ Hosp, Fukui, Japan.*

VEGF-A and C are a main inducer of angiogenesis and lymphangiogenesis which are closely involved in renal fibrosis status after renal injury. Although proximal renal tubular cells produce the two VEGFs and probably affect reconstitution of interstitial vessel networks in the injured kidney, the production alteration and its mechanism have not been fully clarified in the renal cells under hypoxia and/or inflammation and on glucocorticoid (GC) treatments as an essential remedy for severe nephritis.

Confluent human proximal renal tubular epithelial cells (HPTECs) were treated with TGF-β (1-5 ng/ml), TNF-α (10 ng/ml), high glucose (HG; 450mg/dl) and/or GC (0.1-1 μM) for up to 48 h under normoxic or hypoxic conditions. TGF-β and hypoxia induced VEGF-A production (2-3 fold and 1.5 fold) via p38 MAPK but not ERK pathway and Src family tyrosine kinase pathway, respectively, while TNF-α and HG had no influence on the production. In contrast, TNF-α and HG increased VEGF-C production (3 fold and 1.3 fold), while TGF-β and hypoxia did not change the production. Induction of VEGF-C by TNF-α was mediated largely via p38 MAPK pathway but not ERK or Src family pathway. Dexamethasone (DXA) did not affect hypoxia-inducible factor-1α amount and activity under hypoxia, nor did hypoxia influence on DXA-activated GC response element activity. Hydrocortisone (HC) and DXA down-regulated basal VEGF-A and -C production, independently and dependently of the GC receptor, respectively, without VEGF mRNA destabilization. Finally, GC also decreased hypoxia-induced VEGF-A production and TNF-α-induced VEGF-C production.

Theses results suggest that VEGF-A and -C are discretely regulated by hypoxia, inflammatory cytokines, and HG in HPTECs and that GCs suppress hypoxia- or inflammation–stimulated expression of the two factors, potentially leading in part to impairment of orderly neovascularization and ensuing tissue restoration after renal injury.

## TH-PO715

**Experimental Sepsis in Tamm-Horsfall Protein-Deficient Mice** Hajamohideen S. Raffi,[1] James M. Bates,[1] Zoltan G. Laszik,[2] Satish Kumar.[1] *[1]Medicine, University of Oklahoma HSC and VA Medical Center, Oklahoma City, OK; [2]Pathology, University of California San Francisco, San Francisco, CA.*

Tamm-Horsfall protein (THP) is the most abundant protein in normal urine. In previous studies, we generated THP gene knockout ($THP^{-/-}$) mice by homologous recombination and found them to be more susceptible to experimentally induced urinary tract infection. In this study, we examined the susceptibility of $THP^{-/-}$ mice to systemic sepsis.

Eight $THP^{+/+}$ and $THP^{-/-}$ mice were selected. Baseline urine and blood samples were collected. Sepsis was induced by the cecal ligation and puncture (CLP) method. The mice were euthanized at 24 hrs. The abdomen was opened. Urine was collected by needle aspiration from the bladder and blood by cardiac puncture. Bacteremia and bacteriuria were assessed by blood and urine cultures. Colony forming units (CFU) were counted and expressed as CFU/ml. Systemic response to sepsis was assessed by total and differential white blood cell count. Acute kidney injury was assessed by renal histology and by neutrophil gelatinase-associated lipocalin (NGAL) levels in plasma and urine. Proliferative activity in renal tubules was evaluated by quantitation of proliferating cell nuclear antigen (PCNA) expression. Renal function was assessed by serum cystatin C.

Plasma NGAL levels were lower ($THP^{+/+}$, 336 ng/ml ± 56 vs. $THP^{-/-}$, 171 ng/ml ± 23 p = 0.008) and serum cystatin C levels were higher ($THP^{+/+}$, 569 ng/ml ± 37 vs. $THP^{-/-}$, 667 ng/ml ± 36, p = 0.040) in $THP^{-/-}$ mice at baseline but similar between the two groups 24 hours after CLP. Plasma NGAL levels rose after CLP in both groups but the increase was higher in $THP^{-/-}$ mice ($THP^{+/+}$, 66 ± 93 vs. $THP^{-/-}$, 335 ± 109 p = 0.041). No significant difference were found between $THP^{-/-}$ and $THP^{+/+}$ mice in bacteremia, bacteriuria, blood white cell counts, renal histology, PCNA indices, and urine NGAL levels.

We conclude that absence of THP has minimal effect on the response to sepsis in mice.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO716

**The Role of IL-6 in Neutrophil Recruitment to Glomerular Endothelial and Epithelial Co-Cultures, a Model of the Glomerular Micro-Environment** Sahithi Josna Panchagnula,[1] Simon C. Satchell,[3] Moin Saleem,[3] Lorraine Harper,[1] Helen M. Mcgettrick,[2] Edward Rainger,[2] Samantha Tull,[1] Julie M. Williams,[1] Caroline O. S. Savage.[1] *[1]School of Immunity, Infection and Inflammation, University of Birmingham, Birmingham, United Kingdom; [2]School of Clinical and Experimental Medicine, University of Birmingham, Birmingham, United Kingdom; [3]Academic Renal Unit, Univeristy of Bristol, Bristol, United Kingdom.*

**Background:** We have examined the hypothesis that glomerular epithelial cells (GEpCs) co-operate with glomerular endothelial cells (GEnCs) to modulate neutrophil recruitment in a simulated inflammatory environment and have investigated the mechanisms involved in the demonstrated cross-talk.

**Methods:** An *in vitro* static co-culture system was used to study neutrophil recruitment by endothelium in the presence of GEpCs following cytokine stimulation (0-100U/ml TNF-α for 4h). The conditionally immortalized human GEnCs and GEpCs were cultured on opposite sides of 3.0 μm pore transwell filters in double chamber wells allowing cell-cell interactions. Neutrophils were added to the upper chamber in contact with the GEnCs. Soluble mediators released into the cell supernatants were analysed by multiplex assay. Anti–IL-6 monoclonal antibody (5μg/ml, R&D systems) was used to block IL-6 function.

**Results:** I*n vitro* static co-cultures of TNF-treated GEnCs/GEpCs demonstrated reduced neutrophil recruitment by up to 40 % compared to monocultures of GEnCs. The reduced neutrophil recruitment was dependent on both cell-cell contact and on soluble mediator(s) release. Supernatants from co-cultures showed an 8-fold increase in soluble IL-6 concentrations compared to monocultures following analysis by multiplex assay. Function-neutralising anti–IL-6 antibody added from the initiation of co-culture, reconstituted the neutrophil recruitment to endothelium to control levels.

**Conclusions:** IL-6 can down regulate neutrophil recruitment during GEnC/GEpC co-culture indicating that it plays a negative role in local inflammatory reactions. Thus, IL-6 may be crucial in neutrophil recruitment during pathogenesis of neutrophil-mediated glomerulonephritic disease.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO717

**Targeting Keap1-Nrf2 Pathway Ameliorates Renal Inflammation and Fibrosis in Mice with Protein-Overload Proteinuria** Carlamaria Zoja,[1] Daniela Corna,[1] Monica Locatelli,[1] Chiara Corna,[1] Sara Cattaneo,[1] Colin Meyer,[3] Giuseppe Remuzzi,[1,2] Ariela Benigni.[1] *[1]Mario Negri Institute, Bergamo, Italy; [2]Ospedali Riuniti, Bergamo, Italy; [3]Reata Pharmaceuticals, Irving, TX.*

Bardoxolone methyl (RTA 402), a semi-synthetic triterpenoid, is an Antioxidant Inflammation Modulator (AIM) in clinical development for chronic kidney disease. It exerts antioxidant and antiinflammatory activity via activation of the Keap1-Nrf2 pathway, which in turn suppresses NF-kB activity. We previously showed that in experimental proteinuric nephropathies, proteinuria increases NF-kB activity. By regulating the transcription of genes encoding proinflammatory and fibrogenic molecules involved in renal injury, NF-kB is a key determinant of proteinuria-induced tubulointerstitial injury. Here we investigated the effect of a bardoxolone methyl analog RTA 405 in a murine model of protein-overload proteinuria characterized by tubulointerstitial inflammation and fibrosis. Mice (n=20) underwent uninephrectomy. Five days later they received daily i.p. injections of BSA up to 28d and were treated with vehicle or RTA 405 (100mg/kg/d in the chow). In vehicle-mice proteinuria increased within 2d after BSA, peaked at 14d (77±17 mg/d) and remained sustained at 28d (55±16 mg/d). RTA 405 significantly limited proteinuria at 14d (38±10 mg/d, $P<0.05$) and maintained it at lower level than vehicle-mice at 28d (41±17 mg/d). The presence of a non-responder mouse in the RTA 405 group precluded achievement of statistical significance at 28d. Interstitial accumulation of monocytes/macrophages was lowered by therapy (47±8 vs 70±8 cells/HPF, $P<0.01$). The antiinflammatory action of RTA 405 was accompanied by an antifibrogenic effect as indicated by significantly reduced peritubular α-SMA staining in RTA 405 compared to vehicle-treated mice (score:1.6±0.1 vs 2.2±0.1). In summary, bardoxolone methyl analog limited proteinuria, interstitial inflammation, and fibrosis in a model of proteinuric nephropathy. Studies are ongoing to assess the mediators of inflammation responsible for the protective effects. These data pave the way for clinical application of AIMs as antiinflammatory agents in progressive nephropathies.

**TH-PO718**

**Inhibition of JAK/STAT Pathway Ameliorates TNF-α-Induced Adhesion Molecule Expression in Vascular Endothelial Cells** Ki Dong Lee,[1] Jung Eun Lee,[1] Duk Hoon Kim,[1] Yujin Jung,[1] Aesin Lee,[1] Mi Jeong Sung,[2] Sik Lee,[1] Kyung Pyo Kang,[1] Sung Kwang Park,[1] Won Kim.[1] *[1]Internal Medicine, Research Institute of Clinical Medicine and Diabetes Research Center, Chonbuk National University Medical School; [2]Food Function Research Center, Korea Food Research Institute.*

Vascular endothelial cells play an important role in leukocyte trafficking during inflammatory process. Pro-inflammatory cytokines activate the endothelial cells to express cell adhesion molecules. Janus kinase/signal transducers and activators of transcription (JAK/STAT) is one of the major intracellular cytokine signaling and involved in pathogenesis of renal ischemia/reperfusion injury, diabetic nephropathy. The purpose of our study is to investigate the mechanism of TNF-α-induced cell adhesion molecule by regulation of JAK/STAT pathway in the human umbilical vein endothelial cells (HUVECs).

JAK3 inhibitor, JANEX-1, decreased TNF-α-induced ICAM-1, VCAM-1 and fractalkine expression in the HUVECs. JAK3 inhibitor mediated downregulation of adhesion molecule expression was mediated through suppression of NF-κB activation and STAT3 phosphorylation. The HUVECs treated with TNF-α decreased the suppressor of cytokine signaling (SOCS)-1 and SOCS-3 expressions, however, JAK3 inhibitor attenuated these decrease. Furthermore, JAK3 inhibitor inhibited monocyte adhesion to HUVECs stimulated by TNF-α.

These results demonstrated that inhibition of JAK/STAT pathway by JANEX-1 ameliorates TNF-α-induced adhesion molecule expression in the HUVECs.

**Intrarenal Dopamine Protects Against Angiotensin II-Induced Renal Injury** Shilin Yang, Haichun Yang, Bing Yao, Xiaofeng Fan, Mingzhi Zhang, Raymond C. Harris. *Department of Medicine, Nephrolology Division, Vanderbilt University School of Medicine, Nashville, TN.*

Angiotensin II (Ang II) is a major contributor to progressive renal injury, and Ang II antagonism is a mainstay of therapy in chronic renal disease. Intrarenal dopamine can decrease intrarenal AT1 receptor expression and antagonize Ang II actions in the kidney. We have recently reported that intrarenal dopamine attenuated STZ-induced diabetic nephropathy using 129J/sv COMT KO mice, which have increased kidney dopamine levels due to deletion of the major intrarenal dopamine metabolizing enzyme. Intrarenal dopamine is primarily biosynthesized through the actions of aromatic amino acid decarboxylase (AADC) in the proximal tubule. We have generated mice with kidney dopamine deficiency through selective deletion of AADC in the proximal tubule (AADC KO). The current study investigated whether intrarenal dopamine deficiency would augment renal injury in a model of chronic Ang II infusion (1.4 mg/kg/day) using AADC KO mice on 129J/sv background. Ang II elevated blood pressure to similar levels in WT mice and AADC KO mice (205 ± 4 vs. 200 ± 5 mmHg of AADC KO). Albuminuria was similar in WT mice and AADC KO mice at baseline. Four weeks after Ang II infusion, albuminuria was significantly increased in AADC KO mice vs. WT mice (419 ± 55 vs.187 ± 38 μg/24h, P< 0.01). AADC KO mice showed more vacuoles in proximal tubular epithelial cells and more glomerulosclerosis than WT mice (0.36±0.01 vs. 0.17±0.02, p<0.05), along with more F4/80-positive macrophage infiltration, increased expression of nitrotyrosylated proteins (marker of oxidative stress), Kim-1 (a marker of renal injury) and CTGF. In summary, these results indicate that intrarenal dopamine activity serves as a major defense against Ang II-mediated renal injury.

**TH-PO720**

**Inhibition of Nephrotoxic Nephritis in Mice by the NF-kappaB Inhibitor DHMEQ** Chen Yao,[1] Syed Muhammad Fahad Imran,[1] Eveline Piella,[1] Ulf Panzer,[1] Rolf A. Stahl,[1] Kazuo Umezawa,[2] Gunther Zahner,[1] Friedrich Thaiss.[1] *[1]III. Medical Department, Univ. Hospital, Hamburg, Germany; [2]Faculty of Science and Technology, Keio University, Yokohama, Japan.*

Experimental nephrotoxic nephritis (NTN), a Th1/Th17 cell-mediated disease induced in mice serves as a model of human rapid progressive glomerulonephritis. In this model proinflammatory cytokines activate the transcriptional factor nuclear factor-kappa B (NF-κB) in the kidney. Therefore the therapeutic effect of the NF-κB inhibitor, dehydroxy methyl epoxyquinomicin (DHMEQ), was examined.

NTN was induced by intraperitoneal injection of a sheep polyclonal anti-glomerular basement membrane antibody. DHMEQ (100 mg/kg/bw) was injected three times a week starting prior to disease induction. Clinical and histopathologic severities were determined during a 14 days observation period. Activation of NF-κB was assessed by gel shift experiments. T cells infiltrating the kidneys were quantitated by immuno-histochemistry and kidney chemokine expression determined by RT-PCR.

Kidney function significantly improved in DHMEQ treated mice at early time points (day 4) after the induction of NTN, during later time periods, however, there were no significant differences. Glomerular sclerosis score significantly (p<0.05) improved in treated mice and the number of infiltrating CD3-, Mac2- and F4/80- positive cells was significantly reduced. The reduction in infiltrating inflammatory cells correlated with a significant decrease (p<0.01) in chemokine expression as determined for CCL2, CCL5 and CXCL10. Activation of NF-κB was almost completely abolished in DHMEQ pretreated mice at early time points after NTN-induction not, however, during later time points at day 14.

In conclusion, our studies indicate that NF-κB activation during NTN can be blocked by DHMEQ. Inhibition of NF-κB activation significantly improved kidney function, glomerular morphology and renal inflammatory cell infiltration at early time points. DHMEQ inhibits localization of NF-κB in the nucleus and the inhibitory effect by DHMEQ is more potent on p50/RelA than on p50 homodimers. DHMEQ therefore might be a novel potential therapeutic applicant for patients with glomerulonephritis.

**TH-PO721**

**Characterzation of TNF-Induced Inflammatory Pathways in the Glomerulus** Anela Taubitz, Volker Vielhauer. *Nephrologisches Zentrum, Medizinische Poliklinik, Ludwig-Maximilians-University, Munich, Germany.*

To investigate TNF-mediated inflammatory responses in the glomerulus we isolated glomeruli from wild-type (WT) and TNF receptor (Tnfr) 1 and 2 double-deficient mice without TNF signaling capacity. Gomeruli were challenged with murine TNF in vitro, and global gene expression levels were determined by microarray.

In TNF-stimulated WT glomeruli we found 290 differentially expressed genes, with 219 up-, and 71 down-regulated genes compared to Tnfr1,2-/- glomeruli. Functional groups of TNF-regulated genes included chemokines, cell adhesion proteins, cytokines, NF-kB regulators, apoptosis mediators, cell cycle regulators, and matrix metalloproteases. The proinflammatory chemokine Ccl2 was the most prominently regulated gene in TNF-stimulated WT glomeruli, with a 50-fold induction compared to Tnfr1,2-/-. DAVID analysis identified 136 enriched gene ontology (GO) categories in WT compared to Tnfr1,2-/- glomeruli. Enriched GO terms were highly immune related. Moreover, DAVID found 8 biological pathways enriched in WT glomeruli, including cytokine-cytokine receptor interaction, toll-like receptor signaling, cell adhesion molecules, complement pathway, and apoptosis.

Normal mouse glomeruli expressed both Tnfrs on mRNA and protein level. To determine their relative contribution to TNF-induced glomerular inflammation, we performed expression analyses on TNF-stimulated Tnfr1- and Tnfr2-deficient glomeruli. In Tnfr1-/- glomeruli 219 differentially expressed genes and 77 over-represented GO categories were identified compared to WT, being mostly identical to Tnfr1,2-/- glomeruli. In contrast, we found only 5 genes that were differentially expressed in Tnfr2-/- glomeruli. The predominant role of Tnfr1 in mediating glomerular inflammation was also suggested by compartment-specific flow cytometry of glomeruli isolated from WT and Tnfr-deficient mice after i.p. injection of TNF. Glomerular leukocytes were markedly reduced in Tnfr1-/- and Tnfr1,2-/- mice, with Tnfr2-deficiency only affecting accumulation of mononuclear phagocytes.These data demonstrate a prominent role of Tnfr1 in mediating TNF-induced inflammatory responses in the glomerulus. Only few Tnfr2-specific effects were identified.

**Increased Plasma sVCAM-1 Is Associated with Severity in IgA Nephropathy** Li Zhu,[1,2,3] Sufang Shi,[1,2,3] Lijun Liu,[1,2,3] Jicheng Lv,[1,2,3] Hong Zhang.[1,2,3] *[1]Renal Division, Peking University First Hospital; [2]Peking University Institute of Nephrology; [3]Key Laboratory of Renal Disease, Ministry of Health of China.*

**BACKGROUND**

A considerable part of IgAN patients presented with histological vasculitic/crescentic lesions in glomeruli, accompanied by distinct neutrophils and/or monocytes infiltration, indicating the activation of vascular inflammation in IgAN. sVCAM-1 was a well-proven marker for endothelial injury under inflammatory processes. In the present study, using sVCAM-1 as the marker for vascular inflammation, we investigated its association with IgAN severity, and further explored the mechanism of vascular inflammation in IgAN.

**METHODS**

In our study, 326 biopsy-proven IgAN patients were enrolled. Clinical manifestations at the time of renal biopsy, including eGFR, 24h urine protein excretion and blood pressure, were collected from clinical records. The Oxford classification was used for evaluating the pathological lesions. Plasma sVCAM-1 was measured by ELISA. In vitro, human umbilical vein endothelial cells (HUVEC) were treated with 12.5-200ug/ml IgA1. After 24 and 48 hours treatment, sVCAM-1 in culture supernatant was also measured by ELISA.

**RESULTS**

The plasma sVCAM-1 was significantly correlated with eGFR (r=-0.191, p=0.001) and 24h urine protein excretion (r=0.200, p=0.001), but not systolic blood pressure and diastolic blood pressure, in patients with IgAN. Histologically, patients with higher scores in the variable tubular atrophy/interstitial fibrosis showed significant higher sVCAM-1 (T2:T1:T0=941.98ng/ml : 699.28ng/ml : 700.33ng/ml, p=0.001), patients with higher scores in the variables mesangial hypercellularity and endocapillary hypercellularity showed relative higher sVCAM-1, although do not reach the statistic significance (M1:M0= 749.17ng/ml : 688.15ng/ml, p=0.066; E1:E0= 733.33ng/ml : 716.72ng/ml, p=0.610). In vitro, IgA1 induced the increasing sVCAM-1 in HUVEC culture supernatant in a time- and dose-dependent manner.

**CONCLUSION**

Increased plasma sVCAM-1 was associated with severe clinical and pathological findings in patients with IgAN, which might be resulted from endothelial cells under IgA1 stimulation.

**Interaction of Th1 and Th17 Immune Response in Experimental Glomerulonephritis** Hans-Joachim Paust,[1] Jan-Hendrik Riedel,[1] Jan-Eric Turner,[1] Joachim Velden,[2] Oliver M. Steinmetz,[1] Hans-Willi Mittrücker,[3] Rolf A. Stahl,[1] Ulf Panzer.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Institut für Pathologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]Institut für Immunologie, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Autoreactive CD4+ T cells have been associated with the pathogenesis of autoimmune diseases including crescentic glomerulonephritis. We have recently shown that in addition to Th1 (IFNγ) -mediated immune response IL-17, produced by Th17 cells, contributes to renal tissue damage in experimental glomerulonephritis. However, little is known to date about the time course of Th1 and Th17 cell infiltration, and their potential interactions in immunologically mediated renal disease. Therefore, we analyzed the time dependent interaction of renal and systemic Th1 and Th17 responses in a mice model of glomerulonephritis (nephrotoxic nephritis).

Th17 effector cells could already be detected at day 5 while Th1 effector cells appeared later at day 7 after nephritis induction. The number of infiltrating Th17 cells declined in contrast to numbers of Th1 cells during the course of renal inflammation implicating a time-dependent cascade for renal T cell infiltration and activity.

Systemic immune responses analyzed by antigen-stimulated splenocyte production of IL-17 or IFNγ coincided with the kinetics of renal Th1 and Th17 cell infiltration.

To study functional interactions of Th1 and Th17 immune response in vivo we transferred splenocytes from mice genetically deficient in IFNγ or IL-17 into RAG-1 deficient mice, which lack mature B and T lymphocytes and induced NTN. The renal and systemic Th17 effector cell response was remarkably elevated in mice lacking IFNγ, whereas the Th1 response was unaltered in IL-17 deficient mice. These findings suggest that the Th17 cell function might be downregulated by IFNγ during renal inflammation.

This negative feedback may be important in limiting immune-medited kidney injury.

**Mast Cells Mediate Acute Kidney Injury Induced by Cisplatin** Shaun Andrew Summers, Jacky Chan, Oliver M. Steinmetz, Poh-Yi Gan, A. Richard Kitching, Stephen R. Holdsworth. *Centre for Inflammatory Diseases, Monash University, Melbourne, Victoria, Australia.*

**Aim:** To define the role of Mast Cells (MCs) in experimental acute kidney injury (AKI) induced by cisplatin.

**Methods:** To determine the role of MCs in cisplatin nephrotoxicity we administered cisplatin (12mg/kg) to C57BL/6 wild-type (WT) and Wsh mice, which are deficient in MCs. AKI was assessed 4 days later. Serum blood urea nitrogen (BUN) was used as a measure of renal function, while a semi-quantative scoring system (0-4) was used to assess tubulo-interstitial histological injury. Subsequently we treated WT mice with the MC stabilizer, sodium chromoglycate, or saline control, followed by cisplatin. AKI was assessed 4 days later. Finally, we studied the effect of neutrophil depletion on AKI due to cisplatin therapy in WT mice.

**Results:** Four days after cisplatin treatment AKI was significantly attenuated in Wsh mice compared to WT controls. Serum BUN was significantly decreased (109±6 vs. 45±12mmol/l, P<0.001) in Wsh mice. Assessing tubulo-interstitial histological injury, Wsh mice were afforded significant protection (2.9±0.3 vs. 1.4±0.1, P<0.001) after cisplatin treatment. Consistent with renal injury attributable to MCs, kidney MC chymase expression was elevated in WT mice after cisplatin therapy. MC chymase expression was not detectable in Wsh mice. Prior treatment of WT mice with sodium chromoglycate followed by cisplatin, was renal protective. Sodium chromoglycate treated mice demonstrated decreased BUN (20.4±2.6 vs. 12.5±1.2mmol/l, P<0.05) and histological injury (3.1±1.2 vs. 2.1±0.1, P<0.001) compared to WT mice treated with saline and cisplatin. Owing to the fact that MCs recruit neutrophils, we depleted neutrophils prior to the administration of cisplatin. Mice which were neutrophil depleted prior to cisplatin therapy displayed decreased serum BUN (22.6±3.4 vs. 12.9±2.0mmol/l, P<0.05) and tubulo-interstitial injury (2.5±0.1 vs.1.7±0.1, P<0.001) than control treated WT mice.

**Conclusion:** MCs induce AKI after administration of cisplatin, renal injury is neutrophil mediated. Therapies aimed at inhibiting MC degranulation, using sodium chromoglycate, offer therapeutic promise in the treatment of AKI.

**TH-PO725**

**Sirolimus Inhibits Macrophage-Originated Foam Cell Formation through Activating Cholesterol Efflux Pathways** Kun Ling Ma,[1] Xiong Zhong Ruan.[2] *[1]Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China; [2]Centre for Nephrology, Royal Free and University College Medical School, Royal Free Campus, University College London, United Kingdom.*

**Objective** Studies have shown that infiltrated macrophage is one of the main cell components for the foam cell formation, which is involved in the atherosclerosis. The present study was to test if Sirolimus prevent the macrophage-derived foam cell formation under inflammatory stress.

**Methods** The primary macrophages were cultured from human peripheral blood monocytes which were isolated from buffy coats of healthy donors. The lipid accumulation in macrophages was checked by Oil Red O staining and quantitative assay of intracellular cholesterol. The gene and protein expression of cholesterol trafficking related molecules was respectively examined by real-time PCR, Western Blot, and immunohistochemical staining. Cholesterol efflux from macrophages was also measured by using [$^3$H]-labelled cholesterol.

**Results** Sirolimus inhibited lipid accumulation in macrophages and overrode cholesterol efflux reduction induced by IL-1β. Further analysis showed that Sirolimus upregulated the gene and protein of adenosine triphosphate-binding cassette transporter A1 (ABCA1), liver X receptor-a (LXRa), and peroxisome proliferators activated receptor-a (PPARa) in macrophages in the presence of IL-1b. Furthermore, Sirolimus up-regulated the expression of adenosine triphosphate-binding cassette transporter G1 (ABCG1) in macrophages. These regulatory effects of Sirolimus on cholesterol homeostasis were independent of its roles in cholesterol uptake pathways modulated by lipoprotein receptors (LDL receptor, Scavenger receptor, CD36, e.t.c).

**Conclusion** Sirolimus inhibited macrophage-derived foam cell formation by activating ABCA1 and ABCG1 mediated cholesterol efflux pathways, suggesting that Sirolimus may play important roles in the prevention of glomerulosclerotic progression.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO726**

**Triptolide Inhibits MCP-1 and ICAM-1 Synthesis Via Suppressing NF-κb in TNF-α Stimulated Mesangial Cells** Caifeng Zhu, Bin Zhu, Sheng Wei, Yongjun Wang. *Department of Nephrology, Hangzhou Hospital of Traditional Chinese Medicine (Hangzhou Guangxing Hospital), Zhejiang Chinese Medical University, Hangzhou, Zhejiang, China.*

**Background**

TNF-α stimulated NF--κ**b** signal to induce MCP-1 and ICAM-1 secretion of mesangial cells are the major mechanism in renal injury in various renal diseases including primary and secondary autoimmune nephritis. Triptolide can inhibit renal imflammation in immunity mediated renal disease. However, its mechanism remains unclear.

**Method**

Immortalizied rat mesangial cells line was used in this study. Cells were separated into various groups: normal control cells, TNF-α(10ul/L) treated cells, TNF-α and pyrrolidine dithiocarbamate (PDTC) treated cells, triptolide(low dose, median dose and high dose) treated cells stimulated with TNF-α. MCP-1, ICAM-1, I-κb and phosphorilated IκBα were detected using enzyme-linked immunosorbent assay (ELISA) method. NF-κBp65 activation was measured with a kit adopted a new types of gel protein migration rate method (EMSA) with ELISA method in cell nucleus extractive.

**Results:**

TNF-α increased the MCP-1 and ICAM-1 excretion and activation of NF-κB in mesangical cells. TNF-α also reduced cytoplasmic I-κB. Triptolide significantly inhibited the secretion of MCP-1 and ICAM-1 in a dose-dependent manner in TNF-α treated mesangial cells. It reduced the nucleus NF-κB activation in a dose dependent manner. Triptolide also downregulated IκBα phosphorylation.

**Conclusion**

TNF-α activated IκBα to upregulate activation of NF-κB mediating MCP-1 and ICAM-1 secretion promoting the progress of renal inflammation. Triptolide inhibit IκBα phosphorylation and upregulate cytoplasmic I-κB to reduce NF-κBp65 activation, leading to an inhibition of MCP-1 and ICAM-1 secretion in TNF-α stimulated mesangial cells.

**TH-PO727**

**IL-17 Expression by Tubular Epithelial Cells in Renal Transplant Recipients with Acute Rejection (AR)** A. Loverre,[1] T. Tataranni,[1] G. Castellano,[1] C. Divella,[1] P. Ditonno,[2] M. Battaglia,[2] M. Rossini,[1] Francesco Paolo Schena,[1] G. Grandaliano.[1] *[1]Nephrology, Dialysis and Transplantation Unit; [2]Urology and Transplantation Unit, Univ. of Bari, Italy.*

IL-17 is a key soluble mediator of AR, although its main cellular source in this context remains unclear. Aim of our study was to evaluate IL-17 expression in renal transplant recipients with AR.

To this purpose, we investigated IL-17 protein expression by immunohistochemistry in graft biopsies with acute antibody-mediated rejection (ABMR) (n=20), acute T-cell-mediated rejection (TCMR) (n=10), interstitial fibrosis/tubular atrophy (IFTA) (n=10) and calcineurin inhibitor-induced acute tubular damage (ATD) (n=10). IL-17 staining was mainly localized within graft infiltrating cells in TCMR (IL-17+cells: TCMR 6.4±.3; ABMR .9±.3; IFTA .01±.01; ATD .02±.01 cells+/hpf, p<.0001), whereas ABMR was characterized by a significant increase in tubular IL-17 expression (ABMR 8.0±2; TCMR 3.5±1.5; IFTA .06±.02; ATD .5±.2 IL-17pixel+/total area, p<.0001). IL-17 tubular staining was co-localized with peritubular C4d deposits. The role of complement in IL-17 induction was confirmed by the observation that C3a caused a significant increase of IL-17 protein expression in cultured proximal tubular cells at 48 hours (ELISA: C3a 13.3±4.4, basal 1.0±.2 pg/ml; p=.003. Confocal microscopy: C3a 18.2±.8, basal 6.6±1.4 IL-17+/total area) (p=.001). C3a induced in vitro an increased phosphorylation of JAK2 (250±40% vs basal, p=.02). The inhibition of this tyrosine kinase caused a significant reduction in C3a-induced IL-17 protein expression. ABMR biopsies were characterized by a marked increase of phospho-JAK-2 that co-localized with IL-17. Finally, 12 ABMRs were treated with monoclonal anti-CD3 antibodies and underwent a second biopsy within 30 days after treatment. In this group we observed a significant reduction of both IL-17 protein expression (pre 6.7±3.0; post 2.3±1.0, p=.001) and C4d deposits (pre 2.1±.3; post .6±.1 C4d+/total area).

In conclusion, we demonstrated, for the first time, that tubular cells express high levels of IL-17 in ABMR and this event might be mediated by complement activation featuring this condition.

**Monocyte and Glomerular Calprotectin in ANCA Associated Vasculitis** Ruth J. Pepper,[1] Nicholas D. Mansfield,[2] Sally Hamour,[2] Ruth M. Tarzi,[2] Charles D. Pusey,[2] H. Terence Cook,[2] Alan D. Salama.[1] *[1]Centre for Nephrology, University College London, United Kingdom; [2]Renal Section, Imperial College London, United Kingdom.*

Macrophages are critical for disease development and progression in experimental and human glomerulonephritis. Different macrophage phenotypes are recognised but no clear in vivo marker has been associated with disease. Calprotectin is abundantly expressed in neutrophils, monocytes and infiltrating macrophages and induces inflammatory responses in endothelium and phagocytes. We investigated the role of calprotectin in patients with AAV as well as in nephrotoxic nephritis.

Methods

AAV patients with active and convalescent disease, healthy controls and patients with end-stage renal disease were studied. Serum calprotectin was determined using a sandwich ELISA. Monocytes from healthy controls were stimulated with ANCA, and calprotectin expression determined by FACS.Immunohistochemistry (IHC) was performed on renal biopsies of AAV patients and kidney sections from wild-type and IL-17-deficient mice, which are protected from glomerulonephritis.

Results

Serum levels measured in acute disease (n=22), remission (n=24), HC (n=10) and ESRD (n=59). Levels significantly increased in both acute disease and in remission compared to HC and ESRD ($p<0.001$). IHC demonstrated prominent glomerular macrophage expression of calprotectin. Monocyte derived macrophages expressed the most calprotectin when stimulated with IFNg/LPS. Incubating monocytes with ANCA augmented calprotectin expression. Despite similar numbers of glomerular macrophages in WT animals compared to protected IL17-deficient animals, there were significantly fewer glomerular calprotectin positive cells in IL-17$^{-/-}$ animals.

Conclusion

Patients with AAV demonstrate elevated circulating levels of calprotectin during both active disease and remission, suggesting a persistently activated phenotype, while tissue infiltrating macrophages express calprotectin within inflamed glomeruli. IFNg/LPS or ANCA stimulation upregulated calprotectin expression in monocytes. Animal studies suggest that despite similar macrophage infiltration, calprotectin expression differentiates disease promoting macrophages from others.

**Influence of Lectin Complement Pathway Mediated by Mannose-Binding Lectin to Thickness of Glycocalyx and Expression of Syndecan-1 and Glypican-1 in High Glucose Cultured Human Renal Glomerular Endothelial Cells** Songmin Huang, Hongyu Qiu, Wenxing Fan, Wanxin Tang, Ping Fu. *Department of Nephrology, West China Hospital of Sichuan University, Chengdu, Sichuan, China.*

**Objective:** To investigate the effect of lectin complement pathway (LCP) mediated by mannose binding lectin (MBL) on thickness of the Glycocalyx and expression of Sydecan-1 and Glypican-1 in human renal glomerular endothelial cells (HRGECs) cultured in high concentration of glucose.

**Methods:** HRGECs were cultured in vitro, then randomly divided into six groups: MBL deficient normal glucose as controlled groups; MBL(8μg/ml)+normal glucose groups; MBL+mannitol groups; MBL deficient high glucose groups; MBL + high glucose groups; MBL+ high glucose + anti-MBL groups respectively. After 72 hours cultured, Confocal Laser Scanning Microscopy (CLSM) was used to observe the fully hydrated glycocalyx of HRGECs. Real time-RCR ,Fluorescence microscope and Western blot were used to detect the expression of Syndecan-1 and Glypican-1.

**Results:** Compared with controlled groups, the thickness of Glycocalyx on the surface of HRGECs in high glucose group decreased. and the mRNA and protein expression of Syndecan-1 and Glypican-1 were significantly decreased ($P < 0.01$). Immunofluorescence showed that the depositions of MBL and C3 on the surfaces of HRGECs only in MBL + high glucose groups. Compared with MBL deficient high glucose group, the thickness of Glycocalyx in MBL + high glucose groups decreased. The mRNA and protein expression of Syndecan-1 and Glypican-1 were decreased ($P < 0.01$). Compared with MBL + high glucose groups, the thickness of Glycocalyx in MBL + high glucose+ anti-MBL groups increased. The mRNA and protein expression of Syndecan-1 and Glypican-1 were increased ($P < 0.01$) .

**Conclusion:** High concentration of glucose can reduce thickness of Glycocalyx and decrease expression of core protein Sydecan-1 and Glypican-1. Exogenous MBL could promote the depositions of MBL and C3 on HRGECs in high glucose. High glucose together with MBL can downregulate the thickness of Glycocalyx and expression of Sydecan-1 and Glypican-1. The downregulated effect of MBL could be blocked by MBL-blocking antibody.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO730**

**$A_{2A}$ Adenosine Receptors Activation in Accelerated Kidney Injury in Anti-Glomerular Basement Membrane Antibody-Associated Glomerulonephritis Reveals Their Significant Contribution To Protect Kidney from Damage** Gabriela E. Garcia,[1] Luan D. Truong,[2] Carlos Alberto Roncal-Jimenez,[1] Richard J. Johnson,[1] Lili Feng.[2] *[1]Medicine, University of Colorado Denver, Aurora, CO; [2]Medicine, Baylor College of Medicine, Houston, TX.*

$A_{2A}$ adenosine receptor ($A_{2A}R$) is an endogenous inhibitor of inflammation and accelerates wound healing. We investigated whether selective activation of $A_{2A}R$ will suppress inflammation and protect the kidneys from injury in a model of increased severity of established phase of GN. To accelerate kidney damage, uninephrectomy was performed at day 21 after the injection of anti-GBM Ab. Treatment with $A_{2A}R$ agonist or vehicle was started 5 days after nephrectomy, at day 26 after GN induction, and rats were euthanized at day 32. Pharmacological activation of $A_{2A}R$ significantly blocked macrophage (Mφ) infiltration in glomeruli and interstitium. Consequently, the glomerular lesion was significantly reduced in $A_{2A}R$ agonist-treated group. Importantly, $A_{2A}R$ activation resulted in marked reduction in fibrotic crescent formation and TIN injury. At day 32 in the control group, collagen IV (Col IV) deposition was increased in glomeruli, interstitium and vessels. In contrast, Col IV expression was reduced by $A_{2A}R$ activation. Furthermore, in the control group increased α-smooth muscle actin (α-SMA) was observed in the glomeruli and tubules with E-cadherin loss. $A_{2A}R$ activation restored E-cadherin expression and reduced the appearance of α-SMA. In addition, the uninephrectomy-induced increased glomerular volume was lower in the $A_{2A}R$ agonist-treated group. In vitro studies, robust expression of profibrotic molecules, thrombospondin-1, osteopontin-1, TGF-β and TIMP-1 was observed in Mφ isolated form nephritic glomeruli. The expression of these molecules in nephritic kidney is prevented by $A_{2A}R$ activation. Notably, Mφ from nephritic glomeruli express $A_{2A}R$. $A_{2A}R$ agonist might target Mφ $A_{2A}R$ to inhibit expression of profibrotic molecules to arrest progressive GN. These results indicate that $A_{2A}R$ is crucial endogenous anti-inflammatory molecule in GN. Activation of $A_{2A}R$ represents a potential therapeutic strategy for GN during advanced kidney lesion.

**TWEAK Regulates CXCL16 Expression in Renal Tubular Cells** Maria C. Izquierdo, Ana Belen Sanz, Susana Carrasco, Marta Ruiz-Ortega, Jesus Egido, Alberto Ortiz. *Renal and Vascular Research Laboratory, Division of Nephrology, IIS Fundacion Jimenez Diaz, Madrid, Spain.*

Tumor necrosis factor-like weak inducer of apoptosis (TWEAK, TNFSF12) is a member of the TNF superfamily that regulates the secretion of various chemokines through the engagement of canonical or non-canonical NFKB activation.

We have now explored the regulation of the expression of the cell membrane chemokine CXCL16 by TWEAK in cultured murine tubular cells and in vivo.

In renal tubular cells of proximal (MCT) and distal (NP-1) origin TWEAK up-regulated CXCL16 mRNA expression from 3 to 24 h in a NFKB-dependent manner. Flow cytometry showed an increase in cell surface bound CXCL16 after TWEAK stimulation. TWEAK further potentiated the shedding of CXCL16 from NP-1 cells and there was a trend towards increased cellular CXCL16. Confocal microscopy disclosed that TWEAK increased cytoplasmic and membrane CXCL16 in both MCT and NP-1 cells. Both cell types expressed the receptor for CXCL16, CXCR6. CXCL16 and CXCR6 were found in close association at the cell membrane.

CXCL16 modestly promoted the gene expression of chemokines (MCP-1 and RANTES) and adhesion molecules like ICAM-1 in tubular cells and collaborated with TWEAK in promoting an inflammatory response. However, CXCL16 did not modulate tubular cell proliferation or survival.

In vivo, CXCL16 plays an important role in recruitment of T cells to sites of inflammation and TWEAK induce kidney infiltration by T cells. In this regard, TWEAK increased renal CXCL16 expression and T lymphocyte infiltration in healthy murine kidneys at 4 h and this was inhibited by the NFKB inhibitor parthenolide.

We studied the relationship between TWEAK/Fn14 and kidney CXCL16 expression in acute kidney injury (AKI) induced by folic acid injection. Kidney CXCL16, TWEAK and Fn14 mRNA were upregulated at 24 and 72 h. Tubular cell CXCL16, TWEAK and FN14 protein and interstitial T cells were increased and CXCL16 localized to the basolateral tubular membrane.

In conclusion, TWEAK is a novel regulator of CXCL16 expression in tubular epithelium and CXCL16 has direct proinflammatory actions in renal tubular cells.

**TH-PO732**

**Factor H-Deficiency Enhances Proteinuria and Glomerular Sclerosis in Mice upon Albumin Overload** Mauro Abbate,[1] Daniela Corna,[1] Monica Locatelli,[1] Simona Buelli,[1] Marina Noris,[1] Carlamaria Zoja,[1] Giuseppe Remuzzi.[1,2] *[1]Mario Negri Institute, Bergamo, Italy; [2]Unit of Nephrology and Dialysis, Ospedali Riuniti, Bergamo, Italy.*

Intraglomerular deposition of complement activation products is often detected in biopsies of patients with chronic proteinuric nephropathies, and evidence in experimental models indicates a determinant role of plasma-derived C3 in the progression of injury to sclerosis as a consequence of dysfunction of the glomerular filtering barrier to circulating proteins (JASN 2008, 19, 2158). The influence of control of the alternative pathway C

activation via the key regulator factor H (Cfh) on the evolution of glomerular injury was yet elusive. Here, we compared uninephrectomized Cfh-deficient vs wild type (WT) mice for their susceptibility to a promoter of proteinuria and C3 deposition, i.e., repeated i.p. injections of bovine serum albumin (BSA, n=6/group). Results showed induction of higher levels of proteinuria in Cfh-BSA mice compared to WT BSA mice (study end, d28:158±22 vs 81±33 mg/d, $p<0.05$; baseline values: 6.2 ±0.7 vs 5.7±0.7mg/d, NS). Cfh-BSA mice developed more abundant C3 deposition in glomeruli by confocal microscopy and more severe glomerular sclerosis (GS % at d28: 20±3.5% vs WT BSA 8.8±3.1%; $p<0.05$; lesion absent at baseline). More severe disease in Cfh-deficient mice appears directly related to local C-mediated injury rather than immunologic/antibody-related factors since BSA antibodies were undetectable in this model and Cfh-deficient mice failed to develop proteinuria when subjected to a strong, ad hoc BSA immunogenic protocol (cationized-BSA). We conclude that Cfh deficiency by allowing intraglomerular activation of complement amplifies deleterious consequences of abnormal passage of C3 across the glomerular capillary filter and worsens glomerular sclerosis caused by protein overload proteinuria. If applicable to humans, these findings raise the possibility that Cfh-related genes might have an impact on the course of proteinuric glomerulopathies regardless of etiology, and strengthen the potential for perspectively new approaches simultaneously targeting proteinuria and uncontrolled C activation to halt disease progression.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO733

**ac-SDKP Reduces Proinflammatory Response in PTEC during Pathogenic Albumin Load** Wo-Shing Au,[1] Gary Chan,[1] Joseph C. K. Leung,[1] Loretta Y. Y. Chan,[1] Hui Y. Lan,[2] Kar Neng Lai,[1] Sydney C. W. Tang.[1] *[1]Medicine, The University of Hong Kong, Pokfulam, Hong Kong, China; [2]Medicine and Therapeutics and Li Ka Shing Institute of Health Sciences, The Chinese University of Hong Kong, Shatin, Hong Kong, China.*

We recently demonstrated that ACE inhibitor (ACEi) but not angiotensin receptor blocker significantly ameliorated murine adriamycin nephropathy. Despite both being rennin-angiotensin system (RAS) blockers, ACEi additionally prevents the ACE-mediated breakdown of an endogenous tetrapeptide, N-acetyl-seryl-aspartyl-lysyl-proline (ac-SDKP), which possesses potent anti-inflammatory and anti-fibrotic effects in various hypertensive disease models. We, therefore, hypothesized ac-SDKP may be the candidate mediating the renoprotective effect of ACEi and investigated the renoprotective efficacy of ac-SDKP using renal proximal tubule epithelial cells (PTEC) challenged with pathogenic albumin overload and transforming growth factor beta1 (TGFβ1). Ac-SDKP (1-1000nM) dose-dependently inhibited human serum albumin (HSA) induced ERK signalling and TGFβ1 induced SMAD2/3 phosphorylation in primary human PTEC. In addition, acSDKP treatment at 100nM almost completely abolished HSA/ TGFβ1 induced IL-6 mRNA expression, and, to a lesser extent, significantly inhibited HSA/ TGFβ1 induced MCP-1 mRNA expression by 50%. To examine whether the retarded IL-6 gene induction functionally translated into reduced secretion of pro-inflammatory IL-6, we measured the level of IL-6 in culture media by ELISA. It was found that while HSA and TGFβ1 significantly induced IL-6 secretion by 5- and 3- fold respectively, acSDKP almost completely abrogated these responses. In conclusion, our *in vitro* study supports that ac-SDKP reduces proinflammatory response in PTEC during pathogenic albumin load. These results warrant further study of renoprotective efficacy offered by ac-SDKP using animal models with chronic kidney disorders.

### TH-PO734

**Oncostatin M Is a Potential Early Mediator of the Renal Injury and Repair Response** Valerie A. Luyckx, Catharine Compston, Thomas F. Mueller. *Medicine, University of Alberta, Edmonton, AB, Canada.*

Transcripts associated with the acute phase response (APR) differentiate deceased and living donor kidneys at time of transplantation. Contrary to the expected classical IL6 response, Oncostatin M receptor (OSMR) was the most highly expressed IL6 family receptor. We have shown that OSM induces APR gene expression in renal and vascular cells at 24 hours. We aimed to further characterise the OSM/OSMR APR over time as well as its impact on the anti-inflammatory and repair responses.

In mouse kidney and heart transplants, kinetics of IL6 and OSM transcript expression were measured at 0, 1, 3, 6, 9, 12, 18, 24, 48, 72, 96, 120, 144 and 168 hours post-transplant. These kinetic studies showed an immediate post-transplant increase of OSM, reaching a peak fold-change of 43 after 3 hrs ($p<0.01$) and returning to baseline within the first 24 hrs. In comparison, the IL6 transcript levels increased to a lesser degree but remained higher for a longer period of time.

Kinetic studies were performed in primary vascular smooth muscle (VSMC) and human proximal tubule (PTEC) cells exposed to OSM for 0,1,3,6, 12, 24, 48, 72 and 168 hr. APR gene expression was significantly increased in response to OSM stimulation. These data show that the effect of OSM can be seen as early as 1 hour (IL6, LBP), is generally present by 6 hours (OSMR, SERPINA1, Fibrinogen, LIFR) and persist up to 7 days (OSMR, IL6R, IL6, LIFR, LIF, SERPINA1, Fibrinogen). Baseline SDF1 expression was extremely high in VSMC (6000% HPRT) vs. PTEC (0.4 % HPRT). OSM exposure significantly upregulated SDF1 in both cell types by 3 hours but the effect was longer in PTEC. OSM-mediated induction of SDF1, a stem cell mobilizer, may suggest a role for OSM/OSMR signalling in initiation of renal repair. SOCS3 (suppressor of cytokine signalling 3) expression was significantly increased (up to 20 fold) in PTEC and VSMC from 1 to 48 and 72 hours respectively. Early induction of SOCS3 is consistent with an OSM-induced anti-inflammatory response in both the renal epithelium and the vasculature.

We conclude that OSM is an early inducer of the renal APR and as such, OSM/OSMR signalling may be an important coordinator of the renal response to injury and subsequent repair.

**Triggering Receptor Expressed on Myeloid Cells (TREM)-1 Regulates Monocyte Activation in Kidney Injury** Chien-Liang Chen,[1,2] Jeremy S. Duffield,[1] Ana P. Castano,[1] Shuyu Ren.[1] *[1]Renal Division, Harvard Medical School, Department of Medicine, Boston, MA; [2]Renal Division, Kaohsiung Veterans General Hospital, Department of Medicine, Kaohsiung, Taiwan.*

Using a microarray screen of differentially regulated genes in inflammatory kidney macrophage (MΦ) subpopulations we identified TREM family receptors as highly regulated. Trem-1 ligation results in potent amplification of TLR signaling in infectious diseases. Here we show that Trem-1 is highly upregulated in Ly6C high MΦs in chronic kidney injury, and functions to regulate activation of MΦs by kidney damage-associated molecular patterns (DAMPs) released by injured kidney tissue. Systemic administration of soluble TREM-Fc fusion protein by adenoviral vectors inhibits MΦ activation in vivo and regulates kidney disease progression in mice. Trem-1 is potentially an important therapeutic target to limit monocyte/ MΦ activation in sterile inflammation of the kidney.

**Toll Like Receptor (TLR) Agonists Act as Adjuvants in the Induction of Experimental Autoimmune Glomerulonephritis (EAG) in CD1 Mice** Jitendra K. Gautam, Di Wu, Kline Bolton. *University of Virginia HS, Charlottesville, VA.*

EAG in Wistar Kyoto (WKY) rats can be induced by immunization with recombinant human alpha3(IV)NC1 (m732) resulting in severe glomerulonephritis, immune cell infiltration and proteinuria. Immunization is done with m732 in complete Freund's adjuvant with Mycobacterium tuberculosis h37RA (CFA). The same immunization procedure in CD1 mice results in the development of EAG. Disease progression in the mouse model is slower compared with WKY rats, but the endpoint features are similar.

CFA consists of several known and unknown TLR agonists. The present study was undertaken to examine the ability of various TLR agonists to act as adjuvants in the mouse model of EAG. TLR agonists used in this study were: PAM3CSK4 (TLR1/2), poly IC(TLR3), bacterial LPS(TLR4) and CpG oligos(TLR9). Mice sets (n = 4) were immunized with m732 and individual TLR agonists in saline. m732 with CFA was used as positive and saline as negative control. Spot urine albumin was monitored every two weeks over a 12 week period as a marker for the disease progress. Post experimental kidneys from all the animals were processed for H&E and immunofluorescence staining (total IgG and IgG isotypes) to score the disease severity. ELISA for IgG and isotypes was done on 6 and 12 week serum. Various TLR agonists showed different abilities to induce the disease over age matched controls. TLR2 and TLR3 agonists resulted in a more robust disease initiation followed by CpG. TLR4 agonist bacterial LPS on the other hand acted as a very week inducer of the disease as monitored by urine albumin analysis. Kidney isotype immunofluorescence results and 12 week serum ELISA showed statistical difference in the induction of IgG subclasses by different adjuvant sets over age matched negative control set. Group averages of H&E scores were also different when compared with control set.

These findings suggest that several individual TLR agonists are able to act as adjuvants in the induction of EAG, with variation in their ability to do so. Experiments are underway to confirm if there is a synergistic effect when various agonists are mixed and what combination works best.

### TH-PO737

**Reduced Expression of ATP-Binding Cassette Transporter A1 (ABCA1) Leads to Increased Release of Interleukin-18 (IL-18) from Mononuclear THP1-Cells** Helge Höfeld,[1] Daniel Kraus,[2] Helmut Geiger,[1] Ingeborg A. Hauser,[1] Stefan Gauer.[1] *[1]Department of Nephrology, Hospital of the Johann Wolfgang Goethe-University, Frankfurt am Main, Germany; [2]Department of Nephrology, Universität Würzburg, Würzburg, Germany.*

Patients with CKD are at high risk for atherosclerotic cardiovascular complications. In experimental chronic kidney disease in $apoE^{-/-}$ mice, impaired cholesterol efflux from macrophages due to downregulation of ABCA1 and concurrent activation of nuclear factor-κB was observed. This inflammatory process may depend on ABCA1, since it seems to act anti-inflammatory by activating the JAK/STAT-pathway upon interaction with apoA-1. Our aim was to characterize the role of ABCA1 in the release of IL-18 from mononuclear cells which is closely linked to the development of atherosclerosis and may contribute to kidney allograft injury.

ABCA1 expression was inhibited by stable transfection of THP1-cells with shRNA-plasmids. THP1-cells were incubated with 200nM TPA to induce differentiation into macrophage-like cells. To initiate ABCA1-expression cells were treated with 9-cis-retinoic acid and 22-R-hydroxycholesterol (15µM each) for 24h. During the last 2h synthesis and release of IL-18 was induced by 100 ng/mL LPS and 3 mM ATP. IL-18 in the supernatant of these cells was measured by ELISA (MBL).

Inhibition of ABCA1 transporter function by 100µM glyburide reduced IL-18 in the supernatant of LPS/ATP treated THP-1 cells from 914±11pg/mL to 309±46pg/mL

(mean±SEM). In contrast, reducing ABCA1-expression by 50% via RNA-interference led to a more than ten-fold increase in IL-18 measured in the supernatant compared to THP1-cells with unimpaired ABCA1 expression (851±375pg/mL vs. 81±28.4pg/mL; mean±SEM).

These data indicate that a low expression of ABCA1 leads to increased secretion of the pro-inflammatory cytokine IL-18 from mononuclear cells and that this effect is independent of the ABCA1 lipid transporter function.

Thus our work suggests that ABCA1 has a protective effect with regards to progression of chronic kidney disease and allograft dysfunction not only by protecting vessels and the kidney from foam cell formation but also by reducing the levels of pro-inflammatory cytokines such as IL-18.

**Remission, Relapse and Renal Scarring in Experimental Autoimmune Vasculitis** Bahjat Al-Ani,[1] Hamad Al Nuaimi,[1] Stuart W. Smith,[1] Stephen P. Young,[2] Caroline O. S. Savage,[1] Mark Little.[3] *[1]Renal Institute of Birmingham, University of Birmingham, Birmingham, United Kingdom; [2]Rheumatology Research Group, University of Birmingham, Birmingham, United Kingdom; [3]Centre for Nephrology, UCL, London, United Kingdom.*

Introduction: We have previously described an animal model of acute systemic vasculitis, termed experimental autoimmune vasculitis (EAV), which is generated by immunising WKY rats with human myeloperoxidase (MPO). However, the most important clinical problems in this condition relate to vasculitis relapse and management of the consequence of irreversible organ damage.

Methods and Results: WKY rats were immunised with either MPO or human serum albumin (HSA, control) in adjuvant and sacrificed at 8 or 30 weeks, the latter group being divided into a relapse and no-relapse group. In the MPO-immunised animals, haematuria reached a maximum at 6-8 weeks (mean 3.0±0.1) and thereafter declined steadily until 26 weeks (0.6±0.3). There was a parallel decline in anti-MPO antibody level and degree of leukocyturia, but albuminuria increased slightly. Following re-challenge at this point with soluble MPO (without adjuvant) and endotoxin, haematuria (2.3±0.7) and anti-MPO antibody level increased over a period of 4 weeks. Renal scarring, as assessed by silver and picro-sirius red staining, was increased in MPO-immunised animals at 30 weeks compared to 8 weeks. No scarring was evident in control animals. We then went on to determine whether the urinary metabolite profile changed during the evolution of glomerulonephritis, scarring and relapse. Using principal components analysis of urine NMR spectra we found significant clustering in the 3 groups, indicating that active vasculitic glomerular inflammation could be distinguished by the urinary metabolome.

Conclusion: This relapsing model of anti-MPO associated vasculitis will play a role in assessing novel maintenance therapies and biomarkers of disease.

**TH-PO739**

**Novel Role of Toll Like Receptor 3 Signal Pathway in the Pathogenesis of the RSV Nephropathy** Yuhong Tao, Zheng Wang. *Department of Pediatric, West China second University Hospital, Sichuan University, Chengdu, Sichuan, China.*

**Background:** Viral transactivation of transcription mediated by nuclear factor kappa B (NF-kB) contributes to the pathogenesis of minimal change nephritic syndrome(MCNS) triggered by respiratory syncytial virus(RSV), and the pathological change of RSV nephropathy is similar with MCNS. But the mechanism of activating NF-kB remains unclear. Toll like receptor 3(TLR3) play a bridging role in connecting virus infection and many kinds of kidney injury.

**Objective:** To investigate whether RSV evoke NF-kB activation through TLR3 signal pathway in RSV nephropathy.

**Methods:** RSV nephropathy model was established. SD rat were sacrificed at days 4,8,14,28,56 and 84 postinoculation ($RSV_4$, $RSV_8$, $RSV_{14}$,$RSV_{28}$, $RSV_{56}$ and $RSV_{84}$) after inoculation of $6\times10^6$PFU RSV. Expression of TLR3 in kidney was measured with Real time RT-PCR, immunohistochemisty and Western blot. MyD88 ,P38MAPK and NF-kB in kidney were detected through immunohistochemisty and Western blot. ELISA was used to detect the concentration of IL-6 in serum .

**Results:** After inoculation of RSV , the urinary protein increased gradually, $RSV_{14}$> $RSV_{28}$>$RSV_8$>$RSV_4$>$RSV_{56}$>$RSV_{84}$Compared with day 4,56,84 and normal group,TLR3 expression was increased significantly at day 8,14 and 28. The increased activity and nuclear translocation of NF-kB was observed at RSV 4,8 ,14 and 28. The concentration of IL-6 in serum and the protein expression of pp-P38 MAPK at RSV4, 8, 14 and 28 was significantly higher than that at RSV56 and 84, while there is no significant change in MyD88 at all time points. **Conclusion:** Toll like receptor 3 mediated activation of NF-kB through a MyD88-independent pathway in RSV nephropathy

**Statin Attenuates Experimental Anti-Glomerular Basement Membrane Glomerulonephritis Together with the Augmentation of Alternatively Activated Macrophages** Emiko Fujita,[1] Akiko Mii,[2] Megumi Fukui,[2] Akira Shimizu.[1] *[1]Department of Analytic Human Pathology, Nippon Medical School, Tokyo, Japan; [2]Department of Internal Medicine (Division of Neurology, Nephrology and Rheumatology), Nippon Medical School, Tokyo, Japan.*

Macrophages(Mφ) are heterogeneous and include classically activated M1 and alternatively activated M2 Mφ, characterized by pro- and anti-inflammatory functions, respectively. Mφ that express heme oxygenase-1 (HO-1) also exhibit anti-inflammatory effects. We assessed the anti-inflammatory effects of statin in anti-glomerular basement membrane (GBM) glomerulonephritis (GN) in WKY rats, focusing on the Mφ heterogeneity and intraglomerular cytokines. Rats were treated with atorvastatin (20 mg/kg/day) or vehicle from 3 days before induction of anti-GBM GN. Control rats showed infiltration of ED1+ Mφ in the glomeruli at day 3, and developed severe crescentic GN by day 7, together with increased mRNA levels of M1 Mφ-associated cytokines, IFN-γ, TNF-α, and IL-12 ($p<0.05$). In contrast, statin reduced the level of proteinuria, reduced infiltration of ED1+ Mφ in glomeruli with suppression of MCP-1 expression, and inhibited the formation of necrotizing and crescentic lesions. The number of ED3+ activated Mφ decreased in glomeruli with down-regulation of M1 Mφ-associated cytokines. Furthermore, statin augmented ED2+ M2 Mφ with up-regulation of M2 Mφ-associated chemokine and cytokine, CCL17 and IL-10 ($p<0.01$). Statin also increased the number of IL-10-expressing HO-1+ macrophages in glomeruli. In addition, we performed in vitro study using human monocytic U937 cell line. The results indicated that the statin affect monocytes directly and inhibited the Mφ differentiation as well as mediated HO-1+ anti-inflammatory Mφ. Moreover, in vitro study using rat peritoneal Mφ, statin inhibited the development of ED3+ Mφ, and augmented ED2+ Mφ in M2-associaated cytokine environment. We conclude that statin augmented M2 and HO-1+ Mφ and inhibits glomerular inflammation in anti-GBM GN. The anti-inflammatory effects of statin are mediated through inhibition of Mφ infiltration and pro-inflammatory Mφ as well as augmentation of the anti-inflammatory Mφ.

**Effects of Bardoxolone Methyl (BARD) on Renal Protein Handling and Secondary Nephropathy** Irina Dulubova, Ron Bumeister, Rhesa D. Stidham, Pritam Kambuj, Jeffrey Laidlaw, Colin Meyer, Deborah A. Ferguson, Christian Wigley. *Reata Pharmaceuticals, Inc., Irving, TX.*

The initiating event in tubulointerstitial injury is believed to be defects in glomerular permeability that lead to increased levels of protein in the filtrate delivered to the proximal tubules. It is now understood that protein uptake into the proximal tubules and chronic overload of the protein endocytosis machinery, and not the mere presence of urinary protein, lead to interstitial inflammation and fibrosis. Elevated levels of albumin in proximal tubule cells correlate with increased ROS, which activate NF-κB signaling, leading to increased expression of proinflammatory mediators and subsequent structural damage. BARD is the lead compound from the Antioxidant Inflammation Modulator (AIM) class and is currently being studied in a Phase 2b clinical trial in patients with chronic kidney disease. BARD and other AIMs exhibit broad antioxidant and tissue protective activity and mitigate damage in several models of renal injury through induction of the Keap1-Nrf2 pathway and suppression of NF-κB. Since tubulointerstitial injury is mediated by reabsorption of protein and activation of NF-κB, the effects of BARD on this process were investigated. Expression levels of the components of the megalin/cubilin endocytic complex, NF-κB target genes, and Nrf2 target genes were measured by qPCR following BARD treatment. NF-κB activity was also assessed by western blot. Urine samples from patients were analyzed by SDS-PAGE and western blot. BARD potently induced Nrf2 target genes in multiple cell types of renal origin, suggesting broad renoprotective activity. It inhibited TNFα-mediated increases in proinflammatory targets in glomerular endothelial cells and suppressed albumin-induced proinflammatory signaling in PTECs. BARD also decreased the expression of the components of the megalin/cubilin complex in PTECs. Analysis of urine samples from patients treated with BARD revealed a pattern consistent with downregulation of the megalin/cubilin complex. These data suggest that BARD may be therapeutic in the prevention or treatment of secondary nephropathy through reduction of protein reabsorption and suppression of NF-κB activation.

**TH-PO742**

**Bardoxolone Methyl (BARD) Improves Markers of Endothelial Function in Cultured Cells** Deborah A. Ferguson,[1] Christian Wigley,[1] Elke H. Heiss,[2] Verena M. Dirsch.[2] *[1]Reata Pharmaceuticals, Inc., Irving, TX; [2]University of Vienna, Vienna, Austria.*

Endothelial dysfunction is characterized by a decreased vasodilatory response caused by an insufficient amount of bioavailable nitric oxide (NO). The development of chronic kidney disease (CKD) is preceded by the appearance of endothelial dysfunction and oxidative stress markers and the levels of these markers correlate positively with disease progression. Bardoxolone methyl (BARD) is a compound from the Antioxidant Inflammation Modulator (AIM) class that potently induces activity of the antioxidant Keap1-Nrf2 pathway. To determine whether BARD improves endothelial function *in vitro*, primary human umbilical endothelial cells were treated with BARD and the levels of bioavailable NO and reactive oxygen species (ROS) were measured using fluorescent probes. Additionally, eNOS and

HO-1 protein levels were assessed by Western blot. Treatment with BARD increased the amount of bioavailable NO. This increase was accompanied by a dose-dependent decrease in ROS production and a dose-dependent increase in HO-1 protein levels. Consistent with published results for another AIM compound (*Heiss et al., JBC 284:31579-31586*), BARD treatment reduced eNOS protein levels, despite the observed increase in bioavailable NO. This Nrf2-mediated effect ensures that the stoichiometric ratio between eNOS and its cofactor, tetrahydrobiopterin, is maintained thereby preventing uncoupling and production of excess ROS. Taken together, these data demonstrate that BARD improves endothelial function *in vitro*, as measured by increased bioavailable NO and reduced oxidative stress and suggests that BARD may be effective in treating endothelial dysfunction in patients with CKD.

**Targeting Stat4 Transcription Factor in Severe Lupus Nephritis Reveals Stage Dependent Different Pathophysiological Effects** Julia Menke. *I. Department of Medicine, Johannes Gutenberg-University, Mainz, Rheinland-Pfalz, Germany.*

Polymorphisms in the Stat4 gene have been recently described as risk factors for systemic lupus erythematosus(SLE). Although some polymorphisms showed a strong association with auto-Abs and nephritis, the impact on pathophysiology is still unknown. We studied the impact of Stat4 on the progression of lupus nephritis in MRL-Faslpr mice in two approaches targeting Stat4: A Stat4-deficient MRL-Faslpr strain and blockade of Stat4 by delivering antisense-oligonucleotides. MRL-Faslpr mice lacking Stat4 did not show differences in survival and renal function compared to Stat4 intact MRL-Faslpr (wild type=WT) mice. However, circulating IL-18 levels were markedly elevated in Stat4 deficient compared to WT mice suggesting that IL-18 Stat4 independently might drive the progression of lupus nephritis. In the second approach, Stat4 antisense-(AS), missense-(MS) oligonucleotides or PBS were applied to MRL-Faslpr mice with advanced lupus nephritis. Interestingly, proteinuria was reduced in the AS compared to MS/PBS groups. In contrast to targeting Stat4 at gene level we found a significantly reduced leukocyte infiltration in kidneys treated with AS. However, the levels of circulating IgG subtypes did not differ between groups. In conclusion, we now report that Stat4 independent factors can drive autoimmune lupus nephritis in targeted deleted MRL-Faslpr mice, while blocking Stat4 in advanced nephritis can ameliorate disease suggesting different pathomechanisms in different stages of disease.

### TH-PO744

**Mesenchymal Stromal Cells Reduces Renal Injury in a Rat Model of Renal Interstitial Fibrosis** Giulia Bedino, Chiara Balenzano, Chiara Rocca, Teresa Valsania, Elisa Gabanti, Grazia Soccio, Marilena Gregorini, Teresa Rampino, Antonio Dal Canton. *Unit of Nephrology Dilaysis and Tranplantation, IRCCS Fondazione Policlinico San Matteo and University of Pavia, Pavia, Italy.*

Mesenchymal stromal cells (MSC) are multipotent cells with anti-inflammatory effect, they have beneficial effect in acute renal damage but are not yet known in chronic kidney disease. Unilateral ureteral obstruction (UUO) is a model of interstitial fibrosis. We investigated whether MSC infusion modified histopathology of kidney in a rat model of UUO.

Methods

We studied two groups of Sprague-Dawley rats. Group A: 12 rats were undergone UUO. Group B: 12 rats were undergone UUO and injected with MSC at day 0. Animals were sacrificed at days 1, 7 and 21 after UUO and kidneys were removed for histological and morphometric analysis. IL6, TGFbeta and angiotensin II levels were measured. ED1 positive cells were evaluated, TGFbeta tissue levels by ELISA, apoptosis by TUNEL, maximal tubular diameter (MDT) was measured. Renal fibrosis was measured by Sirius Red staining.

Results

AT II increased significantly after ureteral ligation in group A on day 7, but did not increase in group B (A day 7: 7.3+/-2, day 0 0.94+/-0.32, p=0.05). IL-6 was significantly higher in group A compared to group B on day 7 (A 101.6+/-6.4, B 36.1+/-0.8, p=0.05). The number of apoptotic cells was significantly greater in group A than group B (day 7 A 1.1+/-0.1, B 0.3+/-0.07, p=0.01). On day 21 serum and tissue levels of TGFbeta were significantly higher in untreated rats compared to MSC treated rats. MTD was significantly smaller in obstructed kidneys of group B than in group A (A 81.29+/-54.3; B 48.9+/-29.13, p=0.0001). In MSC treated rats monocytes number was lower than in untreated rats (day 7, number of ED1 cells/microscopic field A 43.2+/-10.36, B 19.31+/-5.2, p=0.0001). The fibrosis was significantly less severe in group B than in group A (p=0.0001).

Conclusion

Our results demonstrate that MSC infusion in experimental model of UUO attenuates renal injury, inhibiting tubular cells apoptosis, modulating the release of inflammatory and profibrotic cytokines, reducing tubular atrophy and interstitial fibrosis.

### TH-PO745

**Identification of Tubular Heparan Sulfate as a Major Docking Platform for the Alternative Complement Component Properdin in Proteinuric Renal Disease** Azadeh Zaferani,[1] Romain Vives,[4] Mohamed R. Daha,[1,3] Jelleke J. Hakvoort,[1] Gerjan Navis,[1] Harry Van Goor,[2] Pieter van der Pol,[3] Hugues Lortat-Jacob,[4] Marc Seelen,[1] Jacob Van den Born.[1] *[1]Nephrology, Univ Med Center Groningen; [2]Pathology, Univ Med Center Groningen; [3]Nephrology, Univ Med Center Leiden, Netherlands; [4]Institut de Biologie Structurale, Grenoble, France.*

**Background**: Properdin (P) binds to Proximal Tubular Epithelial Cells (PTEC) and activates the complement system via the Alternative Pathway (AP) in vitro. Cellular ligand(s) for P have not been identified yet. As P was known to interact with solid-phase heparin, we investigated whether heparan sulfate (HS) proteoglycans could be the physiological ligand of P. **Methods**: The binding of purified human P to HK-2 PTECs, and to immobilized HS has been analyzed by ELISA and Surface plasmon resonance spectroscopy (BIAcore). Functional activity of HS-bound P on HK-2 cells was investigated by FACS analysis. The binding specificity of P was determined using HS-degrading enzymes and competition assays with modified and intact HS-like polysaccharides. **Results**: Kidneys from proteinuric rats showed tubular presence of P, which was not seen in control renal tissue. In vitro, HK-2 cells did not constitutively express P. However, P binds to these cells in a dose-dependent fashion. Binding was prevented by heparitinase pretreatment of the cells, and was dose-dependently inhibited by exogenous heparin. ELISA and BIAcore showed a strong dose-dependent interaction between HS and P (KD=128 nM). Pretreatment of HS proteoglycan with heparitinase abolished this interaction in ELISA. Competition assays, using a library of HS-like polysaccharides showed that sulfation pattern, chain length and backbone composition determine interaction. Interestingly, two non-anticoagulant heparin derivatives inhibited P-HS interaction in ELISA and BIAcore. C3 binding upon P incubation on HK-2 cells was HS dependent as shown by FACS. **Conclusion**: Our data identify tubular HS as a novel docking platform for AP activation *via* P, which might play a role in proteinuric renal damage. Our study also suggests non-anticoagulant heparinoids for renoprotection in complement dependent renal diseases.

### TH-PO746

**Lack of the Lectin-Like Domain of Thrombomodulin Worsens Shigatoxin (Stx)-Induced HUS in Mice** Carlamaria Zoja,[1] Monica Locatelli,[1] Chiara Pagani,[1] Edward M. Conway,[3] Giuseppe Remuzzi,[1,2] Marina Noris.[1] *[1]Mario Negri Institute for Pharmacological Research, Bergamo, Italy; [2]Unit of Nephrology and Dialysis, Azienda Ospedaliera Ospedali Riuniti di Bergamo, Italy; [3]Centre for Blood Research, University of British Columbia, Vancouver, Canada.*

Mutations of thrombomodulin (TM), a transmembrane endothelial cell glycoprotein with anticoagulant, anti-inflammatory and cytoprotective properties, have been recently implicated in the development of atypical HUS. We and others have found that in vitro TM expression was decreased in microvascular endothelial cells exposed to Stx, the causative agent of diarrhea-associated HUS (D+HUS), suggesting that impaired TM activity/levels may play a role also in D+HUS. In a murine model of Stx-HUS we studied the effect on disease course and severity of deletion of the lectin-like domain of TM that is critical for its anti-inflammatory and cytoprotective properties. Disease was induced by i.p. injection of Stx2 (200ng) plus LPS 75ug) in mice lacking the lectin-like domain ($TM^{Led/Led}$ mice) or in wild type mice ($TM^{wt/wt}$). $TM^{Led/Led}$ mice had higher ($p<0.01$) mortality after Stx2/LPS than $TM^{wt/wt}$ mice. $TM^{Led/Led}$ mice exhibited more severe thrombocytopenia and renal failure (BUN: 24h,104±6 vs 54±8 mg/dl, $p<0.01$) compared to $TM^{wt/wt}$. In $TM^{Led/Led}$ mice, intraglomerular fibrinogen deposits were detected earlier (at 3h) than in $TM^{wt/wt}$ mice (at 6h). More abundant fibrinogen deposits were also found in the brain of $TM^{Led/Led}$ mice. Lack of the lectin-like domain of TM resulted in a stronger inflammatory reaction in the kidney after Stx2/LPS, with a higher number of neutrophils infiltrating glomeruli and renal interstitium ($p<0.01$ vs WT mice). Interstitial accumulation of monocytes/macrophages was also more abundant ($p<0.05$ vs $TM^{wt/wt}$ mice). These data document that $TM^{Led/Led}$ mice exhibited earlier onset of HUS that, over the follow-up, was worse than in the $TM^{wt/wt}$ mice, suggesting that loss of TM function may increase susceptibility to the development of thrombotic microangiopathic lesions after Stx infection. These findings suggest that TM may be a therapeutic target for D+HUS.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO747

**Changing Pattern of Pediatric Nephropathy in Korea over the Last Thirty Years; a Review of Pathologic Diagnosis** Kyoung Hee Han,[1] Yun Hye Jung,[1] Hyun Kyung Lee,[1] Il-Soo Ha,[1] Hae Il Cheong,[1] Yong Choi,[2] Hee Gyung Kang.[1] *[1]Department of Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Department of Pediatrics, Inje University Haeundae Paik Hospital, Pusan, Republic of Korea.*

During the last thirty years, two major changes that might affect the pattern of pediatric nephropathy were made in Korea; mandatory hepatitis B virus (HBV) vaccination launched in 1985 and nation-wide school urinalysis screening legislated in 1998. In this study, the pathologic diagnosis during the last 30 years at our center, a tertiary-referral hospital of Korea, were studied to assess the pattern of pediatric nephropathy in Korea, .

A total of 1,769 cases (M: F 1.7:1) of pathologic diagnosis were made in pediatric native kidneys between 1980 and 2010. During the recent years since 1998 (n=786), the most common indication of renal biopsy was nephrotic syndrome (NS, in 26.5%), followed by glomerulopathy with gross hematuria (GHU, 24.4%), asymptomatic urinary abnormalities (AUA, 21.6%), and nephropathy with systemic symptoms (12.4%). On the other hand, before the legislation of school urinary screening in 1998 (n=983), NS had been the far more common indication of renal biopsy (49.7%) and AUA was uncommon (4.4%), while the others were similar.

During the recent years, the most common pathologic diagnosis was IgA Nephropathy (IgAN, 32.4%), followed by focal segmental glomerulosclerosis (FSGS, 12.7%) and minimal change disease (MCD, 10.4%). The ranks of diagnoses were different in the past; before 1998, MCD was the most common (24.6%) and IgAN (17.2%) was in the third place following FSGS (13.8%). Membranous nephropathy (MN) decreased over time from 5.2 % in the past to 2 % recently, while the proportions of other diagnoses were similar over the years.

Over the past 30 years, the pattern of pediatric nephropathy in Korea did change reflecting the changes of social system. IgAN increased after legislation of school screening, and MN decreased because the mandatory HBV vaccination eradicated HBV-associated MN, the major cause of childhood MN in Korea in the past. In addition, MCD decreased because biopsy is not performed for steroid-sensitive NS any more.

**Nationwide Epidemiological Survey of Biopsy-Proven Renal Diseases in Japan by National Hospital Organization** Kensuke Joh, Akira Sugawara. *National Hospital Organization Kyoto Medical Center, Clinical Research Center, Kyoto, Japan.*

National Hospital Organization (NHO) Kidney Network conducted nationwide registry from the 18 centers in order to elucidate epidemiological data including age, gender, laboratory data, and frequency of biopsy-proven renal diseases in Japan, because there has been no concrete data in Japanese population. The 1806 renal biopsies (male 51%, female 49%) from all native kidneys were available from 2004 to 2007. To analyze the data set, the classification of the diagnoses for each case was determined by clinical diagnoses (WHO), etiological diagnoses (A), and morphological diagnoses (B) according to Japan Renal Biopsy Registry System. Most common clinical diagnosis was chronic nephritic syndrome (CNS) (65%) followed by nephrotic syndrome (NS) (24%), rapidly progressive nephritic syndrome (RPNS) (6%), acute nephritic syndrome (ANS) (2%), and others. Most common etiological diagnosis was IgAN (37%) followed by primary GN (33%) and others. Morphological diagnosis consisted of mesangial proliferative GN (42%), minimal change disease (18%), membranous GN (MGN) (9%), Crescentic GN (7%), MPGN (6%) and others. The distribution of the diagnoses was separated by age respecting each clinical and pathological diagnoses A and B. ANS showed a peak at 10's, whereas NS consisting of minimal change NS (33%), MGN (26%), DM nephropathy (11%), and others (30%) as well as RPNS consisting of CrGN showed peak at 60's. CNS showed biphasic peaks and consisted of IgAN (10's and 50's, 49%), primary GN (19%), HSPN (0's and 70's, 5%), and hypertensive nephropathy (7%). Primary GN consisted of MCNS (41%), MGN (26%), crescentic GN (11%), and MPGN 5%. As for CKD profile, IgAN, MGN, DM nephropathy, and hypertensive nephropathy showed peaks at CKD stage 1, stage 2, stage 3, and stage 3, respectively. In conclusion, classifying data set by 3 categorical diagnoses was useful. Although renal biopsies are underwent by different policy in each country, epidemiological data of biopsy-proven renal diseases in Japan can be compared with those of foreign countries and proposed a starting point of international action against CKD.

**Descriptive Epidemiology of Biopsy-Proven Glomerular Diseases in Children from the University of Florida-Shands Hospital Renal Biopsy Registry over Three Decades (1979-2009)** Ruth Indahyung, Corinne Ahmar, Kenneth E. Lamb, Stephen I.-Hong Hsu. *Division of Nephrology, Hypertension and Renal Transplantation, College of Medicine, University of Florida, Gainesville, FL.*

**Purpose**: We determined incidence of all glomerulonephritides (GNs) for children in a new renal biopsy registry for the UF-SH located in Gainesville, FL, representative of the unique racial/ethnic and age composition of the population served by our single academic medical referral center. **Methods**: Among 3,422 cases of renal biopsies performed during 1979-2009, we identified 1,517 unique cases of diagnostic biopsies including 1,331 glomerular diseases (GDs). We studied all 686 cases of GD in children age 0-19, further subcategorized into 4-year age intervals. 91% of cases resided in FL. **Results**: In our study cohort (N=686) the number of cases in each 4-year interval was similar above age 3 (20-25%) and slightly lower below age 3 (13%); M/F ratio was 1.16/1. Caucasians (58.1%) were overrepresented compared to African Americans (25.8%) or Hispanics (4.5%). The most common GNs were minimal change disease/MCD (17.5%), lupus nephritis/LN (16.4%), primary focal segmental glomerulosclerosis (12.4%) and IgA nephropathy/IgAN (10.2%). The most common primary GNs (PGNs) were MCD (26%), FSGS (18.4%) and IgAN (15.2%). The most common secondary GNs were LN (54%), post-infectious GN (9.9%) and diabetic nephropathy/DM (8.5%). The incidence declined dramatically after age 15 for MCD (22-26% vs 7%) and mesangiocapillary glomerulonephritis (10-22% vs 2%). The incidence of rose sharply after age 12 for LN (2-6% vs 31%) and DM (0% vs 8%) was observed. **Conclusion**: Unlike reports of a low incidence of IgAN (1-2%) in children by other registries in the US and India that only studied GN with nephrotic syndrome, we report the novel finding that the incidence of IgAN was as high as FSGS among PGNs. MCD remained the most common PGN. MCD and MesGN were more common in younger children age 0-15; LN and DM were more common in older children age 12-19, indicating that age can be useful in predicting the likely etiology of GN. These findings suggest differences in geographic patterns of incidence in children for the most common GNs in the US.

**Descriptive Epidemiology of Biopsy-Proven Primary Glomerular Diseases in Adults from the University of Florida-Shands Hospital (UF-SH) Renal Biopsy Registry over Three Decades (1979-2009)** Ruth Indahyung, Corinne Ahmar, Kenneth E. Lamb, Stephen I.-Hong Hsu. *Division of Nephrology, Hypertension and Renal Transplantation, College of Medicine, University of Florida, Gainesville, FL.*

**Purpose**: We determined the incidence pattern of primary glomerulonephritides (PGNs) for adults in a newly created renal biopsy registry for the UF-SH in Gainesville, FL, representing the unique racial/ethnic and age composition of the population served by our single academic medical referral center. **Methods**: Among a total of 3,422 cases of renal biopsies performed during the period of 1979-2009, we identified 1,517 unique cases of diagnostic renal biopsies. Glomerular disease was diagnosed in a total of 1,331 cases of which 638 were adults (age ≥20 years). We studied all 308 cases of PGNs in adults age 20-85. 97% of cases resided in FL. **Results**: Our study cohort (N=308) had similar numbers of young (age 20-39) vs older adults (age ≥40) (48.7 vs 50.6%); M/F ratio was 0.88/1. Caucasians (CCs, 64%) were overrepresented compared to African Americans (AAs, 22.7%) and Hispanics (HSPs, 4.9%). Among the 3 most common PGNs the incidence of IgAN (25.6%), FSGS (24.4%) and MGN (24%) was not statistically different across race except for IgAN in AAs (<1%). Incidence between age groups (young/older adults) was different for IgAN (34/17.9%) and MGN (16/32.1%) and identical for FSGS (24/23.7%). Comparison by race and age (CCs/AAs/HSPs and young/older adults) revealed significant race-age incidence patterns for IgAN (25.3/0.67/4% vs 14.1/1.3/0.64%), FSGS (10.7/12/0% vs 14.1/5.8/1.9%) and MGN (7.3/5.3/0.67% vs 19.9/8.3/1.9%). **Conclusion**: Unlike previous reports, we found that incidence associated with race alone could not predict the likelihood of a pathologic diagnosis of IgAN, FSGS or MGN. Instead, age-race incidence showed that IgAN was most common in young adult CCs. (25.3%), while MGN was most common in older adult CCs (19.9%); FSGS was similarly more common in young AAs (12%) and older CCs (14.1%). These findings suggest differences in geographic patterns of incidence for the most common PGNs in the US.

**Zero-Time Kidney Histology Predicts Early Graft Function** Helena Viana, Fernanda Carvalho, Maria Joao Galvao, Ana Rita, Fernando Nolasco. *Department Nephrology, Hospital Curry Cabral, Lisbon, Portugal.*

Our purposes are to determine the impact of histological factors observed in zero-time biopsies on early post transplant kidney allograft function. We specifically want to compare the semi-quantitative Banff Classification of zero time biopsies with quantification of % cortical area fibrosis.

Sixty three zero-time deceased donor allograft biopsies were retrospectively semi-quantitatively scored using Banff classification. By adding the individual chronic parameters a Banff Chronic Sum (BCS) Score was generated. Percentage of cortical area Picro Sirius Red (%PSR) staining was assessed and calculated with a computer program.

A negative linear regression between %PSR/ GFR at 3 year post-transplantation was established (Y=62.08 +-4.6412X; p=0.022). A significant negative correlation between arteriolar hyalinosis (rho=-0.375; p=0.005), chronic interstitial (rho=0.296; p=0.02) , chronic tubular ( rho=0.276; p=0.04) , chronic vascular (rho= -0.360;P=0.007), BCS (rho=-0.413; p=0.002) and GFR at 3 years were found. However, no correlation was found between % PSR, Ci, Ct or BCS.

In multivariate linear regression the negative predictive factors of 3 years GFR were: BCS in histological model; donor kidney age, recipient age and black race in clinical model.

The BCS seems a good and easy to perform tool, available to every pathologist, with significant predictive short-term value. The %PSR predicts short term kidney function in univariate study and involves extra-routine and expensive-time work. We think that %PSR must be regarded as a research instrument.

**TH-PO752**

**Intimal Arteritis Has No Impact on Graft Survival in T Cell-Mediated Rejection** Joana Sellares, Jeff Reeve, Michael Mengel, Declan G. de Freitas, Banu Sis, Philip F. Halloran. *Department of Medicine, University of Alberta, Edmonton, AB, Canada.*

We analyzed 314 kidney transplant biopsies for cause resulting from 314 recipients, between 6 days to 32 years post-transplant. Biopsies were classified according to a modified Banff classification that included C4d-negative antibody-mediated rejection (ABMR). Death censored graft survival analysis was performed using the Kaplan–Meier method.

The current Banff i-score was not associated with graft survival (Fig.1A). Severe tubulitis correlated with worse outcomes (Fig.1B): of the 9 failures, 3 were attributed to polyoma virus nephropathy and all the 6 remaining rejection cases except for one had

donor-specific antibodies (DSA) at the time of biopsy and failure could be attributed either to ABMR, non-adherence or medical conditions. Endothelialitis was present in 19 grafts of which 11 were T cell-mediated rejection (TCMR), 7 ABMR and 1 mixed: 13 of them had v1, five v2 and one case had v3 with fibrinoid necrosis. Intimal arteritis was not associated with worse outcomes (Fig.1C); only 5 grafts failed: 3 were ABMRs and 2 TCMRs. One of these two patients was found to be non-adherent and the graft failed one year after the biopsy having DSA, and the other failed due to medical conditions months after the biopsy. Nearly 50% of the cases with v-lesions were treated with steroids alone, and almost all of them were TCMRs.

Infiltrates in non-scarred areas have no impact on graft survival: mainly represent potentially reversible conditions such as TCMR when properly treated. Severe tubulitis is associated with poor outcomes when is present in other entities than TCMR alone. Endothelialitis does not confer an additional risk when it occurs in TCMR alone regardless of the treatment received. The prognostic significance of these lesions is determined by the disease that is causing them: the lesions *per se* are non-specific.

**Cytometry Enhancement of Transplant Kidney Biopsies: Leukocyte Identification** Kimberly A. Muczynski, Nicolae Leca, Susan K. Anderson. *Medicine, University of Washington, Seattle, WA.*

The renal biopsy has been the gold standard for assessing transplanted kidneys. However, histology shows neither the leukocytes circulating within the kidney nor the type or activation state of leukocytes that have migrated into the tissue. Flow cytometry is a technique with the potential for providing this information.

We developed a procedure for reducing 16 gauge core renal biopsies to suspensions of cells for flow cytometric analysis without losing leukocyte epitopes (NDT, 2010) and are now characterizing leukocyte subsets and their activation state in transplant biopsies to better define the immunologic processes active in allografts. We find the following:

1) Peripheral circulating CD45+ leukocytes differ from those found within human kidneys and their activation states are also distinct. For example, granulocytes predominate in the peripheral circulation but are rarely found in normal native or transplanted kidneys.

2) Rejection is associated with a predominance of CD8+ over CD4+ T cells; this may allow rejection to be distinguished from BK nephropathy and nonspecific interstitial inflammation.

3) Renal CD3+ T cells express increased levels of HLA-DR with inflammatory conditions of rejection, BK nephropathy and nonspecific interstitial inflammation.

4) Invariant NKT cells are present in normal kidney; CD1d is expressed on renal microvascular endothelial cells and on some leukocytes.

5) NK (CD56+, CD3-) and NKT (CD56+, CD3+) cells are present in normal native and transplanted kidneys.

Flow cytometry is a valuable addition to traditional histology for evaluating immune processes in transplanted kidneys. Information provided by cytometry will likely be useful in directing immunosuppression.

**Renal Transplantation in Recipients with Positive Luminex and Negative CDC (Complement-Dependent Cytotoxicity) Crossmatch** Dong Jin Joo, Kyu Ha Huh, Yu Seun Kim, Tae-Hyun Yoo. *Transplantation Center, Yonsei University College of Medicine, Seoul, Korea.*

**Background:** The presence of preformed antibodies against HLA (human leukocyte antigen) is considered as contraindication to renal transplantation. CDC (complement-dependent cytotoxicity) crossmatch has been used to identify the donor-specific HLA antibodies. Recently, Luminex-crossmatch (LumXm, DSA; Tepnel Lifecodes, Stamford, CT) with the advantage of greater sensitivity and specificity was introduced. The aim of this study is to evaluate clinical outcomes in positive Luminex and negative CDC crossmatch (CDCXm) renal transplantation.

**Methods:** Three hundred-six renal transplants were performed from February 2008 to April 2010. Forty-four recipients had negative CDCXm with more than 20% PRA (Panel-reactive antibody). Of this 44 recipients, 17 patients showed positive LumXm defined as positive class I and/or II LumXm and 27 patients showed negative LumXm. Post-transplant outcomes of LumXm(+) was compared with those of LumXm(-) group.

**Results:** Mean follow-up duration was 11.5 ± 8.5 and 12.9 ± 7.2 months for LumXm(+) and LumXm(-) groups, respectively (p=0.582). During this period, there was no patient death and graft failure. Incidence of acute rejection which was diagnosed by biopsy or clinical evaluation was higher in LumXm(+) group (n=11, 64.7%) than in LumXm(-) group (n=5, 18.5%) (p=0.004). All biopsy-proven acute rejection (n=10) was diagnosed as cellular rejection. Mean serum creatinine of LumXm(+) and LumXm(-) group at post-ransplant 3 month was 1.18 ± 0.26 and 1.18 ± 0.23 (mg/dL), respectively (p=0.994).

**Conclusion:** Renal transplant recipients with LumXm(+) and CDCXm(-) predispose to acute rejection compared with those with LumXm(-). Short-term post-transplant graft function of LumXm(+) was comparable to LumXm(-) group.

Posttransplant Outcomes

| | LumXm(+) (n=17) | LumXm(-) (n=27) | p-value |
|---|---|---|---|
| DGF | 2 (11.8%) | 1 (3.8%) | 0.552 |
| Acute rejection | 11 (64.7%) | 5 (18.5%) | 0.002 |
| sCr-1mon (mg/dL) | 1.45±0.76 | 1.19±0.36 | 0.140 |
| sCr-3mon (mg/dL) | 1.18±0.26 | 1.18±0.23 | 0.994 |
| Graft failure | none | none | |
| Patient death | none | none | |

Disclosure of Financial Relationships: nothing to disclose

**Urinary MCP1 Decrease Predicts Long Term Prognosis in Proliferative Lupus Nephritis** Patrícia Malafronte, Aline Resende, Cristiane Bitencourt Dias, Cilene Carlos Pinheiro, Rui Toledo Barros, Viktoria Woronik. *Nephrology, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, São Paulo, Brazil.*

Urinary MCP1 is related to inflammatory state and flare activity in Lupus Nephritis (LN). Its importance in renal prognosis has not been clearly established. The aim was to describe any relations of urinary MCP1 with clinical characteristics, especially renal outcomes. Twenty-three female newly diagnosed with proliferative LN were prospectively followed-up during 3.6±0.9 years. Urinary MCP1 was collected on diagnosis and after six months of treatment. Conventional laboratory tests were collected on diagnosis and on last follow-up. Patients were stratified in two groups according to renal outcome: GFR ≤ 60 mL/min/1.73m$^2$ (n=7) and GFR > 60mL/min/1.73m$^2$ (n=16). Considering treatment, all patients received prednisone and 6 pulses of cyclophosphamide (CYA) on induction. Results in Table 1.

Table1. Clinical and biochemical characteristics of patients

| | GFR > 60ml/min/1,73m2 (n=16) | GFR ≤ 60ml/min/1,73m2 (n=7) | P |
|---|---|---|---|
| Age (years) | 25.6 ± 7.5 | 29,0 ± 14.5 | ns |
| Initial GFR – MDRD (ml/min/1,73m2) | 43.0 ± 25.4 | 25.7 ± 18.4 | ns |
| Initial Proteinuria (g/dia) | 4.2 ± 2.3 | 5.5 ± 2.5 | ns |
| Systemic SLEDAI | 25.5 ± 4.8 | 24.7 ± 3.6 | ns |
| Renal SLEDAI | 13.2 ± 2.4 | 12.6 ± 1.5 | ns |
| Follow-up (years) | 3.7 ± 0.7 | 3.8 ± 1.8 | ns |
| Flare (n) | 0.4 ± 0.5 | 1.4 ± 0.5 a | 0.01 |
| Last GFR – MDRD (ml/min/1,73m2) | 98.1 ± 19.1 | 32.6 ± 16.8 | <0.0001 |
| Last Proteinuria (g/day) | 0.4 ± 0.4 | 2.8 ± 2.0 | 0.03 |
| Initial Urinary MCP1 (pg/mL) | 3133.7 ± 2165.8 | 1809.1 ± 1040.7 | ns |
| 6 months Urinary MCP1 (pg/mL) | 822.9 ± 649.9 | 1019.3 ± 554.2 | ns |
| Δ Urinary MCP1 (initial - 6 months) | 2311 ± 2237 | 790 ± 766 | 0.025 |

X ± SD a n=5

Urinary MCP1 delta values during induction treatment correlates with delta GFR on follow-up (r = -0.5, p = 0.01). Summary- Patients with proliferative LN and worse renal outcome showed lower decrease (Δ) of urinary MCP1 calculated by initial values and after 6 months of induction treatment. However, there was no correlation with absolute values of initial and 6 months urinary MCP1.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO756**

**The Morphological Evidence for the Importance of Neutrophilic to Development of Active Lesion on Lupus Nephritis (LN)** Noriko Uesugi, Michio Nagata. *Dep. of Renal Pathology, Uviversity of Tsukuba, Tsukuba, Ibafaki, Japan.*

The recent evidence of high ANCA level and lower degradation abilities for neutrophilic extracelluar traps (NET) in LN patient suggest importance of pathogenic role of neutrophil for progression of LN. Activated neutrophils release neutrophilic elastase (Ela) and myeloperoxidase (MPO) which coordinate macrophages to promote LN progression. In this regards, *in situ* interaction between neutrophils and macrophages in LN provides clue to understand pathophysiology in LN. The present study enrolled 42 renal biopsy specimens of LN (RPS/INS Class II 7, III 10, IVS 5, IVG 12 and V 8 for immunohistochemical study. Using serial sections, each glomerulus was evaluated for type of active lesions, such as crescent, endocapillary proliferation, necrosis, hyaline thrombi(HyT) and Wire loop (WL). In addition, Elas, MPO and CD68-positive cells are counted in each glomerulus. Results: Glomerular infiltration of MPO, Elas and CD68 positive cells revealed significantly higher in Class IVG and IVS than that with II, III and V(p=0.05). CD68-positive cells are highest cells. Glomeruli with necrosis, cellular crescent and endocapillary proliferation contain higher number of MPO and Elas-positive cells than WL and HyT. Extra-cellular localization

of MPO and Elas in active proliferative lesion suggests presence of NET in situ. MPO-positive cells were significantly more than that of Elas. There noted MPO and CD68- double rebelled cells in the active lesions. The number of MPO and Ela positive cells are good correlation with that of CD68 positive cells (r=0.73, 0.69, respectively).

Infiltrating cells and active lesion

| Predominant lesion | Cellular Cre | FC Cre | Necrosis | Endo | HyT | WL |
|---|---|---|---|---|---|---|
| No. of gl | 23 | 12 | 7 | 121 | 9 | 77 |
| CD68+cells /gl | 12.0±8.0 | 7.8±5.5 | 21.5±15.1 | 16.3±9.8 | 12.5±4.9 | 13.2±8.7 |
| MPO+cells /gl | 10.0±5.5a | 3.1±2.4 | 20.5±5.8b | 10.9±8.8a | 5.4±5.4 | 3.9±3.0 |
| Elas+cells /gl | 5.8±2.7 | 2.8±2.4 | 17.8±13.1c | 6.6±5.3 | 4.5±5.3 | 2.9±5.3 |

a p=0.05 vsWL, b p=0.05 vs FC cre,HyT,WL

Conclusion: Neutrophils and macrophages may involve active proliferative lesions in LN *via* production of MPO, suggesting that MPO and NET may promote tissue injury severe active LN.

Disclosure of Financial Relationships: nothing to disclose

**Repeated Renal Biopsy in Lupus Nephritis** Jianxin Lu, Bonnie Kwan, Kai Ming Chow, Philip K. T. Li, Cheuk-Chun Szeto. *Dept of Medicine and Therapeutics, Prince of Wales Hospital, The Chinese University of HongKong, HongKong, China.*

*Background* The role of sequential renal biopsies in lupus nephritis (LN) patient with regard to clinical factor remains elusive. *Methods* Clinical and pathological documents of 151 LN Patients with repeat renal biopsies (242 times) were collected from database. *Results* The percent of transformation of biopsy class from first to second biopsy is between 50-96.67%. The percent of transformation of biopsy class for III or IV, pure V and III or IV plus V is 60.47%, 47.59% and 55.56% respectively. Chronicity index is significantly different between first and second biopsy ($p<0.001$). LN patients with treatment during sequential biopsies are more likely to transform compare with patients without treatment (p=0.04). *Conclusion* In patients with lupus nephritis, there is a high frequency of transformation of biopsy class during repeat biopsy. The sequential renal biopsies have clinical meaning and can be used as a marker for the development and treatment of LN.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO758

**Renal Expression of Vasohibin-1, a Novel Endothelium-Derived Angiogenesis Inhibitor, in Patients with Renal Disorders** Norikazu Hinamoto, Yohei Maeshima, Tatsuyo Nasu, Masaru Kinomura, Shinji Kitamura, Hitoshi Sugiyama, Hirofumi Makino. *Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama-shi, Japan.*

Glomerulosclerosis and tubulointerstitial injuries are involved in the progression of renal disorders. Vasohibin-1 is an unique endogeneous angiogenesis inhibitor, initially identified in endothelial cells induced by proangiogenic factors such as VEGF-A, serving as a negative feedback regulator of angiogenesis as well as a maturation factor of neovessels. We previously reported the therapeutic efficacy of Vasohibin-1 in a mouse diabetic nephropathy model (Diabetes, 2009). The aim of the current study is to examine the renal expression of Vasohibin-1 in patients with various renal disorders and to evaluate its clinical usefulness. We examined renal expression of Vasohibin-1 by immunohistochemistry using renal biopsy sections obtained from 26 patients with renal disorders including chronic glomerulonephritis, nephrotic syndrome and diabetic nephropathy. The number of Vasohibin-1+ cells in glomeruli, cortical or medullary tubulointerstitium was determined, and correlation with clinical and histological parameters were examined. Vasohibin-1 was observed in endothelial and mesangial cells in glomerulus, and in endothelia of peritubular capillaries and inflammatory cells in tubulointerstitium. The number of Vasohibin-1+ cells in cortex correlated with the number of glomerular Vasohibin-1+ cells (r=0.78, $P<0.01$) and crescent formation (r=0.48, $P=0.03$), and tended to correlate with eGFR (r=0.40, $P=0.07$) and the number of Vasohibin-1+ cells in medulla (r=0.59, $P=0.09$). The number of Vasohibin-1+ cells in medulla correlated with crescent formation (r=0.81, $P<0.05$) and tended to correlate with proteinuria (r=0.80, $P=0.05$) and interstitial fibrosis (r=0.62, $P=0.19$). Further analysis on the renal levels of VEGF-A and microvascular density is underway. Taken together, these results suggest that endogenous Vasohibin-1 may be associated with renal function, crescentic lesion, interstitial fibrosis and proteinuria in various renal disorders, thus implicating its potential to serve as a novel renal biomarker.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO759

**Urinary Exosomal Fetuin-A Level Correlated with Urinary beta-2 Microglobulin Concentration in Patients with Various Renal Diseases** Sayaka Oshikawa,[1] Hiroko Sonoda,[1] Saki Takahashi,[1] Shigehiro Uezono,[2] Akira Ueda,[2] Naoko Yokota-Ikeda,[2] Masahiro Ikeda.[1] *[1]Veterinary Pharmacology, University of Miyazaki, Miyazaki, Japan; [2]Internal Medicine, Miyazaki Prefectural Miyazaki Hospital, Miyazaki, Japan.*

Urinary exosomes are originated from glomerular podocytes and epithelial cells lining the renal tubules, and are known to carry protein biomarkers of renal dysfunction and injury. Fetuin-A, a potent inhibitory protein of systemic calcification, in urinary exosomes has been identified as one of the biomarkers for kidney diseases such as acute kidney injury and urolithiasis. However the relationship of urinary exosomal fetuin-A level with conventional renal disease markers remains largely unknown. In this study, we examined the correlation of urinary exosomal fetuin-A level with conventional markers such as serum creatinine concentration (SCr), creatinine clearance (CCr), urinary N-acetyl-beta-D-glucosaminidase activity (NAG), and urinary beta-2-microglobulin concentration (B2M). The institutional review boards of Miyazaki Prefectural Miyazaki Hospital approved this study in accordance with Ethical Guidelines for Clinical Studies in Japan. Spot urine and blood samples were collected from 30 patients with various types of renal diseases including IgA nephropathy, membranous nephropathy, focal glomerulosclerosis, ANCA-associated glomerulonephritis, acute kidney injury, and etc. In order to isolate exosomes, urine samples were subjected to differential centrifugation, and then urinary exosomal fetuin-A was analyzed by immunoblotting. Urinary exosomal fetuin-A level in all patients did not correlate with SCr, CCr, or NAG. However exosomal fetuin-A abundance significantly correlated with urinary B2M ($r = 0.64$, $P < 0.01$). Urinary exosomal fetuin-A level in 14 patients who had higher urinary B2M (more than 200 mg/l) tended to be increased (3 fold), compared to that in 16 patients with normal range B2M. When reabsorptive ability for filtered B2M is impaired in proximal tubular cells, urinary B2M is known to be increased. Thus, together with present data, it is considered that urinary exosomal fetuin-A may be indicative of a disorder of reabsorption function of proximal tubule cells.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO760

**Urinary Levels of MMP-2, MMP-7, MMP-9, TIMP-1, and TIMP-2 in Pediatric Nephrotic Syndrome and FSGS** Kimberly Czech, Michael R. Bennett, Mark Mitsnefes, Prasad Devarajan. *Pediatric Nephrology & Hypertension, Cincinnati Children's Hospital, Cincinnati, OH.*

Most idiopathic nephrotic syndrome in children is steroid responsive and has a good long-term prognosis. About 10% of cases are steroid resistant and are diagnosed with focal segmental glomerulosclerosis (FSGS). Metalloproteinases and their inhibitors (TIMPs) are involved in tissue-remodeling. We hypothesize that urinary levels of these enzymes are increased in FSGS as compared to steroid-sensitive minimal change disease (SSNS).

**Objective**: Compare urinary levels of MMP-2, MMP-7, MMP-9, TIMP-1, and TIMP-2 in SSNS, FSGS, and healthy age-matched controls.

**Methods**: Urine and clinical data were collected from patients at Cincinnati Children's Hospital with FSGS, SSNS (relapse & remission) as well as healthy controls. Urinary measurements of MMP-2, MMP-7, MMP-9, TIMP-1, and TIMP-2 were performed using a commercially available ELISA kit.

**Results**: This study included subjects in the following three groups: biopsy-proven FSGS and steroid resistant clinical course (n=16), steroid-sensitive clinical course (n=19), and normal controls (n=15). Median levels were calculated and subjected to Kruskal-Wallis One Way ANOVA (Dunn's multiple comparison test). MMP-2, -7, -9, and TIMP-1, 2 were all significantly elevated ($P<0.05$) in FSGS as compared to SSNS and controls. When, we looked at MMP-2,-7, -9/timp1 ratios a significant decrease ($p<0.05$) was seen in FSGS compared to SSNS and controls. MMP-2,-7,-9/timp2 ratios were not different between the groups.

**Conclusion**: MMP-2,-7,-9 are significantly elevated in the urine of FSGS patients as compared to SSNS. However, inhibitory enzyme levels (TIMPs 1, 2) in the urine are also significantly increased, possibly indicating a compensatory mechanism to slow matrix remodeling enzymes. Urinary levels of MMPs and TIMPs are potential biomarkers to distinguish between FSGS and SSNS.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO761

**Correlation of NGAL Levels with RIFLE Categories in Critically Ill Patients** Lars O. Uttenthal. *BioPorto Diagnostics A/S, Gentofte, Denmark.*

NGAL levels are raised in patients with acute kidney injury (AKI), but NGAL release is not specific to the injured kidney. Urine and plasma NGAL levels were correlated with RIFLE categories of AKI in unselected critically ill patients including confounding conditions such as sepsis and cancers, and samples were used to validate a new fully automated NGAL turbidimetric assay.

Urine and EDTA-plasma levels of NGAL were monitored (daily to alternate days) in 135 consecutive patients admitted to intensive care; 3 patients were excluded because of incomplete data. NGAL was measured in all samples with the BioPorto ELISA kit. Data are reported as median (interquartile range) in ng/mL. The new turbidimetric assay uses polystyrene particles coated with mouse monoclonal antibodies and recombinant NGAL as calibrator. The assay was run on a Hitachi 917 and used to measure urine samples from 130 and plasma samples from 40 of the patients.

Of 70 patients with AKI, 15 were classified as "risk" (R), 11 as "injury" (I) and 44 as "failure" (F); 62 patients did not have AKI. Urine NGAL was significantly ($p<0.0001$, Kruskal-Wallis) higher in patients with AKI [R 377 (102-830), I 519 (321-1845) and F 2747 (559-7621)] than in patients without AKI [51 (29-213)]. Plasma NGAL was also significantly ($p<0.0001$) higher in patients with AKI [R 354 (259-511), I 546 (331-1106) and F 1062 (584-1817)] than in those without [199 (128-308)]. The turbidimetric assay showed a measuring range of 25-5000 ng/mL, within-run imprecision of 2.0% and 1.2% at 200 and 500 ng/mL, respectively, and linearity from 20 to 5000 ng/mL. No effect of antigen excess was seen up to 40,000 ng/mL. Potentially interfering substances (hemoglobin 500 g/L, bilirubin 30 g/L and emulsified lipid 5.0%) had only marginal effects (<4%) on measurements. There was no statistically significant difference between ELISA and turbidimetric results for either urine or plasma samples.

Both urine and plasma levels of NGAL reflect the degree of AKI in unselected critically ill patients despite confounding conditions and may therefore be useful for the diagnosis of renal injury and monitoring of patients in intensive care; in this process the fully automated turbidimetric NGAL test can be a useful aid.

**Epithelial-Mesenchymal and Endothelial-Mesenchymal Transdifferentiation Processes in Glomerular Diseases** Flaviu Bob,[1] Gheorghe Gluhovschi,[1] Cristina A. Gluhovschi,[1] Diana Herman,[2] Elena Potencz,[2] Ligia Petrica,[1] Silvia Velciov,[1] Gheorghe Bozdog,[1] Florica Gadalean,[1] Alin Nes.[1] *[1]Nephrology, University of Medicine and Pharmacy, Timisoara, Romania; [2]Pathology, University of Medicine and Pharmacy, Romania.*

The fibroblast, the key mediator of fibrosis, originates from resident fibroblasts, from epithelial cells through epithelial-to-mesenchymal transdifferentiation, and, as recently described, from endothelial cells through endothelial-to-mesenchymal transdifferentiation. In order to assess the process of transdifferentiation we studied the expression of markers of activated fibroblasts (alpha smooth muscle actin-SMA and vimentin-Vim), of the transforming growth factor β (TGF) and of CD34, at the level of tubular epithelial cells (TEC) and interstitial vascular endothelial cells (VEC).

We studied retrospectively 41 renal biopsies from patients with primary and secondary glomerulonephritis [M-24p,F-17p,mean age 45.5±12.9y]. Immunohistochemistry using monoclonal antibodies (SMA,Vim,CD34,TGFβ) was assessed using a semiquantitative score, that was correlated with biological and histological data (quantified using a scoring system in order to assess active-inflammatory and chronic- sclerotic/fibrotic lesions).

The presence of SMA and Vim as markers of the transdifferentiation process was found in TECs and VECs. TEC Vim expression correlated with interstitial Vim expression, (R=0.38;p=0.008), interstitial infiltrate (R=0.31;p=0.027), interstitial fibrosis(R=0.25;p=0.042), GFR(R=-0.35;p=0.016), SMA(R=-0.42;p=0.015), and TGF (R=0.25;p=0.046). VEC Vim expression showed indirect correlations with interstitial infiltrate(R=-0.32;p=0.023), activity index (R=-0.33;p=0.02), interstitial fibrosis (R=-0.34;p=0.017), chronicity index(R=-0.33;p=0.023), vascular CD34 (R=-0.5, p=0.001). VEC TGF correlated with the activity index(R=0.27;p=0.04), with vascular CD34 (R=0.28, p=0.04). We found a correlation of VEC CD34 with creatinine(R=0.27,p=0.04), GFR(R=-0.44, p=0.002), activity index (R=0.28,p=0.04), chronicity index(R=0.28, p=0.04), interstitial fibrosis(R=0.35,p=0.01).

The study reflects the complexity of the transdifferentiation process with the involvement of both TECs and VECs.

**TH-PO763**

**End-Stage Renal Failure in a Young Adult: An Unusual Presentation of Late-Onset Cobalamin C Disease** Karine Hadaya,[1] Luisa Bonafé,[3] Vincent Bourquin,[1] Pierre-Yves F. Martin,[1] Olivier Boulat,[4] Matthias R. Baumgartner,[5] Brian Fowler,[6] Ilse Kern.[2] *[1]Nephrology, Geneva University Hospital, Geneva, Switzerland; [2]Pediatrics, Geneva University Hospital, Geneva, Switzerland; [3]Molecular Pediatrics, centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [4]Clinical Chemistry, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [5]Metabolism, Children's Hospital, Zurich, Switzerland; [6]Metabolism, Children's Hospital, Basel, Switzerland.*

The cblC type of methylmalonic aciduria and homocystinuria (cblC) is a rare autosomal recessive disorder leading to defective intracellular cobalamin metabolism. Late-onset disease in young adults has been reported in less than 20 cases, characterised by neuro-psychiatric and/or thrombo-embolic manifestations and a more favourable outcome than in early-onset cases.

In this report, we describe the clinical, biochemical and molecular findings in a 23-year- old man who was initially misdiagnosed as essential malignant hypertension with haemolytic uremic syndrome (HUS). He progressed to end-stage renal failure 15 days after admission. Thereafter, the finding of hyperhomocysteinemia prompted further studies in fibroblasts leading to the diagnosis of the cblC disorder. Sequencing of the *MMACHC* gene showed the homozygous missense mutation c.565C>A. Hyperhomocysteinemia decreased rapidly under intensive treatment with i.v. hydroxycobalamin, oral betaine, folate and carnitine, allowing the patient to undergo a living related renal transplantation. Eighteen months post-transplant, biochemical parameters had improved dramatically and kidney function is normal.

Renal complications such as thrombotic microangiopathy, proximal renal tubular acidosis, and chronic renal failure have been described mainly in early-onset CblC disease. To our knowledge, this is the first case of end-stage renal failure with HUS in a young adult, presumably secondary to thrombotic microangiopathy, although this could not be confirmed since hypertensive crisis precluded a diagnostic kidney biopsy.

cblC disease should be included in the differential diagnosis of malignant hypertension and/or HUS in adults, as cblC disease, although rare, is a treatable disorder.

**TH-PO764**

**The Injurious Role of IL-33 in Cisplatin-Induced Acute Kidney Injury** Ali Akcay, Quocan Nguyen, Kultigin Turkmen, Zhibin He, Sarah Faubel, Alkesh Jani, Charles L. Edelstein. *Univ of Colorado Denver.*

Caspase-3 is a mediator of cisplatin-induced apoptosis and necrosis of endothelial cells in kidney and induces release of uncleaved (active) IL-33 from necrotic endothelial cells. IL-33 signals via the ST2 receptor on CD4 T cells resulting in the production of pro-inflammatory cytokines. The aim of this study was to investigate the potentially injurious role of IL-33 in cisplatin-induced acute kidney injury (Cis-AKI). Mice were injected with cisplatin 25 mg/kg. There was tubule apoptosis (day 1), necrosis (day 2) and elevated serum creatinine (SCr) (day 3). IL-33 was measured by ELISA and the uncleaved and the cleaved forms on immunoblot. Serum IL-33 (pg/mL) was 58.7 in vehicle-treated (V) and 370.9 on day 2 (P<0.05). IL-33 (pg/mg) in kidney was 280 in V and 380 on day 1 (P<0.01). On immunoblot there was a 3-fold increase in both uncleaved and cleaved IL-33 on days 1 in nuclear and whole kidney extracts (P<0.01). On IF staining of kidney, IL-33 was localized in the endothelium. Cultured microvascular endothelial cells exposed to 10 and 50 μM Cis showed a 4-fold increase in uncleaved and a 3-fold increase in cleaved IL-33 in the medium on immunoblot that was prevented by the pancaspase inhibitor QVD-OPH (50 μM) establishing that active IL-33 is released from injured endothelial cells. To determine the injurious role of IL-33, mice were either injected with recombinant IL-33 (rIL33) or sST2, a fusion protein that can neutralize IL-33 activity by acting as a decoy receptor. SCr (mg/dL) was 0.6 in mice injected with low-dose Cis (15 mg/kg)+V and 1.7 in mice injected with low-dose Cis+rIL-33 (P<0.001). SCr was 2.2 in Cis+V and 1.0 in Cis+sST2 (P<0.01). To demonstrate the effect of IL-33 on CD4 T cells, low-dose Cis+rIL-33 was injected into the CD4 T cell -/- mice. SCr was 1.9 in WT+Cis+IL-33 and 0.6 in CD4 -/- +Cis+IL-33 (P<0.01). In summary, IL-33 is abundantly present in endothelial cells in the kidney. Cis induces a systemic IL-33 response that precedes AKI. Injection of rIL33 worsens Cis-AKI in WT but not CD4 T cell -/- mice. Inhibition of IL-33 protects against Cis-AKI. In conclusion, IL-33 may have an important role in the pathogenesis of Cis-AKI.

**TH-PO765**

**Engulfment of Apoptotic Cells by Kidney Injury Molecule-1 Is Mediated by Tyrosine Phosphorylation and Src Kinase Signaling** Lakshman Gunaratnam,[1,2] Joseph V. Bonventre,[3] Xizhong Zhang.[1,2] *[1]Medicine and Microbiology & Immunology, Schulich School of Medicine and Dentistry and The University of Western Ontario, London, ON, Canada; [2]Lawson Health Research Institute, London Health Sciences Centre, London, ON, Canada; [3]Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.*

Apoptosis or programmed cell death is a mechanism of eliminating damaged, harmful or useless cells and is crucial for maintaining tissue homeostasis in multicellular organisms. Kidney injury molecule-1 (KIM-1) has been recently identified as a scavenger receptor that transforms renal proximal tubular epithelial cells (PRTECs) into semi-professional phagocytes for clearance of apoptotic cells resulting from acute kidney injury. KIM-1 specifically recognizes phsophatidylserine (PtdSer) and oxidized lipids, both classical "eat-me" signals displayed on the surface of cells undergoing programmed cell death. The purpose of this study was to decipher how KIM-1 transduces signals downstream of PtdSer recognition to mediate engulfment of apoptotic cells. First we show that two tyrosine residues within the cytoplasmic tail of KIM-1 are tyrosine phosphorylated when KIM-1-expressing cells are treated with a protein-tyrosine phosphatase inhibitor (pervanadate). In addition, overexpression of active or wild type Src kinase in PRTECs was sufficient to trigger phosphorylation of KIM-1 while inhibition of Src activity blocked endogenous KIM-1 phosphorylaiton in PRTECs. We also show that Src activity is essential for KIM-1-mediated oxidized LDL-uptake and phagocytosis of apoptotic cells. Finally, expression of phosphorylation-defective double tyrosine mutant KIM-1 in PRTECs dramatically inhibited oxidized LDL-uptake and phagocytosis of apoptotic cells compared to wild type KIM-1 expressing cells. We propose that ligand-dependent KIM-1 activation initiates Src-dependent KIM-1 phosphorylation that is required for the phagocytic function of KIM-1 in PRTECs. Hence, KIM-1 is a functional receptor with an extracellular domain that recognizes "eat-me" signals, and an intracellular domain that regulates phagocytosis through tyrosine phosphorylation-Src-mediated signaling.

**TH-PO766**

**HuR Inhibits Apoptosis in Proximal Tubule Cells by Activating PI3K/Akt Signaling Via Grb10** Mamata Singh, Beth S. Lee. *Physiology and Cell Biology, The Ohio State University College of Medicine, Columbus, OH.*

HuR is an RNA-binding protein with multiple post-transcriptional effects on gene expression. Under cellular stress, HuR translocates from the nucleus to the cytoplasm, where it binds and stabilizes a subset of mRNAs bearing adenine and uridine rich sequences in their 3' untranslated regions. We previously demonstrated an anti-apoptotic role for HuR in ATP-depleted proximal tubule cells, suggestive of its protective function in native proximal tubules against ischemic stress. We also demonstrated specific upregulation of HuR expression in ATP-depleted cultured proximal tubule cells and in native rat proximal tubules subjected to ischemia-reperfusion injury. We have since found HuR to be protective against both the intrinsic and extrinsic apoptotic pathways, with its greatest effect in the intrinsic pathway. Here we used PCR array analysis to determine how suppression of HuR levels might affect expression of mRNAs within apoptotic pathways. Control- or siRNA-

treated proximal tubule cells were ATP-depleted and subjected to PCR array analysis. mRNAs with at least a 2-fold increase or decrease in response to HuR knockdown were taken into consideration.

The major effect of HuR knockdown in proximal tubule cells was suppression of anti-apoptotic mRNAs such as those encoding Akt and members of the Bcl-2 family. We found that HuR plays a central role in PI3K/Akt signaling, as not only did knockdown of HuR suppress many members of this pathway, but inhibition of PI3K also resulted in suppression of HuR levels, suggesting a role for HuR in a positive feedback loop. In particular, Grb10, an adaptor protein with anti-apoptotic activities downstream of PI3K/Akt, was found to be strongly suppressed by HuR knockdown. Further, Grb10 was found to contain a consensus HuR binding site in its 3' untranslated region. Therefore, these data demonstrate a central role for HuR in cell survival as both an activator of PI3K/Akt signaling and as a downstream target of PI3K/Akt-mediated gene regulation.

**Lung Inflammation after Acute Kidney Injury (AKI) Is Dependent on Alveolar Macrophages (MØ)** Chris Altmann, Ana Andres-Hernando, Nilesh Ahuja, Zhibin He, Sarah Faubel. *Renal, University of Colorado Denver.*

We have shown that systemic depletion of Mø in CD11b Tg mice improves AKI-mediated lung injury, characterized by a decrease in lung CXCL1 (KC) and lung MPO activity (a marker of neutrophil infiltration). The role of **alveolar** Mø in AKI-mediated lung injury is unknown. To determine the role of alveolar Mø in AKI-mediated lung injury, we administered intratracheal (IT) liposome encapsulated clodronate (LEC) to deplete alveolar Mø, but not systemic Mø. Sham operation (Sham) or 22 min of renal pedicle clamping (AKI) were performed in IT vehicle-treated (Veh) or IT LEC-treated C57BL6 mice. As determined by flow cytometry for Mø markers F4/80 and CD11c in the bronchoalveolar lavage fluid (BALf), IT LEC injection resulted in a significant decrease in alveolar Mø compared to IT Veh (29% vs 71%, $P < 0.01$, $N = 5$). 4 hours post-procedure, lung MPO activity and lung CXCL1 were reduced in Mø depleted mice (Table 1). SCr and serum IL-6 were the same in AKI with and without Mø depletion. Interestingly, pulmonary capillary leak, as measured by lung Evans blue dye (EBD) and BALf protein, was *worse* after alveolar Mø depletion in AKI, suggesting a protective role of alveolar Mø in maintaining the pulmonary capillary membrane. These data emphasize that alveolar Mø play an important role in mediating lung inflammation after AKI.

Table 1

| | Sham + Veh | Sham + IT LEC (Alveolar MØ depleted) | AKI + Veh | AKI + IT LEC (Alveolar MØ depleted) |
|---|---|---|---|---|
| Serum creatinine (mg/dL) | 0.6 ± 0.1 | 0.6 ± 0.1 | 0.9 ± 0.2 † | 1.0 ± 0.2 † |
| Serum IL-6 (pg/mL) | 153 ± 77 | 152 ± 62 | 941 ± 550 † | 1094 ± 120 † |

## TH-PO768

**Lack of Splenic IL-10 Production Exacerbates Lung Injury after Ischemic Acute Kidney Injury (AKI) in Mice** Ana Andres-Hernando, Chris Altmann, Nilesh Ahuja, Zhibin He, Takuji Ishimoto, Sarah Faubel. *University of Colorado Denver.*

In this study, we examined the early pro-inflammatory response of AKI and the development of lung injury in a mouse model of ischemic AKI. Kidney, spleen and liver mRNA for IL-1β, TNF-α, CXCL1, IL-6 were determined at baseline, 2, 4 and 6 hours by QPCR after sham operation (S) or ischemic AKI (22 minutes of bilateral renal pedicle clamping). In the kidney, IL-6, CXCL1, and IL-1β were increased by 2 hours after AKI (25, 28 and 8 fold increase vs. S). In the liver, IL-6 and IL-1β were increased by 2 hours after AKI (11 and 5 fold increase vs. S) and CXCL1 was increased 4 hours after AKI (6 fold increase vs. S). In the spleen, CXCL1 was increased at 2 hours (9.5 fold increase vs. S), IL-6 by 4 hours (100 fold increase vs. S), and IL-1β and TNF-α increased by 6 hours (24 and 8 fold increase vs. S). Since splenic pro-inflammatory cytokines were increased, we hypothesized that splenectomy (Splnx) would protect against AKI-mediated lung injury. On the contrary, Splnx with AKI resulted in increased serum IL-6 and worse lung injury than AKI alone. Since Splnx exacerbated the lung injury in the setting of AKI, we hypothesized that the spleen might produce a beneficial factor after AKI. We examined splenic production of the anti-inflammatory cytokine IL-10, and found that IL-10 production in the spleen was highly up-regulated 2 hours post AKI (5 fold increase vs. S), while IL-10 did not increase in the kidney. To confirm that IL-10 down-regulates the pro-inflammatory response of AKI, IL-10 was administered to splenectomized mice with AKI which reduced serum IL-6 (2599±437 pg/mL) vs. vehicle (1052±281 pg/mL) and was associated with a reduction in lung CXCL1 and lung MPO activity as well as improved lung histology. Our data demonstrate that a counter anti-inflammatory response by extra-renal IL-10 production is necessary to limit the pro-inflammatory response of AKI. In patients, AKI in the setting of conditions which limit the anti-inflammatory response may lead to acute lung injury.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO769

**Protective Role of Autophagy in Oxidant and ER Stress in Renal Tubular Cells** Sarika Kadam, Cheng Yang, Christian Herzog, Gur P. Kaushal. *Division of Nephrology, University of Arkansas for Medical Sciences,CAVHS, Little Rock, AR.*

Autophagy is a dynamic process of degradation of damaged cytoplasmic organelles and macromolecules in lysosomes to produce free amino and fatty acids that are recycled for energy production and protein synthesis. Autophagy aids cell survival during stress. Since acute kidney injury is associated with cellular stress we hypothesize that induction of autophagy during oxidative and endoplasmic reticulum (ER) stress will be protective to renal tubular epithelial cells.

Methods and Results: $H_2O_2$ and tBHP (tertiary-butyl hydroperoxide) markedly induced autophagy in LLC-PK1 cells as detected by (1) punctate staining of autophagosomes following GFP-LC3 plasmid transfection, (2) Induction of the autophagy related proteins like Atg5 & Beclin1, (3) conversion of LC3-I to lipidated LC3-II.

Overexpression of Atg5 and Beclin1 protected LLC-PK1 cells from $H_2O_2$ and tBHP induced cell death. (Data: cell death at 1 h 200μM $H_2O_2$ = 17%, $H_2O_2$+ overexpressed Atg5 = 9%, $H_2O_2$+ overexpressed Beclin1=13%. SiRNA inhibition of autophagy: 200μM $H_2O_2$=17%, $H_2O_2$+si RNA beclin1=50%, $H_2O_2$+ siRNA atg5 =98% cell death. Cell death with autophagy inhibitors at 1 h: $H_2O_2$ =37%, $H_2O_2$+ wortmannin =54%, $H_2O_2$+chloroquine =46 %). LDH and MTT assays were used for cell death determination.

Autophagy inhibition did not increase caspase 3/7 at 1, 2 and 4 h after $H_2O_2$ treatment.

We examined induction of autophagy and its role in ER stress by tunicamycin in LLC-PK1 cells. Autophagy was induced by 2μg/ml tunicamycin treatment for 16 h. (Data:(1) cell death at 1h, 5 h $H_2O_2$=73%; 81%, pretreated tunicamycin +$H_2O_2$ =28%; 13% (2) cell death at 1 h 40μM tBHP was 27% but tunicamycin pretreatment decreased cell death to 4.54%). All results are the average of at least 4 times repeated experiments.

Conclusions: (1) Autophagy is induced during $H_2O_2$ and tBHP injury in LLC-PK1 cells. (2) Autophagy provided cytoprotection from the oxidant stress. (3) Autophagy inhibition caused caspase-independent cell death. (4) Tunicamycin-induced ER stress induced autophagy and protected LLC-PK1 cells from oxidant stress.

Induction of autophagy may serve as an intervention in preventing AKI.

## TH-PO770

**Monocyte Chemoattractant Protein-1 (MCP-1) and Associated Gene Activating Histone Marks: Tools for Studying Experimental and Clinical Acute Kidney Injury** Raj P. Munshi,[3] Edward Siew,[2] Jonathan Himmelfarb,[1] T. Alp Ikizler,[2] Richard A. Zager.[1] *[1]Medicine, University of washington, Seattle, WA; [2]Medicine, Vanderbilt University, Nashville, TN; [3]Pediatrics, Seattle Children's Hospital Medical Center, Seattle, WA.*

Monocyte chemoattractant protein 1 (MCP-1) is a mediator of acute ischemic and toxic kidney injury (AKI). This study assessed whether urinary MCP-1 concentrations, and markers of MCP-1 gene activity (mRNA, MCP-1 gene-associated histone changes), have potential utility as AKI biomarkers with implied mechanistic significance. Kidney and urine samples were obtained from mice with intra-renal (maleate), pre-renal (endotoxemia), or post renal (ureteral obstruction) AKI. Independent effects of uremia (mice with bilateral ureteral transection) were also assessed. Selected samples were assayed for MCP-1, MCP-1 mRNA, and for an activating histone mark (H3K4m3) at urinary fragments of the MCP-1 gene. Results were contrasted to those obtained for NGAL, used as a comparator 'AKI biomarker' gene. To assess potential clinical relevance, comparable assays were performed on urines from critically ill ICU patients with (n,10) or without (n,10) severe AKI (ultimate need for dialysis). Patients were matched by age, sex, ethnicity, sepsis status and closest APACHE II scores. Maleate induced early (4 hr), marked (3-9x) increases in urine MCP-1 protein and mRNA (≥ NGAL). Endotoxemia and ureteral obstruction induced comparable NGAL and MCP-1 up-regulation. Conversely, uremia induced the NGAL, but not the MCP-1 gene (suggesting potentially greater MCP-1 specificity). Clinical assessments confirmed MCP-1's utility (complete separation of urine MCP-1 concentrations in AKI+ vs. AKI- populations). Increased MCP-1 gene activation in AKI+ patients was supported by increased urine levels of MCP-1 mRNA and of H3K4m3 at the MCP-1 gene. Conclusions: 1) coordinated assessments of urinary MCP-1 protein / mRNA have potential value as AKI biomarkers; and 2) the results of the urinary H3K4m3 assessments provide the first 'proof of concept' that quantifying histone alterations at specific genes can provide pathogenic insights in patients with kidney disease.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO771**

**Are TNF-α, IL-6 and IL-10 Genetic Polymorphisms Risk Factors to Acute Kidney Injury (AKI) in ICU Patients?** Maria Dalboni, Marie Beata Redublo Quinto, Roberto Narciso, Julio Cesar Monte, Marcelino Durao, Oscar Pavao Dos Santos, Caren Cristina Grabulosa, Miguel Cendoroglo, Marcelo Costa Batista. *Medicine/Nephrology, Universidade Federal de São Paulo, São Paulo, Brazil.*

Introduction: Patients in ICU with SIRS have a high risk to development acute renal failure (AKI) and death. Genetic polymorphism studies of cytokines represent a perspective to the understanding of AKI in ICU settings.

Aim: To investigate whether genetic polymorphism of –308 TNF-α, -174 G>C IL-6 and 1082 G>A IL-10 gene could to predispose ICU patients with SIRS to development AKI and death.

Methods: In a prospective nested case-control study, we enrolled 797 ICU patients. The study group included those development AKI (n = 221/27.7%)) and the control group included those without AKI (n = 576/72.3%) according to AKIN criteria. We measured lipid profiles, CRP, albumin and accessed genetic polymorphism to TNF-α, IL-6 e IL-10.

Results: AKI patients presented a higher APACHE and CRP levels and lower cholesterol HDL and LDL levels than non-AKI ($p<0.01$). AKI patients who died had a higher APACHE and lower albumin and HDL compared to non AKI. In univariate analysis, we observed that frequency of GG genotype TNF-α (high producer) was 29% in AKI vs. 11% in non-AKI ($p<0.01$). To IL-6 the frequency of GG genotype (high producer) was 43% in AKI vs. 19% in non-AKI ($p<0.01$). However, in multivariate analysis this difference did not remain significant after adjustment for risk factors associated with AKI and death. The IL-10 genotype most frequent was GCC ACC (intermediate producer) in 42% in AKI and 17% non-AKI patients ($p = 0.003$). In this case, the difference remained significant after applying multivariate analysis.

Conclusion: Low levels of lipid profile and albumin in patients with AKI was associated with a high mortality rate. Although the high producer of TNF-α and IL-6 polymorphism among AKI patients may lead to a pro-inflammatory state, these polymorphisms did not predict AKI or death in our population. On the other hand, the GCC ACC IL-10 variant remained significant predictor for AKI occurrence, suggesting that these polymorphisms might be an independent risk factor for this complication.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO772**

**Regulation of Autophagy by Caspase-Dependent Cleavage of ATG5 and Beclin1 in Cisplatin Injury to Renal Tubular Epithelial Cells** Christian Herzog, Cheng Yang, Gur P. Kaushal. *Medicine, University of Arkansas for Medical Sciences & CAVHS, Little Rock, AR.*

Autophagy is a catabolic process within cells for the purpose of cellular regeneration. Normally autophagy plays a pro-survival role however excessive or unchecked autophagy leads to autophagic cell death. We have recently demonstrated that autophagy as well as key autophagy proteins LC3, Beclin1 and Atg5 were induced in cisplatin injury to LLC-PK1 cells during the pre-apoptotic lag phase and this induction of autophagy suppressed apoptosis and played an adaptive role (AJP-RP 294:777). Our present study shows that in LLC-PK1 cells Atg5 and Beclin1 are cleaved after treatment with cisplatin (CP) at a time when cisplatin-induced caspase activation maximally occurs. The pan-caspase inhibitor ZVAD-fmk prevented cisplatin-induced cleavage of Atg5 and Beclin1, suggesting that caspases are involved in the breakdown of key autophagy proteins. Neither caspase-3 inhibitor DEVD-fmk nor calpain-I/-II inhibitors ALLM or ALLN prevented the cleavage, suggesting that caspases other than caspase-3 are involved in the cleavage. ZVAD-fmk treatment prevented cisplatin-induced caspase activation (-97.4%) as well as subsequent apoptosis and enhanced autophagy as revealed by conversion of LC3-I to lipidated LC3-II. However, ZVAD-fmk did not completely prevent cisplatin-induced cell death but resulted in cisplatin-induced cytotoxicity as shown by MTT assay (%viability after 16h CP: 70.9±3.2, CP+ZVAD-fmk: 85.4±5.8) and LDH-release (% cytotoxicity after 16h CP: 9.1±0.7, CP+ZVAD-fmk: 22.9±2.2). The autophagy inhibitor 3-methyl adenine significantly reduced ZVAD-fmk-induced cytotoxicity in cisplatin-treated cells, suggesting a switch from apoptosis to autophagic cell death. These findings reveal that inhibition of caspase activity by ZVAD-fmk prevented cleavage of Atg5 and Beclin1 that regulated autophagy and switched cisplatin-induced apoptosis to autophagic cell death. In conclusion, our studies demonstrate that in cisplatin injury to LLC-PK1 cells, autophagy is regulated by breakdown products of key autophagic proteins Beclin1 and Atg5 and that inhibition of cisplatin-induced apoptosis results in autophagic cell death.

**TH-PO773**

**Glycoprotein nmb (Gpnmb) Is Highly Upregulated Macrophage Protein in Ischemia/Reperfusion Injured Kidneys and Shed into Urine** Letian Zhou,[1] Takaharu Ichimura,[1] Michael A. Ferguson,[2] Sushrut S. Waikar,[1] Joseph V. Bonventre.[1] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Nephrology, Children's Hospital Boston, Boston, MA.*

Gpnmb is a glycosylated transmembrane protein which is expressed in various types of cells, including macrophages (MΦs) and dendritic cells (DCs). Gpnmb modulates inflammation in MΦs and activation of T lymphocytes. Gpnmb is expressed at high levels in post-ischemic kidney, but the function of Gpnmb in injury and repair has not been elucidated. We investigated the expression and function of Gpnmb in postischemic kidney in vivo and in bone marrow-derived macrophages (BMMΦs) in vitro. Gpnmb was highly expressed in MΦs in the outer medulla in rat and mouse kidneys after ischemia/reperfusion injury. Gpnmb positive MΦs were detected in the interstitium at 48 hours and were subsequently located in the kidney tubule lumina at 96 hours after ischemic injury. Flow cytometry of isolated CD45 positive cells from the post-ischemic kidney revealed surface Gpnmb on MΦs but also on CD3+T lymphocytes which do not express endogenous Gpnmb. In vitro, a majority of primary cultured mouse large multinucleated and small mononucleated BMMΦs expressed Gpnmb. Lipopolysaccharide activation strongly induced Gpnmb secretion into the conditioned media from BMMΦs and RAW264.7 mouse monocytic leukemia cells. Since Gpnmb can bind to the surface of leukocytes, we determined whether Gpnmb-Fc bound to BMMΦs and DCs. Gpnmb-Fc strongly and specifically bound to the surfaces of BMMΦs and DCs, and was quickly endocytosed moving to lysosomes.

The robust secretion of Gpnmb suggests that Gpnmb can be a biomarker of inflammation, produced by inflammatory MΦs in injured kidneys. Using Western blot analysis and ELISA, we detected that Gpnmb protein was markedly increased in urine after murine ischemic kidney injury, as early as 6hr after reperfusion, as well as in humans with kidney disease.

These data suggest that Gpnmb may play a role in the modulation of MΦs, DCs and T lymphocytes activation during injury and repair. Furthermore, Gpnmb may serve as a biomarker of inflammation associated with acute kidney injury in humans and rodents.

**Autophagy Plays Cytoprotective Role in Cisplatin Nephrotoxicity In Vitro and In Vivo** Cheng Yang,[1] Christian Herzog,[1] Sarika Kadam,[1] Gur P. Kaushal.[1,2] *[1]Medicine, UAMS, Little Rcok, AR; [2]Medicine, CAVHS, Little Rock, AR.*

Autophagy is a physiologically regulated and evolutionarily conserved process in which cellular organelles and macromolecules sequestered in a double-membraned autophagosomes are delivered to lysosomes for degradation. The degraded cellular components are recycled to meet energy demands of the cell. We have previously reported autophagy is induced in response to cisplatin (CP) and suppressed apoptosis *in vitro* and played an adaptive role in CP injury to renal tubular epithelial cells (RTEC). (AJP Renal Physiol. 2008 294(4):F777-87). To further investigate the role of autophagy in CP nephrotoxicity *in vivo*, we examined the expression of autophagic proteins and formation of autophagosomes during the progression of CP nephrotoxicity in a mouse model and in RTEC *in vitro*. The key autophagy proteins LC3, Atg5, Atg12, and beclin-1 were induced after 1 day of CP administration and their expression was markedly increased at 2, 3, and 4 days. In addition, the formation of lipidated LC3 (LC3-II) from LC3-I was significantly increased in the kidneys at 2, 3, and 4 days following CP administration. The autophagosomes were maximally detected in the kidney cortex at 3 day after CP administration. The punctate fluorescent staining of autophagosomes was identified after administration of adeno-GFP-LC3 to the kidneys and by immunostaining with specific antibody to LC3. Overexpression beclin-1 and Atg5 by transfection with pmCherry-ATG5 and pcDNA3-Beclin1 in RTEC prevented CP induced cell death as revealed by LDH release and caspase assays. Since chloroquine inhibits the fusion of autophagosomes with lysosomes to prevent the efflux of autophagy process, we examined the effect of chloroquine in renal injury during CP nephrotoxicity. Administration of chloroquine increased kidney dysfunction as revealed by BUN and creatinine and kidney histology. These findings suggest that during the progression of CP nephrotoxicity, autophagy is maximally induced at the injury-repair junction and plays a cytoprotective role. Thus, the autophagy pathway may serve as an important therapeutic intervention for preventing or reducing CP-induced acute kidney injury.

**Chemical Anoxia (CA) Activates 5' Adenosine Monophosphate-Activated Protein Kinase (AMPK) Which Ameliorates Apoptosis of Renal Tubular Cells (RTCs) by Stimulating the Akt Pathway** Wilfred Lieberthal,[1] Leiqing Zhang,[1] Vimal Patel,[2] Jerrold S. Levine.[2] *[1]Medicine, Stony Brook Medical Center, New York, NY; [2]Medicine, University of Chicago at Illinois, Chicago, IL.*

AMPK is a ubiquitous kinase that is activated by any form of cell stress that reduces ATP levels. AMPK is a heterodimer comprised of a catalytic (α-) and two (β and γ) regulatory subunits. ATP depletion activates AMPK by inducing phosphorylation of its catalytic subunit . There is evidence that activation of AMPK ameliorates ischemic injury in brain, heart and liver. However, its role in determining the renal response to acute injury is not known. We have evaluated the role of AMPK in modulating the fate of cultured renal tubular cells (RTC) exposed to chemical anoxia (CA) by "knocking-down" expression of the catalytic domain of AMPK using short-hairpin RNA (shRNA).

There are two isoforms of the catalytic subunit of AMPK (α-1 and α-2 ) each encoded by a separate gene. We show that while both isoforms are expressed in substantial amounts in heart and liver, the α2 isoform represents most (>85%) of the total catalytic domain expressed in RTCs. We also show that shRNA directed against the α2-subunit, knocks down the expression of this isoform by >80%. CA induced by 2-deoxyglucose (DOG) reduces ATP levels, increases phosphorylation (activation) of AMPK, and induces apoptosis of RTCs. Knocking down expression of the α2 subunit of AMPK during CA reduces the level of total and activated AMPK (by >80%) and markedly exacerbates apoptosis of RTCs without altering cellular ATP levels. Interestingly, in addition to activating AMPK, CA also activates Akt. Furthermore, knocking down the expression of the α2 subunit of AMPK inhibits Akt activation, suggesting that AMPK acts upstream in the activation of Akt by CA.

Conclusions: i) The α2-subunit is the predominant catalytic isoform of AMPK expressed in RTCs; ii) AMPK plays an important role in reducing apoptosis of RTCs subjected to CA; iii) AMPK's protective effect is independent of changes in cellular ATP levels; iv) reduction of apoptosis by AMPK may be mediated, at least in part, by activation of Akt by AMPK.

## TH-PO776

**Kidney Biopsies in Patients with Cardiorenal Syndrome Awaiting Heart Transplant** Priya Deshpande,[1] James M. Pullman,[2] Ladan Golestaneh.[1] *[1]Medicine, Division of Nephrology, Montefiore Medical Center, Bronx, NY; [2]Pathology, Montefiore Medical Center, Bronx, NY.*

Background: Cardiorenal syndrome is defined as the renal manifestations of hemodynamic failure; renal parenchymal disease is not a part of this definition.

Purpose: We characterized the renal biopsies of patients awaiting heart transplantation and diagnosed with cardiorenal syndrome.

Methods: Nine heart transplant candidates underwent kidney biopsies from January 2007 to Februrary 2010 at Montefiore Medical Center. The biopsies were done to evaluate the presence of parenchymal disease in patients with CKD III or worse. Proteinuria was not a factor in the decision to do the biopsy. The renal pathology regarding the appearance of the glomeruli, tubules, interstitium and blood vessels were assessed.

Results: All 9 patients were male, 7 of whom had ischemic cardiomyopathy and 2 with non-ischemic cardiomyopathy. None of the patients had significant proteinuria or sonographic abnormalities in kidney size. The average eGFR was 33.6 mL/min. Five patients had evidence of expansion of the mesangial matrix, 4 of whom had glomerulomegaly. Five patients also showed mild to severe atrophy of the tubules, and 2 patients had acute tubular necrosis. Six patients had mild to moderate interstitial fibrosis. Two patients had hyaline changes in the blood vessels, and 3 patients had mild or focal arteriolosclerosis.

| Patient | Cardiac disease | Comorbidities | Cr | eGFR (mL/min) | Proteinuria | Ultrasound | Renal pathology |
|---|---|---|---|---|---|---|---|
| 1 m-ale | Ischemic CM | atrial fibrillation<br>hypertension<br>PVD | 2 | 34 | 0.3 | R 12.7, L 13.2 | glomeruli: mabtic moderately expanded<br>tubules: moderate atrophy<br>interstitium: moderate fibrosis<br>blood vessels: hyaline change |
| 2 m-ale | Non-ischemic dilated | hypertension<br>diabetes<br>MGUS | 2.1 | 35 | n/a | R 11.3, L 11.5 | glomeruli: glomerulomegaly<br>tubules: mild atrophy<br>interstitium: mild fibrosis<br>blood vessels: mild arteriolosclerosis |
| 3 m-ale | Ischemic CM | diabetes<br>hyperlipidemia<br>atrial fibrillation | 2 | 35 | 0.18 | R 13.2, L 13.5 | glomeruli: ↑m-esangium, glomerulomegaly<br>tubules: moderate atrophy<br>interstitium: moderate fibrosis<br>blood vessels: focal hyaline change |
| 4 m-ale | Ischemic CM | diabetes<br>hypertension<br>atrial fibrillation | 1.9 | 36 | 0.5 | R 10.8, L 11.1 | glomeruli: some enlarged glomeruli<br>tubules: mild atrophy<br>interstitium: mild atrophy<br>blood vessels: focal arteriolosclerosis |
| 5 m-ale | Ischemic CM | hypertension<br>atrial fibrillation<br>hyperlipidemia | 2.2 | 35 | none | R 14.1, L 14.8 | glomeruli: glomerular enlargement, ↑ m-esangium<br>tubules: no atrophy<br>interstitium: no fibrosis<br>blood vessels: no inflammatory lesions |
| 6 m-ale | Ischemic CM | hypertension<br>diabetes | 2.4 | 29 | 0.36 | R 12.9, L 12.9 | glomeruli: glomerulosclerosis; ↑ mesangial matrix<br>tubules: severe atrophy<br>interstitium: moderate to severe fibrosis<br>blood vessels: arteriolar hyaline changes |
| 7 m-ale | Ischemic CM | none | 1.8 | 38 | none | R 9.6, L 10.3 | glomeruli: n/a<br>tubules: n/a<br>interstitium: mild fibrosis<br>blood vessels: n/a |
| 8 m-ale | Non-ischemic Dilated CM | atrial fibrillation<br>hypertension | 5.1 | 13 | n/a | R 12.2, L 10.6 | medulla only<br>luminal necrotic cells consistent with ATN |
| 9 m-ale | Ischemic CM | Hypertension | 1.6 | 47 | 0.05 | R 9.7, L 10.4 | glomeruli: normal<br>tubules: normal<br>interstitium: normal<br>blood vessels: mild arteriosclerosis |

Conclusion: In this cohort of heart transplant candidates with cardiorenal syndrome but without evidence of significant proteinuria, renal biopsies showed some consistent parenchymal abnormalities, including tubular atrophy, interstitial fibrosis, glomerulomegaly and mesangial expansion. These findings are contrary to the common belief that cardiorenal syndrome is solely secondary to hemodynamic perturbations without parenchymal renal disease.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO777

**Rapid Restoration of ATP by SS-31, an Inhibitor of Mitochondrial Permeability Transition, Prevents Tubular Cytoskeletal Rearrangement in Renal Ischemia-Reperfusion Injury** Hazel H. Szeto, Shaoyi Liu, Yi Soong, Surya V. Seshan. *Pharmacology and Pathology, Weill Cornell Medical College, New York, NY.*

*Purpose*. ATP depletion during renal ischemia induces rapid rearrangement of b1-integrin, E-cadherin, and $Na^+K^+$-ATPase, leading to acute kidney injury. SS-31, an inhibitor of mitochondrial permeability transition (MPT), was shown to accelerate the recovery of ATP during early reperfusion and prevented tubular necrosis. Here we examined the effects of SS-31 on tubular cell architecture during early reperfusion after prolonged ischemia.

*Methods.* Sprague Dawley rats were subjected to bilateral renal ischemia for 45 min followed by reperfusion. SS-31 (2 mg/kg) or saline was given s.c. 30 min before ischemia and prior to reperfusion. Kidneys were harvested after 5, 20, 60 min or 24 h reperfusion for mitochondrial studies, ATP content, histopathology and immunohistochemistry of E-cadherin, b1-integrin and $Na^+K^+$-ATPase. Blood and urine were collected at 24 h for renal function.

*Results*. The early recovery of ATP provided by SS-31 preserved brush border and b1-integrin and prevented cell detachment. Preservation of E-cadherin on the lateral membrane and $Na^+K^+$-ATPase on the basal membrane led to reduction in serum creatinine and fractional $Na^+$ excretion at 24 h (***P<0.001).

Effects of SS-31 on early cytoskeletal changes

| Parameter | 5 min | | 20 min | | 60 min | |
|---|---|---|---|---|---|---|
| | saline | SS-31 | saline | SS-31 | saline | SS-31 |
| Brush border | disrupted | present | some loss | present | dramatic loss | some loss |
| β1-integrin | some loss | present | loss | present | dramatic loss | present |
| Cell detachment | no | no | no | no | yes | no |
| E-Cadherin | present | present | present | present | redistribution | present |
| Na+K+-ATPase | present | present | present | present | redistribution | present |
| Histopathology | some swollen cells | some swollen cells | swollen cells | few swollen cells | sloughed cells | few swollen cells |

*Conclusion*. These results indicate that prevention of MPT during renal ischemia results in rapid restoration of ATP upon reperfusion that is critical for maintaining tubular epithelial cytoskeleton and polarity, and minimizes tubular necrosis and renal dysfunction. SS-31 is a promising drug candidate for acute kidney injury.

**Generation and Characterization of Site-Specific Heme Oxygenase-1 Overexpressing Mice** Subhashini Bolisetty,[1,2,3] Amie Traylor,[1,3] Daniel Mcfalls,[3] Anupam Agarwal.[1,2,3] *[1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]Cell Biology, University of Alabama at Birmingham, Birmingham, AL; [3]Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL.*

Heme Oxygenase-1 (HO-1), an anti-oxidant enzyme is induced during oxidative stress and is protective against cell death. HO-1 catalyzes the degradation of heme, resulting in the liberation of biliverdin, iron and carbon monoxide. HO-1 deficient mice are highly sensitive to acute kidney injury secondary to ischemia, rhabdomyolysis and nephrotoxins and prior induction of HO-1 is protective. It has been suggested that generalized HO-1 overexpression may be harmful due to excess generation of its by-products. The purpose of this study was to generate cre-lox inducible site-specific overexpression of HO-1 in mice. To this end, we generated a floxed expression vector (chicken ß-actin CMV hybrid promoter (CBA)–lox-lac z-stop signal cassette-lox-HO-1). This vector expresses only the lac Z gene and not HO-1. However, in the presence of cre recombinase, the lox sites recombine to release the lac Z-stop signal cassette, resulting in HO-1 overexpression. Transgenic mice harboring the CBA lox HO-1 construct were generated and the presence of the transgene was verified by PCR, Southern blot analysis. These mice were first characterized for the expression of lac Z in various organs by staining for β-galactosidase. The proximal tubules are the primary target of damage in acute kidney injury and are also the site where maximal HO-1 induction occurs. Therefore, CBA lox HO-1 mice were bred with phosphoenolpyruvate carboxykinase cre mice (PEPCK cre mice, obtained from Dr.Volker Haase). Successful cre recombination was confirmed in kidneys of double transgenic mice by positive immunostaining for HO-1 in renal proximal tubules using lotus lectin as a marker for proximal tubules. Proximal tubular cells isolated from double transgenic mice also showed increased HO-1 expression compared to the PEPCK-cre mice. These mice will be a valuable tool for further in vivo studies to test the effects of site specific HO-1 expression in renal proximal tubules in models of acute kidney injury.

**Hibernation Affects Kidney Function and Morphology** Alkesh Jani, Jessica Martin, Elaine Epperson, Kultigin Turkmen, Kameswaran Ravichandran, Arijana Pacic, Danica Ljubanovic, Sandy Martin, Charles L. Edelstein. *U of Colorado.*

Prolonged cold ischemia (CI)/warm reperfusion (WR) are important causes of DGF that manifest as apoptosis, necrosis and brush border injury (BBI). The 13-lined ground squirrel is a hibernating mammal that cycles through alternating phases of extreme CI for several days during torpor (T) followed by re-warming during interbout arousal (IBA) each winter. Hibernation is a natural model of repeated prolonged CI followed by WR. We hypothesized that hibernating squirrel kidneys are protected from apoptosis, necrosis and BBI. Methods Radiotelemeters were implanted in 1-2 yr old squirrels, and CBT was monitored constantly. Kidneys from summer control animals (S), Torpid (T), and IBA animals were assessed. Tubules displaying apoptosis, necrosis and BBI were counted. Results There were no necrotic and very few apoptotic cells at all stages. BBI was significantly worse and more severe in IBA (table 1).

Table 1

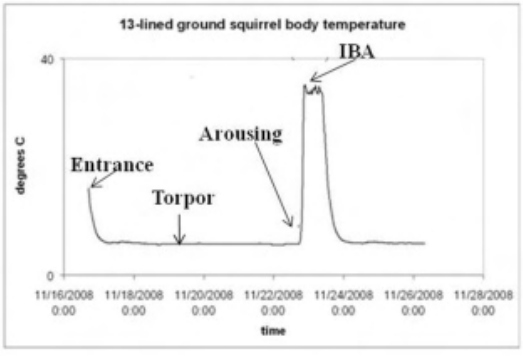
| Stage | Apoptotic cells/10 hpf | Necrotic cells/10 hpf | BBI/100 tubules | Severity of BBI |
|---|---|---|---|---|
| Summer (S) | 2 | 0 | 44±6 | 1+ |
| Torpor (T) | 1 | 0 | 0 | 0 |
| IBA | 1* | 0 | 74±3** | 3+ |

n = 3; * p = NS vs S, T ; **p<0.05 vs S, LT

To assess the functional significance of BBI we measured serum creatinine (SCr) and urine osmolality (Uosm) at various stages (Table 2) SCr peaked during the Arousing phase (the transition phase between Torpor and IBA), following 1-2 weeks of CI, but then normalized during IBA suggesting a return of renal function.

| Stage | Duration | CBT (°C) | sCr | Urine osm |
|---|---|---|---|---|
| Summer (S) | 5 mos | 37 | 0.3 | 2172± 364 |
| Entrance (E) | 25 hrs | 37→4 | 0.3 | 558±94 |
| Torpor (T) | 5-20 days | 0-4 | 0.4 | 840±115 |
| Arousing | 2 hrs | 4→37 | 0.7* | 491±87 |
| IBA | 12 hrs | 37 | 0.3 | 1491± 157 |

* $p < 0.001$ vs. S, E, T, IBA



Uosm peaked in Summer animals, was lowest in T animals and approached Summer values during IBA. Conclusion Despite extreme CI followed by repeated WR, hibernating kidneys are completely protected from apoptosis and necrosis. With WR during IBA, BBI was significantly worse but remarkably, SCr rapidly normalized and the ability to concentrate urine returned.

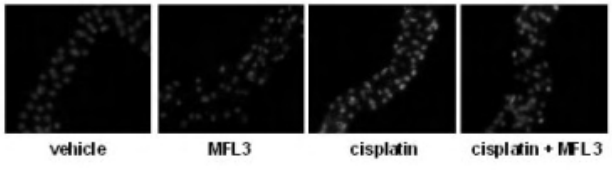
**Fas Ligand Mediates Fratricide of Tubular Cells In Vivo** Andreas Linkermann,[1] Nina Himmerkus,[2] Ulrich Kunzendorf,[1] Stefan Krautwald.[1] *[1]Nephrology and Hypertension, Christian-Albrechts University, Kiel, Germany; [2]Institute for Physiology, Christian-Albrechts University, Kiel, Germany.*

The apoptosis inducing death factor Fas Ligand (FasL) is best characterized for its function in T-cells and NK-cells regarding the clearance of virally infected cells and the termination of an immune response by activation-induced cell death, a process referred to as fratricide. Recent reports have suggested a physiologically relevant expression of FasL in the kidney. We treated SCID/beige mice with the FasL-neutralizing monoclonal antibody MFL3 that completely restored survival after otherwise lethal CIN, suggesting a functionally relevant source of FasL in renal homeostasis besides immune cells. In order to analyze whether kidney cells, like T-cells, die in a FasL-dependent manner after cisplatin-stimulation, we isolated segments of the thick ascending limb (TALs) from mouse kidneys and determined FasL-mediated apoptosis, which could be blocked with MFL3 in the complete absence of immune cells.



Furthermore, cisplatin-stimulated primary tubular cells induced apoptosis in TALs freshly isolated from GFP-transgenic mice. This renal-cell fratricide could be blocked by MFL3. We conclude that CIN is mediated though FasL, which is functionally expressed on fratricide-inducing tubular cells. Our observations reveal an additional mechanism that significantly contributes to organ failure besides the infiltration of FasL-bearing immune cells into the kidney.

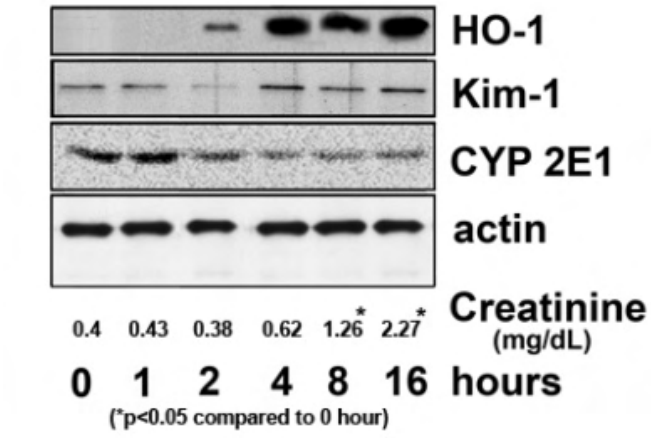
**Cytochrome P450 (CYP) 2E1 Mediates Rhabdomyolysis-Induced Acute Kidney Injury** Radhakrishna Baliga, Niu Tian, Istvan Arany. *Pediatrics, University of Mississippi Med Ctr, Jackson, MS.*

Catalytic or "free" iron released from heme proteins following rhabdomyolysis plays an important role in ROS mediated acute kidney injury (AKI ) . The source of this catalytic iron is currently not known even though myoglobin has been implicated. CYPs are a group of heme proteins that can function as oxidases, degrade the heme protein and promote the release of "free" iron. We have previously demonstrated a marked increase in catalytic iron accompanied by a significant decrease in the CYP content in the kidneys in this model of injury ( Kid Int: 49:362, 1996 ). CYP 2E1 has been identified to the rat renal tubular cells however its role in rhabdomyolysis induced AKI has not been previously examined. Rats injected with 50% glycerol ( 8ml/Kg/IM ) following overnite fast had marked increase in myoglobin in the kidney and plasma as early as 15min with no significant change in the liver. The onset of AKI as demonstrated by the upregulation of the kidney injury molecule-1 (KIM-1 ) occurred at 4h following glycerol injection and prior to significant deterioration in renal function.



This clearly indicates that despite very early and markedly elevated levels of myoglobin in the kidney the onset of AKI occurs only following the breakdown of the CYP 2E1 heme protein and the induction of heme oxygenase (HO-1)- an indicator of oxidative stress . Administration of Chlormethiazole ( CMZ ) a specific inhibitor of CYP2E1 transcription, completely inhibited the CYP 2E1 induction of the mRNA and the enzyme levels, and provided significant functional protection (SCr: Gly 1.6 vs Gly+CMZ 0.8 mg/dl, $P < 0.05$) against glycerol induced- AKI. Our results thus suggest an important role of CYP 2E1 as a source of catalytic iron in rhabdomyolysis induced oxidant injury.

**Up-Regulated Sirt1 in Renal Ischemia/Reperfusion Injury Causes Autophagy and Inhibits Apoptosis and Protects Against Oxidative Stress in Renal Tubules** Yoshiko Shimamura. *Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Kohashu, Oko-cho, Nankoku, Japan.*

Autophagy has been shown to contribute to the elimination of accumulated misfolded proteins. In the previous study we reported autophagy occurred in the rat AKI model. One genetic pathway that mediates cell response to ROS stress comprises the sirtuin family. Sirt1 deacetylates many target proteins, which protect against ROS stress and plays an essential part in mediating the survival of many types of the cells.

To clarify the significance of Sirt1 pathway in AKI, we used a rat AKI model *in vivo* and cultured renal tubular cells (NRK-52E cells) as an *in vitro* model. After clamping renal artery for 1 h, kidney homogenate at 1~72 h after reperfusion was extracted. Sirt1 expression and deacetylates activity is increased at 12-24h. To understand the regulation of Sirt1, we transfected Sirt1-promoter-luciferase construct to NRK-52E cells. $H_2O_2$ significantly increase promoter activity and protein expression of Sirt1.Overexpression of Sirt1 and resveratrol protect $H_2O_2$-induced apoptosis . Furthermore, to examine Sirt1 causes autophagy or not, we established NRK-52E cells which stably transfected with a fusion protein between GFPand light chain 3 as a marker of autophagy. Using this cell line, we detect autophagy as a GFP-positive-autophagosome. Overexpression of Sirt1 caused autophagy and the number of autophagosome markedly increased by resveratrol.

In conclusion, Sirt1 is transcriptionally up-regulated in hypoxic condition . Sirt1 constitutes a determinant of renal tubular cell apoptosis and autophagy. The current study therefore unravels both physiological and pathological significance of Sirt1 in ROS-dependent cell autophagy and apoptosis of renal tubular cells in vivo and in vitro.

**Src Family Kinases Regulate Renal Epithelial Dedifferentiation through Activation of EGFR/PI3K Signaling** Shougang Zhuang. *Department of Medicine, Brown University School of Medicine, Rhode Island Hospital, Providence, RI.*

Dedifferentiation, a process by which differentiated cells become mesenchymal-like proliferating cells, is the first step in renal epithelium repair and occurs *in vivo* after acute kidney injury and *in vitro* in primary culture. However, the underlying mechanism remains poorly understood. We studied the signaling events that mediate dedifferentiation of proximal renal tubullar cells (RPTC) in primary culture. RPTC dedifferentiation characterized by increased expression of vimentin concurrent with decreased expression of cytokeratin-18 was observed at 24 h after the initial *plating of* freshly *isolated* proximal *tubules* and persisted for 72 h. At 96 h, RPTC started to redifferentiate as revealed by reciprocal expression of cytokeratin-18 and vimentin and completed at 120 h. Phosphorylation levels of Src, epidermal growth factor receptor (EGFR), AKT [a target of phosphoinositide-3-kinase (PI3K)] and ERK1/2 were increased in the early time course of culture (<72 h). Inhibition

of Src family kinases (SFKs) with PP1 blocked EGFR, AKT and ERK1/2 phosphorylation, as well as RPTC dedifferentiation. Inhibition of EGFR with AG1478 also blocked AKT and ERK1/2 phosphorylation and RPTC dedifferentiation. Although inactivation of the PI3K/AKT pathway with LY294002 inhibited RPTC dedifferentiation, blocking the ERK1/2 pathway with U0126 did not show such an effect. Moreover, inhibition of SFKs, EGFR, PI3K/AKT, but not ERK1/2 pathways, abrogated RPTC outgrowth. SFK inhibition also decreased RPTC proliferation and migration. These findings demonstrate a critical role of SFKs in mediating RPTC dedifferentiation through activation of the EGFR/PI3K signaling pathway.

**p53 Target Siva Regulates Apoptosis in Ischemic Mice Kidneys** Babu J. Padanilam, Kurinji Singaravelu. *Cellular and Integrative Physiology, University of Nebraska Medical Center, Omaha, NE.*

The role of p53 in inducing apoptosis following AKI is well established; however, the molecular mechanisms remain largely unknown. We report here that the p53 pro-apoptotic target Siva and its receptor CD27, a member of TNFR family, are upregulated following renal IRI. Inhibition of Siva using antisense oligonucleotides conferred functional and morphological protection, and prevented apoptosis post-renal IRI in mice. Renal IRI in CD27-deficient mice displayed functional protection, attenuated caspase-8 activation and partial inhibition of apoptosis, suggesting an incomplete role for CD27 in Siva-mediated apoptosis. In vitro, hypoxia induced Siva expression in LLCPK1 cells in a p53-dependent manner and Siva inhibition prevented apoptosis. In Siva transfected LLCPK1 cells, Siva is persistently expressed in the nucleus at 3h onwards and its translocation to mitochondria and the plasma membrane occurred at 6h. Moreover, Siva overexpression induced mitochondrial permeability, cytochrome c release, caspase-8 and -9 activation, translocation of apoptosis-inducing factor (AIF) to the nucleus, and apoptosis. Inhibition of Siva in ischemic kidneys prevented mitochondrial release of cytochrome c and AIF. These data indicate that Siva function is pivotal in regulating apoptosis in the pathology of renal IRI. Targeting Siva may offer a potential therapeutic strategy for renal IRI.

**The Mismatch Repair Protein MSH2 Is a Novel Regulator of ATR during Cisplatin-Induced DNA Damage Response and Apoptosis in Kidney Cells** Navjotsingh P. Pabla,[1] Zheng Dong.[1] *[1]Department of Cellular Biology and Anatomy, Medical College of Georgia and Charlie Norwood VA Medical Center, GA; [2]; [3]GA.*

p53 is activated during cisplatin treatment of renal cells and tissues and contributes to cisplatin-induced nephrotoxicity or acute kidney injury (AKI). Recent work has further shown that p53 activation in cisplatin-AKI involves ATR (ATM- and Rad3-related) and Chk2 (checkpoint kinases-2), two important DNA damage response protein kinases. ATR is activated early during cisplatin treatment, leading to Chk2 activation and subsequent phosphorylation and activation of p53, resulting in the expression of pro-apoptotic genes such as PUMA-a and subsequent apoptosis. Despite these findings, the early molecular events responsible for ATR activation are not known. In this study, we used the Blue-native PAGE technique to reveal several proteins that interact with ATR. Tandem Mass Spectrometry further identified one of the ATR-interacting proteins to be MSH2, a DNA mismatch repair protein. ATR/MSH2 interaction was drastically induced during cisplatin treatment of renal tubular cells. Importantly, cisplatin-induced ATR activation or nuclear foci formation was diminished in MSH2-knockout mouse embryonic fibroblasts and MSH2-knockdown kidney cells. Consistently, in these cells cisplatin-induced Chk2 activation, p53 induction and PUMA-a accumulation were all suppressed, so was apoptosis. On the other hand, MSH2 deficiency did not affect cisplatin-induced translocation of the 9-1-1 (Rad9-Hus1-Rad-1) protein complex, the canonical system for ATR activation. Thus we have identified a novel mechanism of ATR activation via MSH2, which plays a key role in cisplatin-induced DNA damage response and apoptosis.

**Distinct Pathophysiologic Mechanism of Septic Acute Kidney Injury: Role of Tregs and the Effect of Mesenchymal Stem Cells** So-Young Lee,[1] Sang-Kyung Jo,[2] Kichul Yoon,[2] Myung-Gyu Kim,[2] Won-Yong Cho.[2] *[1]Nephrology, Eulji Medical Center, Seoul, Republic of Korea; [2]Nephrology, Korea University Hospital, Seoul, Republic of Korea.*

Introduction : Although mechanisms of sepsis on acute kidney injury (AKI) has been known to be associated with intense renal vasoconstriction with tissue inflammation, precise pathophysiologic mechanisms leading to AKI is unknown. Recent reports suggested that excessive immune suppressive status (CARS) following SIRS in sepsis might be responsible for transient organ dysfunction. The purpose of this study was to examine the mechanisms of septic AKI by providing on-site quantitative comparison between septic vs ischemia/reperfusion (I/R) AKI and also examine the effect of mesenchymal stem cells (MSCs) on septic AKI.

Methods : At 24 h after cecal ligation puncture, biochemical, histologic kidney injury, kidney and systemic inflammation were assessed and effect of MSCs on these parameters were also compared.

Results : Despite comparable level of functional impairment in both groups, degree of systemic and kidney inflammation and histologic kidney injury showed marked differences. While tubular necrosis, predominant in I/R kidneys was hardly observed in septic kidneys, the amount of apoptosis and caspase 3 activation showed positive correlation with plasma creatinine in septic AKI. Serial systemic cytokine profile indicated the possible conversion from SIRS to CARS and this was also associated with scant tissue inflammation in septic AKI. Percentage of immunosuppressive Tregs increased in spleen of septic mice and depletion of Treg abrogated kidney dysfunction. Administration of MSCs that has known to have immune-modulatory effect protected kidney dysfunction in septic AKI. The beneficial effect of MSCs in septic AKI was associated with paradoxical increase in kidney inflammation and decrease in percentage of Treg.

Conclusion : These results suggest that septic AKI is mediated via distinct pathophysiologic mechanisms. Apoptosis might substantially contribute to kidney dysfunction and excessive immune suppressive status induced by sepsis is thought to be responsible for transient functional impairment in septic AKI.

**Renal Gene Expression Profiling Demonstrates a Local Inflammatory Response Induced by Cardiopulmonary Bypass in Rat** Hjalmar R. Bouma, Iryna V. Samarska, Maria Schenk, Leo E. Deelman, Robert H. Henning. *Clinical Pharmacology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands.*

**Background:** Cardiopulmonary bypass (CPB) is a commonly used technique in cardiac surgery. However, CPB is associated with acute kidney injury (AKI). Also, a temporary peri-operative decrease of renal function negatively influences long-term survival. To obtain more insight into the pathogenesis of impaired renal function following CPB, we performed a microarray analysis of kidney gene expression in rat.

**Methods:** Rats underwent CPB or Sham procedure and were sacrificed at 60 min, 1 and 5 days following the procedure. Microarray analysis was used to determine expression changes in the kidney following CPB and Sham.

**Results:** Expression of 421 genes was significantly altered in CPB as compared to Sham, of which 407 genes in the acute phase (60 min) following CPB. Gene-ontology analysis revealed 28 of these genes involved in inflammatory responses, with major activation of mitogen activated protein-kinase (MAP-kinase) signaling pathways. Potent inducers identified constitute of the interleukin-6 cytokine family that consists of interleukin-6 (IL-6) and oncostatin M (OSM), which signal through the gp130-cytokinereceptor. Downstream signaling leads to production of chemokines, adhesion molecules and molecules involved in coagulative pathways. Production of chemokines and adhesion molecules stimulate early influx of monocytes, neutrophils and lymphocytes, thereby augmenting the renal inflammatory response.

**Conclusions:** The signaling pathways identified may represent pharmacological targets to limit CPB induced renal injury.

**HuR: A Candidate Post-Transcriptional Regulator of Immune Responses during Acute Kidney Injury** Rudolf Pullmann,[1] Gang Jee Ko,[1] Bernard S. Marasa,[2] Magdalena Juhaszova,[2] Yanfei Huang,[1] Karl L. Womer,[1] Hamid Rabb.[1] *[1]Division of Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD; [2]Biomedical Research Center, NIA, Baltimore, MD.*

Immune responses are important in the pathogenesis of renal ischemia reperfusion injury (IRI). Post-transcriptional regulation of gene expression is a powerful adaptive mechanism in immune activation. RNA-binding protein HuR functions as a positive regulator of mRNA stability, and/or translation, regulating immune genes such as IL-2, -4, and TNF-α.

We hypothesized that HuR level changes in T cells can underlie immune responses during AKI.

We isolated T cells from various locations [spleen, kidneys, kidney draining lymph nodes (LN)] in C57BL6 mice subjected to severe bilateral IRI, and studied the expression of HuR and its subcellular distribution.

As demonstrated by immunohistochemistry in splenic T cells, IRI caused translocation of HuR from nucleus to cytoplasm starting 4h post-IRI (1.8-fold elevation), persisting until 24h (2.1-fold elevation) and returning to baseline within 48h. By western blotting, total HuR protein levels remained unaffected within 24h in every evaluated T cell population. Using real-time PCR, there was 1.6-fold increase of HuR mRNA in splenic T cells, and 4.4-fold increase of HuR mRNA in kidney isolated T cells 24h post-IRI. T cells from kidney draining LN showed no change in HuR mRNA 24h post-IRI. In comparison to T cells, whole kidney levels of HuR at 4 and 24h after IRI remained unchanged at both mRNA and protein levels. Total HuR levels were also measured up to 4 weeks in mice subjected to moderate (30 min) of unilateral ischemia. At 10 days post-IRI, the total HuR levels in splenic T cells were 70% of the baseline, and returned to baseline by 4 weeks.

HuR translocation into cytoplasm of T cells during IRI suggests its role in regulating immune response genes. HuR mRNA elevation can be explained by increased transcription of HuR or increased HuR mRNA stability as HuR binds and stabilizes its own mRNA. Furthermore, decreased total HuR protein levels in T cells 10 days after IRI could contribute to the increased susceptibility to infection during AKI.

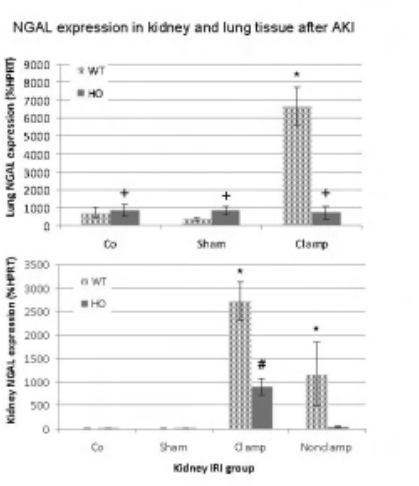
**Oncostatin M Receptor Is a Major Gateway of the Local and Systemic Inflammatory Response after Acute Kidney Injury** Barbara Pedrycz, Catharine Compston, Lin-Fu Zhu, Colin C. Anderson, Valerie A. Luyckx, Thomas F. Mueller. *Medicine, Nephrology and Immunology, Edmonton, AB, Canada.*

Oncostatin M - Oncostatin M receptor (Osm-Osmr) signalling induces a strong renal acute phase response as shown in human kidney implant biposies and cell lines. This study investigates in more detail the local and systemic response to ischemia-reperfusion injury (IRI) using wild type (WT) and Osmr deficient (HO) mice [Blood 2003; 102:3154].

Acute kidney injury (AKI) was induced by clamping of the pedicle of one kidney for 45 mins followed by 24 hrs of reperfusion. Transcript levels of Osm, Osmr, Il6, Il6r, Lif, Lifr, Serpina3, and Ngal were measured in clamped, nonclamped contralateral, sham operated and untouched control kidneys and lungs of mice from each kidney experimental group by real-time RT-PCR.

The local inflammatory/injury response was significantly higher in the kidneys of the WT compared to the Osmr deficient mice after clamping. The significantly lower Ngal levels in the HO vs. WT clamped kidneys may suggest some protection against the IRI in Osmr deficient mice (# p<0.0001).



In addition both inflammatory and injury response (Ngal expression) in the lungs and contralateral nonclamped kidneys was significantly increased only in WT mice (* p<0.001). This suggests absence of distal effects of local inflammation in Osmr deficient mice.

In conclusion Oncostatin M receptor is a major gateway for amplification of the local inflammatory and injury response as well as a likely important mediator of injury and inflammation in distal organs.

**The Role of Chloride Intracellular Channel 4 (CLIC4) in Acute Tubular Injury** Christina R. Kahl, John C. Edwards. *Department of Medicine, UNC Kidney Center, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Chloride intracellular channel 4 (CLIC4) is highly expressed in both proximal tubule epithelial cells and peritubular capillaries, and previously published studies indicate CLIC4 may act as both an ion channel and an intracellular signaling molecule involved in apoptosis and TGFβ signaling pathways. The aim of this study is to determine if CLIC4 modulates the response to acute tubular injury in a mouse model system. *Clic4-/-* mice are viable and have normal renal development histologically. The folic acid nephrotoxic model of acute kidney injury results in rapid tubular injury and apoptosis followed by a recovery phase. Cohorts of *Clic4-/-* and wild type mice of similar age were injected with folic acid. The degree of acute renal injury was assessed by plasma BUN and histology. Male *Clic4-/-* mice demonstrated statistically significant lower BUN values than wild type mice at baseline (p<0.05).

Renal Injury After Injection

| Type of mouse | Number of mice | BUN baseline | BUN day 2 | Percent with BUN≥50 |
|---|---|---|---|---|
| Wild type male | 22 | 36 | 114 | 68 |
| *Clic4-/-* male | 20 | 25 | 74 | 30 |
| Wild type female | 17 | 28 | 208 | 76 |
| *Clic4-/-* female | 30 | 24 | 238 | 73 |

Following treatment, 68% of wild type male mice develop renal injury (which was defined as BUN≥50 2 days after injection) versus only 30% of male *Clic4-/-* mice (p<0.05), and there is a trend towards lower BUN values in *Clic4-/-* males. For female mice, 76% of wild type mice and 73% of *Clic4-/-* mice develop injury with similar average BUN values at day 2. Surprisingly, about 40% of *Clic4-/-* female mice died (or were sacrificed due to severe clinical illness) several days after folic acid injection compared to no deaths among wild type or *Clic4-/-* males. These results demonstrate a significant dichotomy in acute renal injury in male versus female *Clic4-/-* mice, providing a useful model to study differences in acute tubular injury between males and females. Consistent with the hypothesis that CLIC4 may regulate apoptotic and TGFβ pathways, male *Clic4-/-* mice demonstrate significant protection from acute tubular injury and allow an opportunity to elucidate functions of CLIC4 using an *in vivo* system.

**Activation of NALP3 Inflammasome in Cisplatin-Induced Acute Kidney Injury** Ali Akcay, Quocan Nguyen, Kultigin Turkmen, Dong Won Lee, Zhibin He, Alkesh Jani, Sarah Faubel, Charles L. Edelstein. *Univ of Colorado Denver.*

We have demonstrated that caspase-1 activity is increased in the kidney and caspase-1-deficient mice are protected against cisplatin-induced acute kidney injury (Cis-AKI). The "inflammasome" is a cytosolic protein complex composed of NALPs, ASC-CARD and caspase-5 that are required for the activation of caspase-1 and "leaderless proteins" such as the proinflammatory cytokine, IL-1α and the proapoptotic protein, BID. The aim of the study was to determine whether the inflammasome is activated in Cis-AKI. Wild-type mice were injected with cisplatin 25 mg/kg and sacrificed on days 1, 2 and 3. BUN and serum creatinine were elevated on day 3. On quantitative PCR of whole kidney, levels of NALP3 mRNA expression were increased on day 3 *vs.* on day 1 and vehicle-treated (Veh) (P<0.001, 0.75 *vs.* 0.1 fold change) and on day 3 *vs.* day 2 (P<0.01, 0.75 *vs.* 0.25 fold change). There was no increase in NALP1 mRNA levels (P>0.05). On immunoblots, NALP3 (106 kDa) was present in the freshly isolated proximal tubules, but not in cisplatin-treated endothelial cells or LPS-treated macrophages. On immunoblot of whole kidney, there were a 2-fold increase in ASC-CARD (22 kDa) (p<0.05) and a 3-fold increase in caspase-5 (47 kDa) after cisplatin on days 2 and 3 (P<0.05 *vs.* Veh). Caspase-5 activity measured by the fluorescent substrate WEHD-AMC was 11.2 in Veh and 29.2 in Cis-AKI (p<0.01). IL-1α (pg/mg) was 0.1 in Veh, 2.4 in Cis-AKI (P<0.001 *vs.* Veh) and 0.1 in caspase-1 -/- Cis-AKI (P<0.001 *vs.* Cis-AKI). Immunoblot of whole kidney showed a 2-fold increase increase in parent BID (22 kDa) and a 2-fold increase in caspase-1 cleaved BID (15 kDa) on day 3 (P<0.05 *vs.* Veh). In summary, the NALP3 inflammasome is activated in Cis-AKI as evidenced by increased caspase-1, caspase-5, ASC-CARD, IL-1α and BID. In conclusion, the exact role of the inflammasome in Cis-AKI merits further studies.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO792**

**Oxidative and Inflammatory Renal Injury Signaling Pathways Differ between the Sexes in Tubulointerstitial Fibrosis** Hong Ji,[1] Wei Zheng,[1] Jun Liu,[1] Xie Wu,[1] Janet J. Zhu,[1] Thurston Sandberg,[1] Kathryn Sandberg.[1] *[1]Medicine, Georgetown University, Washington, DC; [2]Washington, DC; [3]Washington, DC.*

Renal disease progression is faster in men compared to women in a number of nondiabetic renal diseases and this sex difference is also observed in numerous experimental animal models of chronic and acute renal disease including the unilateral ureteral obstruction (UUO) model of interstitial fibrosis. To study the underlying mechanisms of this sex difference, we investigated the mRNA expression of oxidative stress and inflammatory markers in male (M) and female (F) mice subjected to UUO. UUO increased the expression of the $p40^{phox}$ NADPH oxidase regulatory subunit to a 2.1-fold (p<0.01) greater extent in the male than in the female kidney one week after UUO [(AU): M-Sham, 0.20±0.02; M-UUO, 6.81±0.77; F-Sham, 0.21±0.04; F-UUO, 3.27±0.03]. Similar findings were observed for other key NADPH oxidase regulatory subunits; $p67^{phox}$ and $gp91^{phox}$ were increased by a 3.1-fold and 2.3-fold greater extent in the male than in the female kidney, respectively. Compared to sham surgery, monocyte chemotactic protein-1 (MCP-1) increased to a 4.5-fold (p<0.02) greater extent in the male compared to the female kidney [MCP-1 (AU): M-Sham, 0.22±0.01; M-UUO, 12.4±1.3; F-Sham, 0.19±0.03; F-UUO, 2.38±0.61]. Similar findings were observed for Th2 cytokines; the UUO-induced increase was greater in the male compared to the female kidney [IL-4 (UUO/Sham): M, 5.2-fold vs F, 2.6-fold, p<0.03][IL-10 (UUO/Sham): M, 8.1-fold vs F, 2.3-fold, p<0.02]. In contrast, the Th1 cytokines increased to the same extent in both male and female kidneys after UUO (data not shown). These data suggest that NADPH oxidase signaling pathways and Th2 but not Th1 signaling cascades are amplified in the male kidney compared to the female and that these sex differences in signal transduction underlie why the progression of renal interstitial fibrosis is greater in the male compared to the female mouse kidney. Supported by NIA R01 AG019291.

**Expression of Calcineurin and Regulator of Calcineurin 1 (RCAN1) in the Rat Kidney Following Lipopolysaccharide Administration** Jae-Youn Choi, So Young Lee, Jin Kim, Jung Ho Cha. *Anatomy, The Catholic University of Korea, College of Medicine, Seoul, Republic of Korea.*

RCAN1 (calcipressin 1, DSCR1, or MCIP1), an inbibitor of calcineurin, has been known to be a stress responsive protein that can be induced by multiple stresses. It is likely that RCAN1 may also play roles in a variety of organ including the kidney. However, no study about renal RCAN1 has been reported. In this study, we investigated the expression patterns of RCAN1 and calcineurin in the rat kidney after injection of lipopolysacchride (LPS). Male SD rats were subjected to a LPS injection (20 mg/kg bw, ip) and sacrificed at 8h, 1, 3, 7d after injection. Immunohistochemistry was perfomed using polyclonal anti-RCAN1 and anti-calcineurin Aα, Aβ and Aγ antibodies. In normal kidney, RCAN1 was expressed moderlately in S3 portion of proximal tubule (PT) compared with totally negative in S1 & S2

portions of PT, weakly in distal tubule (DT), cortical collecting duct (CCD), outer and inner medullary collecting duct (OMCD & IMCD), thick ascending limb (TAL), juxtaglomerular cell (JGC) and interlobular arteries (IR). RCAN1 was localized mainly in the cytoplasm, but in a few of cells, nuclear immunostaings were deteced. After LPS administration, RCAN1 was upregulated progressively to 1d, and RCAN1 immunoreactivity had returned to normal control levels by 7d. In 1d kidney, RCAN1 expression was very strong in S3 portion of PT, moderately strong in DT and CCD, and moderate in TAL, MCD, JGC and IR. After LPS administration, nuclear immunostaings were also increased progressive to 3d, especially in inner medulla, about half of IMCD cells showed nuclear staing. Calcineurin Aα and Aβ was expressed strongly in JGC, and thin limbs of inner medulla, and weakly in IMCD in normal kidney. After LPS administration, calcineurin Aα and Aβ was strongly induced in IR and some cells of CCD, OMCD and TAL. No calcineurin Aγ expression was detected both in the normal and LPS-treated kidney. Taken together, these results suggest that RCAN1 may play a role in LPS-induced renal hemodynamic change by regulating calcineurin activity both in IR and JGCs, and also perform some calcineurin-independent function especially in S3 segment of PT.

**Autophagy Induction and Alterations of Multiple Signaling Pathways in Response to Hypoxic and Ischemic Renal Injury** Man Jiang, Zheng Dong. *Department of Cellular Biology and Anatomy, Medical College of Georgia and Charlie Norwood VA Medical Center, Augusta, GA.*

Recent work has demonstrated autophagy and its protective role in hypoxic and ischemic renal injury. However, it remains unclear how autophagy is induced and regulated under these pathological conditions. The current study examined the signaling pathways that may contribute to the regulation of autophagy during hypoxia (1% $O_2$ in full culture medium) and anoxia-reoxygenation (<0.1% $O_2$ in glucose-free buffer followed by recovery in full culture medium with 21% $O_2$) in renal proximal tubular cells. In the hypoxia model, autophagy was induced within 6 hours of hypoxia and significantly increased after 12-24 hours. HIF-1α was induced at 1 hour of hypoxia, reached the peak at 3 hours and decreased thereafter. Bnip3, a BH3-only protein that has been suggested to regulate mitophagy, was induced in a HIF1-dependent manner and its up-regulation was paralleled with autophagy progression during hypoxia. In contrast, AMPK was not activated until 12-24 hours. Akt was transiently phosphorylated at 3-6 hours of hypoxia, while mTOR was inactivated at 12-24 hours. The changes of AMPK, Akt and mTOR showed temporal correlation with autophagy during the late time points of hypoxia incubation. In the anoxia-reoxygenation model, anoxia alone induced LC3-II accumulation but not formation of GFP-LC3 puncta. During the reperfusion phase, autophagy was induced undoubtedly, indicated by both GFP-LC3 punctuated cells and a time-dependent LC3-II turnover. HIF-1α was slightly upregulated during anoxia, whereas both Akt and mTOR were inactivated. MAP kinases, including ERK1/2, JNK1/2/3 and p38, were activated during reoxygenation. N-acetylcysteine significantly suppressed autophagy during anoxia-reoxygenation, suggesting a role for oxidative stress in autophagy in this model.

**Cdk2-Dependent Phosphorylation of p21 Regulates Cdk2 Role in Cisplatin (CP) Toxicity** Rawad Hodeify, Adel Tarcsafalvi, Judit Megyesi, Robert L. Safirstein, Peter M. Price. *UAMS, Little Rock, AR.*

CP cytotoxicity is dependent on Cdk2 activity *in vivo* and *vitro*. We are studying the substrates phosphorylated by this kinase after cells are exposed to cisplatin. Cdk-cyclins can form stable complexes with their substrates that can subsequently be phosphorylated *in vitro*. Cdk2 was IP'ed from mouse proximal tubule (TKPTS) cells before and after CP exposure, and bound proteins were phosphorylated by Cdk2. We found that a 18 kDa protein was not phosphorylated before CP exposure and that its phosphorylation increased starting twelve hours after CP, which coincided with the time when Cdk2 inhibition no longer protected from CP cytotoxicity.

Mass spectrometry identifed the 18 kDa protein as $p21^{WAF1/CIP1}$. This protein was identified as a Cdk inhibitor induced by CP, and whose induction prior to CP exposure protected from cytotoxicity by inhibiting Cdk2. Analysis showed it was phosphorylated by Cdk2 at serine 78, a site not previously identified. This site lies within the region of p21 that stearically blocks the ATP binding site of the Cdk and prevents Cdk catalytic activity. We therefore hypothesized that phosphorylation of this residue could affect the role of endogenous induced p21 as a Cdk inhibitor. To investigate the effect of serine 78 phosphorylation on p21 activity, we replaced serine 78 with aspartic acid, creating the phosphomimic $p21^{S78D}$. Mutant $p21^{S78D}$ was an inefficient inhibitor of Cdk2 and we subsequently found that it was inefficient at protecting TKPTS cells from cisplatin-induced cell death. Previous studies showed that both Cdk2 and p21 are induced after cisplatin exposure, and that p21 is a Cdk2 inhibitor that can prevent CP cytotoxicity. However, even though p21 is induced after CP exposure, it only reduces rather than protects from cytotoxicity. We now report that induced p21 is phosphorylated by Cdk2 at Ser78. This phosphorylation reduces the activity of p21 as a Cdk inhibitor and significantly reduces its ability to protect from CP cytotoxicity.

We conclude that phosphorylation of p21 by Cdk2 limits the effectiveness of p21 to inhibit Cdk2, which is the mechanism for continued CP cytotoxicity even after the induction of a protective protein.

**Serum from Rats with Acute Kidney Injury Appears To Stimulate the Metabolic Activity and Reduce the Proliferation of Proximal Tubular and Mesenchymal Stem Cells** Jon D. Ahlstrom,[1] Jake C. Jones,[1] Florian E. Toegel,[2] Zhuma Hu,[1] Ping Zhang,[1] Christof Westenfelder.[1,3] *[1]Medicine, University of Utah and VA Medical Centers, Salt Lake City, UT; [2]Medicine, Cornell College of Medicine, New York, NY; [3]Physiology, University of Utah, Salt Lake City, UT.*

Acute kidney injury (AKI) is a common and largely treatment-resistant syndrome in which complex mechanisms mediate injury and repair. To investigate how an AKI-induced "uremic" milieu affects the biology of tubular cells (principal target of AKI) or Mesenchymal Stem Cells (MSC; renoprotective), we cultured normal rat proximal tubular cells and MSCs in 10% rat serum collected at 24 hrs post ischemia/reperfusion AKI (SCr 4-5 mg/dL) and in 10% serum from shams. Incubation of both cell types with 10% AKI serum resulted in significantly increased metabolic activity when assessed by the conversion of resazurin to resorufin (CellTiter-Blue/Alamarblue cell viability assay). As metabolic activity is generally proportional to cell numbers, this suggested that AKI serum might be highly mitogenic for cultured cells. Paradoxically, when direct cell counts were performed there were significantly fewer cells in the AKI serum- than in sham serum-treated wells (at 48-72 hours). Hence, even though there were fewer cells in the post-AKI serum wells, the post-AKI serum treated cells had higher cellular metabolism as assessed by CellTiter-Blue. A possible explanation for these responses may be that uremic serum damages cell membranes and reduces mitogenesis, associated with membrane leakiness, which can result in enhanced LDH release. The former would result in reduced cell numbers, while the latter would increase their apparent metabolic rate, due to LDH mediated conversion of resazurin to resorufin. Conclusion: if this explanation is confirmed, this would require caution with the use of this viability assay in settings where cellular LDH is released. More importantly, our data warrant investigation of the mechanisms whereby AKI serum exerts this cytotoxicity, an adverse effect that may further aggravate the overall magnitude of cell injury and also affect stem cell-based interventions in AKI.

**TH-PO797**

**Levels of Angiotensin II (AII) Decrease by Lipopolissacaride (LPS) from E. coli and Occurs through p-Akt in Immortalized Human Mesangial Cells (hMC) in Culture** Nayda P. Abreu,[1] Edgar Maquigussa,[1] Renata Cristina Tassetano,[1] Jessica S. Garcia,[1] Elizabeth B. Oliveira-Sales,[2] Guilherme Albertoni,[1] Fernanda Teixeira Borges,[1] Nestor Schor.[1] *[1]Medicine, UNIFESP, Sao Paulo, Brazil; [2]Cardiovascular Physiology, UNIFESP, Sao Paulo, Brazil.*

Acute Kidney Injury(AKI)is associated with sepsis. AII plays a role in maintaining blood pressure in sepsis, but few is known about it signaling pathway on hMC. The aim of this study was to evaluate the effect of LPS in activating the Akt/NFkB signaling and also tested the hypothesis that changes in levels of AII is modulated by Akt/NFkB. hMC were cultivated in DMEM exposed to LPS(100ug/ml)for sepsis induction during 30min, 1h, 5h and 24 hours. mRNA expression of p65(NFkB member)were estimated by RT-PCR, AII quantification by ELISA,calcium concentration $[Ca^{(2+)}]i$ using fura-2, nitric oxide(NO) by Griess, apoptosis/necrosis by flow citometry and Western blot for p-Akt molecule. After 24h of LPS, mRNA expression levels of p65 were increased compared to untreated hMC(3.3±0.6vs1.0±0.09 Arbitrary Units,$p<0.05$). Moreover, in LPS-treated hMC the onset of p-Akt was seen after 30min. Interestingly AII decreased after LPS30min(0.14±0.01ng/ml) and 1h(0.07±0.01ng/ml)compared to untreated control(0.08±0.008ng/ml,$p<0.05$). Under Akt inhibitor(LY294002) AngII level of same groups, did not decrease. Additionally,$[Ca^{(2+)}]i$ decreased with LPS for 1h(188.5±18.2% basal/peak) compared to control (265.0±18.4%basal/peak, $p<0.05$) but not decrease under LY inhibitor. Contrarily, NO rise after 5h(0.18±0.03uM/mg of protein) and 24h(0.17±0.02uM/mg of protein)in LPS treatment compared with untreated cells(0.07±0.01uM/mg,$p<0.05$). Apoptosis was increased after LPS 5h(32.6 ± 8.3vs20.3 ± 4.3 %,$p<0.05$), while necrosis rise after LPS 1h(46.0±13.2 vs 8.8±2.3%,$p<0.05$)compared with control. These data suggest LPS exposure decrease the production of AII through the activation of Akt signaling pathway and possibly NFkB. The action of LPS on hMC involves an early stage(up to 5 hours)with inhibition of AII and decreases in intracellular calcium mediated by Akt and a late phase(over 5h) which involves rise in NO and apoptosis.

**Inhibition of Renin Angiotensin System Decreases TLR 4 in Kidney Injured by Ischemia-Reperfusion** Ki Ryang Na,[1] Jin Young Jeong,[1] Ji Yoon Jung,[1] Dong-Suk Chang,[1] Dae Eun Choi,[1] Yoon-Kyung Chang,[2] Kang Wook Lee,[1] Young Tai Shin,[1] Sarah Chung.[1] *[1]Internal Medicine, Chungnam National University Hospital, Daejeon, Korea; [2]Internal Medicine, Daejeon St Mary's Hospital, Daejeon, Korea.*

**INTRODUCTION:** It is well known that renin angiotensin system (RAS) plays important role in ischemia reperfusion (IR) injury of kidney. It was revealed IR renal injury activates innate immunity through the engagement of Toll-like-receptors (TLR) by endogenous ligands, and suppression of TLR attenuate IR renal injury. Although it was reported angiotensin II activate innate immunity recently, there are little study of relationship between RAS and TLR signaling in IR injured kidney. We examined whether RAS inhibition by AT1 receptor blocker modulates the renal expression of TRL4 and its ligands and attenuates renal injury induced by IR of kidney.

**METHODS:** We use male Spargue-Dawley rats which were divided into 4 groups; sham group, losartan treated sham group, control IR group, and losartan treated IR group. Losartan (40mg/kg) was injected intraperitoneally 60 minutes before IR injury. Duration of renal ischemia is 30min. We sacrificed rats 24hr after reperfusion. We evaluated BUN, serum creatinine, and the renal mRNA expression levels of TLR4, HMGB1, MCP-1, TNF-α, and IL-6 by real-time RT-PCR. We also evaluated renal inflammation by H&E stain and ED1 immunohistochemistry.

**RESULTS:** The levels of BUN and serum creatinine (s-Cr) in control IR rats were significantly increased compared to sham group (all. $p$ <0.05). The levels of BUN and s-Cr of losartan treated IR group were significantly lower than those of control IR group (all, $p$ <0.05).Losartan treated IR group showed significantly lower levels of renal TLR4 and HMGB1 mRNA expression than those of control IR group (all, $p$<0.05). Losartan decreased significantly renal mRNA expressions of TNF-α, MCP-1, and IL-6 (all, $p$ <0.05). Losartan also reduced significantly infiltration of the ED1 positive cells in IR injured kidneys ($p$ <0.05).

**CONCLUSIONS:** Losartan attenuated the renal inflammation induced by renal IR rats and at least in part, suppression of TLR4 may be involved in this mechanism.

## TH-PO799

**Glomerular Endothelial Cells Express the Proinflammatory Cytokine Interleukin-17 in Acute Glomerular Disease** Tanja Loof, Stephanie Kraemer, Hans-Hellmut Neumayer, Harm Peters. *Depart. of Nephrology, Charité Universitätsmedizin Berlin, Berlin, Germany.*

**Purpose**

Overexpression of pro-fibrotic and pro-inflammatory cytokines and extracellular matrix accumulation are hallmarks of acute glomerular injury. A connection between TGF-ß signaling and the inflammatory cytokine IL-17, as well IL-17 expression by renal cells in kidney diseases has recently been proposed. The present study investigated IL-17 expression in different glomerular cells in a rat model of acute anti-Thy1 glomerulonephritis (aGN).

**Methods**

aGN was induced in male Wistar rats by i.v. injection of anti-Thy1 OX-7 antibody. Tissues were harvested at the day 5 (matrix expansion), PBS-injected animals served as controls (con). Immunofluorescence was performed for cell marker (OX-7: mesangial cells, PECAM: endothelial cells, synaptopodin: podocytes) and IL-17. For *in vitro* experiments NRK 52E cells were used.

**Results**

Induction of aGN was characterized by marked proteinuria (d5 113±12 mg/d; 3.9-fold vs. con; p<0.001) and histological glomerular-matrix accumulation (d5 +3-fold vs. con; p<0.001), in parallel with highest TGF-ß1 and IL-17 mRNA expression (+2.25-fold; +6.50-fold vs. con; p<0.05). Immunofluorescence staining with synaptopodin and OX-7 showed no colocalization with IL-17, whereas PECAM was highly colocalized with IL-17. In vitro, IL-17 was secreted by NRK 52E at basal levels, up-regulated after exposure to 25 mM glucose (+7-fold) and reversed in the presence of a specific TGF-ß receptor blocker (SB 431542). Stimulation of cells with TGF-ß1 or IL-6 amplified IL-17 expression by 2.0-fold. Co-administration of TGF-ß and IL-6 led to highly synergistically enhanced IL-17 secretion by more than 4000-fold.

**Conclusion**

This study documents that the glomerular expression of IL-17 cytokine is localized into glomerular endothelial cells in acute, anti-Thy1 glomerulonephritis, thus under pro-fibrotic and pro-inflammatory conditions. Downregulation of IL-17 expression by TGF-ß receptor antagonism in vitro points a crucial regulatory interaction with TGF-ß signalling.

## TH-PO800

**Urotensin II Protects Rat Renal Tubular Cell from Gentamicin-Induced Apoptosis through Prostacyclin-Mediated Pathway** Yung-Ho Hsu,[1] Tso Hsiao Chen,[2] Cheng-Hsien Chen.[1,2] *[1]Division of Nephrology, Taipei Medical University-Shuang Ho Hospital, Taipei, Taiwan; [2]Division of Nephrology, Taipei Medical University-Wan Fang Medical Center, Taipei, Taiwan.*

Urotensin II (UII) is a cyclic vasoactive peptide expressed in multiple organs. Kidney appears to be a major source of both circulating and urinary UII. Studies investigated effects of UII on renal function yielded conflicting results. Whether UII has a causative or protective influence on renal disease remains to be determined. In this study, we studied the protective effect and mechanism of UII on gentamicin-induced apoptosis in rat renal tubular cells (NRK-52E). We found gentamicin induced UII generation in these cells within 24 hours, but this UII induction did not influence gentamicin-induced apoptosis. Pretreatment of UII reduced the quantity of cleaved caspase-3 and increased Bc*L*-$x_L$ expression, resulting in protecting NRK-52E cells from gentamicin-induced apoptosis. This anti-apoptotic effect of UII was inhibited by the pretreatment of UII antagonist, urantide. UII was also found to decrease $PGE_2$ and increase the $PGI_2$ generation in NRK-52E cells. Because $PGI_2$ is a potential ligand for IP receptor and peroxisome proliferator-activated receptors alpha and delta (PPARa and PPARd), we blocked those receptors by the neutralization of IP receptor and siRNA transfection of PPARa and d to investigate the $PGI_2$ signaling pathways involved in UII protective mechanism. We found PPARa blockage reduced the anti-apoptotic effect of UII more potently. Our results reveal that UII protects rat renal tubular cells from gentamicin-induced apoptosis through $PGI_2$ and PPARa-signaling pathways.

**Acute Kidney Injury after Syngeneic Orthotopic Liver Transplantation in Rats** Nan Chen, Jun Wang, Zhiyong Du, Wen Zhang, Chenghong Peng. *Department of Nephrology, Ruijin Hospital, Shanghai, China.*

**Objective:** Orthotopic liver transplantation is the optimal treatment for end stage liver disease and acute kidney injury (AKI) is a frequent complication after liver transplantation. The prognosis of AKI post-liver transplantation is poor because mechanisms are incompletely characterized, in part due to the lack of experimental research. In this research we studied AKI post-liver transplantation in the syngeneic orthotopic liver transplantation (SOLT) rat model and attempted to investigate the mechanism of AKI post-liver transplantation.

**Methods:** Sprague-Dawley rats were separated to sham-operated group and SOLT group. SOLT was performed according to the Kamada and Calne's cuff technique. Sham-operated rats were subjected to laporotomy and identical liver manipulations without the vascular occlusion. The animals were sacrificed 24h after surgery.

**Results:** SOLT rats developed typical histological changes of acute tubular injury including loss of brush border, flattening of the tubular epithelium, medullary congestion and hemorrhage. In addition, marked rarefaction of renal peritubular capillary was also observed in SOLT rats. Macrophages infiltration and upregulation of macrophage-derived cytokine like interleukin-6, interleukin-1β, and tumor necrosis factor-α were obvious in the renal tissue of SOLT rats. There was a downregulation of angiogenic factor like vascular endothelial growth factor and an upregulation of antiangiogenic factors like thrombospondin-1 and matrix metalloproteinase 9 in the renal tissue of SOLT rats compared with sham-operated rats.

**Conclusions:** Our results show that AKI develops rapidly in rats post-liver transplantation and is characterized by renal tubular injury, peritubular capillary rarefaction, and inflammatory changes. The rat model of AKI post SOLT may be useful in delineating the mechanisms and discovering potential therapies for AKI post-liver transplantation.

## TH-PO802

**Regulation of Megalin and Cubilin during Lipopolysacchride-Induced Acute Renal Failure in the Mouse** Klaus Höcherl. *Institute of Physiology, University of Regensburg, Regensburg, Germany.*

Hypoalbuminemia is a common finding in septic patients and is associated with higher morbidity and mortality rates. Because severe sepsis is often accompanied by acute renal failure (ARF) with renal tubular dysfunction, an impairment of proximal tubular endocytosis of glomerular-filtered albumin may result in the development of albuminuria during sepsis. Since the multiligand receptors megalin and cubilin are of major importance for proximal tubular reabsorption of albumin, we investigated in the present study the regulation of these receptors during severe experimental inflammation.

Male C57BL/6J mice (n=6 per group) were injected with lipopolysaccharide (LPS) and the time- and dose-dependent effects on the expression of megalin and cubilin were determined. In addition, plasma and urinary levels of albumin were determined by ELISA.

Treatment with LPS (10 mg/kg; i.p.) for 12 hours caused a decrease in plasma albumin levels from 41 ±2 mg/ml to 22 ±5 mg/ml which was paralleled by a 3.1-fold increase in the urinary excretion of albumin without alterations in hepatic albumin expression. Injection of LPS caused a time-dependent decrease in cubilin mRNA abundance to 68, 51 and 44 % of control values after 3, 6 and 12 h, respectively. Further, LPS dose-dependently decreased cubilin mRNA expression to about 74, 57 and 42% of control values 12h after the injection of 1, 3 or 10 mg/kg of LPS, respectively. Furthermore, injection of LPS caused a time-dependent decrease in megalin mRNA abundance to about 84, 60 and 34 % of control levels after 3, 6 and 12 h, respectively. Moreover, LPS dose-dependently decreased megalin mRNA expression to about 67, 51 and 39% of control values 12h after the injection of 1, 3 or 10 mg/kg of LPS, respectively. In addition, we found a decrease in megalin protein expression 12h after the injection of LPS. Megalin immunoreactivity was clearly decreased in the apical membrane of proximal tubules in mice treated with LPS.

Taken together, these data indicate that the expression of megalin and cubilin is decreased during experimental endotoxemia and that this downregulation may contribute in part to the development of albuminuria and also to hypoalbuminemia during sepsis.

## TH-PO803

**Lowering Dietary Phosphorus (Pi) Results in an Improvement of Blood Pressure, an Increase in Both Urinary Na Losses and Fractional Excretion of Na (FENA), and a Reduction in Blood Levels of Parathyroid Hypertensive Factor (PHF) in Dahl Salt-Sensitive Hypertensive Rats (SSR)** Larry A. Slomowitz,[1] Christina G. Benishin,[2] Brian E. Peerce.[3] *[1]Duophos LLC, Vancouver, BC, Canada; [2]Department of Physiology, University of Alberta, Edmonton, AB, Canada; [3]Dpeartment of Neuroscience and Cell Biology, UTMB, Galveston, TX.*

Given that interventions therapeutic for progressive renal failure are usually also effective for hypertension, we studied the response to moderate Pi restriction in SSR. After an equilibration phase when rats were fed normal rat chow, two groups of SSR were pair-fed high-salt diets (9%). Group1 (n=6) received high Pi diets (0.7%), Group2 (n=12) received moderate Pi-restricted diets (0.2%). A second set of studies employed moderate salt-restricted diets (Group3- 4%NaCl + 0.7%Pi, n=6; Group 4- 4%NaCl + 0.2%Pi, n=6). Blood pressure between Groups 1&2 began to diverge after 4 wks of Pi restriction, and by

6 wks, Group1 developed hypertension as expected (sys 193±7, dia 123±8, MAP 147±8 mmHg), while Group2 did not (sys 147±6, dia 100±6, MAP 115±4 mmHg, all significant p≤0.025). Rats given 4%NaCl needed more time to become hypertensive, but benefited from Pi restriction: After 12 wks, Group3-sys 168±5, dia 132±5, MAP 144±4 mmHg; Group4-sys 143±5, dia 102±6, MAP 129±6 mmHg (all signficant p≤ 0.05). After 6 wks, blood and urine were collected from Groups 1&2. With Pi restriction, urinary sodium losses and FENA jumped 36% and 43%, respectively (p≤0.05). Group 1 versus 2 blood levels of PTH, Vit D3, FGF-23, aldosterone, and PRA were not significantly different. PHF blood levels fell with Pi restriction (Group1- 1.9±0.15, Group2- 1.05±0.25 U/kg body wt, p≤0.05).

The results indicate moderate Pi restriction is linked to blood pressure and sodium balance in SSR. The nexus between a function ascribed to distal tubule elements (FENA) and a proximal tubule function (Pi balance) is novel and unexplained. The data support the proposed role of PHF in the developement of hypertension in SSR. PHF blood levels correlated with Pi intake in SSR, suggesting that a regulatory loop might be present. Studies to determine the role of dietary Pi in human hypertension are needed.

**Dietary Phosphate Restriction Ameliorates Endothelial Function in Adenine-Induced Chronic Kidney Disease Model Rats** Vu Van Tan, Eriko Watari, Yutaka Taketani, Tomoyo Kitamura, Asuka Shiota, Ayako Tanimura, Hironori Yamamoto, Eiji Takeda. *Department of Clinical Nutrition, University of Tokushima, Tokushima, Japan.*

Chronic kidney disease (CKD) causes the dysregulation of systemic mineral metabolism including hyperphosphatemia that is a risk factor for cardiovascular disease (CVD) by leading both endothelial dysfunction and vascular calcification. Control of serum phosphate (P) level by dietary P restriction or P binders is considered to be beneficial to prevent CVD in CKD patients, but it has been unclear whether keeping lower serum P level can ameliorate endothelial function. In this study we investigated whether low-P diet can improve endothelial function in adenine-induced CKD rats model. In first, 7 week-old Sprague-Dawly rats were divided into two groups: control group rats were fed with control-P diet containing 1% P, and CKD group rats were fed with adenine diet containing 0.75% adenine and 1% P for three weeks to induce CKD. Then, CKD group rats were divided into two groups: one group rats were received control-P diet (CKD-CP) and the other group were received low-P diet containing 0.2% P (CKD-LP). After sixteen days, aortic rings were prepared for evaluation of acetylcholine-induced vasodilation by using isometric transducer, and blood samples were also collected. Serum P and creatinine levels were 17.0±0.85 and 2.09±0.12 mg/dl in CKD group (n=6), and 5.50±0.25 and 0.64±0.05 mg/dl in control (n=6), respectively. Acetylcholine-dependent vasodilation in CKD rats was significantly deteriorated compared with control group rats. After sixteen days treatment with low-P diet (CKD-LP), serum P level was significantly lower (3.24±0.46 vs 10.6±1.79 mg/dl, p<0.01) despite a high creatinine level (2.71±0.48 mg/dl). Acetylcholine-dependent vasodilation in CKD-LP rats was improved compared with CKD-CP rats (85.1±2.64% vs 60.1±3.25%, respectively, p<0.05). This improvement was thought to be due to a decrease in serum P level by dietary P restriction. In conclusion, dietary P restriction would be a beneficial way to ameliorate endothelial function, and useful to reduce a CVD risk under CKD condition.

### TH-PO805

**All-Trans Retinoic Acid Maintains the Blood Phosphate Levels through the Positive and Negative Regulation of Type II Sodium-Dependent Phosphate Co-Transporter Family Genes in Kidney and Intestine** Masashi Masuda,[1] Hironori Yamamoto,[1] Mina Kozai,[1] Yuichiro Takei,[1] Otoki Nakahashi,[1] Shoko Ikeda,[1] Ayako Otani,[1] Yutaka Taketani,[1] Ken-Ichi Miyamoto,[2] Eiji Takeda.[1] *[1]Dept. Clinical Nutrition, Inst. Healthbioscience, Univ. Tokushima, Tokushima, Japan; [2]Dept. Molecular Nutrition, Inst. Healthbioscience, Univ. Tokushima, Tokushima, Japan.*

It has been known that the type II sodium-dependent phosphate co-transporter (Npt2) family (Npt2a, Npt2b and Npt2c) play a critical role for the Pi absorption in kidney and intestine. Vitamin A metabolites are potent regulators of a variety of physiological processes including development, cell differentiation and proliferation, reproduction and bone formation. All-trans retinoic acid (ATRA) and 9-cis retinoic acid have been recognized as important signaling molecules and physiological ligands for the retinoic acid receptors and the retinoid X receptors, which act as ligand-activated transcription factors controlling the expression of a number of target genes. Recently, we published that vitamin A-deficient (VAD) rats increased the levels of urine Pi but not plasma Pi, and renal expression of Npt2a and Npt2c genes are transcriptionally up-regulated by ATRA and its receptors (Biochemical J. 2010). In this study, we addressed the effect of VAD diet and ATRA administration on the Pi absorption and Npt2b gene expression in small intestine. VAD rats decreased fecal Pi excretion and increased intestinal Pi uptake activity. Western blots and quantitative RT-PCR analysis revealed that Npt2b protein and its mRNA expression were up-regulated by VAD. In contrast, the administration of ATRA to VAD rats significantly suppressed the Pi uptake activity and the Npt2b gene expression in intestine. These results suggest that ATRA inhibit the intestinal Npt2b gene expression. In summary, ATRA maintains the blood Pi levels through the positive and negative regulation of Npt2 family genes in kidney and intestine.

### TH-PO806

**The Identification of histidine-712 as a Critical Residue for Constitutive TRPV5 Internalization** Theun de Groot, Sjoerd Verkaart, Rene J. Bindels, Joost G. Hoenderop. *Department of Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

The epithelial Ca2+ channel transient receptor potential vanilloid 5 (TRPV5) constitutes the luminal entry gate for active Ca2+ reabsorption in the distal part of the nephron. As TRPV5 is the rate-limiting factor in active Ca2+ reabsorption, understanding channel regulation is essential to comprehend renal Ca2+ handling. Molecular regulation of TRPV5 by calciotropic hormones, associated proteins and other factors is highly concentrated in the carboxy (C)-terminus. To fully identify the role of the C-terminus in TRPV5 function, we generated channels harboring C-terminal deletions. Fura-2 analysis was employed to measure the intracellular Ca2+ concentration ([Ca2+]i) in TRPV5-expressing human embryonic kidney (HEK) 293 cells. TRPV5 Ca2+ and Na+ currents were determined by electrophysiology, while cell surface biotinylation was implemented to investigate TRPV5 plasma membrane expression and internalization. Analysis of the [Ca2+]i of TRPV5 deletion mutants demonstrated that removal of amino acid histidine-712 (H712) elevated TRPV5 activity. Substitution of the positively charged H712 for a negative (H712D) or neutral (H712N) amino acid also stimulated TRPV5 activity. This critical role of H712 was confirmed by patch clamp analysis, which demonstrated increased Na+ and Ca2+ currents for TRPV5-H712D. Cell surface biotinylation studies revealed an enhanced cell surface presence of TRPV5-H712D as compared to wild-type (WT) TRPV5. This elevated plasma membrane expression was not due to the increased [Ca2+]i, as a Ca2+-impermeable pore mutant TRPV5-H712D-D542A, which does exhibit Na+ currents, was also more abundant at the cell surface then TRPV5-WT-D542A. An internalization assay revealed a delayed cell surface retrieval for TRPV5-H712D. Experiments using sucrose and filipin indicate that caveolae-mediated endocytosis of TRPV5-H712D is affected, rather than clathrin-mediated endocytosis of TRPV5. These results demonstrate that residue H712 mediates TRPV5 internalization and thereby controls Ca2+ reabsorption, as few constitutively open TRPV5 channels at the cell surface allow a massive Ca2+ influx.

**Insulin Increases TRPM6 Activity by Raising Cell Surface Expression** Anil V. Nair, Rene J. Bindels, Joost G. Hoenderop. *Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Diabetes type 2 (DM2) is associated with insulin resistance and renal $Mg^{2+}$ wasting, but the molecular mechanism of this defect is unknown. DM2-related hypomagnesemia has been linked to coronary artery diseases, hypertension, diabetic retinopathy, nephropathy, neuropathy, abnormal platelet activity, and foot ulcerations. To investigate the molecular mechanism behind renal $Mg^{2+}$ wasting associated with DM2, we measured the effect of insulin on the activity of renal epithelial $Mg^{2+}$ channel, the transient receptor potential M6 (TRPM6). We performed whole-cell patch clamp recordings of TRPM6 expressed in human embryonic kidney 293T (HEK293T) cells. Stimulation of the insulin receptor (IR) increased the current through TRPM6 expressing cells in a dose dependent manner ($EC_{50}$ = 0.102 nM) but not through the non-transfected cells. To address whether the stimulatory action of insulin was specific to IRs, we added a high-affinity peptide antagonist of the IR, the S961, which abolished the stimulatory effect of insulin on TRPM6-mediated current. The effect of insulin on TRPM6 was abrogated by the application of phosphoinositide 3 kinase (PI3K) (a downstream effector of insulin signaling cascade) inhibitors wortmannin and LY294002. Activation of Rac1, another effector of PI3K, increased the TRPM6-mediated current. In contrast, co-expression of TRPM6 with the dominant negative Rac1 mutant (Rac1-T17N) failed to show increase in current by insulin stimulation. Total internal reflection fluorescence microscopy showed an increased trafficking of TRPM6-containing vesicles towards the plasma membrane upon insulin application. In summary, insulin mediated stimulation of TRPM6 current which occurs via PI3K and Rac1 signaling, thereby increasing the amount of plasma membrane availability of TRPM6 from the endomembranes. These results show a possible regulatory mechanism for transepithelial $Mg^{2+}$ transport in the kidney and consequently whole-body $Mg^{2+}$ homeostasis mediated by insulin signaling. The impaired insulin signaling due to insulin resistance and subsequent inability to retain $Mg^{2+}$ through TRPM6 in kidney may explain hypomagnesemia in DM2 patients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO808

**Interaction between TRPM6 and EGF in a Rat Model of Cyclosporine Nephrotoxicity** Kristien J. Ledeganck,[1] Caroline Aj Horvath,[2] Inge Brouns,[3] Rita M. A. Van den Bossche,[4] Benedicte Y. De Winter,[1] Gert A. Verpooten.[1] *[1]Labo Experimental Medicine and Pediatrics; [2]AMBIOR; [3]Labo Cell Biology and Histology; [4]Labo of Pharmacology, University of Antwerp, Belgium.*

Hypomagnesemia is a well known side effect of cyclosporine (CsA) treatment in humans due to renal Mg loss but the underlying mechanisms are still unclear. Recently, it was shown that epidermal growth factor (EGF) stimulates Mg reabsorption in the distal convoluted tubule via TRPM6. We studied the renal expression of TRPM6, TRPM7 and EGF in a rat model of CsA nephrotoxicity, the effect of EGF administration on the Mg homeostasis and the expression of TRPM6, TRPM7 and EGF. A daily dose of 15 mg/kg CsA was given subcutaneously to male Wistar rats during 4 weeks. Two groups received a daily dose of 150 µg/kg hEGF subcutaneously during 4 weeks. Real-time RT-PCR analyses were performed to determine the renal mRNA expression levels of TRPM6, TRPM7, EGF, TGF- and PAI-1. The CsA treatment resulted in an increased plasma creatinine (0.45±0.05

mg/dL in the CsA-treated groups vs 0.26±0.07 mg/dL in the controls), and an increase in fractional excretion of Mg (12.02±3.32 % in the CsA-treated group vs 8.9±4.02% in the controls). Microscopically cortical areas of tubular vacuolisation, tubular dilatation and juxtaglomerular apparatus hyperplasia were noticed. RT-PCR analysis showed that CsA significantly decreased the renal mRNA expression of TRPM6 (Normalized ratio (NR): 1.25±0.32 vs 1.48 0,24 in controls), TRPM7 (NR: 1.35±0.4 vs 1.62±0.22 in controls) and EGF (NR: 0.51±0.39 vs 1.74±0.45 in controls). In control rats treated with EGF an increase in renal expression of TRPM6 (NR: 1.77±0.25) and EGF (NR: 1.95±0.28) was demonstrated together with a decrease in fractional excretion of Mg (5.49±2.34% vs 8.9±4.02% in controls). On the other hand there was no effect of EGF administration on the renal expression of TRPM6 (NR: 0.99±0.13), TRPM7 (0.99±0.23) and EGF (0.49±0.14) in CsA-treated rats. CsA-induced renal Mg loss may be the result of the downregulation of TRPM6. These findings further support the hypothesis that EGF plays an important role in the renal expression/activation of TRPM6.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO809

**Genome-Wide Association Study of Serum Calcium Levels Reveal Common Variants in the Calcium Sensing Receptor Gene Associated with Features of Familial Hypocalciuric Hypercalcemia** Anna Kottgen,[1,9] Conall M. O'Seaghdha,[2] Qiong Yang,[3] Nicole Glazer,[4] Tennille S. Leak,[5] Abbas Dehghan,[6] Albert Vernon Smith,[7] Vilmundur Gudnason,[7] Yongmei Liu,[8] Wen Hong Linda Kao,[9] Bryan R. Kestenbaum,[4] Caroline S. Fox.[2] *[1]Freiburg University Hospital, Germany; [2]NHLBI's Framingham Heart Study; [3]Boston University; [4]University of Washington Seattle; [5]University of Pittsburgh; [6]Erasmus MC, Rotterdam, Netherlands; [7]Icelandic Heart Association, Iceland; [8]Wake Forest University; [9]Johns Hopkins University.*

Serum calcium levels are tightly regulated and highly heritable, but the role of common genetic variation influencing serum calcium concentrations in the physiologic range is largely unknown.

We performed genome-wide association analyses (GWAS) in population-based studies participating in the CHARGE Consortium to uncover common genetic variation associated with serum calcium levels. GWAS of serum calcium concentrations was performed in 20,611 individuals of European ancestry for ~2.5 million genotyped and imputed single-nucleotide polymorphism (SNPs).

The SNP with the lowest p-value was intronic rs17251221 (p=2x10^-22, minor allele frequency 14%) in the calcium sensing receptor gene (CASR). This SNP was associated with higher serum calcium levels (0.06 mg/dl per copy of the minor G allele). The G allele of rs17251221 was also associated with higher serum magnesium levels (p=1x10^-3), lower serum phosphate levels (p=3x10^-7) and lower bone mineral density at the lumbar spine (p=0.038). No additional genomic loci contained SNPs associated at genome-wide significance (p<5x10^-8).

These associations resemble clinical characteristics of patients with familial hypocalciuric hypercalcemia, an autosomal-dominant Mendelian disease arising from rare mutations in the CASR gene. Common genetic variation in the CASR gene is associated with similar but milder features in the general population, and suggests that the causal variant results in reduced CASR function.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO810

**Decline of Renal Klotho Expression Is Associated with Hypercalciuria in Patients with Diabetes** Osamu Asai,[#1] Kimihiko Nakatani,[#1] Hirokazu Sakan,[#1] Ken-Ichi Samejima,[#1] Shuhei Yoshimoto,[#1] Tomohiro Tanaka,[#2] Masayuki Iwano,[#1] Akihiro Imura,[#2] Yo-Ichi Nabeshima,[#2] Yoshihiko Saito.[#1] *[1]First Department of Internal Medicine, Nara Medical University, Kashihara, Nara, Japan; [2]Department of Pathology and Tumor Biology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

The Klotho(KL) is expressed predominantly in renal distal convoluted tubules, where transepithelial $Ca^{2+}$ reabsorption is actively regulated. Hypercalciuria has been documented in human and experimental diabetic nephropathy(DN), but its detailed mechanism is still unclear. In this study, we studied the association of renal KL expression levels with hypercalciuria in human DN and STZ-diabetic model mice. We evaluated fractional excretion of Ca (FeCa) for DN(n=74), and also quantitatively evaluated KL mRNA expression for 31 renal frozen biopsy specimens with DN by real-time PCR. We also studied for IgA nephropathy(IgAGN)(n=90), and minor glomerular abnormalities(MCD)(n=26), as control. Patients with DN showed significantly lower levels of renal KL expression and higher levels of FeCa, than those with IgAGN and MCD. Moreover, FeCa was significantly correlated with renal KL mRNA expression levels, and multiple regression analyses showed FeCa was significantly and negatively associated with renal KL expression levels as independent variables in order of importance. In STZ-induced diabetic mice, renal KL mRNA levels were significantly decreased and urinary Ca excretions increased at 8 weeks after the induction ofdiabetes, compared with control mice. To confirm whether the reduction of renal KL expression was associated with hypercalciuria in DN, we induced diabetes in $KL^{+/-}$ mice and wild-type mice by STZ injection. When diabetes was induced, $KL^{+/-}$ mice showed the significant increase of urinary Ca excretions, compared with wild-type mice, at 2 weeks after the induction of diabetes. In conclusion, remarkable reduction of renal KL expression levels may lead to hypercalciuria in DN.

### TH-PO811

**Major Facilitator Superfamily (MFS) Transporters Mediate Cellular Effects of Phosphate in Drosophila S2R+ Cells** Clemens Bergwitz,[1] Charles Derobertis,[1] Sumi Sinha,[1] Hway Helen Chen,[1] Harald Jueppner,[1] Matthew D. Rasmussen,[3] Norbert Perrimon.[2] *[1]Endocrine Unit/Dept. of Pediatrics, Massachusetts General Hospital, Boston, MA; [2]Dept. of Genetics, Harvard Medical School/Howard Hughes Medical Institute, Boston, MA; [3]Computer Science and Artificial Intelligence Lab, MIT, Cambridge, MA.*

Pho84 is a proton-dependent phosphate co-transporter, which permits yeast to sense the environmental phosphate concentration. It belongs to the major facilitator superfamily (MFS) of transporters, which includes 77 members in yeast, 219 members in Drosophila, and 229 members in humans. Database searches based on protein sequence conservation alone have been unable to identify the pho84 ortholog in higher species. We postulated that activation of MAPK by phosphate and phosphate-transport after expression of candidates in Xenopus oocytes can be used to functionally evaluate members of the MFS to identify pho84 orthologs, which are involved in metazoan phosphate sensing.

We used BLAST followed by Bayes phylogenetic analysis to identify 29 fly orthologs that are most closely related to pho84 and human SLC17A1-9, an anion transporter subfamily with members known to mediate phosphate transport. Some of these transporters are expressed in the fly hemocyte cell line S2R+. Individual RNAi knockdown identified three fly SLC17A orthologs, which inhibited phosphate-induced activation of MAPK in S2R+ cells, while knockdown of the Drosophila Pit1 ortholog was less effective. We next injected cRNA encoding each individual fly transporter into Xenopus oocytes and identified one transporter, which mediates uptake of [33P]-orthophosphate in a sodium-dependent fashion. Phosphate conductance by this fly transporter was blocked by phosphonoformic acid and appears to be independent of protons.

Our findings suggest that MFS transporters mediate cellular effects of phosphate in fly S2R+ cells. The transmembranous sodium-gradient rather than a proton-gradient may be used to permit import of phosphate into fly cells against it's electrochemical gradient. Multiple MFS members may be involved in phosphate-induced activation of MAPK in fly.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO812

**Regulation of Renal Cortical $Ca^{2+}$ Transporters and Tight Junction Proteins in Rats on High-Salt Diet** Midori Sasaki Yatabe,[1,3] Junichi Yatabe,[1,2] Hironobu Sanada,[2] Kimura Junko,[3] Tsuyoshi Watanabe.[1] *[1]Dept. of Nephrology, Hypertension, Diabetology, Endocrinology and Metabolism, Fukushima Medical University, Fukushima, Japan; [2]Division of Health Science Research, Fukushima Welfare Federation of Agricultural Cooperatives, Fukushima, Japan; [3]Dept. of Pharmacology, Fukushima Medical University, Fukushima, Japan.*

Introduction: Excess dietary salt intake increases urinary $Ca^{2+}$ excretion. However, this mechanism and chronic effects of salt on calcium-transporting molecules and paracellular pore/barrier proteins are not clear.

Methods: Wistar-Kyoto rats (8-week old) were fed either 0.3% or 8% NaCl diet for 8 weeks with regular urine collections. Kidneys were collected at the end of the study.

Results: Urinary $Ca^{2+}$ excretion increased with high-salt diet (0.3% vs 8% NaCl, 0.70±0.05 vs. 4.56±0.27 mg/day, n=15, p<0.001). Renal cortical $Na^{+}/Ca^{2+}$ exchanger 1 (NCX1) mRNA (100±9% vs. 120±15%, n=15, p<0.05) and protein (100±6% vs. 126±6%, n=15, p<0.05) expressions were higher in the high-salt group. Apical $Ca^{2+}$ channel, TRPV5 (mRNA; 100±7% vs. 158±18%, protein; 100±8% vs. 143±10%, both n=15, p<0.05), and intracellular $Ca^{2+}$ shuttle, calbindin-D28k (mRNA: 100±9% vs. 148±20%, n=14-16, p<0.05), also increased with high-salt diet. Basolateral $Ca^{2+}$ pump, PMCA1b, expression was not altered. Renal cortical claudin 7 and 8 mRNA levels were similar between the groups. However, claudin 2 mRNA level was greater in the high-salt than the control group (100±12 vs. 140±8, n13-14, p<0.05).

Conclusion: Renal cortical claudin 2, TRPV5, calbindin-D28k, and NCX1 increased with chronic high-salt diet. Claudin 2 is a proximal tubule tight junction protein that forms cation pore. TRPV5, calbindin-D28k and NCX1 in the distal tubule facilitate $Ca^{2+}$ reabsorption. Although the functions of these proteins may be altered by excess salt intake, extrapolating from their basal functions suggests that these changes may be adaptive to minimize urinary $Ca^{2+}$ loss. Further study is necessary to clarify the mechanism and consequences of these up-regulations in salt-induced calciuria, which may be involved in the pathophysiology of osteoporosis, renal calculi and hypertension.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO813

**Role of NHERF PDZ Proteins in the Differential Regulation of the Proximal Tubule NaPi Transporters** Hector Giral-Arnal,[1] Luca Lanzano,[2] Yupanqui A. Caldas,[1] Judith Blaine,[1] Kayo Okamura,[1] Enrico Gratton,[2] Moshe Levi.[1] *[1]Renal Division, U of Colorado Denver, Aurora, CO; [2]LFD, U of California Irvine, Irvine, CA.*

The Na-dependent phosphate (NaPi) transporters NaPi-2a and NaPi-2c play a major role in the renal reabsorption of Pi. The functional need of several transporters accomplishing the same role is still not clear. However, the fact that the transporters show differential regulation under dietary and hormonal stimuli suggests different roles in Pi reabsorption. The pathways controlling this differential regulation are still unknown. One of the candidates involved in this regulation is the NHERF family of PDZ proteins. We

propose that differences in the molecular interaction with these PDZ proteins are related with the differential adaptation of the NaPi transporters. To test if NHERF proteins play a different role in the regulation of NaPi transporters we studied the NHERF-3 (PDZK1) KO mouse. NHERF-3 KO adapted to low Pi diets showed an increased expression of NaPi-2a protein in the apical membrane of proximal tubules, but an impaired upregulation of NaPi-2c protein levels. Similar results were obtained when analyzing the total renal homogenates. These results suggest that NHERF-3 has an important role in the stabilization of NaPi-2c in the apical membrane. We studied the specific protein-protein interactions of NaPi-2a and NaPi-2c with NHERF-1 and NHERF-3 by Fluorescence Lifetime Imaging (FLIM)-FRET technique. FRET efficiency measurements showed a stronger interaction of NHERF-1 with NaPi-2a than with NaPi-2c. However, both NaPi transporters showed similar FRET efficiencies with NHERF-3. Interestingly, when the cells where adapted to several Pi concentrations mimicking the in vivo model, a gradual increase in the FRET efficiency was observed under lower Pi concentrations in the pairs NaPi-2c/NHERF-3 and NaPi-2a/NHERF-1. These results suggest that differential affinity of the NaPi transporters for NHERF-1 and -3 could partially explain their differential regulation and stability in the apical membrane. In this regard, direct interaction between NaPi-2c and NHERF-3 seems to play an important role in the physiological regulation of NaPi-2c.

**Phosphate Transporters in Human Urine: Window into the Molecular Physiology and Pathophysiology of Renal Phosphate Handling** Ion Alexandru Bobulescu, Anthony S. Nguyen, Orson W. Moe. *Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX.*

The kidney is key for total body phosphate (PO4) homeostasis. Filtered PO4 is reabsorbed in the proximal tubule via 3 sodium-coupled transporters (NaPi-2a, NaPi-2c, and Pit-2) with different substrate affinities, stoichiometries, pH-dependence, and regulatory characteristics. Numerous physiologic and pathophysiologic conditions involve regulation or dysregulation of renal PO4 transporters. To fully understand PO4 handling, and to pave the way for novel diagnostic tools and better treatment options for PO4 disorders, it is crucial to study PO4 transporters individually. Rodent studies are informative but insufficient, since gene inactivation studies have shown that the relative contribution of individual transporters to PO4 homeostasis is significantly different in mice compared to humans. Clinical evaluation of individual PO4 transporters in humans has been impossible to date. We developed a simple and reliable assay to measure PO4 transporters in sediment-free human urine, based on the Wessel-Flugge protein precipitation method. This assay is much simpler, faster, and less expensive than urinary exosomal preparations. We conducted several studies to validate this assay: 1) In rats given sodium phosphate gavage or dietary PO4 manipulation (0.1%, 0.6% and 1.2% PO4 diets), we correlated changes in PO4 transporter levels in the urine and in renal brush border membrane vesicles. 2) In healthy human volunteers given a PO4 load or a PO4 binder, urinary NaPi-2a excretion reflected the expected changes in proximal tubule brush border NaPi-2a. 3) In a patient with tumor-induced osteomalacia, both urinary NaPi-2a and NaPi-2c were low, and increased after surgical removal of the disease-causing tumor, concomitant with decreased renal PO4 wasting. Taken together, these findings indicate that the levels of urinary PO4 transport proteins provide an invaluable window into the molecular physiology and pathophysiology of renal PO4 handling. This will take clinical pathophysiology to a new level, where the roles of individual PO4 transporters can be studied in addition to plasma and urinary chemistry.

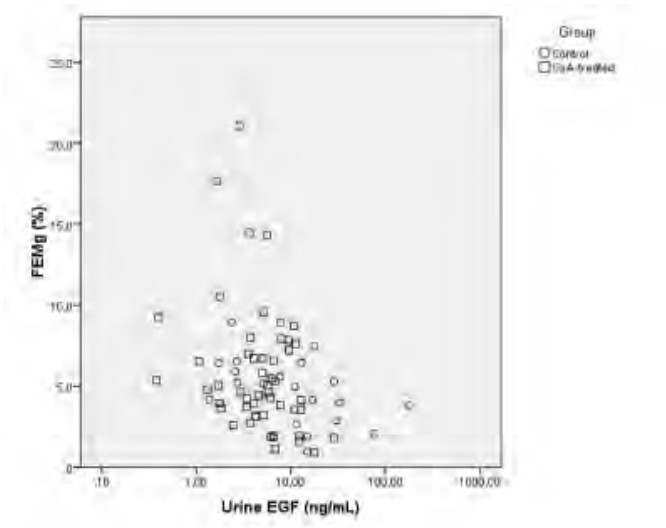
**Decreased Urinary EGF Excretion Is Associated with Renal Mg Leak in Transplant Patients Treated with Cyclosporine** Kristien J. Ledeganck,[1] Annelies Van den Driessche,[2] Jean-Louis Bosmans,[1,2] Marie M. Couttenye,[1,2] Benedicte Y. De Winter,[1] Gert A. Verpooten.[1,2] *[1]Experimental Medicine and Pediatrics, Univ Antwerp; [2]Dept of Nephrology, Antwerp Univ Hosp, Edegem, Antwerpen, Belgium.*

Hypomagnesemia is a well known side effect of cyclosporine (CsA) treatment in humans due to renal Mg loss but the underlying mechanisms remain unclear. It was recently shown that epidermal growth factor (EGF) stimulates Mg reabsorption in the distal convoluted tubule via TRPM6. We investigated the urinary excretion of EGF in patients treated with CsA and its relation to the fractional excretion of Mg. 25 kidney transplant patients treated with CsA and 11 controls were recruited at our hospital. Two or more blood and urine samples were taken from each patient with a time interval of at least 1 month. Urinary EGF was measured using an EGF human Elisa kit. Mean eGFR was comparable in both CsA-treated patients (44±27 mL/min/1.73m²) and controls (44±16 mL/min/1.73m²). Serum Mg was decreased in the CsA-treated group (1.87±0.24 mg/dL) compared to the control group (1.94±0.21 mg/dL) although this difference is not significant (p=0.27). The fractional excretion of Mg was increased in the CsA-treated group (5.9±4.1%) compared to the controls (4.8±2.2), although not significantly (p=0.25). Urinary excretion of EGF was significantly decreased in the CsA-treated patients (6.2±5.0 ng/dL) compared to the controls (22.1±38.4 ng/dL, p=0.01). Analysis using a Generalized Linear Model showed that, in both groups, log urinary EGF concentration was inversely correlated with FEMg (p=0.04).



A 5-fold decrease in urinary EGF excretion was found in CsA-treated patients. The decrease in EGF excretion was correlated with an increased fractional excretion of Mg. These findings support the hypothesis that EGF plays an important role in de renal excretion of Mg and confirm the results of animal studies in humans.

**TH-PO816**

**Urinary Calcium Excretion Is Controlled by the Circadian Gene Clock** Vlasta Zavadova,[1] Svetlana Nikolaeva,[1] Dmitri Firsov,[1] Olivier Bonny.[1,2] *[1]Department of Pharmacology and Toxicology, University of Lausanne, Lausanne, Switzerland; [2]Service of Nephrology and Hypertension, Lausanne University Hospital, Lausanne, Switzerland.*

Circadian rhythms have been described for plasma calcium, parathormone (PTH) and for urinary calcium under constant conditions, and may play a role in kidney stone formation and osteoporosis. The mechanisms underlying these rhythms remain however largely unknown. Entrainment by systemic cues or regulation by local molecular clock have been proposed. Here, we aimed (i) at describing the physiological circadian rhythms for calcium in the mouse, (ii) at measuring the diurnal variations in mRNA levels of the main renal calcium transporters and (iii) at assessing the role of the molecular clock in the regulation of calciuria. We first studied the variations in plasma calcium, PTH, and in calciuria every 4 hours for 24h in C57BL/6 mice. Circadian variations of, respectively, 2.5, 40 and 20% over the 24h mean has been observed under light/dark cycles and under constant darkness. Second, the renal mRNA levels for the main partners involved in calcium reabsorption have been assessed by qPCR every 4 hours for 24h. TRPV5 and NCX1 mRNA levels were varying by 17 and 12% over the 24 hours mean, respectively, while calbindin-D28K and PMCA did not change significantly. NCX1 protein variations were confirmed by Western Blot analysis. Third, we studied the effect of the *clock* gene on calciuria. In metabolic cages, *clock*-deficient mice displayed higher urine calcium excretion (34.7% higher in light/dark conditions and 46.2% in constant darkness) and exhibited a disturbed circadian rhythm compared to their wildtype littermates. In *clock*-deficient mice, plasma calcium and PTH levels were not significantly different from wildtype mice. Overall, we characterized in detail the plasma calcium, PTH and calciuria circadian rhythms in the mouse and we showed that TRPV5 and NCX1 renal mRNAs expression were also varying over 24h. In addition, our data suggest that the *clock* gene is involved in the regulation of calciuria, as clock-deficient mice are hypercalciuric. In order to define the cause of hypercalciuria, kidney-specific disruption of the molecular clock is awaited.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO817**

**Renal Extracellular Ca2+-Sensing Receptor CaSR Regulates Calcium Homeostasis Independently of Parathyroid Hormone** Alexandre Loupy,[1] Bharath Wootla,[1] Suresh Krishna Ramakrishnan,[1] Kamel Laghmani,[1] Patrick Bruneval,[2] Chantal Mandet,[2] Pascal Houillier.[1] *[1]INSERM U872; [2]INSERM U872.*

CaSR plays a crucial role in Ca2+ homeostasis by tuning parathyroid hormone (PTH) secretion. However, the homeostatic importance of extraparathyroid CaSR is less understood. CaSR is significantly expressed in the thick ascending limb where its role remains uncertain. The aim of the present study is to determine if CaSR is able to control Ca homeostasis independently of PTH, and how CaSR acts on the renal tubule.

In thyroparathyroidectomized, PTH-supplemented rats (1U/hr), the CaSR antagonist NPS2143 (1mg daily) elicited a significant decrease in urinary Ca excretion on the first day of treatment (from 2.2±0.1 to 0.8±0.02 mM/mM creatinine, p<0.01), creating a positive Ca balance. Blood ionized calcium concentration was increased by 29% at day-2, 30% at day-4 and finally 35% at day-7 of treatment in the NPS-treated rats as compared to controls (p<0.03 in all cases). Besides its effects on Ca, treatment with NPS2143 did not alter glomerular

filtration rate, blood electrolytes concentrations, urine output and urinary electrolytes excretions. No change occurred in the control group throughout the experiment.

In in vitro microperfused cortical TAL, the peritubular addition of 1 μM NPS2143 reversibly increased by 50 % net Ca2+ reabsorption and transepithelial permeability to calcium, as compared to control period ($p<0.03$), without any modification in NaCl transport or transepithelial voltage.

Taken together, our results demonstrate that inhibiting the extraparathyroid CaSR increases renal tubular Ca absorption through an increase in the paracellular pathway permeability to Ca in the TAL, and blood Ca2+ concentration, independently of changes in PTH secretion. Renal CaSR may act as an additional player besides PTH in the regulation of extracellular calcium metabolism.

**TH-PO818**

**Differential Regulation of the Sodium Phosphate Cotransporters NAPI2A and NAPI2C at the Apical Membrane by Parathyroid Hormone** Judith Blaine, Kayo Okamura, Hector Giral-Arnal, Omid Masihzadeh, Yupanqui A. Caldas, Moshe Levi. *Medicine, University of Colorado Denver, Aurora, CO.*

Parathyroid hormone (PTH) plays a critical role in the regulation of phosphate homeostasis which is crucial for cellular energetics and signaling. In the kidney, PTH regulates phosphate reabsorption via the sodium phosphate cotransporters NaPi2a and NaPi2c which are found on the brush border membrane (BBM) of renal proximal tubule cells. The kinetics of regulation of the cotransporters by PTH, however, are markedly different. Whereas NaPi2a is removed from BBM microvilli within an hour of PTH treatment the same process takes 4 to 6 hours for NaPi2c. The reasons for this difference are not known. We have previously shown that the unconventional myosin motor myosin VI is required for PTH-induced removal of NaPi2a from BBM microvilli using total internal reflection fluorescence microscopy (an excellent technique for examining membrane events). Here we demonstrate that myosin VI is also required for PTH-induced removal of NaPi2c from microvilli. In addition, we use fluorescence correlation spectroscopy to show that at baseline the diffusion coefficients for NaPi2a and NaPi2c within the BBM are the same. After addition of PTH, however, NaPi2a has an early increase in its diffusion coefficient which is not seen for NaPi2c. Thus NaPi2a and NaPi2c appear to be released from membrane tethers on different timescales after PTH treatment which can partially account for their differential response to PTH.

**TH-PO819**

**Characterization of the Specific Effects of Renal Tubular Calcium-Sensing Receptor (CaR)** Renaud De la Faille, Alexandre Loupy, Pascal Houillier. *centre de Recherche des Cordeliers, Université Pierre et Marie Curie, INSERM UMRS 872, Paris, France.*

CaR regulates the secretion of parathyroid hormone (PTH) and calcitonin in response to changes in extracellular calcium concentration. In the kidney, it inhibits calcium reabsorption in thick ascending limb of Henle's loop. Direct effects of CaR activation on the renal handling of other ions and water remain unclear.

Objectives: to define the specific role of renal tubular CaR using specific allosteric agonists of CaR, AMG073 and NPS R568, and a non-specific agonist of CaR, namely calcium.

Methods: Thyro-parathyroïdectomized (TPTX), PTH-supplemented (1 U/hr) male Sprague-Dawley rats were orally treated with AMG073, NPS R568, high (3 %)-calcium diet or vehicle for 1 week. All rats were studied in metabolic cages. Time-courses of serum calcium, and urinary calcium, phosphate, magnesium, sodium, potassium, ammonium and water excretions were recorded. The renal expression of CaR, Bumetanide Sensitive Cotransporter of Henle's loop (BSC1), and aquaporin 2 (AQP2) was studied by immunoblot on membrane fractions of cortex and outer medulla.

Results: In TPTX, PTH-supplemented rats, treatment with AMG073 or NPS R568 transiently increased urinary calcium excretion on the first day of treatment and elicited a stable decrease in serum calcium concentration by the second day of treatment ; no significant change in urine volume, or other electrolyte excretions was observed. Conversely, high-calcium diet induced hypercalcemia, hypercalciuria, hypermagnesiuria, polyuria, transient natriuresis and metabolic acidosis. After 1 week of study, expressions of CaR, BSC1 and AQP2 were unchanged in the group treated with CaR agonists, but were decreased in the high-calcium diet group.

Conclusion: CaR activation decreases renal tubular calcium reabsorption by an effect independent on PTH. Moreover, CaR activation not fully explains all the tubular effects of hypercalcemia, particularly polyuria and natriuresis.

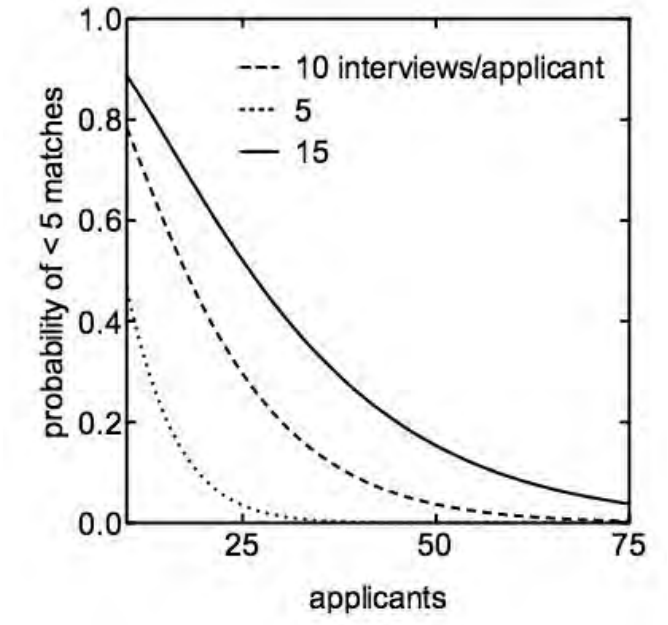
**TH-PO820**

**How Many Applicants Should a Fellowship Program Interview: A Conservative and Probabilistic Approach** Brent Wagner,[1] Julie A. Harris,[1] Casey Cotant.[2] *[1]Department of Medicine, University of Texas Health Science Center, San Antonio, TX; [2]Nephrology, Wilford Hall Medical Center, Lackland Air Force Base, TX.*

Background: The NRMP was established to provide a fair recruiting process for both programs and applicants to positions in graduate medical education. Failure of a training program to fill all available positions leads to a "scramble". Common advice is to interview 10 applicants for every training slot, but there is a paucity of literature that supports this. Our purpose was to use a computer simulator to calculate the minimal number of applicants per training slot that are required for ranking. Methods: A simulation of a match was created using Excel. Hypothetical results based on varying the number of interviews (n) per applicant were generated. The probability of matching (P(m)) was estimated as 1/(n). The $P(m) < 5$ positions was calculated as the sum of the probabilities of filling 0, 1, 2, 3, or 4 positions. Results: When plotting fellowship slots against the number of ranked applicants, the mean P(m) follows a linear relationship with a slope of 1/(n). When extrapolated, the probability of not matching is inversely related to n.



For example, if the n is 10, a program with 5 available positions will need to rank 27 and 47 applicants for a 75% and 95% chance, respectively, to fill all slots. Conclusion: There is a balance between the labor-intensive investment in interviewing a large number of applicants with the goal of a high-probability successful match. The practical application of this simulator is to define how many applicants it is reasonable to interview in order to minimize the risk of not filling a fellowship slot. Our data support the anecdotal recommendation to interview at least 10 applicants for every fellowship position.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO821**

**"The Amazing Base": A Novel Use of Technology and Game Theory in Undergraduate Medical Education** Maury N. Pinsk,[1] Brettany Johnson,[2] Robert Hayward.[2] *[1]Pediatric Nephrology, University of Alberta, Edmonton, AB, Canada; [2]Centre for Health Evidence, University of Alberta, Edmotnon, AB, Canada.*

Introduction: Acid base physiology is one of the more challenging concepts that first year medical students learn. To assist with learning, we introduced an application of Game Theory utilizing HOMER, an online learning environment developed in the Faculty of Medicine. Methods: Building on the premise of the reality show "The Amazing Race", students were organized into small groups of 10 students. At the beginning of the workshop, the group logged into HOMER and started "The Amazing Base", a series of four stations where students either answer a mathematical or knowledge-based question relating to acid base physiology, or perform a task related to acid base concepts learned in lecture. Responses to each station were entered into HOMER and scored in real time. Group progress through the stations was logged online with time stamps as they moved through each station. The workshop culminated with an in-class review of the problem set answers and awarding of a prize to the group finishing with the most correct answers. Results: 87 students (60%) responded to post-workshop questionnaires. As the workshop was voluntary, self-reported attendance was 66%. 60% of respondents stated they found the workshop useful and assisted their learning. Of the attendees, 64% felt they agreed or strongly agreed that the workshop was excellent. Specific strengths of the workshop included aspects of teamwork, the introduction of a fun, creative way to learn, and the usefulness of supplementing a didactic lecture. Weaknesses included poor attendance by some groups and frustration when choosing tasks rather than calculations. Tracked progress of the groups detected unprofessional behavior in one group who claimed they had finished the race without evidence of data entry. Conclusion: "The Amazing Base" is a novel way to reinforce concepts of acid base physiology using Game Theory. The method is well received by first year medical students, provides opportunity for communication and collaboration between students, encouraged pre-workshop preparation, and has the ability to identify issues of professionalism.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO822**

**Factors Associated with Kidney Transplant Education: Results of a National Survey** Kamna Balhara, Lauren M. Kucirka, Bernard G. Jaar, Dorry L. Segev. *Johns Hopkins University School of Medicine, Baltimore, MD.*

**Background:** Patient education about kidney transplantation (KT) plays an important role in determining access to KT. While education modalities differ, counseling time provided by the patient's nephrologist may be pivotal to patient decision-making regarding KT. The goal of this study was to assess factors affecting duration and format of KT education provided by nephrologists.

**Methods:** An anonymous online survey was completed by 471 nephrologists across the US. Associations with length of KT education were examined using generalized linear models.

**Results:** 96% of respondents stated the nephrologist is most responsible for advocating for KT to eligible patients, and 95% felt reimbursement was needed for time spent on KT education. 77% reported that the ideal time to spend was over 20 minutes, but only 43% reported actually spending over 20 minutes. 82% reported that this discrepancy was due to lack of time; 28% cited lack of reimbursement, and 11% cited lack of patient interest. Spending >20 minutes on KT education (table) was associated with greater depth of counseling (covering more KT topics) and having one-on-one conversations. Those who reported that >50% of their patients were African-American had a 33% lower rate of spending >20 minutes on KT education.

**Conclusion**: In this national survey, we found significant associations between provider characteristics, the demographics of a provider's practice, and time spent on KT education. A better understanding of the mechanisms underlying these differences is needed to reduce potential discrepancies in quality of education provided to different patient populations.

**Factors Associated with Spending >20 minutes on Transplant Education**

| Factor | Relative Rate | P-value |
|---|---|---|
| ***Provider characteristics*** | | |
| Increasing age | 1.16 (1.02-1.32) | 0.02 |
| Increasing years in practice | 1.11 (1.03-1.19) | 0.006 |
| Non-profit center | 1.42 (1.05-1.92) | 0.02 |
| ***Patient characteristics*** | | |
| >50% African-American patients | 0.67 (0.48-0.92) | 0.01 |
| >50% female patients | 0.86 (0.58-1.28) | 0.5 |
| ***Format and depth of education*** | | |
| Greater depth of counseling | 1.39 (1.25-1.56) | <0.001 |
| One-on-one conversation with patient | 1.31 (1.06-1.61) | 0.01 |
| Discuss transplant repeatedly with reluctant eligible patients | 1.30 (1.12-1.51) | 0.001 |

Disclosure of Financial Relationships: nothing to disclose

**TH-PO823**

**The Relationship between Health-Related Quality of Life with EuroQol (EQ-5D) and Renal Prognosis in Chronic Kidney Disease Patients in Japan** Reiko Tajima, Hirayasu Kai, Chie Saito, Shuichi Tsuruoka, Kunihiro Yamagata. *Pathophysiology of Renal Disease, University of Tsukuba, Tsukuba, Ibaraki, Japan.*

**Background**: Chronic kidney disease (CKD) is a health-related quality of life (HRQOL) deteriorating disease which is not only a public health but also socioeconomic problem. Interest in developing cost-effective interventions to control CKD has increased. The aim of this study was to measure HRQOL for cost-effectiveness analysis using EQ-5D in patients with CKD. The relationships between the measured HRQOL and progression of CKD stage/ the incidence of cardiovascular disease (CVD) were also analyzed.

**Methods**: EQ-5D, a generic preference-based instrument, was administered to 475 CKD outpatients at Tsukuba University Hospital between November and December 2008.

Data on sex, age, creatinine, hemoglobin, serum albumin, and presence of CVD were obtained from the patients' records, and followed one year after HRQOL measurement.

**Results**: Measured quality-adjustment weights by the CKD stage were 0.940 (95% C.I.: 0.915-0.965), 0.918 (0.896-0.940), 0.883 (0.857-0.909), 0.839 (0.794-0.884), and 0.798 (0.757-0.839) for stages 1 to 5, respectively. The decrease in weight was significant by ANOVA (P<0.0001), and the weight for all stages was 0.885 (0.871-0.898). During the one-year observation period, CKD stage progression was observed in 22.3% of CKD stage 1, 6.8 % of stage2, 8.6% of stage 3 and 22.8% of stage 4, and 41.8% of stage 5 patients (end-stage renal failure). Incidence of CVD was 1.4, 0.7, 1.4, 2.9 and 6.0% for stages 1-5, respectively. Average weight of the subjects who showed progression of CKD stages (0.895) was significantly lower than those of stable renal function (0.834).

**Conclusions**: HRQOL decreases with progression of the CKD stage and decreased HRQOL also affect the prognosis in CKD patients.

**TH-PO824**

**Taking Time To Think: Does Scheme-Inductive Reasoning Improve Diagnostic Performance in Nephrology Physicians and Trainees?** Adam J. Bass,[1] Colin C. Geddes,[2] Kevin McLaughlin.[1] *[1]Nephrology, University of Calgary; [2]Nephrology, Glasgow University.*

Erroneous information processing contributes to most cases of medical error. As the most frequent processing error is premature closure, cognitive strategies have been developed to reduce the risk of this. In this study we hypothesized that analytic information processing would improve diagnostic performance compared to automatic processing (or pattern recognition) alone. We also predicted that scheme-inductive reasoning, by virtue of superior organization and efficiency, would be a more effective analytic processing strategy than hypothetico-deductive reasoning. Our participants were physicians at 2 academic centres: the University of Calgary and Glasgow University, and we randomly allocated them to receive one of two booklets containing ten identical challenging nephrology cases that differed only in the reasoning instructions given for each case. Participants were given an initial case vignette without imaging or laboratory investigations, and were asked to provide an initial diagnosis. They were subsequently directed to use either scheme-inductive reasoning or hypothetico-deductive reasoning to generate differential diagnoses. Finally, they were given additional information and then asked to decide upon their final diagnosis. Nine practicing nephrologists and six nephrology fellows completed the cases. We found that when participants used any form of analytic information processing their diagnostic success improved significantly – from 34.7% to 67.3% (p<0.0001). There was no difference between the nephrology staff and fellows in diagnostic success and there was no difference between the two centres. There was also no difference in diagnostic performance between using scheme-inductive reasoning and hypothetical-deductive reasoning. In conclusion, analytic information processing, irrespective of the type of processing, improves diagnostic performance in Nephrologists.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO825**

**Life after Renal Fellowship Survey** Deepti D. Torri, Kellie R. Calderon, Hitesh H. Shah, Kenar D. Jhaveri. *Nephrology, North Shore/LIJ Health System & Hofstra Medical School, NY.*

**Introduction:** The outlook for nephrology jobs has been one of the weakest in the past 25 years. If one looks at the NEJM classified advertising pages, you notice a 50% decrease in nephrology positions across the health care market. In order to assess how the graduating renal fellows are doing this year we conducted a simple survey which consisted of 9 questions. The survey was created online using survey monkey website. The link was placed in popular nephrology fellow blogging sites. The survey was anonymous.

**Methods:** The fellows were asked about their region of training in the US; if they were a US citizen or green card holder; if they are an American based medical university graduate, what their dream job is; do they have a job position secured for July 2010; if yes, what type of job; and finally if they enjoyed doing nephrology.

**Results:** 30% of the graduating renal fellows responded to our survey. 34.5% of the graduating fellows did not have job yet and 8.8% of the fellows are doing extra training in nephrology to buy time to look for job of interest. When the question was asked regarding "dream job", only 3.4% chose to be hospitalist but in fact 13% of them will be hospitalist after completing the training. 18.6% of the fellows said that "They were not glad that they chose nephrology as a career". There are several factors this year that are playing a role in decrease job opportunities for graduating nephrology fellows like economical recession, housing market collapse and passing of health care reform.

In summary, even though nephrology positions are out there, this year and probably for the next year to come, there is a high possibility that one may not find pure Nephrology jobs and many will have to take other options such as hospitalists and internal medicine. There is also high possibility that one may not find the location of practice where they primarily desire. As a profession, we have to better promote our field and not have close to 20% of fellows feel that they made a wrong decision.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO826**

**Educational Tools in Nephrology: Creative Writing** Kellie R. Calderon, Rajiv S. Vij, Kenar D. Jhaveri. *Nephrology, North Shore/LIJ & Hofstra Medical School, NY.*

**Purpose:** To enhance traditional renal medical education with creative writing exercises.

**Introduction:** American medical students have traditionally matriculated through a four-year medical education system with a clear distinction between the basic science and clinical years that has seen little change since the Flexner report of 1910. Medical students and residents are often overwhelmed and find little time for reading as they enter the latter portion of their training. As an adjunctive effort, our institution has been experimenting with creative writing exercises to encourage reading in an entertaining way.

**Methods:** Twenty-eight medical residents completed a 5 question pre-test on tubulo-glomerular feedback. They were then randomly assigned to one of two groups of 14 house-staff each to receive either a basic review article on the renin-angiotensin system or a fictional short story that described the same system from the point of view of the renin enzyme entitled "The Call of Renin." The next day, the same five questions were administered to the house-staff. Eleven house-staff in each group completed the post-test. Statistical Analysis was done using GraphPad statistical software.

**Results:** There was no statistical difference in the pre test scores between the two groups (p=0.69). There was a statistically significant difference between pre and post creative reading scores with p value of 0.027 and t 2.38. Also there was a statistically significant difference between pre and post basic review article scores with p value of 0.019 with t 2.58. There was no difference between the post test scores of both groups (p= 0.71). Of the house-staff who received the creative writing exercise, 82% (9 of 11) reported reading any amount of the material, compared to only 45% (5 of 11) of house-staff who received the basic review article ( p=0.09, Fischer Exact test). Of the responders who read the creative writing exercise, 78% felt it was a helpful supplemental teaching tool.

**Conclusions:** Our study shows that when used by residents, the two teaching materials had similar effect. The benefit of the creative writing exercise however, was the 37% increase in the number of house-staff who read the material.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO827

**Patient Knowledge Is Associated with Systolic Blood Pressure in Patients with CKD** Julie A. Wright, T. Alp Ikizler, Kerri L. Cavanaugh. *Division of Nephrology and Hypertension, Vanderbilt University Medical Center, Nashville, TN.*

Data are scarce concerning disease specific knowledge and outcomes in patients with chronic kidney disease (CKD). We examined associations between patient hypertension knowledge and blood pressure measurements.

Established adult patients with non-dialysis dependent CKD (Stages 1-5), seen at least once previously in Nephrology Clinic, were enrolled from April to October 2009. Patients self reported hypertension (HTN). Knowledge questions included "Can high blood pressure hurt the kidney (Yes/No)?", and target blood pressure goal, "On average, your blood pressure should be (160/90, 150/100, 170/80, Lower than 130/80)?" with "lower than 130/80" considered correct. Blood pressure measurements (mmHg) were performed by trained personnel using automated sphygmomanometers. Awareness of CKD diagnosis was also assessed.

Of 401 participants, 86% reported having HTN. The mean (SD) age was 58 (16) years, 55% were male, 82% were Caucasian, and 79% had CKD Stage 3-5. Twenty-nine percent were aware of CKD diagnosis, 97% knew hypertension may harm the kidney, and 91% identified the correct blood pressure goal. The systolic blood pressure (SBP) range was 75 - 217 mmHg, with a mean (SD) of 136 (22) mmHg. Higher SBP was associated with older age (rho = 0.20, p<0.01), male sex [male, mean (SD) 138 (22) vs. female 133 (23) mmHg; p=0.04], not knowing HTN can hurt the kidney [No 152 (29) vs. Yes 136 (22) mmHg; p=0.03], lack of knowledge of blood pressure target [Incorrect 145 (25) vs. Correct 135 (22) mmHg; p=0.02], and lack of awareness of CKD diagnosis [Unaware 140 (23) vs. Aware 134 (22) mmHg; p=0.04]. A model adjusted for age, sex, race, income, stage of CKD, HTN knowledge, number of physician visits, and awareness of CKD diagnosis, revealed that only age (β = 0.30, p<0.01) and knowledge of blood pressure goal (β = -10.6, p=0.02) were independently associated with SBP.

Patients with established CKD, who report more hypertension-specific knowledge, had lower systolic blood pressures. Efforts to increase patients' knowledge, particularly about blood pressure goals, may have an important role in optimizing hypertension management in patients with CKD.

**Assessing Blood Pressure Control in Diabetic Patients in an Internal Medicine Residency Continuity Clinic** Michael Grant Selby,[1] Jason Post,[1] Suzanne Norby.[2] *[1]Internal Medicine, Mayo Clinic, Rochester, MN; [2]Nephrology & Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** Optimal BP control in diabetics can slow the progression of diabetic nephropathy, and the State of MN has established BP <130/80 as a reportable quality measure in diabetics. To fulfill our program's requirement that each internal medicine (IM) resident participate in a quality improvement project, BP control rates for diabetic patients in an IM resident continuity clinic (CC) were measured in order to design a subsequent intervention to improve BP control rates. **Methods:** The number of diabetics with hypertension (HTN) assigned to 23 resident patient panels in this CC was determined by reviewing an electronically generated list of assigned patients. Medical records of 184 diabetics were audited, and patients were classified as having controlled, uncontrolled, and/or unidentified HTN based on most recent clinic BP measurement. Also, visit notes were reviewed to ascertain whether uncontrolled HTN had been addressed in the care plan. Next, each resident was provided with feedback on HTN control rates in diabetics in the form of a bar graph illustrating individual and anonymous aggregate data, allowing comparison of his/her own patients' control rate with those of other residents. **Results:** Overall, 32% (range 9.1-80%) of diabetic patients assigned to IM resident patient panels had uncontrolled HTN, and 5.4% (range 0-40%) had unidentified HTN. Of those with uncontrolled HTN, only 10% (range 0-100%) had HTN addressed in care plans. Although each patient was assigned to an IM resident panel, 22% (0-75%) had not been seen by the primary resident. **Conclusion:** Most residents identify uncontrolled HTN in diabetics but do not document a HTN treatment plan. Opportunities exist to improve HTN control in diabetics in this IM resident CC practice overall. The ability to determine HTN control rates for individual IM residents based on patient panel assignments could be limited since patients may not have been seen by the primary resident. Another audit of these parameters could be completed in the future to determine if HTN control rates in diabetics improve in this IM resident CC practice following performance feedback.

## TH-PO829

**Efficacy of Clinical Audit To Improve Blood Pressure Control in Hemodialysis Patients** Pasquale Esposito,[1] Attilio Di Benedetto,[3] Carmine Tinelli,[2] Daniele Marcelli,[4] Antonio Dal Canton.[1] *[1]Nephrology, Dialysis and Transplantation Unit, Fondazione IRCCS Policlinico "San Matteo", Pavia, Italy; [2]Unit of Biometry and Clinical Epidemiology, Fondazione IRCCS Policlinico "San Matteo"; [3]NephroCare Medical Direction Italia, Italy; [4]NephroCare Coordination EMEA- LA, Germany, Germany.*

Introduction

High prevalence of hypertension in hemodialysis patients(HD)is related to cardiovascular disease risk.Various therapeutic approaches have been proposed to ameliorate blood pressure(BP)in HD patients.We evaluated the effects of a clinical audit in BP management.

Patients and methods

We studied 71 patients undergoing on-line HDF from NephroCare Clinics.For each patient we recorded,on an individual chart,predialysis BP,demographic factors,comorbidities,dry weight,interdialytic weight gain,drug therapy,patient compliance,hematocrit and epoetin therapy.Moreover,we also considered KT/V and dialysate conductance and temperature. These data were collected from the last 6 HD sessions performed before the audit notification(PRE) at the audit(AUDIT) and 1(POST 1) and 6(POST 6) months after the audit. We assumed a value of ≤ 140/90 mmHg as BP target.On the basis of BP value we suggested individual strategies to improve BP management,such as reduction of dry weight,increase of dialysis dose and/or changes in antihypertensive treatments.

Results

There was a significant improvement of BP control after the audit, associated to a reduced interdialytic weight gain in presence of a concomitant reduction of the use of antihypertensive drugs.No significant differences in dialytic parameters were found.

Table 1

| | PRE | AUDIT | POST 1 | POST 6 |
|---|---|---|---|---|
| Systolic BP>140 mmHg(pts %) | 39.4 | 43.7 | 31.2 | 25.4 * |
| Dry weight(kg) | 65.6±12.2 | 66.5± 12.2 | 65.6 ± 12.8 | 65.4 ± 13.3 |
| Interdialytic weight gain>5% dry weight(pts %) | 16.4 | 13.0 | 12.5 | 8.7 * |
| Pts on antihypertensive treatment(%) | 52.24 | 57.14 | 48.48 | 45.61 |

* p<0,05vsPRE

Conclusions

Clinical audits are a part of the quality improvement process.Through the comparison between clinical outcome and established standards, they lead to implement changes in clinical practice.Our study shows the efficacy of a clinical audit to promote improvements in BP management in HD patients.

## TH-PO830

**Survey of Statistical Methods Used in the Clinical Nephrology Literature for Teaching Purposes** Eleanor D. Lederer,[1,2] Snehal S. Patel,[2] Ryan L. Haulk,[2] Michael Brier.[1,2] *[1]Medicine, Robley Rex VA Medical Center, Louisville, KY; [2]Medicine, University of Louisville, Louisville, KY.*

In order to evaluate the published clinical literature, post graduate trainees should receive training in statistical methods; however, this endeavor is not adequately documented. To test the hypothesis that instruction in interpretation of clinical literature is not adequate in nephrology training programs, we surveyed nephrology training programs on statistics education and tabulated statistical methods in the 2008 issues of the Journal of the American Association of Nephrology (JASN), Clinical JASN, Kidney International (KI) and the American Journal of Kidney Disease (AJKD). We found the following number of articles: JASN, 211; CJASN, 156; KI, 86; AJKD, 149. The tests with the highest frequencies were: crosstabulation 35.8%, t-test 32.3%, nonparametric t-test 26.2%, survival analysis 17.6%, nonparametric related tests 15.1%, paired t-test 10.5%, logistic regression 13.6%, anova 12.8%, correlation analysis 7.6%, linear regression 6.1%, and nonlinear regression 5.2%. All other methods were less than 2% (multivariate anova, anova with repeated measures, generalized linear regression, ROC). Certain tests were more prevalent in specific journals. Chi-square & survival analysis (CJASN, AJKD), anova (JASN), correlation & linear regression (AJKD) and logistic regression (KI, AJKD) (p<0.001). The survey results from 69 Training Program Directors indicated that statistics are primarily taught through informal discussion (78.3%) by someone experienced in statistical methods (78.8%). However, fellows are not formally tested (91.3%) and most directors were only somewhat confident in the fellows ability to assess the clinical literature (65.2%). We conclude that fellowship programs would benefit from development of a standardized curriculum to teach and evaluate trainees in critical literature analysis, including the statistical methods employed. The significant journal dependent differences in use of applied statistical techniques suggest that fellows should read and critique manuscripts from multiple journals in order to attain competency in a variety of statistical methods.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO831**

**Patient Educational Programme (PEP) in Subjects with Unplanned Haemodialysis Treatment May Increase the Number of Home Dialysis Therapies** Edyta Golembiewska,[1] Joanna Kabat-Koperska,[1] Kazimierz Ciechanowski,[1] Ewa Suchowierska,[2] Michal Mysliwiec,[2] Jozef Penar,[3] Marian Klinger,[3] Jacek Lange,[4] Danuta Deckert.[4] *[1]Nephrology, Transplantology, Medical Univ., Szczecin, Poland; [2]Nephrology and Transplantology with Dialysis Unit, Medical Univ., Bialystok, Poland; [3]Nephrology and Transplantation, Univ. of Medicine, Wroclaw, Poland; [4]Baxter HealthCare.*

Purpose: Approximately 50%of patients with end-stage renal disease (ESRD) start renal replacement therapy (RRT) as an acute,life-saving treatment.Unplanned start of dialysis treatment using temporary access is associated with increased morbidity, mortality and number of hospitalizations.In some centers, after routine implementation of haemodialysis treatment,the method of peritoneal dialysis can be introduced to patients.The purpose of the study was to assess how many patients (%) would choose peritoneal dialysis as a method of chronic treatment.

Results:Median age of the patients was 64.5 years (range 21 to 80 years. There were 11 females and 9 males. The causes of ESRD were as follows: diabetes (8patients), hypertension (5 patients), glomerulonephritis (3patients),other (5 patients). 11 patients started haemodialysis without prior nephrological care. In 6 patients nephrological care lasted below 6 months, in remaining three lasted from 1 to 10 years. Median (range) values of chosen parameters in patients were as follows: urea 190 mg/dL (82-449), albumin 33 g/L (18-40), calcium 8.3 mg/dL (5.9-10.1),phosphorus 5.6 mg/dL (4.3-11.7),CRP 16.35 mg/L (2.0-54.3).

Median eGFR was 10.2 mL/min (range 3.2-25).

No haemodialysis complications were observed. 6 of 20 patients (30%)chose peritoneal dialysis as the mode of chronic RRT.In one patient, dysfunction of Tenckhoff catheter required catheter replacement.No other complications of PD have been observed.

Conclusions:Patient Educational Programme implemented in subjects starting unplanned haemodialysis therapy can increase the number of patients choosing peritoneal dialysis therapy.This can bring potential benefit especially to patients with residual diuresis or awaiting kidney transplantation.Home therapy may also better meet patient's expectations as to quality of life.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO832**

**Prevalence and Utility of "Fellows' Survival Guides" in Post-Graduate Nephrology Training Programs** Alejandro Diez. *Division of Nephrology, Indiana University, Indianapolis, IN.*

Purpose:

Informal discussions amongst nephrology fellows training in the United States reveal that many programs have locally developed versions of a "Nephrology Fellows' Survival Guide". In general, these "fellow survival guides" are compilations of practical tidbits of information, brief "how-to" instructions, and succinct clinical protocols which can be accessed easily and quickly by a trainee in the course of daily practice. Even though many nephrology fellows attest to the value of these guides, no formal data exists as to their prevalence and perceived utility.

Methods:

A web-based survey was designed and implemented on "Survey Monkey", a commercial web-based survey platform. Questions were designed to determine the prevalence, content and perceived utility of these guides. Invitations to complete the survey were e-mailed to nephrology training program directors in the United States via the American Society of Nephrology (ASN) "listserv". Results were collected using 'Survey Monkey's" proprietary software and downloaded to a Microsoft Excel file for further analysis.

Results:

Responses were received from 34 nephrology training programs (approximately 25% of all programs). 55% of the respondents had a locally compiled guide/manual distributed specifically to nephrology trainees. The most common focus of these manuals was administrative (ACGME rules, division policies, fellow responsibilities, etc.) followed by clinical (protocols and guidelines for renal replacement therapy, transplantation, diagnosis and treatment, etc.). Over 75% of respondents rated their guides as "useful" or "very useful", having a positive impact on trainee education (79%) and efficiency (71%).

Conclusions:

While common, "Fellows' Survival Guides" are not ubiquitous. Because these guides have evolved according to institution-specific needs and experiences there is great variability in focus and content. Most programs with these guides recognize their utility and positive impact when used as an adjuvant tool in post-graduate nephrology training.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO833**

**Nephrology as a Source for Ethical Teaching in Medicine. Lessons from Dialysis and Transplantation** Giorgina B. Piccoli, Valentina Consiglio, Rossella Attini. *SS Nephrology, ASOU San Luigi, Torino, Italy.*

**Background.** The history of dialysis is deeply rooted in the history of bioethics; the possibility to live with the help of a machine the initial problem of the limited resources for "artificial kidney" allocation (the Seattle Committee) obliged not only the medical community, but also the laymen to face ethical problems never previously foreseen. Organ shortage for transplantation poses again similar open questions.

**Aim.** Teaching ethical problems in the context of the Nephrology courses may both enhance student interest on our discipline and offer a wide range of practical examples.

**Methods**. In the context of the Medical School (75-100 students/year), ethical problems were posed, via semistructured questionnaires, on different occasions between the 1st and the 4th year.

**Results**. Over 300 questionnaires were gathered in the last 4 years. Three main questions were analysed: would you start dialysis in a patient with a life expectancy not exceeding 6 months; organ shortage for transplantation obliges to choose between choosing younger and fit patients versus high risk patients; a dialysis patient asks on the possibility to buy a kidney abroad. What would you answer?

In the first case, answers were almost evenly divided into not starting dialysis, starting it and uncertain. A similar patter was observed as for choosing younger or sicker patients for transplantation and uncertain. The majority of the students (54%) would allow buying a kidney graft in a foreign Country provided that this is not forbidden by the local laws. Once again, the prevalence of uncertain answers was high (28-32% in the different years). The questionnaire was rated as interesting by over 90% of the students, each year.

**In conclusion,** Nephrology offers a wide range of suggestions for the ethical discussion that should be included in the conventional, often strictly technical, Academic teaching.

**TH-PO834**

**Clinical Impact of Educational Interventions on the Recognition and Treatment of Chronic Kidney Disease in a General Medicine Clinic** Margaret MacDougall, Sriram Narsipur. *Medicine, SUNY Upstate Medical University, Syracuse, NY.*

Under-recognition of chronic kidney disease (CKD) remains a problem in a general medicine population despite attempts at education. We attempted to better define the magnitude of the problem by reviewing charts of patients seen in the Internal Medicine Clinic for primary care to assess recognition and treatment of CKD, Stage 3 or more. At least 30 charts were reviewed in 2005, 2007 and 2010. Patients were excluded if they were co-managed by Nephrology, did not have follow-up visits within the time frames assessed, or were seen by their primary care physician less than 3 times. Data collection included the recognition of CKD, monitoring of phosphorus, intact parathyroid hormone (PTH), and iron studies.

The 2005 chart review indicated that 17% of included patients were properly identified as CKD, Stage 3 or 4. Only 20% of patients had a serum phosphorus and 10% had a PTH checked and 27% had iron studies. Data and results were reviewed with the Internal Medicine Residents and a flow chart of the KDOQI recommendations for metabolic bone monitoring was developed and provided to care-givers. Wall charts were also posted in general medicine clinics for quick reference.

In the 2007 chart audit, the identification of CKD increased to 19% and 58% now had a phosphorus checked but PTH was checked in only 9%. Iron studies were done in 35%. Following the 2007 audit, a focused CKD lecture was given to the housestaff and an audio/slide tape presentation was prepared for review. Wall charts remained visible but individual distribution of the flow chart did not occur yearly.

In the 2010 chart audit, recognition of CKD decreased to 17%. Only 13% of patients had a phosphorus checked and only 7% had a PTH checked. Iron studies increased to 50% of patients.

We conclude that, despite aggressive education and re-enforcement efforts with the internal medicine housestaff, it is apparent that major issues related to CKD are not being recognized and addressed in a general medicine clinic. In an environment with an ever-increasing CKD population, it is clear that attempts to improve recognition and management must improve and novel strategies need to be developed.

**TH-PO835**

**Assessing Patients' Knowledge on Chronic Kidney Disease and Interest in Renal Pharmacy Services** Priscilla P. How,[1,2] Junice Yi Siu Ng,[1] Srinivas Subramanian,[2] Vathsala Anantharaman.[2] *[1]Pharmacy, National University of Singapore, Singapore, Singapore; [2]Medicine (Nephrology), National University Health System, Singapore, Singapore.*

Chronic Kidney Disease (CKD) patients have multiple medical problems and complications. As a result, they may have inadequate knowledge of their disease, be prescribed with several medications and are at increased risk for drug-related problems. Pharmacist-run clinics have been shown to reduce healthcare costs and improve outcomes. However, pharmacist-provided services are not common in outpatient CKD clinics in Singapore. This study was conducted to assess CKD patients' knowledge of their disease and their interest in services provided by a renal pharmacist.

This cross-sectional survey study was conducted in an outpatient CKD clinic in a tertiary hospital in Singapore. Patients ≥21 years old with stage 1-5 CKD were included. Information on patient demographics, patients understanding of CKD and their medications, as well as interest in using renal pharmacy services were collected. These services include collaborative management of CKD and its complications with nephrologists, laboratory monitoring, renal dosing of medications, medication review, education and counseling.

Of the 155 patients interviewed, 61(39.4%) and 19(12.7%) knew the cause and stage of their CKD, respectively, and 74(47.7%) think CKD can be cured. A total of 101(65.2%) patients expressed interest in renal pharmacy services. Most (>90%) patients were aware of the indications and dosing instructions of their medications. However, 114(74.5%) patients did not know their side effects and many (23-56%) had wrong perceptions of their

medications e.g. branded medications are better than generics; development of immunity, tolerance and dependence on their medications; and doubling medication dosage if they missed a dose.

Our patients showed suboptimal understanding of CKD and their medications. Majority were interested in renal pharmacy services. More effort is needed to educate patients of their disease and medications. Pharmacists can play an important role in CKD education, treatment monitoring, as well as medication review and counseling, to improve care and outcomes of these patients.

### TH-PO836

**The Impact of Structured Group Education on Blood Pressure (BP) Control in People with Early Kidney Disease: An Exploratory Randomised Controlled Trial (RCT)** Susan Carr,[1] Jo Byrne,[1] Margaret A. Stone,[2] Azhar Farooqi,[3] Kamlesh Khunti.[2] *[1]Department of Nephrology, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [2]Department of Health Sciences, University of Leicester, Leicester, United Kingdom; [3]East Leicester Medical Practice, Leicester, United Kingdom.*

**Objective:** We conducted an exploratory RCT to assess feasibilty and evaluate the implementation of structured group education to improve BP control in people with early kidney disease.

**Methods:** Patients with sustained hypertension were recruited from nephrology clinics and randomly assigned to either:

- A control group (n=41) that received routine clinical management of hypertension.
- An intervention group (n=40) that received routine care plus structured group education involving facilitated discussion with support to engage and empower patients to improve concordance with treatment and advice.

The primary outcome measure was the proportion of participants in each group achieving recommended BP targets at 12 months. Other outcomes included other cardiovascular risk factors, self-efficacy levels, knowledge of cardiovascular risks, well-being and patient satisfaction with intervention.

**Results:** The intervention was positively received with 100% of participants rating it as enjoyable. However, analysis revealed no significant differences for the other outcomes. The findings of the study showed difficulties with recruitment (only 30% of all patients approached for inclusion) and retention of participants in the intervention group (only 37.5% attended a planned educational session). Lack of interest (44%) and time (48%) were the main reasons cited for not participating. Non-attendance in the intervention group was significantly more likely in older participants (p=0.039) and in those with lower levels of self-efficacy (p=0.034).

**Conclusion:** Although the intervention was well received, the findings suggest that delivering and evaluating an effective group education intervention to improve BP control is difficult to achieve. People are initially reluctant to be involved and do not perceive education as an essential part of their care. Novel ways of delivering education that appeal to patients are required.

### TH-PO837

**Innovative Teaching Tools in Nephrology** Rajiv S. Vij, Kellie R. Calderon, Kenar D. Jhaveri. *Nephrology, North Shore LIJ, Hofstra Medical School & the Raggio Institute, Great Neck, NY.*

**Purpose:** To create innovative teaching tools in Nephrology.

**Introduction:**Teaching any subject with vast spectrum of knowledge is a difficult task. At our institution, we developed many innovative ways of delivering the knowledge of nephrology and allowing it to be a creative and fun experience.

**Methods:**We have developed following tools that are unique and useful in delivering the same message that a traditional lecture would give.

1. Nephrology Crosswords. These are designed by a fellow and faculty member keeping a specific topic of nephrology in mind (peritoneal dialysis, natremias). Active learning is seen and fellows are searching for answers to the clues and trying to solve the puzzle. It provides a nice review of the topic for them that can supplement the traditional lecture format.

2. Role Playing: Fellow and resident driven teaching tool. For example, each participant plays the role of an assigned immunosuppresive agent, with a brief introduction followed by discussion and debates ( staying, of course, in character). This tool is extrapolated further to involve disease states, devices and techniques depending on the topic of discussion.

3. Nephrology Blogs : We have created a blog nephronpower.com in 2009 with goal to further medical education by publishing interesting nephrology cases, journal clubs, quizzes and current news in Nephrology. Contributors to the blog include fellows, academic and private nephrologists from USA and around the world. Nephron Power gets around 60 site visits per day with average 106 page views per day from all over the world.

**Results**:We also conducted an online survey comparing the current traditional teaching methods with above mentioned innovative teaching tools. Survey was open to all students, residents, fellows, nephrologists and other physicians. More than 80% of the people said that incorporating these innovative teaching tools will increase the interest and increase recruitment to the field of Nephrology. Only 50% thought that the current teaching methods were adequate.

**Conclusions:** In addition to traditional teaching methods, there is a clear need and role of creative teaching tools in nephrology.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO838

**Development and Usability Evaluation of a Web-Based Simulation for Teaching Electrolyte and Acid-Base Disorders** Mogamat Razeen Davids,[1] Usuf M. E. Chikte,[3] Mitchell L. Halperin.[2] *[1]Stellenbosch University, Cape Town, South Africa; [2]St Michael's Hospital and University of Toronto, Toronto, ON, Canada; [3]Stellenbosch University, Cape Town, South Africa.*

**Introduction**

We developed a Flash® application to help students learn about electrolyte and acid-base disorders. The subject presents a heavy intrinsic cognitive load, and reducing extraneous load by improving interface design could lead to gains in learning efficiency. This study reports on the development and usability evaluation of our application.

**Methods**

Flash® was used to develop the simulation, with ActionScript™ controlling it by calculating the effects of user-selected therapies on parameters like plasma Na concentration and brain volume, then displaying appropriate messages and animations based on the results of the treatment.

User testing: Morae® software recorded the interaction of participants with the application. Participants also completed a questionnaire including the System Usability Scale (SUS). Usability inspection: Experts conducted a heuristic evaluation (HE). Problems were cataloged and categorized, and their detection by different methods compared.

**Results**

Questionnaire: SUS score was 78.4 ± 13.8. Participants rated the content as scientifically sound (15/16), liked the "clinical detective story" approach (14/16), and would recommend the application to others (15/16).

Morae: Major problems included a "hidden" Lab Data panel. The treatment simulation was completed easily by only 3/15 participants. Most unsuccessfully tried to apply multiple treatments, and had problems using a slider control, resulting in dosages of zero.

Heuristic evaluation detected 22 errors.

The slider control problem was not detected by HE or questionnaire. Most problems with case accuracy were detected via questionnaire and Morae, and problems related to user feedback by HE.

**Conclusion**

We have created an engaging e-learning resource to help students develop expertise in this area. The usability evaluation will guide improvements. Combining evaluation methods ensures that most serious usability problems will be addressed, to maximize the potential for effective learning.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO839

**Do Medical Trainees Receive Adequate Training in the Management of Acute Kidney Injury?** Mansoor N. Ali, Andrew J. P. Lewington. *Renal Medicine, Leeds Teaching Hospitals NHS Trust, Leeds, Yorkshire, United Kingdom.*

**Background:** The recent National Confidential Enquiry into Patient Outcome and Death (NCEPOD) adding insult to injury acute kidney injury (AKI) study identified that only 50% of patients with AKI received good care. One of the issues raised surrounded a lack of medical training on the management of AKI.

**Aim:** To better understand whether medical trainees perceive that they receive adequate training in the management of AKI.

**Method**: A simple questionnaire was used to explore medical trainees understanding of the management of AKI. They completed the questionnaire prior to receiving a lecture on the management of AKI. The questionnaire was completed by 8 final year medical students, 22 interns and 22 residents in a large UK teaching hospital.

**Results:**

Only 6 of the trainees correctly cited the RIFLE/AKIN definition for AKI. The remaining trainees either gave no definition (24) or came up with their own unique definitions (22).

All trainees had managed patients with AKI; most of whom were cared for in the acute admissions wards.

Only 1 trainee felt confident enough to manage AKI, the remaining felt unconfident and were uncertain as to when to refer patients to nephrology.

Medical trainees indicated that there were deficiencies in training at both undergraduate and postgraduate levels in basic skills such as volume assessment and intravenous fluid management.

**Conclusion:** As a result of the questionnaire teaching programmes on the management of AKI are being developed for undergraduate and postgraduate trainees. The first UK wide e-learning module funded by the government will concentrate on AKI.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO840**

**Does Excessive Intake of Sodium Contributes to the Interdialytic Weight Gain?** Bárbara Margareth Menardi Biavo,[1] Clarissa B. B. Uezima,[2] Camila Machado de Barros,[1] Elzo R. Junior,[1] Elvino Barros,[3] João Paulo L. B. Martins,[2] Carmen B. Tzanno-Martins.[2] *[1]Home Dialysis Center, São Paulo, São Paulo, Brazil; [2]Integrated Center of Nephrology, Guarulhos, São Paulo, Brazil; [3]Federal University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil.*

**OBJECTIVE**

The aim of this study was to assess interdialytic weight gain and sodium intake of patients undergoing hemodialysis in a private clinic in São Paulo.

**METHODS**

Cross-sectional study with 97 patients [39 (40.2%) women and 58 (59.8%) males] undergoing chronic hemodialysis. We evaluated the clinical data (kt/V), measured pre-dialysis weight, post-dialysis weight (dry weight) and height in order to calculate interdialytic weight gain and BMI (body mass index) classified according to WHO-1998. In order to assess dietary intakes of sodium, we used three 24-hour recalls, two related to food on days when patients weren't undergoing hemodialysis and another on the day of hemodialysis.

**RESULTS**

Among the 97 study participants, 16 (15.5%) had weight gain above the recommended (> 5% dry weight).

As for sodium intake, comparing the groups that gained less than 5% and more than 5% of dry weight between dialyses, both showed an average sodium consumption of 3000.1 mg and 2975.31 mg respectively, values higher than recommended. Recommended values range from 1000 to 2300 mg per day, according to blood pressure, edema and interdialytic weight gain.

There was no difference in sodium intake in relation to nutritional status. Both eutrophic and overweight patients had similar sodium intake. Kt/V of both groups had similar values (1.18±0.20 - group with adequate weight gain; and 1.20±0.21 - group with weight gain above recommended).

**CONCLUSION**

Sodium consumption was above recommended levels, which did not influence the interdialytic weight gain in the studied population, since most of it had weight gain within normal limits. Still, it is of utmost importance to focus on following a low sodium diet, since sodium excess can aggravate hypertension, a condition present in most of our patients, if not the cause of their CKD.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO841**

**Pre-Emptive Live Donor Kidney Transplants Have Increased by Improving Access to Information** Wendy Brown, Jen C. McDermott, Marina Loucaidou, Tom Cairns. *Imperial College Kidney & Transplant Institute, London, United Kingdom.*

Transplantation is considered the optimum treatment of choice for patients with end stage renal disease. Pre-emptive living donor transplantation is increasing and has benefits over those transplanted post dialysis. However, despite written information; invitations to seminars; discussions with the medical team, coordinators and nurses, living donor transplant rates were static.

Aim: To improve access to information to enable people to make an informed decision regarding living donor transplantation.

Methods: Feedback from patients was reviewed and the structure and content of the information seminars was changed. The seminars became more frequent and less process focused. More patient volunteers and staff were enlisted and seminars now run on Saturdays. The agenda includes factual information e.g. long-term outcome results for donors and recipients by medical experts. Structured small group sessions were introduced where transplant and donor volunteers share their experience with the patients and potential donor group.

Outcome: These changes resulted in a massive increase in attendance at the seminars from 85 attendees in 2007 to 392 attendees in 2009. The proportion of pre-emptive living donor transplants carried out has also significantly increased from 21/81 (25%) in 2006 to 35/79 (44%) in 2009 (p=0.020). The 2 monthly information seminars in 2009 generated 72 self referrals to commence transplant work up.

Conclusion: Attention to the written and verbal feedback from patients has resulted in a programme that is more appropriate, meaningful and now meets patients' needs; Saturday seminars have captured a working audience and the participation by many transplant and donor volunteers has provided valid reassurance and honest explanations of the process. This has resulted in better information and experience for patients; *"thank you for making it easier to understand and therefore [allowing me] to make the right decision"*, and an increase in pre-emptive living donor transplant rates.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO842**

**The Impact of Reporting Estimated Glomerular Filtration Rate** Abdallah Sassine Geara, Nadine Azzi, Pratima Ghimire, Marie Abdallah, Claude Bassil, Ayesha S. Siddiqui, Suzanne E. El Sayegh. *Nephrology, Staten Island University Hospital, Staten Island, NY.*

**Purpose of study:** Our objective is to determine if reporting eGFR while resulting blood tests was beneficial as far as: Physician awareness for CKD, dosage of antibiotic, avoidance of nephrotoxic medications and hydration for IV contrast.

**Methods:** Our laboratory started reporting calculated eGFR starting November 2005. We reviewed 2400 medical records, 1200 before and 1200 after this date. We excluded all non-medical admissions, patients evaluated by a nephrologist for known CKD, ESRD, AKI or nephrolithiasis. We analysed the subgroup of patients with normal Cr (<1.5mg/dl) and a calculated eGFR < 60 ml/min.

**Results:** Most of our patients were elderly female in both groups. We did not notice any significant increase in the number of patients evaluated by or referred to a nephrologist. The prescription of aminoglycosides and NSAIDs did not change significantly. The dose adjustment for antibiotics was in the same range pre- and post-reporting eGFR. We did not notice significant change in the percentage of hydration prior to IV contrast administration.

table 1

| | Pre-reporting GFR | Post-reporting GFR | p-value |
|---|---|---|---|
| Total number | 475 | 680 | |
| CKD stage 3 and normal Creatinine | 132 (27.79%) | 159 (23.38%) | |
| Mean age | 76.05 | 78.2 | |
| Mean GFR (MDRD) | 48.9 | 49.1 | |
| Patients evaluated | 12 (9.09%) | 16 (10.06%) | 0.9362 |
| Renal consult | 5 (3.79%) | 6 (3.77%) | 0.7642 |
| Renal ultrasound | 6 (4.55%) | 9 (5.66%) | 0.8729 |
| Urinalysis | 12 (9.09%) | 16 (10.06%) | 0.9362 |
| Renal referral | 3 (2.27%) | 4 (2.52%) | 0.8057 |
| NSAIDS (in-hospital) | 5 (3.79%) | 12 (7.55%) | 0.2670 |
| NSAIDS (out-hospital) | 2 (1.52%) | 2 (1.26%) | 0.7520 |
| Aminoglycoside | 2 (1.52%) | 5 (3.14%) | 0.6073 |
| Hydration for Radiocontrasts | 2/6 (33.33%) | 12/21 (57.14%) | 0.5714 |
| Antibiotic adjusted | 8/21 (38.1%) | 19/49 (38.78%) | 0.8305 |

**Conclusions:** Reporting eGFR did not translate into an improvement of medical management for the patients with CKD stage 3 and creatinine within the normal reference range. Our results underlie the need to improve the teaching of medical residents and physicians concerning the limitations of creatinine.

**Searching for Medical Information Online: A Survey of Canadian Nephrologists** Salimah Z. Shariff,[1] Shayna Amrita Devi Bejaimal,[1] Jessica M. Sontrop,[2] Matthew A. Weir,[1] Arthur Iansavichus,[1] Amit X. Garg.[1,2,3] *[1]Department of Medicine, University of Western Ontario, London, ON, Canada; [2]Department of Epidemiology and Biostatistics, University of Western Ontario, London, ON, Canada; [3]Department of Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, ON, Canada.*

**Objectives:** Physicians often search for information to answer questions that arise in patient care. We evaluated how nephrologists use online information sources for this purpose.

**Methods:** From the years 2008 to 2010, we asked a random sample of nephrologists practicing in Canada to complete a survey of their online search practices. We queried respondents on their searching preferences, practices and use of nine online information sources.

**Results:** Respondents (n=115; 75% response rate) comprised both academic (59%) and community-based (41%) nephrologists. The average age of respondents was 48 years having practiced nephrology an average of 15 years. Nephrologists used a variety of online sources for information on patient treatment including UpToDate (92%), PubMed (89%), Google (76%) and Ovid MEDLINE (55%). Community-based nephrologists were more likely to consult UpToDate first (91%), while academic nephrologists were divided between UpToDate (58%) and PubMed (41%). When searching bibliographic resources such as PubMed, 80% of nephrologists scan a maximum of 40 citations (the equivalent of two search pages in PubMed). Searching practices did not differ by age, sex or years of practice.

**Conclusions:** Nephrologists routinely use a variety of online resources to search for information for patient care. These include bibliographic databases, general search engines and specialized medical resources.

**Hydroxyl Radical Production Is Increased in Combind Exposure of Iron and TNF-α in Human Mesothelial Cells** Rie Kitamura, Masayoshi Nanami, Takanori Nagai, Aritoshi Kida, Yoshinaga Otaki, Yukiko Hasuike, Takahiro Kuragano, Hiroshi Nonoguchi, Takeshi Nakanishi. *Hyogo College of Medicine, Internal Medicine, Division of Kidney and Dialysis, Nishinoiya, Japan.*

The development of PMC damage could be the significant cause of encapsulating peritoneal sclerosis in continuous ambulatory peritoneal dialysis patients. We have previously demonstrated that TNF-α caused the misregulation of iron transport proteins and accelerated the oxidative stress in human umbilical endothelial cells.[1)] In the present study

we investigated the expression of iron import proteins (transferrin receptor; TfR and divalent metal transporter 1; DMT1) and iron export protein (ferroportin 1; FP1), and the production of radicals in human mesothelial cell lines (MeT-5A) in the presence of TNF-α.

**Methods:** MeT-5A cells were exposed to TNF-α (10-50 μM) for 24h. M-RNA levels of these iron transport proteins were quantitied using RT-PCR.Western blot analysis was also used for the expression of these proteins. A salicylate trap methods was used for the determination of hydroxyl radical production during iron challenge (transferrtn(TF: 50μM) or ferrous sulfate($FeSO_4$: 50μM)).

**Results:** In MeT-5A, TNF-α significantly increased the expression of mRNA levels of TfR and DMT1, but decreased that of FP1.Western blot analysis showed the similar effect as the result of RT-PCR. Only the exposure of TNF-α and TF or $FeSO_4$ to these cells significantly increased hydroxyl radical production.

**Conclusion:** In MeT-5A cells, TNF-α affect the iron transport proteins, which might contribute to the increase in iron and accelerate the production of hydroxyl radical.

**A Two-Hit Approach in the Development of an Experimental Peritoneal Sclerosis Model** Anniek Vlijm, Denise Sampimon, Raymond T. Krediet. *Medicine, Division of Nephrology, Academic Medical Center, Amsterdam, Netherlands.*

Background Models of encapsulating peritoneal sclerosis (EPS) are often based on local administration of chemical irritants. Our aim was to develop a clinically relevant "two-hit" model with incorporation of renal failure and exposure to conventional dialysis solutions.

Methods Thirty-six male Wistar rats underwent a catheter implantation and a 70% nephrectomy. They were randomly divided into 3 peritoneal infusion groups. The experimental group was exposed to a 3.86% glucose-based conventional dialysis solution for 8 weeks and then received a second hit of intraperitoneal blood administration. Two weeks later the rats were sacrificed. Two control groups were exposed to the conventional dialysis solution alone or to a buffer without glucose for 8 weeks. All animals underwent a peritoneal function test at the end of the experiment. The number of peritoneal adhesions was counted at autopsy, and omental tissue was obtained for morphometrics.

Results The rats that received blood as a second hit had developed numerous intraperitoneal adhesions as seen in EPS, but without cocoon formation. Microscopically no differences were present in fibrosis scores and vessel counts between the three groups. Also peritoneal function parameters were similar in all groups.

Conclusion The short infusion period could be the reason that we did not find differences between the groups, with the exception of a large amount of intraperitoneal adhesions in the experimental group. Modifications of the described rat model are required to develop a clinically relevant EPS model. Besides renal failure and long-term exposure to bioincompatible peritoneal dialysis solutions, a different second hit or several additional hits could be incorporated in an experimental model of EPS.

## TH-PO846

**PI3K/Akt Mediate the Epithelial-Mesenchymal Transition (EMT) of Human Peritoneal Mesothelial Cells (HPMCs) during Peritoneal Dialysis In Vitro and In Vivo** Fu-You Liu,[1] Xiang Peng,[1] Youming Peng,[1] Yinghong Liu,[1] Hong Liu,[1] Yashpal S. Kanwar,[2] Lin Sun,[1] Li Xiao.[1] *[1]Department of Nephrology,The Second XiangYa Hospital, Kidney Institute of Central South University, Changsha, Hunan, China; [2]Departments of Pathology and Medicine, FSM, Northwestern University, Chicago, IL.*

To verify the phosphatidyl inositol 3 kinase(PI3K)/Akt regulate the EMT formation of HPMCs during peritoneal dialysis (PD) in vitro and in vivo. We constructed a mice model of PD with mesothelial cells undergo EMT by intraperitoneally injection of 1.5ml of 4.25% peritoneal dialysis solution per day for 30 days (n=18), and EMT HPMCs cell model with 5ng/ml TGF-beta1 treatment as well. The levels of Akt phosphorylation, total Akt and EMT related protein Zo-1, Vimentin were assessed by real-time PCR, Western blot, cell Immunofluorescence. A obvious up-regulation of Akt phosphorylation was seen, which was positively associated with Morphological changes of EMT and its related gene expression in this model compared to control (0.9% NS intraperitoneally injection per day for 30 days, n=18). A similar result was seen in TGF-beta1 induced HPMCs EMT cell model. However, pre-treatment of LY294002 (PI3K/Akt inhibitor) or domain-negative Akt plasmid, decreased Akt phosphorylation and reversed the EMT of HPMCs induced by TGF-beta. Furthermore, the Smad3, phosphorylated-Smad2/3 and smuf2 expressions were up-regulated significantly after stimulated by TGF-beta1, while, these effects was also dramatically inhibited with pre-treatment of LY294002 or domain-negtive Akt plasmid as detected by Western blot assess and cell confocal image. These data suggested that PI3K/Akt plays a crucial role in EMT transformation of HPMCs during PD, which partially through cross-talk with TGF-beta1/Smad pathway and Smurf2, a SMAD specific E3 ubiquitin protein ligase.

## TH-PO847

**Therapeutic Effects of Factor Xa Inhibitor and Saireito on Rat Peritoneal Fibrosis** Akihisa Sugimoto,[1] Takahiko Ono,[2] Kozue Kato,[1] Tatsuya Morimoto.[1] *[1]Division of Molecular Medicine, University of Shizuoka School of Pharmaceutical Sciences, Shizuoka, Japan; [2]Department of Nephrology, Shimada Municipal Hospital, Shimada, Japan.*

Fibrin deposition and angiogenesis in the peritoneum were frequently observed in peritoneal fibrosis induced with long-term peritoneal dialysis. We previously reported that factor Xa inhibitor fondaparinux ameliorated rat peritoneal fibrosis through regulation of angiogenesis (Perit Dial Int 29: 340-351, 2009). In another study, herbal Kampo prescription saireito ameliorated extracellular matrix accumulation in experimental rat glomerulonephritis, partly through anti-oxidative effect. Therefore, we conducted an experimental study to examine the suppressive effects of combination therapy of a factor Xa inhibitor with saireito in rat peritoneal fibrosis. Vehicle of Wistar rats (n = 8) were intraperitoneally injected with chlorhexidine gluconate (CG) everyday. Treatment groups were the fondaparinux group (subcutaneous administration of 0.025 mg/kg/day fondaparinux everyday, n = 8), saireito group (oral 500 mg/kg/day everyday in drinking water, n = 8), and both combination group (n = 8). Twenty-eight days after the injection, the rats were sacrificed and peritoneal specimens were examined by immunohistochemical analyses. Treatments with fondaparinux alone, saireito alone, and combination of them significantly suppressed the increase in macrophage infiltration by 38% ($p < 0.01$), 59% ($p < 0.05$), and 24% ($p < 0.01$) of vehicle group, respectively. Furthermore, these treatments significantly suppressed the increase in CD31-positive vessels number by 64% ($p < 0.001$), 59% ($p < 0.001$), and 42% ($p < 0.001$) of vehicle group, respectively. Although vascular endothelial growth factor (VEGF) mRNA expression was not sufficiently reduced by fondaparinux alone or saireito alone, the combination therapy suppressed the expression significantly ($p < 0.05$). Accordingly, synergistic effect was observed in the combination therapy. Present data suggest that the factor Xa inhibitor and saireito may induce suppressive effects on peritoneal fibrosis in different manners, respectively. Combination of these treatments may effectively regulate peritoneal fibrosis.

## TH-PO848

**Physiological Levels of Endostatin, a Fragment of Collagen XVIII α1 Chain, Attenuate Peritoneal Sclerosis in Mice** Ryota Shirai,[1] Yuki Tokui,[1] Ryota Kimura,[1] Osamu Yokosuka,[2] Makoto Ogawa,[3] Raghu Kalluri,[4] Yuki Hamano.[3] *[1]Drug Information and Communication, Graduate School of Pharmaceutical Sciences, Chiba University, Chiba, Japan; [2]Medicine and Clinical Oncology, Graduate School of Medicine, Chiba University, Chiba, Japan; [3]Nephrology, Chiba University Hospital, Chiba, Japan; [4]Matrix Biology, Medicine, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA.*

**Objective:** Disruption of angiogenesis balance to favor enhanced angiogenesis represents a key step in a number of pathological disorders. Although an emphasis has been placed on the increase of angiogenesis stimulators on the disruption of the balance, the potential role of the physiological levels of endogenous inhibitors of angiogenesis is poorly understood. Peritoneal sclerosis is a major complication of peritoneal dialysis therapy and the progression is related to enhanced angiogenesis. To address the role of endogenous angiogenesis inhibitors in peritoneal sclerosis, the two independent models were induced in mice deficient in endostatin, an endogenous angiogenesis inhibitor.

**Methods:** Peritoneal sclerosis was induced by intraperitoneal injection of either chlorhexidine gluconate (CG) for 2 weeks or 4.25% glucose peritoneal dialysis fluid (PDF) for 2 months. The development of new blood vessels and fibrosis in parietal peritoneum was compared between endostain-deficient (KO) and wild-type (WT) mice.

**Results:** Upon induction of peritoneal sclerosis in WT mice, endogenous endostatin expression was clearly upregulated within the blood vessels. Intraperitoneal injection of either CG or PDF into KO mice compared with WT mice resulted in significant thickening of the submesothelial area, increase in the number of blood vessels and accumulation of extracellular matrices in the peritoneum. Consistent with these results, the expression of profibrotic TGF-β1 and thrombospondin (TSP)-1, an endogenous activator of latent TGF-β and an endogenous angiogenesis inhibitor, was upregulated in the peritoneum of KO mice compared with WT mice.

**Conclusion:** Physiological levels of endostatin, a fragment of collagen XVIII, can serve as a suppressor of angiogenesis and fibrosis in peritoneal sclerosis.

## TH-PO849

**(-)-Epigallocatechin Gallate Suppresses the Progression of Peritoneal Fibrosis in Methylglyoxal Induced Peritoneal Fibrosis Model in Mice** Mineaki Kitamura,[1] Akira Furusu,[1] Yoko Obata,[1] Tomoya Nishino,[1,2] Yoshitaka Hishikawa,[2] Takehiko Koji,[2] Shigeru Kohno.[1] *[1]Second Department of Internal Medicine, Nagasaki University School of Medicine, Nagasaki, Japan; [2]Department of Histology and Cell Biology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.*

**Introduction** Angiogenesis and inflammation caused by the glucose degradation products (GDPs) play a role in peritoneal fibrosis on peritoneal dialysis (PD). Methylglyoxal (MGO) is one of GDPs and enhances the formation of advanced glycation end products (AGEs). AGEs bind to the receptor for AGEs (RAGE) and activate nuclear factor-kB (NF-kB) which regulates angiogenesis and inflammation. Recent studies indicated

that (-)-Epigallocatechin gallate (EGCG), a tea polyphenol, has an inhibitory effect on angiogenesis and inflammation. However, its effect on peritoneal fibrosis remains unknown. In the present study, we examined whether EGCG suppressed the progression of peritoneal fibrosis of mice.

**Methods** C57/BL6 mice were divided into three groups, MGO, MGO + EGCG, and PD group. PD fluid with or without MGO were injected intraperitoneally and EGCG was injected subcutaneously for 3 weeks. Morphologic peritoneal changes were assessed by Masson-Trichrome staining. The expression of CD31, vascular endothelial cell growth factor (VEGF), monocyte chemotactic protein-1 (MCP-1), F4/80 and RAGE were examined by immunohistochemistry. Southwestern histochemistry was used for the detection of activated NF-kB.

**Results** In MGO group, peritoneal tissues showed marked thickening of the submesothelial zone, and the numbers of VEGF, MCP-1, RAGE expressing cells, F4/80 positive macrophages and CD31 positive vessels were significantly increased compared to PD group. The expression level of NF-kB was increased as well. On the contrary, these changes were significantly suppressed in MGO + EGCG group.

**Discussion** These results suggested that EGCG could attenuate peritoneal fibrosis through the suppression of angiogenesis and inflammation.

**Conclusion** We conclude that EGCG might be one of the candidates for a novel therapeutic agent in preventing peritoneal fibrosis.

## TH-PO850

**The Role of 3,4-dideoxyglucosone-3-ene in Peritoneal Fibrosis** Hideki Yokoi,[1] Masato Kasahara,[1] Kiyoshi Mori,[1] Takashige Kuwabara,[1] Ryo Yamada,[2] Shinji Namoto,[2] Takashi Yamamoto,[2] Nana Seki,[2] Taku Yamaguchi,[2] Nozomi Souma,[2] Akira Sugawara,[1] Masashi Mukoyama,[1] Kazuwa Nakao.[1] *[1]Department of Medicine and Clinical Science, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]JMS Co., Ltd., Hiroshima, Japan.*

Peritoneal dialysis solution contains high concentrations of glucose and glucose degradation products (GDPs). Several GDPs have been identified including glyoxal, methylglyoxal, formaldehyde, 3-deoxyglucosone (3-DG), 3,4-dideoxyglucosone-3-ene (3,4-DGE) and 5-hydroxymethyl furaldehyde (5-HMF). 3,4-DGE is recently identified as the most reactive and toxic GDP in peritoneal dialysis (PD) fluids. 3,4-DGE has been shown to induce mesothelial cell death and lose cell viability *in vitro*. However, the role of 3,4-DGE in peritoneal fibrosis *in vivo* was unclear. In this study, we administered 0.1% chlorhexidine gluconate (CG) three times a week for peritoneal injury in male C57BL/6J mice. Control mice received PBS. After peritoneal injury, 145 μM 3,4-DGE dissolved in PBS was given intraperitoneally five times a week for 4 weeks. Control mice were given PBS without 3,4-DGE. There were four groups; initial PBS and following PBS without 3,4-DGE (PBS+3,4-DGE(-)), initial PBS plus following 3,4-DGE in PBS (PBS+3,4-DGE(+)), initial CG plus PBS without 3,4-DGE(CG+3,4-DGE(-)), and CG plus 3,4-DGE in PBS (CG+3,4-DGE(+)). The thickness of peritoneal membrane was significantly increased in CG+3,4-DGE(+) group. TGF-β1, CTGF, fibronectin, COL1A1, VEGF and α-SMA mRNA expressions were upregulated, suggesting that 3,4-DGE is related to peritoneal fibrosis. NADPH oxidase NOX4 was also increased in CG+3,4-DGE(+) mice. We next identified increased apoptotic cells in submesothelial compact zone. Immunohistochemical study showed that type I collagen, fibronectin and α-SMA staining was increased in CG+3,4-DGE(+) mice and that macrophage infiltration was augmented by the analysis of F4/80 immunostaining. These results indicate that 3,4-DGE can increase peritoneal injury when peritoneal membrane was already damaged, by augmenting macrophage infiltration and extracellular matrix deposition.

Disclosure of Financial Relationships: nothing to disclose

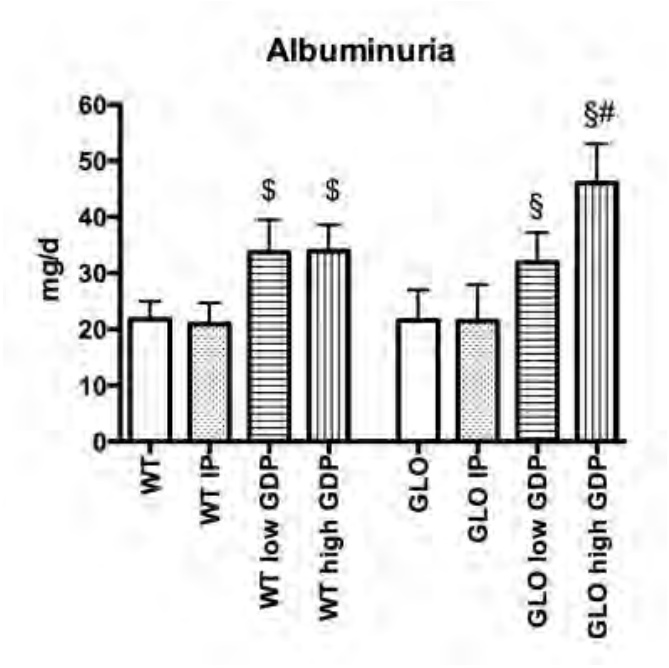
## TH-PO851

**Pronounced Kidney Damage in a Peritoneal Dialysis Model of Glyoxalase I Deficient Mice** Lars Kihm, Sandra Muller-Krebs, Svenja Horlacher, Martin G. Zeier, Vedat Schwenger. *Nephrology, University of Heidelberg, Germany.*

**Background**: Morbidity and mortality of peritoneal dialysis (PD) patients are significantly influenced by residual renal function. Glucose degradation products (GDP) were suggested as contributing factors for deterioration of residual renal function in PD patients. Glyoxalase I plays a critical role in the detoxification of GDP and may be protective in PD.

**Methods:** We compared the effects of peritoneal dialysis fluid (PDF) with different amounts of GDP on morphological changes of the kidney in 48 wild type (WT) and 48 Glyoxalase I -deficient (GLO-) mice. PDF (1 ml) were instilled twice daily over a period of 12 weeks. Groups with 12 animals each received either no manipulation (sham), sham instillation (sham i.p.), and high and low GDP-containing PDF. After 12 weeks albuminuria was measured and kidney damage was quantitated by morphometric analysis and immunohistochemical stainings using an established score was evaluated.

**Results:** After a long-term exposure to GDP-containing PDF Glyoxalase I deficient mice compared to WT mice showed a marked increase of markers of fibrosis (i.e., peritoneal expression of TGFβ1: WT plus high GDP 6.11±0.26 vs. GLO- plus high GDP 7.43±0.40; $p<0.01$) and inflammation (i.e., CD3+ T-cells, IL6 expression). A GDP-dependent increase of renal AGE formation occurred in WT and glyoxalase I deficient mice compared to WT mice when treated with PDF Glyoxalase I deficient mice revealed a significantly increased expression of AGE and the receptor for AGE (i.e. glomerular expression of AGE: WT plus high GDP 3.12±0.35 vs. GLO- plus high GDP 4.53±0.41 $p<0.001$). Albuminuria was highest in Glyoxalase I deficient mice treated with PDF containing high dose GDP.



**Conclusions:** Our findings suggest a pivotal role for Glyoxalase I in GDP associated systemic toxicity in a peritoneal dialysis model in mice.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO852

**MicroRNA Expression Pattern in Human Peritoneal Mesothelial Cells (HPMCs) of CAPD Patients, and Effect of Mir-129-5p and Mir-589 in TGF-beta1 Induced Epithelial-Mesenchymal Transition of HPMCs** Li Xiao,[1] Ke Zhang,[1] Xun Zhou,[1] Lin Sun,[1,2] Guanghui Ling,[1] Youming Peng,[1] Yinghong Liu,[1] Yashpal S. Kanwar,[2] Fu-You Liu.[1] *[1]Department of Nephrology, Second Xiangya Hospital of Central South University, Changsha, China; [2]Department of Pathology and Medicine, Northwestern University Medical School, Chicago.*

We investigated the expression pattern of microRNAs(miRNAs)in human peritoneal mesothelial cells (HPMCs) derived from CAPD patients, and in particular, the role of Mir-129-5p and Mir-589 in the epithelial-mesenchymal transition (EMT) induced by TGF-beta1. Total miRNA was isolated from HPMCs of dialysate effluents of CAPD patients and subjected to miRNA profiling using miRNA array. Compared to baseline (CAPD at 0 day, N=20), expression of 33 microRNA was up-regulated (CAPD at 1 year, N=20); while that of 58 microRNA expression was down-regulated. Similar results were observed in human mesothelial cells treated with TGF- beta1. Among various microRNAs, miR-129-5p and miR-589 expression decreased 2-3 folds as measured by QPCR. The expression of E-cadherin, Claudin1, Vimentin, ZO-1 and FN was assessed by QPCR, Western blot, and Immunofluorescence and Confocal microscopy. Decreased expression of miR-129-5p and mi-R589 correlated with EMT phenotypic changes. The binding of miR-129-5p and miR-589 to 3'UTR regions of transcription factor SIP1 and ets-1 lead to the positive/negative regulation of the genes conducive for the process of EMT. In in vitro experiments, upregulation of SIP1 and ets1 correlated with the expression of EMT related genes in cells treated with TGF-beta1. The expression of these transcription factors was reversed by the pre-treatment of precursor miR-129-5p or mir-589, and this associated with the reversal of EMT. These data suggest that miR-129-5p or mir-589 modulate the EMT partly via post-transcriptional repression of SIP1 and ets1, the latter could serve as novel targets to ameliorate EMT-fibrosis of the peritoneal wall in PD patients.

## TH-PO853

**Target Related Therapy in Encapsulating Peritoneal Sclerosis – Nuclear Receptors and the Role of Tamoxifen** Niko Braun,[1] Peter Fritz,[2] Martin Kimmel,[1] Christoph Ulmer,[4] Dagmar Biegger,[3] Mark Dominik Alscher.[1] *[1]Division of Internal Medicine and Nephrology, Department of Internal Medicine, Robert-Bosch Hospital, Stuttgart, Germany; [2]Division of Pathology, Department of Diagnostic Medicine, Robert-Bosch Hospital, Stuttgart, Germany; [3]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmcology, University of Tubingen, Stuttgart, Germany; [4]Department of Surgery, Robert-Bosch Hospital, Stuttgart, Germany.*

Objective: Encapsulating peritoneal sclerosis (EPS) is a rare but life threatening complication of peritoneal dialysis (PD). The optimal management is not clear. Aim of this study was to look for potential targets for medical therapy. We investigated the expression of progesterone- (PR), androgen- (AR), vitamin D- (VDR) and glucocorticoid-receptor

(GCR) in the human peritoneum. Estrogen-receptor (ER), matrixmetalloproteinase 9 (MMP9) and transforming growth factor-ß1 (TGF-ß1) were investigated in the context of a potential target for therapy with tamoxifen.

Methods: 72 peritoneal biopsies were investigated, including 22 EPS patients, 11 PD patients, 15 uremic patients and 24 controls (hernia repair). Histologic characteristics were investigated and an EPS-score was evaluated. For immunophenotyping we used antibodies raised against VDR, GCR, ER, PR, AR, MMP9 and TGF-ß1.

Results: EPS-score > 6 was highly indicative for the diagnosis EPS. In contrast to ER, PR and AR, VDR and GCR are common in all investigated cells of the peritoneum (98.6% and 87.3%). The distribution of the nuclear receptors is not specific for one group. There is no overexpression of MMP9 and TGF-ß1 in PD or EPS.

Conclusion: We found possible targets in the peritoneum of patients with uremia, EPS or on PD. Glucocorticoids, vitamin D, ACE-inhibitors or ARBs could be suitable therapies. Clinical evidence for the widespread use of tamoxifen is lacking. The mechanism of action is cloudy, receptors in the peritoneum are lacking and data about the discussed pathways (MMP9, TGF-ß) are inconsistent.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO854

**Paricalcitol Induces VDR Expression and Reduces Glucose Profibrotic Effect in Human Mesothelial Cells** Vittoria Esposito, Massimo Torreggiani, Fabrizio Grosjean, Clara Migotto, Giuseppe Sileno, Noemi Maggi, Nicoletta Serpieri, Ciro Esposito, Antonio Dal Canton. *Nephrology, IRCCS San Matteo, Univ. of Pavia, Pavia, Italy.*

Glucose induces peritoneal membrane denudation with loss of mesothelial cells (MC), thickening and sclerosis probably through an excessive production of TGF-b by MC. Paricalcitol (PCT), binding to VDR receptor, can act as antifibrotic agent reducing TGF-b1 expression. We evaluated the effect of PCT on human peritoneal mesothelial cell (HPMC) cultures exposed to glucose. HPMC were extracted from peritoneal effluent, cultured and morphologically characterized. VDR expression was confirmed by RT- PCR, Western blot and immunofluorescence. Cells were treated with: A) glucose 2.3%; B) glucose 2.3% + PCT 0.1 uM; C) glucose 4.25%; D) glucose 4.25% + PCT 0.1 uM; E) mannitol 4.25%; F) mannitol 4.25% + PCT 0.1 uM; G) PCT 0.1 uM. Cells cultured in medium containing FCS 1% were used as controls (H). High glucose induced a significant detachment of cells ($2.1x10^5 \pm 8.1 \times 10^4$ vs $0.4 \times 10^5 \pm 1.6 \times 10^4$ vs $0.6 \times 10^5 \pm 2.5 \times 10^4$ vs $0.6 \times 10^5 \pm 1.6 \times 10^4$ groups C, A, E, H, respectively, $p<0.05$) and this result was not influenced by PCT treatment ($2.5 \times 10^5 \pm 1.1 \times 10^4$ vs $6.6 \times 10^5 \pm 4.2 \times 10^4$ vs $0.8 \times 10^5 \pm 3.2 \times 10^4$ vs $0.7 \times 10^5 \pm 3.0 \times 10^4$ D, B, F, G, respectively). HPMC expressed VDR and paricalcitol increased its expression. Nonetheless, the highest concentration of glucose was able to suppress VDR expression and this effect was not counteracted by PCT. Metalloproteinase 2 (MMP2) activity, measured by zymography , was reduced by glucose in a dose-dependent manner but was not affected by mannitol; this effect was partially prevented by PCT. TGF-b expression was increased by glucose, independently of the dose, and by mannitol. PCT reduced TGF-b1 expression only in the highest glucose concentration group ($0.285 \pm 0.053$ vs $0.217 \pm 0.085$, C and D respectively, NS). In conclusion HPMC express VDR. VDR is increased by paricalcitol and reduced by high glucose. Moreover, PCT blunts the suppression of MMP2 induced by glucose and prevents TGF-b1 increase. Paricalcitol maintains an adequate ECM turnover and prevents peritoneal dialysis associated sclerotic changes.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO855

**Pathological Diagnosis and Staging of Encapsulating Peritoneal Sclerosis (EPS) in PD Patients** Kazuho Honda,[1] Chieko Hamada,[2] Masaaki Nakayama,[3] Masanobu Miyazaki,[4] Takashi Harada,[5] Hideaki Oda.[1] *[1]Pathology, Tokyo Women's Medical University, Tokyo, Japan; [2]Nephrology, Juntendo Medical University, Tokyo, Japan; [3]Dyalisis and Chronic Kidney Disease, Tohoku University Graduate School of Medicine, Sendai, Japan; [4]Miyazaki Clinic, Nagasaki, Japan; [5]Sakuramachi Hospital, Nagasaki, Japan.*

A unique pathological hallmark of encapsulating peritoneal sclerosis (EPS) is a newly-formed membrane on visceral peritoneum which leads to encapsulation of entire abdominal organs. Using the peritoneal biopsy materials obtained at dissecting surgery or catheter removal, we confirmed the presence of encapsulating membrane histologically in 23 cases of PD patients (EPS group, n=23). The encapsulating membrane showed various phases of the pathological consequence, from an early exudative change of fibrin deposition, leading to fibroblast proliferation and fibrosis, and finally resulting in adhesion and scar formation on the peritoneal membrane. Immunostaining of fibrin and podoplanin was useful to evaluate the stage of encapsulating membrane. Fibrin was detected in an early exudative phase (stage I, n=6), whereas podoplanin was detected in the proliferating interstitial cells in stage I and subsequent proliferative phase (stage II, n=9). Neither fibrin nor podoplanin was detected in the late fibrotic phase (stage III, n=8). The extents of peritoneal sclerosis were evaluated by our reported method (Clin J Am Soc Nephrol. 2008; 3:720-8) and compared with those of the duration-matched PD peritoneum without EPS or peritonitis (control group, n=41). The average thickness of submesothelial compact zone was increased in EPS group than in control group ($645.5 \pm 358.8$ vs. $377.7 \pm 164.6$, $p=0.0016$). The lumen/ vessel ratio of post-capillary venule was significantly lower in EPS group than in control group ($0.096 \pm 0.18$ vs. $0.39 \pm 0.29$, $p<0.0001$). These results suggest that (1) the pathological diagnosis of EPS requires confirming a newly-formed encapsulation membrane, (2) fibrin deposition and podoplanin expression of peritoneal interstitial cells are key phenomena to evaluate the stage of EPS, and (3) advanced peritoneal sclerosis is associated with the pathogenesis of EPS.

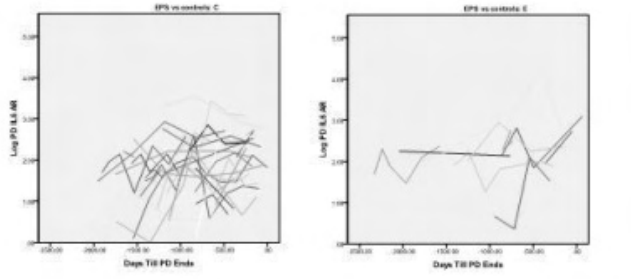
**IL-6 in Peritoneal Dialysate Prior to Encapsulating Peritoneal Sclerosis: Results from the GLOBAL Fluid Study** Mark Lambie,[1] James A. Chess,[2] Simon J. Davies,[1] Nicholas Topley.[2] *[1]Keele University, United Kingdom; [2]Cardiff University, United Kingdom.*

Encapsulating peritoneal sclerosis (EPS) is an inflammatory and fibrotic complication of peritoneal dialysis with significant mortality. Recent evidence suggests changes in the peritoneal membrane several years before EPS so identification of these changes may allow EPS avoidance. One study with limited numbers found a tendency for IL-6 to be elevated in subsequent EPS cases. We sought to confirm this in a larger study.

We identified 13 definite EPS cases from the Global Fluid Study, a prospective, multicentre, international study of incident and prevalent PD patients collecting repeat dialysate and plasma samples from routine PET's every 6 months. The cases were matched on PD duration, age, gender, centre, number of samples and diabetic status with 37 controls who had finished PD, and all samples were analysed by ECL (MSD Pro-inflammatory 4plex) for IFN-γ, TNF-α, IL-1β and IL-6. The results were analysed by linear mixed models built iteratively, adding fixed effects then random effects, using AIC and BIC for model assessment.

No differences between groups in matching criteria were found. Spaghetti plots for dialysate IL-6 appearance rates (AR) suggested a small difference in levels between groups.



A linear mixed model for dialysate IL-6 AR's found EPS status to be a significant association, p=.039, with estimates of 267 and 131 pg/min for cases and controls when stopping PD with an average D/P Cr. UF capacity and gender did not improve the models, but IL-6 AR's increased the closer the sample was taken to the end of PD, p=.038. Other cytokines were not significantly associated with EPS.

These results suggest that peritoneal inflammation, represented by dialysate IL-6, is a necessary precursor to EPS.

## TH-PO857

**Early Changes in Local and Systemic Inflammation in Peritoneal Dialysis: Results from the GLOBAL Study** Mark Lambie,[1] Nicholas Topley,[2] Simon J. Davies.[1] *[1]Keele University; [2]Caridff University, .*

Solute transport increases in the first month of peritoneal dialysis, and after 3 years but between then there is inconsistency. Solute transport is consistently associated with dialysate IL-6 levels, linked with inflammation. We hypothesised there is local inflammation in the first month followed by a suppression over the next 5 months. We undertook an analysis of the Global Fluid Study for supportive evidence of this. Samples were taken every 6 months, so cross-sectional rather than longitudinal analysis was used.

697 patients with samples in the first 6 months from 10 centres in the UK, Canada and Korea had plasma and 4-hour dialysate samples assayed by ECL using a commercial kit (MSD Pro-Inflammatory Multiplex I).

Loess regression of cytokines with time on PD suggests D/P Cr and plasma IL-6, TNF-α and IFN-γ rose during the first month on PD, falling over the following 2 months, whilst dialysate IL-6, IL-1β and TNF-α rose over the first 3 months and fell over the next 3 months. Bivariate correlations for duration of PD with cytokines are shown in the table.

| Weeks of PD | | IL-6 | TNF-α | IFN-γ | IL-1β | D/P Cr |
|---|---|---|---|---|---|---|
| | | Dialysate | Dialysate | Dialysate | Dialysate | |
| 0 to 12 | Spearman's rho | 0.180 | 0.095 | | 0.100 | |
| | p value | <0.001 | 0.024 | NS | 0.016 | |
| 12 to 24 | Spearman's rho | -0.280 | -0.324 | | -0.265 | |
| | p value | 0.003 | 0.001 | NS | 0.006 | |
| | | Plasma | Plasma | Plasma | Plasma | |
| 0 to 4 | Spearman's rho | 0.242 | 0.225 | 0.122 | | 0.220 |
| | p value | <0.001 | <0.001 | 0.035 | NS | <0.001 |
| 4 to 12 | Spearman's rho | -0.145 | -0.120 | | | -0.130 |
| | p value | 0.016 | 0.042 | NS | NS | 0.028 |

Dialysate IL-6 was present at concentrations a median of 2.91 times higher than plasma (IQR 1.05-7.05), suggesting diffusion of IL-6 from local to systemic occurs.

These results, subject to confirmation in a longitudinal study, suggest that starting PD is associated with an increase in local inflammation over 3 months, with a subsequent increase in systemic inflammation and solute transport, but this effect is suppressed after 4 weeks.

Disclosure of Financial Relationships: nothing to disclose

**Systemic Endothelial Albumin Leak Is Associated with Markers of Platelet Activation Independent of Systemic Inflammation in Peritoneal Dialysis Patients** Zanzhe Yu, Boon Kay Tan, Derek L. Mattey, Simon J. Davies. *University Hospital of North Staffordshire, Stoke-on-Trent, United Kingdom.*

Background: Endothelial dysfunction is a feature of renal failure as evidenced by an increased transcapillary albumin escape rate (TERalb). Our purpose was to explore associations between TERalb, systemic inflammation and markers of endothelial injury.

Methods: 41 prevalent PD patients were studied. TERalb was measured from the disappearance rate of radiolabelled albumin. 17 plasma biomarkers, including pro-inflammatory cytokines, endothelial biomarkers and MMPs, were measured by Luminex suspension array multiplex assays. Hierarchical clustering (HCA) and principle component analysis (PCA) were used to identify patient groups with common patterns which were then compared for TERalb and clinical characteristics.

Results: The mean TERalb was 13.7±8.9(%/h), higher than in normal populations (typically 5%). HCA identified three patient groups according to their biomarker results that converged with 3 of 7 distinct factors identified through PCA. (see table) Group 1 was most inflamed, had intermediate TERalb and high Factor 1 (TNF-α, VCAM-1, IFN-ϒ, IL-6, inversely with MMP-3) and Factor 3 (MMP-8, MMP-9 and E-selectin). Group 2 was non-inflamed and had opposite associations to Group 1 with Factors 1 and 3. Group 3 had the highest TERalb, was less inflamed but had the highest Factor 5 (markers of platelet activation, CD40L, P-selectin, MMP-1 and inversely with ICAM-1).

Conclusions: Endothelial barrier function is decreased in PD patients. This is not associated solely with systemic inflammation, but is also seen in relatively non-inflamed patients with markers of platelet activation.

| | Group1(n=14) | Group 2(n=9) | Group3(n=17) |
|---|---|---|---|
| TERalb (%/h) | 13.88±9.23 | 9.12±5.29a | 17.29±9.11 |
| CRP(mg/L) | 14.3(4.8-21)b | 1.5(0.6-4) | 4.6(0.8-9.5) |
| Factor 1 | 0.60±0.95 | -1.00±1.02c | 0.09±0.71 |
| Factor 3 | 0.83±0.92b | -0.33±0.69 | -0.10±1.23 |
| Factor 5 | -0.43±0.86 | -0.39±0.74 | 0.97±0.98d |

a, Group 2 vs 3, P<0.05 b, Group 1 vs 2, P<0.01; Group 1 vs 3, P<0.05 c, Group 2 vs 1 and 3, P<0.01 d, Group 3 vs 1 and 2, P<0.01

**Inflammation Limits the Beneficial Response to Nutritional Supplements in Continuous Ambulatory Peritoneal Dialysis** Alma R. J. Romero,[1] Fabiola Martin del Campo,[1] Laura Cortes Sanabria,[1] Leonardo Pazarin,[2] Alfonso M. Cueto-Manzano.[1] *[1]UIMER, Hospital Especialidades, IMSS, Guadalajara, Jalisco, Mexico; [2]HGR 46, IMSS, Guadalajara, Jalisco, Mexico.*

Inflammation may limit the beneficial effect of nutritional supplements on CAPD patients.

Aim: to compare the effect of systemic inflammation on nutritional response of CAPD patients receiving an oral egg albumin-based supplement.

Twenty-one malnourished patients were randomly selected. All patients received nutritional counselling and oral egg albumin-based supplement during 6 months. Patients were classified according to baseline serum C-reactive protein: with inflammation (≥5 mg/L) and without inflammation (<5 mg/L). All patients had monthly clinical and biochemical evaluations, and dialysis adequacy and nutritional evaluations every 3 months.

Main results are shown in the table.

| Variable | With inflammation (N 6) | | Without inflammation (N 15) | |
|---|---|---|---|---|
| | Baseline | Final | Baseline | Final |
| Time on dialysis (months) | 16 (10-62) | | 12 (4-23) | |
| Previous peritonitis (N) | 0 (0 – 5.7) | | 0 (0 – 1) | |
| Serum albumin (g/dL) | 2.9 ± 0.7 | 2.8 ± 0.8 | 3.1 ± 0.5 | 3.3 ± 0.9 |
| RRF (ml/min) | 0.46 (0.1-2.1) | 0.34 (0-1.4) | 0.86 (0.3-1.8) | 0.21 (0-1.6) |
| Energy intake (Kcal/kg) | 18.3 (14-26) | 25 (15-34) | 24.4 (21-28) | 27.5 (21-44) |
| Protein intake (g/Kg) | 0.81 (0.7-1) | 1.24 (0.6-1.6) | 1.1 (0.8-1.3) | 1.38 (0.7-2.1) |
| Subscapular skinfold (mm) | 16.0 (13-22) | 14.5 (9-19) | 12.5 (8-19) | 12.5 (8-17) |
| Midarm muscle area (cm²) | 22.8 (17-29) | 23.2 (16-33) | 24.9 (21-28) | 28.8 (24-34) |
| Nutritional status (%) | | | | |
| Normal | 0% | 33% | 0% | 33% |
| Mild malnutrition | 50% | 17% | 67% | 67% |
| Moderate/severe malnutrition | 50% | 50% | 34% | 0%£ |

£p<0.05 vs same evaluation in patients with inflammation; RRF: residual renal function

Conclusion: A higher systemic inflammation tended to be associated with a worse baseline nutritional status in CAPD patients, and limited the positive effect on anthropometric variables and subjective global assessment compared with patients without inflammation, even though all patients were receiving oral nutritional supplements.

**TH-PO860**

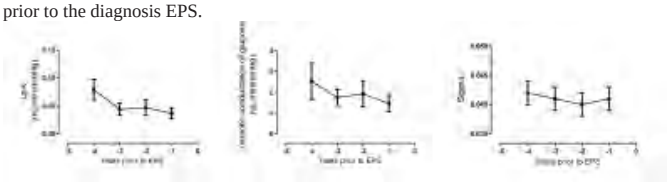
**Longitudinal Analysis of Fluid Transport and Their Determinants in PD Patients Who Develop Encapsulating Peritoneal Sclerosis** Denise Sampimon, Raymond T. Krediet. *Medecine - Division Nephrology, Academic Medical Center, Amsterdam, Netherlands.*

**Background:** Encapsulating peritoneal sclerosis (EPS) is a severe complication of long-term peritoneal dialysis (PD). Almost all patients with EPS have severe decreased fluid transport (ultrafiltration failure). Fluid transport is determined by several factors such as the ultrafiltration coefficient (LpA) and the glucose induced osmotic conductance (GOC). The latter is the product of LpA and the reflection coefficient (sigma). Decreased GOC is an important cause of ultrafiltration failure in long-term PD patients. It remains unclear whether a decreased GOC causes ultrafiltration failure in patients who develop EPS.

The **aim** of this study was to longitudinally analyze the determinants of fluid transport during the time course of the development of EPS.

**Methods:** Twelve PD patients who developed EPS were included for this study. The last 4 peritoneal function tests available were analyzed. The peritoneal function was assessed annually with 3.86% glucose dwell/4 hours with the addition of a volume marker. Sigma was estimated from pore size modeling and LpA from Starlings equation. The determinants of fluid transport were analyzed with a linear mixed model test.

**Results:** During the last 4 years prior to EPS the net ultrafiltration showed a linear decrease. This trend was determined by both a decrease in LpA and a decrease in GOC. Sigma showed an initial decrease however a slight increase was present in the last year prior to the diagnosis EPS.



**Conclusion:** A decrease of fluid transport prior to the development of EPS was present. The increase of sigma one year prior to EPS may be due to thickening of the interstitium or interstitial fibrosis. A follow-up study should compare these results with long-term PD patients with ultrafiltration failure.

**TH-PO861**

**Neutral Solution Suppresses Peritoneal Sclerosis but Promotes Angiogenesis in PD Peritoneum** Kunio Kawanishi,[1] Kazuho Honda,[2] Misao Tsukada,[1] Kosaku Nitta.[1] *[1]Department of Medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan; [2]Department of Pathology, Tokyo Women's Medical University.*

Objective: The present study was performed to explore the effects of neutral peritoneal dialysis (PD) solutions on peritoneal pathology in comparison with acidic, especially on the extent of peritoneal sclerosis and angiogenesis. Methods: Twenty-four patients who had been treated with either acidic solution (n=17) or neutral solution (n=7) were enrolled and each patient was undertaken the parietal peritoneal biopsy at the time of PD catheter removal. We evaluated the extent of peritoneal sclerosis by the previously reported method (CJSN.2008;3:720-8);measuring the thickness of submesothelial compact zone (SMC) and the ratio of lumen/vessel diameter (L/V ratio) of post-capillary venule at 5 different points, respectively. To evaluate the extent of angiogenesis, we underwent CD31 immunostaining and counted the number of blood vessels per unit area(mm²) in the 5 randomly-selected fields (x200) with an image analyzer. The blood vessels were classified by their short axis diameter into the 3 levels; <15μm:capillary (CAP), 15-50μm:post-capillary venule (PCV), >50μm:small artery and vein (SAV).Results: The age (acidic:46.4±4.8 vs. neutral:42.5±7.6) and PD duration (acidic:65.4±5.7 vs. neutral:53.6±8.9 months) were not different. The average thickness of SMC (μm) was lower in the neutral group (292.5±73.7) than acidic (496.1±40.9) (p=0.029). In addition, the average L/V ratio was significantly higher in the neutral group (0.86±0.06) than acidic(0.44±0.04) (p<0.0001). On the other hand, the number of CAP(count/mm²) was significantly higher in the neutral group (107.8±11.8) than acidic (45.9±7.6) (p=0.0002). The number of PCV tended to be higher in the neutral group but not significantly different (10.9±2.1 vs. 6.2±1.4, p=0.0735). The number of SAV was not different(neutral:1.1±0.7 vs. acidic:1.3±0.5, p=0.8276).Conclusions: Neutral solution suppresses the extent of peritoneal sclerosis but promotes capillary angiogenesis in PD peritoneum, suggesting the altered physiological effect by neutral solution can modify the peritoneal morphology and function in the recent PD patients.

**The Effect of Peritoneal Dialysis Prescription in Peritoneal Methothelial Cells** Hideki Yamahara,[1] Takanobu Imada,[1] Sanae Kikuchi,[1] Hiroya Masaki,[2] Mitsushige Nishikawa,[1] Toshiji Iwasaka.[1] *[1]Department of Medicine II, Kansai Medical University, Moriguchi, Osaka, Japan; [2]Department of Laboratory Medicine and Clinical Sciences, Kansai Medical University, Moriguchi, Osaka, Japan.*

**Background:** Continuous ambulatory peritoneal dialysis (CAPD) is an important renal replacement therapy. However, chronic exposure to peritoneal dialysate causes progressive mesothelial cell injury. Recent studies report that an increase in the mesothelial cell surface area indicates degradation of peritoneal membrane. Furthermore, these studies report that within 72 months PD period patients with more than 350 μm² of mean surface area of peritoneal mesothlial cell have risk of sclerosing encapsulating peritonitis (SEP). **Aim:** We investigated the effect of peritoneal dialysis prescription in the surface area of peritoneal mesothelial cell in the CAPD effluent. **Method:** Total of 16 CAPD patients was analyzed. We performed a peritoneal equilibration test and examined a mean surface area of peritoneal mesothelial cell. **Results:** The mean PD period was 23.3±18.7 months. The dose of total small-solute clearance (weekly Kt/V urea)(2.41±0.664) was associated with the surface area of peritoneal mesothelial cell (333±30.1 μm²)(r=0.41, p=0.017). According to linear regression analysis, more than 3.16 weekly Kt/V urea corresponds to

more than 350 μm² of mean surface area of mesothelial cell. **Conclusion:** The main finding of this study is that high dose dialysis prescription is clearly associated with degradation of peritoneal membrane. These results suggest that patients who need high dose dialysis prescription have risk of SEP. Thus, as for the patient whose weekly Kt/v urea is more than 3.16, discontinuation of CAPD is desirable.

**Superior Biocompatibility of Icodextrin by Maintaining the Wound Healing Process of Peritoneal Mesothelial Cells** Masahito Tamura, Tetsu Miyamoto, Narutoshi Kabashima, Ryota Serino, Tatsuya Shibata, Yumi Furuno, Junichi Nakamata, Yoko Fujimoto, Emi Hasegawa, Yutaka Otsuji. *Kidney Center, University of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan.*

Exposure to peritoneal dialysis fluid (PDF) causes structural alterations of the peritoneal membrane such as loss of mesothelial cell monolayer. These alterations of the mesothelium are associated with membrane dysfunction and progressive peritoneal fibrosis. Although icodextrin has been proven to have improved biocompatibility compared to the glucose-containing conventional PDF, effects of icodextrin on peritoneal wound healing have not been elucidated. We investigated the effects of icodextrin on wound healing of peritoneal mesothelial cells and determined the mechanisms involved. We examined the effects of icodextrin on the regeneration process of the peritoneal mesothelial cell monolayer by in vitro wound healing assay in cultured rat peritoneal mesothelial cells (RPMC) treated with icodextrin-containing PDF. Cell migration over fibronectin was inhibited in conventional acidic, lactate buffered glucose-containing PDF in concentration-dependent manner, however, icodextrin-containing PDF had no significant inhibitory effects. To evaluate the sole effect of icodextrin, remesothelialization was also examined in RPMC exposed to icodextrin powder-dissolved culture medium without PDF. Culture medium containing 2.5% glucose inhibited remesothelialization, however, 7.5% icodextrin-dissolved culture medium had no inhibitory effects. Glucose suppressed tyrosine phosphorylation of FAK, a key mediator in the integrin-mediated cell adhesion signaling, formation of focal adhesions, and cell spreading, while icodextrin had no effects on any of these mesothelial cell functions. Our results demonstrated that icodextrin had no deteriorative effects on the wound healing of peritoneal mesothelial cells by preserving integrin-mediated cell adhesion, and suggest that icodextrin-containing PDF may be more biocompatible than conventional glucose-containing PDF.

### TH-PO864

**Clinical and Biochemical Profile of a Low-Glucose Degradation Product Peritoneal Dialysis Fluid: A Four-Year Study** Kar Neng Lai, M. F. Lam, Joseph C. K. Leung, Loretta Y. Y. Chan, Sydney C. W. Tang. *Medicine, University of Hong Kong, Hong Kong, Hong Kong.*

Although peritoneal dialysis (PD) is a widely accepted form of renal replacement therapy, concerns remain regarding the bioincompatible nature of standard peritoneal dialysis fluid (PDF). Short-term studies of new biocompatible low glucose degradation products (GDP) peritoneal dialysis fluid reveal divergent results in patient survival, and peritoneal integrity.

We recruited 125 patients on maintenance PD for at least 12 months. They were previously assigned to receive either conventional or low-GDP PDF at random. Two groups of patients were matched for gender, age, duration of dialysis and incidence of cardiovascular disease or diabetes. Serum samples and overnight effluent dialysate were simultaneously collected and assayed for different cytokines, chemokines, adipokines and cardiac biomarkers.

After an average duration of CAPD treatment of 2.3 years, both groups had comparable weekly creatinine clearance, peritoneal clearance, total Kt/V or peritoneal Kt/V. However, patients receiving low-GDP PDF had better residual renal function with higher urine output. Compared with new patients receiving the first dialysis, higher concentrations of TNF-a, TGF-b, HGF, MIF, IL8, IL6, CRP and leptin comparable to serum level were found in effluent dialysate in both groups of patients on long-term PD. There was also decreased concentration of adiponectin in the effluent. The abnormally raised leptin and reduced adiponectin levels in serum and effluent were partially corrected in patients on low-GDP PDF when compared with the conventional PDF group. The effluent concentration of interleukin 8 was also significantly lower in those using low-GDP PDF. The survival rate and incidence of cardiovascular complications did not differ between two groups of patients after maintenance PD for an average of 3.6 years.

It appears that low-GDP PDF results in an improvement in local peritoneal homeostasis and may potentially have a positive impact on long-term survival and cardiovascular complication by reducing the chronic inflammatory status in the peritoneum.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO865

**Adapted APD, Varying Sequentially Dwell-Time Exchanges Short and Thereafter Longer, and Fill Volume Exchanges Small and Thereafter Larger: Impact on Dialysis Efficacy** Michel Fischbach,[1] Belkacem Issad,[2] Cécile Courivaud,[4] Vincent Dubois,[3] Redouane Taamma.[3] *[1]Dialysis Children's Unit, University, Strasbourg, France; [2]Nephrology, Pitie, Paris; [3]FMC, Paris, France; [4]Neprology, University, Besançon, France.*

Varying the duration of dwell-time or fill volume could modify peritoneal dialysis efficiency. Nevertheless APD is classically given as a recurrent repetition of exchanges each of them having the same dwell-time and the same fill volume, that is conventional APD (APD-C). We propose a new, adapted APD (APD-A) by first using a short dwell time with a small fill volume to favour ultrafiltration (UF) and subsequently using a longer dwell time and a larger fill volume, to promote blood purification. The study was a prospective, cross over, multicenter trial to investigate the impact on overnight UF and weekly peritoneal Kt/$V_{urea}$, weekly peritoneal creatinine clearance per 1.73 m² BSA ($K_{creat}$), phosphate/sodium dialytic removal (PDR, SDR: mmol/session). Normalization to the absorbed glucose estimated the metabolic cost. Blood pressures were recorded. 25 patients were selected in the study, 6 withdrawned, 2 at enrolment, 1 at day 75 (transplantation), 2 at day 30 (catheter dysfunction), 1 for drainage alarms.

The same amount of dialysate (same cost), balance lactate 1.5%glucose, and the same duration of overnight APD were prescribed.

Tolerance was good. APD-A compared to APD-C realized a significant enhancement of Kt/$V_{urea}$, of $K_{creat}$, and of PDR. The glucose metabolic cost for urea, creatinine and PDR was significantly lower in APD-A compared to APD-C. The UF increased during APD-A versus APD-C. The SDR was significantly higher with APD-A compared to APD-C, 35.23±52.00 mmol/session and 18.35±48.68 mmol/session ($p<0.01$). The meanBP (day 45) were significantly lower for the APD-A periods compared to the APD-C periods.

Our study supported that varying the dwell-times short and thereafter longer, and the fill volumes small and thereafter larger as described (APD-A) could improve dialysis efficiency for UF, Kt/v urea, Kcreat, phosphate dialytic removal and sodium dialytic removal. These results where achieved without more costs, even with reduced glucose metabolic cost.

### TH-PO866

**Automated Wearable Artificial Kidney (AWAK): Tidal Peritoneal Dialysis (TPD)-Based Large Volume Dialysate Exchange (LVDE) Using Low Reserve and Tidal Volume** Marjorie Wai Yin Foo,[1] Martin Roberts,[2-4] David B. Lee,[2-4] Siti Noor Huda,[1] Christian G. Bluchel,[5] Kok-Seng Wong.[1] *[1]Renal Medicine, Singapore General Hospital, Singapore; [2]VAGLA, Los Angeles, CA; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]AWAK Technologies, Singapore; [5]Temasek Engineering School, Temasek Polytechnic, Singapore.*

AWAK provides round-the-clock LVDE for steady-state metabolic and fluid regulation and for maximizing toxin clearance. We studied LVDE using TPD with low reserve (R) and tidal (T) volume for minimizing both the weight of AWAK and patient discomfort. We also examined the possibility that rapid dialysate exchanges could enhance ultrafiltration (UF) in high average transporters (HA). Five-hour TPD was conducted using Baxter HomeChoice system and 1.5% pH-neutralized, dextrose dialysate at LVDE (4L/hr). Eight R/T (in mL) combinations with T+R ≤ 1,500 mL, were studied in each of 8 established PD patients (2 low average transporters (LA) and 6 HA). Clearances are tabulated in mL/min and UF in mL/5 h. R500T500 is not included.

| | R250T250 | R250T500 | R250T1000 | R500T250 | R500T1000 | R1000T250 | R1000T500 |
|---|---|---|---|---|---|---|---|
| CUN HA/LA | 12.9/11,9 | 15.5/14.6 | 15.6/15.3 | 13.7/13.3 | 16.1/14.4 | 13.6/14.1 | 17.1/17.0 |
| UF HA/LA | 382/725 | 482/766 | 418/448 | 386/579 | 461/773 | 463/736 | 427/811 |
| Kt/V HA/LA | 3.4/4.2 | 4.1/5.1 | 4.5/5.4 | 3.6/4.7 | 4.3/5.4 | 3.7/5.5 | 5.9/6.5 |

Clearance of urea nitrogen (CUN) ranged from 12.9 to 17.1 which, based on AWAK providing 24/7 dialysis, extrapolates to a weekly Kt/V of 3.4 to 6.5. UF ranged from 382 to 811, which extrapolates to a daily volume of 1.8 to 3.9 L. Compared to LA, HA exhibited higher CUN and lower UF. Patients reported no discomfort and no inflow or drainage problems were encountered. We conclude the use of TPD with low R and T and high dialysate flow in AWAK can achieve high solute clearance and adequate UF even in HA without the need for higher than 1.5% glucose dialysate. Functional optimization of AWAK can be further achieved by using R+T of less than 0.75 L during the waking hours and up to 1.5 L through the sleeping hours.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO867

**Peritoneal and Renal Phosphate Handling in PD Patients** Ana Paula Bernardo,[2] Sebastián Azorín,[1] Gloria Del Peso,[1] M. Auxiliadora Bajo,[1] Marta Ossorio,[1] Amaia Ros Abando,[1] Rafael Selgas.[1] *[1]Nephrology Department, H. Universitario La Paz, Madrid, Spain; [2]Nephrology Department, ULS Castelo Branco, Castelo Branco, Portugal.*

**Introduction and aims:** Phosphate control has shown a major impact on morbidity in dialysis patients. The aim of this study was to evaluate factors associated with hyperphosphatemia (HyPh), to determine the effect of peritoneal characteristics and PD modality on phosphate clearance (PPhCl) and to establish its impact on survival. **Patients and methods:** 264 patients were evaluated at months 3 and 12 (age 51±16 years, 61% on CAPD). PPhCl was calculated from 24h peritoneal effluent samples. Residual renal function (RRF), phosphate(Ph) and creatinine(Cr) dialysate/plasma(D/P) were calculated at a 4h, 3.86%

PET.**Results:**The prevalence of HyPh (>5.5mg/dl) was 27% at baseline and 30% at 1year (1y).On multivariate analysis at baseline, RRF was independently associated with HyPh; at 1y RRF, age and CCPD were associated with HyPh.In anuric patients at 1y, D/PPh was the only independent factor for HyPh.D/PPh correlated with D/PCr at baseline and 1y (r=0.81, both;p<0.0001).PPhCl-1y correlated better with D/PPh-1y(r=0.48;p<0.0001) than with D/PCr-1y(r=0.46;p<0.0001).At 1y we classified patients as low(Lo),low-average(LA),high-average(HA) or high(H) transporters (mean±SD of D/PPh).16% patients were classified as H (D/PPh≥0.68),31% as HA (D/PPh 0.57-0.68),35% as LA(D/PPh 0.47-0.57) and 17% as Lo transporters(D/PPh ≤0.47).Patients with a Lo transport status had lower PPhCl than LA, HA and H transporters(31±14vs34±8vs39±1vs47±13L/wk respectively,p<0.0001).Among H and HA transporters, PPhCl were comparable in both PD modalities.In comparison to CCPD, CAPD was associated with increased PPhCl among LA(36±8vs32±7L/wk,p=0.005) and Lo transporters(34±15vs24±9L/wk,p=0.016).No significant differences on survival concerning HyPh, D/PPh or PPhCl were demonstrated.**Conclusion:**RRF contributes decisively to Ph control in PD patients.In anuric patients, membrane transport determines Ph control.Peritoneal clearance is determined by membrane transport category and PD modality, suggesting that PD regimes with longer dwell times may increase phosphate removal among lower transporters.

## TH-PO868

**Two-in-One Protocol: Simultaneous Free Water Transport Quantification and Standardized Small Solute Rate PET Categorization** Ana Paula Bernardo,[3] Anabela S. Rodrigues,[1] António Cabrita,[1] M. Auxiliadora Bajo,[2] Gloria Del Peso,[2] Rafael Selgas.[2] *[1]Nephrology Department, Centro Hospitalar do Porto, Portugal; [2]Nephrology Department, H. Universitario La Paz, Madrid, Spain; [3]Nephrology Department, ULS Castelo Branco, Portugal.*

**Introduction and aims:**Reduced free water transport (FWT) may contribute to the ultrafiltration failure (UFF) frequently seen in long-term peritoneal dialysis (PD) patients. Our aim was to simultaneously evaluate small solute transport by using a standard 4h dwell PET, to more accurately assess FWT in a group of prevalent PD patients and to further characterize them according to UFF.**Patients and Methods:**We performed a 4h, 3.86% PET with additional measurement of UF at 60 minutes (60') in 66 PD patients (age 50±16 years, 61% female, on PD for 26±23 months).We calculated FWT and %FWT;small pore fluid transport (SPUF);Dialysate(D)/Plasma(P) ratio of sodium (Na) and the dip in D/PNa at 60',120' and 240'. FWT determination was improved by the introduction of a correction algorithm (FWTc).**Results:**The following mean values were obtained:FWT 172±77ml,FWTc 211±79 ml, %FWT 38±0.1,SPUF 301±137 ml,UF60 473±163ml,UF240 673±233ml,D/PNa60 0.89±0.04, dipD/PNa60 0.03±0.04. D/PNa at 60',120' and 240' correlated well with FWT (r=-0.71; r=-0,69; r=-0.62, respectively, p<0.0001).UF240 correlated better with FWT and FWTc than with any other indirect measurement of Na sieving (r=0.37, p=0.002 and r=0.41, p=0.001, respectively).Twelve patients (18%) had UFF (UF240' <400ml).These patients had significant higher values of D/PCr(0.80vs0.72, p=0.0015), D/PNa60(0.92vs0.89, p=0.009), D/PNa120(0.93vs0.89, p=0.008), D/PNa240(0.94vs0.91, p=0.009) and lower values of FWT(113vs184, p=0.001) and FWTc (148vs225,p<0.0001), compared with the normal UF group.Seven UFF patients (58%) were on PD for more than two years, and among these higher compromise of FWT disproportional to small solute transport rate was shown: 5 had FWT<40% and 3 fast transport status. **Conclusion:** Measurement of FWT is feasible by its simultaneous quantification during a modified 3.86% glucose PET and is an important parameter to detect additional causes of UFF besides increased effective capillary surface.

## TH-PO869

**Effect of Fill Volume (FV) on Accelerated Peritoneal Equilibration Examination Time (APEX)** Kassem Safa,[1] Salim K. Mujais,[2] Ali K. Abu-Alfa.[3] *[1]Hospital of St Raphael; [2]Astellas Pharma Global Development; [3]Yale School of Medicine.*

**A**im is to examine effect of increasing FV on APEX using standard PET with 2.5% dextrose dialysate (DD) and to evaluate APEX in different peritoneal membrane transport categories. Verger introduced APEX using 4.25% DD to estimate ultrafiltration (UF) time and predict peritoneal permeability.

**Methods**

19 adult patients on PD for > 3 months underwent PET with 3 different randomly assigned FV (2, 2.5 & 3 L) of 2.5% DD, 1 week apart. Dialysate was obtained hourly between 0 and 4 hrs and blood at 2 hrs. Study was approved by Yale Human Investigation Committee. APEX was determined for each patient by plotting urea D/P and dextrose dissipation Dt/D0 as y-variables, and projecting their intersection on time x-axis (fig 1). Minitab®15 was used for data analysis.

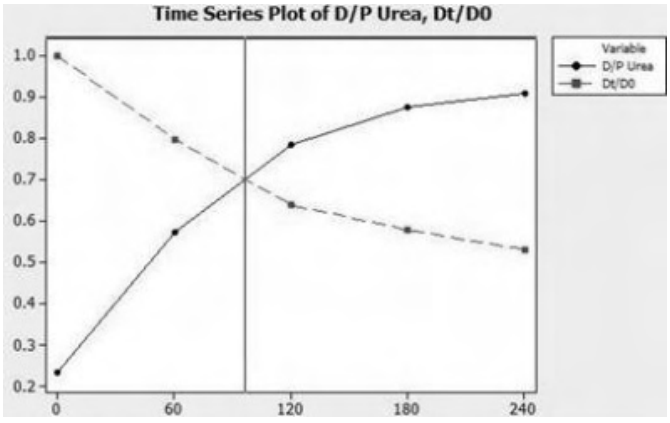

Fig 1. APEX determination

**Results**

11 men and 8 women (APD/CAPD 15/4) were enrolled with membrane types characterized as high (H:3), high average (HA:8), low average (LA:7) and low (L:1). Mean age was 43.1±13.4 yrs and BMI 26.72±5.59 Kg/m². Mean APEXT increased from 95.21±19.92, 110.52±20.54 to 132.36±29.58 min with increase in FV from 2, 2.5 to 3L. (p≤0.001, ANOVA and paired t-test)

Analysis grouping H with HA and L with LA membrane types showed significant increase in APEX as FV increased in both subgroups (p<0.05, ANOVA and paired t-test). Although APEX was consistently longer for L/LA vs. H/HA types, statistical significance was only noted for 2.5L (t-test). Changes in APEX based on interaction between progressive increase in FV and transport status were not statistically significant.

**Conclusion**

APEX responds in biologically plausible fashion to changes in FV and differentiates adequately between peritoneal transport types. It can be a useful summation index that can be used in select patients to determine optimal dwell times on APD appropriate to membrane transport type.

## TH-PO870

**Peritoneal Clearance of N-Terminal Telopeptide X (NTx)** Ramin Tolouian,[1] Sean Connery,[1] Shiva Mansourkhani,[1] Natalia Vega,[1] Ajay Gupta.[2] *[1]Nephrology and Hypertension, Texas Tech University Health Sciences Center, El Paso, TX; [2]Rockwell Medical, Wixom, MI.*

**Introduction**: Peritoneal Equilibrium Test (PET) has been considered the gold standard for measuring small molecule clearance such as urea & creatinine in peritoneal dialysis. Increased middle molecule retention may increase cardiovascular mortality. NTx is a bone marker with molecular weight of 1700 Dalton (Da) considered a middle molecule.

The purpose of this study is to show that NTx is cleared by peritoneal dialysis and thus assess the PET based on middle molecule clearance & potentially assess mineral bone disease simultaneously.

**Methods:** During routine PET, we measured NTx in dialysate at 0, 2 and 4-hour time points & in serum at 2 hours. NTx was measured by enzyme-linked immunosorbent assay (ELISA) according to manufacturer instructions (Wampole Lab, Osteomark; Seattle, WA). NTx is reported in nanomoles Bone Collagen Equivalent (nM BCE).

**Results:** 30 subjects undergoing PET were recruited. Mean Age = 56 yrs, mean length of time on peritoneal dialysis = 2 yrs, 63% male, 97% Hispanic, 67% diabetic. Dialysate/Plasma Ratio (D/P) for Cr, Urea, and NTx; 0.68 ±0.11, 0.91 ±0.05, 2.53 ±1.06 respectively (mean ±SEM). Results of diffusion of molecules measured over time are presented below;

**Diffusion Across Peritoneal Membrane**

| **PD fluid** | | | | **Serum** |
|---|---|---|---|---|
| | **0 hr** | **2 hr** | **4 hr** | **2 hr** |
| **NTx** (nm BCE) | 84.4 ±56.7 | 138.4 ±55.4 | 164.8 ±64.4 | 68.1 ±15.3 |
| % Change | | 270% (140-406%) | 340% (167-514%) | |
| **Cr** (mg/dl) | 0.97 ±0.51 | 4.3 ±1.75 | 5.7 ±2.48 | 8.4 ±3.6 |
| % Change | | 480% (396-548%) | 650% (530-736%) | |
| **Urea** (mg/dl) | 6.4 ±3.13 | 38.4 ±10.9 | 48.5 ±13.97 | 53.3 ±15.2 |
| % Change | | 713% (568-804%) | 897% (720-998%) | |

Mean ±SD or (95% CI)

**Discussion:** The kinetics of NTx transfer across the peritoneal membrane during a PD exchange demonstrated a slower transfer rate of NTx, compared to urea and creatinine, is consistent with a molecular weight of 1700 Da for NTx vs.(Cr= 113 Da, Urea = 60 Da).

This study demonstrates the feasibility of the use of NTx as a marker of middle molecule clearance to study peritoneal membrane characteristics and simultaneously assess mineral bone disease.

**The Role of NGAL in Peritoneal Dialysis Patients** Ilenia Filippi,[1] Francesca K. Martino,[1] Massimo De Cal,[2] Ching Yan Goh,[1] Pierluigi Di Loreto,[1] Maria Pia Rodighiero,[1] Carlo Crepaldi,[1] Claudio Ronco.[1] *[1]Nephrology, S Bortolo Hospital; [2]Medical Surgical Sciences, University Padua.*

**BACKGROUND:** NGAL is a promising biomarker of renal function. Residual renal function (RRF) is the most important prognostic factor in peritoneal dialysis patients (PD pts) and NGAL may be useful in their management. In this study, we aim to access NGAL expression in PD pts and evaluate factors that affect its level.

**METHOD:** We performed a cross-sectional study of 69 pts, who were on PD for ≥3 months. We evaluated their hydration status by bioimpedence, RRF [urine output (UO), renal CrCL, renal Urea CL], dialysis adequacy (weekly CrCL, KT/V), serum NGAL and other biochemical parameters (Albumin, Hb, CRP, Ferritin). All statistical analyses were performed on SPSS version 16.

**RESULTS:** 56.5% of pts were male, 26% were diabetes, 84% had hypertension. Median (Mdn) age was 61years (IQR46-71); mdn duration of RRT 30months (IQR11-51); mdn creatinine 8.7mg/dl (IQR6.7-11.3); mdn UO 800cc/day (IQR400-1200); mdn renal CrCL 2.3ml/min (IQR0.8-4.9); mdn weekly CrCL 67.7L/w (IQR54.9-86.7); mdn KT/V 1.9 (IQR1.76-2.19); mdn Urea CL 1.7ml/min (IQR0.55-2.8); mdn CRP 1.1ng/ml (IQR0.1-1.27); mdn extracellular water (ECW) 17.9L (IQR14.8-20.8); mdn intracellular water (ICW) 18.9L (IQR15.6-22.6).

Mdn NGAL level was 487.5ng/ml (IQR406.5-596.2). NGAL was inversely correlated with UO (ρ=-0.31 p=0.01), renal CrCL (ρ=-0.358 p=0.004), weekly CrCL (ρ=-0.396 p=0.001) and KT/V (ρ=-0.26 p=0.031). However, when we analyzed the correlation between NGAL and weekly CrCL as well as KT/V after correction for RRF, such correlation were lost. There were no correlation between NGAL and CRP, Ferritin, Albumin, ECW and ICW (p>0.05).

**CONCLUSION:** In this analysis, NGAL is significantly correlated with RRF but not with dialysis adequacy, inflammation and hydration in PD pts. Its level may be useful in PD pts management.

**Automated Peritoneal Dialysis (APD) Therapy Prescriptions for Enhancing Fluid and Sodium Removal** Steven Guest, Alp Akonur, James A. Sloand, J. Ken Leypoldt, Ying Lo. *Renal Division, Baxter Healthcare Corporation, McGaw Park, IL.*

Remaining edema-free is a challenge for many APD patients, especially those with fast (or high) transport membrane characteristics. Although increased use of dialysates containing high glucose (G) concentrations may improve volume control, the frequent use of such solutions is undesirable. We used the three-pore kinetic model to evaluate for anuric high and high-average transport patients 3 alternative therapy prescriptions for the day exchange, namely 1) use of a short daytime dwell (5 hrs) with a dry period (Therapy 1); 2) use of a midday exchange (Therapy 2); and 3) use of icodextrin-containing dialysate during a daytime dwell of 14 hrs (Therapy 3). The control therapy used the standard G-containing daytime dwell of 14 hrs. The nighttime prescription was identical for each therapy (10 L over 10 hrs), and all G-containing dialysates contained 2.27% G. Net ultrafiltration (UF), sodium removal (NaR), total carbohydrate absorption (CHO) and weekly urea Kt/V were computed and compared over a 24-hour period (see table). Use of a short daytime dwell with a dry period resulted in substantially higher UF and NaR without significant changes in CHO or urea Kt/V compared with control therapy. Use of a midday exchange does not improve upon UF and NaR compared with a short daytime dwell with a dry period; however, it provides higher Kt/V at the expense of higher G absorption. UF and NaR are highest using a long icodextrin-containing daytime dwell. Compared to standard (control) APD regimens with G, using either a short daytime dwell with a dry period or icodextrin reduces G absorption while enhancing UF and NaR.

Computer Simulated Parameters for APD Prescriptions

| Transport Type | Therapy | UF (L/day) | NaR (meq/day) | CHO (g/day) | Kt/V (per week) |
|---|---|---|---|---|---|
| High | Control | 0.46 | 23 | 177 | 1.80 |
| High | 1 | 0.90 | 74 | 172 | 1.87 |
| High | 2 | 0.83 | 65 | 215 | 2.21 |
| High | 3 | 1.44 | 152 | 173 | 1.97 |
| High-average | Control | 0.73 | 47 | 150 | 1.70 |
| High-average | 1 | 1.13 | 90 | 142 | 1.75 |
| High-average | 2 | 1.21 | 94 | 184 | 2.11 |
| High-average | 3 | 1.62 | 165 | 139 | 1.85 |

**Sodium Balance in an Automated Peritoneal Dialysis (APD) Population** Radu R. Raducu,[1] Aura Cernii,[1] Fredric O. Finkelstein.[1,2] *[1]Department of Nephrology, Hospital of Saint Raphael, New Haven, CT; [2]Yale-New Haven Hospital, CT.*

***Objective:*** The study was designed to evaluate the sodium balance in 61 patients with ESRD maintained on APD.

***Design:*** Longitudinal cohort study based on patient records and data files.

***Setting:*** One outpatient PD unit in New Haven, CT.

***Patients:*** A total of 61 patients who were on APD over a 1 year period (2009-2010).

***Main Outcome Measures:*** For each patient, the following parameters were evaluated: total volume of infused dialysate, total volume of drained dialysate, plasma sodium, dialysate sodium, amount of ultrafiltration, and amount of sodium removed by dialysis.

***Results:*** 61 patients were studied. The patients had mean KT/V of 2 (dialysis and residual). Mean plasma sodium was 139.3 mEq/l. Mean dialysate (drained) [sodium] was 129.7 mEq/l (range of 123-133), compared to an infused dialysate [sodium] of 132 . Mean ultrafiltration was 1.044+/-0.724 L/ 24 hours (mean+/- SD) . Mean sodium removal by peritoneal dialysis was 98.08+/-91.1 mEq daily . The mean decrease in [sodium] in the PD solution was 2.22+/-3.5 mEq/l. The correlation coefficient between amount of ultrafiltration and amount of sodium removed by PD was 0.81. The correlation coefficient between the decrease of [sodium] in the peritoneal fluid and amount of sodium removed by PD or the amount of ultrafiltration was 0.25 and 0.32, respectively.

***Conclusions:*** The data suggest that there is a drop in peritoneal dialysis solution sodium concentration during APD, likely related to water transport via peritoneal membrane aquaporin channels. This sodium sieving reduces the net sodium removal with APD. Decreasing the sodium concentration of peritoneal dialysis fluid during APD (currently set at 132 meq/l) might increase the sodium gradient and sodium clearance in APD patients. This might have important clinical advantages given the association of sodium balance with hypertension and cardiovascular events in ESRD patients.

**Assessment of Volume Status and Its Relationship with RisK of Inflammation and Nutrition in Korean PD Patients (ASKK Study)** Young Youl Hyun,[1] Young Sun Kang,[1] Jinjoo Cha,[1] Young Soo Kim,[2] Kook-Hwan Oh,[3] Yang Wook Kim,[4] Yeong Hoon Kim,[4] Nam Ho Kim,[5] Dae R. Cha.[1] *[1]Nephrology, Korea University, Ansan, Republic of Korea; [2]Nephrology, Catholic University, Republic of Korea; [3]Nephroloy, Seoul National University, Republic of Korea; [4]Nephrology, Inje University, Republic of Korea; [5]Nephrology, Chunnam University, Republic of Korea.*

Volume overload is thought to be associated with microinflammation, endothelial dysfunction, malnutrition and cardiac dysfunction. Adequate volume status is important to prevent worse outcomes in CKD patients. We evaluated the markers of inflammation and malnutrition in peritoneal dialysis(PD) patients according to the objective volume status, and the relationship of volume overload with cardiac dysfunction. Two hundred peritoneal dialysis patients from 5 nephrology center were included in the study. Using body composition monitor, total body water, overhydration, intracellular water(ICW), extracellular water(ECW), lean tissue mass(LTM), adipose tissue mass(ATM), body cell mass(BCM) were mesured. Demographic and laboratory data of inflammatory markers of CRP, TNFα, MCP-1, IL-6 and VEGF, Fractalkine were collected. The patients with excess ECF volume (more than 2.5L) showed lower LTM index, lower Hb, lower calcium, lower protein, lower albumin, lower cholesterol level, higher MCP-1, higher TNF-α, higher glucose and higher antero-posterior calcification scores than that in normohydrated and mild overhydrated patients. Overhydration was positively correlated with the values of MCP-1, VEGF, glucose, ALP, height, systolic blood pressure and negatively correlated with LTM, albumin, Hb level. ECW/ICW ratio was also positively correlated with MCP-1, height, weight discrepancy between patients weight and ideal dry body weight, and negatively with LTM index, ATM index, albumin, Hb. Overhydration was an independent risk factor of LVH, but did not increase the risk of vascular calcification. Conclusively in PD patients, fluid overload was associated with microinflammation, malnutrition, and possibly cardiac dysfunction. Adequate volume monitoring is a cornerstone to improve outcome in PD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO875**

**Bioimpedance Assisted Fluid Management Optimises Blood Pressure Control without Effect on Residual Renal Function** Stanley Fan, Sinead E. Burke. *Renal Unit, Royal London Hospital, United Kingdom.*

Purpose of the study:

Fluid overload predicts hypertension and cardiac dysfunction in dialysis patients. We used the Body Composition Monitor (BCM, Fresenius Medical Care) to screen PD patients and manage their fluid balance

Methods:

Patients were screened to identify severely overhydrated patients (OH > 2.L). These patients were reveiwed monthly, advised on sodium and fluid restriction and their PD regimens were adjusted to optimise ultrafiltration (UF). Residual renal function (RRF) and fat tissue mass were monitored. Achievement of euvolaemia was considered to be a BCM measurement of +/-1.1L.

Results:

Of the 200 PD patients screened, 19 patients (mean age 64.0yrs, Male 90%, CAPD 63%, mean PD vintage 17.5 months) had an OH >2L. 5 could not be followed up because of early PD technique failure or death from CCF. Mean follow up of patients was 8.4 months. Baseline overhydration was +2.4L (Table 1). All patients achieved euvolaemia (OH of +0.4L) after approx 3 months and 70% maintained euvolaemia during the remaining follow up period.

BP remained the same despite a significant reduction of antihypertensive medications use. Mean PD glucose use increased from 410 (38) kCal to 416 (45) kCal but there was no change to fat tissue mass. Residual renal function was also unchanged throughout the study period.

Change in BCM overhydration, MAP, antihypertensive use and RRF

| | BCM | MAP | No of anti-HT | RRF (24hr Vol) | RRF (weekly kt/V) | RRF (CrCl, L/wk) |
|---|---|---|---|---|---|---|
| Baseline | +2.4 (0.3) | 100 (6) | 1.1 (0.2) | 598 | 0.72 | 39.0 |
| Follow up | 0.4 (0.2)* | 95 (6) | 0.6 (0.3)* | 607 | 0.57 | 37.0 |

* denotes p<0.005 from baseline

Conclusion:

Bioimpedance identified patients that have benefited from optimisation of fluid balance. It permitted a significant reduction in antihypertensive medication without impact on BP control. Despite higher glucose usage to achieve euvolaemia, there has been no increase to fat tissue mass observed. Importantly, residual renal function has not been compromised in these patients.

We suggest that the BCM is a useful tool and achieving euvolaemia does not compromise residual renal function in PD patients.

**TH-PO876**

**Is N-Terminal Probrain Natriuretic Peptide a Marker of Volume Overload in Peritoneal Dialysis Patients?** Jenny Papakrivopoulou, Andrew Davenport. *Center for Nephrology, University College London Medical School, London, United Kingdom.*

Recent reports have suggested that peritoneal dialysis (PD) patients are volume overloaded.

We audited the usefulness of N-terminal probrain natriuretic peptide (NTproBNP) in determing volume overload in 80 ambulant PD patients, 45.7% male, 24.7% diabetic, mean age 57.1±1.7 yr, 73.4% treated by peritoneal cyclers, 82.7% icodextrin and 55.6% used one or more 2.27% glucose exchanges, mean dialysis vintage 32.9±3.3 months, mean urine output 1050±88.7 ml/day. Mean systolic blood pressure 137.9±2.8 and diastolic blood pressure 79.8±1.5 mmHg, 58% prescribed antihypertensives and 47.4% diuretics. Mean logNTproBNP 2.46±0.07 pmol/l.

Patients underwent chest X ray, 2dimensional transthoracic echocardiography, asssessment of peritoneal dialysis adequacy and transport status, and volume using 8 contact electrode multifrequency bioimpedance.

Simple correlations were found between logNTproBNP and cardiac size (left ventricular end systolic volume, diameter, and end diastolic diameter), right ventricular systolic pressure, residual renal function (urine output, urine sodium, urine Kt/V and creatinine clearance) volume (extracellular water to total body water (ECW/TBW)), 24 hour peritoneal ultrafiltration volume, icodextrin usage, serum albumin and prescription of antihypertensive medications, but not blood pressure measurements, cardiothoracic ratio, sex, age, diabetes, CRP, peritoneal dialysis clearances, transport status or dialysis prescription.

On logistical regression analysis only 4 factors remained independent predictors of logNTproBNP; liters creatinine cleared per week (F20.8, β -0.006, 95%CL 0 to-0.008, p<0.001), number of blood pressure medications prescribed (F8.04, β0.132, 95%CL 0.39 to-0.226, p=0.007), volume status ECW/TBW (F7.43, β13.75, 95%CL 3.62 to 23.9, p=0.009) and left ventricular end systolic diameter (F5.84, β0.186, 95%CL0.019 to0.032, p=0.019).

In peritoneal dialysis patients BNP increases with volume overload (raised ECW/TBW) but is also affected by residual renal function, hypertension and left ventricular size.Thus a single point BNP estimation alone may not be a strong indictor of volume status in PD patients.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO877**

**Hydration Status, Cardiac Function and Brain Natriuretic Peptide in Peritoneal Dialysis** Gianpaolo Amici,[1] Adriana Caberlotto,[1] Paolo Cogliati,[2] Carmelo Cascone.[1] *[1]Nephrology and Dialysis, Regional Hospital, Treviso, Italy; [2]Medical Department, Fresenius Medical Care Italy, Palazzo Pignano, Italy.*

Hydration status affects cardiac function in peritoneal dialysis (PD) where obtaining the necessary ultrafiltration can give inflammatory stress to the biologic membrane. In this clinical contest blood and instrumental indices of heart function can be integrated by the multifrequency bioimpedance analysis giving relevant quantitative data. A cross-sectional study was performed on 27 prevalent PD patients, 19 APD and 8 CAPD, 17 males and 10 females, aged 64±16 years, on dialysis for 2.8±2.6 years, 5 patients used icodextrin and 6 were diabetics. In all patients body composition analysis was performed using BCM-FMC spectroscopy estimating overhydration status (OH, L), Total Body Water (L), Extra-Cellular Water (L), Intra-Cellular Water (L), Lean Tissue Mass (LTM kg), Fat Tissue Mass (FTM kg) and echocardiography with Ejection Fraction % and LVMI (g/sqm, Devereux-Penn). N-terminal pro-brain natriuretic peptide (NT-ProBNP) pg/mL (n.v. 0-125) was assayed in all patients. Statistical analysis was performed by JMP SAS software. Median NT-ProBNP showed high values 5398 pg/mL with a wide dispersion (range 266-35000) so in the following analyses has been transformed (Log), EF % was 65.7±8.7, LVMI 176±60 g/mq, SBP 156±27 and DBP 95±18 mmHg, OH 1.8±1.6 L, TBW 35±7 L, ECW 17±3 L, ICW 18±4 L, LTM 37±11 kg, FTM 23±9 kg. LogBNP showed linear correlations with residual diuresis (r-0.576 p=0.003), GFR (r-0.627 p=0.002) total weekly CLCR (r-0.588 p=0.004); with EF% (r=-0.603 p=0.003), LVMI (r=0.458 p=0.032) and spectroscopy data: OH (r=0.528 p=0.007), ICW (r=-431 p=0.032). Applying a multivariate regression model LogBNP is explained (rsq=0.834) by diuresis (F=38.1, p<0.001), LVMI (F=26.9, p<0.001), age (F=5.6, p=0.006) and OH (F=4.0, p=0.016). The complex of evaluated indices shows a relationship between residual renal function, hydration status and cardiac function in PD patients suggesting a diagnostic scheme. NT-ProBNP assay and spectrometry analysis are of primary interest for the follow-up of the patient integrating more complex cardiovascular exams and giving clinically relevant data.

**Left Atrial Volume Index (LAVI) and Left Ventricular End Diastolic Volume Index (LVEDVI) May Not Reflect Overhydration in Peritoneal Dialysis Patients with Hypertensive Cardiac Injury** Boon Kay Tan,[1] Frauke Wenzelburger,[1] Biju John,[1] Yu Ting Tan,[2] John E. Sanderson,[2] Simon J. Davies.[1] *[1]Institute for Science and Technology in Medicine, Keele University, Stoke on Trent, Staffordshire, United Kingdom; [2]Cardiovascular Medicine, University of Birmingham, Birmingham, West Midlands, United Kingdom.*

Background:

Left atrial volume (LAV) and left ventricular end diastolic volume (LVEDV) are often considered measures of fluid status. We want to establish whether LAV and LVEDV are more dilated in PD patients compared to non CKD patients with a similar history of hypertension.

Method:

30 stable PD patients (15 male, mean age 60±17) and 30 non CKD hypertensive patients (12 male, mean age 67±6) were studied. They were matched for gender, mean BP and duration of hypertension. Left ventricular mass index (LVM),LVEDV and LAV were determined using standard full Doppler-2D-echocardiography with M-Mode and calculated according to the guidelines of the American society of echocardiography and adjusted for body surface area (BSA). Plasma volume (PVc) was measured using 125I-albumin and corrected for BSA (in PD patients only); extracellular (ECW) to total body water (TBW) ratio were determined by Bioimpedance analysis (Xitron Hydra) in PD patients and predicted using Lindley and Lopot equation in non CKD patients.

Result:

While PVc was found to be within the normal range in > 85% of PD patients, ECW:TBW was significantly higher compared to non CKD patients. (0.478±0.356 v 0.458±0.104, p=0.005). LVMI was greater in PD patients than in non CKD patients (111.72 ± 29.54 g/m2 v 89.54 ± 31.48 g/m2, p<0.05) but LAVI and LVEDVI were comparable in both groups of patients (31.86 ± 12.67 ml/m2 v 29.94 ± 10.54 ml/m2 and 43.48 ± 15.52 ml/m2 v 40.80 ± 9.02 ml/m2, respectively. p=ns). LAVI correlated with LVMI only in PD but not in non CKD patients (r=0.44, p<0.05).

Conclusion:

Both LAVI and LVEDVI may not be reliable surrogate parameters of current fluid excess in PD patients with established hypertensive heart disease. The correlation between LAVI and LVMI seen in PD patients may suggest more diastolic dysfunction and reduced left ventricular compliance in PD patients compared to non CKD hypertensive patients.

**Impact of Body Mass Index (BMI) on Early and Late Mortality and Technique Failure in Peritoneal Dialysis (PD)** Kelvin Leung, Manish M. Sood, Paul Komenda, Mauro Verrelli, Claudio Rigatto. *Medicine, University of Manitoba, Winnipeg, MB, Canada.*

Increasing BMI is associated with higher mortality in the general population. In PD patients, however, the relationship between BMI and outcomes is unclear. Some studies demonstrate lower, and others higher mortality with high BMI. These variable results

may reflect either a time dependent relationship (e.g. different impact on early and late mortality in PD) or a J-curve phenomenon. To test these hypotheses we analyzed data from a prospective database of all 727 incident patients initiating PD between 1997 and 2007 in the province of Manitoba, Canada. Separate proportional hazards models were constructed to model the impact of BMI on early (<12 months) and late (>12 months) mortality and technique failure, with adjustment for the following confounders: age, sex, race, cause of end stage renal disease, residual renal function, peritoneal KT/V, peritoneal transport, and comorbid medical conditions). The average BMI was 27.1 (S.D. 5.8). Most patients (64%) were overweight (BMI>25) with 31% obese (BMI>30). Total mortality and technique failure during the follow up period was 45.9% and 47.2% respectively. Increasing BMI was associated with lower adjusted early mortality (hazard ratio [HR] 0.762, 95% CI: 0.584-0.996, P<0.05) and lower rate of adjusted early mortality or technique failure (HR 0.741, 95% CI 0.601-0.914, P<0.01). No association was apparent between BMI and late mortality, or BMI and late technique failure. A J-curve phenomenon could not be demonstrated when BMI was analyzed as quartiles or as a quadratic polynomial. In summary, low BMI was consistently associated with high early mortality, but no association was apparent between BMI and late mortality. These findings support the concept that the association of BMI and outcomes may differ in the early versus late period after starting PD.

**Complementary Therapy Might Be Effective To Preserve Peritoneal Function** Nanae Matsuo, Keitaro Yokoyama, Yukio Maruyama, Yoshimi Ueda, Rinako Iida, Yudo Tanno, Kazushige Hanaoka, Hiroyasu Yamamoto, Tatsuo Hosoya. *Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Complementary therapy, which comprises 6 days of PD combined with 1 HD session per week, is the treatment of choice for PD patients who cannot control body fluid status and/or cannot achieve adequate solute removal by PD alone. We previously reported several benefits of complementary therapy including improvement of hydration status, correction of inadequate solute removal and improvement of anemia (Clini Neph in press). Oppositely, there is a possibility to increase peritoneal damage resulting the prolonged PD duration as to complementary therapy. The aim of this study was to evaluate the influences of complementary dialysis on peritoneal damage.

In this prospective cohort study, we recruited twenty patients with complementary therapy. Markers of peritoneal damage as well as fast peritoneal equilibration test (PET) were compared before and 1year after starting complementary therapy.

D/P-cre decreased significantly 1 year after starting complemantary therapy. Level of MMP-2 in PET drainage also decreased significantly. In addition, level of CA125 in PET drainage increased significantly, and it might reflect the improvement of peritoneal mesothelial cells viability. Furthermore, serum C-reactive protein and fibrinogen decreased significantly. The mechanism of the preservation of peritoneal function by complementary therapy was quite obscure. However, the reduction of glucose exposure form PD solution on PD free day (performed HD day), together with adequate dialysis after starting complementary therapy, might be lead patients to improve in inflammation and peritoneal function. We concluded that complementary therapy might be effective to preserve peritoneal function.

## TH-PO881

**Icodextrin Blocks Progression of Cardiac Hypertrophy and Arterial Valve Calcification in Incident Peritoneal Dialysis Patients** Takeyuki Hiramatsu, Shinji Furuta, Yoshiyasu Iida. *Department of Nephrology, Konan Kosei Hospital, Konan, Aichi, Japan.*

Background and aim : We reported use of icodextrin ameliorates cardiovascular (CV) parameters in peritoneal dialysis (PD) patients. One of remaining questions would be when icodextrin to be started for better CV management. Therefore, we retrospectively compared the change in CV parameters, according to when they started icodextrin after the start of PD therapy.Methods and patients : A total of 45 incident PD patients with available 2-year data was analyzed retrospectively. Group A (n=7); started icodextrin within 1 month after the start of PD, Group B (n=10); started icodextrin between 1 month to 2 years on PD , Group C (n=28); never used icodextrin for 2 years after the start of PD. The criteria to start icodextrin were overt edema and ultrafiltration volume less than 500mL/day. Results : At baseline, brain natriuretic peptide (BNP) and left ventricular mass index (LVMI) in Group B were significantly higher than those in Group C. Aortic valve calcification and plaque score in cervical artery in Group A were significantly worse than those in Group C. Thus, some cardiovascular parameters in group A and B were worse than those in Group C at baseline. However, the ameliorations in those parameters after 2 years were observed in both Group A and B, whereas those in Group C deteriorated as shown in the Table 1.

Changes in CV parameters in each group:values at 2 years minus baseline

| parameter | Group A | Group B | Group C |
|---|---|---|---|
| BNP (pg/mL) | -281(0.0047) | -526(<0.001) | 188 |
| LVMI (g/m2) | -47.9 (<0.001) | -78.2(<0.001) | 28.4 |
| Aortic valve calcification grade | -1.29 (<0.001) | -0.70 (<0.001) | 0.79 |
| Intima Media Thickness (mm) | -0.20(0.001) | -0.04(0.088) | 0.11 |
| Plaque score | -2.97 (<0.001) | -0.56(0.037) | 1.85 |

(p value vs Group C)

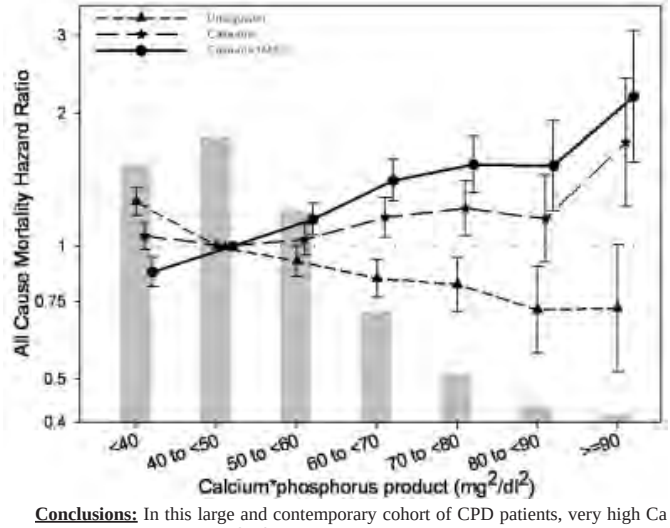
There was no association between the change in CV parameters and month of icodextrin started.Conclusion : Icodextrin can be started whenever it is necessary even from the start of PD for the sake of better CV management.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO882

**Association of Serum Calcium-Phosphorus Product and 6-Year Mortality in Chronic Peritoneal Dialysis Patients** Uyen Duong,[1] Rajnish Mehrotra,[2] Csaba P. Kovesdy,[3] Lilia R. Lukowsky,[1] Allen R. Nissenson,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Salem VA Medical Center, Salem, VA; [4]Davita, Lakewood, CO.*

**Background:** Previous studies have showed that higher serum calcium (Ca) and phosphorus (P) levels and their product (Ca x Phos) were incrementally associated with increased death risk in hemodialysis patients. We hypothesized a similar mortality predictability of Ca x Phos product in chronic peritoneal dialysis (CPD) patients. **Methods:** We examined a large contemporary cohort of CPD patients who underwent CPD treatment for at least 90 days in any DaVita dialysis clinic from July 2001 through June 2006, with additional survival follow up until June 2007. **Results:** We identified 12,269 CPD patients whose serum minerals were measured during the 5 year cohort. They were 54±16 year old and included 47% women, 23% African Americans and 13% Hispanics. Ca x Phos product was categorized into 7 a priori selected groups of <40 $mg^2/dl^2$ to ≥ 90 $mg^2/dl^2$ and 5 groups of 10 $mg^2/dl^2$ increments in-between (reference: 40-<50 $mg^2/dl^2$). A Ca x Phos product greater than 90 $mg^2/dl^2$ was associated with 2-times increased death risk; Death hazard ratio (95% CI) was 2.1(1.5-2.9) (See Figure).



**Conclusions:** In this large and contemporary cohort of CPD patients, very high Ca x Phos product, esp >≥ 90 $mg^2/dl^2$, is associated with increased death risk. Examining interventions to reduce Ca x Phos product are warranted.

Disclosure of Financial Relationships: nothing to disclose

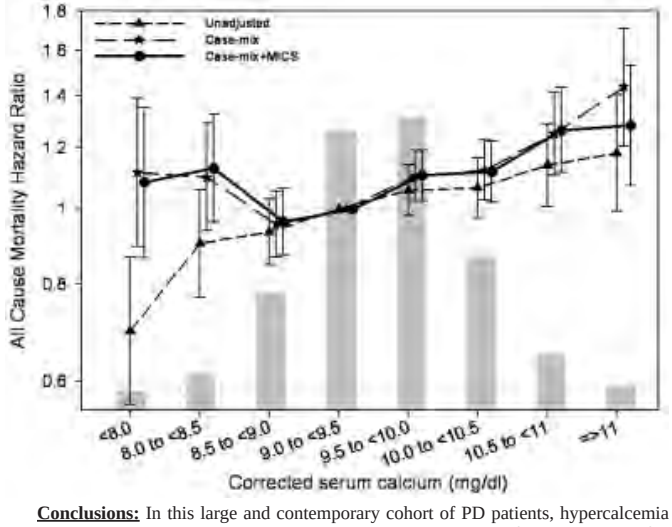
**Serum Calcium and Mortality in Peritoneal Dialysis Patients** Uyen Duong,[1] Rajnish Mehrotra,[2] Csaba P. Kovesdy,[3] Lilia R. Lukowsky,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Salem VA Medical Center, Salem, VA.*

**Background:** Hypercalcemia independently increases death risk in hemodialysis (HD) patients. However, it is not clear if such associations apply to peritoneal dialysis (PD) patients.

**Methods:** We examined a large contemporary cohort of all PD patients who underwent dialysis treatment for at least 90 days in DaVita dialysis from July 2001 through June 2006 and followed up to June 2007. All serum calcium values measured within a 3-month calendar quarters were averaged into one single value. Associations with mortality were examined in Cox models. **Results:** We identified 12,173 PD patients who had calcium measure during their base calendar quarter; they were 54.4±16.4 years old and included 47% women, 23% African Americans and 13% Hispanics. Albumin adjusted calcium was categorized into 8 a priori selected groups of <8.0mg/dl to ≥ 11.0 mg/dl and 6 groups of 0.5 mg/dl increments in-between. Taking calcium 9.0-9.5 mg/dl as the reference, calcium levels greater than 9.5 mg/dl was associated with increase death risk after adjusting for demographics, co-morbid conditions and additional malnutrition-inflammation complex syndrome (MICS). Death hazard ratio (HR) and 95% CI for calcium in 9.5-<10 mg/dl, 10.0-<10.5mg/dl, 10.5-<11.0 and ≥11.0 mg/dl were 1.10(1.02-1.19); 1.11 (1.02-1.22); 1.27 (1.12-1.44) and 1.28(1.07-1.53), respectively. (See Figure).



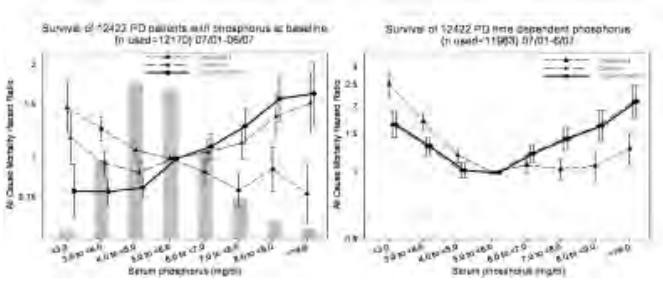
**Conclusions:** In this large and contemporary cohort of PD patients, hypercalcemia appears independently associated with increased death risk, after controlling for demographic and laboratory data. In particular, serum calcium >9.5 mg/dL is associated with mortality.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO884**

**Serum Phosphorus and 6-Year Mortality in Chronic Peritoneal Dialysis (CPD) Patients** Uyen Duong,[1] John J. Sim,[1] Rajnish Mehrotra,[2] Csaba P. Kovesdy,[3] Allen R. Nissenson,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Salem VA Medical Center, Salem, VA; [4]Davita, Lakewood, CO.*

**Background:** Both very low and high serum phosphorus (phos) levels are related to mortality in maintenance hemodialysis patients (pts). The mortality predictability of phos in chronic peritoneal dialysis (CPD) pts may be different. **Methods:** We examined a large contemporary cohort of over 12,000 CPD pts who underwent peritoneal dialysis treatment for at least 90 days in DaVita dialysis clinics from July 2001 through June 2006 and were followed up to June 2007. Baseline and time-dependent Cox models were examined. **Results:** We identified 12,170 CPD pts whose serum phos levels were measured; they were 54.4±16.4 year old and included 47% women, 23% African Americans and 13% Hispanics. Phos was categorized into 8 a priori selected groups of <3.0, ≥9.0 and 6 groups of 1 mg/dL increment in-between. Taking phos 5.0-6.0 mg/dl as reference, phos greater than 7.0 was associated with increased death risk after adjusting for demographics, co-morbid conditions and surrogates of malnutrition-inflammation complex syndrome (MICS). Death hazard ratios (and 95% CIs) in baseline model (Left Figure) for phos in 7.0-<8.0 mg/dl, 8.0-<9.0 mg/dl, ≥9.0 mg/dl were 1.3(1.1-1.5); 1.6(1.3-1.9) and 1.6(1.3-2.0), respectively, whereas lower baseline phos levels (<5.0mg/dl) appeared protective: 4.0-<5.0 mg/dl, 3.0-<4.0 mg/dl, <3.0 mg/dl were 0.79 (0.65-0.96); 0.78 (0.71-0.86); 0.81 (0.75-0.87), respectively. Time-dependent model (Right Figure) showed a U-shaped association.



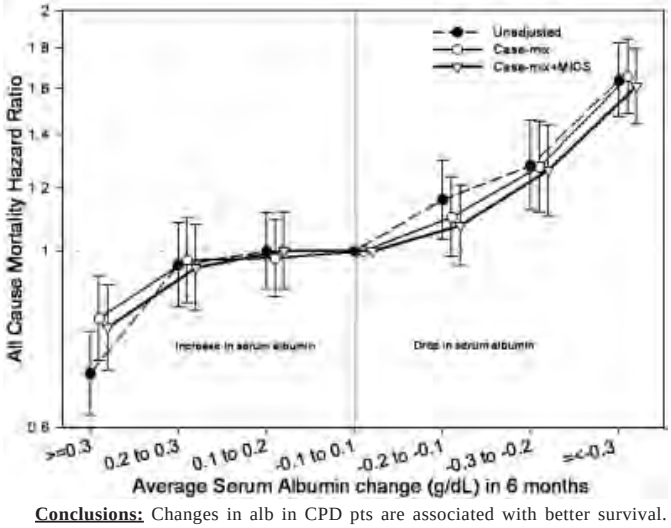
**Conclusions:** In this large and contemporary cohort of CPD pts, hyperphosphatemia (>7.0mg/dl) appears an incremental death risk.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO885**

**Changes in Serum Albumin over 6 Months Are Associated with Significant Changes in Survival in Peritoneal Dialysis Patients** Uyen Duong,[1] Rajnish Mehrotra,[2] Csaba P. Kovesdy,[3] John J. Sim,[5] Lilia R. Lukowsky,[1] Allen R. Nissenson,[4] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Salem VA Medical Center, Salem, VA; [4]DaVita, Lakewood, CO; [5]Kaiser Permanente, Los Angeles, CA.*

**Background:** Higher serum albumin (alb) is by far the strongest predictor of greater survival compared to other outcome predictors in dialysis patients (pts). It is not known whether changes in alb over time are associated with survival in chronic peritoneal dialysis (CPD) pts independent of baseline alb and other covariates. **Methods:** We examined a large cohort of all CPD pts who underwent peritoneal dialysis treatment for at least 90 days in any DaVita dialysis clinic from July 2001 through June 2006 and followed their survival up to June 2007. Associations with all-cause mortality were examined in Cox models. Albumin change within -0.1 and +0.1g/dL over 6 month were considered stable (reference group). Pts whose alb changed beyond +/-0.1 g/dl were subdivided into decrements or increments of 0.1 g/dL.**Results:** We identified 8,568 CPD pts who survived and had alb measured at baseline and the next 6 months. They were 54±16 years old and included 47% women, 22% African Americans and 15% Hispanics. After adjusting for baseline alb, demographics and surrogates of malnutrition-inflammation-cachexia syndrome, patients with fall in alb between 0.2 and 0.3 g/dl and greater than 0.3 g/dl had all-cause death hazard ratio (HR) and 95% confidence interval (95% CI) of 1.3(1.1-1.4) and 1.6(1.4-1.8), respectively, whereas a rise in alb beyond 0.3 g/dl exhibited an HR of 0.8(0.7-0.9) (Figure).



**Conclusions:** Changes in alb in CPD pts are associated with better survival. Interventional studies to modulate serum albumin are indicated.

Disclosure of Financial Relationships: nothing to disclose

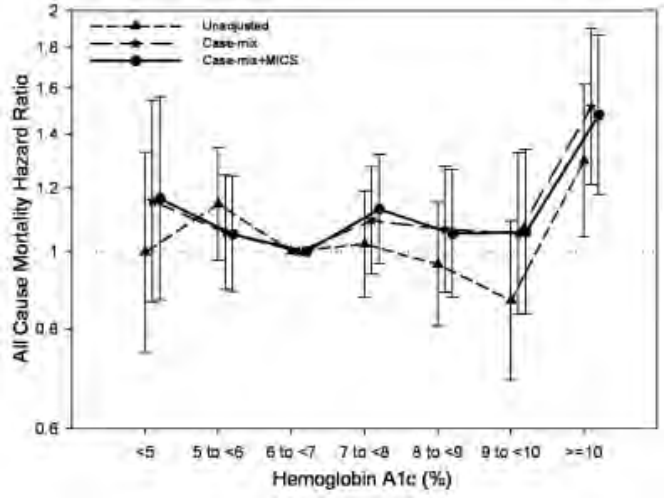
**Hemoglobin A1c and 6-Year Survival in 2,798 Chronic Peritoneal Dialysis Patients with Diabetes Mellitus** Jong C. Park,[1] Rajnish Mehrotra,[2] Uyen Duong,[1] John J. Sim,[4] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA; [2]David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Salem VA Medical Center, Salem, CA; [4]Kaiser Pamanente, Los Angeles, CA.*

**Background:** There is mixed data about the mortality predictability hemoglobin A1c in diabetic hemodialysis patients. In chronic peritoneal dialysis (CPD) patients, the association may be confounded by glucose loading in PD fluid. **Methods:** We examined a large cohort of diabetic CPD patients who underwent peritoneal dialysis treatment for at least 90 days

in any DaVita dialysis clinic from July 2001 through June 2006 and followed up to June 2007. **Results:** We identified 2,798 diabetic CPD patients who had A1c measure during their base calendar quarter; they were 58±12.8 years old and included 44% women, 20% African Americans and 16% Hispanics. A1c was then categorized into 7 a priori selected groups of <5%, >=10% and 1% increments in-between. A U-shaped trend with death hazard ratios (HR) was noted. Taking A1c 6-6.9% as the reference, A1c>=10% had a 5-year death HR (and 95% confidence interval [CI]) of 1.3 (1.1-1.6), 1.5 (1.2-1.9) and 1.5 (1.2-1.9) representing the unadjusted, case-mix (gender, age, race, ethnicity, dialysis vintage, type of insurance, 10 comorbid conditions, smoking residual renal function and Kt/V) adjusted and additional malnutrition-inflammation complex syndrome (MICS) (BMI, serum albumin, ferritin, creatinine, phosphorus, calcium, bicarbonate, TIBC, WBC, and lymphocyte percentage and blood hemoglobin) adjusted models, respectively (see figure).



**Conclusions:** In this large national cohort of diabetic CPD patients, A1c≥10% appears associated with 50% increased mortality compared to A1c 6-7%. Clinical trials to examine the benefit of glycemic control in CPD patients are indicated.

Disclosure of Financial Relationships: nothing to disclose

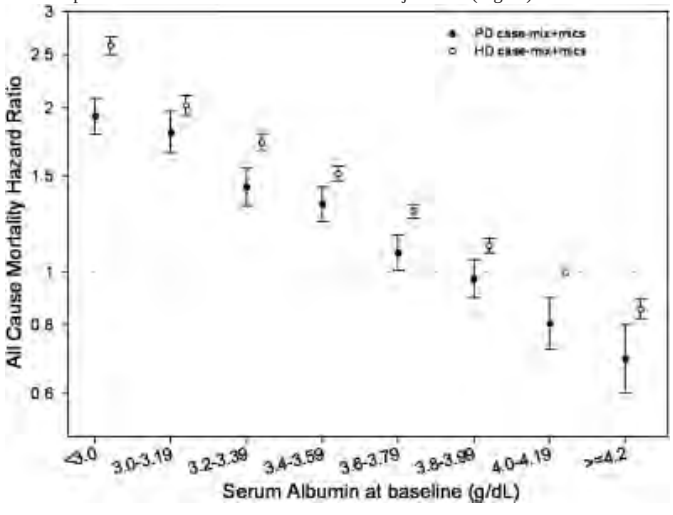
## TH-PO887

**Comparing Mortality-Predictability of Serum Albumin Levels between Hemodialysis and Peritoneal Dialysis Patients** Rajnish Mehrotra, John J. Sim, Uyen Duong, Lilia R. Lukowsky, Allen R. Nissenson, Csaba P. Kovesdy, Kamyar Kalantar-Zadeh.

**Background:** Serum albumin is an independent and strong predictor of mortality in both hemodialysis (HD) and peritoneal dialysis (HD) patients. It is not known if this mortality predictability is different between HD and PD patients.

**Methods:** We examined a large and contemporary cohort of all HD and PD patients who underwent dialysis treatment for at least 90 days in any DaVita dialysis clinic from July 2001 through June 2006 with survival follow-up till June 2007. Associations with all-cause mortality were examined in Cox models.

**Results:** We identified 120,592 HD and 12269 PD patients who had serum albumin measurements during their base calendar quarter; they were 62±16 and 54±16 years old and included 45% and 47% women and 32% and 22.6% African Americans, respectively. HD and PD patients were then divided into 8 albumin increments of albumin <3g/dL and ≥ 4.2g/dL and 0.2 g/dL intervals in-between. Taking HD patients with albumin 4.0-<4.2g/dL as a reference, we found that in any given albumin groups, PD patients had better survival than HD patients even after extensive multivariate adjustment (Figure).



**Conclusions:** In this large nationally representative cohort of HD and PD patients higher serum albumin was associated with greater survival and PD patients appeared to have superior survival to HD patients given same serum albumin level.

## TH-PO888

**The Impact of Dialysis Modality on Incidence of 2009 Pandemic H1N1 Influenza in ESRD Patients** Jang-Hee Cho,[1,4] Young-Deuk Yoon,[1,4] Ja-Yong Park,[1,4] Eun-Joo Song,[1,4] Ji-Young Choi,[1,4] Se-Hee Yoon,[1,4] Sun-Hee Park,[1,4] Chan-Duck Kim,[1,4] Jong-Won Park,[2,4] Jun-Young Do,[2,4] Duk Hyun Lee,[3,4] Sung-Ho Kim,[3,4] Yong-Lim Kim.[1,4] *[1]Nephrology, Kyungpook National University School of Medicine; [2]Nephrology, Yeungnam University Hospital; [3]Nephrology, Daegu Fatima Hospital; [4]Clinical Research Center for End Stage Renal Disease in Korea.*

**Background.** This study evaluated the effect of dialysis modality on the incidence of 2009 pandemic H1N1 influenza in ESRD patients and identified the characteristics of dialysis patients with pandemic H1N1 influenza.

**Methods.** We defined the dialysis population as dialysis patients regularly visiting three general hospitals from Sep 2009 to Dec 2009. Patient demographics and comorbidities were evaluated, with analysis of comorbidity based on the Davies comorbidity score. We surveyed clinical data derived from interviews and chart reviews for all laboratory-confirmed patients.

**Results.** As of Dec. 31, 2009, 862 dialysis patients were recruited for the dialysis population and 18 cases of pandemic H1N1 influenza were confirmed from three general hospitals. H1N1 incidence was lower in the peritoneal dialysis (PD) group (4/525, 0.8%) than in the hemodialysis group (14/337, 4.2%, $P = 0.001$). The PD group was younger (53.6 ± 14.1 vs 57.3 ± 13.0, $P < 0.001$) and had lower Davies comorbidity scores ($P < 0.001$). Patients with pandemic H1N1 influenza were younger compared to the general dialysis population (46.6 ± 14.0 vs 55.1 ± 13.8, $P = 0.010$). Fifty-six percent had more than one comorbidity and the most common symptoms were fever and cough (77.8%). All patients were treated with oseltamivir except one patient with zanamivir. 6 patients (33.3%) were admitted and the median hospitalization length was 15 days (range 2-51). The mean age (58.5 ± 10.3 vs 39.9 ± 11.5, $P = 0.004$), Davies score ($P = 0.016$), and proportion of pneumonia (50.0% vs 0.0%, $P = 0.025$) among inpatients with pandemic H1N1 influenza were higher compared to outpatients.

**Conclusion.** Incidence of pandemic H1N1 influenza in dialysis patients was lower in the PD group. Hospitalization rate in dialysis patients was associated with older age, comorbidity, and presence of pneumonia

Disclosure of Financial Relationships: nothing to disclose

## TH-PO889

**Regional Variations in Length of Time Treated with Peritoneal Dialysis (PD) in United States** Rajnish Mehrotra,[1] Kenneth Story,[2] Steven Guest,[2] Michelle Fedunyszyn.[2] *[1]LA Biomed at Harbor-UCLA, CA; [2]Baxter HealthCare, IL.*

**Background**: The length of time a patient is treated with PD (PD time on therapy, PD-TOT) can be prolonged by reducing mortality rate and transfer to HD. Thus, PD-TOT is potentially an important measure for continuous quality improvement. We tested the null hypothesis that there is no relationship between facility neighborhood characteristics and geographic location on PD-TOT, censored for renal transplantation, among new U.S. PD patients using Baxter supplies from 2004 to 2009.

**Methods**: Survival analyses were used to estimate the association of period prevalent facility census, dialysis facility zip code level neighborhood characteristics (per capita income, % household units occupied by owner, % residents > 25 yrs with high school diploma, % with college degree, % Blacks) and geographic location (End-Stage Renal Disease Network) with PD-TOT.

**Results**: Of the 62,948 eligible subjects, zip code information was available for 58,700 subjects (55% men, known diabetic, 35%). The median PD-TOT for this cohort was 24 months. Except for a small effect size of per-capita income, neither the facility neighborhood characteristics nor the period prevalent patient census were predictive of PD-TOT. PD-TOT was significantly longer for patients in Networks 14, 15, 17, and 18 but shorter for patients in Network 11 (AHR, 1.09 (1.03, 1.15)). The longest PD-TOT was for patients in Network 18 (33 months) and shortest for patients in Network 11 (20 months). The probability of < 90 d PD-TOT was lower for patients treated in Networks 13, 15, 17, and 18.

**Conclusions**: To our knowledge, this is the first study to describe that PD-TOT varies considerably by geographic location in the United States and this difference is not explained by differences in either the socio-economic characteristics of facility neighborhood, or period prevalent facility census. Investigating the reasons underlying regional differences may help identify best-demonstrated practices that could prolong PD-TOT and reduce morbidity of PD patients.

**TH-PO890**

**Association of Facility Census and Location with Transfer of Peritoneal Dialysis (PD) Patients to Hemodialysis (HD)** Rajnish Mehrotra,[1] Kenneth Story,[2] Steven Guest,[2] Michelle Fedunyszyn.[2] *[1]LA Biomed Res Inst at Harbor-UCLA, CA; [2]Baxter Health Care, IL.*

In most recent cohorts, there is no difference in the five-year adjusted survival of HD and PD patients. However, the risk of HD transfer remains high for PD patients. We tested the relationship between facility neighborhood characteristics and geographic location on risk of HD transfer among new PD patients using Baxter supplies from 2004 to 2009 (n=58,700). Survival analyses were used to estimate the association of period prevalent facility census, dialysis facility zip code level neighborhood characteristics (per capita income, % household units occupied by owner, % residents > 25 yrs with high school diploma, % with college degree) and geographic location (end-stage renal disease network) with time to HD transfer. Logistic regression was used to identify predictors of early transfers (within first 90 d). At a median follow-up of 45 months, 29% transferred to HD; 6% of all transfers were early. The overall transfer risk was significantly lower in facilities with 5-15 patients (adjusted hazards ratio (AHR) (95% confidence interval), 0.93 (0.89, 0.97)). However, there was no relationship between facility census and early transfer. There was no association between facility neighborhood characteristics and HD transfer, including early transfer. The overall risk for HD transfer was significantly lower in Networks 1, 5, 9, 10, 14, 17, and 18 but higher for patients in Network 16 (AHR, 1.10 (1.01, 1.19)). The risk for early transfer was lower for patients treated in Network 18 (adjusted odds ratio (AOR), 0.84 (0.72, 0.98)) but higher in Network 16 (AOR, 1.25 (1.06, 1.48)). To conclude, our study suggests that the relationship between risk for HD transfer and facility census may not be linear. To our knowledge, this is the first study to describe that the risk for HD transfer varies considerably by geographic location in the United States and this difference is not explained by differences in socio-economic characteristics of facility neighborhood. Investigating the reasons underlying regional differences may help identify best-demonstrated practices that could reduce transfers of PD patients to HD.

**TH-PO891**

**Determinants of Peritoneal Dialysis (PD) Uptake: Physician Bias or Renal Clinic Practice?** Jay Hingwala,[1] Jeffrey Edward Diamond,[2] Paul Klassen,[3] Manish M. Sood,[1] Claudio Rigatto,[1] Mauro Verrelli,[1] Joe A. Bueti,[1] Paul Komenda.[1] *[1]Medicine, University of Manitoba, Winnipeg, MB, Canada; [2]TRLabs, Winnipeg, MB, Canada; [3]InfoMagnetics Technologies Corporation (IMT), Winnipeg, MB, Canada.*

***Background*:** ESRD rates are rapidly increasing, placing great burdens on healthcare resources. PD as an initial dialysis modality has shown more cost effective than Hemodialysis with at least equal survival. There are relatively few contraindications limiting its use. Significant variation in PD penetration patterns exist all over the world, suggesting a complex interplay of patient, social, economical, & political factors. In Canada, the prevalence rates for PD range from 14-35%, with significant variation within the same healthcare regions. Our study attempts to isolate the effect of differing practice patterns on initiation of PD as a renal replacement therapy in Manitoba (MB).

***Methods*:** We performed a retrospective review of the MB Renal Program Database from 2004–2010 comprising over 1081 records of patients starting dialysis. We calculated rates of PD starts by individual nephrologist associated with each patient. The majority were followed in a multidisciplinary clinic. We used a propensity matched genetic algorithm to adjust the impact of nephrologist for a wide array of demographic & comorbidity factors that could influence PD suitability.

***Results*:** The overall PD prevalence in MB ranged from 18-21% annually. The rate of PD starts by individual nephrologist associated with a patient ranged from 0.16–0.46 with a mean of 0.33 ($p<0.01$). Individual nephrologist remained a significant predictor of PD uptake after propensity matching. Patients with Polycystic Kidney Disease ($p<0.02$), glomerulonephritis ($p<0.001$), younger age ($p<0.01$) & of Caucasian race ($p=0.019$) were more likely to try PD, while a history of pulmonary edema ($p<0.002$) was a negative predictor.

***Conclusion*:** In a province with universally homogenous funding models, reimbursement schemes & clinic structures, it appears that individual nephrologist bias may be a significant modifiable factor in patient uptake of PD. To grow this modality further, health policy schemes should address this with improved education & clinic processes.

**TH-PO892**

**Australian Nephrologist Survey Strongly Supports Home Therapies: Both HD and PD** John W. M. Agar, Carmel M. Hawley. *Home Dialysis Advisory Group, Kidney Health Australia, Melbourne, Victoria, Australia.*

**Background:** Australia remains significantly supportive of home-based dialysis therapies (HBDT). At 31.12.08, although 32% of all national dialysis was by HBDT (peritoneal dialysis (PD) 22% and home haemodialysis (HHD) 10%), a marked regional variation was noted in the 32 largest dialysis services, with HHD in particular varying 0% to >25%.

**Objective:** To survey Australian Heads of Units (HoU) and practicing nephrologists (PNx) regarding their attitudes to HBDT versus facility-based HD.

**Methods:** An online survey of all HoU and PNx was conducted in April 2009. 76 questions covered: unit demographics, medico/nursing staffing and respondent experience in HBDT (both PD and HHD), the current availability of HBDT training in units and unit training practices, the adequacy of facilities and support systems, the separate attitudes of respondents to recommending PD and/or HHD, and what perceived barriers might exist to inhibit any increase if the uptake of HBDT.

**Results:** 71 of ~300 known Australian nephrologists replied, representing 35% of all HoU and 16% of all PNx. Most Australian units were represented in the responses with most offering or accessing all modalities of care. In-centre HD was offered by 99% and satellite HD by 93%. Training and support was available and used for HPD (98%) and HHD (92%). 92% offered vascular access surgery and 90% Tenchkoff catheter insertion. 97% had onsite nephrology (bed mean = 15±9). 88% of all responses agreed longer-hour, more frequent HD confered an outcome advantage for HD. 93% believed this was best accomplished by HHD. PD was not considered inferior and 34% of PNx reported practicing a 'PD first' policy where possible. Social work, water, equipment maintenance and industry support was thought adequate but psychiatric support, respite care, home visits, dietitian access and concerns re patient-centric financial disadvantage for HHD were thought to be the major short-comings.

**Conclusion:** Despite long-hour HD and a further expansion of HBDT being strongly supported, HBDT is not currently proportionately expanding in Australia. This survey identified several perceived barriers to HBDT and where opportunities to expand HBDT utilisation exist.

**Telomerase Knockout Mice – A Model for Renal Transplants with Limited Regenerative Capacity** Christoph Jacobi,[1] Andrea Weißbrodt,[1] Song Rong,[2] Verena Broecker,[3] Chunfang C. Wang,[4] Faikah Gueler,[2] Anette Melk.[1] *[1]Department of Pediatric Nephrology, Hannover Medical School, Hannover, Germany; [2]Department of Nephrology, Hannover Medical School, Hannover, Germany; [3]Department of Pathology, Hannover Medical School, Hannover, Germany; [4]Institute for Ageing and Health, Newcastle University, Newcastle upon Tyne, United Kingdom.*

Objectives: Cellular senescence results in reduced regenerative ability. Telomerase (Terc) KO mice show critically short telomeres in late generations. The outcome of Terc KO kidneys in a syngeneic life-supporting transplantation (tx) model is evaluated.

Methods: Early (G1,n=9) and late (G4,n=5) generation male Terc KO kidneys were transplanted into female WT recipients with nephrectomy of both recipient kidneys (d0+d4) and sacrificed after 6 wks.

Results: Survival after transplantation was not different between the groups (G1: 8/9, G4: 5/5). G4 transplants showed significantly more interstitial fibrosis (IF) (G4: .42, G1: .22 % of tubulo-interstitial area; $p<.05$) and a tendency to more glomerulosclerosis. Markers for telomere-dependent senescence were significantly higher in G4 transplants: more H2AX positive cells (fig.1A) and higher p21 mRNA expression (fig.1B). Interestingly, $p16^{INK4a}$ mRNA expression, a marker for telomere-independent, stress-induced senescence, even though it was higher in G4 kidneys prior to tx, was not different after tx between groups (fig.1C).

Conclusions: Mild transplantation stress induced telomere-dependent and -independent senescence. This was more pronounced in G4 mice leading to increased IF, reflecting the situation of old donor transplants. The increases in $p16^{INK4a}$ seen also for G1 mice suggest that senescence can be triggered even in ideal donors. As this tx model enables us to mimic the human situation, it should be used to explore factors that reduce regeneration even in optimal transplants.

**TH-PO894**

**A Novel Clinically Relevant Strategy To Abrogate Autoimmunity and Regulate Alloimmunity** Andrea Vergani,[1] Mohammed Javeed Ansari,[2] Mohamed H. Sayegh,[1] Paolo Fiorina.[1] *[1]Childrens' Hospital-Harvard Medical School, Boston; [2]Northwestern Memorial Hospital, Chicago.*

OBJECTIVES—To investigate a new clinically relevant immunoregulatory strategy based on treatment with murine Thymoglobulin (mATG) and CTLA4-Ig in NOD mice in order to prevent allo- and autoimmune activation using a stringent model of islet transplantation and diabetes reversal.

RESEARCH DESIGN AND METHODS— Using allogeneic islet transplantation models as well as NOD mice with recent onset type 1 diabetes, we addressed the therapeutic

efficacy and immunomodulatory mechanisms associated with a new immunoregulatory protocol based on prolonged low-dose mATG plus CTLA4-Ig.

RESULTS— BALB/c islets transplanted into hyperglycemic NOD mice under prolonged mATG+CTLA4-Ig treatment showed a pronounced delay in allograft rejection compared with untreated mice (mean survival time: 54 vs. 8 days, $p<0.0001$). Immunological analysis of mice receiving transplants revealed a complete abrogation of autoimmune responses and severe downregulation of alloimmunity in response to treatment. The striking effect on autoimmunity was confirmed by 100% diabetes reversal in newly hyperglycemic NOD mice and 100% indefinite survival of syngeneic islet transplantation (NOD.SCID into NOD mice).

CONCLUSIONS— The capacity to regulate alloimmunity and to abrogate the autoimmune response in NOD mice in different settings confirmed that prolonged mATG+CTLA4-Ig treatment is a clinically relevant strategy to translate to humans with type 1 diabetes.

## TH-PO895

**Characterization of Regulatory and Effector T Cells in Renal Transplant Recipients after Induction with Thymoglobulin vs. Basiliximab: An Interim Report** Sacha A. De Serres, Bechara G. Mfarrej, Monica Grafals, Ciara N. Magee, Adam Hetland, Christine Dyer, Anil Chandraker, Nader Najafian. *Transplantation Research Center, Brigham & Women's Hospital, Harvard Medical School, Boston, MA.*

ATG (Thymoglobulin) at low, non-depleting doses, promotes expansion and *de novo* generation of human regulatory T cells (Tregs) *in vitro*. We hypothesized that ATG given at standard induction doses may also expand Tregs *in vivo* in kidney transplant recipients.

22 subjects enrolled in this ongoing, single-center, prospective, longitudinal observational study. Subjects received induction with ATG (1.5 mg/kg/day x 5 days, n=11) or basiliximab (20 mg on days 0 and 4, n=11) and were maintained on Prograf and Cellcept. Blood was collected before (n=22) and at 3 (n=21), 6 (n=19) and 12 (n=7) months after transplant. $CD4^+$ T cell subsets including $25^+Foxp3^+$ (Tregs), $45RO^+$ (memory) and $25^{hi}45RA^+31^+$ (recent thymic emigrant nTregs) were monitored by flow cytometry. Statistical analysis of absolute cell counts and ratios were performed using mixed models.

ATG led to profound depletion of $CD4^+$ (pretransplant, 3, 6, 12mo: 0.60, 0.12, 0.15, 0.20 $x10^3/\mu L$; $p<0.01$), Tregs (0.026, 0.008, 0.009, 0.009; $p<0.01$) and memory T cells (0.43, 0.09, 0.12, 0.10; $p<0.01$). In contrast, basiliximab did not cause significant depletion of $CD4^+$ (0.50, 0.49, 0.48, 0.47; $p=0.01$ *vs* ATG) or memory T cells (0.37, 0.30, 0.27, 0.25; $p=0.02$ *vs* ATG), but intriguingly led to reduction in the Treg population (0.023, 0.011, 0.014, 0.013; $p=0.22$ *vs* ATG). Thus, the percentage of Tregs among $CD4^+$ cells increased in the ATG (4.3, 6.8, 6.8, 8.0%), but decreased in the basiliximab group (4.7, 2.8, 2.9, 2.5; $p<0.04$ *vs* ATG). Over time, there was a trend towards a higher ratio of Tregs:Teffector cells with ATG (0.06, 0.10, 0.10, 0.21) compared to basiliximab (0.06, 0.05, 0.05, 0.07; $p=0.08$). There was no evidence of an increase in the thymic emigrant proportion within Tregs in either group.

These observations suggest that induction with ATG, but not basiliximab, leads to an increase in Tregs:Teffector ratio, mainly by relative Treg sparing. It further suggests that thymic output of nTregs is not affected by these drugs.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO896

**Prolonged Allograft Survival with Partial Deletion of T-bet in a Model of Chronic Rejection** Bara Sarraj,[1] Vishnupriya Samarendra,[1] Guodong Chen,[1] Omar A. Shah,[1] Zheng Jenny Zhang,[1] Mohamed H. Sayegh,[2] Mohammed Javeed Ansari.[1] *[1]Comprehensive Transplant Center, Northwestern University Feinberg School of Medicine, Chicago; [2]Brigham and Women's Hospital, Boston.*

INTRODUCTION: T-bet, which affects T helper cell differentiation, plays an important role in inhibiting proinflammatory Th17 type immune response while positively regulating Th1 immunity in a dose-sensitive manner. Reduced T-bet expression might afford protection from both Th1/Th17 mediated allograft rejection and vasculopathy, allowing long-term allograft survival and tolerance.

METHODS: We investigated graft survival and alloimmune responses in T-bet+/- recipients, with appropriate controls in an established MHC class-II mismatched (bm12 into B6) model of chronic cardiac allograft rejection, 14 days post-transplantation by multi-parameter flow-cytometry (MFC), cytokine bead array (CBA) and allograft histology.

RESULTS: Partial deletion of T-bet gene reversed the Th17 phenotype in T-bet-/- recipients and graft survival was significantly prolonged in T-bet+/- compared to WT and T-bet-/- (83%, 66%, 0% respectively; $p<0.05$). Leukocyte infiltration 14 days post-transplantation in grafts from WT, T-bet+/- and T-bet-/- recipients were of lymphocytic, mixed lymphocytic/granulocytic and predominantly granulocytic in nature, respectively. CD8 T cell infiltration and IL-17 expression in grafts is reduced in T-bet+/- compared to WT and T-bet-/-. In vitro, T-bet+/- splenocytes produced higher levels of IL-10 compared to WT and T-bet-/- (4804.3, 1834.9, 2475.3pg/ml respectively; $p<0.05$). There was a corresponding increase in IL-10 producing CD4 T cells in the grafts (5.3, 1.19, 2.14% respectively).

CONCLUSION: In a model of chronic cardiac allograft rejection, reduced, but not absent, T-bet expression promotes longer allograft survival by modulating the proinflammatory cytokine IL-17 by CD8 T cells and regulatory cytokine IL-10 production by CD4 T cells. These data suggest that strategies targeting both Th1/Th17 cytokines may prevent chronic rejection and promote tolerance.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO897

**ESRD-Related Premature Ageing of T Cells Significantly Decreases the Risk for Acute Rejection after Renal Transplantation** Michiel G. H. Betjes, Elly L. E. A. De Wit, Willem Weimar, Nicolle H. R. Litjens. *Dept of Nephrology, Erasmus Medical Center, Rotterdam, Netherlands.*

**Background:** ESRD is associated with an impaired T cell immunity which may be related to excessive premature ageing of circulating T cells. In this study the hypothesis was tested that ESRD-related premature ageing decreases the risk for acute rejection after renal transplantation.

**Patients and methods:** Prior to transplantation the circulating CD4pos and CD8pos T cells of 188 ESRD patients were analyzed for their differentiation profile using the combination of markers;CD4, CD8, CD45RO, CCR7 and CD28 . Healthy individuals matched for age, socio-economic status and CMV-seropositivity were included as controls. The basic immune suppressive drug regimen consisted of MMF, tacrolimus and prednisone. After transplantation, the patients were followed for 1-2 years.

**Results:** Forty-eight acute rejections were observed of which 95% occurred in the first year after transplantation. Overall, patients showed a significant decreased number of circulating naïve T cells and an increased terminal differentiation of memory T cells both in the CD4pos and CD8pos compartment, compatible with the notion of ESRD-related premature ageing. In many aspects, premature ageing of T cells was less or absent in rejectors. Rejectors as compared to non-rejectors, had a significantly higher number of HLA-mismatches with the donor kidney, a higher number of circulating CD4 T cells, and a lower percentage of highly differentiated CD4 and CD8 memory T cells negative for CD28. In a multivariate analysis, only HLA mismatches and the percentage of highly differentiated CD8 T cells (known as Temra cells) were significantly related to acute rejection. Patients in the lowest tertile of Temra cells had a 4-fold increased risk for acute rejection compared to patients in the highest tertile (11% versus 43 %, $p<0.01$).

**Conclusion:** ESRD-related premature ageing, specifically of the CD8pos T cells, yields significant protection against acute rejection after renal transplantation. Pre-transplantation assessment of T cell ageing offers a promising new concept for patient-tailored immune suppressive regimens.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO898

**Apoptotic Endothelial Cell Microenvironment Reprograms Macrophages into Reparative Cells** Jean-Francois Cailhier, Stephanie Lepage, Marie-Joelle Brissette. *Medicine, CRCHUM, Centre Hospitalier de l'Université de Montréal, Institut du Cancer de Montréal, Montreal, QC, Canada.*

Chronic transplant vasculopathy (CTV) is an important cause of interstitial fibrosis and tubular atrophy in the renal allograft. It is characterized by the presence of apoptotic endothelial cells (EC), which generate a microenvironment that leads to the typical myointimal proliferation found in CTV. Macrophages (Mφ) play an important role in CTV. However, the exact nature of the reprogramming induced by this microenvironment on Mφ phenotype and potential mediators responsible are ill defined.

Human umbilical vein and murine EC were serum-starved for 4 h as a model of apoptotic EC [apoptotic serum-starved conditioned medium (SSC)]. Non-apoptotic SSC was generated where apoptosis was prevented by caspase-3 inhibition prior to starvation (caspase-3 inhibitor, SSC-DEVD vs SSC-DMSO control). A proteomic approache was used to identify a secretome specific to apoptotic EC. To evaluate reprogramming, we stimulated different leukocyte subsets. Monocytes were harvested from healthy donors by Ficoll gradient and immunomagnetic selection and matured for 5-7 days to generate monocyte-derived Mφ (HMφ). HMφ and murine bone marrow-derived Mφ (MMφ) were stimulated for 24h with SSC. Cells were harvested and supernatants kept for ELISA analysis to determine cytokine/chemokine production.

We identified that milk fat globule-epidermal growth factor 8 (MFG-E8) was secreted during apoptosis. Since MFG-E8 is important in Mφ biology, we characterized it further. Immunoblotting of apoptotic EC revealed that intracellular MFG-E8 decreased overtime whilst its secretion was increased in SSC. Caspase-3 inhibition prevented MFG-E8 release. MMφ produced more TGF-β and VEGF and less MIP-2 when stimulated with SSC-DMSO compared to SSC-DEVD. HMφ generated less IL-6, IL-8 and MCP-1 when exposed to SSC-DMSO.

This study constitutes the first description of the apoptotic-dependent release of MFG-E8 by EC. It also demonstrates the importance of the apoptotic microenvironment in the reprogramming of a regulatory, pro-fibrotic Mφ phenotype. These results suggest an important contribution of Mφ in the CTV-associated fibrosis.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO899

**Partial Deletion of T-bet Favorably Modifies the Alloimmune Response in Acute Allograft Rejection** Bara Sarraj,[1] Vishnupriya Samarendra,[1] Guodong Chen,[1] Omar A. Shah,[1] Zheng Jenny Zhang,[1] Mohamed H. Sayegh,[2] Mohammed Javeed Ansari.[1] *[1]Comprehensive Transplant Center, Northwestern University Feinberg School of Medicine, Chicago; [2]Brigham and Women's Hospital, Boston.*

INTRODUCTION: T-bet, a master regulator of Th1 immune response, plays an important role in inhibiting proinflammatory Th17 immune response. As T-bet regulates Th1 response in a dose-dependent manner, reduced T-bet expression might afford protection from both Th1/Th17 mediated allograft rejection, allowing long-term allograft survival and tolerance.

METHODS: We investigated the alloimmune responses in T-bet+/- recipients in an established full MHC-mismatched (BALB/c into B6) model of acute cardiac allograft rejection, 7 days post-transplantation by multi-parameter flow-cytometry (MFC), cytokine bead array (CBA) and allograft histology.

RESULTS: Leukocyte infiltration in grafts in WT, T-bet+/- and T-bet-/- recipients were of lymphocytic, mixed lymphocytic/granulocytic and predominantly granulocytic nature, respectively. Serum TNF-a was lower in T-bet+/- and WT compared to T-bet-/- (3.2, 3.5, 10.7pg/ml; $p<0.05$). CBA analysis following in vitro allostimulation revealed, proportional increase in IL-17 and decrease in IFN-g with T-bet gene zygosity. IL-10 was preserved in T-bet+/- and diminished in T-bet-/- compared to WT (24.3, 6.9, 22.9pg/ml; $p < 0.05$). Interestingly, MCP-1, the ligand for CCR2/CCR4 important in Th17 cell and Th17-induced monocyte recruitment, was reduced in T-bet+/- recipients compared to WT and T-bet-/- (22.6, 102.9, 65.9pg/ml; $p<0.05$). MFC analysis showed a decrease in CD4 memory generation and IL-17 production by these cells in the spleen and reduced graft-infiltration of IL-17 producing CD4 and CD8 memory cells in T-bet+/- compared to WT or T-bet-/-, whereas IL-10 and Foxp3 expression in CD4 cells was preserved in T-bet+/- recipients.

CONCLUSION: Reduced expression of T-bet has multiple beneficial effects on the acute alloimmune response: reduction in IL-17 and MCP-1, restoration of IL-10 and Foxp3 expression together may contribute to immune regulation leading to reduced memory cell generation and infiltration of grafts and facilitate longer graft survival in T-bet+/- recipients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO900

**T Regulatory Cells (CD4+CD25+FOXP3+) Function in Transplant Recipients with Chronic Allograft Dysfunction** Raj K. Sharma, Sharad Mittal, Amit Gupta, Sita Naik. *Nephrology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, UP, India.*

We studied the role of CD4+CD25+FOXP3 T regulatory cells (Tregs in renal transplant patients with chronic graft dysfunction. Patients with Gr-I chronic graft dysfunction (n=20, Serum Creatinine; range 2.0 to 4.23mg/dl), Gr-II patients with normal graft function (n=20, Serum Creatinine; 0.8 to 1.5mg/dl) for >2.5 years, Gr-III healthy volunteers (n=10) were enrolled. Of 20 patients with chronic allograft dysfunction, 10 patients had evidence of immune mediated chronic rejection, post RT, 1-6 yrs and 10 had non immunological graft dysfunction (intestinal fibrosis or tubular atrophy ). CD4+CD25+FOXP3+ Tregs were enumerated by flow cytometry. CD4+CD25+ T cells (Tregs) and CD4+CD25- cells (Teffector) from PBMC of renal patients were isolated. Teff cells were stimulated with anti CD3 for 3 days and cocultured in the presense and absence of Tregs at ratios (Tregs:Teff) of 1:1 and 2:1. Proliferation was measured using the thymidine (H3) uptake. Suppression was calculated using the following formula: % suppression = [(Teff proliferation without Tregs-Teff proliferation with the Tregs)/Teff proliferation without Tregs)*100]. The median suppressive capacity of CD4+CD25+ Tregs of patients with chronic graft dysfunction (n=20) was 20.4% (range 0 to 51.29) at 1:1 ratio and 8.95% (0 to 28.5) at 2:1 ratio. This was significantly less than in patients with normal graft function at 1:1 ratio (median 66.38%; range 30.1 to 95.35; $p<0.05$) and at 2:1 ratio (23.3%; 0 to 59; $p<0.05$). Frequency of Tregs in patients with chronic allograft dysfunction (median 7.54%; range 2.61 to 15.45) and patients with normal graft function (8.21%; 3.25 to 19.1) was similar but higher than healthy control (5.53%; 3.79 to 10.79; $P<0.05$). We conclude that functionally Tregs in patients with chronic allograft dysfunction were less suppressive as compared to patients with normal graft function, However, expansion of Tregs was similar in both group of renal transplant patients with chronic graft dysfunction. Expanded Tregs with suppressive potential may be functionally important for the maintenance of the good graft function in renal transplant recipients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO901

**CXCR3+ and CCR5+ Tregs Positively Correlate with Renal Allograft Function in Patients Receiving a Tacrolimus Based Immunosuppression** Andre Hoerning,[1] Sebastian Köhler,[2] Jun Cao,[2] Jian Fu,[2] David M. Briscoe,[3] Thorsten Feldkamp,[2] Andreas Kribben,[2] Peter F. Hoyer,[1] Oliver Witzke.[2] *[1]University Hospital Essen, Pediatric II, Nephrology and Gastroenterology, University Duisburg-Essen, Essen, NRW, Germany; [2]University Hospital Essen, Nephrology, University Duisburg-Essen, Essen, NRW, Germany; [3]Transplantation Research Center, Harvard Medical School, Boston, MA.*

Background: Several chemokine ligands are expressed in allografts at early and late times post transplantation, and previous rodent studies have demonstrated that the chemokine receptors CCR5 and CCR7 play a major role in Treg cell recruitment. Here, we investigated whether the expression of the chemokine receptors CXCR3, CCR5 and CCR7 in CD4+FOXP3+ Tregs that are circulating in human peripheral blood of renal transplant patients correlate with allograft function (MDRD) up to 12 months after Tx.

Methods: Four color FACS analysis of PBMCs of 30 renal transplant recipients receiving a calcineurin inhibitor based immunosuppression for CD4, CD39, FOXP3 and CXCR3 or CCR5 or CCR7 was performed. Mean age in the studied group was 51 years (±13), mean time after Tx was 4.4 months (±3), mean cold ischemia time was 14 hrs (±6.7) and mean MDRD was 45 ml/min/1.73m2 (±11). Correlation analysis was performed with Pearson's test.

Results: The percentage of circulating CD4+FOXP3+ (6.1 ± 2.2%, n=30) or CD4+CD39+FOXP3+(1.8 ± 0.8%, n=25) Tregs did not correlate with MDRD. Among CD4+FOXP3+ cells mean expression of CXCR3 was 42 ± 7.8% (n=30), of CCR5 23 ± 9.2% (n=30) and of CCR7 20 ± 7.8% (n=30), respectively. Also, among CD4+CD39+FoxP3+ cells expression of CXCR3, CCR5 or CCR7 showed no correlation to MDRD. Subgroup analysis revealed that FOXP3+ Tregs that co-express CXCR3 or CCR5 ($r=0.72$, $p<0.01$ and $r=0.68$, $p=0.02$) positively correlated with MDRD in patients receiving tacrolimus (n=12), but not CsA (n=18). For CCR7 in both groups no correlation was found.

Conclusion: These results suggest a previously unrecognized graft-protective role of both CXCR3+FOXP3+ and CCR5+FOXP3+ Tregs circulating in the periphery of renal transplant recipients receiving a tacrolimus based immunosuppression.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO902

**Infiltrating Macrophages in Renal Allograft Glomerulitis Are Association with Peritubular Capillaries C4D Deposition** Juan Jin, Pingping Wu, Huiping Wang, Qiang He, Jianghua Chen. *Kidney Disease Center, The First Affiliated Hospital of Medical College, Zhejiang University, Hangzhou, Zhejiang, China.*

The aim of our study was to determine the amount and composition of immune cells within glomeruli and its relationship with peritubular capillaries (PTC) C4d deposition. Fifty-one biopsy specimens with acute rejection and glomerulitis were immunostained for macrophages, T cells and C4d. Gromeruli macrophages and T cells were counted and mean numbers of them per glomerulus were determined.

C4d staining was present in 26 biopsy specimens (C4d-positive [$C4d^+$] group) and negative in 25 specimens ($C4d^-$ group)**.** The total number of infiltrating cells in glomerulitis in $C4d^+$ group significantly higher than in $C4d^-$ group (17.79±7.70 vs 8.17±3.80, $P<0.0001$). Although the $C4d^+$ group showed a significantly higher mean number of macrophages per glomerulus (13.73±7.03) than in $C4d^-$ group (2.57±1.22, $P <0.0001$), the $C4d^-$ group showed a higher mean number of T cells per glomerulus (5.60±2.81) than in $C4d^+$ group (4.05±2.60, $P=0.023$). Comparing cell counts in diffuse $C4d^+$ and focal $C4d^+$ groups, a significant difference of absolute numbers of intracapillary cells could be observed in glomeruli ( 23.25±4.71 vs 14.49±6.86, $p=0.01$). The mean number of macrophages per glomerulus in diffuse $C4d^+$ group (19.62±4.97) was significantly greater than that of the focal $C4d^+$ group (9.11±4.48, $P<0.0001$). while mean T cells per glomerulus was less in cases of diffuse $C4d^+$ (3.64±1.50) than in focal $C4d^+$ glomerulitis (4.38±3.24). The differences however, did not achieve statistical significance ($p=0.74$). The total number of infiltrating cells in glomerulitis has association with PTC C4d deposition, the infiltrating cells were predominantly macrophages in $C4d^+$ group, especially in diffuse $C4d^+$ group, significantly higher than in the $C4d^-$ group. whereas, the infiltrating cells were predominantly T cells in $C4d^-$ group, greater than in $C4d^+$ group.

**Bone Marrow Derived Immature Dendritic Cells Transfected with Adenovirus Carrying IDO Gene Suppress T Cell Proliferation in Allogeneic Reaction In Vitro** Diana Vavrincova-Yaghi,[1] Maria Sandovici,[1] Marc Seelen,[2] Peter Vavrinec,[1] Harry Van Goor,[3] Robert H. Henning,[1] Leo E. Deelman.[1] *[1]Clinical Pharmacology-Experimental Pharmacology, University Medical Center Groningen, Groningen, Netherlands; [2]Internal Medicine, University Medical Center Groningen, Groningen, Netherlands; [3]Pathology and Laboratory Medicine, University Medical Center Groningen, Groningen, Netherlands.*

Background: Kidney transplantation is the treatment of choice for patients with end-stage renal disease. Because current immunosuppressive therapy is accompanied by serious side-effects, new therapies are investigated. Indoleamine 2,3-dioxygenase (IDO) is involved in maternal tolerance and prevents rejection of allografts, including the kidney. However, the mechanisms still remain unclear. Immature dendritic cells (DC), characterized by low expression of MHC II and costimulatory-molecules, play pivotal role in the induction of tolerance. The aim of this study is to investigate, whether immature dendritic cells transfected with RGD modified adenovirus carrying IDO gene (RGD-AdTIDO) are able to suppress T cell proliferation in vitro.

Methods: Immature DC, obtained from bone marrows from Brown Norway (BN) rats, were transfected with RGD-AdTIDO at day 9 after harvesting. At day 11, cells were used as stimulators in mixed leukocyte reaction (MLR) with naive Lewis rat lymphocytes as responders. DC transfected with RGD modified adenovirus carrying gene for GFP (RGD-AdTL) and mature DC were used as a control. To assess phenotype of DCs, fluorescence-activated cell sorting (FACS) was performed. The proliferation of T cells was quantified by CyQUANT Proliferation Assay kit.

Results: FACS of RGD-AdTIDO transfected DC revealed significantly decreased expression of CD11c, CD86 and MHC II molecules ($p<0.05$), compared to mature DC. In co-culture with Lewis T cells, RGD-AdTIDO transfected immature DC significantly suppressed the proliferation, compared to RGD-AdTL transfected DC and mature DC ($p<0.05$).

Conclusion: Our results show that immature DCs expressing the IDO gene effectively inhibited T cell proliferation in alloreaction, indicating a therapeutic potential for IDO in preventing transplant allograft rejection.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO904**

**The Prevalence and Clinical Significance of HLA-Cw and HLA-DP Antibodies in Sensitized Patients on the Kidney Transplant Waiting List**
Min Ling, Amy D. Lu, Daniel G. Glicklich, Graciela De Boccardo, Milan Kinkhabwala, Enver Akalin. *Montefiore Einstein Transplant Center and Renal Division, Albert Einstein College of Medicine, Bronx, NY.*

Antibodies to HLA-Cw and HLA-DP have not been studied routinely in the management of kidney transplant recipients. We have studied anti-HLA antibodies of 778 patients on the kidney transplant waiting list by Luminex PRA (Panel Reactive Antibody). While 580 patients had 0% PRA, the remaining 198 patients had PRA > 0%. The specificity of antibodies to HLA-A, B, Cw, DR, DQ, and DP were determined by Luminex single antigen beads and the strength of the antibodies by median fluorescence intensity values (MFI). Of the 198 patients, 116 were female, 82 male, 90 African-American, median age of 51 (range, 20-79), median calculated PRA 45% (range, 2-100%) and median time on the waiting list was 763 days (range, 13-8,328). While 18 patients did not have any history of sensitization, 56% had blood transfusion, 41% pregnancy and 38% previous organ transplantation. 113 patients had more than one sensitizing event and 67 had only one sensitizing event: prior transplantation (32), blood transfusion (21), and pregnancy (14).The frequency of anti-HLA antibodies to HLA-Cw (55%) and HLA-DP (35%) were lower than HLA-A (77%), -B (86%), -DR 9 (68%) and DQ (71%) ($p < 0.01$). Median MFI values of the strongest antibodies were also lower in HLA-Cw (5,547) and HLA-DP (2,752) compared to HLA-A (11,318), -B (11,497), -DR (9,033), and –DQ (9,187) ($p < 0.01$). Unacceptable antigens were reported to UNOS if the MFI values were over 5,000. The percentage of unacceptable antigens was lower in HLA-DP (33%) and HLA-Cw (53%) compared to HLA-A (76%), -B (78%), -DR (67%) and DQ (70%) ($p < 0.01$). While the risk factors for the development of anti-HLA-A and HLA-DR antibodies were blood transfusion, pregnancy and previous transplantation, only a history of previous transplantation was a risk factor for HLA-Cw and HLA-DP, but not blood transfusion or pregnancy. Our results suggest that anti-HLA-Cw and HLA-DP are lower in both prevalence and intensity compared to anti-HLA-A, B, DR, and DQ, and that prior organ transplantation is the main sensitizing event.

**The Association between CYP3A4,CYP3A5,ABCB1 Genetic Polymorphisms and Kidney Grafe Rejection, CNI Nephrotoxicity**
Chuan-Ming Hao. *Huashan Hospital, Fudan University.*

**Background** CNI(calcineurin inhibitor) is a substrate of both cytochrome P450 3A (CYP3A) and P-glycoprotein (P-gp),some of the single nucleotide polymorphisms (SNPs) in these genes are associated with interindividual variations in CNI pharmacokinetics.We studied the influence of these SNPs on the incidence of acute cellular rejection(ACR),CNI nephrotoxicity,and anti-HLA antibody and anti-MICA antibody positive,which are associated with chronic rejection. **Methods** A total of 208 renal transplant recipients receiving CNI were genotyped for ABCB1 (C1236T,G2677T/A, and C3435T), CYP3A4*18B,and CYP3A5*3 by direct sequencing method,and presence of anti-HLA antibody and anti-MICA antibody of 94 renal transplant recipients were determined by Luminex microbeads technology. Retrospective case control study was utilized to identify the association between these SNPs and CNI-related outcomes.**Results** The patients with a CYP3A4*18B/*18B genotype were found to have a higher incidence of ACR compared with those with CYP3A4*1/*1(P=0.016),as well as between the subjects with the CYP3A4*18B/5*1 AA-AA genotype and those with GG-GG genotype(P=0.046).The positive of anti-MICA antibody was higher in patients with a CYP3A4*18B/*18B or CYP3A5*1/*1 genotype compared with those with CYP3A4*1/*18B or CYP3A5*1/*3(P=0.012;P=0.002);but the positive of anti-HLA antibody and CNI nephrotoxicity were comparable in genotype groups. **Conclusions** We conclude that CYP3A4*18B/*18B and CYP3A5*1/*1 genotype predict increased risk of ACR and anti-MICA antibody positive.But the recipient's CYP3A4*18B, CYP3A5*3 and ABCB1 genotype are not the risk factor of CNI nephrotoxicity.Genetic evaluation may help to identify patients at risk and to modulate CNI therapy.

**Tolerogenic Antigen Presenting Cells (APCs) Are Responsible for Induction and Maintenance of Tolerance by ECDI-Fixed Donor Splenocytes**
Taba Kheradmand,[1] Xun-Rong Luo.[1,2] *[1]Comprehension Transplant Center, Northwestern University Feinberg school of Medicine; [2]Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL.*

**Background** Previously we showed that infusion of BALB/c splenocytes chemically fixed with ethylcarbodiimide (ECDI) induces indefinite protection of islet allografts in diabetic C57BL/6 mice. **Material and Methods** Diabetic B6 mice were transplanted with BALB/c islets on day 0. 1x108 ECDI-treated donor splenocytes were injected on day -7 and +1. **Results** Splenectomized mice that were treated with ECDI-fixed splenocytes rejected their grafts, suggesting that the spleen is obligatory for tolerance induction. Injection of LPS activated recipient DCs pulsed with donor lysates abrogates tolerance induction. In tolerized mice, TCR transgenic TEa CD4 T cells showed initial vigorous proliferation in the spleen in response to alloantigen-loaded APCs followed by profound depletion in numbers. The remaining cells were sequestered in the spleen. In contrast, in non-tolerized hosts these cells traffic to the dLNs following significant proliferation, and persisted in numbers. During tolerance maintenance, mice nephrectomized and re-grafted with islets from the same donor were able to retain the second graft if re-transplanted immediately or up to 30 days post nephrectomy, but not later. Skin transplants from the same donor but not third party were able to break established tolerance, as were LPS-activated donor DCs. T cells from tolerized hosts were able to reject same donor islets in RAG-/- hosts. **Conclusions** Depletion and sequestration of alloreactive T cells in response to alloantigen-loaded APCs in the spleen is a mechanism for tolerance induction. Tolerance maintenance requires persistence of alloantigen and can be overcome by activated APCs. Collectively these data supports a role of tolerogenic APCs for controlling allo-specific T cells in this regimen.

**Temporally Mediated Abrogation of T Cell Receptor Signals Alters CD8 Memory T Cell Differentiation**
Jonathan S. Maltzman,[1] Evann Corbo,[1] E. John Wherry,[2] Karla Wiehagen.[1] *[1]Department of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Department of Microbiology, University of Pennsylvania, Philadelphia, PA.*

Memory T cells are a barrier to successful solid organ transplantation. The need for persistent signaling through the T cell receptor (TCR) during memory T cell differentiation is unclear. In contrast to signals generated by MHC plus antigenic peptide that result in an immune response to pathogen, the "tonic" TCR-generated signals are weaker and generated by interaction with MHC:self-peptide. The SH2-domain-containing phosphoprotein of 76 kilodaltons (SLP-76) adaptor protein is critical for proximal TCR-generated signaling. To assess CD8 memory T cell generation, we ablate TCR signals through conditional deletion of SLP-76 in antigen-specific memory T cells. Specifically, mice were infected with lymphocytic choriomeningitis virus (LCMV) Armstrong strain, SLP-76 was deleted ten or thirty days following infection. LCMV-specific CD8 T cells are identified using H-2Db:GP33 tetramer staining and deletion is monitored using the ROSA26R-EYFP Cre reporter. Deletion during the contraction phase of the immune response shifts the response to one that favors memory precursor formation based on cell surface expression of KLRG-1 and IL7Ra. By delaying deletion until thirty days after infection, we allow normal generation of the CD8 memory T cell compartment. Abrogation of tonic TCR signals during the memory phase does not alter the ability to form an antigen-specific central memory compartment. Interestingly, the shift from predominantly effector memory to central memory occurs more rapidly than in control mice. Taken together, these data indicate that normal CD8 memory T cell differentiation requires tonic TCR signals throughout both the contraction and memory phases of an immune response and have applicability in development of vaccines and transplant immunosuppression.

**Renoprotective Effects of Green Tea Extract on Renin Angiotensin Aldosterone System in Chronic Cyclosporine Treated Rats**
Byung Chul Shin,[1] Jung Hoon Chung,[2] Hyun Lee Kim.[3] *[1]Internal Medicine, Seonam University Namgwang Hospital, Gwang-ju, Republic of Korea; [2]Internal Medicine, Chosun University Hospital, Gwang-ju, Republic of Korea; [3]Internal Medicine, Chosun University Hospital, Gwang-ju, Republic of Korea.*

**Purpose:** Cyclosporine A (CsA) is a potent and effective immunosuppressive agent, but use is frequently accompanied by severe nephrotoxicity. Renin angiotensin aldosterone system (RAAS) activation plays an important role in CsA nephropathy. For the aims we tested whether the administration of green tea extract (GTE) prevents the development of CsA-induced nephrotoxicity and found its mechanisms. **Method**: The rats were treated for 21 days and divided into 4 groups (n=6/group): control group (0.9% saline injection), CsA group (30 mg/Kg/day by intraperitoneal injection), CsA-GTE group (CsA plus GTE 100mg/Kg/day subcutaneous injection), GTE group (GTE alone). **Results:** There were significant increased serum blood urea nitrogen and creatinine in CsA group compared with that of control group and significantly improved in CsA-GTE group compared with that of CsA group ($p<0.01$). Biochemical analysis showed that the plasma renin activity and serum concentration of aldosterone were significantly increased in CsA group compared with control group and significantly decreased in CsA-GTE group compared with CsA group ($p<0.05$). Total amount of renin protein expression was significantly higher in the CsA group than in the control group and was lower in the CsA-GTE group than that of CsA group ($p<0.05$). In the histologic examination, there were proximal tubular necroses and mild interstitial inflammation in the kidneys of rats in CsA group but no significant pathologic changes in CsA-GTE group. **Conclusion:** CsA-treatment increases the plasma renin activity and intrarenal renin levels and induces the nephrotoxicity. The protective effects of GTE on CsA-induced structural and functional alternations of the kidney may be blockage of RAAS.

**The Association of IL-2/IL-2Rβ Genetic Polymorphisms with Acute Renal Allograft Rejection in Korean Population** Seok Ju Park,[1] Hyun Seung Lee,[1] Sunwoo Kang,[1] Yang Wook Kim,[2] Tae Hee Kim,[1] Miseon Kang,[3] Sang Seop Lee,[4] Yeong Hoon Kim.[1] *[1]Internal Medicine, Busan Paik Hospital, Busan, Republic of Korea; [2]Internal Medicine, Haeundae Paik hospital, Busan, Republic of Korea; [3]Pathology, Busan Paik Hospital, Busan, Republic of Korea; [4]Phamacology and Phamacogenomics Research Center, Busan Paik Hospital, Busan, Republic of Korea.*

Background: Advancement of immunosuppressive therapy has improved the allograft survival in patients undergone transplantation surgery. However, acute rejection (AR) of transplanted allograft in certain subgroup of patients still remains a major obstacle to overcome. The occurrence of acute rejection shows inter-individual variation and genetic make-up of patients may contribute to higher risk of AR. Since interleukin 2 (IL-2) plays a key role in immune modulation and target pathway to immunosuppressive therapy, the effect of genetic polymorphisms of IL-2 and IL-2 receptor beta (IL-2Rβ), two key molecules of IL-2 signal pathway, on renal AR risk was investigated in 337 Korean kidney transplant recipients.

Methods: Common haplotype tagging SNPs in IL-2 and IL-2Rβ genes were genotyped by polymerase chain reaction followed by restriction fragment length polymorphism in 61 AR patients and 276 control renal allograft recipients.

Results: All of four tagging SNPs of IL-2 and IL-2Rβ genes showed Hardy-Weinburg equilibrium in both AR and control groups. The occurrence of AR was significantly associated with the presence of allelic variation of IL-2Rβ gene ($P$=0.016). Genetic variations of IL-2 gene also showed tendency of AR association, but could not reach statistical significance. When haplotype distribution was tested for the association, both IL-2 and IL-2Rβ genes showed significant association with AR risk.

Conclusion: Our results demonstrate that genetic variations of IL-2Rβ and IL-2 genes are associated with the development of acute rejection. Though further confirmative evidence will be required, our data suggest that genotyping of these genes may help predict AR risk in kidney transplantation patients.

**Remote Ischemic Preconditioning Using the Hind Limb Protects Against Renal Ischemia Reperfusion Injury** Kimberley E. Wever,[1,2] M. C. Warle,[1,3] Frank Adtg Wagener,[1,2] Rosalinde Masereeuw,[1,2] Gerard Rongen,[1,2] J. Adam Van der Vliet.[1,3] *[1]Radboud University Medical Centre; [2]Dept. of Pharmacology & Toxicology; [3]Dept. of Surgery.*

Remote ischemic preconditioning (RIPC) is a strategy to protect a target organ against ischemia/reperfusion injury (IRI) by inducing brief ischemia/reperfusion (I/R) in a remote organ. RIPC of the kidney by brief I/R of a limb would be a safe, cheap and non-invasive method to prevent renal IRI in e.g. transplantation and aortic surgery. We investigated the optimal remote ischemic stimulus in the hind limb to protect the kidney against IRI. Anesthetized rats underwent either no RIPC, unilateral RIPC (one limb) or bilateral RIPC (both limbs). Limbs were occluded using a 1.9cm blood pressure cuff. The preconditioning stimulus was either continuous (12'/12' I/R), or fractionated (3 times 4'/4' I/R). After the last reperfusion period, we induced 25' ischemia in the right kidney and the left kidney was nephrectomized. Renal damage was assessed after 48h of reperfusion. Plasma creatinin and urea were improved in both bilateral RIPC groups and in the fractionated unilateral group. Kidney injury molecule-1 (KIM-1) mRNA was reduced in the unilateral continuous and bilateral fractionated RIPC groups. Renal damage, as scored in histological sections of the cortex, was reduced 3 out of 4 RIPC groups. Notably, the persisting residual injury provides opportunities to further enhance RIPC pharmacologically. In conclusion, we found that RIPC using the hind limb as remote organ reduces renal IRI, making it a promising tool to prevent renal damage. Bilateral RIPC appeared to be more effective than unilateral RIPC, and fractionated RIPC appeared to be more effective than continuous RIPC.

**Cold Preservation of Kidneys from Hibernating Squirrels** Alkesh Jani, Jessica Martin, Elaine Epperson, Kultigin Turkmen, Arijana Pacic, Danica Ljubanovic, Sandy Martin, Charles L. Edelstein. *U of Colorado.*

We have shown that cold ischemia (CI) results in increased caspase-3 activity, tubular apoptosis, and brush border injury (BBI) in mouse kidneys. The 13-lined ground squirrel (GS) is a hibernating mammal that undergoes alternating periods of *torpor* when core body temperature (CBT) is very low at 4C for 7-18 days, followed by re-warming during *interbout arousal* (IBA) when CBT rises to 37C for 12 hrs. These cycles occur >15 times each winter. Since IBA is preceded by a prolonged period of CI during torpor, we hypothesized that kidneys from IBA animals would better tolerate *ex vivo* CI than kidneys from non-hibernating summer ground squirrels.Methods Radiotelemeters were implanted in 1-2 yr old GS, and CBT was remotely monitored. The kidneys of 1-2 year old summer and IBA GS were perfused with cold University of Wisconsin (UW) solution. The right kidney was used as a control and the left kidney was stored *ex vivo* in UW for 72 hours at 4C. Tubules with BBI and apoptotic cells/hpf were counted. Caspase-3/7 activity was measured using fluorescent substrates.Results(Table): Caspase-3/7 activity was significantly greater in IBA vs summer kidneys after 72 hrs of *ex vivo* CI. Neither the number of apoptotic cells/hpf nor the BBI score differed significantly between IBA and summer kidneys at 72 hrs of ex *vivo* CI. The levels of apoptosis and BBI in all animals were extremely low. Conclusion Squirrel kidneys have markedly less apoptosis and BBI on cold preservation compared to what we have previously reported in mouse kidneys. Both summer and IBA animals were protected from *ex vivo* apoptosis and BBI. IBA animals had significantly greater caspase-3/7 activity after 48 hrs of CI but this did not result in more apoptosis or BBI, suggesting resistance to caspase-mediated injury. These results indicate that the ability to tolerate severe, prolonged CI is present year-round, as opposed to being specifically induced during hibernation.

| | Apoptosis (cells/hpf) | | BBI score | | Caspase-3 activity (nmol/min/mg) | |
|---|---|---|---|---|---|---|
| | 0 hr CI | 72 hr CI | 0 hr CI | 72 hr CI | 0 hr CI | 72 hr CI |

**Preconditioning with Immunosuppressive Drugs to Donors in Renal Transplant Attenuates Ischemia Reperfusion Injury and Downregulates Local Immflamatory Markers** Federico Cicora,[1,] Diego Guerrieri,[1,2] Natalia Lausada,[1] Pablo Stringa,[1] Paola Cicora,[1] Daniela Vasquez,[1] Gustavo Palti,[1] Pedro Gonzalez,[1] Eduardo Chuluyan,[2] Clemente Raimondi.[1] *[1]Fundacion para la Investigación y Asistencia de la Enfermedad Renal, La Plata, Argentina; [2]Departamento de Farmacología, Facultad de Medicina, UBA, Buenos Aires, Argentina.*

Isogenic renal transplant (IRT) in rats is the most widely used model for the study of non-immunological damage factors. Our aim was to determine if the administration of immunosuppressive drugs to donors modify the IRI process. **Materials and methods**: IRT was performed in 18 rats. Donors were untreated (Group 1) or treated with 2 mg/kg Rapamycin (Group 2) or 0,3 mg/kg Tacrolimus (Group 3), 6-12 hs before the rats were sacrificed. Then, donor left kidney was removed washed and stored (3 hs, 4ºC). Grafts were implanted after a bilateral nephrectomy of the receptors. A Sham Group (n=6) was also assessed. Plasma urea and creatinine determinations are shown as the difference before and after the transplant. Histological samples were analyzed for tubular injury and apoptosis. TNF-a, IL-6, IL-17, IL-21 receptor and C3 *in situ* expression were measured by immunohistochemistry. **Results:** A decrease in plasma urea (G1=2,2±0,06; G2=1,9±0,06; G3=1,5±0,06 mg/dl) and creatinine (G1=4,7±0,55; G2=2,1±0,04; G3=2,0±0,13) were observed for treated rats (G1vsG2 p<0,05; G1vsG3 p<0,01 for urea and creatinine). Less damage was also observed among the control and treated groups (G1vsG2 p<0.01 and G1vsG3 p<0,05). Remarkably, less apoptotic nuclei were observed in G2 (22±1.8) and G3 (60±13) compared to G1 (140±10); G1vsG2 p<0.01 and G1vsG3 p<0.05. The cortex and medulla tubular epithelium expression of pro-inflammatory markers C3, IL-6, TNF-a and IL-21 receptor but not IL-17 was increased in G1 compared to G2 or G3. **Conclusion:** administration of Rapamycin or Tacrolimus to donors attenuates the IRI process in kidney transplant. We suggest that isogenic renal transplant is a pro-inflammatory process and induces a potent IRI. The decrease expression of IL-6 and IL-21 receptor in situ, both related to Th17 differentiation, might generate a hostile environment to Th17 differentiation.

**TH-PO913**

**Association of Specific HLA Alleles with the Risk of High PRA and Acute Rejection in Kidney Allograft Recipients** Nilgun Kacak,[1] Krzysztof Kiryluk,[1] Eric K. Ho,[2] Nicole Suciu-Foca,[2] David J. Cohen,[1] Ali G. Gharavi.[1] *[1]Medicine, Div. of Nephrology, Columbia University, New York; [2]Pathology and Cell Biology, Div. of Immunogenetics, Columbia University, New York.*

Objective: To determine the impact of HLA antigens on the Panel Reactive Antibody (PRA) levels and the risk of biopsy proven acute rejection in kidney allograft recipients.

Methods: We analyzed 705 kidney allograft recipients including 336 (47.7%) Caucasians, 200 (28.4%) Hispanics, 115 (16.3%) Blacks, and 40 (5.7%) Asians transplanted at our medical center. HLA alleles were determined by tissue typing. We analyzed the association of HLA types with PRA levels stratified by ethnicity and adjusted for known risk factors (prior pregnancies, transfusions, and previous transplants). We also analyzed the association of HLA alleles with the risk of acute rejection adjusted for HLA mismatch, high PRA titers, pregnancies, transfusions, prior transplants, and ethnicity. Multivariate analyses were performed using logistic regression (SPSS v.17.0).

Results: The cohort characteristics included: mean age 46 (range 5-84); male-female ratio 1.5, average follow-up time 6.6 (+/-5.8) years. During the follow-up period, 214 (30.4%) of patients were diagnosed with acute rejection by biopsy. Pre-transplant PRA levels were high (>30) in 79 (11.2%) patients, with a notable trend for greater frequency in Blacks (16.5% vs. 10.5% in non-Blacks, p=0.066). After multivariate adjustment, HLA alleles that were associated with high PRA included HLA-A66 (p=0.007) and HLA-DR9

(p=0.0004). The HLA-A66 association was strongest in Whites (p=0.018), while HLA-DR9 in Blacks (p=0.009). In the analysis of acute rejection, we detected an association with increased risk for HLA-DR3 (OR=1.9, 95%CI: 1.04-3.7, p=0.039), B52 (OR=2.3, 95%CI: 1.05-5.1, p=0.036), and B81 (OR=5.33, 95%CI: 1.03-27.6, p=0.046). In addition, we replicated a previously reported protective effect of HLA-DR1 on rejection (OR=0.55, 95%CI: 0.33-0.92, p=0.023).

Conclusions: Distinct HLA alleles influence the risk of high PRA and acute rejection independently of the known risk factors. These data may help to identify individuals at high risk of developing elevated PRA or acute rejection.

**Long Term Gene Therapy with Thrombospondin 2 Is Anti-Inflammatory but Increases Capillary and Lymphatic Vessel Rarefaction during Chronic Allograft Nephropathy in the Rat** Christoph Daniel,[1] Regina Vogelbacher,[1] Andrea Stief,[1] Christian Hugo.[2] *[1]Nephrology and Hypertension, University of Erlangen-Nürnberg, Erlangen, Germany; [2]Nephrology, University of Dresden, Dresden, Germany.*

We recently identified Thrombospondin-2 (TSP-2) as a regulator of matrix remodelling and inflammation in experimental kidney disease by using TSP-2 null mice or TSP-2 overexpression. In this study we investigated if long term TSP-2 overexpression is also capable to ameliorate the progression of a chronic kidney disease using the chronic allograft nephropathy (CAN) F344-Lewis model in the rat.

Two weeks after renal transpantation rats were transfected with either a TSP-2 overexpressing plasmid (n=8) or a luciferase-expressing plasmid as control (n=8). Rats were monitored for renal function and histological changes in the graft using immunohistochemistry 30 weeks after transplantation. Surprisingly, only in the TSP-2 treated group 2 rats died before the end of the experiment. Renal function tended to be worsened in the TSP-2 group compared to the luciferase-treated controls. In addition, glomerular sclerosis (score:1,9±0,6 vs. 1,3±0,3) and tubular interstitial injury (score: 2,2±0,7 vs. 1,2±0,3) as well as cortical fibronectin deposition (score: 2,2±0,4 vs. 1,5±0,2) was significantly increased in the TSP-2 treated kidneys. Long term TSP-2 therapy impaired repair of renal endothelium, as demonstrated by significant higher glomerular (% pos. area: 7,5±2,3 vs. 18,6±7,5) and peritubular (score: 49,6±4,3 vs. 62,4±4,5) endothelial rarefaction in the transplanted kidneys from TSP-2 treated rats compared to controls. Furthermore, number of lymphatic vessels, as assessed by podoplanin staining, was significantly reduced in TSP-2 treated rats compared to luciferase-treated controls.

In contrast, renal inflammation was significantly ameliorated in the TSP-2 treated group, as assessed by counting macrophages, CD8 positive T-cells and CD45R positive B-cells reaching reduction rates from 31% up to 68%. In conclusion, despite its anti-inflammatory effects, TSP-2 gene therapy did not ameliorate but rather worsened experimental CAN most likely via increased capillary and lymphatic vessel rarefaction.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO915**

**Loss of Peritubular Capillaries Induced by Renal Ischemia Reperfusion Injury Is Associated with a Dysbalance of Angiopoietins and a Loss of Pericytes** Meriem Khairoun,[1] Pieter van der Pol,[1] Hetty C. de Boer,[1,2] Kyra A. Gelderman,[1] Nicole Schlagwein,[1] Dorottya De Vries,[3] Ellen Lievers,[1] Cees van Kooten,[1] Ton J. Rabelink,[1,2] Anton Jan Van Zonneveld,[1,2] Marlies Reinders.[1] *[1]Nephrology, LUMC; [2]Einthoven Laboratory for Experimental Vascular Research, LUMC; [3]Surgery, LUMC, Leiden, Netherlands.*

Introduction: Peritubular capillaries (PTCs) are highly susceptible to ischemia reperfusion injury (IRI) after renal transplantation. This microvascular injury contributes to graft dysfunction and ultimately graft loss. Pericytes play a critical role in the stabilization and proliferation of endothelial cells (ECs). This process is mediated by angioregulatory factors, including the anti-inflammatory factor Angiopoietin-1 (Ang-1) produced by pericytes and the proinflammatory factor Angiopoietin-2 (Ang-2) produced by ECs. Here, we investigated the impact of IRI on pericyte and angiopoietin expression.

Methods: Male Lewis rats (n=6 per group) were subjected to 45 minutes of unilateral renal ischemia followed by removal of the contralateral kidney and sacrificed at 2, 5, 24, 48 and 72 hr after IRI. Leukocyte infiltration (CD45), EC integrity (RECA-1), pericytes (NG2), Ang-1, and Ang-2 were measured and quantified using immunohistochemistry. Sham operated rats and contralateral kidneys served as control.

Results: Our study shows a significant loss of PTCs after IRI in the cortex after 24 hr ($p< 0.05$) and an increase of infiltrating leucocytes after 48 hr ($p< 0.05$). Furthermore, we found a decrease in pericytes at 5 hr, reaching significance at 48 and 72 hr after IRI ($p< 0.05$). This was accompanied by a reduction in Ang-1 after 24 hr and remained decreased up to 72 hr ($p< 0.001$). In contrast, Ang-2 increased after 24 hr ($p< 0.01$) and remained elevated up to 48 hr ($p< 0.05$) after IRI.

Conclusions: Our results demonstrate that decrease in PTCs induced by renal IRI is associated with a dysbalance of angiopoietins and a loss of pericytes. Since pericytes and angiopoietins are considered as important hallmarks of microvascular integrity, strategies to counteract microvascular destabilization after IRI may well improve long term graft function.

**Pharmacodynamic Monitoring of mTOR-Inhibitor Based Immunosuppression in a Cell Culture Model: Establishment of a Novel ELISA Method for Quantitative Assessment of phospho-p70 S6K** Bertram Hartmann,[1] Xuemei He,[1] Frieder Keller,[1] Michael Fischereder,[2] Holger Schmid,[2] Markus Guba.[3] *[1]Medical Department I, Section of Nephrology, Ulm University, Ulm, Germany; [2]Medical Department I, Section of Nephrology, Munich University Hospital, Campus Grosshadern, Munich, Germany; [3]Department of Surgery, Munich University Hospital, Campus Grosshadern, Munich, Germany.*

Background

Rapamycin is a critical dose drug with a low therapeutic index. Current pharmacokinetic monitoring may not correlate with the pharmacological effects of rapamycin on immune cells. Semiquantitative Western blot analysis has been used to investigate the immunosuppressive properties of rapamycin by assessing phosphorylation status at the Thr 389 site of the p70 S6 kinase (phospho-p70 S6K) a downstream effector of mTOR. A pharmacodynamic approach by quantitative assessment of phospho-p70 S6K via ELISA-technique might provide a novel and clinically feasible way to directly analyze the effects of rapamycin.

Methods

Phosphorylation status of p70 S6K was analysed in a cell culture model (Jurkat cells and PBMCs from buffy coats) before and after stimulation with the phorbol-ester PMA. Phospho-p70 S6K expression was measured by (i) semiquantitative Western blot analysis, recognizing both isoforms of S6 kinase1 (p70 S6K and p85 S6K) and (ii) a newly established ELISA based assay.

Results

Average levels of phospho-p70 S6K were increased after PMA-stimulation in Jurkat cells (unstimulated 4.18 vs. stimulated 7.65 U/100 µg protein) and in PBMCs (3.09 vs. 12.39 U/100 µg protein). We found an obviously dose-dependent down-regulation of phospho-p70 S6K induced by rapamycin in PMA-stimulated PBMCs ($n = 20$, $P< 0.05$), which was not statistically significant in unstimulated PBMCs.

Conclusions

Here we successfully established a novel ELISA-based method, which allowed reproducible quantitative measurement of phospho-p70 S6K in an in vitro model. Large scale studies have now to demonstrate, that this ELISA assay is capable to optimize immunosuppressive therapy.

**Human Polyomavirus BK-Encoded microRNA Suppresses p53 and p21 Expressions and Maintains Host Cell Survival** Ya-Chung Tian, I.-Jung Li, Cheng-Hao Weng, Hsin-Hsu Wu, Yung-Chang Chen, Cheng-Chieh Hung, Chih-Wei Yang. *Nephrology, Lin-Kou Chang-Gung Memorial Hospital, Taiwan.*

**Background** Polyomavirus BK (BKV) infection has been identified as an important cause of early renal transplant graft failure. Following primary infection, BKV remain latent in host cells through regulating host cell cycles. Various viral microRNAs have been shown to be capable of controlling post-transcription gene expression in host cells. The aim of this study was to determine whether BKV microRNA could regulate host cell cycle.

**Method** A fragment of BKV genome, including candidate encoded microRNA (miR-B1) and its flanking regions, was cloned into expression vectors. Following transfection of renal proximal tubular cells, HK-2, with miR-B1 for 24 hr, real-time PCR using stem-loop primers was utilized to assess miR-B1 expression.

**Results** Transfection of HK-2 cells with pre-miR-B1 expression vector successfully produced mature miRNAs assessed by real-time PCR. p53 transcripts contain a match to miR-B1. We generated a luciferase-reporter containing entire p53 3'-UTR. Dual luciferase assay revealed that miR-B1 suppressed luciferase activity of this p53-3' UTR reporter in comparison with the control vector. In addition, miR-B1 overexpression reduced endogenous p53 protein level measured by Western blot analysis in a dose-dependent manner. Similarly, miR-B1 also suppressed p21 protein expression. These suggest that miR-B1 can suppress p53 and p21 expression, therefore potentially driving cell cycle progression. Furthermore, administration of cisplatin (5 mM) led to an increase in p53 protein expression. Overexpression of miR-B1 suppressed cisplatin-induced p53 and p21 expression. Finally, miR-B1 overexpression also attenuated cisplatin-mediated inhibition of cell proliferation determined by BrdU immunostaining.

**Conclusion** Our findings showed that the BKV-encoded miRNA, miR-B1, suppressed p53 and p21 protein expressions and attenuated cisplatin-mediated inhibition of cell proliferation. Since p53 can promote apoptosis, the inhibition of host p53 production may prevent host cells from apoptosis, thus benefiting viral survival and providing a long latency.

**Surrogates, Predictors and Outcomes in Renal Transplantation (*Sports*) Study – Rationale and Design** Adekunle Bamidele Adesina, Christopher Edwards, Andrew J. Williams, Jonathan Bailey. *Renal Unit, Morriston Hospital, Swansea, United Kingdom.*

**Rationale**

The optimal immunosuppressive therapy of posttransplant patients requires a delicate balance of prevention of rejection whilst minimising complications. Clinicians rely on monitoring of clinical signs, drug lvels, and routine laboratory parameters to guide treatment decisions. A combination of immune parameters may allow early detection and adequate prediction of likelihood competing long-term outcomes including rejection, tolerance, infection and malignancy.

**Purpose of study:** To determine a reliable and valid composite index of immune status manging renal transplant patients.

**Methods:** Systematic review of published studies of asessment of immune status in relation to renal transplant outcomes, followed by statistical analysis to determine the most valid and reliable predictive assays, and then conduct a prospective trial of a candidate multiparameter composite index of immunosuppression.

**Results** Our on-going review of the literature identified forty-three (43) published studies in which posttransplant immune status was assessed as a means of profiling recipients' likelihood of developing either rejection, tolerance, infections or malignancy in the post transplant period. Seventeen (17) different cellular/cytokine and antibody-based immune assays were found, of which only one cellular assay, which is rather non-transplant-specific has been approved by the FDA for routine use in posttransplant immune monitoring.

**Conclusion**: The growing body of research data on parameters for monitoring posttransplant immune status indicate clinician interest in more relaible and scientifically valid tools for tailoring immunosuppression. Although several urine and serological assays are predictive of transplant outcomes of interest, only one has been formally approved for routine use. We are now computing a novel composite assay of postransplant immune status based on both humoral and cellular parameters that are scientifically sound surrogates and predictive of transplant outcomes. We are also designing a prospective study to assess the feasibility, validity and clinical utility of the composite index of post transplant immune status.

**TH-PO919**

**HLA-DR$^+$-Regulatory T Cells Are Involved in the Induction of Preterm Labor during Pregnancy and in the Induction of Organ Rejection after Transplantation** Matthias Schaier,[1] Nicole Seissler,[1] Friederike Hug,[1] Luis Eduardo Becker,[1] Martin G. Zeier,[1] Andrea Steinborn.[2] *[1]Department of Nephrology, University of Heidelberg, Heidelberg, Germany; [2]Department of Obstetrics and Gynecology, University of Heidelberg, Heidelberg, Germany.*

Regulatory T cells (Tregs) were shown to suppress alloimmune responses after organ transplantation and are known to be of substantial importance for the induction of maternal tolerance towards the fetal antigens during pregnancy.

We assessed the percentage of CD4$^+$CD127$^{low+/-}$CD25$^+$-Tregs and a FoxP3$^+$DR$^+$-Treg subset in healthy volunteers, in healthy and preterm-laboring pregnant women and in kidney transplant patients with stable transplant function or acute rejection. In addition, the suppressive activity of CD4$^+$CD127$^{low+/-}$CD25$^+$-Tregs was tested by co-culture suppression assays.

In comparison to healthy volunteers, the total number of CD4$^+$CD127$^{low+/-}$CD25$^+$-Tregs was significantly decreased, both during the normal course of pregnancy and after successful kidney transplantation. It was decreased in neither preterm-laboring women nor in kidney recipients with acute rejection. In analogy, the percentage of the FoxP3$^+$DR$^+$-Treg subpopulation decreased during the normal course of pregnancy and was also not diminished in preterm-laboring women or in transplant patients showing acute rejection. However, the HLA-DR expression of the FoxP3$^+$DR$^+$-Treg cells was significantly reduced, both in preterm-laboring women and in kidney transplant patients with acute rejection. This weak expression of HLA-DR ex vivo points to a reduced suppressive potency of the FoxP3$^+$DR$^+$-Treg subset under these conditions. Interestingly, the suppressive activity of the CD4$^+$CD127$^{low+/-}$CD25$^+$-Tregs, isolated from the same preterm-laboring women and transplant patients with acute rejection, was significantly decreased.

Hence, our results propose that the FoxP3$^+$DR$^+$-Treg subset may essentially contribute to the suppressive activity of the total CD4$^+$CD127$^{low+/-}$CD25$^+$-Treg cell pool and that the immunologic mechanisms leading to preterm labor may be similar to those leading to acute rejection after organ transplantation.

**TH-PO920**

**Bortezomib for Desensitization of Patients in Awaiting List for Deceased Donor Kidney Transplant: Experience in Mexico City** Sergio A. Leyva Campillo, Lluvia A. Marino-Vazquez, Luis E. Morales-Buenrostro. *Nephrology, INNSZ, Mexico City, DF, Mexico.*

Introduction:

In our experience for acute humoral rejection, the use of 4 doses of bortezomib in days 1, 4, 7, and 10 (1.3 mg/m2 BSA each) plus 3 plasmapheresis (PP) sessions produced both: a good clinical response and a reduction in DSA. In this report, we showed our experience using this treatment for desensitization.

Patients and Methods:

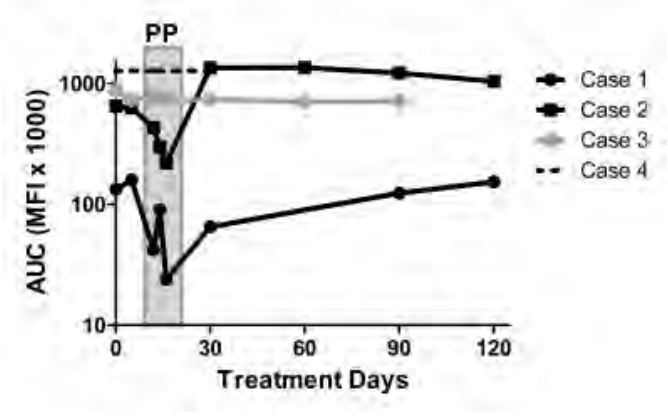
Four adult patients in the awaiting list for deceased donor kidney transplant underwent desensitization protocol with Bortezomib (1.3mg/m2 BS, days 1,4,7,10) + Plasmapheresis (PP) with or without rituximab in 3 patients and only bortezomib in 1 case. Pre and posttreatment sera samples were tested by Luminex Single Antigen assay, and the change in mean fluorescence intensity (MFI) for all specificities was analyzed with Area Under Curve (AUC) to examine the changes in antibody levels and to evaluate the efficacy of the treatments. Patients with pretreatment antibodies of MFI great than 10,000 at neat were further tested at 1:8 and 1:32 dilutions.

Results:

In 2 of the 4 patients, antibody reduction from pre to post treatment was observed but only after PP, but returned to baseline level early after treatment (figure). In those non-responders, a further dilutions analysis showed a transient reduction of antibody levels after PP.

Conclusions:

In highly sensitized patients, the use of Bortezomib for desensitization is not as effective as it was for acute humoral rejection. It has been suggested that long living plasma cells (probably the main cells in our cases) are not susceptible to Bortezomib. This result must be confirmed with larger studies. Testing the sera at dilution may aid in a more accurate assessment of antibody removal in those patients.



Disclosure of Financial Relationships: nothing to disclose

**TH-PO921**

**Effect of Proteasome Inhibition by Bortezomib on HLA-Antibody Titers and Specificity in Sensitized Patients Awaiting Renal Allograft Transplantation** Martina Guthoff,[1] Barbara Schmid-Horch,[2] Katja C. Weisel,[3] Nils Heyne.[1] *[1]Dept. of Diabetes and Endocrinology, Angiology, Nephrology and Clinical Chemistry, University of Tuebingen, Tuebingen, Germany; [2]Center of Clinical Transfusion Medicine, University of Tuebingen, Tuebingen, Germany; [3]Dept. of Hematology, Oncology and Immunology, University of Tuebingen, Tuebingen, Germany.*

Sensitization to human leukocyte antigen (HLA) prolongs waiting list time and reduces allograft survival in organ transplantation. Current antibody depleting strategies include B-cell directed therapy and extracorporeal techniques. Considerable interest has arisen from initial reports using the proteasome inhibitor bortezomib in antibody mediated rejection, in addition to standard therapy. Potential benefits include direct targeting of the antibody producing plasma cell and memory B-cells with alteration of donor specificity. We report bortezomib preconditioning in sensitized patients awaiting transplantation, providing first clinical data on dynamics and donor specificity of preformed HLA antibodies in response to bortezomib alone.

**Methods**: Two highly sensitized patients awaiting third kidney transplantation were treated with bortezomib (1.3 mg/kg bwt., days 1, 4, 8, 11). Time-course and levels of HLA antibody titers, as well as specificity to previous transplant antigens were monitored weekly by luminex.

**Results**: Bortezomib was well tolerated without side effects. In all patients, changes in IgG levels were small and no sustained reduction in HLA class I or II antibody titers was observed following bortezomib preconditioning over more than 100 days of follow-up. No differences among antibody responses to donor specific and non-donor specific antigens were oberserved.

**Conclusion**: Bortezomib preconditioning alone does not result in sustained reduction of HLA antibody titres in sensitized patients. Also, no change in specificity of antibody production was observed over a period of time clearly exceeding half-life of preformed IgG HLA antibodies. Hence, in a pretransplant setting, combination immunosuppressive strategies are required to obtain benefit from proteasome inhibition.

**TH-PO922**

**Outcome after Renal Transplantation in Systemic Amyloidosis** Jennifer H. Pinney,[1,2] Helen J. Lachmann,[1] Prayman Sattianayagam,[1] Simon Gibbs,[1] Ashutosh D. Wechalekar,[1] Carol J. Whelan,[1] Philip Hawkins,[1] Julian D. Gillmore.[1] *[1]National Amyloidosis Centre, Division of Medicine, UCL Medical School, Royal Free Campus, London, United Kingdom; [2]Centre for Nephrology, Division of Medicine, UCL Medical School, Royal Free Campus, London, United Kingdom.*

Renal transplantation (RTx) is contentious in patients with systemic amyloidosis because of the progressive and multi-system nature of the disease and the risk of amyloid recurrence in the graft.

We report outcome following isolated RTx in 98 patients with various forms of systemic amyloidosis evaluated at the UK National Amyloidosis Centre (NAC) between 1978 and 2009. Patient and graft survival were estimated by Kaplan-Meier analysis.

Twenty-eight patients with AL amyloidosis followed for a median of 58 months from RTx, 39 with AA amyloidosis followed for a median of 62 months, 15 with fibrinogen Aa-chain amyloidosis (AFib) followed for a median of 63 months, 13 with apolipoprotein AI amyloidosis (AApoAI) followed for a median of 111 months and 3 with lysozyme amyloidosis (ALys) followed for 14, 26, and 83 months respectively, received 28, 41, 16, 15 and 3 RTx respectively (total 103). Median age at RTx in AL, AA, AFib, AApoAI, and ALys was 61, 36, 60, 45, and 46 years respectively. One and 10 year patient survival in AL amyloidosis was 93% and 47%, in AA amyloidosis was 92% and 84%, in AFib was 100% and 48%, in AApoAI was 92% at one year with no further deaths at 10 years, and no patient with ALys had died following transplantation at the time of censor. One and 10 year renal allograft survival in AL amyloidosis was 100% and 93%, in AA amyloidosis was 94% and 89%, in AFib was 81% and 27%, in AApoAI was 100% and 71%, and in ALys was 100% with no ALys patient followed for 10 years from RTx. Recurrence of amyloid was evident in 7 AL, 12 AA, 3 AFib, 2 AApoAI and no ALys patients but only caused 6 grafts (3 AA and 3 AFib) to fail, the earliest after 70 months.

This data supports RTx in selected patients with AL and AA amyloidosis. Pre-emptive RTx should be considered in all patients with hereditary systemic amyloidosis who progress to end stage renal failure.

**TH-PO923**

**Transplant Nephrectomy: Association with Survival, Retransplantation, and Sensitization** Sejan B. Patel, Stephen R. Smith. *Division of Nephrology, Duke University Medical Center, Durham, NC.*

Patients with renal allograft failure make up an increasing fraction of patients initiating dialysis. The management of the allograft after failure remains controversial. We examined the impact of transplant nephrectomy on survival, retransplantation, and sensitization.

We performed a retrospective study of subjects with allograft failure returning to dialysis between 1994 and 2009 in our institution. The primary outcome was time to all cause death. The secondary outcome was time to retransplantation and second allograft failure.

Of 248 subjects with allograft failure, 103 subjects (42%) had a nephrectomy. Subjects with nephrectomy were younger and had fewer comorbidities (age 43±11 vs. 49±13 years, cerebrovascular disease 2% vs. 10%, coronary artery disease 10% vs. 26%, diabetes mellitus 25% vs. 43%, $p<0.01$) than those with no nephrectomy. There was no difference in PRA before transplant. There were 113 deaths over a mean period of 3.9±3.6 years after allograft failure associated with 5-year survival of 70% with nephrectomy vs. 45% with no nephrectomy ($p<0.001$). Cox regression adjusting for demographics, comorbidities, deceased donor transplant, allograft failure > 12 months, and PRA > 30% showed that nephrectomy was associated with a 60% hazard reduction for all cause death (HR 0.41, 95%CI 0.24-0.70, $p<0.001$). There were 14 subjects with nephrectomy and 12 subjects with no nephrectomy who were retransplanted. Of those with nephrectomy, the PRA increased from 10±25% before the first transplant to 56±40% before the second transplant ($p<0.01$). Of those with no nephrectomy, there was no difference in PRA before the first and second transplant. There was no difference in time to retransplantation and no difference in allograft survival after the second transplant.

Transplant nephrectomy was associated with better survival but greater sensitization, although there was no difference in time to retransplantation or second allograft failure.

**TH-PO924**

**Immunosuppression Protocols and Cardiovascular Risk Factor Monitoring Techniques at Midwest Pediatric Nephrology Consortium Member Centers** Raquel Mitchell, Donald J. Weaver. *Pediatrics, Levine Children's Hospital at Carolinas Medical Center, Charlotte, NC.*

**Introduction:** One reported risk factor for the continued progression of cardiovascular disease in pediatric renal transplant recipients is steroid use. The goal of the current study is to obtain information on trends of steroid utilization and methods for monitoring cardiovascular risk factors in the pediatric renal transplant recipients.

**Methods:** Member centers of the MWPNC were surveyed on immunosuppressive protocols and methods of cardiovascular risk factor monitoring.

**Results:** At the 11 centers that responded, 120 transplants were performed annually and over 500 transplant recipients were followed. Eighteen percent of surveyed centers utilized protocols completely steroid-free. Forty-six percent had used rapid discontinuation of steroids, 55% used a steroid avoidance regimen, and 36% used a steroid minimization protocol. As an induction regimen, four centers used thymoglobulin with anti-interleukin 2 therapy, three used thymoglobulin alone, three reported using basiliximab alone, and one used alemtuzumab. For maintenance therapy, 64% of hospitals used MMF, TAC, and steroids whereas 27% used MMF/TAC only. Finally, 9% used MMF/TAC/CYC. No centers were using sirolimus. Seven centers obtained annual echocardiograms; two centers only performed echocardiograms on patients who were hypertensive. Only one center used ambulatory blood pressure monitoring routinely. Hemoglobin A1c levels and glucose tolerance testing were not performed routinely. More than 80% of centers obtained annual lipid measurements. Primary indications for use of steroid-free immunosuppression were living-related donor transplant and first renal transplant.

**Conclusions:** The results of this survey reflect the variability in renal transplant protocols utilized by North American centers. This study highlights the importance of developing a consensus protocol for managing the pediatric renal transplant patient population to better assess long-term outcomes. Moreover, standardized protocols for cardiovascular risk surveillance are imperative because of the significant morbidity and mortality inherent in this patient population.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO925**

**Donor Pair Effect on Post Transplant Kidney Outcome and Function** Carol A. Traynor, Frank J. O Brien, Colm Magee, Peter J. Conlon. *Nephrology, Beaumont Hospital, Dublin, Ireland.*

**Background**

Donor characteristics such as age and cause of death are known to contribute to the incidence of both delayed graft function (DGF) and graft survival. We aim to assess the genetic effect of paired donor kidneys transplanted into different recipients on DGF and kidney function at 1 & 5 years post transplant.

**Methods**

We conducted a retrospective analysis of deceased donor kidneys transplanted between Jan 1 1992 and Dec 31 2008. Recipients all underwent transplant at a single centre. We excluded unpaired single kidneys, nephron dosing, en bloc kidneys and SPK recipients. DGF was defined as the need for dialysis in the first week after kidney transplantation. We estimated attributable risk (AR) to compare the relative proportion of the risk for DGF experienced by recipients when DGF occurred in the recipient of the contralateral kidney. We also examined the relationship within pairs for serum creatinine at 1 year and at 5 years post transplant using Spearmans Correlation.

**Range**

652 recipient pairs were analysed. The incidence of delayed graft function was 11%.

When DGF occurred in one recipient, the attributable risk for DGF in the recipient of the contralateral kidney was 0.322 (95% CI, 0.237 to 0.425), allowing for adjustment for confounding variables including donor age and sex, donor cause of death, HLA mismatch, recipient age and sex, PRA and CIT. The odds ratio of DGF occurring if the contralateral kidney had DGF was 5.986 (95% CI, 3.186 to 11.247).

Spearmans correlation between the kidney pairs for creatinine at year 1 and year 5 post renal transplant was 0.29 at year 1 and 0.29 at year 5($p<0.001$).

**Conclusions**

There is a significant degree of correlation within pairs of kidneys transplanted from the same donor for the occurrence of delayed graft function and also for serum creatinine at 1 year and 5 year post transplant. We conclude that a hidden genetic and environmental effect of the donor has a significant effect on post transplant outcomes. Important work needs to be done to establish the genes that affect these outcomes.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO926**

**Evaluation of Native Kidney Function after Simultaneous Liver-Kidney Transplant (SLK)** Jean M. Francis,[1] Matthew R. Palmer,[2] Michael P. Curry,[2] Didier A. Mandelbrot.[2] *[1]Renal section, Boston University, Boston, MA; [2]Renal Section, Beth Israel Deaconess Medical Center, Boston, MA.*

There is controversy over which patients with kidney disease that are candidates for liver transplantation should undergo liver transplant alone versus SLK. Identifying predictors of native kidney function recovery after SLK requires an accurate measure of the relative function of all three kidneys in patients with SLK. We report important modifications of standard Mag 3 renal scans that allow us to accurately measure the relative function of the transplant kidney and native kidneys in 13 SLK recipients.

The distance of a transplanted kidney from the renal scan camera can be substantially different from that of native kidneys. We developed a technique to correct for attenuation of the counts of all three kidneys based on their distance from the camera. Attenuation correction increased the measured renal function of native kidneys by up to 29%, demonstrating the importance of this procedure for detecting recovery of native kidney function.

The table shows clinical characteristics of the 13 SLK patients and the relative function of each kidney.

| Pt | Age/sex | eGFR baseline/peak | AKI duration (days) | Dialysis | Corrected % function | | | Met UNOS-proposed criteria for SLK |
|---|---|---|---|---|---|---|---|---|
| | | | | | L | R | Tx | |
| 1 | M/55 | >60/25 | 25 | Yes | 13% | 16% | 71% | No |
| 2 | M/52 | >60/9 | 7 | No | 6% | 7% | 87% | No |
| 3 | M/72 | >60/11 | >90 | No | 4% | 4% | 92% | Yes |
| 4 | F/51 | >60/6 | 15 | Yes | 15% | 11% | 74% | No |
| 5 | M/56 | 39/19 | 30 | No | 23% | 22% | 55% | No |
| 6 | M/61 | 44/9 | >90 | Yes | 4% | 6% | 90% | Yes |
| 7 | F/48 | 17/17 | >90 | No | 1% | 4% | 95% | Yes |
| 8 | M/60 | >60/15 | >90 | No | 24% | 24% | 52% | Yes |
| 9 | M/62 | >60/6 | 65 | Yes | 33% | 19% | 48% | Yes |
| 10 | M/51 | >60/15 | 30 | Yes | 9% | 5% | 86% | No |
| 11 | F/37 | >60/8 | >90 | Yes | 25% | 40% | 35% | Yes |
| 12 | F/63 | ESRD | >90 | Yes | 31% | 17% | 52% | Yes |
| 13 | M/46 | 33/12 | 62 | No | 19% | 5% | 76% | Yes |

Eight Patients (3, 6, 7, 8, 9, 11, 12 and13) met the UNOS-proposed criteria for SLK, but four of these (8, 9, 11, and 12) nevertheless had significant (>40% function) native kidney function. Five patients (1, 2, 4, 5, and10) did not meet the UNOS-proposed criteria for SLK, yet only one of these (5) had native kidney function recovery.

We report that modifications of the Mag 3 renal scan improve the measurement of the relative function of all three kidneys after SLK. The criteria proposed by UNOS to determine that SLK is indicated, and thus that native kidney recovery is not expected, are not always accurate. Further study of factors associated with native kidney recovery after SLK is required.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO927

**Serum Angiopoetin-2 Concentrations Correlate with Renal Resistance Index and Transplant Function in Renal Allograft Recipients** Ute Eisenberger,[1] Alexander Lukasz,[2] Ivo Peter Bergmann,[1] Elisabeth Weber-Bach,[1] Jan T. Kielstein,[2] Felix J. Frey,[1] Philipp Kümpers.[2,3] *[1]Nephrology and Hypertension, University Hospital Bern, Bern, Switzerland; [2]Nephrology, Medical School Hannover, Hannover, Germany; [3]General Internal Medicine, Nephrology and Rheumatology, University Hospital Münster, Münster, Germany.*

**Introduction:** Renal allograft dysfunction and mortality are associated with the Renal Resistance Index (RI) as an indicator for impaired intrarenal hemodynamics. Angiopoietin-2 (Ang-2), a circulating antagonistic ligand of the endothelial-specific Tie2 receptor, has been identified as non-redundant primer for endothelial activation. We tested the hypothesis whether Ang-2 serum concentrations are associated with renal transplant function, arterial stiffness and RI in renal allograft recipients.

**Methods**. We performed a prospective single centre cohort study of 200 renal allograft recipient (mean time after transplantation 7.0 ± 6.2yrs). At study inclusion, Ang-2 serum concentrations were measured by an in-house immuno-luminometric assay and RI was determined in segmental arteries of the allograft by colour-coded duplex ultrasound. Current mean follow-up time is 3.3 ± 0.5 yrs.

**Results**: Mean (SD) patient age at inclusion was 53 ± 13 years, eGFR 61± 20 ml/min, serum albumin 3.9 ± 0.3g/dl, cholesterol 206 ± 42 mg/dl, pulse pressure 52 ± 17 mmHg, RI 0.71 ± 0.07 and Ang-2 serum concentrations 2.8 ± 1.7ng/ml. Ang-2 values are correlated with renal resistance index (r=0.32; p<0.001), $eGFR_{Nankivell}$ (r=-0.29, p<0.001), recipient age (r=0.27; p<0.005), serum albumin (r=-0.26;p<0.01); C-reactive protein (r=0.26; p<0.01), Framingham risk score (r=0.22; p<0.05) and mean arterial pressure (r=0.23; p<0.05), but not with donor age, arterial stiffness measured by pulse pressure, total cholesterol, HbA1c or PTH. After multivariate adjustment in a regression analysis, Ang-2 remained an independent predictor of RI (standard coefficient 0.15; p<0.01).

**Conclusion:** In addition to established cardiovascular risk factors, circulating Ang-2 appears to be a relevant determinant of renal resistance index and allograft function and deserves consideration in prospective outcome trials in renal transplantation.

## TH-PO928

**Poor Outcomes Associated with Neutropenia after Kidney Transplantation: Analysis of USRDS** Frank P. Hurst,[1] Stephen W. Olson,[1] Robert Nee,[1] Lawrence Agodoa,[3] Rahul Jindal,[2] Kevin C. Abbott.[1] *[1]Nephrology, Walter Reed AMC, Washington, DC; [2]Organ Transplant, Walter Reed AMC, Washington, DC; [3]NIDDK, NIH, Bethesda, MD.*

**Background:** Post-transplant neutropenia (PTN) is relatively common after kidney transplantation and frequently leads to reduction in immunosuppressive agents, which can be associated with acute rejection. Granulocyte colony-stimulating factors (GCSF) have been used to treat PTN, although outcomes associated with the use of this medication in this population are unknown.

**Methods:** In a retrospective cohort of 41,705 adult Medicare primary patients transplanted from January 2001 to June 2006 and followed through December 2007, we assessed Medicare claims for neutropenia and GCSF use, respectively. Outcomes included allograft loss and death.

**Results:** There were 6043 (14.5%) patients with claims for PTN. Neutropenia occurred at a mean of 0.58 ± 0.65 years after transplantation. Factors associated with PTN included female gender, Caucasian ethnicity, ischemic heart disease, donor CMV positive, deceased donor, expanded criteria donor, delayed graft function, elevated PRA level, increased HLA mismatch, and later year of transplant. Thymoglobulin induction and maintenance tacrolimus and mycophenolate were also associated. PTN was less frequent among patients with CHF, recipient CMV positivity, and IL-2 induction. PTN was associated with increased risk of subsequent allograft loss [AHR 1.59 (95% CI 1.43-1.76)] and death [AHR 1.74 (95% CI 1.59-1.90)]. Of the 6043 patients with PTN, 740 (12.2%) received GCSF. While there was no effect on allograft loss, patients who received GCSF had a lower risk of death on unadjusted analysis.

**Conclusions:** Neutropenia after renal transplantation is common and is associated with an increased risk of allograft loss and death. GCSF was used in 12% of cases and did not increase risk of allograft loss. Strategies to avoid neutropenia and greater use of GCSF may be indicated to prevent graft loss and death.

The views expressed in this abstract are those of the authors and do not reflect the official policy of the National Institutes of Health, the Department of Defense, or the United States government.

## TH-PO929

**Serum FGF-23 Levels Predict Mortality and Allograft Loss in Kidney Transplant Recipients** Istvan Mucsi,[1] Miklos Z. Molnar,[1,2] Maria Eszter Czira,[1] Anna Rudas,[1] Akos Ujszaszi,[1] Istvan Kiss,[3] Adam Remport,[3] Laszlo Rosivall,[1] Csaba P. Kovesdy,[4] Myles S. Wolf.[5] *[1]Semmelweis University, Budapest, Hungary; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]Szent Imre Hospital, Budapest, Hungary; [4]Salem VA Medical Center, Salem, VA; [5]University of Miami Miller School of Medicine, Miami, FL.*

Background: Significant associations have been demonstrated between increased serum FGF-23 levels and adverse clinical outcomes. No published studies examined the association between FGF-23 and outcomes in kidney transplant (Tx) recipients.

Methods: Stable prevalent Tx recipients (n= 984; mean age 51±13 years, 57% males, mean eGFR 51±21 ml/min/1.73m2, median Tx vintage 72 months [interquartile range 74 mo] and 21% diabetics) were enrolled. Serum FGF-23 was measured using a C-terminal enzyme-linked immunosorbent assay. To assess if serum FGF-23 predicts the risk of all-cause mortality and of death censored graft loss we used semiparametric competing risks regression analysis.

Results: During the 37 months follow-up, 87 subjects died and 101 patients returned to dialysis. Both mortality and death-censored allograft loss was significantly higher in patients in the higher tertiles of baseline FGF-23 (Figure A and B). Ln-transformed serum FGF-23 was independently associated with mortality (HR associated with 1 log-unit higher FGF23 = 1.78; 95% CI: 1.39-2.28) and of death censored graft loss (1.60; 95% CI: 1.26-2.03) in multivariable-adjusted models. In the multivariable models, the highest tertile of FGF-23 was independently associated with a 2.29 (95% CI 1.15, 4.55) HR of mortality, and a 2.77 (95% CI 1.29, 5.92) HR of death-censored allograft loss.

Conclusions: High FGF-23 levels are independently associated with increased risk of mortality and death-censored graft loss in prevalent kidney transplant recipients.

## TH-PO930

**Single Nucleotide Polymorphisms and Decline in Renal Function Post-Transplant** Ajay K. Israni,[1] John H. Holmes,[2] Robert Leduc,[3] David P. Schladt,[3] Pamala A. Jacobson,[4] William S. Oetting,[4] Arthur J. Matas.[5] *[1]Medicine, Hennepin County Medical Center, University of Minnesota (MN), Minneapolis, MN; [2]Epidemiology, CCEB, University of Pennsylvania, Philadelphia, PA; [3]Biostatistics, University of MN, Minneapolis, MN; [4]Pharmacy, University of MN, Minneapolis, MN; [5]Surgery, University of MN, Minneapolis, MN.*

**Background**: We examined the association between single nucleotide polymorphisms (SNPs) and chronic graft dysfunction (CGD) in a multicenter, prospective cohort of kidney transplant (Tx) recipients from six international transplant centers in Canada and the United States. In order to determine SNPs associated with CGD after accounting for a strong Tx center effect, we used knowledge discovery methods.

**Methods:** Our cohort consisted of 966 patients receiving kidney Tx between 2006-2008. Genotyping was conducted for 2,723 SNPs. CGD was defined as a persistent 25% decline in eGFR from a baseline established at 3 months post-transplant. We used a correlational feature selection algorithm from the Weka data mining software suite called best-first procedure to select SNPs associated with CGD at each center separately. We then used a rule discovery tool named "JRip" which returns a set of "IF-THEN" rules, where the outcome is CGD. The "IF" side is comprised of one or more SNPs from the best-first procedure, such as if SNP x and SNP y are present, then CGD=Yes.

**Results:** The mean eGFR at baseline was 56±37 ml/min and 188 (19%) of the subjects experienced CGD at a mean time of 17± 8 months post-tx. Among subjects with a biopsy, the following distribution of biopsy scores: 28 % ci≥2, 28 % ct≥ 2, 27 % I ≥2, 24% T≥2, 11% CV≥2, 5% CG≥2, 5% g≥2, 2% AH≥2 and 2% V≥2.

There were 39 SNPs that were present in the 16 rules associated with CGD. The SNPs in these rules were in pharmacogenomic genes such as ABCC1, ABCC2, SLCO1B3, GSTA4, CYP1A1, cyclophilin A, and immune related genes such as IL12A, NFKB1 and PPARA.

**Conclusions:** Novel methods were used to determine SNPs associated with CGD after accounting for transplant center influences. These findings will be validated in another cohort of over 2,000 kidney transplants.

## TH-PO931

**Pre-Transplant Peripheral Blood Myeloid Dendritic Cell Levels Associated with Infection and Death Following Kidney Transplantation** Qianmei Sun,[1] Pamela R. Patton,[2] Yanfei Huang,[1] Cassie B. Zhang,[1] Dorry L. Segev,[1] Karl L. Womer.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]University of Florida, Gainesville, FL.*

Background: Dendritic cells are potent antigen presenting cells important for immunity and tolerance. We previously demonstrated a significant reduction of pre-transplant peripheral blood dendritic cell (PBDC) levels in renal transplant patients with evidence of post-transplant BKV reactivation, suggesting PBDC deficiency identifies a group of patients particularly susceptible to post-transplant infections. In the current report, we determined the association of PBDCs with other outcomes following kidney transplantation.

Methods: Pre-transplant peripheral blood myeloid and plasmacytoid DC levels (mDC and pDC, respectively) were measured by FACS in 79 patients with ESRD undergoing kidney transplantation and reported as absolute number of cells/mL blood. Post-transplant outcomes data were collected, including infection, rejection, graft loss and patient death for a minimum follow-up of 4.5 years. PBDC levels were compared across strata of outcomes by t-tests. Associations between PBDC levels and survival were assessed by Cox proportional hazards models.

Results: There was a trend towards lower DC levels in patients with any post-transplant infection compared to those without, with significance in the mDC subset (mean mDC level 8294.5 vs 10832.5 cells/mL; p=0.04). Significance in this DC subset was also observed when the outcome was limited to CMV infection (6930.4 vs 9673.2; p=0.05). DC levels were not associated with development of rejection. However, there was a strong association of mDC level with death (5758.1 vs 9678.6; p=0.02); for every quartile decrease in mDC level, the risk of death doubled (hazard ratio 2.12; 95% CI 1.16-3.89; p=0.01).

Conclusions: Pre-transplant peripheral blood mDC deficiency is associated with post-transplant infection and death in renal transplant patients. PBDC level monitoring may prove to be a useful clinical tool that allows individualization of immunosuppression and prediction of adverse outcomes.

## TH-PO932

**Renal Allograft Loss during Transfer of Care to Adult Healthcare Services in Canadian Pediatric Renal Transplant Patients** Susan M. Samuel,[1] Brenda Hemmelgarn,[1] Marcello Tonelli,[2] Alberto Nettel-Aguirre,[1] Andrea Soo,[1] Camillia G. Clark,[1] R. Todd Alexander,[2] Bethany J. Foster.[3] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada; [3]McGill University, Montreal, QC, Canada.*

**Rationale:** Among pediatric renal transplant patients, transition to adult-oriented programs usually occurs during adolescence, around age 18. We sought to determine if a *'transition period'*, defined as a 3-yr time interval centered around the first visit at an adult oriented care center, was associated with increased risk of renal allograft loss in this population. **Methods:** We used population-based data from a national organ failure registry. Patients (ages 0-18) undergoing kidney transplantation in a Canadian pediatric centre between 1992 and 2007 were included and followed until death, loss to follow-up or Dec 31, 2007. Primary outcome was time to first allograft loss. We defined *'transition period'* as the interval 1.5 years before and 1.5 years after first recorded visit to adult care; results were adjusted for gender, donor type, age at transplant, race. **Results:** We included 460 pediatric transplant patients of whom 227(49.3%) received living donor transplants. In total, 98 (21.3%) patients experienced first graft loss by study end. Median time to first graft loss was 4.87 (IQR 1.87-7.66) years. Compared with experience outside the transition period, the adjusted hazard ratio (HR) for first renal allograft loss within the transition period was 2.38 (95 % CI 1.53-3.71). Black race was associated with increased risk of graft loss compared to Caucasians (adjusted HR 2.90; 95% CI 1.15-7.32). Age at first renal transplant of 10-15y or 15-18y was also associated with increased risk of allograft loss compared with 0-10y (adjusted HRs 10-15y: 2.61(95% CI 1.49-4.55), 15-18y: 2.38(95% CI 1.35-4.19)). **Conclusion:** We found increased risk of renal allograft loss during the *'transition period'* defined as 1.5 years before and after the date of transfer to adult care. Adolescent age (10-18y) at transplant and Black race were associated with increased risk of first graft loss. Further studies are needed to determine causes of graft loss during the transition period.

## TH-PO933

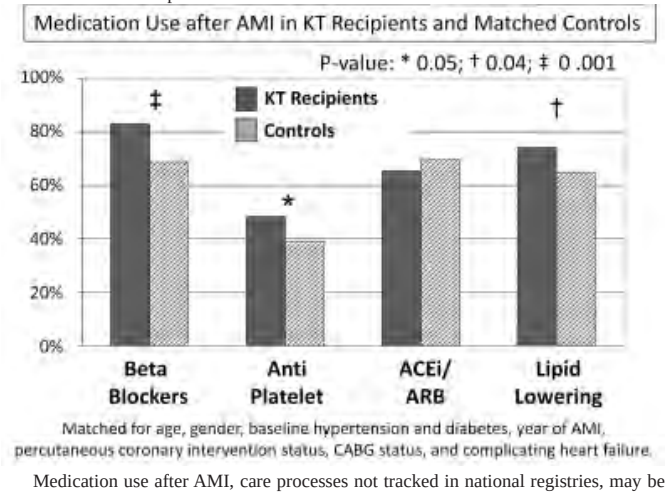
**Novel Approaches to Quantifying Cardioprotective Medication Use in High-Risk Transplant Recipients** Krista L. Lentine,[1] Kevin C. Abbott,[2] Daniel C. Brennan.[3] *[1]Saint Louis University; [2]Walter Reed; [3]Washington University.*

Understanding medication use among kidney transplant (KT) recipients may identify opportunities for care process improvement

We examined a novel database linking OPTN data for KT recipients to billing claims (2003-2006) of a private health insurer. KT recipients with posttransplant acute myocardial infarction (AMI) were identified by diagnosis codes on claims (n=209). General beneficiaries with AMI were identified by the same algorithm. The prevalence of beta-blocker (BB), antiplatelet, ACE inhibitor/angiotensin-2 receptor blocker (ACEi/ARB) and lipid-lowering agent use within 60d after AMI was ascertained by pharmacy claims.

In multiple logistic regression with adjustment for demographic and clinical factors (including peri-AMI revascularization and heart failure), KT status was associated with increased likelihood of BB (aOR 2.50, 95% CI 1.70–3.68) and lipid-lowering medication (aOR 1.53, 95% CI 1.08–2.15) use after AMI. The likelihood of ACEi/ARB and anti-platelet use after AMI did not differ significantly in KT vs general patients.

In a separate analysis, we also matched KT recipients 1-to-1 with general beneficiaries on the vector of factors associated with medication use after AMI in the sample. Compared to matched controls, KT recipients with AMI more commonly received BB (83.0% vs 69%, P=0.001) and lipid-lowering agents (74% vs 65%, P=0.04), and showed a non-significant trend towards more common receipt of anti-platelets (48% vs 39.0%, P=0.05). The frequency of ACEi/ARB prescriptions after AMI did not differ significantly by KT status in matched comparison.



Medication use after AMI, care processes not tracked in national registries, may be monitored in administrative data. While KT status does not appear to be a barrier, there may be room for optimizing potentially cardioprotective medication use after AMI in KT patients.

Disclosure of Financial Relationships: Research Funding: Novartis Pharma.

## TH-PO934

**Impact of Etiology of Acute Kidney Injury (AKI) on Outcomes Following Liver Transplantation: Acute Tubular Necrosis (ATN) Versus Hepatorenal Syndrome (HRS)** Mitra K. Nadim, Christopher A. Tokin, Wei Ye, Rick Selby. *University of Southern California.*

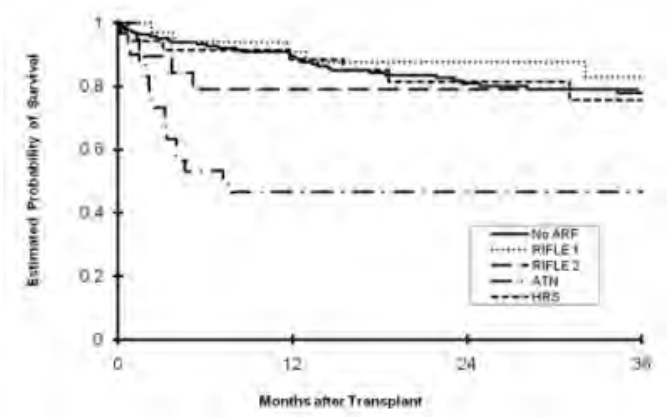
Background:AKI at the time of liver transplantation (LT) has been associated with increased morbidity & mortality. Previous studies have focused mainly on severity of renal dysfunction or duration of dialysis pre-LT on post transplant outcomes. The purpose of this study was to determine the impact of etiology of AKI (ATN vs HRS), on post LT outcomes.

Methods:We reviewed 293 patients who underwent LT following the MELD-based allocation. Patients were stratified according to the severity of AKI at the time of LT based on RIFLE classification: Risk, Injury, Failure. The "Failure" group was subdivided based on etiology of AKI as either HRS (defined by IAC criteria) or ATN.

Results: 1 and 3 year patient survival following LT were the lowest in patients with ATN (p<0.001). Multivariate analysis revealed that the presence of ATN was the ONLY variable associated with higher mortality at 1 year after LT (HR 2.97;CI 0.84-10.54;P< 0.025). Complete renal recovery at 1 year was: 71% (Risk), 47% (Injury), 20% (ATN) and 71% (HRS). Duration of pretansplant dialysis in the HRS & ATN groups was similar.

Patient Characteristics & Outcomes

| | No AKI (n=165) | Risk (n=34) | Injury (n=19) | Failure (n=65) | | p-value |
|---|---|---|---|---|---|---|
| Patient Characteristics at Time of Transplant | | | | ATN (n=30) | HRS (n=35) | |
| MELD-median | 22 | 28 | 29 | 40 | 40 | <0.001 |
| In ICU-% | 3 | 5 | 21 | 80 | 49 | <0.001 |
| SOFA score-median | 4 | 6 | 8 | 14 | 12 | <0.001 |
| On Dialysis-% | | | | 73 | 86 | 0.21 |
| Patient Survival-% | | | | | | <0.001 |
| 1 year | 89 | 91 | 79 | 47 | 89 | |
| 3 year | 78 | 80 | 79 | 47 | 77 | |
| Incidence of CKD | | | | | | <0.001 |
| 1 year | 11 | 13 | 21 | 53 | 12 | |
| 3 year | 22 | 19 | 37 | 59 | 23 | |



Conclusions: Our study is the first to show that AKI etiology, rather than severity or duration of dialysis, has the greatest impact on patient and renal outcomes following LT.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO935

**The Association between Inflammation and Serum Erythropoietin Level in Kidney Transplanted Recipients** Miklos Z. Molnar,[1,2,3] Maria Eszter Czira,[2] Anna Rudas,[2] Akos Ujszaszi,[2] Marta Novak,[2,5] Laszlo Rosivall,[1,4] Istvan Mucsi.[2,4] *[1]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [2]Institute of Behavioral Sciences, Semmelweis University, Budapest, Hungary; [3]Harold Simmons Center for Chronic Disease Research & Epidemiology, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, UCLA, Torrance, CA; [4]Hungarian Academy of Sciences and Semmelweis University Research Group for Pediatrics and Nephrology, Budapest, Hungary; [5]University of Toronto, Toronto, ON, Canada.*

**Background:** The presence of iron deficiency and inflammation are associated with erythropoietin (EPO) resistance in patients on maintenance dialysis and with post-transplant anemia in kidney transplant (Tx) recipients. These factors may contribute to resistance to endogen erythropoietin in Tx patients resulting in higher serum EPO levels. To assess this hypothesis we analyzed the cross-sectional association between serum EPO versus markers of inflammation and iron deficiency in Tx patients.

**Methods:** We collected socio-demographic parameters, medical and transplant history and laboratory data from a prevalent cohort of 891 Tx patients not treated with erythropoiesis stimulating agents. A solid-phase, chemiluminescent immunometric assay was used to measure baseline serum erythropoietin (EPO).

**Results:** Mean age was 51±13 years, 60% of the patients were males, 21% had diabetes. The median of serum EPO was 10.8 U/l (IQR=7.4 U/l). The age and eGFR adjusted serum EPO level was significantly correlated with serum IL-6 (rho=0.229) and CRP (rho=0.128) and also with the serum soluble transferrin receptor concentration (rho=0.308) and the percentage of hypochromic reticulocytes (rho=0.228), p<0.001 for all. In a linear regression model serum IL-6, the percentage of hypochromic reticulocytes and serum soluble transferrin receptor were significantly associated with the log-transformed serum EPO after adjusting several clinical, socio-demographic and laboratory co-variables.

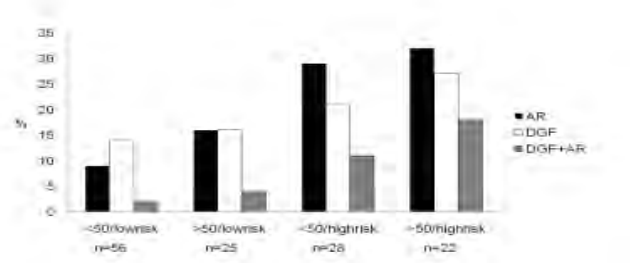
**Conclusions**: Iron deficiency and inflammation are independently associated with serum EPO levels in kidney transplanted patients.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO936

**Cellular or Humoral Presensitization Increases the Risk of Delayed Graft Function and Acute Rejection in Recipients of Kidneys from Older Donors** Donald E. Hricik,[1] Joshua J. Augustine,[1] Aparna Padiyar,[1] Peter S. Heeger.[2] *[1]Medicine, University Hospitals Case Medical Center, Cleveland, OH; [2]Medicine, Mt. Sinai School of Medicine, New York, NY.*

Outcomes of kidney transplantation are influenced by donor age but may be modifed by recipient alloreactivity. We hypothesized that patients at high immune risk, defined by pretransplant donor specific ELISPOT for interferon gamma ≥ 25/300k cells and/or PRA>80%, may have particularly bad outcomes after receiving kidneys from older donors. We reviewed outcomes of 131 deceased donor recipients in whom pretransplant values for both ELISPOT and PRA were available. 52 patients were enrolled in an NIH-sponsored CTOT study. Based on donor age <or ≥ 50 yrs, we categorized patients into 4 groups (see x axis of figure). Population characteristics: recipient age 48.3±11 yrs, 62% male, 53% African American, HLA mismatches 4.0±1.9. High risk patients included 46 with high ELISPOT alone, 7 with high PRA alone, and 3 with both. The incidence of delayed graft function (DGF), acute rejection (AR) and AR after DGF (DGF+AR) are shown in the figure.



AR occurred in 32% of the ≥50/highrisk group vs 9% in the <50/lowrisk group (p<0.001). DGF occurred in 27% of the ≥50/highrisk group vs 14% in the <50/lowrisk group (p=0.014). Logistic regression showed that the combination of high risk status and donor age ≥50 increased the risk of AR (odds ratio 1.7, p=0.007), and DGF+AR (odds ratio 2.1, p=0.036) independent of recipient age, gender, ethnicity, and HLA mismatch. The results show that cellular or humoral presensitization magnify the adverse effects of advanced donor age. Caution should be used in offering kidneys from older donors to patients with cellular or humoral presensitization. In the absence of presensitization, recipients of kidneys from older donors have outcomes similar to those with younger donors.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO937

**Association of Body Mass Index and Abdominal Circumference with Mortality in Kidney Transplant Recipients** Csaba P. Kovesdy,[1,2] Maria Eszter Czira,[3] Anna Rudas,[3] Akos Ujszaszi,[3] Laszlo Rosivall,[3] Marta Novak,[3] Kamyar Kalantar-Zadeh,[4] Miklos Z. Molnar,[3,4] Istvan Mucsi.[3] *[1]Salem VA Medical Center, Salem, VA; [2]University of Virginia, Charlottesville, VA; [3]Semmelweis University, Budapest, Hungary; [4]Harbor-UCLA, Torrance, CA.*

Higher body mass index (BMI) is associated with lower mortality in patients with CKD and ESRD, but it is unclear if this is a result of higher muscle mass or higher fat mass, both of which could be reflected by elevated BMI. The impact of BMI and body composition on survival is unclear in kidney transplant (KT) recipients.

We examined the association of BMI and abdominal circumference (AC) with all-cause mortality in 993 KT recipients. Associations were examined in Cox models with adjustment for AC (in the case of BMI) and BMI (in the case of AC) and for age, gender, transplant vintage, delayed graft function, diabetes, Charlson index, smoking, blood pressure, eGFR, albumin and CRP.

In unadjusted analyses neither BMI nor AC was associated with mortality (Table). However, higher BMI was associated with lower mortality after adjustment for AC, and higher AC was associated with higher mortality after adjustment for BMI (Table). These associations remained significant after additional adjustments (Table).

In KT higher BMI and AC displayed opposite associations with mortality. Since AC-adjusted BMI could be considered a marker of muscle mass and BMI-adjusted AC a marker of fat mass, these associations may reflect a protective effect of muscularity but a detrimental effect of adiposity. The impact of strategies aimed at lowering elevated BMI prior to and after transplantation should be critically assessed based on their effects on body composition.

All-cause mortality associated with a one standard deviation higher BMI and AC

| | Unadjusted | Adjusted for AC (BMI only) and for BMI (AC only) | Multivariable adjusted |
|---|---|---|---|
| BMI (5 kg/m2 higher) | 0.84 (0.67, 1.06) p=0.15 | 0.38 (0.25, 0.59) p<0.001 | 0.55 (0.36, 0.84) p=0.005 |
| Abdominal circumference (15 cm higher) | 1.14 (0.91, 1.41) p=0.25 | 2.47 (1.63, 3.73) p<0.001 | 1.65 (1.04, 2.60) p=0.042 |

HR, 95%CI

**TH-PO938**

**Initial Comparisons of Performing Routine Surveillance Protocol Biopsies vs No Surveillance Biopsies: Analysis of the Mycophenolic Acid Observational Renal Transplant (MORE) Registry** Ali Olyaei,[1] Laurence Chan,[2] Anne Wiland,[3] Kevin M. Mccague,[3] Richard W. Carson.[4] *[1]Oregon State University/ OHSU, Portland, OR; [2]University of Colorado, Denver, CO; [3]Novartis, East Hanover, NJ; [4]Providence Sacred Heart Medical Center, Spokane, WA.*

Surveillance Biopsies (BXs) have been recommended to detect early subclinical rejection and calcineurin inhibitor (CNI) toxicity. Early treatment of rejection or immunosuppressive (IS) modifications may alter the natural history of chronic allograft injury (CAI) in renal transplant recipients (RTRs). The objective of this analysis was to evaluate the utility of surveillance renal BXs in detecting early rejection, CNI toxicity and other complications. **Methods:** Using data reported to the MORE Registry, we analyzed whether surveillance BXs are associated with a greater detection of biopsy-proven acute rejection (BPAR), early graft failure, improved serum creatinine (SCr), CAI and CNI toxicities at 6 months post-transplant. Standard-of-care was determined by local practice at 40 US sites. The outcomes of 722 RTRs were reviewed (mean age 51 yrs, 63% male). Log-rank tests were used to compare graft survival (GS), patient survival (PS) and cumulative incidence of first BPAR. **Results:** Preliminary data were analyzed {213 patients underwent surveillance BXs, 509 did not (control group)}. There were no significant differences in GS (98.1/99.0%, p=0.70), PS (99.5/99.3%, p=0.23), BPAR (7.6%/5.9%, p=0.33), mean SCr (1.47/1.49 mg/dL, p=0.83) or GFR by MDRD (58.8/56.8 mL/min, p=0.25) in the BX group vs. control group. CAI or CNI toxicities were noted in 1.4/0.8% and 0.9/2.0% (NS) of surveillance BX group vs. the control group. The incidences of BK nephropathy, GI toxicities, CV complications, tacrolimus levels, mycophenolate and prednisone dosage were similar between groups. There were more reported infections (17.8/11.7%, p=0.03) and CMV (7.0/3.1%, p=0.03) in the surveillance BX group. **Conclusion:** Early rates of BPAR, CAI and CNI toxicity were similar between the two groups. Newer IS regimens have reduced the overall incidence of clinical rejection, potentially resulting in reduced benefit of early post-transplant surveillance BXs in RTRs.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO939**

**Enteric-Coated Mycophenolate Sodium (EC-MPS) Versus Mycophenolate Mofetil (MMF) in African American (AA) Renal Transplant Recipients from the Mycophenolic Acid Observational Renal Transplant (MORE) Registry** Mohanram Narayanan,[1] Oleh G. Pankewycz,[2] Mohamed A. El-Ghoroury,[3] Anne Wiland,[4] Kevin M. Mccague,[4] John A. Daller.[5] *[1]Scott and White Clinic, Temple, TX; [2]Buffalo General Hospital, Buffalo, NY; [3]St. Clair Specialty Physicians, Detroit, MI; [4]Novartis, East Hanover, NJ; [5]Temple University, Philadelphia, PA.*

**Introduction:** The MORE Registry, a prospective study of adult de novo renal transplant recipients (RTRs) receiving mycophenolic acid (MPA) therapy, is designed to determine effectiveness, tolerability and safety of EC-MPS vs. MMF regimens. **Methods:** Based on practices at 40 US sites, outcomes analyzed included: graft survival (GS), patient survival (PS), first biopsy-proven acute rejection (BPAR), adverse event (AE) rates, serum creatinine (SCr) and proportion of RTRs maintained on at least full recommended MPA dose (1.44/2.0 g/day, EC-MPS/MMF). A total of 165 AA (114 EC-MPS/51 MMF) and 521 non-AA (352 EC-MPS/169 MMF) tacrolimus-treated RTRs were included. **Results:** At 1, 3, 6 and 12 months, more AA EC-MPS RTRs received full MPA dose (EC-MPS/MMF: 83.3/ 74.5%, p=0.20; 67.6/ 66.0%, p=0.85; 62.4/ 43.6%, p=0.05; 50.0/45.5%, p=0.68). This was also observed in the non-AA patients (EC-MPS/ MMF: 79.1/69.9%, p=0.02; 73.6/57.8%, p<0.01; 54.8/46.3%, p=0.13; 48.1/42.1%, p=0.34). Comparable 6-month effectiveness, tolerability and safety outcomes were achieved in both groups. In the AA RTRs, there were less frequent GI AEs in the EC-MPS group (58/75%, p=0.05). Comparing EC-MPS/MMF in the AA RTRs, there was similar GS (99.1/100%, p=0.18), PS (100/98.0%, p=0.07), BPAR (12.9/12.3%, p=0.61), mean SCr (1.58/1.94 mg/dL, p= 0.19) and non-GI AEs by organ system, infections or neoplasia. Comparing AA to non-AA RTRs regardless of MPA type, both BPAR (12.7/4.5%, p<0.01) and SCr (1.70/1.41 mg/dL, p<0.01) were higher whereas GS (99.4/98.8%) and PS (99.3/99.4%) were similar. **Conclusion:** More AA and non-AA RTRs treated with EC-MPS were maintained on full doses of MPA. Despite this, AA RTRs exhibited higher BPAR and mean SCrs than non-AAs which may impact clinical outcomes at later timepoints in this study.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO940**

**Predictors of Compensatory Hyperfiltration Years after Kidney Donation** Marc L. Weber,[1] Aleksandra Kukla,[1] Richard S. Spong,[1] Erin Leister,[1] Arthur J. Matas,[2] Hassan N. Ibrahim.[1] *[1]Medicine - Division of Renal Diseases and Hypertension, University of Minnesota, Minneapolis, MN; [2]Surgery, University of Minnesota, Minneapolis, MN.*

Without compensatory hyperfiltration, the best post-donation GFR would be half of the pre-donation value. GFR values increase in the months after donation. There is little data regarding change in GFR many years after donation. We studied a representative sample of 255 kidney donors from a pool of 3698 donors 12.2±9.2 years after donation to determine the pattern and predictors of GFR change overtime. Characteristics of these donors, GFR estimated using the re-expressed MDRD formula and other formulas are shown in table. 70% of post-donation $eGFR_{MDRD}$ values were less than 85% of pre-donation $eGFR_{MDRD}$ and the average decline in $eGFR_{MDRD}$ was 21 mL/min/1.73m². Nearly 20% of patients had a post-donation $eGFR_{MDRD}$ within 15% of their pre-donation $eGFR_{MDRD}$ and about 10% of kidney donors actually had a post-donation $eGFR_{MDRD}$ greater than their pre-donation $eGFR_{MDRD}$.

| | |
|---|---|
| n | 255 |
| Female | 61.6% |
| White | 98.8% |
| Age | 40.9±11.0 |
| BMI | 26.0±4.2 Kg/m² |
| Creatinine (pre-donation) | 0.90±0.22 mg/dL |
| Creatinine $clearance_{CG}$ (pre-donation) | 88.5±23.1 mL/min/1.73m² |
| $eGFR_{CKD-EPI}$ (pre-donation) | 99.1±20.0 |
| Mean $eGFR_{MDRD}$ (pre-donation) | 92.9±234 mL/min/1.73m² |
| Mean $eGFR_{MDRD}$ (post-donation) | 71.6±14.9 mL/min/1.73m² |
| Change in $eGFR_{MDRD}$ (pre & post-donation) | -21.8±21.6 mL/min |
| $eGFR_{MDRD}$ (post-donation outcomes) | Post-donation eGFR < 85% of two kidney eGFR: 70.2% |
| | Post-donation eGFR within 15% of two kidney eGFR: 19.8% |
| | Post-donation eGFR 15% of two kidney eGFR: 9.9%≥ |

Pre-donation higher GFR, higher BMI, and the development of hypertension post-donation were associated with a lower compensatory increase in GFR. A more robust increase in post-donation GFR is predicted with a pre-donation BMI less than 30 Kg/m². This data demonstrates that nearly a third of kidney donors attain a 12-year post-donation eGFR that is near to or greater than their pre-donation two kidney eGFR and a lean body habitus at donation was associated with higher post-donation GFR.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO941**

**Moderate Alcohol Consumption Is Associated with Low Prevalence of Post-Transplant Diabetes and Reduced Risk for Mortality in Renal Transplant Recipients** Dorien M. Zelle,[1] Eva Corpeleijn,[2] Ronald Stolk,[2] Jaap Homan vd Heide,[1] Willem Van Son,[1] Gerjan Navis,[1] Stephan J. L. Bakker.[1] *[1]Kidney Centre, University Medical Center Groningen, Netherlands; [2]Epidimiology, University Medical Center Groningen, Netherlands.*

Renal transplant recipients (RTR) are often advised to refrain from alcohol because of use of immunosuppressive drugs. While in the general population moderate alcohol consumption is associated with reduced risk for diabetes and mortality, it is unknown if the same holds true for RTR. Therefore we investigated the association of alcohol consumption with post transplant diabetes (PTD) and mortality in RTR.

RTR were investigated between 2001 and 2003. Alcohol consumption was assessed by self-report. Mortality was recorded until May 2009.

A total of 600 RTR (age 51±12 years, 55% men) participated at a median time of 5.9 years post-transplant. Of these RTR, 288(48%) were abstainers, 94(16%) sporadic users, 210(35%) had moderate intake and 8(1%) were heavy drinkers. Total prevalence of PTD was 78(12%). Moderate alcohol consumption was associated with low prevalence of PTD (OR= 0.33 [0.2-0.6], P<0.002). During median follow-up for 7.0 years, 33(15.7%) subjects died in the group of moderate alcohol consumption, while 75(26.0%), 23(24.5%), and 2(25%) died in the groups of abstainers, sporadic and heavy drinkers resp. (P=0.01).

In univariate Cox-regression analyses moderate alcohol intake was associated with reduced risk for mortality (HR=0.56 [0.4-0.8],P=0.005). Adjustment for potential confounders, including diabetes and smoking did not materially change this association.

Moderate alcohol consumption is associated with low prevalence of PTD and reduced risk for mortality in RTR. In contrast with common advices, drinking moderate amounts of alcohol appears to be protective against diabetes and mortality in RTR, similar to the general population.

**Luminex-Based Desensitization Protocols: Short Term Outcomes** Arjang Djamali, Brenda L. Muth, David Lorentzen, John D. Pirsch, Anthony M. D'Alessandro, Hans Sollinger. *Medicine and Surgery, UW Madison School of Medicine and Public Health, Madison, WI.*

We have demonstrated that pretransplant donor specific antibody (DSA) levels > 100 mean fluorescent intensity (MFI) by Single Antigen Bead Luminex Assay (One Lambda) are associated with antibody mediated rejection (AMR). There is no information on whether

Luminex-based preconditioning protocols are effective desensitization strategies. We have developed protocols based on MFI levels in patients with a negative CDC crossmatch.

| Protocol number | Transplant Type | MFI | Induction | Pheresis + IVIG |
|---|---|---|---|---|
| P1 | Live | 100-500 | Basiliximab | - |
| P2 | Live | 500-1000 | Basiliximab | 2 pre 2 after |
| P3 | Live | 1000-3000 | Basiliximab | 4 pre 2 after |
| P4 | Deceased | 100-500 | Basiliximab | - |
| P5 | Deceased | 500-1000 | Thymoglobin | - |
| P6 | Deceased | 1000-3000 | Thmyglobin | 1 pre 3 after |

Live donor recipients are treated with TAC and MPA for 1 week pretransplant. All patients receive maintenance immunosuppression with TAC, MPA and steroids. Between January 2009 and December 2010 we performed 249 kidney transplants, of those 48 (23%) were sensitized across the HLA barrier (P1-P6) and required desensitization (mean MFI values against HLA 1 and 2 were 1,100 and 900 MFI and peak PRA 23%). Median age in sensitized and non-sensitized groups was 48.5 vs 52 years (p=ns). Most patients were male (56% vs 65%, p=ns). There were more retransplants (50% vs 18%, p<0.001) and live donor transplants (56% vs 30%, p<0.001) in the sensitized group. The incidence of AMR (25% vs 12.5%, p=0.008) and acute cellular rejection (23% vs 14%, p=0.02) was significantly higher in the sensitized group. However, mixed rejection (8%), graft loss (0 vs 6) or patient death (0 vs 3) were not significantly different between sensitized and control groups. Furthermore, 6 months (1.5 vs 1.4 mg/dL) and last (1.3 vs 1.4 mg/dL) serum creatinine levels were similar between the two groups. In conclusion Luminex based preconditioning protocols may be used in sensitized patients. However, long-term data are required to assess the efficacy of these protocols.

**Basiliximab Is Associated with New Onset Diabetes Mellitus (NODAT) after Transplantation** Willy Aasebo,[1] Hallvard Holdaas.[2] *[1]Medical Department, Akershus University Hospital, Lorenskog, Norway; [2]Medical Department, Oslo University Hospital, Rikshospitalet, Oslo, Norway.*

**Background.** The interleukin-2 antibody basiliximab suppresses proliferation of T cells resulting in an impairment of regulatory T-cell function. Regulatory T-cells are associated with autoimmune diseases, diabetes mellitus included. Even though NODAT resembles diabetes type-2 more than type-1 we hypothesized that basiliximab might be associated with NODAT after transplantation.

**Methods**. In a retrospective study we included all kidney recipients >18 years of age without diabetes mellitus transplanted in 2005, 2006 or 2007 (n = 485). Our immunosuppressive protocol consisted of steroids, mycophenolate and cyclosporine/tacrolimus. Basiliximab was introduced as induction therapy in 2007, and were given to 264 recipients. The recipients transplanted in 2005 and 2006 not receiving induction therapy served as a control group. At week 10 post transplant an oral glucose tolerance test was performed (75 mg Dextrose). Diagnosis of diabetes mellitus was defined as a fasting plasma glucose ≥7.0 mmol/l or two hours plasma glucose ≥11.1 mmol/l.

**Results.** In the basiliximab-group 52/264 (19.7%) developed NODAT, versus 24/221 (10.9%) in the group with no induction therapy (p = 0.0068). Analysis from a subgroup of recipient without rejection, hence with comparable total steroid load, showed NODAT in 34/184 (18.5%) in the basiliximab group and 6/123 (4.9%) in the no induction group (p <0.001)

In multivariate logistic regression odds ratio for NODAT was 2.3 (95% CI: 1.3-4.2) (p = 0.056) in the basiliximab group compared to the group with no induction, after adjusting for age, CMV-infection, donor type (LD/DD), rejection and BMI.

**Conclusion**. Basiliximab use is associated with an increased risk for developing in NODAT short-time after transplantation.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO944

**The Clinical Outcome after ABO Incompatible Kidney Transplantation in Patients with High Baseline Antibody Titer** Byung Ha Chung, Sun Ryoung Choi, Bumsoon Choi, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang. *Department of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

**Purpose**: The aim of this study is to investigate the clinical outcome of ABO incompatible kidney transplantation (ABO icKT) in patients with high baseline anti-ABO antibody titer.

**Methods**: This retrospective study was done about 12 cases of ABO icKT performed in our center. High titer was defined when baseline anti-ABO antibody titer was over 1:256. We used preparation composed of rituximab, plasmapheresis (PP) and intravenous immune-globulin (IVIG).

**Results**: Six patients belonged to high titer group and another six were low titer group. The highest titer was 1:1024. Mean follow-up period was 22.3±21.3 weeks in high titer group and 27.7±12.3 weeks in low titer group. More session of pre-transplant (9.3±3.0 vs. 6.0±1.38, respectively) and post-transplant PP/IVIG (2.3±2.9 vs. 0) was required in high titer group compared to low titer group. Protocol biopsy was done in five patients and C4d was diffusely positive in four cases (80%) without any evidence of antibody mediated rejection. There has been no episode of antibody mediated rejection during follow up period in both groups. There were total three cases of infectious complication (two viral infections in high titer and one pyoknee in low titer group) and all of them were cured by anti-viral or antibiotics. There were two cases of post-operative bleeding, one in high titer and one in low titer group. The patient from high titer group suffered nephrectomy because of uncontrolled bleeding. All patients show immediate graft function in early post-transplant period. Six patients have been observed for longer than six months (two patients from high titer group and another four were low titer group) and the serum creatinine level was 1.18±0.24 mg/dL in high titer group and 1.07±0.28 mg/dL in low titer group at six months after KT. .

**Conclusion**: ABO icKT can be carried out even in patients with high baseline antibody titer without increased risk for humoral rejection. However, we should be careful about post-operative bleeding in those patients because increased number of pre and post-transplant PP/IVIG can increase bleeding tendency.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO945

**Plasma EPO Is an Independent Predictor of Cardiovascular and Total Mortality in Renal Transplant Recipients** Steef Jasper Sinkeler, Jaap Homan vd Heide, Gerjan Navis, Stephan J. L. Bakker. *Nephrology, University Medical Center Groningen, Groningen, Netherlands.*

Cardiovascular disease (CVD) is the main cause of mortality in renal transplant recipients (RTR). Classical risk factors are involved, but only partly explain the excess risk. We hypothesized high EPO levels – a combined marker for inflammation, angiogenesis and hypoxia – might be a novel risk factor for CVD in RTR.

606 RTR from our center (age 51±12 years; 45 % female; creatinine clearance (CrCl) 57±20 mL/min/1.73 m²) were included at median 6 [IQR 3-11] years after Tx. All patients on exogenous EPO were excluded (n=18). Endogenous EPO levels were measured by Roche enzymatic assay.

Median EPO level was 17.4 [11.9–24.4] IU/L. Baseline EPO values were positively associated with waist circumference (r=0.08, p=0.04), CVD history (r=0.13, p=0.001), CRP (r=0.10, p=0.01), MCV (r=0.10, p=0.02), CrCl (r=-0.13, p=0.001) and proteinuria (r=0.10, p=0.02) and inversely with RAAS blockade (r=-0.15, p<0.001), Hb (r=-0.16, p<0.001) and borderline with ferritin (r=-0.07, p=0.09). During follow-up for 7 [6-7] years, 134 RTR died, of which 70 from CV causes. High EPO levels (per 10 IU/L) predicted both CV (HR 1.19 (95%CI 1.11–1.28), P=0.009) and total mortality (HR 1.15 (1.08 - 1.23), P<0.001).

These were independent of age, gender, CVD history, Hb, CRP, ferritin, CrCl, use of RAAS inhibitors, proteinuria and Framingham risk factors (smoking, diabetes, total and HDL- cholesterol and systolic blood pressure) in a multivariate Cox-regression analysis, with HR (per 10 IU/L EPO) 1.15 (1.04–1.28), P=0.009 for CV mortality and 1.11 (1.01–1.21), P=0.03 for total mortality.

In conclusion, EPO levels predict total and CV mortality in RTR, independent of potential confounders, including inflammation, renal function and levels of hemoglobin. This suggests other mechanisms may be involved. Further dissecting the determinants of EPO levels in RTR may provide new possibilities for reducing CV mortality in this population.

Disclosure of Financial Relationships: nothing to disclose

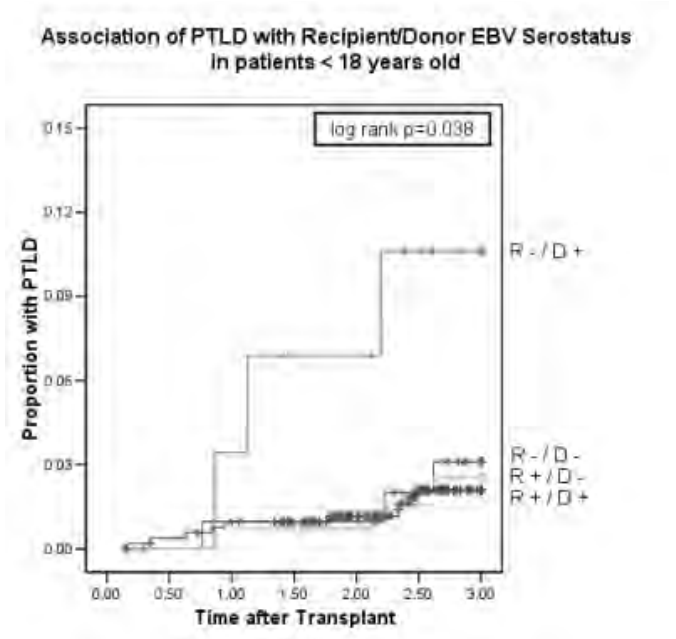
### TH-PO946

**Risk Factors and Prognosis of Posttransplant Lymphoproliferative Disorders after Renal Transplantation: Analysis of USRDS** Robert Nee,[1] Frank P. Hurst,[1] Lawrence Agodoa,[3] Rahul Jindal,[2] Kevin C. Abbott.[1] *[1]Nephrology, Walter Reed Army Medical Center, Washington, DC; [2]Organ Transplant, Walter Reed Army Medical Center, Washington, DC; [3]NIDDK, National Institutes of Health, Bethesda, MD.*

**Background:** Post-transplant lymphoproliferative disorders (PTLD) represent a well-recognized complication of renal transplantation. Known risk factors include Epstein-Barr virus (EBV) seronegativity and over-immunosuppression, with others to be further characterized.

**Methods:** In a retrospective cohort of 53,719 Medicare primary patients transplanted from January 2001 to June 2006 and followed through December 2007, we assessed Medicare claims for PTLD.

**Results:** There were 719 (1.3%) patients with claims for PTLD. Caucasian ethnicity, recipient history of malignancy, and rejection within the first year post-transplant were associated with an increased risk of PTLD. Sirolimus and tacrolimus were also associated with a higher risk. PTLD is associated with an increased risk of death [AHR 3.84 (95% CI 3.27-4.50); p < 0.001]. EBV serostatus was missing for 10.9% of recipients and 74.3% of donors. Given this limitation, paired recipient (R) negative and donor (D) positive EBV serostatus was not associated with PTLD in this cohort. However, in an unadjusted analysis of patients 18 years or younger, the EBV R-/D+ combination was associated with a higher risk for PTLD (p = 0.038).



**Conclusion:** Our results from recent USRDS data further support the higher mortality risk and delineate risk factors for PTLD. The EBV R-/D+ combination was associated with a higher risk for PTLD in younger patients.

The views expressed in this abstract are those of the authors and do not reflect the official policy of the National Institutes of Health, the Department of Defense, or the United States government.

### TH-PO947

**Previous Renal Support and Classic Risk Factors for Renal Disease Are Predictors for Chronic Renal Replacement Therapy (RRT) after Orthotopic Liver Transplantation (OLT)** Maria C. C. Andreoli, Maria P. V. Coelho, Nadia K. Guimaraes, Miguel A. Goes, Adriano L. Ammirati, Thais N. Matsui, Ilson Jorge Iizuka, Fabiana Dias Carneiro, Jose Ben-Hur Ferraz-Neto, Bento Santos. *Centro de Diálise Einstein, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

In the MELD (Model for End-Stage Liver Disease) era of organ allocation, RRT has been very common in OLT patient and the probability of kidney function recovery is essential for transplant program management. In this study we evaluated a sample of stable post-Intensive Care hemodialysis (HD) patients from a group of 297 adults who were submitted to OLT in an urban tertiary medical center from June 1, 2005, to December 31, 2009. The aim was to evaluate the average time of renal function recovery (out of need of RRT) in OLT patients on post intensive care HD and determine risk factors for chronic HD support during a 1-year follow-up period. Patients were censored at recovery of kidney function, death on HD or end of the follow-up period. The Cox proportional hazards model was used to compare the relative risk (RR) of remained or not in HD after 1 year. We evaluated data of 83 patients (50±14 yo, 64% male, 22% pre-OLT diabetes mellitus[DM], 31% HCV- disease, MELD 27.5±11.8, pre-OLT serum creatinine 1.5±1,4mg/dL, 17% acute re-OLT, 37% pre-OLT RRT, 28% pre-OLT proteinuria). During the study period, 70 (84%) were removed from dialysis; of these, 6 (7%) remained on HD for more than 90 days until renal function recovery and the longest period was 184 days. Nine (11%) patients died on HD and only 4 (5%) patients were on HD after 1 year. The median of recovery time was 28 days (from 6 to 184d). Classic risk factors for renal disease like age, DM and pre-OLT RRT were significant predictors of chronic RRT. Of note, the liver re-transplant did not have any impact in renal function recovery rate. In the multivariate analysis, the most important prognostic factor for chronic RRT was the presence of pre-OLT RRT (RR= 1.89, 95%IC= 1.15 to 3.13, p= 0,013). In conclusion, kidney transplantation after or concomitant to OLT must be judiciously done, especially in OLT patients who were not submitted to pre-OLT RRT.

Disclosure of Financial Relationships: nothing to disclose

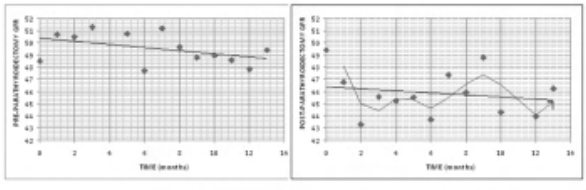
### TH-PO948

**Impact of Post Kidney Transplant Parathyroidectomy on Early Graft Function** Samir Parikh, Anil K. Agarwal. *Nephrology, The Ohio State University Medical Center, Columbus, OH.*

INTRODUCTION: The impact of parathyroidectomy (PTx) on kidney transplant (KTx) function is unclear. While worsening graft function in presence of uncontrolled hyperparathyroidism is proposed to be an indication for PTx, the procedure itself reportedly affects graft function. METHODS: We conducted a retrospective analysis of 3000 KTx patients from 1988 to 2008. 33 from this group underwent PTx secondary to uncontrolled hyperparathyroidism. All patients were monitored for change in e-GFR for one year pre and post PTx, graft loss, and patient death. RESULTS: The demographics are listed in Table. Following PTx mean GFR declined significantly in first 3 months with a mean GFR slope of -3.0611/month compared with mean GFR slope of -0.12853/month pre-PTx (p= 0.001). By 1 year, the mean GFR significantly improved with overall mean GFR slope of -0.08515/ month compared with mean GFR slope pre-PTx, a difference of -0.0438/month. (p=0.001). During median follow up of 58.6 months, 6(18 %) patients lost their graft with mean time of 35 months. No graft loss occurred during first year and causes of graft loss were rejection(2), reflux pyelonephritis(1) and chronic allograft nephropathy(3). 3 patients died in one year after parathyroidectomy secondary to MI, surgical complication and sepsis.

Demographics and Clinical Characteristics

| Patient Population | Number |
|---|---|
| Age (Years) (mean ± S.D) | 49.27 |
| Male Sex | 5:3 |
| Caucasian Race | 81.81% |
| BMI(mean) | 29.13 |
| DM | 36% |
| HTN | 97% |
| PRA > 10% | 15% |
| Non Primary Transplant | 18% |
| Time to parathyroidectomy from KTx | 45 months |
| Subtotal vs. total Parathyroidectomy | 32:1 |
| PTH- Baseline | 629.27 |
| PTH- 1 week | 85.05 |
| Ca2+ -Baseline | 10.03 |
| Ca2+ - 1 week | 7.86 |
| GFR – Baseline | 47.146 |
| Median time to follow up | 58.6 months |



CONCLUSION: Post PTx, GFR may decline transiently in the first few months but subsequently improve to a level significantly superior to pre-PTx values.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO949

**Providers' Reports of Discussion of Transplant Options at the Time of Dialysis Initiation** Kirsten L. Johansen,[1,3] Rebecca H. Zhang,[2,3] Yijian Huang,[2,3] Nancy G. Kutner.[2,3] *[1]UCSF; [2]Emory University; [3]USRDS Rehab/QOL SSC.*

In 2005, the ESRD Medical Evidence Report Form was altered to include information about whether transplant options were discussed and reasons for not discussing these options. We used these data to determine the rates of transplant discussion among incident dialysis pts, reasons for non-discussion, and the association of non-discussion with delays in wait listing. Pts aged ≥18 who started dialysis from 2005-2008 were included in the analysis. Pts who had been wait listed or had received a previous transplant (n=9,350) were excluded. Pts were stratified into age categories: 18-34, 35-49, 50-64, 65-79, 80+. 317,434 pts (age 63±15, 56% male, 30% Black) were included. Overall, 70% of pts were informed about transplant options, but rates varied by age, ranging from 84% of pts age 18 to 34 to 53% of pts 80+. Reasons for not being informed by age are shown in the Table.

Reasons for not being informed of transplant option (among those not informed)*

| Reason | 18≤Age<35 | 35≤Age<50 | 50≤Age<65 | 65≤Age<80 | Age≥80 |
|---|---|---|---|---|---|
| Pt has not been assessed, % | 70.3 | 68.3 | 62.4 | 40.0 | 20.6 |
| Unsuitable due to age, % | 0.2 | 0.1 | 1.0 | 26.3 | 59.2 |
| Medically unfit, % | 13.1 | 19.0 | 26.2 | 36.6 | 34.1 |
| Psychologically unfit, % | 2.2 | 3.6 | 3.4 | 2.6 | 2.8 |
| Pt declines information, % | 0.6 | 1.0 | 1.2 | 1.8 | 1.5 |
| Other, % | 16.7 | 11.5 | 9.7 | 5.9 | 3.5 |

*Column % total greater than 100% because more than one reason was permitted. All reasons differed across age groups, p<0.0001.

Of those who were not informed about transplant options, 43.9% had not been assessed (13.3% of total cohort). Not being assessed was the most common reason cited for not informing pts of transplant options in the younger age groups. Those who had not had transplant discussed had lower rates of and longer time to transplant wait listing (HR of 0.70 (p<0.0001) for not being informed because of not assessed and HR 0.30 (p<0.0001) for any other reason in Cox regression analysis). While a smaller proportion of young pts have not had transplant discussed, more of them are simply not assessed, which is associated with delayed wait listing.

Disclosure of Financial Relationships: Research Funding: Amgen, Abbott Laboratories; Scientific Advisor: Amgen Nephrology Advisory Board.

**TH-PO950**

**Higher Mean Tacrolimus Levels at Day 2 to 5 Post Transplant Are Associated with Reduced Rates of Acute Cellular Rejection in the Era of Routine Basiliximab Induction** James Lineen, Wael F. Hussein, Frank J. O Brien, Amin Bahabri, Paul J. Phelan, Colm Magee, Peter J. Conlon. *Nephrology and Transplantation, Beaumont Hospital, Dublin, Ireland.*

**Introduction:** In a previous study by our group, higher mean tacrolimus levels between day 2 to 5 post renal transplantation were independently associated with reduced rates of acute cellular rejection (ACR) in the first 3 months post transplant. In this study we aimed to establish whether this beneficial effect persisted following the introduction of routine anti- CD25 induction therapy.

**Methods:** Three hundred and twenty two consecutive single organ cadaveric kidney transplant recipients were retrospectively stratified into 4 groups based on quartiles of mean tacrolimus levels at D2-5 post op. In addition to standard immunosupression with tacrolimus, mycophenolate mofetil and corticosteroids, all patients received basiliximab induction. Patients were followed for 3 months. Acute cellular rejection and delayed graft function were defined by standard criteria.

**Results:** Results are presented in the table 1: Subsequent multivariate analysis showed that the reduction in ACR was statistically significant (OR 0.63, p 0.033). Increased Delayed Graft Function (DGF) was also statistically significant on multivariate analysis (OR 1.63, p 0.008).

Table 1:

| Variable | Quartile 1 | Quartile 2 | Quartile 3 | Quartile 4 | p Value |
|---|---|---|---|---|---|
| TAC | 11 | 16 | 22 | 29 | 0.001 |
| Age | 42.5 | 44.1 | 50.7 | 55.2 | 0.001 |
| Donor Age | 39.5 | 37.2 | 44.8 | 46.7 | 0.001 |
| Time on Dialysis | 2.4 | 2.7 | 3.8 | 3.0 | 0.016 |
| CIT | 15.4 | 16.5 | 15.3 | 16.3 | 0.348 |
| HLA Mismatches | 3.5 | 3.2 | 3.5 | 3.5 | 0.338 |
| PRA group 1/2/3 | 47/17/36 | 41/32/27 | 54/19/27 | 47/23/30 | 0.258 |
| ACR (%) | 13 | 12 | 4 | 6 | 0.107 |
| DGF (%) | 4 | 12 | 18 | 26 | 0.001 |

TAC- mean tacrolimus level; CIT- cold ischaemia time; PRA group-low/medium/high; results expressed as mean unless otherwise stated

**Conclusions:** Higher mean tacrolimus levels at Day 2-5 post transplant are associated with reduced ACR at 3 months at the expense of increased DGF.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO951**

**Five Year Experience with Sirolimus-Based Immunosuppression in Pediatric Renal Transplantation** Leonard C. Hymes, Barry L. Warshaw. *Emory University and Children's Healthcare of Atlanta, Atlanta, GA.*

From 2003-2008, we employed a protocol for replacing calcineurin inhibitors (CNI) with sirolimus (SRL) in a cohort of low-risk pediatric renal transplant recipients. We report graft survival, acute rejection episodes, renal function and adverse events in children converted to SRL.

**Methods:** All patients initially received basiliximab induction, tacrolimus (TAC), mycophenolate and prednisone. Criteria for conversion to SRL included first renal transplants without clinical acute rejection (AR) or histologic AR on 3 month surveillance biopsies. Exclusion criteria included BK virus nephropathy, history of nephrotic syndrome, or multiple organ transplants.

**Results:** From Dec 2003 to Dec 2008, 51 patients met the criteria among 117 first renal transplants and received SRL for 45 months (mean) after withdrawing TAC. Actuarial graft survival was 91% at 5 years (Figure). AR had occurred in 13% by the first transplant year after conversion to SRL, 30% by 3 years, and none thereafter (Figure). Estimated GFR data showed preservation of renal function from the time of starting SRL to 36 month post-transplant (71 ± 18 ml/min vs. 72 ± 18 ml/min, p =.76, n= 22). Complications during SRL included aphthous ulcers (30%), BK viremia (20%), EBV (13%), CMV (3%), proteinuria (7%), elevated cholesterol (7%), IDDM (2%), leukopenia (2%), thrombocytopenia (2%), erectile dysfunction (2%) and lymph edema (2%). PTLD did not occur. SRL was discontinued in 20% within 1 year, predominantly for apthous ulcers.

**Conclusions:** Our experience from Dec 2003-2008 demonstrates excellent graft outcome and stable renal function utilizing a SRL-based, CNI-free regimen. Aphthous ulcers and BK viremia were the most prevalent adverse events.

**TH-PO952**

**Renal Transplantation in Patients with Sarcoidosis: A French Multicenter Study** Jessie Aouizerate,[1] Marie Matignon,[1] Nassim Kamar,[2] Eric Thervet,[3] Bruno Moulin,[4] Emmanuel Villar,[5] Vincent Audard,[1] Philippe Lang,[1] Philippe Grimbert.[1] *[1]Nephrology and Transplantation Department, Henri Mondor Hospital, AP-HP, Creteil, France; [2]Nephrology and Transplantation Department, Rangueil Hospital, Toulouse, France; [3]Transplantation Department, Necker Hospital, Paris, France; [4]Nephrology and Transplantation Department, Strasbourg Hospital, Paris, France; [5]Nephrology and Transplantation Department, Hospices Civils de Lyon, Lyon, France.*

*Objectives*: The outcome of renal transplantation on patients with sarcoidosis is not well known. A few case reports have described recurrence of sarcoidosis after transplant. We report for the first time results and outcome of renal transplantation in a serie of patients with sarcoidosis.

*Patients*: Eighteen patients with sarcoidosis who underwent renal transplantation were identified retrospectively in 8 french renal transplantation departments.

*Results*: Initial renal disease was related to sarcoidosis in 10 patients. At the end of the follow-up (median 42 months (range 18-196)), patient and death-censored graft survival were 94.4% and the mean GFR was 60 (+/- 25) ml/min/1.73m². Five patients (27%) experimented recurrence of sarcoidosis including extra renal involvement in two patients and renal involvement in three patients. Median GFR was lower in the group of patients with renal recurrence: 31 ml/min/1.73 m² ($p<0.05$). Recurrence occurred shortly after transplantation (median period: 13 months (range 7-192)). Risk factors for recurrence included primary renal disease related to sarcoidosis and a shorter delay between the last episode of sarcoidosis and renal transplantation.

*Conclusions*: Our results indicate that renal transplantation may be carried out safely in transplant candidates with sarcoidosis. Recurrence is not rare and is likely to impact on graft outcome and these results justify a clinical and histological monitoring mainly during the early post-transplant period.

**Association between Circulating Angiopoietin-2 Levels and Serum Phosphorus in Kidney Transplant Recipients** Istvan Mucsi,[1] Philipp Kümpers,[2] Maria Eszter Czira,[1] Anna Rudas,[1] Akos Ujszaszi,[1] Mario Schiffer,[3] Jan T. Kielstein,[3] Miklos Z. Molnar.[1,4] *[1]Semmelweis University, Budapest, Hungary; [2]University Hospital Münster, Münster, Germany; [3]Hannover Medical School, Hannover, Germany; [4]Harbor-UCLA Medical Center, Torrance, CA.*

Introduction: Hyperphosphatemia is an important risk factor for cardiovascular disease (CVD) in patients with chronic kidney disease (CKD). Recent data suggest a link between phosphate (PO4) load and endothelial dysfunction. Angiopoietin 2 (Angpt2) impairs endothelial function. Serum Angpt2 increases with progression of CKD and correlates with arteriosclerotic burden in dialysis patients. Here we examined whether circulating Angpt2 levels are associated with serum PO4 in renal transplant recipients (Tx).

Methods: Data from 258 Tx patients (age 54+12, mean eGFR 42+21 ml/min/1.73m2) from a single transplant center were analyzed. Serum Angpt2 was measured by immuno-luminometric assay. Correlation analysis and multivariable regression analysis was used to assess the independent association between serum PO4 and serum Angpt2 levels. Variables with skewed distribution were natural log-transformed.

Results: We observed a moderate positive correlation between serum Angpt2 versus serum PO4 ($r=0.337$, $p<0.001$). In addition, serum Angpt2 was negatively correlated with eGFR ($r=-0.330$, $p<0.001$) and serum albumin ($r=-0.327$, $p<0.001$) but positively correlated with serum CRP ($r=0.246$, $p<0.001$). The correlation between serum Angpt2 versus serum PO4 has remained significant after adjusting for age, gender and eGFR. Furthermore, in a multivariable linear regression model serum PO4 (beta=0.180, p=0.006) was independently associated with serum Angpt2 after statistical adjustment for age, gender, eGFR, comorbidity, serum albumin, CRP and LDL-cholesterin and use of calcineurin inhibitors and steroids.

Conclusion: Serum PO4 is independently associated with Angpt2 in kidney transplant recipients. These findings may be consistent with a hypothesis postulating serum PO4 as a novel risk factor for endothelial dysfunction and may demonstrate a novel mechanism to explain the relationship between higher serum PO4 level and cardiovascular risk.

### TH-PO954

**Dietary Sodium Intake as Risk Factor for High Blood Pressure in Renal Transplant Recipients** Else van den Berg,[1,2] Marielle Francis Engberink,[1,3] Johanna M. Geleijnse,[1,3] Jaap Homan vd Heide,[2] Gerjan Navis,[1,2] Stephan J. L. Bakker.[1,2] *[1]Top Institute Food and Nutrition, Wageningen, Netherlands; [2]Nephrology, University Medical Center Groningen, Netherlands; [3]Division of Human Nutrition, Wageningen University, Netherlands.*

Hypertension is ubiquitous after renal transplantation and a risk factor for graft failure and mortality. Blood pressure (BP) control is of major importance in renal transplant recipients (RTR). Sodium ($Na^+$) intake is a determinant of BP in the general population, and even more so in renal patients. DASH guidelines recommend a maximum salt intake of 6g/24h (100mmol $Na^+$/24h). The association between $Na^+$ intake and BP in RTR has not been well-established. Therefore, we investigated the association of $Na^+$ intake with BP in a large single center RTR cohort.

Outpatient RTR (n=499, age 53±13 year (mean±SD) 58% male, 83% on antihypertensive drugs, number of these drugs 2.0±0.9) who were at least one year post-transplantation were included. $Na^+$ intake was assessed from 24h urine, and adequacy of collection checked from 24h creatinine excretion. The morning after completion of urine collection, BP was measured for 15 minutes (half-sitting) with an automatic device (Dinamap®). Values of three last measurements were averaged.

Systolic and diastolic BP were 137±18 and 83±11 mmHg respectively. $Na^+$ excretion was 156±61 mmol/24h (range 19-374); 85% had a $Na^+$ excretion above 100mmol/24h. Both systolic and diastolic BP were positively associated with 24h urinary $Na^+$ excretion (B=0.048 mmHg per mmol/24h, P=0.006 and B=0.032 mmHg per mmol/24h, P=0.002 resp.) independent of age, sex, body surface area, use of antihypertensive drugs and renal function.

Thus, $Na^+$ intake is an important determinant of BP in RTR. The majority of RTR has a $Na^+$ intake above current guidelines. Translation of these cross-sectional data to a reduction of $Na^+$ intake by 100 mmol/d in RTR would theoretically reduce systolic and diastolic BP by 4.8 and 3.2 mmHg respectively, which exceeds similar calculations for the general population (2.4 mmHg per 100 mmol/day). Better control of $Na^+$ intake in RTR may help to prevent occurrence of graft failure and mortality due to hypertension among RTR.

### TH-PO955

**Aortic Pulse Wave Velocity as a Predictor of Long-Term Renal Allograft Function** Joerg Seckinger,[1] Bernd Krumme,[2] Anna K. Schlenker-Bø,[1] Claudia Sommerer,[1] Martin G. Zeier,[1] Vedat Schwenger.[1] *[1]Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany; [2]Department of Nephrology, Deutsche Klinik fuer Diagnostik, Wiesbaden, Germany.*

**Purpose:** Aortic pulse wave velocity (PWV) is an established marker of atherosclerotic vascular damage and cardiovascular risk. We examined the role of PWV as a predictor of long-term renal allograft function.

**Methods:** In a retrospective analysis the records of 147 renal transplant recipients with a history of PWV measurements were studied. All patients were treated with calcineurin-inhibitors as the primary immunosuppressive drug. Exclusion criteria were: measurement of PWV >5 yrs. post transplantation (TX) (n=76), preemptive TX (n=9), switching of the primary immunosuppressive drug (n=11). The remaining 51 patients were distributed into groups A (PWV>=9 $ms^{-1}$; n=25) and B (PWV<9 $ms^{-1}$; n=26).

**Results:** There were no significant differences between the two groups concerning age distribution (49.6±11.5 vs. 45.3±13.1 yrs., p=0.11), time on dialysis (4.5±2.9 vs. 5.6±3.9 yrs., p=0.16), time of initial PWV assessment (2.2±1.8 vs. 2.4±1.9 yrs. post TX, p=0.41), renal transplant function (MDRD-clearance 55.0±19.6 vs. 64.6±20.1, p=0.06; s-creatinine 1.5±0.64 vs. 1.3±0.38 mg/dl, p=0.09), renal resistance indices (RI 0.65 vs. 0.64, p=0.49) or pulse pressure (PP) (52.8±12.6 vs. 47.7±10.9 mmHg, p=0.06). The concomitant immunosuppressive therapy and overall acute rejection rate was comparable in both groups. The follow-up period after PWV measurement was 5.0±1.3 and 5.2±1.1 yrs., respectively (p=0.16). While PP (46.7±23.4 vs. 47.3±15.1 mmHg, p=0.38) and RI (0.69 vs. 0.68, p=0.35) showed no significant differences at the time of the follow-up, the allograft function in group A (elevated PWV) was significantly reduced (MDRD-clearance 41.4±20.2 vs. 58.8±24.7, p=0.005; s-creatinine 2.1±1.6 vs. 1.6±1.3 mg/dl, p=0.03).

**Conclusion:** In renal transplant recipients an elevated aortic pulse wave velocity of >=9 $ms^{-1}$ was associated with a significantly impaired long-term allograft function. Routine assessment of PWV in renal transplant recipients may help to improve the long-term outcome by identifying patients at risk for chronic allograft dysfunction.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO956

**Prediction of Cardiovascular Disease during Pre-Transplant Evaluation** Nimrit Goraya, Mohanram Narayanan, Luis A. Concepcion. *Nephrology, Texas A & M, Scott and White Hospital, Temple, TX.*

Cardiovascular disease (CAD) is a major contributor to overall mortality in renal transplant recipients. Stress echocardiography (SE) is generally the most commonly employed tool for pre-transplant evaluation of diabetic ESRD patients. Out of a total of 368 patients who underwent pre-transplant evaluation at our transplant clinic from year 2000-2009, all our diabetic patients (DM) (n= 89) were screened with cardiac catheterization (CC) irrespective of their SE findings and data compared to that of non-diabetics (NDM) (N=29) who underwent CC. Of the combined 118 patients who underwent CC, some of the variables tested are included in the table.

Variables of all patients who underwent cardiac catheterization

| | mean | standard deviation |
|---|---|---|
| age years | 57.2 | 10.7 |
| BMI | 29 | 5.6 |
| Total Cholesterol | 160 | 45.47 |
| LDL | 79.9 | 30.27 |
| time to cath from dialysis (months) | 37 | 118 |
| time to transplant from dialysis onset (months) | 55 | 143 |
| Number of stents | 0.31 | 0.7 |

No difference in demographic variables was noted between DM and NDM for age, sex, race, BMI, cholesterol and EF with the exception of patients with CAD requiring CABG who had higher cholesterol (p =0.07) and lower EF (p=0.031). Additionally, EF > or < than 50% was not a predictor of CAD in DM or NDM patients (p=0.632) and SE abnormality was not a predictor of CAD in DM (p=0.76). Comparison of demographic and echocardiographic variables according to gender and race, did not reveal any statistically significant difference in gender but African-Americans (AA) were more likely to have a higher BMI ( p=0.049) and lower EF (p=0.021) as compared to Caucasians. Our data shows that use of conventional SE to predict CAD in diabetics may not be an accurate diagnostic tool and cardiac catheterization should be considered in all diabetic patients undergoing pre-transplant evaluation.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO957

**Early and Late-Term Outcomes of Preemptive Simultaneous Pancreas-Kidney and Living Donor Kidney Transplantation** Edmund Huang, Hung-Tien Kuo, Sean Michael Masao Okumura, Suphamai Bunnapradist. *Medicine, UCLA David Geffen School of Medicine, Los Angeles, CA.*

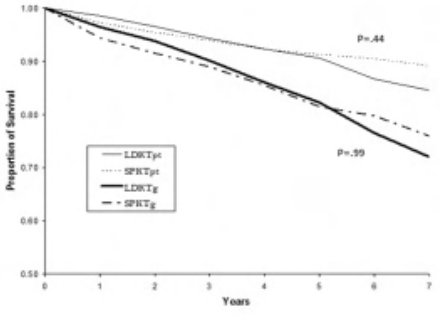
Introduction: In order to minimize dialysis time, type I diabetics (DM) with end-stage renal disease are often recommended for living donor kidney transplantation (LDKT) if a suitable donor is available rather than wait for a simultaneous pancreas-kidney transplant (SPKT). However, it is unclear how outcomes of LDKT compare with SPKT when pre-transplant dialysis can be avoided.

Methods: Using Organ Procurement and Transplantation Network/United Network of Organ Sharing data as of November 27, 2009, all preemptive type I DM recipients of a LDKT (N=1353) and SPKT (N=1429) from 2000-2009 were selected. The Kaplan-Meier product limit method was used to generate patient and kidney graft survival curves. Cox regression models were used to compare patient and kidney graft survival of LDKT and SPKT recipients.

Results: LDKT recipients were older and more likely to be obese and have cardiovascular disease compared to SPKT. Median age of donors was higher for LDKT than SPKT (42 vs. 23, P<0.001). SPKT recipients had greater median waiting time than LDKT (211 vs. 134 days, P<0.001). Although there was no difference in overall patient survival over 7 years of follow-up (log-rank P=0.44), survival was lower for SPKT compared to LDKT until approximately 3.5 years after transplant. No difference in kidney graft survival was observed over the study period (log-rank P=0.99), although after approximately 5 years there was a trend towards decreased graft survival for LDKT.

Conclusion: A trend towards greater long-term patient and graft survival was observed with preemptive SPKT recipients compared to LDKT, however this came at the expense of higher mortality earlier after transplantation. These findings should be considered when counseling type I DM candidates about transplantation options.

Figure 1. Unadjusted patient (pt) and graft (g) survival according to transplant type.



| Year | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|---|---|---|---|---|---|---|---|---|
| LDKTpt | 1353 | 1103 | 930 | 761 | 593 | 438 | 300 | 185 |
| SPKTpt | 1429 | 1128 | 921 | 708 | 537 | 392 | 290 | 202 |
| LDKTg | 1353 | 1083 | 914 | 741 | 575 | 427 | 293 | 178 |
| SPKTg | 1429 | 1097 | 896 | 686 | 516 | 374 | 279 | 194 |

## TH-PO958

**Efficacy of Two Different Plasma Volume Expansion/Vasoconstriction Regimens Compared to Tips in Patients with Hepatorenal Syndrome Type-2 Waiting for Liver Transplantation – A Prospective Randomized Trial** G. Junge,[1] Lioba Schewior.[2] *[1]University Hospital Charite Berlin; [2]University Hospital UKE Hamburg.*

**Background**

Hepatorenal Syndrome (HRS) is a reversible renal failure which occurs in patients with advanced liver disease and portal hypertension and is characterized by a marked decrease in GFR and RPF in absence of other identifiable causes. Vasodilatation theory is currently the most accepted hypothesis to explain the pathogenesis. In decompensated cirrhotics, probability of developing HRS is 8-20%/yr and increases to 40% at 5 yrs. Ideal treatment is LTx. However, there is an urgent need for effective alternative treatments to increase survival chances for pts until LTx can be performed. Interventions that have shown some promise are vasoconstrictors in splanchnic circulation and TIPS. Main objective was to compare efficacy of two different regimens (albumin/terlipressin (IIa) resp HES/terlipressin (IIb) both w/wo midodrine) versus TIPS (IIc) whereas eGRF was considered as primary efficacy endpoint.

**Patients/Method**

Dx of HRS was based on criteria, as proposed by International Ascites Club. Only patients with ESLD on the waiting list for LTx were eligible for enrolment. Patients were assigned to 3 treatment arms (IIa,b,c) and randomized w/wo midodrine. Volume/vasoconstrictor treatment lasted for 10d, mitodrine was continued; follow up for 90d.

**Results**

| | pts no | age | Gender [f:m] | CHILD | MELD |
|---|---|---|---|---|---|
| II a | 20 | 47 | 9/11 | 10 ±2 | 26 ±4 |
| II b | 15 | 48 | 8/7 | 10 ±2 | 27 ±4 |
| II c | 10 | 52 | 4/6 | 9 ±1 | 23 ±3 |

| | Crea [mg/dL] | eGFR [mL/min] | UVol [mL/24h] | Urine Na [mmol/L] | MAP [mmHg] | COP [mmHg] |
|---|---|---|---|---|---|---|
| II a | 2.8 ±0.4 | 24.0 ±5.6 | 585 ±72 | 12.2 ±3.1 | 93 ±5 | 16.0 ±0.9 |
| II b | 3.1 ±0.5 | 21.0 ±4.8 | 590 ±105 | 13.3 ±3.4 | 94 ±5 | 15.8 ±0.9 |
| II c | 2.7 ±0.4 | 25.0 ±6.9 | 680 ±113 | 17.5 ±3.4 | 94 ±6 | 16.4 ±0.6 |

**Discussion**

Combination of volume expansion/vasoconstriction effectively improved eGFR (urine output, MAP and COP) in patients with HRS Typ-2. Use of albumin shows no advantage compared to (cost effective) HES. Although a marked improvement was observed during iv-treatment, renal function deteriorated upon treatment withdrawal whereas patients with continued midodrine showed sustained treatment response.

## TH-PO959

**Routine Doppler Sonography in Kidney Graft Recipients: Should We Do It?** Ana Cortesao Costa, Alice Santana, José Guerra, Antonio Gomes da Costa. *Nephrology and Kidney Transplantation, CHLN-HSM, Lisbon, Portugal.*

Renal vein thrombosis is an infrequent complication after renal transplantation, occurring in less than 5% of cases. The spectrum of signs and symptoms is broad and ranges from anuria and sudden onset of pain in the graft to the absence of any symptoms. It is a serious complication that often leads to renal graft loss but when the diagnosis is made early allows for therapeutic intervention that can save the organ. The Doppler ultrasonography is a noninvasive method with high specificity and sensitivity for diagnosis. In our unit Doppler sonography is carried out routinely on all kidney graft recipients in the period after transplantation and has made the early diagnosis of partial renal vein thrombosis in 7 patients. In 4/7 patients the diagnosis was made at 1 month after transplantation and in the remaining at 2, 3 and 5 months. Only one patient had symptoms (edema in the ipsilateral leg), in the other six cases there were no signs or symptoms and the diagnosis was made on routine Doppler. In all cases, anticoagulant therapy was instituted, initially with low molecular weight heparin and subsequently with oral anticoagulation with warfarin, which was maintained for a minimum period of six months. Full patency of the vein was restored in all cases. There were no identifiable risk factors for venous thrombosis in these patients. The average age of the donor was 51 +/-7 years, and recipient age 41 +/-11 years. The etiology of CKD was ADPKD in 2 cases, GNC in 2, diabetic nephropathy in 2 and unknown in the remaining. The duration of dialysis before transplantation was highly variable between 7 and 192 (mean 87 +/- 67) months. Of the seven patients only one had delayed graft function and there were no episodes of acute rejection. In conclusion, the performance of Doppler routinely in our patients allowed early diagnosis of treatable vascular complications. More studies are needed to establish the frequency with which these tests should be performed after renal transplantation.

## TH-PO960

**Preservation of Renal Function in Kidney Tranplant Recipients Exposed to Epoetin Therapy** Ingeborg A. Hauser, Andeep Singh Pannu, Aida Asbe-Vollkopf, Stefan Gauer, Helge Höfeld, Ernst H. Scheuermann, Helmut Geiger. *Department of Nephrology, J. W. Goethe University, University Hospital, Frankfurt/Main, Germany.*

Post-transplant anemia (PTA) in kidney transplant recipients (KTR) occurs in 20-40% caused by comorbidities, drug therapy and declining epoetin secretion. In this single center retrospective study the clinical course of 207 anemic KTR (120 male) receiving epoetin (EPO)-therapy for at least 6 months (m) between 1999 and 2009 was analyzed.

Demographic, donor-and recipient related clinical data were collected. Information on concomitant medication, rejection episodes, hematological parameters, cardiovascular events and GFR were gathered from 12 m pre-EPO-treatment to 24 m post-EPO-initiation.

Mean age at transplantation (Tx) was 47.0±15.2 y, at initiation of EPO therapy 52.4±14.0 y. The median time between discharge after Tx and EPO start was 7.4 m. EPO α (22.2%), -b (42.5%), darbepoetin (34.7%) and C.E.R.A. (1.4%) were used. Mean Hb levels were 10.5±1.2 (at discharge after Tx), 12.8±1.6 (1 y post-Tx), 10.4±1.2 (EPO start), 12.3±1.3 (12 m EPO) and 12.2±1.4 g/dL (24 m EPO). Mean serum creatinine was 1.8±0.7 (1 y post-Tx), 2.1±0.8 (EPO start), and 2.2±1.1 mg/dL (24 m EPO). Mean GFR (MDRD) was 44.3±18.4 (at discharge), 40.8±15.8 (1 y post-Tx), 39.9±13.5 (1 y pre-EPO), 35.3±13.8 (EPO start), 35.7±14.7 (12 m EPO) and 34.7±14.8 ml/min (24 m EPO). The mean yearly loss of GFR pre-EPO therapy was 5.7±14.6 ml/min (median 2.80), undergoing a significant decrease to 0.85±6.30 ml/min (median 0.80) after EPO start ($p<0.01$). During 24 m of EPO therapy,18/207 (9.2%) recipients encountered central (3), cardiac (15) or peripheral (6) cardiovascular events. 4 KTR died, 1 experienced graft loss during the 24 m observation period.

In this observational study a renoprotective effect of EPO, initiated due to anemia, is demonstrated. Across a heterogeneous range of patients, encompassing over a decade, and initiated at various time points post Tx, the decline in renal function was significantly reduced in the presence of EPO therapy without severe side effects. Future prospective studies are needed to examine this renoprotective effect of EPO therapy in KTR.

## TH-PO961

**Use of Rituximab for Membranous Nephropathy in Renal Transplant Allografts** Alejandro Diez, Dennis P. Mishler, Tim E. Taber, Asif A. Sharfuddin. *Division of Nephrology, Indiana University, Indianapolis, IN.*

Purpose:

The treatment of membranous nephropathy (MN), a leading cause of nephritic syndrome, remains controversial. MN in the setting of a renal transplant, whether arising de novo or as recurrence of primary disease, is particularly challenging to treat given the paucity of available data. Rituximab, an anti-CD20 monoclonal antigen, may prove to be a therapeutic option in patients already receiving calcineurin inhibitors.

Methods:

A single-center retrospective review of biopsy proven cases of MN occurring in renal transplants was performed. Cases in which rituximab was used as a treatment modality were identified. Changes in proteinuria and serum creatinine were used as markers for response to treatment and allograft function.

Results:

Four cases of idiopathic MN treated with rituximab were identified. Three of the four cases were recurrence of the primary disease. In all cases maintenance immunosuppression at the time of diagnosis consisted of tacrolimus and mycophenolate mofetil. Rituximab was dosed at 375 mg/m², with either two or four doses given. No adverse effects were noted. Three patients had significant decreases in proteinuria lasting greater than six months.

Conclusions:

Rituximab appears to be a viable treatment option in renal transplant patients with MN. Studies with larger cohorts and longer follow-up periods will aid in the validation of this therapeutic approach.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO962

**A Prospective, Randomized, Single Center Trial of Calcineurin Inhibitor (CNI) Avoidance in Kidney Transplantation: 5-Year Results** Heidi M. Schaefer, Irene D. Feurer, J. Harold Helderman, David Shaffer. *Vanderbilt University, Nashville, TN.*

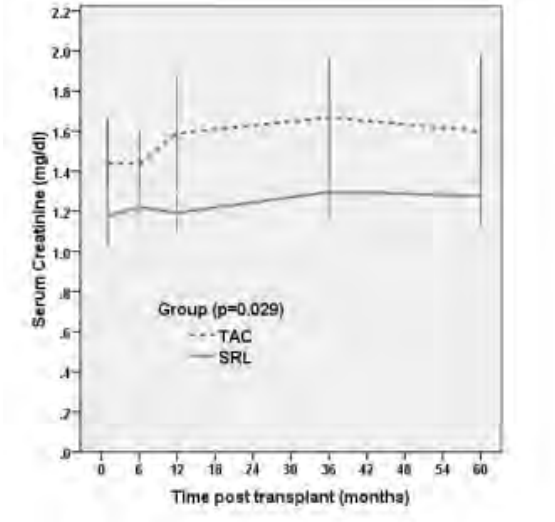
**Purpose:** Calcineurin inhibitor (CNI)-associated nephrotoxicity may exacerbate chronic allograft nephropathy (CAN) and reduce long-term graft survival. We report 5-year results comparing sirolimus (SRL) and tacrolimus (TAC) in kidney transplantation.

**Methods:** We randomized 60 recipients (31 SRL, 29 TAC) of primary cadaver or non-HLA identical kidney transplants to either SRL 5 mg QD beginning POD#3 (target level 8-12 ng/ml) or TAC 0.075 mg/kg BID POD#1 (target level 8-12 ng/ml). All received Thymoglobulin induction, mycophenolate mofetil 1 gm BID, and prednisone tapered to 5-10 mg QD by 3 mos.

**Results:** Baseline characteristics were similar between groups. Mean f/u was 1626 d for SRL and 1625 d for TAC.

At 5 yrs, there was no difference in patient survival (87% vs 89%, p=0.432) or graft survival (80% vs 75%, p=0.992) in SRL vs TAC treated pts. The incidence of biopsy proven rejection (16% vs 10%) was comparable between groups.

Linear mixed models were used to test the effect of drug on renal function over time. Serum creatinine was significantly lower in SRL-treated recipients over the 5-yr period (p=0.029).



14 pts (45%) in SRL group discontinued SRL a mean of 854 days (range 233-1467) post transplant, including 5 for late wound complications. The remainder discontinued SRL due to rejection (3), anemia (2), proteinuria (2), pulmonary toxicity (1), and diarrhea (1). In contrast, only 4 pts (14%) in TAC group discontinued TAC due to BK virus (2), CAN (1) and neurotoxicity (1).

**Conclusion:** Although complete CNI avoidance with SRL maintenance resulted in improved serum creatinine and comparable patient and graft survival vs. TAC over 5 yrs, long-term use of SRL was poorly tolerated requiring discontinuation of study medication in a significant number of patients.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO963

**Post-Transplantation Encapsulating Peritoneal Sclerosis Contributes Significantly to Mortality after Kidney Transplantation** Mario R. Korte,[1] Sayed Meelad Habib,[2] Hester Lingsma,[3] Willem Weimar,[2] Michiel G. H. Betjes.[2] *[1]Department of Internal Medicine, Albert Schweitzer Hospital, Dordrecht, Netherlands; [2]Department of Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands; [3]Department of Public Health, Erasmus Medical Center, Rotterdam, Netherlands.*

Encapsulating peritoneal sclerosis (EPS) is a severe complication of peritoneal dialysis (PD). EPS occurs frequently after kidney transplantation, known as post-transplantation EPS. In general, EPS has a high mortality, but the impact of post-transplantation EPS on patient survival after kidney transplantation is unknown.

From January[1st] 1996 until July[1st] 2007 fifty post-transplantation EPS patients were identified from the Dutch multicenter EPS study. In the partcipating centers overall 1254 PD patients were transplanted. The medical records of all transplanted PD patients were analyzed using the data from the Dutch renal registry (RENINE) and the Dutch transplantation foundation (NTS). EPS patients were younger at last transplantation than non-EPS patients (38.2 ± 14.6 vs. 46.1 ± 14.7, p<0.0001). Pre-transplant dialysis duration was longer in EPS patients (66.8 ± 37.1 vs. 34.7 ± 25.5 months, p=0.004) and EPS patients had more transplantations (1.56 ± 0.8 vs. 1.2 ± 0.5, p<0.0001).

Two-hundred-nine (16.7%) patients died after transplantation, of which twenty-five EPS patients. The majority of EPS patients died within one year after the diagnosis (median time of 10.05 ± 18.8 months). After infection (23%) and cardiovascular disease (21.1%), EPS (12%) was the third known cause of death after transplantation.

Ten-years survival of transplanted PD patients with EPS was worse compared to non-EPS patients, p-value < 0.0001. EPS, age at last transplantation, dialysis duration and transplant failure were associated with increased risk for death after kidney transplantation. Post-transplantation EPS contributes significantly to overall mortality after transplantation and lowers the survival of transplanted PD patients.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO964

**Does Donor Neutrophil Gelatinase-Associated Lipocalin (NGAL) Predict Post Transplant Allograft Function?** G. Junge,[1] Lioba Schewior.[2] *[1]University Hospital Charite Berlin; [2]University Hospital UKE Hamburg.*

**Background:**

The donor pool for KTx has plateaued worldwide. Expansion of the pool by including LR-donations and donors who previously were not accepted is the only way to increase the numbers. Data on specific parameters to predict success/failure of KTx are limited. It has been suggested that NGAL may serve as an early marker for renal injury, but have not as yet been investigated in kidney donors (KD). Therefore, it was the objective to evaluate NGAL in KD as a predictor of early allograft function after KTx.

**Method:**

We prospectively evaluated NGAL (urine, serum) in healthy volunteers (n=30) to compare results with (1) BDOD before organ procurement (n=58), (2) LR kidney donors (n=15), (3) KTx recipients who received an allograft from a BDOD (n=58) and (4) KTx recipients who received an allograft from LR donor (n=15). In addition, we followed the function of associated kidneys in correspondent transplant recipients that were classified into 2 groups depending on allograft function after KTx: IF vs DGF. The primary objective was to evaluate the predictive value of NGAL for post transplant allograft function. Secondary objectives were: (1) To compare NGAL levels in BDOD and CKD stage V patients on HD to healthy volunteers, (2) to evaluate NGAL evolution post (LR-)KTx by visit, etc.

**Results:**

We were able to show that urine (and serum) NGAL levels in corresponding KD correlate with post transplant allograft function where higher NGAL levels where predictive for DGF.

| | Initial allograft function | | DGF | | |
|---|---|---|---|---|---|
| | mean | SD | mean | SD | p=0.05 |
| SCR [mg/dL] | 1.7 | 0.53 | 2.0 | 0.62 | 0.078 |
| BUN [mg/dL] | 66.6 | 27.22 | 54.1 | 31.41 | 0.089 |
| CysC [mg/L] | 0.88 | 0.17 | 1.23 | 0.25 | <0.05[1] |
| eGFR [ml/min] | 79.5 | 12.33 | 63.6 | 12.88 | <0.05[1] |
| sNGAL [ng/mL] | 1242.3 | 502.38 | 1136.1 | 557.48 | 0.454 |
| uNGAL [ng/mL] | 81.9 | 17.42 | 153.8 | 29.41 | <0.05[1] |

**Conclusion:**

In summary, our data indicates that NGAL represents a novel, sensitive and non-invasive urinary (and serum) biomarker predictive for primary graft function after KTx. Even in cases where our classical diagnostic parameters do not allow further differentiation of potential KD (marginal donors), NGAL seems to remain a stable and significant indicator.

## TH-PO965

**Pretransplant Course and Risk of Kidney Transplant Failure in IgA Nephropathy Patients** Rune Bjoerneklett,[1] Bjørn Egil Vikse,[1] Hilde K. Smerud,[4] Torbjorn Leivestad,[2] Bjarne M. Iversen.[1] *[1]Medicine, Haukeland University Hospital, Bergen, Norway; [2]Institute of Immunology, Oslo University Hospital Rikshospitalet, Oslo, Norway; [3]Medicine, Oslo University Hospital Rikshospitalet, Oslo, Norway; [4]Smerud Medical Researche International AS, Oslo, Norway.*

**Background:** Few studies have investigated whether the presentation and course of IgA nephropathy (IgAN) prior to end-stage renal disease (ESRD) are risk factors for graft loss after kidney transplantation. The outcome with living genetically related (LRD) compared with unrelated donor (UD) grafts in transplanted IgAN patients is also not well studied.

**Material and Methods:** Patients diagnosed with IgAN between 1988 and 2006 (registered in the Norwegian Kidney Biopsy Registry) who later received a kidney transplant (registered in the Norwegian Renal Registry) were included. The cohort was followed up

regarding death censored graft loss through 2008. Graft survival with a rapid progressive (RP) vs. a slow progressive (SP) course of IgAN (annual GFR loss of more or less than 30ml/min/1.73m2) were studied.

**Results:** Duration of follow-up with the first kidney transplant was 6.9±4.4 (range 0.1-19) years. There were 14 graft losses. Graft loss rate was 1.9/100 patient years.

Patients with RP had a higher graft loss rate compared to SP patients (6.3 vs. 1.3/100 patient years p<0.001).

Recipients with LRD organs had the same graft loss rate as UD recipients (1.8 vs. 2.0/100 patient years p=0.68) but were more often rapid progressors than UD recipients (18 vs. 4%, p=0.01).

In SP patients, LRD recipients had a lower graft loss rate than UD recipients, (0.3 vs. 2.1/100 patient years, p=0.055).

**Conclusions:** A rapid pretransplant course is a strong risk factor for transplant failure in IgAN patients. In SP patients, LRD may have a better graft survival than UD organs.

## TH-PO966

**Successful Renal Transplantation in Muckle-Wells Syndrome Treated with Anti-IL1β-Monoclonal Antibody** Birgit Kortus-Götze, Joachim Hoyer. *Division of Nephrology, University of Marburg, Germany.*

Background

The Muckle-Wells syndrome (MWS) belongs to the group of rare hereditary cryopyrin-associated periodic syndromes (CAPS) and causes recurrent fever attacks, myalgia, arthralgia, urticarial rash, headache, sensorineural deafness and a severe fatigue syndrome. The development of systemic AA amyloidosis and especially renal amyloidosis is a severe complication of the Muckle-Wells syndrome. Only little is known about the feasibility of renal transplantation in Muckle-Wells syndrome patients and its impact on MWS activity.

Methods

The anti-IL1ß-monoclonal antibody canakinumab has been recently introduced as a specific treatment option in patient with Muckle-Wells syndrome with normal and impaired renal function. Here we report on a 32-year old woman with Muckle-Wells syndrome and biopsy proven systemic AA amyloidosis and end stage renal disease treated with canakinumab subcutaneously in a dosage of 150 mg every eight weeks who underwent renal transplantation.

Results

In the pre-transplantation period the patient was stable with low activity markers (CRP<5mg/l, SAA<6.4mg/l) under therapy with canakinumab. The immunological challenge after renal transplantation and the triple immunosuppressive therapy (CyA, MMF, prednisone) had no impact on activity of Muckle-Wells syndrome. The patient had no flares of Muckle-Wells syndrome under an excellent graft function (creatinine 1.2 mg/dl) and therapy with canakinumab after renal transplantation. No severe infections or adverse events were observed under canakinumab in combination with immunosuppressive therapy.

Conclusions

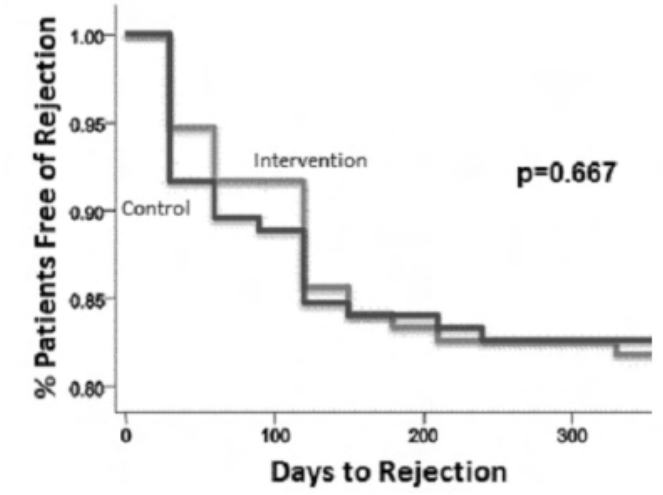
To our best knowledge, we describe the first case of a patient with Muckle-Wells syndrome and end stage renal disease successfully treated with canakinumab before and after renal transplantation. In our opinion, treatment with the anti-IL1ß-monoclonal antibody canakinumab in patients with Muckle-Wells syndrome and renal transplantation is feasible, safe and without severe side effects.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO967

**Rejection Risk of Tacrolimus Minimization Assessed by Surveillance Biopsies in Renal Transplantation** Peter C. Chang,[1] Ali Olyaei,[1,2] Eric D. Langewisch,[1] Jagdeep Obhrai,[1] Anuja Mittalhenkle,[1] Douglas J. Norman.[1] *[1]Oregon Health & Science University; [2]Oregon State University.*

**Introduction:** There is much interest in renal transplant immunosuppressive protocols that minimize nephrotoxicity. At our institution, we adopted tacrolimus (FK) minimization in 2008. With surveillance biopsies at 3 and 12 months along with ones for cause, we were able to evaluate the risk of acute rejection. **Methods:** All patients received thymoglobulin or daclizumab as induction based on immunologic risk then maintained on FK, mycophenolate and prednisone. We compared 137 adult single organ kidney transplant recipients with FK target of 5-10ng/ml to a historical group of 132 recipients with FK target of 10-15ng/ml for three months followed by 5-10ng/ml. Primary endpoint of interest is biopsy proven acute rejection (BPAR) within the first year; secondary endpoints were serum creatinine at 3 and 12 months, development of opportunistic infections and calcineurin inhibitor (CNI) toxicity on biopsy. Independent t-test was used to compare continuous variables while chi-square test was used for categorical variables; time to first BPAR was analyzed using the Kaplan-Meier method. **Results:** Immunosuppression did not differ except for FK levels which were 11.5±1.0ng/ml vs 8.0±0.9ng/ml in the first three months and 8.3±1.2ng/ml vs 7.7±0.9ng/ml thereafter between the control and intervention arms. Time to first BPAR was not different:



There were also no differences among our secondary endpoints:

| | Control | Intervention | p-value |
|---|---|---|---|
| 3m Cr* | 1.34 | 1.37 | 0.72 |
| 12m Cr* | 1.32 | 1.31 | 0.88 |
| CNI Toxicity | 15/95 | 22/86 | 0.32 |
| BK | 15/131 | 16/110 | 0.92 |
| CMV | 10/128 | 13/111 | 0.12 |

*mean

**Conclusion:** With the use of surveillance biopsies, we found no increased risk of BPAR with de novo low dose FK. Our findings support the safety of adopting CNI minimization protocols in renal transplantation.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO968

**Bimodal Relationship between Urinary Uromodulin and Renal Allograft Failure** Anna Reznichenko,[1] Marcory Van Dijk,[2] Marc Seelen,[1] Jaap Homan vd Heide,[1] Gerjan Navis,[1] Stephan J. L. Bakker.[1] *[1]Nephrology, Univ Med Centre Groningen; [2]Pathology, Univ Med Centre Groningen, Netherlands.*

Background

Urinary uromodulin excretion (UE) predicts progressive renal function decline in native kidneys. We investigated whether UE predicts renal function loss (graft failure, GF) in renal transplant recipients (RTR).

Methods

Outpatient RTR (n=606; age 51.5±12.1 yrs, 55% male; median [IQR] 6.0 [2.6-11.4] yrs post-transplant) with a functioning graft >1 yr were included. Uromodulin urinary concentration was measured by ELISA at baseline. In a subset (n=59) biopsies were scored according to Banff classification, and interstitial fibrosis/tubular atrophy (IFTA) assessed semi-quantitatively. Control values for UE were obtained in healthy volunteers (n=20), in which interindividual variation of UE was 22% (intra-day) and 60% (day-to-day), intraindividual – 89% (intra-day) and 60% (day-to-day).

Results

During the follow-up of 5.3 [4.5-5.7] yrs 42 (6.9%) RTR developed GF and 95 (15.7%) RTR died. UE was 20.3 [14.0-39.4] mg/24h in RTR versus 5.3 [2.2-10.3] mg/24h in controls (p<0.0001).

There was a curvilinear association between UE and death-censored GF, with 5.5%; 11.9% and 3.5% cases of GF in subsequent tertiles for UE, respectively (p=0.002). On multivariate Cox regression analysis hazard ratios for GF for the 1st and 3rd tertiles were 0.37 [95% CI 0.17-0.80] (p=0.01) and 0.18 [0.07-0.44] (p=0.0002) respectively, in the model adjusted for serum creatinine and proteinuria. Histopathologically IFTA was prevalent in the middle tertile of UE, whereas in case of morphologically preserved, non-atrophic tubuli both lower and higher levels of UE were observed. In line with worse morphology and graft survival, renal function by creatinine clearance was significantly lower in the second tertile of UE (p<0.05).

Conclusions

UE is associated with GF in a non-linear, bimodal fashion with reduced risk at lower and higher values. Non-linear association holds also between UE and allograft histopathology in terms of IFTA. Described association pattern is unusual for biomarkers. Dissection of the disparate mechanisms of GF prediction by UE might provide new clues for its role in progressive renal disease.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO969**

**Corticosteroid Withdrawal in Renal Transplant Recipients: An Analysis of the Mycophenolic Acid Observational Renal Transplant (MORE) Registry** Kimi Ueda Stevenson,[1] Anne Wiland,[2] Kevin M. Mccague,[2] V. Ram Peddi.[1] [1]*California Pacific Medical Center, San Francisco, CA;* [2]*Novartis, East Hanover, NJ.*

**Introduction:** Corticosteroid withdrawal (CSW) protocols are desired by renal transplant recipients (RTRs) given the potential for reduction of corticosteroid adverse effects (AEs). **Methods:** Using data from the MORE registry, a prospective, observational study of adult RTRs receiving mycophenolate (MPA) where standard-of-care is determined by 40 US sites, 6-month CSW protocol outcomes were analyzed. CSW was defined as withdrawal of steroids by 3-months post-transplant. A total of 645 tacrolimus-treated RTRs (267 CSW, 378 CS) were analyzed. **Results:** There were no differences in patient demographics (mean age 51.4 yrs, 63% male, 25% African American, 42.6% living donor RTRs). Nearly 100% of the RTRs received at least one induction agent (CS/CSW: 57.1/66.7% thymoglobulin; 4.5/20.2% alemtuzumab; 28.0/11.2% basiliximab; 12.7/0.8% daclizumab). Tacrolimus trough levels at months 1, 3, 6 and 12 were similar between groups (CS/CSW: 10.5/9.9 ng/mL; 9.4/9.0 ng/mL; 8.1/7.8 ng/mL; 7.5/7.5 ng/mL). Biopsy-proven acute rejections (BPAR) were low (7% CS vs. 5% CSW, p=0.21). Interim results at 1, 3, 6 and 12 months showed that more of the CS patients were maintained on at least full dose of MPA (CS/CSW: 85.0/68.6%, p=<0.01; 77.0/55.6%, p=<0.01; 63.6/38.1%, p=<0.01; 54.1/37.1%, p=<0.01). There was a statistically significant difference in graft survival (100 vs. 99.5%, p=<0.01) favoring the CSW group. Patient survival was similar. The CS RTRs had a higher mean serum creatinine (CS 1.52 vs.CSW 1.41mg/dL, p=0.05) but there were no differences in reported infections (including CMV and BK), bone disease, cardiovascular events, diabetes, malignancies or GI events. There was a significant difference in hematological AEs in the CSW RTRs (57.7% vs. 26.2%, p=<0.01). **Conclusions:** CS allowed for better tolerance of full dose MPA, however, there was no difference in BPAR. More RTRs in the CSW group received depleting antibody induction (86.9% vs. 61.6%). Graft survival and SCr were better in the CSW group in the short-term, however, longer follow-up is needed to assess long-term outcomes of CSW.

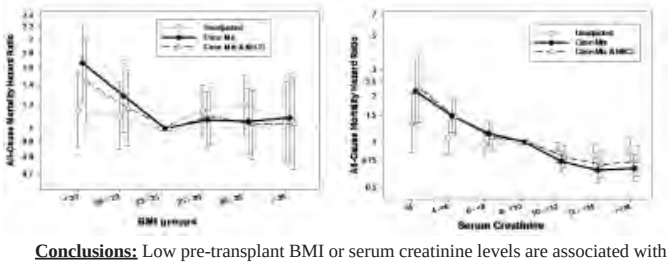
**TH-PO970**

**Associations of Pre-Transplant Obesity and Muscle Mass with Mortality in Renal Transplant Recipients** Miklos Z. Molnar,[1,2] Elani Streja,[1] Elani Streja,[1] Csaba P. Kovesdy,[3] Suphamai Bunnapradist,[4] Jennie Jing,[1] Allen R. Nissenson,[5] Istvan Mucsi,[2] Kamyar Kalantar-Zadeh.[1] [1]*Harold Simmons Center, Harbor-UCLA Medical Center, Torrance, CA;* [2]*Semmelweis University, Budapest, Hungary;* [3]*Salem VA Medical Center, Salem, VA;* [4]*Division of Transplantation, UCLA, Los Angeles, CA;* [5]*DaVita Inc, Lakewood, CO.*

**Background:** The association between pre-transplant body composition and post-transplant graft and patient survival in renal transplant recipients is not clear. We hypothesized that higher estimated muscle mass, represented by pre-transplant serum creatinine level, and larger body size, represented by higher BMI, are associated with better post-transplant outcomes. **Methods:** Linking the 5-year patient data of a large dialysis organization (DaVita) to the Scientific Registry of Transplant Recipients, we identified 10,090 maintenance hemodialysis patients who underwent their first kidney transplantation during the 7/2001-6/2007 period. **Results:** Renal transplant recipients were 49±13 years old and included 49% women and 45% diabetics. Increased mortality and worse combined patient and graft survival were associated with pre-transplant BMI<20 kg/m$^2$, whereas higher BMI values (>25 kg/m$^2$) were not associated with increased mortality or graft loss. There was a 2.3-fold increased risk of combined death and graft loss with the pre-transplant serum creatinine <4 mg/dL (p=0.002), whereas creatinine >14 mg/dL exhibited 26% greater graft and patient survival (p=0.01, reference: creatinine 8 to <10 mg/dL).



**Conclusions:** Low pre-transplant BMI or serum creatinine levels are associated with the worst post-transplant outcomes, whereas highest pre-transplant serum creatinine, a surrogate of larger muscle mass, is associated with the best post-transplant graft and patient survival.

**Impact of Donor and Recipient Body Mass Index Incompatability on Graft Function after Kidney Transplantion** Catherine Morgan, Rhonda Rosychuck, Stephen Newman, Sita Gourishankar. *University of Alberta, Edmonton, AB, Canada.*

Size compatibility between renal graft and recipient may have an impact on graft outcomes. Matching donor to recipient based on measures of graft mass relative to recipient size adds complexity to organ allocation and has the potential to change an individual's access to an organ. Our aim was to evaluate the relationship between donor and recipient size compatibility and graft outcome, using donor to recipient body mass index ratio (D/R BMI) as a predictor. We studied 538 first, non-expanded criteria donor, kidney transplants at the University of Alberta with graft survival past 6 months. Multiple linear regression was used to determine the association between D/R BMI and estimated glomerular filtration rate (eGFR) at 1, 3 and 5 years posttrasplant as well as annualized change in GFR. Cockcroft-Gault adjusted to body surface was used to determined eGFR and annualized change in GFR was determined by application of linear regression methods to serial posttransplant eGFR measurements. D/R BMI predicted eGFR at 1 year; eGFR increased as D/R BMI decreased (p=0.004 ). D/R BMI was also a significant predictor of eGFR at 3 and 5 years, an effect which was attenuated after adjusting for eGFR at 1 year. In subsequent regression which included recipient BMI category (by World Health Organization definition), the significance of D/R BMI effect disappeared. Associations were not modified by donor source (living / deceased) and there was no synergistic effect between D/R BMI and factors previously reported to influence graft function. There was little change in mean eGFR at different times after transplant and we found no association between D/R BMI and annualized change in GFR. Coupled with our finding that D/R BMI is associated with eGFR at 1 year but not 3 or 5 years after adjusting for early graft function suggests that any effect on graft survival is likely determined in the early post transplant period. The finding that the association between D/R BMI and eGFR is attenuated by including recipient BMI category in additional multivariate models indicates that recipient BMI may underlie the observed relationship between D/R BMI and graft function.

**Association of Immunosuppressive Regimen with the Development of Native Kidney and Allograft Cysts after Renal Transplantation** Matthew K. Abramowitz, Pooja Malhotra, Maria C. Bermudez, Maria Coco, Graciela De Boccardo, Enver Akalin, Daniel G. Glicklich. *Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY.*

Background: Acquired cystic kidney disease (ACKD) is a recognized risk factor for the development of renal cell carcinoma. We sought to identify risk factors for ACKD in patients after renal transplantation.

Methods: A retrospective chart review was performed of adult renal transplants at Montefiore Medical Center from 1996 – 2007. ACKD was identified by routine screening ultrasound. Patients were excluded if sonograms at baseline and a minimum of 1 year post-transplantation were not available. Logistic regression models were created to examine the association of covariates with ACKD in patients without baseline cystic disease.

Results: 472 of 887 patients met inclusion criteria. The mean age was 48 years, 43% were women, 56% were white, 34% were black, 57% underwent cadaveric transplantation, 42% had pre-transplant dialysis, 65% were treated with tacrolimus, 21% with cyclosporine, 28% with rapamycin, and 50% with mycophenolate, and median baseline serum creatinine was 1.9 mg/dL (interquartile range (IQR) 1.3 – 3.5). Overall, 1812 sonograms were performed over a median 5.2 years (IQR 3.7 – 8.1). Baseline cysts were present in the native kidney and allograft in 138 (29.2%) and 27 (5.7%) patients, respectively. Of those without baseline ACKD, 132 of 334 (39.5%) developed native kidney cysts and 51 of 445 (11.5%) developed allograft cysts during follow-up. After adjustment for the aforementioned characteristics and etiology of ESRD, only age (odds ratio (OR) per 10 year higher age, 1.43; 95% CI 1.08 – 1.88) and rapamycin use (OR 0.51, 95% CI 0.25 – 1.03) were associated with native ACKD. Covariates associated with allograft ACKD included cyclosporine use (OR 3.47 versus tacrolimus, 95% CI 1.32 – 9.10) and pre-transplant dialysis (OR 2.55, 95% CI 1.08 – 6.06).

Conclusions: ACKD is common after renal transplantation. Potential risk factors include older age, pre-transplant dialysis, and cyclosporine use, while rapamycin may have a protective effect. Further studies are needed to examine the effect of immunosuppression on ACKD.

Disclosure of Financial Relationships: nothing to disclose

**TH-PO973**

**Hyperparathyroidism Bone Health and Aortic Calcification in Renal Transplant Recipients** Sinead Kinsella,[1] Joe P. Coyle,[2] Abina Harrington,[1] Michael G. Molloy,[3] Conor Bogue,[2] Joseph A. Eustace.[1] [1]*Renal Medicine;* [2]*Radiology;* [3]*Rheumatology, Cork University Hospital, Ireland.*

**Introduction:**The relationship between post transplant hyperparathyroidism (HPT) decreased bone mineral density (BMD) and vascular calcification is unclear.

**Methods:**This is a prospective study quantifying these relationships in 1st renal allograft recipients (eGFR >30ml/min).Patients undergo DXA scan, markers of bone turnover,plain XRay of the L1-L4 spine to quantify aortic calcification score (AoCS) using a standard Framingham method (Range 0-24) and pulse wave velocity (PWV) measurement.Results expressed as mean (SD).Correlation by Spearman Rank unless otherwise stated

**Results:**Study population (n=89):61% male, age 46.6(13)yrs, dialysis vintage 2.5 (1.9) yrs, median transplant duration 3.6 yrs.MDRD eGFR was 53(16)ml/min.

Median (IQR) iPTH was 98ng/ml(72–142). 79% had PTH >65ng/ml. Median PTH was similar in 8 patients with vs. those without prior subtotal parathyroidectomy (94 vs. 98ng/ml). T-score at lumbosacral spine, neck of femur and forearm was -0.1(1.6), -0.7(1.3) and -1.1(1.4) respectively.22% had osteoporosis.Forearm DXA was associated with wrist fracture independent of age and gender, adjusted OR(aOR)0.50(0.29, 0.87). PTH positively correlated with bone specific alkaline phosphatase (r=0.62, p<0.001,Pearsons), tartrate resistant acid phosphatase 5b (r=0.48,p=0.001, Pearsons),urinary N-Telopeptide(r=0.65,p<0.001) and ionised calcium (r=0.37,p=0.001).15% of patients had subnormal phosphate and there was a significant negative correlation between PTH and phosphate(r=-0.45, p<0.001) 84% of patients were Vitamin D deficient (<50nmol/L), mean 25-hydroxyvitamin D: 37(13) nmol/L. 68% had aortic calcification, 8.2% had a score ≥10. AoCS correlated with PWV(r=0.24, p=0.046). PWV and AoCS were associated with history of atherosclerotic cardiovascular disease on univariate analysis but only PWV was independent of age(aOR 1.3; p=0.01).Neither PWV nor AoCS were independently associated with PTH or markers of bone turnover.

**Conclusion:**Post transplant HPT is common and is associated with decreased BMD, increased markers of bone turnover and prior wrist fracture but not with Aortic calcification or PWV

Disclosure of Financial Relationships: nothing to disclose

## TH-PO974

**Evaluation of the Performance of Estimated GFR To Estimate the Evolution of Measured GFR over Time in Kidney Transplant Patients** Olivier Moranne,[1] Nicolas Maillard,[2] Christopher R. Mariat.[2] *[1]Service de Néphrologie et Département de Santé Publique, CHU Nice, Nice, France; [2]Service de Néphrologie et Laboratoire d'Explorations Fonctionnelles, CHU Saint Etienne, Saint Etienne, France.*

Analysis of estimated GFR to estimate the evolution of mGFR was done in native kidney but remains largely unknown in kidney transplant patients. Objective of the study was to evaluate the performance of estimated GFR with MDRD, Cockroft and Gault formula and 1/Serum creatinin (SC) to estimate the evolution of measured GFR (mGFR) in kidney transplant patients.

In one Nephrology department, since 1996 all patients have had a mGFR at 1 year and every 5 years with urine inuline clearance. All consecutive patients with at least 3 mGFR were selected for a modelisation of the evolution of GFR over time. A generalized linear mixed model effect was used to estimate the mean baseline GFR and slope for each method. Agreement and precision between mGFR and eGFR over time was determined with calculation of bias (differences in mean slope), intraclass correlation (IC).

Two hundred and two patients were studied with 688 mGFR whom 15%, 79% and 6% have had 3, 4, 5 measures respectively. At baseline, mean age was 45 years, 75% were men, mean mGFR were 50 mL/min/1.73m2 and a first transplant in 88%. Estimation of mean baseline GFR (mL/min/1.73m2) and slope by year were as follows: mGFR[CI95%]: **48.4** [46-51] **- 0.24** [-0.46;-0.02]; MDRD: **49.0** [46-51] **- 0.15** [-0.32; 0.05]; CG: **30.0** [29-31] **– 0.27** [-0.39; 0.17]; 1/SC: **64.0** [62-67] **– 0.05** [-0.2; 0.25]. The mean bias between eGFR and mGFR for the slope was +0.11 ± 0.41; – 0.04 ± 0.4 and + 0.30 ± 0.47 ml/min/1.73m2/ year respectively for MDRD, CG and 1/SC. The intraclass correlation for the slope were 0.63, 0.65 and 0.55 respectively for MDRD, CG and 1/SC.

In this study with MDRD, the bias to estimate the mean mGFR at baseline was moderate but the slope was underestimated by 40%. The CG formula underestimates the mean baseline GFR and over estimates the slope. The 1/SC over estimates mean baseline GFR and underestimate the slope.

In clinical research mGFR has to be used. Failing to dispose of mGFR, MDRD equation could be used knowing that it will underestimate the slope by 40%.

**Transplantation after Encapsulating Peritoneal Sclerosis (EPS)** David Makanjuola,[1] Hersharan Sran,[1] Peter A. Andrews.[1] *[1]Nephrology, St. Helier Hospital, Surrey, United Kingdom; [2]Nephrology, St. Helier Hospital, Surrey, United Kingdom; [3]Nephrology, St. Helier Hospital, Surrey, United Kingdom.*

Background

EPS is a rare but serious disease, often associated with a very poor prognosis. Risk factors associated with its development include longer duration of peritoneal dialysis, high transport membrane characteristics, and frequent episodes of peritonitis.

Several reports have described the development of EPS after renal transplantation, and have proposed a link between cessation of PD, and the use of calcineurin inhibitors with the development of acute EPS.

We describe two patients whose details are described in the table below. One patient underwent peritoniectomy and enterolysis prior to transplantation, while the other was managed medically alone. Both required total parenteral nutrition, but improved sufficiently to undergo transplantation, and are surviving 41 and 11 months post-transplantation respectively with functioning grafts.

Demographics and current status

| | Patient 1 | Patient 2 |
|---|---|---|
| Age at diagnosis (years) | 47 | 40 |
| Gender | M | F |
| Cause of ESRD | FSGS | MPGN |
| Duration on Peritoneal Dialysis | 15 months | 60 months |
| Surgery for EPS | No | Yes |
| Pre-transplant immunosuppression | Tamoxifen, Prednisolone, Azathioprine | Tamoxifen, Prednisolone, Azathioprine |
| Nutrition | TPN | TPN |
| Time from EPS diagnosis to transplantation | 21 months | 20 months |
| Type of transplant | Living related | Cadaveric |
| Post-transplant immunosuppression | Prednisolone, Tacrolimus, Mycophenolate Mofetil | Prednisolone, Tacrolimus, Mycophenolate Mofetil |
| Transplant complications | Nil | Delayed graft function for 2 months, Acute rejection at 2 weeks & 3months |
| Current creatinine | 109 µmol/l | 189 µmol/l |
| Graft survival to date | 41 months | 12 months |

Conclusion

Our experience suggests that aggressive medical and surgical management of EPS can be successfully pursued with the goal of eventual organ transplantation and that the results are acceptable in highly selected patients.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO976

**The Assessment of Expected Versus Observed Post-Transplant Function by Integrating Kidney Donor and Transplant Recipient Characteristics Improves Outcome Prediction** Shuai (Stone) Li, Gordan Broderick, Kelly L. Craig, Valerie A. Luyckx, Thomas F. Mueller. *Medicine, University of Alberta, Edmonton, AB, Canada.*

Transplant recipient (R) metabolic demand and kidney donor (D) supply are the major determinants of the expected post-transplant function. However, clinically only R based serum creatinine or glomerular filtration rate are used to assess transplant function. Our study tried to integrate R and D factors to compare expected to observed post-transplant kidney function.

First we calculated the adaptive capacity (AC) of single native kidneys after donation in living donors (n=28). In average the GFR in the single remaining kidney increased by 35% post-donation ($R^2$=0.66, p<0.0001). This AC was independent of D age, gender, and weight. Next we identified the lowest observed s-crea in living (n=77, s-crea 108 ± 25 umol/L) and deceased (n=58, s-crea 110 ±30 umol/L) donor kidney recipients in the first post-transplant year. Then we calculated metabolic demand and supply in the R and D (incl. R/D age, weight, height, gender and D s-crea) and adjusted for an AC of 35%. The resulting formula of optimum expected transplant function allowed for a comparison to the observed s-crea. Despite similar observed s-crea, CG and MDRD values at 1, 2 and 3 yrs post-transplant between deceased and living donor transplants the calculation of expected vs observed s-creas differed significantly in the long-term (p<0.05). The overall regression formula showed a significant correlation and 30% prediction accuracy of 81% in LD and 65% in DD recipients. Weight differences b/w R and D were the major cause for discrepancies in expected vs observed s-crea levels. High R weight and low D weight lead to a higher than expected GFR, i.e. hyperfiltration, exceeding the usual 35% AC.

The integration of D and R characteristics in the assessment of kidney function might permit a more robust evaluation of post-transplant organ performance and identify kidneys that do not perform as they should.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO977

**Impact of ESAs, Blood Transfusions, and Iron Supplementation on Patient and Graft Survival in Anemic Kidney Transplant Recipients** Rajiv J. Gandhi, Aleksandra Kukla, Arthur J. Matas, Hassan N. Ibrahim. *Department of Medicine, Division of Renal Diseases and Hypertension, University of Minnesota, Minneapolis, MN.*

Post-transplantation anemia is associated with reduced patient and graft survival. Moreover, the use of erythropoiesis stimulating agents (ESAs) in kidney transplant recipients is linked to increased mortality at high (≥ 12.5 g/dL) hemoglobin (Hb). This data is primarily from centers with smaller numbers of patients. Herein, we describe the prevalence of anemia and the use of ESAs, transfusions, and iron supplementation in 1520 recipients transplanted from 2000 to 2010 and assess the adjusted risk of graft and patient loss associated with anemia and its treatment.

Results: Fifty-four percent of all recipients had anemia (Hb < 12 g/dL). Women, non-whites, those with previous transplants, and those exposed to pre-transplant dialysis were more likely to be anemic. In anemic recipients not receiving iron, 22.5% received ESAs alone, 37.5% received transfusions alone, 31.4% received both, and 8.9% received neither. In those on iron, corresponding percentages were 20.8, 18.1, 41.6, and 19.5. Results of a multivariate risk analysis of graft and patient loss adjusted for demographics, comorbidities, and laboratory values are shown in the table.

Predictors of Graft Loss and Recipient Death

| Predictor | | Graft Loss* | Recipient Death |
|---|---|---|---|
| Untreated anemia | | HR 3.0(95% CI 1.8-4.8),p<.01 | 1.6(0.9-3.2),0.13 |
| Treated anemia | | | |

| | Iron+ESA | 2.8(1.3-6.2),<.01 | 2.2(0.8-6.1),0.13 |
| | Iron+ESA+pRBC | 3.4(2.0-5.9),<.01 | 3.6(1.9-6.8),<.01 |

*Death censored graft loss followed a similar pattern

Conclusion: Anemia after transplantation is common, as are transfusions. Transfusions are associated with adverse patient and graft outcomes. These results indicate no adverse consequences of ESA use in this population.

Disclosure of Financial Relationships: nothing to disclose

**Serum Asymmetric Dimethylarginine (ADMA) Levels Are Associated with Serum Tumor Necrosis alpha and Hypoalbuminemia in Prevalent Kidney Transplant Recipients** Jan T. Kielstein,[1] Miklos Z. Molnar,[2,3] Mario Schiffer,[1] Maria Eszter Czira,[2] Anna Rudas,[2] Akos Ujszaszi,[2] Stefanie M. Bode-Böger,[4] Philipp Kümpers,[5] Adam Remport,[6] Istvan Mucsi.[2] *[1]Hannover Medical School, Hannover, Germany; [2]Semmelweis University, Budapest, Hungary; [3]Harbor-UCLA Medical Center, Torrance, CA; [4]Otto-von-Guericke University, Magdeburg, Germany; [5]University Hospital Münster, Münster, Germany; [6]Szent Imre Hospital, Budapest, Hungary.*

Background: Asymmetric dimethylarginine (ADMA) has been implicated in inflammation through induction of proinflammatory genes. We analyzed the association between serum ADMA, C-reactive protein (CRP), serum interleukin 6 (IL6) and tumor necrosis factor-alpha (TNF-alpha) levels in kidney transplant recipients (Tx).

Methods: Data from 258 prevalent Tx patients (age 54+12, mean eGFR 42+21 ml/min/1.73m2) from a single transplant center were analyzed. ADMA was determined using liquid chromatography-mass spectrometry. Serum IL-6 and TNF-alpha levels were measured with ELISA. Correlation analysis and multivariable regression analysis was used to assess the independent association between inflammatory markers and serum ADMA. Variables with skewed distribution were natural log-transformed.

Results: Serum ADMA was negatively correlated with eGFR (r=-0.407, p<0.001) and serum albumin (r=-0.248, p<0.001), positively correlated with IL6 (r=0.165, p=0.007) and TNF-alpha (r=0.322, p<0.001) but not with serum CRP (r=0.105, p=0.081). The correlation between serum IL6 has become non-significant after adjusting for age, gender and eGFR but the correlation between TNF-alpha and ADMA remained significant. In a multivariable linear regression model ln-TNF-alpha (beta=0.205, p<0.001) but not ln-IL6 or ln-CRP were independently associated with serum ADMA after adjustment for age, gender, eGFR, comorbidity, serum albumin and LDL-cholesterin.

Conclusion: Serum ADMA is independently associated with TNF-alpha but not with IL6 in kidney transplant recipients. Also, ADMA increases in the state of malnutrition. Hence, ADMA may be an important player of the malnutrition, inflammation atherosclerosis (MIA) syndrome in patients with impaired kidney function.

**Recurrence of Primary Glomerular Disease in Second and Subsequent Kidney Transplants** Claire Kennedy, Frank J. O Brien, Ayanfeoluwa Obilana, Peter J. Conlon. *Department of Nephrology, Beaumont Hospital, Dublin, Ireland.*

Introduction

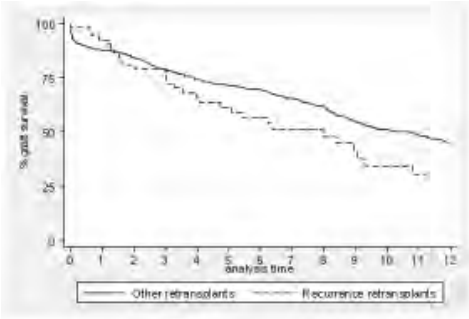
Primary glomerular diseases such as IgA Nephropathy, membrano-proliferative glomerulonephritis (MPGN) and primary focal segmental glomerular sclerosis (FSGS) are known to recur in kidney transplants and can lead to graft loss. The rate of recurrence in second kidney transplants, following failure of the first due to recurrence, is largely unknown.

Methods

A retrospective review of the Irish transplant database from 1982 – 2009 was performed. Patients were included for analysis if they had two or more kidney transplants and their first graft failed due to recurrence of the primary disease.

Results

40 patients had a deceased donor re-transplant following first graft loss to recurrence. Overall, the median graft survival of such re-transplants was 10.5 years in the case of IgA Nephropathy, 8 years in the case of MPGN, and 6 years in the case of FSGS. The median graft survival was 10.5 years for all other re-transplants (p=0.0915).



We identifed several factors which were predictive of recurrence and time to recurrence.

Conclusion

Glomerular disease does not necessarily recur in second grafts following loss of the first graft to recurrence. Graft survival following recurrence in re-transplants is comparable to survival in all other re-transplants.

Patients whose first kidney transplant fails due to recurrent glomerular disease should not be precluded from receiving a second transplant.

## TH-PO980

**In Pancreas after Kidney Transplant Recipients (PAK), the Pre-Pancreas Level of Kidney Allograft Function Is Associated with Kidney Allograft Failure** Sarah A. Browne, Jagbir Gill, James Dong, Caren L. Rose, John S. Gill. *UBC Division of Nephrology, St Pauls Hospital, Vancouver, BC, Canada.*

There is limited information to guide the selection of diabetic kidney transplant recipients for subsequent pancreas transplantation. In clinical practice, the level of kidney allograft function is relied upon to guide selection of PAK candidates.

Methods:In this analysis of n = 3030 diabetic kidney transplant recipients in the UNOS/OPTN database between 1989- 2007 who subsequently received a pancreas transplant we determined the independent association of last available GFR prior to pancreas transplantation with all-cause kidney allograft failure after the pancreas transplant.

Results: The median GFR prior to pancreas transplantation was 57ml/min (95% CI 29-93ml/min). The loss of GFR in kidney allograft recipients prior to pancreas transplant was negligible (mean GFR slope -0.07 ml/min/year, 95% CI -0.42 – 0.28). The table shows that patients with a higher pre-pancreas transplant GFR had a lower risk of all-cause kidney allograft failure after pancreas transplantation.

| Factors | Risk of kidney allograft failure |
|---|---|
| | HR (95%CI) |
| **eGFR pre-Pancreas transplant (ml/min)** | Ref <45ml/min |
| 45-60 | 0.67(0.56-0.79) |
| 61-90 | 0.58(0.48-0.69) |
| >90 | 0.49(0.33-0.74) |

1)Cox Mulitivariate Regression adjusted for patient age, gender,race, year of kidney transplantation, dialysis exposure prior to kidney transplantation, kidney donor source, and time between kidney and pancreas transplantation. 2)GFR estimated using 4 variable MDRD equation and last available creatinine prior to pancreas transplantation. GFR slope(ml/min/1.73m$^2$/year) determined using mixed effects repeated measures model

Conclusion: In this cohort of kidney allograft recipients who were selected to receive a pancreas based on their stability of kidney allograft function, the level of kidney allograft function prior to pancreas transplantation was still associated with all-cause kidney allograft failure after the pancreas transplant.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO981

**Allograft Nephrectomy: A Nine Year Experience in One Center** Samir Baroudi,[1] Nicholas J. Mayer,[1] Omar S. Abu-Romeh,[1] Mihoko Yoshino,[2] Kiyoko Oshima,[2] Bahar Bastani.[1] *[1]Division of Nephrology, Saint Louis University Health Sciences Centre, Saint Louis, MO; [2]Division of Nephropathology, Saint Louis Universiy Health Sciences Centre, Saint Louis, MO.*

**Objectives:** There is controversy on the role of transplant nephrectomy in the management of patients with failed kidney allografts. Herein, we reviewed our experience with allograft nephrectomy.

**Methods:** This retrospective observational study included patients with allograft nephrectomy performed from January 2001 through December 2009 in Saint Louis University Hospital. Clinical, laboratory and pathological data were collected. Indications for nephrectomy and the associated complications were analyzed.

**Results:** We identified 98 patients, with 100 allograft nephrectomies. The mean (±SD) duration of dialysis prior to nephrectomy was 8±15 months with 73% of patients being on low dose steroids at the time of nephrectomy. Causes of graft failure were: chronic allograft nephropathy 82%, acute rejection 4% , acute tubular necrosis 4%, vascular thrombosis 3%, and recurrent primary disease 3%. Indications for transplant nephrectomy were: hematuria 28%, local tenderness 26%, re-transplant 19%, fever 15%, and graft infection 5%. Post operative blood transfusion was required in 54% of nephrectomies. Complications were reported in 26% (n=26):10 hematoma/bleeding, 5 wound infections, 4 pneumonia, 3 sepsis, 2 intra-abdominal infection, 1 varicella zoster and 1 death (1%). The mean duration

of hospitalization was 8.9±10.6 days. The most common pathologies in the allograft nephrectomy were: vascular (arterial rejection, transplant arteriopathy or thrombosis) in 96% followed by ischemia/necrosis in 48% and hemorrhage in 14%.

**Conclusion:** Mortality and morbidity from allograft nephrectomy remains high in contemporary experience. Medical management of the failed allograft, unless serious indications for surgery (i.e., allograft infection, thrombosis/infarction, bleeding), might be a preferred approach.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO982

**Clinical Significance of Early-Onset Hyperuricemia in Renal Transplant Recipients** Byung Ha Chung, In O. Sun, Hoon Suk Park, Jayoung Lee, Sun Ryoung Choi, Seokhui Kang, Bumsoon Choi, Cheolwhee Park, Yong-Soo Kim, Chul Woo Yang. *Department of Internal Medicine, Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

***AIMS***: It is undetermined whether the effect of uric acid on graft outcome is independent of graft dysfunction. This study was designed to explore whether early-onset hyperuricemia has clinical significance regardless of graft function.

***Methods***: This study was done based on retrospective chart review. We calculated time-average uric acid (TA-uric acid) and estimated glomerular filtration rate (TA-eGFR) from the value at 3, 6, 9 month after transplantation. Hyperuricemia was defined when TA-uric acid is more than 7.0 mg/dL in male and 6.0 mg/dL in female. Reduced graft function was defined when TA-eGFR is less than 60 mL/min/1.73m$^2$. One year eGFR, cardiovascular complications during follow-up and long-term graft survival were assessed according to uric acid level and graft function.

***Results***: Three hundred and fifty one patients were included. Two hundred and two patients belonged to hyperuricemia and One hundred forty eight patients were normouricemia group. Acute rejection episode within one year of transplant, delayed graft function and deceased donor increased the risk for development of hyperuricemia. Hyperuricemia increased the risk for cardiovascular complications (HR=2.8, 95% CI: 1.1 – 7.1, *P*=0.02) but reduced graft function did not. In hyperuricemia group, 5,10 year graft survival was significantly lower than in normouricemia group (89, 81% vs. 96, 92% respectively, *P*=0.02) In reduced graft function group, those were also lower than in normal graft function group (89, 81% vs. 96, 93% respectively, *P*=0.02). In multivariate analysis, both of hyperuricemia (HR = 1.3, 95% CI: 1.0–1.6, *P* = 0.04) and reduced graft function (HR = 0.97, 95% CI: 0.95–1.0, *P* = 0.03) significantly increased the risk for graft failure and the presence of both factors gave the highest risk for graft failure (HR = 4.4, 95% CI: 2.0–9.7, *P* = 0.000).

***Conclusion***: Early-onset hyperuricemia is a significant predictor for cardiovascular complication and graft survival independent of graft function.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO983

**Assessing Renal Graft Function in the First Week Post-Transplant by Comparing Different Clearance Estimation Equations to Renal Scintigram Using DTPA-99Tc** Nuno Figueiredo, Susana Machado, Rui Alves, Fernando Macário. *Nephrology, Hospitais Universidade Coimbra, Coimbra, Portugal.*

Introduction: The surveillance of glomerular filtration rate(GFR) is very important in management of kidney transplant recipients.

Methods: From January to October of 2009 a renal scintigram was performed in the first week post-transplant in 63 patients and GFR was determined by DTPA-99Tc. We then assessed the performance of 3 different estimation equations as compared to DTPA-99Tc GFR namely: modification of diet in renal disease (MDRD), Nankivell and Cockcroft-Gault methods.

Results: Sample characterized by 63 kidney transplanted patients, with a mean age of 50,55 ± 13,46 years, 97,1% were Caucasian and 2,9% African, 55,7% were masculine and 44,3% feminine. The mean donor age was 52,48 ± 16 years, 62 transplants were from deceased donors, one from a living donor and 54,3% were from extended criteria donors. The mean cold ischemia time was 16,75 ± 4,9 hours. The mean HLA match was 2(28,6%), with a minimum of 0 in 8,6% and a maximum of 5 in 4,3%. About 55,6% received induction (36,5% Thymoglobulin and 19,1% Basiliximab). All had a calcineurin inhibitor (61,9% FK and 38,1% cyclosporine). The mean DTPA-99Tc GFR was 56,7 ± 29,1 ml/min/1,73M2. The mean differences observed comparing to DTPA-99Tc GFR were: 11,9±17,2 ml/min/1,73M2 for MDRD equation, 8,18 ± 17,4 ml/min/1,73M2 for Cockcroft-Gault equation and 35 ± 17,7 for Nankivell equation, all with a p<0,01. When we assessed the correlation between the three equations compared DTPA-99Tc GFR, all were statistically significant (p<0,01) and the highest Pearson correlation value was found for Nankivell equation(R=0,976).

Conclusion: The overall performance of the Nankivell equation to estimate the GFR in the 1st week post-transplant was superior to the other studied formulas.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO984

**End Stage Renal Disease in Lung Transplant Recipients** Ritu Khanna, Holly J. Kramer, Charles Alex, David Holt, John Milner, Susan H. Hou. *Department of Medicine, Division of Nephrology and Hypertension, Loyola University Medical Center, Maywood, IL.*

BACKGROUND: Improved outcomes in recipients of nonrenal solid organ transplants have resulted in an increased frequency of chronic kidney disease. The goal of this study was to determine the incidence of ESRD in our lung transplant population, the time to renal replacement therapy (RRT), and the difference in survival between patients who underwent dialysis vs. renal transplantation. METHODS: We reviewed the records of 627 recipients who underwent lung transplantation between January 1991 and April 2009 and were followed at our institution. Data were reviewed through June 2010. We excluded patients dialysed as part of a terminal illness. RESULTS: Of 481 patients who survived to >1 year, 37 needed RRT. Three patients needed dialysis from the time of lung transplant and died within 18 months. Thirty four patients required RRT later in their course. For 19 patients, time to dialysis varied from 17 to 168 months with a mean of 73.7 months. Of 22 dialysis patients, 3 are alive at 18 to 72 months. Mean survival for those who died was 23.4 months. A total of 15 patients received a kidney transplant (10 living donor, 3 deceased donor, 2 unknown). Eight were preemptive and 3 were done after a short period of dialysis (7 to 22 months). Data for the remaining 4 are unknown. The time to renal transplantation ranged from 27 to 141 months post lung transplant with a mean of 96.4 months. Eleven patients are currently alive with a mean survival of 56.7 months. Two were lost to follow up and 2 are deceased. Patient and renal graft survival was 100% at 1 year and 90.9% at 3 years (and 87.5% at 5 years) compared to dialysis patient survival of 64.7% at 1 year and 30.7% at 3 years (p<0.02). Five percent of 5 year lung transplant survivors and 33.3% of 10 year survivors needed chronic RRT. CONCLUSIONS: ESRD is a common complication of lung transplant seen in approximately one third of 10 year survivors. Survival in lung transplant patients treated with dialysis was significantly worse than in renal transplant recipients. Short term graft survival is comparable to graft survival in other renal transplant recipients.

Disclosure of Financial Relationships: nothing to disclose

### TH-PO985

**Risk Factors for Severity of Acute Rejection on Kidney Allograft Biopsies** Ajay K. Israni,[1] Robert Leduc,[2] David P. Schladt,[2] Pamala A. Jacobson,[3] William S. Oetting,[3] Arthur J. Matas.[4] *[1]Medicine, Hennepin County Medical Center, University of Minnesota (MN), Minneapolis, MN; [2]Biostatistics, University of MN, Minneapolis, MN; [3]Pharmacy, University of MN, Minneapolis, MN; [4]Surgery, University of MN, Minneapolis, MN.*

**Introduction**: We examined the clinical risk factors associated with severity of acute rejection (AR) in a multicenter, prospective cohort of kidney transplant (Tx) recipients from six transplant centers in Canada and the United States.

**Methods:** Our study consisted of patients receiving kidney Tx between 2006-2008 from 6 transplant centers. We had 155 recipients with clinical AR and another 216 with biopsies for cause which did not show AR and the remaining 620 with no biopsies and no clinical AR. In order to assess severity of AR, we divided the study population into 3 groups: t-score ≥2, t-score ≤1 and no biopsy group. We then used a multinomial logistical regression model to determine risk factors associated with severity of tubulitis. Since the t-scores were strongly correlated with the i-scores, we did not repeat the same analysis for i-score.

**Results:** 966 kidney transplant recipients were genotyped. Their average age was 49 ± 14 years, 17% were African Americans (AA). The 155 AR biopsies showed 70% cell-mediated AR, 18% antibody mediated and 10% with features of both and 2% other. The following t-scores for those recipients with an AR were observed: 51% t-score ≥2, 34% with t=1 and 15% with t=0. The following t-scores for those recipients without AR were observed: 2% t-score≥2, 11% with t=1 and 87% with t=0.

During the median follow-up period of 22 months post-tx, the rate of return to dialysis or retransplantation was 10% in the t ≥2 group, 5% in the t ≤1 and 1% in the no biopsy group. The factors that were associated with increasing severity of tubulitis were: *transplant center (p<0.0001), younger recipient age (p=0.002), male gender (p=0.007), PRA greater than 10% (p=0.007), increasing number of HLA mismatches (p=0.007) and donor age (p<0.0001).*

**Conclusions:** Clinical factors as well as the transplant center were significantly associated with severity of tubulitis.

### TH-PO986

**Presence of Calcium Oxalate Deposits in Protocol Transplant Biopsies Does Not Affect Kidney Allograft Prognosis** Manish Nepal,[1] Ping L. Zhang,[2] Anil Kotru,[1] Patrick Dorion,[1] Michael F. Schultz,[1] Joseph V. Bonventre.[3] *[1]Nephrology, Transplant and Pathology, Geisinger Medical Center, Danville, PA; [2]Pathology, William Beaumont Hospital, Michigan, PA; [3]Renal Division, Brigham and Women's Hospital, Boston, MA.*

Presence of renal parenchymal calcium oxalate (CaOx) deposits can be confirmed in renal biopsy by examining the birefringence of CaOx under polarized light microscopy. Deposition of such crystals in renal tubular cells has been described with short term adverse

effect like acute tubular injury and long term effects such as nephrocalcinosis and poor allograft survival. This study was designed to identify CaOx in protocol renal biopsies and evaluate an association between CaOx deposition and prognosis.

We evaluated 232 renal transplant recipients between Jan 2002 to July 2006 at Geisinger Medical Center of whom 68 patients had undergone protocol renal biopsies. Protocol biopsies performed mainly at 4 weeks, 8 weeks, 12 weeks and one year post transplant were analyzed. Mean creatinine at biopsy was 1.4 mg/dl for CaOx group and 1.6 for the non-oxalate group. Patients did not show evidence of rejection or acute kidney injury. Serum tacrolimus levels were within normal limits. Hematoxylin and eosin stained sections were (N = 68) examined under polarized light microscopy under 40 x magnification. CaOx crystals containing tubule cross sections were identified. 22/68 (32.3%) patients had CaOx deposits in the allograft biopsy. These patients had no history of hyperoxaluria or evidence of oxalate calculi. Biomarkers of injury including kidney injury molecule-1 (KIM-1) and NGAL were not detectable in renal tubules and C4d staining was also negative in peritubular capillaries. Mean follow-up time at outcome analysis was 66 months for the CaOx group (n = 22) and 68 months for the non-oxalate group (n = 46). Patient survival and graft survival were 86% and 77% for the CaOx group and 84% and 80% for the non-oxalate group.

We conclude that CaOx deposits in the allograft renal biopsy without clinical evidence of graft malfunction may represent an incidental finding and should not be taken as a prognostic marker of long term allograft function.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO987

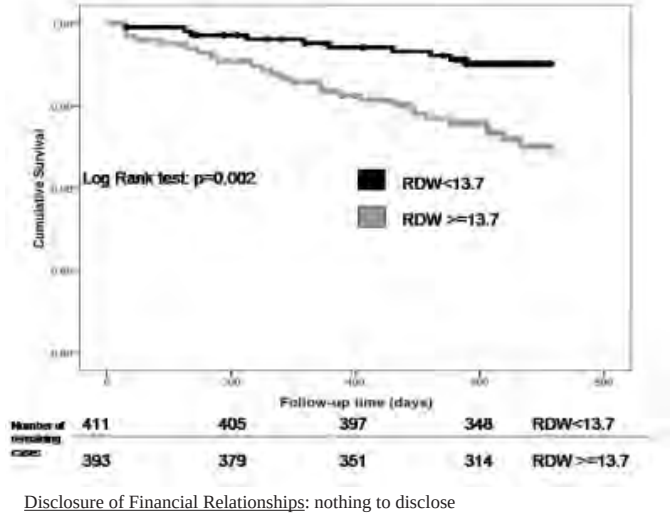
**The Red Cell Distribution Width Is Associated with Mortality in Kidney Transplanted Recipients** Miklos Z. Molnar,[1,2,3] Maria Eszter Czira,[2] Anna Rudas,[2] Akos Ujszaszi,[2] Istvan Kiss,[4] Adam Remport,[4] Marta Novak,[2] Laszlo Rosivall,[1,5] Istvan Mucsi.[2,5] *[1]Institute of Pathophysiology, Semmelweis University, Budapest, Hungary; [2]Institute of Behavioral Sciences, Semmelweis University, Budapest, Hungary; [3]Harold Simmons Center for Chronic Disease Research & Epidemiology, Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, UCLA, Torrance, CA; [4]Dept. of Nephrology, Szent Imre Hospital, Budapest, Hungary; [5]Hungarian Academy of Sciences and Semmelweis University Research Group for Pediatrics and Nephrology, Budapest, Hungary.*

**Background:** Red Cell Distribution Width (RDW) is associated with inflammation, ineffective erythropoiesis, iron deficiency and impaired renal function in patients with heart failure. It is also associated with increased morbidity and mortality risk. No published data is available about the association between mortality and RDW in kidney transplanted patients.

**Methods:** We collected socio-demographic parameters, medical and transplant history and laboratory data from 804 prevalent kidney transplant recipients. RDW was measured as part of a standard complete blood count measurement. To assess if RDW predicts with all-cause mortality risk we used Cox proportional hazards regression.

**Results:** During the 22 month follow-up, 37 subjects died. Mean age was 51±13 years, 56% of the patients were males, 21% were diabetics. Mortality was significantly higher in patients with high vs low (above vs below median) RDW at baseline. RDW was a significant predictor of mortality both in the univariate model ($HR_{1\ increase}$ = 1.594; 95% CI: 1.353-1.877) and also in a multivariate model ($HR_{1\ increase}$ = 1.451; 95% CI: 1.139-1.848) adjusting for several co-variables (age, gender, eGFR, Charlson Comorbidity Index, CRP and albumin).

**Conclusions**: RDW independently predicts mortality in prevalent kidney transplant recipients.



Disclosure of Financial Relationships: nothing to disclose

## TH-PO988

**Effect of Early Steroid Withdrawal (ESW) in a Mexican Kidney Transplants Recipients (KTR) Cohort, Treated with Tacrolimus (TAC) and Mycophenolate Mophetil (MMF)** Jorge Andrade-Sierra,[1,3] Enrique Rojas-Campos,[1] Ernesto Cardona,[3] Abel Puentes Camacho,[2] Luis Alberto Evangelista Carrillo,[2] Trinidad Orlando Lugo Lopez,[2] Benjamin Gomez-Navarro,[2] Mario Sandoval Sandoval.[2] *[1]Medical Research Unit in Renal Diseases, IMSS, Guadalajara, Jalisco, Mexico; [2]Nephrology and Organ Transplant, IMSS, Guadalajara, Jalisco, Mexico; [3]Physiology, University of Guadalajara, Guadalajara, Jalisco, Mexico.*

**Introduction:** Acute rejection (AR), is a risk in ESW. **Objective:** Compare the effect of ESW (<1week), on AR, metabolic profile, frequency of TAC toxicity. **Methods:** Retrospective cohort; 61 KTR, with PRA<20%, between Dec/2005-Mar/2010; 31 (ESW-G) 30 (CG), TAC, MMF, PDN (CG), as maintenance; ESW-G, MPD reduction from 250 (day1) to 0mg (day 5). Evaluations at baseline, 3, 6, 12 mo. Age, BP, time of RT, HLA matching, serum glucose, triglycerides, cholesterol, lipoproteins; antihypertensive and lipid lowering treatment, and eGFR by MDRD, in all evaluations graft biopsies were done to detect AR/Tox **Statistical analysis:** Comparisons between ESW/CG, were done with student´s *t* and $c^2$ tests. **Results:** Main results in Table.

Comparisons between ESW vs control group.

| | ESW Group (31) | | Control Group (30) | |
|---|---|---|---|---|
| | Baseline | Follow-up | Baseline | Follow-up |
| Receptor Age (years) | 25±9 | | 25±10 | |
| Time at follow-up (months) | 21±20 | | 31±22 | |
| HLA antigens matching | 3.6±1.7 | | 3.2±1.6 | |
| PRA (%) Class I | 1.8±2.4 | | 3.9±5.5 | |
| PRA (%) Class II | 6.9±8.2 | | 7.4±9.3 | |
| Acute rejection (%) | | 10% | | 28% |
| TAC toxicity (%) | | 38% | | 14%* |
| SBP mmHg | 132±16 | 112±9 | 147±21* | 121±15* |
| DBP mmHg | 82±10 | 71±7 | 90±15* | 81±7* |
| Lipid lowering treatment % | 10% | 20% | 10% | 27% |
| Antihypertensive treatment % | 71% | 13% | 83% | 60%* |
| Glucose (mg/dl) | 100±37 | 88±12 | 90±10 | 93±14 |
| Triglycerides (mg/dl) | 151±53 | 135±40 | 192±112 | 174±60* |
| Cholesterol (mg/dl) | 154±33 | 147±35 | 190±64* | 183±45* |
| HDL (mg/dl) | 40±13 | 50±14 | 40±14 | 44±17 |
| LDL (mg/dl) | 87±23 | 88±27 | 103±30* | 101±21* |
| eGFR ml/min | 8±4 | 81±25 | 10±15 | 65±23* |

*p<0.05 vs same evaluation ESW-group.

**Conclusions:** ESW-G had lower BP and less antihypertensive use; CG had higher total/LDL cholesterol and triglycerides vs ESW-G. A trend to lower AR in ESW-G and significant higher TAC tox in ESW-G.

Disclosure of Financial Relationships: nothing to disclose

## TH-PO989

**Protocol Biopsies (PB) Preserves Renal Allograft Function in Patients with Acute Calcineurin-Inhibitor Toxicity (CIT): A Single Center Experience** Adriana Banda Lopez,[1] Enrique Rojas-Campos,[2] Maria Guadalupe Salcedo Ceja,[1] Paul Garcia Cobian,[1] Benjamin Gomez-Navarro,[1] Francisco Ramos Solano.[3] *[1]Nephrology and Organ Trasplant Unit, CMNO, IMSS, Guadalajara, Jalisco, Mexico; [2]Medical Research Unit in Renal Diseases, CMNO, IMSS, Guadalajara, Jalisco, Mexico; [3]Unit of Pathology, CMNO, IMSS, Guadalajara, Jalisco, Mexico.*

**Objective**: Evaluate the effect of acute CIT on eGFR at 1 year in RTRs.

**Methods:** 166 RTRs between Jan-2006 to Nov-2008, with diagnostic of acute CIT, followed for 1 year. Serum Cr, glucoses, eGFR, Proteinuria, Blood pressure, at 0,3,6, 12 months were registered. Cohort was divided into: PB (69 RTRs) and biopsies for indication IB (97 RTRs).

**Outcomes**. 119(72%) were man, 144(87%) with unknown cause of ESRD. 156(94%) had living related donor. Table 1 shows clinical and biochemical comparisons. Fig.1 shows the evolution of eGFR between those with CIT and added AR.

Table 1. Features baseline and follow up

**Cause of Death in Kidney Transplant Patients – Single Center Study** Seung Yeup Han, Mi Hyun Jang, Choong-Hwan Kwak, Eun-Ah Hwang, Sung Bae Park, Hyun Chul Kim. *Internal Medicine, Keimyung University Dongsan Medical Center, Daegu, Korea.*

**Purpose** : Graft survival rate in kidney transplantation (KT) has improved over the last two decades, however patients death has been major cause of graft loss. This study performed to identify cause of death and changes according to time.

**Method** : We reviewed retrospectively medical data of patients received KT in Keimyung university Dongsan medical center from Nov. 1982 to Aug. 2009. Patients death included death with functioning graft (DWF) and death less than 3months after graft loss.

**Results** : There were 837 cases of KT in 769 patients. During average follow up duration 81±73.5 months, 72(9.4%) patients died. There were 63(87.5%) DWF. The mean age of dead patients was 39.4±11.1 years(16~59), and there was a male predominance(1.8:1). The causes of patients death were infections including sepsis constituted the largest group(30.6%). The second common cause was malignancy (22.2%), and then cardiovascular disease (11.1%). The causes of patients death were grouped for ananlysis in three time interval: less than 1year, 1year to 5years, and after 5years KT. Infection was the most common cause of death less than 1year (35.7%) and cardiovascular disease was second cause(28.6%). In 1year to 5years after transplantation, also infection was the most common cause(35.5%). After 5years transplantation, malignancy was the most common casuse(42.3%). The major causes of infection consisted of cytomegalovirus(22.7%), bacterial sepsis(22.7%), tuberculosis(18.2%), bacterial pneumonia(13.6%), meningitis(9.1%), fungus(9.1%). Major causes of malignancy were post-transplant lymphoproliferative diseases(25%), lung cancer(18.8%), renal cell carcinoma(12.5%), hepatoma(12.5%). Survival rate of transplant patients at 10 years was 88.3%. Graft survival was 51.5% when DWF was considered as a graft failure, but DWF was considered as censored data, the graft survivial rate increased to 57%. **Conclusion** : Infection was the most common cause of death less than 5years, and malignancy was the most common cause after 5years. DWF was major cause of graft loss, so early detection and treatment of cancer or infection should be paid to transplant patients.

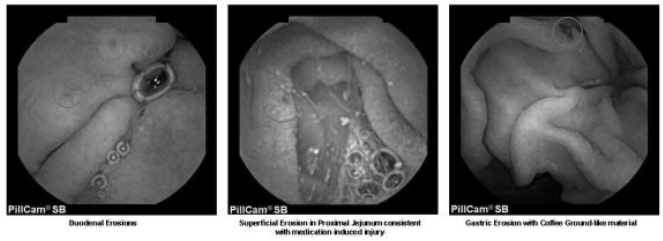
**Endoscopic Observations of Gastrointestinal Symptoms and Lesions in Patients Converted from Mycophenolate Mofetil to Enteric-Coated Mycophenolate Sodium** Suphamai Bunnapradist, Alan H. Wilkinson, Phuong-Thu T. Pham, Edmund Huang, Gabriel M. Danovitch. *UCLA Medical Center, Los Angeles, CA.*

**Introduction:** Mycophenolic acid toxicity is associated with gastrointestinal (GI) complications in renal transplant. Our goal is to evaluate GI mucosal changes in patients receiving mycophenolate mofetil (MMF) using small bowel capsule endoscopy (SBCE), and to determine if equimolar conversion to enteric-coated mycophenolate sodium (EC-MPS) may alleviate GI side effects as demonstrated by SBCE and the Gastrointestinal Symptom Rating Scale (GSRS).

**Methods:** Adult kidney only recipients transplanted more than 30 days presenting with GI symptoms underwent SBCE and completed a GSRS questionnaire, a 15 question self-assessment to rate specific GI symptoms using a 7 tier scoring scale. All were receiving tacrolimus, corticosteroids and MMF (500mg-1000mg bid). MMF was converted an equimolar dose of EC-MPS. At day 30, another SBCE and GSRS questionnaire were repeated.

**Results:** Eleven subjects completed the study (39-68 y/o, 3-8 months post-transplant), and 10 of them reported improvement of symptoms. The average GSRS at baseline and 30-days post-conversion was 3.16 and 1.79, respectively ($p < 0.01$). Baseline SBCE confirmed that 9 subjects had small bowel pathology, including: deunuded mucosa, ulcerations, lymphangiectasia, and erythema. Other findings included gastritis and colonic ulcers. At 30-days post-conversion, there was no clear correlation between resolution of symptoms and improvement in SBCE findings.



**Conclusion:** Small bowel mucosal pathology was common in kidney recipients with GI symptoms on MMF treatment. Conversion to EC-MPS for 30-days significantly improved GSRS by an average of 1.37 (clinically meaningful difference). A repeat SBCE at longer follow-up time post-conversion will be essential to evaluate whether mucosal injury may eventually improve.

**Conversion to Sirolimus (SRL) of Pediatric Renal Transplant (TX) Patients: A Single Center Experience** Marta L. Monteverde, Juan Ibañez, Alicia Chaparro, Mario Diaz, Amalia F. Turconi. *Nephrology Unit, Hospital JP Garraham, Buenos Aires, Argentina.*

We reviewed 92 children (age at TX 10, 5 ± 4, 1 y) switched from cyclosporine (86/92) to SRL after 106 ± 96 months after TX; in 57, from a cadaver donor. Conversion was due to: Chronic allograft nephropathy (CAN), 69%, Ebstein Barr virus related diseases, 12%, and thrombotic microangiopathy, 6.5%. Median time of follow up: 75 months. All patients were on ACE inhibitors. Results: In the whole group, eGFR (Schwartz formula) and proteinuria increased significantly at 3 months and then did not change. In patients with CAN grade I, eGFR increased at 3 months and remained increased up to 36 month; proteinuria did not change. In patients with CAN grade II eGFR did not change in 36 months; proteinuria increased at 3 months and then remained unchanged. Patients who increased eGFR >15 ml/min had an initial eGFR > 50 ml/min. At baseline 47% (n= 43) of patients needed another antihypertensive drug to achieve normal blood pressure; at month 3, 12% (n= 11; $p<0.01$). Two deaths occurred: one from relapse of an EBV- related B lymphoma, the other, in an accident. Actuarial patient survival was 100% at 1 year, and 96, 5% at 3, 5, 7 y 10 years. Graft survival was 96% at 1 year 90 % at 3 and 5 y; 75% at 7 y and 70% at 10; 10/92 patients lost the graft (10, 8%) due to: CAN, N=9; recurrent FSGS, N=1. SRL was stopped in 15/92 patients (16%) due to nephrotic proteinuria with or without renal failure. eGFR < 30 ml/ min at conversion and SRL withdrawal were predictors of graft loss ($p=0.001$). There were 2 de novo neoplasias: PTLD and multiple leiomiomatosis. There were 2 biopsy proven, steroid sensitive acute rejections. 51% patients had 1 or more episodes of infection (50% during the first 3 months): Low respiratory tract infection, 29%, diarrhea,15%, Herpes Zoster,13%, chicken pox, 9%; TBC in 2 patients and no late CMV infections. Non-infectious adverse events (64% in the first 3 months) were: diarrhea, 62%, oral ulcers, 15%, acne, 7%, severe anemia, 7%. We conclude that conversion to SRL can be done safely in children with good graft survival and tolerable side effects, but improvement of renal function depends on baseline CAN grade and eGFR.

**Is Voiding Cystourethrography Necessary for Pediatric Renal Transplant Candidates as Pre-Transplant Evaluation?** Yun Hye Jung,[1] Kyoung Hee Han,[1] Hyun Kyung Lee,[1] Il-Soo Ha,[1] Hae Il Cheong,[1] Yong Choi,[2] Hee Gyung Kang.[1] *[1]Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Pediatrics, Inje University Haeundae Paik Hospital, Busan, Republic of Korea.*

For adult renal transplant candidates, a voiding cystourethrography (VCUG) is no longer considered to be necessary as urologic evaluation unless the patient has a history of genitourinary abnormalities. However for children, it is still considered necessary despite its invasiveness and the risk of post-VCUG urinary tract infection (UTI). Thus, to investigate the necessity of pre-transplant VCUG for children, we reviewed 122 children with non-urologic causes of end-stage renal disease (ESRD, M:F 75:47) who underwent renal transplantation at our center between 1983 and 2010.

Primary diagnoses leading to ESRD were glomerular disease (n=60), cystic kidney disease (n=18), tubulointerstitial disease (n=7), others (n=8) and unknown (n=29). VCUG revealed vesicoureteral reflux (VUR) in 33 cases (26.8%, Gr I -III in 31, and IV in 1). Although UTI did not complicate the procedure of VCUG in these patients, two of them experienced extravasation of the contrast through their unused bladder.

During the follow-up of 7.95 years (range 0.16 - 26.92), 7 patients caught UTI 5.2 months (range 0.7-121.8 months) after transplantation, with the post-transplant UTI incidence of 0.71 /100 patient–year. Five of the 7 patients with post-transplant UTI had VUR, Gr. I (n=2) or II (n=3). On risk factor analysis, abnormal finding of VCUG was the only significant risk factor for post-transplant UTI.

In our study, VCUG as pre-transplant urologic evaluation revealed VUR in significant number of the patients. On the other hand, while the procedure of VCUG itself may cause UTI, the incidence of UTI for our pediatric kidney transplant recipients (5.7%) was not higher than that for general population of childhood (reported as up to 8%). Thus, despite the significance of low-grade VUR as a risk factor for post-transplant UTI shown in this study, we suggest that the procedure of VCUG is not cost-effective, if not unnecessary, in the pediatric population for the purpose of identifying patients at risk of post-transplant UTI.

**Characteristics & Outcome of Pediatric Atypical Hemolytic Uremic Syndrome (aHUS) at a Tertiary Care Center** Melissa A. Cadnapaphornchai,[1] Danielle Soranno,[1] Douglas M. Ford,[1] Gary M. Lum,[1] Frederick Karrer.[2] *[1]Pediatrics, University of Colorado Denver, Aurora, CO; [2]Pediatric Surgery, University of Colorado Denver, Aurora, CO.*

**Background:** aHUS is a rare condition affecting 3.3 per million children. It is associated with high risk of chronic renal failure (CRF)/end-stage renal disease (ESRD) and recurrent aHUS following isolated renal transplantation. **Purpose**: To evaluate the epidemiology and outcomes in children with aHUS at a pediatric tertiary care center. **Methods:** We reviewed the medical records of children ≤18 years of age with aHUS with respect to clinical course and outcome. **Results:** 9 children with aHUS were identified at our institution from 1993-2008. 66% were male. The mean ± SD age at presentation was 4.6 ± 3.7 yrs (0.3-11.2 yrs). Two subjects had documented influenza infection. All subjects required dialysis during initial hospitalization. Of these, five (56%) showed no evidence of renal recovery. Of four subjects who recovered renal function, two demonstrated recurrent aHUS leading to ESRD and one had residual CRF leading years later to ESRD. Extensive genetic evaluation demonstrated 4 subjects with factor H mutation. One subject was found to have low serum factor I but full evaluation was not obtained prior to death from unrelated causes. Five subjects received plasma infusion and/or plasmapheresis, including one with factor H deficiency; only one showed improvement in aHUS. Nine renal transplants were performed in six children, including one with factor H deficiency who underwent isolated kidney transplant lost to recurrent aHUS and then combined liver-kidney transplant with death from complications of liver transplant. One child with a factor H mutation thrombosed two renal transplants but then achieved successful transplantation with anticoagulation. A child with the same factor H mutation underwent renal transplantation without incident. Successful renal transplantation was achieved in 56%. Recurrent aHUS was noted in 1 of 8 isolated renal transplants. **Conclusion:** aHUS may be more common than previously reported. Studies are needed to identify factors favoring successful isolated renal transplant.

**Renal Proximal Tubule Specific GSK3 Deletion Protects from Acute Neprotoxic Injury in Miceβ** Reena Rao,[1] Raymond C. Harris.[1] *[1]Nephrology, Vanderbilt University, Nashville, TN; [2]Nephrology, Vanderbilt University, Nashville, TN.*

Glycogen synthase kinase 3 (GSK3) is a serine/threonine protein kinase that plays an important role in cell survival, proliferation and epithelial to mesenchymal transition. In the current study, we examined whether GSK3 plays an essential role in injury and recovery of renal proximal tubules after nephrotoxic acute kidney injury (AKI). We used renal proximal tubule specific GSK3 knockout mice (KO) generated by breeding GSK3 floxed mice with gamma GT-CRE mice. To examine if GSK3 gene deletion affected renal injury or repair, the mice were treated with a single subcutaneous dose of 8.14mg/Kg of HgCl2 and their renal structure and function were monitored for 8 days. Treatment with HgCl2 reduced survival rate by 40% in the WT group but only 10% in the KO group. By day 2 of treatment, the blood urea nitrogen (BUN) levels peaked in KO mice, increasing by 4-fold, and then decreased sharply, returning to baseline levels by day 4. However, in WT mice, BUN levels increased by 8-fold and its decrease was delayed, remaining above baseline even by day 8. Histological examination revealed tubular dilatation, cellular necrosis and loss of defined brush border membrane in both WT and KO kidneys. However, injury levels were markedly reduced in KO mice. This was supported by observations that renal expression of proapoptotic caspase 3 and BAX levels were lower in KO mice compared to WT. Renal tubular repair and regeneration was also accelerated in the KO mice, as indicated by morphological observations as well as increased levels of cell proliferative markers, Ki-67 and BRDU staining. GSK3 is generally constitutively active in cells. In WT mice, AKI induced by HgCl2 treatment led to a time dependent decrease in GSK activity, as indicated by an increase in the inactive phospho-GSK3 levels as well as increase in levels of -catenin, a substrate of GSK3. These results indicate that in the KO mice, HgCl2-induced proximal tubule injury is reduced and cellular repair is accelerated compared to WT mice. This study suggests that modulation of GSK3ß activity is crucial for HgCl2-induced acute nephrotoxic injury and repair in mice.

**Obestatin Improves Renal Function and Ameliorates Renal Ischemia/Reperfusion Injury in Rats Via a Neutrophil-Dependent Mechanism** Mehmet Koc,[1] Zarife Ozdemir,[2] Gulsun Memi,[2] Naziye Ozkan,[3] Sule Cetinel,[3] Berrak Yegen.[2] *[1]Division of Nephrology; [2]Department of Physiology; [3]Department of Histology, Marmara University Medical Faculty, Istanbul, Turkey.*

Obestatin (OBS)is a newly described hormone derived from the same gene with ghrelin, shown to have antiinflammatory properties. Recently, OBS was also reported to protect cardiac and intestinal cells against ischemia-reperfusion (I/R) injury and apoptosis. In order to investigate the potential protective effects of OBS in renal I/R injury, male Sprague Dawley rats underwent right nephrectomy and I/R was induced by placing a microvascular clamp across left renal artery for 60 minutes, while the control group had no clamp placement (n=8). Immediately after clamp placement, rats were injected intraperitoneally with either saline (n=9) or 10 µg/kg (n=6) or 30 µg/kg (n=5) or 100 µg/kg (n=6) OBS. Following a 24-h reperfusion period, serum and kidney samples were obtained for the assessment of histopathological changes and the determination of malondialdehyde (MDA), glutathione (GSH) levels and myeloperoxidase (MPO) activity, an index of tissue neutrophil infiltration. In saline-treated I/R group, serum creatinine level was increased significantly as compared to sham-operated group ($p<0.05$), while OBS at all doses prevented I/R-induced increase in creatinine levels ($p<0.05$). Renal MPO activity in the saline-treated group was significantly increased ($p<0.05$), but only 10 µg/kg dose of OBS abolished I/R-induced neutrophil infiltration. MDA or GSH levels were not different among experimental groups. Histological analysis revealed severe injury in the kidney samples of saline-treated rats, characterized by congestion, hyalinization and hemorrhage in the cortex and medulla along with tubular necrosis. However, in the OBS-treated (10 and 30 µg/kg) I/R groups the cortical and medullary injuries were ameliorated and the given scores were reduced ($p<0.05$). The present data demonstrate that OBS ameliorates renal I/R-injury by its possible anti-inflammatory properties, which appear to involve the suppression of neutrophil accumulation. Obestatin merits further investigation for its supportive use in ischemic renal injury.

**Knock-Down of HGF and VEGF Production Reduces the Renoprotective Effects of Adipose-Derived Stromal Cells in the Acute Kidney Injury** Takayuki Katsuno,[1] Hansu Kim,[1] Kazuhiro Furuhashi,[1] Yosuke Saka,[1] Takenori Ozaki,[1] Tokunori Yamamoto,[2] Waichi Sato,[1] Naotake Tsuboi,[1] Enyu Imai,[1] Yasuhiko Ito,[1] Seiichi Matsuo,[1] Shoichi Maruyama.[1] *[1]Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan; [2]Urology, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.*

**Introduction:** We have previously reported that human adipose-derived stromal cells (ASC) cultured in low (2%) serum media (hLASC) secreted higher levels of HGF and VEGF than in high (20%) serum media (hHASC) and markedly promoted kidney repair in a rat AKI model (ASN Renal Week 2009 Katsuno). The aim of this study is to further analyze the therapeutic effects of hLASC and to investigate the mechanisms involved.

**Methods:** AKI was induced by folic acid in nude rats at one week after heminephrectomy. Simultaneously, hLASC, hHASC or control media were given into the renal subcapsular space. Macrophage infiltration and rat HGF and VEGF in the renal cortex were assessed on day 2. Staining for αSMA and Collagen III was evaluated on day 14. In the hLASC tracking study, frozen sections were stained with anti human specific nuclear antigen. In vitro, siRNA targeted to human HGF and VEGF were transduced into hLASC respectively. Knock-down efficiency was determined by the protein levels in the supernatant. HGF knock-down hLASC, VEGF knock-down hLASC, hLASC with negative control siRNA or control media were administrated in the same AKI model, and renal function analysis was assessed.

**Results:** Administration of hLASC attenuated macrophage infiltration and interstitial fibrosis. The levels of rat HGF in the renal cortex were significantly higher in the hLASC group. Transplanted hLASC stayed alive in the subcapsular space for at least 14 days. In vitro, greater than 80% knock-down of HGF and VEGF was recognized for 96 hours after transfection. In vivo, knock-down of either HGF or VEGF in hLASC significantly reduced renoprotective effects.

**Conclusion:** We identified that hLASC modify the early inflammation and subsequent regenerative process in the AKI. Our study demonstrated that HGF, as well as VEGF, is an important mediator in the renoprotective effects of hLASC.

**Renal Protection by Bile Acids in Experimental Models of Acute Kidney Injury** Kajohnsak Noppakun,[1, 2] Shunan Li,[1, 2] Lawrence Wang,[1] Sandeep Gupta.[1, 2] *[1]Stem Cell Institute; [2]Division of Renal Diseases and Hypertension, University of Minnesota, Minneapolis.*

**Background:** Presently there are no treatments available for amelioration and prevention of acute kidney injury (AKI). Tauroursodeoxycholic acid (TUDCA) acid and ursodeoxycholic acid (UDCA) are bile acids with anti-apoptotic and pro-survival properties that are protective in animal models of acute tissue injury.

**Objective:** To determine and elucidate mechanisms of renal protection by TUDCA/UDCA in animal and cell culture models of AKI.

**Methods:** *In vivo*: Three rats each in the experimental and control groups were given daily IP injection of TUDCA (400 mg/kg/d) or vehicle from day -3 until day 6; day 0 being the day of bilateral renal artery clamping for 45 minutes. Kidney function was determined by daily estimation of blood urea nitrogen. Kidneys were harvested 5 days following AKI. Apoptotic cells in kidney sections were detected by TUNEL assay. Histological damage was scored . *In vitro*: Rat proximal tubular cells were grown in medium containing either 150 µM solution of TUDCA/UDCA or vehicle. Cells were subsequently treated with 20 µM cisplatin for 20 hours. Early apoptotic event was determined by Annexin V assay and late apoptotic event was determined by Western blot analysis for activated Poly ADP ribose polymerase (PARP) and caspase-3 enzyme activity. Mitochondrial pathway of apoptosis was assessed by translocation of cytochrome C from the mitochondria to the cytosol by Western blot analysis.

**Results:** *In vivo*: Rats treated with TUDCA had significantly less severe injury, and faster recovery of renal function. There were significantly less apoptotic cells in the TUDCA group at the cortico-medullary junction and medulla, and less severe histological damage in the deep cortex. *In vitro*: TUDCA/UDCA significantly inhibited early apoptotic events and activation of PARP. Caspase-3 activity was significantly reduced after treatment with UDCA. The translocation of cytochrome C to the cytosol following cisplatin induced injury was blocked by TUDCA.

**Conclusions:** TUDCA/UDCA can ameliorate rat experimental AKI both *in vivo* and *in vitro* and has high translational potential for use in treating clinical AKI.

**F-PO999**

**Relaxin Ameliorates Ischemia Reperfusion Induced Acute Kidney Injury** Takuya Yoshida,[1] Naoki Ikegaya,[2] Hiromachi Kumagai,[1] Tatsuo Yamamoto,[3] Akira Hishida.[4] *[1]Dep. of Clin. Nutrition, University of Shizuoka, Shizuoka, Japan; [2]Med. Care Center, Shizuoka Univ., Shizuoka, Japan; [3]Dep. of Health and Nutrition Sciences, Hamamatsu Univ., Hamamatsu, Jamaica; [4]First Dept. of Med., Hamamatsu Univ. Sch. of Med., Hamamatsu, Japan.*

Relaxin (RLX), the pregnancy hormone, has anti-apoptotic, anti-oxidative and anti-inflammatory properties. We have previously reported protective effects of RLX on renal ischemia-reperfusion (IR) injury (ASN2009). In this study we investigated the effects of RLX on IR induced injury and expression of hemeoxygenase-1 (HO-1) in kidneys. Male rats underwent unilateral nephrectomy and contralateral renal IR (45 min of renal pedicle clamping). A sham-operated group served as the control. Four groups were studied: (1) Sham, (2) IR, (3) RLX before IR, (4) RLX after IR. RLX was infused at 0.8 µg/h via subcutaneous osmotic minipump for 24 h beginning 2 h before renal IR (RLX before IR) or just after IR (RLX after IR). At 24 h of reperfusion, renal function was assessed and kidneys were removed. There was no significant difference in blood pressure among 4 groups. Increased levels of serum creatinine and urea nitrogen (BUN) were identified in the IR group compared to the Sham group. The RLX treated groups showed significantly lower serum creatinine (mean +/- SEM: IR, 3.12 +/- 0.48; RLX before IR, 1.70 +/- 0.33; RLX after IR, 1.37 +/- 0.48 ; Sham, 0.17 +/- 0.01 mg/dl) and BUN. Semi-quantitative assessment of the histological lesions showed that the IR rats developed marked structural damage, whereas significantly less tubular damage was observed in the IR-RLX rats. The expression of HO-1 was significantly increased in the IR and IR-RLX kidneys compared

to the Sham kidneys. Despite significantly decreased serum creatinine and histological injury in the RLX treated group, the increase of HO-1 of the RLX-treated group was comparable to the IR group.

These results clearly demonstrate that administration of RLX before or after ischemia attenuated tubular injury, suggesting that RLX can be a promising protective and therapeutic tool for renal IR injury.

**F-PO1000**

**Pituitary Adenylate Cyclase-Activating Polypeptide Prevents Cyclosporine A-Nephrotoxicity** Altaf-M. Khan,[1] Min Li,[1] Elizabeth Jane Brant,[1] Kristine E. Gullo,[1] Anna Wei Cai,[1] Dewan S. Majid,[2] Eric E. Simon,[1,3] Vecihi Batuman.[1,3] *[1]Section of Nephrology and Hypertension, Tulane University School of Medicine; [2]Physiology, Tulane University School of Medicine; [3]Veterans Affairs, Southeast Louisiana Veterans Health Care System, New Orleans, LA.*

Cyclosporine A (CsA) is a widely used drug for organ transplantation. Acute and long-term toxic effects on the kidney are the major dose-limiting factors. We recently showed that pituitary adenylate cyclase-activating polypeptide (PACAP) protects the kidney from ischemic and nephrotoxin-induced injury both *in vitro* and *in vivo*. This study evaluates the effects of PACAP38 on CsA nephrotoxicity in human renal proximal tubule epithelial (HK-2) cells and in intact mice. CsA caused marked morphological alterations, apoptosis in cell cultures, increased expression of transforming growth factor (TGF)-β1, and evidence of oxidative injury (NADPH oxidase and $H_2O_2$ assays). The addition of $10^{-8}$ M PACAP38 restored cell confluency, reduced TGF-β1 secretion and preserved cell integrity as indicated by lactate dehydrogenase and TUNEL assays. For studies *in vivo*, male BALB/c mice (8-10 wk old) were given a single intraperitoneal injection of CsA (5 mg/kg bw). Treatment groups received 20 μg of PACAP38 2 h before exposure to CsA, and additional doses daily for 10 days. CsA caused severe tubular injury characterized by extensive loss of tubular epithelial cell brush border membranes, tubular collapse, cellular necrosis, interstitial fibrosis, elevated serum creatinine (3.39 ± 0.21 vs 0.13 ± 0.02 mg/dl in controls, $p < 0.01$, N= 5 in each group), and significantly stimulated the production of TGF-β1 in mouse kidneys. Treatment with PACAP38 resulted in a decrease TGF-β1 and tumor necrosis factor-α production in kidney, and reduced serum creatinine levels to 1.01 ± 0.18 mg/dl, $p < 0.01$ vs CsA group. PACAP38 ameliorated renal tubular injury, inhibited the expression of proinflammatory and profibrotic cytokines, and reactive oxygen species production in CsA-exposed murine kidneys, and prevented epithelial-mesenchymal transition of the renal cells. PACAP could be a novel renoprotective agent for CsA-induced nephrotoxicity.

**Mitochondrial Injury of Collecting Duct Aggravates Cisplatin Nephrotoxicity** Dae Eun Choi,[1] Jin Young Jeong,[1] Ji Yoon Jung,[1] Dong-Suk Chang,[1] Sarah Chung,[1] Yoon-Kyung Chang,[2] Ki Ryang Na,[1] Kang Wook Lee,[1] Young Tai Shin.[1] *[1]Internal Medicine, Chungnam National University Hospital, Daejeon, Korea; [2]Internal Medicine, Daejeon St Mary's Hospital, Daejeon, Korea.*

**Introduction:** It is known that cisplatin induces injury of mitochondria in tubular cells in kidney. However, there are confusing reports whether inhibiton of mitochondrial function aggravates cisplatin nephrotoxicity. Some reported that inhibition of mitochondrial function aggravates cisplatin injury of tubular cell. However, others reported opposite results. We made collecting duct specific mitochondrial injury model using Cre-lox system. We investigated whether mitochondrial inhibition aggravates cisplatin nephrotoxicity.

**Methods:** In vitro, we used mIMCD cell, and divided 4 groups ;scRNA-mIMCD cells, crif1-siRNA-mIMCD cells, cisplatin treated scRNA-mIMCD cells, and cisplatin treated crif1-siRNA-mIMCD cells. In vivo, we got crif1 flox mice (crif1 (flox/flox)) and collecting duct cell specific crif1 knockout (KO) mice (crif1 (Δ/Δ)) via mating C57Bl/6 background HoxB7 Cre mice and crif1 flox mice. We divided 4 groups, crif1 (flox/flox), crif1 (Δ/Δ)), cisplatin treated crif1 (flox/flox), and cisplatin treated crif1 (Δ/Δ)). We evaluated functional, histologic, and molecualr studies.

**Results:** There were significant decreased in mitochondrial membrane potential, O2 consumption, and complex I, II, III, and IV in crif1-siRNA-mIMCD cells compared to scRNA-mIMCD cells. Viable cell were significantly decreased in cisplatin treated crif1-siRNA-mIMCD cells compared to cisplatin treated scRNA-mIMCD cells. The level of BUN and serum creatinine and damaged collecting tubular cells were significantly increased in cisplatin treated crif1 (Δ/Δ)) compared with cisplatin treated crif1 (flox/flox). There were no significant difference in TUNEL positive cells in both cisplatin treated crif1 (Δ/Δ)) and cisplatin treated crif1 (flox/flox).

**Conclusions:** Collecting duct cell specific crif1 deletion induced collecting duct specific mitochondrial injury including functional and structural injury. Collecting duct cell specific mitochondrial injury aggravates cisplatin nephrotoxicity.

**Phosphodiesterase 5 Inhibitor Can Ameliorate Radiocontrast-Induced Nephropathy in Rat Model of Chronic Kidney Disease** Byoung Geun Han, Jae Won Yang, Seung Tae Han, Seung-Ok Choi. *Nephrology, Yonsei University Wonju College of Medicine, Wonju, Gangwon, Republic of Korea.*

Backgrounds: Radiocontrast agent causes damage to the kidney by contracting renal arterioles and by direct toxic effect to tubular epitheliums. Phosphodiesterase-5 inhibitors (PDEi-5) are known to have not only vasodilative but also anti-oxidative effect. We investigate whether PDEi-5 ameliorates radiocontrast induced nephropathy (CIN) and N-acetylcysteine (NAC) has benefits and/or synergistic effects with PDEi-5 in rat model of chronic kidney disease.

Methods: 48 male SD rats were performed 5/6 nephrectomy and divided into 4 groups: vehicle, PDEi-5 (1.5mg/kg) treated group, NAC (60 mg/kg) treated group, and combination group. All rats received drugs 4 times every 12 hrs. Radiocontrast agent (Iopromide 10ml/kg) was injected 1 hour after 3rd injection. Blood and 24 hours urine were taken every 48 hrs for 6 days. Rats were sacrificed at 2nd and 6th day of experiment. Serum NGAL, cystatin C, BUN, and creatinine were measured. The expression of iNOS, eNOS, MCP-1, and nitrotyrosine were measured and TUNEL stain were performed in kidney.

Results: There were no significant changes of BUN and creatinine levels among groups. PDEi-5 (0.43±0.13mg/ml/100g) and NAC group (0.39±0.79mg/ml/100g) had significant improvements of creatinine clearance compared to vehicle group (0.25±0.87 mg/ml/100g) at 6th day. Serum NGAL significantly decreased in PDEi-5 (68.3±5.5 vs 82.79±11.25ng/ml, 64.1±10.1 vs 83.6±7.6ng/ml) and NAC group (58.3±19.6 vs 82.79±11.25ng/ml, 53.8±19.3 vs 83.6±7.6ng/ml) compared to vehicle group at 2nd and 4th day respectively. Serum cystatin C also significantly decreased in PDEi-5 (5.28±0.9ng/ml) and NAC group (5.8±0.66ng/ml) compared to vehicle group (7.53±1.3ng/ml) at 2nd day. At 2nd day, eNOS expression was significantly decreased in PDEi-5 group. MCP-1 and nitrotyrosine expression decreased in PDEi-5 and NAC group. At 6th day, the expression of MCP-1 and nitrotyrosine increased in vehicle and combination group. TUNEL stain showed decreased apoptosis in PDEi-5 and NAC group but not in combiantion group.

Conclusion: PDEi-5 may prevent and ameliorate CIN via anti-oxidative and anti-apoptotic potentials.

**Beneficial Effects of Darbepoietin Alpha Administration in Renal Ischemic Injury: Promotion of Tubular Adhesion** Ignacio Blanco Sanchez,[1] Elisa Conde,[1] Elia Aguado Fraile,[1] Edurne Ramos,[1] Marta Martinez,[1] Rafael Selgas,[2] Jose-Antonio Sanchez-Tomero,[3] Laura Garcia-Bermejo.[1] *[1]Pathology, Hospital Univ. Ramon y Cajal; [2]Hospital Univ. la Paz; [3]Hospital Univ. la Princesa.*

Recent studies suggest that exogenous EPO administration can exert a cytoprotective effect in renal ischemic injury although mechanisms underlying this effect are still poorly understood. We assess the effect of Darbepoetin α (DPO) during renal ischemia/reperfusion (I/R) using two experimental models: 1. an *in vivo* mouse model of renal bilateral clampling, using different DPO concentrations: high dose (HD) 25mg/kg and low dose (LD) 10mg/kg, administrated as a single injection after ischemia; 2. an *in vitro* model of hypoxia/reoxygenation (H/R) in mouse proximal tubular cells (MCT), were DPO is added at different concentrations: 100/250/500 ng/ml starting reoxygenation. Our previous studies demonstrate that HD of DPO protects from I/R injury and LD of DPO accelerates recovery. Here, we asses the mechanisms responsible for both effects. *In vitro* studies demonstrate that cell adhesion is compromised during H/R. X-celligence equipment and fluorescent microscopy after BCECF-AM labelling was used. DPO increase impedance levels in a dose-dependent manner, indicating promotion of adhesion. Moreover, adhesion assays in DPO-treated MCT cells after hypoxia confirming this. By immunofluorescence (INF), we studied localization and expression of adhesion molecules, i.e: ZO-1 for tight junctions, paxillin and actin for focal adhesions and tubulin for cytoskeleton. We found that DPO prevent ZO-1 disruption, reduces loss of actin-paxillin colocalization and prevent tubulin network impairment. In agreement, DPO reduces cell detachment and improves monolayer integrity. Immunohistochemistry and INF of those adhesion molecules in renal tissue of DPO treated mice subjected to I/R, confirms DPO capacity to protect adhesive structures. In summary, we prove the beneficial effect of DPO during I/R by maintaining the localization of proteins responsible for cellular adhesion and structure. These results strongly suggest a potential DPO therapeutic effect in nephropathies associated to tubular epithelium damage.

**Amphiregulin Promotes Renal Recovery after Acute Kidney Injury** Monika Gupta,[1] Peifeng Deng,[1] Peter Green,[1] Judit Megyesi,[2] Rick G. Schnellmann.[3] *[1]Medicine, Medical University of South Carolina; [2]Medicine, University of Arkansas for Medical Science, Little Rock, AR; [3]Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

While molecular mechanisms that regulate renal tissue repair and regeneration after acute kidney injury (AKI) are not fully understood, epidermal growth factor receptor (EGFR) appears to be critical for renal recovery. **The aim of the current study was to determine the role of amphiregulin (AR), an EGFR ligand, in AKI using a renal ischemia–reperfusion (I/R) mice model.** C57/BL6 mice underwent bilateral renal I/R injury and either received an intravenous dose of AR (10μg) or saline 2 hr after injury. Serum creatinine levels (mean ± SEM) 24, 48 and 72 hr post surgery was 2.3 ± 0.1 mg/dL, 2.5 ± 0.2 mg/dL, and 2.2 ±

0.4 mg/dL, respectively in the control group, and 1.8 ± 0.1 mg/dL, 1.4 ± 0.1 mg/dL, and 1.0 ± 0.1 mg/dL, respectively in the AR group. Histological changes were examined 72 hr after ischemia. While tubular dilation, loss of brush border, tubular necrosis and number of tubular cast were similar between the two groups, distal tubular damage was significantly lower in mice that received AR. Sham-operated mice had no tubular injury. We then examined the effect of AR on apoptosis using TUNEL assay and immunohistochemistry for active caspase-3. Compared to the I/R group, mice that received AR had lower numbers of TUNEL and caspase-3 positive cells. We further analyzed leukocyte infiltration in injured kidneys by staining neutrophils and monocytes with naphthol AS-D chloroacetate esterase. Prominent interstitial infiltration of neutrophils and monocytes was observed at 72 hr in the I/R group. Treatment with AR decreased leukocyte infiltration. We next examined the effect of AR on tubular cell proliferation by evaluating proliferating cell nuclear antigen (PCNA) positive cells. There was no difference in the number of PCNA positive cells between the two groups. **Hence, amphiregulin promotes renal recovery by decreasing inflammation, and apoptosis of tubular epithelial cells.**

**Platelets Are Relevant Mediators of Renal Injury Due to Primary Endothelial Lesions** Claudia Schwarzenberger, Sandy Walther, Christian Hugo, Bernd Hohenstein. *Department of Internal Medicine III, Division of Nephrology, Dresden, Germany.*

**Introduction:** Platelets are an important part of the coagulation system. While studies have shown angiogenic factors in platelets others suggest a more (pro)inflammatory role. We investigated platelets' role in a mouse model of selective endothelial cell (EC) injury using the P2Y12 blocker clopidogrel (clopi) or platelet depletion and tested whether platelet microparticles (PMP) reflect disease activity.

**Material and Methods:** First, 5 C57Bl/6 mice received 0.2mg anti-GPIb ab to induce rapid platelet depletion, 5 mice served as controls. 24 h later EC injury was induced by selective renal arterial perfusion of ConA/anti-ConA, sacrificial biopsies were taken after 24h. PMP were extracted from 20 mice sacrificed either 0.5h, 2h or 5d after EC injury and platelet rich plasma was analyzed by FACS (CD41 positive PMP). Next, 14 C57Bl/6 mice were treated with clopi (20mg/kg bw) or placebo via oral gavage once daily starting day -1 until sacrifice on d3. We assessed tail bleeding time, urine and blood samples and renal tissues from all mice by immunohistochemistry.

**Results:** Clopi treatment prolonged tail bleeding compared to controls ($P<0.05$). On d3, by PAS and AFOG stains glomerular injury and glomerular fibrin thrombus formation were reduced in clopi mice ($P<0.05$). EC injury (by CD31/MECA32) and EC proliferation (PCNA) demonstrated preservation of glomerular/peritubular capillaries and cell proliferation ($P<0.05$) in clopi treated mice. In parallel, platelet depletion prevented EC loss on day 1 ($P<0.05$) and EC proliferation was reduced, indicating reduced repair subsequent to reduced EC injury ($P<0.01$).

PMP in diseased animals demonstrate a rapid reduction of circulating platelets (30min: 38%, 2h: 19%) and the generation of large amounts of PMP (30min: 50%, 2h: 60%). A significant number of PMP can be found even 5 days after disease induction (51%) compared to controls (16%).

**Conclusion:** Platelets are important mediators of injury after primary EC lesions. Clopi treatment can prevent injury /improve EC repair. PMP persist beyond the time of initial EC injury indicating the presence of a long lasting procoagulant state.

**Osteopontin Predicts Survival in Critically Ill Patients with Acute Kidney Injury** Johan Lorenzen M. Lorenzen,[1] Robert Faulhaber-Walter,[1] Hermann G. Haller,[1] Jan T. Kielstein,[1] Danilo Fliser.[2] *[1]Nephrology, Hanover Medical School, Hannover, Germany; [2]Nephrology, Saarland University Medical Center, Homburg, Germany.*

Background: The cytokine osteopontin is involved in the pathophysiology of experimental acute kidney injury. We have tested the hypothesis that osteopontin levels might serve as a biomarker predicting outcome in critically ill patients requiring renal replacement therapy after acute kidney injury.

Methods: We measured circulating plasma osteopontin levels in 109 critically ill patients with acute kidney injury at inception of renal replacement therapy and 4 weeks thereafter. Critically ill patients without acute kidney injury served as controls. Osteopontin was measured with ELISA.

Results: Baseline osteopontin levels in patients with acute kidney injury were significantly higher compared to controls ($p<0.0001$). Baseline osteopontin levels in patients recovering from acute kidney injury were significantly elevated compared to patients with permanent loss of kidney function after acute kidney injury ($p=0.01$). In addition, in patients recovering from acute kidney injury without further need for renal replacement therapy osteopontin levels were significantly lower 4 weeks after initiation of renal replacement therapy ($p=0.0005$). Moreover, multivariate Cox analysis revealed osteopontin levels at renal replacement therapy inception as an independent and powerful predictor of mortality ($p<0.0001$). In the ROC-curve analysis an osteopontin cut-off value of 577 ng/mL separated survivors from non-survivors with a sensitivity of 100% and a specificity of 61% (AUC 0.82; 95% confidence interval: 0.74 to 0.89; $p<0.0001$).

Conclusions: Osteopontin may serve as a novel biomarker for both, overall survival and renal outcome in critically ill patients with acute kidney injury that require renal replacement therapy.

**Cyto-Protector Effect of a VDR Activator at the Mitochondrial Level in an Obstructive Nephropathy Model** Leon F. Ferder,[1] Walter Ariel Manucha.[2] *[1]Physiology and Pharmacology, Ponce School of Medicine, Ponce, PR; [2]Área de Fisiopatología, Facultad de Ciencias Médicas, UN de Cuyo, Mendoza, Argentina.*

Activators of vitamin D receptors have suppressant effect on the RAS, as well as anti-inflammatory and anti-fibrotic effects. This study investigates, in an obstructive nephropathy animal model, structural and functional changes in the kidney, and paricalcitol effects on these changes.

Methods: Ten adult female Wistar rats were obstructed surgically at urethero-pelvic level. They were divided in two groups: control and treated. The treatment was done for a 15 days, injecting intraperitoneally 30 ng/Kg/day. We evaluated blood pressure (BP), PTH, calcium and phosphorous levels. Kidney was also evaluated histologically for fibrosis with Masson´s trichomic, for apoptosis with TUNNEL technique, and electronic microscopy (EM) for mitochondrial evaluation.

Results: The biochemical changes in calcium, phosphorous, and PTH were not significant.

*BP*: controls 110±5mmHg, treated controls 112±7 mmHg, obstructed 145±8 mmHg ($p<0.01$) and treated obstructed 130±9 mmHg ($p<0.05$). Blood pressure was taken by plethysmography and checked intra-arterially.

*Masson Trichromic (fibrosis)*: obstructed 60±10% vs. control 5±2% ($p<0.01$) and vs. treated obstructed 20±5% ($p<0.01$).

*TUNNEL*: positive cells in obstruction 20±7 vs. controls 3±2 ($p<0.01$) and treated obstructed 10±2 ($p<0.01$). Use of this improved technique that revealed apoptotic cells, as well as those previous to apoptosis.

*Tubular Dilation*: obstructed 30 ±7 μm vs. control 10±4 μm ($p<0.01$) and treated obstructed 15±3 μm ($p<0.01$).

Changes in the kidney showed interstitial fibrosis with increased apoptosis. Both results decreased in the animals treated with paricalcitol. EM revealed, in obstructed non-treated animals, electronically luminous nuclear material in the nucleus. We also noted that the mitochondria were increased in size with dilated crests and spaces in their interior. These mitochondrial changes were not present in the paricalcitol-treated animals.

Conclusions: These results show a cyto-protected effect of the activator of Vitamin D receptors, paricalcitol, revealing for the first time a possible protective effect at mitochondrial level.

**F-PO1008**

**Could Cyclosporine Be Renal Protective in Acute Kidney Injury?** Xiao Yan Wen,[1] Zhiyong Peng,[1] Yingjian Li,[2] Hongzhi Wang,[3] Kai Singbartl,[1] John A. Kellum.[1] *[1]CRISMA Center, Critical Care Medicine, University of Pittsburgh, Pittsburgh, PA; [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA; [3]Intensive Care Unit, Beijing Cancer Hospital and Institute, Beijing, China.*

Introduction: Acute kidney injury (AKI) often represents the combined effects of ischemic, toxic and inflammatory insults. Cyclosporine mediates T-cell receptor signaling, suppresses inflammatory cytokine expression, reduces apoptosis and inhibits leukocyte migration. These properties make it a potentially valuable drug to prevent or treat AKI. However, cyclosporine carries a significant risk of nephrotoxicity especially with chronic use; though a single dose of cyclosporine might be protective while limiting nephrotoxicity.

Methods: This study was designed to evaluate the effect of cyclosporine on apoptosis, inflammation and interstitial fibrosis during folic acid(FA)-induced AKI. We hypothesize that a single, low dose of cyclosporine can ameliorate FA-induced AKI without causing nephrotoxicity. We randomly assigned mice receiving FA to one of three different doses of cyclosporine or vehicle.

Results: Intraperitoneal injection of FA consistently induced AKI, characterized by significant increases in serum creatinine, and tubular epithelial cell apoptosis. Plasma IL-6 and urinary NGAL rose 1 day after FA-injection, indicating a strong inflammatory reaction. Compared to sham treatment, low dose (1 and 5mg/kg) cyclosporine significantly reduced kidney tubular cell apoptosis, serum creatinine, plasma IL-6 and urinary NGAL 2 days after FA-injection. Moreover, low dose cyclosporine blocked the inflammatory mediator TWEAK expression, NF B activation, inflammatory cell infiltration, and interstitial fibrosis 2 weeks after treatment in a dose dependent fashion. By contrast, 10mg/kg dosing of cyclosporine resulted in nephrotoxicity.

Conclusion: Low dose cyclosporine significantly protects mice from FA-induced AKI, presumably through inhibition of inflammation, tubular cell apoptosis, interstitial cell infiltration, and fibrosis. The protective effects of a single dose of cyclosporine have the potential to open a completely new line of investigation to prevent or treat AKI.

**F-PO1009**

**AMPK Inducer, AICAR, Is Protective in Ischemia-Reperfusion Injury**
Joseph Satriano, Anne-Emilie Decleves, Volker Vallon, Kumar Sharma. *Dept of Medicine, UC San Diego & VASDHS, San Diego, CA.*

Ischemia reperfusion (IR) causes a cascade of cellular events prompting cellular damage leading to cell death. A response to ischemia is the activation of AMP-activated protein kinase (AMPK). AMPK induces a number of protective, cell survival mechanisms. We propose that inducing AMPK activity prior to IR could prove beneficial.

Sprague-Dawley rats were divided into 4 groups: 1) Control, 2) IR, 3) AMPK inducer, AICAR, 4) IR+AICAR. AICAR (0.1g/kg) was administered 24h prior to ischemia. Three weeks after nephrectomy (all groups) kidney ischemia was performed for 30 min, with reperfusion for 24 hrs. AICAR significantly increased AMPK activity (pAMPK/AMPK ratio: C 1.13±0.32, IR 1.82±0.19, AICAR 2.39±0.35, IR+AICAR 4.15±0.32*, N=4-5 for each group, mean±SEM; * P<0.05 v IR).

Immunoblotting showed an increase in autophagy protein LC3-I in AICAR samples (C 3608±174; IR 3687±309, AICAR 6183±285, IR+AICAR 7137±326*; relative densitometric units). During autophagy, cytosolic LC3-I is converted to an active autophagosome bound LC3-II form. LC3-II increases with IR and significantly further in IR+AICAR (C 318±103, IR 1179±111, AICAR 743±144, IR+AICAR 3629±629*). Autophagy rids the cell of damaged proteins and organelles, suppressing oxidative stress and cell death. In accord with increased autophagy we observed a decrease in the apoptotic execution caspase-3 expression in IR with AICAR (C 1353± 100, IR 4286± 246, AICAR 2039± 62, IR+AICAR 3208± 255*). IR decreased the gap junction protein Cx43, limiting the spread of IRI associated signaling molecules, and increased cyclin kinase inhibitor p27KIP1 and ROS generating NOX4 expressions. AICAR significantly attenuated these responses to IR, again implying less extensive injury (Cx43: C 697±104, IR 345±32, AICAR 1258±71, IR+AICAR 544±30*; p27: C 622±151, IR 4983±515, AICAR 1010±80, IR+AICAR 2709±154*; NOX4: C 624±108, IR 4275±665, AICAR 769±130, IR+AICAR 2858±346*). Parallel changes occurred in response to the AMPK agonist, metformin.

There are currently no clinical procedures in place to safeguard the kidney from IRI. This data implies AMPK induction, in part through induction of autophagy, can provide protective effects in IR.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1010**

**Hepatocyte Growth Factor /c-Met Signaling Contributes to the Acquired Resistance after Acute Subclinical Kidney Damage with Uranyl Acetate**
Tomoyuki Fujikura, Akashi Togawa, Hiroyuki Suzuki, Hideo Yasuda, Akihiko Kato, Yoshihide Fujigaki. *First Department of Medicine, Hamamatsu University School of Medicine, Shizuoka, Japan.*

Animals recovered from acute kidney injury (AKI) are resistant to subsequent nephrotoxic insults, which is called acquired resistance. We previously reported that rats recovered from subclinical kidney damage without renal dysfunction induced sub-toxic dose of uranyl acetate (UA) showed partial resistance to subsequent nephrotoxic dose of UA in association with reduced renal dysfunction and accelerated cell proliferation compared with vehicle treated as the first insult.(Sun et. al. 2010)

In the present study, we examined possible roles of HGF/c-Met signaling in this acquired resistance model in vivo and in vitro. Rats recovered from subclincal kidney damage by sub-toxic dose of UA (0.2mg/kg), followed by nephrotoxic dose of UA (4mg/kg), were analyzed. After the second nephrotoxic insult, c-Met proteins in the renal tissues were higher than in vehicle pre-treated rats. Using confluent monolayer of primary cultured tubular cells from rats treated with sub-toxic dose of UA or vehicle by collagenase digestion, the cell migration was analyzed by wound-healing assay with or without hepatocyte growth factor (HGF). Wound closure of cells from UA (0.2mg/kg) treated rats was as same as cells from vehicle-treated rats without HGF. However, wound closure was significantly different with HGF after 12hr culture between them(91.8±8.7% vs. 74.0±5.8%). These results suggest that HGF/c-Met signaling may contribute accelerated tubular cell migration in rats that recovered from subclincal kidney damage, followed by nephrotoxic insult, resulting in the partial acquired resistance.

**F-PO1011**

**SIRT1 Activation by Resveratrol Ameliorates Cisplatin-Induced Renal Injury through Deacetylation of p53**
Kyung Pyo Kang,[1] Duk Hoon Kim,[1] Yujin Jung,[1] Aesin Lee,[1] Jung Eun Lee,[1] Ki Dong Lee,[1] Mi Jeong Sung,[2] Sik Lee,[1] Sung Kwang Park,[1] Won Kim.[1] *[1]Internal Medicine, Research Institute of Clinical Medicine, Chonbuk National University Medical School, Jeonju, Republic of Korea; [2]Food Function Research Center, Korea Food Research Institute, Songnam, Republic of Korea.*

Nephrotoxicity is one of the important dose-limiting factors during cisplatin treatment. There is a growing body of evidence that activation of p53 has a critical role in cisplatin-induced renal apoptotic injury. The nicotinamide adenine dinucleotide-dependent protein deacetylase, SIRT1 decreases apoptosis through deacetylating of p53 and resveratrol is known as an activator of SIRT1. To study the role of SIRT1 in cisplatin-induced renal injury through interaction with p53, the mouse proximal tubular cells (MPT) were treated with cisplatin and examined the expression level of SIRT1, acetylation of p53, PUMA-α, Bax, the ratio of cytosolic/mitochondrial cytochrome c, and active caspase-3. The expression of SIRT1 was decreased by cisplatin. Resveratrol, a SIRT1 activator, ameliorated cisplatin-induced acetylation of p53, apoptosis and cytotoxicity in MPT cells. In addition, resveratrol remarkably increased cisplatin-induced decrease of Bcl-xL in MPT cells. Further specific SIRT1 inhibition with EX 527 or siRNA specific to SIRT1 reversed the effect of resveratrol on cisplatin-induced toxicity. SIRT1 protein expression after cisplatin treatment was significantly decreased in kidney. SIRT1 activation by resveratrol decreased cisplatin-induced apoptosis as demonstrated by TUNEL assay. Taken together, our findings suggest that the modulation of p53 by SIRT1 could be a possible target to attenuate cisplatin-induced kidney injury.

**Beneficial Effect of Mineralocorticoid Receptor Antagonism in Acute Cyclosporine A Nephrotoxicity**
Jean-Philippe Bertocchio,[1] Jean-Paul Duong van Huyen,[2] Soumaya El Moghrabi,[1] Philippe Rieu,[3] Frederic Jaisser.[1] *[1]Centre de Recherche des Cordeliers Team 1, INSERM U872, Paris, France; [2]Service d'Anatomo-Pathologie, Hôpital Européen Georges Pompidou, Paris, France; [3]Service de Néphrologie, CHU de Reims, Reims, France.*

Cyclosporine A (CsA) nephrotoxicity is one of its most frequent adverse effect but its physiopathology remains unclear. The implication of aldosterone has been proposed based on experimental studies in rat showing that pharmacological blockade of the Mineralocorticoid Receptor (MR) prevents nephrotoxicity of the CsA by modulating the expression of vaso-active factors (Perez-Rojas et al. AJPRP 2005). We have recently shown that MR is expressed in the endothelium of the renal vasculature and that endothelial-specific MR overexpression alters vascular function (Nguyen Dinh Cat et al. FASEBJ 2010). Our working hypothesis is that the activation of vascular MR plays a key role in CsA nephrotoxicity. The first step of our work was to study the effect of pharmacological blocade of MR on acute CsA toxicity in mice.

We used three groups of 8 weeks FVB/N male mice under low salt diet: control (Ctrl, vehicle), CsA (CsA 100mg/kg/d) and CsA+C (CsA + canrenoate 30mg/kg/d). CsA was administered daily by subcutaneous injection and canrenoate in the drinking water until sacrifice at day 10. Canrenoate had a clear beneficial effect on the survival of CsA mice. At day 7, 40% of the CsA mice were dead versus 0 in the CsA+C mice ($p<0.05$). CsA nephrotoxicity was prevented by canrenoate. Creatinine clearance (in mL/min/100g) was : in Ctrl : 1.15±0.13 ; in CsA : 0.74±0.17 ; in CsA+C : 1.31±0.24, $p<0.05$. CsA-induced proximal tubular vacuolisations were partially prevented by canrenoate. Canrenoate also prevented the increase in urinary NGAL, a biomarker of renal damage, observed in CsA. However, CsA and CsA+C groups presented similar increase in urinary excretion of 8-isoprostane; a global marker of oxidative stress.

In conclusion, we demonstrate that pharmacological MR antagonism has beneficial effects on survival and prevents histological and functional alterations in a mouse model of acute CsA nephrotoxicity. The implication of the endothelial MR is currently under investigation.

**Inhibition of Renin Angiotensin System Decreases TLR2 and TLR4 in Obstructed Kidney**
Jin Young Jeong,[1] Ji Yoon Jung,[1] Dong-Suk Chang,[1] Sarah Chung,[1] Dae Eun Choi,[1] Yoon-Kyung Chang,[2] Ki Ryang Na,[1] Kang Wook Lee,[1] Young Tai Shin.[1] *[1]Internal Medicine, Chungnam National University Hospital, Daejeon, Korea; [2]Internal Medicine, Daejeon St Mary's Hospital, Daejeon, Korea.*

**INTRODUCTION:** Many studies show TLR signaling and renin angiotensin system (RAS) respectively are important role inflammation and fibrosis of obstructed kidney. However, there are little study of relationship between RAS and TLR signaling in obstructed kidney. We evaluated that inhibition of RAS may modulate TLR2 and TRL4 and its ligands and renal inflammation and fibrosis.

**METHODS:** We use unilateral ureteral obstruction (UUO) model and female C57Bl/6 mice weigh 25~28g which were divided into 4 groups; sham group, enalapril treated sham group, UUO group, and enalapril treated UUO group. Enalapril, angiotensin converting enzyme inhibitor was administrated via drinking water (100mg/L) 1 day before sham and UUO operation and continued until harvest of kidneys 5 days after operation. We performed realtime RT PCR and immunohistochemistry for molecular study and H&E stain and Masson trichrome (MT) stain for histological examination.

**RESULTS:** The levels of mRNA expression of TLR2, TLR4, Myd88, renin, renin receptor in UUO kidneys were significantly increased compared to sham operated group (all, $p<0.05$). The mRNA levels of TLR2, TLR4 and Myd88 of enalapril treated UUO group were significantly lower than those of control UUO group (all, $p<0.05$). The renal mRNA expressions of TNF-α, MCP-1, TGF-β, and α-SMA in enalapril treated UUO group ($p<0.05$) were significantly lower than those of control UUO group. Enalapril also significantly reduced number of CD68 positive cell, MT stained area, and immunostained area of TGF-β and α-SMA in UUO kidneys ($p<0.05$).

**CONCLUSIONS:** Enalapril attenuated renal inflammation and fibrosis in obstructed kidney via both inhibition of RAS and reducing TLR 2 and TLR4.

**Hypoxia and GSK3β/β-Catenin Signaling in Wound Healing of Renal Proximal Tubular Cells** Jianping Peng, Zheng Dong. *Department of Cellular Biology and Anatomy, Medical College of Georgia and Charlie Norwood VA Medical Center, Augusta, GA.*

Wound and subsequent healing in tissues are frequently associated with hypoxia due to vascular damage and decreased blood supply. While hypoxia induces angiogenesis for tissue remodeling during wound healing, it may also affect the healing response of the parenchymal cells. Whether and how wound healing is affected by hypoxia in renal cells and tissues are largely unknown. Here we used a scratch wound healing model to examine the effect of hypoxia in cultured renal proximal tubular cells (RPTC). The results show that wound healing was significantly slower in hypoxic (1% oxygen) RPTC than the cells cultured in normal (21%) oxygen. To explore the signaling pathway, we initially focused on GSK3β and β-catenin. It was shown that β-catenin expression increased in the cells at the wound edge. Hypoxia led to the inactivation of GSK3β and activation of β-catenin. Pharmacologic inhibition of GSK3β with LiCl and SB216763 could also activate β-catenin, resulting in the suppression of wound healing. Consistently, knockdown of β-catenin could improve wound healing in hypoxic cells. These results suggest that GSK3β/ β-catenin signaling may be involved in the defective wound healing in hypoxic renal cells and kidney tissues.

**cGMP Phosphodiesterase-5 Inhibitor Ameliorates Renal Injury in Rats with Cyclosporine A Induced Nephrotoxicity Via eNOS and VEGF** Byoung Geun Han, Jae Won Yang, Seung Tae Han, Seung-Ok Choi. *Nephrology, Yonsei University Wonju College of Medicine, Wonjuj, Gangwon, Republic of Korea.*

Backgrounds: The mechanism of Cyclosporine-A (CsA) induced nephrotoxicity have been suggested vasoconstriction due to the reduction of nitric oxide (NO), VEGF. The cyclic guanosine monophosphate (cGMP) phosphodiesterase (PDE)-5 inhibitor has been reported to ameliorate renal injury. The PDE-5 inhibitor was studied to determine whether it ameliorated CsA nephrotoxicity and altered the expression of eNOS and VEGF compared to nitroprusside.

Methods: All groups (SD, N=24, 200-250g, male) were divided 4 groups: Control group (N=6), CsA group (N=6) treated with 15 mg/kg cyclosporine-A, Nitroprusside group (N=6) treated with 5mg/kg nitroprusside on CsA group, PDEI group (N=6) treated with 10 mg/kg PDEI (udenafil) on CsA group for 28 days.

Results: In comparison with the CsA group, the Nitroprusside group showed no significant reduction of the BUN and creatinine (Cr), but the PDEI group showed a significant reduction of the BUN and Cr ($p$=0.041, $p$=0.004). In H&E stain, the CsA group showed that the shape of the proximal tubules was not maintained and that vacuolization of the cytoplasm as well as reduction of nuclei were present compared with Control group. In the Nitroprusside and PDEI group, the vacuolization of the cytoplasm of the proximal tubules was observed, nonetheless, the shape was maintained, and the number of nuclei was partially recovered. The protein expression of eNOS and VEGF in the CsA group were decreased compared with the control group, after the administration of nitroprusside or PDEI, were increased compared with the CsA group. The expression of eNOS mRNA was reduced in the CsA group ($p$=0.029) compared with Control group,and increased in the PDEI group ($p$=0.029) compared with CsA group. The expression of VEGF mRNA was reduced in the CsA group ($p$=0.027) compared with Control group, increased in the PDEI group ($p$=0.027) compared with CsA group.

Conclusion: We suggest that cGMP PDE inhibitor ameliorated kidney injury in a rat model of CsA-induced nephrotoxicity via eNOS and VEGF.

**Mesenchymal Stem Cells and Darbepoetin-alpha Ameliorate Acute Kidney Injury** Rahmi Yilmaz,[1] Bulent Altun,[1] Hadim Akoglu,[1] Serhan V. Piskinpasa,[1] Mustafa Arici,[1] Duygu U. Cetinkaya,[2] Petek Korkusuz,[3] Nuhan Purali,[4] Fazil T. Aki,[5] Cetin Turgan.[1] *[1]Nephrology, Medical Faculty of Hacettepe University, Ankara, Turkey; [2]Pediatric Hematology, Medical Faculty of Hacettepe University, Ankara, Turkey; [3]Histology and Embryology, Medical Faculty of Hacettepe University, Ankara, Turkey; [4]Biophysics, Medical Faculty of Hacettepe University, Ankara, Turkey; [5]Urology, Medical Faculty of Hacettepe University, Ankara, Turkey.*

**Introduction**

Bone marrow originating stem cells and erythropoietin have a possible role in recovery of ischemia induced acute kidney injury (AKI). We aimed to compare the therapeutic potential of mesenchymal stem cells (MSCs), darbepoetin-alfa (DPO) or combination of them in a rat model of ischemia/ reperfusion (I/R) AKI.

**Methods**

In a parallel group study design, rats (Male, Spraque Dawley) were randomly assigned to groups treated with % 0.9 NaCl (n=5) (control), subcutaneous DPO (1mcg/kg) (n=5), intra-arterial MSCs ($1.5x10^6$/animal) (n=5) or combination of DPO and MSCs (n=5) immediately after I/R. We monitored hematocrit, serum creatinine (SCr) (24, 48, 72 hours after operation) and obtained renal tissue on 3rd day after nephrectomy. Tissue injury was quantified by application of a standardized histological scoring system using light and electron microscope.

**Results**

Renal function was significantly improved by treatment with MSCs or DPO (mean SCr levels on 3rd day; in control group:2.00±0.14 mg/dL, in MSCs group:1.16±0.69 mg/dL, in DPO group:1.44±0.31 mg/dL, $p<0.05$) although hematocrit levels were similar in all groups. Improvement of renal function in rats treated with combination of MSCs and DPO was better than the other groups (mean SCr: 0.76±0.19mg/dL, $p<0.05$). Histological analysis demonstrated a significantly decreased tissue injury in rats treated with MSCs or DPO (Histological score in control group:108±10, in MSCs group: 57±10, in DPO group: 74±17 $p<0.05$). Best histological score was observed in rats treated with combination of MSCs and DPO (Histological score:37±11 $p<0.05$).

**Conclusion**

These results suggest the potential clinical application of DPO and MSCs in combination as a novel renoprotective therapy for patients who developed ischemic renal injury.

**Endogenous BMP-7 Is a Critical Molecular Determinant of the Reversibility of Obstruction-Induced Renal Injuries** Scott R. Manson,[1] Keith A. Hruska,[2] Paul Austin.[1] *[1]Surgery, Washington University, Saint Louis, MO; [2]Medicine, Washington University, Saint Louis, MO.*

**PURPOSE:** Although obstructive nephropathies are frequently correctable through surgical intervention, the potential for permanent renal injury remains even following surgery. Little is known about the intrinsic mechanisms that determine the reversibility of renal injuries. We and others have found that exogenous BMP-7 inhibits the pathogenesis of renal injury. Here, we examine the role of endogenous BMP-7 in the outcome of renal recovery following the correction of obstructive nephropathies.

**METHODS:** A reversible murine model of ureteral obstruction was used to characterize renal recovery following the correction of short-term obstructions that lead to 'reversible' renal injuries and prolonged obstructions that lead to 'irreversible' renal injuries. The role of BMP-7 was examined by treatment with either BMP-7-neutralizing antibodies or exogenous BMP-7.

**RESULTS:** While BMP-7 levels are upregulated following the correction of obstruction in 'reversible' renal injuries, the upregulation of BMP-7 is diminished in 'irreversible' renal injuries. The activation of the BMP-7 pathway is required for several processes that contribute to renal recovery including the suppression of TGF-β-dependent pro-fibrotic pathways, the resolution of fibrotic lesions, and the regeneration of renal architecture. Importantly, the therapeutic restoration of BMP-7 in 'irreversible' renal injuries enhances renal recovery following the correction of obstruction.

**CONCLUSIONS:** While BMP-7 plays a critical role in the repair of obstruction-induced renal injuries, the potential for renal recovery in prolonged obstructions is diminished, in part, due to the dysregulation of BMP-7. Accordingly, renal recovery from obstructive nephropathies may be optimized through timely intervention and adjuvant approaches to restore BMP-7 activity.

**Cytosolic Phospholipase A2α (IVa) Interacts with Sirt2 and Attenuates Its Deacetylase Activity** Said Movahedi Naini, Joseph V. Bonventre. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Cytosolic phospholipase A2α (cPLA2α) has been shown to play a role in different physiological and pathological conditions such as ischemia/reperfusion (I/R), inflammatory and infectious diseases and progression of cancer. To identify potential mechanisms of action of cPLA2α, we searched for its potential interacting partners. We show by two hybrid screening and by co-immunoprecipitation that cPLA2α interacts with Sirt2. Sir2 (Sirtuin) family of proteins are involved in aging, life span due to calorie restriction and cell cycle regulation. We have identified the region of interaction to within 88 amino acids within a recognized RING domain of SIRT2. We show that Sirt2 is expressed in the kidney after I/R with highest levels at 5 days after injury. We show that endogenous Sirt2 interacts with cPLA2α in primary mouse mesangial cells. We also show that overexpression of cPLA2α decreases tubulin deacetylase activity of Sirt2 in vivo and in vitro and this inhibition is independent of phospholipase activity of cPLA2α. We further show that overexpression of cPLA2α can inhibit the checkpoint function of Sirt2 during mitosis in responce to Microtubule inhibitors (MTIs). These data suggest an important role for cPLA2α in the regulation of Sirt2 function.

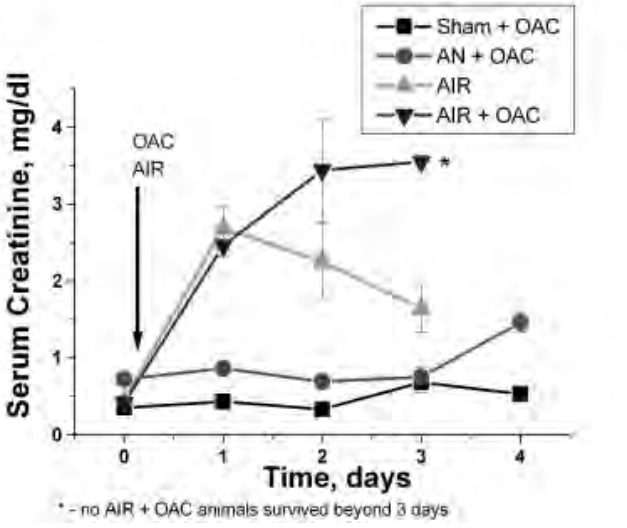
**Overanticoagulation Causes Acute Kidney Injury (AKI) in Experimental Animals** Sergey V. Brodsky, Kyle M. Ware, Jon R. Von Visger, Lee A. Hebert, Gyongyi Nadasdy, Anjali A. Satoskar, Tibor Nadasdy. *The Ohio State University, Columbus, OH.*

We recently reported that acute increase in international normalized ratio (INR)>3.0 may associate with AKI in patients with chronic kidney disease (CKD). Morphological findings included glomerular hemorrhage with formation of obstructive red blood cell (RBC) casts. We referred this condition as warfarin related nephropathy (WRN). WRN often resulted in CKD acceleration. We tested the possibility that overanticoagulation (OAC) may affect renal function in experimental animals. OAC was induced by feeding Sprague Dawley rats with brodifacoum. We used acute ischemia-reperfusion injury (AIR) and 5/6 nephrectomy

[ablative nephropathy, (AN)] as experimental models. Treatment with brodifacoum resulted in a significant increase in prothrombin time in all experimental groups. Morphologically, sham-OAC did not have RBC casts associated with OAC, although hematuria was present. Both AIR-OAC and AN-OAC groups had features of glomerular hemorrhage and occlusive RBC casts on histological examination. AN animals showed significant proteinuria and increase in serum creatinine (SC) levels before OAC was initiated. SC levels were not changed in sham-OAC group, but AN-OAC animals had an increase in SC associated with OAC. In AIR-OAC group SC levels did not improve after the surgery, as compared to AIR only. The mortality was significantly increased in the AIR-OAC group.



Based on these data, we conclude that OAC results in glomerular hemorrhage with formation of occlusive RBC casts and impairment of renal function in animals with underlying kidney conditions. These findings are similar to our previous observation on patients with increased INR. Therefore, we can model OAC-associated kidney injury in experimental animal, which will allow to study the WRN pathogenesis.

**In Vivo Multiphoton Imaging of Mitochondrial Function in the Rodent Kidney** Andrew Michael Hall,[1] George Rhodes,[2] Ruben M. Sandoval,[2] Bruce A. Molitoris.[2] *[1]Centre for Nephrology, University College London, United Kingdom; [2]Indiana Centre for Biological Microscopy, Indiana University School of Medicine, Indianapolis, IN.*

Mitochondrial dysfunction has been implicated in the pathogenesis of ischemia-reperfusion induced acute kidney injury (AKI). We have demonstrated, using *in vivo* multiphoton microscopy, that mitochondrial function can be imaged in kidneys of anesthetized rats.

Ischemia-reperfusion was induced by clamping then releasing the renal artery. Mitochondrial NADH was excited at 720nm (Fig 1A) and increased in response to ischemia (1B). Mitochondrial membrane potential ($\Delta\Psi_m$) was measured using rhodamine 123 (1C) or tetramethylrhodamine methyl ester (TMRM) (1D) excited at 800-850nm; following bolus intravenous injection rapid uptake was observed in mitochondria in proximal tubules (PTs). Fluorescence signals decayed over time in PTs, probably due to dye extrusion. Neither verapamil (inhibitor of MDR) nor cimetidine (inhibitor of OCTs) prevented the decay; however, a steady state could be achieved using a constant dye infusion over 50 minutes. TMRM signal in distal tubules (DTs) did not decay; 20 minutes post injection mean signal in DTs (1248.7±229.5 A.U.) was greater than in PTs (464.4±83.4, $p<0.05$). Uptake of rhodamine 123 into DTs was low; after 20 minutes mean signal was higher in PTs (1224.7±156.3) than DTs (644.0±132.9, $p<0.05$). Rhodamine 123 signal in glomeruli was also low compared to TMRM. Following the onset of ischemia, control TMRM signal (1E) decreased rapidly in PTs (1F) consistent with dissipation of $\Delta\Psi_m$. Injection of TMRM post reperfusion lead to heterogeneous uptake.

In summary, mitochondrial function was imaged in a rat model of AKI using *in vivo* multiphoton microscopy. Constant intravenous infusion of TMRM leads to a steady state signal in the PT and better uptake in glomeruli and DTs when compared to rhodamine 123.

**Dendritic Cells Induce an Anti-Inflammatory Phenotype on Tubule Epithelial Cells after Kidney Injury** Suetonia Palmer, Takaharu Ichimura, Benjamin D. Humphreys, Joseph V. Bonventre. *Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

The mechanisms by which dendritic cells (DCs) modulate kidney tissue responses to injury remain incompletely understood. The aim of our study was to determine whether DCs interact with tubular epithelial cells to alter the inflammatory response of the kidney after injury.

DCs and macrophages accumulate in the renal interstitium adjacent to injured tubules that express Kim-1. Cultured mouse proximal tubule cells express Kim-1 and release high levels of TNFα and monocyte chemoattractant protein (MCP-1). Conditioned media from normal tubular epithelial cells markedly increases TNFα and MCP-1 production by RAW 264.7 cells, a macrophage cell line, suggesting kidney epithelial cells are pro-inflammatory *in vitro*. Pre-incubation of kidney epithelial cells with bone marrow-derived DCs significantly reduces the pro-inflammatory effect of proximal tubule cells on macrophages. Direct cell-to-cell contact between DCs and kidney epithelial cells is necessary for this anti-inflammatory effect of DCs to be observed. DCs maintain steady-state expression of antigen-presentation and co-stimulatory molecules when in contact with kidney epithelial cells. DCs strongly stimulate epithelial cell expression of MCP-1, IL-10, and IL-6. In addition, DCs completely protect cultured kidney epithelial cells (LLC-PK1) from necrotic injury after exposure to oxidative stress induced by $H_2O_2$ (1 mM).

In conclusion, tubular epithelial cells are important targets of DC actions in the kidney. DCs may induce an anti-inflammatory epithelial cell phenotype after kidney injury via both alterations in epithelial cell cytokine expression and protection against tubule cell death. Increased anti-inflammatory cytokine and MCP-1 expression by renal epithelial cells in direct contact with resident and infiltrating DCs may promote the homing of a subpopulation of macrophages to the peritubular interstitium that drives tissue healing and repair.

**The Effect of CCR5 and CCR2 Deficiency on Renal Ischemia-Reperfusion Injury in Mouse Model** Ran-Hui Cha,[1] Seung Hee Yang,[2] Yon Su Kim.[1,2] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea; [2]Kidney Research Institute, Seoul National University Medical Research Center, Seoul, Korea.*

***Background*** Various factors including chemokines participate in ischemia-reperfusion injury (IRI). CCR2 is known to be responsible for renal IRI and CCR5 together with its ligand RANTES are also assumed to be associated with renal IRI. We evaluated the role of CCR5 and CCR2 on renal IRI via *in vitro* hypoxia-reoxygenation experiment using human renal tubular epithelial cells (TECs) and *in vivo* IRI experiment using CCR5 and CCR2 knock out mice.

***Methods*** Human renal TECs were incubated at a hypoxic condition (1% $O_2$) for 6 hours and then, cells were placed under a normoxic condition (20% $O_2$) for 18 hours. Proliferation of TECs was determined using colorimetric MTS assay kits. IRI was induced in C57BL/6

wild, CCR5$^{-/-}$, CCR2$^{-/-}$, and CCR5$^{-/-}$CCR2$^{-/-}$ mice. Kidney tissues were assayed for cytokines using a multiplex cytokine bead array system (Bio-Plex).

***Results*** *In vitro*, human renal TECs proliferated well under normoxic condition, but their proliferation was significantly hampered under hypoxic condition. Recombinant CCR5 more inhibited the proliferation of TECs with dose-dependent pattern, on the contrary, neutralizing antibody to CCR5 partially restored. *In vivo*, the absence of CCR2 and CCR5 lessened the severity of renal IRI, histologically and functionally. IRI induced tubular necrosis and the damage was more extensive in wild type mice than in knock out mice. The intra-renal infiltration of T cells and macrophages was markedly inhibited in knock out mice than in wild type mice. Tubular CCR2 expression was reduced in CCR5$^{-/-}$ mice and CCR5 expression was reduced in CCR2$^{-/-}$ mice, either. Level of serum BUN and creatinine was lower in CCR5$^{-/-}$ and CCR2$^{-/-}$ mice than in wild type, furthermore, CCR5$^{-/-}$CCR2$^{-/-}$ mice showed the least level of those markers. Results from Bio-Plex revealed that these were mediated by IL-4, IL-10, and IL-13 pathway activation in knock out mice.

***Conclusion*** These findings demonstrate that absence of CCR5 together with CCR2 exert protective effects on kidneys, suggesting that CCR2 and CCR5 may be a feasible target in protecting kidneys from IRI.

**Kidney Injury Molecule-1 (Kim-1) Down-Regulates the Proximal Tubule Innate Immune Response to Injury** Li Yang,[1, 2] Craig R. Brooks,[1] Joseph V. Bonventre.[1] [1]*Renal Division, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA;* [2]*Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China.*

Our laboratory has shown that Kidney Injury Molecule-1 (Kim-1) is a phosphatidylserine receptor, which mediates phagocytosis of apoptotic cells and oxidized lipids by renal proximal tubular cells. In unpublished studies of Kim-1 mutant and wild-type mice we have found that Kim-1 is protective against acute ischemic and toxic kidney injury. The purpose of this study was to investigate how human Kim-1 (KIM-1) expression and facilitated phagocytosis of apoptotic cells modulates the kidney innate immune response to acute injury.

In control pCDNA vector-transfected HEK293 cells and LLC-PK1 cells, LPS treatment (5mg/ml) for 24 hours increased mRNA and protein levels of Toll-like receptor 4 (TLR4). Increased expression of KIM-1 resulted in decreased TLR4 mRNA and protein levels in both cell lines. Pre-feeding epithelial cells with apoptotic T-lymphocytes 2 h before LPS treatment further decreased TLR4 expression in KIM-1-expressing cells. The supernatant from LPS-treated control LLC-PK1 cells markedly increased the mRNA levels of MCP-1, TNF-$\alpha$ and IL-1$\beta$ in RAW264.7 cells. The expression of KIM-1 in LLC-PK1 cells mitigated the RAW cell activation. Feeding KIM-1-expressing cells with apoptotic cells resulted in further reductions in supernatant-induced RAW activation.

In primary cultured mouse proximal tubular cells, approximately 30% of cells expressed Kim-1. LPS treatment increased TLR4 expression in non-Kim-1 expressing cells, but not in Kim-1 expressing tubular cells, presumably because Kim-1 expression suppressed TLR4 expression. In human kidneys from patients with AKI, TLR4 was detected in proximal tubular cells, with either apical membrane linear or intracellular granule-like distribution. TLR4 expression was markedly reduced in proximal tubule cells that express KIM-1.

In conclusion the expression of Kim-1 in proximal tubules, especially in the presence of apoptotic cell uptake, down-regulates the innate immune response, which may explain the protective effects of Kim-1 in models of acute kidney injury.

## F-PO1024

**SIRT1, a Stress-Responsive Deacetylase, Mediates Age-Related Response to Acute Kidney Injury** Hong Fan,[2] Haichun Yang,[1,2] Wenjuan He,[1] Li You,[2,1] Chuan-Ming Hao.[1, 2] [1]*Nephrology, Vanderbilt University, Nashville, TN;* [2]*Nephrology, Huashan Hospital Fudan University, Shanghai, China.*

It has been documented that older individuals are more susceptible to acute kidney injury (AKI). The mechanism underlying this age-related susceptibility to AKI is incompletely defined. Sirt1, a NAD+ dependent deacetylase and stress response molecule, has been demonstrated to mediate caloric restriction associated life-span extension. The aim of the present study was to investigate whether SIRT1 is associated with age-related response to AKI in mice.

Immunoblot shows that the Sirt1 expression in the kidney of 7-week old mice (younger mice) is significantly higher compared with 22-week old mice (older mice) (1.0±0.2 vs 0.45±0.13, p<005). Following renal ischemia-reperfusion (I/R, 40 min bilateral renal artery clamp), the BUN was markedly increased in older mice, but only mildly elevated in younger mice (day 2, 190.9±20 vs 38.6±6.8 mg/dl, n=8, p<005), suggesting that younger mice were more resistant to AKI. Loss of one allele of Sirt1 significantly enhanced the kidney injury following I/R (BUN 141.4±14.4 of SIRT1+/- mice vs 94.0±13.7 mg/dl of SIRT1+/+ mice, n=12, p<0.05). The kidney from SIRT1+/- mice following I/R also exhibited more apoptotic cells assessed by TUNEL assay and activated caspase 3 levels compared with wild type mice. In contrast, a Sirt1 selective activator, SRT1270, protected the kidney from I/R induced injury (BUN 113.4±14.8 vs 169.2±19.0, n=13, p<005). All the renal function results (BUN) were supported by histology scores. SRT1720 treatment was associated with lower levels of activated caspase 3 compared with vehicle treatment. In the older mice following I/R, the expression levels of p53 and p21 in the kidney were significantly higher than younger mice (p53 2.3±0.4 vs 0.9±0.4, p21 2.4±0.4 vs 0.3±0.04, p<005). SRT1720 treatment significantly attenuated, while deletion of one allele of Sirt1 gene increased p53 and p21 protein expression levels in the kidney.

These results suggest that reduced expression of SIRT1 is associated with increased susceptibility to AKI, and therefore Sirt1 could be a potential target for the prevention and treatment of AKI.

## F-PO1025

**Thick Limb-Associated Tamm-Horsfall Protein Regulates MIP-2 Expression in the S3 Segment: A Case for Tubular Cross-Talk** Tarek M. Elachkar, Ruth A. Mccracken, Michael I. Rauchman. *Medicine, Saint Louis University and the Saint Louis VA, Saint Louis, MO.*

Tamm-Horsfall Protein (THP) is a glycoprotein with unclear functions expressed exclusively in thick ascending limbs (TAL) of the kidney. We recently described a novel protective role for this protein in Acute Kidney Injury (AKI), whereby THP decreased inflammation in the outer medulla. Using an ischemia-reperfusion model, we showed that S3 proximal segments and not TAL are the main tubules injured during AKI. To explain how TAL-associated THP affects S3 segments, we hypothesize that THP released basolaterally from TAL modulates the expression of pro-inflammatory mediators by S3 segments. Using Immunofluorescence microscopy and 3D volumetric imaging, we show that THP expression is increased with ischemia at the basolateral side of TAL and in the interstitial area around S3 segments. The scavenger receptor SRB-1, a potential receptor for THP, is also expressed at the basolateral aspect of S3 segments. Using Real-time PCR performed on whole kidney extracts from THP-/- and THP+/+ mice, we measured mRNA of the cytokine TNF$\alpha$ and the chemokines MCP-1 (macrophage chemo-attractant) and MIP-2 (neutrophil chemo-attractant). Only MIP-2 showed a differential increased expression in THP knockout vs. wild type mice at baseline and after ischemia. MIP-2 protein expression was localized predominantly to S3 segments in THP-/- mice after ischemia. This also correlated with neutrophil infiltration around these tubular segments. To validate this direct effect of THP on proximal cells, MIP-2 mRNA was measured in HK-2 proximal tubular cells subjected to chemical anoxia with or without pre-incubation with THP. MIP-2 expression was significantly increased after anoxia, but this expression was markedly diminished by pretreatment with purified THP. In conclusion, our findings support that THP released from TAL down-regulates MIP-2 in neighboring proximal cells, an effect consistent with its protective propertied during AKI. We propose that THP is a mediator of tubular cross-talk aimed at stabilizing the outer medulla in the face of injury.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1026

**Identification of Stage-Specific Markers of Acute Kidney Injury** Anne Katharina Wübken,[1] Kai M. Schmidt-Ott.[1, 2] [1]*Max-Delbrueck Center for Molecular Medicine, Berlin, Germany;* [2]*Experimental and Clinical Research Center, Charité Berlin, Berlin, Germany.*

Several biomarkers of acute kidney injury have been proposed, including neutrophil gelatinase-associated lipocalin and kidney injury molecule-1. While these markers detect the presence and intensity of renal tubular injury, they are elevated for extended periods following tubular damage. Hence, an elevated level of these markers at a single given time point does not differentiate the hyperacute stage of tubular injury (e. g. 2-24 hours after ischemic injury in mice) from the regeneration phase (e. g. 2-5 days after ischemic injury). Yet a differentiation of these stages will be clinically relevant to allow for an accurate assessment of the timing of disease progression and to target stage-specific pharmacotherapy. To identify stage-specific markers of acute kidney injury, we analyzed gene expression signatures in mouse kidneys at three different time points (6h, 48h and 7d) following ischemia reperfusion injury using microarray analysis and identified time point-specific transcripts. In the early, hyperacute phase (6h post injury), we found an antiproliferative and proapoptotic gene signature, including several components of the ATF4-ATF3-CHOP pathway. Two genes of this hyperacute signature, cation transport regulator-like protein 1 (Chac1) and angiopoietin-like 7 (Angptl7), were highly responsive to injury and rapidly normalized at later time points. Immunofluorescence staining indicated induction of Chac1 in damaged tubular cells. Conversely, 48 hours post injury a gene signature representative of tubular proliferation was observed. Of these genes, baculoviral IAP repeat-containing 5 (Birc5/survivin) displayed co-induction with the proliferation marker Ki-67, a marked degree of responsiveness, and tubular-restricted expression according to immunofluorescence staining. Together, our data identify Chac1/Angptl7 and Birc5 as stage-specific markers of acute kidney injury representing the hyperacute and proliferative phases, respectively. In the future, these markers may facilitate risk assessment and guidance of pharmacotherapy in patients with acute kidney injury.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1027

**Inducible PAX8-Driven Knockout of the Von-Hippel-Lindau Protein Protects from Acute Kidney Injury** Christian Rosenberger,[1] Alexander Paliege,[2] Harm Peters,[1] Hans-Hellmut Neumayer,[1] Robert Koesters,[3] Sebastian C. Bachmann.[2] [1]*Nephrology and Renal Transplantation, Charité Universitaetsmedizin, Berlin, Germany;* [2]*Anatomy, Humboldt University, Berlin, Germany;* [3]*Hopital Tenon, Inserm/Université Pierre et Marie Curie, Paris, France.*

The Von-Hippel-Lindau (VHL) protein is a key suppressor of hypoxia-inducible factors (HIFs). We generated a mouse strain with conditional paired box protein (PAX)8-driven knockout of VHL gene (VHL-KO) that provides a model of normoxic HIF activation. In the mice, conditional PAX8-VHL-KO led to robust activation of both HIF-1$\alpha$ and -2$\alpha$ in

all nephron segments and approximately 20% of hepatocytes. VHL-KO mice developed significant polyglobulia within 2 wk due to liver EPO production and showed increased renal capillary density in parallel with increased VEGF expression. Protein excretion, renal function and gross renal and liver histology were not altered in VHL-KO mice over 9 mo (kept on a normal Hb by repeated bleeding). When VHL-KO mice were subjected to systemic hypoxia by subacute bleeding anemia, there was no change in pattern or expression intensity of the renal and liver HIF-1α signals. When VHL-KO animals were exposed to rhabdomyolysis-induced acute kidney injury (AKI), which serves as a model of hypoxic damage to proximal tubules, kidneys showed persistently enhanced HIF-1α, but de novo activated cell protective HIF target genes in proximal tubules, such as heme oxygenase-1 and glucose transporter-1. At 48 h after injury, VHL-KO mice had better renal function and less proximal tubular damage, including necrosis as compared to wildtype mice with similar rhabdomyolysis-induced AKI. We conclude that 1) *in vivo* VHL-KO activates both HIF-1α and -2α and leads to polyglobulia and renal angiogenesis; and 2) VHL-KO ameliorates AKI associated with tubular hypoxia, potentially through tubular survival genes and/or renal angiogenesis.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1028

**Mitochondria Targeted Heme Oxygenase-1 (HO-1) Reduces Oxidative Stress in Renal Epithelial Cells** Subhashini Bolisetty,[1,2,3] Amie Traylor,[1] Karina Claudia Ricart,[3] Michelle S. Johnson,[3] Aimee L. Landar,[3] Victor M. Darley-Usmar,[3] Anupam Agarwal.[1,2,3] *[1]Medicine, Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL; [2]Cell Biology, University of Alabama at Birmingham, Birmingham, AL; [3]Pathology, University of Alabama at Birmingham, Birmingham, AL.*

Oxidative stress and mitochondrial dysfunction play a major role in the pathogenesis of acute kidney injury. One of the key mediators of oxidative stress is the generation of reactive oxygen species (ROS) by mitochondria, leading to damage of several cellular components. HO-1, an anti-oxidant enzyme, is induced during oxidative stress and is protective against cell death. The purpose of this study was to determine the role of HO-1 in modulating mitochondria-derived oxidative stress, mitochondrial function and cell death. We generated a mitochondria-targeted HO-1 cell line by transfecting HEK293 cells with the MnSOD mitochondria leader sequence fused to HO-1 cDNA (Mito-HO-1). Non-targeted HO-1 overexpressing cells (3.1/HO-1) and empty vector cells (control) served as controls. Both Mito-HO-1 and 3.1/HO-1 cells showed a significant increase in HO-1 expression by western blot analysis. Furthermore, Mito-HO-1 cells showed an increase in mitochondrial HO-1 expression compared to 3.1/HO-1 cells. Mitochondrial localization of HO-1 in Mito-HO-1 cells was confirmed by co-localization with mitotracker and cytochrome C oxidase. Additionally, to evaluate the functional significance of mitochondria-targeted HO-1, cells were exposed to the electrophilic lipid, 15d-$PGJ_2$, a product of the cyclooxygenase pathway. Mito-HO-1 cells generated significantly lower levels of ROS as compared to control cells by the DCF assay and were also protected against heme cytotoxicity. These results suggest that HO-1 can be targeted to specific organelles within the cell and that overexpression of HO-1 in the mitochondrial compartment is protective. Targeted HO-1 expression represents a novel strategy to overcome mitochondria-derived oxidative stress and may be more beneficial than generalized overexpression of HO-1 in acute kidney injury.

## F-PO1029

**The Outcome of Lipocalin-Positive Acute Kidney Injury: A Multicenter Study** Michael Haase,[1] Anja Haase-Fielitz,[1] Rinaldo Bellomo,[2] Prasad Devarajan,[3] Dinna N. Cruz,[4] Gebhard Wagener,[5] Catherine D. Krawczeski,[3] Jay L. Koyner,[6] Patrick T. Murray,[7] Michael Zappitelli,[8] Stuart Goldstein,[3] Konstantinos Makris,[9] Claudio Ronco,[4] Peter R. Mertens.[10] *[1]Nephrology, Charite Berlin; [2]Melbourne; [3]Cincinnati; [4]Vicenza; [5]NY; [6]Chicago; [7]Dublin; [8]Montreal; [9]Athens; [10]Nephrology, Magdeburg.*

**Background**

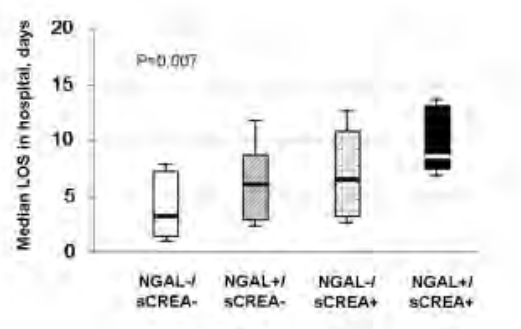
Increases in neutrophil gelatinase-associated lipocalin (NGAL) detect acute kidney injury (AKI) hours to days before serum creatinine and may be clinically significant. We aimed to test the hypothesis that, independent of changes in serum creatinine, increased NGAL levels identify patients with AKI and therefore, worse prognosis.

**Methods**

We analyzed pooled data from 1,217 patients from seven prospective observational studies of NGAL. We used the terms NGAL(-) or NGAL(+) to study-specific NGAL cut-off values for optimal AKI prediction and the terms sCREA(-) or sCREA(+) according to RIFLE-AKI.

**Results**

Of study patients, 661 (54.3%) were NGAL(-)/sCREA(-), 231 (19.0%) NGAL(+)/sCREA(-), 80 (6.6%) NGAL(-)/sCREA(+) and 245 (20.1%) NGAL(+)/sCREA(+). There was a progressive increase in median number of intensive care and in-hospital days with increasing biomarker positivity: NGAL(-)/sCREA(-): 3.2 and 8.3 days; NGAL(+)/sCREA(-): 5.8 and 9.3 days; NGAL(-)/sCREA(+): 6.9 and 18.0 days; NGAL(+)/sCREA(+): 8.3 and 19.8 days; P=0.007 and P=0.04, respectively.



There was a similar and consistent stepwise increase in subsequent renal replacement therapy initiation (0%, 1.3%, 8.8% and 11.4%, respectively), hospital mortality (4.1%, 6.1%, 8.8%, 16.7%, respectively) and their combination (P<0.001).

**Conclusions**

Irrespective of associated diagnostic increases in serum creatinine, NGAL detects patients with AKI who have an increased risk of adverse outcomes including death. The concept and definition of AKI may need re-assessment.

**p66shc and Cisplatin-Mediated Neprotoxicity** Istvan Arany, Jeb S. Clark, Radhakrishna Baliga. *Pediatrics, University of Mississippi Medical Center, Jackson, MS.*

Cancer patients often develop serious renal failure due to treatment with the anticancer drug cisplatin (CP) that induces apoptotic death of renal proximal tubules. The p66shc adaptor protein plays a pivotal role in apoptosis but its role in CP-mediated nephrotoxicity is unknown. Here, we show that CP treatment phosphorylates p66shc at its Serine36 residue both in the kidney and in cultured renal proximal tubule cells. We found that overexpression of p66shc exacerbates while knockdown of p66shc or mutation of its Serine36 phosphorylation site to alanine (S36A) ameliorates CP-induced caspase-3 activation, membrane permeabilization, LDH release, collapse of the actin cytoskeleton and consequent apoptosis *in vitro*. We also determined that the extracellular signal regulated kinase (ERK) serves as the kinase that phosphorylates p66shc at its Serine 36 residue after treatment with CP. Accordingly, pharmacologic or dominant negative inhibition of ERK mitigates while adenoviral overexpression of activated ERK exacerbates CP-induced Ser36 phosphorylation of p66shc and consequent activation of caspase-3 and LDH release.

These results suggest that CP activates the ERK-p66shc pathway that leads to apoptosis in renal proximal tubule cells. Thus, manipulation of p66shc expression and/or phosphorylation might offer new therapeutic means to ameliorate CP-induced nephrotoxicity in cancer patients.

**Up-Regulated HNF-1β during Experimental Acute Kidney Injury Plays a Crucial Role in Renal Tubular Regeneration** Koji Ogata. *Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi University, Nankoku, Japan.*

HNF-1β is a transcription factor expressed in the kidney, liver, and other epithelial organs.HNF-1β was reported binds to the SOCS3 promoter and represses SOCS3 transcription. However, the signaling pathways and tubular regeneration controlled by HNF-1β are poorly understood in ischemia/reperfusion renal injury.

The aim of this study is to understand the functional roles of HNF-1β, SOCS3 and STAT3 in tubular damages in AKI in vivo and in vitro, and examine the effect of HNF-1β on renal tubular formation using 3-D-gels.

To clarify the significance of HNF-1β pathway in AKI, we used a rat AKI model *in vivo* and cultured renal tubular cells (NRK-52E cells) as an *in vitro* model. After clamping renal artery for 1 h, kidney homogenate at 2, 3, 6, 12, 24, 48, and 72 h after reperfusion was extracted. In Western blot analysis, HNF-1β and phosphorylated-STAT3 expressions were increased at 2-12h and 6-24h. In immunohistological examination, expression of HNF-1β was increased in proximal tubules at 12h. To understand the downstream signaling of HNF-1β in renal tubular cells, we transfected HNF-1β construct to NRK-52E cells. Overexpression of HNF-1β increased $^3$H-thymidine uptake in NRK-52E cells. Furthermore, we used 3-D-gels to examine the role of HNF-1β for tubular formation. Overexpression WT HNF-1β promoted tubular formation. Tubular formation is inhibited by overexpression of DN HNF-1β.

In conclusion, HNF-1β is up-regulated in ischemia/reperfusion renal tubular injury at proximal tubular cells in vivo, and HNF-1β regulates cell proliferation and tubular formation by regulating SOCS3 expression and STAT3 activation. The current study therefore unravels both physiological and pathological significance of HNF-1β pathway in ischemia/reperfusion renal injury in vivo and in vitro.

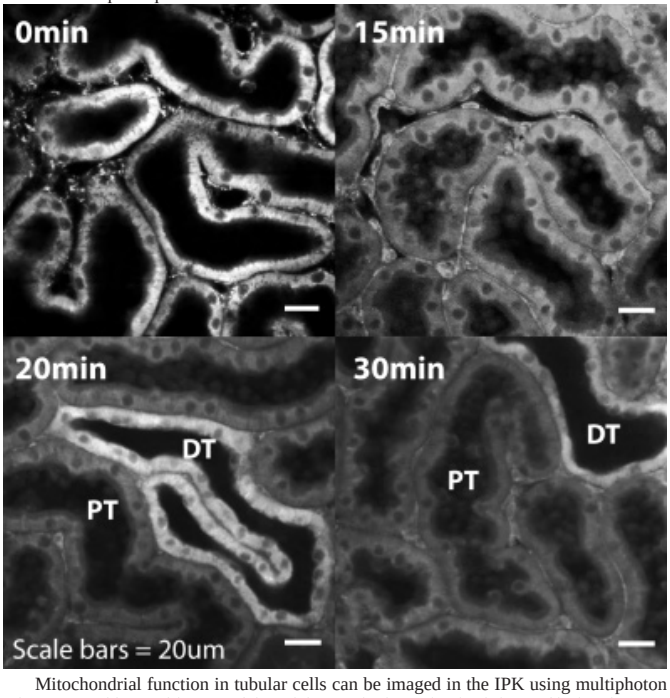
**F-PO1032**

**Multiphoton Imaging of Mitochondrial Function in the Isolated Perfused Rat Kidney** Andrew Michael Hall,[1] Carol Crawford,[2] Robert J. Unwin,[1] Michael Duchen,[3] Claire M. Peppiatt-Wildman.[2] *[1]Centre for Nephrology, University College London, United Kingdom; [2]Urinary Systems Physiology Unit, Royal Veterinary College, London, United Kingdom; [3]Cell and Developmental Biology, University College London, United Kingdom.*

Mitochondrial dysfunction is central to the pathogenesis of ischemic acute kidney injury (AKI). We used multiphoton microscopy to image mitochondrial function in isolated perfused kidneys (IPKs).

Adult male Sprague-Dawley rats were anesthetized with intra-peritoneal pentobarbitone. The right renal artery was cannulated and perfusion was commenced immediately with a HEPES-buffered solution at 37ºC. The preparation was moved to a custom built chamber and imaged with a Zeiss LSM510 microscope coupled to a Coherent Chameleon laser. Dyes were loaded using a recirculating perfusion system. Ischemia was induced by stopping perfusion.

Mitochondrial signals were co-imaged with proximal tubule (PT) uptake of fluorescent-labeled insulin, to provide simultaneous measurements of transport and metabolism. Reactive oxygen species production was measured using dihydroethidium; after 20min of perfusion, the mean signal was higher in PTs (1582.8±150.9 A.U.) than in distal tubules (DTs: 694.9±133.6, $p<0.05$). Mitochondrial NADH was used as a readout of redox state and increased in response to hypoxia. Mitochondrial membrane potential was measured using tetramethyl rhodamine methyl ester (TMRM). Control TMRM signal in the PT (1496.8±132.7) decreased after 30min of ischemia (870.4±92.8, $p<0.05$), but there was no significant change in the DT (1772.7±149.3 vs 1458.5±359.9, $p>0.05$) (Figure 1). Widespread cellular debris was observed in the PT lumen during ischemia, which impaired tubular flow upon reperfusion.



Mitochondrial function in tubular cells can be imaged in the IPK using multiphoton microscopy; this provides a useful model to study the pathophysiology of ischemic AKI.

**Experimentally Induced Overload Albuminuria Increases Urinary Cystatin C Excretion** Maryam Nejat, Jonathan V. Hill, John W. Pickering, Zoltan H. Endre. *Christchurch Kidney Research Group, Department of Medicine, University of Otago Christchurch, Christchurch, New Zealand.*

Introduction:

Megalin mediated transport is responsible for the reabsorption of most filtered proteins including cystatin C (CysC), neutrophil gelatinase-associated lipocalin (NGAL), and liver fatty acid binding protein (L-FABP). We used a model of transient proteinuria induced by intraperitoneal (IP) administration of Bovine Serum Albumin (BSA), to examine whether competition for megalin mediated transport by albumin could cause increased urinary CysC excretion in the presence of proteinuria.

Methods:

Seven male and female (6-8 week old) Sprague-Dawley rats received 5 $mg.day^{-1}.g$ body $wt^{-1}$ BSA in saline twice daily for 2 consecutive days (Day 0 and 1). Four rats of each sex received saline only. Albumin, total protein and CysC were measured in timed collection of spontaneously voided urine on Day -1, Day 2, and Day 6. Repeated measures two-way ANOVA was used to explore the effects of proteinuria, sex, and time.

Results:

The CysC excretion rate was correlated with albumin ($r^2=0.29$, $p<0.01$) and total protein ($r^2=0.58$, $p<0.001$) excretion rates. BSA treatment increased excretion rates of protein, albumin, and CysC ($p<0.01$, $p<0.001$, and $p<0.001$ respectively) by Day 2. All excretion rates returned to pre-treatment rates by Day 6. Male rats excreted more protein, albumin, and CysC than females ($p<0.001$, $p<0.001$, and $p<0.05$, respectively). The control groups showed no significant changes in urine analytes over time.

Conclusion:

Overload proteinuria resulted in a proportional increase in albumin and CysC excretion. Male rats had higher albuminuria and cystatinuria than females. Increased urinary CysC excretion may reflect increased permeability of the glomerular filtration barrier or impaired proximal tubule reabsorption. These data suggest the clinical interpretation of urinary CysC and other filtered biomarkers of AKI transported by megalin require concomitant assessment of proteinuria.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1034**

**Heat Shock Protein 72 (Hsp72) Is an Early and Sensitive Biomarker To Detect Acute Kidney Injury (AKI)** Jonatan Barrera-Chimal,[1,2] Rosalba Pérez-Villalva,[1,2] Marcos Ojeda,[1,2] Gerardo Gamba,[1,2,3] Luis E. Morales-Buenrostro,[2] Norma Bobadilla.[1,2] *[1]Molecular Physiology Unit, Instituto de Investigaciones Biomédicas, UNAM; [2]Instituto Nacional de Ciencias Médicas y Nutrición SZ; [3]Instituto Nacional de Cardiología ICh.*

Given that Hsp72 is induced in renal tubules during AKI and that proximal tubular detachment is projected to the urinary space, we reasoned that the urinary Hsp72 levels could serve as an early biomarker to detect, monitor and/or stratify AKI. For this purpose, 72 Wistar rats were divided into six groups: sham-operated and rats subjected to 10, 20, 30, 45 and 60 min of bilateral-ischemia (I) and 24-h of reperfusion (R). Different times of reperfusion were also evaluated in 30 other rats subjected to 30 min of ischemia. Hsp72 mRNA and protein levels were determined in both kidney and urine by RT-PCR and WB, respectively. Tubular injury (TI) was scored in kidney sections by morphometry. In addition, Hsp72-specificity as a biomarker to assess the success of a renoprotective intervention was evaluated in spironolactone treated rats before I/R.

Urinary Hsp72 mRNA and protein levels, gradually increased relative to the extent of renal injury induced by different periods of ischemia quantified by histomorphometry as a benchmark of TI ($r=0.82$ and $r=0.94$, respectively). Urinary Hsp72 increased significantly after 3-h, it continued rising until 18-h, and a restoration was seen after 120-h of reperfusion, consistent with TI ($r=0.74$). Spironolactone renoprotection was associated with normalization of urinary Hsp72 levels. Accordingly, urinary Hsp72 levels significantly increased in patients with clinical AKI (58.3 ± 8.5 arbitrary units), compared to healthy volunteers in which, Hsp72 levels were almost undetectable (3.7 ± 0.7).

Our results show that urinary Hsp72 is a reliable biomarker for the early detection of AKI. This novel biomarker was adequately sensitive for stratifying different degrees of tubular injury, tubular regeneration and recovery, as well as for monitoring a renoprotective intervention. These findings were confirmed in patients diagnosed with AKI, revealing that this protein is a promising biomarker for both early detection and stratification of AKI.

**F-PO1035**

**Nitric Oxide Induces Tubular Cell Hypertrophy Via Cyclic GMP-Dependent Protein Kinase in Rat Compensatory Renal Hypertrophy** Hajime Nagasu, Minoru Satoh, Naruya Tomita, Tamaki Sasaki, Naoki Kashihara. *Division of Nephrology and Hypertension, Department of Internal Medicine, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: Renal hypertrophy as an early compensatory mechanism to replace the loss of functioning tissue ultimately turns into a maladaptive process leading to progressive deterioration of renal function. We previously reported that nitric oxide (NO) production in the kidney is increased in the early phase after nephrectomy. However, the precise mechanism of increased NO production and its role in compensatory renal hypertrophy following nephrectomy remain unclear. Endothelial nitric oxide synthase (eNOS) is the key enzyme of vascular homeostasis involved in the pathophysiology of cardiovascular and renal diseases. We therefore hypothesize that the eNOS-soluble guanylate cyclase (sGC)-protein kinase G (PKG) pathway plays a crucial role in compensatory renal hypertrophy following unilateral nephrectomy.

Methods and results: We used the following three groups of mice: wild-type (WT), eNOS knockout (eNOS-KO) and endothelial specific eNOS transgenic (ECeNOS-TG) mice. These mice underwent left unilateral nephrectomy (i.e., WT-Nx, eNOS-KO-Nx and ECeNOS-TG-Nx), and their right kidney and serum were obtained for examination 2 weeks after nephrectomy. A control group of mice underwent sham operation (i.e., WT-sham, eNOS-KO-sham and ECeNOS-TG-sham) and these mice were similarly examined. Compensatory renal hypertrophy was markedly suppressed in the eNOS-KO-Nx group compared with the WT-Nx group. On the other hand, the ECeNOS-TG-Nx group exhibited enhanced compensatory renal hypertrophy than the other two groups. In addition, we examined the effects of BAY 41-2272 in vivo by treating eNOS-KO mice with BAY 41-2272 after unilateral nephrectomy. GSNO and BAY 41-2272 treatments stimulated the PKG activity and phosphorylation of Akt, s6 kinase and 4E-binding protein in hPTECs. Treatment with BAY41-2272 significantly enhanced compensatory renal hypertrophy in the eNOS-KO-Nx mice.

Conclusion: These results indicate that eNOS-sGC-PKG pathway plays a crucial role in the compensatory renal hypertrophy following unilateral nephrectomy.

**F-PO1036**

**Urinary Thioredoxin Is a Quick and Predictive Biomarker of Acute Kidney Injury** Kenji Kasuno,[1] Eri Muso,[2] Daisuke Mikami,[1] Naoki Takahashi,[1] Hideki Kimura,[1] Tomomi Kurose,[1] Yasunari Nobukawa,[1] Haruyoshi Yoshida.[1] *[1]Nephrology and Clinical Laboratories, University of Fukui Faculty of Medical Sciences, Fukui, Japan; [2]Nephrology and Dialysis, Kitano Hospital, The Tazuke Kofukai Medical Research Institute, Osaka, Japan.*

Thioredoxin (TRX) is a redox regulating protein induced by oxidative stress, however, little is known concerning the role of urinary TRX. We measured urinary levels of TRX by an ELISA in patients with acute kidney injury (AKI) (N=10), mesangial proliferative glomerulonephritis (mPN) (N=10), tubulointerstitial nephritis (TIN) (N=13), IgA nephropathy (N=20), membranous nephropathy (N=6), non-IgA mesangial proliferative glomerulonephritis (N=10), focal segmental glomerulonephritis (N=10), lupus nephritis (N=6), and healthy individuals (N=11). In addition, we performed an experimental study on mice with ischemia-reperfusion, and investigated the origin of urinary TRX. As a result, urinary levels of TRX were predominantly increased in patients with AKI. The quickness of the elevation of urinary TRX was equal or superior to neutrophil gelatinase-associated lipocalin in urine samples from patients on cardiopulmonary bypass surgery. Patients with full recovery of the urinary TRX elevation to the bottom levels showed better outcomes of renal function. A positive correlation was observed between urinary TRX and N-acethy-β-D-glucosaminidase levels in these patients. The urinary levels of TRX correlated with the degree of renal tubular atrophy. In an immunohistochemical study on mice with ischemia-reperfusion, stains of 8-Hydroxydeoxyguanosine and TRX were co-localized. Whereas a diffuse staining in the tubular cytosol in sham-operated mice, TRX became to eccentrically-locate in the apical side of the tubular cytosol, and then only in the urinary lumen in ischemia/reperfusion condition. Western blot analysis in the kidney tissue showed that ischemia/reperfusion caused a drastic decrease of TRX compared with the sham-operation. Urinary TRX excretion increases rapidly as patients with AKI. These findings suggest that urinary TRX dominantly originates from tubular cells and the measurement is useful in the diagnosis and the prognostic prediction of AKI.

**Histone Deacetylase 1/2 Mediates Proliferation of Renal Interstitial Fibroblasts and Expression of Cell Cycle Proteins** Shougang Zhuang. *Department of Medicine, Brown University School of Medicine, Rhode Island Hospital, Providence, RI.*

Proliferation and activation of renal interstitial fibroblasts is associated with the development and progression of renal fibrosis. We recently reported that the histone deacetylase (HDAC) activity *is required for* activation of renal interstitial fibroblasts. In this study, we further determined the role of HDACs, in particular, HDAC1 and HDAC2, in proliferation of renal interstitial fibroblasts and expression of cell cycle proteins. Inhibition of HDAC activity with trichostatin A (TSA), blocked cell proliferation, decreased expression of the, positive cell cycle regulator cyclin D1, and increased expression of p27 and p57, two negative cell cycle regulators. Silencing HDAC1 or HDAC2 with siRNA also significantly inhibited cell proliferation, decreased expression of cyclin D1, and increased expression of p57. Down-regulation of HDAC2, but not HDAC1, resulted in increased expression of p27. Further, we revealed that HDAC1 and HDAC2 are required for tyrosine phosphorylation and deacetylation of STAT3 (signal transducer and activator of transcription 3), and we showed that blockade of STAT3 with S3I-201 or siRNA decreased renal fibroblast proliferation. Finally, mouse embryonic fibroblasts (MEFs) lacking STAT3 demonstrated a reduced inhibitory effect of TSA on cell proliferation; add-back of wild type STAT3 to STAT3$^{-/-}$ MEFs restored the effect of TSA. Collectively, our results reveal an important role for HDAC1 and 2 in regulating proliferation of renal interstitial fibroblasts, expression of cell cycle proteins and activation of STAT3. Further, STAT3 mediates the proliferative action of HDACs.

**The Kidney Defends the Urinary System from Infection by Secreting NGAL** Neal A. Paragas, Ritwij Kulkarni, Andong Qiu, Adam J. Ratner, Jonathan M. Barasch. *Medicine, Columbia University, New York, NY.*

NGAL is a critical component of innate immunity because it binds catecholate-siderophores which microorganisms require for the capture of iron. Urinary NGAL (uNGAL) is expressed at mg/L levels after either septic or aseptic diseases of the kidney and has two potential functions, epithelial growth and/or bacteriostasis. Here we examined the activity of uNGAL in the infection of the urogenital tract with uropathogenic E. coli (CFT073). We found that NGAL significantly inhibited bacterial growth in vitro, an effect which could be rescued by the addition of iron. In a murine model of E. coli cystitis without pyelonephritis, the intensity and timing of urinary colony forming units was mirrored by the intensity and timing of uNGAL, including a decrease in uNGAL coincident with the resolution of infection. NGAL-deficient mice cleared E. coli urinary tract infections with delayed kinetics compared to matched wild-types. Likewise, conditional knockout of NGAL in the HoxB7 domain of the CD resulted in a similar phenotype despite normal levels of NGAL in other tissues. We determined the relative contribution of bladder and kidney to the uNGAL pool.Surprisingly, the kidney had a 168.10% percent increase in NGAL message while the bladder had a 7.68% increase in NGAL message in response to infection. Primary cells from the mouse kidney upregulated NGAL transcription in response to lipid A or heat-inactivated CFT073, indicating that the kidney was the critical responsive organ to infections of the bladder. Additional studies suggest that toll-like receptors are critical local sensors of infection. We conclude that uNGAL is essential for rapid clearance of uropathogenic E. coli in a mouse model of acute urinary tract infection and that the kidney responds to even a localized infection by secreting NGAL. These findings provide an explanation for the abundant NGAL secretion from the kidney observed in both septic and some aseptic states, demonstrating that the kidney defends the urinary system via exocrine delivery of NGAL.

Disclosure of Financial Relationships: nothing to disclose

**A High Throughput Respirometric Assay for Mitochondrial Biogenesis and Toxicity** Craig Cano Beeson, Gyda C. Beeson, Rick G. Schnellmann. *Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Mitochondria are a common target of toxicity for drugs and other chemicals, and injury results in decreased aerobic metabolism and cell death. In contrast, mitochondrial biogenesis restores cell vitality and there is a need for new agents to induce biogenesis. Current cell-based models of mitochondrial biogenesis or toxicity are inadequate because cultured cell lines are highly glycolytic with minimal aerobic metabolism and altered mitochondrial physiology. In addition, there are no high-throughput, real-time assays that assess mitochondrial function. We adapted primary cultures of renal proximal tubular cells (RPTC) that exhibit in vivo levels of aerobic metabolism, are not glycolytic, and retain higher levels of differentiated functions and used the Seahorse Biosciences analyzer to measure mitochondrial respiration in real time in multi-well plates. Changes in carbonylcyanide-4-(trifluoromethoxy)-phenylhydrazone (FCCP)-uncoupled respiration, a measure of electron transport chain (ETC) integrity, were used to quantify mitochondrial toxicity and biogenesis. The nephrotoxicants cisplatin, mercury(II) chloride and gentamicin induced statistically significant decreases in the FCCP-uncoupled rates of 13 – 35% relative to controls prior to decreases in basal respiration and cell death. Conversely, 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI), SRT1720, resveratrol, daidzein, and metformin produced mitochondrial biogenesis in RPTC as measured from statistically significant increases in FCCP-uncoupled respiration rates ranging from 20 – 55% of control. The latter results demonstrate that an increased FCCP-uncoupled rate is a new, phenotypic biomarker of biogenesis. The merger of the RPTC model and multi-well respirometry results in a single high-throughput assay to measure mitochondrial biogenesis and toxicity, and nephrotoxic potential.

Disclosure of Financial Relationships: nothing to disclose

**MicroRNA687 Is a Novel Regulator of PTEN during Renal Hypoxia and Ischemia-Reperfusion** Kirti Bhatt, Qingqing Wei, Zheng Dong. *Department of Cellular Biology and Anatomy, Medical College of Georgia and Charlie Norwood VA Medical Center, Augusta, GA.*

MicroRNAs are small endogenous non-coding RNAs that have recently emerged as important regulators of gene expression in various pathophysiological conditions. In kidneys, conditional knockout of Dicer (a key enzyme for microRNA production) from podocytes leads to glomerular defects and kidney failure, suggesting a role for microRNAs in the maintenance of podocyte homeostasis and function during kidney development. On the other hand, targeted deletion of Dicer from proximal tubules protects against renal ischemia-reperfusion injury (IRI), suggesting the involvement of microRNAs in the pathogenesis of renal IRI. Despite these findings, the specific microRNA species that contribute to renal IRI are not known. To identify the pathogenic microRNAs, we analyzed microRNA expression by microRNA microarray. Out of 220 detectable microRNAs, 138 (~60%) were decreased to varying degrees while 70 microRNAs (~30%) showed up-regulation during renal IRI in C57BL/6 mice. Fifteen microRNA species showed significant changes. Among these microRNAs, we confirmed by real-time PCR and Northernblot analysis that microRNA-687 (miR-687) was drastically up-regulated during renal IRI. Consistently, miR-687 was induced during hypoxic incubation of renal proximal tubular cells in vitro. Bioinformatic analysis suggested that the tumor suppressor PTEN is a likely target gene of miR-687. We further showed that, when miR-687 was induced by hypoxia, there was a concomitant decrease of PTEN expression. Notably, blockade of miR-687 with anti-miR-687 LNA could prevent PTEN decrease during hypoxic incubation and enhance apoptosis. The 3'UTR of PTEN gene contains miR-687 binding sequence and miR-687 mimic could decrease luciferase activity in cells transfected with a luciferase reporter vector bearing PTEN 3'UTR. Together, this study has identified miR-687 as a novel regulator of PTEN during renal hypoxia and ischemia-reperfusion injury.

**F-PO1041**

**Novel Use of Ultrasound To Assess Renal Reperfusion and P-Selectin Expression Following Unilateral Renal Ischemia in Mice** Erika I. Boesen, Jennifer C. Sullivan. *Vascular Biology Center, Medical College of Georgia, Augusta, GA.*

Incomplete restoration of blood flow following ischemia likely contributes to hypoxia-induced injury. We tested if high resolution ultrasound (Vevo 770) is a viable non-invasive alternative to traditional perivascular flow probe methods to assess reperfusion after 60 min of unilateral renal ischemia in mice. Renal blood flow velocity was measured by pulse-wave Doppler in anesthetized C57Bl/6 mice prior to renal ischemia/reperfusion (I/R) surgery,

and at 1 and 24 h post-ischemia. Male and female mice (n=6-7) displayed similar deficits of renal blood flow at 1 h (56±9% and 69±10% of baseline; P=0.4) and 24 h post-ischemia (40±8% and 46±7% of baseline; P=0.6). In a separate group of male mice, perivascular flow probes revealed a similar deficit of blood flow recovery at 1 h post-ischemia (66±6%, n=8) to that seen with ultrasound. Additional studies used antibody-tagged contrast agent to test if ultrasound imaging could be used to measure I/R-induced increases in endothelial adhesion molecule expression. P-selectin targeted contrast agent was infused i.v. 1 h post ischemia, and contrast agent signal intensity compared in post-ischemic and contralateral kidneys before and after a high frequency "destruction sequence" that disrupts adherent contrast agent. Thus, a fall in signal intensity is proportional to the adherence of contrast agent to the endothelium. Male and female mice (n=5-6) displayed a significant fall in signal intensity in the post-ischemic renal cortex (-35±6% and -33±6%; P<0.001 versus contralateral kidney), whereas the contralateral kidney showed virtually no change in signal intensity (-7±3% in both groups). These data indicate a significant up-regulation of P-selectin in the cortical endothelium of the post-ischemic kidney after 1 h reperfusion. There were no sex differences in any variables measured. This study validates the use of high resolution ultrasound as a non-invasive means to assess both renal reperfusion and vascular endothelial adhesion molecule expression in mice. This methodology has the potential to address key mechanistic questions relating to the pathogenesis of renal damage in multiple disease models.

## F-PO1042

**The Contribution of EGR-1 to Renal Injury Following Renal Ischaemia and Reperfusion Injury Is Dependent on PAR-1** Jonathan H. Erlich.[1] *[1]Dept of Nephrology / Prince of Wlaes Clinical School, UNSW, Sydney, NSW, Australia; [2]Dept of Paediatrics/ Prince of Wlaes Clinical School, UNSW, Sydeny, NSW, Australia; [3]Departement of Nephrology, Prince of Wales Hospital, Randwick, NSW, Australia.*

Background: EGR-1 is a zinc finger transcription factor that is normally expressed in cells at low level but upon appropriate cellular stress such as hypoxia is found to be rapidly elevated and then translocated to the nucleus where it stimulates pro inflammatory mediators. We have shown that protease activated receptor -1 (PAR-1) is an important mediator in renal IR injury and EGR-1 has been suggested to regulate PAR-1. Further EGR-1 has also been shown to be an important mediator in various models of ischaemia reperfusion injury.

Methods and Results: Using a mouse model of renal IR with 25 min ischaemia and up to 24 h reperfusion we found that EGR-1 assessed by real time RT PCR was similarly and maximally elevated in both C57BL6 mice and PAR-1-/- mice at 2 h reperfusion (C57BL6 19.7±7.48 vs 0.13±0.04, and PAR-1-/- 22.9±4.9 vs 0.8±0.3, WT vs Sham p<0.05) decreased at 5 h (C57BL6 11.8±3.9 vs 0.25±0.18 and PAR-1-/- 3.2±1.43 vs 0.42±0.26 IR vs sham P< .05) with a decrease toward baseline by 24 h reperfusion. However, PAR-1-/- mice developed less severe renal injury compared to WT mice (123 ± 24.8 micromol/L vs 216.2 ± 7.2 micromol/L, p< 0.01). Further, an EGR-1 regulated gene tissue factor was similarly expressed in PAR-1-/- and WT mice. The data suggests that EGR-1 is an upstream mediator of PAR-1 and that in this model EGR-1 effects are PAR-1 dependent.

This has important implications for designing therapeutic strategies to limit the effect of inflammatory injury following renal IRI.

## F-PO1043

**Diagnosis and Staging of Acute Renal Failure in Cardiac Surgery: Comparison between AKIN and RIFLE Criteria** Carmen Bernis,[1] Ana Perez de José,[1] Rosario Madero,[2] Pablo Alonso,[3] Juan Bustamante,[4] Jose-Antonio Sanchez-Tomero.[1] *[1]Nephrology, H.U. Princesa, Madrid, Spain; [2]biostatistics unit; [3]ICU; [4]Cardiac Surgery, .*

Several diagnostic criteria have been proposed for AKI classification .The aim of this study is to compare AKIN ( Crit Care; 2007) and RIFLE (Critical Care ;2004) classifications for AKI diagnosis and for predicting outcome in a cohort of patients who underwent cardiac surgery

**Methods**

Patients who underwent coronary artery bypass(30%), valve heart surgery(70%) or both, between January 2007 and December 2008 were retrospectively evaluated. Data were prospectively collected. The statistical package SPSS was used.

**Results**

601 patients (mean age 65,9 ± 11,7 years; 40,3 % females; mean Cleveland Score 3.3 ± 1.8 were evaluated.

AKIN criteria compared to RIFLE allowed the identification of more patients as having any stage of AKI (16.6% vs 7.2%). AKIN increases patients classified as Stage I (category R in RIFLE) from 4.2% to 13.6%. 57 patients (9,5%) were not considered AKI according to RIFLE classification and were stage 1 according to AKIN criteria. No significant differences were observed for stage 2 (injury in RIFLE) and for stage 3 (failure in RIFLE). RIFLE and AKIN concordance is moderate, kappa index 0,55 (IC 95% 0,45-0,65, p<0,05). Using Mc Nemar test discrepancies are significant (p<0,001).

The area under the ROC curve for hospital mortality was 0.70 for AKIN criteria ($P < 0.001$) and 0.66 for RIFLE criteria ($P < 0.001$). However, in these 57 patients with AKIN stage 1 , (and no AKI according to RIFLE), mortality was 18.3% higher than in patients with no AKI ( 4,6%, p=0,05) with a risk of death 3,4 times higher (OR 3.4, IC 95% 1,44-7,99).

**Conclusions**

1- AKIN criteria improves the sensitivity compared to RIFLE. 2-As global classifications, considering all stages, there are no significant differences between RIFLE and AKIN . 3- However, patients with AKIN stage 1( considered as no AKI according to RIFLE), have a significant higher mortality than patients with no AKI.4-The modification of the RIFLE criteria proposed by AKIN, has epidemiological relevance , is associated with mortality and can help to identify more patients at risk

Disclosure of Financial Relationships: nothing to disclose

## F-PO1044

**BMP-2 Induces a Pro-Fibrotic Phenotype in Adult Renal Progenitor Cells (ARPC) through Nox4 Activation** S. Simone, C. Cosola, Fabio Sallustio, A. Loverre, G. Grandaliano, Francesco Paolo Schena, G. Pertosa. *Nephrology, Dialysis and Transplantation Unit, Univ. of Bari, Italy.*

CD133+CD24+Pax-2+ ARPCs, isolated in human adult kidney, contribute to repair processes featuring acute kidney injury (AKI). BMPs are involved in differentiation, modeling and regeneration. The role of BMP-2 in AKI is still unclear. Aim of the study is to evaluate the expression of BMP-2 in ARPCs and its biological action on these cells.

BMP-2 expression in ARPCs was studied in vivo by confocal microscopy on adult human renal tissue. ARPCs were isolated by magnetic cell sorting. BMP-2 and BMP receptors (BMPRs) gene and protein expression were evaluated by RT-PCR and ELISA/ immunoblotting. Myofibroblastic markers (alpha-SMA, collagen-I, fibronectin) and Nox4 (NADPH oxidase renal isoform) protein expression were studied by immunoblotting. Intracellular reactive oxygen species (ROS) production was measured by 2',7' dichlorodihydrofluorescein fluorescence. Superoxide production by NADPH oxidase was studied by chemiluminescence.

BMP-2 is basally expressed in normal adult human kidney by ARPCs. In vitro, these cells express BMPRs, ALK-2, 3 and 6. TNF-alpha (200 U/ml) significantly induced both BMP-2 gene [fold change (fc) 1.7±.2 vs basal, p=.03] and protein expression (basal 48h 65±.1; TNF-alpha 48h 152±19 pg/ml, p=.002) in ARPCs. After incubation with BMP-2 (30 ng/ml) ARPCs showed an increased ROS production (basal 36±15; BMP-2 15' 65±17 AU, p=.05), NADPH oxidase activity (basal 86±38; BMP-2 15' 212±75 AU, p=.01) and Nox4 protein expression (basal .3±.2; BMP-2 5' 1±.6 AU, p=.03). BMP-2 incubation for 5 days induced α-SMA (basal .3±.1; BMP-2 .8±.2 AU, p=.02), collagen-I (fc 2.4±.6 vs basal, p=.03) and fibronectin (fc 1.4±.1 vs basal, p=.04) protein expression in ARPCs, but not in HK-2 cells. Incubation with the anti-oxidant N-acetyl-cysteine reverses BMP-2-induced alpha-SMA expression (fc BMP-2 2.2±.6 vs basal p=.03; BMP-2+NAC 1.3±.4 vs BMP-2 p=.04).

We demonstrated for the first time that: 1. ARPCs express BMP-2; 2 this expression is significantly induced by inflammatory stimuli; 3. BMP-2 may commit ARPCs towards a myofibroblastic phenotype. 4. This pro-fibrotic effect is mediated by Nox4 activation.

**Trends in Acute Kidney Injury Associated with Coronary Stenting in the United States from 2000 to 2007** Ankit Sakhuja, Abhishek Deshmukh, Nilay Kumar, Rahul S. Nanchal, Aaron T. Dall, Gagan Kumar. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

**Introduction:**

In hospital mortality of acute myocardial infarction (AMI) has improved over the past few years due to early cardiac catheterization. Acute Kidney Injury (AKI) can occur either due to hypotension resulting from AMI, athero-embolic phenomenon or as a complication from the contrast dye. We studied the trends of AKI in patients admitted with AMI.

**Methods**

Retrospective observational study was utilized to analyze the Nationwide Inpatient Sample from year 2000 to 2007. The adult patients (>18 years age) with a primary discharge diagnosis of AMI were identified using ICD-9 code. Pearson correlation and Chi square were used to compare the variables for unadjusted analysis and logistic regression was used to obtain adjusted odds ratios. The model adjusted for age, sex, race, hospital characteristics and the risk factors for developing AKI like diabetes mellitus, hypertension, chronic kidney disease and hypovolemia including shock. α was set at 0.05.

**Results**

There were an estimated 15,459,503 admissions with the primary diagnosis of AMI over 8 years. The frequency of AKI increased from 2.6% in 2000 to 6.5% in 2007. The odds for developing AKI was 1.52 times higher in 2007 when compared to 2000 (OR 1.52, 95%CI 1.48-1.57). AKI was an independent predictor of mortality in patients after AMI (OR 4.04; 95%CI 3.89-4.19). There was a significant decrease in mortality in patients with AMI with AKI (2.8% in 2000 vs. 1.4% in 2007).

**Conclusion**

The in hospital frequency of AKI has increased 1.5 times in patients admitted with and undergoing catheterization for AMI over this new millennium. The all cause in hospital mortality has nevertheless decreased in patients following treatment of AMI whom developed AKI.

**Distinct Effects on Long Term Function of Injured and Contralateral Kidneys Following Acute Unilateral Ischemia Reperfusion** David P. Basile, Ellen Leonard, Jessica Friedrich. *Cellular & Integrative Physiology, Indiana University, Indianapolis, IN.*

AKI induced by ischemia reperfusion injury in rats can have persistent effects function, predisposing salt-sensitive hypertension and CKD. Immune suppression can ameliorate salt-sensitive hypertension and renal fibrosis following recovery from AKI. The current study was designed to investigate further the hypothesis that the chronic effects of AKI on salt sensitivity are mediated, in part, via circulating factors secondary to injury. SD rats (maintained 0.4% NaCl diet) were subjected to 40 minutes of left unilateral renal ischemia or sham-surgery. The effect of unilateral I/R on the contralateral kidney was evaluated by removal of the (left) injured kidney at 5 weeks of recovery and subjecting rats to elevated salt intake (4% NaCl) for an additional 4 weeks. Blood pressure values, measured by telemetry, were significantly higher in animals from which a previously injured kidney had been removed vs sham-operated Unx controls (MAP 124 ± 7 vs 108± 3 mm Hg). Rats from which an injured kidney had been removed had similar creatinine clearance and protein excretion rates as sham-operated UNx controls. The remaining untouched kidney from I/R treated rats showed significantly greater hypertrophy relative to the sham-operated UNx controls (3.5 ± 0.2 g vs 2.9 ± 0.3g, P < 0.05), showed moderate evidence of increased interstitial SMA and CD4+ interstitial cells relative to shams. A third group of animals evaluated the effect of a solitary injured kidney (by removing the untouched contralateral kidney) and subsequent exposure to elevated salt intake. Animals with a solitary post I/R kidney showed an elevation in blood pressure, a 5-fold increase in protein excretion and a significant ~75% reduction in creatinine clearance. The solitary post I/R kidney was significantly atrophied relative to shams (2.2 ± 0.3 g) and had widespread interstitial fibrosis. The data suggest that the chronic effects of AKI on hypertension and CKD are mediated primarily via direct effects on tissue injury, but are also partially mediated by indirect effects of I/R injury mediated possibly via circulating humoral factors.

**Relation between Obstructive Sleep Apnea and Acute Kidney Injury** Michal P. Nowicki,[1] Anna Zawiasa,[1] Malgorzata Kolodziejska,[1] Maciej Banasiak,[1] Piotr Bialasiewicz,[2] Dariusz Nowak.[2] *[1]Department of Nephrology, Hypertension and Kidney Transplantation, Medical University of Lodz, Lodz, Poland; [2]Chair of Clinical and Experimental Physiology, Medical University of Lodz, Lodz, Poland.*

**Introduction**. Obstructive sleep apnea (OSA) is characterized by recurrent episodes of hypoxia and hypercapnia that may cause repeated ischaemia-reperfusion injury and thereby subclinical acute kidney injury (AKI).

The aim of the study was to assess the effect of OSA on urine markers of AKI, arterial stiffness and central aortic pressure.

**Patients and methods**. 20 males with polysomnography-based diagnosis of sleep apnea syndrome and $GFR_{CKD-EPI}$> 60ml/min/1,73 m² were recruited to a prospective, interventional pilot study. The patients were divided into two groups, i.e. with mild OSA (8 patients, age 39,6±9 years, BMI 29±4 kg/m², $GFR_{CKD-EPI}$ 88,2±17,7 ml/min, apnea-hypopnea index (AHI) 5,8±3,8 episodes/hour) and severe OSA (12 patients, age 49,6±9,4 years, BMI 38,0±6,0 kg/m ², $GFR_{CKD-EPI}$ 82,9±14,1 ml/min, AHI 68,5±24,3 episodes/hour). Central blood pressure in the aorta and pulse wave velocity **(**PWV) were measured with ECG-synchronized tonometry (PulsePen, DiaTecne., Milan, Italy). Serum creatinine hsCRP and urine AKI markers: cystatin C, NGAL, L-FABP were assessed both before and after polysomnography (diagnostic night). Patients with severe OSA were treated with the continuous positive airway pressure (CPAP). After 6 to 8 weeks of CPAP therapy all measurements were repeated as at baseline (therapeutic night).

**Results**: Both urine NGAL and L-FABP tended to increase after both diagnostic and therapeutic night but the changes were not significant. Only urine cystatin C significantly increased after the diagnostic night in patient with severe OSA (from 84.1±37.4 to 117.5±33.3 ng/ml; p=0,002). The increase of cystatin C was lower after CPAP therapy (from 93.2±48.4 to 108.9±41.9 ng/ml; p=0,045). Aortic stiffness (PWV and Aortic Index) did not correlate with severity of OSA.

**Conclusion**: This pilot study results seem to support the concept that OSA may cause subclinical acute kidney injury and that the treatment of severe OSA with CPAP may reduce an extend of the injury.

**Impact of Acute Kidney Injury after Acute Myocardial Infarction on Short- and Mid-Term Survival: A Contemporary Analysis** Ana Cortesao Costa, Luis Resende, José Lopes, Antonio Gomes da Costa. *Nephrology and Kidney Transplantation, CHLN-HSM, Lisboa, Portugal.*

Acute kidney injury (AKI) often complicates patients with Acute Myocardial Infarction (AMI) and carries an ominous prognosis. We retrospectively evaluated the impact of AKI, defined and stratified based on RIFLE (Risk, Injury, Failure, Loss and End-stage kidney disease) criteria, on in-hospital mortality, and on survival at 3 years of follow-up among patients who had hospital discharge. Chronic kidney disease patients were excluded from analysis. In all, 264 patients with AMI hospitalized in the Department of Cardiology of our Hospital in 2006 were studied. AKI occurred in 65 patients (24.6%) as follows: 8.7% were on Risk, 8.3% were on Injury and 7.6% were on Failure. In-hospital mortality was higher in AKI ($P$<0.0001), as compared with no AKI patients, and it increased in accordance to AKI severity (Risk, Injury, Failure; $P$=0.009). Adjusting for age, gender, race, ST-segment elevation, AMI location, ejection fraction, vasopressors use, and need of mechanical ventilation, AKI (AKI odds ratio 4.57, 95% confidence interval 1.48-14.16, $P$=0.008) was as independent predictor of in-hospital mortality. Injury and Failure classes also predicted independently in-hospital mortality (Injury odds ratio 5.36, 95% confidence interval 1.25-23 $P$=0.024; Failure odds ratio 13.34, 95% confidence interval 2.83-62.93, $P$=0.01), while Risk class did not (Risk odds ratio 2.1, 95% confidence interval 0.45-9.7, $P$=NS). Survival at 3 years of follow-up was lowest among AKI patients ($P$<0.0001), as compared with patients with no AKI. The negative impact of AKI on 3-year survival was particularly relevant for moderate and severe AKI forms (Risk, Injury, Failure; $P$<0.0001). After adjusting for age, gender, race, and comorbidity (diabetes mellitus, hypertension, previous AMI, heart failure, cerebrovascular disease, and peripheral vascular disease), AKI increased 3-year mortality. In addition, Injury and Failure classes also has an independent detrimental effect on 3-year mortality, while Risk class did not. AKI is frequent after AMI and it has a negative impact on short-and mid-term survival, mainly in its moderate and severe forms.

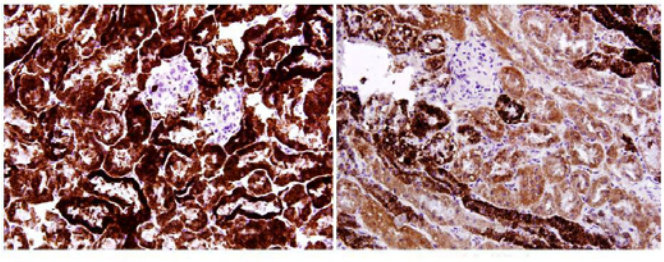
**Mitochondrial Impairment without Cell Death in Sepsis-Induced Acute Kidney Injury** Amit Bardia,[1] Zsuzsanna Zsengeller,[2] S. Ananth Karumanchi,[1] Isaac E. Stillman,[2] Samir M. Parikh.[1] *[1]Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; [2]Pathology, Beth Israel Deaconess Medical Center, Boston, MA.*

BACKGROUND: Recent case series and meta-analyses have shown a paucity of structural changes in kidney specimens obtained during sepsis-induced AKI. We used the murine endotoxemia (lipopolysaccahrides, LPS) model of sepsis-induced AKI to explore the role of functional, rather than structural, impairments in the septic kidney.

RESULTS: 10 mg/kg LPS given intraperitoneally to 8-week old BL6/J male mice increased Blood urea nitrogen (BUN) and creatinine at 18 and 42 hrs. Apoptosis, as measured by cleaved caspase-3 immunohistochemistry, and necrosis were unchanged compared to controls. Despite a marked reduction in renal blood flow, renal tissue oxygenation, as measured by BOLD MRI, was also unchanged, suggesting an impairment of oxygen consumption in the septic kidney. Enzyme activity of cytochrome C oxidase, a key member of the electron transport chain, was greatly diminished in the septic kidney.

Figure 1: Cytochrome C oxidase staining in control (A) and septic (B) mice kidneys.



A (Control kidneys) B (Septic kidneys)

Moreover, treatment of cultured renal proximal tubular cells with TNF-alpha reduced both basal oxygen consumption and uncoupled oxygen consumption without reducing mitochondrial abundance, thus specifically implicating a functional mitochondrial impairment.

CONCLUSIONS: Mitochondrial dysfunction is more strongly associated with septic AKI than cell death. We speculate a contributory role for this phenomenon in the development of depressed renal function during sepsis.

**Genetic Polymorphism of TGB-β and IFN – γ and Its Influence on the Occurrence of Acute Kidney Injury (AKI)** Caren Cristina Grabulosa, Maria Dalboni, Marie Beata Redublo Quinto, Edgar Ferreira Cruz, Julio Cesar Monte, Marcelino Durao, Oscar Pavao Dos Santos, Miguel Cendoroglo, Marcelo Costa Batista. *Medicine/Nephrology, Universidade Federal de São Paulo, Sao Paulo, Brazil.*

Introduction: We conjecture that genetic polymorphisms of TGF-beta and INF-gamma cytokines have crucial role in the outcome to AKI in critically patients.

Objective: To assess the genetic polymorphism of TGF - β and IFN-γ in patients with SIRS in the occurrence of AKI in patients admitted in intensive care unit (ICU).

Materials and Methods: We performed a nested case-control study with 797 critically patients admitted in ICU. The AKIN criteria were used to characterize patients with AKI. We evaluated polymorphism TGF-β and IFN -γ in 150 patients who developed AKI (case group) and a control group of 150 individuals without AKI. We investigated the polymorphism codon 10T/C and codon 25C/G of TGF-β and intron +874T/A IFN-γ by PCR-SSP.

Results: Patients who progressed to AKI showed higher APACHE score (20+/- 7 vs. 17+/- 5, p < 0.01) and CRP (9+/- 9 vs. 7+/- 8, p = 0.01). In univariate analysis we observed that patients with AKI had a higher frequency of TC GG genotype (high producer) for TGF-beta polymorphism compared to non-AKI (19.5% vs. 7.6%, p < 0.01). Similarly, patients

with AKI showed a higher frequency of TC genotype (intermediate producer) for IFN-Y polymorphism than non-AKI group (39.8% vs. 17%, p<0.01). In respect to the phenotype, we observed an increased prevalence of high producers of TGF-beta (58.4% vs. 26.6%, p< 0.01) and IFN-Y (50.7% vs. 21 0%, p<0.01) in patients with AKI compared without AKI. However, in multivariate analysis model taking both polymorphisms as possible independent predictors adjusted by ethnicity, age, gender and APACHE II score, the TC GG and TC genotypes did not remained statistically related with AKI occurrence.

Conclusions: Although we found an increased prevalence of high producer phenotypes and a high expression of 10T/C 25C/G TGF-β and +874T/A INF-γ polymorphism in patients who developed AKI in ICU setting, this study did not show that these polymorphism could independently determine AKI occurrence.

### F-PO1051

**Microarray Analysis of Isolated Proximal Tubules in Rats with Cisplatin-Induced Nephrotoxicity** Satohiro Masuda,[1] Kumiko Nishihara,[1] Atsushi Yonezawa,[1] Aiko Ozawa,[1] Takaharu Ichimura,[2] Joseph V. Bonventre,[2] Ken-Ichi Inui.[1] [1]*Pharmacy, Kyoto University Hospital, Kyoto, Japan;* [2]*Renal Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

**[Backgrounds]** Cisplatin has been identified as a substrate of the kidney specific organic cation transporter OCT2/SLC22A2, and its cellular uptake into the tubular epithelium was found to be a crucial step for subsequent nephrotoxicity (Yonezawa et al., Biochem Pharmacol, 70, 1823-31, 2005; Tanihara et al., Biochem Pharmacol, 78, 1263-71, 2009). Therefore, cisplatin-induced nephrotoxicity may be characterized by a gene expression profile in proximal tubules, which may serve as an early specific marker for detection of cisplatin-induced tubular damage. **[Aim]** we have used microarray analysis to evaluate gene expression in isolated proximal tubules of the rats with cisplatin-induced nephrotoxicity. **[Methods]** Renal proximal tubules were isolated under microscopy, and transcriptome data were collected with Rat Genome Survey Microarray® (Applied Biosystems) (Nishihara et al., Am J Physiol Renal Physiol, 298, F923-34, 2010). **[Results]** Among 17,000 transcripts examined, the mRNA expression levels of chemokine (C-C motif) ligand (Ccl) 2 (as also called MCP-1) as well as kidney injury molecule 1 (Kim-1) was significantly increased after treatment with cisplatin. Immunofluorescent analysis showed that the positive signals for Ccl2 were initially and specifically detected in the proximal tubular epithelial cells. In addition, urinary Ccl2 as well as Kim-1 protein was significantly increased approximately 3-fold compared to controls on the day after administration of cisplatin (5mg/kg intraperitoneal administration), respectively. However, no changes were observed in the levels of plasma creatinine, blood urea nitrogen and plasma Ccl2. **[Conclusions]** Urinary Ccl2 and Kim-1 are suggested to serve as sensitive and noninvasive markers for early detection of tubular injury secondary to cisplatin treatment. The production of Ccl2 at the proximal tubular cells may play a pathophysiological role contributing to the deterioration the proximal tubule that characterizes cisplatin-induced nephrotoxicity.

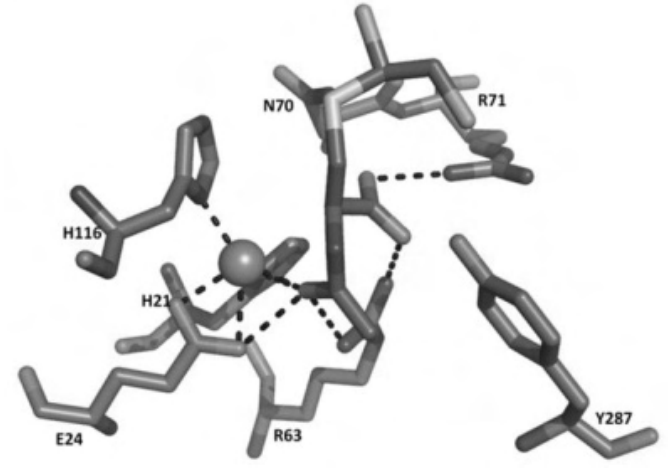
**Structural Aspects of Mercapturate Deacetylation by Aminoacylase 3 in Renal Proximal Tubule** Kirill Tsirulnikov,[1] Jennifer Hsieh,[2] Natalia Abuladze,[1] Nathaniel Magilnick,[1] Debra Newman,[1] Jeff Abramson,[2] Ira Kurtz,[2] Alexander Pushkin.[2] [1]*Medicine/Nephrology, UCLA, Los Angeles;* [2]*Physiology, UCLA, Los Angeles.*

Toxic mercapturates (N-acetyl conjugates of cysteine) are known to selectively damage renal proximal straight tubule. We have recently shown that their deacetylation mediated by aminoacylase 3 (AA3) is a key step in the mercapturate induced nephrotoxicity. Although inhibition of AA3 may be used to ameliorate nephrotoxic effects of mercapturates, the absence of a high-resolution structure of AA3 significantly limits generation of highly specific inhibitors of AA3. Here we report the crystal structure of AA3 in complex with a toxic mercapturate N-acetyl-1,2-dichlorovinyl-L-cysteine (shown in purple).



The substrate binds through a hydrogen bond network (dashed lines) to the *N*-acetyl-α-amino carboxylic acid component of the substrate while the side chain constituent is secured solely by van der Waals interactions (not shown). Comparison of the structures of free AA3 and AA3 complexed with the mercapturate in conjunction with biochemical analysis indicate that AA3 has a dynamic substrate recognition mechanism capable of accommodating a broad range of substrates. The results provide the basis for generation of highly specific inhibitors of AA3 that may be used for amelioration of mercapturate nephroxicity. Funding Source: NIH ES012935.

### F-PO1053

**Involvement of DDAH-ADMA Axis in Accelerated Renal Injury in Acute Ischemia-Reperfusion Injury** Yosuke Nakayama, Seiji Ueda, Yusuke Kaida, Ryotaro Ando, Kei Fukami, Seiya Okuda. *Division of Nephrology, Department of Medicine, Kurume University, Kurume, Fukuoka, Japan.*

***Background.*** Recent evidence suggests that injury to the renal vasculature may play an important role in the pathogenesis of ischemic acute kidney injury (AKI). Since nitric oxide (NO) is a vasodilator and known to play an important role in the maintenance of renal microvasculature and its flow and may exert a protective role against AKI, it is conceivable that asymmetric dimethylarginine (ADMA), an endogenous inhibitor of NO synthase, could enhance tubulointerstitial injury during AKI by decreasing NO bioavailability. However, the association between ADMA and AKI remain to be elucidated.

***Methods.*** To determine the role of ADMA in AKI, eight-week-old male C57BL/6J (wild) mice and DDAH-1, a key enzyme for ADMA degradation, transgenic (Tg) mice were used in this study. Ischemia- reperfusion (IR) injury were performed in wild mice with (n=10) or without (n=15) ADMA infusion (0.01mg/kg/min) and Tg mice (n=5). Sham operated mice (n=10) were used as control. Renal function, morphology of acute renal injury,and rarefaction rate of renal capillaries were compared after IR. Tissue or plasma levels of ADMA were measured by HPLC. ADMA-related related enzymes such as DDAH and PRMT, an enzyme for ADMA synthesis, were measured by western blot analysis.

***Results.*** Western blot analysis revealed significant decreases in renal DDAH1 expression levels during IR injury associated with increased ADMA levels in wild mice. Compared with IR-treated wild mice, ADMA infusion markedly enhanced capillaries rare faction, tubular injury and increases in BUN levels, whereas these changes were significantly attenuated in IR-treated DDAH Tg mice.

***Conclusion.*** These results strongly suggest that the active involvements of ADMA-DDAH axis in the pathogenesis of IR injury. ADMA-DDAH axis could be a novel target for patients with AKI.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1054

**Development of an *In Vitro* Model To Investigate Changes in Kidney-Derived Exosomes with Disease** Jonathan M. Street, Matthew A. Bailey, David J. Webb, James W. Dear. *Centre for Cardiovascular Science, University of Edinburgh, Edinburgh, United Kingdom.*

Acute kidney injury (AKI) is a significant cause of mortality. Our ability to detect and treat AKI has been limited and mortality has remained high. Although a number of new biomarkers for the detection of AKI are currently under development our understanding of AKI is still limited. A number of groups have studied exosomes, small lipid membrane bound vesicles released by cells, as a method to study cellular state within the kidneys. We have confirmed the presence of exosomes in the urine using the markers Tsg-101, Flotillin-1 and CD24, density determination on a sucrose gradient and by direct visualisation using transmission electron microscopy. Using GeLC-MS/MS we have identified 88 proteins within the urinary exosomes which represent all regions of the nephron. To study the factors effecting exosome release and the effect of exogenous exosomes on the kidney we have developed an *in vitro* murine cortical collecting duct (mCCD) cell model. These cells constitutively release exosomes as determined by western blot for known exosomal markers and density determination. Release of exosomes can be enhanced by ionomycin, a known promoter of exosome release. We have previously shown that the transcription factor cJun is present in the urinary exosomes of septic patients but not healthy controls. In contrast cJun was present in the mCCD cell derived exosomes prior to stimulation and was not increased following stimulation with TNFα. We also investigated the effect of cisplatin treatment on the mCCD cell derived exosomes. It has previously been suggested that exosomal fetuin-A is a marker of cisplatin toxicity. In our model cisplatin treatment, at sub-apoptosis inducing concentrations, did not increase fetuin-A in exosomes. Characterisation of exosome release under physiological, inflammatory and toxic conditions is ongoing. The developed cell model has the potential to connect changes seen in the exosomal proteome to the changes seen in the kidney with AKI.

**F-PO1055**

**Monitoring of Urinary L-FABP and Renal Microcirculation in Mouse Radiocontrast-Induced Acute Kidney Injury** Kousuke Negishi,[1] Kent Doi,[1] Tokunori Yamamoto,[2] Takeshi Sugaya,[3] Toshiro Fujita,[1] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan; [2]Urology, Nagoya University, Nagoya, Aichi, Japan; [3]CMIC Co. Ltd., Tokyo, Japan.*

Radiocontrast-induced acute kidney injury (RC-AKI) remains to be a critical issue because of its association not only with renal outcome but with the impact on survival. Since L-type fatty acid-binding protein (L-FABP), expressed in proximal tubules of the human kidney, is established as a fine sensor of renal hypoxia by basic and clinical studies (*J Am Soc Nephrol 18:2894-902, 2007*), we evaluated whether urinary L-FABP is a useful marker for early diagnosis of RC-AKI using human L-FABP transgenic mice.

Mice were subjected unilateral nephrectomy 7 days before RC injection. After water restriction for 24 h, mice were intraperitoneally injected indomethacin (I), L-NAME (L) and low-osmolar RC iohexol (3 g Iodine/kg, R). Equivalent volume of saline was injected as control for each reagent (S). Using metabolic cages, serial urine and blood sampling was carried out. Moreover, renal peritubular capillary (PTC) blood flow at 12 h was directly monitored by intravital CCD videomicroscope. All mice were sacrificed at 48 h.

Urinary L-FABP in the animals with indomethacin, L-NAME, and RC injection (I-L-R) at 12 h significantly increased up to 3000-fold from the baseline. BUN was also peaked at 12 h [0 h; 44.6 ± 8.7, 12 h; 92.1 ± 5.1 (mg/dl, Mean ± SE)]. Significant increase of urinary NAG was shown at 24 h, but not at 12 h. PTC flow velocity in I-L-R was significantly decreased than that in S-S-S.

Histological analysis revealed vacuolation and increased L-FABP expression in proximal tubules were limited only in ILR. Moreover, ROC analysis for predicting vacuolation at 48 h demonstrated an excellent accuracy of urinary L-FABP at 12 h and at 24 h (area under the ROC curve; 0.917, 0.955, respectively). Furthermore, Log converted urinary L-FABP showed a positive correlation with BUN at 12h ($r^2 = 0.790$, $p = 0.00001$).

In summary, urinary L-FABP demonstrated good performance as a RC-AKI biomarker for detecting both structural and functional change of the kidney.

**F-PO1056**

**Mitochondrial Damage Is Attenuated during Hypoxia/Reoxygenation by Delipidated Bovine Serum Albumine and Glutamine** Özlem Köse, Oliver Witzke, Tobias Tuerk, Andreas Kribben, Thorsten Feldkamp. *Nephrology, University Duisburg-Essen, Essen, Germany.*

We have shown that hypoxia induced accumulation of nonesterified fatty acids (NEFA) plays a pivotal role in the pathogenesis of mitochondrial damage in proximal tubule (PT) during hypoxia and reoxygenation (H/R). We studied, whether binding of NEFA during H/R with delipidated bovine serum albumine (dBSA) attenuates mitochondrial damage. Mitochondrial function was assessed by measuring ATP production of freshly isolated rat PT and accumulation of NEFA was assessed during H/R. 45 min of H lowered tubular ATP content after 60 min of R significantly compared to 105 min of normoxia (Tab. 1, $p<0.01$ vs. normoxia n=5-8). Addition of glutamine during R resulted in an increased ATP content compared to H/R alone, even though it was still significant lower than during normoxia (Tab. 1, $p<0.05$ vs. H/R alone, n=6). Addition of dBSA during R to bind NEFA resulted in an increased ATP content after R compared to H/R alone (Table 1, $p<0.05$ vs. H/R alone n=4). The combination of glutamine with dBSA during R fully recovered ATP content to levels in normoxia (Tab. 1, $p<0.01$ vs. H/R+glutamine, n=4). Tubular NEFA levels were significantly higher after H/R without or with glutamine compared to normoxia (Tab. 1, $p<0.01$ vs. normoxia, n=4-8). Addition of dBSA during H/R without or with glutamine further increased NEFA levels compared to H/R alone, because NEFAs bound to dBSA were also detected by the assay (Tab. 1, $p=0.075$ and $p<0.01$ resp. vs. H/R alone, n=4-8).

| Condition | ATP (nmol/mg protein) | NEFA (nmol/mg protein) |
|---|---|---|
| Normoxia | 11.01± 0.38 | 3.32±0.21 |
| H/R | 2.88± 0.40 | 7.90±1.20 |
| H/R + Glutamine | 5.88± 0.37 | 6.68± 2.02 |
| H/R +dBSA | 4.08± 0.37 | 12.14± 2.38 |
| H/R+ Glutamine+ dBSA | 11.75±0.98 | 15.79± 2.16 |

Table 1

In summary, dBSA and glutamine improve mitochondrial function during H/R induced mitochondrial damage. NEFA accumulate during H/R which is further enhanced by dBSA, presumably by binding NEFA and preventing mitochondrial NEFA metabolism. A mechanism for the attenuation of mitochondrial damage by dBSA could be the prevention of oxygen radical production induced by mitochondrial NEFA metabolism.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1057**

***In Vivo* Architecture and Regulation of Heme Oxygenase-1 Gene Expression in "Humanized" Transgenic Mouse** Junghyun Kim, Abolfazl Zarjou, Amie Traylor, Reny Joseph, Carl A. Frizell, Anupam Agarwal. *Medicine, Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL.*

Heme oxygenase-1 (HO-1) catalyzes the degradation of free heme and produces carbon monoxide, iron, and biliverdin. In addition to heme degradation, HO-1 is known to protect against various cellular insults and disease states including acute kidney injury, atherosclerosis, vascular restenosis and transplant rejection. HO-1 gene expression is regulated at the level of transcription initiated by changes in chromatin conformation. However, there is no currently available *in vivo* model to study mechanisms of the human HO-1 gene transcription. To enable such an in vivo analysis, we generated transgenic mice to study transcription of the human HO-1 gene by integrating a 87-kb bacterial artificial chromosome (BAC), a portion of human chromosome 22 containing the human HO-1 gene and its regulatory elements with the mouse genome. We obtained two founders and confirmed the BAC DNA integration by PCR-based genotyping. Immunohistochemistry on tissues from brain, heart, lungs, liver, spleen, and kidneys revealed that the HO-1 is overexpressed in all organs tested. HO-1 mRNA and protein were also overexpressed from multiple organs from the BAC transgenic mice. Using these BAC transgenic mice, we generated a "humanized" BAC transgenic mouse (hHO-1 BAC) by crossing HO-1 BAC transgenic mice with HO-1 knockout ($HO\text{-}1^{-/-}$) mice. In addition to the overexpression of human-specific HO-1 mRNA and protein expression, the human HO-1 gene in hHO-1 BAC mice rescued the typical phenotype observed in the $HO\text{-}1^{-/-}$ mice such as increased incidence of abortion and embryonic lethality, heightened sensitivity to acute kidney injury, iron overload, anemia, and splenomegaly. These humanized HO-1 BAC transgenic mice will serve as a valuable model system to study the regulation of the human HO-1 gene and will provide information on the *in vivo* architecture of the HO-1 gene in acute kidney injury.

**Exercise Exacerbates Ischemia-Reperfusion (IR) Induced Acute Kidney Injury (AKI) in the Sprague Dawley (SD) but Not Fisher 344 (F344) Rat** Natasha C. Moningka,[1] Mark W. Cunningham,[1] Myrline Sterling,[1] Christine Baylis.[1,2] *[1]Physiol., University of Florida, Gainesville, FL; [2]Med., University of Florida, Gainesville, FL.*

If renal blood flow falls (RBF) during exercise, this may reduce the shear stress induction of endothelial nitric oxide synthase (eNOS) and extracellular superoxide dismutase (EC-SOD), and increase susceptibility to oxidative stress mediated AKI. Here, we investigated the impact of 12 weeks low intensity exercise (EX) by voluntary wheel running, compared to rats that remained sedentary (SED) in two rat strains, the SD and F344, subjected to renal IR. The right kidney was removed as a control and the left kidney received 35 min. of ischemia and 24 hr. reperfusion, followed by renal function measurements. In the control kidney cortex of the SD rat, EX reduced eNOS and EC SOD, did not change renal NOx (metabolites of NO) levels, decreased the NADPH oxidase subunit p22phox, and had no effect on H2O2. In the control kidney cortex of the F344 rat, EX increased eNOS, EC-SOD, NOx, p22phox and H2O2 . In response to IR, SD EX rats experienced a greater fall in inulin clearance (CIN) and further increase in plasma creatinine (PCr) compared to SED SD IR. In contrast, EX F344 displayed less functional impairment with IR than the SED F344 IR, exactly opposite to the SD (Table). Conclusion: Susceptibility to IR was predicted by the directional change in eNOS and EC-SOD in response to EX, with the SD showing increased vulnerability and the F344 showing relative protection. Mechanisms for these marked differences in renal responses to EX remain to be determined. We speculate that the SD reduce RBF with EX (consistent with decreased p22phox), whereas the F344 may increase cardiac output more efficiently with preservation, or even some increase in RBF, consistent with increased renal p22phox and H2O2.

Table. *p<0.05 vs. SED IR.

| | SD | | F344 | |
|---|---|---|---|---|
| | $P_{Cr}$ (mg/dl) | $C_{IN}$ (ml/min/100g BW) | $P_{Cr}$ (mg/dl) | $C_{IN}$ (ml/min/100g BW) |
| SED IR | 1.2±0.2 | 0.17±0.04 | 1.9±0.2 | 0.06±0.02 |
| EX IR | 2.4±0.4* | 0.04±0.01* | 1.5±0.3 | 0.15±0.06 |

**Acute Renal Failure Induced by Hantavirus Infection Differs from Acute Tubulointerstitial Nephritis by Affecting Podocytes** Ellen Krautkrämer,[1] Stephan Grouls,[1] Jochen Reiser,[2] Martin G. Zeier.[1] *[1]Nephrology, University of Heidelberg, Heidelberg, Germany; [2]Nephrology and Hypertension, University of Miami.*

Purpose:

The typical histopathological findings in hantavirus-induced acute renal failure correspond to acute tubulointerstitial nephritis. However, these lesions do not explain the massive glomerular-type proteinuria observed in the infection. Therefore, we compared structure of glomeruli of patients with acute renal failure induced by hantavirus infection and of patients with tubulointerstitial nephritis.

Methods:

Cryo-sections of renal biopsies of patients with serologically confirmed hantavirus infection and of patients with non-hantaviral acute tubulointerstitial nephritis were analyzed by immunofluorescence. Sections were stained for proteins of tight and adherens junction, for marker proteins of podocytes and their glomerular slit diaphragms (GSD). The localization of proteins was analyzed by microscopy and expression levels were quantified by analyzing mean fluorescence intensity. To examine mechanisms of hantavirus-induced alterations, we infected human epithelial tubular cells and podocytes in vitro.

Results:

Our analysis of renal biopsies of patients suffering from hantavirus infection demonstrate that expression levels of specific proteins of tight and adherens junctions in tubular epithelia and the GSD in podocytes are mislocalized and dysregulated in hantavirus-infected patients. In contrast, biopsies of patients with tubulointerstitial nephritis showed no alteration of GSD structures or expression levels of marker proteins. Infection of tubular epithelial cells and podocytes in vitro results in relocalization and decrease of junctional proteins and the breakdown of the integrity of the epithelial barrier.

Conclusion:

The disassembling of GSD in podocytes that is specific for the hantavirus infection may explain the clinical picture of hantavirus-induced acute renal failure that is characterized by massive proteinuria compared to the tubulointerstitial nephritis. These findings provide useful insights in the pathogenesis of hantavirus-induced renal failure accompanied with massive proteinuria.

**Global Gene Expression Analyses in Renal Ischemia-Reperfusion Injury (IRI) from Mice Lucking Hif-1a Gene** Toshiaki Tamaki,[1] Shuji Kondo,[2] Shoji Kagami,[2] Shuhei Tomita.[1] *[1]Pharmacology, The University of Tokushima Graduate School, Tokushima-city, Tokushima, Japan; [2]The University of Tokushima Graduate School, Tokushima-city, Tokushima, Japan.*

We have shown that amelioration of acute tubular necrosis (ATN) in ischemic acute renal failure was impaired in mice lucking hypoxia inducible factor-1α gene in the previous ASN meeting. However, there are many unanswered questions as to how HIF-1α causes protective response to the ischemic acute renal injury. To investigate molecular mechanisms how HIF-1α-downstream molecules contribute to the protective events against ischemic renal injury, we subjected Hif-1$\alpha^{+/-}$ mice to renal IRI and performed global gene expression analyses.

Transcripts were obtained from corticomedullary junction in the left kidney of Hif-1$\alpha^{+/+}$ of Hif-1$\alpha^{+/-}$ mice, at 6 hrs, 12 hrs and 24 hrs after initiation of the reperfusion, and were used for gene expression analyses. Global gene expression profile in time-coursed transcripts from the kidneys after I/R injury showed that increase of the expression levels of HIF-1α gene after I/R injury in the Hif-1$\alpha^{+/-}$ mice was relatively lower than that of the control mice. Majority of extracted genes from time-point 6 hrs after I/R injury included functions related to cellular stress response, such as, redox response, immune response, energy metabolism. In the latter phases, 12-24 hrs after I/R injury, the functions included in majority of extracted genes were changed to a restore and regeneration of tissues and cells, such as growth signaling, cell cycle, cytoskeleton associated genes. Consistent with the results described above, immunohistochemical study showed that the number of proliferating cells stained for Ki-67 and tubular epithelial cells stained for Pax-2, a marker of renal cell differentiation, were both significantly decreased in the mutant kidney, compared to that in the controls. Additionally, 63 genes in which expression levels in the mutant mice were different from the controls at the time point 6 hrs after initiation of reperfusion, were extracted, and we identified 7 genes including chemokine, matrix metallopeptidase, cation transport regulator, by qPCR experiments.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1061**

**Connexin43 Hemichannels Exaggerate Cadmium-Induced Oxidative Stress and Cell Injury in Renal Tubular Epithelial Cells** Jian Yao,[1] Wei Sun,[2] Tao Huang,[1] Shotaro Nakajima,[1] Masanori Kitamura.[1] *[1]Department of Molecular Signaling, University of Yamanashi, Chuo, Yamanashi, Japan; [2]Department of Nephrology, Affiliated Hospital of Nanjing University of Traditional Chinese Medicine, Nanjing, Jiangsu, China.*

Gap junctions, formed by special protein called connexin (Cx), play important roles in the determination of cell survival in various pathological situations, especially those involving oxidative stress. Here we investigated whether and how gap junctions were involved in the cadmium ($Cd^{2+}$)-elicited renal tubular cell injury. 1) Transfection of renal tubular epithelial cell line LLC-PK1 with a wild-type connexin43 (Cx43) significantly sensitized them to $Cd^{2+}$-elicited cell injury, which was associated with increased JNK activation. Inhibition of JNK could largely prevent $Cd^{2+}$-elicited tubular cell injury. 2) The LLC-PK1 cell susceptibility to $Cd^{2+}$ was increased by depletion of glutathione (GSH) with DL-Buthionine-[S,R]-Sulfoximine (BSO), and decreased by N-acetyl-cysteine (NAC) or glutathione reduced ethyl ester, indicating an determinant role of oxidative status in JNK activation and cell survival. 3) To analysis the mechanisms, fibroblasts derived from Cx43 wild-type (Cx43+/+), heterozygous (Cx43+/-) and knockout (Cx43-/-) fetal littermates were used. These cells also displayed different susceptibility to $Cd^{2+}$. The severity of cell injury in these cells was closely related to the intracellular levels of reactive oxygen species (ROS) and c-Jun N-terminal kinase (JNK) activation. 4) $Cd^{2+}$ caused a reduction in intracellular GSH, but an elevation in extracellular GSH. This effect of $Cd^{2+}$ was significantly more dramatic in Cx43-positive cells than Cx43-negative cells. 5) Treatment of Cx43-positive cells with $Cd^{2+}$ caused a Cx43-hemichannel-dependent intracellular influx of Lucifer Yellow (LY) and extracellular efflux of ATP. Collectively, our study demonstrates that connexin43 sensitizes renal tubular cells to $Cd^{2+}$-initiated cytotoxicity through hemichannel-mediated regulation of intracellular redox status. Manipulation of connexin-forming channels could be a novel approach for prevention and treatment of $Cd^{2+}$-induced renal tubular cell injury.

**H2O2 but Not ATP Depletion Activates Gα12/Src To Stimulate Disruption of TJs** Wanfeng Yu, Sarah Beaudry, Bradley M. Denker. *Renal Division, Brigham and Women's Hospital, Boston, MA.*

Acute kidney injury(AKI) is a frequent complication of hospitalization and is associated with substantial morbidity, mortality and health care expenditure. Ischemia/reperfusion(I/R) is among the most common causes of AKI. With I/R injury, generation of ROS is an important mechanism leading to cellular damages including loss of tight junction(TJs).

Our previous studies indicate that Gα12 activation delays TJ recovery,stimulates apoptosis and may play a pivotal role in epithelial injury. To examine Gα12 in injury,we examined TJ loss/recovery in two models of stress:ATP depletion/repletion and H2O2/calatase. MDCK cells with inducible Gα12 over-expression or shGα12 were compared with controls and barrier function monitored by transepithelial resistance (TER),biochemical and immunofluorescent analysis. ATP depletion(10μM antimycin A+2mM 2-deoxy-D-glucose) for one hour,was followed by repletion with normal media. H2O2(5mM) for one hour was followed by 5000U/ml catalase. ATP depletion caused a rapid drop of TER in both celllines plus controls. Recovery of TER from ATP repletion was delayed in Gα12 over-expressing cells and accelerated in shGα12 cells,which is consistent with Gα12 functioning to delay TJ assembly. H2O2 promoted rapid loss of the barrier in Gα12 over-expressing and control cells but shGα12 cells were completely protected from TJ disruption. GST-TPR pulldowns revealed activated Gα12 within 30 min of H2O2 exposure but not with 30 min of ATP depletion. H2O2 significantly increased Src and RhoA activities in control cells and led to disruption of ZO-1 and phalloidin staining. Inhibiting Rho kinase had little effect on loss of barrier while Src inhibition was fully protective. H2O2 treated shGα12-MDCK cells were protected from loss of TER and changes in ZO-1/phalloidin staining. Taken together,these findings indicate that H2O2 and ATP depletion in MDCK cells activate different injury pathways. H2O2 induces Gα12/Src but not Rho for TJ disruption. However, the recovery of TJs is also affected by Gα12, but was independent of the specific stress. Defining these mechanisms in vivo may provide a novel target to uncouple numerous adverse responses to injury.

**NGAL Scavenges Iron by Forming a Complex with Catechol, an Endogenous "Siderophore"** Jonathan M. Barasch, Andong Qiu, Neal A. Paragas, Kristen Mcnierney. *Columbia.*

Ngal is a carrier protein that is expressed at low levels, until the kidney is stimulated by ischemia, hypoxia, nephrotoxins, sepsis. R. Strong demonstrated that Ngal binds bacterial siderophores which are essential for iron capture and microbial growth but yet Ngal is generally expressed in aseptic diseases. To determine whether Ngal can bind additional ligands we turned to the urine as a source of biomolecules because upon acute kidney injury Ngal is abundantly expressed in this compartment. We collected 400 liters of urine from our medical students, and using an Ngal:ligand:iron type binding assay we identified the catechol family of amino acid and polyphenol metabolites as Ngal dependent iron chelators. The catechols demonstrated the greatest iron binding activity of many aromatic compounds. These included Catechol, 4-methylcatechol, 3-methylcatechol, benzene triol which are present in micromolar levels in the urine. Remarkably, each of these bound Ngal with poor affinity (200nM), but when iron was added the affinity for ligand rose 100-500 fold (2nM, 0.4nM) and the solution of catechol:Fe changed from blue to bright red in color as tris-catechol:Fe formed within the binding cleft of Ngal. X-ray crystallography showed the catechol:Fe moiety sandwiched between amino acids which bound the catechol moiety of the bacterial siderophores, defining a critical site of molecular recognition. The Ngal:tris-catechol:Fe complex could form in vivo, in serum, and then traffic iron to the kidney which was absorbed in the megalin pathway of the proximal tubule. Iron delivery could be seen by autoradiography. The complex was pH sensitive and released its iron below pH 6.5-6.0, resulting in iron delivery. These data define the Ngal pathway of iron traffic based on a novel extracellular co-factor. The authors are grateful for the collaboration of Matt Clifton and Roland Strong, and Trisha Hoette and Kenneth Raymond.

Disclosure of Financial Relationships: Research Funding: A study of Ngal in the Emergency Room supported by Abbott Labs.; Patent: Columbia has licensed Ngal to Abbott and Biosite.

**Tropomyosin-1 Acts Through RhoA Pathway To Regulate Cofilin Activity** Morgan S. A. Gilman,[1] Sarah N. Young,[1] Mark A. Hallett,[2] Sarah E. Wean,[2] Simon J. Atkinson,[2] Bruce A. Molitoris,[2] Sharon L. Ashworth.[1] *[1]Molecular and Biomedical Sciences, University of Maine, Orono, ME; [2]Division of Nephrology, Indiana University School of Medicine, Indianapolis, IN.*

The actin cytoskeleton in kidney proximal tubule cells is essential for maintenance of proper cellular structure. The actin cytoskeleton is dynamic, relying on the ability of actin to exist both as a filament (F-actin) and as a monomer (G-actin) to fulfill its many unique roles in the cell. Destruction of F-actin has been shown to occur in response to models of renal ischemia, including clamping of the renal pedicle in the rat and ATP depletion of cultured cells. ADF/cofilin, an actin binding and severing family of proteins, is activated in response to ischemia. Binding of ADF/cofilin to F-actin results in F-actin severing and an increase in free actin monomers. However, tropomyosin-1 (TM1) binding protects F-actin from the activity of ADF/cofilin. The competitive roles of these two proteins assist in maintaining proper balance between F-actin and G-actin in accordance with the existing needs of the cell. Cofilin activity is suppressed by phosphorylation at serine 3, a process

occurring downstream of the GTPase RhoA. A decrease in RhoA activity leads to a decrease in cofilin phosphorylation and an increase in active cofilin. We sought to further understand the role TM1 plays in the regulation of actin dynamics. LLC-$PK_{A4.8}$ cells were transfected with pEYFP-C1 plasmid containing TM1 cDNA. EYFP-TM1 localized to actin stress fibers, cell edges and cellular extensions, which were present 3.6 times more often in these cells. EYFP-TM1 expression also led to a 51.9% decrease in cofilin phosphorylation, a 10.9% decrease in RhoA activity and a 29.5% increase in expression of death associated protein kinase 2 (DAPK2). In EYFP-TM1 expressing cells, cofilin was dephosphorylated at an earlier time point than in non-expressing cells in ATP depletion studies. In a cellular pull down assay, histidine tagged TM1 bound to DAPK1, a protein known to phosphorylate TM1, and the DAPK1 related protein, DAPK2. These findings suggest TM1 plays a role in the regulation of cofilin phosphorylation, a process mediated by RhoA.

**Renal Tubular Fluid Shear Stress Stimulates Inflammation: Role of TNF-α**
Mathieu Miravete,[1] Julie Klein,[1] Julien Gonzalez,[1] Christianne Pecher,[1] Jean-Loup Bascands,[1] Joost Schanstra,[1] Muriel Mercier-Bonin,[2] Benedicte Buffin-Meyer.[1] *[1]U858, Inserm, Toulouse, France; [2]UM 14/LISBP, INSA, Toulouse, France.*

Renal tubulointerstitial fibrosis (TIF) is strongly correlated with the progression towards end stage renal disease. TIF is in most cases initiated by aggression of renal tubular cells. Injured cells subsequently produce cytokines leading to inflammation followed by interstitial extracellular matrix accumulation. In most chronic renal diseases, urinary fluid flow and composition are changed leading to modified tubular shear stress. This could be an early tubular aggression and contribute to the development of TIF. Therefore the aim of our study was to evaluate the contribution of fluid shear stress (FSS) on inflammation, a key and early event in TIF.

For this purpose, we exposed human renal tubular cells (HK-2) to laminar FSS of 0.01 Pa for 30 min. Then we studied the ability of resulting conditioned medium (FSS-CM) to stimulate monocytes (THP-1) and endothelial cells (HMEC-1). HK-2 cells maintained in static conditions served as controls.

48 h treatment of THP-1 cells with FSS-CM inhibited mRNA expression of monocyte marker C-C Chemokine receptor 2 and stimulated that of macrophage marker CD68. It also increased mRNA levels of inflammatory cytokines tumor necrosis factor-α (TNF-α) and interleukin-1β, but did not modify mRNA expression of the anti-inflammatory cytokines transforming growth factor-β and interleukin-10.

Incubation of HMEC-1 cells with FSS-CM for 6h increased the expression of vascular cell adhesion molecule-1 (VCAM-1) and stimulated the endothelial adhesion of phorbol ester activated-monocytes. These effects were mediated by TNF-α since incubation of FSS-CM with a TNF- α neutralizing antibody or soluble TNF-α receptor abolished both VCAM-1 induction and monocyte adhesion.

These results suggest that renal tubular cells stimulated by FSS release inflammatory mediators including TNF- α which improve the adhesion of monocytes on endothelial cells and activate their differentiation into inflammatory macrophages. Consequently, we suggest that modification of FSS during nephropathies plays an important role in the development of TIF by promoting inflammation.

**F-PO1066**

**A Microfluidic Model of Albumin Handling by Proximal Tubule Cells**
Nicholas J. Ferrell,[1] Kevin Ricci,[1] Joseph J. Groszek,[1] William Fissell.[1,2] *[1]Biomedical Engineering, Cleveland Clinic; [2]Nephrology and Hypertension, Cleveland Clinic.*

We have developed two *in vitro* microfluidic models to evaluate albumin handling by proximal tubule cells. For the first system, cells were grown on solid glass substrates with apical microchannels. In the second system, a porous membrane was added to provide both an apical and basolateral compartment. Opossum kidney (OK) epithelial cells were grown in the microchannels and exposed to physiologically relevant fluid flow. Cells were grown to confluence, then exposed to 50 μg/ml of fluorescein isothiocyanate (FITC) labeled albumin. Uptake of FITC-albumin was determined by measuring the fluorescence of cell lysates. Confocal fluorescence microscopy was used to compare uptake profiles in cells grown under flow and static conditions. Albumin processed by the cells was examined by size exclusion chromatography (SEC) and SDS-PAGE. Results showed that uptake per unit of cell growth area was significantly higher under flow compared to static conditions. This was confirmed by confocal microscopy. Size exclusion chromatography and SDS-PAGE showed that FITC-albumin was broken down into small molecular weight fragments and excreted by the cells. No trace of intact albumin was detectable by either SEC or SDS-PAGE. These results show that fluid flow has a significant impact on cellular uptake of albumin by OK cells. Analysis of processed albumin further confirms that it is broken down into small molecular weight fragment, likely via lysosomal degradation, and these fragments are excreted from the cells. This microfluidic *in vitro* model provides a novel system to further investigate tubular protein handling.

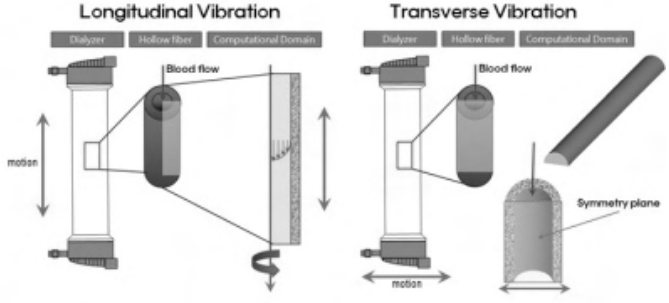
**Effects of Mechanical Vibration on Solute Removal in Hollow-Fiber Hemodialyzer: Numerical Analysis**
Jeong Chul Kim,[1,2,3] Francesco Garzotto,[1,2] Dinna N. Cruz,[1,2] Alessandra Brendolan,[1,2] Federico Nalesso,[1,2] Claudio Ronco.[1,2] *[1]Nephrology Dialysis & Transplantation, S. Bortolo Hosp, Vicenza, Italy; [2]International Renal Research Institute Vicenza (IRRIV), Vicenza, Italy; [3]Institute of Medical & Biological Engineering, Medical Research Center, Seoul National Univ., Seoul, Korea.*

Blood-membrane interaction during dialysis forms secondary protein layer on the surface of membrane. Operating condition control to inhibit concentration polarization and membrane fouling is very important to achieve targeted dialysis dose. Mechanical vibration can be one of useful methods to maintain the membrane mass transfer performance during dialysis. In this study we analyzed the effects of mechanical vibration on hemodyanmics in hollow fiber and their effects on mass transfer to optimize the operating condition dialysis.



Using finite volume based commercial code we simulated the vibrating hollow-fiber system. Wall shear stress (WSS) distributions were analyzed to different frequencies, directions and accelerations. The mechanical vibrations enhanced the relative motion of boundary layer, which increased WSS at the surface of membrane as shown in Table.

Time-averaged wall shear stress (TAWSS) for vibration amplitude of 10 mm

| Motion | Direction | TAWSS @ 1Hz | TAWSS @ 2Hz | TAWSS @ 4Hz |
|---|---|---|---|---|
| Sinusoidal | Longitudinal | 1.97 | 2.16 | 4.4 |
| Sinusoidal | Transverse | 4.38 | 4.52 | 4.83 |
| Square wave | Longitudinal | 1.9 | 1.95 | 3.59 |
| Square wave | Transverse | 4.2 | 4.2 | 4.5 |

Sinusoidal vibration was more effective than square wave vibration and transverse motion enhanced WSS compared to longitudinal one. However, acceleration induced by vibration may provide more absorption capacity to low molecular proteins.

The optimal mechanical vibration of hollow-fiber dialyzer during dialysis can be used to improve the dialysis efficiency.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1068**

**A Longitudinal Study of Hemodynamic and Luminal Changes in a Porcine Synthetic Arteriovenous Graft Model**
Yan-Ting E. Shiu,[1,2] Randy Jay Christopherson,[1] Christi M. Terry,[2] Huan Li,[2] Ilya S. Zhuplatov,[2] Alfred K. Cheung.[2,3] *[1]Bioengineering, Univ. of Utah, SLC, UT; [2]Medicine, Univ. of Utah, SLC, UT; [3]Medical Service, VASLCHCS, SLC, UT.*

A common complication of hemodialysis arteriovenous (AV) grafts is neointimal hyperplasia (NH) occurring at the venous anastomosis, leading to stenosis. Abnormal blood flow patterns and their associated wall shear stress (WSS) in the graft likely modulate vessel wall remodeling and the development of NH, but these relationships have not been well characterized. The purpose of this study is to use contrast-free magnetic resonance imaging (MRI) and computational fluid dynamics (CFD) to elucidate how the changing hemodynamic characteristics lead to anatomical changes in the lumen of the graft and adjacent vessels over a 6-week time course in a porcine model of synthetic AV graft stenosis. The graft was placed bilaterally between the common carotid artery and the external jugular vein. Time-of-flight MR images collected weekly after graft placement were used to create 3D reconstructions of the luminal geometry of the graft and adjacent vessels. Cine phase-contrast MR data collected at the same time points were used to obtain flow rates and direction in the graft and adjoining proximal and distal segments of artery and vein. The in vivo flow data and luminal geometries were used as input for detailed hemodynamics analysis using CFD. We found that 5 days after graft placement, the WSS increases in the arterial and venous anastomoses were 1.5- and 8-fold, respectively, when compared to the WSS in the control artery and vein. There was no remodeling of the arterial anastomosis over 6 weeks, though there was a slight and gradual narrowing of the distal artery. In contrast, the vein underwent substantial changes over the 6 weeks with the most notable feature being a substantial narrowing of the lumen over time. This suggests a thickening of the venous wall as an adaptive response to the significantly increased WSS seen in the vein. Work is ongoing to further examine the relationship between abnormal WSS and the location and degree of NH at the venous anastomosis determined from MRI.

**Intracellular Volume Shift: Standard vs UF-Control Treatment** Francesco Garzotto,[1,2] Flavio Basso,[1,2] Jeong Chul Kim,[1,2] Dinna N. Cruz,[1,2] Massimo De Cal,[1,2] Nicola Marchionna,[1,2] Alessandra Brendolan,[1] Federico Nalesso,[1,2] Claudio Ronco.[1,2] *[1]Nephrology Dept., S Bortolo Hosp, Vicenza, Italy; [2]IRRIV, Vicenza, Italy.*

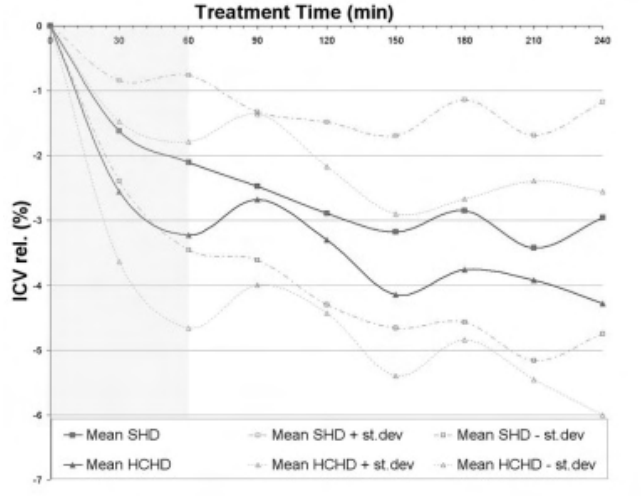
Body Fluid shifts are natural phenomena during hemodialysis (HD). Ultrafiltration (UF) results in intravascular hypovolemia and, correspondingly, in an increase in plasma colloid osmotic pressure, initiating a volume shift from interstitial to vascular space. The relative contribution of Extra (ECV) and Intra (ICV) volume to the UF volume is poorly defined. Our aim was to evaluate the ICV movement during a standard HD treatment (SHD) vs UF controlled (Hemocontrol, Gambro) dialysis (HCHD).

Methods

Whole body bioimpedance spectroscopy (50 frequencies, 5-1,000 kHz)(Fresenius Medical Care) was performed during HD every 30 min in 20 stable ESRD patients, 10 on HCHD. Weight Loss (WL), Dialysate (DNa) and Plasma (PNa) were recorded.Relative ICV (ICVrel) was calculated as % of ICV loss during HD.

Results

During HD PNa may change as a function of the sodium gradient between dialysate and plasma (ΔD-PNa).When effective ECV osmolarity exceeds that of ICV, fluid exits from the ICV to the ECV compartment.In the first section (FS) of HCHD, the dialysate fluid has the maximum permitted value of Na (range within -5, +10 mmol/L of prescribed in the Hemocontrol settings) reaching the higher ΔD-PNa.In the FS, ICVrel decreases more rapidly in the HCHD treatments (where ΔD-PNa is higher), than in SHD and its final value is lower in HCHD than in SHD.



Conclusion

Bioimpedence during HD treatment may improve fluid management giving information regarding the volume shift between body compartments. ICVrel seems strongly correlate with (ΔD-PNa).A biofeedback system in the sodium profile of the HD treatments may be potentially implemented.

| | SHD | HCHD |
|---|---|---|
| WL | 3.1± 1.0 | 3.3± 1.1 |
| ΔD-PNa | 5.4±3.2 | 10.2±2.9 |
| ICV | 20.3±3.19 | 21.2±3.9 |
| UFV | 3.1±1.0 | 3.0±0.7 |

**F-PO1070**

**Intravital Measurement of Glomerular Capillary Displacement in Rodents** Joel M. Henderson,[1] George Rhodes,[2] Lyne Lucien,[1] Philip A. Bondzie,[1] Bruce A. Molitoris.[2] *[1]Pathology, Boston University, Boston, MA; [2]Medicine, Indiana University, Indianapolis, IN.*

PURPOSE: Glomerular capillary hypertension and structural abnormalities of the glomerular capillary wall are associated with glomerular injury, and highlight the role of biomechanics in glomerular disease. To fully understand this relationship, methods are needed for measuring mechanical phenomena in the intact, living glomerulus. The aim of this project is to develop methods for intravital dynamic measurement of glomerular capillary displacement, in response to changes in capillary blood pressure.

METHODS: Renal capsular surface of 2 Munich-Wistar rats and surgically exposed deep renal cortex of 1 BL6 mouse were examined with a Biorad MRC1024 two-photon inverted microscope under general anesthesia. Fluorescent high molecular weight dextrans and Hoechst 33342 were injected to label vascular space and nuclei. Stable, clearly visible cross sections of glomerular capillaries were identified and imaged with a single scan line at 512 lines/s to create a 2D image of capillary width over time. Time-varying capillary width (displacement) was extracted by image segmentation to compute % change in width (strain). Ultrastructural examination was performed on murine kidney post-procedure to evaluate tissue integrity.

RESULTS: Between 4 and 11 glomerular capillaries were measured in each rodent. Capillary width cyclically varied 6.1% and 5.7% in rats, and 8.1% in the mouse, with regularly cyclic (heart rate) width variation most apparent in murine capillaries. Corresponding cyclic variation in intracapillary pressure was inferred by RBC shadow indications of changing flow rate. Ultrastructural examination of the cut surface of murine kidney post-procedure revealed intact glomerular capillary wall structures in exposed glomeruli.

CONCLUSION: The methods applied here successfully resolved cyclic changes in glomerular capillary width. Measurements obtained in this way suggest that rodent glomerular capillaries are relatively rigid compared to other vascular structures. This approach may be applied to studies of glomerular capillary structure and mechanics, and their role in glomerular disease.

**F-PO1071**

**Different Glomerular Permeability between Munich Wistar Rat Strains** Ruben M. Sandoval, Monika D. Gandhi, Mark C. Wagner, George Rhodes, Exing Wang, Silvia B. Campos-Bilderback, Sarah E. Wean, Bruce A. Molitoris. *Nephrology, Indiana University, Indianapolis, IN.*

Recent studies using intravital imaging of rat kidneys has provided new insight and raised new questions into the mechanisms that lead to proteinuria. In particular, these studies provide data supporting an increased glomerular permeability and indicating that the proximal tubule, via its absorptive capacity, has an increased regulatory role in determining levels of proteinuria.

To investigate this further and attempt to reconcile some of the clear differences between earlier studies, we have compared permeability between the Simonsen Munich Wistar (used for intravital imaging studies) and the Fromter Munich Wistar (used for most micropuncture studies). Note that the Simonsen MW rats have fewer surface glomeruli, do not develop spontaneous proteinuria with age and are therefore rarely used to study disease progression. These studies all utilized rats of 180-270g, all imaging was done under identical conditions using maximized parameters on the same scope (Olympus FV1000 microscope adapted for two-photon microscopy using high sensitivity Gallium Arsenide non-descanned 12-bit detectors), and rat temperature, BP, & hydration were monitored and maintained.

We calculated the glomerular sieving coefficient using TxR-albumin and measuring the fluorescence ratio of Bowman's space/capillary lumen. Background fluorescence was subtracted from each compartment and no saturation was present. Our data show that Fromter MW rats have a lower GSC (0.011) than the Simonsen MW rats (0.036) of the same weight and age, $p<0.0001$. In addition, we addressed the important issue of dietary state by comparing fasting versus fed Simonsen rats. Interestingly, the fasted rats had a significantly reduced GSC (0.016) compared to either the fed ($p<0.0001$) or the Fromter rat ($p=0.0014$). These studies support that some of the variability between investigators is the result of strain differences, and that feeding increases the GSC in Simonsen MW rats.

**Different Gene Expression Profiles between Arterial and Venous Anastomoses in a Porcine Arteriovenous (AV) PTFE Graft Model** Li Li,[1] Randy Jay Christopherson,[2] Mary Carlson,[1] Donald Blumenthal,[3] Christi M. Terry,[1] Yan-Ting E. Shiu,[1,2] Alfred K. Cheung.[1,4] *[1]Internal Medicine, University of Utah; [2]Bioengineering, University of Utah; [3]Pharmocology, University of Utah; [4]Medical service, VASLC Healthcare System, SLC, UT.*

Neointimal hyperplasia (NH) is the predominant cause of AV PTFE graft failure and occurs mostly at the venous anastomosis (VA). The underlying molecular mechanisms of the different propensities for stenosis between the arterial anastomosis (AA) and VA are unclear. This study was conducted to compare the temporal gene expression between AA and VA through microarray analysis. Carotid-jugular PTFE grafts were placed in 4 pigs. Five days (n=2) or 14 days (n=2) post-operatively, the AV graft lumen geometry and blood flow data were obtained from black blood and cine-phase contrast MRI. The animals were then immediately euthanized. The anastomotic tissues and contralateral control carotid artery and jugular vein were explanted. The RNA from these tissues was subjected to cDNA microarray analysis. Statistical analysis revealed significant differences in expression of 70 genes between AA and VA. Specifically at 14 days, complement 3 and somatostatin were up-regulated (8-fold and 16-fold, respectively, above control vein) in VA, but not in AA. Computational fluid dynamics (CFD) simulations were used to assess the average wall shear stress (WSS) in these regions based on MRI results. The WSS in VA and AA at 5 days were the same order of magnitude, $60 \pm 28.3$ dyn/cm$^2$, which was higher than the WSS in control vein ($7.5 \pm 3.5$ dyn/cm$^2$) and control artery ($40 \pm 0$ dyn/cm$^2$). The WSS increase at the AA at 5 days was less profound (1.5-fold). Further investigations are required to determine (1) if the changes in WSS and gene expression in the VA are causally related to each other; and (2) if the differences in the magnitude of WSS changes explain the differential propensity to neointimal hyperplasia between VA and AA. Understanding the molecular mechanisms and their relationships to alterations in hemodynamic stresses will facilitate the identification of novel targets and strategies to inhibit stenosis in hemodialysis vascular accesses.

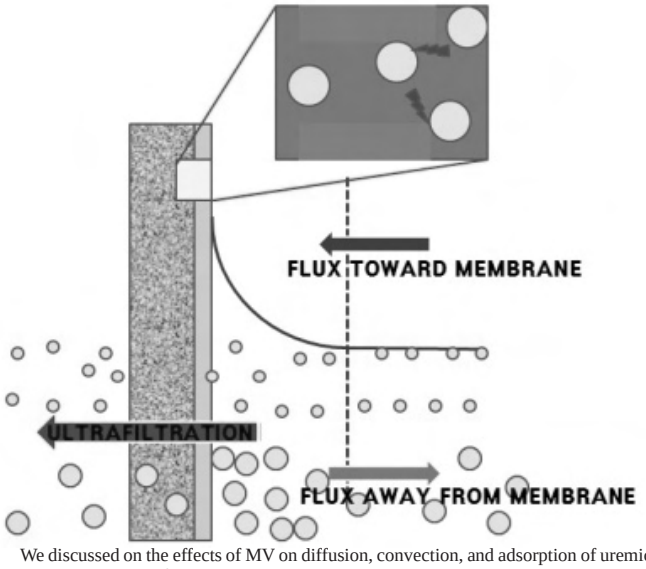
**Enhancement of Solute Removal in Hollow-Fiber Hemodialyzer by Mechanical Vibration** Jeong Chul Kim,[1,2,3] Francesco Garzotto,[1,2] Dinna N. Cruz,[1,2] Alessandra Brendolan,[1,2] Federico Nalesso,[1,2] Claudio Ronco.[1,2] *[1]Nephrology Dialysis & Transplantation, S. Bortolo Hosp., Vincenza, Italy; [2]International Renal Research Institute Vicenza (IRRIV), Vicenza, Italy; [3]Institute of Medical & Biological Engineering, Medical Research Center, Seoul National Univ., Seoul, Korea.*

Blood-membrane interaction during dialysis results in development of secondary layer on the surface of membrane. The vibratory shear enhanced process was recently introduced in membrane technology to minimize the secondary layer development at membrane surface. The mechanical vibration (MV) produces high wall shear stress (WSS) at the surface of membrane, which reduces the thickness of concentration boundary layer and inhibits gel layer development.



We discussed on the effects of MV on diffusion, convection, and adsorption of uremic solutes during dialysis for sinusoidal and triangle wave vibratory motions. Longitudinal vibration generates reverse flow inside membrane by moving wall motion, which increases WSS magnitude of hollow fiber. Transverse vibration generates swirling motion of fluid inside membrane, which enhances mixing and inhibits the secondary layer formation. Acceleration induced by triangle wave vibration could provide more absorption capacity to middle molecular solutes. MV could enhance solute removal by minimizing change in membrane morphology by secondary layer formation during hemodialysis.

Effects of mechanical motions on mass transfer in hollow-fiber hemodialyzer

| **Motions** | **Longitudinal** | | **Transverse** | |
|---|---|---|---|---|
| | Sinusoidal | Square wave | Sinusoidal | Square wave |
| Diffusion | ++ | + | ++ | + |
| Convection | ++ | + | ++ | + |
| Adsorption | + | + | + | ++ |

However, safety aspects such as hemolysis, user interface membrane mechanical property should be considered for clinical application of MV. Optimal MV conditions are to be investigated with simulation and experiments in the future.

**Novel Cell and Gene Therapy for Anemia of CKD** Matthew H. Wilson, Joseph Edward Doherty, Daniel L. Galvan, Sunandan Saha. *Medicine, Baylor College of Medicine, Houston, TX.*

EPO-deficient anemia of CKD is currently treated with recombinant EPO analog injections which are recently associated with undesired side effects such as increased risk of stroke, heart attacks, and deep vein thrombosis that complicate use of this therapy. Although the mechanisms of these side effects are unclear, it is clear that bolus dosing of EPO analogs either weekly or monthly does not recapitulate the physiologic regulation of this important hormone. Thus, there is a need to develop alternative therapies for anemia of CKD. We are developing an innovative approach for therapy of anemia of CKD using genetically modified T lymphocytes whose specificity is directed to persistent (latent) viruses such as Epstein-Barr virus (EBV) and survive long-term (>8 years) in stable numbers *in vivo* due to chronic viral antigen stimulation. Moreover, preclinical and recent clinical studies have shown T cells can be readily induced to apoptose by activation of a co-transferred suicide gene, providing an additional layer of safety and control. We *hypothesize* that virus specific T cells genetically modified to inducibly express EPO and a separately inducible suicide gene represent an ideal candidate cell population for sustained and safe treatment of anemia of CKD. We have successfully used the non-viral *piggyBac* transposon system to efficiently genetically modify mouse and human T cells achieving long-term gene expression. We have achieved inducible (tetracycline regulated) EPO expression in vitro in human cells and in vivo after somatic cell gene transfer with regulation of hematocrit levels in intact mice. We are modifying virus specific murine T cells to inducibly express EPO and a suicide gene that will be infused into wild type and CKD mice to measure their effectiveness in regulating hematocrit levels *in vivo*. We are also modifying human T cells and testing them *in vitro* for their ability to be propagated long-term via chronic viral antigen stimulation, as well as inducibly express EPO and undergo selectively induced cell ablation if needed. This innovative approach has the potential to provide safe cell therapy for anemia of CKD and can easily be adapted for a variety of other human diseases.

**Endothelial Progenitors Encapsulated in Bioartificial Niches Are Insulated from Systemic Cytotoxicity and Are Angiogenesis-Competent** Brian B. Ratliff,[1] Tammer Ghaly,[1] Philip Brudnicki,[1] Kaoru Yasuda,[1] Antonis K. Hatzopoulos,[2] Michael S. Goligorsky.[1] *[1]New York Medical College, Valhalla, NY; [2]Vanderbilt University, Nashville, TN.*

Intrinsic stem cells (SC) participate in tissue remodeling and regeneration in various diseases and following toxic insults. Failure of tissue regeneration is in part attributed to lack of SC protection from toxic stress of noxious stimuli, thus prompting intense research efforts to develop strategies for SC protection and functional preservation for in vivo delivery. One strategy is creation of artificial SC niches in attempt to mimic the requirements of endogenous SC niches by generating scaffolds with properties of extracellular matrix. We investigated the use of hyaluronic acid (HA) hydrogels as an artificial SC niche and examined regenerative capabilities of encapsulated embryonic endothelial progenitor cells (eEPC) in vitro and in three different in vivo models. Hydrogel encapsulated eEPC preserved their phenotype and survived better in HA-hydrogels coated with pronectin. Hydrogel encapsulated vis-à-vis surface-cultured eEPC demonstrated improved resistance to cytotoxic adriamycin insult in vitro. Implantation of HA-hydrogels containing eEPC to mice with adriamycin nephropathy or renal ischemia resulted in eEPC mobilization to injured kidneys (and to a lesser extent to the spleen) and improvement of renal function, which was equal or superior to adoptively transferred EPC by IV infusion. In mice with hind limb ischemia, EPC encapsulated in HA-hydrogels and timely released by local application of hyaluronidase dramatically accelerated the recovery of collateral circulation with the efficacy superior to IV infusion of EPC. In conclusion, HA-hydrogels protect eEPC against adriamycin cytotoxicity and implantation with timely release of eEPC encapsulated in HA-hydrogels supports renal regeneration in ischemic and cytotoxic (adriamycin) nephropathy and neovascularization of ischemic hind limb, thus establishing their functional competence and superior capabilities to deliver stem cells stored in and released from this bioartificial niche.

**F-PO1076**

**Novel Growth Factor Containing Hydrogel To Support Tubular Repair after Acute Kidney Injury** Peter V. Hauser,[1] Mikhail V. Tsurkan,[2] Raquel Carvalhosa,[1] Benedetta Bussolati,[1] Carsten Werner,[2] Giovanni Camussi.[1] *[1]Center for Molecular Biotechnology, University of Torino, Torino, TO, Italy; [2]Leibniz-Institut of Polymer Research, Dresden, Germany.*

**Aim:** Stem cell injection contributes to regeneration after acute kidney injury (AKI), most likely by endo- or paracrine action. To test if a novel hydrogel could serve as a local deposit for growth factors, we induced AKI in mice and measured the tubular proliferation in kidneys after injection with growth factor containing hydrogel.

**Methods:** A hydrogel was developed by carbodiimide chemistry crosslinking of end-functionalized polyethylene glycol (sPEG) and heparin (Mw≈14kDa) in a ratio of 1:1,5. The gel was grounded and extensively washed with PBS. Next, EGF or bFGF were disolved in the gel with a concentration of 2µg/ml. AKI was induced by injecting c57b WT mice intramuscular with glycerol (7.5 g/g bw). On day 3, 20 animals were injected with 100µl hydrogel containing EGF (n=10) or bFGF (n=10) subcapsular into the left kidney. Biopsies were taken on days 2 and 5 after hydrogel injection, and the proliferative response of treated kidney ($k_t$) was compared to the untreated contralateral kidney ($k_{ctrl}$) by counting Pcna and BrdU positive tubular cells. Serum creatinine and BUN was measured in treated animals and in controls.

**Results and Conclusion:** The PEG-gel has been shown to release bFGF at a 2% rate over 48 hours in *in vitro* studies and similar activity was expected *in vivo*. Visual examination revealed stability of the injected gel during the *in vivo* experiments. Preliminary results showed that at day 2 after injection, the bFGF-hydrogel injected kidneys (n=5) exhibited a significant higher number of BrdU positve cells ($k_t$:13.9±8.6; $k_{ctrl}$:7.5±7.9) and Pcna ($k_t$:28.8±16.3; $k_{ctrl}$:13.1±16.7) positive cells per high power field (hpf). Kidneys injected with EGF containing hydrogel (n=5)showed a non-significant increase of BrdU ($k_t$:22.9±6.8; $k_{ctrl}$:20.6±4.1) and Pcna ($k_t$:51.7±1; $k_{ctrl}$:44.2±3.6) positive cells/hpf. Serum creatinine and BUN of treated animals did not differ from control animals.

Preliminary results suggest that the hydrogel can serve as deposit and deliver growth factors locally in order to support regeneration.

**Developing the Optimal siRNA/Nanocarrier Complex for Glomerular-Targeted Molecular Therapy in Mice** Hideki Shimizu,[1] Yuichi Hori,[1] Shinya Kaname,[2] Kanjiro Miyata,[3] Nobuhiro Nishiyama,[3] Akira Yamada,[2] Kazunori Kataoka,[3] Toshiro Fujita.[1] *[1]Department of Nephrology and Endocrinology, University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]First Department of Internal Medicine, Kyorin University School of Medicine, Tokyo, Japan; [3]Department of Materials Engineering, University of Tokyo School of Engineering, Tokyo, Japan.*

We have recently developed a gene delivery system using new blockcopolymers composed of polyethylene glycol-poly(L-lysine) (PEG-PLL) in experimental glomerulonephritis (JASN 2010;21:622). However, it is not known what is the best design of the nanocarriers with regard to the gene silencing effect. To answer this question, we prepared a complex of MAPK1 siRNAs /PIC (polyion complex) nanocarriers at various N/P ratios, i.e. primary amino groups in PLL (N) / phosphate units in siRNA(P), and examined the delivery and gene-silencing effect in cultured mesangial cells and in MRL/lpr mice. *In vitro* study showed that the complexes formulated at an N/P ratio of 1.0 to 1.4 were most efficient in transfection and also in an inhibitory effect of MAPK1 expression. *In vivo* study showed that intraperitoneal administration of the PIC nanocarriers at an N/P ratio of 1.4 was most effective in inhibiting the glomerular expression of MAPK1 and also in ameliorating glomerulosclerosis and BUN. The complexes were proven to be neutral or slightly positively charged and had a size of several ten nanometers. In summary, we were able to determine the best design of PIC nanocarriers by modifying PEG-PLL-based blockcopolymers, which may contribute to the development of molecular therapy in glomerular diseases.

**Enhanced β2-Microglobulin Clearance by Silicon Nanopore Membranes** William Fissell,[1,2] Nicholas J. Ferrell,[1] Joseph J. Groszek,[1] Albert Terrence Conlisk,[3] Dharmeshkumar M. Kanani,[4] Andrew L. Zydney.[5] *[1]Biomedical Engineering, Cleveland Clinic, Cleveland, OH; [2]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [3]Mechanical Engineering, The Ohio State University, Columbus, OH; [4]Chemical Engineering, The Pennsylvania State University, University Park, PA.*

Background: Conventional polymer hollow-fiber dialysers tend to retain B2-microglobulin (B2mg) and other middle-molecular weight solutes, as performance is constrained by the absolute need to retain albumin and the limited selectivity of the membrane material. Selectivity is governed by pore shape and polydispersity of pore size. We tested predictions of enhanced selectivity of silicon nanopore membranes with monodiperse slit pores using bovine serum albumin and human B2-mg. Methods: Silicon nanopore membranes with nominal pore size of 7nm x 45 microns were manufactured, coated with polyethylene glycol, and placed in an ultrafiltration cell as previously described. Human serum albumin and B2-mg were dissolved in phosphate buffered saline. After wetting the membrane, the albumin-B2mg solution was filtered under pressure and feed and ultrafiltrate samples collected (n=5). The first 2 samples were discarded as they were diluted by wetting solution. Protein concentrations in feed and permeate solutions were measured by size-exclusion chromatography with online UV absorption at 280 nm. Results: albumin was not detectable in the permeate solution, and the apparent sieving coefficient for B2mg was 0.52 +/- 0.04. The data matched a steric-electrostatic prediction model for hindered transport of albumin and B2-mg in slit shaped pores. Discussion: A membrane of uniform slit shaped pores appears to maximize selectivity. A novel membrane for renal replacement assembled using top-down nanotechnology demonstrated very high clearance of a uremic solute while retaining albumin.

**Development of an Open-Source Platform To Support Analysis, Integration and Representation of Kidney and Urinary Pathways (KUP)-Related –Omics Data** Julie Klein,[1] Simon Jupp,[2] Jean-Loup Bascands,[1] Robert Stevens,[2] Joost Schanstra.[1] *[1]U858, Inserm, Toulouse, France; [2]School of Computer Science, University of Manchester, Manchester, United Kingdom.*

Kidney research continues to produce large data sets obtained from different biological levels. Mining this data for new knowledge is hindered by the size of these data sets and the absence of user-friendly data analysis tools. To facilitate data exploration and analysis, and to help generate new hypothesis in kidney research, a supporting database of biological knowledge related to the KUP, that allows integration of existing knowledge from databases and scientific literature, would be of great help.

We have developed a prototype KUP Knowledge Base (KUPKB) that integrates KUP related data across the different –omic levels. A specialised KUP Ontology (KUPO) provides a common schema for annotating the data and allows for richer queries over the data to obtain information on genes, proteins, and pathways in the context of the kidney. Currently the KUP KB consists of gene expression data in specific kidney compartments linked to several public biological databases including Entrez gene, Uniprot, GO Annotations and Kegg. Simple queries in the KUPKB are as follows: "In which cells is gene "x" expressed?" or "Which genes are upregulated in the glomerulus compared to other renal compartments?". Answering those queries is interesting for two reasons: the kidney is highly cellular with each cell having distinct functions, and most of the large scale data obtained in human disease comes from analysis of urine, that needs to be put into the 'kidney' context. Short terms aims of the KUP KB are to allow queries more specific such as: "In which renal diseases my differentially expressed genes have the same regulation profile?" or "Which urinary proteins are expressed in the proximal tubule cells and are linked to inflammation". In conclusion the KUPKB prototype is a flexible tool allowing data integration, query and representation and will help to generate new knowledge and hypothesis in kidney research.

**NHLBI *AbDesigner*: Artificial Intelligence-Based Software for Design of Peptide-Directed Antibodies** Trairak Pisitkun, Mark A. Knepper. *NHLBI, NIH.*

Over the years, our laboratory has developed a large number of polyclonal antibodies to transporters and regulatory proteins expressed in the kidney. The choice of the sites in target proteins to use for synthesis of immunizing peptides has been based on a desire to optimize immunogenicity, antibody specificity, multi-species conservation, and robustness in the face of post-translational modifications. To create a tool for semi-automatic choice of immunizing peptides that optimize the above factors, we are developing an artificial intelligence-based software program called NHLBI AbDesigner written in *Java*. It predicts optimal sites along the primary sequence of individual proteins by calculating and extracting information as follows: 1) immunogenicity score based on secondary structure prediction and hydropathy; 2) uniqueness score [predicting specificity of an antibody produced by a particular peptide]; 3) conservation score [predicting likelihood of multi-species recognition of an antibody produced by a particular peptide]; and 4) protein features that describe regions or sites of interest in the protein sequence such as post-translational modifications, binding sites, enzyme active sites, sequence conflicts, and other characteristics reported in the appropriate Swiss-Prot records. It displays the prediction in an easy-to-view graphic user interface including heat maps for the scored predictors. To test the software algorithm, we have used NHLBI AbDesigner to select immunizing peptides for producing peptide-directed antibodies against the water channel aquaporin-2 and two podocyte-specific proteins, nephrin and podocin. These 3 antibodies have performed remarkably well in terms of both sensitivity and specificity. In summary, NHLBI AbDesigner is a Java-based "expert system" that codifies the principles developed for optimal antibody design developed in prior studies and it is currently being made available in the form of stand-alone and web applications.

**The Engineering of Anemia Management Protocols in Chronic Kidney Disease** Michael J. Germain,[5] William C. Vogt,[2] Rajiv P. Shrestha,[1] Brendan Nichols,[1] Christopher V. Hollot,[4] Joseph Horowitz,[3] Yossi Chait.[1] *[1]Mechanical & Industrial Engineering, University of Massachusetts, Amherst, MA; [2]Biomedical Engineering & Sciences, Virginia Polytechnic Institute & State University, Blacksburg, VA; [3]Mathematics & Statistics, University of Massachusetts, Amherst, MA; [4]Electrical & Computer Engineering, University of Massachusetts, Amherst, MA; [5]Nephrology, Baystate Medical Center, Springfield, Ma.*

Background. Anemia management protocols (AMP) for EPO-dosing based on hemoglobin measurements inherently form a feedback system wherein the protocol acts as a feedback controller. As such, the design of an AMP should be informed by the dynamic structure of the erythropoiesis system, together with models of the system's uncertainties, including variations in EPO responsiveness and intercurrent events such as infection and internal bleeding.

Methods. This study combines PK/PD models, retrospective data of 49 HD patients collected over two years, and modern robust control system design to synthesize new protocols.

Results. The system comprises models of PK, early-stage erythropoiesis dynamics, and reticulocyte and RBC compartments. For each subject, we quantified parameter ranges and designed a robust feedback controller (protocol) as shown in Figure 1. This protocol, simulated in feedback with a subject-specific erythropoiesis model, was successfully tested against Hgb measurement noise and system uncertainties. Figure 2 shows a simulation comparing the ability of a standard protocol and the new protocol to maintain a target Hgb level of 11.5.

Conclusions. The design of an AMP for EPO dosing in ESRD should use robust control methods. Such protocols can maintain Hgb target levels and reduce Hgb variability in the face of intercurrent events and variations in EPO responsiveness.

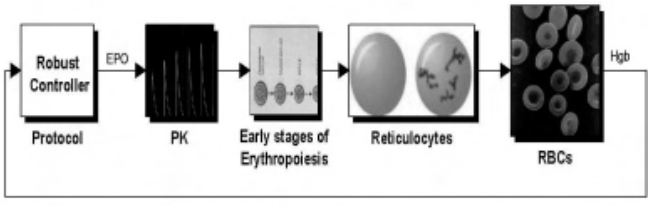

*Figure 1: The feedback control system comprised of the erythropoiesis system and robust controller (protocol).*

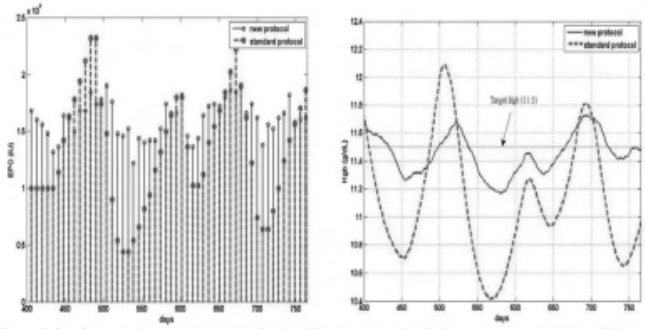

*Figure 2: Simulation results comparing a standard and the new protocol in the face of measurement noise; Values of weekly EPO doses (3x per week) are shown to the left and resulting subject's Hgb values are shown to the right.*

**Regulatory Networks at Work in IgA Nephropathy Elucidated through Contextual Modeling of CCL5 Transcription** Peter J. Nelson,[1] Matthias Kretzler,[4] Bernhard Banas,[2] Elisabeth Groene,[3] Clemens D. Cohen,[5] Dilip Kumar.[1] *[1]Medical Policlinic, Ludwig-Maximilians-University Munich, Munich, Germany; [2]Internal Medicine II, Nephrology, University of Regensburg, Regensburg, Germany; [3]Division of Cellular and Molecular Pathology, German Cancer Research Center, Heidelberg, Germany; [4]Internal Medicine, University of Michigan, Ann Arbor, MI; [5]Institute of Physiology, University of Zurich, Zurich, Switzerland.*

The prediction and analysis of the regulatory networks underlying gene expression is an important challenge in systems biology. Molecular characterization of the contextual transcription of the chemokine CCL5 was used to help elucidate regulatory networks linked to the development of IgA nephropathy, a glomerular disease characterized by activation of renal mesangial cells. CCL5 is associated with amplification and propagation of the disease. In mesangial cells CCL5 is optimally induced in response to TNF-alpha and IFN-gamma stimulation where JNK, IRF and NF-kappaB regulatory pathways independently converge on the promoter to control CCL5 transcription through p50/p65, IRF-1 and JunD/Fra1/CREB binding to their cognate sites. Convergent evolution can lead to a core organization of conserved transcription factor binding sites within gene promoters whose products need to be co-expressed within the same biologic context. A model based on the spatial orientation of functional binding elements for CCL5 was used to identify similar hierarchical features in a human promoter database. The results were interfaced with transcriptomic data from microdissected glomerular renal biopsies from patients with IgA nephropathy (n=27). Overlapping genes were identified, and of these, RIG I and IL-32 were demonstrated to be tightly co-regulated with CCL5 in mesangial cells in response to TNF-alpha/IFN-gamma. The approach demonstrates that experimental analysis of a promoter in a specific tissue context can be used to identify networks of co-regulated genes independent of a priori knowledge about their biological connection and provides information about common regulatory pathways.

**Reduction of Glomerular Injury by Raising Podocyte pH** Mehmet M. Altintas,[1] Kumiko Moriwaki,[1] Clemens C. Möller,[2] Jan Flesche,[2] Changli Wei,[1] Jing Li,[1] Suma Yaddanapudi,[2] Jochen Reiser.[1] *[1]Division of Nephrology and Hypertension, University of Miami Miller School of Medicine, Miami, FL; [2]Division of Nephrology and Program in Glomerular Disease, Massachusetts General Hospital, Boston, MA.*

Podocytes are highly differentiated cells and represent critical elements for the filtration barrier of the kidney. Loss of their foot process architecture results in urinary protein loss, a hallmark of kidney disease. Here we show a novel role for the neutral amino acid glutamine in structural and functional regulation of the kidney filtration barrier. Based on proteomic and genetic information, we created a metabolic map of podocytes and analyzed their metabolism using Metabolic Flux Analysis. We characterized amino acid fluxes in podocytes using genetic, toxic and immunologic models and identified commonly dysregulated glutamine utilization pathways in podocytes that were not uniformly present in fibroblasts or other eukaryotic cells. Glutamine uptake is increased in diseased podocytes to couple the increased demand for nutrient support during the disease state. This feature can be further exploited to pharmacologically increase glutamine uptake into podocytes. Glutamine uptake raised the podocyte cytosolic pH from 7.0 to >7.2. This pH increase was functionally significant as the determined pH optimum for cytosolic cathepsin L lies at 7.0 and showed a 60% reduction at pH 7.2. Glutamine supplementation did not change the normal functioning of healthy podocytes but led to a strong reduction of cytosolic cathepsin L protease activity in diseased podocytes resulting in protection of the known cathepsin L targets, dynamin and synaptopodin. We tested these findings in mice and supplemented high doses of glutamine before challenging the animals with LPS. The glutamine-loaded animals had alkalinized glomeruli shown by pH indicator labeling, reduced foot process effacement and lower levels of proteinuria. In summary, our data unravels specific amino acid pathways that provide a metabolic opportunity to combat urinary protein loss through modulation of podocyte pH.

**F-PO1084**

**PodoNet – A Podocyte Protein Interaction Network for the Analysis of Expression Data** Gregor Warsow,[1,2] Nicole Endlich,[1] Sandra Schordan,[1] Eric Schordan,[1] Georg Fuellen,[2] Karlhans Endlich.[1] *[1]Anatomy and Cell Biology, Ernst Moritz Arndt University, Greifswald, Germany; [2]Institute for Biostatistics and Informatics in Medicine and Ageing Research, University of Rostock, Rostock, Germany.*

In recent years, microarray and proteomic analyses have become frequently used methods to assess gene and protein expression in podocytes and glomeruli. However, tools for the analysis of large data sets specifically for podocyte or glomerular genes and proteins are not available. In view of the large amount of data that is generated by microarray and proteomic experiments, meaningful data reduction represents a critical step. We built a protein interaction network for the podocyte (PodoNet), and we prepared an electronic representation of the network in Cytoscape software. PodoNet consists of 148 nodes and 239 edges that represent proteins and protein-protein interactions, respectively. The network is based on expert knowledge; podocyte proteins and protein-protein interactions were selected by literature search. Gene or protein expression data can be mapped onto the network and differential expression can be visualized. As protein-protein interactions depend on the amounts of interacting proteins, differential expression changes the strengths of interactions. Using protein expression data or assuming proportionality between transcript and protein expression, differential interaction strengths can be visualized in PodoNet. Selecting edges with highest differential interaction strength, the network size can be interactively reduced to core network modules. Using publicly available microarray data obtained from freshly isolated and cultured mouse podocytes as a test input for PodoNet, differentially regulated core modules are identified, e.g. the nephrin/ podocin module. In summary, we have developed PodoNet, a protein interaction network of podocytes, as a valuable tool for the analysis of podocyte and glomerular expression data.

**Metabonomic Analysis of Serum Metabolites in Kidney Transplant Recipients with Cyclosporine A- or Tacrolimus-Based Immunosuppression** Chan-Duck Kim,[1] Sun-Hee Park,[1] Yong-Lim Kim,[1] Geum-Sook Hwang,[2] Tae-Hwan Kwon.[3] *[1]Dept of Internal Medicine, School of Medicine, Daegu, Republic of Korea; [2]Joint Bioanalytical Analysis Team, Korea Basic Science Institute, Seoul, Republic of Korea; [3]Dept of Biochemistry and Cell Biology, School of Medicine, Daegu, Republic of Korea.*

**Background:** Cyclosporine (CsA) and tacrolimus (TAC) affect the body metabolism of renal transplant recipients differently. We applied a novel method of $^{1}$H-nuclear magnetic resonance (NMR)-based metabonomics to integrate the serum metabolic profiles of transplant recipients with normal allograft function and identify time-dependent changes in the levels of serum metabolites in response to CsA- or TAC-based immunosuppression after kidney transplantation (KT).

**Methods:** Fifty-seven consecutive renal transplant recipients were treated with CsA-based (CsA, MMF, and steroid, n = 27) or TAC-based (TAC, MMF, and steroid, n = 30) regimens. Serum samples were analyzed at baseline (pre-transplant), and 1, 3, and 6 months after KT.

**Results:** The PLS-DA score plots showed a clear separation between levels at baseline and at 1, 3, and 6 months after KT in both groups. The levels of lipid metabolites were increased after KT in both groups and importantly CsA-group demonstrated higher levels than TAC-group. The metabolites for which the levels differed between the CsA-group and TAC-group and that changed according to treatment duration were glucose, hypoxanthine, lactate, succinate, and taurine. In contrast, trimethylamine-N-oxide levels, known to be associated with graft dysfunction, did not differ between the two groups.

**Conclusions:** These data indicate that CsA- and TAC-based immunosuppression elicits unique changes in serum metabolic profiles after KT. $^{1}$H-NMR-based metabonomics could provide new insights regarding the side effects of immunosuppressive regimens.

**Application of a Uromodulin Exclusion List Improves Depth of Urine Exosomal Protein Coverage by LC-MS/MS** Thomas F. Hiemstra,[1, 2] Svenja S. Hester,[2] Kathryn S. Lilley,[2] Fiona E. Karet.[1] *[1]Medical Genetics and Renal Medicine, University of Cambridge, United Kingdom; [2]Centre for Proteome Research, University of Cambridge, United Kingdom.*

Introduction: Discovery of urinary biomarkers for detection and monitoring of kidney disease is of considerable health-economic importance. Advances in the sensitivity of mass spectrometry (MS) have encouraged interest in its deployment in urine biomarker studies, but success has been limited. The abundant urinary protein uromodulin (UMOD) represents a practical contaminant which limits MS sensitivity, and may account for this paradox. UMOD depletion has been attempted, but is labour- and time-intensive, and may alter or remove other proteins. We describe the application of an exclusion list (EL) of UMOD-related peptide ions coupled with high sensitivity mass spectrometric analysis to increase the depth of coverage of the urinary exosomal (UEx) proteome.

Methods: UEx were differentially centrifuged from the urine of 5 healthy male volunteers. Separate exosomal samples were subjected to GelC-MS/MS on an LTQ-Orbitrap instrument. Spectra were analyzed using MASCOT-PERCOLATOR. Samples were then re-run, with m/z corresponding to the 20 most intense UMOD spectra rejected by forced exclusion. Spectra were searched against the human IPI protein database (v4.3), setting a false discovery rate of 0.1 for all analyses.

Results: A mean of 158 (range 114–231) UMOD spectra were identified per run by conventional methods (CM) whereas 0 UMOD spectra were identified by applying a UMOD EL, indicating the list's effectiveness. We identified 476 proteins overall by CM, of which 188 were also present on the EL list. With the application of the EL, an additional 80 proteins were identified that CM had not found, representing an increase of 17%.

Conclusion: CM give greater coverage of abundant proteins, whereas EL identifies an additional set of proteins but with fewer identifications overall. The combined use of UMOD EL and CM significantly improves depth of UEx protein coverage, providing an attractive alternative to UMOD depletion.

**Comparison of High-Throughput Sequencing (HTS) and Quantitative Realtime (qRT)-PCR for MicroRNA Profiling in Murine Kidneys** Jennifer Yi-Chun Lai,[1] David L. Turner,[2] Andrew S. McLellan,[3] Robert C. Thompson,[2] Markus Bitzer.[1] *[1]Internal Medicine, University of Michigan, Ann Arbor, MI; [2]Biological Chemistry, University of Michigan, Ann Arbor, MI; [3]Genetics, Einstein, Bronx, NY.*

Background: miRNA play important roles in disease development and their expression profiles can identify disease subtypes. Because accurate determination of miRNA expression is essential, potential differences between miRNA profiling methods need to be identified. Therefore, we compared HTS and qRT-PCR to determine miRNA expression.

Methods: Total RNA was extracted from whole kidneys of 3, 12 and 20 months old C57BL/6 mice using TRIzol. For HTS, the small RNA fraction (18 to 40 nucleotides) was sequenced using Illumina/Solexa genome analyzer standard protocol. The program *Bowtie* was used for genome alignment and specific criteria were implemented to optimize mapping accuracy. For miRNA profiling by qRT-PCR in the same RNA-pool miRNA Taqman Array (Applied Biosystems) were used.

Result: HTS output provided 2 to 6 million reads per sample up to 36 nucleotides length. The mean mapping efficacy was 69%. An average of 83% of the aligned reads matched to annotated miRNAs (miRbase V14). Out of 827 annotated miRNAs, approx. 18% were highly expressed (>1000 sequence reads). Furthermore, sequence polymorphism and length variations were detected for most miRNAs. I.e. 261850 total reads were identified for mir192, of which 84% (220761) exhibit 3' and 4% (11332) 5' terminal end-variations, and 2% have sequence mismatches. miRNA profiling by qRT-PCR detected 58% out of 517 murine miRNAs on the array. Only 50% of all expressed miRNAs were detected by both assays. No significant correlation between these methods was identified (R2 = 0.0082, P value = 0.07).

Conclusion: Absolute miRNA levels differ substantially between HTS and qRT-PCR with looped reverse transcriptase primers. Most likely, miRNAs with 3'end variations (miRNA isoforms and post-transcriptional modifications) are not detected by this qRT-PCR method. Comparisons of relative expression levels between samples are underway. These insights will improve our understanding of miRNA expression profiling and miRNA biology.

**Non-Invasive Assessment of Disease Activity in Lupus Nephritis by MRI-Based Molecular Imaging** Siranush Anna Sargsyan,[1] Kendra Hasebroock,[2] Brandon Renner,[1] Natalie J. Serkova,[2] Conrad R. Stoldt,[3] V. Michael Holers,[1] Joshua M. Thurman.[1] *[1]Medicine, University of Colorado School of Medicine, Aurora, CO; [2]Anesthesiology and Radiology, University of Colorado School of Medicine, Aurora, CO; [3]Mechanical Engineering, University of Colorado Boulder, Boulder, CO.*

Lupus nephritis is characterized by immune-complex deposition and complement activation within the glomeruli. We have developed a non-invasive method for detecting tissue-bound iC3b/C3d using superparamagnetic particles of iron oxide (SPIO) linked to the iC3b/C3d binding region of complement receptor type 2 (CR2). SPIO cause a reduction in the spin-spin T2-relaxation time and cause negative enhancement (i.e. darkening) of T2-weighted MRI images of tissues in proportion to the abundance of iC3b/C3d. We hypothesized that this agent could be used to monitor disease activity in a murine model of lupus nephritis. SPIO were synthesized and encapsulated using amine-functionalized phospholipids as ~75 nm aggregates. The particles were conjugated to a recombinant protein that contains the SCR1-2 iC3b/C3d binding region of CR2, generating CR2-targeted SPIO. MRL/lpr mice spontaneously develop a progressive lupus-like glomerulonephritis as they age. MRL/lpr mice and control MRL/MpJ mice were injected with CR2-targeted SPIO at 12, 16, 20 and 24 weeks of age. T2-relaxation times were acquired prior to and at 48 hours post injection. We found that CR2-targeted SPIO reduced the T2-relaxation time in the cortex and outer medullas of MRL/lpr mice, but did not affect the T2-relaxation time in the kidneys of control mice. Histological examination demonstrated that degree of iC3b/C3d deposition in the glomeruli of diseased animals in the diseased kidneys positively correlated with disease severity. Negative enhancement of the renal cortex and outer medulla after injection with CR2-SPIO was strongest in the 20 week-old MRL/lpr mice, corresponding to the peak glomerular iC3b deposition. MRI of the kidneys after injection with CR2-targeted SPIO may provide a quantitative non-invasive alternative for monitoring disease activity in patients with lupus nephritis.

**Diagnostic Accuracy of Dual-Source 64-Slice Multidetector CT Coronary Angiography for the Evaluation of Coronary Artery Disease in Patient with ESRD** Joon Seok Oh, Joong Kyung Kim, Yong Hoon Sin, Seong Min Kim, Ji-Min Jeon, Yong-Ki Park, Gun Ung Jeon. *Internal Medicine, Bong Seng Hospital, Busan, Korea.*

Background: Invasive coronary angiography remains the gold standard in the diagnosis of coronary artery disease. However, multidetector computed tomography (MDCT) coronary angiography is an emerging technique that is available for the non-invasive detection of coronary artery stenoses. Few studies about diagnostic accuracy of MDCT coronary angiography in patients with end stage renal disease (ESRD) were performed. So we investigate the diagnostic accuracy of dual-source 64-slice MDCT coronary angiography in patients with ESRD. Methods : 24 patients (11 males and 13 females; mean age, 59.1 ± 9.5 years) were included in this study. All segments of coronary arteries based on the ACC/AHA classification system were analyzed for the presence of significant stenosis (≥50% diameter stenosis) and compared with the quantitiative coronary angiographic findings. Results : 360 coronary artery segments were assessed quantitatively by both dual-source 64-slice MDCT and conventional coronary angiography. 138 significant stenoses were detected by conventional coronary angiography. On a segment-based analysis, the senisitivity, specificity, and positive and negative predictive values of dual-source 64-slice MDCT were 96, 100, 100, and 50%, respectively.

Diagnostic accuracy of dual-source 64-slice MDCT compared to conventional coronary angiography for detection of significant coronary stenoces in patients with ESRD

| Coronary segment | Number | Sensitivity(%) | Specificity(%) | Positive predictive value(%) | Negative predictive value(%) |
|---|---|---|---|---|---|
| All segments | 360 | 96 | 100 | 100 | 50 |
| LM | 24 | 67 | 95 | 67 | 95 |
| LAD | 120 | 80 | 95 | 89 | 90 |
| LCX | 96 | 92 | 81 | 65 | 97 |
| RCA | 120 | 92 | 76 | 73 | 93 |

LM, Lt. main; LAD, Lt. ant. descending; LCX, Lt. circumflex; RCA, Rt. coronary artery

Conclusions : This study demonstrated that dual-source 64-slice MDCT coronary angiography shows the similar diagnostic accuracy as conventional coronary angiography for the detection of coronary artery disease. In patients with ESRD, dual-source 64-slice MDCT may replace the more invasive coronary angiography.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1090**

**Evaluation of Renal Function by Means of Diffusion Tensor MR Imaging (DTI) and Its Relationship with CKD Stages: Preliminary Results** Emiliana Ferramosca,[1] Marcora Mandreoli,[1] Caterina Gaudiano,[2] Fiorenza Busato,[2] Rita Golfieri,[2] Antonio Santoro.[1] *[1]Nephrology, Dialysis and Hypertension, S. Orsola-Malpighi Hosp, Bologna, Italy; [2]Radiology Institute, S. Orsola-Malpighi Hosp, Bologna, Italy.*

Diffusion Tensor MR Imaging (DTI) is a MR imaging technique used to show molecular diffusion. The apparent diffusion coefficient (ADC) combines the effects of capillary perfusion and water diffusion in the extracellular space. DTI provides information on perfusion and diffusion simultaneously. Fractional anisotropy (FA) is a quantitative value that provides information on direction of water molecules flow within a tissue.

We evaluated feasibility of DTI in assessment of renal function in 2 groups of patients (pts): **A** (CKD 1-2) and **B** (CKD 3-4).

Ten CKD 1-2 (3M, 7F, 50 ±18 ys) and 10 CKD 3-4 (4M, 6F, 58 ±10 ys) pts were enrolled. All pts underwent morphological MR evaluation of kidneys with transverse T1 and T2 weighted acquisition, followed by transverse fat-saturated echo-planar DTI during breath-holding (with a *b*-value 500 sec/mm$^2$). ADC and FA in cortex and medulla were evaluated. Cockcroft and Gault formula was used for GFR assessment. T-test was performed for statistical analysis.

In **A**, GFR was 76±12 ml/min, in B was 33±10 ml/min. In **A**, ADC was higher in cortex than in medulla (2.55±0.09 and 2.10 ±0.08 x $10^{-3}$ mm$^2$/sec), while FA was higher in medulla than in cortex (0.280±0.04 and 0.195±0.03 mm$^2$/sec).

In **B**, ADC and FA were distributed as in **A** (ADC 2.0±0.04 and 1.80±0.05 $mm^2$/sec; FA 0.130±0.03 and 0.160±0.04), but with lower values ($p<0.05$). Our finding was the result of the water molecules flow, that in medulla has a radial direction due to the presence of tubular structure.

DTI of kidneys is feasible with excellent cortex-medulla differentiation. According to literature, we found lower ADC values in patients with moderate-severe renal failure, than in pts with mild degree of renal impairment. In **B**, the reduction in FA is more significant than the reduction in ADC, and particularly evident in medulla. FA may play an important role in detecting early renal damage, even before the onset of renal function impairment. More data are needed to confirm our preliminary results.

**Direct Visualization of the Oscillations in Proximal Tubule NADPH Oxidase Activity In Vivo** Zalan Peterfi, Arnold Sipos, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Multiphoton fluorescence microscopy is a non-invasive, quantitative imaging tool to study important kidney functions, e.g. single nephron GFR and renal blood flow (RBF). RBF and GFR are autoregulated by adjustments in afferent arteriolar diameter. An intrinsic action of vascular smooth muscle cells, known as the myogenic mechanism, and tubuloglomerular feedback (TGF) mediate autoregulation. Both the myogenic mechanism and TGF operate in the vasculature of every nephron, and each mechanism generates its own characteristic autonomous oscillation with a frequency of 0.12 and 0.023 Hz respectively. Proximal tubule (PT) reabsorption is regulated by reactive oxygen species (ROS) and the flow rate of tubular fluid. Also, it is established that tubular flow increases the production of ROS by NADPH oxidase (NOX). PT flow rate oscillates as part of the TGF oscillation, but it is not known whether the production of ROS and reabsorption in the PT oscillate in response. We aimed to directly and quantitatively visualize NADPH oxidase activity in vivo by imaging tissue autofluorescence in C57Bl6 mice with multiphoton microscopy. The PT autofluorescence intensity was the highest in the brush-border membrane area, suggesting that the highest NADPH concentration is present close to apical microvilli (membrane localization). Autofluorescence changed rapidly in response to variations in TGF phase and tubular flow. Also, autofluorescence measured in real-time showed regular oscillations with a frequency that matched TGF characteristics. Furthermore, we detected a transitional increase in autofluorescence after the iv administration of the NOX inhibitor apocynin, confirming the origin of the fluorescence signal (NADPH) and suggesting the involvement of a NOX enzyme in the process. These novel findings demonstrate the feasibility of in vivo autofluorescence measurements in the intact PT, and support our hypothesis that PT reabsorption, controlled by ROS physiologically oscillates with a frequency similar to that of TGF. Moreover, this reproducible method to measure NOX activity in vivo is a high impact finding useful to directly assess the specific role of ROS, NOX in PT function.

**High Frequency Ultrasound Assessment of Arterio-Venous Fistulae Vessel Wall Thickness To Track Fistula Maturation and To Predict Cannulation Readiness** Sandra A. Donnelly, Rosa M. Marticorena. *Medicine-Nephrology, St. Michael's Hospital, Toronto, ON, Canada.*

**Objectives:**

Post operative wall thickness changes of newly created native arterio-venous fistulae (AVF) measured by high frequency ultrasound might provide a quantitative assessment of vascular remodeling associated with fistula maturation and cannulation readiness.

**Methods:**

High frequency ultrasound evaluation (35-60 MHz) of vessel wall thickness was performed at baseline, 2, 4 and 6 weeks post AVF creation in 17 hemodialysis (HD) patients with newly created AVF (6 radiocephalic, 7 brachiocephalic, 3 brachiobasilic, 1 ulnarcephalic; mean fistula age 0.23 +/-0.16 years). Fistula diameter, size, volume flow, with particular attention to the near field fistula wall within 7 days of cannulation were also made. Images were obtained at 5, 10 and 15 cm from the anastomosis by a single sonographer and measurements were generated by 3 independent and blinded observers. Intra-class correlation analysis was performed. The decision to cannulate the new fistula was made using standard clinical assessment and cannulation was performed by two experienced HD nurses. The definition of "Cannulation readiness" was operationalized as "no extravasation" during the dialysis treatment at 200-250 ml/min blood pump speeds.

**Results:**

Fifteen fistulae met the criteria of cannulation readiness, where 6 treatments were associated with extravasation and further time for maturation was needed. Intimal medial thickness at the arterial puncture site was 0.169 +/-0.02 mm; in the no extravasation group compared to 0.103 +/-0.02 mm in the extravasation group ($p<0.001$). A minimum wall thickness of 0.13 mm ($p<0.001$) is associated with successful cannulation, particularly for the arterial site.

**Conclusions:**

Preliminary data suggests that arterio-venous fistulae wall thickness assessed by high frequency ultrasound predicts cannulation readiness. This may be used clinically to avert fistula damage by premature cannulation and to maximize successful cannulation.

**High Field MRI Methods for the Assessment of Mouse Kidney Structure and Function** Feng Wang,[1] Rosie T. Jiang,[2] Mohammed Noor Tantawy,[1] Keiko Takahashi,[2] Raymond C. Harris,[2] Christopher Chad Quarles,[1] Takamune Takahashi.[2] [1]*Vanderbilt University Institute of Imaging Science, Nashville, TN;* [2]*Vanderbilt O'Brien Mouse Kidney Physiology and Disease Center, Nashville, TN.*

In vivo imaging techniques are widely used for the evaluation of functional, structural, and metabolic integrity of the compromised kidney in human renal pathologies. However, the application of these methods to investigate disease progression in mouse models of renal pathology is highly limited. The overall goal of this study is to develop, optimize, and apply qualitative and quantitative non-invasive MRI methods for the assessment of mouse renal function and injury.

In normal and unilateral ureteral obstruction (UUO) injured mice, $T_1$/$T_2$/$T_2$*-weighted, diffusion-weighted, contrast enhanced perfusion and magnetization transfer imaging protocols were optimized on a high-field 7T MRI system. To minimize the influence of motion artifacts we compared multiple rapid acquisition MRI methods such as coherent gradient echo, multi-slice inversion-recovery fast gradient echo, fast spin echo, and multi slice multi-gradient echo MRI sequences. Relevant imaging parameters and contrast agent doses were varied to optimize structural delineation, signal to noise and image contrast. We also evaluated the use of respiratory gating and fat saturation. The relative blood volume (rBV) measurement was utilized for mapping and characterizing vascular beds in mouse kidney.

Here, we demonstrate that these methods can provide the quantitative evaluation of structural (size, shape, contrast, thickness) and vascular variation (rBV) of mouse kidney during the progression of disease such as UUO. Fine structural changes of kidney were detected at the day (day 0) of UUO surgery and progressive reduction of each renal compartments and the rBV were quantitatively assessed. Thus, high-field MRI measurements allow the non-invasive assessment of kidney structure and function during disease progression in mice. These imaging efforts complement the physiological information obtained from conventional assays of kidney function and facilitate the understanding of pathological mechanisms of kidney disease.

**Evaluation of Left Ventricular Hypertrophy in Patients with CKD Stage 3-4 – Which Is the Best Imaging Technique?** Gavin Dreyer,[1] Tom Burchell,[2] Mark Westwood,[2] Martin J. Raftery,[1] Magdi Yaqoob.[1] [1]*Renal Unit, Royal London Hospital, United Kingdom;* [2]*Cardiology, London Chest Hospital, United Kingdom.*

Introduction

Cardiac magnetic resonance imaging (CMR) is considered the gold standard to assess LVH in end stage kidney disease since 2D echocardiography consistently overestimates these parameters probably due to fluid shifts during dialysis. However, CMR is expensive (approximately $750) and not widely available. We studied patients with early CKD (stage 3-4) to determine if 2D echocardiography compared to CMR can determine the presence of LVH with similar accuracy in this patient group.

Methods

Nineteen patients with CKD stage 3-4 (9 male, mean eGFR 37.4 ml/min/$m^2$, mean age 43.3 yrs) underwent CMR and 2D echocardiography. CMR was performed using a Philips Achieva CV 1.5T. LV mass was measured from the steady state free precession contiguous short axis cine stack (8mm slice thickness and 2mm interslice gap, with whole LV coverage) using Philips MR WorkSpace software. LV mass by echocardiography was calculated by the 2D truncated ellipsoid method. Left ventricular mass index (LVMI) is normalized to body surface area (g/$m^2$).

Results

The mean LV mass and LVMI were significantly higher by echocardiography compared to CMR.

LV mass and LVMI values

| | Echocardiography | CMR | p value |
|---|---|---|---|
| LV mass (g) | 142.1 | 97.3 | <0.001 |
| LVMI (g/m2) | 79.3 | 51.9 | <0.001 |

There is a strong positive correlation between LV mass (r=0.64) and a positive but weaker correlation between LVMI (r=0.42) by both techniques. Two patients (10.5%) are classified with LVH by echocardiography but matched values for these patients by CMR are within established normal ranges. No patients with normal values at CMR were misclassified with LVH by 2D echocardiography.

Conclusion

2D echocardiography performs well compared to CMR for evaluation of LVH in CKD 3-4. However, 10.5% of patients in this series are misclassified with LVH by echocardiography. Based on the cost and availability of CMR, we recommend echocardiography as a first line investigation for LVH in patients with CKD 3-4. The presence of LVH on echocardiography should be confirmed by CMR prior to diagnosing, starting or intensifying therapies for LVH.

**F-PO1095**

**Detecting Microchimerism with Real-Time Quantitative Polymerase Chain Reaction (qPCR) Based on Insertion-Deletion Polymorphisms** Suzanne Wilhelmus, Mathilde M. M. Almekinders, Juan D. Diaz de Pool, Hans J. Baelde, Jan A. Bruijn, Ingeborg M. Bajema. *Pathology, Leiden University Medical Center, Leiden, Netherlands.*

Microchimerism is an intriguing phenomenon playing a role in both renal transplantation and autoimmune diseases such as SLE. Microchimerism is defined as the presence of < 1% of cells present in one individual which are derived from another individual. Previous studies on microchimerism have been limited by the detection of chimeric cells on the basis of a sex-difference: in these studies, Y-chromosome positive cells were used to determine the amount of chimerism in female tissues and/or blood. We here present a technique based on the detection of a mismatch in polymorphisms in a previously described set of bi-allelic insertion deletion polymorphisms (Indels) by qPCR (Alizadeh, Blood 2002).

Twenty couples consisting of related subjects (parent and child) donated oral mucosal cells for the determination of the presence of Indel polymorphisms from our selected set. These Indels are bi-allelic polymorphisms that are common in the population and are located on 9 different chromosomes.

Using the Indel-set we were able to distinguish 85% of related couples. In tested samples, a sensitivity of 1:100.000 genome equivalents and specificity of 100% could be reached. We set up a real-time qPCR using SYBR Green for the detection of all Indels.

Detection of microchimerism is technically challenging. It requires the presence of allogeneic markers and a method with high specificity and sensitivity. Using real-time qPCR with SYBR Green intercalation to detect microchimerism based on different Indels, we were able to distinguish offspring derived chimeric cells in healthy individuals with a sensitivity of 1:100.000 genome equivalents. This method has the ability of quantifying a small amount of DNA in the presence of a large amount of background DNA. This technique bypasses the gender-mismatch limitation, and is applicable for research on chimerism in renal transplantation and autoimmunity.

**F-PO1096**

**Measuring Nephron Endowment in the Intact Kidney Using MRI** Scott Charles Beeman, Teresa Wu, Min Zhang, Kevin Bennett. *Arizona State University, Tempe, AZ.*

The goal of this work was to nondestructively measure nephron endowment using MRI. A reduction in the number of nephrons is associated with a host of renal and systemic diseases, though this information is unavailable in the clinic due to the need for sectioning or maceration of the kidney for counting. Were a nondestructive method available, counting glomeruli could serve an important clinical role. We show that nephrons may be counted in a whole kidney using targeted MRI contrast agents. This, along with previous detection in-vivo (Bennett, Mag. Res. Med., 2008), suggests the possibility of counting nephron in the clinic.

Rats were given bolus IV injections of either cationized ferritin (CF) or native ferritin (NF). Rats were perfused and the kidneys removed. The left kidney was imaged and the right kidney was acid macerated for histological counting. Glomeruli were counted in the MRI volumes using morphological algorithms. Right kidney histological counts were estimated based on observed glomeruli per unit area using a counting chamber.

Imaging showed glomeruli exposed to CF were labeled while glomeruli exposed to NF were not. Counting of labeled glomeruli from MRI yielded 31,046±2,429 glomeruli (n=3). The same counting algorithm yielded 2,788 glomeruli for the control kidney. This number of false positives is approximately equal to the difference between the MRI counting of labeled glomeruli and the histological count of 29,212±1,856 glomeruli (n=3). We conclude that our MRI technique yields comparable results to histological methods with the advantage of maintaining the entire organ. This result, along with previous in-vivo detection of glomeruli, suggests the possibility of counting glomeruli in the clinic.

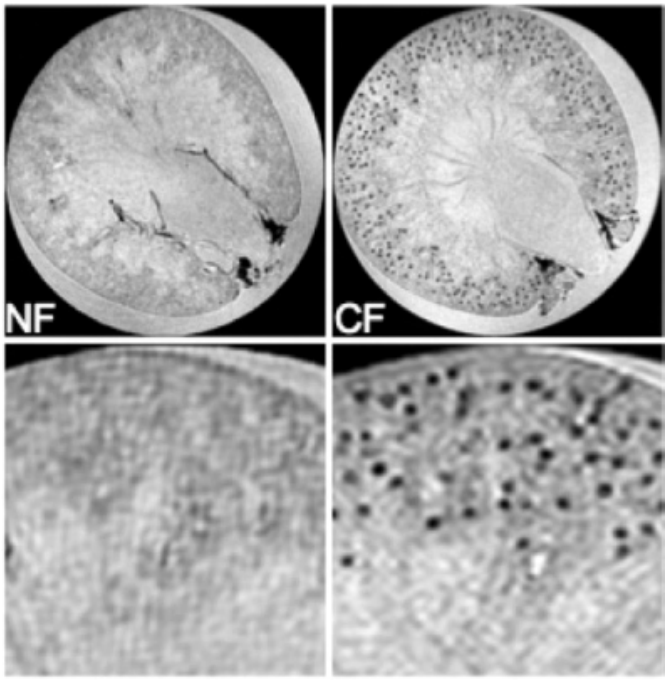

Figure: MRI of excised kidneys with magnifications below. Dark spot to the right represent individual glomeruli labeled with CF. No glomeruli were labeled with NF.

**Improved Efficacy with Increasing Dose of Biomimetic Membrane Device in Septic Shock** L. Lou,[1] M. Wang,[1] P. Smith,[1] A. Westover,[1] J. Jung,[2,3] D. Buffington,[1] K. Johnston,[1] David Humes.[1,2,4] *[1]Innovative BioTherapies; [2]Univ of Michigan; [3]Chungnam Nat Univ; [4]CytoPherx.*

Sepsis is the leading cause of death in critically ill patients in the United States. Sepsis syndrome is defined as the systemic inflammatory response to infection. We have developed a selective cytopheretic device (SCD) composed of a synthetic biomimetic membrane that binds and sequesters activated leukocytes from the systemic circulation along an extracorporeal blood circuit. This device was evaluated in an established acute porcine model of septic shock. **Methods:** The circulating blood entering the extracapillary space of the SCD was anticoagulated with either citrate (0.7 $m^2$ or 1.8 $m^2$ SCD-C) or heparin (SCD-H). Cardiovascular and pulmonary function, systemic inflammatory indices and activated neutrophil levels were measured. **Results:** The SCD-C maintained cardiovascular, pulmonary and renal function, ameliorated the degree of capillary leak, minimized the systemic level of neutrophil activation compared to SCD-H group. Cardiovascular, pulmonary and renal parameters were significantly better ($p<0.05$) in the SCD-C groups, with 1.8 $m^2$ showing most improvement, versus SCD-H group. These differences in cardiovascular and hemodynamic parameters were associated with significantly longer survival times in the SCD-C groups compared to the SCD-H group, with the 1.8 $m^2$ showing longest survival times. SCD-C treatment has a dampening effect on circulating neutrophil activation levels when compared to the SCD-H treatment group ($p=0.031$). Significant differences were found between the SCD-H and SCD-C treated groups with respect to both total eluted cells and the differential profiles, with the most significant difference seen between the SCD-H and 1.8 $m^2$ SCD-C treated animal groups. **Conclusions:** The results indicate efficacy of SCD-C compared with SCD-H in the amelioration of cardiovascular parameters, inflammatory indicators and increased survival time in a porcine model of septic shock, with increasing SCD membrane surface area as a dose adjustment.

**The CARPEDIEM Project: Cardio Renal Pediatric Dialysis Emergency Machine. A New CRRT Equipment for the Treatment of AKI in Infants** Claudio Ronco,[1] Dinna N. Cruz.[1] *[1]Department of Nephrology and IRRIV, San Bortolo Hospital, Vicenza, Italy; [2]Pediatric Intensive Care, Ospedale Bambin Gesù, Roma, Italy.*

Acute Kidney Injury may occur in infants due to severe dehydration or complicated cardiac surgery. This syndrome can be considered an orphan disease since only a few cases are reported annually in pediatric intensive care centers and these cases may not receive optimal renal replacement therapy because of the lack of dedicated technology. Infants with body weigth between 2 and 8 Kg must in fact be treated with dialysis machines designed for adults in which pediatric blood lines are utilized. In spite of all adjutments, most machines

are used off label in patients below 15 Kg of body weight. In these circumstances, fluid balance may not be sufficiently accurate and circuit priming volume may result excessive putting the small patients at risk.

Based on these considerations, we designed a miniaturized machine for renal replacement therapy to be used specifically in patients under 10 Kg. The machine isdesigned based on specifications for small infants featuring a low priming extracorporeal circuit (less than 35 ml), a 0.3 sqm hemofilter, a small blood pump delivering a blood flow between 0 and 80 ml/min, small dialysate/filtrate pumps with an operational range between 0 and 15 ml/min, and scales with accuracy of 0.1 g. The equipment can perform ultrafiltration, dialysis and hemofiltration in continuous mode providing continuous feedback on the operational parameters and featuring all classic safety characteristics of a dialysis machine. Sterile fluids for dialysate or replacement solutions are provided in 0.5-1 liter bags. Heparin pump and a drug delivery pump are incorporated in the machine for anticoagulation or combined drug therapies.

This is the first machine in the world specifically designed for infants with body weight below 10 Kg. The project has been supported by a consortium of 3 non profit organizations and the construction has been commissioned to an industry of the field who accepted a non commercial partnership. The machine is CE maked and it will be tested in a multicenter prospective trial.

**First Implantation of Silicon Nanopore Membrane Hemofilter** William Fissell,[1,2] Joseph J. Groszek,[1] Shuvo Roy,[4] Matthew N. Simmons.[3] *[1]Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; [2]Biomedical Engineering, Cleveland Clinic, Cleveland, OH; [3]Urology, Cleveland Clinic, Cleveland, OH; [4]Department of Biopharmaceutical Sciences, University of California, San Francisco, San Francisco, CA.*

**Background:** An implanted hemofiltration membrane might offer patients the benefits of quotidian hemodialysis with the ease of use of peritoneal dialysis. A novel membrane technology based on silicon nanotechnology appears enabling for implanted devices. **Methods:** Silicon nanopore membranes (SNM) were coated with PEG as described previosuly. Computational fluid dynamics simulations were used to design a pumpless implant cartridge, which was machined out of medical-grade polycarbonate, and the SNM were installed in the cartridge. Yorkshire breed pigs (n=2) were anesthetised with isofluorane and underwent uninephrectomy. The SNM hemofilter was flushed and connected to remnant renal artery and vein via 7mm PTFE end-to-end grafts and the animals heparinized. Brisk blood flow was observed. Ultrafiltrate production was measured gravimetrically over the 4 hour experiments. **Results:** Stable ultrafiltrate production over 4 hours was observed in both animals. In one animal, accidental kinking of the PTFE graft resulted in cessation of blood flow for 45 minutes, but not cartridge or membrane thrombosis occurred, and repositioning restored blood flow and ultrafiltrate production. Discussion: these pilot large animal experiments demonstrate that SNM are sufficiently robust to withstand packaging and surgical handling, as well as arterial blood pressure, without membrane leakage or thrombosis. more study is needed to estimate in-vivo lifetime and optimal configuration.

**The Effects of a Novel Selective Cytopheretic Device on Mortality and Renal Function in the Intensive Care Unit: A Pilot Study** David Humes,[3] James A. Tumlin,[2] Alexander S. Yevzlin.[1] *[1]Internal Medicine, University of Wisconsin, Madison, WI; [2]Internal Medicine, SERRI, Chattanooga, TN; [3]Internal Medicine, University of Michigan, Ann Arbor, MI.*

Acute kidney injury initiates a systemic inflammatory response state often leading to multiorgan dysfunction. A novel biomimetric membrane called a selective cytopheretic device (SCD), was developed to bind activated leukocytes. The SCD is incorporated in series with a standard hemofilter along a continuous renal replacement therapy (CRRT) extracorporeal blood circuit and pump system coupled with regional citrate anticoagulation. This system has been shown in a porcine model of septic shock to ameliorate cardiovascular instability, minimized the sequestration of activated leukocytes in lung tissue, reduced renal dysfunction and improved survival times compared to control groups. This effect was associated with minimal elevations of systemic neutrophil activation. Two exploratory Phase I/II clinical studies of 10 and 24 patients have been completed (Humes, HD, Sobota, JT, Ding, F, Song, JH. A Selective Cytopheretic Inhibitory Device to Treat the Immunological Dysregulation of Acute and Chronic Renal Failure. Blood Purif 2010;29:183-190; and Ding F, Yevzlin AS, Humes HD. A Selective Cytopheretic Inhibitory Device (SCD) Accelerates Renal Recovery and Improves Mortality in ICU Patients with AKI and MOF in an Exploratory Clinical Study. Abstract: ASAIO annual scientific meeting 2010) and have shown improved survival rates and faster time to renal recovery than concurrent or historical controls utilizing conventional CRRT. No major safety concerns have been observed. Accordingly, an FDA approved IDE pilot study has been initiated in 7 U.S. medical centers. This pilot study is a single arm study with SCD treatment in ICU patients with AKI and multiorgan failure or sepsis requiring CRRT. Up to 35 patients will be recruited. This study is designed to evaluate the safety of this device and early efficacy parameters of mortality at 28 and 60 days and time to renal recovery. Full results of this trial will be presented at the time of these scientific meetings.

**Integration of a Selective Cytopheretic Inhibitory Device (SCD) into a Portable Sorbent Dialysis System** K. Johnston,[1] L. Lou,[1] D. Buffington,[1] K. Lee,[2] A. Rojas,[2] David Humes.[1,2] *[1]Innovative BioTherapies; [2]Univ of Michigan.*

Sorbent based dialysis systems regenerate dialysate, permitting the use of only 6L tap water per treatment. When these cartridges are exhausted, ammonium is produced from the breakdown of urea. Certain chelators, i.e. citrate, inadvertently bind the cartridges resulting in premature exhaustion. A novel selective cytopheretic inhibitory device (SCD) requiring citrate anticoagulation has been shown to improve survival in systemic inflammatory response syndrome (SIRS) and associated septic shock, which often lead to multiple organ dysfunction (MOD) and acute kidney injury (AKI). Integration of these two technologies would readily adapt to treating trauma victims from military engagements or natural disasters in remote areas. **Methods:** 60kg pigs (n=7) were made acutely uremic via bilateral nephrectomy and intravenous urea load to achieve systemic BUN >75mg/dl. After heparinization, 6 hours of hemodialysis was administered using the Aliant® sorbent system connected in series with the SCD. Six liters of tap water was used to create the dialysate. Citrate was infused into the blood line pre-SCD with 2% CaCl infused into the venous return post-SCD to compensate for iCa bound by citrate. Blood gas, electrolytes, BUN, CREA, and citrate levels were monitored. Dialysate was tested hourly to detect ammonia breakthrough. **Results:** Serum BUN levels declined throughout the study. Ammonia breakthrough was observed in 3 animals as was predicted based on urea load. Systemic levels of iCa decreased over time but remained within the normal range. **Conclusion:** Successful setup of a Sorbent-SCD circuit capable of the regeneration of dialysate throughout a 6 hour treatment with only 6L of tap water allows for treatment benefits of both dialysis and the use of the SCD in a format that is ideal for field hospital application. This initial study demonstrates the feasibility of using the SCD in a Sorbent circuit for the treatment of SIRS and septic shock.

**Rapid Determination of Kidney Function in Dogs with Acute Kidney Injury Using a Portable Fiber Optic Fluorescence Ratiometric Analyzer** Vanessa E. Von Hendy-Willson,[1] Barrak M. Pressler,[1] Daniel J. Meier,[3] Ruben M. Sandoval,[2] Exing Wang,[2] Bruce A. Molitoris.[2] *[1]Purdue Univeristy; [2]Indiana University School of Medicine; [3]Fast Diagnostics, Inc.*

Rapid quantification of glomerular filtration rate (GFR) in acute kidney injury (AKI) is important for initial diagnosis and for determination of disease severity. We have previously presented our design of a fiber optic fluorescence ratiometric kidney function analyzer that in theory should allow bed-side calculation of GFR and plasma volume within one hour of marker administration using a two compartment model. This novel system consists of dual LED excitation sources, two PMTs, a sub-millimeter optic fiber, and computer hardware with software handling control, data acquisition, and analysis capability. We now report our further work on optimization of the fluorescence markers/reporter molecules and the suitability of the ratiometric analyzer for determination of GFR in dogs. The optimized conjugates (freely filterable 5 kDa FITC-dextran and non-filterable 150 kDa 2-sulfohexamine-rhodamine-dextran) are both much brighter than alternative commercially available fluorescent markers, thus permitting a large reduction in injected conjugate volume. We also compared iohexol clearance and fluorescence-determined GFR values in healthy laboratory dogs under normal physiological conditions and following gentamicin- or LPS-induced AKI. A wide range of GFR values expected in naturally-occurring AKI was successfully generated using these models. Very good correlation existed between the two methods of GFR determination (r=0.89). As expected, occasional movement by the dogs during the data acquisition period resulted in background noise when measuring fluorescence; however, the analyzer's software was able to remove these data points, resulting in a characteristic smooth elimination curve, and an associated increase in accuracy. Finally, no apparent toxic effects were noted following repeated administration of both fluorescent markers over a 4-month period to study dogs. Based on the success of these pilot studies we anticipate progression to a phase I human study with rapid bedside monitoring of GFR and plasma volume.

**First Prototype of a Peritoneal Dialysis-Based Automated Wearable Artificial Kidney (AWAK)** Christian G. Bluchel,[1] Martin Roberts,[2-4] David B. Lee,[2-4] Jui Pin Er.[1] *[1]Temasek Engineering School, Temasek Polytechnic, Singapore; [2]VAGLA Healthcare System, Los Angeles, CA; [3]David Geffen School of Medicine at UCLA, Los Angeles, CA; [4]AWAK Technologies, Singapore.*

Continuous peritoneal dialysis (CAPD) leads to "patient fatigue" and provides marginal dialytic adequacy, particularly in anuric patients. AWAK is a wearable system that automates dialysate exchange and markedly enhances adequacy. This is accomplished by automated and continuous regeneration of spent dialysate and recycling of the regenerated, fresh dialysate at a high flow rate (4L/h) using tidal PD (TPD). TPD will be conducted with low reserve (RV) and tidal (TV) volume (RV+TV≤ 1.5L) for minimizing both the weight of AWAK and patient discomfort. The prototype weighs about 3 kg and consists of inter-connected disposable and non-disposable assemblies. Operation initiates with the "outflow mode" (OM), during which spent dialysate is drained from the peritoneal cavity (PC) through a sorbent cartridge, where it is regenerated. The regenerated dialysate is then reconstituted with electrolytes and glucose as prescribed. The OM is followed by the "inflow mode" (IM), during which the regenerated and reconstituted dialysate stored in a module in the disposable assembly, is returned into the PC. An ammonia detector monitors for sorbent cartridge exhaustion. OM-IM cycle is continuously repeated in sequence. Prior to replacing the sorbent cartridge (every 12 hours), the PC is completely drained into an UF module in the disposable assembly. The prescribed RV and TV is then pumped back into the PC. The remainder fluid is discarded as UF. Preliminary TPD studies indicate a weekly Kt/V of 3.4 to 6.5 and a daily UF of 1.8 to 3.9 L can be attained.

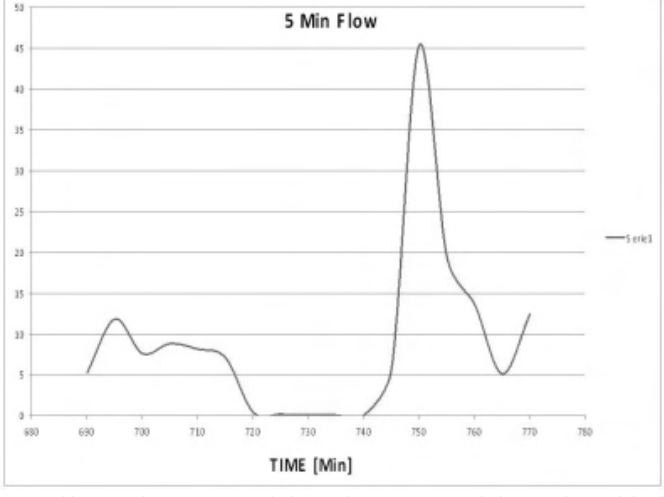
**URINFO® in the Early Detection of Acute Kidney Injury** Anthi Panagiotou,[1,3] Francesco Garzotto,[1,3] Matteo Floris,[1,3] Federico Nalesso,[1,3] Dinna N. Cruz,[1,3] Claudio Ronco.[1,3] *[1]Nephrology, S Bortolo Hosp, Vicenza, Italy; [2]IRRIV, Vicenza, Italy.*

INTRODUCTION: RIFLE consensus classification was the first accepted definition for acute kidney injury (AKI). RIFLE criteria are based on creatinine and urine output changes and define severity classes of AKI. However, many patients with AKI are not identified early enough since changes in creatinine level have a 48 hours time window even though AKI is already present. Standardized manual urine output (UO) measurements in most of critical care units are inaccurate and inconsistent. We describe the first preliminary results from a clinical trial that was conducted in our center using the URINFO® System.

METHODS: In critical ill patients urine volume and flow variation are important parameters. URINFO® system is an innovative digital urine meter that provides continuous minute based monitoring of UO allowing kidney monitoring and reliable information for UO in real time. Since all data are automatically stored in a designated data logger, urine monitoring does not require manual intervention. Continuous urine measurement allows physicians to identify early UO variations and to obtain rapid information about kidney function and potential development of AKI, making an earlier clinical patient's management.

RESULTS: Analyzing our data, urine flow diagram can be used as other vital signs for patient's monitoring.



In this case, that we presented above, the UO curve variation can be explained as mechanical problem due to catheter kicking only and not as real AKY because after the kicking detection UO was restored immediately as the curve demonstrated. CONCLUSIONS: The use of URINFO® system can be a new and easy approach for the UO monitoring in order to consent an earlier AKI identification by RIFLE criteria. This approach can consequently allow rapid therapeutic interventions.

**LNA Antisense Are Potent, Specific and Long Lasting Inhibitors of mRNA in the Kidney** Bo R. Hansen. *Research Division, Santaris Pharma A/S, Hørsholm, Denmark.*

BACKGROUND: Oligonucleotides comprising Locked Nucleic Acid (LNA) exhibits unprecedented high RNA binding affinity. The high affinity offers the opportunity to reduce the oligonucleotide length and at the same time maintaining the potency. LNA improves the *in vivo* potency/efficacy significantly, and notably without conjugation ligands and special lipid formulations. The biodistribution of LNA oligonucleotides is broad and shows a high uptake into kidney tissue with a long tissue half-life due to the much improved stability of LNA oligonucleotides. Hyperlipidemia and hypercholesterolemia has shown to contribute to the pathogenesis of progressive renal disease and apolipoprotein B-100 (ApoB) has been found to play a significant role. METHODS: The 13-mer LNA SPC3833 was selected from a series of LNA oligonucleotides targeting the human and murine ApoB mRNAs and tested *in vitro* and *in vivo* in two different rodents. C57BL/6 mice (5 animals/group) were dosed i.v. with oligonucleotides diluted in saline at doses of 0.2 mg/kg and 1.0 mg/kg per day or saline for three consecutive days and sacrificed 24 hours after the last dosing. The expression levels of ApoB mRNA were analyzed in kidney tissue. Wistar rats (5 animals/groups) were dosed s.c. with SPC3833 diluted in saline at doses of 5 mg/kg and 10 mg/kg per day or saline once weekly for four consecutive weeks and sacrificed 7 days after the last dosing. ApoB mRNA was analyzed in kidney tissue. RESULTS: In the mouse studies the groups of mice dosed with 13-mer LNA oligonucleotide SPC3833 resulted in a 70% reduction of the target mRNA at 0.2mg/kg and a 85% reduction of the target mRNA at 1.0mg/kg compared to saline treated control animals. In the rat studies SPC3833 resulted in a 70% reduction of the target mRNA in the kidney tissue at the 5 mg/kg dose compared to the saline treated control animals while the target mRNA was hardly detectable in the kidney tissue in the 10 mg/kg treated animals even 7 days after the last dosing. CONCLUSIONS: These studies showing the high potency and long duration of action of a short LNA oligonucleotide *in vivo* demonstrate the broad possibilities of using LNA antisense therapeutics for ApoB and other RNA targets in renal disease.

**F-PO1106**

**Assessment of Glomerular Filtration Rate in Chinese Patients with Chronic Kidney Disease Using a Radial Basis Function Neural Network** Xun Liu,[1,2] Xiaoming Wu,[2] Ningshan Li,[2] Tan-Qi Lou.[1] *[1]Division of Nephrology, Department of Internal Medicine, The Third Affiliated Hospital of Sun Yet-Sun University, Guangzhou, Guangdong, China; [2]College of Biology Engineering, South China University of Technology, Guangzhou, Guangdong, China.*

Background Artificial neural networks have been widely used in the field of engineering forecasting. This paper attempts to predict glomerular filtration rate (GFR) in Chinese patients with chronic kidney disease (CKD) by radial basis function (RBF) neural network.

Materials and methods 327 patients with CKD who had undergone 99mTc-DTPA-glomerular filtration rate (GFR) estimation were enrolled. SC was determined enzymatically. The 99mTc-DTPA-GFR was used as the reference standard GFR (sGFR). The input layer of the RBF network consisted of only one unit, the patients' records of SC. The output layer consisted of one unit representing sGFR. Average sGFR was 44.5 (±26.9) ml/min/1.73 m2 (range, 2.8-140.0 ml/min/1.73 m2). The Cockcroft-Gault-equation, Jelliffe-1973-equation, Bjornsson-equation, Ruijin-equation and RBF network were compared. The accuracy of estimated GFR (eGFR) was compared with sGFR in various stages of CKD.

Results Bland-Altman analysis demonstrated that RBF network was better than the other equations. Only the agreement limits of the RBF network exceeded the prior acceptable tolerances defined as 60 ml/min/1.73 m2. The slope of the regression line estimated by the RBF network was smaller than those of the other equations. Median % absolute difference of the RBF network was significantly less than those of the other equations. The accuracy with a deviation less than 30% from the sGFR of the RBF network was significantly higher than those of the Jelliffe-1973-equation and Ruijin-equation. When compared the bias as well as accuracy of eGFR with sGFR in different stages of CKD, GFR estimated by RBF network showed good results.

Conclusion Our data indicated that when SC was measured by the enzymatic method, based on both overall performance as well as performance in different CKD stages, this RBF network model is suitable for the specific Chinese population tested. Further procedures are needed to facilitate the validation of the model.

**Modeling of Individual Hemoglobin Responses to Erythropoietin (EPO) in DCI Hemodialysis Patients Using Retrospective Data** John Mcmichael,[1] Klemens B. Meyer,[3] Dana C. Miskulin,[3] Kevin Ho.[2] *[1]Dimensional Dosing Systems Inc., Wexford, PA; [2]University of Pittsburgh Medical Center, Pittsburgh, PA; [3]Tufts University, Boston, MA.*

We used the Intelligent Dosing System (IDS) to model a retrospective DCI EPO dosing dataset. The IDS is an FDA Class II medical device that uses a nonlinear equation to correlate changes in dose to changes in level or response. The IDS equation consists of 3 equations: (1) calculates EPO dose based on dose- response Hgb, (2) stochastic loop modifies result of 1st equation to account for non-linear, patient-specific effects, (3) calculates expected Hb following the dose adjustment. The retrospective analysis was conducted on a dataset with 1.9 million dosing observations on 11,083 chronic DCI hemodialysis patients which

included EPO dose, Hgb level, date of EPO administration. Data was organized into a tabular view so that each row contained the appropriate data elements which represented a dosing interval. Variability when no dose change is made and non-logical observations could be attributed to changes in the patient's clinical status; these was not analyzed. We used 5 different strategies to select the best input parameters. To conduct this retrospective analysis, EPO Dose1, EPO Dose2 and Hgb1 were used as inputs to the IDS equation to calculate Hgb2. We calculated the absolute error between the observed next Hgb2 and the IDS calculated Hgb2. The IDS also uses a stochastic loop to individualize therapy based on previous dosing experience to further increase predictive accuracy. Since this would necessitate a prospective study, this component could not be tested.

Results

| | Total # Observations | # Abs Err <0.3 g/dL | % <0.3 g/dL | # Abs Err <0.5 g/dL | % <0.5 g/dL | # Abs Err < 1.0 g/dL | % <1.0 g/dL |
|---|---|---|---|---|---|---|---|
| Model 1 | 730787 | 57432 | 30.7 | 86889 | 41 | 138897 | 65.6 |
| Model 2 | 1182835 | 94751 | 25.7 | 144688 | 39.2 | 237210 | 64.2 |
| Model 3 | 534708 | 43328 | 33.5 | 64482 | 49.8 | 96940 | 74.9 |

## F-PO1108

**Bayesian Classifier vs Relevant Physiological Parameters** Francesco Garzotto,[1,3] Matteo Recchia,[1,3] Dinna N. Cruz,[1,3] Matteo Floris,[1,3] Alessandra Brendolan,[1,3] Federico Nalesso,[1,3] Pasquale Piccinni,[1,2] Claudio Ronco.[1,3] *[1]Nephrology, St. Bortolo Hosp, Vicenza, Italy; [2]Intensive Care Unit, St. Bortolo Hosp, Italy; [3]IRRIV.*

Acute kidney injury (AKI) is a common problem, especially in critically ill patients. Prediction of AKI in a simple manner without costly biomarkers is a desirable clinical goal. The aim of the study is use the Bayesian classifier (BC) approach to predict an event AKI in order to provide the intensivist with a tool to aid in medical decision-making

Methods

Data from the NefroInt project (Italian prospective multicenter study) were used. Database requires clinician to indicate the patient's renal outcomes as A)Dialysis dependent,B)Dialysis-independent but renal function not at baseline,C)Renal function returned to baseline & D)No renal dysfunction during ICU stay. For the model, we defined only 2 classes: AKI (A+B+C) vs Normal(D).Using 6670 days recorded from 600 patients of 10 different ICU, we derived a probabilistic classifier based on Bayes theorem, using the same parameters found in severity of illness scores (APACHE II,SOFA,SAPSII), as well as several variables commonly considered by clinicians (e.g. baseline renal function, diuretic use, fluid balance).Forward linear method was used to identify parameters that give maximum accuracy. Models design was based on a leave-one-out supervised classification implemented in the software Rapidminer.

contingency table

| | TRUE | | | |
|---|---|---|---|---|
| | AKI | Normal | | |
| AKI | 320 | 78 | 80.40% | ppv |
| Normal | 39 | 165 | 80.88% | npv |
| | 89.14% | 67.90% | | |
| | sensitivity | specificity | | |

Accuracy of BC to classify AKI vs Normal patients was 80.56%.The forward linear technique give 7 parameters necessary to attain this level of accuracy: creatinine, urine output 24h, worst urine output 6h, MAP, chronic disease, urinary pathology, sepsi.Sensitivity was 89.14% and specificity was 67.90%

Conclusion

A tool based on BC without any type of medical information could predict with an high accuracy AKI in critically ill patients. The seven clinical parameters used by BC to obtain the results are physiologically relevant for a nephrologist

A more sophisticated classifier capable of predicting more detailed renal outcome (e.g.4 classes) would be the logical next step.

Disclosure of Financial Relationships: nothing to disclose

## F-PO1109

**Evaluation of Bioartificial Renal Epithelial Cell System (BRECS) Therapy in a Porcine Septic Shock (PSS) Model** A. Westover,[1] D. Buffington,[1] L. Lou,[1] M. Wang,[1] P. Smith,[1] K. Johnston,[1] C. Pino,[1] J. Jung,[2,3] David Humes.[1,2] *[1]Innovative BioTherapies; [2]U Michigan; [3]Chungnam Nat U.*

Renal cell therapy incorporated into conventional CRRT circuit has shown metabolic, immunologic and survival benefits in renal failure in preclinical and clinical studies. To improve upon previously used hollow fiber based delivery platforms, a miniaturized, freezable BRECS has been developed. The device is fabricated with approximately $10^8$ renal epithelial cells seeded onto trabeculated carbon disks maintained by continuous perfusion. BRECS are evaluated using a previously established model of sepsis.

**Methods**: Hemofiltration is established in a PSS model with incorporation of the BRECS into an ultrafiltrate (UF) loop with processed UF returned to the animal allowing for maintenance of cell viability and communication between the device and host. SS is simultaneously induced by the introduction of bacteria into the peritoneum resulting in multiorgan dysfunction. Hemodynamic parameters including cardiac output, mean arterial pressure and systemic vascular resistance were monitored through death or up to 12 hours. Systemic inflammation was evaluated using serum cytokines, neutrophil (NE) expression of CD11b and evaluation of NE extravasation into lung tissue by post mortem immunohistochemistry. Cell Viability within BRECS was verified post study using $O_2$ consumption and using a fluorescein diacetate based viable dye.

**Results:** To date 8 BRECS and 7 acellular BRECS have been evaluated. A significant improvement in cardiovascular parameters (CVP) was observed T=2 hours through study termination. Average survival time was increased from 7.7 to 10.9 hours, with 4 animals in the treated group surviving up to the predetermined stop point of 12 hours, even though CVP indicated that survival times would be much longer. Significant differences in serum cytokines were not observed; the CD11b expression by NEs was significantly altered, peaking at T=4 vs T=10 hours. Aggregation of activated NEs into lungs was 50% lower in BRECS treated animals compared to sham controls.

**Conclusion**: BRECS therapy may ameliorate the course of SS by modulating inflammation and providing cardiac support.

## F-PO1110

**Arteriovenous Fistula Remodeling from a Multi-Center Phase I/II Trial Investigating the Use of Allogeneic Endothelial Cell Implants: V-HEALTH Study** Michael S. Conte,[1] Helen Nugent,[2] Prabir Roy-Chaudhury.[3] *[1]University of California, San Francisco, CA; [2]Pervasis Therapeutics, Cambridge, MA; [3]University of Cincinnati, Cincinnati, OH.*

Arteriovenous fistula (AVF) is the preferred type of access for hemodialysis to treat end stage renal disease. However, a high proportion of AVF are never used for dialysis because the vein fails to mature. We previously described the safety of Vascugel (allogeneic aortic endothelial cells in a gelatin matrix) when placed around the anastomotic and venous outflow sites of AVFs (V-HEALTH study). In this retrospective analysis, we describe the remodeling of AVF assessed by serial ultrasound measurements of lumen diameter. Thirty-one AVF patients received either Vascugel or control matrices (placebo) at surgery and were followed for 24 weeks. Venous lumen diameter was measured at 1, 3 and 5 cm from the anastomosis. Vein remodeling (mm change in lumen diameter at 4, 12 and 24 weeks compared to baseline diameter at 2 weeks) was analyzed using a mixed model repeated measures analysis of covariance. The results indicate that diabetes (DM) is a significant predictor of poor venous remodeling post AVF creation ($P$<0.03, Figure 1A). The average change in lumen diameter from 2 to 24 weeks was -0.75 mm in DM patients (N=12) and +0.94 mm in non-DM patients (N=15), with the major effect seen at 24 weeks (difference of 2.3 mm, 95% CI 1.2-3.4, p=0.0002). Treatment with Vascugel showed a positive trend in change in lumen diameter (0.62 mm vs. -0.44 for placebo, 95% CI for difference is -0.33, 2.46, p=0.13). Specifically, comparing Vascugel-treated DM patients to placebo-treated DM patients, this difference was 2.24 mm (95% CI 0.1-4.4, p=0.04), indicating that treatment with Vascugel positively mitigated the effect of DM on remodeling (Figure 1B). We conclude that DM negatively impacts AVF remodeling, and Vascugel may ameliorate this effect.

**Interaction of ELMO1 with COX-2 Increases COX-2-Mediated Fibronectin Upregulation** Andrey Sorokin, Chen Yang. *Medicine, Medical College of Wisconsin, Milwaukee, WI.*

Renal glomerulosclerosis, the final major lesion of many primary and secondary glomerular diseases, is characterized by accumulated deposits of extracellular matrix (ECM) proteins in glomeruli. Renal glomerular mesangial cells (GMC) play a pivotal role in the development of glomerular injury and in response to pathological stimuli produce ECM proteins such as collagens and fibronectin which result in irreversible glomerular injury. Increased glomerular cyclooxygenase-2 (COX-2) expression has been reported in many glomerular diseases and even though selective inhibition of COX-2 retarded the progression of glomerular injury the precize mechanisms by which COX-2 causes glomerular injury have not yet been elucidated. Engulfment and cell motility 1 (ELMO1), a bipartite guanine nucleotide exchange factor for the small GTPase Rac1, was identified as a susceptibility gene for glomerular disease. To elucidate the role of ELMO1 in the development and progression of glomerular injury, we examined the expression of ELMO1 protein in anti-Thy-1 glomerulonephritis rats. By immunofluorescence double staining, we demonstrated that the expression of ELMO1 and COX-2 was increased in the glomeruli of these rats. We detected co-localization of ELMO1 with COX-2 in cultured human GMC by immunofluorescence and proved interaction of ELMO1 with COX-2 by co-immunoprecipitation. Furthermore, we identified ELMO1 as a posttranslational regulator of COX-2 activity. We found that COX-2 increased fibronectin upregulation through its cyclooxygenase activity and protein-protein interaction between ELMO1 and COX-2 increased COX-2-mediated fibronectin expression. We also found that ET625, the dominant negative form of ELMO1 lacking Rac1 activity, still interacted with COX-2, increased cyclooxygenase activity of COX-2 and enhanced COX-2-mediated fibronectin upregulation. We also evaluated effect of the constitutive active Rac1 ($Rac1^{Q63E}$), and found that activation of Rac1 signaling had no effect on COX-2-mediated fibronectin promoter activity. Our data suggest that ELMO1 contributes to the development of glomerular injury at least partially acting as a posttranslational regulator of COX-2 activity by Rac1-independent mechanism.

**The Regulation of EDA+ Fibronectin Production in Human Tubule Cells** Mysore Keshavmurthy Phanish, Ioana Niculescu-Duvaz, Elisha Seah, Mark Edward Dockrell. *SW Thames Institute for Renal Research, London, United Kingdom.*

Fibronectin (Fn) is an important extracellular matrix component which is expressed as several variant proteins produced as a result of pre-mRNA alternative splicing. The EDA+ variant of Fn is particularly associated with fibrotic diseases including renal fibrosis. EDA+ Fn accelerates fibrosis in a number of diverse ways. In this work, we investigate the regulation of EDA+ Fn in human proximal tubule epithelial cells (PTEC).

Primary and transformed (HKC8) cells were used. Fn expression was assessed by immunofluorescence, Western Blotting (with antibodies to total and EDA+ Fn) and RT-PCR (with a single primer pair producing separate products for EDA+ and EDA-).

Involvement of the splicing factor SRp40 was investigated using RNA interference, Western blotting and immunoprecipitation.

The role of CLK/Sty was investigated using the inhibitor TG003 (10 μM). The role of PI 3-kinase/Akt pathway was investigated using the PI 3-kinase inhibitor LY294002 (5-10 μM) and Western blotting for p-AKT following immunoprecipitation (IP) with SRp40 antibody.

TGFb1 (2.5ng/ml) induced EDA+Fn expression, which was selectively inhibited by SRp40 knock-down. TG003 did not alter TGFb1-induced EDA+ Fn expression; however LY294002 did significantly reduce EDA+ expression. Furthermore LY294002 treatment altered the intracellular distribution of SRp40. TGFb1 also increased the association of SRp40 and p-AKT in IP experiments, which was LY294002 sensitive.

We have presented the first evidence for the regulation of Fn RNA splicing by SRp40, a member of the SR protein family of splicing factors in renal tubule cells. We provide evidence that PI3kinase-AKT signaling regulates this process by a direct interaction between pAKT and SRp40. Targeting the splicing of Fn pre-RNA such that EDA+ inclusion is prevented is an attractive and novel option to combat fibrosis while leaving the more physiological isoforms of Fn intact.

**A Feedback Loop in High Glucose-Induced Inactivation of FoxO1 Regulates Akt Activation, Mesangial Cell Hypertrophy and Fibronectin Expression Via Downregulation of Catalase** Falguni Das,[1] N. Ghosh-Choudhury,[2] C. Mandal,[2] Nirmalya Dey,[1] B. S. Kasinath,[1] Goutam Ghosh-Choudhury.[1] *[1]Medicine, UTHSCSA, San Antonio, TX; [2]Pathology, UTHSCSA, San Antonio, TX.*

We have recently shown that Akt kinase contributes to increased expression of matrix protein fibronectin and hypertrophy of mesangial cells (MC) in response to high glucose (HG; 25 mM). As a mechanism, we considered the Akt substrate transcription factor, FoxO1. HG increased phosphorylation of FoxO1 in MC in a time-dependent and sustained manner, concomitant with enhanced phosphorylation/activation of Akt kinase. To elucidate the role of FoxO1, phosphorylation-deficient constitutively active mutant of FoxO1 (FoxO1/A3) was used. Expression of FoxO1/A3 inhibited and dominant negative FoxO1 (DN FoxO1) increased HG-induced fibronectin expression, respectively. Furthermore, FoxO1/A3 blocked HG-stimulated phosphorylation of the negative regulator of TORC1, PRAS40, resulting in inhibition of TORC1 activation and suppression of protein synthesis, which caused attenuation of MC hypertrophy. Since Akt kinase regulates MC hypertrophy and fibronectin expression, we examined the effect of FoxO1 on Akt activation. FoxO1/A3 decreased HG-stimulated Akt phosphorylation while DN FoxO1 increased it. To elucidate the mechanism, we considered the anti-oxidant protein catalase, which quenches H2O2. HG significantly reduced the expression of catalase in MC in a time-dependent manner, which followed the same kinetics of phosphorylation of Akt and FoxO1. HG induced transport of FoxO1 from the nucleus to cytosol, indicating a role of this transcription factor in reduction of catalase expression. Expression of FoxO1/A3 increased expression of catalase, resulting in reduced abundance of reactive oxygen species. DN FoxO1 decreased the expression of catalase. Furthermore, FoxO1/A3 increased transcription of catalase in a reporter transfection assay. These results represent the first evidence for the presence of a positive feedback loop for phosphorylation of Akt in response to HG involving inactivated FoxO1-dependent catalase downregulation, which may contribute to fibronectin expression and hypertrophy of MC.

**C-Terminal CTGF Fragment Alone Selectively Modulates Pro-Fibrotic Signaling in PTECs** Simon Winn, Ekram Nabi, Mysore Keshavmurthy Phanish, Mark Edward Dockrell. *SW Thames Institute for Renal Research, London, United Kingdom.*

As a matricellular modulator, full-length Connective Tissue Growth Factor (flCTGF) is associated with fibrosis. Cleavage products of CTGF are found in various biological fluids and organ systems. We have previously demonstrated binding to BMP-7 and attenuation of its canonical signaling pathway by a purified 11kDa C-terminal fragment of CTGF (cCTGF). We have further investigated binding to TGFβ and whether other BMP-7 and TGFβ signaling pathways implicated in fibrosis might be similarly affected.

Transformed HKC-8 proximal tubule epithelial cells, known to possess the full complement of ALK receptors, were used to compare the effects of "in-house" flCTGF and cCTGF (Peprotech) on BMP-7 and TGFβ induced signaling using immunoblotting techniques. Real time molecular binding of cCTGF to TGFβ was investigated using Surface Plasmon Resonance, by immobilizing carrier-free cCTGF (129fM/$mm^2$) to a CM5 sensor chip.

TGFβ demonstrated dose dependent binding to the cCTGF peptide across a range of 10 - 40nM; comparable to that seen with BMP7. Unlike BMP7-induced Smad signaling, BMP-7-induced p38 activation was not reduced by co-incubation with flCTGF (100 and 200ng/ml) nor cCTGF (25 and 50ng/ml). Furthermore, the significant induction of pSmads and pp38 by TGFβ (1.25ng/ml) were differentially modulated by co-incubation with similar doses of CTGF; adjunct flCTGF (200mg/ml) caused a further 10-30% increase in the activation of pSmads 1, 2 and 3 as well as pp38 whilst, in the presence of cCTGF, this synergism was only seen for pSmad 3 and pp38 (for TGFβ 5ng/ml) but absent for pSmads 1 and 2.

These results identify cCTGF as a binding partner for TGFβ and BMP-7 and further indicate the emergence of a differential role for flCTGF and cCTGF in the modulation of pro-fibrotic stimuli. The effects on BMP-7 and TGFβ signaling cannot simply be ascribed to extracellular trapping phenomena and likely involve as yet undefined interactions of CTGF peptides with their target receptors. Interestingly, cCTGF by promoting TGFβ induced activation of Smad 3 and p38, as well as selectively attenuating BMP-7 induced Smad signaling may favor a pro-fibrotic phenotype.

**Inhibition of PAI-1 Enhances Transforming Growth Factor β (TGF-β)-Induced Endothelial-to-Mesenchymal Transition (EndMT)** Li-Jun Ma,[1] Dan Gao,[1, 2] Bridgette Corsa,[1] Agnes B. Fogo.[1] *[1]Department of Pathology, Vanderbilt University; [2]Department of Nephrology, First Affiliated Hospital of ZhengZhou University, ZhengZhou, China.*

Background: TGF-β induces both epithelial-to-mesenchymal transition (EMT) and endothelial-to-mesenchymal transition (EndMT), processes that may contribute to kidney fibrosis. TGF-β also induces plasminogen activator inhibitor-1 (PAI-1). We investigated whether inhibition of endogenous PAI-1 in endothelial cells affects TGF-β-induced endMT.

Methods: Mouse glomerular endothelial cells (GENs) were transfected with PAI-1 siRNA (PAI-1 KD, n=3) or CONT siRNA (CONT, n=3) or untreated, and were then stimulated by TGF-β (5 ng/ml) for 48 hrs. Expression of PAI-1 protein, pSmad2 and claudin 5 was examined by Western blot. EndMT was assessed morphologically as well as by expression of mesenchymal marker α-smooth cell actin (α-SMA). Data are expressed as mean±SE.

Results: TGF-β treatment in GENs induced marked transition of endothelial cells into smooth muscle-like cells in vitro, which was associated with increased p-Smad2 expression (11.8-fold, $p<0.05$ vs baseline), and prominent expression of α-SMA, a mesenchymal marker (3.1-fold vs baseline, $p<0.05$). Targeting endogenous PAI-1 in GENs using siRNA reduced PAI-1 protein levels about 80-90%. When siRNA treated GEN cells were stimulated by TGF-β, p-Smad2 levels were significantly but similarly increased in PAI-1 knockdown GENs vs CONT. However, α-SMA protein level was 5.3-fold higher (α-SMA/GAPDH 0.16±0.04 vs 0.03±0.01, $p<0.05$) and claudin 5, a marker of endothelial cells, protein expression was 23% lower in PAI-1 knockdown GEN cells vs CONT, indicating enhanced TGF-β-induced EndMT.

Conclusions: Inhibition of PAI-1 enhances TGF-β-induced endothelial-to-mesenchymal transition through a non-pSmad2 pathway. We speculate that altered proteinases and/or metalloproteinase by PAI-1 in GENs may play an important role in TGF-β-induced EndMT.

**αvβ3-Integrin Activation Promotes TGF-β1 Induction of Collagen Production Via Enhanced Rac1 Activity in Human Kidney Epithelial Cells** Tomoko Hayashida, H. William Schnaper. *Pediatrics, The Feinberg School of Medicine, Northwestern University and Childrens' Memorial Research Center, Chicago, IL.*

We previously showed that integrin engagement-dependent focal adhesion kinase (FAK) phosphorylation modulates TGF-β/Smad fibrogenic signals, via ERK-MAP kinase-mediated phosphorylation of the Smad3 linker region (Hayashida, J Cell Sci, 2007). Utilizing β1-integrin knockdown (k/d) cells, we unmasked the function of αvβ3-integrin, which promotes renal cell collagen production in culture via enhanced Rac1 and ERK activity (ASN 2009). Here, we have applied these findings in regular, β1-integrin-expressing kidney epithelial cell lines (HKC) and sought to further define a mechanism by which αvβ3-integrin interacts with TGF-β/Smad signaling. Phosphorylation of both tyrosine 747 and -759 residues of the β3-integrin cytoplasmic tail in HKCs was induced after 30 min treatment with TGF-β. However, phosphorylation of Tyr 747, but not Tyr 759, was detected in immunoprecipitates with an antibody to αvβ3-integrin, suggesting that phosphorylation of the former is specific to αvβ3-integrin activity. Indeed, in β1-k/d cells where αvβ3-integrin activity is increased, Tyr 747, but not Tyr 759, was constitutively phosphorylated. TGF-β induction of type I collagen promoter activity, determined with a -378 COL1A2-luciferase construct, was enhanced in β3-integrin-overexpressing HKCs compared to control HKCs, whereas Y747F-, but not Y759F mutant of β3-integrin abrogated the response. On the other hand, the collagen response was significantly diminished in CT26 fibroblast-like colon carcinoma cells that lack β3-integrin. Furthermore, β3-integrin-overexpressing HKCs showed enhanced Rac1 activity, similar to those in β1-integrin k/d cells. These findings support the notion that the level of β3-integrin expression is a critical factor for αvβ3-integrin activity that promotes TGF-β-mediated cellular collagen production via Rac1-mediated ERK activity, and that αvβ3-specific tyrosine 747 phosphorylation of β3-integrin is essential for the interaction between the Smad and integrin signals.

**ITA-1 – A Novel Inhibitor of TGF-β1 Signalling** James B. Corcoran, Sarah Mccarthy, Una Bhreathnach, Brenda Griffin, Fionnuala B. Hickey, Finian Martin, Catherine Godson, Madeline Murphy. *Diabetes Research Centre, University College Dublin, Dublin, Ireland.*

We have recently described *Induced in high glucose-1 (IHG-1),* an evolutionarily conserved gene transcript increased in diabetic nephropathy. IHG-1 enhances the actions of TGF-β1 and may contribute to the development of tubulointerstitial fibrosis (TIF) (Murphy et al., J. Am Soc Nephrol 2008) TGF-β1 plays a key role in TIF. Although highly conserved IHG-1 has no functional homology to other proteins apart from a putative mitochondrial targeting sequence (mts). We have confirmed that IHG-1 localizes primarily to mitochondria in mammalian cells. Here we investigate whether mitochondrial localization of IHG-1 is necessary to amplify TGF-β1 signal transduction. Amino acids 9-22 of the putative mts were deleted (Δmts-IHG-1) and the mutant IHG-1 protein expressed in human renal epithelial (HK-2) cells. Overexpressed Δmts-IHG-1 localised to the cytoplasm indicating the putative mts is essential for mitochondrial localization of IHG-1. Δmts-IHG-1 inhibited TGF-β1- fibrotic responses including increased expression of fibronectin, CTGF and the notch ligand Jagged1. Δmts-IHG-1 expression also decreased TGF-β1-driven activation of the PAI-1 promoter, pARE-lux, a Smad 2 responsive promoter and SBE-luc a Smad3 responsive promoter. Δmts-IHG-1 inhibited gene expression of fibronectin, CTGF and Jagged1 induced by overexpression of the constitutively active TGF-β type 1 receptor and the TGF-β1 signal mediators Smad 2 and Smad3, indicating modulation of Smad function. Increased migratory ability of epithelial cells is a feature of epithelial-to-mesenchymal transition, a process believed to contribute to TIF. Δmts-IHG-1 inhibited TGF-β- stimulated HK-2 cell migration. These data indicate that (1) the putative mts is necessary for localization of IHG-1 to mitochondria (2) IHG-1 must retain the potential to associate with mitochondria in order to amplify TGF-β1 induced transcriptional responses and (3) Δmts-IHG-1 is an inhibitor of TGF-β1 induced cellular responses. We have renamed Δmts-IHG-1 as ITA-1 i.e. inhibitor of TGF-β1 activity 1 and propose ITA-1 as a novel biotherapeutic for the treatment of fibrotic kidney disease

**Active PI3-Kinase Maintains Expression of the EMT-Antagonist Protein SARA** Constance Runyan, Xiaoying Liu, H. William Schnaper. *Division of Kidney Diseases, Department of Pediatrics, Feinberg School of Medicine, Northwestern University, Chicago, IL.*

TGF-β1 promotes renal fibrosis in part, by promoting epithelial to mesenchymal transition (EMT). We have previously shown that the Smad anchor for receptor activation (SARA) helps maintain an epithelial cell phenotype, and that reduction of SARA by TGF-β1 or other means stimulates events associated with EMT. Here we investigated signaling pathways that might regulate SARA expression. Treatment of human kidney proximal tubular epithelial (HKC) cells with a panel of kinase inhibitors demonstrated variable effects on SARA expression levels. The PI3-kinase (PI3K) inhibitor LY294002 caused a reduction in SARA protein expression independently of TGF-β1. Conversely, expression of the constitutively active catalytic subunit of PI3K increased SARA expression. Additionally, we found a correlation between basal SARA expression and PI3K activity in a variety of cell types. Together these data suggested that PI3K activity levels might be related to SARA expression with high levels of active PI3K being protective for expression of SARA. In agreement with our previous findings that a loss of SARA expression was sufficient to induce de novo expression of the EMT marker αSMA, the expression of αSMA was elevated in LY294002-treated HKC. Treatment of HKC with an inhibitor specific for the PI3K downstream signaling-mediator Akt (Akt inhibitor IV) caused a similar reduction in SARA to that of LY294002, suggesting that downstream signaling is required. Neither LY294002 nor Akt inhibitor IV affected SARA mRNA expression, so the stabilizing effect of PI3K activity is likely at the level of SARA protein. Although endosomal localization is considered crucial for SARA function, we found no appreciable difference in co-localization between SARA and the early endosomal marker EEA1 in the presence of LY294002. Taken together these results suggest that high levels of active PI3K and downstream Akt may stabilize SARA protein expression by some means other than modification of SARA transcription or localization.

**F-PO1119**

**Renal Lipocalin-Type Prostaglandin D2 Synthase (L-PGDS) Exerts Reno-Protective Effects on Unilateral Ureteral Obstruction (UUO)** Hideyuki Ito,[1] Motoaki Sano,[2] Yasunori Utsunomiya,[1] Keiichi Fukuda.[2] *[1]Division of Kidney and Hypertension, The Jikei University School of Medicine, Tokyo, Japan; [2]Division of Cardiology, Keio University School of Medicine, Tokyo, Japan.*

L-PGDS is responsible for the synthesis of PGD2 from common precursor PGH2. We recently reported that L-PGDS-mediated PGD2 *de novo* synthesis plays a cardioprotective role in ischemia/reperfusion injury (JCI 2009). In addition, several clinical studies have linked L-PGDS to a variety of pathological conditions in human. The serum and urinary L-PGDS level, for instance, is increased in patients with hypertension and with diabetic nephropathy. Recent studies revealed that L-PGDS is endogenously expressed in kidneys, especially in the proximal tubules. However, the precise roles for L-PGDS mediated $PGD_2$ constructional system in the tubulointerstitium remain to be elucidated. Then, to investigate whether renal L-PGDS have reno-protective effects, we performed UUO in L-PGDS knockout (LKO) mice and wild-type (WT) mice.

As the results, L-PGDS protein and gene expression drastically increased in the cortexes from UUO kidneys of WT mice and that L-PGDS immunoreactivity was significantly increased in the proximal tubules. Furthermore, UUO-induced tubular dilatation and tubulointerstitial fibrosis deteriorated in UUO kidneys of LKO mice compared to those of WT mice. At that point, the gene expression of IL-1β was significantly up-regulated, and those of IL-6, TGF-β and TNF-α also pointed to increase in WT/UUO kidneys comparing with LKO/UUO kidneys. In contrast, the expressions of local renin and angiotensinogen in LKO/UUO kidneys resembled those in WT/UUO kidneys. Of note, quantitative RT-PCR showed that the gene expression of angiotensin II type 2 receptor (AT2R) was down-regulated in LKO/UUO kidneys, whereas AT1R expressed in LKO/UUO kidneys as the same to WT/UUO kidneys. In addition, AT2R gene expression was down-regulated not only in kidney, but in brain and in heart obtained from LKO mice.These data suggest that L-PGDS is up-regulated in the proximal tubules of UUO kidneys and that L-PGDS may attenuate tubulointerstitial injury through modulating the gene expression of AT2R.

**Sphingosine-1-Phosphate Is One of the Key Molecules Directly/Indirectly Mediating Fibrosis in the Kidney** Shunji Shiohira, Takumi Yoshida, Junko Kohei, Hidekazu Sugiura, Michihiro Mitobe, Ken Tsuchiya, Kosaku Nitta. *Department of Medicine IV, Tokyo Women's Medical University, Shinjuku, Tokyo, Japan.*

The major sphingolipid metabolite, sphingosine-1-phosphate (S1P), is now attractive and bioactive molecule for a potential mediator of renal fibrosis. In our past report, S1P induced fibrosis *in vitro* in normal rat kidney interstitial fibroblast cells (NRK-49F), and *in vivo* in the kidneys of a mouse model of unilateral ureteral obstruction (UUO). S1P is likely to have potentiality to mediate directly renal fibrotic processs in addition to via inflammaroy pathway. To clarify the mechanism of S1P in renal fibrosis, we adopted UUO model using nude mice which were characterized by deficit of immune response. The expression of S1P receptor subtype was analyzed in UUO and NRK-49F. The expression (mRNA and Western blot) of fibrosis marker, such as α-SMA, E-cadherin, etc., were examined and also histological changes were analyzed. (fibronectin (FN) and collagen type1 (COL1)). S1P receptor subtype (1-5) mRNA expression was examined by RT-PCR in NRK-49F and UUO. Fibrotic change was successfully induced in nude mice in which the staining intensity of FN and COL1 was prominent. The change was attenuated directly by FTY720 (S1P receptor 1,3,4,5 as antagonist), or DMS (sphingosine kinase inhibitor), suggesting another possible mechanism of S1P-induced fibrosis in addition to the inflammatory pathway. On the other hand, S1P is known to have unique tissue distribution of the receptor subtypes and the differing signaling pathways resulting from S1P receptor (S1PR) subtype activation. NRK-49F showed mRNA expressions of S1PR 1, 2, 3 and 5, but not S1PR 4. FTY720 is S1PR 1,3,4,5 antagonist. S1PR 1 is mostly related with inflammatory pathway and S1PR 5 is involved in the regulation of nervous system. Thus, these results suggest that S1PR 3 is likely to play main role in renal fibrosis. In conclusion, S1P is a hitherto unrecognized

profibrotic mediator in the renal tubulo-interstitium that functions through S1PR signaling pathways, in part, via direct fibrotic effect.

**Nephrogenic Systemic Fibrosis: The Gadolinium-Based Magnetic Resonance Imaging Contrast Agent, Omniscan, Triggers Fibroblast Proliferation and Fibronectin Synthesis in a Redox-Dependent Manner** Brent Wagner.[1,2] *[1]Audie L. Murphy Memorial Hospital, South Texas Veterans Health Care System, San Antonio, TX; [2]Department of Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX.*

**Purpose of the study:** Nephrogenic systemic fibrosis (NSF) is a recently recognized disorder in acute kidney injury, chronic kidney and end stage renal diseases. NSF is strongly correlated with exposure to gadolinium-based magnetic resonance imaging (MRI) contrast. Little is known about the mechanisms that trigger NSF and current treatments do not yield promising results. This study was conducted to examine potential mechanisms by which a common contrast reagent, Omniscan, elicits fibrosis.

**Methods:** Human foreskin fibroblasts (HFFs) were treated with clinically-relevant doses of Omniscan. Fibronectin and levels of phosphorylated protein were assessed by immunoblot. DNA synthesis was measured by incorporation of [$^3$H]-thymidine into TCA-precipitable material. Reactive oxygen species generation was assessed by confocal microscopy of 2',7'-dichlorodihydrofluorescein- (DCF-) loaded cells.

**Results:** Omniscan induced fibronectin synthesis in HFFs by 24 and 48 h in dose-dependent manners. MRI contrast-treated cells expressed $\alpha$-smooth muscle actin$^+$ stress fibers to a similar degree as TGF-$\beta$ treatment. Time-dependent reactive oxygen species generation was also induced by Omniscan. Both Omniscan-induced fibronectin synthesis and DNA synthesis were suppressed by pretreatment with *N*-acetyl cysteine (NAC). After Omniscan treatment, levels of phospho-extracellular signal-regulated kinase (ERK) and phospho-Akt increased in time-dependent manners. Both NAC and the ERK inhibitor U0126 suppressed the Omniscan-induced fibronectin increase. Omniscan treatment decreased the cell cycle inhibitor $p27^{Kip1}$.

**Conclusions:** Pharmacologically-relevant doses of the MRI contrast agent Omniscan led to an increase in fibronectin and DNA synthesis in HFFs *in vitro*. These data demonstrate that the mechanisms are redox- and ERK pathway-dependent. Elucidation of the cellular effects of gadolinium-based contrast on fibroblasts may aid in tailoring therapies to this devastating disease.

### F-PO1122

**Activated EPAC-Rap1 GTPase Signaling Pathway Attenuates Membrane Trafficking of $Na^+/H^+$ Exchanger 3 (NHE3) Induced by Angiotensin II in Proximal Tubular Cells** Ping Xie,[1] Lin Sun,[1] Fu-You Liu,[2] Yashpal S. Kanwar.[1] *[1]Department of Pathology, Northwestern University Medical School, Chicago, IL; [2]Department of Nephrology, Second Xiangya Hospital of Central South University, Changsha, Hunan, China.*

Angiotensin II (ANG II) acts directly on the proximal tubules in promoting $Na^+$ reabsorption by modulating Na/H exchanger 3 (NHE3). NHE3 is considered to be regulated by cAMP stimulation. The purpose of the present study was to determine the effect of EPAC, a guanine nucleotide exchange factor for Rap1, on the ANG II modulation of NHE3 in Sprague-Dawley rat kidney slices and LLC-PK1 cells. Incubation of kidney slices up to 15 min with $10^{-11}$M ANG II induced the NHE3 redistribution from base to the tip of microvilli in proximal tubules. This process was attenuated by the addition of EPAC activator (8-pCPT-2'-O-Me-cAMP-AM) without any discernible change in total and phosphorylated NHE3. In LLC-PK1 cells, the membrane trafficking of NHE3 induced by ANG II was also attenuated by activation of EPAC pathway, and this effect of EPAC was blocked by transfection of LLC-PK1 cells with dominant negative mutant of EPAC1. In addition, the activity of Rap1, downstream effector of EPAC, was noted to be decreased by stimulation of ANG II in LLC-PK1 cells, and this effect was significantly diminished by blockade of ANG II type I receptor with losartan. To confirm the role of Rap1 in the regulation of NHE3, constitutively active mutants of Rap1a (G12V and T35A) as well as the dominant negative mutant of Rap1a (S17A) were introduced into the LLC-PK1 cells. The activated Rap1 reversed the NHE3 membrane trafficking induced by ANG II. Inhibitory effect of the EPAC activator on NHE3 membrane trafficking was blocked by the dominant negative mutant of Rap1a. No significant differences in the expression of total NHE3 or phosphorylated NHE3 in various groups were observed. These results suggest that EPAC1-Rap1 axis may be a novel potential pathway in the NHE3 regulation by ANG II in proximal tubules.

Disclosure of Financial Relationships: nothing to disclose

### F-PO1123

**Attenuation of Angiotensin (Ang) II-Induced Cells Signalling by Ang1-7 Is cAMP-PKA Dependent** George Chu Liu,[1] Xiaohua Zhou,[1] James W. Scholey.[1] *[1]Medicine, University of Toronto, Toronto, ON, Canada; [2]Medicine, University of Alberta, Edmonton, AB, Canada.*

The renin-angiotensin system (RAS) plays an important role in renal physiology and pathophysiology. Although the cellular effects of the RAS activation are generally attributed to AngII, the recent identification of angiotensin converting enzyme-2 (ACE2) has shifted focus to the biologic effects of other angiotensin peptides, including Ang1-7. The G protein coupled receptor for Ang1-7, mas, is expressed by mesangial cells (MC), and Ang1-7 has been reported to attenuate AngII cell signalling in MC. Accordingly, we sought to better understand both the signal transduction pathways activated by Ang1-7, and the interaction between Ang1-7 and AngII in MC. We first observed that there was a time and concentration-dependent effect of Ang1-7 on ERK phosphorylation. Pre-treatment of MC with the mas receptor antagonist D-Ala$^7$ but not the $AT_1$ antagonist, loasrtan, or the $AT_2$ antagonist, PD11042, abrogated Ang1-7 induced ERK activation. Neither pre-treatment with the NADPH oxidase inhibitors, DPI (10$\mu$M) and apocynin (100$\mu$M), nor pre-treatment with the EGF receptor antagonists, AG1478 (0.2$\mu$M) and PD158780 (10$\mu$M), attenuated Ang1-7 activation of ERK, although each of these compounds abolished activation of ERK by AngII. Ang1-7 increased intracellular cAMP levels and activated protein kinase A (PKA) in MC, and inhibition of adenylyl cyclase (SQ22536, 0.1mM) or inhibition of PKA activity (H89, 1$\mu$M) attenuated Ang1-7 induced ERK activation. Pre-treatment with Ang1-7 reduced Ang II-induced NADPH oxidase activation and ERK activation in MC in a cAMP-PKA-dependent manner. In conclusion, Ang1-7-induced activation of ERK is cAMP/PKA dependent in MC, and independent of NADPH oxdase and the EGF receptor. Ang1-7 also inhibits AngII-induced NADPH oxidase thus preventing ERK activation by AngII. These effects may account, at least in part, for the attenuation of experimental models of glomerular injury by Ang1-7.

### F-PO1124

**Ryanodine Receptors Mediate Calcium Sensing Receptor-Induced Inhibition of Renin** Mahendranath Reddy, Cecilia Ortiz-Capisano, Jeffrey L. Garvin, William H. Beierwaltes. *Dept. Int Med, Hypertension Research Div., Henry Ford Hospital, Detroit, MI.*

Renal juxtaglomerular (JG) cells contain G-protein coupled calcium-sensing receptors (CaSR) which sense changes in extracellular calcium, stimulating calcium-mediated intracellular signaling. The ryanodine receptor regulates release of calcium from intracellular stores. We hypothesized calcium activation of JG cell CaSR initiates a pathway involving the ryanodine receptor, release of intracellular calcium, inhibiting cAMP production, reduced protein kinase A, retarding cAMP-mediated renin secretion. We measured renin released from primary cultures of JG cells isolated from C57 mice, plated at 80-90% confluence for 48 hrs. Activation of JG cell CaSR using the calcimimetic Cinacalcet ($1_\mu$M) in media containing low, normal or high calcium decreased renin release by 70% in all three (0.88±0.15 to 0.24±0.05, 0.84±0.18 to 0.20±0.04, and 0.50±0.12 to 0.15±0.04 ug ANG-I/ml/hr/mg prot, ($p<0.005$). In contrast, adding the calcilytic Ronacaleret ($1_\mu$M) completely inhibited extracellular calcium-mediated activation of CaSR. This shows that changes in extracellular calcium are sensed by JG cell CaSR to regulate renin release. Inhibiting the ryanodine receptors with high concentrations ($0.1_\mu$M) of ryanodine reversed Cinacalcet inhibition of renin (0.13±0.02 to 0.07± 0.01 ugAng1/ml/mg prot with Cinacalcet, $p<0.01$, returning to 0.13±0.01 uAng-I/ml/hr/mg prot with Cinacalcet plus Ryanodine). Similarly, cinacalcet reduced JG cell cAMP formation (from 1.09±0.to 0.75±0.26 pM/mg prot, $p<0.025$, but returned to 1.50±0.35 pM/mg prot with cinacalcet plus ryanodine. This suggests CaSR activation of the ryanodine receptor results in calcium-mediated inhibition of cAMP formation. To mimic the effect of cAMP, we added NZ-B6, a Protein Kinase-A (PKA) agonist (0.2 mM), which increased renin release from 0.51±0.11 to 0.85±0.18 uAng-I/ml/hr/mg prot ($p<0.025$). Our data suggest extracellular calcium activation of the JG cell CaSR results in activation of a pathway involving ryanodine receptor induced release of intracellular calcium stores, inhibiting adenylyl cyclase cAMP production, diminishing PKA, and retarding cAMP-mediated renin secretion.

### F-PO1125

**Convergence of Serine/Threonine and Tyrosine Signaling on Synaptopodin Balances Cathepsin-Regulated Actin Dynamics** Lisa Buvall,[1] Hoon Young Choi,[3] Christian Faul,[2] Peter H. Mundel.[1] *[1]Dep of Medicine/Division of Molecular Medicine, University of Miami, Miami, FL; [2]Dep of Medicine/Division of Nephrology, University of Miami, Miami, FL; [3]Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea.*

Serine/threonine and tyrosine signal-transduction pathways influence many aspects of cell behavior, including spatial and temporal regulation of cytoskeletal dynamics. We previously reported a physiological role for cathepsin L (CatL) in the cytoplasm, where it mediates the calcineurin-dependent, CatL-mediated proteolysis of synaptopodin, a regulator of Rho GTPases in kidney podocytes. Phosphorylation of synaptopodin by PKA or CaMKII promotes 14-3-3 binding and protects synaptopodin from cleavage by CatL. Dephosphorylation of synaptopodin by calcineurin abrogates 14-3-3 binding, thereby allowing the degradation of synaptopodin by CatL. Here we identify a signaling pathway that directly links serine/threonine to tyrosine phosphorylation-controlled actin remodeling. We found that the tyrosine kinase Src can bind to synaptopodin and induce the tyrosine phosphorylation of synaptopodin. This, in turn increases the binding of calcineurin to synaptopodin, thereby promoting serine/threonine dephosphorylation and CatL-mediated synaptopodin degradation and loss of stress fibers. Src-resistant Synpo-TA, calcineurin-resistant Synpo216E619D, and CatL-resistant Synpo-CM1+2 are protected from Src-induced, CatL-mediated degradation of synaptopodin. Our results unveil how dual serine/threonine and tyrosine phosphorylation of an actin organizing protein can regulate cytoskeletal dynamics in an antagonistic fashion.

**F-PO1126**

**Podocytes Lacking CD2AP Have Less Non-Muscle Myoin II Activity** Hani Suleiman, Andrey S. Shaw. *Pathology & Immunology, Washington University, Saint Louis, MO.*

CD2-associated protein (CD2AP) is a scaffold protein that plays a critical role in the maintenance of the kidney filtration barrier. Previous works suggested a role for CD2AP in regulating the actin cytoskeleton. We show that conditionally immortalized mouse podocytes lacking Cd2ap (-/-) have less prominent actin stress fibers. Moreover, Cd2ap (-/-) podocytes have a defect in focal adhesion turnover. This phenotype can be partially rescued by introducing Cd2ap back to the cells. Non-muscle myosin II is an actin-binding protein important for actin cross-linking as well as providing the cell with contractile properties. Here, we show that Cd2ap (-/-) podocytes lacks myosin light chain phosphorylation (pMLC) on Ser19, a key regulated for non-muscle myosin II activity. Data from our lab suggests a defect in RhoA-Rock pathway, a major regulator of pMLC, to be the cause of this phenotype.

Disclosure of Financial Relationships: nothing to disclose

**Pdlim2 Is a Novel Podocyte Protein Involved in Actin Dynamics** Laleh Sistani, Karl Tryggvason, Jaakko Patrakka. *Division of Matrix Biology, Department of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden.*

Pdlim2 is a member of a family of ALP proteins containing both PDZ and LIM domains. These proteins have been implicated in the actin filament organization. We have identified Pdlim2 as a novel podocyte foot process protein by microarray analyses of the mouse glomerulus transcriptome, and subsequent generation of an antibody against the corresponding human protein. Using this antibody, Pdlim2 was detected in immunofluoresence staining exclusively in podocyte foot processes. This specific expression pattern was confirmed by Western blotting. To define the role of Pdlim2 in podocytes, we used yeast-2-hybrid screening, and found interaction with the disease-associated protein, α-actinin-4, which was confirmed with co-immunoprecipitation. This interaction was mapped to the C-terminus of α-actinin-4, whereas pdlim2 needed both pdz- and lim-domains for the interaction with α-actinin-4. In cultured podocytes, Pdlim2 localizes to stress fibers and cortical actin. Both pdz- and lim-domains were required for the targeting of pdlim2 to these structures. In podocytes, pdlim2 stabilized stress fibers as these structures were more resistant to latrunculin A treatment in the presence of pdlim2. In conclusion, we have identified Pdlim2 as a new molecular component of podocyte foot processes in where it seems to play a role in regulating actin cytoskeleton dynamics.

Disclosure of Financial Relationships: nothing to disclose

**Nephrin Recruits the Cellular Inositol Phoshpatase SHIP2 To Regulate Actin Filament Morphology** Puneet Garg, Leslie Cook, Kamal Abuarquob, Madhusudan M. Venkatareddy. *Department of Internal Medicine, University of Michigan, Ann Arbor, MI.*

Regulated actin dynamics determines podocyte morphology during development and in response to podocyte injury. Nephrin-Neph1 receptor complex has been shown to regulate actin dynamics by assembling a protein complex including Nck, Grb2, Arp2/3 and nWASp which are involved in nucleation of the actin filament. To identify proteins which interact with Nephrin we generated a library of 140 SH2 domain containing recombinant proteins. We report here that Nephrin recruits SHIP2 a SH2-containing 5'-inositol phosphatase2 in a phosphorylation dependent manner and in doing so regulates the morphology of actin filament. SHIP2 is a phosphatase that dephosphorylates phosphoinositol 3,4,5 phosphate (PIP3) to generate phosphoinositol 3,4 phosphate [PI(3,4)P2]. We have previously shown that Nephrin interacts with p85 subunit of PI3 Kinase. Activation of PI3 kinase at the membrane by Nephrin results in generation of PIP3. Nephrin further recruits Ship2 which dephosphorylates PIP3 to PI(3,4)P2 providing a lipid signaling platform essential for the specific recruitment of the cytoskeletal regulator Lamellipodin to control actin pedestal morphology. We hypothesized that Nephrin-p85 interaction results in generation of PI(3,4) P2 in a SHIP2 dependent fashion. We were able to co-immunoprecipitate Nephrin and SHIP2 from glomerular lysates, and also in lysates from transfected podocytes. Using a cultured podocyte model of Nephrin activation described previously by us (induced clustering of CD16/7-Nephrin chimeric protein and various mutants), we found that nephrin activation and clustering results in recruitment of GFP-SHIP2 to Nephrin. Furthermore RNAi mediated Ship2 knock down in cultured cells resulted in distinctly different and aberrant actin tail morphology in response to clustering of CD16/CD7/ Nephrin chimeric protein. These observations provide evidence that Nephrin is not only able to initiate actin polymerization but also assembles/regulates a complex of proteins which not only maintains the actin filament but also determines the architecture of the generated actin network.

**Fluid Shear Stress Induces Renal Epithelial Gene Expression through Polycystin-2 Dependent Trafficking of Extracellular Regulated Kinase** Rajeev Rohatgi,[1, 2, 3] G. Luca Gusella,[1] Daniel Armando Flores.[1] *[1]Medicine, The Mount Sinai School of Medicine, New York, NY; [2]Medicine, The James J. Peters VA Medical Center, Bronx, NY; [3]Pediatrics, The Mount Sinai School of Medicine, New York, NY.*

The cilium and cilial proteins have emerged as the principal mechanosensors of renal epithelial cells responsible for translating mechanical forces into intracellular signals. Polycystin-2 (PC-2), a cilial protein, regulates shear induced changes in intracellular $Ca^{2+}$ and, recently has been implicated in the regulation of mitogen activated protein (MAP) kinases. We hypothesize that fluid shear stress (FSS) activates PC-2 which regulates MAP kinase and, in turn, induces MAP kinase dependent gene expression, specifically, monocyte chemoattractant protein-1 (MCP-1) mRNA. To test this, PC-2 expression was constitutively reduced in a murine inner medullary collecting duct (IMCD3) cell line, and the expression of FSS-induced MCP-1 mRNA expression (by quantitative RT-PCR) and MAP kinase signaling (by Western blotting) compared between the parental (PC-2 expressing) and PC-2 deficient IMCD3 cells. FSS of 0.4 dynes/cm$^2$ (a physiologic level of FSS) for 2 hrs induced MCP-1 mRNA expression by ~10 fold in IMCD3 cells compared to static controls ($p<0.05$). IMCD3 cells treated to the same level and duration of FSS induced extracellular regulated kinase (ERK) and c-Jun N-terminal kinase (JNK) phosphorylation, as early as 10 and 60 min, respectively, after exposure to FSS. Inhibition of the ERK (U0126, 10μM) or JNK (SP600126, 30μM) pathways either abrogated or reduced the FSS-induced MCP-1 mRNA response, respectively, in IMCD3 cells. In contradistinction, FSS **did not** induce MCP-1 mRNA expression in PC-2 deficient cells, but **did** increase phosphorylation of the upstream ERK and JNK proteins. Immunocytochemistry of PC-2 expressing and deficient cells did not reveal gross abnormalities in cilia structure. However, wildtype cells exposed to FSS augmented the nuclear abundance of phospho-ERK in 3 of 4 experiments while PC-2 deficient cells did not (n=2). We conclude that PC-2 is a regulator of FSS-induced ERK trafficking and gene expression in collecting duct cells.

**Epidermal Growth Factor (EGF) Suppresses Chaperone-Mediated Autophagy (CMA) Via FoxO1 Transcription Factors in Kidney Cells** Harold A. Franch,[1,2] Changlin Ding,[2] Sara Zoromsky.[2] *[1]Atlanta VAMC; [2]Emory University.*

Reduced CMA during diabetic renal hypertrophy causes accumulation of oxidized proteins. Kidney growth suppresses CMA via Akt signaling. However, oxidative stress (OS) increases CMA but also increases Akt signaling. How can Akt suppress CMA when OS activates Akt? Perhaps isoform differences in EGF and OS Akt-mediated phosphorylation (P) of forkhead transcription factors (FoxOs 1,3a, and 4) explain different CMA activities. At 48 hrs in NRK-52E tubular cells, 10 nM EGF reduced proteolysis, increased CMA marker protein pax2(2.7 fold), and decreased the CMA receptor, LAMP2a (54%, $p<0.05$, n=4), consistent with reduced CMA. OS ($H_2O_2$100μM) did not reduce proteolysis, increase pax2, or decrease LAMP2a. EGF and OS both increased Akt phosphorylation equally and,using a FoxO response element luciferase reporter, reduced FoxO transcription. Akt regulates FoxO abundance and thus activity by P on T and S sites. Using phospho-specific antibodies, EGF for one hour induced FOXO1 T34 P(255%, $p<0.05$) and FoxO3a T24 P(>10-fold), while OS had little effect (40% & -4%, NS, n=3). EGF increased FoxO4 S193 P (220% $p<0.05$), while OS induced phosphorylation of FoxO4 S193 (>10-fold). EGF decreased FoxO1 and FoxO4 abundance by 40% and 31%($p<0.05$)at one hour, but did not change FoxO3a. OS decreased FoxO4 abundance by 69%($p<0.05$), but not FoxO3a or FoxO1. Adenoviral expression of constitutively active (CA) FoxO1 activated FoxO luciferase 3-fold, reversed EGF-induced Pax2 and GAPDH accumulation, and increased the expression of the LAMP2a consistent with increased CMA. CA FoxO1 accelerated lysosomal protein-degradation by 21+4% (n=12, $p<0.01$) and FoxO1 DN reduced proteolysis. siRNA against FoxO1 or 3a reduced these proteins by >60% or >80% and FoxO luciferase activity 50% or 20% respectively. EGF or FoxO1 siRNA, but not OS, scrambled or FoxO3a siRNA, reduced CMA as measured by peri-nuclear LAMP2a aggregates. Thus EGF and OS both activate Akt, but EGF reduces FoxO1 abundance which regulates CMA, while OS reduces FoxO3a and FoxO4 abundance. FoxO isoform specificity may allow for growth factor suppression of CMA in the presence of oxidative stress during diabetes.

**Anti-Inflammatory Potential of Subtilase Cytotoxin: Dual Suppression of NF-κB Via Induction of C/EBPβ and mTOR-Mediated Dephosphorylation of Akt** Shotaro Nakajima, Tao Huang, Jian Yao, Masanori Kitamura. *Department of Molecular Signaling, University of Yamanashi, Chuo, Yamanashi, Japan.*

We recently reported that administration of subtilase cytotoxin (SubAB) triggers the unfolded protein response (UPR) and protects mice from endotoxic lethality and collagen arthritis (J Immunol. 183: 1368-1374, 2009). We found that pretreatment with SubAB suppressed TNF-α-induced activation of NF-κB and NF-κB-dependent gene expression. To elucidate underlying mechanisms, we investigated involvement of C/EBPβ and Akt, the putative regulators of NF-κB. Among members of the C/EBP family, SubAB preferentially induced expression of C/EBPβ. Overexpression of C/EBPβ suppressed TNF-α-induced NF-κB activation, and knockdown of C/EBPβ blunted the suppressive effect of SubAB on NF-κB. We identified that the ATF6 branch of the UPR played a crucial role in the

induction of C/EBPβ. In addition to this effect, SubAB depressed basal and TNF-α-inducible phosphorylation of Akt via mTOR, which was also mediated by the ATF6 pathway. Several inducers of the UPR shared this suppressive effect, and chemical chaperones reversed the inhibition of Akt by SubAB. Blockade of Akt phosphorylation attenuated activation of NF-κB by TNF-α, suggesting that Akt is another target of SubAB-triggered, UPR-mediated NF-κB suppression. These results elucidated that SubAB depresses activation of NF-κB through dual mechanisms; *i.e.,* ATF6-mediated induction of C/EBPβ and suppression of Akt via mTOR.

**Activation of ERK and mTOR Signalling Pathways Via the Purinergic Receptors in Macrophages** Simona Deplano,[1] Reiko Hewitt,[1] Robert J. Unwin,[2] Frederick W. K. Tam.[1] *[1]Renal Medicine, Imperial College Kidney and Transplant Institute, London, United Kingdom; [2]Nephrology, University College London Medical School, London, United Kingdom.*

**Purpose:**

P2X7 receptor (P2X7R) plays a critical role in the pathogenesis of glomerulonephritis and in the release of active pro-inflammatory cytokines from LPS-primed macrophages. There is an incomplete understanding of the signalling cascade following ATP stimulation.

**Methods:**

Primary bone marrow derived macrophages (BMDM) from wild type (WT) and P2X7R knock out (P2X7-/-) mice were used.

(1). We examined the effects of P2X7R agonist BzATP on IL-1β secretion in both WT and P2X7-/- BMDM. ELISA was used to detect mature IL-1β in cell culture supernatant.

(2). We examined the effect of BzATP stimulation on the activation of two key regulators of cell growth, ERK and mTOR, in WT and P2X7-/- BMDM. Western blotting was used to detect both phosphorylated and total ERK, and S6 proteins.

**Results:**

(1). As already shown in peritoneal macrophages, our data confirm that LPS-primed BMDM from WT mice produce high levels of IL-1β in response to BzATP stimulation, while the P2X7-/- BMDM failed to produce this active cytokine. Furthermore, the WT BMDM produced high levels of active IL-1β when stimulated with the human cathelicidin-derived peptide LL37, a novel P2X7R activator, in a dose-dependent manner.

(2). BzATP stimulation led to a greater increase of ERK phosphorylation in WT BMDM compared with P2X7-/- BMDM, suggesting direct involvement of P2X7 receptor in this event. BzATP stimulation also induced an increase in phosphorylation of S6, a downstream effector of mTOR, but no significant differences were observed between the WT and P2X7-/- BMDM, suggesting that other purinergic receptors may be involved in this process.

**Conclusions:**

These preliminary data show the contribution of the P2X7R in the activation of the ERK signalling pathway, which is known to regulate many important processes such as cell growth and apoptosis. Further, investigations are required to identify the purinergic receptors activating the mTOR signalling pathway.

**F-PO1133**

**Differential Regulation of Adenylyl Cyclases in Lipid Rafts in Human Kidney Cells** Peiying Yu,[1] Yanrong Zhang,[2] Pedro A. Jose.[3] *[1]Center for Molecular Physiology Research, Children's National Medical Center, Washington, DC; [2]Center for Molecular Physiology Research, Children's National Medical Center, Washington, DC; [3]Center for Molecular Physiology Research, Children's National Medical Center, Washington, DC.*

Dopamine $D_1$-like receptors ($D_1$ and $D_5$) stimulate adenylyl cyclase (AC), whereas the $D_2$-like receptors ($D_2$, $D_3$ and $D_4$) inhibit AC. We tested the hypothesis that $D_1$ and $D_5$ receptors differentially regulate AC isoform expression and activity in lipid rafts (LRs) in human embryonic kidney (HEK-293) cells heterologously expressing either human $D_1$ or human $D_5$ receptor (HEK-h$D_1$ and HEK-h$D_5$ cells). In the basal state, AC6 was expressed in LRs to a greater extent in HEK-h$D_1$ cells (84.5±2.3 %) than in HEK-h$D_5$ cells (68.9±3.1 %) (ANOVA, $P<0.05$, n=4) while AC7 expression in LRs was similar in the two cell lines (12.1± 0.8% and 13.3±4.1%, respectively). The $D_1$-like receptor agonist fenoldopam (1μM/15 min) *increased* AC6 expression in LRs up to 92.5±1.4% ($P<0.01$, vs. control, n=4) in HEK-h$D_1$ cells. In contrast in HEK-h$D_5$ cells, fenoldopam (1μM/l5 min) decreased AC6 expression in LRs down to 48.9±5.3% ($P<0.05$, vs. control, n=4). Disruption of LRs with methyl-β-cyclodextrin (βCD, 2%/1hr) markedly decreased AC activity in both cell lines ($D_1$R: 0.20± 0.08 vs. control=3.54± 0.22 pmol/mg/50μl; $D_5$R: 0.61± 0.11 vs. control=6.01± 0.59 pmol/mg/50μl, $P<0.001$, n=4/groups, ANOVA). Fenoldopam differentially augmented AC activity in cells pre-treated with βCD; a greater stimulatory effect was noted in HEK-h$D_1$ than in HEK-h$D_5$ cells (HEK-h$D_1$: βCD+Fen=+653 ±73% vs. βCD alone; HEK-h$D_5$: βCD+Fen=315.7±14.7% vs. βCD alone, n=4/group, $P<0.05$ ANOVA). These studies show for the first time that: 1) AC6 is differentially distributed in LRs and nonLRs; 2) disruption of LRs also differentially affects agonist-dependent cAMP accumulation in HEK-h$D_1$ and HEK-h$D_5$ cells. We conclude that LRs are essential not only for the proper membrane distribution and maintenance of AC6 activity but also the regulation of $D_1$ and $D_5$ receptor-mediated AC signaling.

**Endoplasmic Reticulum Stress Disturbs Erythropoietin Gene Expression in a HIF-Dependent Manner** Chih-Kang Chiang, Masaomi Nangaku, Tetsuhiro Tanaka, Toshiro Fujita, Reiko Inagi. *Division of Endocrinology & Nephrology, University of Tokyo School of Medicine, Tokyo, Japan.*

Purpose of study: Some patients with renal anemia suffer from resistance against treatment with erythropoietin (EPO), and this is often associated with chronic inflammatory states. Evidences suggest that impaired endoplasmic reticulum (ER) homeostasis encountered during chronic inflammatory status. Here we investigated a role of disturbance in the homeostasis of ER in hypoxia-induced EPO production.

Methods: HepG2 cells, a hepatoma cell line obtained from RIKEN Japan, were incubated in the hypoxia chamber (1%), or by added cobalt chloride (100uM) in culture medium to activate hypoxia-inducible factor (HIF), the master gene switch of hypoxic responses. Thapsigargin (THG, 50ng/ml) or tunicamycin (TUN, 4ug/ml) were used to induce ER stress in vitro. Male Wistar rats (150~200g) were treated by TUN (i.p. 0.3mg/kg), and then received cobalt chloride (s.c. 60mg/kg) to activate HIF. EPO gene expression was analyzed by the quantitative real-time PCR. Nuclear levels of HIF 1α and 2α were evaluated by Western blotting analysis.

Results: We first tested two representative ER stressors in the HepG2 hepatoma cell line: THG and TUN. As we expected, both compounds induced ER stress (7.7 and 6.8 times increased as compared with control), estimated by the induction of GRP78, an indicator of ER stress. Both of the ER stressors markedly suppressed the basal expression level of EPO mRNA under normoxic conditions (0.55-in TUN and 0.32-fold in THG, $p<0.05$). Further, both THG and TUN suppressed cobalt chloride-induced and hypoxia-induced EPO mRNA expression (0.54-in TUN and 0.34-fold in THG, $p<0.05$), which accompanied by inhibition of HIF-1α and HIF-2α nuclear translocation. We performed further experiments in rats treated with TUN and found that ER stress readily suppressed cobalt chloride-induced hepatic and renal EPO gene expression by 91.5 and 87.6% ($P<0.01$), respectively.

Conclusions: Inhibition of HIF activation seems to be involved in the suppression of EPO gene expression by the induction of ER stress in vitro, and may be responsible for impaired EPO synthesis in chronic inflammatory states in vivo.

**Impact of Anthracyclines on Hypoxia Response in Tubular Epithelial Cells** Tetsuhiro Tanaka,[1,2] Toshiro Fujita,[2] Masaomi Nangaku.[2] *[1]Division for Health Service Promotion, University of Tokyo, Tokyo, Japan; [2]Division of Nephrology and Endocrinology, University of Tokyo School of Medicine, Tokyo, Japan.*

Anthracyclines are widely used to treat tumors of lymphoid and other origins. Upon administration, they distribute in multiple organs including the kidney, at various concentrations and with diverse consequences, but their impact on tubular epithelium remains unknown. In this study, we investigated the effect of anthracyclines on hypoxia response of renal tubular cells, in light of the emerging concept that tubulointerstitial hypoxia plays a critical role in the progression of kidney disease.

In cultured human proximal tubular cells (HK-2), doxorubicin dose-dependently inhibited transcriptional activity of hypoxia-inducible factor-1 (HIF-1), as demonstrated by luciferase reporter assay, which was reflected by transcriptional downregulation of HIF-target genes such as vascular-endothelial growth factor (VEGF) and glucose transporter 1

(GLUT1). On the other hand, doxorubicin neither influenced the expression level of HIF-1alpha and its binding partner, HIF-1beta, nor did it have any effect on the heterodimer formation. However, chromatin immunoprecipitation assays revealed that the recruitment of the HIF-heterodimer to its consensus hypoxia-responsive element was markedly weakened in the presence of doxorubicin, with the following impairment of its target gene transcription. This study uncovers a novel mechanism by which anthracyclines dampen hypoxia response in proximal tubular cells of the kidney. Impaired recruitment of the HIF-heterodimer to its consensus cis-element was mainly responsible for the transcriptional downregulation of HIF-target genes.

**Fructose Activates the Polyol Pathway in the Development of Metabolic Syndrome** Miguel A. Lanaspa, L. Gabriela Sanchez-Lozada, Carlos Alberto Roncal-Jimenez, Ana Andres-Hernando, Richard J. Johnson. *University of Colorado Denver.*

Excessive fructose intake can induce features of metabolic syndrome in experimental animals and man. Fructose intake, primarily in the form of added sugar correlates closely with the epidemics of obesity and diabetes. These observations have led to much interest in the role of exogenous dietary sugars (containing fructose) in the current epidemic of metabolic syndrome. However, fructose can also be generated from endogenous sources via the polyol pathway. Aldose reductase, the rate limiting enzyme of this pathway converts glucose into sorbitol which is the metabolized to fructose by sorbitol dehydrogenase (SDH). Here, we demonstrate that postpandrial levels of fructose (1 mM) are able to significantly up-regulate aldose reductase expression within 4 hours after exposure in hepatocytes HepG2 cells (2.6-fold increase between control, $p<0.01$). SDH expression is further up-regulated at 8 hours after exposure (0.7-fold increase in the first 4 hours, $p=0.07$ and 2.05-fold increase after 8 hours, $p<0.01$) indicating that AR is creating the pool of sorbitol needed for SDH over-expression. This up-regulation occurs at both the transcriptional and translational level since an increase in both mRNA and protein expression was observed. The mechanism by which fructose up-regulates aldose reductase is mediated by the ability of this sugar to induce intracellular uric acid and reactive oxygen species (ROS). Scavenging ROS with a NADPH oxidase inhibitor (apocynin) or inhibition of uric acid generation (oxypurinol) dramatically diminished the up-regulation of the enzymes of the polyol pathway. This data strongly suggests that the polyol pathway is activated by fructose. Hence it is possible that subjects with metabolic syndrome, who have postpandrial hyperglycemia and hyperuricemia, may have substantial endogenous fructose production that may continue to maintain or accelerate features of the metabolic syndrome even if the original underlying mechanism driving it (exogenous fructose ingestion) is curtailed.

**Clopidogrel Effectively Suppresses Endothelial Microparticle Generation Induced by Uremic Toxin Via Inhibition of the p38 MAPK Pathway** Jung-Hwa Ryu,[1] Seung-Jung Kim,[1] Dong-Ryeol Ryu,[1] Duk-Hee Kang,[1] Kyu Bok Choi.[1] *[1]Division of Nephrology, Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Republic of Korea; [2]Medical Research Institute, Ewha Womans University School of Medicine, Seoul, Republic of Korea.*

Vascular access failure is one of the most common problems in hemodialysis patients and is closely related with endothelial injury. Endothelial microparticles (EMPs) are fragments shed from the activated or apoptotic cell membrane and are closely associated with thrombotic propensity and vascular dysfunction. To identify drugs with beneficial effects on injured endothelium, we investigated the effects of anti-proliferative drugs on EMP generation induced by uremic toxin in human umbilical vein endothelial cells (HUVECs). We then examined the involvement of the MAPK in EMP generation and effects of MAPK inhibitors on EMP production. CD31+CD42-EMP counts were measured by flow cytometry in supernatants of HUVECs incubated with indoxyl sulfate and the EMP responses to anti-proliferative drugs (losartan, lovastatin, clopidogrel, and mesoglycan) were examined. We then measured the effects of MAPK inhibitors on EMPs. The results were as follows: 1) indoxyl sulfate induced EMP release in HUVECs in a dose-dependent fashion; 2) losartan, lovastatin, clopidogrel, and mesoglycan inhibited EMP generation induced by indoxyl sulfate at concentrations of 10-50 μM, with clopidogrel the most effective; 3) the p38 MAPK inhibitor (SB-203580, 20 μM) effectively suppressed EMP generation induced by indoxyl sulfate; And 4) clopidogrel significantly suppressed MAPK signaling pathways; p38, ERK1/2, and JNK activated by indoxyl sulfate, with the most potency on p38. These results collectively suggest that p38 signaling involves EMP generation induced by indoxyl sulfate and is effectively suppressed by clopidogrel. Further studies will be necessary to define the therapeutic benefit of these drugs for prevention of vascular access stenosis *in vivo*.

**Agonist-Activated, Endocytosed Dopamine D3 Receptor Traffics through the Endosomal Network and Interacts with GADD34** Maria João Pinho,[1] Van Anthony M. Villar,[2] Yanrong Zhang,[2] John Edward Jones,[2] Patricio Soares-da-Silva,[1] Pedro A. Jose.[2] *[1]Instituto de Farmacologia e Terapêutica, Faculdade de Medicina da Universidade do Porto, Porto, Portugal; [2]Center for Molecular Physiology Research, Children's National Medical Center, Washington, DC.*

During conditions of moderate sodium excess, the peripheral dopaminergic system regulates blood pressure and water and electrolyte balance via the dopamine receptors, including the dopamine $D_3$ receptor (DRD3). While the association of DRD3 dysfunction with hypertension is fairly established, not much is known about how the activated receptor is subsequently processed and modified for eventual recycling or degradation. This study aimed to demonstrate the trafficking of DRD3 in human proximal tubule cells (hPTCs) and to characterize its interaction with GADD34, a regulatory subunit of phosphatase 1 (PP1) that recruits the catalytic subunit that dephosphorylates target proteins. Confocal microscopy revealed that DRD3 is localized in the cytoplasm and partially at the plasma membrane. DRD3 agonist PD128907 treatment resulted in receptor endocytosis and accumulation at the perinuclear area, and increased receptor colocalization with EEA1 (sorting endosome marker), Rab4 (fast recycling endosome) and Rab11 (slow recycling endosome) in hPTCs. Agonist stimulation markedly enhanced the colocalization with Rab7 (late endosome), LAMP-1 (lysosome) and $p44S^{10}$ (proteasome); endocytosed receptors are degraded via the lysosome or proteasome. Agonist treatment increased DRD3 phosphorylation. The DRD3/GADD34interaction was confirmed through a His pulldown between heterologously expressed DRD3 and endogenous GADD34. Overexpression of GADD34 increased the phosphatase activity in hPTCs, while RNAi silencing of GADD34 did not change the activity. DRD3 and GADD34 colocalized in the proximal tubules of human kidney, and agonist stimulation resulted in increased colocalization of DRD3 with GADD34 and PP1γ in hPTCs. Our data indicate that agonist activation promotes DRD3 phosphorylation, endocytosis, endosomal trafficking, and possible degradation via the lysosomes and proteasome, and suggest an important role for GADD34 in DRD3 function in hPTCs.

**Protein Kinase C-ε Activation Induces Mitochondrial Dysfunction in Renal Proximal Tubules** Grazyna Nowak, Diana Bakajsova. *Pharmaceutical Sciences, University of Arkansas for Medical Sciences, Little Rock, AR.*

Activation of protein kinase C-ε (PKC-ε) mediates protection from ischemia/reperfusion injury in the heart. Mitochondria are a subcellular target of these protective mechanisms of PKC-ε. We have previously shown that PKC-ε activation and translocation to mitochondria is involved in mitochondrial dysfunction in oxidant-injured renal proximal tubular cells (RPTC). However, mitochondrial targets of PKC-ε were unknown. The goal of this study was to determine the role of PKC-ε activation in mitochondrial dysfunction and to identify mitochondrial targets of PKC-ε in RPTC. The constitutively active (caPKC-ε) and inactive (dnPKC-ε) mutants of PKC-ε were overexpressed in primary cultures of RPTC using adenoviral technique. The cells were collected at different time points after transfection to measure mitochondrial functions, ATP production and content, oxidant generation, and cell viability. Protein levels of caPKC-ε increased at 12 hr after transfection and remained elevated for another 36 hours. Increases in caPKC-ε levels in RPTC were accompanied by caPKC-ε translocation to mitochondria. Sustained PKC-ε activation resulted in decreases in state 3 respiration, electron transport rate, activities of complexes I and IV, ATP production, ATP content, and $F_0F_1$-ATPase activity. Furthermore, PKC-ε activation increased $\Delta\Psi_m$ and oxidant production and induced mitochondrial fragmentation and RPTC death. Antioxidants blocked PKC-ε-induced increases in oxidant generation but did not prevent mitochondrial fragmentation and cell death. Inactive PKC-ε mutant had no effect on mitochondrial functions and morphology, reactive oxygen species production, and RPTC viability. We conclude that activation of PKC-ε in RPTC targets complex I, complex IV, and $F_0F_1$-ATPase, mediates mitochondrial dysfunction, hyperpolarization and fragmentation, and induces RPTC death but oxidative stress is not the mechanism of PKC-ε induced loss of RPTC viability. These results show that, in contrast to protective effects of PKC-ε activation in cardiomyocytes, sustained PKC-ε activation is associated with oxidant generation and is detrimental to mitochondrial function and viability in RPTC.

**Functional Discrimination of Intrarenal and Renal Pelvic Capsaicin-Sensitive Peptidergic Afferent Nerve Fibers** Tilmann Ditting, Wolfgang Freisinger, Kristina Rodionova, Sonja Heinlein, Karl F. Hilgers, Roland Veelken. *Nephrology, University Erlangen, Erlangen, Germany.*

Kidneys have a complex sympathetic efferent and peptidergic afferent innervation expressing TRPV1. The renal pelvis is very densely innervated with afferent nerves which are functionally far better understood than the intrarenal afferents, that are however likely to be important in health, renal disease and hypertension. However, a clear-cut functional distinction of renal pelvic and intrarenal afferents has not yet been described. We tested the hypothesis that intrarenal and renal pelvic afferent nerve fibers can be discriminated functionally using a multifiber nerve recording approach.

8 anesthetized SD rats were equipped with art. and ven. catheters for blood press. recording and application of fluids and drugs, a stainless steel electrode for recording of afferent renal nerve activity (ARNA), a triple lumen renal pelvic (rp) catheter for urine drainage and increasing rp pressure (+15 cmH20) and for rp drug perfusion to stimulate

(CAP=Capsaicin 3.3*10-7M, 10µl/1min) or block (CPZ=Capsacepine 3.3*10-4M, 90µl/9min) renal pelvic ARNA via TRPV1; a renal artery catheter for intrarenal ARNA stimulation (CAP=Capsaicin 3.3, 6.6, 10*10-7M 10µl bolus). Mechanical stimulation of rp ARNA (pressure increase) was followed by chemical stimulation of rp and intrarenal ARNA (CAP). This was repeated after rp perfusion with CPZ to block rp ARNA and once more after rp perfusion with saline to unblock rp ARNA

Mechanical and chemical rp stimulation significantly increased ARNA (289±39%, 299±47%, respectively). To achieve a similar peak ARNA increase (302±51%) by intrarenal chemical stimulation, via renal artery, higher CAP concentrations were necessary (2.5-fold). Renal pelvic perfusion with CPZ reversibly blocked renal pelvic mechanic and chemical stimulation effects efficiently. Interestingly, the intrarenal CAP effect was only just sligthly diminished (-9%; n.s.) during blockade of pelvic fibers.

For the first time, our study provides direct neurophysiological evidence for the existence of a putatively functionally relevant intrarenal peptidergic innervation that is independent from renal pelvic innervation.

**Rosuvastatin Reduces Pressure-Induced Fibrotic Signals in Rat Renal Tubular Cell** Tso Hsiao Chen,[1] Yen Cheng Chen,[1] Cheng-Hsien Chen,[1] Yung-Ho Hsu.[2] *[1]Division of Nephrology, Taipei Medical University-Wan Fang Medical Center, Taiwan; [2]Division of Nephrology, Taipei Medical University-Shuang Ho Hospital, Taiwan.*

HMG-CoA reductase inhibitors, a class of drugs known as statins and initially described as lipid-lowering drugs, have anti-inflammatory and immunomodulatory actions. Recently, many studies revealed that the pressure force is an important mechanisms contributing to the induction and progression of tubulo-interstitial fibrogenesis in diabetic nephropathy and ureteric obstruction. In this study, we established an *in vitro* pressure culture system to study the influence of statins on renal fibrosis in rat renal tubular cells (NRK-52E). NRK-52E cells were cultured under 60 mmHg pressure, and we found that the fibrotic signals were significantly induced depend on pressured time. Connective tissue growth factor (CTGF) was induced at 2 and 8 h, and Transforming growth factor beta (TGF-b) as well as fibronectin increased at 8 and 24 h. These pressure-induced CTGF and fibronectin were reduced by rosuvastatin in a dose-dependent manner, but pressure-induced TGF-b was not influenced by rosuvastatin. We further found that rosuvastatin also reduced the TGF-b-induced expression of fibronectin, CTGF and COX-2 in a dose-dependent manner. Both pressure and TGF-b induced PGE2 secretion and this induction was inhibited by rosuvastatin in NRK-52E cells. The specific inhibitor for COX-2, NS398, inhibited pressure-induced PGE2 secretion and enhanced the anti-fibrotic effect of rosuvastatin. When we added PGE2 back to the pressure-treated cells, rosuvastatin-reduced fibrotic signals were recovered. Therefore, rosuvastatin may prevent rat renal tubular cells from pressure-induced fibrosis by inhibiting PGE2 generation.

**Rapid, Non-Genomic Regulation of Multidrug Resistance Protein 2 by Glucocorticoids in Renal Proximal Tubules** Rosalinde Masereeuw,[1] Brigitte Prevoo,[1,3] Kimberley Wever,[1] David S. Miller,[2] Gert Flik.[3] *[1]Pharmacology and Toxicology (149), Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [2]Laboratory of Pharmacology, NIH/NIEHS, Research Triangle Park, NC; [3]Dept. Organismal Animal Physiology, Radboud University, Nijmegen, Netherlands.*

Multidrug resistance protein 2 (Mrp2) in renal proximal tubules is concerned with active transport of many compounds, including drugs and metabolic wastes, into the urine. Upon exposure to nephrotoxic agents or during endotoxemia, Mrp2 activity and expression are tightly controlled. This may result from an induced de-novo synthesis of Mrp2, or from post-transcriptional regulation involving receptors and signaling pathways. Here we investigated glucocorticoid signaling to Mrp2. For transport experiments, freshly isolated killifish renal tubules were exposed to dexamethasone without and with inhibitors of signaling. Fluorescein-methotrexate (FL-MTX) was used to measure Mrp2-mediated transport by confocal microscopy and quantitative image analysis. Exposure of renal tubules to dexamethasone (0.25 – 10 µM) for 3 h increased FL-MTX transport at all concentrations tested ($p<0.01$). Other glucocorticoid receptor (GR)-ligands, cortisol and triamcinolone acetonide (both at 1.0 µM), also stimulated Mrp2-mediated transport ($p<0.01$). Cortisone, an inactive metabolite, was without effect. The GR-antagonist, RU-486 (0.5 µM), abolished the effects ($P<0.01$ for all three ligands). Consistent with action through a non-genomic mechanism, dexamethasone up-regulation of Mrp2-mediated transport was insensitive to cycloheximide. Immunohistochemistry revealed that dexamethasone did not alter Mrp2 expression at the luminal membrane. K252a, an inhibitor of the tyrosine kinase subfamily, reduced the dexamethasone effect, as did the specific c-Met kinase inhibitor, PHA-665752 ($p<0.001$). Protein kinase C signaling was not involved. In conclusion, we demonstrate a novel signaling pathway for the rapid induction of Mrp2-mediated transport in renal proximal tubules. Signaling involved glucocorticoids acting through GR and tyrosine kinases, but did not involve increases in protein synthesis or Mrp2 expression.

**Coordination of ARLs in Cilia** Yujie Li, Jinghua Hu. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Joubert syndrome (JS) is the most common inherited cerebellar malformation disorder that belonging to a rapidly expanding group of human diseases called ciliopathies. All identified JS loci encode cilia-related proteins, however, with the precise roles enigmatic. Here, we address the function of the small GTPase ARL-13, the sole *C. elegans* orthologue of human ARL13B, in regulating cilia biogenesis. In *C. elegans*, ARL-13 localizes to ciliary doublet segment in its proline-rich C-terminus dependent manner. *arl-13* animals exhibit shortened cilia with various cilia ultrastructural defects as well as disrupted association between intraflagellar transport (IFT) subcomplex A and B. Intriguingly, depletion of ARL-3, another evolutionarily conserved ciliary small GTPase, can suppress ciliogenesis defects in *arl-13* via a microtubule associated deacetylase HDAC-6 dependent pathway by restoring the binding efficiency between IFT complex A and B. We further identified several ARL-13 interacting proteins in yeast-two-hybrid screens and will elucidate their roles in ARL-13-mediated ciliogenesis and IFT regulation.

**AOPPs-Induced Endothelial Ezrin Activation Potentiates Monocyte Transendothelial Migration through a RAGE-Rho/ROCK-NADPH Oxidase-Mediated Pathway** Zhijian Guo, Ying Zhang, Fan Fan Hou, Xun Zhang. *Nephrology, Nanfang Hospital, Guangzhou, Guangzhou, Guangdong, China.*

The accumulation of advanced oxidation protein products (AOPPs), a class of potential proinflammatory mediators, has been linked to the increased monocyte infiltration into vessel intima in the previous study. However, the underlying mechanism is still unknown. The hypothesis that AOPPs modified human serum albumin (AOPPs-HSA) may contribute to the monocyte transendothelial migration (TEM) process by modulation of endothelial permeability was investigated. Incubation of AOPPs-HSA with human umbilical vein endothelial cells (HUVECs) resulted in increased enzyme activities of Rho and Rho-associated kinase (ROCK). This Rho/ROCK activation enhanced the activity of endothelial NAD(P)H oxidase as demonstrated by inducting phosphorylation of p47phox and p47phox membrane translocation. Exposure of HUVECs to AOPPs-HSA also increased the phosphorylation of ezrin, a key protein regulating endothelial cytoskeleton rearrangement, causing a shift in F-actin distribution from web-like structure to polymerized stress fiber. The cytoskeleton rearrangement was accompanied by increased endothelial permeability to monocytes as detected by a double-chamber culture system. This cascade of events could be largely inhibited by blocking the receptor for advanced glycation end products (RAGE), by the special inhibitor of Rho/ROCK and NADPH oxidase, and by the small interfering RNA to ezrin. These data suggested that AOPPs-HSA induced endothelial ezrin activation precipitating cytoskeleton rearrangement and endothelial permeability via a RAGE-mediated signals involving Rho/ROCK and NADPH oxidase.

**Caveolin/Caveolae Expression in Proximal Tubule (PT) Cells in Culture but Not In Situ: Isolated PTs Are Contaminated with Endothelial Cells** Zhenjie Jane Zhuang, Vladimir Marshansky, Sylvie Breton, Dennis Brown. *Center for Systems Biology, Program in Membrane Biology and Division of Nephrology, Massachusetts General Hospital, Boston, MA.*

Kidney proximal tubules (PT) are composed of epithelial cells that are specialized for the uptake and transport of ions, solutes, peptides and proteins. These functions are often regulated by hormones that signal at the cell surface and are subsequently internalized by clathrin-mediated endocytosis. However, the caveolin/caveolae pathway has also been implicated in normal proximal tubule function, often based on data from isolated PTs or PT cells in culture. Although we reported previously that caveolae and caveolin 1 are not detectable in PTs in situ, reports of caveolin expression and its functional consequences in PT cells appear periodically in the literature. Therefore, we re-examined caveolin expression in PTs in situ, in isolated, purified PTs, and in cultured PT cells. Caveolin 1 and 2 immunofluorescence was undetectable in PTs in situ using different specific antibodies, but all PT cell cultures examined (MTC, IRPT and LLC-PK1) and IMCD cells expressed caveolin 1 and 2. Furthermore, both caveolin 1 and 2 mRNAs were detected in collagenase-isolated PTs along with the endothelial markers CD31 and ICAM1. In contrast, no caveolin or endothelial marker mRNAs were detectable in PT samples isolated from snap frozen kidneys by laser cut microdissection, which eliminates contamination by endothelial cells. We conclude: a) caveolin 1 and 2 are not normally expressed by PT cells in situ, and caveolae are not present; b) caveolin expression is activated in cultured PT cells; c) endothelial cell contamination is a potential source of caveolins that must be taken into account when collagenase-isolated PT are used in studies to correlate expression of these proteins with proximal tubule function.

**Exosomes Derived from Primary Renal Cells Contain microRNAs That Can Potentially Drive Therapeutically-Relevant Outcomes in Models of Chronic Kidney Disease** Roger Ilagan, Sumana Choudhury, Andrew T. Bruce, Joydeep Basu, Kelly I. Guthrie, Bryan R. Cox, Chris Genheimer, Rusty Kelley, John W. Ludlow, Sharon C. Presnell. *Tengion, Inc., Winston-Salem, NC.*

Paracrine effects have become a focus for understanding mechanisms of regeneration. MicroRNAs (miRNAs) transferred through the extracellular space via exosomes can affect mRNAs of other cells. Here, we correlated specific exosome-derived miRNAs with functionally-relevant outcomes in target cells *in vitro* to inform the design of *in vivo* renal regeneration mechanistic studies.

Conditioned media effects on signaling pathways associated with regeneration were investigated with human cell lines: HK-2 (proximal tubule), HRMC (mesangial), and HUVEC (endothelial). RNA content in exosomes from human and rat primary renal cell cultures (UNFX) was screened by PCR-based array designed to detect known miRNAs. Low oxygen can affect exosome shedding; therefore, some cultures were exposed to low oxygen (2% $O_2$) for 24 hours prior to media collection. Exosomes were separated from cellular debris in UNFX conditioned media by FACS.

UNFX-conditioned media affected specific signaling pathways associated with regeneration; non-conditioned media did not. NFkB (immune response) and epithelial-to-mesenchymal transition (fibrotic response) was attenuated in HK-2 cells, PAI-1 (fibrotic response) was attenuated in HRMC cells, and angiogenesis was promoted in HUVEC. PCR array screening of exosome content from UNFX-conditioned media indicated that UNFX produces exosomes containing miRNA sequences consistent with the observed responses.

UNFX cells shed exosomes containing known miRNAs. UNFX-conditioned media affects responses associated with regeneration in human cell lines. The cause and effect relationship between detected miRNAs and observed regenerative responses is under investigation; however, results achieved to date suggest that UNFX cells have the potential to produce therapeutically-relevant paracrine effects via exosome-mediated transfer of miRNAs to target cells and tissues.

**Regulation of HSP27 in Unilateral Obstructed Kidney and in RMIC Subjected to Mechanical and Inflammatory Stress** Inge Gram Carlsen,[1,2] Rikke Norregaard,[1,2] Jorgen Frokiaer.[1,2] *[1]The Water and Salt Research Center, University of Aarhus; [2]Institute of Clinical Medicine, University of Aarhus, Aarhus University Hospital-Skejby, Aarhus, Denmark.*

In vivo, renal medullary interstitial cells (RMIC) are subjected to mechanical and inflammatory stress as a result of ureteral obstruction. It has previously been demonstrated that heat shock protein (HSP) 27 is expressed in RMIC in vivo and in vitro. HSP27 exists in a phosphorylated active form (pHSP27) which plays a role in stabilization of actin filaments and has anti-apoptotic function.

In vivo studies using rats subjected to unilateral ureteral obstruction for 6h and 12h; showed unchanged HSP27 mRNA and protein level in kidney inner medulla (IM). However, pHSP27 protein level was increased in obstructed kidney IM compared to both sham and contralateral kidney. To further examine the activation of HSP27 in response to mechanical and inflammatory stress in vitro we subjected RMIC to pressure and stimulation with interleukin 1β (IL-1β). Using a novel pressure apparatus, pressure of 60 mm Hg over time (2-8 h) was explored directly in RMIC which increased expression of HSP27 protein level after 6h and remained increased at 8h. Using the p38 MAPK inhibitor (SB202190), it was demonstrated that the induction of pHSP27 was down-regulated in a dose-dependent manner.

During inflammatory stress, stimulation with IL-1β over time (2-24h) showed unchanged HSP27 mRNA and protein level whereas pHSP27 protein was increased in response to 8 h stimulation.

These data indicate that different forms of cellular stress activate HSP27 and pressure induced HSP27 phosphorylation in RMICs are p38 MAPK dependent. This may affect the ability of RMIC to mount an effective cytoprotective response.

**Phosphatidylinositol 3-Kinase (PI3K) p85α Subunit Expression Is Downregulated in the Kidney of Spontaneously Hypertensive Rats** Maribel Ch. Chavez,[1] Jose L. Arcaya,[1] Jose D. Herrera,[1] Richard J. Johnson,[3] Bernardo Rodriguez-Iturbe,[2] Freddy J. Romero.[2] *[1]Universidad del Zulia, Maracaibo, Venezuela; [2]Instituto Venezolano de Investigaciones Cientificas (IVIC-Zulia), Maracaibo, Venezuela; [3]University of Colorado, Denver.*

**Background:** Mice with reduced expression of the insulin receptor in renal tubules, resulting from renal epithelial cell-specific knockout, have significant increments of systolic blood pressure and reduced sodium and nitric oxide excretion, which suggest a potential role of the insulin receptor-activated pathways in blood pressure control. Previous studies have demonstrated that the density and mRNA levels of insulin receptors in the kidney of spontaneously hypertensive rats (SHR) do not differ from those in Wistar Kyoto (WKY) rats. However, is not known if the phosphatidylinositol 3-kinase (PI3K) pathway, one of the major downstream mediators of insulin receptor, is altered in the kidney of SHR. The present study was carried out to investigate the PI3K pathway components in the kidney of SHR.

**Methods**: Studies were done in male SHR and WKY rats aged 10 weeks (n=6 each) in which harvested kidneys were used for mRNA and protein expression of the constituents of the insulin PI3K pathway.

**Results:** No differences were detected in the renal transcript abundance of regulatory subunit p85β, and catalytic subunits p110α, p110β, and IRS-1 in the SHR and WKY rats. However, SHR had reduced renal mRNA levels of PI3K p85α subunit (SHR=0.28 ± 0.15 versus WKY=1.00 ± 0.12, respectively, $p< 0.01$). Western blot analysis demonstrated a reduction in the expression of PI3K p85α subunit in the renal cortex of SHR versus WKY (0.36 ± 0.05 vs. 1.04 ± 0.08, $p<0.01$)

**Conclusions**: PI3K p85α subunit expression is downregulated in the kidney of SHR. Suppressed activity of insulin receptor-activated pathways, resulting from reduced renal PI3K signaling may play a role in the pathogenesis of hypertension in the SHR.

**Diabetes and Mitochondrial Dysfunction; IHG-1 Binds to Mitofusion 1 & 2 and Regulates Mitochondrial Dynamics** Brenda Griffin, Fionnuala B. Hickey, James B. Corcoran, Una Bhreathnach, Catherine Godson, Madeline Murphy. *Diabetic Research Centre, University College Dublin, Dublin, Ireland.*

Mitochondrial dysfunction is a major contributor to hyperglycaemic-induced renal damage. In mammalian cells mitochondria undergo continuous changes in morphology as they constantly divide and fuse. Morphology and function are closely related. Fusion is regulated by the GTPAse proteins, mitofusin 1 and 2 (Mfn1 and Mfn2) and OPA1 while fission is regulated by DRP1 and Fis1.

The glucose regulated gene transcript Induced in High Glucose I (IHG-1) is associated with the development of tubulointerstitial fibrosis in diabetic nephropathy. We have previously shown that IHG-1 contributes to the TGF-ß1 induced profibrotic changes in tubular cells that prime for TIF. On discovery IHG-1 had no known function or functional classification apart from a predicted mitochondrial localisation signal sequence.

Here we show that IHG-1 is localised to mitochondria in mammalian cells by immunogold cryosection electron microscopy. Using fluorescent confocal microscopy, IHG-1 overexpression demonstrated an altered mitochondrial morphology consistent with increased fusion. Conversely, loss of IHG-1 expression using shRNAmir resulted in a fragmented mitochondrial morphology consistent with increased fission or loss of fusion. Additionally we overexpressed known mediators of fusion (i.e. Mfn1, Mfn2, OPA1) and fission (Drp-1, Fis1) by transient transfection in cell culture. Characteristic mitochondrial morphologies were demonstrated by fluorescent confocal microscopy.

In order to investigate how IHG-1 mediates mitochondria fusion we investigated whether IHG-1 could interact with these mediators of fusion and fission. Co-immunoprecipitation experiments indicate that IHG-1 binds to Mfn1 and Mfn2 but not OPA1, DRP1 or Fis1.

In summary these data indicate that IHG-1 regulates mitochondrial dynamics by binding to the GTPase proteins Mfn1 and Mfn2. Future work will elucidate whether binding is necessary or sufficient for IHG-1's profibrotic role.

**Zebrafish (*Danio Rerio*) Require Cofilin 1 for Renal Function** Sharon L. Ashworth,[1,2,4] Hannah B. Marquis,[1] Christopher Preziosi,[2] Jessica K. Kaufeld,[3,4] Mario Schiffer.[3,4] *[1]Biology and Ecology, University of Maine, Orono, ME; [2]Molecular and Biomedical Sciences, University of Maine, Orono, ME; [3]Division of Nephrology, Hanover Medical School, Hanover, Germany; [4]Mount Desert Island Biological Laboratory, Salisbury Cove, ME.*

Regulated actin dynamics is critical for normal kidney cellular functions. Cofilin 1, an 18 kDa non-muscle actin binding protein, is an essential regulator of actin dynamics in renal function. The zebrafish model system is an ideal vertebrate model organism to study kidney function due to large brood sizes, rapid generation time, embryo transparency, availability of morpholinos and mutants, and accessibility to a simplified kidney structure or pronephros. To investigate the role of cofilin in zebrafish development and renal function, we studied cofilin 1 mutants and morphants. The cofilin 1 mutant embryos contained the *hi3736aTg* proviral insertion downstream of the first exon of the *cofilin 1* gene. This recessive mutation required PCR identification and maintenance of a heterozygous cofilin 1 mutant population to breed homozygous cofilin 1 mutant embryos. Cofilin 1 zebrafish mutants developed pericardial edema at 48 hours post fertilization (hpf). At 72 hpf pericardial edema increased and an abnormal heart structure was observed. At 148 hpf the heart rate was 20% slower than the wildtype larva heart rate. Atypical head and jaw development, smaller eyes with deformed pupils and lack of a swim bladder were also observed. Integrity of the glomerular filtration barrier function was tested by measuring clearance of 70 kDa FITC-dextrans from the retinal blood vessels over a 48 hour time course. Both the cofilin 1 mutant and morphant embryos exhibited a significant decrease in FITC fluorescence compared to wildtype controls which suggested the glomerular filtration barrier was compromised. TEM studies demonstrated podocyte effacement in both cofilin mutant and morphant zebrafish larva. Using fluorescent dyes, leakage from the pronephric tubules was detected by confocal microscopy at 120 hpf. These studies demonstrated cofilin 1 is essential to normal zebrafish development and pronephros function.

**Influence of Tumor-Necrosis-Factor (TNF) on Tunneling Nanotube (TNT) Mediated Cell-to-Cell Communication** Julia Ranzinger,[1] Amin Rustom,[2] Lars Kihm,[1] Margarete Witkowski,[3] Peter E. Scheurich,[3] Martin G. Zeier,[1] Vedat Schwenger.[1] *[1]Nephrology, University of Heidelberg, Heidelberg, Germany; [2]Dept. of Biophysical Chemistry, University of Heidelberg, Heidelberg, Germany; [3]Institute of Cell Biology and Immunology, University of Stuttgart, Stuttgart, Germany.*

**Background**

TNTs allow intercellular communication between various cells and have important physiological functions in health and disease. Here, we show for the first time the existence of TNTs between human primary peritoneal mesothelial cells and the effect of TNF on TNT-mediated intercellular communication.

**Methods**

Fluorescence microscopy was applied to detect TNTs in i) mesothelial cells from omentum of healthy donors and ii) mesothelial cells isolated from effluents in dialysis fluid from patients undergoing continuous ambulatory peritoneal dialysis (CAPD). To investigate both the effect of a changed cholesterol content in the plasma membrane and the presence of TNF on the TNT-formation, cells were treated with Methyl-ß-Cyclodextrine. Moreover, microinjection experiments were performed to elucidate a shuttling of molecules between TNT-bridged cells.

**Results**

The experiments show that the number of TNTs strongly depends on the concentration of cholesterol available in the plasma membrane. Incubation of cells with TNF reveals a stimulating effect on the TNT-formation. Analysing the ability of cells from patients undergoing CAPD to form TNTs, our study show that the number of TNTs built is significantly higher as compared to cells from healthy donors. In the course of microinjection experiments, we further provide evidence for a directed transport of molecules via TNTs.

**Conclusions**

The existence of TNTs connecting mesothelial cells points to a distinctive communication among the cells under *in vitro* conditions. We show that the cholesterol content of the cell membrane, as well as the presence of TNF have a strong influence on the TNT-formation. The significantly higher TNT number among cells from patients undergoing CAPD reflects the stimulating effect of TNF, given that the TNF concentration is elevated in patients undergoing CAPD due to the durable exposition of dialysis solution in the peritoneal cavity.

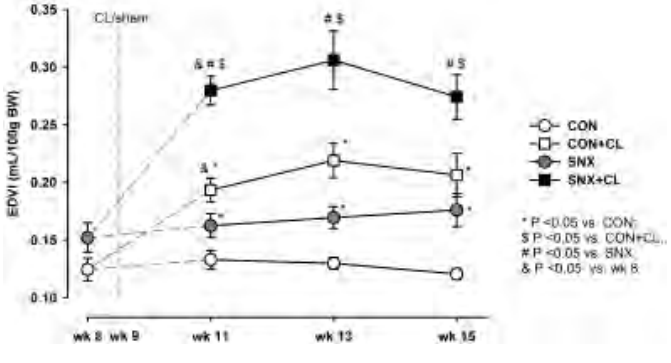
**F-PO1152**

**Reciprocal Organ Damage in Combined Experimental Chronic Kidney Disease and Myocardial Infarction** Lennart G. Bongartz,[1] Jaap A. Joles,[1] Marianne Christina Verhaar,[1] Maarten Jan M. Cramer,[2] Roel Goldschmeding,[3] Carlo A. Gaillard,[4] Pieter Doevendans,[2] Branko Braam.[5] *[1]Nephrology, UMC; [2]Cardiology, UMC; [3]Pathology, UMC, Utrecht; [4]Nephrology, Meander Medical Center, Amersfoort, Netherlands; [5]Nephrology & Immunology, University of Alberta, Edmonton, AB, Canada.*

In humans co-existence of chronic kidney disease (CKD) and heart failure (HF) is associated with accelerated failure of each organ and worse outcome. However, the reciprocal nature of cardiorenal interactions has scarcely been studied in animal models. We hypothesized that pre-existent chronic CKD worsens cardiac outcome after MI, and conversely that MI worsens CKD.

We subjected male Lewis rats to subtotal nephrectomy (SNX) or sham (CON). In wk 9, we performed coronary ligation (CL) or sham-surgery to realize 4 groups: CON, SNX, CON+CL, and SNX+CL. *In vivo* cardiorenal measurements were performed in wk 8, 11, 13 and 15. In wk 16, hemodynamic studies were performed and end-organ damage was assessed.

Proteinuria per level of SBP was significantly higher in SNX+CL vs. SNX, whereas there was no difference between CON+CL and CON. Correspondingly glomerulosclerosis was worsened in SNX+CL vs. SNX. Two wks after MI, rats with SNX+CL had more cardiac dilatation compared to CON+CL (end-diastolic volume index (EDVI): 0.28±0.01 vs. 0.19±0.01 mL/100g BW; *P*<0.001), despite similar infarct size.



During follow-up, SNX+CL rats developed a lower ejection fraction and increased mortality rate (only SNX+CL rats died, 2 out of 9). In SNX+CL, end-diastolic pressure (18±2 mmHg) and *tau* (29±4 msec), the time-constant of active relaxation, were significantly higher compared to SNX (13±1 mmHg, 20±1 msec; *P*<0.01) and CON+CL(11±2 mmHg, 17±1 msec; *P*<0.01).

This study demonstrates the existence of reciprocal organ damage in a model of combined CKD and MI, which cannot be explained by hemodynamic changes.

**A New Mechanism for Angiotensin II-Induced Cardiac Fibrosis and Dysfunction: A New Role for SGK-1 Signaling** Jizhong Cheng, Anlin Liang, William E. Mitch, Jie Du. *Internal Medicine, Baylor College of Medicine, Houston, TX.*

It is widely agreed that the inflammation induced by an infusion of angiotensin II (Ang II) contributes to cardiac interstitial fibrosis. To understand how angiotensin II causes cardiac fibrosis, we studied Ang II-infused mice and evaluated a new cell signaling pathway based on serum- and glucocorticoid-regulated kinase 1(SGK-1) plus activation of NF-κB. First, we used an echocardiography analysis comparing mice infused with either Ang II or saline for one month. Ang II caused a decrease in left ventricular fractional shortening and an increase in left ventricular diameters (P<0.05) during diastole. In the heart, we also found that Ang II induced phosphorylation and nuclear translocation of the p65 subunit of NF-κB. Second, we evaluated downstream signaling responses to NF-κB (i.e., MCP-1 and IL-8) in cardiac endothelial cells. Both mediators were upregulated by Ang II infusion. The hearts also exhibited increased infiltration with macrophages, accompanied by cardiac remodeling and an increase in fibrosis. Third, we found that Ang II stimulated SGK-1 expression in both cultured SMCs and cardiac fibroblasts. However, SGK-1 mRNA and protein levels were inhibited > 95% by the MEK1/2 inhibitor, U0126, indicating that Ang II induces SGK-1 expression via a MEK-ERK signaling pathway.

To explore whether SGK-1 influences cardiac fibrosis, SGK-1 knockout (KO) mice were studied. In hearts of SGK-1 KO mice infused with Ang II: 1) there was a sharp decrease in p65 NF-κB nuclear translocation and the expression of inflammatory markers; 2) cardiac fibrosis and inflammation were absent; and 3) the absence of SGK-1 dramatically decreased expression of α-smooth muscle actin, collagen I, fibronectin and decreased fibrosis. Importantly, echocardiography analysis of Ang II infused, SGK-1 KO mice showed no signs of heart dysfunction. Thus, we have uncovered a new pathway causing fibrosis and functional impairment in the heart. Inhibition of SGK-1 function could be a therapeutic target for preventing cardiac dysfunction in conditions associated with excess Ang II.

**Rapamycin Reduces Cardiac Fibrosis in Experimental Uremic Cardiomyopathy** Steven T. Haller,[1] George Budny,[1] Joe Xie,[1] Jiang Tian,[1] Mohammad Taleb,[1] Sankaridrug Periyasamy,[1] Deepak K. Malhotra,[1] Olga Fedorova,[2] Alexei Bagrov,[2] Joseph I. Shapiro.[1] *[1]Medicine, University of Toledo Medical Center, Toledo, OH; [2]National Institute on Aging, Baltimore, MD.*

Experimental uremic cardiomyopathy causes cardiac fibrosis and is associated with increased levels of the cardiotonic steroid marinobufagenin (MBG), a ligand of the Na/K-ATPase. The mammalian target of rapamycin (mTOR) is a serine/threonine kinase implicated in tissue fibrosis. Treatment with rapamycin (an mTOR inhibitor) has been shown to attenuate renal fibrosis in experimental renal failure. Rapamycin has also been noted to decrease the activity of CYP27A1, an enzyme believed to be important in MBG synthesis. To address how rapamycin would attenuate uremic cardiomyopathy, male Sprague Dawley rats weighing between 250-300 gms were divided into six groups consisting of sham surgery, partial nephrectomy (PNx), MBG infusion (10 ug/kg/day) and the combination of rapamycing (0.2 mg/kg/day) with the other manipulations.The PNx-rapamycin group demonstrated a significant decrease in systolic BP by the third week of treatment compared to PNx (149 ± 2 vs 166 ± 1 mmHg, P<0.01). Plasma MBG levels were significantly decreased in the PNx-rapamycin animals compared to PNx (248 ± 30 vs 684 ± 40 pmol/L, P<0.01). The PNx-rapamycin animals showed a substantial decrease in cardiac fibrosis compared to PNx animals as assessed by both tissue collagen expression and quantitative histology. MBG treated animals also had significant increases in systolic BP, and cardiac fibrosis compared to controls, and rapamycin treatment did not significantly lower MBG levels in these animals. However, rapamycin did appear to lower fibrosis as assessed by collagen expression and quantitative histology. In vitro studies in cardiac fibroblasts confirmed that rapamycin at doses as low as 10 ng/ml prevented MBG induced increases in collagen expression. Our results suggest that rapamycin exerts its protective effects both through inhibition of MBG synthesis and also through the mTOR pathway. Treatment with rapamycin may provide a novel therapy for reducing cardiac fibrosis in the setting of uremic cardiomyopathy.

**F-PO1155**

**Treatment with Nrf-2 Activator Ameliorates Uremia-Induced Endothelial Dysfunction and Hypertension** Stanislav Shelkovnikov,[1] Zhenmin Ni,[1] Hyun Ju Kim,[1] Colin Meyer,[2] Ardeshir Rahimi,[1] Nosratola D. Vaziri.[1] *[1]Medicine, University of California, Irvine, Irvine, CA; [2]Reata Pharmaceuticals, Inc, Irving, TX.*

Chronic kidney disease (CKD) results in endothelial dysfunction, hypertension, accelerated atherosclerosis and cardiovascular disease, events which are driven by oxidative stress (OS) and inflammation. The nuclear factor, Nrf2 regulates expression of genes encoding antioxidant and cytoprotective molecules which protect against OS and inflammation. We recently found that OS and inflammation in 5/6 nephrectomized rats are associated with impaired Nrf2 activation and downregulation of the corresponding antioxidant molecules [Am J Physiol, 298:F662, 2010]. Bardoxolone methyl and its analogs are potent Nrf2 activators that reduce production of reactive oxygen species and activation of NF-κB in endothelial, renal and cardiac cells. Therefore, we hypothesized that Nrf2 activator therapy may attenuate CKD-induced OS and endothelial dysfunction. To this end 5/6 nephrectomized rats were treated with a bardoxolone methyl analog (RTA 405, 20 mg/kg/day) or vehicle for 6 weeks. Acetylcholine, phenylephrine and sodium ntroprusside (SNP) concentration–response curves were obtained, and EC50 values were determined in isolated carotid artery rings by cumulative addition of the given agonists. Compared to the Sham-operated controls, CKD rats showed significant elevation of blood pressure and plasma lipid peroxidation product, malondialdehyde (MDA, 3.05±0.26 vs. 2.18±0.22 nM, P<0.01) and reduced vasodilatory response to acetylcholine (EC50; 181±20 nM vs. 38±3 nM, P<.01), denoting the presence of OS and endothelial dysfunction. RTA 405 therapy reversed CKD-associated hypertension, lowered plasma MDA (2.56±0.28 nM) and restored vasodilatory response to acetylcholine (EC50, 29±4 nM, P<.01). The response to phenylephrine and SNP was not altered by either CKD or RTA 405 therapy. Thus, Nrf2 activator ameliorates oxidative stress, hypertension and endothelial dysfunction, representing a potentially novel tool for management of CKD-associated endothelial dysfunction and cardiovascular disease.

**F-PO1156**

**Luminal Alkalization Attenuates Superoxide Production Induced by Fatty Acid-Bound Albumin in Renal Proximal Tubular Cells Through Pyk2-Dependent Pathways** Tomokazu Souma,[1,2] Michiaki Abe,[1] Takashi Moriguchi,[2] Takaaki Abe,[1,3] Sadayoshi Ito.[1] *[1]Department of Nephrology, Endocrinology and Vascular medicine, Tohoku University Graduate School of Medicine, Sendai, Miyagi, Japan; [2]Department of Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, Miyagi, Japan; [3]Division of Medical Science, Tohoku University Graduate School of Biomedical Engineering, Sendai, Miyagi, Japan.*

Proximal tubular cells are physiologically exposed to a highly acidic environment as a consequence of their reabsorption of HCO3-. However, it remains unclear whether this luminal acidity affects the progression of tubular cell damage induced by proteinuria. In the present study, we investigated the contribution of luminal acidity to O2•- production induced by oleic acid-bound albumin (OA-Alb) in proximal tubular cells. Acidic media significantly enhanced the OA-Alb induced O2•- production in the HK-2 proximal tubular cell line up to 7-fold (p<0.001). Of note, Proline-rich tyrosine kinase 2 (Pyk2), an intracellular pH sensor, was strongly phosphorylated by simultaneous treatment with both OA-Alb and acidic media. Highly phosphorylated Pyk2 was associated with activation of Rac1, a subcomponent of NAD(P)H oxidase. Furthermore, Pyk2-specific siRNA-knockdown attenuated the OA-Alb induced O2•- production by 70% (p<0.05). Assuming that luminal alkalization possibly exerts therapeutic effects on proteinuria-induced tubular damage, we employed a mouse model of protein overload nephropathy. Proximal tubules of protein-overloaded mice showed marked accumulation of oxidative DNA damage; oxidative stress was assessed by measuring accumulation of 8-OHdG immunoreactivity and augmentation of DCFDA, oxidation-sensitve dye, -intensity by flowcytometry. NaHCO3-feeding selectively alkalized the urine and dramatically attenuated the accumulation of proteinuria-induced oxidative DNA damage and subsequent tubulointerstitial injury (p<0.05). Overall, these observations suggest that luminal acidity is an intrinsic precipitating factor that aggravates proteinuria-induced tubular damage, and that modulation of this acidic environment is a potential therapeutic target for chronic proteinuric kidney disease.

**Knockout of Nuclear Receptor 4a1 on a Hypertensive Genetic Background Results in Severe Renal Injury** Kevin R. Regner,[1] Jessica A. Eisenhauer,[1] Cary T. Stelloh,[1] David L. Mattson,[2] Michael R. Garrett.[1] *[1]Nephrology, Medical College of Wisconsin, Milwaukee, WI; [2]Physiology, .*

The NR4A subgroup of nuclear hormone receptors (NR) have been implicated in apoptosis, cancer, atherosclerosis, and most prominently in metabolic disease. However, the role of NR4A in the kidney has not been well characterized. Nr4a1 knockout rats generated using an ENU mutagenesis strategy on the genetic background of the fawn-hooded hypertensive (FHH) rat were originally characterized using a high throughput phenotypic protocol for heart, vascular, and renal parameters through the PhysGen program at the Medical College of Wisconsin. Increased proteinuria was the most prominent phenotype observed in Nr4a1-/- compared to FHH controls. To more closely evaluate the onset and progression of renal injury, the temporal relationships in blood pressure, proteinuria, renal function and metabolic parameters in the Nr4a1-/- and FHH were evaluated from 4-24 weeks of age. Nr4a1-/- rats exhibited decreased creatinine clearance and ~4-fold higher proteinuria (81±11.5 mg/24hrs/100g BW) compared to FHH (21±1.0) at week 24. No differences in telemetry measured BP were observed between groups. At week 24, Nr4a1-/- animals also showed 3-4 fold higher cholesterol and triglyceride levels compared to the FHH. FHH and Nr4a1-/- kidneys exhibited similar glomerular pathology at each time point as evaluated by light microscopy and electron microscopy (EM) and was characterized by mesangial expansion and podocyte foot process effacement. Compared to the FHH, Nr4a1-/- kidneys demonstrated a significant increase in tubulointerstitial injury characterized by severe tubular atrophy, protein casts, and interstitial fibrosis. At the EM level, proximal tubule cells demonstrated increased lipid-like inclusions along with an increased number of autophagosomes and/or lysosomes. Immunohistological localization demonstrated that NR4a1 is expressed in all tubular components, but not observed to any great extent in the glomeruli or vessels. These data demonstrate that loss of NR4a1, on a genetic background predisposed to hypertension, results in progressive renal injury and loss of renal function likely through a tubular mediated mechanism.

**Obesity Induced-Proteinuria Modulates Tight Junction Protein Expression and Function** Li-Jun Ma,[1] Fnu Bhawana,[2] Amar B. Singh.[2] *[1]Departments of Pathology, Vanderbilt University, Nashville, TN; [2]Surgery, Vanderbilt University, Nashville, TN.*

Background: Obesity induces proteinuria and chronic kidney injury. Tight junctions help maintain paracellular permeability and integrity of renal tubular epithelial cells. However, effect of obesity-related proteinuria upon tight junction structure/function is poorly understood. We investigated the effects of obesity-induced proteinura upon tight junction composition and function.

Methods: 8-10 weeks old male DBA mice were fed standard normal chow (NC, n=8) or a high-fat diet (HFD, n=9) for 24 wks. Metabolic parameters and kidney morphology were assessed. Expression of tight or adherent junction proteins in kidney was assessed. In addition, effects of conditioned medium from differentiated adipocytes upon permeability and resistance were determined using MDCK-II cells. Data are expressed as mean±SE.

Results: HFD feeding significantly increased body weight (39.3±2.9 vs 29.8±0.8 g, p<0.01), albumin-creatinine ratio (ACR, 242±56 vs 95±33 ug/mg, p<0.01), and induced extensive tubular vacuolization and dilation (0-4 score: 2.5±0.4 vs 0.6±0.1 p<0.01), although mesangial expansion was not different in HFD vs NC (0-4 score: 1.2±0.3 vs 1.1±0.1). Interestingly, expression of all tight junction proteins investigated was highly increased in HFD-fed vs NC-fed mice: Occludin (2.58 fold), claudin-1 (1.54 fold) and claudin-4 (6.02 fold). Notably, the HFD-induced increase for tight junction proteins was highest for claudin-2 (19.69 fold, p<0.05 HFD vs NC), a claudin family member expressed exclusively in the proximal tubular epithelial cells. No change in the expression of E-cadherin or β-catenin in the same samples confirmed specificity. In vitro, exposure of polarized MDCK II cells to conditioned medium from adipocytes increased paracellular permeability for FITC-dextran (50.50±4.0 vs. 33.75±2.1, p<0.05).

Conclusions: Our data demonstrate, for the first time, that obesity induced-proteinuria is associated with significant and specific changes in tight junction composition and function and thus suggest important role of paracellular transport in the pathology of obesity-induced proteinuria.

**Mechanism of Glomerular Disease Initiation in Alport Syndrome** Dominic E. Cosgrove. *Boys Twon National Research Hospital, Omaha, NE.*

Alport syndrome is a delayed onset progressive glomerular disease caused by mutations in type IV collagen genes. Studies using animal models for Alport syndrome have revealed many aspects of the pathobiology of the glomerular disease, and have suggested several therapeutic avenues for treatment. The mechanism of Alport glomerular disease initiation, however, has remained elusive. It has been known for some time that abnormal laminins (laminin 111 and 211) accumulate in the GBM of Alport mice, dogs and humans. The functional significance of this observation was unclear. Here we show that activation of abnormal GBM laminin expression results in activation of focal adhesion kinase (FAK) in podocytes. FAK activation is associated with cytoskeletal rearrangements with the formation of large stress fibers and the induction of maladaptive genes including MMP-10 and MMP-12, both of which are implicated in GBM proteolysis. Both FAK siRNA knockdown and small molecule inhibitors of FAK reverse the actin cytoskeletal phenotype and block MMP induction. CD151 knockout mice, which have weakened α3β1 integrin adhesion to laminin 521 also show laminin 111 and 211 accumulation in the GBM. Both SiRNA knockdown of integrin linked kinase (ILK) and biomechanical strain of cultured podocytes induces abnormal laminin expression, and abnormal laminin accumulation is exacerbated in Alport mice by hypertension. Collectively, these data suggest that reduced ILK activity due to strained α3β1 integrin interaction with laminin 521 results in activation of abnormal laminin expression and accumulation in the GBM, which in turn activates FAK, resulting in maladaptive gene regulation. We suggest these events constitute the molecular mechanism of Alport glomerular disease initiation.

**Defining an Angiotensin II-Stimulated Proteome in Human Kidney Cells** Ana Konvalinka,[1] Eleftherios P. Diamandis,[2] James W. Scholey.[1] *[1]Medicine, University of Toronto, Toronto, Canada; [2]Pathobiology, Mount Sinai Hospital/ University Health Network, Toronto, Canada.*

**PURPOSE:** Activation of the renin angiotensin system and the generation of Angiotensin II (ANGII) is an important determinant of kidney disease progression, but there are currently no measures of renal ANGII activity. Accordingly, we sought to define an ANGII-stimulated proteome in primary human proximal tubule epithelial cells (PTEC) in order to identify potential biomarkers of ANGII activity in the kidney.

**METHODS:** We utilized stable isotope labeling with amino acids (SILAC) in PTECs under two sets of paired conditions: 1) ANGII and Control, and 2) ANGII and ANGII plus AT-1 receptor blockade (Losartan). Lysates from each SILAC pair were dialyzed, lyophilized, reduced, alkylated, trypsin-digested and fractionated using high performance liquid chromatography (LC). Fractions were zip-tipped and injected on the LC coupled to LTQ-Orbitrap MS. The resulting raw mass spectra were analyzed using Mascot on the IPI Human database. Protein identification and calculation of peptide ratios was performed by MaxQuant software.

**RESULTS:** The labeling efficiency of SILAC was confirmed by comparing lysates from untreated labeled cells. In each experiment more than 2500 proteins were identified. Of these proteins 349 were regulated by ANGII – 198 proteins were up-regulated and 151 were down-regulated. Ontology analysis revealed that metabolic processes were over-represented in the differentially-expressed proteins. Ingenuity Pathway Analysis determined that NFkB associated protein network was upregulated by ANGII. Several interesting candidate biomarkers emerged: for example, myosin heavy chain9 (MYH9), macrophage migration inhibitory factor (MIF) and cysteine-rich protein (CYR61) which is related to connective tissue growth factor. Interestingly, Losartan blocked ANGII-stimulated expression of CYR61, but not expression of MYH9 and MIF.

**CONCLUSIONS:** We have successfully utilized SILAC with human PTECs to define proteins differentially expressed by ANGII, and this strategy has identified novel proteins that may serve as biomarkers of ANGII activity in the kidney.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1161**

**TGF-β Was Upregulated in Renal Fibrosis Model of Klotho Defect Mouse and Affected Renal Klotho Expression Level** Hidekazu Sugiura, Takumi Yoshida, Junko Kohei, Shunji Shiohira, Michihiro Mitobe, Ken Tsuchiya, Kosaku Nitta. *Fourth Department of Internal Medicine, Tokyo Women's Medical University, Tokyo, Japan.*

Klotho is well known as an anti-aging gene that is mainly expressed in the kidney, which protein is essential for the functioning of endogenous fibroblast growth factor 23 (FGF23). We previously reported more severe tubulointerstitial fibrosis in klotho defect mice (Klotho (-/-) mice) comparing with wild type mice (Klotho(+/+) mice). It is well known that TGF-β is one of major fibrotic progression gene, so we investigated to clarify whether TGF-β is Klotho mediating signaling pathway in the process of renal fibrotic change in *in vivo* and *in vitro*. In practice, the relationship of the expression between Klotho and TGF-β in mice deficient for the klotho gene and in HK2 cells (in which Klotho expression is confirmed) adding TGF-β. We investigated renal fibrosis in the classical model of unilateral ureteral obstruction (UUO) in klotho hetero defect mice (Klotho (+/-) mice), then HK2 cells incubated with TGF-β (10 ng/ml) for 24, 46, 72, 96 and 120 hours with/without TGF-β1 receptor inhibitor (ALK5 inhibitor). Expression of renal TGF-β was analyzed by ELISA and that of renal fibronectin and Klotho was by Western blotting and/or immunohistochemical staining. UUO treatment induced the expression of TGF-β (1.4-fold, $p<0.05$) and fibronectin (1.6-fold, $p<0.05$) in the kidney of Klotho (+/-) mice comparing with Klotho (+/+) mice. Klotho expression was significantly reduced (0.4-fold, $p<0.05$) in the Klotho (+/-)-UUO-mice comparing with the Klotho (+/-)-sham-mice and the Klotho (+/+)-UUO-mice. Klotho (+/-)-UUO-mice demonstrated prominent fibrosis of kidney tissues. Klotho expression was significant suppression was observed in late phase, 72 to 120 hours in cultured HK2 cells in a time dependent manner, suggesting not acute but chronic effects of by TGF-β on Klotho expression. The effect was attenuate by co-incubation with ALK5 inhibitor. Together with our previous observations, there is a cross-talk between Klotho and TGF-β in the kidney, and Klotho is likely to play its potential roles, in part, mediating TGF-β signaling pathway.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1162**

**Dynamic Analysis of Renal Autoregulation in Experimental Chronic Kidney Disease** Maarten P. Koeners,[1] William A. Cupples,[2] Jaap A. Joles.[1] *[1]Nephrology, UMC, Utrecht, Netherlands; [2]Biology, Univ. Victoria, BC, Canada.*

Renal autoregulation, the kidneys' intrinsic property to maintain constant renal blood flow (RBF) and glomerular filtration (GFR) with fluctuating renal perfusion pressures, is necessary for normal renal function and volume homeostasis, and to protect the kidney against increased pressures. Impaired renal autoregulation is believed to be responsible for enhanced susceptibility to renal damage in chronic kidney disease (CKD).

In contrast to steady-state, dynamic analysis of autoregulation can be used to study multiple controllers operating in parallel under physiologically relevant conditions. As the level and pattern of BP fluctuation can vary significantly, BP was forced by a computer-driven suprarenal aortic clamp. Such broadbandforcing ensures that all relevant input frequencies are equally represented and that relevant control loops are opened. Dynamic analysis of renal autoregulation was assessed under isoflurane anesthesia in male CKD rats (5/6 subtotal nephrectomy) vs. Sprague Dawley control. Male Fawn-Hooded Hypertensive (FHH) rats, a genetic model for defective autoregulation and progressive glomerulosclerosis, were used as positive controls.

Body weight, mean arterial pressure and left kidney RBF were similar between groups. GFR was lower in CKD than in control rats (0.55±0.03 vs 1.24±0.19 ml/min, $p<0.001$).

Renal blood flow dynamics

| | | RPP, forced | Slope of gain reduction | Phase Peak |
|---|---|---|---|---|
| | *n* | *mmHg* | *dB/decade* | *rad* |
| Control | 8 | 95±2 | 24±3 | 1.11±0.12 |
| CKD | 5 | 95±4 | 12±3# | 0.56±0.15# |
| FHH | 4 | 85±3 | 6±1# | 0.33±0.11# |

# $P<0.05$ vs. Control

Dynamic analysis of renal autoregulation revealed gain reduction <~0.2 Hz, and associated phase peak in controls, indicating effective autoregulation mediated by the myogenic mechanism (0.06 to 0.2 Hz). CKD rats displayed marked impairment of the myogenic mechanism shown by inhibition of slope of gain reduction ($p=0.03$ vs control) and lower phase peak ($p=0.012$ vs control), both of which approached values seen in FHH rats.

In conclusion, these data are consistent with pressure-passive behavior of the renal circulation in experimental CKD resembling an accepted model of impaired renal autoregulation and progressive injury.

**Pro-Fibrotic Role of Matrix Metalloproteinase-9 in a Murine Fibrotic Model of Unilateral Ureteral Obstruction** Thian Kui Tan,[1] Guoping Zheng,[1] Tim Tzu-Ting Hsu,[1] Xinrui Tian,[1,2] Qi Cao,[1] Ya Wang,[1] Yiping Wang,[1] Vincent W. S. Lee,[1] Dong Zheng,[1] David C. Harris.[1] *[1]Centre for Transplantation and Renal Research, Westmead Millennium Institute, Sydney, New South Wales, Australia; [2]Department of Respiratory Medicine, The Second Hospital of Shanxi Medical University, Shanxi, China.*

Matrix metalloproteinase-9 (MMP-9) appears to promote renal fibrosis. Previously, we showed that macrophage MMP-9 causes tubular cell (TEC) epithelial-mesenchymal transition (EMT); TGF-β-induced TEC EMT is dependent on MMP-9 activity; and MMP-9 is upregulated in murine unilateral ureteral obstruction (UUO). The aim of this study was to determine the profibrotic role of MMP-9 in murine UUO via stage-specific inhibition of MMP-9 activity. Renal MMP-9 expression in BALB/c mice with UUO was examined on day 1, 3, 5, 7, 9, 11 and 14. To inhibit MMP-9 activity, MMP-2/9 inhibitor (Inh) or MMP-9 neutralising antibody (Ab) (2mg/kg) was administered daily for 4 consecutive days from day 0-3, 6-9, or 10-13 and tissues harvested at day 14. In UUO, there was a biphasic (early and late-stage but not mid-stage) upregulation of MMP-9 activity. Double immunofluorescence staining revealed co-localisation of MMP-9 with TEC, macrophages and myofibroblasts in UUO kidney. Early- and late-stage but not mid-stage inhibition of MMP-9 by MMP-2/9 Inh or MMP-9 Ab resulted in a significant (at $P<0.05$) reduction of fibrosis [51% & 29% Inh; 31% & 73% Ab]; macrophage infiltration [20% & 34% Inh; 27% & 33% Ab], α-SMA expression [46% & 76% Inh; 51% & 62% Ab] and MMP-cleaved osteopontin expression [61% & 57% Inh; 78% & 91% Ab] in obstructed kidney. Cytoplasmic & nuclear translocation of membrane β-catenin, indicating EMT, was also reduced by the MMP-2/9 Inh and MMP-9 Ab. In conclusion, our study has demonstrated an important role of MMP-9 in causing renal fibrosis in UUO, the time dependency of its expression and its potential as a therapeutic target.

**F-PO1164**

**Renal Phenotypes in Mice with Homozygous Mutation of the Gene Encoding Canonical Transient Receptor Potential 1 Channel (TRPC1): Evidence for Renal Failure in a Novel Mouse Model of Chronic Kidney Disease** Kai Lau,[1,5] Bonnie Eby,[1] Chris Skaggs,[4] Erin Johnston,[1] Richard Matthew Atkins,[1] Jan L. Guz,[2] Joel Abramowitz,[3] Lutz Birnbaumer,[3] Leonidas Tsiokas.[2] *[1]Medicine, University of Oklahoma, Oklahoma City, OK; [2]Cell Biology, University of Oklahoma, Oklahoma city, OK; [3]Intramural Research, NIEHS, Research Triangle Park, NC; [4]Radiology, University of Oklahoma, Oklahoma City, OK; [5]Medicine, VA Hospital, Oklahoma City, OK.*

TRP is a superfamily of various cation-permeable channels implicated in ion homeostasis and/or signal transduction. We found a critical role of TRPC1 in cardiac hypertrophic signaling. Others showed its role in vascular smooth muscle proliferation & hyperplasia and in mesangial cell contractility. TRPC1 heteromultimerizes with polycystin 2 to form a ion channel distinct from that created by the complexes of polycystins 1 & 2, suggesting a possible role in cystogenesis. Its expression is down-regulated in diabetes. Since its in-vivo role is unknown, we studied serial renal functions & structures in 12 age-matched pairs of male TRPC1 -/- & +/+ mice of the 129 Sv background. At 7 mon, kidney volume by echo (0.38 vs. 0.46 cc., $p<0.01$) & kidney weight (KW) to body (B) W (1.2 vs. 1.45 %, $p<0.04$) were 17% lower in -/- mice. At 11 mon, echogenicity was similar, but volume remained 16% lower (0.42 vs. 0.5 cc., $p<0.01$) & KW:BW fell further in -/- mice (1.1 vs. 1.53 %, $p<0.01$). At 12 mon, serum creatinine by HPLC was similar but by 17 mon increased by 87% in -/- mice (0.103 vs. 0.055 mg/dl, $p<0.01$). Creatinine clearance by HPLC fell by 42 % (0.66 vs. 1.13 ml/min/mouse, $p<0.01$) & by 50% when factored for BW (1.7 vs. 3.4 ml/100g, $p<0.01$). Hypercalciuria or proteinuria were absent. Concentration ability was intact by urine osmolality after 17 h dehydration. Acidification was impaired

by urine pH (6.0 vs. 5.2, p<0.01). Since -/- mice developed diabetes at 12 mon, our data support the hypothesis that TRPC1 protein plays a key role in normal renal development & in the adaptive hypertrophic & hyperfiltration responses to diabetes. Its absence may accelerate progression to renal failure induced by diabetes.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1165**

**Lysosome Membrane Protein-2, a Urinary Exosomal Marker for Idiopathic Membranous Nephropathy** Michael Merchant,[1] Jeroen Deegens,[2] Ilse M. Rood,[2] Daniel W. Wilkey,[1] Terry Zhang,[3] Brad H. Rovin,[4] Vlad Zabrouskov,[3] Jack F. Wetzels,[2] Jon B. Klein.[1,5] *[1]University of Louisville; [2]Radboud University Nijmegen Medical Center; [3]Thermo Fisher Scientific; [4]Ohio State University; [5]Veterans Administration Medical Center.*

Urinary exosomes are the intraluminal vesicles of multi-vesicular bodies and contain proteins specific for podocytes and tubular cells. We hypothesized that the proteome of urinary exosomes isolated from patients with idiopathic membranous nephropathy (iMN) and focal segmental glomerular sclerosis (FSGS) would be different from normal control (NC) urine samples. Exosomes were isolated from urine collected from iMN (n=5) and FSGS (n=5) patients with biopsy proven disease and compared with those from NC urine (n=3). Exosomes were analyzed using a multiplexing approach (8-plex iTRAQ) and LCMS methods (1D-RP-HPLC-ESI-LTQ-VELOS-Orbitrap and Proteome Discover Software). Stringent analysis of iTRAQ labels (one way ANOVA and t-test p-value less than 0.01) indicated changes in abundance of nine proteins. One protein, lysosome membrane protein 2 (LIMP2) also known as scavenger receptor class B, member 2 (SCARB2), was increased greater than two-fold in iMN exosomes above FSGS and control samples. To explore our proteomic findings, IHC analysis of human renal biopsies from FSGS, iMN, disease controls (diabetic nephropathy with proteinuria) and normal controls suggests a striking increase in tubular and glomerular staining for LIMP2 in iMN and FSGS sections over controls. LIMP2 gene mutations have been associated with action myoclonus-renal failure syndrome (AMRF) that presents with focal collapsing glomerulosclerosis. These mutations lead to LIMP2 retention in the endoplasmatic reticulum. In the puromycin aminonucleoside rat model of FSGS, the loss of podocyte foot processes correlated with LIMP2 over-expression. We conclude that renal LIMP2 is upregulated in iMN and FSGS. However, as shown in AMRF, LIMP2 may be unable to reach lysosomes and exosomes in patients with FSGS, resulting in glomerulosclerosis. Urinary LIMP2 is a candidate biomarker for iMN and demonstrates the potential value of urinary exosomes in the diagnosis of renal diseases.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1166**

**Role of Mineralocorticoid Receptor/Rho/Rho-Kinase Pathway in Obesity-Related Renal Injury** Hirobumi Tokuyama, Shu Wakino, Koichi Hayashi. *Medicine, Keio University, Tokyo, Japan.*

Both aldosterone and Rho-kinase are demonstrated independently to play an important role in renal injury and impaired insulin signalling. We therefore examined whether aldosterone/Rho/Rho-kinase pathway contributed to obesity-associated nephropathy. C57BL/6J mice were fed a high fat (HFD) or low fat diet (LFD) and mice on HFD were treated with a mineralocorticoid receptor (MR) antagonist, eplerenone. The mice on HFD developed obesity, and hyperglycemia compared with those on LFD, but manifested similar levels of systolic blood pressure. In HFD-fed mice, glomerular hypercellularity and increased mesangial matrix were noted, which paralleled the increase in albuminuria (HFD, 0.13±0.04mg/gCr, P<0.01 vs LFD, 0.02±0.01mg/gCr). The treatment with eplerenone alleviated the histological changes and albuminuria (0.04±0.01mg/gCr, P<0.01 vs HFD) without alterations in systemic blood pressure. Adipose tissue weight and adipocyte size of HFD-fed mice were increased, which were ameliorated by eplerenone. Furthermore, enhanced Rho-kinase activity was noted in kidneys (2.0-fold, p<0.05) and adipose tissues (1.8-fold, p<0.05) from HFD-fed mice, as well as increased expressions of MCP-1, TNF-α and PDGF-B. All of these changes were attenuated by eplerenone. In HFD-fed mice, MR protein levels in the nuclear fraction were increased in kidneys (2.3-fold, p<0.05) and adipose tissues (2.0-fold, p<0.05) without elevation in serum aldosterone levels (LFD, 278±14mg/dl, HFD, 297±12mg/dl). Finally, in mesangial cells, stimulation with aldosterone increased Rho-kinase activity, and pre-incubation with eplerenone prevented the aldosterone-induced activation of Rho-kinase. In conclusion, excess fat intake causes obesity and renal injury in C57BL/6J mice, and these changes are mediated by an enhanced mineralocorticoid receptor /Rho/Rho-kinase pathway and inflammatory process. Mineralocorticoid receptor activation in the kidney and the adipose tissue and the subsequent Rho-kinase stimulation are likely to participate in the development of obesity-associated nephropathy without elevation in serum aldosterone levels.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1167**

**Targeted Degradation of Cytosolic β-Catenin Dissociates Profibrotic from Anti-Inflammatory Effects of TGF- β1** Xinrui Tian,[1,2] Guoping Zheng,[1] Thian Kui Tan,[1] Tim Tzu-Ting Hsu,[1] Ya Wang,[1] Qi Cao,[1] Dong Zheng,[1] Yiping Wang,[1] Vincent W. S. Lee,[1] David C. Harris.[1] *[1]Centre for Transplantation and Renal Research, Westmead Millennium Institute, Sydney, New South Wales, Australia; [2]Department of Respiratory Medicine, The Second Hospital of Shanxi Medical University, Shanxi, China.*

**Aim**: To differentiate the profibrotic role of TGF- β1 from its anti-inflammatory effect by targeting cytosolic β-catenin.

**Background:** TGF- β1 is known to be both anti-inflammatory and profibrotic. β-catenin, as a central mediator of some TGF- β1 pathways is activated during fibrosis and tissue remodeling and was found dispensable for hematopoiesis, lymphopoiesis and B cell development and function under physiological conditions. Targeting β-catenin holds a potential to dissect the profibrotic property of TGF- β1 from its immunosuppressive effect.

**Methods:** A protein knockdown chimera (F-Trcp-Ecad) in murine C1.1 tubular epithelial cell and J774 murine macrophages to decrease the levels of cytosolic and presumably nuclear β-catenin was used to test its roles in TGF- β1-induced epithelial-mesenchymal transition (EMT) in C1.1 cells and in inhibition of macrophage activation.

**Results:** F-trcp-Ecad preferentially targeted soluble nuclear/cytosolic β-catenin for degradation. TGF-β1-induced EMT and E-cadherin, snail transcription and MMP-9 activity in C1.1 cells was reduced by cytosolic β-catenin knockdown. However, the steady state level of β-catenin in J774 cells was low and there was no change when J774 cells were exposed to IFN-γ or LPS with or without TGF-β1. TGF-β1 inhibition of LPS-induced TNF-α mRNA and IFN-γ-stimulated iNOS mRNA expression was not affected in J774 cells expressing wild type β-catenin or F-trcp-Ecad.

**Conclusio**n: In this study, we present novel evidence that degrading unphosphorylated β-catenin in the cytosol resulted in the inhibition of EMT induced by TGF-b1 in tubular epithelial cells but had no effect on TGF- β1 inhibition of macrophage activation. This suggests that the profibrotic and anti-inflammatory pathways of TGF- β1 can be dissociated, with implications for therapy targeting TGF- β1.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1168**

**Correction of Lysosomal Dysfunction and Autophagy in Diabetes by Tunneling Nanotube (TNT) Exchange between Endothelial and Endothelial Progenitor Cells (EPC)** Kaoru Yasuda, Leonid Buryanovskyy, Anupama Khandare, Peter Jose Hayek, Frank Fan Zhang, Alberto Nasjletti, Michael S. Goligorsky. *New York Medical College, Valhalla, NY.*

We have demonstrated that diabetic milieu triggers collapse of lysosomal pH gradient, lysosomal permeabilization, and frustrates autophagy - leading to developing stress-induced premature senescence (SIPS) of vascular endothelium and vasculopathy. Adoptive transfer of bone marrow-derived cells markedly improved macro- and microvasculopathy. In the present investigation we analyzed the ability of EPC to transfer lysosomes to HUVEC (and vice-versa) via TNT. We examined the transfer ratio, HUVEC viability and SIPS under diabetic-like milieu. Application of non-enzymatically glycated collagen (GC) for 3 days resulted in a dramatic increase in the population of non-viable, senescent, and apoptotic cells, which were decreased approximately 2-fold after 24 h co-incubation of HUVEC with intact EPC. Disruption of TNT formation with cytochalasin B annulled this effect of EPC. Differential labeling of HUVEC and EPC with the Celltracker CFDA and Lysotracker provided direct evidence of TNT formation between these cells. The rate of exchange was 29.97±0.80% after co-culture for 24 hours. Egress of highly acidic lysosomes from EPC along the TNT toward GC-treated HUVEC, which express lysosomes with the collapsed pH gradient was examined using acridine orange labeling of acidic compartments. Transferred lysosomes maintained pH gradient associated with the improved fusion of lysosomes and autophagosomes. In vivo, STZ-treated diabetic mice received an adoptive transfer of intact EPC or EPC pretreated with cytochalasin B. EPC treatment resulted in improved acetylcholine-induced relaxation of aortic rings and reduced number of senescent cells in the adventitial layer. However, prevention of TNT formation resulted in the reduced efficacy of adoptively transferred EPC. In conclusion, in vitro TNT formation between EPC and injured endothelial cells is partially responsible for restoration of functional lysosomal pool resulting in correction of autophagy with improved cell viability and in vivo improvement in macro- and micro- vasculopathy.

Disclosure of Financial Relationships: nothing to disclose

**A Novel Role for miR-382: Targeting of SOD2 during TGFβ1-Induced Loss of Epithelial Characteristics in Human Renal Epithelial Cells** Alison J. Kriegel,[1] Yong Liu,[1] Yi Fang,[2] Domagoj Mladinov,[1] Xiaoqiang Ding,[2] Mingyu Liang.[1] *[1]Department of Physiology, Medical College of Wisconsin, Milwaukee, WI; [2]Division of Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

We recently identified microRNA-target pairs showing differential expression after TGFβ1 treatment of HK-2 human renal epithelial cells by combining microRNA and proteomic analysis. That analysis revealed that TGFβ1 treatment (3 ng/ml, 24 hours) increased miR-382 expression and suppressed protein expression of predicted miR-382 target Mn-superoxide dismutase (SOD2), an enzyme important for the protection against

mitochondrial oxidative stress. Here we validated these results and investigated the functional role of miR-382 interaction with SOD2 in the development of TGFβ1-induced loss of epithelial characteristics in HK-2 cells. Targeting of SOD2 transcript by miR-382 was confirmed by 3'-untranslated region reporter assay. Knockdown of miR-382 by anti-miR-382 transfection attenuated the loss of epithelial marker E-cadherin with TGFβ1 treatment. In addition, the reduction in SOD2 protein levels with TGFβ1 treatment was blunted by knockdown of miR-382. Overexpression of SOD2 significantly attenuated TGFβ1-induced reduction in E-cadherin. These results indicate that TGFβ1 up-regulates miR-382, which contributes to down-regulation of SOD2 and loss of renal epithelial characteristics. This novel mechanism might be relevant to the development of renal interstitial fibrosis.

Disclosure of Financial Relationships: nothing to disclose

**F-PO1170**

**MicroRNA miR-382 Contributes to the Development of Renal Interstitial Fibrosis** Alison J. Kriegel, Kristie Usa, Mingyu Liang. *Department of Physiology, Medical College of Wisconsin, Milwaukee, WI.*

We previously found an increase in miR-382 expression in cultured human renal epithelial cells treated with TGFβ1. In the current study we examined the in vivo role of miR-382 in the development of renal interstitial fibrosis. Exposure of CD-1 mice to 3 days of unilateral ureteral obstruction (UUO) increased miR-382 expression in the kidney by 363 ± 121% (vs. sham operated controls, $p<0.05$; n=6/group). Locked nucleic acid (LNA)-modified anti-miR-382 or scrambled anti-miR (10 mg/kg) was delivered by tail vein injection prior to UUO or sham surgery and repeated 24 hours following surgery (n=8-10/group). Fibrosis measurements were made in the cortex, outer medulla, and inner medulla of trichrome stained kidney sections after 3 days of UUO. UUO, again, produced a nearly 3 fold increase in miR-382 expression in mice receiving scrambled anti-miR. The anti-miR-382 treatment completely prevented this increase in miR-382. In scrambled anti-miR treated mice, UUO significantly increased the percent areas of fibrotic tissue in the outer medulla and inner medulla. Treatment with anti-miR-382 significantly reduced percent fibrotic areas in the inner medulla from 16.0 ± 1.3% in UUO mice treated with scrambled anti-miR to 10.2 ± 1.5% in UUO mice treated with anti-miR-382 ($P<0.05$), the latter no longer significantly different from sham animals receiving scrambled anti-miR (9.3 ± 2.0%). Moreover, anti-miR-382 reduced baseline miR-382 expression in sham animals by 46.5 ± 8.2% ($P<0.05$). Concomitantly, sham animals treated with anti-miR-382 had significantly less fibrosis in the cortex and outer medulla than animals receiving scrambled anti-miR (1.4 ± 0.1% vs. 2.1 ± 0.2% and 1.6 ± 0.1% vs. 2.9 ± 0.4 %, respectively; $p<0.05$ for each). These data indicate that miR-382 contributes importantly to the development of renal interstitial fibrosis in vivo.

**Administration of Adiponectin Retards the Progression of Diabetic Nephropathy in db/db Mice through Targeting the RAS** Xiaohua Guo,[1] Yufeng Huang,[1] Guangyu Zhou,[1] Alfred K. Cheung,[1,2] Srinivasan Beddhu.[1,2] *[1]Univ Utah; [2]VA, SLC, UT.*

Adiponectin is an anti-inflammatory adipokine and its deficiency in obesity is considered to play a major role in insulin resistance. However, some large epidemiological studies suggest that higher levels of serum adiponectin are associated with kidney disease progression. Because of these counter-intuitive data, we sought to examine whether administration of recombinant ADPN retards or accelerates the progression of glomerulosclerosis in the db/db mice uninephrectomized at week 8 (a model of type II diabetes where overt nephropathy is established at 20 weeks of age). Recombinant human ADPN was administered at a dose of 30μg or 150ug per day (ip, twice-daily) from week 19 for two consecutive week. Rosiglitazone (20mg/kg BW by gavage daily) served as therapeutic control. Untreated uninephrectomized db/db mice developed progressive albuminuria and glomerular mesangial matrix expansion associated with increased expression of TGFß1, PAI-1, type 1 collagen and fibronectin, compared with nondiabetic db/m mice. Although body weight and blood glucose were comparable in all diabetic mice, treatment with ADPN at either 30μg or 150μg prevented the increases in albuminuria and markers of renal fibrosis seen in db/db mice. The effect of ADPN on Ang II-related fibrogenic action in cultured glomerular mesangial cells (GMCs) was further investigated. Ang II (10-6M) increased the mRNA expression of TGFß1 by 3 fold ($P<0.01$) and PAI-1 by 2 fold ($P<0.01$) at 24h and increased the mRNA expression of collagen I by 2.3 fold ($p<0.01$) and fibronectin by 2.2 fold ($P<0.01$) in mouse GMCs. Interestingly, ADPN obliterated the stimulatory effect of Ang II on GMCs mRNA expression in a dose-dependent manner. These observations suggest that ADPN treatment halts glomerulosclerosis resulting from type 2 diabetes through targeting the renin-angiotensin-system. Thus, the therapeutic administration of ADPN has promise in preventing the progression of diabetic nephropathy.

**ARF6, a Novel Target for Renal Fibrosis, Mediates TGFβ-Induced Epithelial Mesenchymal Transition in Renal Tubular Epithelial Cells** Xiaohua Guo, Dean Y. Li. *Molecular Medicine Program, University of Utah, Salt Lake City, UT.*

Renal fibrosis is as a result of aberrant accumulation of extracellular matrix in kidney produced by myofibroblasts which mainly originate from renal tubular epithelial that undergo epithelial mesenchymal transition (EMT). ADP-ribosylation factor (ARF6), of the ARF family of small GTP-binding proteins, has been shown to participate in a wide variety of cellular events including regulation of membrane trafficking and actin cytoskeleton remodeling. In our experiment, we found markedly increase of ARF6 activity either in a mouse model of unilateral ureteral obstruction (UUO) induced renal fibrosis or in TGFβ induced EMT in renal tubular epithelial cells when compared with normal control group. Administration of inhibitor of Arf6 activity significantly attenuates extracellular matrix production in UUO mouse either Day 5 or Day 10, as well as myofibroblast markers αSMA and vimentin. Inhibitor of Arf6 activity also reverses EMT induced by TGFβ in renal tubular epithelial cell. Further evidence showed Arf6 plays a critical role in the breakdown of adherens junction, a key event during EMT process. The new finding indicating that inhibition of Arf6 activity is a promising strategy to treat renal fibrosis disease.

**IL-25 Promotes Th2 Response and Induces Alternatively Activated Macrophages in Protection of Renal Injury** Qi Cao,[1] Changqi Wang,[1] Dong Zheng,[1] Ya Wang,[1] Yuan Min Wang,[2] Vincent W. S. Lee,[1] Guoping Zheng,[1] Thian Kui Tan,[1] Stephen I. Alexander,[2] David C. Harris,[1] Yiping Wang.[1] *[1]Centre for Transplantation and Renal Research, Westmead Millennium Institute, Sydney, NSW, Australia; [2]Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia.*

IL-25 is a recently described cytokine which has a role in regulation of inflammation in the gastrointestinal tract and autoimmune diseases. In the present study, the effects of IL-25 in chronic kidney disease were examined in a murine model of adriamycin nephropathy (AN). **Methods:** Murine AN was induced by 10 mg/kg adriamycin in BALB/c mice and 5.4 mg/kg in SCID mice. IL-25 was given by 7 consecutive daily injections starting at day 5 after adriamycin administration. **Results:** Kidneys from AN BALB/c mice administered with IL-25 had less glomerulosclerosis, tubular atrophy and interstitial expansion than did control AN BALB/c mice. AN mice infused with IL-25 also had significantly reduced proteinuria compared to AN alone mice. The possible mechanisms underlying the protective effect of IL-25 were examined. *In vivo*, IL-25 increased the levels of IL-4, IL-5 and IL-13 in serum and induced alternatively activated macrophages (M2) in the kidney. To determine whether the protective effect of IL-25 in AN BALB/c mice was Th2 response dependent or due to a direct effect on M2, IL-25 was further examined in AN SCID mice in which T and B cells were deficient. IL-25 failed to induce M2 or protect against renal structural and functional injury in AN SCID mice. **Conclusion:** IL-25 protected against renal injury in AN model. Its protective effects are dependent on induction of Th2 immune responses.

**Ex Vivo Modified Plasmacytoid Dendritic Cells but Not Bone Marrow Dendritic Cells Ameliorate Experimental Chronic Inflammatory Renal Disease** Dong Zheng, Qi Cao, Changqi Wang, Ya Wang, Vincent W. S. Lee, Guoping Zheng, Thian Kui Tan, Yiping Wang, David C. Harris. *Centre for Transplantation and Renal Research, The University of Sydney, Sydney, NSW, Australia.*

Plasmacytoid dendritic cells (pDC), which are regarded usually as being of lymphoid origin, display a regulatory role in autoimmune diseases and graft-versus-host disease. Dendritic cells (DC) from bone marrow (BM) have also been shown to induce immune tolerance and prevent rejection in transplantation. However, the effect of pDC and DC from BM in chronic kidney disease (CKD) is unknown. Our study aimed to explore the role of pDC and DC from BM in treating murine adriamycin (ADR) nephropathy (AN), and possible mechanisms involved in their protective effects.

pDC were separated from spleen of BALB/c mice using anti-mPDCA-1 magnetic microbeads (MACS) (naïve pDC) and stimulated with LPS (0.5μg/ml) for 24 hrs to become regulatory pDC. BM DC were prepared from BM, and cultured with GM-CSF and IL-10 for 7 days, followed by LPS for 24h. One million cells were transferred into each BALB/c mouse on day 5 after ADR administration. Renal function and histology were analysed quantitatively at 4 weeks. pDC localised to renal cortex, but BM DC did not appear in kidney. pDC, but not BM DC, reduced glomerulosclerosis (normal vs ADR vs naïve pDC vs regulatory pDC: 2.3±0.3 vs 28.0±4.6 vs 28.4±3.7 vs 12.6±1.8%, $p<0.01$), tubular atrophy (tubular cell height 7.34±0.38 vs 1.45±0.23 vs 1.11±0.29 vs 5.72±0.91μm, $p<0.05$), and interstitial expansion (interstitial volume 1.8±0.6 vs 26.8±1.1 vs 28.3±2.5 vs 12.6±1.0%, $p<0.01$). Transfusion with regulatory pDC also significantly reduced proteinuria and impairment of creatinine clearance. The mechanisms underlying the protective effects of modified pDC in AN involved their ability to transform naïve T cells into Foxp3+ Tregs (naïve pDC vs regulatory pDC 6.67±0.76% vs 18.69±2.52%, $p<0.01$) and to deactivate effector macrophages.

Modified pDC, but not BM DC protect against structural and functional injury in AN, providing a potential therapeutic strategy for CKD.

**F-PO1175**

**The Transcription Factor ETS-1 Mediates Angiotensin II Induced Fibronectin Transcription in Mesangial Cells Via Cooperative Interactions with CREB** Ping Hua,[1] Wenguang Feng,[1] Shaonin Ji,[1] Gabriel Rezonzew,[1] Edgar A. Jaimes.[1 2] *[1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]VA Medical Center, Birmingham, AL.*

Angiotensin II (Ang II) plays a critical role in the pathogenesis of CKD in large part by increasing the glomerular deposition of extracellular matrix. We have previously shown that Ang II increases the expression of the transcription factor ETS-1 in mesangial cells (MC) and that ETS-1 mediates MC fibronectin (FN) expression (AJP'08) by directly binding and activating the fibronectin promoter (ASN' 09). In the current studies we further investigated the transcriptional regulation of FN by ETS-1 in rat MC. Mutation of two putative ETS-1 binding sites (M1 and M2) on the FN promoter fragment nt-943/+106 were generated by site-directed mutagenesis and ligated to reporter plasmid pGL3/basic. When pGL3/M1 or pGL3/M2 were co-transfected with a mouse ETS-1 expression vector into MC, the promoter activities decreased by 32.5% and 37.5% respectively in comparison with the WT construct pGL3/-943/+106. Double mutation of both M1 and M2 did not further decrease promoter activities. Mutation of a cAMP-responsive element binding site (CM) decreased promoter activity by 63.5% in comparison with the WT construct pGL3/-943/+106, thus indicating that cAMP-responsive element binding protein (CREB) is needed for FN promoter activity transducted by ETS-1. To better study the interaction between ETS-1 and CREB, we performed Co-IP and Electromobility Shift Assays (EMSA) in MC stimulated with Ang II ($10^{-7}$ M for 2 hours)**.** By Co-IP we determined direct binding of ETS-1 and CREB in nuclear protein extracts from MC treated with Ang II. By EMSA we determined that oligonucleotides covering either M2 or CM, but not M1, bind strongly to nuclear protein extracts from MC stimulated with Ang II. The specificity of the DNA/protein complexes was confirmed by supershift assay with an ETS-1 antibody (M2) and a CREB antibody (CM). In summary, we have identified two active ETS-1 binding sites on the rat FN promoter and have also established the role of CREB as a critical co-activator in the transcriptional regulation of FN by ETS-1 in MC.

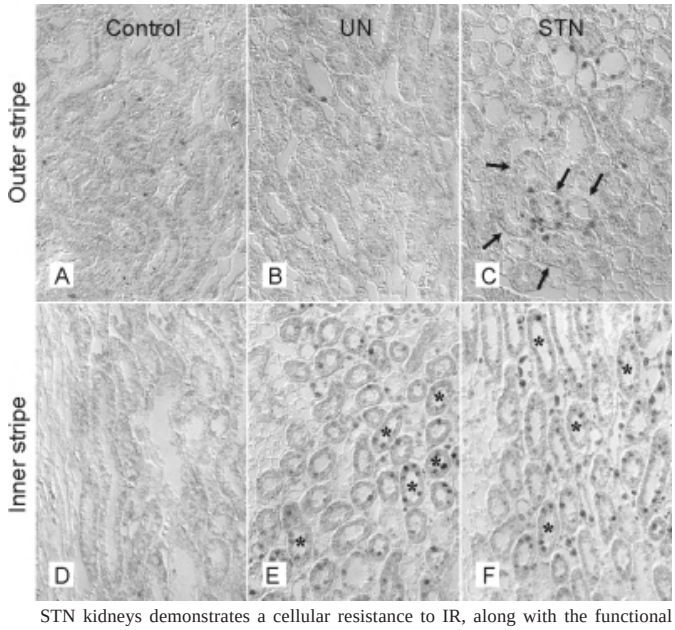
**Pre-Conditioning by Hypoxia Inducible Factor in Subtotal Nephrectomy** Prabhleen Singh,[1] Christian Rosenberger,[2] Francis B. Gabbai,[1] Scott C. Thomson,[1] Roland C. Blantz.[1] *[1]UCSD&VASDHS; [2]Charité - Universitätsmedizin Berlin.*

We have reported an unexpected, functional resistance to ischemia reperfusion (IR) in rats after subtotal nephrectomy (STN) despite major reduction in renal mass and function (ASN 2009). After IR in STN, the GFR was lowered by only 25%, but in unilateral nephrectomy (UN) controls, a precipitous drop in GFR of 75% (p=0.0001) was observed. We have also reported that early hemodynamic adaptations in STN, such as lack of normal tubuloglomerular feedback (AJP 2009), which typically curtails the GFR after IR, may pre-condition the kidney against IR.

Presently, we examined the morphological and molecular components of this pre-conditioning response. We assessed tubular necrosis after IR by semiquantitative histological scoring, and found significantly lower scores for severe tubular necrosis in STN compared to UN (78 vs. 189, p=0.03).

We, then, examined the expression of hypoxia inducible factor (HIF) by immunohistochemistry, as prior activation of HIF is known to afford cellular protection against IR. In STN only, we observed clusters of HIF positive cells in the S3 segment of the proximal tubule (arrows in Figure 1C), the usual site of injury during IR. Medullary thick ascending limb cells (asterixes in Figure 1) were also positive for HIF with a modestly stronger signal in STN vs. UN. This pattern of HIF expression has never been reported. In further support, GFR was nearly preserved after IR in UN treated with cobalt chloride, a known HIF inducer (1.4 vs. 0.5 ml/min in untreated, p=0.0001).



STN kidneys demonstrates a cellular resistance to IR, along with the functional preservation. This suggests that molecular events in STN confer cellular protection beyond what can be afforded simply by the hemodynamic adaptations. An important role of HIF may be implicated in this pre-conditoning phenomenon naturally occuring in early STN.

**Localization and Functional Role of Thioredoxin-Related Protein 14 (TRP14) in the Mouse Kidney** Sunjoo Park,[1] Su-Youn Lee,[2] Woojin Jeong,[1] Ki-Hwan Han,[2] Sue Goo Rhee.[1] *[1]Division of Life and Pharmaceutical Sciences, Ewha Womans University, Seoul, Korea; [2]Department of Anatomy, Ewha Womans University, Seoul, Korea.*

A novel 14 kDa thioredoxin-related protein (TRP14), which shares 20% sequence identity and 37% similarity with thioredoxin 1 (Trx1), is highly expressed in the kidney, but its exact localization and role have not been determined. To study the function of TRP14, we generated transgenic knockdown (KD) mice by siRNA. Kidney tissues were processed for immunohistochemistry and immunoblot analysis. TRP14 was expressed primarily in the proximal tubule and medullary collecting duct in the mouse kidney, showing similar expression patterns of Trx1. There were no detectable changes in renal function in young TRP14 KD mice. However, in old aged mice, genetic ablation of TRP14 resulted in tubular damages and significant elevation in serum BUN and creatinine. Electron microscopy demonstrated severe mitochondrial damage and accumulation of numerous autophagic vacuoles in the proximal tubule. Ratios of LC3 II to LC3 I and Atg5 expression increased in old TRP14 KD mice. These findings suggest that TRP14 may play an important role in protecting kidney during normal aging process.

**In Contrast to Healthy Bone Marrow, Uremic Bone Marrow Cannot Restore GFR in CKD** Arianne van Koppen, Jaap A. Joles, Marianne Christina Verhaar. *Nephrology & Hypertension, UMC, Utrecht, Netherlands.*

Healthy bone marrow derived cells (BMDC) confer functional protection in a rat model of CKD (ASN 2009). Hence we compared functional and structural effects of healthy and uremic BMDC in this model. In Lewis rats, CKD was induced by 5/6 nephrectomy (SNX), plus L-NNA, a NO-synthase inhibitor (20 mg/L for 9 wk), and 8% salt diet until sacrifice. Six wk after SNX, CKD rats received 50*106 BMDC (N=7) obtained from healthy eGFP transgenic Lewis rats, or 50*106 BMDC (N=7) obtained from uremic eGFP transgenic Lewis rats, or 0.5 ml vehicle (N=9) by single renal artery injection. CKD in donor $GFP^+$SNX and recipient SNX rats was confirmed by uremia (resp. 14±1 and 13±2 vs. 6±1 mmol/L in healthy controls) and hypertension (resp. 143±19 and 140±14 vs. 101±6 mm Hg). Plasma urea, systolic blood pressure (SBP) and 24h-proteinuria were assessed fortnightly. 14 wk after BMDC or vehicle, GFR (inulin) and effective renal plasma flow (RPF; PAH) were determined under barbiturate anesthesia. Renal injury was scored.

Both healthy and uremic BMDC reduced SBP, proteinuria, glomerulosclerosis and tubular atrophy compared to vehicle in CKD rats. However, uremic BMDC was not effective after 14 wk: GFR: 1.1±0.4 vs. 1.0±0.6 ml/min, RPF: 4.6±1.4 vs. 3.1±1.8 ml/min and renal blood flow: 7.7±2.5 vs. 5.3±3.1 ml/min were not significantly different. In contrast, healthy BMDC administration vs. vehicle was functionally effective in CKD

rats after 14 wk: GFR: 1.8±0.4 vs. 1.0±0.6 ml/min ($p<0.05$), RPF: 5.5±1.8 vs. 3.1±1.8 ml/min ($p<0.05$) and renal blood flow: 9.4±2.9 vs. 5.3±3.1 ml/min ($p<0.05$). Healthy but not uremic BMDC decreased tubular inflammation and fibrosis.

In sum, in CKD rats, intrarenal injection of healthy $eGFP^+$ BMDC, but not of uremic $eGFP^+$ BMDC, ameliorates loss of kidney function.

**Dysregulation of Hepatic β-Chain ATP Synthase, SRB-1 and PDZK1 in Nephrotic Syndrome: Contribution to Defective HDL-Mediated Reverse Lipid Transport** Hamid Moradi, Nosratola D. Vaziri. *Medicine/Nephrology, University of California, Irvine, Irvine, CA.*

Heavy proteinuria (nephrotic syndrome) is associated with profound dysregulation of lipid/lipoprotein metabolism, impaired HDL-mediated reverse cholesterol transport and a high risk of atherosclerosis. HDL serves as a vehicle for uptake and transport of surplus lipids from the peripheral tissues for disposal in the liver. The latter involves two important receptors: a – SRB-1 which serves as the HDL docking receptor enabling HDL to unload its lipid cargo in the liver and return to circulation to repeat the cycle; and b – β chain ATP synthase which serves as an HDL endocytic receptor mediating the removal and catabolism of lipid-poor HDL particles. Expression of SRB-1 is regulated by PDZK1, a multifunctional membrane-associated protein which promotes SRB-1 production at the post-translational level. Given the critical role in hepatic SRB-1, β chain ATP synthase and PDZK1 in HDL-mediated reverse lipid transport, we studied expression of these proteins in the liver of rats with chronic puromycin-induced nephrotic syndrome and normal control rats. The nephrotic animals exhibited severe proteinuria, hypoalbuminemia, hypercholesterolemia, hypertriglyceridemia, reduced HDL/total cholesterol ratio and normal glomerular filtration rate. This was accompanied by a significant upregulation of the endocytic HDL receptor, β chain of ATP synthase (+62%, $P = <0.01$). In contrast, SRB-1 abundance was significantly reduced (-50%, $P = <0.01$) in the liver of nephrotic animals confirming our earlier studies (Kidney Int 56:621-626, 1999), which showed marked reduction of SRB-1 protein abundance despite normal SRB-1 mRNA abundance. The reduction in SRB-1 protein abundance was accompanied by a parallel decline in PDZK1 abundance (-24%, $P=0.01$). Thus, nephrotic syndrome results in a rise in hepatic β chain ATP synthase and a decline in SRB-1 protein abundance. The latter is associated with and, in part, mediated by the reduction of PDZK1 abundance. Together, these abnormalities can increase catabolism and diminish recycling of HDL and contribute to the defective reverse cholesterol/lipid transport in nephrotic syndrome.

**Urinary HIFs and miRNA 29b as Biomarkers in a New Rat Fibrosis Model** Hua Zhou, Asada Leelahavanichkul, Xuzhen Hu, Takayuki Tsuji, Zachary Dezman, Lara Zafrani, Peter S. Yuen, Robert A. Star. *NIDDK, NIH, Bethesda, MD.*

Chronic tubulointestitial fibrosis, a histological finding of many forms of chronic kidney disease, initially progresses insidiously without significant renal dysfunction, as measured by creatinine/eGFR. Typically, rat folic acid models produce transient renal tubular damage and renal dysfunction without long-term sequelae. We developed a new rat model of chronic progressive renal fibrosis and searched for early urinary biomarkers for renal fibrosis. Sprague Dawley rats were injected with folic acid (FA, 400mg/kg, i.v.) to induce acute kidney injury (AKI), and 4 injections were given weekly starting at day 14 (post-AKI). Blood and urine were obtained at pre-, day 2, week 1, 2, 3, 4, 5, 7, 20, or 32; organs were harvested at pre-, day2, week 2, 7, 20, or 32. Serum creatinine (Scr) peaked (3.43±0.62 mg/dL at day 2, $p<0.01$) then returned to baseline (0.45±0.03 mg/dL at 2 weeks vs preinjection 0.43±0.03 mg/dL). Albumin to creatinine ratio (ACR) did not increase until 20 weeks (293±102 μg/mg vs. baseline 3.4±3.2 μg/mg); Scr increased 30% at 32 weeks in both FA-treated and age-matched controls (0.6 vs 0.45 mg/dL). Despite apparently normal values for conventional renal biomarkers, we could detect significant fibrosis in kidney, abdominal aorta, and heart at 7 wks by Masson's trichrome staining; kidney scarring was detected by microCT. Urinary exosomal HIF-1α and HIF-2α were undetectable in normal rats and increased in 5/6 FA rats; urinary exosomal miR29b decreased ~8-fold at 7 wks when Scr and ACR remained normal. Urinary microRNA-29b at 7 weeks correlated with the tubulointerstitial fibrosis score at at 7 weeks ($R^2=0.68$, $p=0.012$). We conclude that 1) multiple injections of folic acid can induce chronic progressive tubulointerstitial fibrosis in rats along with aortic and cardiac fibrosis; 2) urinary exosomal HIF-1α and HIF-2α increased and miR29b decreased in the early, silent phase of chronic tubulointerstitial fibrosis; 3) urinary HIFs and miR 29b are potentially useful biomarkers that can non-invasively diagnose chronic renal fibrosis.

**Differential Activations of Unfolded Protein Response in Unilateral Ureteral Obstruction Renal Fibrosis Model** Chih-Kang Chiang,[1,2,3] Kuan-Yu Hung,[2] Shing-Hwa Liu.[3] *[1]Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital; [2]Department of Internal Medicine, National Taiwan University Hospital; [3]Institute of Toxicology, School of Medicine, National Taiwan University, Taipei, Taiwan.*

The aims of this study are to investigate whether endoplasmic reticulum (ER) stress involved in renal tubular cell loss and renal interstitial fibrosis by unilateral ureteral obstruction (UUO) rat model. Either candesartan (25 mg/kg/d) or vehicle alone was orally administered to male wistar rats from day 1 after unilateral ureteropelvical ligation was performed. As our hypothesis, ureteral ligation induced 3 times of GRP78 protein expression (an indicator of GRP78) within 24 hours, and then was maintained until day 14. The three ER stress branches (Inositol-requiring 1,IRE1; PKR-like ER kinase, PERK; and transcription factor 6, ATF6) were activated in response to UUO stress. We found that IRE1-splicing XBP-1 activities were attenuated by persistent ER stress induced by UUO. By contrast, PERK signaling, including translational inhibition and proapoptotic transcription regulator C/EBP homologous protein (CHOP) induction, was maintained. These results suggest a causal link between the differential expression of UPR branch signaling leading to tubular cell apoptosis and development of interstitial fibrosis. Candesartan-treated UUO rats showed less tubulointerstitial apoptosis and renal fibrosis. In contrast to vehicle-treated UUO kidney, candesartan successfully maintained the expression of splicing XBP1 and attenuated ATF4, splicing ATF6 and CHOP1 protein expression. Procaspase 12, an ER stress-related apoptosis signal, was also abolished by candesartan treatment. Base on these findings, we suggested that candesartan ameliorates renal apoptosis and fibrosis induced by UUO model is associated with the differential activation of the ER stress signaling.

**PI3K and Smad3 Mediate Murine Renal Fibrosis through Distinct Mechanisms** Gal Finer,[1] Tomoko Hayashida,[2] Yashpal S. Kanwar,[2] Leileata M. Russo,[3] Herbert Y. Lin,[3] H. William Schnaper.[2] *[1]Pediatrics, Children's Memorial Hospital, Northwestern University, Chicago, IL; [2]Pediatrics, Northwestern University, Feinberg School of Medicine, Chicago, IL; [3]Massachusetts General Hospital, Harvard Medical School.*

TGF-β plays a central role in renal fibrogenesis. We previously showed in vitro that PI3K and TGF-β-stimulated Smad3 activity lead to collagen I expression; this work is aimed to extend these findings to an in-vivo model. Balb/c mice treated with ADR (0.15 mg, iv) showed massive albuminuria and advanced global glomerulosclerosis, as described by others. Last year we showed that PI3K is activated in this model and its inhibition by LY294002 (25mg/kg, i.p, 2x/week) prevents ADR-induced fibrotic changes. Further work implicated PI3K p110 γ catalytic unit in this model, with increased mRNA expression of the isoform in ADR-treated kidneys and in cultured mouse podocytes treated with TGF-β. Here, we report studies in a mouse strain that more closely models human focal sclerosis/hyalinosis (FSGS) and implicates TGF-β/Smad signaling. ADR-treated 129/sj mice manifested nephrotic syndrome including albuminuria, hypoalbuminemia and hypercholesterolemia, and elevation of serum creatinine and BUN starting at fifth day after ADR administration. Histological changes, including segmental sclerosis and crescent formation, were more consistent with FSGS than those in Balb/c. PI3K activation was similar in the two strains. In ADR-treated 129/sj mice, Smad3 phosphorylation and nuclear localization shown by immunostaining, implicated TGF-β. A TGF-β inhibitor, soluble TGF-β type II receptor (sTβRII.Fc), ameliorated Smad3 activation and protected 129/sj mice from ADR-induced glomerular changes. Inhibition of TGF-β signaling diminished collagen I, αSMA and fibronectin mRNA expression, without effecting albuminuria. Thus, ADR-induced nephropathy in 129/sj mice shows features similar to human FSGS, and can be used to dissect disease mediated signaling mechnisms. PI3K plays a role in fibrogenesis and proteinuria whereas TGF-β is implicated only in extracelluar matrix accumulation, suggesting distinct mechanisms for proteinuria and fibrogenesis in kidney disease.

**F-PO1183**

**Association of Proteinuria with Urinary Concentration Defect in Puromycin Aminonucleoside Nephrosis** Gheun-Ho Kim, Sua Kim, Chor Ho Jo, Joon-Sung Park, Chang Hwa Lee. *Department of Internal Medicine, Hanyang University College of Medicine, Seoul, Republic of Korea.*

**Purpose**: Puromycin aminonucleoside (PA) can induce nephrotic syndrome in rats. In glomerular disease, proteinuria is known to be an important mediator of tubulointerstitial injury. Thus, it is conceivable that glomerular proteinuria may affect tubular function such as urinary concentration. We investigated whether urinary concentration defect is associated with proteinuria in PA-induced nephrosis and whether it is relieved by angiotensin converting enzyme (ACE) inhibition.

**Methods**: Glomerular proteinuria was induced by a single intraperitoneal injection of PA (150 mg/kg BW) in male Sprague-Dawley rats. In a half of them, enalapril (35 mg/kg BW) was daily given in food mixture for two weeks. After the animal experiment, kidneys were harvested for immunoblot analysis and histopathologic examination.

**Results**: Compared with controls (n=4), PA-treated rats (n=8) had overt proteinuria, polyuria and a lower urine osmolality. PA treatment induced remarkable tubulointerstitial injury and significant reductions in protein abundances of aquaporin-1 and Na-K-2Cl

cotransporter type 2 (NKCC2). Proteinuria was significantly correlated with osteopontin expression in the kidney (r=0.79, P<0.01), and inversely correlated with renal expression of aquaporin-1 (r=-0.85, P<0.01), aquaporin-2 (r=-0.79, P<0.01) and NKCC2 (r=-0.67, P<0.05) as well. The degree of tubulointerstitial injury was significantly correlated with proteinuria (r=0.90, P<0.01), urine output (r=0.67, P<0.05), and osteopontin expression (r=0.73, P<0.01), and inversely correlated with urine osmolality (r=- 0.77, P<0.01) and renal expression of aquaporin-1 (r=- 0.81, P<0.01), aquaporin-2 (r=- 0.86, P< 0.01) and NKCC2 (r= - 0.78, P<0.01). No differences in parameters between PA-treated rats with and without ACE inhibition were found probably because of large individual variations.

**Conclusion**: In acute PA-induced nephrosis, glomerular proteinuria was associated with tubulointerstitial injury and urinary concentration defect. Altered expression of osteopontin, aquaporin-1, aquaporin-2 and NKCC2 may be involved in this glomerulotubular connection.

**Aggravated Renal Tubular Damage and Interstitial Fibrosis in Mice Lacking Guanylyl Cyclase-A (GC-A), a Receptor for Atrial and B-Type Natriuretic Peptides** Fumiki Yoshihara,[1] Takeshi Tokudome,[1] Ichiro Kishimoto,[2] Takeshi Horio,[1] Yuhei Kawano.[1] *[1]Division of Hypertension and Nephrology, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan; [2]Division of Endocrinology and Metabolism, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan.*

Background: Chronic angiotensin II (Ang II) infusion causes to an increase of renal interstitial fibrosis. Aim: We infused Ang II (1.0 mg/kg/day) in GC-A-deficient mice (GC-A-KO), to evaluate the pathophysiological significance of natriuretic peptides-GC-A system. Methods and results: We created 5 groups (Wild-Saline: n=12, Wild-Ang II: n=14, GC-A-KO-Saline: n=11, GC-A-KO-Ang II: n=13, GC-A-KO-Ang II-Hydralazine: n=10). Saline or Ang II were infused subcutaneously using osmotic minipump for 3 weeks. Hydralazine was administered orally (0.05 g/L in drinking water). Systolic blood pressure in GC-A-KO-Saline (130±12 mmHg) was significantly higher than that in Wild-Saline (105±30 mmHg), and was comparable to Wild-Ang II (141±17 mmHg) and GC-A-KO-Ang II-Hydralazine (140±20 mmHg). Systolic blood pressure in GC-A-KO-Ang II (159±21 mmHg) was significantly higher than the other 4 groups. The severity of renal tubular atrophy and interstitial fibrosis were significantly aggravated in GC-A-KO-Ang II (atrophy: 13.4%, fibrosis: 12.0%) compared to Wild-Saline (0%, 2.0%), Wild-Ang II (2.9%, 4.4%) and GC-A-KO-Saline (0%, 2.6%). Hydralazine could not inhibit the aggravation (GC-A-KO-Ang II-Hydralazine: 13.5%, 11.3%). Ang II infusion promoted the immunohistochemical staining intensities of monocyte chemoattractant protein-1 in medullary collecting duct cells and of F4/80 and alpha-smooth muscle actin in the interstitium, whereas Ang II infusion reduced the staining of E-cadherin in atrophic renal tubular cells. Conclusions: Natriuretic peptides-GC-A system might play inhibitory roles for Ang II-induced renal tubular atrophy, interstitial fibrosis, and phenotypic transformation in renal tubular cells and fibroblasts.
